Considerations: Cytochrome P450 enzyme systems P450 1A1 and P450 1A2 are heterogeneously distributed within human populations. Each 1 is induced by a number of environmental factors including various procarcinogens.
Interpretation and Analysis: The recombinant P450 1A1 and P450 1A2 from cDNA clones are regioselective for R-warfarin 6- and 8-hydroxylation and possess very similar Km values (1.4 mM 6-hydroxylation; 1.2 mM 8-hydroxylation; 1.6 mM 6-hydroxylation; 1.4 mM 8-hydroxylation, respectively). The R-warfarin enantiomer may therefore exhibit binding competition between the 2 forms. However, when comparing 6- and 8-hydroxylation, P450 1A1 shows weak regioselectivity for 8-hydroxylation, whereas P450 1A2 displays a strong regioselectivity for 6-hydroxylation, with 6-hydroxylation/8-hydroxylation ratios of 0.6 and 5.0, respectively. Analyses utilizing microsomal fractions isolated from (i) HepG2 and MCF-7 cells expressing only P450 1A1 (ratios of 0.7) exposed to 2,3,7,8-tetrachlorodibenzo-p-dioxin; and (ii) hepatic cells expressing only P450 1A2 (average ratios of 4.0) confirm this perception. Immunoblot densitometry scans of P450 1A2 in liver preparations correlate with R-warfarin 6-hydroxylation rates ($r^2 = 0.83$) and caffeine 3-demethylation rates ($r^2 = 0.67$), but not with R-warfarin 8-hydroxylation rates. The biotransformation of R-warfirin to 6-hydroxy-warfarin or 8-hydroxy-warfarin is not recognized for P450 enzyme fractions CYP2A6, CYP2B6, CYP2C9, CYP2D6, CYP2E1, and CYP3A4.

Human cytochromes P450 1A1 and P450 1A2: R-warfarin metabolism as a probe. Zhang Z, Fasco MJ, Huang Z, Guengerich FP, Kaminsky LS. Drug Metab Dispos 1995 Dec; 23 (12), pp. 1339–46.

Hepatic Cytochrome P450 1A2 (CYP1A2) Metabolic Capacity
Caffeine

Cellular/Molecular Mechanism of Action: Caffeine is a substrate for cytochrome P450 1A2 and the biochemical activity of this enzyme system yields a metabolite that can be measured or quantified.
Application: Measurement of the *in vivo* biochemical activity of cytochrome P450 1A2 relevant to the ability of this enzyme system to metabolize pharmaceuticals, optimize dosage schemes, determine individual susceptibility to protoxin biotransformation, and/or detect therapeutic non-compliance.
Route of Administration: The distribution/activity of this enzyme is reported to be reflected by metabolic ratios.
Considerations: Several metabolic ratios using different combinations of urinary metabolites have been used to measure cytochrome P450 1A2. Utilization of this biochemical probe has resulted in some uncertainty about the distribution of this enzyme system.

Comparisons of 5 mathematical models that calculate the metabolic ratio for caffeine and therefore represent an estimate of CYP1A2 reveal that all of the methods produce a symmetrical distribution. Of these 5 ratio estimates, 3 different parameters are approximated and none of the 5 ratios correlate closely within 1 another. Based on the interpretation of findings generated by the 5 mathematical models, the complex metabolism of caffeine together with different parameters controlling the renal clearance of each metabolite, the criticism has been made that caffeine is an inaccurate probe for assessing the distribution of CYP1A2 activity in populations applying calculations for estimating urinary metabolic ratios.

Caffeine as a metabolic probe: A comparison of the metabolic ratios used to assess CYP1A2 activity. Notarianni LJ, Oliver SE, Dobrocky P, Bennett PN, Silverman BW. Br J Clin Pharmacol 1995 Jan; 39 (1), pp. 65–9.

Hepatic Cytochrome P450 1A2 (CYP1A2) Metabolizing Capacity
Caffeine

Application: Estimation of hepatic cytochrome CYP1A2 metabolizing capacity.
Route of Administration: Caffeine (oral).
Dosage: Caffeine (100 mg).
Considerations: A caffeine-free diet must be enforced prior to the initiation of the diagnostic procedure.
Diagnostic Strategy: Establishing correlations between different parameters related to plasma, saliva, and urine caffeine clearance/excretion with 2 measures of caffeine clearance, CL(oral) and CL(137X $\rightarrow$ 17X), functioning as reference standards.
Examples of Clinical Implementation: Both plasma and saliva total clearances of caffeine highly correlate with each other ($r^s = 0.97$, $p < 0.0001$). The ratio 17X/137X restricted to 1 sampling point taken 4 hours after administration reveals a high degree of correlation (r^s) with CL(oral) and CL(137X $\rightarrow$ 17X) in plasma (0.84/0.83) and saliva (0.82/0.77) ($p < 0.0001$ for all the correlation values) where 17X is 1,7-dimethylxanthine (paraxanthine) and 137X is 1,3,7-trimethylxanthine (caffeine). Additionally, the ratio (AFMU + 1U + 1X + 17U + 17X)/137X in 0 to 24 hours urine samples highly correlate with CL(137X $\rightarrow$ 17X) ($r^s = 0.85$, $p < 0.001$) where AFMU is 5-acetylamino-6-formylamino-3-methyluracil, 1U is 1-methyluracil, 1X is 1-methylxanthine, and 17U is 1,7-dimethyluric acid. The major estimates of CYP1A2 activity are significantly less in non-smoking females and are probably related to the use of oral contraceptives in this subpopulation.
Interpretation and Analysis: The biochemical conversion of caffeine to its metabolite directly corresponds to hepatic cytochrome CYP1A2 metabolizing capacity. Among caffeine-based approaches for CYP1A2, it is recommend that either plasma or saliva 17X/137X ratio and the urinary (AFMU + 1U + 1X + 17U + 17X)/137X) ratio be delineated for sampling intervals of at least 8 hours (T_0 = time of caffeine intake). These indices are simple, reliable, and relatively inexpensive estimates of (human population) CYP1A2 activity.

Evaluation of caffeine as an *in vivo* probe for CYP1A2 using measurements in plasma, saliva, and urine. Carrillo JA, Christensen M, Ramos SI, Alm C, Dahl ML, Benitez J, Bertilsson L. Ther Drug Monit 2000 Aug; 22 (4), pp. 409–17.

Hepatic Cytochrome P450 1A2 Metabolic Capacity
Caffeine

Application: Determining certain forms of hepatic cytochrome P450 biochemical function that corresponds to human P450 1A2 activity.
Considerations: Primary steps in the metabolism of caffeine and theophylline are cleavage of methyl groups and/or hydroxylation at position 8, mediated by cytochromes P450. Chinese hamster cells (V79) genetically engineered for stable expression of single forms of rat cytochromes P450 IA1, P450 1A2, and P450 IIBI and human P450 1A2 and rat liver epithelial cells expressing murine P450 1A2 can be used to overcome problems arising from the proper allocation of metabolic pathways to specific isoforms by conventional techniques.
Interpretation and Analysis: Caffeine is metabolized by human, rat, and murine P450 1A2, resulting in the formation of 4 primary demethylated and hydroxylated metabolites. However, there are differences in the relative amounts of the quantities of individual metabolites generated. The human and the mouse P450 1A2 isoforms predominantly mediate 3-demethylation of caffeine. The rat cytochrome P450 1A2 mediates both 3-demethylation and 1-demethylation of caffeine to a similar extent. Theophylline is metabolized mainly via 8-hydroxylation. The vast majority of these cell lines is capable of carrying out this reaction, with highest activities in cell lines expressing rat or human P450 1A2 or rat P450 1A1.
Instrumentation: High-performance liquid chromatography for the analysis and measurement of caffeine and/or theophylline concentrations.

Biotransformation of caffeine and theophylline in mammalian cell lines genetically engineered for expression of single cytochrome P450 isoforms. Fuhr U, Doehmer J, Battula N, Wölfel C, Kudla C, Keita Y, Staib AH. Biochem Pharmacol 1992 Jan 22; 43 (2), pp. 225–35.

MICROSOMAL CYTOCHROMES P450 2A6, 2C9, 2C19, 2D6, AND 2E1

Distinguishing Cytochrome P450 2A6 (CYP2A6) Metabolizing Capacity/CYP2E1
Disulfiram/Coumarin

Cellular/Molecular Mechanism of Action: Disulfiram and its principal metabolite (diethyldithiocarbamate) directly inhibit the biochemical activity of cytochrome P450 2E1 (CYP2E1) isotype. Diethyldithiocarbamate *in vitro* also inhibits hepatic CYP2A6 (human).

Coumarin is selectively catalyzed *in vivo* by cytochrome P450 isotype CYP2A6 to 7-hydroxycoumarin.
Application: Single-dose administration of disulfiram can be applied to delineate the role of P450 2E1 in the metabolism of specific pharmaceutical agents or prevent CYP2E1-mediated biotransformation. Disulfiram can be used to distinguish between CYP2E1 and CYP2A6 cytochrome P450 isotype metabolism capacity.
Route of Administration: Disulfiram (oral) followed 10 hours later by coumarin (oral).
Dosage: Disulfiram (500 mg) followed 10 hours later by the ingestion of coumarin (50 mg).
Examples of Clinical Implementation: The combination of disulfiram and coumarin have been utilized to determine if disulfiram and its metabolite, diethyldithiocarbamate, inhibit the *in vivo* biochemical activity of both CYP2E1 and CYP2A6 cytochrome P450 isotypes. The basis for this consideration is based on *in vitro* observations that have noted that disulfiram inhibits CYP2E1 while its metabolite, diethyldithiocarbamate, suppresses the biochemical activity of CYP2A6 cytochrome P450 isotype.
Interpretation and Analysis: The area under the plasma 7-hydroxycoumarin vs time curve (2.69 $\pm$ 0.90 μg.hr/ml) is not decreased after disulfiram pretreatment (3.33 $\pm$ 0.93 μg.hr/ml). Furthermore, maximum plasma concentration (Cmax) of 7-hydroxycoumarin (1.4 $\pm$ 0.5 vs 1.8 $\pm$ 0.6 μg/ml) and time to reach Cmax (1.0 $\pm$ 0.2 and 1.0 $\pm$ 0.4 hour) are unchanged by disulfiram pretreatment. Urinary 7-hydroxycoumarin excretion over a 24-hour period (38.9 $\pm$ 10.8 mg) is also not diminished by disulfiram pretreatment (45.2 $\pm$ 6.6 mg). Based on the interpretation of preliminary *in vivo* research findings, single-dose disulfiram does not appear to inhibit *in vivo* CYP2A6 activity. When single-dose disulfiram is used as an *in vivo* probe, the detection of inhibited drug metabolism suggests involvement of the CYP2E1 but not CYP2A6 cytochrome P450 isotype
Instrumentation: High-performance liquid chromatography analysis for the measurement of urine 7-hydroxycoumarin and plasma coumarin concentrations.

Single-dose disulfiram does not inhibit CYP2A6 activity. Kharasch ED, Hankins DC, Baxter PJ, Thummel KE. Clin Pharmacol Ther 1998 Jul; 64 (1), pp. 39–45.

Hepatic and Adrenal Metabolization: Microsomal CYP2D/(Inhibition of CYP2D Biochemical Activity)
Adenocorticotropic Hormone (ACTH)

Application: Induction of cytochrome CYP2D in the adrenal cortex and liver hepatocytes.
Route of Administration: ACTH.
Dosage: ACTH for 1, 3, or 7 days.
Animal Model: Guinea pigs treated with ACTH for 1, 3, or 7 days. In addition, some animals receive ACTH for 7 days and then untreated for an additional 3 or 7 days to test for reversibility of ACTH actions.
Interpretation and Analysis: ACTH treatment causes a time-dependent decrease in the rates of adrenal microsomal bufuralol metabolism, a CYP2D-catalyzed reaction; hepatic bufuralol metabolism is unaffected by ACTH. Adrenal enzyme activity is significantly reduced by ACTH within 1 day and decreases by 80% after 7 days. Western blotting and *in situ* hybridization analyses reveal corresponding declines in adrenal CYP2D16 protein and mRNA concentrations. Nuclear runoff assays indicate that ACTH treatment inhibits CYP2D16 expression at the transcriptional level. Adrenal 17 α-hydroxylase activities are increased by ACTH treatment, but CYP17 protein concentrations are not affected. Following the cessation of ACTH administration, the rates of adrenal bufuralol metabolism and CYP2D16 protein and mRNA concentrations return to control levels within 7 days. In summary, ACTH has a relatively rapid and reversible effect on the inhibition of adrenal CYP2D16 transcription, thereby decreasing adrenal xenobiotic metabolism. Thus, the actions of ACTH on CYP2D16 expression are opposite to those on other adrenal P450 isozymes, indicating unique regulatory mechanisms.

Downregulation of CYP2D16 by ACTH in the guinea pig adrenal cortex: Time course, reversibility, and mechanism of action. Colby HD, Longhurst PA, Burczynski JM, Hayes JR, Yuan BB, Voigt JV. Pharmacology 2003 Mar; 67 (3), pp. 121–7.

Hepatic Cytochrome P450 2A6 (CYP2A6) Metabolizing Capacity/Fadrozole/ Nitrosoamines/Aflatoxin B1
Coumarin/Nicotine/Cotinine

Cellular/Molecular Mechanism of Action: Coumarin undergoes 7-hydroxylation by high-affinity hepatic cytochrome CYP2A6 (human) in liver microsomes. Several mutated or deleted CYP2A6 alleles have been characterized. Although CYP2A6 represents up to 15% of human microsomes P450 proteins, it is still 1 of the less well characterized cytochrome P450 enzymes.
Application: Selective evaluation of cytochrome CYP2A6 metabolizing capacity in the context that coumarin can be applied as an *in vitro* and *in vivo* probe for detecting the activity of this biochemically-mediated metabolizing system. CYP2A6 may be inducible by antiepileptic drugs and it is decreased in alcohol-induced severe liver cirrhosis. Several mutated or deleted CYP2A6 alleles have been characterized.
Considerations: CYP2A6 is a major contributor to the oxidative metabolism of nicotine and cotinine, and it also contributes, to a larger or smaller extent, to the metabolism of a few pharmaceuticals (e.g., fadrozole), nitrosamines, other carcinogens (e.g., aflatoxin B1) and a number of coumarin-type alkaloids.

CYP2A6: A human coumarin 7-hydroxylase. Pelkonen O, Rautio A, Raunio H, Pasanen M. Toxicology 2000 Apr 3; 144 (1–3), pp. 139–47.

Hepatic Cytochrome P450 2C9 (CYP2C9) Metabolizing Capacity
Flurbiprofen/Sulfrapenazole/Piroxicam

Cellular/Molecular Mechanism of Action: Flurbiprofen is a non-steroidal anti-inflammatory drug (NSAID) that is metabolized by both oxidation to a 4-hydroxy-flurbiprofen metabolite (cytochrome P450 2C9) and conjugation (glucuronidation). Alternatively, sulfraphenazole functions as an inhibitor of cytochrome P450 2C9. Piroxicam functions as a non-steroidal anti-inflammatory agent that inhibits the biochemical activity of cyclooxygenase and the generation of prostaglandin species from arachidonic acid substrate.
Application: Flurbiprofen can potentially functions as both an *in vitro,* and possibly an *in vivo* probe for the detection and measurment of cytochrome P450 2C9 biochemical activity.
Interpretation and Analysis: Increases in the extent and rate of flurbiprofen biotransformation to 4′-hydroxy-flurbiprofen directly corresponds to the metabolizing capacity of hepatic P450 2C9 and its R144C variant.

The 4′-hydroxylated metabolite of flurbiprofen is not generated by CYP1A2, CYP2C8, CYP2E1, or CYP3A4 at physiologically relevant concentrations of this NSAID agent. Conversely, inhibition of (R)- and (S)-flurbiprofen 4′-hydroxylation occurs with the inhibitors of P450 2C9, sulfaphenazole (Ki = 0.07 and 0.06 μM, respectively), and the NSAID piroxicam (Ki = 10 and 7 μM, respectively). Furthermore, cytochromes CYP1A1, CYP2A6, CYP2B6, CYP2C19, and CYP2D6 are not involved in flurbiprofen hydroxylation at physiological relevant flurbiprofen concentrations. Such findings are particularly important due to the sequence homology and potential substrate overlap of P450 2C9 and 2C19. Conversely, inhibition of (R)- and (S)-flurbiprofen 4′-hydroxylation occurs with the P450 2C9 inhibitors, sulfaphenazole (Ki = 0.07 and 0.06 μM, respectively), and the NSAID piroxicam (Ki = 10 and 7 μM, respectively). Collective evaluation of research investigations conducted to date strongly suggests that P450 2C9 may be the only isoform involved to any substantial degree in flurbiprofen 4′-hydroxylation.

Studies of flurbiprofen 4′-hydroxylation. Additional evidence suggesting the sole involvement of cytochrome P450 2C9. Tracy TS, Marra C, Wrighton SA, Gonzalez FJ, Korzekwa KR. Biochem Pharmacol 1996 Oct 25; 52 (8), pp. 1305–9.

Hepatic Cytochrome P450 2C9 (CYP2C9) Metabolizing Capacity
Diclofenac (Ineffective)

Cellular/Molecular Mechanism of Action: Diclofenac is biochemically metabolized by the cytochrome CYP2C9 enzyme system to 4′-hydroxydiclofenac.
Application: *In vivo* cytochrome CYP2C9 probe based on either the measurment of the urinary 4′-hydroxydiclofenac/diclofenac metabolic ratio (MR) compared to the apparent partial metabolic clearance of diclofenac through its biochemical conversion to 4′-hydroxydiclofenac.
Route of Administration: Diclofenac (oral).
Dosage: Diclofenac (50 mg). Blood and urinary pharmacokinetics of diclofenac are studied over a 48-hour time period.
Considerations: Identification of the CYP2C9 alleles (CYP2C9*1, CYP2C9*2, and CYP2C9*3) can be established by performing genomic DNA sequence analysis.
Interpretation and Analysis: Dramatic interindividual variability in the delay of diclofenac intestinal absorption can often be appreciated because its 1st detectable blood concentration ranges from between 0.5 hours to more than 12 hours after a single dose. Oral dosage forms of diclofenac creates results that suggest that no correlation exists between the metabolic clearance of diclofenac into 4′-hydroxydiclofenac and the different urinary 4′-hydroxydiclofenac/diclofenac metabolic ratios calculated at 0 to 4 hours, 0 to 8 hours, 0 to 12 hours, 0 to 24 hours, and 0 to 48 hours urinary collections. In conclusion, diclofenac, in its enteric-coated form, is not a useful *in vivo* CYP2C9 probe probably because of its highly variable intestinal absorption rate.

Is diclofenac a valuable CYP2C9 probe in humans? Morin S, Loriot MA, Poirier JM, Tenneze L, Beaune PH, Funck-Brentano C, Jaillon P, Becquemont L. Eur J Clin Pharmacol 2001 Jan–Feb; 56 (11), pp. 793–7.

Hepatic Cytochrome P450 2C9 (CYP2C9) and P450 2C19 (CYP2C19) Metabolizing Capacity/(Genetic Polymorphisms)
Tolbutamide/Glucose

Cellular/Molecular Mechanism of Action: Tolbumamide can function as a selective probe for assessing and measurement of hepatic cytochrome metabolizing capacity (e.g., human CYP2C9).
Application: Evaluation of hepatic cytochrome CYP2C19 and CYP2C9 xenobiotic metabolizing capacity.
Route of Administration: Tolbutamide (oral).
Dosage: Tolbutamide (500 mg). Serum glucose concentrations are measured before and after oral intake of 100 g dextrose. Pharmacokinetic parameters are estimated from plasma and urine concentrations of tolbutamide and 4-hydroxytolbutamide.
Examples of Clinical Implementation: Several recent *in vitro* investigations have revealed that human CYP2C19 and CYP2C9 are involved in 4-methylhydroxylation of tolbutamide.

Distinguishing between predominantly CYP2C19 or CYP2C9 mediated cytochrome metabolization of pharmaceuticals and toxins can be established utilizing tolbutamide as a biochemical probe. In subjects heterozygous for the CYP2C9*3 allele, the C_{max} and AUC for tolbutamide are significantly greater and the plasma half-life significantly longer than in homozygous CYP2C9*1 subjects. No pharmacokinetic differences can be found between CYP2C19 EM and PM genotype subjects. The estimated AUC of the increase in serum glucose after oral intake of 100 g dextrose is 2.7-fold higher with the CYP2C9 vs the CYP2C9*1/*3 genotypes than in those with CYP2C9*1/*3. However, CYP2C19 genetic polymorphism does not alter the blood glucose lowering effect of tolbutamide. The plasma AUC for 4-hydroxytolbutamide and the ratio of 4-hydroxytolbutamide/tolbutamide does not differ significantly between CYP2C19 that demonstrate either poor or extensive metabolizing capacity. Conversely, plasma AUC for 4-hydroxytolbutamide and the ratio of 4-hydroxytolbutamide/tolbutamide are about twice as high in the CYP2C9 wild genotype than in CYP2C9*3 heterozygotes ($p < 0.05$). Results from these investigations strongly suggest that the disposition and hypoglycemic effect of tolbutamide are affected mainly by CYP2C9 genetic polymorphism, but not by CYP2C19 polymorphism. The *in vivo* contribution of CYP2C19 to tolbutamide 4-methylhydroxylation appears to be minor in humans.

Human Model: Normal healthy volunteers (Korean descent).
Interpretation and Analysis: Tolbutamide promotes declines in blood glucose levels. In this context, the level of 4-methylhydroxylation of tolbutamide by hepatic cytochrome systems is indirectly proportional to plasma glucose concentrations. This suggests that, at least *in vivo*, tolbutamide remains a selective probe for measuring CYP2C9 activity in humans.

Effects of CYP2C19 and CYP2C9 genetic polymorphisms on the disposition of and blood glucose lowering response to tolbutamide in humans. Shon JH, Yoon YR, Kim KA, Lim YC, Lee KJ, Park JY, Cha IJ, Flockhart DA, Shin JG. Pharmacogenetics 2002 Mar; 12 (2), pp. 111–9.

Hepatic Cytochrome P450 2C19 (*2 & *3): Genotype Polymorphism/Cytochrome P450 3A4 (*1B, *2 & *3)
Omeprazole/(Helicobacter pylori Eradication Therapy Outcome Prediction Variable)

Cellular/Molecular Mechanism of Action: Cytochrome P450 2C19 (*2 & *3) and P450 3A4 (*1B, *2 & *3) function as hepatic enzyme metabolizing systems.
Application: Characterize the potential efficacy of *Helicobacter pylori* eradication therapy as a function of cytochrome P450 (CYP) genotype polymorphism.
Implementation: Evaluation of human genomic DNA, CYP2C19 (*2 and *3) and CYP3A4 alleles (*1B, *2, and *3) by polymerase chain reaction-restriction fragment length polymorphism assays (confirmed by amplicon sequencing) can be applied to diagnose and characterize cases of *H. pylori* infections and their treatment with 1-week triple therapy (European Helicobacter Pylori Study Group guidelines; n = 143 Italian Caucasians).
Interpretation and Analysis: Most diagnosed cases of *H. pylori* infection can be irradicated of the microorganism according to a endoscope "gold-standard" (e.g., n = 93/143). Essentially all of the cases that remain infected with *H. pylori* and are of the CYP2C19 genotype can also be be found to be either homozygous or heterozygous extensive metabolizers (e.g., n = 50). Homozygous extensive metabolizers experience a significantly lower level of eradication than do heterozygous extensive metabolizers. Furthermore, the homEM genotype has value as a predictive variable for failure (univariate/multivariate analyses). Carriers of CYP3A4 polymorphisms achieved favorable eradication rates similar to cases with the CYP2C19 genotype. Cases with single CYP3A4*2 polymorphism (e.g., n = 4) achieve eradication, and only 29% (5/17) of all CYP3A4*1B carriers do not achieve eradication. A high percentage of carriers with CYP3A4 polymorphisms within CYP2C19 hetEM subgroups are cured (e.g., n = 9/9), suggesting a possible positive synergism between CYP3A4 and CYP2C19. Similar to Asian populations, different expression patterns for the CYP2C19 genotype are probably relevant in Caucasians receiving *H. pylori* eradication regimens that include omeprazole. The possibility of a favorable drug interaction mediated by CYP2C19 and CYP3A4 requires further research in future investigations.

The clinical role of cytochrome P450 genotypes in Helicobacter pylori management. Sapone A, Vaira D, Trespidi S, Perna F, Gatta L, Tampieri A, Ricci C, Cantelli-Forti G, Miglioli M, Biagi GL, Paolini M. Am J Gastroenterol. 2003 May; 98 (5), pp. 1010–5.

Hepatic Cytochrome P450 CYP2C9/CYP2C19/CYP2D6/Drug-Induced Adverse Reactions: Increased Risk/Genetic Polymorphism of "Poor Metabolizers"
Psychiatric Agent/Anticoagulant Agent

Background Information: Genetic polymorphism has been characterized for the drug-metabolising cytochrome P450 (CYP) enzymes CYP2C9, CYP2C19 and CYP2D6.
Application: Profiling genetic polymorphism for the drug-metabolising cytochrome P450 (CYP) enzymes CYP2C9, CYP2C19 and CYP2D6 can serve as an avenue for predicting increased susceptibility to the development of pharmaceutical-induced adverse reactions. Presently, CYP genotyping (CYP2C9/2C19/2D6) is most frequently requested in psychiatry and anticoagulant therapy, but the field is expanding. Important factors for implementation of pharmacogenetic methods are accuracy of diagnosis, quality of reports, response time, and cost.
Interpretation and Analysis: Several variations in the expression of cytochrome P450 (CYP) metabolizing enzymes CYP2C9, CYP2C19 and CYP2D can lead to reduced or absent biochemical activity. Occurance of such genetic-based deficiencies is of clinical importance mainly in patients having 2 non-functional alleles, phenotypically characterized as "poor metabolizers" (1–10% of Caucasians). Because most pharmaceuticals are transformed into inactive or less active metabolites, "poor metabolizers" are at increased risk of developing drug-induced adverse reactions. In practice, pharmacogenetic analyses will significantly contribute to reducing treatment costs for drug-induced adverse reactions and costs of sick leave, by predicting the best drug and the most effective and safest dosage.

Individualized pharmacotherapy based on cytochrome P450 (CYP) genotyping. (Article in Norwegian.) Johansen PW, Bergan S, Rootwelt H, Kvittingen EA, Rugstad HE. Tidsskr Nor Laegeforen 2002 Nov 30; 122 (29), pp. 2781–3.

Hepatic Cytochrome P450 2C9 (CYP2C9) Metabolizing Capacity/NAT2 Inborn Errors and Acetylator Polymorphism
Sulfonamides/Hydroxylamines

Background Information: Since the discovery of polymorphic N-acetylation of drugs nearly 40 years ago, great progress has been made in understanding the molecular genetics of acetylation as well as the clinical consequences of being a rapid or slow acetylator.

Interpretation and Analysis: Inborn errors (several different alleles) at the NAT2 locus are responsible for the traditional acetylator polymorphism. Studies have revealed variant alleles at the NAT1 locus as well. The consequences of pharmacogenetic variation in these enzymes include (i) altered kinetics of specific drug substrates; (ii) drug-drug interactions resulting from altered kinetics; (iii) idiosyncratic adverse drug reactions. The latter have been extensively investigated for the arylamine-containing sulfonamide antimicrobial drugs. Individual differences in multiple metabolic pathways can increase the likelihood of covalent binding of reactive metabolites of the drugs to cell macromolecules with resultant cytotoxicity and immune response to neoantigens. This can result clinically in an idiosyncratic hypersensitivity reaction, manifested by fever, skin rash, and variable toxicity to organs including liver, bone marrow, kidney, lung, heart, and thyroid. Slow acetylation by NAT2 is a risk factor for such reactions to sulfonamides. Given the incidence of these severe adverse drug reactions (much $<$ 1/1,000), slow acetylation cannot be the sole mechanism of predisposition in the population. Differences in rates of production of hydroxylamine metabolites of the drugs by cytochrome P450 (CYP2C9), myeloperoxidase, and thyroid, roxidase, along with an inherited abnormality in detoxification of the hydroxylamines are critically important in determining individual differences in adverse reaction risk. Both NATs, particularly NAT1, also can further metabolize hydroxylamine metabolites to N-acetoxy derivatives. Intensive investigation of patients with these rare adverse reactions using a variety of tools from *in vitro* cell toxicity assays through molecular genetic analysis will help elucidate mechanisms of predisposition and ultimately lead to diagnostic tools to characterize individual risk and prevent idiosyncratic drug toxicity.

N-acetyltransferases: Pharmacogenetics and clinical consequences of polymorphic drug metabolism. Spielberg SP. J Pharmacokinet Biopharm 1996 Oct; 24 (5), pp. 509–19.

Hepatic Cytochrome P450 Polymorphism/P450 2C9*2 (CYP 2C9*2)/P450 2C9*1/*3 (CYP2C9*1/*3)/P450 2C9*4 (CYP2C9*4)
(S)-Warfarin/Delayed Pharmacokinetic Clearance/Interpatient Variability

Background Information: Warfarin is 1 of the most widely prescribed oral anticoagulants. However, optimal use of the drug has been hampered by its $>$ 10-fold interpatient variability in the doses required to attain therapeutic responses. Pharmacogenetic polymorphism of cytochrome P450 (CYP) may be associated with impaired elimination of warfarin and exaggerated anticoagulatory responses to the drug in certain patients. Clinically available warfarin is a racemic mixture of (R)- and (S)-warfarin, and the (S)-enantiomer has 3 to 5 times greater anticoagulation potency than its optical congener. Both enantiomers are eliminated extensively via hepatic metabolism with a low clearance relative to hepatic blood flow. CYP2C9 is almost exclusively responsible for the metabolism of the pharmacologically more active (S)-enantiomer.

Implementation: Several human allelic variants of CYP2C9 have been cloned, (e.g., designated CYP2C9*1 reference sequence or wild-type allele), CYP2C9*2, CYP2C9*3, and CYP2C9*4, respectively.

Interpretation and Analysis: The allelic frequencies for these variants differ considerably among different ethnic populations. Caucasians appear to carry the CYP 2C9*2 (8 to 20%) and CYP2C9*3 (6 to 10%) variants more frequently than do Asians (0% and 2 to 5%, respectively). In an *in vitro* environment the metabolic activities of the CYP2C9 variants reveal that the catalytic activity of CYP2C9*3 expressed from cDNA is significantly less than that of CYP2C9*1. Human liver microsomes obtained from individuals heterozygous for CYP2C9*3 show significantly reduced (S)-warfarin 7-hydroxylation compared with those obtained from individuals of the CYP2C9*1 genotyped.

Pharmacokinetic (*in vivo*) clearance of (S)-warfarin in the homozygous CYP2C9*3 genotype as well as the heterozygous CYP2C9*1/*3 genotype, have a significantly reduced pharmacokinetic clearance of (S)-warfarin (-90% and -60%, respectively) compared with those with the CYP2C9*1 homozygous genotype (e.g., Japanese patients). The maintenance dosages of warfarin required for Japanese patients with heterozygous and homozygous CYP2C9*3 mutations are significantly lower than those in patients with CYP2C9*1/*1. In addition, 86% of British patients exhibiting adequate therapeutic responses with lower maintenance dosages of warfarin ($<$ 1.5 mg/day) have either the CYP2C9*2 or CYP2C9*3 mutation singly or in combination, whereas only 38% of randomly selected patients receiving warfarin express the corresponding mutations. Furthermore, the former group shows more frequent episodes of major bleeding associated with warfarin therapy. Such observations indicate that the CYP2C9*3 allele may be associated with retarded elimination of (S)-warfarin and induce or prolong certain clinical effects. However, relationships between CYP2C9 genotype, enzyme activity, metabolism of probe substrates, dosage requirements and bleeding complications should be interpreted with caution, and further studies are required.

Pharmacogenetics of warfarin elimination and its clinical implications. Takahashi H, Echizen H. Clin Pharmacokinet 2001; 40 (8), pp. 587–603.

Hepatic Cytochrome P450 Metabolizing Enzymes/P450 2C19 (CYP2C19)/P450 2D6 (CYP2D6)
Tricyclic Antidepressants/Selective Serotonin Uptake Inhibitors

Background Information: Both noradrenaline (NA) and serotonin (5-HT) appear to be involved in depression. Evidence suggests that dual-acting antidepressants, that is, those that affect both monoamine systems, such as tricyclic antidepressants and the noradrenergic and specific serotonergic antidepressant mirtazapine, may have greater efficacy and a faster onset of action than drugs that act on a single monoamine system only, such as the selective serotonin reuptake inhibitors (SSRIs). Cell firing is reduced by SSRIs in the short-term, but is increased by mirtazapine, probably due to its actions on both NA (via $alpha_2$ antagonism) and 5-HT (via $alpha_1$-stimulation by NA). This may help to explain clinical evidence suggesting that mirtazapine has a faster onset of action than the more selective antidepressants.

Both noradrenaline (NA) and serotonin (5-HT) appear to be involved in depression. Evidence suggests that dual-acting antidepressants, that is, those that affect both monoamine systems, such as tricyclic antidepressants and the noradrenergic and specific serotonergic antidepressant mirtazapine, may have greater efficacy and a faster onset of action than drugs that act on a single monoamine system only, such as the selective serotonin reuptake inhibitors (SSRIs). Cell firing is reduced by SSRIs in the short-term, but is increased by mirtazapine, probably due to its actions on both NA (via $alpha_2$ antagonism) and 5-HT (via $alpha_1$-stimulation by NA). This may help to explain clinical evidence suggesting that mirtazapine has a faster onset of action than the more selective antidepressants.

Application: Individualized design of dosage regimens for antidepressant therapies.

Implementation: Characterization of the cytochrome P450 enzymes CYP2D6 and CYP2C19 genotypes in a manner that complements clinical evaluation and therapeutic monitoring procedures.
Interpretation and Analysis: In literature searches reviewing 32 antidepressants marketed in Europe, Canada, and the United States, a number of studies have compared the pharmacokinetic parameters of antidepressants among cases with poor, intermediate, extensive, and ultrarapid levels of metabolization. Regarding 14 different antidepressants, distinct dose recommendations for extensive, intermediate and poor metabolizers of either CYP2D6 or CYP2C19 have been described. For the tricyclic antidepressants, dose reductions around 50% are generally recommended for poor metabolizers of substrates for CYP2D6 or CYP2C19, whereas differences are reportedly smaller for the selective serotonin reuptake inhibitors. Review of databases can facilitate the formulation of average dose suggestions based on the phenotype or genotype.

Hepatic Cytochrome P450 2D6 (CYP2D6) Biochemical Metabolization/β-Adrenergic Blockers/Tricyclic Antidepressants/Class 1C Antiarrhythmics
Debrisoquine

Cellular/Molecular Mechanism of Action: Debrisoquine (antihypertensive) is metabolized to 4-hydroxydebrisoquine (4-OHD) by hepatic cytochrome CYP2D6 fractions.
Application: Phenotyping of individuals to predict if they have either an extensive or poor capacity to metabolize various pharmaceutical agents including β-adrenergic blockers, tricyclic antidepressants, and class 1C antiarrhythmics.
Route of Administration: Debrisoquine sulfate (oral).
Dosage: Debrisoquine sulfate (10 mg). All the urine excreted during the following 8-hour period is collected for analysis of metabolite concentrations.
Interpretation and Analysis: The debrisoquine metabolic ratio (DMR) is calculated as a percentage of the dose excreted as debrisoquine vs the percent dose excreted as 4- hydroxydebrisoquine. The debrisoquine recovery ratio (DRR) is calculated as the percent dose excreted as 4-hydroxydebrisoquine vs the percentage of dose excreted as debrisoquine plus 4-hydroxydebrisoquine.
Examples of Clinical Implementation: Hypertensive patients displaying a debrisoquine metabolic ratio of < 12.6 or a debrisoquine recovery ratio higher than 0.12 are classified as individuals with an extensive metabolic capacity. A high degree of enantioselectivity in the 4-hydroxylation of debrisoquine favouring the S-(+) enantiomer occurs resulting in R-(-)-4-hydroxydebrisoquine not detected in the urine of hypertensive patients that possess extensive metabolizing capacity.
Instrumentation: Reversed-phase high-performance liquid chromatography (HPLC) for the selective quantification of debrisoquine, 4-hydroxydebrisoquine, S-(+) 4-hydroxydebrisoquine, and R-(-) 4-hydroxydebrisoquine in urine samples without the need for derivatization techniques. Debrisoquine and its metabolite can be detected in urine samples by HPLC using (i) a reversed-phase Select B LiChrospher column; (ii) acetate buffer (0.25 N) and acetonitrile (pH 5) reverse phase (9:1, v/v); and (iii) fluorescence detector. The limit of quantitation with this system is 25.0 ng/ml for debrisoquine and 18.75 ng/ml for 4-hydroxydebrisoquine. Intra-day and interday relative standard deviations (RSDs) are $< 10\%$.

Direct enantioselective separation on chiral stationary phase involved resolution of S-(+)-4-OHD and R-(-)-4-OHD on a Chiralcel OD-R column with a mobile phase of 0.125 N sodium perchlorate, pH 5-acetonitrile-methanol (85:12:3, v/v/v). The quantitation limit of each enantiomer is 3.75 ng/ml of urine. Intra- and interday RSDs are $< 10\%$ for each enantiomer.

Enantioselectivity of debrisoquine 4-hydroxylation in Brazilian Caucasian hypertensive patients phenotyped as extensive metabolizers. Cerqueira PM, Mateus FH, Cesarino EJ, Bonato PS, Lanchote VL. J Chromatogr B Biomed Sci Appl 2000 Dec 1; 749 (2), pp. 153–61.

Hepatic Cytochrome P450 2D6 (CYP2D6) and P450 3A (CYP3A)
Dextromethorphan (DM)/Dextrorphan/ 3-Methoxymorphinan

Cellular/Molecular Mechanism of Action: Dextromethorphan is O-demethylated to dextrorphan by the human cytochrome P450 designated as CYP2D6, while it is N-demethylated to 3-methoxymorphinan via P450 3A (CYP3A).
Application: Dextromethorphan can be used as a probe to detect and measure cytochrome CYP2D6 biochemical activity.
Implementation: Dextromethorphan and its 3 demethylated metabolites can be measured in 4-hour spot urine samples employing high-performance liquid chromatography (HPLC) analyses. The urinary dextromethorphan-dextrorphan molar ratio is used to assess CYP2D6 activity while dextromethorphan/3-methoxymorphinan is calculated to determine CYP3A biochemical/metabolic activity.
Interpretation and Analysis: DM-3MM ratios are sensitive to the co-administration of selective CYP3A inhibitors grapefruit juice and erythromycin. In addition, in healthy volunteers and cancer patients, the N-demethylation of DM correlated with the CYP3A-mediated metabolism of verapamil and tamoxifen. DM appears to be a promising way to simultaneously phenotype patients for CYP2D6 and CYP3As.
Instrumentation: Processing involving HPLC solid-phase extraction (C18 column); phenyl column analysis [mobile phase, methanol-acetonitrile-phosphate buffer (10 mM, pH 3.5, 20:25:55, v/v)] in concert with fluorescence detection (excitation at lambda=228 nm, no emission cut-off filter).

Dextromethorphan as an *in vivo* probe for the simultaneous determination of CYP2D6 and CYP3A activity. Ducharme J, Abdullah S, Wainer IW. J Chromatogr B Biomed Sci Appl 1996 Mar 29; 678 (1), pp. 113–28.

Hepatic Cytochrome P450 2D6 (CYP2D6) Metabolizing Capacity/Individualization of Antipsychotic Agent Dosage: Schizophrenia
Clozapine

Background Information: The reintroduction of clozapine, the prototype of atypical antipsychotics, in the late 1980s has led to significant advances in the pharmacological management of schizophrenia. Since then, there has been a rapid development of novel "atypical" antipsychotic agents that have been pharmacologically modeled, to a certain extent, after their predecessor clozapine.
Implementation: As with all antipsychotics, there is variability among individuals in their response to "atypical" antipsychotic agents. Pharmacogenetic concepts provide a valuable foundation for understanding interindividual variability observed with responses to antipsychotic agents. Delineation of pharmacokinetic and pharmaco-

dynamic parameters are integral factors that need to be addressed in the pursuit of this rationale.

Molecular biology (genetic) and proteomic laboratory techniques represent powerful laboratory methodologies that provide additional insight about mechanisms associated with interindividual variations in response to pharmaceuticals such as clozapine and establishing phenotype and genotype classification schemes (e.g., variable cytochrome P450 CYP2D6 expression). Findings observed during the course of such laboratory-based investigations provide a basis for formulating recommendations for optimizing the pharmacokinetic profiles of antipsychotic agents; designing optimum dosage/frequency regimens and establishing recommendations for patient monitoring. In this fashion, it will ultimately be possible in the field of psychiatric pharmacogenetics to individualize pharmacotherapy of schizophrenia, and may also lead to the development of newer, more efficacious antipsychotic agents.

Pharmacogenetic methods as a complement to therapeutic monitoring of antidepressants and neuroleptics. Dahl ML, Sjoqvist F. Ther Drug Monit 2000 Feb; 22 (1), pp. 114–7.

Pharmacogenetics of antipsychotic treatment: Lessons learned from clozapine. Masellis M, Basile VS, Ozdemir V, Meltzer HY, Macciardi FM, Kennedy JL. Biol Psychiatry 2000 Feb 1; 47 (3), pp. 252–66.

Hepatic Cytochrome P450 2D6 (CYP2D6) Metabolizing Capacity/Dopamine D1 Receptor Genotype: Treatment Resistant/Individualization of Antipsychotic Agent Dosage: Schizophrenia

Clozapine/[^{18}F]-Fluorodeoxyglucose

Cellular/Molecular Mechanism of Action: [^{18}F]-fluorodeoxyglucose: functions as a false glucose analog that can detect alterations in glucose metabolism within the brain.
Physiological Mechanism of Action: Potentiate the effects of GABA-mediated presynaptic and postsynaptic inhibitory pathways.
Background Information: A goal of pharmacogenetics is to clarify associations between allelic variation and risk factors in psychiatric illness.
Application: Characterization of different patterns in dopamine alleles that correlated with resistance to therapeutic management in conditions of treatment-resistant schizophrenia. A close relationship exists between regional brain metabolic activity and clinical response to clozapine that is related to the D1 receptor genotype.
Implementation: Positron emission tomography (PET) scans with [^{18}F]-fluorodeoxyglucose are performed on cases of treatment-resistant schizophrenic subjects after 5 weeks of clozapine treatment (vs placebo).
Interpretation and Analysis: Significant regional brain metabolic effects can be found for D1 receptor genotypes ($p < 0.05$: adjusted for multiple comparisons). Metabolic decreases for the 2,2 genotype but not the 1,2 genotype can be observed in all major sectors of the brain, with the exception of the ventral parts of the caudate and putamen. Frontal, temporal, parietal, and occipital neocortices show decreases in metabolism as do the cingulate juxtaallocortex and the parahippocampal allocortex. Decreases can also be observed in the thalamus, amygdala, and cerebellum bilaterally. No significant metabolic differences by genotype have been observed for D3, 5HT(2A), and 5HT(2C) polymorphisms. In terms of clinical response, the DRD1 2,2 genotype significantly improves with clozapine treatment, demonstrating a 30% decrease in the Brief Psychiatric Rating Scale positive symptoms in contrast to a 7% worsening for the 1,2 genotype ($p < 0.05$). Therefore, brain metabolic activity, and clinical response to clozapine appears to be related to the D1 receptor genotype.

D1 receptor alleles predict PET metabolic correlates of clinical response to clozapine. Potkin SG, Basile VS, Jin Y, Masellis M, Badri F, Keator D, Wu JC, Alva G, Carreon DT, Bunney WE Jr, Fallon JH, Kennedy JL. Mol Psychiatry 2003 Jan; 8 (1), pp. 109–13.

Hepatic Cytochrome P450 2D6 (CYP2D6)/CYP2D6 Genotype Polymorphism

Nortriptyline Pharmacokinetics/Antidepressant Therapy

Background Information: The administration of nortriptyline results in approximately a 21% total interindividual variance in oral clearance, and 34% of that in steady state plasma concentrations.
Application: The pharmacokinetic profile for nortriptyline is significantly influenced by the expression of the CYP2D6 genotype. Prior knowledge of CYP2D6 expression characteristics could realistically aid in attempts to predict plasma concentration of the drug and thus allow for the tailoring of patient-specific dosage regimens.
Route of Administration: Nortriptyline (oral/per os).
Implementation: Establish a quantitative clearance model for nortriptyline as a function of the cytochrome CYP2D6 genotype. Such information can in effect serve as an avenue for establishing to what extent the CYP2D6 genotype contributes to the interindividual variability in steady state plasma concentration and metabolic clearance. Such information can be gained in healthy subjects (e.g., $n = 20$) administered a single dose of nortriptyline for comparison with cases suffering from depression undergoing steady state oral treatment. Plasma concentrations are analyzed by standard non-linear regression and non-linear mixed effect models. All experimental cases are genotyped for CYP2D6 polymorphism prior to the initiation of the study.
Interpretation and Analysis: The pharmacokinetic model that appropriately fits the plasma concentration data sets is a 1-compartment model with 1st-order absorption and elimination characteristics. The pharmacokinetic model with the closest fit of plasma concentration profiles is 1 where the intrinsic clearance is a linear function of the number of viable genes expressing CYP2D6 and where hepatic blood flow is fixed (60 L/h). Stable estimates can ultimately be obtained for population pharmacokinetic parameters and interindividual variances. Assuming 100% absorption, the model allows systemic clearance and bioavailability to be estimated. Bioavailability usually varies between 0.17 and 0.71, depending on the genotype. Using the frequency distribution of the CYP2D6 genotype, it is possible to estimate the number of functional CYP2D6 genes in individuals on nortriptyline monotherapy.

The pharmacokinetic profile for nortriptyline is significantly influenced by the expression of the CYP2D6 genotype and such factors may account for the substantial interindividual variance recognized for nortriptyline. In this context, non-linear mixed-effects modelling can be used to quantify the influence of the number of functional CYP2D6 genes on the metabolic clearance and plasma concentration of drugs metabolized by this cytochrome enzyme system.

Quantitative pharmacogenetics of nortriptyline: A novel approach. Kvist EE, Al-Shurbaji A, Dahl ML, Nordin C, Alvan G, Stahle L. Clin Pharmacokinet 2001; 40 (11), pp. 869–77.

Hepatic Cytochrome P450 2E1 Metabolizing Capacity

Chlorzoxazone/Chlorzoxazone: 6-Hydroxychlorzoxazone Hydroxylation Index

Cellular/Molecular Mechanism of Action: Chlorzoxazone is as substrate for and metabolized by cytochrome P450 2E1 enzyme fractions to 6-hydroxychlorzoxazone.

Application: The urinary excretion of 6-hydroxychlorzoxazone is limited by the rate of formation. Chlorzoxazone may therefore be utilized as an *in vivo* probe for evaluating P450 2E1 function based on the measurement of urinary 6-hydroxychlorzoxazone excretion as a parameter for assessing the metabolic capacity of this enzyme system.
Route of Administration: Chlorzoxazone (oral).
Dosage: Chlorzoxazone (500 mg) and plasma is collected at 3.5, 4.5, 5.5, and 6.5 hours after dosing in addition to the collection of urine for an 8-hour period.
Interpretation and Analysis: Plasma and urine samples can be applied to define the absorption phase and plasma area under the concentration-time curve of chlorzoxazone and the urinary kinetics of the 6-hydroxy metabolite. A parameter that can be applied as a measure of CYP2E1 activity is the hydroxylation index (mmole oral chlorzoxazone dose/mmole 6-hydroxychlorzoxazone in 8-hour urine).

There is a significant positive correlation between the plasma elimination rate constant for chlorzoxazone (Ke) and urinary metabolite excretion ($n = 27$, $r = 0.42$, $p < 0.03$) while a significant negative correlation exists between plasma Ke and the hydroxylation index ($n = 27$, $r = -0.41$, $p < 0.04$). The mean absorption rate constant for chlorzoxazone of 3.11 ± 4.67/hr is 5-fold greater than the plasma Ke of 0.57 ± 0.17/hr for full kinetic studies. The formation clearance of 6-hydroxy metabolite is negative between the plasma Ke of the parent compound and the disposition rate constant for urinary excretion of the 6-hydroxy metabolite ($n = 15$, $r = 0.85$, $p < 0.0001$).
Instrumentation: Chlorzoxazone and the 6-hydroxy metabolite are measured by high-performance liquid chromatography.

Urinary excretion of 6-hydroxychlorzoxazone as an index of CYP2E1 activity. Dreisbach AW, Ferencz N, Hopkins NE, Fuentes MG, Rege AB, George WJ, Lertora JJ. Clin Pharmacol Ther 1995 Nov; 58 (5), pp. 498–505.

Hepatic Cytochrome P450 2E1 (CYP2E1) Metabolizing Capacity
Chlorzoxazone

Cellular/Molecular Mechanism of Action: Chlorzoxazone is a substrate for cytochrome CYP2E1 and the biochemical activity of this system produces the metabolite, 6-hydroxy-chlorzoxazone.
Application: Measurement of the *in vivo* biochemical activity of cytochrome CYP2E1 relevant to the ability of this enzyme system to metabolize pharmaceuticals, optimize dosage schemes; determine individual susceptibility to pro-toxin biotransformation and/or detection of therapeutic non-compliance.
Interpretation and Analysis: In a population reference controls, both oral (330 ± 111 ml/min, mean $\pm$ SD) and fractional (213 ± 86 ml/min) clearances can vary substantially (e.g., 4-fold to 5-fold). Simple visual inspection of "raw" data usually reveals normal unimodal distribution profiles.

Interestingly, some investigations have reported clearance values being one-third greater in men than in women, but such differences are less striking after normalization according to body weight. Attempts to develop a single-time-point measure of 6-hydroxylating ability on the basis of plasma levels or urinary excretion of chlorzoxazone or its metabolite have been unsuccessful.

Genetic polymorphisms (Pst I and Rsa I restriction fragment length polymorphisms) in the 5′-flanking region of (human) CYP2E1 deoxyribonucleic acid obtained from peripheral leukocytes are not associated with differences in the disposition of chlorzoxazone. Similarly, no major effects on 6-hydroxylation is associated with mutations in intron 6 associated with a Dra I restriction fragment length polymorphism. The interindividual variability in CYP2E1 activity as measured *in vivo* in normal reference controls is considerably less than that expected based on *in vitro* studies. How closely associated such forms of variability correlate with individual susceptibility to CYP2E1-mediated biotransformation of various pro-toxic agents remains to be determined.

Interindividual variability of chlorzoxazone 6-hydroxylation in men and women and its relationship to CYP2E1 genetic polymorphisms. Kim RB, O'Shea D. Clin Pharmacol Ther 1995 Jun; 57 (6), pp. 645–55.

Hepatic Cytochrome P450 2E1 (CYP2E1) Metabolism Capacity
Chlorzoxazone

Cellular/Molecular Mechanism of Action: Chlorzoxazone is a substrate for cytochrome CYP2E1 yielding the metabolite 6-hydroxy-chlorzoxazone.
Application: Measurement of the *in vivo* biochemical activity of cytochrome P450 2E1 (CYP2E1) relevant to the ability of this enzyme system to metabolize pharmaceuticals, optimize dosage schemes; determine individual susceptibility to pro-toxin biotransformation and/or detection of therapeutic non-compliance.
Route of Administration: Chlorzoxazone (oral).
Dosage: Chlorzoxazone (250 mg).
Examples of Clinical Implementation: Prolonged fasting produces a significant increase in circulating ketone bodies that occurs simultaneously with declines in the oral clearance of chlorzoxazone (human mean $\pm$ SD, 5.79 ± 1.04 to 3.69 ± 1.54 ml/min/kg; $p < 0.03$). The 0- to 24-hour urinary recovery of the 6-hydroxy metabolite is substantial (human: 50% to 80%), and reductions in clearance reflect a lower 6-hydroxylating ability after fasting. The elimination half-life of the drug is increased similar to clearance parameters (1.00 ± 0.09 vs 1.50 ± 0.42 hours; $p < 0.004$), but the apparent volume of distribution is unaffected by fasting. Alternatively, obesity tends to significantly increase the oral clearance and distribution of chlorzoxazone on both an absolute and weight-normalized basis; (e.g., 4.15 ± 0.81 vs 6.23 ± 1.72 ml/min/kg and 0.50 ± 0.28 vs 0.82 ± 0.19 L/kg). Elimination half-life values are similar in both groups of subjects. Measurement of 6-hydroxychlorzoxazone concentrations reveals that obesity increases estimates of the fractional clearance of this metabolite. The difference in the oral clearance and 6-hydroxylating ability of non-obese men and women is also statistically different.

In the comparison of experimental findings observed in rats and man, fasting appears to have a different affect in these 2 species. Such discrepancies may reflect an interspecies difference in CYP2E1 regulation or, more likely, destruction of the enzyme by lipid peroxidation resulting from prolonged periods of fasting. Conversely, extreme obesity in humans increases 6-hydroxylation of chlorzoxazone, consistent with induction of CYP2E1 biochemical activity. Accordingly, such individuals may be at increased risk of CYP2E1-mediated toxicities and adverse effects caused by the formation of CYP2E1-mediated metabolites of environmental agents. In addition, the efficacy of an active drug that is a CYP2E1 substrate may be reduced in obese patients.
Interpretation and Analysis: In animals (e.g., rat) levels of CYP2E1 are induced by both fasting and obesity. Studies have investigated whether these 2 physiologic factors are determinants of the metabolism and disposition of chlorzoxazone in humans.

Effect of fasting and obesity in humans on the 6-hydroxylation of chlorzoxazone: A putative probe of CYP2E1 activity. O'Shea D, Davis SN, Kim RB, Wilkinson GR. Clin Pharmacol Ther 1994 Oct; 56 (4), pp. 359–67.

Hepatic Cytochrome P450 2E1 (CYP2E1) Metabolizing Capacity
Sevoflurane/Chlorzoxazone

Cellular/Molecular Mechanism of Action: Sevoflurane is a metabolic substrate for hepatic cytochrome CYP2E1 resulting in the production of free fluoride ion levels within the plasma.

Application: Sevoflurane and chlorzoxazone can be utilized to assess hepatic cytochrome CYP2E1 metabolizing capacity. In situations where high preoperative chlorzoxazone metabolic ratios are detected, then there is significant merit to the evaluation of renal function in the postoperative period following sevoflurane anesthesia.

Route of Administration: Sevoflurane (inhalation) compared to chlorzoxazone (oral).

Dosage: Sevoflurane (inspired concentration 1–3%) compared to chlorzoxazone (500 mg).

Considerations: Chlorzoxazone and its 6-hydroxymetabolite concentrations are measured in plasma 2 hours after drug administration. Anesthesia can be induced with propofol, fentanyl, and atracurium intravenously and maintained with sevoflurane. Plasma fluoride concentrations are determined before the induction of anesthesia, at the cessation of sevoflurane, and 2, 4, 6, 10, and 24 hours thereafter.

Implementation: Evaluation and characterization of increases in plasma fluoride concentrations (sevoflurance) and chlorzoxazone metabolic ratio (6-hydroxy-chlorzoxazole/chlorzoxazole).

Interpretation and Analysis: The area under the plasma fluoride concentration-time curve (AUC) can be calculated up to 24 hours after sevoflurane cessation. The chlorzoxazone metabolic ratio correlates significantly with plasma fluoride AUC measurements ($r^2 = 0.28$, $p < 0.025$); the elimination constant calculated for the postanesthetic 10- to 24-hour period ($r^2 = 0.30$, $p < 0.025$); and plasma fluoride levels 24 hours after cessation of sevoflurane ($r^2 = 0.48$, $p < 0.05$). A comparison between subjects receiving sevoflurane vs chlorzoxazone reveals that the administration of chlorzoxazone itself does not alter postanesthetic fluoride kinetics. Therefore, the interindividual variability in perianesthetic plasma fluoride levels after sevoflurane anesthesia is reflected by differences in the chlorzoxazone metabolic ratio, and effectively detects interindividual variability in CYP2E1 activity. In the application of sevoflurane anesthesia, it has subsequently been concluded that there is significant merit for examining renal function in the postoperative period if high preoperative metabolic ratios of chlorzoxazone are detected.

The relationship between cytochrome P450 2E1 activity and plasma fluoride levels after sevoflurane anesthesia in humans. Wandel C, Neff S, Keppler G, Böhrer H, Stockinger K, Wilkinson GR, Wood M, Martin E. Anesth Analg 1997 Oct; 85 (4), pp. 924–30.

Hepatic Cytochrome P450 2E1 (CYP2E1) Metabolizing Capacity
Chlorzoxazone

Cellular/Molecular Mechanism of Action: Chlorzoxazone is a substrate for cytochrome CYP2E1 which biochemically creates its 6-hydroxy metabolite.

Application: Cytochrome CYP2E1 is considered to play an important role in the metabolic activation of procarcinogens such as N-nitrosoamines and low molecular weight organic compounds.

Considerations: An RsaI polymorphism is present in the 5′-flanking region of the CYP2E1 gene, which could possibly affect its transcription. However, the relationship between genotype and the phenotypic catalytic activity of the enzyme has not been defined. Also, the effects in humans of specific dietary factors, other than ethanol, which have been shown in animal and in *in vitro* studies to modulate CYP2E1 activity, remain largely unknown.

Examples of Clinical Implementation: The metabolism (oral clearance) of chlorzoxazone by CYP2E1 to its 6-hydroxy metabolite is substantially less in healthy Japanese-Americans compared to analogous values reported in European-Americans. Applying adjustments for age and sex, the oral clearance of chlorzoxazone significantly decreases with the number of variant c2 alleles, and its mean in the c2/c2 genotype (147 ml/min) is statistically lower ($p \leq 0.05$) than for either the homozygous wild type (238 ml/min) or the heterozygote (201 ml/min) genotypes. Body weight is a major contributor to interindividual variability in the oral clearance of chlorzoxazone, accounting for 43% of the variance when analyzed applying stepwise multiple regression analysis. Dietary consumption (e.g., lettuce, broccoli, black tea) contributes to the introduction of additional variability (7, 5, and 6%, respectively), as does medication use (3%), age (4%), and CYP2E1 genotype (5%). Overall, 73% of the variance can be accounted for by these variables. Body weight, lettuce, and use of medications are associated with increased CYP2E1 activity, and the other covariates are associated with reduced enzyme function. Because of the role that CYP2E1 plays *in* procarcinogen activation, especially of N-nitrosamines involved *in* lung cancer, the identified factors may account *in* part for observed differences in individual susceptibility to disease and may also have implications for cancer prevention.

Interpretation and Analysis: Alterations in the rate and extent of endogenous biochemical conversion of chlorzoxazone to its 6-hydroxy metabolite positively correspond to CYP2E1 associated metabolizing capacity of this cytochrome system.

Genetic and dietary predictors of CYP2E1 activity: A phenotyping study in Hawaii Japanese using chlorzoxazone. Marchand LL, Wilkinson GR, Wilkens LR. Cancer Epidemiol Biomarkers Prev 1999 Jun; 8 (6), pp. 495–500.

Hepatic Cytochrome P450 2E1 (CYP2E1) Metabolizing Capacity/(Posttransplant)
Chlorzoxazone

Application: Determination of phenotypic cytochrome CYP2E1 expression and establishing hepatic metabolic capacity (e.g., post liver transplant) as a measure of physiological integrity. Parameters generated from establishing the degree or extent of chlorzoxazone metabolism by CYP2E1 can be utilized to adjust dosage regimens for pharmaceuticals in certain disease states or following various surgical procedures. Importance of this consideration is based on the observation that drug metabolism is actually not uniformly depressed after liver transplantation.

Dosage: Chlorzoxazone (250 mg) with the collection of urine and blood samples over an 8-hour period. The chlorzoxazone metabolic ratio is calculated as the plasma concentration of 6-hydroxychlorzoxazone/chlorzoxazone at 4 hours after chlorzoxazone administration (phenotypic index). Additional blood samples can be collected to facilitate the calculation of chlorzoxazone pharmacokinetic profiles applying non-compartmental methods.

Examples of Clinical Implementation: The chlorzoxazone metabolic ratio in the 1st month following liver transplant (mean $\pm$ SD, 6.4 ± 5.1) is significantly higher than observed after 1 month postsurgery (2.1 ± 2.0), when the chlorzoxazone metabolic ratio is not different from control subjects (0.8 ± 0.5). These findings reveal that significant induction of CYP2E1, as indicated by the chlorzoxazone metabolic ratio, occurs during the 1st month following liver transplant procedures. The maximum observed 6-hydroxychlorzoxazone plasma concentration is more highly variable but statistically

greater compared to healthy normal controls ($p < 0.05$). The maximum observed concentration of chlorzoxazone, the chlorzoxazone apparent oral clearance, and the formation clearance of 6-hydroxychlorzoxazone are also significantly different following liver transplant procedures.

Interpretation and Analysis: The chlorzoxazone metabolic ratio (plasma concentration of 6-hydroxychlorzoxazone/chlorzoxazone at 4 hours) is directly proportional to hepatic metabolizing capacity.

Instrumentation: High-performance liquid chromatography.

Induction of CYP2E1 activity in liver transplant patients as measured by chlorzoxazone 6-hydroxylation. Burckart GJ, Frye RF, Kelly P, Branch RA, Jain A, Fung JJ, Starzl TE, Venkataramanan R. Clin Pharmacol Ther 1998 Mar; 63 (3), pp. 296–302.

Hepatic Cytochrome P450 2E1 (CYP2E1) Metabolizing Capacity
Chlorzoxazone

Cellular/Molecular Mechanism of Action: Chlorzoxazone is a metabolic substrate for hepatic cytochrome CYP2E1 metabolizing systems.

Dosage: Chlorzoxazone (reported range = 250–750 mg) and timed blood and urine samples are obtained for 10 hours in order to measure chlorzoxazone and 6-hydroxychlorzoxazone concentrations. Recent investigations indicate that a chlorzoxazone dose of 250 mg should be used and that a single plasma ratio obtained 2 to 4 hours after dosing is reflective of chlorzoxazone 6-hydroxylation and thus may serve as a measure of the cytochrome P450 2E1 phenotypic trait.

Considerations: Chlorzoxazone is being developed and proposed for use as a probe to measure *invivo* cytochrome P450 2E1 activity, but the phenotypic trait measures that are used vary. Although the doses proposed for phenotyping range from 250 mg to 750 mg, the effect of dose on chlorzoxazone hydroxylation has not previously been evaluated.

Interpretation and Analysis: Increases in the rate of chlorzoxazone metabolism directly (positively) correlate with relative hepatic P450 2E1 biochemical activity. A parameter used to reflect chlorzoxazone metabolism is the 6-hydroxychlorzoxazone-to-chlorzoxazone plasma concentration ratio measured at 2 to 4 hours post administration. Pharmacokinetic parameters are estimated using non-compartmental methods.

Evaluation of phenotypic trait measures show that 6-hydroxychlorzoxazone to chlorzoxazone plasma concentration ratios highly correlate with metabolite formation clearance measurements ($r = 0.9$; $p < 0.001$). Urine-based parameters (e.g., total recovery) are not significantly related to formation clearance ($r = 0.5$; $p > 0.05$). Dose dependency in chlorzoxazone metabolism is reflected by a 30% increase ($p < 0.05$) in the dose-normalized area under the concentration-time curve (AUC) of chlorzoxazone and lower incremental dose-normalized urinary recovery of 6-hydroxychlorzoxazone at early timepoints after administration of 750-mg doses of chlorzoxazone. In addition, the plasma ratio of 6-hydroxychlorzoxazone to chlorzoxazone at 4 hours is reduced by 48% in 5 of 6 subjects after 750-mg dosages ($p > 0.05$). Speculation suggests that at the higher dosage levels 6-hydroxylation biochemical mechanisms become saturated and further support the concern about the importance of cytochrome phenotyping as a basis for the design of optimal dosage regimens.

Use of chlorzoxazone as an *in vivo* probe of cytochrome P450 2E1: Choice of dose and phenotypic trait measure. Frye RF, Adedoyin A, Mauro K, Matzke GR, Branch RA. J Clin Pharmacol 1998 Jan; 38 (1), pp. 82–9.

Hepatic Cytochrome P450 2E1 (CYP2E1) Metabolizing Capacity
Chlorzoxazone/Disulfiram

Cellular/Molecular Mechanism of Action: Chlorzoxazone (CLZ) is a selective substrate for hepatic cytochrome P450 CYP2E1 enzyme systems. Disulfiram (DSF) is a mechanism-based inhibitor of cytochrome CYP2E1.

Application: Chlorzoxazone (CLZ) is a selective (*in vivo*) probe for detecting and measuring hepatic cytochrome P450 CYP2E1 biochemical activity. Disulfiram, has potential value as a strategy for preventing CYP2E1-mediated xenobiotic toxicity.

Route of Administration: Disulfiram (oral).

Dosage: Disulfiram (500 mg SID).

Examples of Clinical Implementation: Chlorzoxazone can be applied *in vivo* to determine baseline CYP2E1 activity (CLZ plasma clearance and 6-hydroxychlorzoxazone fractional metabolic clearance). Investigations are then complemented 1 week later by the subsequent administration disulfiram in concert with chlorzoxazone intake approximately 12 hours later and then again on days 3, 6, 8, 10, and 13. A terminal DSF metabolite, 2-thiothiazolidine-4 carboxylic acid, can also be measured in urine samples at 24-hour intervals. The mean CLZ clearance and 6-hydroxychlorzoxazone fractional metabolic clearance on day 1 declines to 10.2% and 5.5% of baseline values, which reflect rapid and profound CYP2E1 inhibition. On day 3, CYP2E1 activity usually has returned to half that of control and by day 8 has returned to baseline values. Assuming zero-order synthesis and 1st-order degradation, the *in vivo* CYP2E1 synthesis rate and degradation half-life is estimated to be 11 ± 5 nmol/hr and 50 ± 19 hr, respectively. Significant amounts of 2-thiothiazolidine-4 carboxylic acid are present only on day 1 suggesting that the return of *in vivo* CYP2E1 activity is not associated with inhibitor washout, but instead by enzyme resynthesis. Results regarding CYP2E1 disposition may be useful for modeling the effects of CYP2E1 inducers and inhibitors. For prevention of CYP2E1-mediated bioactivation, depending on protoxicant disposition, a 2nd DSF dose might be necessary to completely prevent toxicity.

Interpretation and Analysis: Results regarding CYP2E1 disposition may be useful for modeling the effects of CYP2E1 inducers and inhibitors. For prevention of CYP2E1-mediated bioactivation, depending on protoxicant disposition, a 2nd DSF dose might be necessary to completely prevent toxicity.

Duration of cytochrome P450 2E1 (CYP2E1) inhibition and estimation of functional CYP2E1 enzyme half-life after single-dose disulfiram administration in humans. Emery MG, Jubert C, Thummel KE, Kharasch ED. J Pharmacol Exp Ther 1999 Oct; 291 (1), pp. 213–9.

Hepatic Steroid 15-α-Hydroxylase (CYP2A4)/Steroid 16-α-Hydroxylase (CYP2D9)/Estrogen Receptor-Alpha (ERα)/Signal Transducers and Activators of Transcription (STAT)
Estrogen/Growth Hormone

Cellular/Molecular Mechanism of Action: CYP2A4 (steroid 15-α-hydroxylase) and CYP2D9 (steroid 16-α-hydroxylase) function as biochemical enzyme fractions that hydrolyze steroid hormone substrates.

Physiological Mechanism of Action: CYP2A4 (steroid 15-α-hydroxylase) and CYP2D9 (steroid 16-α-hydroxylase) function as female-specific and male-specific genes, respectively, that are regulated through estrogen receptor complexes (ERα) and the Stat5b form of STAT (signal transducers and activators of transcription).
Application: Potential modification of the expression of sex-specific CYP2A4 (steroid 15-α-hydroxylase) and CYP2D9 (steroid 16-α-hydroxylase) applying various hormonal agents (e.g., estrogen, growth hormone).
Interpretation and Analysis: The female-specific enzyme CYP2A4 (steroid 15-α-hydroxylase) is directly regulated by the binding of estrogen to ERα receptor complexes. Suppression of ERα expression decreases female (murine) CYP2A4 expression. Interestingly, the CYP2D9 gene continues to be expressed in ERα-deficient males and does not appear to be ERα regulated. Nuclear localization of Stat5b occurs in both sexes of ERα-deficient mice, although it is normally observed in only wild-type males. Nuclear localization of Stat5b correlates with the repression of CYP2A4 and expression of CYP2D9, respectively. Because Stat5b is not detectable in liver nuclear extracts prepared from hypophysectomized ERα-deficient females, the regulation by ERα appears to be mediated through a pituitary hormone (i.e., growth hormone). Thus, ERα appears to play a key role in the mechanism that inhibits nuclear localization of Stat5b in female mice, leading to feminization of the ERα-GH-Stat5b pathway and CYP expression. Defaulting to this ERα-dependent mechanism results in localization of Stat5b to nuclei, which masculinizes the expression of CYP genes in male mice.

Developmental action of estrogen receptor-alpha feminizes the growth hormone-Stat5b pathway and expression of CYP2A4 and CYP2D9 genes in mouse liver. Sueyoshi T, Yokomori N, Korach KS, Negishi M. Mol Pharmacol 1999 Sep; 56 (3), pp. 473–7.

MICROSOMAL CYTOCHROMES P450 3A

Hepatic Cytochrome P450 3A (CYP3A) Metabolic Capacity/Renal Dysfunction: End-Stage
Rifampicin/Erythromycin Breath Test

Background Information: The cytochrome P450 (CYP) oxidative enzyme system, located primarily in the liver and small intestine, is responsible for the metabolism and detoxification of numerous endogenous and exogenous substances. The most abundant CYP enzyme, CYP3A, is known to be involved in the metabolism of more than 200 commonly used medications. In experimental models of renal failure, both hepatic function and CYP enzyme content are reduced; however, direct evidence in humans is lacking. Evaluation of drug metabolism in patients with end-stage renal disease is important because these patients use a large number of medications and are at risk of adverse reactions and drug-drug interactions.
Implementation: Measurement of hepatic CYP3A activity at baseline and after rifampicin enzyme induction in 12 patients with end-stage renal disease and 12 healthy, age-matched controls. Hepatic CYP3A phenotype can be characterized with the erythromycin breath test (ERBT), and enzyme induction capacity is evaluated with a short course of rifampicin (600 mg/d for 6 days).
Interpretation and Analysis: In end-stage renal disease, baseline ERBT values are 28% lower than reference controls ($p < .05$). However, enzyme induction capacity after rifampicin administration is similar between groups ($p = 0.70$).

Characterization of hepatic cytochrome P450 3A activity in patients with end-stage renal disease. Dowling TC, Briglia AE, Fink JC, Hanes DS, Light PD, Stackiewicz L, Karyekar CS, Eddington ND, Weir MR, Henrich WL. Clin Pharmacol Ther 2003 May; 73 (5), pp. 427–34.

Hepatic Cytochrome P450 3A (CYP3A) Metabolic Capacity/Liver Biopsy
Midazolam (MDZ)/Cyclosporine

Cellular/Molecular Mechanism of Action: Midazolam is a substrate for cytochrome P450 3A and yields the metabolite 1′-hydroxy-midazolam.
Background Information: The clearance of MDZ in humans is principally facilitated by metabolic biotransformation catalyzed by P450 3A isoforms.
Application: Optimization of dosage schemes, identification of individuals with susceptibility to protoxin biotransformation, and/or detection of therapeutic non-compliance as a function of measuring the *in vivo* biochemical activity of cytochrome P450 3A (CYP3A) enzyme systems.
Route of Administration: Midazolam (IV), cyclosporine (IV).
Considerations: Midazolam 1′-hydroxylation can be measured in liver biopsy specimens collected within 24 hours of initiation of pharmacokinetic studies utilizing tissue supernants produced following ultra-centrifugation (e.g., 13,000 × g).
Examples of Clinical Implementation: The clearance of midazolam and cyclosporine approximately 10 days after liver transplant surgery reveals that the *in vitro* rate of 1′-hydroxy-MDZ formation closely correlates with the total CYP3A content in hepatic S-13 fractions ($r = .84$, $p < 0.01$).

Total midazolam clearance measured *in vivo* highly correlates with hepatic CYP3A content measured *in vitro* ($r = 0.93$, $p < 0.001$), and with *in vivo* cyclosporine clearance ($r = 0.81$, $p < 0.001$). The intrinsic clearance of midazolam to 1′-hydroxy-midazolam (Vmax/Km) *in vitro* measured in ultra-centrifugation supernatants can be scaled to accommodate for total liver mass and applied to the model of hepatic clearance to yield a prediction of *in vivo* midazolam clearance (e.g., data set of $n = 5$ cases). The mean value predicted for midazolam clearance based on the interpretation of *in vitro* 1′-hydroxylation data is identical to the mean clearance observed *in vivo* (0.60 ± 0.24 vs 0.59 ± 0.25 liter/min). Such results suggest that variability in hepatic CYP3A expression in liver transplant recipients, and possibly in other populations, can be determined by the measurement of midazolam metabolic clearance.

Use of midazolam as a human cytochrome P450 3A probe: I. *In vitro-in vivo* correlations in liver transplant patients. Thummel KE, Shen DD, Podoll TD, Kunze KL, Trager WF, Hartwell PS, Raisys VA, Marsh CL, McVicar JP, Barr DM, et al. J Pharmacol Exp Ther 1994 Oct; 271 (1), pp. 549–56.

Hepatic Cytochrome P450 3A (CYP3A) Metabolic Capacity/S-Mephenytoin Poor Metabolizer Phenotype
Proguanil/Benzo-a-Pyrene/Caffeine/Omeprazole/S-Mephenytoin (Inhibitor)/Troleandomycin (Inhibitor)/α-Naphthoflavone (Activator)

Cellular/Molecular Mechanism of Action: Proguanil is a substrate for isoenzymes in the cytochrome CYP3A superfamily. Proguanil is also a substrate for S-mephenytoin hydroxylase. One important metabolite produced as a product from these 2 hepatic enzyme systems is cycloguanil.
Application: Measurement of the *in vivo* biochemical activity of cytochrome P450 2E1 (CYP2E1) and S-mephenytoin hydroxylase as it correlates with the ability of these 2 enzyme systems to metabolize

pharmaceuticals, optimize dosage schemes, determine individual susceptibility to protoxin biotransformation, and/or detect therapeutic non-compliance.

Interpretation and Analysis: In hepatic microsome preparations (human), the apparent Km values for proguanil range between 35 μM to 183 μM (n = 17 livers, 6.3-fold range in activity). Importantly, the rates of proguanil activation correlate significantly with CYP3A activity assessed through the measurement of benzo[a] pyrene metabolism, caffeine 8-oxidation, and omeprazole sulfone formation, in addition to parameters such as CYP3A immunoreactive content. A significantly high level of correlation also is associated with the rates of hydroxyomeprazole formation. In contrast, correlations with activities selective for CYP1A2, CYP2C9/10, and CYP2E1 and with immunoreactive CYP1A2 content are not significant.

Proguanil activation is inhibited by R,S-mephenytoin, troleandomycin, anti-CYP3A antiserum, and anti-CYP2C IgG but is activated by α-naphthoflavone. Inhibitors selective for CYP1A2, CYP2E1, CYP2A6, or CYP2C9/10 have little or no effect on proguanil activation. The extents of inhibition by R,S-mephenytoin, troleandomycin, and the 2 antibodies vary with the immunoreactive CYP3A content of the microsomes used. It is concluded that proguanil activation to cycloguanil by human liver microsomes is mediated both by S-mephenytoin hydroxylase and isoforms of the CYP3A subfamily. This has implications for the use of proguanil as an *in vivo* probe for the S-mephenytoin poor metabolizer phenotype.

In vitro proguanil activation to cycloguanil by human liver microsomes is mediated by CYP3A isoforms as well as by S-mephenytoin hydroxylase. Birkett DJ, Rees D, Andersson T, Gonzalez FJ, Miners JO, Veronese ME. Br J Clin Pharmacol 1994 May; 37 (5), pp. 413–20.

Hepatic Cytochrome P450 3A (CYP3A) Metabolization
Erythromycin (Breath Test)/Midazolam

Cellular/Molecular Mechanism of Action: Erythromycin and midazolam both are biochemically metabolized by hepatic cytochrome CYP3A enzyme fractions.

Application: Erythromycin and midazolam can be applied to assess the cytochrome CYP3A metabolizing capacity of the liver. Parameters generated in this manner can be applied to estimate the relative extent certain xenobiotics will be metabolized. More recently, the hydroxylation of midazolam has been suggested as an alternative *in vivo* probe , because it allows for estimation of CYP3A activity in both the hepatic parenchyma and intestinal epithelium.

Route of Administration: [^{14}C-N-methyl]-erythromycin (intravenous), and midazolam (intravenously [1 mg] or orally [2 mg]).

Dosage: [^{14}C-N-methyl]-erythromycin (3 μCi), midazolam (1 mg intravenously, or 2 orally). An erythromycin breath test (ERBT) can be performed 60 minutes after administration, and clearances estimated after midazolam administration. In addition, an endogenous 0- to 4-hour urinary 6-beta-hydroxycortisol/cortisol ratio can be measured to complement the aquired data set.

Considerations: Cytochrome CYP3A activity exhibits considerable interindividual variability, and an *in vivo* probe to measure such differences would serve several purposes. The ERBT is an established approach that has proven useful in this regard, but it has several limitations. More recently, the hydroxylation of midazolam as an *in vivo* probe has been suggested as an alternative approach for estimating CYP3A activity in the intestinal epithelium as well as in the liver.

Examples of Clinical Implementation: All 3 measured drug trait values vary approximately 3-fold to 5-fold, whereas the endogenous phenotype measure exhibit far greater variability (> 100-fold). A relatively low degree of correlation ($p < 0.05$) exists between any of the trait values including the erythrocyte breath test parameter obtained through the intravenous administration of the radiolabeled probe and the systemic clearance of midazolam, expressed in terms of either total or unbound drug, or on an absolute or a body weight-corrected basis ($r = 0.03$ to $r = 0.24$; $p = 0.08$ to $p = 0.90$). Substratification according to sex generally does not improve correlation statistics.

Interpretation and Analysis: Despite the biochemical conversion of both erythromycin to its N-demethylated metabolite, and the transformation of midazolam to its hydroxylated metabolite by cytochrome CYP3A, there is little correlation in the parameters generated by these 2 agents when they are applied *in vivo* as diagnostic probes. Indirect measurements such as the ERBT may reflect CYP3A activity and be useful for some purposes, but the estimation of the oral and intravenous clearance of midazolam has additional advantages, and they may be more applicable and have broader usefulness as quantitative estimates of CYP3A activity.

Failure of erythromycin breath test to correlate with midazolam clearance as a probe of cytochrome P450 3A. Kinirons MT, O'Shea D, Kim RB, Groopman JD, Thummel KE, Wood AJ, Wilkinson GR. Clin Pharmacol Ther 1999 Sep; 66 (3), pp. 224–31.

Hepatic Cytochrome P450 3A (CYP3A) Metabolizing Capacity
Midazolam

Application: Functions as an *in vivo* probe for measuring cytochrome CYP3A activity in order to predict or quantify hepatic xenobiotic metabolic capabilities.

Interpretation and Analysis: Plasma concentration-time curves following intravenous and oral administration of midazolam can be generated applying non-compartmental pharmacokinetic analysis. Concentration at the mean residence time (MRT) represent the best predictor for calculated estimates of total area-under-the-curve (AUC) parameters according to the concepts of statistical moment theory. Following IV or oral midazolam administration, the average MRT is approximately 3.5 hours, suggesting that the optimal single sampling time to predict AUC is between 3 and 4 hours. The concentrations of midazolam measured 4-hours after an IV or oral dose accounts for 80 and 91% of the constitutive interindividual variability in midazolam AUC, respectively. The 4-hour midazolam measurement can also function as an excellent predictor of drug-drug interactions involving CYP3A induction and inhibition.

In vivo phenotyping for CYP3A by a single-point determination of midazolam plasma concentration. Lin YS, Lockwood GF, Graham MA, Brian WR, Loi CM, Dobrinska MR, Shen DD, Watkins PB, Wilkinson GR, Kharasch ED, Thummel KE. Pharmacogenetics 2001 Dec; 11 (9), pp. 781–91.

Hepatic Cytochrome P450 3A4
Alprazolam/Citalopram/Fluoxetine

Physiological Mechanism of Action: Citalopram is a selective serotonin reuptake inhibitor antidepressant.

Background Information: The selective serotonin reuptake inhibitor (antidepressant) fluoxetine decreases or prevents alprazolam metabolism *in vivo* through cytochrome P450 3A4 inhibition. Both *in vitro* and *in vivo* observations suggest that citalopram has a minimal effect on cytochrome P450 3A4.

Application: Alprazolam can be applied as a probe to evaluate the metabolism of other pharmaceutical agents through cytochrome P450 3A4 isoenzyme pathways.

Dosage: Alprazolam (1 mg).
Implementation: Evaluation of the potential for citalopram to be metabolized *in vivo* by cytochrome P450 3A4-mediated enzyme systems determined as a function of alprazolam metabolism. Theoretically, therapeutic doses of citalopram (20 mg/d), as compared with fluoxetine (20 mg/d), should create less impairment on the metabolism of the probe drug alprazolam (1 mg) through inhibition of the cytochrome P450 3A4 isozyme as measured by *in vivo* pharmacokinetic and pharmacodynamic parameters.
Interpretation and Analysis: Fluoxetine prolongs the half-life of alprazolam by 16% and increases the area under the curve 0-infinity of alprazolam by 32%, while citalopram does not affect these parameters, although the time of maximum concentration of alprazolam is prolonged by 30 minutes after citalopram administration. Neither selective serotonin reuptake inhibitor significantly affects the pharmacodynamic profile of alprazolam. This experiment suggests differential effects by citalopram and fluoxetine on alprazolam kinetics.

Pharmacokinetic and pharmacodynamic evaluation of the inhibition of alprazolam by citalopram and fluoxetine. Hall J, Naranjo CA, Sproule BA, Herrmann N. J Clin Psychopharmacol 2003 Aug; 23 (4), pp. 349–57.

Hepatic Cytochrome P450 3A4 (CYP3A4): Endobiotic Metabolism/Xenobiotic Metabolism: Pharmaceuticals and Environmental Toxins
Steroids

Background Information: Marked interindividual variability exists in the expression of the cytochrome P450 3A4 metabolizing enzyme system.
Application: Determination of the genetic variability of cytochrome CYP3A4 expression can serve as an avenue for determining the pharmacogenetic implications related to individual differences in the metabolization of endogenous substances and xenobiotics, including the metabolism of steroids, environmental toxins and therapeutic pharmaceuticals.
Implementation: Determination of the genetic variability of cytochrome CYP3A4 expression can be achieved through the analysis of DNA samples from hepatic tissue harvested from known cases of the CYP3A4 phenotype.

Human Model: Cases of the CYP3A4 phenotype (e.g., Caucasians n = 53; African-Americans n = 21; CYP3A4 metabolism "outliers" n = 7; poor nifedipine metabolizers n = 5; DNA Polymorphism Discovery Resource subset [Coriell Institute] n = 8; 9 ethnic group representatives n = 89).
Interpretation and Analysis: Five non-synonymous mutations in the coding region of CYP3A4 have been identified.. CYP3A4*14 (T44C) in exon 1 results in an L15P change; CYP3A4*15 (G14387A) in exon 6 resulted in a R162Q substitution; CYP3A4*10 (G14422C) in exon 6 results in a D174H substitution; CYP3A4*16 (C15721G) in exon 7 results in a T185S amino acid substitution; and CYP3A4*12 (C22002T) in exon 11 results in a L373F change in the CYP3A4 protein. An additional observation that can be appreciated is 6 single nucleotide polymorphisms (SNPs) in the 5′-UTR, 13 SNPs in the introns and 3 SNPs in the 3′-UTR. Extensive population differences exist in the frequencies of various CYP3A4 alleles. None of the 28 CYP3A4 SNPs identified in CYP3A4 phenotyped persons (most individuals being heterozygous for any CYP3A4 variant) is associated with low hepatic CYP3A4 protein expression or low CYP3A4 activity *in vivo.*

Common allelic variants of cytochrome P450 3A4 and their prevalence in different populations. Lamba JK, Lin YS, Thummel K, Daly A, Watkins PB, Strom S, Zhang J, Schuetz EG. Pharmacogenetics 2002 Mar; 12 (2), pp. 121–32.

Hepatic Cytochrome P450 3A (CYP3A) 1st-Pass Activity/Non-Pharmacokinetic (Miosis Measurement)
Alfentanil

Cellular/Molecular Mechanism of Action: Alfentanil is an opioid that is a metabolic substrate for hepatic cytochrome CYP3A that is extracted from the plasma on 1st-pass perfusion of the liver.
Application: Non-invasive molecular probe that can be utilized in the assessment of 1st-pass hepatic cytochrome P450 3A metabolizing capacity through the indirect evaluation of the influence of alfentanil on pupil size (promotes miosis). Plasma concentrations of alfentanil directly correlate with the degree of observed miosis.
Route of Administration: Alfentanil (oral).
Dosage: Efficacy trial evaluating escalating dosage of 23, 30, 43, and 75 μg/kg administered orally on separate days.
Interpretation and Analysis: Oral alfentanil is rapidly absorbed (time to maximum concentration T_{max} = 0.7 ± 0.5 hours). Mean values for area-under-the-plasma-concentration-time-curve extrapolated to infinity [$AUC_{infinity}$ (27 ± 14, 38 ± 22, 57 ± 31, and 105 ± 59 ng/hr/ml] and maximum concentration (16 ± 8, 23 ± 16, 31 ± 18, and 50 ± 22 ng/mL) reveal a linear relationship to dose, but are associated with a substantial degree of interindividual variability. Parameters that are independent of administered dose include T_{max}, elimination half-life (1.0 ± 0.2 hours), total body clearance after oral administration [20 ± 18 ml/kg/min], and dose-normalized AUC ($AUC_{infinity}$). In contrast, alfentanil deposition is dose-dependent and displays a direct relationship to changes in clinical effect. The miosis created by alfentanil is variable to the extent that it may not be detectable in some cases at the lower dosage range. Mean miosis AUC (AUEC) and peak miosis are log-dose linear and the effective half-life (1.3 ± 0.9 hours) parallels the pharmaceutical's plasma half-life.

Oral alfentanil is rapidly absorbed (time to maximum concentration T_{max} = 0.7 ± 0.5 hours), exhibits linear and dose-independent kinetics, and undergoes substantial 1st-pass metabolism. Oral alfentanil may be a suitable probe for 1st-pass CYP3A activity. Measurement of the biological effect of alfentanil (miosis) may be an acceptable surrogate for plasma alfentanil concentrations (pharmacokinetic profiles). Further studies are warranted to determine whether oral alfentanil and alfentanil effect kinetics may be a suitable non-invasive *in vivo* probe for 1st-pass hepatic CYP3A activity

Disposition and miotic effects of oral alfentanil: A potential non-invasive probe for 1st-pass cytochrome P450 3A activity. Kharasch ED, Hoffer C, Walker A, Sheffels P. Clin Pharmacol Ther 2003 Mar; 73 (3), pp. 199–208.

Hepatic Cytochrome P450 3A4 (CYP3A4) 1st-Pass Activity /Non-Pharmacokinetic (Miosis Measurement)
Alfentanil/Midazolam/Rifampil/Troleandomycin

Cellular/Molecular Mechanism of Action: The opioid alfentanil is a CYP3A4 substrate and its rate and extent of plasma clearance depends exclusively on hepatic CYP3A4 biochemical activity.
Application: Determination of the CYP3A4 biochemical metabolizing capacity of the liver. Results from such evaluations are potentially valuable in predicting drug-interaction phenomenon, sequelae, and optimizing plasma pharmacokinetic profiles.
Route of Administration: Midazolam (IV); alfentanil (IV).

Dosage: Medazolam (1 mg) followed 1 hour later by intravenous alfentanil (15 μg/kg). Induction of CYP3A4 is achieved with rifampicin, while CYP3A4 inhibition is produced with troleandomycin administration.
Considerations: Pharmacokinetic studies are invasive and time-consuming, and they require extensive analytical effort. Alternatively, alfentanil-induced miosis (drug effect) can be used as a surrogate measure for assessing alfentanil plasma concentrations. Alfentanil can therefore be utilized as a non-invasive probe for hepatic CYP3A4 xenobiotic metabolizing systems.
Examples of Clinical Implementation: Dark-adapted pupil diameter and dynamic light response are measured coincident with venous blood sampling for up to 8 hours. Plasma concentrations of alfentanil and midazolam (an additional CYP3A4 probe) and pupil diameter vs time data can be analyzed by use of non-compartmental modeling. Pupil diameter change can be analyzed analogously to determine the area under the alfentanil effect (miosis)-time curve (AUEC), effect clearance (CL_{miosis}), and effect half-time.
Interpretation and Analysis: Compared with control, CYP3A4 induction and inhibition significantly alters the clearances of alfentanil (2.8 ± 1.4, 5.3 ± 1.0, and 0.42 ± 0.1 ml/kg/min, respectively; $p < .05$ vs control) and midazolam. Dark-adapted resting diameter (in millimeters) is the best measure of alfentanil pupil effects. Alfentanil-dependent miosis is significantly altered by CYP3A4 modulation, and $\log(\text{diameter}_0 - \text{diameter}_t)$ vs time curves resemble alfentanil plasma disposition. $AUEC_{infinity}$ values after control, CYP3A4 induction, and inhibition are 280 ± 150, 120 ± 22, and 1030 ± 240 mm × min, respectively ($p < 0.05$ vs control). Effect clearances (CL_{miosis}) are approximately 4.2 ± 1.3, 8.8 ± 2.4, and 1.2 ± 0.8 μg/mm × min, respectively, and effect half-times are 62 ± 23, 34 ± 27, and 211 ± 35 minutes, respectively ($p < 0.05$ vs control). CL_{miosis} significantly correlates with plasma clearances of alfentanil ($r = 0.77$, $p < 0.001$) and midazolam ($r = 0.80$; $p < 0.001$).

Alfentanil effect (miosis) may be a sensitive and reliable surrogate for plasma alfentanil concentrations. Alfentanil kinetics profiles may be used as a non-invasive surrogate for conventional pharmacokinetic studies. Effective clearance as measured by miosis response appears to be a highly suitable non-invasive *in vivo* probe for hepatic CYP3A4 biochemical metabolizing capacity, and its merits warrant further investigation. In summary, alfentanil clearance is an excellent *in vivo* probe for assessing hepatic CYP3A4 biochemical activity and drug interactions in humans.
Instrumentation: Ophthalmascope for evaluation of papillary responses and a gas chromatography-mass spectrometry for quantifying midazolam and alfentanil contained in biological fluid samples.

A pilot evaluation of alfentanil-induced miosis as a non-invasive probe for hepatic cytochrome P450 3A4 (CYP3A4) activity in humans. Phimmasone S, Kharasch ED. Clin Pharmacol Ther 2001 Dec; 70 (6), pp. 505–17.

Hepatic Cytochrome P450 3A4 (CYP3A4) Metabolizing Capacity
Dexamethazone (CYP3A4)/Ketoconazole (−CYP3A4)/ Furafyllin (−CYP1A)/Tolbutamide (CYP2C)/ Sulfaphenazole (−CYP2C)

Cellular/Molecular Mechanism of Action: Dexamethazone is a synthetic glucocorticoid that can serve as an *in vitro* and *in vivo* probe for detecting and measuring cytochrome CYP3A4 biochemical activity. Ketoconazole functions as a inhibitor of cytochrome CYP3A4 biochemical activity. Furafylline is a CYP1A inhibitor, tolbutamide is a CYP2C substrate, and sulfaphenazole functions as a CYP2C inhibitor.
Interpretation and Analysis: In liver preparations (human), the following metabolites of dexamethazone can be identified; 6-beta-hydroxydexamethasone, 6-alpha-hydroxydexamethasone, 6-hydroxy-9-alpha-fluoro-androsta-1,4-diene-11 beta-hydroxy-16 alpha-methyl-3,17-dione (6-hydroxy-9 alpha-F-A) and 9 alpha-fluoro-androsta-1,4-diene-11 beta-hydroxy-16 alpha-methyl-3,17-dione (9 alpha-F-A). Dexamethasone undergoes side-chain cleavage to form 9 alpha-F-A, which then becomes a substrate for 6-hydroxylation. Interindividual variability in metabolic profiles is considerable. Mean (+/-S.D.) K_m values for 6-beta-hydroxydexamethasone and 6-alpha-hydroxydexamethasone formation are 23.2 ± 3.8 and 25.6 ± 1.6 μM ($n = 4$), respectively. The corresponding V_{max} values are 14.3 ± 9.9 and 4.6 ± 3.1 pmol/min/mg protein. Ketoconazole (3 μM) completely inhibits 6-alpha-hydroxylation and 6-beta-hydroxylation in a manner that suggests that the formation of both metabolites is catalyzed by CYP3A4. Further evidence validating this concept includes the degree of correlation between the rate of metabolite formation and the relative expression of CYP3A4 [6-beta-hydroxydexamethasone ($r = 0.74$ at $p = 0.003$); and 6-alpha-hydroxydexamethasone ($r = 0.70$ at $p = 0.006$)]. In addition to ketoconazole, both ellipticine and gestodene cause marked inhibition of 6-hydroxylation. Ellipticine is clearly not a selective CYP1A inhibitor as has been stated previously. However, furafylline (CYP1A inhibitor), tolbutamide (CYP2C substrate), and sulfaphenazole (CYP2C inhibitor) are essentially non-inhibitory. The relatively simple metabolic profile of dexamethasone compared to other steroids may point to this being a potentially useful *in vivo* probe for CYP3A4 in humans.
Instrumentation: Radiometric high-performance liquid chromatography and liquid-chromatography-mass spectrometry in concert with the identification of the major metabolite 6-beta-hydroxydexamethasone by co-chromatography with a chemically synthesized standard.

Dexamethasone metabolism by human liver *in vitro*. Metabolite identification and inhibition of 6-hydroxylation. Gentile DM, Tomlinson ES, Maggs JL, Park BK, Back DJ. J Pharmacol Exp Ther 1996 Apr; 277 (1), pp. 105–12.

Hepatic Cytochrome P450 3A4 (CYP3A4) Metabolizing Capacity
Erythromycin Breath Test (ERBT) (CYP3A4)/Phenyltoin (+CYP3A4)/Dexamethazone (+CYP3A4)

Cellular/Molecular Mechanism of Action: Erythromycin is a substrate for hepatic P450 isoenzyme CYP3A4 and radioactive carbon atoms from labeled analogs are expired by pulmonary mechanisms.
Application: Determination of the metabolizing capacity of hepatic P450 isoenzyme CYP3A4 in order to approximate the biochemical degradation rate of selected chemotherapeutic agents. Delineation of such parameters can faciliate optimal CYP3A4 metabolization of cytotoxic agents.
Route of Administration: [^{14}C]-erythromycin (intravenous) and erythromycin lactobionate (intravenous).
Dosage: [^{14}C]-erythromycin (4 μCi) followed on day 2 by 10-minute infusion of 100 mg of erythromycin lactobionate.
Implementation: Evaluation of hepatic cytochrome P450 3A4 microsomal enzyme activity. One experimental protocol that can be used for this purpose involves collection of breath samples on day 1 after the administation of [^{14}C]-erythromycin. The breath [$^{14}CO_2$] flux (CERt) is then estimated at 11 time points over a 2-hour period. On day 2, the ERBT is repeated midway through an infusion of erythromycin lactobionate, and the plasma pharmacokinetic profile for erythromycin established.

Interpretation and Analysis: Increases in the expiration of [$^{14}CO_2$] in the ERBT directly corresponds with the P450 isoenzyme CYP3A4 associated metabolizing capacity of the liver.

The infusion of 100 mg of erythromycin does not significantly modify the results generated by the ERBT. Measurements of the conventional ERBT parameter CER20 minutes obtained on day 1 are comparable for most subjects (0.03–0.06% dose/min) except in situations associated with the co-administration of dexamethazone and phenytoin (known CYP3A4 inducers: 0.14% dose/min). A significant correlation does not exist between any of the conventional ERBT parameters and erythromycin clearance. However, 2 parameters reflecting early emergence of breath radioactivity (1/TMAX and CER3 min/CERMAX) correlate significantly with erythromycin clearance ($p = 0.005$ and 0.006, respectively). Novel parameters derived from the ERBT significantly correlate with the clearance of erythromycin even in the presence of confounding factors, such as metastatic liver disease, altered protein binding, and therapeutic co-administration.

Optimizing the erythromycin breath test for use in cancer patients. Rivory LP, Slaviero K, Seale JP, Hoskins JM, Boyer M, Beale PJ, Millward MJ, Bishop JF, Clarke SJ. Clin Cancer Res 2000 Sep; 6 (9), pp. 3480–5.

Hepatic Cytochrome P450 3A4 (CYP3A4) Metabolizing Capacity
Alfentanil (CYP3A4)/Midazolam (CYP3A4)/Rifampicin (+CYP3A4)/Troleandomycin (−CYP3A4)

Cellular/Molecular Mechanism of Action: Alfentanil (metabolic substrate for P450 3A4); midazolam (reference CYP3A4 probe); rifampicin (induction of P450 3A4 activity); and troleandomycin (selective P450 3A4 inhibitor).

Application: Alfentanil can be applied *in vivo* to assess cytochrome P450 3A4 (CYP3A4) biochemical activity. Justification for performing alfentanil-based diagnostic testing procedures is supported by the (i) known population variability in P450 3A4 activity to the extent that it complicates the design of dosage regimens for alfentanil and other pharmaceutical agents metabolized by this cytochrome system; and (ii) propensity of certain pharmaceuticals to enhance or inhibit the biochemical activity of P450 3A4 that in turn can influence the metabolism of co-administered pharmaceutical agents. Lastly, the *in vitro* evaluation of alfentanil metabolism utilizing liver microsomal enzyme preparations (human) is an excellent supplemental model for predicting alfentanil metabolism *in vivo* (human).

Route of Administration: Alfentanil (intravenous) 30 minutes after midazolam (intravenously). Induction of high P450 3A4 activity can be achieved by the administration of rifampicin, while low P450 3A4 activity can be promoted with the selective inhibitor troleandomycin.

Dosage: Alfentanil (20 μg/kg) 30 minutes after midazolam (1 mg) on 3 occasions: control; high P450 3A4 activity (rifampicin induction); and low P450 3A4 activity (selective inhibition by troleandomycin). Venous blood samples are collected for a period of 24 hours and plasma concentrations of midazolam and alfentanil and their primary metabolites 1′-hydroxymidazolam and noralfentanil measured.

Considerations: There is considerable unexplained variability in alfentanil pharmacokinetics, particularly with regard to systemic clearance.

Interpretation and Analysis: Pharmacokinetic parameters are determined by 2-stage analysis using both non-compartmental and 3-compartment models.

Plasma alfentanil concentration-time profiles depend significantly on P450 3A4 activity. Alfentanil non-compartmental clearance is 5.3 ± 2.3, 14.6 ± 3.8, and 1.1 ± 0.5 ml/kg/min, while the elimination half-life is 58 ± 13; 35 ± 7; and 630 ± 374 minutes, respectively, in P450 3A4 activity classified as normal/controls; high/ rifampicin; and low/troleandomycin (means ± SD; $p < 0.05$ compared with controls). Multicompartmental modeling suggests a time-dependent inhibition-resynthesis model for the troleandomycin effects on P450 3A4 activity, characterized as $k10_t = k10[1\text{-}\pi\ e\text{-}\alpha(t\text{-}tzero)]$, where $k10_t$ is the apparent time-dependent rate constant, k10 is the uninhibited rate constant, π is the fraction of P450 3A4 inhibited, and α is the apparent P450 3A4 reactivation rate. Furthermore, a significant degree of correlation ($r = 0.97$, $p < 0.001$) exists between alfentanil systemic clearance and P450 3A4 activity. Alfentanil clearance is positively affected by rifampicin (13.2 ± 3.6 ml/kg/min), but negatively influenced by troleandomycin (1.5 ± 0.8 ml/kg/min) compared to reference controls (4.9 ± 2.1 ml/kg/min). Based on the influence of rifampicin and troleandomycin on alfentanil clearance and their known biological effect on CYP3A4, alfentanil metabolism and clearance is predominantly influenced by cytochrome P450 3A4 biochemical activity.

This observation, combined with the known population variability in P450 3A4 activity, provides a mechanistic explanation for the interindividual variability in alfentanil disposition. Furthermore, the known susceptibility of P450 3A4 (human) activity to induction and inhibition provides a conceptual framework for understanding and predicting clinical alfentanil drug interactions.

Instrumentation: Gas chromatography-mass spectrometry.

The role of cytochrome P450 3A4 in alfentanil clearance. Implications for interindividual variability in disposition and perioperative drug interactions. Kharasch ED, Russell M, Mautz D, Thummel KE, Kunze KL, Bowdle A, Cox K. Anesthesiology 1997 Jul; 87 (1), pp. 36–50.

Hepatic Cytochrome P450 3A4 (CYP3A4) Metabolizing Capacity
Quinine (CYP3A4)/ Erythromycin (Breath Test: CYP3A4)/Troleandomycin (−CYP3A4)

Cellular/Molecular Mechanism of Action: Quinine can be used as a substrate to assess hepatic CYP3A4 biochemical activity. Troleandomycin functions as a selective cytochrome P450 3A4 inhibitor. Erythromycin is a substrate (probe) for hepatic P450 isoenzyme CYP3A4.

Application: Detection of elevations or declines in the biochemical capacity of hepatic cytochrome P450 type 3A4 in response to xenobiotic substances. The agents can also be utilized to delineate individual variations in the capacity to metabolize pharmaceuticals or toxins.

Route of Administration: Quinine sulfate (oral).

Dosage: Quinine sulfate (600 mg), troleandomycin (TAO; 500 mg every 8 hours).

Implementation: Evaluate the potential of the antimalarial agent quinine to function *in vivo* as a molecular probe for hepatic cytochrome CYP3A4 activity. Plasma and urine samples are collected before the administration of quinine, and then over the next 48-hour period. Detection is achieved with the aid of high-performance liquid chromatography analysis for both quinine and its CYP3A4-generated metabolite, 3-hydroxyquinine. During both phases, the erythromycin breath test (ERBT) is administered at specific times to assess hepatic CYP3A4 activity.

Interpretation and Analysis: Compared with reference controls, troleandomycin significantly decreases the mean time-averaged ERBT result by 77% (95% CI, 68, 85%), the mean apparent

oral clearance of quinine (CL/F) by 45% (95% CI, 39, 52%), and the mean apparent formation clearance of 3-hydroxyquinine (CL3-OH) by 81% (95% CI, 76, 87%). There is apparently no correlation between the troleandomycin-mediated percent decrease in the time-averaged ERBT result and the percent decrease in mean apparent oral clearance of quinine CL/F or apparent formation clearance of 3-hydroxyquinine. When TAO and control treatments are analyzed separately, no significant correlation can be appreciated between the time-averaged ERBT result and CL/F, CL3-OH, or single plasma quinine concentration (12, 24, or 48 hours).

Prolonged plasma clearance of intact quinidine implies compromised cytochrome P450 metabolism. Quinine may be a useful probe for detecting inhibition of liver CYP3A4 activity within an individual. Further studies are needed to determine whether it can provide a quantitative measure of CYP3A4 activity suitable for intersubject comparison.

Instrumentation: High-performance liquid chromatography analyses.

Is quinine a suitable probe to assess the hepatic drug-metabolizing enzyme CYP3A4? Wanwimolruk S, Paine MF, Pusek SN, Watkins PB. Br J Clin Pharmacol 2002 Dec; 54 (6), pp. 643–51.

Hepatic Cytochrome P450 3A4/5 (CYP3A4/5) Metabolization

Dextromethorphan (Substrate)/Rifampicin (+CYP3A4)/Erythromycin (−CYP3A4)

Cellular/Molecular Mechanism of Action: Dextromethorphan is N-demethylated to 3-methoxymorphinan by CYP3A4/5 (human). Rifampicin can function as an inducer of P450 3A4 activity. Alternatively, erythomycin inhibits the biochemical activity of P450 3A4 biochemical activity.

Application: Dextromethorphan is used widely as an *in vivo* probe for phenotyping the polymorphical expression of cytochrome P450 2D6 (CYP2D6) biochemical activity. More recent investigations have concluded that dextromethorphan can be effectively applied as an *in vivo* marker system for the detection and measurement of both CYP3A and CYP2D6 biochemical activity. Dextromethorphan is N-demethylated *in vitro* to 3-methoxymorphinan by human CYP3A4/5.

Dosage: Rifampicin (300 mg b.i.d. for 7 days), erythromycin (250 mg q.i.d. for 7 days).

Implementation: Evaluate the potential for erythromycin to inhibit metabolism of dextromethorphan by cytochrome P450 3A4, and determine the ability of rifampicin to enhance dextromethorphan metabolism through induction of hepatic cytochrome P450 3A4 microsomal enzyme fractions.

Interpretation and Analysis: The urinary excretion of 3-methoxymorphinan is rate limiting when metabolization by CYP2D6 is extensive and necessitates a longer time period for urine collection (0–72 hours) to obtain true values for CYP3A metabolic ratios (3-methoxymorphinan/dextromethorphan). Conversely, urinary excretion of dextromethorphan and 3-methoxymorphinan is delayed when CYP2D6 metabolizing capacity is low but appears to be formation rate limiting. Delayed excretion in conditions of poor metabolizing capacity necessitates longer urine collection intervals (0–11 days) in order to estimate the true CYP3A metabolic ratio, while the necessary collection interval for establishing true CYP2D6 metabolic ratios is slightly shorter (0–8 days). However, a 72-hour collection in poor metabolizers can be used as an index of the true dextromethorphan/3-methoxymorphinan metabolic ratio.

Rifampicin (300 mg b.i.d. for 7 days) significantly reduces the 0-to-72-hour dextromethorphan/3-methoxymorphinan metabolic ratio consistent with an 830% (± 1,808%) induction of CYP3A activity (n = 8). Conversely, erythromycin significantly increases the dextromethorphan/3-methoxymorphinan metabolic ratio, corresponding to a 34% ± 44% inhibition of activity, respectively, in conditions where extensive CYP3A metabolization exists and in situations of low-level degradation. The changes in CYP3A activity are independent of CYP2D6 phenotype and can be observed after 24- and 48-hour urine collections in conditions of either extensive or suboptimal metabolization. In addition, metabolic ratios reflecting CYP2D6 and CYP3A do not significantly correlate with 1 another.

Determination of cytochrome P450 3A4/5 activity *in vivo* with dextromethorphan N-demethylation. Jones DR, Gorski JC, Haehner BD, O'Mara EM Jr, Hall SD. Clin Pharmacol Ther 1996 Oct; 60 (4), pp. 374–84.

Hepatic Cytochrome P450 (CYP3A4) Metabolization Capacity

Contraceptives (Male)/Potential Application of Dextromethorphan (Substrate), Rifampicin (+CYP3A4), and Erythromycin (−CYP3A4)/T ethanate

Cellular/Molecular Mechanism of Action: The CYP3A4 gene encodes for a major hepatic T-inactivating enzyme.

Background Information: Clinical trials of hormonal male contraceptive regimens have identified a consistent population polymorphism in susceptibility to hormone-induced azoospermia. Using identical hormonal regimens, fewer men of European origin (approximately two-thirds) become azoospermic compared with Asian men, who virtually all become azoospermic. This variation within and between populations remains unexplained but has been spectulated to be due to a pharmacogenetic difference in androgen metabolism.

Application: Delineate the possible existence of pharmacogenetic differences in androgen metabolism or action that may correlate with variable susceptibility to hormonal-induced azoospermia.

Considerations: Citation represents an example of an experimental approach to investigating the pharmacogenetic properties associated with a given biological observation.

Implementation: Evaluation of single nucleotide polymorphism in the CYP3A4 gene (encodes the major hepatic T-inactivating enzyme), and CAG and GGC triplet repeats in the AR gene have been characterized to delineate the pharmacogenetic differences in androgen metabolism in human males (e.g., n = 75 receiving hormonal contraceptives; and n = 106 negative reference controls). Identification of A/G variants in the promoter region of the CYP3A4 gene can be delineated applying a mutagenically differentiated polymerase chain reaction (PCR) methodology. Fluorescent-labeled DNA fragments containing either CAG or GGC repeats are amplified from genomic DNA, and their sizes determined based on capillary electrophoresis analysis.

Interpretation and Analysis: Human subjects can be classified into groups according to whether 6 months of weekly T enanthate injections produce azoospermia (n = 54), near-azoospermia (n = 7), and non-azoospermia (n = 14). The G allele of CYP3A4 gene is absent from the non-azoospermia and near-azoospermia groups, but overall this single nucleotide polymorphism distribution does not differ significantly between azoospermia males and reference contol populations. There is no significant difference in distribution of CAG and GGC triplet repeats among 3 groups or between them and population controls based on the maximum likelihood estimate of odds ratio and CLUMP II analyses. Therefore, neither genetic polymorphisms in the AR gene (CAG and GGC repeats) nor that in hepatic forms of the gene appear to be influenced.

Pharmacogenetic polymorphisms of the AR and metabolism and susceptibility to hormone-induced azoospermia. Yu B, Handelsman DJ. J Clin Endocrinol Metab 2001 Sep; 86 (9), pp. 4406–11.

Hepatic Cytochrome P450 3A4 (CYP3A4) Metabolizing Capacity
Steroids

Cellular/Molecular Mechanism of Action: The enzyme CYP3A4 has an important role in endogenous processes, most notably steroid catabolism.

Background Information: The enzyme CYP3A4 is the most abundant cytochrome P450 in human liver, comprising approximately 30% of the total liver P450 content and plays a fundamental role in the metabolism of more than half of the clinically used drugs currently prescribed. Majority of the substrates for CYP3A are also capable of upregulating CYP3A activity, mainly through transcriptional activation. The molecular mechanisms that underlie the transcriptional activation of CYP3A4 are complex, involving many steroid hormone nuclear receptors, including GR, PXR, VDR and CAR, which play a role in these mechanisms. However, the net result of transcriptional activation is an increase in the metabolism of the inducing compounds and, therefore, increased clearance. An important side effect of this transcriptional activation is that coadministered chemicals metabolized by CYP3A may also have their pharmacokinetics altered. Such changes can result in reduced clinical efficacy of drugs, resulting in poor patient response, or the development of adverse drug responses.

Evaluation of the toxicological relevance of CYP3A4 induction. Plant NJ, Gibson GG. Curr Opin Drug Discov Devel 2003 Jan; 6 (1), pp. 50–6.

Hepatic vs Intestinal Cytochrome P450 3A (CYP3A) Metabolizing Capacity/Pharmaceutical Metabolizing Capacity
Midazolam/Ketoconazole

Cellular/Molecular Mechanism of Action: Midazolam is a substrate for cytochrome isotype CYP3A while ketoconazole function as an inhibitor of CYP3A activity.

Application: Determine the intestinal and hepatic contribution to the bioavailability of midazolam with use of the CYP3A inhibitor ketoconazole.

Route of Administration: Midazolam (intravenous and oral) and ketoconazole (oral).

Dosage: Midazolam (2 mg IV and 6 mg oral) and ketoconazole (200 mg).

Considerations: The cytochrome P450 3A (CYP3A) isoforms are responsible for the metabolism of a majority of therapeutic compounds, and they are abundant in the intestine and liver. CYP3A activity is highly variable, causing difficulty in the use of therapeutics that are substrates for P450 3A enzyme systems.

Implementation: Midazolam can be employed as a practical *in vivo* probe for characterizing both intestinal and hepatic CYP3A activity. Previous reports have described the calculation of midazolam pharmacokinetic profiles utilizing single doses of 2 mg (IV) and 6 mg (oral).

Interpretation and Analysis: Area-under-the-concentration-vs-time-curve of midazolam increases 5-fold after intravenous midazolam administration ($p \leq 0.001$) and 16-fold after oral midazolam administration ($p \leq 0.001$). Comparison of the midazolam pharmacokinetic profile for this administration scheme compared to a schedule that also includes 3 doses of 200 mg oral ketoconazole results in decreases in intrinsic clearance (84%, $p = 0.003$) and increases in total bioavailability from 25% to 80% ($p < 0.001$). The intestinal component of midazolam bioavailability increases to a greater extent than the hepatic component (2.3-fold [$p = 0.003$] and 1.5-fold [$p \leq 0.001$], respectively). In reference controls, females have greater midazolam clearance values than male subjects. In summary, ketoconazole causes a marked inhibition of CYP3A activity that is greater in the intestine than the liver. Administration of single doses of oral and intravenous midazolam with and without oral ketoconazole exemplifies a practical method for differentiating intestinal and hepatic CYP3A activity.

Differentiation of intestinal and hepatic cytochrome P450 3A activity with use of midazolam as an *in vivo* probe: Effect of ketoconazole. Tsunoda SM, Velez RL, von Moltke LL, Greenblatt DJ. Clin Pharmacol Ther 1999 Nov; 66 (5), pp. 461–71.

HEPATIC CYTOCHROME P450 4 MICROSOMAL ENZYMES

Cytochrome P450 4B1 (CYP4B1)/Cytotoxicity Induction/Herpes Simplex Virus Type I Thymidine Kinase/Ganciclovir/Pharmacogene Therapy Systems: Bystander Effect/Biosafety Enhancers: Gene Marking or Replacement Studies/Biosafety Enhancers: Lymphocyte Infusions Postallogeneic Marrow Transplant
4-Ipomeanol (4-IM)/2-Aminoanthracene (2-AA)

Application: Determination of the time course of cytotoxicity induction and the bystander effect for (rabbit) cytochrome CYP4B1/4-IM or 2-AA pharmacogene therapy systems. A weak bystander effect together with a fast induction of cytotoxicity may provide marked advantages for the use of cytochrome CYP4B1 systems as biosafety enhancers for gene marking or replacement studies and donor lymphocyte infusions after allogeneic bone marrow transplantation.

Implementation: The time course of cytotoxicity induction and the bystander effect of the rabbit cytochrome CYP4B1/4-IM or 2-AA pharmacogene therapy systems has been characterized for comparison with the herpes simplex virus type 1 thymidine kinase/ganciclovir (HSV-tk/GCV) system.

Cellular Model: Rat 9L gliosarcoma cells stably expressing CYP4B1 (9L-4B1), HSV-tk (9L-tk), or their enhanced green fluorescent protein (EGFP) fusion genes.

Interpretation and Analysis: CYP4B1-mediated activation of 2-AA shows a high cell killing efficiency during only a 48-hour window and with an onset after only 15 minutes of prodrug exposure. Residual 9L-4B1 cells are mostly damaged sublethally upon 2-AA treatment, showing an S phase arrest by cell cycle analysis. 4-ipomeanol treatment of 9L-4B1 cells generates an overall weaker cell killing, especially after prodrug exposure periods of < 48 hours. Residual cells surviving 4-IM treatment show a G2/M arrest and restarted proliferation after prodrug treatment is stopped. HSV-tk/GCV pharmacogene therapy results in a slower cytotoxicity induction than CYP4B1/2-AA treatment with a significantly lower cell killing efficiency after 24 and 48 hours. HSV-tk/GCV-mediated cytotoxicity is similar to the cytotoxicity induced by CYP4B1/4-IM with the exception of a continuous 48-hour prodrug exposure where 4-IM treatment shows a significantly higher cell killing rate. Cells surviving HSV-tk/GCV suicide gene therapy are not viable and show an S-phase arrest. Whereas HSV-tk/GCV induce a strong bystander effect, only moderate bystander cell death depending on cell-to-cell contact is demonstrated in 9L/9L-4B1 co-cultures upon 2-AA treatment and is even absent with 4-IM, in contrast to previously

published reports. The absence of a strong bystander effect may limit the overall utility of the CYP4B1 systems for cancer gene therapy. Alternatively, a weak bystander effect together with the fast induction of cytotoxicity may provide marked advantages for the use of the CYP4B1 systems as biosafety enhancers for gene marking or replacement studies and donor lymphocyte infusions after allogeneic bone marrow transplantation.

Differential cytotoxicity and bystander effect of the rabbit cytochrome P450 4B1 enzyme gene by 2 different prodrugs: Implications for pharmacogene therapy. Frank S, Steffens S, Fischer U, Tlolko A, Rainov NG, Kramm CM. Cancer Gene Ther 2002 Feb; 9 (2), pp. 178–88.

Hepatic Cytochrome P450 4B1 (CYP4B1)/ Polymorphic Screening Aberrant Activating Enzyme Systems
4-Ipomeanol (4-IM): Antineoplastic Prodrug

Cellular/Molecular Mechanism of Action: 4-ipomeanol functions as a DNA alkylating agent once it has been converted to its active form by rabbit hepatic cytochrome P450 4B1 enzyme systems.
Physiological Mechanism of Action: 4-ipomeanol induces the development of glioblastoma in rabbits after it has been converted from a prodrug form to its biologically active metabolite.
Background Information: Gene therapy using vector-mediated transfer of prodrug activating genes is a promising treatment approach for malignant tumors. The novel prodrug activating gene coding for rabbit cytochrome CYP4B1 is able to induce tumor cell death at low micromolar concentrations in glioblastoma cells after *in vitro* and *in vivo* treatment with the prodrug 4-IM. The (rabbit) cytochrome P450 system, CYP4B1, converts this prodrug and other furane analogs and aromatic amines, such as 2-aminoanthracene, into highly toxic alkylating metabolites, whereas the human isoenzyme exhibits only minimal enzymatic activity.
Application: The prodrug 4-IM can potentially be applied in combination with appropriate enzyme systems capable of activating this therapeutic agent to its biologically active form. Pharmacogenetic screening could be employed to identify cases that idiosyncratically express aberrant enzyme systems capable of activating 4-IM in a manner that exerts cytotoxic properties against normal/health tissues and organ systems.
Dosage: 4-ipomeanol (0.5 to 2.0 μg/ml).
Implementation: Sequences of cDNA encoding for cytochrome P450 4B1 (rabbit CYP4B1) can be used for pharmacogene therapy of hepatocellular carcinoma (HCC). Cell clones derived from the human HCC cell lines Hep3B, HuH-7, and HepG2 that stably express the chimeric protein CYP4B1-EGFP (CYP4B1 coding sequence fused to the enhanced green fluorescent protein [EGFP] gene) are then identified for application in prodrug activation investigations. Appropriate reference controls can include HCC clones that express EGFP.
Interpretation and Analysis: The prodrug 4-IM rapidly induces tumor cell death in CYP4B1-EGFP-expressing clones at low concentrations (a 50% lethal dose of between 0.5 and 2 μg/mL). No signs of toxicity can be appreciated in control cells expressing EGFP even at high prodrug concentrations (20 μg/mL). Cell death occurs by apoptosis and independent of functional p53. A pronounced direct bystander effect can be observed in Hep3B cells, whereas bystander HepG2 and HuH-7 cells are highly resistant to toxic 4-IM metabolites. The CYP4B1/4-IM system efficiently and rapidly induces cell death in HCC cells, and a cell line-specific mechanism may exist that limits the extent of the bystander effect of this novel prodrug activating system.

Rabbit cytochrome P450 4B1: A novel prodrug activating gene for pharmacogene therapy of hepatocellular carcinoma. Mohr L, Rainov NG, Mohr UG, Wands JR. Cancer Gene Ther 2000 Jul; 7 (7), pp. 1008–14.

MICROSOMAL FLAVIN-BASED METABOLIZING SYSTEMS

Hepatic Flavin-Containing Monooxygenase Biochemical Activity
Benzydamine-N-Oxide/N-Benzylimidazole (CYP Inhibitor)/Methimazole

Cellular/Molecular Mechanism of Action: Benzydamine metabolized by hepatic flavin-containing monooxygenases (FMO) to an N-oxide metabolite. N-benzylimidazole is a non-specific CYP inhibitor, while methimazole is a competitive flavin monooxygenase inhibitor.
Application: Evaluate the influence of FMO on the disposition of xenobiotics.
Route of Administration: In preliminary investigations, benzydamine has been incubated with human liver microsomes and recombinant enzymes to evaluate the metabolism schemes that this pharmaceutical is vulnerable to in an effort to determine its suitability as a potential *in vivo* probe for determining hepatic flavin monooxygenases metabolic capacity.
Dosage: Not applicable.
Interpretation and Analysis: Benzydamine N-oxide formation rates in liver microsomes follow Michaelis-Menten kinetic patterns (mean Km = 64.0 μM, mean Vmax = 6.9 nmol/mg protein/min; n = 35). The non-specific CYP inhibitor, N-benzylimidazole, and selective inhibitors of various CYP isoforms do not affect benzydamine N-oxidation. Alternatively, formation of the N-oxide metabolite of benzydamine is almost abolished by heat treatment of microsomes in the absence of NADPH and is strongly inhibited by methimazole (competitive flavin monooxygenase inhibitor). Recombinant FMO3 and FMO1 (not expressed in human liver), but not FMO5, possess an ability to metabolize benzydamine to its N-oxidase metabolite. Respective Km values for FMO3 and FMO1 are 40.4 μM and 23.6 μM, and respective Vmax values for FMO3 and FMO1 are 29.1 and 40.8 nmol/mg protein/min. Based on the interpretation of findings from preliminary investigations, benzydamine could be used as a model substrate for human liver FMO3 activity *in vitro* and may be further developed as an *in vivo* probe reflecting FMO3 activity.
Instrumentation: Human liver samples can be genotyped using polymerase chain reaction (PCR)-restriction fragment length polymorphism methodologies.

Benzydamine N-oxidation as an index reaction reflecting FMO activity in human liver microsomes and impact of FMO3 polymorphisms on enzyme activity. Störmer E, Roots I, Brockmöller J. Br J Clin Pharmacol 2000 Dec; 50 (6), pp. 553–61.

Hepatic Flavin Monooxygenase Metabolizing Capacity
Benzydamine

Cellular/Molecular Mechanism of Action: Benzydamine is a substrate for flavin-containing monooxygenase isoenzymes FMO1 and FMO3.

Application: Detection and characterization of hepatic FMO metabolizing capacity.
Implementation: Determination of the FMO and P450 isoform selectivity for metabolism of benzydamine and caffeine in order to determine their individual potential to function as *in vivo* probes for flavin-containing monooxygenase isoenzyme fractions (e.g., human FMO3).
Route of Administration: Benzydamine.
Laboratory Methodology: Preliminary investigations have performed metabolic incubations at a physiological pH using substrate concentrations of 0.01 to 10 mM with either recombinant human flavin monooxydases, cytochrome P450 fractions, or human liver microsomes serving as sources of biochemical enzymes.
Considerations: Speculation suggests that it is likely that the metabolic capacity of hepatic FMO3 is a much greater contributor to plasma levels of the N-oxide metabolite *in vivo* than is the FMO1 extrahepatic isoenzyme.
Examples of Research Implementation: Caffeine is metabolized by CYP1A2 but not by any of the human flavin-containing monooxydases. In contrast, benzydamine can function as a substrate for human flavin-containing monooxygenases (isotypes FMO1, FMO3, FMO4, and FMO5). Apparent Km values for benzydamine N-oxygenation are 60 ± 8 μM, 80 ± 8 μM, > 3 mM, and > 2 mM, for FMO1, FMO3, FMO4, and FMO5, respectively. Corresponding Vmax values are 46 ± 2 min^{-1}, 36 ± 2 min^{-1}, < 75 min^{-1}, and < 1 min^{-1}. Small quantities of benzydamine N-oxide are also formed by CYPs 1A1, 1A2, 2C19, 2D6, and 3A4 isoenzymes.
Interpretation and Analysis: The rate and extent of conversion to metabolites is directly proportional to the concentration and biochemical capacity associated with hepatic cytochrome protein fractions. The rate and extent of caffeine metablism correlates to CYPA2 activity in contrast to benzydamine metabolism facilitated through 4 different flavin-containing monooxygenases (isotypes FMO1, FMO3, FMO4, and FMO5).

Flavin-containing monooxygenase isoenzymes FMO1 and FMO3 catalyse benzydamine N-oxygenation with the highest level of efficiency. However, it is likely that the metabolic capacity of hepatic FMO3 is a much greater contributor to plasma levels of the N-oxide metabolite *in vivo* than is extrahepatic FMO1. Therefore, benzydamine, but not caffeine, is a potential *in vivo* probe for human FMO3.
Instrumentation: Products of caffeine and benzydamine metabolism are analyzed by reversed-phase high-performance liquid chromatography in concert with UV and fluorescence detection systems.

In vitro evaluation of potential *in vivo* probes for human flavin-containing monooxygenase (FMO): Metabolism of benzydamine and caffeine by FMO and P450 isoforms. Lang DH, Rettie AE. Br J Clin Pharmacol 2000 Oct; 50 (4), pp. 311–4.

Hepatic Flavin Monooxygenase Metabolizing Capacity (FM01, FM02, FM03, FM05)/ Cytochrome P450 Hepatic Metabolizing Capacity *Ranitidine/Metimazol/Tranylcypromine (−CYP2C19)/a-Naphthoflavon (−CYP1A2)/Quinidine (−CYP2D6)*

Cellular/Molecular Mechanism of Action: Ranitidine is a substrate for hepatic microsomal oxidation to N-oxide (66–76%), S-oxide (13–18%), and desmethylranitidine (12–16%) metabolites. Metimazol is an inhibitor of flavin-containing monooxygenase. Alternatively, tranylcypromine, α-naphthoflavon, and quinidine inhibit P450 2C19, P450 1A2, and P450 2D6, respectively.
Application: Urinary contents of ranitidine N-oxide can be used as an *in vivo* probe to detect and measure hepatic FMO3 activity.
Examples of Research Implementation: The N-oxidation and S-oxidation of ranitidine is inhibited by metimazol (flavin-containing monooxygenase [FMO] inhibitor) 96–97% and 71–85%, respectively. Desmethylation of ranitidine is inhibited 71–95% by SKF525A (cytochrome P450 [CYP] inhibitor). Recombinant FMO isozymes FMO1, FMO2, FMO3 and FMO5 produce 39, 79, 2180, and 4 (pmol/min/nmol FMO) 4 ranitinine N-oxide, compared to 45, 0, 580, and 280 (pmol/min/nmol FMO) ranitinine S-oxide, respectively. Desmethyranitinine is not produced by recombinant FMOs. Production of desmethylranitidine by rat and human liver microsomes is inhibited by tranylcypromine, α-naphthoflavon and quinidine, which are known to inhibit CYP2C19, 1A2 and 2D6, repectively. Ranitidine N-oxide and S-oxide are produced at a 4-to-1 ratio by isoenzyme FM03 (major form in adult liver). Conversely, FM01 (major renal isoenzyme) is 55-fold and 13-fold less efficient than hepatic FM03 in producing ranitidine N-oxides and S-oxides respectively. Isoenzymes FMO2 and FMO5, although expressed slightly in human liver, kidney, and lung, are not efficient producers of ranitidine N- and S-oxides.
Interpretation and Analysis: Increases in the extent and rate that ranitidine is converted biochemically to ranitidine N-oxide directly corresponds to hepatic FM03 metabolic activity.

Oxidation of ranitidine by isozymes of flavin-containing monooxygenase and cytochrome P450. Chung WG, Park CS, Roh HK, Lee WK, Cha YN. Jpn J Pharmacol 2000 Oct; 84 (2), pp. 213–20.

MICROSOMAL MIXED FUNCTION OXIDASES

Hepatic Mixed Function Oxidases/Depression (Individualization of Dosage Regimens) *Amitriptyline/Hamilton Score/Multiple Points Method/Modified Bayesian Method*

Background Information: Individualization of an amitriptyline dose regimen offers substantial advantages over non-individualized treatments.
Application: Individualization of amitriptyline dose regimens for the purpose of maximizing therapeutic effect and minimizing adverse side effects.
Implementation: In patients with disorders of major depression and receiving amitriptyline therapy, the assessment of clinical effects, adverse effects, and plasma steady state concentrations can be applied to evaluate cases within the following 3 categories: (i) patients in Group A taking non-individualized doses of amitriptyline; (ii) patients in Group B taking doses of amitriptyline individualized by a modified Bayesian method; and (iii) patients in Group C taking doses of amitriptyline individualized by a multiple point method.
Interpretation and Analysis: Individuals within Group A take significantly higher doses throughout the treatment course; the initial doses for cases in Group B are higher than doses for the patients in Group C, but after corrections based on measured steady state plasma concentrations they can be found to be similar.

While the Hamilton score descends uniformly in all 3 groups, both adverse effects and steady state plasma concentrations of amitriptyline are higher in the non-individualized group during the whole treatment course. The multiple points method is considered to be the most precise technique, but it is a tedious and impractical technique. The modified Bayesian method with corrections based on 1st measured plasma steady state concentrations of amitriptyline

offers similar therapeutic outcome and adverse effects scores combined with low cost and convenient and an easy-to-use protocol.

Comparison of 2 approaches to amitriptyline dose individualisation. Jankovic SM, Timotijevic I, Mihajlovic GS, Dukic-Dejanovic S. Eur J Drug Metab Pharmacokinet 1999 Apr–Jun; 24 (2), pp. 163–8.

Mixed Function Oxidases/Fescue Endophyte Ingestion (Sheep)/Mental Depression
Cimetidine/Antipyrine

Cellular/Molecular Mechanism of Action: Cimetidine competitively inhibits binding of histamine to gastric H2 receptor complexes and may also influence the activity of hepatic mixed function oxidases. Antipyrine is believed to be metabolized through hepatic cytochrome P450 activity.
Application: The combined application of antipyrine and cimetidine can be used to delineate how a paticular toxin or pharmaceutical is metabolized or to detect abnormalities in hepatic function/integrity.
Route of Administration: Cimetidine (intravenous).
Dosage: Cimetidine (800 mg).
Implementation: Evaluation of the influence of endophyte-infected fescue (Kentucky 31) hay and cimetidine on respiration rates, rectal temperatures, and hepatic antipyrine uptake. Hepatic antipyrine uptake can be measured as an indirect indicator of hepatic mixed-function oxidase (MFO) activity.

Animal Model: Ovine (n = 3 mature ewe sheep exposed to endophyte-infected fescue [Kentucky 31]). Experimental Design: Ewes during a period of consuming endophyte-free (one exp/ewe, control), endophyte-infected (2 exp/ewe, EIF), and endophyte-infected fescue hay plus cimetidine (2 exp/ewe, EIFC).
Interpretation and Analysis: Respiration rates increase ($p < 0.05$) 2.6-fold after 11 days on EIF from 26 to 68 and decrease ($p < 0.025$) to 27 breaths/minute after 4 days of cimetidine treatment. Rectal temperatures increase ($p < 0.05$) 1.1°C after 8 days on EIF. Cimetidine lowers temperatures to control levels by day 4. Endophyte-infected fescue hay increases ($p < 0.05$) hepatic antipyrine uptake 70% after 11 days, but uptake is lowered to control levels by cimetidine by day 4. Increased respiration rates and rectal temperatures in animals consuming EIF seem to be related to increased MFO activity. Cimetidine reversed some of these effects.

Effects of endophyte-infected fescue and cimetidine on respiration rates, rectal temperatures and hepatic mixed function oxidase activity as measured by hepatic antipyrine metabolism in sheep. Zanzalari KP, Heitmann RN, McLaren JB, Fribourg HA. J Anim Sci 1989 Dec; 67 (12), pp. 3370–8.

PHASE II METABOLIZING ENZYME SYSTEMS

CONJUGATION SYSTEMS

Glutathione-S-Transferases (GST): Alzheimer's Therapy/Glutathione Conjugation: Isoenzymes GST M1 and GST T1/Prediction of Hepatotoxicity Susceptibility: Alzheimer's Therapy
Tacrine Reactive Metabolites

Background Information: Glutathione conjugation of tacrine reactive metabolites depends in part on the activity of GST, of which 2 isozymes (GST M1 and GST T1) are polymorphically expressed.
Application: Detection of combined alleles M1 and T1 deficiencies in glutathione-S-transferase genes serve as predictive paramaters related to an increased susceptibility to tacrine hepatotoxicity relevant to the therapeutic management of mild and moderate cases of Alzheimer's disease.
Implementation: Determination of the potential association between the parameters of (i) GST M1; (ii) GST T1; and (iii) the combined GST M1 and GST T1 null genotypes and the prediction of individual susceptibility to tacrine hepatotoxicity.
Interpretation and Analysis: In cases of mild to moderate Alzheimer's disease on tacrine therapy, some cases display elevations in alanine aminotransferase levels (e.g., n = 52/141) at least 3 times the upper limit of normal. The remaining subpopulation of mild to moderate Alzheimer's disease cases (e.g., n = 89/141) have normal alanine aminopeptidase values (≤ upper limit of normal).

Approximately 20% of such cases (e.g., 28/141 [95% CI]) are GST T1-negative while 48% (e.g., 68/141 (95% CI)] are GST M1-negative. The combined GST M1-T1 null genotype can be observed in approximately 13% of mild to moderate severity Alzheimer's disease cases (e.g., n = 18 [95% CI]) and large percentage of this subpopulation (e.g., n = 13/18 or 72%) display elevated plasma ALT levels that are at least 3 times the upper limit of normal. Although the cumulative percentage of elevated plasma ALT tends to be higher in the GST M1 null genotype, neither GST M1 nor GST T1 alone can predict individual susceptibility to tacrine hepatotoxicity. Multivariate Cox hazards model show that the association of the GST M1-T1 null genotype is an independent risk factor of hepatotoxicity. Presence of combined alleles M1 and T1 deficiencies in glutathione-S-transferase genes therefore increases susceptibility to tacrine hepatotoxicity.

Combined glutathione-S-transferase M1 and T1 genetic polymorphism and tacrine hepatotoxicity. Simon T, Becquemont L, Mary-Krause M, de Waziers I, Beaune P, Funck-Brentano C, Jaillon P. Clin Pharmacol Ther 2000 Apr; 67 (4), pp. 432–7.

Methylation/Catechol O-Methyltransferase (COMT)/ Genetically Regulated Thermal Stability/(Hepatic Biopsy Specimens)
Adrenergic Neurotransmitters

Cellular/Molecular Mechanism of Action: Catechol O-methyltransferase activity mediates the biochemical inactivation of epinephrine and norepinephrine neurotransmitters.
Application: Detection of COMT genotypes and characterization of COMT genetic polymorphism.
Considerations: The level of COMT activity and COMT thermal stability in human tissue is controlled by a common genetic polymorphism.
Implementation: Individual hepatic biopsies are collected for analysis (e.g., from individuals with high, low, or intermediate COMT biochemical activity and thermal stabilities) to determine if the molecular mass (M_r) and/or isoelectric point (pI) of COMT enzymes differs in tissue from subjects with different presumed genotypes for the COMT genetic polymorphism. Laboratory techniques employed entail the partial purification of COMT from individual hepatic tissue samples by (i) sequential ion exchange and gel filtration chromatography; (ii) photoaffinity labeling performed with [^{3}H-methyl]-S-adenosyl-L-methionine (functions as the methyl donor for the COMT enzymatic reactions); and (iii) 2-dimensional sodium dodecylsulfate polyacrylamide gel electrophoresis (2-D SDS-PAGE) analysis.
Interpretation and Analysis: Two-dimensional sodium dodecylsulfate polyacrylamide gel electrophoresis (2-D SDS-PAGE) analysis of individual samples consistently shows the presence of 3 [^{3}H-methyl]-S-adenosyl-L-methionine photoaffinity-labeled proteins

with pI values of 5.4, 5.5, and 5.7 (all 3 have M_r values of approximately 27.1 kDa). The same pattern can be observed in all samples irrespective of COMT phenotype. Western blot analysis of 2-D SDS-PAGE gels utilizing rabbit polyclonal antibodies to partially purified human kidney COMT reveals a pattern similar to that found with photoaffinity labeling. Once again, the same pattern is found in all samples irrespective of COMT phenotype. Therefore, neither photoaffinity labeling nor Western blot analysis reveal differences in either M_r or pI of cytoplasmic COMT in hepatic tissue from subjects selected on the basis of different phenotypic expression of the COMT genetic polymorphism.

Catechol O-methyltransferase pharmacogenetics: Photoaffinity labeling and Western blot analysis of human liver samples. Aksoy S, Klener J, Weinshilboum RM. Pharmacogenetics 1993 Apr; 3 (2), pp. 116–22.

Methylation/Catechol-O-Methyltransferase (COMT)/Pharmacogenetic Polymorphism: Lack of Relevance
Lithium

Application: Lithium is frequently used for the modification of mood disorders. However, the response outcome to lithium therapy does not appear to be a function of the genetic variation in the expression of COMT G158A, monoamine oxydase A (MAO-A) 30-bp repeat, G-protein beta 3-subunit (Gbeta3) C825T polymorphism.
Implementation: Delineation of the possible relationship between the prophylactic efficacy of lithium administration and genetic variations in the expression of COMT G158A, monoamine oxydase A (MAO-A) 30-bp repeat, and G-protein beta 3-subunit (Gbeta3) C825T. Polymorphism can be detected through the application of polymerase chain reaction (PCR) methodologies.
Interpretation and Analysis: In cases of psychological disorders (e.g., n = 201; bipolar n = 160/201; major depression n = 41/201) monitored prospectively for an average of 59.8 months reveals that COMT, MAO-A, and Gbeta3 variants are not associated with lithium outcome. Similarly, analysis of stratification effects such as sex, polarity, age at onset, duration of lithium treatment, and previous episodes does not reveal the existence of any relationship between lithium response and expression of genetic variants.

Pharmacogenetics of lithium prophylaxis in mood disorders: Analysis of COMT, MAO-A, and Gbeta3 variants. Serretti A, Lorenzi C, Lilli R, Mandelli L, Pirovano A, Smeraldi E. Am J Med Genet 2002 May 8; 114 (4), pp 370–9.

Methylation/Trans-Methylation, Trans-Sulfuration, Remethylation/Hyperhomocysteinemia: Endstage Renal Failure/Single-Carbon Group Transfer (5,10-Methylenetetrahydrofolate)/Hepatic Cytosol and Mitochondria
Carbon Dioxide Breath Tests/[$^2H_3$C-1(-13)C]-Methionine/[2,3,3-$^2H_3$] Serine

Cellular/Molecular Mechanism of Action: Substrates that can be applied as "probes" to detect alterations in the biochemical activity of specific enzyme systems involved in metabolic pathways.
Application: Estimation of trans-methylation, trans-sulfuration, and remethylation rates, and evaluation of carbon group transfer.
Route of Administration: Intravenous.
Implementation: Evaluation of whole-body trans-methylation, trans-sulfuration, and remethylation rates (e.g., [$^2H_3$C-1(-13)C]-methionine]. Following administration, carbon radioisotope contained in exhaled air as carbon dioxide is then measured. Preparations of [2,3,3-$^2H_3$] serine can be applied to evaluate the transfer of a 1-carbon group from serine via 5,10-methylenetetrahydrofolate in human hepatocyte cytosol and mitochondria, respectively.
Animal Model: Ovine.
Interpretation and Analysis: The amount of carbon radioisotope contained in exhaled air is directly proportional to the rate the test molecular is metabolized *in vivo* following injection. Tissue-free methionine enrichments after infusion of universally labeled [U-^{13}C] methionine show the highest remethylation activity in postmortem investigation of jejunum, liver, and kidney tissue samples, but no such activity can be appreciated in muscle and brain preparations.
Instrumentation: Methods to quantitate 1-carbon acceptor metabolism pathways and folate metabolism have recently become available.

In vivo stable isotope measurements of methyl metabolism: Applications in pathophysiology and interventions. de Meer K, van den Akker JT, Smulders Y, Stam F, Stehouwer CD, Finglas P. Food Nutr Bull 2002 Sep; 23 (3 Suppl), pp. 113–9.

Methylation/5,10-Methylenetetrahydrofolate Reductase (MTHFR) Gene (C677) Polymorphism/TT Genotype
Methotrexate (MTX)

Background Information: About 10% to 12% of the human population carries the MTHFR TT genotype (enzyme activity, 30% of wild type [CC]).
Application: Detection of the influence of MTHFR gene (C677) polymorphism on the response to MTX.
Implementation: Marrow allografts and short-course MTX administration regimens in cases suffering from chronic myelogenous leukemia (e.g., n = 220). Measures of MTX toxicity include the oral mucositis index (OMI), speed of engraftment (platelet and granulocyte counts), and bilirubin.
Interpretation and Analysis: Cases with lower MTHFR activity (TT genotype) have a 36% higher mean OMI during days 1–18 (+5.7, p = 0.046) and 20% higher OMI between days 6 and 12 (+3.8, p = 0.27). Platelet counts recover more slowly among patients with the TT genotype compared to wild type (24% slower recovery to 10,000 platelets/μL, p = 0.23; 34% slower to 20,000/μL, p = 0.08). Patients with decreased MTHFR activity appear at risk of higher MTX toxicity. Because of the high prevalence of the TT genotype, these results may have implications for guiding the design of MTX administration regimens.

Pharmacogenetics of methotrexate: Toxicity among marrow transplantation patients varies with the methylenetetrahydrofolate reductase C677T polymorphism. Ulrich CM, Yasui Y, Storb R, Schubert MM, Wagner JL, Bigler J, Ariail KS, Keener CL, Li S, Liu H, Farin FM, Potter JD. Blood 2001 Jul 1; 98 (1), pp. 231–4.

Methylation/5,10-Methylenetetrahydrofolate Reductase (MTHFR) Gene (C677) Polymorphism/TT/CT/CC Genotypes
Methotrexate (MTX)

Cellular/Molecular Mechanism of Action: Methylenetetrahydrofolate reductase C677T catalyzes reduction of 5,10-methylenetetrahydrofolate to 5-methyltetrahydrofolate.

Background Information: Methylenetetrahydrofolate reductase C677T polymorphism is a common mutation of the gene encoding the enzyme that catalyzes reduction of 5,10-methylenetetrahydrofolate to 5-methyltetrahydrofolate, a carbon donor in the metabolism of folate. Mutations of this type evoke a striking reduction in enzyme activity in carriers that have a homozygous mutation.
Application: Identification of cases with MTHFR C677T polymorphism that closely correlate with an increased risk of developing methotrexate toxicity. The TT genotype may indicate a need to reduce the dose of MTX during prolonged administration. Considering the high prevalence of homozygous individuals in the Italian population, pretreatment screening may be worthwhile.
Implementation: Characterization of the vulnerability to MTX intoxication (genotype) as a function of MTHFR C677T polymorphism in cases of acute leukemia undergoing maintenance chemotherapy. Toxicity to MTX is evaluated through assessement of bone marrow, liver, and mucosa integrity and function (e.g., n = 61 cases).
Interpretation and Analysis: The incidence of C677T mutation in the general Italian population corresponds to (i) 23.08% TT cases; (ii) 38.46% CT cases; and (iii) 38.46% of CC cases. The TT genotype is significantly associated with an increase of toxicity during periods of MTX administration. No specific pattern of toxicity can be appreciated; however, myelosuppression and liver toxicity are noticeably more pronounced with the TT genotype.

Preponderance of methylenetetrahydrofolate reductase C677T homozygosity among leukemia patients intolerant to methotrexate. Chiusolo P, Reddiconto G, Casorelli I, Laurenti L, Sora F, Mele L, Annino L, Leone G, Sica S. Ann Oncol 2002 Dec; 13 (12), pp. 1915–8.

Methylation/5,10-Methylenetetrahydrofolate Reductase Gene (C677) Polymorphism/G Allele (TT vs TG/GG Genotypes)/Rheumatoid Arthritis: Severe vs Mild-Moderate (Prediction of Disease Severity)/Tumor Necrosis Factor-Alpha I (TNF-α) Receptor Type II (TNFRII): Exon 6 Polymorphism
Methotrexate (MTX)/Anti-TNF-α Response

Application: Characterizing severe vs mild-moderate conditions of rheumatoid arthritis as a function of exon 6 TNFRII gene polymorphism. The G allele appears to have utility in predicting the degree of responsiveness to anti-TNF-α treatment while the GG genotype for the exon 6 TNFRII polymorphism may be useful in predicting the more aggressive form of rheumatoid arthritis.
Implementation: Characterization of exon 6 TNFRII gene polymorphism in cases of (i) mild-moderate synovitis classified as responders to MTX therapy (e.g., n = 97) for comparison with (ii) "non-responder" cases receiving anti-TNF-α treatment due to severe and aggressive disease (e.g., n = 78); and (iii) cases with severe rheumatoid arthritis monitored for 6 months during anti-TNF-α therapy. Results are evaluated pertaining to response according to genotype and compared to matched age, sex, and ethnic reference controls (e.g., n = 84).
Interpretation and Analysis: A distinct trend exists toward increases in the frequency of the GG genotype in patients with severe rheumatoid arthritis (6.4%) compared to cases of mild-moderate disease (3.1%) and reference controls (1.2%). Evaluation of the response to anti-TNF-α therapy after 12 weeks of treatment reveals that 37.8% of the TT genotype pass from high to medium-low disease activity. Such observations are in contrast to the 10.7% of the TG/GG genotype that pass from high to medium-low disease activity (p = 0.03).

Collective evaluation of laboratory results therefore suggests that in cases of rheumatoid arthritis classified according to response to the conventional therapy and by disease severity, there is a discernable trend toward a higher prevalence of the GG genotype for the exon 6 TNFRII polymorphism in less responsive cases displaying a more aggressive form of disease. In addition, the G allele tends to promote a lower degree of response to anti-TNF-α treatments.

Tumor necrosis factor-alpha receptor II polymorphism in patients from southern Europe with mild-moderate and severe rheumatoid arthritis. Fabris M, Tolusso B, Di Poi E, Assaloni R, Sinigaglia L, Ferraccioli G. J Rheumatol 2002 Sep; 29 (9), pp. 1847–50.

N-Acetyltransferase Metabolizing Capacity
Caffeine

Cellular/Molecular Mechanism of Action: Caffeine is a substrate for N-acetyltransferase.
Application: Detection and evaluation of N-acetyltransferase metabolic capacity and genetic polymorphism.
Route of Administration: Caffeine (oral).
Dosage: Caffeine (200 mg).
Examples of Clinical Implementation: Inactivation of the antituberculosis drug isoniazid occurs principally through metabolizing mechanisms that create an N-acetylated metabolite. Genetically, there exists a degree of polymorphism within a given population with regard to the expression of N-acetyltransferase. As a metabolic probe, caffeine has been applied to determine N-acetyltransferase polymorphism within Greek populations by means of the molar urine ratio of 5-acetylamino-6-formylamino-3-methyluracil and 1-methylxanthine determined following caffeine ingestion. Frequency distribution analysis of the metabolic ratios 5-acetylamino-6-formylamino-3-methyluracil/1-methylxanthine reveals that 2 distinct groups exist that are either slow (2/3) or fast (1/3) rapid caffeine acetylators and are in agreement with findings noted in populations from other regions of the world.
Interpretation and Analysis: The activity of N-acetyltransferase can be estimated from the urinary metabolic ratio of 2 caffeine metabolites, namely, 5-acetylamino-6-formylamino-3-methyluracil (AFMU) and 1-methylxanthine (1X) after the ingestion of caffeine. The use of caffeine as a metabolic probe is a reliable method for assessing N-acetyltransferase activity.

Determination of N-acetylation phenotyping in a Greek population using caffeine as a metabolic probe. Asprodini EK, Zifa E, Papageorgiou I, Benakis A. Eur J Drug Metab Pharmacokinet 1998 Oct–Dec; 23 (4), pp. 501–6.

Sulfate Conjugation: Phase II Biotransformation/ Pharmaceuticals and Xenobiotics
Sulfotransferase (SULT) Enzyme/Genetic Polymorphism

Cellular/Molecular Mechanism of Action: Sulfotransferase (SULT) enzymes catalyze an important phase II reaction in the biotransformation of many drugs and other xenobiotics.
Application: Evaluate the possible contribution of sulfotransferase polymorphisms to variation in the sulfate conjugation of drugs, other xenobiotics and/or disease pathophysiology.
Implementation: Cloning of human SULT1C1 cDNA as a step towards a foundation for establishing a pharmacogenetic database reference. The exons, portions of the introns flanking the exons and approximately 315 bp of the 5′ flanking region of SULT1C1 have been "resequenced" in Caucasian DNA samples (e.g., n = 89) in order to identify common genetic polymorphisms. Expression con-

structs can be created for all of the non-synonymous cSNPs observed, and those constructs used to transfect COS-1 cells.

Interpretation and Analysis: Nineteen separate polymorphisms have been recognized, including 4 non-synonymous coding region single nucleotide polymorphisms (cSNPs) and 5 insertions/deletions. These data can be used to determine and/or infer common SULT1C1 haplotypes. Three of the 4 non-synonymous cSNPs have allele frequencies greater than 1%, including 1 with a frequency of 6.7%. Three of the 4 SULT1C1 variant allozymes have significantly reduced enzyme activity when compared with the wild-type enzyme. Among the variant allozymes, apparent Km values for 3′-phosphoadenosine 5′-phosphosulfate (PAPS), the sulfate donor for the reaction, varies 7-fold. Quantitative Western blot analysis shows variable levels of immunoreactive protein when compared to the wild-type enzyme. Therefore, mechanisms responsible for decreased activity involve both alterations in enzyme protein levels and alterations in substrate kinetics. Therefore, application of a "genotype to phenotype" strategy has facilitated the identification of a series of functionally significant common genetic polymorphisms for SULT1C1.

Human sulfotransferase SULT1C1 pharmacogenetics: Gene resequencing and functional genomic studies. Freimuth RR, Eckloff B, Wieben ED, Weinshilboum RM. Pharmacogenetics 2001 Dec; 11 (9), pp. 747–56.

Sulfate Conjugation: Phase II Biotransformation/ Pharmaceuticals and Xenobiotics
Sulfotransferase (SULT) Enzymes/3′-Phosphoadenosine 5′-Phosphosulfate

Cellular/Molecular Mechanism of Action: 3′-phosphoadenosine 5′-phosphosulfate (PAPS) is the sulfate donor co-substrate for all SULT enzymes. Sulfotransferases catalyze the sulfate conjugation of many endogenous and exogenous compounds, including drugs and other xenobiotics. In humans, PAPS is synthesized from adenosine 5′-triphosphate (ATP) and inorganic sulfate (SO_4^{-2}) by 2 enzyme isoforms, PAPSS1 and PAPSS2.

Background Information: Rare mutations that inactivate PAPSS2 are associated with human spondyloepimetaphyseal dysplasia and murine brachymorphism.

Application: Delineation of the functional significance of PAPSS2 genetic polymorphisms pertaining to its potential contribution to *in vivo* variations in sulfate conjugation of pharmaceuticals and other xenobiotics.

Implementation: The human PAPSS2 gene has been cloned to aid in determining whether or not more common genetic polymorphisms that do not completely inactivate the enzyme might be 1 factor responsible for individual differences in sulfate conjugation. In part this entailed the "resequencing" of all twelve PAPSS2 exons and splice junctions, as well as approximately 500 bp of the 5′-flanking region (e.g., Polymorphism Discovery Resource [PDR] DNA samples from the Coriell Cell Repository; n = 90).

Interpretation and Analysis: Twenty-two single nucleotide polymorphisms (SNPs) have been identified including 4 non-synonymous coding region SNPs (cSNPs) that alter the following amino acids: Glu10Lys, Met281Leu,Val291Met and Arg432Lys. Four insertions/deletions, have also been observed including 1 sample that is homozygous for an 81-bp deletion in the 5′-flanking region 286 bp upstream from the site of transcription initiation. Transient expression studies show that 2 of the non-synonymous cSNPS (those that resulted in Glu10Lys and Val291Met alterations in encoded amino acids), show significant decreases in levels of PAPSS activity. In the case of Glu10Lys, decreased activity is paralleled by a decrease in immunoreactive protein, while the Val291Met allozyme displays a significant decrease in affinity for both ATP and Na_2SO_4 when compared to the "wild-type" enzyme, but without a significant alteration in the levels of immunoreactive protein.

Human 3′-phosphoadenosine 5′-phosphosulfate synthetase 2 (PAPSS2) pharmacogenetics: Gene resequencing, genetic polymorphisms and functional characterization of variant allozymes. Xu ZH, Freimuth RR, Eckloff B, Wieben E, Weinshilboum RM. Pharmacogenetics 2002 Jan; 12 (1), pp. 11–21.

Sulfotransferase (Hepatic SULT2A1)/Pharmacogenetic-Relevant Polymorphism
Steroid Sulfate Conjugation

Cellular/Molecular Mechanism of Action: SULT2A1 catalyzes the sulfate conjugation of dehydroepiandrosterone (DHEA) as well as other steroids.

Application: Characterization of the common genetic polymorphisms for SULT2A1 as it relates to *in vivo* variations (e.g., reductions) in levels of both activity and enzyme protein. Preliminary research suggests the possibility that ethnic-specific pharmacogenetic variation exists in SULT2A1-catalyzed sulfation of both endogenous and exogenous substrates for this phase II drug-metabolizing enzyme.

Implementation: The pharmacogenetic relevance of SULT2A1 can be discerned through the analysis of DNA preparations collected from different phenotype subpopulations (e.g., African-American n = 60; Caucasian-American n = 60). The "resequencing" of the SULT2A1 gene involves sequencing of all exons, splice junctions, and approximately 370 bp located 5′ of the site of transcription initiation.

Interpretation and Analysis: A total of 15 single nucleotide polymorphisms (SNPs) exist, including 3 non-synonymous coding SNPs (cSNPs) that are present only in DNA from African-American subjects. Linkage analysis reveals that 2 of the non-synonymous cSNPs are tightly linked. Expression constructs created for all non-synonymous cSNPs, including a "double variant" construct that includes 2 linked cSNPs, are expressed in COS-1 cells, which facilitates a more in-depth analysis of transcription/translation events. In this context, SULT2A1 activity is significantly decreased for 3 of the 4 variant allozymes. Western blot analysis demonstrates that decreased levels of immunoreactive protein appear to be the major mechanism responsible for decreases in activity, although apparent Km values also vary among the recombinant allozymes. In addition, the most common of the non-synonymous cSNPs disrupts the portion of SULT2A1 involved with dimerization, and this variant allozyme behaves as a monomer rather than a dimer during gel filtration chromatography.

Human sulfotransferase SULT2A1 pharmacogenetics: Genotype-to-phenotype studies. Thomae BA, Eckloff BW, Freimuth RR, Wieben ED, Weinshilboum RM. Pharmacogenomics J 2002; 2 (1), pp. 48–56.

Sulfoxidation/Hydroxylation Metabolization
S-Carboxymethyl-L-Cysteine/Debrisoquine

Cellular/Molecular Mechanism of Action: S-carboxymethyl-L-cysteine and debrisoquine are substrates for biochemical mechanisms that create sulfoxide and hydroxylated analogs.

Application: Measurement of the *in vivo* biochemical activity of hepatic hydroxylation and sulfoxidation mechanisms relevant to the

ability of these enzyme systems to metabolize pharmaceuticals, optimize dosage schemes, determine individual susceptibility to protoxin biotransformation, and/or detect therapeutic non-compliance. In this context, chlorpromazine can be applied as an *in vivo* probe to detect scenarios conducive to the development of chlorpromazine jaundice.

Route of Administration: S-carboxymethyl-L-cysteine (oral); debrisoquine (oral).

Dosage: S-carboxymethyl-L-cysteine (750 mg) and the unchanged compound and sulfoxide metabolites are measured in urine.

Implementation: Detection and evaluation of cases susceptible to chlorpromazine jaundice facilitated by the administration of S-carboxymethyl-L-cysteine and debrisoquine.

Interpretation and Analysis: The amount of sulfoxide S-carboxymethyl-L-cysteine analogue and hydroxylated debrisoquine (4-hydroxydebrisoquine) excreted into the urine directly (positively) correlates with hepatic sulfoxidation and hydroxylation metabolizing capacity. Individuals that are susceptible to chlorpromazine jaundice have a poor capacity to create sulfoxide-analogs of S-carboxymethyl-L-cysteine. However, this same pattern can also be recognized in some reference controls that do not have a history of chlorpromazine jaundice or liver disease (statistically significant difference between groups = $p < 0.001$). A history of chlorpromazine jaundice does not correlate with evidence of impaired hydroxylation capacity as assessed by recovery of 4-hydroxydebrisoquine in urine following oral debrisoquine administration. Susceptibility to the development of chlorpromazine jaundice appears to be an inherent metabolic disorder.

A proposed mechanism for chlorpromazine jaundice—Defective hepatic sulfoxidation combined with rapid hydroxylation. Watson RG, Olomu A, Clements D, Waring RH, Mitchell S, Elias E. J Hepatol 1988 Aug; 7 (1), pp. 72–8.

Sulfoxidation/Hydroxylation Metabolization
S-Carboxymethyl-L-Cysteine/Debrisoquine

Cellular/Molecular Mechanism of Action: S-carboxymethyl-L-cysteine and debrisoquine are substrates for biochemical mechanisms that create sulfoxide and hydroxylated analogs.

Application: Measurement of the *in vivo* biochemical activity of hepatic hydroxylation and sulfoxidation mechanisms relevant to the ability of these enzyme systems to metabolize pharmaceuticals, optimize dosage schemes, determine individual susceptibility to pro-toxin biotransformation, and/or detect therapeutic non-compliance. In this context, chlorpromazine can be applied as an *in vivo* probe to detect scenarios conducive to the development of chlorpromazine jaundice.

Route of Administration: S-carboxymethyl-L-cysteine (oral); debrisoquine (oral).

Dosage: S-carboxymethyl-L-cysteine (750 mg) and the unchanged compound and sulfoxide metabolites are measured in urine.

Implementation: Detection and evaluation of cases susceptible to chlorpromazine jaundice the administration of S-carboxymethyl-L-cysteine and debrisoquine.

Interpretation and Analysis: The amount of sulfoxide S-carboxymethyl-L-cysteine analogue and hydroxylated debrisoquine (4-hydroxydebrisoquine) excreted into the urine directly (positively) correlates with hepatic sulfoxidation and hydroxylation metabolizing capacity. Individuals that are susceptible to chlorpromazine jaundice have a poor capacity to create sulfoxide-analogs of S-carboxymethyl-L-cysteine. However, this same pattern can also be recognized in some reference controls that do not have a history of chlorpromazine jaundice or liver disease (statistically significant difference between groups = $p < 0.001$). A history of chlorpromazine jaundice does not correlate with evidence of impaired hydroxylation capacity as assessed by recovery of 4-hydroxydebrisoquine in urine following oral debrisoquine administration. Susceptibility to the development of chlorpromazine jaundice appears to be an inherented metabolic disorder.

A proposed mechanism for chlorpromazine jaundice—Defective hepatic sulfoxidation combined with rapid hydroxylation. Watson RG, Olomu A, Clements D, Waring RH, Mitchell S, Elias E. J Hepatol 1988 Aug; 7 (1), pp. 72–8.

Sulfurtransferase/Dehydroepiandrosterone Sulfotransferase (DHEA ST)
Dehydroepiandrosterone (DHEA)

Cellular/Molecular Mechanism of Action: Dehydroepiandrosterone sulfotransferase catalyzes the sulfation of DHEA and other hydroxysteroids.

Background Information: Dehydroepiandrosterone sulfotransferase enzymatic activity in individual human liver biopsy samples has been shown to vary over a 5-fold range, and frequency distribution histograms are bimodal, with approximately 25% of subjects included in a high activity subgroup.

Application: Identification of common genetic polymorphisms within the dehydroepiandrosterone sulfotransferase gene will now facilitate the testing of how genetic polymorphism alters the *in vivo* expression and/or function of this (human) steroid-metabolizing enzyme.

Implementation: Characterization of the molecular basis for variation within the human liver for dehydroepiandrosterone sulfotransferase biochemical activity can be delineated applying immunodetection methodologies (e.g., Western blot analysis). Performing quantitative Western analysis involves prepration of cytosol isolates from liver samples (e.g., n = 92 human liver specimens). Establishment of laboratory reference control values entails the analyis of liver speciments that have previously been phenotyped with regard to their level of DHEA ST enzymatic activity.

Characterization of genetic polymorphysim of dehydroepiandrosterone sulfotransferase can be determined through the isolation of DNA extracts of liver specimens obtained from cases that express "low" and "high" DHEA ST biochemical activity. Exons and the 5′-flanking region of the DHEA ST gene (STD) are then amplified by the polymerase chain reaction (PCR) for each tissue sample. Complementary laboratory procedures include sequence analysis of hepatic DNA from at exons 2 and 4 for the DHEA ST gene (STD) utilizing liver specimens obtained from individuals previously phenotyped for DHEA ST biochemical activity.

Interpretation and Analysis: There is a highly significant correlation ($r^s = 0.635$, $p < 0.0001$) between levels of DHEA ST activity and immunoreactive protein identified by Western Blot analysis. When compared with "wild type" STD sequence, some tissue samples contain a T → C transition at DHEA ST cDNA nucleotide 170, located within exon 2, resulting in a change at the Met 57 amino acid residue (Met 57 → Thr). Other samples can contain an A → T transversion at nucleotide 557 within STD exon 4 that results in a Glu 186 → Val change.

The allele frequency for the exon 2 polymorphism is 0.027, whereas that for the exon 4 polymorphism is 0.038, but neither polymorphism is systematically related to the level of enzyme activity.

Transient expression in COS-1 cells of cDNA that contain nucleotide 170 and 557 polymorphisms, either separately or together, result in decreased expression of both DHEA ST enzymatic activity and the level of immunoreactive protein, but only when the nucleotide 557 variant is present.

Human dehydroepiandrosterone sulfotransferase pharmacogenetics: Quantitative Western analysis and gene sequence polymorphisms. Wood TC, Her C, Aksoy I, Otterness DM, Weinshilboum RM J Steroid Biochem Mol Biol 1996 Dec; 59 (5–6), pp. 467–78.

Thiopurine Methyltransferase (TPMT): Genetic Polymorphism
Thiopurines

Cellular/Molecular Mechanism of Action: Thiopurine methyltransferase catalyzes the S-methylation of thiopurine drugs.
Background Information: Individual variation in the toxicity and therapeutic efficacy of thiopurine drugs is associated with a common genetic polymorphism that controls levels of TPMT activity and immunoreactive protein in human tissues. Because of the clinical significance of "pharmacogenetic" regulation of this enzyme, it would be important to clone the gene for TPMT in humans and to study the molecular basis for the genetic polymorphism.
Application: Molecular cloning and structural characterization of the TPMT gene as well as elucidation of the molecular basis for a common TPMT genetic polymorphism will help make it possible to develop DNA-based diagnostic tests for polymorphism and to determine the mechanism by which it results in decreased expression of this important drug-metabolizing enzyme.
Implementation: The cloning of the gene for TPMT can be achieved through the rapid amplification of genomic DNA ends to obtain a TPMT-specific intron sequence. Such a DNA sequence can be used as a template for designing primers for a polymerase chain reaction (PCR). In this fashion it is possible to establish the location of the active gene for TPMT on human chromosome 6. A TPMT-positive cosmid clone is then isolated from a human chromosome 6-specific genomic DNA library, and the gene sublocalized to chromosome band 6p22.3 by fluorescence *in situ* hybridization.
Interpretation and Analysis: The gene for TPMT has been determined to be approximately 34 kb in length and to consist of 10 exons and 9 introns. On the basis of the results of 5′-rapid amplification of cDNA ends, transcription initiation occurs at or near a point 89 nucleotides upstream from the translation initiation codon of previously reported TPMT cDNAs. Following the determination of the structure for TPMT gene, it becomes possible to perform PCR analysis with primers complementary to the sequences of introns flanking each exon that encodes enzyme protein with template DNA obtained from subjects with known phenotypes for the TPMT genetic polymorphism.

In studies where DNA is isolated from blood samples from unrelated subjects with genetically low TPMT activity (e.g., n = 4) and unrelated subjects with high TPMT activity (e.g., n = 4), it can be appreciated that all subjects with low TPMT activity are homozygous for 2 point mutations-a G → A transition at nucleotide 460 in exon 7 and an A → G transition at nucleotide 719 in exon 10. Both mutations result in alterations in amino acid sequence, with Ala-154 → Thr and Tyr-240 → Cys, respectively. All DNA samples isolated from the blood of subjects with high TPMT activity contain "wild-type" sequence. Results obtained with these blood samples can be confirmed when DNA from human liver samples (n = 4) with high TPMT activity have a wild-type sequence at nucleotides 460 and 719, while some liver samples with intermediate enzyme activity (i.e., samples presumed to be heterozygous for the polymorphism) are heterozygous for the exon 7 and exon 10 mutations present in the blood samples of homozygous low subjects. Transient expression in COS-1 cells of TPMT expression constructs that contain both of the mutations in exons 7 and 10, as well as each independently, demonstrate that each mutation, as well as both together, result in decreased expression of TPMT enzymatic activity and immunoreactive protein.

Thiopurine methyltransferase pharmacogenetics: Human gene cloning and characterization of a common polymorphism. Szumlanski C, Otterness D, Her C, Lee D, Brandriff B, Kelsell D, Spurr N, Lennard L, Wieben E, Weinshilboum R. DNA Cell Biol 1996 Jan; 15 (1), pp. 17–30.

Thiopurine Methyltransferase (TPMT): Genetic Polymorphism
Thiopurines

Background Information: Genetic polymorphism of TPMT has been shown to have a highly significant clinical impact, namely in the therapeutic efficiency of thiopurine drugs used in the treatment of a wide range of diseases. Available diagnostic methods, although reproducible and sensitive, are relatively laborious, thus population studies are still very scarce.
Application: Detection and characterization of genetic polymorphism for TPMT relevant to the therapeutic management of disease conditions (e.g., acute lymphoblastic leukemia) that require the administration of thiopurine-based pharmaceutical agents.
Implementation: A new polymerase chain reaction-single strand confirmational analysis-based protocol for specific TPMT detection has been developed that has been technically simplified. The method avoids the use of restriction enzyme treatment after polymerase chain reaction amplification. The use of this laboratory protocol allows the simultaneous detection of T474 to C substitutions that is known to be a frequent silent mutation (e.g., North Portuguese populations: TPMT*1S = 0.215).
Interpretation and Analysis: Approximately 4.8% (e.g., n = 15/310) of unrelated Northern Portuguese individuals are heterozygous for the TPMT*3A allele (defined by the presence of 2 transitions, G460 to A and A719 to G) that is associated with TPMT enzymatic deficiency (corresponding gene frequency estimate = 0.024). In children suffering from acute lymphoblastic leukemia (e.g., n = 24), some degree of correlation exists between molecular genotype for TPMT expression and their reaction/response to curative therapy with thiopurine chemotherapeutics. In this context, cases that are heterozygous for the TPMT*3A allele have a high incidence of exhibited signs for severe hepatic toxicity during treatment.

Thiopurine methyltransferase pharmacogenetics: Alternative molecular diagnosis and preliminary data from Northern Portugal. Alves S, Prata MJ, Ferreira F, Amorim A. Pharmacogenetics 1999 Apr; 9 (2), pp. 257–61.

Thiopurine Methytransferase (TPMT): Genetic Polymorphism/Leukemic Blast and Erythrocyte TPMT Biochemical Activity/Mercaptopurine: 6-Thioguanine Metabolite Accumulation
Thiopurines/Methotrexate

Background Information: The activity of TPMT exhibits genetic polymorphism, with approximately 1 in 300 individuals inheriting TPMT deficiency as an autosomal recessive trait, and about 11% having intermediate activity (i.e., heterozygotes). In situations of TPMT deficiency, excessive concentrations of 6-thioguanine nucleotides (TGNs) accumulate resulting in the development of severe toxicity when standard dosages of mercaptopurine

are administered. Conversely, high TPMT activity has been associated with lower concentrations of 6-thioguanine nucleotides yielding a higher risk of treatment failure in children with acute lymphoblastic leukemia (ALL).

Implementation: Investigation of the biochemical basis of the pharmacodynamic relationships between mercaptopurine plasma concentrations and TPMT genetic polymorphism through the analysis of red blood cell and lymphoblast TPMT activity in cases of ALL.

Interpretation and Analysis: A 58-fold range of erythrocyte TPMT biochemical activity can be observed among cases receiving ALL chemotherapy (0.6–34.9 U/mL packed erythrocytes), but relatively low intrapatient variability (coefficient of variation, 13.5%) is observed (e.g., over a period of 1 year; n = 119 cases). A 27-fold range in TPMT biochemical activity can be appreciated in leukemic blasts obtained from cases at initial diagnosis (e.g., n = 42 with 3.3 to 88.9 U/1 $\times$ 10^9 cells). Thiopurine methyltransferase activity in leukemic blasts at diagnosis significantly correlates with TPMT in erythrocytes before therapy (r^s = .75, $p < 0.0001$, n = 13). Therefore, extensive interpatient variability exists with respect to TPMT biochemical activity in ALL blasts. However, these findings correlate with polymorphic TPMT activity in erythrocytes, thereby providing a new mechanism by which erythrocytes serve as prognostic markers of mercaptopurine metabolism and TPMT activity in children with ALL.

Polymorphic thiopurine methyltransferase in erythrocytes is indicative of activity in leukemic blasts from children with acute lymphoblastic leukemia. McLeod HL, Relling MV, Liu Q, Pui CH, Evans WE. Blood 1995 Apr 1; 85 (7), pp. 1897–902.

Thiopurine Methyltransferase (Metabolism)/Acute Lymphocytic Leukemia (ALL): Response Variability/Prognosis: Prediction of Relapse
Methotrexate/6-Mercaptopurine

Background Information: The intensity of cancer chemotherapy has been reported to influence clinical responses to several drug-sensitive cancers.

Application: Delineation of the relationship between systemic exposure to high-dose methotrexate (HDMTX) and clinical response in childhood ALL.

Route of Administration: High-dose methyltrexate (intravenous); methotrexate (oral/per os); low-dose 6-mercaptopurine (oral/per os).

Dosage: High-dose methyltrexate (1,000 mg/m^2 over 24 hours weekly for 3 weeks, then every 6 weeks for 72 weeks); methotrexate (25 mg/m^2 per week); low-dose 6-mercaptopurine (50 mg/m^2 per day).

Implementation: Initiation of postinduction therapy with high-dose methyltrexate superimposed on conventional therapy with low-dose 6-mercaptopurine and methotrexate in untreated children with "standard-intermediate risk" (e.g., n = 108).

Interpretation and Analysis: The systemic clearance of HDMTX ranges from 40 to 131 ml/min/m^2 yielding MTX steady state plasma concentrations (Cpss) ranging from 9.3 to 25.4 μM during the infusion ("standard-intermediate risk" children). A higher probability of developing any type of relapse is observed with median MTX Cpss < 16 μM during the HDMTX infusion (e.g., n = 59) in contrast to cases with MTX Cpss greater than 16 μM (e.g., n = 49; $p < 0.05$). In univariate analysis, cases with MTX Cpss ≤ 16 μM are approximately 3.2 times more likely to relapse on therapy (p = 0.01) and 6.9 times more likely to have a hematologic relapse on therapy (p = 0.001). Multivariate and stepwise Cox's regression analyses indicate that MTX Cpss retains its prognostic importance even when other prognostic variables (i.e., DNA Index, WBC, hemoglobin) are considered.

Clinical pharmacodynamic studies of high-dose methotrexate in acute lymphocytic leukemia. Evans WE, Abromowitch M, Crom WR, Relling MV, Bowman WP, Pui CH, Ochs J, Dodge R. NCI Monogr 1987; (5), pp. 81–5.

Thiopurine Methyltransferase (TPMT): Homozygous Wild Type/Acute Lymphoblastic Leukemia (ALL): Childhood Form/Prediction of Event-Free Survival (EFS)
6-Mercaptopurine

Background Information: 6-mercaptopurine (6MP) and methotrexate are the backbone of continuation therapy for childhood ALL. In studies of oral 6MP and methotrexate, indices of chronic systemic exposure to active metabolites of these agents, namely, red blood cell (RBC) concentrations of methotrexate polygluta-mates (MTXPGs) and thioguanine nucleotides (TGNs), have been positively correlated with EFS.

Application: Determination of the potential to form RBC concentrations of methotrexate polyglutamates and thiguaninine nucleotides as a potential EFS prognostic marker.

Considerations: Increased dose intensity of oral 6MP is an important determinant of EFS in ALL, particularly among children with a homozygous wild-type TPMT phenotype.

Route of Administration: Methotrexate (parenteral); 6-mercaptopurine (oral).

Dosage: Methotrexate (40 mg/m^2 once/week).

Implementation: Delineation of the prognosis in conditions of childhood ALL based on analysis of dose intensity responses for methotrexate and 6-mercaptopurine administration. Parameters tabulated include dose intensity information (dose received divided by protocol dose per week; n = 19,046 weeks of 6-mercaptopurine and methotrexate). Measurement of complementary variables include the quantification of RBC MTXPGs; MTXPGs (n = 418); TGNs (n = 709); and TPMT (n = 267).

Protocol: Administration of methotrexate and 6-mercaptopurine is administered to cases in remission (e.g., n = 182) complemented by pulse chemotherapy every 6 weeks during the 1st 1-year period of management.

Interpretation and Analysis: Only higher dose intensity 6MP and weekly methotrexate are significant predictors of overall EFS (univariant analyses p = 0.006 and 0.039, respectively). The occurrence of neutropenia is associated with poorer case outcome (p = 0.040). Only higher dose intensity 6MP (p = 0.020) is a significant predictor of EFS, while lower TPMT activity (p = 0.096) tends to be associated with better outcome (multivariate analyses). 6-mercaptopurine dose intensity is also associated (p = 0.007) with EFS among patients with the homozygous wild-type TPMT phenotype. Lower 6-mercaptopurine dose intensity is primarily due to missed weeks of therapy and not to reductions in daily dose. Increased dose intensity of oral 6MP is an important determinant of EFS in ALL, particularly among children with a homozygous wild-type TPMT phenotype. However, increasing intensity of therapy such that neutropenia precludes chemotherapy administration may be counterproductive.

Prognostic importance of 6-mercaptopurine dose intensity in acute lymphoblastic leukemia. Relling MV, Hancock ML, Boyett JM, Pui CH, Evans WE. Blood 1999 May 1; 93 (9), pp. 2817–23.

Thiopurine Methyltransferase (TPMT) Genetic Polymorphism/Xanthine Oxidase: Variation in Genetic Expression/Toxic 6-Thioguanine Nucleotide Metabolites/Alternative Selection of Cyclosporine A, Mycophenolate Mofetil, or Tacrolimus
Azathioprine/Cyclosporine A

Physiological Mechanism of Action: Cyclosporine A and azathioprine function as immunosuppressive agents.
Background Information: Immunosuppressive regimens employed following solid organ transplantation commonly entail the use of cyclosporine A, azathioprine, and steroids. Azathioprine is known to carry the risk of severe myelosuppression and is catabolized *in vivo* by xanthine oxidase and TPMT, an enzyme that exhibits a common genetic polymorphism (e.g., 11% of Caucasians are heterozygous and 0.3% are homozygous with respect to TPMT deficiency). Toxicity and immunosuppressive effects have been attributed to the 6-thioguanine nucleotides generated from azathioprine.
Application: Characterization of variations in individual expression of TPMT activity in order to identify individuals at risk of metabolizing azathioprine to the toxic 6-thioguanine nucleotide metabolites.
Implementation: Measurement of TPMT activity and 6-thioguanine nucleotide concentrations in erythrocytes harvested to evaluate and monitor immunosuppressive therapeutic regimens (e.g., cardiac and renal transplant patients). Erythrocyte thiopurine methyl-transferase can be determined by a radioenzymatic assay and erythrocyte 6-thioguanine nucleotide concentration with high-performance liquid chromatography. Thiopurine methyltransferase activity (median [range, 10th–90th percentile]) is significantly ($p < 0.05$) higher in patients ($n = 39$) receiving azathioprine (285 [218–362] vs 262 [160–352] mU/I erythrocytes) than in healthy blood donor controls ($n = 120$). When stratified according to TPMT phenotype, a few cases homozygous for the low allele exhibit excessive erythrocyte 6-thioguanine nucleotide concentrations (2,210 pmol/0.8 $\times 10^9$ erythrocytes). Heterozygous patients have significantly higher 6-thioguanine nucleotide concentrations (median: 435 pmol/0.8 $\times 10^9$ erythrocytes) compared with concentrations for patients homozygous for the high allele (median: 86 pmol/0.8 $\times 10^9$ erythrocytes; $p < 0.01$), although the azathioprine dosage does not differ ($p = 0.66$). Erythrocyte TPMT determination therefore identifies patients at high risk of accumulating 6-thioguanine nucleotides. The monitoring of this enzyme may contribute to the safer management of immunosuppressive therapy with azathioprine. Alternative regimens such as cyclosporine A/mycophenolate mofetil or tacrolimus should also be considered for this patient group.

Azathioprine pharmacogenetics: The relationship between 6-thioguanine nucleotides and thiopurine methyltransferase in patients after heart and kidney transplantation. Schutz E, Gummert J, Armstrong VW, Mohr FW, Oellerich M. Eur J Clin Chem Clin Biochem 1996 Mar; 34 (3), pp. 199–205.

Thiopurine S-Methyltransferase (TPMT): Genetic Polymorphism/Rheumatoid Arthritis: Predictive Model for Cost-Effectiveness
Azathioprine (AZA)

Cellular/Molecular Mechanism of Action: Thiopurine S-methyltransferase catalyzes the inactivation of AZA.
Background Information: Thiopurine S-methyltransferase exhibits genetic polymorphism that results in dose-related, serious toxicities (mainly hematological cytopenias) in 10 to 15% of individuals treated with AZA. Polymerase chain reaction (PCR)-based methodologies provide a sensitive, specific means of prospectively identifying these patients before AZA therapy and minimizing toxicity through dosage reduction.
Application: Characterization of thiopurine S-methyltransferase genetic polymorphism in order to identify subpopulations vulnerable to developing dose-related toxicity associated with azothioprine administration. In this manner it is possible to identify cases that require a reduction in the conventional dose of azothioprine. In addition, an analytical model has been developed to delineate the cost-effectiveness of azothioprine therapy for the management of rheumatoid arthritis.
Implementation: Design of a decision analytic model for application in delineating the cost-effectiveness and outcomes of patients undergoing different azothioprine therapeutic strategies. Data applied to the model includes (i) positive and negative predictive values of PCR analyses for detecting TPMT genetic polymorphism; (ii) the probabilities of adverse events due to AZA; and (iii) the costs associated with management. Sources of data can include published clinical trials, diagnostic test evaluations, surveillance trials, and economic evaluations.
Interpretation and Analysis: Dose-related toxicities result in azothioprine discontinuation rates of 10 to 20%. The traditional dosing strategy costs $677 per patient, whereas the genotype directed dosing strategy costs $663 per patient (Canadian). In the genotype dosing strategy, the number needed to treat and avoid 1 adverse event over 6 months is 20. Thus, the genotype-based dosing strategy is superior to usual dosing strategies. One-way sensitivity analyses reveal that estimates are robust within ranges of $\pm$ 30% for the costs, the properties of the PCR test, and the probability of adverse events. The introduction of PCR testing to identify TPMT polymorphisms prior to AZA treatment may represent good value in certain health care settings.

Practical pharmacogenetics: The cost-effectiveness of screening for thiopurine s-methyltransferase polymorphisms in patients with rheumatological conditions treated with azathioprine. Marra CA, Esdaile JM, Anis AH. J Rheumatol 2002 Dec; 29 (12), pp. 2507–12.

Thiopurine S-Methyltransferase (Hepatic): Genetic Polymorphism/(UGT1A1)/(DPD)/(TS)/(MTHFR)/(FCGR3A)/(XPD)/(XRCC1)
Thiopurines

Background Information: Interindividual variability in the efficacy and toxicity of drug therapy is associated with polymorphisms in genes encoding drug-metabolizing enzymes, transporters, or drug targets. Pharmacogenetics aims to identify individuals predisposed to high risk of toxicity from conventional doses of cancer chemotherapeutic agents.
Interpretation and Analysis: Genetic polymorphisms in UGT1A1 and TPMT, as well as mutations in DPD, directly influence drug disposition and toxicity. Pharmacogenetic determinants may also influence treatment outcomes. The clinical significance of polymorphisms in TS, MTHFR, and FCGR3A, as well as the polymorphic DNA repair genes XPD and XRCC1, is related to their influence on chemotherapy response and survival outcomes. Several potential implications exist related to transporter pharmacogenetics pertaining to their influence on drug bioavailability.

Pharmacogenetics in cancer treatment. Nagasubramanian R, Innocenti F, Ratain MJ. Annu Rev Med 2003; 54, pp. 437–52. Epub 2001 Dec 03.

UDP-Glucuronosyl Transferase Polymorphism/ Parkinson's Disease: Susceptibility to Hepatotoxicity
Tolcapone (TASMAR)

Application: Characterization of UDP-glucuronosyl transferase 1A gene complex expression can be applied to identify increased susceptibility to the development of hepatotoxic responses associated with the administration of tolcapone (TASMAR) for the therapeutic management of Parkinson's disease.
Implementation: Delineation of the genotype for 30 previously described or newly characterized bi-allelic single nucleotide polymorphisms representing 12 candidate genes selected based on the known metabolic pathways involved in the tolcapone elimination. Samples of DNA can be processed from biological material collected from cases (e.g., n = 135) displaying elevations of ≥ 1.5 times the upper limit of normal and findings compared with matched reference control DNA samples obtained from cases administered tolcapone but without evidence of elevated transaminase levels.
Interpretation and Analysis: Single nucleotide polymorphisms located within the UDP-glucuronosyl transferase 1A gene complex coding for enzymes involved in the main elimination pathway of the tolcapone (TASMAR) are significantly associated with the occurrence of tolcapone-associated elevations in liver transferase concentrations.

Pharmacogenetic analysis of adverse drug effect reveals genetic variant for susceptibility to liver toxicity. Acuna G, Foernzler D, Leong D, Rabbia M, Smit R, Dorflinger E, Gasser R, Hoh J, Ott J, Borroni E, To Z, Thompson A, Li J, Hashimoto L, Lindpaintner K. Pharmacogenomics J 2002; 2 (5), pp. 327–34.

EXTRAHEPATIC PHARMACOGENETICS

EXTRAHEPATIC—CARDIOVASCULAR SYSTEM

Angiotensin-Converting Enzyme (ACE) Deletion Allele Polymorphism/Congestive Heart Failure Left Ventricular Ejection Fraction 0.24 ± 0.08/ Transplant-Free Survival Prediction
Adrenergic β-Blocker Therapy Response

Cellular/Molecular Mechanism of Action: Angiotensin-converting enzyme inhibitors disrupt the biochemical activity of angiotensin-converting enzyme in a manner that prevents the production of renal angiotensin II from angiotensin I and decreases the destruction of bradykinin.
Background Information: Activation of the renin-angiotensin and sympathetic nervous systems adversely affects the progression of heart failure. The ACE deletion allele (ACE D) is associated with increased renin-angiotensin activation; however, its influence on patient outcomes remains uncertain, and pharmacogenetic interactions with β-blocker therapy have not been thoroughly evaluated to date.
Application: Estimation of the transplant-free survival time in cases of cardiac disease as a function of ACE genotype expression related to β-blocker pharmaceuticals.
Implementation: Evaluation of the influence of the ACE-D allele on transplant-free survival (medial follow-up 21 months) in cases with systolic dysfunction (e.g., n = 328; age, 56.1 ± 11.9 years) that display abnormalities in left ventricular ejection fraction measurements (e.g., 0.24 ± 0.08).
Interpretation and Analysis: Transplant-free survival is significantly poorer for cases with the D allele (1-year percent survival II/ID/DD = 94/77/75; 2-year = 78/65/60; ordered log-rank test, p = 0.044). In cases not treated with β-blockers (e.g., n = 208), the adverse impact of the ACE D allele is dramatically increased (1-year percent survival II/ID/DD = 95/75/67; 2-year = 81/61/48; p = 0.005). Conversely, the ACE genotype has no influence on transplant-free survival when β-blocker therapy is administered (1-year percent survival II/ID/DD = 91/80/86; 2-year = 70/71/77; p = 0.73). Therefore, in cases suffering from systolic dysfunction, the ACE D allele is associated with a significantly poorer transplant-free survival. This effect is most evident in the absence of β-blockers administration and is not a pattern observed with β-blocker therapeutic regimens. Such observations suggest that a potential pharmacogenetic interaction exists between the ACE D/I polymorphism and therapy with β-blockers in the determination of heart failure survival.

Pharmacogenetic interactions between β-blocker therapy and the angiotensin-converting enzyme deletion polymorphism in patients with congestive heart failure. McNamara DM, Holubkov R, Janosko K, Palmer A, Wang JJ, MacGowan GA, Murali S, Rosenblum WD, London B, Feldman AM. Circulation 2001 Mar 27; 103 (12), pp. 1644–8.

Angiotensin-Converting Enzyme (ACE) Deletion Allele Polymorphism (ACE D/I)/Renin-Angiotensin/ Left Ventricular (LV) Modeling Post–Myocardial Infarction (MI)
Ramipril

Cellular/Molecular Mechanism of Action: Angiotensin-converting enzyme proteolytically generates angiotensin from a biologically inactive precursor. Angiotensin-converting enzyme inhibitors disrupt the biochemical activity of ACE in a manner that prevents the production of renal angiotensin II from angiotensin I and decreases bradykinin distruction.
Background Information: The D/I (deletion, D, insertion, I) polymorphism of the ACE gene has been extensively studied for its association with a number of different cardiovascular conditions and other disease states. However, its potential association with the differential clinical efficacy of ACE inhibitors (ACE-I) administered to patients who have suffered a myocardial infarction (i.e., the prevention of LV remodeling) has so far not been specifically studied.
Application: Detection and evaluation of ventricular modeling post–myocardial infarction.
Considerations: Evidence does not currently exist that demonstrates an association between ACE D/I polymorphism and the risk of LV remodeling post-MI in the presence of ACE-I therapy. Therefore, there is no relationship between the differential clinical efficacy of ACE inhibitors and D/I polymorphism of the ACE gene as a genetic marker.
Implementation: Determination of the level of association between D/I polymorphism of the ACE gene with the incidence of post-MI LV remodeling. In this context, an ACE inhibitor (ACE-I, e.g., ramipril) is administered in concert with reductions in LV enlargement in cases of acute anterior wall mitral insufficiency (n = 265 subjects: Healing and Early Afterload Reducing Therapy [HEART] study). Characterization of ACE D/I polymorphism can be determined through the application of various analytical techniques including the polymerase chain reaction (PCR).
Interpretation and Analysis: Selected frequencies for the ACE D and I alleles are 0.59 and 0.41 (placebo-high dose group), 0.56 and 0.44 (low dose-low dose group), and 0.60 and 0.40 (high dose-high dose group), respectively. All observed genotype frequencies are in

Hardy-Weinberg equilibrium. An association between genotype and outcome regarding LV size or function cannot be detected, nor with the initial blood pressure response after ACE-I administration (adjusted for co-variates).

A prospective evaluation of the angiotensin-converting enzyme D/I polymorphism and left ventricular remodeling in the "Healing and Early Afterload Reducing Therapy" study. Zee RY, Solomon SD, Ajani UA, Pfeffer MA, Lindpaintner K; Heart Investigators. Clin Genet 2002 Jan; 61 (1), pp. 21–5.

Angiotensin-Converting Enzyme (ACE) Genetic Polymorphism/Variability in Efficacy
ACE Inhibitors/Imidapril

Cellular/Molecular Mechanism of Action: Angiotensin-converting enzyme inhibitors disrupt the biochemical activity of ACE in a manner that prevents production of renal angiotensin II from angiotensin I and decreases the destruction of bradykinin.
Background Information: Angiotensin-converting enzyme inhibitors (e.g., imidapril [enalapril, captopril]) are reported to prevent neointimal formation after balloon injury in animal models, but in most prospective studies in humans, ACE inhibitors fail to prevent restenosis after percutaneous transluminal coronary angioplasty (PTCA).
Application: Imidapril can be applied as an ACE inhibitor for the purpose of preventing restenosis after PTCA. However, ACE insertion/deletion (I/D) polymorphism may influence the effectiveness of ACE inhibitors in this therapeutic role.
Dosage: Imidapril (5 mg SID) for 3 to 6 months.
Implementation: The ACE genotype assigned by an I/D polymorphism is known to affect the potency of ACE inhibitors in several conditions of renal disease. To determine how ACE genotype influences the efficacy of ACE inhibitors on restenosis related to PTCA, subjects are given imidapril (5 mg imidapril SID for 3 to 6 months starting 1 day before PTCA). Efficacy of imidapril is determined through the evaluation of vessel integrity.

Human Model: Cases with the ACE genotype and subjected to PTCA procedures (e.g., n = 46 controls [65 vessels]; n = 32 imidapril test subjects [43 vessels]).
Interpretation and Analysis: The minimal lumen diameter before and after the procedure does not differ significantly among the 3 ACE genotypes (II, ID, and DD) in both the control and imidapril groups. Late luminal loss during the follow-up period is not related to ACE genotype in the control group but is significantly related in the imidapril group (II, 0.63 ± 0.19 mm; ID + DD, 1.12 ± 0.14 mm, $p < 0.05$). Furthermore, in the II genotype, imidapril significantly reduces the late loss and restenosis rate as defined by most of the frequently used definitions.

Pharmacogenetic analysis of the effect of angiotensin-converting enzyme inhibitor on restenosis after percutaneous transluminal coronary angioplasty. Okamura A, Ohishi M, Rakugi H, Katsuya T, Yanagitani Y, Takiuchi S, Taniyama Y, Moriguchi K, Ito H, Higashino Y, Fujii K, Higaki J, Ogihara T. Angiology 1999 Oct; 50 (10), pp. 811–22.

Angiotensin-Converting Enzyme (ACE) Genetic Polymorphism/Blood Pressure: Genetic Response Variation/Antihypertensive Agents: Genetic Variation
ACE Inhibitors/Lisinopril

Cellular/Molecular Mechanism of Action: Angiotensin-converting enzyme inhibitors suppress or prevent the biochemical generation of angiotensin.
Physiological Mechanism of Action: Angiotensin-converting enzyme inhibitor agents lower peripheral vascular blood pressure.
Background Information: It has been well known for 70 years that familial factors influence blood pressure levels. Modern genetics suggest that 30–40% of blood pressure variation reflects genetic factors. Interindividual variation in response to specific antihypertensive agents has been documented for more than 40 years, with little insight beyond demographics into the responsible mechanism for the variation in efficacy. Only recently has interest been evident in attempts to bring these 2 questions together. Specifically, do familial factors influence the response to specific antihypertensive therapy?
Implementation: A substantial degree of variation can be observed between individuals in their response to ACE inhibitors.
Interpretation and Analysis: Interindividual variation in the response to ACE inhibitors is considered to be a phenotype characteristic directly influenced by genetic factors. Similarly, it has been recognized that ACE inhibition reverses many of the features of nonmodulation, which is the expression of an angiotensinogen (AGT) gene polymorphism. The ESPRIT Study was the 1st to enroll hypertensive sibling pairs into a therapeutic trial, designed to assess responses to ACE inhibitor treatment with lisinopril. This pathway of investigation is likely to be very fruitful over the next several decades, to the point that "pharmacogenetics" will be an element in selecting antihypertensive therapy.

One's grandparents as the determinant of effective antihypertensive therapy. Hollenberg NK. Blood Press Monit 1999; 4 Suppl 1, pp. S15–8.

Butyrylcholinesterase (Plasma): Genetic Asp70Gly Mutations
Succinylcholine/Mivacurium

Cellular/Molecular Mechanism of Action: Butyrylcholinesterase enzymatically metabolizes mivacurium and succinylcholine.
Background Information: The enzymatic function of butyrylcholinesterase is significantly impaired with mutations at Asp70Gly.
Implementation: Application of a simple polymerase chain reaction (PCR) method for the detection of genetic mutations of butyrylcholinesterase. A relatively high percentage of cases tested after episodes of prolonged apnea are positive for the presence of an altered genetic sequence responsible for Asp70Gly mutations (e.g., n = 13/16; homozygotes = 50.0%; heterozygotes = 31.3%). Such alterations detected by PCR tests explain certain observed clinical events and an avenue for prevention in relatives.

Rapid identification of atypical variant of plasma butyrylcholinesterase by PCR. Ceppa F, Gidenne S, Benois A, Fontan E, Burnat P. Clin Chem Lab Med 2002 Aug; 40 (8), pp. 799–801.

Cardiac Arrythmias: Congenital Long Q-T1 (LQ-T1) Syndrome/Silent LQ-T1 Mutation Carriers
Epinephrine

Cellular/Molecular Mechanism of Action: Epinephrine is an endogenous neurotransmitter that functions as a positive adrenergic agonist/sympathomimetic agent at α-adrenergic and β-adrenergic postsynaptic receptor complexes.
Background Information: The LQ-T1 form of congenital LQ-T syndrome is associated with high vulnerability to sympathetic stimulation and appears with incomplete penetrance.
Application: Detection of silent LQ-T1 mutation carriers.
Route of Administration: Epinephrine (infusion).
Dosage: Epinephrine (0.1 μg/kg/min).

Implementation: Evaluation of the LQ-T1 form of congenital LQ-T syndrome using epinephrine by infusion. Electrocardiographic (12-lead) parameters are recorded before and after epinephrine infusion.

Human Model: Congenital LQ-T1 (n = 19 mutation carriers with a baseline corrected Q-T interval (Q-Tc) of > 460 ms (Group I), 15 mutation carriers with a Q-Tc of < 460 ms (Group II), 12 non-mutation carriers (Group III), and 15 controls (Group IV).

Interpretation and Analysis: The mean corrected Q-Tend (Q-Tce), Q-Tpeak (Q-Tcp), and Tpeak-end (Tcp-e) intervals among 12 leads prior to epinephrine are significantly larger in Group I than in other case groups. Epinephrine significantly increases the mean Q-Tce, Q-Tcp, Tcp-e, and the dispersion of Q-Tcp in Groups I and II, but not in Groups III and IV. Sensitivity and specificity of Q-Tce measurements to identify mutation carriers are approximately 59% (20/34) and 100% (27/27), respectively, before epinephrine, and the sensitivity is substantially improved to 91% (31/34) without sacrificing specificity (100%, 27/27) after epinephrine. The mean Q-Tce, Q-Tcp, and Tcp-e before and after epinephrine are significantly larger in symptomatic (e.g., n = 15) than in asymptomatic (n = 19) mutation carriers in case Groups I and II, and the prolongation of the mean Q-Tce with epinephrine is significantly larger in symptomatic cases. Epinephrine challenge can function as a powerful test to establish electrocardiographic diagnosis in silent LQ-T1 mutation carriers, thus allowing implementation of prophylactic measures aimed at reducing sudden cardiac death.

Epinephrine unmasks latent mutation carriers with LQ-T1 form of congenital long Q-T syndrome. Shimizu W, Noda T, Takaki H, Kurita T, Nagaya N, Satomi K, Suyama K, Aihara N, Kamakura S, Sunagawa K, Echigo S, Nakamura K, Ohe T, Towbin JA, Napolitano C, Priori SG. J Am Coll Cardiol 2003 Feb 19; 41 (4), pp. 633–42.

Cardiac Arrythmias: Long Q-T Syndrome (LQ-TS)/Genotype LQ-T1, LQ-T2, and LQ-T3
Phenylephrine/Dobutamine

Cellular/Molecular Mechanism of Action: Phenylephrine and dobutamine function as catecholamine agonists.

Application: Electropharmacology challenge tests with phenylephrine and dobutamine for identifying alterations in repolarization lability in patients with genotyped LQ-TS. Quantification of such phenomenon may assist in identifying LQ-TS patients with an increased risk of sudden cardiac death.

Route of Administration: Intravenous.

Implementation: Determination of the effects of phenylephrine and dobutamine on repolarization lability in patients with genotyped LQ-TS. Electrocardiographic stress testing involving aperiodic repolarization lability is quantified from digitized electrocardiograms recorded during catecholamine challenge with phenylephrine and dobutamine. T wave lability quantified as a root-mean-square of the differences between corresponding signal values of subsequent beats. The magnitude of aperiodic T wave lability is quantified by using a newly derived T wave lability index (TWLI).

Human Model: Cases with the genotyped LQ-TS (n = 13 LQ-T1; n = 7 LQ-T2; n = 3 LQ-T3; n = 16 reference controls).

Interpretation and Analysis: The TWLI is significantly greater in LQ-TS genotypes relative to controls (0.0945 + 0.0517 vs 0.0445 + 0.0123; $p < 0.003$). Marked T wave lability (TWLI ≥ 0.095) can be detected in all 3 LQ-TS genotypes (10/23) but not in reference controls ($p < 0.003$). There is no correlation between TWLI and baseline corrected Q-T interval. High-risk patients that have either a history of out-of-hospital cardiac arrest or syncope almost invariably have a TWLI of 0.095 or greater. Beat-to-beat non-alternating T wave lability occurs in cases with LQ-T1, LQ-T2, and LQ-T3 during catecholamine provocation and is associated with a history of prior cardiac events. Quantification of this novel phenomenon may assist in identifying LQ-TS cases with increased risk of sudden cardiac death.

Instrumentation: Electrocardiography system.

Catecholamine-induced T wave lability in congenital long Q-T syndrome: A novel phenomenon associated with syncope and cardiac arrest. Nemec J, Hejlik JB, Shen WK, Ackerman MJ. Mayo Clin Proc 2003 Jan; 78 (1), pp. 40–50.

Lipid Metabolism: Cardiovascular Disease
Hypolipemic Agents

Background Information: Pharmaceutical therapy in the management of abnormal plasma lipid concentrations in patients suffering from cardiovascular disease often results in a wide variety of individual responses.

Considerations: Cardiovascular disease is associated with non-modifiable risk factors such as age, gender, and genetic background, and with modifiable risk factors such as lipid concentrations. Lowering serum lipid levels has been demonstrated to slow the progression of, or even induce regression in atherosclerosis.

Interpretation and Analysis: Pharmacogenetics provides the experimental foundation for understanding the variability in response to drugs as a function of individual genetic makeup. Information from small clinical trials reveals that several candidate genes may hold some promise in the quest to predict individual success to hypolipemic drug treatment. However, the current clinical relevance of this knowledge is quite limited due to the small effects observed for each of the genetic markers examined. Future progress in this area will be driven by studying gene-gene and gene-treatment interactions in much larger patient populations.

Pharmacogenetics of lipid-lowering therapies. Ordovas JM, Shen H. Curr Atheroscler Rep 2002 May; 4 (3), pp. 183–92.

3-Hydroxy-3-Methylglutaryl Coenzyme A (HMG-CoA)/HMG-CoA Genetic Polymorphism/Coronary Heart Disease (CHD)
Statins: HMG-CoA Inhibitors/Cholesterol-Lowering Agents

Background Information: Cholesterol-lowering therapy is the central approach in the primary and secondary prevention of cardiovascular disease, the leading cause of death in industrialized countries. 3-hydroxy-3-methylglutaryl coenzyme A reductase inhibitors (statins) are currently the most potent and widely used cholesterol-lowering drugs. Large-scale clinical trials unequivocally demonstrate the efficacy of statin treatment in reducing the risk of cardiovascular events.

Interpretation and Analysis: In general, HMG-CoA reductase inhibitors are well tolerated, although in a minority of patients severe adverse effects like myopathy or rhabdomyolysis may develop. The incidence of these potentially life-threatening side effects increases with co-adminstration of pharmaceuticals that are metabolized via the same biochemical pathways or at high-dose statin therapy. The recent focus on the pleiotropic effects of statins that are more frequently observed at higher doses and the conclusion drawn from the large statin trials that low-density lipoprotein (LDL) cholesterol is "the lower the better" may need careful consideration in individuals at risk of adverse drug reactions. On the other hand, not all patients respond to statin therapy with a reduction in CHD risk. It is therefore of interest to develop diagnostic test systems that allow the identification of cases at increased risk of developing adverse drug reactions

or scenarios where a lack of therapeutic effect can be anticipated. Besides exogenous factors, genetic variability determines the response of an individual to drug therapy, and the analysis of genetic variants affecting pharmacokinetic or pharmacodynamic aspects of drug therapy is the subject of pharmacogenomics.

Pharmacogenomics and pharmacogenetics of cholesterol-lowering therapy. Schmitz G, Drobnik W. Clin Chem Lab Med 2003 Apr; 41 (4), pp. 581–9.

EXTRAHEPATIC—CENTRAL NERVOUS SYSTEM

Alcohol Sensitivity
Ethanol/Calcium Chloride/A23187 (Calcium Ionophor)

Physiological Mechanism of Action: Ethanol functions as a central nervous system depressant.
Application: Characterization of differences in central nervous system ethanol metabolism.
Route of Administration: Ethanol is administered orally (per os).
Implementation: Sensitivity to ethanol is measured as a function of the blood ethanol concentration at the point where the righting reflex is lost.
Interpretation and Analysis: Sensitivity to ethanol is increased significantly in SS but not LS mice following intracerebroventricular (ICV) administration of calcium chloride or A23187, a calcium ionophore. Magnesium chloride or lanthanum chloride, ICV, does not alter sensitivity to ethanol in either SS or LS mice, further indicating a specificity for calcium cation. Calcium does not affect sensitivity to halothane narcosis in LS or SS mice. Endogenous brain calcium content is similar in these mouse lines, and ethanol administration either *in vivo* or *in vitro* does not alter brain calcium concentration. Differences in brain sensitivity to ethanol are therefore mediated, in part, by genetic differences in calcium-related processes and support the hypothesis that ethanol-induced narcosis may be due to alterations in calcium metabolism in the CNS.

Calcium influence on neuronal sensitivity to ethanol in selectively bred mouse lines. Morrow EL, Erwin VG. Pharmacol Biochem Behav 1986 Apr; 24 (4), pp. 949–54.

Alcoholism: Genetic-Associated Senstivity/Central Nervous System Electroencephalogram (EEG) Patterns
Ethanol/EEG Analysis/(Electropharmacogenetics)

Physiological Mechanism of Action: Ethanol functions as a central nervous system depressant.
Background Information: Electroencephalogram analysis offers several advantages for performing pharmacogentic related studies because it simultaneously evaluates both genetic traits and challenge characteristics.
Application: Delineation of alterations in EEG tracings induced by ethanol that are associated with specific genetic characteristics that may be related to a predisposition for alcoholism.
Route of Administration: Ethanol is administered orally to effect.
Implementation: Pharmacogenetic studies employing EEG analysis have been applied to characterize the influence of acute ethanol dosing on brain function. Performance of such investigations in twin individuals has facilitated the discovery of certain ethanol-induced alterations in brain wave profiles that are directly related to genetic-related characteristics.
Interpretation and Analysis: Pharmacogenetic studies employing EEG analysis combined with acute ethanol dosing in twin individuals reveals that certain alterations in EEG tracings profiles induced by this depressant are genetic regulated in nature. Among the various genetically determined variants of EEG tracings, the poorly synchronized αEEG exhibits the most pronounced response. Examination of a series of alcoholics of both sexes as well as their 1st-degree relatives reveals that in females the poorly synchronized αEEG may be an indicator that reflects a predisposition for alcoholism. Such observations support the perception that a disposition toward alcoholism is under genetic influence not only at the metabolic but also at the pharmacodynamic level.

Pharmacogenetics of alcohol's CNS effect: Implications for the etiology of alcoholism. Propping P. Pharmacol Biochem Behav 1983; 18 Suppl 1, pp. 549–53.

Alcoholism: Genetic-Associated Sensitivity/ Cholinergic Function
Ethanol/[^{3}H]-Quinuclidinyl Benzilate

Physiological Mechanism of Action: Ethanol functions as a central nervous system depressant.
Application: Characterization of pharmacogentic properties associated with vulnerability or resistance to the development of alcoholism pertaining to different aspects of cholinergic function within the autonomic nervous system.
Route of Administration: Ethanol is traditionally administered orally (per os).
Dosage: Ethanol (4.6 g/kg).
Implementation: Evaluation of alterations in choline acetyltransferase (ChAT), acetylcholinesterase (AChE) activity, and [^{3}H]-quinuclidinyl benzilate (QNB) binding within different regions of the brain following ethanol administration (4.6 g/kg BW).
Animal Model: Murine (inbred strains).
Interpretation and Analysis: Choline acetyltransferase in striatum and septum of mouse strain C57BL/6 exhibit greater sensitivity to ethanol compared to BALB/c mice. The limbic system and related structures of BALB/c mice show greater sensitivity to ethanol relative to C57BL/6 mouse strains. Acute ethanol administration in C57BL/6 mice increases striatal ChAT activity (up to 22% with 60-minute latency). Ethanol-induced augmentation of ChAT activity in this manner is associated with non-synchronous decreases in kinetic characteristics of stratum QNB binding. In contrast, no such changes are seen in BALB/c striatum, except the observation of an increase in Kd up to 90 minutes after acute ethanol treatment. Similar significant increases in ChAT activity can also be observed in C57BL/6 septum 165 minutes after ethanol administration. However, the septum in BALB/c mice does not exhibit comparable changes. Ethanol increases ChAT activity in several brain areas of both C57BL/6 and BALB/c strains of mice. Regions of the CNS that are affected include the hippocampus, temporal limbic cortex, and piriform cortex or paleocortex. Interestingly, the latencies to increased ChAT activity in these areas are much shorter in BALB/c than in C57 mice. The kinetic characteristics of QNB binding sites (Bmax and Kd) and AChE activity are unchanged in all regions of the brain and do not differ between strains (except where previously indicated). Genetic differences in ethanol preference and sensitivity in these strains therefore are accompanied by differential sensitivity of ChAT to acute ethanol. Genotypic variations in dopaminergiccholinergic interactions in striatum, hippocampus, septum, temporal limbic, and piriform cortex could contribute to genetic differences in cholinergic sensitivity to ethanol. In addition, different blood-brain barrier and membrane properties may also contribute to genetic differences in the sensitivity of cholinergic function to ethanol. The differential

effects on ChAT activity could possibly be responsible for genetic differences in memory disorders (limbic system and related structures) and motor incoordination (basal ganglia) following high dose alcohol administration.

Genetically-determined responses of central cholinergic markers: The effects of ethanol on inbred strains of mice. Hashemzadeh-Gargari H, Mandel P. Neurotoxicology 1989 Fall; 10 (3), pp. 555–68.

Attention Deficit Hyperactivity/Dopamine Transporter Gene/Homozygote vs Heterozygote
Methylphenidate (MPH)

Background Information: The homozygosity of the 10-repeat allele at dopamine transporter gene (DAT1) seems to be associated with a poor response to MPH in children with attention deficit hyperactivity disorder (ADHD).
Implementation: Simultaneously assessment of polymorphisms at DAT1, response to MPH, and neuroimaging of cerebral blood flow in cases of childhood ADHD that display at least a moderate response to MPH.
Interpretation and Analysis: Significantly higher regional cerebral blood flows assessed by single photon emission computed tomography (SPECT) can be detected in medial frontal and left basal ganglia areas in children with homozygosity for the 10-repeat allele at DAT1 gene ($n = 4$) compared to children without this genotype ($n = 4$; $p < 0.05$). Such findings provide a preliminary connection between pharmacogenetics and neurobiological investigations on stimulant treatment of ADHD.

Dopamine transporter gene, response to methylphenidate and cerebral blood flow in attention-deficit/hyperactivity disorder: A pilot study. Rohde LA, Roman T, Szobot C, Cunha RD, Hutz MH, Biederman J. Synapse 2003 May; 48 (2), pp. 87–9.

Neurolepsy: Genetic-Associated Variable Effect
Haloperidol

Background Information: Several factors may account for the variability recognized for individual responses to neuroleptic agents. Examples include variables such as length of illness before treatment, age at onset, and the presence of negative symptoms, and pharmacologic factors such as rates of drug metabolism. However, in the general population, notable pharmacodynamic differences in therapeutic response to haloperidol have been observed between Chinese and Caucasian patients. Response rates may also reflect clinical heterogeneity, although familiality, history of obstetric trauma, or ventricular enlargement have been shown to not be significant factors. It is also possible that genetic differences in receptors that are targets for these drugs may influence response.
Considerations: Factors that influence response to neuroleptic drugs are poorly understood.

Functional neuroimaging and pharmacogenetic studies of clozapine's action at dopamine receptors. Kerwin RW, Pilowsky L, Munro J, Shaikh S, Gill M, Collier D. J Clin Psychiatry 1994 Sep; 55 Suppl B, pp. 57–62.

Nicotine Sensitivity: Genetic-Associated Sensitivity/ Induced Alterations in Neurological Function
Nicotine

Cellular/Molecular Mechanism of Action: Nictotine binds to and stimulates cholinergic nicotinic receptor sites for the neurotranmitter acetylcholine within the parasympathetic segment of the autonomic nervous system.
Physiological Mechanism of Action: Parasympathomimetic activity.
Application: Delineation of genetic-associated alterations in neurologic function related to nicotine responsiveness, nicotinic receptor properties, and nicotine metabolisms/elimination.
Implementation: Male mice from 19 inbred strains serve as an investigative platform of determining their existing genetic difference in the response to nicotine exposure. Physiological parameters measured include the responses of respiratory rate, acoustic startle, Y-maze crosses, Y-maze rears, heart rate, and body temperature. Dose-response curves are then constructed for each strain on each test in a multitest battery.
Interpretation and Analysis: Physiological responses to nicotine are strongly influenced by animal genotype. Comparison of the results from 6 evaluation parameters measured in addition to observations reported for nicotine-induced seizures in the same strain of mice indicate that responses can be grouped into 2 major classes: a set characterized by Y-maze crosses, Y-maze rears, and body temperature, and a set characterized by seizure sensitivity and seizure latency. Responses observed for respiratory rate and startle response share characteristics with both of these sets, while the effects of nicotine on heart rate are fairly unique. The results have identified strains of mice that are differentially sensitive to the effects of nicotine.

Genetic influences on nicotine responses. Marks MJ, Stitzel JA, Collins AC. Pharmacol Biochem Behav 1989 Jul; 33 (3), pp. 667–78.

Pain Sensation/Threshold
Antinoceceptive Morphine Sensitivity

Background Information: Chromosomal loci containing genes affecting antinociceptive sensitivity to morphine have been identified, but virtually nothing is known about the genetic mediation of sensitivity to over-the-counter analgesics. Such knowledge would be of great clinical interest, as prodigious interindividual variability has been noted in the efficacy of these ubiquitously used drugs.
Application: Characterization of genetic variations in pain perceptions/response and evaluation of genetic difference in analgestic properties associated with non-steroidal anti-inflammatory drugs (NSAIDs).
Implementation: Assessed heritability and genetic correlations among 3 over-the-counter analgesics.

The heritability and genetic correlations among 3 over-the-counter analgesics have been assessed against noxious stimuli (e.g., 12 inbred murine strains utilizing the 0.9% acetic acid [i.p.] writhing test). Candidate analgesics have included the centrally acting analgesic acetaminophen (150 mg/kg, s.c.), the NSAIDs indomethacin (40 mg/kg, s.c.), and lysine-acetylsalicylic acid (800 mg/kg, s.c.).
Interpretation and Analysis: Evaluation of the response to the centrally acting analgesic, acetaminophen and the NSAIDs indomethacin and lysine-acetylsalicylic acid reveals significant differences between individual strains (genetically distinct populations) of mice. Narrow-sense heritability estimates range from 23 to 45%. Similar strains are sensitive and resistant, respectively, to the 2 NSAIDs ($r^s = 0.64$). In contrast, a completely different pattern of sensitivities is observed for acetaminophen, implying a genetic dissociation ($r^s = 0.29$ and 0.02) compared with the NSAID preparations. Related investigations performed on the 2 murine strains, C57BL/6 and DBA/2, show that they display extreme sensitivities to acetaminophen. Interestingly, the plasma acetaminophen levels in these strains of mice are not significantly different during the time of

antinociception assessment, suggesting the existence of genetic factors affecting acetaminophen pharmacodynamics rather than variations in pharmacokinetic parameters.

The heritability of antinociception II: Pharmacogenetic mediation of 3 over-the-counter analgesics in mice. Wilson SG, Bryant CD, Lariviere WR, Olsen MS, Giles BE, Chesler EJ, Mogil JS. J Pharmacol Exp Ther 2003 May; 305 (2), pp. 755–64.

Pain Sensation/Threshold/Genetic-Based Variability in Analgesia/(Non-Pharmacokinetic Related)
Non-Steroidal Anti-Inflammatory Drugs (NSAIDs)/Acetaminophen/Indomethacin/Lysine-Acetylsalicylic Acid

Background Information: Chromosomal loci containing genes affecting antinociceptive sensitivity to morphine have been identified, but virtually nothing is known about the genetic mediation of sensitivity to over-the-counter analgesics. Such knowledge would be of great clinical interest, as prodigious interindividual variability has been noted in the efficacy of these ubiquitously used drugs.
Route of Administration: Acetaminophen (s.c. in mice), indomethacin (s.c. in mice), and lysine-acetylsalicylic acid (s.c. in mice).
Dosage: Acetaminophen (150 mg/kg in mice), and the NSAIDs indomethacin (40 mg/kg in mice) and lysine-acetylsalicylic acid (800 mg/kg in mice).
Implementation: Assessment of the heritability and genetic correlations among 3 over-the-counter analgesics on the 0.9% acetic acid (i.p.) writhing test (e.g., mice of 12 inbred mouse strains: C57BL/6 and DBA/2). Analgesics evaluated can include the centrally acting analgesic acetaminophen (150 mg/kg, s.c.), the NSAIDs indomethacin (40 mg/kg, s.c.), and lysine-acetylsalicylic acid (800 mg/kg, s.c.).
Interpretation and Analysis: Significant strain differences exist in sensitivity to centrally acting acetaminophen, in addition to the NSAIDS indomethacin and lysine-acetylsalicylic acid, with narrow-sense heritability estimates ranging from 23 to 45%. Similar strains of mice are sensitive and resistant, respectively, to indomethacin and lysine-acetylsalicylic acid ($r^s = 0.64$). In contrast, a completely different pattern of sensitivities is observed for acetaminophen, implying genetic dissociation ($r^s = 0.29$ and 0.02) compared with indomethacin and lysine-acetylsalicylic acid. Investgations performed in murine strains C57BL/6 and DBA/2 reveal extreme sensitivities to acetaminophen. Plasma acetaminophen levels in these strains are not significantly different during the time of antinociception assessment, suggesting the existence of genetic factors affecting acetaminophen pharmacodynamics rather than pharmacokinetics.

The heritability of antinociception II: Pharmacogenetic mediation of 3 over-the-counter analgesics in mice. Wilson SG, Bryant CD, Lariviere WR, Olsen MS, Giles BE, Chesler EJ, Mogil JS. J Pharmacol Exp Ther 2003 May; 305 (2), pp. 755–64.

Psychosis: Dopamine D2 Receptor Gene Taq I Polymorphism
Haloperidol

Background Information: Pharmacogenetic influences on therapeutic response to neuroleptic treatment are poorly understood.
Implementation: Treatment of patients with acute psychosis with haloperidol for 28 days (e.g., n = 57). Improvement and response are measured using a Positive and Negative Syndrome Scale. Genetic profiling for the DRD2 gene Taq I polymorphism is then performed (e.g., n = 41/57 vs n = 16/57 heterozygous).
Interpretation and Analysis: On all treatment days, heterozygous patients show a greater improvement in positive, but not in negative, symptoms compared to cases that are homozygous for allele 2. Differences in improvement of positive symptoms reach statistical significance on days 14, 21, and 28. On treatment day 14, approximately 62.5% (e.g., n = 10/16) of heterozygous patients have at least a 50% improvement of positive symptoms, compared with approximately 28.9% homozygous patients (e.g., n = 11/38). Genetic variations in the DRD2 gene may therefore influence response to antipsychotics.

Association of short-term response to haloperidol treatment with a polymorphism in the dopamine D(2) receptor gene. Schafer M, Rujescu D, Giegling I, Guntermann A, Erfurth A, Bondy B, Moller HJ. Am J Psychiatry 2001 May; 158 (5), pp. 802–4.

Schizophrenia: Familial Clusters of Disease
Lithium

Background Information: Selecting a drug according to the treatment response in a family relative has been widely accepted advice in the management of mood disorders. However, this recommendation has not been adequately substantiated in the literature. Minimal information is known as to what degree response to long-term lithium treatment is a familial trait.
Implementation: Comparison of the response to long-term lithium treatment in bipolar relatives of bipolar lithium responders and bipolar controls. Validation of a diagnosis for bipolar disorder can be determined using the Schedule for Affective Disorders and Schizophrenia-Lifetime Version (SADS-L) and Research Diagnostic Criteria (RDC). Lithium response is evaluated on a rating scale reflecting the quality and quantity of available data.
Interpretation and Analysis: Comparison of 24 relatives with bipolar disorder, identified in families of 106 cases with lithium-responsive bipolar disorder, to 40 lithium-treated bipolar cases serving as a comparison control reveals a prevalence of unequivocal response among relatives of 67%, compared to a response rate of 35% in a comparison group ($chi^2 = 6.04$, df = 1, p = 0.014). The highly significant difference in observed responses between relatives and reference control groups supports the perspective that lithium prophylaxis clusters exist within families and the general population.

Is response to prophylactic lithium a familial trait? Grof P, Duffy A, Cavazzoni P, Grof E, Garnham J, MacDougall M, O'Donovan C, Alda M. J Clin Psychiatry 2002 Oct; 63 (10), pp. 942–7.

Schizophrenia/Serotonin (2A) Receptor: 102-T/C Genetic Polymorphism/Risperidone Efficacy Variability
Risperidone

Application: Delineation of variations in risperidone efficacy as a function of 102-T/C polymorphism in the 5-HT(2A) receptor gene.
Implementation: Administration of rispiridone in patients suffering from acute exacerbated schizophrenia (e.g., n = 100 for 42 days) performed in combination with genotype analysis for 5-HT(2A) polymorphisms. Psychopathology is measured biweekly with the Positive and Negative Syndrome Scale during the time frame of risperidone administration. Generalized estimating equation methods are used to analyze the effects of treatment duration, T/C genotypes, and other prognostic factors on Positive and Negative Syndrome Scale performance.

Interpretation and Analysis: Patients with the C/C genotype have lower total scores, negative subscale scores, and general psychopathology scores but not positive subscale scores on the Positive and Negative Syndrome Scale than patients with the 102-T/C genotype. Patients with the T/C and T/T genotypes have comparable total and subscale scores. The number of previous hospitalizations and the dose of risperidone also affects Positive and Negative Syndrome Scale total scores.

Association of risperidone treatment response with a polymorphism in the 5-HT(2A) receptor gene. Lane HY, Chang YC, Chiu CC, Chen ML, Hsieh MH, Chang WH. Am J Psychiatry 2002 Sep; 159 (9), pp. 1593–5.

Schizophrenia: Serotonin (2A) Receptor: 102-T/C Genetic Polymorphism/Risperidone: Optimal Dosing Strategies (Acute Schizophrenia)
Risperidone

Background Information: The optimal risperidone dosing strategy for acute schizophrenia requires elucidation through the conduction of clinical research investigations. Plasma levels of risperidone and its active metabolite (9-hydroxyrisperidone) at a given dose vary greatly among different individuals. For patients who metabolize risperidone slowly, a medium dose results in excessively high plasma levels, which might be related to adverse events and perhaps poor response.
Application: Detection of pharmacogenetic variations related to therapeutic response and induced side effects associated with risperodone administration.
Dosage: Risperidone (6.0 mg/day × days if tolerated).
Implementation: Evaluate the potential for reductions in dose to diminish adverse reactions associated with ordinary risperidone administration, but still maintain efficacy for acutely exacerbated schizophrenia. Toward this objective cases of acutely exacerbated schizophrenia (DSM-IV) have been managed with titrated doses of risperidone over 3 days (6 mg/day if tolerated) with administration levels lowered if undesirable side effects become apparent. Clinical efficacy and side effects are then assessed on days 0, 4, 14, 28, and 42. End point steady state plasma levels of risperidone and 9-hydroxyrisperidone are subsequently measured by high-performance liquid chromatography analysis.
Human Model: Cases suffering from acutely exacerbated schizophrenia.
Interpretation and Analysis: Approximately 50% of cases (e.g., n = 17/31) can tolerate the 6-mg target dose without significant side effects, while as little as < 30% of individuals (e.g., n = 13/31) require lowering of dosage levels (mean ± SD = 3.6 ± 0.9 mg, p = 0.0001) in order to curtail treatment-induced side effects. At end point, 92.3% of low-dose individuals respond to treatment (20% or more reduction in total Positive and Negative Syndrome Scale score), compared with 52.9% of high-dose subjects (p < 0.05). No significant between-group differences exist in other minor efficacy measures. Of note, end point plasma levels of the active moiety (risperidone + 9-hydroxyrisperidone) are similar between the low- and high-dose groups (40.4 ± 31.1 ng/mL vs 49.7 ± 13.4 ng/mL, NS).

Risperidone appears to be efficacious in the treatment of acute exacerbation of schizophrenia up to a dosage level of 6 mg/day. Approximately 60% of such cases can tolerate the administration of risperidone at this dosage level. Alternatively, approximately 40% of cases require the use of substantially lower doses of risperidone (e.g., mean = 3.6 ± 0.9 mg) in order to reverse observed side effects despite achievement of appreciable efficacy. The 2 dose groups are comparable in the end point steady state plasma drug concentrations.
Instrumentation: High-performance liquid chromatography analysis utilizing an ultraviolet-based detector modality.

Risperidone in acutely exacerbated schizophrenia: Dosing strategies and plasma levels. Lane HY, Chiu WC, Chou JC, Wu ST, Su MH, Chang WH. J Clin Psychiatry 2000 Mar; 61 (3), pp. 209–14.

EXTRAHEPATIC—ENDOCRINE/REPRODUCTIVE

Estrogen Receptor-Alpha (ERα) Polymorphism
Estrogen

Cellular/Molecular Mechanism of Action: Estrogen receptors bind estrogen, which functions as a female sex steroid.
Physiological Mechanism of Action: Functions as a critical hormone that regulates a multitude of female physiological proceses and the viability of certain cancer cell types including human mammary carcinoma.
Background Information: Recent clinical trials of hormone replacement therapy for cardiovascular disease have yielded surprisingly negative results, shifting clinical opinions from a position of presumed cardiovascular benefit to 1 of confirmed harm. Understanding why hormone replacement therapy has beneficial effects on intermediate risk markers for cardiovascular disease, but produces an increase in cardiovascular events, is an important public health question with the potential to elucidate fundamentally important aspects on atherogenesis, cardiovascular disease, and the biology of estrogen action. One question concerning the cardiovascular effects of hormone replacement therapy is whether genetic factors can substantially modify individual responses to estrogen treatment. New clinical trial evidence is emerging that links the presence of particular variants in the estrogen receptor to the response of high-density lipoprotein and other intermediate end points to hormone replacement therapy.
Application: Characterization of ERα polymorphism and correlation of these findings to observations related to response to estrogen therapy and the risk of clinical cardiovascular events.
Interpretation and Analysis: One or more common variants in ERα are associated with a differential response to hormone replacement therapy in several domains of estrogen action. However, the effect of these variants on the risk of clinical cardiovascular events in the setting of hormone replacement therapy is not yet known. Additional research focusing on the clinical impact of common variants in ERα, ERβ, and the progesterone receptor promise to improve clinical decision making concerning the use of hormone replacement therapy and other novel estrogen agonists.

Role of estrogen receptor-alpha in pharmacogenetics of estrogen action. Herrington DM. Curr Opin Lipidol 2003 Apr; 14 (2), pp. 145–50.

Hypogonadal States: Androgen Receptor Gene [AR $(CAG)_n$ Polymorphism]/Secondary Prostate Enlargement
Testosterone/T-Enanthate/T-Undecanoate/Human Chorionic Gonadotropin

Background Information: Testosterone (T) substitution in hypogonadal men results in growth of the prostate gland. The effects of testosterone are mediated via the AR. The length of the $(CAG)_n$ polymorphism of the AR gene is negatively associated with transcriptional activity and might account for variations in prostate growth during substitution therapy.
Application: Characterization of AR gene $(CAG)_n$ polymorphism to detect increased susceptibility to secondary enlargement/

growth of the prostate in hypogonadal males receiving androgen substitution therapy.

Implementation: Assessment of the influence of various testosterone preparations on enlargement of the prostate as a function of AR $(CAG)_n$, sex hormone levels, and anthropometric measures. Studies directed at achieving this objective have evaluated hypogonadal males (e.g., n = 131, 18–69 yrs) by (i) assessing prostate volume longitudinally (transrectal ultrasonography), in concert with the evaluation of (ii) AR $(CAG)_n$, (iii) sex hormone levels, and (iv) anthropometric measures. Substitution therapy with IM injections of T enanthate (n = 81), transdermal T preparations (n = 19), SQ injections of human chorionic gonadotropin (n = 17), or oral T undecanoate (n = 14) is then initiated over a prolonged period of administration (e.g., n = 69 males with primary and n = 62 males with secondary hypogonadism for 2.4 ± 0.8 years).

Interpretation and Analysis: Average prostate size increases from approximately 15.8 ± 6.1 ml to 23.0 ± 6.8 ml. ANOVA including covariates reveals initial prostate size to be dependent upon age ($p < 0.001$) and baseline T levels ($p = 0.01$) but not on the number of $(CAG)_n$ (ranging from 13 to 30; mean, 21.4 ± 3.5). Prostate growth per year and absolute prostate size under substituted T levels (6.1 ± 3.3 to 21.6 ± 10.3 nmol/liter) are strongly dependent on $(CAG)_n$, with lower treatment effects in longer repeats (both $p < 0.001$). Other significant predictors include initial prostate size (negative for growth rate and positive for absolute size) and age (positive for both growth rate and absolute size). The odds ratio for men with $(CAG)_n < 20$, compared with those with $(CAG)_n$ of 20 or more, to develop a prostate size of at least 30 ml under testosteroine substitution is 8.7 (95% confidence interval, 3.1–24.3; $p < 0.001$). Such observations demonstrate a strong age-related dependence with a more pronounced odds ratio in males older than 40 years of age.

Prostate volume and growth in testosterone-substituted hypogonadal men are dependent on the CAG repeat polymorphism of the androgen receptor gene: A longitudinal pharmacogenetic study. Zitzmann M, Depenbusch M, Gromoll J, Nieschlag E. J Clin Endocrinol Metab 2003 May; 88 (5), pp. 2049–54.

Progesterone/Testosterone Nuclear Receptor: Constitutive Active Receptor (CAR)
Testosterone/Progesterone

Background Information: Steroid hormones modulate activity of the nuclear receptor CAR (or constitutive androstane receptor) in mouse liver. Progesterone and testosterone repress the constitutive activity of mouse CAR (mCAR) in cell-mediated transfection assays, whereas estrogens activate the repressed receptor. Similar repression and activation phenomenon are not observed with CAR expressed in human cell types.

Application: Utilization of various chimeric and mutated receptor complexes to determine their responsiveness to steroid hormones in a manner that can delineate the structural basis that confers hormone responsiveness to murine CAR (mCAR).

Interpretation and Analysis: Hormone responsiveness resides near or within the AF-2 domain of mCAR. Moreover, a single mutation of threonine at position 350 to the corresponding methionine in the human counterpart abolishes the repression of mCAR by steroid hormones. Co-activation by steroid receptor co-activator 1 (SRC-1) of mCAR does not depend on the threonine 350 amino acid residue. However, overexpression of SRC-1 counteracts progesterone to repress mCAR activity. Thus, threonine at amino acid residue 350 seems to regulate hormone responsiveness of mCAR (indirect interference) and interaction of the receptor with a coactivator.

Residue threonine 350 confers steroid hormone responsiveness to the mouse nuclear orphan receptor CAR. Ueda A, Kakizaki S, Negishi M, Sueyoshi T. Mol Pharmacol 2002 Jun; 61 (6), pp. 1284–8.

EXTRAHEPATIC—RENAL SYSTEM

Cortisol Metabolism/$^{11}\beta$-HSD_2 Biochemical Activity (Renal)
Deuterium-Labeled Cortisol

Cellular/Molecular Mechanism of Action: Deuterium-labeled cortisol is a "tracer" analog of endogenous cortisol.

Application: Deuterium-labeled cortisol can be used as a labeled marker molecule to access *in vivo* alterations in endogenous cortisol metabolism mediated by $^{11}\beta$-HSD_2 activities based on urinary excretion of cortisol, cortisone, and their A-ring reduced metabolites.

Route of Administration: Deuterium-labeled cortisol (oral).

Implementation: Evaluation of cortisol metabolism through the measurement of deuterium-labeled cortisol and its deuterium-labeled metabolites. Sample evaluation involves the application of GC/MS analyses performed simultaneously with the detection of endogenous cortisol, cortisone, and their A-ring reduced metabolites.

Human Model: Normal cases without evidence of disease.

Interpretation and Analysis: The stable isotope approach offers unique advantages in assessing the appropriateness of measuring unconjugated and total (unconjugated + conjugated) cortisol, cortisone, and their A-ring reduced metabolites in urine as indices of renal $^{11}\beta$-HSD_2 activity. Measurement of urinary unconjugated cortisol and cortisone has many advantages for assessing $^{11}\beta$-HSD_2 activity.

Instrumentation: Integrated gas chromatography/mass spectrometry system.

The use of deuterium-labeled cortisol for *in vivo* evaluation of renal $^{11}\beta$-HSD_2 activity in man: Urinary excretion of cortisol, cortisone and their A-ring reduced metabolites. Kasuya Y, Shibasaki H, Furuta T. Steroids 2000 Feb; 65 (2), pp. 89–97.

Excretion Profiling: Renal Tubular Function/Tubular Transporter Mechanisms
[^{3}H]-Indoxyl Sulfate/Para-Aminohippuric Acid (PAH)/Benzylpenicillin/Cimetidine/3-Carboxy-4-Methyl-5-Propyl-2-Furanpropanoic Acid/Hippuric Acid

Cellular/Molecular Mechanism of Action: Indoxyl sulfate is a uremic toxin and radiolabeled analogs can function as tracer molecules.

Background Information: Indoxyl sulfate is a uremic toxin that accumulates in the body because of the patient's inability to excrete it, and it induces a number of uremic symptoms and leads to chronic renal failure. The functional failure of the excretion system for indoxyl sulfate causes its accumulation in blood.

Application: Uremic toxins (indoxyl sulfate; 3-carboxy-4-methyl-5-propyl-2-furanpropanoic acid hippuric acid); weak acids (PAH; benzylpenicillin); weak bases; (cimetidine); and other substances (salicylic acid, indomethacin, 3,5,3′-triiodo-l-thyronine, and indole acetic acid [IA]) can be applied in various fashions to evaluate renal excretory function.

Implementation: Evaluate and characterize transport mechanisms for the renal excretion of [^{3}H]indoxyl sulfate using an *in vivo* tissue-sampling single-injection technique (kidney uptake index [KUI] method).

Animal Model: Xenopus laevis oocyte expressing rat organic anion transporter 3 (rOAT3).
Interpretation and Analysis: Probenecid shows a concentration-dependent inhibitory effect on the uptake of [^{3}H]indoxyl sulfate using the KUI method, and uptake is inhibited by organic anions such as PAH and benzylpenicillin, by weak bases such as cimetidine, and by uremic toxins, such as 3-carboxy-4-methyl-5-propyl-2-furanpropanoic acid (CMPF) and hippuric acid (HA). However, salicylic acid, indomethacin, 3,5,3′-triiodo-l-thyronine, and indole acetic acid (IA) have no effect on the uptake. rOAT3-expressing oocytes exhibit uptake of [^{3}H]indoxyl sulfate by rOAT3 (Km = 158 μmol/L). Moreover, a number of uremic toxins inhibit the uptake of [^{3}H]indoxyl sulfate by rOAT3. Uptake of indoxyl sulfate appears, therefore, to be mediated by rOAT3 activity. Uremic toxins share the transport mechanism for indoxyl sulfate. Mutual inhibition of these uremic toxins via OAT3 may accelerate their accumulation in the body and, thereby, the progression of nephrotoxicity in uremia.

Major role of organic anion transporter 3 in the transport of indoxyl sulfate in the kidney. Deguchi T, Ohtsuki S, Otagiri M, Takanaga H, Asaba H, Mori S, Terasaki T. Kidney Int 2002 May; 61 (5), pp. 1760–8.

Hydroxylation Capacity: Renal Metabolizing Capacity
Phenylalanine

Cellular/Molecular Mechanism of Action: Phenylalanine is metabolized in the kidney to a hydroxylated analog.
Background Information: Although phenylalanine hydroxylase activity is detectable in *in vitro* renal tissue preparations, no data on *in vivo* phenylalanine hydroxylation in the human kidney, or its possible contribution to whole-body hydroxylation, currently exist.
Application: Evaluation of the hydroxylation capacity of the kidney.
Implementation: Evaluate measurements of whole-body, renal, and splanchnic phenylalanine hydroxylation to tyrosine, as well as phenylalanine and tyrosine rates of appearance (Ra) and disposal (Rd), in postabsorptive states by means of renal and splanchnic arteriovenous catheterization combined with phenylalanine and tyrosine isotope infusions.
Interpretation and Analysis: In the kidney, relevant phenylalanine hydroxylation activity can be detected (3.51 ± 0.97 μmol/min × 1.73 m^2 of body surface), whereas it is 2.48 + 1.35 μmol/min × 1.73 m^2 across the splanchnic area. These 2 sites together account for virtually the entire whole-body phenylalanine hydroxylation capacity. Renal production of tyrosine from phenylalanine hydroxylation accounts for approximately 13% of whole-body tyrosine Ra, whereas renal total tyrosine Ra account for approximately 34% of whole-body tyrosine Ra. In the splanchnic area, these figures are approximately 9% and 40%, respectively. Hydroxylation accounts for approximately 70% of phenylalanine Rd in the kidney, as opposed to approximately 8% in the splanchnic area.

Phenylalanine hydroxylation across the kidney in humans rapid communication. Tessari P, Deferrari G, Robaudo C, Vettore M, Pastorino N, De Biasi L, Garibotto G. Kidney Int 1999 Dec; 56 (6), pp. 2168–72.

EXTRAHEPATIC—RESPIRATORY SYSTEM

Ventilatory Responses: Regulation
S-Nitrosylation

Background Information: New genomic and proteomic techniques offer remarkable promise as tools to address long-standing questions regarding molecular mechanisms involved in the control of breathing.
Interpretation and Analysis: Application of genomic and proteomic techniques and related molecular methodologies are providing valuable observations and insight into the role of S-nitrosylation signaling reactions in regulating ventilatory responses.

Functional genomics and proteomics in control of breathing. Gaston B. Respir Physiol Neurobiol 2003 May 30; 135 (2–3), pp. 231–8.

EXTRAHEPATIC—MUSCULOSKELETAL SYSTEM

Malignant Hyperthermia (MH)
Caffeine/Diffusible CO_2

Background Information: Susceptibility to MH can be diagnosed by performing an *in vitro* contracture test, which requires acquiring an open muscle biopsy sample.
Route of Administration: Caffeine (intramuscular).
Dosage: Caffeine (500 ml of an 80 mmol/L formulation).
Implementation: Evaluate the influence of intramuscular caffeine injection on local carbon dioxide pressure (pCO_2) in conditions of MH compared to normal negative reference controls. Measurements for pCO_2 are obtained from the rectus femoris muscle during local stimulation with injected caffeine.
Human Model: Cases susceptible to MH (n = 12), cases classified as non-susceptible (n = 8), and 7 healthy/normal controls.
Interpretation and Analysis: In susceptible individuals, pCO_2 temporarily increases to a maximum of 63 mm Hg (IQR 61–69) compared with 44 mm Hg (43–47) for non-susceptible participants (p = 0.003) and 42 mm Hg (41–46) in controls (p = 0.003). Systemic side effects usually cannot be appreciated. Metabolic monitoring of the highly diffusible CO_2 stimulated by caffeine might allow a minimally invasive test for susceptibility to MH.

Diagnosis of susceptibility to malignant hyperthermia by use of a metabolic test. Anetseder M, Hager M, Müller CR, Roewer N. Lancet 2002 May 4; 359 (9,317), pp. 1579–80.

Malignant Hyperthermia (MH): Genetic Predisposition/(*Ex Vivo* Preaparation of Skeletal Muscle Biopsies)
Caffeine/Caffeine and Halothane

Application: Caffeine and caffeine + halothane can be applied as investigative probes to characterize certain intrinsic properties of skeletal muscle tissues. In this context, caffeine and caffeine + halothane can serve as indicator agents for the detection of individuals with a genetic predisposition to the development of MH (potentially fatal complication of general anesthesia).
Implementation: Skeletal muscle in *ex vivo* preparations is exposed to caffeine or caffeine + halothane and the subsequent induction of contracture responses is then measured for comparison with negative reference controls.
Interpretation and Analysis: In confirmed or suspected cases of MH and their genetic relatives, the responsiveness of muscle specimens can often vary over 2 orders of magnitude. Frequency distribution curves suggest that variations do not represent a continuum but rather are represented as 3 or more clusters of functional variants. Muscle specimens from males are on average more responsive to caffeine than is skeletal muscle collected from female subjects. Correlations within father-son and brother-brother pairs indicate complete heritability of responsiveness. Interestingly, there appears to be a lack of correlation between induced muscle contraction of muscle

biopsies collected from mother-daughter pairs. There is an intermediate correlation in father-daughter pairs. The sex difference in heritability could be due to gender-related modifying genes or due to secondary modification of the muscle response in females by sex-related, perhaps hormonal factors. Among the effects of age appeared to be poor development in early childhood of the potentiation of the caffeine contracture by halothane.

Pharmacogenetics of caffeine and caffeine-halothane contractures in biopsies of human skeletal muscle. Kalow W, Sharer S, Britt B. Pharmacogenetics 1991 Dec; 1 (3), pp. 126–35.

Malignant Hyperthermia (MH): Genetic Variation (Arg614→Cys: RYR1 C1840T)/Genomic Analyses and Provocative Testing Correlation
Caffeine/Halothane

Physiological Mechanism of Action: In conditions of MH, exposure of *ex vivo* muscle tissues to caffeine/halothane promotes an exaggerated contractile response.
Background Information: Malignant hyperthermia is an important cause of anesthesia-induced death. The caffeine/halothane contracture test (CHCT) test is highly invasive, expensive, and lacks 100% specificity. Genetic and biochemical evidence provide strong support for the view that substitution of cysteine for arginine 614 (Arg614Cys) in the human ryanodine receptor gene is 1 of several mutations that are likely to cause human MH.
Application: Detection and characterization of MH conditions.
Route of Administration: Traditionally applied by topical exposure for *ex vivo* tissue-based challenge studies.
Implementation: Delineation of a possible genetic basis for a predisposition to MH pertaining to the presence of Arg614Cys (RYR1 C1840T) mutations detected through a combination of polymerase chain reaction and restriction endonuclease digestion. Blood samples are utilized as a source of biological material for DNA analyses. Alternatively, detection of MH susceptibility can be established using the *in vitro* CHCT that employs fresh muscle biopsy specimens. Results from CHCT and DNA-based diagnostic parameters are then compared to determine their potential value in predicting MH susceptibility in large MH families that possess Arg614Cys mutations.

Human Model: Cases selected from a large Mennonite MH kindred identified by an index patient who died at age 45 years of an MH crisis after general anesthesia. Case population: n = 68 family members, n = 19/68 muscle biopsies, n = 1/681 documented crisis without biopsy. Family members can be classified as MH-susceptible or MH-normal on the basis of the CHCT.
Interpretation and Analysis: Previous investigations that have analyzed family clusters of MH have identified approximately 33% of relatives to be heterozygous for the Arg614Cys mutation (n = 22/68) and slightly less than one-fourth may have prior positive CHCT results (e.g., n = 5/22), while a small percentage may have an MH crisis without the benefit of a previous biopsy screening procedure. Utilizing DNA testing, it is possible to detect a relatively large number of cases within a related kindred that are normal for the allele (e.g., n = 44). Of these, slightly less than 25% can be classified as MH-normal while some may be determined to be MH-susceptible (e.g., n = 5) on the basis of CHCT evaluations. Based on the interpretation of the data obtained in earlier CHCT diagnoses, the condition of the muscle is poor, with no twitch, for approximately 60% of cases homozygous for the normal allele but originally classified as MH-susceptible (e.g., n = 3/5) and for a small percentage that are homozygous for the normal allele and originally classified as MH-normal. Observations from CHCT results performed for such individuals (e.g., n = 4) can often be considered invalid. The twitch response is good for a small number of cases (e.g., n = 2 remaining) that are homozygous for the normal allele but classified as MH-susceptible if contracture can be observed with appropriately low levels of both caffeine and halothane.

An absolute correlation between DNA test results and CHCT assignment can often not be established. Possible explanations for discordance are that the Arg614Cys mutation is not linked to MH, that a 2nd MH mutation is segregating in the family, or that there are errors in the CHCT. Because there is strong evidence supporting the causal nature of the Arg614Cys mutation, the discordant cases are not closely related within the pedigree as they would be if a 2nd MH mutation were segregating, and the CHCT is not 100% accurate. It has therefore been proposed that observed discordance between DNA test results and CHCT assignment in example kindred analyses can be attributed to false-positive diagnoses associated with the CHCT (e.g., n = 2 tests).

Comparison of the segregation of the RYR1 C1840T mutation with segregation of the caffeine/halothane contracture test results for malignant hyperthermia susceptibility in a large Manitoba Mennonite family. Serfas KD, Bose D, Patel L, Wrogemann K, Phillips MS, MacLennan DH, Greenberg CR. Anesthesiology 1996 Feb; 84 (2), pp. 322–9.

Malignant Hyperthermia (MH): Ryanodine Receptor (RYR1) Gene
Halothane

Background Information: Malignant hyperthermia is a potentially lethal disease triggered by volatile anesthetics and succinylcholine in genetically predisposed individuals. Because of the heterogenetic nature of MH, a simple genetic-based diagnostic test is not feasible and diagnosis requires an invasive open muscle biopsy followed by performing an *in vitro* contracture test (IVCT).
Implementation: Determine if measurements of halothane-induced increases in intracellular calcium ion concentration $[Ca^{2+}]_i$ in cultured human skeletal muscle cells can be used to phenotype MH susceptibility and if different mutations in the RYR1 gene affect halothane-induced increases in $[Ca^{2+}]_i$.
Primary cultures of human skeletal muscle cells are acquired from cases previously determined to suffer from MH. Cell lines are then individually screened for the presence of the most common mutations in the RYR1 gene. $[Ca^{2+}]_i$ is measured in 10 cells from each case that have been subjected to 5 different halothane concentrations.

Human Model: Cases of MH (n = 54) diagnosed by the IVCT according to the protocol of the European MH Group and classified as MH-susceptible (n = 22), MH-negative (n = 18), or MH-equivocal (n = 14).
Interpretation and Analysis: Halothane-induced increases in $[Ca^{2+}]_i$ vary significantly between different classification groups. Interestingly, different mutations of the RYR1 gene do not have a specific impact on halothane-induced increases in $[Ca^{2+}]_i$. Therefore, measurements of $[Ca^{2+}]_i$ in human skeletal muscle cells can be used to phenotype MH susceptibility; however, mutation in the RYR1 gene do not closely correlate with specific effects related to halothane-induced increases in $[Ca^{2+}]_i$.
Instrumentation: Fluorescent digital microscopy using fura-2/AM can be applied for the measurement of calcium ion concentrations contained within biological samples.

Phenotyping malignant hyperthermia susceptibility by measuring halothane-induced changes in myoplasmic calcium concentration in cultured human skeletal muscle cells. Girard T, Treves S, Censier K, Mueller CR, Zorzato F, Urwyler A. Br J Anaesth 2002 Oct; 89 (4), pp. 571–9.

Malignant Hyperthermia (MH)
Caffeine/Halothane/Calcium-Induced Calcium Release

Application: Detection and characterization of MH conditions.
Route of Administration: Topical application (emersion) of *ex vivo* muscle biopsy specimens.
Implementation: Comparison of results of the *in vitro* caffeine-halothane contracture test (CHCT) according to the protocols of the North American Malignant Hyperthermia Group (NAMHG) and the European Malignant Hyperthermia Group (EMHG) with the Ca^{++}-induced Ca^{++} release (CICR) rate test. Muscle biopsies are usually obtained from the musculus vastus lateralis. Diagnostic cutoff points and procedures for CHCT protocols are as described in the original and renewal versions of NAMHG and EMHG. The CICR rate test is performed according to the protocol reported by Endo et al.

Human Model: Cases of suspected MH (n = 16; and n = 5 normal negative reference controls).
Interpretation and Analysis: Normal controls and cases with abortive MH (e.g., n = 2), postoperative hyperthermia (e.g., n = 2), and high serum creatinine kinase levels (e.g., n = 3) may all display normal results in diagnostic screening tests. According to NAMHG criteria, patients with MH reactions (e.g., n = 3) or with a history of masseter spasms (e.g., n = 1) may be classified as MH-positive, while the EMHG guidelines would classify such cases as MH-susceptible and MH-equivocal, respectively. Some patients may display discordant findings based on a comparison of results from CHCT and CICR rate tests (e.g., n = 5 cases). It has therefore been proposed that muscle biopsy for the diagnosis of MH susceptibility should combine the CHCT with the CICR rate test, which may identify the defective site of Ca^{++} release channels.

Comparison of the *in vitro* caffeine-halothane contracture test with the Ca-induced Ca release rate test in patients suspected of having malignant hyperthermia susceptibility. Oku S, Mukaida K, Nosaka S, Sai Y, Maehara Y, Yuge O. J Anesth 2000 Jan 20; 14 (1), pp. 6–13.

Malignant Hyperthermia (MH)
4-Chloro-m-Cresol (4-CmC)/Caffeine/Halothane

Background Information: *In vitro* contracture test (IVCT) for diagnosis of MH has been reported to have a sensitivity of 100% and a specificity of 93%. The results are equivocal in 10 to 15%, and supplementary tests may thus be required.
Application: The agents 4-CmC, caffeine, and halothane can be applied to detect and characterize conditions of MH.
Implementation: Evaluation of the potential for 4-CmC to function as a supplementary test for MH. One investigative approach involves the collection of muscle tissue in the form of biopsy specimens for utilization in an IVCT. In this context, muscle biopsies are topically exposed *ex vivo* to increasing concentrations of 4-CmC (25, 50, 75, 100, 150, and 200 μmol/l) and the corresponding force profiles recorded. Diagnosis of MH susceptibility is established with standard halothane and caffeine tests and classified as MHS (MH-susceptible), MHN (MH-negative), or MHE (equivoval result).

Human Model: Cases subjected to skeletal muscle biopsy (n = 41 from n = 7 families).
Interpretation and Analysis: At all concentrations of 4-CmC, the increase in baseline force is significantly greater in the MHS group compared to the MHN group ($p < 0.05$). Muscle from MH-susceptible cases (e.g., n = 15) responds to 4-CmC with increasing force at a threshold concentration of 75 μmol/l or less, whereas muscle tissues from cases classified as MH-non-susceptible (e.g., n = 23) have thresholds of 100 μmol/l or more. The accuracy of the chlorocresol test is approximately 100% (95% confidence limits 90.75–100%) at a threshold of 75 μmol/l. Amplitude of contractures at 2 mmol/l caffeine is not different from contractures at 75 μmol/l of 4-CmC in either the MHS or the MHN group ($p > 0.05$). *In vivo* concentrations of chlorocresol from clinical use of insulin and somatropin are estimated to be 20 times less than the threshold concentration and thus these drugs seem safe in MH cases. Therefore, 4-CmC may be a suitable aid to clarify puzzling results of standard testing of MH susceptibility.

4-Chloro-m-cresol test—A possible supplementary test for diagnosis of malignant hyperthermia susceptibility. Ording H, Glahn K, Gardi T, Fagerlund T, Bendixen D. Acta Anaesthesiol Scand 1997 Sep; 41 (8), pp. 967–72.

Rhabdomyolysis: Recurrent/Exertional (Equine)/Myoplasmic Calcium Concentration Estimation/Heritable Myopathy
Caffeine/4-Chloro-m-Cresol (4-CmC)

Physiological Mechanism of Action: Caffeine promotes contraction of skeletal muscle tissue in *ex vivo* preparations.
Route of Administration: Topical (*ex vivo)* bathing of muscle tissue biopsy specimens.
Implementation: Delineate if alterations in myoplasmic calcium regulation can be identified in muscle cell cultures (myotubes) and intact muscle fiber bundles derived from Thoroughbreds affected by recurrent exertional rhabdomyolysis (RER). Laboratory procedures that can be employed to address such an objective may utilize myotube cell cultures grown from satellite cells obtained from muscle biopsy specimens from horses affected by RER. Fura-2 fluorescence can be used to measure resting myoplasmic calcium concentration as well as caffeine- and 4-CmC-induced increases in myoplasmic calcium. In addition, intact intercostal muscle fiber bundles are prepared from both types of horses, and their sensitivities to caffeine and 4-CmC-induced contractures determined.

Animal Model: Equine (n = 6 related Thoroughbreds with RER; n = 8 clinically normal control Thoroughbred or crossbred horses).
Interpretation and Analysis: Myotubes of RER-affected and control horses have identical resting myoplasmic calcium concentrations. Myotubes from RER-affected horses have significantly higher myoplasmic calcium concentrations than myotubes from control horses following the addition of ≥ 2mM caffeine; however, there is no difference in their response to 4-CmC (≥ 1 mM). Caffeine contracture thresholds for RER and control intact muscle cell bundles (2 vs 10mM, respectively) are significantly different, but 4-CmC contracture thresholds of muscle bundles from RER-affected and control horses (500 μM) do not differ. An increase in caffeine sensitivity for muscle cells derived from a family of related RER-affected horses has been detected *in vitro* by use of cell culture with calcium imaging and by use of fiber bundle contractility techniques. An alteration in muscle cell calcium regulation is a primary factor in the cause of this heritable myopathy.

Myoplasmic calcium regulation in myotubes from horses with recurrent exertional rhabdomyolysis. Lentz LR, Valberg SJ, Herold LV, Onan GW, Mickelson JR, Gallant EM. Am J Vet Res 2002 Dec; 63 (12), pp. 1724–31.

PHARMACOGENETICS OF PROGNOSIS AND THERAPEUTIC RESPONSE

The number of citations described in this section represents only a small segment of the extensive amount of research and clinical knowledge developed to date related to this particular subject.

Chemotherapeutic Resistance Potential/ Radioresistance: Mammary Carcinoma
Insulin-Like Growth Factor-I Receptor mRNA/Antisense Insulin-Like Growth Factor-I Receptor (IGF-IR)

Cellular/Molecular Mechanism of Action: The IGF-IR plays a critical role in breast cancer cell growth regulation and transformation. Antisense IGF-IR nucleotides inhibit the transcriptin of IGF-IR mRNA gene sequences.
Application: Expression of insulin like growth factor I receptor mRNA can serve as a prognostic markers pertaining to the potential of antisense IGF-IR to reverse resistance to radiation and chemotherapy in neoplastic cell populations (e.g., mammary carcinoma). Strategies designed to disrupt the biological expression of IGF-IR may be a fruitful avenue for achieving enhanced resolution of neoplastic disease states.
Route of Administration: Antisense IGF-IR nucleotide (intravenous).
Dosage: Antisense IGF-IR nucleotide.
Implementation: Evaluaton of the radiosensitivity of NIH 3T3 fibroblasts overexpressing either wild-type or mutant IGF-IR complex, complemented by immunohistochemical analysis of primary mammary carcinoma neoplastic lesions for the expression of IGF-IR complexes.
Interpretation and Analysis: High levels of wild-type IGF-IR confer radioresistance, and mutational analysis has revealed that this effect correlates with the transforming capacity but not the mitogenic activity of the receptor. The radioresistant phenotype is reversed when the cells are incubated with antisense oligonucleotides targeted to IGF-IR mRNA, demonstrating that IGF-IR directly influences radioresistance. Immunohistochemical analysis of primary breast tumors reveals that high levels of IGF-IR in tumor samples highly correlates with ipsilateral breast tumor recurrence (IBTR) following lumpectomy and radiation therapy ($p = 0.001$). Subgroup analysis reveals that, for early breast tumor relapses (within 4 years of initial breast tumor diagnosis), a strong association exists between elevated IGF-IR levels and ipsilateral breast tumor recurrence (IBTR, $p = 0.004$). However, IGF-IR expression appears to have minimal prognostic value for IBTR from breast cancer patients with late relapses ($p = ns$).

Insulin-like growth factor-I receptor overexpression mediates cellular radioresistance and local breast cancer recurrence after lumpectomy and radiation. Turner BC, Haffty BG, Narayanan L, Yuan J, Havre PA, Gumbs AA, Kaplan L, Burgaud JL, Carter D, Baserga R, Glazer PM. Cancer Res 1997 Aug 1; 57 (15), pp. 3079–83.

Colorectal Cancer: Metastatic Potential
Tegafur-Uracil/CD44 Expression/Thymidylate Synthase Expression

Cellular/Molecular Mechanism of Action: Tegafur-uracil may induce apoptosis of tumor cells by inhibition of thymidylate synthase. The cell adhesion molecule CD44 may contribute to the pathogenesis of metastatic processes.
Background Information: Tegafur-uracil is commonly used to treat digestive cancers. However, the inhibition of metastasis by this agent has not been fully characterized.
Application: Expression of CD44 could potentially be used as a possible independent predictor of survival and represents an independent prognostic factor. Tegafur-uracil, via the inhibition of CD44 expression, may promote an inhibition of distant metastasis. Analysis of CD44 expression and apoptosis phenomenon may serve as predictive variables pertaining to potential efficacy of tegafur-uracil.
Route of Administration: Tegafur-uracil (oral/per os).
Dosage: Tegafur-uracil—preoperatively (600 mg SID $\times$ 3–7 days); postoperatively (400 mg SID $\times$ 2 years).
Implementation: Characterization of CD44 and apoptosis phenomenon in neoplastic tissue harvested from cases subjected to curative resection of colorectal cancer (e.g., $n = 66$). Postoperative therapy includes tegafur-uracil (600 mg) administered orally every day for 3 to 7 days before surgery, and tegafur-uracil (400 mg) administered orally every day for 2 years after surgery.

Detection of CD44 and apoptosis is determined in neoplastic tissue samples applying immunohistochemical analysis and by the TUNNEL method, respectively. The thymidylate synthase inhibition rate is calculated from the total thymidylate synthase level, and free thymidylate synthase levels by a modified Spears' method using fresh tumor tissue specimens.
Interpretation and Analysis: The thymidylate synthase inhibition rate of non-recurrent cases is significantly higher than that of recurrent cases ($p < 0.05$). The 5-year survival rate in CD44-low grade positive/negative patients (81.6%) is significantly higher than that in CD44-high grade positive patients (46.4%) ($p < 0.005$). The 5-year survival rate in apoptosis-high grade positive patients (89.7%) is significantly higher than that in apoptosis-low grade positive/negative patients (46.4%) ($p < 0.001$). With respect to the relationship between CD44 and apoptosis, the proportion of apoptosis-high grade positive patients among CD44-low grade positive/negative patients (55.3%) is significantly higher than that among CD44-high grade positive patients (28.6%) ($p < 0.05$). Multivariate analysis suggests that CD44 expression may represent an independent prognostic factor.

Do the expression of CD44, apoptosis, and thymidylate synthase inhibition rate correlate with the efficacy of chemotherapy in colorectal cancer? Tachikawa D, Arima S, Futami K, Iwashita A. Anticancer Res 2000 Jan–Feb; 20 (1C), pp. 595–600.

Diamminedichloroplatinum (II) Resistance/ Squamous Cell Carcinoma: Head and Neck (HNSCC)/Membrane Protein Fraction Markers: Glycoprotein Hormone Marker

Cellular/Molecular Mechanism of Action: The chemotherapeutic agent *cis*-diamminedichloroplatinum (II) (cDDP) exerts antineoplastic properties by promoting intrastrand and interstrand DNA cross-linking.
Background Information: Mechanisms involved in the acquired resistance of cancer cells to to *cis*-diamminedichloroplatinum (II) (cDDP) have not been thoroughly characterized.
Application: Discovery of gene sequences and protein fractions expressed by head and neck squamous cell carcinoma that correlate with resistance and vulnerability to the antineoplastic properties of *cis*-diamminedichloroplatinum (II).
Implementation: Gene expression profiles can be established for HNSCC cell populations that are both sensitive and resistant to the antineoplastic properties of *cis*-diamminedichloroplatinum (II). Both a fluorescent differential display and cDNA microarray analyses can be applied to distinguish gene profiles expressed between KB, a human HNSCC line, and its cDDP-resistant variant (KB/cDDP). Laboratory findings can subsequently be validated by Northern blot analysis.
Interpretation and Analysis: One upregulated gene, glycoprotein hormone alpha-subunit, and 2 downregulated genes coding membrane proteins, human folate receptor and tumor-associated

antigen L6, have been identified in KB/cDDP cell lines. Based on these findings, it is believed that development of cDDP-resistant phenotypes is accompanied by alternations of gene expression including a glycoprotein hormone and membrane proteins. Such gene products could represent new molecular markers for identifying cDDP resistance.

Differentially expressed genes associated with CIS-diamminedichloroplatinum (II) resistance in head and neck cancer using differential display and CDNA microarray. Higuchi E, Oridate N, Furuta Y, Suzuki S, Hatakeyama H, Sawa H, Sunayashiki-Kusuzaki K, Yamazaki K, Inuyama Y, Fukuda S. Head Neck 2003 Mar; 25 (3), pp. 187–93.

Leukemia and Lymphoma/Dihydropteridine Reductase/Efficacy of Chemotherapeutic Intervention
Neopterin: [Urine]

Application: Neopterin levels in the urine and dihydropteridine reductase concentrations have been applied as sensitive and reliable early prognostic marker systems pertaining to the severity of malignancy and long-term survival in conditions of leukemia and lymphoma ($p < 0.00001$). Alterations in concentrations of these prognostic marker systems in response to chemotherapy can provide prognostic information pertaining to therapeutic response and long-term survival.

Implementation: Evaluation of urinary neopterin levels and blood dihydropteridine reductase activity as well as other frequently used clinical parameters in cases suffering from various types of lymphomas and leukemias (e.g., n = 110).

Interpretation and Analysis: All patients with active disease have significantly raised urinary neopterin levels compared to those in remission and healthy controls. Of cases with active disease approximately 96% are above the upper limit seen in healthy subjects (e.g., n = 66/69). In addition, the highest neopterin excretion is found in patients with active chronic myeloid leukemia (1,469 ± 479 μmol/mol creatinine n = 16). In contrast, only approximately 2.4% of stable responsive disease and remission states have increases in urinary neopterin levels above the upper limit (e.g., n = 1/41). Dihydropteridine reductase (DHPR) activities can also be detected in all patients and control groups. In active disease slightly reduced (DHPR) activities are evident (3.42 ± 0.37 for controls, 2.92 ± 0.39 in active disease, and 3.28 ± 0.42 nmol red cytochrome C/min/5 mm diameter disc in remission patients). However, in patients under medication this pattern of association is strengthened. Therefore, dihydropteridine reductase activity may be affected by chemotherapeutic intervention. Reductions in dihydropteridine reductase activities may also be an underlying cause for the neurological disorders that are commonly seen in patients with hematological malignancies.

Dihydropteridine reductase activity and neopterin levels in leukemias and lymphomas: Is there any correlation between these 2 parameters? Altindag ZZ, Sahin G, Isimer A, Akpek G, Kansu E. Leuk Lymphoma 1999 Oct; 35 (3–4), pp. 367–74.

Mammary Carcinoma/Reversion-Inducing Cysteine-Rich Protein/Kazal/Response to Therapeutic Intervention/Type 1 Matrix Metalloproteinase

Cellular/Molecular Mechanism of Action: Reversion-inducing cysteine-rich protein with Kazal motifs (RECK) inhibits membrane Type 1 matrix metalloproteinase (MMP-14), MMP-2, and MMP-9 secretion and enzymatic activity. Its expression is essential for normal vasculogenesis, RECK being an important tumor-suppressor gene.

Application: Detection of downregulated levels of RECK has been implicated in tumor angiogenesis and progression of neoplastic disease states. Therefore, possibility exists of (i) applying RECK as a pharmaceutical mimetic; (ii) drugs activating endogenous RECK expression as therapeutic or preventive agents; (iii) the reality of prognostic factor for predicting response to therapeutic intervention pertaining to breast carcinoma.

Implementation: Assessment of the prognostic value of RECK expression in human mammary carcinoma tissue specimens (e.g., n = 278 cases; median follow-up = 75 months; range, 2–169 months). Quantitative measurement of RECK mRNA sequences is performed by real-time quantitative reverse transcriptase-polymerase chain reaction.

Interpretation and Analysis: In some cases, the expression levels of RECK are lower in tumor tissue specimens than in adjacent normal breast tissue (e.g., n = 10; p = 0.028). No relevant associations of RECK with established clinicopathologic factors or treatment regimens can be appreciated. Expression of RECK can serve as an indicator for predicting a longer recurrence-free survival time (RFS; p = 0.037) at the optimal cutoff value (hazard ratio, 0.66; 95% confidence interval, 0.44–0.98). A large number of cases with neoplastic lesions that exhibit low levels of RECK have a mean RFS time of 80.4 months and a 61.8% 5-year RFS rate (e.g., n = 100 cases), in contrast to cases with tumors with high RECK expression, which have a mean RFS time of 91.2 months and a 73.0% 5-year RFS rate (e.g., n = 178 cases). Based on multivariate Cox regression analysis, RECK expression provides significant independent prognostic value for RFS time (p = 0.047).

Matrix metalloproteinase inhibitor reversion-inducing cysteine-rich protein with Kazal motifs: A prognostic marker for good clinical outcome in human breast carcinoma. Span PN, Sweep CG, Manders P, Beex LV, Leppert D, Lindberg RL. Cancer 2003 Jun 1; 97 (11), pp. 2710–5.

Rheumatoid Arthritis: Severe vs Mild-Moderate (Prediction of Disease Severity)/5,10-Methylenetetrahydrofolate Reductase Gene (C677) Polymorphism/G Allele (TT vs TG/GG Genotypes)/Tumor Necrosis Factor-Alpha (TNF-α) Receptor Type II (TNFRII): Exon 6 Polymorphism
Methotrexate/Anti-TNF-α Response

Application: Characterizing severe vs mild-moderate conditions of rheumatoid arthritis as a function of exon 6 TNFRII gene polymorphism. The G allele appears to have utility in predicting the degree of responsiveness to anti-TNF-α treatment while the GG genotype for the exon 6 TNFRII polymorphism may be usefull in predicting more aggressive forms of rheumatoid arthritis.

Implementation: Characterization of exon 6 TNFRII gene polymorphism in cases of (i) mild-moderate synovitis classified as responders to methotrexate therapy (e.g., n = 97) for comparison with; (ii) "non-responder" cases receiving anti-α-TNF treatment due to severe and aggressive disease (e.g., n = 78); and (iii) cases with severe rheumatoid arthritis monitored for 6 months during anti-TNF-α therapy. Results are evaluated pertaining to response according to genotype and compared to matched age, sex and ethnic reference controls (e.g., n = 84).

Interpretation and Analysis: A distinct trend exists towards increases in the frequency of the GG genotype in patients with severe rheumatoid arthritis (6.4%) compared to cases of mild-moderate disease (3.1%) and reference controls (1.2%). Evalaution of the response to anti-TNF-α therapy after 12 weeks of treatment reveals that 37.8% of the TT genotype pass from high to medium-low disease activity. Such observations are in contrast to the 10.7% of the

TG/GG genotype that pass from high to medium-low disease activity ($p = 0.03$).

Collective evaluation of laboratory results therefore suggest that in cases of rheumatoid arthritis classified according to response to the conventional therapy and by disease severity, there is a decernable trend towards a higher prevalence of the GG genotype for the exon 6 TNFRII polymorphism in less responsive cases displaying a more aggressive form of disease. In addition, the G allele tends to promote a lower degree of response to anti-TNF-α treatments.

Tumor necrosis factor-alpha receptor II polymorphism in patients from southern Europe with mild-moderate and severe rheumatoid arthritis. Fabris M, Tolusso B, Di Poi E, Assaloni R, Sinigaglia L, Ferraccioli G. J Rheumatol. 2002 Sep;29(9):1847–50.

Sampling Methods for Nucleic Acids (DNA)
Buccal Mouthwash

Application: Collection of cellular populations suitable for the extraction of DNA to be utilized in pharmacogenetic-based methodologies. The mouthwash method for collection of genomic DNA is a simple, inexpensive, and non-invasive method that poses less risk than venipuncture and may be used in a variety of settings. Genomic DNA in mouthwash is stable for prolonged periods at room temperature, and the quantity of DNA recovered from this method is more than sufficient for pharmacogenetic studies. Such an approach should be valuable to pharmacogenetic researchers and others who are conducting genetic research.

Implementation: Collection of biological material in the form of buccal cell populations suitable of application in molecular biology-oriented pharmacogenetic methodologies. Buccal cells are harvested from collected mouthwash samples. Stability of genomic DNA is determined by measuring DNA yield from mouthwash samples. Different volumes of mouthwash are used to identify optimization of the cell collection technique (e.g., 5-ml vs 10-ml mouthwash). Quality of genomic DNA is assessed by determining the success rate of DNA amplification with polymerase chain reaction (PCR) testing and by genotyping.

Interpretation and Analysis: In stability studies, the quantity of genomic DNA decreases over time with storage at room temperature (overall $p < 0.01$), with the largest declines occurring at 60 and 90 days. Median DNA recovery at 30 and 90 days is 59% and 28% of that at baseline, respectively. Mean ± standard deviation, median, and range for recovery of genomic DNA (e.g., $n = 201$ samples) is 45.2 ± 55 μg, 25.2 μg, and 1–330 μg, respectively. Median recoveries of DNA from the 1-rinse and 3-rinse methods are not statistically significantly different (9.1 vs 10.5 μg). Essentially all samples can be amplified successfully by PCR for the purpose of genotyping. The quality of the DNA samples for such purposes therefore is sufficient.

Collection of genomic DNA by the non-invasive mouthwash method for use in pharmacogenetic studies. Andrisin TE, Humma LM, Johnson JA. Pharmacotherapy 2002 Aug; 22 (8), pp. 954–60.

7 Integumentary System

Anhydrosis
Epinephrine/Ephedrine

Diagnostic Application: Diagnosis of equine anhydrosis based upon a lack of response at the site of intradermal injection.
Route of Administration and Dosage: Intradermal injection at dilutions of 1:1,000, 1:10,000, 1:100,000, 1:1,000,000. A positive diagnosis of anhydrosis is based on a lack of an observed dermal response at epinephrine injection sites using preparations formulated at concentrations of ≥ 1:1,000 (e.g., identical or highly similar to the negative reference control injection site).
Considerations: Epinephrine occasionally produces localized leukotrichia at the site of intradermal injection.
Interpretation and Analysis: Presence of cutaneous sweating at the site of intradermal injection is considered a positive (normal) response that would be expected to be observed in negative reference controls unaffected by anhydrosis.

Eczema: Atopic/Efficacy Evaluation of Therapeutic Intervention
Aeroallergen Challenge/Atopy Patch Test (APT)

Background Information: Pharmacologic studies in atopic eczema (AE) are difficult to standardize. Patients with AE differ in the stage of their skin disease (acute, subacute, chronic).
Application: Aeroallergen challenge (APT) can be applied to evaluate the effect of topical anti-inflammatory agents (topical glucocortico-steroids; tar) on allergic inflammatory responses in conditions of AE.
Route of Administration: Aeroallergen challenge (APT: topical/intradermal injection).
Implementation: Efficacy evaluation of candidate therapeutics for AE by performing topical tests on non-lesional skin regions of the back of cases. Segments of skin are treated for approximately 3 weeks at different sites (e.g., n = 3) with agents such as triamcinolonacetonide (1%) in cetamacrogol ointment (GCSs), pix liquida (10%) in cetamacrogol ointment (tar), and cetamacrogol ointment (vehicle). Atopy patch tests are then performed, and biopsy specimens collected from each test site (time = 0 and 24 hours) for immunohistochemical analysis.

Human Model: Cases of AE (n = 6).

Interpretation and Analysis: Treatment with both GCSs and tar reduces the severity of responses detected on macroscopic examination of APT reactions. Furthermore, both treatment modalities have an almost equal inhibitory effect on the influx of T cells, eosinophils, $CD1^+$, $RFD1^+$, interferon-gamma$^+$, and interleukin-4^+ cell populations, , as well as on the percentage of vessels expressing adhesion molecules, E-selectin, and vascular cell adhesion molecule 1 (VCAM-1) in response to epicutaneous aeroallergen challenge. Although both treatments significantly reduce the various cellular constituents of allergic inflammation, all cell types remain present. In this context, aeroallergen challenge (e.g., ATP) can be used to evaluate the effect of topical anti-inflammatory treatments on allergic inflammation in patients with AE.

Modulation of the atopy patch test reaction by topical corticosteroids and tar. Langeveld-Wildschut EG, Riedl H, Thepen T, Bihari IC, Bruijnzeel PL, Bruijnzeel-Koomen CA. J Allergy Clin Immunol 2000 Oct; 106 (4), pp. 737–43.

Laser-induced fluorescence spectroscopy for *in vivo* diagnosis of non-melanoma skin cancers. Panjehpour M, Julius CE, Phan MN, Vo-Dinh T, Overholt S. Lasers Surg Med 2002; 31 (5), pp. 367–73.

Scleroderma/Systemic Sclerosis (SSc)/Follicle-Stimulating Hormone (FSH)/Lutenizing Hormone (LH)/Prolactin/Skin Sclerosis/Prolactin/Peripheral Vascular Involvement/Prolactin/Pulmonary Involvement
Gonadotropin-Releasing Hormone (GnRH)/ Thyrotropin-Releasing Hormone (TRH)

Background Information: Scleroderma is a chronic hardening and shrinking of the connective tissues on any part of the body, including the skin, heart, esophagus, kidney, and lung. Skin may appear thickened, hard, and rigid with pigmented patches. The condition can be generalized or limited to distal parts of the extremities, face, or digits (oval or linear in shape).
Application: To evaluate basal and dynamic levels of pituitary gonadotropin release in female cases of SSc that are of child-bearing age in addition to postmenopausal SSc women.
Implementation: Evaluation of responses to GnRH and TRH stimulation tests during the early follicular phase. Serum concentrations of FSH, LH, and prolactin are then measured. Blood samples may also be collected after performing TRH stimulations in postmenopausal women with SSc. In the latter situation, only serum prolactin concentrations are determined because elevated basal concentrations of FSH and LH can be expected to be observed. Hormone

concentrations are estimated by radioimmunoassay. Comparisons are made with healthy control women matched for age and reproductive status.

Human Model: Female cases in their child-bearing years with systemic sclerosis (n = 12 SSc with mean age [S.E.M] 34.8 + 2.4 years). In addition, postmenopausal female cases (n = 6) with systemic sclerosis (mean age 46.8 [2.4] years).

Interpretation and Analysis: In cases with systemic sclerosis of child-bearing age, basal FSH, LH, and oestradiol (E_2) levels are not significantly different from reference controls, whereas basal prolactin concentrations are significantly higher than reference controls ($p = 0.0001$). After a stimulation test, the peak concentrations of FSH ($p = 0.0001$) and prolactin ($p < 0.0001$) are significantly higher than controls. The net integrated response curves (net area under the curve [AUC]) for FSH and LH do not differ significantly between systemic sclerosis cases and controls. On the contrary, the net AUC for prolactin in response to TRH stimulation is significantly higher than reference controls ($p = 0.001$). In postmenopausal patients, basal estrogen E_2, FSH, LH, and prolactin levels are not significantly different between women with systemic sclerosis and controls. Similarly, after TRH stimulation, peak levels and net AUC for prolactin are not significantly higher in cases than those in reference controls. No significant correlations can be appreciated between basal and stimulated FSH, LH, and prolactin levels and the severity of involvement of various organ systems. However, multiple regression analysis reveals that basal and stimulated prolactin concentrations are associated with skin sclerosis and peripheral vascular and lung involvement. Results suggest that subclinical primary hypogonadism can occur in SSc patients. Some studies have established that alterations exist in the mechanism for prolactin secretion and release, which may not only contribute to further disturbance of the reproductive axis but may also have an influence on the pathogenesis of disease.

Assessment of pituitary gonadotropin release to gonadotropin releasing hormone/thyroid-stimulating hormone stimulation in women with systemic sclerosis. La Montagna G, Baruffo A, Pasquali D, Bellastella A, Tirri G, Sinisi AA. Rheumatology (Oxford) 2001 Mar; 40 (3), pp. 310–4.

Ulcers: Dermal Microvascular Disease (Diabetes-Associated Foot Lesions)
Fluorescein

Background Information: Fluorescein dermofluorometry can be used to relate the skin uptake of fluorescein to regional vascular blood flow.

Application: The dye wash-in time constant parameters are inversely proportional to local dermal blood flow.

Implementation: Evaluation of fluorescein dermofluorometry for the detection and characterization of dermal ulcers. Following intravenous injection of sodium fluorescein, the change in the fluorescein signal with time is continuously measured at the plantar surface of the foot. Both the initial slope of the signal and the wash-in time constant are then calculated. The outcomes of the patients with foot ulcers are then documented 4–14 months after diagnostic evaluation.

Human Model: Cases of cutaneous diabetic foot ulcers (n = 4 groups: non-diabetic control patients, diabetic control patients, diabetic patients with chronic foot ulcers, and diabetic patients with acute foot ulcers).

Interpretation and Analysis: Significant differences in the wash-in time constant can be appreciated between diabetic and non-diabetic cases and between diabetic subjects with and without foot ulcers. In cases with foot ulcers, a relatively large percent may not display an early washout in the dermofluorometer signal and later require amputation (e.g., n = 2/8 or 25%). The fluorescein wash-in time constant demonstrates better correlation with the presence of diabetic microvascular disease than does the initial slope of the signal. Differences in the wash-in time constants of non-diabetic and diabetic subjects support the hemodynamic hypothesis for the development of microvascular disease. The indication of early washout of the fluorescein signal may also be useful in the prediction of ulcer healing.

Fluorescein dermofluorometry for the assessment of diabetic microvascular disease. Oh DK, Jones RN, Marshall W, Magin RL. Skin Res Technol 2001 May; 7 (2), pp. 105–11.

Urticaria/Idiopathic-Acquired Cold Urticaria
Tiaramide

Application: Characterization of conditions of idiopathic-acquired cold urticaria.

Route of Administration: Tiaramide (oral).

Dosage: Multiple doses of 250 mg, q.i.d., for 1 week administered after a single oral dose of 500 mg.

Considerations: Provocative test is associated with no adverse effects with the exception of the possible development of idiosyncratic reactions.

Implementation: The skin of the forearm of each subject is exposed to cold stimuli for 1, 2, 3, 4, and 5 minutes by placing 5 ice cubes on the ventral surface at 1-minute intervals followed by their simultaneous removal 5 minutes after contact with the 1st cube.

Interpretation and Analysis: Challenge sites are observed for 10 minutes and the wheal surface area, intensity of edema, and time of contact necessary to induce the skin response recorded. The results of the provocative test following the single and multiple dosage administration of tiaramide are compared to baseline skin responses. After 1 week of tiaramide treatment at 250 mg, q.i.d., there is a marked attenuation of skin responses to cold-challenge.

Preliminary report on the effects of tiaramide on the ice cube test in patients with idiopathic cold urticaria. Petillo JJ, Natbony SF, Zisblatt M, Vukovich RA, Neiss ES, Kaplan AP. Ann Allergy 1983 Nov; 51 (5), pp. 511–4.

Vasculature Perfusion: Microvasculature/Ulcers: Dermal Vasomotor Responses in Diabetes-Associated Foot Lesions
Sodium Fluorescein

Background Information: A loss of sympathetic function could lead to changes in capillary fluid filtration in diabetic patients.

Application: Delineation of an association between abnormal capillary leakage with decreases in sympathetically mediated dermal vasomotion in diabetic conditions.

Implementation: Evaluation of sensory and motor nerve function of the distal extremities assessed by standard neurography and expressed as a sensory-motor nerve function score. Sympathetic vasomotion of the skin microcirculation is assessed by determining the power of blood flow variability in the low-frequency (0.02–0.14 Hz) band by spectral analysis of laser Doppler flowmetry at the median ankle. Skin capillary leakage is evaluated by sodium fluorescein videodensitometry at the same site of the foot.

Human Model: Cases of diabetic cutaneous foot ulcers (n = 3 matched groups: n = 18 diabetic patients with documented peripheral neuropathy [DN]; n = 18 diabetic patients without peripheral neuropathy [D]; n = 18 healthy control subjects [C]).

Interpretation and Analysis: Sympathetically mediated vasomotion of the microcirculation in the skin of the foot is lower in diabetic patients with documented peripheral neuropathy compared with diabetic patients without peripheral neuropathy and control subjects ($p < 0.001$). Capillary sodium fluorescein leakage is greater in diabetic patients with documented peripheral neuropathy ($n = 18$) than in diabetic patients without peripheral neuropathy ($p < 0.02$) and C ($p < 0.005$). Multiple regression analysis reveals that a reduced sympathetically mediated vasomotion, together with a lower sensory-motor nerve function score, independently contributes to variance in sodium fluorescein leakage, for 30% ($p < 0.001$) and 17% ($p < 0.01$), respectively. A loss of sympathetic tone, apart from sensory-motor nerve dysfunction, seems to be a major determinant for increased capillary permeability in diabetic patients with neuropathy.

Sympathetic mediated vasomotion and skin capillary permeability in diabetic patients with peripheral neuropathy. Lefrandt JD, Bosma E, Oomen PH, Hoeven JH, Roon AM, Smit AJ. Diabetologia 2003 Jan; 46 (1), pp. 40–7.

8 Musculoskeletal System

BONE AND SYNOVIAL STRUCTURES

Bone/Growth and Physiology/Aluminum ($Al(OH)_3$) Body Stores/Overload/Toxicity/Hemodialysis/ Hematopoietin/Iron Absorption: Iron Deficiency
Tetracycline/Desferrioxamine/Deferoxamine/[^{59}Fe]

Cellular/Molecular Mechanism of Action: Tetracycline is incorporated into bone hydroxyapetite deposits. Desferrioxamine and deferoxamine are metallic ion chelating agents. Desferrioxamine can induce elevations in basal plasma aluminum concentrations.
Application: Desferrioxamine can be applied to characterize body aluminum stores while tetracycline can be used as a marker for profiling bone physiology and the rate or extent of new bone deposition.
Implementation: Evaluation of the influence of hemofiltration (HF) and hemodialysis (HD) in connection with the risk of aluminum overload/intoxication and renal osteodystrophy by analysis of double bone biopsies after double tetracycline labeling and use of the desferrioxamine test.

Human Model: Cases managed by hemofiltration (n = 12 HF) and hemodialysis (n = 15 HD). No cases are included that have received 1 alpha-OH-D.
Interpretation and Analysis: Aluminum concentrations are low (less than 0.6 μmol/l) in both the dialysate and the substitution fluid. The duration of treatment (about 2 years) and the cumulative doses of $Al(OH)_3$ and $CaCO_3$ are comparable in the 2 groups. The aluminum balance during an HF run ranges from −22 to +1.8 μmol/l, the balance being positive only when the plasma aluminum is less than 0.5 μmol/l. Basal plasma aluminum and its increase induced by desferrioxamine are comparable in the 2 groups. Bone aluminum content is also comparable but is about 10 times higher than in 7 non-uremic controls. Bone aluminum content and plasma aluminum increase after desferrioxamine can be correlated to $Al(OH)_3$ cumulative dose. No cases have florid osteomalacia with osteoid thickness, and few have traces of stainable aluminum (e.g. n = 1/27). The mineralization front is decreased in most cases of hemofiltration (e.g., n = 8/12) and hemodialysis cases (n = 9/14) to the extent that differences cannot be appreciated between each management scheme. The predominant histological bone picture of the patients is osteitis fibrosa, which is present in a large percent of hemofiltration and hemodialysis cases (e.g., n = 10/12 HF and n = 13/15 HD). Mean osteoclast count and active resorption surface are comparable in the 2 groups but are increased (5–10 times the mean of the controls).

Comparative evaluation of bone aluminum content and bone histology in patients on chronic hemodialysis and hemofiltration. Sebert JL, Fournier A, Leflon P, Fohrer P, de Frémont JF, Morinière P, Galy C, Marie A, Demontis R, Boudailliez B, et al. Nephron 1986; 42 (1), pp. 34–40.

Bone Growth Marker
Tetracycline

Cellular/Molecular Mechanism of Action: Tetracycline becomes associated with and incorporated into hydroxyapetite crystals within the osseous bony matrix.
Diagnostic Application: Detection and measurement of new osseous bone growth. Recently, tetracyclines have also been reported to be beneficial in correcting certain equine angular limb deformities if administered in the early days of life shortly after parturition.
Route of Administration and Dosage: Oral or intravenous.
Considerations: Can cause severe diarrhea in equine patients due to disruption of normal gastrointestinal bacterial flora that can occasionally lead or predispose to development of life-threatening Salmonella enteritis.
Implementation: Following administration, a portion of the dose is incorporated into bone in a manner that can function as a physiological marker for assessment of the rate and extent of bone growth.
Interpretation and Analysis: Measurement of the osseous segment deposited following tetracycline administration is an indication of the extent of new bone growth.

Bioassayable growth hormone activity in blood from healthy individuals and acromegalic patients. Thorngren KG, Hallengren B. Acta Endocrinol (Copenh) 1986 Jan; 111 (1), pp. 3–9.

Effects of unilateral arterial infusion of GH and IGF-I on tibial longitudinal bone growth in hypophysectomized rats. Nilsson A, Isgaard J, Lindahl A, Peterson L, Isaksson O. Calcif Tissue Int 1987 Feb; 40 (2), pp. 91–6.

Osteopenia and Osteoporosis/Tubular Acidosis Type I (Incomplete)/Distal Renal Tubular Acidification Capacity
Ammonium Chloride Loading/Frusemide

Cellular/Molecular Mechanism of Action: Chloride ion is transported by the renal epithelium into the urinary filtrate.
Background Information: Chronic metabolic acidosis may increase alkali mobilization from the bone and thus promote the development of osteoporosis.
Application: Detection and characterization of incomplete renal tubular acidosis type I (RTA I).
Route of Administration: Frusemide (oral ingestion); ammonium chloride loading (oral).
Dosage: Frusemide (40 mg); ammonium chloride loading (0.1 g/kg body weight).
Implementation: Evaluation and comparison of renal function in cases of osteopenia and osteoporosis (reduced mineral content) relative to negative reference control subjects with normal bone

density. Distal tubular acidification can be characterized applying an oral ammonium chloride loading test and the oral frusemide test.

Human Model: Cases of osteopenia or osteoporosis devoid of overt metabolic acidosis, derangement of potassium homeostasis, or renal insufficiency (n = 46; n = 41 females; n = 5 males). Negative age- and sex-matched (normal) reference controls (n = 20; n = 17/20 females, n = 3/20 males).

Interpretation and Analysis: The urinary pH in controls is <5.5 following frusemide ingestion. In cases with reduced bone mineral density, the oral ammonium chloride loading test can aid in establishing a diagnosis of incomplete RTA I (n = 10/46 or 22%). Disorders possibly related to RTA I can also be detected (e.g., n = 8/10). A large percentage of cases will display normal urinary pH responses following oral ammonium chloride loading (e.g., n = 36/46). Oral frusemide fails to lower urinary pH < 5.5 in a little more than one-third of cases (e.g., n = 16/46 or 35%) and encompasses cases with incomplete RTA I (e.g., n = 10) or with a normal oral ammonium chloride loading test (n = 6). An abnormal frusemide test may be appreciated in 35% of cases with reduced bone mass but is a feature rarely if ever detected in normal controls ($chi^2 = 7.39$; < 0.01). With the ammonium chloride test functioning as a gold standard for the diagnosis of distal RTA, the frusemide test shows a sensitivity of 1.0 (95% CI, 0.69–1.0) and a specificity of 0.89 (95% CI, 0.78–0.96) for the diagnosis of distal RTA. Patients with incomplete RTA I tend to be younger in age than those without incomplete RTA I (42 ± 16 vs 54 ± 14 years; p = 0.025; mean ± SD). Basal serum bicarbonate concentrations and capillary pH do not differ between evaluation groups.

Therefore, incomplete RTA I may be prevalent in a significant proportion of cases suffering from osteopenia or osteoporosis. The outcome of the frusemide test suggests either a defect of the H^+ATPase in the cortical collecting tubule (CCT) or a defective Na^+ reabsorption in the CCT. Prospective studies are needed to further elucidate the impact of incomplete RTA I on the development of reduced bone mineral content.

Prevalence and characterization of renal tubular acidosis in patients with osteopenia and osteoporosis and in non-porotic controls. Weger W, Kotanko P, Weger M, Deutschmann H, Skrabal F. Nephrol Dial Transplant 2000 Jul; 15 (7), pp. 975–80.

Osteosarcoma: Hydroxyapatite (HA) Deposition/ Osteoblastic Activity/Atherosclerosis
Near-Infrared (NIR) Light Emitting Probes/Fluorescent Bisphosphonate Derivatives

Background Information: In vertebrates, the development and integrity of the skeleton requires HA deposition by osteoblasts. Sites of osteoblastic activity have most commonly been imaged *in vivo* using gamma-emitting radioisotopes. The scan times required are long, and the resultant radioscintigraphic images suffer from relatively low resolution.

Application: Hydroxyapatite deposition can function as an indicator of, or participant in, processes as diverse as cancer and atherosclerosis.

Semi-Synthetic Methods: Production of an NIR fluorescent bisphosphonate derivative.

Implementation: Evaluation of the ability for NIR fluorescent bisphosphonate derivatives to physically bind to hydroxyapatite deposits.

Interpretation and Analysis: Near-infrared light-based probes like fluorescent bisphosphonate derivatives possess an ability to bind to hydroxyapatite under *in vitro* conditions, in addition to recognizing osteoblastic activity in living animals. Such biotechnology can be applied to study skeletal development, osteoblastic metastasis, coronary atherosclerosis, and other disease states.

In vivo near-infrared fluorescence imaging of osteoblastic activity. Zaheer A, Lenkinski RE, Mahmood A, Jones AG, Cantley LC, Frangioni JV. Nat Biotechnol 2001 Dec; 19 (12), pp. 1148–54.

Pain and Lameness Disorders/Musculoskeletal vs Neurologic Disorders
Lidocaine/Mepivicaine/Bupivicaine

Cellular/Molecular Mechanism of Action: Inhibits axonal membrane-associated Na^+/K^+ pump activity, thereby diminishing the rate or completely preventing transmission of neurologic impulses.

Diagnostic Application: Localize sites of musculoskeletal-associated pain. Local peripheral nerve blocks can also be applied to differentiate musculoskeletal pain from neurologic deficits.

Route of Administration: Intra-articular or selective injection in a juxtaposition in the immediate proximity of peripheral nerves.

Considerations: Lidocaine has an onset of action of approximately 5 minutes with a duration of action approaching 30–45 minutes. Mepivicaine (Carbocaine) has a slightly longer onset of action and a duration of activity lasting approximately 45–60 minutes. Bupivicaine (Marcaine) has the longest onset of action and the longest duration of activity that on average can last between 3 and 4 hours.

Onset of action and duration of activity are inversely related to and are dependent upon the individual diffusion characteristics of each local anesthetic agent in order across axonal membrane structures. Duration of activity can be enhanced with preparations containing epinephrine (promotion of localized vasoconstriction), thereby inhibiting diffusion away from the site of local injection. Dextrose has also been included in preparations of local anesthetic agents in order to increase their osmotic characteristics, thereby promoting a net accumulation of tissue fluid at the site of injection and a decreased net diffusion away from the site of local injection.

Interpretation and Analysis: Alleviation of pain or signs of abnormal locomotion or gait usually suggest that clinical signs are due to a musculoskeletal condition instead of a neurological disease state.

Pain/Lameness: Lower Extremity (Coxalgic vs Neuropathic)
Bupivicaine

Application: Characterization of lower-extremity pain below the knee in cases of spinal and hip osteoarthritis (OA) to determine whether the leg symptoms are coxalgic or neuropathic.

Route of Administration: Intra-articular or selective injection in a juxtaposition in close proximity to peripheral nerves.

Interpretation and Analysis: The test procedure facilitates accurate identification of the anatomical location of painful foci with a sensitivity of 87%, a specificity of 100%, and an efficiency of 88%. This office test also provides significant savings in terms of diagnostic tests and patient discomfort.

The value of bupivicaine hip injection in the differentiation of coxarthrosis from lower extremity neuropathy. Kleiner JB, Thorne RP, Curd JG. J Rheumatol 1991 Mar; (3), pp. 422–7.

Rheumatoid Arthritis/Matrix Metalloprotease Protein 3 (MMP-3)
Corticosteroids

Cellular/Molecular Mechanism of Action: Corticosteroids inhibit phospholipase A2 biochemical activity.

Physiological Mechanism of Action: Corticosteroids exert anti-inflammatory and immunosuppressive properties, presumably due to their ability to generally suppress protein synthesis and stabilize cellular membrane structures.
Application: Delineation of potential relationships between rheumatoid arthritis, expression profiles for interleukins (IL) and metalloproteases (MMP), and corticosteroid production.
Implementation: Evaluate expression profiles for IL-1β, tumor necrosis factor-alpha (TNF-α), IL-6, IL-4, IL-10, MMP-1, MMP-3, and MMP-13 in freshly isolated peripheral blood (PBMC) and synovial fluid mononuclear cells (SFMC) in early rheumatoid arthritis (never-treated [ENT-RA] vs non-acute, treated rheumatoid arthritis [NAT-RA]). Characterization of expression profiles entails the application of ELISA and quantitative and semi-quantitative RT-PCR/analyses.

Human Model: Cases suffering from early rheumatoid arthritis (n = 14 RA; n = 7/14 early RA [< 1 year of evolution] never treated with corticosteroids or disease-modifying antirheumatic drugs, and n = 7/14 non-acute RA [> 2 years of evolution] treated with disease-modifying antirheumatic drugs). Reference controls: A group of 14 healthy subjects matched for sex and age.
Interpretation and Analysis: Statistically significant differences in the protein or transcript levels for the cytokines of interest cannot be appreciated between ENT-RA and NAT-RA case groups. The cytokine mRNA expression by freshly isolated PBMC and SFMC in both case types is IL-1β > TNF-α > IL-10 > IL-6, with no mRNA IL-4 expression. In contrast, cytokine serum levels in ENT-RA and NAT-RA patients exist in an inverse order as follows: IL-6 > IL-10, while IL-1 β, TNF-α, and IL-4 are undetectable. Metalloprotease protein 3 mRNA expression by the PBMC of NAT-RA patients is statistically different to that in ENT-RA patients. Similar levels of mRNA expression of MMP-1, MMP-3 and MMP-13 by the PBMC and SFMC in both RA groups can be appreciated. A close equilibrium between MMP and pro-/anti-inflammatory cytokine production is observed in ENT-RA and NAT-RA patients. This balance is apparently not influenced by the length of the disease. Highly sensitive methods such as quantitative RT-PCR and ELISA, and even studying freshly isolated MC, show sustained cytokine secretion at the local level (synovial fluid/SFMC) and scarce translation at the peripheral level (serum/PBMC). Expression of MMP mRNA needs to be further evaluated in order to know whether its peripheral expression reflects local activity in RA patients.

Expression of interleukin-1β, tumor necrosis factor-alpha, interleukins-6, -10 and -4, and metalloproteases by freshly isolated mononuclear cells from early never-treated and non-acute treated rheumatoid arthritis patients. Vázquez-Del Mercado M, Delgado-Rizo V, Muñoz-Valle JF, Orozco-Alcalá J, Volk HD, Armendáriz-Borunda J. Clin Exp Rheumatol 1999 Sep–Oct; 17 (5), pp. 575–83.

Rheumatoid Arthritis: Severe vs Mild-Moderate/ Prediction of Disease Severity: G Allele (TT vs TG/GG Genotypes)/Tumor Necrosis Factor-Alpha (TNF-α) Receptor Type II (TNFRII): Exon 6 Polymorphism
Anti-TNF-α Response/Methotrexate

Application: Characterizing severe vs mild-moderate conditions of rheumatoid arthritis as a function of exon 6 TNFRII gene polymorphism. The G allele appears to have utility in predicting the degree of responsiveness to anti-TNF-α treatment while the GG genotype for the exon 6 TNFRII polymorphism may be useful in predicting more aggressive forms of rheumatoid arthritis.
Implementation: Characterization of exon 6 TNFRII gene polymorphism in cases of (i) mild-moderate synovitis classified as responders to methotrexate therapy (e.g., n = 97) for comparison with (ii) "non-responder" cases receiving anti-TNF-α treatment due to severe and aggressive disease (e.g., n = 78); and (iii) cases with severe rheumatoid arthritis monitored for 6 months during anti-TNF-α therapy. Results are evaluated pertaining to response according to genotype and compared to matched age, sex, and ethnic reference controls (e.g., n = 84).
Interpretation and Analysis: A distinct trend exists toward increases in the frequency of the GG genotype in patients with severe rheumatoid arthritis (6.4%) compared to cases of mild-moderate disease (3.1%) and reference controls (1.2%). Evaluation of the response to anti-TNF-α therapy after 12 weeks of treatment reveals that 37.8% of the TT genotype passes from high to medium-low disease activity. Such observations are in contrast to the 10.7% of the TG/GG genotype that passes from high to medium-low disease activity (p = 0.03).

Collective evaluation of laboratory results therefore suggests that in cases of rheumatoid arthritis classified according to response to the conventional therapy and by disease severity, there is a discernable trend toward a higher prevalence of the GG genotype for the exon 6 TNFRII polymorphism in less-responsive cases displaying a more aggressive form of disease. In addition, the G allele tends to promote a lower degree of response to anti-TNF-α treatments.

Tumor necrosis factor-alpha receptor II polymorphism in patients from southern Europe with mild-moderate and severe rheumatoid arthritis. Fabris M, Tolusso B, Di Poi E, Assaloni R, Sinigaglia L, Ferraccioli G. J Rheumatol 2002 Sep; 29 (9), pp. 1847–50.

SKELETAL MUSCLE

Devitalized Tissues
Organic Iodine (e.g., Betadine)

Cellular/Molecular Mechanism of Action: Exclusionary vitality stain. Damaged or devitalized tissues (musculoskeletal lacerations) assimilate a greater amount of organic iodine relative to normal tissues.
Diagnostic Application: Identification of devitalized musculoskeletal tissues such as those found in lacerated wounds.
Route of Administration and Dosage: Topical application onto regions of suspected tissue devitalization.
Considerations: Septic wounds with extensive neutrophil infiltration will convert organic iodine solution from a rich brown color to an almost colorless iodine preparation. This occurs due to the activity of halogen-myeloperoxidase system within neutrophil populations.
Interpretation: Devitalized tissues will appear a different color than non-affected (normal) tissues.

Hyperkalemic Periodic Paralysis (HYPP): Equine
Potassium Chloride (KCl)

Cellular/Molecular Mechanism of Action: Stabilizes propagation of electrolyte-mediated electrical impulses across (along) cell membranes. Normally, potassium (K^+) is maintained at a relatively higher concentration intracellularly in contrast to the extracellular environment. Additionally, sodium (Na^+) is usually in relatively higher concentration in the extracellular environment than in the intracellular milieu. During membrane depolarization, Na^+ conductance intracellularly increases, which is followed by increased extracellular K^+ conductance during the repolarization process. In this

context, administration of large amounts of K^+ serves to inhibit the processes of membrane depolarization/repolarization.

Diagnostic Application: Stabilization of excitable membrane structures for the diagnosis of conditions including cases suffering from HYPP syndrome. Positive diagnosis is recognized by a progressive increase in muscle weakness that can advance to a state of collapse.

Route of Administration: Orally by nasogastric tube.

Dosage: KCl (88–160 gm/kg).

Considerations: False negative results can be observed when the lower dose range is administered.

Implementation: Administration should begin at the lower dose of approximately 40 g of KCl in water (6 L). Blood samples are collected for measurement of KCl concentrations. Some patients with periodic hyperkalemic syndrome will not respond to the potassium chloride challenge test. In such instances, these cases can be diagnosed by increasing the dosage of potassium chloride in increments of 20 grams. Only 1 challenge test should be performed within any given 24-hour period and horses should not be left unattended following KCl administration (2- to 4-hour period following dosage).

Interpretation and Analysis: Normal horses have a modest increase in plasma potassium concentrations but do not develop abnormal clinical signs even at the 180 mg/kg KCl dose level. Reversal of clinical signs of HYPP following induction by potassium chloride administration can be achieved with the subsequent administration of calcium chloride or calcium gluconate. Calcium gluconate can be administered at a dose of 0.2 to 0.4 ml/kg diluted to 1 to 2 liters in 5% dextrose and given intravenously. Response rate following calcium gluconate is rapid. Alternatively dextrose 5% (D5W) at 4.4 to 6.6 ml/kg or $NaHCO_3$ at 1 mEq/kg can be administered rapidly by intravenous infusion.

Laboratory Instrumentation: Electron capture instrumentation is applied to measure concentrations of potassium cation.

Hyperkalemic Periodic Paralysis (HYPP)
Potassium/Acetazolamide/Calcium Glucuronate/ Biocarbinate/Bicarbonate/Glucose (+/− Insulin)

Cellular/Molecular Mechanism of Action: Acetazolamide inhibits carbonic anhydrase activity. Pharmaceuticals within the thiazide class act directly on the kidney and increase the excretion of sodium chloride, potassium chloride, and water. At sufficient doses, pharmaceuticals within this class such as acetazolamide also promote bicarbonate excretion. Potassium excretion is achieved through a combination of enhanced excretion at the distal tubule, accented by drug-induced microvascular hyperperfusion at the level of the distal renal tubule.

Diagnostic Application: Hyperkalemic periodic paralysis in the acute stages can be reversed by calcium gluconate, bicarbonate, glucose, and/or insulin. Hyperkalemic periodic paralysis can be induced or initiated by the administration of potassium electrolyte.

Background Information: Hyperkalemic periodic paralysis is characterized by sporadic attacks of muscle tremors, weakness, and/or collapse, lasting for variable periods of time. Diagnosis is based on physical findings in association with hyperkalemia. In horses with HYPP, the regulation of ion transport through myocyte sodium channels occasionally fails, causing uncontrollable muscle twitching. Further investigations into molecular genetic profiles reveal a mutation in the gene responsible for sodium and potassium regulation. The identification of this gene mutation is the basis for the blood test used to diagnose HYPP. Hyperkalemic periodic paralysis is inherited as an autosomal dominant trait.

Dosage: Reports have described the use of acetazolamide at 2.2 mg/kg body weight in the horse. Other pharmacokinetic-based studies have characterized serum acetazolamide concentration profiles following the administration of intravenous (4 mg/kg IV) and oral(8 mg/kg) doses.

Route of Administration: Acetazolamide (IV or oral).

Considerations: Administration can promote a hypokalemia. Acetazolamide can also promote the development of hyperglycemia, in addition to elevations in triglycerides and cholesterol.

Pharmacokinetics: The pharmacokinetics of acetazolamide (IV or per os) can be established in horses (e.g., $n = 6$) by the administration of 2 doses (4 mg/kg of body weight, IV; 8 mg/kg, per os) and blood samples collected at regular intervals before and after administration. Assay for acetazolamide concentrations can be determined by high-performance liquid chromatography. Following IV administration of acetazolamide, data analysis reveals a median mean residence time of 1.71 ± 0.90 hours and median total body clearance of 263 ± 38 ml/kg/h. Median steady state volume of distribution is 433 ± 218 ml/kg. After oral administration, mean peak plasma concentration is 1.90 ± 1.09 μg/ml. Mean time to peak plasma concentration is 1.61 ± 1.24 hours. Median oral bioavailability is $25 \pm 6\%$. Oral pharmacokinetic disposition of acetazolamide in horses is characterized by rapid absorption, low bioavailability, and slower elimination than observed initially after IV administration. Pharmacokinetic data can therefore facilitate estimation of appropriate dosages for acetazolamide use in horses with hyperkalemic periodic paralysis.

Interpretation and Analysis: During HYPP attacks, the intravenous administration of calcium gluconate, bicarbonate, and glucose results in a rapid reversal of clinical signs. Administration of potassium as an electrolyte solution can precipitate the condition in cases with a genetic predisposition.

HYPP—Hyperkalemic periodic paralysis in horses. Zeilmann M. Tierarztl Prax 1993 Dec; 21 (6), pp. 524–7.

Pharmacokinetics of acetazolimide after intravenous and oral administration in horses. Alberts MK, Clarke CR, MacAllister CG, Homer LM. Am J Vet Res 2000 Aug; 61 (8), pp. 965–8.

Malignant Hyperthermia (MH)
Midazolam/Caffeine/Halothane

Cellular/Molecular Mechanism of Action: Midazolam (water-soluble benzodiazepine).

Application: Premedicant for induction of anesthesia, but can additionally be applied to screen for patients susceptible to the development of MH. Midazolam is not an effective diagnostic pharmaceutical for the screening of patients susceptible to the development of MH.

Dosage: Midazolam (ca. 0.5 μg/ml).

Considerations: Midazolam is applied to determine its influence on the resting tension of directly stimulated muscle biopsies. Interactions between midazolam and the 2 most commonly used MH diagnostic agents (halothane and caffeine) have also been examined.

Interpretation and Analysis: Midazolam, at maximum therapeutic concentrations (ca. 0.5 μg/ml), has no detectable effects on muscle contraction in control and MH preparations. However, midazolam does elicit contracture responses in control and MH-positive preparations when used within a concentration range between 160 and 1,280 μg/ml. There are no significant differences between control and MH-positive patients at minimum concentration of midazolam causing contracture or the strength of contracture at the respec-

tive eliciting concentration. There appears to be no interaction between midazolam and either halothane or caffeine on the resting tension of directly stimulated muscle twitch preparation.

Effects of midazolam on directly stimulated muscle biopsies from control and malignant hyperthermia positive patients. Fletcher JE, Rosenberg H, Hilf M. Can Anaesth Soc J 1984 Jul; 31 (4), pp. 377–81.

Malignant Hyperthermia (MH)
Caffeine/Halothane/Haloperidol/Succinylcholine/Caffeine

Cellular/Molecular Mechanism of Action: Succinylcholine is an analog of the neurotransmitter acetylcholine.
Physiological Mechanism of Action: Droperidol and haloperidol are butyrophenone neuroleptic agents that induce a state of quiescence and reduced motor activity. Ketamine is a dissociative anesthetic agent.
Application: Utilized in the *in vitro* diagnostic screening of muscle strips from human patients being diagnostically screened for MH and muscle strips from rat diaphragm preparations are exposed to droperidol, haloperidol, or ketamine prior to challenge with halothane, succinylcholine, or caffeine (used to screen the MH potential of droperidol, haloperidol, ketamine).
Route of Administration: Halothane (inhalation); succinylcholine (intravenous).
Considerations: If any agent augments the contracture response to the MH triggering or diagnostic agents, then the agent is considered unsafe for use in MH-susceptible patient cases.
Interpretation and Analysis: Droperidol (10 μmol/l) and ketamine (100 μmol/l) do not induce contractures in human or rat skeletal muscle when added alone, nor do they augment halothane, succinylcholine, or caffeine contractures. Therefore, these agents appear to be safe for use in patients susceptible to MH. In contrast, haloperidol (10 μmol/l) augments responses to succinylcholine about 1.5-fold and may be contraindicated in MH-susceptible cases.

Effects of droperidol, haloperidol, and ketamine on halothane, succinylcholine, and caffeine contractures: Implications for malignant hyperthermia. Fletcher JE, Rosenberg H, Lizzo FH. Acta Anaesthesiol Scand 1989 Apr; 33 (3), pp. 187–92.

Malignant Hyperthermia (MH)
Caffeine/Diffusible CO_2

Background Information: Susceptibility to MH can be diagnosed by implementation of a contracture test, which requires obtaining an open muscle biopsy sample.
Route of Administration: Caffeine (intramuscular).
Dosage: Caffeine (500 μl of an 80 mmol/L formulation).
Implementation: Evaluate the influence of intramuscular caffeine injection on local carbon dioxide pressure (pCO_2) in conditions of MH compared to normal negative reference controls. Measurements for pCO_2 are obtained from the rectus femoris muscle during local stimulation with injected caffeine.

Human Model: Cases susceptible to MH (n = 12); cases classified as non-susceptible (n = 8); and 7 healthy/normal controls.
Interpretation and Analysis: In susceptible individuals, pCO_2 temporarily increases to a maximum of 63 mm Hg (IQR 61–69) compared with 44 mm Hg (43–47) for non-susceptible participants ($p = 0.003$) and 42 mm Hg (41–46) in controls ($p = 0.003$). Systemic side effects usually cannot be appreciated. Metabolic monitoring of highly diffusible CO_2 stimulated by caffeine could possibly serve as a minimally invasive test for susceptibility to MH.

Diagnosis of susceptibility to malignant hyperthermia by use of a metabolic test. Anetseder M, Hager M, Müller CR, Roewer N. Lancet 2002 May 4; 359 (9317), pp. 1579–80.

Malignant Hyperthermia (MH)
Caffeine/Halothane/Calcium-Induced Calcium Release

Application: Detection and characterization of MH conditions.
Route of Administration: Topical application (emersion) of muscle biopsy specimens.
Implementation: Comparison of results of the *in vitro* caffeine/halothane contracture test (CHCT) according to the protocols of the North American Malignant Hyperthermia Group (NAMHG) and the European Malignant Hyperthermia Group (EMHG) with the Ca^{2+}-induced Ca^{2+} release (CICR) rate test. Muscle biopsies are usually obtained from the musculus vastus lateralis. Diagnostic cut-off points and procedures for CHCT protocols are as described in the original and renewal versions of NAMHG and EMHGs. The CICR rate test is performed according to the protocol reported by Endo et al.

Human Model: Cases of suspected MH (n = 16; n = 5 normal negative reference controls).
Interpretation and Analysis: Essentially a very large proportion of normal subjects (e.g., n = 5/5 or 100%); some abortive cases of MH (e.g., n = 2); some cases of postoperative hyperthermia (e.g., n = 2); and some cases with high serum creatinine kinase (e.g., n = 3) will have normal results from all 3 tests. Some cases with MH reactions (e.g., n = 3) or that have a history of masseter spasm (e.g., n = 1) may be classified as MH-positive according to NAMHG criteria and MH-susceptible and MH-equivocal according to EMHG criteria. Some cases will have discordant results between the CHCT and CICR rate tests (e.g., n = 5 patients). It has therefore been proposed that muscle biopsy for diagnosis of MH susceptibility should combine the CHCT with the CICR rate test, which may identify the defective site of Ca^{2+} release channels.

Comparison of the *in vitro* caffeine-halothane contracture test with the Ca-induced Ca release rate test in patients suspected of having malignant hyperthermia susceptibility. Oku S, Mukaida K, Nosaka S, Sai Y, Maehara Y, Yuge O. J Anesth 2000 Jan 20; 14 (1), pp. 6–13.

Malignant Hyperthermia (MH)
4-Chloro-m-Cresol (4-CmC)/Caffeine/Halothane

Background Information: *In vitro* contracture test (IVCT) for diagnosis of MH has been reported to have a sensitivity level of 100% and a specificity of 93%. The results are equivocal in 10 to 15% of cases, and supplementary tests may thus be required
Application: The agents 4-CmC, caffeine, and halothane can be applied to detect and characterize conditions of MH.
Implementation: Evaluation of muscle tissue collected as a biopsy specimen applying an IVCT performed by topical exposure to increasing concentrations of 4-CmC (25, 50, 75, 100, 150, and 200 μmol/l). Corresponding real-time force profiles are then recorded. Diagnosis of MH susceptibility is established with standard halothane and caffeine tests and test subjects classified as MHS (MH-susceptible), MHN (MH0negative), or MHE (equivocal result).

Human Model: Cases subjected to skeletal muscle biopsy (n = 41 from n = 7 families).
Interpretation and Analysis: At all concentrations of 4-CmC, the increase in baseline force is significantly greater in the MHS group compared to the MHN group ($p < 0.05$). Muscle from MH-susceptible cases (e.g., n = 15 MHS) responds to 4-CmC with increasing force at a threshold concentration of 75 μmol/l or less,

whereas muscle tissues from cases classified as MH-non-susceptible (e.g., n = 23 MHN) have thresholds of 100 μmol/l or more. The accuracy of the chlorocresol test is approximately 100% (95% confidence limits, 90.75–100%) at a threshold of 75 μmol/l. Amplitude of contractures at 2 μmol/l caffeine is not different from contractures at 75 μmol/l of 4-CmC in either the MHS or the MHN group ($p > 0.05$). *In vivo* concentrations of chlorocresol from clinical use of insulin and somatropin are estimated to be 20 times less than the threshold concentration and thus these drugs seem safe in MH cases. Therefore, 4-CmC may be a suitable aid to clarify puzzling results of standard testing of MH susceptibility.

4-Chloro-m-cresol test—A possible supplementary test for diagnosis of malignant hyperthermia susceptibility. Ording H, Glahn K, Gardi T, Fagerlund T, Bendixen D. Acta Anaesthesiol Scand 1997 Sep; 41 (8), pp. 967–72.

Malignant Hyperthermia (MH)/Genomic Analyses and Provocative Testing Correlation/Mutation: Arginine-614 → Cysteine (Arg614Cys: RYR1 C1840T)

Caffeine/Halothane

Physiological Mechanism of Action: In conditions of MH, exposure of muscle tissue to caffeine/halothane promotes an exaggerated contractile response.

Background Information: Malignant hyperthermia is an important cause of anesthesia-induced death. The caffeine/halothane contracture test (CHCT) is highly invasive, expensive, and lacks 100% specificity. Genetic and biochemical evidence provide strong support for the view that the substitution of cysteine for arginine 614 (Arg614Cys) in the human ryanodine receptor gene is 1 of several mutations that are likely to be responsible for MH in humans.

Application: Detection and characterization of MH conditions.

Route of Administration: Traditionally applied topically during exposure of biopsy tissue specimens in *ex vivo* based challenge studies.

Implementation: Delineation of a possible genetic basis for a predisposition to MH pertaining to the presence of Arg614Cys (RYR1 C1840T) mutations detected through a combination of polymerase chain reaction and restriction endonuclease digestion. Blood samples are utilized as a source of biological material for DNA analyses. Alternatively, detection of MH susceptibility can be established using the *in vitro* CHCT that employs fresh muscle biopsy specimens. Results in the form of CHCT and DNA-based diagnostic parameters are then compared to determine their potential value in predicting MH susceptibility in large MH families that possess Arg614Cys mutations.

Human Model: Cases selected from a large Mennonite MH kindred identified by an index patient that died at age 45 years of an MH crisis after general anesthesia. Case population: N = 68 family members, n = 19/68 muscle biopsies, n = 1/68 documented crisis without biopsy.

Interpretation and Analysis: Family members can be classified as MH-susceptible or MH-normal on the basis of results from CHCT procedures. Approximately 33% of cases can be found to be heterozygous for the Arg614Cys mutation (n = 22/68) and slightly less than one-fourth have prior positive CHCT results (e.g., n = 5/22), while a small percentage have an MH crisis without a biopsy procedure. On DNA testing, it is possible to detect a relatively large number of cases within a related kindred that are normal for the allele (e.g., n = 44). Of these, slightly less than 25% can be classified as MH-normal, while some may be determined to be MH-susceptible (e.g., n = 5) on the basis of CHCT evaluations. Based on the interpretation of the data obtained in earlier CHCT diagnoses, the condition of the muscle is poor, with no twitch, for approximately 60% of cases of individuals homozygous for the normal allele but originally classified as MH-susceptible (e.g., n = 3/5) and for a small percentage that are homozygous for the normal allele and originally classified as MH-normal. Observations from caffeine/halothane contraction test results performed for such individuals (e.g., n = 4) can often be considered invalid. The twitch response is good for a small number of cases (e.g., n = 2 remaining) that are homozygous for the normal allele but classified as MH-susceptible if contractures can be observed with appropriately low levels of both caffeine and halothane.

An absolute correlation between DNA test results and CHCT assignment can often not be established. Possible explanations for discordance are that the Arg614Cys mutation is not linked to MH, that a 2nd MH mutation is segregating in the family, or that there are errors in the CHCT. Because there is strong evidence supporting the causal nature of the Arg614Cys mutation, the discordant cases are not closely related within the pedigree as they would be if a 2nd MH mutation were segregating, the CHCT is not 100% accurate, and it has been proposed that the observed discordance between DNA test results and CHCT assignment in this kindred results from 2 false-positive diagnoses by the CHCT.

Comparison of the segregation of the RYR1 C1840T mutation with segregation of the caffeine/halothane contracture test results for malignant hyperthermia susceptibility in a large Manitoba Mennonite family. Serfas KD, Bose D, Patel L, Wrogemann K, Phillips MS, MacLennan DH, Greenberg CR. Anesthesiology 1996 Feb; 84 (2), pp. 322–9.

Malignant Hyperthermia (MH)/Ryanodine Receptor (RYR1) Gene

Halothane

Background Information: Malignant hyperthermia is a potentially lethal disease triggered by volatile anesthetics and succinylcholine in genetically predisposed individuals. Because of the heterogenetic nature of MH, a simple genetic-based diagnostic test is not feasible and diagnosis requires an invasive open muscle biopsy followed by the *in vitro* contracture test (IVCT).

Implementation: Establish if measurements of halothane-induced increases in intracellular calcium ion concentration $[Ca^{2+}](i)$ in cultured human skeletal muscle cells can be used to phenotype MH susceptibility and if different mutations in the RYR1 gene affect halothane-induced increases in $[Ca^{2+}](i)$.

Primary cultures of human skeletal muscle cells can be acquired from cases previously determined to suffer from MH. Cell lines are then individually screened for the presence of the most common mutations in the RYR1 gene. $[Ca^{2+}](i)$ is measured in 10 cells from each case that has been subjected to 5 different halothane concentrations.

Human Model: Cases of MH (n = 54) diagnosed by the IVCT according to the protocol of the European Malignant Hyperthermia Group can be classified as MH-susceptible (n = 22), MH-negative (n = 18), or MH-equivocal (n = 14).

Interpretation and Analysis: Halothane-induced increases in $[Ca^{2+}](i)$ differ significantly between different classification groups. Interestingly, different mutations of the RYR1 gene do not have a specific impact on halothane-induced increases in $[Ca^{2+}](i)$. Therefore, measurements of $[Ca^{2+}](i)$ in human skeletal muscle cells can be used to phenotype MH susceptibility; however, mutation in the RYR1 gene does not closely correlate with a specific effect related to halothane-induced increases in $[Ca^{2+}](i)$.

Instrumentation: Fluorescent digital microscopy using fura-2/AM can be applied for the measurement of calcium ion concentrations contained within biological samples.

Phenotyping malignant hyperthermia susceptibility by measuring halothane-induced changes in myoplasmic calcium concentration in cultured human skeletal muscle cells. Girard T, Treves S, Censier K, Mueller CR, Zorzato F, Urwyler A. Br J Anaesth 2002 Oct; 89 (4), pp. 571–9.

Malignant Hyperthermia (MH): Genetic Predisposition/(*Ex Vivo* Preparation of Skeletal Muscle Biopsies)
Caffeine/Caffeine and Halothane

Application: Caffeine and caffeine + halothane can be applied as investigative probes to characterize certain intrinsic properties of skeletal muscle tissues. In this context, caffeine and caffeine + halothane can serve as indicator agents for the detection of individuals with a genetic predisposition to the development of MH (potentially fatal complication of general anesthesia).
Implementation: Skeletal muscle *ex vivo* preparations are exposed to caffeine or caffeine + halothane and the subsequent induction of contracture responses is measured for comparison with negative reference controls.
Interpretation and Analysis: In confirmed or suspect cases of MH and their genetic relatives, the responsiveness of the muscle specimens often varies over 2 orders of magnitude. Frequency distribution curves suggest that the variation does not represent a continuum but rather represents 3 or more clusters of functional variants. Muscle specimens from males are on average more responsive to caffeine than is skeletal muscle collected from female subjects. Correlations within father-son and brother-brother pairs indicate complete heritability of responsiveness. Interestingly, there appears to be a lack of correlation between induced contraction of muscle biopsies collected from mother-daughter pairs. There is an intermediate correlation in father-daughter pairs. The sex difference in heritability could be due to gender-related modifying genes or due to secondary modification of the muscle response in females by sex-related characteristics such as hormonal factors. Among the effects of different variables as a function of age, it appears that poor development in early childhood corresponds to or correlates with the potentiation of the caffeine contracture by halothane.

Pharmacogenetics of caffeine and caffeine-halothane contractures in biopsies of human skeletal muscle. Kalow W, Sharer S, Britt B. Pharmacogenetics 1991 Dec; 1 (3), pp. 126–35.

Myasthenia Gravis (MG)
4-Aminopyridine (4-AP)

Cellular/Molecular Mechanism of Action: 4-aminopyridine is a general blocker of voltage-dependent K^+ channels.
Background Information: This pyridine derivative has also been shown to inhibit T cell proliferation, to modulate immune responses, and to alleviate some of the symptoms associated with neurological disorders such as multiple sclerosis, MG, and Alzheimer's disease. 4-aminopyridine triggers a Ca^{2+} response in lymphocytes, astrocytes, neurons, and muscle cells, but little is known about the regulation of the 4-AP response in these cells.
Implementation: Evaluation of suspect conditions of MG.
Interpretation and Analysis: Alleviation of clinical signs suggests a diagnosis of MG.

Myasthenia Gravis (MG)
Thyrotropin-Releasing Hormone (TRH)

Cellular Mechanism of Action: Hypothalamic TRH promotes the synthesis/release of thyroid-stimulating hormone (TSH) from the pituitary.
Implementation: Administration of TRH to measure TSH responses in cases of MG.
Interpretation and Analysis: Some cases of MG display an elevated response to TRH administration reflected by abnormally high increases in TSH produced following administration (e.g., n = 6/13 MG cases). Findings are usually accompanied by normal free thyroxine indices and the absence of antithyroid antibodies. This latter observation is relevant when the association of MG with hyperthyroidism, thyroiditis, and hypothyroidism is considered.

Gonadotropin, prolactin, and TSH secretion in patients with myasthenia gravis. Shapiro MS, Weiss E, Kott E, Taragan R, Shenkman L. J Endocrinol Invest 1984 Dec; 7 (6), pp. 579–83.

Myasthenia Gravis (MG)/Complications/Side Effects/Sequellae
Edrophonium (Tensilon)/Sleep Test/Ice Test

Background Information: The incidence of life-threatening complications from edrophonium chloride (Tensilon) testing for suspected MG is thought to be extremely low.
Implementation: Survey of physician members of the North American Neuro-ophthalmology Society (n = 357) regarding (i) number of years clinician had practiced neuro-ophthalmology; (ii) the estimated number of edrophonium tests performed since completion of training; (iii) number and nature of major complications from edrophonium; and (iv) preference for the sleep test or ice test to edrophonium testing.
Interpretation and Analysis: Of a group of 199 respondents, 105 (53%) may have practiced neuro-ophthalmology for at least 10 years. Estimates of the number of edrophonium tests performed for diagnostic purposes can be very high (e.g., n = 21,111), of which approximately 0.16% (e.g., n = 37) may be associated with a serious complication, mostly attributed to bradyarrythmias and syncope. Respiratory failure, seizure, severe vomiting, and transient ischemic attack may also be recognized. Approximately one-sixth (e.g., n = 31) of respondents (16%) prefer the sleep test or ice test to the edrophonium test and one-third of this group may have observed serious complication with edrophonium. The rate of significant complications of edrophonium testing is low, but the complications can be potentially life threatening.

The complication rate of edrophonium testing for suspected myasthenia gravis. Ing EB, Ing SY, Ing T, Ramocki JA. Can J Ophthalmol 2000 Apr; 35 (3), pp. 141–4; discussion 145.

Myasthenia Gravis (MG)/(Safety Evaluation)
Edrophonium Chloride (Tensilon Test)

Cellular/Molecular Mechanism of Action: Edrophonium chloride is a potent inhibitor of cholinesterase biochemical activity. Inhibition of this enzyme promotes elevated accumulation of acetylcholine (cholinergic neurotransmitter) in the vicinity of presynaptic membranes.
Physiological Mechanism of Action: Edrophonium chloride enhances cholinergic activity (parasympathomimetic properties).
Background Information: Cholinesterase inhibitors (CEIs) have been known to improve strength in patients with MG since the 1930s and have been used as a diagnostic test since the early 1950s.
Application: To evaluate the safety of edrophonium chloride in the course of the Tensilon test by measurement of hemodynamic and ECG parameters and the observation of adverse events.
Implementation: Evaluation of the influence of Tensilon in conditions of suspected MG. Blood pressure, heart rate, continuous

ECG, and adverse events are recorded 10 minutes following intravenous application of Tensilon.

Human Model: Cases of suspected MG (n = 25: open, prospective study).

Interpretation and Analysis: Blood pressure and heart rate do not change significantly during the observation period. Some patients on β-blockers may develop grade I AV block. Self-limiting adverse events of short duration have also been observed (e.g., n = 11 cases). Serious adverse events such as syncope or hemodynamic deterioration usually do not occur. The Tensilon test therefore appears to be a safe procedure. A detailed clinical cardiac history, the history of medication, and 12 lead ECG recordings should be documented in all patients undergoing the Tensilon test. Patients with a history of dysrhythmia receiving digitalis, β-blocking agents, or Ca antagonist therapy should be managed with special care, as Tensilon enhances vagal effects.

Edrophonium chloride (Tensilon) test: A safe method in diagnosing myasthenia gravis. Domanovits H, Wenger S, Schillinger M, Mayr N, Holzer M, Laggner AN, Zeitlhofer J. Wien Klin Wochenschr 2000 Jul 7; 112 (13), pp. 592–5.

The edrophonium test. Pascuzzi RM. Semin Neurol 2003 Mar; 23 (1), pp. 83–8.

Myasthenia Gravis (MG): Dysphagia
Edrophonium Chloride (EC)/Esophogeal Function

Cellular/Molecular Mechanism of Action: Edrophonium chloride is a short-acting acetylcholinesterase inhibitor.

Background Information: Myasthenia gravis is an autoimmune disease in which impairment of neuromuscular transmission results in a pathological fatigability of striated muscles. Dysphagia is a common symptom in MG. It is caused by a weakness of the striated muscles in the pharynx and esophagus.

Application: Detection and characterization of esophageal dysfunction in conditions of MG.

Dosage: Edrophonium chloride (10 mg).

Implementation: Evaluation of esophageal transit facilitated by the application of scintigraphy to assess responses to a multiple swallow test protocol. Cases are studied (i) under baseline conditions, and (ii) immediately after pharmacological stimulation with EC.

Human Model: Cases of clinically proven MG (n = 15; n = 10/15 with a history of dysphagia; n = 6/15 oculopharyngeal manifestation; n = 9/15 generalized weakness).

Interpretation and Analysis: Under baseline conditions, the vast majority of cases (e.g., n = 15/15) show impaired esophageal function (emptying [%]= 58% ± 21; normal range > 85%). In some individuals (e.g., n = 14/15), esophageal transit improves after EC administration (emptying [%]= 75% ± 18; $p < 0.01$), reaching the normal range in slightly less than 30% of cases (e.g., n = 6/15). Esophageal transit, therefore is often compromised in MG. Functional abnormalities may be also present in patients without a history of dysphagia. Inhibition of cholinesterase positively affects striated muscles in the pharynx and upper esophagus, thus improving esophageal transit. Esophageal scintigraphy may be considered a simple, non-invasive method for diagnosing impairment of esophageal function in MG and for monitoring the changes under pharmacological stimulation.

Assessment of esophageal function in patients with myasthenia gravis. Linke R, Witt TN, Tatsch K. J Neurol 2003 May; 250 (5), pp. 601–6.

Protein (Muscle) Breakdown Rate
L-[ring-$^{13}C_6$]Phenylalanine/Leucine Kinetics/ Phenylalanine Kinetics

Cellular/Molecular Mechanism of Action: L-[ring-$^{13}C_6$] phenylalanine is a radioactive analog of the amino acid phenylalanine and therefore closely mimics its metabolism, catabolism, and synthetic incorporation into biological proteins (translation).

Application: L-[ring-$^{13}C_6$]phenylalanine can serve a non-invasive marker molecular for detecting alterations in phenylalanine metabolism, phenylalanine catabolism, protein synthesis, and protein catabolism.

Dosage: L-[ring-$^{13}C_6$] phenylalanine (4–6 mg/kg).

Implementation: Determination of the fractional synthesis rate (FSR) and breakdown rate (FBR) of muscle protein employing a method that utilizes a pulse tracer injection and measurement of enrichment in the arterial blood and muscle at 3 time points. The calculations of FSR and FBR are based on the precursor-product principle. One agent that can be applied for such purposes includes L-[ring-$^{13}C_6$] phenylalanine (4–6 mg/kg).

Animal Model: Rabbit (n = 5 normal/healthy).

Interpretation and Analysis: Measured FBR values (0.233 ± 0.060%/h) are almost identical ($p = 0.35$) to that (0.217 ± 0.078%/h) estimated with a leg arteriovenous balance model (Biolo G, Chinkes D, Zhang X-J, Wolfe RR. J Parenter Enteral Nutr 1992; 16, pp. 305–15). The measured FSR value tends to be lower than that estimated from a leg model (0.125 ± 0.036 vs 0.185 ± 0.086%/h; $p = 0.14$), possibly because the new method measures only muscle FSR, whereas the leg balance model also includes the determination of skin and bone contributions. The pulse tracer injection does not affect muscle protein kinetics as measured by leucine and phenylalanine kinetics in the leg. In related studies (n = 5 rabbits), it has been demonstrated that sampling can be reduced to either 1 or 2 muscle biopsies when multiple pulse injections are used. This method can be completed within a period of 1 hour with 1 muscle biopsy and has technical advantages over currently used methods.

Measurement of muscle protein fractional synthesis and breakdown rates from a pulse tracer injection. Zhang XJ, Chinkes DL, Wolfe RR. Am J Physiol Endocrinol Metab 2002 Oct; 283 (4), pp. E753–64.

Rhabdomyolysis: Recurrent/Exertional (Equine)/Myoplasmic Calcium Concentration Estimation/Heritable Myopathy
Caffeine/4-Chloro-m-Cresol (4-CmC)

Physiological Mechanism of Action: Caffeine promotes contraction of skeletal muscle tissue in *in vitro* preparations.

Route of Administration: Topical (*in vitro*) bathing of muscle tissue biopsy specimens.

Implementation: Delineate if alterations in myoplasmic calcium regulation can be identified in muscle cell cultures (myotubes) and intact muscle fiber bundles derived from Thoroughbreds affected with recurrent exertional rhabdomyolysis (RER). Laboratory procedures that can be employed to address such an objective may employ myotube cell cultures grown from satellite cells obtained from muscle biopsy specimens collected from horses affected by RER. Fura-2 fluorescence can be used to measure resting myoplasmic calcium concentration as well as caffeine- and 4-CmC-induced increases in myoplasmic calcium. In addition, intact intercostal muscle fiber bun-

dles can be prepared from both types of horses, and their sensitivities to caffeine and 4-CmC-induced contractures determined.

Animal Model: Equine (n = 6 related Thoroughbreds with RER; n = 8 clinically normal control Thoroughbred or crossbred horses).

Interpretation and Analysis: Myotubes of RER-affected and control horses have identical resting myoplasmic calcium concentrations. Myotubes from RER-affected horses have significantly higher myoplasmic calcium concentrations than myotubes from control horses following the addition of ≥ 2mM caffeine; however, there is no difference in their response to 4-CmC (≥ 1 mM). Caffeine contracture thresholds for RER and control intact muscle cell bundles (2 vs 10 mM, respectively) are significantly different, but 4-CmC contracture thresholds of muscle bundles from RER-affected and control horses (500 μM) do not differ. An increase in caffeine sensitivity of muscle cells derived from a family of related RER-affected horses has been detected *in vitro* by use of cell culture with calcium imaging and by use of fiber bundle contractility techniques. An alteration in muscle cell calcium regulation is a primary factor in the cause of this heritable myopathy.

Myoplasmic calcium regulation in myotubes from horses with recurrent exertional rhabdomyolysis. Lentz LR, Valberg SJ, Herold LV, Onan GW, Mickelson JR, Gallant EM. Am J Vet Res 2002 Dec; 63 (12), pp. 1724–31.

9 Reproductive System

Amniotic Fluid Volume Estimation
Aminohippurate Sodium

Cellular/Molecular Mechanism of Action: Aminohippurate sodium can be applied as a tracer molecule to monitor physiological processes and estimate fluid compartment volumes.
Application: Utilization of aminohippurate sodium as a reagent in dye-dilution techniques suitable for accurately estimating amniotic fluid volume.
Route of Administration: Amniocentesis.
Implementation: Evaluation of the fluid volume for amniotic fluid obtained from normal singleton pregnancies with intact membranes (Cesarean deliveries).

Human Model: Women (n = 15; cases with amniocentesis at delivery n = 6; Cesarean delivery n = 9 with samples collected 4–24 hours prior to surgery).
Interpretation and Analysis: Good concordance between the dye-determined and direct measurement of amniotic fluid volume can be appreciated in women undergoing amniocentesis (e.g., n = 6/6 cases; r = 0.99, p = < 0.001). Among women with varying times from amniocentesis to direct assay measurements (e.g., n = 9 cases), the correlation is not significant (e.g., n = 9 cases; r = 0.36, p = 0.08). The percent difference between dye-determined and directly measured amniotic fluid volume is significantly smaller in women undergoing amniocentesis just prior to delivery (7%) compared to the women with varying times from amniocentesis to delivery (37%, $p < 0.001$). Dye-determined amniotic fluid volume accurately reflects actual amniotic fluid volume but the dye-determined concentrations, *in vivo*, may undergo rapid changes.

Dye-dilution techniques using aminohippurate sodium: Do they accurately reflect amniotic fluid volume? Magann EF, Whitworth NS, Files JC, Terrone DA, Chauhan SP, Morrison JC. J Matern Fetal Neonatal Med 2002 Mar; 11 (3), pp. 167–70.

Cervical Cell Type Differentiation/Normal vs Abnormal/Cell Nuclei Visualization
Acetic Acid

Cellular/Molecular Mechanism of Action: Acetic acid chemically modifies the physical properties of different cellular constituents.
Application: The use of high-resolution *in vivo* confocal imaging may offer a clinically useful adjunct to standard methods for the diagnosis and screening of epithelial precancers.
Implementation: Assess the feasibility of real-time confocal reflectance imaging of cervical tissue and the use of acetic acid as a contrast agent to increase visualization of cell nuclei.

***Ex Vivo* Model:** Confocal microscopy image evaluation of cervical cells and colposcopically normal and abnormal cervical biopsy specimens. Images are obtained before and after the application of 6% acetic acid.
Interpretation and Analysis: Confocal microscopy imaging can resolve subcellular detail throughout the entire epithelial thickness. Normal and abnormal tissues are clearly able to be differentiated. Addition of acetic acid enhances nuclear signal in all acquired images. High-contrast reflected light images of cervical tissue are attainable in near real time. Acetic acid significantly increases light scattering from cell nuclei, which may partially explain why acetowhitening occurs.

Laser scanning confocal microscopy of cervical tissue before and after application of acetic acid. Drezek RA, Collier T, Brookner CK, Malpica A, Lotan R, Richards-Kortum RR, Follen M. Am J Obstet Gynecol 2000 May; 182 (5), pp. 1135–9.

Endometriosis/Prolactin Response: Lack of Discrimination
Thyrotropin-Releasing Hormone (TRH)/Insulin Challenge

Application: Detection and characterization of endometriosis conditions.
Implementation: Evaluation of prolactin secretion applying a TRH test and an insulin challenge test in conditions of female endometriosis.

Human Model: Female cases of endometriosis (n = 10) treated with danazol at a dose of 200 mg 3 times daily for 6 months (evaluated after the reappearance of 2nd menses). Reference controls include normal females (n = 10 in follicular phase; test performed only once).
Interpretation and Analysis: The absence of a significant difference in basal prolactin levels or responses to the TRH and insulin challenge tests between controls and patients with endometriosis, before and after danazol treatment, supports the view that hyperprolactinemia should not be considered as a cause of infertility in endometriotic women. Furthermore, significant reductions in prolactin response to provocative tests during danazol treatment may be associated with the low estrogen levels caused by the medication. Finally, inadequate prolactin responses to insulin-induced hypoglycemia in cases with endometriosis and in normal women shows that this provocative test is not effective for hypothalamic stimulation of prolactin.

Provocative tests of prolactin before, during and after long-term danazol treatment in patients with endometriosis. Panidis D, Vavilis D, Rousso D, Panidou E, Kalogeropoulos A. Gynecol Endocrinol 1992 Mar; 6 (1), pp. 19–24.

Endometriosis: Infertility (Hyperprolactenemia)/ Ovulatory Dysfunction and Infertility
Thyrotropin-Releasing Hormone (TRH)/ [Metoclopramide]

Cellular/Molecular Mechanism of Action: Metoclopramide functions as a dopaminergic type 2 (DA2) receptor competitive antagonist.
Background Information: The origin of infertility in patients with endometriosis without tubal occlusion has not yet been clearly

defined. Several reports show an abnormal pituitary-ovarian axis in this group of patients. Moreover, prolactin (PRL) and growth hormone (GH) secretion is closely related to reproductive status.

Implementation: Evaluation of minimal/mild endometriosis conditions as a function of PRL and GH responses following the infusion of metoclopramide and TRH infusion. Metoclopramide or TRH is administered randomly in 2 sequential menstrual cycles (cycle days 3–5). Serum PRL and GH secretion before and after dopaminergic type 2 (DA2) receptor blockade and TRH are compared.

Human Model: Cases of infertility due to minimal/mild endometriosis (n = 64 females; composed of n = 33 fertile without endometriosis; n = 10 fertile with minimal/mild endometriosis; n = 21 infertile with mild/moderate endometriosis)

Interpretation and Analysis: Higher serum PRL levels are observed in cases with endometriosis at baseline and after 15 and 30 minutes of TRH administration. Also, infertile cases with endometriosis have lower serum estradiol levels than fertile patients. Moreover, the dopaminergic blockade does not result in abnormal PRL or GH secretion. Decreases in serum estradiol levels and altered PRL secretion after TRH administration in infertile cases with minimal/mild endometriosis are related to ovulatory dysfunction and infertility in this group of patients without tubal occlusion.

Prolactin and growth hormone secretion after thyrotrophin-releasing hormone infusion and dopaminergic (DA2) blockade in infertile patients with minimal/mild endometriosis. Cunha-Filho JS, Gross JL, Lemos NA, Dias EC, Vettori D, Souza CA, Passos EP. Hum Reprod 2002 Apr; 17 (4), pp. 960–5.

Endometriosis Stages I, II, III, and IV
Thyrotropin-Releasing Hormone (TRH)

Background Information: Hyperprolactinemia has been described in previous reports to be associated with infertility and endometriosis.

Application: Characterize serum prolactin concentrations in cases with infertility and endometriosis.

Implementation: Evaluation of basal serum prolactin levels and prolactin levels after TRH administration.

Human Model: Cases of infertility and laparoscopically proven endometriosis (n = 40).

Interpretation and Analysis: The mean basal serum prolactin concentrations are 12.5, 16.5, 19.5, and 26.5 ng/ml compared to post-TRH administration levels of 88.3, 114.2, 125.3, and 138.8 ng/ml in cases with stages I, II, III, and IV endometriosis, respectively. A statistically significant relationship exists between basal serum prolactin levels as well as those after TRH injection and the stage of the endometriosis. In cases that either do not receive treatment or have been initially treated with gonadotropin-releasing hormone (GnRH) analogues (24 weeks) and other therapeutic schemes to improve fecundity, the fertility rate is not noticeably different. Cases that do not become pregnant, however, have higher serum prolactin concentrations after TRH administration as compared to those who conceive. Occult hyperprolactinemia may therefore be a cause of infertility in cases with endometriosis.

Evaluation of serum prolactin levels in patients with endometriosis and infertility. Gregoriou G, Bakas P, Vitoratos N, Papadias K, Goumas K, Chryssicopoulos A, Creatsas G. Gynecol Obstet Invest 1999; 48 (1), pp. 48–51.

Impotency: Male
Papaverine

Route of Administration: Intracavernous (IC) applying autoinjection techniques.

Considerations: Vasoactive drugs can be described as being inducers (drugs that induce a rigid erection, even in the presence of the doctor), facilitating drugs (pharmaceuticals that produce a rigid erection only if sexual stimulation is also present), and inhibitors (agents that stop an erection). The former group (principally papaverine) produces a significant number of side effects, not least of these being priapism; there is a risk of lasting iatrogenic impotence that is not negligible.

Sequelae are reduced considerably when one uses facilitating drugs that, although less powerful, suffice in treating a large proportion of cases of impotence.

Interpretation and Analysis: A substantial number of impotent cases (25%) improve after papaverine, while 50% of cases suffering from impotence of psychological origin also note an improvement. Intracavernous treatment now seems justified in most cases that have not responded to traditional therapeutic strategies, and this includes cases of psychological origin. Papaverine cannot be replaced as a diagnostic drug but facilitating drugs should be used 1st in therapy and inducers should be used only if facilitating drugs have failed.

The role of adrenomedullin in varicocele and impotence. Ozbek E, Yurekli M, Soylu A, Davarci M, Balbay MD. BJU Int 2000 Oct; 86 (6), pp. 694–8.

Infertility/Female Fertility/Thyroid-Stimulating Hormone (TSH)/Prolactin (PRL) Responses
Metoclopramide/Thyrotropin-Releasing Hormone (TRH)

Cellular/Molecular Mechanism of Action: Metoclopramide functions as a dopaminergic DA2 receptor competitive antagonist.

Application: Characterization of female fertility and infertility conditions.

Implementation: Evaluation of TSH determinations before and after TRH stimulation. During the same period, PRL may be determined after TRH stimulation in the early follicular phase and after metoclopramide stimulation in the luteal phase.

Human Model: Cases of female infertility (n = 834 women subjected to a TRH stimulation test between 1982 and 1985 in Germany; and n = 759 females subjected to the metoclopramide stimulation test).

Study Design: Cross-sectional study.

Interpretation and Analysis: Thyroid function disturbances can be appreciated in 20% of women evaluated, which is in accordance with the prevalence in South Germany. Postcoital tests are significantly poorer in females with subclinical hypothyroidism than in euthyroid patients. Spontaneous conception is more frequent in euthyroid (16%) than in hypothyroid (6%) conditions. The pregnancy rate is not improved by the administration of dopamine agonists in women with an exaggerated response to TRH or metoclopramide.

Such findings suggest that subclinical hypothyroidism as well as disorders of PRL secretion may play a role in female infertility. The TRH test has been proposed as an approach for ruling out thyroid dysfunction. Neither the TRH nor the metoclopramide test is useful for the prognostic differentiation of PRL secretion disorders.

Thyrotropin-releasing hormone (TRH) and metoclopramide testing in infertile women. Gerhard I, Eggert-Kruse W, Merzoug K, Klinga K, Runnebaum B. Gynecol Endocrinol 1991 Mar; 5 (1), pp. 15–32.

Infertility/Female Fertility/Growth Hormone (GH)/Estradiol/Insulin-Like Growth Factor (IGF)/Prolactin (PRL)/Thyroid-Stimulating Hormone (TSH)
Metoclopramide/Thyrotropin-Releasing Hormone (TRH)

Cellular/Molecular Mechanism of Action: Metoclopramide functions as a dopaminergic DA2 receptor competitive antagonist.
Background Information: The origin of infertility in patients with endometriosis without tubal occlusion has been shown in several reports to be due to abnormal pituitary-ovarian axis in this group of patients. Moreover, PRL and GH secretion is closely related to reproductive status.
Application: Characterization of infertility in women with endometriosis without tubal occlusion.
Implementation: Evaluation of PRL and GH secretion during the early follicular phase. Metoclopramide is administered and blood samples collected at −15, 0, 15, 30, 45, and 60 minutes for the measurement of PRL, GH, estradiol, IGF-I, TSH, and glucose concentrations (insulin measured at −15 and 0 minutes). Existence of a correlation between GH and PRL secretion can then be determined.

Human Model: Cases of normal fertility (n = 22 females) presented with normal serum levels of estradiol, PRL, insulin, fasting glucose, and IGF-I.

Study Design: Cross-sectional study.
Interpretation and Analysis: Serum GH levels are not changed after metoclopramide infusion ($p = 0.302$), but there is a significant alteration in serum PRL ($p = 0.0001$) with the highest levels after 30 (mean: 237.20 ng/ml ± 95.86) and 45 (mean: 211.80 ng/ml ± 83.24) minutes. Serum GH levels do not correlate with serum PRL levels after the dopaminergic DA2 blockade. Therefore, GH secretion is not modulated by a direct effect of Type 2 dopamine receptor.

Growth hormone and prolactin secretion after metoclopramide administration (DA2 receptor blockade) in fertile women. Cunha-Filho JS, Gross JL, Vettori D, Dias EC, Passos EP. Horm Metab Res 2001 Sep; 33 (9), pp. 536–9.

Infertility: Female vs Male/Oocyte Maturity
Follicle-Stimulating Hormone: Purified (pFSH)/Menopausal Gonadotropin

Physiological Mechanism of Action: Promotes maturation of ovarian follicles and subsequent ovulation.
Application: Both pFSH and human menopausal gonadotropin (hMG) can be used in concert with intraplasmic sperm injection to improve the fertilization potential in females experiencing persistent infertility through improved follicle/oocyte maturation.
Route of Administration: Follicle-stimulating hormone (purified).
Dosage: Follicle-stimulating hormone (purified).
Background Information: Intracytoplasmic sperm injection (ICSI) is widely employed today in cases of severe male factor infertility. The technique requires denuding the oocytes from the surrounding granulosa cells prior to sperm injection. One can thus assess oocyte maturity more accurately and can study the effects of various ovarian stimulation protocols on egg maturation and the rest of the parameters of the outcome of ICSI.
Implementation: Evaluation of the influence of ovarian stimulation using hMG compared to that achieved with pFSH.
Interpretation and Analysis: Significantly higher fertilization rate can be appreciated with the administration of pFSH preparations. The parameters of percentage of mature oocytes and pregnancy rate are similar for both pFSH and hMG preparations. Pregnancy rate does not seem to be affected by the gonadotropin preparation employed for ovarian stimulation. Recognition of this consideration has economic implications due to the financial cost of certain gonadotropin preparations and quantities of such products are frequently limited.

A comparative study of the effect of ovarian stimulation protocols with different gonadotropin preparations on the biological and clinical parameters of the outcome of intracytoplasmic sperm injection. Drakakis P, Loutradis D, Kallianidis K, Bletsa R, Milingos S, Dionyssiou-Asteriou A, Michalas S. Clin Exp Obstet Gynecol 2002; 29 (4), pp. 286–9.

Infertility: Male/Spermatozoa Fertilization Potential
Hemizona Assay

Application: Prediction of the fertilization potential of domestic animal and human spermatozoa. Theoretically, the analysis assay would also be of value to exotic animal breeding programs in zoo wildlife refuge impoundments.
Validation Investigations: Evaluation of spermatozoa fertilization potential (e.g., equine) can be established by obtaining equine ovarian oocytes collected immediately postmortem or by ultrasound-guided follicle aspiration. Oocytes are then denuded from cumulus cells and stored in salt solution at 4°C prior to use. Oocytes are then bisected to provide 2 equal matching hemizonae from each oocyte. Semen samples from cases with known fertility data are then used to assess the number of spermatozoa bound to the outer surface of the hemizona after *in vitro* incubation. Sperm binding to matching hemizonae of a particular individual (e.g., stallion) has been found to be similar and corresponds to results observed with the hemizona assay. In horses, spermatozoa hemizona binding capacity of 10 pairs of stallions has been compared by incubating 1 hemizona with the semen of a stallion and the matching hemizona with the semen of another stallion from the same stud farm. Applying 5 matching pairs of hemizonae for each pair of stallions, it can be observed that there is a significant relationship between the mean number of spermatozoa bound to matching hemizonae and stallion fertility indices from each stud farm ($p < 0.0001$).
Interpretation and Analysis: The hemizona assay can be used as a valuable diagnostic tool in analyzing the quality and function of spermatozoa.

Testicular Function/Cryptorchidism (Unilateral or Bilateral) vs Unilateral or Bilateral Castration/Aggressive Cryptorchid Behavior
Human Chorionic Gonadotropin (hCG)

Cellular/Molecular Mechanism of Action: Human chorionic gonadotropin induces synthesis and release of testosterone from testicular Leydig cells.
Application: Detection of conditions of cryptorchidism (unilateral or bilateral) when it is uncertain if cases may actually be normal but have previously been subjected to bilaterial or unilateral castration.
Background Information: Horses with cryptorchidism tend to be ill-tempered. Sometimes insufficient history is available to know if a horse has or has not been previously castrated (e.g., non-castrated cryptorchid vs unilateral castration).
Considerations: Horses less than 3 years of age and all donkeys cannot be evaluated using a single measurement of (resting) blood

esterone sulfate for the purpose of detecting conditions of cryptorchidism.

Route of Administration: Human chorionic gonadotropin (intravenous injection).

Dosage: Intravenous injection of hCG at a dosage of 6,000 IU per 450 kg with blood sample collected prior to and 30 to 120 minutes after injection.

Implementation: Detection of conditions of unilateral or bilateral cryptorchidism by measuring increases in serum testosterone levels induced by hCG administration compared to preinjection concentrations.

Interpretation and Analysis: Cryptorchid patients have basal systemic esterone sulfate concentrations in excess of 400 pg/ml. Alternatively, in situations where the esterone sulfate assay is not an appropriate diagnostic approach, the administration of hCG will induce increases in blood testosterone levels. Prior to hCG administration, cryptorchid cases will have resting testosterone levels in excess of 100 pg/ml, whereas horses not affected by cryptorchidism will have resting testosterone concentrations below 40 pg/ml that will not change following hCG administration.

Laboratory Instrumentation: Assay of either growth hormone (GH) concentrations by either radioimmunoassay (RIA) or ELISA.

Cryptorchidism. Cox JE (pp. 571–3). Current Therapy in Equine Medicine 2, ed Robinson NE. WB Saunders, Philadelphia (Copyright 1987).

Is human chorionic gonadotropin useful for identifying and treating nonpalpable testis? Bukowski TP, Sedberry S, Richardson B. J Urol 2001 Jan; 165 (1), pp. 221–3.

10 Renal and Urinary Systems

Anuria/Oligouria
Dopamine

Cellular/Molecular Mechanism of Action: Promotes direct dilation of the renal artery, thereby increasing renal perfusion.
Diagnostic Application: Detection of acute oliguria or anuria associated with hypoxia resulting from decreased renal perfusion as occurs with hypotensive (e.g., endotoxic) shock. Initially, patients suspected of being oliguric or anuric are administered polyionic intravenous fluids. If urine production is not appreciated, the 2nd phase of diagnostic evaluation entails the administration of 1 to 2 doses of furosemide. Failure to produce urine after furosemide administration implies the necessity to evaluate the potential for renal urine production with dopamine in stage 3 of the diagnostic procedure.
Route of Administration and Dosage: Administered as a slow drip diluted in 5% sterile dextrose. In potentially oliguric and anuric patients, dopamine is administered intravenously at a rate of between 1 to 5 μg/kg/min, thereby directly promoting vasodilation of the renal artery. Administration of dopamine at dose rates greater than 5 μg/kg/min results in renal artery vasoconstriction. Heart rate and abdominal discomfort should be monitored closely.
Considerations: Due to the adrenergic (sympathetic) properties of dopamine, gastrointestinal ileus and possibly physical (feed-related) obstruction of the gastrointestinal tract may be experienced. Dietary management can often assist in reducing the severity and risk of such sequela (e.g., equine).
Interpretation and Analysis: Absence of urine production following administration suggests the presence of oliguria or anuria condition that may be temporary or permanent in duration.
Laboratory Instrumentation: Not applicable.

Anuria/Oligouria/Severity in Acute Renal Failure: Reversible/Non-Reversible
Furosemide (Lasix)/Bumetanide

Cellular/Molecular Mechanism of Action: Furosemide is a classic potassium-wasting "loop diuretic" that inhibits electrolyte reabsorption primarily in the "thick" ascending region of the loop of Henle. Perfusion of blood within the kidney is increased but the filtration rate remains essentially unchanged. This latter phenomenon is most prominent when furosemide is administered intravenously. Furosemide also weakly inhibits carbonic anhydrase and promotes vasodilation in part through induction of prostacyclin (PGI_2) synthesis.
Physiological Mechanism of Action: Bumetanide is a potent, rapid-acting loop diuretic (potency 40 > furosemide) applied to determine the severity of acute renal failure.
Diagnostic Application: Detection of acute oliguria or anuria associated with hypoxia resulting from decreased renal perfusion as occurs with hypotensive (e.g., endotoxic) shock or other forms of acute renal failure. Initially, patients suspected of being oliguric or anuric are administered intravenous polyionic fluids. If urine production is not appreciated, the 2nd phase of diagnostic evaluation entails the administration of 1 to 2 doses of furosemide. Failure to produce urine after furosemide administration implies the necessity to evaluate the potential for renal urine production with dopamine in stage 3 of the diagnostic procedure.
Route of Administration and Dosage: Intravenous and/or intramuscular injection of standard dose normally applied to induce diuresis.
Considerations: Lasix is a potassium-wasting diuretic.
Interpretation and Analysis: Urinary output should occur within 30 minutes of intravenous injection. Absence of urine production during this time period implies the presence of profound renal dysfunction.
Laboratory Instrumentation: Not applicable.

Biochemical Metabolism: Cortisol/11β-HSD2 Biochemical Activity
Deuterium-Labeled Cortisol

Cellular/Molecular Mechanism of Action: Deuterium-labeled cortisol is an analog of endogenous cortosol.
Application: Deuterium-labeled cortisol can be used as a labeled marker molecule for assessing *in vivo* alterations in endogenous cortisol metabolism mediated by 11β-HSD2 activities based on urinary excretion of cortisol, cortisone, and their A-ring reduced metabolites.
Route of Administration: Deuterium-labeled cortisol (oral).
Implementation: Evaluation of cortisol metabolism determined through the measurement of deuterium-labeled cortisol and its deuterium-labeled metabolites. Sample evaluation involves the application of GC/MS analyses simultaneously with the detection of endogenous cortisol, cortisone, and their A-ring reduced metabolites.
Human Model: Normal cases without evidence of disease.
Interpretation and Analysis: The stable isotope approach offers unique advantages in assessing the appropriateness of measuring unconjugated and total (unconjugated + conjugated) cortisol, cortisone, and their A-ring reduced metabolites in urine as indices of renal 11β-HSD2 activity. Measurement of urinary unconjugated cortisol and cortisone has many advantages for assessing 11β-HSD2 activity.
Instrumentation: Integrated gas chromatography/mass spectrometry system.

The use of deuterium-labeled cortisol for *in vivo* evaluation of renal 11β-HSD activity in man: Urinary excretion of cortisol, cortisone and their A-ring reduced metabolites. Kasuya Y, Shibasaki H, Furuta T. Steroids 2000 Feb; 65 (2), pp. 89–97.

Biochemical Metabolism: Hydroxylation Capacity
Phenylalanine

Cellular/Molecular Mechanism of Action: Phenylalanine is metabolized in the kidney to a hydroxylated analog.
Background Information: Although phenylalanine hydroxylase activity is detectable in *in vitro* renal tissue preparations, minimal

knowledge exists regarding *in vivo* phenylalanine hydroxylation across the human kidney or the possible contribution of the kidney to whole-body hydroxylation.

Application: Evaluation of renal hydroxylation capacity.

Implementation: Evaluate measurements of whole-body, renal, and splanchnic hydroxylation of phenylalanine to tyrosine, as well as phenylalanine and tyrosine rates of appearance (Ra) and disposal (Rd), in postabsorptive states by means of renal and splanchnic arteriovenous catheterization combined with phenylalanine and tyrosine isotope infusions.

Interpretation and Analysis: In the kidney, relevant phenylalanine hydroxylation activity can be detected (3.51 ± 0.97 μmol/min $\times$ 1.73 m^2 of body surface), whereas it is 2.48 ± 1.35 μmol/min $\times$ 1.73 m^2 across the splanchnic area. These 2 sites together account for virtually the entire whole-body phenylalanine hydroxylation capacity. Renal production of tyrosine from phenylalanine hydroxylation accounts for approximately 13% of whole-body tyrosine Ra, whereas renal total tyrosine Ra accounts for approximately 34% of whole-body tyrosine Ra. In the splanchnic area, these figures are approximately 9% and 40%, respectively. Hydroxylation accounts for approximately 70% of phenylalanine Rd in the kidney, as opposed to approximately 8% in the splanchnic area.

Phenylalanine hydroxylation across the kidney in humans rapid communication. Tessari P, Deferrari G, Robaudo C, Vettore M, Pastorino N, De Biasi L, Garibotto G. Kidney Int 1999 Dec; 56 (6), pp. 2168–72.

Detrusor Contractions: Spontaneous/Urinary Frequency Secondary to Benign Prostatic Obstruction

Adenosine Triphosphate (ATP)-Sensitive Potassium Channel Openers (KCOs)/A-278637 (Dihydropyridine Analog)/ZD6169 WAY-133537

Cellular/Molecular Mechanism of Action: Adenosine triphosphate–sensitive potassium channel openers.

Physiological Mechanism of Action: Relaxation of involuntary detrusor contractions.

Application: Characterization of male urinary frequency/urgency.

Route of Administration: Oral (rat).

Dosage: ZD6169 (10 μmol/kg) and A-278637 (3 μmol/kg).

Considerations: Symptoms of urinary frequency and urgency secondary to benign prostatic obstruction are common in elderly men. In many patients, these symptoms correspond to the urodynamic finding of involuntary detrusor contractions during filling cystometry (i.e., detrusor instability). Spontaneous non-voiding contractions during filling can be modeled in animals by subchronic, partial urethral obstruction. However, many investigators remove the obstructive ligature a few days prior to cystometrical evaluation (which may not be an ideal representation of the clinical situation where obstruction is still present), and all perform cystometry within 3 days post-bladder catheterization surgery (i.e., while considerable wound healing is present).

Implementation: Evaluation of structurally diverse ATP-sensitive KCOs ($n = 3$) for their ability to influence spontaneous detrusor contractions secondary to obstruction with an intact obstructive ligature at the time of testing and 2 weeks post–bladder catheterization.

Animal Model: Rats.

Interpretation and Analysis: The agents ZD6169, WAY-133537, and the novel dihydropyridine KCO, A-278637, all significantly decrease spontaneous bladder contractions at 30 minutes post-dosing (p.o.). However, only ZD6169 (10 μmol/kg) and A-278637 (3 μmol/kg) attenuate such bladder contractions at doses that concurrently do not significantly affect mean arterial blood pressure and heart rate. These data confirm the efficacy of KCOs to inhibit unstable contractions in obstructed rats, and they further demonstrate the positive effect of the bladder-selective KCO, A-278637, in an animal model with potentially less artifact than observed in previous animal models.

K-ATP opener-mediated attenuation of spontaneous bladder contractions in ligature-intact, partial bladder outlet obstructed rats. Lynch JJ 3rd, Brune ME, Lubbers NL, Coghlan MJ, Cox BF, Polakowski JS, King LL, Sullivan JP, Brioni JD. Life Sci 2003 Mar 14; 72 (17), pp. 1931–41.

Effective Renal Plasma Flow (ERPF)

Paraaminohippuric Acid/[^{131}I]-Iodohippurate

Cellular/Molecular Mechanism of Action: Hippuric acid perfuses through the glomerular apparatus, thereby becoming a constituent within the plasma filtrate. Within the renal tubule, hippuric acid is reabsorbed from the glomerular filtrate.

Diagnostic Application: Determination of the relative level of effective renal plasma flow (ERPF) in disease conditions. The agent does not per se selectively evaluate renal tubular function. Various forms of hippuric acid can be used to evaluate the potentially renal toxic properties associated with new candidate pharmaceutical agents or injury precipitated during the course of disease.

Route of Administration: Intravenous administration only.

Implementation: Evaluation of renal glomerular function by measuring plasma clearance of the radiolabeled marker molecules.

Interpretation and Analysis: Estimates of ERPF using [^{131}I]-iodohippurate are slightly higher than values obtained using [^{14}C]-inulin and [^{3}H]-tetraethylammonium. Estimates of ERPF in cats are lower than those observed in dogs. [^{125}I]-iothalamate has also been used to measure estimated glomerular filtration rate (GFR). Note: Filtration fraction = GF/ERPF.

Concentration measured as a function of spectrophotometric absorbance [^{123}I]-ortho-iodohippuric acid. Prévot A, Mosig D, Martini S, Guignard JP. Pediatr Res 2004 Feb; 55 (2), pp. 254–60.

Evaluation of renal function in transplant patients on tacrolimus therapy. Agarwala S, Culligan E, Jain A, McCauley J, Shapiro R, Chakrabarti P, Burckart G, Venkataramanan R. J Clin Pharmacol 2002 Jul; 42 (7), pp. 798–805.

Effective Renal Plasma Flow (ERPF)

Hippurate/Benzoate Metabolite/[^{14}C]Hippurate/[^{3}H]Hippurate/[^{14}C]Benzoate

Cellular/Molecular Mechanism of Action: Hippurate functions as a passive tracer/marker molecular that is compatible with *in vivo* living systems.

Application: Assessment of effective renal plasma flow.

Implementation: Evaluation of the relative extent of excretion for [^{14}C]hippurate and [^{3}H]hippurate utilizing a single-pass flow through the kidney.

***Ex Vivo* Model:** Rat (isolated kidney preparation perfused at 8 ml/min containing tracer concentrations of [^{14}C]benzoate and [3H]hippurate).

Interpretation and Analysis: The steady state renal extraction ratio of [^{14}C]benzoate is 0.26 ± 0.04 and is associated with a renal clearance of 1.13 ± 0.17 ml/min/g. The urinary clearance of [^{14}C]benzoic acid is low (0.011 ± 0.01 ml/min/g), yielding a low fractional excretion (unbound urinary clearance/glomerular filtration rate [GFR}) value of 0.27 ± 0.19 and suggesting that glycination of [^{14}C]benzoate to [^{14}C]hippurate accounts almost completely for the

total renal clearance. Fractional excretion for preformed [^{3}H]hippurate is 8 times that of GFR, but the steady state renal extraction ratio of preformed [^{3}H]hippurate, E_{pmi} (0.24 ± 0.05) is much lower than the apparent extraction ratio of the renally formed [^{14}C]hippuric acid [E_{mi} = 0.39 ± 0.09] ($p < 0.05$). The theoretical basis for the discrepancy can be explored with mathematical formulations developed from a physiologically based model of the kidney. It has been found that parent drug kinetic parameters (transport and metabolic intrinsic clearance of benzoate) are unimportant for E_{mi} or E_{pmi}. Rather, the value of EK_{mi} exceeds EK_{pmi} because the ratio of efflux clearances at the basolateral and luminal membranes for hippurate (corrected) is less than 26.089, a value determined by the GFR, plasma renal flow, and the unbound fraction of hippurate of the system that would render E_{mi} to equal E_{pmi} in the system. The influx clearance for hippurate to enter from plasma to cell at the basolateral membrane and the reabsorption clearance of hippurate to enter from tubular urine to cell at the luminal membrane fails to alter the ratio of EK_{pmi}/EK_{mi}. Note: Filtration fraction = GF/ERPF.

Differences in excretion of hippurate, as a metabolite of benzoate and as an administered species, in the single-pass isolated perfused rat kidney explained. Geng W, Pang KS. J Pharmacol Exp Ther] 1999 Feb; 288 (2), pp. 597–606.

Glomerular Filtration
Creatinine Clearance

Cellular/Molecular Mechanism of Action: Creatinine is a substance that is endogenously synthesized by muscle tissue (myocytes). Creatinine in the intravascular compartment is excreted by glomerular filtration.

Diagnostic Application: The rate at which creatinine is cleared from the intravascular compartment can be utilized to estimate the rate of glomerular filtration (GFR). It is often used to diagnose renal disease in patients with normal blood urea nitrogen (BUN) and serum creatinine concentrations. Inulin can also be used to evaluate GFR in addition to [^{51}Cr] ethylene-diamine-tetra-acetic acid (EDTA) and [^{99m}Tc]-diethylenetriamine pentaacetic acid (DTPA).

Route of Administration: Subcutaneous.

Considerations: Tubular secretion of creatinine (in dogs) can lead to an overestimation of GFR of ≤ 25%. The influence of tubular creatinine secretion on U_{cr} is compensated for by non-creatinine chromagens on P_{cr} that makes this measurement an effective diagnostic approach.

Interpretation and Analysis: Endogenous creatinine clearence in the dog and cat is approximately 2–5 ml/min/kg. Results often approximate those recognized for inulin clearance tests.

Glomerular Filtration
Inulin Excretion Test/Iohexol

Cellular/Molecular Mechanism of Action: Inulin and iohexol per se do not exert any significant molecular or cellular mechanism of action.

Application: Iohexol and inulin can be used simultaneously to calculate estimates of glomerular filtration rate (GFR) as can inulin, [^{51}Cr] ethylene-diamine-tetra-acetic acid (EDTA), and [^{99m}Tc]-diethylenetriamine pentaacetic acid (DTPA).

Route of Administration: Inulin and iohexol can be applied as inert molecular tracer molecules for the purpose of estimating GFR.

Implementation: Measurement and estimation of GFR using a single injection inulin methodology. The total clearance can be calculated from the decay of serum inulin concentrations after injection of 3,000 mg/m^2 body surface area using a 2-compartment model.

Animal Model: Feline (n = 53 young healthy adults; n = 23 > 10 years or near abnormal serum creatinine).

Interpretation and Analysis: Concomitant inulin and iohexol clearance can potentially show excellent correlation with 1 another (e.g., n = 9 cats). Calculated normal values for GFR are 35.9–58.5 (median 46.0) ml/min/m^2 or 2.07–3.69 (median 2.72) ml/min/kg (e.g., n = 30/50 cats). Some cases with normal creatinine or blood urea nitrogen levels can have reduced GFR and therefore may be in a state of early renal dysfunction. Studies indicate that single-injection inulin clearance is a valuable tool for routine GFR measurements in cats. An "inulin excretion test" using only 1 blood sample 3 hours after the administration of 3,000 mg/m^2 body surface area can be a viable alternative for assessing renal function in daily practice.

Single-injection inulin clearance for routine measurement of glomerular filtration rate in cats. Haller M, Rohner K, Müller W, Reutter F, Binder H, Estelberger W, Arnold P. J Feline Med Surg 2003 Jun; 5 (3), pp. 175–81.

Glomerular Filtration
Iohexol/Exogenous Creatinine Clearance

Application: Analysis of the pharmacokinetic profile for iohexol to estimate glomerular filtration rate (GFR). Inulin can also be used to evaluate GFR, in addition to [^{51}Cr] ethylene-diamine-tetra-acetic acid (EDTA) and [^{99m}Tc]-diethylenetriamine pentaacetic acid (DTPA).

Route of Administration: Iohexol (intravenous). If creatinine is administered in the same animal it can be given 1 hour following iohexol (s.c. in 3 approximately equal amounts on the side under the skin near the axilla, pectoral area, and caudolateral to the withers followed 25 minutes later by the administration of the remaining 35% injected at the same sites on the contralateral side of the animal).

Dosage: Iohexol (150 mg/kg/30 seconds). Creatinine is administered as a solution (1 g/12 ml sterile LRS; final concentration = 80 mg/ml) at a dose of 60 mg/kg.

Implementation: Delineation of the pharmacokinetic profile of iohexol following a single injection and measurement of concentrations in blood samples collected at 5, 20, 40, 60, 120, 180, 240, and 360 minutes. High-pressure liquid chromatography is then used as an analysis technique for the measurement of serum iohexol concentrations (Shihabi et al and Finco et al). Exogenous creatinine can be administered as a reference control for the measurement of creatinine clearance parameters.

The bladder is evacuated and urine samples collected serially for analysis in a manner that chronologically parallels the collection of serum samples.

Animal Model: Equine (foals n = 10).

Interpretation and Analysis: Serum iohexol concentrations best display a 3-compartment open model. Comparison of calculated values from the model can then be made with creatinine clearance measurements. Separate limited-sample models can be created with various combinations of sample times from the terminal slope of the plasma vs time profile for iohexol. Mean exogenous creatinine clearance is 2.17 mL/min/kg, while the mean value for iohexol is 2.15 mL/min/kg, which is not significantly different from mean creatinine clearance. Iohexol can therefore be applied to predict exogenous creatinine clearance and can be determined from 2 blood samples taken after a single intravenous injection. Appropriate correction factors for adult horses and horses with abnormal glomerular filtration rate need to be determined.

Evaluation of iohexol clearance used to estimate glomerular filtration rate in clinically normal foals. Gonda KC, Wilcke JR, Crisman MV, Ward DL, Robertson JL, Finco DR, Braselton E. Am J Vet Res 64; 12, pp. 1486–90.

Iohexol determination by direct injection of serum on the HPLC column. Shihabi ZK, Thompson EN, Constantinescu MS. J Liquid Chromatogr 1993; 16, pp. 1289–96.

Relationship between plasma iohexol clearance and urinary exogenous creatinine clearance in dogs. J Vet Intern Med 2001; 15, pp. 368–73.

Glomerular Filtration/Neonatal Renal Function
β-2-Microglobulin

Cellular/Molecular Mechanism of Action: Excreted by glomerular filtration.

Application: Assessment of glomerular filtration rate (GFR) as an alternative or complementary test to radioisotopic filtration and creatinine/blood urea nitrogen (BUN) measurements.

Considerations: The protein β-2-microglobulin can be labeled/radiolabeled with an appropriate marker system for application as a radiobiopharmaceutical agent designed to assess elimination/clearance by glomerular filtration.

Route of Administration: Intravenous.

Implementation: Evaluation of renal function utilizing a panel of analysis procedures including standard tests for estimating BUN, serum creatinine, blood pH, serum bicarbonate, serum and urinary electrolytes, urine output, and urinalysis. Urinary β-2-microglobulin levels are estimated from urine collected on day 1 and day 3 (e.g., all neonates) and on day 7 (n = 18 neonates) applying radioimmunoassay methodologies.

Human Model: Term "sick" neonates (n = 46 cases) transferred for neonatal care compared to healthy term neonates (n = 40 reference control cases).

Interpretation and Analysis: Statistically significant elevations of mean urinary β-2-microglobulin concentrations can be appreciated in sick neonates compared to normal controls irrespective of primary disease, indicating tubular dysfunction (41/46 = 90%). Approximately 15% (e.g., n = 7/46) may have abnormalities indicative of renal involvement when judged by standard tests. Very high levels of urinary β-2-microglobulin can be detected in conditions of birth asphyxia (e.g., n = 9), sepsis (e.g., n = 8), and renal disease (e.g., n = 7). Transient elevation of urinary β-2-microglobulin can be noted in meconium aspiration syndrome (e.g., n = 4).

Some surgical cases with non-renal congenital malformations (e.g., n = 10) may show high urinary β-2-microglobulin, while a relatively large percent of cases (e.g., n = 12/18 or 67%) tested on day 7 have persistently high urinary β-2-microglobulin due to multiple factors.

Elevated urinary β-2-microglobulin may be detected in approximately 90% of sick neonates with apparently normal renal parameters (e.g., n = 34/41), which indicates the presence of subclinical proximal tubular dysfunction, especially in neonates with asphyxia, sepsis, and congenital malformations. Persistent elevations of urinary β-2-microglobulin appears to be a sensitive diagnostic indicator for defining a group of neonates with subtle renal tubular dysfunction. Serum β-2-microglobulin is a simple, economical, specific, sensitive, and accurate test for assessing glomerular filtration. It is superior to radioisotopic GFR, serum creatinine, and BUN.

Renal dysfunction detected by β-2 microglobulinuria in sick neonates. Mehta KP, Ali US, Shankar L, Tirthani D, Ambadekar M. Indian Pediatr 1997 Feb; 34 (2), pp. 107–11.

Glomerular Filtration
Creatinine/Cystatin C/Sodium Thiosulfate

Cellular/Molecular Mechanism of Action: Creatinine enters the urinary filtrate at the level of the renal glomerulus. Once creatinine enters the plasma/urinary filtrate, its concentration is not affected by renal tubular transport mechanisms. Passive filtration of creatinine into the plasma/urinary filtrate is the major route and rate-limiting step by which the compound is eliminated from the intravascular compartment.

Application: Creatinine, cystatin C, and sodium thiosulfate can be utilized to evaluate glomerular filtration parameters.

Implementation: Evaluate the reliability and efficacy of serum cystatin C measurements for the estimation of glomerular filtration rate (GFR). Complementary analysis can include the evaluation of 24-hour creatinine clearance (24-hour C(Cr)) and performance of a standard sodium thiosulfate clearance test (C(Thio)) within a week of blood sample collection.

Human Model: Cases of renal disease (n = 212).

Interpretation and Analysis: Serum cystatin C concentrations determined by a particle-enhanced immunonephelometry method. C(Thio) and 1/cystatin C, 24-hour C(Cr), 1/β-2-microglobulin, and 1/creatinine are well correlated. The correlation coefficients for C(Thio) obtained by 24-hour C(Cr) and 1/cystatin C are comparable to each other (0.701 vs 0.679). Receiver-operated characteristic (ROC) analysis reveals that 24-hour C(Cr) shows the highest area under the curve when C(Thio) = 60 ml/min or C(Thio) = 100 ml/min are applied as the discrimination point. However, the ROC value obtained by cystatin C is slightly greater than 24 hours C(Cr) when C(Thio) = 80 ml/min is used as the discrimination point. Patient age, gender, glucose tolerance, presence of proteinuria, systemic inflammation, lupus, or systemic use of steroids do not interfere in the relationship between C(Thio) and 1/cystatin C. Serum cystatin C measurement is an excellent diagnostic test for detecting conditions of subclinical renal dysfunction.

Serum cystatin C reliably detects renal dysfunction in patients with various renal diseases. Kazama JJ, Kutsuwada K, Ataka K, Maruyama H, Gejyo F. Nephron 2002 May; 91 (1), pp. 13–20.

Glomerular Filtration Rate (GFR): Chronic Renal Failure
Creatinine Clearance/[^{99m}Tc]-Diethylenetriamine Pentaacetic Acid (DTPA)

Cellular/Molecular Mechanism of Action: Creatinine and DTPA when applied to measure GFR do not per se exert a molecular or cellular mechanisms of action. Instead, they function as molecular tracers that are passively excreted into the urinary plasma filtrate.

Application: Creatinine and DTPA in the form of [^{99m}Tc]-DTPA can both be applied to estimate renal GFR. In this context, [^{99m}Tc]-DTPA can be detected externally by scintigraphy methods, while progressive declines in intravascular compartment creatinine concentrations can be measured directly within plasma samples.

Estimation of changes in glomerular filtration can be evaluated in the assessment of conditions like chronic renal failure where parameters are compared to reference controls. Additionally, methodologies can enhance the accuracy of the captorpril test. Accuracy of the original method is improved by replacing the Tonnesen formula that estimates renal depth with direct measurement from lateral views to calculate tissue attenuation correction.

Route of Administration: Intravascular.

Implementation: Evaluation of GFR estimated through the implementation of a computerized version of the Gates' method for calculating radionuclide glomerular filtration rate (RGFR). In this context, the creatinine clearance test (CCT) and dynamic [^{99m}Tc]-DTPA renal scintigraphy (DRS) can be used to estimate renal GFR. Renal GFR is quantified from the attenuation-corrected absolute DTPA uptake for kidneys on DRS between 120 and 180 seconds after injection. Attenuation correction is estimated using lateral views of the kidneys taking into account the distance from the computed geometric center of the kidneys to the posterior body surface along a line vertical to the collimator surface. Creatinine clearance and GFR estimates from DRS are then compared by linear regression.

Human Model: Conditions of chronic renal failure (n = 38).

Interpretation and Analysis: Radionuclide GFR estimates agree well with CCT, yielding a correlation coefficient of 0.92 (e.g., n = 38 cases) and 0.90 (e.g., n = 11, case subgroup suffering from chronic renal failure). Modifications can be made to improve the accuracy of RGFR estimates to the precision range of blood sample–based methods. This modified method requires little additional work and no extra cost in patients undergoing DRS. Calculation of RGFR may be advantageous in cases when 24-hour urine collection for CCT cannot be obtained, and it should improve the accuracy of the captopril test.

Renal depth estimates to improve the accuracy of glomerular filtration rate. Steinmetz AP, Zwas ST, Macadziob S, Rotemberg G, Shrem Y. J Nucl Med 1998 Oct; 39 (10), pp. 1822–29.

Glomerular Filtration Rate (GFR) *Creatinine (Exogenous)/[^{14}C]-Inulin/Iothalamate*

Cellular/Molecular Mechanism of Action: Creatinine, iothalamate, and [^{14}C]-inulin are passively excreted into the urine/ plasma filtrate. In this context, plasma creatinine enters the urinary filtrate after passing across membranes of the renal glomerulus. Once creatinine enters the plasma/urinary filtrate, its concentration is not affected by renal tubular transport mechanisms. Passive filtration of creatinine into the plasma/urinary filtrate is the major route and rate-limiting step by which the compound is eliminated from the intravascular compartment.

Physiological Mechanism of Action: Estimation of renal GFR.

Application: Assessment of GFR in a manner similar to the applications of [^{51}Cr] ethylene-diamine-tetra-acetic acid (EDTA) and [^{99m}Tc]-diethylenetriamine pentaacetic acid (DTPA).

Route of Administration: Creatinine (intravenous); iothalamate (intravenous); [^{14}C]-inulin (intravenous).

Dosage: Creatinine (exogenous at 40, 80, and 160 mg/kg).

Implementation: Evaluate the capacity of creatinine plasma clearance to accurately assess GFR in dogs. Experimental Protocol #1: Determintion of 24-hour urine clearance of endogenous creatinine, plasma, and urine clearances of exogenous creatinine administered in a crossover design (linearity study), plasma iothalamate clearance, and plasma and urine clearances of [^{14}C]-inulin. Experimental Protocol #2: Plasma creatinine and iothalamate clearances are compared, and a linearity study performed analogous to that applied for Protocol #1 with surgically induced renal impairment. Experimental Protocol #3: compare plasma creatinine clearance with plasma iothalamate clearance before and 3 weeks after induction of moderate renal impairment. Plasma creatinine clearances are calculated by both non-compartmental and compartmental analyses.

Animal Model: Canine (n = 6 healthy dogs/research protocol).

Interpretation and Analysis: In Protocol #1, plasma inulin clearance is higher ($p < 0.001$) than other clearance values. Plasma creatinine clearances at the 3 dose rates do not differ from urine inulin clearance and each other. In Protocol #2, plasma creatinine clearances are about 14% lower than plasma iothalamate clearance ($p < 0.05$). In Protocol #3, decreases in GFR assessed by plasma clearances of iothalamate and creatinine are similar. Renal failure decreases the daily endogenous input rate of creatinine by 25%. Limiting sampling strategies for optimizing GFR calculation have been designed in a manner that allows an error lower than 6.5% with the collection of only 4 blood samples. Determination of plasma creatinine clearance by a non-compartmental approach offers a reliable, inexpensive, rapid, and convenient means of estimating GFR in routine practice.

Plasma exogenous creatinine clearance test in dogs: Comparison with other methods and proposed limited sampling strategy. Watson AD, Lefebvre HP, Concordet D, Laroute V, Ferré JP, Braun JP, Conchou F, Toutain PL. J Vet Intern Med 2002 Jan–Feb; 16 (1), pp. 22–33.

Glomerular Filtration Rate (GFR) *[^{131}I]-Iothalamate/Serum Creatinine [Cockcroft-Gault Formula]*

Cellular/Molecular Mechanism of Action: [^{131}I]-Iothalamate in the plasma enters the urinary filtrate after passing across membranes of the renal glomerulus. Once it enters the plasma/urinary filtrate, its concentrations are not affected by renal tubular transport mechanisms. Passive filtration of [^{131}I]-iothalamate is the rate-limiting step in the elimination of this compound from the intravascular compartment.

Application: Evaluation and characterization of renal excretory function.

Route of Administration: [^{131}I]-iothalamate (intravascular).

Implementation: Assessment of the degree of association between renal function and frequent nighttime urination in older adults. One approach to identifying any such correlation can involve utilization of a 3-day examination period employing 3 GFR measurements. Relevant examples include an estimation of serum creatinine using the Cockcroft-Gault formula, a calculation using 24-hour urine volume, and a determination by [^{131}I]-iothalamate clearance.

Human Model: Cases of advanced age (n = 48; ≥ 65 years old; n = 45/48 completed a 7-day voiding record and were restricted to eating a research diet for 4 days).

Interpretation and Analysis: Cases with frequent nighttime voiding, defined as a mean of 2 or more voiding episodes from 11 P.M. to 7 A.M., have slightly lower but statistically similar GFR measurements than those with a mean of less than 2 nighttime voids. The glomerular filtration rate does not correlate with the number of nighttime voids (Pearson correlation coefficient −0.006, p = 0.971). Mean 24-hour urine output is similar in the 2 groups and the correlation of the number of nighttime voids with 24-hour urine output is insignificant (Pearson correlation coefficient −0.06, p = 0.683). A greater number of nighttime voids is associated with producing more urine at night and smaller mean voided volume. As determined by a gold standard GFR measurement, renal function does not appear to be associated with the number of nighttime voids. Total 24-hour urine output is also not associated with the number of nighttime voids. Such findings confirm the positive association of a greater number of nighttime voids with greater nighttime urine production and lower bladder voided volume.

A prospective evaluation of the glomerular filtration rate in older adults with frequent nighttime urination. Johnson TM 2nd, Sands JM, Ouslander JG. J Urol 2002 Jan; 167 (1), pp. 146–50.

Glomerular Filtration Rate (GFR)/Hepatic Substrate Metabolism/Hepatic Substrate Clearance
Toborinone Pharmacokinetics/Iothalamate/ Caffeine/Indocyanine Green (ICG)

Cellular/Molecular Mechanism of Action: Caffeine is a substrate for hepatic cytochrome P450 1A2 (CYP1A2) and the biochemical activity of this enzyme system yields a metabolite that can be measured or quantified. Indocyanine green is not metabolized by the liver but instead is removed from the intravascular compartment by hepatocytes and eliminated in the bile. Iothalamate is simply eliminated from the intravascular compartment by passive mechanisms of glomerular filtration and excreted in the urinary filtrate.
Application: Plasma clearance of iothalamate can be used to evaluate glomerular filtration. Caffeine metabolism is useful as a molecular probe for evaluating hepatic metabolic capacity, while ICG can serve as a marker molecule for characterizing hepatic clearance parameters.
Implementation: Evaluation of the GRF using iothalamate clearance. Hepatic function is assessed by utilizing the caffeine metabolism test and determining ICG clearance.

Human Model: Delineation of the pharmacokinetic profile of toborinone in cases of congestive heart failure (CHF) complicated by concomitant renal and/or hepatic disease. Cases are grouped based on estimated creatinine clearance and serum bilirubin concentrations.
Interpretation and Analysis: No significant differences can be observed for mean toborinone pharmacokinetic parameters among the 4 study groups. Positive correlations can be appreciated between toborinone clearance and measured indices for renal and hepatic function: creatinine clearance, iothalamate renal clearance, paraxanthine/caffeine ratio, and ICG clearance. Toborinone clearance decreases with decreasing creatinine clearance, decreasing GFR, decreasing demethylation metabolic activity, and decreasing hepatic blood flow, although no significant differences can be observed in any mean toborinone pharmacokinetic parameters evaluated among the 4 study groups.

The pharmacokinetics of toborinone in subjects with congestive heart failure and concomitant renal impairment and/or concomitant hepatic impairment. Tammara B, Trang JM, Kitani M, Miyamoto G, Bramer SL. J Clin Pharmacol 2002 Dec; 42 (12), pp. 1318–25.

Glomerular Filtration Rate (GFR) ($<$ 20 ml/min)/ [Plasma/Renal Clearance]
Iohexol

Cellular/Molecular Mechanism of Action: Iohexol is an iodinated organic molecule that when used to estimate glomerular filtration rate does not per se exert a cellular or molecular mechanism of action. Instead, it functions as a passive marker or tracer molecule.
Application: Iohexol can be applied as a passive marker/tracer compound for measuring or estimating glomerular filtration, plasma clearance, and renal clearance.
Route of Administration: Iohexol (intravenous).
Dosage: Iohexol (10 ml; 300 mg iodine/ml).
Implementation: Evaluation of iohexol (non-ionic low-osmolar contrast medium) as a molecular marker for measuring GFR. Simultaneous determinations of renal clearance and plasma clearance, both as slope clearance and single sample clearance, are performed after intravenous injection of iohexol. Plasma samples are collected early (around 3 hours) and late (up to 24 hours) after injection. Urine is collected during 4 40-minute periods (Case Group I) and during 1 3-hour period (Case Group II along with estimation of residual urine by ultrasound). Plasma and urine iodine concentrations are analyzed by x-ray fluorescence. Tubular function test and S-creatinine are monitored to detect signs of nephrotoxicity. Iohexol is injected to assess extrarenal clearance in anuric cases (e.g., n = 6 Case Group III).

Human Model: Cases with stable renal function (n = 53 total; Group I: n = 32, Group II: n = 21) with clearance values $\leq$ 30 ml/min/1.73 m^2 body surface (40 patients $<$ 20 ml/min/1.73 m^2 body surface). Anuric cases (n = 6).
Interpretation and Analysis: In Case Groups I and II the slope clearance closely correlates with the single sample clearance (r = 0.99) when a late plasma sample is used in both techniques. In Case Group II, where residual urine is estimated by ultrasound, renal clearance correlates better with slope clearance than in Case Group I (r = 0.94 vs r = 0.89). There are no signs of nephrotoxicity in the parameters noted. In Case Group III, extrarenal plasma clearance of iohexol does not exceed 2 ml/min/1.73 m^2. Glomerular filtration rates $<$ 20 ml/min can accurately and safely be determined as renal clearance or plasma clearance of iohexol after an intravenous dose of 10 ml 300 mg I/ml. Plasma clearance techniques that have the practical clinical advantage of no urine sampling do at low GFR require collection of a late plasma sample, for instance, 24 hours after injection of iohexol, irrespective of whether slope technique or single sample technique or 1-compartment or poly-compartment models are used.
Instrumentation: Reanalyzer PRX90, Provalid AB, Sweden.

The use of iohexol clearance to determine GFR in patients with severe chronic renal failure—A comparison between different clearance techniques. Frennby B, Sterner G, Almén T, Hagstam KE, Hultberg B, Jacobsson L. Clin Nephrol 1995 Jan; 43 (1), pp. 35–46.

Glomerular Function/Albuminuric States/Albumin Clearance
[^{3}H]-Albumin

Cellular/Molecular Mechanism of Action: Albumin *in vivo* primarily maintains plasma oncotic pressure and can serve as a reserve protein fraction during episodes of starvation. The inorganic compound NH_4Cl is an inhibitor of renal protein uptake.
Background Information: Recent studies have demonstrated that the normal glomerular capillary wall (GCW) is not charge selective to albumin. This means that albumin flux across the GCW is high. This has been confirmed in studies where albumin uptake by the tubules has been inhibited. Therefore, there must be a high-capacity postglomerular retrieval pathway in normal kidneys that returns filtered albumin back into the intravascular compartment.
Application: Evaluation of the albumin-filtering capacity of the kidney.
Implementation: Identify the presence of glomerular filtered albumin in the renal vein from the analysis of the decrease of radioactivity in the venous effluent after the injection of a pulse of [^{3}H]-labeled albumin into the renal artery *in vivo* and in the isolated perfused kidney (IPK).

Animal Model: Rat.
Interpretation and Analysis: Glomerular filtered albumin is returned to the blood supply by a high-capacity pathway that transports labeled albumin at a rate of 1,830 $\pm$ 292 μg/min rat kidney (n = 14) (mean $\pm$ SEM). This pathway has been identified under physiological conditions *in vivo* and in the IPK. The pathway is specific for albumin, as it does not occur for horseradish peroxidase (HRP).

The pathway is inhibited in a non-filtering kidney. The pathway is also inhibited by NH_4Cl, an inhibitor of protein uptake. The high-capacity retrieval pathway for albumin is most likely associated with transtubular cell transport. It is also apparent that most albuminuric states could be accounted for by the malfunctioning of this pathway without resorting to any change in glomerular permselectivity.

The return of glomerular filtered albumin to the rat renal vein—The albumin retrieval pathway. Eppel GA, Osicka TM, Pratt LM, Jablonski P, Howden B, Glasgow EF, Comper WD. Ren Fail 2001 May–Jul; 23 (3–4), pp. 347–63.

Glomerular Hydrostatic Pressure/(Calcium Antagonist)
Efonidipine/Lisinopril

Cellular/Molecular Mechanism of Action: Calcium antagonist.
Physiological Mechanism of Action: Dilation of afferent and efferent arterioles in a manner that reduces glomerular hydrostatic pressure.
Laboratory Methodology: Four-week-old spontaneously hypertensive rats (SHRs) given efonidipine (25 mg/kg/day) or lisinopril (3 mg/kg/day) until the age of 22 weeks.
Dosage: Efonidipine (25 mg/kg/day) and lisinopril (3 mg/kg/day) in rats.
Implementation: Evaluation of glomerular hydrostatic pressure utilizing efonidipine or lisinopril.

Animal Model: Rat (4-week-old SHRs) given efonidipine or lisinopril until the age of 22 weeks.
Interpretation and Analysis: Fixed, maximal dilation can be observed at 22 weeks after receiving either efonidipine (25 mg/kg/day) or lisinopril (3 mg/kg/day). Morphometrical measurements show that efonidipine and lisinopril treatments cause structural alteration of the vasculature, resulting in significantly greater efferent arteriolar diameters than in untreated reference controls. In addition, lisinopril-treated rats have wider afferent lumina. The renoprotective effect of efonidipine and lisinopril might be partly due to the structurally larger efferent arteriolar lumen.

Effects of efonidipine hydrochloride on renal arteriolar diameters in spontaneously hypertensive rats. Nakamura M, Notoya M, Kohda Y, Yamashita J, Takashita Y, Gemba M. Hypertens Res 2002 Sep; 25 (5), pp. 751–5.

Glomerulonephritis (Chronic)/Renal Function/ Prognostic Factors: Markovian Analysis
Phenolsulfonphthalein (PSP)

Cellular/Molecular Mechanism of Action: Phenolsulfonphthalein is secreted by the proximal renal tubular epithelium.
Application: Estimation of prognosis for conditions of chronic glomerulonephritis.
Implementation: Delineation of the incidence of hypertension in chronic glomerulonephritis and its influence on the clinical course of the disease applying statistical techniques (especially Markovian process).
Interpretation and Analysis: In cases of chronic glomerulonephritis, the incidence of hypertension is approximately 15.2% (e.g., n = 283/1,862) but if renal function is approximately one-half, then the incidence increases to 50% (e.g., n = 930/1,862).

The average blood pressure in such disease states tends to become elevated with decreases in 15-minute values for PSP excretion tests and with increasing serum creatinine levels (Note: Variations are large). After a fall of renal function to approximately one-third of normal, progression rates for declines in the clinical course of the disease become markedly more rapid. The prognosis for the progressive type of chronic glomerulonephritis is obviously shortened by the presence of hypertension. According to the results obtained by the Markovian approach, survival years of the patients with a wide range of renal functions can be predicted with relative accuracy.

Prognosis of chronic glomerulonephritis with special reference to hypertension and renal function. Urakabe S, Shirai D, Orita Y, Ando A. Jpn Circ J 1975 Jul; 39 (7), pp. 815–21.

Low-Density Lipoprotein (LDL) Assimilation: Hemodialysis and Diabetes/Atherosclerotic Lesion Pathogenesis: LDL Accumulation
[^{125}I]-LDL

Cellular/Molecular Mechanism of Action: [^{125}I]-labeled LDLs are radiolabeled analogs of LDLs. Low-density lipoproteins can function as a transport platform in the plasma and contain a relatively high amount of triglycerides and cholesterol compared to high-density lipoproteins.
Background Information: In conditions requiring chronic hemodialysis treatment there is an elevated atherogenic risk, and dyslipidemia appears to be 1 of the major risk factors. However, most affected cases exhibit elevated serum triglycerides, whereas serum cholesterol and LDL cholesterol levels are in the normal range.
Application: Characterization of *in vitro* and *in vivo* LDL metabolism.
Route of Administration: In animal (*in vivo*) models, [^{125}I]-labeled LDLs are usually given intravenously.
Implementation: Evaluate the influence of hypertriglyceridemia under the condition of hemodialysis and diabetes mellitus on LDL metabolism.

Low-density lipoproteins are isolated from whole blood and separated into 6 subfractions by density gradient ultracentrifugation and then characterized pertaining to lipid/protein composition, degree of glycation, and oxidation. Uptake of [^{125}I]-labeled LDL is examined via LDL receptors of HepG2 cells and scavenger receptors of mouse peritoneal macrophages.

Human Model: Cases of hypertriglyceridemic diabetes, non-diabetic hemodialysis cases, and healthy reference controls (n = 30, n = 10/case group).
Interpretation and Analysis: Hemodialysis procedures promote elevations in serum triglycerides but cholesterol levels are within normal ranges. Triglyceride enrichment occurs in the very low-density lipoprotein (VLDL) class and LDL class, and an accumulation of a highly atherogenic small dense LDL subfraction can be detected predominantly in cases of non-insulin-dependent diabetes mellitus. Low-density lipoprotein concentrations in response to hemodialysis also contain elevated levels of lipid peroxidation products, which are at even higher levels in diabetic conditions. Alterations in composition, size, and configuration of LDL in response to hemodialysis in diabetic and non-diabetic conditions impair LDL receptor-mediated degradation and enhance uptake of such modified LDL particles via non-saturable scavenger receptors. Diminished LDL receptor-mediated uptake of modified, triglyceride-rich, small dense LDL most likely leads to accumulation of these lipoproteins *in vivo*, favoring development of atherosclerotic lesions. Future clinical studies must be conducted to demonstrate whether patients benefit from reducing atherogenic particles by lipid-lowering intervention.

Abnormalities in lipoprotein metabolism in hemodialysis patients. Köniğer M, Quaschning T, Wanner C, Schollmeyer P, Krämer-Guth A. Kidney Int Suppl 1999 Jul; 71, pp. S248–50.

Nephropathy: Chronic Renal Failure (Reflux Type)/ Effective Renal Plasma Flow (ERPF)/Glomerular Filtration Rate (GFR)
Inulin/Para-Hippurate/Amino Acid Formulations

Application: Inulin-based molecules can be applied to evaluate GFR, while *p*-hippurate can be used to measure (effective) renal plasma flow.

Considerations: Reflux nephropathy is an important cause of chronic renal failure in children. After the parenchymal scar, the progression is thought to be mediated by glomerular hypertension in remnant nephrons, resulting in modifications in permselectivity to macromolecules. Proteinuria correlates with a progressive course.

Implemenation: Evaluation of glomerular permselectivity to macromolecules in basal conditions and after acute hemodynamic stress. Bilateral renal scarring (0–8 scale for both kidneys) is 4.3 ± 1.6. Albuminuria (UAE) is evaluated in basal and under acute hyperfiltration conditions induced by infusion of amino acid formulations. After isotonic saline at 310 ml/hour/1.73 m^2, 6 mg/kg/min of amino acid formulations are infused for 2 hours.

Human Model: Cases with bilateral vesico-ureteric reflux (VUR; n = 28) that have previously been surgically corrected (meanly 5.6 years before) accompanied by normal creatinine clearance (CrCl).

Interpretation and Analysis: Urine albumin is significantly higher than controls in basal conditions ($p < 0.01$) and further increases after amino acid formulation infusion ($p < 0.02$). Microalbuminuria is detectable in 53.5% of children in basal conditions and in 64.3% after infusion of amino acid formulations. Also urinary β-2-microglobulin significantly increases at the end of the test ($p < 0.001$). Creatinine clearance significantly increases at the 1st hour ($p < 0.05$). Children with severe renal parenchymal scarring have greater urine albumin ($p < 0.01$) and β-2M ($p < 0.02$) values after provocative tests than those with mild renal damage. In children, GFR and ERPF can be measured by means of inulin and *p*-hippurate clearance, respectively. The variations in UAE during the infusion of amino acid formulations significantly correlate with GFR dynamics ($p < 0.05$), while they are not influenced by ERPF modifications. Note: Filtration fraction = GF/ERPF.

Concentration measured as a function of spectrophotometric absorbance [^{123}I]-ortho-iodohippuric acid. Prévot A, Mosig D, Martini S, Guignard JP. Pediatr Res 2004 Feb; 55 (2), pp. 254–60.

Evaluation of renal function in transplant patients on tacrolimus therapy. Agarwala S, Culligan E, Jain A, McCauley J, Shapiro R, Chakrabarti P, Burckart G, Venkataramanan R. J Clin Pharmacol 2002 Jul; 42 (7), pp. 798–805.

Perfusion/Effective Renal Plasma Flow (ERPF)/ Glomerular Filtration Rate (GFR)
Sodium Sulfanilic (SS) Acid/Phenolsulfonphthalein (PSP)/Hippuric Acid/Inulin

Cellular/Molecular Mechanism of Action: Removal from the systemic intravascular compartment primarily occurs through proximal renal tubular excretion. Inulin is eliminated from the intravascular compartment by passive diffusion into the plasma filtrate at the level of the glomerulus.

Diagnostic Application: Selective assessment of renal tubular function.

Dosage: Injected intravenously as an aqueous solution (20%) at a dose rate of 10 mg/kg. Dosage in dogs is 20 mg/kg and 11 mg/kg for cats.

Considerations: The test should not be performed in animals that have received systemic sulfonamide therapy because they cross react with sulfanilite. The advantage of this test is that collection of urine is not required, but the disadvantage is that a numerical value for GFR is not obtained.

Implementation: Evaluation of the excretion of creatinine, SS, and PSP. Heparinized blood samples are collected at 10, 15, 30, 60, and 90 minutes following administration.

Animal Model: Companion animals and domestic livestock.

Reference Example: Caprine (healthy goats).

Interpretation and Analysis: Renal clearance of SS acid after intravenous injection displays a $T_{1/2}$ = 39.5 ± 4.4 minutes. In dogs normal values have been reported to be 50–80 minutes and 42–82 minutes. The normal sodium sulfanilic acid clearance in cats is 37–57 minutes. Plasma $T_{1/2}$ half-life ranges between 30 to 90 minutes in normal horses with a mean value of 39.5 ± 4.4 minutes.

In conscious goats, mean (± SEM) inulin clearance is 2.26 0.08 ml/min/kg of body weight. Endogenous creatinine clearance, 1.97 ± 0.09 ml/min/kg, underestimates inulin clearance ($p < 0.01$), probably because of the presence of non-creatinine chromogens in caprine plasma. The estimated renal clearance of PSP is 6.88 ± 0.39 ml/min/kg, whereas the estimated renal clearance of SS is 3.71 ± 0.39 ml/min/kg. Both exceed inulin clearance ($p < 0.01$), confirming renal tubular secretion of both compounds. In anesthetized goats (e.g., n = 6), exogenous creatinine clearance and SS clearance exceed inulin clearance ($p < 0.05$). Results of stop-flow experiments document secretion of creatinine and SS by the proximal portion of the caprine nephron. Plasma half-life of PSP in uninephrectomized goats exceeds that in intact goats (20.2 ± 1.5 minutes vs 11.9 ± 0.7 minutes; $p < 0.01$). Similarly, plasma half-life of SS is greater in goats after uninephrectomy (58.2 ± 6.2 minutes vs 30.4 ± 1.2 minutes; $p < 0.01$). Note: Filtration fraction = GF/ERPF.

Determination of excretion of inulin, creatinine, sodium sulfanilate, and phenolsulfonphthalein to assess renal function in goats. Brown SA, Groves C, Barsanti JA, Finco DR. Am J Vet Res 1990 Apr; 51 (4), pp. 581–6.

Perfusion (Renal): Microperfusion and Free-Flow Micropuncture/Fluid Reabsorption in Microperfused Nephron Segments/Glomerular Filtration Rate (GFR)
Iothalamate/[^{3}H]-Methoxy-Inulin

Background Information: Inulin remains the gold standard for measurements of fluid reabsorption (Jv) and single nephron glomerular filtration rate (SNGFR) in micropuncture experiments. However, the method used to measure cold inulin in nanoliter samples is time-consuming, while the use of radiolabeled inulin is disadvantaged by possible radioactive contamination, disposal of radioactive material, and cost of the isotope. It has been reported that non-radiolabeled iothalamate may be a suitable alternative for estimation of whole kidney GFR.

Application: Iothalamate and inulin can both be applied to assess glomerular filtration. Iothalamate has been used to measure fluid reabsorption (Jv) in microperfusion and free-flow micropuncture experiments and therefore can function as a standard reference method for the detection of fluid reabsorption in microperfused nephron segments.

Route of Administration: Iothalamate (intravenous).

Dosage: Iothalamate IV (18.3 mg/h).

Implementation: Evaluate the potential for iothalamate to be used to measure Jv in microperfusion and free-flow micropuncture experiments. Superficial loops of Henle (LOH) are perfused from late proximal to early distal tubules with an end-like proximal solution. In the 1st set of experiments, the perfusate contains both iothalamate (1.9 mmol/L) and [^{3}H]-methoxy-inulin (50 μCi/mL). To test if iothalamate is able to detect changes in Jv, 2 additional sets of experiments can be performed: (i) mannitol (61 mmol/L) added to the perfusate to partially replace NaCl, a condition known to inhibit Jv; and (ii) LOH of remnant kidneys perfused (shown in previous investigations to have a higher Jv). Lastly, free-flow micropuncture experiments are performed by infusing iothalamate IV at 18.3 mg/h. Iothalamate analysis in nanoliter samples of renal tubular fluid obtained *in vivo* is performed by capillary electrophoresis (CE).

Animal Model: Rat.

Interpretation and Analysis: In the 1st set of experiments, liquid scintillation counting of [^{3}H]-methoxy-inulin vs iothalamate analysis with CE results in almost identical calculations of perfusion rates (20.4 ± 0.6 vs 20.6 ± 0.7 nL./min, n = 20) and tubular fluid/perfusate ratios (TF/P; 1.35 ± 0.04 vs 1.36 ± 0.04) and thus also fluid reabsorption (Jv 5.17 ± 0.50 vs 5.38 ± 0.59 nL/min). In mannitol investigations, iothalamate measurements show that the addition of mannitol significantly reduces fluid reabsorption (Jv) from 4.98 ± 0.40 (n = 19) to 0.72 ± 0.58 nL/min (n = 33; $p < 0.0001$). Iothalamate determinations by CE are able to detect a significant increase in fluid reabsorption (Jv) in LOH of remnant rats perfused at 40 nL/min (from 8.40 ± 0.73 [n = 20] in sham-operated to 17.8 ± 2.9 nL/min [n = 6] in remnant animals; $p < 0.0001$]. In free-flow micropuncture experiments the ratio of tubular fluid to plasma iothalamate (TF/P) along the proximal tubule is 1.62 ± 0.10 (n = 15). Therefore, iothalamate can replace inulin to measure Jv in microperfusion and free-flow micropuncture experiments. Since iothalamate analysis by CE technique is a fast, easy, and highly reproducible technique, it may become the gold standard method for the detection of fluid reabsorption in microperfused nephron segments.

Instrumentation: Capillary electrophoresis.

Iothalamate measured by capillary electrophoresis is a suitable alternative to radiolabeled inulin in renal micropuncture. Capasso G, Unwin RJ, Pica A, Quagliuolo L, Giovane A. Kidney Int 2002 Sep; 62 (3), pp. 1068–74.

Polyuria
Antidiuretic Hormone (ADH, Vasopressin)

Diagnostic Application: Utilized to evaluate renal function in debilitated patients in which a water deprivation test would be considered hazardous.

Route of Administration and Dosage: Intravenous administration of ADH at a dose rate of 11 mU/kg over a period of 60 minutes. The bladder is then emptied of urine. Solute of the urine is measured at time zero, and then at 30-minute intervals for 3 hours. After each measurement, the bladder is emptied to improve the accuracy of the test.

Considerations: Values are usually lower than those observed with the standard water deprivation test, which is the preferred initial test procedure.

Implementation: The repositol vasopressin test entails IM administration of 3 to 5 units of ADH tannate in oil. Evacuation of the bladder is done within 6 hours of administration.

Interpretation and Analysis: Maximal response to aqueous ADH is observed at 60 minutes (S.G. 1.009–1.033; urine osmolality 429–1437 mOsm/kg; urine/plasma osmolality 1.5–5.1).

In the repositol vasopresson test, urine solute concentrations are measured at 6-hour intervals over a period of 24 hours. Maximal response occurs at 8 to 12 hours (USG 1.024–1.060; urine osmolalities 1.033–2.001; urine/plasma 3.8–7.4).

Polyuria
Hypertonic Saline (Hickey-Hare Test)

Diagnostic Application: Utilized to distinguish polyuric states complicated by renale medulary washout. Administration of hypertonic saline evaluates the ability of the pituitary-renal axis (antidiuretic hormone [ADH]: renal tubule) to reduce urine production following induction of plasma hyperosmolality.

Route of Administration and Dosage: Hypertonic saline (2.5%) is administered to a water-"loaded" patient (e.g., dog).

Considerations: The water deprivation test is safer, and easier to perform in most patients suffering from polyuria and polydypsia conditions.

Interpretation and Analysis: Administration of hypertonic saline normally should simultaneously stimulate pituitary ADH secretion and replenish sodium chloride in situations of renal "washout." Normal patients (e.g., canine) display a ≥ 25% reduction in urine production (flow rate). Patients suffering from central (pituitary) diabetes insipidus or nephrogenic diabetes insipidus fail to reduce urine production following adminstration of hypertonic saline. In contrast, psychognic polydypsia patients reduce urine production following administration of hypertonic saline.

Renal Failure: Acute/Plasma Protein Binding Changes with Phenolsulfonphthalein (PSP) in Acute Renal Failure (ARF)
PSP

Cellular/Molecular Mechanism of Action: Phenolsulfonphthalein is secreted by the proximal renal tubular epithelium.

Application: Phenolsulfonphthalein can be applied to detect alterations in renal tubular function such as those associated with acute and chronic renal failure.

Route of Administration: Phenolsulfonphthalein (intravenous).

Implementation: Determine the influence of ARF on the disposition of PSP.

Animal Model: Rat (acute renal failure induced by subcutaneous injection of uranyl nitrate). In order to clarify the regulatory mechanisms of PSP excretion between liver and kidney in ARF, a simultaneous perfusion system of rat liver and kidney can be utilized that controls the flow rate and the constituents of the perfusate.

Interpretation and Analysis: Renal excretion of PSP decreases significantly in ARF compared to that in normal controls. In conditions of ARF, increases in biliary PSP excretion can be detected and reflects a process that compensates for reductions in renal excretion. Consequently no significant change can be appreciated in total body clearance of PSP between control and ARF. Binding investigations (*in vitro*) reveal that the bound fraction of PSP to plasma proteins in conditions of ARF is significantly lower than observed in reference control plasma.

Applying the simultaneous perfusion system, neither biliary excretion nor the protein binding of PSP differs significantly between control and ARF, though its renal excretion decreases in ARF in a similar manner as observed *in vivo*. These results suggest

that alterations in plasma protein binding as well as renal excretory function are determinants of PSP disposition in ARF.

Influence of acute renal failure on pharmacokinetics of phenolsulfonphthalein in rats: A comparative study *in vivo* and in the simultaneous perfusion system of liver and kidney. Yasuhara M, Katayama H, Fujiwara J, Okumura K, Hori R. J Pharmacobiodyn 1985 May; 8 (5), pp. 377–84.

Renal Plasma Flow: Effective Renal Plasma Flow (ERPF)
[^{123}I]-Orthoiodohippurate (OIH)

Cellular/Molecular Mechanism of Action: [^{123}I]-orthoiodohippurate is a radioiodinated analog of OIH that functions as a passive tracer/marker molecule and does not per se exert any true biological effect.
Background Information: The methods of measuring ERPF based on the 2-compartment analysis of plasma clearance of [^{123}I]-OIH disregard the distribution of [^{123}I]-OIH into erythrocytes, resulting in an overestimation of ERPF.
Application: Passive molecular marker for measuring ERPF.
Route of Administration: [^{123}I]-orthoiodohippurate (intravascular).
Implementation: Measurement of ERPF using a modified methodology in order to obtain more accurate estimates. Intercompartmental clearance rates among plasma, erythrocytes, and extracellular fluid are determined through *in vitro* and *in vivo* experiments to facilitate performing 3-compartment analysis of plasma clearance curves for [^{123}I]-OIH using multiple blood samplings in comparison with 2-compartment analysis. Multiplying renal blood flow derived from 2-compartment analysis of the whole blood clearance curve by (1-hematocrit/100) is a new modified approach for measuring ERPF resulting in reduced complexity of 3-compartment analysis methods and can serve to characterize the distribution of [^{123}I]-OIH to erythrocytes.
Interpretation and Analysis: Comparing ERPF derived from the modified 2-compartment analysis technique with that from 3-compartment analysis technique demonstrates good agreement ($r = 0.883$, $p = 0.001$) between the 2 methods. Effective renal plasma flow derived by this new method is also compared with the clearance of paraaminohippurate (PAH), resulting in a regression line that is much closer to unity and produces a better correlation between them ($r = 0.926$) than between PAH clearance and ERPF ($r = 0.909$) derived from conventional 2-compartment analysis. Note: Filtration fraction = GF/ERPF.

Modification of measurement of effective renal plasma flow from blood pool clearance curve of [^{123}I]-orthoiodohippurate using single blood sampling. Akutsu T, Komatani A, Yamaguchi K, Takahashi K, Konta T. Radiat Med 1998 Jul–Aug; 16 (4), pp. 245–50.

Renal Tubular Absorption Mechanisms/Organic Anion Transporter 1 and 3
Phenolsulfonphthalein (PSP)/Paraaminohippuric Acid/[Cimetadine]

Cellular/Molecular Mechanism of Action: Removed from the systemic intravascular compartment predominantely by excretion through the proximal renal tubule (94%). A minor component (6%) is eliminated through the glomerulus.
Background Information: Paraaminohippuric acid, a substrate of rat organic anion transporter1 (rOat1), and cimetidine, a substrate of rOat3, both reduce the urinary excretion of PSP.
Diagnostic Application: Selective assessment of renal tubular function. Formulated at 1% solution in sodium bicarbonate (0.1 N) and administered systemically by intravenous injection (pH adjusted to 7.4). Collection of blood is performed at 2, 5, 10, 15, 20, 30, 35, 45, and 60 minutes following injection. Plasma $T_{1/2}$ = 6 minutes (range = 5.6–9.3 minutes).
Route of Administration and Dosage: Intravenous injection at a dose of 1 mg/kg.
Interpretation and Analysis: The uptake of PSP by kidney slices is found to consist of 2 components. The IC50 values of rOat1 substrates are higher than those of rOat3 substrates. In the presence of cimetidine, the Eadie-Hofstee plot is a single straight line. The profile of PSP uptake component in the presence of cimetidine is similar to that of the low-affinity component in the absence of cimetidine. Therefore, rOat1 and rOat3 are involved in the renal uptake of PSP, and PSP is a high-affinity substrate for rOat3 but is a relatively low-affinity substrate for rOat1.

Major role of organic anion transporters in the uptake of phenolsulfonphthalein in the kidney. Itagaki S, Sugawara M, Kobayashi M, Nishimura S, Fujimoto M, Miyazaki K, Iseki K. Eur J Pharmacol 2003 Aug 15; 475 (1–3), pp. 85–92.

Renal Tubular Acidosis
Ammonium Chloride (NH_4Cl)

Diagnostic Application: Diagnostic detection of renal tubular acidosis, which can be either a primary or secondary condition.
Background Information: Renal tubular acidosis Type I–Distal renal tubular acidosis due to inability to excrete sufficient H^+ ion that prevents the kidney from being able to optimally acidify the urine. Type II–Proximal renal tubules are unable to appropriately absorb urinary bicarbonate. Type IV–Distal renal tubular acidosis results in an inability to secrete both potassium and hydrogen ions.
Route of Administration: Preparations of NH_4Cl are given orally.
Dosage: Preparations of NH_4Cl are given at a dose of 0.1 gm/kg.
Considerations: Administration of NH_4Cl should be avoided in conditions of metabolic and respiratory acidosis (academia). In dogs, the test is discontinued if the urine pH falls below 6.0, which occurs in normal dogs between 2 and 8 hours following NH_4Cl administration.
Interpretation and Analysis: Following administration of NH_4Cl, and removal of urine from the bladder by catheterization, the urine pH is measured at 6-hour intervals. In dogs, the NH_4Cl test is performed after a fast and hourly urine specimens are collected with the 1st sample obtained at 2 hours postinjection. Normal (equine) patients display a significant decrease in urine pH to approximately 6.5 by 4 hours postadministration. The degree of acidification in herbivores is less than in humans and dogs that usually display urine with a pH of approximately 5.5.
Laboratory Instrumentation: Measurement of renal pH using conventional clinical pathology instrumentation and methodologies.

Renal Tubular Acidosis/Tubular Acidosis Type I (Incomplete)/Distal Renal Tubular Acidification Capacity/Osteopenia and Osteoporosis
Ammonium Chloride Loading/Frusemide

Cellular/Molecular Mechanism of Action: Chloride ion is transported by the renal epithelium into the urinary filtrate.
Background Information: Chronic metabolic acidosis may increase alkali mobilization from the bone and thus promote the development of osteoporosis.

Application: Detection and characterization of incomplete renal tubular acidosis Type I (RTA I).
Route of Administration: Frusemide (oral ingestion); ammonium chloride loading (oral).
Dosage: Frusemide (40 mg); ammonium chloride loading (0.1 g/kg body weight).
Implementation: Evaluation of renal function and urinary acidification in cases of osteopenia and osteoporosis. Distal tubular acidification can be characterized by applying an oral ammonium chloride loading test and the oral frusemide test.

Human Model: Cases of osteopenia or osteoporosis devoid of overt metabolic acidosis, derangement of potassium homeostasis, or renal insufficiency (n = 46; n = 41 females, n = 5 males). Negative age- and sex-matched (normal) reference controls (n = 20; n = 17/20 females, n = 3/20 males).
Interpretation and Analysis: The urinary pH in controls is < 5.5 following frusemide ingestion. In contrast, in cases with reduced bone mineral density, the oral ammonium chloride loading test can aid in establishing a diagnosis of incomplete RTA I (n = 10/46 or 22%). Disorders possibly related to RTA I can also be detected (e.g., n = 8/10). A large percentage of cases will display normal urinary pH responses following oral ammonium chloride loading (e.g., n = 36/46). Oral frusemide fails to lower urinary pH < 5.5 in a little more than one-third of cases (e.g., n = 16/46 or 35%) and may include cases with incomplete RTA I (e.g., n = 10) or with a normal oral ammonium chloride loading test (n = 6). An abnormal frusemide test may be appreciated in 35% of cases with reduced bone mass but is a feature rarely if ever detected in normal controls ($chi^2 = 7.39$; $p < 0.01$). With the ammonium chloride test functioning as a gold standard for the diagnosis of distal RTA, the frusemide test shows a sensitivity of 1.0 (95% CI, 0.69–1.0) and a specificity of 0.89 (95% CI, 0.78–0.96) for the diagnosis of distal RTA. Patients with incomplete RTA I tend to be younger in age than those without incomplete RTA I (42 ± 16 vs 54 ± 14 years; p = 0.025; mean ± SD). Basal serum bicarbonate concentrations and capillary pH do not differ between evaluation groups.

Therefore, incomplete RTA I may be prevalent in a significant proportion of cases suffering from osteopenia or osteoporosis. The outcome of the frusemide test suggests either a defect of the H^+ATPase in the cortical collecting tubule (CCT) or a defective Na^+ reabsorption in the CCT. Prospective studies are needed to further elucidate the impact of incomplete RTA I on the development of reduced bone mineral content.

Prevalence and characterization of renal tubular acidosis in patients with osteopenia and osteoporosis and in non-porotic controls. Weger W, Kotanko P, Weger M, Deutschmann H, Skrabal F. Nephrol Dial Transplant 2000 Jul; 15 (7), pp. 975–80.

Renal Tubular Acidosis: Distal Tubular Acidosis/ Reduced Distal Nephron Proton Secretion
Bicarbonate Loading

Background Information: Recent classifications of the several pathophysiologic types of distal renal tubular acidosis (secretory, voltage dependent, and gradient) have been based on the response of acidification parameters to a series of provocative *in vivo* and *in vitro* maneuvers. A reduction in the difference in urine and blood CO_2 tension during bicarbonate loading (U-B pCO_2 gradient), a widely applied parameter, has been employed as an index of reduced distal nephron proton secretion.

Application: Detection and characterization of reductions in distal nephron proton secretion associated with conditions of distal renal tubule acidosis.
Route of Administration: Sodium bicarbonate (Na_2CO_3; oral).
Implementation: Evaluation of reductions in distal nephron proton secretion by measuring reductions in the difference in urine and blood CO_2 tension during bicarbonate loading (U-B pCO_2 gradient). Such parameters can be employed for the detection and evaluation of distal renal tubular acidosis conditions. Example: Evaluation of the validity of U-B pCO_2 gradients in a variety of experimental models of distal renal tubular acidosis by measuring and comparing disequilibrium pH (a direct technique to detect H^+ secretion *in situ*) with *in vivo* pCO_2 in the papillary collecting duct during bicarbonate loading. Chronic amiloride, lithium chloride, and amphotericin-B administration and the postobstructed kidney models can all potentially be employed.

Animal Model: Rat (papillary collecting duct).
Interpretation and Analysis: Amiloride results in an acidification defect that does not respond to sulfate infusion (urine pH = 6.15 ± 0.08) and is associated with an obliteration of the acid disequilibrium pH (−0.26 ± 0.05 – −0.08 ± 0.03) and reduction in papillary pCO_2 (116.9 ± 3.2 – 66.9 ± 2.5 mm Hg). Defects induced by lithium administration respond to Na_2SO_4 (urine pH = 5.21 ± 0.06) but are similar to amiloride with respect to observed reductions in disequilibrium pH (−0.04 ± 0.02) and pCO_2 (90.3 ± 3.0 mm Hg). The postobstructed kidney model is characterized by an abnormally alkaline urine pH that is unresponsive to sulfate (6.59 ± 0.06) and a reduction in disequilibrium pH (+0.02 ± 0.06) and pCO_2 (77.6 ± 3.6 mm Hg). Amphotericin-B results in a gradient defect characterized by excretion of an acid urine after infusion of sodium sulfate (5.13 ± 0.06). Unlike other models, however, amphotericin-B is associated with a significant acid disequilibrium pH (−0.11 ± 0.05) and an appropriately elevated urine pCO_2 (119.8 ± 6.4 mm Hg) that does not differ from the corresponding control values. Thus, these findings support the use of the U-B pCO_2 as a reliable means of demonstrating impaired distal nephron proton secretion in secretory and voltage-dependent forms of distal renal tubular acidosis.

Validation of the difference in urine and blood carbon dioxide tension during bicarbonate loading as an index of distal nephron acidification in experimental models of distal renal tubular acidosis. DuBose TD Jr, Caflisch CR. J Clin Invest 1985 Apr; 75 (4), pp. 1116–23.

Renal Tubular Concentrating Capacity
1-Desamino-8-Arginine Vasopressin (DDAVP)/ (Pitressin Tannate in Oil Alternative)

Cellular/Molecular Mechanism of Action: 1-desamino-8-arginine vasopressin promotes the production of concentrated urine in normal individuals.
Application: Assessment of renal urine concentrating capability.
Route of Administration: Intranasal.
Dosage: A reappraisal of a previous opinion and subsequent comparative work leads to the conclusion that 40 μg DDAVP administered instransally is a preferable dose to 20 μg to use as a urinary concentrating agent in the diagnostic context, and that it is quite comparable to the standard agent, pitressin tannate (5 IU) in oil.
Considerations: 1-desamino-8-arginine vasopressin is superior to the use of pitressin tannate in oil as a diagnostic agent.
Interpretation and Analysis: Consistently results in an increased production of urine with an osmolality of 800 mosmol/kg or more, with no untoward effect (evaluation performed over a period of approximately 8 and a half hours).

Renal Tubular Dysfunction: Distal Tubule Injury
Vasopressin (Inhalation)/Ammonium Chloride (Short Urinary Acidification Test)

Cellular/Molecular Mechanism of Action: Desamino-*d*-arginine vasopressin, also known as antidiuretic hormone (ADH), interacts with receptor complexes expressed on the membrane surface of renal epithelial cells lining the distal renal tubules.
Physiological Mechanism of Action: One function of desamino-*d*-arginine vasopressin is the promotion of increased urinary filtrate concentration.
Application: Desamino-*d*-arginine vasopressin inhalation.
Route of Administration: Desamino-*d*-arginine vasopressin (intranasal inhalation).
Implementation: Evaluation of glomerular filtration rate (GFR) and plasma electrolyte concentrations. In addition, renal distal tubular function is assessed by measurement of overnight urinary concentration after intranasal desamino-*d*-arginine vasopressin inhalation and by a standard short urinary acidification test following the administration of oral ammonium chloride.

Human Model: Cases treated with a serial course of cisplatinum combination chemotherapy (n = 22).
Interpretation and Analysis: Cumulative and dose-related hypomagnesemia can be observed in the vast majority of cases (e.g., n = 22/22), but can be unassociated with clinical symptoms. No significant fall in GFR is seen as a whole but approximately 30% of cases evaluated in a comprehensive manner develop impairment of urinary concentrating and acidifying abilities, independent of any change in GFR (e.g., n = 4/12). Such profiles indicate that cisplatinum exerts a selective effect at the level of the renal distal tubule.

Cis-platinum and distal renal tubule toxicity. Swainson CP, Colls BM, Fitzharris BM. N Z Med J 1985 May 22; 98 (779), pp. 375–8.

Renal Tubular Excretion/Renal Plasma Flow/Urine Flow/Protein Binding: Non-Linear/Glomerular Filtration/Tubular Secretion/Tubular Accumulation
Phenolsulfonphthalein (PSP)

Cellular/Molecular Mechanism of Action: Phenolsulfonphthalein is secreted by the proximal renal tubular epithelium.
Route of Administration: Phenolsulfonphthalein (intravenous).
Dosage: Phenolsulfonphthalein (1.0 g).
Implementation: Evaluation of renal tubular function. Plasma kinetics and renal excretion of intravenous PSP (1.0 g) can be evaluated with and without concomitant administration of probenecid or salicyluric acid (SUA). A physiologically based kidney model has been developed that incorporates the functional characteristics of the kidney and is capable of determining (predicting) the excretion of PSP taking into account the variables of renal plasma flow, urine flow, non-linear protein binding, glomerular filtration, tubular secretion, and tubular accumulation.

Animal Model: Canine (beagle dog).
Interpretation and Analysis: Pharmacokinetic analysis reveals that tubular secretion is the predominant route of excretion, and that secretion is inhibited by both SUA and probenecid. The model enables an accurate description and analysis of the measured plasma levels and renal excretion rates. The interaction with probenecid and SUA can be adequately described as a inhibition of the carrier-mediated uptake of PSP into the proximal tubular cells. However, both compounds clearly differ in their inhibitory action. Whereas probenecid shows simple competitive inhibition, for SUA a considerably more complex interaction (2-site competitive system) has to be taken into consideration. Especially in the interaction experiments, only satisfactory fits to the model are obtained when secretion is assumed to be dependent on unbound PSP concentrations. Model calculations show that in controlled experiments tubular secretion is accompanied by a pronounced accumulation of PSP within the proximal tubular cells, which is clearly diminished in the presence of SUA or probenecid. The predicted accumulation ratios are in good agreement with previous studies.

Physiologically based pharmacokinetic model for the renal clearance of phenolsulfonphthalein and the interaction with probenecid and salicyluric acid in the dog. Russel FG, Wouterse AC, van Ginneken CA. J Pharmacokinet Biopharm 1987 Aug; 15 (4), pp. 349–68.

Renal Tubular Excretion/Renal Glomerular Filtration
Phenolsulfonphthalein (PSP) Excretion/Inulin Clearance/Paraaminohippurate (PAH) Clearance

Cellular/Molecular Mechanism of Action: Phenolsulfonphthalein is excreted into the urine by the proximal renal tubular epithelium. Alternatively, inulin and PAH are removed passively from the plasma and pass into the urinary filtrate at the level of the renal glomerulus.
Application: Detection of alterations in renal tubule excretory capacity (PSP), effective renal plasma flow (ERPF) (PAH), and glomerular filtration rate (GFR) (inulin).
Implementation: Evaluation of alterations in renal function induced by exposure to a toxic agent. Assessment of renal function can be determined by measuring (i) exogenous PSP excretion; (ii) inulin clearance; (iii) PAH clearance (monkeys only); (iv) endogenous serum creatinine; and (v) blood urea nitrogen (BUN) at multiple time points during the study.

Toxicity Model: Toxic challenge can be induced by exposure to triclopyr (3,5,6-trichloro-2-pyridinyloxyacetic acid) in order to determine its influence on renal function following oral administration (e.g., beagle dog and rhesus monkey). Male rhesus monkeys are orally administered triclopyr by gavage at a dose of 5 mg/kg/day, 7 days/week for 28 days, after which the dosage is increased to 20 mg/kg/day for 102 consecutive days. Groups of male dogs can be administered either a single oral dose of 5 mg/kg triclopyr or are fed a diet spiked with triclopyr at a dose of 5 mg/kg/day for 47 consecutive days.

Animal Model: Canine (beagle dog).
Animal Model: Primate (male rhesus monkey).
Interpretation and Analysis: Creatinine, BUN, and inulin clearance are within the normal range from both species following triclopyr administration and indicate that repeated administration of triclopyr in the dog and monkey has no effect on GFR. In monkeys, the percentage excretion of PSP and PAH appears to increase following triclopyr administration (20 mg/kg/day), suggesting that these weak organic acids may be competing for the same plasma protein-binding site enhancing their clearance. More importantly, triclopyr does not appear to be competing with PSP or PAH for the active secretory site within the monkey kidney proximal tubules. In contrast, PSP clearance studies in dogs reveal that triclopyr administration (5 mg/kg) can significantly decrease the percentage of PSP excreted even following a single-dose administration. The decrease in percentage PSP is reversible and inversely related to the plasma triclopyr concentration. Therefore, triclopyr appears to effectively compete with PSP for the active secretory site within the dog kidney proximal tubules. In contrast, monkeys are insensitive to the effects of triclopyr on the active secretory process even at doses 4-fold higher

(20 mg/kg/day) than the effective dose in the dog (5 mg/kg/day). These findings suggest that the effect observed on PSP and PAH excretion in the dog represent a physiological competition for excretion and not toxicity. Note: Filtration fraction = GF/ERPF.

Evaluation of renal function in rhesus monkeys and comparison to beagle dogs following oral administration of the organic acid triclopyr (3,5,6-trichloro-2-pyridinyloxyacetic acid). Timchalk C, Finco DR, Quast JF. Fundam Appl Toxicol 1997 Mar; 36 (1), pp. 47–53.

Renal Tubular Excretion: Purines (Allantoin)/ Ruminant Allantoin Plasma Clearance *[^{14}C]-Allantoin*

Application: Evaluation of purine derivative plasma clearance by renal mechanisms. The agent 4,5-[^{14}C]allantoin can be applied to measure the proportion of plasma allantoin excreted in the urine of sheep. Using this method it may be feasible to validate purine derivative excretion models in ruminant livestock.
Route of Administration: 4,5-[^{14}C]allantoin (intravenous).
Implementation: Evaluate the recovery of [^{14}C]allantoin in urine following intravenous injection and degradation of allantoin by rumen microorganisms. The urine [^{14}C]-allantoin is then recovered for measurement.

Animal Model: Sheep (n = 8 normal/healthy animals).
Interpretation and Analysis: Individual values of [^{14}C]allantoin recovery vary from 66 to 95% (mean value 83 [SE 1.6%]). The recovery of [^{14}C]allantoin shows no relation to the level of feed intake. There is some evidence that glomerular filtration rate is an important factor affecting the amount of urinary allantoin recovered. Incomplete recovery of plasma [^{14}C]allantoin in the urine indicates losses of plasma [^{14}C]allantoin via non-renal routes. Such observations occur in concert with the disappearance of [^{14}C] from rumen contents incubated *in vitro* with [^{14}C]allantoin for 48 hours (88%) and the presence of [^{14}C] in saliva *in vivo* from sheep sampled after dosing with [^{14}C]allantoin. However, the amount of [^{14}C] activity in the saliva is very low (equivalent to only 1.5% of the total dose in sheep producing saliva at a rate of 15 liters/day). The proportion of renal and non-renal excretion of purine derivatives is unpredictable both between and within individual animals. The factors responsible for this variability need to be identified, and existing models of excretion of purine derivatives may need to be modified accordingly to improve their accuracy of prediction. A single intravenous injection of 4,5-[^{14}C]allantoin provides a simple alternative to infusion methods used to measure the proportion of plasma allantoin excreted in the urine of sheep. Using this method it may be feasible to validate PD excretion models in other ruminant livestock.

Variation between sheep in renal excretion of [^{14}C]allantoin. Prasitkusol P, Ørskov ER, Chen XB, Hovell FD, Kyle DJ. Br J Nutr 2002 Jun; 87 (6), pp. 561–8.

Renal Tubular Excretion Profiling/Tubular Transporter Mechanisms *[^{3}H]-Indoxyl Sulfate/Paraaminohippuric Acid (PAH)/ Benzylpenicillin/Cimetidine/3-Carboxy-4-Methyl-5-Propyl-2-Furanpropanoic Acid/Hippuric Acid*

Cellular/Molecular Mechanism of Action: Indoxyl sulfate is a uremic toxin and radiolabeled analogs function as tracer molecules.
Background Information: Indoxyl sulfate is a uremic toxin that accumulates in the body because of the patient's inability to excrete it, thereby inducing a number of uremic symptoms that can lead to chronic renal failure. The functional failure of the excretion system for indoxyl sulfate causes its accumulation in the intravascular compartment.
Application: Uremic toxins (indoxyl sulfate, 3-carboxy-4-methyl-5-propyl-2-furanpropanoic acid hippuric acid); weak acids (paraaminohippuric acid, benzylpenicillin); weak bases (cimetidine); and other substances (salicylic acid, indomethacin, 3,5,3′-triiodo-l-thyronine, and indole acetic acid [IA]) can be applied in various fashions to evaluate renal excretory function.
Implementation: Evaluate and characterize [^{3}H]indoxyl sulfate renal transport mechanisms involved in excretion using an *in vivo* tissue-sampling single-injection technique (kidney uptake index [KUI] method).

***Ex Vivo* Model:** Xenopus laevis oocyte expressing rat organic anion transporter 3 (rOAT3).
Interpretation and Analysis: Probenecid shows a concentration-dependent inhibitory effect on the uptake of [^{3}H]indoxyl sulfate using the KUI method, and uptake is inhibited by organic anions such as PAH and benzylpenicillin, by weak bases such as cimetidine, and by uremic toxins, such as 3-carboxy-4-methyl-5-propyl-2-furanpropanoic acid (CMPF) and hippuric acid (HA). However, salicylic acid, indomethacin, 3,5,3′-triiodo-l-thyronine, and indole acetic acid (IA) have no effect on the uptake. rOAT3-expressing oocytes exhibit uptake of [^{3}H]indoxyl sulfate by rOAT3 (Km = 158 μmol/L). Moreover, a number of uremic toxins inhibit uptake of [^{3}H]indoxyl sulfate by rOAT3. Uptake of indoxyl sulfate appears therefore to be mediated by rOAT3 activity. Uremic toxins share the transport mechanism for indoxyl sulfate. Mutual inhibition of these uremic toxins via OAT3 may accelerate their accumulation in the body and, thereby, the progression of nephrotoxicity in uremia.

Major role of organic anion transporter 3 in the transport of indoxyl sulfate in the kidney. Deguchi T, Ohtsuki S, Otagiri M, Takanaga H, Asaba H, Mori S, Terasaki T. Kidney Int 2002 May; 61 (5), pp. 1760–8.

Renal Tubular Reabsorptive Mechanisms *Myo-Inositol/[^{14}C]-Inulin*

Background Information: Filtered myo-inositol, an important renal intracellular organic osmolyte, is almost completely reabsorbed.
Implementation: Evaluation of tubule reabsorption sites and specificity for myo-inositol, and thus identification of possible mechanisms involved in this process. Investigations involve microinfusion of myo-[^{3}H]inositol or D-[^{3}H]glucose into early proximal (EP), late proximal (LP), or early distal tubule sections of superficial nephrons and into long loops of Henle (LLH) of juxtamedullary nephrons and papillary vasa recta in rats *in vivo* et *situ* for the determination of urinary fractional recovery of the [^{3}H] label compared with co-microinfused [^{14}C]-inulin. To determine the extent to which the proximal convoluted tubule (PCT) alone contributes to myo-inositol reabsorption, tubular segments can be microperfused between EP and LP puncture sites. Specificity of reabsorptive carrier(s) can be examined by adding high concentrations of other polyols and monosaccharides to the infusate.

Animal Model: Rat EP, LP, early distal tubule sections of superficial nephrons; LLH of juxtamedullary nephrons; papillary vasa recta.
Interpretation and Analysis: Greater than 60% of the physiological glomerular load of myo-inositol can be reabsorbed in the PCT and > 90% in the short loop of Henle (SLH) by a saturable, phloridzin-sensitive process. Myo-inositol can also be reabsorbed in

the ascending limb of LLH and can move from the papillary vasa recta blood into ipsilateral tubular structures. Essentially no reabsorption occurs in nephron segments beyond the SLH or in collecting ducts. Specificity studies indicate that reabsorption probably occurs via a luminal [Na^+]-myo-inositol co-transporter.

Tubular reabsorption of myo-inositol vs that of D-glucose in rat kidney *in vivo* et *situ*. Silbernagl S, Völker K, Dantzler WH. Am J Physiol Renal Physiol 2003 Jun; 284 (6), pp. F1181–9.

Renal Tubular Resorption/Differentiation between Competitive vs Non-Competitive Tubular Absorption
Phenolsulfonphthalein (PSP)

Cellular/Molecular Mechanism of Action: Phenolsulfonphthalein excreted by the proximal renal tubular epithelium.
Application: Evaluation of renal tubular function pertaining to excretory mechanisms.
Implementation: Evaluation of the plasma kinetics and renal excretion of salicyluric acid (SUA; 0.8 g), administered intravenously with and without concomitant PSP administration.
Animal Model: Canine (beagle dogs).
Interpretation and Analysis: Pharmacokinetic analysis reveals that tubular secretion is the predominant route of elimination and that secretion is inhibited by PSP. A physiologically based kidney model has been developed that comprises all the functional characteristics of the kidney that determine the excretion of salicyluric acid (renal plasma flow, urine flow, non-linear protein binding, glomerular filtration, tubular secretion, and tubular accumulation). The model facilitates an accurate description and analysis of measured plasma levels and renal excretion rates. The interaction with PSP can be adequately described with the model by non-competitive inhibition of a carrier-mediated uptake of SUA into the tubular cells. Furthermore, a small but significant reduction in non-renal SUA clearance can be observed. Model calculations show that, in controlled investigations, tubular secretion is accompanied by a pronounced accumulation of SUA within cells, which is clearly diminished in the presence of phenolsulfonophthalein. The predicted accumulation ratios are in good agreement with previously reported *in vitro* values.

Physiologically based pharmacokinetic model for the renal clearance of salicyluric acid and the interaction with phenolsulfonphthalein in the dog. Russel FG, Wouterse AC, van Ginneken CA. Drug Metab Dispos 1987 Sep–Oct; 15 (5), pp. 695–701.

Renal Tubule Acid Transport/Prolongation of Pharmaceutical Clearance
Probenecid

Cellular/Molecular Mechanism of Action: Competes with other acidic pharmaceuticals that are excreted by mechanisms dependent upon renal tubular acid transport systems.
Physiological Mechanism of Action: Competitively decreases the renal excretion of acidic pharmaceutical agents circulating within the intravascular compartment in a manner that prolongs their pharmacokinetic profile.
Application: Prolong the exposure of acidic diagnostic pharmaceutical agents to desired organ/tissue/lesion target sites.
Route of Administration: Probenecid (oral).
Dosage: Probenecid (100 mg/kg).
Implementation: In rabbits receiving pranofen (5 mg/kg IV), levels of (−)-(R)- and (+)-(S)-pranoprofen and their glucuronide (after hydrolysis with sodium hydroxide) can be measured in plasma, urine, and several tissues to established pharmacokinetic parmeters. The plasma concentration of the (+)-(S)-isomer is higher than that of the (−)-(R)-form. Oral co-administered probenecid (100 mg/kg) results in increased plasma concentrations of both enantiomers. Probenecid reduces the apparent total clearance and excretion of pranoprofen enantiomers in urine. Probenecid (100 mg/kg) has a slight effect on the tissue distribution of pranoprofen but significantly reduces the formation of glucuronide for both enantiomers to the same extent in kidney microsomes. The differences caused by probenecid are significant with respect to its ability to inhibit glucuronidation in the kidney and subsequent excretion into urine, but enantioselective effects are negligible.

Probenecid-induced changes in the clearance of pranoprofen enantiomers. Imai T, Nomura T, Otagiri M. Chirality 2003 May 5; 15 (4), pp. 318–23.

Renal Tubule Concentrating Capacity/Renal Failure
Desamino Arginine Vasopressin (DDAVP)/[Antidiuretic Hormone (ADH)]

Physiological Mechanism of Action: Promotes constriction of smooth muscle tissues of capillaries and arterioles resulting in an elevation in blood pressure. Secondary affects include stimulation of intestinal smooth muscle and increased peristaltic activity. One of the most significant properties of vasopressin is its effect on epithelial cells of the distal renal tubule in a manner the promotes water resorption independent of solids, resulting in elevations in urine concentration.
Background Information: Vasopressin is 1 of the hormones formed by the neuronal cells of the hypothalamic nuclei and stored in the posterior lobe of the pituitary gland.
Application: Comprehensive 1-day renal function test.
Route of Administration: Desamino arginine vasopressin (intranasal).
Dosage: Desamino arginine vasopressin (20 μg).
Implementation: Evaluation of the influence of DDAVP on urine osmolality over a period of 8 and a half hours.
Human Model: Normal "young" cases (n = 33).
Interpretation and Analysis: A 20-μg intranasal dose of DDAVP consistently results in the production of a urinary osmolality of 800 mosmol/kg or more, with no detectable untoward effects. There are several advantages associated with DDAVP that make it a viable alternative to pitressin tannate in oil as a diagnostic agent.

Desamino arginine vasopressin (DDAVP) as a diagnostic agent. Somerfield SD, Hocken AG. N Z Med J 1977 Nov 23; 86 (600), pp. 472–3.

Renal Tubule Excretion of Phosphorous/Renal Dopamine Metabolism/Renal Brush Border Membranes
Gamma-L-Glutamyl-L-dopa (Gludopa)/Dopamine (DA)/L-Dopamine (L-dopa)

Cellular/Molecular Mechanism of Action: Synthetic dipeptide gludopa can serve as an inactive precursor (pro-prodrug) of dopamine (DA).
Background Information: For treatment of phosphate (Pi) overload in various pathophysiological states, an agent that selectively increases renal Pi excretion would be of major value. Previ-

ously, it has been shown that DA inhibits Na^+-Pi co-transport in renal epithelia. However, the administration of DA or its immediate precursor L-dopa increases DA in multiple tissues. Synthetic dipeptide gludopa can serve as an inactive precursor (pro-prodrug) of DA.
Application: Delineation of renal phosphorous physiology.
Implementation: Evaluation of the hypothesis that gludopa may elicit phosphaturia by action of DA generated within the kidney due to the unique co-localization of gamma-glutamyltransferase (gamma-GT), aromatic amino acid decarboxylase, Na^+-Pi co-transporter, and Na^+-L-dopa co-transporter in brush border membrane (BBM) of proximal tubular cells.

Investigation Design: Evaluation of gludopa, or gludopa in combination with acivicin (gamma-GT inhibitor). Urinary excretion of Pi, Ca^{2+}, Na^+, K^+, DA, cAMP, and cGMP can then be determined along with Na^+-Pi co-transport measured in renal BBMs prepared from rats at the end of the investigation period.

Animal Model: Rat (thyroparathyrectomized).
Interpretation and Analysis: Administration of gludopa results in (i) an inhibition of Na^+-Pi co-transport, but not co-transport of Na^+-proline and Na^+-alanine in BBM; (ii) an increase (+300%) of fractional excretion (FE) of Pi and declines (−35%) in plasma Pi, whereas plasma levels and FEs of Ca^{2+}, Na^+, and K^+ remain unchanged; (iii) an increase in urinary excretion of cAMP, but not cGMP; (iv) a 1,000-fold increase of urinary excretion of DA, without a change in excretion of norepinephrine; and (v) incubation of gludopa with BBM *in vitro,* which causes a release of L-dopa, and the *in vivo* administration of acivicin, which blocks actions of gludopa to inhibit Na^+-Pi co-transport and increases urinary Pi and DA excretion. Co-localization of enzymes of biotransformation, BBM transporters, and the autocrine/paracrine DA system in cells of proximal tubules constitutes a cellular basis for the potent and specific phosphaturic action of gludopa.

Gamma-L-glutamyl-L-DOPA inhibits Na(+)-phosphate co-transport across renal brush border membranes and increases renal excretion of phosphate. de Toledo FG, Thompson MA, Bolliger C, Tyce GM, Dousa TP. Kidney Int 1999 May; 55 (5), pp. 1832–42.

Renal Tubule Fractional Clearance Rates/Charge Selectivity
Negatively Charged Ficoll/Uncharged Ficoll

Cellular/Molecular Mechanism of Action: Passive marker system.
Background Information: Recent studies using low-temperature perfusion of rat kidneys have claimed the existence of renal charge selectivity simply on the basis of the differential excretion rates of uncharged Ficoll and charged proteins.
Application: Evaluation of renal tubule charge selectivity and fractional clearance rates.
Route of Administration: Intravenous.
Implementation: Determination of the existence of *in vivo* charge selectivity evaluated by measuring the clearance of negatively charged Ficoll compared with uncharged Ficoll. A short-term approach to steady state is used to study renal tubule fractional clearance rates. Relative clearances can also be examined using an osmotic pump technique where the tracers reach a steady state value after a period of 7 days.

Animal Model: Rat (n = 5 conscious).
Interpretation and Analysis: Carboxymethyl Ficoll is stable during filtration and renal passage, is not taken up by the kidneys, and does not bind to plasma proteins. There is no significant difference in the fractional clearance of molecules with a radius of 36 Å for Ficoll (fractional clearance = 0.048 ± 0.038) and negatively charged carboxymethyl Ficoll (fractional clearance = 0.028 ± 0.019). For molecules with radii greater than 36 Å, carboxymethyl Ficoll has facilitated clearance with respect to uncharged Ficoll (example: radius of 60 Å fractional clearance for Ficoll = 0.0012 ± 0.0005, compared to carboxymethyl Ficoll = 0.015 ± 0.005). Renal function is not compromised by carboxymethyl Ficoll as uncharged Ficoll in urine exhibits similar hydrodynamic size profiles when studied in the presence of excess unlabeled carboxymethyl Ficoll. The facilitated clearance of negatively charged Ficoll with respect to uncharged Ficoll reveals a property of the capillary wall, which has been previously observed with other non-proteinaceous polyanions. The glomerular capillary wall is not charge selective in the form of excluding negatively charged Ficoll. However, the charge properties of the capillary wall may influence the facilitated transport of charged Ficoll compared with uncharged Ficoll.

Anomalous fractional clearance of negatively charged Ficoll relative to uncharged Ficoll. Guimaraes MA, Nikolovski J, Pratt LM, Greive K, Comper WD. Am J Physiol Renal Physiol 2003 Dec; 285 (6), pp. F1118–24.

Renal Tubule Resorption Capacity
Phenol Red/Bromophenol Blue/Bromothymol Blue

Cellular/Molecular Mechanism of Action: Phenol red, bromophenol blue, and bromothymol blue appear to be excreted by renal tubule acid transport mechanisms and are reabsorbed in a manner that is proportional to glomerular load.
Application: Evaluation of renal tubule excretory function.
Route of Administration: Phenol red, bromophenol blue, and bromothymol blue (intravenous).
Implementation: Potential application for evaluating renal tubule acid transport mechanisms.

Animal Model: Rabbit.
Interpretation and Analysis: Net tubular excretion of phenol red reaches a maximal value of 8 μmol/min at a plasma concentration of ultrafilterable dye of about 0.1 mM and is decreased at higher plasma concentrations. Decreases in net tubular excretion at high plasma concentrations are also obtained for bromophenol blue and bromothymol blue, suggesting tubular reabsorption in addition to tubular secretion of the dye. Conclusive evidence for reabsorption is provided by administration of probenecid, which causes a fall in the excretion of the dyes below that filtered by the glomeruli. Tubular reabsorption of phenol red during probenecid administration appears to be proportional to the glomerular load and is increased under experimental conditions leading to decreases in urinary pH. Experiments involving efflux of phenol red from liposomes provides no evidence of a significant role of trans-membrane passage by non-ionic diffusion. The dependence of the reabsorptive process is the result of preferential reabsorption of the acid as compared to the basic form of the indicator dye across a hydrophilic pathway in the transporting membranes. The clearance ratio of phenol red to that of *p*-aminohippurate at low plasma concentrations is about 0.3. The low degree of extraction of phenol red from renal plasma is attributed both to tubular reabsorption and binding of the dye by plasma proteins. Note: Filtration fraction = GF/ERPF.

Renal handling of phenol red. III. Bidirectional transport. Gerdes U, Kristensen J, Møller JV, Sheikh MI. J Physiol 1978 Apr; 277, pp. 115–29.

URINARY BLADDER

Contractions/(Potassium Adenosine Triphosphate [KATP] Channel Opener) *[^{125}I]A-312110*

Cellular/Molecular Mechanism of Action: [^{125}I]A-312110 or [(9R)-9-(4-fluoro-3-^{125}iodophenyl)-2,3,5,9-tetrahydro-4H-pyrano[3,4-b]thieno[2,3-e]pyridin-8(7H)-one-1,1-dioxide] functions as a KATP channel opener in cardiac tissues.
Physiological Mechanism of Action: The *in vivo* application of [^{125}I]A-312110 or [(9R)-9-(4-fluoro-3-^{125}iodophenyl)-2,3,5,9-tetrahydro-4H-pyrano[3,4-b]thieno[2,3-e]pyridin-8(7H)-one-1,1-dioxide] can suppress action potential duration (APD) in Purkinje fibers and relax electrical field-stimulated bladder contractions.
Application: [^{125}I]A-312110 or [(9R)-9-(4-fluoro-3-^{125}iodophenyl)-2,3,5,9-tetrahydro-4H-pyrano[3,4-b]thieno[2,3-e] pyridin-8(7H)-one-1,1-dioxide] can be applied to detect and characterize KATP channels. In this context, [^{125}I]A-312110 can be used to delineate the molecular and functional properties of the KATP channel complex and the identification of new channel blockers and openers that interact with cardiac/smooth muscle-type K^+ATP channels.
Route of Administration: [^{125}I]A-312110 (intravenous).
Dosage: [^{125}I]A-312110 or [(9R)-9-(4-fluoro-3-^{125}iodophenyl)-2,3,5,9-tetrahydro-4H-pyrano[3,4-b]thieno[2,3-e]pyridin-8(7H)-one-1,1-dioxide].
Considerations: Although ATP-sensitive K^+ channels continue to be explored for their therapeutic potential, developments in high-affinity radioligands to investigate native and recombinant KATP channels have been less forthcoming.
Interpretation and Analysis: The agent [^{125}I]A-312110 binds with high affinity to a single class of binding sites in guinea pig cardiac (KD = 5.8 nM) and urinary bladder (KD = 4.9 nM) membranes in a manner that is saturable. Displacement of [^{125}I]A-312110 by structurally diverse potassium channel openers (K^+COs) indicates a similar rank order of potency in both guinea pig cardiac and bladder membranes (Ki, heart): A-312110 (4.3 nM) > N-cyano-N′-(1,1-dimethylpropyl)-N′′-3-pyridylguanidine (P1075) > (−)-N-(2-ethoxyphenyl)-N′-(1,2,3-trimethylpropyl)-2-nitroethene-1,1-diamine (Bay X 9228) > pinacidil > (−)-cromakalim > N-(4-benzoyl phenyl)-3,3,3-trifluro-2-hydroxy-2-methylpropionamine (ZD6169) > 9-(3-cyanophenyl)-3,4,6,7,9,10-hexahydro-1,8-(2H,5H)-acridinedione (ZM244085) >> diazoxide (16.7 μM). Displacement by KATP channel blockers, the sulfonylurea glyburide, and the cyanoguanidine N-[1-(3-chlorophenyl)cyclobutyl]-N′-cyano-N′′-3-pyridinyl-guanidine (PNU-99963) are biphasic in the heart but monophasic in bladder with about a 100- to 500-fold difference in Ki values between high- and low-affinity sites. Good correlations exist between cardiac or bladder-binding affinities of potassium channel openers and functional activation as assessed by their respective potencies to either suppress APD in Purkinje fibers or to relax electrical field-stimulated bladder contractions. Collectively, these results demonstrate that [^{125}I]A-312110 binds with high affinity and has an improved activity profile compared with other radiolabeled potassium channel opener agents. [^{125}I]A-312110 is a useful tool for investigating the molecular and functional properties of the K^+ATP channel complex and for the identification, in a high throughput manner, of both novel channel blockers and openers that interact with cardiac/smooth muscle-type KATP channels.

[^{125}I]A-312110, a novel high-affinity 1,4-dihydropyridine ATP-sensitive K^+ channel opener: Characterization and pharmacology of binding. Davis-Taber R, Molinari EJ, Altenbach RJ, Whiteaker KL, Shieh CC, Rotert G, Buckner SA, Malysz J, Milicic I, McDermott JS, Gintant GA, Coghlan MJ, Carroll WA, Scott VE, Gopalakrishnan M. Mol Pharmacol 2003 Jul; 64 (1), pp. 143–53.

Detrusor Muscle Overactivity/Lower Motor Neuron vs Upper Motor Neuron Hyperactivity *Tramadol*

Physiological Mechanism of Action: Tramadol can function as an effective analgesic agent.
Background Information: Cerebrovascular disease, such as stroke, frequently results in incontinence by reducing suprapontine micturition control. Intraluminal occlusion of the middle cerebral artery (MCA), which produces detrusor overactivity, has been introduced as a useful model of stroke-induced lower urinary tract dysfunction. Recently, tramadol has been found to possess inhibitory actions on normal rat micturition.
Application: Potential differentiation of upper motor neuron disease from lower motor neuron disease pertaining to dysfunction related to micturition processes.
Route of Administration: Tramadol (intravenous).
Dosage: Tramadol (5 mg/kg).
Implementation: Evaluation of detrusor muscle overactivity due to cerebral infarction applying cystometry analysis in combination with tramadol administration. At 72 hours posturinary catheterization, continuous cystometry is performed in awake animals and the effects of tramadol determined.
Animal Model: Rat (female Sprague-Dawley strain with cerebral ischemia induced by occlusion of the MCA). Additional features/requirements involved in the application of the animal model include the placement of urinary bladder catheters.
Interpretation and Analysis: In cerebral infarcted rats, bladder capacity is lower (48 ± 9%) and micturition pressure higher (76 ± 21%) than in control rats. Tramadol increases bladder capacity (59 ± 29%) and threshold pressure (47 ± 32%) to values similar to those detected in reference controls. However, micturition pressure is not significantly altered. Tramadol induces diuresis in some, but not all, conditions of cerebral infarction (rat). Tramadol normalized detrusor overactivity in MCA-occluded rats. Tramadol may therefore have applicability in cases with detrusor overactivity following vascular accidents like cerebral stroke.

Effects of tramadol on rat detrusor overactivity induced by experimental cerebral infarction. Pehrson R, Stenman E, Andersson KE. Eur Urol 2003 Oct; 44 (4), pp. 495–9.

Neoplastic Disease: Urinary Bladder Cancer *5-Aminolevulinic Acid (ALA)/5-Aminolevulinic Acid Methyl Ester (AME)*

Refer to the neoplastic disease chapter (chapter 12) in Section II.

A study of 5-aminolevulinic acid and its methyl ester used in *in vitro* and *in vivo* systems of human bladder cancer. Manivasager V, Heng PW, Hao J, Zheng W, Soo KC, Olivo M. Int J Oncol 2003 Feb; 22 (2), pp. 313–8.

Overactive Bladder: Urgency/Detrusor Pressure/ Increase Precision of Urodynamic Procedures *Lidocaine/Provocative Water Cystometry*

Cellular/Molecular Mechanism of Action: Lidocaine combines with a specific receptor site within sodium channel complexes associated with cell membrane structures, resulting in the inhibition of trans-membrane Na^+ transport.

Physiological Mechanism of Action: Inhibition of depolarization events normally propagated along cell membrane structures including those associated with neurons. In this manner, normal nerve transmission becomes compromised. The effect is most prominent in small, unmyelinated neurons.
Application: Increase the precision of the urodynamic diagnosis of bladder overactivity/urgency.
Route of Administration: Lidocaine (intravesicular delivery).
Dosage: Lidocaine (3 g for 20 minutes).
Implementation: Evaluation of the effect of intravesical lidocaine on urinary bladder control. Repeat cystometry is performed after the bladder had been bathed in lidocaine (3 g for 20 minutes).

Human Model: Cases with symptoms of urinary urgency with or without incontinence.
Interpretation and Analysis: Provocative water cystometry is not able to demonstrate signs of unstable detrusor function. However, all cases evaluated display a continuous, steep rise of detrusor pressure at the end phase of urinary bladder filling. Repeat cystometry performed after intravesicular lidocaine administration (3 g; 20 minutes) results in no detectable change in the configuration of the cystometrogram profiles in most affected cases. Certain groups of cases display decreases in detrusor pressure, and there is also a detectable influence on phasic bladder contractions. In some cases (e.g., n = 3), phasic detrusor contractions develop after lidocaine administration. Thus, intravesical lidocaine seems to be a useful tool to increase the precision of the urodynamic diagnosis in bladder overactivity.

Lidocaine cystometry in the diagnosis of bladder overactivity. Edlund C, Peeker R, Fall M. Neurourol Urodyn 2001; 20 (2), pp. 147–55.

Overactive Bladder vs Sensory Urgency
Edrophonium Chloride/Provocative Filling Cystometry

Cellular/Molecular Mechanism of Action: Edrophonium chloride is a potent inhibitor of cholinesterase biochemical activity. Inhibition of this enzyme promotes elevated accumulation of acetylcholine (cholinergic neurotransmitter) in the vicinity of presynaptic membranes.
Physiological Mechanism of Action: Edrophonium chloride enhances cholinergic activity (parasympathomimetic properties). Bethanecol stimulates bladder activity.
Background Information: Overactive bladder, a highly prevalent disorder, is suspected of having a low detection rate due to the lack of sensitive diagnostic tools. Recent studies imply the involvement of the cholinergic system in the pathophysiological mechanism underlying overactive bladder.
Application: Edrophonium chloride can significantly increase the sensitivity of provocative filling cystometry procedures, thereby facilitating the identification of case subsets with overactive bladder that have previously been classified with sensory urgency.
Route of Administration: Edrophonium chloride (intravenous).
Dosage: Edrophonium chloride (10 mg).
Implementation: Determination of the potential for *in vivo* pharmaceutical enhancement of cholinergic activity to be applied as a means of detecting and evaluating subtle conditions of urinary bladder urgency. Bladder function in this context can be established using multichannel video urodynamic methodologies to evaluate filling cystometry procedures following edrophonium chloride administration. Response to edrophonium is defined as a significant change in sensation and decreased bladder capacity, the induction or amplification of involuntary detrusor contractions, or significant decreases in detrusor compliance. Findings are then compared in responders and non-responders.

Human Model: Cases of bladder hyperactivity (n = 27).
Interpretation and Analysis: Slightly more than 30% of cases evaluated can be classified as responders (e.g., n = 11/27; compared to n = 16 non-responders). In addition, a response can be noted in 78% of the cases with the symptomatology of overactive bladder. A response cannot be appreciated in the vast majority of cases with no specific complaints suggestive of bladder overactivity (e.g., approximately 100%). In approximately two-thirds of responders, values for baseline cystometry can be interpreted as being normal (e.g., n = 7/12 or 64%). In cases classified as responders, uninhibited urinary leakage can be observed in response to edrophonium (e.g., n = 6/11 or 54%). Therefore, preliminary findings to date imply that edrophonium may serve as a novel, practical, and safe drug for provocative cystometry. By significantly increasing cystometry sensitivity the drug would facilitate the identification of case subsets with overactive bladder that have previously been classified with sensory urgency. Note: Serious adverse reactions to the drug are rarely observed.

The effect of cholinergic enhancement during filling cystometry: Can edrophonium chloride be used as a provocative test for overactive bladder? Yossepowitch O, Gillon G, Baniel J, Engelstein D, Livne PM. J Urol 2001 May; 165 (5), pp. 1441–5.

Overactive Conditions of the Urinary Bladder/ Serotonin (5-HT) Production in the Central Nervous System (CNS)
Clomipramine CL)/Fluoxetine

Cellular/Molecular Mechanism of Action: Clomipramine modifies (reduces) concentrations of serotonin within the CNS. Fluoxetine is a selective serotonin uptake inhibitor within the CNS.
Physiological Mechanism of Action: Clomipramine promotes endogenous CNS depression. In contrast, fluoxetine can reverse these CNS properties induced by clomipramine.
Background Information: Serotonin in the CNS may inhibit bladder activity. Based on this consideration, it has been postulated that CNS depression associated with altered 5-HT production may be associated with, or the cause of, conditions such as overactive bladder (OAB).
Application: Detection and evaluation of physiological functions or conditions (e.g., OAB) that may be associated with alterations in 5-HT production within the CNS.
Dosage: Clomipramine hydrochloride (22.5 mg/kg body weight) compared to an equal volume of sterile physiological saline administered by injection to negative reference controls. Fluoxetine (20 mg/kg daily).
Implementation: Evaluation of the influence of CL hydrochloride on urinary voiding frequency at 10 and 15 weeks. Behavioral correlates of depression are assessed using a forced-swim challenge. At age 15 weeks cystometry (CMG) analysis is performed. Fluoxetine is then co-administrated with clomipramine or saline followed by the measurement of void frequency (VF) and reevaluation of CMG analyses.

Animal Model: Rat (Wistar pups, postnatal days 8 to 21), endogenous model for depression promoted by lowering serotonin (5-HT) concentrations.
Interpretation and Analysis: Clomipramine increases immobility when combined with forced-swim challenge testing (indication of depression). Clomipramine promotes more frequent voiding compared to negative saline controls at 10 and 15 weeks. Interestingly, the difference is significant only in females. Cystometry of

CL/females reveals decreased bladder capacity, micturition volume, and intermicturition contractions compared with negative saline reference controls. Fluoxetine reverses these changes (comparable to saline negative reference controls). Such observations support the hypothesis that OAB may be associated with altered 5-HT function and may explain previous descriptions of an association between depression and OAB.

Alterations in voiding frequency and cystometry in the clomipramine induced model of endogenous depression and reversal with fluoxetine. Lee KS, Na YG, Dean-McKinney T, Klausner AP, Tuttle JB, Steers WD. J Urol 2003 Nov; 170 (5), pp. 2067–71.

Traumatic Rupture
Fluorescein Dye

Cellular/Molecular Mechanism of Action: Functions as a detectable dye marker in biological systems. Reacts with ultraviolet light to produce a fluorescent green color.
Diagnostic Application: Detection of traumatic rupture of the urinary bladder. Fluorescein dye is an appropriate visible *in vivo* marker for a variety of purposes.
Route of Administration and Dosage: Traumatic rupture of the urinary bladder is detected by direct infusion into the urinary bladder utilizing a urethral catheter.
Considerations: Fluorescein dyes can on occasion diffuse rather rapidly across intact barriers such as the urinary bladder. For this reason, the interval between infusion and collection must be of a relatively short duration. Alternatively, fluorescein dye can be conjugated to large molecular weight substances, such as a polypeptide protein or dextran molecule, that do not readily diffuse across intact anatomical structures such as the bladder or diaphragm.
Interpretation and Analysis: Detection of fluorescein dye in abdominal fluid following direct infusion into the urinary bladder utilizing a urethral catheter system implies the presence of a physical defect within the bladder wall.
Laboratory Instrumentation: In a clinical environment, presence of fluorescein dye localized within devitalized segments of devitalized intestinal tract, or within abdominal fluid samples, is usually accomplished by direct visual observation.

Traumatic Rupture
Glucose

Cellular/Molecular Mechanism of Action: Detectable molecular marker molecule.
Diagnostic Application: Detection of a ruptured urinary bladder.
Route of Administration: Direct infusion into the urinary bladder by catheter following the removal of any residual urine.
Dosage: Infusion of a 50% formulation of dextrose sufficient to moderately distend the urinary bladder of a normal individual.
Considerations: Dextrose may immediately drain into the abdomen of a patient with a ruptured urinary bladder. Obvious care must be taken to avoid puncture of the urethra and urinary bladder with the catheter, or rupture of an already distended bladder. Peritoneal fluid samples should be collected within a few minutes of bladder infusion of dextrose due to the diffusible nature of the molecule.
Interpretation and Analysis: Traumatic rents in the urinary bladder can be diagnosed by measuring the concentration of glucose within the peritoneal fluid depending on the size, shape, and location of the full-thickness defect.
Laboratory Instrumentation: Measurement of glucose concentrations applying conventional clinical pathology techniques and instrumentation (spectrophotometer).

Urolithiasis: Feline Struvite Crystal Formation
Walpole's Buffer Solution pH 4.5

Application: Diagnosis of struvite urolithiasis.
Implementation: Sterile Walpole's solution is formulated at a pH of 4.5 and can be used to detect and treat struvite urolithiasis.
Animal Model: Feline.

The use of sterile Walpole's buffer solution pH 4.5 as a diagnostic agent and a treatment of struvite urolithiasis in the cat. Jackson OF. Vet Rec 1970 Nov 21; 87 (21), pp. 667–8.

IMAGING ENHANCEMENT

Renal Artery Stenosis (RAS) with Hypertension
Captopril/[^{99m}Tc]-Mercaptoacetyltriglycine-3 (MAG-3) Validation

Cellular/Molecular Mechanism of Action: Captopril (oral) functions as an angiotensin-converting enzyme (ACE) inhibitor. [^{99m}Tc]-MAG3 is eliminated from the body through mechanisms of renal glomerular filtration.
Application: Detection of RAS. Captopril can enhance [^{99m}Tc]-MAG3 renography for assessment of renal plasma flow.
Route of Administration: Captopril (oral).
Dosage: Captopril (50 mg) premedication 1 hour before performing [^{99m}Tc]-MAG3 renal scintigraphy.
Considerations: In the reference trial, baseline studies are obtained only for those patients showing abnormal findings during provocative diagnostic tests.
Interpretation and Analysis: Sensitivity and specificity for the detection of RAS with greater than 50% occlusion are 89% and 91%, respectively. After captopril administration, tracer parenchymal transit time increases significantly in ischemic kidneys (334 $\pm$ 93 seconds in baseline conditions vs 468 $\pm$ 96 seconds after captopril, $p < 0.001$) but not in kidneys without RAS or RAS $<$ 50% (243 $\pm$ 46 seconds vs 271 $\pm$ 95 seconds, $p =$ ns). False-positive responses are mostly bilateral and associated with marked decreases in blood pressure. Therefore, [^{99m}Tc]-MAG3 is an effective compound for detecting RAS $\geq$ to 50% with captopril renal scintigraphy. Performing the provocative test as a 1st step considerably reduces the number of scintigraphic studies required.
Instrumentation: Computer-integrated scintigraphic camera.

Use of technetium-99m-MAG3 for renal scintigraphy after angiotensin-converting enzyme inhibition. Dondi M, Monetti N, Fanti S, Marchetta F, Corbelli C, Zagni P, De Fabritis A, Losinno F, Levorato M, Zuccalá A. J Nucl Med 1991 Mar; 32 (3), pp. 424–8.

Renal Artery Stenosis (RAS) with Hypertension
Captopril/[^{99m}Tc]-Mercaptoacetyltriglycine ([^{99m}Tc]-MAG3)

Application: Detection of RAS in cases of hypertension.
Route of Administration: Captopril (oral) [^{99m}Tc]-MAG3 (intravascular).
Dosage: Captopril (50 mg) followed in 60 minutes by [^{99m}Tc]-MAG3 (120 mBq).
Implementation: Evaluation of the renogram shape, relative tracer uptake, time to peak counts, and parenchymal transit time uti-

lizing [^{99m}Tc]-MAG3 for scintigraphic detection of RAS. In cases with a normal outcome, no further scintigraphic test are performed. In all other cases a baseline study is performed within 2 to 3 days. Where an apparent improvement is found in baseline conditions compared to the provocative test (upslope of the renogram, increased tracer uptake, and reduction of parenchymal transit time), the study is considered positive for significant RAS.

Human Model: Renal artery stenosis in 102 hypertensive patients who underwent renal angiography within 4 weeks of scintigraphic assessment.

Interpretation and Analysis: At renal angiography, a number of arteries with RAS can be detected (e.g., n = 48 with occlusion > 50%; n = 27 RAS with < 50% occlusion). Sensitivity and specificity for detection of RAS > 50% occlusion is approximately 89.6% and 91.6%, respectively. In kidneys affected by RAS > 50%, captopril administration typically induces prolongation in parenchymal transit time (324 ± 90 seconds, baseline conditions, vs 408 ± 122 seconds, postcaptopril, $p < 0.01$) compared to 255 ± 70 vs 251 ± 64, p = ns, in kidneys supplied by patent arteries or with RAS < 50% occlusion.

Captopril renal scintigraphy with [^{99m}Tc]-mercaptoacetyltriglycine (^{99m}Tc-MAG3) for detecting renal artery stenosis. Dondi M. Am J Hypertens 1991 Dec; 4 (12 Pt 2), pp. 737S–40S.

Renal Obstruction: Chronic/Partial
Captopril/[^{99m}Tc]-Mercaptoacetyltriglycine-3 (MAG-3) Validation/Furosemide

Cellular/Molecular Mechanism of Action: Captopril is an angiotensin-converting enzyme (ACE) inhibitor.

Background Information: A growing body of evidence suggests that the renin-angiotensin system is a key factor in the onset and progression of renal damage in chronic partial obstruction, and therefore often represents a complex diagnostic challenge.

Application: Characterization and evaluation of chronic partial renal obstruction.

Dosage: Captopril (0.75 mg/kg).

Considerations: Angiotensin-converting enzyme inhibitors may worsen the excretory phase of diuretic renography for obstructive hydronephrosis.

Implementation: Evaluation of the efficacy of captopril/[^{99m}Tc]-mercaptoacetyltryglycerine-3 or [^{99m}Tc]-MAG-3 renography as a diagnostic approach for the detection of early obstruction. Basal and captopril-enhanced diuretic renography with [^{99m}Tc]-MAG-3 is performed within 24 hours using the same hydration and diuretic stimulus (furosemide 0.75 mg/kg), and captopril is administered orally 60–90 minutes before scintigraphy.

Human Model: Postsurgical cases (n = 12 pyeloplasty including n = 10 males, 2–72 months old; median age 7) with unilateral hydronephrosis, normal renal function, and normal blood pressure.

Interpretation and Analysis: Captopril enhances diuretic renography with [^{99m}Tc]-MAG-3. No adverse effects or modifications of blood pressure can be observed after captopril administration. The diuretic response is markedly worsened by ACE inhibition in each hydronephrotic kidney even when the basal study is only slightly abnormal (15-minute washout basal −27 ± 16%, after captopril −9 ± 13, $p < 0.005$). After surgical correction the diuretic washout during angiotensin inhibition appears normal in the vast majority of cases (e.g., n = 12/12; 15-minute washout −56 ± 14%). Separate renal function and parenchymal transit of MAG-3 are not modified by ACE inhibition, preoperatively or postoperatively.

Data confirm the influence of angiotensin on the kidney excretory system in human hydronephrosis and suggest a role for captopril-enhanced diuretic renography in the early diagnosis of pyeloureteral obstruction. Further work is needed to evaluate ACE inhibition as a protective agent in obstructive nephropathy.

Angiotensin-converting enzyme inhibition worsens the excretory phase of diuretic renography for obstructive hydronephrosis. Zucchetta P, Carasi C, Marzola MC, Murer L, Passerini-Glazel G, Rigamonti W, Zacchello G, Bui F, Montini G. J Urol 2001 Jun; 165 (6 Pt 2), pp. 2296–9.

11 Respiratory System

RESPIRATORY PHYSIOLOGY

Bronchial Constriction Responses/Sites of Action
Methacholine (MCh)/Helium/Oxygen (HeO_2)

Cellular/Molecular Mechanism of Action: Methacholine is a parasympathomimetic/cholinergic agonist that recognizes, binds to, and activates parasympathetic receptor complexes.
Background Information: Bronchodilator agents are an important class of drug for patients with chronic obstructive pulmonary disease. Methacholine is used as a popular bronchial provocative agent. Although the major site of action for bronchodilator agents is known, the site of action for MCh is still in debate.
Application: Methacholine can be applied as a reactive agent in bronchial provocation tests.
Route of Administration: HeO_2 is administered by inhalation.
Implementation: Determination of the site of action for MCh. One approach to achieving this objective involves the evaluation of upper respiratory tract infection applying spirometry, MCh bronchial provocation, and 5 minutes of inhalation of an HeO_2 mixture over the course of a single 24-hour period. Spirometry and the bronchodilator test, in concert with 5-minute inhalations of HeO_2 and expiratory flow-volume (F-V) curve, are subsequently performed on a 2nd (separate) day. Changes in pre- and post-HeO_2 VE_{Max50} are calculated as delta VE_{Max50}. The pre- and postbronchodilator VE_{Max50} and delta VE_{Max50} differences are then counted to determine the acting site for a given bronchodilator. After a bronchial provocative test with MCh, the volume of isoflow (VisoV) can be estimated from pre- and post-HeO_2 F-V curve to establish the acting site for MCh.

Human Model: Cases with upper respiratory tract infection (n = 30).
Interpretation and Analysis: Small airways appear to be the major acting sites of bronchodilators, in contrast to large airways that are the reaction target sites for MCh. Similarly, upper respiratory tract infections (URIs) affect primarily the larger airways. Although airway hyperresponsiveness is more severe in cases with positive MCh responses, the recovery of spirometry values is not significantly different between MCh-positive and MCh-negative groups. Therefore, it appears that the major sites of action for bronchodilator, MCh, and URI are the small and large bronchioles, and large airways, respectively. Bronchial hyperresponsiveness is not a cause of quick restoration of spirometry values in subjects with positive MCh response.

The acting site of bronchodilator, methacholine and upper respiratory tract infection on airways. Ting YM, Liang L, Lu JY. Zhonghua Yi Xue Za Zhi (Taipei) 1997 Dec; 60 (6), pp. 283–9.

Bronchial Constriction Responses/Bronchial Provocation/Cardiac Effects/Provocative Test Safety
Methacholine (MCh)

Cellular/Molecular Mechanism of Action: Methacholine is a cholinergic receptor agonist (parasympathomimetic agent).
Physiological Mechanism of Action: Promote parasympathetic activity.
Application: During a bronchial provocation test (BPT), the performance of maximal inspiratory-expiratory maneuvers, causing abrupt and marked shifts in intrathoracic pressure, may increase the risk of cardiac arrhythmias. Moreover, the inhalation of MCh, a cholinergic agonist agent, could favor the development of unwelcome cardiovascular events, namely, cardiac arrhythmias.
Implementation: Evaluation of the severity of cardiac arrhythmias by ECG-Holter monitoring before, during, and after BPT with MCh challenge. A routine pulmonary function test (PFT) is performed, followed by BPT, during ECG-Holter monitoring. Complementary tests include measurement of serum potassium concentrations, baseline arterial blood gas analysis, and monitoring of oxyhemoglobin saturation.

Human Model: Cases with clinical indications for BPT without pre-existing cardiovascular diseases and not receiving arrhythmogenic drugs (n = 46 cases; n = 28 males; n = 18 female).
Interpretation and Analysis: No significant increase in the number of supraventricular and ventricular arrhythmias can be detected during the performance of PFTs and of BPTs with MCh, either with or without bronchial hyperresponsiveness (BHR). However, during the performance of BPTs, a significant reduction in mean heart rate can be detected. Such findings indicate that the performance of PFTs and BPTs with MCh does not increase the risk of cardiac arrhythmias in conditions without evidence of cardiovascular diseases, as well as during BHR evaluations suggesting that these tests are safe to perform in most subjects.

Cardiac arrhythmia monitoring during bronchial provocation test with methacholine. Malerba M, Radaeli A, Politi A, Ceriani L, Zulli R, Grassi V. Chest 2003 Sep; 124 (3), pp. 813–8.

Bronchial Constriction Responses: Provocative Test Frequency/Incidence of Side Effects/Doubling Dose
Histamine/Methacholine (MCh)/Forced Expiratory Volume in 1 Second (FEV1)

Cellular/Molecular Mechanism of Action: Methacholine is a parasympathomemetic/cholinergic agonist that recognizes, binds to, and activates parasympathetic receptor complexes.
Dosage: Increasing doses reaching a maximum of 4 μM (histamine) and 12 μM (MCh) according to the method of Yan et al corresponding to the dose of agonist causing a 20% fall in FEV1 referred to as PD20.
Considerations: Measurement of bronchial reactivity is widely used in epidemiological surveys. Side effects are mild with both histamine and MCh, but histamine more frequently causes voice change (21% vs 11%).
Implementation: Evaluation of bronchial reactivity in conditions of respiratory wheeze signs.

Human Model: Case subjects (n = 108 subjects in addition to n = 95 subjects selected because of wheeze in the last 12 months).

Interpretation and Analysis: More subjects have a measurable PD20 with MCh than with histamine (e.g., n = 25/108 vs 11/108, $p < 0.01$; and wheeze subjects n = 67/108 vs 48/95). A random sample of repeatability of tests in subjects with signs of wheezing within the last year reveals that the 95% range for a single estimation of PD20 in cases with a measured PD20 on at least 1 occasion is ± 2.5 doubling doses for histamine (n = 25) and ± 2.1 doubling doses for MCh (n = 33). Thus MCh has advantages over histamine for community studies of bronchial reactivity, as it is possible to use doses that produce more PD20 measurements with fewer side effects.

Comparison of histamine and methacholine for use in bronchial challenge tests in community studies. Higgins BG, Britton JR, Chinn S, Jones TD, Vathenen AS, Burney PG, Tattersfield AE. Thorax 1988 Aug; 43 (8), pp. 605–10.

Bronchial Contriction Responses: Reflex Airway/ Asthma Safety
Lidocaine/Bupivacaine/Procaine/Histamine/Serotonin/ Methacholine (MCh)

Application: Intravenous lidocaine is commonly used to treat ventricular arrhythmias and to attenuate reflex airway constriction and intracranial pressure elevation during airway manipulation in intensive care units. Much controversy exists as to the actions of lidocaine on the airway.
Route of Administration: Intravenous local anesthetics (lidocaine, bupivacaine, procaine).
Dosage: Lidocaine (0–10 mg/kg)/, bupivacaine (0–2.5 mg/kg), procaine (0–20 mg/kg), histamine (10 μg/kg + 500 μg/kg/hr; serotonin (10 μg/kg + 500 μg/kg/hr; and MCh (0.5 μg/kg + 300 μg/kg/hr).
Implementation: Compare, in detail, the actions of lidocaine with those of bupivacaine and procaine on airway caliber and the associated changes in plasma catecholamine concentrations in the dog. Such an objective can be addressed through the evaluation of the effects of (i) local anesthetics (lidocaine n = 7; bupivacaine n = 7; procaine n = 7) on basal airway tone; (ii) lidocaine on agonist-induced bronchoconstriction mediated by histamine (n = 6; MCh n = 7); (iii) lidocaine on vagal nerve stimulation (n = 7). Bronchial cross-sectional area at the 3rd bronchial bifurcation is subsequently monitored continuously through the use of a fiberoptic bronchoscope.
Animal Model: Canine (mongrel dogs). Design: Prospective, randomized, controlled experimental *in vivo* and *in vitro* study.
Interpretation and Analysis: Local anesthetics produce a dose-dependent decrease in basal bronchial cross-sectional area. Similarly, lidocaine significantly potentiates histamine and serotonin-induced bronchoconstriction. Lidocaine antagonized MCh- and vagal nerve stimulation-induced bronchoconstriction. Lidocaine may produce direct bronchoconstriction and worsen some agonist-induced bronchoconstriction, but it prevents reflex airway constriction. Therefore, it has been by suggested by some clinicians that this agent be used with caution in asthmatics.

Bronchoconstrictive and relaxant effects of lidocaine on the airway in dogs. Hirota K, Hashimoto Y, Sato T, Yoshioka H, Kudo T, Matsuki A, Lambert DG. Crit Care Med 2001 May; 29 (5), pp. 1040–4.

Bronchial Constriction Responses: Standardized Inhalation Test Procedure
Histamine/Methacholine (MCh)

Cellular/Molecular Mechanism of Action: Histamine binds to and activates histamine H_1 and histamine H_2 receptor complexes. The H_2 receptor complexes are recognized for their influence on gastric acid secretion. Alternatively, MCh binds to and activates muscarinic acetylcholine receptor complexes.
Physiological Mechanism of Action: Histamine promotes inflammatory responses (e.g., increased vascular permeability, leukocyte activation, bronchoconstriction) while MCh functions as a parasympathomimetic agent, thereby promoting bronchoconstrictive responses along the network of the bronchial tree.
Implementation: Evaluation of bronchial responses to standardized inhalation test procedures. In standardized inhalation tests, histamine and MCh have been compared to determine their degree of reproducibility and the relative extent to which each agent can induce a response. Each set of duplicate tests is carried out on a separate day within a given 1-week period. Results are expressed as the concentration of histamine or MCh that causes a 20% fall in forced expiratory volume in 1 second (PC20).
Interpretation and Analysis: Responses to histamine and MCh are highly reproducible (coefficients of determination [r^2] = 0.994 and 0.990, respectively). Responsiveness to histamine correlates closely with responsiveness to MCh ($r^2 = 0.85$). There is a small but significant cumulative dose effect with MCh ($p < 0.01$) but not with histamine. Side effects of throat irritation, flushing, and headache are more frequent with histamine than MCh and are dose-related. The high level of reproducibility indicates the efficiency of the test procedure. The similar severity of effects by the 2 agents with different mechanisms of action suggests that the primary cause of non-specific bronchial hyperreactivity lies at the level of bronchial smooth muscle.

Reproducibility and comparison of responses to inhaled histamine and methacholine. Juniper EF, Frith PA, Dunnett C, Cockcroft DW, Hargreave FE. Thorax 1978 Dec; 33 (6), pp. 705–10.

Bronchial Response Test: Allergen Sensitivity-Induced Constriction
Salbutamol/Beclomethazone Diproprionate/ [Methacholine (MCh) Hyperresponsive Test]

Cellular/Molecular Mechanism of Action: Methacholine functions as a cholinergic/parasympathomimetic agent. Salbutamol functions as a β_2-adrenoceptor agonist.
Physiological Mechanism of Action: Methacholine promotes bronchoconstriction. Corticosteroids like beclomethazone inhibit phospholipase A2 (inhibit prostaglandin/leukotriene production) and stabilize cell membrane structures (inhibit leukocyte degranulation). In addition, like adrenergic agonists, and clenbuterol, corticosteroids promote bronchodilation by promoting increases in intracellular adenylcyclase activity (increased cAMP) within bronchial smooth muscle.
Application: Determination of bronchial dilation capacity in conditions of allergen-induced asthma.
Route of Administration: Salbutamol can be delivered by inhalation methods.
Dosage: Salbutamol (0.3 mg, t.i.d.); beclomethazone diproprionate (0.2 mg, t.i.d.).
Implementation: Determine the effect of a 1-week treatment schedule with inhaled salbutamol plus placebo (S + P) vs salbutamol combined with beclomethasone dipropionate (S + BDP) on early and late asthmatic responses to inhaled allergen. Affected cases are subjected to 2 different weeklong exposure periods, with a 15-day interval between them: (i) salbutamol (t.i.d.) + placebo, and (ii) salbutamol + BDP (t.i.d.); at the end of each treatment period, a specific bronchial provocative test (sBPT) is performed and the last treatments are given 1.5–2 hours before and 3–4 hours after allergen

challenge. As an adjuct form of evaluation, non-specific bronchial hyperresponsiveness to MCh can be induced before each treatment period, after 6 days of treatment before sBPT, and the day after sBPT at the end of the treatment period.

Human Model: Cases of atopy (e.g., n = 10) employed in a randomized, double blind, crossover study. All cases have previous evidence of a dual-type response to an sBPT.

Interpretation and Analysis: Salbutamol + beclomethasone dipropionate completely prevents both early and late responses to allergen, while S + P reduces but does not completely inhibit early and late responses. The difference between the 2 exposure schemes is significant for early and late asthmatic responses. Following MCh challenge, there is only a mild increase in PD15FEV1 MCh after 6 days of treatment with S + BDP in comparison with S + P treatment. These results suggest that salbutamol + beclomethasone effectively prevents the occurrence of early and late asthmatic reactions.

Salbutamol plus beclomethasone dipropionate, but not salbutamol alone, completely prevent early and late asthmatic responses to allergen. Paggiaro PL, Dente FL, Vagaggini B, Bacci E, Talini D, Testi R, Mapp CE, Fabbri LM, Giuntini C. Respir Med 1991 Sep; 85 (5), pp. 401–6.

Bronchodilator Response (BDR)/Bronchoconstrictor Response/Childhood Asthma/ *Salbutamol (Albuterol)/Methacholine (MCh) Influence on BDR*

Cellular/Molecular Mechanism of Action: Methacholine is a parasympathomimetic agent that recognizes, binds to, and activates cholinergic receptor complexes. Salbutamol belongs to the class of selective β_2-adrenergic agonists that recognizes, binds to, and activates sympathetic, adrenergic β_2 receptor complexes.

Physiological Mechanism of Action: Methacholine can promote bronchoconstriction of the major airways. Salbutamol promotes bronchodilation.

Background Information: Airway responses to a BDR and to MCh are frequently measured in the assessment of childhood asthma and in pulmonary research.

Route of Administration: Salbutamol (inhaled).

Dosage: Salbutamol (800 μg).

Implementation: Evaluation of the BDR measured twice in random order on consecutive days in conditions of childhood asthma in concert with assessment of MCh hyperresponsiveness. In this manner, it can be determined if it is possible to obtain a reliable BDR immediately following completion of an MCh challenge test. Bronchodilator response can be calculated as a function of the change in forced expiratory volume in 1 second (FEV1) before and 20 minutes after salbutamol inhalation (metered dose inhaler with a spacer), expressed as a percentage of the predicted value (deltaFEV1%pred). On 1 day, BDR is measured immediately after completing an MCh challenge, on another separate day without any preceding challenge.

Human Model: Cases of asthmatic children (n = 24).

Interpretation and Analysis: Mean (SD) baseline FEV1%pred is not significantly different between test days (98.6 ± 14.2% and 98.1 ± 13.8%, respectively, p = 0.53). The geometric mean provocative dose of MCh producing a 20% fall in FEV1 (PD20) is 56.2 μg (range 10.3–306.2 μg). The mean (SEM) BDR without preceding MCh challenge is approximately 10.8 ± 1.4%, while after a preceding MCh challenge it is 5.2 ± 1.5% (mean difference 5.6%, 95% CI 3.0–8.1%, p < 0.001). Mean (SEM) postbronchodilator FEV1%pred is 109.4 ± 3.0% without and 103.4 ± 2.7% with preceding MCh challenge (mean difference 6.0%, 95% CI 3.5–8.6%, p < 0.001). Therefore, a preceding MCh challenge significantly reduces BDR in asthmatic children. And therefore, a BDR, measured immediately after completing an MCh challenge, cannot be used as a substitute for a separate bronchodilator test.

Bronchodilator response in asthmatic children is significantly reduced when measured immediately after methacholine challenge. Kamps AW, Brand PL, Vermeer K, Roorda RJ. J Asthma 2002 Dec; 39 (8), pp. 737–41.

Bronchodilator Response Test: Allergen Sensitivity *Phleum Pratensis/Methacholine (MCh) Inhalation Test*

Cellular/Molecular Mechanism of Action: Methacholine activates muscarinic acetylcholine receptor complexes.

Physiological Mechanism of Action: Methacholine promotes bronchoconstriction.

Application: Detection and characterization of patterns for airway response to a specific bronchial provocative test (sBPT)

Route of Administration: Inhalation.

Dosage: Phleum pratensis extracts (0.01–2.5 standardized biological units [BU]).

Implementation: Evaluation of seasonal asthma conditions by characterizing airway response patterns to sBPT utilizing Phleum pratensis extracts in addition to MCh inhalation challenge tests and assessement of allergologic parameters. Respiratory function is determined by monitoring FEV1 to assess early (EAR) and late (LAR) airway responses.

Human Model: Cases of seasonal asthma due to grass pollen (n = 27) tested during non-pollen seasons with n = 10/27 cases also tested during the peak pollen seasons.

Interpretation and Analysis: Outside the pollen season sBPT elicites an isolated EAR in about 60% of cases (n = 16/27) and a dual asthmatic response (DAR) in about 41% of cases (n = 11/27). Significant differences do not exist between EAR and DAR cases with regard to the provocative dose causing a 15% fall in FEV1 (PD15FEV1) MCh, EAR (expressed by PD15FEV1 allergen), or allergologic data. There is a significant relationship between PD15FEV1 allergen and PD15FEV1 MCh (r = 0.43, p < 0.05). Assessment of sBPT outside the pollen season reveals correlation coefficients between the 2 tests are r = 0.91, p < 0.001 for the total delivered dose of allergen during sBPT; r = 0.79, p < 0.01 for PD15FEV1 allergen; and r = 0.95, p < 0.001 for the maximum percent fall in FEV1 during LAR. In situations when the evaluation tests are performed during grass pollen season, PD15FEV1 MCh and baseline FEV1 decrease significantly but PD15FEV1 allergen does not change significantly during the season.

Instrumentation: A DeVilbiss 646 nebulizer can be used to deliver increasing doses (0.01n2.5 BU) of the allergen solution.

Natural exposure to pollen reduces the threshold but does not change the pattern of response to the allergen in allergic subjects. Dente FL, Bacci E, Di Franco A, Giannini D, Vagaggini B, Paggiaro PL. Respir Med 2000 Nov; 94 (11), pp. 1073–8.

Bronchodilatory Capacity Postbronchoconstriction/ Asthma: Mild/Bronchodilator Efficacy *Methacholine (MCh)/(Isoflurane)*

Cellular/Molecular Mechanism of Action: Methacholine activates acetylcholine receptor complexes (cholinergic/parasympathomimetic agonist).

Physiological Mechanism of Action: Methacholine promotes bronchoconstrictive responses within the pulmonary airways.

Background Information: Volatile anesthetics used in high concentrations are potent bronchodilators. The effect of lower

subanesthetic concentrations has been not completely documented, particularly in humans with provoked bronchial obstruction.

Application: Methacholine can be applied as a bronchoconstrictive agent for evaluation of the efficacy of candidate bronchodilation agents.

Implemenation: Evaluation of the potential of either 100% oxygen or 0.75% isoflurane in oxygen (8 minutes via a face mask) to reverse MCh-induced bronchconstriction. The MCh provocative test is 1st performed to produce a decrease in forced expiratory volume in 1 second (FEV1) of at least 20%. Either 100% oxygen or 0.75% isoflurane in oxygen is then inhaled for 8 minutes using a face mask.

Human Model: Cases with mild asthma (n = 7) during asymptomatic periods.

Interpretation and Analysis: During isoflurane inhalation, subjects lose consciousness but recover quickly. There is no significant improvement in FEV1 with isoflurane inhalation and maximum expiratory flow at 50% vital capacity (MEF50) recorded 3, 6, 9, 14, and 19 minutes after the end of isoflurane inhalation compare with time-control values. Therefore, lung function in mild asthmatic subjects challenged with MCh is not improved after administration of a low subanesthetic concentration of isoflurane. This may be important during recovery from general anesthesia.

Lack of bronchodilator effect after administration of subanaesthetic concentration of isoflurane in mild asthmatic subjects challenged with methacholine. Mercier FJ, Benhamou D, Denjean A. Br J Anaesth 1995 Mar; 74 (3), pp. 301–5.

Bronchodilatory Response
Atropine

Cellular/Molecular Mechanism of Action: Atropine inhibits parasympathomimetic activity through blockage of muscarinic cholinergic neuromuscular receptor sites. At the level of the smooth muscle, atropine inhibits phosphodiesterase, thereby reducing degradation of cAMP and promoting bronchodilation.

Physiological Mechanism of Action: Atropine promotes bronchodilation during conditions of excessive parasympathetic (cholinergic) tone.

Diagnostic Application: Evaluate dilatory capacity of respiratory bronchial tree.

Dosage: Subcutaneous or intramuscular injection.

Considerations: Atropine can produce undesirable sequela associated with inhibition of the parasympathetic autonomic nervous system. A viable example is the profound ability of atropine to inhibit gastrointestinal motility in equine patients.

Interpretation and Analysis: Atropine can promote bronchodilation by suppressing parasympathetic tone at the level of the bronchial smooth muscle.

Bronchodilatory Response/Capacity
Isoproterenol

Cellular/Molecular Mechanism of Action: Isoproterenol is a selective β_1/β_2-adrenergic agonist and has essentially no effect as an α-adrenergic receptor complex. At the level of the smooth muscle, isoproterenol and other adrenergic agonists (e.g., isoproterenol, clenbuterol) enhance adenylcyclase activity, thereby increasing cAMP synthesis.

Physiological Mechanism of Action: Increases in intracellular cAMP created by the influence of adrenergic agonists (e.g., isoproterenol, clenbuterol) on adenylcyclase activity promote bronchodilatory responses.

Diagnostic Application: Evaluate the dilatory capacity of the respiratory bronchial tree in disease conditions of compromised function (equine chronic obstructive lung disease [COPD], heaves). Parameters evaluated during isoproterenol challenge include alterations in respiratory rate, blood gas profile, expired vs inspired gas composition profile, and upper respiratory tract luminal pressure profile.

Route of Administration: Isoproterenol (intravenous; given by slow continuous infusion in horses).

Dosage: Isoproterenol (0.1 mg added to 250 ml of lactated Ringer's solution in horses).

Considerations: Diagnostically, isoproterenol is superior to atropine in horses because it imposes significantly fewer alterations in gastrointestinal motility. Isoproterenol administration should be terminated when the heart rate doubles compared to preadministration values.

Implementation: Evaluation of the capacity for isoproterenol to reverse bronchoconstrictive processes.

Animal Model: Equine.

Interpretation and Analysis: Evidence of induced bronchodilation is a positive respose to isoproterenol and suggests that the bronchocontrictive process is reversible (lack of permanent fibrous tissue replacement).

Laboratory Instrumentation: Measurement of arterial blood oxygen levels, mass spectroscopy for gas composition determinations, and micro-pressure sensor device for airway measurements.

Bronchodilatory Response Postbronchoconstriction
Clenbuterol (β_2-Adrenergic Bronchodilator)

Cellular/Molecular Mechanism of Action: Clenbuterol is a selective β_2-adrenergic agonist. Adrenergic agonists (e.g., isoproterenol, clenbuterol) and corticosteroids promote increases in intracellular adenylcyclase activity (increases cAMP) within bronchial smooth muscle.

Physiological Mechanism of Action: Increases in intracellular cAMP created by the influence of adrenergic agonists (e.g., isoproterenol, clenbuterol) on adenylcyclase activity promote bronchodilation responses.

Application: Bronchodilator agent (differentiation between responsive and non-responsive bronchoconstriction due to elevated production of inflammatory mediators).

Interpretation and Analysis: Improved respiratory function due to bronchodilation following administration suggests that chronic fibrosis of the respiratory tree has not occurred and that the pulmonary system is responsive to bronchodilatory agents.

Carbon Monoxide Diffusing Capacity
Pulmonary Function Test

The carbon monoxide diffusing capacity test [D(LCO)] is a commonly performed pulmonary function test that requires technical expertise and attention to detail to get acceptable results. With the advent of automated devices and powerful computer programs, D(LCO) measurement has rapidly gained wide clinical acceptance. But there are many subtle aspects to performing the test that can diminish its accuracy and repeatability. During its application, it must be ensured that D(LCO) instrumentation is correctly calibrated; that inhalation is at least 90% of the largest previously measured vital capacity; that quick, smooth inhalations are executed within 2 seconds; that the breath-hold is 9–11 seconds; that the breath-hold is without straining (devoid of Valsalva or Müller maneuvers); that exhalation is quick and smooth; that a representative gas sample is obtained from the correct portion of the exhalation; and that at least 5 minutes elapse between D(LCO) tests. At least 2 but no more than 5 D(LCO) tests should be conducted, and testing is complete when 2

tests are within 10% or 3 D(LCO) units (mL CO/min/mm Hg) of each other. The reported D(LCO) value is the average of the 1st 2 tests that meet the reproducibility criteria, but if 5 tests are performed and no 2 meet the reproducibility criteria, the reported value is the average of the 2 tests with the highest inspiratory volumes. These quality controls will help laboratories achieve consistent high D(LCO) accuracy.

Diffusing capacity: How to get it right. Jensen RL, Crapo RO. Respir Care 2003 Aug; 48 (8), pp. 777–82.

Carboxylic Acid Metabolism: Hereditary Disorders/ Nitrogen Metabolism Disorders (Acquired)/ Gastrectomy, Hepatic Failure, Renal Failure, Myotonic Dystrophy/Valine Metabolism
1-[^{14}C]-Alpha-Ketoisovaleric Acid (KIV)/[$^{14}CO_2$ Breath Excretion Test]

Cellular/Molecular Mechanism of Action: 1-[^{14}C]-alpha-ketoisovaleric acid is a keto analogue of valine and can function as a biochemical substrate for mechanisms of carboxylic acid metabolism.
Background Information: The keto analogues of essential amino acids represent a promising therapeutic modality in hereditary and acquired disorders of nitrogen metabolism. The utilization of these substances in humans has been primarily for nitrogen balance studies.
Application: Endogenous biochemical metabolism of KIV can be measured using the $^{14}CO_2$ breath excretion test. In this context, the agent can be applied as a tool for evaluation of certain diet formulations.
Route of Administration: Oral.
Implementation: Assessement of the *in vivo* decarboxylation of KIV through measurement of $^{14}CO_2$ using a simple and accurate breath excretion test. Protein diets (5 g) supplemented with essential amino acids and KIV (in place of valine) are then evaluated. Diets of 120 g of protein/day are then reevaluated in normal volunteers and gastrectomy cases.
Human Model: Normal volunteers and diseased cases (n = 6 diseased; gastrectomy, hepatic failure, renal failure, and myotonic dystrophy).
Interpretation and Analysis: In situations of low protein intake, 13–32% of ingested KIV undergoes rapid decarboxylation, and this proportion appears to correlate inversely with damage to organ systems containing the branched-chain keto acid dehydrogenase. With high protein intake, the proportion of KIV decarboxylated increases to 44% to 53%. Such findings confirm that the decarboxylation of KIV in man varies under different conditions of dietary intake and metabolic disease. The $^{14}CO_2$ breath excretion test is applicable to other related analyses of carboxylic acid metabolism in human subjects.

Decarboxylation of alpha-ketoisovaleric acid after oral administration in man. Epstein CM, Chawla RK, Wadsworth A, Rudman D. Am J Clin Nutr 1980 Sep; 33 (9), pp. 1968–74.

Epithelium Integrity and Viability/Pulmomary Pathophysiology/Asthma Bronchiale
L-[Guanidino$^{15}N_2$]-Arginine Monohydrochloride/ [^{15}NO] Exhalation/[Breath Test]

Cellular/Molecular Mechanism of Action: The amino acid L-[guanidino$^{15}N_2$]-arginine monohydrochloride is resorbed within the lung and is partially metabolized to [^{15}NO].
Background Information: Conventional diagnostic evaluation of the pulmonary tract uses physical methods such as spirometry and oscillometry. However, the inhalation of a chemical diagnostic agent ought to provide novel ways of more specific diagnosis, for instance of inflammatory states of the bronchial and lung mucosa. The stable isotope technique using a [^{15}N]-labeled substrate appears to be a suitable tool for this application.
Application: Inhalation breath test for evaluating pulmonary integrity/function. The amount of [^{15}NO] yielded after the inhalation of [^{15}N]-labeled arginine could be a potential marker for demonstrating pathophysiological changes in the lung epithelium.
Route of Administration: L-[guanidino$^{15}N_2$]-arginine monohydrochloride (inhaled).
Dosage: L-[guanidino$^{15}N_2$]-arginine monohydrochloride (700 mg of aqueous solution, 20 atom % [^{15}N]).
Implementation: Evaluation of conditions of asthma bronchiale with defined amounts of inhaled amino acid L-[guanidino$^{15}N_2$]-arginine monohydrochloride. The exhaled air is collected under defined conditions in 10-L breath bags and analyzed for NO using chemiluminescence.
Human Model: Cases suffering from asthma bronchiale (n = 7) and healthy/normal volunteers (n = 6).
Interpretation and Analysis: Under standardized test conditions, healthy cases exhale 0.97 ± 0.08 μmol NO/m^3 and asthmatics 1.17 ± 0.14 μmol NO/m^3. A better distinction can be expected when making comparisons using measurements of [^{15}NO] exhalation. Between 30 and 80 minutes after inhalation of [^{15}N]arginine, a maximum (plateau of the [^{15}NO] abundance) is found in exhaled air at which time healthy and asthmatic cases exhibit clear differences in amounts of [^{15}NO] exhaled. Under standardized test conditions, healthy cases exhale 102.3 ± 6.7 nmol [^{15}NO/m^3], whereas asthmatic cases exhale only 76.1 ± 10.9 nmol [^{15}NO/m^3].
Instrumentation: Cryotrap gas chromatography-mass spectrometry system for analyzing the [^{15}N] abundance of NO gas.

[$^{15}N_2$]arginine as a 1st potential inhaled diagnostic agent to characterize respiratory diseases. Krumbiegel P, Denk E, Russow R, Rolle-Kampczyk U, Metzner G, Herbarth O. Exp Lung Res 2002 Oct–Nov; 28 (7), pp. 535–42.

Epithelium Integrity and Viability/Respiratory Inhalation Test/Regional Inflammation/Localized Decompensated Cellular Function
1-[^{13}C]Hexadecanol/1-[^{13}C]Glucose

Cellular/Molecular Mechanism of Action: 1-[^{13}C]hexadecanol and 1-[^{13}C]glucose can be absorbed across the surface of the pulmonary epithelium, transported to the liver through the intravascular compartment, and metabolized by hepatocytes to CO_2 that is then transported to the lung where it can be detected in exhaled air.
Background Information: Conventional [$^{13}CO_2$] breath tests, and also [^{15}N] urine tests, always start with an oral administration of a test substrate. The test person swallows a stable isotope-labelled diagnostic agent. This technique has been used to study several pathophysiological changes in gastrointestinal organs. However, to study pathophysiological changes of the bronchial and lung epithelium, the inhalative administration of a stable isotope labeled agent appears to have some distinct advantages.
Application: Detection and evaluation of alterations in respiratory function (e.g., pulmonary inflammation of certain sections and decompensated cell functions).
Implementation: Evaluation of 1-[^{13}C]exadecanol and 1-[^{13}C] glucose as inhaled pulmonary diagnostic agents. Complementary investigations can involve assessment of the practicality and reproducibility of 1-[^{13}C]glucose as an agent in inhalation tests. Using the APS aerosol provocation system and a nebulizer, a 25% aqueous solution can be inhaled with breath samples then collected at 15-

minute intervals and analyzed for [$^{13}CO_2$] 75–120 minutes after the end of inhalation.

Human Model: Healthy individuals (n = 18).

Interpretation and Analysis: Inhaled 1-[^{13}C]hexadecanol does not yield [$^{13}CO_2$] in exhaled air in contrast to 1-[^{13}C]glucose. A highly reproducible maximum delta [^{13}C] value of 6% over baseline (DOB) is detectable (e.g., n = 12 healthy probands). The optimum inhalative dose of [^{13}C]glucose has been determined to be 205 mg under certain conditions (e.g., n = 6 self-tests). Speculation that the pulmonary resorption of [^{13}C]glucose is the rate-limiting step of elimination suggests that decompensations in the epithelium should be reflected by changes in 1-[^{13}C]glucose resorption rates and changes in [$^{13}CO_2$] output. Inhalation of suitable [^{13}C]-labeled substrates may ultimately facilitate the development of improved [$^{13}CO_2$] breath tests that can aid in characterizing specific pathophysiological changes in the pulmonary tract, such as areas of regional inflammation with decompensated cellular function.

Instrumentation: "Medic Aid" nebulizer (Erich Jaeger, Würzburg).

Toward an inhalative ^{13}C breath test method. Krumbiegel P, Rolle-Kampczyk U, Liebergeld P, Herbarth O, Körich R. Isotopes Environ Health Stud 2002 Jun; 38 (2), pp. 65–70.

Respiratory Center Depression/Brainstem Suppression vs Primary Pulmonary Dysfunction
Doxopram (Dopram)

Cellular/Molecular Mechanism of Action: Doxopram directly stimulates the central respiratory centers located in the reticular formation of the brainstem.

Diagnostic Application: Stimulate elevated respiratory function through direct stimulation of the brainstem respiratory center.

Route of Administration and Dosage: Intravenous injection.

Application: Differentiation between reversible suppression of central brainstem respiratory center function and primary respiratory function as a cause for subnormal arterial oxygen levels (e.g., blood gas analysis of premature neonates).

Interpretation and Analysis: Subnormal blood oxygen concentrations attributed to primary pulmonary dysfunction will not be corrected by Doxopram administration.

Laboratory Instrumentation: Evaluation of respiratory rate, in concert with measurement of arterial blood oxygen and carbon dioxide concentrations.

Ventilation/Perfusion Mismatch
Oxygen Inhalation

Cellular/Molecular Mechanism of Action: Oxygen diffuses from the respiratory alveoli across the pulmonary vascular endothelium. Oxygen then ultimately diffuses across the red blood cell (RBC) membrane and binds to 1 of the porphyrin Fe^{+2} sites within molecular hemoglobin. Oxygen is not as lipid soluble as CO_2 so the latter gas is able to diffuse faster and to a greater extent across cell membrane/basement membrane structures.

Diagnostic Application: Characterization of causes for observed declines in arterial oxygen concentration including detection and classification of ventilation/prefusion mismatch conditions. Related examples include conditions such as those recognized with pulmonary thromboembolism, congenital cardiac malformation, and neonatal hylan membrane disease. In this condition, there is either an anatomical malformation or physical barrier present that limits or prevents normal pulmonary-cardiovascular gas exchange and oxygenation of arterial blood.

Route of Administration and Dosage: Respiratory inhalation of oxygen gas.

Interpretation and Analysis: In instances of compromised oxygenation of RBC hemoglobin due to deficiencies in ventilation, inhalation of gas with a higher oxygen content results in improved oxygenation of the peripheral blood. Alternatively, in instances of hylan membrane disease (e.g., oxygen diffusion barrier), there is no subsequent increase in systemic arterial blood oxygen level. Similarly, in instances of congenital cardiac defects such as a right to left shunt, increased oxygen inhalation fails to result in an increase in arterial blood oxygen concentrations. In this context, abnormalities classified as a mismatch in ventilation (respiratory) and perfusion (cardiovascular) almost invariably fail to respond to inhalation of gas with an increased oxygen content.

Alveolar Gas Concentrations

Ventilation Perfusion Ratio: Normal and Abnormal:

	PO_2 (mm HG)	PCO_2 (mm HG)
Normal Ventilation/Perfusion Ratio	104	40
Ventilation Deficit (V/Q Mismatch)	40	45
Perfusion Deficit (V/Q Mismatch)	149	0

If V/Q is below normal, then ventilation function is insufficient and a portion of the blood perfusing the lung is not oxygenated (amount = physiological shunt blood).

If V/Q is abnormally large, then pulmonary perfusion is insufficient. In the table above, CO_2 more rapidly and more extensively diffuses out of the alveolus compared to O_2, which is known to have a lower capacity of ablity to diffuse across intact cell membranes.

Laboratory Instrumentation: Mass spectroscopic analysis.

RESPIRATORY DISEASE CONDITIONS

Bronchial Reactivity/(Hyperresponsiveness): Occupational Agents
Histamine

Cellular/Molecular Mechanism of Action: Histamine binds to and activates histamine H_1 and H_2 receptor complexes.

Physiological Mechanism of Action: Histamine directly promotes contraction of smooth muscle of the bronchi and intestine (H_1 receptors), while in small vascular structures it promotes relaxation of smooth muscle tissues (H_1 and H_2 receptor complexes). Depending on the receptor complex, histamine can promote profound inflammatory responses. Gastric acid secretion is mediated through H_2 receptor complexes.

Background Information: Specific bronchial reactivity to occupational agents may decline after exposure in the workplace ceases, leading to falsely negative specific inhalation challenges.

Application: The increase in non-specific bronchial hyperresponsiveness after a specific inhalation challenge can be an early and sensitive marker of bronchial response to occupational agents, especially in subjects removed from workplace exposure for a long time. Non-specific bronchial hyperresponsiveness should be systematically assessed after specific inhalation challenges in the absence of changes in airway caliber (diameter).

Route of Administration: Inhalation.

Implementation: Histamine administration can be applied to determine if increases in non-specific bronchial hyperresponsiveness

can facilitate the detection of bronchial responses to occupational agents during specific inhalation challenges.

In cases thought to possibly suffer from occupational asthma due to various causes, challenges are performed over a 2-hour period/day with the suspected agent. Cases not displaying an asthmatic reaction are then rechallenged in 24 hours over a 2- to 3-hour period. The provocative concentration of histamine that causes a 20% fall (PC20) in the forced expiratory volume in 1 second (FEV1) is then assessed at the end of the control day as well as 6 hours after each challenge that does not cause a $\geq$ 20% fall in FEV1. Cases that have significant ($\geq$ 3.1-fold) reductions in PC20 value at the end of the 2nd challenge day are requested to perform additional specific inhalation challenges.

Interpretation and Analysis: The 1st test day elicits an asthmatic reaction in less than half of suspected cases (e.g., n = 25/66). A relatively low percentage of the remaining cases (e.g., 4/45 or 12% with a CI of 95% between 4% and 26%) will exhibit a $\geq$ 3.1-fold fall in PC20 values after inhalation challenge and develop an asthmatic reaction during the 2nd (n = 3) or 3rd (n = 2) challenge exposure. Examples of offending "occupational" agents include persulphate (n = 1), wood dust (n = 2), isocyanate (n = 1), or amoxycillin (n = 1). In some instances, workers have left their job-place for a longer period (mean 21 $\pm$ 14) months) than those who react after the 1st specific inhalation challenge (mean 8 $\pm$ 11 months).

Increase in non-specific bronchial hyperresponsiveness as an early marker of bronchial response to occupational agents during specific inhalation challenges. Vandenplas O, Delwiche JP, Jamart J, Van de Weyer R. Thorax 1996 May; 51 (5), pp. 472–8.

Cell Infiltration: Inflammatory
Methacholine (MCh)/Nitric Oxide Exhalation

Cellular/Molecular Mechanism of Action: Methacholine is a parasympathomimetic agent that recognizes, binds to, and activates cholinergic receptor complexes.

Physiological Mechanism of Action: Methacholine can promote bronchoconstrictive responses.

Background Information: Monitoring of inflammation is an important factor in asthma management. The gold standard for measuring direct airway inflammation is bronchial biopsy specimens taken from proximal airways through a fiber optic bronchoscope. As a non-invasive procedure, the use of exhaled nitric oxide (FENO) for monitoring airway inflammation has been reported in many studies.

Implementation: Evaluate the degree of correlation between FENO with direct measurements of airway inflammation in biopsy specimens and pulmonary function tests (PFTs). Histopathologic features are characterized for bronchial biopsy specimens collected from cases of stable mild-moderate asthma. Parameters are also assessed for measurements acquired from PFTs, FENO levels, blood eosinophil count, and bronchoscopy with bronchial biopsies and bronchoalveolar lavage. In some cases with forced expiratory volume in 1 second (FEV1) > 80% the MCh challenge test can be performed as a complementary diagnostic procedure.

Human Model: Cases of stable mild-moderate asthma (n = 9), in addition to individuals with FEV1 > 80% (n = 5) subjected to the MCh challenge test. Ideally, cases should have had no prior anti-inflammatory therapy for asthma.

Interpretation and Analysis: There is no correlation among PFTs, blood eosinophil count, and FENO levels. There is a negative correlation between PC20 and FENO. Though there is no correlation between bronchial biopsy eosinophil, monocyte and lymphocyte counts, and FENO, a weak positive correlation exists between total inflammatory cell count in bronchial biopsies and FENO levels. A negative significant correlation exists between FENO levels and epithelial desquamation ($p < 0.05$, $r = 0.7$). These results suggest that FENO levels reflect the increased number of activated inflammatory cells in airways, while a negative correlation with epithelial desquamation reflects the role of epithelium in NO syntheses. Exhaled nitric oxide should not be interpreted as a specific inflammation marker for asthma.

Correlation of exhaled nitric oxide levels and airway inflammation markers in stable asthmatic patients. Turktas H, Oguzulgen K, Kokturk N, Memis L, Erbas D. J Asthma 2003 Jun; 40 (4), pp. 425–30.

Chronic Obstructive Pulmonary Disease (COPD)/ Autonomic Dysfunction and Breathlessness
Acetylcholine/[Dermal Sweat-Spot Test]

Cellular/Molecular Mechanism of Action: Induces parasympathomimetic activity at nicotinic and muscarinic neuromuscular receptor sites.

Background Information: Cases with hypoxic COPD have evidence of a subclinical parasympathetic autonomic neuropathy, with apparent preservation of sympathetic function. However, these findings discovered using cardiovascular-respiratory tests might have been biased by concomitant chest disease.

Diagnostic Application: Detection and assessement of pulmonary hypersensitivity to allergen exposure. The acetylcholine sweat-spot test avoids the bias of concomitant chest disease.

Route of Administration: Acetylcholine (intradermal).

Dosage: Acetylcholine (0.1 ml of 1%).

Considerations: Gastrointestinal stimulation.

Implementation: Following intradermal injection of acetylcholine into the dorsum of the feet, the number of sweatglands able to respond in a given surface area is recorded. Cardiovascular autonomic nerve function, arterial oxygen and carbon dioxide tensions, lung function, and cigarette consumption are also recorded.

Human Model: Cases with hypoxemic COPD (n = 35); and age-matched controls (n = 7).

Interpretation and Analysis: The sweat-spot test assesses sympathetic nerve function and it relies upon the fact that denervated sweat glands do not produce sweat. Excessive bronchoconstriction (pulmonary hypersensitivity) implies that environmental exposure to an allergenic substance has occurred. Positive results may suggest the need to avoid further exposure if possible and the prophylactic administration of agents that prevent activation of peroxidation reactions in an effort to prevent development of COPD.

The acetylcholine sweat-spot test is highly repeatable in COPD patients (e.g., n = 8/35 and no person with normal or frankly abnormal function being wrongly assigned). Age-matched controls have normal acetylcholine sweat-spot scores and cardiovascular autonomic tests. The acetylcholine sweat-spot test can be abnormal in a relatively large percent of suspect cases (e.g., n = 24/35), with small numbers showing borderline (e.g., n = 8/35) or normal (e.g., n = 3) responses. Case groups with abnormal sweat-spot tests have significantly worse FEV1, arterial blood gases, and autonomic function. The acetylcholine sweat-spot score correlates with the severity of arterial hypoxemia ($r = 0.78$, $p < 0.001$) and with the parasympathetic cardiovascular tests ($r = 0.80$, $p < 0.001$). Therefore, patients with hypoxemic COPD have a parasympathetic cardiovascular and a peripheral sympathetic autonomic neuropathy. The acetylcholine sweat-spot test is repeatable, easy to perform, and a sensitive indicator for autonomic dysfunction in breathless individuals with COPD.

Autonomic nerve dysfunction in COPD as assessed by the acetylcholine sweat-spot test. Stewart AG, Marsh F, Waterhouse JC, Howard P. Eur Respir J 1994 Jun; 7 (6), pp. 1090–5.

Chronic Obstructive Pulmonary Disease (COPD)/ Pulmonary Function/Forced Vital Capacity and Forced Expiratory Volume
Salbutamol/Forced Expiratory Volume in 1 Second (FEV1)

Cellular/Molecular Mechanism of Action: Salbutamol selectively recognizes, binds to, and activates β_2-sympathetic/adrenergic receptor complexes within the autonomic nervous system.
Physiological Mechanism of Action: Salbutamol (bronchodilation).
Implementation: Evaluation of the effects of an inspiratory maneuver preceding forced expiration on functional tests performed under routine conditions before and after bronchodilator inhalation (salbutamol). Forced vital capacity (FVC) maneuvers are performed either immediately after a rapid inspiration (maneuver no. 1) or after a slow inspiration with a 4- to 6-second pause (maneuver no. 2).
Human Model: Cases of COPD (n = 150).
Interpretation and Analysis: Under baseline conditions, FEV1 values are approximately 8% (% control) larger with maneuver no. 1 than no. 2. Forced expiratory volume in 1 second values increase with salbutamol administration by approximately 8% and are, on average, still 7% larger with maneuver no. 1 than no. 2. The incidence of reversibility, assessed according to American Thoracic Society criteria, is 76% when maneuver no. 2 is selected to represent baseline conditions and maneuver no. 1 is chosen to represent the effects of bronchodilator administration, whereas the lowest incidence (2%) is found when maneuver no. 1 is selected to represent baseline conditions and maneuver no. 2 is chosen to represent the effects of bronchodilator administration. The time dependence of the FVC maneuver has an important impact on the assessment of routine lung function in a clinical setting and supports the notion that the time course of the inspiration preceding the FVC maneuver should be standardized.

Bronchodilation test in COPD: Effect of inspiratory manoeuvre preceding forced expiration. Santus P, Pecchiari M, Carlucci P, Boveri B, Di Marco F, Castagna F, Centanni S. Eur Respir J 2003 Jan; 21 (1), pp. 82–5.

Chronic Obstructive Pulmonary Disease (COPD) vs Asthma/Pulmonary Function Tests: [Forced Expiratory Volume in 1 Second (FEV1), Maximal Mid-Expiratory Flow (MMEF), Airway Resistance (Raw), Specific Airway Conductance (sGaw)]/ Differentiation: Asthmas vs COPD (sGaw)
Albuterol/[Isoproterenol]

Cellular/Molecular Mechanism of Action: Albuterol is a selective sympathomimetic β_2-adrenergic receptor agonist. Proterenol is a non-selective sympathomimetic β_1/β_2-adrenergic agonist. At the level of the bronchial smooth muscle, adrenergic agonists and corticosteroids increase the activity of adenylcyclase, thereby increasing intracellular cAMP levels.
Physiological Mechanism of Action: Increases in intracellular cAMP created by adrenergic agonists promote bronchodilation responses.
Implementation: Evaluation of the relative influence of albuterol and isoproterenol as a bronchodilator in pulmonary function tests and their value as diagnostic probes in the differential diagnosis of asthma and COPD.
Human Model: Cases of asthma (n = 59) and COPD (n = 37). Patients of each group are randomly divided into 2 subgroups. The 2 adrenergic agonists are evaluated using a crossover study design on odd or even days.
Interpretation and Analysis: The changing rates of pulmonary functions induced by albuterol and isoproterenol in the 2 case group types are positively correlated ($p < 0.005$). The changing rates of FEV1, MMEF, Raw, and sGaw induced by albuterol are higher than the corresponding measurements for isoproterenol in asthma conditions ($p < 0.02$); however, the changing rates of forced vital capacity (FVC) and peak expiratory flow rate (PEF) in asthma cases and all the above parameters mentioned for COPD cases are not significantly different between the 2 drugs ($p > 0.10$). The comparison of positive case numbers between asthma and COPD cases induced by both drugs shows significant difference ($p < 0.005$), especially when the positive rate of sGaw induced by albuterol in asthma cases reaches 98%, the positive rates in COPD cases is generally much lower. Bronchodilation testing, therefore, is a valuable diagnostic method for asthma. Albuterol appears to be superior to isoproterenol. The most sensitive index in bronchodilation testing is sGaw, then, in order, FEV1(92%), MMEF, and Raw; the FVC and PEF are relatively insensitive evaluation parameters.

A comparison between the effects of albuterol and isoproterenol in bronchodilation test. Yuan Y, He T, Wang L, Zeng J, Luo Y. Hua Xi Yi Ke Da Xue Xue Bao 2001 Dec; 32 (4), pp. 551–4.

Epithelium: Inflammation vs Non-Inflamed
Arachidonic Acid/Prostaglandin E_2 (PGE_2)

Background Information: Eicosanoids such as PGE2, thromboxane A2 (TXA_2), and peptidoleukotrienes (pLT) are known to be highly biologically active lipid-derived endogenous mediators, especially in human lung epithelium. PGE2 is thought to have mostly bronchoprotective effects, whereas pLT and TXA_2 are bronchoconstrictive.
Implementation: Assessment of the release and interaction of eicosanoids in human bronchial biopsy specimens of normal and inflamed mucosa. One laboratory approach to achieving this objective involves evaluation of the *ex vivo* release of pLT, TXA_2 (measured as TXB_2), and PGE_2 in tissue biopsies.
Human Model: Cases with severe bronchial epithelial inflammatory processes (n = 7) and cases without signs of inflammation (n = 9).
***Ex Vivo* Preparation:** Inflammed bronchial epithelium harvested as a biopsy specimen and subjected to a "functional *in vitro* test" and exposure to various molecular stimuli (e.g., arachidonic acid, PGE_2).
Interpretation and Analysis: Bronchial tissue biopsies incubated with arachidonic acid release higher amounts of pLT, TXB_2, and PGE_2 than unstimulated specimens. Preincubation with PGE_2 results in a significant inhibition of arachidonic acid-induced release of pLT and TXB_2 (> 50%). The inhibitory effect is higher in normal than in inflamed epithelium. Therefore, exogenous PGE_2 has inhibitory effects on the release of pLT and TXB_2 in human bronchial biopsy specimens. This finding could explain the bronchoprotective effect of inhaled PGE_2 in normal subjects and asthmatic subjects as direct eicosanoid interactions. It also supports the concept of PGE_2 as a bronchoprotective endogenous substance. The complex effects of PGE_2 as a modulating mediator in inflammation may justify further investigation.

Effect of prostaglandin E2 on eicosanoid release by human bronchial biopsy specimens from normal and inflamed mucosa. Schäfer D, Lindenthal U, Wagner M, Bölcskei PL, Baenkler HW. Thorax 1996 Sep; 51 (9), pp. 919–23.

Immune Hyperactivity: Asthma
n-3 Polyunsaturated Fatty Acids (PUFA)/Methacholine (MCh)-Induced Respiratory Distress

Application: Detection and characterization of asthmatic conditions and efficacy evaluation of agents that can potentially be applied for therapeutic intervention.
Dosage: Sequential oral ingestion of n-3 PUFAs in ratios to n-6 PUFAs of 0.1:1 and 0.5:1 for 1 month each.
Considerations: Asthma may respond to dietary modification, thereby reducing the need for pharmacologic agents.
Implementation: Evaluation of the potential effectiveness of n-3 PUFA ingestion to ameliorate MCh-induced respiratory distress in conditions of asthma through the assessment of urinary leukotriene excretion and alterations in respiratory function parameters. Forced vital capacity (FVC), forced expiratory volume for 1 second (FEV1), peak expiratory flow (PEP), and forced expiratory flow 25–75% (FEF25–75) are measured along with weekly 24-hour urinary leukotriene concentrations.
Interpretation and Analysis: Methacholine-induced respiratory distress increases with low n-3 PUFA ingestion. Alterations in urinary 5-series leukotriene excretion can predict treatment efficacy with high n-3 PUFA ingestion. Elevated n-3 PUFA ingestion results in a positive MCh bronchoprovocation dose change in $> 40\%$ of the test subjects (responders). The provocative dose that causes a 20% reduction (PD20) in FEV1, FVC, PEF, and FEF25–75 values cannot be calculated because of a lack of significant respiratory reduction. Conversely, elevated n-3 PUFA ingestion causes some cases (non-responders) to further lose respiratory capacity. Five-series leukotriene excretion with high n-3 PUFA ingestion is significantly greater for responders than for non-responders. A urinary ratio of 4-series to 5-series leukotrienes < 1, induced by n-3 PUFA ingestion, may predict respiratory benefit.

Reduced asthma symptoms with n-3 fatty acid ingestion are related to 5-series leukotriene production. Broughton KS, Johnson CS, Pace BK, Liebman M, Kleppinger KM. Am J Clin Nutr 1997 Apr; 65 (4), pp. 1011–7.

Immune Hyperimmune Response/Rhinitis: Seasonal Allergic Reactions
Allergen Provocation/[Interleukin (IL)-4 Expression Profile]

Cellular/Molecular Mechanism of Action: Allergens stimulate the immune system and may create hypersensitivity responses.
Application: Detection and characterization of seasonal allergic rhinitis-type hyperimmune reactions. Measurement or detection of IL-4 can therefore theoretically be applied as an indicator of disease or a molecular marker for validating pharmaceutical efficacy.
Implementation: Evaluation of conditions of seasonal allergy as a function of cytokine expression analyzed by reverse transcriptase-polymerase chain reaction (RT-PCR). The time-course study during winter includes repeated local allergen provocation with subsequent nasal biopsies as well as biopsies taken during pollen season.
Human Model: Cases of seasonal allergic rhinitis ($n = 17$; $n = 10$ healthy controls).
Interpretation and Analysis: The RT-PCR for CD44 yields positive bands in the vast majority of affected cases (e.g., $n = 65/71$ cases). Evaluation of messenger RNA (mRNA) for IL-2, IL-4, and IL-5 (PCR analyses/semi-nested) in these cases reveals that IL-4 mRNA is almost exclusively expressed by allergic patients. During provocation a significant increase in IL-4 can be detected compared to reference controls ($p = 0.043$). Similarly, during the natural pollen season, IL-4 mRNA expression is significantly higher in cases not using nasal corticosteroids compared with those who do ($p = 0.011$). No differences in IL-2 or IL-5 can be appreciated in these same case group types. Such findings, together with the observations of T-cell activation (e.g., phenotype switch toward T-helper 2 [Th2] cells; accumulation [homing] of these T cells in the nasal mucosa) indicate that T cells constitute the main source for IL-4 in the nasal mucosa. Therefore, allergic patients have an increased synthesis of IL-4 when provoked with the allergen, and during natural pollen season this synthesis can be downregulated by corticosteroids. Furthermore, this study exemplifies the versatility of molecular biology in surgical pathology and that even low-copy-number cytokine mRNA can be examined in routinely snap-frozen surgical specimens.

Nasal messenger RNA expression of interleukins 2, 4, and 5 in patients with allergic rhinitis. Karlsson MG, Davidsson A, Viale G, Graziani D, Hellquist HB. Diagn Mol Pathol 1995 Jun; 4 (2), pp. 85–92.

Immune Hypersensitivity/Allergic Asthma/Smokers: Chronic Airflow Obstruction
Citric Acid Cough Threshold/Histamine/Airway Responsiveness

Application: Characterization of respiratory function in cases of asthma and in smokers.
Route of Administration: Citric acid.
Implementation: Determination of parameters for the citric acid cough threshold and airway hyperresponsiveness in non-smokers with allergic asthma. Cough thresholds are determined on 2 occasions by administering doubling concentrations of citric acid.
Human Model: Non-smokers with allergic asthma ($n = 11$; means FEV1 94% predicted) and non-smokers with chronic airflow obstruction (e.g., $n = 25$; mean FEV1 65%).
Interpretation and Analysis: Greater than 50% of asthmatic subjects (e.g., $n = 7/11$) and smokers with chronic airflow obstruction (e.g., $n = 14/25$) have a positive cough threshold on both test days. Cough threshold measurements are reproducible in both groups (standard deviation of duplicate measurements 1.2 doubling concentrations in asthma, 1.1 doubling concentrations in chronic airflow obstruction). Citric acid provocation does not cause bronchial obstruction in most patients, though some cases (e.g., $n = 4/36$) display a fall in FEV1 of more than 20% for a short time on 1 occasion only. No significant difference in cough threshold can be appreciated between non-smokers with allergic asthma and non-smokers with chronic airflow obstruction despite appreciable differences in baseline FEV1 values. There is no significant correlation between cough threshold and the provocative concentration of histamine causing a 20% fall in FEV1 (PC20) histamine in either case group. Based on observations in previous investigations, it can be concluded that sensory nerves can be activated with a tussive agent in cases with asthma and chronic airflow obstruction without causing bronchial smooth muscle contraction.

Citric acid cough threshold and airway responsiveness in asthmatic patients and smokers with chronic airflow obstruction. Auffarth B, de Monchy JG, van der Mark TW, Postma DS, Koeter GH. Thorax 1991 Sep; 46 (9), pp. 638–42.

Immune Hypersensitivity: Airway/Allergen-Induced Stimulation/Type Th2-Dominated Allergic Airway Response
Interleukin-16 (IL-16)

Cellular/Molecular Mechanism of Action: Interleukin-16 has been described as a natural soluble CD4-ligand.
Physiological Mechanism of Action: In an *in vitro* environment, IL-16 exerts immunosuppressive effects but little is known about the *in vivo* effect of IL-16 on immune responses.
Application: Suppression of antigen-induced asthma.
Route of Administration: Interleukin-16 (intraperitoneally in a murine animal model).
Dosage: Interleukin-16.
Interpretation and Analysis: Intraperitoneal administration of IL-16 completely inhibits antigen-induced airway hyperresponsiveness and significantly decreases the number of eosinophils in bronchoalveolar lavage fluid (> 90%) and airway tissue of ovalbumin-sensitized and challenged mice. Thoracic lymph node cells isolated from *in vivo* IL-16-treated ovalbumin-challenged animals produce less IL-4 (77%) and IL-5 (85%) upon antigenic restimulation, compared to vehicle-treated mice. Preincubation of lymphocytes with IL-16 *in vitro* reduces antigen-induced proliferation (55%) and T-helper 2 (Th2)-type cytokine production (IL-4: 56%, IL-5: 77%). The presence of IL-16 during priming cultures of TCR transgenic T cells (DO11.10) reduces IL-4 (33%) and IL-5 (35%) but not IL-10 and interferon-gamma levels upon restimulation. Collectively, these findings support the concept that IL-16 has potent immunosuppressive effects on a Th2-dominated allergic airway response.

Exogenous interleukin-16 inhibits antigen-induced airway hyperreactivity, eosinophilia, and Th2-type cytokine production in mice. De Bie JJ, Jonker EH, Henricks PA, Hoevenaars J, Little FF, Cruikshank WW, Nijkamp FP, Van Oosterhout AJ. Clin Exp Allergy 2002 Nov; 32 (11), pp. 1651–8.

Immune Hypersensitivity: Asthma/Allergen-Induced: House Dust Mite (HDM)-Provoked Asthma/Aspirin-Intolerant Asthma (AIA)
Aspirin/Pranlukast/HDM Inhalation Provocation/ Luekotriene Receptor Antagonist (LTRA)

Cellular/Molecular Mechanism of Action: Panlukast is an LTRA.
Background Information: Leukotrienes (LTs) are important in asthma, and LT modifiers modulate antigen-induced asthma. Overproduction of LT by suppression of cyclooxygenase activity occurs in patients with AIA.
Application: Possible differentiation between HDM-provoked asthma (LT overproduction and Ag/Ab reactions) and AIA (LT overproduction and 5-lipoxygenase shift in the arachidonic cascade).
Route of Administration: Aspirin oral provocation.
Implementation: House dust mite–inhalation provocation tests performed in HDM-sensitive asthmatic inpatients without AIA (HDM type cases). In addition, an aspirin oral provocation test can be employed to evaluate cases of asthma that are intolerant to aspirin administration (ASA type cases). Tests are repeated using the same regimen after 7 days of treatment with an LTRA. The effects of an LTRA on changes in sputum LTC_4-LTD_4, eosinophil cationic protein (ECP), eosinophil count, urinary LTE_4/creatinine, 11-dehydrothromboxane B_2 (11-dhTXB_2)/creatinine, serum LTC_4-LTD_4, and peripheral blood eosinophil count, during immediate asthmatic reaction (IAR) and late asthmatic reaction (LAR) in the HDM cases and during immediate asthmatic reaction IAR in ASA cases for each test, are then compared.
Human Model: Cases of HDM-sensitive asthma without AIA (n = 6 HDM group type), and aspirin-insensitive asthma conditions subjected to an aspirin provocation test (n = 7 ASA group type).
Interpretation and Analysis: In cases of HDM-sensitive asthma without aspirin insensitivity, immediate (IAR) and late (LAR) asthmatic reactions can be observed. Sputum LTC_4-LTD_4 and urinary LTE_4/creatinine both increase significantly during IAR and LAR. Sputum ECP increases during IAR and further increases during LAR. Eosinophil count in the sputum does not increase during IAR but significantly increases during LAR. Leukotriene receptor antagonism (pranlukast) suppresses declines in FEV1 both during IAR and LAR (73.8% and 51.9%, respectively) and inhibits increases in sputum eosinophil count during LAR and sputum ECP during IAR and LAR. In cases of AIA subjected to an aspirin provocation test, aspirin-induced IAR is associated with a fall in urinary 11-dhTXB_2/creatinine and increases in levels of sputum LTC_4-LTD_4, ECP, and urinary LTE_4/creatinine. Leukotriene receptor antagonism (pranlukast) suppresses IAR and inhibits increases in the level of sputum ECP but fails to change aspirin-induced LT production in the sputum and urine. The levels of sputum LTC_4-LTD_4 and urinary LTE_4/creatinine in the stable phase in the ASA group are significantly greater than those in the HDM group. Therefore, it appears that HDM-provoked asthma is associated with overproduction of LT with an antigen-antibody reaction, while AIA is associated with overproduction of LT with a shift to the 5-lipoxygenase series of the arachidonate cascade. Leukotriene receptor antagonist may be useful against both types of asthma through inhibition of LT activity and eosinophilic inflammation of the airways.

Effects of pranlukast on chemical mediators in induced sputum on provocation tests in atopic and aspirin-intolerant asthmatic patients. Obase Y, Shimoda T, Tomari SY, Mitsuta K, Kawano T, Matsuse H, Kohno S. Chest 2002 Jan; 121 (1), pp. 143–50.

Immune Hypersensitivity: Asthma/Aspirin-Induced Bronchoconstriction
Lysine Acetylsalicylate (LASA)/Cromoglycate (Sodium)/ Nedocromil (Sodium)

Background Information: The protective activity of nedocromil sodium and of sodium cromoglycate against aspirin-induced asthma has never been investigated in controlled studies. Reports have described the occurrence of aspirin-induced platelet-mediated cytotoxic activity *in vitro* is inhibited after treatment *in vivo* with nedocromil but not with cromoglycate.
Application: Partial validation of bronchoconstriction induced by aspirin administration.
Route of Administration: Nedocromil sodium (inhalation), sodium cromoglycate (inhalation) or placebo.
Dosage: Nedocromil sodium (4 mg), cromoglycate (10 mg), or placebo.
Implementation: Delineation of the potential protective activity of nedocromil and cromoglycate against aspirin-induced bronchoconstriction. Three bronchial challenges with a single dose of LASA are performed that are capable of causing decreases in forced expiratory volume in 1 second (FEV1) of 25% or more in preliminary dose-response tests 30 minutes after inhalation of nedocromil sodium, sodium cromoglycate, or placebo. Forced expiratory volume in 1 second and specific airway resistance (SRaw) are recorded at intervals for 195 minutes.
Human Model: Cases of aspirin-induced asthma (n = 10).
Interpretation and Analysis: Following a placebo, LASA causes a maximal decrease in FEV1 that is 42 ± 4% of baseline. After cromoglycate and nedocromil the maximal decrease in FEV1

is reduced to 20 ± 3% and 18 ± 4%, respectively ($p < 0.01$ vs placebo for both treatments), without significant differences between the 2 treatments. Similar results can be observed for SRaw. Therefore, at recommended therapeutic doses, sodium cromoglycate and nedocromil sodium are equally effective in attenuating aspirin-induced bronchoconstriction, and it is unlikely that platelet activation participates in the pathogenesis of aspirin-induced asthma.

Attenuation of aspirin-induced bronchoconstriction by sodium cromoglycate and nedocromil sodium. Robuschi M, Gambaro G, Sestini P, Pieroni MG, Refini RM, Vaghi A, Bianco S. Am J Respir Crit Care Med 1997 Apr; 155 (4), pp. 1461–4.

Immune Hypersensitivity: Asthma/Asthma-Associated Severe Bronchial Obstruction/Aspirin-Intolerant Asthma/Rhinitis
Lysine Acetylsalicylic Acid (L-ASA)

Background Information: Nasal provocation tests with lysine-aspirin have recently been introduced for assessment of aspirin-intolerant asthma.
Application: Nasal challenge with L-ASA can be used as a diagnostic test even in asthmatic patients with severe bronchial obstruction.
Route of Administration: Lysine acetylsalicylic acid (intranasal infusion).
Dosage: Lysine acetylsalicylic acid (25 mg).
Implementation: Evaluation of the usefulness of acoustic rhinometry, a new non-invasive technique, for the diagnosis of aspirin-intolerant asthma/rhinitis. Methodologies that can be used in investigative protocols include challenge tests with L-ASA or saline (0.9% NaCl) and 25 mg L-ASA instilled into each nostril of the nose on 2 separate days. Clinical response is evaluated based on nasal symptoms (sneezes, itching, secretion, and blockage). Nasal response is measured by acoustic rhinometry. Symptoms and rhinometry curves are recorded at 10-minute intervals for 3 hours, 1 hour before challenge and 2 hours after challenge.

Human Model: Cases of aspirin-intolerant asthma/rhinitis ($n = 15$; $n = 9/15$ females age 54.7 ± 14 years; $n = 8$ aspirin-tolerant asthma/rhinitis; $n = 3/8$ women mean age = 52.6 ± 7.8 years; $n = 8$ normal healthy volunteers; $n = 2/8$ women, mean age 32.5 ± 9.7 years).
Interpretation and Analysis: L-lysine acetylsalicylic acid challenge induces a significant increase in symptoms in conditions of aspirin-intolerant asthma/rhinitis. No difference in the clinical response can be detected in cases with aspirin-tolerant asthma/rhinitis or healthy subjects. Lysine acetylsalicylic acid challenge induces a significant decrease in nasal volume measured by acoustic rhinometry in cases of aspirin intolerance. No differences can be detected between challenges in aspirin-tolerant cases. If a 25% decrease in nasal volume is taken as the cutoff point, the specificity of the test is approximately 94% with a corresponding 73% level of the sensitivity. The nasal challenge is well tolerated by all subjects. Acoustic rhinometry may be used to study the nasal response to L-ASA.
Instrumentation: Acoustic rhinometry.

Intranasal challenge with aspirin in the diagnosis of aspirin intolerant asthma: Evaluation of nasal response by acoustic rhinometry. Casadevall J, Ventura PJ, Mullol J, Picado C. Thorax 2000 Nov; 55 (11), pp. 921–4.

Immune Hypersensitivity: Asthma/Asthmatic Responses: Early vs Late/Chemotactic Properties Mediated by Mast Cell vs Mononuclear Cells
Lysine Aspirin Bronchoprovocation (L-ASA BPT)

Application: Differentiation between "early" and "dual" aspirin-sensitive asthma response based on the liberation of serum chemotactic properties by either mast cell or monocyte cell populations.
Route of Administration: Lysine aspirin (inhalation).
Implementation: Evaluation of pathogenic mechanisms involved in the early vs late asthmatic response as a function of serum neutrophil chemotactic activity (NCA) and histamine production. Following bronchoprovocation with lysine aspirin. Sera is collected before, then 30 minutes and 240 minutes after L-ASA BPT.

Human Model: Cases of aspirin-sensitive asthma ($n = 13$ ASA; $n = 7$ early responders; $n = 6$ dual responders).

Analytical: Chemotactic activity of human neutrophils can be evaluated using a Boyden chamber apparatus. Histamine can be assayed using an automated fluorometric analyzer.
Interpretation and Analysis: Serum neutrophil chemotactic activity increases significantly after 30 minutes ($p = 0.02$) and decreases significantly at 240 minutes ($p = 0.02$) in aspirin-sensitive asthma cases/early responders, while serum NCA in aspirin-sensitive asthma/dual responders increases significantly at 30 minutes ($p = 0.04$) but tends to increase further up to 240 minutes (not statistically significant). Neutrophil chemotactic activity at 240 minutes in aspirin-sensitive asthma/dual responders is significantly higher than baseline NCA ($p = 0.02$). Serum NCA values collected before and at 240 minutes are significantly higher in aspirin-sensitive asthma/dual responders than in aspirin-sensitive asthma/early responders ($p < 0.05$). There are no significant changes in serum histamine levels during lysine aspirin bronchoprovocation in either of these case group types.

Neutrophil chemotactic activity derived from mast cell may contribute to the development of early asthmatic responses induced by L-ASA inhalation. There may be possible involvement of NCA derived from mononuclear cells during late asthmatic response.
Instrumentation: Boyden chemotactic chamber and automated fluorometric analyzer (histamine assay).

Enhanced serum neutrophil chemotactic activity was noted in both early and late asthmatic responses during lysine-aspirin bronchoprovocation test in ASA-sensitive asthmatic patients. Kim SS, Park HS, Yoon HJ, Lee YM, Lee SK, Nahm DH. J Korean Med Sci 2003 Feb; 18 (1), pp. 42–7.

Immune Hypersensitivity: Asthma/β-Adrenergic Receptor Expression (Bronchial)/Function
Isoproterenol Sulfate (Isoprenaline)

Cellular/Molecular Mechanism of Action: Isoproterenol is a selective β_1/β_2-adrenergic agonist and has essentially no effect as α-adrenergic receptor complexes. At the level of the smooth muscle, isoproterenol and other adrenergic agonists (e.g., clenbuterol) enhance adenylcyclase activity, thereby increasing cAMP synthesis.
Physiological Mechanism of Action: Increases in intracellular cAMP created by the influence of adrenergic agonists (e.g., isoproterenol, clenbuterol) on adenylcyclase activity promote bronchodilation responses.
Route of Administration: Isoproterenol (intravenous).
Implementation: Evaluation of complete *in vitro* and *in vivo* dose-response curves for isoproterenol. Complete *in vivo* dose-response curves for isoproterenol are obtained to determine its effect on bronchial muscle (forced expiratory volume in 1 second), heart rate, blood pressure, and skeletal muscular tremor in conditions of chronic intrinsic asthma. In this context, an isoproterenol test is performed before and during oral treatment with a long-acting selective β-adrenergic stimulator (terbutaline sulfate, 5 mg 3 times daily). Evaluation is performed over 12 months to avoid seasonal variation in basal levels of obstruction and is concluded by adding inhaled terbutaline (2 inhalations 4 times daily) to oral therapy.

Human Model: Cases of chronic intrinsic asthma (n = 3 for *in vitro* studies; n = 8 for *in vivo* studies; n = 60 negative reference controls).

Interpretation and Analysis: Complete *in vitro* dose-response curves for isoproterenol (isoprenaline) sulfate reveal no functional defects in bronchial muscular β-adrenergic receptors in chronic intrinsic asthma, compared to negative reference controls. Complete *in vivo* dose-response curves for intravenously infused isoproterenol reveal that no patterns of "resistance" develop in bronchial β-adrenergic receptors during prolonged exposure. Inhalation therapy in addition to oral therapy improves bronchodilation without causing resistance. Even at 6 inhalations given 4 times daily (4- to 5-hour intervals), isoproterenol does not cause any bronchial resistance; however, resistance develops in skeletal muscles with decreased tremor and in cardiac β-adrenergic receptors.

Development of "resistance" in β-adrenergic receptors of asthmatic patients. Svedmyr NL, Larsson SA, Thiringer GK. Chest 1976 Apr; 69 (4), pp. 479–83.

Immune Hypersensitivity: Asthma/Bronchial Obstruction (Severe)/Aspirin-Intolerant Asthma/ Rhinitis: Leukocyte Response
Lysine Acetylsalicylic Acid (L-ASA)/[Cysteinyl-Leukotriene]

Background Information: Aspirin-induced asthma (AIA) is a clinical syndrome related to cysteinyl leukotriene overproduction in airways. The confirmation of the diagnosis requires inconvenient provocation tests with acetylsalicylic acid (ASA).

Application: Detection and characterization of AIA cannot be effectively determined through the measurement of leukocyte cysteinyl leukotrienes.

Implementation: Detection of AIA conditions with ASA evaluated through the *in vitro* measurement of cysteinyl leukotrienes (cys-LTs) release from isolated peripheral blood leukocytes. In this context, a cellular allergen stimulation test, CAST, can be adapted for the measurement of leukotriene release from leukocytes following stimulation with L-ASA, N-formyl-Met-Leu-Phe (*f*MLP), or both *f*MLP and L-ASA, in buffer containing IL-3, and results compared with the response of human leukemia cell line (Hl-60) to L-ASA. Cysteinyl leukotrienes measured in cell supernatant fluids by ELISA.

Human Model: Isolated leukocyte populations harvested from cases of aspirin-tolerant asthma (ATA; n = 32; n = 26 aspirin-intolerant asthmatics).

Interpretation and Analysis: Acetylsalicylic acid has a rather weak stimulatory effect on cys-LT release in both case group types. Contrary to some previous studies, no significant differences can be appreciated between cys-LT release by leukocytes from AIA and ATA or by differentiated Hl-60 cells. Measurement of cysteinyl-leukotriene release by peripheral blood leukocytes pretreated with aspirin has no value for diagnosis of AIA.

A moderate and unspecific release of cysteinyl leukotrienes by aspirin from peripheral blood leucocytes precludes its value for aspirin sensitivity testing in asthma. Pierzchalska M, Mastalerz L, Sanak M, Zazula M, Szczeklik A. Clin Exp Allergy 2000 Dec; 30 (12), pp. 1785–91.

Immune Hypersensitivity: Asthma/Bronchial Responsiveness
Salmeterol/Methacholine (MCh)

Cellular/Molecular Mechanism of Action: Salmeterol functions as a β_2 agonist at adrenergic receptor complexes while MCh is a cholinergic receptor agonist.

Physiological Mechanism of Action: Salmeterol promotes bronchodilation by sympathomimetic qualities, while MCh promotes bronchoconstriction through parasympathomimetic properties.

Background Information: Asthma is characterized by hyperresponsiveness of the airways to bronchoconstrictive stimuli. Long-acting β_2-adrenoceptor agonists have been introduced as a new therapeutic approach, but there is growing concern about whether control of asthma may deteriorate with the regular use of these agents.

Application: Detection and characterization of the bronchodilatory capacity of airways in asthmatic cases and their potential hyperresponsiveness to bronchoconstrictive stimuli induced by MCh.

Route of Administration: Salmeterol (inhalation).

Dosage: Salmeterol (50 μg, b.i.d.).

Implementation: Evaluation of the bronchodilatory response to salmeterol, complemented by the delineation of potential hyperresponsiveness to the bronchoconstrictive properties of MCh, can provide valuable diagnositic information in cases of respiratory asthma. In the performance of such survey studies, patients are given inhaled salmeterol (or saline palacebo) with MCh challenge being performed before, during, and after each exposure period. Methacholine responsiveness is measured as the provocative concentration (PC20) that causes a 20% decrease in the forced expiratory volume over a period of 1 second (FEV1).

Interpretation and Analysis: Significant increases in FEV1 are present 1 hour after inhalation of salmeterol ($p = 0.006$), which does not differ significantly on days 0, 28, and 56 of the exposure period (increase, 9.8, 9.4, and 8.8% of predicted FEV1, respectively; $p = 0.91$). On the 1st exposure day, salmeterol evokes significant protection against MCh-induced bronchoconstriction, as reflected by a 10-fold increase in the PC20 compared to analogous values from pretreated reference controls ($p < 0.001$). After 4 and 8 weeks of salmeterol, however, the salmeterol-induced changes in PC20 are significantly attenuated ($p < 0.001$) to only a 2-fold increase. Two and 4 days after termination of salmeterol exposure, the PC20 is not significantly different from pre-exposure reference control values ($p = 0.15$). Appreciation of these findings suggests that regular treatment of mild asthma cases with salmeterol leads to tolerance phenomenon with regard to the protective effects against bronchoconstrictor stimulus (e.g., inhaled MCh). Such a finding raises concern about the effectiveness of prolonged therapy with long-acting β_2-adrenoceptor agonists in asthma and may in concept be similar to observations of the downregulation of β receptor complexes in cardiac cases treated long-term with propanolol.

Long-term effects of a long-acting β_2-adrenoceptor agonist, salmeterol, on airway hyperresponsiveness in patients with mild asthma. Cheung D, Timmers MC, Zwinderman AH, Bel EH, Dijkman JH, Sterk PJ. N Engl J Med 1993 Mar 4; 328 (9), pp. 665–6.

Immune Hypersensitivity: Asthma/Bronchial Responsiveness
Cromolyn Sodium/Cockroach (CR) Antigen

Physiological Mechanism of Action: Cromolyn sodium inhibits histamine release mediated through basophil/mast cell degranulation events.

Application: Characterization of asthmatic responses associated with CR antigen.

Implementation: Application of the bronchial provocative test (BPT) with CR antigen in cases of asthma. Evaluation of allergen-specific asthmatic responses induced by CR utilizing a skin test protocol.

Human Model: Cases of asthma (n = 22).

Interpretation and Analysis: Skin tests utilizing CR antigen can result in postive reactions in a large percentage of subjects (e.g., n = 16/22). Coversely, immediate bronchoconstrictive responses can be appreciated following antigen inhalation (e.g., n = 14/16) in CR-positive asthmatics, while no CR-negative asthmatics show bronchospasm (n = 6). Late asthmatic responses can also be appreciated in a large number of CR-positive asthmatic cases following a BPT and CR antigen challenges (e.g., n = 13/16). The dual asthmatic reactions in CR-positive individuals can to a large degree be inhibited by the prior administration of cromolyn sodium. Threefold increases in peripheral eosinophil counts can be appreciated 24 hours following BPT with CR antigen. Speculation therefore suggests that CR-induced asthmatic responses are allergen-specific and CR plays a causative role in allergic asthma in certain populations.

Study on cockroach antigen as a probable causative agent in bronchial asthma. Kang B. J Allergy Clin Immunol 1976 Sep; 58 (3), pp. 357–65.

Immune Hypersensitivity: Asthma/Bronchial Responsiveness
Acetaldehyde/Adenosine 5′-Monophosphate (AMP)/ Methacholine (MCh)

Cellular/Molecular Mechanism of Action: Methacholine binds to and activates cholinergic receptor complexes (parasympathomimetic).
Physiological Mechanism of Action: Inhaled acetaldehyde and adenosine 5′-monophosphate (AMP) cause bronchoconstriction in asthmatics by a mechanism believed to involve histamine release from airway mast cells.
Application: Characterization of airway function in cases of asthma.
Route of Administration: Inhalation.
Dosage: Progressive increase in dosage concentrations and amount delivered.
Implementation: In asthmatics, the evaluation of airway function can be assessed with the aid of inhlation studies employing acethaldehyde, adenosine 5′-monophosphate, and MCh administered at increasing concentrations. Response to each bronchoconstrictor agent is measured by the PC20 (provocative concentration required to produce a 20% fall in forced expiratory volume over a period of 1 second, or FEV1).
Interpretation and Analysis: The geometric mean (range) PC20 values is approximately 3.1 mmol/l (0.5–46.0 mmol/l) for MCh; 883.1 mmol/l (190.7–1,816.1 mmol/l) for acetaldehyde, and 50.1 mmol/l (3.2–1,152.1 mmol/l) for AMP. Thus, acetaldehyde is 18-fold less potent than AMP in causing bronchoconstriction. A similar correlation can be observed between PC20 acetaldehyde and either PC20 AMP ($r = 0.58$, $p = 0.02$) or PC20 MCh ($r = 0.56$, $p = 0.02$). The challenge procedure with acetaldehyde is moderately repeatable (coefficient of repeatability = ± 1.4 doubling concentrations, intraclass correlation coefficient = 0.64). Inhaled acetaldehyde therefore is less potent than AMP in causing bronchoconstriction in asthma, and the response to inhaled acetaldehyde is repeatable. Furthermore, it has been speculated that acetaldehyde responsiveness and AMP responsiveness are not identifying the same alterations in airway functions.

Airway obstruction induced by inhaled acetaldehyde in asthma: Repeatability relationship to adenosine 5′-monophosphate responsiveness. Prieto L, Gutierrez V, Cervera A, Linana J. J Investig Allergol Clin Immunol 2002; 12 (2), pp. 91–8.

Immune Hypersensitivity: Asthma/Bronchial Responsiveness/Airway Reactivity
Methacholine (MCh)/Corticosteroids/Nitric Oxide (Exhaled)

Cellular/Molecular Mechanism of Action: Methacholine is a parasympathomimetic agent that recognizes, binds to, and activates cholinergic receptor complexes. Corticosteroids inhibit phospholipase A2 biochemical activity in a manner that prevents or severely inhibits the subsequent production of prostaglandin species.
Physiological Mechanism of Action: Methacholine can promote bronchoconstriction of the major airways. Salbutamol promotes bronchodilation. Corticosteroids can exert an anti-inflammatory and immunosuppressive response in part due to their ability to promote inhibition of protein synthesis and stabilization of biological membrane structures.
Background Information: Bronchial reactivity and exhaled nitric oxide (eNO) are not often used to monitor the control and severity of asthma in clinical practice.
Application: Correlation of airway reactivity to MCh to alterations in eNO, which are also related to conditions of atopy.
Implementation: Evaluation of the relationship between asthma and different physiologic measures (pulmonary function, nonspecific bronchial reactivity, and eNO).
Human Model: Cases of asthma in various stages of severity (n = 392; cross-sectional, hospital-based study design).
Interpretation and Analysis: Inhalation of corticosteroids does not influence eNO levels. However, the percentage of predicted forced expiratory volume in 1 second (FEV1) and the provocative dose of MCh causing a 20% decrease in FEV1 are significantly lower with inhaled corticosteroids (ICS group) compared with cases not receiving inhaled corticosteroids (NICS mean, 83.2%; 95% confidence interval [CI], 80.4–86.0%; vs mean, 94.1%; 95% CI, 91.1%–97.1%; $p = 0.001$; and geometric mean, 0.32 mg; 95% CI, 0.23–0.45 mg; vs geometric mean, 0.58 mg; 95% CI, 0.42–0.81 mg; $p = 0.01$, respectively). In conditions with severe bronchial hyperresponsiveness, there is a lower predicted FEV1 percent value ($p < 0.001$) and levels of eNO significantly increase with increasing bronchial hyperresponsiveness ($p < 0.001$). There is no relationship between the percentage of predicted FEV1 and eNO. Conditions of atopy have significantly higher eNO levels than do non-atopic patients (geometric mean, 11.21 ppb; 95% CI, 10.07–12.49 ppb; vs geometric mean, 7.76 ppb; 95% CI, 6.11–9.85 ppb; $p = 0.006$, respectively). Therefore, values for eNO are not related to the degree of airway obstruction but are related to airway reactivity and atopic status independent of inhaled corticosteroid use. Higher values of eNO are seen with increased airway reactivity.

Relationship among pulmonary function, bronchial reactivity, and exhaled nitric oxide in a large group of asthmatic patients. Langley SJ, Goldthorpe S, Custovic A, Woodcock A. Ann Allergy Asthma Immunol 2003 Oct; 91 (4), pp. 398–404.

Immune Hypersensitivity: Asthma/ Bronchoconstriction/Bronchodilation
N-Formyl-Met-Leu-Phe (fMLP)/Ipratropium Bromide/Fenoterol

Cellular/Molecular Mechanism of Action: N-formyl-Met-Leu-Phe is an acylated tripeptide bacterial neutrophil chemotactic factor. Ipratropium bromide functions as an anticholinergic agent, and fenoterol is a β_2 agonist.
Physiological Mechanism of Action: N-formyl-Met-Leu-Phe has been shown *in vivo* to have bronchoconstrictor properties

following inhalation in man. The compound has a putative role in the generation of bronchoconstriction associated with bacterial bronchial infection. Ipratropium bromide promotes bronchodilation through parasympatholytic mechanisms, while fenoterol improves flow through the bronchial tree by sympathomimetic processes.

Application: Detection of asthmatic conditions and characterization of the severity of their condition through the evaluation of respiratory function and response testing.

Route of Administration: N-formyl-Met-Leu-Phe (*f*MLP) is delivered by nebulization.

Implementation: Evaluation of bronchoconstriction responses in non-asthmatic subjects administered nebulized after pretreatment with saline, ipratropium bromide, or fenoterol.

Human Model: Non-asthmatics (n = 10 at 21 to 28 years of age).

Interpretation and Analysis: Approximately 80% of non-asthmatic subjects exposed to nebulized *f*MLP will display a 20% level of bronchoconstriction. In individuals that bronchoconstrict in response to nebulized *f*MLP, there is a significant increase in the concentration of the agent required to reach a 20% fall in forced expiratory volume in 1 second (FEV1/PC20*f*MLP) when either ipratropium bromide or fenoterol has been preadministered. Fenoterol is substantially more effective in this regard than is ipratropium bromide. Comparisons made using absolute fall in FEV1 (including all subjects tested; e.g., n = 10) the same results can be appreciated. Partial inhibition of *f*MLP-induced bronchoconstriction by ipratropium bromide suggests that part of the effect of *f*MLP is vagally mediated. Furthermore, it is proposed that fenoterol acts via the modulation of *f*MLP-induced rises in intracellular free calcium.

The effect of anticholinergic and β agonist pretreatment on bronchoconstriction induced by N-formyl-methionyl-leucyl-phenylalanine. Peters MJ, Breslin AB, Berend N. Eur Respir J 1989 Nov; 2 (10), pp. 946–9.

Immune Hypersensitivity: Asthma/Juvenile Asthma-Like Conditions
Salbutamol

Cellular/Molecular Mechanism of Action: Salbutamol belongs to the class of selective β_2-adrenergic agonists that recognizes, binds to, and activates sympathetic, adrenergic β_2 receptor complexes.

Physiological Mechanism of Action: Salbutamol promotes bronchodilation.

Background Information: A significant response in a bronchodilation test is 1 of the main diagnostic criteria of asthma. However, it is not known what the significant bronchodilator response (BDR) is by the interrupter technique (IR), based on measurements of respiratory resistance (Rint) during tidal breathing.

Route of Administration: Salbutamol (inhalation).

Implementation: Evaluation of asthma conditions following subjection to an 8-minute free running test outdoors. Flow-volume spirometry (FVS) and IR measurements are performed before and 10 minutes after running exercise. Thereafter, a salbutamol inhalation test is performed, and pulmonary function measurements acquired 15 minutes later. Case group types can be divided into 3 categories according to postexercise pulmonary function: FEV1 > 100% of predicted (Type I, n = 15), FEV1 86–99% of predicted (Type II, n = 20), and FEV1 < 85% of predicted (Type III, n = 15).

Human Model: Cases diaplaying signs suggestive of juvenile asthma (n = 50).

Interpretation and Analysis: There are no differences in BDRs between Types I and II; the mean increases in FEV1 are 4–6% and in MMEF 20–23%, and the mean decreases in Rint are 23–26%. The mean change in Type III is significantly higher: 15% (p = 0.004) in FEV1, 55% (p = 0.021) in MMEF, and 38% (p = 0. 014) in Rint. Bronchodilator response is positive (FEV1 rise > 10%) in some cases (e.g., n = 15/50; n = 5/20 Type II; n = 10/15 Type III). For MMEF and Rint, the best combination of sensitivity and specificity is achieved by a limit of 35%. Utilizing this limit, MMEF and Rint can identify positive cases (e.g. n = 14/50 and n = 15/50). The IR technique agrees with both FEV1 and MMEF in the majority of cases (e.g., 73%). The IR technique provides an alternative to conventional ventilatory function measurements in bronchodilation tests in children. A decrease of 35% or more in Rint can serve as diagnostic criteria in postexercise bronchodilation tests.

Evaluation of the interrupter technique in measuring postexercise bronchodilator responses in children. Kannisto S, Vanninen E, Korppi M. Clin Physiol 2000 Jan; 20 (1), pp. 62–8.

Immune Hypersensitivity: Asthma/Predicted Absence
Skin-Prick Test (SPT)/Methacholine (MCh)

Cellular/Molecular Mechanism of Action: The SPT employs a battery of foreign environmental substances that can function as immunogens. The biological preparations applied in the SPT are recognized by the immune system and if they are perceived as allergens, they activate various immune and inflammatory pathways. In classic anaphylactic reactions, antigen is recognized by IgE and the resulting Ag:IgE complex can activate the complement cascade and bind to Fc receptors expressed on the exterior surface membrane of mast cell populations. A wide spectrum of endogenous inflammatory mediators is subsequently released by activated mast cell populations (e.g.. histamine).

Background Information: None of the existing tests for the diagnosis of asthma are considered to be definitive. Certain circumstances require prompt diagnosis, and a test able to predict the absence of asthma would be very useful.

Application: The SPT may be valuable in predicting the probability of asthma in young adults.

Dosage: Methacholine administered at an exposure level capable of causing a 20% fall in forced expiratory volume in 1 second (FEV1) (PC20) at < 4 mg/mL while utilizing < 8 mg/mL as diagnostic cutoff value for asthma in the MCh challenge test (MCT).

Implementation: Evaluation of asthmatic conditions utilizing (i) SPT for the diagnostic introduction of a battery of common aeroallergens; and (ii) MCT. The sensitivity, specificity, positive predictive value, and negative predictive values (NPVs) of the SPT are calculated using provocative concentrations of MCh. The Bayes' formula can be used to determine posttest probabilities of having asthma, both for positive and negative SPT results.

Human Model: Cases suffering from asthma consisting of 3 groups of subjects aged 18–24 years: Group A, asthmatic patients (n = 175); Group B, control subjects (n = 100); and Group C, subjects with suspected asthma (n = 150) with normal spirometry findings and a negative exercise challenge test result.

Interpretation and Analysis: A positive SPT result to at least 1 allergen can be detected in approximately 95.5%, 54%, and 69% of cases classified as asthmatics, reference controls subjects, and suspected asthmatics, respectively. Sensitivity, specificity, and NPVs of the SPT are 90.7%, 52.0%, and 84.8%, respectively, with a cutoff value of PC20 < 8 mg/mL. The lower cutoff, PC20 < 4 mg/mL, increases the sensitivity and NPVs to 98.2% and 97.8%, respectively. A negative SPT result decreases the probability of having asthma by 10-fold to 20-fold in subjects that have a low to moderate pretest probability. Incorporating an SPT into the workup of subjects with suspected asthma can reduce the cost of this process significantly.

The SPT may be used as a simple, fast, safe, inexpensive, and reliable method to predict the absence of asthma in young adults.

Value of a negative aeroallergen skin-prick test result in the diagnosis of asthma in young adults: Correlative study with methacholine challenge testing. Graif Y, Yigla M, Tov N, Kramer MR. Chest 2002 Sep; 122 (3), pp. 821–5.

Immune Hypersensitivity: Asthma/Septic Inflammatory Responses/Alveolar Macrophages and Blood Monocytes/Cytokine Responses: Interleukin (IL)-10, Macrophage Inflammatory Protein-1alpha (MIP-1α), Interferon-Gamma (IFN-γ), Granulocyte-Macrophage Colony-Stimulating Factor (GM-CSF)
Dexamethasone/Lipopolysaccharide/IL-1β

Cellular/Molecular Mechanism of Action: Dexamethasone inhibits phospholipase A2 biochemical activity. Lipopolysaccharide (LPS) is also referred to as bacterial endotoxin. Systemically, it can bind to LPS-binding protein in plasma and membrane-associated LPS receptor complexes (CD14) on the surface of leukocytes and vascular endothelium.

Physiological Mechanism of Action: Dexamethasone functions as an immunosuppressive agent due to its ability to inhibit normal protein synthesis and stabilize cell membranes in a manner that inhibits cell activation and degranulation phenomenon. Bacterial LPS fractions (endotoxin) promote inflammatory responses in primarily leukocyte and endothelial cell populations. The cytokine IL-1β functions as an endogenous mediator of inflammation.

Application: Lipopolysaccharide (bacterial endotoxin) can be utilized to induce septic inflammatory responses. Dexamethasone can be used as a probe to study alterations in the production of endogenous mediators associated with inflammatory and immune responses during allergen-induced reactions.

Implementation: Evaluation of the effect of inhaled corticosteroid, and budesonide, on the release of the anti-inflammatory cytokine, IL-10, and of proinflammatory cytokines, MIP-1α, IFN-γ, and GM-CSF, from blood monocytes and alveolar macrophages.

Human Model: Cases of mild asthma used as donors for alveolar macrophages obtained by bronchoalveolar lavage at the end of each treatment phase (double blind, crossover, placebo-controlled study).

Interpretation and Analysis: Budesonide reduces bronchial hyperresponsiveness and improves baseline forced expiratory volume in 1 second (FEV1). Interleukin-10 from blood monocytes is not altered, but both IL-10 messenger RNA (mRNA) and protein expression from alveolar macrophages stimulated by lipopolysaccharide and IL-1β are increased after corticosteroid therapy. Alternatively, alveolar macrophages release significantly less MIP-1α, IFN-γ, and GM-CSF after steroid challenge. In comparison to alveolar macrophages from normal non-asthmatic reference controls, those from cases suffering from asthma release more MIP-1α, IFN-γ, and GM-CSF but lower amounts of IL-10 particularly at baseline and after IL-1β stimulation. The ability of steroids to inhibit proinflammatory cytokines but to enhance the anti-inflammatory cytokine such as IL-10 may contribute to their beneficial actions in asthma. Asthma is characterized by alveolar macrophages exhibiting both an enhanced capacity to release proinflammatory cytokines and a reduced capacity to produce IL-10.

Inhaled corticosteroids increase interleukin-10 but reduce macrophage inflammatory protein-1alpha, granulocyte-macrophage colony-stimulating factor, and interferon-gamma release from alveolar macrophages in asthma. John M, Lim S, Seybold J, Jose P, Robichaud A, O'Connor B, Barnes PJ, Chung KF. Am J Respir Crit Care Med 1998 Jan; 157 (1), pp. 256–62.

Immune Hypersensitivity: Asthma/"Skiers Asthma"/ Budesonide Efficacy Evaluation
Methacholine (MCh)

Cellular/Molecular Mechanism of Action: Methacholine is a parasympathomimetic agent that recognizes, binds to, and activates cholinergic receptor complexes.

Background Information: Asthma-like symptoms, MCh hyperresponsiveness, frequent inhaled steroid use, airway inflammation, and increased tenascin expression in the reticular basement membrane have all been reported in competitive cross-country skiers.

Application: Methacholine can be applied to detect bronchial hyperresponsiveness in conditions including various forms of asthma or asthma-like alterations in respiratory function (e.g., skiers asthma) in addition to functioning as a molecular probe for evaluating pharmaceutical efficacy.

Route of Administration: Budesonide (inhaled).

Dosage: Budesonide (400 μg b.i.d.).

Implementation: Delineate the effect of inhaled budesonide on indices of airway inflammation in conditions of skiers asthma. Bronchial biopsy and bronchoalveolar lavage (BAL) analysis of samples is performed to determine the influence of budesonide on levels of cellular inflammation within bronchial mucosal tissues.

Human Model: Competitive cross-country skiers (n = 25; n = 19/25 male; mean age = 18 [16–20] years) with a mean (range) treatment period of 22 (10–32) weeks during the competition season. Cases also previously determined to be affected by skiers asthma defined as asthma-like symptoms within the previous year in addition to bronchial hyperresponsiveness to MCh.

Design: A randomized double blind placebo-controlled parallel group.

Interpretation and Analysis: No changes can be appreciated regarding cellular inflammation in the bronchial mucosa or tenascin expression. In the BAL fluid, both groups have a significant decrease in activated T-suppressor (CD8) lymphocytes and an increase in macrophages, with no differences across the case group types. In cases given budesonide, there is a decrease in IL-2 receptor-activated T-helper lymphocytes and an improvement in forced expiratory volume in 1 second (FEV1). Asthma-like symptoms are unchanged in about 68% of skiers (n = 17/25). Methacholine provocation test is negative in 60% of cases (n = 15/25) and remains positive in a small percentage of cases (n = 5/25 or 20%) in both case group types. Improvement in bronchial responsiveness occurs in both groups and is not accompanied by a decrease in cellular inflammation. Budesonide does not appear to exert any clear beneficial effect in skiers asthma. As changes in training intensity probably account for the spontaneous improvement in bronchial responsiveness, more attention should be directed at reducing environmental stress to the airways than at attempting pharmacological modulation of induced inflammatory changes.

Placebo-controlled study of inhaled budesonide on indices of airway inflammation in bronchoalveolar lavage fluid and bronchial biopsies in cross-country skiers. Sue-Chu M, Karjalainen EM, Laitinen A, Larsson L, Laitinen LA, Bjermer L. Respiration 2000; 67 (4), pp. 417–25.

Immune Hypersensitivity: Asthma (Allergen Identification) Histamine Provocation Test
Bronchial Provocation Test/Radio Allergosorbent Test/ Skin-Prick Test (SPT)

Cellular/Molecular Mechanism of Action: Histamine binds to and activates histamine H_1 and H_2 receptor complexes.

Physiological Mechanism of Action: Histamine directly promotes contraction of smooth muscle in the bronchi and intestine (H_1 receptors), while in small vascular structures it promotes relaxation of smooth muscle tissues (H_1 and H_2 receptor complexes). Depending on the receptor complex, histamine can promote profound inflammatory responses. Gastric secretion is mediated through the H_2 receptor.
Application: Identification of offending asthma-inducing agents.
Implementation: Occupational exposure to allergens can produce marked signs of wheezing that are not appreciated when in a home environment. A strategy than can be employed to identify the offending allergen can include diagnostic procedures that involve acquiring serial peak flow recordings (not diagnostic) in addition to SPTs, radio allergosorbent test (RAST) measurements, and specific bronchial provocation testing. The bronchial provocation testing is performed by a dust tipping method in a single blind manner, with lactose as an inert control and suspected allergen as the active agent. Serial measurements of forced expiratory volume in 1 second (FEV1) are recorded in addition to identification of the histamine provocative concentration that causes a 20% fall in FEV1 (PC20) tests, which are established before and 24 hours after each challenge.
Interpretation and Analysis: Examples of asthmatic reponses include isolated early reactions, isolated late reactions, and early and late reactions. Many cases may demonstrate increases in non-specific bronchial responsiveness after active challenge. In this context, some cases (e.g., n = 4 men) can be identified that suffer from occupational asthma associated with exposure to an allergen (e.g., amylase: *Bacillus licheniformis*-derived contained in detergent washing powders). The introduction of encapsulated enzymes in the detergent industry has produced reductions in the incidence of respiratory sensitization.

Occupational asthma caused by bacillary amylase used in the detergent industry. Hole AM, Draper A, Jolliffe G, Cullinan P, Jones M, Taylor AJ. Occup Environ Med 2000 Dec; 57 (12), pp. 840–2.

Immune Hypersensitivity: Asthma (Allergic vs Non-Allergic)/Aspirin-Sensitive and Aspirin-Insensitive Asthma/Histamine Release (HR)/Sulfidoleukotriene (LTR) Release
Interleukin-3 (IL-3)/Anti-IgE/C5a/Basophil Stimulation Test

Cellular/Molecular Mechanism of Action: The immunoglobulin fraction anti-IgE binds to and neutralizes the biological activity of IgE, which is an antibody isotype that binds to Fe receptors on the surface membrane of basophils and is intimately involved in the initiation of allergic and anaphylactic immune hypersensitivity reponses. The complement fraction C5a among other properties is classified as an anaphylatoxin.
Physiological Mechanism of Action: The interleukin IL-3 appears to be necessary for the development/maturation of mast cell populations. The complement fraction C5a, among its many other properties, functions as an anaphylatoxin related to the initiation of anaphylactic immune hypersensitivity reactions.
Background Information: The differentiation between allergic and non-allergic asthma is a common and important challenge for the clinician. Until now, no *in vitro* diagnostic characteristics have been described to distinguish between these types of asthma.
Application: Differentiation between allergic and non-allergic conditions of asthma, but aspirin-sensitive asthma cannot be distinguished from non-allergic asthma without aspirin tolerance.
Implementation: Characterize and profile mediator release induced by anti-IgE and C5a exposure (basophil stimulation test) in different conditions of bronchial asthma. The *ex vivo* analysis procedure involves the isolation of peripheral blood leukocytes (PBLs) by dextran sedimentation. After priming with IL-3, PBLs are stimulated with anti-IgE and C5a to facilitate the measurement of released histamine (HR) and LTRs in the supernatant. Additionally, purified leukocyte fractions can be evaluated to selectively determine the cellular source of mediator release.

Human Model: Cases of aspirin-sensitive asthma (n = 10); non-allergic asthma without aspirin tolerance (n = 12 NAA); allergic asthma (n = 7 AA); negative healthy reference controls (n = 9).
Interpretation and Analysis: Upon stimulation with anti-IgE, LTRs are slightly, but not significantly, lower in aspirin-sensitive asthma and NAA compared to AA and controls. In contrast, C5a-triggered LTR is significantly higher in ASA (14.4 ± 12.88 pg/105 cells) and NAA (22.9 ± 22.61 pg/105 cells) than in AA (9.6 ± 3.29 pg/105 cells) and controls (7.5 ± 7.19 pg/105 cells) ($p < 0.05$). This difference between aspirin-sensitive asthma and NAA vs AA and controls is even more pronounced when determining the quotient C5a-/anti-IgE-induced LTR ($p < 0.001$). At an optimal cutoff point of 1.0, calculated by relative operating characteristics (ROC) analysis, the positive predictive value for a donor to belong to aspirin-sensitive asthma or NAA is 0.94. No significant differences can be detected in HR between conditions of asthma and healthy controls in either case. As cellular source of LTR and HR in basophils can be determined. Delineation of anti-IgE- and C5a-induced LTR from basophils allows differentiation between allergic and non-allergic asthmatic patients. The quotient C5a-/anti-IgE-induced LTR is diagnostically more significant than considering a single parameter. Aspirin-sensitive asthma cannot be distinguished from NAA.

Differential mediator release from basophils of allergic and non-allergic asthmatic patients after stimulation with anti-IgE and C5a. Abrahamsen O, Haas H, Schreiber J, Schlaak M. Clin Exp Allergy 2001 Mar; 31 (3), pp. 368–78.

Immune Hypersensitivity: Asthma (Aspirin-Induced)/Cysteinyl-Leukotriene Production: Peripheral Blood Leukocytes [Diagnostic Value Limited]
Lysine Acetylsalicylic Acid/fMLP/IL-3

Background Information: Aspirin-induced asthma (AIA) is a clinical syndrome related to cysteinyl leukotriene overproduction in airways. The confirmation of the diagnosis requires inconvenient provocation tests with acetylsalicylic acid (ASA).
Implementation: Evaluate the *in vitro* influence of ASA stimulation of isolated peripheral blood leukocytes on measurements for the release of cysteinyl leukotrienes (cys-LTs) as a potential diagnostic molecular marker for AIA. Potential validation of this theory can be achieved through the use of a cellular allergen stimulation test (CAST) adapted for the measurement of leukotriene release from isolated leukocytes. Isolated cell preparations are stimulated with (i) L-ASA; (ii) N-formyl-Met-Leu-Phe (*f*MLP); or (iii) both *f*MLP and L-ASA, in a buffer containing interleukin-3 cytokine. Results are then compared with human leukemia cell line (Hl-60) responses to L-ASA. Cysteinyl leukotrienes can be measured in cell supernatant fluids by ELISA.

Human Model: Cases of aspirin-tolerant (ATA; n = 32) and aspirin-intolerant (n = 26) asthmatics.
Interpretation and Analysis: Acetylsalicylic acid has a rather weak stimulatory effect on cys-LTs release in conditions of both aspirin-tolerant and aspirin-intolerant asthma. In contrast to findings reported in some related investigations, some studies have detected no significant difference between cys-LTs release by leukocytes from AIA and ATA or by differentiated Hl-60 cells. Measurement of

cysteinyl-leukotriene release by peripheral blood leukocytes pretreated with aspirin has no value for diagnosis of AIA.

A moderate and unspecific release of cysteinyl leukotrienes by aspirin from peripheral blood leucocytes precludes its value for aspirin sensitivity testing in asthma. Pierzchalska M, Mastalerz L, Sanak M, Zazula M, Szczeklik A. Clin Exp Allergy 2000 Dec; 30 (12), pp. 1785–91.

Immune Hypersensitivity: Asthma (Asymptomatic) *Metaproterenol (Aerosol)/Histamine/Methacholine (MCh)/[Quinine Fluorescence]*

Cellular/Molecular Mechanism of Action: Metaproterenol functions as a competitive inhibitor of adrenergic neurotransmitter agents due to binding avidity for β-adrenergic receptor complexes.
Physiological Mechanism of Action: Methacholine is a parasympathomimetic/cholinergic agonist that promotes bronchial constriction.
Application: Induction of bronchoconstriction for the detection of aymptomatic asthma conditions.
Route of Administration: Aerosol inhalation.
Considerations: Studying normal subjects and asthmatics allows the comparison of metaproterenol responsiveness after widely divergent doses of the bronchoprovocative agents.
Implementation: Evaluation of the potential for bronchoprovocative test reagents to achieve the same degree of bronchoconstriction as occurs in aymptomatic cases of asthma. Asymptomatic asthmatics inhale a dry aerosol (mass median aerodynamic diameter, 1.5 microns) with increasing concentrations of MCh or histamine to produce a 35% decrease in specific airway conductance (sGaw), followed by a single inhalation of a metaproterenol aerosol.

Airway deposition of MCh, histamine, and metaproterenol can be measured using a quinine fluorescence technique.
Interpretation and Analysis: At an equivalent degree of bronchoconstriction, metaproterenol responsiveness is influenced by the dose of MCh but not the dose of histamine. The differential metaproterenol response may be related to a functional antagonism between muscarinic and β-adrenergic agonists.

Mean baseline sGaw, metaproterenol responsiveness, and metaproterenol mass deposited are similar in normal subjects and asthmatics. Likewise, mean sGaw after completion of MCh and histamine challenge and subsequently deposited metaproterenol mass are similar in each case group type. After MCh challenge (mean ± SD provocative drug mass causing a 35% decrease in sGaw, PM35: 8.94 ± 5.96 μmol in normal subject and 0.30 ± 0.29 μmol in asthmatics), metaproterenol increases mean sGaw by 89 ± 33% in normal subjects and by 190 ± 55% in asthmatics ($p < 0.05$, 2-way analysis of variance). After histamine challenge (PM35, 2.92 ± 2.49 μmol in normal subjects and 0.17 ± 0.29 μmol in asthmatics), metaproterenol increases mean sGaw by 111 ± 38% in normal subjects and 113 ± 69% in asthmatics (p = not significant).

Metaproterenol responsiveness after methacholine- and histamine-induced bronchoconstriction. Elsasser S, Donna E, Demirozu CM, Danta I, Wanner A. Chest 1996 Sep; 110 (3), pp. 617–23.

Immune Hypersensitivity: Asthma (Grain Dust [GD])/Mast Cells: Tryptase Expression/Neutrophils: Elastase Expression/Interleukin-8 (IL-8) Expression *GD Bronchoprovocation Test/Bronchial Mucosa Biopsy*

Background Information: The immunopathological mechanism for occupational asthma induced by GD remains to be clarified. There have been a few reports that have suggested the involvement of neutrophils and their capacity to induce bronchoconstriction after GD inhalation.
Implementation: Evaluation of the phenotype of leukocytes that infiltrate the bronchial mucosa in conditions of GD-induced asthma. Bronchial biopsy specimens are obtained by fiber-optic bronchoscopy in GD-induced asthmatics. Bronchial biopsy specimens are examined by immunohistochemistry analyses using a panel of monoclonal antibodies to tryptase-containing mast cell (AA1), activated eosinophil (EG2), pan T-lymphocyte (CD3), and neutrophil elastase (NE). Induced sputum is collected before and after initiation of the GD bronchoprovocation test. The IL-8 level in the sputum is also measured using ELISA techniques.

Human Model: Cases of GD-induced asthma ($n = 6$); and house dust mite sensitivity ($n = 6$).
Interpretation and Analysis: There is a significant increase in the number of tryptase-containing mast cell (AA1+) and neutrophil elastase positive (NE+) cells in bronchial mucosa of GD-induced asthma, compared with those of allergic asthma ($p = 0.01$, $p = 0.01$, respectively). No significant differences can be observed in the number of EG2+ and CD3+ cells ($p = 0.13$, $p = 0.15$, respectively). Interleukin-8 is abundant in the sputum of all GD-induced asthma patients and significantly increases after the bronchial challenges compared with baseline values ($p = 0.03$). Such findings support the perspective that neutrophil recruitment together with mast cells may contribute to the bronchoconstriction induced by GD antigen. A possible involvement of IL-8 in such processes has been proposed.
Instrumentation: Fiber-optic bronchoscope.

Neutrophil infiltration and release of IL-8 in airway mucosa from subjects with grain dust-induced occupational asthma. Park HS, Jung KS, Hwang SC, Nahm DH, Yim HE. Clin Exp Allergy 1998 Jun; 28 (6), pp. 724–30.

Immune Hypersensitivity: Asthma (Late Reactions)/(Bronchial Responsive Challenge) *Histamine/Methacholine (MCh)*

Cellular/Molecular Mechanism of Action: Histamine binds to and activates histamine H_1 and H_2 receptor complexes. Methacholine recognizes, binds to, and activates parasympathetic/cholinergic receptor sites.
Physiological Mechanism of Action: Methacholine promotes parasympathomimetic-mediated bronchocontriction. Histamine directly promotes contraction of smooth muscle of the bronchi tree and intestine (H_1 receptors), while in small vascular structures it promotes relaxation of smooth muscle tissues (H_1 and H_2 receptor complexes). Depending on the receptor complex, histamine can promote profound inflammatory responses. Gastric secretion is mediated through the H_2 receptor.
Application: Assess the frequency of changes in bronchial responsiveness in conditions of late asthmatic reactions.
Dosage: Albuterol (200 μg).
Considerations: Late asthmatic reactions generally can be demonstrated to have increased bronchial responsiveness and are considered to respond poorly to inhaled bronchodilators.
Implementation: Assess the frequency of changes in bronchial responsiveness in conditions of late asthmatic reactions and cases with isolated immediate reactions following specific inhalation challenges (e.g., occupational agents).

Human Model: Cases with (i) late asthmatic reactions ($n =$ 101 record review); (ii) isolated immediate reactions after specific inhalation challenges to various occupational agents that had undergone non-specific inhalation challenges to histamine or MCh on a control day and after the late reaction when FEV1 had returned to

± 10% baseline (n = 63); and (iii) late reactions and those administered an inhaled β_2 agent (albuterol, 200 μg) during the late reaction (n = 99 record review).

Interpretation and Analysis: Review of cases with late reactions previously administered an inhaled β_2 agent (albuterol, 200 μg) during the late reaction (e.g., n = 99) reveals that approximately half of these subjects (e.g., n = 57/101 or 56%) with late reactions and those with isolated immediate reactions (e.g., n = 24/63 or 38%) demonstrate a requirement for a 2-fold or greater change in provocative concentration of histamine or MCh in order to cause a 20% change in FEV1 (PC20) from baseline (p = 0.02; odds for the presence of significant changes in PC20 in subjects with late reactions, 56%; odds for the absence of significant changes in PC20 in subjects with immediate reactions, 62%). Changes in FEV1 greater than 20% after administering albuterol at the time of the late reactions occur in approximately 78% of cases tested, and in 66% the FEV1 estimate returns to greater than 90% of baseline. Such retrospective studies demonstrates that changes in bronchial responsiveness after late reactions are not constant and do not appear to distinguish satisfactorily late from immediate reactions. Furthermore, late reactions respond well to β_2 agonist.

Late asthmatic reactions to occupational sensitizing agents: Frequency of changes in non-specific bronchial responsiveness and of response to inhaled β_2-adrenergic agent. Malo JL, Ghezzo H, L'Archeveque J, Cartier A. J Allergy Clin Immunol 1990 May; 85 (5), pp. 834–42.

Immune Hypersensitivity: Asthma (Mild Intermittent Allergic)
Salmeterol/Allergen (Bronchoconstriction)

Physiological Mechanism of Action: Salmeterol provides a protective β_2 agonist effect on early airway response to allergen early airway response (EAR).

Regular use of short-acting β_2 agonists (salmeterol) has been shown to induce tolerance to allergen (EAR) and adenosine 5′-monophosphate challenge.

Application: Assess whether withdrawal from salmeterol for 3 days (72 hours) can restore its bronchoprotective ability on specific bronchial provocative test (sBPT) with allergen.

Route of Administration: Inhalation.

Dosage: Salmeterol, 50 μg/day for 4 days (± allergen).

Example Clinical Trial: Cases undergoing sBPT with allergen after a single dose of inhaled salmeterol (50 μ) (test 1); and then undergo sBPT after 1 week of regular treatment with inhaled salmeterol (50 μ b.i.d.) (test 2); followed by continued inhaled salmeterol treatment for 4 days, then changed to inhaled salmeterol with placebo (2 puffs b.i.d.) for 3 days (72 hours) and subjected to sBPT with allergen after a single dose of salmeterol (50 μ) (test 3).

Considerations: The bronchoprotective effect of salmeterol on allergen-induced EAR, completely lost after 1 week of regular treatment with salmeterol, may be partially restored by withdrawal of salmeterol for 3 days (72 hours). However, the withdrawal time period is not sufficient to recover the baseline bronchoprotective efficacy of 1st-dose salmeterol.

Interpretation and Analysis: The EAR to allergen (Delta forced expiratory volume in 1 second [FEV1] ≥ 20% with respect to postdiluent value) is completely abolished by a single dose of salmeterol (test 1; protection index [PI] ≥ 50%) but is still present after 1 week of regular treatment with salmeterol (test 2; PI < 50%). The maximum FEV1 percentage fall during sBPT with allergen is significantly lower after withdrawal of regular inhaled salmeterol (test 3) than after regular treatment with salmeterol (test 2) (mean, 23% vs 29.5%; range, 4–41% vs 18–49%, respectively; p < 0.05); a similar result is obtained when considering the PI of salmeterol on sBPT with allergen (mean, 44% vs 20%; range, 2–86% vs −11–49%, respectively; p < 0.05). However, the maximum FEV1 percentage fall and PI are significantly different in test 3 than after test 1, and a significant proportion of cases will show (test 3) a PI ≥ 50%.

Tolerance to the protective effect of salmeterol on allergen challenge can be partially restored by the withdrawal of salmeterol regular treatment. Giannini D, Di Franco A, Bacci E, Dente FL, Bartoli ML, Vagaggini B, Paggiaro P. Chest 2001 Jun; 119 (6), pp. 1671–5.

Immune Hypersensitivity: Asthma (Mild to Moderate)/Hyperresponsive Airway/Cellular Airway Infiltration
Methacholine (MCh)/Agonists (β_2)/[Corticosteroids]

Cellular/Molecular Mechanism of Action: Methacholine recognizes, binds to, and activates parasympathetic/cholinergic receptor sites.

Physiological Mechanism of Action: Methacholine promotes parasympathomimetic-mediated bronchocontriction. Corticosteroids like beclomethazone inhibit phospholipase A2 (inhibit prostaglandin/leukotriene production) and stabilize cell membrane structures (inhibit leukocyte degranulation). In addition, like adrenergic agonists and clenbuterol, corticosteroids promote bronchodilation by increasing intracellular adenylcyclase activity (elevates cAMP) within bronchial smooth muscle.

Background Information: Current guidelines for the management of asthma advocate the use of anti-inflammatory agents in all but mild disease conditions. Disease control can be defined in terms of clinical criteria such as lung function and symptoms. However, the relationship between the clinical control of the disease and inflammation of the airways is not clear.

Application: Detection and characterization of the number of infiltrating leukocytes such as mast cells, (activated) eosinophils, CD8+, and CD45RO+ cells in bronchial biopsy specimens in mild to moderate conditions of asthma. These properties appear to correspond with the observation of airway hyperresponsiveness to MCh.

Implementation: Delineate correlations between airway inflammation and measures of clinical control and bronchial hyperresponsiveness (MCh challenge test) in asthmatic conditions during simultaneous steroid inhalation. Biopsy specimens are taken by fiber-optic bronchoscopy from the carina of the right lower and middle lobes, and from the main carina. Immunohistochemical staining is performed on tissue sections with monoclonal antibodies against eosinophil cationic protein (EG1, EG2), mast cell tryptase (AA1), CD45, CD22, CD3, CD4, CD8, CD25, and CD45RO. The number of positively stained cells in the lamina propria is counted twice by using an interactive display system.

Human Model: Cases of mild to moderate asthma (n = 26 atopic adults with baseline forced expiratory volume in 1 second [FEV1] ≥ 50% predicted, concentration of histamine causing a 20% fall in FEV1 [PC20] 0.02–7.6 mg/ml) on regular treatment with inhaled steroids. Histories and bronchoscopic examinations are utilized to determine use of β_2-adrenergic agonists, peak flow variability, and symptom scores.

Investigation Design: Cross-sectional study.

Interpretation and Analysis: No difference exists in cell numbers in biopsy specimens collected from the carina of the right lower and middle lobes, and from the main carina. The PC20 for MCh is inversely related to the average number of total leukocytes, EG1+,

and EG2+ cells, mast cells, CD8+, and CD45RO+ cells in the lamina propria. These relationships are similar for each of the biopsy sites. Symptom scores, β_2 agonist usage, FEV1, and peak flow variability do not appear to consistently correlate with tissue biopsy cell count. Therefore, infiltration of inflammatory cells in the lamina propria of the airways seems to persist in asthmatic outpatients despite regular treatment with inhaled steroids. The number of infiltrating leukocytes such as mast cells, (activated) eosinophils, CD8+, and CD45RO+ cells in bronchial biopsy specimens from these patients appears to be reflected by airway hyperresponsiveness to MCh, but not by symptoms or lung function. These findings may have implications for the adjustment of anti-inflammatory treatment of patients with asthma.

Instrumentation: Cryostat histology sectioning unit.

Relationship between the inflammatory infiltrate in bronchial biopsy specimens and clinical severity of asthma in patients treated with inhaled steroids. Sont JK, Han J, van Krieken JM, Evertse CE, Hooijer R, Willems LN, Sterk PJ. Thorax 1996 May; 51 (5), pp. 496–502.

Immune Hypersensitivity: Asthma (Mild to Moderate Degree)/Steroid Therapy: Administration Detection/Neuroendopeptidase/CD10 Expression *Methacholine (MCh)/Histamine/Corticosteroids*

Cellular/Molecular Mechanism of Action: Methacholine recognizes, binds to, and activates parasympathetic/cholinergic receptor sites. Corticosteroids inhibit the biochemical activity of phospholipase A2, thereby diminishing the production of both prostaglandins and leukotrienes.

Physiological Mechanism of Action: Methacholine promotes parasympathomimetic-mediated bronchocontriction. Corticosteroids like beclomethazone inhibit phospholipase A2 (inhibit prostaglandin/leukotriene production) and stabilized cell membrane structures (inhibit leukocyte degranulation). In addition, like adrenergic agonists and clenbuterol, corticosteroids promote bronchodilation through increases in intracellular adenylcyclase activity (increased cAMP) within bronchial smooth muscle.

Background Information: Expression of the endogenous neuropeptide-degrading enzyme neutral endopeptidase (NEP; CALLA, CD10, E.C.3.4.24.11) on cultured human airway epithelial cells can be upregulated by corticosteroids.

Implementation: Evaluation of the potential for NEP expression in the airway epithelium or lamina propria in bronchial biopsies to be enhanced in atopic asthmatics on regular inhaled steroids as compared with those without steroid treatment. Tissue biopsies are taken at (sub)segmental levels from the right lower lobe, the middle lobe, and the main carina. Immunohistochemical staining can be performed on cryostat sections using the VIL-A1 monoclonal antibody against CD10 (NEP).

Human Model: Cases affected by mild to moderate degrees of asthma ($n = 40$ age 19–48 years non-smoking adults; forced expiratory volume in 1 second $\geq$ 50% pred.; histamine PC20 range = 0.02–7.6 mg/ml; $n = 23$ with regular inhaled steroids; $n = 17$ without regular inhaled steroids).

Interpretation and Analysis: In airway epithelium, NEP-positive sites are within the basal layer and, in contrast with studies applying other antibodies, also at apical sites and within the lamina propria. In both the epithelium and lamina propria, NEP expression is not significantly different between the right lower lobe, the middle lobe, and the main carina biopsy sites (Friedman's non-parametric 2-way analysis of variance; $p > 0.68$), nor is expression in the lamina propria associated with inhaled steroid usage (Mann-Whitney U test; $p = 0.98$). However, NEP expression is significantly enhanced in the airway epithelium in patients using inhaled steroids as compared with non-steroid users (mean rank: 23.4 and 15.5, respectively; $p = 0.02$). Among non-steroid-using subjects, NEP expression is related to symptoms and the MCh PC20 (Rs: -0.69 and 0.49, respectively; $p \leq 0.04$). Expression of NEP is therefore enhanced in airway epithelium in bronchial biopsy specimens from patients with atopic asthma who are regularly using inhaled steroids compared with cases that do not. This fits the hypothesis that the anti-inflammatory effect of corticosteroids within the airways is partially mediated by the upregulation of the endogenous neuropeptide-degrading enzyme NEP.

Enhanced expression of neutral endopeptidase (NEP) in airway epithelium in biopsies from steroid- vs nonsteroid-treated patients with atopic asthma. Sont JK, van Krieken JH, van Klink HC, Roldaan AC, Apap CR, Willems LN, Sterk PJ. Am J Respir Cell Mol Biol 1997 May; 16 (5), pp. 549–56.

Immune Hypersensitivity: Inhaled Allergens/ Allergic Reactions/[Interleukin (IL)-2, IL-3, IL-4, IL-5, IL-6, IL-8, IL-10, IL-13, Interferon-Gamma (IFN-γ), RANTES, Tumor Necrosis Factor-Alpha (TNF-α)] *Single Allergen Provocation Test/Nasal Biopsy*

Background Information: The local production and release of a number of cytokines regulates allergic upper airway inflammation. Medication is usually used at the presentation of the 1st symptoms. There are, however, clues that it is advisable to start taking the corticosteroid before the grass pollen season begins.

Application: The single allergen provocation test can be applied to detect natural allergens responsible for inducing hyperactive immune responses *in vivo* in addition to functioning as a tool for evaluating the efficacy of anti-inflammatory and immunosuppressive agents.

Implementation: Evaluation of preventative therapies for inhaled allergic reactions applying the single allergen provocation protocol conducted in autumn (non–hay fever season). Nasal mucosa biopsies are collected twice before provocation (before and after 4 weeks of preventive treatment) and 3 times after allergen provocation (1 hour, 24 hours, and 1 week). Eosinophils and messenger RNA (mRNA) positive cells (in situ hybridization for IL-2, IL-3, IL-4, IL-5, IL-6, IL-8, IL-10, IL-13, IFN-γ, RANTES, and TNF-α) are then counted in biopsy samples.

Human Model: Cases receiving either fluticasone propionate aqueous nasal spray (FPANS; $n = 10$) or a placebo ($n = 9$).

Interpretation and Analysis: Preventive treatment with FPANS out of season results in a decrease in eosinophils and mRNA positive cells for IL-5 and IL-6. After allergen provocation, levels of most of the measured cytokines (IL-3, IL-5, IL-6, IL-13, IFN-γ, RANTES, and TNF-α) and eosinophils are reduced with corticosteroids. The numbers of cells (eosinophils, IL-3, IL-6, and IL-8) correlate with nasal symptoms. Significant correlations in the early and late allergic phase can be appreciated between eosinophils and cytokines (IL-3, IL-10, and IL-13). These results indicate that preventive treatment with FPANS prior to contact with grass pollen is effective in reducing the increase of cytokine mRNA positive cells in reaction to grass pollen contact.

Preventive treatment of intranasal fluticasone propionate reduces cytokine mRNA expressing cells before and during a single nasal allergen provocation. Kleinjan A, Holm AF, Dijkstra MD, Boks SS, Severijnen L, Mulder PG, Fokkens WJ. Clin Exp Allergy 2000 Oct; 30 (10), pp. 1476–85.

Immune Hypersensitivity and Inflammatory Responses/Asthma: Molecular Pathogenesis of Inflammatory Responses/Sepsis: Molecular Pathogenesis of Inflammatory Responses/Alveolar Macrophages: Septic Inflammatory Responses in Asthma/Cytokine Responses: Interleukin (IL)-10, Macrophage Inflammatory Protein-1alpha (MIP-1α), Interferon-Gamma (IFN-γ), Granulocyte-Macrophage Colony-Stimulating Factor (GM-CSF)
Lipopolysaccharide/Dexamethasone/IL-1β

Cellular/Molecular Mechanism of Action: Lipopolysaccharide (LPS) is also referred to as bacterial endotoxin. Systemically, it can bind to lipopolysaccharide-binding protein and membrane-associated LPS receptor complexes (CD14).
Physiological Mechanism of Action: Bacterial lipopolysaccharide fractions (LPS, endotoxin) promote inflammatory responses in primarily leukocyte and endothelial cell populations.
Background Information: Inflammation in asthma is characterized by a T-helper 2 (Th2) response. In many experimental systems, this response can be regulated by IL-10 and IL-12. Interleukin-10 deactivates T cells, and IL-12 reorients the response toward a Th1 pattern. Alveolar macrophages (AM) can secrete both of these cytokines, and thus regulate T-cell behavior in asthma. They can enhance the Th2 response by turning off their secretion of IL-10 and IL-12 or tend to downregulate it by producing these cytokines.
Application: Delineate the molecular pathogenesis of immune responses and septic inflammatory reactions in addition to functioning as a model agent for evaluating the potential efficacy of candidate anti-inflammatory and immunosuppressive agents.
Implementation: Evaluate IL-10 and IL-12 production in AM populations. Alveolar macrophages are recovered by bronchoalveolar lavage (BAL) from the lung. They are isolated and cultured for 24 hours without stimulation or in the presence of LPS fractions. Assays are then performed for IL-10 and the p40 subunit of IL-12 in BAL fluid samples and in AM culture supernatants by ELISA.

Human Model: Cases of adult asthma (n = 11; n = 4 normal healthy controls, n = 6 asthmatics treated with inhaled corticosteroids).
Interpretation and Analysis: Spontaneous AM IL-10 production is higher in asthmatics, particularly in treated cases. Alveolar macrophage IL-10 production after LPS stimulation is also elevated in asthmatics, but mainly so in untreated cases. Levels of IL-12 are higher in BAL fluids from untreated cases than healthy reference controls. The production of IL-12 in LPS-stimulated AM from such cases is increased. Alveolar macrophages are at least primed for the production of IL-10 and IL-12 in asthma. Such phenomenon suggests that these cells could be involved in the resolution of asthmatic-associated inflammatory processes.

Alveolar macrophage interleukin (IL)-10 and IL-12 production in atopic asthma. Magnan A, van Pee D, Bongrand P, Vervloet D. Allergy 1998 Nov; 53 (11), pp. 1092–5.

Immune Hypersensitivity and Inflammatory Responses/Molecular Pathogenesis/ Bronchoalveolar Lavage Fluid Cell Populations/ Endogenous Inflammatory Mediators: Interleukin (IL)-2, IL-4, IL-5, IL-6, IL-10, Interferon-Gamma (IFN-γ), Inducible Nitric Oxide Synthase (iNOS)
Ovalbumin/Aminophylline

Cellular/Molecular Mechanism of Action: Ovalbumin is the avian equivalent to mammalian serum albumin, and it can function as a potent immunogen/allergen. Aminophylline inhibits phosphodiesterase in a manner that directly inhibits the degradation of cAMP, thereby promoting bronchial smooth muscle relaxation.
Background Information: Evidence has shown that aminophylline has bronchoprotective, anti-inflammatory, and immunomodulatory effects.
Route of Administration: Aminophylline (intraperitoneal/rat).
Dosage: Aminophylline (Group 1 = 25 mg/kg; Group 2 = 5 mg/kg).
Implementation: Evaluation of the effect of different doses of aminophylline on the late-phase reaction, bronchial hyperresponsiveness (BHR), and T cell-related cytokine messenger RNA (mRNA) expression induced by ovalbumin (OA) sensitization.

In this context, aminophylline can be used as a molecular probe for evaluating immune and septic inflammatory reactions. The effect of aminophylline can be evaluated at different concentrations to determine its influence on respiratory function based on the interpretation of pulmonary function tests that are performed at baseline and after varying doses of acetylcholine. Thereafter, bronchoalveolar lavage and histiological analysis of the lungs is performed. Total RNA is extracted from lung tissue and reverse transcriptase-polymerase chain reaction performed using primers for IL-2, IL-4, IL-5, IL-6, IL-10, IFN-γ, iNOS, and β-actin.

Animal Model: Rat (n = 40 Brown Norway strain divided into 4 groups. Groups I, II, and III sensitized and subsequently provoked with OA). Group I (aminophylline at 25 mg/kg); Group II (aminophylline at 5 mg/kg); Group III (intraperitoneal normal saline); Group IV (enhaled aerosol saline control).
Interpretation and Analysis: Group III subjects have worse pulmonary function tests, more severe BHR, and more severe lung inflammation, higher IL-4 and IL-10 cytokine levels in bronchoalveolar lavage fluid, and higher IL-4, IL-5, IL-6, IL-10, tumor necrosis factor-alpha (TNF-α), and iNOS mRNA expression than the other 3 groups. Expression of IL-2 and IFN-γ is significantly reduced in Group III. Aminophylline at both low and high doses is effective in preventing late-phase bronchoconstriction, BHR, and an inflammatory response. Aminophylline decreases T-helper cell 2-related cytokine mRNA expression but increases T-helper cell 1-related cytokine mRNA expression.

Pulmonary function changes and immunomodulation of Th2 cytokine expression induced by aminophylline after sensitization and allergen challenge in Brown Norway rats. Ann Allergy Asthma Immunol 2002 Feb; 88 (2), pp. 215–22.

Immune Hypersensitivity Reactions: Bronchial Responsiveness: Hyperresponsiveness/Allergic Airway Eosinophilia Reactions/Type T-Helper 1 (Th1) and Th2 Cytokine Expression Profiles
Ovalbumin/Dexamethasone/Cyclosporine

Cellular/Molecular Mechanism of Action: Ovalbumin is the avian equivalent of mammalian serum albumin and can be applied as an immunogenic protein fraction. Dexamethasone is a corticosteroid that has an ability to inhibit phospholipase A2 biochemical activity.
Physiological Mechanism of Action: Dexamethasone is a corticosteroid that promotes immunosuppressive properties in part due to inhibition of leukocyte degranulation phenomenon and general inhibition of protein synthesis.
Background Information: Cyclosporine A and dexamethasone exhibit different effects on allergic airway eosinophilia and bronchial hyperresponsiveness (BHR).
Application: Characterization of the molecular pathogenesis of normal and hypersensitivity immune responses including alteration

of cytokine expression such as changes in the profile of Th1- vs Th2-derived cytokines. The investigative strategy can also be applied to delineate the efficacy of various therapeutic agents possessing anti-inflammatory and immunosuppressive properties.

Implementation: Evaluation of the influence of cyclosporine or dexamethasone on the development of immune hypersensitivity reactions to ovalbumin aerosol challenge. Bronchial responsiveness is measured 18–24 hours after aerosol exposure. Airway cellular influx can be determined by bronchoalveolar lavage and tissue immunohistochemistry. Expression of Th1 and Th2 cytokine messenger RNA (mRNA) are then analyzed by reverse transcriptase-polymerase chain reaction (RT-PCR).

Animal Model: Rat (Brown Norway rats sensitized to ovalbumin).

Interpretation and Analysis: Ovalbumin exposure induces significant bronchial hypersensitivity reactions (BHR), with increases in eosinophils, lymphocytes, and neutrophils in bronchoalveolar lavage fluid and an increase in eosinophils, $CD2^+$, and $CD8^+$, but not $CD4^+$ T cells, in the airway submucosa. Interleukin (IL)-2, interferon-gamma (IFN-γ), IL-4, and IL-5 mRNA expression in ovalbumin-sensitized lungs increases ($p < 0.05$) compared with controls. Cyclosporine A does not have a significant effect on BHR and neutrophil accumulation but reduces the number of bronchoalveolar lavage eosinophils ($p < 0.002$), airway submucosal eosinophils, and $CD4^+$ and $CD8^+$ T cells ($p < 0.02$). It also suppresses induced expression of IL-2, IL-4, IL-5, and IFN-γ mRNA transcripts. By contrast, the inflammatory cell influx and mRNA expression of IL-2, IL-4, and IL-5, as well as BHR, is suppressed by dexamethasone. However, increases in IL-10 and IFN-γ mRNA expression can sometimes not be detected depending on the analytical system evaluated. The differential activities of cyclosporine A and dexamethasone on inflammatory cell influx, particularly neutrophils, or cytokine expression such as IL-10 and IFN-γ may underlie their contrasting effects on BHR.

Diagnostic pharmacology: Differential effect of corticosteroids and cyclosporine differential regulation of cytokine expression after allergen exposure of sensitized rats by cyclosporine A and corticosteroids: Relationship to bronchial hyperresponsiveness. Huang TJ, Newton R, Haddad EB, Chung KF. J Allergy Clin Immunol 1999 Sep; 104 (3 Pt 1), pp. 644–52.

Immune Hypersensitivity Reactions: Bronchial Responsiveness: Hyperresponsiveness/Allergic Airway Eosinophilia Reactions/Type T-Helper 1 (Th1) and Th2 Cytokine Expression Profiles
Ovalbumin/Dexamethasone/Cyclosporine

Cellular/Molecular Mechanism of Action: Ovalbumin is the avian equivalent of mammalian serum albumin and can be applied as an immunogenic protein fraction. Dexamethasone is a corticosteroid that has an ability to inhibit phospholipase A2 biochemical activity.

Physiological Mechanism of Action: Dexamethasone is a corticosteroid that promotes immunosuppressive properties in part due to inhibition of leukocyte degranulation phenomenon and general inhibition of protein synthesis.

Background Information: Cyclosporine A and dexamethasone exhibit different effects on allergic airway eosinophilia and bronchial hyperresponsiveness (BHR).

Application: Characterization of the molecular pathogenesis of normal and hypersensitivity immune responses including alteration of cytokine expression such as changes in the profile of Th1- vs Th2-derived cytokines. The investigative strategy can also be applied to delineate the efficacy of various therapeutic agents possessing anti-inflammatory and immunosuppressive properties.

Implementation: Evaluation of the influence of cyclosporine or dexamethasone on the development of immune hypersensitivity reactions to ovalbumin aerosol challenge. Bronchial responsiveness is measured 18–24 hours after aerosol exposure. Airway cellular influx can be determined by bronchoalveolar lavage and tissue immunohistochemistry. Expression of Th1 and Th2 cytokine messenger RNA (mRNA) is then analyzed by reverse transcriptase-polymerase chain reaction (RT-PCR).

Animal Model: Rat (Brown Norway rats sensitized to ovalbumin).

Interpretation and Analysis: Ovalbumin exposure induces significant bronchial hypersensitivity reactions (BHR), with increases in eosinophils, lymphocytes, and neutrophils in bronchoalveolar lavage fluid and an increase in eosinophils, $CD2^+$, and $CD8^+$, but not $CD4^+$ T cells, in the airway submucosa. Interleukin (IL)-2, interferon-gamma (IFN-γ), IL-4, and IL-5 mRNA expression in ovalbumin-sensitized lungs increases ($p < 0.05$) compared with controls. Cyclosporine A does not have a significant effect on BHR and neutrophil accumulation but reduces the number of bronchoalveolar lavage eosinophils ($p < 0.002$), airway submucosal eosinophils, and $CD4^+$ and $CD8^+$ T cells ($p < 0.02$). It also suppresses induced expression of IL-2, IL-4, IL-5, and IFN-γ mRNA transcripts. By contrast, the inflammatory cell influx and mRNA expression of IL-2, IL-4, and IL-5, as well as BHR, is suppressed by dexamethasone. However, increases in IL-10 and IFN-γ mRNA expression can sometimes not be detected depending on the analytical system evaluated. The differential activities of cyclosporine A and dexamethasone on inflammatory cell influx, particularly neutrophils, or cytokine expression such as IL-10 and IFN-γ may underlie their contrasting effects on BHR.

Immune Hypersensitivity Response/Allergen: Grass and Pollen Immune Response/Late Induction (Nasal Mucosa)/Grass/Pollen Hypersensitivity Immune Responses/Efficacy Evaluation of Anti-Inflammatory/Immunosuppresive Agents
Allergen Challenge Test/Fluticasone Proprionate

Cellular/Molecular Mechanism of Action: Grass/pollen extracts function as allergens that activate immune systems that have been presensitized by exposure to these biological antigens. Fluticasone proprionate is a corticosteroid preparation that can inhibit phospholipase A2 biochemical activity.

Physiological Mechanism of Action: Fluticasone proprionate can exert anti-inflammatory and immunosuppressive properties by decreasing prostaglandin production, inhibition of protein synthesis, and stabilization of cellular protein structures.

Background Information: Allergen-induced late nasal responses are associated with recruitment and activation of T lymphocytes and eosinophils accompanied by preferential messenger RNA (mRNA) expression of T-helper type 2 (Th2) cytokines.

Application: Fluticasone proprionate can be applied as a molecular probe for delineating endogenous inflammatory mediator profiles in conditions of immune hyperreactivity responses and inflammatory reactions in addition to evaluation of the efficacy of immunosuppressive and anti-inflammatory reagents.

Implementation: Detection of allergens responsible for inducing allergic reactions and evaluating the efficacy of potential therapeutic

agents (e.g., anti-inflammatory agents and corticosteroids). An example in this regard is the application of allergen challenge to evaluate the efficacy of topical corticosteroids (fluticasone propionate) and their ability to inhibit late responses by suppressing cellular transcription of Th2-type cytokine mRNA sequences. Nasal biopsies are taken at baseline and repeated 24 hours after local nasal allergen provocation following 6 weeks of treatment (e.g., fluticasone propionate 200 μg or placebo nasal spray twice daily).

Human Model: Cases of grass pollen sensitivity (n = 48 adults) analyzed in a randomized double blind placebo-controlled trial.

Interpretation and Analysis: Baseline mRNA expression for interleukin-4 (IL-4) ($p = 0.01$) and IL-5 ($p = 0.002$) is higher in cases of grass pollen sensitivity. Topical corticosteroid treatment significantly inhibits immediate nasal symptoms, with almost complete inhibition of the late response following allergen challenge. This is associated with a marked decrease in the allergen-induced increases in cells expressing mRNA for IL-4 ($p = 0.002$) but not for IL-5. Inhibition of the late response is also accompanied by decreases in CD25+ cells, presumed T lymphocytes, and eosinophils. A significant correlation exists between decreases in IL-4 mRNA+ cells and in eosinophils after treatment ($r = 0.46$, $p < 0.05$). Therefore, prolonged treatment with topical corticosteroid inhibits allergen-induced early and late nasal responses and the associated tissue eosinophilia, which at least in part may result from inhibition of cells expressing IL-4 mRNA sequences.

Topical glucocorticosteroid (fluticasone propionate) inhibits cells expressing cytokine mRNA for interleukin-4 in the nasal mucosa in allergen-induced rhinitis. Masuyama K, Jacobson MR, Rak S, Meng Q, Sudderick RM, Kay AB, Lowhagen O, Hamid Q, Durham SR. Immunology 1994 Jun; 82 (2), pp. 192–9.

Immune Hypersensitivity: Rhinitis (Allergic)/(Asthma)
Adenosine 5′-Monophosphate (AMP)/Methacholine (MCh)/[Forced Expiratory Volume in 1 Second (FEV1)]

Physiological Mechanism of Action: Adenosine and its related nucleotide, AMP, both induce bronchoconstriction in asthma and asthma-like conditions. Such events are probably caused by histamine release from airway mast cell populations.

Application: Adenosine 5′-monophosphate can be used in the detection and characterization of conditions including allergic rhinitis and asthma.

Route of Administration: Adenosine 5′-monophosphate is utilized as an inhaled agent.

Dosage: Adenosine 5′-monophosphate.

Implementation: Evaluation of allergic rhinitis conditions detected by challenge with exposure to increasing concentratons of AMP and MCh. Airflow is assessed after the administration of each different concentration of provocative agent. Responses to each bronchoconstrictor agent are then measured pertaining to the provocative concentration required to produce a 20% fall (PC20) in FEV1.

Interpretation and Analysis: A very high percentage of asthma cases (e.g., n = 14/14) and approximately 30% of allergic rhinitis cases (e.g., n = 10/28) display signs of AMP hyperresponsiveness. Subjects with allergic rhinitis have a higher prevalence of hyperresponsiveness to AMP than do healthy controls ($p = 0.038$). Although the prevalence of hyperresponsiveness for MCh and for AMP in subjects with allergic rhinitis is similar (39% vs 36%, respectively), some cases will be hyperresponsive to (i) MCh but not to AMP (e.g., n = 4/28); or (ii) hyperresponsiveness to AMP but not to MCh (e.g., n = 3/28). In this context, inhaled AMP causes airway narrowing in a significantly higher proportion of subjects with allergic rhinitis than healthy volunteers. Furthermore, MCh and AMP hyperresponsiveness are not detected in the same individuals with allergic rhinitis, thus suggesting that responsiveness to the 2 bronchoconstrictor stimuli is not evoking the same type of abnormalities within the airways.

Bronchoconstriction induced by inhaled adenosine 5′-monophosphate in subjects with allergic rhinitis. Prieto L, Gutierrez V, Linana J, Marin J. Eur Respir J 2001 Jan; 17 (1), pp. 64–70.

Immune Hypersensitivity: Rhinitis (Allergic)/Asthma with Airway Inflammation
Adenosine 5′ Monophosphate (AMP)/Methacholine (MCh)/(Exhaled Nitric Oxide)

Background Information: Some studies have reported that the levels of exhaled nitric oxide (ENO) in asthmatics are similar to those in subjects with allergic rhinitis, and it has been postulated that atopic status might be the determinant of enhanced nitric oxide production in asthma.

Implementation: Adenosine 5′-monophosphate and MCh have been employed to determine the differences in ENO levels between asthmatics and subjects with allergic rhinitis (sensitized to the same allergen), in order to correlate nitric oxide concentrations with airway responsiveness. Such clinical investigative strategies have been employed for the purpose of evaluating cases of asthma and allergic rhinitis monosensitized to Parietaria pollen. The response to each bronchoconstrictor agent is measured by the provocative concentration required to produce a 20% fall in forced expiratory volume in 1 second (FEV1) (PC20), and ENO can be measured by the single-exhalation method.

Interpretation and Analysis: The geometric mean (95% confidence interval) ENO values are significantly higher in asthmatics than in subjects with allergic rhinitis: 72.4 p.p.b. (54.9–93.3 p.p.b) vs 44.7 p.p.b. (30.9–64.6 p.p.b., $p = 0.03$). In asthmatics, a significant correlation can be found between ENO and PC20 AMP values ($p = -0.57$, $p = 0.02$), whereas no correlation can be detected between ENO and PC20 MCh ($p = -0.35$, $p = 0.14$). It is therefore suggested that atopy is not the only determinant of increased ENO levels detected in subjects with asthma, and that responsiveness to AMP may be a more sensitive marker for assessing airway inflammation in asthma compared to MCh.

Concentrations of exhaled nitric oxide in asthmatics and subjects with allergic rhinitis sensitized to the same pollen allergen. Prieto L, Gutierrez V, Uixera S, Bruno L. Clin Exp Allergy 2002 Dec; 32 (12), pp. 1728–33.

Immune Hypersensitivity: Rhinitis (Allergic) and Asthma
Acetaldehyde

Background Information: Asthmatic subjects have an exaggerated airway response to inhaled acetaldehyde, but no information is available on airway responsiveness to this bronchoconstrictor agent in subjects with allergic rhinitis.

Application: Characterization of cases suffering from allergic rhinitis.

Route of Administration: Inhalation.

Dosage: Gradient increases with pulmonary function evaluated after each change in concentration inhaled.

Considerations: Minimal information is available about airway responsiveness to acetaldehyde as a bronchoconstrictor agent in subjects with allergic rhinitis.

Implementation: Acetaldehyde and methacholine (MCh) have been employed at gradient concentration in provocative testing procedures to characterize conditions of allergic rhinitis and asthma. The response to each bronchoconstrictor agent is measured by the provocative concentration required to produce a 20% fall in forced expiratory volume over 1 second [FEV1/PC20].

Interpretation and Analysis: The geometric mean PC20 acetaldehyde value for asthmatics is approximately 35.5 mg/ml compared with 67.6 mg/ml in subjects with allergic rhinitis and with 80.0 mg/ml for healthy reference control subjects ($p < 0.001$). The PC20 acetaldehyde values in cases of allergic rhinitis are also significantly lower than in healthy negative reference controls ($p = 0.04$). A large percentage of subjects with allergic rhinitis with an increased responsiveness to acetaldehyde show MCh-induced airway hyperresponsiveness (e.g., n = 43/43). However, some subjects (e.g., n = 9/43) with a hyperresponsiveness to MCh fail to respond to acetaldehyde. Clinical evaluations of acetaldehyde have therefore suggested that subjects with allergic rhinitis are less responsive to inhaled acetaldehyde than cases of asthma, but more so than are healthy reference controls. Furthermore, only approximately half of the cases of allergic rhinitis and airway hyperresponsiveness to MCh exhibit bronchoconstriction with inhaled acetaldehyde, thereby suggesting that airway hyperresponsiveness to MCh may not be the sole factor leading to bronchoconstriction in response to acetaldehyde.

Airway responsiveness to inhaled acetaldehyde in subjects with allergic rhinitis: Relationship to methacholine responsiveness. Prieto L, Sanchez-Toril F, Gutierrez V, Marin MJ. Respiration 2002; 69 (2), pp. 129–5.

Immune Hypersensitivity: Rhinitis/Nasal/(Gastric and Duodenal Ulcers)
Cimetidine and Famotidine/Histamine

Cellular/Molecular Mechanism of Action: Cimetidine functions as an H_2 receptor antagonist that inhibits cellular cAMP synthesis (H_2 receptor agonists promote mast cell membrane stabilization).

Application: Histamine can be applied as an agent for assessing the efficacy/anti-inflammatory properties of candidate agents.

Implementation: Determine the influence of H_2-blockers on nasal hypersensitivity reactions following histamine challenge.

Interpretation and Analysis: A 7-day administration of cimetidine tends to lower the histamine threshold in contrast to famotidine administration, which does not significantly decrease the histamine threshold. Therefore, it has been postulated that famotidine should be preferred to cimetidine as an H_2-blocker in patients with gastric and/or duodenal ulcers.

Effect of H_2-blockers, cimetidine and famotidine, on histamine nasal provocative test. Ogino S, Irifune M, Harada T, Matsunaga T ORL. J Otorhinolaryngol Relat Spec 1992; 54 (3), pp. 152–4.

Immune Hypersensitivity Rhinitis (Allergic)/Type T-Helper 2 (Th2) Cytokine Expression Responses/ Interleukin (IL)-13 Expression
Grass Pollen Extract/Fluticasone Propionate/Nasal Tissue Biopsies

Cellular/Molecular Mechanism of Action: Grass pollen extract can function as an allergen in immunehypersensitivity reactions. Fluticasone proprionate can inhibit phospholipase A biochemical activity.

Physiological Mechanism of Action: Fluticasone proprionate can promote immunesuppressive responses and anti-inflammatory properties in part due to their ability to inhibit both protein synthesis and leukocyte degranulation events.

Background Information: The allergen-induced late nasal response (LNR) is associated with high expression of IL-4 and IL-5 messenger RNA (mRNA) in the nasal mucosa, suggesting a role for Th2-type cytokines in the development of the LNR. Moreover, topical corticosteroid-mediated inhibition of the LNR is accompanied by inhibition of IL-4, but not IL-5 mRNA expression. Interestingly, IL-13 shares a number of functions with IL-4, including IgE switching and vascular cell adhesion molecule-1 (VCAM-1) upregulation.

Application: Grass pollen extract can be used to initiate inflammatory and immune responses in conditions of immunehyperactive immune responses associated with this source of allergen. Fluticasone can be used as a probe to study alterations in the production of endogenous mediators of inflammatory and immune responses to allergen-induced responses.

Implementation: Evaluate the influence of fluticasone propionate on the expression of IL-4 and IL-13 mRNA sequences and immunoreactivity in nasal mucosa tissue biopsy specimens. The design of investigations to address this objective can involve the administration of either topical or inhaled fluticasone propionate in conditions of allergic rhinitis. Nasal biopsies are harvested before treatment and 24 hours after local nasal allergen provocation with a grass pollen extract.

Human Model: Nasal biopsy tissue specimens in conditions of allergic rhinitis (n = 20; n = 10 normal healthy reference control; n = 10/20 enhaled fluticasone propionate; n = 10/20 topical fluticasone propionate b.i.d. for 6 weeks).

Interpretation and Analysis: No significant difference between the allergic rhinitis patients and controls in the expression of IL-13 mRNA and immunoreactivity can be detected prior to treatment.

After allergen provocation/challenge, significant increases in IL-13 mRNA-positive and immunoreactive cells at 24 hours can be detected in the absence of corticosteroid exposure (placebo $p < 0.001$). Inhibition of the LNR after corticosteroid treatment is associated with a marked decrease in allergen-induced IL-13 mRNA-positive ($p < 0.001$) and immunoreactive cells ($p < 0.001$). In the absence of steroid exposure (e.g., placebo), 76.9 ± 5.5% of IL-13 mRNA-positive cells after allergen are $CD3^+$, whereas 11.2 ±2.7% co-express immunoreactivity for mast-cell tryptase. In these cases, increases in cells expressing IL-13 mRNA are greater than for IL-4 mRNA ($p = 0.001$), and double in situ hybridization studies reveal that 100% of the IL-4 mRNA-positive cells co-express IL-13 mRNA, whereas 66.6 ± 10.5% of IL-13 mRNA-positive cells co-express IL-4 transcripts after allergen challenge. Such findings suggest that IL-13 expression is a prominent feature of the LNR, and that inhibition of the LNR following steroid therapy may be partly attributable to inhibition of IL-13 expression.

IL-13 mRNA and immunoreactivity in allergen-induced rhinitis: Comparison with IL-4 expression and modulation by topical glucocorticoid therapy. Ghaffar O, Laberge S, Jacobson MR, Lowhagen O, Rak S, Durham SR, Hamid Q. Am J Respir Cell Mol Biol 1997 Jul; 17 (1), pp. 17–24.

Inflammatory Responses: Molecular Pathogenesis/ Nasal Mucosa Cyclooxygenase (COX)-1 and COX-2 Synthesis
Dexamethasone/Interleukin (IL)-10/Actinomycin-D/ Cyclohexamide/Proinflammatory Mediators (Interferon-Gamma [IFN-γ], IL-1β, and Tumor Necrosis Factor-Alpha [TNF-α])

Cellular/Molecular Mechanism of Action: Actinomycin-D (dactinomycin) intercalates between DNA strands within the DNA

helix at adjacent guanine-cytosine base pairs, resulting in the formation of a stable complex. Dexamethasone inhibits phospholipase A2 biochemical activity.

Physiological Mechanism of Action: Dexamethasone functions as an immunosuppressive and anti-inflammatory agent due to an ability to inhibit normal protein synthesis and stabilize cell membranes in a manner sufficient to inhibit cell activation and leukocyte degranulation events. Actinomycin-D inhibits (blocks) RNA polymerase-mediated transcription events. Alternatively, cyclohexamide inhibits translation events. Interleukin IL-10 exerts relatively profound anti-inflammatory properties.

Background Information: Cyclooxygenase converts arachidonic acid in prostanoids. Cyclooxygenase exists in 2 isoforms; COX-1 is the constitutive, whereas COX-2 is the inducible isoform. The regulation of COX-1 and COX-2 expression in nasal mucosa has not been extensively investigated.

Application: Characterization of the molecular pathogenesis of disease states, immune reactions/responses, and efficacy of various forms of therapeutic intervention. Dexamethasone, therefore, can be utilized as a probe for delineating the role of endogenous inflammatory mediators in immune responses and inflammatory reactions.

Implementation: Evaluation of alterations in endogenous COX-1 and COX-2 production *in vitro* in nasal biopsy tissues applying agents that promote proinflammatory and anti-inflammatory properties, in addition to the utilization of molecular probes that function as inhibitors of transcription and translation events. In this manner, it is possible to gain greater understanding about mechanisms involved in the expression and regulation of COX-1 and COX-2 by cytokines and corticosteroids. The specific design of such investigations can entail employing the use of cultured normal/healthy human nasal explants exposed/incubated with individual agents known to promote (i) proinflammatory properties (IFN-γ, IL-1β, and TNF-α); and (ii) anti-inflammatory properties (dexamethasone; IL-10) and inhibitors of translation (actinomycin-D) and transcription (cyclohexamide) events. Tissue culture preparations are subsequently analyzed for the detection of alterations in COX-1 and COX-2 expression applying semi-quantitative competitive polymerase chain reaction (PCR) and Western blot analyses.

Human *Ex Vivo* Model: Nasal mucosa biopsy tissues.

Interpretation and Analysis: Baseline expression of COX-2 messenger RNA (mRNA) is higher than COX-1 mRNA. In a tissue culture environment, there is a slight spontaneous upregulation of COX-1 and a strong COX-2 mRNA and protein upregulation. Incubation of nasal explants with proinflammatory cytokines increases the expression of COX-2 mRNA and protein, from 1 to 24 hours of incubation in a dose-related manner. Regulation of these effects occurs at the levels of both transcriptional and posttranscriptional phases. Dexamethasone and IL-10 abrogate cytokine-induced COX-2 mRNA and protein expression. Proinflammatory cytokines, dexamethasone, and IL-10 have no effect on COX-1 mRNA expression. Prostanoids therefore appear to have important regulatory effects on immunologically (cytokine) mediated inflammatory responses.

Regulation of cyclooxygenase-1 and -2 expression in human nasal mucosa. Effects of cytokines and dexamethasone. Fernández-Morata JC, Mullol J, Fuentes M, Pujols L, Roca-Ferrer J, Pérez M, Xaubet A, Picado C. Clin Exp Allergy 2000 Sep; 30 (9), pp. 1275–84.

Surfactant: Respiratory/Surfactant Distribution
Fluorescent Bodipy-Labeled Surfactant Protein B

Cellular/Molecular Mechanism of Action: Surfactant lowers the viscosity (surface tension) of pulmonary fluid in a manner that prevents collapse of terminal alveoli.

Application: Fluorescent bodipy-labeled surfactant protein B can be applied to determine the distribution of endotracheally administered surfactant at the alveolar level in an animal model of acute respiratory distress syndrome.

Route of Administration: Intratracheal.

Semi-Synthetic Methods: Covalent conjugation/cross-linking of fluorescent bodipy-labeled surfactant protein B.

Implementation: To measure surfactant distribution *in vitro*, a glass trough mimicking dichotomic lung anatomy can be used to determine the spreading properties of bovine lung surfactant extract supplemented with fluorescent bodipy-labeled surfactant protein B. To measure surfactant distribution *in vivo*, anesthetized rats are exposed to aerosolized lipopolysaccharide (12 mg/kg body weight) to induce lung injury that resembles acute respiratory distress syndrome. In control rats, buffered saline is alternatively aerosolized. Twenty-four hours later rats are anesthetized, tracheotomized, and mechanically ventilated (peak airway pressure = 20 mbar; positive end-expiratory pressure = 6 mbar; inspiration time = expiration time = 0.6 seconds; Fio2 = 50%). Surfactant (bovine lung surfactant extract, supplemented with fluorescent bodipy-labeled surfactant protein B; 50 mg/kg body weight) is given as a bolus; in control rats, a bolus of saline is administered. Rats are then ventilated for 5, 15, 30, or 60 minutes (n = 8 or 9 for each group) and their lungs excised and sliced. Lung slices, divided into aerated (open), underinflated (dystelectatic), or collapsed (atelectatic) alveolar areas are subsequently examined by both light and fluorescence microscopy.

Interpretation and Analysis: Surfactant spreads independent of glass trough geometry and lowers the surface tension to equilibrium values (25 mN/m) within a few seconds in *in vitro* preparations. Administration of surfactant *in vivo* distributes preferentially into underinflated and aerated alveolar areas. Surfactant distribution is not affected by length of mechanical ventilation. When conventional mechanical ventilation is used in lipopolysaccharide-induced lung injury, surfactant preferentially distributes into underinflated and aerated alveolar areas. Because surfactant rarely reaches collapsed alveolar areas, methods aiding in alveolar recruitment (e.g., open lung concept or body positioning) should precede surfactant administration.

I n vitro and *in vivo* intrapulmonary distribution of fluorescently labeled surfactant. Diemel RV, Walch M, Haagsman HP, Putz G. Crit Care Med 2002 May; 30 (5), pp. 1083–90.

BREATH TESTS

Note: Additional breath tests have been included in the hepatic metabolism section (see chapter 6).

Carbon Group Metabolization/Trans-Methylation, Trans-Sulfuration, Remethylation/ Hyperhomocysteinemia: Endstage Renal Failure/Single-Carbon Group Transfer (5,10-Methylenetetrahydrofolate)/Hepatic Cytosol and Mitochondria
Carbon Dioxide Breath Tests/[$^{2}H_3$C-1-[^{13}C]-Methionine/[2,3,3-$^{2}H_3$] Serine

Cellular/Molecular Mechanism of Action: Substrates that can be applied as "probes" to detect alterations in the biochemical activity of specific enzyme systems involved in metabolic pathways.

Application: Estimation of trans-methylation, trans-sulfuration, and remethylation rates, and evaluation of carbon group transfer.

Route of Administration: Intravenous.

Implementation: Evaluation of whole-body trans-methylation, trans-sulfuration, and remethylation rates (e.g., [$^{2}H_3$C-1-[^{13}C]-

methionine). Following administration, carbon radioisotope contained in exhaled air as carbon dioxide is then measured. Preparations of [2,3,3-$^{2}H_3$] serine can be applied to evaluate the transfer of a 1-carbon group from serine via 5,10-methylenetetrahydrofolate in human hepatocyte cytosol and mitochondria, respectively.

Animal Model: Ovine.

Interpretation and Analysis: The amount of carbon radioisotope contained in exhaled air is directly proportional to the rate at which a molecular substrate probe is metabolized *in vivo* following injection. Tissue-free methionine enrichments after infusion of universally labeled [U-^{13}C] methionine show the highest remethylation activity in postmortem investigation of jejunum, liver, and kidney tissue samples, but no such activity can be appreciated in muscle and brain preparations.

Instrumentation: Methods to quantitate 1-carbon acceptor metabolism pathways and folate metabolism have recently become available.

In vivo stable isotope measurements of methyl metabolism: Applications in pathophysiology and interventions. de Meer K, van den Akker JT, Smulders Y, Stam F, Stehouwer CD, Finglas P. Food Nutr Bull 2002 Sep; 23 (3 Suppl), pp. 113–9.

Carboxylic Acid Metabolism/Nitrogen Metabolism/ Gastrectomy, Hepatic Failure, Renal Failure, Myotonic Dystrophy
1-[^{14}C-Alpha-Ketoisovaleric Acid (KIV)/[$^{14}CO_2$ Breath Excretion Test]

Cellular/Molecular Mechanism of Action: 1-[^{14}C]-alpha-ketoisovaleric acid is a keto analogue of valine and can function as a biochemical substrate for mechanisms of carboxylic acid metabolism.

Background Information: The keto analogues of essential amino acids represent a promising therapeutic modality in hereditary and acquired disorders of nitrogen metabolism. The utilization of these substances in humans has been assayed primarily by nitrogen balance studies.

Application: Endogenous biochemical metabolism of KIV can be measured using the $^{14}CO_2$ breath excretion test. In this context, the agent can be applied as a tool for evaluation of certain diet formulations.

Route of Administration: Oral.

Implementation: Assessement of the *in vivo* decarboxylation of KIV measurement of $^{14}CO_2$ using a simple and accurate breath excretion test. Protein diets (5 g) supplemented with essential amino acids and KIV (in place of valine) are then evaluated. Diets of 120 g protein/day are then reevaluated in normal reference controls and postoperative gastrectomy cases.

Human Model: Normal volunteers and diseased cases (n = 6 diseased; gastrectomy, hepatic failure, renal failure, and myotonic dystrophy).

Interpretation and Analysis: In situations of low protein intake, 13–32% of ingested KIV undergoes rapid decarboxylation, and this proportion appears to correlate inversely with damage to organ systems containing the branched-chain keto acid dehydrogenase. With high protein intake, the proportion of decarboxylated increases to 44% to 53%. Such findings confirm that the decarboxylation of KIV in man varies under different conditions of dietary intake and metabolic disease. The $^{14}CO_2$ breath excretion test is applicable to other related analyses of carboxylic acid metabolism in human subjects.

Decarboxylation of alpha-ketoisovaleric acid after oral administration in man. Epstein CM, Chawla RK, Wadsworth A, Rudman D. Am J Clin Nutr 1980 Sep; 33 (9), pp. 1968–74.

Enteropathy: Childhood
Lactose Breath Hydrogen Test/D-Xylose Absorption Test/[Jejunal Biopsy Alternative]

Cellular/Molecular Mechanism of Action: Lactose and D-xylose are normally absorbed across the surface of normal/healthy intestinal mucosa.

Background Information: Three widely used screening tests for enteropathy in childhood are the lactose breath hydrogen test, the 1-hour serum D-xylose absorption test, and the 72-hour fecal fat determination.

Application: Lactose and D-xylose can be applied to detect alterations in the absorptive function of the intestinal mucosa.

Route of Administration: Lactose and D-xylose (oral/per os).

Implementation: Correlate findings from the lactose hydrogen breath test, D-xylose absorption test, and 72-hour fecal fat determination with results from jejunal biopsy evaluations in cases of juvenile enteropathy.

Interpretation and Analysis: Results from D-xylose and fecal fat tests each significantly correlate with jejunal biopsy results (e.g., normal result of either test is highly predictive of a normal biopsy finding). Combining the results of 2 or more screening tests does not improve predictive value. The xylose test is preferable on the basis of greater sensitivity and ease of patient compliance.

Screening tests for enteropathy in children. Levine JJ, Seidman E, Walker WA. Am J Dis Child 1987 Apr; 141 (4), pp. 435–8.

Gastric Emptying/Gastric Motility
[^{13}C]-Acetate/[Breath Test]

Cellular/Molecular Mechanism of Action: [^{13}C]-acetate is a radioactive analog of acetic acid that is absorbed from the gastrointestinal tract, enters the portal circulation, is removed from the portal circulation by the liver, and then is metabolized within hepatocytes in a manner that results in the generation of $^{13}CO_2$, which is then exhaled from the respiratory system.

Background Information: Elderly people frequently have symptoms of fullness and appetite loss due to impaired gastric motor activity. These symptoms may cause malnutrition, immunosuppression, and other complications.

Application: Evaluation of gastric motility by [^{13}C]-acetate breath test in combination with electrogastrography techniques.

Route of Administration: [^{13}C]-acetate (oral ingestion).

Implementation: Electrogastrography evaluation of gastric emptying before and after oral ingestion of [^{13}C]-acetate-mixed liquid meal. Expired air is then sampled every 10 minutes for the measurement of $^{13}CO_2$ concentration.

Human Model: Cases of advanced age (n = 7 active/healthy; n = 7 reduced mental/physical capacities with inactive behaviors; n = 7 young healthy volunteers).

Interpretation and Analysis: The ratio of the incidence of the 3-cpm wave (gastric intrinsic frequency) during the postprandial period compared to the fasting state is reduced in active and inactive geriatric cases compared to young adults. Such reductions are greater in inactive elderly cases than in active elderly cases. The ratio of the amplitude of the peak frequency during the postprandial period to that in the fasting state (power ratio) also decreases with advanced age. The time of peak $^{13}CO_2$ expiration is delayed in the active elderly cases, but more so in inactive elderly. Postprandial peristalsis and gastric contractile force are reduced in the elderly, and gastric emptying is delayed, indicating a reduction in gastric motor activity.

Evaluation of gastric motor activity in the elderly by electrogastrography and the [^{13}C]-acetate breath test. Shimamoto C, Hirata I, Hiraike Y, Takeuchi N, Nomura T, Katsu K. Gerontology 2002 Nov–Dec; 48 (6), pp. 381–6.

Gastric Emptying/Gastric Motility (Delayed)/ Functional Dyspepsia
[^{13}C]-Octanoic Acid/[Breath Test]

Background Information: As a non-invasive modality by which to evaluate the gastric emptying of a solid meal, the [^{13}C]-octanoic acid breath test has recently become more widely used. Previously, ultrasonography has also been reported as another non-invasive and reliable method for assessing gastric motility.
Application: Evaluation of gastric motility.
Route of Administration: [^{13}C]-octanoic acid (oral).
Dosage: [^{13}C]-octanoic acid (100 mg).
Implementation: Evaluation of gastric emptying applying the solid test meal consisting of a scrambled egg labeled with [^{13}C]-octanoic acid (100 mg) served with a bowl of rice and boiled chicken (total 424 kcal). After ingestion of the test meal, examinations are performed in a sitting position. Ultrasonography images are obtained every 15 minutes for 3 hours. Breath sampling schedules follow the same time schedule as for ultrasonographic imaging, with an additional 3 hours of sampling at 30-minute intervals. Results are applied to establish half emptying times ($T_{1/2}$) and lag phase.

Human Model: Cases of functional dyspnea (n = 17 compared to n = 10 normal healthy volunteers).
Interpretation and Analysis: The $T_{1/2}$ values determined by ultrasonography-based methods and the breath test are positively correlated ($r^2 = 0.638$); however, there is no significant agreement between study groups. Both the $T_{1/2}$ and the lag phase are prolonged in cases of functional dyspepsia compared with the healthy volunteers, regardless of the method of measurement. The lag phase significantly correlates ($r^2 = 0.864$) with the $T_{1/2}$ established with breath test methods. Although the [^{13}C]-octanoic acid breath test cannot assess gastric emptying of solids as reliably as ultrasonography, both tests are useful for evaluating functional dyspepsia patients with delayed gastric emptying.

Evaluation of gastric emptying measured with the [^{13}C]-octanoic acid breath test in patients with functional dyspepsia: Comparison with ultrasonography. Aoki S, Haruma K, Kusunoki H, Hata J, Hara M, Yoshida S, Tanaka S, Chayama K. Scand J Gastroenterol 2002 Jun; 37 (6), pp. 662–6.

Gastric Helicobacter Pylori: Intragastric Urease Activity
[^{13}C]-Urea Breath Test

Application: Detection and characterization of *H. pylori* populations residing within the gastrointestinal tract. The reagent can also be applied to evaluate the efficacy of therapeutic agents.
Implementation: Assessment of intragastric urease activity by the [^{13}C]-urea breath test can be performed before and after 1 day of dosing with either De-Noltabs (tripotassium dicitrato bismuthate, 1 tablet 1 q.d.s.), Pepto-Bismol liquid (bismuth salicylate 30 ml q.d.s.), or Roter tablets (bismuth subnitrate, 1 tablet q.d.s.) in 12 *H. pylori*–positive patient volunteers.
Interpretation and Analysis: There is a significant decrease in the excess of [$^{13}CO_2$] after 1 day of dosing with each of the 3 bismuth compounds, but analysis of variance detects no difference between the effects of the 3 compounds. Systemic absorption of bismuth following oral dosing with either Pepto-Bismol or Roter is minimal, yet both compounds have a suppressive effect on *H. pylori* similar to that of De-Noltab. The action of all 3 bismuth compounds is within the gastric lumen, and that systemic absorption of bismuth is not necessary for activity against *H. pylori*.

Comparison of 1-day oral dosing with 3 bismuth compounds for the suppression of Helicobacter pylori assessed by the [^{13}C]-urea breath test. Prewett EJ, Luk YW, Fraser AG, Lam WM, Pounder RE. Aliment Pharmacol Ther 1992 Feb; 6 (1), pp. 97–102.

Gastric Motility
[^{13}C]-Octane Acid/[Breath Test]

Cellular/Molecular Mechanism of Action: [^{13}C]-octane acid is a radioactive analog of octane acid that is absorbed from the gastrointestinal tract and then enters the portal circulation, where it is then removed from the portal circulation by the liver. Hepatocytes metabolize the molecule, resulting in the generation of $^{13}CO_2$ that is then exhaled by the respiratory system.
Background Information: Disordered gastric motility may be a significant factor in the pathogenesis of many equine conditions. Although tests for liquid phase emptying rate have been validated in the horse, there are no effective tests for solid phase emptying measurement that can be performed routinely in the field.
Application: Assessment of a stable isotope technique, the [^{13}C]-octane acid breath test (^{13}C-OABT), for the measurement of gastric emptying of solid ingesta, compared to the optimum method of gastric scintigraphy.
Implementation: A test meal is used containing baked egg yolk labeled with both [^{13}C]-octanoic acid and [^{99m}technetium]-sulphur colloid. Simultaneous, serial lateral gastric scintigraphic images and expiratory breath samples are obtained after voluntary test meal ingestion. Analysis of breath $^{13}CO_2$:$^{12}CO_2$ ratio is then performed by mass spectrometry. Power regression is then used to determine the gastric emptying coefficient, the gastric half-emptying time ($T_{1/2}$), and duration of the lag phase (T_{lag}).

Animal Model: Equine (n = 12 healthy horses).
Interpretation and Analysis: Significant correlations ($p < 0.001$) can be appreciated between the 2 techniques for both $T_{1/2}$ and T_{lag} measurements. In addition, scintigraphic left $T_{1/2}$ significantly correlates with breath test gastric emptying coefficients ($p < 0.001$).

It has been proposed that the [^{13}C]-octanoic acid breath test is a reliable diagnostic procedure for measuring gastric emptying rate of solids in the horse. Being safe, non-invasive, and easy to perform, this test has potential value as both sensitive diagnostic modality and humane research tool for motility studies.
Instrumentation: Continuous flow isotope ratio mass spectrometry.

Validation of the [^{13}C]-octanoic acid breath test for measurement of equine gastric emptying rate of solids using radioscintigraphy. Sutton DG, Bahr A, Preston T, Christley RM, Love S, Roussel AJ. Equine Vet J 2003 Jan; 35 (1), pp. 27–33.

Gastrointestinal: Small Intestine Motility/Orocecal Transit Time: Infants (< 8 months)
Lactose-[^{13}C]-Ureide Breath Test (LUBT)

Background Information: The lactose-[^{13}C]ureide breath test is a novel, non-invasive test to determine orocecal transit time. Lactose ureide resists the enzymatic action of brush border enzymes and is metabolized by colonic bacteria.
Application: Gastrointestinal tract tracer that can be used to determine orocecal transit time in infants < 8 months of age.
Dosage: 500 mg unlabeled lactose ureide; 250 mg lactose-[^{13}C]ureide.

Implementation: Adaptation of the lactose-[^{13}C]ureide breath test for various age groups (children) to determine whether it can be applied in infants, newborns, and preterms to study the development of small intestinal motility. In this manner, a breath test is performed after induction of unlabeled lactose ureide (500 mg) 3 times a day over a 24-hour period. A liquid test meal (chocolate milk) with lactose-[^{13}C]ureide (250 mg) is also ingested. Breath samples are collected every 15 minutes for 10 hours. In a 2nd investigation (age range, 0–3 years), only the *in vitro* stool analysis may be performed for comparison.

Stools are collected from each subject for *in vitro* stool incubation analyses. The procedure involves utilization of a blank stool sample and a sample produced after induction with unlabeled lactose ureide and then incubated with 10 mg lactose-[^{13}C]ureide within small, sealed bottles. Ten-milliliter CO_2 samples are aspirated from the bottles using a needle and a syringe every 30 minutes for 24 hours.

The LUBT results are then compared with findings from *in vitro* stool sample analyses.

Human Model: Children (n = 20 at 3 to 17 years of age; compared to n = 32 of which n = 6 at 1 to 3 years, n = 6 infants 6–12 months, n = 13 infants 0–6 months, n = 7 preterm infants).

Interpretation and Analysis: The mean orocecal transit time in cases 3–17 years of age is 255 minutes (range, 165–390 minutes). Stool incubations demonstrated a clear [$^{13}CO_2$] peak in all infants more than 8 months of age, indicating that their colonic bacterial enzymic activity hydrolyses lactose ureide. However, in all infants < 6 months of age, and in preterm infants, the [$^{13}CO_2$] signal is absent, indicating that those subjects are unable to hydrolyze lactose ureide. Infants < 6 months of age do not host the appropriate bacterial enzymic activity for splitting lactose ureide. In conclusion, the LUBT can be applied in infants more than 8 months of age, after weaning to solid foods, to determine orocecal transit time.

Lactose-[^{13}C]ureide breath test: A new, non-invasive technique to determine orocecal transit time in children. Van Den Driessche M, Van Malderen N, Geypens B, Ghoos Y, Veereman-Wauters G. J Pediatr Gastroenterol Nutr 2000 Oct; 31 (4), pp. 433–8.

Hepatic Biochemical Capacity/Age-Related Alterations/Geriatric Function/Biochemical Capacity: Changes with Age/Geriatric Liver: Changes with Advancing Age
[^{13}C]-Methacetin Breath Test

Cellular/Molecular Mechanism of Action: [^{13}C]-methacetin is a radioactive analog of methacetin that can be metabolized in the liver, yielding [$^{13}CO_2$].

Background Information: The issue of whether or not liver function is compromised in the healthy elderly population remains unsolved. However, it is known that endogenous CO_2 production changes with age, motor activity, and nutrition.

Application: Evaluation of the biochemical capacity of the liver. In this manner it can be used to investigate the putative age-related modifications of hepatic function in the form of the [^{13}C]-methacetin breath test.

Implementation: Evaluation of hepatic biochemical capacity by assessment of CO_2 production following [^{13}C]-methacetin administration. Trans-abdominal echosonography with Doppler pulsed wave analysis of the celiac axis and portal vein can be used to complement the [^{13}C]-methacetin breath test.

Human Model: Geriatric (n = 29 elderly cases; n = 17/12 female/male ratio; mean age = 79.8 +/− 7.9 years); and adults (n = 28 adults; n = 13/15 female/male ratio; mean age = 40.6 ± 12.3 years).

Interpretation and Analysis: Although the [$^{13}CO_2$] peak occurs within 15 to 30 minutes in both elderly and adult subjects, it is significantly decreased in the former (30.66% ± 9.2% vs 38.33% ± 6.05%; $p < 0.001$), as is the cumulative excretion (33.07% ± 7.06% vs 39.81% ± 5.68%; $p < 0.001$). When correcting for the effects of CO_2 excretion by age, the age-related modification of the cumulative dose becomes more evident (elderly group 30.15% ± 6.46% vs adult group 37.97% ± 5.92%; $p < 0.0001$). Elderly cases also show an increase in the intrahepatic resistance index using Doppler pulsed wave analysis that inversely correlates with results from breath tests. Hepatic function is not well preserved in healthy humans throughout life and may be due to an increase in vascular resistance.

Study of liver function in healthy elderly subjects using the [^{13}C]-methacetin breath test. Ciccocioppo R, Candelli M, Di Francesco D, Ciocca F, Taglieri G, Armuzzi A, Gasbarrini G, Gasbarrini A. Aliment Pharmacol Ther 2003 Jan; 17 (2), pp. 271–7.

Hepatic Biochemical Function/Cirrhosis (Alcohol-Induced)/Biochemical Transsulferation Capacity
[$^{2}H_3$]-Methyl-1-[^{13}C]Methionine/[$^{13}CO_2$] Exhalation

Cellular/Molecular Mechanism of Action: [$^{2}H_3$]-methyl-1-[^{13}C]methionine is a radiolabeled analog of methionine that is metabolized within the liver along the same pathways as is the amino acid methionine. In this context, methionine can become a substrate for both trans-sulfuration and remethylation metabolic pathways. Trans-sulfuration through decarboxylation of [$^{2}H_3$]-methyl-1-[^{13}C]methionine to yield [$^{13}CO_2$] is followed by remethylation involving the replacement of the labeled methyl group by an unlabeled methyl group.

Background Information: Disturbances of the methionine cycle may result in liver injury. Patients with alcohol-induced liver disease often exhibit hypermethioninemia and a delayed clearance (CL) of methionine, but the extent to which trans-sulfuration and remethylation pathways of the cyclic methionine metabolism are affected is unknown.

Application: Characterization of trans-sulfuration by its decarboxylation to [$^{13}CO_2$] and remethylation by replacement of the labeled methyl group by an unlabeled one.

Route of Administration: [$^{2}H_3$]-methyl-1-[^{13}C]methionine (oral).

Dosage: [$^{2}H_3$]-methyl-1-[^{13}C]methionine (2 mg/kg).

Implementation: Evaluation of methionine metabolism in conditions of alcohol-induced cirrhosis. Oral administration of 2 mg/kg [$^{2}H_3$]-methyl-1-[^{13}C]methionine.

Human Model: Cases of alcohol-induced cirrhosis (n = 6 cases; n = 7 normal healthy volunteers).

Interpretation and Analysis: Basal plasma concentrations of endogenous methionine (50 + 5 vs 25 + 2 μmol/L, mean ± SEM, $p < 0.001$) are significantly higher in patients with cirrhosis and its clearance is significantly decreased (774 + 103 vs 2,050 + 141 mL/min, $p < 0.001$). Methionine turnover is much slower in conditions of cirrhosis compared to healthy controls (e.g., 27 + 3 vs 42 + 4 μmol/kg/hour, $p < 0.05$) in controls and patients with cirrhosis, respectively. The fraction of administered methionine undergoing remethylation is lower in cirrhosis (7.6 + 1.5 vs 14.1 + 1.1%, $p < 0.005$). However, because of the larger pool of circulating methionine, the total flux of methionine through the remethylation pathway is similar in both cirrhosis and normal reference controls. A significantly lower fraction of the administered dose appears in the form of

[$^{13}CO_2$] in breath in patients with cirrhosis (2.2 + 0.4 vs 11.0 + 0.8%, $p < 0.001$). Cirrhosis of the liver compensates for a decreased activity of remethylating enzymes by operating at higher concentrations of methionine. In contrast, trans-sulfuration is impaired in patients with alcohol-induced cirrhosis such that an assessment of trans-sulfuration by a simple breath test may provide a clinically useful estimate of hepatic function.

Remethylation and transsulfuration of methionine in cirrhosis: Studies with L-[H3-methyl-1-C]methionine. Russmann S, Junker E, Lauterburg BH. Hepatology 2002 Nov; 36 (5), pp. 1190–6.

Hepatic Biochemical Function/Decarboxylation Capacity (Mitochondrial)/Mitochondrial Respiration Uncoupling
[^{14}C]-Alpha-Ketoisocaproic Acid/Exhaled [$^{14}CO_2$]/Ethanol/Sodium Salicylate

Cellular/Molecular Mechanism of Action: Alpha-ketoisocaproic acid is a substrate for enzyme decarboxylation mechanisms mediated by hepatic mitochondria. Ethanol suppresses these biochemical processes. Sodium salicylate uncouples mitochondrial respiration and can therefore promote increased decarboxylation processes.
Application: Alpha-ketoisocaproic acid can be applied in a breath test to assess *in vivo* hepatic mitochondrial function. Ethanol can be applied as a control reagent due to its ability to inhibit hepatic mitochondrial decarboxylation mechanisms.
Route of Administration: 1-[^{14}C]-alpha-ketoisocaproic acid (intraperitoneal).
Implementation: Evaluation of *in vivo* hepatic mitochondrial metabolic capacity as a function of [$^{14}CO_2$] exhalation following 1-[^{14}C]-alpha-ketoisocaproic acid administration.
Animal Model: Rat.
Interpretation and Analysis: Following administration of 1-[^{14}C]-alpha-ketoisocaproic acid, exhaled [$^{14}CO_2$] reaches a peak within 10 to 20 minutes and then declines exponentially, with a half-life of 14.3 minutes. In controls, approximately 38.6% of the administered radioactivity is exhaled within 1 hour. In functionally anhepatic animals, [$^{14}CO_2$] in breath amounted to 23% of that in control animals, indicating that alpha-ketoisocaproic acid decarboxylation reflects mainly *in vivo* hepatic mitochondrial function. Ethanol (3 gm per kg) significantly decreases alpha-ketoisocaproic acid decarboxylation (21.8% of the dose appearing in breath in 1 hour), probably due to the ethanol-induced shift in the NAD+:NADH ratio. In contrast, uncoupling of mitochondrial respiration with sodium salicylate (375 mg per kg), increases decarboxylation of alpha-ketoisocaproic acid (56.3% of the dose recovered as [$^{14}CO_2$] in 1 hour). Mitochondrial damage induced by 4-pentenoic acid decreases decarboxylation of alpha-ketoisocaproic acid but does not affect the microsomal metabolism of antipyrine. Such findings indicate that the alpha-ketoisocaproic acid breath test provides a non-invasive estimate of hepatic mitochondrial function *in vivo* that, when applied to man, might yield clinically useful information.

Assessment of mitochondrial function *in vivo* with a breath test utilizing alpha-ketoisocaproic acid. Michaletz PA, Cap L, Alpert E, Lauterburg BH. Hepatology 1989 Nov; 10 (5), pp. 829–32.

Pancreatic Insufficiency
[^{13}C]-Egg White Breath Test/[Indirect Pancreatic Function Test]

Cellular/Molecular Mechanism of Action: [^{13}C]-egg white can function as a substrate for pancreatic enzyme fractions. The proteolytic peptide fragments are then absorbed in the gastrointestinal tract and metabolized to [$^{13}CO_2$] that is in turn exhaled from the respiratory tract.
Background Information: The recent availability of egg white protein highly enriched with [^{13}C] has allowed breath test technology to be adapted for the study of protein digestion and absorption. Pancreatic trypsin is considered to be the key enzyme in the proteolytic cascade. The aim is to evaluate trypsin activity in the small intestine of healthy volunteers and patients with pancreatic disease by a recently developed [^{13}C]-egg white breath test.
Application: Indirect effect on pancreatic function.
Route of Administration: [^{13}C]-labeled egg protein (oral).
Dosage: [^{13}C]-labeled egg protein (22 g).
Implementation: Evaluation of pancreatic disease states with the ingestion of a test meal consisting of [^{13}C]-labeled egg protein. Breath samples are taken before and after ingestion of the meal and analyzed for [$^{13}CO_2$] concentration. Moreover, pancreatic trypsin output after maximal stimulation is also measured.
Human Model: Cases with pancreatic disease (n = 30; and n = 48 normal volunteers). Pancreatic trypsin output after maximal stimulation measured in n = 13/30 affected cases and n = 9/48 healthy volunteers.
Interpretation and Analysis: The 6-hour cumulative [$^{13}CO_2$] excretion in breath is significantly lower in patients than observed in controls (mean [SEM]: 6.23 + 0.82% vs 19.16 + 0. 58%, $p < 0.0001$). An excellent correlation can be appreciated between the 6-hour cumulative [$^{13}CO_2$] excretion and trypsin activity after maximal pancreatic stimulation. The non-invasive [^{13}C]-egg white breath test is promising as an indirect pancreatic proteolytic function test.

[^{13}C]-egg white breath test: A non-invasive test of pancreatic trypsin activity in the small intestine. Evenepoel P, Hiele M, Geypens B, Geboes KP, Rutgeerts P, Ghoos Y. Gut 2000 Jan; 46 (1), pp. 52–7.

Pulmonary Epithelium Integrity/Viability/Pulmomary Pathophysiology
L-[Guanidino$^{15}N_2$]-Arginine Monohydrochloride/[^{15}NO] Exhalation/[Breath Test]

Cellular/Molecular Mechanism of Action: The amino acid L-[guanidino$^{15}N_2$]-arginine monohydrochloride is resorbed within the lung and partly metabolized to [^{15}NO].
Background Information: Conventional diagnosis of the pulmonary tract uses physical methods such as spirometry and oscillometry. However, the inhalation of a chemical diagnostic agent ought to provide novel ways of more specific diagnosis, for instance of inflammatory states of the bronchial and lung mucosa. The stable isotope technique using a [^{15}N]-labeled substrate appears to be a suitable tool for this application.
Application: The [^{15}NO] yielded after the inhalation of [^{15}N]-labeled arginine could be a potential marker for demonstrating pathophysiological changes in the lung epithelium. This method could establish a new diagnostic principle of "inhalative breath test."
Route of Administration: L-[guanidino$^{15}N_2$]-arginine monohydrochloride (inhaled).
Dosage: L-[guanidino$^{15}N_2$]-arginine monohydrochloride (700 mg of aqueous solution, 20 atom % [^{15}N]).
Implementation: Evaluation of conditions of asthma bronchiale with defined amounts of inhaled amino acid L-[guanidino$^{15}N_2$]-arginine monohydrochloride. The exhaled air is collected under defined conditions in 10-L breath bags and analyzed for NO using chemiluminescence.
Human Model: Cases suffering from asthma bronchiale (n = 7) and healthy/normal volunteers (n = 6).

Interpretation and Analysis: Under standardized test conditions, healthy cases exhale 0.97 ± 0.08 μmol NO/m^3 and asthmatics 1.17 ± 0.14 μmol NO/m^3. A better distinction is expected when comparing affected cases and normal reference controls when using [^{15}NO] exhalation as a diagnostic procedure. Between 30 and 80 minutes after inhaling [^{15}N]arginine, a maximum plateau of [^{15}NO] abundance is found in the exhaled air, at which time healthy and asthmatic cases exhibit clear differences in exhaled [^{15}NO] amounts. Under standardized test conditions, the healthy cases exhale 102.3 ± 6.7 nmol [^{15}NO/m^3], whereas asthmatic cases exhale only 76.1 ± 10.9 nmol [^{15}NO/m^3].

Instrumentation: Cryotrap gas chromatography–mass spectrometry system for analyzing the [^{15}N] abundance of NO gas.

[$^{15}N_2$]arginine as a 1st potential inhaled diagnostic agent to characterize respiratory diseases. Krumbiegel P, Denk E, Russow R, Rolle-Kampczyk U, Metzner G, Herbarth O. Exp Lung Res 2002 Oct–Nov; 28 (7), pp. 535–42.

2 GENETIC DISORDERS, INFECTIOUS DISEASE, NEOPLASIA, AND METABOLIC CONDITIONS

12 Cancer/Neoplastic Disease

GENERAL

Adhesion of Cells to Endothelium: Colon Carcinoma/Intravital Observation of Cancer Cell/Microcirculation Interactions
CalceinAM

Background Information: Organ-specific tumor cell adhesion within the microcirculation of host organs is an important step in the metastatic cascade. Circulating tumor cells have to adhere within the microcirculatory vessels, quickly stabilize their adhesion, and probably leave the circulation to avoid toxic effects of hydrodynamic shear forces of circulating blood.
Application: Intravital observation of colon carcinoma cell adhesion within the hepatic microcirculation.
Implementation: CalceinAM can be used to label colon carcinoma cell populations (e.g., HT-29 [human] and CC531 [rat]) that are then injected intra-arterially as single-cell suspensions. Intravital fluorescence microscopy is then applied to detect adhesive interactions between circulating tumor cells and endothelial surfaces within the hepatic microcirculation. These interactions are then analyzed regarding their time course and site localization within the vascular tree.
Animal Model: Rats (Sprague-Dawley).
Interpretation and Analysis: Autofluorescence of liver parenchyma is sufficient for distinction of hepatic sinusoids. Intravital microscopy is capable of differentiating early events in adhesion formation within hepatic sinosoids, adhesion stabilization, and extravasation of the tumor cells into the liver parenchyma. Tumor cell adhesion occurs almost exclusively within sinusoidal capillaries; however, the diameter of these vessels is usually larger than that of the tumor cells. Colon carcinoma cells rapidly migrate into the liver parenchyma after successful adhesion within the sinusoids. In contrast to common end point assays of the metastatic cascade, this *in vivo* model allows investigations of metastatic colon carcinoma cell adhesion within the liver microcirculation as specific steps during the formation of hematogenous metastasis and their underlying mechanisms.
Instrumentation: Intravital fluorescence microscopy.

An intravital model to monitor steps of metastatic tumor cell adhesion within the hepatic microcirculation. Haier J, Korb T, Hotz B, Spiegel HU, Senninger N. J Gastrointest Surg 2003 May–Jun; 7 (4), pp. 507–14; discussion 514–5.

Angiogenesis/Tumor Dimethylarginine Dimethylaminohydrolase (DDAH) Overexpression
NC100150/Hoechst 33342

Cellular/Molecular Mechanism of Action: The molecular orientation of NC100150 becomes altered within a magnetic field while the agent Hoechst 33342 emits fluorescent light energy.
Background Information: Intracellular factors that regulate nitric oxide (NO) synthesis represent important targets in tumor progression. Overexpression of DDAH, which metabolizes the endogenous inhibitors of NO synthesis (asymmetric dimethylarginine and N-monomethyl-L-arginine), results in C6 gliomas with enhanced growth rate compared with wild types.
Application: NC100150 can be utilized as an intravascular blood pool contrast agent that is detectable by MRI methodologies. Hoechst 33342 can be used as a fluorescent perfusion-marker dye for fluorescent detection systems.
Route of Administration: Utilization of NC100150 and Hoechst 33342 for detection of neoplastic lesion angiogenesis more frequently would require the delivery of these agents intravascularly.
Implementation: Determine the *in vitro* effects of DDAH on tumor vascular morphogenesis by measurement of the transverse relaxation rates R_2* and R_2 in (i) clone D27 gliomas overexpressing DDAH; (ii) C6 wild-type gliomas using intrinsic susceptibility magnetic resonance imaging (MRI) sensitive to changes in endogenous deoxyhemoglobin; (iii) determination of susceptibility contrast-enhanced MRI using NC100150 as an intravascular blood pool contrast agent; and (iv) compare results observed with the perfusion marker Hoechst 33342 applied in combination with the use of tumor fluorescence microscopy analyses.
Interpretation and Analysis: Baseline R_2* is significantly faster in D27 tumors, consistent with a greater vascular development ($p < 0.02$, ANOVA). There is no significant difference between the response of the 2 tumor types to hypercapnia (5% CO_2/95% air), when used as a probe for vascular maturation, or hyperoxia (5% CO_2/95% O_2, when used as a probe for vascular function. NC100150 increases the R_2* and R_2 rates of both tumor types and demonstrates a significantly larger blood volume in D27 tumors ($p < 0.02$, ANOVA). This correlates with a significantly greater uptake of Hoechst 33342 in D27 tumors compared to C6 wild-type tumors ($p < 0.02$, ANOVA). Despite increased tumor blood volume, the Delta R_2*/Delta R_2 ratio, an index of microvessel size, shows that the capillaries in the 2 tumor types are of a similar caliber. Such observations demonstrate the potential of susceptibility MRI-derived quantitative end points to non-invasively assess tumor angiogenesis. Application of intravascular blood pool contrast agents such as NC100150 for such purposes appears very promising. Overexpression of DDAH results in increased *in vivo* neovascularization of C6 gliomas. The lack of significant difference in hypercapnic/hyperoxic response between the C6 and D27 tumors and the similar vessel caliber are also consistent with a role for DDAH in the initial stages of vasculogenesis.
Instrumentation: Magnetic resonance imaging and fluorescence microscopy instrumentation.

Effects of overexpression of dimethylarginine dimethylaminohydrolase on tumor angiogenesis assessed by susceptibility magnetic resonance imaging. Kostourou V, Robinson SP, Whitley GS, Griffiths JR. Cancer Res 2003 Aug 15; 63 (16), pp. 4960–6.

Chemosensitivity
Near-Infrared Fluorescent (NIRF) Annexin V

Background Information: A rapid and accurate assessment of the antitumor efficacy of new therapeutic drugs could speed up drug discovery and improve clinical decision making.

Implementation: Based on the hypothesis that most effective antitumor agents induce apoptosis, the agent NIRF annexin V has been developed for optical sensing of tumor environments. To demonstrate probe specificity, both an active (i.e., apoptosis-recognizing) and an inactive form of annexin V have been developed that have very similar properties (to account for non-specific tumor accumulation).

Animal Model: Murine (nude mice each bearing a cyclophosphamide [CPA] chemosensitive [LLC] and a chemoresistant LLC [CR-LLC] properties).

Interpretation and Analysis: After injection with active annexin V, the tumor-annexin V ratio (TAR; tumor NIRF/background NIRF) for untreated mice is 1.22 ± 0.34 for LLC and 1.43 ± 0.53 for CR-LLC (n = 4). The LLC of CPA-treated mice has significant elevations of TAR (2.56 ± 0.29, p = 0.001, n = 4), but only moderate increases are obtained for CR-LLC (TAR = 1.89 ± 0.19, p = 0.183). The *in vivo* measurements correlate well with terminal deoxyribosyl transferase-mediated dUTP nick end labeling indexes. When inactive Cy-annexin V is used, with or without CPA treatment and in both CCL and CR-CCL tumors, tumor NIRF values range from 0.91 to 1.17 (i.e., tumors are equal to background). Therefore, active Cy-annexin V and surface reflectance fluorescence imaging provide a non-radioactive, semi-quantitative method of determining chemosensitivity in LLC xenografts. The method may be used to image pharmacologic responses in other animal models and, potentially, may permit the clinical imaging of apoptosis with non-invasive or minimally invasive instrumentation.

Optical imaging of apoptosis as a biomarker of tumor response to chemotherapy. Schellenberger EA, Bogdanov A Jr, Petrovsky A, Ntziachristos V, Weissleder R, Josephson L. Neoplasia 2003 May–Jun; 5 (3), pp. 187–92.

Mitosis/Proliferation Rate of Cell Populations/ Neoplastic Lesions: Potential Application
3′-Deoxy-3′-[^{18}F]Fluorothymidine

Cellular/Molecular Mechanism of Action: Thymidine is rapidly assimilated by proliferating cell populations.

Application: 3′-deoxy-3′-[^{18}F]fluorothymidine has been designed as a new agent for positron emission tomography imaging for visualizing cellular proliferation *in vivo* based on the metabolism of thymidine

Route of Administration: Variable but most often intravascular.

Semi-Synthetic Methods: A reliable technique for the radiosynthesis of 3′-deoxy-3′-[^{18}F]fluorothymidine ([^{18}F]-FLT) has been developed based on [^{18}F]10 mCi (370 MBq) of radiochemically pure [^{18}F]1 Ci/μmol (37 GBq/μmol) at EOS within 100 minutes and in 13% radiochemical yield (end of bombardment [EOB]; 7% end of synthesis [EOS]).

Implementation: Evaluation of neoplastic lesions that display relatively rapid rates of proliferation/growth.

Interpretation and Analysis: Detection of increased radioactivity at a specific anatomical location corresponds to a region with a relatively high rate of cellular proliferation.

Radiosynthesis of 3′-deoxy-3′-[^{18}F]fluorothymidine: [^{18}F]FLT for imaging of cellular proliferation *in vivo*. Grierson JR, Shields AF. Nucl Med Biol 2000 Feb; 27 (2), pp. 143–56.

Optical (Near-Infrared [NIR]) Imaging/ Endoscopy/Videoendoscopy
[Bis-Propanoic Acid Cyanine]-IgG

Cellular/Molecular Mechanism of Action: Receptor-specific small peptide molecule that selectively recognizes and physically binds to complexes expressed on the exterior surface membrane of certain neoplastic cell types.

Application: Potential *in vivo* optical imaging of neoplastic lesions using endoscopy/videoendoscopy.

Route of Administration: [Bis-propanoic acid cyanine]-IgG (intravenous).

Semi-Synthetic Methods: Conjugation of the NIR dyes indocyanine green (ICG) and its derivatized analogue, bis-propanoic acid cyanine dye (cypate), to a biological peptide molecule.

Implementation: Evaluation of the ability of an NIR dye-peptide conjugate to function as a tumor-targeting agent.

Animal Model: Rat (n = 6; neoplastic cell type CA20948 that expresses the corresponding biological protein receptor complex).

Interpretation and Analysis: Tumor retention of 2 non-tumor-specific dyes, ICG and its derivatized analogue, bis-propanoic acid cyanine dye (cypate), is negligible. In contrast, the receptor-specific peptide-cypate conjugate (cytate) is retained within CA20948 tumor, with an excellent tumor-to-normal-tissue ratio (e.g., n = 6 rats). Optical detection of tumors with a receptor-targeted fluorescent contrast agent has been demonstrated. These results represent a new direction in cancer diagnosis and patient management.

Instrumentation: A simple continuous-wave optical imaging system, consisting of an NIR laser diode, a cooled charge-coupled device (CCD) camera, and an interference filter.

Novel receptor-targeted fluorescent contrast agents for *in vivo* tumor imaging. Achilefu S, Dorshow RB, Bugaj JE, Rajagopalan R. Invest Radiol 2000 Aug; 35 (8), pp. 479–85.

Visual Detection of Neoplastic Disease
Tumor Receptor Binding Ligand Conjugate/ Indocyanine Green (ICG)/Bis-Propanoic Acid Cyanine Dye (Cypate)

Cellular/Molecular Mechanism of Action: Indocyanine green and bis-propanoic acid cyanine dye (cypate) function as dye marker reagents that when activated emit light energy in the near-infrared (NIR) range. Tumor receptor ligands recognize and physically bind selectively to complexes associated with the exterior surface membrane of cancer cells.

Application: Indocyanine green and bis-propanoic acid cyanine dye reagents can be applied as visible marker molecules to facilitate optical imaging modalities. In this context, they can be conjugated to small peptides that specifically recognize (bind to) tumor-associated receptor complexes.

Route of Administration: Intravenous.

Semi-Synthetic Methods: Covalent conjugation of an NIR dye to a biologically active peptide that recognizes and binds to tumor-associated receptor complexes.

Implementation: Evaluation of the ability of a semi-synthetic NIR dye-peptide conjugate for its ability to selectively localize with tumor lesions. Detection is achieved with a simple continuous-wave optical imaging system.

Animal Model: Rat tumor model (CA20948) known to express receptors for a specific peptide (e.g., n = 6).

Interpretation and Analysis: Tumor retention of 2 non-tumor-specific dyes, ICG and its derivatized analogue, bis-propanoic acid cyanine dye (cypate), is negligible. In contrast, the receptor-specific peptide-cypate conjugate (cytate) is retained by CA20948 tumors, producing an excellent tumor-to-normal-tissue ratio.

Instrumentation: A simple continuous-wave optical imaging system, consisting of an NIR laser diode, a cooled charge-coupled device (CCD) camera, and an interference filter.

Novel receptor-targeted fluorescent contrast agents for *in vivo* tumor imaging. Achilefu S, Dorshow RB, Bugaj JE, Rajagopalan R. Invest Radiol 2000 Aug; 35 (8), pp. 479–85.

Visual Detection of Neoplastic Disease: Selective Recognition
HAT-DO1 Fluorescent Agents

Cellular/Molecular Mechanism of Action: Fluorescent molecular system that can be covalently conjugated to a selective "targeting" agent for the detection of specific biological entities without the simultaneous delivery of photodynamic properties.
Application: Principally used as a sensor or indicator molecular that facilitates external detection of "targeting" modalities designed to selectively interact with a specific biological/pathological entity.
Synthesis and Design Considerations: Various heterodimers linked by various types of "spacers" between a chlorine derivative and its Mn or Cu complex can be synthesized. One representative agent referred to as HAT-DO1 has a molecular formula of m-phthalyl-([13,17-bispropanoic acid-3-ethenyl-8-formylethylidene-7-hydroxy-2,7,12,18-tetramethyl- porphyrinate]-manganese (III))-[3′-ethenyl-8′-formylethylidene-7′-hydroxy-2′,7′,12′,18′-te tramethyl-porphine-13′,17′-bispropanoyl aspartic acid]-bishydrazone.

Tumor-localizing fluorescent diagnostic agents without phototoxicity. Takemura T, Nakajima S, Sakata I. Photochem Photobiol 1994 Mar; 59 (3), pp. 366–70.

CENTRAL NERVOUS SYSTEM

Glioma Cell Type
EtNBA Fluorescent Dye

Cellular/Molecular Mechanism of Action: EtNBA emits a fluorescent color when exposed to certain wavelengths of light energy.
Background Information: Nile blue dyes have been shown to have a higher affinity for tumor tissue, as compared to surrounding normal tissue, and to be relatively non-toxic. The agent EtNBA, a lipophilic, fluorescent benzophenoxazine dye, has been employed in murine models to determine the capacity of this agent to image subcutaneous and intracranial U-87 glioma implants.
Application: The fluorescent dye marker EtNBA can function as a detectable signal molecule that can facilitate the external detection and characterization of neoplastic lesions (e.g., glioma cell types).
Dosage: EtNBA (2.5–5.0 mg/kg).
Implementation: Tumors are illuminated with a 632.8-nm diffuse beam from a helium-neon laser. The resulting video image is processed using an image processor to give real-time pseudocolor and enhanced black and white images.
Animal Model: Mouse (expressing U87-MG glioma solid tumor implants).
Interpretation and Analysis: Following subcutaneous injection of EtNBA dye at doses of 2.5 to 5.0 mg/kg bw, a gradual increase in the fluorescent signal can be observed from tumors that peaks 1–3 hours postinjection with variable selectivity (typically 4:1) for tumor to normal surrounding tissues permitting clear tumor demarcation. The reagent EtNBA is a safe and effective photodiagnostic agent when applied *in vivo* and is capable of demarcating U87-MG solid tumors on a real-time basis (2.5–5.0 mg/kg) for 1 to 3 hours following administration.
Instrumentation: Imaging systems for detecting fluorescence can consist of a silicon-intensified target (SIT) video camera fitted with a zoom microscope-magnifying lens complemented by an image processor to give real-time pseudocolor and enhanced black and white images.

Fluorescent imaging in a glioma model *in vivo*. Nikas DC, Foley JW, Black PM. Lasers Surg Med 2001; 29 (1), pp. 11–7.

Gliosarcoma/Proliferation Rate
Hoechst 33258 Dye/Rhodaminated Long-Circulating Dextran-Coated Iron Oxide (LCDIO)/Green Fluorescent Protein

Cellular/Molecular Mechanism of Action: Hoechst 33258 dye can be applied as an intravital endothelial stain. Rhodaminated LCDIO particles can preferentially localize intracellularly within certain malignant neoplastic cell types (e.g., gliosarcoma).
Application: Detection and characterization of central nervous system neoplastic lesions (e.g., gliosarcoma).
Route of Administration: Intravascular.
Implementation: Determination of the distribution of LCDIO preparation in tumors. Accumulation of LCDIO in tissue sections is evaluated using multichannel fluorescence microscopy with rhodaminated LCDIO, green fluorescent protein as a tumor marker, and Hoechst 33258 dye as an intravital endothelial stain. Uptake into tumor cells is corroborated with results of immunohistochemical analyses and cell culture uptake experiments.
Animal Model: Rodent gliosarcoma.
Interpretation and Analysis: Tumoral accumulation of LCDIO is 0.11% ± 0.06 of the injected dose per gram of tissue in brain tumors and sufficient for detection using magnetic resonance imaging (MRI). In tumor sections, LCDIO preferentially localizes in tumor cells (49.0% ± 4.6) but is also taken up by macrophages in tumors (21.0% ± 3.1) and by endothelial cells in the areas of active angiogenesis (6.5% ± 1.4). In cell culture, LCDIO uptake strongly correlates with the growth rate of tumor cell lines. Tumoral LCDIO accumulation is not negligible and helps explain MRI signal intensity changes observed in clinical trials. Microscopically, LCDIO accumulates predominantly in tumor cells and tumor-associated macrophages. Uptake into tumor cells appears to be directly proportional to cellular proliferation rate.
Instrumentation: Magnetic resonance imaging signal intensity evaluated utilizing a 1.5-T superconducting magnet for the detection of intratumor LCDIO uptake.

Tumoral distribution of long-circulating dextran-coated iron oxide nanoparticles in a rodent model. Moore A, Marecos E, Bogdanov A Jr, Weissleder R. Radiology 2000 Feb; 214 (2), pp. 568–74.

Neuroendocrine Neoplasia/ Somatostatin Receptor Expression
Indotricarbocyanine-Octreotate/(Cyanine Dye: Somatostatin Conjugate)

Cellular/Molecular Mechanism of Action: Octreotate is a biologically functional analog of somatostatin.
Application: Contrast agent for the optical *in vivo* imaging of neoplastic lesions that express somatostatin receptors at relatively high densities so that they can be visualized using endoscopy/videoendoscopy.
Route of Administration: Indotricarbocyanine-octreotate (intravenous).
Implementation: Indotricarbocyanine-octreotate.
Animal Model: Mouse (xenographs of human neuroendocrine neoplastic cell types).

Interpretation and Analysis: During *in vivo* imaging procedures, indotricarbocyanine-octreotate preferentially accumulates in tumors (murine xenografts). The level of fluorescence for tumors rapidly increases and is often more than 3-fold higher than that of normal tissue between 3 and 24 hours after application. The targeting conjugate is internalized by primary human neuroendocrine tumor cells. Imaging applying such an approach combines the specificity of ligand/receptor interaction with near-infrared fluorescence detection, and therefore may be applied in various other fields of cancer diagnosis.

Receptor-targeted optical imaging of tumors with near-infrared fluorescent ligands. Becker A, Hessenius C, Licha K, Ebert B, Sukowski U, Semmler W, Wiedenmann B, Grotzinger C. Nat Biotechnol 2001 Apr; 19 (4), pp. 327–31.

GASTROINTESTINAL TRACT

Carcinoid Syndrome: Midgut/Hepatic Neoplastic Disease: Metastatic Midgut Carcinoid *Pentagastrin/Calcium Infusion/Ketanserin*

Application: Detection of midgut carcinoma conditions.
Background Information: Both 5-hydroxytryptamine (serotonin, 5-HT) and substance-P (SP) are expressed at supranormal plasma concentrations in conditions of midgut carcinoma with hepatic metastasis. The agent 5-HT is important for the development of gastrointestinal symptoms but is not associated with flushing conditions. Substance-P may contribute to but not function as the sole mediator of flushing. Ketanserin may alleviate gastrointestinal symptoms in carcinoid conditions.
Route of Administration: Pentagastrin (IV) and calcium infusion.
Implementation: Evaluation of responses to calcium infusion and pentagastrin as a diagnostic approach to detecting and characterizing carcinoid syndrome conditions.
Interpretation and Analysis: Pentagastrin causes flushing and gastrointestinal symptoms and elevated levels of circulating 5-HT, but not of SP. Pretreatment with a 5-HT2 receptor blocking agent (ketanserin) alleviates gastrointestinal symptoms but has no influence on either 5-HT release or pentagastrin-induced flushing. Calcium infusion induces carcinoid symptoms in only about a third of cases (e.g., n = 2/6). Elevated 5-HT levels can be detected in this case group, in contrast to elevations in SP levels, which are only seen in about 15% of cases (e.g., n = 1/6).

Differential responses to pentagastrin suggest that substance-P is released from a different anatomical location or involves different mechanisms than those associated with 5-HT (serotonin). Substance P and 5-HT do not seem to share a common release mechanism. It appears that PG testing is superior to calcium infusion as a provocative test in patients with the carcinoid syndrome. Based on observations noted in preliminary investigations, the pentagastrin test with measurements of 5-HT levels in peripheral blood seems to be superior to calcium infusion as a provocative test in documenting a diagnosis of carcinoid disease.

Pretreatment with a 5-HT2-receptor blocking agent, ketanserin, abolishes the gastrointestinal effects but has virtually no influence on either 5-HT levels or flushing induced by intravenous pentagastrin. In contrast, calcium infusion induces carcinoid symptoms in only about 30% of cases (e.g., n = 2/6), and this is consistently associated with the stimulation of circulating serotonin levels.
Instrumentation: High-performance liquid chromatography-electron capture and radioimmunoassay methodologies.

The pentagastrin test in the diagnosis of the carcinoid syndrome. Ahlman H, Dahlstrom A, Gronstad K, Jaffe BM, Nilsson O, Oberg K. J Cardiovasc Pharmacol 1985; 7 Suppl 7, pp. S86–8.

Colorectal Cancer/Gastric Cancer *[Indocyanine Green (ICG)]-Anti-MUC1 Mucin*

Cellular/Molecular Mechanism of Action: Monoclonal antibody (IgG) with selective binding properties directed at MUC1 mucin recognizes and physically binds to the corresponding complexes expressed on the exterior surface membrane of certain neoplastic cell types.
Background Information: Videoendoscopy has not significantly advanced diagnostic accuracy beyond that attainable by conventional fiberscopy, with respect to microcarcinomas of the digestive tract. Theoretically, it is possible to selectively label such lesions with agents that can be detected by videoendoscope. Digital processing of the images could facilitate more accurate endoscopic diagnosis of microcarcinomas.
Application: [Indocyanine green]-anti-MUC1 mucin can be utilized to detect and characterize conditions of gastric and colorectal cancer lesions when used in combination with direct visualization using videoendoscopy methodologies.
Route of Administration: [Indocyanine green]-anti-MUC1 mucin (intravenous).
Implementation: Evaluation of the ability of [ICG]-anti-MUC1 mucin to selectively recognize and bind *in vivo* to gastric and colorectal cancer cell types. Validation of findings established by immunohistochemistry analysis using labeled secondary antibody.
Animal Model: Murine (nude mouse with human gastric or colorectal cancer cell types).
Interpretation and Analysis: [Indocyanine green]-anti-MUC1 mucin preferentially accumulates within gastric and colorectal cancer explants in nude mice that can be appreciated on gross examination and by examination of tissue samples applying histochemical analysis. Therefore, antibody labeled with an ICG derivative may be clinically useful in detecting gastrointestinal microcarcinoma by videoendoscopy.
Instrumentation: Videoendoscopy.

Vital immunostaining of human gastric and colorectal cancers grafted into nude mice: A preclinical assessment of a potential adjunct to videoendoscopy. Kusaka Y, Ito S, Muguruma N, Tadatsu M, Bando T, Ii K, Irimura T, Shibamura S. J Gastroenterol 2000; 35 (10), pp. 748–52.

Colorectal Cancer/Terminal α-N-Acetylgalactosaminyl (GalNAc)/Tn Antigen *Fluorescein Isothiocyanate (FITC)-Conjugated GS I-A4/Lectins DBA and LBL*

Cellular/Molecular Mechanism of Action: Lectin GS I-A4 binds to terminal α-N-acetylgalactosaminyl (GalNAc) groups (which include the Tn antigen) but not to the closely related tumor-associated epitope sialylated Tn antigen. The lectin also precipitates asialo OSM but not its native sialylated form.
Application: Lectin histochemistry with human colonic tissues reveals that GS I-A4 specifically stains specimens of colon cancer and colonic tissues from individuals with FAP; however, normal colonic tissues from patients without colonic disease are rarely stained with this lectin.
Dosage: A dose-response study conducted using 10–160 μg/ml of GS I-A4 demonstrates significant dose-related toxicities against LS174t and SW1116 cells.
Interpretation and Analysis: Glycoconjugates bound by GS I-A4 can be observed on the surface membranes of LS174t and SW1116 human colon cancer cell lines when exposed to FITC-conjugated GS I-A4. GS I-A4 is toxic to these 2 human colon cancer cell lines in monolayer culture. In this context, at concentrations > 80

μg/ml, > 99% of LS174t and > 90% of SW1116 cells are killed. At 4 mM, GalNAc specifically inhibits the cytotoxic effect of GS I-A4 ($p < 0.001$), whereas 4mM N-acetylglucosamine (GlcNAc) has no effect. In the light of these findings, it has been speculated that GS I-A4 may have potential use as a diagnostic agent against colorectal cancer. Other lectins that recognize terminal α-GalNAc residues including DBA and LBL are significantly less cytotoxic to colon cancer cells than GS I-A4.

The lectin Griffonia simplicifolia I-A4 (GS I-A4) specifically recognizes terminal alpha-linked N-acetylgalactosaminyl groups and is cytotoxic to the human colon cancer cell lines LS174t and SW1116. Chen YF, Boland CR, Kraus ER, Goldstein IJ. Int J Cancer 1994 May 15; 57 (4), pp. 561–7.

Colorectal Carcinoma/Intraoperative Lesion Localization
[^{125}I]-B72.3 Anti-Colorectal Carcinoma Monoclonal Antibody (MAb)

Cellular/Molecular Mechanism of Action: [^{125}I]-B72.3 MAb selectively binds to antigenic complexes expressed by lesions of colorectal carcinoma.
Application: Intraoperative detection of tumor location using a handheld gamma probe.
Route of Administration: [^{125}I]-B72.3 MAb (intravenous).
Examples of Clinical Implementation: Evaluation of a new intraoperative approach to tumor localization using radiolabeled MAb B72.3 has been devised that involves the use of a handheld gamma-detecting probe (GDP). Surgical procedures can be performed between 5 and 35 days postadministration of [^{125}I]-labeled MAb B72.3 IgG preparations. Analysis of resected tumor and normal tissues involves measurement of relative [^{125}I]-labeled MAb B72.3 IgG (e.g., injected dose/gram tissue).
Interpretation and Analysis: Applying a handheld GDP, surgeons intraoperatively can successfully localize lesions 68% of the time (e.g., n = 21/31). Resected tumor radiolocalization indices range from 0.5 to 543 with radiolocalization indices of 3.0 or higher in 71% (e.g., n = 22/31) of the tumor specimens. Sixty-eight percent of carcinoma lesions positively detected intraoperatively with a handheld GDP will also have levels of tumor antigen expression that can be detected with an immunoperoxidase-based assay, while approximately 8% of lesions that cannot be detected intraoperatively are also antigen negative. Alternatively, about 24% of carcinoma lesions cannot be localized intraoperatively based on the use of the GDP, while immunohistopathology analysis reveals positive expression of detectable levels of tumor antigen. The [^{125}I]-labeled MAb B72.3 IgG reagent recognizes all histologic grades of colorectal cancer. In most situations, higher *in vivo* probe ratios and radiolocalization indices can be observed when intraoperative handheld gamma scans are performed 20–35 days following injection of MAb and preparations are successful in detecting colorectal carcinoma lesions that have metastasized to the mesenteric and peri-aortic lymph nodes, liver, lung, and peri-rectal soft tissue. A strong degree of correlation ($p = 0.001$) can be appreciated between the intraoperative detection of tumorous lesions with increased MAb B72.3 localization, and the *in vitro* measurement of cpm/g of tumor tissue compared to normal/healthy tissue samples.

Intraoperative radioimmunolocalization of colorectal carcinoma with a handheld gamma probe and MAb B72.3: Comparison of *in vivo* gamma probe counts with *in vitro* MAb radiolocalization. Tuttle SE, Jewell SD, Mojzisik CM, Hinkle GH, Colcher D, Schlom J, Martin EW. Int J Cancer 1988 Sep 15; 42 (3), pp. 352–8.

Colorectal Carcinoma Cell Adhesion to Endothelium/Intravital Observation of Cancer Cell/Microcirculation Interactions
CalceinAM

Background Information: Organ-specific tumor cell adhesion within the microcirculation of host organs is an important step in the metastatic cascade. Circulating tumor cells have to adhere to the luminal surface of microcirculatory vessels, quickly stabilize their adhesion, and then leave the circulation to avoid toxic effects of hydrodynamic shear forces of circulating blood.
Application: Intravital observation of colon carcinoma cell adhesion within the hepatic microcirculation.
Implementation: CalceinAM is used to label colon carcinoma cell populations (e.g., HT-29 [human] and CC531 [rat]) that are then injected intra-arterially as single-cell suspensions. Intravital fluorescence microscopy is then applied to detect adhesive interactions between circulating tumor cells and endothelial surfaces within the hepatic microcirculation. These interactions are then analyzed regarding their time course and site localization within the vascular tree.
Animal Model: Rats (Sprague-Dawley).
Interpretation and Analysis: Autofluorescence of liver parenchyma is sufficient for distinction of hepatic sinusoids. Intravital microscopy is capable of differentiating early events in adhesion formation within hepatic sinosoids, adhesion stabilization, and extravasation of the tumor cells into the liver parenchyma. Tumor cell adhesion occurs almost exclusively within sinusoidal capillaries; however, the diameter of these vessels is usually larger than that of the tumor cells. Colon carcinoma cells rapidly migrate into the liver parenchyma after successful adhesion within the sinusoids. In contrast to common end point assays of the metastatic cascade, this *in vivo* model allows investigations of metastatic colon carcinoma cell adhesion within the liver microcirculation as specific steps during the development of hematogenous metastasis and their underlying mechanisms.
Instrumentation: Intravital fluorescence microscopy.

An intravital model to monitor steps of metastatic tumor cell adhesion within the hepatic microcirculation. Haier J, Korb T, Hotz B, Spiegel HU, Senninger N. J Gastrointest Surg 2003 May–Jun; 7 (4), pp. 507–14; discussion 514–5.

Esophogeal Squamous Cell Carcinoma/Elevated Epidermal Growth Factor Receptor (EGFR) Expression
Anti-EGFR Coated Supermagnetic Particles

Cellular/Molecular Mechanism of Action: Anti-EGFR monoclonal antibody recognizes and physically binds to membrane-associated EGFR.
Background Information: Epidermal growth factor receptors are overexpressed in conditions of esophageal squamous cell carcinoma.
Application: Enhanced detection of esophageal squamous cell carcinoma employing an endoluminal surface coil.
Route of Administration: Anti-EGFR-coated supermagnetic particles (intravascular).
Semi-Synthetic Methods: Coating superparamagnetite particles with monoclonal antibodies (MAbs) directed against EGFRs.
Animal Model: Rat (athymic bearing TE8 or H69 tumors).
Human Model: Cases of esophageal cancer (n = 30).
Interpretation and Analysis: In terms of depth of cancer invasion, the accuracy rate of magnetic resonance imaging (MRI) using

the endoluminal surface coil is 83%. In conclusion, MRI with an endoluminal surface coil will be a useful examination strategy for esophageal cancer in the future. Anti-EGFR-coated supermagnetic particles possess EGFR-specific MRI contrast detection characteristics *in vivo* in tumor-bearing rats. Immunospecific MRI using magnetite particles coated with MAbs against EGFR seems to be useful in the diagnosis of squamous cell carcinoma of the esophagus.

Instrumentation: Endoluminal 1.5-T serconductive MR system.

What's new in imaging? New magnetic resonance imaging of esophageal cancer using an endoluminal surface coil and antibody-coated magnetite particles. Ozawa S, Imai Y, Suwa T, Kitajima M. Recent Results Cancer Res 2000; 155, pp. 73–87.

Gastric Carcinoma: Metastasis/Retrovirus Delivery
Green Fluorescent Protein (GFP)

Cellular/Molecular Mechanism of Action: Retroviral agents expressing the GFP gene can insert their genome into certain mammalian cell populations. Cells that have been transfected by such retroviral agents express the GFP gene and emit a green color when exposed to certain wavelengths of light.

Application: Visualization of future regional and distant metastases.

Route of Administration: Intraperitoneal (other routes possible).

Implementation: Green fluorescent protein retroviral supernatants are injected intraperitoneally (i.p.) from day 4 to day 10 after implantation of gastric cancer cells. Tumor and metastasis fluorescence are then visualized every other week with the use of fluorescence optics via a laparotomy.

Animal Model: Mouse (intraperitoneally growing human gastric neoplasia).

Interpretation and Analysis: At 2 weeks after retroviral GFP delivery, GFP-expressing tumor cells can be observed in gonadal fat, greater omentum, and intestine, indicating that these primary i.p. growing tumors are efficiently transduced by the GFP gene and could be visualized by its expression. During 2nd and 3rd laparotomies, GFP-expressing tumor cells can be observed spreading to lymph nodes in the mesentery and other regional sites. At the 4th laparotomy, widespread tumor growth is visualized by GFP expression, including liver metastasis. Normal tissues are rarely transduced by the GFP retrovirus. Thus, reporter gene transduction of the primary tumor can enable detection of its subsequent metastasis. This gene therapy model could be applied to primary tumors before resection or other treatment to have a fluorescent early detection system for metastasis and recurrence.

In vivo tumor delivery of the green fluorescent protein gene to report future occurrence of metastasis. Hasegawa S, Yang M, Chishima T, Miyagi Y, Shimada H, Moossa AR, Hoffman RM. Cancer Gene Ther 2000 Oct; 7 (10), pp. 1336–40.

Gastrinoma: Zollinger-Ellison Syndrome
Secretin and [Ca^{2+}]

Cellular/Molecular Mechanism of Action: Induces gastrin secretion.

Application: To evaluate criteria of positivity for and usefulness of both the secretin and calcium gastrin-provocative tests in patients with the Zollinger-Ellison syndrome. Design: Prospective trial in consecutive patients.

Route of Administration: Kabi-secretin (intravenous bolus); calcium gluconate (10% intravenous).

Dosage: Kabi-secretin (2 U/kg bolus); calcium gluconate 10% (54 mg/kg/hr as 5 mg/kg/hr of calcium continuously infused for 3 hours).

Considerations: The distinct advantages (short test period, low patient morbidity, and relatively great potency) of the calcium + secretin test make it an attractive alternative to other previously described provocative tests for the diagnosis of gastrinoma. There are usually no false-positive or false-negative tests with the calcium + secretin.

Implementation: Evaluation of suspected cases of gastrinoma as a function of response to Kabi-secretin and calcium gluconate (10%) (54 mg/kg/hr [5 mg/kg/hr of calcium]) given by continuous intravenous infusion for 3 hours. Serum gastrin is measured at −15 and −1 minutes before, and 2, 5, 10, 15, 20, and 30 minutes after secretin, or every 30 minutes for 3 hours during calcium infusion. Serum calcium and serum gastrin are measured simultaneously during calcium infusion. Criterion for diagnosis is either a 50% increase or a 200 pg/ml increase above the basal gastrin level.

Human Model: Cases suspected of having Zollinger-Ellison syndrome (n = 80).

Interpretation and Analysis: There is no significant difference in the responses of cases with different extents or locations of the tumor, presence or absence of multiple endocrine neoplasia, type-I, or with fasting gastrin $<$ or $>$ 1,000 pg/mL. In cases with fasting gastrin of $<$ 1,000 pg/mL, sensitivity of the secretin test using the criterion of an increase in gastrin of at least 110 pg/mL is 93% (CI, 76–99%) and for an increase of 200 pg/mL it is 85% (CI, 66–96%) ($p > 0.05$). With the calcium infusion test, the sensitivity using the criterion of an increase of 395 pg/mL is 43% (CI, 23–66%) and for an increase of 50% is 74% (CI, 52–90%) ($p < 0.01$). The calcium infusion test is positive in 33% of cases with a negative secretin test. Applying the secretin test, 75% of cases have a positive response by 5 minutes, 95% by 10 minutes, 100% by 15 minutes, and 6% only at 2 minutes. Utilizing calcium infusions, cases have positive responses at 120 to 180 minutes. The secretin test is preferred over the calcium test because of its greater sensitivity and simplicity. The recommended criteria are a 200 pg/mL increase for the secretin test and a 395 pg/mL increase for the calcium test. The calcium test should be reserved for patients having a negative secretin test, gastric acid hypersecretion, and a strong clinical suspicion of the Zollinger-Ellison syndrome.

Instrumentation: Laboratory facilities and instrumentation for immunodetection methodologies (RIA, ELISA).

Secretin and calcium provocative tests in the Zollinger-Ellison syndrome. A prospective study. Frucht H, Howard JM, Slaff JI, Wank SA, McCarthy DM, Maton PN, Vinayek R, Gardner JD, Jensen RT. Ann Intern Med 1989 Nov 1; 111 (9), pp. 713–22.

Gastrinoma: Zollinger-Ellison Syndrome (Persistent)
Methylene Blue

Route of Administration: Intra-arterial.

Considerations: Localizing studies can include ultrasonography, computed tomography, magnetic resonance imaging, duodenal endoscopy, endoscopic ultrasonography, and intraoperative endoscopic transillumination of the duodenum (all negative postop in this case report).

Implementation: Evaluation of Zollinger-Ellison syndrome lesions using methylene blue injection is used to identify a 6-mm gastrinoma in the duodenum that has been locally excised.

Human Model: Case of Zollinger-Ellison syndrome (persistent postsurgical excision of a 4-cm duodenal gastrinoma; 40 years old).

Interpretation and Analysis: Methylene blue injection facilitated the identification of an excisable 6-mm gastrinoma in the duodenum.

Selective intra-arterial methylene blue injection: A novel method of localizing gastrinoma. Ko TC, Flisak M, Prinz RA. Gastroenterology 1992 Mar; 102 (3), pp. 1062–4.

Gastrinoma/[Insulinoma]/[Intestinal Carcinoid Syndrome]/Zollinger-Ellison Syndrome
Calcium/Pentagastrin/Secretin

Background Information: Calcium infusion has been advocated as a provocative test for the diagnosis of some endocrine tumors of the pancreas and gastrointestinal tract (gastrinoma, insulinoma, intestinal carcinoids).
Application: The calcium infusion test is recommended in Zollinger-Ellison syndrome when the results of secretin stimulation test are equivocal.
Route of Administration: Intravenous injection.
Interpretation and Analysis: The release of gastrin from gastrinoma tissue is very sensitive to alterations in the serum calcium level. The calcium provocative test in the detection of insulinoma and carcinoid tumors is less reliable than other safer and simpler procedures. Intravenous injection of calcium followed by pentagastrin stimulates the release of somatostatin in cases with somatostatinoma and offers a reliable means for establishing the diagnosis of this tumor type. Calcium administration has not proven to be useful in the diagnosis of other endocrine tumors of the digestive system.

Use of calcium provocative test in the diagnosis of gastroenteropancreatic endocrine tumors. Vezzadini C, Poggioli R, Casoni I, Vezzadini P. Panminerva Med 1996 Dec; 38 (4), pp. 255–8.

Intestinal and Colon Microcarcinomas/Colorectal Cancer/Gastric Cancer
[Indocyanine Green (ICG)]-Anti-MUC1 Mucin

Cellular/Molecular Mechanism of Action: Monoclonal antibody (IgG) with selective binding properties directed at MUC1 mucin recognizes and physically binds to the corresponding complexes expressed on the exterior surface membrane of certain neoplastic cell types.
Background Information: Videoendoscopy has not significantly advanced diagnostic accuracy beyond that attainable by conventional fiberscopy, with respect to microcarcinomas of the digestive tract. Theoretically, it is possible to selectively label such lesions with agents that can be detected by videoendoscope. Digital processing of the images could facilitate more accurate endoscopic diagnosis of microcarcinomas.
Application: [Indocyanine green]-anti-MUC1 mucin can be utilized to detect and characterize conditions of gastric and colorectal cancer lesions when used in combination with direct visualization using videoendoscopy methodologies.
Route of Administration: [Indocyanine green]-anti-MUC1 mucin (intravenous).
Implementation: Evaluation of the ability of [ICG]-anti-MUC1 mucin to selectively recognize and bind *in vivo* to gastric and colorectal cancer cell types. Validation of findings established by immunohistochemistry analysis using labeled secondary antibody.
Animal Model: Murine (nude mouse with human gastric or colorectal cancer cell types).
Interpretation and Analysis: [Indocyanine green]-anti-MUC1 mucin preferentially accumulates within gastric and colorectal cancer explants in nude mice that can be appreciated on gross examination and by histochemical analysis. Therefore, antibody labeled with an ICG derivative may be a clinically useful strategy for detecting gastrointestinal microcarcinoma by videoendoscopy.
Instrumentation: Videoendoscopy.

Vital immunostaining of human gastric and colorectal cancers grafted into nude mice: A preclinical assessment of a potential adjunct to videoendoscopy. Kusaka Y, Ito S, Muguruma N, Tadatsu M, Bando T, Ii K, Irimura T, Shibamura S. J Gastroenterol 2000; 35 (10), pp. 748–52.

Intestinal/Colon Carcinoma/Optical Lesion Imaging
Indotricarbocyanine (ITCC)/ITCC-Transferrin/ ITCC-Human Serum Albumin

Cellular/Molecular Mechanism of Action: Indotricarbocyanine is a dye that can serve as a detectable marker molecule in biological systems.
Background Information: Macromolecules accumulate in solid tumors and can thus be used as carriers for the delivery of attached contrast agents to tumors.
Application: Indotricarbocyanine can be applied as a contrast agents for optical imaging of neoplastic lesions.
Route of Administration: Intravascular.
Semi-Synthetic Methods: Production of serum protein-dye conjugates consisting of transferrin (Tf) or human serum albumin (HSA) covalently linked to ITCC derivative.
Implementation: Evaluation of the ability of semi-synthetic ITCC-HSA and ITCC-Tf conjugates pertaining to (i) photophysical properties; (ii) ability to bind *in vitro* to tumor cells; and (iii) *in vivo* for their potential to detect/characterize experimental tumors.
Model: Human HT29 colon cancer cell types propagated *in vitro* in a tissue culture environment and HT29 tumor-bearing nude mice.
Interpretation and Analysis: In contrast to ITTC-HSA, ITCC-Tf displays *in vitro* receptor-mediated uptake by HT29 human colon cancer cells. After intravenous injection, ITCC-HAS and ITCC-Tf both induce increased *in vivo* fluorescence contrast of tumors. After 24 hours the contrast between tumor and normal tissue is significantly higher for ITCC-Tf than for HAS-ITCC-HSA. Dye-induced fluorescence can be found to be predominantly located in perinecrotic areas of tumor lesions. Furthermore, ITCC-Tf produces fluorescence of viable tumor cells, whereas ITCC-HAS fluorescence can be detected along connective tissue. Therefore, ITCC-labeled Tf and HSA can serve as macromolecular contrast agents for the optical imaging of tumors, with ITCC-Tf showing higher efficiency.

Macromolecular contrast agents for optical imaging of tumors: Comparison of indotricarbocyanine-labeled human serum albumin and transferrin. Becker A, Riefke B, Ebert B, Sukowski U, Rinneberg H, Semmler W, Licha K. Photochem Photobiol 2000 Aug; 72 (2), pp. 234–41.

Oral Cancer Lesions/Differentiation: Premalignant vs Malignant Lesions
5-Aminolevulinic Acid (5-ALA)-Induced Protoporphyrin IX (PPIX) Fluorescence

Cellular/Molecular Mechanism of Action: 5-aminolevulinic acid is capable of promoting fluorescence from PPIX compounds.
Background Information: 5-aminolevulinic acid induces fluorescence of PPIX that provides a sensitivity level of 95 to 100% for the diagnosis of oral cancer with a corresponding specificity of only approximately 50–60%.
Application: Differentiation of premalignant from malignant forms of oral cancer applying PPIX fluorescence endoscopy and fluorescence image quantification.

Route of Administration: Topical.
Implementation: Characterization of oral premalignant and malignant lesions applying PPIX fluorescence endoscopy and fluorescence image quantification. To improve diagnostic specificity, 5-ALA mediated digitized fluorescence endoscopic imaging systems have been designed that enable on-line image acquisition, analysis, and fluorescence quantification for early detection of oral cavity neoplasms.

Human Model: Cases of suspected premalignant and malignant lesions of the oral cavity (e.g., n = 16).
Interpretation and Analysis: Head and neck clinical trials have shown that the red-to-blue intensity ratio of malignant tissue is larger than that of benign tissue. By applying the intensity ratio as a diagnostic algorithm, both high specificity and sensitivity can be achieved for discriminating malignant tissue from benign tissue, and the capability of classifying different histopathological stages of oral lesions has also been demonstrated. Red fluorescence intensity distribution in lesion areas could also be obtained to better understand PPIX tissue accumulations. Our initial results indicate that the digitized endoscopic imaging system combined with the fluorescence image quantification method and the ratio diagnostic algorithm has the potential to significantly improve the non-invasive *in vivo* diagnosis of early oral neoplasms.

Detection of neoplasms in the oral cavity by digitized endoscopic imaging of 5-aminolevulinic acid-induced protoporphyrin IX fluorescence. Zheng W, Soo KC, Sivanandan R, Olivo M. Int J Oncol 2002 Oct; 21 (4), pp. 763–8.

Oral Lesions/Differentiation: Oral Premalignant vs Malignant Squamous Cell Carcinoma
5-Aminolevulinic Acid-Induced Protoporphyrin IX (PPIX) Fluorescence

Background Information: Studies of 5-aminolevulinic acid-induced PPIX fluorescence have shown a sensitivity of 95 to 100% for oral cancer diagnosis, but the specificity is only about 50 to 60%.
Application: Quantifying PPIX fluorescence imaging for specific diagnostic detection of early oral lesions (differentiation of premalignant from malignant disease states).
Implementation: Detection and characterization of suspected premalignant or malignant oral cavity lesions utilizing quantifying PPIX fluorescence endoscopic imaging modalities. Biopsy samples are also collected from tissue sites imaged for evaluation using histological analysis. The red-to-blue and red-to-green intensity ratios are then calculated from fluorescent images for correlation with histology analysis.

Human Model: Cases with known or suspected premalignant or malignant oral cavity lesion (e.g., n = 28 and n = 70 biopsy specimens).
Interpretation and Analysis: Suspicious lesions display bright reddish fluorescence, while normal mucosal tissues exhibit blue color background in the fluorescence images. The red-to-blue and red-to-green intensity ratios of malignant tissues are larger than those of benign tissues. Combining the 2 ratio diagnostic algorithms yields a sensitivity and specificity of 95% and 97%, respectively, exceeding each diagnostic algorithm alone for discriminating malignant tissue from benign tissue. Quantifying PPIX fluorescence endoscopic images combined with ratio diagnostic algorithms has the potential to significantly improve the *in vivo* non-invasive diagnosis of oral cavity lesions.
Instrumentation: Fluorescence endoscopy.

Detection of squamous cell carcinomas and pre-cancerous lesions in the oral cavity by quantification of 5-aminolevulinic acid induced fluorescence endoscopic images. Zheng W, Soo KC, Sivanandan R, Olivo M. Lasers Surg Med 2002; 31 (3), pp. 151–7.

Pancreas: Insulin (Islet Cell) Adenoma
Calcium

Application: Diagnosis of insulin-secreting tumors, including islet cell adenoma, that are undetectable during the course of preoperative morphologic (imaging) modalities.
Route of Administration: Calcium test (selective intra-arterial catheterization).
Dosage: Calcium gluconate (4 mg/kg/hour) is infused over a 2-hour period of time.
Considerations: Calcium ion *in vitro* plays a fundamental role in regulating insulin secretion but the influence of calcium excess on insulin release *in vivo* has not been clearly defined. The described test is not of diagnostic value for the stated purpose.
Implementation: Evaluate the efficacy of the intra-arterial calcium test for the purpose of localizing sources of hyperinsulinism that remain undetectable at preoperative morphologic studies (e.g., ultrasound, computed tomography, magnetic resonance imaging, endoscopic US, abdominal arteriography). The calcium test is performed, whereby insulin concentrations are measured in hepatic venous blood after selective intra-arterial calcium stimulation.

Human Model: Cases of clinically proven endogenous hyperinsulinism due to tumorous insulin production (e.g., n = 24). Of these cases, approximately 30% (n = 7/24) will have negative morphologic findings (n = 5/7 females, n = 2/7 males; age range, 30–66 years; mean age, 47 years).
Interpretation and Analysis: Approximately 30% of affected cases will have negative results from morphological analyses (e.g., n = 7/24). Surgical intervention may lead to the detection of solitary insulinomas (e.g., n = 6 with a mean diameter, 0.73 cm) and nodular hyperplasia (e.g., n = 1). Calcium tests allow accurate localization of the pathologic source of insulin secretion (e.g., n = 7/7). In less than 50% of cases, results of arterial calcium stimulation with hepatic venous sampling (ASVS) may affect intraoperative management (e.g., n = 3/7). An increase in insulin concentration after stimulation in the hepatic artery is not observed, making hepatic metastases unlikely. Arterial calcium stimulation with hepatic venous sampling, which is procedurally simpler than trans-hepatic pancreatic venous sampling, is effective for localizing sources of hyperinsulinism not detected with preoperative morphologic studies.

Other clinical trials have reported mean calcium plasma levels can increase from 9.6 ± 0.4 to 11.6 ± 0.8 mg/100 ml. During calcium infusion, blood glucose and plasma insulin concentrations can remain unchanged. Observations noted in these case-based studies suggest that calcium fails to stimulate basal insulin secretion even in cases of organic hyperinsulinism, and that calcium infusion is not helpful as a provocative test in the diagnosis of insulinoma.

Insulinoma and islet cell hyperplasia: Value of the calcium intra-arterial stimulation test when findings of other preoperative studies are negative. Pereira PL, Roche AJ, Maier GW, Huppert PE, Dammann F, Farnsworth CT, Duda SH, Claussen CD. Radiology 1998 Mar; 206 (3), pp. 703–9.

Pancreatic Insulin (Islet Cell) Adenoma/ [Lack of Diagnostic Efficacy]
Calcium Gluconate

Cellular/Molecular Mechanism of Action: Calcium gluconate *in vivo* does not promote the release of insulin from insulinoma lesions.

Background Information: Calcium ion *in vitro* plays a fundamental role in regulating insulin secretion but the influence of calcium excess on insulin release *in vivo* has not been clearly defined. The described test is not of diagnostic value for the stated purpose.
Application: Calcium gluconate *in vitro* promotes the release of insulin but *in vivo* it is ineffective in this capacity and is therefore of no diagnostic benefit in the detection and diagnosis of insulin-secreting tumors.
Route of Administration: Calcium gluconate (intravenous).
Dosage: Calcium gluconate (4 mg/kg/hr infused over a period of 2 hours).
Interpretation and Analysis: Mean calcium plasma levels increase from 9.6 ± 0.4 to 11.6 ± 0.8 mg/100 ml. During calcium infusion, blood glucose and plasma insulin concentrations remain unchanged. These observations suggest that calcium fails to stimulate basal insulin secretion even in cases of organic hyperinsulinism. They show that calcium infusion is not helpful as a provocative test in the diagnosis of insulinoma.

Lack of effect of calcium *infusion on blood glucose and plasma insulin levels in patients with insulinoma.* De Palo C, Sicolo N, Vettor R, Federspil G. J Clin Endocrinol Metab 1981 Apr; 52 (4), pp. 804–6.

Pancreatic Tumors: Vasoactive Intestinal Peptide (VIP) Secreting/VIPoma Syndrome: VIP/Pancreatic Peptide/Neurotensin/Enhanced Immunohistopathology Accuracy
Calcium, Pentagastrin

Diagnostic Application: Detection of patients suffering from pancreatic tumors consistent with VIPoma syndrome.
Background Information: Pancreatic endocrine tumors (PETs) may secrete a variety of peptide hormones, either alone or in combination, and intravenously administered provocative agents have been used to stimulate hormone release to aid in the diagnosis and localization of lesions in suspected cases.
Route of Administration: Intravenous injection.
Dosage: Pentagastrin (0.5 mg/kg/5 sec or 0.5 mg/kg/min); rapid calcium infusion (2 mg/kg/min).
Semi-Synthetic Methods: Plasma hormone radioimmunoassays and immunohistochemical studies are performed for a panel of peptide hormones, including VIP, neurotensin, and pancreatic polypeptide (PP). Acid alcohol extracts of tumor specimens are analyzed for the peptide hormones as well.
Implementation: Before surgical intervention, 4 different provocative test regimens can be administered intravenously after an overnight fast: (i) pentagastrin (0.5 mg/kg/5 sec); (ii) rapid calcium infusion (2 mg/kg/min); (iii) a combination of calcium (2 mg/kg/min) followed by pentagastrin (0.5 μg/kg/min); and (iv) secretin (2 clinical units/kg bolus). Blood samples are collected before each test and 1, 2, 3, 5, and 10 minutes after infusions.

Case Example: Detailed biochemical investigations and provocative testing in a 26-year-old man with a 5-cm VIP-secreting tumor located at the head of the pancreas.
Interpretation and Analysis: Increases in the production/release of vasoactive intestinal peptide, neurotensin, and PP can be detected in both serum samples and within tumor biopsies by immunohistochemical analysis. Coexpression of VIP and neurotensin can be seen immunohistochemically within some individual tumor cells. Provocative testing results in maximal stimulation of VIP and neurotensin secretion with pentagastrin administration, which produces increases in plasma levels of VIP and neurotensin over basal levels of 81% and 87%, respectively. After surgery, plasma levels of VIP, neurotensin, and PP are undetectable before and after administration of pentagastrin. Such observations emphasize the importance of comprehensive biochemical evaluation in cases of VIPoma syndrome to detect production of a range of peptide hormones. Administration of intravenous pentagastrin appears to stimulate release of VIP and neurotensin and should be evaluated further as a provocative agent for the diagnosis and follow-up of cases with these tumors.

Stimulation of vasoactive intestinal peptide and neurotensin secretion by pentagastrin in a patient with VIPoma *syndrome.* Brunt LM, Mazoujian G, O'Dorisio TM, Wells SA Jr. Surgery 1994 Mar; 115 (3), pp. 362–9.

ENDOCRINE

Adrenal Incidentaloma/Cushing's Syndrome: Preclinical/21-Hydroxylase and 11β-Hydroxylase Biochemical Activity/Tetrahydrocortisol, Tetrahydrocortisone, Tetrahydroaldosterone/ Potential to Distinguish between Non-Functioning Adrenocortical Adenoma (NFI) and Preclinical Cushing's Syndrome (PCS)/Hepatic Cortisol 5β-Reduction/Cytochrome 450 CYP21B Gene Expression
1-24 Adenocorticotripic Hormone (1-24ACTH) Stimulation Test

Background Information: Adrenal incidentalomas are mostly NFIs. However, in 5 to 12% of patients, a PCS is present with autonomous tumor cortisol production. Urinary free cortisol excretion is not sensitive enough to detect subclinical conditions of hypercortisolism. A limited amount of information is known about daily aldosterone production.
Route of Administration: 1-24ACTH stimulation test (intravenous).
Dosage: 1-24ACTH stimulation test (250 μg).
Implementation: Delineation of the relative sensitivity of tetrahydrocortisol, tetrahydrocortisone, and urinary free cortisone together with urinary free cortisol concentration as markers for characterizing increases in daily cortisol production recognized in conditions of adrenal incidentalomas. Note: Urinary free cortisol excretion is not sensitive enough to determine subclinical hypercortisolism. Complementary analyses involve the measurement of excreted aldosterone metabolites. Determination of the types of steroidogenic enzymes that have altered activities is done with the aid of the 1-24ACTH stimulation test, combined with the determination of multiple steroids. In situations where it is assumed that a 21-hydroxylase deficiency, or even an 11β-hydroxylase deficiency, may be involved in adrenal tumourigenesis, the prevalence of germline CYP21B and CYP11B1 mutations can be studied in the same cases that have been evaluated applying the ACTH stimulation test. Note: The ACTH stimulation test can detect increased responses in the form of precursor production within the glucocorticoid and mineralocorticoid pathway.

Human Model: Cases of adrenal incidentalomas (n = 35; n = 29 NFI; n = 6 PCS; n = 35 healthy controls). Performance of the 1-24ACTH stimulation test (n = 25 cases; n = 18 healthy controls).
Interpretation and Analysis: Glucocorticoid metabolites are within the normal range in a small percentage of NFI cases (e.g., n = 3/29). As a group, cases have subtle alterations in cortisol metabolism. Tetrahydrocortisol excretion is elevated in NFI and PCS compared to normal subjects (2.1 ± 0.2 and 2.5 ± 0.5 vs 1.5 ± 0.1 mg/24 h; $p < 0.05$). Accordingly, a 2-fold elevation of the tetrahydrocortisol/free cortisol ratio indicates increases in 5β-reduction

of cortisol in the liver. Tetrahydroaldosterone and aldosterone-18-glucuronide excretions are not different relative to controls. In incidentaloma cases, an increased response to ACTH can be appreciated as a function of changes in the concentrations of 17-hydroxyprogesterone (595 ± 133 vs 160 ± 25 ng/dL), 21-desoxycortisol (105 ± 25 vs 29 ± 9 ng/dL), and 11-desoxycortisol (401 ± 40 vs 293 ± 17 ng/dL).

In a small percentage of cases (n = 1/25 or 4%), a heterozygous deletion in exon 3 of the CYP21B gene can be detected. Therefore, even the excretion of the main glucocorticoid metabolites appears not to be a marker that is sensitive enough to distinguish between NFI and PCS. However, it is also possible that alterations in cortisol secretion are qualitative rather than quantitative. Zona glomerulosa function is not influenced. The elevation of 21-desoxycortisol represents evidence that argues against an impairment of 11β-hydroxylase and is instead better explained by decreased 21-hydroxylase activity. The remainder of cases evaluated will have wild-type sequences of both genes. In conclusion, neither 21-hydroxylase deficiency nor 11β-hydroxylase deficiency are predisposing factors for adrenal tumourigenesis.

Metabolism of glucocorticoids and mineralocorticoids in patients with adrenal incidentalomas. Maser-Gluth C, Reincke M, Allolio B, Schulze E. Eur J Clin Invest 2000 Dec; 30 Suppl 3, pp. 83–6.

Aldosterone-Producing Adenoma (APA)/Adrenal Mineral Corticoid Function/Dopamine Excretion: Urinary
Metoclopramide/High-Salt Intake/Low-Salt Intake

Physiological Mechanism of Action: Metoclopramide enhances cholinergic activity at muscarinic synapses and suppresses/antagonizes central nervous system (CNS) dopaminergic activity. Normally, dopaminergic input inhibits aldosterone secretion.
Background Information: Impairment of renal dopamine excretion on high-salt diet (HS) may account for increased blood pressure (BP) in hypertensive subjects. Whether such impairment of dopaminergic activity exists in the adrenal gland is unknown.
Route of Administration: Metoclopramide (intravenous).
Dosage: Metoclopramide (10 mg).
Implementation: Delineate the degrees of dopaminergic inhibition of aldosterone secretion in conditions of an APA. More specifically, evaluate APA conditions on diets containing different levels of salt at the end of which a 24-hour ambulatory BP recording is obtained in concert with measurements of daily urine catecholamine and the performance of a metoclopramide test.

Human Model: Cases of unilateral APA (n = 15) fed a low-salt diet (LS) for 1 week, followed by another week on a high-salt diet. At the end of each diet period, 24-hour ambulatory BP recording, daily urine catecholamine measurement, and a metoclopramide test are performed.
Interpretation and Analysis: A high-salt diet increases both daytime and nighttime blood pressure (BP at $p < 0.001$), and urine dopamine excretion ($p < 0.01$). Intravenous metoclopramide injection increases plasma aldosterone concentrations (PAC) on both diets. The area-under-the-curve for PAC between LS and HS is not different, but the area-under-the-curve for PAC increment is greater on HS ($p < 0.05$). Less than half of affected cases with increment areas on HS greater than those on LS by 50% are termed "suppressible" (n = 6/15), and the remainder are referred to as "non-suppressible." On a high-salt diet, so-called "suppressible" cases have greater urine dopamine and less urine norepinephrine excretions ($p < 0.05$). The "non-suppressible" cases have a greater percentage increase of nighttime BP by HS than the suppressible (for systolic BP, 13.1% vs 4.5%, $p < 0.01$; for mean BP, 12.0% vs 5.1%, $p < 0.01$, respectively), but no difference in daytime blood pressure.

Two subtypes of APA can be defined according to their responses to metoclopramide during salt manipulation. On a high-salt diet, the non-suppressible subjects, with less dopaminergic inhibition of aldosterone secretion, have less urinary dopamine excretion and greater BP elevation. The renal and adrenal dopaminergic activities are regulated in a parallel fashion.

Dopaminergic modulation of aldosterone secretions on changes of sodium intake in aldosterone-producing adenoma. Wu KD, Chen YM, Chu TS, Chueh SC, Tsai GC, Tseng YZ, Hsieh BS. Am J Hypertens 2002 Jul; 15 (7 Pt 1), pp. 609–14.

Multiple Endocrine-Related Neoplasias/Multiple Endocrine Neoplasia Type 2A Syndrome (MEN 2A)/Multiple Endocrine Neoplasia Type 2B (MEN 2B)/Familial Medullary Thyroid Carcinoma (FMTC)
Pentagastrin and Calcium Chloride/[Pentagastrin and Calcium Gluconate]

Cellular/Molecular Mechanism of Action: Combined influence of pentagastrin and calcium chloride ($CaCl_2$) promotes the release of calcitonin from certain types of endocrine neoplasias.
Application: Characterization and detection of MEN 2A. The pentagastrin provocative test and biochemical screening can be applied to rule out either hyperparathyroidism or pheochromocytoma.

Medullary thyroid carcinoma (MTC) is a malignancy of the thyroid C-cells that comprises 5–10% of all thyroid cancers. It occurs in both sporadic and familial forms, the latter making up 25% of all MTCs and being comprised of 3 distinct syndromes that have been recognized, including MEN 2A, MEN 2B, and FMTC. To date, screening for MTC has been performed using the pentagastrin stimulation test, which is a provocative test for calcitonin release.
Route of Administration: Pentagastrin (intravenous bolus), calcium chloride (intravenous over 5 minutes).
Dosage: Pentagastrin (0.5 μg/kg); calcium infusions (2 mg/kg).
Considerations: RET proto-oncogene analysis can be carried out by automatic DNA sequencing in concert with adequate digestion of polymerase chain reaction (PCR) amplified products for exons 10 and 11. Two distinct mutations in the RET proto-oncogene have been identified. A T >A transition at position 1783 (codon 618) in exon 10 has been detected in 1 family, and a G >A replacement at position 1832 (codon 634) in exon 11 in others. Germline mutations in the RET proto-oncogene have been identified in families manifesting these syndromes and genetic screening of individuals at risk of 1 of these syndromes has become integral to their clinical management. The majority of the mutations associated with MEN 2A and FMTC are tightly clustered in a cysteine-rich region of the RET receptor. A single mutation associated with MEN 2B is in the tyrosine kinase domain of the RET receptor.
Implementation: Evaluation of MEN 2A as a function of calcitonin release in response to pentagastrin and calcium chloride administration.

Human Model: Cases (n = 44) related to 3 individuals with proven MEN 2A and negative reference controls.
Interpretation and Analysis: Peak calcitonin (CT) levels are usually reached within 2 to 5 minutes after administration of provocative stimulus. Normal subjects have no significant difference in the mean basal CT levels between males (54.8 ± 21.7 pg/ml) and females (56.5 ± 34.8 pg/ml). Mean peak response values for males

is 146.3 ± 120.6 pg/ml, which is significantly different from the mean value of females, namely 71.6 ± 39.0 pg/ml. No significant correlations exists between the basal CT level, peak CT response, and age.

Calcium infusions (2 mg/kg/5 min) in normal individuals (e.g., n = 18 males; n = 37 females) yields a significantly greater secretory response than does pentagastrin (0.5 μg/kg bolus). In cases with medullary thyroid carcinoma (e.g., n = 12), pentagastrin is a better secretagogue than calcium ($p < 0.001$). Therefore, some recommendations have suggested routine measurement of plasma silica-extractable calcitonin and pentagastrin injection as the provocative test of choice for the detection and management of MTC. The short calcium-infusion test is a good alternative.

In cases from families with a history of MEN 2A, approximately 20% display exaggerated calcitonin responses to combined pentagastrin/$CaCl_2$ sufficient to warrant thyroidectomy. Histological examination can confirm the presence of C-cell hyperplasia (CCH) (n = 1/9) or MTC (n = 8/9). A relatively high percentage of cases (33%) will have high basal plasma calcitonin. Postoperatively, basal plasma calcitonin levels decline and response to pentagastrin/$CaCl_2$ produces a flat baseline concentration profile. Screening of cases with histological proof of MTC or CCH for a genetic linkage to the gene for MEN 2A using an MCK2 probe usually shows some correlation.

Several families (n = 10) FMTC due to V804M mutation have been reported in the literature. Some reports have also described kindreds with not only heterozygous but also homozygous members with the V804M mutation. In gene carriers with the V804M mutation (e.g., n = 4 homozygous; n = 22 heterozygous) the pentagastrin stimulation test result is within normal range for the vast majority of heterozygous gene carriers (thyroidectomy not indicated). Therefore, in some cases, the V804M mutation in heterozygous cases seems not to be enough to express the full disease.

In non-gene carriers, false-positive results for basal calcitonin (6.6%) and for the pentagastrin provocative test (15.4%) can be observed. Based on these observations, the specificity of basal and pentagastrin-stimulated calcitonin is rather limited and RET proto-oncogene analysis is considered by many investigators and clinicians to be the 1st-line screening procedure of choice for the identification of gene carriers.

Experience with provocative and genetic tests strongly supports the concept of the indolent behavior of V804M RET proto-oncogene mutation. Counseling for preventive total thyroidectomy, the specific mutation of RET proto-oncogene, and also the natural history of the disease within a particular family should be considered.

Instrumentation: Scintilation counter and minor laboratory instrumentation necessary for the utilization of a commercial radioimmunoassay for the measurement of serum calcitonin. Radioimmunoassays for human calcitonin in whole plasma are limited in sensitivity and specificity; basal values of calcitonin are often undetectable in normal plasma, and non-specific increases are occasionally found in seemingly healthy persons. Such problems can be avoided by applying a silica-cartridge extraction-concentration technique for calcitonin assay, and the effectiveness of 2 calcitonin stimulation tests in healthy volunteers and patients with medullary thyroid carcinoma is then compared. The radioimmunoassay can be improved by using a new antiserum and a sequential incubation procedure that reduces the previously used sample-volume requirement and incubation period substantially. The method can be used to measure mean basal plasma levels of calcitonin (± SD) in 45 normal men (8.2 ± 5 pg/ml) and 47 normal women (4.8 ± 4 pg/ml) ($p < 0.001$).

Pars Intermedia Pituitary Adenoma (PIPA)/ Cushing's Syndrome

Dexamethasone Suppression/Thyrotropin-Releasing Hormone (TRH)

Cellular/Molecular Mechanism of Action: Dexamethasone suppresses hypothalamic corticotropin-releasing hormone (CRH) synthesis/release, which in turn decreases adenocorticotripic hormone (ACTH) synthesis.

Application: Detection and characterization of horses affected by PIPA. To evaluate results of a combined dexamethasone suppression/TRH stimulation test in horses suspected clinically of having a PIPA.

Route of Administration: Dexamethasone (intravenous); TRH (intravenous).

Dosage: Dexamethasone (40 μg/kg [18 μg/lb] of body weight); TRH (1.1 mg).

Implementation: Evaluation of changes in cortisol concentrations in conditions of PIPA induced by dexamethasone administration. Blood samples are collected at baseline prior to dexamethasone suppression and then at 3 hours postinjection. A dose of TRH is then administered, followed by the collection of serial blood samples at 15, 30, 45, 60, and 90 minutes and 21 hours after TRH administration (24 hours after dexamethasone injection). Cortisol concentrations are measured in all blood samples collected for analysis.

Animal Model: Equine (n = 5 horses suspected of having PIPA; n = 7 healthy adult horses).

Interpretation and Analysis: Baseline cortisol concentrations are significantly lower in horses suspected of having a PIPA compared to healthy horses. Cortisol concentrations are suppressed by dexamethasone in both groups; however, after TRH administration, cortisol concentrations returned to baseline values in horses suspected of having a PIPA, but not in healthy horses. Concentrations are still less than baseline values 24 hours after dexamethasone administration in healthy horses.

The combined dexamethasone suppression/TRH stimulation test may be a useful diagnostic test in horses suspected of having a PIPA. For clinical application, collection of a blood sample 30 minutes after TRH administration is recommended.

Results of a combined dexamethasone suppression/thyrotropin-releasing hormone stimulation test in healthy horses and horses suspected to have a pars intermedia pituitary adenoma. Eiler H, Oliver JW, Andrews FM, Fecteau KA, Green EM, McCracken M. J Am Vet Med Assoc 1997 Jul 1; 211 (1), pp. 79–81.

Pheochromocytoma

Glucagon

Background Information: Pheochromocytoma cases frequently have elevated plasma concentrations of adrenaline and noradrenaline in addition to increases in urinary vanillylmandelic acid, metanephrine, and/or normetanephrine.

Glucagon-receptor messenger RNA (mRNA) can be detected by reverse transcription-polymerase chain reaction in human pheochromocytomas, but not in normal adrenal medullas. Quantitative autoradiography can detect the presence of abundant [^{125}I]-$Thyr_{10}$ glucagon binding sites in pheochromocytomas, which are recognized with cold glucagon and the glucagon receptor antagonist $Des\text{-}His_1[Glu_9]$glucagon amide (GR-A). The adrenal medulla is weakly labeled, and the binding is not displaced by GR-A. Glucagon enhances epinephrine and norepinephrine release by pheochromocytoma slices, minimal and maximal effective concentrations being

10^{-8} M and 10^{-6} M. Adrenomedullary slices have a weak catecholamine response only to 10^{-5} M glucagon. GR-A abolishes the secretory response to glucagon of pheochromocytomas, but not of adrenal medullas. Collectively, these observations indicate that (human) pheochromocytomas, but not adrenal medulla, express glucagon receptors and possess a marked secretory response to glucagon, thereby providing the rationale to explain the specificity of the glucagon provocative test in the diagnosis of pheochromocytoma.

Application #1: Study of pig adrenal medulla or human pheochromocytoma to determine the influence of glucagon infusion. In the 1st experiment a continuous flow incubation system has been developed in which the secretory response to these drugs is characterized by a serial fluorimetric assay of catecholamines in the effluent medium.

Application #2: Characterize the *in vivo* effect of glucagon on blood pressure and urinary catecholamine levels of healthy control subjects and of patients suffering from essential hypertension, thyroid disease, diabetes mellitus, and acromegaly.

Route of Administration: Pheochromocytoma and chromaffin granules of the pig adrenal medulla in experimental *ex vivo*/*in vitro* scenarios.

Dosage: Glucagon (10^{-4}) infusion for 10 minutes following 2 hours of preincubation.

Considerations: Most patients suffering from pheochromocytoma are diagnosed by measuring urine concentrations of vanillylmandelic acid, metanephrine, and/or normetanephrine in addition to plasma catecholamine concentrations. However, a subset of patients suffering from the condition will not have elevated concentrations of the metabolites in the plasma or urine.

Administration of phenotolamine (blocking agent) prior to histamine challenge test in order to protect against hypotension or catecholamine-induced arrythmias.

Implementation (Clinical): Evaluation of conditions of suspected pheochromocytoma as a function of catecholamine and blood pressure response to glucagon challenge.

Human Model: Extra-adrenal pheochromocytoma.

Interpretation and Analysis: During *in vitro* preparations, glucagon (10^{-4}) exposure for 10 minutes following a 2-hour incubation period results in abrupt increases in adrenaline and noradrenaline (epinephrine to 0.08 μg/mg, and norepinephrine to 0.07 μg/mg). Systemically (*in vivo*), there is initially a massive release of catecholamines that declines to basal levels (0.02 μg/mg) after 1.5 hours. During the course of *in vivo* administration trials, glucagon induces a slight but constant increase in blood pressure. By contrast no significant urinary catecholamine elevation may be evoked. Adjunct diagnostics can include detection using [^{131}I]-metaiodobenzylguanidine (MIBG) scintigraphy.

Human pheochromocytomas, but not adrenal medulla, express glucagon-receptor gene and possess an *in vitro* secretory response to glucagon**.** Albertin G, Aragona F, Gottardo L, Malendowicz LK, Nussdorfer GG. Peptides 2001 Apr; 22 (4), pp. 597–600.

Pheochromocytoma *[Metaclopramide]/[^{131}I]-Metaiodobenzylguanidine (MIBG)*

Background Information: Pheochromocytoma accounts for approximately 25% of incidentally discovered adrenal masses. Certain diagnostic procedures (e.g., adrenal arteriography, needle biopsy of an adrenal mass), anesthesia, and abdominal surgery may cause a sudden release of catecholamines from a pheochromocytoma and induce paroxysmal attacks of hypertension. In addition, pheochromocytoma is well known to cause unsuspected operating room deaths. Therefore, it is important to carefully separate this functioning neoplasm from other types of adrenal masses.

Pheochromocytoma cases frequently have elevated plasma concentrations of adrenaline and noradrenaline in addition to increases in urinary vanillylmandelic acid, metanephrine, and/or normetanephrine.

Application: Detection of pheochromocytoma.

Route of Administration: Metaclopramide (IV); [^{131}I]-MIBG (IV).

Considerations: In situations where results from these assays are negative, both the metaclopramide (provocative test) and [^{131}I-] or [^{123}I]-MIBG (scintigraphy) can be performed as an alternative diagnostic strategy.

Implementation: Compare results of non-invasive tests including (i) assay of urinary catecholamines and their metabolites; (ii) a provocative pharmacologic test using metoclopramide (MCP test); and (iii) [^{131}I]-MIBG scintigraphy to screen for pheochromocytoma.

Human Model: Cases with an incidentally discovered adrenal mass (n = 10; n = 6 pheochromocytomas, n = 4 non-functioning adrenocortical adenomas).

Interpretation and Analysis: Urinary excretion of catecholamines, metanephrines, and vanillylmandelic acid may be positive in only 50% of cases (e.g., n = 5/10; n = 4 negative; n = 1 false-negative; sensitivity = 83%, specificity = 100%). The [^{131}I/^{123}I]-MIBG reagent uptake within adrenal lesions is increased to the extent they can be visualized in diagnostic nuclear medicine studies. The MCP test may be positive in < 50% of cases (e.g., n = 3/7; n = 3/7 negative; n = 1 false-negative; sensitivity = 75%, specificity = 100%). Metaiodobenzylguanidine scintigraphy may similarly be positive in over 50% of cases (e.g., n = 4/7; n = 1/7 negative; n 2/7 false-negative; sensitivity = 67%, specificity = 100%). Such observations suggest that all patients with an incidentally discovered adrenal mass should undergo a determination of the 24-hour urinary excretion of catecholamines and their metabolites, including metanephrines. If this urine assay is negative, other non-invasive tests including the MCP test and MIBG scintigraphy should be considered in selected patients with radiographic characteristics of pheochromocytoma.

Non-invasive screening for pheochromocytoma in patients with an incidentally discovered adrenal mass: Usefulness of provocative test with metoclopramide and [^{131}I]-metaiodobenzylguanidine scintigraphy. Yokoyama H, Tsuji Y. Hinyokika Kiyo 1999 Oct; 45 (10), pp. 677–80.

Pheochromocytoma (Silent/Subclinical) *Glucagon/[^{131}I]-Metaiodobenzylguanidine (MIBG)*

Application: Diagnosis of subclinical/silent pheochromocytoma.

Route of Administration: Glucagon (IV) and [^{131}I]-MIBG (IV).

Considerations: Adrenal masses can sometimes be incidentally discovered during abdominal ultrasonography and computed tomography procedures in cases that are normotensive, asymptomatic, and have nearly normal plasma catecholamine levels. However, urinary levels of catecholamine metabolites are often slightly elevated in such cases.

Implementation: Evaluation of suspected conditions of pheochromocytoma. Note: A cutoff at 4.0 cm of tumor mass size can be set for differentiating benign and malignant tumors.

Interpretation and Analysis: A glucagon provocative test and [^{131}I]-MIBG scintigram can be useful for diagnosing atypical pheochromocytoma. In cases classified as incidentaloma, 82.5% are benign masses, of which 35.0% (n = 36/85) are non-functional adre-

nal cortical adenomas, and 11.7% (n = 12/85) are pheochromocytoma. Cases with malignant masses are significantly younger than patients with adenomas ($p < 0.05$), and adenomas are significantly smaller than malignant lesions ($p < 0.001$). During the diagnosis of atypical incidentaloma, it's essential to evaluate hormonal activity and assess the risk for malignancy. If the mass size is 4 cm or larger, the risk of malignancy increases. More attention should be paid to subclinical hyperfunctional state.

A clinical analysis of 103 cases of adrenal incidentaloma. Tao H, Lu ZL, Li HZ. Zhongguo Yi Xue Ke Xue Yuan Xue Bao 2003 Apr; 25 (2), pp. 172–5.

Thyroid Cancer
Thyroid-Stimulating Hormone (TSH)

Background Information: Detection of recurrent thyroid cancer tumor requires TSH stimulation for radioiodine scanning and thyroglobulin (Tg) measurement. Temporary thyroid hormone withdrawal has previously been used, but causes hypothyroidism and, rarely, tumor progression.
Implementation: Evaluation of recombinant thyrotropin (rTSH) assessed in 2 randomized clinical trials in which cases have had [^{131}I] and Tg testing twice: (i) initially after rTSH, and (ii) after thyroid hormone withdrawal. Note: Quality of life comparisons have subsequently been made in preliminary investigations.
Interpretation and Analysis: In trials with positive-scan cases (49% of total), rTSH is equivalent to withdrawal in 66%, superior in 5%, and inferior in 29% ($p < 0.05$), suggesting a lesser sensitivity for rTSH scans. In a 2nd trial employing enhanced techniques, patients with positive scans (49%), there is no difference in the number of superior rTSH and withdrawal scans. Furthermore, among all cases with withdrawal study evidence of residual thyroid tissue, 74% of all patients with residual thyroid tissue and 100% of cases with tumor metastases have rTSH-stimulated thyroglobulin values above 2 ng/mL. Naturally, cases experience significantly more symptoms and diminished quality of life in a hypothyroid state than after rTSH. Therefore, combined rTSH-stimulated radioiodine and Tg testing is as sensitive as thyroid hormone withdrawal to detect recurrent thyroid cancer, and causes less morbidity.

Recombinant thyrotropin for detection of recurrent thyroid *cancer*. Ladenson PW. Trans Am Clin Climatol Assoc 2002; 113, pp. 21–30.

Thyroid Cancer/Medullary Thyroid Carcinoma (MTC)/(Induced Calcitonin Secretion)
Histamine/Calcium/Pentagastrin Infusion/Glucagon

Cellular/Molecular Mechanism of Action: Histamine promotes a secretagogue effect on calcitonin in conditions of MTC.
Application: Characterization of cases of MTC due to its ability to induce calcitonin secretion. Glucagon and calcium are other known stimuli for calcitonin secretion in cases of MTC. Histamine will not replace these agents in provocative tests but can provide better insight into the behavior of this neoplastic cell type.
Implementation: Determination of the relative effectiveness of histamine, calcium/pentagastrin, and glucagon as calcitonin secretagogues in cases of MTC.
Interpretation and Analysis: In cases of MTC with undetectable levels of basal plasma calcitonin (e.g., n = 7/15), calcium and pentagastrin can promote detectable elevations in plasma calcitonin concentrations. Similar responses cannot be appreciated for histamine or glucagon administration. Alternatively, in cases of MTC that do express detectable baseline levels of calcitonin (e.g., n = 8/15), significant responses can be seen in response to glucagon, calcium/pentagastrin, and histamine but the calcium/pentagastrin combination induces the most potent secretagogue effect. Blockade of H_2-receptor complexes with cimetidine has no effect on basal calcitonin concentrations and does not suppress responses to histamine, calcium, or pentagastrin. The variable secretagogue effect of histamine may be mediated through H_1-receptors, through non-specific vascular dilation "washing out" preformed calcitonin, or through its destruction to varying degrees by histaminase, present in most medullary thyroid tumors. Histamine is unlikely to replace calcium/pentagastrin as the most discriminating provocative diagnostic agent in MTC. However, correlation of secretory responses with tissue histaminase concentrations and attempted blockade with differing antihistamines will further understanding of this tumor type.

Some laboratories have proposed that a definitive diagnosis can be established by measuring calcitonin and carcinoembryonic antigen (CEA) levels in sera. In cases with normal levels of calcitonin and CEA, the provocative test (Ca-gluconate plus pentagastrin) can be useful [e.g., (pt. no. 11,K.N.)].

Histamine and calcitonin release from medullary thyroid carcinoma. Farndon JR, Lewis KR, Dale JK, Hinshaw WM, Dilley WG, Wells SA Jr. Cancer 1983 Apr 1; 51 (7), pp. 1221–5.

Thyroid Cancer (Differentiated)/Metastatic Disease
Recombinant Thyrotropin

Cellular/Molecular Mechanism of Action: Recombinant thyrotropin stimulates iodine uptake in thyroid tissue.
Application: Detection of differentiated thyroid cancer (± metastasis).
Considerations: Recombinant thyrotropin is a safe and effective diagnostic agent for cases that require radioiodine scanning for routine follow-up. The use of recombinant thyrotropin has fewer adverse effects than does the alternative, which is withdrawal of thyroid hormone replacement, although nausea and headache have been reported. Recombinant thyrotropin is relatively expensive.
Interpretation and Analysis: A serum thyroglobulin > 2 ng/mL and/or a positive whole-body scan after recombinant thyrotropin stimulation suggest residual thyroid tissue or neoplastic disease. The combined application of measured serum thyroglobulin concentrations and whole-body radioiodine scintigraphy can identify virtually all patients with distant metastatic disease.

The use of recombinant thyrotropin in the follow-up of patients with differentiated thyroid cancer. Basaria M, Graf H, Cooper DS. Am J Med 2002 Jun 15; 112 (9), pp. 721–5.

Thyroid Carcinoma: Medullary Thyroid Carcinoma (MTC; Hereditary)/(C-Cell Disease)
Omeprazole/Pentagastrin

Cellular/Molecular Mechanism of Action: Pentagastrin and omeprazole both induce the synthesis/release of calcitonin that becomes excessively increased within the plasma in conditions of MTC.
Application: Diagnosis of MTC through the induction of increased serum calcitonin.
Route of Administration: Omeprazole (oral).
Dosage: Omeprazole (20 mg twice a day for 4 days); pentagastrin (0.5 μg/kg of body weight).
Implementation and Validation: Evaluation of conditions of hereditary MTC.

Interpretation and Analysis: In conditions of hereditary MTC, pentagastrin administration produces a significantly higher increase in serum calcitonin than does omeprazole. Occasional unpleasant side effects are associated with the administration of pentagastrin by injection, including substantial "tightness" being appreciated in almost all cases. Alternatively, omeprazole is not associated with inducing any significant adverse side effects. A direct positive correlation exists between calcitonin-% (ratio of calcitonin peak to basal value × 100) and gastrin-% (ratio of gastrin peak to basal value × 100) during the omeprazole test in MTC patients ($r = 0.73$; $p < 0.001$). In spite of several adverse effects, pentagastrin remains the best provocative test for the diagnosis of MTC. Omeprazole may be useful when pentagastrin is contraindicated or refused because of the unpleasant side effects, but further validation is needed.
Instrumentation: Laboratory facilities and reagents necessary for calcitonin radioimmunoassay or ELISA-based methodologies.

Comparison of 2 provocative tests for calcitonin in medullary thyroid carcinoma: Omeprazole vs pentagastrin. Vitale G, Ciccarelli A, Caraglia M, Galderisi M, Rossi R, Del Prete S, Abbruzzese A, Lupoli G. Clin Chem 2002 Sep; 48 (9), pp. 1505–10.

Thyroid Medullary Carcinoma/ (Familial Chromaffinomatosis)
Oral Whiskey/Pentagastrin

Cellular/Molecular Mechanism of Action: Induces or promotes the secretion of calcitonin.
Background Information: Familial medullary carcinoma of thyroid (MCT) can be diagnosed early by measuring stimulated plasma calcitonin following provocation with oral whiskey or pentagastrin. The calcitonin release, however, can be variable following both stimuli.
Diagnostic Application: Detection of cases associated with thyroid medullary carcinoma.
Route of Administration: Whiskey (oral ingestion); pentagastrin (intravenous).
Dosage: Whiskey (50 ml); pentagastrin (0.5 μg/kg).
Implementation: Determine whether a humoral mechanism might be involved in mediating calcitonin release assessed by measuring 9 gut peptides, histamine, alcohol, calcium, and calcitonin plasma concentrations.

Human Model: Cases affected by multiple endocrine neoplasia Type II (MEN II) syndrome ($n = 8$).
Interpretation and Analysis: Pentagastrin produces significant rises in plasma calcitonin, histamine, and pancreatic polypeptide. Whiskey induces a variable rise in plasma alcohol but significant rises in plasma calcitonin, histamine, and pancreatic polypeptide, as well as insulin ($p < 0.05$). Such observations suggest that histamine may be the mediator of calcitonin release following provocation by either pentagastrin or alcohol. Histamine infusion requires evaluation as a screening test for MCT in MEN II syndrome.

Multiple endocrine neoplasia type II: The role of gastrointestinal humoral factors in calcitonin release following alcohol and pentagastrin stimulation. Fletcher DR, Gamvros O, Man WK, Ahmed Y, Trayner I, Adrian T. Aust N Z J Surg 1984 Jun; 54 (3), pp. 271–5.

Pentagastrin, calcium and whisky stimulated serum calcitonin in medullary carcinoma of the thyroid. Emmertsen KK, Nielsen HE, Mosekilde L, Hansen HH. Acta Radiol Oncol 1980; 19 (2), pp. 85–9.

Whisky: A new provacative test for calcitonin secretion. Dymling JF, Ljungberg O, Hillyard CJ, Greenberg PB, Evans IM, MacIntyre I. Acta Endocrinol (Copenh) 1976 Jul; 82 (3), pp. 500–9.

IMMUNE SYSTEM

Lymph Node: Sentinel Mapping/ Adenocarcinoma Colorectal Cancer
Isosulfan Blue Dye

Cellular/Molecular Mechanism of Action: Isosulfan blue is a pigment-based dye reagent.
Background Information: Sentinel lymph node (SLN) biopsy is a widely accepted method for staging breast cancer and melanoma, and it has recently been proposed as a means of improving staging in colorectal cancer. However, lymphatic mapping in colorectal cancer has been plagued by studies demonstrating high false-negative rates.
Application: Evaluate possible mechanisms for high false-negative rates after SLN biopsy in colorectal cancer. Poor accuracy may be due to bulky tumor mass or complete replacement of lymph nodes by tumor lesions.
Route of Administration: Isosulfan blue dye (intralesional injection).
Dosage: Isosulfan blue dye (1 ml volumetric).
Implementation: Intraoperative injection of isosulfan blue dye into colorectal adenocarcinoma lesions for the purpose of lymphatic mapping using either an *in vivo* or *ex vivo* technique. Routine pathological evaluations are then performed. Sentinel node are examined by hematoxylin and eosin stains, and if they are negative they are subsequently evaluated by cytokeratin immunohistochemistry. The patient's age, operation type, tumor stage, tumor diameter, method of SLN detection, presence of palpable nodes, and pathological description of nodes completely replaced by tumor are recorded.

Human Model: Cases undergoing colorectal cancer resection (mean age = 62.8 years, 50% male).
Interpretation and Analysis: Evaluation of lymphatic mapping procedures for the assessement of colorectal cancer conditions. Right- and left-sided colorectal resections are almost equally distributed (48% vs 42%). Sentinel lymph nodes can be successfully identified in a large percentage of cases (e.g., n = 47/51 or 92%). The mean number of SLNs obtained from each specimen is approximately 1.5 (range, 1–5). Routine pathological evaluation demonstrates lymph node metastasis in less than half of cases (e.g., n = 20/47 or 43%) that have SLN identified. The SLN is positive for metastasis in about half of these cases (e.g., n = 10/20). Approximately half of cases with metastasis have a negative SLN resulting in a false-negative rate of 50% (e.g., n = 10/20 cases). The rate of false-negatives is significantly higher in patients undergoing left-sided procedures vs right-sided procedures. Differences among gender, tumor stage, tumor diameter, method of SLN detection, presence of palpable nodes, and pathological description of nodes completely replaced by tumor are not associated with a higher false-negative rate.

Does tumor burden limit the accuracy of lymphatic mapping and sentinel lymph node biopsy in colorectal cancer? Broderick-Villa G, Ko A, O'Connell TX, Guenther JM, Danial T, DiFronzo LA. Cancer J 2002 Nov–Dec; 8 (6), pp. 445–50.

Lymphoma/Leukemia Nucleoli Targeting/ Gene Expression
Fluorescein-Labeled Phosphorothioate (PS)-Triple Helix-Forming Oligonucleotide (TFO)/Antisense Oligonucleotides

Cellular/Molecular Mechanism of Action: Oligonucelotide sequences can be designed that recognize and bind to specific gene/messenger RNA (mRNA) sequences.

Physiological Mechanism of Action: Selective inhibition of the transcription/translation of specific genes.
Background Information: The c-myc gene is frequently deregulated and overexpressed in human cancers, and strategies designed to inhibit c-myc expression in cancer cells may have considerable therapeutic value.
Application: Detection and characterization of lymphoma/leukemia cell types based on the detection of the homopurine-homopyrimidine sequence in the P2 promoter of the c-myc gene. Resistance to intra- and extracellular nucleases is a property that is required for the design of oligonucleotides intended for *in vivo* testing and therapeutic applications.
Route of Administration: Potentially variable (intravenous, intralesional).
Semi-Synthetic Methods: Triple helix-forming oligonucleotide can be synthesized with PS internucleotide linkages to confer resistance to intra- and extracellular nucleases. The resulting preparation can be conjugated with fluorescein as a tracer agent to identify selective accumulations within certain tissues and subcellular organelles.
Implementation: Characterize the antigen and antiproliferative activity of a TFO targeted to a homopurine-homopyrimidine sequence in the P2 promoter of the c-myc gene.
Interpretation and Analysis: Phosphorothioate-modified triple helix-forming oligonucleotide forms triplex DNA complexes with affinity and specificity comparable with that of the corresponding phosphodiester TFO, as delineated by gel mobility shift and footprinting assays. Fluorescence microscopy and polyacrylamide gel analysis reveal that fluorescein-labeled PS-TFO accumulates in the nuclei of CEM leukemia cells and remains intact for a duration of at least 72 hours. Incubation of CEM cells with PS-TFO reduces c-myc RNA and protein levels. A single exposure of leukemia cells to the PS-TFO is sufficient to induce dose-dependent growth inhibitory effects. Growth inhibition correlates with accumulation of cells in S phase and with induction of cell death by apoptosis. Preparations of PS-TFO are also effective in other leukemia and lymphoma cell lines. Control oligonucleotides have minimal effects in all assays. These data indicate that c-myc-targeted PS-TFO is an effective antigene and antiproliferative agent, with potential as an agent for *in vivo* testing as a novel approach to cancer therapy/detection.

Antigene and antiproliferative effects of a c-myc-targeting phosphorothioate triple helix-forming oligonucleotide in human leukemia cells. McGuffie EM, Pacheco D, Carbone GM, Catapano CV. Cancer Res 2000 Jul 15; 60 (14), pp. 3790–9.

Lymphoma/Mammary Carcinoma
Fluorescein-Somatostatin Receptor-Avid Peptide/ Fluorescein-Bombesin/Carbocyanine-Somatostatin Receptor-Avid Peptide/Carbocyanine-Bombesin

Cellular/Molecular Mechanism of Action: Somatostatin receptor-avid peptides and bombesin recognize and possess binding avidity for somatostatin receptor complexes.
Background Information: Site-specific delivery of drugs and contrast agents to tumors protects normal tissues from the cytotoxic effects of drugs and enhances the contrast between normal and pathologic tissues. One approach to achieve selective detection is to target overexpressed receptors on the exterior surface membranes of tumor cells and to visualize the tumors by a non-invasive optical imaging method.
Application: Detection and characterization of neoplastic lesions that express increased densities of membrane-associated somatostatin receptor complexes.
Semi-Synthetic Methods: Fluorescein and carbocyanine dyes can be conjugated to somatostatin and bombesin receptor-avid peptides. Receptor binding avidities and selectivity can be determined using whole cell or membrane preparations. Dual-imaging probes consisting of a bioactive peptide for tumor targeting, a biocompatible dye for optical imaging, and a radioactive or paramagnetic metal chelator can be prepared for potential use as scintigraphic or magnetic resonance imaging agents.
Interpretation and Analysis: Carbocyanine derivatives of somatostatin and bombesin analogues retain high binding for their respective receptors. Further evaluation of representative molecules in rats bearing somatostatin- and bombesin-positive tumors show selective uptake of the agents by the tumor cells. Unlike carbocyanine derivatives, receptor binding of fluorescein-somatostatin peptide conjugates is highly sensitive to the type of linker and the site of fluorescein attachment on the non-receptor binding region of the peptide. In general, the presence of flexible linkers disrupts binding affinity, possibly due to the interaction of the linker's thiourea group with the peptide's cyclic disulfide bond. While the receptor binding affinity of the dual probes is not dependent on the type of chelating group examined, it is affected by the relative positions of fluorescein and chelator on the lysine linker. For somatostatin compounds, best results are obtained when the chelator is on the alpha-amino lysine linker and fluorescein is on the epsilon-amino group. In contrast, conjugation of the chelator to epsilon-amino and fluorescein to the alpha-amino lysine linker of bombesin peptides results in high receptor binding. These findings indicate that despite their small size, conjugation of dyes to truncated somatostatin and bombesin peptide analogues results in the generation of promising diagnostic agents that retain high *in vitro* receptor binding activity. These contrast agents can selectively and specifically localize in receptor-positive tumors in rat models.

Synthesis, *in vitro* receptor binding, and *in vivo* evaluation of fluorescein and carbocyanine peptide-based optical contrast agents. Achilefu S, Jimenez HN, Dorshow RB, Bugaj JE, Webb EG, Wilhelm RR, Rajagopalan R, Johler J, Erion JL. J Med Chem 2002 May 9; 45 (10), pp. 2003–15.

INTEGUMENTARY SYSTEM

Carcinoma of the Dermus: Differentiation/Basal Cell Carcinoma (BCC)/Squamous Cell Carcinoma (SCC)/Precancerous Lesions/Benign Lesions
Nitrogen/Dye Laser (410 nm)

Cellular/Molecular Mechanism of Action: Induced fluorescence of neoplastic tissues.
Application: Laser-induced fluorescence spectroscopy for *in vivo* diagnosis of non-melanoma skin cancers in a manner that can accurately differentiate normal tissues from basal cell carcinoma, squamous cell carcinoma, precancerous lesions, and benign lesions based on the interpretation of emissions profiles.
Implementation: Cases are classified as having either skin types I, II, or III and biopsy samples from abnormal tissues collected by biopsy for evaluation. Each analysis measurement is designated as being either normal, BCC, SCC, precancerous, or benign. The total emission photon count is used as a discriminating index. A threshold value is calculated to separate normal tissue indices from indices of cancer tissues. The classification accuracy of each data point is determined using a threshold value.
Human Model: Cases with either skin types I, II, or III (n = 49 total; n = 279 analyses on normal and abnormal tissues).
Interpretation and Analysis: Applying the described classification/categorization scheme, cancers can be classified 93%, 89%,

and 78% correctly in cases with skin types I, II, and III, respectively. Normal tissues can be classified 93%, 88%, and 50% correctly in cases with skin types I, II, and III, respectively. Using the same threshold, precancerous spectra can be classified 78% and 100% correctly in skin types I and III, respectively. Benign lesions can be classified 100%, 46%, and 27% correctly in patients with skin types I, II, and III, respectively. Therefore, *in vivo* laser-induced fluorescence spectroscopy at 410 nm (excitation) and using the intensity of emission signal is an effective approach for detecting BCC, SCC, and actinic keratosis, especially in patients with light-colored skin.

Instrumentation: Nitrogen/dye laser tuned at 410 nm, an optical multichannel analyzer, and a fiber optic probe for excitation of tissue and collection of fluorescence emission.

Laser-induced fluorescence spectroscopy for *in vivo* diagnosis of non-melanoma skin cancers. Panjehpour M, Julius CE, Phan MN, Vo-Dinh T, Overholt S. Lasers Surg Med 2002; 31 (5), pp. 367–73.

Melanoma/Non-Invasive Transcutaneous Detection
Fluorescein-Isothiocyanate-Labeled Antimelanoma IgG/Texas Red-Labeled Dextran

Cellular/Molecular Mechanism of Action: Fluorescein-isothiocyanate and Texas Red emit fluorescent color when exposed to light energy of a specific wavelength.

Application: Fluorescein-isothiocyanate and Texas Red can be used as visual color marker or tracer molecules in biological systems. Fluorescein-isothiocyanate-labeled antimelanoma and Texas Red-labeled dextran can be applied for the transcutaneous detection of melanoma lesions.

Route of Administration: Variable.

Semi-Synthetic Methods: Covalent conjugation and cross-linking conjugation strategies for the semi-synthetic production of fluorescein-isothiocyanate-labeled antimelanoma IgG and Texas Red-labeled dextran.

Implementation: Determination of the relative effectiveness of 3 different fluorescein-isothiocyanate-labeled antimelanoma antibodies to selectively localize within melanoma lesions. Detection is achieved *in vivo* by applying a single-channel confocal imaging system.

Animal Model: Mice (athymic BALB/c strain) with human melanoma cells (n = 3 cell lines) culture from human skin implanted intradermally into the haunch skin of anesthetized mice and allowed to grow to a maximum size of 2 mm in diameter.

Interpretation and Analysis: Fiber-optic confocal imaging performed following intravenous administration of fluorescent-labeled antibodies and Texas Red-dextran facilitates the *in vivo* detection of melanoma and surrounding blood vessels in athymic mice. Using non-invasive techniques, the overall *in vivo* melanoma detection rate for tumors within 0.2 mm of the skin surface is 84% (27 of 32 tumors). Normal cultured human skin cells have little or no fluorescence after administration of the fluorescein-isothiocyanate-labeled antibodies and tumors are not labeled by an isotype control antibody. Dual-channel *in vivo* imaging of implanted melanoma tumors and surrounding dermal vasculature reveals increased blood vessel density at the melanoma site. Detection *in vivo* of melanoma tumors up to 0.2 mm below the skin surface by fiber-optic confocal imaging can be confirmed by conventional immunoperoxidase histology.

Instrumentation: Single-channel confocal imaging system.

In vivo detection of small subsurface melanomas in athymic mice using non-invasive fiber optic confocal imaging. Anikijenko P, Vo LT, Murr ER, Carrasco J, McLaren WJ, Chen Q, Thomas SG, Delaney PM, King RG. J Invest Dermatol 2001 Dec; 117 (6), pp. 1442–8.

Melanoma: Sentinel Lymph Nodes/Guide for Sentinel Lymphadenectomy
Isosulfan Blue Dye/[^{99m}Tc]-Human Serum Albumin (HSA)/[^{99m}Tc]-Sulfur Colloid (SC)

Cellular/Molecular Mechanism of Action: Isosulfan blue dye serves as a fluid pigment-based marker system. [^{99m}Tc]-HSA and [^{99m}Tc]-SC can be phagocytized by reticuloendothelial cell populations residing within peripheral lymph nodes.

Background Information: Radiopharmaceutical agents appear to improve the accuracy of sentinel node (SN) identification in patients with early-stage melanoma, but the optimal radiopharmaceutical agent and its timing from injection to surgery remain controversial.

Application: [^{99m}Tc]-SC and [^{99m}Tc]-HSA can be used intraoperatively as probes for lymphatic mapping in radiopharmaceutical-directed sentinel lymphadenectomy (LM/SL) procedures.

Route of Administration: Isosulfan blue dye, [^{99m}Tc]-SC, and [^{99m}Tc]-HSA can be administered intraoperatively into lymphatic vessels.

Implementation: Cutaneous lymphoscintigraphy (LS) performed before LM/SL utilizing 1 of 3 techniques including (i) [^{99m}Tc]-HSA injected at least 24 hours before LM/SL (n = 124 patients); (ii) filtered [^{99m}Tc]-SC injected no more than 4 hours before LM/SL (same-day SC, n = 95 patients); or (iii) [^{99m}Tc]-SC injected at least 18 hours before LM/SL (prior-day SC, 28 patients). At the time of LM/SL, isosulfan blue dye is injected alone (SC groups) or with a 2nd dose of HSA (HSA group). A handheld gamma probe is used to determine the radioactive (hot) counts of blue-stained and non-stained nodes, and the *in vivo* and *ex vivo* node-to-background count ratios of the nodes compared.

Human Model: Melanoma (n = 247; American Joint Committee on Cancer stage I or II).

Interpretation and Analysis: Preoperative LS can identify a large percentage of drainage basins (e.g., n = 299 in 247 cases). Lymphatic mapping with radiopharmaceutical-directed LM/SL is capable of identifying at least 1 sentinal lymph node in a large percentage of cases. Specific examples include (i) 119 (98%) of 121 basins using same-day SC; (ii) 142 (97%) of 146 basins using HAS; and (iii) 32 (100%) of 32 basins using prior-day SC. There is no difference ($p = 0.62$) in the accuracy rate between the 3 techniques. In the scenario described, a total of 463 sentinel nodes in 247 cases. Same-day SC yields higher intraoperative node-to-background count ratios than do either of the other techniques ($p < 0.0001$). Same-day SC also has the greatest relative change in radioactivity between the blue sentinel node and the postexcision basin ($p < 0.0001$), and the highest rate of SNs that are both blue and hot (*in vivo* or *ex vivo* ratio ≥ 2, $p = 0.05$). Therefore, LS and LM/SL performed on the same day with a single injection of filtered [^{99m}Tc]-SC serves as the most useful method for probe-directed LM/SL. The technique demonstrates the highest *in vivo* and *ex vivo* count ratios, fall-off of radioactivity between the excised nodes and postexcision basin, and concordance between blue dye and hot nodes. It should be recommended as the method of choice for probe-directed LM/SL.

Standardized probe-directed sentinel node dissection in melanoma. Essner R, Bostick PJ, Glass EC, Foshag LJ, Haigh PI, Wang HJ, Morton DL. Surgery 2000 Jan; 127 (1), pp. 26–31.

MUSCULOSKELETAL SYSTEM

Osteosarcoma: Hydroxyapatite Deposition/ Osteoblastic Activity/Atherosclerosis
Near-Infrared (NIR) Light-Emitting Probes/ Fluorescent Bisphosphonate Derivatives

Background Information: In vertebrates, the development and integrity of the skeleton requires hydroxyapatite (HA) deposition by osteoblasts. Sites of osteoblastic activity have most commonly been imaged *in vivo* using gamma-emitting radioisotopes. The scan times required are long, and the resultant radioscintigraphic images suffer from relatively low resolution.
Application: Hydroxyapatite deposition is a marker of, or a participant in, processes as diverse as cancer and atherosclerosis.
Semi-Synthetic Methods: Production of an NIR fluorescent bisphosphonate derivative.
Implementation: Evaluation of the ability for NIR fluorescent bisphosphonate derivatives to physically bind to hydroxyapatite deposits.
Interpretation and Analysis: Near-infrared light-based probes like fluorescent bisphosphonate derivatives possess an ability to bind to hydroxyapatite under *in vitro* conditions, in addition to recognizing osteoblastic activity in living animals. Such biotechnology can be applied to study skeletal development, osteoblastic metastasis, coronary atherosclerosis, and other disease states.

In vivo near-infrared fluorescence imaging of osteoblastic activity. Zaheer A, Lenkinski RE, Mahmood A, Jones AG, Cantley LC, Frangioni JV. Nat Biotechnol 2001 Dec; 19 (12), pp. 1148–54.

RENAL/URINARY SYSTEMS

Urinary Bladder Cancer
5-Aminolevulinic Acid (5-ALA)/ 5-ALA Methyl Ester (AME)

Cellular/Molecular Mechanism of Action: 5-aminolevulinic acid and its AME derivative emit fluorescent light energy. Certain neoplastic cell populations preferentially accumulate these agents intracellularly.
Background Information: The use of 5-ALA and its esters to induce endogenous porphyrins for the purpose of detecting epithelial cancers has been studied extensively at many centers around the world. The challenge is to prepare an efficacious formulation for the purpose of cancer detection. Photodynamic diagnosis of cancer using 5-ALA and its ester derivatives is being actively investigated.
Application: 5-aminolevulinic acid and AME can be used as fluorescent imaging agents for the detection of exterior neoplastic lesions such cancers of the urinary bladder.
Implementation: Compare 5-ALA with AME derivative in terms of protoporphyrin IX (PPIX) fluorescence intensity in *in vitro* and *in vivo* systems of bladder carcinoma. Complementary studies involve comparison evaluation of intravenous and topical application modes for drug administration in *in vivo* systems with RT112 xenografts. An endoscopy system is used to obtain macroscopic fluorescence images. The macroscopic images are further analyzed for fluorescence intensity distribution.
Animal Model: Rodent (tumor-bearing RT112 xenographs of a human bladder cancer cell type).
Interpretation and Analysis: For intravenous administration, over all time points studied (1, 3, 6 hours), AME-PPIX fluorescence is lower than ALA-PPIX fluorescence and is cleared at a faster rate than ALA-PPIX when administered intravenously. Topical application with 2 different polymers, Gantrez and Polyvinyl pyrrolidone (PVP), which are fast-releasing polymers, has been comparable for inducing PPIX fluorescence. Topical AME-PPIX fluorescence is comparable with ALA-PPIX fluorescence. The agent AME also appears to be applicable as a viable diagnostic agent.
Instrumentation: Karl Storz fluorescence endoscopy system.

A study of 5-aminolevulinic acid and its methyl ester used in *in vitro* and *in vivo* systems of human bladder cancer. Manivasager V, Heng PW, Hao J, Zheng W, Soo KC, Olivo M. Int J Oncol 2003 Feb; 22 (2), pp. 313–8.

REPRODUCTIVE SYSTEM

Mammary Carcinoma/Lymphoma
Fluorescein-Somatostatin Receptor-Avid Peptide/ Fluorescein-Bombesin/Carbocyanine-Somatostatin Receptor-Avid Peptide/Carbocyanine-Bombesin

Cellular/Molecular Mechanism of Action: Somatostatin receptor-avid peptides and bombesin recognize and possess binding avidity for somatostatin receptor complexes.
Background Information: Site-specific delivery of drugs and contrast agents to tumors protects normal tissues from the cytotoxic effects of drugs and enhances the contrast between normal and pathologic tissues. One approach for achieving selectivity is to target overexpressed receptors on the membranes of tumor cells and to visualize the tumors by non-invasive optical imaging methods.
Application: Detection and characterization of neoplastic lesions that express an increased density of membrane-associated somatostatin receptor complexes.
Semi-Synthetic Methods: Conjugation of fluorescein and carbocyanine dyes to somatostatin and bombesin receptor-avid peptides. Binding avidity and selectivity for receptor complexes can be assessed applying whole-cell or membrane preparations. In this context, it is possible to prepare dual-imaging probes consisting of a bioactive peptide for tumor targeting, a biocompatible dye for optical imaging, and a radioactive or paramagnetic metal chelator for scintigraphic or magnetic resonance imaging of tumors.
Interpretation and Analysis: Carbocyanine derivatives of somatostatin and bombesin analogs retain high binding characteristics for their respective receptors. Further evaluation of representative molecules in rats bearing somatostatin- and bombesin-positive tumors shows selective uptake of the agents by tumor cells. Unlike carbocyanine derivatives, receptor binding of fluorescein-somatostatin peptide conjugates is highly sensitive to the type of linker and the site of fluorescein attachment on the non-receptor binding region of the peptide. In general, the incorporation of flexible linkers disrupts binding affinity, possibly due to the interaction of the linker's thiourea group with the peptide's cyclic disulfide bond. While the receptor binding affinity of the dual probes is not dependent on the type of chelating group examined, it is affected by the relative positions of both fluorescein and chelator on the lysine linker. For somatostatin compounds, best results are obtained when the chelator is on the alpha-amino lysine linker and fluorescein is on the epsilon-amino group. In contrast, conjugation of the chelator to epsilon-amino and fluorescein to the alpha-amino lysine linker of bombesin peptides results in high receptor binding. These findings indicate that despite their small size, conjugation of dyes to truncated somatostatin and bombesin peptide analogs results in the generation of promising diagnostic agents that retain high *in vitro* receptor binding activity. These contrast agents can selectively and specifically localize in receptor-positive tumors in rat models.

Synthesis, *in vitro* receptor binding, and *in vivo* evaluation of fluorescein and carbocyanine peptide-based optical contrast agents. Achilefu S, Jimenez HN, Dorshow RB, Bugaj JE, Webb EG, Wilhelm RR, Rajagopalan R, Johler J, Erion JL. J Med Chem 2002 May 9; 45 (10), pp. 2003–15.

Mammary Carcinoma Ex-Plants
Glucamine-Substituted Cyanine/ Gluosamine-Substituted Cyanine

Application: Glucamine and gluosamine-substituted cyanine are dyes structurally related to indocyanine green (ICG) that can be applied as contrast-enhancing optical imaging agents for the detection of neoplastic lesions (e.g., human mammary carcinoma explants in rats) utilizing near-infrared modalities.
Route of Administration: Intravenous.
Semi-Synthetic Methods: Production of a group of glucamine and gluosamine-substituted cyanine dyes structurally related to ICG.
Implementation: Characterization of glucamine and gluosamine-substituted cyanine dyes structurally related to ICG for their potential as contrast agents for biomedical optical imaging. Derivatives with the highest hydrophilicity are evaluated for their efflux from tumor and normal tissue by monitoring with intensity-modulated diffuse optical spectroscopy after intravenous injection.

Animal Model: Rat (tumor-bearing).

Interpretation and Analysis: Glucamine and gluosamine-substituted cyanine dyes exhibit increased hydrophilicity and less plasma protein binding ($< 50\%$) compared to ICG. Accordingly, they also have different pharmacokinetic properties. Measurable enhancement in fluorescence quantum yields (7–15%) can be detected in a physiological environment compared to ICG. The derivative 5a has the highest level of hydrophilicity. In comparison with ICG, derivative 5a exhibits considerably enhanced tissue-efflux half-life (73 minutes vs less than 10 minutes for ICG in tumor tissue) and a 2-fold higher initial tissue absorption coefficient compared to ICG, and it generates an elevated tumor-to-tissue concentration gradient up to 1 hour after injection. In conclusion, compounds such as 5a are promising contrast agents for optical imaging and can facilitate highly sensitive and specific detection of breast cancer or other malignancies by utilizing mechanisms similar to contrast-enhanced magnetic resonance imaging or computerized tomography.

Hydrophilic cyanine dyes as contrast agents for near-infrared tumor imaging: Synthesis, photophysical properties and spectroscopic *in vivo* characterization. Licha K, Riefke B, Ntziachristos V, Becker A, Chance B, Semmler W. Photochem Photobiol 2000 Sep; 72 (3), pp. 392–8.

Mammary Gland Disease Differentiation/ Optical Imaging
Indocyanine Green (ICG)/Gadolinium/ Near-Infrared (NIR) Diffuse Optical Tomography

Cellular/Molecular Mechanism of Action: Indocyanine green is an albumin-bound absorbing dye.
Application: Indocyanine green is an absorbing dye commonly used as a marker system within the plasma compartment. Under certain conditions, ICG possesses the potential to differentiate disease based on the quantified enhancement of suspicious lesions using MRI concurrently with NIR diffuse optical tomography (contrast enhancement properties).
Route of Administration: Intravascular.
Implementation: Near-infrared diffuse optical tomography (DOT) analysis of the mammary gland applied in combination/concurrently with magnetic resonance imaging (MRI). Results are then correlated with histopathological evaluation of suspicious lesions.

Human Model: Cases scheduled for excision biopsy or surgery.

Interpretation and Analysis: The ICG-enhanced optical images co-register accurately with gadolinium-enhanced magnetic resonance images, thereby validating the ability of DOT to image breast tissue. In contrast to simple transillumination, DOT appears to provide for localization and quantification of exogenous tissue chromophore concentrations. Additionally, ICG has demonstrated a potential to differentiate disease based on the quantified enhancement of suspicious lesions.

Concurrent MRI and diffuse optical tomography of breast after indocyanine green enhancement. Ntziachristos V, Yodh AG, Schnall M, Chance B. Proc Natl Acad Sci U S A 2000 Mar 14; 97 (6), pp. 2767–72.

13 Genetics and Nucleic Acids

Anemia: Fanconi's Syndrome
Nitrogen Mustard (NTM)/[Diepoxybutane (DEB)]

Cellular/Molecular Mechanism of Action: Nitrogen mustards and DEB can function as DNA alkylating agents.
Background Information: Fanconi's anemia (FA) is an autosomal recessive inherited disorder that is associated with a variety of congenital anomalies. These include morphometric abnormalities involving mainly the head and face, skeletal malformations particularly of the radial ray, growth retardation, abnormal skin pigmentation, deafness, and renal, ocular, genital, and cardiac defects. The cardinal clinical feature is a severe progressive pancytopenia.
Application: Compare 2 different alkylating agents that would permit rapid and unequivocal detection of FA.
Implementation: Evaluate the potential to detect conditions of FA) rapidly and accurately applying alkylating agents as screening agents. In this context, NTM and DEB tests are performed in concert with the determination of baseline chromosomal breakage analyses.
Human Model: Cases suspected of suffering from Fanconi's syndrome anemia (n = 271).
Interpretation and Analysis: Chromosomal breakage analyses can facilitate the detection of cases with FA (e.g., n = 72) in contrast to cases unaffected by the condition (e.g., n = 136). Studies of family members of affected FA cases (e.g., n = 63 individuals) reveal that NTM seems more specific to identify chromosomal breakages in FA parents than is possible with DEB.

Differential diagnosis of Fanconi's anemia by nitrogen mustard and diepoxybutane. Deviren A, Yalman N, Hacihanefioglu S. Ann Hematol 2003 Apr; 82 (4), pp. 223–7.

DNA Intercalation/Neoplastic Disease: Topoisomerase I & II/Adenocarcinoma (HT29)/ Gliobastoma (U87MG)/Melanoma (A375M Antigen Positive)/Rational Chemotherapeutic Selection
[^{11}C]-9-Methoxyphenazine-1-Carboxamide/[^{11}C]2-(4-Pyridyl)Quinoline-8-Carboxamide/[^{11}C]DACA/ [Topoisomerases I & II]

Cellular/Molecular Mechanism of Action: The tricyclic carboxamide N-[2-(dimethylamino)ethyl]acridine-4-carboxamide (DACA) is a DNA-intercalating agent capable of inhibiting both topoisomerases I and II enzyme fractions.
Background Information: The tricyclic carboxamide DACA is currently in Phase II clinical trial. Many related analogues have been developed, but despite their potent *in vitro* cytotoxicities, they exhibit poor extravascular distribution.
Application: Delineation of rational drug selection.
Semi-Synthetic Methods: Each candidate compound shares a common structural feature, N-dimethyl side chain, which is radiolabeled with [^{11}C] functioning as a positron-emitting radioisotope.
Implementation: Evaluate the biodistribution and metabolite profiles of the prototype compound, DACA, with 3 analogues to aid rational drug selection in order to identify agents that are "minimal intercalators" that have lower DNA association constants. In this fashion, promising candidates will be identified in emerging preclinical studies in animals that can ultimately be evaluated in humans using positron emission tomography (PET).
Animal Model: Murine (mice bearing human tumor xenografts).
Interpretation and Analysis: Acridine DACA, phenazine SN 23490, pyridoquinoline SN 23719, and dibenzodioxin SN 23935 are cytotoxic when evaluated with *in vitro* assays utilizing HT29, U87MG, and A375M cell lines (IC50 of 1.4 to 1.8 μM, 0.4 to 0.6 μM, 1.3 to 1.6 μM, and 24 to 36 μM, respectively). *Ex vivo* biodistribution studies with [^{11}C]-radiolabeled compounds in mice bearing human tumor xenografts show rapid clearance of [^{11}C] radioactivity (parent drug and metabolites) from blood and major organs. Rapid hepatobiliary clearance and renal excretion can also be observed. There is low (< 5% of injected dose/g [%ID/g]) and variable uptake of [^{11}C] radioactivity in 3 tumor types for all of the compounds. Tumor (U87MG) to blood [^{11}C] radioactivity for [^{11}C]DACA, [^{11}C]-9-methoxyphenazine-1-carboxamide (SN 23490), [^{11}C]2-(4-pyridyl) quinoline-8-carboxamide (SN 23719), and [^{11}C]dibenzo[1,4]dioxin-1-carboxamide (SN 23935) at 30 minutes is approximately 2.9 ± 1.1, 2.3 ± 0.6, 2.6 ± 0.6, and 0.7 ± 0.2, respectively. For SN 23719, the distribution of [^{11}C] radioactivity in normal tissues and tumors determined *ex vivo* is in broad agreement with that determined *in vivo* by whole-body PET scanning. [^{11}C]DACA is rapidly and extensively metabolized to several plasma metabolites and a major tumor metabolite. In contrast, [^{11}C]SN 23935, [^{11}C]SN 23490, and [^{11}C]SN 23719 show less extensive metabolism. In tumor samples, parent [^{11}C]DACA and [^{11}C]SN 23935 are present at between 0.3 and 1.5%ID/g, whereas [^{11}C]SN 23490 and [^{11}C]SN 23719 is present at between 1.5 and 2.8%ID/g. Therefore, by using a strategy employing [^{11}C] labeling, it is possible to determine the tissue distribution and metabolic stability of novel tricyclic carboxamides.

Given the objective of identifying analogs with potentially improved *in vivo* activity against solid tumors, the agents SN 23490 and SN 23719 have more favorable distribution and metabolic stability compared with DACA and SN 23935. Such observations suggest that further development and evaluation are warranted. The radiolabeling strategy used allows *ex vivo* and *in vivo* evaluation of promising anticancer agents in animals and offers the potential of rapid translation to studies in humans using PET.

Comparative biodistribution and metabolism of carbon-11-labeled N-[2-(dimethylamino)ethyl]acridine-4-carboxamide and DNA-intercalating analogues. Osman S, Rowlinson-Busza G, Luthra SK, Aboagye EO, Brown GD, Brady F, Myers R, Gamage SA, Denny WA, Baguley BC, Price PM. Cancer Res 2001 Apr 1; 61 (7), pp. 2935–44.

DNA Synthesis: Neoplastic Disease/Cellular Proliferation Rate/Thymidine Kinase Expression
5-Iodo-4′-Thio-2′-Deoxyuridine (ITdU)

Cellular/Molecular Mechanism of Action: 5-Iodo-4′-thio-2′-deoxyuridine is a metabolically stable nucleoside that can function as a substrate for cellular thymidine kinase biochemical activity.

Application: Radioiodinated forms of ITdU and 5-iodo-2′-deoxyuridine (IUdR) can be applied to detect elevations in DNA synthesis for cell populations that positively express thymidine kinase activity. In this capacity, both ITdU and IUdR can serve as indicator molecules for measuring alterations in cellular proliferation especially relevant to the characterization of neoplastic disease states.

Route of Administration: Usually ITdU or IUdR would most frequently be administered intravenously/intravascularly. Theoretically, it may be possible to effectively image lesions if the agents are administered intrathecally for central nervous system (CNS) tumors, by direct injection into tumors, or into the arterial network supplying a suspected neoplastic lesion.

Semi-Synthetic Methods: Radiolabeling of ITdU and 5-iodo-1-(4-thio-β-D-arabinofuranosyl)uracil (ITAU) with [^{125}I] utilizing a destannylation reaction of the trimethylstannyl precursor of each nucleoside. The products can be isolated in high yields and with a > 99% level of radiochemical purity.

Implementation: Evaluation of ITdU and ITAU for their ability to assess cell growth based on DNA content.

Ex Vivo Model: Thymidine kinase-expressing L-M cell rather than a thymidine kinase-deficient mutant L-M (TK$^-$) cell.

Interpretation and Analysis: [^{125}I]-ITdU is effectively phosphorylated by cytosolic nucleoside kinases and specifically incorporated into a thymidine kinase-expressing L-M cell rather than a thymidine kinase-deficient mutant L-M (TK$^-$) cell. In addition, *in vitro* cell metabolism studies employing [^{125}I]-ITdU reveal that [^{125}I]-ITdU is effectively and specifically incorporated into a DNA fraction (> 90% at 60 minutes). Therefore, [^{125}I]-ITdU appears to be as effective of a DNA synthesis marker system as is IUdR. In contrast, [^{125}I]-ITAU is neither remarkably phosphorylated by cytosolic nucleoside kinases nor extensively incorporated into an L-M cell rather than an L-M (TK$^-$) cell. [^{125}I]-ITdU and [^{125}I]-ITAU show a higher resistance to phosphorolytic cleavage by recombinant thymidine phosphorylase than does [^{125}I]-IUdR. Furthermore, biodistribution of [^{125}I]-ITdU and [^{125}I]-ITAU display better *in vivo* stability of radioiodination than do [^{125}I]-IudR preparations. [^{125}I]-ITdU also displays a significantly higher uptake in proliferating organs (thymus, spleen, small intestine, and bone) than in non-proliferating organs (brain, muscle, liver, and lung), as does [^{125}I]-IUdR, at 18 hours postinjection. As indicated by *in vitro* studies, [^{125}I]-ITAU does not show any significant uptake in proliferating organs. Therefore, radioiodinated ITdU is potentially useful as a proliferation-imaging agent, and further studies should focus on clarifying the usefulness of this compound as a single photon emission computed tomography (SPECT) tumor-imaging agent.

Rationale of 5-[^{125}]I-iodo-4′-thio-2′-deoxyuridine as a potential iodinated proliferation marker. Toyohara J, Hayashi A, Sato M, Tanaka H, Haraguchi K, Yoshimura Y, Yonekura Y, Fujibayashi Y. J Nucl Med 2002 Sep; 43 (9), pp. 1218–26.

Gene Therapy Assessment Model/Neoplastic Disease: Leukemia Nucleoli Targeting/c-myc Gene Overexpression

Fluorescein-Labeled Phosphorothionate-Triple Helix-Forming Oligonucleotide (PS-TFO)/Antisense Oligonucleotides/Homopurine-Homopyrimidine P2 Promoter Sequence for c-myc

Cellular/Molecular Mechanism of Action: Oligonucelotide sequences can be designed that recognize and bind to specific gene/messenger RNA (mRNA) sequences.

Physiological Mechanism of Action: Selective inhibition of the transcription/translation of specific genes.

Background Information: The c-myc gene is frequently deregulated and overexpressed in human cancers, and strategies designed to inhibit c-myc expression in cancer cells may have considerable therapeutic value.

Application: Characterize the antigene and antiproliferative activity of a triple helix-forming oligonucleotide (TFO) targeted to a homopurine-homopyrimidine sequence in the P2 promoter of the c-myc gene.

Route of Administration: Potentially variable (intravenous, intralesional).

Semi-Synthetic Methods: Triple helix-forming oligonucleotide can be synthesized with phosphorothioate (PS) internucleotide linkages to confer resistance to intra- and extracellular nucleases. The resulting preparation can be conjugation with fluorescein as a tracer agent to identify selective accumulation within certain tissues and subcellular organelles.

Implementation: Delineation of the affinity of fluorescein-labeled PS-TFO.

Interpretation and Analysis: Resistance to intra- and extracellular nucleases is a property that is required for the design of oligonucleotides intended for *in vivo* testing and therapeutic applications.

Phosphorothioate-modified triple helix-forming oligonucleotides form triplex DNA complexes with affinity and specificity comparable with that of the corresponding phosphodiester TFO, as delineated by gel mobility shift and footprinting assays. Fluorescence microscopy and polyacrylamide gel analysis reveal that fluorescein-labeled PS-TFO accumulates in the nuclei of CEM leukemia cells and remains intact for a duration of at least 72 hours. Incubation of CEM cells with PS-TFO reduces c-myc RNA and protein levels. A single exposure of leukemia cells to the PS-TFO is sufficient to induce dose-dependent growth inhibitory effects. Growth inhibition correlates with S-phase accumulation of cells and with induction of cell death by apoptosis. Preparations of PS-TFO are also effective in other leukemia and lymphoma cell lines. Control oligonucleotides have minimal effects in all assays. Such findings indicate that c-myc-targeted PS-TFO is an effective antigene and antiproliferative agent, with potential for testing *in vivo* as a novel approach for the diagnosis and therapy of neoplastic disease states.

Antigene and antiproliferative effects of a c-myc-targeting phosphorothioate triple helix-forming oligonucleotide in human leukemia cells. McGuffie EM, Pacheco D, Carbone GM, Catapano CV. Cancer Res 2000 Jul 15; 60 (14), pp. 3790–9.

Malignant Hyperthermia (MH)/Genomic Analyses and Provocative Testing Correlation/Arginine-614 → Cysteine (Arg614Cys: RYR1 C1840T)

Caffeine/Halothane

Physiological Mechanism of Action: In conditions of MH, exposure of muscle tissue to caffeine/halothane promotes an exaggerated contractile response.

Background Information: Malignant hyperthermia is an important cause of anesthesia-induced death. The caffeine/halothane contracture test (CHCT) is highly invasive, expensive, and lacks 100% specificity. Genetic and biochemical evidence provide strong support for the view that the substitution of cysteine for arginine 614 (Arg614Cys) in the human ryanodine receptor gene is 1 of several mutations that are likely to cause human MH.

Application: Detection and characterization of MH conditions.

Route of Administration: Traditionally applied as a topic exposure for an *ex vivo* tissue-based challenge study.

Implementation: Delineation of a possible genetic basis for a predisposition to MH pertaining to the presence of Arg614Cys (RYR1 C1840T) mutations detected through a combination of polymerase chain reaction and restriction endonuclease digestion. Blood samples are utilized as a source of biological material for DNA analyses. Alternatively, detection of MH susceptibility can be established using the *in vitro* CHCT that employs fresh muscle biopsy specimens. Results from CHCT and DNA-based diagnostic parameters are then compared to determine their potential value in predicting MH susceptibility in large MH families that possess Arg614Cys mutations.

Human Model: Cases selected from a large Mennonite malignant hyperthermia kindred identified by an index patient that died at age 45 years of an MH crisis after general anesthesia. Case population: N = 68 family members, n = 19/68 muscle biopsies, n = 1/681 documented crisis without biopsy. Family members can be classified as MH-susceptible or MH-normal on the basis of the CHCT.

Interpretation and Analysis: In some family cohorts, as high as 33% of cases can be found to be heterozygous for the Arg614Cys mutation (n = 22/68) and slightly < one-fourth have prior positive CHCT results (e.g., n = 5/22), while a small percentage may have an MH crisis without a biopsy procedure. Utilizing DNA testing, it is possible to detect a relatively large number of cases within a related kindred that are normal for the allele (e.g., n = 44). Of these, slightly < 25% can be classified as MH-normal, while some may be determined to be MH-susceptible (e.g., n = 5) on the basis of CHCT evaluations. Based on the interpretation of the data obtained in earlier CHCT diagnoses, the condition of the muscle is poor, with no twitch for approximately 60% of cases of individuals homozygous for the normal allele but originally classified as MH-susceptible (e.g., n = 3/5) and for a small percentage that are homozygous for the normal allele and originally classified as MH-normal. Observations from caffeine/halothane contraction test results performed for such individuals (e.g., n = 4) can often be considered invalid. The twitch response is good for a small number of cases (e.g., n = 2 remaining) that are homozygous for the normal allele but classified as MH-susceptible if contracture can be observed with appropriately low levels of both caffeine and halothane.

An absolute correlation between DNA test results and CHCT assignment can often not be established. Possible explanations for discordance are that the Arg614Cys mutation is not linked to MH, that a 2nd MH mutation is segregating in the family, or that there are errors in the CHCT. Because there is strong evidence supporting the causal nature of the Arg614Cys mutation, the discordant cases are not closely related within the pedigree as they would be if a 2nd MH mutation was segregated, and the observed CHCT not 100% accurate. It has therefore been proposed that the observed discordance between DNA test results and CHCT assignment in 1 example kindred results from 2 false-positive diagnoses by the CHCT.

Comparison of the segregation of the RYR1 C1840T mutation with segregation of the caffeine/halothane contracture test results for malignant hyperthermia susceptibility in a large Manitoba Mennonite family. Serfas KD, Bose D, Patel L, Wrogemann K, Phillips MS, MacLennan DH, Greenberg CR. Anesthesiology 1996 Feb; 84 (2), pp. 322–9.

Methylation of RNA (Guided) *snoRNA-2 Gene*

Background Information: Trypanosomatids are the causative agent of several major parasitic diseases including African trypanosomiasis, American trypanosomiasis, and leishmaniasis. These parasites possess unique RNA-processing mechanisms including trans-splicing of pre-mRNA and RNA editing of mitochondrial transcripts.

Implementation: A novel group of trypanosomatid small nucleolar RNAs has been identified that belongs to the box C/D snoRNA, which has been shown to guide ribose methylation on rRNA. Three snoRNA genes include snoRNA-2 carrying a single snoRNA and g2 and b2 coding for single or multiple snoRNAs, respectively. Mapping of the methylation sites guided by snoRNA-2 using 2 different approaches suggest that snoRNA-2 has the potential to guide methylation on both 5.8S and 18S rRNAs. The trypanosomes follow the same guide-methylation rule established for yeast and for mammals. As a 1st attempt to change the methylation pattern of target RNAs, trans-genic parasites have been generated that carry the B2 and snoRNA-2, which have been engineered to shift the methylation site on rRNA.

Interpretation and Analysis: Despite efficient expression of these tagged snoRNAs, novel methylation sites have been very difficult to generate. However, efficient expression of tagged snoRNAs in trans-genic parasites opens the possibility of engineering novel methylation sites on different target RNAs *in vivo*.

Novel trypanosomatid small nucleolar RNAs that guide methylation: Their genome organization, expression and potential use to direct specific methylation on target RNA molecules. Xu YX, Liu L, Michaeli S. Isr Med Assoc J 2000 Jul; 2 Suppl, pp. 58–62.

Rheumatoid Arthritis: Severe vs Mild-Moderate/ Prediction of Disease Severity: G Allele (TT vs TG/GG Genotypes)/Tumor Necrosis Factor-Alpha Receptor Type II (TNFRII): Exon 6 Polymorphism *Anti-TNF-α Response/Methotrexate*

Application: Characterizing severe vs mild-moderate conditions of rheumatoid arthritis as a function of exon 6 TNFRII gene polymorphism. The G allele appears to have utility in predicting the degree of responsiveness to anti-TNF-α treatment, while the GG genotype for the exon 6 TNFRII polymorphism may be useful in predicting more aggressive forms of rheumatoid arthritis.

Implementation: Characterization of exon 6 TNFRII gene polymorphism in cases of (i) mild-moderate synovitis classified as responders to methotrexate therapy (e.g., n = 97) for comparison with (ii) "non-responder" cases receiving anti-TNF-α treatment due to severe and aggressive disease (e.g., n = 78), and (iii) cases with severe rheumatoid arthritis monitored for 6 months during anti-TNF-α therapy. Results are evaluated pertaining to response as it relates genotype and compared to matched age, sex, and ethnic reference controls (e.g., n = 84).

Interpretation and Analysis: A distinct trend exists toward increases in the frequency of the GG genotype in patients with severe rheumatoid arthritis (6.4%) compared to cases of mild-moderate disease (3.1%) and reference controls (1.2%). Evaluation of the response to anti-TNF-α therapy after 12 weeks of treatment reveals that 37.8% of the TT genotype pass from high to medium-low disease activity. Such observations are in contrast to the 10.7% of the TG/GG genotype that pass from high to medium-low disease activity ($p = 0.03$).

Collective evaluation of laboratory results therefore suggests that in cases of rheumatoid arthritis classified according to response to the conventional therapy and by disease severity, there is a discernable trend toward a higher prevalence of the GG genotype for the exon 6 TNFRII polymorphism in less responsive cases displaying a more aggressive form of disease. In addition, the G allele tends to promote a lower degree of response to anti-TNF-α treatments.

Tumor necrosis factor-alpha receptor II polymorphism in patients from southern Europe with mild-moderate and severe rheumatoid arthritis. Fabris M, Tolusso B, Di Poi E, Assaloni R, Sinigaglia L, Ferraccioli G. J Rheumatol 2002 Sep; 29 (9), pp. 1847–50.

GENE DELIVERY AND TARGETING

Gene Delivery
Cationic Liposome-Mediated Gene Delivery/ Mechanisms of Intracellular Incorporation

Cellular/Molecular Mechanism of Action: Protection and/or selective delivery of diagnostic pharmaceuticals and biological/ genetic agents.
Application: Cationic liposome-mediated gene delivery as an alternative approach for promoting internalization of large lipoplex particles.
Interpretation and Analysis: Significant changes are observed in particle size and zeta potential of liposomes and their structures (assessed by atomic force microscopy) are created upon addition of DNA sequences. These alterations appear to be dependent on the relative (±) charge ratio that develops. Atomic force microscopy images reveal that lipoplexes are formed from extensively fused and apparently homogeneous lipid particles encapsulating DNA. Lipoplexes are internalized into cells by processes of endocytosis. Lipoplex-cell fusion occurs mainly at the plasma membrane level; however, this lipoplex-cell membrane fusion is essential for the uptake of the large particles.
Instrumentation: Atomic force microscopy.

Cationic liposome-mediated gene delivery: Biophysical study and mechanism of internalization. Almofti MR, Harashima H, Shinohara Y, Almofti A, Baba Y, Kiwada H. Arch Biochem Biophys 2003 Feb 15; 410 (2), pp. 246–53.

Gene Delivery
Cationic Liposomes

Background Information: Cationic liposomes are useful to transfer genes into eukaryotic cells *in vitro* and *in vivo*. However, liposomes with good transfection efficiency are often cytotoxic and also require serum-free conditions for optimal activity.
Route of Administration: Potentially variable.
Semi-Synthetic Methods: Formulation of cationic liposomes containing DC-6-14, O,O′-ditetradecanoyl-N-(α-trimethylammonioacetyl)diethanolamine chloride, dioleoylphosphatidylethanolamine, and cholesterol.
Interpretation and Analysis: Liposomes containing DC-6-14, O,O′-ditetradecanoyl-N-(α-trimethylammonioacetyl)diethan olamine chloride, dioleoylphosphatidylethanolamine and cholesterol dispersed in 5% serum-containing growth medium, efficiently deliver plasmid DNA for green fluorescent protein (GFP) into more than 80% of cultured human cell hybrids derived from HeLa cells and normal fibroblasts. Flow cytometric analysis reveals an efficiency of the GFP gene expression of 40 to 50% in tumor-suppressed cell hybrids, while it is greatly reduced in the tumorigenic counterpart. The enhanced GFP expression in tumor-suppressed cell hybrids is quantitatively well correlated with a prolonged presence of the plasmid DNA that has been labeled with the fluorescent probe ethidium monoazide within cells. Newly developed cationic liposomes appear to be useful for gene delivery into human cells bathed in serum-supplemented media, and the stability of the plasmid DNA inside the cell is a crucial step in liposome-mediated gene expression.

A new cationic liposome for efficient gene delivery with serum into cultured human cells: A quantitative analysis using 2 independent fluorescent probes. Serikawa T, Suzuki N, Kikuchi H, Tanaka K, Kitagawa T. Biochim Biophys Acta 2000 Aug 25; 1467 (2), pp. 419–30.

Gene Delivery/Hepatic Asialoglycoprotein
Glycosylated Cationic Liposomes

Cationic liposomes have been considered as a potential non-viral vector for gene delivery because they possess low immunogenicity, unlike viral vectors. The gene transfer efficiency of cationic liposomes is lower than that of viral vectors, but recent advances have shown that it is possible to enhance the gene expression levels for cationic liposomes. The main problem with cationic liposomes seems to be the lack of organ or cell selectivity because the lung has the highest level of gene expression after intravenous injection. Applying cell-specific targeting technology to liposomes would improve *in vivo* gene delivery and reduce any unexpected side effects. Both liver parenchymal and non-parenchymal cells exclusively express large numbers of high-affinity asialoglycoprotein and mannose receptors, respectively. Receptor-mediated gene delivery systems are able to introduce foreign DNA into specific cell types *in vivo*. However, the authors of the study discussed in the referenced paper have confirmed that not only the nature of the ligands grafted to carriers but also the overall physicochemical properties of the complexes need to be optimized for effective cell-selective targeting of plasmid DNA. In this article, the authors attempt to evaluate a gene delivery system based on the physicochemical properties of plasmid DNA/glycosylated cationic complexes.

Glycosylated cationic liposomes for cell-selective gene delivery. Kawakami S, Yamashita F, Nishida K, Nakamura J, Hashida M. Crit Rev Ther Drug Carrier Syst 2002; 19 (2), pp. 171–90.

Gene Delivery/Endothelium of Hepatic Sinusoids/ Antisense Oligonucleotide/[*In Vivo* Genetic Messenger RNA (mRNA) Expression]
Albumin-Coated Cationic Lipoplexes/Anti ICAM-1/ Antisense Oligonucleotides (ODN)/Cationic Lipid (DOTAP)/Polyethylene Glycol (PEG)/Aconitylated Albumin (AcoHSA)/Anti-ICAM-1-ODN-[DOTAP]-PEG-Neutral Lipid (Aco-HAS)

Background Information: Massive *in vivo* uptake of surface-modified (negatively charged) liposomes including AcoHSA preparations by liver sinusoidal endothelial cells (ECs) has been previously reported.
Route of Administration: Albumin-coated cationic lipoplexes (intravascular).
Semi-Synthetic Methods: Anti ICAM-1 ODN is complexed with the cationic lipid DOTAP and the complex coated by an excess of neutral lipids including a lipid-anchored poly(ethylene glycol). Aco-HSA is coupled to the coated cationic lipoplexes (CCLs).
Implementation: Plasma disappearance and organ and intrahepatic distribution of Aco-HSA modified CCLs can be determined using [^{3}H]-cholesteryl oleyl ether and [^{32}P]-labeled ODN as markers.
Animal Model: Rat.
Interpretation and Analysis: Aco-HSA coupled CCLs are $<$ 160 nm in size and contain 1.03 ± 0.35 nmol ODN and 54 ± 18 μg Aco-HSA per μmol total lipid. Such CCLs are rapidly eliminated from plasma with about 60% of the injected dose of [^{3}H]- or [^{32}P]-label entering the liver after 30 minutes. Within the liver, the ECs account for two-thirds of total liver uptake. Control non-targeted CCLs are eliminated very slowly because after 30 minutes, $>$ 90% of the particles are still present in the blood. Our results demonstrate efficient targeting of antisense ODN to EC *in vivo*, employing plasma-

stable coated cationic lipoplexes, surface modified with negatively charged albumin. Forty percent of the injected ODN is delivered to predetermined "target cells" within 30 minutes.

Massive and selective delivery of lipid-coated cationic lipoplexes of oligonucleotides targeted *in vivo* to hepatic endothelial cells. Bartsch M, Weeke-Klimp AH, Meijer DK, Scherphof GL, Kamps JA. Pharm Res 2002 May; 19 (5), pp. 676–80.

Gene Delivery/Endothelium of Vascular Structures and Melanoma
Liposomes: Artificial Virus (Vector) Particles

Semi-Synthetic Methods: A semi-synthetic liposome has been designed that can function as a vector in part due to its composition being formulated to mimic the properties of retroviral envelope structures (serum-resistant, non-toxic, $\leq$ 200 nm in size). The DNA is condensed using low molecular weight branched PEI.
Interpretation and Analysis: Addition of a cyclic Arg-Gly-Asp (RGD) peptide ligand to these particles as targeting device (i) renders them selective for tumor endothelial and melanoma cells that express high levels of $\alpha v\beta 3$-integrins; and (ii) allows for an efficient delivery of the enclosed genetic material. The specificity of the vector system for melanoma cells theoretically can be further improved by using a melanocyte-specific tyrosinase promoter to drive transgene expression.

A new colloidal lipidic system for gene therapy. Fahr A, Muller K, Nahde T, Muller R, Brusselbach S. J Liposome Res 2002 Feb–May; 12 (1–2), pp. 37–44.

Gene Delivery/Ophthalmic
PEO-PPO-PEO Non-Ionic Copolymeric Micelles/Plasmid DNA: lacZ Gene

Cellular/Molecular Mechanism of Action: Poly(ethylene oxide)-poly(propylene oxide)-poly(ethylene oxide) or PEO-PPO-PEO non-ionic copolymeric micelles can be used as a delivery modality for genetic DNA strands.
Application: Poly(ethylene oxide)-poly(propylene oxide)-poly (ethylene oxide) non-ionic copolymeric micelles can be applied as an *in vivo* carrier for eyedrop gene delivery of plasmid DNA (e.g., lacZ gene).
Implementation: Pyrene fluorescence probe methods, zeta potential, and dynamic light scattering test (DLS) can be applied to characterized micelle formation of PEO-PPO-PEO block copolymers with plasmids. Gene expressions can be visualized by both the quality of an enzymatic color reaction using X-gal staining and by the quantification of the substrate chlorophenol red galactopyranoside (CPRG) in enucleated eyes on day 2 after gene transfer. In addition, microscopy can be used to identify the types of cells showing uptake and expression of the transferred gene sequence.
Interpretation and Analysis: Block polymeric micelles are formed above 0.1% (w/v) of block copolymer with a size of 160 nm and a zeta potential of -4.4 mV. After 2 days of topical delivery 3 times a day, the most intense gene expression is observed on days 2 and 3. Reporter expression is detected around the iris, sclera, conjunctiva, and lateral rectus muscle of rabbit eyes and also in intraocular tissues of nude mice upon *in vivo* topical application for 48 hours with a DNA/polymeric micelle formulation. Furthermore, after 2 enhancement treatments, the transport mechanisms of the block copolymeric micelles are found through endocytosis in tissues by enhancement through the tight junction pathway. Thus, efficient and stable transfer of the functional gene can be achieved with PEO-PPO-PEO polymeric micelles through topical delivery in mice and rabbits. These *in vivo* experiments indicate the possible potential use of block copolymers for DNA transfer.

In vivo gene delivery into ocular tissues by eyedrops of poly(ethylene oxide)-poly(propylene oxide)-poly(ethylene oxide) (PEO-PPO-PEO) polymeric micelles. Liaw J, Chang SF, Hsiao FC. Gene Ther 2001 Jul; 8 (13), pp. 999–1004.

Gene Delivery (Oligonucleotides)/ Neoplasia (Solid Tumor)
Liposome: Cationic (100–200 nm)/Porphyrin Derivatives ($<$ 1 nm)/Branched-Chain Dendrimers (10 nm)/Polyethylenimine Polymers (10 nm)/ Nanoparticles (20–1,000 nm)/Microspheres ($>$ 1 μm)/ Cyclodextrins (CyDs 1.5 nm)

Background Information: The vasculature of a tumor provides the most effective route by which neoplastic cells may be reached and eradicated by drugs. The fact that a tumor's vasculature is relatively more permeable than healthy host tissue should enable selective delivery of drugs to tumor tissue. Such delivery is relevant to carrier-mediated delivery of genetic medicine to tumors. Cationic liposomes have been used for the introduction of nucleic acids into mammalian cells for more than a decade.
Application: Nucleic acid delivery into cells (*in vitro* and *in vivo*).
Semi-Synthetic Methods: Cationic liposomes are generally 100–200 nm in diameter, whereas cyclodextrins (CyDs) typically span 1.5 nm across.

Evaluate the potential of delivering therapeutic ONs to tumors using cationic liposomes and CyDs, and evaluate the major hindrances posed by the tumor itself on such delivery.
Interpretation and Analysis: Cyclodextrin molecules are routinely used as agents that engender cholesterol efflux from lipid-laden cells, thus having an efficacious potential in the management of atherosclerosis. A recent trend is to employ these oligosaccharide molecules for delivering nucleic acids in cells both *in vitro* and *in vivo*. Comparisons have been made with other oligonucleotide delivery agents, such as porphyrin derivatives ($<$ 1 nm), branched-chain dendrimers (approximately 10 nm), polyethylenimine polymers (approximately 10 nm), nanoparticles (20–1,000 nm), and microspheres ($>$ 1 μm), in the context of delivery to solid tumor. The chemical and physical properties of these carriers and how they may affect the uptake of oligonucleotides into cells, particularly *in vivo*, is of critical importance.

Vehicles for oligonucleotide delivery to tumors. Dass CR. J Pharm Pharmacol 2002 Jan; 54 (1), pp. 3–27.

Gene Delivery: Central Nervous System (Hippocampus)/Neuronal Nucleoli Entry
Anionic Liposomes/Liposome-Encapsulated Cy3-Labeled Oligonucleotides

Background Information: Anionic liposomes can efficiently introduce foreign DNA into postmitotic neurons and other cell types.
Application: Liposome-encapsulated Cy3-labeled oligonucleotides can be applied to deliver DNA sequences into the nucleus of CNS neurons.
Implementation: Evaluate the mechanism of liposome uptake established through characterization of internalization processes for anionic liposome-encapsulated Cy3-labeled oligonucleotides (AL-Cy3ONs) by hippocampal neurons.

Interpretation and Analysis: Uptake of AL-Cy3ONs is widespread and a function of time- and temperature-dependent variables, indicative of receptor-mediated endocytosis. The low-density lipoprotein receptor-related protein (LRP) is crucial for anionic liposome endocytosis because the receptor-associated protein or an anti-LRP antibody inhibits internalization, and fibroblasts lacking LRP do not internalize AL-Cy3ONs. Using selective endocytosis inhibitors, it can be determined that liposome endocytosis and intracellular transport require clathrin, dynamin, an intact cytoskeletal network, and phosphatidylinositol 3-kinase activity. Cy3ONs does not significantly co-localize with recycling endosomal/lysosomal markers and enter neuronal nuclei within 1 to 3 hours of incubation. Approximately 50% of the internalized liposomal phospholipids are recycled back to the cell surface, in keeping with the fluidity of their acyl chains. Liposome endocytosis does not require heparan sulfate proteoglycans or cause calcium influx into neurons. Thus, constitutive endocytosis of anionic liposomes by LRP utilizes only 1 component, in contrast to the more involved heparan sulfate proteoglycan-LRP pathway implicated in the pathogenesis of Alzheimer's disease.
Instrumentation: Confocal microscopy.

Low-density lipoprotein receptor-related protein mediates the endocytosis of anionic liposomes in neurons. Lakkaraju A, Rahman YE, Dubinsky JM. J Biol Chem 2002 Apr 26; 277 (17), pp. 15085–92.

Gene Delivery: *In Vivo*/Potential Strategy for the Detection of Messenger RNA (mRNA) Expression
Antisense Oligonucleotides Liposomes

Cellular/Molecular Mechanism of Action: Antisense constructs can be designed to bind to either specific sequences within genomic DNA or mRNA strands.
Physiological Mechanism of Action: Antisense constructs can be designed to block/inhibit either transcription (genomic DNA → mRNA) or translation (mRNA → protein) processes.
Background Information: Mice with a targeted mutation of the Hoxa10 gene demonstrate uterine factor infertility. It is unclear if the defect in the uterine environment arises due to the absence of Hoxa10 expression during embryonic development or in the adult. It has recently been demonstrated that HOXA10 expression in human endometrium rises dramatically at the time of implantation, suggesting maternal expression of Hoxa10/HOXA10 may be essential to the process.
Application: Delivery of DNA sequences (e.g., uterus).
Route of Administration: Intrauterine infusion.
Semi-Synthetic Methods: Oligonucleotide constructs that correspond to the "opposite-strand" of either specific genomic DNA or mRNA sequences.
Implementation: Utilization of DNA/liposomes to deliver oligonucleotide constructs capable of altering maternal Hoxa10 expression prior to implantation.
Animal Model: Mouse (gestation period = day 2).
Interpretation and Analysis: Transfection with a Hoxa10 antisense oligodeoxyribonucleotide significantly decreases the number of implantation sites. Transfection with a plasmid that constitutively expresses Hoxa10 optimizes survival of implanted embryos, resulting in increased litter size. Maternal Hoxa10 expression is therefore essential for implantation and is the 1st report of the maternal alteration of a gene known to affect implantation specifically. Furthermore, DNA/liposome complexes containing the same Hoxa10 constructs that alter fertility in mice can also affect Hoxa10 expression in a human endometrial cell line. Alteration of human endometrial HOXA10 via liposome-mediated gene transfection is a potential contraceptive agent or fertility treatment.

Alteration of maternal Hoxa10 expression by *in vivo* gene transfection affects implantation. Bagot CN, Troy PJ, Taylor HS. Gene Ther 2000 Aug; 7 (16), pp. 1378–84.

Gene Delivery: Macrophages/Kupffer Cells (KCs)/ Transgene Expression (Enhanced/Prolonged)/ Enhanced Adenoviral Vector Delivery
Clodronate Liposomes

Background Information: Tissue macrophages, in particular hepatic KCs, contribute to early inflammatory responses following adenoviral vector administration.
Implementation: Evaluate the effect of selective and transient (3 days) depletion of hepatic KCs by a single injection of clodronate liposomes on the *in vivo* performance of high-capacity adenoviral (HC-Ad) vectors.
Interpretation and Analysis: Interestingly, in the majority of animals of both strains, depletion of KCs is sufficient to prevent the generation of anti-hAAT antibodies, resulting in prolonged transgene expression. Thus, short-term and selective depletion of hepatic macrophages at the same time significantly increases hepatic transgene expression and reduces the humoral immune response to the transgenic protein.

Selective depletion or blockade of Kupffer cells leads to enhanced and prolonged hepatic transgene expression using high-capacity adenoviral vectors. Schiedner G, Hertel S, Johnston M, Dries V, van Rooijen N, Kochanek S. Mol Ther 2003 Jan; 7 (1), pp. 35–43.

Gene Delivery: Neoplasia/Ovarian Carcinoma/ Plasmid Transfection/Non-Viral Vector Platform/ Green Fluorescent Protein (GFP)/DDC/DNA Complex
Cationic DOTAP:DOPE:Cholin Liposomes

Application: Various attempts have been made to design strategies and efficient protocols for ovarian cancer gene therapy, but there has been little progress in their clinical application.
Semi-Synthetic Methods: Preparations of DDC liposome are produced by mixing DOTAP:DOPE:Cholin at a 1:0.7:0.3 molar ratio using the extrusion method.
Implementation: Plasmid DNA (pEGFP-C1) and DDC are complexed at various weight ratios to find the optimum efficacy. The percentage of transfected cells is determined by selecting a GFP expressing cells using flow cytometry instrumentation. The transfection efficiency of the DDC liposome is compared with 3[N-(N,N-dimethylaminoethylene) carbamoyl] cholesterol (DC-Chol)/DOPE liposome and commercially available lifopectin.
Interpretation and Analysis: Evaluation of the capacity for cationic liposomes of dioleoyltrimethylaminopropane (DOTAP), 1,2-dioleoyl-3-phosphophatidylethanolamine (DOPE), and cholesterol (Chol)(DDC) to facilitate plasmid DNA transfer into ovarian cancer cells. The optimal transfection of plasmid DNA can be achieved at a 1:4 (w/w) ratio of DDC to DNA. The DDC/DNA complex exhibits higher transfection efficiency in human ovarian cancer cells (OVCAR-3 and SK-OV-3 cells) compared to that in other types of cell lines (NCI-NIH:522 and HepG2 cells). Flow cytometric analysis reveals that the DDC/DNA complex exhibits an over 4-fold increase in GFP expression levels compared with DC-Chol/DOPE or lipofectin in OVCAR-3 cells. Such findings can be further confirmed by confocal microscopy and reverse transcriptase-polymerase chain reaction (RT-PCR) analysis. Therefore, cationic liposome (DDC) appears to be a promising non-viral vector for treating ovarian adeno-

carcinoma because of its selective high gene transfer ability in ovarian cancer cells.

Instrumentation: Flow cytometry.

Non-viral vector for efficient gene transfer to human ovarian adenocarcinoma cells.Kim CK, Haider KhH, Choi SH, Choi EJ, Ahn WS, Kim YB. Gynecol Oncol 2002 Jan; 84 (1), pp. 85–93.

Gene Delivery: Neoplasia Oncogene Detection Strategy/Melanoma c-myc Oncogene/ Neuroblastoma Disialoganglioside (GD_2)
Cationic Immuno-Lipsomes/Anti-Disialoganglioside (GD_2)

Background Information: Melanoma is a highly malignant and increasingly common tumor. Because the cure rate of metastatic melanoma by conventional treatment is very low, new therapeutic approaches are needed. Reports have previously described that coated cationic liposomes (CCL) targeted with a monoclonal antibody against the GD_2 and containing c-myb antisense oligodeoxynucleotides (asODNs) result in a selective inhibition of the proliferation of GD_2-positive neuroblastoma cells *in vitro*.

Application: Selective delivery to melanoma and neuroblastoma neoplastic cell types.

Route of Administration: Intravascular.

Implementation: Evaluation of the selective *in vivo* delivery capabilities of antisense liposomal formulations with antineoplastic properties that target the c-myc oncogene of melanoma, a neuroectodermal tumor sharing with neuroblastoma the expression of GD_2.

Interpretation and Analysis: Preparations of stable GD_2-targeted liposomes can be produced that entrap 90% of added c-myc asODNs. Such liposomes show a selective binding for GD_2-positive melanoma cells *in vitro*. Melanoma cell proliferation is inhibited to a greater extent by GD_2-targeted liposomes containing c-myc asODNs (aGD_2-CCL-myc-as) than by non-targeted liposomes or free asODNs. The pharmacokinetic results obtained after intravenous injection of [^{3}H]-myc-asODNs, free or encapsulated in non-targeted CCLs or GD_2-targeted CCLs, reveal that free c-myc-asODNs are rapidly cleared, with less than 10% of the injected dose remaining in blood at 30 minutes after injection. Sequences of c-myc-asODNs encapsulated within either CCL or aGD_2-CCL demonstrate a more favorable profile in blood, with about 20% of the injected dose of each preparation remaining *in vivo* at 24 hours after injection. In an *in vivo* melanoma experimental metastatic model, aGD_2-CCL-myc-as, at a total dose of only 10 mg of asODN per kilogram, significantly inhibits the development of microscopic metastases in the lung compared with animals treated with myc-asODNs, free or entrapped in non-targeted liposomes, or aGD_2-CCL encapsulating scrambled asODNs ($p < 0.01$). Moreover, mice bearing established subcutaneous human melanoma xenografts treated with aGD_2-CCL-myc-as exhibits significantly reduce tumor growth and increase survival ($p < 0.01$ vs control mice). The mechanism for the antitumor effects appears to be associated with a downregulation of c-myc protein expression and interruption of c-myc-mediated signaling: induction of p53 and inhibition of Bcl-2 proteins, leading to extensive tumor cell apoptosis. Such observations suggest that inhibition of c-myc proto-oncogene by GD_2-targeted antisense therapy could provide an effective approach for the treatment of melanoma in an adjuvant setting.

Targeted liposomal c-myc antisense oligodeoxynucleotides induce apoptosis and inhibit tumor growth and metastases in human melanoma models. Pastorino F, Brignole C, Marimpietri D, Pagnan G, Morando A, Ribatti D, Semple SC, Gambini C, Allen TM, Ponzoni M. Clin Cancer Res 2003 Oct 1; 9 (12), pp. 4595–605.

Gene Delivery: Neoplastic Disease/Prostatic Carcinoma: Potential Messenger RNA (mRNA) Detection Strategy
[Gd]-Anti-mRNA Oligonucleotide Strand/Trans-Membrane Carrier Peptide

Cellular/Molecular Mechanism of Action: The physical properties/orientation of gadolinium becomes altered when placed within a magnetic field. Trans-membrane carrier proteins are transported across cell membrane structures by specific membrane-associated complexes. Oligonucleotides can be designed as the complementary sequence to specific mRNA strands and the resulting cDNA/mRNA duplex effectively prevents translation of the mRNA strand. Diagnostically, complementary strands of cDNA theoretically would accumulate intracellularly within cells that are actively transcribing the corresponding mRNA sequence that cDNA strands have been designed to recognize.

Background Information: The term "molecular imaging" can be broadly defined as the *in vivo* characterization and measurement of biological processes at the cellular and molecular level.

Application: Concept and methodology strategy for diagnostically detecting *in vivo* gene expression by magnetic resonance imaging (MRI). Example: Specific oncogenes within neoplastic cell types.

Route of Administration: Intravenous may be the preferred method of delivery.

Semi-Synthetic Methods: Development of a novel intravital and intracellular MRI contrast agent composed of a gadolinium complex, an oligonucleotide sequence (peptide nucleic acid [PNA]), and a trans-membrane carrier peptide that is composed of a peptide sequence similar to that of the homeodomain of the Antennapedia protein.

Implementation: Determine if [Gd]-oligonucleotide complexes (i) can accumulate in tumor cells *in vitro* and *in vivo*; and (ii) whether the specificity of a PNA for the upregulated c-myc mRNA in the cell's cytoplasm has an effect on contrast agent retention within tumor cells.

Tissue Culture Model: HeLa cell lines.

Animal Model: Rat (Dunning R3327 AT1 rat prostate adenocarcinoma).

Intracellular visualization of prostate cancer using magnetic resonance imaging. Heckl S, Pipkorn R, Waldeck W, Spring H, Jenne J, von der Lieth CW, Corban-Wilhelm H, Debus J, Braun K. Cancer Res 2003 Aug 15; 63 (16), pp. 4766–72.

Gene Delivery-Expression/Neoplasia (Green Fluorescent Protein [GFP])/Detection of Future Regional and Distant Metastases
Retrovirus

Cellular/Molecular Mechanism of Action: Retroviral agents expressing the GFP gene are capable of inserting their genome into certain mammalian cell populations. Cells that have been transfected by such retroviral agents express the GFP gene and emit a green color when exposed to certain wavelengths of light.

Application: Visualization of future regional and distant metastases.

Route of Administration: Intraperitoneal (other routes possible).

Implementation: Green fluorescent protein retroviral supernatants are injected intraperitoneally from day 4 to day 10 after implantation of gastric cancer cells. Tumor and metastasis fluorescence are then visualized every other week with the use of fluorescence optics via a laparotomy on the tumor-bearing animals.

Animal Model: Mouse (intraperitoneally growing human gastric neoplasia).

Interpretation and Analysis: At 2 weeks after retroviral GFP delivery, GFP-expressing tumor cells can be observed in gonadal fat, greater omentum, and intestine, indicating that these primary intraperitoneally growing tumors can be efficiently transduced by the GFP gene and can be visualized by its expression. At 2nd and 3rd laparotomies, GFP-expressing tumor cells can be observed spreading to lymph nodes in the mesentery and other regional sites. At the 4th laparotomy, widespread tumor growth is visualized by GFP expression, inducing liver metastasis. Normal tissues are rarely transduced by the GFP retrovirus. Thus, reporter gene transduction of the primary tumor can enable detection of its subsequent metastasis. This gene therapy/diagnostic model could be applied to primary tumors before resection or other treatment to have a fluorescent early detection system for metastasis and recurrence.

In vivo tumor delivery of the green fluorescent protein gene to report future occurrence of metastasis. Hasegawa S, Yang M, Chishima T, Miyagi Y, Shimada H, Moossa AR, Hoffman RM. Cancer Gene Ther 2000 Oct; 7 (10), pp. 1336–40.

Gene Delivery-Transfer/Central Nervous System (CNS)
Liposome/Plasmid DNA Complexes/[Lipoplexes]

Background Information: Acute cerebral ischemia causes hypoxic neuronal cell death by necrosis and apoptosis. Expression of antiapoptotic transgenes in ischemic brain may provide a useful therapeutic strategy for alleviation of postischemic damage.

Route of Administration: Lipoplexes (intrathecal).

Implementation: Evaluation of the potential for liposomes to mediate transfer of human bcl-2 protein into the CNS during conditions of focal transient cerebral ischemia. Two different types of plasmid vectors can be used for bcl-2 expression: (i) 1 driven by the constitutive cytomegalovirus promoter (pCMV), and (ii) a 2nd based on the hypoxia-inducible human vascular endothelial growth factor promoter (pHRE). Cationic liposome/plasmid DNA complexes (lipoplexes) are injected directly into the cerebrospinal fluid (CSF) of rats immediately after middle cerebral artery (MCA) occlusion. The brains of treated and control animals are analyzed 48 hours later. Infarct volumes and numbers of apoptotic cells are then quantified.

Animal Model: Rat (focal transient ischemia created by MCA occlusion).

Interpretation and Analysis: Occlusion of the MCA results in ipsilateral cerebral infarcts. Transfer of the bcl-2 gene results in high-level widespread protein expression in the case of the pCMV-bcl2 plasmid, while animals treated with the pHRE-bcl2 vector show lower expression levels of bcl2 that are limited to areas of ischemia. Treatment with pCMV-bcl2, but not with pHRE-bcl2, is able to significantly reduce infarct volumes (109 ± 8 mm^3 for pCMV-bcl2; 152 ± 29 mm^3 for pHRE-bcl2; and 155 ± 18 mm^3 for control animals). Animals transfected with either of the 2 vectors have significant reductions in apoptotic cell numbers within infarcts and penumbra area compared to controls. There are no short-term neurological side effects from CSF lipoplex injection or bcl-2 expression. Hypoxia-inducible bcl-2 expression mediated by intrathecal lipoplexes may represent a novel, biologically safe, and lesion-selective diagnostic and therapeutic approach for detection and neuroprotection after acute cerebral ischemia.

Liposome-mediated transfer of the bcl-2 gene results in neuroprotection after *in vivo* transient focal cerebral ischemia in an animal model.Cao YJ, Shibata T, Rainov NG. Gene Ther 2002 Mar; 9 (6), pp. 415–9.

Gene Delivery-Transfer/Endothelium: Capillaries in Central Nervous System (CNS)/Gene Transfer Model
Hemagglutination Virus of Japan (HVJ)-Liposomes/ Liposome Encapsulated β-Gal Plasmid

Background Information: Bioactive proteins or peptides cannot be effectively delivered into brain capillary endothelial cells (BCECs) or brain parenchyma.

Route of Administration: Superselective internal carotid artery catheterization.

Implementation: Evaluation of the effectiveness of transferring the *Escherichia coli* β-galactosidase gene (β-gal) as a model gene into BCECs utilizing the HVJ-liposomes. HVJ-liposomes encapsulating a β-gal plasmid can be used *in vitro* to transfect mouse brain capillary endothelial cells (MBEC4) cells and also delivered *in vivo* by selective administration.

Animal Model: Rat via the internal carotid artery.

Interpretation and Analysis: Success of the procedure is confirmed by the detection of 116 kDa β-gal protein in transfected MBEC4 cells and in brain capillaries isolated from transfected rats, by Western blot analysis and histological staining. The enzymatic activities of β-gal are 5- to 10-fold and 20-fold higher than when β-gal-containing liposomes without fusogenic activity (uncoated liposomes) or plasmid alone are employed *in vitro* and *in vivo*, respectively. Thus, HVJ-liposomes have demonstrated applicability as a vector for the transfer of foreign genes into brain capillary endothelium *in vivo* (transluminal route).

Transluminal gene transfer into brain capillary endothelial cells *in vivo* with HVJ-liposomes.Jiang C, Matsuo H, Koyabu N, Ohtani H, Fujimoto H, Yonemitsu Y, Kaneda Y, Narro M, Tsuruo T, Sawada Y. J Drug Target 2002 Jun; 10 (4), pp. 345–52.

Gene Delivery-Transfer/Endothelium: Central Nervous System (CNS) Capillaries/Gene Transfer Model
Hemagglutination Virus of Japan (HVJ)-Liposomes/ Liposome Encapsulated β-Gal Plasmid

Application: Gene delivery into the CNS (e.g., evaluation of the protective effect for dopamine neuron against a retrograde 6-hydroxydopamine [6-OHDA]).

Route of Administration: HVJ-liposomes (internal carotid artery).

Semi-Synthetic Methods: The gene encoding mouse glial cell-derived neurotrophic factor (mGDNF gene) can be transfected into brain capillary endothelial cells (BCECs) with the aim of delivering the gene product extensively into the brain parenchyma by making use of BCEC secretory function. First, the mGDNF gene is transfected *in vitro* into cultured BCECs (mouse brain capillary endothelial cells [MBEC4]). The amount of mGDNF protein secreted from the transfected cells into the medium is about 1,500 to 3,200 pg/mg of cell protein/day, or about 7-fold higher than that accumulated intracellularly. Furthermore, the basolateral-directed secretion of mGDNF protein from the transfected MBEC4 cells is 5-fold higher than the apical-directed secretion.

Implementation: Evaluation of the capacity of the HVJ-liposomes to deliver an encapsulated gene (e.g., mGDNF) into the CNS.

Animal Model: Rat.

Interpretation and Analysis: Transfected rats show a marked increase in the brain level of GDNF as assessed by means of ELISA and Western blotting on day 3 after the administration, and the level remains significantly elevated for at least 12 days. Furthermore, im-

munohistochemical staining reveals an increase in GDNF immunoreactivity throughout the transfected forebrain. Such profiles indicate that the gene can be successfully transferred *in vivo* from HVJ-liposomes into BCECs, where it is expressed, and the gene product is secreted into the brain. Using this delivery method, the protective effect for dopamine neuron against a retrograde 6-hydroxydopamine (6-OHDA) lesion can be evaluated and assessed as a function of behavioral and neurochemical indices.

In vivo delivery of glial cell-derived neurotrophic factor across the blood-brain barrier by gene transfer into brain capillary endothelial cells. Jiang C, Koyabu N, Yonemitsu Y, Shimazoe T, Watanabe S, Naito M, Tsuruo T, Ohtani H, Sawada Y. Hum Gene Ther 2003 Aug 10; 14 (12), pp. 1181–91.

Gene Delivery-Transfer/Neoplasia: Central Nervous System (CNS) Gliosarcoma
TEAPC-Chol/DOPE Cationic Liposome/Precondensing Plasmid DNA with Poly-L-Lysine/Polyethylene Glycol (PEG)

Application: Delivery and transfection of genetic DNA sequences into cells within the CNS.
Semi-Synthetic Methods: Cationic liposome can be prepared from triethyl aminopropane carbamoyl cholesterol (TEAPC-Chol) and a helper lipid, dioleoylphosphatidylethanolamine (DOPE).
Implementation: Evaluation of a strategy for transfecting genes into gliosarcoma cell lines (9L) using an original cholesterol-based cationic liposome as carrier.
Animal Model: Murine (nude mice).
Interpretation and Analysis: Liposomes at specific concentrations are not cytotoxic based on 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) analysis. TEAPC-Chol/DOPE liposomes allow plasmids encoding reporter genes to enter the nucleus as observed both by electron microscopy and functionality tests using fluorescence detection of green fluorescent protein (GFP) and luminometric measurements of luciferase activity. By changing the cationic lipid/DNA molar charge ratio, optimal conditions can be determined. Further, improvement of the transfection level can be obtained by either precondensing plasmid DNA with poly-L-lysine or by adding PEG in the transfection medium. The optimal conditions determined are different depending on whether the transfection is made with cells in culture or with tumors induced by subcutaneous injection of cells in nude mice. For *in vivo* assays, a simple method to overcome the interference of hemoglobin with the chemiluminescence intensity of luciferase has been used. These results would be useful for gaining knowledge about the potential for the cationic liposome TEAPC-Chol/DOPE to transfect brain tumors efficiently.

Evaluation and optimization of DNA delivery into gliosarcoma 9L cells by a cholesterol-based cationic liposome.Lesage D, Cao A, Briane D, Lievre N, Coudert R, Raphael M, Salzmann J, Taillandier E. Biochim Biophys Acta 2002 Aug 31; 1564 (2), pp. 393–402.

Gene Delivery-Transfer/Neoplasia: Leukemia (Hairy-Cell Type)
Human Papilloma Virus/Epstein-Barr Virus/Antisense Nucleic Acids

Cellular/Molecular Mechanism of Action: Antisense oligonucleotides, are small chains of nucleic acids capable of binding to cellular RNA sequences (hybridization).
Application: Antisense oligonucloetides can be applied as diagnostic and therapeutic pharmaceuticals. In the field of nuclear imaging, radiolabeled antisense oligonucleotides can be applied as a diagnotic imaging modality.
Considerations: The use of anti-sense oligonucleotides as *in vivo* diagnostic agents is attractive because it brings molecular imaging to a level of detecting real-time gene expression.
Interpretation and Analysis: Oligonucleotides are non-canonical radiopharmaceuticals and much progress is needed to adapt them to *in vivo* imaging. The requirements to reach this goal include improvements in radiosynthesis, stability, targeting, and specific and non-specific binding.

Simultaneous detection by non-isotopic *in situ* hybridization of human papilloma viruses and Epstein-Barr virus during the lytic cycle in oral hairy leukoplakia lesions. Courtade M, Brousset P, Delsol M, Gorguet B, Viraben R, Voigt JJ, Delsol G. Ann Pathol 1992; 12 (6), pp. 353–7.

Gene Delivery-Transfer-Expression/Lymphocytes/ Hunter's Syndrome: Iduronate-2-Sulfatase (IDS)
Peripheral Lymphocyte-Mediated Delivery/Retroviral Vectors

Cellular/Molecular Mechanism of Action: Utilization of the natural (native) homing properties of peripheral blood lymphocytes to selectively deliver diagnostic agents.
Application: Example: Hunter's syndrome (peripheral blood lymphocytes (PBL[MPS]).
Route of Administration: Intravenous.
Biological Preparation and Analysis: Utilizing PBLs from Hunter's syndrome patients (PBL[MPS]), the expression of IDS can be induced through the use of 3 different promoter segments associated with 4 retroviral vectors (i.e., the long-term repeat, or LTR, in vectors L2SN and L2, avian β-actin promoter in LB2, and the cytomegalovirus [CMV] early promoter in LNC2). The production of PBL(MPS) in this manner involves exposure to packaging cell supernatant resulting in transduction frequencies ranging 10-fold between 5 and 49%.

Surprisingly, IDS activities were equally high in all transduced lymphocyte populations: 515 U/mg/hr in PBL(MPS)-L2SN, 734 in PBL(MPS)-LB2, 352 in PBL(MPS)-L2, and 389 in PBL(MPS)-LNC2 compared to controls (< 10 in PBL(MPS)-LXSN or PBL (MPS)). The half-life of endocytosed IDS in PBL(MPS) is approximately 1.9 days. However, the level of lymphocyte IDS activity from proviral expression is only a fraction of the total, a large portion being derived from reuptake of enzyme from murine packaging cells, or a "2nd source" of enzyme.
Considerations: Measurement of transgene lysosomal enzyme soon after exposure of target cells to vector supernatant may yield a gross overestimate of long-term transgene expression by transduced cells. Nevertheless, patient fibroblasts co-cultured with transduced PBL(MPS) have reduced [$^{35}SO^{4}$]-GAG accumulation, levels similar to those of normal fibroblasts.
Interpretation and Analysis: Cells can be charged with a lysosomal enzyme to levels much higher than those found in nature. By "supercharging" cells with a lysosomal protein (or other molecule bearing the mannose-6-phosphate ligand), such cells may be exploited as vehicles for systemic delivery of therapeutic or diagnostic agents.

Combined ultrafiltration -transduction in a hollow-fiber bioreactor facilitates retrovirus-mediated gene transfer into peripheral blood lymphocytes from patients with mucopolysaccharidosis type II.Pan D, Shankar R, Stroncek DF, Whitley CB. Hum Gene Ther 1999 Nov 20; 10 (17), pp. 2799–810.

Gene Delivery-Transfer-Expression/Pulmonary Expression: Cystic Fibrosis (CF)/Trans-Membrane Conductance Regulator Gene
(CFTR-DNA)-DC-Chol/DOPE Cationic Liposomes/ Genetic DNA Sequences

Background Information: The major cause of mortality in patients with CF is lung disease. Expression of the CF trans-membrane conductance regulator (CFTR) gene product in the airways is a potential treatment. Clinical studies in which the CFTR cDNA is delivered to the respiratory epithelia of CF patients have resulted in modest, transient gene expression. It seems likely that repeated administration of the gene transfer vector will be required for long-term gene expression.

Application: Delivery of genetic DNA sequences (*in vitro* and *in vivo*) into cell populations to induce selective gene expression.

Route of Administration: DNA/liposome formulation (intravascular).

Implementation: Evaluation of multiple doses of a DNA/liposome formulation for their ability to serve as a delivery platform into nasal epithelium (double blinded study). Complementary *in vivo* investigations can employ the administration of plasmid DNA expressing the CFTR cDNA complexed with DC-Chol/DOPE cationic liposomes (e.g., n = 10; n = 2 placebo controls). Each case receives 3 doses, administered 4 weeks apart.

***Ex Vivo* Model:** Nasal epithelium harvested from cases of CF.

Human Model: Cases of CF.

Interpretation and Analysis: There is no evidence of inflammation, toxicity, or an immune response toward the DNA/liposomes or the expressed CFTR. Nasal epithelial cells are collected 4 days after each dose for a series of efficacy assays including quantitation of vector-specific DNA and messenger RNA (mRNA), immunohistochemistry of CFTR protein, bacterial adherence, and detection of halide efflux *ex vivo*. Airway ion transport is also assessed *in vivo* by repeated nasal potential difference measurements. On average, 60% of the treated subjects can be expected to be positive for CFTR gene transfer after each dose. All subjects positive for CFTR function are also positive for plasmid DNA, plasmid-derived mRNA, and CFTR protein.

Repeat administration of DNA/liposomes to the nasal epithelium of patients with cystic fibrosis.Hyde SC, Southern KW, Gileadi U, Fitzjohn EM, Mofford KA, Waddell BE, Gooi HC, Goddard CA, Hannavy K, Smyth SE, Egan JJ, Sorgi FL, Huang L, Cuthbert AW, Evans MJ, Colledge WH, Higgins CF, Webb AK, Gill DR. Gene Ther 2000 Jul; 7 (13), pp. 1156–65.

Gene Delivery-Transfer-Expression/Stem Cells: Hematopoietic/EGFP and LNGFR Hematopoietic Stem Cell (HSC) Populations
Retroviral Vectors

Background Information: Retroviral vectors are widely used to deliver foreign genes to HSCs. Improvement of marking protocols allows for reporter genes to be rapidly detected and efficient selection of transduced cells. Both EGFP and LNGFR hold great potential as reporter systems and can be used simultaneously to compare their properties using the same retroviral backbone and the same gene transfer procedures.

Application: Delivery of genetic sequences for their expression in mammalian cell systems. Such strategies could theoretically be utilized to deliver sense or antisense nucleotide strands for various diagnostic purposes.

Implementation: The EGFP and LNGFR coding sequences are separately cloned into an MFG retroviral vector backbone. A cloning strategy that assures that both genes utilize the same ATG as the start codon can be applied. Marker gene expression, viral titers, transduction efficiency, and vector stability can be evaluated in expanded amphotropic packaging clones and human hematopoietic cell lines by flow cytometry and polymerase chain reaction (PCR) analysis. Vectors are also tested for their ability to transduce CD34+ peripheral blood cells.

Interpretation and Analysis: A significantly larger number of MFG-LNGFR packaging clones are obtained that produced high viral titers. A direct correlation between viral titer and marker gene expression in packaging clones can be demonstrated for both constructs. Similar expression kinetics and absence of *in vitro* toxicity in transduced cells are also observed for both constructs. Successful infection of CD34+ cells can be achieved after only a short time of exposure to recombinant viruses.

The marker genes EGFP and LNGFR have been demonstrated to be equally useful for a rapid, specific, and non-toxic detection of transduced cells. The MFG-EGFP construct appears useful to optimize gene transfer protocols *in vitro*. On the other hand, the MFG-LNGFR construct, for making possible a more efficient selection of high titer producer clones, as well as for safety and adaptability to the *in vivo* use, is more suitable for clinical applications.

A comparative evaluation of gene transfer into blood cells using the same retroviral backbone for independent expression of the EGFP and delta LNGFR marker genes. Giaretta I, Madeo D, Bonaguro R, Cappellari A, Rodeghiero F, Giorgio P. Haematologica 2000 Jul; 85 (7), pp. 680–9.

Gene Transfer (Selective): Neoplastic Disease
Plasmid/Transferrin-PEG-Polyethylenimine/TNF-cDNA

Considerations: Tumor-targeting DNA complexes that can readily be generated by the mixing of stable components and freeze-thawed would be very advantageous for their subsequent application as diagnostic/therapeutic products.

Semi-Synthetic Methods: Complexes are formulated by the mixing of plasmid DNA, linear polyethylenimine (PEI22, 22 kDa) as the main DNA condensing agent, PEG-PEI (poly(ethylene glycol)-conjugated PEI) for surface shielding, and Tf-PEG-PEI (transferrin-PEG-PEI) to provide a ligand for receptor-mediated cell uptake.

Within the shielding conjugates, PEG chains of varying size (5, 20, or 40 kDa) are conjugated with either linear PEI22 (22 kDa) or branched PEI25 (25 kDa). The 3 polymer components are mixed together at various ratios with DNA; particle size, surface charge, *in vitro* transfection activity, and systemic gene delivery to tumors for subsequent detection. In general, increasing the proportion of shielding conjugate in the complex reduces surface charge, particle size, and *in vitro* transfection efficiency in transferrin receptor-rich K562 cells.

Interpretation and Analysis: The particle size or surface charge of the complexes containing the PEG-PEI conjugate does not significantly change after freeze-thawing, while complexes without the shielding conjugate aggregate. Complexes containing PEG-PEI conjugate efficiently transfected K562 cells after freeze-thawing. Furthermore, the systemic application of freeze-thawed complexes exhibits *in vivo* tumor targeted expression. For complexes containing the luciferase reporter gene the highest expression is found in tumor tissue of mice. An optimum formulation for *in vivo* application, PEI22/Tf-PEG-PEI/PEI22-PEG5, containing plasmid DNA encoding for the tumor necrosis factor-alpha (TNF-α), inhibits tumor growth in 3 different murine tumor models. These new DNA complexes offer simplicity and convenience, with tumor targeting activity *in vivo* after freeze-thawing.

Novel shielded transferrin-polyethylene glycol-polyethylenimine/DNA complexes for systemic tumor-targeted gene transfer. Kursa M, Walker GF, Roessler V, Ogris M, Roedl W, Kircheis R, Wagner E. Bioconjug Chem 2003 Jan–Feb; 14 (1), pp. 222–31.

GENE EXPRESSION

Gene Expression
Phosphoric Diester-Modified Oligonucleotides

Cellular/Molecular Mechanism of Action: Oligonucleotide phosphorothioates are modified oligonucleotides. Some of these incorporate "hairpin" structures at the 3′ end or are "chimeras" that bear 2 modified oligonucleotides. To further enhance their effectiveness, bioreversible analogs of oligonucleotides can be synthesized. Several isosteric analogs of phosphoric diester oligonucleotides with neutral achiral backbones, and other novel molecules, such as peptide nucleic acids and circular oligonucleotides, are also reported to form stable duplexes with complementary RNA/DNA strands.
Interpretation and Analysis: Oligonucleotides can be synthesized that carry a variety of fluorescent tags that are effective as probes in a manner that makes them suitable as potential diagnostic agents.

Modified oligonucleotides as therapeutic and diagnostic agents. Agrawal S, Iyer RP. Curr Opin Biotechnol 1995 Feb; 6 (1), pp. 12–9.

Gene Expression/Double-Strand DNA Selective Targeting
Circular Triplex-Forming Oligonucleotides (CTFOs)

Cellular/Molecular Mechanism of Action: Circular triplex-forming oligonucleotides possess tight binding avidity for short single-stranded homopurine DNAs in a sequence-specific manner. Recent investigations have demonstrated their ability to bind to double-helical DNA segments.
Considerations: Binding experiments with DNA show that a CTFO can recognize its homopurine target when the target is embedded in a long duplex. Unlike their linear oligonucleotides, CTFOs bind the double helix in 2 topologically distinct forms. The more stable of the 2 complexes is found to be a pseudorotaxane, having the same topology as the sliding clamp protein subunits associated with some DNA and RNA polymerases.
Interpretation and Analysis: Circular triplex-forming oligonucleotides have been shown to bind the DNA double helix in a topological manner that is unprecedented among synthetic ligands. This novel binding motif allows a synthetic CTFO to be irreversibly locked onto a circular double-stranded DNA target without covalently modifying the target.

Triplex-directed self-assembly of an artificial sliding clamp on duplex DNA. Ryan K, Kool ET. Chem Biol 1998 Feb; 5 (2), pp. 59–67.

Gene Expression: Altered Gene Function/Mutation
Mu-lac Transducing Phage

Application: Assay for transcription of genes to detect alterations in gene function, regulation, and mutation. Potential model for mammalian genome systems.
Interpretation and Analysis: Bacterial lactose structural genes without the lactose promoter can be incorporated into the bacteriophage Mu genome to form a Mu-lac specialized transducing phage. This phage also carries a gene encoding resistance to ampicillin (Ap)[Mu(Ap, lac)]. After infection and upon establishment of lysogeny, the Mu(Ap, lac) genome can integrate into apparently random sites within the *Escherichia coli* chromosome. When integration occurs within a gene in the orientation of its transcription, the lactose structural genes are so situated that they become expressed solely from the promoter of that gene. Thus, expression of the lactose genes of Mu(Ap, lac) can be used as an assay for transcription of that gene and for functional and mutational studies of gene regulation.

Lactose genes fused to exogenous promoters in 1 step using a Mu-lac bacteriophage: *In vivo* probe for transcriptional control sequences. Casadaban MJ, Cohen SN. Proc Natl Acad Sci U S A 1979 Sep; 76 (9), pp. 4530–3.

Gene Expression: Cardiac/Myocardium/Imaging the Location, Magnitude, and Time Course of Gene Expression
Adenovirus-Expressing Firefly Luciferase/D-Luciferin

Cellular/Molecular Mechanism of Action: D-luciferin is a fluorescent substrate for firefly luciferase enzyme fractions.
Background Information: Studies of cardiac gene transfer rely on postmortem analysis using histologic staining or enzyme assays. Non-invasive imaging of the temporal and spatial characteristics of cardiac gene expression in the same subject offers significant advantages.
Application: Fluorescent marker system for validating the positive detection of gene-specific transcription processes.
Route of Administration: D-luciferin can be injected intraperitoneally following adenovirus-facilitated firefly luciferase gene expression.
Implementation: Direct myocardial injection via left thoracotomy with adenovirus-expressing firefly luciferase (Ad-CMV-Fluc; n = 30). The reporter substrate D-luciferin can be injected intraperitoneally. Serial images are acquired by use of a cooled charged-coupled device (CCD) camera. Results are expressed as relative light unit per minute (RLU/min). To assess the detection sensitivity, serially diluted titers of Ad-CMV-Fluc can be injected: 1×10^9 (195,393 ± 14,896), 1×10^8 (33,777 ± 18,179), 1×10^7 (417 ± 91), 1×10^6 (185 ± 64), 1×10^5 (53 ± 1), and control (54 ± 1) ($p < 0.05$ for 1×10^9, 1×10^8, and 1×10^7 plaque-forming units vs control adenovirus-expressing mutant thymidine kinase [Ad-CMV-HSV1-sr39tk]; n = 3).
Animal Model: Rat.
Interpretation and Analysis: Rats transduced with 1×10^9 plaque-forming units show decremental cardiac luciferase activity over time: 152,070 ± 21,170 (day 2), 195,806 ± 62,630 (day 5), 7,250 ± 2,941 (day 8), and 2,040 ± 971 RLU/min (day 14). Rats are sacrificed, and *in vitro* luciferase activity correlated with *in vivo* CCD signals ($r^2 = 0.92$). Such observations demonstrate the feasibility of imaging the location, magnitude, and time course of cardiac reporter gene expression in living rats. Cardiac gene therapy studies could be aided with wider application of this approach.

Optical imaging of cardiac reporter gene expression in living rats. Wu JC, Inubushi M, Sundaresan G, Schelbert HR, Gambhir SS. Circulation 2002 Apr 9; 105 (14), pp. 1631–4.

Gene Expression: Central Nervous System (CNS)/ Huntington's Disease (HD): Huntingtin RNA Genetic Targeting/Macromolecule CNS Delivery/Transferrin Receptor Complexes
[^{125}I]-Peptide Nucleic Acid-[Anti-Transferrin Receptor IgG]/Antisense Gene Targeting/In Vivo Gene Expression Quantification

Cellular/Molecular Mechanism of Action: The peptide nucleic acid (PNA) agent is a 16-mer PNS that is the antisense strand

that corresponds to the segment around the methionine initiation codon of the huntingtin gene of HD. In this context, it recognizes and physically binds to huntingtin RNA (HD exon-1 messenger RNA).

Background Information: Disease-specific genes of unknown function can be imaged *in vivo* with antisense radiopharmaceuticals, providing the transcellular transport of these molecules is enabled with drug-targeting technology.

Route of Administration: [^{125}I]-PNA/8D3 conjugate (intravenous).

Semi-Synthetic Methods: Biotinylation of PNA. Covalent cross-linking of strepavidin and rat 8D3 monoclonal antibody (mAb) to the mouse transferrin receptor (TfR). The latter moiety contains a tyrosine residue that can facilitate [^{125}I] radioiodination. The reformulated PNA antisense radiopharmaceutical conjugated to 8D3 mAb is designated as [^{125}I]-PNA/8D3.

Implementation: Evaluation of biotinylated PNA that can be rapidly captured by conjugates of covalently cross-linked strepavidin and [anti-mouse transferring receptor] IgG. Complementary *in vivo* studies in mice can be used to determine the biodistribution of the PNA analog, [^{125}I]-PNA/8D3, through harvest of tissue/organ systems 6 hours postadministration for frozen sectioning of the brain and quantitative autoradiography.

Animal Model: Murine (littermate control mice or to R6/2 transgenic mice that express the exon 1 of the human HD gene for HD).

Interpretation and Analysis: Despite covalent cross-linking of the PNA analog, [^{125}I]-PNA/8D3 to monoclonal antibody, it can gain access to endogenous transferrin transport pathways at both the blood-brain barrier and the brain cell membrane and undergo both import from the blood to the brain and export from the brain to the blood through the TfR complex. In this manner, it is able to hybridize with "target" huntingtin RNA based on analysis from both cell-free translation assays and ribonuclease protection assays.

Approximately a 3-fold increase in sequestration *in vivo* can be appreciated for antisense [^{125}I]-PNA/8D3 radiopharmaceutical conjugates in the brains of HD transgenic mice. Such observations are consistent with the selective expression of the HD exon-1 messenger RNA in these animals. Therefore, gene expression *in vivo* can be quantitated with antisense radiopharmaceuticals, providing these molecules are reformulated with drug-targeting technology. Drug targeting enables access of the antisense agent to endogenous transport pathways, which permits passage across the cellular barriers that separate blood and intracellular compartments of target tissues.

Imaging gene expression in the brain *in vivo* in a transgenic mouse model of Huntington's disease with an antisense radiopharmaceutical and drug-targeting technology. Lee HJ, Boado RJ, Braasch DA, Corey DR, Pardridge WM.J Nucl Med 2002 Jul; 43 (7), pp. 948–56.

Gene Expression: Detection *In Vivo* (General Concept)
Antisense Oligonucleotides

Cellular/Molecular Mechanism of Action: Selective *in vivo* detection of messenger RNA (mRNA) gene expression. Antisense oligonucleotides bind to cellular RNA sequences by hybridization mechanisms.

Application: Non-invasive, *in vivo* detection modality, imaging agent, and as selective therapeutic delivery platform.

Route of Administration: Intravenous.

Considerations: Labeled oligonucleotides can function as non-canonical radiopharmaceuticals and much progress needs to be made in adapting them to *in vivo* imaging methodologies. The requirements to reach this goal include improvements in radiosynthesis, stability, targeting, and specific and non-specific binding.

Reagent Design and Validation: *In vitro*, antisense oligonucleotides are widely used as reagents to detect or block specific RNA sequences. The use of antisense as an *in vivo* diagnostic agent is attractive because it advances molecular imaging modalities to the level of evaluating gene expression.

Interpretation and Analysis: Signal labeled antisense oligonucleotides can function as a valuable molecular modality for detecting and characterizing "real-time" *in vivo* gene expression.

In vivo antisense imaging.Tavitian B. Q J Nucl Med 2000 Sep; 44 (3), pp. 236–55.

Gene Expression: Neoplasia/HSV1-tk(+) Reporter Gene/[Oncogenes]/[Hereditary Disorders]
[^{123}I]-2′-Fluoro-2′-Deoxy-1-β-D-Arabinofuranosyluracil/[^{125}I]-2′-Fluoro-2′-Deoxy-1-β-D-Arabinofuranosyluracil

Cellular/Molecular Mechanism of Action: The molecular agent 2′-fluoro-2′-deoxy-5-iodo-1-β-D-arabinofuranosyluracil has been designed to function as a substrate for herpes simplex virus type 1 thymidine kinase (HSV1-tk) biochemical activity.

Background Information: Previous studies have shown that HSV1-tk, in combination with effective radiolabeled substrates (e.g., [I*]-2′-fluoro-2′-deoxy-5-iodo-1-β-D-arabinofuranosyluracil, or I*-FIAU, where the asterisk indicates the use of any radioactive iodine isotopes), can be used as a reporter gene for *in vivo* monitoring of gene transfer and expression.

Application Model: Potential gene expression imaging. In this context, [^{123}I]-2′-fluoro-2′-deoxy-1-β-D-arabinofuranosyluracil and [^{125}I]-2′-fluoro-2′-deoxy-1-β-D-arabinofuranosyluracil can be applied as radiolabeled substrates for HSV1-tk gene expression. Note: The *in vivo* detection of HSV1-tk gene expression utilizing [^{123}I]-2′-fluoro-2′-deoxy-1-β-D-arabinofuranosyluracil and [^{125}I]-2′-fluoro-2′-deoxy-1-β-D-arabinofuranosyluracil represents a model feasibility study designed to determine optimum conditions and methodologies that can be extrapolated to *in vivo* detection of altered expression of other unrelated genetic sequences (e.g., oncogenes, hereditary disorders).

Route of Administration: [^{123}I]-2′-fluoro-2′-deoxy-1-β-D-arabinofuranosyluracil and [^{125}I]-2′-fluoro-2′-deoxy-1-β-D-arabinofuranosyluracil (intravenous).

Semi-Synthetic Methods: The molecular agent 2′-fluoro-2′-deoxy-1-β-D-arabinofuranosyluracil (FAU) can be radioiodinated (e.g., [^{123}I] or [^{125}I]) using the iodogen method. High-performance liquid chromatography purification results in a yield of product with a high specific activity and radiochemical purity for both tracers ([^{123}I]-FIAU and [^{125}I]-FIAU).

Implementation: Evaluate the early kinetics of [^{123}I] or [^{125}I]-labeled 2′-fluoro-2′-deoxy-5-iodo-1-β-D-arabinofuranosyluracil (I*-FIAU) and delineate the potential utilization of [^{123}I]-labeled FIAU for imaging of gene expression. Fibrosarcoma CMS-5 cells can be transduced *in vitro* with the retroviral vector STK containing the HSV1-tk gene. Complementary investigations can be conducted to determine the biodistribution profiles for individual radiopharmaceutical agents established by gamma camera imaging at 0.5, 1, 2, and 4 hours postinjection. In addition, the genomic DNA of the tumors can be isolated for the measurement of accumulated activity resulting from the [^{125}I]-FIAU incorporation.

Animal Model: Murine (fibrosarcoma cells are transduced *in vitro* with the retroviral vector STK containing the HSV1-tk gene.

BALB/c mice are inoculated subcutaneously with HSV1-tk(+) and tk(−) cells into both flanks).

Interpretation and Analysis: Biodistribution studies 0.5 hours postinjection reveal tumor/blood and tumor/muscle ratios of 3.8 and 7.2, respectively, for the HSV1-tk(+) tumors, and 0.6 and 1.2, respectively, for negative control tumors. Fast renal elimination of the tracer from the body results in rapidly increasing tumor/blood and tumor/muscle ratios that reach values of 32 and 88 at 4 hours postinjection, respectively. Tracer clearance from blood is biexponential, with an initial half-life of 0.6 hours followed by a half-life of 4.6 hours. The tracer half-life in herpes simplex viral thymidine kinase-expressing tumors is 35.7 hours. The highest activity accumulation (20.3% ± 5.7% ID/g) in HSV1-tk(+) tumors can be observed 1 hour postinjection. At that time, 46% of the total activity found in HSV1-tk(+) tumors is incorporated within genomic DNA. Planar gamma camera imaging reveals distinct tracer accumulation as early as 0.5 hours postinjection, with an increase in contrast over time. Such findings suggest that sufficient tumor/background ratios for *in vivo* HSV1-tk expression imaging with [^{123}I]-FIAU are reached as early as 1 hour postinjection.

In vivo imaging of herpes simplex virus type 1 thymidine kinase gene expression: Early kinetics of radiolabeled FIAU. Haubner R, Avril N, Hantzopoulos PA, Gansbacher B, Schwaiger M. Eur J Nucl Med 2000 Mar; 27 (3), pp. 283–91.

Gene Expression: Neoplasia/Mammary Carcinoma Prognostic Marker
RECK Messenger RNA (mRNA)

Cellular/Molecular Mechanism of Action: Reversion-inducing cysteine-rich protein with Kazal motifs (RECK) functions as a tumor suppressor gene.

Background Information: The recently described RECK inhibits membrane Type 1 matrix metalloproteinase (MMP-14), MMP-2, and MMP-9 secretion and enzymatic activity. Its expression is essential for normal vasculogenesis. Downregulation of RECK has been implicated in tumor angiogenesis and progression.

Application: Determination of the prognosis for human mammary carcinoma and possibly a target for the molecular design of a new class of imaging agent.

Interpretation and Analysis: The expression of RECK mRNA as determined by real-time polymerase chain reaction (PCR) in breast carcinoma tissue specimens (n = 278) on day 1 and on a 2nd date sometime between 2 to 169 months later reveals a degree of accuracy in predicting a longer recurrence-free survival time (RFS; p = 0.037) at the optimal cutoff value (hazard ratio, 0.66; 95% confidence interval, 0.44–0.98). Cases with tumors exhibiting low levels of RECK (n = 100) have a mean RFS time of 80.4 months and a 61.8% 5-year RFS rate, whereas cases with tumors with high RECK expression (n = 178) have a mean RFS time of 91.2 months and a 73.0% 5-year RFS rate. The expression of RECK mRNA maintains a significant independent prognostic value for RFS time (p = 0.047) based on multivariate Cox regression analysis. No relevant associations of RECK with clinicopathologic factors or treatment regimens can be appreciated.

Due to its desirable characteristics, RECK could be applied as a template for the molecular design of pharmaceutical mimetics, or drugs activating endogenous RECK expression, as possible diagnostic, therapeutic, and preventive agents for breast carcinoma.

Instrumentation: Real-time quantitative reverse transcriptase-polymerase chain reaction.

Matrix metalloproteinase inhibitor reversion-inducing cysteine-rich protein with Kazal motifs: A prognostic marker for good clinical outcome in human breast carcinoma. Span PN, Sweep CG, Manders P, Beex LV, Leppert D, Lindberg RL. Cancer 2003 Jun 1; 97 (11), pp. 2710–5.

Gene Expression: Neoplasia/Pulmonary Non-Small Cell Lung Carcinoma
Modified Oligonucleotide Phosphorothionates

Cellular/Molecular Mechanism of Action: Selective recognition or detection of specific messenger RNA (mRNA) strands or DNA gene segments through the formation of stable heteroduplexes (cDNA/mRNA) or homoduplexes (cDNA/DNA).

Application: Oligonucleotides carrying a variety of fluorescent tags have been used as probes with potential for diagnostic applications. Represents a possible modality capable of facilitating the detection of various pathological conditions precipitated by infectious agents (human immunodeficiency virus) or associated with conditions of neoplastic disease.

Considerations: Some of the most extensively investigated agents in this class of compounds are the oligonucleotide phosphorothioates. Many of these incorporate hairpin structures at the 3′ end and "chimeras" that bear 2 modified oligonucleotides, all are potentially of value as diagnostic/therapeutic agents. To further enhance their applicability, bioreversible analogs of oligonucleotides have been synthesized. Several isosteric analogs of phosphoric diester oligonucleotides with neutral achiral backbones, and other novel molecules, such as peptide nucleic acids and circular oligonucleotides, are also reported to form stable duplexes with complementary RNA/DNA and are currently under investigation.

Additionally, oligonucleotides carrying a variety of fluorescent tags have been used as probes for diagnostic applications.

Activation of peroxisome proliferator-activated receptor-gamma stimulates the growth arrest and DNA-damage inducible 153 gene in non-small cell lung carcinoma cells. Satoh T, Toyoda M, Hoshino H, Monden T, Yamada M, Shimizu H, Miyamoto K, Mori M, Yamada M, Mori M. Oncogene 2002 Mar 28; 21 (14), pp. 2171–80.

Growth enhancement of normal human keratinocytes by the antisense oligonucleotide of retinoblastoma susceptibility gene. Koike M, Ishino K, Ikuta T, Huh N, Kuroki T. Oncogene 1995 Jan 5; 10 (1), pp. 117–22.

Gene Expression: Neoplasia (General Cancer)/ HSV-tk
2′-Deoxy-2′-Flouro-5-Methyl-1-β-D-Arabinofuranosyluracil (FMAU)/9-[(3-[^{18}F]-Fluoro-1-Hydroxy-2-Propoxy)Methyl]-Guanine ([^{18}F]-FHPG)/ 9-(4-[^{18}F]-Fluoro-3-Hydroxy-Methylbutyl)Guanine ([^{18}F]-FHBG)

Application: 2′-deoxy-2′-flouro-5-methyl-1-β-D-arabinofuranosyluracil (FMAU) has demonstrated potential utilization as a positron emission tomography (PET) radiotracer for imaging HSV-tk gene expression.

Interpretation and Analysis: *In vitro* experiments demonstrate that the accumulation of [^{14}C]-FMAU in HSV-tk-expressing cells is 2.4-fold ($p < 0.02$), 4.0-fold ($p < 0.001$), and 5.3-fold ($p < 0.001$) higher than the wild-type cells at 1, 3, and 5 hours, respectively. *In vivo* studies reveal that the tumor uptake in HSV-tk-expressing cells is 2.3-fold ($p < 0.001$), 3.0-fold ($p < 0.001$), and 5.5-fold ($p < 0.001$) higher than the control cells at 1, 2, and 5 hours, respectively. FMAU is more sensitive compared to earlier studies using [^{18}F]-FHPG and [^{18}F]-FHBG in the same cell lines, although the specificity is less than FHBG. While FMAU labeled with PET isotopes may be useful for imaging HSV-tk-expressing tumors *in vivo*, multitracer

studies across additional tumor models are necessary in order to identify an optimal PET radiotracer.

Evaluation of 2′-deoxy-2′-flouro-5-methyl-1-β-D-arabinofuranosyluracil as a potential gene imaging agent for HSV-tk expression *in vivo*. Alauddin MM, Shahinian A, Gordon EM, Conti PS. Mol Imaging 2002 Apr–Jun; 1 (2), pp. 74–81.

Gene Expression: Neoplasia Chemotherapeutic Resistance Potential/Radioresistance: Mammary Carcinoma

Antisense Insulin-Like Growth Factor-I Receptor (IGF-IR)/IGF-IR Messenger RNA (mRNA)

Cellular/Molecular Mechanism of Action: The IGF-IR plays a critical role in cell growth regulation and transformation. Antisense IGF-IR nucleotides inhibit the transcription of IGF-IR mRNA gene sequences.

Application: Expression of IGF-IR mRNA can serve as a prognostic marker pertaining to the potential of antisense IGF-IR to reverse resistance to radiation and chemotherapy in neoplastic cell populations (e.g., mammary carcinoma). Strategies designed to disrupt the biological expression of IGF-IR may be a fruitful avenue for achieving enhanced resolution of neoplastic disease states.

Route of Administration: Antisense IGF-IR nucleotide (intravenous).

Dosage: Antisense IGF-IR nucleotide.

Implementation: Evaluation of the radiosensitivity of fibroblasts (e.g., NIH 3T3 cell line) that overexpress either wild-type or mutant IGF-IR complexes (e.g., IGF-IR). Supplementary analysis can entail immunohistochemical analysis of primary mammary carcinoma neoplastic lesions to detect the expression of IGF-IR complexes.

Interpretation and Analysis: High levels of wild-type IGF-IR confer radioresistance, and mutational analysis has revealed that this effect correlates with the transforming capacity but not the mitogenic activity of the receptor. The radioresistant phenotype is reversed when the cells are incubated with antisense oligonucleotides targeted to IGF-IR mRNA, demonstrating that IGF-IR directly influences radioresistance. Immunohistochemical analysis of primary breast tumors reveals that high levels of IGF-IR in tumor samples highly correlates with ipsilateral breast tumor recurrence (IBTR) following lumpectomy and radiation therapy ($p = 0.001$). Subgroup analysis reveals that, for early breast tumor relapses (within 4 years of initial breast tumor diagnosis), elevated levels of IGF-IR are strongly associated with IBTR ($p = 0.004$), but IGF-IR expression is not prognostic for IBTR from breast cancer patients with late relapses (p value not significant).

Insulin-like growth factor-I receptor overexpression mediates cellular radioresistance and local breast cancer recurrence after lumpectomy and radiation. Turner BC, Haffty BG, Narayanan L, Yuan J, Havre PA, Gumbs AA, Kaplan L, Burgaud JL, Carter D, Baserga R, Glazer PM. Cancer Res 1997 Aug 1; 57 (15), pp. 3079–83.

Genetic Expression: Oligonucleotide (Hybridization)

Magnetic Bead-Linked Oligonucleotide Probes

Cellular/Molecular Mechanism of Action: Oligonucelotides incorporated into magnetic bead-linked oligonucleotide probes will hybridize (e.g., form cDNA/cDNA diamers or messenger RNA [mRNA]/cDNA heteriomers).

Application: Methodology for the detection of gene expression that could potentially be developed or adapted as a technique for the non-invasive detection of gene expression events in both *ex vivo* or *in vivo* environments.

Route of Administration: Intravascular most commonly (selective and non-selective delivery).

Implementation: Hybridization of a target oligonucleotide to magnetic bead-linked oligonucleotide probes is followed by binding of the streptavidin-coated metal nanoparticles to the captured DNA, dissolution of the nanometer-sized gold tag, and potentiometric stripping measurements of the dissolved metal tag at single-use thick-film carbon electrodes.

An advanced magnetic processing technique is used to isolate the DNA duplex and to provide low-volume mixing. The influence of relevant experimental variables, including the amounts of the gold nanoparticles and the magnetic beads, the duration of the hybridization and gold dissolution steps, and the parameters of the potentiometric stripping operation upon the hybridization signal have been optimized in several laboratories.

Interpretation and Analysis: Transmission electron microscopy micrographs indicate that the hybridization event leads to the bridging of the gold nanoparticles to the magnetic beads. Further signal amplification and lowering of the detection limits to the nanomolar and picomolar domains are achieved by precipitating gold or silver, respectively, onto the colloidal gold label. The new electrochemical stripping metallogenomagnetic protocol couples the inherent signal amplification of stripping metal analysis with discrimination against non-hybridized DNA, the use of microliter sample volumes, and disposable transducers and, hence, offers great promise for decentralized genetic testing.

Metal nanoparticle-based electrochemical stripping potentiometric detection of DNA hybridization. Wang J, Xu D, Kawde AN, Polsky R. Anal Chem 2001 Nov 15; 73 (22), pp. 5576–81.

14 Inflammation, Infection, and Sepsis

GENERAL ABSCESS FORMATION, SEPSIS, AND INFLAMMATION

General Abscess Formation: Non-Septic Inflammation
[^{99m}Tc]-Interleukin-8 (IL-8)

Cellular/Molecular Mechanism of Action: Interleukin-8 recognizes and binds to IL-8 receptor complexes expressed on the exterior surface membrane of neutrophil and monocyte populations.

Physiological Mechanism of Action: Interleukin-8 can function as a neutrophil chemotactic agent but this has little relevance to the use of this agent as an *in vivo* diagnostic agent in the field of nuclear medicine.

Route of Administration: [^{99m}Tc]-IL-8 (intravenous).

Implementation: Evaluation of the specificity of [^{99m}Tc]-IL-8 for detecting focal non-septic abscess lesions as a function of biodistribution patterns and pharmacokinetics profiles. Complimentary analyses include determination of the interaction of [^{99m}Tc]-IL-8 with circulating blood cells achieved through characterization of the radiolabel in peripheral leukocytes, red blood cells, and plasma. The *in vivo* kinetics of [^{99m}Tc]-IL-8 can be studied by quantitative analysis of whole-body images acquired between 0 and 6 hours postinjection. The results of this analysis (*in vivo* biodistribution) can be validated by *ex vivo* counting of radioactivity in dissected tissues.

Animal Model: Rabbit (turpentine-induced abscesses in neutropenic and normal rabbits).

Interpretation and Analysis: The abscess uptake (percentage of injected dose per gram of tissue [%ID/g] $\pm$ standard error of measurement [SEM]) in immunocompetent rabbits (0.41 $\pm$ 0.05) is 10 times higher than that in neutropenic rabbits (0.038 $\pm$ 0.014) and demonstrates specificity of target uptake for [^{99m}Tc]-IL-8. Abscess-to-muscle ratios $\pm$ SEM are also 10 times higher (110 $\pm$ 10 vs 10 $\pm$ 5). Lung and spleen uptake is 3-fold less with conditions of neutropenia compared to normal reference controls. The blood clearance of the radiolabel in conditions of neutropenia is similar to that in normal reference controls. In the vascular compartment, most of the [^{99m}Tc]-IL-8 (70%) is found in the plasma. Less than one-third is associated with red blood cells, and only a very low percentage ($<$ 2.5%) is associated with white blood populations. Image analysis reveals a gradual increase in abscess uptake over time up to $>$ 15%ID, which can be confirmed by *ex vivo* gamma counting of infected muscle. The highest increases in abscess uptake can be observed $>$ 2 hours postinjection when most of the [^{99m}Tc]-IL-8 has cleared from the blood, suggesting specific neutrophil-mediated accumulation of [^{99m}Tc]-IL-8 within abscesses. Furthermore, region-of-interest (ROI) analysis reveals that gradual accumulation of [^{99m}Tc]-IL-8 in abscesses is accompanied by a simultaneous clearance of activity from the lungs, suggesting that neutrophil-associated [^{99m}Tc]-IL-8 that was initially trapped in the lungs migrates to abscess lesions at later time points, favoring neutrophil-bound transportation from the lungs to the abscess. Substantial evidence supports the hypothesis that [^{99m}Tc]-IL-8 localizes within abscesses, primarily due to physical binding to peripheral neutrophils. Accumulation in abscesses is a highly specific, neutrophil-driven process. As assessed by *in vivo* and *ex vivo* analyses, the total fraction that accumulates in inflamed tissue is extremely high (up to $>$ 15 %ID) compared with that of other agents used for imaging infection and inflammation.

Kinetics of [^{99m}Tc]-labeled interleukin-8 in experimental inflammation and infection. Rennen HJ, Boerman OC, Oyen WJ, Corstens FH. J Nucl Med 2003 Sep; 44 (9), pp. 1502–9.

General Abscess Formation: Septic Inflammation
Anti-DTPA Antibody/[In]-DTPA-Bovine Serum Albumin/ [^{111}In]-DTPA (Bivalent)/[3-Phase Injection Scheme]

Application: A new 3-step approach to imaging infectious and inflammatory foci has been developed and optimized in a rat model. The approach relies on the non-specific localization of an anti-diethylenetriaminepentaacetic acid (DTPA) antibody in inflamed tissue. In this study, the 3-step strategy can be enhanced by selecting the most suitable radiolabeled hapten and optimizing the dosing schedule.

Route of Administration: Anti-DTPA antibody, [^{111}In]-DTPA-bovine serum albumin, and [^{111}In]-diDTPA (intravenous).

Semi-Synthetic Methods: An N2S2 core is attached to the diDTPA compound, thereby allowing [^{99m}Tc] radiolabeling.

Implementation: Evaluation of focal septic inflammatory lesions by initial "priming" with the anti-DTPA antibody DTIn-1 (0.67, 2, or 6 nmol per rat). In the 2nd phase (1–24 hours later), the anti-DTPA activity within the intravascular department is blocked with unlabeled [In]-DTPA-bovine serum albumin (0.3, 1, or 3 nmol per rat). In the 3rd step (5–30 minutes later), the radiolabeled hapten (monovalent or bivalent [^{111}In]-DTPA) is administered. The *in vivo* distribution of the radiolabel is monitored by scintigraphic imaging and by *ex vivo* counting of dissected tissues.

Animal Model: Rat (Wistar strain) injected with *Staphylococcus aureus* in the left calf muscle.

Interpretation and Analysis: Scatchard analysis reveals that the affinity of DTIn-1 for bivalent [^{111}In]-diDTPA is 6 times higher than its affinity for monovalent [^{111}In]-DTPA ($K_a = 0.87 \times 10^{-9}$ mol/L vs 5.3×10^{-9} mol/L). The uptake of the bivalent chelate within abscesses is 2.5-fold higher than that for monovalent [^{111}In]-DTPA. Most important, the bivalent chelate is completely retained in the abscess over time. Using the bivalent chelate, the optimal dosing scheme can be determined with respect to the DTIn-1 dose (2 nmol per rat), the blocking agent dose (1 nmol per rat), and radiolabeled chelate dose (40 pmol per rat). The procedure is rapid with infectious foci clearly visualized at 1 hour postinjection of [^{111}In]-labeled diDTPA (5 hours after administration of the anti-DTPA antibody). The non-targeted radiolabel is rapidly cleared into the urine and is only retained within abscess and the kidney (4–6% of injected dose). The 3-step diagnostic protocol enables rapid imaging of infectious foci with minimal uptake in non-inflamed tissues.

A 3-step pretargeting strategy to image infection. Boerman OC, van Eerd J, Oyen WJ, Corstens FH. J Nucl Med 2001 Sep; 42 (9), pp. 1405–11.

General Abscess Formation (Septic) *[^{99m}Tc]-HYNIC-C5adR/[^{99m}Tc]-HYNIC-C5a*

Cellular/Molecular Mechanism of Action: Complement fraction C5a and its natural metabolite C5a des Arg(74) (C5adR) recognize and bind to receptor complexes expressed on the exterior surface membrane of neutrophil and monocyte populations.

Application: The complement anaphylatoxin C5a and its natural metabolite C5adR are involved in several stages of the inflammatory process. Both act on a common receptor expressed by different cell types, including neutrophils and monocytes. The receptor binding affinity of C5a is in the nanomolar range and exceeds that of C5adR by 1 to 2 orders of magnitude. The biologic potency of C5a is considerably higher than that of C5adR.

Semi-Synthetic Methods: Labeling of proteins can be achieved utilizing [^{99m}Tc] following initial conjugation with an appropriate moiety such as hydrazinonicotinamide (HYNIC).

Implementation: Evaluation of intramuscular septic abscesses induced by bacterial injection utilizing [^{99m}Tc]-HYNIC-C5a and [^{99m}Tc]-HYNIC-C5adR as imaging agents. Biodistribution of the radiolabel can be determined by gamma camera imaging and by counting dissected tissues at 5 hours postinjection.

Interpretation and Analysis: Complement fractions [^{99m}Tc]-HYNIC-C5a and [^{99m}Tc]-HYNIC-C5adR display *in vivo* abscess uptake values of 0.12 and 0.025 percentage injected dose (%ID)/g, abscess/muscle ratios of 76 and 14, abscess/blood ratios of 9.1 and 2.6, and region-of-interest (ROI)-derived target-to-background ratios of 5.9 and 2.1, respectively, at 5 hours postinjection. Therefore, [^{99m}Tc]-HYNIC-C5a provides superior capabilities as an agent for *in vivo* imaging of foci of sepsis (e.g., abscess formation). However, C5a is a very bioactive protein, and this biological property impedes its clinical use as an infection imaging agent. The naturally occurring partial agonist C5adR has less biological effect but shows suboptimal imaging characteristics. Therefore, for adequate localization of a receptor binding ligand, the affinities for the receptor in the nanomolar range are required.

Tc-99m-labeled C5a and C5a des Arg74 for infection imaging. Rennen HJ, Oyen WJ, Cain SA, Monk PN, Corstens FH, Boerman OC. Nucl Med Biol 2003 Apr; 30 (3), pp. 267–72.

General Abscess Formation (Septic) *[^{99m}Tc]-HYNIC-Interleukin-8 (IL-8)*

Cellular/Molecular Mechanism of Action: Interleukin-8 recognizes and binds to IL-8 receptor complexes expressed on the exterior surface membrane of neutrophil and monocyte populations.

Background Information: Previous investigations have demonstrated that IL-8 can be labeled with [^{99m}Tc] using hydrazinonicotinamide (HYNIC) as a bifunctional coupling agent and tricine as a co-ligand. Such preparations possess excellent characteristics for imaging infections (e.g., rabbit model of soft-tissue infection).

Route of Administration: [^{99m}Tc]-HYNIC-IL-8 (intravenous).

Semi-Synthetic Methods: Propylaldehyde hydrazone formulations of HYNIC can be utilized to stabilize HYNIC-IL-8 conjugation products. [^{99m}Tc]-HYNIC-IL-8 can be prepared using 5 different co-ligand formulation protocols. In this context, HYNIC-conjugated IL-8 can be labeled with [^{99m}Tc] in the presence of either (i) tricine; (ii) ethylenediaminediacetic acid (EDDA); (iii) tricine and trisodium triphenylphosphinetrisulfonate (TPPTS); (iv) tricine and nicotinic acid (NIC); or (v) tricine and isonicotinic acid (ISONIC). These preparations can be characterized *in vitro* by (i) reverse phase high-performance liquid chromatography (RP-HPLC) analysis; (ii) measurement of octanol/water partition coefficient parameters; (iii) establishing molecular stability; and (iv) receptor affinity analysis (ligand binding assays).

Implementation: Evaluation of the *in vivo* biodistribution of [^{99m}Tc]-HYNIC-IL-8 in conditions of induced localized sepsis (*Escherichia coli*–induced soft-tissue infection) and evaluated by gamma camera imaging as well as by tissue counting at 6 hours postinjection.

Animal Model: Rabbit (*E. coli*–induced soft-tissue septic lesions).

Interpretation and Analysis: Specific activity (MBq/μg) is highest for (ISO)NIC (up to 80) > TPPTS (40) > tricine (15) > EDDA (7). Reverse phase high-performance liquid chromatography and octanol/water partition coefficients show a shift toward higher lipophilicity for TPPTS preparations. The leukocyte receptor binding fractions are around 40 to 55% for all preparations except for TPPTS, which displays predominantly non-specific binding. All preparations are stabile in serum, but the stability in PBS is highest for NIC and TPPTS > EDDA > ISONIC > tricine. Profiles for *in vivo* biodistribution show highest abscess/muscle for NIC and ISONIC (> 200) > EDDA and tricine (approximately 100) > TPPTS (< 40). Gamma camera imaging rapidly visualizes abscesses from 2 hours postinjection onward for all formulations. The abscess/background (A/B) at 6 hours postinjection for ISONIC is significantly higher ($p < 0.05$) than that of tricine and the A/B of TPPTS is significantly lower ($p < 0.05$). Interleukin-8 can be rapidly and easily labeled with [^{99m}Tc] using HYNIC as a chelator in combination with various co-ligands. The most optimal infection imaging characteristics can be appreciated with formulations using nicotinic acid/tricine as a co-ligand system, which simultaneously provides high specific activity and high *in vitro* stability with high abscess/muscle ratios (> 200) and high abscess/background ratios (> 20). Protein doses can be administered as low as 70 ng/kg bodyweight. At these low protein doses, side effects are not to be expected in the human system.

Instrumentation: Gamma camera imaging.

Effects of co-ligand variation on the *in vivo* characteristics of Tc-99m-labeled interleukin-8 in detection of infection. Rennen HJ, van Eerd JE, Oyen WJ, Corstens FH, Edwards DS, Boerman OC. Bioconjug Chem 2002 Mar–Apr; 13 (2), pp. 370–7.

General Abscess Formation (Septic): *Escherichia Coli*–Induced/Comparison of Radioiodination Methods/Plasma Kinetic Profiles: $T_{1/2}$ *[^{123}I]-Interleukin-8 (IL-8)*

Background Information: Several small receptor-binding agents have been tested for imaging of infection and inflammation. The potential of chemotactic peptides and of interleukins is promising and superior to that of conventional agents.

Application: Detection and characterization of septic and potentially non-septic inflammatory lesions.

Route of Administration: [^{123}I]-IL-8 (intravenous).

Dosage: [^{123}I]-IL-8 (18.5 MBq).

Semi-Synthetic Methods: Radiolabeling of biological protein fractions with radioiodine [^{123}I, ^{124}I, ^{125}I, ^{127}I] facilitated by the application of Bolton-Hunter reagent.

Implementation: Imaging of septic abscesses can be performed 24 hours postinduction with [^{123}I]-IL-8 preparations. Gamma camera images can be obtained at 5 minutes and at 1, 4, and 8 hours after injection. Biodistribution is determined 8 hours after injection. Gamma camera imaging is then performed at 5 minutes and at 1, 4, and 8 hours postinjection with biodistribution profiles established at 8 hours postinjection.

Animal Model: Rabbits (*E. coli*–induced abscesses in the left thigh muscle).

Interpretation and Analysis: Radioiodinated [^{123}I]-IL-8 is rapidly cleared from the blood. Accumulation of [^{123}I]-IL-8 in abscesses is visible as early as 1 hour postinjection. The highest abscess uptake can be appreciated 4 hours after injection (2.6 ± percentage injected dose [%ID]), whereas [^{123}I]-IL-8 rapidly clears from all other tissues. Approximate increases in abscess-to-background ratios are 13.0 ± 0.7 (8 hours postinjection), as determined by quantification of the images. In tissue biodistribution investigations (8 hours postinjection), abscess uptake is 0.057 ± 0.011 %ID/g with abscess-to-contralateral muscle ratios of 114.7 ± 23.0. The radioiodination method clearly affects the *in vivo* biodistribution of IL-8 because IL-8 iodinated using the Iodo-Gen method cleared significantly slower from the blood and most other organs, resulting in poor visualization of the abscess. The superior characteristics of IL-8 radioiodinated using the Bolton-Hunter method—that is, high abscess uptake and rapid background clearance within a few hours—make IL-8 a promising agent for imaging septic (infection) and inflammatory lesions.

Radiolabeled interleukin-8: Specific scintigraphic detection of infection within a few hours. van der Laken CJ, Boerman OC, Oyen WJ, van de Ven MT, van der Meer JW, Corstens FH. J Nucl Med 2000 Mar; 41 (3), pp. 463–9.

General Abscess Formation (Septic): Systemic Foci/Leukotriene B_4 (LTB_4) Receptor Complexes *[^{99m}Tc]-RP517*

Cellular/Molecular Mechanism of Action: The agent [^{99m}Tc]-RP517 recognizes and physically binds to LTB_4 receptor complexes.

Background Information: In a search for a rapid and accurate imaging agent for scintigraphic detection of infection and inflammation, an LTB_4 receptor antagonist, [^{99m}Tc]-RP517, has been developed that contains a hydrazinonicotinamide moiety.

Application: Detection and characterization of systemic septic foci including abscess formation.

Route of Administration: [^{99m}Tc]-RP517 (intravenous).

Implementation: Determination of the *in vivo* behavior of [^{99m}Tc]-RP517 in an abscess model. Detection of created abscesses can be established by gamma camera imaging, which can additionally be utilized to establish the *ex vivo* biodistribution of the agent several hours postinjection. Complementary studies can entail cannulation of the choledochal duct to facilitate quantitative monitoring of hepatobiliary radiopharmaceutical clearance.

Animal Model: Rabbit abscesses (induced by intravenous injection of *Escherichia coli* bacteria).

Animal Model: Rabbit (choledochal duct cannulation).

Interpretation and Analysis: The *ex vivo* receptor-bound fraction of radiolabeled RP517 exceeds 70%. Accumulation of [^{99m}Tc]-RP517 within abscesses can be visualized as early as 1 hour postinjection. Due to rapid blood clearance ($t_{1/2}$ alpha = 18 ± 0.6 minutes, $t_{1/2}$ beta = 6.5 ± 0.4 hours) and high abscess uptake, the abscess-to-muscle ratios increase with time from 7.0 ± 2.3 at 1 hour postinjection to 44.3 ± 4.6 at 20 hours postinjection. The agent is mainly cleared via hepatobiliary excretion: 50% of the radiolabel can be recovered in the small bowel at 1 hour postinjection, whereas 85% can be found in the cecum and sigmoid at 20 hours postinjection. In conclusion, [^{99m}Tc]-RP517 can facilitate rapid visualization of *E. coli* abscesses in rabbits. The agent rapidly clears from the blood, mainly via the hepatobiliary route. Considerably high abscess-to-background target ratios can be achieved. Accumulation within the intestines may limit the applicability of the agent for detecting infectious processes within the abdominal cavity. The development of a more hydrophilic analogue of [^{99m}Tc]-RP517 could improve the clinical applicability of this agent.

A [^{99m}Tc]-labeled leukotriene B4 receptor antagonist for scintigraphic detection of infection in rabbits. Brouwers AH, Laverman P, Boerman OC, Oyen WJ, Barrett JA, Harris TD, Edwards DS, Corstens FH. Nucl Med Commun 2000 Nov; 21 (11), pp. 1043–50.

General Sepsis: Bacterial Infection *[^{99m}Tc]-Labeled Ciprofloxacin/[^{99m}Tc]-Hexamethylpropyleneamine Oxime (HMPAO)-Labeled White Blood Cells (WBCs)*

Cellular/Molecular Mechanism of Action: Ciprofloxacin (infecton) when applied as an imaging agent localizes in high concentrations within living bacteria.

Application: [^{99m}Tc]-labeled ciprofloxacin (infecton) has been developed for detecting infectious foci.

Route of Administration: [^{99m}Tc]-labeled ciprofloxacin and [^{99m}Tc]-HMPAO-labeled WBC preparations are injected intravenously.

Dosage: [^{99m}Tc]-HMPAO-labeled WBC (185–200 MBq). [^{99m}Tc]-labeled ciprofloxacin (370–400 MBq).

Considerations: Previous reports have described greater specificity of radiolabeled ciprofloxacin for bacterial infections compared to radiolabeled WBC scans.

Implementation: Performance of scintigraphic image analysis in suspected cases of bone or joint sepsis using [^{99m}Tc]-labeled ciprofloxacin and [^{99m}Tc]-WBC preparations (e.g., n = 51; n = 21/51 prosthetic implant materials). Procedures that can complement or validate findings observed in scintigraphic image analyses include biochemical, radiographic, and microbiologic data in addition to clinical history (e.g., outcomes). Scintigraphic images are performed at 1 and 4 hours postinjection of 370–400 MBq [^{99m}Tc]-labeled ciprofloxacin or 185–200 MBq [^{99m}Tc]-HMPAO-WBCs. At least a 2-day and at most a 7-day lag-time period occurs between the imaging agent administration and the acquisition of scintigraphic images.

Interpretation and Analysis: Scintigraphic imaging with [^{99m}Tc]-labeled ciprofloxacin and [^{99m}Tc]-HMPAO-labeled WBC populations in cases of bone or joint sepsis produces a variety of image assessment classifications including true-positives (e.g., n = 30/32 vs n = 20/32); false-positives (e.g., n = 4/24 vs n = 1/24); true-negatives (e.g., n = 20/24 vs 23/24), and false-negatives (e.g., n = 2/22 vs 12/22), respectively. Corresponding values for sensitivity, specificity, and accuracy are approximately 94%, 83%, and 89% ([^{99m}Tc]-labeled ciprofloxacin), and 63%, 96%, and 77% ([^{99m}Tc]-HMPAO-labeled WBC), respectively. Differences between the 2 agents are statistically significant ($p < 0.001$). [^{99m}Tc]-labeled ciprofloxacin and WBC scan results are in general concordance for 77% of sites (n = 43/56). [^{99m}Tc]-HMPAO-labeled WBC results for vertebral infections are the most notable. [^{99m}Tc]-labeled ciprofloxacin scans are positive in a large percentage of patients with vertebral osteomyelitis (e.g., n = 83% or 5/6). White blood cell scans can show photon-deficient areas in some of these cases (e.g., n = 4/6), but normal distribution in the remaining scenarios (e.g., n = 2/6). [^{99m}Tc]-labeled ciprofloxacin is a useful agent for detecting infectious foci in bones and joints. Moreover, the [^{99m}Tc]-labeled ciprofloxacin scans seem to be a more powerful tool in diagnosing vertebral infections than WBC scintigraphy.

Usefulness of [^{99m}Tc]-ciprofloxacin (infecton) scan in diagnosis of chronic orthopedic infections: Comparative study with [^{99m}Tc]-HMPAO leukocyte scintigraphy. Sonmezoglu K, Sonmezoglu M, Halac M, Akgun I, Turkmen C,

Onsel C, Kanmaz B, Solanki K, Britton KE, Uslu I. J Nucl Med 2001 Apr; 42 (4), pp. 567–74.

General Sepsis: Bacterial Infection (Focal) *[^{18}F]-2-Deoxy-2-Fluoro-D-Glucose (FDG)/[^{3}H]-2-Deoxy-2-Fluoro-D-Glucose (FDG)/[^{125}I]-Human Serum Albumin (^{125}I-HSA)/L-[^{11}C]-Methionine/L-[^{3}H]-Methionine/[^{3}H]-Thymidine*

Application: Detection of focal sites of septic inflammation within extravascular tissues applying positron emission tomography (PET) imaging modalities.

Implementation: Determination of the relative biodistribution of [^{18}F]- or [^{3}H]-FDG, [^{3}H]-thymidine, L-[^{11}C]- or [^{3}H]-methionine, gallium-67 citrate ([^{67}Ga]-citrate), and iodine-125 human serum albumin ([^{125}I]-HSA) in cases of focal sepsis (e.g., rat left calf muscles infected with *Escherichia coli* suspension). Uptake of [^{3}H]-FDG within infectious foci is evaluated by autoradiography of histological sections.

Interpretation and Analysis: Although [^{18}F]-FDG, [^{67}Ga]-citrate, and [^{125}I]-HSA showed comparatively high uptake in the infected muscle (the percentage activity of injected dose [ID] per gram of tissue normalized for rat weight in kilogram [%ID/g] $\times$ kg at 2 hours postinjection is as follows: [^{18}F]-FDG, 0.184$\pm$ 0.026 to 0.218 $\pm$ 0.046; [^{67}Ga]-citrate, 0.221 $\pm$ 0.016; [^{125}I]-HSA, 0. 198 $\pm$ 0.019), the infected muscle-to-blood ratio is much higher for [^{18}F]-FDG than for [^{67}Ga]-citrate or [^{125}I]-HSA ([^{18}F]-FDG, 10.31 $\pm$ 0.76 to 14.89 $\pm$ 2.26; [^{67}Ga]-citrate, 1.24 $\pm$ 0.67; [^{125}I]-HSA, 0.20 $\pm$ 0.02). The draining reactive lymph nodes also show higher accumulation of [^{18}F]-FDG than of [^{67}Ga]-citrate or [^{125}I]-HSA. The uptake of [^{3}H]-thymidine and L-[^{11}C]-methionine or [^{3}H]-methionine in the infected muscle is lower than that of [^{18}F]-FDG or [^{3}H]-FDG (at 2 hours postinjection, [^{3}H]-thymidine = 0. 039 $\pm$ 0.005 and L-[^{3}H]-methionine = 0.063 $\pm$ 0.007 [%ID/g] $\times$ kg). Autoradiographs reveal that the highest [^{3}H]-FDG uptake occurs in the area of inflammatory cell infiltration surrounding necrotic regions. In conclusion, [^{18}F]-FDG, which rapidly accumulates in sites of bacterial infection and in reactive lymph nodes with a high target-to-background ratio, appears to be a promising infection detection agent.

Uptake of positron emission tomography tracers in experimental bacterial infections: A comparative biodistribution study of radiolabeled FDG, thymidine, L-methionine, [^{67}Ga]-citrate, and [^{125}I]-HSA. Sugawara Y, Gutowski TD, Fisher SJ, Brown RS, Wahl RL. Eur J Nucl Med 1999 Apr; 26 (4), pp. 333–41.

General Sepsis: Differentiated from Non-Septic Inflammation *[^{99m}Tc]-UBI 29-41*

Cellular/Molecular Mechanism of Action: A [^{99m}technetium]-labeled peptide derived from ubiquicidine, referred to as [^{99m}Tc]-UBI 29-41, targets bacterial and fungal infections, but not sterile inflammatory processes, in experimental animals.

Application: Differentiation between conditions of septic inflammation due to bacterial pathogens vs non-septic inflammatory responses utilizing [^{99m}Tc]-UBI 29-41 or [^{99m}Tc]-Sc-UBI 29-41.

Route of Administration: [^{99m}Tc]-UBI 29-41 and [^{99m}Tc]-Sc-UBI 29-41 (intravenous).

Semi-Synthetic Methods: Radiochemical analyses of [^{99m}Tc]-UBI 29-41 and a radiolabeled scrambled version of this peptide, that is, [^{99m}Tc]-Sc-UBI 29-41, reveal that both peptides can be (i) labeled rapidly (within 10 minutes); (ii) generate little colloid formation (less than 5% of the total radioactivity); and (iii) produce very little free pertechnetate (or radioactive intermediates) in the preparations containing radiolabeled peptide.

Implementation: Delineation of the relative capacity of [^{99m}Tc]-UBI 29-41 and [^{99m}Tc]-Sc-UBI 29-41 to differentiate between septic inflammatory responses and conditions of non-septic inflammation. In this manner, greater insight can be achieved in delineating the regions of the amino acid sequence for UBI 29-41 that are the most critical to selectively imaging bacterial infections.

Animal Model: Murine (*Staphylococcus aureus*–infected mice).

Interpretation and Analysis: The molecular interaction of peptides with bacteria can be enhanced utilizing a relative excess of unlabeled peptide and this physical association has been shown to be a temperature-dependent process. Based on *in vitro* observations of this nature, labeling of peptides with [^{99m}Tc] by a direct method of this type is rapid, efficient, and safe. Scintigraphy demonstrates that radioactivity is rapidly removed from the circulation (half-lives of UBI 29-41 and Sc-UBI 29-41 are 16 and 21 minutes, respectively) and primarily by renal clearance mechanisms. Analysis of murine blood reveals that only a small proportion of the intravenously injected [^{99m}Tc]-peptides is associated with blood cells. Although both types of radiolabeled peptides accumulate rapidly at sites of infection, the values for [^{99m}Tc]-UBI 29-41 are higher ($p < 0.05$) than for [^{99m}Tc]-Sc-UBI 29-41. Moreover, injection of excess unlabeled UBI 29-41, but not Sc-UBI 29-41, in scenarios of *S. aureus* infections prior to injection of [^{99m}Tc]-UBI 29-41 significantly ($p < 0.05$) reduces the accumulation of this radiopharmaceutical at the site of sepsis infiltration. In addition, significantly ($p < 0.01$) higher amounts of [^{99m}Tc]-UBI 29-41 can be appreciated at the site of infection in mice using a carrier-free formulation of radiolabeled UBI 29-41 peptide in contrast to unpurified preparations containing radiolabeled UBI 29-41 peptide. Such *in vivo* data implies that the amino acid sequence of [^{99m}Tc]-UBI 29-41 contributes to its accumulation at sites of infection.

Radiochemical and biological characteristics of [^{99m}Tc]-UBI 29-41 for imaging of bacterial infections. Welling MM, Mongera S, Lupetti A, Balter HS, Bonetto V, Mazzi U, Pauwels EK, Nibbering PH. Nucl Med Biol 2002 May; 29 (4), pp. 413–22.

General Sepsis: Differentiated from Sterile Inflammation *[^{99m}Tc]-Labeled Ubiquicidin (UBI) Peptides*

Cellular/Molecular Mechanism of Action: Human UBI is an antimicrobial peptide that physically binds to bacterial organisms.

Application: Discrimination between bacterial infections and sterile inflammatory reactions.

Route of Administration: [^{99m}Tc]-labeled ubiquicidin (intravascular).

Implementation: Evaluate the *in vitro* binding of various [^{99m}Tc]-labeled natural or synthetic peptides (based on the sequence of the human antimicrobial peptide UBI or human lactoferrin [hLF]) to bacteria and leucocytes. Complementary investigations can entail the *in vivo* evaluation of these same radiolabeled peptides injected into mice intraperitoneally infected with *Klebsiella pneumoniae* in order to identify sequences that preferentially bind to bacteria compared to host cell populations. The amount of radioactivity associated with bacteria and leukocytes is then quantified. Discovery of the ability for candidate [^{99m}Tc]-labeled peptides to discriminate between bacterial infections and sterile inflammatory processes can be established in mice intramuscularly infected with various bacteri-

al organisms (e.g., multi-drug-resistant *Staphylococcus aureus*) and in animals injected with lipopolysaccharides (LPS) of bacterial origin (sterile inflammatory process). Complementary validation studies can entail determination of [^{99m}Tc]-labeled UBI 29-41 and UBI 18-35 distribution in rabbits having an experimental thigh muscle infection induced with the introduction of *K. pneumoniae,* and in rabbits injected with LPS.

Animal Model: Murine (mouse sepsis: intraperitoneal injection of *K. pneumoniae*).

Animal Model: Rabbit (intramuscular injection of *K. pneumoniae* (septic foci model) and lipopolysacchairde fractions (sterile LPS inflammatory model).

Interpretation and Analysis: In both *in vitro* and *in vivo* binding assays, the 2 peptides, UBI 29-41 and UBI 18-35, are 2 candidates platforms for image analysis of infection. The radiolabeled peptides can detect infections with both gram-positive and gram-negative bacteria in mice as early as 5–30 minutes after injection, with a target-to-non-target (T/NT) ratio between 2 and 3; maximum T/NT ratios can be seen within 1 hour after injection. In rabbits, high T/NT ratios ($>$ 5) for [^{99m}Tc]-labeled UBI 29-41 are observed from 1 hour after injection. No accumulation of candidate [^{99m}Tc]-labeled UBI-derived peptides can be observed in thighs of mice and rabbits previously injected with LPS. Scintigraphic investigations into the biodistribution of [^{99m}Tc]-labeled UBI peptides reveal that these peptides are rapidly removed from the circulation by renal excretion. Similar data can be observed for [^{99m}Tc]-labeled defensin 1-3. Preliminary investigations utilizing [^{99m}Tc]-labeled hLF and related peptides indicate that these compounds are less favorable for infection detection. Taken together, [^{99m}Tc]-labeled UBI 18-35 and UBI 29-41 enable discrimination between bacterial infections and sterile inflammatory processes in both mice and rabbits. Based on their characteristics and properties, these peptides are candidate platforms for the preferential detection of bacterial infections.

Technetium-99m labeled antimicrobial peptides discriminate between bacterial infections and sterile inflammations. Welling MM, Paulusma-Annema A, Balter HS, Pauwels EK, Nibbering PH. Eur J Nucl Med 2000 Mar; 27 (3), pp. 292–301.

General Sepsis: *Escherichia Coli* Targeting/E. Coli Envelope Proteins *Sulfosuccinimidyl-6-Biotinamido-Hexanoate (NHS-LC-Biotin)/Succinimidyl-6-Biotinamido-Hexanoate (NHS-A-Biotin)*

Cellular/Molecular Mechanism of Action: Succinimidyl-6-biotinamido-hexanoate and NHS-LC-biotin function as (covalent) primary amine coupling reagents.

Considerations: High sucrose concentrations appear to chemically change components such as outer membrane protein-F (OmpF) found in the outer membrane structure of *E. coli* bacteria to the extent that they can no longer be recognized applying NHS-A-biotin as a detection agent.

Interpretation and Analysis: Both hydrophobic NHS-A-biotin and hydrophilic NHS-LC-biotin preferentially label outer membrane, periplasmic, and inner membrane proteins in *E. coli* preparations. NHS-A- and NHS-LC-biotin can also label a specific inner membrane marker protein (Tet-LacZ). Neither hydrophobic NHS-A-biotin nor hydrophilic NHS-LC-biotin probes label a cytosolic marker (the omega fragment of beta-galactosidase). Applying labeling procedures, *E. coli* populations grown in low-salt Luria broth medium reveal that both reagents react with outer membrane protein-A (OmpA) and outer membrane protein-C (OmpC) when bacteria are grown in the presence of sucrose formulated at gradient concentrations (e.g., 0%, 10%, and 20% sucrose supplementation). Conversely, only NHS-A-biotin labels OmpF in media containing 0 and 10% sucrose, and neither reagent detects this outer membrane protein fraction at 20% sucrose concentrations. A difference in the amount of OmpF contained in *E. coli* populations grown at 0%, 10%, and 20% cannot be detected in Coomassie-stained acrylamide gels. However, similar quantities of OmpF can be detected in *E. coli* cells grown at all 3 sucrose concentrations.

In vivo labeling of *Escherichia coli* cell envelope proteins with N-hydroxysuccinimide esters of biotin. Bradburne JA, Godfrey P, Choi JH, Mathis JN. Appl Environ Microbiol 1993 Mar; 59 (3), pp. 663–8.

General Septic Inflammation and Disease/ Radiolabeling Efficiency/Radiolabel Stability: *In Vivo*/Kinetic Profile: In Vivo/Dosimetry: *In Vivo Stabilized [^{99m}Tc]-Exametazime-Labeled Leukocytes*

Background Information: Labeling leukocytes with [^{99m}Tc]-exametazime is a validated technique for imaging infection and inflammation. A new radiolabeling technique has been described that enables leukocyte labeling with a more stable form of [^{99m}Tc]-exametazime.

Application: Detection and characterization of inflammatory and septic disease states.

Route of Administration: Stabilized [^{99m}Tc]-exametazime-labeled leukocytes (intravascular).

Semi-Synthetic Methods: Labeling of autologous leukocyte populations with [^{99m}Tc] using stabilized exametazime.

Implementation: Evaluation of the *in vivo* radioactive distrubution, kinetic profile, and dosimetry of stabilized [^{99m}Tc]-exametazime-labeled autologous leukocytes. Serial whole-body imaging and blood sampling are performed up to 24 hours after injection. Cell-labeling efficiency and *in vivo* viability, organ dosimetry, and clearance calculations are obtained from the blood samples and imaging data as well as samples of urine and stool collected up to 36 hours after injection.

Human Model: Cases in normal health (n = 10 volunteers).

Interpretation and Analysis: Cell-labeling efficiencies of 87.5% $\pm$ 5.1% can be achieved, which is similar to or better than that reported with the standard preparation of [^{99m}Tc]-exametazime. *In vivo* stability of the radiolabeled leukocytes is also similar to *in vitro* results with stabilized [^{99m}Tc]-exametazime and better than previously reported for the *in vivo* stability of non-stabilized [^{99m}Tc]-exametazime-labeled leukocytes. Organ dosimetry and radiation-absorbed doses are similar with a whole-body absorbed dose of 1.3 $\times$ 10^{-3} mGy/ MBq. Urinary and fecal excretion of activity is minimal, and visual assessment of images shows little renal parenchymal activity and no bowel activity up to 2 hours after injection.

Cell labeling and *in vivo* stability appear to be improved compared to leukocytes labeled with the non-stabilized [^{99m}Tc]-exametazime preparations. Advantages of the methodology include increased preparation cost-effectiveness of stabilized [^{99m}Tc]-exametazime and an extended window for clinical usage, with good visualization of abdominal structures on early images. No significant increase in specific organ and whole-body dosimetry estimates has been noted compared with previous estimates using non-stabilized [^{99m}Tc]-exametazime-labeled leukocytes.

Biodistribution and radiation dosimetry of stabilized [^{99m}Tc]-exametazine-labeled leukocytes in normal subjects. Robins PD, Salazar I, Forstrom LA, Mullan BP, Hung JC. J Nucl Med 2000 May; 41 (5), pp. 934–40.

ORGAN- AND TISSUE-ASSOCIATED SEPSIS AND INFLAMMATORY RESPONSES

Cardiovascular/Vascular Permeability: Septic Inflammation (Osteomyelitis) *[^{99m}Tc]-Sulesomab/[^{99m}Tc]-Human Serum Albumin (HSA)*

Cellular/Molecular Mechanism of Action: [^{99m}Tc]-sulesomab and [^{99m}Tc]-HSA have similar molecular weights (molecular mass). Human serum albumin within the intravascular compartment is primarily responsible for maintaining plasma oncotic pressure. However, when it is labeled and applied for diagnostic purposes, it per se exerts not true biological/molecular mechanism of action while functioning like a "blood-pool" agent.

Background Information: [^{99m}Tc]-sulesomab, the Fab fragment of anti-NCA-90, is used as an *in vivo* granulocyte labeling agent for imaging inflammation. It is not clear to what extent it can target cells that have already migrated into the interstitial space of an inflammatory lesion as opposed to circulating cells. The signal contribution of radioprotein diffusion in scenarios of increased vascular permeability has also been poorly documented.

Application: Detection and characterization of septic osteomyelitis conditions.

Route of Administration: [^{99m}Tc]-sulesomab and [^{99m}Tc]-HSA (intravascular).

Implementation: Evaluation of orthopedic infections (e.g., septic osteomyelitis) utilizing [^{99m}Tc]-sulesomab and [^{99m}Tc]-HSA as a function of their local kinetic profiles. [^{99m}Tc]-sulesomab and [^{99m}Tc]-HSA are administered in sequence separated by an interval of 2 to 6 days. Images are obtained 1, 3, 4, and 6 hours after injection, and multiple venous blood samples obtained for the calculation of blood clearance parameters. Patlak-Rutland (P-R) analysis is performed to measure lesion and control tissue protein clearance. Target-to-background tissue (T/Bkg) ratios are calculated for each radioprotein and compared with the T/Bkg ratio for [^{111}In]-leukocytes. [^{99m}Tc]-sulesomab binding to granulocytes can be measured *in vitro*, in *ex vivo* preparations, and *in vitro* to primed and activated granulocytes.

Human Model: Cases of septic osteomyelitis (n = 7) already previously detected as being clearly positive on [^{111}In]-leukocyte scintigraphy analysis.

Interpretation and Analysis: After intravenous injection, $<$ 5% of the circulating radioactivity is cell-bound for both radioproteins so that the P-R curves can therefore be assumed to represent extravascular uptake of free protein. The blood clearance (mean $\pm$ SD) of sulesomab is 23.4 $\pm$ 11.7 mL/min, which is approximately 5 times greater than that of HSA (4.8 $\pm$ 3.1 mL/min). Likewise, clearance into the lesion by sulesomab is consistently higher than for HSA (on average about 3 times as high). Nevertheless, the T/Bkg ratios for sulesomab and HSA are similar, except at 6 hours when that of HSA (2.14 $\pm$ 0.6) is higher than that of sulesomab (1.93 $\pm$ 0.5; p approximately 0.01). Both values are considerably less than the T/Bkg ratio on the [^{111}In]-leukocyte images, which, at 22 hours, is 12.3 $\pm$ 5.3. Moderate clearance of sulesomab, but not HSA, occurs in control tissue regions. Granulocytes bind significantly more [^{99m}Tc]-sulesomab *in vitro* when primed or activated. In conclusion, (i) sulesomab does not localize in inflammation as a result of binding to circulating granulocytes; (ii) sulesomab is cleared into inflammation non-specifically via increased vascular permeability; nevertheless, it may be cleared after local binding to primed granulocytes or bind to activated granulocytes that have migrated extravascularly; and (iii) HSA produces a similar or higher T/Bkg ratio than sulesomab because sulesomab is cleared into normal tissues and because image positivity in inflammation is significantly dependent on local blood-pool expansion.

Mechanism of accumulation of [^{99m}Tc]-sulesomab in inflammation. Skehan SJ, White JF, Evans JW, Parry-Jones DR, Solanki CK, Ballinger JR, Chilvers ER, Peters AM. J Nucl Med 2003 Jan; 44 (1), pp. 11–8.

Cardiovascular: Endocarditis (Septic/Bacterial)/ Platelet GP IIb/IIIa Receptor Expression Postactivation *DMP444*

Cellular/Molecular Mechanism of Action: The agent DMP444 recognizes GP IIb/IIIa receptors expressed by activated platelet populations.

Background Information: Bacterial endocarditis is an important clinical problem that may result in persistent bacteremia and irreversible cardiac damage. The condition is also characterized by the aggregation of activated platelets, fibrin, and bacteria.

Application: Scintigraphic detection and characterization of bacterial endocarditis conditions.

Route of Administration: [^{99m}Tc]-DMP444 (37 MBq/kg).

Dosage: [^{99m}Tc]-DMP444 (intravenous).

Implementation: Evaluation of the expression of GP IIb/IIIa receptors by activated platelets utilizing [^{99m}Tc]-labeled DMP444, which functions as a high-affinity antagonist of activated platelet GP IIb/IIIa receptor complexes. At 24 hours postinjection of bacterial populations, 37 MBq/kg [^{99m}Tc]-DMP444 is administered (IV). A non-specific control agent that can be applied in conditions of focal sepsis (e.g., 37 MBq/kg [^{99m}Tc]-IgG). Image analysis can be performed up to 4 hours postinjection. Samples are then obtained for tissue counting, microbiology, and histology.

Animal Model: Canine (n = 7 beagles [11–15 kg] with catheterization of their left ventricle through the right carotid artery; n = 2 complete sham procedures [reference controls]). One hour following catheterization, a dose of 5×10^7 colony-forming units of *Staphylococcus aureus* bacteria is injected intracardially (n = 5/7 beagles). Half an hour later, catheters are removed.

Interpretation and Analysis: At or greater than 1 to 2 hours postinjection, there is clear focal accumulation of DMP444 in the aortic valve region when endocarditis lesions exist, with an observed accumulation of agent over time. The non-infected and the [^{99m}Tc]-IgG injected models show only persistent blood pool activity without evidence of focal abnormality. At 4 hours postinjection, the *in vivo* valve-to-blood pool ratios are 1.87 $\pm$ 0.18 in endocarditis, 1.01 $\pm$ 0.05 in non-infected controls, and 1.09 $\pm$ 0.02 in [^{99m}Tc]-IgG injected dogs ($p < 0.05$). Targeting of activated platelets with the [^{99m}Tc]-labeled GP IIb/IIIa antagonist DMP444 allows determining a final diagnosis of experimental bacterial endocarditis within 4 hours facilitated by high, specific, and rapid *in vivo* uptake.

Scintigraphic detection of acute experimental endocarditis with the technetium-99m labeled glycoprotein IIb/IIIa receptor antagonist DMP444. Oyen WJ, Boerman OC, Brouwers FM, Barrett JA, Verheugt FW, Ruiter DJ, Corstens FH, van der Meer JW. Eur J Nucl Med 2000 Apr; 27 (4), pp. 392–9.

Central Nervous System (CNS): Septic and Non-Septic Inflammation/Glucocorticoid Influence on Inflammatory Responses/Multiple Sclerosis: Potential Applications/Leukocytes: *In Vivo* Labeling of Neutrophil and Macrophage Tuftsin Receptors *[^{99m}Tc]-RP128*

Cellular/Molecular Mechanism of Action: The agent RP128 functions as a chelation agent for [^{99m}Tc] in addition to recognizing

and binding to tuftsin receptors expressed by neutrophils and monocyte-macrophages.

Application: The agent [^{99m}Tc]-RP128 can be applied for the *in vivo* labeling of neutrophil and macrophage tuftsin receptor complexes for the purpose of detecting and characterizing focal lesions of septic inflammation. Additionally, the agent may be potentially applicable for the detection and characterization of human multiple sclerosis.

Route of Administration: Intravascular.

Implementation: Administration of [^{99m}Tc]-RP128 for the *in vivo* detection of CNS inflammation (e.g., experimental allergic encephalomyelitis).

Animal Model: Murine (experimental allergic encephalomyelitis [EAE] utilized as a reference disease model for human multiple sclerosis).

Interpretation and Analysis: The radiopharmaceutical [^{99m}Tc]-RP128 can be detected at significantly increased levels within EAE-diseased CNS tissues at 0.5, 1.0, and 3.0 hours postinjection using a dual radioisotope technique to correct for non-extravasated tracer ($p < 0.05$). Moreover, extravascular accumulation of [^{99m}Tc]-RP128 can clearly be demonstrated in inflamed tissues with minimal loss of sensitivity when the secondary isotopic correction for blood volume is omitted. In addition, [^{99m}Tc]-RP128 can successfully monitor glucocorticoid suppression of inflammation ($p < 0.05$), detected as a typical dose-response to increasing steroid concentration. Clearly, [^{99m}Tc]-RP128 can quantitatively detect CNS inflammation and assess responses to therapy, indicating potential value as an imaging agent both clinically and as a research aid. Furthermore, the rapid *in vivo* labeling by [^{99m}Tc]-RP128 of specific inflammatory cells combined with the ability to monitor the progress of anti-inflammatory therapeutics may validate the use of this cellular radiolabeling agent for detecting a variety of inflammatory conditions.

The detection and quantitation of inflammation in the central nervous system during experimental allergic encephalomyelitis using the radiopharmaceutical [^{99m}Tc]-RP128. Paul C, Peers SH, Woodhouse LE, Thornback JR, Goodbody AE, Bolton C. J Neurosci Methods 2000 May 15; 98 (1), pp. 83–90.

Gastrointestinal: Diarrhea: *Escherichia Coli* Enterotoxin-Induced Diarrhea/Intestinal Absorption *[^{51}Cr]-EDTA/D-Xylose*

Cellular/Molecular Mechanism of Action: [^{51}Cr]- ethylenediaminetetraacetic (EDTA) is an organic chelate of radioactive ^{51}chromium that is normally not significantly absorbed across intact, normal intestinal mucosa. Alternatively, D-xylose is absorbed across the surface of the small intestine mucosa.

Application: Detection and characterization of alterations in the intestinal permeability ([^{51}Cr]-EDTA) and absorptive capacity, including conditions associated with *E. coli* enterotoxin-induced diarrhea.

Route of Administration: D-xylose and [^{51}Cr]-EDTA can be administered orally for the purpose of evaluating intestinal absorption and permeability.

Implementation: Evaluation of alterations in intestinal absorptive capacity in diarrhea induced by the administration of *E. coli* enterotoxins. Intestinal absorption is evaluated using D-xylose and [^{51}Cr]-EDTA absorption tests.

Animal Model: Murine (*E. coli* heat-stable, heat-labile, and both heat-stable and heat-labile enterotoxin-induced diarrhea).

Interpretation and Analysis: The absorption of D-xylose is greatest 45 minutes after ingestion in both control and enterotoxin-treated groups. There is a significant ($p < 0.01$) decrease in xylose absorption at 45 minutes following exposure to all 3 entertoxin formulations compared to reference controls. Such findings may be due to changes in membrane fluidity and hence changes in membrane permeability, whereas [^{51}Cr]-EDTA absorption is at its maximum 15 minutes after ingestion in both controls and following enterotoxin exposure. No significant ($p < 0.05$) increase can be appreciated for [^{51}Cr]-EDTA absorption in enterotoxin-treated groups when compared to reference controls. Findings of this nature suggest a change in tight junctional permeability that may be due to alterations in cytoskeletal microfilaments. Both these tests do, however, demonstrate that *E. coli* enterotoxin-induced diarrhea results in absorption and permeability changes.

[^{51}Cr]-labeled ethylenediaminetetraacetic acid and D-xylose absorption test in *Escherichia coli* enterotoxin-induced diarrhea in mice. Verma M, Ganguly NK, Majumdar S, Walia BN, Verma M, Ganguly NK, Majumdar S, Walia BN. Scand J Gastroenterol 1995 Sep; 30 (9), pp. 886–91.

Gastrointestinal and Musculoskeletal Inflammation/ Intestinal Lesions: Non-Steroidal Anti-Inflammatory Drug (NSAID)-Associated/Intestinal Lesions: Crohn's Ileitis/Musculoskeletal: Rheumatoid Arthritis *[^{111}In]-Leukocytes/Tauro 23 [^{75}Se]-Selena-25-Homocholic Acid/[^{58}Co]-Labeled Cyanocobalamine*

Cellular/Molecular Mechanism of Action: The agent tauro 23 [^{75}Se]-selena-25-homocholic acid is a bile acid analog, while [^{58}Co]-labeled cyanocobalamine is an analog of vitamin B_{12}. Radiolabeled [^{111}In]-leukocytes behave *in vivo* like endogenous leukocytes of the same cell type.

Application: The agents tauro 23 [^{75}Se]-selena-25-homocholic acid and [^{58}Co]-labeled cyanocobalamine can be applied to evaluate intestinal absorption. Conversely, [^{111}In]-leukocytes can be used to detect foci of inflammation and sepsis.

Route of Administration: Intravenous.

Implementation: Evaluation of residual inflammatory lesions following discontinuation of NSAIDs using [^{111}In]-leukocyte scintigraphy imaging methodologies.

Human Model #1: Cases of rheumatoid arthritis ($n = 90$) and osteoarthritis ($n = 7$).

Human Model #2: Cases treated with NSAIDs ($n = 19$), healthy controls ($n = 20$), and Crohn's ileitis ($n = 13$).

Interpretation and Analysis: Using a [^{111}In]-leukocyte imaging technique reveals that cases of rheumatoid arthritis and osteoarthritis administered NSAIDs are associated with gastrointestinal lesions. More specifically, approximately two-thirds of all cases evaluated on long-term treatment display inflammatory lesions that may persist for up to 16 months following discontinuation. The prevalence and magnitude of the intestinal inflammation is unrelated to the type and dose of non-steroidal drugs and previous or concomitant 2nd-line drug treatment. There is a significant inverse correlation ($r = -0.29$, $p < 0.05$) between fecal [^{111}In] excretion and hemoglobin levels in cases treated with NSAIDs. The kinetics of fecal [^{111}In] excretion in cases treated with NSAIDs are almost identical to that of patients with small bowel Crohn's disease. Small bowel radiological examination of cases on NSAIDs reveals that approximately one-sixth have asymptomatic ileal disease with ulceration and strictures (e.g., $n = 3/18$ cases). Evaluation of cases on anti-inflammatory agents, normal healthy controls, and cases of Crohn's ileitis with tauro 23 [^{75}Se]-selena-25-homocholic acid and [^{58}Co]-labeled cyanocobalamine reveals several abnormalities. On day 4, more than half the cases with rheumatoid arthritis have evidence of bile acid malabsorption, but the ileal dysfunction is much milder than recognized with conditions of Crohn's ileitis.

Non-steroidal anti-inflammatory drug-induced intestinal inflammation in humans. Bjarnason I, Zanelli G, Smith T, Prouse P, Williams P, Smethurst P, Delacey G, Gumpel MJ, Levi AJ. Gastroenterology 1987 Sep; 93 (3), pp. 480–9.

Gastrointestinal Inflammation/Intestinal Lesions: Human Immunodeficiecy Virus (HIV) vs Acquired Immune Deficiency Syndrome (AIDS)/Intestinal Lesions: Crohn's Ileitis
[^{111}In]-Leukocytes/Tauro 23 [^{75}Se]-Selena-25-Homocholic Acid/[^{58}Co]-Labeled Cyanocobalamine

Cellular/Molecular Mechanism of Action: The agent tauro 23 [^{75}Se]-selena-25-homocholic acid is a bile acid analog, while [^{58}Co]-labeled cyanocobalamine is an analog of vitamin B_{12}. Alternatively, radiolabeled [^{111}In]-leukocytes behave *in vivo* like endogenous leukocytes of the same cell type.

Background Information: Previous investigations have examined small intestinal absorption-permeability, intestinal inflammation, and ileal structure and function (e.g., alterations in HIV-positive male homosexuals).

Application: The agents tauro 23 [^{75}Se]-selena-25-homocholic acid and [^{58}Co]-labeled cyanocobalamine can be applied to evaluate intestinal absorption. Conversely, [^{111}In]-leukocytes can be used to detect foci of inflammation and sepsis.

Implementation: Evaluation of intestinal absorption permeability and [^{111}indium] leukocyte distribution studies in order to detect and characterize intestinal inflammation in HIV-positive conditions. Complementary studies can be designed to characterize AIDS cases with a dual radioisotopic ileal function test (whole-body retention of tauro 23 [^{75}Se]-selena-25-homocholic acid and [^{58}cobalt]-labeled cyanocobalamine). Such cases can be evaluated using ileocolonoscopy in concert with terminal ileal biopsy.

Human Model #1: Cases of HIV that are seropositive ($n = 30$ at various stages of disease).

Human Model #2: Cases of AIDS ($n = 26$; $n = 17/26$ evaluated by ileocolonoscopy and terminal ileal biopsy).

Interpretation and Analysis: Normal intestinal absorption-permeability can be appreciated in well, HIV-infected cases, but both functions are impaired upon the development of AIDS. The median fecal excretion of [^{111}indium] in well patients (0.66%) does not differ significantly ($p > 0.5$) from controls (0.46%), but subjects with AIDS who are well or who have had diarrhea have significant ($p < 0.005$) intestinal inflammation (1.33% and 2.18%, respectively). The median 7-day retention of tauro 23-[^{75}Se]-selena-25-homocholic acid in well patients with AIDS (38.9%) does not differ significantly ($p > 0.2$) from controls (39.3%), whereas the absorption of [^{58}cobalt]-labeled cyanocobalamine is significantly ($p < 0.05$) lower than observed in controls (32.1% and 59.4%). Patients with AIDS-diarrhea have significant ($p < 0.001$) malabsorption of both the bile acid (7.7%) and vitamin B_{12} (8.9%), which is more severe than in Crohn's ileitis (14.2% and 30.3%, respectively). Morphometric analyses of ileal biopsies is unremarkable in AIDS. Such findings depict the presence of low-grade enteropathy in conditions of AIDS, severe ileal malabsorption in cases with AIDS diarrhea, and relatively minor ileal morphologic changes. Malabsorption of bile acids may play a pathogenic role in patients with AIDS and diarrhea.

Intestinal inflammation, ileal structure and function in HIV. Bjarnason I, Sharpstone DR, Francis N, Marker A, Taylor C, Barrett M, Macpherson A, Baldwin C, Menzies IS, Crane RC, Smith T, Pozniak A, Gazzard BG. AIDS 1996 Oct; 10 (12), pp. 1385–91.

Gastrointestinal Inflammation: Colitis (Acute Chemically Induced)
[^{99m}Tc]-HYNIC-Interleukin-8 (IL-8)/[^{99m}Tc]-Granulocytes

Cellular/Molecular Mechanism of Action: Interleukin-8 binds to its corresponding membrane-associated receptor complex expressed at relatively high densities by neutrophil and monocyte cell types. Granulocytes are chemotactically attracted to sites of septic and non-septic inflammation.

Physiological Mechanism of Action: Interleukin-8 can function as a chemotactic agent for granulocyte populations.

Implementation: Evaluation of acute colitis conditions facilitated by scintigraphic image analysis with [^{99m}Tc]-HYNIC-IL-8 and [^{99m}Tc]-granulocytes (purified cell populations). Gamma camera images are acquired at 2 minutes and at 1, 2, and 4 hours postinjection. At 4 hours after injection in animal models (e.g., rabbits), the uptake of the radiolabel in dissected tissues can be determined. The dissected colon is imaged and the inflammatory lesions are scored macroscopically. For each affected colon segment, the colitis index (affected colon-to-normal colon uptake ratio, CI) can be calculated and correlated with the macroscopically scored severity of inflammation.

Animal Model: Rabbit (chemically induced acute colitis).

Interpretation and Analysis: Both agents can facilitate visualization of colitis conditions within 1 hour after injection. [^{99m}Tc]-HYNIC-IL-8 images of colonic abnormalities are more accurate and the intensity of uptake in regions of affected colon continuously increase up to 4 hours after injection, whereas no further increases can be appreciated scintigraphically 1 hour after injection of [^{99m}Tc]-hexamethylpropyleneamine oxime (HMPAO)-granulocytes. Absolute uptake within affected colon is much higher for IL-8 than for radiolabeled granulocytes with the percentage of injected dose per gram equal to (%ID/g) 0.41 ± 0.04 %ID/g and 0.09 ± 0.05 4 %ID/g hour after injection, respectively. With increasing severity, the CI at 4 hours after injection for [^{99m}Tc]-HYNIC-IL-8 is approximately 4.4 ± 0.6, 13.5 ± 0.5, and 25.8 ± 1.0; for granulocytes, the CI at 4 hours after injection is 1.5 ± 0.1, 3.4 ± 0.2, and 6.4 ± 0.5, respectively. The CI correlates with the severity of the inflammation ($r = 0.95$, $p < 0.0001$ for IL-8; $r = 0.95$, $p < 0.0001$ for granulocytes). Therefore, within 1 hour after injection, visualization of the extent of colon inflammation *in vivo* is possible with [^{99m}Tc]-HYNIC-IL-8 and [^{99m}Tc]-HMPAO-granulocytes. Within 2 hours after injection, [^{99m}Tc]-IL-8 allows a good evaluation, and within 4 hours after injection, a meticulous evaluation of the severity of inflammatory bowel disease (IBD). Although [^{99m}Tc]-HMPAO-granulocytes are able to delineate the extent of IBD within 2 hours after injection, an accurate estimation of the severity of inflammation is not possible. [^{99m}Tc]-HYNIC-IL-8 is an inflammation-imaging agent that has demonstrated promising results in this study. [^{99m}Tc]-IL-8 can be prepared off-the-shelf and yields excellent imaging with high target-to-background ratios.

Instrumentation: Gamma camera imaging capabilities.

Rapid imaging of experimental colitis with [^{99m}Tc]-interleukin-8 in rabbits. Gratz S, Rennen HJ, Boerman OC, Oyen WJ, Corstens FH. J Nucl Med 2001 Jun; 42 (6), pp. 917–23.

Gastrointestinal Septic Foci/Appendicitis/Diverticulitis
Leukocytes/[^{99m}Tc]-HMPAO-Labeled Neutrophils

Cellular/Molecular Mechanism of Action: The preparation [^{99m}Tc]-hexamthylpropyleneamineoxide (HMPAO) functions as a radiolabeling agent for leukocytes.

Physiological Mechanism of Action: Radiolabeled neutrophils preferentially localize at sites of inflammation and sepsis in response to chemotactic stimuli in a manner highly analogous to if not identical to "native" neutrophil populations.
Application: Identification of septic and inflammatory foci (e.g., appendicitis). Neutrophils are the cell type most widely used for such diagnostic purposes.
Considerations: Diagnostic imaging with [^{99m}Tc]-HMPAO-labeled leukocytes is valuable for the detection of appendicitis and other intra-abdominal septic/inflammatory conditions. In 1 *in vivo* trial, 8 scans interpreted as negative for acute appendicitis were alternatively positive for other conditions, including 5 positive cases of diverticulitis, 1 case of neoplastic disease, 1 case of tubo-ovarian abscessation, and 1 case of small intestinal infarction.
Interpretation and Analysis: In *in vivo* clinical trials, the sensitivity of [^{99m}Tc]-HMPAO leukocyte scans is 87%, while their specificity rate is 92% and overall accuracy rate 89% for the detection of septic/inflammatory foci.

Gastrointestinal Septic Inflammatory Foci/ Appendicitis
[^{99m}Tc]-Labeled Anti-CD15 IgM Immunoglobulin

Cellular/Molecular Mechanism of Action: Anti-CD15 immunoglobulin M monoclonal antibody recognizes and binds to CD-15 complexes expressed on the exterior surface membrane of polymorphonuclear neutrophils. The difference between IgG and IgM immunoglobulin is that IgM is the principal immunoglobulin produced after the 1st exposure to an antigen while IgG is the principal immunoglobulin produced after 2nd exposure to the same antigen. IgM is composed of a pentomer of IgG-like molecules and generally has less specific antigen-binding properties than does IgG, but IgM has a higher propensity to generate multimolecular antigen/antibody complexes.
Application: Detection and monitoring of septic foci and lesions.
Route of Administration: Anti-CD15 immunoglobulin M monoclonal antibody (LeuTech: intravenous).
Dosage: Anti-CD15 immunoglobulin M monoclonal antibody (LeuTech: 10–20 mCi of Tc-99m).
Semi-Synthetic Methods: Preparations of anti-CD15 immunoglobulin M monoclonal antibody (e.g., LeuTech) avidly bind to circulating and sequestered human polymorphonuclear neutrophils *in vivo,* eliminating the need for *in vitro* cell labeling and the risks of blood handling.
Implementation: Evaluation of the safety and efficacy of anti-CD15 immunoglobulin M monoclonal antibody (LeuTech) imaging in cases of suspected acute appendicitis. An effective procedure includes the acquisition of serial dynamic and static planar images for up to 3 hours after intravenous administration. Scans are read as positive or negative for acute appendicitis or other intra-abdominal (septic) infection. The institutional diagnosis can be validated by surgery and histopathology of the appendix, results of other diagnostic studies, or 2-week clinical follow-up.

Human Model: Cases presenting with equivocal clinical signs (e.g., n = 99).
Interpretation and Analysis: Scans are usually positive in a very high percentage of cases of suspected appendicitis with validation of the condition at surgery (e.g., n = 39/40, sensitivity 98%). Conversely, images are negative for appendicitis in a large percentage of cases found not to have appendicitis (e.g., n = 49/58 = specificity 84%). Accuracy, positive predictive, and negative predictive values are approximately 90, 81, and 98%, respectively. In patients with appendicitis and positive scans, more than 50% of the images are positive at 4 minutes, and essentially all images are positive by 1 hour. Mean time of 1st positive image is about 15 minutes. Serious adverse reactions are generally rare. Imaging with anti-CD15 immunoglobulin M monoclonal antibody (LeuTech) is considered to be a highly sensitive diagnostic agent for detecting appendicitis in equivocal cases. Advantages of this agent over the other currently used radiotracers include greater convenience and time to diagnosis, particularly the expedient nature with which acute appendicitis will be visualized on scintigraphic images.

Scintigraphic determination of equivocal appendicitis. Rypins EB, Kipper SL. Am Surg 2000 Sep; 66 (9), pp. 891–5.

Histamine Receptor Agonist: H_3 Selective Avidity
Histamine H_3 Ligand

Cellular/Molecular Mechanism of Action: Highly selective H_3 receptor agonist with virtually no H_4 subtype receptor affinity.
Application: Evaluation of histamine function and image analysis of histamine receptor site distribution.
Semi-Synthetic Methods: A series of cyclopropane-based conformationally restricted analogues of histamine, the "folded" *cis*-analogues—that is, (1S,2R)-2-(aminomethyl)-1-(1H-imidazol-4-yl) cyclopropane (11), (1S,2S)-2-(2-aminoethyl)-1-(1H-imidazol-4-yl) cyclopropane (13), and their enantiomers ent-11 and ent-13, and the "extended" *trans*-analogues, that is, (1R,2R)-2-(aminomethyl)-1-(1H-imidazol-4-yl)cyclopropane (12) and its enantiomer ent-12—have been designed as histamine H_3 receptor agonists. These targeting compounds are synthesized from the versatile chiral cyclopropane units, (1S,2R)- and (1R,2R)-2-(tert-butyldiphenylsilyloxy)methyl-1-formylcyclopropane (14 and 15, respectively) or their enantiomers ent-14 and ent-15.
Interpretation and Analysis: Among the conformationally restricted analogues, the "folded" analogue 13 (AEIC) having the *cis*-cyclopropane structure has been identified as a potent H_3 receptor agonist, which shows significant binding affinity (K_i = 1.31 ± 0.16 nM) and has an agonist effect (EC_{50} value of 10 ± 3 nM) on the receptor. The compound owes its importance to being the 1st highly selective H_3 receptor agonist to have virtually no effect on the H_4 subtype receptor. Preliminary studies have therefore demonstrated that the *cis*-cyclopropane structure is very effective in the conformational restriction of histamine to improve the specific binding to the histamine H_3 receptor.

Cyclopropane-based conformational restriction of histamine. (1S,2S)-2-(2-aminoethyl)-1-(1H-imidazol-4-yl)cyclopropane, a highly selective agonist for the histamine H_3 receptor, having a cis-cyclopropane structure. Kazuta Y, Hirano K, Natsume K, Yamada S, Kimura R, Matsumoto S, Furuichi K, Matsuda A, Shuto S. J Med Chem 2003 May 8; 46 (10), pp. 1980–8.

Musculoskeletal: Osteomyelitis
[^{99m}Tc]-PEG Liposomes/[^{99m}Tc]-HYNIC-IgG/ [^{99m}Tc]-MDP/[^{111}In]-Granulocytes/[^{67}Ga]-Citrate

Background Information: Assessment of disease activity and disease extent in chronic osteomyelitis remains a difficult diagnostic problem. Radiographic imaging is not a particularly sensitive diagnostic modality for this particular purpose. Scintigraphic techniques can be more helpful, but routinely available agents lack specificity (e.g., [^{99m}Tc]-methylene diphosphonate (MDP); [^{67}Ga]-citrate) or are laborious to prepare (e.g., [^{111}In]-leukocytes).
Route of Administration: [^{99m}Tc]-PEG liposomes (intravenous); [^{99m}Tc]-HYNIC-IgG (intravenous); and [^{99m}Tc]-MDP (intravenous); [^{111}In]-granulocytes (intravenous); or [^{67}Ga]-citrate (intravenous).

Dosage: [^{99m}Tc]-PEG liposomes (37 MBq/rabbit); [^{99m}Tc]-HYNIC-IgG (37 MBq/rabbit); and [^{99m}Tc]-MDP (37 MBq/rabbit); [^{111}In]-granulocytes (18 MBq/rabbit); or [^{67}Ga]-citrate (18 MBq/rabbit).

Implementation: Scintigrahic image analysis of osteomyelitis lesions of the femur 4 weeks after bacterial infusion applying [^{99m}Tc]-PEG liposomes, [^{99m}Tc]-HYNIC-IgG, and [^{99m}Tc]-MDP on 3 consecutive days and imaged up to 4 hours (MDP) or 22 hours (liposomes and IgG) postinjection. On day 4, preparations of [^{111}In]-granulocytes or [^{67}Ga]-citrate can be injected and imaged up to 44 hours after injection. Uptake in the septic femur is determined within regions of interest. Ratios of infected-to-sham-operated femur can be calculated. In animal models, the left and right femur scored for microbiologic and histopathologic evidence of osteomyelitis can be established after acquiring the last scintigraphic image.

Animal Model: Chronic osteomyelitis is induced by inserting *Staphylococcus aureus* into the right reamed and washed femoral canal (rabbits). The canal is closed with cement and a sham operation performed on the left femur. Routine radiographs are obtained immediately after surgery and before scintigraphy.

Interpretation and Analysis: [^{99m}Tc]-PEG liposomes and [^{99m}Tc]-HYNIC-IgG can correctly identify lesions of osteomyelitis in a high percentage of cases (e.g., n = 6/6). In a small percentage of cases, [^{111}In]-granulocytes and [^{67}Ga]-citrate can produce equivocal results (e.g., 15% or n = 1/6), and [^{99m}Tc]-MDP may miss lesions of osteomyelitis (e.g., 15% or n = 1/6). Uptake in affected regions does not differ significantly between the imaging agents, although [^{99m}Tc]-MDP tends to produce higher values (MDP, 4.75 ± 1.23 percentage injected dose per gram [%ID/g]; [^{67}Ga], 2.05 ± 0.54 %ID/g; granulocytes, 1.56 ± 0.83 %ID/g; liposomes, 1.75 ± 0.76 %ID/g, and IgG, 1.96 ± 0.27 %ID/g). The ratios of infected-to-normal femur are also not significantly different for the respective radiopharmaceuticals. Radiography visualizes only severe osteomyelitis. [^{99m}Tc]-PEG liposomes and [^{99m}Tc]-HYNIC-IgG perform at least as well as [^{111}In]-granulocytes and [^{67}Ga]-citrate in the localization of chronic osteomyelitis (e.g., rabbits). The ease of preparation, the better image quality, and the lower radiation dose suggest that [^{99m}Tc]-PEG liposomes and [^{99m}Tc]-HYNIC-IgG might be suitable alternatives for [^{67}Ga]-citrate and [^{111}In]-granulocytes in the scintigraphic evaluation of osteomyelitis.

Scintigraphic evaluation of experimental chronic osteomyelitis. Dams ET, Nijhof MW, Boerman OC, Laverman P, Storm G, Buma P, Lemmens JA, van der Meer JW, Corstens FH, Oyen WJ. J Nucl Med 2000 May; 41 (5), pp. 896–902.

Musculoskeletal: Osteomyelitis
[^{67}Ga]-Citrate/[^{99m}Tc]-Methylene Diphosphonate (MDP)/[^{99m}Tc]-Interleukin-8 (IL-8)

Cellular/Molecular Mechanism of Action: [^{99m}Tc]-MDP is believed to be assimilated by active ostoblasts/osteoclasts at sites of dynamic bone growth and destruction.

Background Information: Early and accurate diagnosis of osteomyelitis remains a clinical problem. Acute osteomyelitis often occurs in infants and most often is located in the long bones. Radiologic images show changes only in advanced stages of disease. Scintigraphic imaging with [^{99m}Tc]-MDP, or bone scanning, is much more sensitive in detecting acute osteomyelitis but lacks specificity.

Application: Detection and characterization of septic osteomyelitis lesions.

Route of Administration: [^{99m}Tc]-MDP (intravenous), [^{99m}Tc]-IL-8 (intravenous).

Dosage: [^{99m}Tc]-MDP (18.5 MBq), [^{99m}Tc]-IL-8 (18.5 MBq).

Implementation: Scintigraphic characterization of osteomyelitis lesions 10 days following induction (e.g., n = 10 rabbits; n = 5/group) utilizing injections of either 18.5 MBq [^{111}In]-granulocytes or 18.5 MBq [^{67}Ga]-citrate. Images are acquired at both 24 hours and 48 hours postinjection. On day 12, serial images are acquired at 0, 1, 2, 4, 8, 12, and 24 hours after injection of either 18.5 MBq [^{99m}Tc]-MDP or 18.5 MBq [^{99m}Tc]-IL-8 preparations. Uptake in the infected femur is determined by establishing regions of interest (ROIs). Ratios of infected femur (target) to sham-operated femur (background) (T/Bs) are then calculated. In animal models, the right femur can be harvested postmortem to facilitate dissection and analysis of tissue samples for microbiological and histopathological evidence of osteomyelitis.

Animal Model: Acute pyogenic osteomyelitis can be induced in rabbits (e.g., n = 10) by inserting sodium morrhuate and *Staphylococcus aureus* into the medullary cavity of the right femur. The cavity is then closed with liquid cement. A sham operation is performed on the left femur. Routine radiographs are obtained just before scintigraphy imaging. Acute osteomyelitis develops in a high percentage of rabbits (e.g., n = 8/10).

Interpretation and Analysis: All imaging agents can correctly detect acute osteomyelitis in a very high percentage of cases (e.g., n = 8/8). The extent of infection can be optimally visualized with [^{67}Ga]-citrate and by delayed bone scanning, whereas diaphyseal photopenia can be detected with both [^{99m}Tc]-IL-8 and [^{111}In]-granulocytes. Some false-negative (e.g., n = 1/8) and false-positive (e.g., n = 1/8) image results can be observed with [^{111}In]-granulocytes and [^{99m}Tc]-MDP, respectively. Quantitative analysis of the images reveals that the uptake in the infected region is highest with [^{67}Ga]-citrate (4.9 ± 0.8 percentage injected dose [%ID]) and [^{99m}Tc]-MDP (4.7 ± 0.7 %ID), whereas the uptake in the infected area is significantly lower with [^{99m}Tc]-IL-8 (2.2 ± 0.2 %ID) and [^{111}In]-granulocytes (0.8 ± 0.2 %ID) ($p < 0.0042$). In contrast, the T/Bs are significantly higher for [^{99m}Tc]-IL-8 (T/B, 6.2 ± 0.3 at 4 hours after injection) than for [^{67}Ga]-citrate, [^{99m}Tc]-MDP, and [^{111}In]-granulocytes, which have ratios of 1.5 ± 0.4, 1.9 ± 0.2, and 1.4 ± 0.1, respectively ($p < 0.0001$). Radiography correctly reveals acute osteomyelitis in only a relatively small percentage of cases (e.g., n = 2/8). In experimentally induced osteomyelitis, [^{99m}Tc]-IL-8 clearly detects the osteomyelitic lesion. Although the absolute uptake in the osteomyelitic area is significantly lower than that obtained with [^{99m}Tc]-MDP and [^{67}Ga]-citrate, the T/Bs are significantly higher for [^{99m}Tc]-IL-8 because of fast background clearance. The ease of preparation, good image quality, and lower radiation burden suggest that [^{99m}Tc]-IL-8 may be a suitable imaging agent for the scintigraphic evaluation of acute osteomyelitis.

[^{99m}Tc]-interleukin-8 for imaging acute osteomyelitis. Gratz S, Rennen HJ, Boerman OC, Oyen WJ, Burma P, Corstens FH. J Nucl Med 2001 Aug; 42 (8), pp. 1257–64.

Musculoskeletal: Osteomyelitis
[^{99m}Tc]-Labeled Interleukin-8 (IL-8)

Cellular/Molecular Mechanism of Action: The cytokine IL-8 binds with high affinity to the CXCR1 and CXCR2 receptors on neutrophils.

Application: Previous investigations have shown that [^{99m}Tc]-IL-8 can rapidly and effectively delineate foci of infection and inflammation in rabbit models of intramuscular infection, colitis, and osteomyelitis.

Semi-Synthetic Methods: A derivative of hydrazinonicotinamide (HYNIC) can be used as a bifunctional coupling agent to label protein fractions with the [^{99m}Tc] radioisotope.

Implementation: Delineation of [^{99m}Tc]-IL-8 pharmacokinetic profiles in conditions of neutropenia compared to normal states and determination of the ability of [^{99m}Tc]-IL-8 to detect septic abscesses. To investigate the interaction of [^{99m}Tc]-IL-8 with blood cells in circulation (e.g., normal rabbits), the distribution of the radiolabel relative to circulating white and red blood cells and plasma is determined. The *in vivo* kinetics of [^{99m}Tc]-IL-8 is established by quantitative analysis of whole-body images acquired between 0 and 6 hours after injection. The results of such analyses (*in vivo* biodistribution) are validated by *ex vivo* counting of radioactivity residing within dissected tissue samples.

Animal Model: Turpentine-induced abscesses in both neutropenic and normal rabbits.

Interpretation and Analysis: The abscess uptake (percentage of injected dose per gram of tissue [%ID/g] ± standard error of measurement [SEM]) in immunocompetent rabbits (0.41 ± 0.05) is 10 times higher than that in neutropenic rabbits (0.038 ± 0.014), demonstrating specificity of the target uptake of [^{99m}Tc]-IL-8. Abscess-to-muscle ratios ± SEM are also 10 times higher (110 ± 10 vs 10 ± 5). Lung and spleen uptake in normal rabbits is 3 times higher than that in neutropenic rabbits. The blood clearance of the radiolabel in neutropenic rabbits is similar to that in normal rabbits. In circulation, most of the [^{99m}Tc]-IL-8 (70%) is found within the plasma fraction. Less than one-third is associated with red blood cells, and only a very low percentage (< 2.5%) is associated with white blood cells. Image analysis reveals a gradual increase in abscess uptake over time up to > 15%ID, which can be confirmed by *ex vivo* gamma counting of infected muscle tissue. The highest increase in uptake in abscesses is observed after 2 hours following injection, when most [^{99m}Tc]-IL-8 is cleared from the blood, suggesting specific neutrophil-mediated accumulation of [^{99m}Tc]-IL-8 within abscesses. Furthermore, region-of-interest analysis demonstrates gradual accumulation of [^{99m}Tc]-IL-8 within abscesses that is accompanied by a simultaneous clearance of activity from the lungs, suggesting that neutrophil-associated [^{99m}Tc]-IL-8 initially trapped in the lungs migrates to the abscess at later time points, favoring neutrophil-bound transportation from the lungs to the abscess. Substantial support exists for the hypothesis that [^{99m}Tc]-IL-8 localizes in the abscess, mainly bound to peripheral neutrophils. Accumulation within abscesses is a highly specific, neutrophil-driven process. As assessed by *in vivo* and *ex vivo* analysis, the total fraction that accumulates in the inflamed tissue is extremely high (up to > 15 %ID) compared with that of other agents used for imaging infection and inflammation.

Kinetics of [^{99m}Tc]-labeled interleukin-8 in experimental inflammation and infection. Rennen HJ, Boerman OC, Oyen WJ, Corstens FH. J Nucl Med 2003 Sep; 44 (9), pp. 1502–9.

Musculoskeletal: Osteomyelitis
[^{99m}Tc]-Labeled Antigranulocyte Antibody Fragments

Cellular/Molecular Mechanism of Action: Antigranulocyte antibody possesses binding avidity for membrane-associated antigens that are unique to neutrophil populations. Neutrophils are chemotactically attracted to areas of (septic) inflammation. The Fab fragment of IgG has the advantage of being devoid of the Fc fragment. Therefore, it minimally binds to membrane-associated Fc receptor complexes expressed by the mononuclear phagocytic system residing within the liver and spleen and is generally associated with a lower level of non-specific binding.

Application: Detection and characterization of septic inflammatory lesions.

Route of Administration: [^{99m}Tc]-labeled antigranulocyte antibody fragment (intravenous).

Dosage: [^{99m}Tc]-labeled antigranulocyte antibody fragment (740 MBq [20 mCi]).

Implementation: Immunoscintigrams performed with [^{99m}Tc]-labeled antigranulocyte antibody fragments for the detection of focal lesions of septic inflammation. Validation of findings can be established by histopathology, magnetic resonance imaging, computed tomography, and monitoring of clinical signs.

Interpretation and Analysis: The percentage of true-positive images obtained with [^{99m}Tc]-labeled antigranulocyte antibody fragments for the detection of septic inflammation is approximately 67% (e.g., n = 20/30). The number of false-positive results is relatively low (e.g., n = 3/30). Approximately 20% of images will be true-negatives (e.g., n = 6/30). Consequently, [^{99m}Tc]-labeled antigranulocyte antibody fragments can achieve high levels of sensitivity (e.g., 95%), moderately high specificity (e.g., 67%), and high diagnostic accuracy (e.g., 86%). Therefore, [^{99m}Tc]-labeled monoclonal antibody-Fab fragments are suitable for the detection of osteomyelitis. Their clinical application is simple, and their use guarantees a reliable and accurate diagnostic result just 1–2 hours after injection, making a late scan unnecessary. Coxarthrosis or hyperostosis can lead to false-positive results. A perforating ulcer of the foot may result in a false-negative conclusion.

Imaging osteomyelitis with Tc-99m-labeled antigranulocyte antibody Fab fragments. Von Rothenburg T, Schaffstein J, Ludwig J, Vehling D, Koster O, Schmid G. Clin Nucl Med 2003 Aug; 28 (8), pp. 643–7.

Musculoskeletal: Osteomyelitis/Sepsis: Inflammatory Reponses/[Diabetes Mellitus]
[^{131}I]-Interleukin-8 (IL-8) (Recombinant)/[^{99m}Tc]-Hydroxyethylene Diphosphonate

Cellular/Molecular Mechanism of Action: Neutrophils perceive IL-8 as a chemotactic factor and, therefore, express membrane-associated IL-8 receptor complexes.

Background Information: The chemotactic cytokine IL-8 plays an important role in the attraction and activation of polymorphonuclear leukocytes in infection and inflammation.

Application: Detection and characterization of septic inflammatory disease states. In this context, [^{131}I]-human recombinant IL-8 (rhIL-8) accumulates rapidly within infected foci in osteomyelitis and cellulites.

Route of Administration: [^{131}I]-rhIL-8 (intravenous).

Semi-Synthetic Methods: Radioiodination of rhIL-8 with [^{131}I] (specific activity, 0.4–0.7 MBq [11–18 μCi] [^{131}I]/μg IL-8).

Implementation: Detection and characterization of septic disease states applying [^{131}I]-rhIL-8 as an imaging agent.

Human Model: Cases of diabetes mellitus (n = 8 active foot infections with evidence of osteomyelitis; n = 2 successfully treated osteomyelitis; n = 1 cellulitis of the thumb).

Interpretation and Analysis: Focal accumulation of [^{131}I]-rhIL-8 can be seen in a high percentage of cases with active foot infection (e.g., n = 8/8). In other affected appendages, the image profile may appear diffuse (e.g., n = 1/1 thumb cellulitis). In cases successfully treated for osteomyelitis, multiphase [^{99m}Tc]-hydroxyethylene diphosphonate bone scans may be negative early, but late-phase (> 3 hours) uptake can detect degenerative lesions that are not initially detected by imaging with [^{131}I]-rhIL-8 (e.g., n = 2/2 cases). [^{131}I]-rhIL-8 accumulates rapidly within infected foci in

osteomyelitis and cellulitis but not in successfully treated infections or degenerative joint disease.

Imaging of human infection with [^{131}I]-labeled recombinant human interleukin-8. Gross MD, Shapiro B, Fig LM, Steventon R, Skinner RW, Hay RV. J Nucl Med 2001 Nov; 42 (11), pp. 1656–9.

Musculoskeletal Abscess Formation/Septic Inflammation and Infection
[^{111}In]-DPC11870-11/Leukotriene B_4 (LTB_4) Receptor-Binding Ligands

Cellular/Molecular Mechanism of Action: The agent DPC11870-11 is an antagonist of LTB_4 at its respective membrane-associated receptor complex.

Background Information: Several radiolabeled chemotactic peptides have been tested for their suitability to show infection and inflammation. Leukotriene B_4 receptor-binding ligands could be useful agents for revealing neutrophilic infiltrations because the LTB_4 receptor is abundantly expressed on neutrophils after an inflammatory stimulus.

Route of Administration: [^{111}In]-DPC11870-11 (intravenous).

Implementation: Detection of septic foci applying scintigraphic imaging techniques facilitated by radiolabeling the LTB_4 antagonist DPC11870-11 with [^{111}In]. Complementary investigations entail that delineation of the pharmacokinetics and biodistribution of [^{111}In]-DPC11870-11 established with serial scintigraphic imaging (0–24 hours after injection) and by *ex vivo* counting of dissected tissues (6 and 24 hours after injection). Receptor-mediated *in vivo* localization of the radiobiopharmaceutical agent can also be more precisely determined following the administration of an excess of non-radioactive indium-labeled agent 2 minutes before the administration of the [^{111}In]-labeled LTB_4 antagonist.

Animal Model: Rabbit (n = 3 New Zealand White rabbits with *Escherichia coli* infection induced by local injection into the left thigh muscle).

Interpretation and Analysis: In rabbits with intramuscular *E. coli* infection, abscesses can be visualized as early as 2 hours after injection. Accumulation in the abscess increases with time, resulting in the acquisition of excellent images at 6 hours postinjection. Blood clearance is rapid in the 1st hours after injection (alpha-half-life = 30 ± 6 minutes, 85%; beta-half-life = 25.7 ± 0.8 hours, 15%). Abscess-to-background ratios, as derived from the region-of-interest analysis, increases to 34 ± 7 at 24 hours after injection. Images of both groups show moderate uptake in the liver, spleen, kidneys, and bone marrow. No activity can be appreciated in the bladder, indicating almost complete retention in the kidneys. Accumulation within the abscess can be blocked completely by the injection of an excess of non-radioactive agent, indicating the occurrence of specific receptor-ligand interactions of the radiolabeled agent in infected/septic tissues. Biodistribution data show that after saturation of the LTB_4 receptor, the abscess uptake, in percentage injected dose per gram, is significantly reduced (0.03 ± 0.02 vs 0.24 ± 0.06, p = 0.008). The modified LTB_4 antagonist identifies/detects infectious foci rapidly after injection because of specific receptor-ligand interaction. Because of the high abscess-to-background ratios that are obtained and the fact that no accumulation of radioactivity is observed in the gastrointestinal tract, this compound has excellent characteristics for revealing infectious and inflammatory foci.

A bivalent leukotriene B_4 antagonist for scintigraphic imaging of infectious foci. van Eerd JE, Oyen WJ, Harris TD, Rennen HJ, Edwards DS, Liu S, Ellars CE, Corstens FH, Boerman OC. J Nucl Med 2003 Jul; 44 (7), pp. 1087–91.

Renal and Hepatic Cyst Formation/Septic vs Non-Septic Disease Differentiation/Polycystic Kidney Disease: Autosomal Dominant
[^{18}F]-Fluorodeoxyglucose (FDG)

Background Information: Infection of a renal or hepatic cyst is a serious complication of autosomal dominant polycystic kidney disease (ADPKD). Although crucial for successful management, early diagnosis is difficult, largely because of non-specific symptoms and limitations of conventional imaging techniques. Because of an increased metabolic rate, inflammatory cells take up large amounts of glucose. [^{18}F]-FDG, therefore, represents a promising agent for detection of cyst infections using positron emission tomography (PET).

Implementation: Performance of [^{18}F]-FDG PET scan imaging in cases of ADPKD suspected of being affected by renal or hepatic cyst infection (e.g., n = 7 FDG PET scans in 3 ADPKD cases suspected of renal or hepatic cyst infection; n = 2 PET scans of case A (PET 1 and 2); n = 1 PET scan of case B (PET 3); and n = 4 PET scans of case C (PET 4, 5, 6, and 7).

Interpretation and Analysis: [^{18}F]-FDG PET can identify infected cysts in conditions of (i) renal cyst infection; (ii) hepatic cyst infection; and (iii) simultaneous renal and hepatic cyst infection. Evaluations utilizing FDG PET imaging modalities have proven to be very helpful in establishing diagnoses and in excluding renal and hepatic cyst infections. Based on experience with FDG PET, this diagnostic strategy has promise as an imaging technique enabling early identification of renal and hepatic cyst infections in ADPKD patients.

Diagnosis of renal and hepatic cyst infections by [^{18}F]-fluorodeoxyglucose positron emission tomography in autosomal dominant polycystic kidney disease. Am J Kidney Dis 2003 Jun; 41 (6), pp. E18–21.

Respiratory Disease: Inflammation/Acute Respiratory Distress Syndrome (ARDS)
[^{111}In]-Labeled Neutrophils/[^{111}In]-aICAM-1/[^{111}In]-Labeled Normal Mouse IgG (nmIgG)/[^{111}In]-Labeled Rat Serum Albumin (RSA)

Cellular/Molecular Mechanism of Action: Fractions of aICAM-1 recognize and physically bind to ICAM-1 complexes (intracellular adhesion molecule-1). Neutrophils through mechanisms of chemotactic activity migrate to anatomical regions of inflammation and sepsis.

Background Information: Previous study of the bleomycin-induced lung injury model suggested that [^{111}In]-labeled anti-rat intercellular adhesion molecule-1 (aICAM-1) might be a useful diagnostic agent for detecting and characterizing conditions of ARDS.

Application: Detection and characterization of inflammation in the lung including ARDS.

Implementation: Evaluation of the diagnostic agent biodistribution, scintigraphic image profiles, and lung ICAM-1 upregulation utilizing [^{111}In]-labeled polymorphonuclear leukocytes (PMNs), [^{111}In]-aICAM-1, nmIgG, and [^{111}In]-labeled RSA injected 18–24 hours before euthanasia.

Animal Model: Rat neutrophils (polymorphonuclear leukocytes or PMNs) and rat *in vivo* radioactive distribution studies following induced injury with oleic acid.

Interpretation and Analysis: [^{111}In]-RSA and [^{111}In]-nmIgG localize in inflamed lung at 5 minutes postinjury (PI). [^{111}In]-PMN uptake increases significantly only at 24 hours PI. [^{111}In]-aICAM-1

localization increases significantly (30–60%) at 1 hour postinjury and remains elevated up to 24 hours postinjury. Lung/blood ratios (L/B) at 1 and 4 hours postinjury are very low (< 0.6) for [^{111}In]-nmIgG and [^{111}In]-PMN rats; however, for [^{111}In]-aICAM-1 rats, they are > 1 and 25–60% higher than those observed in reference control samples. A low L/B suggests poor detection of inflammation on acquired images. Images and region-of-interest analysis confirm that only [^{111}In]-aICAM-1 can distinguish inflamed lungs at 4 hours postinjury. ICAM-1 is up-regulated at 4 and 24 hours postinjury. Under certain circumstances, [^{111}In]-aICAM-1 can detect lung inflammation very early in the course of the disease and suggests that [^{111}In]-aICAM-1 could be a very early, highly specific ARDS diagnostic agent and may be useful to detect a wide range of inflammatory conditions.

Early detection of oleic acid-induced lung injury in rats using [^{111}In]-labeled antirat intercellular adhesion molecule-1. Weiner RE, Sasso DE, Gionfriddo MA, Thrall RS, Syrbu S, Smilowitz HM, Vento J. J Nucl Med 2001 Jul; 42 (7), pp. 1109–15.

Viral Infections: Human Immunodeficiency Virus (HIV)/Biological Proteins: Selective Binding
Aptamers (SELEX-Derived Small Oligonucleotides)/ [Systematic Evolution of Ligands by Exponential Enrichment]

Cellular/Molecular Mechanism of Action: Aptamers have been developed (designed/evolved) to bind biological proteins that are associated with a number of disease states. In this fashion, powerful antagonists of such biological proteins can be developed.

Application: Strategic development of powerful antagonists against biological proteins associated with the pathogenesis of certain disease states. Example: Detection of HIV infections.

Example: Human immunodeficiency virus.

Route of Administration: Intravenous (most often).

Dosage: Designed to directly establish a correlation between the specific biological activity (efficacy) of aptamer preparations and the corresponding pathological condition.

Considerations: Aptamers are small oligonucleotides derived from an *in vitro* evolution process called SELEX. The modest chemical functionality of nucleic acids poses some limits on their versatility as binders and catalysts. In addition, the sensitivity of pure RNA- and DNA-based aptamers to nucleases restricts their use as therapeutic and diagnostic agents.

Synthetic chemistry strategies have been established for modifying nucleotides to enhance aptamer affinity for targets and increase their stability in biological fluids. Implementation of *in vitro* selections with modified nucleotides promises to be an elegant technique for the creation of ligands with novel physical and chemical properties and is anticipated to have a significant impact on biotechnology, diagnostics, and drug development.

Although very effective *in vitro*, only a few examples are available showing their potential *in vivo*. In order for these antagonists to work in animal models of disease and in humans, it is necessary to modify aptamers. Sugar modifications of nucleoside triphosphates are necessary to render the resulting aptamers resistant to nucleases found in serum. Changing the 2′OH groups of ribose to 2′F or 2′NH_2 groups yields aptamers that have a plasma half-life of a relatively prolonged duration. The low molecular weight of aptamers (8,000–12,000) leads to rapid clearance from the blood. Conjugation to larger molecular weight compounds or delivery modalities can be utilized to extend the pharmacokinetic profile of aptamers within the intravascular compartment.

Synthetic Design: Combinatorial library selections through the systematic evolution of ligands by exponential enrichment (SELEX) technique identify so-called nucleic acid aptamers that bind with high affinity and specificity to a wide range of selected molecules.

Interpretation and Analysis: When modified conjugated aptamers are injected into animals, they inhibit physiological functions known to be associated with their target proteins. Aptamer arrays on solid surfaces will become available because SELEX protocols have been successfully automated. The use of photo-cross-linkable aptamers will allow the covalent attachment of aptamers to their cognate proteins, with very low background levels appreciated from other proteins found in body fluids. Finally, protein staining with any reagent that distinguishes functional groups of amino acids from those of nucleic acids (and the solid support) will give a direct readout of proteins on the solid support.

The influence of a well-characterized pseudoknot RNA aptamer selected for tight binding to HIV type 1 reverse transcriptase on HIV replication has been demonstrated in preliminary investigations. Transient intracellular expression of a chimeric RNA consisting of the human initiator tRNA(Met) (tRNA(Meti))/aptamer sequence in human 293T cells shows inhibition of HIV particle release by $>$ 75% when the cells are co-transfected with proviral HIV-1 DNA. Subsequent virus production by human T-lymphoid C8166 cells, infected with viral particles derived from co-transfected 293T cells, is reduced by $>$ 75% compared to reference controls. As the observed effects are additive, in this model for virus spread, the total reduction of HIV particle formation by transient intracellular expression of the pseudoknot RNA aptamer amounts to $>$ 95%. Low-dose HIV infection of human T cells stably expressing the aptamer does not show any virus replication over a period of 35 days. These investigations therefore represent an example of an RNA aptamer selected against a viral enzyme target that shows powerful antiviral activity in HIV-1-permissive human T-lymphoid cell lines.

Endogenous expression of a high-affinity pseudoknot RNA aptamer suppresses replication of HIV-1. Chaloin L, Lehmann MJ, Sczakiel G, Restle T. Nucleic Acids Res 2002 Sep 15; 30 (18), pp. 4001–8.

Viral Infections: Human Immunodeficiecy Virus (HIV) Targeting
Bis-Tetraazamacrocycle Xylyl-Bicyclam/Metal-Binding Platform

Cellular/Molecular Mechanism of Action: Macrocycles can function as radioisotope delivery modalities. Macrocycles are rigid enough to provide strong metal binding sites that can stereoselectively orient functional groups while retaining sufficient flexibility to accommodate structural changes required for induced-fit recognition of biological targets.

Application: Radioisotope delivery whereby they function as a molecular platform for the design of metal-based therapeutic and diagnostic agents.

Dosage: Designed to directly establish a correlation between the specific biological activity (efficacy) of aptamer preparations and the corresponding pathological condition of interest.

Implementation: Evaluation of the recognition of the Zn^{+2} complex of the bis-tetraazamacrocycle xylyl-bicyclam, a potent anti-HIV agent, by the co-receptor CXCR4, a G-protein-coupled receptor used by HIV for membrane fusion and cell entry.

Synthetic Chemistry and Analysis: Nuclear magnetic resonance (NMR) studies show that the macrocycles of $[Zn^{2+}]_2$-xylyl-bicyclam perchlorate exist in aqueous solution as 2 major configurations, *trans*-I (nitrogen chirality R,S,R,S), and *trans*-III (S,S,R,R). Acetate addition induces major structural changes. X-ray crystallography shows that the acetate complex contains the unusual *cis*-V cyclam configuration (R,R,R,R and folded) with bidentate coordination of acetate to $[Zn^{2+}]$ plus 2nd-coordination-sphere double H-bond formation between diagonal NH protons on the opposite cyclam face and acetate carboxylate oxygens. Detailed 1D and 2D NMR studies show that the major configuration of $[Zn^{2+}]_2$-xylyl-bicyclam acetate in aqueous solution is *cis*-V/trans-I. Molecular modeling shows that an analogous *cis*-V site can be formed when $[Zn^{2+}]_2$-xylyl-bicyclam binds to CXCR4, involving the carboxylate groups of Asp262 ($[Zn^{2+}]$coordination) and Glu288 (double H-bonding). The 2nd cyclam can adopt the *trans*-I (or *trans*-III) configuration with $[Zn^{2+}]$ binding to Asp171.

Implementation: Evaluation of the recognition of $[Zn^{2+}]$ complex associated with bis-tetraazamacrocycle xylyl-bicyclam, (potent anti-HIV agent), by the co-receptor CXCR4 (G-protein-coupled receptor used by HIV for membrane fusion and cell entry).

Interpretation and Analysis: The observed molecular interactions are consistent with the known structure-activity relationships for bicyclam anti-HIV activity and receptor mutation. Recognition of the anti-HIV activity of xylyl-bicyclam complexes of other metal ions suggests that affinity for carboxylates, configurational flexibility, and kinetic factors may all play roles in receptor recognition. For example, Pd(II) cyclam complexes interact only weakly with axial ligands and are inflexible and inactive, whereas $[Co^{3+}]$ cyclams bind carboxylates strongly, are configurationally flexible, and yet have low activity. Results from preliminary investigations are anticipated to facilitate the future design of new generations of active macrocycles, including highly specific chemokine receptor antagonists.

Structure and dynamics of metallomacrocycles: Recognition of zinc xylyl-bicyclam by an HIV co-receptor. Liang X, Parkinson JA, Weishäupl M, Gould RO, Paisey SJ, Park HS, Hunter TM, Blindauer CA, Parsons S, Sadler PJ. J Am Chem Soc 2002 Aug 7; 124 (31), pp. 9105–12.

PARASITOLOGY

Onchocerca volvulus
Mazzotti Test (Diethylcarbamazine)

Cellular/Molecular Mechanism of Action: Induces microfilaremia.

Application: Diagnosis of *Onchocerca volvulus.*

Route of Administration: Dethylcarbamazine (oral), but a topical variation has been described.

Dosage: Diethylcarbamazine citrate (1.6% in Nivea lotion as a topical diagnostic test).

Implementation: Evaluate by comparison the diagnostic accuracy associated with results from skin biopsies for microfilariae, nodule examination, enzyme-linked immunosorbent assay (ELISA), and the Mazzotti test (dethylcarbamazine challenge).

Human Model: Children in 3 age groups in Guatemala.

Diagnosis of Onchocerca *volvulus* infection in Guatemalan children. Campbell CC, Figueroa H, Collins RC, Lujan R, Collins WE. Am J Trop Med Hyg 1983 Jul; 32 (4), pp. 760–3.

Onchocerciasis focus in Colombia: Follow-up study after 12 years. Ewert A, Corredor A, Lightner L, D'Alessandro A. Am J Trop Med Hyg 1979 May; 28 (3), pp. 486–90.

The use of a topical Mazzotti *test in the diagnosis of onchocerciasis***.** Kilian HD. Trop Med Parasitol 1988 Sep; 39 (3), pp. 235–8.

Trypanosoma Gambiense
Chlorambucil and Prednisolone

Application: Latent infection detection of Trypanosoma gambiense.

Considerations: Evaluation of the efficacy of chlorambucil and prednisolone for the diagnosis of Trypanosoma gambiense.

Interpretation and Analysis: Increased release of trypanosomes is observed within the peripheral blood following administration, thereby facilitating the diagnosis of latent trypanosomiasis.

Wuchereria Bancrofti/Dipetalonema Perstans
Daytime/Nighttime Diethylcarbamazine (DEC)

Application: Detection and characterization of *W. bancrofti* and *Dipetalonema perstans* microfilaremia.

Background Information: Sometimes a false-negative DEC provocative test is obtained with such findings emphasizing the importance of cytology and adjunct diagnostic methods for detecting conditions of amicrofilaremia.

Parasitic infections are common in the developing countries, but the cytologic diagnosis of such infections is infrequent or rare. Detection of microfilariae in pleural fluid in the absence of classic symptoms and signs of tropical pulmonary eosinophilia has been reported**.**

Considerations: Large-scale filariasis surveys in rural areas for microfilaremia, especially of periodic types such as *W. bancrofti,* are known to cause considerable administrative, technical, and social problems.

Implementation: Determination of the sensitivity and specificity of 2 diagnostic strategies: (i) daytime DEC provocative tests (blood smear and microfilter concentration analyses); and (ii) night-blood examination by blood smear and microfilter concentration analyses, especially for *W. bancrofti.*

Human Model: Population of 2 villages in the Malumfashi district of the Northern Nigerian savanna.

Human Model: Cases of *W. bancrofti* infestation (n = 2 with undetectable nocturnal microfilaremia despite Nuclepore filtration, thus suggesting the possible merits of cytology in the primary diagnosis of a filarial infection).

Interpretation and Analysis: Daytime DEC provocative tests are more efficient in terms of sensitivity and specificity, compared with some night-blood methods for *W. bancrofti* detection but less so for *Dipetalonema perstans* (the other blood microfilaria frequently found in some populations). A regression line can be calculated between night-blood survey results for *W. bancrofti* and the results from daytime DEC provocative test. Using such a regression line, it is possible to estimate *W. bancrofti* microfilarial prevalence for night surveys, using the DEC provocative test results of daytime surveys. This can be done with minimal, but known, loss of accuracy and imposes fewer administrative, technical, and social difficulties.

Peripheral microfilaremia is recognized in a high percentage of affected cases. Attention can be drawn to the need for a high index of suspicion on the part of the cytologist in the identification of parasitic organisms in material from high-risk groups to achieve an early diagnosis of such infections and the prompt institution of appropriate chemotherapy. This may obviate the more serious pathologic

changes of advanced disease, especially the disfigurement of chronic and late filariasis.

Evaluation of the diethylcarbamazine provocative test in the diagnosis of Wuchereria bancrofti infections in the Nigerian savanna and the effects on Dipetalonema *perstans.* Wijeyaratne PM, Singha P, Verma OP, Motha B. Trans R Soc Trop Med Hyg 1982; 76 (3), pp. 387–91.

Wuchereria Bancrofti Microfilaremia: Pacific Variant *Diethylcarbamazine (DEC)*

Application: Induction of microfilaremia in cases (n = 70) of subperiodic Pacific-variant *W. bancrofti* infection 1 hour following DEC administration.
Route of Administration: Diethylcarbamazine (oral).
Dosage: Diethylcarbamazine (5 mg/kg), while other references have described total doses of 100 mg, 150 mg, or 200 mg of DEC (e.g., administered at noon).
Implementation: Detection of alterations in microfilaremia in conditions of *W. bancrofti* infestations. Before DEC administration, blood samples of 60 microliters are obtained by finger-prick at 2-hour intervals for 24 hours. A blood sample is then taken just before each carrier case is administered 3 DEC doses orally at noon. After drug administration, blood samples are obtained at 45 and 60 seconds and at 2, 3, 4, 5, 10, 15, 20, 25, 30, 40, 50, 60, 90, and 120 minutes. Samples are then taken at 2-hour intervals for the next 12 hours and at 6-hour intervals for the next 7 days. Both *W. bancrofti* and *Brugia malayi* showed typical nocturnal periodicity.

Human Model: Cases classified as nocturnal microfilarial carriers (n = 3 *W. bancrofti;* n = 3 *B. malayi*) from mainland China (n = 6 total) selected to determine the earliest appearance and peak count of microfilariae following the administration of DEC at 12:00 noon.
Interpretation and Analysis: In contrast to the immediate DEC-induced increase in microfilaremia previously described in patients with nocturnal periodic filariasis, DEC has also been reported to fail to elicit such responses in cases with subperiodic bancrofti infections. In this context, 1 hour after oral DEC the number of circulating microfilariae may be reduced to about 8% of pretreatment values.

Case reports have described the initial detection of microfilaremia in the peripheral blood 45 seconds in a microfilaria carrier. The microfilaria peak counts can be appreciated 1–40 minutes after a noon DEC dose. The nocturnal cycle occurs during the 1st 2 days after DEC administration and becomes regular with a much lower peak count by the 3rd day after administration. Results from such surveys indicate that the provocative effect of DEC on microfilaria is very fast (1st appearance in the peripheral blood vessels could be under 45 seconds).

Bancroftian filariasis: Long-term effect of the DEC provocative day test on microfilaraemia. Simonsen PE, Meyrowitach DW, Makunde WH. Trans R Soc Trop Med Hyg 1997 May–Jun; 91 (3), pp. 290–3.

Determination of the earliest appearance and peak count of microfilariae of Wuchereria *bancrofti and Brugia malayi after taking a single dose of diethylcarbamazine at noon.* Fan PC. J Helminthol 1994 Dec; 68 (4), pp. 301–4.

15 Metabolism, Electrolytes, and Hypoxia

Anoxia/Aglycemia/Ischemia: γ-Glutamyl Transpeptidase/Glutamate Carboxypeptidase II/ Cystine Oxidation

Acivicin/N-Acylated γ-Glutamyl-Glutamate/ γ-Glutamyl-Glutamine/γ-Glutamyl-Glutamate/ β-Mercaptoethanol

Cellular/Molecular Mechanism of Action: Acivicin is a γ-glutamyl transpeptidase inhibitor.

Phosphonate and phosphinate analogues of N-acylated γ-glutamylglutamate inhibit glutamate carboxypeptidase II (GCP II). γ-glutamyl-glutamine and γ-glutamyl-glutamate are both γ-glutamyl transpeptidase substrates.

Background Information: Extracellular metabolism of the protective substance glutathione (γ-glutamyl-cysteinyl-glycine) may generate cysteine, glycine, several γ-glutamyl-containing dipeptides and possibly free glutamate, all of which could participate in neurotoxicity events.

Application: Potential utility of these compounds as diagnostic agents and probes to understand folate or antifolate poly-γ-glutamate metabolism.

Considerations: The comparison of the results to previously reported inhibitory studies of the same compounds toward folylpoly-γ-glutamyl synthetase (FPGS) and γ-glutamyl hydrolase (γ-GH) provides insight into structural and mechanistic features of each enzyme.

Implementation: Examine how blockage of γ-glutamyl transpeptidase, the key enzyme in glutathione degradation, influences the extracellular concentrations of glutathione, cysteine, and related metabolites during anoxia/aglycemia.

Animal Model: Rat (hippocampal slices).

Interpretation and Analysis: Phosphonate and phosphinate analogues of N-acylated γ-glutamyl-glutamate inhibit GCP II, reflected by IC_{50} values in the low nanomolar range.

The net efflux (i.e., increase in extracellular concentration) due to changes in release and/or uptake of cysteine, cysteine sulfinate, γ-glutamyl-glutamate, γ-glutamyl-glutamine, glutathione, γ-glutamyl-cysteine, and glutamate increases as a result of anoxia/aglycemia. These increases in net efflux of cysteine, cysteine sulfinate, γ-glutamyl-glutamate, and γ-glutamyl-glutamine are reduced or blocked by acivicin, an inhibitor of γ-glutamyl transpeptidase. In contrast, acivicin causes an increase in both basal and anoxia/aglycemia-induced net efflux of glutathione, whereas the basal and anoxia/aglycemia-induced efflux of glutamate is unchanged by acivicin exposure. The effect of acivicin on the efflux of γ-glutamyl-cysteine is similar to that of glutathione, although less pronounced. Addition of β-mercaptoethanol to the incubation medium during and after 30 minutes of anoxia/aglycemia decreases the net efflux of cysteine sulfinate specifically, indicating that the increase in cysteine sulfinate during anoxia/aglycemia may be partly derived from the spontaneous oxidation of cysteine. Such findings suggest that γ-glutamyl transpeptidase may be involved in the regulation of the extracellular concentrations of cysteine, several γ-glutamyl-containing dipeptides, and glutathione, but not glutamate, during ischemia.

Net efflux of cysteine, glutathione, and related metabolites from rat hippocampal slices during oxygen/glucose deprivation: Dependence on γ-glutamyl transpeptidase. Li X, Wallin C, Weber SG, Sandberg M. Brain Res 1999 Jan 2; 815 (1), pp. 81–8.

Apoptosis and Oncosis: Cardiac Myocardial Cells/ Apoptosis: Doxorubicin-Induced/Oncosis: Isoproterenol-Induced

[^{111}In]-Antimyosin Antibody/[^{99m}Tc]-Glucaric Acid

Background Information: Non-invasive imaging techniques would be highly desirable to differentiate oncotic cell death from apoptotic cell death.

Application: [^{99m}Tc]-glucaric acid can be applied to detect oncotic myocardial cell death. Conversely, radiolabeled antimyosin is capable of detecting both oncotic and apoptotic types of myocardial cell death.

Route of Administration: [^{111}In]-antimyosin and [^{99m}Tc]-glucaric acid (intravenous).

Implementation: Evaluation of the diagnostic efficacy of dual administration of [^{111}In]-antimyosin antibody and [^{99m}Tc]-glucaric acid in a manner that can facilitate the detection of and differentiation between doxorubicin-induced myocardial apoptosis and isoproterenol-induced myocardial oncosis. Scanning electron microscopy, DNA laddering, terminal deoxynucleotidyl transferase-mediated deoxyuridine triphosphate nick-end labeling (TUNEL) staining, [^{111}In]-antimyosin antibody, and [^{99m}Tc]-glucaric acid can be collectively utilized *in vitro* and *in vivo* to detect doxorubicin-induced apoptosis or isoproterenol-induced myocardial oncosis.

***Ex Vivo* Model:** Cultured rat H9C2 embryonic cardiocytes. In this context, myocardial cell apoptosis can be induced by exposure of H9C2 embryonic cardiocytes to serial dilutions of doxorubicin.

Animal Model: Rats (CD1 strain for *in vivo* investigations). Myocardial apoptosis can be induced *in vivo* in rats by doxorubicin administration. Related investigations can employ heat or subcutaneous isoproterenol administration to induce myocardial oncosis.

Interpretation and Analysis: Scanning electron microscopy, DNA laddering, and TUNEL staining of H9C2 cardiocytes treated with doxorubicin all show cell death by apoptosis. Rat hearts treated with doxorubicin (10 and 20 mg/kg) are DNA ladder-positive and are associated with significantly greater [^{111}In]-antimyosin antibody (mean ± SD, 0.1942 ± 0.0150% injected dose per gram [%ID/g] and 0.1825 ± 0.0238 %ID/g, respectively) than normal hearts (0.1154 ± 0.0270 %ID/g, $p < 0.05$). Increases in myocardial [^{99m}Tc]-glucaric acid activity cannot be observed in rat hearts after 6, 12, and 24 hours of doxorubicin injection (0.0311 ± 0.0066 %ID/g, 0.0356 ± 0.007 %ID/g, and 0.0368 ± 0.0047 %ID/g, respectively; control hearts, 0.0352 ± 0.0099 %ID/g; p = not significant). Alternatively, [^{99m}Tc]-glucaric acid uptake is significantly greater in isoproterenol-induced oncotic hearts (0.1256 ± 0.1023 %ID/g) than in controls ($p < 0.0001$). [^{99m}Tc]-glucaric acid is avid only for the oncotic myocardium. Antimyosin, on the other hand, is positive for both oncotic and apoptotic myocardium.

Indium 111 antimyosin and Tc-99m glucaric acid for non-invasive identification of oncotic and apoptotic myocardial necrosis. Khaw BA, Silva JD, Petrov A, Hartner W. J Nucl Cardiol 2002 Sep–Oct; 9 (5), pp. 471–81.

Apoptosis Phenomenon: Hepatic and Thymic *[^{99m}Tc]-Hydrazinonicotinamido (HYNIC)-Annexin V*

Cellular/Molecular Mechanism of Action: Annexin V, a 32-kDa endogenous human protein, has a high affinity for membrane-bound phosphatidylserine.

Background Information: Either inadequate or excessive apoptosis (programmed cell death) is associated with many diseases. A method to image apoptosis *in vivo*, rather than acquiring histologic tissue samples for evaluation, could assist with therapeutic decision making in these disorders. Programmed cell death is associated with a well-choreographed series of events resulting in the cessation of normal cell function and the ultimate disappearance of the cell. One component of apoptosis is signaling adjacent cells that a cell is committing suicide by externalizing phosphatidylserine to the outer leaflet of the cell membrane.

Application: [^{99m}Tc]-HYNIC-annexin V can be utilized for the *in vivo* detection and quantification of apoptosis phenomenon in tissues and organ systems. Dexamethasone can be applied to induce thymic apoptosis.

Route of Administration: [^{99m}Tc]-HYNIC-annexin V (intravenous).

Dosage: Dexamethasone (1–20 mg/kg) 5 hours prior to [^{99m}Tc]-HYNIC-annexin.

Semi-Synthetic Methods: Covalent coupling of annexin V with the bifunctional hydrazinonicotinamide reagent (HYNIC) for the preparation of [^{99m}Tc]-HYNIC-annexin V.

Implementation: Detection of apoptosis phenomenon in the liver and thymus. Biodistribution analysis of [^{99m}Tc]-HYNIC-annexin V can be performed (in rats) 10–180 minutes following intravenous injection. Delineation of the degree of apoptosis required for *in vivo* localization of [^{99m}Tc]-annexin V (mice) can be determined with the aid of dexamethasone administered 5 hours prior to [^{99m}Tc]-HYNIC-annexin V. The thymus is then excised 1 hour after radiolabeled HYNIC-annexin V injection; thymocytes isolated, incubated with Hoechst 33342 followed by propidium iodide, and analyzed on a fluorescence-activated cell sorter. Each sorted cell population is counted in a scintillation counter. Evaluation of [^{99m}Tc]-HYNIC-annexin V as a tracer for external radionuclide imaging of apoptotic cell death can then be performed by radionuclide imaging 1 hour following injection of anti-Fas IgG in Fas-defective mice (lpr/lpr mice) and wild-type mice.

Animal Model: Rat and mouse.

Interpretation and Analysis: Biodistribution analysis of [^{99m}Tc]-HYNIC-annexin V in rats reveals a blood clearance half-time of less than 10 minutes. The kidneys have the highest concentration of radioactivity at any particular time point. Studies in the mouse thymus have demonstrated a 40-fold increase in [^{99m}Tc]-HYNIC-annexin V concentration in apoptotic thymocytes compared with viable cell populations. A correlation value of $r = 0.78$ can be appreciated between radioactivity and flow cytometric and histologic evidence of apoptosis. Imaging studies in lpr/lpr and wild-type mice show a substantial increase in activity within the liver of wild-type mice treated with anti-Fas, while there is no significant change, irrespective of anti-Fas administration, in lpr/lpr mice. Excellent imaging of hepatic apoptosis can be obtained in wild-type mice 30 minutes after injection of [^{99m}Tc]-HYNIC-annexin V. Imaging results are consistent with histologic analysis.

Technetium-99m HYNIC-annexin V: A potential radiopharmaceutical for the *in vivo* detection of apoptosis. Ohtsuki K, Akashi K, Aoka Y, Blankenberg FG, Kopiwoda S, Tait JF, Strauss HW. Eur J Nucl Med 1999 Oct; 26 (10), pp. 1251–8.

Apoptosis: Neoplastic Disease/Gliosarcoma/ Lewis Lung Carcinoma *Cy Annexin V*

Cellular/Molecular Mechanism of Action: Annexin V is a 32-kDa endogenous human protein that has a high affinity for membrane-bound phosphatidylserine, which is expressed at higher concentrations in cells undergoing apoptosis phenomenon.

Background Information: Non-invasive imaging using radioactive annexin V is an emerging strategy for the *in vivo* assessment of cell death.

Application: Detection and characterization of apoptosis phenomenon, including the evalatuion of neoplastic disease response to therapeutic intervention.

Semi-Synthetic Methods: Preparation of active Cy-annexin (an equimolar fluorophore dye:protein ratio) and an inactive Cy-annexin probe ($>$ 2 dyes/mol protein) that does not bind to apoptic Jurkat T cells.

Implementation: Evaluate the capacity for active annexin V labeled with fluorophore Cy5.5 (Cy annexin) with binding avidity for apoptotic Jurkat T cells to function as a probe for imaging (tumor apoptosis using near-infrared fluorescence (NIRF). To detect the influence of chemotherapy on the development of apoptosis, (tumors can be imaged with and without cyclophosphamide treatment).

Neoplastic Disease Model: 9L gliosarcoma, constitutively expressing green fluorescent protein marker, and the CR8 variant of Lewis lung carcinoma, stably transfected to express DsRed2. The expression of transfected fluorescent protein provides an indication of tumor margins and a means of defining tumor-associated NIRF signal intensity with both tumor models.

Interpretation and Analysis: In both tumor models active Cy-annexin V tumor NIRF signal increases 2 to 3 times after the treatment. A tumor NIRF signal develops by 75 minutes after active Cy-annexin injection and remains positive for a 20-hour observation period. Application of inactive annexin V as a control using the CR8 carcinoma cell type results in a low non-specific signal. With the 9L gliomosarcoma model, active Cy-annexin V binds to both tumor cells (Cy-annexin V staining only) and endothelial cells (co-stained with Cy-annexin V and antibody to the endothelial marker CD31). Such observations demonstrate that active Cy-annexin can be used as a NIRF probe to image apoptosis from outside an intact living animal and may facilitate the development of non-radioactive methods of measuring the antiproliferative effects of cancer chemotherapeutic regimens.

Near-infrared fluorescent imaging of tumor apoptosis. Petrovsky A, Schellenberger E, Josephson L, Weissleder R, Bogdanov A Jr. Cancer Res 2003 Apr 15; 63 (8), pp. 1936–42.

Apoptosis: Neoplastic Disease State/ Chemotherapeutic-Induced *[^{99m}Tc]-Annexin V/[Cyclophosphamide]/ TUNEL Tissue Analysis*

Cellular/Molecular Mechanism of Action: Annexin V is a human protein that possesses a high affinity for phosphatidylserine.

Application: Annexin V can be labeled with [^{99m}Tc] to detect apoptosis *in vivo*.

Route of Administration: [^{99m}Tc]-annexin V (intravenous).
Semi-Synthetic Methods: Radiolabeling of annexin V with [^{99m}Tc] (specific activity, 3.0 MBq/μg protein).
Implementation: Determine the ability of [^{99m}Tc]-annexin V to detect apoptosis identified by alterations in biodistribution profiles within innoculated allogenic hepatoma lesions 20 hours after cyclophosphamide administration. Radioactivity within specific tissues is then quantified 6 hours after [^{99m}Tc]-annexin V administration. As a form of reference control, tumor uptake of [^{14}C]-iodoantipyrine can be employed as a marker of tumor blood flow. Terminal deoxynucleotidyl transferase-mediated deoxyuridine triphosphate nick-end labeling (TUNEL) of tissue harvested at necropsy (animal model) can be utilized to validate detection of apoptosis within tumor tissue specimens.

Animal Model: Rat (inoculated with allogenic hepatoma cells [KDH-8] in the left calf muscle, followed 11 days later by randomized administration of a single dose of cyclophosphamide [150 mg/kg intraperitoneally]. Negative reference controls are not administered the chemotherapeutic agent).
Interpretation and Analysis: Cyclophosphamide treatment significantly increases tumor uptake (percentage activity of injected dose per gram of tissue after normalization to the animal's weight [%ID/g/kg]) of [^{99m}Tc]-annexin V (0.070 ± 0.007 %ID/g/kg for treated rats compared to 0.046 ± 0.009 %ID/g/kg for controls, $p < 0.001$). [^{14}C]-iodoantipyrine uptake is similar in the treated and untreated groups. The number of TUNEL-positive cells in the tumor is significantly larger in the treated rats (297.70 ± 50.34 cells/mm^2) than in the control rats (168.45 ± 23.60 cells/mm^2, $p < 0.001$). Tumor uptake of [^{99m}Tc]-annexin V correlates with the number of TUNEL-positive cells within tumor specimens ($r = 0.712$; $p < 0.001$). Tumor uptake of [^{99m}Tc]-annexin V is significantly increased by a single dose of cyclophosphamide treatment, and the increase is concordant with the number of TUNEL-positive cells in the tumor. Such observations suggest the utility of [^{99m}Tc]-annexin V as a noninvasive means to assess tumor response, although further testing, including clinical evaluation, is required.

Detection of apoptotic tumor response *in vivo* after a single dose of chemotherapy with [^{99m}Tc]-annexin V. Mochizuki T, Kuge Y, Zhao S, Tsukamoto E, Hosokawa M, Strauss HW, Blankenberg FG, Tait JF, Tamaki N. J Nucl Med 2003 Jan; 44 (1), pp. 92–7.

Apoptosis: Renal
[^{99m}Tc]-Hydrazinonicotinamido (HYNIC)-Annexin V

Background Information: [^{99m}Tc]-HYNIC-annexin V is a novel tracer for *in vivo* imaging of apoptosis.
Route of Administration: [^{99m}Tc]-HYNIC-annexin V (intravenous).
Dosage: [^{99m}Tc]-HYNIC-annexin V (250 MBq).
Implementation: Imaging is initiated with a transmission scan using a [^{57}Co]-flood source to obtain a map of the local thickness of the volunteer. [^{99m}Tc]-HYNIC-annexin V is then injected directly, followed by a 30-minute dynamic study. Whole-body scans are obtained at about 30 minutes, 3 hours, 6 hours, and 24 hours after injection. Organ uptake is determined after correction for background, scatter, and attenuation. The MIRDOSE3.1 program can be used to calculate organ-absorbed doses and effective dose. Signs of adverse effects can be detected by monitoring renal and liver function, hematology profiles, blood coagulation parameters, and vital signs (blood pressure, pulse, respiration rate, temperature, and electrocardiogram).

Human Model: Healthy male volunteers (n = 6).
Interpretation and Analyses: The kidneys accumulate 49.7 ± 8.1% of the injected dose (%ID) at 3 hours after injection; the liver, 13.1 ± 1.0 %ID; the red marrow, 9.2 ± 1.8 %ID; and the spleen, 4.6 ± 1.6 %ID. More than 90% of the blood activity is cleared with a half-life of 24 ± 3 minutes. The biologic half-life of the activity registered over the total body is long (69 ± 7 hours). Excretion of the activity is almost exclusively through the urine (22.5 ± 3.5 %ID at 24 hours), and hardly any activity is seen in the bowel or feces. Absorbed doses are approximately 196 ± 31 μGy/MBq for the kidneys, 41 ± 12 μGy/MBq for the spleen, 16.9 ± 1.3 μGy/MBq for the liver, and 8.4 ± 0.9 μGy/MBq for the red marrow. The effective dose is approximately 11.0 ± 0.8 μSv/MBq, or 2.8 ± 0.2 mSv for the average injected activity of 250 MBq. No adverse effects are usually observed. Therefore, [^{99m}Tc]-HYNIC-annexin V is a safe radiopharmaceutical, having a favorable biodistribution for imaging of apoptosis in the abdominal region as well as for the thoracic cavity at a radiation dose considered acceptable.
Instrumentation: A dual-head gamma camera can be used to acquire conjugate anterior and posterior views.

Safety, biodistribution, and dosimetry of [^{99m}Tc]-HYNIC-annexin V, a novel human recombinant annexin V for human application. Kemerink GJ, Liu X, Kieffer D, Ceyssens S, Mortelmans L, Verbruggen AM, Steinmetz ND, Vanderheyden JL, Green AM, Verbeke K. J Nucl Med 2003 Jun; 44 (6), pp. 947–52.

Beta-Oxidation: Hepatic Viability
p-[^{123}I]-Iodophenylenanthic Acid (IPEA)/ [$^{1\text{-}11}$C]-Octanoate

Cellular/Molecular Mechanism of Action: Octanoate and iodophenylenanthic acid are organic molecules that can be used to detect hepatic beta-oxidation capacity.
Background Information: Radiopharmaceuticals that reflect beta-oxidation in hepatocytes will provide useful information on the prognosis after surgery or on the efficacy of treatment, because beta-oxidation is the main pathway responsible for adenosine triphosphate in hepatocytes. The agent [$^{1\text{-}11}$C]-octanoate has been developed as a diagnostic agent for determining hepatic viability by means of positron emission tomography (PET).
Application: The agent *p*-[^{123}I]-iodophenylenanthic acid ([^{123}I]-IPEA) is a radiopharmaceutical that is potentially useful for the diagnosis of hepatic viability based on energy metabolism. Single photon emission computed tomography (SPECT) has the advantage of being more widely used than PET.
Route of Administration: *p*-[^{123}I]-iodophenylenanthic acid (intravenous).
Semi-Synthetic Methods: Production of 2 radioiodinated omega-(4-iodophenyl)-medium chain fatty acids, *p*-iodophenylvaleric acid (IPVA) and *p*-iodophenylenanthic acid (IPEA).
Implementation: Evaluation of IPVA and IPEA as candidate radiopharmaceuticals for the determination of hepatic viability. Utilizing SPECT methodologies, these agents can be applied to differentiate between conditions of hepatitis and normal liver function.

Animal Model: Rat (normal and hepatitis model).
Interpretation and Analysis: Metabolite *in vitro* and *in vivo* analyses and biodistribution studies in normal mice indicate that both compounds are actively taken up by the liver and metabolized by beta-oxidation. However, these studies also indicate that IPEA is more suitable as an imaging agent than IPVA [^{123}I]-IPEA. Hepatic [^{123}I-]IPEA time-activity curves reveal a 2-phase clearance of radioactivity in both normal and hepatitis model rats, but the clearance is delayed depending on the severity of hepatitis. Furthermore, the

clearance rate of the 1st phase correlates with adenosine triphosphate (ATP) levels in hepatocytes, which can be used as an index for energy production capacity in hepatocytes. In conclusion, IPEA is metabolized predominantly by beta-oxidation, and the clearance of IPEA from the liver is closely associated with the ATP concentration in the liver. Thus, [^{123}I]-IPEA is a potentially useful new radiopharmaceutical for diagnosis of hepatic viability as a function of energy metabolism.

Evaluation of radioiodinated medium chain fatty acids as new diagnostic agents for the determination of hepatic viability. Yamamura N, Magata Y, Konishi J, Saji H. Eur J Nucl Med 1999 Dec; 26 (12), pp. 1597–605.

Beta-Oxidation of Fatty Acids: Mitochondrial Disorders
Glucose/Pyruvate/Carnitine Loading/Phenylpropionic Acid Loading/Long-Chain Fat Loading

Cellular/Molecular Mechanism of Action: Glucose and pyruvate are precursors for the biochemical production of lactate.
Background Information: Since the discovery of muscle carnitine palmitoyltransferase deficiency in 1973, a dozen separate defects of mitochondrial fatty acid beta-oxidation in man have been identified. With the exception of medium-chain acyl-CoA dehydrogenase (MCAD) deficiency, which occurs with a frequency approaching 1:10,000 among Caucasians of Northern European origin, the other defects are quite rare. Collectively, however, they are common causes of disease resembling Reye's syndrome in early life, and some have a later and more chronic presentation with cardiomyopathy and skeletal muscle weakness. They also represent a small, but significant, proportion of cases of sudden and unexplained death within the 1st 2 years of life. Diagnosis of these disorders has become increasingly sophisticated, with the advent of new analytical technologies and an increased awareness of the appropriate clinical and laboratory investigations needed in order to evaluate potential defects of this pathway.
Diagnostic Application: Identification of mitochondrial "respiratory chain" disorders.
Implementation: Evaluation of mitochondrial disorders applying various molecular probes including pyruvate and glucose, in addition to performing provocative testing (e.g., carnitine loading, phenylpropionic acid loading, long-chain fat loading).
Interpretation and Analysis: Elevation in lactate concentrations following loading-dose administration of glucose and pyruvate compared to normal reference control subjects implies the presence of a biochemical defect in the assimilation of lactate at the level of the mitochondria (e.g., Krebs cycle). Application of these methodologies permits a specific diagnosis in the case of several, although not all, of the disorders of this pathway. Methods for the measurement of all of the enzymes of beta-oxidation are now available to enhance this diagnostic capability. There remain, however, many patients in whom clinical and laboratory signs point to a defect in beta-oxidation, but in whom no specific diagnosis has yet been made.
Laboratory Instrumentation: Conventional clinical pathology assay of serum lactate concentrations in addition to tandem fast atom bombardment-mass spectrometry and stable isotope dilution gas chromatography-mass spectrometry.

New developments in the diagnosis and investigation of mitochondrial fatty acid oxidation disorders. Coates PM. Eur J Pediatr 1994; 153 (7 Suppl 1), pp. S49–56.

Carbon Group Metabolization/Trans-Methylation, Trans-Sulfuration, Remethylation/ Hyperhomocysteinemia: Endstage Renal Failure/ Single-Carbon Group Transfer (5,10-Methylenetetrahydrofolate)/Hepatic Cytosol and Mitochondria
Carbon Dioxide Breath Tests/[$^{2}H_3$C-1-^{13}C]-Methionine/ [2,3,3-$^{2}H_3$] Serine

Cellular/Molecular Mechanism of Action: Collectively represent substrates that can be applied as "probes" to detect defects in hepatic biochemical function or capacity pertaining to the activity of specific enzyme systems involved in metabolic pathways.
Application: Estimation of *trans*-methylation, *trans*-sulfuration, and remethylation rates; and evaluation of carbon group transfer.
Route of Administration: Intravenous.
Implementation: Evaluation of whole-body *trans*-methylation, *trans*-sulfuration, and remethylation rates (e.g., [$^{2}H_3$C-1-^{13}C]-methionine]. Following administration, carbon radioisotope contained in exhaled air as carbon dioxide is then measured. Preparations of [2,3,3-$^{2}H_3$] serine can be applied to evaluate the transfer of a 1-carbon group from serine via 5,10-methylenetetrahydrofolate in human hepatocyte cytosol and mitochondria, respectively.
Animal Model: Ovine.
Interpretation and Analysis: The amount of carbon radioisotope contained in exhaled air is directly proportional to the rate the test molecular is metabolized *in vivo* following injection. Tissue-free methionine enrichments after infusion of universally labeled U-[^{13}C] methionine show the highest remethylation activity in postmortem investigation of jejunum, liver, and kidney tissue samples, but no such activity can be appreciated in muscle and brain preparations.
Instrumentation: Methods to quantitate 1-carbon acceptor metabolism pathways and folate metabolism have recently become available.

In vivo stable isotope measurements of methyl metabolism: Applications in pathophysiology and interventions. de Meer K, van den Akker JT, Smulders Y, Stam F, Stehouwer CD, Finglas P. Food Nutr Bull 2002 Sep; 23 (3 Suppl), pp. 113–9.

Carbonic Anhydrase (CA) Deficiency Syndromes/ (Genetic Disease of the Bone, Brain, and Kidney)
N-1-Tritylsulfenyl Histamine

Cellular/Molecular Mechanism of Action: Activation of carbonic anhydrase biochemical activity.
Application: Classes of CA activators can facilitate the development of drugs/diagnostic agents related to CA deficiency syndrome (genetic disease state affecting the bone, brain, and kidneys).
Chemistry: N-1-tritylsulfenyl histamine can be synthesized by reacting histamine (Hst) with tetrabromophthalic anhydride followed by protection of its imidazole moiety with tritylsulfenyl chloride. After hydrazinolysis, it affords a key intermediate, which is derivatized at the aminoethyl group in order to obtain new types of activators of the zinc enzyme carbonic anhydrase (CA, EC 4.2.1.1). Reaction of the key intermediate with 4-chlorophenylsulfonylureido amino acids (cpu-AA) in the presence of carbodiimides affords, after deprotection of the imidazolic nitrogen atom, a series of compounds with the general formula cpu-AA-Hst (cpu, 4-$ClC_6H_4SO_2NHCO$).
Considerations: Some structurally related dipeptide derivatives with the general formula cpu-AA1-AA2-Hst (AA, AA1, and AA2 represent amino acyl moieties) can also be prepared by a strategy similar to that applied for the amino acyl compounds mentioned above.

Interpretation and Analysis: The new derivatives proved to be efficient activators of 3 CA isozymes. Best activity can be detected against hCA I and bCA IV, for which some of the new compounds show affinities in the 1–10 nM range (h, human; b, bovine isozymes). hCA II, on the other hand, is less prone to activation by the new derivatives, which possess affinities around 20–50 nM for this isozyme.

Carbonic anhydrase activators: Synthesis of high affinity isozymes I, II, and IV activators, derivatives of 4-(4-tosylureido-amino acyl)ethyl-1H-imidazole (histamine derivatives). Scozzafava A, Iorga B, Supuran CT. J Enzyme Inhib 2000; 15 (2), pp. 139–61.

Carboxylic Acid Metabolism
1-[^{14}C]-α-Ketoisovaleric Acid (KIV)

Cellular/Molecular Mechanism of Action: 1-[^{14}C]-α-ketoisovaleric acid is a keto analogue of valine and can function as a biochemical substrate for molecular mechanisms of carboxylic acid metabolism.

Background Information: The keto analogues of essential amino acids represent a promising therapeutic modality in hereditary and acquired disorders of nitrogen metabolism. The utilization of these substances in humans has been assayed primarily by nitrogen balance studies.

Application: Endogenous biochemical metabolism of KIV can be measured using the $^{14}CO_2$ breath excretion test. In this context, the agent can be applied as a tool for the evaluation of certain diet formulations.

Route of Administration: Oral.

Implementation: Assessement of *in vivo* decarboxylation of KIV as a function of exhaled $^{14}CO_2$ using a simple and accurate breath excretion test. The experimental protocol applied in such investigations entails the utilization of protein diets (5 g) supplemented with essential amino acids and KIV (in place of valine). Diets of 120 g protein/day are then reevaluated in normal volunteers and gastrectomy cases.

Human Model: Normal volunteers and cases affected by a spectrum of disease states (n = 6 diseased; gastrectomy, hepatic failure, renal failure, and myotonic dystrophy).

Interpretation and Analysis: In situations of low protein intake, 13–32% of ingested KIV undergoes rapid decarboxylation, and this proportion appears to correlate inversely with damage to organ systems containing the branched-chain keto acid dehydrogenase. With high protein intake, the proportion of decarboxylated substrate increases between 44 to 53%. Such findings confirm that the decarboxylation of KIV in man varies under different conditions of dietary intake and metabolic disease. The $^{14}CO_2$ breath excretion test is applicable to other related analyses of carboxylic acid metabolism in human subjects.

Decarboxylation of α-ketoisovaleric acid after oral administration in man. Epstein CM, Chawla RK, Wadsworth A, Rudman D. Am J Clin Nutr 1980 Sep; 33 (9), pp. 1968–74.

Cortisol Metabolism/11-β-HSD$_2$ Biochemical Activity (Renal)
Deuterium-Labeled Cortisol

Cellular/Molecular Mechanism of Action: Deuterium-labeled cortisol is an analog of endogenous cortisol.

Application: Deuterium-labeled cortisol can be used as a labeled marker molecule for accessing *in vivo* alterations in endogenous cortisol metabolism mediated by 11-β-HSD$_2$ activities based on urinary excretion of cortisol, cortisone, and their A-ring reduced metabolites.

Route of Administration: Deuterium-labeled cortisol (oral).

Implementation: Evaluation of cortisol metabolism as a function of measurements of deuterium-labeled cortisol and its deuterium-labeled metabolites. Sample evaluation involves the application of GC/MS analyses simultaneously with the detection of endogenous cortisol, cortisone, and their A-ring reduced metabolites.

Human Model: Normal cases without evidence of disease.

Interpretation and Analysis: The stable isotope approach offers unique advantages in assessing the appropriateness of measuring unconjugated and total (unconjugated + conjugated) cortisol, cortisone, and their A-ring reduced metabolites in urine as indices of renal 11-β-HSD$_2$ activity. Measurement of urinary unconjugated cortisol and cortisone has many advantages for assessing 11-β-HSD$_2$ activity.

Instrumentation: Integrated gas chromatography/mass spectrometry system.

The use of deuterium-labeled cortisol for *in vivo* evaluation of renal 11-β-HSD activity in man: Urinary excretion of cortisol, cortisone, and their A-ring reduced metabolites. Kasuya Y, Shibasaki H, Furuta T. Steroids 2000 Feb; 65 (2), pp. 89–97.

Diabetes: Charge Permselectivity of Protein
Captopril/Clonidine

Cellular/Molecular Mechanism of Action: Captopril (angiotensin-converting enzyme inhibitor).

Physiological Mechanism of Action: Clonidine (tricyclic antidepressant).

Application: Determination of the charge permselectivity of proteins in conditions of diabetes after systemic and renal hemodynamic changes induced by an intravenous injection of captopril or clonidine.

Route of Administration: Captopril (IV) or clonidine (IV).

Dosage: Captopril (25 mg/100 ml in 5 minutes), clonidine (150 μg/100 ml), or placebo (100 ml saline).

Considerations: Anionic immunoglobulin clearance (IgG4) has been compared with that of total immunoglobulins, (same size but are mostly cationic), and of albumin.

Implementation: Evaluation of charge permselectivity of proteins in conditions of diabetes following systemic and renal hemodynamic changes induced by captopril or clonidine. Glomerular filtration rate (GFR) and renal plasma flow (RPF) are measured before and during test evaluations.

Human Model: Cases without signs of clinical nephropathy or other disorders. Ten type I hypertensive diabetic patients (Group 1), 10 type 2 hypertensive diabetic patients (Group 2), 5 type 1 normotensive diabetic patients (Group 3), 10 subjects with essential hypertension (Group 4), and 7 normal volunteers (Group 5) are administered captopril (25 mg/100 ml in 5 minutes). Hypertensive diabetic patients (e.g., n = 12) can be evaluated utilizing clonidine (150 μg/100 ml) (Group 6) as a 2nd provocative test. Negative reference controls (Group 7) can be administered as a placebo (100 ml saline).

Interpretation and Analysis: A significant decrease in diastolic blood pressure can be observed in case group types (CGT) 1, 2, 4, and 6, together with an increase in the GFR and RPF values in CGT 1, 2, 3, and 4 only, as well as a decrease in renal vascular resistances in CGT 1, 2, 3, 4, and 6. Both clearances and fractional clearances of IgG4 and IgG decrease after captopril in CGT 1 and 2.2+. The decrease in IgG4 clearance can be correlated with renal vascular resistant CGT cases. A significant decrease in the anionic-cationic immunoglobulin ratio (IgG4/IgG) is observed in CGT 1, 2, and 3.

Selective decrement of anionic immunoglobulin clearance after induced renal hemodynamic changes in diabetic patients. Di Mario U, Bacci S, Morano S, Pugliese G, Pietravalle P, Andreani D, Morabito S, Simonetti B, Pierucci A. Am J Physiol 1992 Mar; 262 (3 Pt 2), pp. F381–8.

Diabetes Insipidus/Hypothalamus/Pituitary/Adrenal Axis Function/Desamino-D-AVP (DDAVP) Replacement Therapy Response
Corticotropin-Releasing Hormone (CRH)/Arginine Vasopressin (AVP)

Cellular/Molecular Mechanism of Action: Hypothalamic CRH promotes release of adenocorticotropic hormone (ACTH) from the pituitary, which in turn promotes the release of cortisol by the adrenal gland.
Application: Assessment of hypothalamus-pituitary-adrenal axis integrity and function.
Considerations: A strong relationship has been found between AVP and hypothalamus-pituitary-adrenal axis in humans.
Implementation: Evaluation of baseline and CRH-stimulated ACTH and F levels in patients with central diabetes insipidus (CDI), before and after replacement therapy with DDAVP. A standard CRH test is performed in all subjects involving the measurement of plasma ACTH and serum F before and every 15 minutes for 2 hours after the administration of 100 μg of human CRH preparations. In patients with CDI, CRH tests are repeated after 1 week of DDAVP administered at standard doses.
Interpretation and Analysis: Initially, ACTH and F levels are significantly higher in patients with CDI than in controls either at baseline (ACTH: 45.5 ± 4.8 vs 18.5 ± 3.3 ng/l, $p < 0.05$; F: 375.1 ± 55.7 vs 146.6 ± 19.4 μg/l, $p < 0.05$) or after CRH test considered as a peak (ACTH: 90.8 ± 14.4 vs 42.5 ± 7.4 ng/l, $p < 0.05$; F: 501.6 ± 65.7 vs 226.3 ± 25.6 μg/l, $p < 0.05$) and area-under-the-curve (AUC) values (ACTH: 3,997.0 ± 571.7 vs 2,136.0 ± 365.8 ng/l/120 min, $p < 0.05$; F: 31,489.0 ± 4,299.4 vs 14,854.5 ± 1,541.5 μg/l/120 min, $p < 0.05$). In patients with CDI, 1 week of replacement with DDAVP results in diminished ACTH concentrations (peak: 56.9 ± 9.3 ng/l; AUC: 2390.7 ± 480.7 ng/l/120 min) and F (peak: 310.3 ± 39.5 μg/l; AUC: 17,555.5 ± 2008.7 μg/l/120 min) responses to CRH to normal but do not significantly modify baseline hormone levels (ACTH: 29.6 ± 3.6 ng/l; F: 239.0 ± 32.3 μg/l). In this context, CDI is associated with increased baseline ACTH and F levels and increased responsiveness of ACTH and F to CRH administration. In addition, replacement treatment with DDAVP normalizes CRH-induced but not baseline ACTH and F secretion.

Hypothalamus-pituitary-adrenal axis in central diabetes insipidus: ACTH and cortisol responsiveness to CRH administration. Pivonello R, Faggiano A, Filippella M, Di Somma C, De Martino MC, Gaccione M, Lombardi G, Colao A. J Endocrinol Invest 2002 Dec; 25 (11), pp. 932–7.

Diabetes Mellitus: Erythrocyte Anionic Charge (RBCCh)/Diabetic Nephropathy/Microalbuminuria/Altered Glomerular Charge Selectivity
Lysine/[Urinary Glycosaminoglycan Excretion]

Application: Detection and evaluation of diabetic RBCCh and albuminuria.
Implementation: Evaluation of the anionic charge on the surface of erythrocytes and the sialic acid and acid glycosaminoglycans (GAGs) content within erythrocyte membrane structures.

Human Ex Vivo Model: Cases of insulin-dependent diabetes that have albumin excretion rates less than 300 mg/24 hours.
Interpretation and Analysis: Statistically significant reductions in RBCCh and GAGs content in erythrocyte ghosts can be appreciated. In view of the demonstration of a negative correlation between RBCCh and albuminuria after a lysine provocative test, these observations support the hypothesis that the onset of microalbuminuria in human diabetes is sustained by an alteration of glomerular charge and consequently of glomerular charge selectivity. Many insulin-dependent diabetic patients with albuminuria in the "not at risk range" for diabetic nephropathy display high urinary excretion rates of glycosaminoglycans. A lysine provocative test in these subjects reveals abnormal urinary excretion of albumin, unlike findings obtained in insulin-dependent diabetic patients with normal urinary excretion rates of glycosaminoglycans. Such findings support the hypothesis that high urinary excretion of glycosaminoglycans is a marker of glomerular involvement in diabetes mellitus.

Abnormal erythrocyte charge in diabetes mellitus. Link with microalbuminuria. Gambaro G, Baggio B, Cicerello E, Mastrosimone S, Marzaro G, Borsatti A, Crepaldi G. Diabetes 1988 Jun; 37 (6), pp. 745–8.

Diabetes Mellitus: Impaired Glucose Tolerance/Diabetes Mellitus: Non-Insulin-Dependent Diabetes Mellitus
Low-Osmolality Glucose/Glucose

Application: Screening agent for impaired glucose tolerance or non-insulin-dependent diabetes mellitus.
Route of Administration: Glucose (oral).
Dosage: Standard (1.38 mol/L) 75-g oral glucose tolerance test solution. Lower osmolar (0.62 mol/L) 50-g glucose solution.
Considerations: A 75-g oral glucose tolerance test beverage (gold standard for diagnosis of diabetes in accordance with criteria established by the World Health Organization) can be applied in combination with the collection of 1- and 2-hour blood glucose values.
Implementation: Evaluation of glucose regulation in response to the administration of a 75-g oral glucose tolerance test beverage or 50-g glucose solution. Blood samples are drawn at baseline and 30, 60, and 120 minutes after ingestion of each glucose solution.
Interpretation and Analysis: Both solutions were shown to have a high sensitivity and specificity for detecting diabetes and impaired glucose tolerance at 30 and 60 minutes.

The physiologic 50-g solution uses less glucose, is highly palatable, and is similar in sweetness and carbohydrate concentration commonly employed in the production of soft drink beverages. Studies need to be performed in small animal species to determine the feasibility of applying lower osmolality formulations of glucose as a screening technique for the diagnosis of impaired glucose tolerance or non-insulin-dependent diabetes mellitus. The ability to perform high-sensitivity and high-specificity screening of cases suffering from diabetes or impaired glucose tolerance with a single timed blood sample could make mass screening more practical.
Instrumentation: Glucometer.

Use of a physiologic oral glucose solution for screening for impaired glucose tolerance and non-insulin-dependent diabetes mellitus. Phillips WT, Tilson KS, Schwartz JG. Arch Pathol Lab Med 1996 Sep; 120 (9), pp. 842–6.

Diabetes Mellitus: Insulin Resistant/Growth Hormone: Pituitary Dwarfism/Acromegaly
Insulin

Cellular/Molecular Mechanism of Action: Promotes transport of glucose across cellular membranes into the cytosol.
Diagnostic Application: Pituitary-based (feline) acromegaly.
Route of Administration: Subcutaneous injection.
Dosage: Insulin (25 U/day/feline).

Interpretation and Analysis: Patients (feline) displaying insulin-resistant diabetes mellitus (persistent hyperglycemia) following administration of insulin at a dose equal to or greater than 25 U/day should be considered as possibly suffering from pituitary-based acromegaly. Additional clinical signs that support the diagnosis of acromegaly would include the presence of arthropathy and cardiomyopathy. Acromegaly patients will have excessively high systemic concentrations of growth hormone (GH) within the intravascular compartment. Further diagnostic pharmacology can be utilized to verify a diagnosis of acromegaly through the application of a glucose suppression test because glucose suppresses pituitary GH secretion (see glucose suppression test).
Laboratory Instrumentation: Laboratory facilities and instrumentation necessary for performing immunoassay procedures (RIA or ELISA).

Diabetes Mellitus: Residual Beta-Cell Secretory Capacity/Short-Term vs Long-Term Diabetes Mellitus/C-Peptide Response
Glucose/Tolbutamide/Glucagon

Application: Assessment of residual beta-cell secretory capacity in short-term (2 months–2 years) and long term (5–8 years) insulin-dependent diabetes by measuring serum C-peptide immunoreactivity.
Implementation: Evaluation of insulin-dependent conditions as a function of C-peptide responses to glucose, tolbutamide, and glucagon stimulatory tests.
Interpretation and Analysis: Minimal C-peptide secretion can be detected in only a small percentage of test cases following stimulatory tests in long-term diabetics (n = 1/7). A very high percentage of short-term diabetics will respond to at least 1 provocative test for beta-cell reserve (e.g., n = 7/7), although these responses are blunted. The greatest C-peptide responses occur after glucagon administration (mean increase 0.62 pmol/ml) in short-term responders. Patients that respond to 1 test do not necessarily respond to another stimulus. There is no correlation between basal C-peptide levels and the ability to provoke further C-peptide secretion by any of the 3 tests. C-peptide responses do not correlate with % hemoglobin A1c, mean fasting blood glucose levels, or mean blood glucose concentrations during oral glucose tolerance tests. Such observations suggest that stimulation tests are only useful in assessing endogenous beta-cell reserve in patients with diabetes of less than 5 years duration. In diabetics of longer duration there is little insulin reserve above basal levels.

A 2-year pilot trial of continuous subcutaneous insulin infusion vs intensive insulin therapy in patients with newly diagnosed type 1 diabetes (IMDIAB 8). Pozzilli P, Crinò A, Schiaffini R, Manfrini S, Fioriti E, Coppolino G, Pitocco D, Visalli N, Corbi S, Spera S, Suraci C, Cervoni M, Matteoli MC, Patera IP, Ghirlanda G. Diabetes Technol Ther 2003; 5 (6), pp. 965–74.

Electrolyte Membrane Transport Complexes/ Myocardial Na/K-ATPase
[^{125}I]-Digoxin/[^{125}I]-Digoxin-Iodohistamine (bis(O-Carboxymethyloxime))/Ouabain Displacement

Cellular/Molecular Mechanism of Action: Cardiac glycosides recognize and physically bind to membrane-associated myocardial Na/K-ATPase complexes.
Background Information: Cardiac glycosides have a high binding avidity for myocardial Na/K-ATPase complexes.
Implementation: Survey of radioiodinated digoxin (cardiac glycoside) derivatives as potential candidates for myocardial imaging with particular emphasis on non-invasive monitoring of cardiac glycoside therapy.
Interpretation and Analysis: One radioiodinated digoxin derivative, [^{125}I]-digoxin-iodohistamine(bis(O-carboxymethyloxime)) accumulates at relatively high levels in the myocardium and displays similar binding avidity for Na/K-ATPase as digoxin itself against ouabain displacement, as indicated by *in vivo* and *in vitro* studies. Based on these results, [^{123}I] labeling of digoxin-histamine(bis(O-carboxymethyloxime)) and imaging analyses in a dog demonstrate uptake of the agent within the myocardium.

High myocardial accumulation of radioiodinated digoxin derivative: A possible Na/K-ATPase imaging agent. Fujibayashi Y, Takemura Y, Matsumoto K, Wada K, Yonekura Y, Konishi J, Yokoyama A. J Nucl Med 1992 Apr; 33 (4), pp. 545–9.

Extrahepatic Metabolism/Vascular Perfusion: Hepatic Blood Flow/[Xenobiotic Metabolism]
Phenol Red/Lidocaine (Monoethylglycinexylidide [MEGX])

Background Information: Xenobiotic metabolism in extrahepatic tissues has been extensively studied *in vitro*, but it is difficult to estimate *in vivo* the share of xenobiotic transformation in extrahepatic tissues for lack of a suitable approach.
Application: Assessment of extrahepatic metabolism established by investigating the conversion of lidocaine to the metabolite MEGX.
Animal Model: Rat (rats were anesthetized with ethyl ether inhalation). In exposed livers, the hepatic liver artery is ligated, and the portal vein is clamped at its distal end. The left hepatic lobe is partly excised along its inferior margin, and a heparinized silicone catheter, diameter 0.2 cm, is inserted into the portal and left hepatic veins to allow recirculation of portal vein blood. Sham operations are performed in control group.
Interpretation and Analysis: Phenol red test shows that hepatic blood supply is absolutely blocked in model rats. At 30 minutes after establishing the portal-cavum bypass, the renal function and electrolytes do not change, but serum glucose decreases by 64.4 ± 30.4%; 30 minutes after intravenous administration of 1.0% lidocaine 2 mg/kg, serum MEGX in model rats is 32.0 ± 7.14% of that in the control group, which mostly exists in a free form and is not induced by phenobarbital pretreatment. The model is easy to establish and provides an *in vivo* method to study the extrahepatic metabolism of xenobiotics.

An *in vivo* rat model for assessment of extrahepatic metabolism. Ping H, Zhen-Fu C, Shao-Qing X, Ming L, Jian W, Guo-Qing Z, Lin Z, Lin-Fang L, Meng-Chao W. J Pharmacol Toxicol Methods 2001 May–Jun; 45 (3), pp. 181–5.

Gluconeogenesis: Hepatic Glucose Production (Glucose-6-Phosphatase Activity)/Abnormal Plasma Concentrations/Preterm Infants
Glucagon/(Tolerance Test)

Background Information: Developmental failures to adequately control postnatal blood glucose levels are common in the transition from fetal to infant life and can persist for many months. The standard method of functionally measuring hepatic glucose production and/or disordered glucose production is the response to a glucagon tolerance test.
Application: Detection and characterization of abnormalities in hepatic glucose production and glucose metabolism.

Implementation: Evaluation of an adapted version of the standard glucagon tolerance test currently used for children and adults for application in preterm infants.

Human Model: Consecutive cases of preterm infants (n = 79 preterm gestational age range 25–36 weeks; mean 32.2 weeks; mean birth weight 1.66 kg admitted to an intensive care unit that survived to time of discharge). At the time of discharge to home care, characteristics of the study group consist of adjusted mean gestational age 36.7 weeks, mean discharge weight 2.23 kg.

Interpretation and Analysis: Following the administration of a glucagon tolerance test, preterm infants display a maximal increase in plasma glucose of 1.39 ± 0.07 mmol/L (range 0–3.98 mmol/L for n = 78). An increase in plasma glucose of less than 4 mmol/L is considered abnormal in adults following administration of a fasting glucagon tolerance test. The responses of preterm infants and adults to glucagon are clearly different. The attenuated response to glucagon in the preterm infants is consistent with the low levels of hepatic glucose-6-phosphatase activity in premature infants, as glucose-6-phosphatase is the terminal step of the 2 main pathways of liver glucose production.

Developmental disorders of glucose metabolism in infants. Hume R, McGeechan A, Burchell A. Child Care Health Dev 2002 Sep; 28 Suppl 1, pp. 45–7.

Glucose Transport Protein (GluT)
4,6-(R)-O-(2′-Iodoethylidene)-α, β-D-Glucose

Cellular/Molecular Mechanism of Action: Mimics molecular glucose and is therefore subject to the same cellular transport mechanisms.

Application: Characterization of glucose transporter complexes. Characterization of glucose binding complexes and transport mechanisms.

Route of Administration: Intravenous.

Semi-Synthetic Methods: Preparation of 2 iodinated acetals of D-glucose, 4,6-(R)-O-(2′-iodoethylidene)-α, β-D-glucose (#1); and 4,6-(R)-O-(4′-iodobenzylidene)-α, β-D-glucose (#2).

Considerations: Analogs of acetal D-glucose derivatives are known to bind to the exofacial sites of the glucose transport protein (GluT).

Implementation: Assessment of the capacity of iodinated acetals #1 and #2 to interact with the glucose transporter. Radiolabeling of the glucose analogs with [^{123}I] can faciliate the detection and analysis of glucose transport proteins utilizing SPECT imaging analysis.

***Ex Vivo* Model:** Human erythrocytes (GluT1) and neonatal rat cardiomyocytes (GluT4).

Biological evaluation of 2 iodine-123-labeled D-glucose acetals prepared as glucose transporter radioligands. Brunet-Desruet MD, Ghezzi C, Morin C, Comet M, Fagret D. Nucl Med Biol 1998 Jul; 25 (5), pp. 473–80.

Hyperkalemic Periodic Paralysis (HYPP)
Potassium/Acetazolamide/Calcium Glucuronate/ Bicarbonate/Glucose (± Insulin)

Cellular/Molecular Mechanism of Action: Acetazolamide inhibits carbonic anhydrase (CA) activity. Pharmaceuticals within the thiazide class act directly on the kidney and increase the excretion of sodium chloride, potassium chloride, and water. At sufficient doses, pharmaceuticals within this class such as acetazolamide also promote bicarbonate excretion. Potassium excretion is achieved through a combination of enhanced excretion at the distal tubule, accented by drug-induced microvascular hyperperfussion at the level of the distal renal tubule.

Background Information: Hyperkalemic periodic paralysis is characterized by sporadic attacks of muscle tremors, weakness, and/or collapse, lasting for variable periods of time. Diagnosis is based on physical findings in association with hyperkalemia. In horses with HYPP, the regulation of ion transport through the sodium channels in the muscle cells occasionally fails, causing uncontrollable muscle twitching. Further investigations into molecular genetics reveal a mutation in the gene responsible for sodium and potassium regulation. The identification of this gene mutation is the basis for the blood test used to diagnose HYPP. Hyperkalemic periodic paralysis is inherited as an autosomal dominant trait.

Pharmacokinetics: The pharmacokinetics of intravascular and orally administered acetazolamide can be established in horses (e.g., n = 6) by the administration of 2 doses (4 mg/kg of body weight, IV; 8 mg/kg, per os) and blood samples collected at regular intervals before and after administration. Assay for acetazolamide concentrations can be determined by high-performance liquid chromatography. Following IV administration of acetazolamide, data analysis reveals a median mean residence time of 1.71 ± 0.90 hours and median total body clearance of 263 ± 38 ml/kg/hr. Median steady state volume of distribution is 433 ± 218 ml/kg. After oral administration, mean peak plasma concentration is 1.90 ± 1.09 μg/ml. Mean time to peak plasma concentration is 1.61 ± 1.24 hours. Median oral bioavailability is 25 ± 6%. Oral pharmacokinetic disposition of acetazolamide in horses is characterized by rapid absorption, low bioavailability, and slower elimination than observed initially after IV administration. Pharmacokinetic data can therefore facilitate estimation of appropriate dosages for acetazolamide use in horses with HYPP.

Diagnostic Application: Hyperkalemic periodic paralysis in the acute stages can be reversed by calcium gluconate, bicarbonate, glucose, and/or insulin. Hyperkalemic periodic paralysis can be induced or initiated by the administration of potassium electrolyte.

Route of Administration: Acetazolamide (e.g., orally.)

Dosage: Acetazolamide (2.2 mg/kg = equine).

Considerations: Administration can promote hypokalemia. Acetazolamide can also promote the development of hyperglycemia, in addition to elevations in triglycerides and cholesterol.

Interpretation and Analysis: During HYPP attacks, the intravenous administration of calcium gluconate, bicarbonate, and glucose results in a rapid reversal of clinical signs. Administration of potassium as an electrolyte solution can precipitate the condition in cases with a genetic predisposition.

HYPP—hyperkalemic periodic paralysis in horses. Zeilmann M. Tierarztl Prax 1993 Dec; 21 (6), pp. 524–7.

Hyperkalemic Periodic Paralysis (HYPP): Equine
Potassium Chloride (KCl)

Cellular/Molecular Mechanism of Action: Stabilizes propagation of electrolyte-mediated electrical impulses across cell membranes. Normally, potassium (K^+) is maintained at a relatively higher concentration intracellularly in contrast to the extracellular environment. Additionally, sodium (Na^+) is usually in relatively higher concentration in the extracellular environment than in the intracellular milieu. During membrane depolarization, Na^+ conductance intracellularly increases, which is followed by increased extracellular K^+ conductance during the repolarization process. In this context,

administration of large amounts of K^+ serves to inhibit the processes of membrane depolarization/repolarization.

Diagnostic Application: Detection of cases suffering from HYPP syndrome. Positive diagnosis is recognized by a progressive increase in muscle weakness that can progress to collapse.

Route of Administration: Orally by nasogastric tube.

Dosage: KCl (88–160 gm/kg).

Considerations: False negative results can be observed when the lower dose range is administered.

Implementation: Administration should begin at the lower dose of approximately 40 g of KCl in water (6 liters). Blood samples are collected for measurement of KCl concentrations. Some patients with periodic hyperkalemic syndrome will not respond to the potassium chloride challenge test. In such instances, these cases can be diagnosed by increasing the dosage of potassium chloride in increments of 20 g. Only 1 challenge test should be performed within any given 24-hour period and horses should not be left unattended following KCl administration (2–4-hour period following dosage).

Interpretation and Analysis: Normal horses have a modest increase in plasma potassium concentrations but do not develop abnormal clinical signs even at the 180 mg/kg KCl dose level. Reversal of clinical signs following their induction by potassium chloride administration can be achieved with the subsequent administration of calcium chloride or calcium gluconate. Calcium gluconate can be administered at a dose of 0.2 to 0.4 ml/kg diluted to 1 to 2 liters in 5% dextrose and given intravenously. Response rate following calcium gluconate is rapid. Alternatively, dextrose 5% (D5W) at 4.4 to 6.6 ml/kg or $NaHCO_3$ at 1 mEq/kg can be administered rapidly by intravenous infusion.

Laboratory Instrumentation: Electron capture instrumentation is applied to measure concentrations of potassium cation.

Hypokalemic Periodic Paralysis (HYPP): Human *Glucose/Insulin*

Background Information: Some cases of hypokalemic periodic paralysis can present with signs of a sudden onset of flaccid paralysis. After exclusion of central nervous system involvement, marked hypokalemia implies a diagnosis of hypokalemic periodic paralysis, which can often be completely reversed with oral and parenteral potassium administration.

Application: Diagnosis of human hypokalemic paralysis.

Considerations: Pathogenetically, this syndrome is characterized by an excessive intracellular shift of potassium ions into myocytes. Therapeutic measures include potassium-sparing diuretics, beta blockers, acetazolamide, or diclofenamide. In less severe cases, oral potassium may be sufficient to reverse the symptoms.

Implementation: Administration of glucose and insulin to create hypokalemia and incipient paralysis of the limbs (provocative diagnostic test).

Interpretation and Analysis: Hypokalemia and incipient paralysis of the limbs induced by glucose and insulin confirms a diagnosis of hypokalemic periodic paralysis.

Sudden onset of paralysis in a twenty year-old male patient. Wallner M, Prischl FC, Pichler F, Kramar R. Wien Klin Wochenschr 1994; 106 (19), pp. 615–6.

Hyperthermia: Malignant Hypertheramia (MH) *Midazolam (Ineffective)/Caffeine/Halothane*

Cellular/Molecular Mechanism of Action: Midazolam (water-soluble benzodiazepine) potentiates the inhibitor effect of the neurotransmitter gamma amino butyrate (GABA) within the central nervous system (CNS). Investigations have demonstrated that the benzodiazopines possess binding avidity for GABA receptor sites.

Physiological Mechanism of Action: Raises the threshold for CNS toxicity for local anesthetics but has little effect on respiration and does not potentiate opioid-induced respiratory depression. Tends to produce amnesia and a state of tranquility/mild sedation.

Application: Premedicant for induction of anesthesia. Unfortunately, midazolam is a pharmaceutical that is not an effective agent for diagnostic screening of patients susceptible to the development of MH.

Dosage: Midazolam (ca. 0.5 μg/ml).

Considerations: Midazolam is applied to determine its influence on the resting tension of directly stimulated muscle biopsies. Interactions between midazolam and the 2 most commonly used MH diagnostic agents (halothane and caffeine) have also been examined.

Interpretation and Analysis: Midazolam, at maximum therapeutic concentrations (ca. 0.5 μg/ml), has no detectable effects on muscle contraction in control and MH preparations. However, midazolam does elicit a contracture from control and MH-positive preparations when used within a concentration range between 160 and 1,280 μg/ml. There are no significant differences between control and MH-positive patients in minimum concentration of midazolam causing contracture or the strength of contracture at the respective eliciting concentration. There appears to be no interaction between midazolam and either halothane or caffeine on the resting tension of the directly stimulated muscle twitch preparation.

Effects of midazolam on directly stimulated muscle biopsies from control and malignant hyperthermia positive patients. Fletcher JE, Rosenberg H, Hilf M. Can Anaesth Soc J 1984 Jul; 31 (4), pp. 377–81.

Hypoxia: Cardiovascular/Myocardial/Myocardial Oxygen Availability/Myocardial Intracellular Energy Level/Myocardial Mitochondrial Redox State *[^{99m}Tc]-Nitroimidazole*

Physiological Mechanism of Action: Nitroimidazole is preferentially internalized and retained by hypoxic cardiac myocardium.

Background Information: The agent, [^{99m}Tc]-labeled nitroimidazole is preferentially taken up and retained by hypoxic cardiac myocardium.

Application: Nitroimidazole is a candidate agent for the detection and characterization of myocardial hypoxia, including conditions such as myocardial ischemia.

Route of Administration: Nitroheterocycle (isolated perfused hearts but in a clinical scenario would be given intravascularly).

Implementation: Evaluation of the influence of O_2 or N_2 equilibrated cell-free medium perfused into hearts on the uptake of infused nitroheterocycle and its subsequent washout.

***Ex Vivo* Model:** Rat (isolated perfused hearts).

Interpretation and Analysis: Nitroheterocycle displays biphasic kinetic washout patterns in isolated perfused hearts (rat). For both uptake and washout, the early phase is very rapid, whereas the late phase is much slower. The amount of radioactivity retained after 40 minutes of clearance is about 2-fold greater in hypoxic hearts than in normoxic hearts. Cardiac myocytes and mitochondria isolated from rat heart also accumulate nitroheterocycle. Association of the compound with heart cells is inversely related to the level of available oxygen and is independent of intracellular energy level or mitochondrial redox state in the presence of oxygen. The results indicate that this [^{99m}Tc]-labeled nitroimidazole may serve as a sensitive marker of hypoxic myocardium.

The agent [^{99m}Tc]-labeled nitroimidazole is preferentially taken up and retained by hypoxic cardiac myocardium.

A novel [^{99m}]technetium-labeled nitroheterocycle capable of identification of hypoxia in heart. Rumsey WL, Cyr JE, Raju N, Narra RK. Biochem Biophys Res Commun 1993 Jun 30; 193 (3), pp. 1239–46.

Hypoxia/Infarction: Myocardial
[Antimyosin]-Poly(Ethylene Glycol) (PEG)/Liposomes/ PEG and Selective Antibody Content

Cellular/Molecular Mechanism of Action: Liposomes function as a physical barrier to dilution of pharmaceutical agents into biological fluids, prevent accelerated excretion or metabolism, and serve as a modality for selective delivery at "high" concentrations.
Background Information: Determination of the biodistribution and relative infarct accumulation of different liposome preparations in rabbits with experimental myocardial infarction have been previously described.
Application: Liposomes formulated with optimized concentrations of PEG and antimyosin immunoglobulin can function as a delivery format for the detection and characterization of experimental lesions of myocardial infarction.
Route of Administration: Intravenous.
Implementation: Delineation of the influence of such parameters as liposome size, presence or absence of PEG, and infarct-specific antimyosin antibody (AM) on *in vivo* liposome behavior.
Interpretation and Analysis: The variables of liposome size, PEG content, and infarct-specific antimyosin antibody all affect patterns of liposome biodistribution. Liposome size is the least significant variable. Statistical analysis reveals that of all variables, PEG coating expresses the strongest influence on liposome blood clearance, significantly ($p = 0.0001$) increasing the mean level of blood radioactivity in all conditions. Infarct accumulation depends upon the presence of both PEG ($p = 0.0013$) and antimyosin monoclonal antibody content ($p = 0.005$). The infarct-to-normal ratio is affected by the presence of antimyosin monoclonal antibody ($p = 0.0002$), but the extent of the effect depends also on the presence of PEG ($p = 0.01$). The 2 different mechanisms of slow accumulation via the impaired filtration (accumulation of PEG-liposomes) and specific binding of immunoliposomes with the exposed antigen (AM-liposomes) collectively contribute to the development of relatively high target-to-background ratios. Both mechanisms are supplementary (complementary) in scenarios of liposomes carrying PEG and AM simultaneously. Multiple strategies exist for futher optimizing PEG/AM liposome preparations as a delivery modality.

Poly(ethylene glycol)-coated anticardiac myosin immunoliposomes: Factors influencing targeted accumulation in the infarcted myocardium. Torchilin VP, Narula J, Halpern E, Khaw BA. Biochim Biophys Acta 1996 Feb 21; 1279 (1), pp. 75–83.

Hypoxia/Ischemia: Myocardial
Dithiosemicarbazone Derivatives (DTS)/[^{62}Cu or ^{64}CU]-DTS/[Tc]-ATSM(2)

Application: Dithiosemicarbazone derivatives radiolabeled with divalent copper (^{62}Cu, ^{64}Cu) have demonstrated potential value for detecting ischemic tissues. Development of analogous derivatives labeled with the more readily available [^{99m}Tc]-technetium radioisotope would be highly desirable.
Route of Administration: Intravascular.
Semi-Synthetic Methods: Radiolabeling of various synthesized DTS derivatives using a macromolecular [Sn^{2+}]-complex under an anaerobic condition at pH 3.4–4.5 in concert with ascorbate solution stabilization at pH 6.7–7.0. Characterization of [Tc]-DTS derivatives can be achieved applying various analytical methods (thin-layer chromatography [TLC], high-performance liquid chromatography [HPLC]).
Implementation: Evaluation of the ability of agents to detect regions of myocardial ischemia.
Animal Model: Mouse and rat (normal/healthy utilized in a vascular occlusion model: myocardial left anterior descending coronary artery).
Interpretation and Analysis: The dithiosemicarbazones [Tc]-ATSE, [Tc]-ATSM, and [Tc]-ATSM(2) have distinctive characteristics, with the latter preparations displaying high myocardium uptake in regions of ischemia in left anterior descending artery (LAD) rat myocardium models. The [Cu]-DTS mimetic agent [Tc]-ATSM(2) may have potential as an ischemia-damaged myocardium imaging agent.

The development of [^{99m}Tc]-analog of Cu-DTS as an agent for imaging hypoxia. Horiuchi K, Tsukamoto T, Saito M, Nakayama M, Fujibayashi Y, Saji H. Nucl Med Biol 2000 May; 27 (4), pp. 391–9.

Insulin (Islet Cell) Adenoma
Calcium

Application: Diagnosis of insulin-secreting tumors, including islet cell adenomas that remain undetectable applying preoperative morphology-based imaging modalities.
Route of Administration: Calcium test (selective intra-arterial catheterization).
Dosage: Calcium gluconate (4 mg/kg/hr) is infused over a 2-hour period of time.
Considerations: Calcium ion *in vitro* plays a fundamental role in regulating insulin secretion, but the influence of calcium excess on insulin release *in vivo* has not been clearly defined. The described test is not of diagnostic value for the stated purpose.
Implementation: Evaluate the efficacy of the intra-arterial calcium test for the purpose of localizing sources of hyperinsulinism that remain undetectable at preoperative morphologic studies (e.g., ultrasound, computed tomography, magnetic resonance imaging, endoscopic ultrasound, abdominal arteriography). The calcium test involves the measurement of insulin concentrations contained in hepatic venous blood after selective intra-arterial calcium stimulation.
Human Model: Cases of clinically proven endogenous hyperinsulinism due to tumorous insulin production (e.g., $n = 24$). Of these cases, approximately 30% ($n = 7/24$) will have negative morphologic findings ($n = 5/7$ females, $n = 2/7$ males; age range, 30–66 years; mean age, 47 years).
Interpretation and Analysis: Approximately 30% of affected cases will have negative results from morphology-based diagnostic methodologies (e.g., $n = 7/24$). Surgical intervention may lead to the detection of solitary insulinomas (e.g., $n = 6$ with a mean diameter, 0.73 cm) and nodular hyperplasia (e.g., $n = 1$). Calcium tests allow accurate localization of the pathologic source of insulin secretion (e.g., $n = 7/7$). In less than 50% of cases, results of arterial calcium stimulation with hepatic venous sampling (ASVS) may affect intraoperative management (e.g., $n = 3/7$). An increase in insulin concentration after stimulation in the hepatic artery is not observed, making hepatic metastases unlikely. Arterial calcium stimulation with hepatic venous sampling, which procedurally is simpler than transhepatic pancreatic venous sampling, results in effective localization of sources of hyperinsulinism not detected with preoperative morphologic studies.

Other clinical trials have reported mean calcium plasma levels can increase from 9.6 ± 0.4 to 11.6 ± 0.8 mg/100 ml. During calcium infusion, blood glucose and plasma insulin concentrations can

remain unchanged. Observations noted in these case-based studies suggest that calcium fails to stimulate basal insulin secretion even in cases of organic hyperinsulinism, and that calcium infusion is not helpful as a provocative test in the diagnosis of insulinoma.

Insulinoma and islet cell hyperplasia: Value of the calcium intra-arterial stimulation test when findings of other preoperative studies are negative. Pereira PL, Roche AJ, Maier GW, Huppert PE, Dammann F, Farnsworth CT, Duda SH, Claussen CD. Radiology 1998 Mar; 206 (3), pp. 703–9.

Ischemia: Brain Lesions/N-Methyl-D-Aspartate (NMDA) Receptor Activation

N-(1-Naphthyl)-N′-(3-[^{125}I]-Iodophenyl)-N′-Methylguanidine

Cellular/Molecular Mechanism of Action: N-(1-naphthyl)-N′-(3-iodophenyl)-N′-methylguanidine or CNS 1261 is a ligand that interacts with NMDA receptors following their activation.

Application: N-(1-naphthyl)-N′-(3-[^{125}I]-iodophenyl)-N′-methylguanidine or [^{125}I]-CNS 1261 can potentially function as a radioligand for imaging NMDA receptor activation.

Route of Administration: [^{125}I]-CNS 1261 (intravascular).

Semi-Synthetic Methods: Preparations of [^{125}I]-CNS 1261 can be produced by radioiodination of N-(1-naphthyl)-N′-(3-tributylstannylphenyl)-N′-methylguanidine using Na[^{125}I] and peracetic acid.

Implementation: Evaluation of the ability to detect regional areas of cerebral ischemia using [^{125}I]-CNS 1261.

Animal Model: Rat.

Interpretation and Analysis: Uptake of [^{125}I]-CNS 1261 *in vivo* reflects NMDA receptor distribution in normal rat brain, whereas in ischemic rat brain, uptake is markedly increased in areas of NMDA receptor activation. Radiolabeled CNS 1261 appears to be a good candidate for further development as a single photon emission computed tomography tracer in the investigation of NMDA receptor activation in cerebral ischemia.

Synthesis and binding characteristics of N-(1-naphthyl)-N′-(3-[^{125}I]-iodophenyl)-N′-methylguanidine ([^{125}I]-CNS 1261): A potential SPECT agent for imaging NMDA receptor activation. Owens J, Tebbutt AA, McGregor AL, Kodama K, Magar SS, Perlman ME, Robins DJ, Durant GJ, McCulloch J. Nucl Med Biol 2000 Aug; 27 (6), pp. 557–64.

Ischemia: Cardiovascular/Myocardial Ischemia/Perfusion-Metabolism Mismatch

[^{123}I]-(Rho-Iodophenyl)-3-R,S-Methylpentadecanoic Acid (BMIPP)/Non-Metabolized BMIPP Myocardial Backdiffusion/Long-Chain Fatty Acid BMIPP: Decreased Tissue Uptake

Background Information: [^{123}I]-(rho-iodophenyl)-3-R,S-methylpentadecanoic acid is a fatty acid analog that possesses the unique property of being able to detect perfusion-metabolism mismatch in conditions of ischemic heart disease. The mechanism by which the agent exactly functions remains uncertain.

Application: Detection and characterization of perfusion-metabolism mismatch in cases with ischemic heart disease applying single photon emission computed tomography (SPECT) imaging methodologies.

Route of Administration: [^{123}I]-(rho-iodophenyl)-3-R,S-methylpentadecanoic acid (intravascular).

Implementation: The agent BMIPP is injected into the left anterior descending artery (LAD), followed by the collection of blood samples from either the cardiac vein and abdominal aorta; or serial biopsy specimens are harvested from the LAD region for comparison to reference controls. The catabolites of BMIPP, including backdiffusion of non-metabolized BMIPP, are measured utilizing high-performance liquid chromatography (HPLC in efflux study). Thin-layer chromatography (TLC) techniques can be applied for the analytical evaluation of tissue specimens.

Animal Model: Canine (n = 11 dogs subjected to open-chest thoracotomy under anesthesia to facilitate a system developed for the release of all blood within the great cardiac vein outside without recirculation, and the LAD is occluded for 30 minutes after reperfusion; n = 6/11 dogs cardiac vein and abdominal aorta blood collection post-BMIPP injection, n = 5/11 dogs used for collection of serial biopsy specimens from the LAD region).

Interpretation and Analysis: The agent BMIPP is rapidly extracted from the plasma by the myocardium and the subsequent retention is unchanged. The early washout (8 minutes) of radioactivity significantly increases (51% ± 12% to 65% ± 7%; $p < 0.05$) with ischemia. The metabolites from the myocardium consist of a backdiffusion of non-metabolized BMIPP, alpha, intermediate, and fully oxidized metabolites. Among these metabolites, backdiffusion of non-metabolized BMIPP in blood significantly increases (27.9% ± 7.7% to 42.3% ± 8.1%; $p < 0.05$), especially in the early phase of ischemia. In tissue, radioactivity is concentrated in the triglyceride pool even in the early phase. In addition, BMIPP and alpha-oxidized metabolite significantly decreases in the early phase with ischemia (t = 1 minute after BMIPP injection, 25.9% ± 8.6% to 14.5% ± 2.1%, $p < 0.01$; t = 2 minutes, 8.9% ± 5.0% to 4.5% ± 1.7%, $p < 0.05$). Such findings demonstrate that backdiffusion of non-metabolized BMIPP from the myocardium increases and BMIPP (long-chain fatty acids) in tissue decreases with ischemia, suggesting backdiffusion of non-metabolized BMIPP might play an important role in myocardial perfusion-metabolism mismatch on SPECT images in cases of ischemic cardiac disease.

Myocardial metabolism of [^{123}I]-BMIPP in a canine model with ischemia: Implications of perfusion-metabolism mismatch on SPECT images in patients with ischemic heart disease. Hosokawa R, Nohara R, Fujibayashi Y, Okuda K, Ogino M, Hirai T, Fujita M, Tamaki N, Konishi J, Sasayama S. J Nucl Med 1999 Mar; 40 (3), pp. 471–8.

Ketosis without Hypoglycemia

Ketogenic Test

Application: Characterization of ketosis in cases without hypoglycemia.

Implementation: Evaluation of changes in serum free amino acids as a response to ketogenic provocative test. Following the initiation of the provocative test, plasma concentrations for glycemic amino acids (glycine, alanine, glutamine, glutamate) are quantitated.

Human Model: Children with a history of ketosis but without evidence of hypoglycemia (n = 17 tested; n = 3/17 displaying clinical signs).

Interpretation and Analysis: (i) Approximately 29% of cases respond to the test and develop hypoglycemia (n = 5/17 with n = 3/5 hypoglycemic prior to test). (ii) Hypoglycemic and non-hypoglycemic children differ greatly in the decrement of serum total gluconeogenic amino acids after completion of the test due to the relatively lower levels before provocation in the hypoglycemic group and the inversely higher levels in the non-hypoglycemic group. (iii) Gluconeogenic amino acids decreased sharply after administration of the provocative test reflected by alterations in the concentrations of glycine, alanine, glutamine, and glutamate.

Serum free amino acid depletion in ketotic children. Hayashi M, Konishi K, Kameoka A, Mino M. J Nutr Sci Vitaminol (Tokyo) 1981; 27 (5), pp. 449–54.

Lipemia/Fibrin and Fibrinolysis
Heparin (Sodium or Lithium Salt)

Cellular/Molecular Mechanism of Action: Stimulation of lipoprotein lipase activity.
Application: Heparin (bovine lung, porcine mucosal origin) can aid in determining if plasma opacity is due to hyperlipidemia.
Diagnostic Application #1: Detection of systemic lipemia and/or the temporary resolution of hyperlipemia in order to facilitate serum electrolyte analysis. Also applied in the therapeutic management of lipemia.
Diagnostic Application #2: Detection of fibrinolytic activity (FDP formation) and platelet consumption due to disseminated intravascular coagulation (DIC).
Route of Administration and Dosage: Intravenous or subcutaneous only.
Considerations: In man and some animal species, heparin becomes associated with the external surface membrane of red blood cell (RBC) populations, resulting in their premature removal from the intravascular compartment by the reticuloendothelial (RE) system. In general, heparin preparations of porcine intestinal mucosal origin tend to promote less anemia than extracts acquired from bovine lung. Occationally, heparin preparations can also promote thrombocytopenia involving mechanisms analogous to its ability to lower peripheral RBC levels. Heparin should never be administered intramuscularly due to the high probability of hematoma formation.
Laboratory Instrumentation: Serum is simply inspected visually when attempting to detect resolution of systemic hyperlipidemia. Detection of alterations in fibrin and FDP can be performed utilizing ELISA-based techniques.

Lipid Metabolism: Cardiovascular/Myocardial Ischemia vs Infarction
[^{123}I]-(Rho-Iodophenyl)-3-R,S-Methylpentadecanoic Acid (BMIPP)/Non-Radioactive Colored Microspheres

Cellular/Molecular Mechanism of Action: [^{123}I]-BMIPP is a radiolabeled lipid analog that is perceived by cells as an endogenous lipid molecule.
Background Information: The tracer [^{123}I]-BMIPP has been evaluated to determine its ability to function as a molecular probe for characterizing myocardial lipid metabolism. Studies in mice indicate that myocardial BMIPP uptake correlates with adenosine triphosphate (ATP) content. Details, however, of myocardial accumulation during episodes of ischemia from either infarct or ischemia are not well documented.
Application: [^{123}I]-BMIPP can be utilized to detect and characterize myocardial lipid metabolism that can potentially be used as a parameter to differentiate myocardial ischemia from myocardial infarction.
Route of Administration: [^{123}I]-BMIPP (intravascular).
Implementation: Evaluation of myocardial regional wall motion applying echocardiography in the short-axial view from the epicardium. Tissue blood flow can be calculated using non-radioactive colored microspheres. Changes in blood glucose levels, lipid levels, and lactate extraction can be examined in blood collected from the aorta and great cardiac vein (GCV). The ATP concentration and [^{123}I]-BMIPP count are determined by high-performance liquid chromatography and gamma counter measurements, respectively.

Animal Model: Canine (n = 16 adult mongrel dogs). The occluded left anterior descending artery (LAD) alone is reperfused to create an ischemic region, and the 1st diagonal branch of the LAD is kept occluded to make the infarct lesion.

Interpretation and Analysis: Two hours after reperfusion, blood flow decreases to 20% ± 5% in infarct regions and 64% ± 9% in ischemic areas ($p < 0.05$), despite comparable wall-motion reduction (32% ± 5% and 42% ± 12% in the infarct and ischemic areas, respectively). BMIPP content and ATP concentration display parallel reductions: 40% ± 7% and 75% ± 4% ($p < 0.05$) of BMIPP and 32% ± 9% and 69% ± 7% ($p < 0.05$) of ATP in infarct and ischemic regions, respectively. Non-esterified fatty acid extraction, defined as "flow × ([artery] − [GCV])," decreases to 87% ± 5.6% during occlusion and 75% ± 20.1% 2 hours after reperfusion compared to control values. BMIPP uptake correlates well with lipid metabolism and tissue ATP levels and may prove useful in differentiating myocardial infarction from ischemia in the acute phase of ischemic episodes.

Evaluation of myocardial viability with iodine-123-BMIPP in a canine model. Nohara R, Okuda K, Ogino M, Hosokawa R, Tamaki N, Konishi J, Fujibayashi Y, Yonekura Y, Fujita M, Sasayama S. J Nucl Med 1996 Aug; 37 (8), pp. 1403–7.

Lipoprotein Physiology: (Low-Density Lipoproteins [LDLs])/Atherosclerotic Lesion Pathogenesis: Altered Cell LDL Assimilation/Diabetes Mellitus and Hemodialysis
[^{125}I]-Labeled LDLs

Cellular/Molecular Mechanism of Action: [^{125}I]-labeled LDLs are radiolabeled analogs of LDLs. Low-density lipoproteins can function as a transport platform in the plasma and contain a relatively high amount of triglycerides and cholesterol compared to high-density lipoproteins.
Background Information: Patients on chronic hemodialysis treatment have an elevated risk of atherosclerosis disease, and dyslipidemia appears to be 1 of the major risk factors. However, most of these patients exhibit elevated serum triglycerides, whereas serum cholesterol and LDL cholesterol levels are in the normal range.
Application: Characterization of LDL metabolism in *in vitro* and *in vivo* environments.
Route of Administration: In animal (*in vivo*) models, [^{125}I]-labeled LDLs would usually be given intravenously.
Implementation: Evaluate the influence of hypertriglyceridemia condition of hemodialysis and diabetes mellitus on LDL metabolism. One approach to achieving this objective involves the isolation of LDLs from whole blood and separation into 5 subfractions by density gradient ultracentrifugation, followed by their characterization related to lipid/protein composition, degree of glycation, and oxidation. Uptake of [^{125}I]-labeled LDL is examined via LDL receptors of HepG2 cells and scavenger receptors of mouse peritoneal macrophages.

Human Model: Cases of hypertriglyceridemic diabetes; non-diabetic hemodialysis cases; and healthy reference controls (n = 30, n = 10/case group).
Interpretation and Analysis: Hemodialysis procedures promote elevations in serum triglycerides, but cholesterol levels are within normal ranges. Triglyceride enrichment occurs in the very low-density lipoprotein (VLDL) class and LDL class, and an accumulation of a highly atherogenic small dense LDL subfraction can be detected predominantly in cases of non-insulin-dependent diabetes mellitus. Low-density lipoprotein concentrations in responses to hemodialysis also contains elevated levels of lipid peroxidation products, which are at even higher levels in diabetic conditions. Alterations in composition, size, and configuration of LDL in response to hemodialysis in diabetic and non-diabetic conditions impairs LDL receptor-mediated degradation and enhances uptake of such modi-

fied LDL particles via non-saturable scavenger receptors. Diminished LDL receptor-mediated uptake of modified, triglyceride-rich, small dense LDL most likely leads to accumulation of these lipoproteins *in vivo*, favoring the development of atherosclerotic lesions. Future clinical studies must demonstrate whether patients will benefit from reducing these atherogenic particles by lipid-lowering intervention.

Abnormalities in lipoprotein metabolism in hemodialysis patients. Köniğer M, Quaschning T, Wanner C, Schollmeyer P, Krämer-Guth A. Kidney Int Suppl 1999 Jul; 71, pp. S248–50.

Metabolism: Glucose, Amino Acids, and Nucleic Acid/Neoplastic Disease Imaging: Monitoring Treatment Response/Glucose Metabolism/Amino Acid Metabolism/Nucleic Acid Metabolism

2′-Deoxy-5-[^{18}F]Fluorouridine/[^{18}F]-5-Fluorodeoxyuridine/L-Methyl-[^{14}C]Methionine/6-[^{3}H]Thymidine

Cellular/Molecular Mechanism of Action: Reflects neoplastic cell nucleic acid metabolism.
Application: Diagnostic imaging of neoplastic lesions.
Route of Administration: [^{18}F]-5-fluorodeoxyuridine.
Dosage: [^{18}F]-5-fluorodeoxyuridine.
Implementation: Evaluation of metabolic tracers for glucose, amino acid, and nucleic acid metabolism (2-deoxy-2-[^{18}F]fluoro-D-glucose (^{18}FDG), L-methyl-[^{14}C]methionine ([^{14}C]-Met), 6-[^{3}H]thymidine (^{3}H-Thd), and 2′-deoxy-5-[^{18}F]fluorouridine (^{18}FdUrd)], and the conventional radionuclide [^{67}Ga]-citrate can be used to assess the feasibility of monitoring tumor radiotherapy using a quadruple tracer technique. In this context, 2 combinations of 4 tracers (^{18}FDG or ^{18}FdUrd, [^{14}C]-Met, ^{3}H-Thd, and ^{67}Ga) can be compared in a time-course study after single-dose irradiation (20 Gy) and also used in a dose-dependency study performed 6 days after 5, 10, 15, or 20 Gy of irradiation.

Animal Model: Rat AH109A tumor model.
Interpretation and Analysis: Fluorine-18-FDG (^{18}F-FDG) shows a large change in uptake and a steady response to radiotherapy. Fluorodeoxyuridine shows a rapid decrease after radiotherapy, but the range of change in uptake is narrow. Gallium-67 cannot detect tumor response early after treatment but shows a marked change in uptake later. [$^{6\text{-}3}$H]Thd and [^{14}C]-Met show a rapid response to irradiation and a high sensitivity for monitoring radiotherapy, suggesting that they may be applicable for PET studies.

Tracer feasibility for monitoring tumor radiotherapy: A quadruple tracer study with fluorine-18-fluorodeoxyglucose or fluorine-18-fluorodeoxyuridine, L-[methyl-^{14}C]methionine, 6-[^{3}H]thymidine, and gallium-67. Kubota K, Ishiwata K, Kubota R, Yamada S, Tada M, Sato T, Ido T. J Nucl Med 1991 Nov; 32 (11), pp. 2118–23.

Metabolism Conditions: Multiple/Glucose: Ketogentic Hypoglycemia/Branched-Chain Ketoacid Decarboxylase: Leukocyte/Maple Syrup Urine Disease

α-Ketoisocaproic Acid (KIC)/α-Ketoisovaleric Acid (KIV)/Branched-Chain Amino Acids/Isocaloric High Protein/Ketogenic Diet

Cellular/Molecular Mechanism of Action: α-ketoisocaproic acid is a substrate for leukocyte branched-chain ketoacid decarboxylase.
Application: Detection and characterization of ketogenic hypoglycemic conditions.
Implementation: Evaluation of plasma amino acid concentrations during spontaneous episodes of hypoglycemia. Complementary studies include the evaluation of leukocyte branched-chain ketoacid decarboxylase biochemical activity applying KIC as a substrate probe.

Human Model: Cases of ketogenic hypoglycemia (e.g., n = 1 female 8 years old with mental deficiency and retarded motor and somatic development).
Interpretation and Analysis: Analysis of plasma amino acid concentrations during the onset of spontaneous hypoglycemia reveals increases in branched-chain amino acids (e.g., valine [4.1], leucine [7.8], and isoleucine [1.7 mg/100 ml]), while alanine decreases (1.2 mg/100 ml) and ketonuria can be detected. Measurement of branched-chain ketoacid decarboxylase in leukocytes can detect decreases of approximately 50% of normal for KIC as substrate, whereas values for KIV and α-keto-β-methylvaleric acid (MEVA) are normal. Values for fibroblast activities for all 3 substrates are usually within the normal range. Intermittent maple syrup urine disease can be excluded by oral loading tests with the branched-chain amino acids and with an isocaloric, high-protein diet. Impairment of oxydative decarboxylation of leucine, valine, and isoleucine secondary to increased ketogenesis may play an etiological role in ketotic hypoglycemia, because reports have observed, by gaschromatographic analysis, increases in the urinary excretion of KIV (5.5 μmol/h), KIC (29.4), and MEVA (47.9) after a provocative test with an isocaloric ketogenic diet for 36 hours. The significance of branched-chain hyperaminoacidemia and branched chain α-ketoaciduria has been described.

Intermittent branched-chain ketoacidurie in ketotic hypoglycemia: Investigations to localize the biochemical defect (author's transl). Held KR, Sternowsky HJ, Singh S, Plettner C, Grüttner R. Monatsschr Kinderheilkd 1976 Feb; 124 (2), pp. 59–65

Mitosis/Proliferation: Neoplastic Disease/Deoxyribonucleic Acid (DNA) Synthesis/Thymidine Kinase Expression

5-Iodo-4′-Thio-2′-Deoxyuridine (ITdU)/5-Iodo-4′-Thio-2′-Deoxyuridine (IUdR)

Cellular/Molecular Mechanism of Action: 5-iodo-4′-thio-2′-deoxyuridine is a metabolically stable nucleoside that can function as a substrate for cellular thymidine kinase biochemical activity.
Application: Radioiodinated forms of ITdU and IUdR can be applied to detect elevations of DNA synthesis in cell populations that positively express thymidine kinase activity. In this capacity, both ITdU and IUdR can serve as indicator molecules for measuring alterations in cellular proliferation especially relevant to the characterization of neoplastic disease states.
Route of Administration: Most frequently, ITdU or IUdR would be administered intravascularly. Theoretically, it may be possible to effectively image lesions if the agents are administered intrathecally for central nervous system (CNS) tumors, by direct injection into tumors, or into the arterial network supplying a suspected neoplastic lesion. Future investigation remain to be conducted to determine the feasibility, effectiveness, and safety of such applications.
Semi-Synthetic Methods: Radiolabeling of ITdU and 5-iodo-1-(4-thio-beta-D-arabinofuranosyl)uracil (ITAU) with [^{125}I] utilizing a destannylation reaction of the trimethylstannyl precursor of each nucleoside. The products can be isolated in high yields and with a > 99% level of radiochemical purity.
Implementation: Evaluation of ITdU and ITAU for their ability to detect and characterize alterations in cellular proliferation as a function of DNA synthesis.

***Ex Vivo* Model:** Thymidine kinase-expressing L-M cells rather than a thymidine kinase-deficient mutant L-M (TK^-) cells.

Interpretation and Analysis: [^{125}I]-ITdU is effectively phosphorylated by cytosolic nucleoside kinases and specifically incorporated into a thymidine kinase-expressing L-M cell rather than a thymidine kinase-deficient mutant L-M (TK^-) cell. In addition, *in vitro* cell metabolism studies employing [^{125}I]-ITdU reveal that [^{125}I]-ITdU is effectively and specifically incorporated into a DNA fraction (> 90% at 60 minutes). Therefore, [^{125}I]-ITdU appears to be an effective DNA synthesis marker such as IUdR. In contrast, [^{125}I]-ITAU is neither remarkably phosphorylated by cytosolic nucleoside kinases nor notably incorporated into an L-M cell rather than an L-M (TK^-) cell. [^{125}I]-ITdU and [^{125}I]-ITAU show a higher resistance to phosphorolytic cleavage by recombinant thymidine phosphorylase than does [^{125}I]-IUdR. Furthermore, biodistribution of [^{125}I]-ITdU and [^{125}I]-ITAU display better *in vivo* stability of radioiodination than do [^{125}I]-IuUR preparations. [^{125}I]-ITdU also displays a significantly higher uptake in proliferating organs (thymus, spleen, small intestine, and bone) than in non-proliferating organs (brain, muscle, liver, and lung), compared to [^{125}I]-IUdR, at 18 hours postinjection. As indicated by *in vitro* studies, [^{125}I]-ITAU does not show any significant uptake in proliferating organs. Therefore, radioiodinated ITdU is potentially useful as a proliferation-imaging agent, and further studies should be performed to clarify the usefulness of this compound as a single photon emission computed tomography tumor-imaging agent.

Rationale of 5-[^{125}I]-iodo-4′-thio-2′-deoxyuridine as a potential iodinated proliferation marker. Toyohara J, Hayashi A, Sato M, Tanaka H, Haraguchi K, Yoshimura Y, Yonekura Y, Fujibayashi Y. J Nucl Med 2002 Sep; 43 (9), pp. 1218–26.

Mitosis/Proliferation Rate of Cell Populations/ Neoplastic Lesions: Potential Application
3′-Deoxy-3′-[^{18}F]Fluorothymidine

Cellular/Molecular Mechanism of Action: Thymidine is rapidly assimilated by proliferating cell populations.

Application: 3′-deoxy-3′-[^{18}F]fluorothymidine has been designed as an agent for the detection of alterations in *in vivo* cellular proliferation as a function of thymidine metabolism utilizing positron emission tomography imaging techniques.

Route of Administration: Variable but most often intravascular.

Semi-Synthetic Methods: A reliable radiosynthesis of 3′-deoxy-3′-[^{18}F]fluorothymidine ([^{18}F]-FLT) has been developed based on [^{18}F]10 mCi (370 MBq) of radiochemically pure [^{18}F]1 Ci/μmol (37 GBq/μmol) at end of synthesis (EOS) within 100 minutes and in 13% radiochemical yield (end of bombardment [EOB]; 7% EOS).

Implementation: Evaluation of neoplastic lesions that display relatively rapid rates of proliferation/growth.

Interpretation and Analysis: Detection of increased radioactivity at a specific anatomical location corresponds to a region with a relatively high rate of cellular proliferation.

Radiosynthesis of 3′-deoxy-3′-[^{18}F]fluorothymidine: [^{18}F]FLT for imaging of cellular proliferation *in vivo*. Grierson JR, Shields AF. Nucl Med Biol 2000 Feb; 27 (2), pp. 143–56.

Nitric Oxide Production Potential/Gastroenteritis/ Renal Failure/Septic Conditions
Guanidino-Labeled L-Arginine/[Nitrite/Nitrate or Citrulline Metabolites]

Cellular/Molecular Mechanism of Action: Substrate for nitric oxide synthase.

Background Information: Nitric oxide is an important mediator of both physiological and pathophysiological processes. Nitric oxide is produced during direct conversion of arginine to citrulline. Nitric oxide is rapidly metabolized, mainly to nitrite/nitrate, and finally excreted as urinary nitrate. For that reason, plasma and urinary nitrite/nitrate have been measured frequently as indicators of nitric oxide production, but it is becoming clear that these methods only give qualitative data. More recently, stable isotope methods have been introduced for quantitative measurement of nitric oxide production.

Application: Detection and characterization of nitric oxide synthase biochemical activity.

Implementation: Different stable isotope methods are used to measure whole-body nitric oxide production *in vivo*. These methods are all based on infusion of guanidino-labeled L-arginine and subsequent measurement of labeled products (e.g., nitrite/nitrate or citrulline).

Interpretation and Analysis: Nitric oxide synthesis in healthy individuals is found to be in the range of 0.2–1.0 μmol/kg/hour (only 0.5–1% of arginine production). In diseased states, nitric oxide synthesis may be either decreased or increased. Increased nitric oxide synthesis has been observed in gastroenteritis patients and in some animal models of sepsis. In patients with renal failure, however, both increased and decreased nitric oxide production have been reported. Nitric oxide production is not changed in familial hypercholesterolemia patients and after typhoid vaccination. Therefore, application of stable isotopes to measure whole-body nitric oxide production *in vivo* is the most accurate method to study quantitative changes in the nitric oxide production rate. This technique is easy to perform in both healthy and diseased individuals, requiring infusion of stable isotopes for only a few hours and blood sampling.

Isotopic investigation of nitric oxide metabolism in disease. Luiking YC, Deutz NE. Curr Opin Clin Nutr Metab Care 2003 Jan; 6 (1), pp. 103–8.

Oxidation Potential in Tissues/Central Nervous System: Amyloid Beta Deposition/Free Radical Formation/Alzheimer's Disease
N-Tert-Butyl-α-Phenylnitrone/Oxidation-Activated Fluorogenic Probes

Cellular/Molecular Mechanism of Action: N-tert-butyl-α-phenylnitrone functions as a free radical spin trap.

Background Information: Amyloid beta, the primary constituent of senile plaques in Alzheimer's disease, is hypothesized to cause neuronal damage and cognitive failure, but the mechanisms are unknown.

Application: Fluorogenic compounds can be used *in vivo* to determine the degree of association between amyloid beta deposits and free radical production. The compound N-tert-butyl-α-phenylnitrone can be utilized to validate the effectiveness and accuracy of tracers and probes designed to detect anatomical regions of elevated oxidation potential.

Implementation: Evaluation of microenvironments with elevated levels of oxidative potential utilizing compounds that are actively fluorescent that can serve as *in vivo* infrared laser imaging agents.

As a validation procedure, N-tert-butyl-α-phenylnitrone (a free radical spin trap) can be systemically administered to determine the accuracy of oxidation-activated fluorogenic probes. Collectively, these agents can be utilized to delineate if a direct association exists between amyloid beta deposits and free radical production.

Animal Model: Mouse (*in vivo* transgenic Alzheimer's disease).

Human Model: Brain tissue from cases of Alzheimer's disease (*ex vivo*).

Interpretation and Analysis: Fluorescence can be appreciated in dense core plaques, but not diffuse plaques, as determined by subsequent addition of thioflavine S and immunohistochemistry analysis for amyloid beta. Systemic administration of N-tert-butyl-α-phenylnitrone greatly reduces the detection of probes activated by tissue oxidative processes. It is therefore believed that a subset of amyloid plaques produces free radical species in living Alzheimer's models and in human Alzheimer tissue sections. Antioxidant therapy neutralizes these highly reactive molecules and may therefore be of therapeutic value in Alzheimer's disease.

Instrumentation: Multiphoton imaging.

In vivo imaging of reactive oxygen species specifically associated with thioflavine S-positive amyloid plaques by multiphoton microscopy. McLellan ME, Kajdasz ST, Hyman BT, Bacskai BJ. J Neurosci 2003 Mar 15; 23 (6), pp. 2212–7.

Oxidation/Reduction Potential in Tissues: Intracellular Production and Extracellular Release of Reactive Oxygen Species/Myocardium Metabolism
Dihydroethidium/Dityrosine/Protein Kinase Inhibitors/Chelerythrine/PP101/PP149

Cellular/Molecular Mechanism of Action: Dihydroethidium functions as a fluorescent probe; chelerythrine is a protein kinase C (PKC) inhibitor; PP101 is a PKC delta inhibitor; and PP149 is a PKC-epsilon inhibitor.

Background Information: Protein kinase C and reactive oxygen species (ROS) are known to have a role in anesthetic preconditioning (APC). Cardiac preconditioning by triggers other than volatile anesthetics, such as opioids or brief ischemia, is known to be isoform selective, but the isoform required for APC is not known.

Application: Detection and characterization of intracellular ROS production.

Implementation: Identify the PKC isoform that is involved in APC and elucidate the relative positions of PKC activation and ROS formation in the APC signaling cascade. One approach to addressing this objective can involve the evaluation of the influence of sevoflurane APC in heart tissue prior to the initiation of ischemic reperfusion injury in the absence or presence of the non-specific PKC inhibitor chelerythrine, the PKC-delta inhibitor PP101, or the PKC-epsilon inhibitor PP149. Spectrofluorometry and the fluorescent probes dihydroethidium can be used to measure intracellular ROS, while assay of effluent dityrosine is used to measure extracellular ROS release.

Animal Model: Isolated guinea pig hearts subjected to 30 minutes of ischemia and 120 minutes of reperfusion.

Interpretation and Analysis: Previous sevoflurane exposure protects heart tissues against ischemia-reperfusion injury, as previously described. Chelerythrine or PP149 abolishes such protection, but PP101 does not. Reactive oxygen species formation is observed during sevoflurane exposure and is not altered by any of the PKC inhibitors. Anesthetic preconditioning is mediated by PKC-epsilon but not by PKC-delta. Furthermore, PKC activation probably occurs downstream of ROS generation in the APC signaling cascade.

Reactive oxygen species precede the epsilon isoform of protein kinase C in the anesthetic preconditioning signaling cascade. Novalija E, Kevin LG, Camara AK, Bosnjak ZJ, Kampine JP, Stowe DF. Anesthesiology 2003 Aug; 99 (2), pp. 421–8.

Oxygen Concentration (Oximetry)/Neoplastic vs Normal Tissues
Octa-n-Butoxy-Substituted Naphthalocyanine

Application: Detection and characterization of neoplastic cell types.

Semi-Synthetic Methods: The probe is synthesized as a needle-shaped microcrystalline particulate. The particulate shows a single-line electron paramagnetic resonance (EPR) spectrum that is highly exchange-narrowed with a line-width of 210 mG. The EPR line-width is sensitive to molecular oxygen, showing a linear relationship between the line-width and concentration of oxygen (pO_2) with a sensitivity of 8.5 mG/mm Hg.

Implementation: Evaluation of a variety of physicochemical and biological properties of LiNc-BuO particulates to determine the suitability of the probe for *in vivo* oximetry.

Interpretation and Analysis: The probe is unaffected by biological oxidoreductants, stable in tissues for several months, and can be successfully internalized in cells. The probe has been applied to monitor changes in concentration of oxygen in the normal muscle and RIF-1 tumor tissue of mice as a function of tumor growth. The data showed a rapid decrease in the tumor pO_2 with increases in tumor volume. Human arterial smooth muscle cells, upon internalization of the LiNc-BuO probe, show a marked oxygen gradient across the cell membrane. In summary, the newly synthesized octa-n-butoxy derivative of lithium naphthalocyanine has unique properties that are useful for determining oxygen concentration in chemical and biological systems by EPR spectroscopy and also for magnetic tagging of cells.

Instrumentation: Electron paramagnetic resonance spectroscopy.

Novel particulate spin probe for targeted determination of oxygen in cells and tissues. Pandian RP, Parinandi NL, Ilangovan G, Zweier JL, Kuppusamy P. Free Radic Biol Med 2003 Nov 1; 35 (9), pp. 1138–48.

Oxygen Tension Indicator
Hemoglobin (Hb)

Cellular/Molecular Mechanism of Action: Iron ions contained within Hb fractions bind molecular oxygen.

Application: Exogenous molecular Hb is an effective indicator of relative local oxygen tension in magnetic resonance (MR) microscopy studies performed *in vivo*.

Implementation: Injection of Hb to delineate its ability to permeate through relatively dense neural tissues.

Experimental Model: Flies.

Analysis and Interpretation: Exogenous molecular Hb is more sensitive than other agents for application in MRI oximetry methods, and therefore can be used at higher resolutions and in specimens with no blood oxygen level-dependent (BOLD) effects.

Hemoglobin is able to permeate through relatively dense neural tissue but does not detectably disrupt normal neurophysiology. Large changes in signal intensity (40–50%) can be recognized when external O_2 levels are manipulated artificially from 0% to 21% with hemoglobin injections. Oxygen-dependent contrast changes produced by exogenous Hb can be detected by T_2-weighted imaging analysis and can be roughly calibrated if necessary. Therefore, it may be feasible to apply hemoglobin as a contrast agent technique that may be useful for functional MRI (fMRI) studies of metabolism at minute resolution levels (e.g., 10s of microns).

In vivo oxygen detection using exogenous hemoglobin as a contrast agent in magnetic resonance microscopy. Sun PZ, Schoening ZB, Jasanoff A. Magn Reson Med 2003 Apr; 49 (4), pp. 609–14

Superoxide/Anoxia/Reoxygenation/Cerebral Cortex Ischemia-Reperfusion

2-Methyl-6-[p-Methoxyphenyl]-3,7-Dihydroimidazo [1,2-α]Pyrazin-3-One/[Chemiluminescence Probe]

Application: Detection and characterization of superoxide formation, reperfusion injury, and anoxia/ischemia.

Route of Administration: Intravascular.

Implementation: Evaluation of the exact time profile of superoxide generation during anoxia-reoxygenation and ischemia-reperfusion using chemiluminescence techniques with a probe specific for superoxide (e.g., 2-methyl-6-[*p*-methoxyphenyl]-3,7-dihydroimidazo[1,2-α]pyrazin-3-one or MCLA).

MCLA solutions are superfused on the cortex throughout the experimental protocol, and MCLA chemiluminescence is measured using a newly developed photon counting system. Reflectance at 398 nm is simultaneously measured to compensate for hemodynamic artifacts resulting from cerebral blood volume changes. A 90-second anoxia can be induced by the inhalation of 100% nitrogen followed by a 40-minute reoxygenation. In phase II studies, superoxide dismutase (SOD) is continuously superfused and anoxia-reoxygenation is performed in the same manner. In phase II studies, a 15-minute forebrain ischemia is induced by the occlusion of the bilateral common carotid arteries with systemic hypotension (systolic blood pressure less than 50 mm Hg) followed by a 30-minute reperfusion.

Animal Model: Feline cerebral cortex (anoxia-reoxygenation and ischemia-reperfusion; phase I studies n = 19 animals; phase II studies n = 6 animals; phase III studies n = 8 animals).

Interpretation and Analysis: Phase #1 studies: Chemiluminescence decreases during a period of anoxia ($p < 0.01$) and then exceeds baseline levels at 15 and 20 minutes after reoxygenation ($p < 0.05$). Phase II studies: Chemiluminescence decreases during a period of anoxia ($p < 0.05$) but does not exceed baseline levels during the reoxygenation period, indicating that an increase in superoxide production is the main cause of the chemiluminescence increase**.** In phase III studies chemiluminescence decreases during periods of ischemia ($p < 0.01$) and then increases at 20 and 25 minutes after reperfusion ($p < 0.05$). Such findings indicate that superoxide generation decreases during anoxia and ischemia and then increases within 20 minutes after reoxygenation or reperfusion.

In vivo measurement of superoxide in the cerebral cortex during anoxia-reoxygenation and ischemia-reperfusion. Yamaguchi K, Uematsu D, Itoh Y, Watanabe S, Fukuuchi Y. Keio J Med 2002 Dec; 51 (4), pp. 201–7.

Superoxide Anion Production: Myocardium/ Reactive Oxygen Species/K^+/Adenosine Triphosphate (ATP) Channels: Mitochondrial/ Infarct

Dihydroethidium (Fluorescent Probe)/ 5-Hydroxydecanoate (5-HD = K^+/ATP Channel Blocker)/N-Acetylcysteine and N-2-Mercaptopropionyl Glycine (2-MPG) Reactive Oxygen Species (ROS) Scavengers/Triphenyltetrazolium Superoxide Indicator

Cellular/Molecular Mechanism of Action: Dihydroethidium emits fluorescent color when exposed to certain wavelengths of light energy. 5-hydroxydecanoate inhibits the cellular function of membrane-associated K^+/ATP channels. N-acetylcysteine and 2-MPG function as ROS scavengers. Triphenyltetrazolium detects superoxide anion production.

Background Information: It is unknown if the opening of mitochondrial K^+/ATP channels is a trigger or an end effector of anesthetic-induced preconditioning.

Application: Assess superoxide anion production.

Implementation: Determination if opening of mitochondrial K^+/ATP channels *in vivo* triggers isoflurane-induced preconditioning by generating ROS. One approach to addressing this objective can involve the application of the fluorescent probe dihydroethidium to assess superoxide anion production during administration of 5-HD or the ROS scavengers N-acetylcysteine or 2-MPG in the presence or absence of 1.0 minimum alveolar concentration (MAC) isoflurane. Myocardial infarct size and superoxide anion production can be measured using triphenyltetrazolium staining and confocal fluorescence microscopy, respectively.

Animal Model: Rabbits (pentobarbital anesthetized) subjected to a 30-minute coronary artery occlusion followed by a 3-hour period of reperfusion. Rabbits were randomly assigned to receive a vehicle (0.9% saline) or the selective mitochondrial K^+/ATP channel blocker 5-HD alone 10 minutes before or immediately after a 30-minute exposure to 1.0 MAC isoflurane.

Interpretation and Analysis: Isoflurane ($p < 0.05$) decreases infarct size to 19 ± 3% (mean ± standard error of measurement [SEM]) of the left ventricular area at risk as compared to the control (38 ± 4%). 5-HD administered before but not after isoflurane abolishes this beneficial effect (37 ± 4% as compared to 24 ± 3%). 5-HD alone has no effect on infarct size (42 ± 3%). Isoflurane increases fluorescence intensity. Pretreatment with N-acetylcysteine, 2-MPG, or 5-HD before isoflurane abolishes increases in fluorescence, but administration of 5-HD after isoflurane only partially attenuates increases in fluorescence produced by volatile anesthetic agents (e.g., isoflurane). Therefore, mitochondrial K^+/ATP channel opening acts as a trigger for isoflurane-induced preconditioning by generating ROS *in vivo.*

Instrumentation: Confocal fluorescence microscopy.

Mitochondrial adenosine triphosphate-regulated potassium channel opening acts as a trigger for isoflurane-induced preconditioning by generating reactive oxygen species. Tanaka K, Weihrauch D, Ludwig LM, Kersten JR, Pagel PS, Warltier DC. Anesthesiology 2003 Apr; 98 (4), pp. 935–43.

3 CONTRAST AND IMAGE-ENHANCING AGENTS

16 Fluorescent and Pigment Dye Reagents

Biochemical Markers

Enzyme-Activated Near-Infrared (NIR) Fluorescent Magnetic Nanoparticles/[Indocyanine Dye Cy5.5]

Background Information: A number of quantitative 3-dimensional tomographic NIR fluorescence imaging techniques have recently been developed and combined with magnetic resonance imaging (MRI) to yield highly detailed anatomic and molecular information in living organisms.

Application: Can be utilized as magnetic nanoparticle-based MR contrast agents that have NIR fluorescence (NIRF) capabilities that are activated by certain biological enzymes.

Route of Administration: Subcutaneous, but other prototypes could potentially be given intravascularly.

Semi-Synthetic Methods: Probes are prepared by the conjugation of arginyl peptides to cross-linked iron oxide amine (amino-CLIO), either by a disulfide linkage or a thioether linker, followed by the attachment of the indocyanine dye Cy5.5. The NIRF of disulfide-linked conjugate is activated by dithiothreitol (DTT), while the NIRF of thioether-linked conjugate is activated by trypsin. Fluorescent quenching of the attached fluorochrome occurs in part due to interaction with iron oxide, as evident by the activation of fluorescence with DTT in the presence of nanoparticles that have less than 1 dye molecule attached per particle.

Implementation: Evaluate the potential for enzyme-activated NIR fluorescent magnetic nanoparticles to detect specific biochemical entities expressed by specific cell populations.

Interpretation and Analysis: Following subcutaneous injection of the probe, axillary and brachial lymph nodes become darkened on MR images and easily delineated by NIRF imaging. The probes may provide the basis for a new class of so-called smart nanoparticles, capable of pinpointing their position through their magnetic properties, while providing information on their environment by optical imaging techniques.

Near-infrared fluorescent nanoparticles as combined MR/optical imaging probes. Josephson L, Kircher MF, Mahmood U, Tang Y, Weissleder R. Bioconjug Chem 2002 May–Jun; 13 (3), pp. 554–60.

CARDIOVASCULAR SYSTEM

Angiogenesis: Neoplastic Disease/Tumor Dimethylarginine Dimethylaminohydrolase (DDAH) Overexpression

NC100150/Hoechst 33342

Cellular/Molecular Mechanism of Action: The special orientation of NC100150 becomes altered within a magnetic field. Alternatively, Hoechst 33342 emits fluorescent color when exposed to light energy.

Background Information: Intracellular factors that regulate nitric oxide (NO) synthesis represent important targets in tumor progression. Overexpression of DDAH, which metabolizes the endogenous inhibitors of NO synthesis asymmetric dimethylarginine and N-monomethyl-L-arginine, results in C6 gliomas with enhanced growth rate compared with wild types.

Application: NC100150 can be utilized as an intravascular blood pool contrast agent that is detectable by magnetic resonance imaging (MRI). Hoechst 33342 can be used as a fluorescent perfusion-marker dye that can be measured by flourescent detection systems.

Route of Administration: Utilization of NC100150 and Hoechst 33342 for neoplastic lesion angiogenesis requires that these be delivered intravascularly.

Implementation: Evaluation of the *in vitro* effects of DDAH on tumor vascular morphogenesis by measurement of the transverse relaxation rates R_2* and R^2 in (i) clone D27 gliomas overexpressing DDAH; (ii) C6 wild-type gliomas using intrinsic susceptibility MRI sensitive to changes in endogenous deoxyhemoglobin; (iii) evaluation of CN100150 as an intravascular blood pool contrast agent for susceptibility contrast-enhanced MRI; and (iv) comparison of results with fluorescence microscopy utilized to assess tumor uptake of Hoechst 33342 (perfusion marker system).

Interpretation and Analysis: The baseline R_2* is significantly faster in the D27 tumors, consistent with a greater vascular development ($p < 0.02$, ANOVA). There is no significant difference between the response of the 2 tumor types to hypercapnia (5% CO_2/95% air) used as a probe for vascular maturation, or hyperoxia (5% CO_2/95% O_2) used as a probe for vascular function. NC100150 increases the R_2* and R_2 rates of both tumor types and demonstrates a significantly larger blood volume in the D27 tumors ($p < 0.02$, ANOVA). This correlates with a significantly greater uptake of Hoechst 33342 in D27 tumors compared to C6 wild-type tumors ($p < 0.02$, ANOVA). Despite increased tumor blood volume, the Delta R_2*/Delta R_2 ratio, an index of microvessel size, shows that the capillaries in the 2 tumor types are of a similar caliber. Such observations demonstrate the potential of susceptibility MRI-derived quantitative end points to non-invasively assess tumor angiogenesis. Application of intravascular blood pool contrast agents such as NC100150 for such purposes appears very promising. Overexpression of DDAH results in increased *in vivo* neovascularization of C6 gliomas. The lack of significant difference in hypercapnic/hyperoxic response between the C6 and D27 tumors and the similar vessel caliber is also consistent with a role for DDAH in the initial stages of vasculogenesis.

Instrumentation: MRI and fluorescence microscopy instrumentation.

Effects of overexpression of dimethylarginine dimethylaminohydrolase on tumor angiogenesis assessed by susceptibility magnetic resonance imaging. Kostourou V, Robinson SP, Whitley GS, Griffiths JR. Cancer Res 2003 Aug 15; 63 (16), pp. 4960–6.

Blood Volume Estimation/Intravascular Compartment

Fluorescein Isothiocyanate-Labeled Hydroxyethyl Starch/Radiolabeled Red Blood Cells/Radiolabeled Serum Albumin

Cellular/Molecular Mechanism of Action: Labeled albumin, red blood cells, and hydroxyethyl starch can be applied to measure approximate intravascular blood volume.

Application: Estimation of approximate blood volume.
Route of Administration: Intravascular.
Semi-Synthetic Methods: The proprietary brand of hydroxyethyl starch (Elohaes) can be conveniently labeled with fluorescein isothiocyanate.
Implementation: Evaluation of blood volume measurements in suspected cases of polycythemia utilizing labeled albumin, red blood cells, and hydroxyethyl starch (Elohaes). Dilution of labeled hydroxyethyl starch (Elohaes) *in vivo* is used for measuring blood volume, and the results are then compared with values obtained using radiolabeled albumin and radiolabeled red cells.

Human Model: Cases of suspected polycythemia (e.g., n = 17; n = 8 undergoing major surgery and/or receiving intensive postoperative care).
Interpretation and Analysis: The elimination of labeled starch follows the same progress as that of the parent compound, indicating that *in vivo* the fluorescent tag is stable and does not significantly alter the biological properties of the molecule. The volume of distribution of labeled starch is 2.5 mL/kg lower than that for labeled albumin ($p = 0.05$). Blood volume, measured from the dilution of fluorescent starch, is lower (4.9 mL/kg) than that measured with albumin ($p = 0.048$) but higher (6.61 mL/kg) than that measured with red blood cells ($p = 0.0007$). This latter difference may be even smaller at marginally higher doses of the fluorescent starch. Hydroxyethyl starch appears to provide a valid alternative to labeled red cells as a means of calculating blood volume. Labeling of starch with a fluorescent marker makes the assay procedure more sensitive and infinitely easier. The dose required is not high enough to affect hemodynamic parameters.

Measuring blood volume with fluorescent-labeled hydroxyethyl starch. Thomas E, Jones G, de Souza P, Wardrop C, Wusteman F. Crit Care Med 2000 Mar; 28 (3), pp. 627–31.

Capillary Blood Flow/Multiphoton *In Vivo* Imaging
Semiconductor Nanocrystal Fluorescent Markers/Cadmium Selenide-Zinc Sulfide Quantum Dots

Cellular/Molecular Mechanism of Action: Cadmium selenide-zinc sulfide quantum dots modalities emit fluorescent light energy.
Application: Cadmium selenide-zinc sulfide quantum dots can be applied as a fluorescent marker system for evaluation of various physiological parameters.
Implementation: Semiconductor nanocrystals (quantum dots) can be utilized as fluorescent marker agents for application miltiphoton microscopy, enabling the *in vivo* acquisition of multicolor images. Examples in this regard include water-soluble cadmium selenide-zinc sulfide quantum dots because these fluorescent probes have 2-photon action cross sections as high as 47,000 Goeppert-Mayer units, which is by far the largest of any label used in multiphoton microscopy.

Animal Model: Mouse.
Interpretation and Analysis: It is possible to visualize quantum dots dynamically through the skin of living mice, in capillaries hundreds of micrometers deep. Evidence of blinking (fluorescence intermittency) cannot be appreciated in solution on nanosecond to millisecond time scales.
Instrumentation: Multiphoton microscopy.

Water-soluble quantum dots for multiphoton fluorescence imaging *in vivo*. Larson DR, Zipfel WR, Williams RM, Clark SW, Bruchez MP, Wise FW, Webb WW. Science 2003 May 30; 300 (5624), pp. 1434–6.

Capillary Permeability/Blood Flow and Arterial Input Function/Neoplastic Disease (Adenocarcinoma)
Indocyanine Green (ICG)/Methylene Blue (MB)

Cellular/Molecular Mechanism of Action: Indocyanine green and MB are "passive" dye-based marker molecules.
Application: Indocyanine green and MB can be utilized as aqueous soluble molecular marker systems for the evaluation of various physiological processes.
Implementation: Evaluation of the ability for ICG and MB to differentiate between normal and diseased tissues. Following administration of ICG and MB, measurements are conducted with a combined frequency-domain and steady state optical technique that facilitate rapid measurement of tissue absorption in the 650–1,000-nm spectral region. Tumors can also be imaged by use of contrast-enhanced magnetic resonance imaging (MRI) and co-registered with the location of the optical probe. The absolute concentrations of contrast agent, oxyhemoglobin, deoxyhemoglobin, and water are measured simultaneously each second for approximately 10 minutes.

Animal Model: Rat (adenocarcinoma).
Interpretation and Analysis: The differing tissue uptake kinetics of ICG and MB in late-stage tumors arise from differences in their effective molecular weights. Indocyanine green, because of its binding to plasma proteins, behaves as a macromolecular contrast agent with a low degree of vascular permeability (low passive diffusion across endothelial barriers). A compartmental model describing ICG dynamics is used to quantify physiologic parameters related to capillary permeability. In contrast, MB behaves as a small-molecular-weight contrast agent that leaks rapidly from the vasculature into the extravascular, extracellular space and is sensitive to blood flow and the arterial input.

In vivo quantification of optical contrast agent dynamics in rat tumors by use of diffuse optical spectroscopy with magnetic resonance imaging co-registration. Cuccia DJ, Bevilacqua F, Durkin AJ, Merritt S, Tromberg BJ, Gulsen G, Yu H, Wang J, Nalcioglu O. Appl Opt 2003 Jun 1; 42 (16), pp. 2940–50.

Cardiac Output: Cardiography/Cardiac and Intravascular Filling/Output
Lithium Chloride/Lithium Dilution Cardiac Output (LiDCO)

Cellular/Molecular Mechanism of Action: Lithium ion can be applied as a "passive" elemental tracer agent.
Background Information: Lithium dilution cardiac output was primarily developed as a simple calibration for the PulseCO trade mark (LiDCO, London, UK) continuous arterial waveform analysis monitor.
Application: Utilized in minimally-invasive techniques designed to measure cardiac output where lithium is used as a passive tracer element that is detected in dilution-based analysis procedures.
Route of Administration: Lithium chloride (intravenous).
Implementation: Evaluation of cardiac output employing a small dose of lithium chloride injected as an intravenous bolus. Cardiac output is derived from the dilution curve generated by a lithium-sensitive electrode attached to the arterial line.
Interpretation and Analysis: The technique is quick, simple, and requires only an arterial line and central or peripheral venous access. Studies in humans and animals have shown good agreement compared with results obtained with other techniques, and the efficacy of LiDCO in pediatric patients has also been proven. Compared with thermodilution, lithium dilution shows closer agreement in

clinical studies with electromagnetic flow measurement. PulseCO is a beat-to-beat cardiac output monitor that calculates stroke volume from the arterial pressure waveform using an autocorrelation algorithm. The algorithm is not dependent on waveform morphology, but instead it calculates nominal stroke volume from a pressure-volume transform of the entire waveform. The nominal stroke volume is converted to actual stroke volume by calibration of the algorithm with LiDCO instrumentation. Initial studies indicate good fidelity, and results from centers in the United States and the United Kingdom have been very beneficial. The PulseCO trademark monitor incorporates software for interpretation of the hemodynamic data generated and provides a real-time analysis of arterial pressure variations (i.e., stroke volume variation, pulse pressure variation, and systolic pressure variation) as theoretical guides to intravascular and cardiac filling.

Instrumentation: Lithium-sensitive electrode attached to the arterial line.

Lithium dilution measurement of cardiac output and arterial pulse waveform analysis: An indicator dilution calibrated beat-by-beat system for continuous estimation of cardiac output. Jonas MM, Tanser SJ. Curr Opin Crit Care 2002 Jun; 8 (3), pp. 257–61.

Cardiovascular: Volume Estimation/Intravascular (Blood) Volume/Extravascular Volume
Indocyanine Green (ICG) (COLD System)/Methylene Blue (MB)/Dual Thermal-Dye Double Indicator Technique

Cellular/Molecular Mechanism of Action: Indocyanine green and MB are molecules that can function as passive marker molecules within body fluid compartments (e.g., intravascular).

Physiological Mechanism of Action: Methylene blue apparently induces acute vasoconstrictive and positive inotropic effects during episodes of septic shock.

Application: Indocyanine green and MB can be used as detectable molecular markers in biological systems to evaluate a variety of physiological processes.

Route of Administration: Methylene blue (intravenous).

Dosage: Bolus dose of MB (3 mg/kg over 10 minutes).

Implementation: Assessment of the effects of inhibition of guanylate cyclase, an enzyme involved in sepsis-related vascular and myocardial dysfunctions, on hemodynamic variables including blood volume and pulmonary vascular permeability during septic shock.

A fiber-optic catheter is inserted to determine blood and extravascular volumes applying the thermal-dye double indicator technique, using ICG (COLD system) in combination with MB. COLD-derived variables are recorded before MB and 20 minutes, 1 hour, and 2 hours after the end of MB infusion.

Human Model: Septic shock associated with persistent hypotension despite conventional treatment including fluid loading, vasopressors, and inotropes (n = 15 cases). Standard hemodynamic and oxygen-derived variables; total, intrathoracic, systolic, and diastolic cardiac blood volumes; extravascular lung water; plasma osmolarity; and lactate and protein concentrations are recorded.

Interpretation and Analysis: Mean arterial and pulmonary artery pressures, systemic and pulmonary vascular resistances, and left ventricular stroke work index increase, and blood lactate transiently decreases after MB ($p < 0.05$). Other variables recorded are unchanged during a 2-hour period following MB infusion. Such findings demonstrate the acute vasoconstrictive and positive inotropic effects of MB during septic shock. These effects are not associated with changes in blood volume, myocardial diastolic function, or pulmonary vascular permeability assessed by extravascular lung water.

Does methylene blue administration to septic shock patients affect vascular permeability and blood volume? Donati A, Conti G, Loggi S, Münch C, Coltrinari R, Pelaia P, Pietropaoli P, Preiser JC. Crit Care Med 2002 Oct; 30 (10), pp. 2271–7.

Dermal Microvasculature Perfusion/Delineation of Perfused Capillary to Total Capillary Ratio/Dermal Nutritional Capillaries
Sodium Fluorescein

Application: Delination of the nature of temporal variation in capillary numbers, and determination of the proportion of perfused to total nutritional capillaries in normal skin.

Implementation: Using *in vivo* microscopy, the temporal behavior of the number of visible capillaries in the skin of the dorsum of the foot is observed over time periods varying from 5 minutes to 55 days. Capillary perfusion is then studied by comparing capillary numbers before and after intravenous injection of sodium fluorescein.

Human Model: Healthy subjects.

Interpretation and Analysis: The mean percent difference in the number of visible capillaries over a mean period of 25.3 days is 5.5%. The percentage ratio of perfused to total capillaries is 54.2%. There appears to be little quantitative change in capillary numbers over periods of up to 50 days, and under physiological conditions, about half of the nutritional capillaries of the skin are not perfused.

Study of temporal and perfusion physiology of skin capillaries in the dorsum of the foot. Lamah M, Mortimer PS, Dormandy JA. J Vasc Res 2001 Jan–Feb; 38 (1), pp. 59–63.

Dermal Microvasculature Perfusion/Ulcers of Dermal Structures/ Dermal Microvascular Disease (Diabetes-Associated Foot Lesions)/Prognosis and Prediction of Outcome
Sodium Fluorescein

Background Information: Fluorescein dermofluorometry can be used to relate the uptake of fluorescein in the skin to blood flow.

Application: The dye wash-in time constant parameters are inversely proportional to local dermal blood flow.

Implementation: Evaluation of fluorescein dermofluorometry for the detection and characterization of dermal ulcers. Following intravenous injection of sodium fluorescein, changes in the fluorescein signal with time are continuously measured at the plantar surface of the foot. Both the initial slope of the signal and the wash-in time constant are then calculated. In order to establish a correlation between image profiles and prognosis for foot ulcer lesions, outcomes are monitored for a variable period of time following initial evaluation (e.g., n = 4- to 14-month follow-up period).

Human Model: Cases of cutaneous diabetic foot ulcers (n = 4 groups: non-diabetic control patients, diabetic control patients, diabetic patients with chronic foot ulcers, and diabetic patients with acute foot ulcers).

Interpretation and Analysis: Significant differences in the wash-in time constant can be appreciated between diabetic and non-diabetic cases and between diabetic subjects with and without foot ulcers. In cases with foot ulcers, a relatively large percent may not display an early washout in the dermofluorometer signal and later require amputation (e.g., n = 2/8 or 25%). The fluorescein wash-in time constant demonstrates better correlation with the presence of

diabetic microvascular disease than does the initial slope of the signal. Differences in the wash-in time constants of non-diabetic and diabetic subjects support the hemodynamic hypothesis for the development of microvascular disease. The indication of early washout of the fluorescein signal may also be useful in the prediction of ulcer healing.

Fluorescein dermofluorometry for the assessment of diabetic microvascular disease. Oh DK, Jones RN, Marshall W, Magin RL. Skin Res Technol 2001 May; 7 (2), pp. 105–11.

Endothelial Cell Adhesion: Colon Carcinoma/ Intravital Observation of Cancer Cell/ Microcirculation Interactions/Hepatic Metastasis Assessment
CalceinAM

Background Information: Organ-specific tumor cell adhesion within the microcirculation of host organs is an important step in metastatic behavior. Circulating tumor cells have to adhere within the microcirculatory vessels, quickly stabilize their adhesion, and probably leave the circulation to avoid toxic effects of hydrodynamic shear forces of circulating blood.
Application: Intravital observation of colon carcinoma cell adhesion within the hepatic microcirculation.
Implementation: CalceinAM is used to label colon carcinoma cell populations (e.g., HT-29 [human] and CC531 [rat]) that are then injected intra-arterially as single-cell suspensions. Intravital fluorescence microscopy is then applied to detect adhesive interactions between circulating tumor cells and endothelial surfaces within the hepatic microcirculation. These interactions are then analyzed regarding their time course and site location within the vascular tree.
Animal Model: Rats (Sprague-Dawley).
Interpretation and Analysis: Autofluorescence of liver parenchyma is sufficient for distinction of hepatic sinusoids. Intravital microscopy is capable of differentiating early events in adhesion formation within hepatic sinosoids, adhesion stabilization, and extravasation of tumor cells into the liver parenchyma. Tumor cell adhesion occurs almost exclusively within sinusoidal capillaries; however, the diameter of these vessels is usually larger than that of the tumor cells. Colon carcinoma cells rapidly migrate into the liver parenchyma after successful adhesion within the sinusoids. In contrast to common end point assays of the metastatic cascade, this *in vivo* model allows characterization of metastatic colon carcinoma cell adhesion within the liver microcirculation as a specific step during the formation of hematogenous metastasis and underlying mechanisms.
Instrumentation: Intravital fluorescence microscopy.

An intravital model to monitor steps of metastatic tumor cell adhesion within the hepatic microcirculation. Haier J, Korb T, Hotz B, Spiegel HU, Senninger N. J Gastrointest Surg 2003 May–Jun; 7 (4), pp. 507–14; discussion 514–5.

Endothelium Cell Adhesion/Platelet Endothelium Interactions/[Retinal Microvascular Pathology]
Carboxyfluorescein Diacetate Succinimidyl Ester/Platelets (Fluorescent-Labeled)

Cellular/Molecular Mechanism of Action: Carboxyfluorescein diacetate succinimidyl ester interacts with light and emits fluorescent color. In this context, it can function as a fluorescent marker molecule suitable for "tracing" the migration of different cell types.
Application: Visualization of *in vivo* platelet behavior in the retinal microcirculation. The methodology allows for quantitative evaluation of platelet dynamics and platelet-endothelial interactions in retinal pathologic conditions.
Route of Administration: Intravascular.
Considerations: Represents the development of a new method for evaluation of the *in vivo* dynamics of platelets in the retinal microcirculation and quantitative investigation of platelet-endothelial interactions.
Implementation: Isolated platelet samples are labeled *in vitro* with carboxyfluorescein diacetate succinimidyl ester. After intravenous administration, platelet behavior in the retinal microcirculation can be evaluated with a scanning laser ophthalmoscope. Images are recorded on S-VHS videotape and analyzed with a computer-assisted image analysis system. Interactions between platelets and retinal microvascular endothelium can also be investigated employing lipopolysaccharide-stimulated endothelium or platelets activated with thrombin.
Animal Model: Rat retina.
Interpretation and Analysis: Fluorescent platelets are recognized as distinct dots in the retinal microcirculation and can be traced frame by frame. The velocity of platelets in the retinal arteries, capillaries, and veins is approximately 26.1 $\pm$ 6.4, 1.6 $\pm$ 0.4, and 19.9 $\pm$ 8.2 mm/sec, respectively. In control rats, even activated platelets show minimal interaction with retinal endothelial cells. In contrast, stimulated retinal endothelium displays active platelet-endothelial interactions, with many platelets observed rolling and adhering along the major retinal veins. The interactions between platelets and stimulated endothelial cells are substantially inhibited with the injection of P-selectin monoclonal antibody.

In vivo evaluation of platelet-endothelial interactions in retinal microcirculation of rats. Tsujikawa A, Kiryu J, Nonaka A, Yamashiro K, Nishiwaki H, Tojo SJ, Ogura Y, Honda Y. Invest Ophthalmol Vis Sci 1999 Nov; 40 (12), pp. 2918–24.

Extracellular Fluid Space Distribution Parameters/ Interstitial Fluid Compartment/Water Diffusion Coefficients
Gallamine/Inulin

Cellular/Molecular Mechanism of Action: Gallamine and inulin per se do not exert any biochemical or physiological mechanism of action. The mechanism whereby they function as diagnostic agents is based on their molecular weight relative to normal pathological processes of capillary permeability and the capacity for them to be easily detected in biological fluid samples.
Application: Gallamine and inulin can be detected at diluted concentrations within biological fluids were they can function as passive marker molecules.
Route of Administration: Gallamine and inulin (simultaneous intravenous injection).
Implementation: Simultaneous evaluation of the kinetics of inulin and gallamine. The distribution of both compounds in extracellular fluid space can be characterized by a 3-compartment model in which the mean central compartment blood volume of 1.37 liters is essentially identical to expected values.
Animal Model: Canine (anesthetized).
Interpretation and Analysis: The 2 peripheral compartments of the model appear to represent rapid and slow equilibrating interstitial fluid compartments. A mammillary model structure can be selected in which intercompartmental clearance corresponds to trans-

capillary exchange. Previous studies indicate that inulin and smaller hydrophyllic molecules diffuse across capillary walls at rates proportional to their respective free water diffusion coefficients. For the ratio of the transcapillary permeability coefficients of inulin and gallamine to equal their free water diffusion coefficient ratio of 5.34 ± 0.02 (± standard deviation [SD]), it appears that the sum of blood flow to the fast and slow interstitial fluid compartments is less than cardiac output. When this assumption is made, blood flow to fast equilibrating interstitial fluid is estimated to be 39% of cardiac output, in agreement with previous measurements of splanchnic blood flow. This supports the hypothesis that the fast equilibrating interstitial fluid space is supplied by porous splanchnic capillaries that lack a continuous investment of basement membrane.

Heterogeneity of interstitial fluid space demonstrated by simultaneous kinetic analysis of the distribution and elimination of inulin and gallamine. Henthorn TK, Avram MJ, Frederiksen MC, Atkinson AJ Jr. J Pharmacol Exp Ther 1982 Aug; 222 (2), pp. 389–94.

Myocardial Infarct Characterization/Necrosis/Areas of Risk
[^{87}Rb]/Evans Blue Dye/Triphenyl Tetrazolium Chloride/ Glibenclaminde/Pinacidil/Bumetanide

Cellular/Molecular Mechanism of Action: (i) Rubidium ion (Rb^+) is a K^+ tracer element; (ii) glibenclamide is a blocker of adenosine triposphate (ATP)-sensitive K^+ channels; (iii) pinacidil is a K^+(ATP) opener; (iv) bumetanide is a $K^+/Na^+/2Cl^-$ co-transporter inhibitor.

Application: [^{87}Rb] can be applied in magnetic resonance imaging (MRI) procedures to identify and characterize myocardial infarcts. Evans blue and triphenyl tetrazolium chloride staining can be applied to delineate areas at risk (AAR) and areas of necrosis, respectively.

Dosage: Glibenclamide (3 μM); pinacidil (10 μM); bumetanide (10 μM).

Implementation: Delineation of the effect of drugs that can modulate passive permeability of K^+ into cardiomyocytes in normal and reperfusion-damaged cardiac muscle. Rubidium ion (Rb^+) is used as a K^+ tracer and [^{87}Rb]-MRI as a detection method. Preparations are incubated in buffer containing either (i) glibenclamide; (ii) pinacidil; (iii) bumetanide; or (iv) no drug (control). Upon reperfusion 3-dimensional [^{87}Rb] MR images are acquired to obtain kinetic profiles for Rb^+ uptake and its distribution. Areas at risk and areas of necrosis are determined by Evans blue and triphenyl tetrazolium chloride staining, respectively.

Animal Model: Swine (left anterior descending artery [LAD] of isolated pig hearts perfused with Krebs-Henseleit buffer [KHB] was occluded for 2 hours and subsequently reperfused for 2 hours with KHB containing 4.7 mM RbCl instead of KCl).

Interpretation and Analysis: The kinetics remain monoexponential in the affected anterior wall and the uptake rates are approximately 32, 36, 37, and 21% of that in the posterior wall in the control, Glib, Pin, and Bum groups, respectively. Infarct sizes determined histologically as a percentage of total ventricular (left + right) mass (14–22%) correspond to sizes of areas with 20 to 40% of maximal Rb image intensity [I(Rb)(max), 15–22%], except for values observed with pinacidil (12.5 vs 21%). The sizes of areas with 20 to 50% of I(Rb)(max) (30–36%) closely correlate with those of AAR determined histologically (31–33%). Lactate dehydrogenase release does not differ in any of the preparations. Therefore, (i) reperfusion damage quickly inhibits Rb^+ uptake; (ii) Rb^+ uptake in normal and reperfused tissue does not significantly depend on K(ATP) or the $K^+/Na^+/2Cl^-$ co-transporter; and (iii) areas with 20–40% of maximal image intensity correspond to infarct areas.

The effects of drugs modulating K^+ transport on Rb^+ uptake and distribution in pig hearts following regional ischemia: [^{87}Rb] MRI study. Kupriyanov VV, Xiang B, Sun J, Jilkina O. NMR Biomed 2002 Aug; 15 (5), pp. 348–55.

Myocardium/Superoxide Anion Production/ Mitochondrial K^+/Adenosine Triposphate (ATP) Channels/Infarct
Fluorescent Probe/ K^+/ATP Channel Blocker/Vitality Stain/Dihydroethidium (Fluorescent Probe)/ 5-Hydroxydecanoate (5-HD = K^+/ATP Channel Blocker)/ Triphenyltetrazolium (Myocardial Infarct)/ N-Acetylcysteine and N-2-Mercaptopropionyl Glycine (ROS Scavengers).

Cellular/Molecular Mechanism of Action: Dihydroethidium emits fluorescent color when exposed to certain wavelengths of light energy. 5-hydroxydecanoate inhibits the cellular function of membrane-associated K^+/ATP channels.

Background Information: It is unknown if the opening of mitochondrial ATP-regulated potassium (K^+/ATP) channels is a trigger or an end effector of anesthetic-induced preconditioning.

Application: Assess superoxide anion production.

Implementation: Determination of whether opening of mitochondrial K^+/ATP channels *in vivo* triggers isoflurane-induced preconditioning by generating reactive oxygen species (ROS). To address this objective, the fluorescent probe dihydroethidium can be used to assess superoxide anion production during the administration of 5-HD or the ROS scavengers N-acetylcysteine or N-2-mercaptopropionyl glycine (2-MPG) in the presence or absence of 1.0 minimum alveolar concentration (MAC) isoflurane. Myocardial infarct size and superoxide anion production can be measured using triphenyltetrazolium staining and confocal fluorescence microscopy, respectively.

Animal Model: Rabbit (pentobarbital anesthetized) subjected to a 30-minute coronary artery occlusion followed by a 3-hour period of reperfusion. Rabbits were randomly assigned to receive a vehicle (0.9% saline) or the selective mitochondrial K^+/ATP channel blocker 5-HD alone 10 minutes before or immediately after a 30-minute exposure to 1.0 MAC isoflurane.

Interpretation and Analysis: Isoflurane ($p < 0.05$) decreases infarct size to 19 ± 3% (mean ± standard error of measurement [SEM]) of the left ventricular area at risk as compared to the control (38 ± 4%). 5-HD administered before but not after isoflurane abolishes this beneficial effect (37 ± 4% as compared to 24 ± 3%). 5-HD alone has no effect on infarct size (42 ± 3%). Isoflurane increases fluorescence intensity. Pretreatment with N-acetylcysteine, 2-MPG, or 5-HD before isoflurane abolishes increases in fluorescence, but administration of 5-HD after isoflurane only partially attenuates increases in fluorescence produced by volatile anesthetic agents (e.g., isoflurane). Therefore, mitochondrial K^+/ATP channel opening acts as a trigger for isoflurane-induced preconditioning by generating ROS *in vivo.*

Instrumentation: Confocal fluorescence microscopy.

Mitochondrial adenosine triphosphate-regulated potassium channel opening acts as a trigger for isoflurane-induced preconditioning by generating reactive oxygen species. Tanaka K, Weihrauch D, Ludwig LM, Kersten JR, Pagel PS, Warltier DC. Anesthesiology 2003 Apr; 98 (4), pp. 935–43.

Reperfusion Injury/Leukocyte Rolling Phenomenon Following Ischemic Insult
Acridine Orange

Cellular/Molecular Mechanism of Action: Acridine orange emits a fluorescent color when exposed to certain wavelengths of light energy.

Background Information: Recent reports have shown that ischemic preconditioning induces strong protection against retinal damage subsequent to prolonged ischemia and that this protection is mediated by mechanisms involving the adenosine A1 receptor.

Application: Evaluate quantitatively the effects of ischemic preconditioning on leukocyte-mediated reperfusion injury after transient retinal ischemia and define the role of the adenosine A1 receptor in these effects.

Implementation: The adenosine A1 receptor antagonist 8-cyclopentyl-1,3-dipropylxanthine (DPCPX) is administered intramuscularly immediately after ischemic preconditioning. Leukocyte behavior in the retina after 60 minutes of ischemia can be evaluated *in vivo* with acridine orange digital fluorography.

Animal Model: Rats (male) subjected to transient retinal ischemia induced by temporary ligation of the optic nerve. Ischemic preconditioning (5 minutes of ischemia) is induced 24 hours before 60 minutes of ischemia.

Interpretation and Analysis: Ischemic preconditioning inhibits leukocyte rolling. The maximum number of rolling leukocytes is reduced to 3.0% at 12 hours after reperfusion ($p < 0.01$). Subsequent leukocyte accumulation is also decreased with ischemic preconditioning. The maximum number of accumulated leukocytes is reduced to 22.6% at 24 hours after reperfusion ($p < 0.01$). These inhibitory effects are suppressed by the administration of DPCPX ($p < 0.0001$). The numbers of rolling leukocytes at 12 hours after reperfusion and accumulated leukocytes at 24 hours after reperfusion are approximately 102.7% (ns) and 83.4% ($p < 0.01$), respectively, compared with numbers without ischemic preconditioning. Ischemic preconditioning, therefore, has an inhibitory effect on leukocyte rolling and subsequent leukocyte accumulation during retinal ischemia-reperfusion injury. Furthermore, the adenosine A1 receptor may play an important role in these inhibitory effects.

Instrumentation: Digital fluorography.

Inhibitory effect of ischemic preconditioning on leukocyte participation in retinal ischemia-reperfusion injury. Nonaka A, Kiryu J, Tsujikawa A, Yamashiro K, Nishijima K, Miyamoto K, Nishiwaki H, Honda Y, Ogura Y. Invest Ophthalmol Vis Sci 2001 Sep; 42 (10), pp. 2380–5.

Stem Cell Retention, Engraftment, and Migration
Iron Fluorophore Particle (IFP)/Mesenchymal Stem Cells (MSCs)

Cellular/Molecular Mechanism of Action: Stem cells have the potential to differentiate into a multitude of different cell types within tissue/organ environments.

Background Information: Delivery and tracking of endomyocardial stem cells are limited by the inability to image transplanted cells non-invasively in the beating heart.

Application: Mesenchymal stem cells can be labeled with IFP to facilitate *in vivo* magnetic resonance imaging (MRI) to determine the immediate and long-term localization of these cell types in order to assess their retention, engraftment, and migration within tissues/organs.

Route of Administration: Mesenchymal stem cells (variable including percutaneous).

Implementation: Short-term incubation of MSCs with IFP results in efficient dose-dependent labeling. Postlabeling, cells remain viable for multiple passages and retain *in vitro* proliferation and differentiation capacities. Labeled mesenchymal stem cells (10^4–10^6 cells/150 μL) are then injected percutaneously into normal and freshly infarcted myocardium. Serial cardiac MRI (1.5T) is then performed post–myocardial infarction. Magnetic resonance imaging contrast properties are then measured both *in vivo* and *in vitro* for cells embedded in agar.

Animal Model: Swine (mesenchymal stem cells and porcine myocardium [normal & infarcted]). Serial infarction of the myocardium can be induced on days 4, 8, and 21 (e.g., n = 1, 3, and 1 animals, respectively).

Interpretation and Analysis: Iron fluorophore particle labeling of MSCs imparts useful MRI contrast, enabling ready detection in the beating heart on a conventional cardiac MR scanner after transplantation into normal and infarcted myocardium. The dual-labeled MSCs can be identified at locations corresponding to injection sites, both *ex vivo* using fluorescence microscopy and *in vivo* using susceptibility contrast on MRI. This technology may permit effective *in vivo* study of stem cell retention, engraftment, and migration.

Serial cardiac magnetic resonance imaging of injected mesenchymal stem cells. Hill JM, Dick AJ, Raman VK, Thompson RB, Yu ZX, Hinds KA, Pessanha BS, Guttman MA, Varney TR, Martin BJ, Dunbar CE, McVeigh ER, Lederman RJ. Circulation 2003 Aug 26; 108 (8), pp. 1009–14. Epub 2003 Aug 11.

Vascular: Thrombus Detection
Near-Infrared (NIR) Hirudin Conjugated Probe

Cellular/Molecular Mechanism of Action: Hirudin anticoagulant has a relatively strong binding avidity for thrombin and functions as an inhibitor of most biological properties associated with this endogenous enzyme fraction.

Background Information: Thrombin, a serine protease, plays an important role in thrombosis as well as other cellular and developmental processes.

Application: Can be utilized as a thrombin-activatable molecular probe for the detection of thrombin activity at sites of vascular thrombus formation.

Semi-Synthetic Methods: The thrombin probe consists of an NIR fluorochrome attached to a delivery vehicle via a thrombin-specific oligopeptide substrate.

Implementation: Evaluation of the ability of an NIR fluorochrome-hirudin conjugate to detect thrombus formation in both *in vitro* and *in vivo* environments.

Animal Model: Murine (acute thrombosis model).

Interpretation and Analysis: In human blood, endogenous thrombin biochemical (enzymatically) activates the thrombin probe and increases the fluorescence signal by 18-fold ($p = 0.008$). Hirudin, a specific thrombin inhibitor, suppresses probe activation by 82% ($p = 0.007$). Imaging of *in vivo* thrombin activity up to 12 hours using the systemic thrombin probe reveals that focal NIR fluorescence signal enhancement can be rapidly detected within acute and subacute thrombi. In contrast, no thrombosis signal enhancement is seen in similar experiments with a control NIR fluorochrome. Thrombin activity can be imaged *in vivo* by using a novel thrombin-activatable and thrombin-specific NIR molecular probe. The thrombin probe could enhance the understanding of the role of thrombin in thrombogenesis and other homeostatic and pathological conditions.

Vascular: Vascular Permeability (Retinal)/ Minimally-Invasive Diagnostic Strategy [Diabetes]
Sodium Fluorescein

Background Information: Diabetic retinopathy is the leading cause of blindness in working-age individuals in the United States. Breakdown of the blood-retinal barrier is 1 of the earliest events in the progression of diabetic retinopathy. Ideally, therapeutic measures would be directed at this early stage, but there are few sensitive, quantitative methods to assess the retinal vascular barrier *in vivo.*
Application: Quantitative assessment of the retinal vascular barrier.
Implementation: Utilization of 2 fluorescent tracers in combination with fluorescence microangiography to quantitatively assess retinal vascular endothelium barrier integrity (± infusion of a hyperosmolar solution of 1.6 M mannitol for 5 minutes).
Animal Model: Rat (Long-Evans strain).
Interpretation and Analysis: Permeability × surface area/flow (PS/F) describing the retinal vasculature is 0.086 ± 0.031 (n = 13, avg. ± standard deviation). Based on estimates of flow and surface area, estimated permeability of sodium fluorescein is approximately 1.2×10^{-5} cm/s. Infusion of a hyperosmolar mannitol solution significantly increases PS/F within individual veins and significantly increases flow-weighted PS/F from 0.073 ± 0.028 to 0.16 ± 0.034 (n = 3). Quantitative *in vivo* assessment of retinal vasculature can be delineated applying an adapted indicator dilution technique. Dual-tracer fluorescence angiography appears to be a sensitive indicator for detecting increases in the blood-retinal barrier produced by hyperosmolar mannitol. The methodology may be a promising new minimally-invasive strategy that may be adapted to quantitatively monitor retinal vascular permeability.
Instrumentation: Fluorescence microangiography.

Retinal vascular permeability determined by dual-tracer fluorescence angiography. Russ PK, Gaylord GM, Haselton FR. Ann Biomed Eng 2001 Aug; 29 (8), pp. 638–47.

Vascular Blood/Red Blood Cell (RBC) Flow Characteristics
Fluorescent-Labeled RBCs

Considerations: Whole-organ studies in cat skeletal muscle have shown that increases in venous resistance associated with reduced arterial pressures are nearly abolished when the muscle is perfused with a non-aggregating RBC suspension.
Implementation: Delineation of the influence RBC aggregation has on *in vivo* vascular flow patterns and determination if such events lead to blunted RBC velocity profiles at reduced shear rates. In this manner, fluorescent-labeled RBCs applied in tracer quantities can be used to obtain velocity profiles in venous microvessels.
Interpretation and Analysis: Velocity profiles in venous microvessels (45–75 μm) of rat spinotrapezius muscle have centerline velocities between 0.3 and 14 mm/s (pseudoshear rates 3–120/s) under normal (non-aggregating) conditions and following induction of RBC aggregation with dextran 500. Profiles are nearly parabolic (Poiseuille flow) over this flow rate range in the absence of aggregation. When aggregation is present, profiles are parabolic at high shear rates and become significantly blunted at pseudoshear rates of 40/s and below. These results indicate a possible mechanism for increased venous resistance at reduced flows.
Instrumentation: Video system equipped with a gated image intensifier.

Effect of erythrocyte aggregation on velocity profiles in venules. Bishop JJ, Nance PR, Popel AS, Intaglietta M, Johnson PC. Am J Physiol Heart Circ Physiol 2001 Jan; 280 (1), pp. H222–36.

Vascular Blood Flow/Capillary Circulation/Perfusion
Fluorescein Isothiocyanate (FITC)-Labeled Dextran

Cellular/Molecular Mechanism of Action: Fluorescein isothiocyanate can be used as a light-emitting molecular marker system.
Application: Fluorescein isothiocyanate can be used as a light-emitting molecular marker in biological systems. Dextran labeled with fluorescein isothiocyanate can be utilized as an *in vivo* signal/marker molecular system for the evaluation of the acute microhemodynamic effects of various stimuli (e.g., static and alternating magnetic fields delivered at threshold levels in muscle capillary mirocirculation beds).
Route of Administration: Fluoroscein isothiocyanate-dextran solution (intravascular: e.g., vena cava).
Implementation: Evaluation of muscle capillary integrity in response to various stimuli (e.g., electromagnetic field exposure). The skin in a tibialis anterior is circularly removed with 1.5-mm diameter sufficient to faciliate intravital-microscopic recording of capillary blood velocity in the tibialis anterior muscle. Fluorescein isothiocyanate-labeled dextran (MW 150 kDa) can be used as an *in vivo* fluorescent plasma marker of muscle capillaries. Following a bolus injection of FITC-dextran solution into the caudal vein, the peak blood velocity in the muscle capillaries is measured prior to, during, and following exposure to static magnetic fields (SMF) or 50-Hz electromagnetic fields (EMF). The whole body of experimental animals is then placed on an observation stage of a fluorescence microscope and exposed to static magnetic fields (SMF = 0.3, 1, and 10 mT) or 50-Hz EMF (0.3 and 1 mT) for 10 minutes with the electromagnet not energized during sham exposures.
Animal Model: Mouse (anesthetized with pentobarbital and exposed to static and alternating magnetic fields with exposures performed at threshold levels).
Interpretation and Analysis: During and following exposure to SMF of 10 mT, peak blood velocity significantly increases compared to sham exposure. After the withdrawal of SMF and 50-Hz EMF of 1 mT, significant similar effects on the blood velocity develop or are enhanced. These findings suggest that a field intensity of 1 mT might be considered as a threshold level for enhancing muscle microcirculation under pentobarbital-induced hypnosis.
Instrumentation: Utilization of (i) an electromagnet specifically designed to deliver static magnetic fields (SMF = 0.3, 1, and 10 mT); (ii) 50-Hz EMF (0.3 and 1 mT) instrumentation (fluorescence epi-illumination system); and (iii) a fluorescence microscope.

Acute effects of whole-body exposure to static magnetic fields and 50-Hz electromagnetic fields on muscle microcirculation in anesthetized mice. Xu S, Okano H, Ohkubo C. Bioelectrochemistry 2001 Jan; 53 (1), pp. 127–35.

Vascular Blood Flow and Perfusion: Hepatic Blood Flow/[Xenobiotic Metabolism]/Extrahepatic Metabolism
Phenol Red/Lidocaine (Monoethylglycinexylidide [MEGX])

Background Information: Xenobiotic metabolism in extrahepatic tissues has been extensively studied *in vitro,* but it is difficult to estimate in *in vivo* environments the share of xenobiotic transformation in extrahepatic tissues for lack of a suitable approach.
Application: Assessment of extrahepatic metabolism investigated using the conversion of lidocaine to MEGX.

Animal Model: Rat (rats were anesthetized with ethyl ether inhalation). In exposed livers, the hepatic artery is ligated, and the portal vein clamped at its distal end. The left hepatic lobe is partly excised along its inferior margin, and a heparinized silicone catheter, diameter 0.2 cm, is inserted into the portal and left hepatic veins to allow the recirculation of portal vein blood. A sham operation is performed in control groups.

Interpretation and Analysis: Phenol red tests show that hepatic blood supply is absolutely blocked in modified rats. At 30 minutes after establishing the portal-cavum bypass, renal function and electrolytes do not change, but serum glucose decreases by 64.4 ± 30.4%; 30 minutes after intravenous administration of 1.0% lidocaine 2 mg/kg, serum MEGX in model rats is 32.0 ± 7.14% of that in the control group, which mostly exists in a free form that is not induced by phenobarbital pretreatment. The model is easy to establish and provides an *in vivo* method to study the extrahepatic metabolism of xenobiotics.

An *in vivo* rat model for assessment of extrahepatic metabolism. Ping H, Zhen-Fu C, Shao-Qing X, Ming L, Jian W, Guo-Qing Z, Lin Z, Lin-Fang L, Meng-Chao W. J Pharmacol Toxicol Methods, 2001 May–Jun; 45 (3), pp. 181–5.

Vascular Blood Flow Characterization/Aorta/Renal Artery and Vein/Portal Vein/Vena Cava
Indocyanine Green (ICG)/SH U 508 Microbubbles (Levovist)

Cellular/Molecular Mechanism of Action: Indocyanine green and microbubbles can be infused into the intravascular compartment where they dispurse throughout the blood volume.

Application: Indocyanine green and microbubbles can be applied to characterize blood flow through vascular structures.

Route of Administration: Indocyanine green and microbubbles are both administered intravascularly.

Dosage: Indocyanine green (1.25 mg/mL at 0.1 mL/kg); SH U 508 A (300 mg/mL at 0.1 mL/kg).

Considerations: SH U 508 A microbubbles (Levovist) can be detected by Doppler ultrasound.

Implementation: Evaluation of blood flow within the vena cava, aorta, renal artery, renal vein, and portal vein. The kinetics of ICG can be determined by measuring absorbance values using a photodiode, while SH U 508 A microbubbles (Levovist) are detected using Doppler ultrasound.

Animal Model: Rabbit (n = 5).

Interpretation and Analysis: Peak signal intensity is observed immediately after injection of SH U 508 A, followed by a biphasic decay profile. The rates of biphasic decay are similar in all vessels. A 2nd peak of the signal that represents microbubble recirculation is observed within the vena cava. The circulation and recirculation times of the microbubbles after injection of SH U 508 A are similar to that of ICG. These findings suggest that the majority of SH U 508 A microbubbles circulate through the body similar to blood flow, and without retention, in microvasculature structures.

In vivo kinetics of microbubbles of SH U 508 A (Levovist): Comparison with indocyanine green in rabbits. Uchimoto R, Niwa K, Eguchi H, Kamiyama N, Mine Y, Miyazawa T, Brautigam M. Ultrasound Med Biol 1999 Nov; 25 (9), pp. 1365–70.

Vascular Extravasation and Permeability
Evans Blue Dye

Cellular/Molecular Mechanism of Action: Evans blue dye is a pigment-based reagent that can be detected visually within the visible light range.

Background Information: Oxidative stress appears to be relevant to pathogenesis of asthma-like conditions.

Application: Evans blue dye is a pigment-based reagent that can be used as a visual marker or indicator molecule because of its compatability with biological systems. In this context, it is often applied as a dilution marker system within the intravascular compartment for measuring total intravascular compartment size and extrasation of plasma proteins and hematological cell types into the extravascular tissue space.

Implementation: Application of Evans blue dye to evaluate extravasation into bronchoalvealar lavage fluid following antigen-induced pulmonary responses in sensitived rats and to determine the effectiveness of the antioxidant N-acetylcysteine (oral, 1 mmol/kg/day for 7 days before challenge).

Animal Model: Rat (Brown Norway strain).

Interpretation and Analysis: N-acetylcysteine does not reduce the immediate bronchospasms that follow aerosol antigen exposure but does prevent airway hyperreactivity to 5-hydroxytryptamine at 24 hours after antigen challenge, in addition to reducing eosinophil numbers (from 0.178 ± 0.038 in the absence of N-acetylcysteine to 0.064 ± 0.020 × 10^6 cells/ml in the presence of N-acetylcysteine; $p < 0.05$) and decreasing Evans blue dye extravasation in bronchoalveolar lavage fluid. Taurine levels in bronchoalveolar lavage fluid from antigen-challenged rats are higher than control values but treatment with N-acetylcysteine fails to further increase these augmented levels. N-acetylcysteine appears to be beneficially effective when applied *in vivo* in models of experimental asthma and serves to validate related findings pertaining to other models of lung injury.

Effectiveness of oral N-acetylcysteine in a rat experimental model of asthma. Blesa S, Cortijo J, Martinez-Losa M, Mata M, Seda E, Santangelo F, Morcillo EJ. Pharmacol Res 2002 Feb; 45 (2), pp. 135–40.

Vascular Extravasation and Permeability/ Endothelial Injury: Viability/Integrity
Evans Blue Dye Staining

Cellular/Molecular Mechanism of Action: Evans blue dye is a pigment-based reagent that becomes differentially associated with viable tissues compared to compromised cell populations (e.g., vascular endothelium).

Physiological Mechanism of Action: Tumor necrosis factor soluble receptor (TNFsr) has been shown *in vitro* and *in vivo* to neutralize TNF-mediated biological activity.

Background Information: Tumor necrosis factor-alpha (TNF-α) is expressed locally in arteries at sites of balloon injury. *In vitro* studies have shown that TNF inhibits cell cycle progression and induces apoptosis in endothelial cells.

Application: Evans blue dye staining can be applied to evaluate viable *ex vivo* preparations of vascular structures for integrity of endothelial surfaces.

Implementation: Evaluation of the ability to accelerate endothelial recovery following angioplasty by inhibiting TNF utilizing Evans blue dye as a molecular detection modality. Given this objective, treatment groups are administered TNFsr for comparison to reference controls that receive IgG (intraperitoneal injection). Deendothelializing balloon injuries are then created, and the resulting induced lesions evaluated 1 week later for evidence of reendothelialization (Evans blue dye staining) and after 2 weeks to evaluate reendothelialization and endothelial function.

Animal Model: Rat (Sprague-Dawley strain).

Interpretation and Analysis: At both time points, blockade of TNF biological activity with TNFsr results in increased reendothe-

lialization, as measured as absolute area and percent area reendothelialized. Tumor necrosis factor soluble receptor also accelerates functional endothelial recovery that manifests as an increase in nitric oxide production. Neointimal thickening can also be appreciated as being inhibited. Blockade of TNF *in vivo* accelerates functional endothelial recovery after barotraumatic deendothelializing injury. Locally expressed TNF therefore acts to inhibit functional endothelial recovery after angioplasty and transient blockade of TNF may improve the long-term success of angioplasty.

Evans Blue Staining: The reagent facilitates detection of a demarcation between viable endothelial cell populations and subendothelial collagen.

In vivo blockade of tumor necrosis factor-alpha accelerates functional endothelial recovery after balloon angioplasty. Krasinski K, Spyridopoulos I, Kearney M, Losordo DW. Circulation 2001 Oct 9; 104 (15), pp. 1754–6.

Vascular Extravasation and Permeability: Anaphylaxis
Evans Blue Dye/Passive Cutaneous Anaphylaxis Test

Cellular/Molecular Mechanism of Action: Immunoglobulin (IgE) promotes mast cell degranulation in normal individuals.
Diagnostic Application: Detection of immune hypersensitivity conditions.
Implementation: Dilutions of serum potentially containing IgE immunoglobulin are injected intradermally over a grid-like pattern. Purified antigen is then administered by intravenous injection. Simultaneous injection of Evans blue dye markedly increases the sensitivity of visually detecting regions of positive response. In this context, Evans blue dye "leaks" across capillary structures into the surrounding intracellular matrix due to the reaction of vascular capillary endothelium to histamine released from activated mast cell populations.
Interpretation and Analysis: A striking blue discoloration at the site of injection supports a diagnosis of a hypersensitivity reaction.

Vascular Perfusion: Dermal Microvasculature/ Delineation of Perfused to Total Capillary Ratio
Sodium Fluorescein

Application: Delination of the nature of temporal variation in capillary numbers, and determination of the proportion of perfused to total nutritional capillaries in normal skin.
Implementation: Using *in vivo* microscopy, the temporal behavior of the number of visible capillaries in the skin of the dorsum of the foot is observed over periods of time varying from 5 minutes to 55 days. Capillary perfusion is then studied by comparing capillary numbers before and after intravenous injection of sodium fluorescein.
Human Model: Healthy subjects.
Interpretation and Analysis: The mean percent difference in the number of visible capillaries over a mean period of 25.3 days is 5.5%. The percentage ratio of perfused to total capillaries is 54.2%. There appears to be little quantitative change in capillary numbers over periods of up to 50 days, and under physiological conditions, about half of the nutritional capillaries of the skin are not perfused.

Study of temporal and perfusion physiology of skin capillaries in the dorsum of the foot. Lamah M, Mortimer PS, Dormandy JA. J Vasc Res 2001 Jan–Feb; 38 (1), pp. 59–63.

CELLULAR: GENERAL

Vitality Staining of Living Cells
Trypan Blue Dye Exclusion

Cellular/Molecular Mechanism of Action: Penetrates the cell membrane and accumulates within the cytoplasm of non-viable cell populations.
Application: Stain identification of non-viable cell populations.
Route of Administration: Topical *in vitro* bathing.
Implementation: Trypan blue is incubated with cell populations.
Interpretation and Analysis: Non-viable cell populations are positively stained with Trypan blue pigment dye reagent.

Vitality Staining of Living Cells: Biochemical Viability
3-[4,5-Dimethylthiazol-2-yl]-2,5-Diphenyltetrazolium Bromide (MTT Vitality Stain)

Cellular/Molecular Mechanism of Action: Viable cell populations have the necessary biochemical components in their cytoplasm to convert MTT reagent to navy blue furazone crystals.
Application: Assessment of cell viability.
Route of Administration: Topical *in vitro* bathing.
Formulation: The vitality staining reagent MTT is prepared as a solution dispersed in serum-free and pH indicator-free growth media (e.g., 60 ml/300 ml as MTT/RPMI 1640).
Implementation: MTT vitality staining reagent (e.g., 375 μl/well of a 48-chamber plate) is incubated with viable cell populations at 37°C over a 3- to 4-hour period. Cells (e.g., tissue culture monolayers) stained with MTT reagent are then destained with isopropyl alcohol (200 μl) at 25°C for 25 minutes with the aid of gently horizontal agitation. The resulting blue/purple supernatant is harvested by pipette and transferred to a 96-well microtiter plate for measurement of spectrophometric absorbance (550 nm).
Interpretation and Analysis: Values obtained for optical density at 550 nm are directly proportional to the extent of cell viability/ proliferation.

Vitality Staining of Living Cells: Micronucleus Assessment
Acridine Orange/Giemsa/New Methylene Blue

Background Information: The micronucleus test has been widely used as an *in vivo* cytogenetic test. It employs 2 different kinds of supravital staining methods that use either new methylene blue (N) and Giemsa (G) or acridine orange (AO).
Implementation: The methylene blue/acridine orange-staining method involves 3 steps: (i) combination of the target tissue or target cells with an equivalent volume of 0.5% solution of new methylene blue (new methylene blue-staining step); (ii) immediate smear of the mixture, followed by treatment with methanol for 10 minutes for fixation and removal of new methylene blue and drying (referred to as fixed-decolorized specimens); and (iii) staining with 0.007% solution of acridine orange for 3 minutes, followed by washing with Sorensen's buffer (pH 6.8) and covering of specimens before observation (acridine orange-staining step). To examine whether the new methylene blue/acridine orange-staining method is useful for the micronucleus test, comparisons can be made between new methylene blue-, new methylene blue/acridine orange-, and acridine orange-stained specimens prepared supravitally from peripheral blood of rats with and without treatment of cyclophosphamide.

Interpretation and Analysis: Results indicate that N/acridine orange-stained specimens can be supravitally observed after long-term storage with the same coloration and comparable frequencies of micronucleated reticulocytes with a positive response as acridine orange-stained specimens, if the staining process is temporarily stopped before acridine orange staining (as fixed-decolorized specimens) or if the acridine orange-staining step is repeated. The results also show that separate reticulocyte types are supravitally stained in a similar fashion to N-stained specimens but not to acridine orange-stained specimens, indicative of the preservation of the supravital feature of new methylene blue staining. Taken together these results suggest that the new methylene blue/acridine orange-staining procedure could offer an additional useful staining tool for the micronucleus test.

A staining procedure for micronucleus test using new methylene blue and acridine orange: Specimens that are supravitally stained with possible long-term storage. Sugihara T, Sawada S, Hakura A, Hori Y, Uchida K, Sagami F. Mutat Res 2000 Oct 31; 470 (2), pp. 103–8.

CENTRAL NERVOUS SYSTEM AND SPECIAL SENSES

Amyloid: Beta-Sheet Proteins/Amyloid Plaques: Abeta Peptide
Thioflavin Derivatives/Neurofibrillary Tangles: Tau Protein

Cellular/Molecular Mechanism of Action: Thioflavin-T (ThT) derivatives possess binding avidity for beta-sheet proteins deposited in amyloid plaques (abeta peptide) and neurofibrillary tangles (tau protein).
Background Information: The beta-sheet proteins deposited *in vivo* in amyloid plaques (abeta peptide) or neurofibrillary tangles (tau protein) represent a target for the development of biological markers for Alzheimer's disease (AD).
Application: Detection and characterization of beta-sheet proteins deposited in amyloid plaques (abeta peptide) and neurofibrillary tangles (tau protein) similar to those associated with the pathogenesis of AD.
Route of Administration: [Intravenous.] Anticipated that such reagents would be given intravascularly if applied in a clinical environment.
Semi-Synthetic Methods: Production of ThT derivatives and the carbon-11 labeled compound [N-methyl-^{11}C]6-Me-BTA-1.
Implementation: Characterization of the entry into and clearance of [N-methyl-^{11}C]6-Me-BTA-1 from brain tissues.
Animal Model: Mouse (Swiss-Webster).
Interpretation and Analysis: These compounds lack the positively charged quaternary heterocyclic nitrogen of ThT and are therefore uncharged at physiological pH. They are 600-fold more lipophilic than ThT. Derivatives of ThT bind to abeta(1-40) fibrils with higher affinity (Ki = 20.2 nM) than ThT (Ki = 890 nM). The uncharged ThT derivatives stain both plaques and neurofibrillary tangles in postmortem AD brain, showing some preference for plaque staining.

The compound [N-methyl-^{11}C]6-Me-BTA-1 enters the brain at levels comparable to commonly used neuroreceptor imaging agents (0.223 %ID-kg/g or 7.61 %ID/g at 2 minutes postinjection) and shows good clearance of free and non-specifically bound radioactivity in normal rodent brain tissue (brain clearance $T_{1/2}$ = 20 minutes). The combination of relatively high affinity for amyloid, specificity for staining plaques and neurofibrillary tangles in postmortem AD brain, and good brain entry and clearance makes [N-methyl-^{11}C]6-Me-BTA-1 a promising candidate as an *in vivo* positron emission tomography (PET) beta-sheet imaging agent.

Uncharged thioflavin-T derivatives bind to amyloid beta protein with high affinity and readily enter the brain. Klunk WE, Wang Y, Huang GF, Debnath ML, Holt DP, Mathis CA. Life Sci 2001 Aug 17; 69 (13), pp. 1471–84.

Amyloid (Alzheimer's Disease [AD])/Abeta(1-40) Fibrils/Senile Plaques (SPs) and Neurofibrillary Tangles (NFTs)
2-(1-(6-[(2-[^{18}F]Fluoroethyl)-(Methyl)Amino]-2-Naphthyl)Ethylidene)Malononitrile ([^{18}F]FDDNP)

Cellular/Molecular Mechanism of Action: The agent [^{18}F]FDDNP is a hydrophobic dual-function semi-synthetic compound that is fluorescent emitting and possesses binding avidity for certain types of molecular amyloid.
Background Information: Senile plaques and NFTs are hallmark pathological changes that accompany the neurodegeneration involved in AD. Deposits of beta-amyloid (abeta) peptide are a major constituent of SPs.
Application: The hydrophobic, fluorescent molecular-imaging probe [^{18}F]FDDNP can cross the blood-brain barrier and can be utilized to determine the location and deposition load of SPs and NFTs *in vivo* in cases of AD.
Route of Administration: Intravascular.
Implementation: Determination of the binding avidity of FDDNP and its analog, 1-(6-[(2-[^{18}F]fluoroethyl)(methyl)amino] naphthalen-2-yl)ethanone ([^{18}F]FENE), for synthetic fibrils of abeta(1-40) applying fluorimetric and radioactive binding assays.
Interpretation and Analysis: Both FDDNP and FENE bind to kinetically distinguishable binding sites (n = 2 sites) on abeta(1-40) fibrils. Fluorescence titrations yield apparent K_d values of 0.12 and 0.16 nm for high-affinity binding sites for FDDNP and FENE, respectively, and apparent K_d values of 1.86 and 71.2 nm for low-affinity binding sites. Traditional radioactive binding assays produce apparent K_d values in the low nanomolar range. The presence of 2 kinetically distinguishable binding sites for FDDNP and FENE suggests multiple binding sites for SPs and identifies properties that will allow for the structural optimization of this family of probes for *in vivo* use. The high-affinity binding of the probes to multiple binding sites on fibrils is consistent with results obtained with digital autoradiography, immunohistochemistry, and confocal fluorescence microscopy using human brain specimens of AD cases.

Binding characteristics of radiofluorinated 6-dialkylamino-2-naphthylethylidene derivatives as positron emission tomography imaging probes for beta-amyloid plaques in Alzheimer's disease. Agdeppa ED, Kepe V, Liu J, Flores-Torres S, Satyamurthy N, Petric A, Cole GM, Small GW, Huang SC, Barrio JR. J Neurosci 2001 Dec 15; 21 (24), p. RC189.

Amyloid Beta Protein: Extracellular/Abnormal Tau Protein/Abnormal Synuclein Proteins/ [Alzheimer's Disease (AD)]
[Trans/Trans]-1-Bromo-2,5-bis-(3-Hydroxycarbonyl-4-Hydroxy)Styrylbenzene/Thioflavin S

Cellular/Molecular Mechanism of Action: Congo red-derived fluorescent probe [*trans*/*trans*]-1-bromo-2,5-*bis*-(3-hydroxycarbonyl-4-hydroxy)styrylbenzene (BSB) binds to molecular amyloid.
Background Information: The novel Congo red-derived fluorescent probe BSB binds to amyloid plaques of postmortem AD brains and *in vivo* in transgenic mouse brains.
Application: Prototype imaging agent for detecting and characterizing amyloid deposits/plaques (e.g., AD).
Implementation: Evaluation of the ability for BSB to probe postmortem tissues from patients with various neurodegenerative

diseases containing diagnostic lesions. In this context, the agent can be utilized to characterize fibrillar intra- or extracellular lesions and compare properties with standard histochemical dyes such as thioflavin S and immunohistochemical stains specific for the same lesion type.

Interpretation and Analysis: The agent BSB binds not only to extracellular amyloid beta protein but also many intracellular lesions composed of abnormal tau and synuclein proteins, and suggests that radioiodinated BSB derivatives or related ligands may be useful *in vivo* imaging agents to monitor diverse types of amyloid deposition.

The fluorescent Congo red derivative, (trans, trans)-1-bromo-2,5-*bis*-(3-hydroxycarbonyl-4-hydroxy)styrylbenzene (BSB), labels diverse beta-pleated sheet structures in postmortem human neurodegenerative disease brains. Schmidt ML, Schuck T, Sheridan S, Kung MP, Kung H, Zhuang ZP, Bergeron C, Lamarche JS, Skovronsky D, Giasson BI, Lee VM, Trojanowski JQ. Am J Pathol 2001 Sep; 159 (3), pp. 937–43.

Amyloid Beta Protein Detection/Senile Plaques and Neurofibrillary Tangles/Alzheimer's Disease (AD) *Chrysamine-G (CG)/[Congo Red Analog]/[^{14}C]-CG*

Cellular/Molecular Mechanism of Action: Chrysamine-G is a carboxylic acid analogue of Congo red, a histologic dye that stains amyloid protein deposits.

Background Information: CG binds to the beta-amyloid protein of AD *in vitro* and partitions into the brain of normal mice.

Interpretation and Analysis: The agent [^{14}C]-CG possesses increased binding to homogenates of several regions of AD brain tissue compared to control brain tissue. The total binding of CG to AD brain tissue is approximately 2- to 3-fold that of control brain. The cerebellum can serve as an internal standard for each brain because CG binding to cerebellum does not differ between AD and control. The binding of [^{14}C]-CG correlates with numbers of senile plaques and neurofibrillary tangles. Based on the nature of such findings, CG could be used to stain cerebrovascular amyloid in tissue sections. These results suggest that CG may prove useful as an *in vivo* probe of amyloid deposition in AD.

Chrysamine-G binding to Alzheimer and control brain: Autopsy study of a new amyloid probe. Klunk WE, Debnath ML, Pettegrew JW. Neurobiol Aging 1995 Jul–Aug; 16 (4), pp. 541–8.

Amyloid Deposits: [Alzheimer's Disease–Related]/ Differential Stain Recognition: Non-Fibrillar vs Fibrillar Amyloid/Transthyretin: Amyloidic Protein *X-34/Congo Red/Thioflavin S*

Cellular/Molecular Mechanism of Action: The agents Congo red, thioflavin S, and X-34 possess physical binding avidity for molecular amyloid.

Background Information: Transgenic *Caenorhabditis elegans* animals can be engineered to express high levels of the human beta-amyloid peptide (abeta). Histochemistry of fixed tissue from these animals reveals deposits reactive with the amyloid-specific dyes Congo Red and thioflavin S.

Application: Alzheimer's disease.

Implementation: Discovery of the potential for X-34 to bind to amyloid deposits in *Caenorhabditis elegans* applying immunoelectron microscopy as a validation methodology.

Interpretation and Analysis: Immunoelectron microscopy can detect intracellular immunoreactive deposits with classic amyloid fibrillar ultrastructure. These deposits can be visualized in living animals using the newly developed, intensively fluorescent, amyloid-specific dye X-34. Utilizing this amyloid staining dye *in vivo* allows monitoring of amyloid deposition in individual animals over time. The specificity of X-34 staining is demonstrated by examining transgenic animals expressing high levels of a non-fibrillar beta peptide variant, the beta single-chain dimer. These animals have deposits that are immunoreactive with antibeta antibodies but do not have X-34 positive-staining deposits or deposits with a fibrillar ultrastructure. Visualization of putative amyloid deposits resulting from accumulation of human transthyretin, another amyloidic protein can also be achieved *in vivo* using X-34 dye reagent. *In vivo* amyloid staining with X-34 may be a useful tool for monitoring antiamyloid treatments in real time or screening for genetic alterations that affect amyloid formation.

Visualization of fibrillar amyloid deposits in living, transgenic Caenorhabditis elegans animals using the sensitive amyloid dye, X-34. Link CD, Johnson CJ, Fonte V, Paupard M, Hall DH, Styren S, Mathis CA, Klunk WE. Neurobiol Aging 2001 Mar–Apr; 22 (2), pp. 217–26.

Amyloid (Abeta) Fibrils/Alzheimer's Disease (AD): Senile Plaques and Neurofibrillary Tangles *Methoxy-X04 [Congo Red Derivative]/Chrysamine-G*

Cellular/Molecular Mechanism of Action: Similar to Congo red, methoxy-X04 is a fluorescent dye that possesses binding avidity for molecular amyloid beta fibrils.

Background Information: The identification of amyloid deposits in living AD patients is important for both early diagnosis and for monitoring the efficacy of newly developed antiamyloid therapies.

Application: Visual fluorescent detection and characterization of amyloid beta fibrils contained within plaques, tangles, and cerebrovascular amyloid deposits.

Route of Administration: Methoxy-X04 (IV = 5–10 mg/kg; IP = 10 mg/kg in mice).

Dosage: Methoxy-X04 (intravenous, intraperitoneal in mice).

Semi-Synthetic Methods: Methoxy-X04 is a derivative of Congo red and Chrysamine-G that contains no acid groups and is therefore smaller and much more lipophilic than Congo red or Chrysamine-G.

Implementation: Evaluation of the *in vivo* ability of methoxy-X04 to detect individual plaques that can be non-invasively detected applying multiphoton microscopy.

Animal Model: Mouse (PSI/APP).

Interpretation and Analysis: Methoxy-X04 retains *in vitro* binding affinity for amyloid beta (abeta) fibrils (Ki = 26.8 nM) very similar to that of Chrysamine-G (Ki = 25.3 nM). The fluorescent properties of methoxy-X04 facilitate successful staining of plaques, tangles, and cerebrovascular amyloid in postmortem sections of AD brain with good specificity. In an *in vivo* environment (mice), multiphoton microscopy can be applied to obtain high-resolution (1 μm) fluorescent images of the brains. Under such conditions, it is possible to detect individual plaques that can be distinguished within 30 to 60 minutes after a single intravenous injection (e.g., PSI/APP mouse brain). A single intraperitoneal methoxy-X04 injection at 10 mg/kg also produces high-contrast images of plaques and cerebrovascular amyloid (e.g., PSI/APP mouse brain). Complementary quantitative studies using tracer doses of carbon-11-labeled methoxy-X04 show that it enters rat brain in amounts that suggest it is a viable candidate as a positron emission tomography (PET) amyloid-imaging agent for *in vivo* application in human studies.

Instrumentation: Multiphoton microscopy.

Imaging abeta plaques in living transgenic mice with multiphoton microscopy and methoxy-X04, a systemically administered Congo red derivative. Klunk WE, Bacskai BJ, Mathis CA, Kajdasz ST, McLellan ME, Frosch MP,

Debnath ML, Holt DP, Wang Y, Hyman BT. J Neuropathol Exp Neurol 2002 Sep; 61 (9), pp. 797–805.

Amyloid Plaques (Abeta)/Alzheimer's Disease (AD)
Stilbene Derivatives

Cellular/Molecular Mechanism of Action: Stilbene derivatives recognize and physically bind to amyloid plaques analogous to those associated with AD.
Application: [^{11}C]4, N-[^{11}C]methylamino-4′-hydroxystilbene may be useful as a positron emission tomography (PET) imaging agent for mapping abeta plaques in the brain of patients with AD.
Route of Administration: Intravenous.
Semi-Synthetic Methods: Synthesis of a series of stilbene derivatives can be successfully achieved by performing a simple Wadsworth-Emmons reaction between diethyl (4-nitrobenzyl)phosphonate and 4-methoxybenzaldehyde. The [^{11}C]-labeled 4-N-methylamino-4′-hydroxystilbene, [^{11}C]4, is prepared by [^{11}C] methylation of 4-amino-4′-hydroxystilbene.
Interpretation and Analysis: 4-N,N-dimethylamino-4′-methyoxy and the corresponding 4-N-monomethylamino-, 4′-hydroxy stilbenes show good binding affinities toward abeta aggregates *in vitro* [K(i) $<$ 10 nM]. The [^{11}C]4 displays a moderate lipophilicity (log p = 2.36) and shows very good brain penetration and washout from normal rat brain following intravenous injection. *In vitro* autoradiography of transgenic AD mouse brain sections shows a high specific labeling of beta-amyloid plaques, whereas control sections show no binding.

^{11}C-labeled stilbene derivatives as abeta-aggregate-specific PET imaging agents for Alzheimer's disease. Ono M, Wilson A, Nobrega J, Westaway D, Verhoeff P, Zhuang ZP, Kung MP, Kung HF. Nucl Med Biol 2003 Aug; 30 (6), pp. 565–71.

Amyloid Plaques: Dense Beta Deposit Oxidative Properties/Alzheimer's Disease (AD)
Oxidation-Activated Fluorogenic Probes/N-Tert-Butyl-α-Phenylnitrone

Cellular/Molecular Mechanism of Action: *N*-tert-butyl-α-phenylnitrone functions as a free radical spin trap.
Background Information: Amyloid beta, the primary constituent of senile plaques in AD, is hypothesized to cause neuronal damage and cognitive failure, but the mechanisms are unknown.
Application: Fluorogenic compounds can be used *in vivo* to determine the degree of association between amyloid beta deposits and free radical production. The compound *N*-tert-butyl-α-phenylnitrone can be applied as a means for validating the effectiveness and accuracy of tracers and probes designed to detect anatomical regions of elevated oxidation potential.
Implementation: Utilization of compounds that are actively fluorescent following exposure to conditions with elevated oxidative potential for the purpose of infrared laser imaging of anatomical structures. As a validation procedure, *N*-tert-butyl-α-phenylnitrone (a free radical spin trap) can be systemically administered to determine the accuracy of oxidation-activated fluorogenic probes. Collectively, these agents can be applied to delineate if a direct association exists between amyloid beta deposits and free radical production.
Animal Model: Mouse (*in vivo* transgenic AD).
Human Model: Brain tissue from cases of AD (*ex vivo*).
Interpretation and Analysis: Fluorescence can be appreciated in dense core plaques, but not diffuse plaques, as determined by subsequent addition of thioflavin S and immunohistochemistry analysis for amyloid beta. Systemic administration of *N*-tert-butyl-α-phenylnitrone greatly reduces the detection of probes activated by tissue oxidative processes. It is therefore believed that a subset of amyloid plaques produce free radical species in living Alzheimer's models and in human Alzheimer tissue sections. Antioxidant therapy neutralizes these highly reactive molecules and may therefore be of therapeutic value in AD.
Instrumentation: Multiphoton imaging.

In vivo imaging of reactive oxygen species specifically associated with thioflavin S-positive amyloid plaques by multiphoton microscopy. McLellan ME, Kajdasz ST, Hyman BT, Bacskai BJ. J Neurosci 2003 Mar 15; 23 (6), pp. 2212–7.

Choriocapillaris: Choroid Circulation/Angiogram Imaging
Liposomes: Heat Sensitive/Carboxyfluorescein (Encapsulated)/[Laser-Targeted Angiography (LTA)]

Background Information: To obtain high-quality angiograms of the rat choriocapillaris with continuous LTA, for the purpose of assessing the choroidal circulation system.
Application: Characterization of choroidal circulation using angiogram imaging techniques.
Route of Administration: Heat-sensitive liposomes (intravascular).
Implementation: Evaluation of a carboxyfluorescein encapsulated in heat-sensitive liposomes injected intravenously to characterize the choroidal circulatory system. Local release of encapsulated carboxyfluorescein is induced by applying a continuous heat beam emitted by a diode laser (810 nm) of variable power. Video angiograms are recorded with excitation illumination provided by argon laser (488 and 514 nm) to observe highly selective images of the choriocapillaris.
Animal Model: Rat.
Interpretation and Analysis: Three distinct phases (filling, plateau, and draining) can be observed in fluorescent images of choriocapillaris by applying the diode laser continuously. In the plateau phase, a lobe-shaped area of choriocapillaris peripheral to the laser site can be illuminated, and this finite area does not change in size with continuous laser application to the same location. When laser power is increased, a larger area of choriocapillaris can be illuminated in the plateau phase. The filling and draining phases reveal the flow patterns within the choriocapillaris lobules that fill from a central spot and drain along a peripheral ring. Choriocapillaris (rat) is divided into independent functional units and the choroidal circulation is segmental under normal conditions. In LTA, the diode laser warms up a choroidal artery and releases fluorescein that flows downstream to an area of choriocapillaris fed by the same artery. Laser-targeted angiography appears to be a powerful method for analyzing choroidal circulation *in vivo.*
Instrumentation: Modified slit lamp that incorporates 2 kinds of lasers (argon and diode).

In vivo analysis of choroidal circulation by continuous laser-targeted angiography in the rat. Hirata Y, Nishiwaki H, Miura S, Ieki Y, Kiryu J, Honda Y. Invest Ophthalmol Vis Sci 2003 Jul; 44 (7), pp. 3103–9.

Corticospinal Neuron Trophic Dependencies/Response to Pathological Lesions and Therapeutic Agents
Fast Blue

Application: Evaluation of the response of corticospinal neurons (CSN) of the sensory motor cortex to lesions and therapeutic drugs.
Implementation: Before induction of lesions, CSN are retrogradely labeled with Fast blue (FB). A stereotaxic cut lesion through

the entire internal capsule (ICL) is used to axotomize CSN. The extent of axotomy is determined by application of a control tracer.

Animal Model: Rat and mouse (lesion model for the induction of death of analogous populations of CSN in rodent species).

Interpretation and Analysis: In both species, FB-labeled CSN are localized in 3 major areas: (i) the sensory motor cortex; (ii) the supplementary motor and medial prefrontal cortex; and (iii) the somatosensory cortex. The ICL does not lead to complete axotomy of CSN of the rat and mouse somatosensory cortex. In rats, ICL results in complete axotomy of CSN of the sensory motor cortex and incomplete axotomy of the caudal portion of the supplementary motor and medial prefrontal cortex. In mice, the area of axotomized CSN extends significantly further frontally. In both species, axotomy-induced death of CSN is observed in the center of the sensory motor cortex. This lesion model is useful for investigations of the response of CSN of the sensory motor cortex to pathological lesion and therapeutic drugs.

An axotomy model for the induction of death of rat and mouse corticospinal neurons *in vivo*. Bonatz H, Rohrig S, Mestres P, Meyer M, Giehl KM. J Neurosci Methods 2000 Jul 31; 100 (1–2), pp. 105–15.

Cranial Trauma: Cerebrospinal Fuid (CSF) Rhinorrhea
Fluorescein Dye

Background Information: Cerebrospinal fluid rhinorrhea typically results from trauma to the skull base, producing leaks through either the cribiform plate region or the sphenoid bone. Traditional approaches to the repair of such leaks include a frontal craniotomy or external ethmoidectomy. An endoscopic approach through the nose has also proven to be successful.

Application: CSF flow tracing.

Implementation: Evaluation of traumatic CSF rhinorrhea and development of a meningocele in the region of the cribiform plate using fluorescein dye to demonstrate the site of CSF leakage.

Interpretation and Analysis: Visualization of the defect with fluorescein dye can faciliate repair of the defect via a transnasal endoscopic approach. Given this condition a variety of complementary diagnostic procedures (radiographic assessment) and approaches for repair and postoperative care can be employed.

Endoscopic repair of traumatic CSF rhinorrhea in a pediatric patient. Wetmore RF, Duhaime AC, Klausner RD. Int J Pediatr Otorhinolaryngol 1996 Jul; 36 (2), pp. 109–15.

Reconstruction of the lacrimal drainage system. Holt JE, Holt GR. Arch Otolaryngol 1984 Apr; 110 (4), pp. 211–20.

Epilepsy/Spatiotemporal Patterns of Spontaneous Epileptiform Activity
RH414 (Fluorescent Voltage-Sensitive Dye)/Bicuculline

Application: RH414 functions as a fluorescent voltage-sensitive dye and the GABA(A) receptor antagonist bicuculline can be applied to induce acute spontaneous epileptoform discharges.

Implementation: Characterization of spatiotemporal patterns of *in vivo* spontaneous epileptiform activity in the cerebral cortex. The surface of the cerebral cortex is exposed under anesthesia and stained with a fluorescent voltage-sensitive dye, RH414, and optical recording techniques applied for the detection of transmembrane voltage changes. Acute spontaneous epileptiform discharges can be induced by application of bicuculline [GABA(A) receptor antagonist]. Changes in the intensity of fluorescence from the cerebral cortex are recorded using a photodiode system.

Animal Model: Rat cerebral cortex.

Interpretation and Analysis: Spontaneous epileptiform discharge recording can be acquired in a manner that facilitates the construction of initiation-site maps. Initiation sites are neither unique nor randomly located but instead exhibit a multimodal distribution pattern. The incidence of epileptiform discharges is different between the initiation sites, and some sites show dominance in the induction of spontaneous epileptiform discharges.

Instrumentation: Optic fiber photodiode system (464-channel).

Optical analysis of acute spontaneous epileptiform discharges in the *in vivo* rat cerebral cortex. Miyakawa N, Yazawa I, Sasaki S, Momose-Sato Y, Sato K. Neuroimage 2003 Mar; 18 (3), pp. 622–32.

Neoplasia (Gliosarcoma)
Hoechst 33258 Dye/Rhodaminated Long-Circulating Dextran-Coated Iron Oxide (LCDIO)/Green Fluorescent Protein

Cellular/Molecular Mechanism of Action: Hoechst 33258 dye can be applied as an intravital endothelial stain. Rhodaminated long-circulating dextran-coated iron oxide (LCDIO) particles can preferentially localize intracellularly within certain malignant neoplastic cell types (e.g., gliosarcoma).

Application: Detection and characterization of central nervous system neoplastic lesions (e.g., gliosarcoma).

Route of Administration: Intravascular.

Implementation: Determination of the distribution of LCDIO preparation in tumors. Accumulation of LCDIO in tissue sections is evaluated using multichannel fluorescence microscopy in combination with rhodaminated LCDIO, green fluorescent protein functioning as a tumor marker, and Hoechst 33258 dye serving as an intravital endothelial stain. Uptake into tumor cells is corroborated with results from immunohistochemical and cell culture uptake analyses. The effect of intratumoral LCDIO uptake on magnetic resonance imaging (MRI) signal intensity is evaluated with a 1.5-T superconducting magnet.

Animal Model: Rodent gliosarcoma.

Interpretation and Analysis: Tumoral accumulation of LCDIO is $0.11 \pm 0.06\%$ of the injected dose per gram of tissue in brain tumors and is sufficient for detection using MR imaging. In tumor sections, LCDIO preferentially localizes in tumor cells ($49.0 \pm 4.6\%$) but is also taken up by macrophages in tumors ($21.0 \pm 3.1\%$) and by endothelial cells in the areas of active angiogenesis ($6.5 \pm 1.4\%$). In cell culture, LCDIO uptake strongly correlates with growth rate of tumor cell lines. Tumoral LCDIO accumulation is not negligible and helps explain MRI signal intensity changes observed in clinical trials. Microscopically, LCDIO accumulates predominantly in tumor cells and tumor-associated macrophages. Uptake into tumor cells appears to be directly proportional to cellular proliferation rate.

Instrumentation: Magnetic resonance imaging signal intensity evaluated with a 1.5-T superconducting magnet.

Tumoral distribution of long-circulating dextran-coated iron oxide nanoparticles in a rodent model. Moore A, Marecos E, Bogdanov A Jr, Weissleder R. Radiology 2000 Feb; 214 (2), pp. 568–74.

Neuroendocrine Neoplasia/Somatostatin Receptor Expression
Indotricarbocyanine-Octreotate/(Cyanine Dye: Somatostatin Conjugate)

Cellular/Molecular Mechanism of Action: Octreotate is a biologically functional analog of somatostatin.

Application: Contrast agent for the optical *in vivo* imaging of neoplastic lesions that express somatostatin receptors at relatively high densities to the extent that they can be visualized using endoscopy/videoendoscopy.
Route of Administration: Indotricarbocyanine-octreotate (intravenous).
Implementation: Detection and characterization of neuroendocrine neoplastic lesions utilizing indotricarbocyanine-octreotate as a selective optical imaging agent.

Animal Model: Mouse (xenographs of human neuroendocrine neoplastic cell types).
Interpretation and Analysis: During *in vivo* imaging procedures, indotricarbocyanine-octreotate preferentially accumulates in tumors (murine xenografts). The level of fluorescence for tumors rapidly increases and is often more than 3-fold higher than that of normal tissue between 3 and 24 hours after administration. The indotricarbocyanine-octreotate targeting conjugate is also selectively internalized by primary human neuroendocrine tumor cells. Approaches to imaging neuroendocrine neoplastic lesions that combine the specificity of ligand/receptor interaction in concert with near-infrared fluorescence detection represent a diagnostic platform that may be applied in various other fields of clinical oncology.

Receptor-targeted optical imaging of tumors with near-infrared fluorescent ligands. Becker A, Hessenius C, Licha K, Ebert B, Sukowski U, Semmler W, Wiedenmann B, Grotzinger C. Nat Biotechnol 2001 Apr; 19 (4), pp. 327–31.

Stem Cell Migration/[Parkinson's Disease Research]/[Hemopoeitic]
Gadolinium Rhodamine Dextran (GRID)

Cellular/Molecular Mechanism of Action: Rhodamine emits light energy while gadolinium functions as an element that can be selectively detected by magnetic resonance imaging (MRI).
Background Information: The ability to track stem cell transplants in the brain by *in vivo* neuroimaging will improve current understanding about how these cells mediate functional recovery after neural transplantation. One major challenge for the development and refinement of stem cell transplantation is to map the spatial distribution and rate of *in situ* migration.
Application: Gadolinium rhodamine dextran is a bifunctional contrast agent that can emit light energy and be detected in a magnetic field (MRI). These attributes allow it to be applied as a tracer or marker molecule for profiling the migration of transplanted stem cell populations within ischemia-damaged rat hippocampus by MRI.
Route of Administration: Intravenous.
Semi-Synthetic Methods: Conjugation of rhodamine to dextran applying cross-linking strategies. Addition of gadolinium to dextran can potentially be achieved by covalent bond formation or through the application of chelation groups.
Implementation: Assessment of stem cell migration applying *in vitro* labeling of populations with the bifunctional contrast agent GRID prior to transplantation. Detection *in vivo* is achieved applying both MRI and fluorescence microscopy, or with PKH26, visible exclusively under fluorescence microscopy. At different time points following engraftment, brains can be evaluated by both histology analyses and *ex vivo* MRI as validation procedures for research purposes.
Interpretation and Analysis: Transplanted stem cells can be identified by MRI only if prelabeled with GRID, whereas fluorescence microscopy can detect transplanted cells using either labeling reagent. Distribution of GRID-labeled stem cells established by the application of MRI corresponds to results observed using fluorescence microscopy. Stem cells and their migration can therefore be reliably identified applying GRID-enhanced MRI methodologies.

Tracking transplanted stem cell migration using bifunctional, contrast agent-enhanced, magnetic resonance imaging. Modo M, Cash D, Mellodew K, Williams SC, Fraser SE, Meade TJ, Price J, Hodges H. Neuroimage 2002 Oct; 17 (2), pp. 803–11.

Thalamus/Nucleus Rotundus (Crossed-Tectal Projection Tracing)/Thalamic Tectorotundal Pathway Development (Embryonic)
1,1′-Dioctadecyl-3,3,3′,3′-Tetramethylinodocarbocyanine/Cholera Toxin B Subunit

Application: Mapping of axons within the central nervous system.
Implementation: Evaluation of the potential to trace crossed-tectal projections to the nucleus rotundus of the thalamus (tectorotundal pathways). Molecular tracers are injected into the optic tectum under 3 experimental conditions (carbocyanine postfix, carbocyanine *in vivo,* and cholera toxin B subunit *in vivo*) and the anterograde transport of the nucleus rotundus monitored and compared. In the carbocyanine postfix method, small crystals of carbocyanine dye were inserted into the tectum of paraformaldehyde-fixed embryos. A 6-month postinsertion period is required to label the crossed tectorotundal pathway. In the carbocyanine *in vivo* method, a small volume of carbocyanine dye solution is injected into the tectum of living embryos. Similarly, in the cholera toxin B subunit *in vivo* method, a small volume of cholera toxin B subunit solution is injected into the tectum of living embryos.

Animal Model: Avian (paraformaldehyde-fixed and living chick embryos).
Interpretation and Analysis: Tectal neurons do not begin to innervate the ipsilateral nucleus rotundus until embryonic day 9 and the contralateral nucleus rotundus until embryonic day 17. This slow progression of labeling through the crossed-tectal projection results in significant contrast of labeling between the ipsilateral and contralateral nuclei rotundus. In the carbocyanine *in vivo* method, an 8- to 12-hour survival period is sufficient for *in vivo* labeling of the tectorotundal pathway. By embryonic day 8, labeled axons terminate in the ipsilateral nucleus rotundus and the crossed tectorotundal projection can be 1st detected by embryonic day 10. Applying the cholera toxin B subunit *in vivo* method, heavily labeled axons can be found to innervate bilaterally the nucleus rotundus by embryonic day 8 after an initial 6- to 10-hour survival period. This appears to be the earliest time frame for detecting crossed-tectorotundal projection, compared with that of both the postfix and *in vivo* methods of carbocyanine dye. Based on the differences in the detectability of the crossed-tectorotundal projection between the postfix and *in vivo* methods, the present data suggest that the former method is of limited purpose for labeling tectal collaterals during embryogenesis. Moreover, given the rapid transport rate and absence of photobleaching, which is often seen when using carbocyanine dye, the cholera toxin B subunit *in vivo* method appears to be the tracer of choice for investigating embryonic pathways.

Tracing developing pathways in the brain: A comparison of carbocyanine dyes and cholera toxin b subunit. Wu CC, Russell RM, Nguyen RT, Karten HJ. Neuroscience 2003; 117 (4), pp. 831–45.

GASTROINTESTINAL SYSTEM

Mucosal Integrity and Permeability/Bacterial Translocation: Postoperative Hepatic Resection Conditions
Phenolsulfonphthalein (PSP)

Application: One application includes its use in the gastrointestinal system to determine mucosal integrity/permeability. The peroral PSP test appears to be a possible predictor of bacterial translocation after hepatic resection surgery.
Route of Administration: Phenolsulfonphthalein (peroral).
Dosage: Phenolsulfonphthalein (30 mg).
Implementation: Evaluate perioperative changes in intestinal PSP permeability relevant to conditions of hepatic resection. In this context, peroral PSP tests can be scheduled prior to surgery and then on postoperative days 3, 7, and 14, followed by urine collection over a 24-hour period following surgical intervention. Urinary PSP can be measured applying a colorimetric assay. The correlation between the preoperative PSP value and various clinical variables, such as perioperative changes in urinary PSP excretion, and the relationship between the postoperative PSP value and postoperative complications are then determined.

Human Model: Cases of hepatic resection ($n = 50$; $n = 16$ postoperative complications; $n = 10/16$ sepsis).
Interpretation and Analysis: Preoperative urinary PSP excretion increases in a manner proportional to the degree of liver dysfunction. In contrast, urinary PSP excretion does not significantly change during the perioperative period. However, urinary PSP excretion on postoperative day 3 in patients with postoperative infectious complications (27.3%) is significantly greater than that in those without infectious complications (17.4%; $p < 0.05$). Furthermore, PSP excretion on postoperative day 3 in those with infectious complications is also significantly greater as compared to the preoperative level. Cases with a urinary PSP excretion level on postoperative day 3 of greater than 25% exhibit infectious complications more frequently than patients with a level under 25% (60% vs 10.3%, respectively; $p < 0.05$). The peroral PSP test is thus suggested to be a possible predictor of bacterial translocation after hepatic resection.

Significance of the peroral phenolsulfonphthalein test in hepatic resection: A possible predictor of bacterial translocation. Shimada M, Takenaka K, Fujiwara Y, Gion T, Hasegawa H, Shirabe K, Sugimachi K. Hepatogastroenterology 1998 Mar–Apr; 45 (20), pp. 483–7.

Mucosal Integrity and Permeability Tendency/ Hepatic Cirrhosis/Gastrointestinal Surgery
Phenolsufonphthalein (PSP)

Cellular/Molecular Mechanism of Action: Phenolsufonphthalein is a passive marker molecule that is absorbed into the systemic intravascular compartment from the gastrointestinal tract much more extensively in conditions of mucosal damage/injury.
Background Information: The oral PSP absorption test can function as a simple and non-invasive method for the assessment of either the extent of permeability or damage associated with the integrity of the gastrointestinal mucosa.
Application: Assessment of gastrointestinal tract mucosa permeability.
Route of Administration: Phenolsufonphthalein (per os).
Dosage: Phenolsufonphthalein (30 mg).
Implementation: Evaluation of the permeability of the gastrointestinal mucosa in conditions of liver cirrhosis and postoperative gastrointestinal surgery cases utilizing oral phenolsufonphthalein and subsequent measurement of PSP urine concentrations (e.g., urinary recovery rate).
Interpretation and Analysis: Urinary PSP excretion in conditions of liver cirrhosis ($n = 8$; $28.8 \pm 6.0\%$) is significantly higher than in cases subjected to vascular surgery ($n = 8$; $10.0 \pm 1.7\%$) ($p < 0.01$). Such findings reflect the presence of increased gastrointestinal mucosa permeability in conditions of liver cirrhosis. The urinary PSP excretion rates in patients who undergo a total gastrectomy with Roux-en-Y reconstruction are $17.3 \pm 1.7\%$ ($n = 5$ and significantly higher than values observed in controls; $p < 0.05$), while the same rates in cases subjected to a partial gastrectomy ($n = 10$) or colectomy ($n = 10$) are approximately $10.2 \pm 1.8\%$ or $10.6 \pm 0.7\%$, respectively. Parameters of this nature suggest that the intestinal mucosa is damaged by total resection of the stomach. The oral PSP absorption test, which is non-invasive, simple, and inexpensive, is thus considered to be useful for assessing the degree of damage to or the permeability of the gastrointestinal mucosa under various conditions.

Assessing the permeability of the gastrointestinal mucosa after oral administration of phenolsulfonphthalein. Toh Y, Korenaga D, Maekawa S, Matsumata T, Muto Y, Ikeda T, Sugimachi K. Hepatogastroenterology 1997 Jul–Aug; 44 (16), pp. 1147–51.

Mucosal Pathology/Erosions/Histopathological Imaging (*In Vivo*)
Cresyl Violet

Cellular/Molecular Mechanism of Action: Cresyl violet functions as a fluorophore.
Application: Cresyl violet can function as a dye reagent that is compatable in viable biological systems.
Implementation: Confocal laser scanning microscope analysis of *ex vivo* esophageal and gastric mucosa preparations. A series of images is recorded for different levels of cresyl violet concentrations ranging from 0.1% to 10% with staining performed over a time period of 2 minutes after mucolysis with acetylcysteine.

Animal Model: Swine (esophageal and gastric mucosa).
Interpretation and Analysis: Staining with 2% cresyl violet can facilitate the identification of nuclei and cell membranes. Lower concentrations are associated with a lack of homogeneous dye absorption, particularly with regard to the gastric mucosa. Cresyl violet is a clinically usable fluorophore for confocal laser scanning microscopy. Its use in combination with an endoluminally applicable system has the potential applicability for *in vivo* histopathology analysis.

Cresyl violet as a fluorophore in confocal laser scanning microscopy for future *in vivo* histopathology. George M, Meining A. Endoscopy 2003 Jul; 35 (7), pp. 585–9.

Pancreatic Exocrine Insufficiency/ [Renal Failure: Anuria]
Pancreolauryl Test

Cellular/Molecular Mechanism of Action: Pancreolauryl is a substrate molecule that is proteolytically degraded by pancreatic enzymes within the lumen of the intestinal tract. Fluoroscein is subsequently liberated, absorbed across the surface of the intestinal mucosa and excreted in the urine.
Application: Although patients with chronic renal failure have a high incidence of chronic pancreatic disease, the condition is frequently overlooked. Pancreolauryl can be applied to detect and characterize alterations in exocrine pancreatic function in conditions of anuria.
Route of Administration: Pancreolauryl (oral).

Implementation: Modification of the pancreolauryl test as an indirect pancreatic function test for application in cases of anuria.

Interpretation and Analysis: The test permits good discrimination between patients with chronic pancreatic disease and those with a normal pancreas when serum levels of fluorescein are measured 10 hours following administration with a standard meal. The sensitivity at this time interval is 80%, while the level of specificity is approximately 83%. Pancreolauryl test with serum measurements provides a simple, non-invasive, and reliable diagnostic test for chronic pancreatic disease in conditions of simultaneous anuria and chronic renal failure.

Diagnostic value of indirect pancreatic function test in serum of anuric patients with chronic renal failure. Lerch MM, Nolte I, Riehl J, Gladziwa U, Mann H, Sieberth HG, Matern S. Scand J Clin Lab Invest 1994 May; 54 (3), pp. 247–50.

Zollinger-Ellison Syndrome: Gastrinoma Recurrent
Methylene Blue/Secretin

Application: Identification of gastrinoma (e.g., 6 mm) in the duodenum to facilitate surgical excision.

Route of Administration: Selective intra-arterial delivery.

Implementation: Evaluation of Zollinger-Ellison syndrome when other localizing modalities fail to detect a tumor (e.g., ultrasonography, computed tomography, magnetic resonance imaging, duodenal endoscopy, endoscopic ultrasonography, intraoperative endoscopic transillumination of the duodenum). In addition, postoperatively, a negative secretin provocative test result may also be appreciated.

In difficult cases presenting with this type of profile, a novel method can be utilized that involves selective arterial injection of secretin with hepatic venous gastrin sampling to identify the main vessel feeding a gastrinoma lesion. An angiographic catheter is then positioned within the lumen of the identified artery. At laparotomy, methylene blue is injected through this catheter to selectively stain the gastrinoma, thereby facilitating its identification.

Human Model: Cases of persistent Zollinger-Ellison syndrome (n = 1 female, 40 years old) despite excision of a 4-cm duodenal gastrinoma. Localizing studies including ultrasonography, computed tomography, magnetic resonance imaging, duodenal endoscopy, endoscopic ultrasonography, and intraoperative endoscopic transillumination of the duodenum failed to detect the presence or location of a tumor.

Interpretation and Analysis: Selective intra-arterial methylene blue injection can enhance intraoperative detection of small gastrinomas and may improve the rate of curative resection in the Zollinger-Ellison syndrome. Further evaluation of this novel localizing technique is warranted.

Endocrine tumors of the pancreas. Meko JB, Norton JA. Curr Opin Gen Surg 1994, pp. 186–94.

Selective intra-arterial methylene blue injection: A novel method of localizing gastrinoma. Ko TC, Flisak M, Prinz RA. Gastroenterology 1992 Mar; 102 (3), pp. 1062–4.

GENETIC

Gene Therapy Evaluation: Antisense Oligonucleotides/Neoplastic Disease: Leukemia Nucleoli Targeting
Fluorescein-Labeled Phosphorothioate-Triple Helix-Forming Oligonucleotide (PS-TFO)

Cellular/Molecular Mechanism of Action: Oligonucelotide sequences can be designed that recognize and bind to specific gene/messenger RNA (mRNA) sequences.

Physiological Mechanism of Action: Selective inhibition of the transcription/translation of specific genes.

Background Information: The c-myc gene is frequently deregulated and overexpressed in human cancers, and strategies designed to inhibit c-myc expression in cancer cells may have considerable therapeutic value.

Application: Characterize the antigene and antiproliferative activity of a triple helix-forming oligonucleotide (TFO) targeted to a homopurine-homopyrimidine sequence in the P2 promoter of the c-myc gene. Because c-myc is overexpressed in certain neoplastic cell types, genetic targeting modalities could function as effective diagnostic platforms.

Route of Administration: Potentially variable (intravenous, intralesional).

Semi-Synthetic Methods: Triple helix-forming oligonucleotide can be synthesized with phosphorothioate (PS) internucleotide linkages to confer resistance to intra- and extracellular nucleases. The resulting preparation can be conjugated with fluorescein as a tracer agent to identify selective accumulation within certain tissues and subcellular organelles.

Implementation: Delineation of the affinity of fluorescein-labeled PS-TFO.

Interpretation and Analysis: Resistance to intra- and extracellular nucleases is a property that is required for the design of oligonucleotides intended for *in vivo* testing and therapeutic applications.

Phosphorothioate-modified triple helix-forming oligonucleotide forms triplex DNA complexes with affinity and specificity comparable with that of the corresponding phosphodiester TFO, as delineated by gel mobility shift and footprinting assays. Fluorescence microscopy and polyacrylamide gel analysis reveal that fluorescein-labeled PS-TFO accumulates in the nuclei of CEM leukemia cells and remains intact for duration of at least 72 hours. Incubation of CEM cells with PS-TFO reduces c-myc RNA and protein levels. A single exposure of leukemia cells to the PS-TFO is sufficient to induce dose-dependent growth inhibitory effects. Growth inhibition correlates with accumulation of cells in S phase and with induction of cell death by apoptosis. Preparations of PS-TFO are also effective in other leukemia and lymphoma cell lines. Control oligonucleotides have minimal effects in all assays. These data indicate that c-myc-targeted PS-TFO is an effective antigene and antiproliferative agent, with potential for testing *in vivo* as a novel approach to cancer therapy.

Antigene and antiproliferative effects of a c-myc-targeting phosphorothioate triple helix-forming oligonucleotide in human leukemia cells. McGuffie EM, Pacheco D, Carbone GM, Catapano CV. Cancer Res 2000 Jul 15; 60 (14), pp. 3790–9.

HEPATIC SYSTEM

Bile Acid Transport/Visual Detection and Monitoring
Lysyl Fluorescein Conjugated Bile Acid Analogs (LFCBAA)

Background Information: The distribution and metabolism of lysyl fluorescein conjugated bile acid analogues closely parallels the same parameters for their natural counterparts.

Application: Lysyl fluorescein conjugated bile acid analogues can be applied as molecular probes for visualizing bile acid transport within hepatic tissues.

Route of Administration: Intravenous or retrograde injection into the biliary tree.

Semi-Synthetic Methods: Conjugation of lysyl fluorescein to bile acid analogues.

Implementation: Physiological concentrations of the primary bile acid analogue cholyllysyl fluoroscein (CLF) and of the secondary bile acid analogue lithocholyllysyl fluorescein (LLF) are administered, followed by the collection of serial liver biopsies at fixed timed intervals. Both compounds are also injected retrogradely into the biliary tree. Frozen sections are then examined by fluorescence microscopy.

Animal Model: Rat (Wistar).

Interpretation and Analysis: Both CLF and LLF are rapidly taken up from sinusoidal blood but differ significantly in their hepatic handling. Cholyllysyl fluoroscein is rapidly transported into the bile, whereas LLF transport is slower and produces significantly more bile duct fluorescence. Clearance of LLF involves a lobular gradient with the last remaining bile acid being confined (largely zone 3). Both compounds are avidly taken up by cholangiocytes after intravenous or retrograde injection into the biliary tree. Visualization of lysyl fluorescein conjugated bile acid analogues by fluorescence microscopy may yield further information regarding hepatobiliary bile acid localization during studies of physiological and pathological mechanisms involved in the transport of bile acids. The presence of both compounds within cholangiocytes strongly suggests that they may undergo some degree of chole-hepatic recirculation.

Instrumentation: Fluorescence microscopy.

Visualization of the transport of primary and secondary bile acids across liver tissue in rats: *In vivo* study with fluorescent bile acids. Milkiewicz P, Mills CO, Hubscher SG, Cardenas R, Cardenas T, Williams A, Elias E. J Hepatol 2001 Jan; 34 (1), pp. 4–10.

Biliary Excretion Capacity
Sulfobromophthalein (BSP)/Indocyanine Green (ICG)

Route of Administration: Sulfobromophthalein and ICG are given as a single-dose IV injection.

Dosage: Sulfobromophthalein (5 mg/kg); ICG (1.5 mg/kg).

Implementation: Evaluation of hepatic viability as a function of BSP and ICG plasma disappearances. The BSP is given at a dose of 5 mg/kg of body weight, while ICG is given at a dose of 1.5 mg/kg of body weight. The half-life, disappearance rate (percent per minute), and clearance (ml/min/kg) are determined during the initial phase of plasma dye elimination.

Animal Model: Feline.

Interpretation and Analysis: The half-life for BSP is 2.2 ± 0.7 minutes, and for ICG, 3.8 ± 0.9 minutes. The disappearance rate for BSP is 34.7 ± 10.1, and for ICG, 19.2 ± 4.5. The clearance for BSP is 26.3 ± 23.1 and for ICG, 8.6 ± 4.1. The 30-minute percentage retention for BSP is 0.6 ± 0.8% and for ICG, 7.3 ± 2.9%. In the cat, ICG is not cleared as rapidly from the plasma compared to BSP plasma clearance rates. There are no significant differences between males and females for these values. For both BSP and ICG, a significantly shorter half-life, faster disappearance rate, and lower 30-minute percentage retention is observed in the cat, compared with values observed in the dog given similar dye dosages. Clearance curves for BSP and ICG in the cat are similar to those in the dog, indicating that the 2 species may have similar volumes of dye distribution and excretory mechanisms. An assay of a 30-minute plasma level following a 5 mg/kg dose of BSP in normal cats is often too low for measurement, whereas measurement of a 30-minute plasma concentration of ICG following a 1.5 mg/kg dose is adequate. For the 30-minute dye retention test in the cat, ICG may be a preferred diagnostic agent.

Comparison of sulfobromophthalein and indocyanine green clearances in the cat. Center SA, Bunch SE, Baldwin BH, Hornbuckle WE, Tennant BC. Am J Vet Res 1983 Apr; 44 (4), pp. 727–30.

Hepatic Perfusion/Pharmaceutical Modification of Hepatic Blood Flow
Indocyanine Green (ICG)

Cellular/Molecular Mechanism of Action: Indocyanine green is removed from the intravascular compartment by the liver when the reagent enters the hepatic sinusoids and is then excreted into the bile.

Application: Indocyanine green is a hepatic function test marker molecule that is not metabolized by the liver but rather only excreted in the bile. The *in vivo* pharmacokinetic profile of ICG at steady state can be applied to detect pharmaceuticals that alter hepatic blood flow in a manner that can change hepatic blood clearance parameters.

Route of Administration: Indocyanine green (intravenous at a constant infusion rate).

Dosage: Indocyanine green (3.78 mg/kg bolus and constant rate infusion of 10,100 μg/kg/hr is administered until a steady state concentration of Css = 10 μg/ml is achieved at 20, 25, and 30 minutes).

Implementation: Evaluation of the influence of diltiazem (DTZ) on the hepatic blood clearance of ICG as a function of its pharmacokinetic profile at steady state. Following development of a steady state concentration of ICG of 10 μg/ml and a subsequent 90-minute washout period, an intravenous bolus injection (108, 430, 860, and 1,720 μg/kg) and a constant-rate infusion (108, 433, 866, and 1,730 μg/kg/hr) of test pharmaceutical (e.g., DTZ) is introduced into the right femoral vein for the purpose of achieving steady state plasma concentrations (e.g., Css = 50, 200, 400, and 800 ng/ml DTZ) that are confirmed at 60, 70, and 80 minutes. During the steady state phase for the test pharmaceutical (e.g., DTZ), the intravenous bolus injection and the constant-rate infusion of ICG into the left femoral vein are made and also the steady state plasma concentration of ICG measured at 20, 25, and 30 minutes. Plasma concentrations of DTZ and ICG are determined by HPLC analysis.

Animal Model: Rat (left femoral vein injection site).

Interpretation and Analysis: At steady state, the hepatic blood clearance of ICG is derived from values for ICG plasma concentration and the blood-to-plasma concentration ratio (RB). An example of a pharmaceutical that does not influence ICG hepatic clearance is DTZ. Pretreatment with various doses of DTZ does not influence plasma concentrations, RB, and plasma free fraction (fp) of ICG, so the hepatic blood clearance of ICG is independent of DTZ concentration. The hepatic blood clearance of ICG can possibly be affected by both hepatic blood flow and hepatic intrinsic clearance, but there is no change in the hepatic blood clearance of ICG between the control and DTZ-pretreated rats. Diltiazem therefore may not influence hepatic blood flow.

Instrumentation: High-performance liquid chromatography analytical systems.

No effect of diltiazem on the hepatic clearance of indocyanine green in the rats. Joo EH, Lee YB. Arch Pharm Res 1998 Aug; 21 (4), pp. 411–7.

Hepatocellular Function
Indocyanine Green (ICG) Dye

Cellular/Molecular Mechanism of Action: Indocyanine green is removed from the vascular compartment by the function of normal hepatocytes.

Background Information: Although depression in hepatocellular function occurs early after trauma and severe hemorrhage and persists despite fluid resuscitation, it remains unknown whether reactive oxygen species (ROS) play any role in the initiation of hepatocellular depression and damage under those conditions.

Application: Evaluation of hepatic function.

Implementation: Evaluation of the hypothesis that the administration of an ROS scavenger at the beginning of resuscitation attenuates organ injury after severe shock. Male Sprague-Dawley rats following laparotomy are bled and then maintained at a mean arterial pressure of 40 mm Hg until 40% of the maximal bleed-out volume is returned in the form of Ringer's lactate (RL). Animals are then resuscitated with 4 times the volume of maximal bleed-out with RL over a 60-minute period. The ROS scavenger 2-mercaptopropionyl glycine (30 mg/kg) or vehicle is then administered intravenously as a bolus at the beginning of resuscitation. At 2 hours after the completion of crystalloid resuscitation or the equivalent interval after sham operation, cardiac index is measured using a dye-dilution technique. Hepatocellular function, that is, the maximum velocity of ICG clearance (Vmax) and the efficiency of the active transport (Km), can be determined using an *in vivo* hemoreflectometer. Serum levels of tumor necrosis factor-alpha (TNF-α) and alanine aminotransferase can be determined using ELISA and colorimetric methodologies, respectively.

Animal Model: Male Sprague-Dawley rats (275–325 g) subjected to laparotomy (i.e., induction of soft tissue trauma).

Interpretation and Analysis: At 2 hours following trauma, hemorrhage, and resuscitation, cardiac index and hepatocellular function are markedly depressed with concomitant increases in serum levels of TNF-α and alanine aminotransferase ($p < 0.05$). Administration of 2-mercaptopropionyl glycine, however, restores depressed cardiac and hepatic function and markedly attenuates liver enzyme release and serum levels of TNF-α ($p < 0.05$). Reactive oxygen species therefore play a role in the induction of depressed organ function after severe hemorrhagic shock. Adjuncts that attenuate the detrimental effects of ROS may be useful for improving the depressed cardiac and hepatocellular functions after trauma, hemorrhage, and resuscitation.

Critical role of oxygen radicals in the initiation of hepatic depression after trauma hemorrhage. Jarrar D, Wang P, Cioffi WG, Bland KI, Chaudry IH. J Trauma 2000 Nov; 49 (5), pp. 879–85.

Hepatotoxic Injury: Cadmium
Bromosulfophthalein (BSP)

Cellular/Molecular Mechanism of Action: Bromosulfophthalein is removed from the intravascular compartment through the normal functions of liver hepatocytes and the biliary system.

Background Information: Elimination of BSP via the biliary system following intravenous injection requires dissociation from albumin in plasma, translocation across the sinusoidal membrane, conjugation with glutathione within the hepatocyte, translocation across the bile canalicular membrane, and excretion in bile.

Application: Bromosulfophthalein is a relatively non-toxic organic anion used as an *in vivo* indicator of liver performance.

Implementation: Characterization of the *in vivo* hepatotoxicant effects of cadmium (Cd) on BSP kinetics in isolated perfused rat liver (IPRL) to determine the association between liver toxicity and BSP kinetics. After a 30-minute period for acclimation to the IPRL system, livers are dosed with cadmium acetate in the presence of 0.25% bovine serum albumin, sufficient to achieve initial concentrations of 10 and 100 μM. Sixty minutes after Cd dosing, the IPRL system is dosed with BSP to give an initial concentration of 150 μM and the elimination kinetics of BSP from the perfusion medium monitored. Cadmium concentrations in livers at the end of the experiments are 60 ± 4 and 680 ± 210 μmol/kg for the 10 and 100 μM doses, respectively.

Animal Model: Rat (Fisher strain, n = 344 males; isolated perfused liver preparations).

Interpretation and Analysis: Exposure to 10 μM Cd for 60 minutes results in a reduction in bile flow, no significant effect on lactate dehydrogenase (LDH) leakage, and slight effects on BSP clearance. Similar studies following exposure to 100 μM Cd show dramatic decreases in bile flow with complete cholestasis 60 minutes after Cd addition. Total leakage of LDH into perfusion medium is less than 10%, indicating that Cd affects bile production well before the liver shows significant signs of necrosis. Clearance of BSP from the perfusion medium is dramatically reduced. Taken together, the data indicate that Cd has a significant effect on the kinetics of BSP in the IPRL and the dominant effects are mediated through Cd-mediated cholestatic effects.

Effect of cadmium on bromosulfophthalein kinetics in the isolated perfused rat liver system. Soto A, Foy BD, Frazier JM. Toxicol Sci 2002 Oct; 69 (2), pp. 460–9.

Metabolism: Hepatic CYP450 Enzyme Biochemical Activity
Indocyanine Green (ICG)/Lidocaine/Cimetidine

Cellular/Molecular Mechanism of Action: Indocyanine green functions as a global marker of function, while lidocaine and its metabolite, MEGX, can serve as specific markers of the CYP450 enzyme system. Cimetidine functions as a CYP450 enzyme system inhibitor.

Application: Indocyanine green functions as a global marker of function, while lidocaine and its metabolite, MEGX, can serve as specific markers of CYP450 enzyme activity.

Route of Administration: Infusion of ICG and lidocaine via the portal vein after a 40-minute stabilization period until steady state concentrations are reached in the venous outflow.

Dosage: Cimetidine (80 mg/kg daily for 3 days); ICG and lidocaine are infused after a 40-minute stabilization period into the portal vein until steady state concentrations are reached in the venous outflow.

Considerations: Endotoxin administration and cecal ligation and puncture produce significant hepatocellular dysfunction when studied *in vivo.* Specific factors that develop *in vivo* after endotoxin administration and cecal ligation and puncture, such as alterations in liver blood flow, circulating mediators, and hypoxia, can alter hepatic function.

Implementation: Delineation of hepatic clearance and CYP450 function during fabricated conditions of endotoxemia. Indocyanine green (control, n = 6; endotoxin, n = 5) or lidocaine (control, n = 8; endotoxin, n = 8) is infused into livers of control and endotoxin-exposed rat populations. Cimetidine (CYP450 enzyme system inhibitor) can be employed as a reference control (e.g., n = 6 rats).

Animal Model: Rats exposed to endotoxin (*Escherichia coli* lipopolysaccharide at 45 mg/kg intraperitoneally) followed by a 6-hour monitoring period and subsequent isolation of an *in situ* perfused liver preparation. Livers are perfused via the portal vein using a single-pass system with a balanced salt solution 6 hours after receiving either endotoxin or saline or 24 hours after receiving the last dose of cimetidine.

Interpretation and Analysis: Total hepatic clearance and intrinsic hepatic clearance for ICG and lidocaine are unchanged in the livers obtained from endotoxin-treated rats. The animal model can adequately detect CYP450 inhibition because cimetidine-treated rats have significantly lower initial MEGX concentrations (0.63 ± 0.03 mg/L) compared with control (0.77 ± 0.03 mg/L) and endotoxin-treated (0.74 ± 0.04 mg/L) rats. Septic livers have significantly higher initial hepatic oxygen consumption levels (HVO_2) than do control livers (45 ± 3 μL/min/g vs 82 ± 9 μL/min/g). The HVO_2 remains higher in septic livers, significantly increases throughout the

course of observation, and demonstrates that livers remain viable and functional. These data indicate that there is no detectable hepatocellular dysfunction after endotoxin shock using ICG, lidocaine, and MEGX in the isolated perfused liver; therefore the dysfunction reported from *in vivo* studies may be reversible when the liver is removed from such insults.

Effect of endotoxin shock on the clearance of lidocaine and indocyanine green in the perfused rat liver. McKindley DS, Chichester C, Raymond R. Shock 1999 Dec; 12 (6), pp. 468–72.

Sinusoidal Endothelial and Hepatocyte Cell Function/[Experimental Model of Acute and Chronic Liver Failure]
Indocyanine Green (ICG)/Hyaluronic Acid

Cellular/Molecular Mechanism of Action: Indocyanine green and hyaluronic acid are removed from the peripheral circulation by the normal function of hepatocytes and sinusoidal endothelial cells.
Background Information: Experimental models of liver transplantation use normal recipients, although most patients undergoing liver transplantation suffer from acute or chronic liver failure.
Application: Indocyanine green and hyaluronic acid uptake can be utilized to evaluate the *in vivo* function of hepatocytes and sinusoidal endothelial cells.
Implementation: Evaluation of the outcome of orthotopic liver transplantation in compromised hosts. Hepatic injury/dysfunction is evaluated by monitoring enzymes, bilirubin, ammonia levels, prothrombin, thrombin time, and cytokines. The *in vivo* function of hepatocytes and sinusoidal endothelial cells can be evaluated applying ICG and hyaluronic acid uptake.
Animal Model: Rat (D-galactosamine-induced acute liver failure or chronic liver failure secondary to common bile duct ligation). Transplantation performed in normal, acute, and chronic liver failure rats at different time points using either freshly harvested or cold-preserved syngeneic livers.
Interpretation and Analysis: Survival with fresh grafts decreases significantly when transplants are performed 48 hours after the induction of acute liver failure. Rats with acute liver failure almost invariably do not survive transplantation with grafts stored for 12 or 24 hours, but in chronic failure survival is more than 80%. Survival of acute liver failure rats receiving grafts preserved for 6 hours is 16.6% compared with 83.3% observed with fresh grafts transplanted at the same time point after D-galactosamine exposure. Elevated tumor necrosis factor-alpha and interleukin-1beta levels as well as impaired sinusoidal endothelial cell function can be detected in acute liver failure rats with grafts preserved for 6 hours. Speculation therefore suggests that preoperative status and different host factors have a significant effect on outcome and graft function after liver transplantation in rats.

Graft function and survival depend primarily on host factors in compromised recipient models of orthotopic liver transplantation in the rat. Wang L, Roayaie S, Basile J, Florman S, Liu J, Tarcsafalvi A, Boros P, Miller CM. Transplantation 2001 Jan 15; 71 (1), pp. 14–20.

HEMATOLOGY

Cell/Endothelial Adhesion (Colon Carcinoma)/ Intravital Observation of Cancer Cell/ Microcirculation Interactions
CalceinAM

Background Information: Organ-specific tumor cell adhesion within the microcirculation of host organs is an important step in the metastatic cascade. Circulating tumor cells have to adhere within the microcirculatory vessels, quickly stabilize their adhesion, and probably leave the circulation to avoid toxic effects of hydrodynamic shear forces of circulating blood.
Application: Intravital observation of colon carcinoma cell adhesion within the hepatic microcirculation.
Implementation: Characterization of neoplastic cell metastatic phenomenon. CalceinAM can be used to label colon carcinoma cell populations (e.g., HT-29 [human] and CC531 [rat]) that are then injected intra-arterially as single-cell suspensions. Intravital fluorescence microscopy is then applied to detect adhesive interactions between circulating tumor cells and endothelial surfaces within the hepatic microcirculation. These interactions are then analyzed pertaining to their time course and site localization within the vascular tree.
Animal Model: Rats (Sprague-Dawley).
Interpretation and Analysis: Autofluorescence of liver parenchyma is sufficient for distinction of hepatic sinusoids. Intravital microscopy is capable of differentiating early events in adhesion formation within hepatic sinosoids, adhesion stabilization, and extravasation of the tumor cells into the liver parenchyma. Tumor cell adhesion occurs almost exclusively within sinusoidal capillaries; however, the diameter of these vessels is usually larger than that of the tumor cells, leaving remaining lumen of the capillaries available for perfusion. Colon carcinoma cells rapidly migrate into the liver parenchyma after successful adhesion within the sinusoids. In contrast to common end point assays of the metastatic cascade, this *in vivo* model allows investigations of metastatic colon carcinoma cell adhesion within the liver microcirculation as specific steps during the formation of hematogenous metastasis and their underlying mechanisms.
Instrumentation: Intravital fluorescence microscopy.

An intravital model to monitor steps of metastatic tumor cell adhesion within the hepatic microcirculation. Haier J, Korb T, Hotz B, Spiegel HU, Senninger N. J Gastrointest Surg 2003 May–Jun; 7 (4), pp. 507–14; discussion 514–5.

Endothelium Cell Adhesion/Platelet Endothelium Interactions/[Retinal Microvascular Pathology]
Carboxyfluorescein Diacetate Succinimidyl Ester/Platelets (Fluorescent-Labeled)/Platelets (Fluorescein-Labeled)

Cellular/Molecular Mechanism of Action: Carboxyfluorescein diacetate succinimidyl ester interacts with light and functions as a fluorescent marker molecule suitable for "tracing" the migration of different cell types.
Application: Visualization of *in vivo* platelet behavior in the retinal microcirculation. The methodologies utilizing carboxyfluorescein diacetate succinimidyl ester allow for quantitative evaluation of platelet dynamics and platelet-endothelial interactions in conditions of retinal pathology.
Route of Administration: Intravascular.
Considerations: Represents the development of a new method for evaluating the *in vivo* dynamics of platelets in the retinal microcirculation and quantitative investigation of platelet-endothelial interactions.
Implementation: Isolated platelet samples are labeled with carboxyfluorescein diacetate succinimidyl ester. After intravenous administration, platelet behavior in the retinal microcirculation can be evaluated with a scanning laser ophthalmoscope. Images are recorded on S-VHS videotape and analyzed with a computer-assisted image analysis system. The platelet-endothelial interactions in the retinal microcirculation can also be investigated employing lipopolysaccharide-stimulated endothelium or platelets activated with thrombin.

Animal Model: Rat retina.

Interpretation and Analysis: Fluorescent platelets are recognized as distinct dots in the retinal microcirculation and can be traced frame by frame. The velocity of platelets in the retinal arteries, capillaries, and veins is approximately 26.1 ± 6.4, 1.6 ±0.4, and 19.9 ± 8.2 mm/sec, respectively. In control rats, even activated platelets show minimal interaction with retinal endothelial cells. In contrast, stimulated retinal endothelium shows active platelet-endothelial interactions, with many platelets observed rolling and adhering along the major retinal veins. The interactions between platelets and stimulated endothelial cells are substantially inhibited by the injection of P-selectin monoclonal antibody.

In vivo evaluation of platelet-endothelial interactions in retinal microcirculation of rats. Tsujikawa A, Kiryu J, Nonaka A, Yamashiro K, Nishiwaki H, Tojo SJ, Ogura Y, Honda Y. Invest Ophthalmol Vis Sci 1999 Nov; 40 (12), pp. 2918–24.

Hematopoietic Stem Progenitor Cell Tracking
PKH Dyes/PKH2/PKH26/PKH67

Cellular/Molecular Mechanism of Action: PKH dyes can be utilized as marker molecules where they irreversibly bind to cell membrane structures. The lipophilic dyes PKH26 and PKH67 have red and green fluorescent properties, respectively.

Background Information: The process of hematopoietic stem and progenitor cell (HSPC) seeding in recipient bone marrow (BM) early after transplantation has not been fully characterized.

Application: PKH dyes serve as marker molecules that can be utilized to track the *in vivo* migration of cell populations in biological systems.

The PKH dyes were initially developed to provide appropriate probes for *in vitro* and *in vivo* cell tracking. It has been reported for many cell types that PKH binds irreversibly to the cell membrane without significantly affecting cell growth. Thus these probes provide an opportunity for long-term cell monitoring and the identification of cells of interest among a heterogeneous cell population. An important feature is that upon cell division, the probe is partitioned equally between each daughter cell, making it possible to quantify fluorescence by flow cytometry. In this scenario, the flow cytometric study of PKH67 characteristics shows that this probe does not affect the main cell functions such as viability or proliferation. Moreover, the intracellular distribution of PKH67 is demonstrated by following its kinetics of internalization by confocal microscopy. Therefore, PKH67 is a probe suitable for dynamic analysis of cell proliferation as well as the study of intracellular localization and membrane recycling mechanisms.

There are no significant phototoxic effects of PKH2 and PKH26 dyes on cell viability and growth when using dye concentrations up to 5 μM. However, when stained cells are exposed to excitation light, cell viability decreases dramatically, showing the phototoxicity of PKH2 and PKH26 dyes. More than 60% of cells stained with 5 μM PKH26 die after 5 minutes of continuous light exposure. The phototoxic effect is more extensive in cells stained with higher concentrations of the dyes.

Implementation: *In vivo* tracking of HSPCs labeled with PKH dyes facilitated by utilizing an optical window surgically implanted into the femur (e.g., murine model) in a manner that can recognize transplanted cell clusters within recipient BM.

Interpretation and Analysis: In the first 24 hours after intravenous injection, 86 ± 6% of the cells seed in clusters ($p < 0.001$ vs scattered cells) in the endosteal surfaces of the epiphyses. The primary clusters are formed by concomitant seeding of 6 to 10 cells over an area of approximately 70 μm, and secondarily injected cells do not join the already existing clusters but form new clusters. Major antigen-disparate HSPCs participate in formation of primary clusters, and T lymphocytes are also incorporated. After 4–5 days, some cellular clusters can be observed in the more central regions of the BM, where the brightness of PKH fluorescence decreases, indicating cellular division. These later cellular aggregates are classified as secondary clusters, assuming that the mechanisms of migration in the BM may be different from those of primary seeding. Some clusters remain in the periphery of the BM and retain bright fluorescence, indicating cellular quiescence. The number of brightly fluorescent cells in the clusters decreases exponentially to 2 to 3 cells after 24 days ($p < 0.001$). Hematopoietic niche is a functional unit of the BM stromal microenvironment that hosts seeding of a number of transplanted cells, which form a cluster. This may be the site where auxiliary non-HSPC cells, such as T lymphocytes, act in support of HSPC engraftment.

IMMUNOLOGY

Immunity/Antigen Delivery to Nodes and Processing
[Fluorescein Isothiocyanate (FITC)]-H-2K(b) CTL Epitope (SIINFEKL)/pH-Sensitive Liposomes

Cellular/Molecular Mechanism of Action: Fluorescein isothiocyanate is a molecule that emits fluorescent color when excited by certain wavelengths of light energy. Liposomes that are described as being pH sensitive provide a modality for protecting their internal contents from metabolic degradation or accelerated elimination but also have the property of degrading upon exposure to environments within a specific range of hydrogen ion concentration. Fluorescein isothiocyanate-conjugated H-2K(b) CTL epitope (SIINFEKL) is perceived by the immune system as a foreign antigen.

Application: Fluorescein isothiocyanate can be applied as a fluorescent tracer molecule in various biological systems. Fluorescein isothiocyanate-conjugated H-2K(b) CTL epitope (SIINFEKL) can be used as a "labeled" antigen for the purpose of tracing the fate of immunogens within the immune system. Liposomes that have been designed to possess pH-sensitive properties release their internal contents through membrane lysis when exposed to environments within a specific pH range.

Interpretation and Analysis: At 3 hours following immunization, fluorescence can initially be detected in lymph node structures, and its intensity reaches a peak value in superficial inguinal lymph node at 9 hours. Traces of fluorescence can be detected within the spleen even with prolonged monitoring for up to 24 hours. These results strongly suggest that the presentation of CTL-peptide antigen vehicled by pH-sensitive liposomes exclusively occurs within the lymph nodes. In mice immunized with the H-2K(b) CTL epitope encapsulated pH-sensitive liposomes, peptide-specific CTL response can be detected at day 3. The response is strongly augmented by a 2nd immunization and persists up to 45 days or longer. Therefore, liposomes formulated to be pH sensitive can function as potential

adjuvants of peptide antigens and are useful for the *in vivo* induction of antigen-specific CTLsv.

Investigation of antigen delivery route *in vivo* and imune-boosting effects mediated by pH-sensitive liposomes encapsulated with K(b)-restricted CTL epitope. Lee KY, Chun E, Seong BL. Biochem Biophys Res Commun 2002 Apr 5; 292 (3), pp. 682–8.

Lymph Nodes/Guide for Sentinel Lymphadenectomy (Inguinal)/Epidermoid Carcinoma: Anal Canal
Patent Blue V Dye/[^{99m}Tc]-Dextran 500

Implementation: Evaluation of sentinel lymph node structures applying a combination of preoperative lymphoscintigraphy with [^{99m}Tc]-dextran 500 injected around the tumor and intraoperative detection of the sentinel node with a gamma probe. Patent blue V dye can also be injected at the periphery of the tumor to facilitate direct identification of the blue-stained lymph nodes. After removal, the sentinel nodes are studied by hematoxylin and eosin staining for immunohistochemistry to detect pancytokeratins (antigen A1 and A3).

Human Model: Cases of epidermoid carcinoma of the anal canal without clinical evidence of inguinal involvement (n = 14).

Interpretation and Analysis: Detection and removal of sentinel lymph nodes is possible in the vast majority of cases (100% reported). There is no correlation between tumor size and pattern of lymphatic drainage to the groin. Tumors located in the midline of the anal canal give rise to bilateral sentinel nodes in most cases (e.g., n = 8/9; n = 23 sentinel lymph nodes removed). Some cases (n = 1/8) have a node identified as positive for metastatic carcinoma on immunohistochemical staining. Surgical complications are minimal. The standardized technique is safe and highly effective in sampling inguinal sentinel lymph nodes in carcinoma of the anal canal. It has also proved useful as an approach for detecting micrometastatic deposits in clinically normal nodes. Early experience with the technique suggests that the sentinel lymph node procedure may have a role in guiding a more selective approach for patients with anal cancer. Additional studies in a larger patient population are warranted to determine the sensitivity and specificity of this method.

Lymph Nodes: Guide for Sentinel Lymphadenectomy (Melanoma)
Isosulfan Blue Dye/[^{99m}Tc]-Human Serum Albumin ([^{99m}Tc]-HSA)/[^{99m}Tc]-Sulfur Colloid ([^{99m}Tc]-SC)

Cellular/Molecular Mechanism of Action: Isosulfan blue dye serves as a fluid pigment-based marker system. [^{99m}Tc]-human serum albumin and [^{99m}Tc]-SC are phagocytized by reticuloendothelial cell populations residing within peripheral lymph nodes.

Background Information: Radiopharmaceutical agents appear to improve the accuracy of sentinel node (SN) identification in patients with early-stage melanoma, but the optimal radiopharmaceutical agent and its timing from injection until surgery still remains controversial.

Application: Isosulfan blue dye can be used to validate the localization of radiobiopharmaceutical agents within anatomical structures (e.g., lymph nodes).

Route of Administration: Isosulfan blue dye, [^{99m}Tc]-SC, and [^{99m}Tc]-HSA can be administered intraoperatively into lymphatic vessels.

Implementation: Evaluation of intraoperative lymphatic mapping with radiopharmaceutical-directed sentinel lymphadenectomy (LM/SL) procedures (e.g., n = 3). In this regard, cutaneous lymphoscintigraphy can be performed before LM/SL utilizing 1 of 3 techniques including (i) [^{99m}Tc]-HSA injected at least 24 hours before LM/SL (n = 124 patients); (ii) filtered [^{99m}Tc]-SC injected no more than 4 hours before LM/SL (same-day SC, n = 95 patients); or (iii) [^{99m}Tc]-SC injected at least 18 hours before LM/SL (prior-day SC, 28 patients). At the time of LM/SL, isosulfan blue dye is injected alone (SC groups) or with a 2nd dose of HSA (HSA group). A handheld gamma probe is then used to identify radioactive (hot) counts of blue-stained and non-stained nodes, and the *in vivo* and *ex vivo* node-to-background count ratios of the nodes compared.

Human Model: Melanoma (n = 247 classified as American Joint Committee on Cancer stage I or II).

Interpretation and Analysis: Preoperative LS can identify a large percentage of drainage basins (e.g., n = 299 in 247 cases). Lymphatic mapping with radiopharmaceutical-directed sentinel lymphadenectomy (LM/SL) is capable of identifying at least 1 sentinal lymph node in a large percentage of cases. Specific examples in this regard include (i) 119 (98%) of 121 basins using same-day SC; (ii) 142 (97%) of 146 basins using HSA; and (iii) 32 (100%) of 32 basins using prior-day SC. There is no difference ($p = 0.62$) in the accuracy rate between the 3 techniques (total of 463 sentinel nodes identified in 247 cases). Same-day SC yields higher intraoperative node-to-background count ratios than do either of the other techniques ($p < 0.0001$). Same-day SC also has the greatest relative change in radioactivity between the blue sentinel node and the postexcision basin ($p < 0.0001$), and the highest rate of SNs that are both blue and hot (*in vivo* or *ex vivo* ratio ≥ 2, $p = 0.05$). Therefore, LS and LM/SL performed on the same day with a single injection of filtered [^{99m}Tc]-SC serves as the most useful method for probe-directed LM/SL. The technique demonstrates the highest *in vivo* and *ex vivo* count ratios, falloff of radioactivity between the excised nodes and postexcision basin, and concordance between blue dye and hot nodes. It should be recommended as the method of choice for probe-directed LM/SL.

Standardized probe-directed sentinel node dissection in melanoma. Essner R, Bostick PJ, Glass EC, Foshag LJ, Haigh PI, Wang HJ, Morton DL. Surgery 2000 Jan; 127 (1), pp. 26–31.

MEMBRANE CHARACTERIZATION

Liposome Membrane Characterization: Stability/Optimization of Properties
ANS Fluorescent Probe/DPH Fluorescent Probe

Cellular/Molecular Mechanism of Action: Fluorescent probes emit detectable light energy when excited by specific wavelengths of radiant energy.

Application: Fluorescent probes can be applied as visible molecular markers for assessing various *in vitro* and *in vivo* properties associated with liposome preparations.

Implementation: Evaluation of the systematic physicochemical characteristics of 2 branched chain polymers (based on a poly-L-lysine backbone) with the general formula poly[Lys-(DL-Ala_m-X_i)], where X = Orn (OAK) or N-acetyl-Glu (Ac-EAK) and m congruent with 3, using surface pressure and fluorescence polarization methods.

Experimental findings are compared with those of the linear poly(L-Lys) from which OAK and Ac-EAK are derived. Complementary investigations can involve the delineation of interactions between these polymers with phospholipid bilayers (neutral or negatively charged) with vesicles labeled with 2 fluorescent probes: ANS and DPH.

Interpretation and Analysis: The 2 polymers show a moderate surface activity, able to form stable monomolecular layers at the air-water interface. Poly(L-Lys), the most hydrophilic, has the lowest surface activity. Results indicate that the polymers are able to accommodate in their internal structure, mainly through electrostatic interactions, a certain amount of ANS marker molecules, but fluorescence increases with the ANS-polypeptide complexes are so low that its influence in subsequent polarization measurements can be discarded. After interaction with liposomes, polymers induce an increase in the polarization of the probes, thus indicating a rigidification of the bilayers. Electrostatic forces seem to be very important in this interaction; cationic polymers are clearly more active, with PG-containing liposomes, than Ac-EAK. Moreover, in assays, poly(L-Lys) behaves as the more active compound. This fact is probably due to its major ability to form alpha-helical structures that can insert readily into bilayers. Such findings indicate that the polymeric structures studied can be used as carriers for biologically active molecules, because their interactions with bilayers remain soft and have a positive effect on the stability of membranes.

Physicochemical characterization of branched chain polymeric polypeptide carriers based on a poly-lysine backbone. Nagy IB, Hudecz F, Alsina MA, Reig F. Biopolymers 2003 Nov; 70 (3), pp. 323–35.

Macrophage/Mononuclear/Neutrophil/Phagocytic Function
Fluorescent Polymethacrylic Nanoparticles

Cellular/Molecular Mechanism of Action: Fluorescent polymethacrylic nanoparticles are recognized by and intracellularly assimilated by mononuclear cells and, to a lesser extent, neutrophils.

Application: Quantitative evaluation of phagocytosis by human mononuclear and polymorphonuclear cells. One possible application of fluorescent-labled nanoparticles is the simultaneous characterization of cell surface antigens and cell phagocytic activity.

Route of Administration: Intravascular.

Semi-Synthetic Methods: Preparation of nanoparticles involves emulsion copolymerization of methacrylic monomers combined with delineation of their physicochemical properties.

Implementation: Evaluation of fluorescent polymethacrylic nanoparticles (0.3 micron) as a flow cytometric reagent in the quantitative evaluation of phagocytosis by human mononuclear and polymorphonuclear cells. In this context, nanoparticles coupled with a fluorescent agent (ethidium bromide) can be used in flow cytometric assays to study opsonin-independent phagocytosis by human neutrophils (PMNs) and human monocytes. Phagocytosis of nanospheres by monocytes is determined by flow cytometry based on fluorescence distribution, while ingestion is visualized by scanning and transmission electron microscopy.

Instrumentation: Flow cytometry and scanning and transmission electron microscopy.

Flow cytometric quantitative evaluation of phagocytosis by human mononuclear and polymorphonuclear cells using fluorescent nanoparticles. Rolland A, Merdrignac G, Gouranton J, Bourel D, Le Verge R, Genetet B. J Immunol Methods 1987 Feb 11; 96 (2), pp. 185–93.

Membrane Permeable Marker Molecules: Non-Radioactive Tracer
Cyanine Fluorochromes (Aqueous Soluble)/Auto-Quenching Enzyme-Sensitive Near-Infrared (NIR) Fluorescent Probe

Cellular/Molecular Mechanism of Action: Cyanine fluorochromes emit fluorescent light energy in the NIR range.

Background Information: Recently, NIR fluorescence light has been applied to image various biological events *in vivo,* because it penetrates tissue more efficiently than light in the visible spectrum.

Application: Cyanine fluorochromes emit light energy in the NIR range, and this property facilitates their use as tracers or marker molecule systems in living biological systems.

Semi-Synthetic Methods: Synthesis of water-soluble NIR cyanine fluorochromes (n = 4). Each fluorochrome is designed with a monoreactive carboxyl group that can be utilized for labeling purposes. In addition, they possess superior chemical stability and optical properties. An autoquenched enzyme-sensitive NIR fluorescence probe can be designed and synthesized to address the problem of fluorescence quenching when multiple fluorochromes are conjugated to single macromolecules.

Interpretation and Analysis: Certain water-soluble NIR cyanine fluorochromes possess superior chemical stability and optical properties that permit exterior *in vivo* detection. Attachment of multiple fluorochromes to a single macromolecule can result in fluorescence quenching.

Novel near-infrared cyanine fluorochromes: Synthesis, properties, and bioconjugation. Lin Y, Weissleder R, Tung CH. Bioconjug Chem 2002 May–Jun; 13 (3), pp. 605–10.

Membrane Pore Size: Permeation Properties/ Cardiovascular: Myocardial Cells
Ethidium Bromide (EB)

Cellular/Molecular Mechanism of Action: Ethidium bromide selectively binds to nucleic acids, thereby allowing it to function as a passive biological marker molecule. Ethidium bromide also possesses fluorescent properties when exposed to ultraviolet light energy.

Background Information: Strong electric pulses produce reversible or irreversible membrane breakdown (electroporation).

Application: Detection of alterations in membrane pore size.

Implementation: Analyze the permeation properties of minute pores caused by hyperpolarization or lysophosphatidylcholine (LPC) by comparing the amount of charge carried by irregular inward currents (I^{hi}) with changes in EB fluorescence in isolated rabbit ventricular myocytes.

Technique: Forty-second negative pulses from a holding potential of −20 mV induce (I^{hi}), whose conductance increases with hyperpolarization.

Interpretation and Analysis: Mean conductance (G^{hi}) is 63.6 ± 9.9 pS/pF (mean ± standard error of measurement [SEM], n = 9) at −160 mV. Ethidium bromide fluorescence increases during voltage pulses in parallel with the time integral of I^{hi} (Q^{hi}), with the magnitude of increases in nuclear EB fluorescence being 5.3 times greater than in the cytoplasm at −160 mV. Similar hyperpolarization-induced parallel increases in I^{hi} and EB fluorescence are also obtained in Na^+-free, N-methyl-D-glucamine (NMDG) solution. LPC (10 μM) induces large (101.2 ± 21.2 pS pF(−1), n = 16), rapid (rise times, 1–10 ms) I^{hi} with slow relaxation rates at −80 mV that

reflect increases in G^{hi} to 94.3 ± 24.8 pS pF(−1) (n = 8) at 6 minutes. Plots of EB fluorescence vs Q^{hi} are well fitted by a common Hill's equation with a Hill coefficient of 0.97. Taken together, findings indicate that hyperpolarization and LPC produces pores that have the same filter properties for the permeation of small ions, including ethidium^{+}, and that I^{hi} (carried in part by Ca^{2+} generated by membrane breakdown) is capable of supplying sufficient ions to evoke abnormal excitation and contraction in cardiac myocytes.

Hyperpolarization and lysophosphatidylcholine induce inward currents and ethidium fluorescence in rabbit ventricular myocytes. Song YM, Ochi R. J Physiol 2002 Dec 1; 545 (Pt 2), pp. 463–73.

Membrane Protein-Lipid Interactions
N-[10-(1-Pyrenyl)Decanoyl]Sphingomyelin

Cellular/Molecular Mechanism of Action: The agent N-[10-(1-pyrenyl)decanoyl]sphingomyelin is a fluorescent sphingomyelin derivative.

Background Information: Selective enzymatic hydrolysis, lipid compositional analyses, and fluorescence studies have been carried out on acetylcholine receptor (AChR)-rich membranes from Torpedinidae to investigate the topology of sphingomyelin (SM) in the native membrane and its relationship with the AChR protein. Controlled sphingomyelinase hydrolysis of native membranes has shown that SM is predominantly (approximately 60%) localized in the outer half of the lipid bilayer. Differences have also been observed in the distribution of SM fatty acid molecular species in the 2 bilayer leaflets.

Application: Characterization of membrane protein-lipid interactions.

Implementation: A fluorescent SM derivative (N-[10-(1-pyrenyl)decanoyl]sphingomyelin; Py-SM) can be used to study protein-lipid interactions in the AChR-rich membrane and in affinity-purified Torpedinidae AChR reconstituted in liposomes made from Torpedinidae electrocyte lipid extracts. The efficiency of Förster resonance energy transfer (FRET) from protein to the pyrenyl-labeled lipid as a function of acceptor surface density can be used to estimate distances and topography of the SM derivative relative to the protein. The dynamics of the lipid acyl chains can be explored by measuring the thermal dependence of Py-SM excimer formation, sensitive to the fluidity of the membrane.

Interpretation and Analysis: Differences can observed in the concentration dependence of excimer/monomer pyrenyl fluorescence when measured by direct excitation of the probe relative to FRET conditions, indicating differences in the intermolecular collisional frequency of the fluorophores between bulk and protein-vicinal lipid environments, respectively. Py-SM exhibits a moderate selectivity for the protein-vicinal lipid domain, with a calculated relative affinity K_r approximately 0.55. Upon sphingomyelinase digestion of the membrane, FRET efficiency increases by about 50%, indicating that the resulting pyrenyl-ceramide species have higher affinity for the protein than the parental SM derivative.

Sphingomyelin composition and physical asymmetries in native acetylcholine receptor-rich membranes. Bonini IC, Antollini SS, Gutiérrez-Merino C, Barrantes FJ. Eur Biophys J 2002 Oct; 31 (6), pp. 417–27.

Metabolism: Intracellular Reactive Oxygen Species (ROS)/ROS Production: Intracellular
Dihydroethidium

Cellular/Molecular Mechanism of Action: Dihydroethidium functions as a fluorescent probe; chelerythrine is a protein kinase C (PKC) inhibitor; PP101 is a PKC delta inhibitor; and PP149 is a PKC-epsilon inhibitor.

Background Information: Protein kinase C and ROS are known to have a role in anesthetic preconditioning (APC). Cardiac preconditioning by triggers other than volatile anesthetics, such as opioids or brief ischemia, is known to be isoform selective, but the isoform required for APC is not known.

Application: Detection and characterization of intracellular ROS production.

Implementation: Identify the PKC isoform that is involved in APC and elucidate the relative positions of PKC activation and ROS formation in the APC signaling cascade. One approach to addressing this objective can involve the evaluation of the influence of sevoflurane APC in heart tissue prior to the initiation of ischemic reperfusion injury in the absence or presence of the non-specific PKC inhibitor chelerythrine, the PKC-delta inhibitor PP101, or the PKC-epsilon inhibitor PP149. Spectrofluorometry and the fluorescent probe dihydroethidium can be used to measure intracellular ROS, while assay of effluent dityrosine is used to measure extracellular ROS release.

Animal Model: Isolated guinea pig hearts subjected to 30 minutes of ischemia and 120 minutes of reperfusion.

Interpretation and Analysis: Previous sevoflurane exposure protects heart tissues against ischemia-reperfusion injury, as previously described. Chelerythrine or PP149 abolishes such protection, but PP101 does not. Reactive oxygen species formation is observed during sevoflurane exposure and is not altered by any of the PKC inhibitors. Anesthetic preconditioning is mediated by PKC-epsilon but not by PKC-delta. Furthermore, PKC activation probably occurs downstream of ROS generation in the APC signaling cascade.

Reactive oxygen species precede the epsilon isoform of protein kinase C in the anesthetic preconditioning signaling cascade. Novalija E, Kevin LG, Camara AK, Bosnjak ZJ, Kampine JP, Stowe DF. Anesthesiology 2003 Aug; 99 (2), pp. 421–8.

Microsphere Release Evaluation and Characterization
Brilliant Blue Microspheres/Tumor Necrosis Factor-Alpha (TNF-α) Microspheres/Poly(D,L-Lactic-Co-Glycolic Acid) Multiphase Microspheres

Cellular/Molecular Mechanism of Action: Brilliant blue functions as a dye marker reagent that is compatible with biological systems.

Application: Brilliant blue can be applied to evaluate the rate of release of compounds incorporated into microsphere preparations.

Route of Administration: Intravascularly or within individual body cavities.

Semi-Synthetic Methods: The microspheres can be prepared using an anhydrous multiple emulsion solvent evaporation method.

Implementation: Intraperitoneal delivery to evaluate rate of release.

Animal Model: Murine (intraperitoneal).

Interpretation and Analysis: Multiphase microspheres containing brilliant blue exhibit a 3-phase release profile *in vitro* and display a significantly lower level of dye released during the initial phase compared to conventional matrix-type microspheres. Slow release of the dye is observed during the 2nd phase, which is followed by a disintegration of the polymer wall during the 3rd phase of the release process. *In vitro* dissolution profiles of TNF-α are calculated by compensation for the simultaneous degradation of the protein in the dissolution medium. The initial burst release of TNF-α is

significantly reduced with the multiphase microspheres. The 3-phase release profile, as seen with the dye, is not observed for the microspheres containing the TNF-α. The rate of release of protein from microspheres is determined *in vivo* by analyzing the residual level of TNF-α remaining in the particles following intraperitoneal administration of the microspheres to mice. The release of protein from microspheres *in vivo* is significantly faster than predicted from the results of the *in vitro* studies. The absence of an initial burst release of TNF-α from multiphase microspheres is recognized by the observation of a significant reduction in plasma TNF-α levels when compared to matrix-type microspheres and a solution of the protein. The controlled release property of multiphase microspheres is expected to overcome adverse reactions due to dose dumping that can occur following local TNF-α administration.

In vitro and *in vivo* release properties of brilliant blue and tumor necrosis factor-alpha (TNF-α) from poly(D,L-lactic-co-glycolic acid) multiphase microspheres. Iwata M, Nakamura Y, McGinity JW. J Microencapsul 1999 Nov–Dec; 16 (6), pp. 777–92.

MUSCULOSKELETAL SYSTEM

Bone Growth Marker
Tetracycline

Cellular/Molecular Mechanism of Action: Tetracycline becomes associated with and incorporated into hydroxyapatite crystals within the osseous bony matrix.
Diagnostic Application: Detection and measurement of new osseous growth; has also reportedly been successful in the correction of certain equine angular limb deformities if administered in the early days of life shortly after parturition.
Route of Administration and Dosage: Oral or intravenous.
Considerations: Can cause severe diarrhea in equine patients due to disruption of the normal balance of gastrointestinal bacterial flora that can occasionally lead or predispose to development of life-threatening salmonellosis.
Interpretation and Analysis: Measurement of the osseous segment deposited following tetracycline administration is an indication of the extent of new bone growth.

Bioassayable growth hormone activity in blood from healthy individuals and acromegalic patients. Thorngren KG, Hallengren B. Acta Endocrinol (Copenh) 1986 Jan; 111 (1), pp. 3–9.

Effects of unilateral arterial infusion of GH and IGF-I on tibial longitudinal bone growth in hypophysectomized rats. Nilsson A, Isgaard J, Lindahl A, Peterson L, Isaksson O. Calcif Tissue Int 1987 Feb; 40 (2), pp. 91–6.

Bone Physiology and Growth/Aluminum ($Al(OH)_3$) Body Stores/Overload/Toxicity/Hemodialysis/ Hematopoeitin/Iron Absorption: Iron Deficiency
Tetracycline/Desferrioxamine/Deferoxamine/[^{59}Fe]

Cellular/Molecular Mechanism of Action: Tetracycline is incorporated into bone hydroxyapatite deposits. Desferrioxamine and deferoxamine are metallic ion chelating agents. Desferrioxamine can induce elevations in basal plasma aluminum concentrations. Tetracycline is incorporated into bone hydroxyapatite deposits.
Application: Desferrioxamine can be applied to characterize body aluminum stores while tetracycline can be used as a marker for profiling bone physiology and bone deposition parameters.
Implementation: Evaluation of the influence of hemofiltration (HF) and hemodialysis (HD) in connection with the risk of aluminum overload and renal osteodystrophy by analysis of double bone biopsies after double tetracycline labeling and use of the desferrioxamine test.

Human Model: Cases managed by hemofiltration (n = 12 HF) and hemodialysis (n = 15 HD). No cases recieving 1-α-OH-D administration. No cases have florid osteomalacia with increased osteoid thickness, and n = 1 with traces of stainable aluminum.
Interpretation and Analysis: Aluminum concentrations are low (< 0.6 μmol/l) in both the dialysate and the substitution fluid. The duration of treatment (about 2 years) and the cumulative doses of $Al(OH)_3$ and $CaCO_3$ are comparable in the 2 groups. The aluminum balance during an HF run can range from −22 to +1.8 μmol/l, the balance being positive only when the plasma aluminum is less than 0.5 μmol/l. Basal plasma aluminum and its increase induced by desferrioxamine are comparable in the 2 groups. Bone aluminum content is also comparable but is about 10 times higher than in non-uremic controls (e.g., n = 7). Bone aluminum content and plasma aluminum increase after desferrioxamine can be correlated to $Al(OH)_3$ cumulative dose. The mineralization front is decreased in most cases of hemofiltration (e.g., n = 8/12) and hemodialysis cases (n = 9/14) to the extent that differences cannot be appreciated between each management scheme. The predominant histological bone picture of the patients is osteitis fibrosa, which is present in a large percent of hemofiltration and hemodialysis cases (e.g., n = 10/12 HF and n = 13/15 HD, respectively). Mean osteoclast count and active resorption surface are comparable in the 2 groups, but is increased 5–10 times the mean of the controls.

Comparative evaluation of bone aluminum content and bone histology in patients on chronic hemodialysis and hemofiltration. Sebert JL, Fournier A, Leflon P, Fohrer P, de Frémont JF, Morinière P, Galy C, Marie A, Demontis R, Boudailliez B, et al. Nephron 1986; 42 (1), pp. 34–40.

Bone Physiology and Growth: Hydroxyapatite (HA) Deposition/Osteoblastic Activity/Neoplastic Disease: Osteosarcoma/Atherosclerosis
Near-Infrared (NIR) Light-Emitting Probes/Fluorescent Bisphosphonate Derivatives

Background Information: In vertebrates, the development and integrity of the skeleton requires HA deposition by osteoblasts. Sites of osteoblastic activity have most commonly been imaged *in vivo* using gamma-emitting radioisotopes. The scan times required are long, and the resultant radioscintigraphic images suffer from relatively low resolution. One of the advantages of the application of NIR fluorescence light in imaging modalities for various *in vivo* biological processes is related to its ability to penetrate tissues more efficiently than light in the visible spectrum.
Application: Hydroxyapatite deposition as a marker of, or a participant in, processes as diverse as cancer and atherosclerosis.
Semi-Synthetic Methods: Production of an NIR fluorescent bisphosphonate derivative.
Implementation: Evaluation of the ability of NIR fluorescent bisphosphonate derivatives to physically bind to hydroxyapatite deposits.
Interpretation and Analysis: Near-infrared light-based probes like fluorescent bisphosphonate derivatives posess an ability to bind to hydroxyapatite under *in vitro* conditions, in addition to recognizing osteoblastic activity in living animals. Such biotechnology can be applied to study skeletal development, osteoblastic metastasis, coronary atherosclerosis, and other disease states.

In vivo near-infrared fluorescence imaging of osteoblastic activity. Zaheer A, Lenkinski RE, Mahmood A, Jones AG, Cantley LC, Frangioni JV. Nat Biotechnol 2001 Dec; 19 (12), pp. 1148–54.

NEOPLASTIC DISEASE STATES

Neoplasia/Mammary Carcinoma
Indocyanine Green (ICG)

Cellular/Molecular Mechanism of Action: Indocyanine green (extrinsic contrast agent) functions as a non-radioactive tracer molecule.
Route of Administration: Indocyanine green (bolus injection).
Implementation: Evaluation of the uptake of a non-targeted contrast agent by breast tumors using a continuous-wave diffuse optical tomography apparatus (detection of the tracer molecule on the surface of tumor-bearing breast structures [coronal geometry]). A 2-compartment model can be used to analyze the pharmacokinetics of ICG and preprocessing of data, in addition to diffuse optical tomography used for imaging.

Human Model: Clinical scenarios with 3 different pathologies.
Interpretation and Analysis: Localization and delineation of tumor lesions can be achieved in good agreement with prior information. Moreover, different dynamic features can be observed for differing pathologies. Malignant cases exhibit slower rate constants (uptake and outflow) compared to healthy tissue. Such observations provide further evidence that *in vivo* pharmacokinetics of ICG in breast tumors may be a useful diagnostic tool for differentiation (classification) of benign and malignant pathologies.
Instrumentation: The instrument operates in the near-infrared spectral window and employs 16 sources and 16 detectors to collect light in parallel.

In vivo continuous-wave optical breast imaging enhanced with indocyanine green. Intes X, Ripoll J, Chen Y, Nioka S, Yodh AG, Chance B. Med Phys 2003 Jun; 30 (6), pp. 1039–47.

Neoplasia/Mammary Carcinoma: Estrogen Receptors
[Rhenium-N_2S_2]-Z-Aminotamoxifen/[Rhenium- N_2S_2]-E-Aminotamoxifen/[^{99m}Tc-N_2S_2]-Z-Aminotamoxifen/[^{99m}Tc -N_2S_2]-E-Aminotamoxifen

Cellular/Molecular Mechanism of Action: Aminotamoxifen recognizes and binds to membrane-associated estrogen receptor complexes.
Application: Imaging agent for the detection and characterization of breast cancer lesions. Traditionally, tamoxifen is used as a estrogen antagonist chemotherapeutic agent.
Route of Administration: Intravascular.
Semi-Synthetic Methods: The bifunctional chelator agent is conjugated to Z- and E-aminotamoxifens through an amide linker. Both technetium-99m [^{99m}Tc] and rhenium can be bound to N_2S_2 by chelation.
Implementation: Detection and characterization of mammary carcinoma lesions (*in vivo*).
Interpretation and Analysis: For the Z-isomer, chelation with rhenium in the presence of sodium acetate yields a mixture of 2 isomers, anti and syn, in a 1:1 ratio and in the presence of hydroxide results in only the anti isomer. Both the Z- and E-tamoxifen conjugates can be chelated with technetium-99m at tracer levels, yielding a single isomer product, which is assigned as anti based on chromatographic comparison to the rhenium complexes. Radiochemical yields are consistently greater than 80%, with Sep-Pak column purification yielding a final product with $>$ 99% radiochemical purity and no residual starting material. Both *in vitro* and *in vivo* biological evaluation of the tamoxifen chelates indicates very limited estrogen receptor binding.

Single isomer technetium-99m tamoxifen conjugates. Hunter DH, Luyt LG. Bioconjug Chem 2000 Mar–Apr; 11 (2), pp. 175–81.

Neoplasia/Mammary Carcinoma Explants
Glucamine-Substituted Cyanine/Gluosamine-Substituted Cyanine

Background Information: One of the advantages of near-infrared (NIR) fluorescence light for application in imaging modalities for various *in vivo* biological processes is related to its ability to penetrate tissues more efficiently than light in the visible spectrum.
Application: Glucamine and gluosamine-substituted cyanine are dyes structurally related to indocyanine green (ICG) that can be applied as contrast-enhancing optical imaging agents for the detection of neoplastic lesions (e.g., human mammary carcinoma explants in rats) utilizing NIR modalities.
Route of Administration: Intravenous.
Semi-Synthetic Methods: Production of a group of glucamine and gluosamine-substituted cyanine dyes structurally related to ICG.
Implementation: Characterization of glucamine and gluosamine-substituted cyanine dyes structurally related to ICG for their potential to function as contrast agents for biomedical optical imaging modalities. Derivatives with the highest hydrophilicity are evaluated for their efflux from tumor and normal tissue by monitoring with intensity-modulated diffuse optical spectroscopy after intravenous injection.

Animal Model: Rat (tumor-bearing).
Interpretation and Analysis: Glucamine and gluosamine-substituted cyanine dyes exhibit increased hydrophilicity and less plasma protein binding ($<$ 50%) compared to ICG. Accordingly, they also have different pharmacokinetic properties. Measurable enhancement in fluorescence quantum yields (7–15%) can be detected in a physiological environment compared to ICG. The derivative 5a has the highest level of hydrophilicity. In comparison with ICG, derivative 5a exhibits considerably enhanced tissue-efflux half-life (73 minutes vs $<$ 10 minutes for ICG in tumor tissue) and a 2-fold higher initial tissue absorption coefficient compared to ICG, and it generates an elevated tumor-to-tissue concentration gradient up to 1 hour after injection. In conclusion, compounds such as 5a are promising contrast agents for optical imaging and can facilitate highly sensitive and specific detection of breast cancer or other malignancies by utilizing mechanisms similar to contrast-enhanced magnetic resonance imaging or computerized tomography.

Hydrophilic cyanine dyes as contrast agents for near-infrared tumor imaging: Synthesis, photophysical properties, and spectroscopic *in vivo* characterization. Licha K, Riefke B, Ntziachristos V, Becker A, Chance B, Semmler W. Photochem Photobiol 2000 Sep; 72 (3), pp. 392–8.

Neoplasia/Pancreatic Adenocarcinoma
Fluorescein-Neurotensin [Arg(8), Arg(9), and Ile(12)]/[^{111}In]-Diethylenetriamine Pentaacetic Acid (DTPA)-Neurotensin [Arg(8), Arg(9), and Ile(12)]

Cellular/Molecular Mechanism of Action: Native neurotensin (NT) is a tridecapeptide that binds to neurotensin receptor (NTR) and induces tumor growth.
Background Information: The prevalence of NTR in several human tumors makes it an attractive target for the delivery of cytotoxic drugs and imaging agents. Unfortunately, NT has a short plasma half-life, which hinders its use for *in vivo* biomedical applications.

Numerous reports suggest that Arg(8), Arg(9), and Tyr(11)-Ile(12) amide bonds are particularly susceptible to degradation by proteolytic enzymes.

Application: Detection of NTR-positive human adenocarcinoma.

Semi-Synthetic Methods: Substitution of Arg(8), Arg(9), and Ile(12) amino acids with the corresponding commercially available mimics. Preparations can be conjugated to DTPA for subsequent radiolabeling to produce [^{111}In]-DTPA or alternatively conjugated to fluorescein dye.

Animal Model: Mouse (severe combined immunodeficient [SCID] strain bearing NTR-positive human adenocarcinoma [HT29] xenografts).

Interpretation and Analysis: The surrogate amino acids are amenable to standard 9-fluorenylmethyl chloroformate (Fmoc) peptide synthesis strategy, and the resulting compounds are stable in biological media for $>$ 4 hours and bind to NTR with high affinity. Conjugation of DTPA to the synthetic peptides and subsequent labeling with [^{111}In]-DTPA for nuclear imaging or fluorescein for optical imaging does not diminish NTR binding avidity. Evalution of the *in vivo* biodistribution of a representative [^{111}In]-DTPA-NT peptide analogue in HT29-bearing SCID mice reveals that the compound is primarily retained in tumor tissue (2.2% ID/g) and the kidneys (4.8% ID/g) at 4 hours postinjection. Co-injection of cold NT and the radiolabeled NT peptide analogue inhibits tumor but not kidney uptake, and demonstrates that retention of the radiolabeled compound in tumor tissue is mediated by NTR specific uptake while it accumulates in the kidneys by a non-specific mechanism. These findings show that NT peptide analogues are robust and can deliver imaging agents to NTR-positive tumors such as pancreatic cancer.

Novel bioactive and stable neurotensin peptide analogues capable of delivering radiopharmaceuticals and molecular beacons to tumors. Achilefu S, Srinivasan A, Schmidt MA, Jimenez HN, Bugaj JE, Erion JL. J Med Chem 2003 Jul 17; 46 (15), pp. 3403–11.

Neoplasia/Skin Cancer: Melanoma/Non-Invasive Transcutaneous Detection
Fluorescein-Isothiocyanate-Labeled Antimelanoma IgG/Texas Red–Labeled Dextran

Cellular/Molecular Mechanism of Action: Fluorescein-isothiocyanate and Texas Red emit fluorescent color when exposed to light energy of a specific wavelength.

Application: Fluorescein-isothiocyanate and Texas Red can be used as visual color marker or tracer molecules in biological systems. Fluorescein-isothiocyanate-labeled antimelanoma and Texas Red–labeled dextran can be applied for the transcutaneous detection of melanoma lesions.

Route of Administration: Variable.

Semi-Synthetic Methods: Covalent conjugation and cross-linking conjugation strategies for the semi-synthetic production of fluorescein-isothiocyanate-labeled antimelanoma IgG and Texas Red–labeled dextran.

Implementation: Determination of the relative effectiveness of 3 different fluorescein-isothiocyanate-labeled antimelanoma antibodies to selectively localize within melanoma lesions. Detection is achieved *in vivo* by applying a single-channel confocal imaging system.

Animal Model: Mice (athymic BALB/c strain) with human melanoma cells (n = 3 cell lines) cultured from human skin implanted intradermally into the haunch skin of anesthetized mice and allowed to grow to a maximum size of 2 mm in diameter.

Interpretation and Analysis: Fiber-optic confocal imaging performed following intravenous administration of fluorescently labeled antibodies and Texas Red-dextran facilitates the *in vivo* detection of melanoma and surrounding blood vessels in athymic mice. Using non-invasive techniques, the overall *in vivo* melanoma detection rate for tumors within 0.2 mm of the skin surface is 84% (27 of 32 tumors). Normal cultured human skin cells have little or no fluorescence after administration of the fluorescein-isothiocyanate-labeled antibodies and tumors are not labeled by an isotype control antibody. Dual-channel *in vivo* imaging of implanted melanoma tumors and surrounding dermal vasculature reveals increased blood vessel density at the melanoma site. Detection *in vivo* of melanoma tumors up to 0.2 mm below the skin surface by fiber-optic confocal imaging can be confirmed by conventional immunoperoxidase histology.

Instrumentation: Single-channel confocal imaging system.

In vivo detection of small subsurface melanomas in athymic mice using noninvasive fiber optic confocal imaging. Anikijenko P, Vo LT, Murr ER, Carrasco J, McLaren WJ, Chen Q, Thomas SG, Delaney PM, King RG. J Invest Dermatol 2001 Dec; 117 (6), pp. 1442–8.

Neoplasia/Skin Cancer: Trans-Cutaneous Lesion Detection
Light-Emitting Probes/Firefly Luciferase-Tagged Cells/ Fluorescent Protein-Tagged Cells

Cellular/Molecular Mechanism of Action: Firefly luciferase or fluorescent proteins emit color (e.g., red to infrared range $\geq$ 600 nm) when exposed to a specific substrate.

Background Information: *In vivo* imaging of cells tagged with light-emitting probes, such as firefly luciferase or fluorescent proteins, is a powerful technology that enables a wide range of biological studies in small research animals. Reporters with emission in the red to infrared ($>$ 600 nm) are preferred due to the low absorption in tissue at these wavelengths. One of the advantages of the application of near-infrared (NIR) fluorescence light in imaging modalities for various *in vivo* biological processes is related to its ability to penetrate tissues more efficiently than light in the visible spectrum.

Application: Light-emitting probes can be used as visible markers for detecting cell migration and localization in a manner that can be utilized for *in vivo* lesion detection (e.g., neoplastic disease).

Interpretation and Analysis: Reporter molecules that emit light in the red to infrared range ($>$ 600 nm) are preferred due to their low absorption in tissue at these wavelengths. Modeling of photon diffusion through tissue indicates that bioluminescent cell counts as low as a few hundred can be detected subcutaneously, while approximately 10^6 cells are required to detect signals at approximately 2 cm depth in tissue. Signal-to-noise estimates show that cooled back-thinned integrating charged-coupled devices (CCDs) are preferred to image-intensified CCDs for this application, mainly due to their high quantum efficiency (approximately 85%) at wavelengths $>$ 600 nm where tissue absorption is low.

Instrumentation: Cooled back-thinned integrating CCDs are preferred to image-intensified CCDs.

In vivo imaging of light-emitting probes. Rice BW, Cable MD, Nelson MB. J Biomed Opt 2001 Oct; 6 (4), pp. 432–40.

Neoplasia/Skin Cancer Differentiation/Basal Cell Carcinoma (BCC)/Squamous Cell Carcinoma (SCC)/Precancerous Lesions/Benign Lesions
Nitrogen/Dye Laser (410 nm)

Cellular/Molecular Mechanism of Action: Induced fluorescence of neoplastic tissues.

Application: Laser-induced fluorescence spectroscopy for *in vivo* diagnosis of non-melanoma skin cancers in a manner that can accurately differentiate normal tissues from BCC, SCC, precancerous lesions, and benign lesions based on the interpretation of emissions profiles.
Implementation: Cases are classified as having either skin types I, II, or III and biopsy samples from abnormal tissues collected by biopsy for evaluation. Each analysis measurement is designated as being either normal, BCC, SCC, precancerous, or benign. The total emission photon count is used as a discriminating index. A threshold value is calculated to separate normal tissue indices from indices of cancer tissues. The classification accuracy of each data point is determined using the threshold value.

Human Model: Cases with either skin types I, II, or III (n = 49 total; n = 279 analyses on normal and abnormal tissues).
Interpretation and Analysis: Applying the described categorization scheme, cancers can be classified 93%, 89%, and 78% correctly in cases with skin types I, II, and III, respectively. Normal tissues can be classified 93%, 88%, and 50% correctly in cases with skin types I, II, and III, respectively. Using the same threshold, precancerous spectra can be classified 78% and 100% correctly in skin types I and III, respectively. Benign lesions can be classified 100%, 46%, and 27% correctly in cases with skin types I, II, and III, respectively. Therefore, *in vivo* laser-induced fluorescence spectroscopy at 410 nm excitation and using the intensity of emission signal is an effective approach for detecting BCC, SCC, and actinic keratosis, especially in patients with light-colored skin.
Instrumentation: Nitrogen/dye laser tuned at 410 nm, an optical multichannel analyzer, and a fiber-optic probe for excitation of tissue and collection of fluorescence emission.

Laser-induced fluorescence spectroscopy for *in vivo* diagnosis of non-melanoma skin cancers. Panjehpour M, Julius CE, Phan MN, Vo-Dinh T, Overholt S. Lasers Surg Med 2002; 31 (5), pp. 367–73.

Neoplasia/Squamous Cell Carcinoma
Fluoroscein Isothiocyanate (FITC)-CD3 Conjugates

Cellular/Molecular Mechanism of Action: Fractions of CD3 recognize and physically bind to unique membrane-associated complexes expressed on the exterior surface membrane of certain neoplastic cell types. Fluorescein isothiocyanate emits color when exposed to certain wavelengths of light energy.
Application: Fluorescein isothiocyanate can be used as a light-emitting molecular marker system for non-invasive detection and characerization of neoplastic disease states.
Route of Administration: Intravenous, intramuscular, or intralesional (variable).
Semi-Synthetic Methods: Covalent conjugation of the fluorescent agent FITC to the CD3 marker fraction.
Implementation: Intratongue injection of FITC-conjugated CD3 marker for the identification of neoplastic lesions. Detection is performed by excitation of marker molecules with an argon laser (488 nm) and the resulting fluorescence signal measured as a function of time. Biopsies are taken from each mouse and excised tissue histologically evaluated.

Animal Model: Mouse (BALB/c strain; n = 14 mice; n = 7 controls). Seven mice receive injections of a squamous cell carcinoma cell line into the tongue.
Interpretation and Analysis: Analysis of clearance times revealed a 2nd order exponential decay for both groups with a slower pace of signal clearance for sick mice.
Instrumentation: Argon laser (488 nm) and the fluorescence signal measurement.

Laser activated fluorescence measurements and morphological features: An *in vivo* study of clearance time of fluorescein isothiocyanate tagged cell markers. Gannot I, Gannot G, Garashi A, Gandjbakhche A, Buchner A, Keisari Y. J Biomed Opt 2002 Jan; 7 (1), pp. 14–9.

Neoplasia/Squamous Cell Carcinoma/ Differentiation: Oral Premalignant vs Malignant
5-Aminolevulinic Acid (ALA)-Induced Protoporphyrin IX (PPIX) Fluorescence

Background Information: Studies of 5-aminolevulinic acid-induced PPIX fluorescence have displayed sensitivity levels of 95 to 100% for the diagnosis of oral cancer lesions, but the specificity is only about 50 to 60%.
Application: Quantifying PPIX fluorescence imaging for specific diagnostic detection of early oral lesions (differentiation of premalignant from malignant disease states).
Implementation: Fluorescence endoscopy and imaging are performed on cases of suspected premalignant or malignant oral cavity lesions in conjunction with the collection of biopsy samples for histological analysis (e.g., n = 70) harvested from tissue sites following imaging procedures. The red-to-blue and red-to-green intensity ratios are calculated from fluorescent images for correlation with histology analysis.

Human Model: Cases with known or suspected premalignant or malignant oral cavity lesions (e.g., n = 28).
Interpretation and Analysis: Suspicious lesions display bright reddish fluorescence, while normal mucosal structures exhibit blue color background in the fluorescence images. The red-to-blue and red-to-green intensity ratios of malignant tissues are larger than those of benign tissues. Combining the 2 ratio diagnostic algorithms yields a sensitivity and specificity of 95% and 97%, respectively, exceeding each diagnostic algorithm alone for discriminating malignant tissue from benign tissue. Quantifying PPIX fluorescence endoscopic images combined with ratio diagnostic algorithms has the potential to significantly improve the *in vivo* non-invasive diagnosis of oral cavity lesions.
Instrumentation: Fluorescence endoscopy.

Detection of squamous cell carcinomas and precancerous lesions in the oral cavity by quantification of 5-aminolevulinic acid-induced fluorescence endoscopic images. Zheng W, Soo KC, Sivanandan R, Olivo M. Lasers Surg Med 2002; 31 (3), pp. 151–7.

Neoplasia/Squamous Cell Carcinoma/ Differentiation: Premalignant vs Malignant Oral Lesions
5-Aminolevulinic Acid (ALA)-Induced Protoporphyrin IX (PPIX) Fluorescence

Cellular/Molecular Mechanism of Action: 5-aminolevulinic acid is capable of promoting fluorescence from PPIX compounds.
Background Information: 5-aminolevulinic acid induces fluorescence of PPIX that provides a sensitivity level of 95 to 100% for oral cancer diagnosis with a corresponding specificity of only approximately 50–60%.
Application: Differentiation of premalignant from malignant forms of oral cancer applying PPIX fluorescence endoscopy and fluorescence image quantification.
Implementation: Characterization of oral premalignant and malignant lesions applying PPIX fluorescence endoscopy and fluorescence image quantification. To improve diagnostic specificity, ALA-mediated digitized fluorescence endoscopic imaging systems have been designed that enable on-line image acquisition, analysis,

and fluorescence quantification for early detection of oral cavity neoplasms.

Human Model: Cases of suspected premalignant and malignant lesions of the oral cavity (e.g., n = 16).

Interpretation and Analysis: Head and neck clinical trials have shown that the red-to-blue intensity ratio of malignant tissue is larger than that of benign tissue. By applying the intensity ratio as a diagnostic algorithm, both high specificity and sensitivity can be achieved for discriminating malignant tissue from benign tissue, and the capability of classifying different histopathological stages of oral lesions can also be demonstrated. Red fluorescence intensity distribution in lesion areas could also be obtained to better understand PPIX tissue accumulations. Initial results indicate that the digitized endoscopic imaging system combined with the fluorescence image quantification method and the ratio diagnostic algorithm has the potential of significantly improving the non-invasive *in vivo* diagnosis of early oral neoplasms.

Detection of neoplasms in the oral cavity by digitized endoscopic imaging of 5-aminolevulinic acid-induced protoporphyrin IX fluorescence. Zheng W, Soo KC, Sivanandan R, Olivo M. Int J Oncol 2002 Oct; 21 (4), pp. 763–8.

Neoplasia/Urinary Neoplasia/Bladder Cancer
5-Aminolevulinic Acid (ALA)/5-Aminolevulinic Acid Methyl Ester (AME)

Cellular/Molecular Mechanism of Action: 5-aminolevulinic acid and AME derivative emit fluorescent light energy. Certain neoplastic cell populations preferentially accumulate these agents intracellularly.

Background Information: The use of ALA and its esters to induce endogenous porphyrins for the purpose of detecting epithelial cancers is being studied extensively in many centers around the world. One major challenge is the development of techniques for preparation of efficacious formulations for the purpose of cancer detection.

Application: 5-aminolevulinic acid and AME can be used as fluorescent imaging agents for the photodynamic detection of neoplastic lesions on "exterior" dermal or mucosal surfaces such as cancers of the urinary bladder.

Implementation: Compare ALA with AME derivative in terms of PPIX fluorescence intensity applying *in vitro* and *in vivo* systems of bladder carcinoma. Complementary studies involve comparison evaluations of intravenous and topical application modes for drug administration in an *in vivo* system with RT112 xenografts. An endoscopy system is used to obtain macroscopic fluorescence images. The macroscopic images are further analyzed for fluorescence intensity distribution.

Animal Model: Murine (tumor-bearing mice with RT112 xenographs of human bladder cancer cell types).

Interpretation and Analysis: For intravenous administration, over all time points studied (1, 3, 6 hours), AME-PPIX fluorescence is lower than ALA-PPIX fluorescence and is cleared at a faster rate than the ALA-PPIX when administered intravenously. Topical application with 2 different polymers, Gantrez and Polyvinyl pyrrolidone (PVP), which are fast-releasing polymers, is comparable for inducing PPIX fluorescence. Topical AME-PPIX fluorescence is comparable to ALA-PPIX fluorescence. The agent AME also appears to be applicable as a viable diagnostic agent.

Instrumentation: Karl Storz fluorescence endoscopy system.

A study of 5-aminolevulinic acid and its methyl ester used in *in vitro* and *in vivo* systems of human bladder cancer. Manivasager V, Heng PW, Hao J, Zheng W, Soo KC, Olivo M. Int J Oncol 2003 Feb; 22 (2), pp. 313–8.

Neoplasia: Antineoplastic Property Correlation with Biodistribution/Delivery Characterization
[Fluoroscein Isothiocyanate (FITC)]-Glycol-Chitosan Nanoaggregates

Application: Fluoroscein isothiocyanate can be applied as a fluorescent tracer molecular for characterizing a variety of physiological processes or delineating the distrubution of delivery modalities (e.g., [FITC]-glycol-chitosan nanoaggregates).

Route of Administration: Intravenous (e.g., rat tail vein).

Semi-Synthetic Methods: Conjugation of fluoroscein isothiocyanate to glycol-chitosan-doxorubicin (GC-DOX) results in the production of nanoaggregates with a diameter of about 250 nm in aqueous media. To increase the applicability of such preparations, GC-DOX nanoaggregates can be produced that contain an acid-sensitive spacer moiety. Preparations of GC-DOX spontaneously form micelle-like nanoaggregates in aqueous media. Glycol-chitosan-doxorubicin nanoaggregates have a narrow and unimodal size distribution, and their hydrodynamic diameter as measured by dynamic light scattering ranges from 250 to 300 nm. A loading content of doxorubicin into GC-DOX nanoaggregates as high as 38%, with 97% loading efficiency, can be achieved using a physical entrapment method.

Implementation: Characterization of the *in vivo* biodistribution of GC-DOX nanoaggregates (doxorubicin-loaded GC-DOX nanoaggregates or DOX/GC-DOX) facilitated by conjugation to FITC. Observations can be applied to determine if these parameters correlate with the antineoplastic properties exerted by conjugated preparations.

Animal Model: Rat (tumor-bearing animals developed by inoculating tumor cells into the region of the back).

Interpretation and Analysis: Nanoaggregates of FTC-GC are distributed mainly within kidney, tumor, and the liver with very scarce amounts observed in other tissues/organ systems. They maintain high levels for 8 days and their distribution within neoplastic tissues increases gradually. Chitosan nanoaggregates appear to accumulate passively in tumor tissue due to the enhanced permeability and retention (EPR) effect. Tumor growth is suppressed over a 10-day period.

Biodistribution and antitumor efficacy of doxorubicin-loaded glycol-chitosan nanoaggregates by EPR effect. Son YJ, Jang JS, Cho YW, Chung H, Park RW, Kwon IC, Kim IS, Park JY, Seo SB, Park CR, Jeong SY. J Control Release 2003 Aug 28; 91 (1–2), pp. 135–45.

Neoplasia: Colon Cancer/Optical Lesion Imaging
Indotricarbocyanine (ITCC)/ITCC-Transferrin (Tf)/ ITCC-Human Serum Albumin (HAS)

Cellular/Molecular Mechanism of Action: Indotricarbocyanine is a dye that can serve as a detectable marker molecule in biological systems.

Background Information: Macromolecules accumulate in solid tumors and can thus be used as carriers for the delivery of attached contrast agents to tumors.

Application: Indotricarbocyanine can be applied as a contrast agent for the optical imaging of neoplastic lesions.

Route of Administration: Intravascular.

Semi-Synthetic Methods: Production of serum protein-dye conjugates consisting of Tf or HSA covalently linked to ITCC derivative.

Implementation: Evaluation of properties associated with the semi-synthetic ITCC-HSA and ITCC-Tf conjugates pertaining to their individual (i) photophysical characteristics; (ii) ability to bind

in vitro to tumor cells; and (iii) *in vivo* potential to detect/characterize experimental tumors.

Model: Human HT29 colon cancer cell types propagated *in vitro* in a tissue culture environment and HT29 tumor-bearing nude mice.

Interpretation and Analysis: In contrast to ITCC-HSA, ITCC-Tf displays *in vitro* receptor-mediated uptake by HT29 human colon cancer cells. After intravenous injection, ITCC-HAS and ITCC-Tf both induce increased *in vivo* fluorescence of tumors. After 24 hours the contrast between tumor and normal tissue is significantly higher for ITCC-Tf than for HAS-ITCC-HSA. Dye-induced fluorescence can be found to be predominantly located in perinecrotic areas of tumor lesions. Furthermore, ITCC-Tf produces fluorescence of viable tumor cells, whereas ITCC-HAS fluorescence can be detected along connective tissue. Therefore, ITCC-labeled Tf and HSA can serve as macromolecular contrast agents for the optical imaging of tumors, with ITCC-Tf showing higher efficiency.

Macromolecular contrast agents for optical imaging of tumors: Comparison of indotricarbocyanine-labeled human serum albumin and transferrin. Becker A, Riefke B, Ebert B, Sukowski U, Rinneberg H, Semmler W, Licha K. Photochem Photobiol 2000 Aug; 72 (2), pp. 234–41.

Neoplasia: Colon Carcinoma: Endothelium Cell Adhesion/Intravital Observation of Cancer Cell/ Microcirculation Interactions
CalceinAM

Background Information: Organ-specific tumor cell adhesion within the microcirculation of host organs is an important step in the metastatic cascade. Circulating tumor cells have to adhere within the microcirculatory vessels, and then must quickly stabilize their adhesion, followed by exiting the circulation to avoid the toxic effects of hydrodynamic shear forces of circulating blood.

Application: Intravital observation of colon carcinoma cell adhesion within the hepatic microcirculation.

Implementation: CalceinAM can be used to label colon carcinoma cell populations (e.g., HT-29 [human] and CC531 [rat]) that are then injected intra-arterially as single-cell suspensions. Intravital fluorescence microscopy is then applied to detect adhesive interactions between circulating tumor cells and endothelial surfaces within the hepatic microcirculation. These interactions are then analyzed regarding their time course and site localization within the vascular tree.

Animal Model: Rats (Sprague-Dawley).

Interpretation and Analysis: Autofluorescence of liver parenchyma is sufficient for the distinction of hepatic sinusoids. Intravital microscopy is capable of differentiating early events of adhesion formation within hepatic sinosoids, adhesion stabilization, and extravasation of tumor cells into the liver parenchyma. Tumor cell adhesion occurs almost exclusively within sinusoidal capillaries; however, the diameter of these vessels is usually larger than that of the tumor cells leaving the lumen of these perfused capillaries. Colon carcinoma cells rapidly migrate into the liver parenchyma after successful adhesion within the sinusoids. In contrast to common end point assays of the metastatic cascade, this *in vivo* model allows investigations of metastatic colon carcinoma cell adhesion within the liver microcirculation as specific steps during the formation of hematogenous metastasis and their underlying mechanisms.

Instrumentation: Intravital fluorescence microscopy.

An intravital model to monitor steps of metastatic tumor cell adhesion within the hepatic microcirculation. Haier J, Korb T, Hotz B, Spiegel HU, Senninger N. J Gastrointest Surg 2003 May–Jun; 7 (4), pp. 507–14; discussion 514–5.

Neoplasia: Colorectal Cancer/Gastric Cancer
[Indocyanine Green (ICG)]-Anti-MUC1 Mucin

Cellular/Molecular Mechanism of Action: Monoclonal antibody (IgG) with selective binding properties directed at MUC1 mucin recognizes and physically binds to these complexes expressed on the exterior surface membrane of certain neoplastic cell types.

Background Information: Videoendoscopy has not significantly advanced diagnostic accuracy beyond that attainable by conventional fiberscopy, with respect to microcarcinomas of the digestive tract. Theoretically, it is possible to selectively label such lesions with agents that can be detected by videoendoscope. Digital processing of the images could facilitate more accurate endoscopic diagnosis of microcarcinomas.

Application: [Indocyanine green]-anti-MUC1 mucin can be utilized to detect and characterize conditions of gastric and colorectal cancer lesions when used in combination with direct visualization using videoendoscopy methodologies.

Route of Administration: [Indocyanine green]-anti-MUC1 mucin (intravenous).

Implementation: Evaluation of the ability of [ICG]-anti-MUC1 mucin to selectively recognize and bind *in vivo* to gastric and colorectal cancer cell types. Validation of findings can be established by immunohistochemistry analysis using labeled secondary antibody.

Animal Model: Murine (nude mouse with human gastric or colorectal cancer cell types).

Interpretation and Analysis: [Indocyanine green]-anti-MUC1 mucin preferentially accumulates within gastric and colorectal cancer explants in nude mice, which can be appreciated on gross inspection and by examination of histochemical analyses. Therefore, antibody labeled with an ICG derivative may be clinically useful in detecting gastrointestinal microcarcinoma by videoendoscopy.

Instrumentation: Videoendoscopy.

Vital immunostaining of human gastric and colorectal cancers grafted into nude mice: A preclinical assessment of a potential adjunct to videoendoscopy. Kusaka Y, Ito S, Muguruma N, Tadatsu M, Bando T, Ii K, Irimura T, Shibamura S. J Gastroenterol 2000; 35 (10), pp. 748–52.

Neoplasia: Folate Receptors (KB Tumors)/ Nasopharyngeal Epidermoid Carcinoma/ Fibrosarcoma
Near-Infrared (NIR) Folate Receptor (FR) Probe

Background Information: Fluorescence optical imaging technologies are currently being developed to image specific molecular targets *in vivo.* Detection technologies range from those providing microscopic detail to whole-body imaging systems with potential clinical uses. A number of target-specific NIR imaging probes have recently been developed to image receptors, antigens, and enzymes.

Implementation: Evaluation of the capacity of an NIR folate receptor (FR)-targeted imaging probe to improve the detection of FR-positive cancers. Speculation suggests that modification of the folate molecule will retain receptor affinity *in vivo,* despite the bulkier NIR fluorochrome, NIR2 (em = 682 nm).

Interpretation and Analysis: Cellular uptake of the NIR conjugates is significantly higher in FR-positive nasopharyngeal epidermoid carcinoma, KB cells, compared to FR-negative human fibrosarcoma, HT1080 cells. When tumors are implanted *in vivo,* equal-sized KB tumors show a 2.4-fold higher signal intensity compared to HT1080 tumors (24 hours). The maximum signal-to-background ratio (3-fold) is observed at 24 hours in KB tumor. Injection of the unmodified NIR2 fluorochrome does not result in persistent contrast increases under similar conditions. Furthermore, tumor

enhancement with the NIR2-folate probe persists over 48 hours and is inhibited *in vivo* by the administration of unlabeled folate. These results indicate that folate-modified NIR fluorochrome conjugate can be used for improved detection of FR-positive tumors.

Enhanced tumor detection using a folate receptor-targeted near-infrared fluorochrome conjugate. Moon WK, Lin Y, O'Loughlin T, Tang Y, Kim DE, Weissleder R, Tung CH. Bioconjug Chem 2003 May–Jun; 14 (3), pp. 539–45.

Neoplasia: Gastric Carcinoma
Green Fluorescent Protein (GFP)

Cellular/Molecular Mechanism of Action: Retroviral agents expressing the GFP gene can insert their genome into certain mammalian cell populations. Cells that have been transfected by such retroviral agents express the GFP gene and emit a green color when exposed to certain wavelengths of light.
Application: Visualization of metastatic patterns and profiles.
Route of Administration: Intraperitoneal (other routes possible).
Implementation: Identification of potential regional and distance sites of metastasis. One approach to achieving this objective entails the injection of GFP retroviral supernatants intraperitoneally (i.p.) from day 4 to day 10 after implantation of gastric cancer cells. Tumor and metastasis fluorescence are then visualized every other week utilizing fluorescence optics via a laparotomy on the tumor-bearing animals.
Animal Model: Mouse (i.p. implanted with viable human gastric carcinoma cell types).
Interpretation and Analysis: At 2 weeks after retroviral GFP delivery, GFP-expressing tumor cells can be observed in gonadal fat, greater omentum, and intestine, indicating that these primary i.p. growing tumors are efficiently transduced by the GFP gene and can be visualized by its expression. At 2nd and 3rd laparotomies, GFP-expressing tumor cells can be observed spreading to lymph nodes in the mesentery and other regional sites. At the 4th laparotomy, widespread tumor growth is visualized by GFP expression, inducing liver metastasis. Normal tissues can rarely be found to be transduced by the GFP retrovirus. Thus, reporter gene transduction of the primary tumor can enable detection of its subsequent metastasis. This gene therapy model could be applied to primary tumors before resection or other treatment to have a fluorescent early detection system for metastasis and recurrence.

In vivo tumor delivery of the green fluorescent protein gene to report future occurrence of metastasis. Hasegawa S, Yang M, Chishima T, Miyagi Y, Shimada H, Moossa AR, Hoffman RM. Cancer Gene Ther 2000 Oct; 7 (10), pp. 1336–40.

Neoplasia: Gastric Carcinoma/Intestinal Microcarcinomas
Indocyanine Green (ICG)-Labeled Anti-MUC1 Mucin IgG

Cellular/Molecular Mechanism of Action: Anti-MUC1 mucin IgG possesses binding avidity for complexes expressed on the exterior surface membrane of human gastric carcinoma and carcinoma of the colon.
Application: Labeling of microcarcinomas to a degree sufficient for accurate and sensitive detection by videoendoscopy.
Considerations: Videoendoscopy has not significantly advanced diagnostic accuracy beyond that attainable by conventional fiberscopy, with respect to microcarcinomas of the digestive tract.
Semi-Synthetic Methods: Conjugation of ICG to anti-MUC1 mucin immunoglobulin producing a conjugated product that has binding avidity for complexes expressed on the exterior surface membrane of intestinal carcinoma cell types.
Implementation: Detection of foci of gastric carcinoma lesions in the form of intestinal microcarcinomas.
Animal Model: Nude mice transplanted with human gastric cancer or colorectal cancer.
Interpretation and Analysis: Anti-MUC1 mucin antibody binds *in vivo* to human gastric cancer or colorectal cancer transplants in nude mice that can be confirmed by performing immunohistochemistry analysis with a secondary antibody. The antibody labeled with an ICG derivative may therefore be clinically useful in detecting gastrointestinal microcarcinoma by videoendoscopy.
Instrumentation: Videoendoscopy.

Vital immunostaining of human gastric and colorectal cancers grafted into nude mice: A preclinical assessment of a potential adjunct to videoendoscopy. Kusaka Y, Ito S, Muguruma N, Tadatsu M, Bando T, Ii K, Irimura T, Shibamura S. J Gastroenterol 2000; 35 (10), pp. 748–52.

Neoplasia: General/Optical Imaging: Endoscopy and Videoendoscopy
[Bis-Propanoic Acid Cyanine]-IgG

Cellular/Molecular Mechanism of Action: Receptor-specific small peptide molecule that selectively recognizes and physically binds to complexes expressed on the exterior surface membrane of certain neoplastic cell types.
Application: Potential *in vivo* optical imaging of neoplastic lesions using endoscopy/videoendoscopy.
Route of Administration: [*Bis*-propanoic acid cyanine]-IgG (intravenous).
Semi-Synthetic Methods: Conjugation of the near-infrared (NIR) dyes indocyanine green and its derivatized analogue, *bis*-propanoic acid cyanine dye (cypate), to a biological peptide molecule.
Implementation: Evaluation of the ability of an NIR dye-peptide conjugate to recognize tumor-targeting efficacy.
Animal Model: Rat (neoplastic cell type CA20948 that expresses the corresponding biological protein receptor complex).
Interpretation and Analysis: Tumor retention of 2 non-tumor-specific dyes, indocyanine green and its derivatized analogue, *bis*-propanoic acid cyanine dye (cypate), is negligible. In contrast, the receptor-specific peptide-cypate conjugate (cypate) is retained within CA20948 tumors, with an excellent tumor-to-normal-tissue ratio (e.g., n = 6 rats). Optical detection of tumors with a receptor-targeted fluorescent contrast agent has been demonstrated. This result represents a new direction in cancer diagnosis and patient management.
Instrumentation: A simple continuous-wave optical imaging system, consisting of an NIR laser diode, a cooled charged-coupled device (CCD) camera, and an interference filter.

Novel receptor-targeted fluorescent contrast agents for *in vivo* tumor imaging. Achilefu S, Dorshow RB, Bugaj JE, Rajagopalan R. Invest Radiol 2000 Aug; 35 (8), pp. 479–85.

Neoplasia: General/Selective Detection
HAT-DO1 Fluorescent Agents

Cellular/Molecular Mechanism of Action: Represents a fluorescent molecular system that can be covalently conjugated to a selective "targeting" agent for the detection of specific biological entities without the simultaneous delivery of photodynamic properties.
Application: Sensor (tracer) molecule that facilitates the detection of "targeting" modalities designed to selectively interact with a specific biological/pathological foci or entities.

Synthesis and Design Considerations: Various heterodimers linked by several types of "spacers" between a chlorine derivative and its Mn or Cu complex are synthesized. One representative agent referred to as HAT-DO1 has a molecular formula of m-phthalyl-([13, 17-*bis*-propanoic acid-3-ethenyl-8-formylethylidene-7-hydroxy-2, 7,12,18-tetramethyl-porphyrinate]-manganese (III))-[3′-ethenyl-8′-formylethylidene-7′-hydroxy-2′,7′,12′,18′-te tramethyl-porphine-13′,17′-bispropanoyl aspartic acid]-bishydrazone.

Tumor-localizing fluorescent diagnostic agents without phototoxicity. Takemura T, Nakajima S, Sakata I. Photochem Photobiol 1994 Mar; 59 (3), pp. 366–70.

Neoplasia: General/Optical Imaging
Indocyanine Green (ICG)/Bis-Propanoic Acid Cyanine Dye (Cypate)

Cellular/Molecular Mechanism of Action: Indocyanine green and *bis*-propanoic acid cyanine dye (cypate) function as dye marker reagents that are activated when exposed to light energy in the near-infrared (NIR) range. Tumor receptor ligands recognize and physically bind selectively to complexes associated with the exterior surface membrane of cancer cells.
Background Information: Recently, NIR fluorescence light has been applied to image various biological events *in vivo,* because it penetrates tissue more efficiently than light in the visible spectrum.
Application: Indocyanine green and *bis*-propanoic acid cyanine dye reagents can be applied as visible marker molecules for application in optical imaging modalities. In this context, they can be conjugated to small peptides for specific tumor-associated receptor complexes.
Route of Administration: Intravenous.
Semi-Synthetic Methods: Covalent conjugation of an NIR dye to a biologically active peptide that recognizes and binds to tumor-associated receptor complexes.
Implementation: Evaluation of the ability of a semi-synthetic NIR dye-peptide conjugate for its ability to selectively recognize and physically bind to tumor lesions. Detection can be achieved with a simple continuous-wave optical imaging system.

Animal Model: Rat tumor model (CA20948) known to express receptors for a specific peptide (e.g., n = 6).
Interpretation and Analysis: Tumor retention of 2 non-tumor-specific dyes, ICG and its derivatized analogue, *bis*-propanoic acid cyanine dye (cypate), is negligible. In contrast, the receptor-specific peptide-cypate conjugate (cypate) is retained by CA20948 tumors, producing an excellent tumor-to-normal-tissue ratio.
Instrumentation: A simple continuous-wave optical imaging system, consisting of an NIR laser diode, a cooled charged-coupled device (CCD) camera, and an interference filter.

Novel receptor-targeted fluorescent contrast agents for *in vivo* tumor imaging. Achilefu S, Dorshow RB, Bugaj JE, Rajagopalan R. Invest Radiol 2000 Aug; 35 (8), pp. 479–85.

Neoplasia: General (Human): Near-Infrared (NIR) Fluorescence/Molecular/Physiological Marker System: NIR Fluorescence
IRDye78

Cellular/Molecular Mechanism of Action: IRDye78 is a tetra-sulfonated heptamethine indocyanine that can emit NIR fluorescence.
Background Information: The detection of human malignancies by NIR fluorescence usually requires the conjugation of a cancer-specific ligand to NIR fluorophores that have optimal photoproperties and pharmacokinetics. IRDye78, a tetra-sulfonated heptamethine indocyanine NIR fluorophore, meets most of the criteria for an *in vivo* imaging agent and is available as an N-hydroxysuccinimide ester for conjugation to low-molecular-weight ligands. However, IRDye78 has a high charge-to-mass ratio, complicating purification of conjugates. It also has a potentially labile linkage between the fluorophore and ligand.
Application: IRDye78 can be used as a fluorophore marker molecular in biological systems to assess a variety of physiological processes.
Route of Administration: IRDye78 (variable).
Dosage: IRDye78 (variable).
Semi-Synthetic Methods: Purification of IRDye78 can be performed with an ion-pairing purification strategy for IRDye78 that utilizes a standard C18 column under neutral conditions, thus preserving the stability of fluorophore, ligand, and conjugate. By employing parallel evaporative light scatter and absorbance detectors, all reactants and products can be identified, and conjugate purity maximized. During the purification process, reversible and irreversible conversions of IRDye78 can occur, but strategies for preserving conjugate stability have been established. The robust nature of these methodologies has been validated using 7 ligands, spanning several classes of small molecules and peptides (neutral, charged, and/or hydrophobic), and serves to confirm that IRDye78 conjugates so purified retain bioactivity and permit NIR fluorescence imaging of a specific target.

IRDye78 conjugates for near-infrared fluorescence imaging. Zaheer A, Wheat TE, Frangioni JV. Mol Imaging 2002 Oct; 1 (4), pp. 354–64.

Neoplasia: Glioma
Luciferase Transfected Glioma/Antisense Nucleotide Radiopharmaceuticals/[^{125}I]PNA:Antitransferrin Receptor Conjugate/[^{125}I]PNA Avid/Biotin Monoclonal Antibody Conjugate

Application: Reference model for the development of antisense radiobiopharmaceutical imaging agents for the *in vivo* detection and characterization of neoplastic disease affecting the central nervous system.
Route of Administration: [^{125}I]PNA antisense conjugates are administered intravenously.
Dosage: [^{125}I]PNA conjugate.
Background Information: Antisense radiopharmaceuticals can be used *in vivo* to image gene expression in the brain, if it is possible to facilitate the transport of these polar molecules across the blood-brain barrier.
Semi-Synthetic Methods: Production of an antisense imaging agent comprised of an iodinated peptide nucleic acid (PNA) conjugated to a monoclonal antibody to the rat transferrin receptor utilizing avidin-biotin technology. The PNA is a 16-mer antisense to the sequence around the methionine initiation codon of the luciferase messenger RNA (mRNA).
Implementation: Detection *in vivo* of glioma neoplastic cell types utilizing a luciferase expression plasmid. Frozen sectioning of the brain for film autoradiography is then performed 2 hours following intravenous injection of [^{125}I]PNA conjugates.

Animal Model: Rat glioma cells (C6 type) are permanently transfected with a luciferase expression plasmid for development of rat experimental brain tumor model.
Interpretation and Analysis: The expression of the luciferase transgene in the tumors *in vivo* can be confirmed by measurement of luciferase enzyme activity in the tumor extract. No image of the

luciferase gene expression can be obtained after the administration of either the unconjugated antiluciferase PNA or a PNA conjugate that is an antisense strand to the mRNA of a viral transcript. In contrast, tumors can be successfully imaged with [^{125}I]PNA that is an antisense strand to the luciferase sequence and conjugated to the targeting antibody. In conclusion, these studies demonstrate gene expression in the brain *in vivo* can be imaged with antisense radiopharmaceuticals that are conjugated to a brain drug-targeting system.

Antisense imaging of gene expression in the brain *in vivo.* Shi N, Boado RJ, Pardridge WM. Proc Natl Acad Sci U S A. 2000 Dec 19;97(26):14709–14.

Neoplasia: Glioma
EtNBA Fluorescent Dye/Nile Blue Dyes

Cellular/Molecular Mechanism of Action: EtNBA emits a fluorescent color when exposed to certain wavelengths of light energy.
Background Information: Nile blue dyes have been shown to have affinity for tumor tissue compared to surrounding normal tissue and to be relatively non-toxic.
Application: EtNBA can function as a fluorescent dye marker/signal molecular that can be used to detect and characterize neoplastic lesions (e.g., glioma cell types).
Dosage: EtNBA (2.5–5.0 mg/kg).
Implementation: Evaluate the ability of EtNBA, as a lipophilic, fluorescent benzophenoxazine dye, to image subcutaneous and intracranial U-87 glioma implants. Tumors are illuminated with a 632.8-nm diffuse beam from a helium-neon laser. The resulting video image is processed using an image processor to give real-time pseudocolor and enhanced black-and-white images.
Animal Model: Mouse (expressing U87-MG glioma solid tumor implants).
Interpretation and Analysis: Following subcutaneous injection of EtNBA dye at doses of 2.5 to 5.0 mg/kg bw, a gradual increase in the fluorescent signal can be observed from tumors that peaks 1–3 hours postinjection with variable selectivity (typically 4:1) for tumor to normal surrounding tissues, thereby permitting clear tumor demarcation. The reagent EtNBA is a safe and effective photodiagnostic agent when applied *in vivo* and is capable of demarcating U87-MG solid tumors on a real-time basis (2.5–5.0 mg/kg) for 1 to 3 hours following administration.
Instrumentation: Imaging system for detecting fluorescence consisting of a silicon-intensified target (SIT) video camera fitted with a zoom microscope-magnifying lens complemented by an image processor to give real-time pseudocolor and enhanced black-and-white images.

Fluorescent imaging in a glioma model *in vivo.* Nikas DC, Foley JW, Black PM. Lasers Surg Med 2001; 29 (1), pp. 11–7.

Neoplasia: Gliosarcoma/Lewis Lung Carcinoma/Apoptosis/Cell Death
Cy-Annexin V Conjugate

Background Information: Non-invasive imaging using radioactive annexin V is an emerging strategy for the *in vivo* assessment of cell death (apoptosis).
Application: Detection and characterization of *in vivo* tumor apoptosis (cell death) phenomenon.
Semi-Synthetic Methods: Preparation of active Cy-annexin (an equimolar dye:protein ratio) that possesses binding avidity for apoptotic Jurkat T cells complemented by the production of an inactive Cy-annexin probe (> 2 dyes/mol protein) that does not.
Implementation: Evaluation of the capacity for annexin V labeled with the fluorophore Cy5.5 (Cy) to serve as a probe for imaging of tumor apoptosis using near-infrared fluorescence (NIRF). In this context, active Cy-annexin conjugates can be applied to image 9L gliosarcoma, constitutively expressing green fluorescent protein marker, and the CR8 variant of Lewis lung carcinoma, stably transfected to express DsRed2.
Interpretation and Analysis: The expression of transfected fluorescent protein provides an indication of tumor margins and a means of defining tumor-associated NIRF signal intensity with both tumor models. Tumors can be imaged with and without cyclophosphamide treatment. In both tumor models active Cy-annexin V tumor NIRF signals increase 2–3 times after cyclophosphamide treatment. Tumor NIRF signals develop by 75 minutes after active Cy-annexin injection and remain detectable for a 20-hour observation period. Inactive annexin V can be used as a control in the CR8 carcinoma experiments and results in a low non-specific signal. With the 9L gliosarcoma model, active Cy-annexin V binds to both tumor cells (Cy-annexin V staining only) and endothelial cells (co-stained with Cy-annexin V and antibody to the endothelial marker CD31). Such findings demonstrate that active Cy-annexin can be used as a NIRF probe to image apoptosis from outside an intact living animal and may provide a non-radioactive method of measuring the antiproliferative effects of cancer chemotherapeutic regimens.

Near-infrared fluorescent imaging of tumor apoptosis. Petrovsky A, Schellenberger E, Josephson L, Weissleder R, Bogdanov A Jr. Cancer Res 2003 Apr 15; 63 (8), pp. 1936–42.

Neoplasia: Leukemia Nucleoli Targeting/Gene Therapy Evaluation Model: Antisense Oligonucleotides
Fluorescein-Labeled Phosphorothioate-Triple Helix-Forming Oligonucleotide (PS-TFO)

Cellular/Molecular Mechanism of Action: Oligonucelotide sequences can be designed that recognize and bind to specific gene/messenger RNA (mRNA) sequences.
Physiological Mechanism of Action: Selective inhibition of the transcription/translation of specific genes.
Background Information: The c-myc gene is frequently deregulated and overexpressed in human cancers, and strategies designed to inhibit c-myc expression in cancer cells may have considerable therapeutic value.
Application: Gene (oligonucleotide)-directed detection of neoplastic cell types (e.g., leukemias).
Route of Administration: Potentially variable (intravenous, intralesional).
Semi-Synthetic Methods: Triple helix-forming oligonucleotide (TFO) can be synthesized with phosphorothioate (PS) internucleotide linkages to confer resistance to intra- and extracellular nucleases. The resulting preparation can be conjugated with fluorescein as a tracer agent to identify selective accumulation within certain tissues and subcellular organelles.
Implementation: Characterization of the antigene and antiproliferative activity of a TFO targeted to a homopurine-homopyrimidine sequence in the P2 promoter of the c-myc gene. Delineation of the affinity of fluorescein-labeled PS-TFO.
Interpretation and Analysis: Resistance to intra- and extracellular nucleases is a property that is required for the design of oligonucleotides intended for *in vivo* testing and therapeutic applications.

Phosphorothioate-modified triple helix-forming oligonucleotide forms triplex DNA complexes with affinity and specificity compara-

ble with that of the corresponding phosphodiester TFO, as delineated by gel mobility shift and footprinting assays. Fluorescence microscopy and polyacrylamide gel analysis reveal that fluorescein-labeled PS-TFO accumulates in the nuclei of CEM leukemia cells and remains intact for the duration of at least 72 hours. Incubation of CEM cells with PS-TFO reduces c-myc RNA and protein levels. A single exposure of leukemia cells to the PS-TFO is sufficient to induce dose-dependent growth inhibitory effects. Growth inhibition correlates with accumulation of cells in S phase and with induction of cell death by apoptosis. Preparations of PS-TFO are also effective in other leukemia and lymphoma cell lines. Control oligonucleotides have minimal effects in all assays. These data indicate that c-myc-targeted PS-TFO is an effective antigene and antiproliferative agent, with potential for *in vivo* testing as a novel approach to cancer therapy and possibly diagnosis.

Antigene and antiproliferative effects of a c-myc-targeting phosphorothioate-triple helix-forming oligonucleotide in human leukemia cells. McGuffie EM, Pacheco D, Carbone GM, Catapano CV. Cancer Res 2000 Jul 15; 60 (14), pp. 3790–9.

Neoplasia: Lymph Nodes (Sentinel Mapping)/ Adenocarcinoma Colorectal Cancer/Mammary Carcinoma/Melanoma
Isosulfan Blue Dye

Cellular/Molecular Mechanism of Action: Isosulfan blue is a pigment-based dye reagent.
Background Information: Sentinel lymph node (SLN) biopsy is a widely accepted method for staging breast cancer and melanoma, and it has also been applied as a means of improving the staging in colorectal cancer. However, lymphatic mapping in colorectal cancer has been plagued by studies demonstrating high false-negative rates. Poor accuracy may be due to bulky tumor mass or complete replacement of lymph nodes by tumor lesions.
Application: Evaluation of SLNs in conditions of neoplastic disease (e.g., mammary carcinoma, melanoma, colorectal cancer).
Route of Administration: Isosulfan blue dye (intralesional injection).
Dosage: Isosulfan blue dye (1 ml volumetric).
Implementation: Evaluate possible mechanisms for high false-negative rates after SLN biopsy in colorectal cancer. One approach to characterizing the efficacy of isosulfan blue dye can involve the intraoperative injection of isosulfan blue dye into colorectal adenocarcinoma lesions for the purpose of lymphatic mapping using either an *in vivo* or *ex vivo* experimental model. Routine pathological evaluations are then performed. Sentinel nodes are examined by hematoxylin and eosin stains, and if they are negative they are subsequently evaluated by cytokeratin immunohistochemistry. The patient's age, operation type, tumor stage, tumor diameter, method of SLN detection, presence of palpable nodes, and pathological description of nodes completely replaced by tumor are recorded.

Human Model: Cases undergoing colorectal cancer resection (e.g., n = 50; mean age 62.8 years, 50% men) and lymphatic mapping (e.g., n = 51 procedures).
Interpretation and Analysis: Right- and left-sided colorectal resections are almost equally distributed (48% vs 42%). Sentinel lymph nodes can be successfully identified in a large percentage of cases (e.g., n = 47/51 or 92%). The mean number of SLNs obtained from each specimen is approximately 1.5 (range, 1–5). Routine pathological evaluations demonstrate lymph node metastasis in less than half of affected cases (e.g., n = 20/47 or 43%) that have SLN identified. The SLN is positive for metastasis in about half of these cases (e.g., n = 10/20). Approximately half of cases with metastisis have a negative SLN, resulting in a false-negative rate of 50% (e.g., n = 10/20 cases). The rate of false negatives is significantly higher in patients undergoing left-sided procedures vs right-sided procedures. Differences among gender, tumor stage, tumor diameter, method of SLN detection, presence of palpable nodes, and pathological description of nodes completely replaced by tumor are not associated with a higher false-negative rate.

Does tumor burden limit the accuracy of lymphatic mapping and sentinel lymph node biopsy in colorectal cancer? Broderick-Villa G, Ko A, O'Connell TX, Guenther JM, Danial T, DiFronzo LA. Cancer J 2002 Nov–Dec; 8 (6), pp. 445–50.

Neoplasia: Lymphoma/Mammary Carcinoma
Fluorescein-Somatostatin Receptor-Avid Peptide/ Fluorescein-Bombesin/Carbocyanine-Somatostatin Receptor-Avid Peptide/Carbocyanine-Bombesin

Cellular/Molecular Mechanism of Action: Somatostatin receptor-avid peptides and bombesin recognize and possess binding avidity for somatostatin receptor complexes.
Background Information: Site-specific delivery of drugs and imaging agents to tumors protects normal tissues from the cytotoxic effects of drugs and enhances the diagnostic contrast between normal and pathologic tissues. One approach to achieving selectivity is to target overexpressed receptors on the membranes of tumor cells and to visualize the tumors by a non-invasive optical imaging method.
Application: Detection and characterization of neoplastic lesions that express increased densities of membrane-associated somatostatin receptor complexes.
Semi-Synthetic Methods: Covalent conjugation of fluorescein and carbocyanine dyes to somatostatin and bombesin receptor-avid peptides. Complementary investigation can involve the preparation of potential dual-imaging probes consisting of a bioactive peptide for tumor targeting, a biocompatible dye for optical imaging, and a radioactive or paramagnetic metal chelator for scintigraphic or magnetic resonance imaging of tumors.
Implementation: Delineation of the receptor binding affinities of fluorescein and carbocyanine dyes conjugated to somatostatin and bombesin receptor-avid peptides.

Animal Model: Rats bearing somatostatin- and bombesin-positive tumors.
Interpretation and Analysis: Carbocyanine derivatives of somatostatin and bombesin analogues retain high binding for their respective receptors. Further evaluation of representative molecules in somatostatin- and bombesin-positive tumors show selective uptake of the agents by the tumor cells. Unlike carbocyanine derivatives, receptor binding of fluorescein-somatostatin peptide conjugates is highly sensitive to the type of linker and the site of fluorescein attachment on the non-receptor binding region of the peptide. In general, the presence of flexible linkers disrupts binding affinity, possibly due to the interaction of the linker's thiourea group with the peptide's cyclic disulfide bond. While the receptor binding affinity of the dual probes is not dependent on the type of chelating group examined, it is affected by the relative positions of fluorescein and chelator on the lysine linker. For somatostatin compounds, best results are obtained when the chelator is on the alpha-amino lysine linker and fluorescein is on the epsilon-amino group. In contrast, conjugation of the chelator to epsilon- and fluorescein to the alpha-amino lysine linker of bombesin peptides results in high receptor binding. These findings indicate that despite their small size, conjugation of dyes to truncated somatostatin and bombesin peptide analogues results in the generation of promising diagnostic agents that retain high *in vitro* receptor binding activity. These contrast agents

can selectively and specifically localize in receptor-positive tumors in rat models.

Synthesis, *in vitro* receptor binding, and *in vivo* evaluation of fluorescein and carbocyanine peptide-based optical contrast agents. Achilefu S, Jimenez HN, Dorshow RB, Bugaj JE, Webb EG, Wilhelm RR, Rajagopalan R, Johler J, Erion JL. J Med Chem 2002 May 9; 45 (10), pp. 2003–15.

Neoplasia: Mammography/Mammary Adenocarcinoma/Phantom Calibration *NIR96010 (Infrared Contrast Agent)*

Cellular/Molecular Mechanism of Action: NIR96010 is a molecular agent that can emit light energy in the infrared range (755 nm).

Background Information: Near-infrared (NIR) optical mammography without contrast has a low specificity. The application of optical contrast medium may improve the performance. The concentration-dependent detectability of a new NIR contrast medium can be determined with a prototype optical breast scanner.

Application: The NIR contrast agent NIR96010 is a semi-synthesized, hydrophilic contrast agent that can be applied for NIR mammography imaging.

Route of Administration: NIR96010 (intravenous).

Dosage: NIR96010 (2 μmol/kg).

Implementation: Delineation of the potential for NIR96010 to function as an *in vivo* imaging agent for the detection of neoplastic lesions (e.g., mammary adneocarcinoma). One step in this evaluation process can involve determining the concentration-dependent contrast resolution for tissue phantoms (e.g., whole milk powder and gelatin). A central part of the phantoms measuring 2×2 cm^2 without contrast is replaced with phantom material containing 1 μmol/L to 25 nmol/L NIR96010. The composite phantoms are measured with a prototype NIR breast scanner with lasers. Intensity profiles and standard deviations of the transmission signal in areas with and without contrast are determined by linear fit procedures. Signal-to-noise ratios and spatial resolution as a function of contrast concentration are subsequently established. Near-infrared imaging is then performed before and after intravenous NIR96010 injection.

Animal Model: Murine (severe combined immunodeficient [SCID] mice, n = 5, bearing tumor lesions [MX1 breast adenocarcinoma = diameter of 5 to 10 mm]).

Interpretation and Analysis: Spectrometry analysis reveals an absorption maximum of 755 nm for the contrast agent. No spectral shifts occur in protein-containing solutions. Signal-to-noise ratio in the transmission intensity profiles ranges from 1.1 at 25 nmol/L compared to 28 at 1 μmol/L. At concentrations < 40 nmol/L, no differentiation from background is evident. The transitional area between the contrast-free edge of the phantom and the central contrast-containing part appear in the profiles as a steep increase with a width of 4.2 ± 1.8 mm. Experimental tumors can be detected in non-enhanced images as well as contrast-enhanced images, with better delineation after contrast administration. In postcontrast absorption profiles, a 44.1 ± 11.3% greater absorption increase is seen in tumor tissue compared with normal tissue. The laser wavelength λ1 of the prototype laser mammography device is not situated at maximum absorption of the contrast agent NIR96010 but instead on the descending shoulder of the absorption spectrum profile. This implies a 20% signal loss for contrast detection. Despite the non-ideal measurement conditions, *in vitro* concentrations as low as 40 nmol/L are detectable. All tumors *in vivo* were detectable in color-coded non-enhanced scans as well as in contrast-enhanced scans, with better delineation after contrast administration.

Instrumentation: Near-infrared breast scanner with lasers (e.g., $\lambda 1 = 785$ nm and $\lambda 2 = 850$ nm wavelength).

Contrast-enhanced near-infrared laser mammography with a prototype breast scanner: Feasibility study with tissue phantoms and preliminary results of imaging experimental tumors. Boehm T, Hochmuth A, Malich A, Reichenbach JR, Fleck M, Kaiser WA. Invest Radiol 2001 Oct; 36 (10), pp. 573–81.

Neoplasia Angiogenesis/Tumor Dimethylarginine Dimethylaminohydrolase (DDAH) Overexpression *NC100150/Hoechst 33342*

Cellular/Molecular Mechanism of Action: The spacial orientation of NC100150 becomes altered within a magnetic field. Alternatively, Hoechst 33342 emits fluorescent color when exposed to light energy.

Background Information: Intracellular factors that regulate nitric oxide (NO) synthesis represent important targets in tumor progression. Overexpression of DDAH, which metabolizes the endogenous inhibitors of NO synthesis asymmetric dimethylarginine and N-monomethyl-L-arginine, results in C6 gliomas with enhanced growth rate compared with wild type populations.

Application: NC100150 can be utilized as an intravascular blood pool contrast agent that is detectable by magnetic resonance imaging (MRI). Hoechst 33342 can be used as a fluorescent perfusion-marker dye that can be measured by flourescent detection systems.

Route of Administration: Utilization of NC100150 and Hoechst 33342 for neoplastic lesion angiogenesis requires that these be delivered intravascularly.

Implementation: Evaluation of the *in vitro* effects of DDAH on tumor vascular morphogenesis by measurement of the transverse relaxation rates R_2* and R^2 in (i) clone D27 gliomas overexpressing DDAH; (ii) C6 wild-type gliomas using intrinsic susceptibility MRI sensitive to changes in endogenous deoxyhemoglobin; (iii) evaluation of CN100150 as an intravascular blood pool contrast agent for susceptibility contrast-enhanced MRI; and (iv) comparison of results with fluorescence microscopy utilized to assess tumor uptake of Hoechst 33342 (perfusion marker system).

Interpretation and Analysis: The baseline R_2* is significantly faster in the D27 tumors, consistent with a greater vascular development ($p < 0.02$, ANOVA). There is no significant difference between the response of the 2 tumor types to hypercapnia (5% CO_2/95% air), used as a probe for vascular maturation, or hyperoxia (5% CO_2/95% O_2), used as a probe for vascular function. NC100150 increases the R_2* and R_2 rates of both tumor types and demonstrates a significantly larger blood volume in the D27 tumors ($p < 0.02$, ANOVA). This correlates with a significantly greater uptake of Hoechst 33342 in D27 tumors compared to C6 wild-type tumors ($p < 0.02$, ANOVA). Despite increased tumor blood volume, the Delta R_2*/Delta R_2 ratio, an index of microvessel size, shows that the capillaries in the 2 tumor types are of a similar caliber. Such observations demonstrate the potential of susceptibility MRI-derived quantitative end points to non-invasively assess tumor angiogenesis. Application of intravascular blood pool contrast agents such as NC100150 for such purposes appears very promising. Overexpression of DDAH results in increased *in vivo* neovascularization of C6 gliomas. The lack of significant difference in hypercapnic/hyperoxic response between the C6 and D27 tumors and the similar vessel caliber are also consistent with a role for DDAH in the initial stages of vasculogenesis.

Instrumentation: Magnetic resonance imaging and fluorescence microscopy instrumentation.

Effects of overexpression of dimethylarginine dimethylaminohydrolase on tumor angiogenesis assessed by susceptibility magnetic resonance imaging.

Kostourou V, Robinson SP, Whitley GS, Griffiths JR. Cancer Res 2003 Aug 15; 63 (16), pp. 4960–6.

Neoplasia Chemosensitivity
Near-Infrared Fluorescent (NIRF) Annexin V

Background Information: A rapid and accurate assessment of the antitumor efficacy of new therapeutic drugs could speed up drug discovery and improve clinical decision making.
Implementation: Based on the hypothesis that most effective antitumor agents induce apoptosis, the NIRF annexin V can be used for optical sensing of tumor environments. To demonstrate probe specificity, both active (i.e., apoptosis-recognizing) and inactive forms of annexin V have been developed that have very similar properties (to account for non-specific tumor accumulation).

Animal Model: Murine (nude mice bearing a cyclophosphamide [CPA], chemosensitive [LLC], and a chemoresistant LLC [CR-LLC]).
Interpretation and Analysis: After injection with active annexin V, the tumor-annexin V ratio (TAR; tumor NIRF/background NIRF) for untreated mice is 1.22 ± 0.34 for LLC and 1.43 ± 0.53 for CR-LLC ($n = 4$). The LLC of CPA-treated mice has significant elevations of TAR (2.56 ± 0.29, $p = 0.001$, $n = 4$), but only moderate increases are obtained for CR-LLC (TAR $= 1.89 \pm 0.19$, $p = 0.183$). The *in vivo* measurements correlated well with terminal deoxyribosyl transferase-mediated dUTP nick end labeling indexes. When inactive Cy-annexin V is used, with or without CPA treatment and in both CCL and CR-CCL tumors, tumor NIRF values range from 0.91 to 1.17 (i.e., tumor equal to background). Therefore, active Cy-annexin V and surface reflectance fluorescence imaging provide a non-radioactive, semi-quantitative method of determining chemosensitivity in LLC xenografts. The method may be used to image pharmacologic responses in other animal models and, potentially, may permit the clinical imaging of apoptosis with non-invasive or minimally-invasive instrumentation.

Optical imaging of apoptosis as a biomarker of tumor response to chemotherapy. Schellenberger EA, Bogdanov A Jr, Petrovsky A, Ntziachristos V, Weissleder R, Josephson L. Neoplasia 2003 May–Jun; 5 (3), pp. 187–92.

SPECIAL SENSES

Ophthalmic: Choroidal Microvasculature Structures/Estimation of Microvasculature Blood Flow Velocity/Leukocyte Dynamics in the Choroidal Microcirculation
Indocyanine Green (ICG) Dye-Stained Leukocytes

Cellular/Molecular Mechanism of Action: Indocyanine green is a dye marker molecule that can be used *in vivo* as a detection (tracer) molecule.
Application: Visualization of leukocytes moving through the choroidal vessels of pigmented animals in a manner that enables the evaluation of leukocyte dynamics in the choroidal microcirculation.
Route of Administration: Intravascular.
Implementation: Leukocytes are collected by centrifugal separation of autologous blood and then stained with ICG dye. The ICG-stained leukocyte fluid is then injected intravenously, and the fundus image obtained with a scanning laser ophthalmoscope. Images are recorded on videotape and analyzed with a personal computer–based image analysis system.

Animal Model: Pigmented rabbits and monkeys.
Interpretation and Analysis: In pigmented rabbits, fluorescent leukocytes moving in the choroidal circulation are clearly visible for a period of more than 1 hour. In monkeys, distinct fluorescent dots are seen moving approximately 50–200 μm in the foveal avascular zone for more than 30 minutes after injection of ICG-stained leukocyte fluid. Dim fluorescent dots can be seen moving in the fundus. Although the movement of the dim dots is difficult to trace, they seem to be moving in the choroidal vessels. In rabbits, the mean flow velocity of leukocytes moving without plugging is 0.48 ± 0.14 mm/sec in the peripheral choriocapillaris. In the monkeys, the mean flow velocity of distinct fluorescent leukocytes without plugging is 2.45 ± 0.48 mm/sec in the posterior choroid. In pigmented rabbits and monkeys, this method allows visualization of leukocytes passing through the choroidal vessels and provides a new way to investigate, non-invasively and *in vivo,* leukocyte dynamics in the choroidal microcirculation.
Instrumentation: Scanning laser ophthalmoscope.

Evaluation of leukocyte dynamics in choroidal circulation with indocyanine green-stained leukocytes. Takasu I, Shiraga F, Okanouchi T, Tsuchida Y, Ohtsuki H. Invest Ophthalmol Vis Sci 2000 Sep; 41 (10), pp. 2844–8.

Ophthalmic: Retinal Angiography/Choroid/Retinal Pigment Epithelium/[Premortem Diagnostic Agent]
Rose Bengal/Aluminum Phthalocyanine Tetrasulfonate (CASPc)/Chlorin e6/Photosensitizers (Xanthene, Phthalocyanine, Chlorin)

Application: Localization and site of action of photosensitizers in the eye may be important for photodynamic therapy for fundus disorders but remain poorly understood for most agents.
Route of Administration: Rose bengal (intravenous), CASPc (intravenous), chlorin e6 (intravenous).
Dosage: Rose bengal (40 mg/kg), CASPc (5 mg/kg), or chlorin e6 (2 mg/kg). Digital fundus fluorescence angiography: rose bengal (2–4 mg/kg), CASPc (2 mg/kg), and chlorin e6 (2 mg/kg).
Implementation: Evaluate and characterize the intraocular localization of xanthene, phthalocyanine, and chlorin photosensitizers utilizing fluorescence microscopy and digital fundus fluorescence angiography. In this context, rose bengal, CASPc, or chlorin e6 are injected intravenously. The eyes are then enucleated and examined by means of fluorescence microscopy 5, 20, 60, and 120 minutes and 24 hours after dye injection. *In vivo* digital fundus fluorescence angiography can be performed with rose bengal, CASPc, or chlorin e6.

Animal Model: Rabbit (albino).
Interpretation and Analysis: Pathologically, all agents displayed moderate fluorescence from the choroid and retinal pigment epithelium 5 minutes after dye injection. Mild fluorescence detected from the photoreceptor outer segments at 5 minutes is increased at 20 minutes. Angiographic studies with use of rose bengal, CASPc, and chlorin e6 reveal differences in the pattern and rate of photosensitizer accumulation. Rose bengal, CASPc, and chlorin e6 accumulate rapidly in the choroid and retinal pigment epithelium and less rapidly in the outer retina. Differences in ocular localization of the photosensitizers can be demonstrated. The significance of these findings for potential photodynamic therapy with these agents requires further investigation. Potentially the agents xanthene, phthalocyanine, and chlorin photosensitizers could be utilized in concert with fluorescence microscopy in premortem diagnostic procedures.
Instrumentation: Fluorescence microscopy.

Localization of rose bengal, aluminum phthalocyanine tetrasulfonate, and chlorin e6 in the rabbit eye. Haimovici R, Ciulla TA, Miller JW, Hasan T, Flotte TJ, Kenney AG, Schomacker KT, Gragoudas ES. Retina 2002 Feb; 22 (1), pp. 65–74.

Ophthalmology/Ocular Integrity Assessment Following Cataract and Macular Hole Surgical Procedures
Indocyanine Green (ICG)

Cellular/Molecular Mechanism of Action: Indocyanine green emits fluorescent color when excited by certain wavelengths of light energy.
Application: Measurement of the elimination kinetics within the fluid compartments of the ocular globe after intraocular surgical operations using ICG staining and a monitoring indicator.
Route of Administration: Ocular (topical).
Implementation: Intraocular fluorescence of ICG can be determined using the ICG angiographic mode of a scanning laser ophthalmoscope (*in vivo*) and fluorescence microscopy (*in vitro*) after circular curvilinear capsulorhexis with ICG staining during cataract surgery and internal limiting membrane (ILM) peeling with ICG staining during macular hole surgery.

Human Model: White cataract (n = 7 cases and n = 9 eyes) and idiopathic macular holes (n = 14 cases; n = 14 eyes).
Interpretation and Analysis: Scanning laser ophthalmoscopy can reveal fluorescence in the anterior segment in cases with cataracts on the 1st postoperative day, and fluorescence persists for a mean of 6.0 ± 2.2 days. Scanning laser ophthalmoscopy also reveals fluorescence in the posterior pole of patients with macular holes, and it remains for a mean ± standard deviation of 2.7 ± 1.4 months postoperatively. Fluorescence microscopy shows fluorescence of the entire tissues, suggesting that ICG stains not only the surface of membranes but also penetrates these structures. In both operations, visual outcomes are not significantly different from results obtained without ICG. Because entire tissues are stained, the differences in ICG kinetics may also be caused by factors other than differences in stainability, such as the environment surrounding tissue or molecular structural differences between the lens capsule and the ILM. Although complete disappearance of fluorescence and good functional recovery can be appreciated, the longer resident time of the dye after macular hole surgery may suggest a potential risk to intraocular tissues.
Instrumentation: Fluorescence microscopy (*in vitro*) and scanning laser ophthalmoscope (*in vivo*).

Kinetics of indocyanine green dye after intraocular surgeries using indocyanine green staining. Horiguchi M, Nagata S, Yamamoto N, Kojima Y, Shimada Y. Arch Ophthalmol 2003 Mar; 121 (3), pp. 327–31.

Ophthalmology: Retinal Microglial Cell Postnatal Development
Fluorogold (FG)/4-[4-Didecylaminostyryl]-N-Methylpyridinium Iodide (4Di-10ASP)

Cellular/Molecular Mechanism of Action: Fluorogold and 4Di-10ASP function as fluorescent dye reagents.
Application: Characterization of retinal microglial cell populations and their development during the postnatal period.
Route of Administration: Injected into the superior colliculus (SC) at postnatal day 0.
Implementation: Fluorogold or 4Di-10ASP are injected into the SC at postnatal day 0. Retinas are examined to quantify the microglial cells from P5 to adulthood. In addition, the reaction of microglia to optic nerve crush can be studied in adult animals.

Animal Model: Mouse (postnatal day 0 [P0] to adulthood).
Interpretation and Analysis: Fluorogold or 4Di-10ASP are transported retrogradely to the retinal ganglion cell (RGC) soma when either dye is injected into the SC at P0. Some of the labeled RGCs die due to natural apoptosis during this stage of development and are phagocytosed by microglial cells that move to the site of RGC death and become labeled with the same dye. Both dye reagents label RGCs in the contralateral retina and a few RGCs in the retina ipsilateral to the injected superior colliculus (SC). The density of labeled RGCs decreases by 22% between P5 and P7. During this phase, microglial cells become visible as they ingest fluorescent detritus of the dying RGCs. Microglial cells are evenly distributed across the entire retinal surface and migrate to the outer plexiform layer. Migrating microglia consecutively alter their morphology from the amoeboid to the ramified form. In terms of intracellular storage of the dyes, resident microglial cells retain the fluorescent dye 4Di-10ASP over a period of 12 months. Conversely, FG is completely transferred from the RGCs and microglial cells to intramural cells (pericytes) of the retinal capillaries after 10 months. This results in delineation of the entire intraretinal vascular network. Finally, resident retinal microglial cells are also activated by injury to the adult optic nerve and phagocytosed degenerating neurons. Retinal microglial cells can be monitored with vital fluorescent dyes while they migrate across the retina and establish their intraretinal network. It is possible to label microglia with lipophilic dyes, and they remain labeled for an extended period of time. In addition, intramural pericytes can be labeled by slow release of FG from RGCs and microglial cells. Such observations suggest that ingested fluorescent dyes having different properties can be used *in vivo* to study different cell populations of the retina.

Migration of phagocytotic cells and development of the murine intraretinal microglial network: An *in vivo* study using fluorescent dyes. Bodeutsch N, Thanos S. Glia 2000 Oct; 32 (1), pp. 91–101.

Ophthalmology: Retinal Neuron Visualization
Retrogradely Transportable Fluorescent Dyes

Cellular/Molecular Mechanism of Action: Fluorescent reagents emit color when exposed to certain wavelengths of light energy.
Background Information: Posttraumatic death of mature retinal neurons occurs in glaucoma and after optic nerve injury.
Application: Characterization of dynamic processes associated with cell death applying analysis methods that monitor changes over time.
Implementation: Coupling the development of retrograde transported fluorescent dyes with modification of conventional epifluorescence microscopy to manipulate and visualize *in vivo* rat retinal neurons.
Interpretation and Analysis: Retinal conditions can be effectively monitored, including those associated with glaucoma or optic nerve transection, and for evaluation of neuroprotective strategies.

In vivo FM: Using conventional fluorescence microscopy to monitor retinal neuronal death *in vivo.* Thanos S, Indorf L, Naskar R. Trends Neurosci 2002 Sep; 25 (9), pp. 441–4.

Ophthalmic: Retinal Vascular Permeability/ Minimally-Invasive Diagnostic Strategy/Diabetic Retinopathy
Sodium Fluorescein

Background Information: Diabetic retinopathy is the leading cause of blindness in working-age individuals in the United States. Breakdown of the blood-retinal barrier is 1 of the earliest events in the progression of diabetic retinopathy. Ideally, therapeutic measures

would be directed at this early stage, but there are few sensitive, quantitative methods to assess the retinal vascular barrier *in vivo.*

Application: Quantitative assessment of the retinal vascular barrier.

Implementation: Utilization of 2 fluorescent tracers in combination with fluorescence microangiography to quantitatively assess retinal vascular barriers (± infusion of a hyperosmolar solution of 1.6 M mannitol for 5 minutes).

Animal Model: Rat (Long-Evans strain).

Interpretation and Analysis: Permeability × surface area/flow (PS/F) describing the retinal vasculature is 0.086 ± 0.031 (n = 13, avg. ± standard deviation). Based on estimates of flow and surface area, permeability of sodium fluorescein is approximately 1.2×10^{-5} cm/s. Infusion of a hyperosmolar mannitol solution significantly increases PS/F within individual veins and significantly increases flow-weighted PS/F from 0.073 ± 0.028 to 0.16 ± 0.034 (n = 3). Quantitative *in vivo* assessment of retinal vasculature can be delineated applying an adapted indicator dilution technique. Dual-tracer fluorescence angiography appears to be a sensitive indicator for detecting increases in blood-retinal barrier permeability produced by hyperosmolar mannitol. The methodology may be a promising new minimally-invasive strategy that may be adapted to quantitatively track retinal vascular permeability.

Instrumentation: Fluorescence microangiography.

Retinal vascular permeability determined by dual-tracer fluorescence angiography. Russ PK, Gaylord GM, Haselton FR. Ann Biomed Eng 2001 Aug; 29 (8), pp. 638–47.

Ophthalmology/Visual Pathway Staining (*In Vivo* Antegrade Staining)/Retinal Ganglion Staining (*In Vivo* Antegrade Staining)/Vitreoretinal Surgery: Intraoperative Probe
Indocyanine Green (ICG)

Cellular/Molecular Mechanism of Action: Indocyanine green emits fluorescent color when excited by certain wavelengths of light energy.

Background Information: It has been shown that the application of ICG over the retinal surface is followed by prolonged staining of the optic disc.

Application: Indocyanine green can function as a bidirectional axonal tracer that can be used *in vivo* to stain the visual pathway and retinal ganglion. Such properties may be of value as an intraoperative diagnostic pharmaceutical for vitreoretinal surgery and as a tool in performing ophthalmic investigative research.

Implementation: Evaluation of ICG (i) anterograde diffusion after injection into the vitreous; and (ii) retrograde diffusion after microinjection into the lateral geniculate nucleus (e.g., discovery of the extent of ICG diffusion along the optic tract).

Animal Model: Rabbit (vitreous ICG injection) and rats (lateral geniculate nucleus injection).

Interpretation and Analysis: Anterograde and retrograde diffusion occurs along axons at a rate of about 2 mm per hour following ICG injection. Anterograde staining of the visual pathway persists for several weeks. After injection into the lateral geniculate nucleus, fluorescent retinal ganglion cells can be visualized for at least 7 days in conscious rats. Microscopic examination reveals evidence of retrograde-labeled retinas and the detection of ICG vesicles inside the axons, cytoplasm, and dendrites of retinal ganglion cells. Evidence of toxic effects can usually not be detected applying optical microscopy. Injection of ICG into normal vitreous results in long-term staining of the visual pathway. *In vivo* counting of ICG-labeled retinal ganglion cells in rats can be performed for several days after injection. Indocyanine green is therefore potentially of interest for use in experimental neurophysiological studies. It is speculated that in humans, the epiretinal application of ICG results in prolonged staining of the visual pathway. Additional studies of long-term cytotoxic effects of ICG on neural cells are warranted before recommending its use in humans as an intraoperative tool for vitreoretinal surgery.

Instrumentation: Conventional infrared photography.

Axon-tracing properties of indocyanine green. Paques M, Genevois O, Regnier A, Tadayoni R, Sercombe R, Gaudric A, Vicaut E. Arch Ophthalmol 2003 Mar; 121 (3), pp. 367–70.

PATHOLOGY: GENERAL

Lesion Detection
Fluorophore-Antibody Conjugate/Fluorescein Isothiocyanate (FITC)

Cellular/Molecular Mechanism of Action: Fluorescein isothiocyanate emits fluorescent color when exposed to light of certain wavelengths.

Application: Molecular marker (tracer) system that can be applied in biological systems to assess various physiological processes.

Implementation: Evaluation of the capacity of immunoglobulin conjugates to interact with antigens expressed by the diseased tissue or neoplastic lesions, resulting in fluorescent labeling of cell-membrane associated antigen that can be visualized applying optical detection systems. Three-dimensional images can be reconstructed corresponding to the location of a fluorophore (FITC) in tongue tissue. Measurements are performed with the fluorophore embedded at various simulated depths. The simulations are performed with agarose-based gel slabs applied to the tongue as tissue-like phantoms. Reconstructed fluorophore locations agree well with actual observed measurements.

Animal Model: Mouse (tongue imaging with a marker system at various simulated depths).

Interpretation and Analysis: By combining an optical detection system with a reconstruction algorithm developed on the basis of the random-walk model, it is possible to determine the position of the fluorophore (e.g., diseased target cells) in tissue structures.

Instrumentation: Optical detection system.

In vivo quantitative 3-dimensional localization of tumor labeled with exogenous specific fluorescence markers. Gannot I, Garashi A, Gannot G, Chernomordik V, Gandjbakhche A. Appl Opt 2003 Jun 1; 42 (16), pp. 3073–80.

PHARMACEUTICAL DELIVERY

Antineoplastic Property Correlation with Biodistribution/Delivery Characterization
[Fluoroscein Isothiocyanate (FITC)]-Glycol-Chitosan Nanoaggregates

Application: Fluoroscein isothiocyanate can be applied as a fluorescent tracer molecule for characterizing a variety of physiological processes or delineating the distribution of delivery modalities (e.g., [FITC]-glycol-chitosan nanoaggregates).

Route of Administration: Intravenous (e.g., rat tail vein).

Semi-Synthetic Methods: Conjugation of fluoroscein isothiocyanate to glycol-chitosan-doxorubicin (GC-DOX) results in the production of nanoaggregates with a diameter of about 250 nm in aqueous media. To increase the applicability of such preparations,

GC-DOX nanoaggregates can be produced that contain an acid-sensitive spacer moiety. Preparations of GC-DOX spontaneously form micelle-like nanoaggregates in aqueous media. Glycol-chitosan-doxorubicin nanoaggregates have a narrow and unimodal size distribution, and their hydrodynamic diameter as measured by dynamic light scattering ranges from between 250 to 300 nm. A loading content of doxorubicin in GC-DOX nanoaggregates can be as high as 38% with a 97% loading efficiency when using a physical entrapment method.

Implementation: Characterization of the *in vivo* biodistribution of GC-DOX nanoaggregates (doxorubicin-loaded GC-DOX nanoaggregates or DOX/GC-DOX) facilitated by conjugation to FITC. Observations can be applied to determine if these parameters correlate with the antineoplastic properties exerted by conjugated preparations.

Animal Model: Rat (tumor-bearing animals developed by inoculating tumor cells into the region of the back).

Interpretation and Analysis: Nanoaggregates of FITC-GC are distributed mainly within the kidney, tumor, and liver with very scarce amounts observed in other tissues/organ systems. They maintain high levels for 8 days and their distribution within neoplastic tissues increases gradually. Chitosan nanoaggregates appear to accumulate passively in tumor tissue due to a enhanced permeability and retention (EPR) effect. Tumor growth is suppressed over a 10-day period.

Biodistribution and antitumor efficacy of doxorubicin-loaded glycol-chitosan nanoaggregates by EPR effect. Son YJ, Jang JS, Cho YW, Chung H, Park RW, Kwon IC, Kim IS, Park JY, Seo SB, Park CR, Jeong SY. J Control Release 2003 Aug 28; 91 (1–2), pp. 135–45.

Gene Therapy Assessment: Antisense Oligonucleotides/Neoplastic Disease: Leukemia Nucleoli Targeting
Fluorescein-Labeled Phosphorothioate-Triple Helix-Forming Oligonucleotide (PS-TFO)

Cellular/Molecular Mechanism of Action: Oligonucelotide sequences can be designed that recognize and bind to specific gene/messenger RNA (mRNA) sequences.

Physiological Mechanism of Action: Selective inhibition of the transcription/translation of specific genes.

Background Information: The c-myc gene is frequently deregulated and overexpressed in human cancers, and strategies designed to inhibit c-myc expression in cancer cells may have considerable therapeutic value.

Application: Characterize the antigene and antiproliferative activity of a triple helix-forming oligonucleotide (TFO) targeted to a homopurine-homopyrimidine sequence in the P2 promoter of the c-myc gene.

Route of Administration: Potentially variable (intravenous, intralesional).

Semi-Synthetic Methods: Triple helix-forming oligonucleotide can be synthesized with phosphorothioate (PS) internucleotide linkages to confer resistance to intra- and extracellular nucleases. The resulting preparation can be conjugated with fluorescein as a tracer agent to identify selective accumulation within certain tissues and subcellular organelles.

Implementation: Delineation of the binding affinity of fluorescein-labeled PS-TFO for target molecules.

Interpretation and Analysis: Resistance to intra- and extracellular nucleases is a property that is required for the design of oligonucleotides intended for *in vivo* testing and therapeutic applications.

Phosphorothioate-modified triple helix-forming oligonucleotides form triplex DNA complexes with affinity and specificity comparable with that of the corresponding phosphodiester TFO, as delineated by gel mobility shift and footprinting assays. Fluorescence microscopy and polyacrylamide gel analysis reveal that fluorescein-labeled PS-TFO accumulates in the nuclei of CEM leukemia cells and remains intact for a duration of at least 72 hours. Incubation of CEM cells with PS-TFO reduces c-myc RNA and protein levels. A single exposure of leukemia cells to the PS-TFO is sufficient to induce dose-dependent growth inhibitory effects. Growth inhibition correlates with accumulation of cells in S phase and with induction of cell death by apoptosis. Preparations of PS-TFO are also effective in other leukemia and lymphoma cell lines. Control oligonucleotides have minimal effects in all assays. These data indicate that c-myc-targeted PS-TFO is an effective antigene and antiproliferative agent, with potential for testing *in vivo* as a novel approach to cancer therapy.

Antigene and antiproliferative effects of a c-myc-targeting phosphorothioate-triple helix-forming oligonucleotide in human leukemia cells. McGuffie EM, Pacheco D, Carbone GM, Catapano CV. Cancer Res 2000 Jul 15; 60 (14), pp. 3790–9.

Mammary Carcinoma: Potential Delivery Platform/ Central Nervous System Glioma
T3,4BCPC

Cellular/Molecular Mechanism of Action: The exact mechanism that facilitates the selective uptake of T3,4BCPC by certain neoplastic cell types has not been precisely established.

Application: Potential application as a detectable delivery modality that selectively recognizes certain neoplastic cell types (e.g., glioma, mammary carcinoma).

Route of Administration: T3,4BCPC (intravenous).

Dosage: T3,4BCPC (5.0 mg/kg body weight; murine fibrosarcoma model).

Semi-Synthetic Methods: The new water-soluble photosensitizer 5,10,15,20-tetrakis[3,4-bis(carboxymethyleneoxy)-phenyl] chlorin (T3,4BCPC) can be prepared, characterized, and labeled with [^{99m}Tc] radionuclide.

Implementation: Determination of biodistribution studies in mouse and rat tumor models for determining the comparative properties of the tumor-seeking radiopharmaceuticals [$^{99m}Tc^{V}$]-dimercaptosuccinic acid (DMSA), [^{201}Thallous]-chloride (TlCl), and [^{99m}Tc]-citrate using a gamma camera computer system. In the 2nd phase of evaluation, *in vivo* efficacy of the compound is determined by establishing its potential as photodynamic therapeutic agent achieved by the conduction of a preclinical photodynamic therapy (PDT) study performed in fibrosarcoma-bearing mice (postinjection of T3,4BCPC).

Animal Model: Murine (C_3 H/J virus-induced spontaneous mammary tumors).

Animal Model: Murine (fibrosarcoma-bearing).

Animal Model: Rats (Wistar strain).

Animal Model: Rat (N-nitrosomethylurea [NMU]-induced mammary tumors].

Animal Model: Rat (transplanted C_6-glioma).

Interpretation and Analysis: Accumulation of administered activities within the liver, kidney, bladder, and large intestine at 4 hours postinjection indicates that the labeled ligand is largely eliminated through renal excretion and partly through the hepatobiliary system. In NMU-induced rat mammary tumors, the labeled ligand

shows a 5-fold tumor to muscle (T/M) ratio compared to [$^{99m}Tc^{V}$]-DMSA (3-fold) and [^{201}Tl]Cl (3-fold). In the case of C_3 H/J virus-induced spontaneous mammary tumors, differences are not marked. However, in the transplanted rat C_6-glioma, the T/M ratio of the labeled compound is appreciably higher (4-fold) than that noted with [$^{99m}Tc^{V}$]-DMSA (2-fold), [^{201}Tl]Cl (3-fold), and [^{99m}Tc]-citrate (more than 3-fold). Therefore, radiolabeled T3,4BCPC may have potential for the detection of different cancer cell types. Photodynamic therapy applications of T3,4BCPC in fibrosarcoma-bearing mice evaluated following delivery of a laser dose of 20 mW for 60 seconds reveal 80% destruction of tumor mass. The molecule may therefore be useful for PDT of cancer. The labeled agent could also be useful in monitoring the progression/regression of tumors before, during, and after chemotherapy, radiation therapy, or PDT.

Preparation and biological evaluation of the new chlorin photosensitizer T3,4BCPC for detection and treatment of tumors. Murugesan S, Shetty SJ, Srivastava TS, Samuel AM, Noronha OP. J Photochem Photobiol B 2002 Aug; 68 (1), pp. 33–8.

Polypeptide Delivery: Insulin/Sustained *In Vivo* Peptide Release: Insulin
Microspheres: Inherently Fluorescent

Cellular/Molecular Mechanism of Action: Microspheres can function as a delivery platform that prevents degradation, delays the rate of elimination, controls systemic release, and/or facilitates selective delivery in a manner that minimizes innocent organ/tissue exposure and enhances concentrations at desired target regions.
Application: Facilitation of selective or protracted release of biologically active peptide molecules.
Route of Administration: Intravenous.
Semi-Synthetic Methods: Inherently fluorescent microspheres composed of a fluorescent polyanhydride, poly(*p*-(carboxyethylformamido) benzoic anhydride) (PCEFB), and poly(lactide-co-glycolide) (PLGA) can be prepared using the water-in-oil-in-water (w/o/w) emulsion solvent evaporation technique. Characterization of microsphere blends can be achieved applying combinations of size exclusion gel permeation chromatography (GPC), infrared spectrometry (IR), fluorometry, and scanning electron microscopy (SEM) analyses.
Implementation: Evaluation of the effect of the PCEFB/PLGA feed ratio and composition of the oil phase on insulin entrapment and microsphere diameter.
Interpretation and Analysis: Insulin entrapment efficiency increases with PCEFB content and acetone percent in the oil phase. Microsphere diameter decreases as acetone is added into the oil phase. Although slight degradation of PCEFB during the fabrication process can be identified by GPC and IR, PCEFB/PLGA microspheres can still be clearly visualized by either confocal laser scanning microscopy (CLSM) or fluorescent microscopy in a manner that makes it possible to directly detect *in vivo* microspheres by fluorometry without the need for fluorescent dye-labeling techniques. The surface of PCEFB/PLGA (1:2) microspheres is smooth, while PCEFB/PLGA (2:1) microspheres have rough and uneven surfaces. Sustained release of insulin from the microspheres can be achieved for approximately 4 days.

Bioadhesive fluorescent microspheres as visible carriers for local delivery of drugs. I: Preparation and characterization of insulin-loaded PCEFB/PLGA microspheres. Jiang HL, Zhu KJ. J Microencapsul 2002 Jul–Aug; 19 (4), pp. 451–61.

Protection of Fluorescent Probe: Delivery Modification
Probes Encapsulated by Biologically Localized Embedding (PEBBLEs)

Cellular/Molecular Mechanism of Action: Function as a protected delivery format for fluorescent probes.
Route of Administration: Usually by intravascular injection.
Semi-Synthetic Methods: Spherical optical nanosensors, or PEBBLEs, can be produced in sizes ranging between 20 nm and 200 nm in diameter. The sensors are fabricated in a microemulsion and consist of fluorescent indicators entrapped in a polyacrylamide matrix. A generalized polymerization method has been developed that permits production of sensors containing any hydrophilic dye or combination of dyes in the matrix.
Interpretation and Analysis: The PEBBLE matrix protects the fluorescent dye from interference by proteins, allowing reliable *in vivo* dye calibration. Sensor response times are less than 1 ms. Cell viability assays indicate that PEBBLEs are biocompatible and exert negligible biological effects compared to control conditions. Several sensor (tracer) delivery methods have been studied, including liposomal delivery, gene gun bombardment, and pico-injection into single living cells.

Optical nanosensors for chemical analysis inside single living cells. 1. Fabrication, characterization, and methods for intracellular delivery of PEBBLE sensors. Clark HA, Hoyer M, Philbert MA, Kopelman R. Anal Chem 1999 Nov 1; 71 (21), pp. 4831–6.

Stabilization of Optical Tracer Agents
Indocyanine Green (ICG)

Cellular/Molecular Mechanism of Action: Indocyanine green absorbs and fluoresces in the near-infrared (NIR) range.
Background Information: One of the advantages of the application of NIR fluorescence light in imaging modalities for various *in vivo* biological processes is related to its ability to penetrate tissues more efficiently than light in the visible spectrum.
Application: Indocyanine green is a medically useful dye that can be applied as an optical marker (tracer) agent to evaluate liver function and assess cardiac output parameters.
Background Information: The poor stability of ICG in aqueous solution, especially at the high concentrations needed for bolus injection, has been a hindrance in clinical applications.
Implementation: Certain macromolecular additives can be formulated with ICG to improve the stability of this dye when formulated in aqueous solutions.
Interpretation and Analysis: Such non-covalent binding between dye and carrier molecules preserves substantially the dye in aqueous solutions for several weeks with no apparent changes in the measured *in vivo* biological properties.

Stabilization of the optical tracer agent indocyanine green using non-covalent interactions. Rajagopalan R, Uetrecht P, Bugaj JE, Achilefu SA, Dorshow RB. Photochem Photobiol 2000 Mar; 71 (3), pp. 347–50.

RENAL SYSTEM

Glomerulonephritis: Chronic/Prognostic Factors: Markovian Analysis
Phenolsulfonphthalein (PSP)

Cellular/Molecular Mechanism of Action: Phenolsulfonphthalein is secreted by the proximal renal tubular epithelium.

Application: Estimation of prognosis for conditions of chronic glomerulonephritis.
Implementation: Delineation of the incidence of hypertension in chronic glomerulonephritis and its influence on the clinical course of the disease applying statistic techniques (especially Markovian process).
Interpretation and Analysis: In cases of chronic glomerulonephritis, the incidence of hypertension is approximately 15.2% (e.g., n = 283/1,862), but if renal function is approximately one-half then the incidence increases to 50% (e.g., n = 930/1,862).

The average blood pressure in such disease states tends to become elevated with decreases in 15-minute values for PSP excretion tests and with increasing serum creatinine levels (Note: Variations are large). After a fall of renal function to approximately one-third of the normal, declines in the rate of the clinical course become markedly rapid. The prognosis for the progressive type of chronic glomerulonephritis is obviously shortened by the presence of hypertension. According to the results obtained by the Markovian approach, survival years of the patients with a wide range of renal function can be predicted with relative accuracy.

Prognosis of chronic glomerulonephritis with special reference to hypertension and renal function. Urakabe S, Shirai D, Orita Y, Ando A. Jpn Circ J 1975 Jul; 39 (7), pp. 815–21.

Tubular Absorption: Mechanism of Uptake
Phenolsulfonphthalein (PSP)/Paraaminohippuric Acid (PAH)/Cimetidine

Cellular/Molecular Mechanism of Action: Phenolsulfonphthalein is excreted into the urine by the proximal renal tubular epithelium. Alternatively, PAH is removed passively from the plasma and passes into the urinary filtrate at the level of the renal glomerulus.
Background Information: Phenolsulfonphthalein can be used to assess renal tubular function, but its excretion mechanism has not been elucidated.
Application: Evaluation of renal tubular function.
Implementation: Evaluation of the transporter-mediated excretion system for PSP using PAH (rat organic anion transporter1 [rOat1] substrate) and cimetidine (rOat3 substrate) as investigative molecular probes.
Interpretation and Analysis: Paraaminohippuric acid and cimetidine reduce the urinary excretion of PSP. The uptake of PSP by kidney slices involves individual tubular components. The IC50 values of rOat1 substrates are higher than those of rOat3 substrates. In the presence of cimetidine, Eadie-Hofstee plots produce a single straight line. The profile of the PSP uptake component in the presence of cimetidine is similar to that of the low-affinity component in the absence of cimetidine. Therefore, rOat1 and rOat3 appear to be involved in the renal uptake of PSP, and this agent is a high-affinity substrate for rOat3 but is a relatively low-affinity substrate for rOat1.

Major role of organic anion transporters in the uptake of phenolsulfonphthalein in the kidney. Itagaki S, Sugawara M, Kobayashi M, Nishimura S, Fujimoto M, Miyazaki K, Iseki K. Eur J Pharmacol 2003 Aug 15; 475 (1–3), pp. 85–92.

Tubular Excretion/Renal Glomerular Filtration
Phenolsulfonphthalein (PSP) Excretion/Inulin Clearance/Paraaminohippurate (PAH) Clearance

Cellular/Molecular Mechanism of Action: Phenolsulfonphthalein and PAH are secreted by the proximal renal tubule epithelium. Alternatively, inulin and PAH are removed passively from the plasma where at the level of the renal glomerulus it passes into the urinary filtrate.
Application: Detection of alterations in renal excretory capacity (phenolsulfonphthalein) and glomerular filtration (inulin and PAH).
Implementation: Evaluation of alterations in renal function induced by exposure to a toxic agent. Assessment of renal function can be determined by measuring (i) exogenous PSP excretion; (ii) inulin clearance; (iii) PAH clearance (monkeys only); (iv) endogenous serum creatinine; and (v) blood urea nitrogen (BUN) at multiple time points during the study.

Animal Model: Canine (beagle dog). Groups of male dogs are administered either a single oral dose of 5 mg/kg triclopyr or are fed a diet spiked with triclopyr at a dose of 5 mg/kg/day for 47 consecutive days.

Animal Model: Primate (male rhesus monkey). Toxic challenge is induced by exposure to triclopyr (3,5, 6-trichloro-2-pyridinyloxyacetic acid) in order to determine its influence on renal function following oral administration (e.g., beagle dog and rhesus monkey). Male rhesus monkeys are orally administered triclopyr by gavage at a dose of 5 mg/kg/day, 7 days/week for 28 days, after which the dosage is increased to 20 mg/kg/day for 102 consecutive days.
Interpretation and Analysis: Creatinine, BUN, and inulin clearance are within the normal range for both species following triclopyr administration, which indicates that repeated administration of triclopyr in the dog and monkey has no effect on glomerular filtration rate (GFR). In monkeys, the percentage of excreted PSP and PAH appears to increase following triclopyr administration (20 mg/kg/day), suggesting that these weak organic acids may be competing for the same plasma protein-binding site enhancing their clearance. More importantly, triclopyr does not appear to be competing with PSP or PAH for the active secretory site within the monkey kidney proximal tubules. Conversely, PSP clearance studies in dogs reveal that triclopyr administration (5 mg/kg) can significantly decrease the percentage PSP excretion even following a single-dose administration. The decrease in percentage PSP is reversible and inversely related to the plasma triclopyr concentration. Therefore, triclopyr appears to effectively compete with PSP for the active secretory site within the dog kidney proximal tubules. Conversely, the monkey is insensitive to the effects of triclopyr on the active secretory process even at doses 4-fold higher (20 mg/kg/day) than the effective dose in the dog (5 mg/kg/day). These findings suggest that the effect observed on PSP and PAH excretion in the dog represents a physiological competition for excretion and not toxicity.

Evaluation of renal function in rhesus monkeys and comparison to beagle dogs following oral administration of the organic acid triclopyr (3,5,6-trichloro-2-pyridinyloxyacetic acid). Timchalk C, Finco DR, Quast JF. Fundam Appl Toxicol 1997 Mar; 36 (1), pp. 47–53.

Tubular Excretion/Renal Plasma Flow/Urine Flow/ Protein Binding: Non-Linear/Glomerular Filtration/ Tubular Secretion/Tubular Accumulation
Phenolsulfonphthalein (PSP)

Cellular/Molecular Mechanism of Action: Phenolsulfonphthalein is secreted by the proximal renal tubular epithelium.
Route of Administration: Phenolsulfonphthalein (intravenous).
Dosage: Phenolsulfonphthalein (1.0 g).
Implementation: Evaluation of the influence of probenecid or salicyluric acid (SUA) on the plasma kinetics and renal excretion of intravenous PSP. A physiologically based renal model has been developed that incorporates the functional characteristics of the kidney and is capable of determining the excretion of PSP (e.g., renal

plasma flow, urine flow, non-linear protein binding, glomerular filtration, tubular secretion, and tubular accumulation).

Animal Model: Canine (beagle dog).

Interpretation and Analysis: Pharmacokinetic analysis reveals that tubular secretion is the predominant route of excretion, and that secretion is inhibited by both SUA and probenecid. The model enables an accurate description and analysis of the measured plasma levels and renal excretion rates. The interaction with probenecid and SUA can be adequately described with the model by inhibition of the carrier-mediated uptake of PSP into the proximal tubular cells. However, both compounds clearly differ in their inhibitory action. Whereas probenecid shows simple competitive inhibition, for SUA a considerably more complex interaction (2-site competitive system) has to be taken into consideration. Especially in the interaction experiments, only satisfactory fits to the model are obtained when secretion is assumed to be dependent on unbound PSP concentrations. Model calculations show that in control experiments tubular secretion is accompanied by a pronounced accumulation of PSP within the proximal tubular cells, which is clearly diminished in the presence of SUA or probenecid. The predicted accumulation ratios are in good agreement with previous studies.

Physiologically based pharmacokinetic model for the renal clearance of phenolsulfonphthalein and the interaction with probenecid and salicyluric acid in the dog. Russel FG, Wouterse AC, van Ginneken CA. J Pharmacokinet Biopharm 1987 Aug; 15 (4), pp. 349–68.

Tubular Failure: Acute
Phenolsulfonphthalein (PSP)/Plasma Protein-Binding Changes with PSP in Acute Renal Failure (ARF)

Cellular/Molecular Mechanism of Action: Phenolsulfonphthalein is secreted by the proximal renal tubular epithelium.

Application: Phenolsulfonphthalein can be applied to detect alterations in renal tubular function such as those associated with acute and chronic kidney failure.

Route of Administration: Phenolsulfonphthalein (intravenous).

Implementation: Determine the influence of ARF on the disposition of PSP.

Animal Model: Rat (acute renal failure induced by subcutaneous injection of uranyl nitrate). In order to clarify the regulatory mechanisms of PSP excretion between liver and kidney in ARF, a simultaneous perfusion system of rat liver and kidney (rat) can be utilized that controls the flow rate and the constituent of the perfusate.

Interpretation and Analysis: Renal excretion of PSP decreases significantly in ARF compared to that in normal controls. In conditions of ARF, increases in biliary PSP excretion can be detected and reflect a process that compensates for reductions in renal excretion. Consequently no significant change can be appreciated in total body clearance of PSP between control and ARF. Binding investigations (*in vitro*) reveal that the binding fraction of PSP to plasma in conditions of ARF is significantly lower than observed in reference control plasma.

Applying the simultaneous perfusion system, neither biliary excretion nor the protein binding of PSP differs significantly between control and ARF, though its renal excretion decreases in ARF in a similar manner as observed *in vivo.* These results suggest that alterations in plasma protein binding as well as renal excretory function are determinants of PSP disposition in ARF.

Influence of acute renal failure on pharmacokinetics of phenolsulfonphthalein in rats: A comparative study *in vivo* and in the simultaneous perfusion system of liver and kidney. Yasuhara M, Katayama H, Fujiwara J, Okumura K, Hori R. J Pharmacobiodyn 1985 May; 8 (5), pp. 377–84.

Tubular Pharmaceutical Reabsorption/ Differentiation between Competitive vs Noncompetitive Tubular Absorption
Phenolsulfonphthalein (PSP)

Cellular/Molecular Mechanism of Action: Phenolsulfonphthalein is excreted by the proximal renal tubular epithelium.

Application: Evaluation of renal tubular function.

Implementation: Evaluation of the plasma kinetics and renal excretion of salicyluric acid (SUA, 0.8 g), administered intravenously with and without concomitant PSP administration.

Animal Model: Canine (beagle dog).

Interpretation and Analysis: Pharmacokinetic analysis reveals that tubular secretion is the predominant route of excretion, and that secretion is inhibited by PSP. A physiologically based kidney model can be utilized that possesses all the functional characteristics of the kidney and determine the excretion of SUA (renal plasma flow, urine flow, non-linear protein binding, glomerular filtration, tubular secretion, and tubular accumulation). The model facilitates an accurate description and analysis of measured plasma levels and renal excretion rates. The interaction with PSP can be adequately described with the model by non-competitive inhibition of a carrier-mediated uptake of SUA into the tubular cells. Furthermore, a small but significant reduction in non-renal SUA clearance can be observed. Model calculations show that, in controlled investigations, tubular secretion is accompanied by a pronounced accumulation of SUA within cells, which is clearly diminished in the presence of PSP. The predicted accumulation ratios are in good agreement with previously reported *in vitro* values.

Physiologically based pharmacokinetic model for the renal clearance of salicyluric acid and the interaction with phenolsulfonphthalein in the dog. Russel FG, Wouterse AC, van Ginneken CA. Drug Metab Dispos 1987 Sep–Oct; 15 (5), pp. 695–701.

Tubular Resorptive Capacity
Phenol Red/Bromophenol Blue/Bromothymol Blue

Cellular/Molecular Mechanism of Action: Phenol red, bromophenol blue, and bromothymol blue appear to be excreted by renal tubule acid transport mechanisms and are reabsorbed in a manner that is proportional to the glomerular load.

Application: Evaluation of renal tubule excretory function.

Route of Administration: Phenol red, bromophenol blue, and bromothymol blue (intravenous).

Implementation: Potential application includes the evaluation of renal tubule acid transport mechanisms.

Animal Model: Rabbit.

Interpretation and Analysis: Net tubular excretion of phenol red reaches a maximal value of 8 μmol/minute at a plasma concentration of ultrafilterable dye of about 0.1 mM and is decreased at higher plasma concentrations. Decreases in net tubular excretion at high plasma concentrations are also obtained for bromophenol blue and bromothymol blue, suggesting tubular reabsorption in addition to tubular secretion of the dye. Conclusive evidence for reabsorption is provided by administration of probenecid, which causes a fall in the excretion of the dyes below that filtered by the glomeruli. Tubular reabsorption of phenol red during probenecid administration appears to be proportional to the glomerular load and is increased under experimental conditions, leading to a decrease in urinary pH. Experiments involving efflux of phenol red from liposomes provides no evidence of a significant role of transmembrane passage by nonionic diffusion. The reabsorptive process is the result of preferential reabsorption of the acid as compared to the basic form of the indicator

dye across a hydrophilic pathway in the transporting membranes. Clearance ratio of phenol red to that of paraaminohippurate at low plasma concentrations is about 0.3. The low degree of extraction of phenol red from renal plasma is attributed both to tubular reabsorption and binding of the dye by plasma proteins.

Renal handling of phenol red. III. Bidirectional transport. Gerdes U, Kristensen J, Møller JV, Sheikh MI. J Physiol 1978 Apr; 277, pp. 115–29.

Urinary Bladder: Spontaneous Wall Activity
Polystyrene Fluorescent Spheres

Cellular/Molecular Mechanism of Action: Polystyrene fluorescent spheres can function as an *in vivo* detection/marker agent for evaluation of various physiological processes within body fluid compartments.
Background Information: Optical marker tracing methods have been applied successfully in recent years to quantify local (focal) mechanical deformation of heart tissue, skin, and striated muscles.
Application: Detection and characterization of physiological processes and pathological anomalies affecting body fluid compartments.
Route of Administration: Direct delivery.
Implementation: Evaluation of spontaneous bladder wall activity and responses following electrical stimulation of bladder innervating nerve fibers. One approach to acquiring such functional information can entail gluing polystyrene fluorescent spheres (d = 0.6 mm) to the ventral serosal bladder wall. Three-dimensional video registration of the polystyrene spheres can be used to calculate 2 directions of principal strain (epsilon-1, epsilon-2) on the bladder surface *in vivo.*
Animal Model: Rabbit (bladder serosal surface).
Interpretation and Analysis: During spontaneous activity, random contraction and relaxation occurs simultaneously and separately across the bladder wall for the 2 principal epsilon-1 and epsilon-2 strains. After extradural electrical stimulation of sacral nerve root S2, the principal strains epsilon-1 and epsilon-2 synchronize in time in such a way that epsilon-1 and epsilon-2 both represent contraction or both represent relaxation. One and the same bladder wall area passes through phases of contraction followed by relaxation and vice versa. After multiple stimulation periods, the coordination between the 2 principal strains during stimulation is reduced. The technique applied allows *in vivo* identification of local areas of contraction and relaxation in the intact bladder wall. Three-dimensional video detection of polystyrene fluorescent spheres to study bladder wall contraction and its relaxation proved to be a feasible technique, with which electrical stimulation effects and spontaneous activity could be measured.

Three-dimensional registration of mechanical bladder activity using polystyrene fluorescent spheres: A technical note. Kinder MV, Bos R, Willems PJ, Drost MR, Holtzer CA, Janknegt R, Marani E. Arch Physiol Biochem 1999 Jul; 107 (3), pp. 236–41.

REPRODUCTIVE SYSTEM

Amniotic Fluid Volume Estimation
Aminohippurate Sodium

Cellular/Molecular Mechanism of Action: Aminohippurate sodium can be applied as a tracer molecule to monitor physiological processes and estimate fluid compartment volumes.
Application: Utilization of aminohippurate sodium as a reagent for a dye-dilution technique suitable for accurately measuring amniotic fluid volume.
Route of Administration: Variable (amniotic fluid volume).
Implementation: Estimation of amniotic fluid volume assessed by the dye-dilution technique compared to direct measurements determined in singleton pregnancies with intact membranes undergoing a cesarean delivery.
Human Model: Women (n = 15; cases with amniocentesis at delivery n = 6; cesarean delivery n = 9 with samples collected 4–24 hours prior to surgery).
Interpretation and Analysis: Good concordance between the dye-determined and direct measurement of amniotic fluid volume can be appreciated in women undergoing amniocentesis (e.g., n = 6/6 cases; r = 0.99, p = < 0.001). Among women with varying times from amniocentesis to direct measurement, the correlation is not significant (e.g., n = 9 cases; r = 0.36, p = 0.08). The percent difference between dye-determined and directly measured amniotic fluid volume is significantly smaller in women undergoing amniocentesis just prior to delivery (7%) compared to women with varying times from amniocentesis to delivery (37%, p < 0.001). Dye-determined amniotic fluid volume accurately reflects actual amniotic fluid volume but the dye-determined concentrations, *in vivo,* may undergo rapid changes.

Dye-dilution techniques using aminohippurate sodium: Do they accurately reflect amniotic fluid volume? Magann EF, Whitworth NS, Files JC, Terrone DA, Chauhan SP, Morrison JC. J Matern Fetal Neonatal Med. 2002 Mar; 11 (3), pp. 167–70.

Mammary Gland Disease Differentiation/Optical Imaging
Indocyanine Green (ICG)/Gadolinium/Near-Infrared (NIR) Diffuse Optical Tomography

Cellular/Molecular Mechanism of Action: Indocyanine green is an albumin-bound absorbing dye.
Background Information: One of the advantages for applying NIR fluorescence light in imaging modalities for various *in vivo* biological processes is related to its ability to penetrate tissues more efficiently than light in the visible spectrum.
Application: Indocyanine green is an absorbing dye commonly used as a marker system within the plasma compartment. Under certain conditions, ICG possesses the potential to differentiate between diseased and normal tissues based on the quantified enhancement of suspicious lesions using magnetic resonance imaging (MRI) applied concurrently with NIR diffuse optical tomography (contrast enhancement properties).
Route of Administration: Intravascular.
Implementation: Near-infrared diffuse optical tomography (DOT) analysis of the mammary gland applied in combination/concurrently with MRI analysis. Results are then correlated with findings from histopathological evaluation of suspicious lesions.
Human Model: Cases scheduled for excisional biopsy or surgery.
Interpretation and Analysis: The ICG-enhanced optical images co-register accurately with gadolinium-enhanced magnetic resonance images, thereby validating the ability of DOT to image breast tissue. In contrast to simple transillumination, DOT appears to provide for localization and quantification of exogenous tissue chromophore concentrations. Additionally, ICG has demonstrated a potential to differentiate disease based on the quantified enhancement of suspicious lesions.

Concurrent MRI and diffuse optical tomography of breast after indocyanine green enhancement. Ntziachristos V, Yodh AG, Schnall M, Chance B. Proc Natl Acad Sci U S A. 2000 Mar 14; 97 (6), pp. 2767–72.

Sperm: Viability and Intracellular Calcium
Fluorescent Calcium Indicator [Indo-1]/ Chlortetracycline (CTC) Fluorescent Assay

Background Information: Cryopreserved bovine semen is less fertile than fresh semen for reasons that have not been fully elucidated. Cryopreservation is known to disrupt the sperm plasma membrane and it induces premature capacitation of sperm subpopulations, which may be a result of the increased internal calcium levels after thawing.
Application: Assessement of sperm viability.
Route of Administration: Topical *in vitro* bathing.
Implementation: Evaluation of the relationship between the fertility of cryopreserved/thawed sperm and (i) intracellular calcium levels assessed by the application of fluorescent calcium indicators (indo-1), and flow cytometry analysis; or (ii) their physiological status determined by the CTC fluorescent assay.

Animal Model: Bovine (sperm collected from fertile and nonfertile bulls).
Interpretation and Analysis: As detected by indo-1 fluorescence, intracellular calcium levels negatively correlate with bull fertility immediately after thawing ($p = 0.0362$; $n = 3$ ejaculates from each of 10 animals). Moreover, there is a significant difference between the 3 most and least fertile bulls in a herd over 4-hour incubation periods (e.g., $p < 0.05$; $n = 3$ ejaculates/bull). There is a positive correlation between sperm displaying the CTC acrosome reaction pattern and fertility ($p = 0.0014$; $n = 3$ ejaculates from each of 10 bulls).

Sperm calcium levels and chlortetracycline fluorescence patterns are related to the *in vivo* fertility of cryopreserved bovine semen. Collin S, Sirard MA, Dufour M, Bailey JL. J Androl 2000 Nov–Dec; 21 (6), pp. 938–43.

Urogenital: Cervical Cell Types: Biopsy Tissues/ Differentiation of Normal vs Abnormal/Cell Nuclei Visualization
Acetic Acid Enhancement

Cellular/Molecular Mechanism of Action: Acetic acid chemically modifies the physical properties of different cellular constituents.
Application: The use of high-resolution *in vivo* confocal imaging may offer a clinically useful adjunct to standard methods for the diagnosis and screening of epithelial precancers.
Implementation: Evaluate the feasibility of real-time confocal reflectance imaging of cervical tissue and the use of acetic acid as a contrast agent to increase visualization of cell nuclei.

***Ex Vivo* Model:** Confocal microscopy image evaluation of cervical cells and colposcopically normal and abnormal cervical biopsy specimens. Images are obtained before and after the application of 6% acetic acid.
Interpretation and Analysis: Confocal microscopy imaging can resolve subcellular detail throughout the entire epithelial thickness. Normal and abnormal tissues are clearly able to be differentiated. Addition of acetic acid enhances nuclear signals in all acquired images. High-contrast reflected light images of cervical tissue are attainable in near real time. Acetic acid significantly increases light scattering from cell nuclei, which may partially explain why acetowhitening occurs.

Laser scanning confocal microscopy of cervical tissue before and after application of acetic acid. Drezek RA, Collier T, Brookner CK, Malpica A, Lotan R, Richards-Kortum RR, Follen M. Am J Obstet Gynecol. 2000 May; 182 (5), pp. 1135–9.

RESPIRATORY SYSTEM

Surfactant Distribution
Fluorescent Bodipy-Labeled Surfactant Protein B

Cellular/Molecular Mechanism of Action: Surfactant lowers the viscous tension of pulmonary fluid in a manner that prevents collapse of terminal alveoli.
Application: Fluorescent Bodipy-labeled surfactant protein B can be applied to determine the distribution of endotracheally administered surfactant at the alveolar level in an animal model of acute respiratory distress syndrome.
Route of Administration: Intratracheal.
Semi-Synthetic Methods: Covalent conjugation/cross-linking of fluorescent Bodipy-labeled surfactant protein B.
Implementation: To measure surfactant distribution *in vitro,* a glass trough mimicking dichotomic lung anatomy can be used to determine the spreading properties of bovine lung surfactant extract supplemented with fluorescent Bodipy-labeled surfactant protein B. To measure surfactant distribution *in vivo,* anesthetized rats are exposed to aerosolized lipopolysaccharide (12 mg/kg body weight) to induce lung injury that resembles acute respiratory distress syndrome. In control rats, buffered saline is alternatively aerosolized. Twenty-four hours later rats are anesthetized, tracheotomized, and mechanically ventilated (peak airway pressure = 20 mbar; positive end-expiratory pressure = 6 mbar; inspiration time = expiration time = 0.6 seconds; Fio2 = 50%). Surfactant (bovine lung surfactant extract, supplemented with fluorescent Bodipy-labeled surfactant protein B; 50 mg/kg body weight) is given as a bolus; in control rats, a bolus of saline is administered. Rats are then ventilated for 5, 15, 30, or 60 minutes ($n = 8$ or 9 for each group) and their lungs excised and sliced. Lung slices, divided into aerated (open), underinflated (dystelectatic), or collapsed (atelectatic) alveolar areas are subsequently examined by both light and fluorescence microscopy.
Interpretation and Analysis: Surfactant spreads independent of glass trough geometry and lowers the surface tension to equilibrium values (25 mN/m) within a few seconds in *in vitro* preparations. Administration of surfactant *in vivo* distributes preferentially into underinflated and aerated alveolar areas. Surfactant distribution is not affected by length of mechanical ventilation. When conventional mechanical ventilation is used in lipopolysaccharide-induced lung injury, surfactant preferentially distributes into underinflated and aerated alveolar areas. Because surfactant rarely reaches collapsed alveolar areas, methods aiding in alveolar recruitment (e.g., open lung concept or body positioning) should precede surfactant administration.

In vitro and *in vivo* intrapulmonary distribution of fluorescently labeled surfactant. Diemel RV, Walch M, Haagsman HP, Putz G. Crit Care Med 2002 May; 30 (5), pp. 1083–90.

SEPSIS

Sepsis: *Escherichia Coli* (O157:H7)
Adenosine Triphosphate (ATP)/In Vivo Bioluminescence/Immunomagnetic Absorbance

Application: Development of methods for assessing the efficiency of immunomagnetic separation (IMS).

Implementation: Evaluation of the capturing efficiency of biosorbents for *E. coli* O157:H7, constructed using streptavidin-coated magnetic beads and biotinylated antibodies, using both *in vivo* and ATP bioluminescence.

Interpretation and Analysis: Both methods are suitable for the enumeration of bacteria captured by the biosorbents. The level of both ATP and *in vivo* bioluminescence depends on the media used but is unaffected by magnetic beads. The capture efficiency depends on time and sample volume but does not depend on the length of spacer arm of the biotinylation agent. For cell concentrations of $\leq$ 105 cfu/ml, in a 1-ml sample volume, nearly 80–85% recovery of the pathogen can be observed after 0.5 hours of incubation. For an 11-ml sample containing 104 cfu/ml, maximum recovery (50% of cells) is achieved only after 2 hours incubation. The detection limit of an ATP-based bioluminescent assay for *E. coli* O157:H7 can be reduced by 1 log cycle after optimization of IMS. The bioluminescent methods can be used for screening and testing the affinity of antibodies or other affinity elements of biosorbents toward live bacterial cells. Bioluminescent assays provide an easy way to optimize conditions for the capture of bacteria by biosorbents in real time.

Comparison of ATP and *in vivo* bioluminescence for assessing the efficiency of immunomagnetic sorbents for live *Escherichia coli* O157:H7 cells. Sun W, Khosravi F, Albrechtsen H, Brovko LY, Griffiths MW. J Appl Microbiol 2002; 92 (6), pp. 1021–7.

17 Magnetic Resonance Imaging (MRI)

MRI: GENERAL CONCEPTS AND PRINCIPLES

MRI: Concepts and Principles/Hepatic Disease

Magnetic resonance imaging relies on the physical properties of unpaired protons in tissues to generate images. Unpaired protons behave like tiny bar magnets and will align themselves in a magnetic field. Radiofrequency pulses will excite these aligned protons to higher energy states. As they return to their original state, they will release this energy as radio waves. The frequency of the radio waves depends on the local magnetic field, and by varying this over a subject, it is possible to arrange or build anatomical images. In general, MRI has not been sufficiently sensitive or specific in the assessment of diffuse liver disease for clinical use. However, because of the specific characteristics of fat and iron, it may be useful in the assessment of hepatic steatosis and iron overload. Magnetic resonance imaging is useful in the assessment of focal liver disease, particularly in conjunction with contrast agents. Hemangiomas have a characteristic bright appearance on T_2-weighted images because of the slow-flowing blood in dilated sinusoids. Focal nodular hyperplasia (FNH) has a homogenous appearance and enhances early in the arterial phase after gadolinium injection, while the central scar typically enhances late. Hepatic adenomas have a more heterogenous appearance and also enhance in the arterial phase, but less briskly than FNH. Hepatocellular carcinoma is similar to an adenoma but typically occurs in a cirrhotic liver and has earlier washout of contrast. The appearance of metastases depends on the underlying primary malignancy. Overall, MRI appears more sensitive and specific than computed tomography with contrast for the detection and evaluation of malignant lesions.

Magnetic resonance imaging and diseases of the liver and biliary tract. Part 1. Basic principles, MRI in the assessment of diffuse and focal hepatic disease. Macdonald GA, Peduto AJ. J Gastroenterol Hepatol 2000 Sep; 15 (9), pp. 980–91.

MRI: Concepts and Mechanisms/Hepatic Disease

Magnetic resonance cholangiography (MRC) relies on the strong T_2 signal from stationary liquids, in this case bile, to generate images. No contrast agents are required, and the failure rate and risk of serious complications is lower than with endoscopic retrograde cholangiopancreatography (ERCP). Data from MRC can be summated to produce an image much like the cholangiogram obtained by using ERCP. In addition, MRC and conventional MRI can provide information about the biliary and other anatomy above and below a biliary obstruction. This provides information for therapeutic intervention that is probably most useful for hilar and intrahepatic biliary obstruction. Magnetic resonance cholangiography (MRC) appears to be similar to ERCP with respect to sensitivity and specificity in detecting lesions causing biliary obstruction, and in the diagnosis of choledocholithiasis. It is also suited to the assessment of biliary anatomy (including the assessment of surgical bile-duct injuries) and intrahepatic biliary pathology. However, ERCP can be therapeutic as well as diagnostic, and MRC should be limited to situations where intervention is unlikely, where intrahepatic or hilar pathology is suspected, to delineate the biliary anatomy prior to other interventions, or after failed or inadequate ERCP. Magnetic resonance angiography (MRA) relies on the properties of flowing liquids to generate images. It is particularly suited to assessment of the hepatic vasculature and appears as good as conventional angiography. It has been shown to be useful in delineating vascular anatomy prior to liver transplantation or insertion of a transjugular intrahepatic portasystemic shunt. Magnetic resonance angiography may also be useful in predicting subsequent variceal hemorrhage in patients with esophageal varices.

Magnetic resonance imaging and diseases of the liver and biliary tract. Part 2. Magnetic resonance cholangiography and angiography and conclusions. Macdonald GA, Peduto AJ. J Gastroenterol Hepatol 2000 Sep; 15 (9), pp. 992–9.

MRI: Concepts for Masses (Soft Tissue)
Intravenous Contrast Agents/Oral Contrast Agents

Cross-sectional imaging of the abdomen in oncology patients presents unique challenges and opportunities. A close working relationship between the oncologist and radiologist is essential for the exchange of the clinical and imaging information necessary for optimizing patient diagnosis and management. Compared to helical computed tomography (CT), MRI of the abdomen and pelvis offers important advantages, including superior soft-tissue contrast. The multiplanar capabilities of MRI allow for direct coronal or sagittal imaging, providing a truer anatomic presentation of abdominal and pelvic masses. Recent advances in MRI, including the use of intravenous (i.v.) and oral contrast agents, the development of high-performance imagers, and improved surface coil designs, facilitate more rapid abdominal imaging with superior image quality. All of these features combine to produce a versatile imaging examination with exquisite sensitivity for depicting abdominal and pelvic tumors. In this context, they have clinical applicability for hepatic and extrahepatic abdominal MRI in the oncology patient. Techniques and protocols for MRI can be applied to most commercially available high-field MRI instrumentation.

Magnetic resonance imaging of the abdomen: Applications in the oncology patient. Low RN. Oncology (Huntingt) 2000 Jun; 14 (6 Suppl 3), pp. 5–14.

MRI: Concepts and Perspectives/Recent Trends in Contrast Agent Development for MRI/ Contrast-Enhancing Imaging Agents

Historically, small molecular weight gadolinium chelates have functioned as the predominant MRI contrast-enhancing agents. These 1st-generation MR contrast agents distribute into the intravascular and interstitial space, thus allowing the evaluation of physiological parameters, such as the status or existence of the blood-brain barrier or the renal function. Shortly after the 1st clinical use of paramagnetic metallochelates in 1983, several compounds were proposed as potential image-enhancing agents for the liver and cardiac infarcts. Meanwhile, liver-specific contrast agents based on gadolinium, manganese, or iron became a reality. Dedicated blood-pool agents will become available in the near future. These gadolinium or iron-based agents will be beneficial for longer-lasting MRA procedures, such as

cardiac imaging. Contrast-enhanced lymphography after interstitial or intravenous injection will facilitate achieving major steps forward in diagnostic imaging. Metastatic involvement will be seen either after the injection of ultrasmall superparamagnetic iron oxides or dedicated gadolinium chelates. The accumulation of both classes of compounds is triggered by intracellular uptake by macrophages. It is likely that similar agents will augment MRI of atheriosclerotic plaques, a systemic inflammatory disease of the arterial wall. Thrombus-specific agents based on small gadolinium-labeled peptides are currently in development. It is very obvious that the future of cardiovascular MRI will benefit from the development of new paramagnetic and superparamagnetic substances. The expectations for new tumor-, pathology-, or receptor-specific agents are high. However, it is not likely that such a compound will be available for daily routine MRI within the next decade.

Tissue-specific MR contrast agents. Weinmann HJ, Ebert W, Misselwitz B, Schmitt-Willich H. Eur J Radiol 2003 Apr; 46 (1), pp. 33–44.

Phantoms for Computed Tomograph (CT) and MRI
Barium Sulfate-Loaded Agarose Gel/Iodinated Contrast-Loaded Agarose Gel

Cellular/Molecular Mechanism of Action: Iodinated compounds and barium preparations possess radiopaque properties.
Application: Standardization of computed tomography and MRI analyses.
Considerations: Phantom studies are an important part of the evaluation of imaging techniques; however, presently available phantom construction materials are not adequate for studies involving both MRI and CT. It is possible to design a phantom constructed of material useful for multimodality imaging purposes.
Implementation: Iodinated contrast agent or $BaSO_4$ is added to preparations of agarose gels. Both CT and MRI are then performed, and T_1 and T_2 values and CT numbers (in Hounsfield units) are obtained for multiple combinations of contrast materials and agarose.
Interpretation and Analysis: The T_2 values of agarose gels span the range of those values found in biologic tissues. Phantoms containing iodinated contrast agent are not stable because the contrast agent diffuses across concentration gradients. Alternatively, $BaSO_4$-loaded agarose phantoms are stable, and varying barium concentrations produce phantoms that span the range of CT numbers found in biologic tissues. Addition of $BaSO_4$ does not substantially alter T_1 or T_2 values of agarose gels. Agarose concentration has only a small effect on the CT numbers of $BaSO_4$ suspensions.

Agarose gels loaded with $BaSO_4$ represent an effective material for constructing multimodality imaging phantoms. It provides adequate signal intensity for MRI and attenuation for CT, with independently variable contrast in both modalities.

$BaSO_4$-loaded agarose: A construction material for multimodality imaging phantoms. Litt HI, Brody AS. Acad Radiol 2001 May; 8 (5), pp. 377–83.

REACTIONS TO CONTRAST AGENTS

Adverse Reactions: Incidence and Frequency of Reactions to MRI Contrast Agents
Gadodiamide/Gadoteridol

Cellular/Molecular Mechanism of Action: Gadolinium-based compounds.
Application: Magnetic resonance contrast agent for angiography imaging procedures.
Implementation: Conduction of a survey by the American Society of Neuroradiology regarding the incidence of adverse reactions to gadolinium-based contrast agents, the contrast agents responsible, and the management of patients with allergy-like reactions to iodinated or gadolinium-based agents who required MR contrast agent administration.
Interpretation and Analysis: Review and interpetation of a survey from 105 centers (50.5% response rate) regarding a total of 687,255 gadopentetate dimeglumine injections. The approximate rate of adverse non-allergic reactions is 0.046% (e.g., n = 314/687,255) in addition to (i) 0.016% mild reactions (e.g., n = 107/687,255); (ii) 0.004% moderate (e.g., n = 28/687,255); and (iii) 0.001% severe (e.g., n = 5/687,255). Alternatively, of 74,275 recorded injections of gadodiamide, approximately (i) 0.015% (e.g., n = 11/74,275) non-allergic reactions; and (ii) 0.016% mild allergic-like reactions (e.g., n = 12/74,275) can be anticipated to occur. Of 64,005 gadoteridol administrations, reactions can be categorized as (i) 0.267% non-allergic reactions (e.g., n = 171/64,005); (ii) 0.077% mild (e.g., n = 49/64,005); (iii) 0.047% moderate (e.g., n = 29/64,005); and (iv) 0.017% severe (e.g., n = 11/74,275) allergy-like reactions. In one survey, twenty-six radiology departments take no precautions for cases with a previous history of allergy-like reactions to iodinated contrast material. Nineteen radiology departments do not premedicate cases that report previous reactions to gadolinium-based agents before repeat administration of MR contrast agents. Although MR contrast agents are safe, adverse reactions occur. Many centers have not adopted policies for cases with a history of adverse reactions.

Occurrence of adverse reactions to gadolinium-based contrast material and management of patients at increased risk: A survey of the American Society of Neuroradiology Fellowship Directors. Murphy KP, Szopinski KT, Cohan RH, Mermillod B, Ellis JH. Acad Radiol 1999 Nov; 6 (11), pp. 656–64.

Adverse Reactions: Cardiovascular and Hemodynamic Effects/Systemic and Pulmonary Circulation Pressure Flow Dynamics
Gadolinium ([Gd]-DTPA)/Diatrizoate/Iopamidol

Cellular/Molecular Mechanism of Action: Gadolinium and iodinated compound possess radiopaque properties.
Application: Conventionally, gadolinium in the form of [Gd]-DTPA, diatrizoate (ionic), and iopamidol (non-ionic) can be used as positive contrast image-enhancing agents for the detection of anatomical anomalies affecting the cardiovascular system (conventional radiography and MRI).
Route of Administration: [Gd]-DTPA, diatrizoate, and iopamidol can all be given as a bolus intravascular injection for the detection of anatomical anomalies affecting the cardiovascular system.
Dosage: Gadopentate dimeglumine ([Gd]-DTPA [Magnevist] at high dose = 0.6 mmol/kg or 1.2 ml/kg in swine). Diatrizoate (Urografin 76% at high dose = 0.6 mmol/kg or 1.2 ml/kg in swine). Iopamidol (Solutrast 370% at high dose = 0.6 mmol/kg or 1.2 ml/kg in swine).
Implementation: Evaluation of the hemodynamic reactions induced by high-dose gadopentetate dimeglumine compared with the side effects of high-dose ionic (diatrizoate: Urografin 76%) and non-ionic (iopamidol: Solutrast 370%) radiographic contrast media.
Study Design: Assessement of pressure and flow of the systemic and pulmonary circulation following intracardiac bolus injections delivered over a time period of 2 to 4 seconds (e.g., n = 18 swine).
Interpretation and Analysis: Gadolinium, diatrizoate, and iopamidol all transiently decrease aortic pressure ([Gd]-DTPA and

diatrizoate: −25%, iopamidol: −10%; $p < 0.01$). Pulmonary artery pressure, cardiac output, and stroke volume remain increased for several minutes while vascular resistance declines. Diatrizoate induces stronger and longer-lasting side effects ($p < 0.01$) than [Gd]-DTPA and iopamidol. Despite similar osmolalities, [Gd]-DTPA induces weaker side effects than equivolumetric applications of diatrizoate. Other than osmolality, other factors such as viscosity and chemotoxicity also influence the occurence of contrast media–associated side effects.

Gadopentetate dimeglumine and iodinated contrast media. Hemodynamic side effects after bolus injections in pigs. Kuhtz-Buschbeck JP, Ehrhardt K, Kohnlein S, Radtke W, Heintzen P. Invest Radiol 1997 Feb; 32 (2), pp. 111–9.

Adverse Reactions: Hemodialysis Cases
Gadolinium

Implementation: Meassurement of serum gadolinium concentrations in hemodialysis cases following administration of gadolinium MR contrast-image-enhancing agent (e.g., n = 70). Serum gadolinium concentrations are then measured before and after hemodialysis sessions. Cardiovascular, cutaneous, respiratory, psychoneurological, and digestive side effects are also evaluated in concert with any changes in liver and kidney functions, blood counts, and electrolytes.

Hemodialysis Schedule: Hemodialysis performed either on the same day (e.g., n = 16), day 1 (e.g., n = 34), day 2 (e.g., n = 14), or day 3 (e.g., n = 6), and then on a conventional schedule (3 times/week for 4 hours/session).

Interpretation and Analysis: Neither side effects nor blood changes can be appreciated in any of the hemodialysis cases. Average excretory rates are 78.2%, 95.6%, 98.7%, and 99.5% in the 1st to 4th hemodialysis sessions, respectively. Therefore, [Gd] contrast agents can be used in hemodialysis patients if hemodialysis is carried out promptly after performing diagnostic procedures.

Safety of gadolinium contrast agent in hemodialysis patients. Okada S, Katagiri K, Kumazaki T, Yokoyama H. Acta Radiol 2001 May; 42 (3), pp. 339–41.

Adverse Reactions: Renal Dysfunction
Gadolinium/Digital Subtraction Angiography (DSA)

Background Information: To prevent iodinated contrast medium–induced nephrotoxicity, gadolinium has been used increasingly for MR angiography (MRA) or conventional DSA to visualize arterial anatomy in patients undergoing vascular surgery who are considered at high risk because of chronic renal insufficiency.

Application: Postive contrast imaging agent in DSA and MRI procedures.

Dosage: Gadolinium-based contrast agents (≥ 0.25 mmol/kg).

Implementation: Contrast enhancement of images acquired by MR and DSA procedures.

Experimental Model: Single-center retrospective study evaluating the extent of nephrotoxicity induced during the course of MRA procedures (e.g., n = 218) and cases evaluated by DSA (e.g., n = 42) that applied gadolinium as the sole contrast agent (December 1999 to January 2001). Patient comorbid conditions, indications for vascular imaging, contrast dose, urine output, baseline and post-procedure serum creatinine concentration (SCr), and outcome are relevant variables that can provide insight into the relative toxicity of gadolinium contrast media and biological/physiological factors that may contribute to the development of such sequelae.

Interpretation and Analysis: In cases with preimage baseline chronic renal insufficiency, approximately 3.5% will develop acute renal failure following administration of gadolinium-based contrast preparations (e.g., n = 7/195; n = 3/153 MRA; n = 4/42 DSA). In cases classified as having baseline chronic renal insufficiency, serum creatinine concentrations can average approximately 38.2 ± 1.6 Ml/min/1.73 m^2, in contrast to values of 32.5 ± 7.8 Ml/min/1.73 m^2 for conditions of acute renal failure ($p = 0.33$). Doses for gadolinium in cases demonstrating renal failure postinjection can range from 0.31 to 0.41 mmol/kg for MRA and 0.27 to 0.42 mmol/kg for DSA procedures. Interestingly, acute renal failure rarely develops in cases with normal baseline serum creatinine levels (e.g., n = 0/65).

Despite reports of negligible nephrotoxicity, gadolinium-based contrast agents rarely cause acute renal failure in instances where underlying chronic renal insufficiency exist. Estimation of creatinine clearance alone does not enable accurate prediction of which cases are likely to develop acute renal failure. Cases at high risk should be identified, and prophylactic measures exercised to reduce the risk of induced nephrotoxicity.

Safety of gadolinium contrast angiography in patients with chronic renal insufficiency. Sam AD 2nd, Morasch MD, Collins J, Song G, Chen R, Pereles FS. J Vasc Surg 2003 Aug; 38 (2), pp. 313–8.

Adverse Reactions: Renal Dysfunction
Gadolinium Chelates

Background Information: Gadolinium chelates are mainly eliminated by the kidney.

Considerations: Limited information exists about the effects of gadolinium chelates eliminated by the kidney.

Implementation: Evaluation of the renal tolerance and renal function associated with these compounds in an *in vivo* rat model. A combination of renal ischemia and intrarenal iodinated contrast agent infusion (diatrizoate) can function as a reproducible and reversible model of acute renal failure (n = 5). Using this model, the renal tolerance of gadolinium DOTA ([Gd]-DOTA) (n = 10) and gadolinium DTPA ([Gd]-DTPA) (n = 10) can be evaluated, along with determination of the association between the administration of [Gd]-DOTA with diatrizoate (n = 5) and changes in renal function.

Interpretation and Analysis: [Gd]-DOTA induces no change in serum creatinine and creatinine clearance. Gadolinium DTPA induces a significant increase in serum creatinine (50–83 ± 5 and 70 ± 6 μmol/L) before and at 24 and 48 hours, respectively ($p < 0.05$), and a decrease in creatinine clearance from 1.6 ± 0.1 to 0.8 ± 0.1; 1.2 ± 0.1 Ml/Ml before and at 24 and 48 hours, respectively ($p < 0.05$). In this model, [Gd]-DOTA does not modify the renal tolerance of diatrizoate as assessed with serum creatinine and creatinine clearance. Gadolinium DOTA is not nephrotoxic and can be infused in association with iodinated contrast media. In this model, [Gd]-DTPA induces reversible renal failure.

Renal tolerance of gadolinium-DOTA and gadolinium-DTPA in rats. Brillet G, Dubois M, Beaufils H, Bourbouze R, Deray G. Invest Radiol 1994 Mar; 29 (3), pp. 352–4.

Adverse Reaction: Renal Dysfunction/Coronary Angiography: Catheterization Procedures
N-Acetylcysteine

Physiological Mechanism of Action: Traditionally, N-acetylcysteine is applied as a mucolytic agent and as an antidote in the treatment of acetaminophen poisoning, where it functions as a molecular strategy for replenishing hepatic glutathione stores. Glutathione is a reducing antioxidant reagent.

Application: N-acetylcysteine in cases undergoing computerized tomography with intravenous contrast to reduce the incidence of acute renal dysfunction.

Implementation: Administration of N-acetylcysteine (n = 3 doses) prior to cardiac catheterization studies.

Human Model: Cardiac catheterization cases (e.g., n = 5) and "historical" controls (e.g., n = 55) utilized for reference comparison (e.g., total n = 60 with baseline serum creatinine > 1.2 mg/dl and hydrated intravenously before and after catheterization procedures). Baseline creatinine values (N-acetylcysteine = 2.0 ± 0.7 vs no N-acetylcysteine 1.8 ± 0.4 mg/dl; p = 0.04). The amount or type of contrast agent used is consistent and uniform.

Interpretation and Analysis: Univariate analysis of clinical variables reveals no significant difference between cases receiving N-acetylcysteine and those that do not. The mean change in creatinine after 48 hours is −0.4 ± 0.3 (N- acetylcysteine) vs +0.1 ± 0.3 mg/dl for controls ($p < 0.001$). In cases with baseline creatinine > 2 mg/dl, the benefit is larger (−0.4 ± 0.4 vs +0.5 ± 0.3 mg/dl; $p < 0.001$). Multivariate analysis confirms speculation that pretreatment with N-acetylcysteine can produce information that can be applied as an independent predictor of renal protection ($p < 0.001$). Prophylactic use of acetylcysteine therefore prevents declines in renal function after coronary angiography. The benefit is greater in patients with baseline serum creatinine > 2 mg/dl.

Prevention of radiocontrast-induced nephropathy with N-acetylcysteine in patients undergoing coronary angiography. Tadros GM, Mouhayar EN, Akinwande AO, Campbell B, Wood C, Blankenship JA. J Invasive Cardiol 2003 Jun; 15 (6), pp. 311–4.

Adverse Reactions: Sequellae
Gadopentetate Dimeglumine

Route of Administration: Gadopentetate dimeglumine (intravascular).

Dosage: Gadopentetate dimeglumine (0.1 mmol/kg).

Implementation: Magnetic resonance imaging after intravenous administration of 0.1 mmol/kg gadopentetate dimeglumine (e.g., n = 15,496 cases).

Interpretation and Analysis: Adverse reactions are approximately 2.4% of all MRI procedures (e.g., n = 372/15,496). Symptoms abated the same or next day in 94.1% of cases (e.g., n = 350/372). Onset of signs occurs within 30 minutes after injection 49.7% of the time (e.g., n = 185/372), with the onset occurring more than 1 hour after injection in 44.9% of cases (e.g., n = 167/372). A very small percentage of cases may experience serious adverse reactions attributable to underlying disease conditions (e.g., n = 2/372). The rate of adverse reaction is 3.7% in patients with a history of asthma (e.g., n = 31/831 patients) or allergy (e.g., n = 144/3,860 patients). In scenarios where a history exists regarding previous reactions to MRI or iodinated contrast agents the adverse-reaction rate is approximately 21.3% (e.g., n = 16/75) and 6.3% (e.g., n = 54/857), respectively. The rate of adverse reaction is 2.2% with slow administration of gadopentetate dimeglumine compared to approximately 2.9% when injected rapidly.

Clinical safety of gadopentetate dimeglumine. Nelson KL, Gifford LM, Lauber-Huber C, Gross CA, Lasser TA. Radiology 1995 Aug; 196 (2), pp. 439–43.

Adverse Reactions/Sequellae and Relative Safety Compared to Computed Tomography (CT) Contrast Agents/Pancreatitis Animal Model in Rats
Gadolinium-DTPA ([Gd]-DTPA)/Fluorescein Isothiocyanate-Labeled Erythrocytes

Cellular/Molecular Mechanism of Action: The physical orientation of gadolinium is modified when subjected to magnetic energy fields that can be detected by MRI instrumentation.

Background Information: Contrast-enhanced computed tomography (CECT) has been proposed as a gold standard for early evaluation of acute necrotizing pancreatitis. However, iodinated contrast media used for CECT have been shown under certain circumstances to reduce pancreatic capillary flow and increase necrosis and mortality. Recent reports suggest that post-[GD] MRI provides images comparable to CECT in the assessment of severe acute pancreatitis.

Application: Potential MRI image-enhancing agent where it can be applied as a staging tool for assessing acute pancreatitis where it can provide improved levels of safety compared to CT contrast imaging agents.

Route of Administration: [Gd]-DTPA (bolus intravenous injection).

Dosage: [Gd]-DTPA (0.2 Ml/kg).

Implementation: Validation of the safety of [Gd]-DTPA through measurement of its effect on pancreatic capillary perfusion and acinar injury in acute pancreatitis. Evaluation of necrotizing pancreatitis utilizing [Gd]-DTPA for contrast-enhanced computed tomography imaging. Intravital microscopic quantitation of pancreatic capillary blood flow is performed using fluorescein isothiocyanate-labeled erythrocytes after induction of pancreatitis and 30 and 60 minutes after intravenous [Gd]-DTPA administration. Experimental and negative reference controls are compared with regard to mean arterial pressure, heart rate, arterial blood gases, hematocrit, amylase, lipase, and trypsinogen activation peptide production throughout the evaluation period.

Animal Model: Rat (e.g., n = 14 Wistar rats) utilized in a model for necrotizing pancreatitis induced by intraductal glycodeoxycholic acid (10 Mm/L) and intravenous caerulein (5 μg/kg/h) administered over a 6-hour infusion period.

Interpretation and Analysis: [Gd]-DTPA does not reduce capillary flow (1.93 ± 0.05 Nl/capillary/min) compared to the infusions with Ringer's solution (1.90 ± 0.06 Nl/capillary/min). Intravenous injection of [Gd]-DTPA does not further impair pancreatic microcirculation or increase acinar injury in acute necrotizing pancreatitis. Because of this advantage over CT contrast medium, further development of MRI as a staging tool in acute pancreatitis appears to be indicated.

The relative safety of MRI contrast agent in acute necrotizing pancreatitis. Werner J, Schmidt J, Warshaw AL, Gebhard MM, Herfarth C, Klar E. Ann Surg 1998 Jan; 227 (1), pp. 105–11.

Adverse Reactions/Subarachnoid Spaces/ Craniospinal and Cerebrospinal Fluid Leaks/ Subarachnoid Space Flow
Gadopentetate Dimeglumine/ Contrast Myelogram and Contrast Cisternogram

Dosage: Gadopentetate dimeglumine (0.5 ml, 0.7 ml, 0.8 ml or 1.0 ml: Magnevist; Schering, Berlin, Germany).

Implementation: Intrathecal contrast myelogram or cisternogram is performed via lumbar puncture (20–25 gauge needle). Approximately 3–5 mL/ml of cerebrospinal fluid is withdrawn and mixed with a single volume of 0.5 (n = 63), 0.7 (n = 13), 0.8 (n = 12), or 1.0 (n = 7) cc/mL of gadopentetate dimeglumine and then injected into the subarachnoid space. Immediate and delayed (up to 96 hours) T_1- and T_2-weighted MRI are acquired on superconductive, high-field (1.0–1.5 tesla) imaging units in 2 or 3 planes.

Human Model: Ninety-five cases presented with histories of cranial and spinal symptoms (age range: 1 month–78 years; sex: 50 males, 45 females). Following completion of diagnostic procedures, all cases are hospitalized over a 24-hour observation period in concert with a follow-up neurologic examination performed serially for a 6- to 12-month period.

Interpretation and Analysis: The incidence of gross behavioral changes, neurologic alterations, or seizure activity at any time following the procedure is very low (e.g., n = 0/95). Some cases will experience (i) postural postlumbar puncture headache (e.g., n = 19/95 or 20%); (ii) nausea (e.g., n = 6/95 or 6%); or (iii) episodes of vomiting (e.g., n = 2/95 or 2%). Each of these conditions invariably resolves with 24 hours of bed rest following lumbar puncture.

Low dose (0.5–1.0 mL/ml) intrathecal gadopentetate dimeglumine administration is safe, while still capable of providing diagnostic images. Potential clinical applications include the evaluation of obstructions and communications of the various subarachnoid spaces; spontaneous or traumatic/postsurgical craniospinal cerebrospinal fluid leaks; and subarachnoid space cerebrospinal fluid (CSF) flow and central nervous system parenchymal interstitial diffusion dynamics.

Intrathecal gadolinium (gadopentetate dimeglumine)-enhanced magnetic resonance myelography and cisternography: Results of a multicenter study. Tali ET, Ercan N, Krumina G, Rudwan M, Mironov A, Zeng QY, Jinkins JR. Invest Radiol 2002 Mar; 37 (3), pp. 152–9.

Adverse Reactions: Tissue Injury (Relative)
Gadopentetate Dimeglumine (Magnevist)/ Gadoteridol (ProHance)/Gadodiamide (Omniscan)/ Gadoversetamide (Optimark)

Cellular/Molecular Mechanism of Action: Gadolinium possesses radiopaque properties and its physical orientation is modified when exposed to magnetic energy fields.
Background Information: Increasing use of gadolinium-containing contrast agents in higher volumes and at faster injection rates, often with a power injector, elevates concerns regarding the potential for these diagnostic preparations to create extravascular tissue injury.
Application: Contrast image-enhancement agents to improve the diagnostic capabilities of MRI modalities.
Route of Administration (Research Toxicity Study): Gadopentetate dimeglumine (Magnevist), gadoteridol (ProHance), gadodiamide (Omniscan), and gadoversetamide (Optimark) each administered subcutaneously (e.g., mice).
Dosage: Gadopentetate dimeglumine (Magnevist), gadoteridol (ProHance), gadodiamide (Omniscan), and gadoversetamide (Optimark) each given at a dose rate of 0.3 ml per animal (e.g., mouse).
Implementation: Preparations of gadopentetate dimeglumine (Magnevist), gadoteridol (ProHance), gadodiamide (Omniscan), and gadoversetamide (Optimark) formulated as standard concentrations to facilitate comparisons of induced tissue injury in mice relative to reference controls (physiologic saline) and the conventional ionic radiographic contrast medium meglumine diatrizoate (Renografin 60).
Animal Model: Murine.
Each animal (mouse) receives a subcutaneous hindlimb injection of contrast media (e.g., n = 6 experimental groups; n = 15/group). After 48 hours, postmortem tissue samples are obtained for microscopic histopathology analysis.
Interpretation and Analysis: Of the 4 MR contrast agents, gadopentetate dimeglumine causes the greatest tissue damage, and gadoteridol and gadodiamide the lowest amount of tissue damage (e.g., 2 lowest osmolar agents). The difference is statistically significant in terms of both inflammation ($p = 0.0008$ for gadoteridol, and $p = 0.006$ for gadodiamide) and necrosis ($p = 0.0067$ for gadoteridol, and $p = 0.031$ for gadodiamide) when these agents are compared with gadopentetate dimeglumine. In regard to the control experiments, for all 3 variables (necrosis, edema, and inflammation), there is no statistically significant difference between the results with gadoteridol or gadodiamide and values observed for saline. In terms of both edema and inflammation, the effect of gadopentetate dimeglumine, although less, cannot be differentiated with any statistical significance from that of meglumine diatrizoate. Gadoversetamide, which has an osmolality between the ionic agent (gadopentetate dimeglumine) and the other 2 non-ionic agents, causes a reaction that cannot be differentiated from that seen with gadopentetate dimeglumine for both necrosis and edema. Only in the scoring of inflammation is the effect less using gadoversetamide compared to gadopentetate dimeglumine with any statistical significance ($p = 0.021$). The risk of tissue damage due to extravasation is not widely appreciated for gadolinium chelates. Care should be exercised during contrast injection to avoid inadvertent extravasation and its deleterious consequences, in particular with the 2 higher osmolar agents (gadopentetate dimeglumine and gadoversetamide).

Local tissue toxicity in response to extravascular extravasation of magnetic resonance contrast media. Runge VM, Dickey KM, Williams NM, Peng X. Invest Radiol 2002 Jul; 37 (7), pp. 393–8.

Adverse Reactions/Viscosity (High Viscosity of Iodinated Contrast Imaging Agents)/Hemodynamic Effects
Iodixanol

Application: Magnetic resonance image-enhancing contrast agent.
Implementation: High-viscosity, dimeric isoosmolar iodixanol iodinated contrast imaging agent can be injected intravenously to facilitate dynamic diffusion-weighted, echoplanar MRI obtained from b-value single-shot acquisitions and their isotropic apparent diffusion coefficient maps.
Animal Model: Rat (pentobarbital anesthetized).
Interpretation and Analysis: The mean baseline apparent diffusion coefficient value is $1.64 \pm 0.05 \times 10^{-3}$ mm^2/s for the cortex and $1.75 \pm 0.06 \times 10^{-3}$ mm^2/s for the medulla. Injections of iodixanol produce significant decreases in renal diffusion observed at 12 minutes and last for at least 24 minutes. Decreases in diffusion occur earlier for the cortex and last less than for the medulla. There is no significant modification in diffusion over time in the control group. Dynamic diffusion-weighted MRI can be used to non-invasively evaluate the *in vivo* renal hemodynamic response after injection of iodinated contrast (rats).

Hemodynamic effect of iodinated high-viscosity contrast medium in the rat kidney: A diffusion-weighted MRI feasibility study. Laissy JP, Menegazzo D, Dumont E, Piekarski JD, Karila-Cohen P, Chillon S, Schouman-Claeys E. Invest Radiol 2000 Nov; 35 (11), pp. 647–52.

CONTRAST AGENT PROFILES AND PROPERTIES

Contrast Agent Properties: Concentration Time Curve: Influential Variables
Dose vs Concentration

Application: Contrast image enhancement of brain imaging using MR instrumentation.
Dosage: Delineation of the quality of brain MR images as a function of increasing contrast media dosage.
Implementation: Delineation of the effect of varying both concentration and dosage of an intravenously administered MRI contrast agent on the concentration-time curve in brain tissue. Aside from injection time and injection rate, models have been designed that facilitate characterization of the distribution and transit time pertaining to the brain following injection but are independent from (not influenced by) pulse rate, heart volume, or other circulation parameters. The width of the transit-time distribution and the concentration-time

course in the brain can be computed according to the utilization of the indicator dilution theory.

Interpretation and Analysis: Increases in the dosage of administered contrast agent raise the maximum concentration of the agent in the brain, particularly if the injection time is short in duration. Increasing agent concentration (at fixed dosage and injection rate) also increases the maximum concentration within brain capillaries, particularly if the injection time is long. This increase, however, is less than that achieved by raising the dosage.

How do concentration and dosage of the contrast agent affect the signal change in perfusion-weighted magnetic resonance imaging? A computer simulation. Heiland S, Reith W, Forsting M, Sartor K. Magn Reson Imaging 2001 Jul; 19 (6), pp. 813–20.

Contrast Image-Enhancing Agent/MRI and Near-Infrared (NIR) Imaging/Biochemical Markers
Enzyme-Activated NIR Fluorescent Magnetic Nanoparticles/[Indocyanine Dye Cy5.5]

Background Information: A number of quantitative 3-dimensional tomographic NIR fluorescence imaging techniques have recently been developed and combined with MRI to yield highly detailed anatomic and molecular information in living organisms.

Application: Can be utilized as magnetic nanoparticle-based MR contrast agents that have NIR fluorescence (NIRF) capabilities that are activated by certain biological enzymes.

Route of Administration: Subcutaneous (example), but other prototypes could potentially be given intravascularly.

Semi-Synthetic Methods: Probes are prepared by the conjugation of arginyl peptides to cross-linked iron oxide amine (amino-CLIO), either by a disulfide linkage or a thioether linker, followed by the attachment of the indocyanine dye Cy5.5. The NIRF of disulfide-linked conjugate is activated by 1,4-dithio-l-threitol (DTT), while the NIRF of thioether-linked conjugate is activated by trypsin. Fluorescent quenching of the attached fluorochrome occurs in part due to interaction with iron oxide, as evident by the activation of fluorescence with DTT in the presence of nanoparticles that have less than 1 dye molecule attached per particle.

Implementation: Evaluate the potential for enzyme-activated near-IR fluorescent magenetic nanoparticles to detect specific biochemical entities expressed by specific cell populations.

Interpretation and Analysis: Following subcutaneous injection of the probe, axillary and brachial lymph nodes become darkened on MR images and are easily delineated by NIRF imaging. The probes may provide the basis for a new class of so-called smart nanoparticles, capable of pinpointing their position through their magnetic properties, while providing information on their environment by optical imaging techniques.

Near-infrared fluorescent nanoparticles as combined MR/optical imaging probes. Josephson L, Kircher MF, Mahmood U, Tang Y, Weissleder R. Bioconjug Chem 2002 May–Jun; 13 (3), pp. 554–60.

Contrast Image-Enhancing Agent/Properties
[Gd]-TREN-Me-3,2-HOPO/2-Hydroxyisophthalamide/2,3-Dihydroxyterephthalamide/Bis(acetate)/Salicylamide

Cellular/Molecular Mechanism of Action: Tris[(3-hydroxy-1-methyl-2-oxo-1,2-didehydropyridine-4-carboxamido)ethyl]amine (TREN-Me-3,2-HOPO) can function as a tripodal ligand that can form a stable complex with $[Gd^{3+}]$. Salicylamide, 2-hydroxyisophthalamide, 2,3-dihydroxyterephthalamide, and *bis*(acetate) can function as derivatizable chelator groups.

Background Information: TREN-Me-3,2-HOPO has a low level of water solubility that prevents detailed magnetic characterization and practical applicability.

Application: Magnetic resonance imaging contrast agent.

Semi-Synthetic Methods: Mixed ligand systems based on the TREN-Me-3,2-HOPO platform that possess (i) 2 hydroxypyridinone (HOPO) chelators; and (ii) 1 chelator that can be easily functionalized. Ligands can use salicylamide, 2-hydroxyisophthalamide, 2,3-dihydroxyterephthalamide, and *bis*(acetate) as the derivatizable chelators.

Implementation: Evaluation of ligands possessing (i) 2 HOPO chelators groups; and (ii) a chelator that can easily be functionalized.

Interpretation and Analysis: Salicylamide-, 2-hydroxyisophthalamide-, and 2,3-dihydroxyterephthalamide-based ligands possess sufficient thermodynamic stability for *in vivo* applications. The relaxivities of the 3 corresponding $[Gd^{3+}]$ complexes range from 7.2 to 8.8 mM/s at 20 MHz, 25°C, and pH 8.5, significantly higher than the values for clinically employed polyaminocarboxylate complexes (3.5–4.8 mM/s). The high relaxivities of these complexes are consistent with their faster rates of water exchange (< 100 ns), higher molecular weights (> 700), and greater numbers of inner-sphere coordinated water molecules ($q = 2$) relative to those of polyaminocarboxylate complexes. A mechanism for the rapid rates of water exchange has been proposed to involve a low energy barrier between the 8- and 9-coordinate geometries for lanthanide complexes of HOPO-based ligands. The pathway is supported by the crystal structure of La[TREN-Me-3,2-HOPO] [triclinic P1: $Z = 4$, $a = 15.6963(2)$ A, $b = 16.9978(1)$ A, $c = 17.1578(2)$ A, $\alpha = 61.981(1)°$, $\beta = 75.680(1)°$, $\gamma = 71.600(1)°$], which shows both 8- and 9-coordinate metal centers in the asymmetric unit, demonstrating that these structures are very close in energy. These properties make heteropodate $[Gd^{3+}]$ complexes promising candidates for use in macromolecular contrast media, particularly at higher magnetic field strengths.

Syntheses and relaxation properties of mixed gadolinium hydroxypyridinonate MRI contrast agents. Cohen SM, Xu J, Radkov E, Raymond KN, Botta M, Barge A, Aime S. Inorg Chem 2000 Dec 11; 39 (25), pp. 5747–56.

Contrast Image-Enhancing Agent/Properties and Improvement
[Gd]-PCP2A(H_2O_2)

Cellular/Molecular Mechanism of Action: The PCP2A moiety of [Gd]-PCP2A(H_2O_2) serves to chemically fix [Gd] so that the paramagnetic ion does not exist free within biological systems. The orientation of paramagnetic ion gadolinium [Gd] becomes physically altered when subjected to magnetic energy fields.

Application: The agent [Gd]-PCP2A(H_2O_2) can be applied as an (improved) paramagnetic image-enhancing agent for application in MRI.

Route of Administration: [Gd]-PCP2A (intravenous).

Semi-Synthetic Methods: Techniques have been decribed for the synthesis of pyridine-containing macrocycle bearing 2 acetic and 1 methylenephosphonic arms (PCP2A). An efficient synthesis of PCP2A is based on the macrocyclization reaction between 2,6-bis(chloromethyl)pyridine and a 1,4, 7-triazaheptane derivative bearing a methylenephosphonate group on N-4.

Interpretation and Analysis: The Gd(III) complex of PCP2A possesses properties that make it a very promising contrast agent for improved applications in MRI based on the observation that it displays: (i) a very high stability constant ($\log K_{GdPCP2A} = 23.4$) that should guarantee against *in vivo* release of toxic-free Gd(III) ions and free ligand molecules; in addition to (ii) a relaxivity that is about

2 times higher than the values reported for contrast agents frequently used in clinical practice. Its high relaxivity is the result of the presence of 2 water molecules in the inner coordination sphere and a significant contribution from water molecule(s) hydrogen bonded to the phosphonate group. Moreover, the inner sphere water molecules are involved in an exchange with bulk water that is relatively fast. This property is important for the attainment of an even higher relaxivity once the molecular reorientation rate of the [Gd]-PCP2A(H_2O_2) (−) moiety is lengthened by means of conjugation to a macromolecular substrate.

[GdPCP2A(H_2O_2)](−): A paramagnetic contrast agent designed for improved applications in magnetic resonance imaging. Aime S, Botta M, Frullano L, Geninatti Crich S, Giovenzana G, Pagliarin R, Palmisano G, Sirtori FR, Sisti M. J Med Chem 2000 Oct 19; 43 (21), pp. 4017–24.

Contrast Image-Enhancing Agent/ Properties: Physiological, Pharmacology, Toxicology *Gadolinium*

Cellular/Molecular Mechanism of Action: Gadolinium is a lanthanide element that has its physical orientation modified when subjected to magnetic energy fields.
Application: Gadolinium chloride has been (i) applied as a positive contrast agent (gadolinium chelates); (ii) widely used as an inhibitor of stretch-activated ion channels and physiological responses of tissues to mechanical stimulation; and (iii) employed *in vivo* as a selective macrophage inhibitor.
Considerations: Gadolinium can both provide pharmacological benefits and exert toxicological properties. Although adverse reactions to these agents are uncommon, it is known that gadolinium salts can bring about a wide variety of physiological alterations.

Basic experimental studies and clinical aspects of gadolinium salts and chelates. Adding LC, Bannenberg GL, Gustafsson LE. Cardiovasc Drug Rev 2001 Spring; 19 (1), pp. 41–56.

Contrast Image-Enhancing Agent/ MRI Agent: Oxygen-Carrying Compounds *Perfluorochemicals (PFCs)*

Cellular/Molecular Mechanism of Action: Perfluorochemicals possess oxygen-carrying properties. The characteristics that make them unique diagnostic agents pertain to their lack of hydrogen atoms, immiscibility with water, low surface tension, compressibility, and long intravascular persistence when emulsified and given intravenously.
Application: Perfluorochemicals can function as versatile contrast agents with important applications related to radiology (x-ray), ultrasound, or MR. When made radiopaque, they are visible with x-ray computed tomography (CT) and standard radiography.
Interpretation and Analysis: Because the neat liquid is inert, it can be ingested, instilled in the lung, or introduced into any hollow organ to image the lumen without untoward effects. The long intravascular persistence allows the imaging of blood vessels and vascularized tissues. Small or deep vessels become visible on color Doppler imaging and angiographic images of any vascular tree including the coronaries can be rendered from the serial CT images. As PFCs accumulate within reticuloendothelial cells, specific liver and spleen enhancement is achieved, allowing the detection of small tumors within these organs. When injected interstitially, the particles find their way to the draining lymph nodes, providing detail of the internal architecture to detect the presence or absence of tumor involvement on both CT and sonography. Using 19F MR, tissue perfusion and tissue pO_2 measurements can be achieved. As can be seen, the applications of PFC in diagnosis are vast, unique, and important. These new capabilities will carry radiological tools to new horizons.

The potential role of perfluorochemicals (PFCs) in diagnostic imaging. Mattrey RF. Artif Cells Blood Substit Immobil Biotechnol 1994; 22 (2), pp. 295–313.

CARDIOVASCULAR SYSTEM

Angiography: Pulmonary Vasculature/2D Phase-Contrast/Time-of-Flight Sequences/Phased-Array Torso Coils/Contrast-Enhanced Helical Computed Tomography (CT)

In the past few years MR angiography (MRA) of the pulmonary vasculature has advanced from a research tool to a clinically relevant imaging modality. Early 2D phase-contrast and time-of-flight (TOF) sequences without the use of contrast agents were time-consuming and limited by considerable imaging and motion artifacts. Since the introduction of MR scanners with stronger gradients (> 20 mT/m) and contrast-enhanced techniques, imaging of the pulmonary vasculature with adequate spatial resolution within a single breath-hold is now possible. In the detection of pulmonary embolism in the lobar or segmental arteries, contrast-enhanced MRA is now on the verge of being considered an established modality, possibly competing with conventional pulmonary angiography and contrast-enhanced helical CT. In the future, utilization of phased-array torso coils, the application of navigator pulse sequences, and 3D time-resolved ultrafast MRA will overcome the final limitations of current techniques. Blood-pool MR contrast agents may provide a "one-stop-shopping" approach to the investigation of lower extremity veins and pulmonary arteries in venous thromboembolism.

Pulmonary magnetic resonance angiography. Hoffmann U, Schima W, Herold C. Eur Radiol 1999; 9 (9), pp. 1745–54.

Cardiac Imaging/Coronary Artery Stenoses/ Coronary Artery Bypass Grafts/Anomalous Coronary Arteries/Vessel Wall Imaging *Intravascular MRI Contrast Agents*

Multiple cardiovascular MR (CMR) techniques have been developed that make it possible to overcome the substantial difficulties associated with the imaging of coronary arteries. Tortuous small coronary arteries are imaged in 3D-volume data sets. Cardiac motion is reduced by diastolic gating with ultrafast sequences. Respiration is suppressed by breath-holding or respiratory gating. Signal-to-noise can be increased with contrast agents. In clinical trials CMR has been successfully used to assess coronary artery stenoses, coronary artery bypass grafts, and anomalous coronary arteries. Recent developments in steady state imaging, volume selective imaging with tracking, parallel imaging techniques, vessel wall imaging, and intravascular contrast agents may soon enable CMR of the coronary arteries to become an effective and widespread clinical tool.

MR coronary angiography: 2001 update. Bunce NH, Lorenz CH, Pennell DJ. Rays 2001 Jan–Mar; 26 (1), pp. 61–9.

Cardiac Imaging/Myocardial Infarct Characterization *[^{87}Rb]/Evans Blue Dye/Triphenyl Tetrazolium Chloride/Glibenclamind/Pinacidil/Bumetanide*

Cellular/Molecular Mechanism of Action: (i) Rubidium ion (Rb^+) is a K^+ tracer element; (ii) glibenclamide is a blocker of

ATP-sensitive K^+ channels; (iii) pinacidil is a K^+(ATP) opener; (iv) bumetanide is a $K^+/Na^+/2Cl^-$ co-transporter inhibitor.

Application: [^{87}Rb] can be applied in MRI procedures to identify and characterize myocardial infarcts. Evans blue and triphenyl tetrazolium chloride staining can be applied to delineate areas at risk (AAR) and areas of necrosis, respectively.

Dosage: Glibenclamide (3 μM); pinacidil (10 μM); bumetanide (10 μM).

Implementation: Delineation of the effect of drugs that can modulate passive K^+ permeability into cardiomyocytes in normal and reperfusion-damaged cardiac muscle. Rubidium ion is used as a K^+ tracer and [^{87}Rb]-MRI can serve as a method of detection and characterization. Preparations are incubated in buffer contained either in (i) glibenclamide; (ii) pinacidil; (iii) bumetanide; or (iv) no drug (control). Upon reperfusion 3-dimensional [^{87}Rb] MR images are acquired to obtain kinetic parameters for Rb^+ uptake and its distribution. Areas at risk and areas of necrosis are determined by Evans blue and triphenyl tetrazolium chloride staining, respectively.

Animal Model: Swine (left anterior descending artery [LAD] of isolated pig hearts perfused with Krebs-Henseleit buffer [KHB] occluded for 2 hours and subsequently reperfused for 2 hours with KHB containing 4.7 mM RbCl instead of KCl).

Interpretation and Analysis: The kinetics remain monoexponential in the affected anterior wall and the uptake rates are approximately 32, 36, 37, and 21% of that in the posterior wall in the control, Glib, Pin, and Bum groups, respectively. Infarct sizes determined histologically as a percentage of total ventricular (left + right) mass (14–22%) correspond to sizes of areas with 20 to 40% of maximal Rb image intensity [I(Rb)(max), 15–22%], except for values observed with pinacidil (12.5 vs 21%). The sizes of areas with 20 to 50% of I(Rb)(max) (30–36%) closely correlates with those of AAR determined histologically (31–33%). Lactate dehydrogenase release does not differ in all preparations. Therefore, (i) reperfusion damage quickly inhibits Rb^+ uptake; (ii) Rb^+ uptake in normal and reperfused tissue does not significantly depend on K^+(ATP) or the $K^+/Na^+/2Cl^-$ co-transporter; and (iii) areas with 20% to 40% of maximal image intensity correspond to infarct areas.

The effects of drugs modulating K^+ transport on Rb^+ uptake and distribution in pig hearts following regional ischemia: ^{87}Rb MRI study. Kupriyanov VV, Xiang B, Sun J, Jilkina O. NMR Biomed 2002 Aug; 15 (5), pp. 348–55.

Cardiac Imaging/Myocardial Infarct Detection and Characterization
Gadophrin-2/Gadolinium-DTPA ([Gd]-DTPA)

Application: Gadophrin-2 functions as a necrosis-avid contrast agent (NACA); [Gd]-DTPA is a non-specific agent that can be applied to determine myocardial viability (MV) in acute myocardial infarction (AMI) applying MRI analysis.

Route of Administration: [Gd]-DTPA (intracoronary artery); gadophrin-2 (intracoronary artery).

Dosage: [Gd]-DTPA (0.1 mmol/kg); gadophrin-2 (0.005 mmol/kg).

Implementation: [Gd]-DTPA or gadophrin-2 can be delivered into the coronary artery by either fast (n = 3 dogs) or slow bolus (n = 3 dogs). Serial electrocardiogram (ECG)-triggered cardiac MRI of T_1-weighted segmented turbo fast low-angle shot (FLASH) sequence is performed and compared with results observed with triphenyltetrazolium chloride (TTC) histochemical staining. The contrast ratio and infarct size are quantified and analyzed statistically.

Animal Model: Canine (n = 12 dogs subjected to induction of reperfused acute myocardial infarction through the use of a transcatheter balloon occlusion of the coronary artery).

Interpretation and Analysis: Cardiovascular side effects can rarely be appreciated with the local delivery of either [Gd]-DTPA or gadophrin-2 contrast agents. After administration, gadophrin-2 induces a strong (CR ≥ 1.78) and persistent (≥ 10 hours) contrast enhancement of infarcted region. The infarct size defined with gadophrin-2 is almost identical to that observed with TTC staining throughout the postcontrast period. With a dose 20 times higher, [Gd]-DTPA also strongly enhances infarct-to-normal contrast; however, the enhancement diminishes over time (e.g., from early strong to later faint enhancement and eventual loss of contrast). Size of the delineated infarct is also unstable (e.g., from early overestimation to later underestimation and eventual disappearance of the enhanced infarct). In combination with a percutaneous transluminal coronary angioplasty (PTCA) procedure, intracoronary artery–administered MRI contrast agents may prove useful for postprocedure verification of diagnosis. The NACA-enhanced MRI may serve as an *in vivo* surrogate of postmortem histochemical staining for the determination of MV. Although applicable in a clinical setting, cardiac MRI with nonspecific [Gd]-DTPA is less reliable and should be performed within 1 hour after contrast agent injection.

Intracoronary delivery of [Gd]-DTPA and gadophrin-2 for determination of myocardial viability with MR imaging. Ni Y, Pislaru C, Bosmans H, Pislaru S, Miao Y, Bogaert J, Dymarkowski S, Yu J, Semmler W, Van de Werf F, Baert AL, Marchal G. Eur Radiol 2001; 11 (5), pp. 876–83.

Cardiac Imaging/Myocardial Infarction: Acute/Reperfusion Injury
Gadolinium/Gadolinium-DTPA ([Gd]-DTPA)

Background Information: Pixel-by-pixel calculation of T_1 values (T_1 mapping) has been used in different tissues to focus on T_1 changes in a quantitative fashion.

Application: Establish T_1 mapping of human myocardium (1.5 Tesla system) and diagnostic detection and characterization of acute myocardial infarction (AMI).

Implementation: Evaluation of the diagnostic effectiveness of multi-breath-holding provocative test in conditions of reperfused AMI (3 days ± 1 day) established with MRI (1.5 Tesla system) and [Gd]-DTPA applied as a contrast image-enhancing agent (e.g., n = 8 cases). Sets of 5 images with varying T_1 weighting are acquired prior to and after the administration of contrast agent to generate images from calculated T_1 values (T_1 mapping).

Interpretation and Analysis: Prior to contrast agent administration, all cases display T_1 prolongation in the area of infarction, which can be identified in separate measurements using the delayed enhancement approach. Compared to non-infarcted areas, T_1 values in the infarcted areas are increased by 18 ± 7% (standard error, $p < 0.05$). The spatial extent of the area of T_1 prolongation is larger than that of the hyperenhanced areas in conventional contrast-enhanced images. T_1 maps obtained after the application of [Gd]-DTPA reveal a T_1 reduction of approximately 27 ± 4% in infarcted tissue compared to non-infarcted areas ($p < 0.05$). The areas showing T_1 reduction are in agreement with hyperenhanced regions in conventional T_1-weighted images. T_1 mapping can visualize changes in the longitudinal relaxation time induced by AMI. T_1 mapping can detect myocardial necrosis without the use of contrast media. Information that can be extracted from a combination of pre- and postcontrast T_1 maps exceeds that from conventional contrast studies.

T_1 mapping in patients with acute myocardial infarction. Messroghli DR, Niendorf T, Schulz-Menger J, Dietz R, Friedrich MG. J Cardiovasc Magn Reson 2003; 5 (2), pp. 353–9.

Cardiac Imaging/Myocardial Infarction/Acute vs Chronic Myocardial Infarction Differentiation
Gadopentetate Dimeglumine Magnevist/Gadophrin-3

Cellular/Molecular Mechanism of Action: Gadolinium is a component of gadophrin-3 and its spatial orientation becomes altered when subjected to magnetic energy fields.
Background Information: Contrast-enhanced MRI can accurately quantify infarct size; however, some controversies persist about which contrast medium is best suited for this purpose.
Application: Detection and differentiation between acute and chronic myocardial infarction lesions using gadophrin-3 and Magnevist either individually or in combination.
Dosage: Gadophrin-3 (50 μmol/kg 24 hours before image acquisition); Magnevist (100 μmol/kg).
Implementation: Determination of the enhancement profile of a necrosis-specific contrast agent (gadophrin-3) compared to a standard extracellular agent on T_1-weighted MR images in acute and chronic myocardial infarctions (MIs).

Image analysis can be performed at 48 hours and at 6 weeks following induction of infarction lesions created by permanent occlusion of a branch of the left coronary artery. Image analysis by MRI can be performed with the aid of gadophrin-3 as an MRI contrast-enhancement agent. Continuous short-axis views are collected using an inversion recovery turbo fast low angle shot sequence. Imaging is repeated 5–10 minutes following an additional Magnevist injection. The area of hyperenhancement demarcated following gadophrin-3 injection is then compared with the region of hyperenhancement seen on gadophrin-3 plus Magnevist enhanced image using triphenyltetrazolium chloride (TTC) staining as the standard of reference.

Animal Model: Rabbit (n = 13 thoracotomy and permanent occlusion of a branch of the left coronary artery. Note: N = 11 animals survived to 48 hours, and n = 5 survived for 6 weeks).
Interpretation and Analysis: In an acute MI model, the mean difference in size of hyperenhancement seen on 2 different *in vivo* MR scans is approximately $-1.8 \pm 6.0\ mm^2$ ($p > 0.05$). Both measurements show excellent agreement with TTC staining. Chronic myocardial infarctions show no enhanced detection with gadophrin-3, whereas application of Magnevist results in hyperenhancement. Standard extracellular contrast agents do not overestimate the size of acute MI. The combination of gadophrin-3 and Magnevist can distinguish acute and chronic myocardial injury because chronic MIs do not enhance with gadophrin-3.

Imaging of myocardial infarction: Comparison of Magnevist and gadophrin-3 in rabbits. Barkhausen J, Ebert W, Debatin JF, Weinmann HJ. J Am Coll Cardiol 2002 Apr 17; 39 (8), pp. 1392–8.

Cardiac Imaging/Myocardial Infarct Size Delineation [Gadolinium-Based Media]/ Viable Myocyte Labeling: [Magnesium-Based Media]/Myocardial Integrity
Gadoversetamide/Gadopentetate Dimeglumine/ Albumin-Bound [Gd]-Based Media/ Magnesium-Based Contrast Media

Cellular/Molecular Mechanism of Action: The orientation of magnesium and gadolinium atoms becomes altered when subjected to a magnetic energy field.
Application: Magnesium and gadolinium atoms can serve as positive contrast-enhancing agents for MRI techniques. In this context, they can be used in formulations for the detection and characterization of lesions associated with myocardial infarction.
Route of Administration: Magnesium and gadolinium-based positive contrast-enhancing imaging agents are delivered by intravascular injection.
Implementation: Serial image analysis of ligated coronary arteries with segmented inversion-recovery gradient-echo MRI (repetition time msec/echo time msec/inversion time msec [fixed], 5.2/2.5/430; flip angle, 15°) for a period of 1 hour after administration of contrast media facilitated by the use of a 1.5 Tesla MR unit. Serial measurements of the longitudinal relaxation are performed by using the Look-Locker approach (repetition time msec/echo time msec, 1,000/3.5; flip angle, 10°). Detection and size of infarction can be evaluated at each time point and compared with end point histologic findings.

Animal Model: Coronary ligation performed in rats (e.g., n = 30).
Interpretation and Analysis: All manganese-based contrast media clear from the blood pool rapidly. Manganese-based contrast media allow precise labeling of viable cardiomyocytes within 30 minutes, and the labeling persists for at least 1 hour. Accumulation of gadoversetamide in the infarct area is apparent after 5 minutes, and the peak contrast-to-noise ratio (CNR) between infarct and myocardium is comparable to the peak CNR of manganese-based contrast agents. Extracellular gadopentetate dimeglumine provides excellent infarct detection but precise sizing of infarcts can only best be achieved during a small imaging window if a fixed inversion time of 430 msec is used. Albumin-binding gadolinium-based contrast media provides a longer imaging window, but infarct size is overestimated because of the non-specific distribution of unbound gadolinium agent. When extracellular gadolinium-based agents are used for infarct size measurement, imaging parameters and timing are important because the kinetics of both normal and irreversibly injured myocardium must be considered. Manganese-based agents are highly specific and less sensitive to timing for infarct size determination, but further studies are required to determine if they are feasible for human use.

Characterization of viable and non-viable myocardium at MRI: Comparison of gadolinium-based extracellular and blood pool contrast materials vs manganese-based contrast materials in a rat myocardial infarction model. Flacke S, Allen JS, Chia JM, Wible JH, Periasamy MP, Adams MD, Adzamli IK, Lorenz CH. Radiology 2003 Mar; 226 (3), pp. 731–8. Epub 2003 Jan 24.

Cardiac Imaging/Myocardial Perfusion/Tracer Kinetics
CMD-A2-Gd-DOTA

Cellular/Molecular Mechanism of Action: The physical orientation of molecular gadolinium is altered when placed within a magnetic energy field that can be detected by MRI instrumentation.
Background Information: Recent developments in MRI using specific contrast media can facilitate the assessment of myocardial perfusion.
Application: Gadolinium is used as a tracer element that can be detected in biological systems by MRI modalities. CMD-A2-Gd-DOTA is an imaging agent that can be utilized to characterize myocardial perfusion.
Route of Administration: Intravascular.
Implementation: CMD-A2-Gd-DOTA can be applied as an intravascular MRI tracer agent for evaluating myocardial perfusion. To validate the intravascular properties of CMD-A2-Gd-DOTA, the agent can be simultaneously injected with [^{99m}Tc]-labeled red blood cells. Options for subsequent analyses include (i) tracer kinetics of both compounds assessed by coronary sinus effluent sampling, radioactivity counting, and concentration determination in samples

for 1st-pass time curves measurements; and (ii) 2-slice turboFLASH sequence on a 1.5 Tesla whole-body MRI in order to evaluate 1st-pass CMD-A2-Gd-DOTA signal intensity (SI) vs time curves.

Animal Model: Swine (isolated heart preparation perfused at various controlled flow rates). Group 1 (5 hearts: simultaneous injection of CMD-A2-Gd-DOTA and [^{99m}Tc]-labeled red blood cells). Group 2 (5 hearts: 2-slice turboFLASH sequence on a 1.5 Tesla whole-body MRI for evaluation of 1st-pass CMD-A2-Gd-DOTA SI vs time curves).

Interpretation and Analysis: First-pass concentration curves for CMD-A2-Gd-DOTA display flow rates ranging from 0.8 to 3.1 ml/min/g and are typical for an intravascular contrast agent. Parameters for MRI studies reveal an upslope and mean transit time of SI time curves that correlate strongly with myocardial perfusion processes. Within the physiologic range of flows, CMD-A2-Gd-DOTA is able to demonstrate tracer kinetics for *in vivo* assessment of myocardial perfusion using MRI.

Kinetic characterization of CMD-A2-Gd-DOTA as an intravascular contrast agent for myocardial perfusion measurement with MRI. Canet EP, Casali C, Desenfant A, An MY, Corot C, Obadia JF, Revel D, Janier MF. Magn Reson Med 2000 Mar; 43 (3), pp. 403–9.

Cardiac Imaging/Myocardial Perfusion Angiography/Contrast Agent Options/ Microvascular Permeability/Timing of Contrast Agent Injection

Small Molecular Weight Agents/Blood-Pool Agents/ Gadolinium-Chelate/Ultrasmall Superparamagnetic Particles of Iron Oxide (USPIOs)

Cellular/Molecular Mechanism of Action: Gadolinium is classified as a paramagnetic metallic ion and its spatial orientation becomes physically altered when subjected to magnetic energy fields.

Background Information: Currently available MR contrast agents are not confined to the intravascular space because of their small molecular size. These agents produce peak vascular enhancement for only a short period. Conversely, blood-pool agents have longer intravascular residence time and higher relaxivity. Therefore, these agents provide a greater degree of flexibility, versatility, and accuracy in performing MR angiography (MRA) procedures. In the utilization of blood-pool agents, the timing of contrast injection becomes less significant because the optimal imaging window is in tens of minutes rather than seconds. In addition, larger anatomic regions can be imaged optimally.

Application: Gadolinium-chelate that binds *in vivo* to albumin and USPIOs has been applied as blood-pool agents for MRI enhancement. Such preparations can be utilized in MRI methodologies for analysis of anatomical abnormalities affecting vascular structures, including the coronary artery, pulmonary artery, and peripheral arterial networks. Additionally, their use can facilitate the evalution of parameters such as relative myocardial perfusion.

Route of Administration: Gadolinium-chelate (intravascular) and USPIOs (intravascular) are selectively delivered by intravascular injection facilitated by direct catheterization of arterial or venous structures. The timing of contrast injection for blood-pool agents becomes less significant because the optimal imaging window is in tens of minutes rather than seconds. In addition, larger anatomic regions can be imaged optimally.

Interpretation and Analysis: Preliminary evidence appears to support the notion that blood-pool agents may play a diagnostic role in coronary, peripheral, and pulmonary angiography. Blood-pool agents are currently being evaluated in human trials with relevant examples, including gadolinium-chelate that binds *in vivo* to albumin to form blood-pool agents and USPIOs. In this context, contrast-enhanced 3-D MRA permits comprehensive assessment of the supra-aortic arteries as well as the arterial system in the chest, abdomen, and lower extremities. Three-dimensional MRA combines intravenous injection of a non-nephrotoxic, paramagnetic, extracellular contrast agent that increases the signal intensity of blood by shortening its T_1 value with the acquisition of a fast 3D data set. High contrast between the vascular lumen and surrounding tissues, inherent 3-dimensionality, and the ability to collect image data in the chest and abdomen under apnea conditions all contribute to excellent image quality. Besides their ability to increase vascular contrast, blood-pool agents provide physiologic information, including rate of entry, rate of accumulation, and rate of elimination. These qualities of MR blood-pool agents have proven to be of significant value in the assessments of myocardial perfusion and microvascular permeability.

Cardiac Imaging/Myocardial Perfusion/ Coronary Angiography/Pulmonary Angiography/ Peripheral Angiography/Myocardial Perfusion/ Occlusive vs Reperfused Infarction/ Reversible vs Irreversible Myocardial Injury/ Microvascular Integrity Assessment

Blood-Pool MRI Contrast Agents

Magnetic resonance imaging has emerged as a new diagnostic technique for evaluation of the cardiovascular system. The diagnostic benefits of MR contrast agents have been demonstrated in the laboratory and in clinical research that has taken place during the past 12 years. Contrast agents enhance the sensitivity of MR angiography and improve early detection and characterization of myocardial and microvascular injuries. Clinically approved MR contrast agents are not confined to the intravascular space due to their small molecular size (standard extracellular MR contrast agents) and, therefore, they produce peak vascular enhancement for only a short period of time (, 30 minutes). In recent years remarkable progress has been made in the development of blood-pool agents for MRI. Impetus for creation of these agents has come in part from a growing appreciation of MR angiography. Vascular mapping has become an important application of medical imaging. Ample experimental evidence has shown that blood-pool agents may play a significant role in coronary, peripheral, and pulmonary angiography. In addition to their ability to increase vascular contrast, blood-pool agents provide physiological information such as rate of entry, rate of accumulation, and rate of elimination. In the heart, blood-pool contrast agents are useful for estimating relative myocardial perfusion, discriminating between occlusive and reperfused infarction, differentiating between reversible and irreversible myocardial injury, and detecting microvascular integrity. Blood-pool agents are currently being investigated in humans. Initial clinical trials have demonstrated their safety and feasibility and, hopefully, future trials will demonstrate their efficacy.

Value of blood-pool MR contrast agents in imaging of the heart and blood vessels. Saeed M. Drugs Today (Barc) 1999 Nov; 35 (11), pp. 879–92.

Cardiac Imaging/Myocardial Sarcoidosis/ Myocardial Inflammation and Interstitial Edema/ Therapeutic Efficacy Monitoring (Prednisolone) *Gadolinium-DTPA ([Gd]-DTPA)*

Background Information: Cardiac involvement is an important prognostic factor in patients with sarcoidosis.
Application: [Gd]-DTPA-enhanced MRI ([Gd]-MRI) can be used for the diagnosis of cardiac sarcoidosis and monitoring responses to prednisolone therapy.
Implementation: Analysis of conditions of sarcoidosis with cardiac involvement applying Gd-MRI technology with a 1.5 Tesla superconducting magnet system T_1-weighted spin-echo sequence (e.g., n = 16 cases).

Human Model: Cases suffering from cardiac sarcoidosis diagnosed based on histological examination of tissue samples or fulfillment of specific patient profile criteria.
Interpretation and Analysis: Gadolinium can enhance the intensity of localized signals detected by MRI that correspond to lesions associated with (i) interstitial edema within the left ventricle (e.g., n = 8/16); and (ii) thinning of the left ventricular septal wall (e.g., n = 2/16). Monitoring of cases following a 1-month period of prednisolone therapy (60 mg every other day or 30–40 mg s.i.d.) reveals markedly diminished localized high-intensity signals. Images of the heart obtained by gadolinium MRI may reflect active inflammation with interstitial edema in patients with sarcoidosis. Gadolinium MRI may be a useful non-invasive method for early detection of cardiac sarcoidosis and for evaluating the effects of steroid therapy.

Diagnosis of cardiac sarcoidosis and evaluation of the effects of steroid therapy by gadolinium-DTPA-enhanced magnetic resonance imaging. Shimada T, Shimada K, Sakane T, Ochiai K, Tsukihashi H, Fukui M, Inoue S, Katoh H, Murakami Y, Ishibashi Y, Maruyama R. Am J Med 2001 May; 110 (7), pp. 520–7.

Cardiac Imaging/Myocardium Infarction/Detailed Segmental Left Ventricle (LV) Function *Iron Oxide–Loaded Myogenic Precursor Cells*

Cellular/Molecular Mechanism of Action: Myogenic precursor cells detect, migrate to, and accumulate within lesions of myocardial generation.
Application: Evaluation of myocardial implants of myogenic precursor cells (MPC) loaded with iron oxide to determine how reliably they can be detected by *in vivo* cardiac MRI.
Route of Administration: Direct (selective) catheterization.
Implementation: Evaluation of the ability for iron oxide–loaded myogenic precursor cells to detect myocardial lesions. Such an objective can be approached by electromechanical mapping of the LV and performing guided microinjections into normal and infarcted myocardium utilizing autologous MPC delivered through a percutaneous catheter. Cardiac MRI can be used to detect implanted iron oxide nanoparticle-loaded MPC preparations. Magnetic resonance imaging data are then compared to LV electromechanical mapping findings and cross-registered pathology.

Animal Model: Swine (n = farm pigs; n = 4/7 with anterior myocardial infarction).
Interpretation and Analysis: The vast majority of injections into normal (e.g., n = 9/9) and locally damaged (e.g., n = 12/12) myocardium can be detected on T_2-weighted spin echo and inversion-recovery true-fisp MRI (low signal areas) with good anatomical concordance with sites of implantation on electromechanical maps. All sites of injection can be confirmed by correlation with pathology findings, which in all infarct animals reveal iron-loaded MPC at the center and periphery of the infarct as expected from MRI analysis. In summary, targeted catheter-based implantation of iron-loaded MPC into locally infarcted LV myocardium is accurate and can be reliably demonstrated by *in vivo* cardiac MRI. The ability to non-invasively identify intramyocardial cell implantation may be a determinant for future experimental studies designed to analyze subsequent effects of such therapy on detailed segmental LV function.

Magnetic resonance imaging of targeted catheter-based implantation of myogenic precursor cells into infarcted left ventricular myocardium. Garot J, Unterseeh T, Teiger E, Champagne S, Chazaud B, Gherardi R, Hittinger L, Guéret P, Rahmouni A. J Am Coll Cardiol 2003 May 21; 41 (10), pp. 1841–6.

Cardiovascular: Contrast-Enhanced Imaging of Cardiovascular Anatomical Structures/ Intervention MRI/Angioplasty/Gene Delivery/ Growth Factor Delivery

Magnetic resonance imaging can provide a non-invasive combined diagnostic examination of different modalities, including visualization and measurement of cardiac and vascular anatomy, in addition to assessment of blood flow, left ventricular mass, function, perfusion, and viability. Contrast agents for cardiovascular imaging are used to enhance the capability of MRI in assessing perfusion, tissue viability, infarction, and vascular stenosis. Furthermore, contrast agents may be used for guiding procedures and therapies in the evolving field of interventional MRI, such as angioplasty and delivery of genes and growth factors. Targeted MR contrast agents are needed to further improve the specificity of MRI and to monitor pathophysiological processes including necrosis, inflammation, or angiogenesis. The research and development of MR contrast agents will likely continue at the cellular and molecular levels over the next decade.

Contrast agents for cardiovascular magnetic resonance imaging. Current status and future directions. Schalla S, Higgins CB, Saeed M. Drugs R D 2002; 3 (5), pp. 285–302.

Cardiovascular: Myocardial Infarction/ Discrimination: Normal vs Infarcted Myocardium *Superparamagnetic Iron Oxide (SPIO)*

Application: Discrimination between infarcted and normal myocardial tissues using SPIO and high field MRI (7 Tesla).
Dosage: Superparamagnetic iron oxide nanoparticles (T_1 weighted = 1 mg Fe/kg; T_2 weighted = 5 or 10 mg Fe/kg).
Implementation: Evaluation of the capacity for SPIO nanoparticles in combination with T_1-weighted gradient echo sequence to visualize myocardial infarctions 48 hours after ligature. In addition, MRI can be performed using a T_2-weighted RARE sequence and nanoparticles injected 5, 24, or 48 hours after infarction.

Animal Model: Rat (n = 6 induced permanent myocardial infarction for T_1 weighted; and n = 36 rats for T_2 weighted).
Interpretation and Analysis: No changes in contrast between normal and infarcted myocardium can be observed after nanoparticle injection on T_1-weighted images. However, nanoparticles can induce a significant contrast increase between normal and infarcted myocardium on T_2-weighted images whatever the delay is between induced infarction and imaging (2.99 ± 1.66 preinjection vs 7.82 ± 1.96 after SPIO injection at a dose of 5 mg Fe/kg 5 hours postinfarction, p = 0.0001). In summary, it is possible through the application

of injected nanoparticles to discriminate normal from infarcted myocardium on T_2-weighted images. However, the high magnetic field prevents the visualization of the T_1 effect of SPIO nanoparticles.

High field magnetic resonance imaging evaluation of superparamagnetic iron oxide nanoparticles in a permanent rat myocardial infarction. Chapon C, Franconi F, Lemaire L, Marescaux L, Legras P, Saint-André JP, Denizot B, Le Jeune JJ. Invest Radiol 2003 Mar; 38 (3), pp. 141–6.

Vascular Imaging/Adhesion Molecule Expression/ Endothelial Intercellular Adhesion Molecule (ICAM)/ Microvascular (Endothelial) Leukocyte Receptor Complex Expression/Autoimmune Encephalitis *[Anti-ICAM]-Paramagnetic Liposomes (ACPL)*

Application: The *in vivo* targeting of molecules expressed on vascular endothelium, while providing sufficient signal enhancement at these sites for detection by MRI.
Implementation: [Anti-ICAM]-paramagnetic liposomes targeted to ICAM-1 administered *in vivo* for delineating endothelial leukocyte receptor upregulation in the cerebral microvasculature during conditions of autoimmune encephalitis.

Animal Model: Mouse (autoimmune encephalitis).
Interpretation and Analysis: Fluorescence microscopy analysis reveals that fluorescently tagged ACPLs are localized within the central nervous system (CNS) microvasculature in a pattern consistent with ICAM-1 upregulation. Such findings closely correlate with immunohistochemical analyses. High resolution *ex vivo* MRI of mouse brain demonstrates that ACPL binding patterns confer significant enhancement of signal intensity (SI) compared to control images. Preparations of ACPLs therefore appear to be a useful MRI contrast agent for visualization of specific molecules expressed on vascular endothelium during various disease states.
Instrumentation: Magnetic resonance imaging instrumentation.

ICAM-1 expression in autoimmune encephalitis visualized using magnetic resonance imaging. Sipkins DA, Gijbels K, Tropper FD, Bednarski M, Li KC, Steinman L. J Neuroimmunol 2000 Apr 3; 104 (1), pp. 1–9.

Vascular Imaging/Angiogenesis of Endothelium/ Atherosclerosis *Alpha$_v$Beta$_3$ ($\alpha_V\beta_3$)-Integrin-Targeted Paramagnetic Nanoparticles*

Background Information: Angiogenesis is a critical feature of plaque development in atherosclerosis and might play a key role in both the initiation and subsequent rupture of plaques that lead to myocardial infarction and stroke. The precursory molecular or cellular events that initiate plaque growth and that ultimately contribute to plaque instability, however, cannot be detected directly with any current diagnostic modality.
Application: Detection of alterations in vascular angiogenesis.
Route of Administration: Intravascular.
Implementation: Evaluation of angiogenesis phenomenon using $\alpha_V\beta_3$-integrin-targeted paramagnetic nanoparticles injected intravenously.

Animal Model: New Zealand White rabbits (atherosclerosis model dietarily induced by feeding 1% cholesterol for approximately 80 days).
Interpretation and Analysis: Alpha$_V$beta$_3$-integrin-targeted paramagnetic nanoparticles can specifically detect neovasculature structures within 2 hours by routine MRI at a clinically relevant field strength (1.5 Tesla). Increased angiogenesis can be detected as a 47 $\pm$ 5% enhancement in MRI signal averaged throughout the abdominal aortic wall following $\alpha_V\beta_3$-targeted paramagnetic nanoparticle administration. Pretreatment of atherosclerotic rabbits with $\alpha_V\beta_3$-targeted non-paramagnetic nanoparticles competitively blocks specific contrast enhancement of the $\alpha_V\beta_3$-targeted paramagnetic agent. Magnetic resonance imaging analysis can detect patterns of increased $\alpha_V\beta_3$-integrin distribution within the atherosclerotic wall that is spatially heterogeneous along both transverse and longitudinal planes of the abdominal aorta. Histology and immunohistochemistry can detect marked proliferation of angiogenic vessels within the aortic adventitia, coincident with prominent, neointimal proliferation among cholesterol-fed, atherosclerotic *in vivo* models in comparison with a sparse incidence of neovasculature in reference controls. Such approaches for molecular imaging may provide a method for defining the burden and evolution of atherosclerosis in susceptible individuals as well as responsiveness of individual conditions to antiatherosclerotic therapies.

Molecular imaging of angiogenesis in early-stage atherosclerosis with $\alpha_v\beta_3$-integrin-targeted nanoparticles. Winter PM, Morawski AM, Caruthers SD, Fuhrhop RW, Zhang H, Williams TA, Allen JS, Lacy EK, Robertson JD, Lanza GM, Wickline SA. Circulation 2003 Nov 4; 108 (18), pp. 2270–4.

Vascular Imaging: Angiogenesis (Example: Neoplastic Disease)/Tumor Dimethylarginine Dimethylaminohydrolase (DDAH) Overexpression *NC100150/Hoechst 33342*

Cellular/Molecular Mechanism of Action: The orientation of NC100150 becomes altered within a magnetic field. Alternatively, Hoechst 33342 emits fluorescent light energy.
Background Information: Intracellular factors that regulate nitric oxide (NO) synthesis represent important targets in tumor progression. Overexpression of DDAH, which metabolizes the endogenous inhibitors of NO synthesis asymmetric dimethylarginine and N-monomethyl-L-arginine, results in C6 gliomas with enhanced growth rates compared to wild cell types.
Application: NC100150 can be utilized as an intravascular blood-pool contrast agent that is detectable by MRI methodologies. Hoechst 33342 can be used as a fluorescent perfusion-marker dye that can be measured by flourescent detection systems.
Route of Administration: Utilization of NC100150 and Hoechst 33342 for neoplastic lesion angiogenesis requires that these be delivered intravascularly.
Implementation: Determine the (i) *in vitro* effects of DDAH on tumor vascular morphogenesis by measurement of the transverse relaxation rates R_2* and R_2 in clone D27 gliomas overexpressing DDAH and C6 wild-type gliomas using intrinsic susceptibility MRI sensitive to changes in endogenous deoxyhemoglobin; (ii) determine susceptibility contrast-enhanced MRI using NC100150 as an intravascular blood-pool contrast agent; and (iii) compare results with fluorescence microscopy of the tumor uptake of the perfusion marker Hoechst 33342.
Interpretation and Analysis: The baseline R_2* is significantly faster in D27 tumors, consistent with a greater vascular development ($p < 0.02$, ANOVA). There is no significant difference between the response of the 2 tumor types to hypercapnia (5% CO_2/95% air), used as a probe for vascular maturation, or hyperoxia (5% CO_2/95% O_2), used as a probe for vascular function. NC100150 increases the R_2* and R_2 rates of both tumor types and detects a significantly larger blood volume in the D27 tumors ($p < 0.02$, ANOVA). This correlates with a significantly greater uptake of Hoechst 33342 in the D27 tumors compared to C6 wild-type tumors ($p < 0.02$, ANOVA). Despite increased tumor blood volume, the Delta R_2*/Delta R_2 ratio,

an index of microvessel size, shows that the capillaries in the 2 tumor types are of a similar caliber. Such observations demonstrate the potential of susceptibility MRI-derived quantitative end points to non-invasively assess tumor angiogenesis. Application of intravascular blood-pool contrast agents such as NC100150 for such purposes appears very promising. Overexpression of DDAH results in increased *in vivo* neovascularization of C6 gliomas. The lack of significant difference in hypercapnic/hyperoxic response between C6 and D27 tumors and the similar vessel caliber are also consistent with a role for DDAH in the initial stages of vasculogenesis.

Instrumentation: Magnetic resonance imaging and fluorescence microscopy instrumentation.

Effects of overexpression of dimethylarginine dimethylaminohydrolase on tumor angiogenesis assessed by susceptibility magnetic resonance imaging. Kostourou V, Robinson SP, Whitley GS, Griffiths JR. Cancer Res 2003 Aug 15; 63 (16), pp. 4960–6.

Vascular Imaging: Angiogenic Markers Expressed by Endothelium/Alpha$_V$Beta$_3$ ($\alpha_v\beta_3$) Integrin
Anti-$\alpha_V\beta_3$-Integrin-Linked [Gd]-Perfluorocarbon Nanoparticles

Cellular/Molecular Mechanism of Action: Anti-$\alpha_V\beta_3$ integrin monoclonal antibody (anti-$\alpha_v\beta_3$ MoAb) recognizes and physically binds to $\alpha_V\beta_3$ integrin complexes. Gadolinium is an element that undergoes changes in physical orientation when subjected to magnetic energy fields. Nanoparticles can serve as a selective delivery modality for a compound and/or diminish elimination or metabolism within the plasma compartment.

Background Information: Alpha$_v$beta$_3$ integrin is a molecular marker that can be utilized to detect and characterize angiogenic endothelium (e.g., neoplastic lesions).

Application: Site-directed contrast image enhancement of (micro)angiogenic vessels. Gadolinium can be detected by MRI capabilities.

Route of Administration: Intravenous.

Animal Model: Rabbit (corneal micropocket with neovascularization induced using basic fibroblast growth factor).

Interpretation and Analysis: Selective *in vivo* targeting of contrast agent results in a 25% increase in the average MR signal intensity after 90 minutes. Control groups in which nanoparticles are either used alone, linked to an isotype-matched antibody, or linked to DM101 and administered following receptor blocking do not display MR contrast enhancement at similar dose levels. Therefore, antibody-mediated targeting of agents enhances MR signal intensity in the capillary bed when utilized in a corneal micropocket model for angiogenesis, and is selectively retained within the angiogenic region via specific interaction with $\alpha_V\beta_3$ epitopes.

Magnetic resonance contrast enhancement of neovasculature with $\alpha_v\beta_3$-targeted nanoparticles. Anderson SA, Rader RK, Westlin WF, Null C, Jackson D, Lanza GM, Wickline SA, Kotyk JJ. Magn Reson Med 2000 Sep; 44 (3), pp. 433–9.

Vascular Imaging/Angiography: Vascular Perfusion/Imaging Artifacts
Dynamic Susceptibility Contrast MRI/Contrast Agent Concentration

Background Information: Quantification of cerebral perfusion with dynamic susceptibility contrast MRI (DSC-MRI) requires the measurement of arterial input function (AIF) parameters. Conventionally, it is possible to derive the contrast concentration from the DSC sequence by monitoring changes in either the amplitude or the phase signal on the assumption that the signal arises completely from blood. In practice, partial volume artifacts are inevitable because a compromise has to be reached between the temporal and spatial resolution of the DSC acquisition. As the concentration of the contrast agent increases, the vector of the complex blood signal follows a spiral-like trajectory. In the case of a partial-volume voxel, the spiral is located around the static contribution of the surrounding tissue. If the static contribution of the background tissue is disregarded, estimations of the contrast concentration will be incorrect. By optimizing the correspondence between phase information and amplitude information 1 can estimate the origin of the spiral, and thereupon correct for partial volume artifacts. This correction is shown to be accurate at low spatial resolutions for phantom data and to improve the AIF determination in a clinical example.

Correcting partial volume artifacts of the arterial input function in quantitative cerebral perfusion MRI. van Osch MJ, Vonken EJ, Bakker CJ, Viergever MA. Magn Reson Med 2001 Mar; 45 (3), pp. 477–85.

Vascular Imaging/Angiography: Pulmonary Embolism
Blood-Pool Contrast Agents

Magnetic resonance angiography (MRA) has been established as a powerful non-invasive imaging modality. Its applications to the study of the pulmonary vasculature have been hampered by a multitude of factors, such as respiratory and cardiac motion artifacts, saturation problems, long acquisition times, and limited spatial resolution. The recent introduction of contrast-enhanced MRA (CE-MRA) has greatly improved the potential for possible investigation of the pulmonary arteries under clinical conditions. Three-dimensional sequences with minimum TR and TE, a flip angle between 20° and 60°, and minimum slice thickness can be considered an optimal approach for breath-hold imaging combined with the automatic injection of contrast medium. Early studies have demonstrated the superiority of CE-MRA over non-enhanced techniques. The major indication for CE-MRA of the pulmonary vasculature is pulmonary embolism. Here a sensitivity of 85% and specificity of 95% can be obtained. It can be complemented by perfusion imaging, ventilation imaging, functional measurements of the right ventricle, and MR venography of the pelvic and femoral veins. Blood-pool contrast agents will open new perspectives in the future. Reference articles have reviewed the technical aspects of CE-MRA of the pulmonary vasculature, pathologic findings, and their interpretation, as well as present and future clinical applications.

Contrast-enhanced magnetic resonance angiography of the pulmonary vasculature: A review. Kauczor HU. Invest Radiol 1998 Sep; 33 (9), pp. 606–17.

Vascular Imaging: Angiography of Abdominal Vasculature/Relative Effective Diagnostic Window/Relative Contrast-to-Noise Ratio/In-Plane Vascular Imaging
[FeO]-BPA Ultrasmall Superparamagnetic Iron Oxide Agent/WIN 22181 Gadolinium Polymer/Blood-Pool Agent Image Half-Lives

Route of Administration: Ultrasmall superparamagnetic iron oxide agent (FeO-BPA: intravenous); gadolinium polymer (WIN 22191: intravascular).

Implementation: Evaluation of the anatomical integrity of abdominal vasculature applying blood-pool contrast image-enhancing agents utilized in concert with MRI techniques. Coronal T_1-weighted

3-dimensional fast field-echo images can be obtained with a conventional 1.5 Tesla MRI system before and after injection of FeO-BPA. Comparison studies involve conduction of MR angiograms acquired using the gadolinium polymer (WIN 22181). Enhanced images are obtained 5–210 minutes after injection of FeO-BPA and 1–120 minutes after injection of WIN 22181.

Animal Model: Swine (e.g., n = 7 for MRI and n = 7 for MRI angiograms).

Interpretation and Analysis: The ultrasmall superparamagnetic iron oxide and gadolinium polymer blood-pool agents can be used effectively to obtain detailed angiogram images of the abdominal vascular tree when 2-minute image acquisition times are employed. In-plane running vessels can be imaged without saturation effects and with equivalent maximum signal-to-noise ratios. Half the maximum signal-to-noise ratio is reached 150 minutes after FeO-BPA injection, whereas this interval is approximately 70 minutes for gadolinium polymer. Because of these different imaging half-life values, the effective diagnostic window provided by FeO-BPA is 6 to 8 times longer than that of WIN 22181. In the liver, the vascular T_1 shortening and the parenchymal T_2* effect of FeO-BPA complement each other, resulting in an optimal contrast-to-noise ratio that is significantly higher than that achieved with gadolinium polymer (WIN 22181). Such a "double-contrast effect" in the liver is especially helpful when obtaining detailed MR portograms. The blood-pool agents FeO-BPA and gadolinium polymer (WIN 22181) can be used to produce high-quality abdominal MR angiograms on standard MRI equipment. The contrast-to-noise ratio of hepatic vessels is best on iron oxide-enhanced images because of a T_1-T_2* synergistic effect in the liver. The longer diagnostic window provided by FeO-BPA coupled with the option of in-plane imaging suggests the usefulness of FeO-BPA in future MRI-guided vascular interventions.

Abdominal MR angiography performed using blood pool contrast agents: Comparison of a new superparamagnetic iron oxide nanoparticle and a linear gadolinium polymer. Nolte-Ernsting C, Adam G, Bucker A, Berges S, Bjornerud A, Gunther RW. AJR Am J Roentgenol 1998 Jul; 171 (1), pp. 107–13.

Vascular Imaging: Angiography and Neurophysiology/Enhanced Contrast-to-Noise Ratio/Improved Resolution
Magnetite Dextrane Nanoparticles: Blood-Pool Agent/ Functional MRI (fMRI)

Cellular/Molecular Mechanism of Action: Magnetite dextran nanoparticles following direct injection intravascularly remain within this body compartment for a prolonged period of time. The metallic component of the complexes undergoes spacial reorientation when subjected to magnetic energy fields that can be detected by MRI modalities.

Background Information: Functional MRI in awake-behaving primates is an emerging tool for bridging the gap between human fMRI and neurophysiology information from non-human primates.

Application: Magnetite dextran nanoparticles (Feridex) can be applied as a blood-pool agent to enhance fMRI contrast-to-noise ratios (CNRs) and achieve improved levels of resolution.

Dosage: Magnetite dextran nanoparticles.

Implementation: Intravascular injection of magnetite dextran nanoparticles (Feridex) as a blood-pool agent to delineate its capacity to enhance fMRI CNRs.

Animal Model: Primate (macaque monkey).

Interpretation and Analysis: Compared to lanthanide chelates, the intravascular half-life of magnetite dextran is relatively long ($T_{1/2}$ = 198 minutes) with a shortened T_2 relaxation observed in blood and cerebral cortex. Greater than 3-fold enhancement in the percentage MR signal change is observed using nanoparticles (13%) compared with conventional blood oxygen level–dependent (BOLD) fMRI (4%). The calculated regional cerebral blood volume in the primary visual cortex increases 32% with photic stimulation. The increased CNR allows greater flexibility in the design of awake-behaving primate fMRI studies with the potential for improvements in resolution and significantly shortened imaging times.

Enhancing fMRI contrast in awake-behaving primates using intravascular magnetite dextran nanoparticles. Dubowitz DJ, Bernheim KA, Chen DY, Bradley Jr WG, Andersen RA. Neuroreport 2001 Aug 8; 12 (11), pp. 2335–40.

Vascular Imaging/Arteriography of Peripheral and Renal Arteries/Alternative Non-Iodinated Contrast Image-Enhancing Agent/Digital Subtraction Angiography
Gadolinium

Cellular/Molecular Mechanism of Action: Gadolinium formulations possess radiopaque properties and their spatial orientation becomes altered when subjected to magnetic energy fields.

Application: Image enhancement of vascular anatomical abnormalities affecting peripheral and renal arterial vessels utilizing digital subtraction angiography (DSA) as an imaging modality.

Route of Administration: Gadodiamide (intra-arterial).

Dosage: Gadodiamide (mean volume = 136 ± 46 mL [range 60–200]).

Implementation: Peripheral and renal intra-arterial DSA facilitated by the administration of gadodiamide as a positive contrast image-enhancing agent in cases where iodinated contrast media is contraindicated (e.g., n = 17; n = 10 males; mean age 74 years, range 68–83 years). Detection of vascular anatomical abnormalities can subsequently serve as a guide for performing percutaneous intervention procedures (e.g., balloon angioplasty, stent placement).

Interpretation and Analysis: Serious side effects are rarely observed (e.g., n = 0/17 with no detectable changes in renal or thyroid function, and lack of exanthema or other allergic types of reactions). In conditions not requiring renal artery intervention, serum creatinine at discharge remains unchanged (2.57 ± 1.43 mg/dL to 2.40 ± 1.28 mg/dL, p = nonsignificant). In cases undergoing angioplasty/stenting of renal artery stenoses, serum creatinine decreases significantly (e.g., 3.53 ± 1.75 mg/dL to 2.36 ± 1.15 mg/dL [$p < 0.01$]). The diagnostic quality of the peripheral digital subtraction angiographs is often (usually) rated as being "good," but corresponding renal images are often graded as only being of "sufficient" diagnostic quality. In situations where the diagnostic administration of iodinated contrast image-enhancing reagents are contraindicated, gadodiamide may be a suitable alternative for renal or peripheral DSA followed by angioplasty.

Gadodiamide as an alternative contrast agent during angioplasty in patients with contraindications to iodinated media. Zeller T, Muller C, Frank U, Burgelin K, Sinn L, Horn B, Flugel PC, Roskamm H. J Endovasc Ther 2002 Oct; 9 (5), pp. 625–32.

Vascular Imaging/Atherosclerotic Plaque Lesions
Ultrasmall Superparamagnetic Particles of Iron Oxide (USPIOs)/(Sinerem, Guerbet)

Cellular/Molecular Mechanism of Action: Iron oxide particles change their spatial orientation when placed within an intense magnetic energy field. Macrophages perceive such particles as a for-

eign substance and internalize them through phagocytosis mechanisms.

Background Information: Agents classified as USPIOs are phagocytosed by cells of the mononuclear phagocytic system.

Application: Detection and characterization of atherosclerotic plaques.

Dosage: Ultrasmall superparamagnetic particles of iron oxide (Sinerem, Guerbet at 1 mmol Fe/kg).

Implementation: Evaluation of USPIO agents as potential detection agents that recognize biomarkers for atherosclerosis-associated inflammatory changes in the vessel wall before the development of vascular luminal narrowing. One approach to achieving this objective can entail characterization of the thoracic aorta using 3-dimensional MR angiography (MRA) with the enhancement of images using a paramagnetic contrast agent. One week later, all rabbits except 1 of the hyperlipidemic animals are then injected with a USPIO contrast agent (Sinerem, Guerbet) at a dose of 1 mmol Fe/kg.

***Ex Vivo* Model:** Rabbit aorta preparations.

Animal Model: Rabbit (n = 6 heritable hyperlipemic New Zealand White; and n = 3 New Zealand White control rabbits).

Interpretation and Analysis: Three-dimensional MRA data sets collected over 5 days show increasing signal in the aortic lumen. No vascular lesions can be detected at the time of initial imaging. The aortic wall of the control rabbits remains smooth and bright. Marked susceptibility effects become evident on day 4 within the aortic walls of hyperlipidemic rabbits. Results observed *in vivo* can be confirmed *ex vivo* by imaging aortic specimens. Histopathology can detect marked Fe uptake in macrophages embedded in atherosclerotic plaques in scenarios of hyperlipidemia, and electron microscopy analysis reveals multiple cytoplasmic Fe particles within macrophages. No such changes can be appreciated in controls or in conditions of hyperlipidemia not receiving Sinerem. Ultrasmall superparamagnetic particles of iron oxide are phagocytosed by macrophages in atherosclerotic plaques of the aortic wall of hyperlipidemic rabbits in a quantity sufficient to recognize susceptibility effects that can be detected by MRI.

Magnetic resonance imaging of atherosclerotic plaque with ultrasmall superparamagnetic particles of iron oxide in hyperlipidemic rabbits. Ruehm SG, Corot C, Vogt P, Kolb S, Debatin JF. Circulation 2001 Jan 23; 103 (3), pp. 415–22.

Vascular Imaging/Blood-Pool Agent/Neoplastic Lesion Vasculature Networks
Iohexol Liposomes

Background Information: Although soluble non-ionic iodine compounds with low systemic toxic effects have been developed for use in computed tomography (CT), they have short residence times of a few minutes or mere seconds, which is an insufficient period of time for blood-pool imaging, even with high-speed multidetector row spiral CT. Moreover, potential renal toxic effects preclude repeated administration of these contrast agents during imaging, as well as their use in patients with compromised renal function.

Implementation: Develop and evaluate a CT contrast agent for blood-pool imaging that remains in the blood for more than 3 hours and that is relatively non-toxic to the kidneys. A relevant agent in this regard includes liposomal iohexol formulations.

Semi-Synthetic Methods: Determination of the encapsulation efficiency in terms of milligrams of iodine per milliliter of lipid formulation and delineation of preparation *in vitro* stability in phosphate buffer solutions and human plasma. Complementary investigations can assess formulation *in vivo* stability, residence time, and enhancement of contrast on images of various organ systems.

Animal Model: Rabbit.

Interpretation and Analysis: Formulations containing 34.8 mg of iodine per milliliter of liposomal iohexol solution retain stability in blood plasma both *in vitro* and *in vivo* postinjection. An intravenous dose of 475 mg of iodine per kilogram of body weight produces contrast enhancement in the rabbit model of approximately 130 HU in the aorta and liver cortex and approximately 100 HU in the kidney cortex. Contrast enhancement can be maintained for 3 hours postinjection, and minimal clearance of the contrast agent via the kidneys is observed. The liposomal iohexol formulations have a sufficient residence time for blood-pool imaging (rabbit models). Future experiments with long-residence-time iohexol formulations may lead eventually to applications in cardiac imaging and in early tumor detection.

Long-residence-time nano-scale liposomal iohexol for X-ray-based blood-pool imaging. Kao CY, Hoffman EA, Beck KC, Bellamkonda RV, Annapragada AV. Acad Radiol 2003 May; 10 (5), pp. 475–83.

Vascular Imaging/Brain Reperfusion Injury with Ischemia/Oxidative Stress/Brain Tumors/ Neurodegenerative Disorders
MC-PROXYL/Carbamoyl-PROXYL

Background Information: Several investigations have reported that central nervous system (brain) free radicals generation is involved in various brain dysfunctions, including ischemia-reperfusion injury, brain tumors, and neurodegenerative diseases. It has been reported that the spin probe MC-PROXYL can penetrate the blood-brain barrier (BBB) and can be useful for evaluating oxidative stress in the brain.

Application: The agent MC-PROXYL functions as a spin probe for imaging changes in ischemia-reperfusion injury. The agent carbamoyl-PROXYL functions as a BBB impermeable imaging probe.

Route of Administration: Intravenous.

Implementation: Evaluation of reperfusion injury and models of stroke-prone spontaneous hypertensive conditions.

Animal Model: Murine (*in vivo*) and rat (isolated brain: stroke-prone spontaneously hypertensive model).

Interpretation and Analysis: The agent MC-PROXYL, but not carbamoyl-PROXYL, is widely distributed throughout the brain. Rapid decay of 2-dimensional electron spin resonance (ESR) images of MC-PROXYL in isolated stroke-prone spontaneous hypertensive rat (SHRSP) brain can be observed, in contrast to Wistar-Kyoto rats (WKYs), using the ESR imaging system. Furthermore, by using L-band ESR non-invasively, the decay rate of MC-PROXYL in the head region can be found to be faster in live SHRSPs than in live Wistar-Kyoto rats. Taken together, the high oxidative stress sustained by oxygen radical generation in SHRSPs may cause alterations in MC-PROXYL metabolism within the brain. Such results suggest that *in vivo* ESR could be applied for the assessment of antioxidant effects on oxidative stress events in the brain (e.g., animal disease models for SHRSP).

Meassurement of oxidative stress in stroke-prone spontaneously hypertensive rat brain using *in vivo* electron spin resonance spectroscopy. Miyazaki H, Shoji H, Lee MC. Redox Rep 2002; 7 (5), pp. 260–5.

Vascular Imaging/Thromboses (Arterial)
RGD-Ultrasmall Superparamagnetic Particles of Iron Oxide (USPIOs)

Cellular/Molecular Mechanism of Action: The peptide RGD recognizes and physically binds to the exterior surface of activated

platelet populations. The physical orientation of iron ions becomes altered when subjected to magnetic energy fields.

Application: Detection of platelet thromboses, especially those formed within the arterial vasculature, which have a relatively higher platelet composition than do venous thromboses.

Semi-Synthetic Methods: Preparation of USPIOs coupled to an RGD peptide (RGD-USPIO) that selectively recognizes activated platelet populations.

Implementation: Evaluation of thrombus lesions applying USPIOs coupled to an RGD peptide (RGD-USPIO) targeted for activated platelets, applied in combination with MRI modalities. Thrombus visualization *ex vivo* is then compared using RGD-USPIO and a non-targeted USPIO. Relevant variables that can be assessed include determining the influence of the duration of thrombus exposure to RGD-USPIO (*ex vivo*) on thrombus visualization and spatial resolution of MR images (*ex vivo* and *in vivo*).

***Ex Vivo* Model:** Thrombus (*ex vivo* and *in vivo* preparations).

Interpretation and Analysis: RGD-USPIOs provide superior thrombus visualization compared to non-targeted USPIOs *ex vivo*, and maximum enhancement can be achieved after exposure of vascular thrombses to RGD-USPIO preparations for periods of approximately 1 hour. The ability to visualize clots is highly dependent on the spatial resolution of the image. *In vivo*, an in-plane level of resolution of less than 0.2×0.2 mm^2 is required for good clot visualization after contrast enhancement. Achievable resolution and sensitivity is a potential limitation for the usefulness of active vascular MRI targeting.

A targeted contrast agent for magnetic resonance imaging of thrombus: Implications of spatial resolution. Johansson LO, Bjornerud A, Ahlstrom HK, Ladd DL, Fujii DK. J Magn Reson Imaging 2001 Apr; 13 (4), pp. 615–8.

Vascular Thromboses
Gadolinium-DTPA ([Gd]-DTPA) Lipid-Encapsulated Perfluorocarbon Nanoparticle

Cellular/Molecular Mechanism of Action: Fibrin monomer naturally undergoes multimeric (non-covalent) polymerization with other strands of fibrin monomer following the cleavage of a small peptide fragment from fibrinogen by the biochemical activity of thrombin.

Application: Detection and characterization of vascular thrombi.

Route of Administration: Intended for intravascular delivery.

Implementation: Evaluation of the sensitivity of lipid-encapsulated perfluorocarbon nanoparticle with numerous [Gd]-DTPA complexes incorporated into the outer surface in order to function as a contrast imaging agent for detecting intravascular fibrin deposits. One approach for evaluating such properties includes utilizing the agent to determine its capacity to detect fibrin strands in a defined *in vitro* human thrombosis model.

Interpretation and Analysis: After binding to fibrin clots, scanning electron microscopy of treated clots reveals patterns of accumulations of dense nanoparticles on the clot surface. Fibrin clots with sizes ranging from 0.5 to 7.0 mm are imaged at 4.7 Tesla with or without the targeted contrast agent. Regardless of size, untreated clots are not easily detected by T_1-weighted MRI, while targeted contrast agent dramatically improves the detection of all clots. Decreases in T_1 and T_2 relaxation times (20–40%) are measured relative to the surrounding media and reference control clots.

High-resolution MRI characterization of human thrombus using a novel fibrin-targeted paramagnetic nanoparticle contrast agent. Yu X, Song SK, Chen J, Scott MJ, Fuhrhop RJ, Hall CS, Gaffney PJ, Wickline SA, Lanza GM. Magn Reson Med 2000 Dec; 44 (6), pp. 867–72.

CENTRAL NERVOUS SYSTEM

Central Nervous System (CNS)
Ferrimagnetic Iron Oxide Nanoparticles

Application: Potential application for brain imaging.

Route of Administration: Intravascular (proposed).

Semi-Synthetic Methods: Nanoparticles can be prepared by co-precipitation of ferric and ferrous ions in the presence of either dextran or polyvinyl alcohol. The method of preparation results in loosely packed clusters (dextran) or branched chains (polyvinyl alcohol) of particles containing on the order of 600 and 400 particles, respectively.

Implementation: Meassurement of proton transverse relaxation rates (R2) in agar gels with varying concentrations of ferrimagnetic iron oxide nanoparticles in a field strength of 1.5 Tesla.

Interpretation and Analysis: For both methods of particle preparation, concentrations of ferrimagnetic iron in agar gel less than 0.01 mg/ml have no measurable effect on the value of R2 for the gel. The results indicate that MRI-based R2 measurements using 1.5 Tesla clinical scanners are not quite sensitive enough to detect the very low concentrations of nanoparticulate biogenic magnetite reported in human brain tissue.

Instrumentation: Clinical MRI system.

Detection limits for ferrimagnetic particle concentrations using magnetic resonance imaging based proton transverse relaxation rate measurements. Pardoe H, Chua-anusorn W, St Pierre TG, Dobson J. Phys Med Biol 2003 Mar 21; 48 (6), pp. N89–95.

Central Nervous System (CNS)/Amyloid Beta (Abeta) Plaques (Brain): Alzheimer's Disease (AD)
Gadolinium (Gd) Abeta$_{1\text{-}40}$ Nanoparticles/ Monocrystalline Iron Oxide Abeta$_{1\text{-}40}$ Nanoparticles

Cellular/Molecular Mechanism of Action: Abeta$_{1\text{-}40}$ has a high (non-covalent) binding avidity for abeta amyloid.

Background Information: The presence of abeta plaques in the brain is a hallmark pathological feature of AD. Transgenic mice that overexpress mutant amyloid precursor protein (APP), or both mutant APP and presenilin-1 (APP/PS1), develop abeta plaques similar to those in AD patients and have been proposed as animal models in which to test experimental therapeutic approaches for the clearance of abeta. However, there are few *in vivo* whole-brain imaging methods available for detecting abeta plaques in mice or men.

Application: Detection and characterization of abeta plaque deposits *in vivo* within the brain.

Route of Administration: Intra-arterial injection with mannitol to facilitate transient opening of the blood-brain barrier (BBB).

Implementation: Evaluation of the capacity for abeta$_{1\text{-}40}$ peptide magnetically labeled with either gadolinium (Gd) or monocrystalline iron oxide nanoparticles (MION) to detect *in vivo* amyloid plaque deposits.

Animal Model: Murine (transgenic).

Interpretation and Analysis: Magnetically labeled abeta$_{1\text{-}40}$ with mannitol enables the detection of many abeta plaques. Furthermore, the numerical density of abeta plaques detected by MR microimaging (μMRI) and by immunohistochemistry shows excellent correlation. This approach represents an *in vivo* method for detecting abeta in AD transgenic mice and suggests that diagnostic MRI methods to detect abeta in AD patients may ultimately be feasible.

Instrumentation: Magnetic resonance microimaging.

Detection of Alzheimer's amyloid in transgenic mice using magnetic resonance microimaging. Wadghiri YZ, Sigurdsson EM, Sadowski M, Elliott JI, Li Y, Scholtzova H, Tang CY, Aguinaldo G, Pappolla M, Duff K, Wisniewski T, Turnbull DH. Magn Reson Med 2003 Aug; 50 (2), pp. 293–302.

Central Nervous System (CNS)/Blood-Brain Barrier (BBB) Diffusion
Superparamagnetic Solid Lipid Nanoparticles (SLN)

Cellular/Molecular Mechanism of Action: Solid lipid nanoparticles, due to their lipophilic properties, difuse into the lymph following duodenal administration and diffusion across the BBB into the CNS.
Application: Solid lipid nanoparticles can be used to selectively "target" pharmaceutical agents for the lymph.
Route of Administration: Solid lipid nanoparticles (duodenal).
Semi-Synthetic Methods: Preparation of superparamagnetic SLN that are colloidal in size and *in vitro* analysis reveal they possess relaxometric properties similar to Endorem.
Implementation: Magnetic resonance imaging of the CNS with superparamagnetic SLN.
Interpretation and Analysis: Magnetic resonance imaging of the CNS with superparamagnetic SLN reveals they have a slower blood clearance than Endorem. Magnetic resonance imaging data are consistent with CNS uptake of SLN lasting up to a duration of 135 minutes. Therefore, SLN are capable of passively diffusing across an intact BBB, which is a feature that could be utilized for the molecular design of CNS MRI contrast agents.

In vitro and *in vivo* study of solid lipid nanoparticles loaded with superparamagnetic iron oxide. Peira E, Marzola P, Podio V, Aime S, Sbarbati A, Gasco MR. J Drug Target 2003 Jan; 11 (1), pp. 19–24.

Central Nervous System (CNS)/Blood-Brain Barrier Penetration/Transferrin Receptor Complexes/ Demyelinated Axons
Oligodendrocyte Progenitor Cells/[Transferrin Magnetic Nanoparticles]

Cellular/Molecular Mechanism of Action: Oligodendrocyte progenitor cells naturally migrate to specific foci within the CNS, including demyelinated axons.
Background Information: Demyelination is a common pathological finding in human neurological diseases and frequently persists as a result of failure of endogenous repair. Transplanted oligodendrocytes and their precursor cells can (re)myelinate axons, raising the possibility of therapeutic intervention. The migratory capacity of transplanted cells is of key importance in determining the extent of (re)myelination and can, at present, be evaluated only by the use of invasive and irreversible procedures.
Application: Potential delivery modality that recognizes demyelinated axons.
Route of Administration: Presumably intravascular.
Implementation: Delineation of the capacity for transferrin receptors to function as an effective "target" that can facilitate the intracellular delivery of magnetic nanoparticles and guide the migration of transplanted tagged oligodendrocyte progenitor cells into the spinal cord with myelin-deficient neurons.
Animal Model: Rat (myelin-deficient neurons).
Interpretation and Analysis: Cell migration can be easily detected by using 3-dimensional MR microscopy, which demonstrates a close correlation between the areas of contrast enhancement and degree of "new" myelination in an *in vivo* myelin-deficient model. In this context, investigations have demonstrated the feasibility of successfully using MR to track transplanted oligodendrocyte progenitor cells. The technique has the potential of being easily extended into other neurotransplantation research investigations involving different precursor cell types.

Neurotransplantation of magnetically labeled oligodendrocyte progenitors: Magnetic resonance tracking of cell migration and myelination. Bulte JW, Zhang S, van Gelderen P, Herynek V, Jordan EK, Duncan ID, Frank JA. Proc Natl Acad Sci U S A 1999 Dec 21; 96 (26), pp. 15256–61.

Central Nervous System (CNS)/Blood-Brain Barrier (BBB) Permeability/Multiple Sclerosis/Brain Tumor Growth
Intravascular Contrast Agent

Background Information: A non-invasive technique for measuring the permeability of the BBB to water could help to evaluate changes in the functional integrity of the BBB that occur in different pathological conditions, such as multiple sclerosis or growth of brain tumor. Some clinical investigators have proposed an MR method to measure BBB permeability based on the T_1 reductions induced by injecting various doses of paramagnetic contrast agent. However, this method may be difficult to implement in a clinical environment.
Implementation: Utilization of a 2-point technique that applies a spatially selective inversion to measure T_1 prior to and after injection of an intravascular contrast agent. Measurements acquired are compared to numerical simulations generated with a physiological model that accounts for blood flow and includes 2 different blood volumes (e.g., non-exchanging and exchanging).
Animal Model: Rat brain.
Interpretation and Analysis: The permeability of the BBB can be evaluated from the change in T_1 caused by vascular contrast agent. This technique might provide an approach for monitoring changes in BBB permeability to water in clinical studies.

A model of blood-brain barrier permeability to water: Accounting for blood inflow and longitudinal relaxation effects. Barbier EL, St Lawrence KS, Grillon E, Koretsky AP, Decorps M. Magn Reson Med 2002 Jun; 47 (6), pp. 1100–9.

Central Nervous System (CNS)/Cerebral Perfusion/ Induced Vasoconstriction/Blood Oxygen Level–Dependent (BOLD) Baseline Resting Signal
Caffeine / Functional MRI (fMRI)

Physiological Mechanism of Action: Caffeine functions as a cerebral vasoconstrictor.
Background Information: Previous research has demonstrated that caffeine has the ability to reset the level of coupling between blood flow and neuronal activity.
Application: Investigation of the effect of disease processes and pharmaceutical agents on cerebral blood flow.
Implementation: Evaluation of the influence that caffeine has improving BOLD signal response in fMRI-based techniques.
Interpretation and Analysis: Caffeine causes a decrease in cerebral perfusion by as much as 13.2% without a change in performance. Caffeine is a cerebral vasoconstrictor that causes an increase in the concentration of deoxyhemoglobin and thus a decrease in the BOLD baseline resting signal by 4.4%. During activation, the vasculature responds from below-normal baseline levels with a normal increase in blood flow and volume, resulting in an overall increase in BOLD contrast. Such increases can be as large as 22–37% during the performance of a visually cued motor task. The benefit of such a large increase in the BOLD contrast could be used

to improve image resolution, the acquisition scheme, or the task design of fMRI experiments. Caffeine has the potential to be used as a contrast booster for fMRI experiments.

On the use of caffeine as a contrast booster for BOLD fMRI studies. Mulderink TA, Gitelman DR, Mesulam MM, Parrish TB. Neuroimage 2002 Jan; 15 (1), pp. 37–44.

Central Nervous System (CNS)/Dopamine D_2 Receptor Complexes/Bilateral Frontal Cortex Blood Oxygen Level–Dependent (BOLD) Signal Increases/ Psychoactive Pharmacological Agent Efficacy Evaluation
Functional MRI (fMRI) / Sulpiride

Cellular/Molecular Mechanism of Action: Sulpiride functions as a selective D_2-like receptor antagonist.
Physiological Mechanism of Action: Sulpiride promotes increases in frontal dopaminergic function by antagonism of presynaptically located dopamine D_2 receptors within this region of the brain and is consistent with its known therapeutic mechanism of action.
Application: Sulpiride.
Route of Administration: Sulpiride (intravenous).
Dosage: Sulpiride (3 mg/kg vs 10 mg/kg vs 30 mg/kg).
Implementation: Blood oxygen level–dependent contrast fMRI was used to study the effects of the D_2-like receptor selective antagonist, sulpiride, at 2 Tesla in the brain of the alpha-chloralose anesthetized rat.
Interpretation and Analysis: Region of interest (ROI) analysis indicates significant ($p < 0.05$) bilateral increases in BOLD signal intensity in the frontal cortex following a single administration of sulpiride (10 mg/kg). Blood oxygen level–dependent signal changes are slow in onset and increase gradually, reaching $8.0 \pm 0.5\%$ (mean $\pm$ standard error of measurement) above preinjection control values 165 minutes after drug administration. Signal increases remain high up to 3 hours post–sulpiride administration. Sulpiride (30 mg/kg) has a similar effect in the frontal cortex, reflected by signal increases $5.2 \pm 1.8\%$ above control values by 174 minutes. However, the effects of sulpiride at this dosage are more variable (between rats), but this observation is not statistically significant. Sulpiride (3 mg/kg) has no significant effect upon BOLD signal intensity within any region of the brain. No dose of sulpiride within the ranges evaluated induces any significant BOLD signal changes within the striatum or cerebellum. Such observations support the concept that sulpiride causes an increase in frontal dopaminergic function by antagonism of presynaptically located dopamine D_2 receptors within this brain region, consistent with its therapeutic action. Furthermore, the utility of BOLD contrast fMRI as a means of detecting changes in neuronal activity contingent upon the administration of a psychoactive pharmacological agent has been demonstrated.

Detection of pharmacologically mediated changes in cerebral activity by functional magnetic resonance imaging: The effects of sulpiride in the brain of the anesthetised rat. Preece M, Mukherjee B, Huang CL, Hall LD, Leslie RA, James MF. Brain Res 2001 Oct 19; 916 (1–2), pp. 107–14.

Central Nervous System (CNS)/Endothelial ICAM Expression in the CNS/Microvascular (Endothelial) Leukocyte Receptor Complex Expression
[Anti-ICAM]-Paramagnetic Liposomes/Fluorescent-Tagged [Anti-ICAM]-Paramagnetic Liposomes (ACPLs)

Application: The *in vivo* targeting of membrane-associated ICAM complexes expressed by vascular endothelium to create sufficient signal enhancement at these sites for detection by MRI instrumentation.
Implementation: [Anti-ICAM]-paramagnetic liposomes targeted to intercellular adhesion molecule-1 (ICAM-1) administered *in vivo* for delineating the upregulation of endothelial leukocyte receptor complexes of the cerebral microvasculature during conditions of autoimmune encephalitis.
Animal Model: Mouse (autoimmune encephalitis).
Interpretation and Analysis: Fluorescence microscopy analysis reveals that fluorescently tagged ACPLs are localized within the CNS microvasculature in a pattern consistent with ICAM-1 upregulation. Such findings closely correlate with immunohistochemical analyses. High-resolution MRI of mouse brains *ex vivo* demonstrates that ACPL binding patterns confer significant enhancement of signal intensity (SI) as compared to control images. Preparations of ACPLs therefore appear to be a useful MRI contrast agent for visualization of specific molecules expressed on vascular endothelium during various disease states.
Instrumentation: Magnetic resonance imaging instrumentation.

ICAM-1 expression in autoimmune encephalitis visualized using magnetic resonance imaging. Sipkins DA, Gijbels K, Tropper FD, Bednarski M, Li KC, Steinman L. J Neuroimmunol 2000 Apr 3; 104 (1), pp. 1–9.

Central Nervous System (CNS)/Gene Mapping Model: *In Vivo* β-Galactosidase Expression
Galactopyranose Functional Group/Chelated Paramagnetic Ion

Cellular/Molecular Mechanism of Action: Galactopyranose can function as a substrate for the indicator (marker) gene β-galactosidase.
Background Information: High-resolution *in vivo* imaging of gene expression is not possible applying existing techniques.
Application: High-resolution *in vivo* MRI imaging of "reporter" gene expression.
Semi-Synthetic Methods: Preparation of an MRI contrast agent in which the access of water to the 1st coordination sphere of a chelated paramagnetic ion is blocked with a substrate that can be removed by enzymatic cleavage. Following cleavage, the paramagnetic ion can interact directly with water protons to increase the MR signal.
Implementation: Detection and characterization of *in vivo* gene expression.
Interpretation and Analysis: Galactopyranose can function as an effective blocking group that can render an MRI contrast agent sensitive to detecting the expression of β-galactosidase (marker gene). Pertaining to cellular resolution, regions of higher intensity in MR images correlate with regions expressing the marker enzyme. These results offer the promise of *in vivo* mapping of gene expression in transgenic animals and validate a general approach for constructing a family of MRI contrast agents that respond to biological activity.

In vivo visualization of gene expression using magnetic resonance imaging. Louie AY, Huber MM, Ahrens ET, Rothbacher U, Moats R, Jacobs RE, Fraser SE, Meade TJ. Nat Biotechnol 2000 Mar; 18 (3), pp. 321–5.

Central Nervous System (CNS)/Gliomatosis Cerebri
Gadopentetate Dimeglumine

Application: Magnetic resonance imaging characteristics of gliomatosis cerebri reiterate the diffuse nature of this tumor, but such features are non-specific and thus may pose a diagnostic challenge.

Because perfusion MRI can provide a physiologic map of the microcirculation, it is possible to compare the measured relative cerebral blood volume (rCBV) at the time of perfusion imaging with histopathologic findings in gliomatosis cerebri.

Considerations: First-pass bolus infusion utilizing gadopentetate dimeglumine in conjunction with MRI (dynamic contrast-enhanced T_2*-weighted gradient-echo echo-planar images).

Implementation: Retrospective analysis of conventional and perfusion MR images of proven cases of gliomatosis cerebri. Conventional MR images are evaluated for the presence or absence of contrast enhancement, necrosis, and extent of T_2-weighted signal intensity abnormality. Dynamic contrast-enhanced T_2*-weighted gradient-echo echo-planar images are acquired during the 1st pass of a bolus injection of gadopentetate dimeglumine. The rCBV is calculated by using non-diffusible tracer kinetics and expressed relative to normal-appearing white matter. Pathologic findings are reviewed in all patients and compared with the MR perfusion data. Multivoxel 2-dimensional chemical shift imaging proton MR spectroscopic data can also be acquired (e.g., n = 3 cases), as can single-voxel data (e.g., n = 1 case).

Human Model: Cases of gliomatosis cerebri (n = 7).

Interpretation and Analysis: Conventional MR images reveal the presence of diffuse abnormalities in all cases and absence of contrast enhancement in all but 1 case. Average rCBV range is 0.75–1.26 (mean, 1.02 ± 0.42 standard deviation). Magnetic resonance spectroscopic data reveal spectra consistent with the presence of tumoral disease. Histopathologic evaluations reveal an absence of vascular hyperplasia in all specimens. Conclusion: The low MR rCBV measurements of gliomatosis cerebri are in concordance with the lack of vascular hyperplasia found at histopathologic examination; thus, perfusion MRI provides useful adjunctive information that is not available from conventional MRI techniques.

Instrumentation: Magnetic resonance imaging systems.

Central Nervous System (CNS)/Ischemia (Cerebral): Infarct Lesions
$H_2{}^{17}O$/Gadolinium-DTPA ([Gd]-DTPA)

Cellular/Molecular Mechanism of Action: The agent $H_2{}^{17}O$ functions as an analog of water in biological systems.

Background Information: Oxygen-17 enriched water acts as a T_2 shortening contrast agent whose effect can be suppressed by decoupling at the [^{17}O] frequency during TE interval in a spin-echo MR image.

Application: Quantifying low concentrations of $H_2{}^{17}O$ *in vivo* and exploring its utility for assessing cerebral ischemia.

Route of Administration: $H_2{}^{17}O$ (intravenous).

Dosage: $H_2{}^{17}O$ (bolus of 1 ml of 10 atom% $H_2{}^{17}O$).

Implementation: Serial T_2-weighted echo planar images are acquired in phantoms and rat brain with decoupler power alternated every 8 images. The resulting periodic signal change (proportional to $H_2{}^{17}O$ concentration) is subsequently detected by cross-correlating the square-wave decoupler power time course with the signal intensity in each voxel. Natural abundance (0.037 atom%) images of $H_2{}^{17}O$ are then generated (rat brain).

Animal Model: Rat (brain focal ischemic model).

Interpretation and Analysis: The transverse relaxivity of $H_2{}^{17}O$ in brain has been estimated to be $R_2 = 2.4 \pm 0.5\ s^{-1}$ atom%$^{-1}$. Estimated brain $H_2{}^{17}O$ concentrations are 0.06 ± 0.01 atom%. In the rat focal ischemia model, ^{17}O cross-correlation maps compare well with diffusion and [Gd]-DTPA perfusion images for the detection of infarct locations.

MRI of focal cerebral ischemia using ^{17}O-labeled water. de Crespigny AJ, D'Arceuil HE, Engelhorn T, Moseley ME. Magn Reson Med 2000 Jun; 43 (6), pp. 876–83.

Central Nervous System (CNS)/Ischemic Insult to the Brain/Neurologic Ischemia Model/Relative Uptake and Neurotoxicity
Iopromide/Gadobenate Dimeglumine/Gadodiamide

Background Information: Because contrast agent (CA) formulations are injected intravenously to patients who may have a disrupted blood-brain barrier, their neurotolerability ideally should be evaluated.

Route of Administration: Iopromide (intravascular); gadobenate dimeglumine (intravascular); and gadodiamide (intravascular).

Dosage: Iopromide (7 g iodine/kg: 10 times higher than the maximum clinical dose in rats); gadobenate dimeglumine (2.0 mmol/kg; 20 times clinical dose in rats); and gadodiamide (2.0 mmol/kg; 20 times the clinical dose in rats).

Considerations: Iopromide is a poorly neurotolerated iodinated contrast agent.

Implementation: Rats were prepared for electroencephalogram (EEG) recording about 15 days before induction of ischemia in the right hemisphere by 2-hour middle cerebral artery (MCA) occlusion and reperfusion for 3 days. Rats with evidence of CNS ischemia on day 3 after transient MCA occlusion are subsequently selected for neurotolerability studies. Model validation in terms of EEG on day 3 after MCA occlusion is performed in concert with iopromide iodinated contrast agent. Recordings for EEG tracings are analyzed for pathological tracings and for changes in spectral profiles in terms of the frequency index (FI) at 1, 2, and 3 hours after test compound injection. Comparison evaluations between gadobenate dimeglumine and gadodiamide are performed at 2.0 mmol/kg with D-mannitol applied as a reference control. The presence of contrast agent in the brain (rat) is verified by measuring the total gadolinium content by using inductively coupled plasma-atomic emission spectrometry analysis. Given the absence of metabolism for both contrast agents, the values of gadolinium content can be interpreted as representing unmetabolized contrast agent.

Animal Model: Rat (brain ischemia model utilizing EEG as an adjunct detection modality following validation for appropriateness).

Interpretation and Analysis: On days 1, 2, and 3 following transient MCA occlusion, the lesioned hemispheres (rat) display decreases in frequency-index values relative to basal parameters. Intact (unlesioned) hemispheres, after a slight, non-significant decrease in fractional index values on the 1st 2 days, present with normal frequency index values on day 3. Iopromide injected intravenously into ischemic rats at a dose 10 times higher than the maximum clinical dose causes bilateral spikes on EEG tracings and increases in frequency index values for the unlesioned hemisphere without affecting the lesioned hemisphere. Gadobenate dimeglumine, like gadodiamide, when injected into ischemic rats does not cause spikes or further changes in the frequency index values for the lesioned hemisphere and does not modify the normal frequency index value of unlesioned hemispheres. No significant differences between gadobenate dimeglumine, gadodiamide, and D-mannitol

can be appreciated when postinjection frequency index values are compared. Finally, higher levels of gadolinium are found in the lesioned hemisphere with respect to the unlesioned hemisphere after both gadobenate dimeglumine and gadodiamide administration. In summary, (i) EEG tracings are a valuable modality for assessing ischemia induced by transient MCA occlusion in a model designed to evaluate contrast agent neurotolerability because ischemic and contrast agent effects can be clearly differentiated; (ii) the higher level of contrast agent in the lesioned hemisphere compared with the unlesioned 1 (2 to 3 times), even 3 hours after injection, demonstrates that contrast agents effectively penetrated the brain and if they were neurotoxic, any negative effects would be detected; and (iii) gadobenate dimeglumine, like gadodiamide, injected intravenously at a dose 20 times higher than the intended clinical dose for brain MRI is well tolerated and, also like gadodiamide, is suitable for use in neurological diseases for which contrast-enhanced MRI is indicated.

Instrumentation: Inductively coupled plasma-atomic emission spectrometry analysis.

Neurotolerability of contrast agents in rats with brain ischemia induced by transient middle cerebral artery occlusion: EEG evaluation. Frigeni V, Miragoli L, Grotti A, Lorusso V. Invest Radiol 2001 Jan; 36 (1), pp. 1–8.

Central Nervous System (CNS)/Ischemia: Regional *Iopromide/Gadobenate Dimeglumine/Gadobutrol*

Application: Gadobenate dimeglumine possesses a safety profile that demonstrates its suitability for characterizing neurological disease states when contrast-enhanced MRI is indicated.

Route of Administration: Iopromide (intravenously); gadobenate dimeglumine (intravenous); and gadobutrol (intravenous).

Dosage: Iopromide (7 g I/kg [rat]); gadobenate dimeglumine (2 mmol/kg [rat]); and gadobutrol (2 mmol/kg [rat]).

Implementation: Injection of iopromide 3 days following occlusion of the middle cerebral artery (MCA) (rats) to determine its capacity to detect regional areas of ischemia within the CNS.

Rats are prepared for somatosensory-evoked potential recording at least 5 days before ischemia induction. Ischemia is induced by occlusion of the right MCA for a period of 30 minutes following reperfusion for 3 days. The somatosensory-evoked potential responses generated contralaterally relative to the stimulated upper limb are recorded from the primary somatosensory cortical area. Iopromide (poorly neurotolerated iodinated contrast agent) is then injected intravenously for the detection of regions of CNS ischemia on day 3 postocclusion. Comparative imaging analysis is then performed utilizing gadobenate dimeglumine and gadobutrol. Somatosensory-evoked potential responses are then measured as peak latencies (P2 and N2) and peak-to-peak amplitude (P2N2). Brain concentration of iopromide are measured by high-performance liquid chromatography, whereas amounts of the gadolinium contrast agent are quantified by inductively coupled plasma-atomic emission spectrometry analysis; given the absence of metabolism for both contrast agents, the gadolinium content values can be interpreted as representing unmetabolized contrast agent.

Interpretation and Analysis: In the ischemic rats, somatosensory-evoked potential responses of the lesioned hemisphere show significant increases in P2, N2, and interpeak N2-P2 latencies and a significant reduction in P2N2 amplitude. Iopromide dramatically increases the P2N2 amplitude of the somatosensory-evoked potential responses recorded from both hemispheres of ischemic rats without affecting the P2, N2, and interpeak N2-P2 latencies. The iopromide effect coincides with high concentrations of the contrast agent in the brain. Iopromide has no effect on healthy rats. Gadobenate dimeglumine does not induce any alteration in somatosentory-evoked potential components of either the lesioned or unlesioned hemisphere of ischemic rats. No significant difference can be appreciated between responses obtained before and after gadobenate dimeglumine injection. Gadobutrol, administered at the same dose, on the whole shows the same behavior as gadobenate dimeglumine, although a slight but significant decrease in the P2 latency, a sign of excitatory activity, is observed 2 hours after injection. Analytic data indicates the presence of higher levels of contrast agent in the lesioned hemisphere relative to unlesioned hemispheres 2 hours after injection. In summary, (i) evaluation of somatosensory-evoked potentials in ischemic rats is a useful tool for assessing the potential neurological effects of a new contrast agent because ischemic and contrast agent effects can be clearly differentiated; (ii) investigative strategies applied allow the contrast agents to penetrate into the brain, where their activity can be manifested and evaluated; and (iii) complete absence of neurological activity of gadobenate dimeglumine shows its safety profile and confirms its suitability for use in neurological diseases for which contrast-enhanced MRI is indicated.

Comparative study between gadobenate dimeglumine and gadobutrol in rats with brain ischemia: Evaluation of somatosensory-evoked potentials. Frigeni V, Miragoli L, Grotti And A, Lorusso V. Invest Radiol 2001 Oct; 36 (10), pp. 561–72.

Central Nervous System (CNS)/Lesion Detection: Subtle Intracranial Alterations *Pilocarpine*

Application: Pilocarpine can be used to induced status epilepticus. In this context, pilocarpine can be used as an agent for evaluating the ability of imaging modalities to detect subtle pathology within brain parenchyma, including the identification of (i) edematous brain alterations that follow sustained seizures; (ii) regional hyperperfusion; and (iii) neurodegeneration.

Implementation: Functional MRI (fMRI) analysis of the brain at 12 hours following arrest of pilocarpine-induced status epilepticus maintained over a period of 4 hours duration. Regional cerebral blood volume (rCBV) maps are generated using T_2*-weighted gradient-echo images and an ultrasmall superparamagnetic iron oxide contrast agent. Histopathological data, obtained immediately following MRI analysis, is then correlated with the images through careful evaluation of tissues.

Animal Model: Rat (induction of brain status epilepticus applying pilocarpine).

Interpretation and Analysis: Diffusion-weighted and T_2-weighted imaging shows changes throughout the cerebral cortex, hippocampus, amygdala, and medial thalamus. However, only T_2-weighted imaging, based on rapid acquisition relaxation-enhanced sequences, reveals in the cortex inhomogeneous hyperintensity that is highest in a band corresponding to layer V. In the cortex, rCBV peaks in superficial and deep bands exhibiting a distribution complementary to the highest T_2-weighted intensity. Selective rCBV increases are also detectable within the hippocampus and subcortical structures. In tissue sections, alterations indicative of marked edema are found with Nissl staining in areas corresponding to the highest T_2-weighted intensity. Degenerating neurons, detected by Fluoro-JadeB histochemistry, are concentrated in tissue exhibiting hyperperfusion in rCBV maps, such as hippocampal subfields and dentate gyrus, cortical layers II/III and VI, and medial thalamus. Therefore, (i) T_2-weighted imaging provides a sensitive tool to investigate edematous brain alterations that follow sustained seizures; (ii) rCBV maps reveal regional hyperperfusion; and (iii) rCBV peaks in tissue exhibiting marked neurodegeneration may not be selectively revealed by structural MRI. The findings provide an interpretation of

the brain response to sustained seizures revealed *in vivo* by different strategies of MRI analysis.

Magnetic resonance imaging of changes elicited by status epilepticus in the rat brain: Diffusion-weighted and T_2-weighted images, regional blood volume maps, and direct correlation with tissue and cell damage. Central Nervous System (CNS)/Lesions: Intracranial/ Relative Image Quality/Adverse Effects and Safety
Gadoteridol/Gadopentetate Dimeglumine

Application: Detection and characterization of intracranial lesions applying gadoteridol and gadopentetate dimeglumine as MR contrast-enhancing imaging agents.
Dosage: Gadoteridol (0.1 mmol/kg); gadopentetate dimeglumine (0.1 mmol/kg).
Implementation: Utilization of gadoteridol or gadopentetate dimeglumine as positive contrast-enhancing imaging agents for the detection of intracranial lesions applying MR capabilities. The presence of pathology, degree of enhancement, and location and number of lesions, as well as additional information gained, are compared for each subject's unenhanced and enhanced scans for both the gadoteridol and gadopentetate dimeglumine examination. Safety is evaluated in all treated subjects by means of pre- and postdose vital signs along with laboratory tests and monitoring for adverse events.

Human Model: Evaluation by MRI of 80 subjects suspected of suffering from intracranial lesions. Contrast agents are assigned in random order, separated by a 3- to 7-day period between administrations.
Interpretation and Analysis: There is no significant difference in the number of lesions visualized pre- and postcontrast for either gadoteridol or gadopentetate dimeglumine. A high degree of correlation exists between different clinicians evaluating images. When postcontrast image sets are compared between contrast agents, there is no significant difference in superiority of 1 agent over the other ($p > 0.05$). No significant difference for any safety parameter can be appreciated between the 2 agents. In summary, gadoteridol and gadopentetate dimeglumine appear to be effective and well tolerated for use in contrast-enhanced MRI of the CNS at a dose of 0.1 mmol/kg.

Phase III, randomized, double-blind, cross-over comparison of gadoteridol and gadopentetate dimeglumine in magnetic resonance imaging of patients with intracranial lesions. Greco A, Parker JR, Ratcliffe CG, Kirchin MA, McNamara MT. Australas Radiol 2001 Nov; 45 (4), pp. 457–63.

Central Nervous System (CNS)/Meningitis: Idiopathic Hypertrophic Cranial Pachymeningitis/ Corticosteroid Response (± Pulsed Administration)
Gadolinium

Cellular/Molecular Mechanism of Action: Gadolinium is an element that possesses paramagnetic properties.
Background Information: Idiopathic hypertrophic cranial pachymeningitis is a rare disease, of undetermined pathogenesis, that is characterized by inflammation and fibrosis of the dura mater.
Application: Detection and characterization of idiopathic hypertrophic cranial pachymeningitis conditions and their response to therapeutic intervention.
Implementation: Evaluation of idiopathic hypertrophic cranial pachymeningitis conditions to establish clinical presentation, radiological findings, and therapeutic intervention.

Human Model: Cases of idiopathic hypertrophic cranial pachymeningitis ($n = 6$).

Interpretation and Analysis: In cases of idiopathic hypertrophic cranial pachymeningitis, 1 of the main manifestations is cranial nerve palsies and headache (e.g., $n = 6/6$). Three associated conditions are often present, namely optic neuropathy, Tolosa-Hunt syndrome, and diabetes insipidus. Gadolinium-enhanced MRI is of diagnostic benefit and reveals intense dural enhancement in a linear or nodular pattern. Response to corticosteroid therapy is better for cases exhibiting linear, rather than nodular, dural enhancement. In some cases, surgical decompression of the superior orbital fissure provides lasting relief. The course of the disease frequently progresses aaccording to 1 of 3 patterns: (i) sustained remission; (ii) relapse with corticosteroid independence; or (iii) relapse with corticosteroid dependence. Pulse corticosteroid therapy provides significant relief, while reducing the daily corticosteroid requirement and avoiding side effects, for a corticosteroid-dependent relapsing patient. Idiopathic hypertrophic cranial pachymeningitis can progress with a varied clinical course. It is important to prevent irreversible cranial neuropathy during the active phase of the disease, using daily administration of corticosteroids, pulse corticosteroid therapy, or surgical decompression.

Idiopathic hypertrophic cranial pachymeningitis: Clinicoradiological spectrum and therapeutic options. Hatano N, Behari S, Nagatani T, Kimura M, Ooka K, Saito K, Yoshida J. Neurosurgery 1999 Dec; 45 (6), pp. 1336–42; discussion 1342–4.

Central Nervous System (CNS)/Multiple Sclerosis (MS)
Gadolinium (Gd)/[Gd]-DOTA/ Dynamic Susceptibility Contrast (DSC) MR

Background Information: Since the pathogenesis of MS lesions is not yet fully understood, the development of DSC MR perfusion imaging has potential for better characterizing lesion pathology.
Implementation: Utilization of single doses of [Gd]-DOTA contrast agent for the detection and characterization of MS plaque lesions. Magnetic resonance instrumentation (1.5 Tesla scanner) is applied to acquire echoplanar images every 0.5 seconds over a time period of 1 minute. From the signal intensity vs time curves, the relative cerebral blood volume (rCBV) can be evaluated for regions in plaques and in gray and white matter. The rCBV calculated for acute, [Gd]-enhancing plaques is corrected for the effects of blood-brain barrier leakage, using a correction algorithm.

Human Model: Multiple sclerosis patients (e.g., $n = 25$).
Interpretation and Analysis: Acute plaques have significantly higher blood volumes than normal-appearing white matter ($p < = 0.01$). Chronic plaques that appear hypointense on T_1-weighted images have lower rCBV than T_1-isointense plaques ($p \leq 0.03$). Acute phases in MS are accompanied by vasodilation. In the later stages of gliosis, vascular perfusion decreases with increasing axonal injury. Although the DSC technique is less sensitive than conventional MRI, the information provided is essentially different from that obtained with any other MR methods.

Dynamic susceptibility contrast MR imaging of plaque development in multiple sclerosis: Application of an extended blood-brain barrier leakage correction. Haselhorst R, Kappos L, Bilecen D, Scheffler K, Möri D, Radü EW, Seelig J. J Magn Reson Imaging 2000 May; 11 (5), pp. 495–505.

Central Nervous System (CNS)/Multiple Sclerosis (MS)/Active vs Inactive Stage of Disease
Gadodiamide/Single vs Double vs Triple Injection Schemes

Background Information: A triple dose (TD) of gadolinium chelate is a highly sensitive approach for detecting lesion activity in

MS. However, individual TD injections do not provide data on the severity of the pathologic process in a population of lesions, and their clinical use is limited by cost-benefit considerations. One aim of the studies is to determine whether the use of 3 subsequent single doses (SDs) of a gadolinium chelate in brain MRI is useful in detecting MS lesions with different patterns of enhancement.

Application: Detection and characterization of CNS plaque lesions in conditions of MS in order to determine if cases are in the active or inactive stages of disease.

Route of Administration: Gadodiamide (intravascular).

Dosage: Gadodiamide (0.1 mmol/kg).

Implementation: Acquisition of T_1-weighted spin-echo images before and after 3 intravenous injections of gadodiamide in cases of MS.

Human Model: Cases of MS (n = 10).

Interpretation and Analysis: In the vast majority of cases with MS, SD images can detect multiple enhanced lesions. In 1 clinical study, SD gadodiamide was able to facilitate the detection of 6 enhancing plaque lesions in each of 10 MS cases. Double-dose (DD) images detected 13 plaque lesions, and TD images detected 22 plaque lesions. Differences between SD and TD and between DD and TD are usually significant ($p < 0.018$). Approximately (i) 27% of MS plaque lesions are enhanced with all 3 doses (e.g., n = 6); (ii) 32% of MS plaque lesions are enhanced with both DD and TD (n = 7); and (iii) 9 MS plaque lesions enhance with only TD (n = 9). The proportions of cases with at least 1 enhancing lesion are (i) SD n = 4/10; (ii) DD n = 7/10; and (iii) TD n = 9/10. In defining active disease case populations, all that is needed is 19 SD injections, compared to 30 SD injections if a TD administration protocol is implemented. Utilizing 3 subsequent SD injections, the number of enhancing lesions progressively increases. This approach allows the distinction of 3 levels of enhancement, and it reduces the amount of contrast agent needed to distinguish patients with active MS from those with non-active MS.

Three subsequent single doses of gadolinium chelate for brain MR imaging in multiple sclerosis. Sardanelli F, Iozzelli A, Losacco C, Murialdo A, Filippi M. AJNR Am J Neuroradiol 2003 Apr; 24 (4), pp. 658–62.

Central Nervous System (CNS)/Multiple Sclerosis (MS)/Detection of Enhancing Lesions: Magnetic Transfer (±)
Gadoteridol (Gd-HP-DO3A)

Application: Imaging of MS lesions residing within the brain and spinal cord. In this context, Gd-HP-DO3A can function as a 2-compartment paramagnetic contrast agent for MRI.

Dosage: Gadoteridol (Gd-HP-DO3A: 0.1 mmol/kg).

Implementation: Evaluate the possibility of using image subtraction to enhance the detection of MS-associated lesions in brain MR scans with and without magnetic transfer (MT). One approach to achieving this objective involves performing MR brain imaging (1.5 Tesla) with spin-echo T_1-weighted sequences with and without MT, followed by performing a 2nd imaging procedure after the administration of Gd-HP-DO3A. Precontrast and postcontrast images are then digitally recorded. Enhancing lesions are counted on the postcontrast images only (post-Gd), comparing precontrast and postcontrast images by direct visual control (pre-/post-Gd), and on the subtracted images (SI) only.

Human Model: Multiple sclerosis cases (n = 10).

Interpretation and Analysis: Comparisons reveal that the number of enhancing lesions detected post-Gd and pre-/post-Gd is greater with the benefit of MT (e.g., 36 vs 69 and 36 vs 52, respectively). However, the number of enhancing lesions detected with SI is higher in the absence of MT (e.g., 59 vs 50). Significant differences can be appreciated for (i) pre-/post-Gd without MT compared to SI without MT ($p = 0.028$); (ii) pre-/post-Gd without MT compared to pre-/post-Gd with MT ($p = 0.012$); as well as for (iii) pre-/post-Gd with MT compared to post-Gd with MT ($p = 0.028$). Magnetic transfer in combination with pre-/post-Gd allows for the detection of 1.6 enhancing lesions per case more than can be achieved without MT. Subtraction imaging without MT allows the detection of an increased number of enhancing lesions. Conversely, SI with MT does not. Final assessment reveals calculated sensitivity and positive predictive values for (i) no MT, 63 and 94% (post-Gd); (ii) 67 and 100% (pre-/post-Gd); (iii) 96 and 88% (SI); (iv) with MT, 93 and 73% (post-Gd); (v) 96 and 100% (pre-/post-Gd); and (vi) 91 and 98% (SI), respectively. Therefore, SI seems to increase the sensitivity without MT; moreover, it can be used to correct the pseudoenhancement that impairs post-Gd images with MT.

Evaluation of Gd-enhancement in brain MR of multiple sclerosis: Image subtraction with and without magnetization transfer. Sardanelli F, Losacco C, Iozzelli A, Renzetti P, Rosso E, Parodi RC, Bonetti M, Murialdo A. Eur Radiol 2002 Aug; 12 (8), pp. 2077–82. Epub 2002 Feb 05.

Central Nervous System (CNS)/Multiple Sclerosis (MS)/Plaque Formation Monitoring within the CNS
Gadolinium (Example)

Background Information: The time courses for total creatine (Cr), N-acetylaspartate (NAA), choline (Cho), and myo-inositol have not previously been characterized while performing follow-up contrast-enhanced evaluations of MS plaques.

Implementation: Evaluation over a period of 2 years of comparisons for the absolute concentrations of the metabolites Cr, NAA, Cho, and myo-inositol between patients treated with a placebo or 15 ± deoxyspergualin (DSG) and clinical groups with relapsing-remitting or secondary-progressive MS. Diagnostic characterization can involve the application of stimulated-echo acquisition mode sequence (TR/TE = 3,000/20).

Human Model: Deoxyspergualin treatment group (n = 16) compared to normal reference controls (n = 11). The selected cases initially display a contrast-enhancing plaque that is monitored for a 2-year period.

Interpretation and Analysis: In contrast-enhancing plaques, Cho is significantly elevated and shows a significant reduction after both 3 and 12 months. The initially normal Cr significantly increases between 3 and 12 months and is negatively correlated with plaque volume on T_1-weighted MR images. NAA initially shows normal values, a significant decrease at 1 month, and a slow recovery over 2 years. Myo-inositol does not show a clear tendency. Placebo groups do not differ from treatment groups, nor does the relapsing-remitting group differ from the secondary-progressive group. The contradictory time courses of Cr and NAA show that an absolute quantification in proton MR spectroscopy in MS is necessary to avoid a false interpretation of reduced NAA/Cr ratios. The increase in Cr is probably due to remyelination. The initial dip and later recovery of NAA seem to be related to diminishing edema and remyelination.

Serial proton MR spectroscopy of contrast-enhancing multiple sclerosis plaques: Absolute metabolic values over 2 years during a clinical pharmacological study. Mader I, Roser W, Kappos L, Hagberg G, Seelig J, Radue EW, Steinbrich W. AJNR Am J Neuroradiol 2000 Aug; 21 (7), pp. 1220–7.

Central Nervous System (CNS)/Myelogram (Lumbar): T_1 and T_2 Shortening
Iodinated Contrast Media Side-Chain Structure/ Imaging Schedule: < 24 Hours vs 24 Hours vs 48 Hours

Cellular/Molecular Mechanism of Action: Iodinated contrast medias are radiodense elements.
Application: Detection and characterization of anatomical variations within the cerebrospinal fluid (CSF) space surrounding the spinal cord.
Route of Administration: Iodinated contrast media formulations are administered by injection directly into the CSF space surrounding the spinal cord.
Implementation: Lumbar myelography studies applying MRI imaging modalities at completion of contrast agent injection and then at 8 hours and 24 hours postadministration (e.g., n = 20 cases). Measurements are then recorded for the parameters of signal intensities, calculated T_1- and T_2-relaxation times of different iodinated contrast agents, a dilution row of iopamidol, and mixtures of CSF and iotrolan compared with physiological saline solution using different T_1- and T_2-weighted sequences. [^{1}H]-spectroscopy is then performed with several solutions containing iodine or other reagent formulations.
Interpretation and Analysis: A fluid-fluid level of the CSF exists in the lumbar dural sac in the vast majority of cases immediately after lumbar myelography with a non-ionic iodinated contrast agent. Increased signal intensity on T_1-weighted and decreased signal intensity on T_2-weighted sequences can be appreciated for all contrast agents, as well as for the dilution row, compared to physiological saline solution. The structure of the side chains of the contrast agents is responsible for the T_1- and T_2-shortening effect. It is important to be aware of the effect of iodinated contrast agents in MRI. To avoid misinterpretation of atypical findings, MRI of the spine should not be performed earlier than 24 hours after myelography.

Effects of iodinated contrast agents in MR imaging. Hergan K, Doringer W, Langle M, Oser W. Eur J Radiol 1995 Nov; 21 (1), pp. 11–7.

Central Nervous Sytem/Neurophysiology/ Neuroanatomy
Monocrystalline Iron Oxide Nanoparticles

Application: Characterization of primate neurophysiology and neuroanatomy to improve understanding of human neuroimaging modalities.
Implementation: Mapping of functional MRI (fMRI) signals produced by moving stationary stimuli (random → dots or lines).
Animal Model: Primate (fixating monkeys).
Interpretation and Analysis: Functional sensitivity is increased by a factor of approximately 5-fold relative to the blood oxygen level–dependent (BOLD) technique by the injection of monocrystalline iron oxide nanoparticle (MION) as a contrast agent. Areas identified as motion sensitive include V2, V3, MT/V5, vMST, FST, VIP, and FEF (with moving dots), as well as V4, TE, LIP, and PIP (with random lines). These regions sensitive for moving dots are largely in agreement with monkey single unit data and (except for V3A) with human fMRI results. Moving lines activate some regions that have not been previously implicated in motion processing. Overall, there is a defined relationship between a motion pathway and the dorsal stream in primates.

Visual motion processing investigated using contrast agent-enhanced fMRI in awake-behaving monkeys. Vanduffel W, Fize D, Mandeville JB, Nelissen K, Van Hecke P, Rosen BR, Tootell RB, Orban GA. Neuron 2001 Nov 20; 32 (4), pp. 565–77.

Central Nervous System (CNS)/Neurotoxicity: Cytarabine/Acute Leukemia: Childhood Onset/ Cerebral Perfusion/Relative Efficacy of Single Photon Emission Computed Tomography (SPECT) vs MRI
[^{99m}Tc]-Hexamethyl-Propylene-Amine Oxime

Background Information: Cytarabine (ara-C) is 1 of the most effective chemotherapeutic agents in patients with acute leukemia (AL), with a clear dose effect. Use of high-dose ara-C is hampered, however, by a noticeable toxicity, particularly to the CNS.
Application: Assess the usefulness of CNS perfusion imaging with technetium-99m [^{99m}Tc]-hexamethyl-propylene-amine oxime (HMPAO) SPECT concurrent to MRI to specifically assess the effects of standard- and high-dose ara-C in children with AL.
Implementation: Evaluation of cerebral perfusion by [^{99m}Tc]-HMPAO SPECT in cases of childhood AL after induction therapy consisting of a (i) standard-dose ara-C; (ii) immediately after consolidation with high-dose ara-C; and (iii) later during follow-up (range, 6–44 months). The chemotherapy-related adverse events are monitored and correlated to SPECT and MRI.
Human Model: Cases of childhood AL (n = 12; age range = 4–15 years; n = 26 perfusion studies).
Interpretation and Analysis: After the induction phase, all children are neurologically normal on MRI. On SPECT imaging, a number of children (e.g., n = 4/12) display a slightly heterogeneous perfusion pattern. After high-dose ara-C (4–36 g/m^2), slightly more than a third of affected children have regressive neurologic signs of potential toxic origin (n = 5/12), and of these cases, a small percentage will have an abnormal MRI scan (n = 1/5), whereas all cases display evidence of diffuse cerebral and/or cerebellar heterogeneous perfusion on SPECT. Some cases without any neurologic symptoms (e.g., n = 7) and normal MRI scans also display normal SPECT profiles (n = 3/7 normal; n = 4/7 abnormal). On follow-up analysis of cases initially presented with clinical neurological toxicity, (i) a relatively large number display SPECT images that improve (n = 3/4); (ii) a small percentage remain unchanged (e.g., n = 1/4 or 25%); and (iii) some display delayed abnormalities (T_2 white matter hypersignal and cerebellar atrophy) that appear on MRI scans (e.g., n = 2/4). Diffuse heterogeneous brain hypoperfusion is often the sole early objective imaging feature identified by SPECT of high-dose ara-C neurotoxicity, where MRI still demonstrates normal pictures.

Contribution of single-photon emission computed tomography in the diagnosis and follow-up of CNS toxicity of a cytarabine-containing regimen in pediatric leukemia. Véra P, Rohrlich P, Stiévenart JL, Elmaleh M, Duval M, Bonnin F, Bok B, Vilmer E. J Clin Oncol 1999 Sep; 17 (9), pp. 2804–10.

Central Nervous System (CNS)/Neurotoxicity: Kainate-Induced
Paramagnetic Gadolinium (III) Ion: [Gd]-DTPA/ Gadomer-17: Blood-Pool Agent/Polylysine-[Gd]-DTPA: Blood-Pool Agent

Application: Detection and characterization of toxin-induced CNS lesions applying MRI instrumentation.
Implementation: Utilization of MRI in combination with paramagnetic gadolinium^{+3} ion ([Gd]-DTPA) and prototype agents for blood-pool enhancement (Gadomer-17 and polylysine-[Gd]-DTPA) to detect lesions in the CNS. Magnetic resonance is performed with

T_1-weighted spin-echo sequence before and after the administration of kainite and contrast media.

Animal Model: Rat (kainite infused intravenously to induce CNS lesions).

Interpretation and Analysis: Enhancement of lesion rims and other brain tissue abnormalities due to kainite with [Gd]-DTPA, Gadomer-17, and polylysine-[Gd]-DTPA can be observed mainly in the region of hippocampus and in the areas not protected by the blood-brain barrier.

Assessment of kainite toxicity using contrast-enhanced magnetic resonance imaging. Beravs K, Frangez R, Demsar F. Pflugers Arch 2000; 440 (5 Suppl), pp. R153–4.

Central Nervous System (CNS)/Neurotransmitter Dynamics/Relative Cerebral Blood Flow/Drug Abuse/Schizophrenia/Epilepsy/Neurodegeneration
Superparamagnetic Iron Oxide/Amphetamine/Cocaine Analog 2β-Carbomethoxy-3b-(4-Fluorophenyl)Tropane (CFT)

Background Information: The use of functional MRI (fMRI) techniques for evaluating pharmacological stimuli has great potential for understanding neurotransmitter dynamics pertaining to a number of brain disorders, such as drug abuse, schizophrenia, epilepsy, and neurodegeneration. Unfortunately, blood oxygenation level–dependent (BOLD) imaging at common fields strengths, such as 1.5 or 3 Tesla, has very low sensitivity and low contrast-to-noise ratios (CNRs).

Application: Detection and characterization of alterations in neurotransmitter dynamics and relative cerebral blood flow for various conditions affecting the CNS, including drug abuse, schizophrenia, epilepsy, and neurodegeneration.

Route of Administration: Intravascular.

Implementation: Evaluation of the ability for a superparamagnetic iron oxide contrast agent with a long plasma half-life to detect hemodynamic changes related to dopaminergic stimuli using amphetamine or the cocaine analog CFT as provocative diagnostic agents. The technique is sometimes referred to as increased relaxation with iron oxide nanoparticles (IRON).

Interpretation and Analysis: Results indicate that even at field strengths as high as 4.7 Tesla, it is possible to obtain increases in CNR by factors of 2 to 3 over BOLD imaging, which can provide a greater than 1 order of magnitude increase in statistical power with greatly increased sensitivity to hemodynamic changes in brain regions difficult to observe using BOLD imaging. Furthermore, use of the intravascular contrast agent allows for a meaningful physiologic parameter to be measured (relative cerebral blood volume [rCBV]), in contrast to conventional BOLD imaging.

Improved mapping of pharmacologically induced neuronal activation using the IRON technique with superparamagnetic blood pool agents. Chen YC, Mandeville JB, Nguyen TV, Talele A, Cavagna F, Jenkins BG. J Magn Reson Imaging 2001 Nov; 14 (5), pp. 517–24.

Central Nervous System (CNS)/Sarcoidosis/ Optimization of High-Dose Corticosteroid Therapy/ Differentiation of Reversible and Irreversible CNS Lesions/Prevention of Irreversible CNS Damage
Gadolinium

Cellular/Molecular Mechanism of Action: Gadolinium possesses paramagnetic properties.

Background Information: Corticosteroids are applied in the management of CNS-associated sarcoidosis lesions.

Application: Detection and characterization of sarcoidosis affecting the CNS in a manner that can be used to optimize decision making related to responses to therapeutic intervention.

Implementation: Evaluate and document changes observed utilizing sequential MRI for sarcoidosis lesions located within the CNS and determine their response to corticosteroid therapy (mean follow-up period = 36 months). Results are compared before and after therapeutic periods (n = 75) divided into attack (high-dose), upkeep (decreased-dose), and minimal (low-dose) periods. Parenchymal lesions are classified as Type 1 (enhanced with gadolinium), Type 2 (demyelinating), or Type 3 (lacunar), and are assessed (classified) as regressing, stable, or progressing.

Human Model: Cases of sarcoidosis affecting the CNS (n = 24).

Interpretation and Analysis: Slightly greater than 33% of cases have several types of lesions (e.g., n = 7/24). An absence of neurologic defect is only recognized with isolated Type 3 lesions (e.g., n = 6 cases). In approximately half of affected cases with Type I the lesions regress in essentially all attack periods (e.g., n = 13/24 cases; n = 22/22 attack periods), but progress in approximately one-third of upkeep and minimal periods (n = 9/27). Type 2 (n = 7 cases) and Type 3 (n = 13 cases) lesions remain stable in essentially all therapeutic periods (n = 68/68). Type 1 lesions appear in a small number of cases with Type 2 and Type 3 lesions during 2 upkeep and 3 minimal periods (e.g., n = 3 patients). Findings observed on follow-up MRI analysis can function as a basis for (i) reintroducing high-dose corticosteroid therapy (e.g., n = 8 cases); (ii) differentiation between reversible and irreversible lesions in CNS sarcoidosis; and (iii) a reference parameter for adjusting treatment to prevent irreversible CNS damage.

Central nervous system sarcoidosis: Follow-up at MR imaging during steroid therapy. Dumas JL, Valeyre D, Chapelon-Abric C, Belin C, Piette JC, Tandjaoui-Lambiotte H, Brauner M, Goldlust D. Radiology 2000 Feb; 214 (2), pp. 411–20.

Central Nervous System (CNS)/Somatosensory Stimulation Mapping
Manganese Chloride ($MnCL_2$)/Activity-Induced Manganese (Mn^{+2})-Dependent Contrast MRI/Dynamic Activity-Induced Mn^{+2}-Dependent Contrast MRI

Cellular/Molecular Mechanism of Action: In the brain, $MnCl_2$ accumulates in the active region(s) by entering active cells through voltage-gated Ca^{+2} channels.

Background Information: Activity-induced manganese-dependent contrast (AIM) MRI is a hemodynamic-independent functional MRI method that uses manganese ion as an MR-detectable contrast agent.

Application: Activity-induced manganese-dependent contrast MRI of the CNS.

Route of Administration: The agent $MnCl_2$ is infused intra-arterially after modification of the functionality of the blood-brain barrier (BBB) with a hyperosmolar agent.

Implementation: Development of a dynamic activity-induced manganese-dependent (DAIM) paradigm that utilizes sequential MR scans during $MnCl_2$ infusion, prior to and following functional brain stimulation. Time-course analysis can be used to produce stimulation-specific functional maps within the brain. The methodology can be applied to test reactions to glutamate administration and electric stimulation (e.g., rat forepaw).

Interpretation and Analysis: Functional stimulation of the brain facilitates Mn^{+2} accumulation in active region(s) by entering active cells through voltage-gated Ca^{+2} channels, causing local signal increases in T_1-weighted images. The contrast of AIM MRI depends strongly on the depth of anesthesia, and the low levels used in somatosensory stimulation studies can lead to significant non-specific accumulation of manganese ion throughout the brain. Dynamic activity-induced manganese-dependent contrast MRI maps are better confined to the specific region of brain activated by somatosensory stimulation compared to AIM MRI.

Dynamic activity-induced manganese-dependent contrast magnetic resonance imaging (DAIM MRI). Aoki I, Tanaka C, Takegami T, Ebisu T, Umeda M, Fukunaga M, Fukuda K, Silva AC, Koretsky AP, Naruse S. Magn Reson Med 2002 Dec; 48 (6), pp. 927–33.

Central Nervous System (CNS)/Stroke: Acute Vascular/Bolus Tracking MRI

Bolus tracking MRI is a powerful technique for measuring perfusion and is playing an increasing role in the investigation of acute stroke. However, limitations have been reported when assessing patients with steno-occlusive disease. The presence of a steno-occlusive disease in the artery may cause bolus dispersion, which has been shown to introduce significant errors in cerebral blood flow (CBF) quantification. Bolus dispersion is commonly described by a vascular transport function, but the function that properly characterizes the dispersion is unknown. Relevant methods have been described to quantify bolus dispersion errors on perfusion measurements. A realistic patient-specific model can be constructed from anatomical and physiologic MR data, and the arterial blood flow pattern and the transport of the bolus of contrast agent are computed using finite element analysis. Methodologies can also be used to evaluate the accuracy of 3 simple vascular models. A methodology has already been tested on MR data from 2 normal subjects and 2 subjects with mild carotid artery stenosis. The estimated CBF errors are on the order of 15 to 20%. However, the presence of stenosis does not necessarily introduce larger dispersion (not only the geometrical model but also the particular physiologic conditions influence the degree of bolus dispersion). The method described will contribute to a better understanding of errors introduced by dispersion effects, to the assessment and validation of vascular models, and to the development of new methods for the correction of dispersion errors in CBF quantification.

Estimation of bolus dispersion effects in perfusion MRI using image-based computational fluid dynamics. Calamante F, Yim PJ, Cebral JR. Neuroimage 2003 Jun; 19 (2 Pt 1), pp. 341–53.

Central Nervous System (CNS)/Stroke: Vascular/Postcontrast Diffusion-Weighted Images
Gadopentetate Dimeglumine

Background Information: Diffusion-weighted imaging (DWI) is usually done before administration of intravenous contrast agents. Repetition of DWI is occasionally necessary after administration, but the effects of contrast material on DWI and apparent diffusion coefficient (ADC) values have not yet been fully examined.
Application: Detection and characterization of vascular anomalies within the CNS.
Route of Administration: Gadopentetate dimeglumine (intravenous).
Dosage: Gadopentetate dimeglumine (0.1 mmol per 1 kg body weight).
Implementation: Determine if the administration of gadolinium-based contrast material significantly affects DWI and ADC values. In this context, diffusion-weighted images are acquired for conditions of CNS vascular stroke. Scan images are acquired at the acute or subacute stages of infarct from 3 hours to 5 days after onset of symptoms, applying gadopentetate dimeglumine as an injectable contrast image-enhancing agent. Diffusion-weighted images are obtained using single-shot echo-planar imaging with a "b" value of 1,000 s/mm^2. The signal-to-noise ratios are then examined for normal regions of the brain and infarct lesions, in addition to delineation of the contrast-to-noise ratio for each lesion. Other parameters measured include the comparison of the ADC values calculated from DWI before and after administration of contrast. The statistical significance of differences between precontrast and postcontrast administration are determined by use of a paired t test.
Human Model: Cases of vascular stroke affecting the CNS (e.g., n = 39; mean age = 67.9 years; range = 34–87 years).
Interpretation and Analysis: The signal-to-noise and contrast-to-noise ratio of the diffusion-weighted images is not significantly different before and after administration of contrast agent. The ADC values are slightly lower after administration of contrast agent for both normal brain ($p = 0.0011$) and infarcts ($p = 0.038$). The estimated differences in the ADC values are approximately 1.3% and 3.5% for normal brain and infarcts, respectively. The lack of a significant difference between the signal-to-noise and contrast-to-noise ratios of diffusion-weighted images before and after administration of contrast agent indicates the feasibility of postcontrast DWI.

Effect of intravenous gadolinium-DTPA on diffusion-weighted images: Evaluation of normal brain and infarcts. Yamada K, Kubota H, Kizu O, Nakamura H, Ito H, Yuen S, Tanaka O, Kubota T, Makino M, Van Cauteren M, Nishimura T. Stroke 2002 Jul; 33 (7), pp. 1799–802.

Central Nervous System (CNS)/Vocal Centers (High) of the CNS/Nucleus Robustus Archistriatalis/Area X
Manganese (Mn^{+2})/Calcium Analogue

Cellular/Molecular Mechanism of Action: Manganese and calcium analogs have their spatial orientation altered when subjected to magnetic energy fields.
Application: Manganese can be applied as a tracing agent for CNS paramagnetic tract applicable for MRI methodologies.
Route of Administration: Manganese and calcium analogs are injected into the high vocal center of the CNS.
Implementation: Central nervous imaging performed by the injection of Mn^{+2} and a calcium analog into the high vocal center of starlings.
Animal Model: Avian/starling (high vocal center injection).
Interpretation and Analysis: Injection of Mn^{+2} and a calcium analog into the high vocal center of starlings within a few hours labels the nucleus robustus archistriatalis and area X as observed by *in vivo* MRI. Structures highlighted by Mn^{+2} accumulation assume the expected tridimensional shape of the nucleus robustus archistriatalis and area X as identified by classical histological or neurochemical methods. The volume of these CNS nuclei can be accurately calculated by segmentation of the areas highlighted by Mn^{+2}. Besides confirming previously established volumetric sex differences, Mn^{+2} uptake into these nuclei reveals new functional sex differences affecting Mn^{+2} transport. A faster transport is present in males than in females and different relative amounts of Mn^{+2} are transported to the nucleus robustus archistriatalis and area X in males compared to females. Such an *in vivo* approach allows for the acquisition of repeated measures, opens alternative opportunities for

studying seasonal plasticity in size and activity of song-control nuclei, and correlates neuronal activity with behavior. It also provides greater insight into the *in vivo* axonal transport and neuronal activity in song-control nuclei of oscines.

In vivo manganese-enhanced magnetic resonance imaging reveals connections and functional properties of the songbird vocal control system. Van der Linden A, Verhoye M, Van Meir V, Tindemans I, Eens M, Absil P, Balthazart J. Neuroscience 2002; 112 (2), pp. 467–74.

Central Nervous System (CNS) Behavior: Awake-Behaving Function/Regional Cerebral Blood Volume/Primary Visual Cortex
Magnetite Dextran Nanoparticles

Cellular/Molecular Mechanism of Action: Magnetite dextran nanoparticles are passively transported throughout the intravascular compartment and their location within the body can be detectable by MRI instrumentation.
Background Information: Functional MRI (fMRI) in awake-behaving primates is an emerging tool for bridging the gap between human fMRI and neurophysiology information from non-human primates.
Application: Blood-pool agent to enhance fMRI contrast-to-noise (CNR) in mammalian fMRI analyses.
Route of Administration: Intravascular.
Implementation: Evaluation of behavioral changes as a function of various physiological parameters associated with the CNS, including regional cerebral blood flow and volume.
Animal Model: Primate (e.g., macaque).
Interpretation and Analysis: The intravascular half-life of magnetite dextran is long compared to lanthanide chelates ($T_{1/2}$ = 198 minutes) with shortened T_2 relaxation observed in blood and the cerebral cortex. Greater than 3-fold enhancement in the percent change in MR signal can be observed using nanoparticles (13%) compared with conventional BOLD fMRI (4%). The calculated regional cerebral blood volume in primary visual cortex increases 32% with photic stimulation. The increased CNR allows greater flexibility in the design of awake-behaving primate fMRI studies with the potential for improvements in resolution and significantly shortened imaging times.

Enhancing fMRI contrast in awake-behaving primates using intravascular magnetite dextran nanoparticles. Dubowitz DJ, Bernheim KA, Chen DY, Bradley WG Jr, Andersen RA. Neuroreport 2001 Aug 8; 12 (11), pp. 2335–40.

Neoplasia (Central Nervous System [CNS]): Glioma/Microglial Cell Detection and Characterization
Ultrasmall Superparamagnetic Particles of Iron Oxide (USPIOs)

Cellular/Molecular Mechanism of Action: Ultrasmall superparamagnetic particles of iron oxide are perceived as foreign material and internalized (phagocytized) by microglial cell populations residing within the CNS.
Background Information: Microglia are intrinsic immunoeffector cells of the CNS that play a very sensitive, crucial role in the response to almost any brain pathology. Upon stimulation, they are transformed into a state of elevated phagocytic activity.
Application: Reveal the extent of microglial tumors and assess the status of immunologic defense processes.
Implementation: Evaluate the presence and distribution of activated microglial cells residing within the CNS utilizing USPIO preparations in combination with MRI instrumentation.
Animal Model: Glioma cell cultures and rat glioma *in vivo* model.
Interpretation and Analysis: Using USPIOs in cell culture experiments and in a rat glioma model, microglia can be labeled magnetically and detected by confocal microscopy within and around tumors in a typical border-like pattern. Quantitative *in vitro* studies reveal that microglia cells internalize amounts of USPIOs that are significantly higher than those incorporated by tumor cells and astrocytes. Labeled microglia can be detected and quantified with MRI in cell phantoms, and the extent of the tumor can be seen *in vivo* in glioma-bearing rats. Magnetic labeling of microglia provides a potential tool for MRI of gliomas that more precisely reflects tumor morphology. Furthermore, the results suggest that MRI may yield functional data on the immunologic reaction within the CNS.

Magnetic labeling of activated microglia in experimental gliomas. Fleige G, Nolte C, Synowitz M, Seeberger F, Kettenmann H, Zimmer C. Neoplasia 2001 Nov–Dec; 3 (6), pp. 489–99.

Neoplasia (Central Nervous System [CNS]): Gliomas
Contrast-Enhanced Dynamic Susceptibility MRI

Background Information: Abnormalities in the recirculation phase of the passage of a contrast agent bolus have been identified in tumors and have been proposed to represent vascular tortuosity and hypoperfusion in areas of angiogenic neovascularization.
Application: Detection and characterization (grading) of the microcirculation profiles of gliomas within the CNS as a function of vascular tortuosity and regions of hypoperfusion.
Implementation: Characterization of glioma lesions by contrast-enhanced dynamic susceptibility MRI. Residual relaxivity effects are minimized by the injection of contrast agent before the acquisition of dynamic images. Maps of relative cerebral blood volume (rCBV) and relative recirculation (rR) are calculated, and values from enhancing tumor tissue compared with tumor grade.
Human Model: Human glioma cases (e.g., n = 27).
Interpretation and Analysis: Histologic grade categories include grade II-astrocytoma (n = 3); grade III-anaplastic astrocytoma (n = 10); and grade IV-glioblastoma multiforme (n = 14). Relative cerebral blood volume values vary among tumor grades, with higher mean values associated with higher grade tumors ($p < 0.001$). Mean rR values in grade II tumors are not significantly different from those in normal gray and white matter. Mean rR values in grades III and IV tumors are similar and significantly higher than those in grade II tumors ($p < 0.01$). The distribution of the pixel values of rR reveals significant differences between grades III and IV tumors ($p < 0.001$), with low values of skewness in keeping with a normal distribution in grade III tumors and higher values in grade IV tumors. Variation in the recirculation characteristics of a contrast agent bolus is related to tumor grade in gliomas. Abnormalities in contrast agent recirculation appear to provide independent information concerning the microcirculation in imaging studies of angiogenesis and may be of value as surrogate markers in trials of antiangiogenic therapy.

Abnormalities in the recirculation phase of contrast agent bolus passage in cerebral gliomas: Comparison with relative blood volume and tumor grade. Jackson A, Kassner A, Annesley-Williams D, Reid H, Zhu XP, Li KL. AJNR Am J Neuroradiol 2002 Jan; 23 (1), pp. 7–14.

Neoplasia (Central Nervous System [CNS]): Glioma of Murine Origin
Blood-Pool Contrast Agents: MP-2269 and MS-325/ Extracellular Contrast Agent: OptiMARK

Cellular/Molecular Mechanism of Action: MP-2269 and MS-325 are 2 small molecular weight serum albumin-binding blood-pool contrast agents. OptiMARK functions as a compound that remains in extracellular fluid compartments with essentially no intracellular penetration.
Application: Intravenous MRI contrast agents are commonly used to improve the detection of intracranial tumors and other CNS lesions for diagnosis and treatment planning.
Route of Administration: MP-2269 and MS-325 (intravenous), and OptiMARK (intravenous).
Dosage: MP-2269 and MS-325 (30 μmol/kg: small molecular weight, albumin-binding blood-pool contrast agents). OptiMARK (100 μmol/kg: extracellular imaging agent).
Implementation: Detection of CNS neoplastic lesions (glioma) with the small molecular weight blood-pool contrast agents MP-2269 and MS-325 compared to the extracellular contrast agent OptiMARK, utilizing 1.5 Tesla electromagnetic resonance imaging analysis.
Animal Model: Mouse glioma.
Interpretation and Analysis: Tumor image contrast is significantly enhanced and long-lived following administration of MP-2269 and MS-325 blood-pool agents. More specifically, contrast enhancement peaks slowly at 25 to 30 minutes following administration, remains constant for $>$ 3 hours, and returns to baseline within 20 hours. Comparable but "transient" enhancement can be achieved using an extracellular contrast agent (OptiMARK), which demonstrates rapid peaks in contrast enhancement at 2 to 5 minutes following administration and then declines over a 40-minute period. The blood-pool contrast agents demonstrate an approximate 3-fold increase in dose effectiveness and a lengthened window of tumor contrast enhancement compared to commonly available extracellular contrast agents. This demonstrates the potential of alternative contrast-enhanced MRI examination protocols for tumor detection.

Albumin-binding MR blood-pool agents as MRI contrast agents in an intracranial mouse glioma model. Adzamli K, Yablonskiy DA, Chicoine MR, Won EK, Galen KP, Zahner MC, Woolsey TA, Ackerman JJ. Magn Reson Med 2003 Mar; 49 (3), pp. 586–90.

Neoplasia (Central Nervous System [CNS]): Gliosarcoma
Rhodaminated Long-Circulating Dextran-Coated Iron Oxide (LCDIO)/Hoechst 33258 Dye/Green Fluorescent Protein

Cellular/Molecular Mechanism of Action: Hoechst 33258 dye can be applied as an intravital endothelial stain. Rhodaminated LCDIO particles can preferentially localize intracellularly within certain malignant neoplastic cell types (e.g., gliosarcoma).
Application: Detection and characterization of CNS neoplastic lesions (e.g., gliosarcoma).
Route of Administration: Intravascular.
Implementation: Determination of the distribution of an LCDIO preparation in tumors. Accumulation of LCDIO in tissue sections is evaluated using multichannel fluorescence microscopy with rhodaminated LCDIO, green fluorescent protein as a tumor marker, and Hoechst 33258 dye as an intravital endothelial stain. Uptake into tumor cells is correlated (validated) with results from immunohistochemical and cell culture uptake analyses. The effect of intratumoral LCDIO uptake on MRI signal intensity is evaluated with a 1.5 Tesla superconducting magnet.
Animal Model: Rodent gliosarcoma.
Interpretation and Analysis: Tumoral accumulation of LCDIO is 0.11% $\pm$ 0.06 of the injected dose per gram of tissue in brain tumors and sufficient for detection using MRI. In tumor sections, LCDIO preferentially localizes in tumor cells (49.0% $\pm$ 4.6) but is also taken up by macrophages in tumors (21.0% $\pm$ 3.1) and by endothelial cells in the areas of active angiogenesis (6.5% $\pm$ 1.4). In cell culture, LCDIO uptake strongly correlates with growth rate of tumor cell lines. Tumoral LCDIO accumulation is not negligible and helps explain MRI signal intensity changes observed in clinical trials. Microscopically, LCDIO accumulates predominantly in tumor cells and tumor-associated macrophages. Uptake into tumor cells appears to be directly proportional to cellular proliferation rate.
Instrumentation: Magnetic resonance imaging signal intensity evaluated with a 1.5 Tesla superconducting magnet.

Tumoral distribution of long-circulating dextran-coated iron oxide nanoparticles in a rodent model. Moore A, Marecos E, Bogdanov A Jr, Weissleder R. Radiology 2000 Feb; 214 (2), pp. 568–74.

Neoplasia (Central Nervous System [CNS]): Medulloblastoma
Gadolinium-Based Agent

Background Information: Experimental mouse models are emerging as useful systems for the study of human brain tumors. Nuclear MRI methods can non-invasively provide images of complex heterogeneous tissues such as experimental brain tumors.
Route of Administration: Gadolinium-based agents (intravenous).
Implementation: Demonstration of the feasibility of longitudinal high-resolution MRI in detecting and characterizing brain tumors.
Animal Model: Two mouse brain tumor models: patched heterozygous (ptc $\pm$) mice with spontaneously arising posterior fossa tumors that resemble human medulloblastoma, and homozygous nude mice implanted with intracerebral xenografts of human medulloblastoma cell lines.
Interpretation and Analysis: Methods have been optimized to achieve favorable volumetric comparison with histologic methods and submillimeter resolution, improved by contrast enhancement with intravenous administration of a gadolinium-based agent.

Magnetic resonance imaging of patched heterozygous and xenografted mouse brain tumors. Nelson AL, Algon SA, Munasinghe J, Graves O, Goumnerova L, Burstein D, Pomeroy SL, Kim JY. J Neurooncol 2003 May; 62 (3), pp. 259–67.

Neoplastic Disease (Central Nervous System [CNS])/Angiogenesis of Gliomas/Dimethylarginine Dimethylaminohydrolase (DDAH) Overexpression
NC100150/Hoechst 33342

Cellular/Molecular Mechanism of Action: The orientation of NC100150 becomes altered within a magnetic field. Alternatively, Hoechst 33342 emits fluorescent light energy.
Background Information: Intracellular factors that regulate nitric oxide (NO) synthesis represent important targets in tumor progression. Overexpression of DDAH, which metabolizes the endogenous inhibitors of NO synthesis asymmetric dimethylarginine and

N-monomethyl-L-arginine, results in C6 gliomas with enhanced growth rates compared to wild cell types.

Application: NC100150 can be utilized as an intravascular blood-pool contrast agent that is detectable by MRI methodologies. Hoechst 33342 can be used as a fluorescent perfusion-marker dye that can be measured by flourescent detection systems.

Route of Administration: Utilization of NC100150 and Hoechst 33342 for neoplastic lesion angiogenesis requires that these be delivered intravascularly.

Implementation: Determine the (i) *in vitro* effects of DDAH on tumor vascular morphogenesis by measurement of the transverse relaxation rates R_2* and R_2 in clone D27 gliomas overexpressing DDAH and C6 wild-type gliomas using intrinsic susceptibility MRI sensitive to changes in endogenous deoxyhemoglobin; (ii) determine susceptibility contrast-enhanced MRI using NC100150 as an intravascular blood-pool contrast agent; and (iii) compare results with fluorescence microscopy of the tumor uptake for the perfusion marker Hoechst 33342.

Interpretation and Analysis: The baseline R_2* is significantly faster in D27 tumors, consistent with a greater vascular development ($p < 0.02$, ANOVA). There is no significant difference between the response of the 2 tumor types to hypercapnia (5% CO_2/95% air), used as a model for vascular maturation, or hyperoxia (5% CO_2/95% O_2), used as a model for vascular function. NC100150 increases the R_2* and R_2 rates of both tumor types and detects a significantly larger blood volume in the D27 tumors ($p < 0.02$, ANOVA). This correlates with a significantly greater uptake of Hoechst 33342 in the D27 tumors compared to C6 wild-type tumors ($p < 0.02$, ANOVA). Despite increased tumor blood volume, the Delta R_2*/Delta R_2 ratio, an index of microvessel size, shows that the capillaries in the 2 tumor types are of a similar diameter. Such observations demonstrate the potential of susceptibility MRI-derived quantitative end points to non-invasively assess tumor angiogenesis. Application of intravascular blood-pool contrast agents like NC100150 for such purposes appears very promising. Overexpression of DDAH results in increased *in vivo* neovascularization of C6 gliomas. The lack of significant difference in hypercapnic/hyperoxic responses between C6 and D27 tumors and the similar vessel caliber are also consistent with a role for DDAH in the initial stages of vasculogenesis.

Instrumentation: Magnetic resonance imaging and fluorescence microscopy instrumentation.

Effects of overexpression of dimethylarginine dimethylaminohydrolase on tumor angiogenesis assessed by susceptibility magnetic resonance imaging. Kostourou V, Robinson SP, Whitley GS, Griffiths JR. Cancer Res 2003 Aug 15; 63 (16), pp. 4960–6.

Neoplastic Disease/Brain Tumor Diagnostic and Therapeutic Implications
Gadobenate Dimeglumine ([Gd]-BOPTA)

Background Information: Gadobenate dimeglumine has a significantly greater [Gd] uptake by brain tumor tissue than gadopentate dimeglumine ([Gd]-DTPA).

Application: The agent [Gd]-BOPTA is assimilated at relatively high concentrations within certain neoplastic lesions that affect the central nervous system.

Route of Administration: Gadobenate dimeglumine and [Gd]-DTPA (intralesionally and subcutaneous in rat research investigations).

Dosage: Gadobenate dimeglumine and [Gd]-DTPA (0.05 mmol/g tumor weight).

Implementation: Evaluate whether [Gd]-BOPTA is an efficient agent for neutron capture therapy (NCT). Delineation of the imaging properties of [Gd]-BOPTA and [Gd]-DTPA injected intralesionally into tumors. At the peak of [Gd] uptake, thermal neutron irradiation is applied.

Animal Model: Rat (Fisher 344 strain). Four groups of Fisher 344 rats (control, neutron (n), n+ [Gd]-DTPA, n+ [Gd]-BOPTA) injected subcutaneously with 9L gliosarcoma cells in both hind legs.

Interpretation and Analysis: A pronounced delay in tumor growth can be appreciated with [Gd+] formulations compared to control and neutron analyses ($p = 0.0053$, 0.0064, respectively). Furthermore, BOPTA is associated with a significantly prolonged delay of tumor growth compared to DTPA ($p = 0.033$). In addition, [Gd]-NCT demonstrates that [Gd]-BOPTA can function as an effective compound for NCT. Better cytocidal effects of [Gd]-BOPTA warrant further investigation of subcellular [Gd] distribution.

In vivo gadolinium neutron capture therapy using a potentially effective compound ([Gd]-BOPTA). Matsumura A, Zhang T, Yamamoto T, Yoshida F, Sakurai Y, Shimojo N, Nose T. Anticancer Res 2003 May–Jun; 23 (3B), pp. 2451–6.

CENTRAL NERVOUS SYSTEM: SPECIAL SENSES

Special Senses/Cochlear Noise-Related Injury/Damage
GdDTPA-BMA

Cellular/Molecular Mechanism of Action: The element gadolinium (Gd) is a paramagnetic ion that has its physical (special) orientation altered when subjected to magnetic energy fields.

Application: Detection and characterization of normal and noise-damaged cochlea using GdDTPA-BMA in a manner that can facilitate its application as a T_1 contrast agent for MRI modalities.

Route of Administration: GdDTPA-BMA (intravenous).

Implementation: The time course and distribution of the *in vivo* uptake of the gadodiamide chelate bound paramagnetic [Gd] ion (GdDTPA-BMA) throughout the membranous labyrinth of normal and impulse noise-damaged guinea pig cochleas are measured by MRI (4.7 Tesla).

Interpretation and Analysis: Simultaneous signal enhancement of the basal, medial, and apical scala tympani (ST) and scala vestibuli (SV) can be observed within 10 minutes following injection, with maximal levels reached around 100 minutes. Evaluation by ANOVA and post hoc paired t tests reveals statistically significant differences in the levels and rates of [Gd] uptake-enhancement between the scalae. The basal, medial, and apical ST reveal the most rapid and extensive enhancement occurs throughout the period of active [Gd] uptake, while the SV show comparatively slower and less enhancement, and the intact scala media (SM) indicate insignificant enhancement. The *in vivo* penetration of [Gd] and enhancement of the membranous SM increases significantly in the noise-damaged cochlea, suggesting lesioning of the cochlear membranes.

Magnetic resonance imaging of the membranous labyrinth during *in vivo* gadolinium (GdDTPA-BMA) uptake in the normal and lesioned cochlea. Counter SA, Bjelke B, Borg E, Klason T, Chen Z, Duan ML. Neuroreport 2000 Dec 18; 11 (18), pp. 3979–83.

GASTROINTESTINAL SYSTEM

Abdominal Imaging/Oral Contrast Agents
Intravenous Contrast Agent

Cross-sectional imaging of the abdomen in oncology patients presents unique challenges and opportunities. A close working relationship between the oncologist and radiologist is essential for the

exchange of the clinical and imaging information necessary for optimizing patient diagnosis and management. Compared to helical computed tomography (CT), MRI of the abdomen and pelvis offers important advantages, including superior soft-tissue contrast. The multiplanar capabilities of MRI allow for direct coronal or sagittal imaging, providing a truer anatomic presentation of abdominal and pelvic masses. Recent advances in MRI, including the use of intravenous and oral contrast agents, the development of high-performance imagers, and improved surface coil designs, facilitate more rapid abdominal imaging with superior image quality. All of these features combine to produce a versatile imaging examination with exquisite sensitivity for depicting abdominal and pelvic tumors. In this context, they have clinical applicability for hepatic and extrahepatic abdominal MRI in the oncology patient. Techniques and protocols for MRI can be applied to most commercially available high-field MRI instrumentation.

Magnetic resonance imaging of the abdomen: Applications in the oncology patient. Low RN. Oncology (Huntingt) 2000 Jun; 14 (6 Suppl 3), pp. 5–14.

Intestinal/Rectal Carcinoma/Tumor Staging/ Comparison of Sonography with MRI
Gadolinium/Superparamagnetic Iron Oxide

Application: Superparamagnetic iron oxide and gadolinium can be applied in MRI of conditions of rectal cancer, especially in conditions involving proximal and stenotic lesions.
Implementation: Evaluate conditions of rectal cancer that have undergone transrectal sonography performed with a 10-MHz endoanal probe and MRI (1.0 Tesla or 1.5 Tesla) using a whole-body coil. After rectal administration of a superparamagnetic iron oxide MR contrast agent, T_1- and T_2-weighted images and gadolinium-enhanced double-contrast images are obtained. The results of examinations are then compared with the histology of resected specimens.

Human Model: Rectal carcinoma (e.g., n = 39; n = 19/39 females, n = 20 males).
Interpretation and Analysis: Histopathology analyses can detect T_1, T_2, T_3, and T_4 stage tumors (e.g., n = 4 stage-T_1, n = 11 stage-T_2, n = 18 stage-T_3, n = 6 stage-T_4 tumors) using the tumor-node-metastasis (TNM) staging system. Nodal metastases can be seen in a large percentage of cases (e.g., n = 16/39). Transrectal sonography cannot be performed in all conditions due to various factors, including "high" (proximal) tumor location (e.g., n = 11/36). In cases where transrectal sonography is feasible (e.g., n = 28/39), the accuracy of image detection for T-stage conditions is approximately 64% overall (patients not receiving radiation, 69%; patients receiving radiation, 60%) and 70% for N-stage tumors. Conversely, double-contrast MRI can correctly identify T-stage tumors with an accuracy of 64% overall (e.g., n = 39; patients not receiving radiation, 75%; patients receiving radiation, 53%) and N-stage with a 62% level of accuracy. The assessment of rectal wall penetration (Dukes' classification A vs B) predicts sensitivity, specificity, and accuracy levels of 93%, 71%, and 82%, respectively, for transrectal sonography and 100%, 60%, and 85% for MRI. In scenarios where it is technically feasible, transrectal sonography is an accurate method for staging rectal cancer. In proximal or stenotic tumors, double-contrast MRI is the method of choice. Diagnostic accuracy of transrectal sonography and MRI is high for predicting bowel wall penetration.

Comparison of transrectal sonography and double-contrast MR imaging when staging rectal cancer. Fuchsjager MH, Maier AG, Schima W, Zebedin E, Herbst F, Mittlbock M, Wrba F, Lechner GL. AJR Am J Roentgenol 2003 Aug; 181 (2), pp. 421–7.

GENETIC

Gene Mapping Model: *In Vivo* β-Galactosidase Expression
Galactopyranose Functional Group/Chelated Paramagnetic Ion

Cellular/Molecular Mechanism of Action: Galactopyranose can function as a substrate for the indicator (marker) gene β-galactosidase.
Background Information: High-resolution *in vivo* imaging of gene expression is not possible applying existing techniques.
Application: High-resolution *in vivo* MRI imaging of "reporter" gene expression.
Semi-Synthetic Methods: Preparation of an MRI contrast agent in which the access of water to the 1st coordination sphere of a chelated paramagnetic ion is blocked with a substrate that can be removed by enzymatic cleavage. Following cleavage, the paramagnetic ion can interact directly with water protons to increase the MR signal.
Implementation: Detection and characterization of *in vivo* gene expression.
Interpretation and Analysis: Galactopyranose can function as an effective blocking group that can render an MRI contrast agent sensitive to detecting the expression of β-galactosidase (marker gene). Pertaining to cellular resolution, regions of higher intensity in MR images correlate with regions expressing the marker enzyme. These results offer the promise of *in vivo* mapping of gene expression in transgenic animals and validate a general approach for constructing a family of MRI contrast agents that respond to biological activity.

In vivo visualization of gene expression using magnetic resonance imaging. Louie AY, Huber MM, Ahrens ET, Rothbacher U, Moats R, Jacobs RE, Fraser SE, Meade TJ. Nat Biotechnol 2000 Mar; 18 (3), pp. 321–5.

HEMATOLOGY

Hematopoietic Progenitor Cell Migration
Hematopoietic Progenitor Cells/Magnetic Polysaccharide Nanoparticles-Transferrin/ Gadopentetate Dimeglumine Liposomes/P7228 Liposomes/Ferumoxides/Ferumoxtran

Application: Labeling of human hematopoietic progenitor cells with various MRI contrast-enhancing agents to facilitate acquisition of images at 1.5 Tesla.
Route of Administration: Intravascular.
Semi-Synthetic Methods: Labeling of hematopoietic progenitor cells with ferumoxides, ferumoxtran, magnetic polysaccharide nanoparticles-transferrin, P7228 liposomes, and gadopentetate dimeglumine liposomes.
Implementation: Evaluation of the organ/tissue biodistribution of labeled hematopoietic progenitor cells using MRI. Data can be analyzed by measuring MR signal intensities and R1 and R2* relaxation rates of labeled cells and non-labeled reference control cells. Mean quantitative data for the various contrast agents are assessed to detect significant differences compared to reference control cells by means of the Scheffe statistical analysis model. As a reference standard, MRI data can be compared with electron microscopic and spectrometric data.

Interpretation and Analysis: For all contrast agents, the intracellular assimilation into the cytoplasm can be demonstrated with electron microscopy and quantified by spectrometry. Compared with non-labeled control cells, progenitor cells labeled with iron oxides show significantly ($p < 0.05$) increased R2*. Cells labeled with gadopentetate dimeglumine liposomes show significantly increased R1. Detection thresholds are approximately 5×10^5 cells for gadopentetate dimeglumine liposomes and ferumoxtran, 2.5×10^5 cells for ferumoxides and P7228 liposomes, and 1×10^5 cells for magnetic polysaccharide nanoparticles-transferrin. Therefore, hematopoietic progenitor cells can be labeled with MR contrast agents and their detection is possible with a standard 1.5 Tesla MR imager.

Instrumentation: Magnetic resonance imaging with T_1- and T_2-weighted spin-echo and fast field-echo sequences.

Targeting of hematopoietic progenitor cells with MR contrast agents. Daldrup-Link HE, Rudelius M, Oostendorp RA, Settles M, Piontek G, Metz S, Rosenbrock H, Keller U, Heinzmann U, Rummeny EJ, Schlegel J, Link TM. Radiology 2003 Sep; 228 (3), pp. 760–7.

HEPATIC SYSTEM

Hepatic/Backdiffusion Phenomenon of Hepatic Contrast Agent
Diethyl Iminodiacetic Analogues (Diethyl IDA)/ Mebrofenin

Background Information: The kinetics of organic anions are well described and backdiffusion from hepatocyte to plasma is an accepted phenomenon. Although IDAs, as organic anions, should also show bidirectional transport between hepatocyte and plasma, this has not been directly demonstrated.

Application: Hepatic contrast-image-enhancing agent for MRI modalities.

Route of Administration: Diethyl IDAs (intravascular); mebrofenin (intravascular).

Implementation: Evaluate backdiffusion characteristics of hepatic contrast agents into the intravascular compartment and quantify the corresponding fractional rate constant. Kinetics of diethyl IDA can be characterized through the analysis of femoral artery and hepatic venous samples collected following the injection of tracer preparations into a (i) peripheral vein, or (ii) hepatic artery or portal vein. Arterial time-concentration curves can also be compared between peripheral venous and either hepatic arterial or portal venous injections (canine). Complementary findings can be obtained by generating time-activity curves recorded from regions of interest (ROIs) over the cardiac blood-pool and peripheral hepatic parenchyma during routine IDA hepatobiliary imaging with diethyl IDA or mebrofenin and fractional rate constants for clearance of IDA from the hepatocyte compared to compartmental and deconvolution analyses (e.g., $n = 30$ cases).

Animal Model: Anesthetized dogs (e.g., $n = 3$).

Human Model: Hepatobiliary imaging with diethyl IDA ($n = 30$ cases).

Interpretation and Analysis: Following peripheral injection, there is an early arteriovenous concentration gradient that develops across the liver indicating a hepatocyte extraction fraction of 0.9 (dog #1), 0.8 (dog #2), and 0.6 (dog #3). The net extraction fraction decreases exponentially over a 40-minute period. Time-concentration curves for the hepatic vein and femoral artery are virtually superimposed following intrahepatic injections. Peripheral arterial curves, however, have different shapes according to whether injections are delivered intrahepatically or peripherally, and are consistent with the occurrence of significant backdiffusion. In human clinical cases, the blood disappearance curves can be fitted as the sum of 2 exponentials and the liver curves as the difference of 2 exponentials (rate constants = alpha1h and alpha2h). Based on compartmental analysis of the blood curves, the sum of the fractional rate constants of tracer movement from hepatocyte to bile canaliculus (k_{32}) and to plasma (k_{12}) is similar to and correlates with the rate constant, alpha, for the hepatocyte impulse response function ($r = 0.62$, $n = 30$, $p < 0.001$). In contrast, alpha1h and alpha2h are respectively clearly greater and smaller than alpha. Moreover, neither of these hepatic rate constants correlates with alpha. Diffusion of IDA from hepatocyte into the blood is significant and even in the presence of normal liver function accounts for about 50% of IDA transport out of the hepatocyte. It should be taken into account in pharmacokinetic studies based on either compartmental or deconvolution analysis.

Bidirectional transport of iminodiacetic organic anion analogues between plasma and hepatocyte. Peters AM, Myers MJ, Mohammadtaghi S, Mubashar M, Mathie RT. Eur J Nucl Med 1998 Jul; 25 (7), pp. 766–73.

Hepatic/Cholestasis/Tumor Contrast Enhancement Pattern/Invasiveness and Degree of Malignancy: Peritumor Rim Sign
Mangafodipir Trisodium/Manganese Dipyridoxal Diphosphate/Gadoxetic Acid/Gadolinium Ethoxybenzyl Diethylenetriaminopentaacetic Acid/Gadolinium Butylbenzyl Diethylenetriaminepentaacetic Acid

Background Information: Because of the demand to extend the range of diagnostic uses for currently available extracellular MRI contrast agents, a new generation of tissue-specific (i.e., hepatobiliary) contrast agents has been successfully developed to enhance the performance of hepatic MRI. These agents include mangafodipir trisodium (formerly manganese dipyridoxal diphosphate [Mn-DPDP]); gadoxetic acid (formerly gadolinium ethoxybenzyl diethylenetriaminopentaacetic acid—[Gd]-EOB-DTPA); and gadolinium butylbenzyl diethylenetriaminepentaacetic acid (MS-264).

Implementation: Delineation of the imaging behaviors of (i) mangafodipir trisodium (formerly Mn-DPDP); (ii) gadoxetic acid (formerly [Gd]-EOB-DTPA); and (iii) MS-264, for different types of cholestasis and focal liver lesions when applied in combination with MRI modalities. In addition, comparisons are made between agents to identify their similarities or dissimilarities in their possible mechanisms of action and the clinical implications of such observations.

Interpretation and Analysis: The intravenous administration of (i) mangafodipir trisodium (formerly Mn-DPDP); (ii) gadoxetic acid (formerly [Gd]-EOB-DTPA); and (iii) MS-264 can facilitate the identification of both global and local obstructive cholestases in postcontrast images. Liver tumors of different orgins and grades of cellular differentiation can be detected and classified according to their contrast enhancement patterns appreciated in certain postcontrast phases. The invasiveness or degree of malignancy of a given hepatic tumor type can also be presumed as a function of the presence or absence of a peritumoral rim pattern. Such diagnostic information, otherwise only invasively achievable, may prove to be invaluable in clinical decision making.

Enhanced magnetic resonance imaging for tissue characterization of liver abnormalities with hepatobiliary contrast agents: An overview of preclinical animal experiments. Ni Y, Marchal G. Top Magn Reson Imaging 1998 Jun; 9 (3), pp. 183–95.

Hepatic/Hepatocyte Mechanisms of Gadolinium Uptake
Gadolinium [Gd] Complexes/[Gd]-DTPA/ [Gd]-EOB-DTPA/[Gd]-BOPTA/[Gd]-B 20790

Application: Gadolinium complexes can be used as contrast image-enhancing agents for MRI of hepatic structures.
Implementation: Evaluation of the hepatic transport of different gadolinium complexes through delineation of the uptake/assimilation of [Gd]-DTPA, [Gd]-BOPTA, [Gd]-EOB-DTPA, and [Gd]-B 20790 by basolateral rat hepatocyte plasma membrane vesicles. Complementary investigations entail assessment of the rate and extent of gadolinium agent uptake by *Xenopus laevis* oocytes in response to the injection of 5 ng of human OATP cRNA.
Interpretation and Analysis: In basolateral rat hepatocyte plasma membrane vesicles, [Gd]-DTPA uptake is indistinguishable from non-specific binding to vesicles; [Gd]-BOPTA and [Gd]-EOB-DTPA enter plasma membrane vesicles according to a linear, concentration-dependent mechanism up to 1.5 mM of substrate. By contrast, [Gd]-B 20790 uptake follows a saturative kinetic with an apparent Km of 92 $\pm$ 15 μM and a Vmax of 143 $\pm$ 42 pmol/mg prot/15 seconds, and can occur in an osmotic-sensitive space. Sulfobromophthalein and taurocholate, but not unconjugated bilirubin, inhibit the uptake rate of [Gd]-B 20790 but not that of [Gd]-DTPA, [Gd]-BOPTA, or [Gd]-EOB-DTPA.

Injection into *Xenopus laevis* oocytes of 5 ng of human OATP cRNA after 3 days results in a $\geq$ 2-fold stimulation ($p < 0.001$) of transport of [Gd]-B 20790 but not of [Gd]-BOPTA or [Gd]-EOB-DTPA. Hepatic uptake of the MRI contrast agent [Gd]-B 20790 is a carrier-mediated mechanism operated by OATP, while MRI compounds with other chemical structures enter the hepatocyte by other mechanisms.

Molecular mechanisms for the hepatic uptake of magnetic resonance imaging contrast agents. Pascolo L, Cupelli F, Anelli PL, Lorusso V, Visigalli M, Uggeri F, Tiribelli C. Biochem Biophys Res Commun 1999 Apr 21; 257 (3), pp. 746–52.

Hepatic/Hepatocyte Mechanisms of Manganese (Mn^{+2}) Uptake
Manganese Dipyridoxyl Diphosphate ([Mn]-DPDP)/ Manganese Chloride ($MnCl_2$)

Cellular/Molecular Mechanism of Action: A fraction of free paramagnetic Mn^{+2} ion penetrates the cell membrane of hepatocytes through Ca^{+2} channels and then strongly interacts with molecular ATP.
Implementation: Spectroscopic comparisons of the mechanisms of the hepatic uptake for $MnCl_2$ and [Mn]-DPDP. Alterations in the phosphorus-31 [^{31}P]-NMR spectrum for intracellular adenosine 5′-triphosphate (ATP) can be used to monitor internalization of manganese by hepatic tissues.
***Ex Vivo* Model:** Isolated and perfused rat liver.
Interpretation and Analysis: Delivery of Mn^{+2} as $MnCl_2$ in the perfusate rapidly enters hepatocytes, where it strongly interacts with ATP and induces a broadening of the [^{31}P] lines. Nifedipine inhibition of the process confirms the concept that manganese ions cross the cellular membrane at least partly through Ca^{+2} channels. The agent [Mn]-DPDP induces weaker but still significant changes in the ATP spectrum. The inability of pyridoxine to compete for the uptake of manganese confirms that the vitamin B_6 carrier is not involved in the internalization process of the paramagnetic complex. Lastly, preincubation of [Mn]-DPDP with blood does not increase the extent of dissociation. The alterations of the [^{31}P] spectrum in the liver subsequent to the administration of [Mn]-DPDP are attributable to a fraction of free Mn^{+2} released by the chelate and delivered to the hepatocytes.

Dynamic evaluation of the hepatic uptake and clearance of manganese-based MRI contrast agents: A ^{31}P NMR study on the isolated and perfused rat liver. Colet JM, Vander Elst L, Muller RN. J Magn Reson Imaging 1998 May–Jun; 8(3), pp. 663–9.

Hepatic/Portal and Hepatic Vein Selective Imaging
DAB-Am64-(1B4M-Gd)(64)/PAMAM-G4D-(1B4M-Gd)(64)

Cellular/Molecular Mechanism of Action: Hydrophobic molecules reportedly accumulate in the liver more extensively than do hydrophilic compounds.
Background Information: A generation-4 polypropylenimine diaminobutane dendrimer (e.g., DAB-Am64) should theoretically be more hydrophobic than a generation-4 polyamidoamine dendrimer (e.g., PAMAM-G4D). Systemically administered hydrophobic molecules reportedly accumulate extensively within the liver and thus are potentially useful as liver MRI contrast agents.
Semi-Synthetic Methods: A generation-4 polypropylenimine diaminobutane dendrimer (DAB-Am64) is used to synthesize a conjugate with 2-(*p*-isothiocyanatobenzyl)-6-methyl-diethylenetriaminepentaacetic acid (1B4M) [DAB-Am64-(1B4M-Gd)(64)] for the purpose of complexing with Gd(III) ions.
Animal Model: Murine hepatic intravascular image preparations.
Implementation: Evaluation of the relative ability of the DAB conjugate, DAB-Am64-(1B4M-Gd)(64), to accumulate within the liver in addition to other characteristics. Parameters are then compared to those for the PAMAM conjugate PAMAM-G4D-(1B4M-Gd)(64), which is known to be a useful vascular MRI contrast agent, in regard to its availability as a liver MRI contrast agent.
Interpretation and Analysis: This DAB conjugate, DAB-Am64-(1B4M-Gd)(64), quickly accumulates within the liver. DAB-Am64-(1B4M-Gd)(64) accumulates to a significantly greater extent in the liver and less in the intravascular blood pool than does PAMAM-G4D-(1B4M-Gd)(64) ($p < 0.001$). Contrast-enhanced MRI with DAB-Am64-(1B4M-Gd)(64) is able to homogeneously enhance liver parenchyma and visualize both portal and hepatic veins of 0.5 mm diameter in mice. In conclusion, DAB-Am64-(1B4M-Gd)(64) is a good candidate as a liver MRI contrast agent.

Novel liver macromolecular MR contrast agent with a polypropylenimine diaminobutyl dendrimer core: Comparison to the vascular MR contrast agent with the polyamidoamine dendrimer core. Kobayashi H, Kawamoto S, Saga T, Sato N, Hiraga A, Ishimori T, Akita Y, Mamede MH, Konishi J, Togashi K, Brechbiel MW. Magn Reson Med 2001 Oct; 46 (4), pp. 795–802.

Hepatic Adenocarcinoma (VX-2 Metastatic Model)/ Gallbladder Imaging/Hepatocellular Clearance
[Gd]-HP-DO3A/[Gd]-2,5-BPA-DO3A

Application: Detection and characterization of gallbladder abnormalities and conditions of adenocarcinoma.
Route of Administration: The contrast image enhancement agents [Gd]-2,5-BPA-DO3A (15d) and [Gd]-HP-DO3A are both delivered by intravascular injection.
Implementation: Evaluate the effect of substituent lipophilicity, substituent position, and overall charge on the hepatobiliary clearance

and tolerance of a series of aromatic ring-containing macrocyclic [Gd] chelates for the purpose of selecting a candidate compound for evaluation as a hepatobiliary imaging agent. One approach to achieving this objective can involve delineation of tissue distribution patterns (mice) and T_1-weighted pulse sequences or T_1-weighted breath-hold pulse sequences (cats, rabbits, rhesus monkeys) using [Gd]-2,5-BPA-DO3A (15d) and [Gd]-HP-DO3A as a reference control agent.

Animal Model: Cats, rabbits, rat, and rhesus monkey (rabbit: VX-2 adenocarcinoma tranplant model for metastatic liver disease).

Interpretation and Analysis: Each compound is excreted bimodally. [Gd]-2,5-BPA-DO3A (15d) possesses an optimal combination of hepatobiliary clearance (47% in rats, 29% in mice) and tolerance (minimum lethal dose 5.0 mmol/kg). Initial imaging studies demonstrate the feasibility of [Gd]-2,5-BPA-DO3A for hepatic imaging (cat). In VX-2 adenocarcinoma implants, [Gd]-2,5-BPA-DO3A provides sustained hepatic signal intensity (SI) enhancement and lesion conspicuity over a 120-minute imaging time course (rabbit metastatic liver disease model). In normal liver function, sustained hepatic SI enhancement and a time-dependent increase in gallbladder SI over the entire 90-minute imaging time course can be afforded by [Gd]-2,5-BPA-DO3A (rhesus monkey). Dramatic and sustained SI enhancement of hepatic tissue is observed with [Gd]-2,5-BPA-DO3A that is superior in all respects to the extracellular space MRI agent, [Gd]-HP-DO3A, employed as a control (cats, rabbits, rhesus monkey).

Synthesis, characterization, and imaging performance of a new class of macrocyclic hepatobiliary MR contrast agents. Marinelli ER, Neubeck R, Song B, Wagler T, Ranganathan RS, Sukumaran K, Wedeking PW, Nunn A, Runge VM, Tweedle MF. Invest Radiol 2000 Jan; 35 (1), pp. 8–24.

Hepatic Free Radical Production/Hepatic Vein and Inferior Vena Cava Nitric Oxide (NO) Synthase and NO/Endotoxin Shock Model
N-Methyl-D-Glucamine Dithiocarbamate $(MGD)_2$-Fe^{+2}-NO Complex

Cellular/Molecular Mechanism of Action: $(MGD)_2$-Fe^{+2}-NO complexes bind to and function as a competitive inhibitor of nitric oxide synthetase.

Application: Detection of free radical species such as those produced at elevated levels within the liver during conditions of septic inflammation (e.g., endotoxemia/endotoxic shock).

Semi-Synthetic Methods: Nitric oxide is complexed with the Fe^{+2}-chelate spin trap, MGD, and the resulting product $(MGD)_2$-Fe^{+2}-NO is verified by EPR.

Implementation: Evaluation of the distribution of molecular radical formation visualized by MRI applying the agent $(MGD)_2$-Fe^{+2}-NO. Nitric oxide synthase can be verified as the source of NO in a septic shock protocol by the preadministration of the competitive inhibitor N-monomethyl-L-arginine.

Animal Model: Rat endotoxic shock protocol.

Interpretation and Analysis: Complexes of $(MGD)_2$-Fe^{+2}-NO accumulate in the liver (rats) and provide significant contrast-enhanced profiles for vascular structures including the hepatic vein and inferior vena cava. Preadministration with N-monomethyl-L-arginine (NO competitive inhibitor of NO synthase) results in reduced hepatic $(MGD)_2$-Fe^{+2}-NO complex enhancement. The NO complex is more stable *in vivo* and a more effective MRI contrast agent than other stable nitrogen-containing radicals (e.g., nitroxides). The MRI spin-trapping method should be a powerful tool for visualizing spatial distributions of free radicals in pathologic organs and tissues when combined with the appropriate radical complexing agent, such as $(MGD)_2$-Fe^{+2} preparations.

In vivo imaging of spin-trapped nitric oxide in rats with septic shock: MRI spin trapping. Fujii H, Wan X, Zhong J, Berliner LJ, Yoshikawa K. Magn Reson Med 1999 Aug; 42 (2), pp. 235–9.

Hepatic and Pancreatic Lesions
Mangafodipir Trisodium

Background Information: The detection and characterization of pancreatic tumors as well as the reliable staging of pancreatic cancer are important clinical radiographic objectives. Contrast-enhanced helical computed tomography (CT) has been the standard modality for pancreatic imaging at many institutions, but MRI has gained a considerable role in the evaluation of patients with equivocal CT findings.

Application: Detection and characterization of disease states affecting the liver and pancreas, including neoplastic conditions employing MRI analysis.

Interpretation and Analysis: Contrast-enhanced MRI has proven to be very helpful in detecting small tumors or the identification of tumor-like lesions in patients with equivocal CT findings. Mangafodopir may improve the staging of pancreatic cancer by increasing the sensitivity of MRI in the detection of liver metastases. Reviews have been published that summarize the potential of contrast-enhanced MRI and its limitations compared with contrast-enhanced helical CT.

Evaluation of focal pancreatic masses: Comparison of mangafodipir-enhanced MR imaging and contrast-enhanced helical CT. Schima W, Fugger R. Eur Radiol 2002 Dec; 12 (12), pp. 2998–3008. Epub 2002 Jul 12.

Hepatic Imaging/Renal Accumulation/Blood Retention/Liver Accumulation/Intratumor Fine Vessel Resolution/Influence of Molecular Size
Macromolecular Polyamidoamine Dendrimer Cores/ G6D-(1B4M-Gd)(256)/G7D-(1B4M-Gd)(512)/ G8D-(1B4M-Gd)(1024)/G9D-(1B4M-Gd)(2048)

Background Information: Pharmacokinetic characteristics of intravascular macromolecular MRI contrast agents with polyamidoamine dendrimer cores smaller than generation-7 have previously been described in the literature.

Application: Detection and characteriation of hepatic pathology.

Route of Administration: Intravascular.

Semi-Synthetic Methods: The MRI contrast agents GxD-(1B4M-Gd)(2(x+2)) synthesized with generation-7, -8, and -9 polyamidoamine dendrimers and 2-(*p*-isothiocyanatobenzyl)-6-methyl-diethylenetriaminepentaacetic acid (1B4M).

Implementation: Evaluate the effects of greater hepatic uptake on the pharmacokinetics of the larger generation dendrimers [e.g., GxD-(1B4M-Gd)(2(x+2)) synthesized with generation-7, -8, and -9 polyamidoamine dendrimers and 2-(*p*-isothiocyanatobenzyl)-6-methyl-diethylenetriaminepentaacetic acid (1B4M)].

Animal Model: Murine (pharmacokinetic).

Interpretation and Analysis: Delineation of the pharmacokinetic characteristics of G6D-(1B4M-Gd)(256) reveals that in biodistribution and dynamic micro-MRI studies, significantly less renal accumulation of G7D-(1B4M-Gd)(512), G8D-(1B4M-Gd)(1024), and G9D-(1B4M-Gd)(2048) can be appreciated compared to G6D-(1B4M-Gd)(256) ($p < 0.01$). There is a significantly greater accumulation of G8D-(1B4M-Gd)(1024) and G9D-(1B4M-Gd)(2048) in

the liver compared to G6D-(1B4M-Gd)(256) and G7D-(1B4M-Gd)(512) ($p < 0.01$). The highest blood retention of all dendrimer-based MRI contrast agents is exhibited by G7D-(1B4M-Gd)(512) ($p < 0.01$). The normal and intratumoral fine vessels of approximately 100-μm diameter can be visualized in normal or tumor-bearing mice by high resolution 3-dimensional-micro-MR angiographs with G7D-(1B4M-Gd)(512) and G8D-(1B4M-Gd)(1024) with good vessel-to-soft tissue contrast. Therefore, increased accumulation in the liver with concomitant decreased uptake in the kidney is caused by increased molecular sizes of the dendrimer-based MRI contrast agents.

Micro-MR angiography of normal and intratumoral vessels in mice using dedicated intravascular MR contrast agents with high generation of polyamidoamine dendrimer core: Reference to pharmacokinetic properties of dendrimer-based MR contrast agents. Kobayashi H, Kawamoto S, Saga T, Sato N, Hiraga A, Konishi J, Togashi K, Brechbiel MW. J Magn Reson Imaging 2001 Dec; 14 (6), pp. 705–13.

Hepatic Imaging/Selective Visualization
$K_9GdW_{10}O_{36}/K_{11}[Gd(PW_{11}O_{39})_2]$

Cellular/Molecular Mechanism of Action: The basis for the liver-specific properties of $K_9GdW_{10}O_{36}$ and $K_{11}[Gd(PW_{11}O_{39})_2]$ have not been definitively established.

Application: Liver-specific MRI contrast-enhancing agent. But further refinement of $K_9GdW_{10}O_{36}$ and $K_{11}[Gd(PW_{11}O_{39})_2]$ is required in order to diminish their degree of toxicity.

Route of Administration: $K_9GdW_{10}O_{36}$ and $K_{11}[Gd(PW_{11}O_{39})_2]$ are given intravenously.

Implementation: Evaluation of the 2 gadolinium polyoxometalates, $K_9GdW_{10}O_{36}$ and $K_{11}[Gd(PW_{11}O_{39})_2]$, in both *in vitro* and *in vivo* environments to determine their potential as candidates for tissue-specific MRI contrast agents.

Animal Model: Rat (Sprague-Dawley).

Interpretation and Analysis: T_1-relaxivities of 6.89 mM/s for $K_9GdW_{10}O_{36}$ and 5.27 mM/s for $K_{11}[Gd(PW_{11}O_{39})_2]$ are slightly higher than that of the commercial MRI contrast agent ([Gd]-DTPA). Both compounds bind to bovine serum albumin and human serum transferrin. In Sprague-Dawley rats, the agents display favorable liver-specific contrast enhancement when evaluated by MRI methodologies. Imaging studies demonstrate that both agents have a long residence time, showing MR signal enhancement in the liver for more than 40 minutes, which is longer than many commercially available contrast agents. Results from *in vivo* and *in vitro* assays reveal that GdW_{10} and $Gd(PW_{11})_2$ are promising liver-specific MRI contrast agents and GdW_{10} may be used in the diagnosis of pathological states. However, with the higher acute toxicity, the 2 gadolinium polyoxometalates need to be modified and studied further before clinical use.

An evaluation of gadolinium polyoxometalates as possible MRI contrast agent. Feng J, Li X, Pei F, Sun G, Zhang X, Liu M. Magn Reson Imaging 2002 Jun; 20 (5), pp. 407–12.

Hepatic Macrophages/Mononuclear Phagocytic System Activity
Superparamagnetic Iron Oxide (AMI-25)/[^{99m}Tc]-Phytate

Cellular/Molecular Mechanism of Action: Superparamagnetic iron oxide (AMI-25) is non-selectively assimilated intracellularly by the hepatic mononuclear phagocytic system.

Application: Assessment of hepatic phagocytic activity with potential applications for also evaluating the pulmonary phagocytic system.

Route of Administration: Intravascular.

Implementation: Evaluation of the potential for measuring hepatic phagocytic activity by dynamic superparamagnetic iron oxide-enhanced MRI. One approach that can be utilized for achieving this objective includes the application of dynamic MRI analysis in concert with performing a radioisotope study with [^{99m}Tc]-phytate. In a dynamic MR study of this nature, the ratio (Rv) of the distribution volumes of iron oxide (Vm/Ve) can be obtained by applying a 3-compartment model to data obtained simultaneously from the kidney and liver. Changes in Rv caused by silica injection and by dosing superparamagnetic iron oxide, AMI-25, can subsequently be evaluated. In the dynamic MR study using an *in vivo* model the input function can be calculated from data obtained from the hepatic artery and portal vein.

Animal Model: Rabbits (New Zealand White) randomly allocated to normal and silica-treated groups.

Animal Model: Beagle dog (hepatic artery and portal vein).

Interpretation and Analysis: The ratio of the distribution volumes for iron oxide (Vm/Ve) reaches a maximum value at around 80 minutes after AMI-25 injection. The Rv of the normal controls groups is approximately 5.06 ± 1.53, whereas the Rv of the silica-treated group is approximately 2.13 ± 1.20. The results are similar to tissue count data obtained in radioisotope study. The Rv value is not dependent on the injected dose of AMI-25. The rate of transport constants (k1, k2, k3) cannot be estimated with a 3-compartment model regardless of obtaining the input function. It has therefore been concluded that the ratio of the distribution volumes for iron oxide (Vm/Ve) may be a quantitative index reflecting decreases in phagocytic activity within the liver as determined by dynamic superparamagnetic iron oxide–enhanced MRI.

Pharmacokinetic modeling of phagocytic activity of the liver using superparamagnetic iron oxide nanoparticles in dynamic MR imaging. Na JB, Suh JS, Huh YM, Kim SJ, Kim SH, Cha SH, Lee SH. Yonsei Med J 2003 Jun 30; 44 (3), pp. 429–37.

Hepatic Necrosis/Reperfusion Infarct
Gadophrin-2/MP-2229

Cellular/Molecular Mechanism of Action: The mechanisms of action leading to specific localization of necrosis-avid contrast agents (NACAs) such as gadophrin-2 are not well defined. It has been suggested recently that agents with a high degree of serum albumin binding may also serve as NACAs by virtue of non-specific hydrophobic interactions. Both MP-2269 and gadophrin-2 possess albumin-binding avidities and MP-2269 can function as a blood-pool agent.

Application: Gadophrin can be applied to detect and characterize regions of infarction, including artificially-induced reperfused hepatic infarcts that can be recognized by MRI analysis. The agent MP-2269 can function as an albumin-binding blood-pool agent.

Route of Administration: MP-2269 (intravenous); gadophrin-2 (intravenous).

Dosage: MP-2269 (0.05 mmol/kg); gadophrin-2 (0.05 mmol/kg).

Implementation: Evaluation of hepatic reperfusion infarcts with serial T_1-weighted MRI performed before and after administration of MP-2269. The imaging procedure is repeated again 24 hours after intravenous injection of gadophrin-2 at the same dosage (0.05 mmol/kg). Individual MR images are matched with corresponding histomorphological findings. The signal intensity and contrast ratio

of infarcted and normal hepatic lobes are quantified and compared between the 2 agents during the postcontrast phase.

Animal Model: Surgical induction of reperfused infarcts in the right liver lobe of rats (e.g., n = 6).

Interpretation and Analysis: Before contrast, the infarcted lobe is indiscernible from normal liver on T_1-weighted MRI. Shortly after injection of both MP-2269 and gadophrin-2, a negative contrast pattern develops between infarcted and normal liver because of a strong liver signal intensity enhancement and an inferior uptake within necrotic liver tissues. During delayed phase analysis (> 60 minutes), a necrosis-specific contrast enhancement (contrast ratio 1.6) develops with gadophrin-2 but not with MP-2269. The MR images closely correspond with histomorphological findings. Although both MP-2269 and gadophrin-2 possess binding avidity for serum albumin fractions, only gadophrin-2 displays a persistent necrosis-specific contrast enhancement in the rat model of reperfused liver infarction. The role of albumin binding in the mechanisms of NACAs should be reevaluated.

MRI contrast enhancement of necrosis by MP-2269 and gadophrin-2 in a rat model of liver infarction. Ni Y, Adzamli K, Miao Y, Cresens E, Yu J, Periasamy MP, Adams MD, Marchal G. Invest Radiol 2001 Feb; 36 (2), pp. 97–103.

Hepatic Neoplasia

Contrast-Enhancing Agents: [Mn]-DPDP and Ferumoxides/Reticuloendothelial System–Specific Agents: Iron Oxide Particulates/Combined Perfusion/Hepatocyte-Selective: Gadolinium ([Gd])-BOPTA and [Gd]-EOB-DTPA/Computed Tomography during Arterial Portography (CTAP)

Background Information: Optimal detection of focal hepatic lesions in patients with metastases can alter patient management and result in significant cost savings by reducing the number of unnecessary laparotomies for unresectable disease. Comparisons of reticuloendothelial agents and hepatobiliary agents for imaging liver metastases are lacking in the literature. Further studies comparing MRI enhanced with liver-specific contrast agents to CTAP are needed to determine if hepatic MRI can replace CTAP for the preoperative evaluation of hepatic metastases.

Considerations: Most clinical experience is with non-specific extracellular gadolinium chelates. The relatively low cost, safety, good patient tolerance, and ability to help detect and characterize a wide range of liver diseases have greatly contributed to the common use of gadolinium chelates as image-enhancing agents.

Application: A wide variety of MRI agents can be applied for the detection and characterization of hepatic lesions in conditions of hepatic metastatic disease. Examples include contrast agents (ferumoxides & [Mn]-DPDP); non-specific extracellular fluid image contrast agents (gadolinium chelates), reticuloendothelial agents, CTAP, and hepatocellular agents ([Gd]-BOPTA, [Gd]-EOB-DTPA, [Gd]-DTPA).

Route of Administration: Essentially all of the diagnostic image-enhancing agents applied in the detection and characterization of hepatic metastatic disease are delivered by intravascular injection.

Interpretation and Analysis: Liver-specific MRI contrast agents (reticuloendothelial and hepatobiliary agents) offer greater lesion-to-liver contrast on T_2-weighted MR images than the conventional extracellular fluid space MRI contrast agents (gadolinium chelates), which have a non-specific distribution. In effect, this increases the conspicuity of focal hepatic lesions with negligible reticuloendothelial cells (e.g., metastases). Hepatocyte-selective agents increase the signal intensity of background liver on T_1-weighted images, which increases the conspicuity of focal lesions that do not contain hepatocytes (e.g., metastases). For the detection of hepatic metastases, although the work of Seneterre et al suggests that the accuracy of ferumoxide-enhanced MRI is equivalent to that of CTAP, other studies have found CTAP to be superior. For the characterization of focal liver lesions, [Mn]-DPDP and ferumoxides have been added to the small list of FDA-approved contrast agents, and both can help to increase diagnostic specificity. Two of the hepatobiliary agents that are not yet approved, [Gd]-BOPTA and [Gd]-EOB-DTPA, have the potential of characterizing liver lesions during dynamic contrast enhancement (similar to [Gd]-DTPA) and during the hepatocyte phase (similar to [Mn]-DPDP), and may increase the detection of focal liver lesions.

Hepatic Neoplasia/Differentiation Neoplasia vs Parenchyma/Hepatic Lesions and Central Nervous System (CNS) Neoplasia

Gadobenate Dimeglumine ([Gd]-BOPTA)/[Gd]-DTPA

Cellular/Molecular Mechanism of Action: The dimeglumine component of the paramagnetic contrast agent [Gd]-BOPTA is partially eliminated by biliary excretion.

Background Information: After the advent of extracellular contrast media, hepatobiliary-specific gadolinium chelates were developed to improve the diagnostic value of MRI of the liver.

Application: Gadobenate dimeglumine can be used as a contrast image-enhancing agent for improved visualization of the liver and CNS (e.g., brain). In this latter capacity, [Gd]-BOPTA can aid in the detection and characterization of neoplastic lesions affecting the CNS.

Route of Administration: Gadobenate dimeglumine is administered by intravascular injection.

Implementation: Gadobenate dimeglumine through partial biliary excretion can produce prolonged visual enhancement of liver parenchyma on T_1-weighted images.

Interpretation and Analysis: [Gd]-BOPTA shows better MRI enhancement in brain tumors than can be provided by [Gd]-DTPA at every time course up until 2 hours after administration, and no enhancement in peritumoral tissue and normal brain. Conversely, inductively coupled plasma atomic emission spectroscopy (ICP-AES) demonstrates significantly greater uptake of [Gd]-BOPTA in tumor samples than that in peritumoral tissue and normal brain 5 minutes following administration. Gadolinium is retained for a longer period of time within brain tumors when [Gd]-BOPTA rather than [Gd]-DTPA is administered. [Gd]-BOPTA is a useful contrast agent for MRI in brain tumors and possibly an effective absorption agent for neutron capture therapy.

Comparison of gadobenate dimeglumine and gadopentetate dimeglumine: A study of MR imaging and inductively coupled plasma atomic emission spectroscopy in rat brain tumors. Zhang T, Matsumura A, Yamamoto T, Yoshida F, Nose T, Shimojo N. AJNR Am J Neuroradiol 2002 Jan; 23 (1), pp. 15–8.

Hepatic Neoplasia/Hepatocellular Carcinoma/Hepatocellular Adenoma/Focal Nodular Hyperplasia/Hepatic Metastases/Mass Differentiation

Superparamagnetic Iron Oxide Particles (SPIOs)/Ultrasmall Superparamagnetic Iron Oxide Particles (USPIOs)

Application: Limited detection and characterization of hepatic metastases, hepatocellular carcinoma, hepatocellular adenoma, and focal nodular hyperplasia.

Route of Administration: Superparamagnetic iron oxide particles and USPIOs given intravenously.

Implementation: Evaluation of cases with focal hepatic disease utilizing (i) SPIO (e.g., n = 53); and (ii) USPIO (e.g., n = 27) superparamagnetic iron oxide particles in combination with spin-echo T_1- and T_2-weighted imaging (T_1WI, T_2WI) obtained at 1.0 Tesla, before and after intravenous contrast agent administration. The percentage of signal-to-noise ratio (SNR) change and lesion-to-liver contrast (LLC) are then measured and statistically compared.

Human Model: Cases of focal liver disease (e.g., metastases, hepatocellular carcinoma [HCC]; hepatocellular adenoma [HCA]; focal nodular hyperplasia [FNH]).

Interpretation and Analysis: Changes in liver signal intensity (SI) on T_1WI are approximately −28% and +16% following SPIO and USPIO infusion, respectively. On T_2WI, liver decreases in SI on postcontrast images with both agents (−78% SPIO, −73% USPIO), and the difference is not statistically significant ($p \leq 0.07$). Both SPIO and USPIO provide > 500% improvement in LLC on T_2WI. On T_1WI, LLC increases with metastases (120%) and HCC (325%) with SPIO. Post-USPIO, LLC is increased on T_1WI only in metastases (> 500%). Both SPIO and USPIO show excellent hepatic uptake that is presumed to be secondary to reticuloendothelial activity, based on the degree of percent change in SI appreciated in the liver after administration of contrast agent on T_2WI. However, USPIO preparations exhibit blood-pool activity that may aid in further characterization of focal liver lesions, as is evidenced by their greater T_1 effect in the liver and in some focal liver lesions.

MRI in focal liver disease: A comparison of small and ultrasmall superparamagnetic iron oxide as hepatic contrast agents. Mergo PJ, Engelken JD, Helmberger T, Ros PR. J Magn Reson Imaging 1998 Sep–Oct;8 (5), pp. 1073–8.

Hepatic Neoplasia/Metastatic
Carboxydextran Iron-Oxide Nanoparticles (SHU-555A/ Resovist)/Eovist (Gadolinium [Gd]-EOB-DTPA)

Cellular/Molecular Mechanism of Action: Intracellularly internalized by mechanisms of phagocytosis by macrophages (e.g., Kupffer cells) that comprise the hepatic reticuloendothelial system (RES or mononuclear phagocytic system).

Background Information: Injections of Eovist ([Gd]-EOB-DTPA) are selectively taken up by hepatocytes, which increase the signal intensity of normal liver parenchyma on T_1-weighted images. Relative lesion-to-liver contrast is thereby improved because malignant tumors either do not contain hepatocytes or their function has become significantly modified.

Application: Detection and characterization of hepatic neoplastic metastases.

Route of Administration: Intended for intravascular injection.

Dosage: Clinical trials have evaluated the safety and efficacy of Eovist injected at doses up to 100 mmol/kg body weight. Resovist Injection (SHU-555A) contains iron-oxide nanoparticles coated with carboxydextran, which is administered as an intravenous bolus injected as a fixed-volume dose that is dependent on body weight.

Considerations: Following intravenous bolus injection, Eovist is eliminated by both the renal and biliary routes of excretion.

Interpretation and Analysis: The uptake of injected Resovist by RES cells results in a decrease of signal intensity in normal liver parenchyma on both T_2- and T_1-weighted images. Due to the altered phagocytic distribution and activity, the signal intensity in most metastatic tumors is not affected, resulting in improved lesion-to-liver contrast. Both Resovist and Eovist exhibit acceptable safety profiles in clinical trials and have the potential to provide additional information regarding lesion detection, classification, and characterization.

Eovist Injection and Resovist Injection: Two new liver-specific contrast agents for MRI. Mintorovitch J, Shamsi K. Oncology (Huntingt) 2000 Jun; 14 (6 Suppl 3), pp. 37–40.

Hepatic Radiation-Induced Injury/Diminished Hepatic Imaging Secondary to Radiation Therapy
Ferumoxide

Cellular/Molecular Mechanism of Action: Ferumoxide particulate matter within the intravascular compartment is perceived as "foreign" by the reticuloendothelial (mononuclear phagocytic) system and is subsequently phagocytized by cell populations lining the hepatic sinousoids.

Application: Particulate reticuloendothelial MR contrast agents can be utilized to image the liver.

Route of Administration: Ferumoxide particulate reticuloendothelial MR contrast agent (intravenous).

Implementation: Hepatic imaging with a particulate ferumoxide preparation.

Human Model: Radiation therapy–induced hepatic injury (e.g., management of metastatic colon carcinoma).

Interpretation and Analysis: Radiation-induced liver injury can be detected utilizing a particulate reticuloendothelial MR contrast agent. In a relevant example, cases with systemic forms of neoplasia that have been managed with radiation therapy (e.g., metastatic colon carcer) are subject to secondary radiation damage to hepatic parenchyma. The image pattern visualized with ferumoxide preparations applied in combination with MRI fails to produce a darkened image following contrast agent administration. Such findings suggest that detection of metastatic disease after ferumoxide contrast agents may be impaired in patients who have previously received upper abdominal radiation therapy.

Radiation-induced liver injury detected by particulate reticuloendothelial contrast agent. Padhani AR, Husband JE, Gueret Wardle D. Br J Radiol 1998 Oct; 71 (850), pp. 1089–92.

Hepatic Radiation-Induced Injury/Relative Sensitivity
Superparamagnetic Reticuloendothelial System (RES)-Directed Agents/Polycrystalline Iron Oxide Nanocompounds (PION)/Carboxydextran-Coated Maghemite (DDM128N/389 or DDM128)

Route of Administration: Particle-sized superparamagnetic RES-directed agents (i) PION (31 nm) and (ii) DDM128N/389 or DDM128 (59 nm) are delivered by intravenous injection.

Implementation: Compare liver contrast-enhancing characteristics of the 2 particle-sized superparamagnetic RES-directed agents (i) PION and (ii) DDM128N/389 or DDM128 in conditions of hepatic dysfunction. T_2-weighted spin-echo MRI is performed 3 days after x-irradiation at 30 minutes postcontrast.

Animal Model: Experimental protocol for focal radiation-induced hepatitis involves the delivery of a single x-irradiation exposure varying from 10 to 60 Gy on 1 side of the liver.

Interpretation and Analysis: Using the RES-directed PION, the normal, non-irradiated portions of the liver have decreases in signal intensity with a maximum negative enhancement of −66%, while the irradiated portions of liver display decreases in signal intensity of approximately −24% (60 Gy). Signal intensity declines in irradiated liver tissue using PION are dose dependent but can be appreciated at all radiation dose levels (10–60 Gy). The difference in

signal intensity between irradiated (−63%) and non-irradiated (−82%) portions is also statistically different using DDM128 at 60 Gy. However, lower irradiation doses (10 and 30 Gy) fail to produce a statistically significant difference in the enhancement of irradiated and non-irradiated portions of the liver. Sensitivity of liver enhancement with RES-directed agents is size dependent. The smaller particle (PION) is more sensitive for detecting radiation-induced hepatitis compared to larger particle contrast agents (DDM128). The relative insensitivity of DDM128 enhancement for diffuse liver injury is more clinically advantageous for detecting focal lesions in the presence of diffuse hepatic injury.

Contrast-enhanced MR imaging of 2 superparamagnetic RES-contrast agents: Functional assessment of experimental radiation-induced liver injury. Stiskal M, Demsar F, Muhler A, Schwickert HC, Roberts TP, Szolar D, Fischer H, Brasch RC. J Magn Reson Imaging 1999 Jul; 10 (1), pp. 52–6.

MRI of Hepatic Structures
Gadolinium

Following the introduction of rapid, high-quality scan techniques and the development of new, tissue-specific contrast agents, the applications of MRI for liver imaging continue to grow. Magnetic resonance imaging using a T_1-weighted sequence, T_2-weighted sequence, and serial gadolinium-enhanced gradient echo sequences is very effective at both detecting and characterizing various hepatic lesions. The use of a growing number of contrast agents has the potential to increase the sensitivity and specificity of liver MRI in numerous pathological conditions by improving morphological and functional information. Review of the current status of liver MRI, highlighting technical and methodological approaches, contrast agents, and main clinical applications, reveals that MRI appears to be an ideal diagnostic tool for the detection and characterization of liver disease.

MRI evaluation of the liver. Beavers KL, Semelka RC. Semin Liver Dis 2001 May; 21 (2), pp. 161–77.

ISCHEMIA AND INFARCTION

Necrosis of Tissue/Reperfusion Infarct
Gadophrin-2/MP-2269

Cellular/Molecular Mechanism of Action: The mechanisms of action leading to specific localization of necrosis-avid contrast agents (NACAs) such as gadophrin-2 are not well defined. It has been suggested recently that agents with a high degree of serum albumin binding may also serve as NACAs by virtue of non-specific hydrophobic interactions. Both MP-2269 and gadophrin-2 possess albumin-binding avidities and MP-2269 can function as a blood-pool agent.
Application: Gadophrin can be applied to detect and characterize regions of infarction, including artificially-induced reperfused hepatic infarcts that can be recognized by MRI analysis. The agent MP-2269 can function as an albumin-binding blood-pool agent.
Route of Administration: MP-2269 (intravenous); gadophrin-2 (intravenous).
Dosage: MP-2269 (0.05 mmol/kg); gadophrin-2 (0.05 mmol/kg).
Implementation: Evaluation of hepatic reperfusion infarcts with serial T_1-weighted MRI performed before and after administration of MP-2269. The imaging procedure is repeated again 24 hours after intravenous injection of gadophrin-2 at the same dosage (0.05 mmol/kg). Individual MR images are compared with corresponding histomorphological findings. The signal intensity and contrast ratio of infarcted and normal hepatic lobes are quantified and compared between the 2 agents during the postcontrast phase.

Animal Model: Surgical induction of reperfused infarcts in the right liver lobe of rats (e.g., n = 6).
Interpretation and Analysis: Before contrast, the infarcted lobe is indiscernible from normal liver on T_1-weighted MRI. Shortly after injection of both MP-2269 and gadophrin-2, a negative contrast pattern develops between infarcted and normal liver because of a strong liver signal intensity enhancement and an inferior uptake within necrotic liver tissues. During delayed phase analysis (> 60 minutes), a necrosis-specific contrast enhancement (contrast ratio 1.6) develops with gadophrin-2 but not with MP-2269. The MR images closely correspond with histomorphological findings. Although both MP-2269 and gadophrin-2 possess binding avidity for serum albumin fractions, only gadophrin-2 displays a persistent necrosis-specific contrast enhancement in the rat model of reperfused liver infarction. Therefore, the role of albumin binding in the mechanisms of NACAs should be reevaluated.

Oxygen Tension Indicator
Hemoglobin (Hb)

Cellular/Molecular Mechanism of Action: Iron ions contained within Hb fractions bind molecular oxygen.
Application: Exogenous molecular Hb is an effective indicator of relative local oxygen tension in MR microscopy studies performed *in vivo*.
Implementation: Injection of Hb to delineate its ability to permeate through relatively dense neural tissues.

Experimental Model: Insects (flies).
Interpretation and Analysis: Exogenous molecular Hb is more sensitive than other MRI oximetry methods, and therefore can be used at higher resolutions and in specimens with no blood oxygen level–dependent (BOLD) effects.

Hemoglobin is able to permeate through relatively dense neural tissue but does not detectably disrupt normal neurophysiology. Large changes in signal intensity (40–50%) occur when external O_2 levels can be manipulated artificially from 0% to 21% with Hb injections. Oxygen-dependent contrast changes produced by exogenous Hb can be detected by T_2-weighted imaging analysis and can be roughly calibrated if necessary. Therefore, it may be feasible to apply Hb as a contrast agent that may be useful in functional MRI (fMRI) studies for detecting alterations in metabolism at minute resolution levels (e.g., tens of microns).

In vivo oxygen detection using exogenous hemoglobin as a contrast agent in magnetic resonance microscopy. Sun PZ, Schoening ZB, Jasanoff A. Magn Reson Med 2003 Apr; 49 (4), pp. 609–14.

MUSCULOSKELETAL SYSTEM

Arthrography: MR/Contrast Media Compatibility/ Intra-Arterial Placement Confirmation
Gadopentetate Dimeglumine/Methyl Thymol Blue Indicator

Application: Confirmation of the intra-arterial placement of contrast material before performing MR arthrography.

Implementation: Analysis of mixtures of non-ionic and ionic iodinated contrast agent, gadopentetate dimeglumine, lidocaine, and epinephrine using spectrophotometric titration with a gadolinium ion titrant and methyl thymol blue indicator.

Interpretation and Analysis: No significant dissociation of gadolinium ion occurs when gadopentetate dimeglumine is mixed with iodinated contrast agents, lidocaine, or epinephrine over a range of dilutions. Therefore, gadopentetate dimeglumine and iodinated contrast material can be mixed before MRI without any release of free gadolinium and are safe for confirming the intra-articular placement of contrast material before MR arthrography.

Is a mixture of gadolinium and iodinated contrast material safe during MR arthrography? Brown RR, Clarke DW, Daffner RH. AJR Am J Roentgenol 2000 Oct; 175 (4), pp. 1087–90.

Cartilage Integrity/Injury Detection
Gadolinium ([Gd]-DTPA)

Cellular/Molecular Mechanism of Action: Gadolinium possesses radiopaque properties.

Application: Detection of alteration in the molecular integrity of the matix structure/composition of cartilaginous tissue through the identification of changes in magnetized transfer utilizing MRI modalities.

Implementation: Measurement of magnetic transfer (MT) and T_1 and T_2 relaxation of normal, trypsinized, and interleukin-1beta (IL-1β)-treated cartilage in the absence and presence of [Gd]-DTPA.

Interpretation and Analysis: Without the addition of [Gd]-DTPA, neither T_1 nor T_2 detect any significant change with cartilage damage. However, in the presence of [Gd]-DTPA, trypsinized cartilage exhibits substantially shorter T_1 than normal cartilage, as expected due to the glycosaminoglycan (GAG) loss in these samples and associated increases in [Gd]-DTPA concentration. The T_2 results are similar but less dramatic. The MT pseudo 1st-order exchange rate, RM(0B), does not depend on the contrast agent concentration, as expected, and is significantly faster for trypsinized and slower for IL-1β-treated cartilage. In both cases, the MT fraction of the macromolecular pool M(0B) decreases, while only trypsinized cartilage shows an increase in MT exchange rate [R]. The MT ratio (MTR) decreases with increasing [Gd]-DTPA concentration. However, interpretation of the MTR results in the presence of [Gd]-DTPA is complicated due to competing effects of increased longitudinal relaxivity and MT exchange. Therefore, in a cartilage sample with an unknown degree of GAG depletion and some collagen damage, a full MT analysis might be used to probe the molecular state or character of cartilage, but it is not possible to use a simple MTR measurement after the administration of [Gd]-DTPA to differentially determine the amount of cartilage degradation in the sample.

Can MTR be used to assess cartilage in the presence of [Gd]-DTPA 2? Henkelman RM, Stanisz GJ, Menezes N, Burstein D. Magn Reson Med 2002 Dec; 48 (6), pp. 1081–4.

Cartilage Integrity/Glycosaminoglycans (GAGs)/ Cartilage Degradation: Trypsin- and Interleukin-1-Induced Injury
Gadolinium-DTPA^{-2} ([Gd]-DTPA^{-2})

Background Information: Glycosaminoglycans are the main source of tissue fixed charge density (FCD) in cartilage and are lost early in arthritic diseases.

Application: Detect and characterize cartilage degradation.

Implementation: Evaluate the hypothesis that, like Na^+, the charged contrast agent [Gd]-DTPA^{-2} (and hence proton T_1) can be used to measure tissue FCD and hence GAG concentration.

Interpretation and Analysis: Nuclear MR spectroscopy studies of cartilage explants demonstrate that there is a strong correlation ($r > 0.96$) between proton T_1 in the presence of [Gd]-DTPA^{-2} and tissue sodium and GAG concentrations. An ideal 1-compartment electrochemical (Donnan) equilibrium model can be utilized as a means of quantifying FCD from [Gd]-DTPA^{-2} concentration. This approach yields a value 50% less but linearly correlated with the validated method of quantifying FCD from Na^+ ion and can be used as the basis of an empirical model with which to quantify FCD from [Gd]-DTPA^{-2} concentration, or a more sophisticated physical model could be developed. Spatial distributions of FCD can be easily observed in T_1-weighted MRI studies of trypsin- and interleukin-1-induced cartilage degradation, with good histological correlation. Therefore, equilibration of the tissue with [Gd]-DTPA^{-2} gives the opportunity to directly image (through T_1 weighting) the concentration of GAG, a major and critically important macromolecule in cartilage. Pilot clinical studies demonstrate penetration of [Gd]-DTPA^{-2} into cartilage, suggesting that this technique is clinically feasible.

[Gd]-DTPA^{-2} as a measure of cartilage degradation. Bashir A, Gray ML, Burstein D. Magn Reson Med 1996 Nov; 36 (5), pp. 665–73.

Cartilage Integrity/Proteoglycan (PG) Depletion: Detection and Characterization/Papain-Induced Cartilage Injury
Gadolinium-DTPA^{-2} ([Gd]-DTPA^{-2})

Background Information: Loss of PGs from the extracellular matrix of cartilage is an early event that occurs in the initial stages of osteoarthritis.

Application: Detection and characterization of cartilage degradation relevant to degenerative joint disease (DJD).

Implementation: Evaluate the capability of [Gd]-DTPA^{-2}-enhanced MRI to quantitatively assess PG content in a model of cartilage degeneration. One approach to assessment of cartilage PG content can entail the application of [Gd]-DTPA^{-2} as an MRI contrast image-enhancing agent. A series of knee flexions are performed post-[Gd]-DTPA^{-2} injection to facilitate penetration of the contrast agent into cartilage structures.

Animal Model: Goat knee (stifle joint) preparations. Partial to total PG depletion induced by an intra-articular injection of papain 1 day prior to MRI sessions (cartilage degeneration model).

Interpretation and Analysis: A close correlation can be found between the extent of PG loss and [Gd]-DTPA^{-2}-induced T_1 decreases. Papain-induced PG depletion can be confirmed by postmortem histological and biochemical assessments. A 2-hour delay following [Gd]-DTPA^{-2} injection results in optimal accuracy in quantitating cartilage defects. However, DeltaT_1s observed in cartilage of exercised goat knees are not affected by papain or interleukin-1beta pretreatment. Therefore, as long as a preinjection T_1 map is obtained, the [Gd]-DTPA^{-2}-enhanced MRI technique provides good sensitivity in detecting partial loss of PGs from within articular cartilage. Such a pattern appears to be true only when the animal is maintained in a resting state during diffusion of the [Gd]-DTPA^{-2}. This approach is of particular interest for long-term evaluations of cartilage degeneration and regeneration.

In vivo assessment of macromolecular content in articular cartilage of the goat knee. Laurent D, Wasvary J, Rudin M, O'Byrne E, Pellas T. Magn Reson Med 2003 Jun; 49 (6), pp. 1037–46.

Discography: Intervertebral Disc Pathology/MRI: Alternative to Computed Tomography (CT) Discography
Gadolinium

Background Information: Magnetic resonance arthrography with gadolinium has been used to evaluate shoulder, elbow, wrist, hip, knee, and other joints. Gadolinium has not been extensively used as an intradiscal contrast agent. Preliminary results using gadolinium as an intradiscal contrast agent for MR discography have been encouraging.

Application: Gadolinium can be used to perform MR discography to detect and characterize intervertebral disc pathology. Furthermore, MR discography with gadolinium can be recommended for patients allergic to iodinated contrast agents and for individuals who wish to limit the level of radiation exposure normally experienced with CT discography procedures.

Implementation: Evaluation of intervertebral disc disease utilizing water-soluble iodinated contrast and gadopentetate dimeglumine injected at each intravertebral disc level. Following discography, anteroposterior and lateral radiographs, CT scans, and T_1-weighted MRI are performed. Interscan and interobserver interpretation variability is determined for MR discography and CT discography using the Pearson correlation-coefficient r test.

Human Model: Cases with suspected intervertebral disc disease (n = 13; n = 42 disc spaces).

Interpretation and Analysis: Interscan variability is highly correlated between CT discography and MR discography when used to determine disc normality (r = 0.87), general degeneration (r = 0.87), anular fissure (r = 0.89), disc herniation (r = 0.92), and contrast leakage (r = 0.77). Interscan variability can be assessed by the Pearson test, which usually reveals that all "r" values for all examiners noted to be statistically significant at p values = 0.01 or less. Interobserver variability significantly correlates with professional specialization and level of diagnostic experience. Interobserver variability also significantly correlates with CT and MRI discography for disc normality (CT r = 0.60; MRI r = 0.56), general degeneration (CT r = 0.76; MRI r = 0.71), anular fissure (CT r = 0.79; MRI r = 0.84), and disc herniation (CT r = 0.63; MRI r = 0.64). The readings for contrast leakage do not reach statistical significance for CT or MR discography. The high interscan and interobserver correlation rates obtained for MR discography using gadolinium, as compared with the standard CT discography technique, indicate that MR discography may be an acceptable substitute for the imaging of disc pathology. Magnetic resonance discography with gadolinium may be recommended for patients allergic to iodinated contrast agents and for patients who wish to limit their radiation exposure.

Gadopentetate dimeglumine as an intradiscal contrast agent. Huang TS, Zucherman JF, Hsu KY, Shapiro M, Lentz D, Gartland J. Spine 2002 Apr 15; 27 (8), pp. 839–43.

Osteoarthritis/Detection of Mechanical and Enzyme-Induced Lesions
Manganese Chloride Liposomes/ Gadolinium-DTPA ([Gd]-DTPA) Liposomes

Cellular/Molecular Mechanism of Action: Gadolinium and manganese are elements that possess paramagnetic properties.

Application: After intra-articular application of [Gd]-DTPA the visualization cartilage surface roughness is limited because of diffusion into the cartilage. Liposome-entrapped contrast agents can be employed to improve the sensitivity of MR arthrography for the diagnostic detection of cartilage surface abnormalities.

Route of Administration: [Gd]-DTPA, [Gd]-DTPA-liposomes, manganese chloride, and manganese chloride liposomes are all administered intra-articularly.

Implementation: Evaluation of joint structures applying the paramagnetic contrast agents [Gd]-DTPA and manganese chloride in either a free form or entrapped within liposomes utilizing high resolution MRI (7.1 Tesla).

Animal Model: Swine temporomandibular joint and rabbit knee joint.

Interpretation and Analysis: After intra-articular injection of liposome-entrapped contrast agents an excellent contrast between cartilage surface and joint space can be achieved. Diffusion of the contrast agent into the cartilage layer is prevented, and visualization of cartilage surfaces is markedly improved. Small mechanically and enzymatically induced cartilage lesions can be assessed reliably. Intra-articular injection of liposome-entrapped contrast agents can improve the potential of MR arthrography for the detection of early osteoarthritic cartilage changes.

Instrumentation: Magnetic resonance imaging instrumentation (7.1 tesla).

Improved nuclear magnetic resonance microscopic visualization of joint cartilage using liposome entrapped contrast agents. Gründer W, Biesold M, Wagner M, Werner A. Invest Radiol 1998 Apr; 33 (4), pp. 193–202.

Rheumatoid Arthritis (RA)/Bone Erosion Detection/ Synovial Hypertrophy/Synovitis
Contrast Image-Enhancing Agent

Application: Detection and characterization of RA conditions.

Route of Administration: Magnetic resonance contrast image enhancement agent (intravenous).

Implementation: Evaluate affected joints analyzed by radiography (1D) and MRI with the later modality performed before and after the administration of a contrast image-enhancing agent. Image examinations are performed on the 2nd–5th metacarpophalangeal (MCP) joints and wrist. The number of erosions on radiographic examination and MRI are then calculated, and synovitis in the MCP joints and wrists graded semiquantitatively.

Human Model: Cases of RA joint pathology of $\leq$ 1 year duration (e.g., n = 25 and untreated) involving the MCP joints and wrist.

Interpretation and Analysis: Extremity MRI (E-MRI) can detect substantially more bone erosion lesions than conventional radiographic examination (e.g., n = 57 vs 6, respectively; 9.5 to 1 ratio). Synovial hypertrophy grades are significantly higher in RA joints with clinical signs of joint inflammation, including swelling and/or tenderness (median 3, 5th–95th centile 1–4) than without these clinical signs (median 2, 5th–95th centile 1–3), $p < 0.001$. Fifty-one percent of the joints without clinical signs of synovitis show synovial hypertrophy on E-MRI. There is a positive correlation between MRI scores of synovitis and the number of erosions detected by MRI in MCP joints (Spearman $r_s = 0.31$, $p < 0.01$). Healthy controls have no evidence of erosions or synovitis based on MRI interpretations. Joint destruction starts very early in RA and E-MRI allows detailed evaluation of inflammatory and destructive changes in wrists and MCP joints in patients with incipient RA.

Low field dedicated magnetic resonance imaging in untreated rheumatoid arthritis of recent onset. Lindegaard H, Vallø J, Hørslev-Petersen K, Junker P, Östergaard M. Ann Rheum Dis 2001 Aug; 60 (8), pp. 770–6.

Rheumatoid Arthritis (RA)/Synovitis/Joint Effusion/ Fibrovascular Connective Tissue Proliferation/ Pannus Formation

Magnetic resonance imaging is the modality of choice in early diagnosis and management of RA. The pathologic processes in RA involve synovitis, joint effusion, proliferation of fibrovascular connective tissue, and the formation of pannus. Other imaging techniques available for imaging of RA include ultrasound, scintigraphy, computed tomography, and plain radiography (PR). Magnetic resonance imaging provides a high level of sensitivity in detecting inflammatory changes in joint structures. Several studies have reported high intra- and interobserver reliability and low variation for MRI. Magnetic resonance imaging allows detection and, in some cases, quantification of synovial changes. Dynamic MRI is a new technique that utilizes rate of synovial enhancement in evaluation of inflammatory changes. Magnetic resonance imaging allows visualization of erosions in 3 orthogonal planes. It has been shown in many studies to have much greater sensitivity than PR in detecting erosions. Use of a contrast agent further increases the sensitivity in detecting erosions and differentiates and outlines synovial proliferation from fluid collection. Other manifestations of RA such as intraosseous cysts, tenosynovitis, bone marrow edema, and carpal tunnel syndrome can also be visualized on MRI. Advances in MRI include contrast-enhancement, dynamic, and quantitative techniques. Magnetic resonance imaging assists in the early detection of RA, which allows earlier initiation of treatment with disease-modifying therapies.

Magnetic resonance imaging in early detection of rheumatoid arthritis. Tehranzadeh J, Ashikyan O, Dascalos J. Semin Musculoskelet Radiol 2003 Jun; 7 (2), pp. 79–94.

NEOPLASIA

Mammary Carcinoma
Ultrasmall Superparamagnetic Particles of Iron Oxide (USPIO) Enhancement

Application: Ultrasmall superparamagnetic iron oxide–enhanced MRI has the potential to become an adjunct to conventional MRI of the breast for preoperative assessment of axillary lymph nodes in patients with breast cancer.
Implementation: Magnetic resonance imaging of mammary carcinoma lesions within 24 to 36 hours after the start of intravenous slow-drip infusion of USPIO followed by gadolinium-enhanced MRI (1.5 Tesla system). Lymph nodes are staged prospectively by using established criteria, and results are correlated with histologic findings (standard reference control) for comparison with MRI findings.
Human Model: Mammary carcinoma cases (e.g., n = 18).
Interpretation and Analysis: Axillary staging with USPIO-enhanced MRI produces true-positive results in about 50% of cases (e.g., n = 9/18). Approximately 39%, 0%, and 11% of cases are categorized as true-negatives; false-positives; or false-negatives, respectively (sensitivity, 82%; specificity, 100%; positive predictive value, 100%; 2nd reader, = 1.0). Magnetic resonance imaging analysis is capable of detecting a large number of lymph nodes (e.g., n = 405). Lymph node–based sensitivity can vary between 83% and 73% and specificity between 96% and 97% depending on the evaluator (κ = 0.68). Ultrasmall superparamagnetic particles of iron oxide as an intravascular contrast agent cannot replace gadolinium for assessment of the primary tumor; however, no clinically relevant interaction can be appreciated. Thus, an integrated imaging approach is feasible in all patients.

Preoperative breast cancer staging: MR imaging of the axilla with ultrasmall superparamagnetic iron oxide enhancement. Michel SC, Keller TM, Frohlich JM, Fink D, Caduff R, Seifert B, Marincek B, Kubik-Huch RA. Radiology 2002 Nov; 225 (2), pp. 527–36.

Mammary Gland Disease Differentiation
Gadolinium/Indocyanine Green (ICG)/Near-Infrared (NIR) Diffuse Optical Tomography (DOT)

Cellular/Molecular Mechanism of Action: Indocyanine green is an albumin-bound absorbing dye within the intravascular compartment.
Application: Indocyanine green is an absorbing dye commonly used as a marker system within the plasma compartment. Under certain conditions, ICG possesses the potential to differentiate disease based on the quantified enhancement of suspicious lesions using MRI concurrently with NIR DOT (contrast enhancement properties).
Route of Administration: Intravascular.
Implementation: Near-infrared DOT analysis of the mammary gland applied in combination or concurrently with MRI. Results are then correlated with histopathological evaluation of suspicious lesions.
Human Model: Cases scheduled for excisional biopsy or surgery.
Interpretation and Analysis: The ICG-enhanced optical images co-register accurately with gadolinium-enhanced MR images, thereby validating the ability of DOT to image breast tissue. In contrast to simple transillumination, DOT appears to provide for localization and quantification of exogenous tissue chromophore concentrations. Additionally, ICG has demonstrated a potential to differentiate disease based on the quantified enhancement of suspicious lesions.

Concurrent MRI and diffuse optical tomography of breast after indocyanine green enhancement. Ntziachristos V, Yodh AG, Schnall M, Chance B. Proc Natl Acad Sci U S A 2000 Mar 14; 97 (6), pp. 2767–72.

Necrotic Tissues: Neoplastic Lesions
Carborane [Gd]-DTPA 2

Cellular/Molecular Mechanism of Action: [Gd]-carborane complex 2 can function as a carrier complex for boron.
Application: Magnetic resonance *in vivo* imaging of neoplastic lesions that are undergoing active necrosis.
Implementation: Determine *in vivo* the ability for carborane [Gd]-DTPA 2 to detect neoplasic lesions. Validation of *in vivo* findings can be established applying *in vitro* alpha-autoradiography.
Animal Model: Rat (Donryu strain: tumor-bearing).
Interpretation and Analysis: Carborane [Gd]-DTPA 2 is metabolized slower in the body than [Gd]-DTPA 1. The results from inductively coupled plasma atomic emission spectroscopy (ICP-AES) methods indicate that compound 2 is incorporated into normal tissues and metabolized quickly, whereas it does not accumulate in tumor or brain tissues. Alpha-autoradiography reveals that high levels of boron accumulate within internal organs and in necrotic tumor tissue.

In vivo evaluation of carborane gadolinium-DTPA complex as an MR imaging boron carrier. Nakamura H, Fukuda H, Girald F, Kobayashi T, Hiratsuka J, Akaizawa T, Nemoto H, Cai J, Yoshida K, Yamamoto Y. Chem Pharm Bull (Tokyo) 2000 Jul; 48 (7), pp. 1034–8.

Neoplasia/Vascular and Lymphatic Endothelium (Associated)
Nanocrystals/Semiconductor Quantum Dots (qdots)/ Tumor Vasculature-Targeting Peptides/Peptide-Coated ZnS-Capped CdSe qdots/[Nanoparticles]

Background Information: Inorganic nanostructures that interface with biological systems have recently attracted widespread interest in biology and medicine. Nanoparticles are thought to have potential as novel intravascular delivery probes for both diagnostic (e.g., imaging) and therapeutic (e.g., chemotherapy) purposes. Critical issues for successful nanoparticle delivery include the ability to target specific tissues and cell types and the discovery of approaches for escaping the biological particulate filter known as the reticuloendothelial system.
Application: Detection and characterization of vascular and lymphatic structures associated with neoplastic lesions.
Route of Administration: Intravenous.
Implementation: Explore the feasibility of *in vivo* semiconductor qdot targeting. Qdots are small (< 10 nm) inorganic nanocrystals that possess unique luminescent properties because their fluorescence emission is stable and optimized by varying the particle size or composition.
Animal Model: Murine.
Interpretation and Analysis: ZnS-capped CdSe qdots coated with a lung-targeting peptide accumulate in the lungs of mice after intravenous injection, whereas 2 other peptides specifically direct qdots to blood vessels or lymphatic vessels in tumors. Addition of polyethylene glycol to the qdot coating prevents non-selective accumulation of qdots in reticuloendothelial tissues. These results encourage the construction of more complex nanostructures with capabilities such as disease sensing and drug delivery.

Nanocrystal targeting *in vivo*. Akerman ME, Chan WC, Laakkonen P, Bhatia SN, Ruoslahti E. Proc Natl Acad Sci U S A 2002 Oct 1; 99 (20), pp. 12617–21.

Neoplasia/Vascularity of Tumors/Mammary Carcinoma Transplants
Gadolinium: [Gd]-DTPA for MRI/Galactose-Based Ultrasound (US) Contrast Agent

Cellular/Molecular Mechanism of Action: Gadolinium is classified as a paramagnetic metallic ion and its spatial orientation becomes altered when placed within a magnetic energy field.
Background Information: Angiogenesis is essential for spread and growth of malignant tumors. Because non-invasive methods for observing tumor vascularization are limited, most of the current knowledge regarding this field of study is founded on previous results from histology-based investigations.
Application: Dynamic parameters obtained using intermittent contrast-enhanced Doppler sonography and dynamic MRI can be compared and correlated with microvessel density in neoplastic lesions.
Route of Administration: [Gd]-DTPA (intravenous for MRI); galactose-based contrast image-enhancing agent (intravenous for Doppler US).
Implementation: Comparison of dynamic parameters obtained using intermittent contrast-enhanced Doppler sonography and dynamic MRI to determine the degree to which findings correlate with patterns of microvessel density.

Transplanted tumors can be examined with dynamic T_1-weighted sequences using [Gd]-DTPA and images obtained by MR in concert with intermittent power Doppler sonography after a single bolus of galactose-based contrast agent. Following imaging, tumors are harvested for examination aided by immunofluorescence microscopy (e.g., $n = 6$ CD31-type lesions). Using a 2-compartment model, the MR parameters amplitude (reflecting plasma volume) and k_{ep} (influenced by the vessel permeability) are calculated and compared with maximal enhancement (max) and perfusion (p) measured by ultrasound.

Animal Model: Tumor-bearing nude mice (e.g., $n = 11$).
Interpretation and Analysis: The MR amplitude significantly correlates with the max ultrasound parameter ($r = 0.61$; $p = 0.01$): max ($r = 0.67$; $p = 0.01$), amplitude ($r = 0.72$; $p = 0.01$); while perfusion ($r = 0.62$; $p = 0.05$) correlates with microvessel density. Values for k_{ep} moderately correlate with max but not with perfusion and microvessel density. Dynamic MRI and contrast-enhanced ultrasound are complementary methods for examining perfusion and vascularity of experimental tumors.
Instrumentation: Magnetic resonance scanner (1.5 tesla).

Comparing dynamic parameters of tumor vascularization in nude mice revealed by magnetic resonance imaging and contrast-enhanced intermittent power Doppler sonography. Kiessling F, Krix M, Heilmann M, Vosseler S, Lichy M, Fink C, Farhan N, Kleinschmidt K, Schad L, Fusenig NE, Delorme S. Invest Radiol 2003 Aug; 38 (8), pp. 516–24.

Neoplasia: Carcinoma (Prostatic)/Gene Expression Imaging/c-myc Messenger RNA (mRNA) Transcription
Gadolinium ([Gd])-Anti-mRNA Oligonucleotide Strand/ Trans-Membrane Carrier Peptide

Cellular/Molecular Mechanism of Action: The physical orientation of gadolinium changes when placed within a magnetic energy field. Trans-membrane carrier proteins are transported across cell membrane structures by specific membrane-associated complexes. Oligonucleotides can be designed as the complementary sequence to specific mRNA strands and the resulting cDNA/mRNA double strand effectively prevents translation of the corresponding mRNA strand. Diagnostically, complementary strands of cDNA theoretically accumulate within the cytosol of cells that are actively transcribing the corresponding mRNA sequences that cDNA strands have been designed to recognize (hybridize/bend).
Background Information: The term "molecular imaging" can be broadly defined as the *in vivo* characterization and measurement of biological processes at the cellular and molecular level.
Application: Concept and methodology (strategy) for diagnostically detecting *in vivo* gene expression by MRI. Example: Detection of specific oncogenes expressed within neoplastic cell types.
Route of Administration: Theoretically would be administered most commonly by intravenous infusion.
Semi-Synthetic Methods: Development of a novel intravital and intracellular MRI contrast agent composed of a gadolinium complex, an oligonucleotide sequence (peptide nucleic acid [PNA]), and a trans-membrane carrier peptide designed to correspond to a peptide sequence similar to that of the homeodomain of the Antennapedia protein.
Implementation: Determine if a [Gd]-oligonucleotide complex (i) can accumulate in tumor cells *in vitro* and *in vivo*; and (ii) whether the specificity of a PNA for the upregulated c-myc mRNA in the cell's cytoplasm has an effect on contrast agent retention within tumor cells.
Tissue Culture Models: HeLa cell lines.

Animal Model: Rat (Dunning R3327 AT1 rat prostate adenocarcinoma).
Interpretation and Analysis: Using the c-myc-specific and a c-myc-non-specific control PNA, an increase in signal intensity in the tumor cells can be observed after 10 minutes *in vitro* and *in vivo* (maximum reached *in vitro* in HeLa within 60 minutes compared to Dunning R3327 AT1 rat prostate adenocarcinoma cells *in vivo* within 30 minutes). Such increases of signal intensity can be maintained *in vitro* in HeLa cells for only 4 hours and in Dunning R3327 AT1 rat prostate adenocarcinoma cells *in vivo* at least for 5 hours by using the c-myc mRNA-specific PNA as a "retention" agent.

Intracellular visualization of prostate cancer using magnetic resonance imaging. Heckl S, Pipkorn R, Waldeck W, Spring H, Jenne J, von der Lieth CW, Corban-Wilhelm H, Debus J, Braun K. Cancer Res 2003 Aug 15; 63 (16), pp. 4766–72.

Neoplasia: Carcinoma (Prostatic)/Lymph Node Metastases
Lymphotropic Superparamagnetic Nanoparticles

Cellular/Molecular Mechanism of Action: Superparamagnetic nanoparticles have been designed that have high lymphotropic properties.
Background Information: Accurate detection of lymph-node metastases in prostate cancer is an essential component of the approach to treatment.
Application: Detection of small nodal metastases using highly lymphotropic superparamagnetic nanoparticles.
Route of Administration: Intravenous.
Dosage: Lymphotropic superparamagnetic nanoparticles (2.6 mg of iron per kilogram of body weight).
Implementation: Detection of small nodal metastases utilizing highly lymphotropic superparamagnetic nanoparticles that gain access to lymph nodes by means of interstitial-lymphatic fluid transport. All case candidates are examined by MRI before and 24 hours after the intravenous administration of lymphotropic superparamagnetic nanoparticles. Imaging results are then correlated with histopathological findings.

Human Model: Cases with presurgical clinical stage T_1, T_2, or T_3 prostate cancer that have had surgical lymph-node resection or biopsy (n = 80).
Interpretation and Analysis: Analysis of lymph nodes either resected or biopsied (e.g., n = 334 lymph nodes) reveals that approximately 18.9% (e.g., n = 63/334) from 41% of cases (e.g., n = 33/80) have histopathological detectable evidence of metastases. Of these nodes (e.g., n = 63), approximately 71.4% (e.g., n = 45/63) do not fulfill the usual imaging criteria for malignancy. Magnetic resonance imaging with lymphotropic superparamagnetic nanoparticles can correctly identify the vast majority of cases with nodal metastasis (e.g., n = 33/33 or 100%). Node-by-node analysis has a significantly higher level of sensitivity than does conventional MRI (90.5% vs 35.4%, $p < 0.001$) or nomograms. Therefore, high-resolution MRI with magnetic nanoparticles allows the detection of smaller and otherwise undetectable lymph-node metastases in conditions of prostate cancer.
Instrumentation: High-resolution MRI.

Non-invasive detection of clinically occult lymph-node metastases in prostate cancer. Harisinghani MG, Barentsz J, Hahn PF, Deserno WM, Tabatabaei S, van de Kaa CH, de la Rosette J, Weissleder R. N Engl J Med 2003 Jun 19; 348 (25), pp. 2491–9.

Neoplasia: Carcinoma (Squamous Cell Type)/Esophogeal Squamous Cell Carcinoma (SCC) Epidermal Growth Factor Receptor (EGFR) Expression
Anti-EGFR Coated Supermagnetic Particles

Cellular/Molecular Mechanism of Action: Anti-EGFR monoclonal antibody recognizes and physically binds to membrane-associated EGFR.
Background Information: Epidermal growth factor receptors are overexpressed in esophageal SCC.
Application: Enhanced detection of esophageal SCC employing an endoluminal surface coil.
Route of Administration: Anti-EGFR-coated supermagnetic particles (intravascular).
Semi-Synthetic Methods: Coating superparamagnetite particles with monoclonal antibodies (MAbs) directed against EGFRs.
Animal Model: Rat (athymic bearing TE8 or H69 tumors).
Human Model: Cases of esophageal cancer (n = 30).
Interpretation and Analysis: In terms of depth of cancer invasion, the accuracy rate of MRI using the endoluminal surface coil is approximately 83%. MRI with an endoluminal surface coil will be a useful examination approach for detecting esophageal cancer. Anti-EGFR-coated supermagnetic particles possess EGFR-specific MRI contrast capacity *in vivo* in tumor-bearing rats. Immunospecific MRI using magnetite particles coated with MAbs against EGFR seems to be useful for diagnosing SCC of the esophagus.
Instrumentation: Endoluminal 1.5 tesla serconductive MR system.

What's new in imaging? New magnetic resonance imaging of esophageal cancer using an endoluminal surface coil and antibody-coated magnetite particles. Ozawa S, Imai Y, Suwa T, Kitajima M. Recent Results Cancer Res 2000; 155, pp. 73–87.

Neoplasia (Central Nervous System [CNS])/Brain Tumor Diagnostic and Therapeutic Implications
Gadobenate Dimeglumine ([Gd]-BOPTA)

Background Information: [Gd]-BOPTA has a significantly greater [Gd] uptake by brain tumor tissue than gadopentate dimeglumine ([Gd]-DTPA).
Application: The agent [Gd]-BOPTA is assimilated at relatively high concentrations within certain neoplastic lesions that affect the CNS.
Route of Administration: [Gd]-BOPTA and [Gd]-DTPA (intralesionally and subcutaneously in rat research investigations).
Dosage: [Gd]-BOPTA and [Gd]-DTPA (0.05 mmol/g tumor weight).
Implementation: Evaluate whether [Gd]-BOPTA is an efficient agent for neutron capture therapy (NCT).

Delineate the imaging properties of [Gd]-BOPTA and [Gd]-DTPA injected intralesionally into tumors. At the peak of [Gd] uptake, thermal neutron irradiation is applied.

Animal Model: Rat (Fisher 344 strain). Four groups of Fisher 344 rats (control, neutron (n), n+ [Gd]-DTPA, n+ [Gd]-BOPTA) injected subcutaneously with 9L gliosarcoma cells in both hind legs.
Interpretation and Analysis: A pronounced delay in tumor growth can be appreciated with [Gd+] formulations compared to control and neutron analyses (p = 0.0053, 0.0064, respectively). Furthermore, BOPTA is associated with a significantly prolonged

delay of tumor growth compared to DTPA ($p = 0.033$). In addition, [Gd]-NCT demonstrates that [Gd]-BOPTA can function as an effective compound for NCT. Better cytocidal effects of [Gd]-BOPTA warrant further investigation of subcellular [Gd] distribution.

In vivo gadolinium neutron capture therapy using a potentially effective compound ([Gd]-BOPTA). Matsumura A, Zhang T, Yamamoto T, Yoshida F, Sakurai Y, Shimojo N, Nose T. Anticancer Res 2003 May–Jun; 23 (3B), pp. 2451–6.

Neoplasia (Central Nervous System [CNS]): Glioma/ Microglial Cell Detection and Characterization
Ultrasmall Superparamagnetic Particles of Iron Oxide (USPIOs)

Cellular/Molecular Mechanism of Action: Ultrasmall superparamagnetic particles of iron oxide are perceived as foreign material and internalized (phagocytized) by microglial cell populations residing within the CNS.

Background Information: Microglia are intrinsic immunoeffector cells of the CNS that play a very sensitive, crucial role in the response to almost any brain pathology. Upon stimulation, they are transformed into a state of elevated phagocytic activity.

Application: Reveal the extent of microglial tumors and assess the status of immunologic defense processes.

Implementation: Evaluate the presence and distribution of activated microglial cells residing within the CNS utilizing USPIO preparations in combination with MRI instrumentation.

Animal Model: Glioma cell cultures and rat glioma *in vivo* model.

Interpretation and Analysis: Using USPIOs in cell culture experiments and in a rat glioma model, microglia can be labeled magnetically and detected by confocal microscopy within and around tumors in a typical border-like pattern. Quantitative *in vitro* studies reveal that microglia cells internalize amounts of USPIOs that are significantly higher than those incorporated by tumor cells and astrocytes. Labeled microglia can be detected and quantified with MRI in cell phantoms, and the extent of the tumor can be seen *in vivo* in glioma-bearing rats. Magnetic labeling of microglia provides a potential tool for MRI of gliomas that more precisely reflects tumor morphology. Furthermore, the results suggest that MRI may yield functional data on the immunologic reaction within the CNS.

Magnetic labeling of activated microglia in experimental gliomas. Fleige G, Nolte C, Synowitz M, Seeberger F, Kettenmann H, Zimmer C. Neoplasia 2001 Nov–Dec; 3 (6), pp. 489–99.

Neoplasia (Central Nervous System [CNS]): Gliomas/ Angiogenic Neovascularization
Contrast-Enhanced Dynamic Susceptibility MRI

Background Information: Abnormalities in the recirculation phase of the passage of a contrast agent bolus have been identified in tumors and have been proposed to represent vascular tortuosity and hypoperfusion in areas of angiogenic neovascularization.

Application: Detection and characterization (grading) of the microcirculation profiles of gliomas within the CNS as a function of vascular tortuosity and regions of hypoperfusion.

Implementation: Characterization of glioma lesions by contrast-enhanced dynamic susceptibility MRI. Residual relaxivity effects are minimized by the injection of contrast agent before the acquisition of dynamic images. Maps of relative cerebral blood volume (rCBV) and relative recirculation (rR) are calculated, and values from enhancing tumor tissue compared with tumor grade.

Human Model: Human glioma cases (e.g., $n = 27$).

Interpretation and Analysis: Histologic grade categories include grade II-astrocytoma ($n = 3$); grade III-anaplastic astrocytoma ($n = 10$); and grade IV-glioblastoma multiforme ($n = 14$). Relative cerebral blood volume values vary among tumor grades, with higher mean values associated with higher grade tumors ($p < 0.001$). Mean rR values in grade II tumors are not significantly different from those in normal gray and white matter. Mean rR values in grades III and IV tumors are similar and significantly higher than those in grade II tumors ($p < 0.01$). The distribution of the pixel values of rR reveals significant differences between grades III and IV tumors ($p < 0.001$), with low values of skewness in keeping with a normal distribution in grade III tumors and higher values in grade IV tumors. Variation in the recirculation characteristics of a contrast agent bolus is related to tumor grade in gliomas. Abnormalities in contrast agent recirculation appear to provide independent information concerning the microcirculation in imaging studies of angiogenesis and may be of value as surrogate markers in trials of antiangiogenic therapy.

Abnormalities in the recirculation phase of contrast agent bolus passage in cerebral gliomas: Comparison with relative blood volume and tumor grade. Jackson A, Kassner A, Annesley-Williams D, Reid H, Zhu XP, Li KL. AJNR Am J Neuroradiol 2002 Jan; 23 (1), pp. 7–14.

Neoplasia (Central Nervous System [CNS]): Glioma of Murine Origin
Blood-Pool Contrast Agents: MP-2269 and MS-325/ Extracellular Contrast Agent: OptiMARK

Cellular/Molecular Mechanism of Action: MP-2269 and MS-325 are 2 small molecular weight serum albumin-binding blood-pool contrast agents. OptiMARK functions as a compound that remains in extracellular fluid compartments with essentially no intracellular penetration.

Background Information: Intravenous MRI contrast agents are commonly used to improve the detection of intracranial tumors and other CNS lesions for diagnosis and treatment planning.

Application: Intravenous MRI contrast agents are commonly used to improve the detection of intracranial tumors and other CNS lesions for diagnosis and treatment planning.

Route of Administration: MP-2269 and MS-325 (intravenous), and OptiMARK (intravenous).

Dosage: MP-2269 and MS-325 (30 μmol/kg: small molecular weight, albumin-binding blood-pool contrast agents). OptiMARK (100 μmol/kg: extracellular imaging agent).

Implementation: Detection of CNS neoplastic lesions (glioma) with the small molecular weight blood-pool contrast agent, MP-2269 and MS-325, compared to the extracellular contrast agent, OptiMARK, utilizing 1.5 Tesla electromagnetic resonance imaging analysis.

Animal Model: Mouse glioma.

Interpretation and Analysis: Tumor image contrast is significantly enhanced and long-lived following administration of MP-2269 and MS-325 blood-pool agents. More specifically, contrast enhancement peaks slowly at 25 to 30 minutes following administration, remains constant for > 3 hours, and returns to baseline within 20 hours. Comparable but "transient" enhancement can be achieved using an extracellular contrast agent (OptiMARK), which demonstrates rapid peaks in contrast enhancement at 2 to 5 minutes following administration and then declines over a 40-minute period. The blood-pool contrast agents demonstrate an approximate 3-fold increase in dose-effectiveness and a lengthened window of tumor contrast enhancement compared to commonly available extracellular

contrast agents. This demonstrates the potential of alternative contrast-enhanced MRI examination protocols for tumor detection.

Albumin-binding MR blood pool agents as MRI contrast agents in an intracranial mouse glioma model. Adzamli K, Yablonskiy DA, Chicoine MR, Won EK, Galen KP, Zahner MC, Woolsey TA, Ackerman JJ. Magn Reson Med 2003 Mar; 49 (3), pp. 586–90.

Neoplasia (Central Nervous System [CNS]): Gliosarcoma
Rhodaminated LCDIO/Hoechst 33258 Dye/Green Fluorescent Protein

Cellular/Molecular Mechanism of Action: Hoechst 33258 dye can be applied as an intravital endothelial stain. Rhodaminated long-circulating dextran-coated iron oxide (LCDIO) particles can preferentially localize intracellular within certain malignant neoplastic cell types (e.g., gliosarcoma).
Application: Detection and characterization of CNS neoplastic lesions (e.g., gliosarcoma).
Route of Administration: Intravascular.
Implementation: Determination of the distribution of a LCDIO preparation in tumors. Accumulation of LCDIO in tissue sections is evaluated using multichannel fluorescence microscopy with rhodaminated LCDIO, green fluorescent protein as a tumor marker, and Hoechst 33258 dye as an intravital endothelial stain. Uptake into tumor cells is correlated (validated) with results from immunohistochemical and cell culture uptake analyses. The effect of intratumoral LCDIO uptake on MRI signal intensity is evaluated with a 1.5 tesla superconducting magnet.
Animal Model: Rodent gliosarcoma.
Interpretation and Analysis: Tumoral accumulation of LCDIO is 0.11% ± 0.06 of the injected dose per gram of tissue in brain tumors and sufficient for detection using MRI. In tumor sections, LCDIO preferentially localizes in tumor cells (49.0% ± 4.6) but is also taken up by macrophages in tumors (21.0% ± 3.1) and by endothelial cells in the areas of active angiogenesis (6.5% ± 1.4). In cell culture, LCDIO uptake strongly correlates with growth rate of tumor cell lines. Tumoral LCDIO accumulation is not negligible and helps explain MRI signal intensity changes observed in clinical trials. Microscopically, LCDIO accumulates predominantly in tumor cells and tumor-associated macrophages. Uptake into tumor cells appears to be directly proportional to cellular proliferation rate.
Instrumentation: Magnetic resonance imaging signal intensity evaluated with a 1.5 Tesla superconducting magnet.

Tumoral distribution of long-circulating dextran-coated iron oxide nanoparticles in a rodent model. Moore A, Marecos E, Bogdanov A Jr, Weissleder R. Radiology 2000 Feb; 214 (2), pp. 568–74.

Neoplasia (Central Nervous System [CNS]): Medulloblastoma
Gadolinium-Based Agent

Background Information: Experimental mouse models are emerging as useful systems for the study of human brain tumors. Nuclear MRI methods can non-invasively provide images of complex heterogeneous tissues such as experimental brain tumors.
Route of Administration: Gadolinium-based agents (intravenous).
Implementation: Demonstration of the feasibility of longitudinal high-resolution MRI in detecting and characterizing brain tumors.
Animal Model: Two mouse brain tumor models—patched heterozygous (ptc ±) mice with spontaneously arising posterior fossa tumors that resemble human medulloblastoma, and homozygous nude mice implanted with intracerebral xenografts of human medulloblastoma cell lines.
Interpretation and Analysis: Methods have been optimized to achieve favorable volumetric comparison with histologic methods and submillimeter resolution, improved by contrast enhancement with intravenous administration of a gadolinium-based agent.

Magnetic resonance imaging of patched heterozygous and xenografted mouse brain tumors. Nelson AL, Algon SA, Munasinghe J, Graves O, Goumnerova L, Burstein D, Pomeroy SL, Kim JY. J Neurooncol 2003 May; 62 (3), pp. 259–67.

Neoplastic Disease/Diagnostic and Therapeutic Implications
Gadobenate Dimeglumine ([Gd]-BOPTA)

Background Information: Gadobenate dimeglumine has a significantly greater [Gd] uptake by brain tumor tissue than gadopentate dimeglumine ([Gd]-DTPA).
Application: The agent [Gd]-BOPTA is assimilated at relatively high concentrations within certain neoplastic lesions that affect the central nervous system (CNS).
Route of Administration: [Gd]-BOPTA and [Gd]-DTPA (intralesionally and subcutaneously in rat research investigations).
Dosage: [Gd]-BOPTA and [Gd]-DTPA (0.05 mmol/g tumor weight).
Implementation: Evaluate whether [Gd]-BOPTA is an efficient agent for neutron capture therapy (NCT). Complementary investigations can involve delineation of the imaging properties of [Gd]-BOPTA and [Gd]-DTPA injected intralesionally into tumors. At the peak of [Gd] uptake, thermal neutron irradiation is applied.
Animal Model: Rat (Fisher 344 strain). Four groups of Fisher 344 rats (control, neutron (n), n+ [Gd]-DTPA, n+ [Gd]-BOPTA) injected subcutaneously with 9L gliosarcoma cells in both hind legs.
Interpretation and Analysis: A pronounced delay in tumor growth can be appreciated with [Gd+] formulations compared to control and neutron analyses ($p = 0.0053$, 0.0064, respectively). Furthermore, BOPTA is associated with a significantly prolonged delay of tumor growth compared to DTPA ($p = 0.033$). In addition, [Gd]-NCT demonstrates that [Gd]-BOPTA can function as an effective compound for NCT. Better cytocidal effects of [Gd]-BOPTA warrant further investigation of subcellular [Gd] distribution.

In vivo gadolinium neutron capture therapy using a potentially effective compound ([Gd]-BOPTA). Matsumura A, Zhang T, Yamamoto T, Yoshida F, Sakurai Y, Shimojo N, Nose T. Anticancer Res 2003 May–Jun; 23 (3B), pp. 2451–6.

Neoplastic Disease (Central Nervous System [CNS])/ Angiogenesis of Gliomas/Dimethylarginine Dimethylaminohydrolase (DDAH) Overexpression
NC100150/Hoechst 33342

Cellular/Molecular Mechanism of Action: The orientation of NC100150 becomes altered within a magnetic field. Alternatively, Hoechst 33342 emits fluorescent light energy.
Background Information: Intracellular factors that regulate nitric oxide (NO) synthesis represent important targets in tumor progression. Overexpression of DDAH, which metabolizes the endogenous inhibitors of NO synthesis asymmetric dimethylarginine and N-monomethyl-L-arginine, results in C6 gliomas with enhanced growth rates compared to wild cell types.

Application: NC100150 can be utilized as an intravascular blood-pool contrast agent that is detectable by MRI methodologies. Hoechst 33342 can be used as a fluorescent perfusion-marker dye that can be measured by flourescent detection systems.
Route of Administration: Utilization of NC100150 and Hoechst 33342 for neoplastic lesion angiogenesis requires that these be delivered intravascularly.
Implementation: Determine the (i) *in vitro* effects of DDAH on tumor vascular morphogenesis by measurement of the transverse relaxation rates R_2* and R_2 in clone D27 gliomas overexpressing DDAH and C6 wild-type gliomas using intrinsic susceptibility MRI sensitive to changes in endogenous deoxyhemoglobin; (ii) determine susceptibility contrast-enhanced MRI using NC100150 as an intravascular blood-pool contrast agent; and (iii) compare results with fluorescence microscopy of the tumor uptake of the perfusion marker Hoechst 33342.
Interpretation and Analysis: The baseline R_2* is significantly faster in D27 tumors, consistent with a greater vascular development ($p < 0.02$, ANOVA). There is no significant difference between the response of the 2 tumor types to hypercapnia (5% CO_2/95% air), used to evaluate vascular maturation, or hyperoxia (5% CO_2/95% O_2), used to characterize vascular function. NC100150 increases the R_2* and R_2 rates of both tumor types and detects a significantly larger blood volume in the D27 tumors ($p < 0.02$, ANOVA). This correlates with a significantly greater uptake of Hoechst 33342 in the D27 tumors compared to C6 wild-type tumors ($p < 0.02$, ANOVA). Despite increased tumor blood volume, the Delta R_2*/Delta R_2 ratio, an index of microvessel size, shows that the capillaries in the 2 tumor types are of a similar caliber. Such observations demonstrate the potential of susceptibility MRI-derived quantitative end points to non-invasively assess tumor angiogenesis. Application of intravascular blood-pool contrast agents such as NC100150 for such purposes appears very promising. Overexpression of DDAH results in increased *in vivo* neovascularization of C6 gliomas. The lack of a significant difference in hypercapnic/hyperoxic response between C6 and D27 tumors and the similar vessel caliber are also consistent with a role for DDAH in the initial stages of vasculogenesis.
Instrumentation: Magnetic resonance imaging and fluorescence microscopy instrumentation.

Effects of overexpression of dimethylarginine dimethylaminohydrolase on tumor angiogenesis assessed by susceptibility magnetic resonance imaging. Kostourou V, Robinson SP, Whitley GS, Griffiths JR. Cancer Res 2003 Aug 15; 63 (16), pp. 4960–6.

Neoplastic Disease Angiogenesis/Tumor Dimethylarginine Dimethylaminohydrolase (DDAH) Overexpression
NC100150/Hoechst 33342

Cellular/Molecular Mechanism of Action: The orientation of NC100150 becomes altered within a magnetic field. Alternatively, Hoechst 33342 emits fluorescent light energy.
Background Information: Intracellular factors that regulate nitric oxide (NO) synthesis represent important targets in tumor progression. Overexpression of DDAH, which metabolizes the endogenous inhibitors of NO synthesis asymmetric dimethylarginine and N-monomethyl-L-arginine, results in C6 gliomas with enhanced growth rates compared to wild cell types.
Application: NC100150 can be utilized as an intravascular blood-pool contrast agent that is detectable by MRI methodologies. Hoechst 33342 can be used as a fluorescent perfusion-marker dye that can be measured by flourescent detection systems.
Route of Administration: Utilization of NC100150 and Hoechst 33342 for neoplastic lesion angiogenesis requires that these be delivered intravascularly.
Implementation: Determine the (i) *in vitro* effects of DDAH on tumor vascular morphogenesis by measurement of the transverse relaxation rates R_2* and R_2 in clone D27 gliomas overexpressing DDAH and C6 wild-type gliomas using intrinsic susceptibility MRI sensitive to changes in endogenous deoxyhemoglobin; (ii) determine susceptibility contrast-enhanced MRI using NC100150 as an intravascular blood-pool contrast agent; and (iii) compare results with fluorescence microscopy of the tumor uptake of the perfusion marker Hoechst 33342.
Interpretation and Analysis: The baseline R_2* is significantly faster in D27 tumors, consistent with a greater vascular development ($p < 0.02$, ANOVA). There is no significant difference between the response of the 2 tumor types to hypercapnia (5% CO_2/95% air), used as a probe for vascular maturation, or hyperoxia (5% CO_2/95% O_2), used as a probe for vascular function. NC100150 increases the R_2* and R_2 rates of both tumor types and detects a significantly larger blood volume in the D27 tumors ($p < 0.02$, ANOVA). This correlates with a significantly greater uptake of Hoechst 33342 in the D27 tumors compared to C6 wild-type tumors ($p < 0.02$, ANOVA). PANCREAS

Lesions: Pancreatic and Hepatic
Mangafodipir Trisodium

Background Information: The detection and characterization of pancreatic tumors as well as the reliable staging of pancreatic cancer are important objectives for radiologic evaluation. Contrast-enhanced helical computed tomography (CT) has been the standard modality for pancreatic imaging at many institutions, but MRI has gained a considerable role in the evaluation of patients with equivocal CT findings.
Application: Detection and characterization of disease states affecting the liver and pancreas, including neoplastic conditions utilizing MRI analysis.
Interpretation and Analysis: Contrast-enhanced MRI has proven to be very helpful in the detection of small tumors or the identification of tumor-simulating lesions in patients with equivocal CT findings. Mangafodopir may improve the staging of pancreatic cancer by increasing the sensitivity of MRI in the detection of liver metastases.

Evaluation of focal pancreatic masses: Comparison of mangafodipir-enhanced MR imaging and contrast-enhanced helical CT. Schima W, Fugger R. Eur Radiol 2002 Dec; 12 (12), pp. 2998–3008.

Pancreatic Duct Function: Pancreatography
Secretin

Cellular/Molecular Mechanism of Action: Secretin promotes increases in exocrine pancreatic function.
Background Information: Magnetic resonance pancreatography is a new modality for visualizing the pancreatic duct. Prolonged dilation of the pancreatic duct following secretin administration may suggest obstruction at the level of the pancreatic duct orifice.
Application: Enhance visualization of pancreatic duct exocrine flow.
Implementation: Pancreatography of idiopathic acute recurrent pancreatitis aided by secretin-mediated stimulation of exocrine function in concert with subsequent endoscopic retrograde pancreatogram with or without manometry (e.g., n = 10 cases).
Interpretation and Analysis: Visualization of the main pancreatic duct is possible in most cases without evidence of chronic disease (e.g., n = 10/10). Similarly, it is possible to detect cases of pancreas divisum (e.g., n = 2), and prolonged dilation of the pancreatic duct on secretin-stimulated MR pancreatography accompanied by evidence of pancreatic duct outflow obstruction (e.g., n = 3). Some cases of pancreatic duct outflow obstruction have normal secretin-stimulated MR pancreatography (e.g., n = 4). Therefore, secretin-stimulated MR pancreatography provides high-quality pancreatic duct images and has high specificity but low sensitivity for diagnosing pancreatic duct outflow obstruction using manometric/clinical criteria.

Secretin-stimulated magnetic resonance pancreaticogram to assess pancreatic duct outflow obstruction in evaluation of idiopathic acute recurrent pancreatitis: A pilot study. Khalid A, Peterson M, Slivka A. Dig Dis Sci 2003 Aug; 48 (8), pp. 1475–81.

Pancreatitis: Acute Biliary/ Cholangiopancreatography: Pancreatic Morphology Alterations
Secretin

Cellular/Molecular Mechanism of Action: Secretin stimulates exocrine pancreatic function.
Application: Assessment of the potential for acute biliary pancreatitis progressing to pancreatic morphological alterations applying MR cholangiopancreatography. Secretin can be applied to evaluate exocrine pancreatic function and improve visualization of the exocrine pancreatic tree.
Implementation: Characterization of biliary pancreatitis applying MR cholangiopancreatography. Secretin is administered in order to determine if the pancreatic duct is incomplete or absent, and ductal morphology before and after secretin stimulation compared (e.g., n = 16 cases).
Human Model: Cases having undergone cholecystectomy but devoid of alterations of pancreatic function 5 years after the last episode of pancreatitis (e.g., n = 25/40 female, n = 15/40 male; n = 27/40 mild, n = 13/40 severe).
Interpretation and Analysis: Significant differences can be observed when the diameter and length of the main pancreatic duct are compared in cases with reference controls, and can be completely visualized in 60% of cases, in addition to being seen in all cases following secretin stimulation. The comparative statistical analysis of the length and diameter of the pancreatic duct before and after the secretin stimulation shows significant differences. Acute biliary pancreatitis leads to morphological alterations, such as scar lesions that do not become chronic in nature. Secretin stimulation improves the visualization of the main pancreatic duct.

Main pancreatic duct: Morphology after acute biliary pancreatitis with magnetic resonance cholangiopancreatography after secretin stimulation. Pareja E, Artigues E, Mir J, Fabra R, Martinez V, Vazquez A, Trullenque R. Rev Esp Enferm Dig 2003 Jun; 95 (6), pp. 395–400, 389–94 (different versions of same article).

Pancreatitis (Acute): Prognostic Features

Application: Detection, characterization, and prediction of prognosis for survival in cases suffering from acute pancreatitis.
Implementation: Characterization of elevations in peripancreatic signal on fat-suppressed T_1-weighted images. Abdominal MRI from cases of acute pancreatitis are assessed to determine the presence of elevated signal intensity within the peripancreatic fat on fat-suppressed T_1-weighted spooled gradient echo images. The degrees of signal change are then graded as mild, moderate, or severe (e.g., n = 31 cases).
Interpretation and Analysis: Abnormally high signal intensity within the peripancreatic fat on fat-suppressed T_1-weighted images can be detected in approximately 30% of cases (e.g., n = 10/30). A modest number of cases display signal changes graded as mild (e.g., n = 3/10), moderate (e.g., n = 1/10), and severe (e.g., n = 6/10). The mortality rate within a 68-day period for cases graded with severe elevations in peripancreatic soft tissue signal is very high (e.g., n = 6/6). Alternatively, the survival rate for cases without evidence of elevated peripancreatic fat signal is very high (e.g., n = 21/21). The correlation between the presence and severity of elevated peripancreatic MR signal and patient outcome is significant ($p < 0.05$). Therefore, increases in peripancreatic image signals appear to be closely associated with a progressively poorer prognosis for survival in cases suffering from acute pancreatitis. Such techniques may represent a simplified method for prognostic cross-sectional imaging.

High signal peripancreatic fat on fat-suppressed spoiled gradient echo imaging in acute pancreatitis: Preliminary evaluation of the prognostic significance. Martin DR, Karabulut N, Yang M, McFadden DW. J Magn Reson Imaging 2003 Jul; 18 (1), pp. 49–58.

Pancreatitis: Early or Mild Chronic Form
Gadolinium Chelate

Application: Gadolinium chelate image-enhancing agents can be used to diagnose early or mild chronic pancreatitis by dynamic MRI, especially before apparent pancreatic morphologic or signal intensity changes become apparent.
Route of Administration: Gadolinium chelate (intravascular).
Implementation: Evaluation of suspected cases of early or mild chronic pancreatitis classified according to the imaging criteria of (i) equivocal chronic pancreatitis (ultrasound, computed tomography, or endoscopic retrograde cholangiopancreatography [ERCP]) grading; (ii) having dynamic MRI that includes a lack of enhancement; (iii) arterial dominant; and (iv) early venous and late venous phases of contrast enhancement. The signal intensity is measured at the pancreatic head, body, and tail on all phases, and for each, the signal intensity ratio (SIR, the signal intensity in postcontrast divided by that in precontrast) is individually calculated. Images are reviewed for pancreatic morphologic abnormalities without knowing the results of signal intensity measurements.

Human Model: Cases of suspected early or mild chronic pancreatitis (e.g., n = 24). Reference control subjects consist of cases without pancreatic diseases (e.g., n = 20).

Interpretation and Analysis: On unenhanced images, there is no significant difference of signal intensity between control and pancreatitis cases ($p < 0.05$). In pancreatitis conditions, but not controls, the unenhanced signal intensity of the pancreatic head and body are significantly higher than that of the tail ($p < 0.05$). In control cases, the greatest enhancement (highest SIR) after injection is in the arterial phase (1.89 ± 0.31), which is significantly higher than in the early venous phase (1.68 ± 0.17, $p < 0.01$) and in the late venous phase (1.61 ± 0.15, $p < 0.001$). Pancreatitis conditions however, have an arterial phase SIR (1.65 ± 0.23) that is significantly lower than its early venous phase SIR (1.75 ± 0.22, $p < 0.05$) and lower than the arterial phase SIR of the control group ($p < 0.01$). The presence of an SIR < 1.73 in the arterial phase and/or a delayed peak enhancement after contrast agent administration has a sensitivity and specificity of diagnosing early or mild chronic pancreatitis of 92% and 75%, respectively. This sensitivity is significantly higher than the sensitivity of 50% for diagnosis based on morphologic abnormalities ($p < 0.05$). Measuring pancreatic signal intensity on gadolinium chelate dynamic MRI is helpful for diagnosing early or mild chronic pancreatitis, especially before apparent pancreatic morphologic or signal intensity changes are present.

Suspected early or mild chronic pancreatitis: Enhancement patterns on gadolinium chelate dynamic MRI. Zhang XM, Shi H, Parker L, Dohke M, Holland GA, Mitchell DG. J Magn Reson Imaging 2003 Jan; 17 (1), pp. 86–94.

RENAL SYSTEM

Renal Abscesses and Asymptomatic Masses
Gadolinium-DTPA ([Gd]-DTPA)/LumenHance

Implementation: Magnetic resonance imaging of asymptomatic renal masses, with enhancement sufficient to effectively exclude simple and hemorrhagic cysts.

Considerations: Because the MRI appearances of renal cell neoplasm and renal abscess overlap, both must be considered in the differential diagnosis.

Interpretation and Analysis: Focal and multifocal renal abscesses can be positively detected by MRI utilizing [Gd]-DTPA functioning as an imaging contrast-enhancing agent .

Instrumentation: Computer-integrated MRI capabilities.

Asymptomatic renal abscess: Evaluation with gadolinium DTPA-enhanced MRI. Cyran KM, Kenney PJ. Abdom Imaging 1994 May–Jun; 19 (3), pp. 267–9.

Renal Structures/Renal Cancer Staging
Renal Eliminated Paramagnetic Contrast

Magnetic resonance imaging differs fundamentally from other imaging techniques, because for the 1st time 1 method permits simultaneous assessment of macroscopic changes in the kidneys and evaluation of renal functional derangements. To provide morphological information that may compete with the results of computed tomography (CT) and ultrasonography (US), special techniques like artifact compensation, fast imaging, and fat suppression have to be employed. The additional use of a renal-eliminated paramagnetic contrast agent permits assessment of parenchymal perfusion and visualization of the passage of the contrast medium, providing information about renal excretory function. Results and clinical utility of state-of-the-art MRI can be summarized as follows: (i) MR is not a screening method; sensitivity is, however, similar to CT when fat suppression and contrast agents are used. (ii) Classification of renal masses is almost restricted to the differentiation of cystic, fat-containing, and solid lesions. (iii) Contrast-enhanced MRI helps to assess large retroperitoneal masses and to classify them as intra- or extrarenal. (iv) Accurate staging of renal cancers is possible; thus, MRI is a good alternative when CT yields uncertain findings and for patients with known contraindications to the administration of iodinated contrast agents. (v) Contrast-enhanced dynamic MRI studies provide semiquantitative evaluation of global and segmental renal function. (vi) MR angiography offers the possibility to evaluate renal arteries and veins.

Magnetic resonance imaging of the kidneys: Current status. Krestin GP. Magn Reson Q 1994 Mar; 10 (1), pp. 2–21.

Renal Transplant Rejection
Ultrasmall Superparamagnetic Particles of Iron Oxide (USPIOs)

Cellular/Molecular Mechanism of Action: Preparations of USPIOs are perceived as foreign material and internalized by macrophage populations. Prussian blue detects intracellular iron deposits.

Application: Indirect monitoring of the integrity of renal transplants through the detection of macrophage accumulation in situations of kidney rejection.

Implementation: Evaluation of renal transplants non-invasively applying MRI in combination with image-enhancing infusion of USPIOs preparations. In this manner it is possible to determine whether accumulation of immune cells like macrophages in renal transplants can be detected *in vivo* while a kidney transplant is in the process of being rejected. Logistically, this is accomplished by infusion of USPIOs with MRI performed before, immediately after, and 1 day following administration.

Animal Model: Rat (major histocompatibility disparate DA to BN male rat renal transplantation recipients).

Interpretation and Analysis: Infusion of USPIO on the 4th day posttransplantation reveals some rejecting allografts detected as a decrease of MR signal intensity 1 day later. Isografts and allografts with triple immunosuppressant treatment have no MR signal reduction. Immunohistologic staining for ED1+ macrophages and CD4+ and CD8+ T cells in allogeneic transplanted kidneys indicates accumulation of these immune cells as a feature of acute rejection progress. Morphological studies by electron microscopy confirm the existence of iron inside macrophage lysosomes residing within rejected kidneys, while Prussian blue staining detects the presence of iron plaques in macrophages. Isografts and allografts with a triple immunosuppressant treatment exhibit smaller MR signal reductions with minimal histologic changes. The concurrence of MR signal reduction following USPIO infusion with pathological manifestation in a rat renal allograft model suggests the possibility that renal transplantation status may be assessed by MRI using USPIO particles as markers for the accumulation of immune cells, such as macrophages.

Magnetic resonance imaging detection of rat renal transplant rejection by monitoring macrophage infiltration. Zhang Y, Dodd SJ, Hendrich KS, Williams M, Ho C. Kidney Int 2000 Sep; 58 (3), pp. 1300–10.$eref4

Renal/Urinary Bladder and Kidney
Piperidinyl Nitroxide Stable Free Radical Derivative (TES)

Application: Contrast-enhancing pharmaceutical for nuclear magnetic resonance (NMR) procedures.

Implementation: Evaluation of a piperidinyl nitroxide stable free radical derivative, TES, to determine its diagnostic efficacy as an NMR contrast enhancer of renal structures in conditions of normal health, experimentally-induced unilateral renal ischemia, renal vascular congestion, and hydronephrosis.
Interpretation and Analysis: Physiologic measurements indicate that TES is rapidly excreted in the urine with a clearance rate equal to the glomerular filtration rate. Because the compound is strongly paramagnetic, it increases the observable NMR intensity within the kidneys and urine at relatively low doses (0.04–0.9 g/kg). TES-enhanced spin-echo renal images can clearly demonstrate the presence of disease and functional abnormalities in diseased kidneys. These abnormalities are either not evident or only indirectly suggested on non-enhanced NMR images.

Work in progress: Nuclear magnetic resonance study of a paramagnetic nitroxide contrast agent for enhancement of renal structures in experimental animals. Brasch RC, London DA, Wesbey GE, Tozer TN, Nitecki DE, Williams RD, Doemeny J, Tuck LD, Lallemand DP. Radiology 1983 Jun; 147 (3), pp. 773–9.

Renal/Urinary Bladder and Kidney
Tempo Carboxylic Acid (TCA)

Cellular/Molecular Mechanism of Action: Functions as a nitroxide diagnostic agent.
Application: Contrast-enhancing pharmaceutical for MRI procedures.
Considerations: The meglumine salt of TCA (piperidinyl nitroxide stable free radical derivative) functions as an nuclear magnetic resonance (NMR) contrast enhancer.
Interpretation and Analysis: Enhances the signal intensity of the kidney and bladder.

Ideal imaging in MR: Contrast-enhancing pharmaceuticals. Evaluation of tempo carboxylic acid as nitroxide diagnostic agent. Lamarque JL, Almès C, Rouanet JP, Prat X, Bruel JM, Pujol J, Rodière MJ, Martin JM, Lopez P, Rossi M. Eur J Radiol 1986 Feb; 6 (1), pp. 48–52.

Renal Vascular Perfusion: Cortex and Medulla
Iodixanol

Cellular/Molecular Mechanism of Action: Iodinated compounds possess radiopaque properties.
Application: Iodixanol is a high-viscosity, dimeric isoosmolar iodinated contrast medium.
Route of Administration: Iodixanol (intravenous).
Implementation: Assess the abilities of dynamic diffusion-weighted MRI to demonstrate the *in vivo* effects of the high-viscosity iodinated contrast agent (iodixanol) on medullary and cortical blood flow in the kidney. Dynamic diffusion-weighted, echoplanar MR images are acquired from 5 b-value single-shot images and their apparent isotropic diffusion coefficient maps established before and after intravenous injection of iodixanol, and compared with those obtained from negative reference controls.

Animal Model: Rat (pentobarbital-sedated; n = 9 administered iodixanol; n = 4 negative saline controls).
Interpretation and Analysis: The mean baseline apparent diffusion coefficient values are $1.64 \pm 0.05 \times 10^{-3}$ mm^2/s for the cortex and $1.75 \pm 0.06 \times 10^{-3}$ mm^2/s for the medulla. In the iodixanol group, a significant decrease in renal diffusion can be observed at 12 minutes and lasts at least 24 minutes. The decrease in diffusion occurs earlier for the cortex and lasts less than for the medulla. There is no significant modification in diffusion over time in the control group. Preliminary experience in rats reveals that dynamic diffusion-weighted MRI can be used to non-invasively evaluate *in vivo* renal hemodynamic response after injection of iodinated contrast agent.

Hemodynamic effect of iodinated high-viscosity contrast medium in the rat kidney: A diffusion-weighted MRI feasibility study. Laissy JP, Menegazzo D, Dumont E, Piekarski JD, Karila-Cohen P, Chillon S, Schouman-Claeys E. Invest Radiol 2000 Nov; 35 (11), pp. 647–52.

RESPIRATORY SYSTEM

Pulmonary Embolism
Monocrystalline Iron Oxide

Cellular/Molecular Mechanism of Action: The spatial orientation of monocrystalline iron oxide becomes altered within magnetic energy fields, which can be detected by MRI instrumentation.
Background Information: Contrast-enhanced MR angiography could be used as a non-invasive imaging technique to determine the therapeutic effect and end point in thrombolysis of acute pulmonary embolism.
Application: Contrast-enhanced MR angiography. Relevant examples include utilization as a non-invasive imaging technique to determine the therapeutic effect and end point in thrombolysis of acute pulmonary embolism in an animal model.
Route of Administration: Monocrystalline iron oxide (intravenous).
Dosage: Monocrystalline iron oxide (2 mg).
Implementation: Three-dimensional time of flight (TOF) MR angiograms are obtained after intravenous administration of Fe (2 mg) of a long-circulating monocrystalline iron oxide. Animals then receive 5,000 IU heparin and recombinant tissue plasminogen activator (1.3 mg/kg) intravenously. Magnetic resonance angiography imaging is repeated 30 minutes and 60 minutes after initiation of thrombolytic therapy.

Animal Model: New Zealand White rabbits anesthetized and mechanically ventilated (e.g., n = 18). Single (n = 12 emboli) or dual (n = 12 emboli in n = 6 animals) pulmonary emboli are created by the injection of autologous thrombi through a right internal jugular vein.
Interpretation and Analysis: Monocrystalline iron oxide nanoparticle (MION)-enhanced MR angiography accurately detects pulmonary emboli (e.g., rabbits). Thrombolysis during the observation period is successful less than 50% of the time (e.g. n = 8/18). In single emboli, the revascularization rate is approximately 50% (e.g., n = 6/12 emboli). The rate is 33% (e.g., n = 4/12 emboli) with multiple emboli. Magnetic resonance angiography allows determination of thrombus resolution or thrombus persistence. Therefore, it is entirely feasible to diagnose pulmonary embolism accurately and to monitor thrombolysis of pulmonary emboli by MION-enhanced MR angiography.

Efficacy of thrombolytic therapy in pulmonary embolism determined by MION-enhanced MRA: An experimental study in rabbits. Frank H, Loewe R, Loewe C, Oberhuber G, Schwaighofer B, Huber K, Weissleder R. Invest Radiol 1998 Dec; 33 (12), pp. 853–7.

Pulmonary/Thoracic Imaging

The application of MRI for thoracic investigations has become increasingly appealing. This resurgence has been triggered by the enormous improvements in image quality with the development of scanners with faster data-acquisition capabilities and the routine use of contrast agents. In particular, MR pulmonary angiography, an examination that once had been hampered by blurring from respiratory and cardiac motion and magnetic-susceptibility-related signal

loss, has become a robust technique in this scenario. Initial efforts and current trends have been described that focus on fast imaging protocols employing contrast agents that provide exquisite images of the pulmonary vasculature. In addition, the recent introduction of MR lung perfusion and ventilation scans has made available potentially new methods for characterizing diseases that, combined with MR pulmonary angiography, may provide a practical approach for the diagnosis of difficult conditions such as pulmonary embolism, which has long been awaited.

Magnetic resonance pulmonary angiography. Wielopolski PA. Coron Artery Dis 1999 May; 10 (3), pp. 157–75.

Pulmonary Imaging
Intravenous Contrast Agents/Hyperpolarized Noble Gases or Oxygen

Background Information: The lung has long been neglected by MRI. This is due to unique intrinsic difficulties: (i) signal loss due to cardiac pulsation and respiration; (ii) susceptibility artifacts caused by multiple air-tissue interfaces; and (iii) low proton density.
Application: Imaging of the lung to detect and characterize various disease states using MRI methodologies. Such diagnostic approaches can be used on a routine basis for (i) characterization of pulmonary nodules; (ii) staging of bronchogenic carcinoma, in particular assessment of chest wall invasion; (iii) evaluation of inflammatory activity in interstitial lung disease; (iv) acute pulmonary embolism; (v) chronic thromboembolic pulmonary hypertension; (vi) vascular involvement in malignant disease; and (vii) vascular abnormalities.
Implementation: Evaluation of stratigies that can be employed to overcome the problems of MRI of the lung, including (i) breath-hold imaging; (ii) respiratory and cardiac gating procedures; (iii) use of short repetition and echo times; (iv) increase the relaxivity of existing spins by administration of intravenous contrast agents; and (v) enrich spin density by hyperpolarized noble gases or oxygen.
Interpretation and Analysis: Improvements in scanner performance and frequent use of contrast media have increased the interest in MRI and MR angiography of the lung. Future applications include perfusion imaging using extracellular or intravascular (blood-pool) contrast agents and ventilation imaging using inhaled hyperpolarized noble gases, of paramagnetic oxygen or of aerosolized contrast agents. These techniques represent new approaches for functional lung imaging. The combination of visualization of morphology and functional assessment of ventilation and perfusion is unequaled by any other technique.

Contrast-enhanced MRI of the lung. Kauczor HU, Kreitner KF. Eur J Radiol 2000 Jun; 34 (3), pp. 196–207.

Pulmonary Imaging: Aerozolized Contrast Image Enhancement Agents/Signal Increase and Signal-to-Noise Ratios (SNRs)/Relative Aerosolized Effectiveness
Gadoteridol/Gadobutrol/Gadopentetate Dimeglumine (Magnevist)/Gadobenate Dimeglumine/ Gadopentetate Dimeglumine

Cellular/Molecular Mechanism of Action: Gadolinium atom orientation becomes altered when exposed to magnetic energy fields
Application: Detection and characterization of pulmonary disease and alterations in normal respiratory physiology.
Route of Administration: Ventilation of aerosolized contrast agent.
Semi-Synthetic Methods: Utilization of a jet nebulizer to generate aerosolized formulations.
Implementation: Aerozoliation of gadopentetate dimeglumine (Magnevist; Berlex Imaging, Montville, NJ, USA), gadobutrol (Gadovist; Schering, Jarfalla, Sweden), gadoteridol (ProHance; Bracco-Byk Gulden, Konstanz, Germany), gadobenate dimeglumine (MultiHance; Bracco-Byk Gulden, Konstanz, Germany), and gadopentetate dimeglumine (formulated with mannitol and a surface active detergent) can function as potential pulmonary ventilation contrast media for MRI procedures. In this context, aerosolized contrast agents including gadopentetate dimeglumine, gadobutrol, gadoteridol, gadobenate dimeglumine, and gadopentetate dimeglumine (formulated with mannitol and a surface active detergent) are delivered by mechanical ventilation followed by MRI (1.5 Tesla fields). T_1-weighted turbo-spin-echo (TSE) images using respiratory gating are obtained before and after a 10-minute ventilation period. Pulmonary signal intensity (SI) and SNR changes are measured for both lungs.

Animal Model: Domestic swine intubated and administered aerosolized contrast agents delivered by mechanical ventilation (n = 12 animals).
Interpretation and Analysis: Mean increases in SI range between 13.5% and 45.8% (right lung) and 14% and 39.8% (left lung). The SNR changes range from +14.7% to +46.8% and from +13.1% to +40.5% for the right and left lung, respectively. The highest SI and SNR increases are observed with the administration of gadoteridol.

The use of gadolinium for MR ventilation imaging is primarily hindered by its high viscosity and, thus, its capability of aerosolization. The medium with the lowest viscosity at room temperature (gadoteridol) shows the most promising enhancement results. Gadolinium-based contrast agents can potentially be applied as a pulmonary imaging alternative. With a reduction of ventilation duration down to 10 minutes, the method appears tolerable in a clinical setting.

Gadolinium-containing contrast agents for pulmonary ventilation magnetic resonance imaging: Preliminary results. Haage P, Karaagac S, Adam G, Spuntrup E, Pfeffer J, Gunther RW. Invest Radiol 2002 Mar; 37 (3), pp. 120–5.

Pulmonary Imaging
Hyperpolarized Noble Gases/Helium (^{3}He)/ Xenon (^{129}Xe)

Semi-Synthetic Methods: Non-radioactive noble gases with a nuclear spin 1/2 (^{3}He, ^{129}Xe) can be hyperpolarized by optical pumping. Polarization is transferred from circularly polarized laser light to the noble-gas atoms via alkali-metal vapors (spin exchange) or metastable atoms (metastability exchange). Hyperpolarization results in a non-equilibrium polarization 5 orders of magnitude higher than the Boltzmann equilibrium compensating for the several 1,000 times lower density of noble gases as compared with liquid state hydrogen concentrations in tissue, and allows for short imaging times. Hyperpolarization can be stored for a sufficiently long period of time (3 hours to 6 days) to allow for transport and application.
Implementation: Hyperpolarized gases are administered as inhalative "contrast agents," thereby facilitating the imaging of airways and airspaces. Besides the known anesthetic effect of xenon, no adverse effects are associated with its application. Pulse sequences are optimized to effectively use the non-renewable hyperpolarization before it decays or is destroyed, using fast low-flip-angles strategies to allow for dynamic/breath-hold imaging of highly diffusible (He) or soluble (Xe) gases with *in vivo* T_1-times well below 1 minute.

Since helium is not absorbed in considerable amounts, its application is restricted to the lung. Xenon has also been evaluated for imaging of diseases affecting the white matter of the central nervous system and functional studies of cerebral vascular perfusion.

Interpretation and Analysis: Magnetic resonance imaging using hyperpolarized gases is emerging as a technical challenge and opportunity for the MR community. Preliminary experience suggests potential for functional imaging of pulmonary ventilation and cerebral perfusion.

Instrumentation: Magnetic resonance systems equipped with broadband radio-frequency system and dedicated coils.

MRI using hyperpolarized noble gases. Kauczor H, Surkau R, Roberts T. Eur Radiol 1998; 8 (5), pp. 820–7.

Pulmonary Signal Intensity/Aerosol Distribution Homogeneity

Aerosolized Gadopentetate Dimeglumine/Aerosolized Gadoteridol

Route of Administration: Inhalation as aerosolized gadoteridol and gadopentetate dimeglumine.

Implementation: Compare aerosolized gadoteridol and gadopentetate dimeglumine with regard to homogeneity of aerosol distribution and relative pulmonary signal intensity (SI) changes after a 10-minute mechanical ventilation period. Logistically, 1 approach to achieving this objective can entail mechanical aerosolization with nebulized contrast medium (e.g., n = 20 procedures; n = 10 swine). Images are obtained using a respiratory-gated T_1-weighted turbo-spin-echo (TSE) sequence.

Animal Model: Intubated domestic swine (n = 10) mechanically aerosolized with nebulized contrast media.

Interpretation and Analysis: Pulmonary SI increases for the right and left lung are lower for gadopentetate dimeglumine (e.g., 26% ± 25% and 25% ± 12%, respectively), compared to gadoteridol (e.g., 45% ± 12% and 43% ± 10%, respectively). Aerosol distribution is almost invariably homogeneous in character. Therefore, both contrast agents in aerosolized form are capable of depicting pulmonary ventilation in healthy animals with lung capacities comparable to those of humans. Signal intensity differences between gadoteridol and gadopentetate dimeglumine can be explained by their considerable difference in viscosity.

Comparison of aerosolized gadoteridol and gadopentetate dimeglumine for MR ventilation imaging of the lung. Haage P, Karaagac S, Adam G, Glowinski A, Gunther RW. Magn Reson Med 2001 Oct; 46 (4), pp. 803–6.

Pulmonary Vasculature: Spin-Echo MR

Early attempts to image the pulmonary vasculature with spin-echo MRI were hampered by severe image degradation related to respiratory and cardiac pulsation artifact, susceptibility at interfaces between lung parenchyma and vessel wall, and poor contrast between flowing blood and intravascular filling defects of emboli. With the development of gradient-echo MR angiographic techniques, some of these limitations have been overcome; however, the need for multiple breath-holds and the frequent occurrence of flow-related artifacts that could simulate pulmonary emboli have diminished their clinical utility. With the development of contrast-enhanced MR angiography, many of the limitations of earlier techniques have been addressed. Images of both lungs with high signal-to-noise ratios and high contrast between flowing blood and pulmonary emboli can be acquired in a single breath-hold, during "1st-pass" imaging with extracellular contrast agents in the coronal plane. However, subsegmental vessels cannot be assessed with this approach. The technique has been refined further by imaging each lung separately in the sagittal plane; this offers higher resolution and total lung coverage and requires a shorter breath-hold. Finally, several investigators have reported preliminary data on imaging of the pulmonary vasculature with blood-pool agents, exploiting respiratory triggering or navigator echoes to eliminate the need for breath-holding for the detection of pulmonary emboli.

Pulmonary magnetic resonance angiography. Meaney JF, Johansson LO, Ahlstrom H, Prince MR. J Magn Reson Imaging 1999 Sep; 10 (3), pp. 326–38.

Respiratory: Anatomical Structures and Function/ Chronic Obstructive Pulmonary Disease (COPD)/ Ventilation Parameters

Aerosolized MRI Contrast Agents/Sulfur Hexafluoride/ Perfluorcarbons/ Hyperpolarized Noble Gases (^{3}He and ^{129}Xe)

Magnetic resonance imaging instrumentation and techniques have been developed for functional ventilation imaging. The current status and future perspectives in research and clinical applications are summarized. Morphological lung imaging is based on chest radiography and computed tomography, whereas scintigraphy is used for ventilation imaging. During recent years, MRI has emerged as a new means for functional imaging of ventilation. Aerosolized contrast agents and oxygen are used in proton imaging, whereas non-proton imaging relies on fluorine compounds, such as sulfur hexafluoride and perfluorcarbons, or on hyperpolarized noble gases, such as helium-3 [^{3}He] or xenon-129 [^{129}Xe]. All the gases are administered as inhaled "contrast agents" for imaging of the airways and airspaces. In general, straightforward images demonstrate the homogeneity of ventilation in a breath-hold and allow for determination of ventilated lung. The different properties of the different compounds enable the measurement of additional functional parameters. They comprise airspace size, regional oxygen partial pressure, and analysis of ventilation distribution, ventilation/perfusion ratios, and gas exchange, including oxygen uptake. Novel MRI techniques provide the potential for functional imaging of ventilation. The next steps include definition of the value and the potential of the different contrast mechanisms as well as determination of the significance of the functional information with regard to physiological research and patient management in COPD and others.

Assessment of lung ventilation by MR imaging: Current status and future perspectives. Kauczor HU, Hanke A, Van Beek EJ. Eur Radiol 2002 Aug; 12 (8), pp. 1962–70. Epub 2002 May 24.

EXPERIMENTAL IMAGING CONTRAST-ENHANCING AGENTS

MRI Agent (Experimental)

Polygalacturonic Acid

Cellular/Molecular Mechanism of Action: Linear carbohydrate polymer of monomeric galacturonic acid.

Considerations: Pectin and polygalacturonic acid are used extensively as gelling agents and stabilizers by the food industry. In addition, they have applications as therapeutic and diagnostic pharmaceutical agents with examples including the MRI agent LumenHance. Commercially available preparations are composed of apple and citrus pectins that consist of a mixture of partially methoxylated and/or amidated polygalacturonic acids with molecular weights ranging from 25,000 to > 100,000 kDa.

Implementation: Pectin can be chemically or enzymatically hydrolyzed to yield polygalacturonic acid fractions of diverse average molecular weight ranges and polydispersities for a variety of

uses. A simple high-performance size exclusion chromatography (HPSEC) method employing commonly available non-specialized high-performance liquid chromatography (HPLC) instrumentation can be used as a rapid molecular weight screening procedure for determining the average molecular weight range and polydispersity of polygalacturonic acid intended for use in pharmaceutical formulations. A TosoHaas G3000PWXL HPLC column, 50 mM phosphate buffer (pH approximately 6.9) mobile phase, and refractive index detection can be applied.

Interpretation and Analysis: A molecular weight calibration curve is linear for polysaccharide standards of 180 to 100,000 Da with a 0.999 coefficient of correlation. The method has been employed to screen commercially available polygalacturonic acid raw materials for average molecular weight data (Mn, Mw, and Mp) and polydispersity (Mw/Mn).

The use of high-performance size exclusion chromatography (HPSEC) as a molecular weight screening technique for polygalacturonic acid for use in pharmaceutical applications. White GW, Katona T, Zodda JP. J Pharm Biomed Anal 1999 Sep; 20 (6), pp. 905–12.

STEM CELLS

Stem Cell Migration: Brain/[Parkinson's Disease Research]
Gadolinium Rhodamine Dextran (GRID)/ Ex Vivo Stem Cell Labeling

Background Information: The ability to track stem cell transplants in the brain by *in vivo* neuroimaging will improve current understanding about of how these cells mediate functional recovery after neural transplantation. One major challenge for the development and refinement of stem cell transplantation is to map the spatial distribution and rate of *in situ* migration.

Application: Tracking transplanted stem cells in ischemia-damaged hippocampus by MRI.

Implementation: Assessment of stem cell migration applying *in vitro* labeling of populations with the novel bifunctional contrast agent GRID prior to transplantation. Detection is achieved applying both MRI and fluorescence microscopy, or with PKH26, visible exclusively under fluorescence microscopy. At different time points following engraftment, brains are evaluated by both histology and *ex vivo* MRI.

Animal Model: Rat (ischemic hippocampus).

Interpretation and Analysis: Transplanted stem cells can be identified by MRI only if prelabeled with GRID, whereas fluorescence microscopy can detect transplanted cells using either labeling reagent. Distribution of GRID-labeled stem cells established by applying MRI corresponds to results using fluorescence microscopy. Stem cells and their migration can therefore be reliably identified applying GRID-enhanced MRI methodologies.

Tracking transplanted stem cell migration using bifunctional, contrast agent-enhanced, magnetic resonance imaging. Modo M, Cash D, Mellodew K, Williams SC, Fraser SE, Meade TJ, Price J, Hodges H. Neuroimage 2002 Oct; 17 (2), pp. 803–11.

Stem Cell Migration (Mesenchymal)/Mesenchymal Stem Cells/Lymphocytes/Oligodendrocyte Progenitor CG-4 Cells/Cervical Carcinoma/Lymphocytes/[Iron Load: *Ex Vivo*]
Transfection Agents/Ferumoxides/MION-46L/ [Prussian Blue]

Cellular/Molecular Mechanism of Action: Transfection agents incorporate foreign DNA (oligonucleotide) sequences into the genome of "host" cell populations in a manner that allows or facilitates gene expression (e.g., DNA → messenger RNA (mRNA) → biological protein) and gene amplification (e.g., mitosis).

Application: Transfection labeling of mammalian and stem cell populations.

Route of Administration: Intended for intravascular applications.

Semi-Synthetic Methods: Transfection agents are incubated with ferumoxides and MION-46L in cell culture medium at various concentrations. Different viable cell types are subsequently incubated 2–48 hours with 25 μg of iron per milliliter of combined transfection agent/superparamagnetic iron oxide (TA/SPIO). Cellular labeling effectiveness can be assessed with T_2 relaxometry, MRI of labeled cell suspensions, and Prussian blue staining for iron assessment.

Cellular Model: Human mesenchymal stem cells, mouse lymphocytes, rat oligodendrocyte progenitor CG-4 cells, and human cervical carcinoma cells.

Implementation: Evaluation of the proliferation and viability of mesenchymal stem cells and human cervical carcinoma cells labeled with a combination of TAs and ferumoxides.

Interpretation and Analysis: When ferumoxides-TA or MION-46L-TA are utilized, intracytoplasmic particles stained with Prussian blue stain can be detected in all cell types with a labeling efficiency of nearly 100%. Limited or no uptake can be observed for cells incubated with ferumoxides or MION-46L alone. For TA-SPIO-labeled cells, MR images and relaxometry analysis reveal a 50–90% decrease in signal intensity and a more than 40-fold increase in T_2s. Cell viability varies from 103.7% ± 9 to 123.0% ± 9 compared with control cell viability at 9 days, while cell proliferation is not affected by endosomal incorporation of SPIO nanoparticles. Iron concentrations vary with ferumoxides-TA combinations and cells with a maximum of 30.1 pg ± 3.7 of iron per cell for labeled mesenchymal stem cells. Therefore, in summary, magnetic labeling of mammalian cells aided by the use of ferumoxides and TAs is possible and may enable cellular MRI and tracking in experimental and clinical settings.

Clinically applicable labeling of mammalian and stem cells by combining superparamagnetic iron oxides and transfection agents. Frank JA, Miller BR, Arbab AS, Zywicke HA, Jordan EK, Lewis BK, Bryant LH Jr, Bulte JW. Radiology 2003 Aug; 228 (2), pp. 480–7.

Stem Cells (Embryonic)/Migration within the Central Nervous System (CNS)/Lesion Traffic of Stem Cells
MRI Agent Cell Labeling/Lipofection Cell Labeling Methodology

Background Information: *In vivo* monitoring of stem cells after grafting is essential for a better understanding of their migrational dynamics and differentiation processes and of their regeneration potential. Migration of endogenous or grafted stem cells and neurons has been described in vertebrate brain, both under normal conditions from the subventricular zone along the rostral migratory stream and under pathophysiological conditions, such as degeneration or focal cerebral ischemia. However, such relied on invasive analysis of brain sections applied in combination with appropriate staining techniques.

Application: Embryonic stem cells could theoretically function as a selective delivery modality for diagnostic and therapeutic pharmaceutical agents. The concept of labeling stem cell–like populations could also function as a methodology for monitoring the therapeutic or diagnostic infiltration of desirable cell types into specific lesions (e.g., CNS ischemic foci or Parkinson's disease).

Route of Administration: Variable, but most frequently will be infused intravascularly or by direct injection into pathologic lesions.

Implementation: Mapping the *in vivo* dynamics of cell migration over a prolonged period of time. Embryonic stem (ES) cells constitutively expressing green fluorescent protein (GFP) can be labeled with a lipofection procedure employing an MRI contrast agent. Contrast agent–labeled cells are then implanted into the CNS.

Animal Model: Focal cerebral ischemia are induced 2 weeks before implantation of ES cells into the healthy, contralateral hemisphere (rats).

Interpretation and Analysis: Magnetic resonance imaging at 78-μm isotropic spatial resolution permits the observation of implanted cells with high contrast against host tissue background that can be confirmed by GFP detection profiles. During a 3-week period, cells migrate along the corpus callosum into the ventricular walls and massively populate the border zone of damaged brain tissue on the hemisphere opposite to the implantation sites. Embryonic stem cells have high migrational dynamics and are attracted to induced cerebral lesion areas in a relatively selective manner. Techniques employing labeled ES cells are ideally suited for the noninvasive imaging of cell migration, engraftment, and morphological differentiation at high spatial and temporal resolution.

Monitoring of implanted stem cell migration *in vivo*: A highly resolved *in vivo* magnetic resonance imaging investigation of experimental stroke in rat. Hoehn M, Kustermann E, Blunk J, Wiedermann D, Trapp T, Wecker S, Focking M, Arnold H, Hescheler J, Fleischmann BK, Schwindt W, Buhrle C. Proc Natl Acad Sci U S A 2002 Dec 10; 99 (25), pp. 16267–72. Epub 2002 Nov 20.

18 Nuclear Planar Scintigraphy

GENERAL

Artifact Reduction and Imaging Enhancement/ Target to Background Ratio Enhancement/ Acceleration of Liberated Nucleotide Excretion/ Neoplastic Disease: Carcinoembryonic Antigen (CEA)
$CaNa_2EDTA$/[^{111}Indium] ([^{111}In])-Anti-CEA MAb/ [^{90}Y]-Anti-CEA Monoclonal Antibody (Mab)/ Diethylenetriamine Pentaacetic Acid (DTPA) Chelate-Labeled Peptides

Cellular/Molecular Mechanism of Action: $CaNa_2EDTA$ is an organic compound that is capable of chelating the "free" forms of various elemental ions like [^{111}In] and [^{90}Y].
Application: The chelation group $CaNa_2EDTA$ can be applied to bind [^{111}In] and promote [^{90}Y] liberation from DTPA chelation groups for the purpose of generating scintigraphic images of relatively high specificity, selectivity, lesion resolution, and superior target to background ratios.
Semi-Synthetic Methods: Labeling of murine MAb F33-104 with binding avidity for CEA using the diethylenetriamine pentaacetic-anhydride method for the introduction of DTPA chelations groups capable of binding [^{111}In] and [^{90}Y] radioisotopes.
Implementation: Evaluation of murine [^{111}In]-DTPA and [^{90}Y]-DTPA-labeled anti-CEA MAb to determine the influence of $CaNa_2EDTA$ on the *in vitro* loss of radioactivity in serum. Complementary investigations can involve delineation of the effects of $CaNa_2EDTA$, administered before and after [^{111}In]-MAb or [^{90}Y]-MAb, on the biodistribution of radioactive isotopes. Formulations of 0.9% NaCl can be administered as a control in both *in vitro* and *in vivo* investigations.

Animal Model: Murine (nude mice bearing human colon adenocarcinoma LS 180 tumors expressing CEA or negative reference controls consisting of human pulmonary carcinoma PC 9 tumor expressing no CEA).
Interpretation and Analysis: $CaNa_2EDTA$ does not cause any decrease in levels of radioactivity of radiolabeled MAbs. Pre- and posttreatment with $CaNa_2EDTA$ reduces radioctivity in both specific and non-specific tumors at 72 hours after [^{111}In]-MAb injection, resulting in an increase of the specific tumor-to-non-specific-tumor radioactivity ratio. The levels of hepatic and renal radioactivity are also subsequently decreased by $CaNa_2EDTA$. On the other hand, $CaNa_2EDTA$ pre- and posttreatment reduces levels of bony, hepatic, and renal radioactivity at 24, 48, and 72 hours, respectively, after [^{90}Y]-MAb injection, although it has no effect on tumor radioactivity. Therefore, pre- and posttreatment with $CaNa_2EDTA$ would be of great use in humans who undergo radioimmunodiagnostics (RID) or radioimmunotherapy (RIT) with [^{111}In]-MAb and [^{90}Y]-MAb accompanied by disassociation of the labeled radionuclides.

$CaNa_2EDTA$ for improvement of radioimmunodetection and radioimmunotherapy with [^{111}In] and [^{90}Y]-DTPA-anti-CEA MAbs in nude mice bearing human colorectal cancer. Watanabe N, Oriuchi N, Endo K, Inoue T, Kuroki M, Matsuoka Y, Tanada S, Murata H, Kim EE, Sasaki Y. J Nucl Med 2000 Feb; 41 (2), pp. 337–44.

Interference/Incompatible Combinations
[Gd]-Diethylenetriamine Pentaacetic Acid (DTPA) and Gallium-67 ([^{67}Ga])-Citrate

Background Information: Previously, it has been reported that administration of the paramagnetic contrast agent [Gd]-DTPA (gadopentate) prior to [^{67}Ga]-citrate can lead to poor quality scans, characterized by pronounced bone uptake and a loss of tumor avidity. Suggestions that have been offered to account for the occurrence of such profiles include *in vivo* dissociation or the presence of free DTPA in formulations.
Route of Administration: Commercial gadopentate and gadodiamide contrast agents (intravascular); [^{67}Ga]-citrate (intravenous).
Dosage: Commercial gadopentate and gadodiamide contrast agents ($\leq$ 5 mmol/kg).
Implementation: Determine the extent that gadopentate and gadodiamide contrast agents influence 4 hours later the bone uptake and tumor avidity for [^{67}Ga] preparations. Biodistribution profiles are then determined at 24 hours postinjection. Formulations of [Gd]-DTPA containing excess Gd or DTPA are also evaluated for comparison. The model is verified by identical studies using inactive [Ga^{+3}] or [Fe^{+3}] at 0.1 mmol/kg. The effects of [Gd^{+3}] or the DTPA ligand at this dose can also be determined.

Animal Model: Murine (mature female BALB/c mice).
Interpretation and Analysis: Administration of [Gd]-DTPA does not produce marked changes in [^{67}Ga] biodistribution. Minor changes occur after 0. 1mmol/kg [Gd^{+3}] or the DTPA ligand, but cannot account for observed scan changes. Inactive [Ga^{+3}] or [Fe^{+3}] causes a marked reduction of [^{67}Ga] uptake in all tissues except bone, leading to greatly increased total bone:total soft tissue ratios. Therefore, [Gd]-DTPA or its constituents do not significantly alter the biodistribution of [^{67}Ga]-citrate (e.g., murine model). Extrapolating these findings to the human situation suggests that the previously reported scan changes may have been the result of other undetermined factors.

The effect of gadolinium-based MRI contrast agents on the biodistribution of [^{67}Ga]. Baker RJ. Nucl Med Commun 2002 Feb; 23 (2), pp. 139–45.

AMYLOID AND AMYLOIDOSIS

Amyloid/Arthropathy and Hepatic Amyloidosis (Avian Model)
[^{99m}Technetium] ([^{99m}Tc])-MAMA-Chrysamine G (CG)/ Chrysamine G/Congo Red

Cellular/Molecular Mechanism of Action: The radiopharmaceutical [^{99m}Tc]-MAMA-CG is a radiolabeled chrysamine G analogue of Congo red, which is a staining reagent used to selectively detect amyloid deposits present within histopathology tissue sections.

Application: Utilization as a non-invasive diagnostic probe for the *in vivo* detection of amyloid deposits within organ systems.
Considerations: Systemic amyloidosis is currently diagnosed histologically using Congo red staining or *in vivo* using [^{123}I]-labeled serum amyloid P component ([^{123}I]-SAP)for scintigraphic imaging.
Animal Model: Avian (chicken)
Interpretation and Analysis: Scintigraphic imaging *in vivo* with [^{99m}Tc]-MAMA-CG performed in animal models with spontaneous joint amyloidosis display images of radiopharmaceutical uptake in amyloid-loaded organs (liver, joints) at $\geq$ 10 minutes postinjection. Scintigraphic imaging with [^{123}I]-SAP also detects binding to hepatic amyloid deposits. However, up to 11 hours after injection no radioactivity can be appreciated in amyloid positive joints. Autoradiography (*in vitro*) performed on sections of joints with *Enterococcus faecalis*-induced amyloid arthropathy (chjAA) reveals a failure of [^{99m}Tc]-MAMA-CG to bind significantly to amyloid deposits in the presence of 10 μM Congo red reagent. The specificity of [^{99m}Tc]-MAMA-CG localization has also been established by the absence of *in vitro* and *in vivo* binding of [^{99m}Tc]-MAMA-CG to organs devoid of amyloid deposits. Acute toxic reactions with [^{99m}Tc]-MAMA-CG have not been observed (avian).

Evaluation of [^{99m}Tc]-MAMA-chrysamine G as an *in vivo* probe for amyloidosis. Dezutter NA, Landman WJ, Jager PL, de Groot TJ, Dupont PJ, Tooten PC, Zekarias B, Gruys E, Verbruggen AM. Amyloid 2001 Sep; 8 (3), pp. 202–14.

Amyloid Beta (Abeta) Plaque Deposits: Central Nervous System (CNS)/Alzheimer's Disease (AD) *[^{123}I/^{125}I]IMPY/6-Iodo-2-(4′-Dimethylamino-) Phenyl-Imidazo[1,2-a]Pyridine/Thioflavin Dye*

Background Information: Development of small molecular probes for *in vivo* labeling and detection of beta-amyloid (abeta) plaques in patients of AD is of significant scientific interest, and it may also assist the development of drugs targeting abeta plaques for treatment of AD.
Application: Detection and evaluation of amyloid plaque deposits.
Route of Administration: [^{125}I]IMPY (intravascular).
Semi-Synthetic Methods: A novel probe, [^{123}I/^{125}I]IMPY, 6-iodo-2-(4′-dimethylamino-)phenyl-imidazo[1,2-a]pyridine, can be prepared using an iododestannylation reaction catalyzed by hydrogen peroxide.
Implementation: Characterization of amyloid plaque deposits (*in vivo*).
Animal Model: Murine (transgenic mice model (Tg2576) engineered to produce excess amyloid plaques within the brain).
Interpretation and Analysis: The modified thioflavin-T derivative displays good binding affinity for preformed synthetic abeta$_{40}$ aggregates in solution ($K_i = 15 \pm 5$ nM) and shows selective plaque labeling on postmortem AD brain sections. Biodistribution of [^{125}I]IMPY exhibits excellent brain uptake (2.9% initial dose/brain at 2 minutes) and fast washout (0.2% initial dose/brain at 60 minutes). These properties are highly desirable for amyloid plaque imaging agents. *Ex vivo* autoradiograms of brain sections of Tg2576 mice obtained 4 hours after an intravenous injection of [^{125}I]IMPY clearly display distinct plaque labeling with low background levels of activity. When the same brain section is stained with the fluorescent dye thioflavin-S, the same abeta plaques show prominent fluorescent labeling consistent with results observed from autoradiogram analyses. Radioiodinated IMPY demonstrates desirable characteristics for *in vivo* labeling of abeta plaques, and it may be useful as a molecular imaging agent to study amyloidogenesis in the brain of living AD patients.

IMPY: An improved thioflavin-T derivative for *in vivo* labeling of beta-amyloid plaques. Kung MP, Hou C, Zhuang ZP, Zhang B, Skovronsky D, Trojanowski JQ, Lee VM, Kung HF. Brain Res 2002 Nov 29; 956 (2), pp. 202–10.

Amyloid Beta (Abeta) Deposits: Central Nervous System (CNS)/Alzheimer's Disease (AD)/ Vascular Amyloid Deposits *[^{99m}Technetium] ([^{99m}Tc])-MAMA-CG/Chrysamine G*

Cellular/Molecular Mechanism of Action: Chrysamine G (CG), an analogue of Congo red, is known to bind *in vitro* to the beta-amyloid protein (abeta 10-43) and to homogenates of several regions of the brains of AD patients.
Application: Detection of beta-amyloid deposits similar to those recognized in the CNS of cases suffering from AD.
Route of Administration: Intravascular.
Semi-Synthetic Methods: Synthesis of a conjugate of 2-(acetamido)-CG with a bis-S-trityl protected monoamide-monoaminedithiol (MAMA-Tr$_2$) tetraligand that is efficiently deprotected and [^{99m}Tc] labeled with a 75% yield to obtain [^{99m}Tc]-MAMA-CG.
Implementation: Evaluation of hepatobiliary clearance and brain uptake and selective detection of beta-amyloid deposits similar to those found in the CNS in conditions of AD.
Animal Model: Murine
Interpretation and Analysis: In mice, [^{99m}Tc]-MAMA-CG is cleared mainly by the hepatobiliary system, resulting in a fast blood clearance. Brain uptake of [^{99m}Tc]-MAMA-CG is low. Co-injection with the blood-pool tracer iodine-125 human serum albumin ([^{125}I]-HSA) demonstrates a brain/blood activity ratio for [^{99m}Tc]-MAMA-CG that is significantly higher than that for [^{125}I]-HSA (t test for dependent samples, $p < 0.02$), indicating the ability of [^{99m}Tc]-MAMA-CG to cross the blood-brain barrier. *In vitro* autoradiography reveals a pronounced binding of [^{99m}Tc]-MAMA-CG to beta-amyloid deposits in autopsy sections of the parietal and occipital cortex of an AD patient as compared with controls. Adding 10 μM Congo red during incubation displaces the binding of [^{99m}Tc]-MAMA-CG. Congo red staining and autoradiography both identify the same lesions. [^{99m}Tc]-MAMA-CG seems to bind selectively to beta-amyloid deposition in human brain parenchyma and blood vessels *in vitro* and thus might be a lead compound for further development of a useful tracer agent for the *in vivo* diagnosis of AD.

[^{99m}Tc]-MAMA-chrysamine G, a probe for beta-amyloid protein of Alzheimer's disease. Dezutter NA, Dom RJ, de Groot TJ, Bormans GM, Verbruggen AM. Eur J Nucl Med 1999 Nov; 26 (11), pp. 1392–9.

Amyloid Deposit Detection *[^{123}I]-Labeled Serum Amyloid P Component: Human vs Murine*

Cellular/Molecular Mechanism of Action: Amyloid P component binds to amyloid A deposits.
Application: Utilization as a non-invasive diagnostic probe for the *in vivo* detection of amyloid A deposits within organ systems.
Route of Administration: [^{123}I]-labeled serum amyloid P component (intravenous).
Interpretation and Analysis: Highly specific, high-resolution scintigraphic images of amyloid-laden organs in mice with experimentally-induced amyloid A protein (AA) amyloidosis can be ob-

tained with [^{123}I]-labeled serum amyloid P component. Interestingly, a much higher proportion (up to 40%) of the injected dose of heterologous human amyloid P localizes within amyloid deposits and is retained there than occurs with isologous mouse amyloid P, indicating that human amyloid P binds more avidly to mouse AA fibrils than does mouse amyloid P. Specificity of amyloid P localization has been established based on the observation of a failure of the related proteins, human C-reactive protein and Limulus C-reactive protein, to deposit significantly in amyloid and by the absence of human amyloid P deposition in non-amyloidotic organs. However, only partial correlation is observed between the quantity of amyloid P localized and 2 independent estimates, histology examination and RIA analyses for amyloid A of the amount of amyloid in particular organs. Uncertainty exists as to which of the 3 methods most accurately reflects the extent or clinical significance of amyloid deposition. However, the *in vivo* localization of radiolabeled serum amyloid P, detectable and quantifiable by gamma camera imaging, is apparently extremely sensitive. Based on the ability of serum amyloid P to function in this capacity, it may have potential applicability as a specific targeting agent for diagnostic and even therapeutic purposes in clinical amyloidosis.

Specific localization and imaging of amyloid deposits *in vivo* using [^{123}I]-labeled serum amyloid P component. Hawkins PN, Myers MJ, Epenetos AA, Caspi D, Pepys MB. J Exp Med 1988 Mar 1; 167 (3), pp. 903–13.

Amyloid: Familial Amyloid Polyneuropathy/ Hepatic Posttransplant Renal Amyloid Deposition *[^{123}I]-Labeled Serum Amyloid P Component*

Cellular/Molecular Mechanism of Action: Serum amyloid P component (SAP) recognizes and physically binds to amyloid deposits.

Background Information: Familial amyloid polyneuropathy (FAP) associated with transthyretin (TTR) mutations is the commonest type of hereditary amyloidosis. Plasma TTR is produced almost exclusively in the liver. Orthotopic liver transplantation is the only available treatment, although the clinical outcome varies. Serum amyloid P component scintigraphy is a method for identifying and quantitatively monitoring amyloid deposits *in vivo*, but it has not previously been used to study the outcome of visceral amyloid deposits in FAP following liver transplantation.

Application: Detection and characterization of amyloid deposits analogous to those associated with Alzheimer's disease and other conditions.

Route of Administration: Intravascular.

Implementation: Evaluation of amyloid lesions applying whole-body scintigraphy following [^{123}I]-SAP injection in conditions of amyloid polyneuropathy, asymptomatic gene carriers, and postorthotopic liver transplantation.

Human Model: Cases of familial amyloid polyneuropathy (n = 17) associated with the expression of TTR Met30 in addition to asymptomatic gene carriers (n = 5). Follow-up studies of interest can include general cases (n = 10), some of whom have undergone orthotopic liver transplantation 1–5 years beforehand (n = 8/10 cases).

Interpretation and Analysis: An abnormal uptake of [^{123}I]-SAP can be appreciated in the vast majority of cases with FAP including the (i) kidneys (n = 17); (ii) spleen (n = 5/17); and (iii) adrenal gland (n = 3/17). Renal amyloid deposits can also be appreciated in some asymptomatic carriers (n = 3/5). Follow-up studies 1–5 years after liver transplantation show that there is substantial regression of visceral amyloid deposits in some cases (n = 2/10 compared to n = 3/10 modest improvement; n = 2 unchanged amyloid deposits). Therefore, [^{123}I]-SAP scintigraphy can identify unsuspected visceral amyloid cases with FAP due to TTR Met30. The universal presence of renal amyloid probably underlies the high frequency of renal failure that occurs in FAP following liver transplantation. The variable capacity of patients to mobilize amyloid deposits following liver transplantation may contribute to their long-term clinical outcome.

Serum amyloid P component scintigraphy in familial amyloid polyneuropathy: Regression of visceral amyloid following liver transplantation. Rydh A, Suhr O, Hietala SO, Ahlström KR, Pepys MB, Hawkins PN. Eur J Nucl Med 1998 Jul; 25 (7), pp. 709–13.

Amyloidosis of β_2-Microglobulin Origin *[^{111}Indium] ([^{111}In])-Recombinant Human β_2mH5 (Rhβ_2mH5)*

Cellular/Molecular Mechanism of Action: β_2-microglobulin recognizes and physically (chemically) binds to amyloid composed of β_2-microglobulin (β_2m) deposits.

Background Information: Amyloid of β_2m origin can be diagnosed using [^{131}I]-radiolabeled-β_2m scintigraphy in patients with uremia and hemodialysis treatment. As the tracer β_2m is isolated from another case, it carries the common risks, including viral infections such as hepatitis B and C and human immunodeficiency virus (HIV), which are associated with human plasma products.

Application: The *in vitro* production of recombinant human β_2m yields a protein fraction that is devoid of any potential risk of exposing recipients to various viral pathogens. Purified protein fractions can then be radiolabeled for the purpose of detecting and characterizing various conditions of amyloidosis.

Route of Administration: [^{111}In]-rhβ_2mH5 (intravenous).

Semi-Synthetic Methods: β_2m-type amyloid can be produced *in vitro* as rhβ_2m in *Escherichia coli* populations. The expression vector pASK40DeltaLβ_2m(His)5 can be used because it contains a C-terminal (His)5-tag for purification via immobilized metal ion affinity chromatography (IMAC). Size exclusion chromatography on a Superose 12 column can be used as a 2nd purification step. The isolated rhβ_2mH5 reacts in an immunochemically identical manner to native human β_2m, and can be identified as a single band of approximately 11.8 kDa when analyzed by Western blot immunodetection methodologies. Additionally, fractions can be visualized as a single spot in 2-dimensional gel electrophoresis (2D-PAGE: expected molecular mass = 12,415.8 Da). Uniformity can be further proven by crystallization and N-terminal amino-acid sequence analysis.

Implementation: Evaluation of β_2m-amyloidosis conditions applying sterile preparations of rhβ_2mH5 radiolabeled with [^{111}In] to produce [^{111}In]-rhβ_2mH5.

Human Model: Cases managed with hemodialysis (± known β_2m-amyloidosis).

Interpretation and Analysis: The [^{111}In]-rhβ_2mH5 tracer localizes specifically to particular areas known to contain amyloid. Rhβ_2mH5 preparations therefore are suitable for the *in vivo* detection of deposits of β_2m-type amyloid contained within organs and fulfill the requirements of a tracer for common use. Finally, the use of [^{111}In] instead of [^{131}I] reduces the radioactive load and results in higher lesion resolution.

Production of recombinant human β_2-microglobulin for scintigraphic diagnosis of amyloidosis in uremia and hemodialysis. Linke RP, Schäeffer J, Gielow P, Lindner P, Lottspeich F, Plückthun A, Weiss EH. Eur J Biochem 2000 Feb; 267 (3), pp. 627–33.

APOPTOSIS

Apoptosis
[^{99m}Technetium] ([^{99m}Tc])-Hydrazinonicotinamido (HYNIC)-Annexin V

Background Information: [^{99m}Tc]-HYNIC-annexin V is a novel tracer for *in vivo* imaging of cellular apoptosis.
Route of Administration: [^{99m}Tc]-HYNIC-annexin V (intravenous).
Dosage: [^{99m}Tc]-HYNIC-annexin V (250 MBq).
Implementation: Imaging is initiated with a transmission scan using a [^{57}Co]-flood source to obtain a map of the regional "thickness" of the volunteer. [^{99m}Tc]-HYNIC-annexin V is then injected directly, followed by a 30-minute dynamic study. Whole-body scans are obtained at about 30 minutes, 3 hours, 6 hours, and 24 hours after administration. Organ uptake is determined after correction for background, scatter, and attenuation. The MIRDOSE3.1 program can be used to calculate organ-absorbed doses and effective dose. Signs of adverse effects can be detected by monitoring renal and liver function, hematology, blood coagulation, and vital signs (blood pressure, pulse, respiration rate, temperature, and electrocardiogram).
Human Model: Healthy male volunteers (n = 6).
Interpretation and Analysis: The kidneys accumulate 49.7 ± 8.1 percent injected dose (%ID) at 3 hours after injection; the liver, 13.1 ± 1.0 %ID; the red marrow, 9.2 ± 1.8 %ID; and the spleen, 4.6 ± 1.6 %ID. More than 90% of the blood activity is cleared with a half-life of 24 ± 3 minutes. The biologic half-life of the activity registered over the total body is long (69 ± 7 hours). Excretion of the activity is almost exclusively through the urine (22.5 ± 3.5 %ID at 24 hours), and hardly any activity is seen in the bowel or feces. Absorbed doses are found to be 196 ± 31 μGy/MBq for the kidneys, 41 ± 12 μGy/MBq for the spleen, 16.9 ± 1.3 μGy/MBq for the liver, and 8.4 ± 0.9 μGy/MBq for the red marrow. The effective dose is approximately 11.0 ± 0.8 μSv/MBq, or 2.8 ± 0.2 mSv for the average injected activity of 250 MBq. No adverse effects are usually observed. Therefore, [^{99m}Tc]-HYNIC-annexin V is a safe radiopharmaceutical, having a favorable biodistribution for imaging of apoptosis in the abdominal cavity as well as the thoracic region with an acceptable radiation dose.
Instrumentation: A dual-head gamma camera was used to acquire conjugate anterior and posterior views.

Safety, biodistribution, and dosimetry of [^{99m}Tc]-HYNIC-annexin V, a novel human recombinant annexin V for human application. Kemerink GJ, Liu X, Kieffer D, Ceyssens S, Mortelmans L, Verbruggen AM, Steinmetz ND, Vanderheyden JL, Green AM, Verbeke K. J Nucl Med 2003 Jun; 44 (6), pp. 947–52.

Apoptosis/Hepatic and Thymic Phenomenon
[^{99m}Technetium] ([^{99m}Tc])-HYNIC-Annexin V

Cellular/Molecular Mechanism of Action: Annexin V, a 32-kDa endogenous human protein, has a high affinity for membrane-bound phosphatidylserine.
Background Information: Either inadequate or excessive apoptosis (programmed cell death) is associated with many diseases. A method for imaging apoptosis *in vivo*, rather than requiring histologic evaluation of tissue, could assist with therapeutic decision-making requirements associated with these disorders. Programmed cell death is associated with a well-choreographed series of events resulting in the cessation of normal cell function and the ultimate disappearance of the cell. One component of apoptosis is signaling adjacent cells that this cell is committing suicide by externalizing phosphatidylserine to the outer leaflet of the cell membrane.
Application: Technetium-^{99m} HYNIC-annexin V can be utilized for the *in vivo* detection and quantification of apoptosis phenomenon in tissues and organ systems. Dexamethasone can be applied to induce thymic apoptosis.
Route of Administration: [^{99m}Tc]-HYNIC-annexin V (intravenous).
Dosage: Dexamethasone (1–20 mg/kg) 5 hours prior to [^{99m}Tc]-HYNIC-annexin.
Semi-Synthetic Methods: Covalent coupling of annexin V with the bifunctional hydrazinonicotinamide reagent (HYNIC) for the preparation of [^{99m}Tc]-HYNIC-annexin V.
Implementation: Detection of apoptosis phenomenon in the liver and thymus. Biodistribution analysis of [^{99m}Tc]-HYNIC-annexin V is performed (in rats) 10–180 minutes following intravenous injection. Delineation of the degree of apoptosis required for *in vivo* localization of [^{99m}Tc]-annexin V (mice) can be determined with the aid of dexamethasone administered 5 hours prior to [^{99m}Tc]-HYNIC-annexin V. The thymus is then excised 1 hour after radiolabeled HYNIC-annexin V injection; thymocytes isolated, incubated with Hoechst 33342 followed by propidium iodide, and analyzed on a fluorescence-activated cell sorter. Each sorted cell population is counted in a scintillation counter. Evaluation of [^{99m}Tc]-HYNIC-annexin V as a tracer for external radionuclide imaging of apoptotic cell death can be performed by radionuclide imaging 1 hour following injection of anti-Fas IgG in Fas-defective mice (lpr/lpr mice) and wild-type mice.
Animal Model: Rat and mouse.
Interpretation and Analysis: Biodistribution analysis of [^{99m}Tc]-HYNIC-annexin V in rats reveals a blood clearance half-time of less than 10 minutes. The kidneys have the highest concentration of radioactivity at any particular time point. Studies in the mouse thymus have demonstrated a 40-fold increase in [^{99m}Tc]-HYNIC-annexin V concentration in apoptotic thymocytes compared with viable cell populations. A correlation value of r = 0.78 can be appreciated between radioactivity and flow cytometric and histologic evidence of apoptosis. Imaging studies in lpr/lpr and wild-type mice show a substantial increase in activity within the liver of wild-type mice treated with anti-Fas, while there is no significant change, irrespective of anti-Fas administration, in lpr/lpr mice. Excellent imaging of hepatic apoptosis can be obtained in wild-type mice 30 minutes after injection of [^{99m}Tc]-HYNIC-annexin V. Imaging results are consistent with histologic analysis.

Technetium-^{99m} HYNIC-annexin V: A potential radiopharmaceutical for the *in vivo* detection of apoptosis. Ohtsuki K, Akashi K, Aoka Y, Blankenberg FG, Kopiwoda S, Tait JF, Strauss HW. Eur J Nucl Med 1999 Oct; 26 (10), pp. 1251–8.

Apoptosis: Neoplastic Disease States/ Chemotherapeutic-Induced
[^{99m}Technetium] ([^{99m}Tc])-Annexin V/ [Cyclophosphamide]/TUNEL Tissue Analysis

Cellular/Molecular Mechanism of Action: Annexin V is a human protein that possesses a high affinity for phosphatidylserine.
Application: Annexin V can be labeled with [^{99m}Tc] to detect *in vivo* apoptosis phenomenon.
Route of Administration: [^{99m}Tc]-annexin V (intravenous).
Semi-Synthetic Methods: Radiolabeling of annexin V with [^{99m}Tc] (specific activity, 3.0 MBq/μg protein).
Implementation: Evaluate the effectiveness of [^{99m}Tc]-annexin V for determining the degree of apoptosis induced in inoculated allogenic hepatoma lesions 20 hours after the 1st dose of chemotherapy (e.g., cyclophosphamide). Radioactivity within specific tissues is

then determined 6 hours after [^{99m}Tc]-annexin V administration. Tumor uptake of [^{14}C]-iodoanitpyrine can be employed as an indicator or marker for tumor blood flow. Terminal deoxynucleotidyl transferase-mediated deoxyuridine triphosphate nick-end labeling (TUNEL) of tissue harvested at necropsy is then performed to detect evidence of tumor apoptosis phenomenon.

Animal Model: Rat (inoculated with allogenic engraphed hepatoma cells [KDH-8] in the left calf muscle, followed 11 days later by randomized administration of a single dose of cyclophosphamide [150 mg/kg intraperitoneally]. Reference controls include rats not receiving doses of chemotherapeutic agent).

Interpretation and Analysis: Cyclophosphamide treatment significantly increases tumor uptake (percentage activity of injected dose per gram of tissue after normalization to the animal's weight [%ID/g/kg] of [^{99m}Tc]-annexin V, 0.070 ± 0.007 %ID/g/kg for treated rats and 0.046 ± 0.009 %ID/g/kg for controls, $p < 0.001$). [^{14}C]-Iodoantipyrine uptake is similar between treated and untreated groups. The number of TUNEL-positive cells in the tumor is significantly larger in treated rats (297.70 ± 50.34 cells/mm^2) than in control rats (168.45 ± 23.60 cells/mm^2, $p < 0.001$). Tumor uptake of [^{99m}Tc]-annexin V correlates with the number of TUNEL-positive cells within tumor specimens ($r = 0.712$; $p < 0.001$). Tumor uptake of [^{99m}Tc]-annexin V is significantly increased by a single dose of cyclophosphamide treatment, and the increase is concordant with the number of TUNEL-positive cells detected within tumors. Such observations suggest the utility of [^{99m}Tc]-annexin V as a non-invasive means for assessing tumor response, although further testing, including clinical evaluation, is required.

Detection of apoptotic tumor response *in vivo* after a single dose of chemotherapy with [^{99m}Tc]-annexin V. Mochizuki T, Kuge Y, Zhao S, Tsukamoto E, Hosokawa M, Strauss HW, Blankenberg FG, Tait JF, Tamaki N. J Nucl Med 2003 Jan; 44 (1), pp. 92–7.

Apoptosis and Oncosis: Cardiac Myocardial Cells/ Apoptosis: Doxorubicin-Induced/Oncosis: Isoproterenol-Induced
[^{111}Indium] ([^{111}In])-Antimyosin Antibody/ [^{99m}Technetium] ([^{99m}Tc])-Glucaric Acid

Background Information: Non-invasive imaging techniques would be highly desirable to differentiate oncotic from apoptotic cell death.

Application: [^{99m}Tc]-glucaric acid can be applied to detect oncotic myocardial cell death. Conversely, radiolabeled antimyosin is capable of detecting both oncotic and apoptotic types of myocardial cell death.

Route of Administration: [^{111}In]-antimyosin and [^{99m}Tc]-glucaric acid (intravenous).

Implementation: Evaluation of the ability for [^{111}In]-antimyosin antibody and [^{99m}Tc]-glucaric acid to be applied together in a manner that allows detection of and differentiation between doxorubicin-induced myocardial apoptosis and isoproterenol-induced myocardial oncosis. Scanning electron microscopy, DNA laddering, terminal deoxynucleotidyl transferase-mediated deoxyuridine triphosphate nick-end labeling (TUNEL), [^{111}In]-antimyosin antibody, and [^{99m}Tc]-glucaric acid can be collectively utilized *in vitro* and *in vivo* to detect doxorubicin-induced apoptosis or isoproterenol-induced myocardial oncosis.

***Ex Vivo* Model:** Cultured rat H9C2 embryonic cardiocytes. In this context, myocardial cell apoptosis can be induced by serial exposure of H9C2 embryonic cardiocytes to diluted doxorubicin formulations.

Animal Model: Rats (CD1 strain for *in vivo* investigations). Myocardial apoptosis can be induced *in vivo* in rats by doxorubicin administration. Related investigations can employ heat or subcutaneous isoproterenol administration to induce myocardial oncosis.

Interpretation and Analysis: Scanning electron microscopy, DNA laddering, and TUNEL staining of H9C2 cardiocytes treated with doxorubicin all show cell death by apoptosis. Rat hearts treated with doxorubicin (10 and 20 mg/kg) are DNA ladder-positive and localize significantly greater [^{111}In]-antimyosin antibody (mean + standard deviation, 0.1942 ± 0.0150 percent injected dose per gram [%ID/g] and 0.1825 ± 0.0238 %ID/g, respectively) than normal hearts (0.1154 ± 0.0270 %ID/g, $p < 0.05$). Increases in myocardial [^{99m}Tc]-glucaric acid activity cannot be observed in rat hearts after 6, 12, and 24 hours of doxorubicin injection (0.0311 ± 0.0066 %ID/g, 0.0356 ± 0.007 %ID/g, and 0.0368 ± 0.0047 %ID/g, respectively; control hearts, 0.0352 ± 0.0099 %ID/g; p = not significant). Alternatively, [^{99m}Tc]-glucaric acid uptake is significantly greater in isoproterenol-induced oncotic hearts (0.1256 ± 0.1023 %ID/g) than in controls ($p < 0.0001$). [^{99m}Tc]-glucaric acid is avid only for the oncotic myocardium. Antimyosin, on the other hand, is positive in both oncotic and apoptotic myocardium.

Indium 111 antimyosin and [^{99m}Tc] glucaric acid for non-invasive identification of oncotic and apoptotic myocardial necrosis. Khaw BA, Silva JD, Petrov A, Hartner W. J Nucl Cardiol 2002 Sep–Oct; 9 (5), pp. 471–81.

GENE EXPRESSION: *IN VIVO* DETECTION

Gene Expression/Herpes Simplex Virus Type I Thymidine Kinase: HSV1-tk(+) Reporter Gene/ [Oncogenes]/[Hereditary Disorders]
[^{123}I]-2′-Fluoro-2′-Deoxy-1-Beta-D-Arabinofuranosyluracil/[^{125}I]-2′-Fluoro-2′-Deoxy-1-Beta-D-Arabinofuranosyluracil

Cellular/Molecular Mechanism of Action: The molecular agent 2′-fluoro-2′-deoxy-5-iodo-1-beta-D-arabinofuranosyluracil has been designed to function as a substrate for HSV1-tk biochemical activity.

Background Information: Previous studies have shown that the HSV1-tk gene, in combination with appropriate radiolabeled substrates (e.g., [I*]-2′-fluoro-2′-deoxy-5-iodo-1-beta-D-arabinofuranosyluracil, or I*-FIAU, where the asterisk indicates the use of any radioactive iodine isotopes), can be used as a reporter gene detection modality for monitoring *in vivo* gene transfer and expression.

Application: Potential gene expression imaging. In this context, [^{123}I]-2′-fluoro-2′-deoxy-1-beta-D-arabinofuranosyluracil and [^{125}I]-2′-fluoro-2′-deoxy-1-beta-D-arabinofuranosyluracil can be applied as radiolabeled substrates for HSV1-tk gene expression. Note: The *in vivo* detection of HSV1-tk gene expression utilizing [^{123}I]-2′-fluoro-2′-deoxy-1-beta-D-arabinofuranosyluracil and [^{125}I]-2′-fluoro-2′-deoxy-1-beta-D-arabinofuranosyluracil represents a model feasibility study designed to determine optimum conditions and methodologies that can be utilized for the *in vivo* detection of altered expression of other unrelated genetic sequences (e.g., oncogenes, hereditary disorders).

Route of Administration: [^{123}I]-2′-fluoro-2′-deoxy-1-beta-D-arabinofuranosyluracil and [^{125}I]-2′-fluoro-2′-deoxy-1-beta-D-arabinofuranosyluracil (intravenous).

Semi-Synthetic Methods: The molecular agent 2′-fluoro-2′-deoxy-1-beta-D-arabinofuranosyluracil (FAU) can be radioiodinated (e.g., [^{123}I] or [^{125}I]) using the iodogen method. High-performance liquid chromatography purification results in a yield of product with

a high specific activity and radiochemical purity for both tracers ([^{123}I]-FIAU and [^{125}I]-FIAU).

Implementation: Evaluate the early kinetic profiles of [^{123}I]- or [^{125}I]-labeled 2′-fluoro-2′-deoxy-5-iodo-1-beta-D-arabinofuranosyluracil (I*-FIAU) and delineate the potential utilization of [^{123}I]-labeled FIAU for *in vivo* imaging for detecting gene expression events. Fibrosarcoma CMS-5 cells can be transduced *in vitro* with the retroviral vector STK containing the HSV1-tk gene. Complementary investigations can involve determination of the biodistribution profiles for radiopharmaceuticals applying gamma camera imaging at 0.5, 1, 2, and 4 hours postinjection. In addition, the genomic DNA of the tumors can be isolated for measurement of accumulated activity resulting from the [^{125}I]-FIAU incorporation.

Animal Model: Murine (fibrosarcoma cells are transduced *in vitro* with the retroviral vector STK containing the HSV1-tk gene. BALB/c mice can be inoculated subcutaneously with HSV1-tk(+) and tk(−) cells into both flanks).

Interpretation and Analysis: Biodistribution studies 0.5 hours postinjection reveal tumor/blood and tumor/muscle ratios of 3.8 and 7.2, respectively, for the HSV1-tk(+) tumors, and 0.6 and 1.2, respectively, for negative control tumors. Fast renal elimination of the tracer from the body results in rapidly increasing tumor/blood and tumor/muscle ratios that reach values of 32 and 88 at 4 hours postinjection, respectively. Tracer clearance from blood is biexponential, with an initial half-life of 0.6 hours followed by a half-life of 4.6 hours. The tracer half-life in herpes simplex viral thymidine kinase-expressing tumors is 35.7 hours. The highest activity accumulation (20.3% ± 5.7 %ID/g) in HSV1-tk(+) tumors is observed 1 hour postinjection. At that time, 46% of the total activity found in HSV1-tk(+) tumors is incorporated within genomic DNA. Planar gamma camera imaging reveals distinct tracer accumulation as early as 0.5 hours postinjection, with an increase in contrast over time. Such findings suggest that sufficient tumor/background ratios for *in vivo* HSV1-tk expression imaging with [^{123}I]FIAU are reached as early as 1 hour postinjection.

In vivo imaging of herpes simplex virus Type 1 thymidine kinase gene expression: Early kinetics of radiolabeled FIAU. Haubner R, Avril N, Hantzopoulos PA, Gansbacher B, Schwaiger M. Eur J Nucl Med 2000 Mar; 27 (3), pp. 283–91.

Gene Expression: Thymidine Kinase Expression/ Neoplastic Disease: DNA Synthesis/Cellular Proliferation Rate
5-[^{125}I]Iodo-4′-Thio-2′-Deoxyuridine (ITdU)/ 5-[^{125}I]-Iodo-2′-Deoxyuridine (IUdR)

Cellular/Molecular Mechanism of Action: ITdU is a metabolically stable nucleoside that can function as a substrate for cellular thymidine kinase biochemical activity.

Application: Radioiodinated forms of ITdU and IUdR can be applied to detect elevations in DNA synthesis in cell poplulations that positively express thymidine kinase activity. In this capacity, both ITdU and IUdR can serve as indicator molecules for measuring alterations in cellular proliferation (especially relevant to the characterization of neoplastic disease states).

Route of Administration: Usually ITdU or IUdR would most frequently be administered intravascularly. Theoretically, it may be possible to effectively image lesions if the agents are administered intrathecally for central nervous system (CNS) tumors, by direct injection into tumors, or into the arterial network supplying a suspected neoplastic lesion.

Semi-Synthetic Methods: Radiolabeling of ITdU and 5-iodo-1-(4-thio-beta-D-arabinofuranosyl)uracil (ITAU) with [^{125}I] can be performed utilizing a destannylation reaction of the trimethylstannyl precursor of each nucleoside. The products can be isolated in high yields and with a > 99% level of radiochemical purity.

Implementation: Evaluation of ITdU and ITAU for their ability to detect and characterize cellular proliferation rates as a function of thymidine kinase expression.

***Ex Vivo* Model:** Thymidine kinase-expressing L-M cells rather than a thymidine kinase-deficient mutant L-M (TK$^-$) cells.

Interpretation and Analysis: [^{125}I]-ITdU is effectively phosphorylated by cytosolic nucleoside kinases and specifically incorporated into thymidine kinase-expressing L-M cells to a far greater extent than into thymidine kinase-deficient mutant L-M (TK$^-$) cells. In addition, *in vitro* cell metabolism studies employing [^{125}I]-ITdU reveal that [^{125}I]-ITdU is effectively and specifically incorporated into a DNA fraction (> 90% at 60 minutes). Therefore, IUdR or [^{125}I]-ITdU appears to be an effective marker for the detection of DNA synthesis. Conversely, [^{125}I]-ITAU is neither remarkably phosphorylated by cytosolic nucleoside kinases nor notably incorporated into L-M cells relative to L-M (TK$^-$) cells. [^{125}I]-ITdU and [^{125}I]-ITAU show a higher resistance to phosphorolytic cleavage by recombinant thymidine phosphorylase than does [^{125}I]-IUdR. Furthermore, biodistribution of [^{125}I]-ITdU and [^{125}I]-ITAU displays better *in vivo* radioiodination stability than does [^{125}I]-IUdR preparations. [^{125}I]-ITdU also displays a significantly higher uptake in proliferating organs (thymus, spleen, small intestine, and bone) than in non-proliferating organs (brain, muscle, liver, and lung), as does [^{125}I]-IUdR, at 18 hours postinjection. As indicated by *in vitro* studies, [^{125}I]-ITAU does not show any significant uptake in proliferating organs. Therefore, radioiodinated ITdU is potentially useful as a proliferation-imaging agent, and further studies should clarify the usefulness of this compound as a nuclear medicine and tumor-imaging agent.

Rationale of 5-[^{125}I]-iodo-4′-thio-2′-deoxyuridine as a potential iodinated proliferation marker. Toyohara J, Hayashi A, Sato M, Tanaka H, Haraguchi K, Yoshimura Y, Yonekura Y, Fujibayashi Y. J Nucl Med 2002 Sep; 43 (9), pp. 1218–26.

Gene Expression and *In Vivo* Quantification: Antisense Gene Targeting/Huntingtin RNA Genetic Targeting for Huntington's Disease (HD)/Central Nervous System (CNS) Macromolecule Delivery: Transferrin Receptor Complexes
[^{125}I]- Peptide Nucleic Acid (PNA)/8D3/ [^{125}I]-PNA-[Antitransferrin Receptor IgG]

Cellular/Molecular Mechanism of Action: The PNA agent is a 16-mer peptide nucleic acid that is the antisense strand corresponding to the segment around the methionine initiation codon of the huntingtin gene of HD. In this context, it recognizes and physically binds to huntingtin RNA (HD exon-1 messenger RNA).

Background Information: Disease-specific genes of unknown function can be imaged *in vivo* with antisense radiopharmaceuticals, providing the transcellular transport of these molecules is enabled with drug-targeting technology.

Route of Administration: [^{125}I]-PNA/8D3 conjugate (intravenous).

Semi-Synthetic Methods: Biotinylation of PNA. Covalent cross-linking strepavidin and rat 8D3 monoclonal antibody (MAb) to the mouse transferrin receptor (TfR). The latter moiety contains a tyrosine residue that can facilitate [^{125}I] radioiodination. The reformulated PNA antisense radiopharmaceutical conjugated to 8D3 MAb is designated [^{125}I]-PNA/8D3.

Implementation: Evaluation of biotinylated PNA that can be rapidly captured by conjugates of covalently cross-linked strepavidin

and [antimouse transferrin receptor IgG]. Complementary *in vivo* studies in mice can be used to determine the biodistribution of the PNA analogue[^{125}I]-PNA/8D3 through harvest of tissue/organ systems 6 hours postadministration for frozen sectioning of the brain and quantitative autoradiography.

Animal Model: Murine (littermate control mice or littermate R6/2 transgenic mice that express the exon 1 of the human HD gene for HD).

Interpretation and Analysis: Despite covalent cross-linking of the PNA analog, [^{125}I]-PNA/8D3 to MAb, it can gain access to endogenous transferrin transport pathways at both the blood-brain barrier and the brain cell membrane, thereby undergoing both import from the blood to the brain and export from the brain to the blood through the transferin receptor complexes (TfR). In this manner, preparations are able to hybridize with "target" huntingtin RNA based on analyses from both cell-free translation assays and ribonuclease protection assays.

Approximately a 3-fold increase in sequestration *in vivo* can be appreciated for antisense [^{125}I]-PNA/8D3 radiopharmaceutical conjugates in the brains of HD transgenic mice. Such observations are consistent with the selective expression of the HD exon-1 messenger RNA in these animals. Therefore, gene expression *in vivo* can be quantitated with antisense radiopharmaceuticals, providing these molecules are reformulated with drug-targeting technology. Drug targeting enables access of the antisense agent to endogenous transport pathways, which permits passage across cellular barriers that separate blood and intracellular compartments of target tissues.

Imaging gene expression in the brain *in vivo* in a transgenic mouse model of Huntington's disease with an antisense radiopharmaceutical and drug-targeting technology. Lee HJ, Boado RJ, Braasch DA, Corey DR, Pardridge WM. J Nucl Med 2002 Jul; 43 (7), pp. 948–56.

CARDIOVASCULAR: CARDIAC

Cardiovascular: Angina (Coronary Arteriogram) *[^{201}Thallium] ([^{201}Tl])/Dipyridamole Stress Test*

Cellular/Molecular Mechanism of Action: Influences the metabolism and transport of adenosine and adenosine nucleotides. In this context, dipyridamol suppresses intracellular infux of adenosine that is released from myocardial tissues that have been deprived of adequate oxygen.

Physiological Mechanism of Action: Dipyridamole promotes diminished coronary artery vascular resistance, elevated coronary artery blood flow, and increased coronary artery oxygen delivery. One of the most prominent influences of dipyridamole in this regard is its effect on the smaller diameter vascular bed networks supplied by the coronary artery that have minimal effect in regions of ischemia because these same vessels tend to already be maximally dilated.

Induces coronary artery vasodilation due to the promotion of intracellular adenosine influx.

Application: Evaluation of subjects affected by effort-induced angina using the following tests: ECG stress test, stress [^{201}Tl] scan, coronary arteriography; [^{201}Tl] scan, coronary arteriography, hemodynamic, echo 2D, and ecgraphic monitoring during the dipyridamole test (D).

Implementation: Evaluation of cardiac-associated angina conditions induced by stress tests, utilizing dipyridamole-induced vasodilation and scintigraphic image analyses detected with the aid of [^{201}Tl] radionuclide.

Human Model: Cases of cardiac-associated angina. Based on coronary arteriography results, cases can be divided into groups classified as Case Type A (n = 10 patients with significant stenoses ≥ 50%) or Case Type B (n = 9 subjects with no significant stenosis).

Interpretation and Analysis: Case Type A disease states can result in positive stress ECG and scintigraphy images (e.g., n = 9 cases). The dipyridamole test can induce angor and ecgraphic changes (e.g., n = 5 cases) and left ventricle wall motion disorders (e.g., n = 4 cases). Usually, [^{201}Tl] scans are positive in the vast majority of Case Type A subjects (e.g., n = 9/9). Case Type B disease states can be associated with ecgraphic changes in a relatively small number of cases (e.g., n = 2/9), and approximately 2/3 will demonstrate positive [^{201}Tl] scan results (e.g., n = 6/9). In Case Type B subjects, dipyridamole can produce angor (e.g., n = 2/9); ecgraphic changes (e.g., n = 1/9); left ventricle wall motion disorders (e.g., n = 1); and similar [^{201}Tl] defects as previously detected. In both case type groups, identical coronary arteriography findings can be observed immediately before and during dipyridamole infusion. Therefore, dipyridamole confirms provocative tests for ischemia. The same ischemic pattern observed with stress and dipyridamole scintigraphy in patients with no significant coronary stenosis suggests as pathogenetic mechanism the regional lack of dilatory reserve.

Instrumentation: Coronary arteriography; [^{201}Tl] scan, coronary arteriography, hemodynamic, echo 2D, ecgraphic monitoring.

Dipyridamole test and myocardial scintigraphy with Tl-201 in the diagnosis of myocardial ischemic pathology. Caputo V, De Nardo D, Antolini M, Caiazza F, Pitucco G. Radiol Med (Torino) 1987 May; 73 (5), pp. 390–3.

Cardiovascular: Angiotensin II Receptors (Myocardial/Adrenal Cortex)/ Angiotensin II Receptor TH-142177 Occupancy/ Angiotensin II Receptor Losartan Occupancy *[^{125}I]Sar1,Ile8-AII*

Physiological Mechanism of Action: [^{125}I]Sar1,Ile8-AII is a radiolabeled analogue of angiotensin II that recognizes and physically binds to antiogensin II receptor complexes.

Application: Detection and characterization of tissue/organ angiotensin II receptor complexes and determination of ligand receptor occupancy.

Implementation: Evaluation of myocardial, adrenal cortex, and cerebral cortex angiotensin II (AII) receptors at 2, 8, and 24 hours after oral administration of TH-142177 and losartan using the radioligand binding agent [^{125}I]Sar1,Ile8-AII.

Plasma concentrations of both drugs and metabolites in rats can be measured using validated high-performance liquid chromatography (HPLC) assays. Further, systolic blood pressure (SBP) in conscious renal hypertensive rats treated orally with TH-142177 and losartan can be measured by using a tail cuff plethysmographic method.

Animal Model: Rat.

Interpretation and Analysis: Oral administration of TH-142177 (1.8 and 5.5 μmol/kg) and losartan (6.5 and 21.7 μmol/kg) is associated with dose-dependent decreases in [^{125}I]Sar1,Ile8-AII binding sites (Bmax) in the myocardium and adrenal cortex. The extent of receptor occupancy by both drugs is maximal in the adrenal cortex and myocardium at 2 hours and 8 hours, respectively. Furthermore, receptor occupancy is more sustained in the myocardium than in the adrenal cortex. The *ex vivo* binding affinity of TH-142177 for AII receptors in these tissues is roughly 3 times higher than that of losartan. Also, cerebral cortical [^{125}I]Sar1,Ile8-AII binding is significantly reduced by the oral administration of losartan but not by TH-142177. The time course of AII receptor occupancy by both drugs in

adrenal cortex appears to be in parallel with that of their plasma concentrations, while the time course within the myocardium correlates with that of their hypotensive effects rather than plasma concentrations.

Therefore, TH-142177 produces a relatively selective and sustained *ex vivo* occupancy of AII receptors in myocardium and adrenal cortex with approximately 3 times greater potency than losartan. Its time course of myocardial receptor occupancy is in parallel with that of hypotensive effect rather than plasma concentration.

Receptor occupancy in myocardium, adrenal cortex, and brain by TH-142177, a novel AT1 receptor antagonist in rats, in relation to its plasma concentration and hypotensive effect. Nozawa Y, Miyake H, Yamada S, Kimura R. Pharm Res 1998 Jun; 15 (6), pp. 911–7.

Cardiovascular: Apoptosis and Oncosis (Myocardial Cells)/Apoptosis: Doxorubicin-Induced/ Oncosis: Isoproterenol-Induced
[^{111}Indium] ([^{111}In])-Antimyosin Antibody/ [^{99m}Technetium] ([^{99m}Tc])-Glucaric Acid

Background Information: Non-invasive imaging techniques would be highly desirable for differentiating oncotic from apoptotic cell death.

Application: [^{99m}Tc]-glucaric acid can be applied to detect oncotic myocardial cell death. Conversely, radiolabeled antimyosin is capable of detecting both oncotic and apoptotic types of myocardial cell death.

Route of Administration: [^{111}In]-antimyosin and [^{99m}Tc]-glucaric acid (intravenous).

Implementation: Evaluation of the ability for [^{111}In]-antimyosin antibody and [^{99m}Tc]-glucaric acid to be applied together in a manner that allows the detection of and differentiation between doxorubicin-induced myocardial apoptosis and isoproterenol-induced myocardial oncosis. Scanning electron microscopy, DNA laddering, TUNEL staining, [^{111}In]-antimyosin antibody, and [^{99m}Tc]-glucaric acid can be collectively utilized *in vitro* and *in vivo* to detect doxorubicin-induced apoptosis or isoproterenol-induced myocardial oncosis.

***Ex Vivo* Model:** Cultured rat H9C2 embryonic cardiocytes. Myocardial cell apoptosis can be induced by exposure of H9C2 embryonic cardiocytes to serial doxorubicin dilutions.

Animal Model: Rats (CD1 strain for *in vivo* investigations). Myocardial apoptosis can be induced *in vivo* in rats by doxorubicin administration. Related investigations can employ heat or subcutaneous isoproterenol administration to induce myocardial oncosis.

Interpretation and Analysis: Scanning electron microscopy, DNA laddering, and TUNEL staining of H9C2 cardiocytes treated with doxorubicin all showed cell death by apoptosis. Rat hearts treated with doxorubicin (10 and 20 mg/kg) are DNA ladder-positive and localized significantly greater [^{111}In]-antimyosin antibody (mean ± standard deviation, 0.1942 ± 0.0150 percent injected dose per gram [%ID/g] and 0.1825 ± 0.0238 %ID/g, respectively) than normal hearts (0.1154 ± 0.0270 %ID/g, $p < 0.05$). Increases in myocardial [^{99m}Tc]-glucaric acid activity cannot be observed in rat hearts after 6, 12, and 24 hours of doxorubicin injection (0.0311 ± 0.0066 %ID/g, 0.0356 ± 0.007 %ID/g, and 0.0368 ± 0.0047 %ID/g, respectively; control hearts, 0.0352 ± 0.0099 %ID/g; p = not significant). Alternatively, [^{99m}Tc]-glucaric acid uptake is significantly greater in isoproterenol-induced oncotic hearts (0.1256 ± 0.1023 %ID/g) than in controls ($p < 0.0001$). [^{99m}Tc]-glucaric acid is avid only for the oncotic myocardium. Antimyosin, on the other hand, is positive for both oncotic and apoptotic myocardium.

Indium 111 antimyosin and [^{99m}Tc] glucaric acid for non-invasive identification of oncotic and apoptotic myocardial necrosis. Khaw BA, Silva JD, Petrov A, Hartner W. J Nucl Cardiol 2002 Sep–Oct; 9 (5), pp. 471–81.

Cardiovascular: Atherosclerosis
[^{125}I]-Cholesteryl Iopanoate (CI)/ Acetylated Low-Density Lipoprotein (AcLDL)

Cellular/Molecular Mechanism of Action: Radiolabeled cholesterol ester analogue CI/AcLDL conjugate is passively assimilated into vascular cholesterol plaques (e.g., hydrophobic environment and hydrogen ion binding molecular interactions).

Application: Detection of atherosclerosis plaques responsible for disease states including stroke, aneurysm, and myocardial infarction. The agent [^{125}I]-CI/AcLDL is capable of detecting early-stage intravascular cholesterol plaques and the monitoring of therapeutic pharmaceutical efficacy. The early detection of atherosclerotic plaques is considered to be crucial for successful prevention and/or therapeutic and dietary intervention of cardiovascular disease (CVD).

Route of Administration: Intravenous.

Dosage: 2 μCi/kg (rabbits).

Considerations: Incorporation of CI into AcLDL results in the selective localization of CI within atherosclerotic plaque lesions. Radiolabeled CI/AcLDL can potentially to be used as a probe for visualizing early atherosclerotic lesions using scintigraphy-based imaging modalities.

Interpretation and Analysis: The agent [^{125}I]-CI/AcLDL is more sensitive than many other diagnostic methodologies that can only detect abnormalities after they have reached an advanced stage. The injected drug is cleared from blood following a 2-compartment model. Radioactivity in the atherosclerotic aorta can be about 8 times higher than that in normal aorta, suggesting that the proposed diagnostic probe is selectively taken up by the atherosclerotic lesion. The autoradiography and staining confirm that the localization of the proposed probe is superimposed with the atherosclerotic lesion site.

Instrumentation: Computer-integrated scintigraphy.

Radiolabeled cholesteryl iopanoate/acetylated low-density lipoprotein as a potential probe for visualization of early atherosclerotic lesions in rabbits. Xiao W, Wang L, Scott T, Counsell RE, Liu H. Pharm Res 1999 Mar; 16 (3), pp. 420–6.

Cardiovascular: Brugada Syndrome (Arryhythmia)/ Presynaptic Sympathetic Innervation Dysfunction
[^{123}I]-Metaiodobenzylguanidine ([^{123}I]-MIBG)

Cellular/Molecular Mechanism of Action: [^{123}I]-MIBG is an analogue of the adrenergic neurotransmitter norepinephrine.

Background Information: Patients with Brugada syndrome present with characteristic ECG abnormalities (atypical right bundle-branch block and ST-segment elevation) and life-threatening ventricular tachyarrhythmias despite structurally normal hearts. Involvement of the autonomic nervous system is suggested by the occurrence of ventricular tachyarrhythmias and sudden death at rest or during sleep and by changes of typical ECG signs under pharmacological modulation of the myocardial autonomic tone.

Application: Characterization of presynaptic sympathetic innervation to the heart in conditions of Brugada syndrome.

Route of Administration: [^{123}I]-MIBG (intravenous).

Implementation: Evaluation of the presynaptic cardiac neuronal reuptake of norepinephrine (uptake 1) in cases of Brugada syndrome and age-matched control subjects using the norepinephrine

analogue [^{123}I]-MIBG in concert with single photon emission computed tomography (SPECT) and quantitative 33-segment bull's-eye analysis.

Human Model: Brugada syndrome (n = 17; n = 10 age-matched controls).

Interpretation and Analysis: Regionally reduced [^{123}I]-MIBG uptake is present in almost half of all cases with Brugada syndrome (e.g., n = 8/17 or 47%) but not in reference controls. Quantitative analysis shows segmental reduction of [^{123}I]-MIBG uptake in the inferior and septal left ventricular wall in patients with Brugada syndrome compare with control subjects ($p < 0.05$). No correlation can be appreciated between the findings from [^{123}I]-MIBG-SPECT and clinical characteristics of study patients. Abnormal [^{123}I]-MIBG uptake in Brugada syndrome cases indicates presynaptic sympathetic dysfunction exists within the heart. These findings may have potential impact on the pathophysiology and arrhythmogenesis in cases with Brugada syndrome. Future quantitative investigations of the presynaptic and postsynaptic sympathetic and parasympathetic branches of the cardiac autonomic nervous system may clarify whether these observations represent a primary adrenergic dysfunction or an imbalance between sympathetic and parasympathetic innervation of the heart.

Cardiac autonomic dysfunction in Brugada syndrome. Wichter T, Matheja P, Eckardt L, Kies P, Schäfers K, Schulze-Bahr E, Haverkamp W, Borggrefe M, Schober O, Breithardt G, Schäfers M. Circulation 2002 Feb 12; 105 (6), pp. 702–6.

Cardiovascular: Cardiomyopathy (Dilated)/ Left Ventricular Ejection Fraction (LVEF)/ Predict Improved Cardiac Sympathetic Nerve Activity/Predict Improved Cardiac Function/ Predict Improved Symptoms Posttreatment for Dilated Cardiomyopathy

Dobutamine/[^{123}I]-Metaiodobenzylguanidine ([^{123}I]-MIBG)

Cellular/Molecular Mechanism of Action: [^{123}I]-MIBG functions as an analogue of norepinephrine.

Physiological Mechanism of Action: Dobutamine exerts adrenergic/sympathomimetic properties.

Route of Administration: Dobutamine (intravascular).

Dosage: Dobutamine (5, 10, and 15 μg/kg/min).

Implementation: Measure LVEF at rest and in response to gradient increases in the dose of dobutamine infused before therapy in cases of dilated cardiomyopathy (DCM) according to protocols for dobutamine gated blood pool scintigraphy (DOB-GBP). Examinations are performed before and after 1 year of therapy. The heart/mediastinum (H/M) count ratio and total defect score (TDS) are determined for [^{123}I]-MIBG images from anterior planar image and single photon emission computed tomography (SPECT) images. Left ventricular ejection fraction and left ventricular end-diastolic dimension (LVDd) are determined by echocardiography.

Human Model: Cases of dilated cardiomyopathy (n = 22).

Interpretation and Analysis: After 1 year of treatment, echocardiographic LVEF improves > 5% (e.g., n = 11/22 cases). Before treatment, TDS, H/M, LVEF, and LVDd are similar in both groups. However, there is a greater increase in the LVEF during dobutamine infusion in cases displaying improvement compared to those that do not improve ($21 \pm 8\%$ vs $9 \pm 3\%$, $p < 0.001$). If a critical value of 15% for the DeltaLVEF is used to predict the improvement in LVEF after treatment, sensitivity is 91% and specificity is 82%. The TDS, H/M ratio, LVDd, and New York Heart Association functional class improves in cases demonstrating a post–1 year response that is greater than comparable values for cases that do not demonstrate a response. Dobutamine gated blood pool scintigraphy, therefore, can be used to predict improved cardiac sympathetic nerve activity, cardiac function, and symptoms after treatment in patients with DCM.

Dobutamine gated blood pool scintigraphy predicts the improvement of cardiac sympathetic nerve activity, cardiac function, and symptoms after treatment in patients with dilated cardiomyopathy. Kasama S, Toyama T, Hoshizaki H, Oshima S, Taniguchi K, Suzuki T, Kurabayashi M. Chest 2002 Aug; 122 (2), pp. 542–8.

Cardiovascular: Cardiomyopathy/Myocardial Ischemia/Angina Pectoris

[^{99m}Technetium] ([^{99m}Tc])-Methoxy-Isobutyl-Isonitrile (MIBI) and Coronary Angiography/[^{99m}Tc]-MIBI and Trans-Esophogeal Pacing

Application: Detection of alterations in the metabolic/biochemical capacity and function of the myocardium that can become substantially altered during episodes of profound ischemia.

Route of Administration: [^{99m}Tc]-MIBI (intravenous) applied in combination with a maximal stress test (phases of rest, stress, and tranesphogeal atrial pacing).

Considerations: Newly developed radioactive agents with physical and biological properties more favorable than those of [^{201}thallium] include MIBI labeled with [^{99m}Tc]. Such diagnostic agents permit performing simultaneous perfusion and function studies in cases of ischemic cardiopathy.

Trans-esophageal atrial pacing (TAP) techniques have evolved as an alternative provocative test for detecting ischemia.

Interpretation and Analysis: The functional evaluation of myocardial perfusion during stress utilizing [^{99m}Tc]-MIBI scintigraphic imaging in combination with TAP reveals that it is has approximately an 85% level of correlation with [^{99m}Tc]-MIBI scintigraphic imaging applied in concert with coronary angiography evaluations in detecting reversible and irreversible defects. Therefore, TAP can serve as a valid and sensitive provocative test for myocardial ischemia when combined with myocardial [^{99m}Tc]-MIBI scintigraphy.

Diagnosis of coronary artery disease with [^{99m}Tc]-methoxy isobutyl isonitrile and transesophageal pacing. Santomauro M, Cuocolo A, Celentano L, Ferraro S, Pace L, Pappone C, Maddalena G, Salvatore M, Chiariello M. Angiology 1992 Oct; 43 (10), pp. 818–25.

Cardiovascular: Cardiomyopathy/Dilated Cardiomyopathy (DCM)/Heart/Mediastinum Ratio: Prognostic Indicator/[Congestive Heart Failure]

[^{123}I]-Metaiodobenzylguanidine ([^{123}I]-MIBG)

Cellular/Molecular Mechanism of Action: [^{123}I]-MIBG is an analogue of the neurotransmitter norepinephrine that can recognize and physically bind to adrenergic receptor complexes.

Physiological Mechanism of Action: [^{123}I]-MIBG is a reliable marker for the detection of cardiac adrenergic neuronal damage in heart failure.

Application: Evaluation of the potential for repeated measurements of cardiac [^{123}I]-MIBG imaging parameters before and after optimized treatment to predict the prognosis of congestive heart failure (CHF) resulting from DCM.

Route of Administration: [^{123}I]-MIBG (intravascular).

Implementation: Assessment of DCM with [^{123}I]-MIBG and meaurement of neurohumoral factor concentrations at baseline and after 6 months of optimized treatment. Cox proportional hazards

analysis can then be performed to assess various parameters before and after treatment.

Human Model: Dilated cardiomyopathy (n = 85 cases with left ventricular ejection fraction (LVEF) of less than 45%).

Interpretation and Analysis: A relatively large number of cases will experience complications (e.g., n = 12 deaths; n = 11 hospitalizations) over a 2-year mean follow-up period. Although there is no difference between the baseline heart/mediastinum (H/M) ratio measured by MIBG between survivors and non-survivors, the H/M ratio is significantly decreased in non-survivors after 6 months. Multivariate analysis reveals that a high plasma concentration of brain natriuretic peptide levels after 6 months (p = 0.0049) and absolute changes in the H/M ratio (p = 0.0046) are independent predictors of mortality. Comparison of the H/M ratio on MIBG imaging before and after optimized additional treatment provides useful information for predicting mortality and is independent of clinical and neurohumoral factors previously shown to be associated with poor prognosis in patients with DCM.

Prognostic value of repeated [^{123}I]-metaiodobenzylguanidine imaging in patients with dilated cardiomyopathy with congestive heart failure before and after optimized treatments-comparison with neurohumoral factors. Matsui T, Tsutamoto T, Maeda K, Kusukawa J, Kinoshita M. Circ J 2002 Jun; 66 (6), pp. 537–43.

Cardiovascular: Cardiomyopathy (Dilated) (DCM)/ β-Blocker Response
[^{201}Thallium] ([^{201}Tl])/[[^{123}I]-Metaiodobenzylguanidine ([^{123}I]-MIBG)]

Background Information: Metaiodobenzylguanidine is a reliable marker for detecting cardiac adrenergic neuronal damage in heart failure.

Application: Determination of the degree of response to β-blocker therapeutic intervention in conditions of dilated cardiomyopathy.

Route of Administration: Intravenous.

Implementation: Evaluation (co-prediction) of the efficacy of β-blocker therapy in conditions of dilated cardiomyopathy utilizing [^{201}Tl myocardial scintigraphy and [^{123}I]-MIBG myocardial scintigraphy performed before and after the initiation of therapeutic intervention.

Human Model: Cases of dilated cardiomyopathy (n = 47 cases with [^{201}Tl] and [^{123}I]-MIBG scans performed prior to β-blocker therapy). Simple categorization of cases by type can include the following scheme: (i) Classification Group A: cardiac function becomes improved; and (ii) Classification Group B: cardiac function remains unchanged.

[^{201}Tl] extent score (ES) schemes that can be employed for quantitating myocardial damage involve the use of the statistical threshold values of statistical mean-2SD (ES-2) and mean-3SD (ES-3). The ES difference between ES-2 and ES-3 is calculated, and according to ES and ES difference, DCM cases can be classified into 3 groups, including (i) mild-defect type (mild-type); (ii) moderate-defect type (moderate-type); and (iii) severe-defect type (severe-type). The H/M MIBG uptake ratio can be evaluated, and the % washout ratio of myocardial MIBG obtained from these data.

Interpretation and Analysis: For assessment of cases affected by dilated cardiomyopathy, the following patient categorization scheme can be adopted: (i) Group A (n = 18 mild-type, n = 14 moderate-type, n = 1 severe-type cases); and (ii) Group B (n = 5 mild-type, n = 4 moderate-type, n = 5 severe-type cases). A significant degree of correlation can be observed between the defect type detected with [^{201}Tl] and response to β-blocker therapy (p = 0.0090). Both H/M MIBG uptake ratios and washout ratio are not significantly different between the 2 groups. Therefore, [^{201}Tl] may be useful for predicting the response to β-blocker therapy in DCM conditions.

Use of thallium-201 myocardial scintigraphy for the prediction of the response to β-blocker therapy in patients with dilated cardiomyopathy. Hara Y, Hamada M, Ohtsuka T, Ogimoto A, Saeki H, Suzuki J, Matsunaka T, Nakata S, Shigematsu Y. Circ J 2002 Dec; 66 (12), pp. 1139–43.

Cardiovascular: Coronary Spasms/Vascular Spasm Detection and Localization
[^{123}I]-15-(p-Iodophenyl)-3-R,S-Methyl Pentadecanoic Acid/[^{123}I]-Metaiodobenzylguanidine ([^{123}I]-MIBG)

Cellular/Molecular Mechanism of Action: Metaiodobenzylguanidine functions as an analogue of norepinephrine.

Background Information: Although various non-invasive methods have been used to detect vasospasm, none of them are sensitive enough for cases with sporadic attacks. Because abnormal fatty acid metabolism and cardiac adrenergic neuronal damage are observed in ischemic myocardium, [^{123}I]-15-(*p*-iodophenyl)-3-(R,S)-methylpentadecanoicacid ([^{123}I]-BMIPP) and [^{123}I]-MIBG have been proposed as useful tracers for detection of myocardial damage.

Application: [^{123}I]-BMIPP and [^{123}I]-MIBG scintigraphy are highly accurate and non-invasive techniques for determining the presence and location of vasospasm.

Route of Administration: [^{123}I]-BMIPP and [^{123}I]-MIBG are both given intravenously.

Implementation: Evaluation of the relationship between the coronary vasospastic regions, abnormal left ventricular regional wall motion, fatty acid metabolism, and sympathetic nerve functions and their changes during treatment in cases with vasospastic angina. Conditions can be assessed utilizing comparative analysis of (i) territorial regions of the vasospasm-induced coronary artery; (ii) wall motion determined by left ventriculography; and (iii) BMIPP and MIBG uptake.

Human Model: Vasospastic angina (n = 50, of which n = 25 Type A cases with clinically documented vasospasm; n = 25 Type B cases with vasospasm induced by ergonovine provocation; and n = 25 Type C controls with chest pain but normal coronary arteries without ergonovine provocation of spasm). After 6 months, during-treatment vasospasm is reinduced by ergonovine provocation in Type A cases (e.g., n = 6) and not reinduced in Type B cases (n = 10). Reevaluation of Type A conditions following medical intervention (n = 16/25).

Interpretation and Analysis: Regions exhibiting a positive reaction to the ergonovine provocation can be observed in the (i) right coronary artery (e.g., n = 41 cases); (ii) left anterior descending artery (n = 33 cases); and (iii) left circumflex artery (n = 21 cases). Provocation can (i) occur in multiple vessels (e.g., n = 29 or 58%); and/or (ii) promote reduction in wall motion (n = 19 or 38%). Sensitivity and specificity for the identification of vasospastic angina is 86% (n = 43/50 cases) and 88% (n = 22/25 cases), respectively, for BMIPP scintigraphy and 100% (n = 50/50 cases) and 56% (n = 14/25 controls), respectively, for MIBG scintigraphy. In regions exhibiting reductions in left ventricular wall motion, BMIPP or MIBG uptake is decreased. The sensitivity and specificity for determination of vasospasm-induced coronary arteries is 71% (n = 67/95 arteries) and 95% (n = 71/75 arteries), respectively, for BMIPP scintigraphy and 96% (n = 91/95 arteries) and 55% (n = 41/75 arteries), respectively, for MIBG scintigraphy. Reinduced vasospasm (ergonovine provocation) after 6 months during treatment reveals improvements in decreased BMIPP, and MIBG uptake is lower in Type A (25% ± 4% and 16% ± 4%, respectively) than in Type B

(69% ± 4% and 50% ± 3%, respectively; both $p < 0.01$). Regions in which vasospasm is reinduced exhibit decreases in BMIPP and MIBG uptake. Abnormal fatty acid metabolism and cardiac sympathetic denervation are observed more frequently than wall motion abnormalities in the vasospastic region in cases with vasospastic angina. BMIPP and MIBG scintigraphy are highly accurate and noninvasive techniques for determining the presence and location of vasospasm.

Myocardial sympathetic denervation, fatty acid metabolism, and left ventricular wall motion in vasospastic angina. Watanabe K, Takahashi T, Miyajima S, Hirokawa Y, Tanabe N, Kato K, Kodama M, Aizawa Y, Tazawa S, Inoue M. J Nucl Med 2002 Nov; 43 (11), pp. 1476–81.

Cardiovascular: Endocarditis (Septic/Bacterial)/ Platelet GP IIb/IIIa Receptor Expression Postactivation
[^{99m}Technetium] ([^{99m}Tc])-DMP444

Cellular/Molecular Mechanism of Action: The agent DMP444 recognizes GP IIb/IIIa receptors expressed on the exterior surface membrane of activated platelets.
Background Information: Bacterial endocarditis is an important clinical problem that may result in persistent bacteremia and irreversible cardiac damage. The condition is also characterized by the aggregation of activated platelets, fibrin, and bacteria.
Application: Scintigraphic detection and characterization of bacterial endocarditis conditions.
Route of Administration: [^{99m}Tc]-DMP444 (37 MBq/kg).
Dosage: [^{99m}Tc]-DMP444 (intravenous).
Implementation: Evaluation of the expression of GP IIb/IIIa receptors by activated platelets utilizing [^{99m}Tc]-labeled DMP444 as a high-affinity antagonist of activated platelet GP IIb/IIIa receptor complexes. One day following intervention (bacterial challenge), [^{99m}Tc]-DMP444 (37 MBq/kg) or [^{99m}Tc]-IgG (37 MBq/kg non-specific control agent) is injected intravascularly. Images are obtained up to 4 hours postinjection. Samples are then obtained for tissue counting, microbiology, and histology.

Animal Model: Canine (n = 7 beagles [11–15 kg] with catheterization of their left ventricle through the right carotid artery; n = 5 injected with bacteria; n = 5/7 given [^{99m}Tc]-DMP444; n = 2/7 given [^{99m}Tc]-IgG; n = 2 complete sham procedure). One hour following catheterization, a dose of 5×10^7 colony-forming units of *Staphylococcus aureus* bacteria is injected (e.g., intracardiac). Half an hour later, catheters are removed.
Interpretation and Analysis: From 1 to 2 hours postinjection onward, there is clear focal accumulation of DMP444 in the aortic valve region when endocarditis lesions are present, and the accumulation increases with time. The non-infected and the [^{99m}Tc]-IgG injected models show only persistent blood-pool activity without evidence of a focal cardiac abnormality. At 4 hours postinjection, the *in vivo* valve-to-blood-pool ratios are 1.87 ± 0.18 in endocarditis, 1.01 ± 0.05 in non-infected controls, and 1.09 ± 0.02 in [^{99m}Tc]-IgG injected dogs ($p < 0.05$). Targeting of activated platelets with the [^{99m}Tc]-labeled GP IIb/IIIa antagonist DMP444 allows a final diagnosis of experimental bacterial endocarditis within 4 hours that is associated with a high, specific, and rapid *in vivo* uptake of imaging agent.

Scintigraphic detection of acute experimental endocarditis with the technetium-99m-labeled glycoprotein IIb/IIIa receptor antagonist DMP444. Oyen WJ, Boerman OC, Brouwers FM, Barrett JA, Verheugt FW, Ruiter DJ, Corstens FH, van der Meer JW. Eur J Nucl Med 2000 Apr; 27 (4), pp. 392–9.

Cardiovascular: Heart Failure (Chronic)/Adrenergic Receptor Complexes/Metaiodobenzylguanidine (MIBG) Washout Rate Changes/Pharmaceutical Efficacy Evaluation
[^{123}I]-MIBG

Cellular/Molecular Mechanism of Action: [^{123}I]-MIBG functions as a norepinephrine analog.
Background Information: Previous studies have not investigated the efficacy of angiotensin II (AII) receptor antagonists against cardiac sympathetic overactivity in patients with chronic heart failure (CHF) using [^{123}I]-MIBG myocardial imaging.
Application: [^{123}I]-MIBG is a reliable marker for the detection of cardiac adrenergic neuronal damage in conditions of cardiac failure.
Route of Administration: Intravascular.
Implementation: Evaluation of congestive heart failure (CHF) conditions therapeutically managed with an AII receptor antagonist (losartan or candesartan). Image evaluation is performed with MIBG and echocardiograms before and then 6 months after administration in concert with the assessment of neurohumoral parameters.

Human Model: Cases of congestive heart failure patients (n = 34) with fractional shortening of the left ventricular (LV) diameter ≤ 25% or LV ejection fraction ≤ 45% in echocardiogram images.
Interpretation and Analysis: Metaiodobenzylguanidine imaging reveals that the antagonist does not significantly change the heart/mediastinum ratio. However, the washout rate falls significantly (from 32.6% ± 7.6% to 28.2% ± 7.5%; $p < 0.001$). No significant changes occur in LV diameter, fractional shortening, or LV ejection fraction. Circulating atrial (ANP) and brain natriuretic peptides (BNP) and aldosterone fall significantly. Changes in MIBG washout rate correlate positively with changes in BNP ($r = 0.35$, $p < 0.05$). In cases also being treated with angiotensin-converting enzyme (ACE) inhibitors (e.g., n = 19), the MIBG washout rate also falls significantly with AII antagonists, as does BNP and aldosterone. Decreases in MIBG washout and BNP in cases with CHF induced by the AII receptor antagonists suggests the efficacy of these agents in modifying cardiac sympathetic function and neurohumoral factors, even with ACE inhibition. Combination therapy with AII receptor antagonists and ACE inhibitors appears effective for CHF.

Effects of angiotensin II receptor antagonists on [^{123}I]metaiodobenzylguanidine myocardial imaging findings and neurohumoral factors in chronic heart failure. Shinohara H, Fukuda N, Soeki T, Sakabe K, Onose Y, Tamura Y. Heart Vessels 2002 Dec; 17 (2), pp. 47–52.

Cardiovascular: Heart Failure (Congestive)/ Renal Failure: Acute/Endothelin (ET) Receptor Expression: Antagonist Receptor Occupancy/ ET Receptor Antagonist Dosage (Individualized Design of Treatment Schemes)
[^{125}I]ET-1/BQ-123/BQ-788/L-749,329

Cellular/Molecular Mechanism of Action: The agents BQ-123 and BQ-788 bind to and block ETA and ETB type ET receptor complexes and are therefore classified as receptor antagonists. Similarly, the non-peptide antagonist L-749,329 has a relatively balanced affinity for each of the 2 ET receptor subtypes.
Physiological Mechanism of Action: Endothelin is 1 of the most potent vasoconstrictor agents identified to date.
Background Information: Endothelin has been implicated in various disease conditions, including acute renal failure and congestive heart failure. Such observations imply that these disease states can possibly be managed with ET receptor antagonists. However,

establishing the dosages for these antagonists may be difficult because no convenient physiologic indicator of action exists, and because of complexities in receptor function. Two receptor subtypes have been identified for which selective antagonists have been reported (e.g., BQ-123 for the ETA receptor and BQ-788 for the ETB receptor). Of the 3 natural peptide hormones (ET-1, ET-2, and ET-3), ET-1 exhibits high affinity for both subtypes of receptor.

Application: Characterization of the relative expression of 2 endothelium receptor subtypes in a manner that provides information that can be utilized to develop individualized dosages for ET receptor antagonists and facilitate management of various disease states, including acute renal failure and congestive heart failure.

Implementation: Evaluation of the *in vivo* biodistribution of [^{125}I]ET-1 with and without the presence of selective peptide antagonists (BQ-123, BQ-788), and a non-peptide antagonist (L-749,329). The agent [^{125}I]ET-1 possesses binding avidity for ET receptor complexes.

Animal Model: Rat.

Animal Model: Primate (rhesus monkey).

Interpretation and Analysis: The agents BQ-123, BQ-788, and L-749,329 inhibit [^{125}I]ET-1 binding consistent with physical interaction with a single receptor site. However, the sum of inhibition by the selective antagonist is greater than 100% (as defined by inhibition with L-749,329), which suggests (i) lower in vivo selectivity than determined in vitro, and/or (ii) receptor subtype interactions. The latter explanation is supported, in part, by in vitro autoradiographic studies as well as studies in isolated tissues and cell preparations. Synthesized ET-1 labeled with [^{123}I] facilitates the acquisition of images reflecting receptor distribution in 2 in vivo animal models. Therefore, it is possible to visualize, via planar, non-invasive imaging, the occupancy of ET receptor by antagonists in both the kidney and lung. [^{123}I]ET-1 can therefore be used to determine clinically appropriate dosages for antagonist needed for receptor saturation.

Radioiodinated endothelin-1: A radiotracer for imaging endothelin receptor distribution and occupancy. Gibson RE, Fioravanti C, Francis B, Burns HD. Nucl Med Biol 1999 Feb; 26 (2), pp. 193–9.

Cardiovascular: Inflammation/Induced Myocardial Ischemia/Neutrophil Leukotriene B_4 (LTB_4) Receptors
[^{99m}Technetium] ([^{99m}Tc])-RP517/[F]-RP517

Cellular/Molecular Mechanism of Action: In whole blood, [F]-RP517 (500 nmol/L) preferentially labels neutrophil LTB_4 receptor complexes.

Application: [^{99m}Tc]-RP517 is an LTB_4 receptor antagonist that has been developed for imaging acute inflammation or infection. A unique property of [^{99m}Tc]-RP517 is its ability to label white blood cells *in vivo* after intravenous injection.

Route of Administration: [^{99m}Tc]-RP517 (intravenous).

Implementation: Evaluate the relative [^{99m}Tc]-RP517 binding to human leukocyte subtypes and the [^{99m}Tc]-RP517 uptake pattern in myocardium with induced inflammatory lesions. One approach to assessing such conditions can involve delineation of RP517 binding to neutrophil populations *in vitro* within whole blood, and *in vivo* within the intravascular compartment. This can be achieved through the use of fluorescence-activated cell sorter analysis performed on whole human blood samples (n = 2) and isolated neutrophils (n = 4) with a fluorescent analogue of [^{99m}Tc]-RP517 referred to as [F]-RP517. Evaluation strategies *in vivo* can entail administration of [^{99m}Tc]-RP517 to determine its biodistribution within the myocardium before and after coronary occlusion. To facilitate *ex vivo* imaging of the myocardium, the left ventricle can be divided into 72 segments for flow and [^{99m}Tc]-RP517 uptake analyses.

Animal Model: Canine (n = 9 dogs, anesthetized, open-chest surgical exposure before coronary occlusion [90 minutes] and reperfusion [120 minutes]; or n = 3 dogs, before intramyocardial TNF-α administration). In this context, myocardium inflammation can be induced by either coronary occlusion and reperfusion or administration by injection of tumor necrosis factor-alpha (TNF-α) preparations.

Interpretation and Analysis: In whole blood, [F]-RP517 (500 nmol/L) preferentially labels neutrophils. In isolated neutrophil populations, [F]-RP517 (10 nmol/L) binding is inhibited by 44% in the presence of LTB4 (400 nmol/L). In the analysis of *ex vivo* cardiac samples, an inverse exponential relationship can be detected between [^{99m}Tc]-RP517 uptake and occlusion flow (r = 0.73). In the same 15 segments, [^{99m}Tc]-RP517 uptake is highly correlated with neutrophil myeloperoxidase enzyme levels (r = 0.91). *Ex vivo* images reveal tracer uptake in the reperfused area (ischemic to normal count ratio = 2.7 ± 0.2). Therefore, it can be concluded that RP517 binds to the neutrophil LTB4 receptor complex after intravenous injection. After reperfusion, [^{99m}Tc]-RP517 uptake correlates with myeloperoxidase levels and can be observed on *ex vivo* images, indicating that this tracer may have potential as an imaging agent for detecting inflammatory conditions.

Assessment of myocardial inflammation produced by experimental coronary occlusion and reperfusion with [^{99m}Tc]-RP517, a new leukotriene B_4 receptor antagonist that preferentially labels neutrophils *in vivo*. Riou LM, Ruiz M, Sullivan GW, Linden J, Leong-Poi H, Lindner JR, Harris TD, Beller GA, Glover DK. Circulation 2002 Jul 30; 106 (5), pp. 592–8.

Cardiovascular: Myocardial Hypoxia/Myocardial Oxygen Availability/Myocardial Intracellular Energy Level/Myocardial Mitochondrial Redox State
[^{99m}Technetium] ([^{99m}Tc])-Nitroimidazole

Physiological Mechanism of Action: Nitroimidazole is preferentially internalized and retained by hypoxic cardiac myocardium.

Background Information: The agent [^{99m}Tc]-labeled nitroimidazole is preferentially taken up and retained by hypoxic cardiac myocardium.

Application: Nitroimidazole is an agent that can potentially detect and characterize myocardial hypoxia associated with conditions such as cardiac ischemic injury.

Route of Administration: Nitroheterocycle in a research scenario can be applied in isolated perfused (*ex vivo*) hearts but in a clinical environment it would in all probability be given intravascularly.

Implementation: Evaluation of the influence of O_2 or N_2 equilibrated cell-free medium perfused into hearts on the uptake of infused nitroheterocycle and its subsequent washout from myocardial tissues.

***Ex Vivo* Model:** Rat (isolated perfused hearts).

Interpretation and Analysis: Nitroheterocycle displays biphasic kinetic washout patterns in isolated perfused hearts (rat). For both uptake and washout, the early phase is very rapid, whereas the late phase is much slower. The amount of radioactivity retained after 40 minutes of clearance is about 2-fold greater in hypoxic hearts than in normoxic hearts. Cardiac myocytes and mitochondria isolated from hearts also accumulate nitroheterocycle. Association of the compound with heart cells is inversely related to the level of available oxygen and is independent of intracellular energy levels or mitochondrial redox state in the presence of oxygen. The results indicate that [^{99m}Tc]-labeled nitroimidazole may serve as a sensitive marker for detecting hypoxic myocardium.

The agent [^{99m}Tc]-labeled nitroimidazole is preferentially taken up and retained by hypoxic cardiac myocardium.

A novel [^{99m}technetium]-labeled nitroheterocycle capable of identification of hypoxia in heart. Rumsey WL, Cyr JE, Raju N, Narra RK. Biochem Biophys Res Commun 1993 Jun 30; 193 (3), pp. 1239–46.

Cardiovascular: Myocardial Infarction
Antimyosin Monoclonal Antibody (MAb)

Application: Non-invasive *in vivo* detection of acute myocardial infarction.
Route of Administration: Antimyosin MAb (intravenous).
Dosage: Antimyosin MAb.
Design and Validation: Antimyosin antibody preparations have been developed as a diagnostic imaging platform for the *in vivo* detection of acute myocardial infarction. Antimyosin antibody can detect the presence of an assortment of other disease states affecting the heart where the hallmark of the pathogenesis of the condition includes myocyte necrosis. Consistent with this concept, antimyosin antibody has been used as a non-invasive imaging agent for the diagnosis of acute myocarditis, heart transplant rejection, drug-induced cardiotoxicity, and other cardiomyopathies.

Clinical experience gained with 1st-generation antimyosin monoclonal antibody preparations has served as a foundation for the design of 2nd-generation monoclonal antibodies such as antifibrin and antiplatelet immunoglobulins used in the *in vivo* diagnosis of deep venous thrombosis affecting the upper limbs, pulmonary embolism, and antiatherosclerotic lesion-specific antibody for diagnosis of metabolically active lesions. Potential molecular candidates for use in the design of a class of 3rd-generation monoclonal antibodies include ultrasmall antigen-binding immunoglobulin fragments or synthetic peptides and negative charge-modified antibodies.
Interpretation and Analysis: Positive accumulation of antimyosin MAb with a region of the myocardium indicates the presence of some type of injury to the heart (e.g., ischemia/ischemic necrosis). Antimyosin preparations have also been used clinically for non-invasive diagnosis of acute myocarditis, heart transplant rejection, drug-induced cardiotoxicity, and other cardiomyopathies.

Antibody imaging in the evaluation of cardiovascular diseases. Khaw BA, Narula J. J Nucl Cardiol 1994 Sep–Oct; 1 (5 Pt 1), pp. 457–76.

Cardiovascular: Myocardial Infarction/Myocardial Salvage as a Function of Infarct Location/ Myocardial Salvage with AMP579 plus Percutaneous Transluminal Coronary Angioplasty (PTCA) Therapy
^{99m}Technetium ([^{99m}Tc])-SestaMIBI/AMP579

Cellular/Molecular Mechanism of Action: AMP579 is a mixed adenosine agonist with both A1 and A2 properties.
Background Information: Evidence suggests that myocardial ischemic preconditioning and reperfusion injury may be mediated by adenosine A1 and A2 receptors. In animal models of acute myocardial infarction (MI), AMP579 reduces infarct size at serum levels of 15 to 24 ng/mL.
Application: Predictive indicators for myocardial salvage as a function of infarct location.
Route of Administration: AMP579 (6-hour infusion).
Dosage: AMP579 (multiple including 60-mcg/kg).
Considerations: Placebo-controlled studies can be employed.
Implementation: Evaluation of the influence of 3 different AMP579 doses infused continuously over a 6-hour period. The primary end point is final MI size measured by [^{99m}Tc]-sestaMIBI scanning at 120 to 216 hours after PTCA. Secondary end points include (i) myocardial salvage and salvage index values established at the same time interval (case subset subjected to baseline [^{99m}Tc]-sestaMIBI scan); (ii) left ventricular ejection fraction and heart failure at 4 to 6 weeks; (iii) duration of hospitalization; and (iv) cardiac events at 4 weeks and 6 months.
Human Model: Cases undergoing primary PTCA after acute ST-segment elevation MI (n = 311).
Interpretation and Analysis: Final infarct size does not differ among case groups receiving either AMP579 or placebo pertaining to either anterior myocardial infarction or non-anterior myocardial infarction. In conditions of anterior myocardial infarction, success of median myocardial salvage is increasingly higher in cases receiving ascending dosages of AMP579 plus PTCA. Serum levels approaching concentrations that reduce infarct size in animal models can be achieved only with dosages of 60-mcg/kg. In summary, AMP579 is safe at the doses tested, but it does not reduce infarct size. There is a trend toward greater myocardial salvage in treated patients with anterior MI.

A randomized, double-blinded, placebo-controlled, dose-ranging study measuring the effect of an adenosine agonist on infarct size reduction in patients undergoing primary percutaneous transluminal coronary angioplasty: The ADMIRE (AmP579 Delivery for Myocardial Infarction REduction) study. Kopecky SL, Aviles RJ, Bell MR, Lobl JK, Tipping D, Frommell G, Ramsey K, Holland AE, Midei M, Jain A, Kellett M, Gibbons RJ. Am Heart J 2003 Jul; 146 (1), pp. 146–52.

Cardiovascular: Myocardial Infarction or Ischemia/ Lipid Metabolism: Differentiation Parameter
[^{123}I]-15-(p-Iodophenyl)-3-(R,S)-Methylpentadecanoicacid ([^{123}I]-BMIPP)/Non-Radioactive Colored Microspheres

Cellular/Molecular Mechanism of Action: [^{123}I]-BMIPP is a radiolabeled lipid analogue that is perceived by cells within the body as an endogenous lipid molecule.
Background Information: The tracer [^{123}I]-BMIPP has been examined for its ability to reflect myocardial lipid metabolism. Studies in mice indicate that myocardial BMIPP uptake correlates with adenosine triphosphate (ATP) content. Details, however, of myocardial accumulation in the ischemic period with either infarct or ischemia are not well documented.
Application: [^{123}I]-BMIPP can be utilized to detect and characterize myocardial lipid metabolism in a manner that can potentially be used as a parameter to differentiate myocardial ischemia from myocardial infarction.
Route of Administration: [^{123}I]-BMIPP (intravascular).
Implementation: Evaluation of myocardial regional wall motion applying echocardiography in the short-axial view from the epicardium. Tissue blood flow can be calculated using non-radioactive colored microspheres. Changes in blood glucose levels, lipid levels, and lactate extraction can be examined in blood collected from the aorta and great cardiac vein (GCV). The ATP concentration and [^{123}I]-BMIPP count are determined by high-performance liquid chromatography and gamma counter data, respectively.
Animal Model: Canine (n = 16 adult mongrel dogs). The occluded left anterior descending artery (LAD) alone is reperfused to create an ischemic region, and the 1st diagonal branch of the LAD is kept occluded to make the infarct lesion.
Interpretation and Analysis: Two hours after reperfusion, blood flow decreases to 20% ± 5% in infarct regions and 64% ± 9% in ischemic areas ($p < 0.05$), despite comparable (similar)

wall-motion reduction (32% ± 5% and 42% ± 12% in the infarct and ischemic areas, respectively). BMIPP content and ATP concentration display parallel reductions: 40% ± 7% and 75% ± 4% ($p < 0.05$) of BMIPP and 32% ± 9% and 69% ± 7% ($p < 0.05$) of ATP in infarct and ischemic regions, respectively. Non-esterified fatty acid extraction, defined as "flow × ([artery] − [GCV])," decreases to 87% ± 5.6% during occlusion and 75% ± 20.1% 2 hours after reperfusion compared to control values. BMIPP uptake correlates well with lipid metabolism and tissue ATP levels and may prove useful in differentiating myocardial infarction from ischemia in the acute phase of ischemic episodes.

Evaluation of myocardial viability with iodine-123-BMIPP in a canine model. Nohara R, Okuda K, Ogino M, Hosokawa R, Tamaki N, Konishi J, Fujibayashi Y, Yonekura Y, Fujita M, Sasayama S. J Nucl Med 1996 Aug; 37 (8), pp. 1403–7.

Cardiovascular: Myocardial Infarction/Sympathetic (Adrenergic) Neuronal Dysfunction and Receptor Expression Alterations/QT-RR Slope and Metaiodobenzylguanidine (MIBG) Heart/Mediastinum Ratio/QT Dispersion and MIBG Heart/Mediastinum Ratio
[^{123}I]-MIBG

Cellular/Molecular Mechanism of Action: Metaiodobenzylguanidine is an analogue of norepinephrine and recognizes and physically binds to sympathetic/adrenergic receptor complexes.
Background Information: Cardiac [^{123}I]-MIBG imaging is widely used to assess cardiac sympathetic neuronal function. However, physiologic significance of impaired cardiac MIBG uptake has not been fully elucidated.
Application: Detection and characterization of sympathetic adrenergic receptor expression as a parameter that can function as a means for classifying different cardiovascular disease states (e.g., myocardial infarction).
Route of Administration: [^{123}I]-MIBG (intravascular).
Implementation: Evaluate the influences of abnormal cardiac sympathetic neuronal function on heart rate variability (HRV) and ventricular repolarization process in conditions of myocardial infarction. Classification of myocardial infarction can be into various group types based on heart/mediastinum (H/M) ratios established by MIBG scintigraphy. Holter recording and a standard 12-lead electrocardiography can be used for the evaluation of HRV, QT-RR relation, and QT dispersion. The groups are (i) MIBG Classification Scheme I: globally decreased MIBG uptake (H/M < 1.5; n = 10 cases); (ii) MIBG Classification Scheme II: decreased MIBG uptake (H/M ≥ 1.5; n = 19 cases); and (iii) Normal Reference Control Scheme III: (n = 17 cases).

Human Model: Cases of myocardial infarction (n = 29) classified into 2 groups by an H/M ratio established by MIBG scintigraphy.
Interpretation and Analysis: Low, high, and total frequency components are decreased in MIBG Classification Schemes I and II compared to reference controls. Reduction of frequency domain measurements are more severe in Scheme I than in Scheme II cases, but the differences do not reach statistically significant levels. Circadian variation of frequency domain measures disappear in Scheme I cases. The slope of QT-RR relation is significantly greater in group I than in group II or group III. QT dispersion is also greater in group I (64 ± 25 msec) than in group II (43 ± 19 msec) and group III (28 ± 9 msec). Therefore, conditions of sympathetic neuronal dysfunction inferred from globally impaired cardiac MIBG uptake have an altered capacity to modulate ventricular repolarization process as well as displaying decreased HRV.

Modulation of ventricular repolarization and RR interval is altered in patients with globally impaired cardiac [^{123}I]-MIBG uptake. Yoshida N, Nozawa T, Igawa A, Fujii N, Kato B, Mizumaki K, Fujiki A, Asanoi H, Seto H, Inoue H. Ann Noninvasive Electrocardiol 2001 Jan; 6 (1), pp. 55–63.

Cardiovascular: Myocardial Injury (Early)
[^{111}Indium] ([^{111}In])-Antimyosin IgG

Cellular/Molecular Mechanism of Action: Antimyosin recognizes and physically binds to cardiac myosin.
Application: [^{111}In]-antimyosin scintigraphy is very sensitive in detecting myocardial damage similar to that associated with cumulative dose levels of doxorubicin.
Implementation: Evaluate various cumulative anthracycline dose levels applying [^{111}In]-antimyosin scintigraphy in order to identify the early stages of severe cardiac injury and increased long-term risk of cardiac dysfunction. Cases receiving chemotherapeutic agents are monitored at baseline, low (2 cycles), middle (4 cycles), and high (6 cycles) cumulative dose based on the elucidation of [^{111}In]-antimyosin 48-hour heart-to-lung ratios (HLR), left ventricle ejection fractions (LVEF), and peak filling rates (PFR).

Human Model: Cases receiving standard doses of 60 to 75 mg/m doxorubicin or 90 to 112.5 mg/m epirubicin.
Interpretation and Analysis: At low cumulative dose levels only HLR is significantly increased ($p = 0.0001$); at middle dose heart-to-lung-ratio ($p < 0.0001$) and LVEF ($p = 0.0054$), but not PFR, significantly change; and at high dose HLR ($p < 0.0001$), LVEF ($P = 0.0001$), and PFR ($p = 0.033$) all change significantly. Concerning individual results, heart-to-lung-ratios become abnormal in a large percentage of cases (n = 18/24 [75%] at low, n = 22/24 [92%] at middle, and n = 24/24 [100%] at high cumulative doses). Alternatively, LVEF and PFR remain within normal limits in essentially all exposed cases. Myocyte damage appears to precede left ventricle systolic and diastolic dysfunction in anthracycline treatment. [^{111}In]-antimyosin scintigraphy is very sensitive in detecting myocardial damage after cumulative dose levels even as low as 120–150 mg/m doxorubicin or 180–225 mg/m epirubicin. Myocyte damage appears to precede left ventricle systolic and diastolic dysfunction in anthracycline treatment.

High sensitivity of radiolabeled antimyosin scintigraphy in assessing anthracycline-related early myocyte damage preceding cardiac dysfunction. Valdés Olmos RA, Carrió I, Hoefnagel CA, Estorch M, ten Bokkel Huinink WW, López-Pousa J, Dalesio O. Nucl Med Commun 2002 Sep; 23 (9), pp. 871–7.

Hypercholesterolemia in minipigs impairs left ventricular response to stress: Association with decreased coronary flow reserve and reduced capillary density. Theilmeier G, Verhamme P, Dymarkowski S, Beck H, Bernar H, Lox M, Janssens S, Herregods MC, Verbeken E, Collen D, Plate K, Flameng W, Holvoet P. Circulation 2002 Aug 27; 106 (9), pp. 1140–6.

Cardiovascular: Myocardial Injury/Early Detection of Myocyte Apoptosis/Oncotic and Apoptotic Myocardium Detection
[^{111}Indium] ([^{111}In])-Antimyosin Antibody/ [^{99m}Technetium] ([^{99m}Tc])-Glucaric Acid

Cellular/Molecular Mechanism of Action: Antimyosin antibody detects and physically binds to cardiac myosin.
Background Information: Non-invasive imaging techniques would be highly desirable for differentiating between oncotic cell death from apoptotic cell death. [^{111}In]-antimyosin and [^{99m}Tc]-glu-

caric acid have been used to assess such parameters in myocardial cell populations.

Application: Detection and characterization of myocardial (myocyte) injury and damage.

Implementation: Evaluation of the effect of doxorubicin exposure on embryonic cardiocytes and rats in a manner that induces myocardial apoptosis. Acute myocardial oncosis can be induced by heat or subcutaneous isoproterenol administration. Scanning electron microscopy, DNA laddering, TUNEL staining, [^{111}In]-antimyosin antibody, and [^{99m}Tc]-glucaric acid can be utilized to demonstrate *in vitro* and *in vivo* doxorubicin-induced apoptosis or isoproterenol-induced myocardial oncosis.

Animal Model: Rats (CD1 strain).

Animal Model: Cultured H9C2 rat embryonic cardiocytes.

Interpretation and Analysis: Scanning electron microscopy, DNA laddering, and TUNEL staining of H9C2 cardiocytes treated with doxorubicin all demonstrate evidence of cell death by apoptosis. Rat hearts treated with doxorubicin (10 and 20 mg/kg) are DNA ladder-positive and localize (accumulate) significantly greater amounts of [^{111}In]-antimyosin antibody (mean ± standard deviation, 0.1942 ± 0.0150 percent injected dose per gram [%ID/g] and 0.1825 ± 0.0238 %ID/g, respectively) than normal hearts (0.1154 ± 0.0270 %ID/g, $p < .05$). No increase in myocardial [^{99m}Tc]-glucaric acid activity is observed in hearts after 6, 12, and 24 hours of doxorubicin injection (0.0311 ± 0.0066 %ID/g, 0.0356 ± 0.007 %ID/g, and 0.0368 ± 0.0047 %ID/g, respectively; control hearts, 0.0352 ± 0.0099 %ID/g; p = not significant). [^{99m}Tc]-glucaric acid uptake is significantly greater in isoproterenol-induced oncotic hearts (0.1256 ± 0.1023 %ID/g) than in controls ($p < 0.0001$). [^{99m}Tc]-glucaric acid is avid only for the oncotic myocardium. Antimyosin, on the other hand, is positive for both oncotic and apoptotic myocardium.

Indium 111 antimyosin and [^{99m}Tc] glucaric acid for non-invasive identification of oncotic and apoptotic myocardial necrosis. Khaw BA, Silva JD, Petrov A, Hartner W. J Nucl Cardiol 2002 Sep–Oct; 9 (5), pp. 471–81.

Cardiovascular: Myocardial Ischemia
Dithiosemicarbazone (DTS) Derivatives/[Cu]-DTS/[Tc]-ATSM(2)

Background Information: Dithiosemicarbazone derivatives radiolabeled with divalent copper (^{62}Cu, ^{64}Cu) have demonstrated effectiveness as agents for detecting tissue ischemia. Development of analogous derivatives labeled with the more accessible [^{99m}technetium] ([^{99m}Tc]) would be highly desirable.

Application: Detection and characterization of tissue ischemia.

Route of Administration: Intravascular.

Semi-Synthetic Methods: Radiolabeling of various synthesized DTS derivatives using a macromolecular Sn(II)-complex under an anaerobic condition at pH 3.4–4.5 in concert with stabilization with ascorbate solution at pH 6.7–7.0. Characterization of [Tc]-DTS derivatives can be achieved applying various analytical methods (thin layer chromatography [TLC], high-performance liquid chromatography [HPLC], electrophoresis [EP], paper chromatography [PC]).

Implementation: Evaluation of the the capacity for radiolabeled DTS derivatives to detect regions of myocardial ischemia.

Animal Model: Murine and rat (myocardial left anterior descent [LAD] coronary artery occlusion model).

Interpretation and Analysis: The DTSs [Tc]-ATSE, [Tc]-ATSM, and [Tc]-ATSM(2) have distinctive characteristics, with the latter preparations displaying high myocardium uptake in regions of ischemia in LAD rat myocardium models. The [Cu]-DTS mimetic agent [Tc]-ATSM(2) may have potential as an ischemia-damaged myocardium imaging agent.

The development of [^{99m}Tc]-analogue of Cu-DTS as an agent for imaging hypoxia. Horiuchi K, Tsukamoto T, Saito M, Nakayama M, Fujibayashi Y, Saji H. Nucl Med Biol 2000 May; 27 (4), pp. 391–9.

Cardiovascular: Myocardial Ischemia (Acute)/ Prediction Analysis: High vs Low Risk Assessment
[^{99m}Technetium] ([^{99m}Tc])-SestaMIBI

Background Information: In evaluating conditions of non-diagnostic (initial clinical) or ECG findings suggestive of acute cardiac ischemia, continuous 12-lead ECG monitoring increases the detection of diagnostic ECG findings, including ST-segment elevation, in cases awaiting hospital admission. Cardiac markers, particularly the troponins, show great promise for the detection of a wide spectrum of acute coronary syndromes in emergency departments, including cases with minimal myocardial damage that have a high risk for short-term death and non-fatal acute myocardial infarction. Accelerated diagnostic protocols using serial testing with cardiac markers, ECGs, and then provocative testing over a 14-hour period are feasible to perform, safe, and cost-effective.

Application: [^{99m}Tc]-sestaMIBI can be applied to risk stratify low-moderate risk cases into lower and higher risk groups for cardiac events.

Route of Administration: Intravascular.

Implementation: Correlation of resting [^{99m}Tc]-sestaMIBI scans with case history and other diagnostic marker parameters (e.g., 12-lead ECG monitoring; assay of troponin concentrations).

Interpretation and Analysis: Non-stress, at-rest scanning with [^{99m}Tc]-sestaMIBI is able to risk stratify low-moderate risk cases into lower and higher risk groups for cardiac events. Caveats to such diagnostic schemes include the reduced sensitivity of scanning cases that are pain free and the need for follow-up exercise scans for patients free of perfusion defects at rest.

Diagnostic testing of the emergency department patient with chest pain. Zalenski RJ, Shamsa FH. Curr Opin Cardiol 1998 Jul; 13 (4), pp. 248–53.

Cardiovascular: Myocardial Ischemia/Angina Pectoris/Cardiomyopathy
[^{99m}Technetium] ([^{99m}Tc])-Methoxy-Isobutyl-Isonitrile (MIBI) and Trans-Esophogeal Pacing/ [^{99m}Tc]-MIBI and Coronary Angiography

Application: Detection of alterations in myocardial metabolic/biochemical capacity and function that become substantially altered during episodes of profound ischemia.

Route of Administration: [^{99m}Tc]-MIBI (intravenous) applied in combination with a maximal stress test (phases of rest, stress, and tranesphogeal atrial pacing).

Considerations: [^{99m}Tc]-MIBI is a radioactive agent that has been developed with physical and biological properties more favorable than those of [^{201}thallium]. Such diagnostic agents permit performing simultaneous perfusion and function studies in cases of ischemic cardiopathy.

Trans-esophageal atrial pacing (TAP) techniques have evolved as an alternative provocative test of ischemia.

Interpretation and Analysis: The functional evaluation of myocardial perfusion during stress stimuli utilizing [^{99m}Tc]-MIBI scintigraphic imaging in combination with TAP reveals that it has approximately an 85% level of correlation with [^{99m}Tc]-MIBI scintigraphic imaging applied in concert with coronary angiography evaluations

pertaining to the detection of reversible and irreversible defects. Therefore, transesophogeal pacing can serve as a valid and sensitive provocative test for myocardial ischemia when combined with myocardial [^{99m}Tc]-MIBI scintigraphy.

Diagnosis of coronary artery disease with [^{99m}Tc]-methoxy isobutyl isonitrile and transesophageal pacing. Santomauro M, Cuocolo A, Celentano L, Ferraro S, Pace L, Pappone C, Maddalena G, Salvatore M, Chiariello M. Angiology 1992 Oct; 43 (10), pp. 818–25.

Cardiovascular/Myocardial Necrosis: Acute (Carbon Monoxide–Induced)
[^{99m}Technetium] ([^{99m}Tc])-Glucarate/ [^{99m}Tc]-Methoxy-Isobutyl-Isonitrile (MIBI) Alternative

Cellular/Molecular Mechanism of Action: The fundamental myocellular uptake mechanism involves passive distribution across plasma and mitochondrial membranes, and at equilibrium, sestaMIBI is sequestered within the mitochondria in part due to the large negative mitochondrial trans-membrane potential.

Background Information: Cellular and subcellular uptake studies have shown that [^{99m}Tc]-glucarate localizes in necrotic tissues binding primarily to the nucleoprotein subfractions and to a lesser extent to the DNA fractions. Glucarate is taken up rapidly by necrotic myocardium and is cleared relatively rapidly from the circulation, resulting in early, high target-to-background ratios. Reverse distribution into blood stream is stopped by the high membrane potential of the cardiac cells.

Application: Imaging and diagnosis of acute myocardial necrosis ([^{99m}Tc]-glucarate).

Route of Administration: Intravenous.

Considerations: Scintigraphic changes and metabolic abnormalities associated with acute carbon monoxide poisoning can be attributed to tissue necrosis or transitory ischemia.

Implementation: Evaluation of myocardial ischemia.

Interpretation and Analysis: Detection of positive image profiles implies the presence of myocardial ischemia. The blood clearance of [^{99m}Tc]-MIBI is rapid and biexponential, reflected as an initial fast phase followed by a 2nd slower phase. [^{99m}Tc]-MIBI seems to detect accurately the extension of the early necrosis (unreversible) of the myocardium. In acute myocardial infarction studies, [^{99m}Tc]-glucarate (Amiscan) sensitivity is 100% when administered within 9 hours of the onset of chest pain. Preliminary scintigraphic scans with [^{99m}Tc]-glucarate in conditions of acute carbon monoxide poisoning have confirmed that some cases of acute CO poisoning have typical myocardial necrosis. Alternatively, some cases have hibernating and/or stunned myocardium.

Instrumentation: Computer-integrated scintigraphy.

New possibilities in scintigraphy detection of carbon monoxide cardiotoxicity. Pach J, Hubalewska-Hola A, Szybinski Z, Pach D. Przegl Lek 2001; 58 (4), pp. 182–4.

Cardiovascular/Myocardial Necrosis: Acute/Deep Venous Thrombosis
[^{111}Indium] ([^{111}In])-Diethylenetriamine Pentaacetic Acid (DTPA)-Antimyosin-Fab/[^{99m}Technetium] ([^{99m}Tc)]-Antifibrin Fab

Cellular/Molecular Mechanism of Action: Immunoglobulin forms a complex with specific (unique) antigens on the exterior surface of necrotic cells, blood clots, and cellular components of the circulatory system. Besides their level of uniqueness, these antigenic sites are virtually universal pertaining to their expression by cardiovascular tissues/cells across different segments of the human population.

Application: Cardiovascular disorders, including acute myocardial necrosis and deep venous thrombosis.

Considerations: Represents an accurate, safe, non-invasive diagnostic modality. In contrast to tumor markers present on the surface of malignant cells, the epitope for these antibodies is less prone to "shedding" phenomenon. Examples in this regard include the utilization of the 2 immunoscintigraphic diagnostic agents specifically designed for the assessment of cardiovascular disorders, including [^{111}In]-DTPA-antimyosin-Fab fragment for detection of myocardial necrosis/death, and identification of acute venous thrombosis with [^{99m}Tc]-antifibrin Fab′ (T2G1s).

Cardiovascular applications: Current status of immunoscintigraphy in the detection of myocardial necrosis using antimyosin (R11D10) and deep venous thrombosis using antifibrin (T2G1s). Manspeaker P, Weisman HF, Schaible TF. Semin Nucl Med 1993 Apr; 23 (2), pp. 133–47.

Cardiovascular/Myocardial Oncotic Changes/ Myocardium Apoptotic Changes
[^{99m}Technetium] ([^{99m}Tc])-Glucaric Acid/ [^{111}Indium] ([^{111}In])-Antimyosin

Application: The imaging agent [^{99m}Tc]-glucaric acid possesses binding avidity only for the oncotic myocardium. Alternatively, [^{111}In]-antimyosin is positive for both oncotic and apoptotic myocardium changes.

Animal Model: Doxorubicin can be applied to induce apoptosis in cultured rat embryonic cardiocytes (H9C2) and myocardial apoptosis CD1 rats. Acute myocardial oncosis can be induced by heat or subcutaneous isoproterenol administration.

Laboratory Methodologies: Scanning electron microscopy, DNA laddering, TUNEL staining, [^{111}In]-antimyosin antibody, and [^{99m}Tc]-glucaric acid can be applied to demonstrate *in vitro* and *in vivo* doxorubicin-induced apoptosis or isoproterenol-induced myocardial oncosis.

Considerations: Non-invasive imaging techniques would be highly desirable to differentiate oncotic from apoptotic cell death.

Interpretation and Analysis: Scanning electron microscopy, DNA laddering, and TUNEL staining of H9C2 cardiocytes treated with doxorubicin display apoptotic cell death. Rat hearts treated with doxorubicin (10 and 20 mg/kg) are DNA ladder-positive and localize significantly greater [^{111}In]-antimyosin antibody (mean + standard deviation, 0.1942 ± 0.0150 percent injected dose per gram [%ID/g] and 0.1825 ± 0.0238 %ID/g, respectively) than normal hearts (0.1154 ± 0.0270 %ID/g, $p < 0.05$). No increases in myocardial [^{99m}Tc]-glucaric acid activity are observed in rat hearts after 6, 12, and 24 hours of doxorubicin injection (0.0311 ± 0.0066 %ID/g, 0.0356 ± 0.007 %ID/g, and 0.0368 ± 0.0047 %ID/g, respectively; control hearts, 0.0352 ± 0.0099 %ID/g; p = not significant). The uptake of [^{99m}Tc]-glucaric acid is significantly greater in isoproterenol-induced oncotic hearts (0.1256 ± 0.1023 %ID/g) than in controls ($p < 0.0001$).

Indium 111 antimyosin and [^{99m}Tc] glucaric acid for non-invasive identification of oncotic and apoptotic myocardial necrosis. Khaw BA, Silva JD, Petrov A, Hartner W. J Nucl Cardiol 2002 Sep–Oct; 9 (5), pp. 471–81. (Comment in: J Nucl Cardiol 2002 Sep–Oct; 9 (5), pp. 554–60.)

Cardiovascular: Myocardial Perfusion (Kawasaki Disease [KD])/Myocardial Perfusion/Regional Hypoperfusion
[^{99m}Technetium] ([^{99m}Tc])-Tetrofosmin (TF)/ Dipyridamole

Physiological Mechanism of Action: Dipyridamole promotes vasodilator activity.

Background Information: The coronary artery abnormalities in KD often cause myocardial ischemia. Previous publications have described the use of ^{201}thallium myocardial perfusion imaging to determine the extent of ischemia in KD conditions. The technetium perfusion agents offer better resolution and may offer additional information about ventricular function in such conditions.
Application: Tetrofosmin myocardial perfusion imaging can detect regional areas of myocardial hypoperfusion (e.g., KD of children).
Implementation: Evaluation of myocardial perfusion in cases of KD applying [^{99m}Tc]-TF in conjunction with performing a dipyridamole vasodilator stress test. Significant coronary artery stenosis is classified as being ≥ a 75% reduction in luminal diameter. After administration of high-dose dipyridamole infusion (0.70 mg/kg), [^{99m}Tc]-TF is injected, followed by a 2nd [^{99m}Tc]-TF injection at rest 4 hours later. Single photon emission computed tomography (SPECT) images are obtained more than 30 minutes after TF injection.

Human Model: Kawasaki disease (n = 86 cases, 11.5 ± 6.4 years; n = 20 age-matched controls without heart disease). Dipyridamole (high-dose = 0.70 mg/kg); [^{99m}Tc]-TF (1st dose = 74–370 MBq; 2nd dose = 148–740 MBq).
Interpretation and Analysis: Significant coronary artery stenosis; coronary aneurysm without stenosis; and an absence of coronary lesions can be appreciated in a considerable number of cases (e.g., n = 20/86; n = 37/86; and n = 29/86, respectively). Regional myocardial hypoperfusion can be observed in a number of cases that have coronary artery stenosis of 75% or greater (n = 18/86; sensitivity 90%; and specificity 100%). A small percentage of cases do not demonstrate ischemic changes in coronary artery stenosis (n = 2) and some of these cases have good collateral blood flow (n = 1 of 2).

Myocardial ischemia in Kawasaki disease: Evaluation with dipyridamole stress [^{99m}technetium] tetrofosmin scintigraphy. Fukuda T, Ishibashi M, Yokoyama T, Otaki M, Shinohara T, Nakamura Y, Miyake T, Kudoh T, Oku H. J Nucl Cardiol 2002 Nov–Dec; 9 (6), pp. 632–7.

Cardiovascular: Myocardial Perfusion/Influence Hyperlipidemia and Hyperemia on "Washout" Imaging Kinetics
[^{99m}Technetium] ([^{99m}Tc]) Bis(N-Ethoxy, N-Ethyldithiocarbamato)Nitrido

Background Information: *Bis*(N-ethoxy,N-ethyldithiocarbamato)nitrido technetium (V) ([^{99m}Tc]N-NOET) is a myocardial perfusion imaging agent demonstrating significant redistribution that has been utilized in phase III clinical trials. Previous studies have suggested that [^{99m}Tc]N-NOET is bound intravascularly.
Route of Administration: [^{99m}Tc]N-NOET (isolated perfused rat heart bolus; intracoronary artery in dogs).
Dosage: [^{99m}Tc]N-NOET (1.5 MBq in isolated perfused rat heart; 0.75 MBq *in vivo* in dogs).
Implementation: Determine whether modifications in the vascular compartment would provide further insights into the mechanisms of [^{99m}Tc]N-NOET myocardial washout and redistribution. One approach to achieving this objective can entail the evaluation of [^{99m}Tc]N-NOET cardiac washout characteristics in *ex vivo* isolated perfused hearts in the absence or presence of bovine serum albumin (BSA, 0.03%) with or without bound lipids. The intrinsic myocardial washout of the tracer can also be determined *in vivo* following intracoronary bolus injection of the tracer before and after (i) hyperlipidemia induced by intravenous administration of 20% intralipids (300 ml) (n = 3); or (ii) hyperemia induced by intravenous infusion of the adenosine A_{2A} receptor agonist ATL-146e (0.3 μg/kg/min; n = 6).

***Ex Vivo* Model:** Isolated purfused rat hearts (n = 15; n = 6 without albumin; n = 5 also given bound lipid; n = 4 also without bound lipid).

Animal Model: Canine (n = 6 dogs; n = 3 also given intralipids).
Interpretation and Analysis: In isolated hearts, there is no significant myocardial washout of [^{99m}Tc]N-NOET with Krebs-Henseleit buffer. Addition of BSA without bound lipids results in a significant cardiac washout of the tracer ($p < 0.001$ by repeated measures ANOVA). The presence of lipids bound to BSA further accelerates the washout rate of [^{99m}Tc]N-NOET (half-life [$t_{1/2}$], 431.5 ± 23.2 minutes vs 242.9 ± 63.2 minutes; $p < 0.05$). *In vivo* in dogs, intralipid administration significantly increases the intrinsic washout rate of [^{99m}Tc]N-NOET ($t_{1/2}$, 108.0 ± 23.9 minutes vs 51.8 ± 11.8 minutes; $p < 0.05$). In addition, vasodilatation with ATL-146e results in a 4.9-fold increase in coronary flow ($p < 0.05$ vs baseline) and a significantly faster intrinsic [^{99m}Tc]N-NOET myocardial washout ($t_{1/2}$, 81.1 ± 12.1 minutes vs 40.7 ± 7.3 minutes; $p < 0.05$). Therefore, myocardial washout kinetics of [^{99m}Tc]N-NOET is affected by a variety of intravascular factors that support the hypothesis that the tracer is most likely localized on the vascular endothelium. The potential impact of variations in circulating lipid levels on clinical imaging with [^{99m}Tc]N-NOET remains to be fully delineated.

Effects of increased lipid concentration and hyperemic blood flow on the intrinsic myocardial washout kinetics of [^{99m}Tc]N-NOET. Riou LM, Unger S, Toufektsian MC, Ruiz M, Watson DD, Beller GA, Glover DK. J Nucl Med 2003 Jul; 44 (7), pp. 1092–8.

Myocardial Perfusion
[^{201}Thallium] ([^{201}Tl])

Application: Diagnostic imaging for assessment of myocardial perfusion for the purpose of detecting myocardial ischemia and myocardial infarction.
Route of Administration: [^{201}Tl] (intravenous).
Dosage: [^{201}Tl].
Considerations: Measurement of organ-specific uptake applying a gamma-well counter for assessment of internal distribution, combined with the application of autoradiograms, recognizes myocardial [^{201}Tl] accumulation within 5 minutes after injection. Maximum accumulation is achieved at 30 minutes and gradually decreases thereafter.
Interpretation and Analysis: Myocardial scans reliably detect both acute myocardial infarction and transient myocardial ischemia of angina pectoris. In human adults, lesions of myocardial infarction can be clearly detected, but in children it can be difficult to obtain sufficient information due to small heart size and high pulse rate. Judging from the nature of such findings, it has been proposed that it is possible to obtain much clearer images by using a data analyzer. Some clinicians believe that although [^{201}Tl] reliably indicates perfusion defects within the myocardium, its diagnostic use may need to be reserved to clarify such diagnostic problems in cases with coronary artery disease that cannot be satisfactorily explained by conventional diagnostic modalities.
Instrumentation: Computer-integrated scintillation camera.

Cardiovascular: Myocardial Sodium-Potassium ATPase (Na^+/K^+-ATPase)
[^{125}I]-Digoxin/[^{125}I]-Digoxin-Iodohistamine(bis(O-Carboxymethyloxime))

Cellular/Molecular Mechanism of Action: Cardiac glycosides recognize and physically bind to membrane-associated myocardial Na^+/K^+-ATPase complexes.

Background Information: Cardiac glycosides have a high binding avidity for myocardial Na^+/K^+-ATPase complexes.
Implementation: Evaluation of radioiodinated digoxin (cardiac glycoside) derivatives as potential candidates for myocardial imaging with particular emphasis on non-invasive monitoring of cardiac glycoside therapy.

Animal Model: Canine (cardiac scintigraphy).
Interpretation and Analysis: One radioiodinated digoxin derivative, [^{125}I]-digoxin-iodohistamine(*bis*(O-carboxymethyloxime)), achieves a high level of accumulation within the myocardium and has similar binding avidity for Na^+/K^+-ATPase as digoxin itself and behaves in an analogous manner pertaining to ouabain displacement as indicated during the course of *in vivo* and *in vitro* investigations. Based on these results, [^{123}I] labeling of digoxin-histamine(*bis*(O-carboxymethyloxime)) and imaging in a dog demonstrate uptake in the myocardium.

High myocardial accumulation of radioiodinated digoxin derivative: A possible Na^+/K^+-ATPase imaging agent. Fujibayashi Y, Takemura Y, Matsumoto K, Wada K, Yonekura Y, Konishi J, Yokoyama A. J Nucl Med 1992 Apr; 33 (4), pp. 545–9.

Cardiovascular: Sympathetic (Adrenergic) Innervation/Myocardial Infarction (MI)/ Heterogeneous Cardiac Sympathetic Innervation
[^{131}I]-Metaiodobenzylguanidine ([^{131}I]-MIBG)/ [^{125}I]-Iodocyanopindolol ([^{125}I]-ICYP)

Cellular/Molecular Mechanism of Action: Metaiodobenzylguanidine is a norepinephrine analogue that recognizes and physically binds to adrenergic receptor complexes. Iodocyanopindolol is a β-adrenoreceptor ligand.
Application: Detection and characterization of myocardial infarction.
Route of Administration: [^{131}I]-MIBG and [^{125}I]-ICYP are both administered intravenously.
Implementation: Evaluation of cardiac neuronal function and β-receptor expression utilizing a dual-tracer method employing [^{131}I]-MIBG and [^{125}I]-ICYP in heart failure after MI.

Animal Model: Rat (heart failure after induced MI).
Interpretation and Analysis: In conditions of MI (rat), left ventricular (LV) systolic function is decreased, and LV dimension and right ventricular (RV) mass increase gradually. Accumulations of [^{131}I]-MIBG within non-infarcted LV (remote region) and RV decrease by 15% at 1 week compared with sham-operated controls. These same accumulations are restored by 71% and 56%, respectively, at 24 weeks compared with age-matched sham controls, despite sustained depletion of myocardial norepinephrine contents within these anatomical regions. Accumulations of [^{125}I]-ICYP in the remote region and in the RV do not decrease during any stage. Myocardial MIBG distribution is heterogeneous at 1 week and lower in the peri-infarcted region than in the remote region, associated with reduced ICYP accumulation in the peri-infarcted region. At week 12, the heterogeneous distribution of both isotopes disappears. Thus cardiac sympathetic neuronal alteration appears to be coupled with downregulation of β receptors in heart failure after MI (rat). The abnormal adrenergic signaling occurs heterogeneously in terms of ventricular distribution and time course after myocardial infarction.

Heterogeneous cardiac sympathetic innervation in heart failure after myocardial infarction of rats. Igawa A, Nozawa T, Yoshida N, Fujii N, Inoue M, Tazawa S, Asanoi H, Inoue H. Am J Physiol Heart Circ Physiol 2000 Apr; 278 (4), pp. H1134–41.

Cardiovascular: Sympathetic (Adrenergic) Innervation (Denervation)/Ischemia-Related Sympathetic Denervation/Myocardial Sympathoexcitatory Response/[Balloon Coronary Occlusion]
[^{123}I]-Metaiodobenzylguanidine ([^{123}I]-MIBG)

Cellular/Molecular Mechanism of Action: [^{123}I]-MIBG is a norepinephrine analogue that recognizes and physically binds to adrenergic receptor complexes.
Background Information: Alterations of cardiac sympathetic nerve function could modulate sympathetic reflexes originating from areas of ischemic injury.
Application: Detection and characterization of cardiac sympathetic denervation.
Route of Administration: [^{123}I]-MIBG (intravenous).
Implementation: Evaluate conditions of angina pectoris as a function of quantified baseline cardiac sympathetic denervation corresponding to anatomical regions of ischemia utilizing [^{123}I]-MIBG. Complementary diagnostic procedures can include establishing the nature of transient changes in sympathetic activity during balloon coronary occlusion (BCO) by wavelet analysis of RR interval variability. The research objective of the referenced study was to elucidate the influence of cardiac sympathetic denervation on the sympathoexcitatory response to acute myocardial ischemia during BCO.

Human Model: Cases suffering from angina pectoris ($n = 23$) subjected to BCO.
Interpretation and Analysis: Balloon coronary occlusion results in a transient augmentation of low-frequency (LF; 0.04–0.14 Hz) spectral components of RR interval variability in approximately 30% of cases (e.g., $n = 4/12$) with cardiac denervation, and in greater than two-thirds of cases without denervation (e.g., $n = 8/11$; $p < 0.01$ by the chi^2 test). Consequently, increases in LF components are significantly less during BCO in cases with cardiac denervation (34%) than in those without denervation (273%: interaction: $p < 0.05$). In some cases with severe ischemia provoked by a fall of $\geq 10\%$ in the left ventricular ejection fraction, LF components increase by 506% during BCO, regardless of the condition of cardiac denervation ($n = 7/23$ cases). Conversely, in conditions of mild ischemia provoked by a fall of $< 10\%$ in the ejection fraction, the changes of LF components during BCO are significantly less in cases with denervation than in those without denervation (84 vs 344%, $p < 0.05$). Such observations suggest that if provoked ischemia is not severe, cardiac sympathetic denervation could prevent ischemia-induced sympathoexcitation.

Cardiac sympathetic denervation modulates the sympathoexcitatory response to acute myocardial ischemia. Joho S, Asanoi H, Takagawa J, Kameyama T, Hirai T, Nozawa T, Umeno K, Shimizu M, Seto H, Inoue H. J Am Coll Cardiol 2002 Feb 6; 39 (3), pp. 436–42.

Cardiovascular: Sympathetic (Adrenergic) Receptor Expression in Heart Failure/ Clinical Variables in Risk Stratification
[^{123}I]-Metaiodobenzylguanidine ([^{123}I]-MIBG)

Cellular/Molecular Mechanism of Action: [^{123}I]-MIBG is a norepinephrine analogue that recognizes and physically binds to adrenergic receptor complexes.
Background Information: Both myocardial [^{123}I]-MIBG uptake and plasma norepinephrine are markers of sympathetic activation in heart failure that have been shown to be of value in predicting a poorer prognosis. However, these observations have been noted

before treatment with β-blockers became part of standard clinical practice.

Application: Both myocardial [^{123}I]-MIBG uptake and plasma norepinephrine are markers of sympathetic activation in heart failure conditions.

Implementation: Evaluation of conditions of chronic heart failure over a mean follow-up period of 36 months. Potential prognostic parameters are obtained before initiation of β-blocker therapy.

Human Model: Cases of chronic heart failure (n = 58) identified according to the established guidelines (New York Heart Association functional Class II and III, ejection fraction < 35%; 53% ischemic cardiomyopathy).

Interpretation and Analysis: During the observation period, cases may display cardiovascular complications (e.g., n = 17/58 or 29.3%, death or heart transplantation). Multivariate Cox regression analysis, plasma norepinephrine, peak oxygen consumption, end-diastolic volume as measured by echocardiography, and exercise performance during bicycling and walking have prognostic significance in cases with heart failure treated with β-blockers in addition to angiotensin-converting enzyme inhibitors. In both uni- and multivariate analysis, the heart/mediastinum ratio of [^{123}I]-MIBG uptake does not correlate with cardiovascular mortality.

Cardiac [^{123}I]-MIBG imaging and clinical variables in risk stratification in patients with heart failure treated with β-blockers. de Milliano PA, Tijssen JG, van Eck-Smit BL, Lie KI. Nucl Med Commun 2002 Jun; 23 (6), pp. 513–9.

Cardiovascular: Sympathetic (Adrenergic) Receptor Expression/β-blocker Therapeutic Response (Dilated Cardiomyopathy [DCM])
[^{123}I]-Metaiodobenzylguanidine ([^{123}I]-MIBG)/[^{201}Thallium] ([^{201}Tl])

Application: Determination of the degree of response to β-blocker therapeutic intervention in conditions of dilated cardiomyopathy.

Route of Administration: Intravenous.

Implementation: Evaluation (co-prediction) of the efficacy of β-blocker therapy in conditions of dilated cardiomyopathy utilizing thallium-201 [^{201}Tl] myocardial scintigraphy and [^{123}I]-MIBG myocardial scintigraphy performed before and after initiation of therapeutic intervention.

Human Model: Cases of dilated cardiomyopathy (n = 47 cases with [^{201}Tl] and [^{123}I]-MIBG scans performed prior to β-blocker therapy).

[^{201}Tl] extent score (ES) schemes that can be employed for quantitating myocardial damage involve the use of statistical threshold values of statistical mean-2SD (ES-2) and mean-3SD (ES-3). The ES difference between ES-2 and ES-3 is calculated, and according to ES and ES difference, DCM cases can be classified into 3 groups including (i) mild-defect type (mild-type); (ii) moderate-defect type (moderate-type); and (iii) severe-defect type (severe-type). The heart/mediastinum (H/M) MIBG uptake ratio can be evaluated, and the percent washout ratio of myocardial MIBG obtained from these data.

Interpretation and Analysis: In clinical investigations assessing cases of dilated cardiomyopathy (e.g., n = 47), conditions can be categorized according to the following classification schemes: Group A (n = 18 mild-type, n = 14 moderate-type, n = 1 severe-type cases) and Group B (n = 5 mild-type, n = 4 moderate-type, n = 5 severe-type cases). A significant relation can be observed between the defect type on [^{201}Tl] and the response to β-blocker therapy ($p = 0.0090$). Both H/M MIBG uptake ratios and washout ratios are not significantly different between each of the groups. Therefore, [^{201}Tl] may be useful for predicting the response to β-blocker therapy in DCM conditions.

Use of thallium-201 myocardial scintigraphy for the prediction of the response to β-blocker therapy in patients with dilated cardiomyopathy. Hara Y, Hamada M, Ohtsuka T, Ogimoto A, Saeki H, Suzuki J, Matsunaka T, Nakata S, Shigematsu Y. Circ J 2002 Dec; 66 (12), pp. 1139–43.

Cardiovascular: Sympathetic (Adrenergic) Receptor Expression Profiles/Congestive Heart Disease: Heart and Lung/[^{123}I]-Metaiodobenzylguanidine ([^{123}I]-MIBG)/[^{201}Thallium] ([^{201}Tl]) Ratio vs Left Ventricular Ejection Fraction
[^{123}I]-MIBG)/[^{201}Tl]/Cardiac [^{123}I]-MIBG Washout/[^{123}I]-MIBG (Adrenergic Activity)/[^{201}Tl] (Perfusion) Ratio/[^{123}I]-MIBG:[^{201}Tl] vs Plasma Norepinephrine

Cellular/Molecular Mechanism of Action: [^{123}I]-MIBG is a radioiodinated analogue of norepinephrine that recognizes and binds to sympathetic/adrenergic receptor complexes. The radionucleotide [^{201}Tl] per se does not exert a true biological effect.

Application: [^{123}I]-MIBG can be utilized to detect and characterize tissue/organ sympathetic/adrenergic receptor expression profiles. The radionuclide [^{201}Tl] can serve as a tracer molecule suitable for measuring vascular perfusion parameters. Simultaneous use of both of these agents can facilitate assessment of adrenergic activity and perfusion in various organs in conditions of heart failure.

Route of Administration: [^{123}I]-MIBG and [^{201}Tl] (intravascular).

Implementation: Simultaneous assessment of regional adrenergic activity and vascular perfusion with [^{123}I]-MIBG and [^{201}Tl] in various organs. In order to reduce crosstalk from [^{201}Tl] into the [^{123}I] energy window to less than 5%, doses of [^{123}I]-MIBG that are more than 5 times greater than that of [^{201}Tl] are administered following [^{201}Tl] scintigraphy.

Human Model: Cases suffering from congestive heart failure (CHF) (n = 13; n = 13 without heart failure).

Interpretation and Analysis: Regional uptake of [^{201}Tl] (%dose) becomes significantly increased in the heart (left ventricle) and lung (both $p < 0.01$) in conditions of CHF. Increases in global cardiac uptake may be related to left ventricular enlargement. Patterns of regional uptake for [^{123}I]-MIBG (%dose) at 15 minutes are similar to those of [^{201}Tl], suggesting that early [^{123}I]-MIBG uptake could in part depend on regional perfusion in both case group types. At 3 hours, regional uptake of [^{123}I]-MIBG is significantly increased within the heart, lung, and kidney (all $p < 0.01$) in conditions of CHF. Delayed [^{123}I]-MIBG uptake indicates the degree of neuronal accumulation of the tracer, and therefore reflects adrenergic activity. Interestingly, ratios of cardiac [^{123}I]-MIBG (adrenergic activity) to [^{201}Tl] (unit of perfusion) decreases significantly in the heart ($p < 0.01$) but increases significantly in the kidney ($p < 0.01$) in conditions of CHF compared to negative reference controls. Cardiac [^{123}I]-MIBG washout is also significantly increased with congestive heart failure. Moreover, the cardiac [^{123}I]-MIBG:[^{201}Tl] ratio negatively correlates with plasma norepinephrine concentrations ($r = -0.74$, $p < 0.01$), but positively correlates with left ventricular ejection fraction values ($r = 0.60$, $p < 0.01$). These data suggest that there may be impairment of both the neuronal uptake function and the vesicular storage function in the failing heart, and an increment in neuronal uptake function in the kidneys in conditions of congestive heart failure. It is therefore suggested that dual-tracer scintigraphy can function as a useful non-invasive method for the simultaneous assessment of adrenergic activity and perfusion in various organs in conditions of cardiac failure.

Simultaneous assessment of regional adrenergic activity and perfusion with [^{123}I]-MIBG and [^{201}Tl] in congestive heart failure. Seto H, Shimizu M, Nozawa T, Yoshida N, Inagaki S, Kageyama M, Kakishita M. Nucl Med Commun 1996 Mar; 17 (3), pp. 225–30.

Cardiovascular: Sympathetic (Adrenergic) Receptor Expression/Cardiac Arrythmia: Brugada Syndrome/ Sympathetic Innervation Dysfunction (Presynaptic) *[^{123}I]-Metaiodobenzylguanidine ([^{123}I]-MIBG)*

Cellular/Molecular Mechanism of Action: [^{123}I]-MIBG is an analogue of the adrenergic neurotransmitter norepinephrine.

Background Information: Patients with Brugada syndrome present with characteristic ECG abnormalities (atypical right bundle-branch block and ST-segment elevation) and life-threatening ventricular tachyarrhythmias despite structurally normal hearts. Involvement of the autonomic nervous system is suspected by the occurrence of ventricular tachyarrhythmias and sudden death at rest or during sleep and by changes of typical ECG signs under pharmacological modulation of the myocardial autonomic tone.

Application: Characterization of presynaptic sympathetic innervation to the heart in conditions of Brugada syndrome.

Route of Administration: [^{123}I]-MIBG (intravenous).

Implementation: Evaluation of the presynaptic cardiac neuronal reuptake of norepinephrine (uptake 1) in conditions of Brugada syndrome and age-matched control subjects using the norepinephrine analogue [^{123}I]-MIBG in concert with single photon emission computed tomography (SPECT) and quantitative 33-segment bull's-eye analysis.

Human Model: Brugada syndrome ($n = 17$; $n = 10$ age-matched controls).

Interpretation and Analysis: Regionally reduced [^{123}I]-MIBG uptake is present in almost half of all cases with Brugada syndrome (e.g., $n = 8/17$ or 47%) but not in reference controls. Quantitative analysis shows segmental reduction of [^{123}I]-MIBG uptake in the inferior and septal left ventricular wall in patients with Brugada syndrome compare with control subjects ($p < 0.05$). No correlation can be appreciated between the findings from [^{123}I]-MIBG-SPECT and clinical characteristics of study patients. Abnormal [^{123}I]-MIBG uptake in Brugada syndrome cases indicates presynaptic sympathetic dysfunction exists within the heart. These findings may have potential impact on the pathophysiology and arrhythmogenesis in cases with Brugada syndrome. Future quantitative investigations of the presynaptic and postsynaptic sympathetic and parasympathetic branches of the cardiac autonomic nervous system may clarify whether these observations represent a primary adrenergic dysfunction or an imbalance between sympathetic and parasympathetic innervation of the heart.

Cardiac autonomic dysfunction in Brugada syndrome. Wichter T, Matheja P, Eckardt L, Kies P, Schäfers K, Schulze-Bahr E, Haverkamp W, Borggrefe M, Schober O, Breithardt G, Schäfers M. Circulation 2002 Feb 12; 105 (6), pp. 702–6.

Cardiovascular: Sympathetic (Adrenergic)/ Salt Sensitivity and Regulation/Cardiac Neuronal Function: Late Phase Deterioration/Adrenergic β-Receptor Downregulation *[^{131}I]-Metaiodobenzylguanidine ([^{131}I]-MIBG)/ [^{125}I]-Cyanopindolol ([^{125}I]-ICYP)*

Cellular/Molecular Mechanism of Action: [^{131}I]-MIBG is an analogue of norepinephrine and detects and physically binds to adrenergic/sympathetic receptor complexes. [^{125}I]-ICYP also recognizes and binds to sympathetic/adrenergic receptor complexes.

Background Information: Heart failure is associated with sympathetic nervous system activation and downregulation of β receptors. However, the coupling between cardiac sympathetic neuronal function and β receptors during the development of hypertensive heart failure is not clear.

Application: [^{131}I]-MIBG and [^{125}I]-ICYP (intravascular) can be utilized to evaluate and profile adrenergic/sympathetic adrenergic receptor expression.

Route of Administration: [^{131}I]-MIBG and [^{125}I]-ICYP (intravascular).

Implementation: Evaluation of cardiac neuronal function and β receptors utilizing a dual-tracer method employing [^{131}I]-MIBG and [^{125}I]-ICYP under *in vivo* conditions of salt-sensitivity and salt-resistance.

Animal Model: Rats (Dahl salt-sensitive [DS] and salt-resistant [DR]) fed an 8% NaCl diet after the age of 6 weeks. Blood pressure is raised to $>$ 200 mm Hg at 12 weeks in DS rats and remains elevated until 18 weeks, but only slightly in DR rats. Left ventricular (LV) function of DS rats is preserved at 12 weeks but is deteriorated by 18 weeks.

Interpretation and Analysis: Despite a 56% reduction of cardiac norepinephrine content at 12 weeks in salt-sensitive *in vivo* models, neither MIBG nor ICYP uptakes in salt-sensitive *in vivo* models is different from salt-resistant *in vivo* models. At 18 weeks, both MIBG and ICYP uptakes decrease by 52% and 39%, respectively, in association with 71% reductions in cardiac norepinephrine in salt-sensitive *in vivo* models. MIBG uptake of the LV is homogeneous at 6 weeks but lower in the LV endocardial regions at 18 weeks in salt-sensitive *in vivo* models. Cardiac sympathetic neuronal function, therefore, is relatively preserved at the compensated, hypertrophic stage in salt-sensitive *in vivo* models but deteriorates in association with β-receptor downregulation at the failing stage. The cardiac neuronal dysfunction occurs heterogeneously. A combination of scintigraphic portrayal of β receptors with MIBG should provide valuable information regarding sympathetic nerve signaling in living hearts.

Dual-tracer assessment of coupling between cardiac sympathetic neuronal function and downregulation of β receptors during development of hypertensive heart failure of rats. Nozawa T, Igawa A, Yoshida N, Maeda M, Inoue M, Yamamura Y, Asanoi H, Inoue H. Circulation 1998 Jun 16; 97 (23), pp. 2359–67.

Cardiovascular: Sympathetic (Adrenergic) Tone/ Congestive Heart Failure (CHF)/Cardiac Sympathetic Nervous System Function/ Predictive Response to Carvedilol Therapy *[^{123}I]-Metaiodobenzylguanidine ([^{123}I]-MIBG)*

Cellular/Molecular Mechanism of Action: [^{123}I]-MIBG is perceived as an analogue of norepinephrine.

Background Information: Carvedilol treatment reduces the mortality rate in conditions of CHF. It is not known whether carvedilol treatment is effective in heart failure cases with substantial cardiac sympathetic nerve dysfunction.

Application: Assessment of cardiac adrenergic/sympathomimetic tone in various cardiovascular conditions (e.g., CHF), and functions as a probe for evaluating the efficacy of cardiovascular therapeutic agents.

Route of Administration: Intravenous.

Implementation: Evaluate the effect of chronic carvedilol treatment in patients with cardiac sympathetic nerve dysfunction of vary-

ing severity. A viable approach to achieving such an objective can involve assessment of sympathetic nerve function before and after 7.2 ± 2.7 months of carvedilol treatment applying [^{123}I]-MIBG imaging modalities, radionuclide ventriculography, and transmyocardial norepinephrine sampling.

Human Model: Congestive heart failure patients with idiopathic cardiomyopathy (n = 22).

Interpretation and Analysis: Cases of relatively advanced impairment of cardiac sympathetic nerve function, as manifested by a baseline [^{123}I]-MIBG ratio lower than 1.40, have a statistically significant improvement in [^{123}I] heart/mediastinum (H/M) ratio with carvedilol treatment (1.26 ± 0.12 to 1.39 ± 0.20 at $p = 0.004$). Of cases with a baseline [^{123}I]-MIBG ratio lower than 1.40 (e.g., n = 10), a large percentage have an increase in the H/M ratio with carvedilol treatment (n = 9/10 cases). Left ventricular ejection fraction increases from 25.4% ± 7.8% to 37.3% ± 14.7% ($p < 0.001$), with no difference between cases with relatively advanced vs relatively preserved cardiac sympathetic nerve function. Most cases of CHF show a favorable response in left ventricular function to carvedilol treatment, regardless of the baseline level of cardiac sympathetic nervous system function, as assessed by neuronal [^{123}I]-MIBG imaging. Cases with relatively advanced impairment of baseline [^{123}I]-MIBG uptake are most likely to show evidence of improved cardiac sympathetic nervous system function in response to carvedilol therapy.

Carvedilol improves left ventricular function in heart failure patients with idiopathic dilated cardiomyopathy and a wide range of sympathetic nervous system function as measured by iodine 123 metaiodobenzylguanidine. Gerson MC, Craft LL, McGuire N, Suresh DP, Abraham WT, Wagoner LE. J Nucl Cardiol 2002 Nov–Dec; 9 (6), pp. 608–15.

Cardiovascular: Ventricular (Left) Myocardium (Isolated Non-Compaction)/Anatomical and Pathophysiology Parameters/Computed Tomography
^{201}Thallium ([^{201}Tl])/Echocardiography/ Magnetic Resonance Imaging (MRI)/ Computed Tomography (CT)

Application: Detection and characterization of the anatomical features and pathophysiology of isolated non-compaction of the left ventricular myocardium.

Route of Administration: Intravenous.

Implementation: Evaluate the feasibility of ultrafast CT and MRI for anatomical and pathophysiological diagnosis of isolated non-compaction of the left ventricular myocardium (INVM) compared with other imaging modalities including thallium myocardial imaging.

Human Model: Six patients, 3 sets of siblings, ranging in age from 13 to 18 years, were included in this study.

Interpretation and Analysis: Echocardiograms (2-dimensional) reveal numerous prominent trabeculations and deep intertrabecular recesses in 1 or more ventricular wall segments (e.g., n = 6/6 cases). [^{201}Tl] myocardial imaging can detect regions of hypoperfusion corresponding to zones where non-compacted ventricular myocardium is localized. Ultrafast CT shows early defects of varying degrees and rate enhancement of the non-compacted ventricular myocardium, implying fibrosis within these regions. Magnetic resonance imaging detects inner zones of non-compacted myocardium distinguishable from thin outer zones of compacted myocardium. T_2-weighted imaging reveals high-intensity areas at the apex of the left ventricle, suggesting the presence of disturbed microcirculation due to fibrosis, thrombus formation, and hypokinesis. Cine MRI reveals hypokinesis of the non-compacted ventricular wall during the cardiac cycle. Ultrafast CT and MRI provide high-resolution imaging of non-compacted myocardium, and also pathophysiological details regarding this rare disease.

Isolated non-compaction of the ventricular myocardium: ultrafast computed tomography and magnetic resonance imaging. Hamamichi Y, Ichida F, Hashimoto I, Uese KH, Miyawaki T, Tsukano S, Ono Y, Echigo S, Kamiya T. Int J Cardiovasc Imaging 2001 Aug; 17 (4), pp. 305–14.

Cardiovascular: Ventricular (Left) Dysfunction/ Skeletal Muscle Anaerobic Threshold/Exercise Intolerance
[^{201}Thallium] ([^{201}Tl])

Cellular/Molecular Mechanism of Action: ^{201}Thallium is a radioactive isotope that emits photons and does not per se exert any biological effect.

Background Information: Decreased blood flow to working muscles makes an important contribution to exercise intolerance in patients with chronic heart failure.

Application: Radioactive tracer/marker system that can be applied for the detection of alterations in muscle metabolism.

Route of Administration: [^{201}Tl].

Implementation: Determine if maldistribution of skeletal muscle blood flow is closely related to exercise intolerance in conditions of cardiac dysfunction. One approach to determining the implications of this consideration involves performing whole-body thallium scintigraphy during 1-leg exercise challenge in cases of left ventricular (LV) dysfunction. Blood flow distribution to the exercising and resting legs is quantified by expressing regional thallium counts as a percentage of the whole-body counts at rest, at the level of anaerobic threshold, and at peak exercise.

Human Model: Left ventricular dysfunction (LV ejection fraction < 45%; n = 11 cases).

Interpretation and Analysis: At anaerobic threshold, thallium activity of exercising muscle increases from 4.2 ± 0.7% to 14.0 ± 2.5% ($p < 0.05$) in the thigh and from 1.7 ± 0.3 to 4.1% ± 0.9% ($p < 0.05$) in the calf, compared to resting values. Consequently, the ratio of thallium activity between exercising and resting legs increases to 2.7 ± 0.7 ($p < 0.05$) in the thigh and to 2.3 ± 0.7 ($p < 0.05$) in the calf. When plotted as a function of anaerobic threshold, thallium activity of the exercising thigh ($r = 0.78$, $p < 0.05$) and the thallium ratio between exercising and resting thigh ($r = 0.69$, $p < 0.05$) declines with a reduction in exercise tolerance. These correlations are not observed in lower limb musculature. Whole-body thallium scintigraphy demonstrates a maldistribution of leg blood flow in cases with reduced aerobic exercise capacity, suggesting that this abnormality could play an important role in exercising intolerance in such conditions.

Quantitative evaluation of blood flow distribution to exercising and resting skeletal muscles in patients with cardiac dysfunction using whole-body thallium-201 scintigraphy. Wada O, Asanoi H, Miyagi K, Ishizaka S, Kameyama T, Ishise H, Seto H, Inoue H. Clin Cardiol 1997 Sep; 20 (9), pp. 785–90.

Vascular "Blood-Pool"
[^{99m}Technetium] ([^{99m}Tc])-Human Serum Albumin (HSA)/[Kit Preparation Variability]

Physiological Mechanism of Action: Human serum albumin is a protein found in the intravascular compartment that maintains plasmas oncotic pressure and serves as a source of reserve protein/amino acids that can be metabolized during starvation.

Application: Endogenous protein marker system/tracer molecule that can potentially be used to characterize various parameters associated with the size of the intravascular compartment, angiography procedures, and regional tissue/organ perfusion.

Semi-Synthetic Methods: Evaluation of the suitability of 5 different commercially available kits that provide HSA labeled with [^{99m}Tc] for cardiac blood-pool imaging. Four of the kit preparations are produced using a 1-step process employing stannous chloride as the reducing agent; the 5th is based on an electrolytic reduction. Other methods for labeling have also been evaluated (electrolytic method).

Implementation: Radiochemical purity of preparations can be assessed by precipitation with trichloroacetic acid and by gel filtration on a Biogel P4 column. Additional analyses can entail measurement of radioactivity clearance from the blood at frequent time intervals after intravenous injection.

Human Model: Cases in normal health (n = 6/kit preparation).

Interpretation and Analysis: The labeling efficiency of 1-step kits varies between 73 and 93% compared with 94 and 98% for electrolytically labeled albumin. The blood clearance for all 1-step kits is significantly faster than that obtained for the radiopharmaceuticals prepared by the electrolytic method. Radiolabeling of HSA with [^{99m}Tc] by the electrolytic method therefore appears to be the preferred method.

An evaluation of 6 kits of [^{99m}technetium] human serum albumin injection for cardiac blood-pool imaging. Millar AM, Hannan WJ, Sapru RP, Muir AL. Eur J Nucl Med 1979 Apr 1; 4 (2), pp. 91–4.

Vascular: Endothelial Inflammation (Acute)/ Pulmonary Injury: Bleomycin-Induced/LFA-1α *[^{111}Indium] ([^{111}In])-Anti-ICAM-1 Monoclonal Antibody (MAb)*

Cellular/Molecular Mechanism of Action: The antibody component of [^{111}In]-anti-ICAM-1 monoclonal IgG antibody recognizes and physically binds to intracellular adhesion molecule-1 complexes expressed on the exterior surface membrane of "activated" endothelial cells.

Application: Detection of endothelial injury and acute vascular inflammatory responses, including bleomycin-induced pulmonary injury.

Route of Administration: [^{111}In]-anti-ICAM-1 monoclonal IgG antibody (intravascular/intravenous).

Implementation: Evaluation of alterations in endothelial intracellular adhesion molecule expression following bleomycin-induced pulmonary injury employing [^{111}In]-anti-ICAM-1 monoclonal IgG antibody (^{111}In*aICAM-1) compared to [^{111}In]-labeled normal mouse IgG (^{111}In*nmIgG). Tissue samples are harvested 24 hours following image acquisition and their radioactivity measured. Lung tissue can be cryostat-sectioned to detect the presence of ICAM-1 by immunofluorescence, and the upregulation of LFA-1α identified in blood polymorphonuclear leukocytes (PMNs) using fluorescence-activated cell-sorter (FACS) analysis.

Animal Model: Rat (lung injury induced by intratracheal bleomycin injection 4 or 24 hours before humane sacrifice).

Interpretation and Analysis: [^{111}In]-anti-ICAM-1 monoclonal IgG antibody.

The percent injected dose/organ in lungs both at 4 and 24 hours postbleomycin increases significantly with the application of [^{111}In]-anti-ICAM-1 monoclonal IgG antibody in contrast to values in either uninjured control states or the administration of [^{111}In]*nmIgG. At 4 and 24 hours postinjury, the target-to-blood (T/B) ratio is 8/1 and 6/1, respectively. For [^{111}In]*nmIgG, the T/B ratio at 4 hours is 0.5/1 and 0.4/1 at 24 hours. [^{111}In]-anti-ICAM-1 monoclonal IgG antibody preparations administered postbleomycin-induced pulmonary injury produce 4- and 24-hour images that can easily be distinguished from uninjured reference controls. All images with [^{111}In]*nmIgG show only cardiac blood-pool and liver activity with little lung activity. Lung ICAM-1 immunofluorescence intensity increases in the bleomycin-treated pulmonary samples compared to uninjured lungs. Expression of LFA-1α on PMNs increases 19% and 210% at 4 hours and 24 hours postinjury, respectively, compared to control values. Biodistribution and imaging data, therefore, are capable of demonstrating that [^{111}In]-anti-ICAM-1 monoclonal IgG antibody is capable of detecting early acute bleomycin-induced lung injury. Immunofluorescence and FACS data suggest that [^{111}In]-anti-ICAM-1 monoclonal IgG antibody uptake is a specific process. Monoclonal antibody preparations that possess such attributes have potential as an early radionuclide detector of acute inflammation.

Early detection of bleomycin-induced lung injury in rat using indium-111-labeled antibody directed against intercellular adhesion molecule-1. Weiner RE, Sasso DE, Gionfriddo MA, Syrbu SI, Smilowitz HM, Vento J, Thrall RS. J Nucl Med 1998 Apr; 39 (4), pp. 723–8.

Vascular Endothelium: $\alpha_V\beta_3$ Integrin Complexes *[^{99m}Technetium] ([^{99m}Tc])-(HYNIC)-Arg-Gly-Asp/ [^{99m}Tc]-(HYNIC -RGD-4C)*

Cellular/Molecular Mechanism of Action: The peptide amino acid residues, Arg-Gly-Asp (RGD), in vitronectin and fibronectin possess binding affinity for cell membrane–associated $\alpha_V\beta_3$ integrin complexes.

Background Information: Three amino acid residues, Arg-Gly-Asp (RGD), in vitronectin and fibronectin show affinity for $\alpha_V\beta_3$ integrins expressed in vascular endothelial cells. That tumor growth can upregulate the expression of these integrins on tumor cells for invasion and metastasis and in tissue neovasculature suggests the potential of developing radiolabeled RGD peptides as antagonists of $\alpha_V\beta_3$ integrins for broad spectrum tumor-specific imaging. The polypeptide RGD-4C, which contains 4 cysteine residues for cyclization, has shown preferential localization on integrins at sites of tumor angiogenesis.

Application: Detection and characterization of neoplastic cell populations/tumors that express relatively high $\alpha_V\beta_3$ integrin membrane densities.

Route of Administration: Polypeptides RGD-4C and RGE (Arg-Gly-Glu)-4C (intravascular).

Semi-Synthetic Methods: The polypeptide RGD-4C and control RGE (Arg-Gly-Glu)-4C are conjugated with 6-hydrazinopyridine-3-carboxylic acid (HYNIC) to facilitate [^{99m}Tc] radiolabeling. Separation of conjugated products from residual unreacted molecular components can be achieved by C18 chromatography (e.g., Sep-Pak cartridge) applied in combination with 20% methanol solvent. Each of the peptides can be radiolabeled using tricine. For cell binding studies, both [^{99m}Tc] peptides can be further purified by SE HPLC. High specific radioactivity of labeled cyclized RGD/E of about 20 Ci/μmol can be achieved. Both [^{99m}Tc] complexes are stable in the labeling solution for 24 hours at room temperature.

Implementation: Evaluation of the relative binding avidities of RGD-4C and RGE (Arg-Gly-Glu)-4C peptides for endothelial cell membrane preparations. Determination of such properties can be established by exposure of HUVE to RGD-4C or RGE over a 1-hour incubation period (4°C) at concentrations in the picomolar to nanomolar range. Specificity can be approximated by determining at

what concentration native cyclized RGD blocks 50% of the [^{99m}Tc]-labeled RGD binding to cell preparations.

***Ex Vivo* Model:** Human (umbilical vein endothelium or HUVE).

Interpretation and Analysis: In the HUVE cell binding-avidity analyses, cell accumulation of [^{99m}Tc] in the case of RGD can be as much as 16 times greater than the RGE control peptide. Specificity analyses reveal that 7 nM of native cyclized RGD blocked 50% binding of [^{99m}Tc]-labeled RGD to cells. The binding percentage of [^{99m}Tc]-labeled RGD to purified $\alpha_V\beta_3$ integrin protein, as determined by SE HPLC, increases with integrin concentration, while [^{99m}Tc]-labeled RGE displays no binding. The association constant for [^{99m}Tc]-RGD is rather modest at 7×10^6 M^{-1}. In nude mouse tumor models employing both human renal adenocarcinoma (ACHN) and human colon cancer cell lines (LS174T) explants, there is no statistical difference in [^{99m}Tc]-labeled RGD/E accumulation. In conclusion, possibly because of limited numbers of $\alpha_V\beta_3$ integrin receptors per tumor cell and low binding affinity, radiolabeled RGD peptides may have limitations as tumor-imaging agents.

In vitro and *in vivo* evaluation of a [^{99m}technetium]-labeled cyclic RGD peptide as a specific marker of $\alpha_V\beta_3$ integrin for tumor imaging. Su ZF, Liu G, Gupta S, Zhu Z, Rusckowski M, Hnatowich DJ. Bioconjug Chem 2002 May–Jun; 13 (3), pp. 561–70.

Vascular Endotheluim/Cardiac Washout Evaluation/ Lipid Administration Influence *[^{99m}Technetium] ([^{99m}Tc])-N-NOET*

Background Information: *Bis*(*N*-ethoxy,*N*-ethyldithiocarbamato)nitrido technetium or [^{99m}Tc]-*N*-NOET is a myocardial perfusion imaging agent that demonstrates significant systemic redistribution. Previous studies have suggested that [^{99m}Tc]-*N*-NOET is bound intravascularly. The agent has been evaluated in phase III clinical trials.

Application: [^{99m}Tc]-*N*-NOET possesses an affinity for vascular endothelium.

Dosage: [^{99m}Tc]-*N*-NOET (1.5 MBq/*ex vivo* rat heart preparations; 0.75 MBq for canine intracoronary artery injection).

Implementation: Determination of the influence of modifications in the vascular compartment on mechanisms of [^{99m}Tc]-*N*-NOET myocardial washout and redistribution. Cardiac washout studies with [^{99m}Tc]-*N*-NOET can be performed *ex vivo* utilizing isolated hearts after bolus injection (1.5 MBq) in the absence or presence of bovine serum albumin (BSA, 0.03%) with or without bound lipids. The intrinsic myocardial washout of the tracer can also be studied *in vivo* after intracoronary bolus injection of the tracer (0.75 MBq) before and after hyperlipidemia induced by intravenous administration of 300 mL of 20% intralipids (n = 3) or hyperemia induced by intravenous infusion of the adenosine A_{2A} receptor agonist ATL-146e (0.3 μg/kg/min; n = 6).

***Ex Vivo* Model:** Rat hearts (n = 15 isolated and perfused; n = 9/15 with BSA; n = 5 bound lipids; n = 4 without bound lipids).

Animal Model: Canine (n = 6 dogs, intracoronary artery injection).

Interpretation and Analysis: In isolated hearts, there is no significant myocardial washout of [^{99m}Tc]-*N*-NOET with Krebs-Henseleit buffer. Addition of BSA without bound lipids results in a significant cardiac washout of the tracer ($p < 0.001$ by repeated measures ANOVA). The presence of lipids bound to BSA further accelerates the washout rate of [^{99m}Tc]-*N*-NOET (half-life [$t_{1/2}$] 431.5 ± 23.2 minutes vs 242.9 ± 63.2 minutes; $p < 0.05$). Intralipid administration *in vivo* significantly increases the intrinsic washout rate of [^{99m}Tc]-*N*-NOET (canine $t_{1/2}$ 108.0 ± 23.9 minutes vs 51.8 ± 11.8 minutes; $p < 0.05$). In addition, vasodilatation with ATL-146e results in a 4.9-fold increase in coronary flow ($p < 0.05$ vs baseline) and a significantly faster intrinsic [^{99m}Tc]-*N*-NOET myocardial washout ($t_{1/2}$, 81.1 ± 12.1 minutes vs 40.7 ± 7.3 minutes; $p < 0.05$). The myocardial washout kinetics of [^{99m}Tc]-*N*-NOET is affected by a variety of intravascular factors, supporting the hypothesis that the tracer is most likely localized on the vascular endothelium. The potential impact of variations in circulating lipid levels among cases on clinical imaging with [^{99m}Tc]-*N*-NOET requires further investigation.

Effects of increased lipid concentration and hyperemic blood flow on the intrinsic myocardial washout kinetics of [^{99m}Tc]-*N*-NOET. Riou LM, Unger S, Toufektsian MC, Ruiz M, Watson DD, Beller GA, Glover DK. J Nucl Med 2003 Jul; 44 (7), pp. 1092–8.

Vascular Hypertension: Renal Artery Stenosis (RAS)/ Renal Ischemia/[Renal Artery Stenosis > 50%] *[^{99m}Technetium] ([^{99m}Tc])-Mercaptoacetyltriglycine/ Captopril*

Cellular/Molecular Mechanism of Action: Captopril inhibits the biochemical activity of angiotensin-converting enzyme (ACE inhibitor).

Physiological Mechanism of Action: Angiotensin in its most active form promotes increased vascular tone.

Application: Enhanced detection can characterize RAS associated with peripheral vascular hypertension.

Route of Administration: Captopril (oral).

Dosage: Captopril (50 mg).

Implementation: Evaluation of vascular hypertension utilizing renal scintigraphic imaging facilitated by the application of [^{99m}Tc]-mercaptoacetyltriglycine ([^{99m}Tc]-MAG3) 1 hour after captopril premedication. Baseline studies are obtained only for those cases showing abnormal findings in provocative studies in concert with renal arteriography procedures.

Human Model: Cases with vascular hypertension (e.g., n = 82).

Interpretation and Analysis: Sensitivity and specificity for the detection of RAS > 50% are approximately 89% and 91%, respectively. After captopril administration, tracer parenchymal transit time increases significantly in ischemic kidneys (334 ± 93 seconds in baseline conditions vs 468 ± 96 seconds after captopril, $p < 0.001$) but not in kidneys without RAS or RAS < 50% (243 ± 46 seconds vs 271 ± 95 seconds, p = ns). False-positive responses are mostly bilateral and associated with marked decreases in blood pressure. [^{99m}Tc]-MAG3 is an effective compound for detecting RAS ≥ 50% with captopril renal scintigraphy. Performing the provocative test as a 1st step procedure considerably reduces the number of scintigraphic studies required.

Use of technetium-^{99m}-MAG3 for renal scintigraphy after angiotensin-converting enzyme inhibition. Dondi M, Monetti N, Fanti S, Marchetta F, Corbelli C, Zagni P, De Fabritis A, Losinno F, Levorato M, Zuccalá. J Nucl Med 1991 Mar; 32 (3), pp. 424–8.

Vascular Hypertension: Renal Artery Stenosis (RAS) *[^{99m}Technetium] ([^{99m}Tc])-Diethylenetriamine Pentaacetic Acid (DTPA)/Captopril*

Cellular/Molecular Mechanism of Action: Captopril inhibits the biochemical activity of angiotensin-converting enzyme (ACE inhibitor).

Physiological Mechanism of Action: Angiotensin in its most active form promotes increased vascular tone.

Application: Enhanced detection and characterization of renal perfusion applying scintigraphic imaging techniques. Such a diagnostic approach can be particularly beneficial pertaining to conditions of RAS.
Route of Administration: Captopril (oral).
Dosage: Captopril (50 mg).
Implementation: Evaluation of vascular hypertensive cases applying conventional renal scintigraphy followed 2 or 3 days later by captopril-enhanced renal scintigraphy, performed 1 hour after premedication with captopril. Renal arteriography is performed within 15 to 30 days to further evaluate renal vascular integrity.

Human Model: Cases of peripheral vascular hypertension (n = 105).
Interpretation and Analysis: In the population of cases evaluated, approximately 50% will have no evidence of RAS (e.g., n = 55/105); while slightly less than one-third will have unilateral disease (e.g., n = 29/105) and close to 20% will have bilateral involvement (e.g., n = 21/105).

A large percentage of cases evaluated can be diagnosed applying a provocative test when they have at least 1 renal artery affected by stenosis of 50% or greater (e.g., n = 34/37). In conditions where stenosis does not exist (e.g., n = 55) or stenosis < 50% of the lumen diameter (n = 13), a very small number of cases will be classified as false-positives (e.g., n = 2). The sensitivity of the procedure is therefore approximately 92% while the specificity approaches 97%. In a single kidney determined to have stenosis of greater than 50%, the sensitivity of scintigraphy after captopril administration is 94%, with a 98% level of specificity. Captopril enhances renal scintigraphy and its application has therefore been suggested as the 1st test to be performed in hypertensive conditions referred for renal scintigraphic studies. Only those cases with equivocal results require a baseline study for better assessment.

Evaluation of hypertensive patients by means of captopril-enhanced renal scintigraphy with technetium-^{99m} DTPA. Dondi M, Franchi R, Levorato M, Zuccalà A, Gaggi R, Mirelli M, Stella A, Marchetta F, Losinno F, Monetti N. J Nucl Med 1989 May; 30 (5), pp. 615–21.

Vascular Integrity: Renal/Glomerulus/Chronic Allograft/Transplant Rejection
[^{99m}Technetium] ([^{99m}Tc])-Acid Fibroblast Growth Factor 1/[^{99m}Tc]-MAG3

Background Information: Acidic fibroblast growth factor (FGF-1) functions as a potent hormonal inducer of wound repair mechanisms *in vivo*. In addition, the involvement of FGF-1 in a number of pathophysiological conditions, including chronic human renal allograft rejection, has been described. Consequently, there is an increasing need to monitor FGF-1 pharmacokinetics and distribution for both therapeutic and diagnostic opportunities.
Route of Administration: [^{99m}Tc]-MAG3 and [^{99m}Tc]-labeled FGF-1 (intravenous).
Implementation: Evaluation of renal function facilitated by the application of dynamic [^{99m}Tc]-MAG3 imaging and subsequent image analysis of [^{99m}Tc]-labeled FGF-1 (^{99m}Tc-FGF-1) biodistrubution profiles. Complementary validation investigations entail performing microautoradiography of harvested kidneys to facilitate determination of [^{99m}Tc]-FGF-1 compartmental localization.

Animal Model: Rat (sham-operated, syngeneic renal transplanted, and allogeneic renal transplanted rats).
Interpretation and Analysis: Allogeneic renal transplants appear grossly abnormal on [^{99m}Tc]-MAG3 renal scans. In scenarios of this type, imaging analysis detects a significant reduction in [^{99m}Tc]-FGF-1 renal binding/uptake, in contrast to renal binding in the sham-operated and syngeneic renal transplanted scenarios, which are not significantly different. Both groups of renal transplants show a redistribution of FGF-1 to the glomerular compartment. Therefore, [^{99m}Tc]-FGF-1 serves as a radiotracer agent that can effectively target and measure *in vivo* growth factor expression. Reduced renal binding of [^{99m}Tc]-FGF-1 in the allogeneic transplanted kidney correlates with decreases in blood flow. Unique glomerular targeting of [^{99m}Tc]-FGF-1 in the transplanted kidney provides additional evidence supporting a role for this growth factor in the pathogenesis of chronic rejection phenomenon.
Instrumentation: Anger gamma camera.

Glomerular targeting of acidic fibroblast growth factor-1 in renal transplanted rats. Zinn KR, Kelpke S, Akhi K, Viera L, Chaudhuri TR, Thompson JA. Transplantation 2002 May 15; 73 (9), pp. 1447–54.

Vascular Lesions: Balloon Denudation/ Atherosclerotic Arterial Wall Lesions
[^{99m}Technetium] ([^{99m}Tc])-Labeled Endothelin Derivative

Implementation: Evaluation of vascular integrity applying angiogram procedures in combination with scintigraphic imaging facilitated by the injection of [^{99m}Tc]-labeled endothelin derivative. The aorta is then dissected for autoradiography analysis and further evaluated applying sudan-III-staining, morphometry, and immunohistology.

Animal Model: Rabbits (e.g., n = 32) with induction of neointima of different cellularity and various severity levels of stenosis using balloon denudation. Following intervention procedures, distinct (specific) dietary regimens are employed in concert with the administration of test pharmaceutical agents.
Interpretation and Analysis: Induced lesions can be detected *in vivo* (whole-body scintigram) in the vast majority of cases 15 minutes after the injection of [^{99m}Tc]-labeled endothelin derivative. Autoradiography reveals a strong relationship between tracer accumulation and sudan-III-staining of lesions. Accumulation of the endothelin derivative correlates with the number of neointimal smooth muscle cells (SMC) but not with the number of medial SMC, neointimal macrophages, and neointimal area. The *in vivo* imaging of atherosclerosis with an endothelin derivative appears to be a feasible method of detecting and characterizing atherosclerotic arterial wall lesions at early stages.

[^{99m}Tc]-labeled endothelin derivative for imaging of experimentally induced atherosclerosis. Tepe G, Duda SH, Meding J, Brehme U, Ritter J, Hanke H, Hilger CS, Claussen CD, Dinkelborg LM. Atherosclerosis 2001 Aug; 157 (2), pp. 383–92.

Vascular Perfusion and Anatomy (Radioangiographic) Analyses
[^{99m}Technetium] ([^{99m}Tc])-Dextran 70

Application: Characterization of vascular anatomy and evaluation of organ/tissue perfusion parameters.
Route of Administration: [^{99m}Tc]-Dextran 70 (intravenous push).
Dosage: [^{99m}Tc]-Dextran 70 (185 megabecquerels).
Semi-Synthetic Methods: Dextran 70 can be injection-labeled with [^{99m}Tc] by using readily available pharmaceutical components. The radiopharmaceutical can be prepared by mixing 10 mg (0.17 mL) of dextran 70 in sodium chloride with 0.33 mL of 0.9% sodium chloride injection in a 1-mL syringe. This solution is then added to a sterile, pyrogen-free vial containing stannous chloride, and the steps

repeated until 5 vials have been prepared. The contents of each vial are then mixed by swirling until the solid phase has been dissolved. The mixture is incubated for 5 minutes at 22°C, then 1.48 gigabecquerels of sodium pertechnetate [^{99m}Tc] injection in a volume of 0.5 mL is added to each vial. The final mixture is incubated for 15 minutes at 22°C and then stored at room temperature. Thin-layer chromatography is performed after 0, 3, and 6 hours of storage to assess radiochemical purity. Immediately after preparation, a mean ± standard deviation (SD) of 99.0 ± 1.0% of the [^{99m}Tc] is bound to dextran 70. Mean ± SD binding is 98.1 ± 3.7% and 95.8 ± 7.5% at 3 and 6 hours, respectively.

Implementation: Evaluation of the biodistribution profile for [^{99m}Tc]-dextran 70 to determine its suitability to function as an agent for performing radioangiography procedures and assessement of vascular perfusion parameters. Following systemic administration, scintigraphic images are acquired immediately over the anterior chest and then at 1, 2, and 24 hours postinjection.

Human Model: Cases of normal health (n = 5 male volunteers).

Interpretation and Analysis: Scintigraphy analyses yield high-contrast images of the cardiac blood pool with little uptake of the radionuclide within the lungs.

Preparation of dextran 70 injection labeled with [^{99m}technetium] for use as a cardiac blood-pool imaging agent. Dansereau RN, Line BR. Am J Hosp Pharm 1994 Nov 15; 51 (22), pp. 2797–800.

Vascular Perfusion/Hepatic Metastatic Lesions
EOE-13/[^{99m}Technetium] ([^{99m}Tc])-Macroaggregated Albumin (MAA)

Cellular/Molecular Mechanism of Action: Macroaggregated albumin is a biological preparation that is passively retained within the intravascular compartment for a prolonged period of time following intravenous injection due to its relatively large molecular weight.

Application: Assessment of organ and tissue vascular perfusion in a manner that can detect hepatic metastatic lesions.

Route of Administration: Intravenous (catheter infusion at a rate of 0.66 ml/min).

Implementation: Evaluation of hepatic perfusion patterns applying both nuclear scintigraphy and computed tomography (CT) imaging methodologies.

Interpretation and Analysis: Computed tomography with EOE-13 yields more precise anatomic detail and is unique in demonstrating the perfusion status of each hepatic metastasis. Further evaluation of EOE-13 for this purpose is warranted.

Instrumentation: Computer-integrated nuclear medicine scintigraphy camera imaging (CT with EOE-13 used as a validating procedure).

Assessment of perfusion patterns during hepatic artery infusion chemotherapy: EOE-13 CT and ^{99m}Tc-MAA scintigraphy. Miller DL, Schneider PD, Gianola FJ, Willis M, Vermess M, Doppman JL. AJR Am J Roentgenol 1984 Oct; 143 (4), pp. 827–31.

Vascular Perfusion/Iohexol (Non-Ionic) and Iothalamate (Ionic) Contrast Media
[^{99m}Technetium] ([^{99m}Tc])-Macroaggregated Albumin (MAA)/[^{201}Thallium] ([^{201}Tl])

Cellular/Molecular Mechanism of Action: Both [^{99m}Tc]-MAA albumin and [^{201}Tl] per se do not exert a biological function. Macroaggregated albumin instead functions as a passive tracer marker agent applicable for the evaluation of body fluid compartments.

Background Information: Cardiac output is effectively redistributed to each part of the body by regional changes in vascular resistance. The side effects of iodinated contrast media in different organs have been well documented in animal experiments and human clinical studies. However, no simultaneous assessment of regional blood flow change has been described for different organ systems throughout the body.

Application: [^{201}Tl] distribution reflects the fractional distribution of cardiac output and parallels regional blood flow. Macroaggregated albumin instead functions as a passive tracer marker agent applicable for the evaluation of body fluid compartments.

Route of Administration: [^{201}Tl] and [^{99m}Tc]-MAA (intravenous).

Implementation: Evaluation of the effect of contrast media on the regional distribution of [^{201}Tl] in individual organ systems as an estimate of *in vivo* regional blood flow changes using a [^{201}Tl] double-dose method. Contrast media that can be employed include non-ionic (Iohexol) and ionic (Iothalamate).

Animal Model: Rabbit.

Interpretation and Analysis: Distribution of [^{201}Tl] and [^{99m}Tc]-MAA is similar in the heart, spleen, kidneys, and leg muscles in the control animals (r = 0.99). Regional distribution of [^{201}Tl] significantly increases in heart and leg muscle, but decreases in the liver when non-ionic (Iohexol) and ionic (Iothalamate) contrast medium is administered, compared to negative reference controls. There are no significant changes within the kidneys or intestine in case groups receiving either non-ionic (Iohexol) or ionic (Iothalamate). Intravenous infusion of contrast media causes uneven redistribution of regional blood flow in the heart, leg muscle, and liver. These changes are more prominent with the administration of ionic contrast medium.

Effect of ionic and non-ionic contrast media on regional distribution of thallium-201 in rabbits. Seto H, Kageyama M, Shimizu M, Nagayoshi T, Futatsuya R, Kakishita M. Radiat Med 1995 Jan–Feb; 13 (1), pp. 19–22.

Vascular Thromboses: Arterial/Antiplatelet Therapy: Pharmaceutical Efficacy Evaluation
[^{111}Indium] ([^{111}In]) Platelets

Cellular/Molecular Mechanism of Action: The radioisotope [^{111}In] can be used as a tracer agent that emits photon energy. Platelets within the intravascular compartment accumulate at anatomical (e.g., intravascular) sites of platelet aggregation and fibrin monomer polymerization.

Application: Preparations of [^{111}In] platelets can be utilized for the detection of intravascular thrombosis and evaluation of the efficacy of antithrombotic pharmaceutical agents. Aorta (arterial) thromboses are composed of a higher percentage of platelets in contrast to venous thromboses that are composed predominantly of polymerized fibrin monomer (± cross-linking).

Implementation: Combined application of [^{111}In] platelet scintigraphy (PSG) and B-mode ultrasonography (US) for the evaluation of the short-term-effect antiplatelet agents [e.g., 4-cyano-5,5-bis(methoxyphenyl)-4-pentenoic acid (E5510)]. After 8 weeks, [^{111}In]-PSG and US can then be repeated. Platelet deposition is then assessed visually and semi-quantitatively using a platelet accumulation index. Such procedures can then be applied to evaluate the efficacy of antiplatelet or antithrombosis agents.

Human Model: Cases demonstrating platelet deposition at either the carotid bifurcation or abdominal aorta (e.g., n = 15) detected by [^{111}In] platelet scintigraphy. Half of affected cases are administered antiplatelet therapy (e.g., E5510 at 4 mg/day.)

Interpretation and Analysis: Visual analysis reveals that a high percentage of cases demonstrate no evidence of platelet deposition after the administration of effective antithrombotic therapies (e.g., n = 7/8), while essentially none are changed without the benefit of antithrombotic intervention. The platelet accumulation index of vessels with platelet deposition is significantly reduced after delayed antithrombotic treatment (6.0 ± 7.1% vs 12.4 ± 3.9%. $p < 0.01$), while there are no significant changes in vessels without platelet deposition (2.9 ± 3.0% vs 2.9 ± 4.1%). In cases with early-phase antithrombotic therapy, vessels rarely demonstrate any change (8.1 ± 6.4% vs 8.9 ± 7.3%). However, there is no significant reduction of carotid plaque size in either group. Short-term E5510 therapy inhibits platelet deposition in active atherothrombotic lesions, and the *in vivo* combination of PSG and US can be useful for evaluating the effectiveness of antithrombotic pharmaceuticals.

Effect of E5510, a novel antiplatelet agent, on platelet deposition in atherothrombotic lesions: Evaluation by [^{111}In] platelet scintigraphy. Moriwaki H, Matsumoto M, Handa N, Hashikawa K, Hori M, Nishimura T. Nucl Med Commun 2000 Nov; 21 (11), pp. 1051–8.

Vascular Thromboses: Arterial/Hemostatic Stimuli and Devices
[^{111}Indium] ([^{111}In])-Tropolone-Platelets/ [^{99m}Technetium] ([^{99m}Tc])-Hexamethylpropyleneamine Oxime (HMPAO) Platelets

Physiological Mechanism of Action: The function of normal platelets includes maintenance of the integrity of endothelial surfaces and active participation in thrombogenic responses. Thrombi formed within arterial structures have a much higher platelet content than do thrombi found within the venous vasculature.

Background Information: Because the photons emitted from [^{111}In] and ^{99m}Tc are of a high energy [^{111}In, 173 and 247 keV α, $T_{1/2}$ = 2.8 days; ^{99m}Tc, 140 keV α, $T_{1/2}$ = 6.05 hours], lesions located at significant tissue depths can be detected within the thoracic and abdominal cavities. Radiolabeled platelets can also be applied to document the antiplatelet activity of non-steroidal anti-inflammatory drugs (NSAIDS) and to monitor intravascular platelet kinetics in the diagnosis of consumptive disease conditions such as immune-mediated thrombocytopenia (ITP) and disseminated intravascular coagulation (DIC).

Application: Diagnosis and serial evaluation of arterial thrombosis lesions within the pulmonary vein, cerebral hemispheres, and other arterial structures of interest. Radiolabeled platelets can also be utilized to characterize platelet intravascular half-life and assess the potential thrombogenic properties of foreign materials.

Semi-Synthetic Methods: Radiolabeling of platelets with [^{111}In]-tropolone (detergent-free) and [^{99m}Tc]-HMPAO following their isolation and partial purification from fresh whole blood.

Implementation: Evaluation of the platelet thrombogenicity of a hemodialyzer assessed through the application of [^{99m}Tc] platelets and [^{111}In] platelets. Platelets are 1st isolated from whole blood, then radiolabeled with [^{111}In] and [^{99m}Tc]. Following hemodialysis procedures, hollow-fiber dialyzer (HFD) radioactivity is measured with an ionization chamber and imaged with a gamma camera. The radioactivity of hollow fiber samples taken from the top, middle, and bottom of the dialyzer is determined with a gamma counter.

Animal/Human Model: Normal beagle dogs, Yorkshire pigs, and human volunteers. Hemodialysis is performed with an HFD in a flow loop, the temperature of which is maintained at 37°C, with flow rates of 7, 150, and 270 mL/min.

Interpretation and Analysis: Canine platelets are more thrombogenic than porcine and human platelets. The adhesivity of porcine platelets to the biomaterial (cellulose-acetate) of the dialyzer approximates that of human platelets. The [^{99m}Tc] label underestimates thrombus formation ($p < 0.01$). The dynamic processes of thrombosis and embolization from the hemodialyzer result in a large standard deviation around the mean values of the adherent thrombus. In spite of this limitation of the dynamic pathology, the quantitation of comparative thrombogenicity with [^{111}In]- and [^{99m}Tc]-labeled platelets suggests that both radionuclides may be used to measure device-induced thrombogenicity and may provide an estimation of prosthesis-induced thrombogenicity of human platelets by extrapolating from animal studies.

Quantitation of thrombogenicity of hemodialyzer with technetium-99m and indium-111-labeled platelets. Dewanjee MK, Kapadvanjwala M, Ruzius K, Serafini AN, Zilleruelo GE, Sfakianakis GN. Nucl Med Biol 1993 Jul; 20 (5), pp. 579–87.

Vascular Thrombosis: Arterial and Venous/Deep Vein Thrombosis/Pulmonary Embolism/ Arterial Thromboembolic Disorders/Cerebral Vascular Stroke/Coronary Artery Thrombotic Disorders/Peripheral Artery Thromboses
Platelet GPIIb/IIIa Receptor Antagonist/ [^{99m}Technetium] ([^{99m}Tc])-DMP728/ [^{3}H]-DMP728

Cellular/Molecular Mechanism of Action: The agent DMP728 functions as a GPIIb/IIIa receptor antagonist on the exterior surface membrane of platelets.

Physiological Mechanism of Action: Venous thrombi is composed predominantly of fibrin monomer or polymer in constrast to arterial thrombi, which have a much higher platelet content.

Background Information: Either venous or arterial thrombosis is a potentially life-threatening event and many diagnostic modalities are inadequate for diagnostic purposes and for determining the morphology of an evolving thrombus. Thus development of a non-invasive imaging agent that can detect clot location represents a critical need in nuclear diagnostic medicine.

Application: Detection and characterization of intravascular venous and arterial thromboses.

Implementation: Evaluation of artificially (*in vitro*) created venous and arterial type thrombi using the potent radiolabeled GPIIb/IIIa receptor antagonist [^{3}H]-DMP728. Complementary investigations can involve the *in vivo* application of [^{99m}Tc]-DMP728 to determine the clot/blood distribution ratio (e.g., target:background ratio). In addition, non-invasive single photon emission computed tomography (SPECT) of venous clots in deep vein thrombosis can be performed. Thrombin inhibitors can also be evaluated in the same context.

Animal Model: Canine (dogs with mixed arterial/venous or venous clots within arteriovenous shunts and in venous clot foci and deep vein thrombi).

Interpretation and Analysis: Radiolabeled preparations of the GPIIb/IIIa receptor antagonist DMP728 in the form of [^{3}H]-DMP728 and [^{99m}Tc]-DMP728 have been found to retain marked binding avidity for platelet-associated GPIIb/IIIa receptor complexes. DMP728 demonstrates a relatively greater affinity for activated than for unactivated human platelets, which may be essential for attaining an optimal thrombus/blood (target/background) distribution ratio and the optimal detection of small clots (i.e., greater sensitivity). Therefore, [^{99m}Tc]-GPIIb/IIIa receptor antagonists have potential utility in the diagnosis of venous clots in deep vein thrombosis, pulmonary embolism, and arterial thromboembolic disorders,

including stroke and coronary and peripheral artery thrombotic disorders. Thrombin inhibitors do not appear to be as effective in this same context.

Novel technetium-99m-labeled platelet GPIIb/IIIa receptor antagonists as potential imaging agents for venous and arterial thrombosis. Mousa SA, Bozarth JM, Edwards S, Carroll T, Barrett J. Coron Artery Dis 1998; 9 (2–3), pp. 131–41.

Vascular Thromboses: Deep Vein/[Neoplastic Disease States]
[^{111}Indium] ([^{111}In])-Diethylenetriamine Pentaacetic Acid (DTPA)-Fibrinogen/(DTPA Cyclic Anhydride)

Physiological Mechanism of Action: The agent is actively incorporated into intravascular fibrin clots. Initially, the radiolabeled fibrinogen is converted to fibrin by thrombin with greatest level of biochemical activity located on the external surface of fibrin clots. Monomers of fibrin are then covalently cross-linked with adjoining strands by the enzymatic action of coagulation factor XIIIa*.

Background Information: Albumin can be applied as a biological protein for optimizing semi-synthetic conjugation strategies employing DTPA chelation groups. Such methodologies can subsequently serve as an experimental foundation for ultimately designing analogues and techniques for covalently conjugating DTPA (DTPA cyclic anhydride) to selective targeting modalities including immunoglobulin (e.g., monoclonal Fab′ fragment) or fibrinogen/fibrin peptides.

Application: Detection and monitoring of intravascular thromboemboli formation analogous to those that may develop within the pulmonary artery (pulmonary thromboembolism) and iliac vessels of the limbs (deep vein thrombosis).

Considerations: Isotopes that emit low energy photons (^{125}I, 35 keV, $T_{1/2}$ = 60.2 days) are only suitable for imaging superficially located vascular thromboses such as those residing in the iliac veins. Vascular lesions located at greater tissue depths can be more appropriately imaged with isotopes that emit higher energy photons [^{123}I], 159 keV α 83% emission, $T_{1/2}$ = 13.3 hours; [^{124}I] $T_{1/2}$ = 4.2 days); [^{125}I] 27-35 keV α, 60.2 days). Traditionally, [^{131}I] is used for radiation therapy due to its beta emitting characteristics (^{131}I, $T_{1/2}$ = 61 hours; and 364 keV α, $T_{1/2}$ = 8.06 days).

Semi-Synthetic Methods: The DTPA cyclic anhydride chelation group can be covalently conjugated to human fibrinogen. Optimum DTPA cyclic anhydride labeling conditions (e.g., pH, DTPA:fibrinogen labeling ratios) can be established by evaluating the ablity of this biological protein to function as a substrate for thrombin (fibrinogen → fibrin monomer). In an *in vivo* environment, the viability or integrity of fibrinogen in the DTPA-labeled fibrinogen conjugate can be conveniently evaluated by determining its intravascular $T_{1/2}$ compared to native fibrinogen and its ability to be incorporated into intravascular thrombi (e.g., percent of fibrin clot-associated radioactivity).

Implementation: Diethylenetriamine pentaacetic acid cyclic anhydride labeling of human fibrinogen can be used to detect intravascular thrombi, while conjugation to monoclonal antibody fractions could facilitate the identification of a variety of pathological disease states. A relevant example in this regard includes a wide variety of neoplastic conditions and certain septic disease states. Various radioisotopes including [^{111}In] can potentially be chelated with functional DTPA groups.

Animal Model: Canine (*in vivo* pharmacokinetic profiles and thrombogenic catheter-induced intravascular fibrin clots).

Interpretation and Analysis: Clotting times for DTPA:fibrinogen fractions labeled with DTPA cyclic anhydride remain identical to that of the native protein whether the anhydride-to-protein molar ratio is 1:1 or 5:1. During the course of canine *in vivo* studies, the 130-hour blood clearance profiles for [^{125}I]DTPA-fibrinogen and [^{111}In]DTPA-fibrinogen closely correspond to reference controls for both 1:1 or 5:1 coupling ratios. In a canine model employing a thrombogenic catheter, the clot-to-blood ratios for the 2 radiotracers are essentially identical and display the same level of experimental error. Scintigraphic imaging of a jugular vein catheter at 24 hours postinjection of 1:1-coupled canine DTPA-fibrinogen labeled with [^{111}In] clearly detects clotting along the length of the catheter. Therefore, fibrinogen, coupled to DTPA, retains its viability, behaving in a manner analogous to radioiodinated fibrinogen *in vivo*, and [^{111}In]-labeled fibrinogen looks promising as a clinical diagnostic agent.

Evaluation of the viability of In-111-labeled DTPA coupled to fibrinogen. Layne WW, Hnatowich DJ, Doherty PW, Childs RL, Lanteigne D, Ansell J. J Nucl Med 1982 Jul; 23 (7), pp. 627–30.

Vascular Thrombosis: Deep Vein (Venography)/ Thrombosis of the Iliac Vein and Inferior Vena Cava
[^{99m}Technetium] ([^{99m}Tc])-Red Blood Cells (RBC)

Application: The accurate diagnosis of deep vein thrombosis (DVT) is essential in order to prevent associated complications, in addition to the selection and timing of appropriate therapeutic intervention. Doppler ultrasound (DUS), contrast venography, and intravenous radionuclide venography have been used for many years to detect DVT. However, obtaining venous access in the foot for injection of contrast agent can be difficult.

Route of Administration: [^{99m}Tc] (intravenous).

Implementation: Evaluation of venous structures by venography applying [^{99m}Tc] radionuclide injected subcutaneously for *in vivo* labeling of red blood cells. Comparative analyses can involve the simultaneous application of DUS procedures.

Human Model: Cases of normal health subjected to subcutaneous radionuclide venography and ultrasound (n = 60 with n = 120 lower extremity images).

Interpretation and Analysis: The concordance rate is approximately 94% within the femoral veins and 95% in the popliteal veins. Subcutaneous radionuclide venography in some studies has detected 10 iliac vein thromboses (n = 10) and inferior vena cava thromboses (n = 2) that could not be detected by DUS. Subcutaneous radionuclide venography is a useful alternative method for DVT detection. It is particularly valuable for evaluating DVT in the iliac veins and in the inferior vena cava.

Subcutaneous whole-body radionuclide venography using [^{99m}Tc] *in vivo* tagged red blood cells. Yang DC, Ratani RS, Kalani J, Joyce Chen YW, Huang YF, Magzadeh P, Ilkhanizadeh R. Clin Nucl Med 2001 Jun; 26 (6), pp. 491–4.

CENTRAL NERVOUS SYSTEM: NEUROLOGY

Amyloid Beta (Abeta) Deposits: Alzheimer's Disease (AD)/Abeta 10-43 Peptide
Chrysamine G (CG)/[^{99m}Technetium] ([^{99m}Tc])-MAMA-CG

Cellular/Molecular Mechanism of Action: Chrysamine G, an analogue of Congo red, is known to bind *in vitro* to the beta-amyloid protein (abeta 10-43) and to homogenates of several regions of the brain of AD patients.

Application: Detection of beta-amyloid deposits similar to those recognized in the central nervous system (CNS) of AD cases.

Route of Administration: Intravascular.
Semi-Synthetic Methods: Synthesis of a conjugate of 2-(acetamido)-CG with a *bis-S*-trityl protected monoamide-monoaminedithiol (MAMA-Tr(2)) tetraligand that is efficiently deprotected and labeled at a 75% yield with [^{99m}Tc] to obtain [^{99m}Tc]-MAMA-CG.
Implementation: Evaluation of hepatobiliary clearance and brain uptake and selective detection of beta-amyloid deposits similar to those found within the CNS in AD conditions.
Interpretation and Analysis: The agent [^{99m}Tc]-MAMA-CG is cleared mainly by the hepatobiliary system (mice), resulting in a fast blood clearance. Brain uptake of [^{99m}Tc]-MAMA-CG is low. Co-injection with the blood-pool tracer iodine-125 human serum albumin ([^{125}I]-HSA) reveals a brain/blood activity ratio for [^{99m}Tc]-MAMA-CG that is significantly higher than that for [^{125}I]-HSA (t test for dependent samples, $p < 0.02$), indicating the ability of [^{99m}Tc]-MAMA-CG to cross the blood-brain barrier. *In vitro* autoradiography demonstrates pronounced binding of [^{99m}Tc]-MAMA-CG to beta-amyloid deposits in autopsy sections of the parietal and occipital cortex in conditions of AD that are in contrast to reference controls. Adding 10 μM Congo red during incubation displaces the binding of [^{99m}Tc]-MAMA-CG. Congo red staining and autoradiography identifies the same lesions. [^{99m}Tc]-MAMA-CG seems to bind selectively to beta-amyloid deposition in human brain parenchyma and blood vessels *in vitro* and thus might be a lead compound for further development that can be utilized as a useful tracer agent for the *in vivo* diagnosis of AD.

[^{99m}Tc]-MAMA-chrysamine G, a probe for beta-amyloid protein of Alzheimer's disease. Dezutter NA, Dom RJ, de Groot TJ, Bormans GM, Verbruggen AM. Eur J Nucl Med 1999 Nov; 26 (11), pp. 1392–9.

Amyloid Beta (Abeta) Deposits/Amyloid Angiopathy (AA)/(Alzheimer's Disease [AD]) *[^{99m}Technetium] ([^{99m}Tc])-Anti-Abeta Fab*

Cellular/Molecular Mechanism of Action: Murine antihuman abeta amyloid monoclonal antibody recognizes and binds to abeta amyloid deposits.
Application: Detection of amyloid deposits *in vivo* within the central nervous system (CNS) vasculature analogous to those found in AD conditions.
Production and Semi-Synthetic Methods: Extracts of abeta amyloid can be purified for the purpose of producing monoclonal antibody preparations. Appropriateness of the antigenic recognition capabilities of anti-(abeta) monoclonal antibodies involves screening for effectiveness in visualizing AA and neuritic plaques in post-mortem AD brain sections. In an effort to minimize non-specific binding of anti-(abeta) mononclonal antibody to membrane-associated Fc receptors expressed by the mononuclear phagocytic system within the spleen and liver, preparations are enzymatically treated and extracts of Fab fragment purified.
Implementation: Evaluation of preparations of intact anti-(abeta) amyloid monoclonal antibody (± [^{99m}Tc] label: dimercaptide ligand methodology); and anti-(abeta) amyloid Fab fragment (± [^{99m}Tc] label: dimercaptide ligand methodology).
Interpretation and Analysis: Modified and radiolabeled Fab fragments retain activity and specificity toward amyloid-laden blood vessels and neuritic plaques. Highly specific murine monoclonal antibodies can be prepared that possess all the characteristics and properties necessary for the development of effective *in vivo* diagnostic imaging agents. Toxicity studies performed in rats have demonstrated the safety of such preparations. Biodistribution studies in mice have validated the desirability of [^{99m}Tc]-anti-(abeta) Fab fragment as an imaging agent. Advantages associated with the use of [^{99m}Tc]-anti-(abeta) Fab fragment include higher target-to-background ratios compared to radiolabeled IgG monoclonal antibody preparations; non-invasive diagnostic properties; and assessment of the contribution of AA to the pathophysiology and clinical profiles of AD conditions.
Instrumentation: Laboratory facilities for the preparation of abeta amyloid extractions; production of monoclonal antibody fractions; production of monoclonal antibody Fab fractions; and semi-synthesis of [^{99m}Tc]-anti-abeta Fab preparations. Some suppliers of immunology-oriented reagents offer preparations of anti-abeta monoclonal antibody and/or anti-abeta Fab monoclonal antibody.

Development of a monoclonal antibody specific for beta/A4 amyloid in Alzheimer's disease brain for application to *in vivo* imaging of amyloid angiopathy. Majocha RE, Reno JM, Friedland RP, VanHaight C, Lyle LR, Marotta CA. J Nucl Med 1992 Dec; 33 (12), pp. 2184–9.

Development of an anti-abeta monoclonal antibody for *in vivo* imaging of amyloid angiopathy in Alzheimer's disease. Friedland RP, Majocha RE, Reno JM, Lyle LR, Marotta CA. Mol Neurobiol 1994 Aug–Dec; 9 (1–3), pp. 107–13.

Amyloid Beta (Abeta) Plaques/Alzheimer's Disease (AD) *[^{125}I]Abeta 1-40-8D3 Bifunctional Conjugate*

Cellular/Molecular Mechanism of Action: The abeta 1-40-8D3 conjugate is a bifunctional molecular complex. The rat monoclonal antibody 8D3 possesses binding avidity for mouse transferrin receptor (TfR) complexes.
Application: [^{125}I]abeta 1-40 represents a biopharmaceutical platform that could potentially be used to image brain abeta amyloid plaque lesions in AD. One factor that limits the applicability of [^{125}I]abeta 1-40 for such purposes is its limited ability to traverse across an intact blood-brain barrier. Conjugation of various "targeting" modalities represents 1 strategy that can be applied to overcome this particular obstacle.
Route of Administration: Abeta 1-40 and abeta 1-40-8D3 conjugate (intravenous).
Semi-Synthetic Methods: Covalent conjugation of abeta 1-40 to rat 8D3 monoclonal antibody (antimouse transferin receptor) in a manner that creates a bifunctional molecular complex.
Implementation: Delineation of the relative ability of radiolabeled unconjugated abeta 1-40 and abeta 1-40-8D3 conjugate to penetrate the blood-brain barrier can be achieved by performing brain scans 6 hours following administration. Immunocytochemical analyses can additionally be performed to document selective uptake within abeta plaques.
Animal Model: App SW/Psen1 double-transgenic and littermate control mice.
Interpretation and Analysis: Immunocytochemical analysis reveals abundant abeta immunoreactive plaques in the brains of App SW/Psen1 transgenic mice and a selective retention of radioactivity in the brains of these mice at 6 hours after intravenous administration of [^{125}I]-abeta 1-40-8D3 conjugate. Conversely, there is no selective sequestration of either conjugate in control littermate mouse brain or for unconjugated abeta 1-40 in transgenic mouse brain. The blood-brain barrier transport of [^{125}I]-abeta 1-40 in a transgenic mouse model is enabled by conjugation to rat 8D3 monoclonal antibody within selective binding avidity for mouse transferrin receptor complexes. Therefore, it is possible *in vivo* to image the abeta amyloid burden within the brain utilizing an amyloid imaging agent, provided the molecule is conjugated to a blood-brain barrier drug-targeting system.

Imaging brain amyloid of Alzheimer's disease *in vivo* in transgenic mice with an abeta peptide radiopharmaceutical. Lee HJ, Zhang Y, Zhu C, Duff K, Pardridge WM. J Cereb Blood Flow Metab 2002 Feb; 22 (2), pp. 223–31.

Amyloid Beta (Abeta) Plaque Deposits/Alzheimer's Disease (AD)
[^{123}I/^{125}I]IMPY, 6-Iodo-2-(4′-Dimethylamino-)Phenyl-Imidazo[1,2-a]Pyridine/Thioflavin

Background Information: Development of small molecular probes for *in vivo* labeling and detection of beta-amyloid (abeta) plaques in patients of AD is of significant scientific interest, and it may also assist in the development of schemes for the pharmaceutical targeting of abeta plaques relevant to AD conditions.
Route of Administration: [^{125}I]IMPY (intravenous).
Semi-Synthetic Methods: A novel probe, [^{123}I/^{125}I]IMPY, 6-iodo-2-(4′-dimethylamino-)phenyl-imidazo[1,2-a]pyridine, can be prepared using an iododestannylation reaction catalyzed by hydrogen peroxide.
Implementation: Evaluation of *in vivo* plaque labeling strategies.

Animal Model: Mice (normal) and a transgenic mouse model (Tg2576) engineered to produce excess amyloid plaques within the brain.
Interpretation and Analysis: The modified thioflavin-T derivative displays a good binding affinity for preformed synthetic abeta40 aggregates in solution ($K_i = 15 \pm 5$ nM) and shows selective plaque labeling on postmortem AD brain sections. Biodistribution of [^{125}I]IMPY exhibits excellent brain uptake (2.9% initial dose/brain at 2 minutes) and fast washout (0.2% initial dose/brain at 60 minutes). These properties are highly desirable for amyloid plaque imaging agents. *Ex vivo* autoradiograms of brain sections of the Tg2576 mouse obtained 4 hours after an intravenous injection of [^{125}I]IMPY clearly display distinct plaque labeling with low background activity. When the same brain sections are stained with the fluorescent dye thioflavin-S, the same abeta plaques show prominent fluorescent labeling consistent with results observed from autoradiography analyses. Radioiodinated IMPY demonstrates desirable characteristics for the *in vivo* labeling of abeta plaques and it may be useful as a molecular imaging agent to study amyloidogenesis within the brain of living AD patients.

IMPY: An improved thioflavin-T derivative for *in vivo* labeling of beta-amyloid plaques. Kung MP, Hou C, Zhuang ZP, Zhang B, Skovronsky D, Trojanowski JQ, Lee VM, Kung HF. Brain Res 2002 Nov 29; 956 (2), pp. 202–10.

Amyloid Deposition/Familial Amyloid Polyneuropathy (FAP)/Hepatic Posttransplant Renal Amyloid Deposition
[^{123}I]-Serum Amyloid P Component (SAP)

Cellular/Molecular Mechanism of Action: Serum amyloid P component recognizes and physically binds to amyloid deposits.
Background Information: Familial amyloid polyneuropathy associated with transthyretin (TTR) mutations is the commonest type of hereditary amyloidosis. Plasma TTR is produced almost exclusively in the liver and orthotopic liver transplantation is the only available treatment, although the clinical outcome varies. Serum amyloid P component scintigraphy is a method for identifying and quantitatively monitoring amyloid deposits *in vivo*, but it has not extensively been used to study the outcome of visceral amyloid deposits in FAP following liver transplantation.
Route of Administration: Intravascular.
Implementation: Evaluate the effectiveness of injected [^{123}I]-labeled SAP to detect and characterize amyloid lesions *in vivo* applying whole-body scintigraphy techniques.

Human Model: Cases of FAP (n = 17) associated with TTR Met30 in addition to asymptomatic gene carriers (n = 5). Follow-up studies performed in affected cases (n = 10), some of whom have undergone orthotopic liver transplantation 1–5 years beforehand (n = 8/10 cases).
Interpretation and Analysis: An abnormal uptake of [^{123}I]-SAP can be appreciated in the vast majority of cases with FAP, including the (i) kidneys (n = 17); (ii) spleen (n = 5/17); and (iii) adrenal gland (n = 3/17). Renal amyloid deposits can also be appreciated in some asymptomatic carriers (n = 3/5). Follow-up studies 1–5 years after liver transplantation show that there is substantial regression of the visceral amyloid deposits in some cases (n = 2/10 compared to n = 3/10 modest improvement; n = 2 unchanged amyloid deposits). Therefore [^{123}I]-SAP scintigraphy can identify unsuspected visceral amyloid cases with FAP due to TTR Met30. The universal presence of renal amyloid probably underlies the high frequency of renal failure that occurs in FAP following liver transplantation. The variable capacity of patients to mobilize amyloid deposits following liver transplantation may contribute to their long-term clinical outcome.

Serum amyloid P component scintigraphy in familial amyloid polyneuropathy: Regression of visceral amyloid following liver transplantation. Rydh A, Suhr O, Hietala SO, Ahlström KR, Pepys MB, Hawkins PN. Eur J Nucl Med 1998 Jul; 25 (7), pp. 709–13.

Cerebral Cortex Dysfunction/Drug-Resistant Focal Epilepsy/Accuracy of Amobarbital Target Delivery/Temporary Neurologic Deficits/Risk Assessment of Postsurgical Motor Deficits Before Functional Hemispherectomy/Language Area Identification
Amobarital (Sodium) Wada Test/[^{99m}Technetium] ([^{99m}Tc])-Hexamethylpropyleneamine Oxime (HMPAO)/Electrical Stimulation Mapping

Cellular/Molecular Mechanism of Action: Amobarbital is a barbiturate.
Physiological Mechanism of Action: Amobarbital suppresses neurologic function.
Application: Analyze the role of selective middle cerebral artery (MCA) Wada tests in the presurgical workup of patients with drug-resistant focal epilepsies.
Route of Administration: Amobarbital is administered selectively into arterial branches supplying specific regions of the cerebral cortex using a catheter introduced into the carotid artery.
Implementation: Evaluation of cerebral cortex function in conditions of (i) motor cortex cerebral hemisphere lesions (connatal MCA infarct, unilateral cortical dysplasia, Rasmussen encephalitis); (ii) circumscribed neoplastic or non-neoplastic lesions adjacent to the motor cortex or classical regions; and (iii) sleep electrical status elepticus. Sodium amobarbital and [^{99m}Tc]-HMPAO are simultaneously injected through a microcatheter into the distal M1 segment, the inferior MCA trunk, or the MCA branches in order to identify eloquent cortex.

Human Model: Cases of cerebral cortex dysfunction including (i) hemispheric lesions involving the motor cortex (n = 9 cases, of which n = 5/9 connatal MCA infarct, n = 3/9 unilateral cortical dysplasia, n = 1/9 Rasmussen encephalitis); (ii) circumscribed neoplastic or non-neoplastic lesions adjacent to the motor cortex or classic language areas (n = 5 cases); and (iii) purely electrophysiologic

analyses for conditions of electrical status epilepticus in sleep (n = 2 cases). Example Total Wada tests performed = 20.

Interpretation and Analysis: Co-registered single photon emission computed tomography (SPECT) and magnetic resonance imaging (MRI; n = 18) reveal that sodium amobarbital does not reach the target area in some procedures (e.g., n = 3/20). Temporary neurologic deficits can occur in slightly more than half of total Wada procedures performed (e.g., n = 12/20). Cases subjected to surgical intervention require the use of several different surgical approaches, including functional hemispherectomy (n = 3); partial or extended lesionectomy (n = 4); anterior temporal lobectomy (n = 1); and multiple subpial transsections (n = 3). Seizure freedom (Engel Class I) can be achieved in a modest percentage of cases (e.g., n = 5/16 cases). The MCA Wada tests can therefore contribute to risk assessment concerning postsurgical motor deficits before functional hemispherectomy. Other indications are less clear. The identification of language areas is targeted primarily by electrical-stimulation mapping after subdural grid implantations, and selective MCA Wada tests in electrical status epilepticus in sleep (ESES) patients have yet to be validated in large patient groups.

Selective middle cerebral artery Wada tests as a part of presurgical evaluation in patients with drug-resistant epilepsies. Urbach H, Von Oertzen J, Klemm E, Koenig R, Linke DB, Kurthen M, Schramm J, Elger CE. Epilepsia 2002 Oct; 43 (10), pp. 1217–23.

Dopamine Transporter (DAT): Central Nervous System (CNS)/Attention Deficit Hyperactivity Disorder (ADHD)/Parkinson's Disease (PD) *[^{99m}Technetium] ([^{99m}Tc])-Based Tropane Ligand/ FLUORATEC*

Cellular/Molecular Mechanism of Action: Detects and physically binds to the DAT, located presynaptically on dopamine neurons.

Background Information: In ADHD, DAT density levels are elevated, while in PD these levels are depleted. The depletion of DAT levels also corresponds with the loss of dopamine.

Application: Characterization of the density of DAT complex expression within the central nervous system. Dopamine transporters are located presynaptically on dopamine neurons and in concept can function as a biological marker for PD and ADHD.

Semi-Synthetic Methods: Design and synthesis of 2nd-generation [^{99m}Tc]-based tropane ligands (e.g., N-[(2-((3′-N′-propyl-(1′′R)-3′′alpha-(4-fluorophenyl)tropane-2′′beta-1-propanoyl)(2-mercaptoethyl)amino)acetyl)-2-aminoethanethiolato]technetium(V) oxide).

Implementation: Evaluation of the biology and single photo emission computed tomography (SPECT) imaging potential of [^{99m}Tc]-based tropane ligands based on their potent and selective binding avidity for DAT complexes.

Animal Model: Non-human primates.

Interpretation and Analysis: [^{99m}Tc]-based tropane ligands possess improved selectivity and biological stability. Such qualities facilitate sufficient entry of the agent into the brain and label DAT complexes to provide a quantitative measure of DAT densities (non-human primates). The agent N-[(2-((3′-N′-propyl-(1′′R)-3′′alpha-(4-fluorophenyl)tropane-2′′beta-1-propanoyl)(2-mercaptoethyl) amino)acetyl)-2-aminoethanethiolato]technetium(V) oxide, also known as FLUORATEC, functions as a DAT imaging agent that is a representative [^{99m}Tc]-based tropane ligand.

A 2nd-generation [^{99m}technetium] single photon emission computed tomography agent that provides *in vivo* images of the dopamine transporter in primate brain. Meltzer PC, Blundell P, Zona T, Yang L, Huang H, Bonab AA, Livni E, Fischman A, Madras BK. J Med Chem 2003 Jul 31; 46 (16), pp. 3483–96.

Huntington's Disease (HD)/Huntingtin RNA Genetic Targeting/Antisense Gene Targeting: *In Vivo* Gene Expression Quantification/Central Nervous System (CNS) Macromolecule Delivery: Transferrin Receptor Complexes *[^{125}I]-Peptide Nucleic Acid (PNA)-[Antitransferrin Receptor IgG]*

Cellular/Molecular Mechanism of Action: The agent is a 16-mer PNA that has an antisense strand that corresponds to the segment around the methionine initiation codon of the huntingtin gene of HD. In this context, it recognizes and physically binds to huntingtin RNA (HD exon-1 messenger RNA).

Background Information: Disease-specific genes of unknown function can be imaged *in vivo* with antisense radiopharmaceuticals. One of the critical limiting features of such biotechnology is the potential to apply drug-targeting strategies that enhance transcellular transport.

Route of Administration: [^{125}I]-PNA/8D3 conjugate (intravenous).

Semi-Synthetic Methods: Biotinylation of PNA performed in concert with the covalent cross-linking of strepavidin and rat 8D3 monoclonal antibody (MAb) to the mouse transferrin receptor (TfR). The latter moiety contains a tyrosine residue that can facilitate [^{125}I] radioiodination. The reformulated PNA antisense radiopharmaceutical conjugated to 8D3 MAb is designated [^{125}I]-PNA/8D3.

Implementation: Evaluation of biotinylated PNA that can be rapidly captured by conjugates of covalently cross-linked strepavidin and [antimouse transferrin receptor IgG]. Complementary *in vivo* studies in mice can be used to determine the biodistriubtion of the PNA analogue [^{125}I]-PNA/8D3 through harvest of tissue/organ systems 6 hours postadministration for frozen sectioning of the brain and quantitative autoradiography.

Animal Model: Murine (littermate control mice or R6/2 transgenic mice that express the exon 1 of the human HD gene for Huntington's disease).

Interpretation and Analysis: Despite covalent cross-linking of the PNA analog, [^{125}I]-PNA/8D3 to MAb, it can gain access to endogenous transferrin transport pathways at both the blood-brain barrier and the brain cell membrane and undergoes both importation from the blood to the brain and exportation from the brain to the blood through TfR. In this manner, it is able to hybridize with "target" huntingtin RNA based on analysis from both cell-free translation assays and ribonuclease protection assays.

Approximately a 3-fold increase in sequestration *in vivo* can be appreciated for antisense [^{125}I]-PNA/8D3 radiopharmaceutical conjugates in the brains of HD transgenic mice. Such observations are consistent with the selective expression of the HD exon-1 messenger RNA in these animals. Therefore, gene expression *in vivo* can be quantitated with antisense radiopharmaceuticals, providing these molecules are reformulated with drug-targeting technology. Drug targeting enables access of the antisense agent to endogenous transport pathways, which permits passage across the cellular barriers that separate blood and intracellular compartments of target tissues.

Imaging gene expression in the brain *in vivo* in a transgenic mouse model of Huntington's disease with an antisense radiopharmaceutical and drug-targeting technology. Lee HJ, Boado RJ, Braasch DA, Corey DR, Pardridge WM. J Nucl Med 2002 Jul; 43 (7), pp. 948–56.

Hypercapnia/Cerebral Blood Flow Reserves *[^{125}I]-HIPDM*

Application: Detection and characterization of regional alterations in cerebral blood flow and central nervous system (CNS) hypercapnia.
Route of Administration: [^{125}I]-HIPDM (intravascular).
Implementation: Evaluation of normocapnic, hypercapnic, and hyperoxic states utilizing a "conscious-state" 30-minute brain uptake scintigraphic imaging strategy employing [^{125}I]-HIPDM preparations.

Animal Model: Rat (normocapnic rats, n = 8; hypercapnic rats, n = 12; hyperoxic rats, n = 6).
Interpretation and Analysis: A mean 41.2% higher uptake is found in the brains of hypercapnic animals ($p \leq 0.01$). In the 3 groups of rats, brain HIPDM uptake has a negative correlation with body weight ($p \leq 0.001$) and a positive correlation with arterial pCO_2 ($p \leq 0.01$), when adjusted for body weight. Such findings indicate that HIPDM uptake with hypercapnia may be used as a provocative test for measuring cerebral blood flow reserves.

Comparison of [^{125}I]HIPDM and [^{125}I]iodoantipyrine in quantifying regional cerebral blood flow in rats. Albright RE Jr, Friedman AH, Fram EK, Harbury OL, Molter BA, Skatoff JH, Harris CC, Coleman RE, Drayer BP. Stroke 1988 Nov; 19 (11), pp. 1404–10.

Experimental increase in brain HIPDM uptake by hypercapnia. Karatzas ND, Sfakianakis GN, Pappas D, Duncan R, Heal A, Serafini A, Kung HF. J Nucl Med 1988 Oct; 29 (10), pp. 1675–82.

Hypocampus/Neuropeptide Receptor Distribution *RF-Amide/[^{125}I]-RFRP-3/[^{125}I]-Neuropeptide FF (NPFF)*

Cellular/Molecular Mechanism of Action: RF-amide (28 amino acid residues) can be isolated from the bovine hypothalamus.
Application: Characterization of the *in vivo* distribution and expression density of neuropeptide distribution.
Implementation: Determination of the tissue distribution of RFRP-3.

Animal Model: Rat.
Interpretation and Analysis: The tissue distribution of RFRP-3 using a sandwich enzyme immunoassay has revealed that the peptide is found in highest concentration within the hypothalamus. In binding assays, [^{125}I]-labeled RFRP-3 becomes bound to OT7T022 with a high level of affinity, but its binding affinity for HLWAR77 is low. Alternatively, [^{125}I]-labeled NPFF binds to both OT7T022 and HLWAR77 with high affinity. Serial deletion in the N-terminal portions of RFRP-3 and NPFF reveals that 4 C-terminal amino acid residues (PQRFamide), which are common between the 2 peptides, comprise a core sequence responsible for binding with the receptor complexes. In contrast, if 3 amino acid residues (PNL in RFRP-3 and LFQ in NPFF) are added to the N terminus of PQRFamide, substantial changes in agonistic properties are observed for RFRP-3 (OT7T022 cell line) and NPFF (HLWAR77 cell line).

Molecular properties of endogenous RFamide-related peptide-3 and its interaction with receptors. Yoshida H, Habata Y, Hosoya M, Kawamata Y, Kitada C, Hinuma S. Biochim Biophys Acta 2003 Feb 17; 1593 (2–3), pp. 151–7.

Parkinson's Disease (PD)/Attention Deficit Hyperactivity Disorder (ADHD)/Dopamine Transporter (DAT) *[^{99m}Technetium] ([^{99m}Tc])-Based Tropane Ligand/ FLUORATEC*

Cellular/Molecular Mechanism of Action: Interacts with DAT complexes located presynaptically on dopamine neurons.
Background Information: In ADHD, DAT density levels are elevated, while in PD these levels are depleted. The depletion of DAT levels also corresponds with the loss of dopamine.
Application: Characterization of the density of DAT complex expression within the central nervous system. Dopamine transporters are located presynaptically on dopamine neurons and therefore can function as a biological marker for PD and ADHD.
Semi-Synthetic Methods: Design and synthesis of 2nd-generation [^{99m}Tc]-based tropane ligands [e.g., N-[(2-((3′-N′-propyl-(1′′R)-3′′alpha-(4-fluorophenyl)tropane-2′′beta-1-propanoyl)(2-mercaptoethyl)amino)acetyl)-2-aminoethanethiolato]technetium(V) oxide].
Implementation: Evaluation of the biology and single photon emission computed tomography (SPECT) imaging potential of [^{99m}Tc]-based tropane ligands as a function of their potent and selective binding to DAT complexes.

Animal Model: Non-human primates.
Interpretation and Analysis: [^{99m}Tc]-based tropane ligands possess improved selectivity and biological stability characteristics that facilitate transfer of the agent into the brain and label DAT complexes. A sufficient amount of agents enter the brain to provide a quantitative measurement of DAT densities (non-human primates). The agent N-[(2-((3′-N′-propyl-(1′′R)-3′′alpha-(4-fluorophenyl) tropane-2′′beta-1-propanoyl)(2-mercaptoethyl)amino)acetyl)-2-aminoethanethiolato]technetium(V) oxide, also known as FLUORATEC, can therefore function as a DAT imaging agent that is a representative [^{99m}Tc]-based tropane ligand.

A 2nd-generation [^{99m}technetium] single photon emission computed tomography agent that provides *in vivo* images of the dopamine transporter in primate brain. Meltzer PC, Blundell P, Zona T, Yang L, Huang H, Bonab AA, Livni E, Fischman A, Madras BK. J Med Chem 2003 Jul 31; 46 (16), pp. 3483–96.

Somatostatin Receptor (SR) Expressing Neoplasia/ Meningiomas: High-Density SR Expression/ Astrocytoma (High-Grade): High-Density SR Expression/Craniopharyngioma: High-Density SR Expression/Mammary Carcinoma/Lymphoma/ Monitoring SR Expression during Therapy *[^{111}Indium] ([^{111}In])-Pentetreotide*

Cellular/Molecular Mechanism of Action: Pentetreotide recognizes and physically binds to SR complexes.
Background Information: Somatostatin receptors are surface markers that are characteristic of not only APUDomas associated with neuroendocrine neoplasias but also malignancies without neuroendocrine properties. The somatostatin analogue pentetreotide can be labeled with [^{111}In] for the *in vivo* imaging of SR-positive lesions (OctreoScan 111, Mallinckrodt Medical BV).
Application: Detection, characterization, and monitoring the growth and therapeutic response of (neoplastic) cell populations that express SR complexes.
Dosage: [^{111}In]-pentetreotide (111 MBq; 3 mCi).
Implementation: Evaluation of SR-specific scintigraphy as a clinical tool for tissue characterization in correlation with histological and radiological examinations. Scintigraphy can be focused toward and performed in cancer types without neuroendocrine tissue expression (e.g., brain, breast tumors, and lymphomas). Scintigraphic imaging can be performed in order to establish comparisons at 6 and 22 hours after intravenous application of [^{111}In]-pentetreotide.

Human Model: Cases of neoplasia without neuroendocrine tissue expression (n = 6 brain; n = 9 breast tumors; n = 5 lymphomas).

Interpretation and Analysis: In conditions of breast cancer, primary tumors can be visualized in a high percentage of cases (e.g., n = 9/9 or 100% and n = 4 palpable axillary lymph nodes).

Some cases with negative axillary node scans and impalpable nodes can have positive biopsy findings (e.g., n = 3/9) and may be accompanied by mediastinal lymph node involvement (e.g., n = 2/3). So far the role of SR-positive breast cancer scans remains unknown. It is tempting to speculate that in resected women who are histologically and scintigraphically SR positive, it might be of value in the early detection of symptom-free recurrences. High densities of SR are present within both meningiomas, high-grade astrocytoma and craniopharyngioma. Differentiation of low- and high-grade astrocytomas cannot be successfully achieved because both grades showed intense radioactivity uptake, even though high-grade tumors lack SR. The latter might be due to disruption of the blood-brain barrier and poor radioactivity washout observed in high-grade astrocytomas. Often, a large percentage of lymphomas can be detected due to the presence of activated lymphocytes and macrophages that express SR at a sufficient density (e.g., n = 5/5). In conclusion, SR scintigraphy in non-neuroendocrine malignancies does not seem to be reliable for an initial tumor staging but is rather more suitable for tissue characterization and extremely useful for monitoring changes of SR expression after treatment.

Receptor scintigraphy of non-neuroendocrine cancers with In-111 pentetreotide. Limouris GS, Rassidakis A, Kondi-Paphiti A, Triantafyllou N, Manetou A, Gennatas K, Vitoratos N, Gregoriou O, Stavraka A, Vlahos L. Hybridoma 1997 Feb; 16 (1), pp. 133–7.

AUTONOMIC NERVOUS SYSTEM

Parasympathetic Nervous System/Acetylcholine Cardiac Muscarinic Receptors/Central Nervous Sytem Muscarinic Acetylcholinergic Receptors (mAChR)/Carcinoma of the Colon
[^{123}I]-PIP/[^{125}I]-PIP

Cellular/Molecular Mechanism of Action: The agent IPIP functions as a ligand that physically binds to mAChR.
Background Information: Prior to approval for *in vivo* use in humans, organ doses for radioiodinated IPIP ligands must 1st be evaluated.
Application: Radioiodinated IPIP ligands can be applied *in vivo* for imaging mAChR using modalities like single photon emission computed tomography (SPECT).
Implementation: Identify the most optimum mAChR ligand-binding properties of 4 different IPIP sterioisomers through evaluation of their biodistribution pattern. A biokinetic model can be developed for the Z-(S)-IPIP stereoisomer for estimating the internal absorbed dose in humans based on extrapolation from an appropriate rat model.

Animal Model: Rat (IPIP biokinetic model).
Interpretation and Analysis: The thyroid gland following the administration of radioiodinated PIP is a critical organ at risk for innocent radiation exposure. The absorbed dose is estimated to be 2.4 mGy/MBq for both males and females, when labeled with [^{123}I]. Even when blocked, the thyroid is still the critical organ at risk, even with a 90% dose reduction. The heart and brain receive the next highest doses in both males and females. Effective dose estimates for the use of pure [^{123}I]-PIP in humans are 0.16 mSv/MBq for males and 0.14 mSv/MBq for females. Biodistribution studies indicate that the Z-(S)-IPIP stereoisomer shows the most promise as a successful agent for imaging muscarinic receptor sites in the heart and brain. IPIP can potentially be applied as a therapeutic radiopharmaceutical for certain colon carcinomas where muscarinic receptor sites are expressed in the tumor cells. These results provide preliminary data for use of IPIP in clinical studies on humans.

In vivo biodistribution of [^{125}I]-PIP and internal dosimetry of [^{123}I]-PIP radioiodinated agents selective to the muscarinic acetylcholinergic receptor complex. Breeden WK 3rd, Hamby DM, Carey JE Jr, Eckerman KF, McPherson DW, Knapp FF Jr. Med Phys 2000 Apr; 27 (4), pp. 778–86.

Parasympathetic/Acethylcholine Nictotinic $\alpha_4\beta_2$ Receptor Complexes/Neurodegenerative Disease/ Tobacco Dependency
(S)-5-[^{123}I]Iodo-3-(2-Azetidinylmethoxy)Pyridine

Cellular/Molecular Mechanism of Action: (*S*)-5-[^{123}I]iodo-3-(2-azetidinylmethoxy)pyridine selectively binds to $\alpha_4\beta_2$ subtype nicotinic acetylcholine receptor complexes.
Application: The iodinated analogue (*S*)-5-[^{123}I]iodo-3-(2-azetidinylmethoxy)pyridine of A-85380 can be used for the specific detection and characterization of $\alpha_4\beta_2$ subtype nicotinic acetylcholine receptor complexes in neurodegenerative disease states, including conditions associated with tobacco dependency.
Route of Administration: (*S*)-5-[^{123}I]iodo-3-(2-azetidinylmethoxy)pyridine (intravenous).
Implementation: Accurate measurement of (*S*)-5-[^{123}I]iodo-3-(2-azetidinylmethoxy)pyridine plasma concentrations in order to determine its capacity to function as a "tracer" molecule for *in vivo* quantification of $\alpha_4\beta_2$ subtype nicotinic acetylcholine receptor complexes.

Human Model: Non-human and human primates.
Interpretation and Analysis: In human or non-human primate whole blood as well as in plasma, the parent compound is only stable for approximately 5 minutes, while substantial decomposition occurs after this time period. Alternatively, the radioligand is stable in the injection solution and in protein-free (> 30 KMW) plasma ultrafiltrate for at least 18 hours. To preserve the parent compound in plasma the radioactive plasma must be mixed with equal volumes of acetonitrile within 5 minutes after its collection or, alternatively, radioactive blood should be collected and mixed with sodium azide (3 mg/ml blood). The *in vivo* metabolism of [^{123}I]5-IA generates 2 distinct components including (i) a radiometabolite that is less lipophilic than the parent compound; and (ii) a polar radiometabolite that is not free radioiodide because of the absence of radioactivity accumulation in the thyroid.

Measurement of plasma metabolites of (*S*)-5-[^{123}I]iodo-3-(2-azetidinylmethoxy)pyridine (5-IA-85380), a nicotinic acetylcholine receptor imaging agent, in non-human primates. Zoghbi SS, Tamagnan G, Baldwin MF, Al-Tikriti MS, Amici L, Seibyl JP, Innis RB. Nucl Med Biol 2001 Jan; 28 (1), pp. 91–6.

Sympathetic Cardiac Adrenergic Receptor Expression Profiles/Congestive Heart Disease
[^{123}I]-Metaiodobenzylguanidine ([^{123}I]-MIBG)/ [^{201}Thallium] ([^{201}Tl]) Cardiac/[^{123}I]-MIBG Washout/ [^{123}I]-MIBG (Adrenergic Activity)/[^{201}Tl] (Perfusion) Ratio/[^{123}I]-MIBG: [^{201}Tl] vs Plasma Norepinephrine/ [^{123}I]-MIBG/[^{201}Tl] Ratio vs Left Ventricular Ejection Fraction (LVEF)

Cellular/Molecular Mechanism of Action: [^{123}I]-MIBG is a radioiodinated analogue of norepinephrine that recognizes and binds to sympathetic/adrenergic receptor complexes. The radionucleotide [^{201}Tl] per se does not exert a true biological effect.

Application: [^{123}I]-MIBG can be utilized to detect and characterize tissue/organ sympathetic/adrenergic receptor expression profiles. The radionuclide [^{201}Tl] can serve as a tracer molecule suitable for the measurement of vascular perfusion parameters. Simultaneous use of both of these agents can assess adrenergic activity and perfusion in various organs in heart failure conditions.
Route of Administration: [^{123}I]-MIBG and [^{201}Tl] (intravascular).
Implementation: Simultaneous assessment of regional adrenergic activity and vascular perfusion with [^{123}I]-MIBG and [^{201}Tl] in various organ systems. In order to reduce crosstalk from [^{201}Tl] into the [^{123}I] energy window to less than 5%, doses of [^{123}I]-MIBG can be administered that are 5 times greater than that of [^{201}Tl] following [^{201}Tl] scintigraphy.

Human Model: Cases suffering from congestive heart failure (CHF, n = 13; n = 13 without heart failure).
Interpretation and Analysis: Regional uptake of [^{201}Tl] (%dose) becomes significantly increased in the heart (left ventricle) and lung (both $p < 0.01$) in conditions of CHF. Increases in global cardiac uptake may be related to left ventricle enlargement. Patterns of regional uptake for [^{123}I]-MIBG (%dose) at 15 minutes are similar to those of [^{201}Tl], suggesting that early [^{123}I]-MIBG uptake could in part depend on regional perfusion in both case group types. At 3 hours, regional uptake of [^{123}I]-MIBG is significantly increased in the heart, lung, and kidney (all $p < 0.01$) in conditions of CHF. Delayed [^{123}I]-MIBG uptake indicates the degree of neuronal accumulation of the tracer, and therefore reflects adrenergic activity. Interestingly, cardiac [^{123}I]-MIBG (adrenergic activity) to [^{201}Tl] (perfusion parameters) ratios decrease significantly in the heart ($p < 0.01$) but increase significantly in the kidney ($p < 0.01$) in conditions of CHF compared to negative reference controls. Cardiac [^{123}I]-MIBG washout is also significantly increased with CHF. Moreover, the cardiac [^{123}I]-MIBG:[^{201}Tl] ratio negatively correlates with plasma norepinephrine concentrations ($r = -0.74$, $p < 0.01$) but positively correlates with LVEF ($r = 0.60$, $p < 0.01$). Such data suggests that there may be impairment of both the neuronal uptake function and the vesicular storage function in the failing heart and an increment in neuronal uptake function in the kidneys in conditions of CHF. It is therefore suggested that dual-tracer scintigraphy can function as a useful non-invasive method for the simultaneous assessment of adrenergic activity and perfusion in various organs in conditions of heart failure.

Simultaneous assessment of regional adrenergic activity and perfusion with [^{123}I]-MIBG and [^{201}Tl] in congestive heart failure. Seto H, Shimizu M, Nozawa T, Yoshida N, Inagaki S, Kageyama M, Kakishita M. Nucl Med Commun 1996 Mar; 17 (3), pp. 225–30.

Sympathetic: Cardiac/Cardiomyopathy: Dilated/ Heart/Mediastinum (H/M) Ratio: Prognostic Indicator for Mortality
[^{123}I]-Metaiodobenzylguanidine ([^{123}I]-MIBG)

Cellular/Molecular Mechanism of Action: [^{123}I]-MIBG is an analogue of the neurotransmitter norepinephrine that can recognize and physically bind to adrenergic receptor complexes.
Application: Evaluation of the potential for repeated measurements of cardiac [^{123}I]-MIBG imaging parameters before and after optimized treatments to be useful for predicting the prognosis of congestive heart failure (CHF) resulting from dilated cardiomyopathy (DCM).
Route of Administration: [^{123}I]-MIBG (intravascular).
Implementation: Assessment of DCM with [^{123}I]-MIBG and measurement of neurohumoral factor concentrations at baseline and after 6 months of optimized treatments. Cox proportional hazards analysis can be performed to assess the various parameters before and after treatment.

Human Model: Dilated cardiomyopathy (n = 85 cases with left ventricular ejection fraction (LVEF) of less than 45%).
Interpretation and Analysis: A relatively large number of cases will experience complications (e.g., n = 12 death; n = 11 hospitalization) over a 2-year mean follow-up period. Although there is no difference between the baseline H/M ratio measured by MIBG between survivors and non-survivors, the H/M ratio is significantly decreased in non-survivors after 6 months. Multivariate analysis reveals that a high plasma concentration of brain natriuretic peptide levels after 6 months ($p = 0.0049$) and absolute changes in the H/M ratio ($p = 0.0046$) are independent predictors of mortality. Comparison of the H/M ratio on MIBG imaging before and after optimized additional treatment provides useful information for predicting mortality and is independent of clinical and neurohumoral factors previously shown to be associated with poor prognosis in patients with DCM.

Prognostic value of repeated [^{123}I]-metaiodobenzylguanidine imaging in patients with dilated cardiomyopathy with congestive heart failure before and after optimized treatments—Comparison with neurohumoral factors. Matsui T, Tsutamoto T, Maeda K, Kusukawa J, Kinoshita M. Circ J 2002 Jun; 66 (6), pp. 537–43.

Sympathetic Cardiac Denervation and Ischemia/ Myocardial Sympathoexcitatory Response/ [Balloon Coronary Occlusion (BCO)]
[^{123}I]-Metaiodobenzylguanidine ([^{123}I]-MIBG)

Cellular/Molecular Mechanism of Action: [^{123}I]-MIBG is a norepinephrine analogue that recognizes and physically binds to adrenergic receptor complexes.
Background Information: Alterations of cardiac sympathetic nerve function could modulate sympathetic reflexes originating from the ischemic area.
Application: Detection and characterization of cardiac sympathetic denervation.
Route of Administration: [^{123}I]-MIBG (intravenous).
Implementation: Evaluate conditions of angina pectoris as a function of quantified baseline measurements of cardiac sympathetic denervation associated with anatomical regions of ischemia utilizing [^{123}I]-MIBG. Complementary diagnostic procedures can include establishing the nature of transient changes in sympathetic activity during BCO by wavelet analysis of RR interval variability.

Human Model: Cases with angina pectoris (n = 23) subjected to BCO. The research objective of the referenced study was to elucidate the influence of cardiac sympathetic denervation on the sympathoexcitatory response to acute myocardial ischemia during BCO.
Interpretation and Analysis: Balloon coronary occlusion results in a transient augmentation of low-frequency (LF; 0.04–0.14 Hz) spectral components of RR interval variability in approximately 30% of cases (e.g., n = 4/12) with cardiac denervation, and in greater than two-thirds of cases without denervation (e.g., n = 8/11; $p < 0.01$ by the chi^2 test). Consequently, increases in LF components are significantly less during BCO in cases with cardiac denervation (34%) than in those without denervation (273%: interaction: $p < 0.05$). In some cases with severe ischemia provoked by a fall of > 10% in the left ventricular ejection fraction, LF components increase by 506% during BCO, regardless of the condition of cardiac denervation (n = 7/23 cases). Conversely, in conditions of mild ischemia provoked by a fall of < 10% in the ejection fraction, the changes of

LF components during BCO are significantly less in cases with denervation than in those without denervation (84 vs 344%, $p < 0.05$). Such observations suggest that if the provoked ischemia is not severe, cardiac sympathetic denervation could prevent ischemia-induced sympathoexcitation.

Cardiac sympathetic denervation modulates the sympathoexcitatory response to acute myocardial ischemia. Joho S, Asanoi H, Takagawa J, Kameyama T, Hirai T, Nozawa T, Umeno K, Shimizu M, Seto H, Inoue H. J Am Coll Cardiol 2002 Feb 6; 39 (3), pp. 436–42.

Sympathetic Cardiac Denervation/Myocardial Infarction (MI)/Heterogeneous Cardiac Sympathetic Innervation
[^{131}I]-Metaiodobenzylguanidine ([^{131}I]-MIBG)/ [^{125}I]-Iodocyanopindolol ([^{125}I]-ICYP)

Cellular/Molecular Mechanism of Action: Metaiodobenzylguanidine is a norepinephrine analogue that recognizes and physically binds to adrenergic receptor complexes. Iodocyanopindolol is a β-adrenoreceptor ligand.
Application: Detection and characterization of MI.
Route of Administration: [^{131}I]-MIBG and [^{125}I]-ICYP are both administered intravenously.
Implementation: Evaluation of cardiac neuronal function and β receptor utilizing a dual-tracer method of [^{131}I]-MIBG and [^{125}I]-ICYP in rat heart failure after MI.
Animal Model: Rat (MI).
Interpretation and Analysis: In conditions of MI, left ventricular (LV) systolic function is decreased, and LV dimension and right ventricular (RV) mass increase gradually (rat). Accumulations of [^{131}I]-MIBG within non-infarcted LV (remote region) and RV decrease by 15% at 1 week compared with controls (e.g., sham-operated rats). These same accumulations are restored by 71% and 56%, respectively, at 24 weeks compared with age-matched sham rats despite sustained depletion of myocardial norepinephrine content within these anatomical regions. Accumulations of [^{125}I]-ICYP in the remote region and in the RV do not decrease during any stage. Myocardial MIBG distribution is heterogeneous at 1 week and lower in the peri-infarcted region than in the remote region. These profiles are accompanied by reduced ICYP accumulation in the peri-infarcted region. At week 12, the heterogeneous distribution of both isotopes disappears. Thus cardiac sympathetic neuronal alterations appear to be coupled with downregulation of β receptors in rat heart failure after MI. The abnormal adrenergic signaling occurs heterogeneously in terms of ventricular distribution and time course after MI.

Heterogeneous cardiac sympathetic innervation in heart failure after myocardial infarction of rats. Igawa A, Nozawa T, Yoshida N, Fujii N, Inoue M, Tazawa S, Asanoi H, Inoue H. Am J Physiol Heart Circ Physiol 2000 Apr; 278 (4), pp. H1134–41.

Sympathetic: Cardiac Failure/Clinical Variables in Risk Stratification
[^{123}I]-Metaiodobenzylguanidine ([^{123}I]-MIBG)

Cellular/Molecular Mechanism of Action: [^{123}I]-MIBG is a norepinephrine analogue that recognizes and physically binds to adrenergic receptor complexes.
Background Information: Both myocardial [^{123}I]-MIBG uptake and plasma norepinephrine are markers of sympathetic activation in heart failure and have been shown to indicate a poorer prognosis. However, these observations have been noted before treatment with β-blockers became part of standard clinical practice.
Application: Both myocardial [^{123}I]-MIBG uptake and plasma norepinephrine are markers of sympathetic activation in heart failure conditions.
Implementation: Evaluation of chronic heart failure (CHF) cases over a mean follow-up period of 36 months. Potential prognostic parameters are obtained before initiation of β-blocker therapy.
Human Model: Cases of CHF (n = 58) recognized according to established guidelines (New York Heart Association functional Class II and III, ejection fraction < 35%; 53% ischemic cardiomyopathy).
Interpretation and Analysis: During the observation period, cases may display cardiovascular complications (e.g., n = 17/58 or 29.3%, death or heart transplantation). Multivariate Cox regression analysis, plasma norepinephrine, peak oxygen consumption, end-diastolic volume as measured by echocardiography, and exercise performance during bicycling and walking have prognostic significance in conditions of heart failure treated with β-blockers in addition to angiotensin-converting enzyme inhibitors. In both uni- and multivariate analysis, the heart/mediastinum ratio of [^{123}I]-MIBG uptake does not correlate with cardiovascular mortality.

Cardiac [^{123}I]-MIBG imaging and clinical variables in risk stratification in patients with heart failure treated with β-blockers. de Milliano PA, Tijssen JG, van Eck-Smit BL, Lie KI. Nucl Med Commun 2002 Jun; 23 (6), pp. 513–9.

Sympathetic: Cardiac Infarct/Adrenergic Receptor Expression/Sympathetic Neuronal Dysfunction/ QT-RR Slope and Metaiodobenzylguanidine (MIBG) Heart: Mediastinum (H/M) Ratio/QT Dispersion and MIBG H/M Ratio
[^{123}I]-MIBG

Cellular/Molecular Mechanism of Action: Metaiodobenzylguanidine is an analogue of norepinephrine that recognizes and physically binds to sympathetic/adrenergic receptor complexes.
Background Information: Cardiac [^{123}I]-MIBG imaging is widely used to assess cardiac sympathetic neuronal function. However, physiologic significance of impaired cardiac MIBG uptake has not been fully elucidated.
Application: Detection and characterization of sympathetic adrenergic receptor expression as a means of classifying different cardiovascular disease states (e.g., myocardial infarction).
Route of Administration: [^{123}I]-MIBG (intravascular).
Implementation: Evaluation of the influences of abnormal cardiac sympathetic neuronal function on heart rate variability (HRV) and ventricular repolarization process. In this context, conditions of myocardial infarction can be classified into groups based on H/M ratio established by MIBG scintigraphy. Holter recordings and a standard 12-lead electrocardiography can be used for evaluation of HRV, QT-RR relation, and QT dispersion. MIBG Classification Scheme I: globally decreased MIBG uptake (H/M < 1.5; n = 10 cases); MIBG Classification Scheme II: decreased MIBG uptake (H/M ≥ 1.5; n = 19 cases); and Normal Reference Control Scheme III: (n = 17 cases).
Human Model: Cases of myocardial infarction (n = 29) classified into 2 groups by an H/M ratio established by MIBG scintigraphy.
Interpretation and Analysis: Low, high, and total frequency components are decreased in MIBG Classification Schemes I and II compared to reference controls. The reductions of these frequency domain measures are more severe in Scheme I than in Scheme II cases, but the differences do not reach statistically significant levels. Circadian variation of frequency domain measures disappears in

Scheme I cases. The slope of the QT-RR relationship is significantly greater in group I than in groups II and III. QT dispersion is also greater in group I (64 ± 25 msec) than in group II (43 ± 19 msec) and group III (28 ± 9 msec). Therefore, in conditions of sympathetic neuronal dysfunction inferred from globally impaired cardiac MIBG uptake, there are alterations in the modulation of ventricular repolarization process as well as decreased HRV.

Modulation of ventricular repolarization and RR interval is altered in patients with globally impaired cardiac [^{123}I]-MIBG uptake. Yoshida N, Nozawa T, Igawa A, Fujii N, Kato B, Mizumaki K, Fujiki A, Asanoi H, Seto H, Inoue H. Ann Noninvasive Electrocardiol 2001 Jan; 6 (1), pp. 55–63.

Sympathetic: Cardiovascular/Salt Sensitivity and Adrenergic Regulation/Hypertrophic Stage in Salt-Sensitive *In Vivo* Models/Cardiac Neuronal Function: Late Phase Deterioration/Adrenergic β-Receptor Downregulation
[^{131}I]-Metaiodobenzylguanidine ([^{131}I]-MIBG)/ [^{125}I]-Cyanopindolol ([^{125}I]-ICYP)

Cellular/Molecular Mechanism of Action: [^{131}I]-MIBG is an analogue of norepinephrine and detects and physically binds to adrenergic/sympathetic receptor complexes. [^{125}I]-ICYP also recognizes and binds to sympathetic/adrenergic receptor complexes.
Background Information: Heart failure is associated with activation of the sympathetic nervous system and downregulation of β-receptor complexes. However, the coupling between cardiac sympathetic neuronal function and β receptors during development of hypertensive heart failure is not clear.
Application: [^{131}I]-MIBG and [^{125}I]-ICYP (intravascular) can be utilized to evaluate adrenergic/sympathetic adrenergic receptor expression profiles.
Route of Administration: [^{131}I]-MIBG and [^{125}I]-ICYP (intravascular).
Implementation: Evaluation of cardiac neuronal function and β receptors utilizing a dual-tracer method employing [^{131}I]-MIBG and [^{125}I]-ICYP under *in vivo* conditions of salt-sensitivity and salt-resistance.

Animal Model: Rats (Dahl salt-sensitive [DS] and salt-resistant [DR]). Rats are fed an 8% NaCl diet after the age of 6 weeks. Blood pressure is raised to > 200 mm Hg at 12 weeks in DS rats and is maintained at an elevated level until 18 weeks, but is only slightly in DR rats. Left ventricular (LV) function of DS rats is preserved at 12 weeks but deteriorates by 18 weeks.
Interpretation and Analysis: Despite a 56% reduction of cardiac norepinephrine content at 12 weeks in salt-sensitive *in vivo* models, neither MIBG nor ICYP uptake in salt-sensitive *in vivo* models is different from salt-resistant *in vivo* models. At 18 weeks, both MIBG and ICYP uptakes decrease by 52% and 39%, respectively, in association with 71% reductions in cardiac norepinephrine in salt-sensitive *in vivo* models. MIBG uptake of the LV is homogeneous at 6 weeks but lower in the LV endocardial regions at 18 weeks in salt-sensitive *in vivo* models. Cardiac sympathetic neuronal function therefore is relatively preserved at the compensated, hypertrophic stage in salt-sensitive *in vivo* models but deteriorates when associated with β-receptor downregulation at the failing stage. The cardiac neuronal dysfunction occurs heterogeneously. A combination of scintigraphic portrayal of β receptors with MIBG should provide valuable information regarding sympathetic nerve signaling in living hearts.

Dual-tracer assessment of coupling between cardiac sympathetic neuronal function and downregulation of β receptors during development of hypertensive heart failure of rats. Nozawa T, Igawa A, Yoshida N, Maeda M, Inoue M, Yamamura Y, Asanoi H, Inoue H. Circulation 1998 Jun 16; 97 (23), pp. 2359–67.

Trauma-Induced Neurochemical Changes
[^{3}H]Glutamate/[^{3}H]MK801

Background Information: Trauma is the leading cause of death in individuals between the ages of 1 and 44 years. In cases of severe head injury mortality can reach as high as 35–70%. Despite this fact, there has been little progress in the development of effective pharmacological agents to protect brain-injured patients. To date, there is little data on the mechanisms involved in neuronal cellular insult after severe head injury, especially in humans. Glutamate acts both as a primary excitatory neurotransmitter and a potential neurotoxin within the mammalian brain. Evidence indicates that hyperactivity of the glutamate system contributes to neuronal death in brain trauma. Also, in animal models of neurotrauma, neural injury is followed by development of gliosis, which has been linked to the severity of brain injury.
Implementation: Evaluate the glutamate system in brain trauma as a function of [^{3}H]glutamate and [^{3}H]MK801 (a non-competitive N-methyl-D-aspartate [NMDA]-receptor antagonist) binding and [^{3}H]glutamate uptake assays in human cerebral cortex preparations obtained from severely brain-injured and control victims. Investigation of gliosis phenomenon following brain injury can be determined by performing glial fibrillary acidic protein (GFAP) immunohistochemistry.
Interpretation and Analysis: There were no significant differences in [^{3}H]glutamate binding (affinity or density of sites) between the control and head-injured groups. Conversely, cerebral cortical [^{3}H]MK801 binding analysis reveals both a significant increase in the density of sites (Bmax) and a decrease in the dissociation constant (Kd) in groups of head-injury cases when compared to reference controls. There were no significant differences in [^{3}H]glutamate uptake between groups. Injury brains present with an increase number of GFAP-positive astrocytes and a more intense GFAP reaction in comparison to control brains. In the context of traumatic brain injury, results from previous research represent evidence that encourages further investigation into compounds capable of selectively modulating NMDA receptor subtype in humans, which can also serve as an approach for therapeutically manipulating glial cell responses following brain trauma.

Neurochemical characterization of traumatic brain injury in humans. Regner A, Alves LB, Chemale I, Costa MS, Friedman G, Achaval M, Leal L, Emanuelli T. J Neurotrauma 2001 Aug; 18 (8), pp. 783–92.

ENDOCRINE SYSTEM

Adrenal Cortex Hypertrophy
Radioiodinated Cholesterol ([^{123}I]/[^{124}I])/ [^{131}I]-6-Beta-Iodomethyl-19-Norcholesterol.

Cellular/Molecular Mechanism of Action: Radiolabeled cholesterol preferentially accumulates within the mass of the hypertrophied adrenal cortex, where it is perceived as a precursor for steroid hormone synthesis (e.g., cortisol).
Background Information: The adrenal gland consists of cortical and medullary components, both of which may be functionally imaged using radiopharmaceuticals designed to take advantage of the specialized physiology of each tissue.
Diagnostic Application: Radiolabeled cholesterol derivatives are taken up by normal and abnormal adrenal cortex and provide a map of adrenocortical function in Cushing's syndrome, hyperaldosteronism, and hyperadrenogenism.

Route of Administration: Intravenous injection.

Considerations: Radiolabeled cholesterol-based hormones have also been applied for various diagnostic purposes (e.g., radiolabeled estrone sulfate). Radiolabeled metaiodobenzylguanidine (MIBG) is a tracer of Type I uptake and intracellular storage capacity for catecholamines in sympathomedullary tissues and tumors derived from this body system. This permits the location of pheochromocytomas of all types (benign and malignant, intra- and extra-adrenal, sporadic and familial) as well as neuroblastomas in all stages. Other neuroendocrine tumors with Type I uptake capacity may also be imaged. In suitable cases preliminary data suggests the administration of large doses of MIBG may permit internal radiotherapy of otherwise untreatable neuroendocrine tumors.

Implementation: Adrenal and total body scintigraphs performed with [^{131}I]-6-beta-iodomethyl-19-norcholesterol. Results can be compared with roentgenographic findings and liver, bone, and total body [^{67}Ga]-citrate scintigraphs.

Human Model: Cases with a history of a prior resection of adrenal cortical carcinoma (e.g. n = 5).

Interpretation and Analysis: Abnormal lesions are detected as adrenal glands with elevated levels of imaging agent accumulation in addition to irregularities in adrenal gland size and/or shape. Quantification of uptake shows strong correlation with biochemical parameters of adrenocortical hyperfunction. In cases of incidentally discovered euadrenal masses, scintigraphy may help to distinguish between benign, non-functional cortical adenomas and destructive, potentially malignant lesions.

Metastatic lesions can be detected with radiolabeled cholesterol (e.g., n = 4/5 cases, including 3 liver metastases, 2 bone metastases, and 1 lung metastasis). Such lesions may also be demonstrated by one or more other diagnostic modalities. In some cases (e.g., n = 1/5) all initial findings may be negative despite subsequent development of disseminated disease (e.g., brain metastases). The 6-methyl-analog of iodocholesterol makes it possible to detect metastatic adrenocortical carcinoma with total body scans. Whether or not this agent is "tumor specific" and will be of significant clinical utility will have to be determined more fully in a larger series of patients.

Adrenal Gland: Function and Structure
[^{131}I]-6-β-Iodomethyl-Norcholesterol/ [^{75}Se]-Selenomethyl-Norcholesterol/ [^{131}I]-, [^{123}I]-, and [^{124}I]-Metaiodobenzylguanidine (MIBG)/[^{18}F]-Metafluoro-Benzyl-Guanidine/ [^{123}I]-tyr-Octreotide/[^{111}In]-Diethylenetriamine Pentaacetic Acid (DTPA)-Octreotide/[^{111}In]-DOTA-Octreotide/[^{18}F]-2-Fluoro-d-Deoxyglucose/ Metyrapone/Tyrosine Analogues/Low-Density Lipoprotein (LDL) Receptors/Bombesin/Vasoactive Intestinal Polypeptide/Cholecystokinin/Opiate Peptides/[^{11}C]-Acetate

Background Information: Over the last 30 years nuclear medicine imaging of the adrenal gland and its lesions has been achieved by exploitation of a number of physiological characteristics associated with this organ. By seeking and utilizing features that are quantitatively or qualitatively different from those of the adjacent tissues, it is possible to functionally characterize the adrenal gland and associated disease states. In most instances lesions affecting both the cortex and the medulla retain the basic physiology related to their original tissue type. Diagnostic strategies widely used in clinical practice include assessment of (i) radiolabeled cholesterol analog uptake and storage facilitated by LDL receptors and cholesterol ester storage pools in the adrenal cortex utilizing the agents [^{131}I]-6-β-iodomethyl-norcholesterol or [^{75}Se]-selenomethyl-norcholesterol; (ii) catecholamine Type I presynaptic, uptake mechanisms, and intracellular granule uptake and storage processes in the adrenal medulla and extra-adrenal paraganglia utilizing [^{131}I]-, [^{123}I]-, and [^{124}I]-MIBG and [^{18}F]-metafluoro-benzyl-guanidine; (iii) cell surface receptor binding of peptides/neurotransmitters/modulators such as those for the family of 5 subtypes of somatostatin receptors ([^{123}I]-tyr-octreotide, [^{111}In]-DTPA-octreotide, [^{111}In]-DOTA-octreotide, and many others); (iv) increases in tumor glycolysis, particularly in the most malignant adrenal-associated cell types, utilizing [^{18}F]-2-fluoro-d-deoxyglucose, that can be expected to detect certain neoplastic lesions such as malignant pheochromocytomas (particularly the minority of cases that are not detected with MIBG) and adrenal incidentalomas (particularly with known extra-adrenal malignancies).

There are a variety of adrenal tissue characteristics that have the potential for being exploited for various purposes that are not currently employed for clinical uses, but nevertheless have potential as imaging agents. These include (i) inhibitors of adrenal cortical steroid hormone synthesis enzymes (e.g., radiolabeled analogues of metyrapone); (ii) radiolabeled lipoproteins that bind to adrenocortical LDL receptors; (iii) inhibitors of catecholamine biosynthesis enzymes (e.g., radiolabeled analogues of tyrosine and related amino acids); and (iv) cell surface receptors for various peptides and hormones that may be overexpressed by adrenal cortical or adrenal medullary tumors (e.g., radiolabeled analogues of adenocorticotropic hormone (ACTH) for adrenocortical cells of zona fasciculata or zona glomerulosa origin; neurotransmitter/hormone message peptides binding to cell surface receptors such as bombesin, vasoactive intestinal polypeptide, cholecystokinin, and opiate peptides). The adrenal cortex can also synthesize cholesterol from acetate, and preliminary studies with [^{11}C]-acetate positron emission tomography have shown interesting results.

Application: Detection and characterization of the adrenal gland function and dysfunction.

Functional scintigraphy of the adrenal gland. Rubello D, Bui C, Casara D, Gross MD, Fig LM, Shapiro B. Eur J Endocrinol 2002 Jul; 147 (1), pp. 13–28.

Thyroid Gland
Technetium Pertechnetate [^{99m}TcO$_4$]

Cellular/Molecular Mechanism of Action: Radioisotopes accumulate within the parenchymal tissues of the thyroid gland. Abnormal thyroid lesions frequently accumulate [^{99m}Tc] pertechnetate at relatively high tissue densities (activity/gram tissue).

Diagnostic Application: Diagnosis of hyperthyroidism due to adenomatous hyperplasia or certain neoplastic conditions. It is of particular value in detecting metastatic lesions or in cases suspected of suffering an abnormality but that do not display obvious thyroid gland enlargement (thoracic thyroid gland).

Route of Administration: Intravenous [^{99m}Tc]-pertechnetate.

Implementation: Evaluate the accuracy of fine-needle aspiration (FNA) cytology and thyroid scintigraphy (TS) in patients with solitary thyroid nodules. Prior to surgery, cases undergo FNA cytology (e.g., n = 657 cases) and [^{99m}Tc]-pertechnetate scintigraphic imaging (n = 496/657 or 75.5%).

Human Model: Retrospectively review of a series of 657 consecutive patients (n = 531 or 80.8% women and n = 126 or 19.2% men, median age 45 years, range 16–81 years) with solitary thyroid nodules.
