 - Sclerosing adenosis

TREATMENT

ED TREATMENT/PROCEDURES

- Majority of women will not require any medical treatment
- Conservative therapy:
 - Support bra:
 - Reduces tension on supporting ligaments of the breast
 - May reduce inflammatory response and edema
 - Low dose diuretic for 2–3 days before onset of menses
 - NSAIDs
- Dietary changes are somewhat controversial:
 - Restricting dietary fat (to 25% of total calories) and eliminating caffeine
 - Increasing vitamin E and vitamin B₆
 - Herbal preparations such as primrose oil
- Hormonal therapy:
 - Should be initiated by PCP to enable follow-up during course of treatment
 - Oral contraceptives:
 - May decrease symptoms, particularly after 1 yr of use
 - Danazol (synthetic androgen) and Tamoxifen (partial estrogen antagonist):
 - Shown to be equally effective for treatment of severe cyclical mastalgia
 - Use may be limited by side effects (acne, hirsutism, weight gain, teratogenicity)
 - Bromocriptine (inhibits prolactin production):
 - Use also limited by side effects (headache, dizziness, nausea, constipation, weakness)
- Surgical intervention:
 - If a persistent nodule exists, excision is recommended regardless of findings on diagnostic imaging
 - If a large cyst recurs after aspiration on 2 occasions, it should be excised and sent for pathology

MEDICATION

- Bromocriptine: 2.5–5 mg/d BID
- Danazol: 100–400 mg/d BID for 6 mo
- Tamoxifen: 10–20 mg/d
- Oral contraceptive pills (vary)

FOLLOW-UP

DISPOSITION

Discharge Criteria

- Patients with fibrocystic changes are appropriate for discharge with outpatient follow-up
- Encourage patient to keep a breast pain record to determine whether pain is cyclic
- The importance of follow-up should be stressed to ensure patient health, disease prevention, and patient satisfaction
- Encourage regular breast self-exam, annual physical exams, and annual mammograms when appropriate

Issues for Referral

- Practically speaking, all breast masses evaluated in the ED need referral to a primary provider or specialized breast clinic
- Further investigation with imaging and possible biopsy are required for masses that persist throughout menses and are not cyclical
- Referral to a general surgeon may be required in certain cases where tissue biopsy is necessary

PEARLS AND PITFALLS

- Breast cancer may coexist with benign breast disease and fibrocystic changes:
 - _ Consider all cancer risk factors
 - _ Confirm follow-up plan
- Mastitis in a nonlactating patient should be treated as inflammatory carcinoma until proven otherwise
- Fibrocystic changes are usually bilateral; unilateral changes are suspicious for cancer
- Fear of breast cancer is high in all patients:
 - _ Give reassurance that fibrocystic breast changes are not cancerous
 - _ Have a low threshold for referral to a specialist

CODES

ICD9

- 610.1 Diffuse cystic mastopathy
- 610.2 Fibroadenosis of breast
- 610.9 Benign mammary dysplasia, unspecified

ICD10

- N60.19 Diffuse cystic mastopathy of unspecified breast
- N60.29 Fibroadenosis of unspecified breast
- N60.99 Unspecified benign mammary dysplasia of unspecified breast

FIBROMYALGIA

Michael P. Wilson • Austin Hopper

BASICS

DESCRIPTION

- Nonarticular, noninflammatory form of muscular and joint pain more common in females:
 - Widespread pain from stimuli that do not normally cause pain (allodynia)
 - > 11 diffuse tender points
 - Fatigue
 - Sleep disturbance
 - Muscle stiffness
 - Difficulties with attention, memory
 - Limited physical findings
- Not diagnosis of exclusion, may occur with other rheumatic diseases

ETIOLOGY

- Mechanism:
 - Painful symptoms believed to result from greater activation of pronociceptive (pain-causing) system relative to antinociceptive (pain-dampening) system in brain and spinal cord.
- Abnormalities identified as possible mechanism:
 - Increased substance P (facilitates pronociception)
 - Decreased biogenic amines (NE, serotonin, dopamine), which facilitate antinociception
 - Decreased gray matter in brain
 - Genetics: 1/3 of patients with fibromyalgia have a close relative who is affected:
 - Candidate genes include 5-HT_{2A}, serotonin transporter, D₄ receptor, others
 - Like many complex diseases, psychological factors play a role, with high incidence of psychiatric disorders.
 - In genetically predisposed individuals, likely starts as initial insult from age, trauma, illness, inflammation, etc.
 - Hypothalamus–pituitary–adrenal axis stress-response dysfunction has been indicated to precede development of fibromyalgia

DIAGNOSIS

SIGNS AND SYMPTOMS

Widespread pain reported above the waist, below the waist, on the left side of the body, and on the right side of the body along with axial skeleton pain:

- Pain reported for > 3 mo

History

- Generalized musculoskeletal pain and morning stiffness
- Weakness and fatigue
- Sleep disturbance
- Muscle spasms
- Persistent fatigue not relieved with rest (consider chronic fatigue syndrome)
- Numbness or tingling in the arms or legs
- Impaired concentration or memory
- Nausea, vomiting
- Abdominal pain or discomfort relieved with bowel movements (consider irritable bowel syndrome)
- Ear pain
- Sinus pressure (consider sinusitis)
- Jaw or face pain (consider TMJ disorder)
- Temple pain (consider temporal arteritis)
- Pelvic or bladder discomfort (consider interstitial cystitis)
- Tension or migraine headaches (consider causes of chronic headache)
- Irritation or itching at introitus (consider vulvodynia)

Physical-Exam

Exam findings usually limited

ESSENTIAL WORKUP

- History is key to diagnosis.
- In the ED, necessary only to distinguish between acute pain from trauma, injury, or new-onset medical conditions and chronic pain, which will require ongoing care and treatment.
- If a diagnosis of fibromyalgia is required, use classification criteria established by American College of Rheumatology (ACR) for fibromyalgia:
 - *Widespread* pain present for at least 3 mo defined as pain on both left and right side of body, above and below waist, and axial skeletal pain (cervical or anterior chest or thoracic spine or low back pain).
 - 11 of the 18 specific tender points on digital palpation with force of < 4 kg/cm (amount of pressure required to blanch thumbnail) known as the Widespread Pain Index (WPI)
 - The 9 *paired* (bilateral) tender points are located at the:
 - Occiput: Suboccipital muscle insertions
 - Low cervical: Anterior aspects of C5–C7 intertransverse spaces
 - Trapezius: Midpoint of upper border

- Supraspinatus: Above medial border of scapular spine
- 2nd rib: 2nd costochondral junction just lateral to the junctions on upper surfaces
- Lateral epicondyle: ~ 2 cm distal to epicondyles
- Gluteal: Upper outer quadrant of buttocks
- Greater trochanter: Posterior to trochanteric prominence
- Knee: Medial fat pad proximal to joint line
- OR diagnosis can be made with a WPI ≥ 7 and a Symptom Severity (SS) scale ≥ 5 OR WPI 3–6 and SS ≥ 9 .
- The SS scale (0–12) evaluates fatigue, waking unrefreshed, and cognitive symptoms
- The 3 symptoms are rated on the following scale for level of severity over the past week:
 - 0 = no problem
 - 1 = slight or mild problems, generally intermittent
 - 2 = moderate, considerable problems, often present and/or at a moderate level
 - 3 = severe: Pervasive, continuous, life-disturbing problems
- In addition, the SS scale rates somatic symptoms as follows:
 - 0 = no symptoms
 - 1 = few symptoms
 - 2 = moderate number of symptoms
 - 3 = great deal of symptoms
 - Somatic symptoms that might be considered: Muscle pain, irritable bowel syndrome, fatigue/tiredness, thinking or remembering problems, muscle weakness, headache, pain/cramps in the abdomen, numbness/tingling, dizziness, insomnia, depression, constipation, pain in the upper abdomen, nausea, nervousness, chest pain, blurred vision, fever, diarrhea, dry mouth, itching, wheezing, Raynaud phenomenon, hives/welts, ringing in ears, vomiting, heartburn, oral ulcers, loss of/change in taste, seizures, dry eyes, shortness of breath, loss of appetite, rash, sun sensitivity, hearing difficulties, easy bruising, hair loss, frequent urination, painful urination, and bladder spasms.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Required only for evaluation of alternative diagnoses or acute pain:
 - CBC
 - Blood chemistries
 - ESR
 - Muscle enzymes

- Thyroid function tests
- Urinalysis
- No specific lab abnormalities are characteristic of fibromyalgia.

Imaging

No specific radiographic abnormalities are characteristic.

Diagnostic Procedures/Surgery

Required only to evaluate causes of acute pain

DIFFERENTIAL DIAGNOSIS

- Myofascial pain syndrome (*trigger points* present, not *tender points*)
- Chronic fatigue syndrome
- Major depression
- Polymyalgia rheumatica
- Lyme disease
- Hypothyroidism
- Collagen vascular disease
- Electrolyte imbalance
- Myopathies (metabolic and drug induced)
- Osteomalacia
- Psychogenic rheumatism
- Eosinophilia–myalgia syndrome
- UTI
- Spondyloarthropathy
- Multiple chemical sensitivity
- Interstitial cystitis

TREATMENT

ED TREATMENT/PROCEDURES

- Patient education and reassurance:
 - Emphasize that fibromyalgia is not life-threatening and does not reduce life expectancy.
 - Disorder is chronic but not crippling or deforming.
 - Goal is to manage pain and improve functional disability.
- Patients will require ongoing care and should be referred to a primary physician or pain specialist.
- Pharmacologic therapy:
 - Pharmacotherapy for improving pain, relaxing muscles, and improving sleep quality has been most successful with CNS agents such as pregabalin or gabapentin.

- Opioids are not indicated for chronic pain and may actually worsen a patient’s long-term pain by acting as NDMA receptor agonists.
- Combinations of medications (e.g., amitriptyline and fluoxetine or amitriptyline and cyclobenzaprine) may be more beneficial than either medication alone.
- Tricyclic antidepressants (TCAs; amitriptyline, nortriptyline) likely superior to SSRIs.
- Serotonin norepinephrine reuptake inhibitors (duloxetine, milnacipran) may be more effective than SSRIs and better tolerated than TCAs.
- Tramadol is an adjunctive agent.
- Benzodiazepines (clonazepam) are of no benefit other than their role in sleep disturbances.
- NSAIDs and corticosteroids have not been shown to be effective.
- Steroids or local anesthetic (lidocaine) injection into tender points is controversial:
 - No studies available to prove efficacy

MEDICATION

- Acetaminophen: 650 mg PO q4h
- Amitriptyline: 25–50 mg PO at bedtime
- Cyclobenzaprine: 5–10 mg PO TID
- Duloxetine: 60 mg PO daily or BID
- Gabapentin: Start 300 mg PO TID, titrate upward beginning at 300 mg/d to max. of 1200 mg
- Milnacipran: Start at 12.5 mg/d, then titrate upward to max. of 50–100 mg PO BID
- Pregabalin: Start 50 mg PO TID, titrate upward to max. 450 mg/d PO in divided doses
- Tramadol: 300–400 mg/d PO

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with serious underlying disease, intractable pain, or immunocompromised
- Patients with suicidal ideation

Discharge Criteria

Patients with uncomplicated fibromyalgia can be managed as outpatients.

FOLLOW-UP RECOMMENDATIONS

Lifestyle modifications:

- Physical exercise should be encouraged:
 - Exercise program should be gradual to avoid overexertion and discouragement.
 - Aerobic exercise is more beneficial than simple stretching.
 - Efficacy not maintained if exercise stops
- Good sleep pattern should also be discussed:
 - Establishing nightly ritual in preparation for sleep
 - Avoiding caffeine-containing beverages or foods in afternoon or evenings
- Encourage stress management and coping strategies.
- Participation in educational programs (e.g., cognitive-behavioral therapy):
 - Improvement is often sustained for months.

PEARLS AND PITFALLS

As fibromyalgia patients can develop acute symptoms, distinguishing between acute and chronic pain is critical.

ICD10

M79.7 Fibromyalgia

FLAIL CHEST

Stephen L. Thornton

BASICS

DESCRIPTION

- Free-floating segment of chest wall:
 - 3 or more adjacent ribs are fractured in 2 or more places.
 - Rib fractures in conjunction with sternal fractures or costochondral separations
- The free-floating segment of chest wall paradoxically moves inward during inspiration and outward during expiration.
- The principal pathology associated with flail chest is the *associated pulmonary contusion*:
 - There is no alteration in ventilatory mechanics owing to the free-floating segment.

ETIOLOGY

- Blunt thoracic trauma
- Fall from a height
- Motor vehicle accident
- Assault
- Missile injury
- Ribs usually break at the point of impact or posterior angle:
 - Ribs 4–9 most prone to fracture.
 - Weakest point of ribs is 60° rotation from sternum.
- Transfer of kinetic energy to the lung parenchyma adjacent to the injury:
 - Disruption of the alveolocapillary membrane and development of pulmonary contusion
 - Arteriovenous shunting
 - Ventilation/perfusion mismatch
 - Hypoxemia
 - Respiratory failure may result.

Pediatric Considerations

- Relatively elastic chest wall makes rib fractures less common in children.
- Presence of rib fractures implies much higher energy absorption.

Geriatric Considerations

Much more susceptible to rib fractures:

- Described with low-energy mechanisms

- Complicated by osteoporosis

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Blunt thoracic trauma by any mechanism
- Mechanism as described by patient, parent, or pre-hospital personnel:
 - Seat belt usage
 - Steering wheel damage
 - Air bag deployment
- Localized chest wall pain increases with deep inspiration, coughing, moving
- Pleuritic chest pain
- Dyspnea
- Hemoptysis

Physical-Exam

- Flail chest paradoxically moves inward during inspiration and outward during expiration:
 - Can be missed due to muscle spasm and splinting respirations.
 - Inspection under tangential light may be useful.
- Multiple rib fractures:
 - Bony step-offs
 - Ecchymosis
 - Crepitus
 - Edema
 - Erythema and tenderness associated with:
 - Splinting respirations
 - Intercostal muscle spasm
 - Dyspnea, tachypnea
 - Onset may be insidious, increasing over time.
- Cyanosis, tachycardia, hypotension
- Auscultation with initially normal breath sounds progressing to wet rales or absent breath sounds

ESSENTIAL WORKUP

Diagnosis is initially made on clinical grounds and then supported by radiographs.

DIAGNOSIS TESTS & INTERPRETATION

Lab

Arterial blood gas analysis:

- May reveal hypoxemia
- Elevated alveolar–arterial gradient

Imaging

- Chest radiograph aids diagnosis and prognosis:
 - _ May reveal associated intrathoracic pathology:
 - Pneumothorax
 - Hemothorax
 - Pneumomediastinum
 - Pulmonary contusion
 - Widened mediastinal silhouette
 - _ Pulmonary contusion appears within 6–12 hr after injury:
 - Ranges from patchy alveolar infiltrates to frank consolidation
- Thoracic CT is useful in detecting associated intrathoracic injuries not identified on chest radiograph:
 - _ Thoracic CT found to show on average of 3 additional rib fractures compared with plain chest radiographs.

DIFFERENTIAL DIAGNOSIS

- Chest wall contusion or intercostal muscle strain
- Costochondral separation
- Sternal fracture and dislocation
- Radiographic differential diagnosis includes:
 - _ ARDS
 - _ Pulmonary laceration, infarction, or embolism
 - _ CHF
 - _ Pneumonia, abscess, other infectious processes
 - _ Noncardiogenic causes of pulmonary edema

TREATMENT

PRE HOSPITAL

- Positioning the patient with the injured side down can stabilize the involved chest wall:
 - _ Improve ventilation in noninjured hemithorax.
- Thoracic trauma with significant mechanism or combined with pre-existing pulmonary disease should be routed to the nearest trauma center.

INITIAL STABILIZATION/THERAPY

- Manage airway and resuscitate as indicated.
- IV line, O₂, continuous cardiac monitoring, and pulse oximetry

- Control airway:
 - Endotracheal intubation
 - Indicated for patients with severe hypoxemia ($\text{PaO}_2 < 60$ mm Hg on room air, < 80 mm Hg on 100% O_2)
 - Significant underlying lung disease
 - Impending respiratory failure

ED TREATMENT/PROCEDURES

- Maintain adequate oxygenation and ventilation.
- Monitor O_2 saturation and respiratory rate.
- In conscious and alert patients, O_2 administration via face mask is first-line therapy.
- If patient cannot maintain a $\text{PaO}_2 > 80$ mm Hg on high-flow oxygen, consider continuous positive airway pressure via mask or nasal bilevel positive airway pressure.
- Consider early endotracheal intubation and mechanical ventilation if the above fails:
 - Physiologic internal fixation of the flail segment
- External fixation or stabilization of the flail segment is not indicated.
- Adequate pain control is critical to maintaining adequate pulmonary function:
 - Avoid splinting, atelectasis, and pneumonia.
- Search for associated injuries and treat exacerbation of underlying lung disease.
- Intercostal nerve blocks with 0.5% bupivacaine are safe and effective when performed properly:
 - Provides 6–12 hr of pain relief
 - Perform intercostal nerve block posteriorly 2–3 fingerbreadths from the vertebral midline.
 - Inject 0.5–1 mL just under the inferior surface of the rib where the neurovascular bundle is located.
 - Aspirate 1st to be certain that the intercostal vessels have not been punctured.
- Prophylactic antibiotics are not indicated.

ALERT

Avoid overhydration:

- In the setting of pulmonary contusion, the need for IV crystalloid resuscitation must be weighed against the risk of increasing interstitial pulmonary edema.

MEDICATION

- Multiple acetaminophen/opioid analgesic combinations are available; see the alert below.
- Acetaminophen: 300 mg/codeine 30 mg (peds: 0.5–1 mg/kg codeine) PO q4–6h

- Acetaminophen: 500 mg/hydrocodone 5 mg PO q4–6h
- Acetaminophen: 750 mg/hydrocodone 7.5 mg PO q4–6h
- Acetaminophen: 325 mg/hydrocodone 10 mg PO q4–6h
- Acetaminophen: 325 mg/oxycodone 5 mg PO q6h
- Bupivacaine: 0.5% 0.5–1 mL per injection for intercostal nerve blocks
- Hydromorphone: 2–8 mg (peds: 0.03–0.08 mg/kg) PO q4–6h
- Hydromorphone: 1–4 mg (peds: 0.015 mg/kg) IV/IM/SC q4–6h
- Morphine sulfate: 0.05–0.1 mg/kg IV/IM/SC q2–6h
- Patient-controlled analgesia using fentanyl, hydromorphone, or morphine sulfate is effective.

ALERT

- Consider thoracic epidural analgesia for patients with intractable pain, oversedation, or hypoventilation secondary to opioid analgesics.
- NSAIDs discouraged due to the risk of GI bleeding.
- The dose of acetaminophen/opioid analgesic combinations is limited by the hepatic toxicity of acetaminophen.
- The max. acetaminophen dose is 1 g per dose and 4 g/d (peds: 15 mg/kg per dose, do not exceed 5 doses/24 hr)

FOLLOW-UP

DISPOSITION

Admission Criteria

All patients with flail chest should be admitted to critical care setting for close monitoring and adequate pain control.

Discharge Criteria

Patients found to have flail chest, with or without pulmonary contusion, should not be discharged.

PEARLS AND PITFALLS

- Early pain control is key.
- Beware of concomitant injuries such as pulmonary contusion and pneumothorax.
- Elderly patients have significantly poorer outcomes.

FOOT FRACTURE

Stephen R. Hayden

BASICS

DESCRIPTION

Injury to tarsal bones or metatarsals including calcaneus, talus, navicular, cuboid, cuneiform, and metatarsals

ETIOLOGY

- Most common foot injuries are of the metatarsals and phalanges.
- The calcaneus is the most commonly fractured of the tarsal bones.
- Calcaneus fractures: Compression injury from sudden high-velocity impact to heel:
 - 75% are intra-articular; 50% have associated injuries:
 - 10% spine fractures
 - 25% with associated lower extremity trauma
 - 9% bilateral, 5% open
- Metatarsal fractures: Divided into stress fractures, twisting injuries, or direct trauma:
 - 1st metatarsal: Direct applied force
 - 2nd and 3rd metatarsals are most often involved in stress fractures and twisting injuries.
 - 5th metatarsal: Avulsion fracture (dancer's fracture) of proximal apophysis is the most common injury.
 - Jones fracture: Transverse fracture of the metaphyseal–diaphyseal junction of 5th metatarsal; results from twisting while foot inverted.
- Talus: Caused by dorsiflexion with axial load, common snowboarder's injury
- Navicular: Results from axial compression or stress fractures
- Cuboid and cuneiform fractures are rare and occur in conjunction with other injuries, often with tarsal–metatarsal injuries.
- Tarsal–metatarsal injuries (Lisfranc injuries) are high-energy injuries:
 - Axial load on plantar-flexed foot, or hindfoot fixed with forced foot eversion
 - Unstable forefoot on hindfoot
 - 20% go undiagnosed on initial visit.
 - 3 types: Convergent, divergent, and incongruent

Pediatric Considerations

- Metatarsal fractures account for 90% of foot fractures in children, usually from direct trauma:
 - Lesser metatarsal fractures (2–4) most common followed by base of 5th then base of 1st metatarsal.

- Physeal injury may occur with proximal 1st metatarsal fractures.
- Other common injuries include phalangeal fractures (17%) and navicular fractures (5%).
- Fractures of talus or calcaneus occur with distal tibia or fibula fractures (8%).
- Calcaneus fractures are less likely intra-articular. Less common to have associated spine fractures.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- History of preceding trauma most common
- Stress fractures may present with increasing pain in the setting of repetitive activities.

Physical-Exam

- Ecchymosis, pain, swelling, or deformity of foot
- Pain with weight bearing
- Joint instability

ESSENTIAL WORKUP

- Physical exam of extremity is necessary to assess neurovascular status, skin integrity, gross swelling, deformity, or loss of function.
- Exam of spine is also essential in suspected calcaneus fractures, as there is a 10% incidence of coexistent injury.
- Anteroposterior/lateral and oblique views are necessary for all foot fractures.
- Complications:
 - Compartment syndrome most commonly presents as severe pain in a swollen foot:
 - Pressures > 35 mm Hg require opening of all major foot compartments.
 - May have hypesthesia of plantar foot
 - Weak toe flexion
 - Late findings include claw toe deformity.
 - Nonunion and avascular necrosis are common complications with talar neck fractures owing to distal blood supply.
 - Calcaneus fractures may be accompanied by sural nerve injury; test sensation along lateral aspect of foot.

DIAGNOSIS TESTS & INTERPRETATION

Imaging

Special views may be needed for some fractures:

- Lisfranc fractures may require stress views with weight bearing. They may require MRI to evaluate ligamentous stability. May require CT for evaluation of small fractures if clinically suspicious
- Fleck sign: Pathognomonic—avulsion of ligament from 2 MT base or medial cuneiform
- Talar fractures may require a 45° internal oblique view. May require CT.
- Midfoot fractures may require an external oblique foot view.
- Calcaneus fractures require an axial view and may require CT:
 - Bohler's angle $< 20^\circ$ suggests a compression fracture of calcaneus.
 - Lumbosacral spine films are necessary in all patients with calcaneus fractures.
- Stress fractures may require 2 wk to appear on plain films; bone scan or CT may be used to elucidate suspected fractures.

DIFFERENTIAL DIAGNOSIS

- Anterior effects of calcaneus and talar dome fractures can be misdiagnosed as ankle sprains.
- Foot contusions
- Freiberg disease: Osteochondrosis of 2nd metatarsal head may be mistaken for stress fracture.

TREATMENT

PRE HOSPITAL

- Ice bag should be placed on affected foot and foot and ankle immobilized.
- All patients suspected of calcaneus fracture should have spinal immobilization; often, mechanism is fall from height > 6 ft.

INITIAL STABILIZATION/THERAPY

Manage coexisting trauma as indicated.

ED TREATMENT/PROCEDURES

- Airway, breathing, and circulation management
- Assess for neurovascular compromise distal to fracture site.
- Dislocations must be reduced as quickly as possible with assessment of neurovascular status before and after procedure:
 - Procedural sedation usually required
- Immobilize, ice, and elevate in a bulky splint:
 - Application of circumferential cast should be delayed until swelling subsides.
- Crutches

- Pain management:
 - If large amount of swelling and pain with toe movement, suspect compartment syndrome.
 - Ultrasound-guided regional anesthesia may be used for reduction
- Orthopedic consult indicated early for displaced fractures:
 - Many injuries require repair within 6 hr of injury to prevent delay of open reduction with internal fixation for 6–10 days owing to swelling.

MEDICATION

- Cefazolin: 1 g IV/IM (peds: 25 mg/kg IV/IM)
- Diprivan: 40 mg IV q10s until sedation
- Etomidate: 0.1–0.2 mg/kg IV
- Fentanyl: 50–250 µg IV titrated (peds: 2 µg/kg IV)
- Hydromorphone 0.5–2 mg IV q2h (peds: 0.15 mg/kg IV q4–6h)
- Ibuprofen: 800 mg PO (peds: 10 mg/kg PO)
- Meperidine: 25–100 mg IV/IM titrated (peds: 1–1.75 mg/kg IV/IM)
- Methohexital: 1–1.5 mg/kg IV
- Morphine: 2–10 mg IV/IM titrated (peds: 0.1 mg/kg IV)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Open fracture
- Evidence of compartment syndrome or neurovascular injury
- Open reduction internal fixation required immediately

Discharge Criteria

Most patients with metatarsal fractures can be discharged with orthopedic follow-up.

Issues for Referral

All open fractures, as well as all midfoot/Lisfranc injuries and displaced fractures that are not successfully reduced, should be seen in ED by an orthopedic specialist.

FOREARM FRACTURE, SHAFT/DISTAL

Stephen R. Hayden

BASICS

DESCRIPTION

- Forearm shaft fractures (single or paired) are often displaced by contraction of arm muscles; sometimes associated with concurrent dislocations:
 - *Galeazzi* fracture:
 - Distal radius fracture with distal radioulnar dislocation
 - *Monteggia* fracture:
 - Proximal ulnar fracture with dislocation of radial head
- Distal fractures include extension, flexion, and intra-articular classifications:
 - *Colles* fracture:
 - Hyperextension fracture of distal radius
 - Distal fragment displaced dorsally
 - Radial deviation
 - Often involves ulnar styloid and distal radioulnar joint
 - *Smith* fracture:
 - Hyperflexion fracture of distal radius
 - Distal fragment displaced volarly
 - *Barton* fracture:
 - Intra-articular fracture of dorsal rim of distal radius
 - Often associated with dislocation of carpal bones
 - *Hutchinson* fracture:
 - Intra-articular fracture of radial styloid

Pediatric Considerations

- Shaft fractures:
 - *Torus* fracture:
 - Compression (buckling) of cortex on 1 or both sides
 - *Greenstick* fracture:
 - Distraction of 1 side of cortex with opposite side intact
 - Plastic deformity:
 - Bowing of radius or ulna without apparent disruption of cortex
 - Multiple microfractures
- Distal fractures:
 - *Salter–Harris* type fractures (see Salter–Harris classification)

ETIOLOGY

- Direct blow to forearm

- Longitudinal compression load:
 - _ Fall on outstretched hand (FOOSH)
 - _ Horizontal force
- Excessive pronation, supination, hyperextension, or hyperflexion

DIAGNOSIS

SIGNS AND SYMPTOMS

- Deformity
- Pain, edema, erythema

History

- Associated events and concurrent injuries
- Past history of bone disease or old fractures
- History of repetitive stress of forearm movement
- Occupation
- Hand dominance

Physical-Exam

- Physical exam with special attention to skin integrity, deformity, and neurovascular status
- Forearm pain, crepitus, tenderness to palpation, deformity, shortening of forearm
- Forearm edema, ecchymosis, elbow or wrist joint effusions
- Abnormal mobility or loss of function at elbow/wrist/hand
- Neurologic abnormalities
- Vascular compromise

ALERT

Impending compartment syndrome

ESSENTIAL WORKUP

Suspected forearm fractures require anteroposterior (AP) and lateral radiographs, including joint above and joint below injury: Hand, wrist, and elbow.

DIAGNOSIS TESTS & INTERPRETATION

Lab

Preoperative labs as warranted

Imaging

Some intra-articular fractures may require CT imaging.

Diagnostic Procedures/Surgery

Compartment pressures should be measured for suspected compartment syndrome.

DIFFERENTIAL DIAGNOSIS

- Upper extremity muscle, ligamentous injury
- Elbow or wrist dislocations, including pediatric nursemaid's elbow
- Forearm contusions, hematomas
- Cellulitis, abscesses, soft tissue masses
- Forearm osteogenic tumors
- Osteomyelitis
- Upper extremity vascular or neurologic injuries
- Elbow or wrist arthritis, joint effusions
- Pediatric growth plates, nutrient vessels may be mistaken for fractures

TREATMENT

PRE HOSPITAL

- All suspected forearm fractures should be elevated, splinted, and immobilized, including elbow and wrist joints.
- All open fractures should be wrapped with sterile dressing before immobilization:
 - Do not reduce open fractures back under skin in the field.
 - In patients with isolated extremity trauma, analgesia may be administered.

ED TREATMENT/PROCEDURES

- Shaft fractures, nondisplaced:
 - Long-arm splint
 - Orthopedic referral
- Shaft fractures, displaced:
 - Orthopedic consultation
 - Often require open reduction, internal fixation
- Distal fractures, nondisplaced:
 - Forearm sugar-tong or AP splint
 - Orthopedic referral
- Distal fractures: *Colles/Smith*:
 - Simple, noncomminuted, extra-articular Colles and Smith fractures may be reduced in ED:
 - Splint (long-arm sugar-tong splint)
 - Sling
 - Referred to orthopedics
 - Complicated Colles and Smith fractures require orthopedic consultation.
- Distal fractures: *Barton/Hutchinson*:
 - Uncomplicated Barton and Hutchinson fractures

- Splint (AP or sugar-tong splint)
- Place in sling
- Referred to orthopedics
- Complicated fractures require orthopedic consultation.
- Open fractures:
 - Cover with sterile dressings.
 - IM/IV antibiotics
 - Tetanus immunization (if indicated)
 - Splint
 - Immediate orthopedic consultation
- Forearm fractures associated with compartment syndrome or neurovascular compromise require immediate orthopedic consultation.

Pediatric Considerations

- *Torus* and *Greenstick* fractures with $< 10^\circ$ of angulation may be treated with long-arm splint, sling, and orthopedic referral.
- *Plastic deformities* require orthopedic consultation:
 - Some minimally displaced plastic deformities may be placed in long-arm splint and sling.
- *Salter–Harris* type fractures require orthopedic consultation.

MEDICATION

- Acetaminophen: 325–1,000 mg PO q4h (peds: 10–15 mg/kg q4h PO)
- Antibiotics:
 - Open fractures require IM/IV antibiotics.
 - Cefazolin: 1–2 g IM/IV or equivalent 1st-generation cephalosporin; if contaminated, add an aminoglycoside
- Codeine: 15–60 mg PO/IM q4h (peds: > 2 yr, 0.5–1 mg/kg q4h PO/IM)
- Hydrocodone: 5–10 mg PO q4h
- Ibuprofen: 200–800 mg q4–8h (peds: > 6 mo, 5–10 mg/kg per dose q6h)
- Morphine sulfate: 2–10 mg IV/IM; titrate to pain (peds: 0.1 mg/kg per dose IV/IM)
- Tetanus: 0.5 mL IM every 10 yr

FOLLOW-UP

DISPOSITION

Admission Criteria

- Open fractures
- Fractures with compartment syndrome or neurovascular compromise
- Fractures needing immediate operative management or general anesthesia for

reduction

- Suspected nonaccidental trauma

Discharge Criteria

- Appropriate reduction and immobilization
- Arranged orthopedic follow-up
- Adequate pain control measures
- Cast/splint care discharge instructions provided and understood by patient
- Documentation of intact neurovascular function after ED treatment

Issues for Referral

All fractures (or suspected fractures) discharged from ED should be referred to orthopedic surgeon for close follow-up.

FOLLOW-UP RECOMMENDATIONS

All patients should be referred to an orthopedic surgeon or hand surgeon.

PEARLS AND PITFALLS

- Missed 2nd fracture
- Missed concurrent dislocation or subluxation
- Impending compartment syndrome

FOREIGN BODY, EAR

Kathleen Nasci • Charles V. Pollack, Jr.

BASICS

DESCRIPTION

- Foreign bodies (FBs) lodged in the external auditory canal
- The external auditory canal:
 - Cartilaginous and bony passage lined with periosteum and skin
 - The periosteum is extremely sensitive, making removal a painful procedure:
 - In small children general anesthesia may be required to remove the object
 - FBs usually impact at the junction of the inner end of the cartilaginous portion of the canal or at the isthmus
 - Innervated by the facial, glossopharyngeal, vagus nerves
- Inanimate foreign objects are often associated with delayed presentations:
 - Children often delay reporting because of fear of punishment
 - Often the FB is an incidental finding in children during an ear exam
- Physical findings may change due to length of time the object is in the canal
- Children with cerumen impaction or those with pica are predisposed
- The location is often the right ear, due to the predominance of right handedness
- Children and psychiatric patients may insert anything sufficiently small to enter the external auditory canal.
- Ear FBs are most common in children < 8 yr
- Complications:
 - Canal laceration:
 - Usually caused by repeated attempts to remove a nongraspable object
 - Perforation of tympanic membrane:
 - More likely to result from removal procedure than the FB
 - Otitis externa
 - Malocclusion from erosion into the temporomandibular joint
 - Parapharyngeal abscess
 - Mastoiditis
 - Meningitis
 - Brain abscess
 - Insects may injure the tympanic membrane or canal by stinging, biting, or scratching
 - Button batteries can cause significant destruction due to the strong electrical currents and pressure necrosis
 - Typically, the most damage is caused by negative side of the battery
 - Damage to the facial nerve and ossicles have been reported

- Symptoms usually resolve within a few days after FB removal

ETIOLOGY

- Children:
 - Stones
 - Small beads
 - Paper
 - Toys
 - Seeds and popcorn kernels
 - Beans and other food and organic materials
 - Button batteries:
 - Higher risk for necrosis than other FBs
- Competent adults:
 - Cotton-swab tips
 - Earplugs
 - Insects:
 - Cockroach most common in US
 - Hidden illicit drugs

DIAGNOSIS

SIGNS AND SYMPTOMS

- Decreased hearing
- Excessive crying in infants
- Unilateral ear pain
- Fullness
- Loud noises
- Buzzing sound (with live insects)
- Nausea
- Dizziness
- Ipsilateral tearing
- Purulent discharge from the external ear
- Itching
- Bleeding

History

- Travel or camping history or poor living conditions suggests insects in the external ear canal
- Inquire about previous attempts to remove the FB and any trauma associated with these attempts

Physical-Exam

Otoscopic exam should be performed before and after removal of the FB:

- Identify type of FB to determine removal procedure:
 - Button battery
 - Live insect
 - Vegetable
 - Inanimate object
 - Size
 - Risk of swelling when exposed to water
- Perform a bilateral exam; especially important in children and psychiatric patients, and prevent overlooking a quiescent FB in the contralateral ear
- Attempt to visualize tympanic membrane to assess for rupture
- Assess for otitis externa
- Assess for retained fragments after the removal
- Always exam the nonaffected ear and nostrils for additional FBs
- Significant pain, vertigo, or ataxia, nystagmus, hearing loss, otorrhea, or facial nerve paralysis are concerning signs and an otolaryngologist consultation should be considered

ESSENTIAL WORKUP

Careful otoscopic exam:

- Minimize pain
- Gain the patient's trust
- Identify the FB before attempting removal

DIAGNOSIS TESTS & INTERPRETATION

Lab

None indicated

Imaging

CT scan if infectious or erosive sequelae are suspected

Diagnostic Procedures/Surgery

Otomicroscope:

- May be used when standard ED techniques fail or the equipment is available to emergency medical staff

DIFFERENTIAL DIAGNOSIS

- Cerumen impaction
- Granuloma
- Hematoma
- Injury
- Otitis externa

- Perforated tympanic membrane
- Residual otitis externa after self-extraction of the FB
- Tumor

TREATMENT

PRE HOSPITAL

- Cautions:
 - _ Severe ear pain, sensation of movement, and loud, buzzing sound:
 - Typical signs of a live insect in external auditory canal
 - Instill warm lidocaine or mineral oil into affected ear to kill insect
- Controversies:
 - _ Attempts at removal in the field are not indicated:
 - Lack of appropriate equipment
 - Prior failed attempts may make future attempts more difficult

INITIAL STABILIZATION/THERAPY

For a patient in distress because of a live insect:

- Drown or immobilize insect before any removal attempts
- Instill warm solution into the external auditory canal:
 - _ 2% lidocaine solution
 - _ Ether
 - _ Alcohol
 - _ Mineral oil
- Cold fluids should not be used so as to avoid a caloric response

ED TREATMENT/PROCEDURES

- Prepare the equipment and the patient:
 - _ Strong light source
 - _ Otoscope or operating microscope
 - _ Achieve proper head immobilization
 - _ Retract the pinna of the ear in a posterosuperior direction to straighten the canal
- Analgesia:
 - _ Lidocaine instillation for topical anesthesia:
 - Liquid 1–2% solution is preferred to viscous lidocaine.
 - Lidocaine injection of the 4 quadrants of the canal using a tuberculin syringe through the otoscope
 - 1–2% lidocaine, with or without epinephrine
- Procedural sedation:
 - _ Indicated for children and uncooperative adults
 - _ Use before attempts, as unsuccessful efforts may produce bleeding, edema,

- or injury to the tympanic membrane
- Ketamine for children
- Benzodiazepines for older patients
- Consider fentanyl if analgesia is indicated during removal
- Options for removal:
 - Water irrigation:
 - Perform careful visualization
 - Place an Angiocath catheter adjacent to, or preferably distal to, the FB
 - Inject warm water or sterile saline through catheter via a syringe
 - Backwash the FB out
 - Never attempt removal by irrigation when the FB is a button battery
 - Use of instruments to dislodge the FB:
 - Alligator forceps removal
 - Cupped forceps: Numbers 3, 5, and 7 suction tips, preferably with Frazier suction cups
 - Cerumen loops
 - Right-angle blunt hooks
 - Suction catheters:
 - Best used for small objects
 - Fogarty catheter:
 - Carefully pass beyond the FB and inflate and withdraw; this approach puts the tympanic membrane at particular risk of inadvertent injury
 - Cyanoacrylate glue on the tip of a blunt probe:
 - Place on the FB for 10 sec, and then pull
 - May contaminate the ear with glue, and this technique has been associated with tympanic membrane rupture
 - Acetone:
 - Used to dissolve Styrofoam FBs or loosen superglue
 - Otomicroscopy:
 - Usually performed in the OR although reports of use in the ED have been positive
- Vegetable matter:
 - Avoid irrigation of FBs that will swell when exposed to water
 - Attempt removal with instrument
 - Forceps usually work with graspable objects
 - Be certain to delineate clearly between FB and inflamed external auditory canal tissue
- Nonvegetable inanimate FB removal:
 - If easily grasped, attempt removal with forceps
 - If not accessible, attempt removal with irrigation
- Polished or smooth object extraction:
 - Visualize

- Direct suction
- Blunt right-angled probe: Pass beyond the FB; rotate 90°; remove it with the FB
- Fogarty catheter
- Cyanoacrylate glue
- Insect removal:
 - Kill insect by rapidly instilling alcohol, 2% lidocaine (Xylocaine), or mineral oil into the ear
 - Once killed, remove with forceps or by irrigation
 - Re-examine to ensure that all insect parts are removed
- Sharp objects:
 - Remove with operating microscope
 - Consider otolaryngologic referral if there is evidence of trauma or if patient is uncooperative

MEDICATION

First Line

- Fentanyl: 1 µg/kg IV
- Ketamine: 1–2 mg/kg IV or 4 mg/kg IM
- Midazolam: 1 mg IV slowly q2–3min up to 5 mg (peds: 6 mo–5 yr, 0.05–0.1 mg/kg, titrate to max. of 0.6 mg/kg; 6–12 yr, 0.025–0.05 mg/kg, titrate to max. of 0.4 mg/kg)

Second Line

- Cortisporin otic: 4 gtt in ear QID
- Amoxicillin: 500 mg PO (peds: 80–90 mg/kg/24 h) PO TID for 7–10 days.
- Augmentin: 875 mg (peds: 90 mg/kg/24 h) PO BID for 7–10 days.
- Fill ear canal 5× per day with a combination of antibiotic and steroid otic solution for 5–7 days if there is suspected infection or abrasion

FOLLOW-UP

DISPOSITION

Admission Criteria

Hospital admission if the FB is a button battery that cannot be removed

Discharge Criteria

- FB removed
- Inability to remove a FB that will not cause rapid tissue necrosis
- Oral antibiotics (amoxicillin or Augmentin) should be initiated in cases with

tympanic membrane perforation

Issues for Referral

Follow-up with ENT specialist as an outpatient:

- Inability to remove a FB
- Immunocompromised patients with signs of otitis externa

FOLLOW-UP RECOMMENDATIONS

- Patient should be instructed not to place any objects in ear
- A short course of analgesics after traumatic FB removal
- Otitis externa:
 - Topical antimicrobial such as Cortisporin suspension
- Immunocompromised patients may require oral antibiotics
- Perforated tympanic membrane:
 - Prophylaxis with antibiotics
 - Follow-up with ENT specialist
- Avoid submersion in water until follow-up if trauma or infection present

PEARLS AND PITFALLS

- Use procedural sedation with uncooperative patients or when a difficult removal is anticipated
- Irrigation in patients with button batteries in the ear should never be performed as the electrical current or battery contents can cause liquefaction tissue necrosis.

FOREIGN BODY, ESOPHAGEAL

Joanna W. Davidson

BASICS

DESCRIPTION

- Esophageal foreign bodies (FBs) typically lodge at 3 sites of physiologic constriction:
 - Cricopharyngeal muscle—63%, most common (C6)
 - Gastroesophageal junction—20% (T11)
 - Aortic arch—10% (T4)
- 90% of ingested FBs pass spontaneously.
- 10–20% are removed endoscopically, and 1% or less require surgery.

ETIOLOGY

- Most common adult and adolescent FBs are food boluses and bones
- Increased risk:
 - Edentulous adults
 - Intoxicated patients
 - Patients with underlying esophageal disease: Schatzki B-rings or peptic strictures are most common

Pediatric Considerations

- 80% of FB ingestions occur in pediatric age group, peak ages 6 mo–6 yr, particularly younger than 2 yr.
- Coins are most common:
 - Most common: 80% of esophageal FBs
- 2 additional areas of constriction: Thoracic inlet (T1) and tracheal bifurcation (T6)

DIAGNOSIS

SIGNS AND SYMPTOMS

- Acute ingestion:
 - Dysphagia
 - Odynophagia
 - Drooling
 - Retching/self-induced vomiting
 - Choking
 - Gagging
 - Blood-stained saliva
- Chronically retained FB:

- Respiratory symptoms predominate (paraesophageal tissue swelling compromises adjacent trachea):
 - Cough
 - Stridor
 - Hoarseness
- Chest pain
- Site of FB sensation usually corresponds to esophageal level of FB
- Esophageal perforation
- 15–35% if ingest sharp object:
 - Redness
 - Swelling
 - Crepitus in the neck
 - Peritonitis
- <20% asymptomatic

Pediatric Considerations

Signs/symptoms:

- Refusal to eat
- Stridor
- Upper respiratory tract infection
- Neck/throat pain

History

- Adults:
 - Usually provide unequivocal history
 - 80% present within 1st 24 hr
 - 5% will present with airway obstruction (cafe coronary)
- Children:
 - 50% asymptomatic
 - History can be unclear if unwitnessed ingestion is not witnessed
 - Drooling, refusal to eat, unexplained gagging, cough, wheeze, choking
 - More likely than adults to have respiratory symptoms

ESSENTIAL WORKUP

- History about object ingested: Type, when, and how
- Physical exam focused by degree of distress exhibited:
 - Esophagus:
 - Obstruction—saliva pooling, aspiration
 - Perforation—crepitus, pain, pleurisy
 - Hemorrhage
 - Oropharynx:
 - Red, irritated throat
 - Palatal abrasions

- Lung:
 - Stridor and wheezing
- Abdomen:
 - Peritonitis or bowel obstruction

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- Biplane chest radiograph including all of neck for FB localization:
 - Food boluses usually do not need radiographs.
 - Esophageal FBs often align themselves in coronal plane.
 - Esophageal perforation is noted by air in retropharyngeal space, in soft tissues of neck, or by pneumomediastinum.
- Ingested, impacted bones visible on plain film < 50%
- CT scan replacing esophageal contrast studies for nonradiopaque FBs:
 - Radiolucent objects include small pieces of glass, bone fragments, aluminum, plastic, pieces of wood
 - Visualizes perforation or infection
- Endoscopy is a method of choice for localizing and managing most esophageal FBs
 - Ability to inspect surrounding esophageal mucosa for pathology
 - Diagnostic and therapeutic

DIFFERENTIAL DIAGNOSIS

- Globus hystericus phenomenon (“lump in throat”)
- Esophageal mucosal irritation
- Esophagitis
- Croup
- Epiglottitis
- Upper respiratory tract infection
- Retropharyngeal abscess

TREATMENT

PRE HOSPITAL

Cautions:

- Airway maintenance and prevention of aspiration paramount
- Oxygen for patients in distress
- Place patient in whatever position gives most comfort.
- Ipecac and cathartics contraindicated

INITIAL STABILIZATION/THERAPY

- Airway, breathing, and circulation management 1st priority

- Prevent aspiration

ED TREATMENT/PROCEDURES

- Direct laryngoscopy or fiberoptic scope may allow removal of very proximal objects
- Urgent endoscopy recommended:
 - Ingestion of sharp or elongated objects
 - > 6 cm long
 - > 2.5 cm
 - Irregular/sharp edges (toothpicks, soda can tabs)
 - Ingestion of multiple FBs; especially magnets
 - Evidence of perforation
 - Coin at level of cricopharyngeus muscle in a child
 - Airway compromise
 - Presence of FB for > 24 hr
 - Food bolus with complete obstruction
 - Observation can be considered
 - Asymptomatic patients with coins or smooth objects (not button batteries) in distal esophagus:
 - Observe up to 24 hr after ingestion to see whether it will pass into stomach.
 - Objects that reach stomach and are shorter than 5 cm and < 2 cm in diameter usually pass through GI tract without difficulty, but daily radiographs are still recommended.
 - Danger of perforation increases after 24 hr.
 - Removal options:
 - IV glucagon:
 - Decreases lower esophageal sphincter tone without interfering with esophageal contractions
 - Falling out of favor for endoscopy
 - Less effective if underlying Schatzki ring or stricture
 - Permits distal food boluses to pass into the stomach
 - For impactions < 24 hr duration
 - Fluoroscopically guided Foley catheter extraction:
 - Successful and safe in experienced hands
 - Foley catheter (10F–16F) placed nasally, passed into esophagus, tip and balloon pushed beyond FB under fluoroscopic control
 - Foley balloon inflated with contrast and catheter slowly withdrawn
 - Contraindicated in chronic ingestions, uncooperative patients, sharp-pointed objects
 - Foley catheters or dilator (bougienage) may also be used to

push distal FB into stomach

- Endoscopy:
 - Preferred method to remove acute or chronic FBs
 - 98% effective
 - Always used with impactions of long duration (>2–4 days) because of associated esophageal irritation/edema
 - General endotracheal anesthesia needed in difficult cases: Infants, psychiatric patients, difficult FB
 - Risk of complications increases after 24 hr, ideal to be done within 6–12 hr
- Surgical intervention:
 - Reserved for patients in whom FB cannot be removed by other methods
 - ~1–2% of all patients
 - Toothpicks and bones common objects
- Specific ingestions
 - Impacted food bolus obstructing esophagus:
 - Emergent removal indicated
 - Proteolytic enzymes (papain) not recommended because of esophageal perforation, hypernatremia, and aspiration complications
- Button batteries:
 - Extract emergently
 - Batteries frequently leak: Potassium hydroxide and mercuric oxide are the most toxic constituents.
 - Alkali produced from external flow of current can cause liquefaction necrosis.
 - Full-thickness mucosal burns can occur within 4–6 hr (combination of chemical, electrical, pressure injuries).
 - Battery in stomach will usually pass without difficulty; batteries remaining in stomach for >3–4 days should be removed.
 - Once past duodenal sweep, 85% are passed within 72 hr.
- Narcotic/amphetamine packets:
 - Body packing seen in regions of high drug traffic
 - Packets usually seen on radiographs
 - Rupture or leakage of contents can be fatal.
- Magnets/“Bucky Balls”:
 - Opposing magnets attract bringing sections of stomach/bowel together creating obstruction
 - Early GI consult for removal vs. laparotomy

MEDICATION

Glucagon: 1–2 mg IV push after test dose to determine hypersensitivity

DISPOSITION

Admission Criteria

- Seriously ill patients and those with complications such as esophageal perforation, migration of FB through esophageal wall, significant bleeding
- Airway compromise
- Symptomatic patients in whom attempts to remove FB are unsuccessful

Discharge Criteria

- Asymptomatic patients in whom FB has been removed or passed distal to esophagus
- Asymptomatic patients with distal esophageal smooth FBs need re-exam within 12–24 hr to ascertain whether spontaneous passage into stomach has occurred.

Issues for Referral

GI consult for sharp or pointed esophageal FBs, those obstructed in upper or mid esophagus and battery button FBs.

FOLLOW-UP RECOMMENDATIONS

GI referral for patients with suspected underlying etiology for esophageal obstruction

PEARLS AND PITFALLS

- Perform radiographs to locate radiopaque FBs.
- Maintain a high suspicion for esophageal perforation.

FOREIGN BODY, NASAL

Bradley E. Efune • David A. Pearson

BASICS

DESCRIPTION

- Object impacted in the nasal cavity
- Most common site of foreign body insertion in children
- Type of foreign body limited only by nostril size
- Population at risk:
 - Children between 2–6 yr most common
 - Mental retardation
 - Psychiatric illness
- Causes of worsening impaction and difficulties with removal:
 - Organic material may expand if moistened
 - Mucosal swelling over time
- Complications:
 - Sinusitis is the most common complication
 - Foreign bodies may migrate into the sinuses
 - Septal perforation
 - Bronchial aspiration
 - High risk of complications with button batteries:
 - Ischemic mucosa
 - Turbinate or septal damage
 - Saddle-nose deformity

ETIOLOGY

- Food
- Beans
- Seeds
- Beads
- Rocks
- Paper
- Pieces of toys
- Sponge pieces
- Vegetable matter
- Insects and live worms
- Button batteries:
 - High risk of complications compared with other foreign bodies (tissue necrosis, septal perforation, saddle nose); require rapid removal
- Magnets:

- Used to mimic nasal piercing
- Often imbedded in nasal tissue, leading to difficult removal
- May cause intestinal perforation if swallowed, especially newer high-powered neodymium magnets
- Glass fragments

DIAGNOSIS

SIGNS AND SYMPTOMS

- Most nasal foreign bodies are asymptomatic.
- Unilateral nasal obstruction
- Nasal pain
- Difficulties with nasal breathing
- Nasal discharge:
 - Acute or chronic
 - Unilateral
 - Foul smelling
 - Halitosis
- Sinus discomfort
- Persistent epistaxis
- Local inflammation
- Septal perforation
- Ingestion or aspiration of foreign body

History

- Child witnessed putting object into nose
- Foreign body noticed by parent or caretaker
- Many children are reluctant to admit to placing a foreign body for fear of adult disapproval
- Delayed presentation:
 - When placement of the object is unwitnessed, the child may present weeks after with nasal discharge and bleeding
 - Often misdiagnosed at this stage as sinusitis

ESSENTIAL WORKUP

Visualization of the foreign body in the nostril: Always check both nostrils

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- Fiberoptic visualization if foreign body cannot be visualized on rhinoscopy
- Sinus films if present for extended period:
 - Symptom persistence despite removal of the foreign body and antibiotics

- May need chest or abdomen films for aspiration/ingestion

DIFFERENTIAL DIAGNOSIS

- Sinusitis
- Swollen inferior turbinate:
 - May be mistaken for a pink bead
- Rhinitis
- Nasal polyp
- Benign tumors:
 - Hemangioma most common
- Malignant tumors:
 - Lymphoma
 - Rhabdomyosarcoma
 - Nasopharyngeal carcinoma
 - Esthesioneuroblastoma (also known as an olfactory neuroblastoma)
- Congenital masses:
 - Dermoid
 - Encephalocele
 - Glioma
 - Teratoma
- Retropharyngeal abscess
- Traumatic dislocation of nasal bones or septum
- Nasal deformity:
 - Usually associated with cleft palate
- Nasopharyngeal stenosis
- Rhinitis medicamentosa:
 - Rebound nasal mucosal edema caused by extended use of topical decongestants

TREATMENT

PRE HOSPITAL

- Cautions:
 - Transport in sitting position:
 - To avoid posterior displacement and possible aspiration of foreign body
- Avoid interventions that upset the child.
 - Forceful negative inspiration from crying may lead to aspiration

ED TREATMENT/PROCEDURES

- Topical vasoconstrictors:
 - Presence of mucosal edema, or bleeding secondary to removal attempts

- Nebulized epinephrine
- Cocaine: 4%
- Oxymetazoline: 0.05%
- Phenylephrine: 0.125–0.5%
- Positive pressure for children:
 - Occlude contralateral nostril
 - Upright sitting position if possible
 - Positive pressure applied to mouth only (best done by parents)
 - Deliver brisk puff as child begins to inhale
 - Parent may tell the child he or she will be given a “big kiss.”
 - Placement of 4 × 4 gauze pads on caregiver’s cheek
 - Foreign body dislodges onto cheek of the provider or into room
 - Repeated as necessary
 - Can use straw in older children to create pressure without mouth to mouth
 - Alternatively, deliver puff with a bag-mask over the mouth and O₂ at 10–15 L/min.
 - Alternatively, into contralateral nostril male–male adapter on oxygen tubing, deliver wall oxygen at 10–15 L/min.
 - Risk of barotrauma with sustained, unmodulated positive pressure
- Hooked probe, alligator forceps:
 - Anterior foreign bodies that are easily grasped
 - Headlamp, nasal speculum facilitate use
 - Risk of further posterior displacement
- Suction catheter:
 - Best for round, smooth objects
 - Optimal retrieval with suction catheter
 - Suction tip placed against the object
 - Suction turned up to 100–140 mm Hg
 - Catheter and object withdrawn
- Cyanoacrylate tissue glue:
 - Film of glue applied to cut end of hollow plastic swab handle
 - Apply against object for 60 sec, and then withdraw
 - Caution with nontissue cyanoacrylate glues; tissue irritation
- Balloon catheters:
 - Used primarily when instrumentation fails
 - 5F or 6F Foley or Fogarty balloon catheter lubricated with 2% lidocaine jelly
 - Advance catheter past object
 - Following inflation with 2–3 mL of air, gently withdraw catheter
- Magnet for removal of metal foreign body described; limited experience
- Snare technique:
 - 24G wire made into a loop with a hemostat

- Useful when size of object known
- Thin wire can slip through swollen tissue, behind object, allowing it to be pulled free

MEDICATION

- Cocaine: 4% solution, 2 drops affected nares
- Lidocaine: 4% solution, 2 drops affected nares
- Oxymetazoline: 0.05%, 2–3 drops/sprays affected nares
- Phenylephrine: 0.125–0.5%, 2–3 sprays affected nares
- Procedural sedation may be necessary

FOLLOW-UP

DISPOSITION

Admission Criteria

Referral for ambulatory surgical removal:

- Foreign body cannot be recovered in ED
- Removal under general anesthesia is required

Discharge Criteria

- Ensure that there is no airway compromise
- Return if bleeding, infection (nasal discharge)
- If a button battery was removed, monitor for delayed sequelae as outpatient:
 - Ischemic mucosa
 - Turbinate or septal damage
 - Saddle-nose deformity

Issues for Referral

- Follow up with otolaryngologist if:
 - Removal unsuccessful in ED
 - Concern for nasal mucosa injury

FOLLOW-UP RECOMMENDATIONS

- Return to the ED immediately if:
 - Coughing, wheezing, noisy, or difficult breathing
 - Vomiting, gagging, choking, drooling, neck or throat pain, or inability to swallow
- Parents should be instructed to seek medical care for the following:
 - Fever
 - Headache or facial pain
 - Persistent epistaxis

- Persistent drainage of nasal fluid

PEARLS AND PITFALLS

- Consider nasal foreign bodies in children 2–6 yr presenting with what appears to be sinusitis
- Parents are best suited to perform positive-pressure removal to avoid frightening the child
 - Often successful, with little/no sedation
 - Can make other techniques more likely to succeed, even if it fails
- Mix equal parts Lidocaine 4% with oxymetazoline to deliver simultaneously

ADDITIONAL READING

CODES

ICD9

932 Foreign body in nose

ICD10

T17.1XXA Foreign body in nostril, initial encounter

FOREIGN BODY, RECTAL

Joanna W. Davidson

BASICS

DESCRIPTION

- Self-insertion (autoeroticism):
 - Phallic substitutes inserted by patient or partner
 - Usually men aged 20–40 yr, with male to female ratio 20:1
- Ingested objects lodged in rectum:
 - Chicken bones
 - Fish bones
 - Toothpick
- Iatrogenic accidental:
 - Thermometer
 - Enema tips
 - Foreign bodies (FBs) used to aid in removal of feces
- Assault:
 - Knife or pipe forcibly inserted
 - Incidence of perforation is very high.
- Concealment:
 - Body packing, “mules” illegally transporting drugs

DIAGNOSIS

SIGNS AND SYMPTOMS

- Complaint of rectal FB
- Rectal fullness
- Rectal pain
- Perirectal abscess (with imbedded bones/toothpick)
- FB on rectal exam:
 - High-lying FBs are located proximal to rectosigmoid junction and are not palpable on rectal exam.
 - Low-lying FBs are usually located in rectal ampulla and are palpable on rectal exam.
- Some patients may not be forthcoming with history
- Can present with vague symptoms of abdominal pain or obstruction
- Can present as bowel perforation with full peritonitis
- Often late presentation hours or days after placement, following repeated failed attempts at removal
- Rectal Organ Injury Scale (proposed by American Association for the Surgery of

Trauma):

- Grade I—Hematoma: Contusion or hematoma without devascularization:
 - Most injuries due to rectal FB are Grade I
- Grade II—Laceration 50% circumference
- Grade III—Laceration >50% circumference
- Grade IV—Full-thickness laceration with extension into perineum
- Grade V—Devascularized segment

ESSENTIAL WORKUP

- Identify number, type, and duration of FBs and mechanism of insertion.
- Physical exam with emphasis on abdominal and rectal exam
 - Classified as high-riding vs. low-riding based on relationship to rectosigmoid junction
- Biplane radiographic films to confirm number and size of FBs
- Serious injury more common with assault

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - For bleeding or peritonitis
- Urinalysis:
 - For urethral/bladder injuries

Imaging

- Plain radiograph:
 - Consider doing kidneys, ureters, and bladder (KUB) radiograph prior to rectal exam to rule out objects harmful to examiner.
 - Define and locate FB.
 - Assess for complications of retained FB including bowel perforation and obstruction.
 - May be used serially to follow descent of FB
- CT scan of abdomen/pelvis:
 - To exclude perforation or abscess formation

DIFFERENTIAL DIAGNOSIS

- Pseudo-FB:
 - Patients insist there is FB when radiograph, rectal exams, and proctoscopy results are normal.
- Perirectal abscess
- Hemorrhoid

TREATMENT

PRE HOSPITAL

Cautions:

- Patient has usually tried to remove FB and failed.
- Further attempts at extraction will not work and could cause perforation.

INITIAL STABILIZATION/THERAPY

- Perforation with peritonitis and sepsis:
 - _ 0.9% NS IV fluid 500 mL bolus
 - _ Broad-spectrum antibiotics (anaerobic and gram-negative aerobes):
 - Cefoxitin, cefotetan, ticarcillin–clavulanate, ampicillin–sulbactam, imipenem, meropenem, ertapenem, *or*
 - Metronidazole/clindamycin _+ aminoglycoside/3rd-generation cephalosporin/fluoroquinolone/aztreonam
 - _ Urgent surgical consult
- Advanced trauma life support (ATLS) with evidence of other trauma

ED TREATMENT/PROCEDURES

- Appropriate sedation and analgesia is important to overcome spasm, rectal edema.
- Avoid enemas or suppositories.
- Low-lying small rectal FBs that are not fragile or sharp are candidates for ED removal:
 - _ Firmly hold bimanually or with forceps
 - _ Remove with gentle but firm continuous traction to overcome anal sphincter.
 - _ Colonic mucosa tightly adherent to distal end of FB creates vacuum and impedes withdrawal of object:
 - Passage of Foley catheter beyond object with insufflation of air breaks vacuum and permits retrieval.
 - _ Awake and cooperative patients can facilitate transanal extraction with valsalva.
 - _ May use instruments to assist with extraction: Obstetrical forceps, tenaculum, ring forceps, vacuum extractor
 - _ 60% of rectal FBs may be removed transanally in the ED under proper sedation.
 - _ Following extraction, anorectum must be thoroughly evaluated to rule out occult injury.
- High-lying rectal FBs:
 - _ Not immediately accessible through rectum
 - _ Usually require surgical or GI consult

- Attempt may be made to position object into low-lying position with gentle abdominal pressure
- Avoid blind transanal removal
- Direct visualization with lubricated operating anoscope (after blockage of sphincter and pudendal nerve with local anesthesia)
- Admission and observation for spontaneous descent (with serial radiographs)
- Laparotomy may be necessary as last resort if other methods fail, or if patient has evidence of perforation.
- Consider surgical or GI consult for other complicated rectal FBs:
 - Larger objects
 - Objects that have remained > 24 hr with resulting edema
 - Objects with sharp edges
 - Proctoscopy/sigmoidoscopy after extraction to examine colonic mucosa
- Body packers:
 - Ruptured packets of concealed illicit drugs can cause systemic toxicity, bowel necrosis, and death.
 - Sharp instruments should not be used for retrieval, and other instruments should be used with extreme caution.

MEDICATION

- Ampicillin–sulbactam (Unasyn): 3g IV q6h (peds: 100–200 mg/kg/d div. q6h)
- Ceftriaxone (Rocephin): 1–2 g IV q12h (peds: 50–75 mg/kg IV daily)
- Ciprofloxacin (Cipro): 400 mg IV q8–12h
- Clindamycin: 600–900 mg (peds: 20–40 mg/kg/24h) IV q8h
- Levofloxacin (Levoquin): 500 mg IV q24h
- Metronidazole: 15 mg/kg IV once, then 7.5 mg/kg IV q6h
- Piperacillin–tazobactam (Zosyn): 3.75 g IV q6h or 4.5 g IV q8h (peds: 240–400 mg/kg/d div. q6–8h)

Pediatric Considerations

- Removal under general anesthesia for children who are too young to cooperate
- It is probably child abuse if FB other than enema tips or thermometer is present.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Failed extraction in ED requires surgical removal in the operating room.
- Evidence of mucosal tear on proctoscopy should be observed for 24 hr (no antibiotic indicated).

- Symptom of rectal pain associated with removal of sharp FB indicates possibility of small perforation with developing abscess and requires exam under anesthesia.

Discharge Criteria

- Reliable patient with atraumatic insertion and removal of rectal FB
- Instruct to return for rectal pain, abdominal pain, fever, or massive rectal bleeding.

Issues for Referral

GI or surgery consult if unable to remove FB in ED

FOLLOW-UP RECOMMENDATIONS

Flexible sigmoidoscopy or rigid proctoscopy to evaluate for mucosal injury following retrieval of rectal FB regardless of method used is recommended.

PEARLS AND PITFALLS

- Passage of Foley catheter beyond object with insufflation of air breaks vacuum and permits retrieval.
- Provide adequate sedation/analgesia when attempting FB removal in the ED.

ICD10

T18.5XXA Foreign body in anus and rectum, initial encounter

FOURNIER GANGRENE

Gary M. Vilke

BASICS

DESCRIPTION

- Inadequate hygiene leads to scrotal skin maceration and excoriation:
 - Portal of entry for bacteria in tissue
- Once skin barrier is broken, polymicrobial flora spread along *fascial planes* of perineum.
- Colles fascia fuses with urogenital diaphragm, slowing propagation posteriorly and laterally.
- Anteriorly, Buck and Scarpa fascia are continuous, allowing rapid extension to anterior abdominal wall and laterally along fascia lata.
- Testes and urethra are usually spared.
- 3 anatomic origins account for most cases:
 - Lower urinary tract (40%): Urethral strictures, indwelling catheters
 - Penile or scrotal (30%): Condom catheters, hydradenitis, balanitis
 - Anorectal (30%): Fistulas, perirectal infections, hemorrhoids
- Rarely, intra-abdominal sources such as perforating appendicitis, diverticulitis, or pancreatitis have produced Fournier gangrene by dependent contiguous spread.

ETIOLOGY

- Infection by polymicrobial flora (mixed aerobic and anaerobic organisms)
- Mixed bacteria exert synergistic tissue-destructive effect.
- End arterial thrombosis in subcutaneous tissues produces anaerobic environment.
- Bacterial toxins and tissue necrosis factors may contribute to clinical presentation.
- Risk factors:
 - Trauma
 - Diabetes
 - Alcoholism
 - Other immunocompromised states
 - Morbid obesity
 - Abdominal surgery

DIAGNOSIS

SIGNS AND SYMPTOMS

- Rapidly progressive necrotizing infection of *perineum* involving subcutaneous and fascial tissues and often muscle layers:
 - Usually seen in diabetics or immunocompromised patients

- Sources of infection may be flora from genitourinary, rectal, or penile/scrotal regions.

Pediatric Considerations

- Though unusual in children, > 50 cases have been described.
- Most often are complications of burns, circumcision, balanitis, severe diaper rashes, or insect bites
- Organisms are more frequently *Staphylococcus* or *Streptococcus*.
- Pediatric patients have more local disease and are less toxic.

History

- Duration of symptoms:
 - _ Fevers or chills
 - _ Pain is out of proportion to exam in early phases, but eventually dead tissue becomes insensate.
 - _ Nausea and vomiting
 - _ Urinary infection symptoms
- Rapidity with which symptoms are progressing
- Identify if diabetic or immunocompromised
- Lethargy and inappropriate indifference to the illness are common.

Physical-Exam

- Patients are often toxic in appearance with nausea, vomiting, fever, chills, and pain.
- Careful exam of the genitalia and perirectal region
- Assess for skin findings:
 - _ Bronze or violaceous discoloration of skin
 - _ Thin brown watery discharge
 - _ Ulceration, bullous vesicles
 - _ Crepitance, SC air
 - _ Frank necrosis and eschar formation

ESSENTIAL WORKUP

- Fournier gangrene is a clinical diagnosis.
- History and physical exam with special attention to perineum
- Evaluate for signs of sepsis.
- Early surgical consultation for emergent débridement is essential.
- Other workup directed toward relevant comorbid factors such as diabetes or immunocompromised status

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Other than Gram stain of tissue and associated drainage, there are no specific lab tests that are diagnostic of Fournier gangrene.
- Urinalysis should be performed.
- Leukocytosis, anemia, electrolyte imbalances, acidosis, and renal failure are common.
- Disseminated intravascular coagulation (DIC) may be present; PT, PTT, fibrin-split products, and fibrinogen levels help identify.
- If patient is suspected of or known to have diabetes, glucose, electrolytes, and serum ketones to evaluate for diabetes and diabetic ketoacidosis (DKA)
- Culture of blood, urine, and tissue (when available)

Imaging

- Plain films of the pelvis may reveal subcutaneous emphysema and ileus.
- CT scanning helps if intra-abdominal or ischiorectal source is suspected.
- US may be useful in differentiating from other causes of acute scrotum.

Diagnostic Procedures/Surgery

Retrograde urethrography, anoscopy, proctosigmoidoscopy, and barium enemas may be helpful to localize anatomic sources of infection.

DIFFERENTIAL DIAGNOSIS

- Epididymitis/orchitis
- Insect and human bites
- Perirectal infections
- Scrotal abscess/inguinal abscess
- Scrotal cellulitis
- Testicular torsion
- Tinea cruris

TREATMENT

PRE HOSPITAL

Patients may be hypotensive from septic shock and require aggressive fluid resuscitation and vasopressor support.

INITIAL STABILIZATION/THERAPY

- Manage airway and resuscitate as indicated.
- Central venous access, aggressive fluid resuscitation, and pressure support as indicated:
 - Avoid femoral access, femoral venipuncture, and lower extremity venous access
- Early goal-directed therapy if septic

- Foley catheter placement or suprapubic access if indicated

ED TREATMENT/PROCEDURES

- Empiric broad-spectrum antibiotics
- Early emergent aggressive surgical débridement
- Adjunctive hyperbaric oxygen therapy coordinated with surgical care
- Treat dehydration and correct electrolytes.
- Blood products as needed for DIC or anemia; oxygen debt can be minimized by keeping hematocrit > 30%.
- Tetanus prophylaxis as indicated

Pediatric Considerations

- More conservative surgical approach
- Adequate staphylococcal coverage

MEDICATION

- Antibiotic regimens:
 - Multidrug regimen:
 - Ampicillin: 2 g IV q6h (peds: 50 mg/kg) *and*
 - Clindamycin: 900 mg IV q8h (peds: 10 mg/kg) *and*
 - Gentamicin: 5 mg/kg daily load IV q8h
 - Ciprofloxacin: 500 mg IV *and*
 - Clindamycin: 900mg IV initial ED dose
 - Single-drug regimens (peds: Safety not established)
 - Ampicillin/sulbactam: 3 g IV initial ED dose
 - Imipenem: 1 g IV initial ED dose
 - Piperacillin/tazobactam: 3.375 g IV initial ED dose
 - Ticarcillin/clavulanate: 3.1 g IV initial ED dose
- Cover for possible MRSA with Vancomycin 1 g IV initial ED dose
- Blood products as indicated
- Dopamine or dobutamine IV drips starting at 5 µg/kg/min titrating to effect if hypotensive after aggressive hydration
- Insulin adjusted to control glucose and acidosis

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with Fournier gangrene require admission and surgical ICU care.
- Mortality estimates of 3–38% emphasize need for early aggressive care.
- Consider early transfer to facility capable of providing adjunctive hyperbaric

oxygen therapy if stable for transport.

Discharge Criteria

No patients with Fournier gangrene should be discharged.

PEARLS AND PITFALLS

- Failure to perform a careful genital exam, particularly in a pediatric patient
- Failure to initiate antibiotics in a timely manner

ICD10

N49.3 Fournier gangrene

FRACTURE, OPEN

Christy Rosa Mohler

BASICS

DESCRIPTION

- Continuity between skin violation and fracture site, ranging from a puncture wound to grossly exposed bone
- Surgical urgency, as delays in care increase risk of infection and rate of complications
- Predisposition to complications in certain patients:
 - Massive soft tissue damage
 - Severe wound contamination
 - Compromised vascularity
 - Fracture instability
 - Compromised host (diabetes, vascular disease)

ETIOLOGY

Open fractures typically result from significant blunt force or penetrating trauma.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Deformity with nearby violation in skin integrity
- Neurovascular compromise may occur.
- Additional traumatic injuries are frequently present.

History

Significant trauma

Physical-Exam

- Complete neurologic and vascular exam
- Examine thoroughly for other traumatic injuries.

ESSENTIAL WORKUP

- Plain radiographs including joints above and below the affected area
- Guided workup based on mechanism and evidence of other traumatic injuries

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC, chemistry panel, coagulation studies for large-bone (femur, pelvis) fractures or multiple-trauma victims
- Type and screen or type and cross-match for potential of significant blood loss.
- Predébridement and postdébridement cultures have limited value and are not recommended.

Imaging

Doppler or angiography if vascular damage is suspected:

- Posterior knee dislocation
- Ischemic extremity
- Massive soft tissue injury in high-risk areas

Diagnostic Procedures/Surgery

- Measurement of compartment pressures if concern for compartment syndrome
- Consider arthrogram by intra-articular injection of saline or methylene blue if joint involvement is suspected.
- Angiography if noninvasive techniques are inadequate for ruling out vascular compromise

DIFFERENTIAL DIAGNOSIS

Noncontiguous laceration/abrasion

TREATMENT

PRE HOSPITAL

- Moist, sterile dressings over open wounds
- Immobilize joints above and below fracture.
- Control bleeding with local compression.
- Consider tourniquet for traumatic amputations or uncontrollable hemorrhage.
- Longitudinal traction of involved extremity if distal pulses absent

INITIAL STABILIZATION/THERAPY

- Management of ABCs.
- Gentle reduction and immobilization of fracture

ED TREATMENT/PROCEDURES

- Intravenous access
- Keep patient NPO
- Tetanus vaccination, if needed
- Antibiotics reduce the incidence of early infection in open fractures and should be given early in the ED course.
- Minimize number of times dressing is removed to avoid secondary contamination.

- Examine limb regularly for compartment syndrome and neurovascular status.
- Certain large joint open fracture/dislocations should be reduced emergently in the ED (ankle, elbow, knee)
- Urgent orthopedic consultation for formal irrigation, débridement, and possible operative fixation.
- Vascular surgery consultation for injuries with potential vascular damage

MEDICATION

- Cefazolin: 1–2 g (peds: 20 mg/kg IM/IV)
- Add gentamicin: 1.5–2 mg/kg IV for more extensive injuries and highly contaminated wounds (peds: 2–2.5 mg/kg IV)
- Add penicillin G: 4–5 million U IV in farmyard injuries, vascular injuries, and in wounds at risk of contamination with *Clostridium* (peds: 50,000 U/kg IV)
- Tetanus booster: 0.5 mL IM
- Tetanus immunoglobulin: 250 IU IM if not previously immunized against tetanus
- Morphine sulfate: 2–10 mg (peds: 0.05–0.1 mg/kg per dose IV or equivalent analgesic)

Pediatric Considerations

DTaP booster for children <7 yr of age

FOLLOW-UP

DISPOSITION

Admission Criteria

Most patients will be admitted for irrigation, débridement, IV antibiotics, and possibly operative fixation.

Discharge Criteria

Simple open fractures may be washed out and immobilized in the ED after consultation with an orthopedic surgeon. The patient should be discharged with oral antibiotics.

Issues for Referral

Most open fractures will require emergent orthopedic consultation and may require trauma team evaluation for other injuries.

FOLLOW-UP RECOMMENDATIONS

Patients discharged from the emergency department should be followed up with an orthopedic surgeon in 1–2 days.

PEARLS AND PITFALLS

- Open fractures are surgical urgencies requiring prompt orthopedic consultation.
- 40–70% of patients with open fractures have other traumatic injuries.
- Prompt and thorough ED assessment and treatment can significantly decrease morbidity in patients with open fractures.

- S82.90XB Unsp fracture of unsp lower leg, init for opn fx type I/2
- T14.8 Other injury of unspecified body region

FRACTURES, PEDIATRIC

Adam Z. Barkin

BASICS

DESCRIPTION

- 20% of pediatric patients with acute traumatic injuries will have a fracture
- Boys have fractures more commonly than girls
- Anatomy:
 - Diaphysis: Pysis to pysis; bone shaft
 - Epiphysis: Cartilaginous center at or near end of bone that is site of bone growth
 - Epiphyseal (growth) plate: Radiolucent line between epiphysis and metaphysis; cartilaginous
 - Metaphysis: Region of rapidly growing trabecular bone underlying base of cartilaginous growth plate; between diaphysis and epiphysis
 - Most long bones are ossified by the end of puberty
- Bones are highly resilient, elastic, and springy
- Allow for fractures not seen in adults:
 - Greenstick fracture:
 - Incomplete fracture through cortex on opposite side of impact
 - Torus (buckle) fracture:
 - Usually at junction of metaphysis and diaphysis
 - Compression of bone of 1 cortex
 - Plastic deformity:
 - Bowing without disruption of cortex
 - Fractures involving the physis
- Cartilaginous growth plates are potential areas of injury.
- Ligaments more resistant to injury than growth plates
- Salter–Harris classification:
 - Risk of growth disturbance increases from type I to type V.
 - Type I:
 - Separation of epiphysis from metaphysis without displacement or injury to the growth plate
 - Tenderness and pain at point of growth plate
 - Radiograph typically normal
 - Growth disturbance is rare.
 - Type II:
 - Metaphyseal fracture extending to physis
 - Most common
 - Growth disturbance is rare.

- Type III:
 - Intra-articular fracture extending through the epiphysis into the physis
 - Most common site is distal tibial epiphysis.
 - Growth disturbance possible
- Type IV:
 - Epiphyseal, physeal, and metaphyseal fracture
 - Lateral condyle of humerus is the most common site.
 - Growth disturbance highly likely
- Type V:
 - Crush injury to epiphyseal plate, producing growth arrest
 - Usually occurs in joints that move in only 1 plane such as knee
- Fractures often accompany dislocations.
- Nonaccidental trauma (NAT) if history inconsistent with findings

ETIOLOGY

- Mechanism is useful in defining the potential and type of injury
- Obesity and rapid growth spurts are risk factors.
- NAT:
 - Any fracture in a child younger than 1 yr of age in whom history is not consistent with injury
 - Metaphyseal “corner” fractures are pathognomonic.
 - Posterior rib fractures
 - Spiral femur fracture
 - Fractures at different stages of healing
 - Skull fractures crossing suture lines, especially in children younger than 1 yr
 - Unusual behavior in child or parent

DIAGNOSIS

SIGNS AND SYMPTOMS

- Decreased limb movement, unwilling to use
- Swelling
- Tenderness
- Deformity
- Ecchymosis
- Crepitus
- Limp
- Abnormal neurovascular status of extremity
- Compartment syndrome:
 - Severe pain, especially in forearm, calf, foot
 - Pain with passive stretching of fingers or toes
 - Sensory deficit in the distal extremity

- Cool extremity
- Pulseless extremity
- Open fracture may be obvious or subtle (collection of blood with fat globules under skin)

History

- Mechanism of injury:
 - Velocity of car, bike, etc.
 - Height of fall
- Neurologic compromise
- Events surrounding injury
- Other injuries

Physical-Exam

- Thorough secondary survey looking for deformities, bruising, other injuries
- Assess neurovascular status:
 - Motor/sensation
 - Distal pulses
 - Capillary refill
- Range of motion of all joints involved
- Exclude concurrent injuries
- Ensure that history is consistent with injury

ESSENTIAL WORKUP

- Prompt immobilization
- Imaging as below

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Required only if concomitant injuries, surgery anticipated, or multiple/major bone involvement
- CBC, ESR if infection suspected

Imaging

- Anteroposterior (AP), lateral, and oblique radiographs as necessary, including the joint above and below the fracture
- Comparison views may be useful if growth plates are involved.
- Follow-up radiographs at 7–10 days may be required to exclude avascular necrosis or Salter I fractures.
- Bone scan/CT/MRI may be useful to exclude fractures if plain radiographs are unhelpful or to evaluate for infection.

Diagnostic Procedures/Surgery

Arthrocentesis if infection is suspected

DIFFERENTIAL DIAGNOSIS

- Sprain or strain
- Contusion
- Infection
- Tumor
- Neurologic deficits
- Subtle dislocations such as radial head subluxation (nursemaid's elbow)
- NAT

TREATMENT

PRE HOSPITAL

Immobilization

INITIAL STABILIZATION/THERAPY

- Resuscitation for concurrent injuries
- Immobilization

ED TREATMENT/PROCEDURES

- Management of life-threatening concurrent injuries
- Pain control
- Dislocations require immediate assessment and attention to neurovascular compromise:
 - Mechanism helps in understanding the direction of the force required to reduce.
- Alignment is essential, particularly when fracture involves a joint surface.
- Appropriate reporting of NAT

Salter-Harris Fractures

- Type I and type II fractures require immobilization and orthopedic follow-up.
- Type II distal femur fractures, type III, and type IV require urgent orthopedic consultation for anatomic reduction.
- Type V fractures require immobilization and consultation.
- Anatomic reduction does not eliminate possibility of growth disturbance.

Clavicle Fracture

- Figure-of-8 splint or sling for comfort
- Distal 3rd clavicle fractures should be referred with initial sling and swathe or shoulder immobilizer.

Elbow Fracture

- > 50% are supracondylar
 - 10–15% have neural injury
- May present with only posterior effusion on lateral radiograph
- Orthopedic consultation because of potential neurovascular complications
- Brachial artery injury, median nerve injury possible
- Volar compartment syndrome of forearm (results in Volkmann contracture)
- Epiphyseal injury with long-term growth abnormalities

Distal Radius and Ulna Fractures

- Most common site of pediatric fracture: Distal radius
- Reduce angulated fractures > 15°
- Pronator fat pad along volar radius may indicate occult fracture
- Colles fracture:
 - Reduce by traction in the line of deformity to disimpact the fragments, followed by pressure on the dorsal aspect of the distal fragment and volar aspect of the proximal fragment.
 - Correct radial deviation.
 - Immobilize wrist and elbow (sugar-tong splint)
 - Orthopedic consultation
- Torus fracture (incomplete fracture; buckling or angulation on the compression side of the bone only):
 - Most often in distal forearm
- Greenstick fracture (incomplete fracture of diaphysis of long bone with fracture on tension side of cortex):
 - Immobilize.
 - Reduction if angulation > 30° in infants, > 15° in children

Tibia or Fibula Fracture

- Isolated fibular fractures: Short-leg walking cast
- Nondisplaced tibial fracture: Long-leg posterior splint, nonweight bearing
- Displaced tibial fracture and complex fractures require consultation.
- Toddler's fractures:
 - Nondisplaced, oblique, distal tibia fracture
 - May need tangential view radiograph or bone scan to diagnose
 - Splint if suspect and repeat radiograph in 7–10 days.
- May apply Ottawa Ankle Rules to children

Slipped Capital Femoral Epiphysis

- Disruption through capital femoral epiphysis
- Need AP and frog-leg x-rays
- Overweight adolescent boys

- May have referred pain to knee, thigh, or groin
- Nonweight bearing with prompt orthopedic follow-up
- Often bilateral

Femur Fracture

- Most common long-bone fracture

Stress Fractures

- Increasingly common
- Insidious onset
- Vague, achy pain
- Usually associated with rigorous activity
- Treatment:
 - _ Selective bracing
 - _ Activity modification

Open Fractures

- Irrigate and dress with moist saline gauze
- Immobilize
- Cefazolin if only small laceration and minimal contamination
- Gentamicin if moderate contamination, high-energy injury, or significant soft tissue injury
- Consider penicillin if concern for clostridia infection (farm injury, fecal or soil contamination)
- Small wounds with minimal soft tissue injury may be treated with oral antibiotics and immobilization in consultation with orthopedist

Child with Limp

- Careful exam and review of systems for signs of rheumatologic disease, infection, or malignancy
 - _ Pediatric patients with leukemia may present with limp as their initial complaint
- CBC, ESR, CRP, arthrocentesis may be indicated
- Transient synovitis vs. septic hip
 - _ More likely septic if:
 - Fever
 - Elevated ESR/CRP
 - WBC elevation
 - Refusal to bear weight

MEDICATION

- Acetaminophen: 10–15 mg/kg PO(PR (per rectum) q4–6h; Do not exceed 5

doses/24 h

- Cefazolin: 25–100 mg/kg daily IM/IV q8h
- Gentamicin: 2.5 mg/kg IV/IM q8h or 6.5–7.5 mg/kg IV/IM q24h
- Hematoma block: 1% lidocaine without epinephrine (max. 3–5 mg/kg)
- Ibuprofen: 10 mg/kg PO q6–8h (first-line treatment)
- Morphine: 0.05–0.2 mg/kg SC/IM/IV q2–4h

FOLLOW-UP

DISPOSITION

Admission Criteria

- NAT (or per social services)
- Open fracture
- Potential neurovascular compromise/compartment syndrome:
 - Condylar or supracondylar humerus fracture
 - Femoral shaft

Discharge Criteria

- Uncomplicated fracture: No concurrent injury or neurovascular/compartment compromise
- Follow-up arranged and parents understand injury and management

Issues for Referral

All Salter–Harris fractures should have orthopedic follow-up.

PEARLS AND PITFALLS

- History is essential in evaluation of NAT
- Undress patient fully especially if suspicion for NAT
- Have a low threshold to splint and/or consult orthopedist
- Pain control is essential and often underdosed.
- Distal radius is often associated with other fractures: Ulna, elbow, carpal bones

FROSTBITE

Joseph M. Weber

BASICS

DESCRIPTION

- Tissue damage caused by cold temperature exposure
- Mechanism:
 - Tissue damage results from:
 - Direct cell damage: Intracellular ice crystal formation
 - Indirect cell damage: Extracellular ice crystal formation leads to intracellular dehydration and enzymatic disruption.
 - Reperfusion injury: Occurs upon rewarming. Fluid rich in inflammatory mediators (prostaglandin and thromboxane) extravasates through damaged endothelium promoting vasoconstriction and platelet aggregation.
 - Clear blisters form from extracellular exudation of fluid.
 - Hemorrhagic blisters occur when deeper subdermal vessels are disrupted, indicating more severe tissue injury.
 - The end result is arterial thrombosis, ischemia, and ultimately, necrosis.
 - Devitalized tissue demarcates as the injury evolves over weeks to months, hence the phrase “frostbite in January, amputate in July.”

ETIOLOGY

- Cold exposure: Duration of exposure, wind chill, humidity, and wet skin and clothing all increase the likelihood of frostbite.
- Predisposing factors:
 - Extremes of age
 - Altered mental status (intoxication or psychiatric illness)
 - Poor circulatory status

DIAGNOSIS

SIGNS AND SYMPTOMS

- Extremities (fingers, toes) and head (ears, nose) most commonly affected.
- After rewarming frostbite can be classified; however, initial classification often fails to provide an accurate prognosis and does not alter initial management.
- Superficial frostbite:
 - Only skin structures involved. Usually no tissue loss.
 - 1st degree: Erythema and edema with stinging, burning, and throbbing. No

- blisters or necrosis.
- 2nd degree: Significant edema, clear blister formation. Numbness common.
- Deep frostbite:
 - Tissue loss inevitable.
 - 3rd degree: Involves subcutaneous tissue. Hemorrhagic blister formation due to subdermal venous plexus injury:
 - Initially insensate, injuries develop severe pain/burning on rewarming.
 - 4th degree: Involves muscle, tendon, and bone. Initially mottled, deep red, or cyanotic.
 - Unfavorable prognostic indicators include: Hemorrhagic blisters, persistent cyanosis, mottling, anesthesia, and reduced mobility after rewarming.
 - Devitalized tissue demarcates as the injury evolves over weeks to months forming skin necrosis and dry black eschar.

ESSENTIAL WORKUP

- Diagnosis is based on the clinical presentation. Wound description should include skin color and temperature, blister formation and color, and soft tissue consistency.
- A neurologic and vascular exam should include pulses (by Doppler if necessary), cap refill, and 2-point discrimination.
- Look for underlying factors contributing to cold exposure and comorbid conditions requiring emergency management:
 - Hypothermia
 - Trauma
 - Hypoglycemia
 - Cardiac or neurologic problems
 - Intoxication/overdose
 - Compartment syndrome

DIAGNOSIS TESTS & INTERPRETATION

Lab

- None indicated in mild cases
- For deep frostbite:
 - CBC
 - Electrolytes, BUN/creatinine, glucose
 - Urinalysis/CK for evidence for myoglobinuria
- Cultures and Gram stains from open areas when infection suspected

Imaging

Technetium-99 scintigraphy or MRA:

- May be helpful in early identification of salvageable vs. unsalvageable tissue

- Permits earlier decision about amputation

Diagnostic Procedures/Surgery

Method to create a warm water bath in the ED:

- Whirlpool hydrotherapy ideal, however, most EDs do not have
- Mix hot and cold tap water from a standard hospital sink in a large basin
- Use a thermometer to keep temperature between 40°C and 42°C.
- The water will cool quickly: Intermittently add warm water or replace the water to keep the temperature in the proper range.
- Warmer temperatures can cause thermal injury while cooler temperatures delay thawing and decrease tissue survival.

DIFFERENTIAL DIAGNOSIS

- Frostnip:
 - Superficial, reversible ice crystal formation without tissue destruction
 - Transient numbness and paresthesia resolve after dry rewarming.
- Trench (immersion) foot:
 - Exposure to wet cold for prolonged periods
 - Neurovascular damage without ice crystal formation
 - Pallor, mottling, paresthesias, pulselessness, paralysis, and numbness
 - May be difficult to distinguish from post-thaw phase of frostbite
 - Hyperemia with dry rewarming may last up to 6 wk.
- Chilblains:
 - Chronic repeated exposure to dry cold
 - Localized erythema, cyanosis, plaques, and vesicles
 - Recurrent episodes common in patients with underlying vasculitis
 - Symptomatic treatment, dry rewarming

TREATMENT

PRE HOSPITAL

- Protect and immobilize frostbitten area during transport
- Remove restrictive or wet garments
- Avoid dry rewarming of the frostbitten limb if there is a likelihood of refreezing injury during transport.
- If evacuation will be delayed and suitable facilities are available, field rewarming in warm (40°C–42°C) water can be attempted.
- Rubbing, manipulating the limb, or applying snow while it is still frozen is contraindicated.

ALERT

- Hypothermia:

- Common in frostbite victims
- In the severely hypothermic patient, avoid rough handling to minimize risk of cardiac dysrhythmias.

INITIAL STABILIZATION/THERAPY

- ABCs management
- Identify and correct hypothermia.
- IV fluid volume expansion with 0.9% NS for severe frostbite
- Protect frostbitten areas from excessive handling during resuscitation.

ED TREATMENT/PROCEDURES

- If the injury is <24 hr old and has not yet been rewarmed:
 - Initiate rapid rewarming of the frostbitten extremity in a 40–42°C water bath for 15–30 min.
 - Stop treatment when the limb is warm, red, and pliable.
 - Monitor water temperature closely to prevent thermal injury.
- Analgesia: IV morphine
- NSAIDs (e.g., ibuprofen) to combat the effects of prostaglandins on skin necrosis.
- Aloe vera topical cream:
 - Recommended for all intact blisters
 - Combats the arachidonic acid cascade
 - Avoid preparations containing alcohol, scent, salicylates, all of which interfere with aloe effectiveness.
- Blister débridement or aspiration:
 - Indicated for clear blebs:
 - Removes thromboxane and prostaglandins
 - Contraindicated for hemorrhagic blebs:
 - Exposes deeper structures to dehydration and infection
- Tetanus prophylaxis
- Antibacterial prophylaxis:
 - Consider during the hyperemic recovery phase (at least 2–3 days) in severely frostbitten areas
 - Against *Streptococci*, *Staphylococci*, and *Pseudomonas* species (cephalosporin, penicillinase-resistant penicillin, quinolone)
 - Topical antibacterial agents interfere with the use of aloe vera cream and should be considered a 2nd-line approach.
- Elevation and splinting of frostbitten area
- Change dressing 2–4 times daily.
- Avoid vasoconstrictive agents (including tobacco).
- Adjunctive treatments include:
 - Thrombolytic therapy (<24 hr of cold exposure):
 - Both intra-arterial and systemic tPA may improve tissue salvage rates.
 - Consult with plastic/burn surgeon before treatment.

- Vasodilator therapy:
 - Pentoxifylline—limited data
 - Iloprost—limited data and availability

MEDICATION

- Aloe vera: Topical cream (70% concentration) q6h
- Cephalexin (cephalosporin): 500 mg (peds: 25–50 mg/kg/24h q6h) PO QID
- Ciprofloxacin (quinolone): 500 mg PO BID
- Dicloxacillin (penicillinase-resistant penicillin): 500 mg (peds: 12.5–25 mg/kg/24h q6h) PO QID
- Ibuprofen (NSAID): 800 mg (peds: 40 mg/kg/24h q6–8h) PO TID
- Morphine sulfate: 0.1–0.2 mg/kg (peds: 0.1 mg/kg) IV or IM PRN (titrate to patient response)

FOLLOW-UP

DISPOSITION

Admission Criteria

- All but the most superficial cases should be admitted.
- Lower admission threshold where risk of refreezing exists.
- Immersion (trench) foot patients may be discharged only if an environment that allows for proper treatment can be provided.

Discharge Criteria

Minimal superficial injury, all others should be admitted.

Issues for Referral

General, burn, plastic, or hand surgeon should be consulted in all but the most superficial of cases.

FOLLOW-UP RECOMMENDATIONS

All discharged patients should be referred to a general, burn, plastic, or hand surgeon.

PEARLS AND PITFALLS

Pitfalls:

- Allowing freeze, thaw, refreeze cycle to occur
- Failure to keep warm water bath between 40°C and 42°C during rewarming
- Failure to address hypothermia or other systemic illness
- Failure to consider compartment syndrome in a pulseless frostbitten extremity

GALLSTONE ILEUS

Joanna W. Davidson

BASICS

DESCRIPTION

- Mechanical intestinal obstruction secondary to impaction of a gallstone within bowel lumen
- Stone is usually > 2.5 cm
- 1–3% of all intestinal obstructions
- Most cases occur in patients > 65
- Female > male (5:1)
- Mortality 15–18%

ETIOLOGY

- Chronic gallbladder inflammation causes adhesions between gallbladder and adjacent bowel wall
- Cholecystocolonic fistula develops, permitting stone passage into intestine:
 - Duodenum is the most common site of fistula formation, followed by colon
 - Gastric fistulas are possible but rare
- Site of impaction
 - Terminal ileum most common (54–65%)
 - Narrowest part of small intestine at level of ileocecal valve
 - Jejunum (27%)
 - Duodenum (1–3%)
 - Gastric outlet obstruction caused by duodenal impaction referred to as *Bouveret syndrome*
 - Large bowel obstruction is rare

DIAGNOSIS

SIGNS AND SYMPTOMS

- “Tumbling” abdominal discomfort:
 - Episodic abdominal pain as stone lodges and dislodges throughout the intestines.
 - Complete impaction leads to severe, often acute abdominal pain.
- Nausea
- Vomiting:
 - Can be bilious or feculent
- Obstipation
- Abdominal distention and tympany

- Abdominal tenderness:
 - Peritoneal findings develop late in the course of disease
- Abnormal bowel sounds

History

- Only 50–60% of patients have a history of biliary colic or gallstone disease.
- Gallstone ileus has been associated with cardiovascular disease, diabetes, and obesity.

Physical-Exam

- Abdominal exam for:
 - Abdominal distension/tenderness
- Jaundice may occur

ESSENTIAL WORKUP

Evaluate for intestinal obstruction.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Electrolytes, BUN/creatinine, glucose since decreased oral intake and vomiting leads to electrolyte abnormality
- Liver function panel and bilirubin may be elevated
- Amylase:
 - Elevated in late obstructions
- CBC/hematocrit:
 - Hemoconcentration secondary to dehydration
- Elevated WBC nonspecific

Imaging

- Flat and upright abdominal radiographs:
 - Multiple air–fluid levels and distended bowel consistent with bowel obstruction
 - Rigler triad: 2 of 3 pathognomonic (present in 30–50%):
 - Air in the biliary tree (pneumobilia)
 - Partial or complete bowel obstruction
 - Ectopic stone visualized within the intestinal tract
- CXR:
 - Evaluate for pneumoperitoneum
- Abdominal CT scan:
 - Test of choice
 - Can directly visualize and localize stone within intestinal lumen
- Abdominal US:

- Can identify pneumobilia and gallstones, but lower yield in locating obstructing stone

DIFFERENTIAL DIAGNOSIS

- Paralytic ileus
- Extrinsic bowel obstruction:
 - Adhesions
 - Volvulus
 - Hernia
 - Intussusception
- GI malignancy
- Diverticulitis
- Bezoar
- Inflammatory bowel disease
- Pseudo-obstruction
- Cholecystitis
- Ascending cholangitis
- Pancreatitis

TREATMENT

PRE HOSPITAL

Establish IV access

INITIAL STABILIZATION/THERAPY

IV fluid resuscitation

ED TREATMENT/PROCEDURES

- Nasogastric suction to decompress the stomach and intestine
- Nothing PO
- Electrolyte replacement
- Monitor urine output
- Analgesics
- Broad-spectrum antibiotics to cover bowel flora:
 - Piperacillin/tazobactam
 - Ampicillin/sulbactam
 - Ticarcillin/clavulanate
 - Alternatives include imipenem, meropenem, 3rd-generation cephalosporin + metronidazole.
- Surgical consultation

MEDICATION

- Ampicillin/sulbactam: 3 g IV q6h (peds: 100–200 mg/kg/24 h)

- Piperacillin/tazobactam: 3.375 g IV q6h (peds: 240–400 mg/kg/24 h)
- Ticarcillin/clavulanate: 3.1 g IV q4–6h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Admit all patients with gallstone ileus
- Surgical evaluation for emergent operative intervention

Discharge Criteria

None

FOLLOW-UP RECOMMENDATIONS

Surgical consultation in ED for evaluation and operative intervention

PEARLS AND PITFALLS

- Gallstone ileus is a mechanical intestinal obstruction rather than a true ileus.
- Emergent surgical consultation is required for definitive management.
- High mortality rates stem from delay in diagnosis and patient comorbidities.
- Suspect gallstone ileus in elderly patients, especially women, with signs/symptoms of bowel obstruction and no previous surgical history.
- Only 10% of ectopic gallstones can be visualized on plain radiographs. CT imaging is more sensitive and specific for detecting intraluminal stones.
- Only 1/2 of the patients have a previous history of biliary colic or gallstone disease.

GANGRENE

Stephen R. Hayden

BASICS

DESCRIPTION

- Gas gangrene or clostridial myonecrosis
- An acute, rapidly progressive, gas-forming necrotizing infection of muscle and subcutaneous tissue
- Can be seen in post-traumatic or postoperative situations
- Progressive invasion and destruction of healthy muscle tissue

ETIOLOGY

- Clostridial organisms:
 - _ Facultative anaerobic, spore-forming, gram-positive bacillus
 - _ Produces a number of toxins; the most prevalent and lethal is α -toxin.
- *Clostridium perfringens* is the most common bacterium; found in 80–90% of wounds.
- Other clostridial bacteria include *Clostridium novyi*, *Clostridium septicum*, *Clostridium histolyticum*, *Clostridium bifermentans*, and *Clostridium fallax*.
- 2 distinct mechanisms for introduction of clostridial organisms:
 - _ Traumatic and postoperative
 - _ Nontraumatic associated with diabetes mellitus, peripheral vascular disease, alcoholism, IV drug abuse, and malignancies

DIAGNOSIS

SIGNS AND SYMPTOMS

- Sudden severe pain of extremity or involved area
- Low-grade fever
- Tachycardia out of proportion to fever
- Bronzing of the skin over involved area; later can turn purple or red
- Crepitus
- Formation of blebs and bullae
- Thin, serosanguinous exudate and sweet odor
- Rapid local extension
- Obtunded sensorium
- Systemic toxicity

ESSENTIAL WORKUP

- History and physical exam with special attention to clinical evidence of crepitus in soft tissue

- Soft tissue x-rays of involved area to detect gas dissecting along fascial planes:
 - The absence of gas does not exclude significant disease.
- Stat Gram stain of wound exudate for gram-positive bacillus with paucity of leukocytes

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC with differential, electrolytes, BUN, and creatinine
- Coagulation studies
- Evaluate for hemolysis
- Stat Gram stain of wound exudates
- Anaerobic cultures of wound or tissue biopsy

Imaging

- Radiographs may reveal soft tissue gas.
- CT if area involves abdomen or flank.

Diagnostic Procedures/Surgery

All patients with gas gangrene must undergo surgical débridement.

DIFFERENTIAL DIAGNOSIS

- Cellulitis
- Necrotizing fasciitis
- Nonclostridial myositis and myonecrosis
- Other causes of gas in tissues, as from dissection from respiratory or GI tracts

TREATMENT

PRE HOSPITAL

Establish IV and infuse isotonic fluids

INITIAL STABILIZATION/THERAPY

Manage airway and resuscitate as indicated:

- Rapid sequence intubation as needed.
- Supplemental oxygen:
 - Cardiac and oxygen saturation monitors should be placed.
- IV access; consider central venous pressure monitoring; sepsis protocol is appropriate
- Aggressive volume expansion, including crystalloid, plasma, packed RBCs, and albumin if there is septic shock.

ED TREATMENT/PROCEDURES

- Parenteral antibiotic therapy:
 - Initial empiric therapy should cover *Clostridium* species and group A *Streptococcus* as well as mixed aerobes and anaerobes
 - Primary definitive therapy: Penicillin G + clindamycin
 - Alternative: Ceftriaxone or erythromycin
 - If mixed infection: Penicillin + clindamycin, metronidazole, or vancomycin and gram-negative coverage with gentamicin
 - Follow local sepsis protocols
- Surgical consultation:
 - Débridement, amputation, or fasciotomy is required.
- Hyperbaric oxygen (HBO) as adjunctive therapy:
 - Early transfer to hyperbaric facility may be lifesaving.
 - Lack of randomized trials with HBO but nonrandomized studies suggest benefit
- Tetanus prophylaxis
- Observe for major complications including ARDS, renal failure, myocardial irritability, and DIC.
- Polyvalent antitoxin is not made in US and studies have not demonstrated efficacy:
 - Because of the unacceptable hypersensitivity reactions, it is not routinely recommended.

MEDICATION

- Ceftriaxone: 2 g (peds: 100 mg/kg/24h max. 4 g) IV q12h
- Clindamycin: 900 mg (peds: 40 mg/kg/d q6h) IV q8h
- Erythromycin: 1 g (peds: 50 mg/kg/d q6h) q6h IV
- Gentamicin: 2 mg/kg (peds: 2 mg/kg IV q8h) IV q8h
- Metronidazole: 500 mg (peds: Safety not established) IV q8h
- Penicillin G: 24 million IU/24h (peds: 250,000 IU/kg/24h) IV q4–6h
- Tetanus immune globulin: 500 IU IM
- Tetanus toxoid: 0.5 mg IM

First Line

Primary definitive therapy for clostridial species; combination of penicillin G and clindamycin

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with gas gangrene and evidence of myonecrosis *must be admitted* for surgical débridement and IV antibiotics.
- Use of HBO therapy is an important adjunct.

Discharge Criteria

No patient with acute gangrene should be discharged.

Issues for Referral

After stabilization with antibiotics and surgical débridement, consider referral for HBO treatment as an adjunct.

PEARLS AND PITFALLS

- Bacteremia occurs in about 15% and can progress quickly to intravascular hemolysis.
- HBO as adjunctive therapy to surgical débridement and early antibiotics if patient is hemodynamically stable

GASTRIC OUTLET OBSTRUCTION

Jenny J. Lu

BASICS

DESCRIPTION

- Any process impeding the passage of gastric contents into the duodenum
- Causes not limited to gastric pathology and may be duodenal or extraluminal in origin
- Benign and malignant causes, including:
 - Neoplasms (most common cause in adults), intrinsic or extrinsic neoplasms (pancreatic, gastric lymphoma, duodenal, gallbladder). Extrinsic masses may cause compression at pylorus or proximal duodenum
 - Peptic ulcer disease (PUD), no longer most common cause in adults, with treatment of *Helicobacter pylori* and use of H₂ blockers
 - Pyloric stenosis (most common pediatric cause): Incidence 2–5/1,000
 - Postoperative complications, especially from gastric surgeries (e.g., edema, scarring, stricture, or hyperplasia of pylorus or duodenum)
 - Mechanical causes: Gastric volvulus, polyps, bezoars, duplication cysts
 - Edema, scarring, strictures/webs, or hyperplasia of pylorus or duodenum from various causes (e.g., caustic injury, chronic pancreatitis)

ETIOLOGY

- Regardless of exact cause, gastric outlet obstruction characteristically leads to nausea and nonbilious vomiting
- Persistent vomiting may lead to dehydration, electrolyte and acid–base derangements
 - Chronic symptoms may lead to weight loss, malnutrition, failure to thrive
 - Hypokalemic, hypochloremic metabolic alkalosis is classic finding

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Symptoms may be intermittent until obstruction becomes complete
- Nausea and vomiting, *usually* nonbilious
- Abdominal pain, variable in character and often vague
- Early satiety and epigastric fullness
- Epigastric discomfort relieved with emesis
- Weight loss, failure to thrive

Physical-Exam

- Vital signs:
 - May be normal
 - Tachycardia, hypotension if volume depletion is significant
- Abdominal exam:
 - Variable amount of epigastric/abdominal distention
 - Tympanitic to auscultation
 - Succession splash > 4 hr after eating
 - Digital rectal exam: Evaluate for occult blood
- Signs of dehydration in eyes, oral pharynx, mucous membranes, skin turgor
- Signs of malnutrition in chronic or late obstruction
- Weight loss when chronic and with malignancy

Geriatric Considerations

- Abdominal pain, nausea/vomiting: GI symptoms may be more vague/subtle in elderly patients
- If appropriate, consider other causes of symptoms (cardiac causes, neurologic causes)

Pediatric Considerations

- Idiopathic hypertrophic pyloric stenosis:
 - Most common cause in pediatric population
 - “Typical” patient is male (Caucasian and US-born Asians more common)
 - Usually 2–8 wk old but may be diagnosed as early as 1st wk and up to 3 mo of age
 - Initially intermittent, nonprojectile, postprandial vomiting, which progresses to projectile, nonbilious vomiting
 - A midepigastric peristaltic wave occurring prior to vomiting may be visible on exam
 - Epigastric “olive” mass may be palpable in 80–90% of patients

ESSENTIAL WORKUP

Careful history and physical exam

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - Anemia if malignancy or GI blood loss
 - High hematocrit indicating hemoconcentration
- Electrolytes, BUN/creatinine, glucose:
 - Hypokalemia
 - Hypochloremic metabolic alkalosis

- Hypoglycemia
- Prerenal azotemia
- Urinalysis
- Amylase/lipase
- Liver profile, if malignancy suspected
- *H. pylori*, if PUD suspected

Imaging

- Plain abdominal radiographs (obstructive series):
 - Often nondiagnostic
 - Dilated stomach or absence of air in bowel distally may be suggestive
- Abdominal US in pediatric patients:
 - No ionizing radiation
 - Elongated hypertrophic pyloric sphincter
- Abdominal CTs are often very helpful for detecting neoplastic, intraluminal, and extraluminal causes of obstruction.
 - Likely to be most commonly used modality in adults
 - Radiation load is especially undesirable in pediatric population; ultrasound and fluoroscopic UGI series are preferred initial approaches

Diagnostic Procedures/Surgery

- Upper GI series:
 - To demonstrate site and character of obstruction
 - “String sign,” “double track sign,” “beak sign,” “shoulder sign” are characteristic findings in pyloric stenosis
- Upper endoscopy:
 - To visualize gastric interior, gastric outlet, proximal duodenum

DIFFERENTIAL DIAGNOSIS

- Proximal bowel obstruction
- Exacerbation of PUD
- Gastroenteritis
- Cholelithiasis
- Cholecystitis
- Acute pancreatitis
- Diabetic gastroparesis
- Psychogenic vomiting

TREATMENT

PRE HOSPITAL

- Vital signs, airway stabilization, oxygen administration, IV access

- Fluid resuscitation if dehydrated, vomiting

INITIAL STABILIZATION/THERAPY

- 0.9% NS IV fluid resuscitation significant volume losses:
 - _ Adults: 1 L bolus
 - _ Peds: 20 mL/kg bolus
- Correction of electrolyte abnormalities, especially hypokalemia

ED TREATMENT/PROCEDURES

- Nasogastric tube (NGT)
- Foley catheter to monitor urine output
- Surgical consultation/intervention:
 - _ Endoscopic balloon dilatation of benign strictures
 - _ Enteral stent placement (malignant causes)
 - _ Gastrojejunostomy (malignant causes)
 - _ Vagotomy and antrectomy or pyloroplasty or gastrojejunostomy or other variation (benign causes)

MEDICATION

- Famotidine: Adults: 20 mg (peds: 0.6–0.8 mg/kg/24 h div. q6–8h) IV q12h *or*
- Ranitidine: 50 mg (peds: 2–4 mg/kg/24 h div. q6–8h) IV q8h
- Pantoprazole: Adults: 40 mg IV (also *H. pylori* treatment as needed)

FOLLOW-UP

DISPOSITION

Admission Criteria

Most patients with gastric outlet obstruction will be admitted for fluid resuscitation, electrolyte repletion, gastroenterologic, and surgical evaluation.

Discharge Criteria

Rarely, patients may be considered for discharge if:

- Symptoms of abdominal pain, vomiting have resolved
- Evaluated and cleared by surgeon or gastroenterologist during presentation
- Lab parameters, imaging, and patient's volume status are normal

Issues for Referral

Surgical and gastroenterology consultations

FOLLOW-UP RECOMMENDATIONS

Any discharged patient should follow up with surgeon and/or gastroenterologist:

- [Specific instructions to return if symptoms recur](#)

PEARLS AND PITFALLS

- [Misdiagnosing symptoms of gastric outlet obstruction as gastroenteritis](#)
- [Failure to appreciate limitations of plain radiographs in diagnosing this condition](#)
- [Failure to consider gastric outlet obstruction and malignancy in patient with epigastric pain and vomiting](#)
- [Failure to adequately fluid resuscitation of patients, especially elderly or pediatric patients](#)

ADDITIONAL READING

CODES

ICD9

537.0 Acquired hypertrophic pyloric stenosis

ICD10

K31.1 Adult hypertrophic pyloric stenosis

GASTRITIS

Yanina Purim-Shem-Tov

BASICS

DESCRIPTION

- Inflammatory response of gastric mucosa to injury—“gastritis”
- 3 lines of defense of gastric mucosa:
 - Mucous layer that forms protective pH gradient
 - Surface epithelial cells that can repair small defects
 - Postepithelial barrier that neutralizes any acid that has traversed 1st 2 layers
- No definite link between histologic gastritis and dyspeptic symptoms
- Epithelial cell damage with no associated inflammation—“gastropathy”

ETIOLOGY

- Common causes of gastritis: Infections, autoimmune, drugs (i.e., cocaine), hypersensitivity, stress
- Common causes of gastropathy: Endogenous or exogenous irritants, such as bile reflux, alcohol, or aspirin and NSAIDs, ischemia, stress, chronic congestion
- Acute gastritis:
 - Stress (sepsis, burns, trauma):
 - Decrease in splanchnic blood flow leading to decreased mucus production, bicarbonate secretion, and prostaglandin synthesis
 - Results in mucosal erosions and hemorrhage
 - Alcohol:
 - Induces production of leukotrienes that cause microvascular stasis, engorgement, and increased vascular permeability
 - Leads to hemorrhage
 - NSAIDs, including aspirin:
 - Interfere with prostaglandin synthesis, leading to similar cascade as induced by alcohol
 - Results in mucosal erosions
 - Steroids
- Chronic gastritis:
 - Produced by *Helicobacter pylori*
 - Mechanism of *H. pylori* unclear:
 - Gram-negative spiral bacteria found in gastric mucous layer
 - Contains enzyme urease that allows it to change pH level (alkaline) of its microenvironment

SIGNS AND SYMPTOMS

- Dyspepsia
- Bloating
- Nausea/vomiting
- Anorexia
- Epigastric tenderness
- Heartburn

History

- Dyspepsia
- Epigastric pain or discomfort (episodic and chronic)
- Bloating, indigestion, eructation, flatulence, and heartburn
- Anorexia, nausea/vomiting
- Hematemesis, melena

Physical-Exam

- Careful physical exam including stool Hemoccult testing and vital signs with orthostatics
- Dehydration, tachycardia (with vomiting)
- Pallor (hemorrhagic gastritis)
- Abdominal exam
- Nonspecific
- Epigastric tenderness

ESSENTIAL WORKUP

- ABCs
- Hematocrit determination
- Evaluation for dehydration/shock

DIAGNOSIS TESTS & INTERPRETATION***Lab***

- Normal lab values in uncomplicated gastritis
- CBC:
 - Anemia with acute hemorrhagic gastritis
 - Leukocytosis: Infection
- Electrolytes, BUN, creatinine, glucose
- Amylase/lipase for pancreatitis in differential
- Urinalysis:
 - Assess dehydration/ketosis (starvation)

- Bilirubin present with hepatitis

Diagnostic Procedures/Surgery

- ECG:
 - For elderly patients
 - Myocardial ischemia in differential
- Endoscopy:
 - Outpatient unless significant hemorrhage
 - Allows for visualization of bleeding sites, histologic confirmation of mucosal inflammation, and detection of *H. pylori*
- Noninvasive *H. pylori* testing:
 - ¹³C and ¹⁴C urea breath tests
 - Stool antigen test
 - Serology to detect antibodies to *H. pylori*
 - Serum pepsinogen isoenzymes
 - The ratio of pepsinogen isozymes I and II in serum correlates with presence of metaplastic atrophic gastritis (principally autoimmune metaplastic atrophic gastritis and pernicious anemia)

DIFFERENTIAL DIAGNOSIS

- Peptic ulcer disease (PUD)
- Nonulcer dyspepsia (symptoms without ulcer on endoscopy)
- Gastroesophageal reflux
- Biliary colic
- Cholecystitis
- Pancreatitis
- Hepatitis
- Abdominal aortic aneurysm
- Aortic dissection
- Myocardial infarction

TREATMENT

PRE HOSPITAL

- ABCs
- IV fluid resuscitation

INITIAL STABILIZATION/THERAPY

- ABCs with acute erosive or hemorrhagic gastritis that presents with hemodynamic instability
- IV fluid resuscitation with lactated Ringer solution or 0.9% normal saline (NS) via 2 large-bore catheters

- NGT for gastric decompression and lavage when history of hematemesis or unstable vital signs
- Foley catheterization to assess volume replacement

ED TREATMENT/PROCEDURES

- Pain control with:
 - Antacids
 - GI cocktail:
 - 30 mL antacids + 10–20 mL viscous lidocaine
 - H₂ antagonists
 - Proton pump inhibitors (PPIs)
 - Sucralfate
 - Avoid narcotics—may mask serious illness
- Acute hemorrhagic gastritis:
 - IV fluid resuscitation
 - Blood transfusion if low hematocrit
 - Reverse causes (alcohol, sepsis, NSAIDs, or trauma)
 - Prevent *acute* or *erosive* gastritis in critically ill:
 - Antacids hourly or IV PPI or H₂ antagonists
 - Goal is to keep pH level at >4
- Chronic gastritis—*H. pylori* therapy:
 - Treatment of *H. pylori* infection:
 - Invasive or noninvasive testing to confirm infection
 - Oral (PO) eradication antibiotic therapy options
 - Most common therapies for *H. pylori* infection:
 - PPI (omeprazole 20 mg or lansoprazole 30 mg), clarithromycin 500 mg BID for 2 wk, amoxicillin 1 g BID for 2 wk.
 - For penicillin-allergic patients: PPI + clarithromycin 500 mg BID + metronidazole 500 mg BID for 14 days
 - 4-drug therapy: H₂ blocker, bismuth subsalicylate (Pepto-Bismol) + either amoxicillin 1,000 mg BID or tetracycline 500 mg QID in combination with either metronidazole 250 mg QID or clarithromycin 500 mg BID for 14 days
 - Drug resistance in US:
 - Metronidazole: 30–48%
 - Clarithromycin: >10%
 - Amoxicillin: Uncommon
 - Bismuth: None
 - Treatment controversial for asymptomatic or nonulcer dyspepsia gastritis
- Vitamin B₁₂ supplementation for *atrophic gastritis*

MEDICATION

- Bismuth subsalicylate: 525 mg tabs 2 PO QID not to exceed 8 doses in 24 hr
- Cimetidine (H₂ blocker): 800 mg PO at bedtime nightly (peds: 20–40 mg/kg/24 h) for 6–8 wk
- Famotidine (H₂ blocker): 40 mg PO at bedtime nightly (peds: 0.5–0.6 mg/kg q12h) for 6–8 wk
- Lansoprazole (PPI): 30 mg PO BID for 2 wk
- Maalox Plus: 2–4 tablets PO QID
- Misoprostol: 100–200 µg PO QID
- Mylanta II: 2–4 tablets PO QID
- Nizatidine (H₂ blocker): 300 mg PO at bedtime nightly for 6–8 wk
- Omeprazole (PPI): 20 mg PO BID (peds: 0.6–0.7 mg/kg q12–24 h) for 2 wk
- Pantoprazole (PPI): 40 mg PO/IV daily for 2 wk
- Ranitidine (H₂ blocker): 300 mg PO at bedtime nightly (peds: 5–10 mg/kg/24 h given q12h) for 6–8 wk
- Sucralfate: 1 g PO QID for 6–8 wk

First Line

- Triple therapy using a PPI with clarithromycin and amoxicillin or metronidazole given twice daily remains the recommended 1st choice treatment.
- Sequential 10-day therapy in high prevalence areas:
 - Double therapy for 5 days:
 - PPI
 - Amoxicillin
 - Followed by triple therapy for 5 days:
 - PPI
 - Clarithromycin
 - Metronidazole

Second Line

- Bismuth-based quadruple therapies remain the best 2nd choice treatment.
- The rescue treatment should be based on antimicrobial susceptibility testing.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Acute hemorrhagic or erosive gastritis that presents with upper GI tract bleeding, tachycardia, and hypotension
- Uncontrolled pain or vomiting
- Coagulopathy from medication or liver disease

Discharge Criteria

- Unremarkable physical exam with normal CBC and heme-negative stools
- If heme-positive stools, discharge if stable vital signs, normal hematocrit, and negative NGT aspiration for upper GI tract hemorrhage:
 - Outpatient evaluation for endoscopy

Issues for Referral

- Outpatient referral for endoscopy and *H. pylori* testing
- Biopsy for gastric dysplasia and malignancy

FOLLOW-UP RECOMMENDATIONS

Close follow-up with gastroenterologist for endoscopy with biopsy for diagnostic reasons.

PEARLS AND PITFALLS

- Gastritis/gastropathy is a common presentation to ED.
- Symptoms typically are dyspepsia, nausea, and vomiting.
- ED management depends on patient's clinical symptoms, but should include diagnostic and therapeutic components.
- Therapeutic management usually involves treatment of *H. pylori*.
- Drug resistance of *H. pylori* to antibiotics is increasing.
- Close follow-up with gastroenterologist recommended for biopsy and to detect gastric cancers.

- K29.20 Alcoholic gastritis without bleeding
- K29.70 Gastritis, unspecified, without bleeding

GASTROENTERITIS

Isam F. Nasr

BASICS

DESCRIPTION

Inflammation of stomach and intestines associated with diarrhea and vomiting; often the result of infectious or toxin exposure.

ETIOLOGY

Infectious

- **Viruses:**
 - 50–70% of all cases with Norovirus cases on the rise in travelers returning from Mexico and India.
- **Invasive bacteria:**
 - *Campylobacter*: Contaminated food or water, wilderness water, birds, and animals:
 - Most common cause
 - Gross or occult blood is found in 60–90%.
 - *Salmonella*: Contaminated water, eggs, poultry, or dairy products:
 - *Typhoid fever (Salmonella typhi)* characterized by unremitting fever, abdominal pain, rose spots, splenomegaly, and bradycardia
 - Immunocompromised susceptible
 - *Shigella*: Fecal–oral route
 - *Vibrio parahaemolyticus*: Raw and undercooked seafood
 - *Yersinia*: Contaminated food (pork), water, and milk:
 - May present as mesenteric adenitis or mimic appendicitis
 - Specific food-borne disease (food poisoning):
 - *Staphylococcus aureus*:
 - Most common toxin-related disease
 - Symptoms within 1–6 hr after ingesting food
 - *Bacillus cereus*:
 - Classic source is fried rice left on steam tables.
 - Symptoms within 1–36 hr
 - Cholera: Profuse watery stools with mucous (rice-water stools)
 - Ciguatera:
 - Fish intoxication
 - Onset 5 min–30 hr (average 6 hr) after ingestion
 - Paresthesias, hypotension, peripheral muscle weakness
 - Amitriptyline may be therapeutic.

- Scombroid:
 - Caused by blood fish: Tuna, albacore, mackerel, and mahi-mahi
 - Flushing, headache, erythema, dizziness, blurred vision, and generalized burning sensation
 - Symptoms last < 6 hr.
 - Treatment includes antihistamines.
- Protozoa:
 - *Giardia lamblia*:
 - High-risk groups: Travelers, day care children, homosexual men, and campers who drink untreated mountain water

Noninfectious Causes

- Toxins:
 - Zinc, copper, cadmium
 - Organic chemicals: Polyvinyl chlorides
 - Pesticides: Organophosphates
 - Radioactive substances
 - Alkyl mercury
- Altered host response to food substance (tyramine, monosodium glutamate, tryptamine)

Pediatric Considerations

- Focus evaluation on state of hydration
- Most of viral origin and self-limited
- Rotavirus accounts for up to 50%
- *Shigella* infections associated with seizures

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Nausea, vomiting, diarrhea
- Bloody/mucous diarrhea
- Abdominal cramps or pain
- Fever
- Malaise, myalgias, headache, anorexia
- Hypotension, lethargy, and dehydration (severe cases)

Physical-Exam

- Dry mucous membranes
- Tachycardia

- Abdominal tenderness
- Perianal inflammation, fissure, fistula

ESSENTIAL WORKUP

- Digital rectal exam to determine presence of gross or occult blood
- Fecal leukocyte determination:
 - Present with invasive bacteria
 - Absent in protozoal infections, viral, toxin-induced food poisoning

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC indications:
 - Significant blood loss
 - Systemic toxicity
- Electrolytes, glucose, BUN, creatinine—indications:
 - Lethargy, significant dehydration, toxicity, or altered mental status
 - Diuretic use, persistent diarrhea, chronic liver or renal disease
- Stool culture indications:
 - Presence of fecal leukocytes
 - Historical markers (immunocompromised, travel, homosexual)
 - Public health (food handler, day/health care worker)
- Blood culture indications:
 - Suspected bacteremia or systemic infections
 - Ill patients requiring admission
 - Immunocompromised
 - Elderly patients and infants

Imaging

Abdominal radiographs have no value unless obstruction or toxic megacolon suspected.

Pediatric Considerations

- Lab studies not required in most cases
- Rotazyme assay detects rotavirus:
 - Rarely indicated in managing outpatients
 - Helpful to cohort and avoid cross-contamination among inpatients
- Stool culture indication:
 - Fecal leukocytes
 - Toxic
 - Infants
 - Immunocompromised

DIFFERENTIAL DIAGNOSIS

- Gastritis/peptic ulcer disease
- Milk and food allergies
- Appendicitis
- Irritable bowel syndrome
- Ulcerative colitis/Crohn's disease
- Malrotation with midgut volvulus
- Meckel diverticulum
- Drugs and toxins:
 - Mannitol
 - Sorbitol
 - Phenolphthalein
 - Magnesium-containing antacids
 - Quinidine
 - Colchicine
 - Mushrooms
 - Mercury poisoning

TREATMENT

PRE HOSPITAL

- Difficult IV access with severe dehydration.
- Avoid exposure to contaminated clothes or body substances.

INITIAL STABILIZATION/THERAPY

- Management of ABCs
- IV fluid with 0.9% NS resuscitation for severely dehydrated

ED TREATMENT/PROCEDURES

- Oral fluids for mild dehydration (Gatorade/Pedialyte)
- IV fluids for:
 - Hypotension, nausea and vomiting, obtundation, metabolic acidosis, significant hypernatremia, or hyponatremia
 - 0.9% NS bolus (adults: 500 mL–1 L, peds: 20 mL/kg) for resuscitation, then 0.9% NS or D₅ 0.45% peds: NS (peds: D₅ 0.25% NS) to maintain adequate urine output
- Bismuth subsalicylate (Pepto-Bismol):
 - Antisecretory agent
 - Effective clinical relief without adverse effects
- Kaolin–pectin (Kaopectate):
 - Reduces fluidity of stools
 - Does not influence course of disease
- Antimotility drugs (diphenoxylate [Lomotil], loperamide [Imodium], paregoric,

and codeine):

- Appropriate in noninfectious diarrhea
- Initial use of sparse amounts to control symptoms in infectious diarrhea
- Avoid prolonged use in infectious diarrhea—may increase duration of fever, diarrhea, and bacteremia and may precipitate toxic megacolon.
- Antibiotics for infectious pathogens:
 - *Campylobacter*: Quinolones or erythromycin
 - *Salmonella*: Quinolones or trimethoprim–sulfamethoxazole (TMP–SMX)
 - Typhoid fever: Ceftriaxone
 - *Shigella*: Quinolone, TMP–SMX, or ampicillin
 - *V. parahaemolyticus*: Tetracycline or doxycycline
 - *Clostridium difficile*: Metronidazole or vancomycin
 - *Escherichia coli*: Quinolones or TMP–SMX
 - *Giardia lamblia*: Metronidazole
- Antiemetics for nausea/vomiting:
 - Ondansetron
 - Prochlorperazine
 - Promethazine

MEDICATION

- Ampicillin: 500 mg (peds: 20 mg/kg/24 h) PO or IV q6h
- TMP–SMX; Bactrim DS: 1 tab (peds: 8–10 mg TMP/40–50 mg SMX/kg/24 h) PO BID
- Ceftriaxone: 1 g (peds: 50–75 mg/kg/12 h) IM or IV q12h
- Ciprofloxacin (quinolone): 500 mg PO or 400 mg IV BID (> 18 yr)
- Doxycycline: 100 mg PO or 400 mg IV BID
- Metronidazole: 250 mg (peds: 35 mg/kg/24 h) PO TID (> 8 yr)
- Ondansetron 4 mg (peds: 0.1 mg/kg) IV
- Prochlorperazine (Compazine): 5–10 mg IV q3–4h; 10 mg PO q8h; 25 mg per rectum (PR) q12h
- Promethazine (Phenergan): 25 mg IM/IV q4h; 25 mg PO/PR (peds: 0.25–1 mg/kg PO/PR/IM)
- Tetracycline: 500 mg PO or IV QID
- Vancomycin 125–500 mg (peds: 40 mg/kg/24 h) PO q6h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Hypotension unresponsive to IV fluids
- Significant bleeding

- Signs of sepsis/toxicity
- Intractable vomiting or abdominal pain
- Severe electrolyte imbalance
- Metabolic acidosis
- Altered mental status
- Children with > 10–15% dehydration

Discharge Criteria

- Mild cases requiring oral hydration
- Dehydration responsive to IV fluids

Issues for Referral

Cases of prolonged symptoms may be referred to a gastroenterologist for further workup.

FOLLOW-UP RECOMMENDATIONS

Most cases are self-limiting; therefore, follow-up is optional.

PEARLS AND PITFALLS

- Viruses account for over 50% of cases
- Avoid antimotility drugs in cases due to infectious pathogens.
- TMP–SMX (Bactrim DS), ciprofloxacin, doxycycline, and tetracycline are contraindicated in pregnancy. Metronidazole may be used during the 3rd trimester.

- A09 Infectious gastroenteritis and colitis, unspecified
- K52.9 Noninfective gastroenteritis and colitis, unspecified

GASTROESOPHAGEAL REFLUX DISEASE

Yanina Purim-Shem-Tov

BASICS

DESCRIPTION

- Spectrum of pathology in which gastric reflux causes symptoms and damage to esophageal mucosa
- Reflux esophagitis vs. nonerosive reflux disease
- 40% of general population experience symptoms monthly

ETIOLOGY

- Incompetent reflux barrier allowing increase in frequency and duration of gastric contents into esophagus
- Lower esophageal sphincter (LES):
 - Main antireflux barrier
 - Crural diaphragm attachment (diaphragmatic sphincter)
 - Contributes to pressure barrier at gastroesophageal junction
 - Esophageal acid clearance via peristalsis and esophageal mucosal resistance are additional barriers.
 - Most healthy individuals have brief episodes of reflux without symptoms.
- Transient lower esophageal sphincter relaxations (TLESRs):
 - Occur with higher frequency in gastroesophageal reflux disease (GERD) patients
 - Exposed esophageal mucosa becomes acidified and with time necroses
- Decreased LES tone:
 - Smoking
 - Foods: Alcohol, chocolate, onion, coffee, tea
 - Drugs: Calcium channel blockers, morphine, meperidine, barbiturates, theophylline, nitrates
- Delayed gastric emptying, increased body mass, and gastric distention contribute to reflux
- Hiatal hernias associated with GERD:
 - Significance varies in any given individual
 - Most persons with hiatal hernias do not have clinically evident reflux disease
- Acid secretion is same in those with or without GERD
- Associated medical conditions: Pregnancy, chronic hiccups, cerebral palsy, Down syndrome, autoimmune diseases, diabetes mellitus (DM), hypothyroidism

DIAGNOSIS

SIGNS AND SYMPTOMS

- Esophageal manifestations
 - Heartburn (or pyrosis)
 - Regurgitation
 - Dysphagia
- Extraesophageal manifestations
 - Bronchospasm
 - Laryngitis
 - Chronic cough

History

- Typical signs and symptoms:
 - Heartburn (pyrosis):
 - Retrosternal burning pain
 - Radiates from epigastrium through chest to neck and throat
 - Dysphagia:
 - Dysphagia suggests esophageal spasm or stricture.
 - Odynophagia:
 - Odynophagia suggests ulcerative esophagitis.
 - Regurgitation
 - Water brash
 - Belching
 - Esophageal strictures, bleeding
 - Barrett esophagus (esophageal carcinoma)
 - Early satiety, nausea, anorexia, weight loss
 - Symptoms worse with recumbence or bending over
 - Symptoms usually relieved with antacids, although temporarily
- Atypical signs and symptoms:
 - Noncardiac chest pain
 - Asthma
 - Persistent cough, hiccups
 - Hoarseness
 - Pharyngeal/laryngeal ulcers and carcinoma
 - Frequent throat clearing
 - Recurrent pneumonitis
 - Nocturnal choking
 - Upper GI tract bleeding

Physical-Exam

- Nonspecific, may have some epigastric tenderness.
- Symptoms worsen with placing patient flat on the bed or Trendelenburg position

Pediatric Considerations

- Regurgitation is common in infants:
 - Incidence decreases from twice daily in 50% of those age 2 mo to 1% of 1-yr-olds.
- Signs:
 - Frequent vomiting, irritability, cough, crying, and malaise
 - Arching the body (hyperextension) at feeding and refusals of feedings
- Failure to thrive
- Formula intolerance
- Sepsis

ESSENTIAL WORKUP

- Differentiate GERD from more emergent conditions such as ischemic heart pain, esophageal perforation, or aortic pathology.
- Obtain typical history
- Perform thorough physical exam: Vital signs, head, ears, eyes, nose, throat (HEENT), chest and abdominal exams

DIAGNOSIS TESTS & INTERPRETATION

No gold standard

Lab

- CBC:
 - Chronic anemia from esophagitis
- Stool testing for occult bleeding

Imaging

- No routine Imaging
- Chest radiograph:
 - Evidence of esophageal perforation, hiatal hernia, aortic disease

Diagnostic Procedures/Surgery

- Diagnostic trial of antacid:
 - Those with persistent symptoms should be referred for endoscopy
 - 90% of GERD patients respond to proton pump inhibitor (PPI) therapy
- Barium esophagram for prominent dysphagia
- Esophageal pH monitoring:
 - Correlate symptoms to acid reflux
- Esophageal manometry (poor sensitivity):
 - Evaluate LES resting pressure and esophageal peristaltic contractions
- Esophagogastroduodenoscopy (EGD)—detects reflux esophagitis and complications (Barrett esophagus, hiatal hernia, stricture, ulcers, malignancy)

DIFFERENTIAL DIAGNOSIS

- Ischemic heart disease
- Asthma
- Peptic ulcer disease
- Gastritis
- Hepatitis/pancreatitis
- Esophageal perforation
- Esophageal foreign body
- Esophageal infection
- Cholecystitis/cholelithiasis
- Mesenteric ischemia

TREATMENT

PRE HOSPITAL

- Esophageal pain may mimic angina
- Airway may need active control secondary to vomiting

INITIAL STABILIZATION/THERAPY

- ABCs need to be evaluated
- IV fluid resuscitation for blood loss or shock

ED TREATMENT/PROCEDURES

- Symptomatic relief:
 - Antacids
 - Antacids with viscous lidocaine
 - Sublingual nitroglycerine for esophageal spasm
 - Analgesics
- Lifestyle modifications:
 - Avoid late-night or heavy/fatty meals.
 - Minimize time in supine position after eating.
 - Elevation of head of bed
 - Weight loss
 - Eliminate smoking and alcohol intake
 - Avoid direct esophageal irritants such as citric juices and coffee
 - Avoid foods that decrease LES pressures such as fatty foods, chocolate, and coffee
 - Avoid drugs that lower LES tone
- PPIs:
 - More potent long-acting inhibitors of gastric acid secretion than H₂-blockers
 - Faster healing than other drug therapies
 - More efficacious in severe GERD and frank esophagitis

- H₂-blockers:
 - Effective for mild to moderate disease
 - Severe disease requires greater dosage than that used for peptic ulcer disease
- Antacids (Maalox, Mylanta):
 - Treatment of mild and infrequent reflux symptoms
 - Not effective for healing esophagitis
 - Alginic acid slurry floats on surface of gastric contents, providing mechanical barrier
- Sucralfate:
 - Binds to exposed proteins on surface of injured mucosa to form protective barrier
 - May also directly stimulate mucosal repair
- Metoclopramide (prokinetic drug):
 - Improves peristalsis
 - Accelerates gastric emptying
 - Increases LES pressure
- Drugs that modify TLESR
 - Baclofen
 - ADX10059
- Endoscopic therapy:
 - Suturing (plication), thermal injury, chemical injection
- Antireflux surgery (goal: Increase LES pressure):
 - Chronic reflux, younger patients, nonhealing ulceration, severe bleeding
 - Fundoplication can be more effective than medical therapy in selected cases
 - Currently newer incisionless procedure called transoral incisionless fundoplication available

Pregnancy Considerations

- Reflux present in 30–50% of pregnancies
- Increased intra-abdominal pressure, hormonal fluctuations lead to increased TLESRs
- EGD reserved for severe presentations
- H₂-blockers—1st-line therapy (longer safety record)
- PPIs—limited safety history in pregnancy

MEDICATION

- Antacids: 30 mL + viscous lidocaine, 10 mL, PO q6h
- Cimetidine: 400 mg PO BID, 300 mg IM/IV q6–8h
- Esomeprazole: 20–40 mg PO daily
- Famotidine: 20 mg PO/IV BID (peds: 0.5–1 mg/kg/d div. q8–12h, max. 40 mg/d)
- Lansoprazole: 15–30 mg daily

- Metoclopramide: 10–15 mg PO/IV/IM q6h before meals and nightly at bedtime
- Nizatidine: 150 mg PO BID
- Omeprazole: 20–40 mg PO daily
- Pantoprazole: 40 mg PO/IV daily
- Rabeprazole: 20 mg PO daily
- Ranitidine: 150 mg (peds: 5–10 mg/kg q12h) PO BID or 300 mg PO nightly at bedtime
- Sucralfate: 1 g PO 1 hr before meals and nightly at bedtime

First Line

- Life style modifications:
 - Head of bed elevation
 - Dietary modification
 - Refraining from assuming a supine position after meals
 - Avoidance of tight-fitting garments
 - Promotion of salivation by either chewing gum
 - Restriction of alcohol use
 - Reduction of obesity
- Acid-suppressive medications:
 - PPI or H₂ blocker
- Treatment of *H. pylori* infections

Second Line

- Prokinetic drugs (bethanechol, metoclopramide)
- Drugs that inhibit TLESRs (baclofen)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Significant esophageal bleeding
- Uncontrolled reactive asthma
- Dehydration
- Starvation and failure to thrive

Discharge Criteria

Uncomplicated GERD: Refer to patient's primary care physician (PCP) or gastroenterologist for further evaluation.

Issues for Referral

Extraesophageal manifestations such as asthma, laryngitis.

FOLLOW-UP RECOMMENDATIONS

Gastroenterologist for endoscopy in patients who require continuous maintenance medical therapy to rule out Barrett esophagus.

PEARLS AND PITFALLS

- GERD therapy should include lifestyle changes.
- In patients with worse than mild and intermittent GERD symptoms initiate acid-suppressive therapy.
- In patients with GERD and moderate to severe esophagitis, provide acid suppression with a PPI rather than H₂ blockers.
- Endoscopy for patients who fail chronic therapy (at least 8 wk).
- Antireflux surgery for patients on high doses of PPIs, specially in young patients who may require lifelong therapy.
- Complications of GERD
 - Esophagitis
 - Peptic stricture and Barrett metaplasia
 - Extraesophageal manifestations of reflux: Asthma, laryngitis, and cough.

CODES

ICD9

- 530.11 Reflux esophagitis
- 530.81 Esophageal reflux

ICD10

- K21 Gastro-esophageal reflux disease
- K21.0 Gastro-esophageal reflux disease with esophagitis
- K21.9 Gastro-esophageal reflux disease without esophagitis

GASTROINTESTINAL BLEEDING

Czarina E. Sánchez • Leon D. Sánchez

BASICS

DESCRIPTION

- Bleeding from GI tract:
 - Upper GI tract: Proximal to ligament of Treitz
 - Lower GI tract: Distal to ligament of Treitz to anus
- Mortality rate:
 - 10% overall; from <5% in children up to 25% for adults of age >70
 - Upper GI bleed (UGIB) 6–8%; variceal 30–50%
 - Lower GI bleed (LGIB) 2–4%

ETIOLOGY

Upper Gi Bleed (UGIB):

- Ulcerative disease of upper GI tract:
 - Peptic ulcer disease (40%):
 - *Helicobacter pylori* infection
 - Drug-induced (NSAIDs, aspirin, glucocorticoids, K⁺ supplements, Fe supplements)
 - Gastric or esophageal erosions (25%):
 - Reflux esophagitis
 - Infectious esophagitis (*Candida*, HSV, CMV)
 - Pill-induced esophagitis
 - Esophageal foreign body
 - Gastritis and stress ulcerations:
 - Toxic agents (NSAIDs, alcohol, bile)
 - Mucosal hypoxia (trauma, burns, sepsis)
 - Cushing ulcers from severe CNS damage
 - Chemotherapy
- Portal HTN:
 - Esophageal or gastric varices (10%)
 - Portal hypertensive gastropathy
- Arteriovenous malformations:
 - Aortoenteric fistula (s/p aortoiliac surgery)
 - Hereditary hemorrhagic telangiectasia (Osler—Weber—Rendu syndrome)
 - Dieulafoy vascular malformations
 - Gastric antral vascular ectasia (GAVE or watermelon stomach)
 - Idiopathic angiomas

- Mallory–Weiss tear (5%)
- Gastric and esophageal tumors
- Pancreatic hemorrhage
- Hemobilia
- *Strongyloides stercoralis* infection

Lower Gi Bleed (LGIB):

- Diverticulosis (33%)
- Cancer or polyps (19%)
- Colitis (18%):
 - Ischemic, inflammatory, infectious, or radiation
- Vascular:
 - Angiodysplasia (8%)
 - Radiation telangiectasia
 - Aortocolonic fistula
- Inflammatory bowel disease:
 - Crohn's disease and ulcerative colitis
- Postpolypectomy
- Anorectal (4%):
 - Hemorrhoids (internal and external)
 - Anal fissures
 - Anorectal varices
 - Rectal ulcer
 - Foreign body

Pediatric Considerations

Meckel diverticulum and intussusception are the most common causes of LGIB in children.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Both UGIB and LGIB may present with signs/symptoms of hypovolemia
- UGIB classic presentation:
 - Hematemesis or coffee ground emesis
 - Melena: Black tarry stool
- LGIB classic presentation:
 - Hematochezia: Bright red or maroon stool

ALERT
Hematochezia classically signals an LGIB, but can also be seen with brisk UGIB.

History

- Hematemesis and melena most common
- Coffee ground emesis
- Black stools
- Bright red blood per rectum
- Abdominal pain
- Weakness or lightheadedness
- Dyspnea
- Confusion or agitation

Physical-Exam

- Tachycardia
- Hypotension
- Pale conjunctiva
- Dry mucous membranes
- Bloody, melanotic, or heme-positive stools
- Shock

ESSENTIAL WORKUP

- CBC, coagulation studies, electrolytes
- Perform ENT exam. Distinguish between hemoptysis and hematemesis:
 - Pulmonary source:
 - Bright red and frothy in appearance
 - Sputum mixed with blood is likely pulmonary
 - pH >7
 - GI source:
 - Dark red/brown blood, ± gastric contents
 - Associated with nausea/vomiting
 - pH <7
- Consider nasogastric lavage:
 - Might help determine if bleeding is ongoing and facilitate endoscopy
 - Controversial studies have failed to demonstrate outcome benefit. False-negatives, if bleeding beyond pylorus.
- Rectal exam:
 - Inspect for hemorrhoids and anal fissures
 - Examine stool color
 - False-positive Hemocult result:
 - Raw red meat
 - Iron supplements
 - Fruits: Cantaloupe, grapefruit, figs
 - Vegetables: Raw broccoli, cauliflower, radish
 - Methylene blue, chlorophyll
 - Iodide, bromide

- False-negative Hemoccult result:
 - Bile
 - Mg-containing antacids
 - Ascorbic acid
- Agents causing black stools, but negative Hemoccult:
 - Iron
 - Charcoal
 - Bismuth (i.e., Pepto-Bismol)
 - Food dyes
 - Beets

Pediatric Considerations

Bloody stool in newborns may be caused by the infant swallowing maternal blood.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - Anemia (low mean corpuscular volume seen with chronic blood loss)
 - Thrombocytopenia
- Electrolytes, BUN, creatinine, glucose
- Coagulation profile
- Lactate
- LFTs, if upper GI bleeding suspected
- Type and screen/cross for active bleeding or unstable vital signs
- BUN/Cr ratio > 36 has a high sensitivity but low specificity for UGIB

ALERT

Hematocrit can remain normal for a period after acute blood loss; a drop may not be immediately seen.

Imaging

- Upright CXR if concern for aspiration or perforation
- Angiography/arterial embolization:
 - Effective for identifying large, active bleeding
- Radionucleotide (tagged red blood cell) scan:
 - Effective for identifying slow, active bleeding

Diagnostic Procedures/Surgery

- Anoscopy:
 - For suspected internal hemorrhoids or fissures
- Esophagogastroduodenoscopy (EGD):
 - Diagnostic and possibly therapeutic

- Colonoscopy:
 - Diagnostic only
 - Best after adequate bowel prep
- Bowel resection:
 - Reserved for refractory bleeding

DIFFERENTIAL DIAGNOSIS

- Epistaxis
- Oropharyngeal bleeding
- Hemoptysis
- Hematuria
- Vaginal bleeding
- Visceral trauma

TREATMENT

PRE HOSPITAL

- Stabilize airway
 - Intubate for massive UGIB, if patient unable to protect airway
- Establish access
 - Insert large-bore IV (16–18g) and administer crystalloid to keep SBP > 90 mm Hg
 - Attempt 2nd IV line en route to hospital

INITIAL STABILIZATION/THERAPY

- Assess airway, breathing, and circulation
- Control airway in unstable patients, with massive bleeding, or unable to protect airway
- Initiate 2 large-bore (16 g) IVs and place on cardiac monitor
- Provide volume:
 - Administer 1 L NS bolus (peds: 20 mL/kg) and repeat once, if necessary
 - Transfuse RBCs if significant anemia or unstable after crystalloid boluses
 - Cross-matched or type-specific blood, if available
 - Otherwise, O negative for premenopausal women, O positive for others
 - Provide fresh frozen plasma (FFP) along with RBC transfusion in ratio of 1:2–4. For patients requiring massive transfusion, consider adding FFP and platelets in 1:1:1 ratio with RBCs
 - For coagulopathy, administer FFP and vitamin K (if INR > 1.5) and platelets (if platelets < 50,000/uL)

ED TREATMENT/PROCEDURES

- Consult gastroenterology for any significant GI bleeding

- Consider surgical consult and/or interventional radiology for massive active bleeding, unstable patient, or evidence of perforation
- Place Foley catheter to monitor urine output
- Consider nasogastric tube (NGT), as above
- Blood transfusion indications:
 - _ Significant anemia:
 - Hemoglobin <7 g/dL
 - Hemoglobin <10 g/dL when at increased risk of ischemia (e.g., CAD and CVA)
 - Evidence of end-organ ischemia
 - Ongoing chest pain/ischemic EKG changes
 - _ Unstable vital signs despite crystalloid bolus

ALERT

Avoid overtransfusion in variceal bleeding; it can precipitate further bleeding

- UGIB treatment
 - _ IV proton pump inhibitor (PPI) (e.g., pantoprazole)
 - _ Octreotide for suspected variceal bleeding
 - _ Consider vasopressin for active variceal bleeding:
 - Bleeding cessation benefits may be counterbalanced by increased mortality due to ischemia
 - Administer with IV nitroglycerin to reduce tissue ischemia
 - _ High risk for active bleeding with 2 out of 3 risk factors:
 - Bright blood from NGT
 - Hemoglobin <8 g/dL
 - WBC >12,000/uL
 - _ Emergent endoscopy
 - _ Therapeutic options:
 - Cauterization of bleeding ulcers/vessels
 - Endoscopic sclerotherapy
 - _ Balloon tamponade with Blakemore tube is a last resort for varices
 - _ In cirrhotics with UGIB prophylactic antibiotic use reduce bacterial infections and all cause mortality
- LGIB treatment
 - _ Consider angiography for massive, active bleeding with directed vasopressin infusion
 - _ Consider bowel resection for massive bleeding refractory to medical management

MEDICATION

- Pantoprazole: 80 mg (peds: Dosing not approved) IV bolus followed by an infusion of 8 mg/h for 72 hr
- Octreotide: 50 µg (peds: 1–2 µg/kg) bolus, then 50 µg/h (peds: 1–2 µg/kg/h) IV

- Somatostatin: 250 µg (peds: Not established) IV bolus and 250–500 µg/h for 2–5 days (not available in US)
- Vasopressin: 0.4–1 IU/min (peds: 0.002–0.005 IU/kg/min) IV
- Nitroglycerin: 10–50 µg/min (peds: Not established) IV
- Vitamin K: 10 mg (peds: 1–5 mg) PO/SC/IV q24h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Active bleeding
- Age > 65 or comorbid conditions
- Coagulopathy
- Decreased hematocrit
- Unstable vital signs at any time

Discharge Criteria

- Resolution of UGIB with negative nasogastric lavage and EGD
- Minor or resolved LGIB
- Stable hematocrit > 30 or hemoglobin > 10 g/dL
- Otherwise healthy patient

Issues for Referral

Consider referral to gastroenterologist for outpatient colonoscopy and/or EGD

FOLLOW-UP RECOMMENDATIONS

- Patients discharged from the ED should have close follow-up within 24–36 hr
- Give strict discharge instructions to return if further bleeding or other concerning symptoms (lightheadedness, dyspnea, chest pain, etc.) occur
- Patients with UGIB should be discharged on a PPI, and advised to avoid caffeine, alcohol, tobacco, NSAIDs, and aspirin

PEARLS AND PITFALLS

- 10–15% of UGIB present with hematochezia
- Consider GIB in patients presenting with signs of hypovolemia or hypovolemic shock
- Common pitfall: Failure to adequately resuscitate with crystalloid and blood products

Geriatric Considerations

PUD is the predominant cause of GIB in elderly and has a higher associated mortality.

- 535.51 Unspecified gastritis and gastroduodenitis, with hemorrhage
- 578.9 Hemorrhage of gastrointestinal tract, unspecified

ICD10

- K27.4 Chronic or unsp peptic ulcer, site unsp, with hemorrhage
- K29.71 Gastritis, unspecified, with bleeding
- K92.2 Gastrointestinal hemorrhage, unspecified

GERIATRIC TRAUMA

Charles W. O'Connell • Peter Witucki

BASICS

DESCRIPTION

- Geriatric specific considerations and approach to the elderly trauma patient
- Should be used in conjunction with the accepted standard treatment of traumatic injuries (see trauma, multiple)
- Advanced age is a known risk factor for adverse outcomes following trauma
- Generally age >65, age not well defined, difficult to target due to discrepancies between physiologic and chronologic age in individuals

EPIDEMIOLOGY

Incidence and Prevalence Estimates

ETIOLOGY

Most common mechanisms:

- Falls—most common cause of injury in patients of age >65, often occurs on an even, flat surface
- Motor vehicle crashes—2nd leading cause, most common fatal etiology
- Pedestrian—motor vehicle collisions, diminished cognitive skills, poor vision/hearing, impaired gait contribute to increased incidence
- Burns—higher fatality rate than young adults with same extent of burn
- Violence—less common mechanism than in younger ages, have heightened suspicion for elderly abuse, an under recognized issue
- Elderly more susceptible to serious injury from low-energy mechanisms

DIAGNOSIS

- Triage to major trauma center is determined by local protocols
- Injured patients with potential need for surgical, neurosurgical, or orthopedic intervention should be transferred to major trauma center
- Threshold for scene triage or transfer to trauma center should be lower for elderly

SIGNS AND SYMPTOMS

- The same pattern of assessment using primary survey (ABCDE) and secondary survey should be used with geriatric patients as with younger patients (see trauma, multiple)
- Normal vital signs can lead to false sense of security
 - Hypoperfusion often masked by inadequate physiologic response,

underlying medical pathology, and medication effects

Primary survey (ABCDE)

- Airway, cervical spine—establish and maintain a patent airway with C-spine immobilization
 - Anatomic variation in elderly can lead to more difficult airways (dentures, cervical arthritis, TMJ arthritis)
 - Failure to recognize indications for early intubation is a common mistake
- Breathing—maintain adequate and effective breathing and ventilation
 - Weakened respiratory muscles and degenerative changes in chest wall result in diminished effective ventilation
 - Blunted response to hypoxia, hypercarbia, and acidosis delays onset of clinical distress
 - Lower threshold to intubate elderly patients
- Circulation—ensure adequate perfusion
 - Vigilant hemodynamic monitoring, heart rate, and BP do not always correlate well with cardiac output
 - Geriatric patients often have impaired chronotropic response to hypovolemia
 - Cardiovascular response may be blunted by rate controlling meds (β -blockers, Calcium channel blockers)
 - Baseline hypertension, common in elderly, may obscure relative hypotension
 - Bleeding made worse by antiplatelet and anticoagulation medicines
- Disability—rapid neurologic evaluation to assess for intracranial and spinal cord injury
 - Brain atrophy may delay onset of clinical symptoms from compressive effects
 - Grave error to assume alterations in mental status due solely to underlying dementia or senility
- Exposure—patient should be undressed completely
- Secondary survey
 - After the primary survey has been completed
 - Stabilization at each level
 - Complete physical exam from head to toe

History

- The geriatric trauma patient should be viewed as both a trauma and a medical patient
- Elderly patients can have significant comorbidities, past medical history, medications, and allergies are essential
- Comorbid medical conditions may have precipitated the traumatic event
- Consider hypoglycemia, syncope, cardiac dysrhythmia, CVA, UTI, etc.
- Details of the mechanism, initial presentation, and treatment rendered should be

elicited from EMS personnel

- Concurrent medical conditions impede compensation, confound interpretation of severity and response, and complicate resuscitation.

Physical-Exam

Should follow primary and secondary surveys

DIAGNOSIS TESTS & INTERPRETATION

- Primary and secondary survey
- Cervical spine and chest imaging are mandatory for victims of major traumas
- Pelvic radiographs should be performed with clinical suspicion of pelvic trauma or with hemodynamic instability
- CBC, ABG, blood type
- Electrolytes, renal function, serum glucose
- Urine dip for blood, UA if dip shows positive result
- Coagulation profile
- Base deficit, lactate
- Ethanol screen

Imaging

- Liberal use of head CT is recommended for elderly with closed head trauma
- Nexus criteria has been validated in ages >65; however, cervical spine imaging needed in majority of geriatric traumas. CT scan emerging as study of choice for high suspicion, high-risk mechanism or age related changes likely to limit plain films
- Significant blunt and penetrating chest trauma requires objective evaluations of the heart and great vessels with echocardiography, CT scan, angiography, or direct visualization.
- Blunt abdominal trauma requires objective evaluation, modality depends on patient's condition
- Hemodynamically stable patients should have an abdominal CT with IV contrast
- Ensure adequate hydration and assess baseline renal function prior to contrast load when clinical status permits.
- Unstable patients should have FAST exam or diagnostic peritoneal lavage
- CT with contrast is a valuable diagnostic tool for abdominal trauma, but predispose to risk of contrast related renal impairment
- Extremity injury:
 - Radiographs
 - Suspected vascular damage requires angiography or duplex ultrasound

TREATMENT

PRE HOSPITAL

- Emphasis should be placed on airway maintenance, control of external bleeding and shock, immobilization, and immediate transfer to appropriate facility

INITIAL STABILIZATION/THERAPY

- Airway—take into account anatomical variations when establishing an airway
- Breathing
 - Continuous pulse oximetry and capnometry helpful
 - Administer supplemental oxygen to maintain oxygen saturation > 95%
 - Serial ABGs may provide early insight to respiratory function and reserve
 - Timely intubation in patients with ventilatory compromise and more severe injuries
 - Intubation indications: Respiratory rate > 40 breaths/min, PaO₂ is < 60 mm Hg or PaCO₂ > 50 mm Hg
 - Adequate analgesia of chest wall pain is essential for optimizing ventilation
- Circulation—severity of hemodynamic instability often underappreciated by clinicians
 - Serial crystalloid fluid boluses of 250–500 mL
 - Early invasive monitoring has been advocated, better assess need for volume loading and inotropic support
 - Geriatric patients can decompensate from overly aggressive volume replacement
 - Strong consideration for early and liberal use of red blood cell transfusion
 - Target hemoglobin level is controversial, but many authors recommend 10 g/dL
 - Recognize the harmful effects and complications of red blood cell transfusions
 - Blood viscosity, infection, and impairment of immune response
 - Serial base deficit and lactate levels provide good initial measures of shock and can guide resuscitation decisions
 - Creatinine clearance reduced in elderly
 - Kidneys more susceptible to injury from hypovolemia, medications, and nephrotoxins
- Disability:
 - Head Injury: Age is an independent risk factor for morbidity and mortality
 - Age-related atrophy and mental decline may confound the evaluation of mental status
 - Anticoagulated patients with blunt head injury at increased risk for intracranial bleeds and delayed bleeding.
 - Strongly consider repeat imaging to detect delayed bleeds in anticoagulated patients
 - When indicated, initiate treatment for intracranial hypertension, maintain

- spinal immobilization, and obtain definitive airway
- Exposure: Completely undress patient, but prevent hypothermia
 - Age-related changes and medications make elderly more susceptible to hypothermia
 - Hypothermia not attributable to shock or exposure should raise concern for sepsis, endocrinopathy, or drug ingestion
- Common injury patterns:
- Head injury
 - Less prone to epidural hematomas
 - Higher incidence of subdural hematomas
- Cervical spine injuries
 - Propensity to sustain cervical spine injuries from seemingly minor trauma (fall from standing or seated height)
 - C1–C2 and odontoid fractures are particularly more common among elderly
 - Underlying cervical spine pathology, such as arthritis may predispose to spinal cord injuries
 - With hyperextension injuries, increased risk of developing a central cord syndrome
- Vertebral injuries
 - More susceptible to fractures, especially anterior wedge compression fractures
- Chest trauma
 - Rib fracture is most common; in geriatric patients there is an increased risk of pneumonia and mortality with each additional rib fracture
 - Hemopneumothorax, pulmonary contusion, flail chest, and cardiac contusion can quickly lead to decompensation
- Abdominal trauma
 - Similar pattern of injury as younger adults
 - Paramount to recognize signs of hemodynamic stability early
 - Nonoperative treatment of hemodynamically stable blunt hepatic and splenic injuries has emerged as the trend
 - Should have high index of suspicion for internal injuries with associated pelvic and lower rib cage injuries
- Orthopedic injuries—more predisposed due to osteopenia and osteoporotic changes
 - Uniquely susceptible to pelvic and hip fractures
 - Goal of orthopedic injuries is to undertake the least invasive, most definitive procedure that will permit early return to function
- Anticoagulation—consider fresh frozen plasma, cryoprecipitate, and concentrated factor for significant bleeds depending on indications
 - Beware of fluid overload and thrombotic complications

ED TREATMENT/PROCEDURES

- Early monitoring of pulmonary and cardiovascular systems must be instituted

- Prompt stabilization, early recognition of the need for operative intervention, and appropriate and expedient surgical consultation are paramount
- Definitive treatment is often surgical
- Elderly patients benefit from preferential transfer to trauma centers and aggressive, yet thoughtful care
- No reliable age-based criteria upon which to base decisions to triage away from care
- Good outcomes can be achieved with appropriately aggressive trauma care
- Equally important to limit intensive treatment to injuries which are survivable and allow potentially acceptable quality of life
- Seek existence of advance directives, living will, or similar legal document

FOLLOW-UP

DISPOSITION

Admission Criteria

- Most major trauma patients should be admitted for observation, monitoring, and further evaluation
- Lower threshold for admitting geriatric patients to ward, monitored settings, or ICU
- Elderly patients with polytrauma, significant chest wall injuries, abnormal vital signs, evidence of hypoperfusion should be admitted to the ICU

Discharge Criteria

Patients with minor trauma and negative workup/imaging may be observed in the ED for several hours and then discharged

Issues for Referral

Follow-up should be determined by the types of injuries sustained and specialty care required.

FOLLOW-UP RECOMMENDATIONS

Follow-up and referral should be determined by the types of injuries sustained and specialty care required

PEARLS AND PITFALLS

- Minor mechanisms of injury can produce serious injury and complication because of the effect of limited physiologic reserve, medication effects, and unrecognized hypoperfusion
- Frequent use of medications, especially β -blockers and anticoagulants complicate

assessment and management

- Mistaken impression that “normal” BP and heart rate imply normovolemia.
- Geriatric trauma patients must be treated as both trauma and medical patients.

GHB POISONING

Amy V. Kontrick • Mark B. Mycyk

BASICS

DESCRIPTION

- Naturally occurring analog of γ -aminobutyric acid (GABA)
- Used medically for narcolepsy
- Nonmedical uses:
 - Bodybuilding agent
 - Euphoric agent
 - Date-rape/predatory agent
- γ -Hydroxybutyrate (GHB) precursors (γ -butyrolactone [GBL], 1,4 butanediol [1,4-BD], GHV [γ -hydroxyvalerate], and GVL) have same effects as GHB.
- Onset of activity: 15–30 min after ingestion
- Duration of effect: 2–6 hr

ETIOLOGY

Deliberate or accidental ingestion of GHB

DIAGNOSIS

SIGNS AND SYMPTOMS

- CNS:
 - CNS depression
 - Ataxia/dizziness
 - Impaired judgment
 - Aggressive behavior
 - Clonic movements of the extremities
 - Coma
 - Seizures
- Pulmonary:
 - Respiratory depression
 - Apnea
 - Laryngospasm (rare)
- GI:
 - Nausea
 - Vomiting
- Cardiovascular:
 - Bradycardia
 - Atrioventricular block

- Hypotension
- Other:
 - Nystagmus
 - Hypothermia
- Withdrawal symptoms:
 - HTN
 - Tachycardia
 - Hyperthermia
 - Agitation
 - Diaphoresis
 - Tremors
 - Nausea, vomiting, and abdominal cramping
 - Hallucinations, delusions, and psychosis

ESSENTIAL WORKUP

- Diagnosis based on clinical presentation and an accurate history
- Exclude coingestants if signs and symptoms inconsistent with GHB intoxication

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Confirmatory GHB screen is typically a send-out lab and does not change ED management.
- Urine toxicology screen to exclude coingestants
- Serum alcohol level
- Urinalysis and creatine kinase (CK) if suspected rhabdomyolysis from prolonged immobilization or agitation

Imaging

- ECG:
 - Sinus bradycardia
 - Atrioventricular block
- CXR:
 - Aspiration pneumonia
- Head CT if suspected occult head trauma

DIFFERENTIAL DIAGNOSIS

- Alcohol intoxication
- Barbiturate overdose
- Benzodiazepine overdose
- Neuroleptic overdose
- Opiate overdose
- Withdrawal:

- Alcohol withdrawal
- Sedative-hypnotic withdrawal

TREATMENT

PRE HOSPITAL

Transport all pills/bottles and drug paraphernalia involved in overdose for identification in ED.

INITIAL STABILIZATION/THERAPY

- ABCs:
 - Airway control essential
 - Administer supplemental oxygen
 - Intubate if indicated
- Administer thiamine, dextrose (or Accu-Chek), and naloxone for depressed mental status.

ED TREATMENT/PROCEDURES

- Supportive care
- Bradycardia:
 - Atropine
 - Temporary pacing
- Hypotension:
 - 0.9% NS IV fluid bolus
 - Trendelenburg
 - Dopamine titrated to pressure
- Seizures:
 - Treat initially with benzodiazepine.
 - Treat refractory seizures with phenobarbital.
- Withdrawal:
 - Treat aggressively with benzodiazepine.
 - Treat with phenobarbital or propofol if large doses of benzodiazepines unsuccessful.

MEDICATION

- Dextrose: 50–100 mL D₅₀ (peds: 2 mL/kg of D₂₅ over 1 min) IV; repeat if necessary
- Diazepam: 5–10 mg (peds: 0.2–0.5 mg/kg) IV q10–15min
- Dopamine: 2–20 µg/kg/min with titration to effect
- Lorazepam: 2–4 mg (peds: 0.03–0.05 mg/kg) IV q10–15min
- Naloxone: 0.4–2 mg (peds: 0.1 mg/kg; neonatal: 10–30 µg/kg) IV or IM
- Phenobarbital: 10–20 mg/kg IV (loading dose) monitor for respiratory depression with IV administration

- Propofol: 0.5–1 mg/kg IV (loading dose), then 5–50 µg/kg/min (maintenance dose)
- Thiamine (vitamin B₁): 100 mg (peds: 50 mg) IV or IM

FOLLOW-UP

DISPOSITION

Admission Criteria

- Intubated patient
- Patient with hypothermia or other hemodynamic instability
- Coingestion prolonging duration of intoxication

Discharge Criteria

- Asymptomatic after 6 hr of observation
- No clinical evidence of withdrawal syndrome

ALERT

Withdrawal from GHB is life-threatening and appears similar to alcohol withdrawal. Prolonged inpatient treatment may be indicated.

FOLLOW-UP RECOMMENDATIONS

- Substance abuse referral for patients with recreational drug abuse.
- Patients with unintentional (accidental) poisoning require poison prevention counseling.
- Patients with intentional (e.g., suicide) poisoning require psychiatric evaluation.

PEARLS AND PITFALLS

- Consider nontoxicologic causes for persistent altered mental status
- Routine hospital drug testing will not confirm GHB or other common recreational drugs of abuse

ADDITIONAL READING

GIANT CELL ARTERITIS (GCA) (TEMPORAL ARTERITIS)

Donald J. Lefkowitz

BASICS

DESCRIPTION

- Chronic vasculitis of large- and medium-sized vessels that occurs among individuals over 50 yr of age
- Often referred to as temporal arteritis (TA)
- Median age of onset is 72
- Most commonly causes inflammation of arteries originating from the arch of the aorta
- Although usually clinically silent, involvement of the thoracic aorta occurs in a significant minority of patients, and aortic aneurysm or dissection may result
- Thoracic aortic aneurysm is a late manifestation with an incidence 17 times those without TA
- Abdominal aortic aneurysm is about twice as common in those with giant cell arteritis (GCA)
- Pathologic specimens feature patchy mononuclear granulomatous inflammation resulting in a markedly thickened intima and occlusion of the vessel lumen
- Occlusive arteritis may involve thrombosis of the ophthalmic artery resulting in anterior ischemic optic neuropathy (AION) and acute visual loss:
 - Visual symptoms are an ophthalmic emergency
- Inflammation of arteries supplying the muscles of mastication results in jaw claudication and tongue discomfort
- Age is the greatest risk factor:
 - Rare in patients <50 yr old
 - >90% are >60 yr old
 - Prevalence in individuals >50 yr is estimated at 1:500
- Increased prevalence in Northern latitude
- 2 to 4 times more common in women
- Rare in African American patients, common in Whites
- There is a strong association with polymyalgia rheumatica (PMR) ~50%

Genetics

Genetic predisposition is linked to HLA-DR4—60% prevalence

ETIOLOGY

- Unknown
- Genetic, environmental and autoimmune factors have been identified

DIAGNOSIS

- Presence of any 3 or more of the following in patients with vasculitis:
 - ESR > 50
 - Age greater than 50 yr
 - New onset of localized headache
 - Tenderness or decreased pulsation of temporal artery
 - New visual symptoms
 - Biopsy revealing necrotizing arteritis

SIGNS AND SYMPTOMS

- May present with acute, subacute, or chronic symptoms:
 - Headache is the single most frequent symptom (70%)
 - Often localized, boring, or lancinating in quality
 - Often described as unilateral over a temple
- Tongue or jaw claudication upon mastication is the common symptom (50%)
- Constitutional symptoms:
 - Fatigue
 - Malaise
 - Anorexia
 - Weight loss
 - Weakness
 - Arthralgias
 - Low-grade fever
- Visual findings:
 - Findings are usually in 1 eye
 - May develop weeks to months after the onset of other symptoms
 - May fluctuate, but visual impairment does not usually improve over time, even with treatment
 - Amaurosis Fugax
 - Blindness
 - Diplopia
 - Ptosis
 - Extraocular muscle weakness
 - Scotomata
 - Blurred vision
- Scalp tenderness, especially over the temporal artery
- Pulsations over temporal artery:
 - Increased pulsations early in disease
 - Decreased pulsations late in the disease
- Erythema, warmth, swelling, or nodules over scalp arteries
- Bruits or decreased pulses over large arteries
- Sore throat, cough, dysphagia

- Rare findings:
 - Respiratory symptoms
 - Ischemic chest pain
 - Congestive heart failure
- Neurologic problems:
 - Occur in up to one-third of patients:
 - Neuropathies
 - Transient ischemic attacks
 - Cerebral vascular accidents
- Occult manifestations include:
 - Glossitis
 - Lingual infarction
 - Tongue infarction
 - Raynaud phenomenon
- Up to 30% may not present with the classic features of headache, scalp tenderness, visual changes, or jaw claudication
- Frequently associated with PMR (up to 50%):
 - Stiffness
 - Aching pain in the proximal muscles
 - Worse in the morning and decreasing with exercise
- Often associated with synovitis, especially in the knees

ESSENTIAL WORKUP

- Focused physical exam with emphasis on:
 - Temporal artery and scalp abnormalities
 - Complete neurologic exam
 - Ophthalmic exam including visual acuity and visual field testing
- Fundoscopy:
 - Often normal initially
 - Iritis and fine vitreous opacities may be early findings
 - Optic nerve edema
 - Swollen, pale disc with blurred margins
 - Pallor
 - Hemorrhage
 - Scattered cotton-wool spots
 - Vessel engorgement and exudates are seen later
- Any pulse differences in the extremities or bruits over large arteries should be noted

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Elevated ESR, often > 100 mm/hr

- ESR < 40 is rare
- C-reactive protein above 2.45 mg/dL
- Complete blood count (CBC):
 - A mild normochromic anemia is typical
 - Thrombocytosis (often mild)
 - White cell count can be normal or slightly elevated and differential is usually normal
- Liver function tests and prothrombin time may be elevated; creatine phosphokinase, tests of renal function, and urinalysis are generally normal
- Elevation in interleukin-6 (IL-6) is seen during flares

Imaging

- Doppler ultrasound:
 - Decreased blood flow in temporal, facial, and ophthalmic arteries
 - Presence of a halo is highly suggestive of active TA.
- MRI:
 - Indicated for exam of large arteries
- Angiogram:
 - Smooth, tapered occlusions or stenosis

Diagnostic Procedures/Surgery

- Temporal artery biopsy:
 - Multiple sections should be done in as soon as feasible after initiation of steroid therapy
 - Gold standard for diagnosis
 - Contralateral biopsy is recommended if 1st is negative and index of suspicion high

DIFFERENTIAL DIAGNOSIS

- Vasculitides:
 - Polyarteritis nodosa
 - Hypersensitivity vasculitis
 - Systemic lupus erythematosus
 - Takayasu arteritis
 - Wegener granulomatosis
- Thrombosis of retinal, ophthalmic, or temporal arteries
- Lyme disease
- Nonarteritic anterior ischemia optic neuropathy (NAAION)

TREATMENT

PRE HOSPITAL

- Acute symptoms may be confused with stroke
- Initiate appropriate monitoring and oxygen
- Patients may be hypotensive from 1 of the rare sequelae (aortic dissection, abdominal aortic aneurysm, or myocardial infarction)

INITIAL STABILIZATION/THERAPY

Although rare, patients may present with vascular catastrophe such as aortic dissection or myocardial infarction and need appropriate aggressive early management

ED TREATMENT/PROCEDURES

- Steroids:
 - Strong clinical indications should be present if started before temporal artery biopsy
 - Scheduling of TA biopsy should not delay steroid therapy when clinical suspicion is high as pathologic vessel changes resolve slowly and will remain for weeks
 - Early, aggressive treatment can significantly reduce the incidence of blindness
 - Steroids effectively control systemic and local symptoms within days to weeks
 - Treatment with prednisone may continue for years—usual disease length is 3–4 yr
- Symptomatic pain management with NSAIDs, salicylates, and/or narcotics as indicated

MEDICATION

- Prednisone: 60–100 mg PO per day for at least 2 wk before considering tapering
- For acute onset visual symptoms, consider 1,000 mg methylprednisolone IV pulse therapy for the 1st 1–3 days
- Low-dose aspirin therapy to reduce thrombotic risks
- Pain management with NSAIDs or narcotics

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with impending vascular complications or acute focal neurologic findings
- Patients with associated acute visual loss

Discharge Criteria

- Less symptomatic patients without evidence of end-organ involvement

- Follow-up arranged within 1--2 days

Issues for Referral

- Rheumatology
- Ophthalmology if associated with visual symptoms
- Neurology with acute focal neurologic findings

FOLLOW-UP RECOMMENDATIONS

- Rheumatology for steroid management and search for associated connective tissue disorders
- Ophthalmology and neurology for visual disturbance and/or focal neurologic findings.

PEARLS AND PITFALLS

- Permanent visual loss is the most feared complication of GCA
- Do not delay initiation of steroid therapy to await biopsy if strong clinical suspicion for GCA exists or if visual changes are reported
- Jaw claudication and amaurosis fugax, while often dramatic, are symptoms patients often neglect to report. Query directly and specifically about them if TA/GCA is being considered
- 25–50% of patients who present with acute loss of vision in 1 eye who go untreated will develop bilateral blindness

- M31.6 Other giant cell arteritis

GIARDIASIS

Benjamin Mattingly • Joseph B. Schneider

BASICS

DESCRIPTION

- Noninvasive diarrhea
- Found worldwide:
 - 2–15% prevalence in developed nations
 - 20–40% prevalence in developing nations
- 5% of all travelers' diarrhea
- Most common intestinal parasite in US:
 - Highest incidence in early summer months through fall
 - Highest incidence in children aged 1–9 yr and adults aged 30–39 yr
 - In 2010, 19,888 cases reported in US (mostly from Northern States)
- Fecal–oral transmission:
 - Humans are major reservoir
 - Zoonotic reservoir in both domestic and wild mammals
 - Reservoir in contaminated surface water
- Populations at risk:
 - Travelers to endemic areas (developing countries, wilderness areas of US)
 - Children in day care centers and their close contacts
 - Institutionalized persons
 - Practitioners of anal sexual activity

ETIOLOGY

- *Giardia lamblia*:
 - A protozoan flagellate
- Also called *Giardia intestinalis* or *Giardia duodenalis*
- Ingested *Giardia* attach to intestinal villi
- Alters the intestinal brush-border enzymes, impairing digestion of lactose, and other saccharides
- No toxin produced

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Onset 1–2 wk postexposure
- Infection may be asymptomatic (most common).

- Diarrhea of acute onset (90% of symptomatic patients):
 - Foul-smelling stools
 - Steatorrhea
 - Nonbloody
 - Self-limiting within 2–4 wk
 - More severe in immunocompromised patients and patients with underlying bowel disease
- Flatulence and bloating (70–75%)
- Abdominal cramping (70%)
- Nausea (70%)
- Vomiting (30%)
- Malaise (86%)
- Anorexia (66%)
- Weight loss (60–70%)
- Fever is rare (15%)
- 30–50% of acute cases progress to chronic giardiasis (> 4 wk):
 - Fat malabsorption
 - Severe macrocytic anemia secondary to folate deficiency
 - Secondary lactase deficiency (in 20–40% of patients)
- Infection is more severe and harder to eradicate in immunosuppressed patients.

Pediatric Considerations

- Acute infection:
 - Severe dehydration
- Chronic infection:
 - Failure to thrive
 - Growth retardation and cognitive impairment owing to nutrient malabsorption

Physical-Exam

- Abdominal exam is benign.
- Extraintestinal manifestations (10% of patients):
 - Polyarthritits
 - Urticaria
 - Aphthous ulcers
 - Maculopapular rash
 - Biliary tract disease

ESSENTIAL WORKUP

- History:
 - Possible sources of exposure
 - Membership in high-risk group
- Physical exam:

- If gross or occult blood on digital rectal exam, unlikely to be *Giardia*

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Stool sample for microscopy (ova and parasites):
 - 50–70% sensitive if 1 sample
 - 85–90% sensitive if 3 samples taken at 2-day intervals (ideal)
 - 100% specific
 - Ability to detect other parasites as well
- Stool ELISA or immunofluorescent antibody (IFA) assay for *Giardia* antigen:
 - 95% sensitive, 95–100% specific
 - Unlike microscopy, cannot rule out other parasites
- Stool polymerase chain reaction (PCR):
 - 100% sensitive and 100% specific
- Fecal leukocytes and stool culture unnecessary unless enteroinvasive organisms suspected (fever, bloody stool)
- Serology for anti-*Giardia* antibodies not helpful in the ED setting
- Electrolytes, BUN/creatinine, glucose:
 - If prolonged diarrhea or evidence of dehydration
- CBC:
 - Macrocytic anemia in chronic giardiasis
 - Nondiagnostic in acute giardiasis

Imaging

Abdominal CT or ultrasound may show bowel wall thickening and flattened duodenal folds (nonspecific findings)

Diagnostic Procedures/Surgery

- Duodenal sampling:
 - Entero-Test (patient swallows a weighted string, which is later retrieved and examined for *Giardia* using microscopy)
- Endoscopy:
 - Duodenal aspiration
 - Endoscopic duodenal biopsy

DIFFERENTIAL DIAGNOSIS

- Viral gastroenteritis:
 - Norwalk virus
 - Rotavirus
 - Hepatitis A
- Bacterial infections:
 - *Staphylococcus*

- *Escherichia coli*
- *Shigella*
- *Salmonella*
- *Yersinia*
- *Campylobacter*
- *Clostridium difficile*
- *Vibrio cholerae*
- Other protozoa:
 - *Cryptosporidium*
 - Microsporidia
 - *Cyclospora*
 - *Isospora*
 - *Entamoeba*
- Inflammatory bowel disease
- Irritable bowel syndrome
- Lactase deficiency
- Tropical sprue
- Drugs and toxins:
 - Antibiotics
 - Calcium channel blockers
 - Magnesium antacids
 - Caffeine
 - Alcohol
 - Sorbitol
 - Laxative abuse
 - Quinidine
 - Colchicine
 - Mercury poisoning
- Endocrine:
 - Addison disease
 - Thyroid disorders
- Malignancy:
 - Colorectal carcinoma
 - Medullary carcinoma of the thyroid

TREATMENT

INITIAL STABILIZATION/THERAPY

- ABCs: Airway, breathing, circulation
- IV 0.9% NS if signs of significant dehydration

Pediatric Considerations

- For severe dehydration (>10%):
 - IV bolus with 0.9% NS at 20 mL/kg
 - Cardiac monitor
 - Blood glucose determination

ED TREATMENT/PROCEDURES

- Oral fluids for mild dehydration
- Correct any serum electrolyte imbalances.
- Stool sample for microscopy
- If stool sample is positive for *Giardia*: Treat as listed below under medication
- If stool sample negative for *Giardia*:
 - Refer to gastroenterologist for further specialized testing.
 - Consider empiric course of metronidazole if high suspicion for *Giardia*.

MEDICATION

First Line

- Metronidazole or tinidazole are the treatment of choice:
 - 90% cure rate for each
- Metronidazole: 250–500 mg (peds: 15 mg/kg/24h) PO q8h for 5–10 days
- Tinidazole: 2 g (peds [> 3 yr]: 50 mg/kg) PO once

Second Line

Albendazole (78–90% efficacy), quinacrine (90% efficacy), or nitazoxanide (75% efficacy) if 1st-line therapy fails

- Albendazole: 400 mg (peds: 10–15 mg/kg/24h) PO daily for 5–7 days
- Furazolidone: 100 mg (peds: 6–8 mg/kg/24h) PO q6h for 7–10 days (not available in US)
- Nitazoxanide: 500 mg (peds: 100 mg for ages 2–3 yr, 200 mg for ages 4–11 yr) PO BID for 3 days
- Paromomycin: 500 mg (peds: 25–30 mg/kg/24h) PO q8h for 5–10 days
- Quinacrine: 100 mg (peds: 6 mg/kg/24h) PO q8h for 5–7 days (limited availability)

Pediatric Considerations

- Metronidazole is 1st-line therapy (80–95% efficacy)
- Alternatives:
 - Furazolidone (80–85% efficacy)
 - Nitazoxanide (60–80% efficacy)
 - Paromomycin (55–90% efficacy)

Pregnancy Considerations

- Metronidazole contraindicated in 1st trimester

- Albendazole, quinacrine, and tinidazole are contraindicated throughout pregnancy
- Use nitazoxanide instead
- If mild symptoms only, consider deferring treatment until late pregnancy or postpartum

Immunocompromised Considerations

- Immunocompromised patients at risk for disease that is refractory to standard drug regimens:
 - Try drug of a different class/mechanism or metronidazole + quinacrine for at least 2 wk

ALERT

- Use furazolidone in older children only:
 - Causes hemolytic anemia in infants
 - Causes hemolytic anemia in persons with G6PD deficiency
- Avoid quinacrine in G6PD deficiency (causes hemolytic anemia)
- Avoid paromomycin in renal failure

FOLLOW-UP

DISPOSITION

Admission Criteria

- Hypotension or tachycardia unresponsive to IV fluids
- Severe electrolyte imbalance
- Children with > 10% dehydration
- Signs of sepsis/toxicity (rare in isolated giardiasis)
- Patients unable to maintain adequate oral hydration:
 - Extremes of age, cognitive impairment, significant comorbid illness

Discharge Criteria

- Able to maintain adequate oral hydration
- Dehydration responsive to IV fluids

FOLLOW-UP RECOMMENDATIONS

- Gastroenterology referral for diagnostic endoscopy if symptoms persist for > 4 wk despite drug therapy
- Acquired lactose intolerance may develop and last for weeks to months
- Association with postinfectious fatigue syndrome

PEARLS AND PITFALLS

Diagnosis is the greatest challenge in this disease:

- Include giardiasis in the differential diagnosis of all patients with diarrhea:
 - *Giardia* occasionally reported in domestic water supply
 - Patients may not present with the classic history and risk factors to have giardiasis
 - 1 stool sample is frequently insufficient for diagnosis

ICD10

A07.1 Giardiasis [lambliasis]

GLAUCOMA

Yasuharu Okuda • Lisa Jacobson

BASICS

DESCRIPTION

Disease characterized by elevation of intraocular pressure, optic neuropathy, and progressive loss of vision.

ETIOLOGY

- Primary glaucoma:
 - Open-angle glaucoma:
 - Normal anterior chamber angle
 - Insidious onset with persistent rise in intraocular pressure
 - Most common type accounting for 90% of glaucomas in US
 - Leading cause of blindness in African Americans
 - Risk factors include African American, age > 40 yr, family history, myopia, diabetes, and HTN
 - Acute angle-closure glaucoma:
 - Narrowing or closing of anterior chamber angle precluding natural flow of aqueous humor from posterior to anterior chamber of eye and through its filtering portion of trabecular meshwork
 - Usually abrupt onset with sudden increase in intraocular pressure
 - Risk factors include Asians and Eskimos, hyperopia, family history, increased age, and female gender
- Secondary glaucoma occurs from other diseases, including diseases of eye, trauma, and drugs:
 - Can be either open or closed angle
 - Drugs: Steroids, sertraline, bronchodilators, topiramate
 - Diseases: Neurofibromatosis, uveitis, neovascularization, and intraocular tumors
 - Trauma
 - Rapid correction of hyperglycemia

DIAGNOSIS

SIGNS AND SYMPTOMS

Classic descriptions:

- Open angle:
 - Painless and gradual loss of vision
- Closed angle:

- Painful loss of vision with fixed midsized pupil

History

- Primary open-angle glaucoma:
 - Gradual reduction in peripheral vision or night blindness
 - Typically bilateral
 - Painless
- Primary angle-closure glaucoma:
 - Severe deep eye pain and ipsilateral headache often associated with nausea and vomiting
 - Decrease in visual acuity often described as visual clouding with halos surrounding light sources
 - Associated abdominal pain, which may misdirect diagnosis
 - Concurrent exposure to dimly lit environment such as movie theater
 - Use of precipitating medications:
 - Mydriatic agents: Scopolamine, atropine
 - Sympathomimetics: Pseudoephedrine, albuterol
 - Antihistamines: Benadryl, Antivert
 - Antipsychotics: Haldol
 - Phenothiazines: Compazine, Phenergan
 - Tricyclic antidepressants: Elavil
 - Sulfonamides: Topiramate

Physical-Exam

- Primary open-angle glaucoma:
 - Decreased visual acuity
- Primary angle-closure glaucoma:
 - Decreased visual acuity
 - Pupil is mid-dilated and nonreactive.
 - Corneal edema with hazy appearance
 - Conjunctival injection, ciliary flush
 - Firm globe to palpation

ESSENTIAL WORKUP

- Detailed ocular exam
- Visual acuity:
 - Hand movements typically all that is seen
- Tonometry:
 - Normal pressures are 10–21 mm Hg.
 - Primary open-angle glaucoma:
 - Degree of elevation can vary, but 25–30% of patients may have normal intraocular pressures.
 - Primary angle-closure glaucoma:

○ Any elevation is abnormal, but usually seen in ranges >40 mm Hg.

- Slit-lamp exam:
 - Evaluation of anterior chamber angle
 - Used to eliminate other possibilities in differential including corneal abrasion and foreign body

DIAGNOSIS TESTS & INTERPRETATION

Lab

Directed toward workup of differential

Imaging

Directed toward workup of differential

Diagnostic Procedures/Surgery

Gonioscopy:

- This is direct measurement of the angle of closure

DIFFERENTIAL DIAGNOSIS

- Cavernous sinus thrombosis
- Acute iritis and uveitis
- Retinal artery or vein occlusion
- Temporal arteritis
- Retinal detachment
- Conjunctivitis
- Corneal abrasion

TREATMENT

PRE HOSPITAL

- No specific interventions need occur prior to arrival at the hospital in regard to the eye:
 - Pain control may be necessary
 - In traumatic etiologies, stabilize other injuries

INITIAL STABILIZATION/THERAPY

- Initiate steps to lower intraocular pressure in acute closed-angle glaucoma:
 - Address other effects of trauma if this was the etiology
 - Discontinue inciting medication when involved

ED TREATMENT/PROCEDURES

- Primary open-angle glaucoma:

- Recognition and prompt ophthalmologic referral
- Patients maintained on topical β -blockers or prostaglandin analogs to decrease IOP
- Primary angle-closure glaucoma (ophthalmologic emergency):
 - Intraocular pressure reduction:
 - Topical β -blocker, timolol maleate, to decrease aqueous humor production
 - Topical α_2 -agonist, apraclonidine, to decrease aqueous humor production
 - Carbonic anhydrase inhibitor, acetazolamide, for reduction of formation of aqueous humor
 - Hyperosmotic agent, mannitol, to draw aqueous humor from vitreous cavity into blood (indicated for severe attacks).
 - Movement of iris away from trabecular meshwork:
 - Topical parasympathomimetic, pilocarpine hydrochloride, to constrict pupil once intraocular pressure is < 40 mm Hg
 - Reduction of inflammation:
 - Topical corticosteroid, prednisolone acetate
 - Emergent ophthalmology consultation for possible definitive surgical treatment, laser iridectomy, if no improvement with medical management
 - Adequate narcotic analgesia and antiemetics as needed

MEDICATION

- Acetazolamide: 500 mg IV or PO
- Mannitol 20%: 1–2 g/kg IV over 30–60 min
- Pilocarpine hydrochloride 1–2% solution: 1 drop q15–30min until pupillary constriction occurs, then 1 drop q2–3h
- Prednisolone acetate 1% solution: 1 drop q15–30min for total of 4 doses

First Line

- β -Agonists:
 - Timolol maleate 0.25 or 0.5%:
 - 1 drop to affected eye BID
 - Levobunolol 0.25 or 0.5%:
 - 1 drop to affected eye BID
 - Carteolol HCL 1%:
 - 1 drop to affected eye BID
 - Betaxolol 0.25 or 0.5%:
 - 1–2 drop(s) to affected eye BID

Second Line

- Adrenergic agonists:

- Apraclonidine 0.5%, 1%:
 - 1–2 drop(s) to affected eye BID
- Brimonidine:
 - 1 drop to affected eye TID
- Carbonic anhydrase inhibitors:
 - Acetazolamide:
 - 125–250 mg PO QID
 - Methazolamide:
 - 50–100 mg PO BID
 - Dorzolamide HCl 2%:
 - 1 drop in affected eye TID
 - Brinzolamide:
 - 1 drop to affected eye TID
- Prostaglandin analogs:
 - Latanoprost:
 - 1 drop in affected eye QHS
 - Bimatoprost 0.03%:
 - 1 drop in affected eye QHS
 - Travoprost:
 - 1 drop in affected eye QHS
 - Unoprostone:
 - 1 drop to affected eye BID

Considerations in Prescribing

- Prostaglandin analogs have become standard of care for open-angle glaucoma due to an improved side-effect profile
- Due to cost, topical β -blockers are often still used primarily

FOLLOW-UP

DISPOSITION

Admission Criteria

- Severe pain, nausea, or vomiting
- Patients receiving parenteral medications should be observed for side effects.
- Patients without improvement of symptoms or intraocular pressures should be admitted for continued monitoring of intraocular pressure, medical treatment, and possible definitive surgical management:
 - Laser intervention is more likely than operative

Discharge Criteria

Patients with minor symptoms and significant improvement of intraocular pressure may

be safely discharged once seen by ophthalmology and with close, <24-hr follow-up.

Issues for Referral

If no ophthalmologist is available, treatment should be initiated and patient transferred to nearest hospital with ophthalmologic consultation.

FOLLOW-UP RECOMMENDATIONS

- Open-angle glaucoma patients need urgent ophthalmology follow-up to optimize medical management
- Closed-angle glaucoma patients need immediate intervention

PEARLS AND PITFALLS

- Increased IOP can cause vascular insufficiency and with delayed treatment vision loss can be permanent
- Eye pain/headache can be associated with severe abdominal pain—do not ignore the eye and miss the diagnosis
- Patients maintained on topical β -blockers for open-angle glaucoma may present with systemic side effects including orthostatic hypotension, bradycardia, or syncope

- H40.219 Acute angle-closure glaucoma, unspecified eye

GLOBE RUPTURE

Alexander T. Limkakeng, Jr. • Megan G. Kemnitz

BASICS

DESCRIPTION

- A full-thickness corneal or scleral injury owing to trauma
- Blunt trauma/globe rupture:
 - Causes an abrupt rise in intraocular pressure diffusely
 - Subsequent rupture of the eye either opposite the point of impact or at the weakest points:
 - Extraocular muscle insertion
 - Corneoscleral junction
 - Limbus, where the sclera is thinnest
- Penetrating injury/globe laceration:
 - Occurs with sharp objects or projectiles injuring the sclera or anterior eye directly
 - Most commonly anterior—the bony orbit protects the globe laterally and posteriorly
 - Posterior injury can occur with fracture of the bony orbit or with penetrating injuries of the eyelid or eyebrow.
- Prognosis worse with:
 - Larger lacerations
 - Injury posterior to the rectus insertion
 - Blunt injury
 - Intraocular foreign body, especially if made of organic material
 - Vitreous extrusion
 - Lens damage
 - Hyphema
 - Retinal detachment
 - Poor visual acuity at presentation
 - Afferent pupillary defect
 - Increased time to OR

ETIOLOGY

- Falls, impact injuries
- Sport-related injuries (e.g., elbow, ball impacts, arrows, game controllers, etc.)
- Indirect concussive injuries (explosions)
- Sharp instrument/stabbing injuries, accidental or intentional
- Projectile injuries (industrial, firearms, BB pellets, blast explosion shrapnel—glass, etc.)

SIGNS AND SYMPTOMS

- Pain
- Localized ecchymosis and swelling
- Scleral or corneal laceration
- Extrusion of intraocular contents
- Markedly decreased visual acuity
- Limited extraocular motion
- Hyphema
- Severe subconjunctival hemorrhage and edema, especially if circumferential bloody chemosis
- Abnormally deep or shallow anterior chamber
- Low intraocular pressure:
 - Note: Do not perform tonometry if there is suspected rupture.
- Irregular pupil (points toward lesion)
- Subluxed lens
- Commotio retinae—gray-white discoloration of the retina

History

- Mechanism of injury:
 - Assess for possibility of retained intraocular foreign body
- History of previous eye surgery
- Preinjury visual acuity
- Assess tetanus status
- Ascertain time of last PO intake

Physical-Exam

- Penlight or slit-lamp exam observing for signs of globe rupture
- If the diagnosis of ruptured globe is made, defer further ocular exam until the time of surgical repair:
 - Prevents placing any undue pressure on the eye and risking extrusion of the intraocular contents
- If no evidence of globe rupture on initial survey, proceed with thorough ophthalmologic exam:
 - Visual acuity
 - Slit-lamp exam
 - Cornea
 - Anterior chamber
 - Iris
 - Sclera
 - Fundus

- Retina
- Seidel test: Observe if fluorescein moves away as contents (which appear yellow-green) leak out at site of rupture:
- Measure intraocular pressure
 - Perform only if globe rupture is definitely *not* present.
- Ultrasound (only if rupture not suspected)

ESSENTIAL WORKUP

Perform thorough ocular exam as outlined above:

- Once diagnosis of globe rupture is suspected or made, defer further exam until time of repair.

DIAGNOSIS TESTS & INTERPRETATION

Lab

Preoperative labs:

- CBC
- Electrolytes
- Coagulation studies

Imaging

- Orbital radiograph (anteroposterior/lateral) for metallic intraocular foreign body
- CT scan of the orbits (axial and coronal views)
- MRI scan of the orbits after retained metallic foreign body is ruled out
- B-scan US of the eye

Diagnostic Procedures/Surgery

- Slit-lamp
- Fluorescein

DIFFERENTIAL DIAGNOSIS

- Intraocular foreign body
- Hyphema
- Severe subconjunctival hemorrhage and chemosis
- Partial corneal laceration
- Partial scleral laceration

TREATMENT

PRE HOSPITAL

- Place a shield (not patch) over eye with no pressure on the globe.
- Use a Styrofoam cup if no shield available.

INITIAL STABILIZATION/THERAPY

- Keep manipulation of the eye to a minimum if ruptured globe is suspected.
- Try to prevent any activity that will cause an increase in intraocular pressure such as straining, coughing, or vomiting.

ED TREATMENT/PROCEDURES

- Prepare for definitive surgical management:
 - _ Emergent ophthalmologic consultation
 - _ Thorough physical exam to identify concurrent injuries
 - _ Preoperative labs and ECG as indicated
 - _ No food or drink (NPO)
- Minimize intraocular pressure to reduce further injury
 - _ Administer antiemetic for nausea/vomiting
 - _ Elevate the head of the bed
 - _ Protective eye shield (NO pressure on the globe itself)
- Update tetanus status.
- Administer prophylactic antibiotics IV:
 - _ Skin organisms (staph, strep) most common
 - _ Consider injury-specific contaminants in cases of animal bites, organic foreign body, etc.
 - _ Vancomycin + ceftazidime OR vancomycin + ciprofloxacin if allergic to penicillin
- Succinylcholine is relatively contraindicated:
 - _ However, with a defasciculating dose of a nondepolarizing agent and sufficient anesthesia, it may be used.

Pediatric Considerations

- Consider nonaccidental trauma
- Because of risk of extrusion of intraocular contents, straining/crying should be avoided. Try to keep them happy!

MEDICATION

- Ceftazidime: 1–2 g (peds: 30–50 mg/kg) IV q8h
- Ciprofloxacin: 400 mg (peds: 10 mg/kg) IV q12h
- Clindamycin: 450 mg (peds: 8–12 mg/kg) IV q8h
- Ondansetron (Zofran): 4 mg IV
- Prochlorperazine (Compazine): 5–10 mg IV/IM
- Tobramycin: 2 mg/kg (peds: 2 mg/kg) IV q8h
- Vancomycin: 15 mg/kg IV q8–12h (peds: 10 mg/kg IV q6h)

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with globe rupture/penetrating eye injuries
- Early enucleation for severe injury

Discharge Criteria

Globe penetration excluded

Issues for Referral

- Emergent ophthalmologic consultation in the ED may be needed to definitively rule out globe rupture owing to difficulty with exam and the desire to minimize manipulation of the eye.
- Speed is of the essence since the risk of infection increases with prolonged time to operative repair.
- If appropriate, patient should be counseled on use of protective eyewear to prevent recurrence.

FOLLOW-UP RECOMMENDATIONS

Postoperative ophthalmology follow-up

PEARLS AND PITFALLS

- Do not manipulate the eye if you suspect or confirm a ruptured globe:
 - Place eye shield over affected eye.
- Administer antiemetic for patients with nausea and vomiting to prevent elevation of intraocular pressure and extrusion of globe contents.
- Update tetanus
- Empiric antibiotics tailored to clinical scenario

GLOMERULONEPHRITIS

Melissa H. White • Carolyn Maher Overman

BASICS

DESCRIPTION

- Syndrome characterized by:
 - Hematuria
 - Proteinuria
 - Red blood cell casts
 - Hypertension
 - Renal insufficiency
- Common pathway of multiple diseases resulting in intraglomerular inflammation and cellular proliferation
- Contributing factors:
 - Genetics
 - Infectious
 - Rheumatologic
 - Leading to antibody deposition:
 - Antibody attaches to glomerular antigen (native or implanted).
 - Circulating antigen–antibody complex deposited
 - Causing an influx and activation of inflammatory mediators:
 - Leukocytes, complement, cytokines
 - Cell-mediated immune mechanisms
- Results in glomerular dysfunction
- Persistent inflammation that can lead to scarring and permanent damage.

ETIOLOGY

- Postinfectious:
 - Poststreptococcal glomerulonephritis (PSGN):
 - Occurs 7–21 days after *Streptococcal pharyngitis* or skin infection
 - Highest prevalence in ages 2–14 and the elderly
 - Male predominance
 - Ranges from asymptomatic hematuria to oliguric renal failure
 - Can follow other bacterial, fungal, viral, or parasitic infections
- IgA nephropathy (Berger disease):
 - Most common in men in the 3rd and 4th decades of life
 - Possibly related to increased production of IgA after infection usually a URI
 - Henoch–Schönlein purpura (HSP) has IgA nephropathy but affects a younger age and has systemic symptoms
- Rapidly progressive glomerulonephritis (RPGN):

- Can destroy renal function in days
- Crescentic deposits in glomeruli destroy function.
- Pauci-immune (small vessel vasculitides):
 - Often antineutrophil cytoplasmic antibody (ANCA)-positive
 - Can involve other areas (i.e., lungs, skin)
 - Wegener granulomatosis
 - Microscopic polyangiitis
 - Churg–Strauss syndrome
- Immune complex deposits:
 - Postinfectious
 - Endocarditis associated
 - Systemic disease (i.e., systemic lupus erythematosus [SLE], HSP)
- Anti-glomerular basement membrane (GBM) deposits:
 - Older patients of age > 60
 - Goodpasture disease with pulmonary involvement
- Membranoproliferative glomerulonephritis (MPGN):
 - Complement deposits in basement membrane
 - Hepatitis C
 - Non-Hodgkin lymphoma
 - Occult infection

DIAGNOSIS

SIGNS AND SYMPTOMS

- Cardinal signs:
 - Hematuria
 - Proteinuria
- Edema:
 - Owing to renal salt and water retention
 - Periorbital
 - Ascites
 - Pleural effusion
- HTN
- Oliguria
- Azotemia
- CHF
- Renal failure
- Nonspecific manifestations:
 - Fatigue
 - Weight loss
 - Abdominal pain
 - Nausea/vomiting

- Autoimmune disorders:
 - Arthralgias
 - Arthritis
 - Rash
 - Fever
- Goodpasture syndrome:
 - Hemoptysis
- Wegner granulomatosis:
 - Purulent rhinorrhea/sinus pain
 - Arthritis/arthralgias
 - Hemoptysis
- HSP:
 - Abdominal pain
 - Purpura
 - Arthritis

Geriatric Considerations

- Pauci-immune RPGN is common in this population (hematuria, proteinuria, and elevated CR).
- Urgent diagnosis and biopsy are indicated as this may progress to ESRD.
- Consult nephrology to discuss steroids, cyclophosphamide, and plasma exchange.

ESSENTIAL WORKUP

Urinalysis for:

- Hematuria, proteinuria, and RBC casts

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Electrolytes, BUN, Creatinine, GFR:
 - Renal function
 - Hyperkalemia
- Albumin, total protein:
 - Varying degrees of hypoalbuminemia depending on clinical process
- CBC:
 - Anemia secondary to chronic renal disease, neoplasm, Goodpasture, and Wegener
 - With or without elevated WBC in infections
- PT, PTT:
 - Coagulation factors consumed in certain types of GN
- Labs to be considered for consultants:
 - Cultures—throat, skin, blood
 - 24-hr urine collection—protein, urine electrolytes

- Streptozyme or antistreptolysin O titer
- Complement levels (C1, C3, C4, CH₅₀)—reduced in PSGN, MPGN, SLE
- ANA, rheumatoid factor—connective tissue diseases
- ESR and CRP inflammatory markers
- Anti-GBM—Goodpasture
- c-ANCA—Wegener; p-ANCA-pauci-immune
- Anti-DNA antibodies (SLE)
- Hepatitis B and C serologies
- HIV

Imaging

- Renal ultrasound (if GFR is decreased):
 - Kidney size predictor of potential reversibility of disease, alternative diagnosis (i.e., neoplasm, stone)
- Chest radiograph (CXR): Heart size, pulmonary edema, or hemorrhage

Diagnostic Procedures/Surgery

- Renal biopsy: Discern primary glomerulopathies vs. other causes
- Cystoscopy: If concern for bladder neoplasm

DIFFERENTIAL DIAGNOSIS

- Hematologic:
 - Sickle cell disease
 - Coagulopathy
- Renal:
 - Infectious
 - Malformation
 - Neoplasm
 - Ischemic
 - Trauma
 - Vasculitis
- Postrenal:
 - Mechanical (i.e., stones, reflux, obstruction, catheterization)
 - Inflammatory (i.e., cystitis, prostatitis, epididymitis, endometriosis, periurethritis)
 - Neoplasm
- Factitious:
 - Food
 - Drugs
 - Pigmenturia (i.e., myoglobin, porphyria, hemoglobin)
 - Vaginal bleeding

TREATMENT

PRE HOSPITAL

- Supportive
- ABCs and fluid restriction in stable patients with significant edema.

INITIAL STABILIZATION/THERAPY

ABCs: Airway, breathing, circulation

ED TREATMENT/PROCEDURES

- Treatment mainly supportive care:
 - _ BP control: < 125/75 mm Hg
 - Loop diuretics
 - ACE inhibitor for maintenance
 - Treat hypertensive emergencies
 - _ Dialysis:
 - Fluid overload
 - Hyperkalemia
 - Uremia
- PSGN:
 - _ Supportive care
 - _ Usually resolves spontaneously
 - _ No benefit to antibiotics
- IgA nephropathy:
 - _ Supportive care
 - _ Immunosuppressives if inflammation on biopsy
 - _ Variable course, most recover but may relapse
- RPGN:
 - _ Can irreversibly destroy renal function in days
 - _ Emergently consult nephrologist to discuss starting potentially toxic therapies.
 - _ Immunosuppressives and high-dose steroids:
 - Methylprednisolone and prednisone
 - Cyclophosphamide
 - Rituximab
 - Plasmapheresis for anti-GBM antibody
- MPGN:
 - _ Treat underlying disease if known.
 - _ Emergently consult nephrologist to discuss starting potentially toxic therapies.
 - _ May include plasma exchange, cyclophosphamide, and/or steroids

MEDICATION

- Benazepril: 5–40 mg PO daily (or any other ACE inhibitor)
- Cyclophosphamide: Dose in conjunction with nephrology
- Diazoxide: 1–3 mg/kg IV, max. 150 mg, repeat q15min
- Furosemide: 20–80 mg IV; max. 2 mg/kg/d
- Methylprednisolone: 30 mg/kg IV on alternative days for 3 doses, followed by oral prednisone (dose in conjunction with nephrology)
- Nitroprusside: 0.3–10 µg/kg/min IV
- Prednisone: 0.5–2 mg/kg/d

FOLLOW-UP

DISPOSITION

Admission Criteria

- Unstable vital signs
- Oliguria, anuria
- Uremia
- Acute renal failure
- Electrolyte abnormality
- Hypertensive emergency
- CHF
- Infectious cause of GN

Discharge Criteria

Healthy patients with no comorbid illness who present with mild hematuria and proteinuria with:

- Stable vital signs
- No signs of infection
- Otherwise normal lab work
- Close follow-up recommended

FOLLOW-UP RECOMMENDATIONS

All patients with glomerulonephritis should follow-up with nephrology

PEARLS AND PITFALLS

- Discussion with nephrology if management with immunosuppressives is sought.
- The finding of proteinuria or hematuria should always prompt follow-up to ensure that the patient is not progressing to GN.

- N01.9 Rapidly progr nephritic syndrome w unsp morphologic changes
- N05.9 Unsp nephritic syndrome with unspecified morphologic changes

GONOCOCCAL DISEASE

Sunil D. Shroff

BASICS

DESCRIPTION

- 2nd most frequently reported STD in US:
 - _ Estimated 820,000 new cases per year
 - _ <50% reported
 - _ Highest rates in 15–24-yr-old males and females, African Americans
 - _ Increasing incidence in men who have sex with men (MSM):
 - Higher in HIV-positive individuals
 - _ Humans only known host
- Concurrent infection with *Chlamydia trachomatis* is common
- Affects the urethra, rectum, cervical canal, pharynx, upper female genital tract, and conjunctiva
- Urethritis most common presentation in men
- Often asymptomatic in women

ETIOLOGY

Neisseria gonorrhoeae:

- Gram-negative aerobic diplococci

DIAGNOSIS

SIGNS AND SYMPTOMS

- Cervicitis:
 - _ Defined as:
 - Mucopurulent endocervical discharge; OR
 - Easily induced endocervical bleeding
 - _ Most common site of infection
 - _ Up to 80% asymptomatic
 - _ Most symptoms nonspecific:
 - Vaginal discharge
 - Menorrhagia
 - Pelvic pain
 - Dyspareunia
 - Frequency and dysuria
- Pelvic inflammatory disease (PID):
 - _ Up to 20% of untreated cases
 - _ Lower abdominal pain—most common presenting symptom

- Other common signs and symptoms:
 - Dyspareunia, abnormal bleeding, abnormal cervical or vaginal discharge
- Symptoms often occur at onset of menses.
- Fever (50%)
- 2/3 have mild, vague symptoms; may go unrecognized
- Fitz-Hugh–Curtis syndrome: (perihepatitis):
 - 10% occurrence rate
 - Right upper quadrant pain/tenderness
- Bartholin abscess
- Urethritis:
 - Incubation period 2–5 days
 - Symptoms:
 - Penile discharge
 - Dysuria
- Prostatitis—can occur in untreated urethritis
- Epididymitis:
 - Acute, unilateral testicular pain and swelling
- Proctitis:
 - Often asymptomatic
 - Only site of infection in 40% of MSM
 - Rectal infection occurs in 35–50% of women with endocervical infection
 - 3-fold increase in HIV infection risk
 - Symptoms:
 - Perianal pruritus, mucopurulent discharge, mild rectal bleeding, severe rectal pain, tenesmus, and constipation
- Pharyngitis:
 - Sore throat, exudative tonsillitis
- Disseminated gonococcal infections (DGI):
 - Gonococcal bacteremia
 - Arthritis: Dermatitis syndrome:
 - 0.5–3% of untreated mucosal infections
 - Triad of tenosynovitis, dermatitis, and polyarthralgia
 - Fever, chills, malaise
 - Dermatitis:
 - Tender necrotic pustules on an erythematous base, few lesions, begin distally
 - Acute monoarticular or oligoarticular arthritis:
 - Knee most common
 - Warm, erythematous joint with effusion and pain with range of motion
 - Female > male, 3:1:
 - Risk factors: Recent menstruation or recent pregnancy

- Rare manifestations:
 - Hepatitis
 - Myocarditis
 - Endocarditis
 - Meningitis

Physical-Exam

- Cervicitis:
 - Cervical edema, congestion, friability
- PID:
 - Uterine tenderness, adnexal or cervical motion tenderness
- Urethritis:
 - Yellow-white thick discharge, urethral meatal erythema

ESSENTIAL WORKUP

- Clinical diagnosis in male gonorrhea:
 - Gram stain 95% sensitive
- Cervical culture in female gonorrhea
- Also test for chlamydia and syphilis

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Cultures (gold standard):
 - Thayer-Martin medium
 - Mainstay for blood and synovial fluid
- Gram stain:
 - Intracellular gram-negative diplococci:
 - Approaches 100% sensitive in symptomatic men
- Nucleic acid amplification tests (NAATs):
 - DNA or RNA sequences using polymerase chain reaction (PCR)
 - Many also test for chlamydia
 - Useful in urethral, cervical, and urine specimens
- Pharyngeal/rectal cultures for local symptoms in high-risk individuals
- DGI:
 - Synovial fluid analysis:
 - Neutrophilic leukocytosis, $> 50,000$ cells/mm³
 - Positive cultures when $> 80,000$ cells/mm³
 - 2 or more sets of blood cultures
 - Synovial, skin, urethral or cervical, and rectal cultures:
 - Thayer-Martin media
- PID/lower abdominal pain in female:

- CBC
- Urinalysis
- Pregnancy test
- Consider pelvic ultrasound for tubo-ovarian abscess
- Rapid plasma reagin (RPR): For associated syphilis

DIFFERENTIAL DIAGNOSIS

- Urethritis:
 - Chlamydia
 - Trichomonas
 - UTI
 - Syphilis
- DGI:
 - Bacterial arthritis:
 - Meningococcus (rash)
 - Hepatitis B
 - Connective tissue disease:
 - Reiter syndrome
 - Rheumatoid arthritis
 - Psoriatic arthritis
 - Acute rheumatic fever:
 - Poststreptococcal arthritis
 - Infective endocarditis
 - Others:
 - HIV
 - Secondary syphilis
 - Viral infection
 - Lyme disease (rash)
 - Gout (arthritis)

TREATMENT

ED TREATMENT/PROCEDURES

- Hydration (0.9% NS) for nausea/vomiting
- Treat sexual partner. For expedited partner therapy jurisdiction – www.cdc.gov/std/ept
- Patient with gonorrhea should often be presumptively treated for chlamydial infection.
- Cervical, urethral, and anorectal infection:
 - Ceftriaxone: 250 mg IM once OR
 - Also treat for chlamydia:
 - Azithromycin: 1 g PO once OR

- Doxycycline: 100 mg PO BID for 7 days
- PID:
 - Outpatient:
 - Ceftriaxone: 250 mg IM once or cefoxitin 2 g IM and probenecid 1 g PO once or another 3rd-generation cephalosporin (ceftizoxime or cefotaxime) + doxycycline 100 mg BID for 14 days with or without metronidazole 500 mg PO BID for 14 days
 - Inpatient:
 - Cefoxitin 2 g IV q6h or cefotetan 2 g IV q12h + doxycycline 100 mg PO or IV q12h
 - Clindamycin 900 mg IV q8h + gentamicin loading dose (2 mg/kg) followed by (1.5 mg/kg) q8h or 3–5 mg/kg q24h
- Pharyngitis:
 - Ceftriaxone 250 mg IM single dose + treatment for chlamydia
- Epididymitis:
 - Ceftriaxone 250 mg IM once + doxycycline 100 mg BID for 10 days
- Treat sexual partner
- DGI:
 - Ceftriaxone: 1 g IV/IM daily (recommended)
 - Cefotaxime: 1 g IV q8h OR
 - Ceftizoxime: 1 g IV q8h OR
 - 24–48 hr after improvement, additional 7 days with:
 - Cefixime: 400 mg PO BID OR
 - Cefpodoxime: 400 mg PO BID
 - Neonates, incl. gonococcal scalp abscess
 - Ceftriaxone 25–50 mg/kg/d IV/IM for 7 days OR
 - If hyperbilirubinemia-Cefotaxime 25 mg/kg IV/IM q12h for 7 days
- Conjunctivitis:
 - Adults:
 - Ceftriaxone 1 g IM once
 - Ophthalmia neonatorum:
 - Ceftriaxone 25–50 mg/kg IM/IV once
 - Saline irrigation, hospitalize
- Meningitis/endocarditis:
 - Ceftriaxone 1–2 g IV q12h:
 - 10–14 days for meningitis
 - At least 4 wk for endocarditis
- Severe cephalosporin allergy:
 - Consult infectious disease
 - Cephalosporin use postdesensitization best alternative
 - Azithromycin 2 g PO for uncomplicated gonococcal infection:
 - Limit use to prevent resistance

Pediatric Considerations

- Gonococcal ophthalmia neonatorum:
 - Mother with genital tract infection
 - Bilateral conjunctivitis 2–5 days postpartum:
 - If untreated, leads to globe perforation

Pregnancy Considerations

- Gonorrhea: Ceftriaxone/spectinomycin
- Chlamydia: Erythromycin

FOLLOW-UP

DISPOSITION

Admission Criteria

PID—CDC recommendations

- Severely ill (e.g., nausea, vomiting, and high fever)
- Pregnant
- Does not respond to or cannot take oral medication
- Tubo-ovarian abscess
- Other emergency surgical condition possible (e.g., appendicitis).

Discharge Criteria

Uncomplicated genital, pharyngeal, or conjunctival infection

Issues for Referral

- Infertility
- Recurrent infection despite multiple therapy

PEARLS AND PITFALLS

- Epididymitis—rule out torsion
- DGI—strongly consider in young sexually active patient with acute nontraumatic oligoarthritis or tenosynovitis

GOUT/PSEUDOGOUT

Delaram Ghadishah

BASICS

DESCRIPTION

- Uric acid deposition into tissues, affecting mainly middle-aged men and postmenopausal women:
 - Most common crystalline diseases
 - 4 phases:
 - Asymptomatic hyperuricemia (serum urate >7 mg/dL)
 - Acute gout
 - Intercritical gout: Quiet intervening periods
 - Tophaceous gout (up to 45% of cases)
 - Risk factors:
 - Age >40
 - Male/female ratio 2:1–6:1 <65 yr old; 1:1 ≥ 65 yr old
 - Hypertension
 - Use of loop or thiazide diuretics
 - High intake of alcohol, meat, seafood, and fructose-sweetened beverages
 - Obesity
 - Urologic deposition of uric acid calculi may cause renal dysfunction.
 - Associated with avascular necrosis and deforming arthritis
 - Most frequent in previously damaged joints, tissues:
 - Synovium
 - Subchondral bone
 - Bursae (olecranon, infrapatellar, prepatellar)
 - Achilles tendon
 - Extensor surface of the forearms, toes, fingers, ear
 - Rarely CNS or cardiac (valves)
- Pseudogout: A disorder caused by calcium pyrophosphate crystal deposition:
 - Most common cause of acute monoarthritis >60 yr of age
 - Risk factors:
 - Hypercalcemia (e.g., hyperparathyroidism, familial)
 - Hemochromatosis; hemosiderosis
 - Hypothyroidism and hyperthyroidism
 - Hypophosphatemia, hypomagnesemia
 - Amyloidosis
 - Gout

ETIOLOGY

- Deposition of monosodium urate crystals in tissues from supersaturated extracellular fluid owing to:
 - Underexcretion (most commonly) or excessive production of uric acid
 - Any rapid change in uric acid levels
 - Initiation or cessation of diuretics
 - Alcohol, salicylates, niacin
 - Cyclosporine
 - Lead acetate poisoning
 - Uricosurics or allopurinol
- Pseudogout occurs secondary to excess synovial accumulation of calcium pyrophosphate crystals
- Precipitants for both gout and pseudogout include minor trauma and acute illnesses:
 - Surgery, ischemic heart disease

DIAGNOSIS

SIGNS AND SYMPTOMS

- Gout and pseudogout both present as acute monoarticular or polyarticular arthritis:
 - Increased warmth, erythema, and joint swelling are present.
 - Early attacks subside spontaneously within 3–21 days, even without treatment.
 - Later attacks may last longer, cluster, be more severe, and be polyarticular.
- Gout:
 - Symptoms present maximally within 12–24 hr.
 - Tophi and joint desquamation may be present.
 - Women predominantly present after menopause and have polyarticular predominance (up to 70%).
 - Less dramatic presentations in immunosuppressed and elderly
 - Most common: 1st metatarsophalangeal joint (75%) > ankle; tarsal area; knee > hand; wrist
- Pseudogout:
 - Typically involves larger joints than with gout
 - Most common: Knee > wrist > metacarpals; shoulder; elbow; ankle > hip; tarsal joints
 - Monoarticular (25%)
 - Asymptomatic (25%)
 - Pseudo-osteoarthritis (45%): Progressive degeneration, often symmetric
 - Pseudorheumatoid arthritis (in elderly)
- Polyarticular variant with fever and confusion

ESSENTIAL WORKUP

- Arthrocentesis and aspiration of tophi:
 - Examine aspirant for crystals, Gram stain, cultures, leukocyte count, and differential
 - Fluid is typically thick pasty white:
 - Gout: 20,000–100,000 WBC/mm³; poor string and mucin clot; no bacteria
 - Pseudogout: Up to 50,000 WBC/mm³; no bacteria
- Microscopic exam of crystals under polarized light:
 - Gout:
 - Needle shaped
 - Strong birefringence
 - Negative elongation
 - Pseudogout:
 - Rhomboid
 - Weak birefringence
 - Positive elongation

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC often shows leukocytosis.
- Chemistry panel to assess for renal impairment
- Magnesium and calcium, thyroid-stimulating hormone (TSH), and serum iron
- Uric acid level has limited value.
- If infectious arthritis is suspected:
 - Blood and urine cultures
 - Urethral, cervical, rectal, or pharyngeal gonococcal cultures

Imaging

- Plain radiographs to assess the presence of:
 - Effusion
 - Joint space narrowing
 - Baseline status of joint
 - Contiguous osteomyelitis
 - Fractures or foreign body
- Acute gout: Soft tissue swelling; normal mineralization; joint space preservation
- Chronic gout: Calcified tophi; asymmetric bony erosions; overhanging edges; bony shaft tapering
- Pseudogout: Chondrocalcinosis; subchondral sclerosis or cysts (wrist); radiopaque calcification of cartilage, tendons, and ligaments; radiopaque osteophytes
- Dual energy CT to assess for kidney stones or soft tissue urate crystals

Diagnostic Procedures/Surgery

- Arthrocentesis
- Aspiration of tophi

DIFFERENTIAL DIAGNOSIS

- Infectious arthritis
- Trauma
- Osteoarthritis
- Reactive arthritis
- Miscellaneous crystalline arthritis
- Aseptic necrosis
- Rheumatoid arthritis
- Systemic lupus erythematosus
- Sickle cell
- Osteomyelitis
- Psoriatic arthritis

TREATMENT

INITIAL STABILIZATION/THERAPY

- Relieve pain.
- Rule out infectious cause.

ED TREATMENT/PROCEDURES

- NSAIDs are 1st-line treatment.
- If NSAIDS ineffective or contraindicated:
 - Steroids (oral, intravascular, IM, intra-articular)
 - Colchicine (limited by toxicity)
- Joint aspiration
- Avoid aspirin
- Reduction of hyperuricemia and long-term management of gout and pseudogout are not within the usual scope of ED care:
 - Careful withdrawal of gout-producing agent
 - Uricosurics (e.g., probenecid, sulfinpyrazone)
 - Allopurinol to reduce uric acid synthesis
 - Increased fluid intake and urine alkalization to prevent renal stones
 - Long-term colchicine or NSAIDs prophylactically

MEDICATION

- Anakinra: 100 mg SQ QD:
 - Off label use for chronic, treatment refractory gout or pseudogout and with renal failure
- Allopurinol: 100 mg PO QD, increased weekly to max. 800 mg QD:

- Start 1–2 wk after attack has resolved
- Adjust for kidney disease
- Discontinue with rash or fever
- Treatment of choice with uric acid kidney stones
- Doses >400 mg should be taken in divided doses
- Colchicine: 1.2 mg PO upon gout flare followed by 0.6 mg 1 hr later:
 - Can cause bone marrow suppression at high doses
 - Not dialyzable
 - Long-term use may cause myopathy.
 - Adjust dose for liver or kidney disease.
 - Does not prevent monosodium urate deposition or joint damage of chronic gout
- Corticosteroids:
 - Corticotropin: 40 units IM, q8h, up to 2 doses
 - Methylprednisolone: 40 mg (peds: 1–2 mg/kg) IM or IV QD for 3–4 days
 - Prednisone: 40 mg (peds: 1–2 mg/kg) PO QD for 3–4 days; taper over 7–14 days
 - Triamcinolone: 10–40 mg + dexamethasone 2–10 mg intra-articularly
- Febuxostat: 40–80 mg QD:
 - Give with NSAID or colchicine when 1st started
 - Inhibits urate production
 - Safe for mild or moderate kidney disease
- NSAIDs in maximal doses initially for 3 days, then taper over 4 days:
 - Ibuprofen: 800 mg (peds: 10 mg/kg) PO QID
 - Indomethacin: 25–50 mg PO TOD–QID (peds: 2 mg/kg/d TID–QID; *not* for children <14 yr old)
 - Ketorolac: 15–30 mg IM/IV in ED, may repeat for 1 dose (peds: 1 mg/kg to max. 30 mg IM or 0.5 mg/kg to max. 15 mg IV) IM:
 - Naproxen: 500 mg PO TID (peds: 5 mg/kg PO BID)
 - Sulindac: 200 mg PO TID
- Pegloticase: 8 mg IV over 2+ hr q2wk
 - For gout refractory to conventional treatment
 - Premedicate with antihistamine and steroids
 - Associated with anaphylaxis
 - Stop if uric acid increases to >6 mg/dL
 - Contraindicated with G6PD deficiency
- Probenecid: 250–500 mg PO q12h, max. 3 g QD:
 - Promotes excretion of uric acid
 - Not effective or less effective with renal disease or aspirin or diuretic use
 - Relatively contraindicated with presence of uric acid kidney stones
- Riloncept: 2 × 160 mg (2 × 2 mL) SC injected into 2 different sites on the same day, then 160 mg (1 × 2 mL) SC every week –Off label use for acute gout or prophylaxis

– Given during initiation of urate-lowering therapy

- Sulfipyrazone: 200–400 mg PO in divided doses BID with food, maintenance dose 400 mg in divided doses BID, max. 800 mg QD

Geriatric Considerations

NSAIDs may worsen renal function, fluid retention, gastropathy, hepatotoxicity, and cognitive function, particularly in the elderly.

Pediatric Considerations

Gout not usually seen in children, although possible during chemotherapy treatment for cancer.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Suspected infectious arthritis
- Acute renal failure
- Intractable pain

Discharge Criteria

- No evidence of infection
- Adequate pain relief

Issues for Referral

- Septic arthritis
- Renal failure

FOLLOW-UP RECOMMENDATIONS

- Rheumatology follow-up in severe or difficult to control cases
- Renal follow-up if renal insufficiency is present
- Urology follow-up if uric acid stones are present
- Orthopedic follow-up in cases of septic arthritis or significant joint damage
- Advise patient to follow a low-purine diet.

PEARLS AND PITFALLS

- Septic arthritis can occur simultaneously with an acute gout attack.
- NSAIDs are 1st-line treatment if tolerated.
- Attacks generally tend to be self-limited.
- Gout and pseudogout can lead to bony and cartilaginous damage.

GRANULOCYTOPENIA

Richard E. Wolfe • William D. Timbers • Elicia Sinor Kennedy

BASICS

DESCRIPTION

- A significant decrease in the number of granulocytes in the peripheral blood.
- 3 classes of granulocytes:
 - Neutrophils or polymorphonuclear (PMN) cells and bands
 - Eosinophils
 - Basophils
- As PMN cells predominate, the term neutropenia is often used interchangeably with granulocytopenia, as almost all granulocytopenic patients are neutropenic.
- Granulocytes are a key component of the innate immune system.
- The clinical risks resulting from granulocytopenia are best defined by the level of the absolute neutrophil count (ANC):
 - $ANC = WBC \times \text{percentage (PMN + bands)}$
 - Modern automated instruments often calculate and report ANC.
- Neutropenia: $ANC < 1,500 \text{ cells/mm}^3$:
 - Mild: Between 1,000 and 1,500
 - Moderate: Between 500 and 1,000
 - Severe: < 500
 - Agranulocytosis: < 100
 - Patients with a count $< 1,000$ that has recently or rapidly fallen are at greater risk for infection than those with a count < 500 but rising.
 - Patients with myelodysplastic syndromes should be considered granulocytopenic with higher counts because of defective neutrophils.
- 4 basic mechanisms cause granulocytopenia:
 - Decreased production
 - Ineffective granulopoiesis
 - Shift of circulating PMN cells to vascular endothelium
 - Enhanced peripheral destruction.
- Mortality of fever and neutropenia is as high as 50% if untreated:
 - Mortality correlates with the duration and severity of the neutropenia and the time elapsed until the 1st dose of antibiotics.
- 21% of patients with cancer and neutropenic fever develop serious complications.

Pediatric Considerations

- Newborn infants have a physiologically elevated ANC in the 1st few days of life and may be granulocytopenic with levels $> 1,500/\mu\text{L}$.
- Children $> 3 \text{ mo}$ without underlying immunodeficiency or a central venous

catheter unexpectedly found to have isolated moderate neutropenia are not at high risk of serious bacterial infection.

ETIOLOGY

- Most common in patients undergoing myelosuppressive drug therapy or radiation treatment for neoplasms. Most common 5–10 days after chemo.
- Adverse reaction to drugs is the 2nd most common cause:
 - Excludes cytotoxic drugs and requires at least 4 wk of administration prior to the onset of granulocytopenia
 - Discontinuation usually results with correction within 30 days.
 - Drugs with the highest risk:
 - Antipsychotic: Clozapine
 - Antibiotic: Sulfasalazine
 - Antithyroid: Thioamides
 - Antiplatelet agents
 - Antiepileptic drugs
 - NSAIDs
- Drugs that suppress the bone marrow:
 - Methotrexate
 - Cyclophosphamide
 - Colchicine
 - Azathioprine
 - Ganciclovir
- Chemicals
- Bacterial infections:
 - Typhoid
 - Shigella enteritis
 - Brucellosis
 - Tularemia
 - Tuberculosis
- Parasitic infections:
 - Kala azar
 - Malaria
- Rickettsial infections:
 - Rickettsialpox
 - Ehrlichiosis
 - Rocky Mountain spotted fever
- Viral infections
- Postinfectious neutropenia:
 - Most severe and protracted following HIV, hepatitis B, and Epstein–Barr viral infections
- Immune-related:
 - Primary immune neutropenia:

- Due to antineutrophil antibodies
 - Crohn's disease
 - Systemic lupus erythematosus
 - Rheumatoid arthritis
 - Goodpasture disease
 - Wegener granulomatosis
 - Thymoma
 - Complement activation
- Bone marrow infiltration
- Transfusion reaction
- Alcoholism
- Vitamin deficiency (B₁₂/folate/copper)
- Chronic idiopathic neutropenia
- Pure white cell aplasia

Pediatric Considerations

- Congenital neutropenia:
 - Neutropenia with abnormal immunoglobulins
 - Reticular dysgenesis
 - Severe congenital neutropenia or Kostmann syndrome
 - Cyclic neutropenia
- Chronic benign neutropenia
- Neonatal isoimmune neutropenia
- Shwachman–Diamond syndrome
- Cartilage–hair hypoplasia
- Dyskeratosis congenita
- Barth syndrome
- Chédiak–Higashi syndrome
- Myelokathexis
- Lazy leukocyte syndrome
- Cohen syndrome
- Hermansky–Pudlak syndrome type 2

DIAGNOSIS

SIGNS AND SYMPTOMS

- Signs of bacterial or fungal infection:
 - Fever
 - Localized erythema or fluctuance
- Signs of pancytopenia:
 - Fatigue
 - Pallor

- Petechiae
- Epistaxis and other spontaneous bleeding

History

- Medical list should be reviewed for causative drugs.
- Family history of granulocytopenia in neonates and children
- Records of past ANC levels to assess for chronicity
- Question the patient carefully about fever, chills, dizziness, and vomiting as indicators of an underlying serious infection.
- Ask about localizing signs of infection such as cough; shortness of breath; chest pain; dysuria; urinary retention, urgency, or frequency; abdominal pain; and rectal pain.

Physical-Exam

Focus on finding signs of infection:

- Oral exam: Thrush, ulcers, periodontal disease, mucositis
- Lungs: Rales, rhonchi
- Abdominal: Splenomegaly
- Skin: Rashes, ulcers, abscesses
- Perirectal: Although the rectal exam is relatively contraindicated until antibiotics are started, check for abscesses and mucosal lesions.
- Evaluate indwelling catheter sites

ESSENTIAL WORKUP

Complete physical exam:

- Detailed exam of oral mucosa and perianal area
- Palpation of skin
- Location of fluctuance or tenderness
- Careful lung exam and abdominal
- Rectal exam after antibiotics if symptoms suggest perirectal abscess

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC with differential:
 - ANC
- LFTs
- Blood culture before antibiotics from 2 different sites, with 1 from IV catheter site if present
- Urinalysis and urine culture:
 - May not show WBCs or leukocytes esterase OR may be normal
- Sputum Cx if applicable
- Stool Cx if applicable

- Culture indwelling catheters
- Cerebrospinal fluid analysis for altered mental status/signs of meningitis

Imaging

CXR even in absence of lung findings

DIFFERENTIAL DIAGNOSIS

- Lab error
- Neoplasm and chemotherapy
- Medication reaction
- Chemical exposure
- Infections (viral/bacterial/rickettsial)
- Autoimmune syndrome
- Genetic etiology
- Transfusion reaction
- Nutritional deficiency
- Tumor lysis syndrome
- Hypersplenism
- African Americans may have a lower but normal ANC value of 1,000 cells/mm³

TREATMENT

INITIAL STABILIZATION/THERAPY

For patients presenting in shock:

- Administer 1 L 0.9% NS IV fluid bolus (peds: 20 cc/kg).
- Initiate pressors as needed to stabilize BP if no response to IV fluids.
- Consider starting goal-directed therapy.

ED TREATMENT/PROCEDURES

- Strict isolation in a negative airflow room if possible
- Administer broad-spectrum combination antibiotics after cultures for suspected or documented infection:
 - Imipenem/cilastatin or fluoroquinolone
 - Ceftazidime alone or with aminoglycoside (amikacin, tobramycin, gentamicin)
- Cefepime alone
- Aminoglycoside + antipseudomonal β -lactam (mezlocillin, piperacillin, or ticarcillin)
- Vancomycin if patient is at risk to be carrier of *MRSA*

MEDICATION

- Amikacin: 15 mg/kg/24 h (peds: 15–30 mg/kg/24 h) div. q8–12h IV

- Cefepime: 0.5–2 g q12h
- Ceftazidime: 1–2 g (peds: 30–50 mg/kg q8h) q8–12h IV
- Gentamicin: 1 mg/kg (peds: 2–2.5 mg/kg) q8h or 5 mg/kg q24h
- Imipenem/cilastatin: 250–1,000 mg q6–8h
- Levofloxacin: 500 mg IV QID
- Mezlocillin: 3 g q4h over 30 min
- Tobramycin: 1 mg/kg q8h IV (peds: 2–2.5 mg/kg q8h IV)
- Vancomycin: 15 mg/kg q8–12h IV

FOLLOW-UP

DISPOSITION

Risk Stratification

MASCC Score: Identifies febrile neutropenic patients who are at a lower risk of complications.

Admission Criteria

- Signs of infection
- Unreliable patient
- Close follow-up unavailable

Discharge Criteria

- Previously diagnosed granulocytopenia
- Completely asymptomatic
- Close follow-up ensured
- Reliable patient

Issues for Referral

All patients with granulocytopenia should be referred to their physician or a hematologist.

FOLLOW-UP RECOMMENDATIONS

- Patient should return immediately to the ED with fever.
- Follow-up within 48 hr with the patient's physician

PEARLS AND PITFALLS

- Usual signs of infection may be masked because of the impaired immune response in patients with granulocytopenia.
- Rectal exams and rectal temperatures are relatively contraindicated in neutropenic patients but should be performed once antibiotics are started to avoid missing a

perirectal abscess.

- Patients with fever and an ANC < 500 requires immediate and aggressive therapy with broad-spectrum antibiotics and IV fluids.
- Hepatosplenic candidiasis: Complication of resolving neutropenia. Abscess formation as ANC rises. Treat with amphotericin B.

GUILLAIN–BARRÉ SYNDROME

Erin F. Drasler • Jeffrey Druck

BASICS

DESCRIPTION

- Group of peripheral nerve disorders characterized by autoimmune demyelination and axonal degeneration of peripheral nerves leading to acute ascending paralysis
- Humoral and cellular immune mediated
- Leading cause of acute flaccid paralysis worldwide (since polio vaccination)
- Triggered by antecedent bacterial/viral infection
- Increasing incidence with advancing age, male gender
 - Average 1.1 per 100,000 per yr
- Weakness reaches nadir at 2–4 wk
- Spontaneous resolution occurs over weeks to months
 - 80% full recovery at 1 yr
 - 20% unable to walk at 6 mo
 - 5% die of complications (PE, infection, cardiac)
- Acute inflammatory demyelinating polyradiculoneuropathy (AIDP):
 - Most common form of Guillain–Barré syndrome (90% of all GBS cases)
 - Demyelination sometimes accompanied by axonal loss
- Other forms of GBS:
 - Acute motor axonal neuropathy (AMAN):
 - Pure motor axonal involvement
 - 67% seropositive for *Campylobacter jejuni*
 - Recovery often rapid
 - Often pediatric patients
 - Acute motor sensory axonal neuropathy (AMSAN):
 - Degeneration of myelinated motor and sensory nerves without significant inflammation or demyelination
 - Similar to AMAN, but also involves sensory nerves
 - Acute panautonomic neuropathy:
 - Very rare
 - Involves sympathetic and parasympathetic nerves
 - Postural hypotension, dysrhythmias, tachycardia, hypertension
 - Blurry vision, dry eyes, anhidrosis
 - Recovery gradual, often incomplete
 - Miller Fisher syndrome:
 - Rare
 - Rapidly evolving ataxia, areflexia, and ophthalmoplegia without weakness

- Demyelination and inflammation of cranial nerves II and VI, spinal ganglia, and peripheral nerves
- Resolves in 1–3 mo

ETIOLOGY

- Postinfectious:
 - 2/3 with antecedent illness, usually respiratory or GI
 - Different autoantibodies associated with different subtypes
 - 1–3 wk between prodromal illness and neurologic symptoms
 - *C. jejuni* most common antecedent bacterial infection
 - *Cytomegalovirus* most common antecedent viral infection
 - Epstein–Barr virus, VZV, HIV, mycoplasma also associated
- Relationship to vaccines is questionable
 - Slight increased risk ascribed to 1976 swine flu vaccine, no other vaccines have same risk

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Rapidly evolving, symmetric, ascending paralysis
- Absent or mild sensory symptoms (e.g., paresthesias of fingertips or toes)
- Pain, commonly of pelvis, shoulder girdles, posterior thighs
- Cranial nerve involvement may affect swallowing, facial muscles, eye movements
- Preceding bacterial or viral infection
- Progression of symptoms over 8 wk not consistent with GBS, but chronic inflammatory demyelinating polyradiculoneuropathy (CIDP)

Physical-Exam

- Ascending symmetric weakness, legs more affected than arms
- Loss of deep tendon reflexes
- Look for cranial nerve involvement
- Respiratory insufficiency (25% patients)
- Normal sensory exam
- Other subtypes:
 - Autonomic dysfunction:
 - Hypertension
 - Orthostatic hypotension
 - Ileus
 - Dysrhythmias
 - Urinary retention

- Miller Fisher variant:
 - Ataxia
 - Areflexia
 - Ophthalmoplegia
 - Mild limb weakness
- Features that suggest alternative diagnosis:
 - Fever
 - Normal reflexes
 - Upper motor neuron signs
 - Asymmetric neurologic deficits
 - Sharply demarcated sensory level

DIAGNOSIS TESTS & INTERPRETATION

- Diagnosis is generally made on clinical grounds
- Lab and imaging tests can assist with diagnosis and rule out other causes of symptoms

Lab

- Electrolytes (some patients have SIADH)
- Lumbar puncture:
 - Albuminocytologic dissociation-increased protein with few or no WBCs
 - Protein typically 55–350, may be present only after 7–10 days as disease and blood–brain barrier dysfunction progress
 - WBCs > 10–50 suggests other etiology
 - Normal opening pressure

Imaging

CT or MRI to rule out cord compression

Diagnostic Procedures/Surgery

Electrophysiologic studies will be abnormal (nerve conduction confirmatory)

DIFFERENTIAL DIAGNOSIS

Polyneuropathies:

- Acute intermittent porphyria
- Chronic heavy metal poisoning
- Diphtheria
- Lyme disease
- Paraneoplastic disease
- Poliomyelitis
- Sarcoidosis
- Tick paralysis
- Vasculitis

Spinal cord disorders:

- Cord compression
- Transverse myelitis

Neuromuscular junction disorders:

- Botulism
- Eaton–Lambert syndrome
- Myasthenia gravis

Muscle disorders:

- Acute polymyositis
- Critical illness myopathy

Other:

- Hypokalemia
- Psychogenic, malingering

TREATMENT

PRE HOSPITAL

Attention to airway management

INITIAL STABILIZATION/THERAPY

Airway assessment and management:

- Progression to respiratory failure can be rapid

ED TREATMENT/PROCEDURES

- Airway management:
 - _ ~ 30% will need ventilatory support.
 - _ May need intubation within 24–28 hr of onset
 - _ Frequent monitoring of respiratory parameters:
 - Forced vital capacity (FVC) or negative inspiratory flow (NIF) helpful
 - ICU admission if FVC < 20 mL/kg or NIF < 30 cm H₂O
 - Intubation recommended if FVC < 15 mL/kg
- Watch for autonomic dysfunction
- Supportive therapy
- Early neurology consult

MEDICATION

- Plasmapheresis or IV immunoglobulin (IVIG), in conjunction with neurologic consultation:
 - _ Unclear benefit for Miller Fisher or mild GBS
- IVIG: 400 mg/kg/d for 5 days
- Pain control:
 - _ Acetaminophen: 500 mg PO q6h; not to exceed 4 g/24h

- Ibuprofen: 400–800 mg PO q8h
- Gabapentin: Start 300 mg PO per day
- Steroids not beneficial for pain or deficits:
 - Oral steroids delay recovery
 - IV steroids with no benefit

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with GBS or suspected GBS warrant admission for close observation
- ICU admission for those with signs of respiratory compromise, autonomic dysfunction or need for frequent monitoring for progression of illness

Discharge Criteria

Patients should be considered for discharge only after consultation with neurologist

FOLLOW-UP RECOMMENDATIONS

- Follow-up determined by neurologist
- Poor outcome associated with:
 - Older age
 - Longer time to nadir
 - Necessity for ventilator support
 - Preceding diarrheal illness, *C. jejuni*

PEARLS AND PITFALLS

- Pearls:
 - Check FVC and/or NIF frequently to anticipate airway compromise
 - Consider other etiologies if CSF WBC count > 10–50
- Pitfalls:
 - Failure to obtain appropriate imaging of the brain and spinal cord to rule out other potential causes
 - Failure to consult neurology and admit or observe all patients with suspected GBS

HALLUCINATIONS

Michael Ganetsky

BASICS

DESCRIPTION

Hallucinations are a symptom or feature and not a diagnosis. They may be auditory, visual, tactile, gustatory, or olfactory. Hallucinations and similar phenomena are often defined as follows:

- **Hallucination:**
 - Sensory perception that has the compelling sense of reality of a true perception without external stimulation of the relevant sensory organ and is experienced as a sensation through that organ
 - Patients may or may not have insight that they are having the hallucination
- **Illusion:**
 - Misperception or misinterpretation of a real external stimulus
- **Flashback:**
 - Recurrence of a memory, feeling, or perceptual experience from the past that may have the compelling sense of reality
- **Pseudohallucination:**
 - Hallucination that is not experienced by a sensory organ (i.e., voices inside head or “inner voice” as opposed to hearing voices)

EPIDEMIOLOGY

Incidence and Prevalence Estimates

- Lifetime incidence of auditory hallucinations is 4–8% in general population (although some estimates are higher due to vague definitions or inclusion of pseudohallucinations)
- More than 50% of elderly patients with dementia have paranoia or hallucinations

ETIOLOGY

There are numerous causes of hallucinations. The following are common: (An exhaustive list is beyond the scope of this chapter)

- **Psychiatric**
 - Schizophrenia
 - Bipolar disorder, mania
 - Major depression
- **Acute intoxications**
 - Ethanol
 - Cannabis

- Marijuana alternatives (i.e., *K2*, *Spice*)
- Sympathomimetics
 - Amphetamine
 - Methamphetamine
 - Cocaine
 - Synthetic cathinones (i.e., MDPV, ``bath salts'')
- NMDA antagonists
 - Ketamine
 - PCP
 - Dextromethorphan
- Serotonergic
 - MDMA (Ecstasy)
 - LSD
 - Peyote cactus (mescaline)
 - Mushrooms (psilocybin)
 - 2C series (i.e., 2CB, 2CT-7)
 - 5-MeO series (i.e., 5-MeO-DMT)
- Kappa opioid receptor agonist
 - *Salvia divinorum* (cause synesthesias – i.e., hearing colors or smelling sounds)
- Opiates
- Inhalants
 - Toluene
 - Nitrous oxide
- Medications
 - Anticholinergic agents
 - Steroids
 - Methylphenidate
- Withdrawal
 - Ethanol
 - Benzodiazepines
 - Barbiturates
 - GHB
- Substance-induced disorders
 - Methamphetamine-associated psychosis
 - Prolonged duration of psychosis, auditory hallucinations and recurrence without relapse of using drug
 - Cannabis-induced psychosis
- Infectious
 - Meningitis
 - Encephalitis
 - In patients with dementia, any infection (i.e., UTI, pneumonia) can trigger hallucinations

- Metabolic
 - Hypoglycemia
 - Electrolyte imbalances
 - Thyroid disease
 - Adrenal disease
 - Wilson’s disease
 - Thiamine deficiency
- Neurologic
 - Seizures
 - Partial simple or complex seizures can result in visual, auditory, olfactory, and gustatory hallucinations
 - Migraines
 - CNS hemorrhage or tumor
 - CVA
 - Tourette syndrome
 - Neurodegenerative disorders
 - Parkinsons
 - Dementia (Lewy body, Alzheimer)
 - HIV
- Ocular
 - Glaucoma
 - Macular degeneration
 - Charles Bonnet syndrome
- Others
 - Food, sensory, sleep deprivation
 - Fatigue, extreme stress
 - Heat-related illness
 - Religious and ritual activities
 - Falling asleep and awakening from sleep

Pediatric Considerations

Hallucinations are relatively common in children and adolescents and are often developmentally normal. Most children with hallucinations do not have psychosis. Hallucinations can occur as part of a delirium, such as from fever. As with the adult patient, carefully conduct a search for a medical or neurologic etiology.

Geriatric Considerations

In the elderly patient, hallucinations are most often from an organic cause. They can commonly accompany dementia, depression, medication reactions and substance abuse, and are often associated with agitation. Atypical antipsychotic agents are effective treatment for hallucinations with agitation in the elderly.

SIGNS AND SYMPTOMS

History

- Obtaining accurate and thorough history often difficult
 - Collateral history should be obtained from bystanders, EMS, police, family, physicians
- Assess for changes in behavior from baseline
- Explore for delusions or persecutory beliefs
- Previous episodes of hallucinations
- Change in medications
- Substance abuse history
- Alteration in cognition that rapidly develops and waxes and wanes throughout course of the day suggests delirium
- Headache may suggest CNS lesion or migraine

Physical-Exam

- Acute psychosis
 - Disorganized thought
 - Responding to internal stimuli
- Mania
 - Excessive talking or pressured speech
- Delirium
 - Altered level of consciousness
 - Not oriented
 - Abnormal vital signs
- CNS lesion
 - Cranial nerve deficit
 - Aphasia
 - Any focal neurologic finding
 - Gait abnormality
 - External signs of trauma
- Systemic or infectious illness
 - Asterixis
 - Fever
 - Nuchal rigidity
 - Myoclonus
 - Jaundice
 - Ascites
- Signs of intoxication or withdrawal
 - Sympathomimetic intoxication, ethanol/benzodiazepine withdrawal

- Agitation, excited delirium
- Mydriasis
- Tachycardia, hypertension
- Hyperthermia
- Diaphoresis
- Opiate
 - Miosis
 - Bradypnea
 - Needle marks
- Serotonergic
 - Tachycardia, hypertension
 - Hyperreflexia
 - Clonus
 - Tremor
- NMDA antagonism
 - Nystagmus

DIAGNOSIS TESTS & INTERPRETATION

- Common tests:
 - CBC, serum chemistries
 - Ethanol, acetaminophen, salicylate serum concentrations
 - Urinalysis
- More focused studies depending on comorbid conditions or clinical concerns:
 - Urine drug of abuse screen
 - Interpretation can be difficult as this is a test of use and not intoxication. In addition, it is not designed to detect newer drugs of abuse, although some may cross-react with this assay.
 - EKG
 - Thyroid function
 - Liver function tests
 - RPR, folate, B₁₂, thiamine
 - Specific drug concentrations

Imaging

- Brain imaging (CT, MRI)
- Chest x-ray

Diagnostic Procedures/Surgery

- If suspicion exists for medical cause, should consider procedures such as:
 - Lumbar puncture
 - EEG
- If hallucinations are from acute psychiatric illness or decompensation of chronic

psychiatric illness

- Obtain emergent psychiatric consultation

ESSENTIAL WORKUP

Patients with a clear psychiatric history with characteristic symptoms need minimal testing (CBC, chemistries). However, patients with undifferentiated hallucinations, especially those in high-risk groups, require extensive testing.

DIFFERENTIAL DIAGNOSIS

The primary goal of ED evaluation is to differentiate psychiatric from nonpsychiatric cause of hallucination. (See Psychosis, Medical vs. Psychiatric)

- More likely to be from psychiatric illness:
 - Auditory and command hallucination
 - Hallucinations and illusions incorporated into delusional system
 - Age of onset 13–40 yr old
 - Flat affect
 - Normal orientation
 - Disorganized attention
- The following groups are considered to be at higher risk for nonpsychiatric illness:
 - Elderly
 - History of substance abuse
 - No pre-existing psychiatric history
 - Presence of pre-existing medical disorders
 - Lower socioeconomic level
- Visual hallucinations more common:
 - Delirium
 - Dementia
 - Migraines
 - Dopamine agonist therapy (i.e., carbidopa)
 - Posterior cerebral infarcts
 - Narcolepsy

TREATMENT

PRE HOSPITAL

Observe details of patient's environment not available to hospital care team

- Disorganized living environment
- Drug paraphernalia

INITIAL STABILIZATION/THERAPY

- Address ABC's and any abnormal vital signs (i.e., supplemental oxygen for hypoxia)
- Check FSBG

- Consider thiamine 100 mg IV/PO
- Treat acute agitation (see Agitation)
 - De-escalation techniques
 - Physical restraints
 - Chemical sedation

ED TREATMENT/PROCEDURES

- If underlying medical cause identified
 - Treat medical etiology
 - These patients typically do not require antipsychotic medications
- In patients with acute psychosis or decompensation of chronic psychotic illness
 - Use antipsychotics and benzodiazepines (see Psychosis, Acute)
- In patients with hallucinations due to intoxication with excited delirium
 - General supportive care
 - Benzodiazepines
- If dementia with hallucinations
 - Treat underlying medical etiology, if any
 - Atypical antipsychotics have benefits and harm (CVA, extrapyramidal symptoms)

ALERT

When treating hallucinations with an excited delirium due to acute intoxication (except for ethanol), use benzodiazepines.

FOLLOW-UP

DISPOSITION

Admission Criteria

Disposition determined by medical condition or psychiatric evaluation. Hallucinations from some intoxications such as methamphetamine or cannabis may persist even after drug is metabolized.

Admission Criteria

- Medical condition requiring admission
- Acute psychiatric illness or decompensation of chronic psychiatric illness requiring psychiatric hospitalization

Discharge Criteria

- Symptoms have resolved and reversible medical cause (i.e., intoxication, UTI)
- Decompensation of chronic psychiatric condition has been addressed, home environment appropriate and mental health follow-up available.

Issues for Referral

Alcohol/drug treatment as appropriate

FOLLOW-UP RECOMMENDATIONS

As appropriate for medical or chronic psychiatric condition(s)

PEARLS AND PITFALLS

- Do not assume that auditory hallucinations are always from psychiatric illness whereas visual, tactile, olfactory, and gustatory hallucinations are nonpsychiatric – always perform thorough evaluation.
- Even though 10% of cases of schizophrenia occur in patients older than 45, do not assume hallucinations are from psychiatric cause in older age group without extensive workup.
- Do not treat hallucinations with excited delirium from an acute intoxication (except due to ethanol) with antipsychotic agents.

- R44.1 Visual hallucinations
- R44.3 Hallucinations, unspecified

HALLUCINOGEN POISONING

Joanne C. Witsil

BASICS

DESCRIPTION

- Predominantly alters perception, cognition, and mood
- All hallucinogens potentiate neurotransmitter release or bind directly to receptors:
 - Serotonin (5-hydroxytryptamine; 5-HT): Many hallucinogens are agonists or antagonists at 5-HT receptor subtypes.
 - Norepinephrine, N-methyl-D-aspartate (NMDA), dopamine

ETIOLOGY

- Most exposures are intentional
- Common hallucinogens:
 - Indoleamine:
 - Lysergic acid diethylamide (LSD) (duration 6–12 hr)
 - Morning glory (*Ipomoea* spp.)
 - Tryptamines:
 - Psilocybin (*Psilocybe* mushrooms); frequently adulterated with LSD
 - N,N-dimethyltryptamine (DMT); 5-MeO-DMT (“foxy-methoxy”), and other tryptamine congeners
 - Phenylethylamines (hallucinogenic amphetamines):
 - Methylenedioxyamphetamine (MDA)
 - Methylenedioxymethamphetamine (MDEA)
 - Methylenedioxymethamphetamine (MDMA; “ecstasy”; duration 8–12 hr)
 - Paramethoxyamphetamine
 - Dimethoxyamphetamine
 - Mescaline (peyote cactus); frequently adulterated with LSD (duration 6–12 hr)
 - Arylcycloalkylamines:
 - Phencyclidine (PCP), (duration is variable 11–96 hr in 1 report)
 - Ketamine, (duration depends on route of administration 30–120 min)
 - Anticholinergic:
 - Deadly nightshade (*Atropa belladonna*)
 - Jimsonweed (*Datura stramonium*)
 - Other:
 - Piperazines: Benzyl piperazine (BZP) and trifluoromethyl phenylpiperazine (TFMPP)
 - Dextromethorphan (DXM), (duration 3–6 hr)

- Marijuana

DIAGNOSIS

SIGNS AND SYMPTOMS

- Considerable individual variation; effects may last 4–12 hr and ≤ 96 hr depending on agent/dose
- Symptoms characterized by sympathetic arousal
- Usually oriented and able to give history of exposure even while having delusions
- Initial symptoms:
 - Nausea, flushing, chills, tremor
- Neurologic symptoms:
 - Restlessness and dizziness early after ingestion
 - Desire to laugh (especially with *Psilocybe* mushrooms)
 - Anxiety, despair, helplessness, dread
 - Intensified perceptions, visual distortions/intensification
 - Tactile distortions (especially with mescaline)
 - Synesthesia (blending of sensory modalities, e.g., seeing sounds)
 - Religious or mystical experiences
 - Sleep disruption
- Neurologic signs:
 - Unusual/bizarre behavior
 - Speech disruption
 - Mydriasis
 - Piloerection
 - Hyperreflexia
 - Coma with massive exposure
 - Convulsions:
 - Hallucinogenic amphetamines
 - Children who become hyperpyrexia after *Psilocybe* mushroom ingestion
- Pulmonary:
 - Mild tachypnea
 - Respiratory arrest (with massive exposure)
- Cardiovascular:
 - Tachycardia
 - HTN (with hallucinogenic amphetamines)
 - Dysrhythmia (with hallucinogenic amphetamines)
 - Intracerebral hemorrhage (with hallucinogenic amphetamines)
- GI:
 - Nausea/vomiting (especially with mescaline)
- Metabolic:

- Hyperpyrexia:
 - Especially with MDMA use at “rave” clubs
 - Hepatic failure, renal failure, and disseminated intravascular coagulopathy may follow.
 - May be lethal
- Hyponatremia: Has been reported with MDMA use
- Hematopoietic:
 - Coagulopathies and hemorrhage at high doses owing to disruption of platelet serotonin function

History

Identity of agent or agents used including:

- Method of usage
- Quantity
- Time of exposure
- Knowledge of place of exposure

Physical-Exam

- Obtain accurate vital signs including temperature.
- Perform detailed neurologic and psychiatric exam

ESSENTIAL WORKUP

- Core temperature measurement and other vital signs
- ECG monitoring
- Determination of risk of rhabdomyolysis:
 - Creatine kinase level
 - Urine dip or myoglobin level

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Electrolytes, BUN, creatinine, glucose levels, coagulation screen, arterial, or venous blood gas
- Urine toxicology screen:
 - Rarely indicated
 - Distinguishing between hallucinogens is of little value
 - Most hallucinogenic substances are not tested for on routine drug screens
 - Amphetamine screen is frequently negative for hallucinogenic amphetamines (e.g., MDMA)

Imaging

- Consider chest x-ray if looking for aortic dissection, pulmonary aspiration, or trauma-related injury

- Consider CT of head if looking for intracranial bleeds or lesions
- Consider abdominal x-ray if there is suspicion of ingested packets

DIFFERENTIAL DIAGNOSIS

- Hypoglycemia
- Meningitis, encephalitis
- Sepsis
- Intracranial bleeds or lesions
- Withdrawal (ethanol, sedative–hypnotic, baclofen)
- Serotonin syndrome (especially with concomitant serotonergic agents involved)
- Psychiatric illnesses:
 - LSD associated with prolonged psychoses resembling schizoaffective disorders
 - Chronic amphetamine/cocaine abuse
 - Steroids
- Infectious/febrile seizures in hyperpyretic child

Pediatric Considerations

Assess parent–child relationships for possibility of neglect or abuse.

TREATMENT

PRE HOSPITAL

- Controversies:
 - Sedation with benzodiazepines vs. haloperidol vs. physical restraints:
 - Benzodiazepines are generally preferred
 - Sedation masks symptoms and may limit history
- Cautions:
 - Sedate or restrain patient to ensure safe transport
 - For hyperthermic patient:
 - Use sedation rather than physical restraint
 - Begin cooling measures

INITIAL STABILIZATION/THERAPY

- Management of ABCs
- Aggressive cooling if hyperthermic
- IV access/rehydration with isotonic fluids for significant fluid loss or evidence of rhabdomyolysis
- Naloxone, Accu-Chek, dextrose, and thiamine if patient has altered mental status

ED TREATMENT/PROCEDURES

- Cooling measures:

- Cool mist and fans
- Benzodiazepines if agitated
- Paralytics with intubation if needed (generally not succinylcholine)
- Sedate for agitation or autonomic signs:
 - Benzodiazepines
 - Rarely neuroleptics:
 - May intensify hallucinogenic experience
 - Possibly lower seizure threshold
- Activated charcoal (AC) is not expected to be helpful for most agents owing to rapid absorption and delayed patient presentation:
 - Consider AC for oral ingestions within 2–3 hr in patients with intact protective airway reflexes; especially for anticholinergics or seeds owing to delayed GI motility/absorption
- Place in a quiet, calm environment
- Maintain urine output of 2–3 mL/kg/hr and consider urine alkalinization for treatment of rhabdomyolysis

MEDICATION

- Benzodiazepines (diazepam): 5–10 mg IV (peds: 0.2–0.5 mg/kg) IV or lorazepam: 1–4 mg IV/IM (peds: 0.02–0.05 mg/kg) IV/IM, may repeat as needed
- Dextrose (D₅₀W) for hypoglycemia: 1 ampule: 25 g/50 mL (peds: D₂₅W, 0.5–1 g/kg or 2–4 mL/kg) IV, may repeat as needed
- Haloperidol (Haldol): 2.5–5 mg IV or IM may repeat every 30–60 min until calm, usual max. dose is 10–20 mg; not recommended for children
- Naloxone (Narcan): Initial dose: 2 mg (peds: 0.01–0.1 mg/kg) IV or IM, may repeat as needed
- Sodium bicarbonate infusion for rhabdomyolysis: 3 ampules in 1 L of D₅W; infuse at 1.5–2 times maintenance rate (keep urine pH > 7.5)
- Thiamine (vitamin B₁): 100 mg (peds: 25 mg) IV or IM × 1 dose

FOLLOW-UP

DISPOSITION

Admission Criteria

- Severely intoxicated
- Atypical presentation
- Prolonged symptoms (> 12 hr after exposure)
- Prolonged periods of agitation and hyperthermia:
 - Risk of rhabdomyolysis or organ damage

Discharge Criteria

After receiving supportive therapy and observation, most patients can be discharged once they are asymptomatic.

Pediatric Considerations

Suspected cases of child abuse or neglect require referral to child protective services.

FOLLOW-UP RECOMMENDATIONS

Upon discharge, patients should receive follow-up care from their PCP, psychiatrist, or drug counseling facility.

PEARLS AND PITFALLS

- Do not delay in the diagnosis and treatment of hyperthermia. Once hyperthermia is identified, aggressively lower body temperature.
- Use appropriate physical and chemical restraints to control violent and agitated patients to protect the patient and staff from physical injury.
- Conduct serial exams and vital signs (especially temperature). Do not assume once a violently agitated patient is calm that the patient is recovering. The patient may be progressing to serious illness.

HAND INFECTION

Chester D. Shermer

BASICS

DESCRIPTION

- Hand infections are commonly seen in the ED.
- The range of pathology is broad and may include acute *and* chronic conditions.

ALERT

- Serious hand infections are potential liability issues and must be handled with extreme caution.
- Referral to hand surgeon is almost always indicated.

ETIOLOGY

- Bacterial infection of the hand is associated with skin pathogens:
 - Staphylococcus or Streptococcus spp
 - History of a puncture wound
- Anaerobes are identified in 75% of paronychia in children owing to thumb sucking and nail biting.
- Chronic paronychia may be caused by *Candida albicans*.
- Herpetic whitlow is caused by type 1–2 herpes simplex virus.
- Clenched fist injuries involve a variety of pathogens, including anaerobic Streptococcus and Eikenella spp.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Paronychia:
 - Localized edema, erythema, and pain in proximal portion of lateral nail fold
 - Fluctuance may be present and may extend beneath the nail margin.
 - Systemic signs and symptoms are usually not present.
- Felon:
 - Erythema and tense swelling of the distal pulp space that does *not* extend proximal to the proximal interphalangeal (PIP) joint
 - Aching pain early, severe throbbing pain late
 - Systemic signs are usually not present.
- Herpetic whitlow:
 - Distal pulp space is swollen, but remains soft.
 - Lateral nail folds may be affected.

- Throbbing pain of the distal pulp space
- Vesicles containing nonpurulent fluid are present and may form bullae.
- Systemic symptoms may be present:
 - Fever
 - Lymphadenopathy
 - Constitutional symptoms
- Flexor tenosynovitis:
 - Kanavel signs:
 - Severe pain and symmetric edema of the digit
 - Tenderness over the course of tendon sheath
 - Flexed position of the finger at rest
 - Pain on passive extension of the finger—may be the only finding in early infection
- Clenched fist injury:
 - Laceration over the metacarpophalangeal (MCP) joint from striking an object with a clenched fist
 - Any laceration over the MCP must be assumed to be a *human bite wound* until proven otherwise.
- Web space abscess:
 - Pain and edema of the affected web space and adjacent palm
 - Fingers are held abducted.
- Palmar space infections:
 - Thenar space infection:
 - Pain, tenderness, tense edema of thenar eminence
 - Dorsal edema without tenderness
 - Thumb is held abducted and flexed, and passive adduction is painful.
 - Midpalmar space infection:
 - Pain, edema, and tenderness of the midpalmar space
 - Dorsal edema without tenderness
 - Motion of middle and ring fingers is painful
 - Hypothenar space infection:
 - Pain and fullness over hypothenar eminence
 - No limitation of finger movement

History

See Signs and Symptoms.

Physical-Exam

See Signs and Symptoms.

ESSENTIAL WORKUP

Most hand infections are diagnosed by history and physical exam with special attention to neurovascular status.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Although usually not necessary, herpetic whitlow may be confirmed by Tzanck test.
- Gram stain and culture may guide antibiotic choice in felons.
- Blood cultures, CBC are not routinely indicated.

Imaging

- Radiographs are usually not helpful unless there has been trauma or a suspected foreign body.
- With felon, flexor tenosynovitis, and palmar space infection, radiograph may identify osteomyelitis or foreign body.
- Radiographs in clenched fist injury may reveal a fracture.

DIFFERENTIAL DIAGNOSIS

- Paronychia should be differentiated from herpetic whitlow and felon.
- The differential for palmar space infection includes flexor tenosynovitis, cellulitis, and web space infection.

TREATMENT

PRE HOSPITAL

Hand immobilization as appropriate

ED TREATMENT/PROCEDURES

- Paronychia:
 - Early paronychia/simple cellulitis without purulence present may be managed with oral antibiotics and rest:
 - Cephalexin, dicloxacillin
 - Clindamycin or erythromycin, if associated with nail biting or oral contact
 - Superficial infections are drained by inserting a No. 11 blade between nail and eponychium, and lifting the eponychium from the nail.
 - If necessary, the lateral nail fold may be incised tangential to the curvature of the nail.
 - When pus is present under the adjacent nail, 1/4 of the nail should be removed.
 - When pus is present under the dorsal roof of the proximal nail, remove 1/3 of the proximal nail.
- Felon:
 - A lateral incision avoiding the neurovascular bundle is preferred.

- More extensive felons are drained through a unilateral longitudinal incision that does not cross the distal interphalangeal (DIP) flexor crease.
- Disruption of fibrous septa is no longer recommended:
 - Results in an unstable fingertip
 - Loculations may need to be broken up.
- Give oral antibiotics to cover skin pathogens, place a drain, and recheck in 48 hr:
 - Cephalexin, dicloxacillin
- Herpetic whitlow:
 - Usually self-limited; do not incise and drain.
 - Oral acyclovir may be given to patients with systemic involvement.
- Flexor tenosynovitis, web space abscess, palmar space infection:
 - Elevation, IV antibiotics, and pain control:
 - Ampicillin/sulbactam, cefoxitin, ticarcillin/clavulanate
 - All of these infections require immediate consultation with a hand surgeon.
- Clenched fist injury:
 - Elevation, IV antibiotics, tetanus prophylaxis, and pain control in the ED:
 - Ampicillin/sulbactam, cefoxitin, ticarcillin/clavulanate
 - All bite wounds with evidence of infection or joint involvement require emergent consultation with a hand surgeon.
 - If there are no signs of infection and no joint penetration, patients may be considered for outpatient treatment with oral antibiotics after appropriate irrigation and wound care:
 - Ampicillin/clavulanate or penicillin V + cephalexin or dicloxacillin
 - Do *not* primarily close lacerations associated with a human bite; delayed primary closure or healing by secondary intention is appropriate.

MEDICATION

- Acyclovir: 400 mg PO TID for 10 days (peds: Not recommended for herpetic whitlow)
- Amoxicillin/clavulanate: 875/125 mg PO BID (peds: 40 mg/kg/d PO div. q6h)
- Ampicillin/sulbactam: 1.5–3 g IV q6h (peds: Safety not established)
- Cefoxitin: 2 g IV q8h (peds: 80–160 mg/kg/d IV or IM div. q6h)
- Cephalexin: 500 g PO QID for 7 days (peds: 40 mg/kg/d PO div. q6h)
- Clindamycin: 300–450 mg PO QID for 7 days. Can use IV in severe cases: 600–900 mg IV q8h (peds: 20–40 mg/kg/d div. q8h PO IV or IM)
- Dicloxacillin: 500 mg PO QID for 7 days (peds: 12.5–50 mg/kg/d PO div. q6h)
- Erythromycin: 500 mg PO QID for 7 days (peds: 40 mg/kg/d div. q6h PO)
- Penicillin V: 250 mg PO QID (peds: 40 mg/kg/d PO div. q6h)
- Ticarcillin/clavulanate: 3.1 g IV q4–q6h (peds: 150–300 mg/kg/d IV div. q6–8h)

Tailor to etiology

Second Line

Tailor to etiology

FOLLOW-UP

DISPOSITION

Admission Criteria

- Flexor tenosynovitis, web space abscess, palmar space infections:
 - All these infections require admission for IV antibiotics and drainage.
- Clenched fist injury with signs of infection:
 - Requires admission for surgical débridement and IV antimicrobials

Discharge Criteria

- Paronychia and felons:
 - Patients with uncomplicated paronychia or felon may be discharged from the ED with a recheck and drain removal in 48 hr.
- Herpetic whitlow:
 - Patients with herpetic whitlow may be discharged from the ED with appropriate follow-up.
- Clenched fist injury without infection:
 - May be discharged on oral antibiotics with follow-up in 24 hr

Issues for Referral

Immediate consultation in emergency department is indicated

FOLLOW-UP RECOMMENDATIONS

Usually arranged by admitting physician after operative therapy

PEARLS AND PITFALLS

- Missed or delay in diagnosis
- Failure to obtain history of clenched fist injury
- Failure to consult surgeon promptly

CODES

ICD9

- 112.3 Candidiasis of skin and nails
- 681.02 Onychia and paronychia of finger
- 914.9 Other and unspecified superficial injury of hand(s) except finger(s) alone, infected

ICD10

- B37.2 Candidiasis of skin and nail
- L03.019 Cellulitis of unspecified finger
- S61.439A Puncture wound w/o foreign body of unsp hand, init encntr

BASICS

DESCRIPTION

- Hazmat refers to exposure to hazardous materials causing local or systemic toxicity.
- Pathophysiology:
 - Acids cause coagulation necrosis with eschar, usually limiting penetration to deeper tissue.
 - Alkalis cause liquefaction necrosis and soluble complexes that penetrate into deep tissues.
 - Damage also occurs through oxidation, protein denaturation, cellular dehydration, local ischemia, and by metabolic competition/inhibition.

ETIOLOGY

- Hazardous materials are encountered in household, industry, agriculture, transportation accidents, and in criminal/terrorist activities.
- The toxicity of the materials relates to the particular substances and their effects.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Skin:
 - Chemical burns; may appear deceptively mild initially
 - Visible liquid or powder on skin
 - Absorption through skin may cause systemic toxicity.
- Mucous membranes (eyes, nasopharynx; see Corneal Burn):
 - Ranges from subjective irritation to serious mucosal burns
 - Potential airway compromise
- Pulmonary:
 - Cough
 - Pleuritic chest pain
 - Bronchospasm
 - Dyspnea
 - Pulmonary edema (immediate or delayed)
- Systemic (after skin or pulmonary absorption):
 - Altered mental status
 - Seizures
 - Tachy/brady dysrhythmias

- Hypotension/HTN
- GI symptoms
- Electrolyte disturbances
- Carboxyhemoglobinemias and methemoglobinemias
- Cyanide toxicity
- Cholinergic syndrome (see Chemical Weapons Poisoning, Nerve Agents)

History

Elicit type, circumstances, and duration of exposure

ESSENTIAL WORKUP

- Attempt to identify substance using pre-hospital providers, Material Safety Data Sheet (MSDS), and *Chemical Transportation Emergency Center (Chemtrec)*.
- MSDS:
 - Identifies chemicals
 - Differentiates vapor vs. skin hazard
 - Determines need for decontamination
 - Limited treatment data
- Determine route and duration of exposure.
- Inhalation injury more likely in an enclosed space
- Determine toxicity using poison control; computerized databases, such as POISINDEX or TOXNET; or standard toxicology test.
- Observe as needed for systemic toxicity.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Depends on substance
- Electrolytes, BUN, creatinine, and glucose levels
- LFTs
- Calcium level
- Magnesium level
- Phosphorus level
- Arterial blood gases:
 - Metabolic acidosis
 - Carboxyhemoglobinemias and methemoglobinemias
 - Respiratory failure

Imaging

Chest radiograph for pulmonary edema

DIFFERENTIAL DIAGNOSIS

- Skin:

- Hypersensitivity reaction
- Thermal burns
- Pulmonary:
 - Pneumonia
 - Pulmonary embolism
 - Anaphylaxis
- Systemic:
 - Status epilepticus
 - Overdose
 - Psychiatric illness
 - Myocardial infarction

TREATMENT

PRE HOSPITAL

- Recognize a HAZMAT situation:
 - Accident at industrial/agricultural site
 - Accident involving transport of hazardous materials
 - Suspected terrorist mass casualty incident
 - Cholinergic syndrome
 - Irritant mucous membrane symptoms
 - Chemical burns
- Protect yourself:
 - Approach from upwind.
 - Do not enter scene until safety of material is determined.
 - Use Level A protective gear if safety not established
 - Anyone able to walk and talk is minimally contaminated.
- Personal chemical protective equipment:
 - Level A: Positive-pressure self-contained breathing apparatus (SCBA), fully encapsulated chemical-resistant suit, double chemical-resistant gloves, chemical-resistant boots, and airtight seals between suit, gloves, boots
 - Level B: SCBA, nonencapsulated chemical suit, double gloves, boots
 - Level C: Air-purification device, suit, gloves, boots
 - Level D: Common work clothes
 - Identify substance:
 - Department of Transportation (DOT) placard, MSDS, shipping papers, hazard labels
 - If unsuccessful, call Chemtrec (1[800] 424-9300) to determine substance and toxicity.
 - Hazmat teams can do chemical testing.
- Determine toxicity and need for decontamination:
 - Poison control (1[800] 222-1222)

- Chemtrec
- Decontaminate:
 - Hazmat team
- Treat:
 - Provide basic life support and advanced life support care as indicated.
 - Generally basic life support only in a “hot zone”
 - Irrigate skin and ocular burns immediately and continue until arrival at hospital.

INITIAL STABILIZATION/THERAPY

- Protect ED personnel:
 - Secondary contamination can occur from dermal contact or through inhalation of volatile gases/particles.
- Keep patients outside in designated hot zones until decontaminated.
- When in doubt, decontaminate.
- Expect contaminated patients to arrive via emergency medical services or private vehicle.
- If treatment is required before/during decontamination:
 - Use minimum necessary staff in appropriate personal protection gear.
 - Focus on life- and limb-saving care only.
- Decontamination:
 - Security to enforce hot zone
 - Remove, label, and double-bag clothing (including contact lens).
 - Copious irrigation with soap and water for 10–15 min with special attention to obviously contaminated areas, wounds, and exposed eyes
 - Recapture water to prevent contamination of the sewer and downstream areas:
 - In an emergency or mass casualty situation, it is acceptable to let water drain into sewer.
 - Hydrotherapy:
 - Mainstay of therapy for chemical burns
 - Contraindicated only for elemental metals (sodium and potassium)
 - Allow patient to decontaminate himself or herself or use trained decontamination team.
 - Decontaminate children, dependent elderly, mentally/physically challenged and their appliances (e.g., wheelchairs) with caregivers
 - Gloves, masks, goggles, and disposable gowns provide some protection
 - Remove/replace bandages, tourniquets, airway adjuncts, IV sets
 - Re-triage after decontamination.

ED TREATMENT/PROCEDURES

- Provide supportive care as needed.
- Determine if antidotal treatment would be effective and available.

- Hazmat incidents provoke extreme fear:
 - Expect casualties suffering from collective hysteria.
 - Knowledge of toxicologic profile can exclude contamination in these patients.
- ED staff may become symptomatic even if chemical concentrations in the air are below toxic levels and may need to be escorted to fresh air.
- Chemical burns:
 - Irrigation should be started as soon as possible and, if owing to a strong alkali, may need to be continued for hours.
 - Aggressive fluid resuscitation with 2–4 mL/kg lactated Ringer solution per total burn surface area (TBSA) percent over 24 hr with 1/2 given over the 1st 8 hr
 - Pain control
- Pulmonary symptoms:
 - Bronchodilators, oxygen, intubation, and mechanical ventilation
- Selected special treatments:
 - Hydrofluoric acid burns:
 - Calcium gluconate via topical cutaneous gel, SC, or intra-arterial
 - For systemic toxicity: IV calcium gluconate and magnesium
 - Phenol burns:
 - Remove phenol from skin with polyethylene glycol 300 or 400 or with isopropyl alcohol.
 - Nitrates:
 - Ingested or extensive burns may cause methemoglobinemia.
 - Treat levels >30% with high-flow oxygen and IV methylene blue.
 - Elemental metals (sodium/potassium):
 - Water lavage is contraindicated and dangerous.
 - Cover with oil until substance can be débrided from skin.
 - Cyanide toxicity:
 - Hydroxocobalamin administration
 - Organophosphates/carbamate insecticides (see Chemical Weapons Poisoning)

MEDICATION

- Albuterol: 2.5–5.0 mg nebulized
- Calcium gluconate: 10 mL of 10% solution applied topically. Consult poison center for instructions.
- Magnesium: 2 g IV over 20 min
- Methylene blue: 1–2 mg/kg slow IV (peds: *Not recommended for <6 yr old; >6 yr old: 1 mg/kg IV/IM over 5 min*)
- Hydroxocobalamin: 5 mg IV over 5 min, repeat once

FOLLOW-UP

DISPOSITION

Admission Criteria

- Airway compromise, respiratory difficulty (hypoxia)
- Significant systemic symptoms
- Admit patients with chemical burns to burn center.

Discharge Criteria

- Patients who are well after a period of observation and consultation with poison control
- Superficial chemical burns owing to a toxin without potential for systemic toxicity (weak acid/alkali)

FOLLOW-UP RECOMMENDATIONS

Psychiatric or social work referral for victims of chemical terrorist attacks.

PEARLS AND PITFALLS

- Decontaminate stable victims on site when possible.
- Protect medical providers (pre-hospital and ED) with appropriate personal protective equipment.
- Provide specific antidotes for exposures when indicated.
- Victims who can walk and talk are minimally contaminated.

HEAD TRAUMA, BLUNT

Gary M. Vilke

BASICS

DESCRIPTION

Blunt trauma to head resulting in a variety of injuries ranging from closed head injury to death

ETIOLOGY

Blunt trauma to head may cause several types of closed head injuries:

- **Concussion:** Transient (LOC) or amnesia with normal head CT
- **Subdural hematoma:** Tearing of subdural bridging veins and bleeding into the subdural space
- **Epidural hematoma:** Dural arterial injury, especially the middle meningeal artery often associated with a skull fracture:
 - Classically, transient LOC followed by a lucid interval, then rapid demise
- **Subarachnoid hemorrhage:** Bleeding into the subarachnoid space following trauma
- **Cerebral contusion:** Focal injuries to the brain characterized as coup (beneath area of impact) or contrecoup (area remote from impact)
- **Intracerebral hemorrhage:** Mass intracranial lesion with bleeding into the brain parenchyma
- **Diffuse axonal injury:** Microscopic injuries scattered throughout the brain in a patient in deep coma

DIAGNOSIS

SIGNS AND SYMPTOMS

- Evidence of trauma to head includes:
 - Scalp laceration, cephalohematoma, or ecchymosis
 - Raccoon eyes: Bilateral ecchymosis of orbits associated with basilar skull fractures
 - Battle sign: Ecchymosis behind the ear at mastoid process associated with basilar skull fracture
 - Hemotympanum
 - Cerebral spinal fluid rhinorrhea or otorrhea
- Evidence of increasing intracranial pressure includes:
 - Decreasing level of consciousness, falling score on Glasgow Coma Scale
 - Cushing response, bradycardia, HTN, and diminished respiratory rate
 - Dilated pupils associated with decorticate or decerebrate posturing

History

- Mechanism
- LOC or amnesia for event
- Use of anticoagulants
- Headache, visual changes, or hearing loss
- Focal neurologic complaints
- Associated neck pain

Physical-Exam

- Evaluation of head for hematoma, Battle sign, raccoon eyes
- Complete neurologic exam
- Exam of neck/cervical spine

ESSENTIAL WORKUP

- Imaging indicated for patients with any of the following:
 - LOC or amnesia of events
 - Progressive headache
 - Alcohol or drug intoxication
 - Unreliable history or dangerous mechanism
 - Post-traumatic seizure
 - Repeated vomiting
 - Signs of basilar skull fracture
 - Possible skull penetration or depressed skull fracture
 - Glasgow Coma Scale score < 15
 - Focal neurologic findings
- Patients on Coumadin, heparin, or other anticoagulants and those with a history of bleeding dyscrasias must undergo imaging.
 - If initial head CT is negative and < 4 hr post injury, patient must be monitored and repeat head CT 4–6 hr post injury, or earlier if clinical deterioration.
- Alcoholics have an increased risk for bleeding, low threshold for imaging

Geriatric Considerations

- Older patients (> 60–65 yr of age) are at higher risk of intracranial hemorrhage.
- Many are on anticoagulation, take a careful hx.
- Have a low threshold for obtaining CT scan.

DIAGNOSIS TESTS & NTERPRETATION

Lab

- Rapid check of blood glucose level
- CBC, platelet count, and coagulation parameters
- Type and cross-match for surgical candidates.

- Baseline electrolytes, BUN, and creatinine levels
- Blood alcohol level if indicated

Imaging

- CT or MRI of head as indicated
- Cervical spine radiographs or helical CT when indicated

Diagnostic Procedures/Surgery

Lumbar puncture if question of subarachnoid blood on head CT

DIFFERENTIAL DIAGNOSIS

- Penetrating head trauma
- Any condition that alters mental status that may have produced a fall and caused external evidence of head trauma (e.g., hypoglycemic episode, seizure)

TREATMENT

PRE HOSPITAL

- Blunt head trauma patients with risk for intracranial lesion must go to a trauma center:
 - High-risk patients include those with depressed consciousness, focal neurologic signs, multiple trauma, or palpable depressed skull fractures.
- Moderate-risk patients should go to a hospital with availability of prompt neurosurgical consultation:
 - Moderate-risk patients include those with progressive headache, alcohol or drug intoxication, unreliable history, post-traumatic seizure, repeated vomiting, post-traumatic amnesia, signs of basilar skull fracture.
- Protect and manage the airway, including intubation:
 - Routine hyperventilation without signs of cerebral herniation should be avoided.
- If evidence of cerebral herniation (see Signs and Symptoms) or progressive neurologic deterioration in a normotensive patient, initiate measures to decrease intracranial pressure:
 - Mild hyperventilation to keep ETCO₂ about 30–35 mm Hg:
 - 20 breaths/min in adults
 - 25 breaths/min in children
 - 30 breaths/min in infants < 1 yr
 - Elevating head of bed 20–30°
- Cervical spine precautions must be maintained in all patients.
- Cautions:
 - Avoid hypotension (systolic BP < 90 mm Hg); use IV crystalloid solutions to maintain BP.

- Avoid hypoxia (oxygen saturation < 90%); administer 100% oxygen.
- Check blood glucose level.

INITIAL STABILIZATION/THERAPY

Management of ABCs:

- Control airway as needed:
 - Rapid sequence intubation if Glasgow Coma Scale score < 8, unable to protect airway, or evidence of hypoxia
 - Normalize Pco₂, avoid hyperventilation and hypoventilation.
- Treatment with etomidate or fentanyl as induction agent, succinylcholine (pretreat with minidose paralytic), rocuronium, or vecuronium; morphine for ongoing sedation
- Caution with fentanyl in hemodynamically labile patients
- IV catheter placement with crystalloid solution as needed to avoid hypotension (keep systolic BP > 90 mm Hg)
- Cervical spine precautions

ED TREATMENT/PROCEDURES

- Early neurosurgical consultation
- If patient has evidence of cerebral herniation (see Signs and Symptoms), initiate measures to decrease intracranial pressure:
 - *Mild* hyperventilation: 20 breaths/min in adults, 25 breaths/min in children, and 30 breaths/min in infants < 1 yr to keep ETCO₂ about 30–35.
 - Elevate head of bed 20–30°
 - Mannitol boluses IV: Do not administer mannitol unless systolic BP > 100 mm Hg and patient is adequately fluid resuscitated
- Phenytoin to prevent *early* post-traumatic seizures
- Reverse hypocoagulable states
- The use of glucocorticoids is *not* recommended to lower intracranial pressure in head trauma patients.
- Barbiturates are *not* recommended in the initial ED treatment of head-injured patients.
- If definitive neurosurgical care is not immediately available, a single burr hole may preserve life until neurosurgical intervention can be obtained:
 - Perform only in comatose patients with decerebrate or decorticate posturing on the side of a known mass lesion who have not responded to hyperventilation and mannitol.
- Transfuse as needed to keep hematocrit > 30%.
- Avoid hypothermia, which will increase risks of coagulopathy during surgery.
- Maintain NPO status.
- Surgery:
 - Surgical procedure based on findings of CT scan and neurosurgical

MEDICATION

For RSI intubation, increased ICP, seizures, anticoagulation reversal, and pain control

First Line

- Etomidate: 0.2–0.3 mg/kg IV
- Fentanyl: 3–5 µg/kg IV if systolic BP > 100 mm Hg
- Mannitol: 0.25–1 g/kg IV bolus
- Morphine sulfate: 2–20 mg IV (peds: 0.1 mg/kg IV up to adult doses)
- Phenytoin: 15–20 mg/kg IV up to 1,000 mg
- Rocuronium: 0.6 mg/kg IV
- Succinylcholine: 1–2 mg/kg IV
- Vecuronium bromide: 0.1 mg/kg IV; minidose pretreatment: 0.01 mg/kg IV
- Vitamin K:
 - To be used in patients on Coumadin with intracranial hemorrhage
 - 10 mg in 50 mL NS infused over 30 min
- Protamine sulfate:
 - To be considered if taking low molecular weight heparin (LMWH) with intracranial hemorrhage
 - If LMWH used < 8 hr prior, use 1 mg protamine for each mg of LMWH slow IV push over 1–3 min
 - If LMWH used > 8 hr prior, use 0.5 mg protamine for each mg of LMWH slow IV push over 1–3 min

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with mass lesion associated with head trauma must be admitted to the ICU or undergo surgery.
- Patients with subarachnoid hemorrhage and diffuse axonal injury should be initially admitted to the ICU.
- Patients with ongoing symptoms including repetitive questioning, anterograde amnesia, or disorientation should be admitted to a monitored unit for neurologic evaluation.

Discharge Criteria

- Patients with resolved symptoms, negative findings on head CT, and no other comorbid factors (e.g., intoxication, additional trauma needing treatment) may be discharged.

- Patients on anticoagulation need to be observed and have negative findings on a head CT at 4–6 hr after the injury prior to discharge.
- Patients with minor head trauma, no LOC or amnesia, and normal neurologic exam findings may be discharged home with a friend or family member and head injury instructions.

Pediatric Considerations

Cases of suspected nonaccidental trauma must be reported to the appropriate legal agency.

Issues for Referral

If there are symptoms of concussion, patient will need follow-up with PMD, sports medicine physician, or neurologist to determine whether return to sports will be safe.

FOLLOW-UP RECOMMENDATIONS

Return if worsening headache, visual changes, confusion, focal neurologic changes, or other changes in clinical status.

PEARLS AND PITFALLS

- Failure to query about anticoagulant use and image appropriately
- Failure to aggressively reverse hypocoagulable states
- Failure to counsel patient with a concussion for no contact sports until cleared by PMD, sports medicine physician, or neurologist.

HEAD TRAUMA, PENETRATING

Gary M. Vilke

BASICS

DESCRIPTION

Penetrating injury to intracranial contents:

- **High-velocity penetration:** Usually bullets, which cause trauma directly to brain tissue and also have a “shock wave” injury to local surrounding brain
- **Low-velocity penetration:** Usually knives, picks, or other sharp objects, with direct local trauma to brain tissue

ETIOLOGY

- **Direct penetration of the skull into the intracranial cavity by foreign object:**
 - Direct or local damage to brain tissue
 - Intracranial hemorrhage, including subdural, epidural, and intraparenchymal bleeds
- A bullet that hits the skull, ricochets off, and does not fracture the skull can still cause significant trauma to the underlying brain tissue.

DIAGNOSIS

SIGNS AND SYMPTOMS

- **Alteration in level of consciousness and neurologic exam varies based on object and location.**
- **Evidence of increasing intracranial pressure:**
 - Decreasing level of consciousness
 - Falling Glasgow Coma Scale score
 - Cushing response: Bradycardia, hypertension, and diminished respiratory rate
 - Blown pupil associated with decorticate or decerebrate posturing
- **Evidence of penetrating injury to head or basilar skull fracture, or object still remaining in head:**
 - **Raccoon eyes:** Bilateral ecchymosis of orbits associated with basilar skull fractures
 - **Battle sign:** Ecchymosis behind the ear at mastoid process associated with basilar skull fracture
 - Hemotympanum
 - CSF rhinorrhea or otorrhea

History

- Determine the weapon type or caliber of weapon at scene.
- Loss of consciousness (LOC) or amnesia for event
- Use of anticoagulants
- Headache, visual changes, or hearing loss
- Focal neurologic complaints

Physical-Exam

- Evaluation of head for evidence of penetrating injury and if a projectile, for multiple sites
- Complete neurologic exam
- Alteration in level of consciousness and neurologic exam varies based on object and location.
- Evidence of penetrating injury to head

ESSENTIAL WORKUP

- Thorough history and exam to assess extent of injuries
- Imaging study

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Platelet count
- Coagulation parameters
- Type and cross-match
- Electrolytes, BUN, and creatinine baseline levels

Imaging

- CT of head depicts location of lesion and extent of damage.
- Skull radiographs may reveal depth of impalement, location of bone fragments, and presence of fragments within the cranium.
- Cervical spine evaluation (when indicated):
 - Helical CT scanning or anteroposterior, lateral, and odontoid views plain radiographs

DIFFERENTIAL DIAGNOSIS

- Blunt head trauma
- Basilar skull fracture
- Any condition that alters mental status that may have induced a fall and caused secondary penetrating trauma

TREATMENT

PRE HOSPITAL

- Stabilize but do not remove foreign object (e.g., knife).
- Determine the weapon type or caliber of weapon at scene.
- Protect and manage the airway to avoid hypoxemia.
- Avoid hyperventilation.
- Maintain cervical spine precautions.
- Transport to trauma center.
- Avoid hypoxia (oxygen saturation < 90%):
 - 100% oxygen
- Avoid hypotension (systolic BP < 90 mm Hg):
 - Administer IV crystalloid solutions

INITIAL STABILIZATION/THERAPY

- Management of ABCs
- Rapid sequence intubation:
 - For Glasgow Coma Scale score < 8, inability to protect airway, hypoxia, or cerebral herniation
 - Medications include etomidate or fentanyl as induction agent, succinylcholine (pretreat with minidose paralytic), rocuronium, or vecuronium; and morphine sulfate for ongoing sedation
 - Caution with fentanyl in the hemodynamically labile patient
 - Normalize Pco₂. Avoid hyperventilation or hypoventilation.
- IV catheter placement
- Crystalloid solution to maintain systolic BP > 90 mm Hg
- Address other sources of associated trauma.
- Cervical spine precautions should be maintained.

ED TREATMENT/PROCEDURES

- Early neurosurgical consultation
- If patient has evidence of cerebral herniation (see Signs and Symptoms), initiate measures to decrease intracranial pressure:
 - *Mild* hyperventilation: 20 breaths/min in adults, 25 breaths/min in children, and 30 breaths/min in infants < 1 yr to keep ETCO₂ about 30–35 mm Hg.
 - Elevate head of bed 20–30°.
 - Mannitol boluses IV: Do not administer mannitol unless systolic BP > 100 mm Hg and patient is adequately fluid resuscitated.
- Phenytoin intravenously to prevent *early* post-traumatic seizures
- Reverse hypocoagulable states
- Glucocorticoids are *not* recommended to lower intracranial pressure in head trauma patients.
- Barbiturates are *not* recommended in the initial ED treatment.
- Transfuse as needed to keep hematocrit > 30%.

- If definitive neurosurgical care is not immediately available, a single burr hole may preserve life until neurosurgical intervention can be attained:
 - Perform only in comatose patients with decerebrate or decorticate posturing who have not responded to initial treatment on the side of a known mass lesion/hematoma.
- Avoid hypothermia, which will increase risks of coagulopathy during surgery.
- Maintain NPO status.
- Surgery:
 - Based on clinical and radiologic findings and neurosurgical consultation

MEDICATION

For RSI intubation, increased ICP, seizures, and pain control

First Line

- Etomidate: 0.2–0.3 mg/kg IV
- Fentanyl: 3–5 µg/kg IV:
 - If systolic BP > 100 mm Hg
- Mannitol: 0.25–1 g/kg IV bolus
- Morphine sulfate: 2–20 mg IV (peds: 0.1 mg/kg up to adult doses)
- Phenytoin: 15–20 mg/kg IV up to 1,000 mg
- Rocuronium: 0.6 mg/kg IV
- Succinylcholine: 1–2 mg/kg IV
- Vecuronium bromide: 0.1 mg/kg IV:
 - Pretreatment minidose: 0.01 mg/kg IV
- Vitamin K:
 - To be used in patients on Coumadin with intracranial hemorrhage
 - 10 mg in 50 mL NS infused over 30 min
- Protamine sulfate:
 - To be considered if taking low molecular weight heparin (LMWH) with intracranial hemorrhage
 - If LMWH used < 8 hr prior, use 1 mg protamine for each mg of LMWH slow IV push over 1--3 min
 - If LMWH used > 8 hr prior, use 0.5 mg protamine for each mg of LMWH slow IV push over 1--3 min

FOLLOW-UP

DISPOSITION

Admission Criteria

Admit all patients to ICU or transport directly to surgery.

Discharge Criteria

Do not discharge.

FOLLOW-UP RECOMMENDATIONS

All patients with penetrating skull injuries should have been admitted.

PEARLS AND PITFALLS

- Failure to query about anticoagulant use and image appropriately
- Failure to aggressively reverse hypocoagulable states

HEADACHE

Josh W. Joseph

BASICS

DESCRIPTION

- Pain in the cranium, orbits, or upper neck
- Pain within the skull is projected to the surface:
 - Intracranial:
 - Arteries, veins, dura, meninges
 - Extracranial:
 - Skin, scalp, fascia, muscles
 - Mucosal linings of the sinuses
 - Arteries
 - Temporomandibular joints, teeth
- Pain is transmitted via the V cranial nerve.
- May be caused by a number of mechanisms:
 - Nerve irritation
 - Traction on pain-sensitive vessels
 - Vasodilatation of pain-sensitive vessels
 - Hypoxia, hypercapnia, fever, histamine injection, nitroglycerin ingestion
- Complaint in 2–4% of all ED visits:
 - 95% have a benign etiology (lower in patients older than 50 yr)
 - Life-threatening etiologies are rare and can be difficult to diagnose.

ETIOLOGY

- Migraine:
 - Intra/extracranial vasodilatation and constriction of pain-sensitive blood vessels
 - May also involve cortical depression
 - Throbbing headache
- Tension:
 - Requires ≥ 10 attacks of a similar nature
 - Unknown etiology (possibly serotonin imbalance, decreased endorphins, spasm)
 - Most common type of recurring headache
 - Triggered by poor posture, stress, anxiety, depression, cervical osteoarthritis
 - Bilateral, nonpulsatile, band like
 - Mild to moderate intensity
 - 4–13 hr duration

- Cluster headaches:
 - Triggered by alcohol, certain foods, altered sleep habits, strong emotions
 - May involve vasospasm near cranial nerves
- Intracranial (traction, pressure):
 - Mass lesions
 - Idiopathic intracranial hypertension
- Extracranial (compression):
 - Pathology causing pain in a peripheral nerve of the head and neck
- Inflammation:
 - Temporal arteritis
 - Cerebral vasculitis
- Thrombosis:
 - Cerebral venous sinus thrombosis (CVST)
- Impaired vascular autoregulation/endothelial dysfunction:
 - Posterior reversible leukoencephalopathy syndrome (PRES)
 - Reversible cerebral vasoconstriction syndrome (RCVS)

Pediatric Considerations

Serious causes of headache in children are rare but those who come to the ED for this complaint should all have follow-up with a pediatrician.

Geriatric Considerations

Older patients with new headache have a higher likelihood of a serious etiology and should have more thorough evaluation with a low threshold for imaging.

Pregnancy Considerations

In addition to all other causes of headache, pregnant women (and recently postpartum women) are at increased risk for CVST, eclampsia, PRES, and RCVS.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Attributes of the pain—PQRST:
 - Provocative and palliative features:
 - Position of the head, coughing or straining (increase suggests elevated ICP), and movement
 - Quality:
 - Throbbing or continuous
 - Deep or superficial
 - Change compared to prior headaches

- Region
- Severity
- Worst headache of life?
- Timing
- Sudden or gradual?
- Associated findings:
 - Visual symptoms, dizziness, nausea, vomiting
- Historical factors indicating additional testing:
 - New onset:
 - Age > 50
 - HIV, transplant, or cancer patient?
 - Trauma or falls (even without headstrike)
 - Persistent vomiting
 - Any new focal neurologic or visual symptoms
- Risk factors for cerebral sinus thrombosis:
 - Malignancy
 - Pregnancy (or postpartum)
 - Protein S or protein C deficiency
 - Oral contraceptive
 - Ulcerative colitis
 - Behçet syndrome

Physical-Exam

- Complete neuro exam including cranial nerves, motor, sensation, deep tendon reflexes, gait
- Examine for papilledema.
- Evaluate skin for rashes:
 - Zoster
 - Purpura
- Palpate temporal arteries

ESSENTIAL WORKUP

- Detailed history, CNS, HEENT, and neck exam
- Factors indicating testing beyond the history and physical exam:
 - Severely elevated diastolic BP
 - Fever
 - Altered level of consciousness
 - Papilledema
 - Abnormal neurologic exam or meningismus

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CSF:
 - Essential in suspected meningitis, subarachnoid hemorrhage (SAH)
- ESR:
 - If temporal arteritis or other inflammatory disorders suspected:
 - See Giant Cell Arteritis

Imaging

- Head CT scan:
 - Indications:
 - Uncertain diagnosis based on history and physical exam (leaving open the possibility of serious causes)
 - Signs of increased ICP
 - “First or worst” headache
 - Abrupt onset
 - New focal neurologic abnormalities
 - Papilledema
 - Recurrent morning headache
 - Persistent vomiting
 - Associated with fever, rash, and nausea
 - Trauma with loss of consciousness, focal deficits, or lethargy
 - Altered mental status, meningismus
 - Definitive test for SAH if performed within 6 hr of onset and read by an attending radiologist
 - Within 24 hr, > 95% sensitive (sensitivity falls rapidly with time and is 50% at 7 days out)
- Sinus imaging may show acute sinusitis; chronic sinusitis rarely causes acute headache.
- MRI:
 - Indicated to assess for etiologies that are missed by CT scan and LP:
 - Posterior fossa lesion
 - Pituitary apoplexy
 - CVST
- MRA:
 - Indicated if SAH suspected, CT is negative, and unable to perform lumbar puncture
 - Suspicion of carotid or vertebral dissection (e.g., recent neck manipulation or trauma)
 - Nonmigrainous vascular cause suspected (e.g., RCVS)

Diagnostic Procedures/Surgery

Lumbar puncture:

- Perform CT 1st if:

- New focal neurologic finding
- Papilledema
- Abnormal mental status
- HIV positive or immunosuppressed
- Detect intracranial and meningeal infections
- Detect blood not evident on CT scan:
 - There is no specific threshold number of red cells below which SAH is excluded – the RBC count is a function of time from onset.
- Opening pressure:
 - Essential to diagnose pseudotumor cerebri and CVST
 - Can distinguish traumatic tap vs. true hemorrhage.
- Xanthochromia:
 - Should be visible by 12 hr after onset of a SAH
 - Visual inspection is the most commonly used method – spectrometry (is more sensitive but has a high false-positive rate).

DIFFERENTIAL DIAGNOSIS

- Note: There can be significant overlap in these groupings.
- Acute single headache:
 - SAH
 - Meningitis
 - Vascular:
 - Acute intracerebral hemorrhage
 - Hypertensive encephalopathy
 - Cranial artery dissection
 - CVST
 - Cerebellar stroke
 - Ocular:
 - Acute narrow-angle glaucoma
 - Pituitary apoplexy
 - Temporal neuritis
 - Traumatic
 - Acute sinusitis
 - Toxic/metabolic:
 - Fever
 - Hypoglycemia
 - High-altitude disease
 - Carbon monoxide poisoning
 - Narcotic, alcohol, or benzodiazepine withdrawal
 - Post lumbar puncture
 - Cold stimulus headache
- Acute recurrent headache:
 - Presenting within days to weeks of onset

- CVST
- Pseudotumor cerebri
- Temporal arteritis
- SAH (rebleed)
- Migraine, cluster, tension
- Hypoxic
- Trigeminal neuralgia
- Postherpetic neuralgia
- Coital and exertional headache
- Subacute headache:
 - Within weeks to months of onset
 - Chronic subdural hematoma
 - Brain tumor
 - Brain abscess
 - Chronic sinusitis
 - Temporomandibular joint syndrome
 - Chronic post-traumatic headache
 - Pseudotumor cerebri (idiopathic intracranial HTN)
 - Temporal arteritis
- Chronic headache:
 - Months to years since onset
 - Chronic tension headache
 - Analgesic abuse/rebound
 - Depression
 - Extracranial:
 - Trigeminal neuralgia: Transient, shock like facial pain
 - Temporal arteritis: Elderly, severe, scalp artery tenderness/swelling
 - Metabolic: Severe anemia
 - Acute glaucoma: Nausea, eye pain, conjunctival injection, increased IOP
 - Cervical: Spondylosis, trauma, arthritis

TREATMENT

INITIAL STABILIZATION/THERAPY

- ABCs if altered mental status
- Empiric antibiotics if bacterial meningitis is suspected, acyclovir if immunocompromised

ED TREATMENT/PROCEDURES

- Migraine (See Headache, Migraine)
- Tension:

- Aspirin
- Acetaminophen
- NSAID
- Nonpharmacologic (meditation, massage, biofeedback)
- Cluster (See Headache, Cluster)
- Temporal arteritis (See Giant Cell Arteritis)
- Intracranial infection (See Meningitis)
- Intracranial hemorrhage (See Subarachnoid Hemorrhage)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Headache secondary to suspected organic disease
- Intractable vomiting and dehydration
- Pain refractory to outpatient management
- Consider ICU admission:
 - Suspected symptomatic aneurysm
 - Acute subdural hematoma
 - SAH
 - Stroke
 - Increased ICP
 - Intracranial infection

Discharge Criteria

- Most migraine, cluster, and tension headaches after pain relief
- Local or minor systemic infections (e.g., URI)

Issues for Referral

Patients with recurrent headaches should have follow-up with a neurologist or PCP.

MEDICATION

- Chlorpromazine: 25–50 mg IM/IV (peds: 0.5–1 mg/kg/dose IM/IV/PO) q4–6h
- Dexamethasone: 10–24 mg IV once
- Dihydroergotamine: 1 mg IM/IV, repeat q1h; max. dose 3 mg
- Ergotamine: 2 mg PO/SL at onset, then 1 mg PO q30min; max. dose 10 mg/wk
- Ketorolac: 30–60 mg IM; 15–30 mg IV once, then 15–30 mg q6h (peds: 1 mg/kg IV q6h)
- Lidocaine 4%: 1 mL intranasal on same side as symptoms
- Metoclopramide: 5–10 mg IM/IV/PO q6–8h
- Morphine: 2.5–20 mg (peds: 0.1–0.2 mg/kg/dose) IM/IV/SQ q2–6h

- Prochlorperazine: 5–10 mg IM/IM/PO TID–QID; max. 40 mg/d
- Sumatriptan: 6 mg SQ, repeat in 1 hr, up to 12 mg/24h

ALERT

DO NOT use the response to any medication to indicate a benign cause of a headache.

PEARLS AND PITFALLS

- The sensitivity for detecting SAH on CT scan falls rapidly after 24 hr. LP remains essential for all patients with suspected SAH presenting after 6 hr of symptom onset.
- Neurology consultation should not delay urgent imaging in patients with high-risk features.
- Use dopamine antagonists with caution in patients with QT prolongation or electrolyte abnormalities. Use ergotamines and triptans carefully in patients with a documented history of CAD.
- Patients with chronic headaches and multiple visits benefit from consistent protocols for pain management; however, be alert to significant changes in their symptoms
- Do not wait for LP results to empirically treat cases of suspected meningitis.

- G44.009 Cluster headache syndrome, unspecified, not intractable
- R51 Headache

HEADACHE, CLUSTER

Andrew K. Chang

BASICS

DESCRIPTION

- Excruciatingly painful primary headache disorder
 - _ Infrequent cause of ED visits and affects only 0.1% of the population
- Often has abated by time of presentation
 - _ Attacks last between 15 and 180 min (75% last <60 min)
- More common in men (~3:1)
- Onset usually between 30 and 50 yr of age
- Headaches occur in clusters lasting weeks to months followed by remission >1 mo
- Commonly occur 1–3 times per day during cluster period that lasts 2–3 mo
- Often occur during the same time of day
- Often occur during the same time of the year
 - _ Highest incidence in spring and fall
- Chronic cluster headache:
 - _ Remission <1 mo
 - _ Do not experience remission
 - _ 10% of patients
- May have many clinical and pathophysiologic similarities with migraine and variants
- Often follows a trigeminal nerve dermatome

ETIOLOGY

A well-described physiologic reflex arc, the trigeminovascular reflex, potentiates the trigeminal pain and cranial autonomic features of cluster headache by positive feedback mechanisms.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Unilateral pain (usually does not change sides between headaches)
- Sharp, stabbing, boring
- Acute onset and builds in intensity quickly with climax at 5–15 min
- Pain stops abruptly
- Often exhausted after episode
 - _ Location:

- Eye
- Temple
- Radiation to:
 - Ear
 - Cheek
 - Jaw
 - Teeth (often have had extensive dental workup for pain in the past)
 - Nose
 - Ipsilateral neck
- Episodes are often nocturnal
- Attacks are more likely after ingestion of alcohol, nitroglycerine, or histamine-containing compounds
- More likely in times of stress, prolonged strain, overwork, and upsetting emotional experiences
- No prodrome or aura

Physical-Exam

- Agitated, restless
- Prefer to stand and move around as opposed to migraine patients who prefer to lie quietly in a dark room
- Accompanying autonomic symptoms:
 - Ipsilateral to headache
 - Nasal congestion or rhinorrhea (or both)
 - Conjunctival injection or lacrimation (or both)
 - Facial flushing
 - Eyelid edema
 - Ptosis, miosis, or both (partial Horner's syndrome)
 - Sweating of face/forehead

ESSENTIAL WORKUP

- An accurate history and physical exam should confirm the diagnosis
- Life-threatening alternatives should be ruled out

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Lumbar puncture (if meningitis or subarachnoid hemorrhage is suspected)
- Erythrocyte sedimentation rate (ESR); if temporal arteritis is suspected

Imaging

CT scan/MRI if suspect hemorrhage, tumor, etc.

DIFFERENTIAL DIAGNOSIS

- Migraine headache
- Trigeminal neuralgia
- Meningitis
- Temporal arteritis
- Intracerebral mass lesion
- Herpes zoster
- Intracerebral bleed
- Dental causes
- Orbital/ocular disease (acute glaucoma)
- Temporal mandibular joint syndrome

TREATMENT

PRE HOSPITAL

- Recognize more severe life-threatening causes of headache
- Administration of oxygen by face mask may alleviate symptoms

INITIAL STABILIZATION/THERAPY

- Rule out life-threatening causes of headache
- Administration of supplemental oxygen

MEDICATION

- Ergots: DHE 0.5–1 mg IV; repeat in 1 hr if necessary
- Fentanyl: 2–3 µg/kg IV
- Morphine: 2–4 mg IV or IM, may repeat q10min
- NSAIDs: Ketorolac 15–30 mg IM or IV
- Oxygen: 100% via face mask
- Prochlorperazine: 10 mg IM or IV
- Somatostatin: 100 µg SQ
- Sumatriptan: 6 mg SC, may repeat in 1 hr (max. of 2 doses in 24 hr)
- Verapamil immediate release: Preventive drug of choice. Start at 80mg TID

First Line

- Oxygen: 12 L/min via nonrebreather mask for 15 min:
 - May increase to 15 L/min if refractory headache
- Sumatriptan
- DHE

Second Line

- Narcotics
- Corticosteroids

FOLLOW-UP

DISPOSITION

Admission Criteria

- Persistent headache unresponsive to usual measures
- Unclear headache diagnosis

Discharge Criteria

- Patients with moderate to complete pain relief, a normal neurologic exam, and with a confident diagnosis of cluster headache
- Consider prescribing oxygen and/or SC sumatriptan for management at home

Issues for Referral

Follow-up with a neurologist should be arranged

PEARLS AND PITFALLS

- History is essential to diagnose cluster headache as pain may be improved upon presentation
- 100% oxygen should be the 1st treatment initiated
- Cluster headaches may be so severe that they lead to suicide
 - _ Follow-up is essential to manage clusters which may last months

ADDITIONAL READING

- G44.029 Chronic cluster headache, not intractable

HEADACHE, MIGRAINE

Benjamin W. Friedman

BASICS

DESCRIPTION

- Chronic episodic headache disorder
- Neurovascular pathophysiology:
 - Aberrant trigeminal nerve activation
 - Activation of nociceptive pathways within brainstem
 - Vascular dilation reactive rather than causative
 - No longer considered primarily a vascular headache
 - Disordered sensory processing and autonomic dysfunction
 - Cortical spreading depression underlies aura
- 1 million ED visits per year
- Causes majority of ED headache visits
- 3 × as common in women
- Prevalence peaks in 4th decade of life
- Established criteria for migraine without aura:
 - A. 5 attacks fulfilling criteria B, C, D, E
 - B. Attack lasts 4–72 hr
 - C. Headache has 2 of the following:
 - 1. Unilateral location
 - 2. Pulsating
 - 3. Moderate to severe pain (impairs activities)
 - 4. Aggravation by or avoidance of physical activity
 - D. During headache, nausea, or vomiting and/or photophobia + phonophobia
 - E. Not attributable to other cause
- Migraine with aura:
 - Less common
 - Classically, reversible neurologic symptoms that precede headache
 - Some patients report aura at the same time or after the headache
 - Rarer subtypes of migraine include:
 - Basilar type migraine
 - Dysarthria, vertigo, ataxia, diplopia, or decreased level of consciousness
 - Hemiplegic migraine
 - Full reversible motor weakness
 - Retinal migraine
 - Repeated attacks of monocular visual disturbance

Pediatric Considerations

- More commonly bilateral pain and shorter duration of headache
- Associated symptoms may be difficult to elicit and can be inferred from behavior
- Cyclical vomiting syndrome associated with migraine
- High placebo response

ETIOLOGY

Genetic disorder with variable penetrance, influenced by the environmental factors

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- May be precipitated by chocolate, cheese, nuts, alcohol, sulfites, monosodium glutamate (MSG), stress, or menstruation
- Prodrome precedes migraine by several days
 - May consist of cognitive or emotional alterations, yawning, drowsiness
- Aura precedes migraine by 1 hr
 - Most commonly consists of visual or sensory disturbances
 - Scintillating scotoma
 - Fortification spectra
 - Numbness or tingling
- Headache typically unilateral, throbbing
- Sufficiently intense to impair activity
- Can be bilateral
- Usually associated with osmophobia, photophobia, phonophobia, nausea, or vomiting
- Usually gradual onset
- History often reflects similar headache previously

Physical-Exam

- Allodynia (sensitivity to normally non-noxious stimuli) may be present and signifies more refractory migraine
- Physical exam should otherwise be normal
- Physical exam should include exam of fundi and assessment of visual fields
- Elevated blood pressure does not exclude migraine as diagnosis
- Sinus tenderness does not exclude migraine as diagnosis

ESSENTIAL WORKUP

- An accurate history and physical exam confirm the diagnosis
- Patients with new headache syndrome may require workup including imaging and spinal fluid analysis

DIAGNOSIS TESTS & NTERPRETATION

Lab

Clinical diagnosis: None required

Imaging

Clinical diagnosis: None required

Diagnostic Procedures/Surgery

Clinical diagnosis: None required

DIFFERENTIAL DIAGNOSIS

- Cluster headache
- Medication overuse headache
- Tension-type headache
- Allergic or viral rhinosinusitis
- Idiopathic intracranial hypertension (pseudotumor cerebri)
- Reversible cerebral vasoconstriction syndrome

TREATMENT

PRE HOSPITAL

- Allow patients with migraine headache to be in a calm, dark environment
- Oxygen may be beneficial

INITIAL STABILIZATION/THERAPY

- Exclude secondary causes of headache
- Rapid and effective analgesia

ED TREATMENT/PROCEDURES

- Detailed history will exclude secondary cause of headache in most patients
- Provide analgesia without relying upon opioid analgesics
- IV saline hydration is often helpful
- Provide patient with diagnosis – “You have a migraine”, education about trigger avoidance

Pregnancy Considerations

Metoclopramide, prochlorperazine best treatment options in pregnancy

MEDICATION

- Abortive therapy in ED:
 - Dopamine antagonists:

- Prochlorperazine 10 mg IV coadministered with diphenhydramine 25 mg IV to prevent akathisia
- Droperidol 2.5 mg IV coadministered with diphenhydramine 25 mg IV to prevent akathisia (check EKG prior)
- Metoclopramide 10 mg IV
- Trimethobenzamide 200 mg IM
- Triptans:
 - Sumatriptan: 6 mg SC (avoid if cardiac risk factors)
 - Eletriptan 40 mg PO
- Ergot alkaloids:
 - Dihydroergotamine: 1 mg IV, coadministered with an antiemetic (avoid if cardiac risk factors; avoid if on macrolide or antiretrovirals)
- Nonsteroidals
 - Ketorolac 30 g IV
- Corticosteroids
 - Dexamethasone 10 mg IV or IM
 - Prednisone taper

Treatment strategy

- Abortive therapy with antiemetics, triptans, DHE, or nonsteroidals
- Opioids only if no response to several of the above
- Corticosteroids to avoid post-ED headache recurrence

FOLLOW-UP

DISPOSITION

Admission Criteria

- Persistent severe headache or focal neurologic deficits
- Intractable vomiting, electrolyte imbalance, or inability to take oral food or fluid
- Coexisting medication overuse headache

Discharge Criteria

- Headache relief
- Pathologic cause of headache excluded

Issues for Referral

Chronic migraine or frequent episodic migraine should be referred to a clinician with relevant expertise

FOLLOW-UP RECOMMENDATIONS

- Maintain headache diary to identify and avoid triggers
- Persistent primary care follow-up to identify an effective oral migraine therapeutic

PEARLS AND PITFALLS

- Opioids should not be used as first-line therapy in the ED
- Migraine likely to recur after ED discharge—patients should go home with prescription
- Distinguish between migraine, a chronic, recurrent disorder, and new onset progressive headaches

HEART MURMUR

Elizabeth M. Foley • Leon D. Sánchez

BASICS

DESCRIPTION

- Sounds created by physiologic processes or functional and structural anomalies of the heart.
- Stenotic lesions:
 - Pressure overload in the chamber preceding the valve, leading to hypertrophy of the chamber in an attempt to overcome the increased resistance
- Regurgitant lesions:
 - Volume overload of the chamber preceding the valve, leading to chamber dilatation in an attempt to accommodate the regurgitant blood volume
- Genetic abnormalities:
 - Congenital defects associated with abnormal cardiac blood flow

ETIOLOGY

- Aortic stenosis:
 - Rheumatic heart disease
 - Congenital bicuspid valve
 - Calcification
 - Prosthetic valve
- Aortic regurgitation:
 - Rheumatic heart disease
 - Endocarditis
 - Aortic dissection
 - Prosthetic valve
- Mitral stenosis:
 - Rheumatic heart disease
 - Rheumatologic disorders (systemic lupus erythematosus)
 - Calcification
 - Cardiac tumors (atrial myxoma)
 - Congenital
 - Prosthetic valve
- Mitral regurgitation, acute:
 - Endocarditis
 - Papillary muscle rupture or dysfunction
 - Rupture of chordae tendineae
 - Prosthetic valve

- Mitral regurgitation, chronic:
 - Rheumatic heart disease
 - Mitral valve prolapse
 - Connective tissue disease (Marfan syndrome)
- Mitral valve prolapse:
 - Congenital
 - Connective tissue disease
- Tricuspid stenosis:
 - Rheumatic heart disease
- Tricuspid regurgitation:
 - Rheumatic heart disease
 - Endocarditis
 - Pulmonary HTN
- Pericardial friction rub:
 - Pericarditis
 - Pericardial effusion
- Ventricular septal defect:
 - Congenital
 - Traumatic
 - Postinfarction
- Ventricular assist device
 - Implantable pump supplements or replaces ventricular function

Pediatric Considerations

- Pulmonic stenosis:
 - Congenital
 - Maternal–fetal rubella exposure
 - Rheumatic heart disease
- Pulmonic regurgitation:
 - Congenital
 - Rheumatic heart disease
 - Pulmonary HTN
- Atrial septal defect:
 - Congenital
- Patent ductus arteriosus:
 - Congenital
 - Prematurity
 - Maternal–fetal rubella exposure
- Coarctation of the aorta:
 - Congenital
 - Turner syndrome
- Hypertrophic cardiomyopathy/idiopathic hypertrophic subaortic stenosis:
 - Congenital

- Genetic predisposition

DIAGNOSIS

SIGNS AND SYMPTOMS

- Aortic stenosis:
 - Systolic crescendo–decrescendo murmur radiating to carotids
 - Carotid pulse described as parvus et tardus: Diminished intensity and late upstroke
 - Angina
 - Dyspnea on exertion
 - Exertional syncope
- Aortic regurgitation:
 - Diastolic blowing murmur at left sternal border
 - Pulmonary edema
 - Dyspnea
 - Tachycardia
 - Chest pain
 - Widened pulse pressure
 - Austin Flint murmur: Diastolic rumble from exposure of mitral valve to regurgitant flow
 - Corrigan pulse or water hammer pulse: Rapid upstroke and downstroke of the carotid pulse
 - Quincke pulse: Pulsations seen at nail beds
 - de Musset sign: Head bobbing with carotid pulse
- Mitral stenosis:
 - Diastolic, rumbling murmur at apex
 - Loud S₁ with opening snap
 - Dyspnea
 - Orthopnea
 - Hemoptysis
 - Pulmonary edema
 - Emboli to systemic circulation
 - Atrial fibrillation
- Mitral regurgitation, acute:
 - Systolic, harsh, crescendo–decrescendo murmur at apex
 - Pulmonary edema
- Mitral regurgitation, chronic:
 - Holosystolic murmur at apex radiating to axilla
 - Dyspnea on exertion
 - Fatigue
 - Atrial fibrillation

- Mitral valve prolapse:
 - Early to mid-systolic click often followed by systolic murmur
 - Palpitations
 - Chest pain
- Tricuspid stenosis:
 - Diastolic, high-pitched murmur
 - Peripheral edema
 - Hepatosplenomegaly
 - Ascites
 - Fatigue
 - Atrial fibrillation
 - Large A wave in the jugular venous pulse
- Tricuspid regurgitation:
 - Holosystolic, blowing murmur along left sternal border
 - Peripheral edema
 - Hepatosplenomegaly
 - Ascites
 - Atrial fibrillation
 - Large V wave in the jugular venous pulse
- Patent ductus arteriosus:
 - Continuous machinery murmur
 - CHF
- Pericardial friction rub:
 - Intermittent murmur
 - Systolic and/or diastolic component
- Ventricular septal defect:
 - Harsh, holosystolic murmur loudest along lower left sternal border
- Ventricular assist device:
 - Mechanical hum at apex
 - Continuous or pulsatile
 - May have adequate perfusion without palpable pulse or measurable BP

Pediatric Considerations

- Pulmonic stenosis:
 - Systolic crescendo–decrescendo ejection murmur at left upper sternal border
 - Severe lesions may have a thrill
 - Widely split S₂
 - Dyspnea with exertion in serious cases
 - May have signs of right heart failure
- Pulmonic regurgitation:
 - High-pitched, early, decrescendo diastolic murmur
 - Widely split S₂

- Associated with Graham Steell murmur of pulmonary HTN (high-pitched early diastolic murmur)
- May have signs of right heart failure
- Atrial septal defect:
 - Systolic ejection murmur in secundum defect
 - Secundum associated with pulmonary HTN
 - Wide fixed S₂
 - No murmur in PFO
- Patent ductus arteriosus:
 - Continuous machinery murmur at upper left sternal border with systolic thrill
 - Cyanosis
 - Bounding peripheral pulses
 - Tachypnea
- Coarctation of the aorta:
 - Continuous or late systolic murmur
 - Possible aortic click related to bicuspid valve
 - Difference between upper and lower extremity pulses
- Hypertrophic cardiomyopathy/idiopathic hypertrophic subaortic stenosis:
 - Systolic, harsh, crescendo–decrescendo murmur at left sternal border
 - Increased intensity with Valsalva
 - Dyspnea
 - Chest pain
 - Exertional syncope
 - Sudden death

Physical-Exam

- Auscultation of heart and lung sounds
- Evaluation of pulses, peripheral perfusion, and edema

ESSENTIAL WORKUP

For more details, see Valvular Heart Disease, Mitral Valve Prolapse, Congenital Heart Disease, Patent Ductus Arteriosus, Pericarditis, and Pericardial Effusion/Tamponade.

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- EKG
- CXR
- Echo:
 - Evaluate valves, chambers, flow
- CT:

- Rule out aortic dissection

Diagnostic Procedures/Surgery

Acute regurgitant lesions: Cardiac catheterization

DIFFERENTIAL DIAGNOSIS

See Etiology.

TREATMENT

PRE HOSPITAL

- IV fluids:
 - Patients with critical aortic stenosis are very sensitive to fluid shifts.
- Oxygen as appropriate

INITIAL STABILIZATION/THERAPY

- Oxygen
- IV access
- Cardiac monitor
- Treat symptoms (CHF, dysrhythmias)
- Exercise care with fluids and medications in aortic stenosis

ED TREATMENT/PROCEDURES

For more details, see Endocarditis, Valvular Heart Disease, Mitral Valve Prolapse, Congenital Heart Disease, Patent Ductus Arteriosus, Pericarditis, and Pericardial Effusion/Tamponade.

MEDICATION

- Digoxin: 0.5 mg IV, then 0.25 mg IV 6 and 12 hr later
- Diltiazem (Cardizem):
 - 0.25 mg/kg (17.5 mg for 70 kg person) IV over 2 min
 - May reboles after 15 min with 0.35 mg/kg IV
 - Start drip at 5–15 mg/hr
- Furosemide (Lasix):
 - 20–80 mg IV; may increase dose if necessary
 - Max. of 600 mg per 24 hr
- Heparin:
 - 80 U/kg bolus IV, then drip at 18 U/kg/hr
 - Monitor partial thromboplastin time
- Metoprolol (Lopressor): 5 mg IV q5–15 min for 3 doses, as tolerated
- Nitroglycerin:
 - 10–20 µg/min IV
 - Titrate to effect

- Max. 300 µg/min
- Nitroprusside:
 - 0.3 µg/kg/min IV
 - Titrate to effect
 - Max. 10 µg/kg/min
 - Protect bag from light
 - Thiocyanate toxicity from prolonged use
- Propranolol (Inderal):
 - 1--3 mg IV q2--5min up to max 5 mg
 - No additional doses for 4 hrs after reaching max dose or desired response

FOLLOW-UP

DISPOSITION

Admission Criteria

- Signs of cardiac ischemia
- Syncope or near syncope
- Pulmonary edema
- Hemodynamic instability
- Endocarditis
- Arrhythmia

Discharge Criteria

- Asymptomatic
- Hemodynamically stable

Issues for Referral

Patients with new murmurs should be referred to their caregiver or a cardiologist.

FOLLOW-UP RECOMMENDATIONS

- Patients should always inform their medical and dental caregivers that they have a heart murmur.
- To avoid an infection of the lining of the heart, antibiotics may be needed before procedures such as teeth cleaning.

PEARLS AND PITFALLS

Patients with new heart murmurs and fever need to be assessed for endocarditis.

CODES

ICD9

- 394.0 Mitral stenosis
- 424.1 Aortic valve disorders
- 785.2 Undiagnosed cardiac murmurs

ICD10

- I05.0 Rheumatic mitral stenosis
- I35.0 Nonrheumatic aortic (valve) stenosis
- R01.1 Cardiac murmur, unspecified

HELLP SYNDROME

Michael J. Bono

BASICS

DESCRIPTION

- HELLP syndrome: *Hemolysis Elevated Liver enzymes, Low Platelets*
- Continuum with severe preeclampsia as most patients will be hypertensive
- Liver involvement is hallmark:
 - Other organs may be involved (e.g., brain, kidneys, lungs)
- HELLP syndrome divided into 3 groups, representing severity of the disease; severity is directly related to the platelet count:
 - Class 1: Most severe form; platelet nadir $< 50,000$ platelets/ μL
 - Class 2: Less severe; platelet nadir between 50,000 and 100,000 platelets/ μL
 - Class 3: Least severe; platelet nadir between 100,000 and 150,000 platelets/ μL
- Most maternal deaths occur with class 1
- Increased mortality rate is associated with hepatic hemorrhage or CNS or vascular insult to the cardiopulmonary or renal systems
- Incidence: 0.2% of all pregnancies
- 12–18% have normal BP
- Occurs in 20% of pregnancies with severe preeclampsia or eclampsia
- At diagnosis:
 - 52% preterm
 - 18% term
 - 32% postpartum

RISK FACTORS

Frequently white, multiparous, older

Pediatric Considerations

Infant mortality is greater in women with HELLP

ETIOLOGY

- Unclear, but vasospasm is the basis:
 - Fetal-placental debris is released into maternal circulation, causing systemic inflammatory response
 - Vascular constriction causes resistance to blood flow and HTN
 - Vasospasm probably damages vessels directly
 - Angiotensin II causes endothelial cells to contract
 - Endothelial cell is damaged and interendothelial cell leaks are the result

- Small-vessel leaks:
 - Platelets and fibrinogen get deposited in the subendothelium
 - Fibrin deposition develops in severe cases
- Vascular changes and local tissue hypoxia lead to hemorrhage, necrosis, and end-organ damage

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- History and physical exam with attention to symptoms of abdominal pain, nausea, vomiting, and headache
- Obstetric history:
 - Parity
 - Deliveries
 - History of hypertensive disorder during pregnancy
 - Estimated gestational age
 - Prenatal care
- May present with flulike symptoms, such as fatigue or malaise
- Nausea, usually with vomiting
- Right upper quadrant or epigastric pain:
 - Pain increases with severity of disease
- Headache, often with visual changes
- Symptoms which carry higher morbidity:
 - Dyspnea and/or fluid overload to suggest cardiogenic/noncardiogenic pulmonary edema
 - Dyspnea associated with pulmonary embolus
 - Chest pain suggestive of myocardial ischemia
 - Altered mental status, seizures or focal neurologic deficit:
 - Hypertensive encephalopathy
 - Cerebral edema
 - Hemorrhagic cerebrovascular accident
 - Peripheral edema
 - Ascites
 - Hematuria
 - Low urine output

ALERT

Determination of gestational age and fetal viability is critical in HELLP.

Physical-Exam

- Vital signs with attention to BP
- May not have systolic or diastolic HTN
- Many patients will have right upper quadrant pain, concern for liver subcapsular hematoma
- Evidence of fluid overload
- Careful neurologic exam
- Fetal heart tones

ESSENTIAL WORKUP

- Immediate CBC with platelet count and smear, BUN, creatinine, LFTs, coagulation profile, and magnesium level
- Urinalysis for protein; screen for UTI
- Weigh patient to determine recent weight gain

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - Anemia
 - Thrombocytopenia
 - Peripheral smear demonstrates microangiopathic hemolytic anemia (burr cells or schistocytes)
 - Other hemolysis markers are elevated lactate dehydrogenase (LDH) levels, increased reticulocyte count, and elevated bilirubin levels
- Platelet count and smear:
 - $< 100,000$ platelets/ μL
- Disseminated intravascular coagulation screen
- Coagulation profile:
 - PT
 - PTT
- BUN, creatinine, and magnesium levels
- LFTs to assess hemolysis markers and hepatic dysfunction:
 - Elevated aspartate aminotransferase level: > 40 IU/L
 - Elevated alanine aminotransferase level: > 40 IU/L
 - Elevated LDH: > 600 IU/L
 - Elevated serum bilirubin: > 1.2 mg/dL

Imaging

- CXR:
 - Suspected pulmonary edema
- CT of head:
 - Mental status changes or focal neurologic deficit
- US of the pelvis (transabdominal or transvaginal):

- Image fetus and placenta

DIFFERENTIAL DIAGNOSIS

- GI:
 - Cholecystitis
 - Cholelithiasis
 - Biliary colic
 - Pancreatitis
 - Hepatitis
 - Ulcer disease
 - Acute fatty liver of pregnancy
 - Acute gastritis
 - Hiatal hernia
 - Severe gastroesophageal reflux
- Hematologic:
 - Preeclampsia-associated thrombocytopenia
 - Gestational thrombocytopenia
 - Idiopathic thrombocytopenic purpura
 - Thrombotic thrombocytopenic purpura
 - Hemolytic uremic syndrome
- Neurologic:
 - Epilepsy
 - Encephalitis
 - Meningitis
 - Encephalopathy
 - Brain tumor
 - Intracranial hemorrhage
- Other:
 - Drug abuse
 - Pyelonephritis
 - Sepsis

TREATMENT

PRE HOSPITAL

Cautions:

- Transport patient in left lateral decubitus position to prevent inferior vena cava syndrome
- Venous access for anticipated seizure activity
- Routine seizure management (preferably with magnesium sulfate) if the patient seizes

ALERT

Transport to a facility capable of providing high-risk obstetric care.

INITIAL STABILIZATION/THERAPY

- ABC management
- Left lateral decubitus position to prevent inferior vena cava syndrome
- High-flow oxygen via face mask
- Maternal monitoring:
 - Cardiac
 - Pulse oximetry
 - Tocography
- Fetal monitoring

ED TREATMENT/PROCEDURES

- Control HTN with antihypertensives (see Medication):
 - Avoid ACE inhibitors because of fetal side effects
- Heparin should be avoided because of bleeding complications
- Treat preeclampsia or eclampsia with IV magnesium sulfate:
 - Magnesium sulfate is not given to treat HTN
- Order type and screen for possible transfusion
- Call for emergent obstetric consult, consider neonatology consult:
 - Consider emergent delivery
 - Early plasma exchange therapy has shown promise in postpartum patients with severe disease
- Discuss administration of glucocorticoid with consultant:
 - Helps fetal lung maturity
 - IV dexamethasone more effective than IM betamethasone
 - Depends on gestational age of fetus
 - Does not reduce disease severity or duration, but improves platelet counts
- Limit IV fluid administration unless clinical evidence of dehydration:
 - Excess fluids promote further capillary leak
 - Lactated Ringers or NS at 60 mL/hr (no more than 125 mL/hr)
 - Monitor urine output with Foley catheter
- Correct thrombocytopenia by platelet transfusion in women with platelet counts $< 20,000$ platelets/ μL , even without active bleeding, as risk of postpartum bleeding is significantly increased
- Platelet counts $> 40,000$ platelets/ μL are safe for vaginal delivery
- Correct thrombocytopenia to platelet counts $> 50,000$ platelets/ μL if cesarean delivery planned
- If coagulation dysfunction is present, transfusion with fresh frozen plasma and packed RBCs in consultation with obstetrics
- Transfusion with packed RBCs for hemoglobin < 10 g/dL

MEDICATION

First Line

- Hydralazine: 2.5 mg IV, then 5–10 mg q15–20min:
 - Up to 40 mg total dose, to keep diastolic BP < 110 mm Hg
 - IV drip 5–10 mg/hr titrated
- Labetalol: 10 mg IV, then 20–80 mg IV q10min:
 - Up to 300 mg total dose
 - IV drip 1–2 mg/min titrated

Second Line

- Nitroprusside: 0.25 µg/kg/min as a drip:
 - Increase 0.25 µg/kg/min q5min
 - Use only if no response to hydralazine or labetalol
- Magnesium sulfate: 4–6 g in 100 mL IV over 15–20 min as loading dose:
 - Maintenance drip starting at 2 g/hr
 - Titrate to clinical effect
 - Watch for toxicity (antidote is calcium gluconate 10%, 10 mL IV over 3 min).
 - Measure magnesium sulfate level at 4–6 hr; adjust drip to achieve levels between 4 and 7 mEq/L.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Admit all patients to obstetric service for continuous monitoring of mother and fetus
- ICU admission:
 - Pulmonary edema
 - Respiratory failure
 - Cerebral edema
 - GI bleeding with hemodynamic instability

Discharge Criteria

Patients with HELLP syndrome should always be admitted. Discharge should be a decision of the OB Consultant

Issues for Referral

After stabilization in the ED, transfer to facility capable of managing high-risk obstetric conditions unless delivery is imminent.

FOLLOW-UP RECOMMENDATIONS

Patients should be followed closely by OB:

- May develop HELLP after delivery, usually within 48 hr

PEARLS AND PITFALLS

- Hypertensive pregnant women with abdominal pain, elevated LFTs, and decreased platelets need emergent treatment and OB consultation
- Patients with HELLP syndrome may have a normal BP
- Transport to a facility capable of caring for these patients after stabilization is essential

Preeclampsia

CODES

ICD9

- 642.50 Severe pre-eclampsia, unspecified as to episode of care
- 642.51 Severe pre-eclampsia, delivered, with or without mention of antepartum condition
- 642.52 Severe pre-eclampsia, delivered, with mention of postpartum complication

ICD10

- O14.20 HELLP syndrome (HELLP), unspecified trimester
- O14.22 HELLP syndrome (HELLP), second trimester

- O14.23 HELLP syndrome (HELLP), third trimester

HEMATURIA/PROTEINURIA

Andrew Rinne • Edward Ullman

BASICS

DESCRIPTION

- Microscopic hematuria: ≥ 3 red blood cells per high-power field in 2 of the 3 properly collected urine specimens
- Gross hematuria: Visible blood in properly collected urine specimen
- Proteinuria: Urinary protein excretion of > 150 mg/day
- Risk factors for disease in asymptomatic proteinuria:
 - Diabetes
 - HTN
 - NSAID abuse
 - Heroin use
- Risk factors for disease in asymptomatic hematuria:
 - Tobacco use
 - Occupational exposure to benzenes, aromatic amines, and dyes
 - History of gross hematuria
 - Age > 40 yr old
 - History of urologic disorder or disease
 - History of painful voiding
 - History of UTI
 - Analgesic abuse
 - History of pelvic irradiation

ETIOLOGY

- Proteinuria:
 - Glomerular:
 - Nephritic (postinfectious, IgA, lupus, vasculitis)
 - Nephrotic (minimal change, diabetes, preeclampsia)
 - Tubular
 - Overflow (hemolysis, rhabdomyolysis, multiple myeloma)
- Hematuria:
 - UTI
 - Stones (renal, bladder)
 - BPH
 - Cancer (bladder, renal, prostate)
 - Transient unexplained
 - Acute glomerulonephritis

SIGNS AND SYMPTOMS

- Dysuria
- Blood in urine
- Fever
- Flank pain
- Flank ecchymosis
- Initial hematuria (anterior urethral lesion)
- Terminal hematuria (posterior urethra, bladder, neck, trigone)
- Cyclic hematuria (endometriosis or urinary tract)
- Previous upper respiratory tract infection (10–21 days prior)
- Previous skin infection (10–21 days prior)
- Deafness (Alport syndrome)
- Peripheral edema
- CHF
- Hemoptysis (Goodpasture disease)
- Concurrent menstruation
- Testicular, epididymal, and prostatic tenderness or trauma
- Terminal urethral lesion
- Enlarged prostate
- Penile/scrotal hematoma
- Atrial fibrillation:
 - Renal artery embolus or thrombus
- Organomegaly, flank mass
- Pregnancy consideration
- Headache
- HTN (> 140/90 mm Hg)
- Right upper quadrant pain

History

- Characteristics of complaint (onset, duration)
- Associated symptoms (recent illness)
- Past medical history (DM, HTN, pregnancy)
- Medications (nephrotoxic, anticoagulation, antibiotics)

Physical-Exam

- Complete physical exam, special attention to:
 - Edema, including periorbital
 - Thorough GU exam, including prostate
 - Rashes
 - Flank (ecchymosis, tenderness)

ESSENTIAL WORKUP

- Urine dipstick
- Urinalysis with microscopic analysis
- Consider urine culture.
- BUN level
- Serum creatinine level
- CBC
- Pregnancy consideration
- Liver function test
- Platelet count
- Consider coagulation panel.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Urine:
 - Culture
 - Cytology
 - 24 hr urine protein and creatinine levels
 - Spot ratio of urine protein to creatinine
 - Spot ratio of urine protein to osmolality
 - Protein electrophoresis
- Serum:
 - Coagulation studies
 - Protein electrophoresis

Imaging

- Helical CT scan
- Renal US

Diagnostic Procedures/Surgery

- Cystourethroscopy
- Urethrogram
- Cystogram
- Retrograde pyelogram
- IV pyelogram

DIFFERENTIAL DIAGNOSIS

- Glomerular hematuria:
 - IgA nephropathy (Berger disease)
 - Postinfectious glomerulonephritis
 - Membranoproliferative glomerulonephritis
 - Focal glomerular sclerosis

- Lupus nephritis
- Wegener granulomatosis
- Polyarteritis nodosa
- Henoch–Schönlein syndrome
- Thrombotic thrombocytopenic purpura:
 - Hemolytic uremic syndrome
 - Alport syndrome
 - Goodpasture disease
- Nonglomerular hematuria:
 - Infection (pyelonephritis, tuberculosis, schistosomiasis)
 - Inflammation (drug induced, radiation induced)
 - Urothelial malignancy
 - Renal and extrarenal tumor
 - Interstitial nephritis
 - Papillary necrosis
 - Polycystic kidney disease
 - Medullary sponge disease
 - Renal artery embolism/thrombosis
 - Renal vein thrombosis
 - Sickle cell disease
 - Malignant HTN
 - Hypercalciuria
 - Hyperuricosuria
 - Urolithiasis
 - Strictures
 - Endometriosis
 - Foreign bodies
 - Benign prostatic hypertrophy
 - Coagulopathy/bleeding disorders
 - Trauma (renal pedicle injuries, urethral disruptions, bladder rupture)
 - Recent instrumentation
 - Frequent or interrupted coitus
 - Factitious
- Glomerular proteinuria (> 2 g/day):
 - Minimal-change disease
 - Membranous glomerulonephritis
 - Focal segmental glomerulonephritis
 - Membranoproliferative glomerulonephritis
 - DM
 - Collagen vascular diseases
 - Amyloidosis
 - Preeclampsia
 - Infection (HIV, hepatitis B, hepatitis C, poststreptococcal infection, syphilis)

- Lymphoma
- Chronic renal transplant rejection
- Heroin use
- Penicillamine
- Tubular proteinuria:
 - Hypertensive nephrosclerosis
 - Uric acid nephropathy
 - Acute hypersensitivity interstitial nephritis
 - Fanconi syndrome
 - Sickle cell disease
- Overflow proteinuria:
 - Monoclonal gammopathy
 - Leukemia
- Proteinuria, other:
 - Dehydration
 - Stress
 - Fever
 - Heat injury
 - Inflammatory process
 - Orthostatic proteinuria

TREATMENT

PRE HOSPITAL

- Airway, breathing, and circulation management
- Control other trauma, if present.

INITIAL STABILIZATION/THERAPY

- Airway, breathing, and circulation management
- Treat hemodynamically unstable injuries 1st, if present.
- Obtain initial labs (urinalysis with microscopic analysis, BUN, serum creatinine, electrolytes).

Pregnancy Considerations

If considering preeclampsia:

- Aggressive BP control
- Magnesium if indicated
- Prompt OB/GYN consultation

ED TREATMENT/PROCEDURES

- Uncomplicated UTIs:
 - Antibiotics (see Urinary Tract Infection, Adult or Urinary Tract Infection,

Pediatric)

- Pyelonephritis:
 - Antibiotics (see Urinary Tract Infection, Adult or Urinary Tract Infection, Pediatric)
 - Analgesics
 - Antipyretics
- Rapidly progressing glomerulonephropathy:
 - Steroid therapy
 - Nephrology consultation
- Acute renal failure:
 - Hemodialysis
 - Renal US
 - Urine electrolytes
 - Nephrology consultation
- Renal colic:
 - IV fluids
 - Analgesics
 - If initial presentation, noncontrast helical CT scan
- Gross hematuria:
 - Insertion of 3-way Foley catheter with bladder irrigation to clear blood clots that may cause urinary retention from bladder obstruction

MEDICATION

- Antibiotic recommendations for UTI are discussed in the relevant chapters.
- Steroids for rapidly progressing glomerulonephropathy should be discussed with a nephrologist.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Acute renal failure:
- Azotemia/uremia/hyperkalemia
- Hemodynamic instability
- Hematuria with traumatic injuries
- Obstructing ureteral stones with evidence of systemic infection or renal failure
- Hypertensive emergency
- Oliguria/anuria
- Pregnant with preeclampsia, pyelonephritis, obstructing nephrolithiasis
- Intractable pain
- Intolerance of PO fluids and medications

Discharge Criteria

- Hemodynamically stable without life-threatening issues
- Infected ureteral stones without renal failure or obstruction
- Mild hematuria or proteinuria without renal failure
- Hematuria:
 - Gross hematuria, except in young women with proven UTIs, needs urology follow-up.
 - Microscopic hematuria needs repeated U/As and PCP follow-up, and may need urology/nephrology in the future.
 - Pregnant patients with possible infections should have close follow-up to ensure treatment success.
- Proteinuria:
 - Mild cases should be referred to their primary care physician for further workup in an outpatient setting.
 - Nephrotic-range proteinuria, as well as proteinuria with renal failure and no alternative explanation, should be referred to a nephrologist promptly.

PEARLS AND PITFALLS

- Missing acute glomerulonephritis in children, either by misdiagnosing as a UTI based on the U/A, or by failing to consider it in the differential is a pitfall.
- Spot urine protein/creatinine ratio correlates well with 24 hr urine protein (i.e., ratio of 3.5 is roughly equivalent to 24 hr protein excretion of 3.5 g)
- Periorbital edema can be a sign of nephritic syndrome, not just allergic reaction.
- Failing to ensure follow-up for asymptomatic hematuria, especially in patients > 40 yr is a pitfall.

- R80.9 Proteinuria, unspecified
- R31.0 Gross hematuria

HEMOPHILIA

Steven H. Bowman • Christina H. Georgopoulos

BASICS

DESCRIPTION

- Caused by deficiency of functional factor VIII or factor IX
- Lack of functional factor causes partial inactivation of coagulation cascade and impaired hemostasis.
- 2 types:
 - Hemophilia A: Factor VIII deficiency
 - Hemophilia B (Christmas disease): Factor IX deficiency
- Symptoms dependent on factor activity:
 - 5–30% factor activity (mild hemophilia):
 - Bleeding with major trauma or surgery
 - 1–5% factor activity (moderate hemophilia):
 - Bleeding secondary to trauma/surgery
 - Occasional spontaneous hemarthroses (< 1 time per month)
 - < 1% factor activity (severe):
 - Spontaneous bleeding from infancy
 - May bleed as often as 1–2 times per week, often requiring factor replacement
- Complications:
 - Death from hemorrhage
 - Recurrent joint bleeding leads to joint destruction and loss of function
 - Transfusion-transmitted infections (risk reduced with purification of concentrates)
 - Development of inhibitors (IgG antibodies to factors), which prevent hemostasis

ETIOLOGY

Genetics

- X-linked recessive, though 1/3 have a spontaneous mutation
- Rare disease:
 - Hemophilia A: 1 in 5–7,000 males
 - Hemophilia B: 1 in 30,000 males
- Prevalence of inhibitors: 20% of severe hemophilia A and < 5% of severe hemophilia B

DIAGNOSIS

SIGNS AND SYMPTOMS

- **Bleeding:**
 - Hemarthrosis (most common):
 - Knee (most common) > elbow > ankle > shoulder > wrist
 - Muscle hemorrhage
 - Bleeding from soft tissue lacerations
 - Postextraction or oral mucosal bleeding
 - Epistaxis (only in severe disease)
 - Hematuria
 - Intracranial hemorrhage
 - GI bleeding
 - Pseudotumors (blood cysts)

ESSENTIAL WORKUP

Thorough history and physical exam

DIAGNOSIS TESTS & INTERPRETATION

Lab

- PLT count: Normal
- Bleeding time: Normal
- PT: Normal
- PTT: Increased
- Urinalysis: Asymptomatic hematuria (often)
- Specific factor assays:
 - Factor VIII:Ag (measures quantity): Decreased
 - Factor VIII:c (measures activity): Decreased
 - vWF:Ag and vWF: Normal

Imaging

Radiographic studies may be required in certain circumstances:

- Head CT to evaluate for intracranial bleed
- Renal US/cystoscopy to evaluate excessive hematuria or renal trauma
- Abdominal CT to evaluate for retroperitoneal bleeding

DIFFERENTIAL DIAGNOSIS

- Von Willebrand disease
- Anticoagulant drugs
- Antiplatelet agents
- Thrombocytopenia
- Hepatic dysfunction

TREATMENT

INITIAL STABILIZATION/THERAPY

- Control bleeding proximally.
- Establish IV access, draw type and screen.
- Consider PRBCs for transfusion.

ED TREATMENT/PROCEDURES

General

- Patients generally know their doses, type of factor, and whether or not they have inhibitors. Have low threshold for factor replacement when they present with any symptom.
- Coordinate ED care with patient's hematologist.
- Start replacing factors immediately, even before imaging/consults.

Approach to Factor Replacement

- 1 U in 1 mL of normal plasma is considered 100% clotting factor activity.
- People without hemophilia have factor levels between 60% and 150%.
- Step 1: Determine % activity desired based on location/system involved in bleeding:
 - Low to moderate bleeding – want 30–50% activity
 - Soft tissue injury/lacerations
 - Joint or muscle bleeding (except iliopsoas)
 - Moderate to severe bleeding – want 50–100% activity
 - GI or GU bleeding
 - Major muscle bleeds (iliopsoas)
 - Severe to life-threatening bleeding – want 100% activity
 - CNS injury/intracranial bleed
 - Major bleeding from trauma or postsurgery
 - Intra-abdominal/retroperitoneal bleeding
 - Throat/neck bleeds compromising airway
- Step 2: Calculate factor dose for level of activity desired.
 - Factor VIII required (in U) = $\text{wt (kg)} \times 0.5 \times (\% \text{ factor activity desired})$. 1 IU/kg raises activity by 2%. Give every 12 hr for 1–2 days.
 - Factor IX required (in U) = $\text{wt (kg)} \times 1 \times (\% \text{ factor activity desired})$. 1 IU/kg raises activity by 1%. Give every 24 hr for 1–2 days.
 - Factor dose given IV push over 1–2 min

Specific Management Considerations

- Hemarthrosis:
 - Splint, ace, ice

- Arthrocentesis is rarely indicated
- Muscle hemorrhage:
 - Forearm/calf—consider compartment syndrome
 - Psoas hematoma—groin pain, femoral nerve paresthesias
- Post tooth extraction or oral mucosal bleeding:
 - Treat locally with collagen sponge (Avitene) or other hemostatic agent.
 - Replace factor if severe.
 - Aminocaproic acid (Amicar) or tranexamic acid (Cyklokapron) may be useful.
- Hematuria (generally mild):
 - Hydrate
 - Avoid Amicar and cryoprecipitate.
- Intracranial hemorrhage:
 - All head injuries should be considered significant, especially in children.
 - Do not delay therapy for CT head.
- GI bleeding:
 - Secondary to ulcers, polyps, hemorrhoids
 - Replace factor prior to endoscopy.

MEDICATION

To calculate doses for recombinant and plasma-derived factor VIII and factor IX concentrates refer to section Approach to Factor Replacement above.

Patient without Inhibitors

- **First line: Recombinant factor**
 - Recombinant factor VIII options: Recombinate, Kogenate, Advate, Helixate FS, Xyntha
 - Recombinant factor IX options: BeneFIX
- **Second line: Plasma-derived factor**
 - Plasma-derived factor VIII high-purity concentrates: Monoclote-P, Hemofil-M, Koate DVI, Alphanate
 - Plasma-derived factor VIII intermediate-purity concentrates: Humate
 - Only use when previous options are not available.
 - Plasma-derived factor IX high-purity concentrates: AlphaNine, Mononine
- **Other options**
 - Cryoprecipitate (useful only in hemophilia A):
 - Obtained from FFP after thawing at 4°C
 - Contains factor VIII, vWF, fibrinogen
 - Estimated 80–100 U of factor VIII in 1 U of cryoprecipitate
 - Give 10 bags initially, peds dose 1 bag/6 kg
 - Only if factor VIII concentrates are not available
 - FFP (contains factors VIII and IX):
 - 1 U of FFP contains about 200–300 U each of both factor VIII and

- factor IX
 - 1 U of FFP will raise factor level 5–10% in a 60 kg person
 - Readily available in most EDs; useful in life-threatening bleeds when access to specific factor treatment is delayed
- Adjunct to factor therapy: DDAVP (only in hemophilia A)
 - Raises factor VIII level 2–3 times (only use in patients with mild hemophilia, and only with mild bleeds)
 - Side effects: Mild flushing, headache, tachycardia, hypotension, hyponatremia
 - Dose 0.3 µg/kg of DDAVP diluted in 50 mL 0.9% NS given over 15–30 min given IV or SC (intranasal “Stimate” 1 spray each nostril if >50 kg)
 - Should not be used in children <1 yr old
- Adjunct to factor therapy: Antifibrinolytic agents (for mild bleeds)
 - Inhibit plasmin activity, prevents clot lysis
 - Only for mucosa/oral/dental bleeding
 - Do not use in children.
 - Examples: Aminocaproic acid (Amikar) 75 mg/kg every 6 hr up to 4 g or tranexamic acid (Cyklokapron) 25 mg/kg every 8 hr.
- Adjunct to factor therapy: Topical thrombin
 - Useful for localized control of bleeding from lacerated superficial tissues

Patient with Inhibitors

- First line: Recombinant factor VIIa (NovoSeven)
 - 90–120 µg/kg every 2–3 hr
 - Higher doses of up to 300 µg/kg may promote thrombin formation and stabilize fibrin clot in the case of inefficient hemostasis
 - Bypasses the coagulation cascade and works locally, decreasing risk for systemic coagulation
 - Strong safety profile, minimal risk of inhibitor development, expensive
- Second line: Activated prothrombin complex concentrates (APCCs)
 - Examples: FEIBA and Autoplex-T
 - Dose: 75–100 U/kg every 8–12 hr
 - Contains VIIa, IXa, and Xa
 - Bypasses coagulation cascade
 - Thromboembolic events occur with higher doses: DVT, PE, acute MI, DIC
- Other options
 - Use high-dose recombinant or plasma-derived factor concentrates (2–3 times normal range) in those who have low antibody titers (low responders)
 - Porcine factor VIII is now off the market

- Avoid all IM injections of factor concentrates
- Avoid aspirin and aspirin-containing products
- Replace factor before any imaging, consultations, invasive procedures, or hospital transfers

FOLLOW-UP

DISPOSITION

Admission Criteria

- Low threshold for admission
- All joint/muscle bleeds, internal bleeding, severe bleeds
- Bleeding that may require multiple transfusions
- Severe complications or any head trauma

Discharge Criteria

Minor soft tissue bleeding, superficial lacerations with resolution/control of bleeding

Issues for Referral

Hematology for all bleeds

FOLLOW-UP RECOMMENDATIONS

- Hematologist as outpatient
- Return to ER for recurrent bleeding episodes

PEARLS AND PITFALLS

- Do not wait for a head CT before treatment in the setting of head trauma
- In a suspected bleeding emergency in a patient with unknown clotting factor level, assume the level to be 0 and treat as a severe bleed
- Be familiar with different factor replacement therapies for patients with and without inhibitors
- Consult hematologist for appropriate dosing in ER, length of treatment, inhibitor vs. noninhibitor treatment
- Have a low threshold for admission

CODES

ICD9

- 286.0 Congenital factor VIII disorder
- 286.1 Congenital factor IX disorder

ICD10

- D66 Hereditary factor VIII deficiency
- D67 Hereditary factor IX deficiency

HEMOPTYSIS

Amy Kiraly • Peter S. Pang • Navneet Cheema

BASICS

DESCRIPTION

- Expectoration of blood originating from the tracheobronchial tree
- Source of bleeding:
 - Bronchial arteries (90%), usually causes profuse bleeding
 - Pulmonary arteries (5%), usually causes small amounts of bleeding
 - Nonbronchial arteries (5%) including intercostal arteries, coronary arteries, thoracic, upper, and inferior phrenic arteries
- Threshold of massive hemoptysis defined has been defined from 100 mL to 1 L/24 hr:
 - > 8 mL/kg/day in children
 - Most common definition is > 300–600 mL/24 hr
- Mortality:
 - Massive hemoptysis (> 500 mL/24 hr): 38%
 - Trivial to moderate hemoptysis (< 500 mL/24 hr): 4.5%
 - Malignancy and coagulopathy increase the risk of mortality

ETIOLOGY

- Infectious (most common cause):
 - Acute or chronic bronchitis
 - Pneumonia
 - Necrotizing pneumonia or lung abscess (*Klebsiella pneumoniae*, *Pseudomonas aeruginosa*, *Staphylococcus aureus*, *Streptococcus pneumoniae*)
 - Tuberculosis
 - Viral (influenza, varicella)
 - Fungal (*Aspergillus*, *Coccidioides*, *Histoplasma*, *Blastomyces*)
 - Parasitic (*Ascariasis*, *Amebiasis*, *Paragonimiasis*, *Echinococcus*)
- Neoplastic:
 - Squamous cell, small cell, carcinoid
 - Bronchogenic carcinoma
 - Metastatic disease
- Pulmonary:
 - Bronchiectasis
 - Pulmonary embolism/infarction
 - Cystic fibrosis
 - Bronchopleural fistula
 - Sarcoidosis

- Cardiac:
 - Mitral stenosis
 - Tricuspid endocarditis
 - Heart failure
- Systemic disease:
 - Goodpasture syndrome
 - Systemic lupus erythematosus
 - Vasculitis (Wegener granulomatosis, Henoch–Schönlein purpura, Behçet disease)
- Hematologic:
 - Coagulopathy
 - Thrombocytopenia
 - Platelet dysfunction
 - DIC
- Vascular:
 - Pulmonary HTN
 - Arteriovenous malformation
 - Aortic aneurysm
 - Pulmonary artery aneurysm (Rasmussen aneurysm, mycotic, arteritis)
 - Aortobronchial fistula
- Drugs/toxins:
 - Aspirin/antiplatelet therapy
 - Anticoagulants
 - Penicillamine, amiodarone, propylthiouracil, bevacizumab
 - Cocaine (“crack”) lung
 - Organic solvents
- Trauma:
 - Tracheobronchial rupture
 - Pulmonary contusion
- Iatrogenic:
 - Bronchoscopy/lung biopsy
 - Pulmonary artery or central venous catheterization
 - Transtracheal aspirate
- Miscellaneous:
 - Foreign-body aspiration
 - Catamenial hemoptysis (pulmonary endometriosis)
 - Amyloidosis
 - Idiopathic or cryptogenic (between 5% and 30%, depending on patient population)

SIGNS AND SYMPTOMS

- Chest pain
- Dyspnea
- Fever
- Weakness
- Fatigue
- Night sweats
- Weight loss

History

- Inquire about prior lung, renal, or valvular heart disease
- History of cigarette smoking
- Chemical, asbestos, or infectious exposure
- Travel history (consider parasitic or fungal infectious etiology)
- Aspirin, NSAID, or anticoagulant use
- Consider Goodpasture syndrome if a history of hematuria is present.
- Recurrent or chronic hemoptysis raises suspicion of arteriovenous malformations, bronchiectasis, and cystic fibrosis.

Physical-Exam

- Clubbing of the fingers (chronic inflammatory lung diseases)
- Cutaneous ecchymosis (blood dyscrasia or anticoagulants)
- Aphthous ulcers (Behçet disease)
- Nasal septal perforation (Wegener granulomatosis)
- Hematuria (Goodpasture syndrome)
- Unilateral lower extremity edema may indicate DVT.
- Suggestive of pseudohemoptysis:
 - Sinusitis, epistaxis, rhinorrhea, pharyngitis, upper respiratory infection, aspiration

Pediatric Considerations

- Thorough head, eyes, ears, nose, and throat exam to exclude nonpulmonary source of bleeding
- Pulmonary exam is often normal.
- Wheezing may suggest obstruction (e.g., foreign body).
- Crackles may indicate an underlying pulmonary etiology (e.g., pneumonia, hemothorax, heart failure).
- Telangiectasias or hemangiomas raise suspicion of arteriovenous malformations.

ESSENTIAL WORKUP

- Differentiate between hemoptysis and pseudohemoptysis:
 - Note any precipitating factors, duration of symptoms, quantity and quality

of blood.

- Pulmonary source:
 - Bright red blood
 - Frothy in appearance
 - Sputum mixed with blood is likely pulmonary
 - pH > 7
- GI source:
 - Dark red or brown blood
 - Accompanied by gastric contents
 - Worsens in the setting of nausea/vomiting
 - pH < 7
 - Gastric lavage may be used to rule out GI source of bleeding; however, nasal or other trauma may cause further bleeding.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC with differential
- Basic metabolic panel
- PT/INR, PTT
- Urinalysis
- Febrile patient or suspected infectious etiology:
 - Blood cultures
 - Sputum culture and Gram stain
 - Cytology
 - KOH prep for fungal causes
 - AFB stain for tuberculosis
- Hypotensive patient (criteria for massive hemoptysis):
 - Type and cross
 - Complete metabolic (liver and renal function) panel
 - Coagulation profile:
 - Fibrin and fibrinogen degradation products (FDP) or antithrombin III if disseminated IV coagulation suspected
- Pediatric patient:
 - Consider sweat-chloride test if cystic fibrosis is suspected.

Imaging

- CXR:
 - Characterizes pathology (e.g., tumor, cavity, effusion, infiltrate, pneumothorax)
 - Early pulmonary hemorrhage may present as infiltrate.
 - ~20% will be normal.
- CT:

- High-resolution CT has become gold standard for diagnosing bronchiectasis.
- Ideal study for stable patients with hemoptysis and a normal CXR
- Can detect active TB by the presence of cavitary lesions and acinar nodules
- Higher sensitivity for peripheral tumors that may not be apparent on bronchoscopy
- CTA:
 - Known variability in bronchial arterial supply
 - Characterizes origin of bronchial arteries and presence of variants
 - May identify a pulmonary artery as a source of bleeding, show a pulmonary or bronchial artery aneurysm
 - Characterizes abnormal nonbronchial arterial supply, eliminates nonbronchial arteries as possible sources of bleeding
 - identifies pulmonary embolism
- V/Q:
 - If PE is suspected and patient cannot get CTA
 - Limited utility if x-ray is abnormal

Diagnostic Procedures/Surgery

Bronchoscopy:

- Allows direct visualization of tumors, foreign bodies, granulomas, and infiltration
- Valuable for collecting bronchial secretions for cytology and histology
- Limited diagnostic yield in lesions outside the bronchial wall, distal to bronchial stenosis or occlusion, or peripheral lesions.

DIFFERENTIAL DIAGNOSIS

Pseudo-hemoptysis:

- Epistaxis
- Pharyngeal bleeding
- GI bleeding

TREATMENT

PRE HOSPITAL

- Respiratory and contact precautions
- Airway management:
 - Oxygen
 - Suctioning as needed
 - Endotracheal intubation if airway compromised, severe respiratory distress, or hypoxemia
- Dual large-bore IV access
- Volume resuscitation as needed
- Continuous pulse oximetry, close hemodynamic and cardiac monitoring

INITIAL STABILIZATION/THERAPY

- Airway and breathing:
 - Endotracheal intubation for impending respiratory failure
 - >8Fr endotracheal tube to facilitate suctioning and subsequent bronchoscopy
 - Selective intubation of nonbleeding lung with single- or double-lumen endotracheal tubes may be required.
 - Supplemental oxygen as needed
 - Continuous pulse oximetry and cardiac monitoring
- Massive hemoptysis:
 - Principal risk to life is asphyxiation, not exsanguination
 - Maintain dual large-bore IV access.
 - Volume resuscitation with crystalloid or blood products as needed

ED TREATMENT/PROCEDURES

- Antimicrobial therapy if concern for or diagnosed infectious cause
- Correct hypoxemia and/or coagulopathy
- If massive hemoptysis:
 - Multiple large-bore IVs or central access with volume resuscitation and blood products as needed
 - Patient should be positioned upright or in lateral decubitus with affected lung positioned down
 - Intubation for airway protection, impending respiratory failure, or to facilitate bronchoscopic evaluation
 - Endobronchial tamponade with Foley or Fogarty (<4Fr) catheter, or double-lumen endotracheal tube (temporary measures)
 - Bronchoscopy for local therapy including vasoconstrictive agents, stent or balloon tamponade, electrocautery, procoagulants
 - Bronchial artery embolization (success rates reported as high as 98%); rebleeding presents in ~20% of cases
 - Surgery:
 - Lobectomy or pneumonectomy if unsuccessful embolization or in the presence of thoracic aneurysm, trauma, or arteriovenous malformation
 - Surgical resection is most effective for patients with localized lesions and adequate cardiopulmonary reserve

MEDICATION

Refer to specific etiology

FOLLOW-UP

DISPOSITION

Admission Criteria

- ICU:
 - Intubation
 - Massive hemoptysis
 - Hemodynamic instability
 - Hypovolemic shock
 - Severe or refractory hypoxemia
 - Impending respiratory failure
 - Impending airway compromise
- General ward:
 - Mild hemoptysis
 - TB (isolation)
 - Stable foreign body
 - Lung abscess
 - Cavitory lung disease

Discharge Criteria

- Hemodynamically stable
- Mild hemoptysis
- No coagulopathy
- No supplemental oxygen requirement
- History of chronic stable hemoptysis
- Close follow-up

Issues for Referral

- PCP within 7–10 days
- Specialist if etiology warrants referral

FOLLOW-UP RECOMMENDATIONS

- Counsel patient not to smoke.
- Avoid medications that may increase the risk of bleeding, including herbal supplements such as garlic, ginkgo, or ginseng.
- The patient should seek care immediately for:
 - Shortness of breath
 - Chest pain
 - Severe dizziness on standing
 - Fainting
 - Persistent or worsening hemoptysis

PEARLS AND PITFALLS

- Consider early airway management as clinical picture warrants.
- If severe unilateral hemorrhage with hypoxemia, place patient “bad lung” down
- Bronchial artery embolization can be very effective. Discuss case early with IR.

HEMORRHAGIC FEVERS

Fraser C. Mackay • Ben Osborne

BASICS

DESCRIPTION

Hemorrhagic fever describes a multisystem syndrome of vasocapillary permeability and/or organ dysfunction. Viral hemorrhagic fever (VHF) is caused by a distinct group of viruses, but the initial phase resembles influenza-like illness. Hemorrhagic stages typify the minority of patients and the later phases of disease.

RISK FACTORS

- Travel in endemic region
- Biologic warfare
- Close animal contact, insect bite or ingestion

PATHOPHYSIOLOGY

- VHF causes endothelial damage and increase vascular permeability, hemorrhage, and may proceed to shock
- VHF shock state is both hypovolemic and distributive, and is often very difficult to reverse. Hypotension can progress swiftly, and indicates very high mortality.
- DIC appears to be a regular feature of Marburg and Crimean-Congo hemorrhagic fever but is less frequent with Arenavirus infections.
- Dengue hemorrhagic fever is immune mediated and is usually the result of secondary infection. It is among the most common causes for VHF.

ETIOLOGY

- RNA viruses that have zoonotic life cycles in specific geographic areas
- Short incubation period (< 10–21 days)
- More common VHF vectors:
 - Filoviruses: Fruit bat reservoir, unclear mode of transmission (sub-Saharan Africa)
 - Ebola
 - Marburg
 - Arenaviruses: Rodent reservoir, aerosolized rodent excreta (sub-Saharan Africa).
 - Lassa
 - South American hemorrhagic fevers
 - Flaviviruses: Human reservoir, via mosquito (tropics, increasingly worldwide)
 - Dengue (common cause of VHF)
 - Yellow fever

- Bunyaviridae: Rodent reservoir, via tick or mosquito (Europe, South Asia, Africa)
 - Rift Valley fever
 - Crimean-Congo hemorrhagic fever
- Hantaviridae: Rodent reservoir, aerosolized rodent excreta (Southwest USA)
 - Hemorrhagic fever with renal syndrome
 - Hantavirus pulmonary syndrome

ALERT

- Potential biowarfare threat:
 - Aerosols (with exception of dengue) and body fluids highly infectious
 - High morbidity/mortality in some cases
 - Replicate well in cell culture, permitting weaponization

DIAGNOSIS

SIGNS AND SYMPTOMS

- Most common (>50%) symptoms:
 - Acute febrile illness
 - Malaise
 - Headache
 - Nausea/vomiting
 - Flushing
 - Diarrhea (nonbloody)
 - Abdominal pain
 - Myalgias
- Less common (<30%) symptoms:
 - Gingival hemorrhage
 - Conjunctival injection/hemorrhage
 - Petechia
 - Hematemesis
 - Melena
 - Epistaxis
 - Ecchymoses
- Hemorrhagic presentations > 3 days into disease
 - Skin, IV sites, gums, nose, lungs, GI tract, or uterus
 - Diffuse alveolar hemorrhage or ARDS
 - More common in CCHF, Lassa, Marburg, Ebola, Hantavirus
- Exanthems
 - Marburg and Ebola: Nonpruritic centripetal, papular, erythematous eruption appearing between days 5 and 7, which then coalesce into well-demarcated macules that may be hemorrhagic
 - Yellow fever: Jaundice

- Dengue: Bright maculopapular truncal erythroderma that blanches dramatically under light pressure (often on lower extremities)
- Hemodynamic collapse, shock, seizures, coma, death.
 - Late stage of disease, often irreversible

History

- Travel to endemic regions
- Sick contacts
- Clustering of cases should raise concerns of a bioweapon attack or outbreak

Physical-Exam

- Protection of health care workers:
 - Universal blood and body precautions
- Vital signs: Monitor BP, fever, tachycardia
 - Narrowed pulse pressure (< 20 mm Hg) may signal imminent cardiovascular collapse
- Hemorrhage (see Signs and Symptoms)
- Exanthems (see Signs and Symptoms)
- RUQ tenderness or hepatomegaly
 - Hepatitis
- Adventitious lung sounds

ESSENTIAL WORKUP

- Focus on differentiating from other acute febrile illnesses, especially in the traveler.
- Investigate lung involvement, as it can indicate systemic disease and worse outcome
- Recognize possible biologic attack when unusual number of patients present with similar and/or unusual findings.
- History to identify potential pathogen:
 - Include recent travel, illnesses, or other sources of exposure.
 - Often patients are unaware of animal contacts

DIAGNOSIS TESTS & NTERPRETATION

Lab

- CBC:
 - May see leukocytosis, leukopenia, thrombocytopenia, or pancytopenia
 - Abnormally high hematocrit can signify hemoconcentration; may indicate increased 3rd spacing impending shock/cardiovascular collapse.
- Electrolytes, BUN, creatinine, and glucose levels:
 - Consider renal failure
- Liver function tests:

- Hepatic involvement is common, but jaundice occurs mainly with yellow fever.
- Type and screen, prothrombin time, partial thromboplastin time, and d-dimer tests:
 - Look for coagulopathy and DIC (seen in Crimean-Congo hemorrhagic fever, Ebola, and Marburg)
- Special lab test:
 - In specialized labs (biohazard level 4), definitive diagnosis can be made by viral isolation, real-time reverse transcriptase polymerase chain reaction (RT-PCR), and immunohistochemistry techniques:
 - Coordinated with CDC
 - Thick and thin smears to help differentiate from malaria

Imaging

CXR, head, and abdominal CT scanning:

- Rule out pneumonia or ARDS
- Intracranial and intra-abdominal bleeding

Diagnostic Procedures/Surgery

Serum and saliva can be analyzed by RT-PCR in specialized labs.

DIFFERENTIAL DIAGNOSIS

- Malaria:
 - A concern for traveler with fever
- Dengue fever:
 - Common source of fever in traveler
- Rickettsial:
 - Rocky Mountain spotted fever
 - Typhus
- Bacterial:
 - Meningococemia
 - Sepsis
 - EHEC (Escherichia coli O157:H7)
- Systemic disease:
 - Leukemia
 - TTP, ITTP
- Pit viper envenomation

TREATMENT

PRE HOSPITAL

ALERT

- Increasing globalization has increased frequency of imported cases of rare diseases.
- Early detection of VHF, natural, or biologic attack is key to control an outbreak. Report to CDC.
- Most cases will derive from patients who traveled to or had contact with persons from parts of the world where the viruses are endemic.

INITIAL STABILIZATION/THERAPY

Protection of health care workers:

- Universal blood and body precautions
- Isolation of patient
- Use of protective clothing plus HEPA-filtered respirators to minimize exposure to aerosols for those involved in procedures such as suctioning, catheter placement, and wound dressing

ED TREATMENT/PROCEDURES

- Supportive therapy
- Empiric therapy with antimalarial regimens until definitive diagnosis is obtained
- Aggressive treatment of secondary infections
- Bleeding is usually mild, and life-threatening blood loss is rare:
 - If indicated, hemorrhage can be managed by replacement of blood, platelets, and clotting factors.
- Fluid support
 - Patients are prone to 3rd spacing and can go into flash pulmonary edema; be judicious with crystalloids.
 - Reserve colloids/blood products for impending shock/cardiovascular collapse.
- Ribavirin—a synthetic nucleoside:
 - Useful for Lassa, South American hemorrhagic fever, Crimean-Congo hemorrhagic fever, and hemorrhagic fever with renal syndrome; ineffective against filoviruses
 - Causes a reversible hemolytic anemia
- Transfusion of immune plasma (convalescent plasma therapy) for South American hemorrhagic fever within 1st week of symptoms

MEDICATION

- Ribavirin (WHO 2006 recommendations):
 - IV loading dose of 33 mg/kg followed by 16 mg/kg q6h for 4 days, then 8 mg/kg q8h for 3 days
 - Prophylactic 500 mg by mouth q6h for 7 days
- Vaccines:
 - Yellow fever is widely available.
 - South American hemorrhagic fever, Rift Valley fever, Hantavirus, Dengue,

and Ebola/Marburg are under development.

- Other medications under investigation:
 - Nucleoside analog inhibitors of *S*-adenosylhomocysteine hydrolase inhibit Ebola replication in mice.
 - Zidampidine—a derivative of AZT—increases survival of mice infected with Lassa virus

First Line

- Hemodynamic support
- Ribavirin
- Antimalarials

Second Line

Contact the CDC about experimental vaccines and antivirals for postexposure prophylaxis (770) 488-7100 or (800) 311-3435 for all suspected cases.

FOLLOW-UP

DISPOSITION

Admission Criteria

Suspected cases of VHF, particularly those with suspected multisystem involvement/compromise

- Isolation precautions
- ICU for signs of shock or multiorgan system failure

Discharge Criteria

None—if you suspect VHF, ***the patient needs to be isolated and the CDC notified***

FOLLOW-UP RECOMMENDATIONS

Consider experimental postexposure prophylaxis for staff and patient contacts that may include antivirals and vaccines. Coordinate with the CDC at (770) 488-7100 or (800) 311-3435.

PEARLS AND PITFALLS

- **EXTREME** caution with volume resuscitation
- Hemoconcentration and pulmonary involvement are **RED FLAGS**
- Consider hemorrhagic viruses in your differential diagnosis when caring for a sick patient returning from endemic regions of the world
- Employ universal precautions and isolation to minimize the spread of the disease
- Contact the CDC at (770) 488-7100 or (800) 311-3435 for all suspected cases.

HEMORRHAGIC SHOCK

Theodore C. Chan

BASICS

DESCRIPTION

- Loss of effective circulating blood volume resulting in inadequate perfusion
- Blood loss exceeds ability to compensate and tissue and organ perfusion decrease. At the tissue level, hypoperfusion leads to inadequate oxygenation, anaerobic metabolism, cell death
- Hemorrhagic shock is the most common cause of shock from injury
- Compensated shock:
 - Patient's physiologic reserve prevents significant alteration in vital signs
- Decompensated shock:
 - Loss of circulating volume overcomes patient's physiologic reserve, resulting in significant alteration in vital signs.
- Blood loss estimate:
 - Total blood volume ~7% of ideal body weight (4,900 mL in 70 kg adult) or 70 mL/kg
 - Multiply 70 mL/kg × body weight (kg) × percentage loss as determined by class of hemorrhage.

ETIOLOGY

- Trauma—penetrating and blunt:
 - Abdominal:
 - Splenic injury
 - Liver injury
 - Chest:
 - Hemothorax
 - Aorta or great vessel injury
 - Pelvis:
 - Pelvic fracture with vascular injury
- Vascular malformations:
 - May lead to thoracic, intraperitoneal, or retroperitoneal bleeding
 - Aneurysms:
 - Abdominal aortic aneurysm most common
 - Mycotic aneurysm secondary to endocarditis
 - Aortogastric fistula
 - Arteriovenous malformations
- Abortion: Complete, partial, or inevitable
- Ectopic pregnancy

- Epistaxis
- Fractures (especially pelvis and long bones)
- GI bleeding
- Hemoptysis
- Malignancies
- Mallory–Weiss tear
- Placenta previa
- Postpartum hemorrhage
- Retroperitoneal bleeds
- Splenic rupture
- Vascular injuries

DIAGNOSIS

SIGNS AND SYMPTOMS

- Class I hemorrhage: Loss of up to 15% of blood volume (up to 750 mL in 70 kg adult):
 - HR < 100
 - SBP normal
 - Respiratory rate (RR) 14–20
 - Increased or normal pulse pressure
 - Slight anxiety
- Class II hemorrhage: Loss of 15–30% of blood volume (750–1,500 mL):
 - Tachycardia: HR > 100
 - SBP normal, or minimally decreased
 - Tachypnea: RR 20–30
 - Narrowed pulse pressure
 - Mild anxiety
 - Small decrease in urine output
- Class III hemorrhage: Loss of 30–40% of blood volume (1,500–2,000 mL):
 - Marked tachycardia: HR > 120
 - Hypotension: SBP decreased
 - Marked tachypnea: RR 30–40
 - Marked narrowing of pulse pressure
 - Significant change in mental status: Confusion
 - Delayed capillary refill
 - Marked decrease in urine output
- Class IV hemorrhage: Loss of > 40% of blood volume (> 2,000 mL):
 - HR > 140
 - Marked hypotension: SBP decreased
 - RR > 35
 - Very narrow pulse pressure

- Depressed mental status: Confusion, lethargy, loss of consciousness
- Negligible urine output
- Cold and pale skin

ALERT

- Reliance solely on SBP as indicator of shock state can result in delayed recognition

Pediatric Considerations

- Children often have greater physiologic reserve than adults and can preserve normal vital signs longer
- Systemic responses to blood loss in the pediatric patient include:
 - Volume loss < 25%: Weak, thready pulse and tachycardia; lethargy, irritability, and confusion; cool, clammy skin; decreased urine output/increased urine specific gravity
 - Volume loss 25–40%: Tachycardia; marked change in consciousness; dulled response to pain; cyanotic, cold extremities with decreased capillary refill; minimal urine output
 - Volume loss > 40%: Hypotension, tachycardia, or bradycardia; comatose; pale, cold skin; no urine output

Pregnancy Considerations

Physiologic maternal hypervolemia requires greater blood loss to manifest maternal perfusion abnormalities which may result in decreased fetal perfusion.

Geriatric Considerations

Underlying disease and medications may alter responses to hemorrhage and blood loss.

History

Thorough health and past medical history:

- Underlying disease, risk factors, age
- Medications
- Trauma

Physical-Exam

- Complete physical exam to determine shock class and assess for hemorrhage source
- Vital signs including HR, RR, BP
- Temperature
- Mental status (anxiety, confusion, lethargy, obtundation, coma)
- Pulse character, capillary refill and skin perfusion
- Pulse pressure
- Abdominal exam
- Pelvic/rectal exam for bleeding as indicated

ESSENTIAL WORKUP

- Thorough history and physical exam
- IV access for resuscitation
- Blood type and cross-match

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Blood type and cross-match
- Coagulation studies:
 - PT, PTT
 - International normalized ratio
- Other measures of tissue hypoperfusion:
 - Arterial blood gas
 - Base deficit
 - Serum lactate level
 - Serum electrolytes
- Pregnancy test/ β -HCG

ALERT

Massive blood loss may only result in minimal decrease in Hb or Hct initially

Imaging

- CXR:
 - Hemothorax:
 - Blunt chest injuries
 - Thoracic arteriovenous malformation
- Pelvic radiograph for possible occult fracture
- Focused abdominal sonography for trauma (FAST exam):
 - Abdominal trauma
 - Possible abdominal aortic aneurysm
 - Nontraumatic intraperitoneal hemorrhage
 - Fluid in Morrison pouch implies significant hemorrhage or ascites.
 - Negative findings do not rule out intraperitoneal hemorrhage.
- Endovaginal US:
 - Positive pregnancy test
 - Fluid in the cul-de-sac
 - Ectopic pregnancy
- Abdominal CT scan (once patient stable):
 - Detects both intraperitoneal and retroperitoneal hemorrhage
 - Abdominal aortic aneurysm

Diagnostic Procedures/Surgery

- Insert Foley catheter:
 - Monitor urine output.
- Nasogastric tube:
 - For undifferentiated hypovolemic shock to rule out GI hemorrhage
- Diagnostic peritoneal lavage:
 - For unstable trauma patients when US fails to show intraperitoneal hemorrhage
- Endoscopy:
 - In the setting of upper or lower GI bleeding
- Angiography:
 - Pelvic fracture
 - Retroperitoneal hemorrhage
 - Lower GI bleeding
 - Embolization therapy for bleeding from arterial sources can be performed.

DIFFERENTIAL DIAGNOSIS

- Cardiac tamponade
- Tension pneumothorax
- Cardiogenic shock
- Sepsis
- Adrenal insufficiency
- Neurogenic shock

TREATMENT

- Treatment should be initiated as soon as shock state recognized while simultaneously identifying underlying bleeding source
- The goal is to restore tissue and organ perfusion and to control source of hemorrhage
- “Balanced” or “controlled” resuscitation: Approach is to balance goal of perfusion and risk of rebleeding and may vary with patient:
 - In blunt trauma, BP maintenance may take precedence to reduce risk of traumatic brain injury
 - In penetrating trauma with hemorrhage, delayed aggressive fluid resuscitation until definitive control may reduce bleeding risk

PRE HOSPITAL

- Rapid assessment and transport to appropriate care center
- IV access and fluid resuscitation are standard, though delayed fluid resuscitation may be warranted in cases of penetrating trauma.

INITIAL STABILIZATION/THERAPY

- Airway and breathing:
 - Intubation as indicated by patient's respiratory and mental status
 - 100% oxygen via face mask should be administered.
- Circulation:
 - 2 large-bore peripheral IV lines (16G or larger)
 - Central venous line or venous cutdown (saphenous) may be necessary
 - Intraosseous route may be considered
 - Fluid resuscitation with warmed, isotonic crystalloid fluid – total volume based on patient response to initial fluid bolus
- Early transfusion for class III or IV shock:
 - Type-specific and cross-matched blood preferred when time permits, often 1 hr.
 - Type-specific blood is usually available within 10–15 min.
 - Type O blood can be used in immediate, life-threatening situations (type O Rh-negative blood only for women of child-bearing age).

ED TREATMENT/PROCEDURES

- Place patient on continuous monitor.
- NPO status, strict bed rest
- Control hemorrhage (direct pressure, pelvic fixation/stabilization, etc.).
- Central venous access may be indicated for CVP monitoring, but placement of such lines should not interfere with resuscitation.
- Continually reassess patient for clinical response/deterioration:
 - Vital signs, mental status, and urine output.
 - Follow serial blood gas, lactate level, and hemoglobin/hematocrit measurements.
 - Maintain urine output at 50 mL/hr.
- Response to initial fluid resuscitation is the key to determining subsequent therapy:
 - Rapid response to fluid indicates minimal (< 20%) blood loss.
 - Transient response indicates ongoing hemorrhage or inadequate resuscitation; continue fluid and blood administration and obtain necessary studies and consultations
 - Minimal or no response to volume resuscitation indicates ongoing severe blood loss; immediate angiography or surgical intervention is warranted
- Use fluids warmed (~ 39°C [102.2°F]) by microwave ovens, fluid warmers
- Transfuse whole blood, RBCs, platelets, and other blood products as indicated
- Consider autotransfusion devices with tube thoracostomy treatment of large hemothoraces.
- Monitor closely for coagulopathy particularly with massive transfusions
- Specialty consultation and additional procedures (surgery) as indicated by cause and source of hemorrhagic shock

Pediatric Considerations

- Access may be obtained by intraosseous route after 1 or 2 unsuccessful attempts at peripheral access
- Maintain urine output at 1 mL/kg/hr for children and 2 mL/kg/hr for infants

Pregnancy Considerations

Optimizing perfusion and treatment of the mother is treatment of choice for fetus.

MEDICATION

First Line

- IV Fluids:
 - Crystalloids: NS or lactated Ringer
 - Adults: 1–2 L bolus
 - Pediatric: 20 mL/kg bolus:
 - Reassess for clinical response/deterioration.
- Blood products: Cross-matched, type-specific, O-positive, or O-negative:
 - O-negative should be reserved for women of child-bearing age
 - Adult: Initiate with 4–6 U
 - Pediatric: 10 mL/kg

Second Line

- Other blood products:
 - Platelets
 - Coagulation factors, such as fresh frozen plasma, cryoprecipitate
- Antifibrinolytic agents, hemoglobin-based oxygen carriers, perfluorocarbons:
 - Under study, but not yet of proven benefit

FOLLOW-UP

DISPOSITION

Admission Criteria

All patients with hemorrhage should be admitted to the appropriate service.

Discharge Criteria

N/A

Issues for Referral

N/A

PEARLS AND PITFALLS

- Severity of hemorrhagic shock class and volume loss can be determined by vital signs and careful physical exam
- Fluid resuscitation should balance goal of restoring organ perfusion and potential risk of exacerbating bleeding before definitive control
- Response to fluid resuscitation should guide subsequent therapy

HEMORRHOID

Julia H. Sone

BASICS

DESCRIPTION

- General:
 - Normal venous sinusoids of the distal rectum and proximal anal canal
 - Normal vascular cushions of anal canal that contribute to anal continence
 - Arteriovenous shunt system exists at the level of the internal hemorrhoids that accounts for the bright red blood per rectum
- When the hemorrhoids become symptomatic, hemorrhoid disease develops.
- Do not cause pain unless thrombosed or strangulated
- Discrete masses of thick submucosa contain:
 - Blood vessels
 - Smooth muscle
 - Elastic and connective tissue
- Sliding down of part of anal canal lining
- External hemorrhoids:
 - Vessels situated below dentate line
 - Covered by skin/anoderm
 - Drain to internal iliac veins
- Internal hemorrhoids:
 - Submucosal vessels above dentate lines
 - Drain to portal system
 - Usually at left lateral, right posterolateral, and right anterolateral positions
 - Grade 1: Painless, bleeding
 - Grade 2: Prolapse with bowel movement (BM), spontaneously reduce
 - Grade 3: Prolapse with BM, require manual reduction
 - Grade 4: Chronically prolapsed, not reducible

ETIOLOGY

- Exact cause unknown
- Gravitational forces and abdominal pressure cause distention of the sinusoids
- Associated with straining and irregular bowel habits:
 - Hard, bulky stools or diarrhea cause tenesmus/straining.
 - Push anal cushions out of anal canal
 - Weaken submucosal tissue leading to prolapse
- Higher resting anal pressures:
 - Erect posture
- Heredity:

- Absence of valves in veins
- Increased intra-abdominal pressure:
 - Ascites
 - Pregnancy
- Portal hypertension

DIAGNOSIS

SIGNS AND SYMPTOMS

- Painless, rectal bleeding with defecation
- Blood on stool or toilet paper
- Bright red blood drips into toilet bowl
- Rectal discomfort or pressure
- Severe pain if:
 - Internal hemorrhoids prolapse and strangulate
 - External thrombosed hemorrhoids
- Pruritus ani
- May also have fissure

History

- Length of bleeding
- Associate pain
- New lumps or masses by rectum
- Stool consistency: Hard or liquid
- Previous history of rectal problems
- Stool caliber

Physical-Exam

- Exam of perianal area:
 - Gently spread buttocks.
 - Discrete, dark blue, tender mass covered with skin: Thrombosed external hemorrhoid:
 - Can have internal component
 - Purplish, tender mucosal covered mass: Prolapsed, strangulated internal hemorrhoid:
 - Usually associated with enlarged, thrombosed external hemorrhoid
 - Have patient bear down to check for prolapsing hemorrhoids.
 - Digital rectal exam mandatory to rule out cancer
- Anoscopy to visualize anal canal:
 - Identify bleeding internal hemorrhoids.

ESSENTIAL WORKUP

Detailed history with thorough anorectal exam

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC if history of significant blood loss:
 - Hemoglobin/hematocrit
- Platelet count
- PT/PTT/INR if patient on anticoagulants or severe comorbid condition

DIFFERENTIAL DIAGNOSIS

- Rectal prolapse
- Anal fissure
- Perirectal abscess/fistula
- Condyloma acuminata
- Carcinoma or melanoma

TREATMENT

PRE HOSPITAL

Establish IV access if severe bleeding

INITIAL STABILIZATION/THERAPY

Direct digital pressure to control bleeding

ED TREATMENT/PROCEDURES

- Conservative therapy for all patients:
 - Hot sitz baths for 15 min TID and after each BM
 - High-fiber diet—30 g/day:
 - Eat more fresh fruits and vegetables.
 - Increase bran intake.
 - 10–12 glasses of water per day
 - Stool softeners
 - Bulk-forming laxatives
- NSAIDs: Analgesic and anti-inflammatory effects
- Excise thrombosed external hemorrhoid if severe pain, < 5 days old and clot not resolving:
 - Follow with conservative therapy.
 - Place patient in prone jackknife position or left lateral decubitus and tape buttocks apart
 - Infiltrate surrounding skin and underneath clot using 27G needle with lidocaine-containing epinephrine.
 - Make an elliptical incision to excise clot/skin.

- May need silver nitrate sticks for hemostasis
- Place a small piece of Gelfoam and/or gauze onto the wound and tape.
- Remove dressing at time of 1st sitz bath in about 6 hr
- Give analgesics:
 - NSAIDs
 - Acetaminophen
 - Lidocaine 5% ointment to anus: Topical anesthetic for pain relief
 - 0.2% topical nitroglycerin ointment to anus—decreases pain by inhibiting sphincter spasm
- Manually reduce nonthrombosed, prolapsed internal hemorrhoids:
 - Follow with conservative therapy.
 - May need topical anesthetic or anal sphincter block with local anesthesia
 - Can sclerose bleeding internal hemorrhoids with 2.5% sodium morrhuate or 3% hypertonic saline
 - Can rubber band ligate 1 or 2 internal hemorrhoids:
 - Avoid in immunocompromised patients due to perineal sepsis
- Nonreducible internal hemorrhoids:
 - Nonstrangulated: Conservative management and surgical referral
 - Strangulated: Immediate surgical referral for excision

Pregnancy Considerations

- Usually become symptomatic in the 3rd trimester and can be treated conservatively.
- Do not use Analpram-HC (class C)

MEDICATION

- Acetaminophen: 325–650 mg (peds: 15 mg/kg) with codeine 15–30 mg (peds: 0.5 mg/kg) PO q4h PRN
- Bran/fiber: 20 g PO daily
- Docusate sodium (Colace): 50–200 mg (peds: < 3 yr, 10–40 mg/d; 3–6 yr, 20–60 mg/d; > 6–12 yr, 40–150 mg/d) PO q12h
- ELA-Max 5 (5% lidocaine anorectal cream): Apply to perianal area q4h PRN pain (peds: not for < 12 yr of age). Caution: Use very small amount; this product contains about 5 g lidocaine/100 g cream and is readily absorbed.
- Hydrocortisone/pramoxine topical (Analpram-HC) 1%/1% cream; 2.5%/1% cream/lotion (peds: Same dosing) apply thin amount to area TID–QID
- Hydrocortisone/lidocaine topical (AnaMantle HC) 0.5%/3% cream; 2.5%/3% gel (peds: Not indicated) apply to anal canal BID
- Ibuprofen (Motrin): 400–600 mg (peds: 40 mg/kg/d) PO q6h
- Nitroglycerin 0.2% ointment: Apply to area TID with cotton-tipped applicator
- Psyllium seeds: 1–2 tsp (peds: 0.25–1 tsp/d) PO q24h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Strangulated grade 4 hemorrhoids:
 - Surgical consult for prolapsed, thrombosed internal hemorrhoids
- Severe anemia with bleeding hemorrhoids
- Severe bleeding hemorrhoid in pt on anticoagulation or with portal hypertension

Discharge Criteria

Most patients will go home

Issues for Referral

Surgical referral for:

- Grade 3 or 4 internal hemorrhoids
- Suspected anorectal or colonic tumors, inflammatory bowel disease, coagulopathy, pregnancy, or immunocompromised

FOLLOW-UP RECOMMENDATIONS

- Colorectal follow up for grade 3 or 4 internal hemorrhoids or suspected tumor
- Primary care follow-up for uncomplicated hemorrhoids.

ALERT

All patients with bright red blood per rectum should be referred to GI or colorectal surgery to r/o malignancy

PEARLS AND PITFALLS

Hemorrhoids are not the only cause of anorectal pain and bleeding. Investigate for other etiologies when indicated.

- K64.9 Unspecified hemorrhoids

HEMOTHORAX

Anthony C. Salazar

BASICS

DESCRIPTION

- Accumulation of blood in the intrapleural space after blunt/penetrating chest trauma or other nontraumatic etiology. Bleeding is usually a result of disruption of the tissues/vessels of the chest wall, pleura, or intrathoracic structures:
 - Results in decreased vital capacity, hypoxia, and respiratory compromise.
 - Loss of large intravascular volume results in hemodynamic instability and hemorrhagic shock.
 - Massive hemothorax can cause increased intrathoracic pressure, resulting in compromised venous return and decreased cardiac output.
- Rarely a solitary finding in blunt trauma:
 - Commonly associated with pneumothorax (25% of cases), extrathoracic injuries (73% of cases), and pulmonary contusion.
- Large hemothoraces cause the release of substances that can act as anticoagulants and contribute to continued intrathoracic bleeding.
- If left untreated, can lead to empyema and fibrothorax (lung trapping due to adhesions).

ETIOLOGY

- Traumatic injuries (including iatrogenic) to major blood vessels:
 - Common vessels, including intercostal artery, internal mammary artery, pulmonary artery, pulmonary vein, aorta, vena cava, and heart are associated with hemorrhage into the thoracic cavity.
- Traumatic lung parenchymal injuries:
 - Often stops spontaneously as a result of low pulmonary pressures and high concentrations of thromboplastin in the lung.
 - Often associated with pneumothorax.
- Nontraumatic or spontaneous hemothoraces:
 - Very rare.
 - Consider coagulation disorder, malignancy, primary vascular event (such as aortic dissection, ruptured aneurysm), PE with infarction, infection (TB), bullous emphysema, pulmonary AV malformation, lobar sequestration.
- Torn pleural adhesions as a complication of spontaneous pneumothorax or tube thoracostomy

DIAGNOSIS

SIGNS AND SYMPTOMS

- Small amount of blood in thorax (< 400 mL): Little or no change in patient's appearance, vital signs, or physical findings
- Large amount of blood (> 1,000 mL): Restlessness, anxiety, pallor, pleuritic chest pain, hemoptysis, dyspnea, or air hunger:
 - Signs of shock with loss of blood volume $\geq 30\%$ (1,500–2,000 mL).
 - Tachycardia, tachypnea, hypotension.
- With insidious onset (i.e., malignancy): Dyspnea is the most common presenting sign since blood loss is usually not acute enough to produce a visible hemodynamic response.

History

- Acute blunt or penetrating trauma to chest.
- Recent rib fracture or flail chest.
- Delayed hemothorax can occur hours to days later without initial evidence of intrathoracic pathology on CXR; may be related to rupture of chest wall hematoma or disruption of intercostal vessels by rib fracture edges during movement.
- Malignancy or metastatic disease.
- Recent surgical procedure: Thoracentesis, thoracostomy, etc.

Physical-Exam

- Vitals signs: Depending on severity and time course, hypoxia, tachypnea, tachycardia, and hypotension maybe seen.
- Neck: JVD if increased intrathoracic pressure, tracheal deviation
- Chest inspection: Asymmetric expansion, gross deformity, paradoxical wall movement, abrasion, hematoma, and contusion
- Chest wall palpation: Tenderness or crepitus over ribs, clavicles, scapulae, or the sternum; SC emphysema, dullness to percussion
- Auscultation: Decreased or absent breath sounds over ipsilateral side (best appreciated in the upright patient)

ESSENTIAL WORKUP

CXR is the ideal diagnostic tool:

- In the hemodynamically stable patient, upright posteroanterior (PA) projection at full inspiration is optimal:
 - Fluid collections > 200–300 mL can usually be seen on upright or decubitus CXR.
 - In a normal unscarred pleural space, fluid will be noted as a meniscus/fluid level blunting the costophrenic angle.
- In the supine anteroposterior (AP) radiograph (i.e., portable), up to 1,000 mL of blood may not be readily apparent:
 - Only a slight hazy infiltrate over the involved hemithorax maybe seen.
- Look for associated injuries (pneumothorax, rib fractures, pulmonary contusion,

widened mediastinum, etc.) when reading chest radiography.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Hematocrit may be helpful if it shows a drop or changes on serial evaluations.
- Type and cross-match.
- Pulse oximetry, ABG
- Pleural fluid removed should reveal a hematocrit $> 50\%$ of the blood hematocrit.

Imaging

- US diagnostic imaging is a valuable tool in the evaluation of intrapleural fluid collection:
 - _ An extended FAST scan can diagnose hemothorax with a higher sensitivity than a portable CXR in trained hands.
- CT is useful in detecting small amounts of intrapleural fluid not visible on the chest radiograph.

DIFFERENTIAL DIAGNOSIS

- Hemopneumothorax
- Pneumothorax
- Pulmonary contusion
- Pleural effusion
- Empyema/pneumonia

TREATMENT

PRE HOSPITAL

- Assess vital signs and pulse oximetry; administer oxygen and obtain IV access.
- Fluid resuscitation as needed for hypotension
- Cautions:
 - _ Difficult to differentiate hemothoraces from pneumothoraces clinically:
 - All may present with dyspnea, pleuritic chest pain, decreased breath sounds, and hemodynamic instability.
 - Certain clues aid in making the diagnosis, such as SC emphysema for pneumothorax and dullness to percussion for hemothorax.
 - _ Perform needle thoracostomy for potential tension pneumothorax if the patient is hemodynamically unstable.

INITIAL STABILIZATION/THERAPY

- Manage airway, breathing, circulation:
 - _ Control airway as needed; endotracheal intubation for patients with

- impending respiratory failure
- Supplemental oxygen
- 2 large-bore IV access sites and fluid bolus to restore circulating blood volume
- Needle thoracostomy should be performed in patients with hemodynamic instability unless chest tube kit is immediately available.
- Patient should be positioned to sit upright unless contraindicated.

ED TREATMENT/PROCEDURES

- Obtain upright CXR as quickly as possible, but if patient unstable do not wait to administer definitive therapy.
- Hemothorax is treated by evacuating accumulated blood in the intrapleural space.
- Tube thoracostomy evacuates blood; allows for re-expansion of the lung, as well as constant monitoring of blood loss.
- Tube thoracostomy:
 - Use a large-bore chest tube (36–40Fr).
 - Insert in the 4th–5th intercostal space at the mid-axillary line aiming posteriorly and superiorly.
 - Tube is then connected to underwater-seal drainage and suction (20–30 mL H₂O).
 - Correct placement and adequate drainage is confirmed via CXR.
- Autotransfusion should be used if available to replace blood loss.
- Indications for OR thoracotomy:
 - Initial tube drainage > 20 mL/kg of blood (or 1,000 mL of blood for adults from the pleural cavity).
 - Persistent bleeding at a rate > 7 mL/kg/hr (or 200 mL/hr for 4 hr).
 - Increasing hemothorax seen on chest radiography.
 - Patient remains hypotensive despite adequate blood replacement and other sites of blood loss have been ruled out.
 - Patient decompensates after initial response to resuscitation.
- Indications for ED thoracotomy:
 - Penetrating trauma:
 - Traumatic arrest in the ED or within 10 min of ED arrival.
 - Severe shock with clinical signs of cardiac tamponade
 - Blunt trauma: Traumatic arrest in the ED at a trauma center or with surgeon available within 10 min

MEDICATION

- Local anesthetics for cutaneous anesthesia prior to tube thoracostomy in awake, conscious patients
- Procedural sedation (midazolam) and analgesia (fentanyl) may be used for stable, awake patients prior to tube thoracostomy:
 - Fentanyl: Adult/peds: 2–5 µg/kg per dose

- Midazolam: Adult/peds: 0.02–0.04 mg/kg per dose
- Other sedative agents may be considered.

FOLLOW-UP

DISPOSITION

Admission Criteria

Patients with hemothoraces requiring tube thoracostomies should be admitted for monitoring and thoracostomy tube management to the trauma, cardiothoracic, or general surgery service. The admitting unit should be experienced in managing chest tube equipment.

Discharge Criteria

- Patients with isolated small hemothoraces (detected incidentally on US or CT imaging) may be considered for discharge after 4–6 hr of observation if there is no evidence of continued bleeding, the patient is not hypoxic, and is asymptomatic.
- Patients with asymptomatic blunt chest trauma and normal initial chest radiographs do not require repeat films prior to discharge.

PEARLS AND PITFALLS

- Because the pleural cavity of an average 70 kg man can hold over 4 L of blood, an exsanguinating hemorrhage can occur without any evidence of external blood loss.
- Auscultation and percussion of a supine trauma patient with substantial hemothorax may produce equivocal findings due to distribution of blood along the entire posterior aspect of pleural space.
- Without a clear history of trauma, CXR may be incorrectly read as pneumonia.
- If there is a concurrent diaphragmatic injury, a hemothorax may have an intra-abdominal origin.
- Prepare for autotransfusion early, as most blood loss occurs on initial chest tube insertion.
- In the supine trauma patient, a common error in chest tube insertion is placement too anterior and superior, making complete drainage difficult.
- Be sure all chest tube fenestrations are within the thoracic cavity.
- Prophylactic antibiotics administered with chest tube insertion do not decrease the risk of pneumonia or empyema.

HENOCH–SCHÖNLEIN PURPURA

Karem Colindres Duque

BASICS

DESCRIPTION

Vasculitis

ETIOLOGY

Mechanism:

- Increased serum IgA:
 - Circulating IgA complexes
 - Glomerular mesangial deposition of IgA
- Although cause is undefined, there are many associated conditions:
 - Infections
 - Group A streptococcus
 - Mycoplasma
 - Viral: Varicella, Epstein–Barr (EB)
 - Drugs: Penicillin, tetracycline, aspirin, sulfonamides, erythromycin
 - Allergens: Insect bites, chocolate, milk, wheat
- Peak incidence: School-aged children and young adults
- More common in whites
- Males > females
- Occurs more often in winter/spring
- Multisystem involvement can lead to life-threatening or long-term complications:
 - Intussusception
 - Proliferative glomerulonephritis
 - Chronic renal failure:
 - More common in older children and adults (13–14%)
 - Intracranial hemorrhage

DIAGNOSIS

SIGNS AND SYMPTOMS

- General:
 - Well-appearing child, despite nature and extent of rash
 - Recent or current upper respiratory tract infection
 - Malaise
 - Low-grade fever
 - Hypertension, if associated renal failure
 - Children < 3 mo may have only skin manifestations

- Children <2 yr of age may have facial edema alone as presenting symptom
- Skin:
 - Purpuric rash:
 - Presenting sign in 50% of patients
 - 100% of patients develop purpura
 - 1st appears as pink rounded papules that blanch
 - Progresses to 2–3 cm circular palpable purpura within 24 hr; may be discrete or confluent
 - Rash begins in gravity-dependent areas of legs and buttocks, which may extend to upper extremities and trunk
 - Symmetric distribution
 - May involve lower back
 - Rarely involves the face
 - Rash recurs in up to 40% of patients (within 6 wk).
- Abdominal:
 - Abdominal pain:
 - 70–80% of cases
 - Colicky to severe
 - Abdominal findings may precede the rash by 4 wk.
 - GI bleeding:
 - 75% of cases
 - Occult to severe blood loss
 - Intussusception (ileoileal or ileocolic)
- Renal-genitourinary:
 - Asymptomatic hematuria:
 - Occurs in 80% of cases
 - Scrotal pain
 - Testicular swelling
 - Renal failure
- Extremities:
 - Arthritis:
 - 70–80% of cases
 - Migratory periarticular pain
 - Most frequent in knees and ankles
 - Angioedema
- Neurologic:
 - Headache
 - Seizure
 - Altered mental status
 - Focal deficits +/- visual abnormalities and verbal disability

History

- Constitutional symptoms:

- Fever
- Rash:
 - Location, timing, duration, and progression of rash
- Associated symptoms:
 - Abdominal pain, vomiting, and seldom facial edema
 - Timing, duration, and progression of symptoms
- Progression of symptoms:
 - Timing, duration, and progression of symptoms

Physical-Exam

- General appearance:
 - Level of responsiveness, vital signs (high BP)
- Cardiovascular:
 - Quality of heart tones
 - Perfusion (pulses, capillary refill)
- GI:
 - Abdominal distention, tenderness, palpable masses, bloody stools
- Genitourinary:
 - Testicular swelling, tenderness
- Skin:
 - Location
 - Blanching vs. nonblanching
 - Erythematous or purplish raised lesions (papules, purpura) vs. macular lesions (petechia)
 - Hemorrhagic bullous evolution seldom described in children
- Neurologic:
 - Level of consciousness
 - Presence of focal deficits

ESSENTIAL WORKUP

Exclude life-threatening causes of petechia, purpura, severe abdominal pain, hematuria, and CNS findings, if appropriate.

DIAGNOSIS TESTS & NTERPRETATION

Lab

- CBC:
 - Platelet count normal
 - WBC often elevated
- PT, PTT (if bleeding or in shock; or if unsure of diagnosis and concerned about possibility of coagulopathy)
- Electrolytes (if hypertension or urinalysis abnormal)
- BUN, creatinine (if hypertension or urinalysis abnormal):

- May be elevated in cases with serious renal complications
- Urinalysis:
 - Hematuria is common
 - Proteinuria is suggestive of glomerulonephritis
- Cultures to exclude common infections

Imaging

- Abdominal imaging studies:
 - Indicated if abdominal pain or GI bleeding
 - Flat and upright abdominal films of limited use
 - Abdominal US, barium enema, or CT scan may be necessary to rule out intussusception.
- Testicular US:
 - Indicated in patients with testicular pain and swelling
- Head CT:
 - Indicated if CNS findings to exclude bleed

Diagnostic Procedures/Surgery

Lumbar puncture, as clinically indicated

DIFFERENTIAL DIAGNOSIS

- Abdominal pain:
 - Gastroenteritis
 - Appendicitis
 - Inflammatory bowel disease
 - Intussusception
 - Meckel diverticulum
- Arthralgia:
 - Acute rheumatic fever
 - Polyarthriti nodosa
 - Juvenile rheumatoid arthritis
 - Systemic lupus erythematosus
- Rash:
 - Infection:
 - Meningococemia
 - Bacterial sepsis: Streptococcal or staphylococcal
 - Rocky Mountain spotted fever
 - Infectious mononucleosis
 - Bacterial endocarditis
 - Viral exanthem
 - Trauma/child abuse
 - Functional platelet disorders
 - Thrombocytopenia

- Vasculitis
- Erythema nodosum
- Drugs/toxins
- Renal disease:
 - Acute glomerulonephritis
- Testicular swelling:
 - Incarcerated hernia
 - Orchitis
 - Testicular torsion

TREATMENT

PRE HOSPITAL

Stabilize as clinically indicated

INITIAL STABILIZATION/THERAPY

- IV fluids for shock
- Packed RBCs for massive GI hemorrhage

ED TREATMENT/PROCEDURES

- Emergent intervention for life-threatening conditions, if any
- NSAIDs (ibuprofen):
 - Arthralgia
- Prednisone:
 - Severe abdominal pain once life-threatening pathology excluded
 - Painful SC edema or arthritis
 - Renal disease (high-dose pulse therapy required with methylprednisolone)
 - CNS involvement
- Immunosuppressant drugs:
 - Severe, life-threatening disease with HSP nephritis
- Polyclonal immunoglobulin therapy:
 - Severe, life-threatening disease (controversial)

MEDICATION

First Line

Ibuprofen: 600 mg (peds: 5–10 mg/kg per dose) PO q6h

Second Line

Prednisone: 60 mg (peds: 1–2 mg/kg/24 h) PO daily for 5–7 days

FOLLOW-UP

DISPOSITION

Admission Criteria

- Severe abdominal pain
- CNS findings
- GI bleeding
- Intussusception
- Evidence of renal failure

Discharge Criteria

- Normal platelet count
- Normal renal function
- Minimal or no abdominal pain
- If steroids started, follow up within 24 hr.

Issues for Referral

- GI:
 - Severe abdominal pain
- Renal:
 - Evidence of renal failure or insufficiency

FOLLOW-UP RECOMMENDATIONS

Primary care physician:

- Close monitor of BP. Recheck CBC, urinalysis as clinically indicated (recommended for at least 6 mo in children)

PEARLS AND PITFALLS

- Exclude life-threatening causes
- NSAIDs are usually adequate
- Most patients do not require systemic corticosteroids as it has not been shown to affect the prognosis of HSP nephritis

HEPATIC ENCEPHALOPATHY

Sidney James • Matthew N. Graber

BASICS

DESCRIPTION

Hepatic encephalopathy (HE) is characterized by changes in behavior, consciousness, and motor disturbances, associated with hepatic insufficiency and the accumulation of substances normally metabolized by the liver. HE may result from a combination of:

- Accumulation of ammonia (NH_3) from:
 - Protein degradation by colonic bacteria
 - Deamination of glutamine in small bowel, kidney, and muscle.
 - Accumulated NH_3 crosses the blood–brain barrier. Astrocytes uptake NH_3 and metabolize it into glutamine which causes cellular swelling. Ultimately leads to cerebral edema and cerebral mitochondrial dysfunction.
- Accumulation of other neurotoxins:
 - Short-chain fatty acids
 - Manganese toxicity
 - Neurosteroids
 - Phenols
 - Mercaptans
 - Amino acids such as tryptophan
- Increased levels of inhibitory neurotransmitters:
 - Benzodiazepines
 - γ -aminobutyric acid (GABA)
 - Serotonin
- Decreased levels of excitatory neurotransmitters:
 - Glutamate
 - Dopamine
 - Aspartate
 - Catecholamines
- Other contributing factors to HE:
 - Decreased cerebral blood flow and oxygen
 - Increased glucose consumption and possible hypoglycemia
 - Zinc deficiency
- Genetics:
 - Inherited errors of the urea cycle

ETIOLOGY

- Classification based on the 11th World Congress of Gastroenterology:
 - Type A: HE associated with acute liver injury and fulminant hepatic failure

(FHF).

- Type B: HE associated with portosystemic bypass and no intrinsic liver disease.
- Type C: HE associated with cirrhosis and portal hypertension.
- Precipitating events:
 - GI bleeding (more common in elderly)
 - Hypokalemia and hyponatremia.
 - Alkalosis decreases renal NH_4 excretion.
 - Sepsis (e.g., spontaneous bacterial peritonitis [SBP])
 - Constipation
 - Noncompliance with treatment regimen in chronic liver failure
 - High-protein diet
 - Hypoglycemia
 - Hypovolemia (e.g., post large-volume paracentesis)
 - Azotemia (e.g., diuretic or diarrhea induced)
 - Narcotics or sedatives, including alcohol
 - Zinc deficiency as multiple urea cycle enzymes are zinc dependent
 - Hepatocellular injury
 - Viral- or drug-induced hepatitis
 - Post portosystemic shunt placement
 - Recurrent encephalopathy can occur without precipitating factors

DIAGNOSIS

SIGNS AND SYMPTOMS

- Type A: Rapidly progresses to seizures, decerebrate rigidity, coma, and frequently death from cerebral edema.
- Type B and C are chronic conditions that may manifest as minimal or overt HE. Overt HE may be classified as episodic or persistent:
 - Minimal HE: Characterized by impaired psychomotor speed, visual perception, and attention and concentration; slow mental processing; and memory loss. Only detected by psychometric testing.
 - Overt HE: Slow monotonous speech pattern, loss of fine motor skills, hyperreflexia, clonus, hyperventilation, extrapyramidal type movement disorder, seizures, confusion, coma, decerebrate/decorticate posturing.
 - Overt HE episodic: Characterized by short period of changes in consciousness over hours to days that usually return to a normal mental state with treatment. In persistent HE, patients do not return to a normal mental state.
- Grading (West Haven criteria):
 - Stage 0:
 - No apparent clinical changes

- Abnormal neurophysiologic and neuropsychological tests
- No asterixis
- Stage I:
 - Personality changes, irritability, depression, or euphoria
 - Reversal of normal sleep pattern
 - Impairment of writing, drawing, addition, subtraction
 - Asterixis may be present
- Stage II:
 - Significant behavioral changes, often inappropriate
 - Lethargy
 - Slow responses
 - Asterixis
 - Slurred speech
 - Ataxia
- Stage III:
 - Disorientation to time and place
 - Amnesia
 - Paranoia
 - Nystagmus
 - Hypoactive reflexes
 - Positive Babinski reflex
 - Semistupor to stupor
- Stage IV:
 - Dilated pupils
 - Stupor or coma

ESSENTIAL WORKUP

- Elicit history of liver disease and prior episodes of HE.
- Search for precipitating cause (particularly GI bleeding and infection).
- Check for electrolyte abnormalities:
 - Even minimal abnormalities may manifest as significant clinical changes.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Blood NH₃ level:
 - Level correlates poorly with the degree of HE or the presence of cerebral edema.
 - Helpful in detecting HE in cases of altered mental status (AMS) of unknown cause
 - Normal NH₃ level with suspected HE warrants search for other causes of AMS.

- Must be kept on ice and assayed within 30 min.
- Consider hemocult testing and nasogastric (NG) lavage to rule out GI bleeding
- CBC to search for anemia
- Electrolytes, BUN, creatinine, glucose
- PT/INR with elevations suggesting significant liver failure
- Liver profile/liver enzymes
- Urinalysis for possible infection
- Culture urine and ascitic fluid to search for infectious cause
- Toxicology screen for alternate cause of altered level of consciousness:
 - Acetaminophen and alcohol level as necessary
- Additional labs as clinical scenario dictates:
 - TSH
 - Blood gases
 - Magnesium
 - Viral serology

Imaging

- CXR for pneumonia and signs of CHF
- Head CT scan: For new-onset AMS, focal neurologic deficit, suspected cerebral edema, or trauma.
- MRI of the brain is especially helpful in diagnosing HE in patients with portosystemic shunts but no intrinsic liver disease.

Diagnostic Procedures/Surgery

- ECG for arrhythmia and electrolyte imbalance
- CSF exam:
 - For new-onset or unexplained worsening of HE
 - CSF glutamine level correlates with severity of HE.
- Paracentesis for SBP workup and culture of ascitic fluid
- EEG is usually abnormal, most commonly with generalized slowing and other nonspecific changes.

DIFFERENTIAL DIAGNOSIS

- Alcohol withdrawal syndromes including delirium tremens
- Cerebrovascular accident
- Congestive heart failure
- CO₂ narcosis
- Head trauma with concussion or intracranial hemorrhage
- Hypocalcemia and hypercalcemia
- Hypoglycemia
- Hypokalemia
- Meningitis or encephalitis

- Metabolic encephalopathy
- Neuropsychiatric disorders
- Toxic confusional states secondary to:
 - _ Sedative overdose
 - _ Alcohol intoxication
 - _ Illicit drugs
 - _ Medications
- Uremia

Pediatric Considerations

- Consider Reye syndrome early (most common cause of fulminate hepatic failure in children) even if PT is only mildly prolonged.
- Consider fatty acid β -oxidation disorder:
 - _ Freeze serum and urine sample for subsequent testing

TREATMENT

INITIAL STABILIZATION/THERAPY

- Oxygen
- Airway protection:
 - _ Patients with grade 3 or 4 HE may require intubation for airway protection. Propofol is the preferred agent for sedation.
- Cardiac monitor
- Fluid resuscitation
- Initial AMS treatment:
 - _ Naloxone
 - _ D₅₀W (or bedside glucose)
 - _ Thiamine

ED TREATMENT/PROCEDURES

Identification and removal of precipitating factors is key and may improve clinical picture alone.

ALERT

- Liver failure predisposes patients to both hypoglycemia and HE, and these can be additive to the clinical picture; therefore, frequent glucose checks are of absolute importance.
- Identification of early cerebral edema is important as brain perfusion must be preserved and herniation prevented (associated but not limited to grade 3/4 HE)
- Treatment of complicating conditions:
 - _ Acute GI bleeding

- Sepsis
- Electrolyte and pH abnormalities
- Coagulopathy
- Renal and electrolyte disturbances
- Avoid sedative/narcotics if possible:
 - If necessary, use agents not metabolized by the liver
- Increase NH₃ elimination:
 - Bowel cleansing with nonabsorbable sugars (i.e., lactulose is mainstay of treatment). Retention enema preferred in grade 3/4 HE
- Decrease NH₃-producing intestinal flora (in combination with lactulose):
 - Neomycin (nephrotoxic and ototoxic)
 - Metronidazole (PO)
 - Vancomycin (PO)
 - Rifaximin: Recommended for lactulose-resistant HE. Current data suggests it is as effective as lactulose and neomycin and has a favorable safety and tolerability profile, although more expensive
- Treat associated cerebral edema if present
- Correct zinc deficiency
- Short-term restriction of protein intake in diet
- Flumazenil in patients who have received benzodiazepines may provide moderate, short-term improvement.
 - Avoid flumazenil unless you are sure that the patient is not a chronic alcoholic or benzodiazepine user as resultant seizures may occur.
- Precautions to prevent bodily harm to the confused patient with HE
- Liver transplantation provides cure for severe, spontaneous, or recurrent HE
- Possibly of benefit:
 - L-carnitine
 - Albumin dialysis
 - Broad-spectrum antibiotic coverage
 - N-acetylcysteine
 - *Lactobacillus acidophilus* supplementation
 - Ornithine aspartate
 - Benzoate or Bromocriptine
 - Branched-chain amino acids
 - Chelation of manganese with edetate calcium disodium

MEDICATION

- Dextrose: 1–2 amps (25 g) of 50% dextrose (child: 2 mL/kg D₂₅W) IV
- Lactulose: 30 mL (peds: 0.3 mL/kg) PO/NG tube q6h titrated to produce 2 or 3 soft stools per day and stool pH < 5 or retention enema at 300 mL + 700 mL saline/tap water q4–6h
- Metronidazole: 250 mg PO/NG (peds: 10–30 mg/kg/d) q8h for 2 wk

- Narcan: 2 mg (peds: 0.1 mg/kg) IV/IM initial dose
- Neomycin: 1–3 g (peds: 50–100 mg/kg/d) PO q6h
- Rifaximin: 550 mg PO/NG q12h. (safety not established for children < 12 yr)
- Mannitol: 0.5 –1 g/kg IV
- Thiamine (vitamin B₁): 100 mg (peds: 50 mg) IV/IM
- Zinc acetate or sulfate: 220 mg PO/NG q8h

FOLLOW-UP

DISPOSITION

Admission Criteria

- HE grade 2, 3, or 4 or inadequate social support
- Type A HE (any grade) and type B or C (grade 2 or above) should be admitted to the ICU with urgent GI consult
- Associated complicating condition (GI bleeding and sepsis)
- Uncertainty about cause of AMS

Discharge Criteria

- Known chronic or intermittent HE
- Grade 0 or 1 with remediable cause
- Adequate supervision with close follow-up
- Those appropriate for discharge should go home with:
 - Low-protein diet
 - Lactulose prescription

Issues for Referral

- Refer to primary physician or GI for consideration of medication or diet changes if recurrent early stage HE episodes
- For any grade of type A HE, consider transfer to a liver transplant facility

FOLLOW-UP RECOMMENDATIONS

- Dietary consultation if possible cause of exacerbation
- Alcohol counseling if it is a concern

PEARLS AND PITFALLS

- Consider rifaximin for lactulose-resistant HE
- Hypoglycemia is common in HE patients.
- Avoid sedatives and narcotics if possible in HE patients. If necessary, use medications not metabolized by liver.

- K72.91 Hepatic failure, unspecified with coma

HEPATIC INJURY

Stephen R. Hayden

BASICS

DESCRIPTION

- The size and location of the liver places it at significant risk for injury:
 - The liver is the solid organ most frequently injured in penetrating trauma.
 - The liver is the 2nd most commonly injured in blunt abdominal trauma, 2nd to the spleen.
 - Highly susceptible to blunt injuries, by direct blow or deceleration forces
- Mechanism of injury and description of forces are important factors in evaluating patients for possible hepatic injury:
 - Blunt trauma:
 - Obtain information about the forces and direction (horizontal or vertical) of any deceleration or compressive forces.
 - Penetrating trauma:
 - Type and caliber of the weapon
 - Distance from the weapon
 - Variety and length of knife or impaling object
- Hepatic injuries are graded by severity, ranging from subcapsular hematoma and lacerations to severe hepatic fragmentation.
- Associated conditions include rib fractures and injuries to the spleen, diaphragm, kidney, lung, gallbladder, pancreas, and blood vessels.
- Overall mortality of hepatic injury is reported at 8–10%.
- More often nonoperative management is becoming more common in isolated blunt hepatic trauma.

Pediatric Considerations

Poorly developed musculature and relatively smaller anteroposterior diameter increase the vulnerability of liver to compressive forces in children.

ETIOLOGY

Trauma:

- Blunt mechanism:
 - Deceleration
 - Acceleration
 - Compression
- Penetrating mechanism:
 - Stab wound
 - Gunshot wound

- Impaled object

DIAGNOSIS

SIGNS AND SYMPTOMS

Physical exam and history can be variable.

History

History of trauma usually available from patient or pre-hospital providers

Physical-Exam

- Neither sensitive nor specific for hepatic injury
- Systemic signs related to acute blood loss:
 - May present with dizziness and weakness
 - Signs of shock including tachycardia and hypotension
- Local signs:
 - Right upper quadrant tenderness
 - Guarding
 - Abdominal distention
 - Rigidity
 - Rebound
 - Tenderness
 - Contusions/abrasions
 - Penetrating wounds to the right chest, flank, or abdomen

ESSENTIAL WORKUP

- Physical exam is unreliable.
- Objective evaluation includes imaging of the abdomen or surgical exploration.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- No hematologic lab studies are specific for diagnosis of injury to the liver.
- Obtain baseline hemoglobin level.
- Liver function tests are not helpful in the acute setting.
- Consider type and cross if active hemorrhage is suspected.

Imaging

- Consider imaging based on mechanism and physical exam.
- Plain abdominal radiographs:
 - Little value
- Bedside US:

- Screening tool for both blunt and penetrating abdominal trauma
- Procedure of choice in unstable patient
- May identify intra-abdominal fluid in the hepatorenal (Morison) pouch or parenchymal injuries
- Suggests intra-abdominal hemorrhage in patient with blunt, multiple-organ trauma
- CT scan with IV contrast:
 - Best depicts extent of hepatic injury and injuries to adjacent organs
 - Requires patient to be hemodynamically stable
 - Extravasation of IV contrast during arterial phase of CT injection indicative of vascular or high-grade liver injury requiring surgical intervention

Diagnostic Procedures/Surgery

- Diagnostic peritoneal lavage (DPL):
 - Rarely performed; usually done in conjunction with trauma surgeon
 - Sensitive for presence of hemoperitoneum
 - Nonspecific for source of bleeding
 - Surgery and exploratory laparotomy if positive
 - Operative management may be necessary for unstable patients and those with high-grade lesions.
- Lower-grade injuries have been increasingly managed successfully without surgery.

DIFFERENTIAL DIAGNOSIS

- Other causes of intraperitoneal injury
- Retroperitoneal injury
- Thoracic injury
- Diaphragmatic injury
- Splenic injury
- Vascular injury

TREATMENT

PRE HOSPITAL

- Obtain details of mechanism of injury.
- Initiate large-bore IV access:
 - Hemorrhage may be rapid and life-threatening.
- Moist saline dressings over penetrating wounds or evisceration
- Direct pressure to control active bleeding
- Full spinal immobilization except in isolated penetrating trauma

INITIAL STABILIZATION/THERAPY

ABCs:

- Control airway as needed; may have associated injuries including head injury.
- Supplemental oxygen, cardiac monitor, pulse oximetry
- Adequate IV access, including central line, intraosseous line, and cut down as dictated by the patient's status
- Fluid resuscitation, initially with 2 L of crystalloid (normal saline or Ringer lactate), followed by blood products such as packed red blood cells. Consider fresh frozen plasma (FFP) as needed.

ED TREATMENT/PROCEDURES

- Immediate laparotomy may be appropriate in the acutely injured patient with the following conditions:
 - Hemodynamic instability
 - Gunshot wounds to the anterior abdomen
 - Frank signs of intraperitoneal hemorrhage
 - Indications based on diagnostic procedures, such as DPL
 - Failure of nonoperative management
- Stab wounds can be managed by local wound exploration followed by US or DPL when intraperitoneal penetration is not demonstrated or equivocal.
- Consider nonoperative management for the following patients:
 - Hemodynamically stable with normal mental status
 - No evidence of other intra-abdominal injury
 - Isolated low-grade (1–3) hepatic injury confirmed by imaging study
 - Transfusion requirements ≤ 2 U of packed red blood cells
- High-grade liver injuries (4 and 5) have less successful nonoperative rates.
- Diet: Nothing per mouth (NPO)
- Activity: Strict bedrest
- Special therapy:
 - Angiography with embolization: Selective use in patients with persistent bleeding may decrease the need for operative management and blood transfusions
 - Factor VIIa and prothrombin complex have been used as an adjunct in nonoperative management to control significant bleeding.

MEDICATION

- Crystalloid IV fluids: NS or lactated Ringer
- Packed red blood cells
- FFP
- Recombinant factor VIIa: 15–30 $\mu\text{g}/\text{kg}$ IV bolus every 4–6 hr until hemostasis is achieved
- Prothrombin complex concentrate (PCC): 50 U/kg IV

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with hepatic injury require hospitalization for definitive laparotomy or close hemodynamic observation with serial exams or CT scans, as well as hematocrit measurements.
- ICU admission is often indicated in the 1st 48 hr after injury.

Discharge Criteria

Patients with proven or suspected hepatic injuries should not be discharged.

Issues for Referral

Report all gunshot and stab wounds to appropriate local authorities.

FOLLOW-UP RECOMMENDATIONS

Follow-up US, physical exam, and hematocrits are crucial in noting changes in initially benign presentations.

PEARLS AND PITFALLS

- Obtain early surgical consultation in unstable patients.
- Failing to obtain appropriate and adequate imaging studies is a pitfall.
- Do not rely on negative US to rule out hepatic injury.
- Failing to adequately resuscitate with IV fluids and blood products is a pitfall.
- If hepatic injury is confirmed, ensure no trauma to surrounding organ systems.
- Check for pregnancy in women.

HEPATITIS

Jason Koob • Christopher T. Richards

BASICS

DESCRIPTION

- Inflammation of the liver owing to infectious, toxic, and autoimmune disorders
 - Progression from hepatocellular injury (hepatitis) to scarring (cirrhosis)
- Infectious causes are the most common

ETIOLOGY

- Unknown etiology in 5–10% of acute and chronic hepatitis cases and up to 50% in fulminant hepatic failure (FHF)
- Hepatitis A (HAV):
 - Transmission: Fecal–oral
 - Incubation period: 2–7 wk
 - FHF in 0.1%
 - No chronic phase
 - 10% will have a relapsing course over months
- Hepatitis B (HBV):
 - Transmission: Mucous membrane, percutaneous exposure to bodily fluids, perinatal
 - Incubation period: 8–22 wk
 - Subclinical in 70%
 - FHF in 1%
 - Risk of chronic hepatitis increased with age at infection and comorbidities:
 - Neonatal: > 90%
 - Infant: 50%
 - Child: 20%
 - Immunocompetent adult: 1–5%
 - Immunocompromised adult: 50%
 - Risk of cirrhosis, hepatocellular carcinoma
- Hepatitis C (HCV):
 - Transmission: Blood >> sexual and perinatal
 - Incubation period: 6–10 wk
 - FHF rare
 - 80% progress to chronic disease
 - Risk of cirrhosis, hepatocellular carcinoma
- Hepatitis D (HDV):
 - HDV can be transmitted only in the presence of HBV infection
 - 2 patterns of infection: Simultaneous infection with HBV and HDV or

HDV superinfection in an individual with chronic HBV

- Same transmission as HBV
- Incubation period: 3–7 wk
- FHF in 3%
- 5% progress to chronic disease
- Risk of cirrhosis 3 times higher in HDV-infected individual compared with HBV infection alone
- Hepatitis E (HEV):
 - Most common cause of acute hepatitis and jaundice worldwide
 - Rarely found outside developing countries
 - Typically seen as outbreaks
 - Transmission: Fecal–oral, waterborne, foodborne
 - Incubation period: 3–8 wk
 - FHF in 10%
 - Chronic infection almost exclusively in immunocompromised persons
- Alcoholic hepatitis:
 - Associated with > 14 drinks/wk in women and > 21 drinks/wk in men
 - Sequelae of chronic use:
 - Hepatic steatosis in 90–100%
 - Hepatitis in 10–35%
 - Cirrhosis in 5–15%
 - Increased association with chronic viral hepatitis
 - Maddrey discriminant function (MDF) ≥ 32 associated with only 50–65% survival
 - $MDF = 4.6 \times [\text{prolongation of PT above control}](s) + \text{serum bilirubin}(mg/dL)$
- Abscess-induced hepatitis:
 - Entamoeba histolytica, pyogenic
- Secondary hepatitis viruses:
 - CMV, EBV, HSV, HIV
- Medication and toxin induced
- Autoimmune hepatitis:
 - Display concurrent stigmata of autoimmune disease

Pediatric Considerations

- Vast majority of cases are caused by HAV
- Perinatal HBV infection develops into chronic disease 90% of the time

Pregnancy Considerations

- 20% case fatality for HEV during pregnancy.
- Acute fatty liver of pregnancy (AFLP):
 - May progress to DIC

- Hemolysis, Elevated Liver enzymes, and Low Platelets (HELLP) syndrome
- Immunoprophylaxis is safe during pregnancy

DIAGNOSIS

SIGNS AND SYMPTOMS

- Often asymptomatic
- Preicteric phase:
 - Often misdiagnosed as a nonspecific viral syndrome or gastroenteritis
- Icteric phase:
 - Present in 70% of HAV, 30% of HBV, and 20% of HCV
- FHF:
 - Coagulopathy
 - Encephalopathy
 - Cerebral edema

History

- Preicteric phase:
 - Fever, chills
 - Malaise
 - Nausea, vomiting, anorexia
 - Arthralgia
 - Aversion to smoking
- Icteric phase:
 - Jaundice
 - Dark urine
 - Light stools
 - Pruritus
 - Rash
 - Right upper quadrant pain
- FHF:
 - Bleeding
 - Altered mental status

Physical-Exam

- Preicteric phase:
 - Fever
 - Arthritis
 - Dehydration
- Icteric phase:
 - Fever
 - Icterus of skin, sclerae, mucous membranes, and tympanic membranes

- Nonspecific maculopapular or urticarial rash
- Dehydration
- Tender hepatomegaly
- FHF:
 - Bruising
 - Disorientation
 - Asterixis

ESSENTIAL WORKUP

- Detailed history of risk factors for hepatitis, including toxic exposure and drug use
- Viral serologies are the mainstay of diagnosis of viral causes

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC with differential
- Basic metabolic panel:
 - Azotemia with hepatorenal syndrome in FHF
 - Hypoglycemia with severe liver damage
 - Hyponatremia
- LFTs:
 - Elevation in transaminases reflects hepatocellular injury
 - Degree of elevation does not always correlate with severity
 - If alkaline phosphatase more than 4 times normal, consider primary cholestatic process rather than viral hepatitis.
 - Mild to moderate elevation of conjugated bilirubin due to decreased excretion
- Amylase, lipase may indicate pancreatic or biliary etiology
- PT/PTT/INR, albumin
 - Measure of synthetic function of liver
 - Prolonged INR reflects more severe injury
- Ammonia level:
 - For patients with altered mental status
- Viral serologies:
 - HAV:
 - Anti-HAV IgM: Acute infection
 - Anti-HAV IgG: Previous exposure, immunity
 - HBV:
 - HBsAg: Acute infection (appears before symptoms), chronic infection
 - Anti-HBs: Past infection, carrier state, postimmunization
 - Anti-HBc IgM: Acute infection
 - Anti-HBc IgG: Past infection, chronic infection, carrier state
 - HBeAg: Acute infection, some chronic states

- Anti-HBe: Past infection, chronic infection, carrier state
- Postimmunization: Anti-HBs only
- HCV:
 - Anti-HCV: Acute infection, chronic infections, first-line test
 - HCV RNA: Acute infection, chronic infections; confirmatory
- HDV: Anti-HDV or viral RNA, not routine
- HEV:
 - Anti-HEV IgM: Acute infection, detectable for only 3–12 mo
 - Anti-HEV IgG: Persists for years, if not for life
- α -fetoprotein:
 - For chronic HBV or HCV to evaluate for hepatocellular carcinoma
- Monospot: For EBV
- Urinalysis for bilirubin

Imaging

- Head CT to evaluate hepatic encephalopathy
- RUQ US to evaluate for biliary obstruction

DIFFERENTIAL DIAGNOSIS

- Nonalcoholic fatty liver disease
- Cholecystitis and cholangitis
- Reye syndrome
- Liver abscess
- Wilson disease
- Heat stroke
- Fitz-Hugh—Curtis syndrome
- Ischemic hepatitis (“shock liver”)
- Congestive heart failure
- Hemochromatosis
- Budd–Chiari syndrome

TREATMENT

INITIAL STABILIZATION/THERAPY

ABCs and IV fluid resuscitation for FHF and severe hepatic encephalopathy.

ED TREATMENT/PROCEDURES

- Treat hypovolemia judiciously with isotonic fluids
- Correct electrolyte imbalance
- Treat vomiting with ondansetron and metoclopramide
- Avoid hepatotoxic agents: Acetaminophen, alcohol, phenothiazines
- Avoid medications metabolized by liver

- Propofol for sedation preferred
- Fentanyl for pain preferred
- Correct coagulopathy if active bleeding.
- N-acetylcystine (NAC) for acetaminophen-induced hepatitis and consider for FHF
- Consider steroids for severe acute alcoholic hepatitis
- Ursodeoxycholic acid or cholestyramine for cholestasis-induced itching
- Paracentesis for tense ascites leading to respiratory compromise
- Antidotes and activated charcoal for select ingestions
- Postexposure prophylaxis (PEP):
 - HAV:
 - HAV IG 0.02 mL/kg IM within 2 wk of exposure
 - HAV vaccine 1 mL (peds: 0.5 mL) IM
 - HBV:
 - HBV IG 0.06 mL/kg IM within 7 days of exposure
 - HBV vaccine 1 mL (peds: 0.5 mL) IM
 - No effective immunoprophylaxis for HCV or HDV
 - HEV vaccine not available in US

MEDICATION

- Cholestyramine: 4 g PO 2–4 times per day for pruritus
- Metoclopramide: 10 mg IV/IM q6–8h, 10–30 mg PO QID
- NAC 140 mg/kg IV loading dose
- Ondansetron 4 mg IV
- Prednisone 40 mg/d PO
- Thiamine: 100 mg (peds: 50 mg) IV/IM/PO:
 - Prior to glucose if malnourished
- Ursodeoxycholic acid: 3 mg/kg TID
- Vitamin K 10mg IV/PO

FOLLOW-UP

DISPOSITION

Admission Criteria

- Intractable vomiting, dehydration, or electrolyte imbalance not responding to ED treatment
- ICU and consider transfer to transplant center for FHF and acute hepatitis with evidence of significant liver dysfunction:
 - PT > 50% of normal or INR > 1.5
 - Bilirubin > 20 mg/dL
 - Hypoglycemia
 - Albumin < 2.5 g/dL

- Hepatic encephalopathy
- Pregnancy
- Immunocompromised host
- Possibility of toxic hepatitis
- Age > 50

Discharge Criteria

- Normalized electrolytes
- PO tolerance
- Mild hepatic impairment

Issues for Referral

- Hepatology, gastroenterology, and/or infectious disease follow-up for further serologic diagnosis and definitive treatment
- Alcoholics anonymous referral and social work referral for alcohol-related disease

FOLLOW-UP RECOMMENDATIONS

- Strict personal hygiene instructions
- Avoid acetaminophen and alcohol
- Avoid prolonged physical exertion

PEARLS AND PITFALLS

- Acute hepatitis is often misdiagnosed as a nonspecific viral syndrome—screen with urinalysis or serum LFTs
- ED treatment is primarily supportive
- Ask detailed social and travel history
- Early transfer to transplant center for FHF
- Counsel patient on prevention – vaccinations and personal hygiene precautions
- Maintain high index of suspicion for AFLP and HELLP in pregnant patients with compatible symptoms

HEPATORENAL SYNDROME

Matthew T. Keadey • Richard D. McCormick

BASICS

DESCRIPTION

- Renal failure (RF) in patients with acute or chronic liver disease with no other identifiable cause of renal pathology.
- Hepatorenal syndrome (HRS) represents significant decline in renal perfusion due to severe liver disease:
 - Type I HRS:
 - Acute form with spontaneous RF in patients with liver disease
 - Rapidly progressive
 - Decrease in creatinine clearance (CrCl) by 50% or doubling of Cr in 2 wk (>2.5)
 - 90% mortality within 3 mo
 - Seen with acute liver failure or alcoholic hepatitis
 - Oliguric or anuric
 - Type II HRS:
 - Slow course of RF
 - Seen in patients with diuretic resistant ascites
 - Lower mortality rate than type I HRS
- Hallmarks of HRS:
 - Prerenal disease
 - Reversible renal vasoconstriction and mild systemic hypotension
 - Kidneys have normal histology and structure.
 - Lack of improvement in renal function after volume expansion
- Liver disease causes systemic vasodilation with decrease in arterial blood volume:
 - Reflex activation of sympathetic nervous system
 - Activation of rennin–angiotensin–aldosterone system (RAAS)
 - Stimulation of numerous vasoactive substances:
 - Nitric oxide
 - Prostacyclin
 - Atrial natriuretic peptide (ANP)
 - Arachidonic acid metabolites
 - Platelet-activating factor
 - Endothelins
 - Catecholamines
 - Angiotensin II
 - Thromboxane
- Action of vasoconstrictors prevails over vasodilator effects:

- Renal hypoperfusion ensues due to renal cortical vasoconstriction.
- Decrease in renal blood flow and glomerular filtration rates (GFRs)
- Decreased urine sodium excretion (U Na < 10 mEq/day)
- Incidence of HRS:
 - 18% at 1st year, 39% at 5 yr
- Hyponatremia and high plasma renin levels are risk factors.

ETIOLOGY

- Chronic liver disease, especially alcohol related (cirrhosis, severe alcoholic hepatitis)
- Fulminate hepatic failure
- Precipitating factors:
 - Decreased effective blood volume:
 - GI bleeding
 - Vigorous diuresis
 - Large-volume paracentesis
 - Use of nephrotoxic agent:
 - NSAIDs
 - Aminoglycoside
 - Sepsis:
 - Spontaneous bacterial peritonitis (SBP) leads to a 33% chance of developing RF during that year
 - Prophylaxis of SBP reduces the chance of developing acute RF

DIAGNOSIS

SIGNS AND SYMPTOMS

Signs of acute or chronic liver disease:

- Signs of portal hypertension
- Ascites, often tense
- Progressive oliguria
- Jaundice or hepatic encephalopathy
- Coagulopathy
- Tachycardia
- Hypotension
- Dyspnea, tachypnea due to tense ascites

History

Acute or chronic hepatic disease with advanced hepatic failure and portal hypertension:

- Worsening liver function often predates acute renal dysfunction

Physical-Exam

- Consistent with severe hepatic disease
- Vital signs may show:
 - Fever in signs of sepsis
 - Hypotension in sepsis, intestinal bleeding, or even a low baseline intrinsic to liver disease

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - Anemia due to GI bleed
- Electrolytes:
 - Hyperkalemia
 - Acidosis
- Glucose
- Elevated BUN, creatinine (Cr):
 - Normal Cr found with low GFR) in association with muscle wasting, poor nutrition, and ascites.
 - Cr increased by some medications (cimetidine, trimethoprim, and spironolactone) due to inhibition of tubular secretion of Cr.
 - Hyperbilirubinemia can create a falsely lower serum Cr.
- PT, PTT
- Urinalysis:
 - Absence of casts distinguishes HRS from acute tubular necrosis (ATN).
 - Check for UTI.
- Spot urine sodium and Cr, and serum and urine osmolality:
 - Spot urine $\text{Na}^+ < 10 \text{ mEq/L}$
 - Fractional excretion of $\text{Na}^+ < 1\%$
 - Urine/plasma Cr $> 30:1$
 - Hyperosmolar urine $>$ plasma osmolality
- 24 hr urine output (low in the absence of diuretics)
- 24 hr urine CrCl:
 - Accurately assess GFR
- Blood, ascitic fluid, and urine culture as indicated
- Urinary excretion of β_2 -microglobulin—useful marker of acute tubular damage

Imaging

- CXR for signs of CHF or fluid overload
- Renal US: Rule out obstructive uropathy:
 - Duplex Doppler US can be used to assess degree of renal vasoconstriction.

Diagnostic Procedures/Surgery

- ECG for dysrhythmia or signs of hyperkalemia
- Foley catheter placement to assess for urine output and exclude urinary retention as cause of RF
- Central venous pressure (CVP) measurements may help assess volume status:
 - Differentiates prerenal (low) from HRS (elevated)

DIFFERENTIAL DIAGNOSIS

- HRS is diagnosis of exclusion
- Glomerulopathy:
 - Hepatitis B can lead to glomerulonephritis
 - Hepatitis C can cause intrinsic renal damage due to cryoglobulinemia
- ATN:
 - Urine sodium > 30 mEq/L
 - Urine osmolality equals plasma osmolality
 - Urine casts and cellular debris
- Prerenal azotemia:
 - Over diuresis
 - GI bleeding
 - Urine output improves following correction of hypovolemia
- Obstructive uropathy
- Infections or sepsis
- Medications—NSAIDs
- Interstitial nephritis
- Post liver transplant renal dysfunction due to:
 - HRS due to failure of transplanted liver
 - Medications (e.g., cyclosporine)
 - Pre-existing renal disease
 - Perioperative hypovolemia

TREATMENT

PRE HOSPITAL

Attention to ABCs:

- Airway control may be a concern in severe encephalopathy.
- Respiratory failure seen with tense ascites as well as volume overload
- Correction of hypotension and ensure adequate IV access

INITIAL STABILIZATION/THERAPY

- ABCs
- Aggressive correction of hypovolemia with:
 - 0.9% NS IV fluid
 - Colloid volume expanders: 100 g albumin in 500 mL of NS

- Closely monitor clinical status including use of CVP
- Urine output should improve with correction of prerenal azotemia
- Manage life-threatening emergencies of RF:
 - Hyperkalemia
 - Severe acidosis
 - Hypoxemia
 - Uremic pericarditis

ED TREATMENT/PROCEDURES

- Exclude reversible or treatable causes of HRS.
- Supportive care until hepatic function recovers
- *Do no harm*—discontinue potentially nephrotoxic agents:
 - NSAIDs
 - Aminoglycosides
 - Demeclocycline
- Treat primary disease
- Search for and treat coexisting renal disease
- Correct electrolyte imbalances
- Treat any associated cardiopulmonary disorder and hypoxia
- Initiate broad-spectrum antibiotics if sepsis suspected
- Correct liver-associated complications:
 - Obstructive jaundice
 - Hepatic encephalopathy
 - Hypoglycemia
 - Peritonitis
- Consider large-volume paracentesis with IV albumin replacement (to relieve tense ascites):
 - Increases renal blood flow
 - May briefly improve HRS
- Transhepatic intrahepatic portosystemic shunt (TIPS):
 - Promising results, but small studies
 - Those who survived the procedure had 40% survival at 12 mo compared to 90% at 3 mo.
- Dialysis:
 - Useful in correcting fluid, electrolytes, acid–base imbalances, pulmonary edema
 - Indicated for patients who have likelihood of hepatic regeneration, hepatic recovery, or liver transplantation
- Liver transplant:
 - Is currently the only definitive therapy

MEDICATION

- No medications are first line and should only be considered after other causes of

renal dysfunction excluded

- Dopamine (renal dose): 2–5 µg/kg/min:
 - May improve renal function
 - Not curative
- Midodrine (7.5–12.5 mg PO TID) and octreotide (100–200 µg SC TID):
 - Octreotide is the analog of somatostatin
 - Midodrine is a sympathomimetic drug
- Misoprostol: 0.4 mg PO QID:
 - Synthetic analog of prostaglandin E₁
- Ornipressin:
 - Vasopressin analog
 - Increases renal perfusion pressure and function
 - Not available in US
- Terlipressin: 2 mg/d for 2 days:
 - Synthetic analog of vasopressin
 - Intrinsic vasoconstrictor activity
 - Not available in US

FOLLOW-UP

DISPOSITION

Admission Criteria

- All suspected HRS with GI and nephrology consults
- ICU admission for associated cardiopulmonary disease, hepatic encephalopathy, marked electrolyte imbalances

Discharge Criteria

None

PEARLS AND PITFALLS

Any degree of renal dysfunction needs to be evaluated very seriously in patients with liver disease.

- K91.83 Postprocedural hepatorenal syndrome

HERNIAS

Jenny J. Lu

BASICS

DESCRIPTION

- Protrusion of bodily structure or organ through a defect in tissues normally containing it.
- Classified as external (hernia protrudes visibly to outside), internal (herniated contents occur within body cavity), or interparietal (hernial sac contained within abdominal wall)
- Abdominal wall hernia due to weakness or disruption of fibromuscular layer of abdominal wall
- “Groin” hernias include femoral, direct, and indirect inguinal hernias
- “Ventral” hernias include epigastric, umbilical, and spigelian hernias
- External:
 - Indirect inguinal hernia:
 - Results from persistent process vaginalis
 - Peritoneal contents herniate through internal ring
 - Right side more common than left
 - 27% lifetime risk of repair for men; 3% for women
 - Direct inguinal hernia:
 - Due to weakness or defect in transversalis area in Hesselbach triangle:
 - Inguinal ligament inferiorly
 - Inferior epigastric vessels laterally
 - Lateral border of rectus abdominus medially
 - Incisional hernia:
 - Resultant breakdown of previous surgical fascial closure
 - Femoral hernia:
 - Peritoneum herniates into femoral canal beneath inguinal ligament.
 - Incarceration frequent due to protrusion through small orifice
 - Internal: Diaphragmatic, hernias from mesenteric/omental tears, foramen of Winslow
- Other hernias:
 - Obturator (pelvic) hernia:
 - Passes through obturator membrane and exits beneath pectineal muscle
 - Epigastric hernia:
 - Midline between xiphoid and umbilicus
 - Spigelian hernia:

- Protrusion through oblique fascia lateral to rectus abdominus muscle
- Lumbar hernia:
 - Occur in superior and inferior lumbar triangle of posterior abdominal wall (incarcerate in 25% cases)
 - Usually middle-aged men, chronic low back pain with palpable mass
- Umbilical hernia:
 - Congenital failure of umbilical ring to close
 - Protrusion through fibromuscular umbilical ring/umbilicus
 - Often incarcerate in adults, although rarely in infants (often spontaneously close)
 - 20–45% recurrence rate

EPIDEMIOLOGY

- Hernia repair (herniorrhaphy) extremely common general surgical procedure (>750,000 performed in US annually)
- Prevalence: 5% of population
- Groin and femoral hernias account for 85% of hernias:
 - Umbilical and incisional hernias account for additional 10%

ETIOLOGY

- Reducible hernia:
 - Protruding structures can be returned to abdominal cavity
- Incarcerated hernia:
 - Contents of hernia cannot be manipulated back into abdominal cavity
- Strangulated hernia:
 - Vascular compromise of entrapped bowel contained within hernia leading to ischemia and gangrene (skin color changes may be apparent)
 - Higher risk in hernias with small openings and large sacs
 - Signs and symptoms of bowel obstruction or ischemia may occur (nausea/vomiting, fever, leukocytosis)

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Pain and swelling:
 - Localized to region of hernia
- Persistent pain, vomiting, fever may indicate:
 - Incarceration
 - Strangulation
 - Bowel obstruction

Physical-Exam

- Vital signs:
 - Frequently normal
 - Tachycardia with pain, dehydration, infection
 - Hypotension with dehydration, strangulation, infection/sepsis
 - Fever with infection/sepsis
 - Skin color changes with strangulation
- Inguinal hernia:
 - Pain:
 - Localized to inguinal region
 - Exacerbated by straining/positional changes
 - Relieved by rest
 - Swelling:
 - Males: Bulge in scrotum
 - Females: Bulge immediately inferior to inguinal ligament or in labia
 - Swelling of spermatic cord, scrotum, or testes
 - Valsalva maneuver performed with finger directed toward internal ring—may allow hernia sac to descend against finger
- Femoral hernia:
 - Pain/swelling:
 - Localized to femoral orifice inferior to inguinal ligament
- Incisional hernia:
 - Pain/swelling:
 - Localized to previous incision/scar
- Obturator hernia:
 - Nonspecific abdominal pain
 - Intermittent intestinal obstruction
 - Weight loss
 - Pain:
 - Owing to pressure on obturator nerve from hernia (Howship–Romberg sign)
 - Along medial thigh
 - Radiating to hip
 - Relieved with thigh flexion
 - Exacerbated by hip extension, adduction, or external rotation
- Spigelian hernia:
 - Abdominal pain/mass along anterior abdominal wall
 - Increased pain with maneuvers increasing intra-abdominal pressure
 - Intermittent bowel obstruction
 - Palpable mass along spigelian line:
 - Convex line extending from costal arch to pubic tubercle along lateral edge of rectus muscle

Pediatric Considerations

- Diagnosis often difficult:
 - Parents describe bulge in inguinal area often no longer present at time of exam.
 - Incarcerated hernias may present with irritability, abdominal pain, or intermittent vomiting.
- Incidence of incarceration/strangulation is 10–20%:
 - >50% in patients younger than 6 mo of age
 - Incidence of incarceration higher in girls than boys
- Umbilical hernias:
 - Strangulation and incarceration rare
 - Most close spontaneously
 - Most surgeons will delay closure until 4 yr of age, although timing is controversial
- Inguinal hernias (consider hydrocele):
 - If hydrocele, neck narrows at external inguinal canal without extension into inguinal canal

Pregnancy Considerations

- Hernias uncommon during pregnancy, manifesting before or during
- Inguinal hernia: 1:1,000–3,000 incidence, 75% occurring in multiparas
- Recognition of emergent situations (incarceration, strangulation) may be a diagnostic and management challenge
- No consensus exists regarding treatment of unreducible hernia during pregnancy; complications during pregnancy may outweigh elective hernioplasty and emergent surgical consultation recommended

Geriatric Considerations

- Higher risk of bowel resection if older than 65 years of age with incarcerated hernias
- Higher postoperative pulmonary and cardiovascular complications

ESSENTIAL WORKUP

Careful history and physical exam:

- Palpate inguinal/femoral area for tenderness/masses.
- Attempt exam with the patient standing or straining (Valsalva maneuver) if hernia not obvious.
- Pelvic exam in women to evaluate gynecologic etiologies of groin pain

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:

- Leukocytosis with strangulation
- Electrolytes, BUN/creatinine, glucose:
 - If vomiting/dehydration
- Urinalysis:
 - Genitourinary causes of groin pain

Imaging

- Plain abdominal radiographs:
 - Obstructive bowel pattern with incarceration or strangulation
- US:
 - For identifying masses in groin or abdominal wall
 - May be difficult in obese patients
- CT:
 - To diagnose obturator or spigelian hernia
 - Consider in symptomatic patients in whom body habitus precludes adequate physical exam or US study

DIFFERENTIAL DIAGNOSIS

- Hydrocele
- Varicocele
- Lymphadenitis
- Testicular torsion
- Testicular tumor
- Undescended testis
- Renal calculi
- UTI
- Ovarian torsion
- Lymphogranuloma venereum

TREATMENT

INITIAL STABILIZATION/THERAPY

- 0.9% NS IV fluid resuscitation for dehydration, bowel strangulation, obstruction, or sepsis:
 - Adults: 1 L bolus
 - Peds: 20 mL/kg bolus

ED TREATMENT/PROCEDURES

- Incarcerated or strangulated hernias:
 - IVFs
 - Nasogastric tube (NGT)
 - Surgical consultation

- Preoperative broad-spectrum antibiotics for strangulated hernia (controversial)
- Hernia reduction procedure:
 - IV sedation (benzodiazepines) and analgesia (opiates) if necessary
 - Place patient in Trendelenburg position.
 - For spontaneous reduction, allow 20–30 min
 - For manual reduction:
 - Place constant, gentle pressure on hernia.
 - For inguinal hernias, achieve reduction by putting fingers of 1 hand on internal ring while gently pulling then pressing on hernia distal to external ring.
 - Obtain surgical consultation if reduction is unsuccessful after 1 or 2 attempts.
 - Contraindications to reduction include:
 - Fever
 - Leukocytosis
 - Signs of strangulation
 - Complications:
 - Introduction of strangulated bowel into abdomen
 - Further ischemia/necrosis occurs with no clinical improvement.
 - Reduction in girls may be more difficult if ovary encased within hernia.

MEDICATION

- Analgesics:
 - Morphine sulfate: 2–10 mg per dose (peds: 0.1–0.2 mg/kg IV/IM/SC q2–4h) IV/IM/SC
 - Fentanyl: 1–4 µg/kg (peds: 1–4 µg/kg IV) IV
- Sedatives:
 - Lorazepam: 1–2 mg IV
 - Midazolam: 2.5–5 mg (peds: 0.07 mg/kg) IV

FOLLOW-UP

DISPOSITION

Admission Criteria

- Strangulated hernias require immediate surgical intervention.
- Incarcerated hernias require admission for urgent surgical intervention.
- Intestinal obstruction
- Peritonitis
- Vomiting/dehydration
- Severe pain

Discharge Criteria

After successful reduction has been achieved and patient asymptomatic

Issues for Referral

Referral to surgery with instructions to return if recurrent persistent pain, fever, vomiting

FOLLOW-UP RECOMMENDATIONS

General surgery referral

PEARLS AND PITFALLS

- Failure to recognize signs and symptoms of an incarcerated or strangulated hernia
- Forcing reduction of incarcerated hernia
- Reintroducing strangulated bowel back into abdominal cavity

- K40.90 Unil inguinal hernia, w/o obst or gangr, not spcf as recur
- K41.90 Unil femoral hernia, w/o obst or gangrene, not spcf as recur
- K46.9 Unspecified abdominal hernia without obstruction or gangrene

HERPES SIMPLEX

Benjamin Mattingly • Benjamin Wilks

BASICS

DESCRIPTION

- Viral disease characterized by recurrent painful vesicular lesions of mucocutaneous areas
- Lips, genitalia, rectum, hands, and eyes most commonly involved
- Infection is characterized by 2 phases:
 - *Primary*, in which virus becomes established in a nerve ganglion;
 - *Secondary*, involves recurrence of disease at the same site
- Incubation period is ~4 days from exposure
- Viral shedding occurs from 7–10 days (up to 23 days) in primary infection and 3–4 days in recurrent infections
- Neonatal infections can occur in utero, intrapartum (most common), or postnatal
 - Occur in 1/3,500 births per year in the US
- Human-to-human transmission
- 60–90% of population is infected with herpes simplex type 1 (HSV-1) or type 2 (HSV-2)
- More common in blacks than whites in ages <40 yr
- Females affected more than males

ETIOLOGY

- HSV-1 or HSV-2 are DNA viruses of the Herpesviridae family
- Viral transmission may occur via respiratory droplets, contact with mucosa or abraded skin with infected secretions:
 - Recurrent mucosal shedding of HSV may transmit the virus
 - Rate of recurrence varies with virus type and anatomic site
- Both viruses infect oral or genital mucosa:
 - Most common for HSV-1 to cause oral infections and HSV-2 to cause genital infections

DIAGNOSIS

SIGNS AND SYMPTOMS

- Many primary infections go unrecognized and can only be detected by an elevated IgG Ab titer
- Clinically, infection presents with grouped 1–2 mm vesicles on an erythematous base
- Vesicles may be filled with clear or cloudy fluid or may appear as frank pustules

Orofacial infection:

- Primary infection:
 - Gingivostomatitis or pharyngitis:
 - Ulcerative exanthem involving gingival and mucous membranes
 - Fever, malaise, irritability, headache, myalgias, cervical adenopathy
 - Primary infection symptoms typically last 2--4 weeks unless secondarily infected and heal without scarring
 - Inability to eat owing to pain is a risk for dehydration
- Recurrent infection (recrudescence):
 - Usually involves lips, specifically the vermillion border
 - Commonly incited by sunlight, heat, stress, trauma (chapping, abrasions), or immunosuppression
 - Prodrome of itching, tingling, throbbing, or burning followed by erythema, papule/vesicle, ulcer, crust, and healing
 - Transmission can occur in the absence of recognizable lesions
 - Fewer constitutional symptoms
 - Many individuals have a rise in Ab titer and never experience recurrence
 - HSV-1 oral infections recur more often than genital HSV-1 infections. HSV-2 genital infections recur 6 times more frequently than HSV-1 genital infections

Skin infection:

- History of exposure to HSV-1 or HSV-2
- Abrupt onset of fever, edema, erythema, and localized tenderness
- Herpetic whitlow:
 - HSV-2 more common than HSV-1
 - Infection of pulp and lateral aspect of finger with single or multiple vesicles
 - May occur from autoinoculation with primary oral or genital infection or from direct inoculation from occupational exposure
 - Can last 3–4 wk
 - Recurrence possible
 - In young children, it is associated with HSV-1 inoculation through thumb sucking during gingivostomatitis
- Traumatic herpes:
 - Can occur following cosmetic procedures of face, surgical and dental interventions, sun exposure, or burns
- Herpes gladiatorum:
 - Mucocutaneous infection of athletes involving chest, face, and hands transmitted through traumatized skin (often wrestlers)
- Eczema herpeticum:
 - Association between atopic dermatitis and HSV infection
 - HSV-1 more common than HSV-2
 - Occurs in children and young adults with atopic dermatitis
 - Secondary staphylococcal infection commonly occurs

- Higher risk if on steroids or infected with HIV
- Varicelliform eruption with spread to surrounding skin
- Fever, headache, and fatigue
- HSV-associated erythema multiforme:
 - Usually presents on palms and soles
 - Lasts 2–3 wk

Eye:

- Most common cause of corneal blindness
- Caused by extension of facial lesions or direct inoculation
- Acute onset of pain and photophobia
- Periauricular adenopathy, blurry vision, chemosis, and conjunctivitis
- May be unilateral or bilateral
- Dendritic lesions of cornea noted on fluorescein exam
- Different from herpes varicella zoster as dermatome not involved
- Hutchinson sign:
 - Vesicles on tip of nose may indicate ocular disease
 - Involvement of nasociliary nerve

CNS/encephalitis:

- Most common cause of severe sporadic encephalitis in the western world
- Usually from HSV-1 reactivation disease

History

May or may not have known history of exposure to HSV-1 or HSV-2

Physical-Exam

Vesiculoulcerative lesions in orofacial or genital area

Pediatric Considerations

- Up to 60–80% of babies who develop neonatal HSV are born to mothers without history of genital herpes
- Vesicular skin lesions may or may not be present on initial exam
- Primary genital disease of the mother increases risk of transmitting virus to fetus
- Most primary infections occur during childhood; symptomatic in only 5–10% of children
- Orofacial disease is most likely to present as gingivostomatitis in children younger than 5 yr of age
- Whitlow may be caused by thumb-sucking children with oral herpes

ESSENTIAL WORKUP

- Herpes encephalitis:
 - Lumbar puncture if herpes encephalitis is considered
- Herpes ophthalmicus:

- Fluorescein exam if ocular herpes is a concern

DIAGNOSIS TESTS & INTERPRETATION

- Orofacial:
 - Presumptive diagnosis made by history and exam
 - If definitive diagnosis is necessary (e.g., systemic disease, child abuse):
 - Viral culture or polymerase chain reaction (PCR) testing of swabs from vesicles
 - PCR is the most accurate and reliable method for detecting the virus
 - Fluorescent antibody detection of antigen; serum antibody studies
 - Scrapings for Tzanck smear or Papanicolaou stain
 - Skin biopsy if hyperkeratotic or lichenoid lesions
- Eye:
 - Dendritic corneal lesions by fluorescein exam
 - Swab of affected area for viral culture or fluorescent antibody detection
- CNS/encephalitis:
 - Lumbar puncture with CSF pleocytosis and negative bacterial antigens
 - CSF PCR
 - MRI/CT (abnormalities in temporal lobe may be visualized)
 - EEG diagnostic if spike and waves in temporal region

Lab

- Lesion scrapings can be sent for culture or PCR testing
- Tzanck smear demonstrating multinucleated giant cells, atypical keratinocytes, and large nuclei
- Serum testing has limited ED use
- ELISA testing may demonstrate HSV antibodies, determining past exposure only
- Requires 2 wk to > 3 mo to detect seroconversion

DIFFERENTIAL DIAGNOSIS

- Orofacial and skin:
 - Bacterial pharyngitis
 - Mycoplasma pneumoniae pharyngitis
 - Stevens–Johnson syndrome
 - Herpes zoster
 - Varicella
 - Pemphigus
 - Contact or chemical dermatitis
 - Impetigo
 - Syphilis
- Eye:
 - Conjunctivitis: Viral, bacterial, or allergic
 - Herpes zoster ophthalmicus

- Scleritis/episcleritis
- Angle-closure glaucoma
- Corneal abrasion

TREATMENT

PRE HOSPITAL

- Maintain universal precautions.
- Pain control

INITIAL STABILIZATION/THERAPY

Protect airway in comatose or obtunded patients with suspected CNS disease

ED TREATMENT/PROCEDURES

- Orofacial/gingivostomatitis:
 - Primary disease in healthy children is generally not treated
 - Primary disease in normal host with mild disease requires only supportive treatment with hydration and analgesia
 - Severe disease or immunocompromised patients: IV or oral acyclovir, valacyclovir, or famciclovir
 - Oral acyclovir is first-line medication
 - If recurrent disease, oral antivirals are most helpful if started with prodrome or at 1st sign of lesion:
 - Reduces lesions and symptoms by 1–2 days
 - Consider prophylaxis in patients with more than 6 episodes per year; history of herpes-associated erythema multiforme or herpes gladiatorum; upcoming intense sun exposure or stress; perioral/intraoral surgery; cosmetic facial procedures:
 - Prophylaxis reduces frequency and severity of herpes labialis and may help decrease asymptomatic shedding, leading to decreased transmission
 - Does not cure or terminate the disease
 - When prophylaxis is stopped, most patients have recurrences
- Skin (other than orofacial or genital):
 - May be treated with oral acyclovir
 - Antibiotics if secondary bacterial infection
 - *Do not incise and drain*: May lead to spread of infection
- Eye:
 - Oral acyclovir and topical antiviral therapy with trifluridine or vidarabine
 - Vidarabine ointment for children
 - *Do not treat with steroids*: May cause increased viral replication
 - Ophthalmology consult

Pregnancy Considerations

Acyclovir has been used to suppress genital herpes near end of pregnancy and appears safe, but is not FDA approved

MEDICATION

- **Acyclovir:**
 - Orofacial and skin: 400 mg PO TID for 7–10 days or 5–10 mg/kg IV (5–10 mg/kg) q8h for 7–14 days
 - Pediatric mucocutaneous primary infection: 40–80 mg/kg PO in 3–4 div. doses for 5–10 days; max. dose 1 g/d
 - Eyes for suppression therapy: 400 mg PO BID
 - Encephalitis: 60 mg/kg/24h IV div. q8h for 14–21 days
- **Famciclovir:**
 - Primary orofacial: 250 mg PO TID for 7–10 days (immunocompetent), 500 mg PO BID for 7–10 days (immunocompromised)
- **Trifluridine:**
 - Adults and peds older than 6 yr: 1 drop of 1% ophthalmic ointment to eye q2h while awake (max. 9 drops per day) for at least 10 days and then taper under ophthalmology consultation
- **Valacyclovir:**
 - Adults primary mucocutaneous: 1,000 mg PO BID for 7 days
 - Adult recurrent mucocutaneous (nongenital): 500 mg PO BID for 3 days
- **Vidarabine:**
 - Adults or peds older than 2 yr: Topical 0.5 in ribbon of 3% ophthalmic ointment to eye 5 times per day
- **Recurrent mucocutaneous herpes:**
 - Acyclovir: 400 mg PO TID for 5 days
 - Famciclovir: 1,000 mg PO BID for 1 day
 - Valacyclovir: 500 mg PO BID for 3 days
- **Long-term prophylaxis:**
 - Acyclovir: 400 mg PO BID
 - Valacyclovir: 500 mg PO daily
 - Famciclovir: 250 mg PO BID

ALERT

- Antiviral dosing may need adjustment for renal failure
- Topical antivirals are available but have not been shown to reduce the length of symptoms or decrease recurrence

FOLLOW-UP

DISPOSITION

Admission Criteria

- Encephalitis, disseminated disease, dehydration
- Severe local or disseminated disease in immunocompromised host
- Neonatal HSV
- ICU vs. ward based on toxicity and need for airway support
- Ophthalmology consult vs. admission for ocular involvement

Discharge Criteria

Uncomplicated local disease

Issues for Referral

- Suppressive treatment options
- Herpes infection during pregnancy

FOLLOW-UP RECOMMENDATIONS

Skin/genital infection:

- Follow-up with the patient's primary doctor to discuss risks and benefits of suppressive therapy

PEARLS AND PITFALLS

- Failure to consider herpes simplex encephalitis in patients whom you have a concern for meningitis/encephalitis
- Failure to consider ocular herpes in patients presenting with eye pain, decreased vision, and/or lesions on nose
- Failure to warn patients about the risk of transmission to others especially during outbreaks and for 1–2 wk thereafter
- Failure to warn patients to avoid touching the lesions during outbreaks to prevent spread of the lesions to other body areas

HERPES ZOSTER

Aaron Hexdall • Stephen M. Kelly

BASICS

DESCRIPTION

- Commonly known as shingles
- Characterized by unilateral eruption of painful vesicles along a single dermatome
- Disseminates rarely in normal hosts and frequently in immunocompromised hosts
- Most common in patients with decreased cell-mediated immunity:
 - Older than 50 yr of age
 - Neoplastic diseases
 - Immunosuppressive drugs

ETIOLOGY

- Caused by varicella zoster virus (VZV), a DNA virus in the Herpesviridae family
- Reactivation of dormant virus in dorsal root ganglia
- Mostly in individuals who previously had chickenpox and very rarely in vaccinated individuals

Pregnancy Considerations

Zoster in pregnancy is not associated with increased risk of congenital varicella syndrome

Pediatric Considerations

May occur in childhood, most commonly when primary varicella occurred in utero or in the first 6 mo of life

DIAGNOSIS

SIGNS AND SYMPTOMS

- Dermatomal zoster
 - Prodrome of pain and paresthesias in 75% of patients
 - Pain may be sharp, dull, tingling, burning, or intense pruritus
 - Classical rash is grouped vesicles on erythematous base
 - Progress to scab and crust formation over 7–10 days; crusts fall off in 2–3 wk
 - Most common nerve distributions are thoracic and lumbar, followed by trigeminal and cervical
- Zoster sine herpete
 - Syndrome occurs without the rash

- Herpes zoster ophthalmicus (HZO)
 - Involvement of ophthalmic division of trigeminal nerve
 - Hutchinson sign – lesion on tip of nose
 - May cause punctate keratitis or corneal pseudodendrites (elevated mucous plaques, less ulcerative and less fluorescein uptake than HSV dendrites)
- Ramsay Hunt syndrome
 - From VII and VIII cranial nerve involvement
 - Lesions in the external auditory canal, peripheral facial palsy, vertigo and anesthesia of anterior 2/3 of hemitongue
 - Progress to scab and crust formation over 7–10 days; crusts fall off in 2–3 wk
 - Most common nerve distributions are thoracic and lumbar, followed by trigeminal and cervical
- Disseminated disease may cause:
 - Myelitis
 - Meningoencephalitis
 - Peripheral neuropathy
 - Hepatitis
 - Pneumonitis
- Postherpetic neuralgia (PHN) is a complication of zoster:
 - Described as pain that persists at site of zoster lesions for > 3 mo after cutaneous disease has healed
 - 10–70% of patients will have pain after resolution of lesions
 - Incidence increases with age older than 50 yr, severe rash, and severe pain

ESSENTIAL WORKUP

- Clinical presentation is sufficient for diagnosis in most patients
- Labs may aid diagnosis in patients with atypical rash or disseminated disease

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Tzanck Smear
 - Cheap and easy
 - Scrape base of unroofed vesicle
 - Multinucleated giant cells on Giemsa stain
 - Cannot distinguish VZV from HSV
 - Low sensitivity
- PCR is the preferred method
 - From vesicle scraping, blood, CSF or BAL
 - Can distinguish between HSV and VZV
 - More sensitive and specific
- Serology (IgM/IgG)

- More difficult to interpret
- Less sensitive/specific
- Viral culture
 - Slow, insensitive

DIFFERENTIAL DIAGNOSIS

- Primary varicella
- Herpes simplex virus (HSV)
- Cellulitis
- Poison Ivy
- Insect bites
- Bullous impetigo
- Molluscum contagiosum
- Trigeminal neuralgia
- Angina
- Biliary/renal colic
- Radiculopathy
- Bell palsy
- Peripheral vertigo
- Conjunctivitis (nonherpetic)
- HSV keratitis

TREATMENT

PRE HOSPITAL

- Zoster is contagious and may cause varicella in nonimmune health care workers:
 - Lesions should be covered
 - Maintain universal precautions

ED TREATMENT/PROCEDURES

- Generally a self-limited disease
- Goals of treatment are to decrease pain and duration of illness, and to prevent PHN
- Immunocompetent patient
 - Antiviral therapy
 - PO valacyclovir has easiest dosing and seems to be the most effective
 - May also use PO acyclovir (cheapest option) or famciclovir
 - Should be started within 72 hr of rash, but some experts recommend starting later if new vesicles are still appearing
 - Speeds acute healing and resolution of acute pain
 - Unclear if decreases the rate of PHN
 - Analgesics

- Over-the-counter agents (mild disease)
 - Long-acting opioids
- Corticosteroids (controversial)
 - Several studies showed modest improvement in cutaneous healing and acute neuritis
 - Does not help prevent PHN
 - If not otherwise contraindicated, consider in patients with severe disease or CNS involvement
- Immunocompromised patient
 - Antiviral therapy
 - IV acyclovir
 - Analgesics
 - As above
 - Corticosteroids
 - As above
- Herpes zoster ophthalmicus
 - Necessitates ophthalmologic consultation
 - Valacyclovir PO as above
 - IV acyclovir if immunocompromised or cranial nerve involvement
 - Erythromycin ointment for secondary bacterial infection
 - Topical cycloplegic if associated iritis
 - Ophthalmologist may recommend topical steroids
- PHN
 - Antivirals not indicated
 - Long-acting opioids
 - Tricyclic antidepressants are effective
 - Gabapentin and pregabalin may also be helpful
 - Topical lidocaine provides short-term relief
- Postexposure prophylaxis
 - VariZIG is recommended within 72 hr of exposure for the following patients:
 - Immunocompromised
 - Pregnant
 - Exposed premature neonates born < 28 wks gestation
 - Exposed premature neonates born > 28 wks gestation to seronegative mom
 - Neonates born to mother with symptomatic varicella between 5 days predelivery and 2 days postdelivery
 - Must wait 5 mo before giving subsequent vaccine
- Vaccine
 - Zostavax (Merck) recommended for all patients over the age of 60 (unless immunocompromised)
 - Does not reduce risk of recurrence or PHN in patients with zoster

Pregnancy Considerations

- Same treatment as immunocompetent patients
- Vaccine contraindicated in pregnancy

Pediatric Considerations

Neonatal zoster requires treatment with IV acyclovir

MEDICATION

First Line

- **Antivirals:**
 - Valacyclovir 1 g PO q8h × 7 days, Acyclovir 800 mg PO q4h × 7–10 days, Acyclovir 10 mg/kg IV q8h × 7 days
- **Analgesics:**
 - Acetaminophen 500 mg PO q6h; not to exceed 4g/d
 - Ibuprofen 600 mg PO q6h
 - Oxycodone CR 10 mg PO q12h
 - Amitriptyline 25 mg PO qhs, increase as tolerated to 100 mg daily
 - Cyclopentolate ophthalmic 1% apply 1 gtt q8h to affected eye
- **PEP:**
 - Varicella zoster immunoglobulin (VariZIG): 125 U IM/IV per 10 kg body weight, up to max. of 625 U
- **Vaccine:**
 - Zostavax (Merck) one-time SC injection

Second Line

- **Antivirals:**
 - Famciclovir 500 mg PO q8h × 7 days
 - Foscarnet: 90 mg/kg IV as 2 hr infusion every 12 hr (acyclovir-resistant immunocompromised patient)
- **Antibiotics:**
 - Erythromycin ophthalmic ointment USP 0.5% apply 1 in q4h to affected eye
- **Analgesics**
 - Gabapentin: 100–300 mg daily increasing 100–300 mg every 3 days until adequate response or max. 3,600 mg/d
 - Pregabalin: Start 50 mg PO q8h or 75 mg PO q12h, increase to 100 mg q8h within 1 wk
 - Lidocaine patch 5%: Apply up to 3 patches for max. 12 hr within a 24 hr period for severe pain
- **Corticosteroids:**
 - Prednisone: Taper over 7 days (do not extend beyond duration of antiviral therapy)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Immunocompromise
- Disseminated disease
- HZO with cranial nerve involvement
- Intractable pain
- Isolation:
 - Airborne precautions for all patients with primary varicella or disseminated zoster, or immunocompromised patients with dermatomal zoster
 - Patients are infectious from 48 hr before appearance of rash until crusting of all lesions

Discharge Criteria

- Most are managed as outpatients
- Patients should be instructed that lesions may heal with scarring or leave depigmented areas
- Recommend isolation from pregnant or immunocompromised persons until all lesions are crusted
- PHN may require long-term follow-up and/or referral to pain specialist

Pregnancy Considerations

Usually treated as outpatients

Pediatric Considerations

Admit all neonates with zoster

PEARLS AND PITFALLS

- Look for ocular involvement if rash involves the tip of the nose (Hutchinson sign)
- Expose the skin of every patient with chest pain
- Failure to consider the diagnosis in the absence of rash
- Failure to warn patients of the risk of PHN

- B02.21 Postherpetic geniculate ganglionitis
- B02.30 Zoster ocular disease, unspecified

HERPES, GENITAL

Kathleen A. Kerrigan • Jason L. Grimsman

BASICS

DESCRIPTION

- Genital herpes is a lifelong recurrent infection
- ~1 in 4 Americans older than age 30 are seropositive for herpes simplex virus type 2 (HSV-2):
 - Most are asymptomatic
- 1st episode/primary HSV infection:
 - 2–12 day incubation
 - Symptoms peak 8–10 days after onset
 - Lesions heal in 3 wk
 - Primary infection may have more prominent clinical syndrome and complications (e.g., encephalitis, meningitis, hepatitis)
 - Primary infection may also go unnoticed:
 - >50% of 1st recognized signs and symptoms are not primary infection
- Recurrent HSV infection:
 - Average patient has 4 recurrences per year, by herpes simplex virus type 1 (HSV-1) recurs less than HSV-2
 - Virus reactivated from dorsal root ganglia
 - Triggered by local trauma, emotional stress, fever, sunlight, cold or heat, menstruation, or infection
 - Milder clinical syndrome and fewer lesions that usually heal within 10 days
- Asymptomatic HSV infection:
 - Virus is shed intermittently and often transmitted by persons who are without lesions or symptoms

ETIOLOGY

- 70–90% caused by a DNA virus HSV-2:
 - Remainder caused by HSV-1
- Increasing prevalence of genital HSV-1 infection:
 - Higher rates of oral sex
 - Falling incidence of childhood (nonsexual) transmission owing to improved social conditions resulting in a larger pool of susceptible adolescents and adults
- Primary genital infection by HSV-1 is similar to HSV-2 in symptoms and duration, but recurs much less frequently
- Acquisition of HSV-2 in patients with pre-existing HSV-1 infection is less commonly

associated with systemic symptoms:

- Acquisition of HSV-1 in persons with pre-existing HSV-2 infection is rare
- HSV vaccines unsuccessful to date, research is ongoing
- High association with HIV and other STDs

ALERT

- Contact isolation and universal precautions should be maintained
- Patients with HIV coinfection have higher HIV viral levels in the blood and skin lesions during HSV recurrence

DIAGNOSIS

SIGNS AND SYMPTOMS

- Local pain and itching
- Herpetic cervicitis, vaginitis, or urethritis may present with dysuria, urinary hesitance or retention, vaginal discharge, or pelvic pain
- Herpetic pharyngitis or gingivostomatitis may occur with oral acquisition
- Systemic symptoms like fever, headache, malaise, photophobia, anorexia, myalgias, and lymphadenopathy are more common with primary infection

History

- 1–2 day prodrome of local tingling, burning, itching, or pain prior to eruption (can mimic sciatica)
- Classically, lesions are noted on day 2 as macules and papules, then progress to vesicles, pustules, and then ulcerate by day 5
- Skin lesions crust over; mucosal membrane lesions heal without crusting

Physical-Exam

- Lesions on vulva, vagina, cervix, perineum, buttocks; penile shaft or glans
- Grouped vesicles on an erythematous base
- On moist mucosal surfaces, ulcers may predominate
- Atypical features may include localized edema, erythema, crusts, or fissures

Pediatric Considerations

- Neonatal infections are often disseminated or involve the CNS with high morbidity and mortality
- Congenital HSV in the neonate without vesicles may mimic rubella, cytomegalovirus (CMV), or toxoplasmosis
- Consider sexual abuse in children with genital HSV; culture lesions and test for other STDs in suspected cases

ESSENTIAL WORKUP

Diagnosis based on history and physical exam

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Viral load in lesions of primary infection are greater than those seen in recurrence
- Tzanck preparation and staining of fluid from lesions is insensitive and nonspecific
- Viral culture of vesicle fluid or ulcer base positive in 80–95% of cases, decreasing sensitivity as lesions crust and heal:
 - 3–10 days for result
- PCR 1.5–4 times more sensitive than viral culture; test of choice for CSF analysis in suspected CNS infection
- Serologic tests not helpful in acute disease:
 - Highly sensitive and specific; detect anti-gG1 and anti-gG2 antibodies
 - Require 2 wk to > 3 mo to detect seroconversion
 - Cannot distinguish acute from chronic disease
 - HerpeSelect HSV-1/HSV-2 ELISA:
 - Takes hour to days in lab
 - POCKit HSV2, bedside results in 10 min

Imaging

No imaging generally indicated

DIFFERENTIAL DIAGNOSIS

- Syphilis (*Treponema pallidum*)
- Chancroid (*Haemophilus ducreyi*)
- Lymphogranuloma venereum (LGV)
- Granuloma inguinale (*Klebsiella granulomatis*)
- Candidiasis
- Behçet syndrome

TREATMENT

PRE HOSPITAL

Universal precautions should be maintained

INITIAL STABILIZATION/THERAPY

Rarely required unless associated with systemic symptoms requiring hospitalization:

- Disseminated infection
- Hepatitis
- Pneumonitis

- Meningoencephalitis

ED TREATMENT/PROCEDURES

- Treatment partially controls symptoms and lesions; does not eradicate latent virus nor affect recurrences after drug is discontinued
- Episodic treatment of recurrences may shorten duration of lesions or ameliorate recurrences
- Daily suppressive therapy in patients with frequent recurrences (6 or more per year) reduces frequency of recurrences by 75%
- Famciclovir and valacyclovir are equally effective medications with less frequent dosing regimens, all interfere with viral DNA polymerase
- Resistance to acyclovir in immunocompromised individuals is 5–10%:
 - Foscarnet 40 mg/kg IV q8h may be effective
- Consider testing for concomitant STDs, those with an HSV outbreak are more likely to contract HIV
- Consider bladder catheterization, either indwelling or intermittent, for women with difficulty urinating due to possible sacral nerve involvement

Pregnancy Considerations

- Women with primary HSV infection during pregnancy should receive antiviral therapy:
 - High rates of neonatal morbidity in both symptomatic and asymptomatic patients
- Suppressive antiviral therapy after 36 wk associated with decreased incidence of lesions at delivery:
 - Decreased cesarean delivery rates

MEDICATION

- Systemic or severe infection requiring hospitalization:
 - Acyclovir: 5–10 mg/kg IV over at least 1 hr q8h for 5–10 days
 - Neonate/peds: 10–20 mg/kg IV over at least 1 hr q8h for 7–10 days
- 1st episode (7–10 day therapy; extend if not healed in 10 days):
 - Acyclovir: 400 mg PO TID or 200 mg PO 5 times per day:
 - Peds: 20 mg/kg PO TID or 5 mg/kg IV q8h.
 - Famciclovir: 250 mg PO TID for 7–10 days
 - Valacyclovir: 1,000 mg PO BID for 7–10 days
- Recurrent infection (5 day therapy):
 - Must start within 1 day of appearance of lesion or during prodrome
 - Acyclovir: 800 mg PO TID for 2 days or 800 mg PO BID for 5 days.
 - Famciclovir: 1,000 mg PO BID for 1 day or 125 mg PO BID for 5 days.
 - Valacyclovir: 500 mg PO BID for 3 days or 1,000 mg PO daily for 5 days.
- Suppressive therapy (daily):
 - Acyclovir: 400 mg PO BID

- Famciclovir: 250 mg PO BID
- Valacyclovir: 500 mg PO daily or if > 10 recurrences yearly, 1,000 mg PO daily
- Treatment of patients with HIV coinfection:
 - Recurrent infection (5–10 days therapy):
 - Acyclovir: 400 mg PO TID
 - Famciclovir: 500 mg PO BID for 5–10 days
 - Valacyclovir: 1,000 mg PO BID
 - Suppressive therapy:
 - Acyclovir: 400–800 mg PO BID–TID
 - Famciclovir: 500 mg PO BID
 - Valacyclovir: 500 mg PO BID

FOLLOW-UP

DISPOSITION

Admission Criteria

- Systemic involvement (encephalitis, meningitis), significant dissemination
- Severe local symptoms (pain, urinary retention)
- Severely immunocompromised patient

Discharge Criteria

- Immunocompetent patient without systemic involvement
- Discharge counseling:
 - Avoid sexual contact during prodrome until healed
 - Practice safe sex techniques even if there are no lesions
 - Expect future recurrences; consider suppressive therapy if frequent
 - Analgesics and antipruritics as needed
 - Dysuria and urinary retention may be relieved with sitz baths or pouring warm water over lesions during urination

Issues for Referral

- Neonatal herpes infection
- Sexual abuse in children
- Herpes infection during pregnancy

PEARLS AND PITFALLS

- Treat primary infections
- Consider sexual abuse in children with genital herpes
- Herpes is a lifelong infection

HICCUPS

Jeffrey A. Horenstein • Carrie Tibbles

BASICS

DESCRIPTION

- Sudden, involuntary contraction of the diaphragm (usually unilateral) and other inspiratory muscles terminated by abrupt closure of the glottis
- Medical terminology: Singultus
- Usually occur with a frequency of 4–60/min
- Occurs as a result of stimulation of the hiccup reflex arc:
 - Irritation of the vagus and phrenic nerves
 - The “hiccup center” is located in the upper spinal cord or brainstem
- Classification:
 - Hiccup bout: < 48 hr
 - Persistent hiccups: 48 hr–1 mo
 - Intractable hiccups: > 1 mo
- Male > female (4:1)

ETIOLOGY

- GI:
 - Gastric distention, overeating, eating too fast
 - Esophageal: Gastroesophageal reflux, achalasia, candida esophagitis, cancer
 - Gastric: Ulcers, cancer
 - Hepatic: Hepatitis, hepatoma
 - Pancreatic: Pancreatitis, pseudocyst, cancer
 - Bowel obstruction
 - Inflammatory bowel disease
 - Cholelithiasis, cholecystitis
 - Appendicitis
 - Abdominal aortic aneurysm
 - Postoperative, abdominal procedure
- Diaphragmatic irritation:
 - Hiatal hernia
 - Intra-abdominal mass
 - Pericarditis
 - Eventration
 - Splenomegaly, hepatomegaly
 - Peritonitis
- CNS:
 - Vascular lesions: Ischemic/hemorrhagic stroke, head trauma, arteriovenous

- malformations
 - Infectious: Encephalitis, meningitis, abscess
 - Structural: Cancer, Parkinson disease, multiple sclerosis, hydrocephalus
 - Ventriculoperitoneal shunt
- Thoracic:
 - Infectious: Pneumonia, TB
 - Cardiac: MI, pericarditis
 - Aortic aneurysm
 - Cancer
 - Mediastinal lymphadenopathy
- Head and neck:
 - Otic foreign body irritating the tympanic membrane
 - Pharyngitis
 - Laryngitis
 - Goiter
 - Retropharyngeal/peritonsillar abscess
 - Neck mass
- Metabolic:
 - Uremia
 - Hyponatremia
 - Hypocalcemia
 - Gout
 - DM
- Toxic/drug induced:
 - Alcohol
 - Tobacco
 - α -methyldopa
 - Benzodiazepines
 - Steroids
 - Barbiturates
 - Narcotics
 - Chemotherapeutic agents
 - Antibiotics
 - General anesthesia
- Psychogenic causes:
 - Stress/excitement
 - Grief
 - Malingering
 - Conversion disorder
- Idiopathic

SIGNS AND SYMPTOMS

- Characteristic sound abruptly ending an inspiratory effort
- Attacks usually occur at brief intervals and last only a few seconds or minutes.
- Attacks lasting >48 hr or persisting during sleep suggest an organic etiology.

History

- Targeted history and review of systems to determine likelihood of potential underlying etiology:
 - Severity and duration of current episode
 - History of previous episodes and treatment attempts

Physical-Exam

- Careful physical exam in search of an underlying cause, with exam focused on:
 - Head and neck
 - Chest
 - Abdomen
 - Neurologic

ESSENTIAL WORKUP

For persistent or intractable hiccups, a thorough history and physical exam dictate further diagnostic testing.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC with differential
- Electrolytes, BUN, creatinine

Imaging

- CXR
- Further imaging may be indicated depending on clinical suspicion of a particular etiology; this can often be performed on an outpatient basis.

DIFFERENTIAL DIAGNOSIS

Eructation (belching)

TREATMENT

ED TREATMENT/PROCEDURES

- Treat specific causes when identified:
 - Remove foreign bodies from the ear.
 - Relieve gastric distention with a nasogastric tube.

- Nonpharmacologic maneuvers:
 - Catheter stimulation of the posterior pharynx
 - Direct stimulation of the uvula with a cotton swab
 - Supraorbital pressure
 - Carotid sinus massage
 - Digital rectal massage
 - Suboccipital release
 - Gentle traction and pressure applied to the posterior neck, stretching the suboccipital muscles and fascia.
- Pharmacologic treatment:
 - First line, only FDA approved medication for hiccups: Chlorpromazine
- Additional medications:
 - Gabapentin
 - Metoclopramide
 - Baclofen
 - Haloperidol
 - Nebulized lidocaine
 - Amitriptyline
 - Phenytoin

MEDICATION

- Amitriptyline: 10 mg PO TID
- Baclofen: 10 mg PO TID
- Chlorpromazine: 25–50 mg IV/IM, 25–50 mg PO TID–BID
- Gabapentin: 100 mg PO TID–QID
- Haloperidol: 2–5 mg IM
- Lidocaine (4%): 3 mL nebulized, repeat if necessary
- Metoclopramide: 10 mg IV/IM, 10–20 mg PO QID
- Phenytoin: 200 mg IV

FOLLOW-UP

DISPOSITION

Admission Criteria

If hiccups interfere with daily activities and could lead to decreased nutritional or fluid intake, aspirations, insomnia, wound dehiscence

Discharge Criteria

- If hiccups last < 48 hr
- Workup inconsistent with underlying organic etiology

Issues for Referral

Referral in cases of intractable hiccups for investigation into underlying cause and more definitive therapeutic measures:

- Phrenic nerve block, crush, or transection
- Hypnosis
- Behavioral modification
- Acupuncture
- Psychiatric interventions

FOLLOW-UP RECOMMENDATIONS

Home remedies in case of recurrence:

- Swallowing a spoonful of sugar
- Sucking on a hard candy or swallowing peanut butter
- Breath holding/Valsalva maneuver
- Biting a lemon
- Tongue traction
- Lifting the uvula with a cold spoon
- Drinking from the far side of a glass
- Fright
- Noxious stimuli
- Rebreathing into a paper bag

PEARLS AND PITFALLS

Protracted hiccups are strongly suggestive of underlying organic disease.

- R06.6 Hiccough

HIGH-ALTITUDE ILLNESS

Christopher B. Colwell

BASICS

DESCRIPTION

- Incidence dependent on:
 - Rate of ascent
 - Final altitude
 - Sleeping altitude
 - Duration at altitude
- Acute mountain sickness (AMS) incidence:
 - Up to 67% incidence with rapid ascent (1–2 days) to >14,000 ft
 - 22% incidence for skiers visiting resorts and sleeping at 7,000–9,000 ft, 40% at 10,000 ft
- AMS risk factors:
 - Previous history of high-altitude illness
 - Physical exertion
 - Younger persons (< 50 yr)
 - Physical fitness not protective
 - Obesity and existing lung disease increase the risk
- High-altitude pulmonary edema (HAPE) incidence:
 - < 1–2%
 - Varies with rate of ascent
- High-altitude cerebral edema (HACE) incidence < 1%
- HACE and HAPE are unusual at altitudes under 13,000 ft (4000 m)

Pregnancy Considerations

- Relationship between pregnancy and high-altitude illness is not clearly established.
- Pregnancy-induced hypertension, proteinuria, and peripheral edema are more common at high altitude, which may be related to maternal hypoxemia.
- No evidence of increase in spontaneous abortions, placental abruption, or placenta previa at high altitudes
- Travel by pregnant women with normal pregnancies to moderate altitudes appears safe, although caution should be exercised when traveling > 13,000 ft and for women with complicated pregnancies

Geriatric Considerations

Although elderly persons are more likely to have underlying health problems that may be affected by altitude, such as HTN, COPD, and coronary artery disease, the risk of development of AMS is less in those older than 55 than in other age groups.

ETIOLOGY

- Rapid ascent to > 8,000 ft (about 2,500 m) without proper acclimatization is the most common cause of high-altitude–related illness.
- Rapidity of ascent, final altitude reached, sleeping altitude, and individual susceptibility all play a role in development of high-altitude illness as well.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- AMS:
 - Headache + at least 1 of the following:
 - Nausea/vomiting
 - Fatigue/lassitude
 - Dizziness
 - Difficulty sleeping
 - Onset 4–12 hr after ascent
 - Generally benign and self-limited
 - Symptoms may become debilitating.
- HAPE:
 - Onset 2–4 days after ascent, most commonly on 2nd night
 - Can be life threatening
 - Cough (dry at 1st, then productive)
 - Dyspnea at rest
- HACE:
 - Life threatening
 - Occurs in the presence of HAPE and/or AMS:
 - Seen rarely as isolated entity
 - Onset:
 - May occur 12 hr after onset of AMS
 - Generally requires 2–4 days for development
 - Altered mental status
 - Severe or increasing headache
 - Nausea/vomiting

Pediatric Considerations

- AMS in infants and young children manifested by:
 - Increased fussiness
 - Decreased playfulness
 - Decreased appetite
 - Vomiting

- Sleep disturbances
- Incidence of HAPE is greater in younger individuals (< 20 yr) than in older adults
- No cases of HAPE or HACE have been reported in children < 4 yr old

Physical-Exam

- AMS:
 - Without presence of HAPE or HACE, the physical exam will often be normal:
 - Mild stages of AMS are often misdiagnosed as viral syndromes or hangovers from alcohol ingestions
- HAPE:
 - Tachypnea
 - Rales
 - Cyanosis
 - Fever may be present.
 - Severe respiratory distress and death may occur.
- HACE:
 - Ataxia
 - Papilledema, retinal hemorrhages
 - Altered mental status/global encephalopathy:
 - Focal neurologic deficit less common
 - Seizure (rare)
 - Coma
 - Has been described as “end-stage” AMS

ESSENTIAL WORKUP

- Clinical diagnosis in the setting of recent altitude gain
- AMS:
 - Diagnosis made with history of headache + at least 1 of the following:
 - Nausea/vomiting
 - Lassitude/fatigue
 - Dizziness
 - Insomnia
 - No diagnostic lab or imaging studies
- HAPE:
 - Dyspnea on exertion—universal finding at altitude
 - Dyspnea at rest—symptom of HAPE, worse at night
 - Rales, cyanosis, or cough support diagnosis.
 - Tachycardia, tachypnea often correlate with severity.
- HACE:
 - Cerebellar ataxia with or without other symptoms of AMS
 - Papilledema, retinal hemorrhages are associated findings.

DIAGNOSIS TESTS & INTERPRETATION

Lab

Arterial blood gas (ABG) for HAPE:

- Reveals hypoxemia (pO_2 30–50) and respiratory alkalosis, *not* acidosis

Imaging

- CXR in HAPE:
 - Reveals patchy alveolar infiltrates with areas of clearing between patches
 - Unilateral or bilateral infiltrates (right mid-lung field being most common)
 - Cardiomegaly, “batwing” distribution of infiltrates, and Kerley B lines (typical of cardiogenic pulmonary edema)—are generally absent in HAPE
- CT and MRI scans in HACE:
 - Vasogenic edema of white matter

Diagnostic Procedures/Surgery

ECG in HAPE:

- Tachycardia
- Evidence of right-heart strain

DIFFERENTIAL DIAGNOSIS

- AMS:
 - Alcohol hangover
 - Carbon monoxide poisoning
 - Encephalitis
 - Exhaustion
 - Meningitis
 - Viral syndrome
- HAPE:
 - High-altitude bronchitis and pharyngitis
 - Pneumonia
 - Pulmonary embolism:
 - More rapid onset
 - Pleuritic chest pain
- HACE:
 - Cerebrovascular accidents/transient ischemic attacks:
 - Focal neurologic signs suggest vascular lesion.

TREATMENT

PRE HOSPITAL

- Severe cases require immediate evacuation to lower altitude.

- Do not proceed to higher altitude in the presence of symptoms.
- Oxygen delivery or simulated descent in portable hyperbaric chamber (Gamow bag) can be lifesaving temporary measure making self-rescue possible.

INITIAL STABILIZATION/THERAPY

- HAPE and HACE:
 - _ ABCs:
 - Endotracheal intubation for impending respiratory failure or airway protection
 - _ Establish IV access.
 - _ Supplemental oxygen and monitoring
 - _ CPAP for HAPE

ED TREATMENT/PROCEDURES

- AMS:
 - _ Mild cases usually self-limited:
 - Symptomatic treatment
 - Halt ascent until symptoms resolve
 - _ Acetazolamide for moderate to severe symptoms
 - _ Ibuprofen or acetaminophen for headache
 - _ Promethazine or ondansetron for nausea
 - _ Supplemental oxygen in severe cases
 - _ Descent for severe or persistent symptoms
 - _ Acetazolamide for AMS prophylaxis:
 - In high-risk individual with planned rapid ascent
- HAPE:
 - _ Immediate descent for moderate/severe symptoms
 - _ Mild cases may be managed without descent if:
 - Adequate oxygen supplies available
 - Serial medical exam possible
 - Immediate descent for any deterioration in clinical status
 - _ Bed rest to avoid exercise-induced pulmonary HTN
 - _ Supplemental oxygen:
 - High flow rates (6–8 L/min) until improvement, then continue with lower flow rates
 - _ Nifedipine when other interventions are unavailable
 - _ β -agonist inhalers may be helpful.
 - _ Hyperbaric therapy is available and immediate descent is not possible
- HACE:
 - _ Immediate evacuation to lower altitude
 - _ Oxygen
 - _ Dexamethasone
 - _ Bed rest with elevation of head at 30°, and in severe cases, aggressive

management of elevated intracranial pressure

MEDICATION

- Acetazolamide:
 - AMS treatment: 250–500 mg (peds: 5 mg/kg) PO BID
 - AMS prophylaxis: 250 mg PO BID (peds: 5 mg/kg) PO BID; start 24 hr before ascent
- Dexamethasone: 8 mg IV, then 4 mg PO/IV QID
- Ibuprofen: 800 mg (peds: 5–10 mg/kg) PO TID
- Nifedipine: 10 mg PO, then 30 mg sustained release (SR) PO QD
- Promethazine: 12.5–25 mg (peds: 0.25–1 mg/kg) PO/PR (per rectum)/IM q4–6h

First Line

- Acetazolamide (AMS)
- Nifedipine (HAPE)

Second Line

Dexamethasone

The use of multiple medications in treating high-altitude illness is not supported by the current literature

FOLLOW-UP

DISPOSITION

Descent to a lower altitude mandatory in severe cases

Admission Criteria

- Persistent symptoms after observation in lower-altitude ED require admission.
- HAPE
- HACE

Discharge Criteria

Once clinical improvement seen and oxygen saturation > 95% on room air at sea level or appropriate normal saturation at higher altitudes

Issues for Referral

Offer prophylactic therapy for future ascents in patients with recurrent AMS (acetazolamide) or HAPE (nifedipine).

PEARLS AND PITFALLS

- The symptoms of high-altitude illness can resemble mild viral syndromes.

- Failure to consider high-altitude illness is a common pitfall.
- When managing altitude illness, once symptoms have developed and until they resolve, further ascent is contraindicated.
- Ataxia and dyspnea at rest are potentially early indicators of HACE and HAPE, respectively.
- Hyperbaric oxygen and adjunctive medications should be considered when descent is not possible.

HIP INJURY

Siobhan Gray

BASICS

DESCRIPTION

- Hip injury includes hip fractures and dislocations of the proximal femur due to minor or major trauma or overuse.
- Hip fracture: Fracture of proximal femur. Classified as intracapsular or extracapsular.
 - Intracapsular fracture: Femoral head or neck; often associated with disruption of femoral neck vessels; significant morbidity due to AVN:
 - Femoral head fracture: Usually associated with hip dislocation (anterior > posterior).
 - Femoral neck fracture: Usually older adults with minor trauma, or young patient with major trauma; symptoms vary. Patient may or may not be ambulatory. Often site of stress fracture in runners/military recruits.
 - Extracapsular fractures: Below acetabular capsule. Normally do not disrupt blood flow. Morbidity typically due to patient immobilization: DVT, PE:
 - Trochanteric fractures: Greater trochanter usually fractured by avulsed at insertion in gluteus medius. Lesser trochanter usually fractured by avulsed from forceful contraction of iliopsoas; seen in young athletes and children.
 - Intertrochanteric fracture: Defined as occurring in line between greater and lesser trochanters. Common in elderly, osteoporosis patients often due to fall. Marked external rotation and shortening. Can be stable or unstable. Nonambulatory.
 - Subtrochanteric fracture: Usually due to direct, significant trauma in younger patients or lesser trauma in elderly. Common site of pathologic fracture. Can be site of significant blood loss and shock.
- Hip dislocation: Disarticulation of femoral head. Classified as posterior, anterior, and central:
 - Posterior dislocation (most common):
 - Often from motor vehicle accident (MVA) in which knees strike dashboard
 - 10% associated with sciatic nerve injury
 - Anterior dislocation: 10% hip dislocations:
 - Often due to trauma with sudden abduction of thigh
 - Associated femoral head fractures, femoral nerve injury
 - Can be anterior superior, or anterior inferior

- Central dislocation with acetabular fracture:
 - Usually from direct impact to greater trochanter
 - Associated significant blood loss, sciatic nerve injury

Pediatric Considerations

- Hip dislocation: Uncommon; often spontaneously reduced at time of injury. Concern for tissue trapped in joint space:
 - Trivial force required for posterior hip locations in children <10 yr old
- Proximal femoral physeal fracture: Fracture at growth plate; great risk for osseous necrosis
- Slipped capital femoral epiphysis: Minimal trauma, decreased ROM.
- Femoral neck fractures: Relatively common; stress fractures in young athletes
- Intertrochanteric fractures: Rare.
- Must suspect nonaccidental trauma (NAT)
- Consider pathologic fracture with minor trauma.

ETIOLOGY

See individual injuries above.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Groin, hip, thigh, medial knee pain, pain with ambulation/weight bearing in the setting of trauma
- Minor trauma in the elderly due to osteoporosis; high-impact trauma in young adults
- Rarely overuse injury, stress fracture.

Physical-Exam

- Obvious signs of trauma:
 - Deformity or angulation, swelling, open fracture, or missile entrance wound
 - Lower extremity held in position of comfort
- Hip fracture: Flexion, abduction, external rotation
- Posterior hip dislocation: Flexion, *adduction, internal rotation* of hip, flexion of knee, hip immobile
- Anterior hip dislocation: Flexion, *abduction, external rotation* of hip, thigh shortening, hip immobile

Pediatric Considerations

- Pediatric fracture patterns different due to developing cartilaginous components:

- Assess for dislocation of the femoral capital epiphysis.
- Fracture classification and management are also different.
- Suspect NAT without obvious mechanism of injury.
- Consider hip pain due to a separate process (limb-length discrepancy, neuromuscular disorders, neoplastic invasion of bone).

ESSENTIAL WORKUP

- Assess distal pulses, palpate compartments, evaluate sensation and motor function.
- If pulses are not equal or palpable, bedside Doppler or angiography may be necessary.
- Search for associated injuries:
 - Neurologic deficits
 - Vascular injury
 - Pelvic fractures (include acetabular fractures)
 - Spinal fractures
 - Blunt abdominal trauma
- Radiographs as outlined below:
 - Remove splints and clothing when taking films.
 - Positive exam plus negative standard films indicates hip fracture until proven otherwise; further imaging (CT or MRI scan) is indicated.
 - Hip dislocations are orthopedic emergencies and require prompt reduction (<6 hr) with limited attempts.

Pediatric Considerations

- In suspected child abuse, obtain appropriate radiographs to evaluate for other injuries.
- Assess markers for NAT:
 - Delay in presentation; history of mechanism inconsistent with injury
 - Isolated trauma to the thigh, associated burns, bruises, linear abrasions

DIAGNOSIS TESTS & INTERPRETATION

Lab

CBC, type and cross-match, INR if appropriate

Imaging

- Standard films: AP pelvis and true lateral of hip, oblique view.
- Femoral neck fracture: AP pelvis with hip internally rotated 15–20°
- Pubic rami and acetabular fractures: Pelvic inlet and outlet views
- Acetabular fractures: Judet views (oblique views of hip)
- High suspicion with negative plain films: CT, MRI, or bone scan. MRI most sensitive.

- Must get postreduction x-ray and/or CT scan.

Diagnostic Procedures/Surgery

- Joint aspiration with or without arthrogram under fluoroscope if a septic joint, foreign body, or hemarthrosis, especially in gunshot wounds to hip is suspected
- Operative repair or wash out

DIFFERENTIAL DIAGNOSIS

- Pubic ramus fracture
- Acetabular fracture
- Septic joint
- Thigh, knee, ankle, or foot injury
- Trochanteric bursitis
- Iliotibial band tendinitis
- Hip contusion

TREATMENT

PRE HOSPITAL

- Neurovascular exam is essential.
- Immobilize extremity in position of comfort for patient.

INITIAL STABILIZATION/THERAPY

- Airway, head, chest, or abdominal injuries take precedence in multiple trauma.
- Maintain pelvis and hip stability.
- Monitor BP continuously.
- Cautions:
 - DO NOT apply traction.
 - Monitor closely for development of hemorrhagic shock as thigh can contain 4–6 U of blood.

ED TREATMENT/PROCEDURES

- Maintain pelvis and hip stability.
- Remove splint and clothing.
- Pain control:
 - Isolated hip injuries: Parenteral analgesia
 - Multitrauma or pediatric patients: Femoral nerve block
- Orthopedic consultation:
 - Necessary for all hip fractures and dislocations
 - Emergent if neurovascular compromise
 - Open fractures must go directly to the OR for irrigation and debridement.
 - May need reduction in OR after 1–2 quick ED attempts to reduce.

- Fractures requiring surgery:
 - Cefazolin IV
- Open fractures with lacerations, extensive soft-tissue damage, or contamination:
 - Add gentamicin/tobramycin, tetanus.
- If highly contaminated wound: Add penicillin G to cover clostridial species.
- Gunshot wounds:
 - Culture missile track, iodine dressing
- Hip dislocation:
 - A true orthopedic emergency
 - Incidence of avascular necrosis and degenerative joint disease increases linearly with time to reduction:
 - Perform reduction in ED, ideally < 6 hr from onset.
 - Allis or Stimson maneuvers
 - Also described: With patient in lateral decubitus position, move hip from flexed and adducted position to full external rotation with tibia perpendicular to floor.
 - Procedural sedation with etomidate, ketamine, or methohexital + midazolam, propofol + fentanyl
 - Look for fractures on postreduction imaging (plain film, CT).
 - Patients with prior hip arthroplasty may be reduced in the ED with procedural sedation and appropriate monitoring.

MEDICATION

- Antibiotics
 - Cefazolin: 1 g IM/IV q6–8h (peds: 25–50 mg/kg IM/IV div. q6–8h max. 1 g)
 - Gentamicin/tobramycin: 3–5 mg/kg/d IV/IM div. q8h (peds: 2–2.5 mg/kg q8h)
 - Penicillin G: 2 million U IV q4h (peds: 100,000–400,000 U/kg/d IV div. q4–6h to max. 24 million U in 24 hr)
- Moderate sedation:
 - Etomidate: 0.1–0.3 mg/kg IV once (not recommended for < 12 yr)
 - Fentanyl: 1–4 µg/kg IV over 1–2 min once (peds: > 6 mo 1–2 µg/kg IV once)
 - Ketamine: Not recommended in adults owing to emergence reaction (peds: 1–2 mg/kg IV, 4 mg/kg IM once)
 - Methohexital: 1–1.5 mg/kg IV once (peds: Not recommended)
 - Midazolam: 0.07 mg/kg IM or 1 mg slowly q2–3min up to 2.5 mg max. (peds: 0.25–1 mg/kg PO once to a max. of 15 mg PO; 6 mo–5 yr: 0.05–0.1 mg/kg IV titrate to max. 0.6 mg/kg; 6–12 yr: 0.025–0.05 mg/kg IV titrate to max. 0.4 mg/kg)
 - Propofol: 40 mg IV q10sec until induction; 5–10 µg/kg/min IV continuous infusion
- Pain control:

- Hydromorphone: 0.5–2.0 mg IM/SC/slow IV q4–6h PRN; titrate for pain control (peds: 0.015 mg/kg/min per dose IV q4–6h PRN)
- Morphine: 2–10 mg IV q4h, titrate for pain control (peds: 0.1 mg/kg IV q4h, titrate for pain control to max. 15 mg/dose)
 - Morphine pediatrics use preservative free preparation.

First Line

- Antibiotics: Cefazolin IV
- Pain: Morphine
- Sedation: User dependent. Etomidate, adults; ketamine, children.

Second Line

- Antibiotics: Ceftriaxone + gentamicin
- Pain: Hydromorphone, fentanyl, nerve block
- Sedation: Methohexital, midazolam, propofol

FOLLOW-UP

DISPOSITION

Admission Criteria

- All hip fractures
- Septic joint
- Suspicion of occult fracture
- Suspicion of NAT in children
- All pediatric hip fractures and dislocations
- Most dislocations of hip

Discharge Criteria

- Hip pain attributable to other cause
- Fracture ruled out (negative radiographs *plus* negative clinical exam)
- Patient with successful reduction of dislocated hip arthroplasty may be considered for discharge in consultation with orthopedics and with appropriate follow-up.
- Stress fracture, crutches, follow-up with bone scan or repeat x-rays.

Issues for Referral

- Chronic pain may need primary physician and pain specialist.
- Pediatric patients and elderly may need physical therapy.

FOLLOW-UP RECOMMENDATIONS

- Discharged patients with hip pain not due to fracture/dislocation are referred to appropriate primary doctor.

- Stress fracture, nonweight bearing: Follow-up orthopedics 2–3 days

PEARLS AND PITFALLS

- Location of fracture determines risk factors for morbidity such as AVN and bleeding.
- Hip dislocations are orthopedic emergencies and require prompt reduction and few attempts.
- Be suspicious of occult fractures, as x-ray may miss 10% fractures. Follow-up study needed (CT or MRI) and possible admission.

HIRSCHSPRUNG DISEASE

Sheila McMorrow

BASICS

DESCRIPTION

- Described in 1886 by Harold Hirschsprung as a cause of constipation in early infancy
- Congenital aganglionosis megacolon
- 1:5,000 live births
- Overall mortality of Hirschsprung enterocolitis is 35–50%

ETIOLOGY

- Absence of enteric ganglia in the distal bowel
- Normally, ganglia are derived from neural crest and migrate along the intestine, arriving at the proximal colon by 8 wk of gestation and in the rectum by 12 wk of gestation.
- Failure of neural crest cells to migrate into parasympathetic Meissner (submucosal) and Auerbach (myenteric) ganglions results in an aganglionic segment and clinical disease
- Affected bowel classically presents at the internal anal sphincter and involves the rectosigmoid colon (75% of cases)
- May extend the entire length of the GI tract (often fatal)
- Aganglionic segment chronically contracts, forming an obstruction to the passage of stool, and proximal bowel distends to hold the stool that has not passed
- Stimulation of the anus allows passage of stool
- Genetic and other causes
 - Mutations of the *ret* proto-oncogene found in both familial and spontaneous forms
 - Male-to-female ratio 4:1
 - 8% with positive family history; 5–12% of siblings are affected
 - Associated chromosomal abnormality in 5–15%, most commonly trisomy 21 (Down syndrome)
 - Other congenital anomalies in 18%—GI, cardiac, craniofacial, cleft palate, congenital deafness

DIAGNOSIS

SIGNS AND SYMPTOMS

Children with Hirschsprung disease are usually diagnosed by the age of 2 yr

- Three presentations, varying with age:

- Neonatal
 - Abdominal distension
 - Failure of passage of meconium within the 1st 48 hr of life
 - Vomiting
 - Enterocolitis (abdominal pain, fever, foul-smelling and/or bloody diarrhea, vomiting, leading to sepsis and potential intestinal perforation)
 - Sepsis
- Infancy
 - Constipation
 - Chronic abdominal distension
 - Vomiting
 - Failure to thrive
 - Enterocolitis (abdominal pain, fever, foul-smelling and/or bloody diarrhea, vomiting, leading to sepsis and potential intestinal perforation)
 - Toxic megacolon
- Later childhood and adulthood
 - Chronic constipation with obstruction and rare history of overflow incontinence and often refractory to normal treatment protocols
 - Enterocolitis (abdominal pain, fever, foul-smelling and/or bloody diarrhea, vomiting, leading to sepsis and potential intestinal perforation)
 - Abdominal distension
 - Bloody, foul-smelling diarrhea
 - Malnutrition

History

- Sepsis
- Bowel movements frequently require rectal stimulation or enemas
- Narrow caliber stools
- Encopresis and diarrhea are uncommon
- Absence of inciting factors associated with functional constipation (i.e., fissures, toilet training, diet)

Physical-Exam

Possible palpable colon on the left

- Abdominal distension and symptoms of intestinal obstruction
- Findings consistent with malnutrition, failure to thrive
- Rectal exam commonly reveals an empty rectal vault

ESSENTIAL WORKUP

Plain abdominal radiographs:

- Distended small bowel and proximal colon (megacolon) with an empty rectum are common findings
- Transition zone into a narrowed rectosigmoid segment
- In neonates, films will commonly show a distal obstructive pattern
- In children with chronic constipation, films may show only large amounts of stool
- In children with enterocolitis, bowel wall edema or pneumatosis intestinalis may be present

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC, electrolytes, glucose, BUN, Cr
- Urinalysis
- Blood culture, if toxic

Imaging

Barium enema:

- Obtain after stabilization; contraindicated if perforation and enterocolitis are suspected
- Dilated colon proximal to the contracted aganglionic colon with uncoordinated peristalsis, and transition zone between the narrowed aganglionic segment and the dilated and normally innervated segment
 - A transition zone may not be apparent in neonates, because of insufficient time to develop colonic dilatation, or in infants who have undergone rectal exams and enemas
 - May demonstrate a nondistensible rectum, which is a classic sign of Hirschsprung disease
- Delayed barium evacuation

Diagnostic Procedures/Surgery

- Rectal manometry may assist in diagnosis but is often abnormal in long-standing constipation; children with Hirschsprung disease fail to demonstrate reflex relaxation of the internal anal sphincter in response to inflation of a rectal balloon
- Full-thickness rectal biopsy confirms diagnosis by the lack of ganglion cells
 - The definite diagnosis of Hirschsprung disease rests on histologic review of rectal tissue

DIFFERENTIAL DIAGNOSIS

- Neonates
 - Meconium ileus or meconium plug syndrome from cystic fibrosis
 - Intestinal or anal atresia or hypoplasia
 - Malrotation or duplication with volvulus
 - Necrotizing enterocolitis

- Sepsis
- Infants and children
 - Functional constipation
 - Toxic—opiates, anticholinergics
- Infectious—botulism
- Acquired aganglionic colon
 - Metabolic or endocrine—hypothyroid/parathyroid, adrenal insufficiency, electrolyte abnormality
 - Spinal cord defects
- Abdominal masses

TREATMENT

INITIAL STABILIZATION/THERAPY

- Airway, breathing, and circulation management with monitoring as appropriate
- Initial bolus of isotonic IV fluids (20 cc/kg) for shock, dehydration, sepsis

ED TREATMENT/PROCEDURES

- Infants should be managed for bowel obstruction; in the presence of vomiting, an NG tube may be necessary
- Consultation with a pediatric surgeon
 - Triple antibiotics are indicated in toxic patients or those with enterocolitis
- Unstable patients may require decompression by emergent loop colostomy
 - Stable children may have their workup done as an outpatient
 - Definitive treatment is resection of the aganglionic section of bowel to achieve normal ganglion containing bowel within 1 cm of anal opening
- Enterocolitis may occur at any time, even after operative intervention

MEDICATION

- Ampicillin 50 mg/kg div. q6h IV
- Gentamicin 2.5 mg/kg div. q12–24h IV
- Metronidazole 7.5 mg/kg div. q12–48h IV

FOLLOW-UP

DISPOSITION

Admission Criteria

- Neonates and infants presenting with bowel obstruction
- Enterocolitis
- Ill-appearing infants should be admitted to a neonatal/pediatric intensive care unit with available pediatric surgeons

Discharge Criteria

- Well hydrated and taking oral fluids
- Older children with the chief complaint of constipation
- Responsible parents
- Close follow up with a primary care provider

Issues for Referral

Care should be supervised by pediatric gastroenterology and/or pediatric surgery

PEARLS AND PITFALLS

- Presentation varies with the age of the child
- Continuum may vary from toxicity and enterocolitis to chronic constipation
- Toxic child need stabilization, antibiotics and emergent imaging and surgical intervention

HIV/AIDS

Anika Backster • Murtaza Akhter

BASICS

DESCRIPTION

- **AIDS:** Defined as lab evidence of HIV with CD4 < 200 or AIDS defining illness— infection (e.g., cryptosporidium), malignancy (e.g., Kaposi, cervical cancer), or other (e.g., HIV wasting disease, HIV encephalopathy)
- **Opportunistic diseases:**
 - _ CD < 500 cells/mm³:
 - Oropharyngeal candidiasis
 - Pneumococcal infection
 - Hairy leukoplakia
 - Immune thrombocytopenic purpura
 - _ CD4 < 200 cells/mm³:
 - Pneumocystis jiroveci pneumonia (PCP)
 - Cryptococcal infection
 - Disseminated tuberculosis
 - Cryptosporidiosis
 - Isosporiasis
 - Toxoplasmosis
 - Histoplasmosis
 - _ CD4 < 50 cells/mm³:
 - CNS lymphoma
 - Mycobacterium avium complex (MAC)
 - TB pericarditis or meningitis
 - Cytomegalovirus (CMV)
 - Cholangiopathy: Most common cause *Cryptosporidium parvum*

DIAGNOSIS

SIGNS AND SYMPTOMS

- **Primary HIV infection:** 2–6 wk after exposure:
 - _ Fever and malaise
 - _ Rash on face and trunk
 - _ Flu-like syndrome with lymphadenopathy and hepatosplenomegaly
 - _ Pharyngitis
 - _ Diarrhea
 - _ Up to 90% asymptomatic

- Advanced HIV disease (CD4 < 200):
 - Fatigue
 - Fevers and night sweats
 - Weight loss/wasting
 - Alopecia
 - Chronic diarrhea
 - Cough
 - Dyspnea
 - Hemoptysis
 - Chronic low-grade headache
 - Altered mental status
 - Seizures
 - Dementia
 - Neuropathy
 - Painless visual loss
 - Skin lesions

History

- Risk factors:
 - Sexual promiscuity, multiple sexual partners
 - IV drug abuse
 - Men who have sex with men
 - Blood transfusions prior to 1985
 - Unprotected sex with at-risk partners
 - Uncircumcised
- Most recent CD4 count and viral load, lowest CD4 count
- History of or current use of antiretroviral medications
- Medication compliance
- Length of diagnosis/illness
- History of opportunistic infections
- Previous hospitalizations or ICU admissions

ESSENTIAL WORKUP

- HIV serologic tests as noted below:
 - There is a window of 24 wk between primary infection and seroconversion, during which tests may be negative.
 - DNA amplification testing can be positive within 1–2wks of infection, although may not be practical to perform from ED and requires close follow-up and counseling.
- Respiratory symptoms:
 - Chest radiograph
 - Arterial blood gas (ABG)
 - Sputum for Gram stain, AFB, and culture

- Serum LDH—elevated in PCP
- Blood cultures
- Cardiac symptoms:
 - Serum cardiac markers, electrolytes
 - CXR
 - ECG in cases of suspected pericarditis, effusion, or tamponade
 - Blood cultures if endocarditis is suspected
 - Drug screen for cocaine and amphetamines
- Neurologic symptoms:
 - Head CT with and without contrast
 - Lumbar puncture with opening pressure
 - CSF for glucose, protein, Gram stain and culture, cell count with differential, AFB smear, India ink stain, herpes simplex and cryptococcus antigen, and VDRL
- GI symptoms:
 - Stool for ova and parasites, Gram stain, culture, and *Clostridium difficile* assay
 - Urine analysis
 - For women: Urine pregnancy test, pelvic exam with wet mount, and gonorrhea/chlamydia testing
 - Liver functions tests, amylase, and lipase
 - Hepatitis serologies
 - Low threshold for CT abdomen/pelvis
 - US if biliary symptoms present
 - Low threshold for surgical consult, as HIV patients may not present with classic acute abdomen
- Fever workup:
 - Include aerobic/anaerobic, fungal, AFB, and MAC blood cultures
- Ocular symptoms:
 - Fluorescein staining with slit lamp exam

DIAGNOSIS TESTS & INTERPRETATION

Lab

- ELISA:
 - Detects IgG antibody against HIV
 - Sensitivity and specificity ~ 99%
 - Can be negative during the window period
- Western blot:
 - Detects IgG antibody against HIV proteins p24, gp 120, gp 41
 - Used to confirm a positive ELISA
 - Able to detect HIV during the 6 mo seroconversion period
- Rapid HIV testing:

- Results available in 5–20 min
- 4 types of tests currently available
- Samples include oral swabs, whole blood, serum, or plasma
- All reactive tests require confirmatory testing with western blot or ELISA
- >99% specific and sensitive
- Absolute lymphocyte count (ALC):
 - Multiply WBC × percent lymphocytes
 - If ALC >2,000, likely CD4 >200, if ALC <1,000, likely CD4 <200

Imaging

- CXR:
 - Bilateral interstitial infiltrates: PCP
 - Reticulonodular infiltrates: TB, KS, or fungal pneumonia
 - Hilar lymphadenopathy with infiltrate: TB, cryptococcosis, histoplasmosis, neoplasm
 - Lobar consolidation: Bacterial pneumonia
 - Cavitation: TB, necrotizing bacterial pneumonia, coccidioidomycosis
 - Normal x-ray does not rule out PCP or TB
- Head CT with and without IV contrast:
 - Multiple ring-enhancing lesions with edema in basal ganglia or cortex: Toxoplasmosis or CNS lymphoma
 - Subcortical nonenhancing lesions: PML
- Abdominal/pelvic CT:
 - Splenomegaly: CMV, TB
 - Intestinal perforation or bowel obstruction: CMV colitis, lymphoma, histoplasmosis, MAC, appendicitis, ulcer disease, KS
 - Cholecystitis or cholangitis: Cryptosporidium, Microsporidium, CMV
 - Pancreatitis: Medication-related, neoplasm, infectious

DIFFERENTIAL DIAGNOSIS

- For pulmonary symptoms with HIV:
 - Pulmonary emboli
 - Pulmonary HTN
 - TB
 - Pneumonia: Bacterial, fungal, viral
 - Pulmonary malignancies
 - Lymphocytic interstitial pneumonitis
- For CNS symptoms with HIV:
 - Neurosyphilis
 - CMV or HSV encephalitis
 - Toxoplasmosis
 - CNS lymphoma
 - Meningitis (bacterial, coccidioidal, etc.)

- Subarachnoid hemorrhage
- Cerebral infarction
- HIV or metabolic encephalitis
- Progressive multifocal leukoencephalopathy
- Cardiac symptoms with HIV:
 - Cardiomyopathy
 - Pericarditis/myocarditis
 - Endocarditis
 - Acute coronary syndrome
 - Pericardial effusion
- Oral symptoms with HIV:
 - Fungal infection (i.e., candidiasis)
 - Viral lesions (HSV, CMV, hairy leukoplakia)
 - Bacterial lesions (TB, periodontal disease)
 - Autoimmune (salivary gland disease, aphthous ulcers)
 - Neoplasm (KS, lymphoma)
- Esophageal symptoms with HIV:
 - Infectious esophagitis (candida, CMV, HSV)
 - Reflux esophagitis
- Diarrhea with HIV:
 - Medication side effect
 - Parasites (Cryptosporidium, Giardia, Isospora)
 - Bacteria
 - Viral (CMV, HSV, HIV)
 - Fungi (histoplasmosis, cryptococcus)
 - HIV-associated enteropathy
- Hepatomegaly with HIV:
 - Hepatitis
 - Opportunistic infection (CMV, MAC, TB)
- Renal disease with HIV:
 - Drug nephrotoxicity
 - HIV nephropathy
 - Vasculitis
 - Obstruction

TREATMENT

ED TREATMENT/PROCEDURES

- Patients who appear to have bacterial infections, appear toxic, or have rapidly progressive symptoms should receive their 1st dose of antibiotics in the ED.
- Begin HIV treatment if: Low CD4 (< 350) or high viral load, pregnancy, AIDS defining illness or HIV-associated nephropathy (in general, patients with

documented primary HIV infection also undergo resistance testing after the diagnosis has been established)

- Triple therapy (HAART):
 - _ 1 non-nucleoside reverse transcriptase inhibitors (NNRTI) and 2 nucleoside reverse transcriptase inhibitors (NRTI)
 - _ 1 PI and 2 NRTIs
 - _ Triple NRTI
- Postexposure prophylaxis:
 - _ Start therapy within 2 hr if possible and continue for 4 wk
 - _ 2-drug regimen for most exposures:
 - Zidovudine + lamivudine (combivir)
 - Lamivudine + stavudine
 - Stavudine + didanosine
 - _ 3-drug expanded regimen for very high-risk exposure
- Toxoplasmosis: Pyrimethamine:
 - _ Sulfadiazine
 - _ Leucovorin
 - _ Steroids for cerebral edema
 - _ Treat for at least 6 wk
- Cryptococcal meningitis:
 - _ Amphotericin B
 - _ Flucytosine
 - _ Treat with above for 2 wk, then fluconazole for 8 wk
- CMV retinitis: Ganciclovir
- Esophageal candidiasis:
 - _ Fluconazole for 14–21 days
- MAC: Clarithromycin:
 - _ Ethambutol
 - _ May add rifabutin if severe immunosuppression
- PCP:
 - _ Trimethoprim/sulfamethoxazole
 - _ Pentamidine or dapsone for sulfa-allergic patients
 - _ If PaO₂ < 70 mm Hg or A-a gradient > 35 mm Hg, add prednisone 40 mg PO BID for 5 days, then taper
- Oral candidiasis: Clotrimazole troches
- HIV acute demyelinating polyneuropathy: Plasmapheresis

MEDICATION

- Common medication complications:
 - _ Hypersensitivity reaction: Abacavir
 - _ Pancreatitis:
 - Dideoxyinosine
 - Dideoxycytidine

- Didanosine
- Lamivudine
- Cotrimoxazole
- Pentamidine
- Ritonavir
- Stavudine
- Zalcitabine
- _ Peripheral neuropathy:
 - Didanosine
 - Isoniazid
 - Linezolid
 - Stavudine
 - Zalcitabine
- _ Kidney stones: Indinavir and Atazanavir
- _ Hepatotoxicity: All agents to some degree:
 - Nevirapine
 - Didanosine
 - Stavudine
- _ Lactic acidosis: Stavudine:
 - Didanosine
- _ Stevens–Johnson syndrome:
 - Nevirapine
 - Atazanavir
 - Delavirdine
 - Efavirenz
 - Cotrimoxazole
 - Trimethoprim/sulfamethoxazole
- _ Hemolytic anemia:
 - Dapsone (used for treatment of TB)
 - Zidovudine with ribavirin
- _ Psychosis: Efavirenz
- _ Hypoglycemia: Pentamidine
- _ Postural hypotension: Maraviroc
- _ Hyperlipidemia, truncal obesity, and atherosclerosis: Stavudine:
 - Protease inhibitors
- _ Dilated cardiomyopathy: Zidovudine
- _ Benign increase in unconjugated bilirubin: Atazanavir and indinavir
- _ Macrocytic anemia: Zidovudine
- _ Many cause some hematologic effects, GI upset, and rash

DISPOSITION

Admission Criteria

- Unexplained fever with CNS involvement or suspected endocarditis
- Neutropenic fever
- Hypoxemia ($\text{PaO}_2 < 70$ mm Hg)
- Cardiac symptoms suggestive of ACS
- Pericardial effusion
- Suspected bacterial pneumonia or TB
- A change in neurologic status
- New-onset seizures
- Hemodynamic instability
- Inability to ambulate or tolerate oral intake
- Intractable diarrhea with dehydration

Discharge Criteria

The patient can maintain adequate oral intake, provide self-care, and ambulate.

Issues for Referral

- Patient should be referred to a primary HIV care provider for initiation of HAART therapy regimen and ongoing care.
- Be alert for signs of depression and refer for counseling or psychiatric treatment as this may inhibit treatment compliance.
- HIV patients are at higher risk for many malignancies—refer those with concerning symptoms for follow-up.

PEARLS AND PITFALLS

- Immune reconstitution inflammatory syndrome usually manifests within 8 wk of initiation of HAART as symptoms of opportunistic or autoimmune disease.
- For occupation exposures, there is a low risk of seroconversion (0.3% for significant percutaneous exposure and 0.09% for mucocutaneous).
- HIV patients on HAART should be considered at higher risk for insulin resistance and acute coronary syndrome/CAD, independent of other risk factors.
- Measure oxygen saturation after walking in patients with a normal CXR and symptoms of pneumonia to help diagnose PCP.
- HIV is an independent risk factor for COPD, pulmonary hypertension, CVA, venous thromboembolic disease, TTP, osteoporosis, and osteonecrosis of the hip.

HORDEOLUM AND CHALAZION

Shari Schabowski

BASICS

DESCRIPTION

- Result from inflammatory processes involving the glands of the eyelid along the lash line:
 - Hordeolum—acute glandular obstruction resulting in inflammation and abscess formation
 - Chalazion—end result of inspissation of glandular contents and chronic granulomatous inflammation
- Hordeolum:
 - Develops owing to outflow obstruction in 1 or more of the glands of the eyelid
 - Obstructed glands may become secondarily infected.
 - May progress to localized abscess formation or may be complicated by periorbital cellulitis
- Chalazion:
 - Chronic granulomatous inflammation in the meibomian gland:
 - Originates from inspissated secretions
 - Blockage of the gland's duct at the eyelid margin may result in release of the contents of the gland into the surrounding eyelid soft tissue.
 - A lipogranulomatous reaction ensues
 - Occasionally, chalazia become secondarily infected.
 - May evolve from incompletely drained internal hordeolum

ETIOLOGY

Hordeolum:

- May become secondarily infected:
 - Staphylococcus most common
- Predisposing conditions:
 - Meibomian gland dysfunction
 - Blepharitis
 - Rosacea
 - Previous hordeolum

DIAGNOSIS

SIGNS AND SYMPTOMS

- Hordeolum:

- Develops acutely when glandular outflow is obstructed
- Red, tender, painful, swollen mass along the eyelid margin
- Typically solitary, rarely may be multiple
- May be recurrent
- Well-localized inflammation
- Presentation depends on which gland is affected:
 - External hordeolum (stye):
 - Originates from obstruction of the superficial sebaceous or sweat glands whose ducts are located between the eye lashes
 - Exquisitely tender small mass that typically points anteriorly
 - Internal hordeolum:
 - Originates from obstruction of the sebaceous glands whose ducts are located on the inner aspect of the lid margin
 - Painful small mass that is palpable through the eyelid
 - May cause a foreign body sensation in the eye and visual disturbance
 - Typically more inflamed, larger, and more painful
 - May point internally or through skin
- Nonsystemic process
- May be complicated by:
 - Conjunctivitis
 - Periorbital cellulitis
- Chalazion:
 - Firm, circumscribed, nontender, or minimally tender nodule:
 - Typically long standing
 - Noninflamed
 - Symptoms most commonly owing to physical properties:
 - Disrupts natural contour of eye
 - Obstructs visual field/peripheral vision
 - Pressure on globe
 - Corneal desiccation or injury due to exposure
 - Nonacute, nonemergent process, which requires no urgent or emergent intervention unless secondary corneal or significant globe pressure is present.

History

Hordeolum—sudden, well localized, painful mass along the margin of eyelid:

- No systemic symptoms

Physical-Exam

Focal, tender, inflammation of an external or internal gland of the eyelid:

- Minimal surrounding edema may be seen
- Abscess may point within lash line, from palpebral conjunctiva or externally via

skin of the lid

ESSENTIAL WORKUP

- Complete ophthalmologic exam including slit lamp exam and corneal evaluation
- Evaluation for evidence of associated cellulitis and/or systemic findings
- Hordeolum:
 - Identify the origin of the abscess
- Chalazion:
 - Determine whether physical properties of chalazion result in corneal exposure and injury.

DIAGNOSIS TESTS & INTERPRETATION

Lab

Cultures of any drainage rarely aids in management

DIFFERENTIAL DIAGNOSIS

- Blepharitis
- Dacryocystitis
- Dacryoadenitis
- Pyogenic granuloma
- Sebaceous cell carcinoma
- Basal cell carcinoma
- Squamous cell carcinoma

TREATMENT

ED TREATMENT/PROCEDURES

- Hordeolum—relieve obstruction and prevent abscess formation
 - Warm compresses for 15 min 4–6 times per day
 - Gently massage the nodule to express obstructed material
 - Rarely, in severe cases, incision and drainage of internal hordeolum may be necessary:
 - Typically done by ophthalmologist
 - If pointed toward the conjunctiva, vertical incision is made to avoid injury to the meibomian glands and reduce corneal injury from inadvertent scarring.
 - External skin incision is very rarely indicated.
 - When necessary, horizontal incision is used
 - Removing single involved eyelash may be helpful in rare more severe cases of external hordeolum
 - Botox

- Chalazion—complaints typically reflect nonemergent aesthetic and cumbersome physical properties of the mass:
 - Referral to ophthalmology for incision and curettage or steroid injection
 - Lubricating eye drops may provide symptomatic relief

MEDICATION

Ophthalmologic moisturizing drops as needed for comfort.

FOLLOW-UP

DISPOSITION

Discharge Criteria

No indication for admission unless secondary complication is present (i.e., marked periorbital cellulitis with systemic symptoms)

Issues for Referral

- Urgent consultation with ophthalmologist should be considered if incision and drainage of internal hordeolum is deemed indicated.
- Chalazia should be referred to ophthalmologist for definitive treatment options.

FOLLOW-UP RECOMMENDATIONS

- Follow-up with ophthalmology in 1–2 days to evaluate response to conservative management.
- Symptoms should completely resolve in 1–2 wk

PEARLS AND PITFALLS

- Conservative treatment of hordeola with warm compresses and gentle massage is the standard:
 - Majority of cases respond without further intervention
 - Emergent incision and drainage is rarely indicated and should only be considered in extreme cases
 - Incision and drainage may result in long-term complications including corneal injury, fistula formation, and aesthetic complications
 - Consult ophthalmology for incision and drainage if possible
- Chalazia do not require emergent intervention:
 - Referral is the standard management

HORNER'S SYNDROME

Richard S. Krause

BASICS

DESCRIPTION

Unilateral sympathetic denervation of the eye produces signs of Horner's syndrome:

- Relaxation of retracting muscles in upper and lower lids:
 - *Ptosis* (drooping of the lids)
- Loss of pupillary dilator innervation:
 - *Miosis* (unopposed pupillary constriction)
- Loss of sympathetic stimulation of sweat glands:
 - Anhidrosis

ETIOLOGY

- 40% unknown (in 1 large series)
- Tumors of lung or metastases to cervical nodes:
 - May interrupt preganglionic sympathetic fibers (between thoracic sympathetic trunk and superior cervical ganglion)
- Trauma: Penetrating neck wounds directly injure sympathetic fibers
- Pneumothorax:
 - Tension pneumothorax may cause traction on sympathetic fibers owing to shift of mediastinal structures.
- Infiltration or infection of cervical nodes:
 - Sarcoidosis, tuberculosis
- Vascular disorders:
 - Migraine or cluster headaches
 - Carotid artery dissection
- Lateral medullary infarction produces Horner's syndrome as part of the Wallenberg syndrome:
 - Presents with vertigo and ataxia, which may overshadow the Horner's syndrome.
- Cavernous sinus thrombosis may present with some of the features of Horner's syndrome:
 - The condition typically causes headache and/or eye pain.
 - Ocular signs include ocular palsies, pain, chemosis, and proptosis.

Pediatric Considerations

- Hereditary Horner's syndrome:
 - Blue iris (or irregular coloration) on affected side
 - Brown on unaffected side (heterochromia iridis)

- Birth trauma:
 - May cause damage to sympathetic chain
- New Horner's syndrome in a child should prompt workup for tumor (neuroblastoma).

DIAGNOSIS

SIGNS AND SYMPTOMS

- Horner's syndrome is characterized by:
 - *Ptoxis*: Drooping of eyelid on affected side, usually slight
 - *Miosis*: Decrease in pupillary size on involved side (pupillary asymmetry ≥ 1 mm)
 - *Anhidrosis*: Lack of sweating on involved side of face
- The importance of Horner's syndrome is its association with certain disease states.

History

Focus on pre-existing conditions that predispose to Horner's syndrome or are risk factors for these conditions:

- Tumors, vascular disease, trauma:
 - Minor trauma often precedes carotid dissection.
- Cardiovascular risks
- Exposures:
 - For pseudo-Horner
- Pain:
 - Suggests carotid dissection

ALERT

- Acute Horner's syndrome with neck or facial pain:
 - Presume carotid dissection until proven otherwise:
 - 50% of internal carotid artery dissections present with a painful Horner's syndrome.

Physical-Exam

Concentrate on a focused neurologic exam looking to confirm Horner's syndrome and exclude other neurologic deficits:

- General physical exam should focus on identifying signs of other suspected conditions, such as tumor.

ESSENTIAL WORKUP

- History and physical exam focused on neurologic findings
- CXR to screen for tumor or pneumothorax

DIAGNOSIS TESTS & INTERPRETATION

Provocative testing:

- Pharmacologic (cocaine) testing confirms diagnosis of sympathetic ocular lesion:
 - 1 drop of 5% ocular cocaine solution is instilled *into each eye*.
 - Failure of pupil on involved side to dilate as much as other pupil (increase in amount of anisocoria) in 1 hr is confirmatory (positive test).

Lab

Not useful for Horner per se:

- Often needed as part of the workup of causative or associated conditions.

Imaging

- CXR is usually indicated because of the association of chest pathology and Horner's syndrome.
- CT or MRI of head, neck, or chest may be indicated depending on signs and symptoms.
- For suspected carotid dissection:
 - MRA or CTA of the head and neck:
 - Either test is appropriate
 - The lesion is expected to be ipsilateral to the Horner's syndrome.
- Choice of neuroimaging in suspected stroke depends heavily on local protocols and resources.
 - At a minimum, if stroke is suspected CT of the brain is indicated to rule out hemorrhagic stroke.
 - If acute stroke (< 3 hr) is suspected and patient is a candidate for thrombolysis image on STAT basis

Diagnostic Procedures/Surgery

Ocular tonometry is indicated if acute glaucoma is suspected.

DIFFERENTIAL DIAGNOSIS

- Increased intracranial pressure (ICP):
 - Almost always associated with altered level of consciousness (LOC), headache
- *Simple anisocoria (pseudo-Horner's syndrome)*:
 - 15–20% of the population has anisocoria and 3–4% also has miosis and ptosis.
 - Cocaine test is negative (both pupils dilate equally).
 - Inspect photo ID for pre-existing anisocoria.
- Topical medications or exposures are a common cause of miosis.
- Migraine or cluster headache
- Glaucoma, inflammatory ocular diseases, or ocular trauma

TREATMENT

PRE HOSPITAL

Cautions:

- The importance of Horner's syndrome is its association with more serious underlying conditions.
- Patients with increased ICP or tension pneumothorax must be recognized and treated as soon as possible.
- If acute stroke suspected transport to designated stroke center when possible

INITIAL STABILIZATION/THERAPY

- If increased ICP is suspected, initiate measures to control ICP:
 - _ Intubation, osmotic diuretics
- Tension pneumothorax:
 - _ Needle thoracostomy followed by chest tube

ED TREATMENT/PROCEDURES

Horner's syndrome per se requires no ED treatment:

- Causative or associated conditions may require treatment.

MEDICATION

Cocaine: 5% (adult), 2.5% (peds) ophthalmic solution: 1 drop in each eye is diagnostic.

FOLLOW-UP

DISPOSITION

Admission Criteria

Admission for isolated Horner's syndrome is not needed:

- Admission may be needed for underlying condition.

Discharge Criteria

- Stable patients with isolated Horner's syndrome may be discharged with appropriate follow-up arranged for continued workup as outpatient:
 - _ When Horner's syndrome is suspected, emergencies such as carotid dissection or stroke should be ruled out prior to discharge.

FOLLOW-UP RECOMMENDATIONS

Neurologists and ophthalmologists must often be involved in the workup of Horner's syndrome.

PEARLS AND PITFALLS

Must consider underlying etiology

- H02.409 Unspecified ptosis of unspecified eyelid
- H57.03 Miosis

HUMERUS FRACTURE

G. Richard Bruno

BASICS

DESCRIPTION

- Proximal humeral fractures:
 - Typically described as nondisplaced, displaced, and/or fracture/dislocation
 - Account for 5% of all fractures
 - Increased incidence with age
 - 4:1 female to male
 - Vast majority of patients are >60 yr old
 - 3rd most common osteoporotic fracture, after hip and distal radius fractures
 - *Neer classification*: A system that identifies the number of fragments and their location:
 - Fractures consist of 2–4-part fractures; the locations include the anatomic neck, surgical neck, greater tuberosity, and lesser tuberosity.
 - Fracture/dislocations also part of the Neer classification
- Humeral shaft fractures:
 - Account for <3% of fractures
 - May be spiral, oblique, or transverse
 - Humeral shaft fractures (AO classification):
 - Simple
 - Wedge
 - Comminuted (complex)

ETIOLOGY

- Proximal humerus fractures:
 - Most often a history of a fall (low energy)
 - Most common is fall on outstretched hand
 - Less common is violent muscle contraction from shock or seizure or higher-energy injury
- Humeral shaft fractures:
 - High-energy direct trauma (penetrating or blunt) or bending force
 - Less common from fall
 - Stress fractures from throwing injury

DIAGNOSIS

SIGNS AND SYMPTOMS

- Pain, swelling, and tenderness
- Difficulty in initiating active motion
- Arm often closely held against chest
- Shortening of the extremity
- Crepitus may be present
- Ecchymosis
- Neurovascular compromise

History

- Mechanism of injury
- Contributory comorbid factors (age, fall risk, malignancy)
- Associated injuries

Physical-Exam

- Complete exam of the affected extremity:
 - _ Inspect shoulder and humerus for obvious deformity, shortening, and open injuries
 - _ Assess ROM at shoulder, elbow
 - _ Neurovascular exam

ESSENTIAL WORKUP

- Assess individual nerves:
 - _ Radial (special attention in midshaft humeral fractures)
 - _ Median
 - _ Ulnar
 - _ Axillary (sensation to the lateral aspect of the shoulder)
 - _ Musculocutaneous nerve (sensation to the extensor aspect of the forearm)
- Assess vascular supply:
 - _ Presence of radial, ulnar, and brachial pulses
 - _ Good capillary refill in all digits
- Radiology exams to define injury

Pediatric Considerations

- Most common in age <3 or >12 yr
- Neonatal fractures from delivery trauma:
 - _ Most common in neonates >4.5 kg and breech births
 - _ May see pseudoparalysis
- Older children: Same injury mechanisms as adults
- Periosteum thicker in children and limits displacement of humeral shaft fractures
- Proximal humeral fractures:
 - _ Salter I fractures should be considered when films of proximal humerus are normal but significant pain is present

- Salter II most common in younger children
- Consider abuse (especially <3 yr):
 - Injury patterns:
 - Transverse (direct blow)
 - Oblique/spiral (traction and humeral rotation)
 - Metaphyseal fractures (bucket-handle fractures)

DIAGNOSIS TESTS & NTERPRETATION

Imaging

- Plain films:
 - Proximal humeral fractures (at least 3 views):
 - Anteroposterior (AP), lateral, and axillary views
 - Axillary view to assess tuberosity displacement, glenoid articular surface, and relationship of the humeral head to glenoid
 - Humeral shaft fractures:
 - AP and lateral views of entire humerus are mandatory.
 - Include shoulder and elbow views to exclude associated joint involvement.
- CT scan:
 - Helpful in proximal humeral fractures to define complex/comminuted injures and plan surgery
 - Help define relationship of humeral head to glenoid fossa in suspected fracture/dislocations

Diagnostic Procedures/Surgery

Not applicable

DIFFERENTIAL DIAGNOSIS

- Acute hemorrhagic bursitis
- Traumatic rotator cuff tear
- Dislocation
- Acromioclavicular separation
- Calcific tendinitis
- Contusion
- Tendon rupture
- Neurapraxia
- Pathologic fracture

TREATMENT

PRE HOSPITAL

Cautions:

- Avoid excessive movement of the arm, which may produce further neurovascular injury.
- Immobilize with sling and swath and transport.
- Rapid transport in the presence of neurologic or vascular deficits

INITIAL STABILIZATION/THERAPY

- Primary and secondary survey for associated injuries
- Immobilization:
 - _ For comfort
 - _ Prevent fracture displacement
 - _ Prevent neurovascular injury
- Axillary pad may also be used for comfort.
- Pain control
- Application of ice to limit swelling
- Open fractures:
 - _ Cover with a sterile dressing
 - _ Tetanus prophylaxis
 - _ Parenteral antibiotics

ED TREATMENT/PROCEDURES

- Patient should receive adequate analgesia during diagnosis and treatment of injury:
 - _ Narcotics PO/IM/IV are first-line therapy
- Proximal humeral fractures:
 - _ Single-part proximal humeral fractures:
 - >80% of proximal humeral fractures
 - Can be treated nonoperatively
 - Treatment is sling and swath
 - Early ROM exercises often employed
 - _ Displaced, multipart proximal humeral fractures:
 - Use Neer classification to describe
 - >1 cm separation or >45° are considered displaced
 - Orthopedic review and referral is appropriate for 2-part or higher fractures
 - Many 2-part fractures can be reduced and managed nonoperatively
 - 3- and 4-part fractures may need ORIF/hemiarthroplasty
 - Surgical options depend not only on type of fracture, but also patient's age, comorbidities, and patient's functional expectations of the extremity
 - _ Indications for emergent orthopedic consult for proximal humeral fractures:
 - Open fracture
 - Fracture/dislocation that cannot be reduced in ED

- Vascular compromise
- Humeral shaft fractures:
 - Most humeral shaft fractures can be managed nonoperatively and do not require reduction (>90%)
 - 20° of anterior angulation and 30° of varus angulation are well tolerated by the musculature around the humerus.
 - Humerus can tolerate up to 3 cm of shortening with little functional deficit
- Nondisplaced humeral shaft fractures:
 - ED can treat with a coaptation splint
 - Except transverse fractures
 - Functional brace may be utilized by orthopedist
- Transverse fractures:
 - ED treatment should be sling and swath
 - Higher incidence of nonunion
- Displaced humeral shaft fractures:
 - Orthopedist may utilize hanging cast to treat and reduce displaced or shortened fractures.
- Indications for emergent orthopedic consult for humeral shaft fractures:
 - Neurovascular compromise
 - Segmental fractures
 - Fractures extending into articular surface
 - Open fractures
 - “Floating elbow” (fractures with concurrent ipsilateral forearm fractures)

Pediatric Considerations

In children nearing skeletal maturity, it is essential to determine the degree of displacement or separation of the proximal humeral epiphysis, as exact reduction is important to prevent later disturbance of growth.

MEDICATION

- Pain medications:
 - Narcotics (first line)
 - NSAIDS (second line)
- Procedural sedation with closed reductions (see Procedural Sedation)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Open fractures for operative management and parenteral antibiotic therapy
- Fractures associated with vascular compromise

- Displaced fractures that cannot be treated adequately through closed reduction
- Significant associated injuries that require admission and observation

Discharge Criteria

- Nondisplaced fracture
- Fracture treated with closed reduction
- Most closed humeral shaft fractures without other injuries
- More complicated proximal humeral fractures, (i.e., proximal humeral fracture of Neer 3 and 4 type), that may require nonemergent surgery. Discharge should be done in consultation with orthopedist.

Pediatric Considerations

- Pediatric patients are often less compliant with immobilization and less able to verbalize complaints; they may benefit from admission.
- Assess safety of environment in cases suspicious of NAT.

Issues for Referral

- Most humeral fractures should have outpatient orthopedic referral.
- Complicated proximal humeral fractures (Neer classification 2–4) should be reviewed with orthopedist to develop outpatient plan and possible nonemergent intervention.
- Some single-part nondisplaced proximal humeral fractures may be managed by the PCP.
- Displaced humeral shaft fractures require orthopedic referral for definitive care (functional bracing, hanging cast, ORIF, etc.).

FOLLOW-UP RECOMMENDATIONS

- Most patients should be seen in close follow-up for repeat exam of the injured extremity, to verify adequate pain control, and to review treatment plan soon after ED visit.
- Proximal humeral fractures that are stable should be evaluated for early ROM therapy to minimize risk of adhesive capsulitis.

PEARLS AND PITFALLS

- All humeral fractures should have diligent neurovascular exams:
 - Neurovascular exam should be repeated after manipulation.
 - Radial nerve injuries are the most common deficits seen in humeral shaft fractures.
 - Most radial nerve deficits will resolve spontaneously over time (months).
- Avascular necrosis is a risk in proximal humeral fractures that involves the surgical neck or articular surface.
- Patients with multiple-part proximal humeral fractures (Neer 2 or higher) may

often be discharged from the ED, but a plan must be developed with the orthopedist because surgical intervention and/or hemiarthroplasty are possible.

HYDATIDIFORM MOLE

Emi M. Latham

BASICS

DESCRIPTION

- Noninvasive localized tumors arising from trophoblastic tissue
- Can be associated with malignancy
- Twinning with normal pregnancy possible:
 - Higher risk for persistent maternal disease and metastasis
 - Possible to have normal infant
- Complete mole:
 - Estimated in 1/1,500 pregnancies
 - Fetal tissue not present
 - Diffuse chorionic villi swelling
 - Diffuse trophoblastic hyperplasia
 - Malignancy associated in 15–20%, usually lung
 - Genetics:
 - Karyotype: 46,XX (90%); 46,XY (10%)
 - Paternal DNA expressed
 - Enucleate egg fertilized by 2 sperms or by a haploid sperm that duplicates
- Partial mole:
 - Estimated in 1/750 pregnancies
 - Fetal or embryonic tissue often present
 - Focal chorionic villi swelling
 - Focal trophoblastic hyperplasia
 - Malignancy associated in 4–12%
 - Genetics:
 - Karyotype: 90% are triploid 69XXX, 69XXY, rarely 69XYY
 - Maternal and paternal DNA
 - Haploid ovum duplicates and is fertilized by normal sperm, or haploid ovum fertilized by 2 sperms

ETIOLOGY

- Largely unknown
- Extremes of maternal age best estimated risk factor:
 - > 35 yr old carries 5–10-fold risk
 - < 20 yr old
- Previous molar pregnancy carries 1–2% risk in future pregnancies
- Frequency multiple times greater in Asian and Latin American countries:

- 1 per 1,000–1,500 live births in US and Western Europe
- Reported up to 1 per 12–500 live births in other countries
- Deficiency in animal fat and vitamin A
- Smoking (> 15 cigs/day)
- Maternal blood type AB, A, or B
- History of infertility, nulliparity
- Finding in 1 of 600 therapeutic abortions

DIAGNOSIS

SIGNS AND SYMPTOMS

- Usually exaggerated subjective symptoms of pregnancy
- Complete mole:
 - Vaginal bleeding, most common (97%):
 - Late 1st trimester
 - Usually painless and like “prune juice”
 - May also have vaginal tissue passage:
 - Often described as grapelike vesicles
 - Usually occurs in 2nd trimester < 20 wk
 - Hyperemesis from high levels β -hCG
 - Preeclampsia (27%):
 - Visual changes
 - HTN
 - Proteinuria
 - Hyperreflexia
 - Possibly convulsions
 - Hyperthyroidism (7%):
 - Marked tachycardia, tremor
 - Due to high levels of β -hCG or thyroid stimulating substance (thyrotropin)
 - Acute respiratory distress (2%):
 - Tachypnea, diffuse rales, tachycardia, mental status changes
 - Possible embolism of trophoblastic tissue
 - May also be due to cardiopulmonary changes from preeclampsia, hyperthyroidism, or iatrogenic fluid replacement
- Partial mole:
 - Usually does not exhibit dramatic clinical features of complete mole
 - Frequently presents with symptoms similar to patients with threatened or spontaneous abortion:
 - Vaginal bleeding
 - May have fetal heart tones
 - Often presents at more advanced gestational age

History

Similar to that of pregnancy:

- Missed menstrual periods
- Positive pregnancy test
- Nausea, vomiting, vaginal bleeding

Physical-Exam

- Uterine size/date discrepancy occurs in 50–66% of cases
 - Complete mole usually larger than dates would indicate
 - Partial mole can be smaller than dating suggests
- Ovarian masses:
 - Present in complete moles, rarely in partial moles
 - Usually from ovarian enlargement
 - Multiple bilateral theca lutein cysts due to high levels of β -hCG, usually found by US

ESSENTIAL WORKUP

- hCG
 - Complete mole β -hCG > 100,000 mIU/mL, but can be normal
 - Partial mole: Usually lower than that seen with normal pregnancy
 - β -hCG > 40,000 mIU/mL carries poor prognosis
- US:
 - Complete mole:
 - Characteristic “snowstorm” vesicular pattern
 - Absence of fetal tissue and swelling of chorionic villi with anechoic spaces
 - No amniotic fluid
 - Theca lutein cysts
 - Bilateral, multiloculated
 - Large at 6–12 cm
 - Partial mole:
 - “Swiss-cheese” appearance
 - Cystic changes in placenta with scalloping of villa and in shape of gestational sac
 - Fetus may be present

DIAGNOSIS TESTS & INTERPRETATION

Lab

- β -hCG
- Blood type, Rh, and cross-match
- CBC to assess for anemia and thrombocytopenia
- Coagulation profile to assess for disseminated intravascular coagulation

- Electrolytes with BUN and creatinine
- LFTs
- TSH and thyroxin (free T₄) if hyperthyroidism suspected
- Urinalysis to evaluate for protein if preeclampsia suspected

Imaging

- US:
 - May be performed at bedside
- CXR:
 - Assess for pulmonary edema in acute respiratory distress
 - Check for metastatic disease
 - For baseline study

Diagnostic Procedures/Surgery

Pathology/histology:

- All conception products should be sent for formal evaluation
- Products may be the only way to diagnose a partial molar pregnancy
- Complete mole:
 - Edematous chorionic villi
 - Hyperplasia of trophoblasts
- Partial mole:
 - Fetal tissue and vessels
 - Amnion
 - Edematous chorionic villi

DIFFERENTIAL DIAGNOSIS

- Threatened abortion
- Missed abortion
- Incomplete abortion
- Ectopic pregnancy
- Hyperthyroidism
- Hyperemesis gravidarum
- Hypertension
- Preeclampsia

TREATMENT

PRE HOSPITAL

- Ensure patent airway, provide oxygen
- IV access
- Treat convulsions appropriately with benzodiazepine
- Save passed tissue for histologic evaluation

INITIAL STABILIZATION/THERAPY

- IV access
- Cardiac monitoring
- Type and cross-match for blood, especially if patient requires uterine extraction

ED TREATMENT/PROCEDURES

- Acute respiratory distress:
 - Intubation and mechanical ventilation
 - CXR
- Hyperthyroidism:
 - β -adrenergic blockers:
 - Administer before molar evacuation
 - Stress of anesthesia or surgery may precipitate thyroid storm
- Preeclampsia/eclampsia:
 - Convulsions
 - Administer benzodiazepine (diazepam)
 - Administer magnesium sulfate
 - Hypertension:
 - Administer hydralazine or labetalol
- Coagulopathy:
 - Transfuse with blood products as needed
 - Human anti-D immunoglobulin (RhoGAM):
 - Although fetal blood not present in complete mole, may be delay in distinguishing partial vs. complete
- Suction curettage:
 - Done by obstetrician, possibly in ED
 - Curative in 80% of cases
 - Method of choice in women wishing to preserve fertility
 - Oxytocin infusion to induce myometrial tone, may require other uterotonic formulations
- Chemoprophylaxis:
 - Very controversial
 - Prescribed by obstetrician only for patients with follow-up
 - Usually used in high-risk complete mole or if hormonal monitoring is unavailable
- Hysterectomy:
 - Patients in older age group
 - Patients not interested in keeping fertility
 - High-risk disease
 - Does not prevent possible metastasis

MEDICATION

- Diazepam: 0.2–0.4 mg/kg IV, or 0.3–0.5 mg PR, up to 5–10 mg, for max. 30 mg

- Hydralazine: 5–10 mg IV q20min, up to 60 mg.
- Labetalol: 20 mg IV with doubled dosing q10m for max. 300 mg
- Magnesium sulfate: 4–6 g IV over 15–20 min then maintain 1–2 g/h
- Oxytocin: Postpartum bleeding, 10 U IM
- Propranolol: 1 mg IV increments q2m
- RhoGAM: 300 µg within 72 hr

FOLLOW-UP

DISPOSITION

Admission Criteria

- Enlargement of uterus beyond 16 wk of gestation size:
 - The larger the uterus, the greater the risk for uterine perforation during suction curettage, hemorrhage, and pulmonary complications due to embolism
- Clinical evidence of preeclampsia hyperthyroidism, respiratory distress
- Hysterectomy
- Partial molar pregnancy
- Hemodynamic instability

Discharge Criteria

- Uncomplicated dilation and curettage of low-risk and small-size mole in reliable patient
- Stress importance of follow-up
- Pelvic rest for 4–6 wk after uterine evacuation
- Recommend no pregnancies for 12 mo
- Future pregnancies should have early sonographic evaluation due to increased risk in future pregnancies

FOLLOW-UP RECOMMENDATIONS

- Close follow-up and monitoring by OB-GYN
- Serial hCG levels:
 - Obtained weekly for at least 4 wk, then monthly intervals
 - Levels should consistently drop and never increase
 - If increase is noted, evaluation for metastatic disease should ensue
- Use contraception
- US:
 - Early in all future pregnancies
 - Increased risk for future molar pregnancies (1–1.5% with 2nd, 20% after 2 moles)

PEARLS AND PITFALLS

- Missed diagnosis in conjunction with:
 - Normal pregnancy
 - Preeclampsia, especially < 24 wk gestation
 - Hyperemesis with normal pregnancy
- The importance of follow-up must be stressed:
 - If hCG is not followed, may lead to undiagnosed metastatic disease
 - 20% can develop malignancy

HYDROCARBON POISONING

James W. Rhee

BASICS

DESCRIPTION

- Main complication from hydrocarbon exposure is aspiration:
 - Hydrocarbon aspiration primarily affects central nervous and respiratory systems.
- Physical properties determine type and extent of toxicity:
 - Viscosity (resistance to flow):
 - Higher aspiration risk from products with lower viscosity
 - Volatility (ability of a substance to vaporize):
 - Hypoxia from aromatic hydrocarbons displacing alveolar air
 - Surface tension (ability to adhere to itself at liquid's surface):
 - Low surface tension allows easy spread from oropharynx to trachea, promoting aspiration (e.g., mineral oil, seal oil).
- Volatile-substance abuse:
 - Common solvents abused:
 - Typewriter correction fluid
 - Adhesive
 - Gasoline
 - Cigarette-lighter fluid
 - *Sniffing*: Product inhaled directly from container
 - *Huffing*: Product inhaled through a soaked rag held to face
 - *Bagging*: Product poured into bag and multiple inhalations taken from bag
- Major classes of hydrocarbons:
 - Aliphatics:
 - Include kerosene, mineral oil, seal oil, gasoline, solvents, and paint thinners
 - Pulmonary toxicity via aspiration
 - Asphyxiation from gaseous methane and butane by displacement of alveolar oxygen
 - Halogenated hydrocarbons:
 - Include carbon tetrachloride and trichloroethane
 - Found in industrial settings as solvents
 - Well absorbed by lungs and gut
 - High toxicity
 - Liver and renal failure associated with ingestion
 - Cyclics or aromatic compounds include toluene and xylene:
 - Highly volatile and well absorbed from gut

- Death from benzene reported with 15 mL ingestion
- _ Terpenes or wood distillates include turpentine and pine oil:
 - Significant GI tract absorption
 - Significant CNS depression

ETIOLOGY

- Accidental exposures typical in young children
- Inhalation abuse of volatile hydrocarbons
- Suicide attempts in adolescents and adults

DIAGNOSIS

SIGNS AND SYMPTOMS

- Often asymptomatic at presentation
- Odor of hydrocarbons on breath
- Early: Euphoria:
 - _ Disinhibition
- Late: Dysphoria:
 - _ Ataxia
 - _ Confusion
 - _ Hallucination
- Sudden sniffing death:
 - _ Cardiac arrest in volatile-substance abusers secondary to hypersensitization of myocardium leading to malignant dysrhythmias on adrenergic stimulation
- Pulmonary:
 - _ Mild to severe respiratory distress
 - _ Cyanosis
 - _ Aspiration (primary complication)
- CNS:
 - _ Intoxication
 - _ Euphoria
 - _ Slurred speech
 - _ Lethargy
 - _ Coma
- GI tract:
 - _ Local mucosal irritation
 - _ Gastritis
 - _ Diarrhea
- Cardiac:
 - _ Tachycardia
 - _ Dysrhythmias (volatile-substance abuse)
- Dermal:

- Local erythema
- Maculopapular or vesicular eruptions
- Defatting dermatitis from chronic skin exposure
- Huffer face rash in chronic abusers

History

- Route, type, quantity, and time of exposure:
 - Determine intentionality and coingestions
- Symptoms:
 - Vomiting, respiratory distress, mental status change or pain
- Bystander actions or pre-hospital interventions

Physical-Exam

- Evaluate for airway compromise in patients with decreased level of consciousness and vomiting
- Respiratory symptoms generally occur within 30 min but are frequently delayed several hours
- Monitor for hypoxia, hypotension, and cardiac dysrhythmias
- Cyanosis and hypoxia suggest respiratory failure but may result from methemoglobinemia
- Temperature may be elevated at presentation following aspiration and indicates pneumonitis:
 - Fever after 48 hr suggests bacterial superinfection

ESSENTIAL WORKUP

Obtain information on the following:

- Product: Exact name on label, manufacturer, and ingredients
- Nature of ingestion or exposure: Accidental or intentional
- Estimated amount ingested
- In industrial settings, Material Safety Data Sheets (MSDSs)

DIAGNOSIS TESTS & NTERPRETATION

ECG for intoxicated volatile-substance abusers

Lab

- Pulse oximetry:
 - If abnormal, follow with arterial blood gases.
- Electrolytes; BUN, creatinine, and glucose levels; and liver function tests:
 - For halogenated and aromatic hydrocarbon exposure
 - Metabolic acidosis
 - Hypokalemia
- Carboxyhemoglobin levels for methylene chloride exposure:
 - Methylene chloride metabolized to carbon monoxide in vivo

Imaging

CXR:

- Abnormalities visible 20 min–24 hr after exposure (usually by 6 hr)
- Increased bronchovascular marking and bibasilar and perihilar infiltrates (typical)
- Lobar consolidation (uncommon)
- Pneumothorax, pneumomediastinum, and pleural effusion (rare)
- Pneumatoceles resolve over weeks
- Repeat chest radiograph if worsening respiratory symptoms

DIFFERENTIAL DIAGNOSIS

- Caustic, pesticide, or toxic alcohol ingestions
- Accidental vs. intentional:
 - Psychiatric evaluation for all intentional ingestions
- Child neglect:
 - Poor supervision or unsafe home environment

TREATMENT

PRE HOSPITAL

- Decontaminate clothes, skin, and hair of any hydrocarbon exposure
- Do not induce emesis.
- Ipecac contraindicated owing to increased risk of aspiration
- Keep volatile-substance abusers calm and avoid interventions that cause anxiety or distress.
- Management of *accidental* hydrocarbon exposures at home controversial:
 - < 1% require physician intervention.
 - For asymptomatic or quickly asymptomatic after ingestion with reliable observer available
 - Applies only when exact product and its components are known and there is no indication for gastric decontamination or possibility for delayed organ toxicity

INITIAL STABILIZATION/THERAPY

- ABCs
- IV access and fluid resuscitation if hypotensive or ongoing fluid losses
- Oxygen
- Cardiac monitor
- Naloxone, thiamine, D₅₀W (or Accu-Chek) if altered mental status

ED TREATMENT/PROCEDURES

- Supportive care
- Treat respiratory symptoms:

- Oxygen
- Nebulized
- β_2 -agonist for bronchospasm (albuterol)
- Endotracheal intubation and mechanical ventilation for respiratory failure
- Steroids not indicated for bronchospasm
- Avoid using epinephrine in volatile-substance abusers as it may precipitate dysrhythmias

ALERT

- Gastric evacuation not indicated for vast majority of hydrocarbon ingestions:
 - Increases risk of aspiration which can cause significant chemical pneumonitis
 - Aspiration risk higher than risk of systemic absorption for aliphatic hydrocarbon mixtures, which account for most ingestions
 - Contraindicated if spontaneous emesis has occurred
 - Small-bore nasogastric tube aspiration of stomach contents may be indicated for some hydrocarbon (CHAMP) ingestions that have systemic toxicity:
 - CHAMP: Camphor, *halogenated hydrocarbons*, *aromatic hydrocarbons*, *metals* (e.g., lead, mercury), *pesticides*
 - Only for very recent ingestions (60 min)
 - Benefit of doing this procedure needs to be weighed heavily against risk of aspiration and subsequent pneumonitis.
 - Cuffed-tube endotracheal intubation for airway protection during lavage if no gag reflex or altered mental status
- Activated charcoal does not bind to hydrocarbons well, and is not indicated except for significant life-threatening coingestants
- Cathartics not indicated:
 - Diarrhea common with hydrocarbon

MEDICATION

- Albuterol 2.5–5 mg NEB (peds: 0.15–0.3 mg/kg) for bronchospasm
- Dextrose: D₅₀W 1 ampule of 50 mL or 25 g (peds: D₂₅W 2–4 mL/kg) IV
- Naloxone (Narcan): 2 mg (peds: 0.1 mg/kg) IV or IM initial dose
- Thiamine (vitamin B₁): 100 mg (peds: 50 mg) IV or IM

FOLLOW-UP

DISPOSITION

Admission Criteria

- Symptomatic patients
- Patients with potential delayed organ toxicity (carbon tetrachloride or other toxic additives)

Discharge Criteria

- Observe for 6 hr then discharge:
 - Asymptomatic patients with normal chest radiograph and pulse oximetry findings
 - Asymptomatic patients with abnormal CXR and normal oxygenation and respiratory rate may be discharged if reliable follow-up is ensured.
 - Symptomatic patients on presentation who quickly become asymptomatic
- Observe volatile-substance abusers until mental status clears.

Issues for Referral

Psychiatry consultation as needed

FOLLOW-UP RECOMMENDATIONS

- Follow up in 24 hr for patients who remain asymptomatic after a minimum of 6 hr observation
- Asymptomatic patients with an abnormal CXR should have a repeat study in 24 hr

PEARLS AND PITFALLS

- Main complication from hydrocarbon exposure is aspiration:
 - Aspiration risk is inversely related to viscosity and surface tension and directly related to volatility
- Provide external decontamination
- Gastric decontamination is rarely indicated
- Avoid induced emesis and cathartics
- Observe patients a minimum of 6 hr post ingestion for evidence of toxicity
- Admit symptomatic patients to hospital
- Admit when there is potential for delayed organ toxicity
 - CHAMP

- T59.891A Toxic effect of other specified gases, fumes and vapors, accidental (unintentional), initial encounter

HYDROCELE

Jessica L. Osterman

BASICS

DESCRIPTION

- Most common cause of painless scrotal swelling.
- Classified as congenital or acquired (secondary):
 - Congenital result from a patent process vaginalis and communication between tunica vaginalis and peritoneal cavity:
 - Normally occurs spontaneously and most are closed by 2 yr of age
 - Acquired occur secondary to interscrotal infection, neoplasm, inguinal or scrotal surgery, or regional or systemic disease.
- Communicating hydrocele:
 - Patent processus vaginalis
 - Scrotum fills and empties with peritoneal fluid depending on body position and intraperitoneal pressures.
- *Noncommunicating hydrocele* is due to production of serous fluid by a disease process or impaired absorption within the scrotum itself

ETIOLOGY

- Imbalance between production and resorption of fluid within the space between tunica vaginalis and tunica albuginea.
- Disease processes causing adult noncommunicating hydrocele include:
 - Epididymitis
 - Hypoalbuminemia
 - TB
 - Trauma
 - Mumps
 - Spermatic vein ligation
 - In developing world, hydrocele is primarily caused by infections such as *Wuchereria bancrofti* or *Loa Loa* (filariasis is the cause of most hydroceles worldwide)
 - Rarely malignancy (1st-degree testicular neoplasm or lymphoma)
- Rare etiology is the abdominoscrotal hydrocele that may cause hydroureter or unilateral limb edema owing to compression:
 - US reveals single sac extending from scrotum into abdominal cavity via the deep inguinal ring.

Pediatric Considerations

- Congenital in 6% of newborn boys

- Usually diagnosed in newborn nursery
- Caused by patent processus vaginalis, a structure that remains patent in 85% of newborns
- May vary in size owing to position or crying:
 - Patients may present with history of scrotal mass that has resolved.
- Most close by the age of 2 yr

DIAGNOSIS

SIGNS AND SYMPTOMS

Painless scrotal swelling with a sensation of pulling, dragging, or heaviness.

History

History and exam with special attention to identifying torsion of testicle.

Physical-Exam

- Mass may be soft and doughy or firm depending on the amount of fluid present.
- Initial evaluation includes transillumination of affected side (looking for a homogeneous area without internal shadows):
 - This is rapidly being replaced as diagnostic test of choice by bedside US.

ESSENTIAL WORKUP

- Bedside US:
 - Allows visualization of hydrocele as well as of testicle
 - Especially in cases of massive fluid collection, bedside US should be the diagnostic test of choice.
 - May help to identify an underlying mass
- Because of possibility in adults that a hydrocele may be owing to a primary neoplasm, the testicle must be palpated in its entirety.

DIAGNOSIS TESTS & INTERPRETATION

Lab

No specific lab testing is indicated unless underlying cause demands it (UA, AFP, hCG).

Imaging

US is diagnostic and allows visualization of testicular anatomy:

- Appears as large anechoic fluid-filled space surrounding the anterolateral testicle

DIFFERENTIAL DIAGNOSIS

- Epididymitis
- Indirect inguinal hernia

- Orchitis
- Testicular neoplasm
- Testicular torsion
- Varicocele

TREATMENT

INITIAL STABILIZATION/THERAPY

Stabilization should focus on underlying cause (e.g., trauma).

ED TREATMENT/PROCEDURES

Appropriate exam of testicle to exclude primary neoplasm and referral.

MEDICATION

Treat underlying cause.

FOLLOW-UP

DISPOSITION

Admission Criteria

Patients with secondary hydrocele may need admission for further evaluation of underlying pathology (e.g., neoplasm, trauma).

Discharge Criteria

- Otherwise healthy patients without comorbid illness may be referred for further evaluation to urologist.
- Hydrocele is usually repaired if cosmesis is a factor or in cases where it causes discomfort.
- Repair can be:
 - _ Surgical:
 - Aspiration or sclerotherapy are alternatives to open hydrocelectomy.
 - _ Medical:
 - Aspiration of hydrocele contents and sclerotherapy to prevent recurrence.

Pediatric Considerations

- Most hydroceles in infant population will spontaneously resolve by 12 mo of age:
 - _ Referral and observation are appropriate once diagnosis is made.
- After the age of 12–18 mo, refer for surgical repair as communicating hydroceles usually have hernia that needs repair.

FOLLOW-UP RECOMMENDATIONS

Patients should be referred to Urology.

PEARLS AND PITFALLS

The mass may fail to transilluminate due to thickening of the tunica vaginalis.

- Bedside US should visualize both the fluid-filled mass and the testicle.

ICD10

- N43.1 Infected hydrocele
- N43.3 Hydrocele, unspecified
- P83.5 Congenital hydrocele

HYDROCEPHALUS

Richard S. Krause

BASICS

DESCRIPTION

- Increased volume of CSF in cranial cavity
- Cerebral atrophy also leads to increased CSF in the cranial vault but CSF pressure is not increased
- *Obstructive hydrocephalus* is the most common form:
 - Obstruction is within ventricular system or in subarachnoid space
- Acute *obstructive* hydrocephalus may cause rapid rise in intracranial pressure (ICP), rapidly leading to death or permanent cerebral damage
- *Nonobstructive hydrocephalus* causes subacute symptoms and is a potentially treatable form of dementia
- Also described as “communicating” and “noncommunicating”:
 - Communicating hydrocephalus: Flow of CSF is blocked after it exits the ventricles (ventricles still “communicate”)
 - Noncommunicating hydrocephalus: Flow of CSF blocked along 1 or more of the passages connecting the ventricles (ventricles do not “communicate”)

ETIOLOGY

- Obstructive hydrocephalus:
 - Obstruction of:
 - Aqueduct of Sylvius (most common, both lateral ventricles and 3rd ventricle dilated, 4th ventricle is spared)
 - Aqueductal stenosis can be congenital or acquired (tumor, subarachnoid hemorrhage, post meningitis, idiopathic)
 - Foramen of Monro (lateral ventricles dilated, usually both but may be unilateral)
 - Foramina of Luschka and Magendie (4th ventricle blocked followed by 3rd and lateral ventricles)
 - Subarachnoid space around brainstem (postinfectious or postsubarachnoid hemorrhage [post-SAH] entire system dilated)
 - Acute presentations usually secondary to CSF shunt blockage, SAH, or severe head trauma
- Nonobstructive hydrocephalus:
 - Normal pressure hydrocephalus:
 - Increased intracranial volume of CSF without intracranial hypertension
 - Increased ventricular size on CT (without volume loss as in atrophy)

- Sometimes called “chronic hydrocephalus”
- Usually occurs due to inadequate CNS absorption
- Pediatric hydrocephalus:
 - Congenital hydrocephalus owing to neonatal hemorrhage, congenital malformations, or acquired post meningitis secondary to subarachnoid scarring around brainstem

DIAGNOSIS

SIGNS AND SYMPTOMS

- Obstructive hydrocephalus:
 - Headache
 - Nausea and vomiting
 - Decreased level of consciousness
 - Urinary incontinence
 - Ocular palsies
 - Papilledema, decreased vision
 - Pupillary dilation
 - Cushing response:
 - Raised systolic pressure and bradycardia secondary to increased ICP
 - Pediatric patients:
 - Full fontanelle, irritability, and lethargy
 - BP often elevated
 - May present like nonobstructive hydrocephalus if obstruction develops slowly
- Nonobstructive hydrocephalus:
 - Progressive dementia, somnolence
 - Gait disturbance
 - Urinary incontinence
 - Impaired upward gaze
 - Generalized weakness and lethargy
 - Dementia is often insidious with subacute onset of progressive intellectual deterioration
 - No headache or papilledema

Pediatric Considerations

- Pediatric patients increase CSF volume slowly:
 - Craniomegaly
 - Retardation
 - Prominent scalp veins
 - Impaired upward gaze (setting sun sign)

History

- Onset of symptoms
- History of CSF shunt
- Nausea/vomiting
- Headache
- Weakness
- Confusion
- Visual changes
- Incontinence of urine

Physical-Exam

- Thorough neurologic exam:
 - _ Motor
 - _ Sensation
 - _ Deep tendon reflexes
 - _ Gait
 - _ Cranial nerve exam
 - _ Papilledema may be seen
- Confusion
- Decreased level of consciousness
- Palpate CSF shunt if present
 - _ Malfunction indicated by failure to compress (distal shunt malfunction) or failure to refill (proximal shunt obstruction)
- Full anterior fontanelle in children:
 - _ Other findings as noted in Signs and Symptoms

ESSENTIAL WORKUP

CT scan of the head w/o contrast will allow assessment of ventricular size and symmetry:

- Aid in diagnosis of cerebral edema, mass lesions, and hemorrhage

DIAGNOSIS TESTS & NTERPRETATION

Lab

Lumbar puncture (LP) is typically performed after head CT (for nonobstructive causes):

- Opening pressure on LP will reflect increased ICP in nonobstructive hydrocephalus.
- CSF should be sent for routine tests if infection is suspected.
 - _ Gram stain, culture, protein, glucose, and cell count

Imaging

MRI of brain reveals ventricular size and symmetry and may allow for better visualization of masses than CT

Diagnostic Procedures/Surgery

LP may be indicated

DIFFERENTIAL DIAGNOSIS

- Acute cerebral infarction or hemorrhage
- Intracranial infection
- Mass effect from fast-growing tumor or hematoma
- Dementia or delirium of other cause
- Toxic or metabolic encephalopathies

Pediatric Considerations

- Suspect hydrocephalus in an infant whose head circumference is increasing excessively, has progressive lethargy, persistent vomiting, impaired upward gaze, etc.
- Congenital anomalies:
 - Dandy–Walker malformation
 - Arnold–Chiari malformation
 - Meningomyelocele
 - Choroid plexus papilloma
 - Hypoplasia/dysfunction of arachnoid villi
- Infections:
 - Rubella
 - Cytomegalovirus (CMV)
 - Toxoplasmosis
 - Syphilis
 - Bacterial meningitis
 - Reye syndrome
- Tumors, especially posterior fossa tumors:
 - Medulloblastoma
 - Astrocytoma
 - Ependymoma
- Hemorrhage:
 - Intraventricular
 - Subarachnoid

TREATMENT

PRE HOSPITAL

Cautions:

- Elevated ICP/hydrocephalus cannot be definitively diagnosed in the field
- When it is suspected, supplemental O₂ and airway management (if needed) are indicated

- Patients should be transported with head elevated at $\sim 30^\circ$
 - HOB should not be elevated if patient is hypotensive for concern about decreased cerebral perfusion
 - Initial treatment for hypotension is usually volume expansion with normal saline

INITIAL STABILIZATION/THERAPY

- Signs of impending herniation:
 - Rapid-sequence intubation (RSI)
 - Thiopental or etomidate for induction
 - Paralytic choice is controversial
 - Depolarizing agents (succinylcholine) may transiently increase ICP, this effect may not be clinically significant
 - Nondepolarizing agents (rocuronium, vecuronium) may be preferable
 - Controlled ventilation to maintain PaCO₂ at ~ 35 mm Hg
 - Maintain systolic BP > 100 mm Hg (adult) with fluids or pressors.
 - Mannitol
- If a CSF shunt is present and there are signs of impending herniation:
 - Forced pumping of shunt chamber:
 - Flush device with 1 mL saline to remove distal obstruction
 - Slow drainage of CSF from reservoir to achieve pressure < 20 cm H₂O

ED TREATMENT/PROCEDURES

- Hydrocephalus does not generally require ED treatment unless:
 - Signs of impending herniation
 - Acute shunt malfunction
- Definitive treatment involves either placement (or revision) of shunting device or treatment of underlying cause (e.g., tumor)
- Neurologic symptoms (gait disturbance) or severe headache associated with normal pressure hydrocephalus may respond to removal of CSF by LP (20–30 mL)
- If intraventricular hemorrhage (usually from trauma or SAH) causes acute obstructing hydrocephalus a ventriculostomy may be placed in the lateral ventricle
- Patients who are agitated or intubated should be sedated
- Maintain elevation of the head unless hypotensive
- Mannitol may be used
- Consider seizure prophylaxis with fosphenytoin

MEDICATION

- Atropine: 0.02 mg/kg IV (max. 0.1 mg)
- Etomidate: 0.2–0.3 mg/kg
- Lidocaine: 1 mg/kg IV
- Mannitol: 0.5–1.5 g/kg
- Rocuronium: 0.6 mg/kg IV

- Succinylcholine: 1–1.5 mg/kg IV
- Vecuronium: 0.1 mg/kg
- Fosphenytoin: 15–20 mg/kg loading dose

FOLLOW-UP

DISPOSITION

Admission Criteria

Evidence of increased ICP or shunt malfunction requires admission

Discharge Criteria

Patients with presumed normal pressure hydrocephalus may be discharged for follow-up

Issues for Referral

Involvement of a neurosurgeon may be needed in acute obstructive hydrocephalus or for acute shunt malfunction

- Consider transfer if a neurosurgeon is not available at presenting hospital
- Airway management prior to transfer should be considered in acute cases

FOLLOW-UP RECOMMENDATIONS

If patient is stable for discharge, follow-up with neurologist and/or neurosurgeon is essential

PEARLS AND PITFALLS

- LP should not be performed in obstructive hydrocephalus (risk of herniation)
- Suspect hydrocephalus in children whose head circumference is growing rapidly
- Consider hydrocephalus in patients with CSF shunts and any neurologic complaint

ADDITIONAL READING

- G91.9 Hydrocephalus, unspecified

HYPERBARIC OXYGEN THERAPY

Trevonne M. Thompson

BASICS

DESCRIPTION

- Administration of 100% oxygen at > 1 atm (typically 2–3 atm)
- Mechanisms of action:
 - Increases oxygen availability at the cellular level:
 - Breathing 100% oxygen at 3 atm supplies enough dissolved oxygen to support life without hemoglobin.
 - Compresses formed gas bubbles (in cases of air embolism or decompression sickness)
- 2 types of hyperbaric oxygen chambers:
 - Monoplace:
 - Accommodates 1 supine patient
 - Technician outside the chamber for monitoring
 - Compressed with 100% oxygen
 - Multiplace:
 - Holds multiple patients
 - Holds attendants who “dive” with the patients
 - Airlocks available for medication/equipment transfer outside of the chamber
 - Compressed with air—patients breath oxygen by face mask, endotracheal tube, or face hood.

DIAGNOSIS

SIGNS AND SYMPTOMS

Indications for hyperbaric oxygen therapy:

- Arterial gas embolism
- Decompression sickness
- Carbon monoxide toxicity
- Soft tissue infections:
 - Clostridial myonecrosis
 - Necrotizing fasciitis
 - Refractory osteomyelitis
 - Chronic nonhealing wounds
- Wound care:
 - Radiation-induced tissue injury
 - Crush injuries

- Thermal burns
- Compromised skin grafts and flaps

ALERT

The ED physician should focus on arterial embolism, decompression sickness, and carbon monoxide toxicity as uses for hyperbaric oxygen.

ESSENTIAL WORKUP

- Determine need for hyperbaric oxygen therapy as described above.
- Perform a comprehensive physical exam to screen for contraindications to therapy and to establish a pretreatment baseline exam.
- Contraindications to therapy:
 - Untreated pneumothorax is the absolute contraindication:
 - May convert to a tension pneumothorax
 - Cardiovascular instability:
 - Unstable patient cannot be treated in a monoplace chamber.
 - Such a patient may be treated in multiplace chamber if benefit outweighs risk.

DIAGNOSIS TESTS & INTERPRETATION

Lab

Arterial blood gas:

- To evaluate for hypoxia in appropriate cases

Imaging

Chest radiography:

- To evaluate for occult pneumothorax

TREATMENT

INITIAL STABILIZATION/THERAPY

- Manage ABCs
- Establish IV access.
- 100% oxygen
- Cardiac monitor (when appropriate)

ED TREATMENT/PROCEDURES

- Determine need for hyperbaric oxygen therapy.
- Fill any devices with balloons (Foley catheters, endotracheal tubes) with fluid to avoid rupture during therapy.
- Pretreat patients with any sinus complaints with decongestants.
- Place myringotomy tubes in obtunded or mechanically ventilated patients or in

patients with middle ear pathology (e.g., otitis media).

ALERT

Complications of hyperbaric oxygen therapy:

- Sinus/ear pain
- Barotrauma:
 - _ Ruptured tympanic membranes
 - _ Tension pneumothorax
- Seizures:
 - _ May be a result of oxygen toxicity
- Decompression sickness:
 - _ When decompression is too rapid
 - Inability to access an unstable patient when using a monoplace chamber

FOLLOW-UP

DISPOSITION

Admission Criteria

- Arterial gas embolism
- Decompression sickness
- Significant carbon monoxide toxicity

Discharge Criteria

Stable patient with resolved symptoms

Issues for Referral

- May need to transfer to a facility that has a hyperbaric oxygen chamber
- Evaluate risks and benefits when considering the transfer of a potentially unstable patient.
- Divers Alert Network:
 - _ 24 hr emergency hotline for consultation of dive-related injuries
 - _ Referral source for hyperbaric oxygen chambers
 - _ Telephone number:
 - 919-684-9111
 - _ Website:
 - www.diversalertnetwork.org

FOLLOW-UP RECOMMENDATIONS

Hyperbaric follow-up for repeat recompression therapy.

PEARLS AND PITFALLS

- Fill any devices with balloons (Foley catheters, endotracheal tubes) with fluid to avoid rupture during therapy.
- Check for occult pneumothorax.

- T70.3XXA Caisson disease [decompression sickness], initial encounter
- T79.0XXA Air embolism (traumatic), initial encounter

HYPERCALCEMIA

Matthew A. Wheatley • Ryan A. Stroder

BASICS

DESCRIPTION

- Severity depends on serum calcium level and rate of increase
- 0.1–1% of patients on routine screening
- Most cases mild (< 12 mg/dL) and asymptomatic
- Hypercalcemic crisis, usually > 14 mg/dL, causes serious signs and symptoms
- Calcium in bloodstream in 3 forms:
 - Ionized: 45%
 - Bound to protein (primarily albumin): 40%
 - Bound to other anions: 15%
- Ionized calcium—only physiologically active form

ETIOLOGY

- Primary hyperparathyroidism
- Malignancy
- Miscellaneous

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Neurologic:
 - Headache
 - Fatigue, lethargy
 - Weakness
 - Difficulty concentrating
 - Confusion
 - Depression, paranoia
- Renal:
 - Polyuria, polydipsia
 - Complaints related to oliguric renal failure
 - Chronic, complaints related to:
 - Renal calculi
 - Nephrocalcinosis
 - Interstitial nephritis
- GI:

- Anorexia
- Nausea, vomiting
- Abdominal pain
- Constipation
- Chronic, complaints related to:
 - Peptic ulcer disease
 - Pancreatitis
- Dermatologic:
 - Pruritus
 - Mnemonic: “Stones, Bones, Groans, Thrones and Psychiatric Overtones,” “bones” refers to bone pain and “thrones” refers to polyuria.

Pediatric Considerations

- Failure to thrive
- Slow development
- Mental retardation may ensue

Physical-Exam

- Neurologic:
 - Irritability
 - Lethargy
 - Stupor
 - Coma
 - Hyporeflexia
- Cardiovascular:
 - Hypotension, if severely volume depleted, or HTN
 - Sinus bradycardia
 - Cardiac arrest with severe hypercalcemia (rare)
- Renal:
 - Signs of dehydration
- Dermatologic:
 - Band keratopathy
 - Ectopic calcification

Pediatric Considerations

- Characteristic facies: Pug nose, fat nasal bridge, “cupid’s bow” upper lip
- Hypotonia

ESSENTIAL WORKUP

- Ionized and total serum calcium levels, albumin levels:
 - Normal total calcium level is <10.5 mg/dL
 - Must correct for calcium that is protein bound, primarily to albumin

- Corrected total calcium (mg/dL) = measured total calcium (mg/dL) + 0.8 × [4.0 – albumin concentration (g/dL)]
- Electrolytes, BUN/creatinine, glucose
 - Possible oliguric renal failure
- ECG:
 - Shortening of QT interval
 - Prolongation of PR interval
 - QRS widening
 - Accentuated side effects of digoxin
 - Sinus bradycardia, bundle branch block, AV block, cardiac arrest with severe hypercalcemia (rare)
 - Can cause Osborn J-wave at the end of QRS complex that is usually associated with hypothermia

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Phosphate
- Protein
- Urinalysis
- Parathyroid hormone (PTH) level:
 - If elevated or high normal, likely primary hyperparathyroidism.
 - If <20 pg/mL, consider testing PTH-related peptide and vitamin D metabolites.
- Vitamin D metabolites, if suspected
 - 25-hydroxy vitamin D (calcidiol):
 - If elevated, consider exogenous source (i.e., meds, vitamins, supplements).
 - 1,25-dihydroxy vitamin D (calcitriol):
 - If elevated, consider lymphoma or sarcoid
- Digoxin level, if taking
- Thyroid function tests

Imaging

- CT head for altered mental status
- Chest x-ray and workup for occult malignancy, if no other cause for hypercalcemia

Diagnostic Procedures/Surgery

Parathyroidectomy:

- For primary hyperparathyroidism resulting in symptomatic or severe hypercalcemia
- Some patients require urgent parathyroidectomy.

DIFFERENTIAL DIAGNOSIS

- Primary hyperparathyroidism:
 - Most common cause among outpatients
 - Parathyroid adenoma 80%; hyperplasia 15%; carcinoma 5%
 - Usually mild, <11.2 mg/dL
 - Patients can be asymptomatic or have chronically elevated calcium
 - Increased bone resorption, relative decrease in calcium excretion, increased intestinal calcium absorption
- Malignancy:
 - Most common cause in hospitalized patients
 - Usually a rapid rise in serum calcium
 - Patients are more often symptomatic
 - Higher serum calcium concentrations
 - Most common paraneoplastic complication of cancer
 - Common tumors causing hypercalcemia: Breast, lung, colon, stomach, cervix, uterus, ovary, kidney, bladder, head and neck, multiple myeloma, and lymphoma
 - Most commonly from production of PTH-related protein with similar actions
 - May result from production of other bone-resorbing substances by tumor
 - May result from local effects of osteolytic skeletal metastasis
- Miscellaneous:
 - Hypercalcemia associated with granulomatous diseases
 - Excessive calcium supplements
 - Thiazide diuretics causing increased renal reabsorption
 - Familial hypocalciuric hypercalcemia
 - Acute vitamin A intoxication
 - Exogenous vitamin D intake
 - Milk-alkali syndrome from excessive ingestion of calcium and nonabsorbable antacids, such as milk or calcium carbonate
 - Long-term lithium therapy
 - Renal transplantation
 - Hyperthyroidism
 - Acute tubular necrosis

Pediatric Considerations

Differential diagnosis: Differences from adults:

- Primary hyperparathyroidism:
 - Less common than in adults
- Infantile hypercalcemia:
 - Uncertain cause
 - Possibly hypersensitivity and in utero excessive exposure to vitamin D
- Immobilization hypercalcemia:
 - Typically adolescent who is growing rapidly

- Prolonged immobilization, especially in traction, leads to hypercalciuria and then hypercalcemia
- Presumably from increased bone resorption with decreased or arrested bone mineralization

TREATMENT

PRE HOSPITAL

Routine stabilization techniques

INITIAL STABILIZATION/THERAPY

- ABCs, IV access, oxygen, cardiac monitor
- 0.9% NS 1 L bolus (20 mL/kg) for hypotension or severe dehydration
- Naloxone, thiamine, D₅₀W (or stat serum glucose measurement) for altered mental status

ED TREATMENT/PROCEDURES

- General:
 - Immediate therapy for severe hypercalcemia (corrected total > 14 mg/dL) regardless of symptoms, or for symptomatic hypercalcemia
 - Asymptomatic, mild hypercalcemia does not require emergency treatment
- Restoration of IV volume:
 - Isotonic saline:
 - 200–300 mL/hr adjusted to maintain urine output 100–150 mL/hr
 - Often need 2–5 L/day
 - Bedside vigilance necessary to prevent fluid overload
 - Correct other electrolyte abnormalities
 - Cardiovascular status of patient may necessitate central venous pressure monitoring to adjust fluid administration rates
- Renal elimination:
 - After volume expansion and if needed to avoid overload, administer loop diuretics (furosemide)
 - Avoid thiazide diuretics
 - May need peritoneal or hemodialysis against a low calcium dialysate in renal failure
- Inhibition of osteoclastic activity:
 - Reduce mobilization of calcium from bone
 - Administer drug therapy when corrected calcium level > 14 mg/dL or signs or symptoms
 - First-line drug therapy:
 - Bisphosphonates: Pamidronate (more potent and possibly less toxic), etidronate

- Calcitonin: Rapid onset but modest decrease in levels
- Other potential drug therapy:
 - Plicamycin: Efficacious but numerous side effects
 - Hydrocortisone: Especially useful with malignancies, granulomatous disorders, or vitamin D intoxication
- Encourage ambulation in appropriate patients
- Treat underlying disorder:
 - Parathyroidectomy for primary hyperparathyroidism resulting in symptomatic or severe hypercalcemia
 - Discontinue medication if cause of hypercalcemia

MEDICATION

First Line

- Calcitonin: 4 IU/kg IM/SC q12h
- Etidronate: 7.5 mg/kg over 4 hr daily for 3–7 days IV
- Furosemide: 10–40 mg q6–8h (peds: 1–2 mg/kg) IV
- Pamidronate: Single 2–24 hr infusion of 60–90 mg IV (peds: Consult pediatrician)

Second Line

- Gallium nitrate: Continuous infusion of 200 mg/m²/d for 5 days IV
- Hydrocortisone: 200–400 mg/d IV for 3–5 days (peds: Consult pediatrician)
- Plicamycin: 25 µg/kg/d over 4–6 hr IV for 3–8 doses

Pediatric Considerations

- In infants, loop diuretics are rarely necessary and possibly harmful as they may decrease glomerular filtration rate and worsen hypercalcemia
- Bisphosphonates have not been extensively studied in pediatrics but do appear to be safe

FOLLOW-UP

DISPOSITION

Admission Criteria

- Corrected total calcium level > 13 mg/dL
- Signs or symptoms attributed to hypercalcemia, especially EKG changes
- Monitored bed or ICU for corrected level > 14 or serious signs and symptoms

Discharge Criteria

Corrected calcium level < 13 mg/dL and no signs or symptoms of hypercalcemia

Issues for Referral

- Rapid follow-up arranged to determine cause and long-term therapy
- Consultation with endocrinologist should be considered

FOLLOW-UP RECOMMENDATIONS

- Fluid hydration
- Watch for mental status changes

PEARLS AND PITFALLS

- Make decisions based on symptoms or corrected Ca levels
- All patients with serum Ca > 14 mg/dL require treatment regardless of symptoms
- Pay careful attention to EKG changes
- Careful monitoring is required for patients receiving IV volume repletion:
 - They often require a large volume of fluid but care must be taken to avoid volume overload

HYPEREMESIS GRAVIDARUM

David Della-Giustina

BASICS

DESCRIPTION

- Hyperemesis gravidarum is the most severe form along the continuum of nausea and vomiting of pregnancy
- Also known as pernicious vomiting of pregnancy
- Characterized by unexplained intractable vomiting and dehydration
- Occurs in 0.3–2% of pregnancies
- Diagnosis of exclusion

ETIOLOGY

- Exact cause unknown
- Possible causes include the following:
 - Elevated gestational hormone levels of human chorionic gonadotropin (hCG) and/or estradiol
 - Thyrotoxicosis
 - Upper GI motility dysfunction
 - Hepatic abnormalities
 - Autonomic nervous system dysfunction
 - Psychological factors
 - *Helicobacter pylori* infection
 - Genetic predisposition

DIAGNOSIS

SIGNS AND SYMPTOMS

- Nausea and vomiting during pregnancy affects between 50% and 90%
- Onset of symptoms by the 4th–10th wk of pregnancy with resolution by the 20th:
 - Symptoms after the 20th wk should raise one's suspicion of another process
- Peak onset is at 8–12 wks
- Hyperemesis gravidarum is a clinical diagnosis defined by the following:
 - Persistent and severe nausea and vomiting
 - Dehydration
 - Weight loss of > 5% of total body weight
 - Lab findings: Increased urine specific gravity, ketonuria, electrolyte disturbances, ketonemia

History

- Onset of vomiting
- Gestational history:
 - Similar symptoms in prior pregnancies
- Last menstrual period
- Oral intake
- Urine output
- Bloody or bilious vomiting
- Abdominal pain
- Vaginal bleeding
- Risk factors include the following:
 - History of motion sickness
 - Younger age
 - Migraine headaches
 - Symptoms earlier in the day
 - Low prepregnancy body mass index
 - More common in nulliparous women
 - 15% recurrence rate if manifested in previous pregnancy

Physical-Exam

- Observe for signs of dehydration
- Abdominal tenderness

ESSENTIAL WORKUP

- History and physical exam with special attention to state of hydration and abdominal exam for other diagnoses associated with vomiting (appendicitis, cholecystitis, etc.)
- Obtain an uncontaminated urinalysis
- If patient has unremitting vomiting for >24 hr, obtain a CBC, electrolytes, renal function, liver enzymes, bilirubin, and lipase

DIAGNOSIS TESTS & NTERPRETATION

Lab

- Urinalysis:
 - Increased specific gravity and ketonuria
 - Presence of glucose mandates checking serum glucose to rule out diabetes
 - Presence of bilirubin mandates a search to rule out hepatobiliary cause for the vomiting
- CBC:
 - May have an elevated hematocrit owing to dehydration
 - WBC is usually normal
- Electrolytes:
 - Elevated BUN indicating volume depletion; elevated creatinine if renal

failure present

- Hyponatremia, hypokalemia, hypochloremia, and metabolic alkalosis from loss of HCl in emesis
- Liver function tests:
 - Mild increases in bilirubin may occur, but should be < 4 mg/dL.
 - AST and ALT may also be mildly elevated, but not > 100 IU/L
- Amylase/lipase:
 - In 1 study, amylase was elevated in 24% of patients with hyperemesis gravidarum; however, the amylase was salivary in origin; use lipase rather than amylase to evaluate for pancreatitis
- TSH
- Serum hCG levels are not indicated if known intrauterine pregnancy

Imaging

- US when 1st trimester US has not been performed to evaluate for:
 - Molar pregnancy
 - Multiple gestations

DIFFERENTIAL DIAGNOSIS

- Pyelonephritis; most commonly missed
- Gastroenteritis; gastroparesis; intestinal obstruction; Mallory–Weiss tear
- Hepatobiliary disease; hepatitis, cholecystitis, fatty liver of pregnancy, achalasia
- Pancreatitis
- Appendicitis
- Diabetic ketoacidosis
- Hyperthyroidism; hyperparathyroidism
- Uremia; persistent nausea and vomiting are seen with severe renal dysfunction.
- Pseudotumor cerebri

TREATMENT

PRE HOSPITAL

- IV, monitor if signs of significant volume depletion
- IV hydration

INITIAL STABILIZATION/THERAPY

IV hydration using a crystalloid solution (LR or NS)

ED TREATMENT/PROCEDURES

- IV hydration using LR or NS
- Dextrose may be added to help break cycle of ketosis
- Treat until patient is no longer symptomatic from hypovolemia

- Antiemetics administered IV are given to break the vomiting cycle
- Most commonly used medications:
 - Metoclopramide:
 - FDA category B
 - Promethazine and prochlorperazine:
 - Both FDA category C
 - Recent FDA warning regarding complications of IV promethazine administration
 - Ondansetron:
 - FDA category B with recent warning about the risk of prolonged QT syndrome and the recommendation for ECG monitoring of the patient with electrolyte abnormalities such as hypokalemia or hypomagnesemia
 - These have been used extensively in pregnancy, and there is little or no evidence associated with increased risk of congenital anomalies
 - Antiemetics are preferable to the risk of prolonged ketosis and hypovolemia
- Oral rehydration in the ED after the initial fluid resuscitation and antiemetics
- Thiamine 100 mg IV/IM/PO in the patient who requires IV rehydration due to case reports of Wernicke encephalopathy
- Antihistamines have been shown to be effective
- Methylprednisolone may be effective for patients with hyperemesis gravidarum:
 - Last resort
 - Avoid if < 10 wks gestation

MEDICATION

First Line

- Metoclopramide (category B): 10–20 mg IV
- Ondansetron (category B): 4–8 mg IV or 4 mg PO or ODT every 8 hr
- Prochlorperazine (category C): 5–10 mg IV not to exceed 40 mg/d
- Promethazine (category C): 12.5–25 mg IM
- Discharge outpatient medications:
 - Meclizine (category B): 25 mg PO q6h PRN
 - Metoclopramide (category B): 10 mg PO q6–8h PRN
 - Prochlorperazine (category C): 5–10 mg PO q6h or 25 mg PR q12h PRN
 - Promethazine (category C): 12.5–25 mg PO or PR q4–6h PRN
 - Pyridoxine (vitamin B₆; category A): 25 mg PO TID (OTC)
 - Ginger (*Zingiber officinale*): 500–1500 mg div. bid/tid
 - Doxylamine (Unisom—OTC) 12.5 mg PO q6–8h usually with pyridoxine (vitamin B₆)
 - Thiamine: 50 mg PO per day for symptoms > 3 wks

Second Line

Methylprednisolone (category C): 16 mg IV or PO q8h × 3 days and then taper. Should be prescribed in consultation with obstetrician.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Inability to tolerate oral intake after treatment
- Inability to control the emesis despite treatment
- Severe electrolyte or metabolic disturbances
- At highest risk < 8 wk gestation

Discharge Criteria

- Most patients can be discharged as long as they are able to tolerate oral intake and have adequate follow-up
- Correction of dehydration and associated symptoms
- Decreased ketonuria
- Reassure patient that their symptoms are common and usually self-limited
- Patients should be counseled that frequent, small meals may be helpful:
 - Meals should contain simple carbohydrates and be low in fats
 - Avoid irritant or spicy foods
- Home IV therapy can be arranged if indicated

FOLLOW-UP RECOMMENDATIONS

- All patients with diagnosis should take at least 3 mg thiamine/day to help prevent Wernicke encephalopathy; a supplement of 50 mg/day PO is recommended
- Risk for 1st trimester fetal loss is less in women with hyperemesis

PEARLS AND PITFALLS

- Other diagnoses should be explored in patients presenting after 9 wk gestation with nausea and vomiting as initial symptoms
- The use of PICC lines has been shown to carry significantly increased risk of maternal morbidity when compared to patients managed with either NG tube or medications alone
- Be aware of the risk for central pontine myelinosis in hyponatremia patients when replacing sodium
- Wernicke encephalopathy is the most devastating maternal complication:
 - Patients may not have the classic triad of ataxia, nystagmus, and dementia. Be concerned for any evidence of apathy or confusion

- Be sure to give patients thiamine 100 mg IV for any patient who presents with apathy or confusion

CODES

ICD9

- 643.00 Mild hyperemesis gravidarum, unspecified as to episode of care or not applicable
- 643.10 Hyperemesis gravidarum with metabolic disturbance, unspecified as to episode of care or not applicable

ICD10

- O21.0 Mild hyperemesis gravidarum
- O21.1 Hyperemesis gravidarum with metabolic disturbance

HYPERKALEMIA

Christopher B. Colwell

BASICS

DESCRIPTION

- Potassium distribution:
 - Extracellular space: 2%
 - Intracellular space: 98%
- Potassium excretion:
 - Renal: 90%
 - GI: 10%
- Renal (80–90%) and extrarenal mechanisms maintain normal plasma concentration between 3.5 and 5 mmol/L.
- Renal excretion of potassium affected by:
 - Dietary intake
 - Distal renal tubular function
 - Acid–base balance
 - Mineralocorticoids
- Regulation between intracellular and extracellular potassium balance is affected by:
 - Acid–base balance
 - Insulin
 - Mineralocorticoids
 - Catecholamines
 - Osmolarity
 - Drugs

ETIOLOGY

- Decreased potassium excretion:
 - Most common cause: Renal failure (acute or chronic)
 - Distal tubular diseases:
 - Acute interstitial nephritis
 - Renal transplant rejection
 - Sickle cell nephropathy
 - Renal tubular acidosis (diabetes)
 - Mineralocorticoid deficiency:
 - Addison disease
 - Hypoaldosteronism
 - Drugs:
 - ACE inhibitors/angiotensin receptor blockers

- β -blockers
- Potassium-sparing diuretics
- NSAIDs
- Cyclosporine
- High-dose trimethoprim
- Lithium toxicity
- Intracellular to extracellular potassium shifts:
 - Metabolic acidosis:
 - Serum K^+ rises 0.2–1.7 mmol/L for each 0.1 U fall in arterial pH.
 - Hyperosmolar states
 - Insulin deficiency
 - Cell necrosis
 - Rhabdomyolysis
 - Hemolysis
 - Chemotherapy
 - Drugs:
 - Digitalis toxicity
 - Depolarizing muscle relaxants (e.g., succinylcholine)
 - β -blockers
 - α -agonists
 - Hyperkalemic periodic paralysis
- Excess exogenous potassium load:
 - Cellular breakdown:
 - Trauma
 - Tumor lysis
 - Salt substitutes
 - Oral potassium
 - Potassium penicillin G
 - Rapid transfusions of banked blood
- Pseudohyperkalemia:
 - Traumatic venipuncture with hemolysis
 - Postvenipuncture release of potassium can occur in the setting of:
 - Thrombocytosis (platelets $> 800,000/\text{mm}^3$)
 - Extreme leukocytosis (WBC $> 100,000/\text{mm}^3$)
 - Prolonged tourniquet time

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Hyperkalemia is often asymptomatic, even at high levels.

- Neuromuscular symptoms, predominantly weakness, which can progress to paralysis.
- Dyspnea owing to respiratory muscle weakness.
- Cardiac dysrhythmias may be the initial manifestation, so patients could also present with chest pain, palpitations, or syncope.

Physical-Exam

- Muscular weakness (rare except in severe cases)
 - _ Paralysis has been described
- Cardiac dysrhythmias (see ECG Changes)

ESSENTIAL WORKUP

- Serum potassium > 5 mmol/L
- Collect in heparinized tube if pseudohyperkalemia suspected.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Electrolytes, BUN, creatinine, glucose:
 - _ Elevated BUN, creatinine in renal failure
 - _ Hyponatremia with mineralocorticoid deficiency
 - _ Mild metabolic acidosis with type IV renal tubular acidosis
- Arterial blood gases:
 - _ Assess acid–base status
- Creatinine kinase:
 - _ Rhabdomyolysis can lead to renal insufficiency and result in hyperkalemia
- Ca^{2+}
- For hyperkalemia in face of normal renal function, calculate transtubular potassium gradient (TTKG):
 - _ $\text{TTKG} = \text{urine K} \times \text{Posm} / \text{plasma K} \times \text{Uosm}$
 - _ Posm, plasma osmolality; Uosm, urine osmolality
 - _ $\text{TTKG} > 8$ suggests extrarenal cause; $\text{TTKG} < 6$ indicates renal excretory defect.

Diagnostic Procedures/Surgery

- ECG: Changes correlate with degree of hyperkalemia:
 - _ > 5–6.5: Peaking of T-waves; shortening of QT_c interval
 - _ > 6.5–8: PR prolongation; loss of P-waves; widening of QRS complexes
 - _ > 8: Intraventricular blocks; bundle branch blocks; QRS axis shifts; sine wave complex
- Serum potassium cannot be reliably predicted by ECG:
 - _ Some patients (particularly those with chronic renal failure) will tolerate

higher potassium levels than others.

- Potassium effects (as seen on ECG) are more important than potassium level
- While unusual, the ECG can be normal in the setting of severe hyperkalemia

DIFFERENTIAL DIAGNOSIS

Pseudohyperkalemia

ALERT

Most common cause of hyperkalemia reported by lab is pseudohyperkalemia owing to hemolysis of red blood cells.

TREATMENT

PRE HOSPITAL

- Treatment of hyperkalemic-induced dysrhythmias/cardiac arrest involves different drugs from usual advanced cardiac life support (ACLS) measures (see Treatment, below):
 - Inhaled albuterol can lower potassium temporarily by 1 mmol/L.
 - β -agonists can also be administered by metered-dose inhaler or intravenously
 - Sodium bicarbonate can be effective in the setting of a metabolic acidosis.
 - Calcium chloride or gluconate is available in some prehospital systems and should be considered in the unstable patient when hyperkalemia is suspected.
- Diagnosis suggested by prehospital rhythm strip or in at-risk populations (renal failure)

INITIAL STABILIZATION/THERAPY

- ABCs
- IV access
- Cardiac monitor

ED TREATMENT/PROCEDURES

- Hyperkalemia with ECG changes (widened QRS complexes): Antagonize potassium-mediated cardiotoxicity:
 - Administer calcium gluconate (in awake patient) or calcium chloride (in patient without pulse):
 - Onset 1–3 min
 - 30–60 min duration
 - No effect on total serum potassium levels
- Severe (>7) or moderate (6–7) with ECG changes (heightened T-waves or loss of P-wave): Shift potassium intracellularly:
 - Administer combination of insulin and glucose:

- Onset 20–30 min
- 2–4 hr duration
- IV sodium bicarbonate:
 - Much more effective in patient who is acidotic
 - Onset 20 min
 - 2 hr duration
 - Caution in patients at risk for volume overload
 - Worsens concomitant hypocalcemia and hypernatremia
- Inhaled albuterol:
 - Onset within 30 min
 - 2–4 hr duration
- Can also be given by metered-dose inhaler or intravenously
- Calcium should be administered if the patient is unstable
- Enhanced excretion for $K^+ > 6$ without ECG changes:
 - Administer cation exchange resin:
 - Calcium or sodium polystyrene sulfonate PO or per rectum (PR)
 - Avoid in patients with suspected ileus or bowel obstruction.
- All patients:
 - Limit exogenous potassium and potassium-sparing drugs.
 - Treat underlying cause.

Special Situations

- Renal failure:
 - Hemodialysis immediately effective at removing potassium
 - Furosemide:
 - Effective in the absence of oliguric renal failure
 - Causes potassium-losing diuresis
- Cardiac arrest:
 - Administer $CaCl_2$ and $NaHCO_3$ with known or suspected hyperkalemia.
- Digoxin toxicity:
 - Avoid calcium if possible
 - When necessary, administer small doses very slowly.
 - Consider Digibind for $K^+ > 5.5$ mmol/L.
- Mineralocorticoid deficiency:
 - Administer hydrocortisone

MEDICATION

- Albuterol: 10–20 mg (peds: 2.5 mg if < 25 kg; 5 mg if ≥ 25 kg) nebulized over 10 min
- Calcium chloride 10%: 10 mL amp (peds: 0.2 mL/kg per dose) IV over 2–5 min
- Calcium gluconate 10%: 10 mL amp (peds: 0.6–1 mL/kg) IV over 2–5 min
- Furosemide: 40–80 mg (peds: 1 mg/kg) IV—modify dose to achieve appropriate

diuresis

- Hydrocortisone: 100 mg (peds: 1–2 mg/kg) IV
- Insulin and glucose: 10 U (peds: 0.1 U/kg) regular insulin + 50 mL 50% (peds: 0.5–1 g/kg) dextrose IV
- Sodium bicarbonate: 1–3 amps (44 mEq per amp) IV over 20–30 min (peds: 1–2 mEq/kg per dose)
- Sodium polystyrene sulfonate (Kayexalate) or calcium polystyrene sulfonate (preferred with volume overload):
 - Oral: 15 g mixed with water or 50 mL of sorbitol q2h to total of 5 doses
 - Rectal enema: 50 g in 200 mL of sorbitol q4–6h
 - Peds: 1 g/kg orally or rectally

First Line

- Calcium (under appropriate situations)
- Insulin and glucose

Second Line

- Sodium bicarbonate
- Kayexalate
- Albuterol

FOLLOW-UP

DISPOSITION

Admission Criteria

Admit most cases:

- Process of potassium removal is relatively slow.
- Most potassium is intracellular and, therefore, not measured on serum electrolytes.
- Significant changes in levels will take time.
- Levels may continue to rise.

Discharge Criteria

Mild hyperkalemia (< 5.5 mmol/L) provided that:

- Response to treatment has been demonstrated
- Known correctable cause
- Further rises in serum potassium not anticipated
- Early follow-up possible

Issues for Referral

Follow-up to address the underlying cause is important. In many cases, the underlying cause is renal insufficiency and the potassium will become elevated again if this is not

addressed. Often this will mean regular hemodialysis.

FOLLOW-UP RECOMMENDATIONS

Many patients with hyperkalemia will be admitted. For those who are not, close follow-up and in many cases access to hemodialysis will be important.

PEARLS AND PITFALLS

- Potassium effect is more important than absolute potassium level. The ECG is the most important determinate of need to treat acutely.
- Do not wait for confirmation of the potassium level to treat when the ECG indicates a hyperkalemic emergency
- Hyperkalemia is often asymptomatic until late: Obtain an ECG early in patients at risk.
- Sodium bicarbonate administration can easily lead to volume overload if not careful.

HYPERNATREMIA

Linda Mueller

BASICS

DESCRIPTION

Hypernatremia definition: Sodium > 145 mEq/L:

- Mild hypernatremia: Serum sodium 146–155 mEq/L
- Severe hypernatremia: Serum sodium > 155 mEq/L

ETIOLOGY

Divided into 3 categories

hypovolemic Hypernatremia

- Most common
- Loss or deficiency of water and sodium with water losses being greater than sodium losses
- Examples:
 - Renal failure
 - Medications (e.g., diuretics, lactulose)
 - Osmotic diuresis (mannitol, glucosuria, high protein feedings)
 - Insensible losses (burns, sweating)
 - Respiratory loss
 - Defective thirst mechanism
 - Lack of access to water
 - Diarrhea/vomiting
 - Intubated patients

Isovolemic Hypernatremia

- Water deficiency without sodium loss; free water loss
- Examples:
 - Fever
 - Hypothalamic diabetes insipidus (DI):
 - Head trauma
 - Tumor
 - Congenital
 - Infection (TB, syphilis, mycoses, toxoplasmosis, encephalitis)
 - Granulomatous disease (sarcoid, Wegner)
 - Cerebrovascular accident
 - Aneurysm
 - Nephrogenic DI:

- Congenital
- Drugs (lithium, amphotericin B, foscarnet, demeclocycline)
- Obstructive uropathy
- Chronic tubulointerstitial disease (sickle cell nephropathy, multiple myeloma, amyloidosis, sarcoidosis, systemic lupus erythematosus, polycystic kidney)
- Electrolyte disorders (hypercalcemia, potassium depletion)

Hypervolemic Hypernatremia

- Gain of water and sodium, with sodium gain greater than water gain.
- Examples:
 - Iatrogenic—most common cause:
 - Sodium bicarbonate administration
 - NaCl tablets
 - Hypertonic parenteral hyperalimentation
 - Hypertonic IV fluid (IVF)
 - Hypertonic dialysis
 - Hypertonic medicine preparations such as ticarcillin and carbenicillin
 - Cushing disease
 - Adrenal hyperplasia
 - Primary aldosteronism
 - Sea water drownings

Pediatric Considerations

- More prone to iatrogenic causes
- More likely to die or to have permanent neurologic sequelae
- Morbidity ranges from 25% to 50%.
- May present with high-pitched cry, lethargy, irritability, muscle weakness
- Poor breast feeding and inappropriate formula preparations are a potential cause in neonates
- If hypernatremia is due to DKA, follow pediatric DKA protocols for fluid resuscitation
- DDAVP dose for 3 mo–12 yr is 5–30 µg/day intranasally
 - Consider NG hydration

Geriatric Considerations

- Most commonly affected group due to impaired renal concentrating ability and reduced thirst mechanism
- Consider neglect if underlying etiology is dehydration alone

Pregnancy Considerations

- May encounter transient DI of pregnancy

- Vasopressin and desmopressin are category B drugs in pregnancy
- Hydration status much more difficult to evaluate accurately by exam

DIAGNOSIS

SIGNS AND SYMPTOMS

- Most symptoms attributed to underlying cause (e.g., dehydration)
- More marked with acute changes
- Death likely to occur with sodium of ≥ 185 mEq/L
- May see the following symptoms, usually at levels ≥ 160 mEq/L:
 - _ Neurologic:
 - Headache
 - Tremulousness
 - Irritability
 - Ataxia
 - Mental confusion
 - Delirium
 - Seizures
 - Coma
 - Hyperreflexia
 - Asterixis
 - Chorea
 - Subarachnoid, intracerebral, and subdural hemorrhages
 - Dural sinus thrombosis
 - _ Musculoskeletal:
 - Spasticity
 - Muscle weakness
 - Muscle twitching
 - _ Other:
 - Anorexia
 - Tachypnea
 - Poor skin turgor
 - Nausea/vomiting

Hypovolemic Hypernatremia

- Tachycardia
- Orthostasis
- Dry mucous membranes
- Oliguria
- Azotemia

Hypervolemic Hypernatremia

- Pulmonary edema
- Peripheral edema

Physical-Exam

- Evaluate for hydration status
- Look at mucous membranes, neck veins, and skin turgor
- Perform a complete neurologic exam and repeat throughout ED stay
- Obtain orthostatic vital signs

ESSENTIAL WORKUP

Serum Na⁺ level

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Electrolytes, BUN/creatinine, glucose
- CBC
- Urinalysis:
 - Specific gravity
 - Urine/serum osmolality
 - Urine Na⁺

Imaging

- CXR:
 - For infection/aspiration
 - Pulmonary edema with hypervolemic hyponatremia
- CT brain:
 - For altered mental status
 - Venous sinus thrombosis
 - Subarachnoid hemorrhages
 - Subdural hematoma

Diagnostic Procedures/Surgery

Consider Foley catheter to accurately monitor input and output

DIFFERENTIAL DIAGNOSIS

- Diabetic ketoacidosis
- Hyperosmolar coma
- Primary CNS lesions

TREATMENT

PRE HOSPITAL

Volume resuscitation if hypovolemic or evidence of hemodynamic compromise

INITIAL STABILIZATION/THERAPY

- ABCs
- 0.9% NS IV bolus for severe hypotension
- Naloxone, thiamine, D₅₀W (or Accu-Chek) for altered mental status

ED TREATMENT/PROCEDURES

General:

- Calculate water deficit:
 - _ Water deficit = $0.6 (\text{weight in kg}) \times (1 - \text{desired sodium/actual sodium})$
- Do not rapidly correct hypertonicity to normal serum osmolality:
 - _ Rapid correction may cause seizures.
 - _ Reduce serum sodium level by $< 0.5\text{--}0.7 \text{ mEq/L/hr}$.

Hypovolemic Hypernatremia

- Replace volume contraction with 0.9% NS IV bolus.
- Change to D₅W or hypotonic saline once volume replenished and hemodynamically stable.

Isovolemic Hypernatremia

- Calculate water deficit.
- Correct water deficit with D₅W or hypotonic saline:
 - _ Replace half of deficit in 1st 24 hr, then remainder over 1–2 days.

Hypervolemic Hypernatremia

- Remove excess water with diuretics or dialysis.
- When euvolemic, replace water deficit with D₅W.
- Avoid hypertonic saline solutions because patient already has excess of total body sodium.

Diabetes Insipidus Hypernatremia

- Sodium restriction
- Desmopressin:
 - _ Aqueous vasopressin (DDAVP)
 - _ Best therapeutic agent
- Chlorpropamide (Diabinese) enhances effect of vasopressin at renal tubule.
- Carbamazepine causes release of vasopressin.
- Hydrochlorothiazide enhances sodium excretion.
- Discontinue DI-inducing drugs.

MEDICATION

- Chlorpropamide (Diabinese): 100–500 mg/d
- Vasopressin (DDAVP): 1–2 µg IV/SC q12h or 5–20 µg intranasally

First Line

Volume correction starting initially with NS

Second Line

Correct the underlying cause.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Newly diagnosed sodium > 150 mEq/L for monitoring and treatment
- Admit sodium > 160 mEq/L or symptomatic patients to ICU.

Discharge Criteria

- Sodium < 150 mEq/L in asymptomatic patient
- Sodium > 150 mEq/L in patients with history of chronically elevated sodium who are at their baseline and asymptomatic

FOLLOW-UP RECOMMENDATIONS

Repeat serum sodium levels within a week.

PEARLS AND PITFALLS

- Up to 30% of acute hypernatremia patients will have permanent neurologic sequelae, a complete and well-documented neurologic exam is a must.
- Patients at extreme ages and with chronic conditions are most susceptible to neurologic complications:
 - On going fluid losses may require recalculation of fluid needs
 - Repeat lab work to confirm controlled correction of sodium

HYPEROSMOLAR SYNDROME

Matthew T. Robinson

BASICS

DESCRIPTION

- Results from a relative insulin deficiency in the undiagnosed or untreated diabetic
- Sustained hyperglycemia creates an osmotic diuresis and dehydration:
 - Extracellular space maintained by the osmotic gradient at the expense of the intracellular space
 - Eventually profound intracellular dehydration occurs.
- Total body deficits of H_2O , Na^+ , Cl^- , K^- , PO_4^- , Ca^{2+} , and Mg^{2+}
- In contrast to diabetic ketoacidosis (DKA), severe ketoacidosis does not occur:
 - Circulating insulin levels are higher.
 - The elevation of insulin counter-regulatory hormones is less marked.
 - The hyperosmolar state itself inhibits lipolysis (the release of free fatty acids) and subsequent generation of keto acids

Geriatric Considerations

- Most commonly seen in elderly type II diabetics who experience a stressful illness that precipitates worsening hyperglycemia and reduced renal function
- In the elderly, 30–40% of cases are associated with the initial presentation of diabetes.

Pediatric Considerations

Hyperosmolar hyperglycemic states (HHS) rare in pediatric patients

ETIOLOGY

- Hyperosmolar state precipitated by factors that:
 - Impair peripheral insulin action
 - Increase endogenous or exogenous glucose
 - Decrease patient's ability to replace fluid loss
- Infection is the most common precipitating factor in 32–60% of cases.
- Other precipitating causes include:
 - Inadequate diabetes therapy
 - Medication omission
 - Diet indiscretion
 - Infections
 - Pneumonia
 - UTI
 - Sepsis

- Medications/drugs
- Diuretics
- β -blockers
- Calcium channel blockers
- Phenytoin
- Cimetidine
- Amphetamines
- Ethanol
- Myocardial infarction
- Stroke
- Renal failure
- Heat stroke
- Pancreatitis
- Intestinal obstruction
- Endocrine disorders
- Burns
- Heat stroke

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Progression of signs and symptoms typically occur over days to weeks.
- Polyuria/polydipsia/weight loss
- Dizziness/weakness/fatigue
- Blurred vision
- Leg cramps

Physical-Exam

- Dehydration
- Tachycardia
- Sunken eyes
- Hypotension
- Orthostasis
- Dry mucous membranes
- Decreased skin turgor
- Collapsed neck veins
- Coma/lethargy/drowsiness
- Urinary output maintained until late
- Seizures/focal neurologic deficits
- Concurrent precipitating medical illness

ESSENTIAL WORKUP

Diagnostic criteria:

- Serum glucose ≥ 600 mg/dL (usually $> 1,000$ mg/dL)
- Minimal ketosis
- pH ≥ 7.30 , $\text{HCO}_3^- \geq 15$ mEq/L
- Effective serum osmolality > 320 mOsm/kg:
 - _ $= 2 \times \text{Na}^+ + \text{glucose}/18$
 - _ BUN not included because it is freely permeable between fluid compartments

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Broad testing indicated to evaluate hyperosmolar syndrome and for precipitating causes
- Electrolytes:
 - _ K^+ may be elevated even in the presence of total body deficit owing to shift from intracellular space to extracellular space.
 - _ Mild anion gap metabolic acidosis owing to lactic acid, β -hydroxybutyric acid, or renal insufficiency
 - _ Increased sodium—correct for hyperglycemia: Corrected $[\text{Na}^+] = [\text{Na}^+] + 1.6 \times [(\text{glucose in mg/dL}) - 100]/100$
- BUN, creatinine:
 - _ Azotemia with elevated BUN/creatinine ratio owing to prerenal and intrarenal causes
- Venous blood gas (VBG) or arterial blood gas (ABG) to rapidly determine pH:
 - _ ABG necessary to evaluate mixed acid–base disorders
- Serum ketones, β -hydroxybutyrate, and lactate level if pH < 7.3 or significantly elevated anion gap to evaluate mixed acid–base disorder
- Serum osmolality
- CBC:
 - _ Leukocytosis due to infection, stress, or hemoconcentration
 - _ Increased hemoglobin and hematocrit due to hemoconcentration
- Lipase and amylase:
 - _ Pancreatitis common
 - _ Elevated amylase and lipase with no evidence of pancreatitis common
 - _ May be due to increased salivary secretion, hemoconcentration, or decreased renal clearance
- Urinalysis:
 - _ Check for ketones/glucose.
 - _ Assess for UTI.
- Magnesium, calcium, phosphate

- Blood cultures in sepsis
- Creatine kinase for rhabdomyolysis:
 - Incidence as high as 17%
- Urine pregnancy test in females of childbearing years
- Cardiac enzymes and troponin for myocardial infarction

Imaging

- CXR to evaluate for possible underlying pneumonia
- Head CT: When indicated for AMS or with focal neurologic deficit

Diagnostic Procedures/Surgery

ECG:

- Evaluate for electrolyte abnormalities causing conduction impairment
- Evaluate for signs of ischemia as triggering event

DIFFERENTIAL DIAGNOSIS

Differentiate from DKA:

- If acidosis or significant anion gap present, must determine cause (i.e., ketosis, DKA, lactic acidosis, [hypoperfusion, sepsis, or postictal], or other causes of metabolic acidosis)
- Mixed disorder of HHS and DKA present in up to 33% of patients

TREATMENT

PRE HOSPITAL

IV fluid resuscitation and initial stabilization

INITIAL STABILIZATION/THERAPY

ABCs:

- Secure airway in comatose patients.
- Cardiac monitor and 18G IV
- Naloxone, thiamine, and blood glucose for coma of unknown cause
- Restore hemodynamic stability with IV fluids.
- 0.9% NS 1–2 L over the 1st hr
- Larger volumes of fluid may be needed to normalize the vital signs and establish urine output.

ED TREATMENT/PROCEDURES

- General strategy:
 - Frequent reassessment of volume and mental status
 - Electrolyte assessment difficult:
 - Serum levels of Na^+ , K^+ , PO_4^- do not accurately reflect the total

body solute deficits or the intracellular environment.

- Repeat electrolyte and glucose levels hourly.

– Search for a precipitating illness.

- Fluids:

– Begin resuscitation with 0.9% NS 1–2 L over 1–2 hr to restore intravascular volume and achieve hemodynamic stability.

– Use 0.45% saline after initial resuscitation

– Calculate total body water (TBW) deficit using corrected serum sodium:

- $TBW \text{ deficit} = 0.6 \times \text{weight (kg)} \times (1 - 140/\text{corrected Na}^+)$

– Average fluid deficit is 9 L.

– Replace 50% of the fluid deficit over the next 12 hr.

– Change fluid to D5 1/2 NS when serum glucose is < 250 mg/dL.

- Potassium:

– Anticipate hypokalemia:

- Total body deficit of $\sim 5\text{--}10$ mEq/kg body weight (replace over 3 days)

– Begin potassium repletion after urine output is established. Do not start in anuric patients or if initial K^+ level is > 5 mEq/L.

- If the initial K^+ is normal (4–5 mEq/L), give 20–30 mEq KCl in the 1st L of fluids, then give 20 mEq/hr.

- If the initial K^+ is low (3–4 mEq/L), give 40 mEq in 1st L

- If serum K^+ is < 3 mEq/L hold insulin and give 10–20 mEq/h until $K^+ > 3.3$, then add 40 mEq to each liter

- Follow repeat serum K^+ levels q1–2h and adjust treatment accordingly.

- Insulin:

– No role in the early resuscitation

– Earlier use of insulin may cause rapid correction of hyperglycemia with collapse of the intravascular space, hypotension, and shock or hypokalemia and dysrhythmias.

– Some patients will not require insulin.

– Use insulin as sole therapy in patients with fluid overload (i.e., acute renal failure [ARF]).

– Begin only after achieving hemodynamic stability and evaluating for hypokalemia:

- Do not use unless serum $K^+ > 3.3$ mEq/L

– SC or IM insulin not recommended due to erratic absorption

– Titrate drip to optimally decrease serum glucose by 50–90 mg/dL/hr. More rapid correction places the patient at risk for developing cerebral edema.

– Decrease drip rate by 1/2 when serum glucose < 250 mg/dL.

– Adjust insulin drip to maintain serum glucose between 150–200 mg/dL, and

continue until serum bicarbonate is >18 mg/dL and pH > 7.3

- Phosphate:
 - Routine replacement not recommended
 - If serum levels <1 mg/dL, give 20–30 mmol potassium phosphate over 24 hr
 - Monitor serum calcium levels closely
- Magnesium:
 - 0.35 mEq/kg magnesium in fluids for 1st 3–4 hr (2.5–3 g MgSO_4 in 70 kg patient)
 - Caution in ARF
- Anticoagulation:
 - Arterial thrombosis may complicate hyperosmolar state:
 - Consider SC heparin as prophylaxis.
 - Remain vigilant to detect thrombotic complications (e.g., MI, pulmonary embolus, mesenteric ischemia).

MEDICATION

- Insulin: Begin with 0.05–0.1 U/kg/h; modify after assessing clinical response.
- MgSO_4 (magnesium sulfate): 50% (5 g/10 mL; dilute to at least 20% before IV use)
- Naloxone: 2 mg (peds: 0.1 mg/kg) IV push (IVP)
- Potassium phosphate IV: Phosphorous serum level <0.5 mg/dL: 0.5 mmol/kg IV infused over 4–6 hr; phosphorous serum level 0.5–1 mg/dL: 0.25 mmol/kg IV infused over 4–6 hr
- Potassium phosphate PO: Phosphorus 250 mg per tablet and potassium 1.1 mEq per tablet
- Thiamine: 100 mg (peds: 10–25 mg) IVP

FOLLOW-UP

DISPOSITION

Admission Criteria

- All but the mildest cases should be admitted to ICU:
 - Frequent serial labs for the 1st 24 hr
 - Rapid shifts in fluids and electrolytes and the potential for deterioration in mental status and arrhythmias mandate close monitoring.
- Mild cases may be managed in an observation unit over 12–24 hr.

Discharge Criteria

- Patients meeting the diagnostic criteria for hyperosmolar syndrome should not be discharged.
- Mild hyperglycemia patients with mild volume deficits and normal serum

osmolarity can be discharged after hydration and correction of hyperglycemia.

Issues for Referral

Patient should follow-up with endocrinology and with their primary physician within 1 wk postdischarge for long-term blood glucose monitoring and insulin therapy.

PEARLS AND PITFALLS

- Failure to look for precipitating event or cause
- Too rapid correction of glucose—may lead to hypotension
- Continuing isotonic fluids after volume resuscitation—may lead to hypernatremia
- Continuing hypotonic fluids without frequent electrolytes—may lead to cellular edema, cerebral edema
- Failure to prevent hypokalemia: Respiratory depression, dysrhythmias
- Avoid phenytoin in the event of seizure activity:
 - _ Inhibits the endogenous release of insulin

Diabetic Ketoacidosis

CODES

ICD9

- 250.20 Diabetes with hyperosmolarity, type II or unspecified type, not stated as uncontrolled
- 250.21 Diabetes with hyperosmolarity, type I [juvenile type], not stated as uncontrolled
- 276.0 Hyperosmolality and/or hypernatremia

ICD10

- E11.01 Type 2 diabetes mellitus with hyperosmolarity with coma
- E87.1 Hypo-osmolality and hyponatremia

HYPERPARATHYROIDISM

Rami A. Ahmed • Brad D. Gable

BASICS

DESCRIPTION

- Parathyroid hormone (PTH) excess with symptoms owing to PTH actions:
 - _ Decreases urinary Ca^{2+} loss
 - _ Increases urinary PO_4^{2-} loss
 - _ Stimulates vitamin D conversion from 25(OH)-D to 1,25(OH)-D in kidney
 - _ Liberates Ca^{2+} and PO_4^{2-} from bone
 - _ Hypercalcemia is the primary metabolic finding
- Hypercalciuria from hypercalcemia (despite decreased urinary loss) produces increased magnesium loss in urine
- Magnesium (negative feedback to prevent hypercalcemia causes hypomagnesaemia):
 - _ Cofactor in the production of PTH
 - _ Essential for action of PTH in target tissues
- Genetics:
 - _ Associated with multiple endocrine neoplasia type 1:
 - Hyperparathyroidism
 - Pancreatic islet disease
 - Pituitary disease
 - _ Associated with multiple endocrine neoplasia type 2:
 - Hyperparathyroidism (type 2A, rare in 2B)
 - Medullary carcinoma of the thyroid (type 2A and 2B, less virulent in type 2A)
 - Pheochromocytoma (type 2A and 2B)
 - Mucosal neuroma (type 2B)

ETIOLOGY

- Excess secretion of PTH owing to:
 - _ Primary hyperparathyroidism (adenoma 85%, hyperplasia 14%, carcinoma <1%)
 - _ Secondary hyperparathyroidism (response to vitamin D deficiency or chronic renal failure with hyperphosphatemia):
 - Calcium is low or normal, but PTH levels are elevated

DIAGNOSIS

SIGNS AND SYMPTOMS

Stones, bones, abdominal groans, and psychiatric moans

ALERT

- Hypercalcemic crisis:
 - _ Anorexia, nausea, vomiting
 - _ Mental obtundation

History

Depends on the severity and rapidity of hypercalcemia

Pediatric Considerations

- Neonate:
 - _ Hypotonia, weakness, and listlessness
 - _ Following delivery to hypoparathyroid mothers
- Hypercalcemic infants:
 - _ Broad forehead
 - _ Epicanthal folds
 - _ Underdeveloped nasal bridge
 - _ Prominent upper lip

Physical-Exam

- Dehydration
- Cardiac:
 - _ Hypertension (even in the face of dehydration)
 - _ Cardiac conduction abnormalities (*not* proportional to degree of hypercalcemia)
 - _ Bradydysrhythmia
 - _ Bundle branch blocks
 - _ Complete heart block
 - _ Asystole
 - _ Short QT interval (shortened ST segment)
 - _ Potentiation of digitalis effects (Hypercalcemia + digoxin = digitalis toxicity)
- Neurologic:
 - _ Headaches
 - _ Decreased reflexes
 - _ Proximal muscle weakness
 - _ Dementia
 - _ Lethargy
 - _ Coma
- Psychiatric:

- Personality changes
- Depression
- Inability to concentrate
- Anxiety
- Psychosis
- GI:
 - Anorexia, nausea, vomiting
 - Constipation
 - Peptic ulcer disease
 - Pancreatitis
- General:
 - Fatigue
 - Weight loss
 - Polyuria and polydipsia
- Musculoskeletal:
 - Gout/pseudogout
 - Bone pain, bone cysts (osteitis cystica)
 - Arthralgias
 - Chondrocalcinosis
- Renal:
 - Kidney stones
 - Nephrocalcinosis
 - Decreased renal concentrating ability

ESSENTIAL WORKUP

- Calcium level
- Albumin:
 - Elevated albumin—falsely elevated calcium level
 - Low albumin—falsely lowered calcium level
- Evaluate for symptoms of hypercalcemia, especially impending parathyroid storm (hypercalcemic crisis—anorexia, nausea, vomiting, obtundation progressing to coma).
- Review history for medication ingestion (see Differential Diagnosis below)
- No further ED workup if:
 - Asymptomatic
 - Normal ECG
 - Calcium level < 14 mg/dL when corrected for albumin
- If symptomatic with $\text{Ca}^{2+} < 14$ mg/dL or any patient with $\text{Ca}^{2+} \geq 14$ mg/dL, check:
 - Ionized calcium
 - Chest radiograph (for CHF/malignancy)
 - Phosphorus
 - Electrolytes, BUN, creatinine

- Sedimentation rate
- Alkaline phosphatase
- Magnesium
- Thyroid-stimulating hormone (TSH)
- CBC

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Calcium correction for albumin:
 - Corrected Ca^{2+} (mg/dL) = measured Ca^{2+} (mg/dL) + 0.8 [4 – albumin (g/dL)]
 - Acidosis:
 - Decreases affinity to albumin—increases ionized (metabolically active) Ca^{2+}
 - Decrease of 0.1 pH unit increases the ionized Ca^{2+} by 3–8%
- Phosphorus:
 - Low in primary hyperparathyroidism
 - Usually high in secondary hyperparathyroidism
 - Normal or high in malignancy-related hypercalcemia
- Chloride/ PO_4^{2-} ratio:
 - > 33—hyperparathyroidism
 - < 30—malignancy
- Alkaline phosphatase:
 - Increased in 50% of patients with hyperparathyroidism
 - Normal with vitamin D excess
- Erythrocyte sedimentation rate (ESR):
 - Normal in hyperparathyroidism
 - Elevated in malignancy or granulomatous diseases
- Anemia:
 - Present with malignancy or granulomatous disease
 - Absent in hyperparathyroidism
- Magnesium:
 - Low or low normal
- PTH:
 - Elevated in primary and secondary hyperparathyroidism
- PTH-related peptide:
 - Secreted by squamous cell carcinomas of lung, head, neck; renal carcinomas, bladder carcinomas, adenocarcinomas, and lymphomas

Imaging

- Chest radiograph:
 - To assess CHF risk during IV hydration
 - Granulomatous disease or malignancy if cause of hypercalcemia is uncertain

Diagnostic Procedures/Surgery

Definitive treatment is parathyroidectomy to treat and establish cause of hyperparathyroidism

DIFFERENTIAL DIAGNOSIS

- PTH related:
 - Primary or secondary hyperparathyroidism
 - Familial hypocalciuric hypercalcemia
- Malignancy related:
 - PTH-related peptide or Ca^{2+} release from osteolytic tumor
- Vitamin D related:
 - Excess vitamin D intake or vitamin D production by granulomas
- Immobilization:
 - Associated with Paget disease
- Drug induced:
 - Thiazide diuretics
 - Lithium
 - Aluminum-containing antacids
 - Tamoxifen
 - Estrogens
 - Androgens
 - Vitamin A

TREATMENT

PRE HOSPITAL

May present as a primarily psychiatric disorder

INITIAL STABILIZATION/THERAPY

- Cardiac monitor if:
 - Symptomatic hypercalcemia
 - Ca^{2+} level > 14 mg/dL
- Hydrate with IV 0.9% NS.
- Correct acidosis

ED TREATMENT/PROCEDURES

- Treat hypercalcemia:
 - Vigorous hydration with 0.9% NS at minimum of 250 mL/hr unless CHF:

- Lowers calcium 1.5–2 mg/dL in 24 hr
- Achieve urine output 100 mL/hr
- Administer furosemide or other loop diuretic (calciuric) after adequate volume replacement or in the presence of CHF:
 - Common error: Administration of furosemide before adequate hydration
 - If urinary sodium losses exceed replacement sodium, then renal conservation measures impede calcium excretion
- Avoid thiazide diuretics (impede calcium excretion)
- Consider glucocorticoid administration (decreases gut absorption and increases renal excretion of Ca^{2+}); most effective with vitamin D intoxication or granulomatous diseases
- Start bisphosphonates (pamidronate or etidronate) in conjunction with primary physician (inhibits calcium mobilization from bone)
- Treat cardiac dysrhythmias in standard fashion:
 - Correct acidosis
- Determine the cause of the hypercalcemia.
- Stop all medications that may contribute to hypercalcemia
- Exercise extreme caution in the use of digoxin.
- Anticipate CHF and electrolyte imbalance with frequent reassessment of patient and monitoring of serum electrolytes and magnesium levels
- Calcitonin if unable to use hydration
- Emergent dialysis with renal failure

MEDICATION

First Line

- NS hydration: Initial 250–300 mL/h depending on patient's propensity to CHF
- Furosemide: 40 mg IV q2–4h after assurance of adequate hydration
- Prednisone: 40–60 mg PO OR Hydrocortisone: 100 mg (peds: 1–2 mg/kg) IV

Second Line

- IN CONSULTATION WITH ENDOCRINOLOGIST
- Calcitonin salmon 4 U/kg SC if saline hydration contraindicated
 - Test dose: Intradermal 0.1 mL of 10 U/mL solution recommended
 - Initial dose: 4 U/kg SC q12h
- Pamidronate:
 - If albumin-corrected Ca^{2+} level 12–13.5 mg/dL: 60 mg IV infused over 2 hr
 - If albumin-corrected Ca^{2+} level > 13.5 mg/dL: 90 mg IV over 4 hr
 - Dosage should be reduced in renal impairment and infusion time may be extended to reduce nephrotoxic potential but no formal recommendations exist (pregnancy category D – maternal benefit may outweigh fetal risk)

- Zoledronic acid: 4 mg IV over 15–30 min (first-line agent due to efficacy and convenience, but less preferred due to lack of less expensive available generic)
- Cinacalcet (Sensipar): 30 mg PO daily or BID (calcimimetic for secondary hyperparathyroidism or parathyroid carcinoma)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Corrected calcium > 14 mg/dL
- Symptomatic hypercalcemia
- Evidence of abnormal cardiac rhythm or conduction

Discharge Criteria

- Not meeting admission criteria
- Able to maintain adequate hydration

Issues for Referral

If diagnosis is suspected, referral to check PTH levels and response to therapy

FOLLOW-UP RECOMMENDATIONS

- If hyperparathyroidism is suspected arrange follow-up and send a PTH level
- Patient needs to be instructed to maintain hydration and stop medications associated with hypercalcemia (see the list in Differential Diagnosis)

PEARLS AND PITFALLS

- The hypercalcemia of hyperparathyroidism is rarely symptomatic and Ca^{2+} level rarely > 14. (Higher levels are most frequently attributable to neoplastic disease)
- The importance of diagnosis is to prevent long-term complications
- Calcium level should be measured as ionized Ca^{2+} , or corrected for albumin level
- Administration of loop diuretics prior to adequate saline hydration will worsen hypercalcemia; some experts suggest that loop diuretics may be no longer warranted for this indication

- E21.3 Hyperparathyroidism, unspecified

HYPERTENSIVE EMERGENCIES

David F. M. Brown • Eva Tovar Hirashima

BASICS

DESCRIPTION

- *Hypertensive crisis:*
 - Severely elevated BP defined by a SBP > 179 mm Hg or a DBP > 109 mm Hg
- *Hypertensive urgency:*
 - Severely elevated BP without end-organ damage
- *Hypertensive emergency:*
 - Severely elevated BP associated with acute end-organ damage
- Loss of autoregulation of blood flow in hypertensive emergency:
 - Arterioles vasoconstrict to counter pressure
 - High pressures overwhelm arterioles and endothelial damage occurs
 - Endothelial injury leads to increase permeability, activation of the coagulation cascade and platelets, and deposition of fibrin
- Activation of the renin–angiotensin system and the sympathetic nervous system:
 - Leads to further vasoconstriction and production of proinflammatory cytokines
- End-organ ischemia:
 - Renewed release of vasoconstrictors
 - Worsened by pressure natriuresis
 - Triggers a vicious cycle
- Organs affected:
 - Brain (encephalopathy, CVA, ICH)
 - Retina (hemorrhage, papilledema)
 - Heart (MI, aortic dissection, acute HF)
 - Kidneys (acute renal failure)
 - Placenta (preeclampsia/eclampsia)

ETIOLOGY

- Essential HTN
- Renal:
 - Vascular disease
 - Parenchymal disease
- Coarctation of the aorta
- CNS disorders:
 - Head trauma
 - CVA/ICH

- Brain tumor
- Spinal cord injury
- Endocrine:
 - Pheochromocytoma
 - Cushing syndrome
 - Primary hyperaldosteronism
 - Renin-secreting tumor
- Drugs:
 - Cocaine, phencyclidine, amphetamines
 - Erythropoietin, tacrolimus, cyclosporine, corticosteroids, oral contraceptives
 - MAOI interactions
 - Antihypertensive medication withdrawal
 - Lead intoxication
- Autonomic hyperreactivity:
 - Guillain–Barré syndrome
 - Acute intermittent porphyria
- Postop pain and/or anesthesia complications
- Pregnancy related:
 - Preeclampsia/eclampsia

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Inquire about:
 - Use of any prescribed and OTC medication
 - Duration and control of pre-existing HTN
 - Prior end-organ damage
 - Details of antihypertensive therapy
 - Comorbid conditions (obesity, CAD, DM)
 - Recreational drug use
- Assess for end-organ compromise in decreasing order of frequency:
 - Dyspnea
 - Chest pain
 - Headache
 - Altered mental status/confusion
 - Focal neurologic symptoms

Physical-Exam

- BP measured in both arms
 - Use proper cuff size

- Assess for end-organ compromise:
 - Neurologic:
 - Level of consciousness
 - Visual fields
 - Focal motor/sensory deficits
 - Ophthalmologic:
 - Funduscopic exam (retinal hemorrhages, papilledema)
 - Cardiovascular:
 - Elevated JVP
 - Lung crackles
 - Aortic insufficiency murmur
 - S3
 - Asymmetrical pulses

ESSENTIAL WORKUP

- 12-lead EKG:
 - Ischemic changes, LV hypertrophy
- Assess kidney function
 - Acute renal failure may be asymptomatic

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
 - Anemia and thrombocytopenia are present in thrombotic microangiopathy
- Standard hospital protocols for chest pain
- BUN, creatinine
- Electrolytes
 - Hypokalemia present in primary mineralocorticoid excess
- Urinalysis:
 - Proteinuria, hematuria, and casts
- Urine toxicology screen:
 - If recreational drugs are suspected
- HCG

Imaging

- Chest x-ray:
 - If cardiopulmonary symptoms are present
- Head CT:
 - If headache, confusion, neurologic findings
- CTA chest and abdomen:
 - If concern for aortic dissection

Diagnostic Procedures/Surgery

- Arterial line
- Lumbar puncture:
 - Exclude subarachnoid hemorrhage

DIFFERENTIAL DIAGNOSIS

- Acute coronary syndrome (ACS)
- Acute heart failure (AHF)
- Aortic dissection
- Intracerebral hemorrhage (ICH)
- CVA (ischemic or hemorrhagic)
- Preeclampsia/eclampsia
- Withdrawal syndromes:
 - β -blockers
 - Clonidine (central α 2-agonist)
- States of catecholamine excess:
 - Pheochromocytoma
 - Cocaine/sympathomimetic drug intoxication
 - Tyramine ingestion when on MAOIs

TREATMENT

PRE HOSPITAL

- ABCs
- Consider gentle BP reduction.

INITIAL STABILIZATION/THERAPY

- ABC, cardiac monitoring, pulse oximetry
- Oxygen administration
- IV access

ED TREATMENT/PROCEDURES

- Hypertensive urgency:
 - No need to treat, but close follow-up
 - Use oral agents only
 - Give any missed home dose
 - Goal: Lower the BP gradually over 24–48 hr
- Hypertensive emergency:
 - Treat end-organ damage, not absolute BP
 - Reduce MAP by ≤ 20 –25% in the 1st hr
 - Goal: Systolic ~ 160 mm Hg, diastolic ~ 100 mm Hg in 2–6 hr
 - Once BP stable with IV therapy, transition to oral therapy within 6–12 hr
 - More gradual reduction recommended in:

- Acute ongoing injury to CNS
 - More rapid reduction recommended in:
 - Aortic dissection
- *Hypertensive encephalopathy:*
 - Goal: MAP lowered by max. 20% or to DBP 100–110 mm Hg within 1st hr then gradual reduction in BP to normal over 48–72 hr
 - Drug of choice: Nicardipine, clevidipine, or labetalol
- *Ischemic stroke:*
 - CPP = MAP – ICP
 - Decreased CPP from hypotension (low MAP) or cerebral edema (high ICP) may extend infarct
 - Treat only SBP > 220 mm Hg or DBP > 120 mm Hg
 - Lytic candidates should have BP lowered to < 185/110 mm Hg
 - Goal: MAP lowered by no more than 15–20%, DBP not < 100–110 mm Hg in first 24 hr
 - Goal post tPA: BP < 180/105 mm Hg
 - Drug of choice: Nicardipine, clevidipine, or labetalol
- *Hemorrhagic CVA or SAH:*
 - Treat if SBP > 180 mm Hg/DBP > 100 mm Hg
 - Goal: MAP lowered by 20–25% within the 1st hr or SBP 140–160 mm Hg
 - Drug of choice: Nicardipine, clevidipine, or labetalol
 - Avoid dilating cerebral vessels with nitroglycerin or nitroprusside
- *ACS:*
 - Goal: MAP to 60–100 mm Hg
 - Drug of choice: Labetalol or esmolol in combination with nitroglycerin
 - Avoid: Hydralazine (reflex tachycardia) and nitroprusside (“coronary steal”)
- *AHF:*
 - Goal: MAP to 60–100 mm Hg
 - Drug of choice nitroprusside or NTG with ACEI and/or loop diuretic
- *Acute renal failure/microangiopathic anemia:*
 - Goal: MAP lowered by 20–25% within 1st hr
 - Drug of choice: Nicardipine, clevidipine, or fenoldopam. For scleroderma renal crises ACEI are drugs of choice.
- *Aortic dissection:*
 - Reduce shear force (dP/dT) by reducing both BP and HR
 - β -blockade must precede any drug that may cause reflex tachycardia
 - Goal: SBP 100–120 mm Hg and HR < 65 bpm within 1st 20 min
 - Drug of choice: Esmolol in combination with dihydropyridine CCB or nitroprusside
 - Consult vascular surgery if type A
- *Sympathomimetics (pheochromocytoma, cocaine, amphetamines):*
 - Goal: MAP lowered by 20–25% within 1st hr
 - Avoid pure β -blockade (α is left unopposed)

- Drug of choice: Phentolamine or calcium channel blocker with benzodiazepine. Use clonidine in cases of clonidine withdrawal

Pregnancy Considerations

- ***Preeclampsia:***
 - Definition: SBP > 140 or DBP > 90 mm Hg with proteinuria (> 300 mg/24 hr or a urine protein/creatinine > 0.3 or dipstick 1+)
 - Occurs > 20 wk gestation – 4 wk postpartum
 - Headache, vision changes, peripheral edema, RUQ pain
 - Complications: Eclampsia, HELLP
 - Goal: SBP 130–150 mm Hg and DBP 80–100 mm Hg
 - Drug of choice: Labetalol, nicardipine, hydralazine, magnesium
 - Consult Obstetrics
- ***Esmolol:***
 - β 1-blockade
 - Onset 60s, duration 10–20 min
 - Avoid in AHF, COPD, heart block
- ***Labetalol:***
 - Combined α - and β -blocker
 - Onset 2–5 min, duration 2–6 hr
 - No reflex tachycardia due to β -blockade
 - Avoid in: COPD, AHF, bradycardia
- ***Clevidipine:***
 - 3rd generation dihydropyridine CCB
 - Onset 2–4 min, duration 5–15 min
 - Elimination independent of liver/renal function
 - Avoid in allergies to soy or egg products, defective lipid metabolism, AFib
- ***Nicardipine:***
 - 2nd generation dihydropyridine CCB
 - Onset 5–15 min, duration 4–6 hr
 - Avoid in: AHF, coronary ischemia
- ***Nitroglycerin:***
 - Venous > arteriolar dilation
 - Onset 2–5 min, duration 10–20 min
 - Perfuses coronaries, decreasing ischemia
 - Causes reflex tachycardia, tachyphylaxis, methemoglobinemia
- ***Nitroprusside:***
 - Short-acting arterial and venous dilator
 - Onset 3 s, duration 1–2 min
 - Complications:
 - Reflex tachycardia, “coronary steal”, increase ICP
 - Cyanide toxicity after prolonged use
 - Avoid in pregnancy, renal failure (relative)

- Hydralazine:
 - Arteriolar dilator
 - Onset 5–15 min, duration 3–10 hr
 - Hypotensive effect may be less predictable
 - Safe in pregnancy
- Enalaprilat:
 - ACE inhibitor
 - Onset 0.5–4 hr, duration 6 hr
 - Avoid in: Pregnancy, AMI
- Fenoldopam:
 - Selective postsynaptic dopaminergic receptor agonist (DA1)
 - Onset 5–15 min, duration 1–4 hr
 - No reflex tachycardia
 - Maintains renal perfusion
 - Avoid in: Glaucoma
- Phentolamine:
 - α 1-blocker, peripheral vasodilator
 - Onset 1–2 min, duration 10–30 min

MEDICATION

- Clevidipine: 1–16 mg/h IV infusion
- Enalaprilat: 1.25–5 mg q6h IV bolus
- Esmolol: 80 mg IV bolus, then 150 μ g/kg/min infusion
- Fenoldopam: 0.1–0.6 μ g/kg/min IV infusion
- Hydralazine: 10–20 mg IV bolus
- Labetalol: 20–80 mg IV bolus q10min (total 300 mg); 0.5–2 mg/min IV infusion
- Nicardipine: 2–15 mg/h IV infusion
- Nitroglycerin: 5–100 μ g/min IV infusion; USE NON-PVC tubing
- Nitroprusside: 0.25–10 μ g/kg/min IV infusion
- Phentolamine: 5–15 mg q5–15min IV bolus

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with end-organ damage
- ICU for cardiac and BP monitoring

Discharge Criteria

- Absence of end-organ damage
- Likely to be compliant with primary care

- Known history of HTN
- Reversible precipitating cause (e.g., medication noncompliance)
- Able to resume previous medication regimen
- Return with chest pain or headache

FOLLOW-UP RECOMMENDATIONS

Initiation of a suitable medication regimen under care of a primary care provider

PEARLS AND PITFALLS

- Avoid IV agents for hypertensive urgency
- BP goal in hypertensive emergency is a reduction of the MAP by 20–25% within the 1st hr except in ischemic CVA and aortic dissection
- Avoid excessive or precipitous decrease in BP because it may exacerbate end-organ damage
- Avoid reflex tachycardia in aortic dissection
- Avoid unopposed α in catecholamine excess

ICD10

- I10 Essential (primary) hypertension
- I67.4 Hypertensive encephalopathy

HYPERTHERMIA

Michelle J. Sergel • Emily Singer

BASICS

DESCRIPTION

- Range of progressively more severe illnesses due to increasingly overwhelming heat stress
- Begins with dehydration and electrolyte abnormalities and progresses to thermoregulatory dysfunction and multisystem organ failure
- Body temperature is maintained within a narrow range by balancing heat production with heat dissipation
- Oxidative phosphorylation becomes uncoupled and essential enzymes cease to function above 42°C (108°F)

Heat Stroke

- Core body temp > 105°F (40.5°C)
- Failure of thermoregulatory function leads to severe CNS dysfunction and multisystem organ failure
- Classic heat stroke (nonexertional)
 - Occurs in patients with compromised thermoregulation or an inability to remove themselves from a hot environment (e.g., extremes of age, debilitated)
 - Develops over days to weeks, usually during heat waves
 - Severe dehydration, skin warm and dry
- Exertional heat stroke
 - Younger, athletic patients with combined environmental and exertional heat stress (e.g., military recruits)
 - Develops over hours
 - Internal heat production overwhelms dissipating mechanisms, often despite persistent sweating

Heat Exhaustion

- Core temp moderately elevated but usually < 104°F (40°C)
- Fluid and/or salt depletion occurs secondary to heat stress
- Thermoregulatory function is maintained and CNS function is preserved
- Variable nonspecific symptoms including malaise, headache, fatigue, and nausea
- If left untreated, progresses to heat stroke

ETIOLOGY

- Pre-existing conditions that hinder the body's ability to dissipate heat predispose

for heat-related illness

- Age extremes
- Dehydration (incl. gastroenteritis, inadequate fluid intake)
- Cardiovascular disease (incl. CHF, CAD)
- Obesity
- Diabetes mellitus, hyperthyroidism, pheochromocytoma
- Febrile illness
- Skin diseases that hinder sweating (incl. psoriasis, eczema, cystic fibrosis, scleroderma)
- Pharmacologic contributors
 - Sympathomimetics
 - LSD, PCP, cocaine
 - MAO inhibitors, antipsychotics, anxiolytics
 - Anticholinergics
 - Antihistamines
 - β -blockers
 - Diuretics
 - Laxatives
 - Drug or alcohol withdrawal
- Environmental factors
 - Excessive heat/humidity
 - Prolonged exertion
 - Lack of mobility
 - Lack of air conditioning
 - Lack of acclimatization
 - Occlusive, nonporous clothing

Pediatric Considerations

Children are at increased risk of heat illness due to increased body surface area to mass ratio and lower sweat production

DIAGNOSIS

SIGNS AND SYMPTOMS

Heat Stroke

- Classic triad: Hyperthermia, CNS dysfunction, hot skin (often with anhidrosis)
- Core temp: $> 105^{\circ}\text{F}$ (40.5°C)
- CNS:
 - Severe confusion/delirium
 - Lethargy or coma
 - Seizure

- Ataxia
- CV:
 - Tachycardia
 - Wide pulse pressure
 - Low peripheral vascular resistance
 - Hypotension
 - Conduction disturbances
- Pulmonary:
 - Tachypnea
 - Rales due to noncardiac pulmonary edema
 - Respiratory alkalosis (may be substantial enough to cause tetany)
 - Hypoxemia (due to aspiration, pneumonitis, pulmonary edema, and high metabolic demand)
- GI:
 - Nausea/vomiting
 - Diarrhea
- Skin:
 - Cutaneous vasodilation → Hot skin
 - Usually dry, though sweating may be present if not dehydrated
- Acute oliguric renal failure due to dehydration +/- rhabdomyolysis
- Hepatic failure with elevation of transaminases in the tens of thousands
- Coagulopathy, including DIC (poor prognostic sign) → purpura, melena, hematochezia, hematuria, CNS hemorrhage

Heat Exhaustion

- Core temp moderately elevated, usually <104°F (40°C) and never >40.5°C
- CNS:
 - Frontal headache
 - Fatigue/malaise
 - Impaired judgment
 - Vertigo
 - Agitation
 - No severe CNS dysfunction
- CV:
 - Mild tachycardia
 - Dehydration
- Pulmonary: Tachypnea
- GI: Nausea, vomiting
- Skin: Perspiration present, often profuse

Heat Cramps

- Cramps in heavily worked muscles after exercise

- Occurs after profuse sweating and rehydration with hypotonic fluid (i.e., water)
- Results in hyponatremia and hypochloremia without rhabdomyolysis or renal damage
- Treat with oral salt solutions if minor or NS IV if severe

Heat Edema

- Swelling of feet/ankles from environmental heat in nonacclimatized people
- Due to vasodilatation and orthostatic pooling and increased aldosterone
- Resolves after acclimatization. Treatment with elevation or compression stockings.

Heat Syncope

- Unexplained syncope during heat exposure with prolonged standing, especially in elderly
- Cutaneous vessels dilate in an effort to dissipate heat → decreased central blood volume → syncope
- Self-limited illness. Resolves when the patient lays flat.

Prickly Heat

- Pruritic maculopapular/vesicular rash over clothed areas after profuse sweating in tight clothing
- Due to blockage of pores and secondary staphylococcus infection

ESSENTIAL WORKUP

- Accurate core temperature
- History of heat exposure
- Heat exhaustion is a diagnosis of exclusion
- Core temperature > 105°F (40.5°C) and CNS dysfunction required to make diagnosis of heat stroke

DIAGNOSIS TESTS & NTERPRETATION

Lab

For Heat Stroke and Heat Exhaustion

- CBC
 - Leukocytosis, hemoconcentration
- Electrolytes, BUN, Cr, glucose
 - Hypernatremia with severe dehydration
 - Hyponatremia can occur if drinking copious free water
 - Acute renal failure
- UA
 - Myoglobin present in rhabdomyolysis

- Blood and urine cultures to rule out septic etiology
- Toxicology screen
- Serum creatinine kinase to rule out rhabdomyolysis
- ABG
 - Acidosis is common with exertional heat stroke, and lactate is usually elevated

For Heat Stroke

- PT/PTT/DIC panel – coagulopathy implies poor prognosis
- Liver function tests
- Troponin I – poor prognosis if elevated
- Consider lumbar puncture to distinguish from meningitis/encephalitis

Imaging

- EKG in elderly or patients at cardiac risk
- CT head for altered mental status
- CXR for ARDS, aspiration pneumonia, and to rule out septic etiology

DIFFERENTIAL DIAGNOSIS

- Febrile illness/sepsis
- Thyroid storm
- Pheochromocytoma
- Cocaine/PCP
- Anticholinergics
- MAO inhibitors
- Meningitis/encephalitis
- Cerebral falciparum malaria
- Delirium tremens
- Neuroleptic malignant syndrome
- Malignant hyperthermia
- Serotonin syndrome

TREATMENT

PRE HOSPITAL

- Initiate cooling measures for severe heat illness
 - Remove from heat stress
 - Disrobe patient
 - Cover body with wet sheet

INITIAL STABILIZATION/THERAPY

- ABCs

- Continuous core temperature monitoring with a rectal or esophageal probe
- Rapid cooling if temperature $> 104^{\circ}\text{F}$ (40°C)
- Start with IV 0.9% NS 500 cc fluid bolus if hypotensive
- If altered mental status, administer glucose (or Accu-Chek), thiamine, naloxone

ED TREATMENT/PROCEDURES

Cooling Measures

- Initiate for body temperature $> 104^{\circ}\text{F}$ (40°C)
- Evaporative cooling
 - Extremely effective ($0.05\text{--}0.3^{\circ}\text{C}/\text{min}$)
 - Spray disrobed patient with fine mist of warm water (prevents shivering)
 - Airflow with fans blowing over patient
- Conductive cooling
 - Ice packs to groin/axilla. Combine with evaporative cooling treatment above
 - Iced or cold water immersion—effective but impractical
- Iced peritoneal lavage, cardiopulmonary bypass, or HD with cold dialysate for refractory cases – not well studied
- Stop cooling therapy at 102°F (39°C) to avoid overshooting and hypothermia
- Antipyretic agents are not helpful because underlying mechanism does not involve a change in the hypothalamus set point
- Avoid alcohol sponge baths. Toxicity can occur due to dilated cutaneous vessels.

Supportive Measures

- Rehydration for heat stroke/heat exhaustion
 - Initial rehydration with 0.5–1.0 L 0.9% NS
 - Aggressive fluid resuscitation until BP $> 90/60$ or central venous pressure (CVP) > 12 mL H_2O
 - Avoid overhydration, which can contribute to pulmonary edema and ARDS
 - Peds: Start with 20 cc/kg bolus
 - Place Foley catheter to monitor urine output for heat stroke victims and CVP monitor if feasible. Maintain UOP > 2 mL/kg/hr if rhabdomyolysis is present
 - Rehydrate to hemodynamic stability with NS then slowly administer free water if needed for correction of hypernatremia
- Benzodiazepines for seizure, agitation, or to stop shivering
- Tachyarrhythmias can develop, which usually resolve with cooling. Avoid electricity or α -adrenergics until after the myocardium is cooled
- Heat cramps: Analgesics and oral or IV hydration with electrolyte-containing fluid
- Heat edema: Lower extremity elevation + compression stockings
- Prickly heat: Chlorhexidine cream/lotion +/- salicylic acid 1% TID

MEDICATION

- Diazepam: 5–10 mg (peds: 0.2–0.4 mg/kg) IVP
- Lorazepam: 1–2 mg (peds 0.05–0.1 mg/kg) IVP
- Naloxone (Narcan): 2 mg (peds: 0.1 mg/kg) IVP

FOLLOW-UP

Admission Criteria

- Heat stroke – admit to the ICU
- Heat exhaustion – admit to general or monitored floor if:
 - Severe electrolyte abnormalities
 - Renal failure or evidence of rhabdomyolysis
 - Elderly

Discharge Criteria

All patients except those with heat stroke or severe heat exhaustion may be discharged

PEARLS AND PITFALLS

- Cannot make diagnosis of heat stroke without temp $> 40.5^{\circ}\text{C}$ and severe CNS dysfunction.
- Management of heat stroke requires management of ABCs and rapid cooling.
- Continuous core monitoring with a rectal or esophageal probe is standard of care.
- Evaporative cooling is the cooling method of choice.

HYPERTHYROIDISM

Rita K. Cydulka • Christopher S. Campbell

BASICS

DESCRIPTION

- Excessive thyroid hormone production results in a continuum of disease caused by both the direct physiologic effect of thyroid hormones as well as increased catecholamine sensitivity:
 - Subclinical or mild hyperthyroidism
 - Thyrotoxicosis
 - Thyroid storm or thyrotoxic crisis with life-threatening manifestations:
 - 1–2% of patients with hyperthyroidism
- Regulation of thyroid hormone:
 - Thyrotropin-releasing hormone (TRH) from hypothalamus acts on the anterior pituitary
 - Thyroid stimulating hormone (TSH) released by anterior pituitary gland and results in increased T_3 and T_4 from the thyroid gland:
 - Most of circulating hormone is T_4 , which is peripherally converted to T_3
 - T_3 is much more biologically active than T_4 although it has a shorter half-life
- Genetics:
 - Interplay between genetics and environment
 - Graves disease is associated with HLA-B8 and HLA-DR3
 - Autosomal dominant inheritance seen in some families with nontoxic goiter

ETIOLOGY

- Primary hyperthyroidism:
 - Toxic diffuse goiter (Graves disease)
 - Toxic multinodular (Plummer disease) or uninodular goiter
 - Excessive iodine intake (Jod-Basedow disease)
- Thyroiditis:
 - Postpartum thyroiditis
 - Radiation thyroiditis
 - Subacute thyroiditis (de Quervain)
 - Chronic thyroiditis (Hashimoto/lymphocytic)
- Metastatic thyroid cancer
- Ectopic thyroid tissue (struma ovarii)
- Pituitary adenoma

- Drug induced:
 - Amiodarone
 - Lithium
 - α -interferon
 - Interleukin-2
 - Iodine (radiographic contrast agents)
 - Excessive thyroid hormone (factitious thyrotoxicosis)
 - Aspirin overdose

DIAGNOSIS

ALERT

Thyroid storm is a life-threatening condition, which may be precipitated by:

- Infection
- Trauma
- Diabetic ketoacidosis
- Organophosphate intoxication
- Cytotoxic chemotherapy
- Myocardial infarction
- Cerebrovascular accident
- Surgery
- Abrupt withdrawal of antithyroid medication or acute ingestion of thyroid medication

SIGNS AND SYMPTOMS

- Signs and symptoms reflect end-organ responsiveness to thyroid hormone:
 - Signs:
 - Fever
 - Tachycardia, wide pulse pressure
 - Diaphoresis/sweating
 - Congestive heart failure (CHF)
 - Shock
 - Tremor
 - Disorientation/psychosis
 - Goiter/thyromegaly
 - Thyrotoxic stare/exophthalmos/lid lag
 - Hyperreflexia
 - Pretibial myxedema
 - Symptoms:
 - Weight loss despite increased appetite
 - Dysphagia or dyspnea secondary to obstruction by a goiter
 - Rash/pruritus/hyperhidrosis
 - Palpitations/chest pain

- Diarrhea and vomiting
- Myalgias and weakness
- Nervousness/anxiety
- Menstrual irregularities
- Heat intolerance
- Insomnia and fatigue
- Thyroid storm involves exaggerated signs and symptoms of thyrotoxicosis:
 - Extreme tachycardia/dysrhythmias
 - CHF
 - Shock
 - Disorientation and mental status changes including coma and seizure
 - Thromboembolic events

Geriatric Considerations

Apathetic hyperthyroidism:

- Owing to multinodular goiter, often have history of nontoxic goiter
- Subtle clinical findings that often reflect single-organ system dysfunction:
 - CHF
 - Refractory atrial fibrillation (AFib)
 - Weight loss
 - Depression, emotional lability, flat affect
 - Tremor
 - Hyperactivity

History

Gradual onset of aforementioned signs and symptoms

Physical-Exam

- Vital signs:
 - Fever
 - Tachycardia
 - Elevation of systolic blood pressure
 - Widened pulse pressure
 - Tachypnea/hypoxia
- Alopecia
- Exophthalmos or lid lag
- Thyromegaly or goiter, thyroid bruit
- Fine, thin, diaphoretic skin
- Irregularly irregular heartbeat
- Lung rales (CHF)
- Right upper quadrant tenderness/jaundice
- Muscular atrophy/weakness

- Tremor
- Mental status changes/coma

ESSENTIAL WORKUP

- Find underlying cause/precipitating factors.
- Plasma TSH is the initial ED test of choice:
 - _ Normal level usually rules out hyperthyroidism:
 - TSH may be low with normal T₄. Get T₃ level to rule out T₃ thyrotoxicosis
 - _ If TSH levels unavailable, clinical suspicion should prompt initiation of therapy

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Thyroid function tests for:
 - _ Symptoms of hyperthyroidism
 - _ Elderly patient with new-onset CHF
 - _ New AFib/supraventricular tachycardia (SVT)
- TSH (usually decreased)
- Free T₄ (usually elevated):
 - _ If free T₄ is unavailable, total T₄ and resin T₃ uptake
 - _ 5% will have T₃ thyrotoxicosis, if low TSH with normal T₄, send T₃ to rule out
- Lab studies are often not helpful/nonspecific, get as needed to look for underlying precipitants:
 - _ CBC to rule out anemia
 - _ Chemistry panel:
 - BUN, creatinine may be elevated secondary to dehydration
 - Hypokalemia, hyperglycemia
- Liver function tests (increased transaminases)
- ABG for hypoxemia and acidosis
- Cardiac markers

Imaging

CXR (in CHF or sepsis)

Diagnostic Procedures/Surgery

EKG:

- Most commonly sinus tachycardia
- Rule out MI as precipitant of thyroid storm

- New-onset AFib

DIFFERENTIAL DIAGNOSIS

- Pheochromocytoma
- Sepsis
- Sympathomimetic ingestion
- Psychosis
- Heat stroke
- Delirium tremens
- Malignant hyperthermia
- Neuroleptic malignant syndrome
- Hypothalamic stroke
- Hypothyroidism (may mimic apathetic hyperthyroidism)
- Factitious thyrotoxicosis

TREATMENT

PRE HOSPITAL

Stabilization and supportive care

INITIAL STABILIZATION/THERAPY

- Airway, breathing, and circulation management
- Cardiac monitor
- Supplemental oxygen
- IV fluids
- Initiate cooling measures:
 - _ Acetaminophen for fever:
 - Avoid aspirin (displaces thyroid hormone from thyroglobulin, elevates free T₄)
 - _ Cooling blanket

ED TREATMENT/PROCEDURES

- Identify and treat the precipitating event
- For thyroid storm, initiate treatment sequence outlined below based on clinical suspicion
- Inhibit hormone synthesis using thioamides:
 - _ Propylthiouracil (PTU):
 - Drug of choice
 - Decreases hormone synthesis and reduces peripheral conversion of T₄
 - _ Methimazole (MMI)
- Block hormone release using iodine *only after hormone synthesis is inhibited as above*:
 - _ Oral Lugol solution (saturated potassium iodide solution), or

- Iopanoic acid (Telepaque)
- Give iodine at least 1 hr after thioamides to prevent increased hormone production
- Consider lithium in patient allergic to iodine
- Block peripheral effects of thyroid hormone:
 - β -blockade:
 - Propranolol is first line as it also inhibits T_4 conversion to T_3
 - Esmolol, β -1 selective so may be used in patient with active CHF, asthma, etc.
 - Reserpine, guanethidine
 - Albumin solution
 - Cholestyramine to reduce enteric reabsorption of thyroid hormone
- Dexamethasone/hydrocortisone:
 - Prevents peripheral T_4 to T_3 conversion
- Treatment of thyrotoxicosis, secondary thyroiditis:
 - β -blockade
 - Anti-inflammatory medications
- General thyrotoxicosis support:
 - Acetaminophen for hyperpyrexia
 - Treat CHF with usual methods
 - Manage dehydration with 10% dextrose solution (D 10) to restore depleted hepatic glycogen
- Identify and treat associated and underlying conditions (infection, ketoacidosis, pulmonary thromboembolism, stroke, etc.)

MEDICATION

- Cholestyramine: 4 g PO QID
- Dexamethasone: 2 mg IV q6h (peds: 0.15 mg/kg q6h)
- Esmolol: 500 μ g/kg IV over 1 min followed by 50 μ g/kg/min IV; titrate to effect
- Guanethidine: 30–40 mg PO q6h for 1–3 days
- Hydrocortisone: 100 mg IV initially, followed by 100 mg IV q8h for first 24–36 hr
- Iopanoic acid: 1 g IV q8h for first 24 hr, then 500 mg IV BID
- Lithium carbonate: 300 mg PO QID (peds: 15–60 mg/kg/d div. TID–QID)
- Lugol solution: 5 drops (250 mg) PO q6h
- MMI: 60–80 mg/d PO (peds: 0.4 mg/kg) (peds: 0.2 mg/kg/d) in 3 div. doses
- Propranolol: 0.5–1 mg IV + subsequent 2–3 mg doses over 10–15 min q several hours, *or* 60–80 mg PO q4h
- PTU: 100–150 mg PO q8h initially then 200–250 mg PO q4h (peds: 5–7 mg/kg/d in 3 div. doses)
- Reserpine: 1–5 mg IM, then 0.07–0.3 mg/kg in the 1st 24 hr

First Line

- PTU
- Propranolol
- Iodine therapy (Lugol), 1 hr after PTU

Second Line

- MMI
- Esmolol
- Lithium (only with iodine allergy)
- Guanethidine (for patients with bronchospasm), reserpine

Pregnancy Considerations

- Physiologic changes associated with pregnancy may resemble many symptoms of hyperthyroidism
- Poorly controlled hyperthyroidism during pregnancy may result in:
 - Hyperemesis gravidarum
 - Premature labor
 - Preeclampsia
 - Low birth weight
 - Spontaneous abortion
 - Stillbirth
- Thyroid storm often precipitated by stressors including infection, labor, birth
- Treatment:
 - Initial stabilization as in the nonpregnant patient (ABCs, supportive measures)
 - PTU considered safer than MMI. Both cross the placenta. PTU should be \leq 200 mg/day
 - Propranolol may be safely used
 - Radioactive iodine absolutely contraindicated when pregnant or nursing
 - Thyroidectomy is the only other option if unable to tolerate PTU while pregnant
- Postpartum thyroiditis:
 - 5–10% of patients within 6 mo of delivery
 - May require antithyroid medications
 - 50% affected become euthyroid within 1 yr
 - Transient hypothyroidism may follow

FOLLOW-UP

DISPOSITION

Admission Criteria

- Thyroid storm

- Requiring IV medications to control heart rate
- Significantly symptomatic or unstable patients

Discharge Criteria

Minimal symptoms that respond well to PO therapy

FOLLOW-UP RECOMMENDATIONS

- Should have PCP follow-up within a few weeks depending on symptoms
- May benefit from endocrinology referral

PEARLS AND PITFALLS

- Thyroid storm can be fatal. Diagnosis requires a high level of suspicion and treatment often needs to be started presumptively
- Radioactive iodine is never a treatment option in the pregnant patient with hyperthyroidism
- Never give iodine before blocking hormone synthesis with PTU or MMI in thyroid storm

- E05.90 Thyrotoxicosis, unspecified without thyrotoxic crisis or storm

HYPERVENTILATION SYNDROME

Robert F. McCormack

BASICS

DESCRIPTION

- Hyperventilation syndrome describes a constellation of symptoms:
 - Most commonly: Dyspnea, chest pain, lightheadedness, and paresthesias
- Produced by a nonphysiologic increase in minute ventilation:
 - Minute ventilation may be increased by increasing respiratory rate or tidal volume (sighs).
- Pathologic or physiologic causes of hyperventilation must be excluded before the diagnosis of hyperventilation syndrome can be assigned.
- Prevalence:
 - 10–15% in the general population
 - More common in women (may be related to progesterone)

ETIOLOGY

- Etiology of symptoms is unclear:
 - Usually a response to psychological stressors
- Controversy exists regarding underlying disorders that may contribute to hyperventilation:
 - Hypocapnia
 - Hypophosphatemia
 - Hypocalcemia

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Past episodes
 - Duration
 - Triggers
 - Past treatment
 - Typical time point of onset during the day
- Cardiac:
 - Chest pain
 - Dyspnea
 - “Air hunger”
 - Palpitations

- Neurologic:
 - Dizziness
 - Lightheadedness
 - Syncope
 - Paresthesias
 - Headache
 - Carpopedal spasm
 - Tetany
- Psychiatric:
 - Intense fear, anxiety
 - Giddiness
 - Feeling of unreality
- General:
 - Fatigue
 - Weakness
 - Malaise

Physical-Exam

- Clinical signs are rare and varied:
 - Tachypnea most common
 - However, tachypnea may not be present. Patient may increase tidal volume rather than respiratory rate.
- Carpopedal spasm:
 - May be dramatic
- Chvostek sign may be present

ESSENTIAL WORKUP

- Diagnosis of exclusion:
 - Primary pathologic or physiologic causes of hyperventilation must be investigated and excluded.
- Clinical diagnosis based on the history and physical exam
- Vital signs including pulse oximetry
- Hyperventilation syndrome will not result in hypoxia.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Consider an ABG in any hypoxic patient.
- Electrolytes, BUN, creatinine, and glucose levels for suspected acidosis/diabetic ketoacidosis
- EKG if chest pain present

Imaging

CXR of any patient with hypoxia or focal findings on lung exam

Diagnostic Procedures/Surgery

- Hyperventilation provocation test after resolution of symptoms:
 - Forced overbreathing for 3 min may be attempted to reproduce the symptoms.
 - Diagnostic accuracy is controversial.
 - Reproducibility of the symptoms may help the patient understand the role of overbreathing and help manage future attacks.

DIFFERENTIAL DIAGNOSIS

- Pathologic
- Hypoxia:
 - Asthma
 - CHF
 - Pulmonary embolus
 - Pneumonia
- Severe pain
- CNS lesions
- Acidosis (DKA)
- Pulmonary HTN
- Pulmonary embolus
- Hypoglycemia
- Mild asthma
- Drugs:
 - Aspirin intoxication
 - Withdrawal syndrome (e.g., alcohol, benzodiazepines)
- Physiologic
- Pregnancy
- Pyrexia
- Altitude

TREATMENT

PRE HOSPITAL

- Patients with abnormal vital signs require IV access and pulse oximetry.
- Supplemental oxygen if hypoxic

INITIAL STABILIZATION/THERAPY

- Patients with abnormal vital signs require IV access and pulse oximetry.
- Initiate therapy for pathologic or physiologic cause of hyperventilation.

ED TREATMENT/PROCEDURES

- Initiate treatment of hyperventilation syndrome if initial workup does not support a pathologic or physiologic cause, and history and physical exam findings suggest the diagnosis of hyperventilation syndrome.
- Reassurance, calming, and explanation of the voluntary component of the patient's symptoms often have immediate dramatic results.
- Do not use paper bag rebreathing to increase the PCO₂. This has not been supported in the literature:
 - It may be dangerous in patients with hypoxia or a pathologic or physiologic cause for hyperventilation.
- Clarification of the psychological stressors helps the patient avoid further attacks.
- Assess for need of psychiatric evaluation (i.e., suicidal ideation).
- Anxiolytics:
 - Benzodiazepine if symptoms persist to break the cycle of anxiety and hyperventilation
 - Short course of anxiolytics may benefit patients with definable temporary stressors.

MEDICATION

- Alprazolam 0.25–0.5 mg PO
- Lorazepam: 1–2 mg PO or IV
- Diazepam: 2–5 mg PO or IV
- Outpatient treatment:
 - Buspirone: 5 mg PO TID
 - Diazepam: 2–5 mg PO BID–QID

FOLLOW-UP

DISPOSITION

Admission Criteria

Hyperventilation syndrome does not require admission.

Discharge Criteria

- Exclusion or successful treatment of primary pathologic or physiologic causes of hyperventilation
- No acute psychiatric issues
- Adequate follow-up with a primary care physician

FOLLOW-UP RECOMMENDATIONS

- Follow-up with primary care physician
- Assess the need for psychiatric follow-up.

PEARLS AND PITFALLS

- Exclude pathologic or physiologic causes of hyperventilation.
- Hyperventilation syndrome will not result in hypoxia.

F45.8 Other somatoform disorders

HYPERVISCOSITY SYNDROME

Matthew B. Mostofi

BASICS

DESCRIPTION

- Hyperviscosity syndrome (HVS) is the clinical consequence of increased blood viscosity.
- The classic clinical symptoms are the triad of mucosal bleeding, visual disturbances, and neurologic signs.
- Viscosity is the resistance a material has to change in form.
- The higher the blood viscosity, the more the internal resistance to blood flows.
- Increased cardiac output is required to provide adequate perfusion of hyperviscous blood.
- Oxygen delivery is impaired as transit through the microcirculatory system slows. This impaired microcirculatory oxygenation gives rise to the clinical symptoms of this syndrome.

ETIOLOGY

- Hyperviscosity occurs when there is elevation of either the cellular or acellular components of circulating blood.
- Acellular (protein) hyperviscosity:
 - The most common cause (85–90%) of hyperviscosity is increased concentration of γ globulins:
 - Monoclonal gammopathies: From malignant diseases like Waldenstrom macroglobulinemia and multiple myeloma
 - Polyclonal gammopathies: Usually rheumatic diseases (very rare)
- Cellular (blood cell) hyperviscosity:
 - Much less common (10–15%)
 - Increased numbers of RBC, as in polycythemia vera
 - Increased concentration ($> 100,000$) of WBC, as in acute and chronic leukemia
 - Thrombocytosis

DIAGNOSIS

SIGNS AND SYMPTOMS

- Classic triad:
 - Mucosal bleeding
 - Visual disturbances
 - Neurologic

- Hematologic:
 - Bleeding is the most common manifestation. Mechanism thought to be platelet dysfunction.
 - Epistaxis
 - Gingival, rectal, uterine bleeding
 - Prolonged postprocedural bleeding
 - Blood dyscrasias
 - Pruritus owing to red cell breakdown products
 - Splenic enlargement
- Ocular:
 - Change in visual acuity:
 - Blurring
 - Diplopia
 - Visual loss
 - Characteristic “link-sausage effect” on funduscopy
 - Alternating bulges and constrictions within the retinal veins
 - Retinal hemorrhage, detachment
 - Exudate, microaneurysm formation
 - Papilledema
- Renal:
 - Nephritic or nephrotic syndrome
 - Hematuria
 - Sterile pyuria
- Neurologic:
 - Headache
 - Ataxia
 - Mental status changes/coma
 - Dizziness/vertigo
 - Nystagmus
 - Tinnitus, hearing loss
 - Paresthesia, peripheral neuropathy
 - Seizure
 - Intracranial hemorrhage
- Cardiovascular:
 - Angina or myocardial infarction
 - Dysrhythmias
 - CHF
- Dermatologic:
 - Raynaud phenomenon
 - Livedo reticularis
 - Palpable purpura
 - Eruptive spider nevus–like lesions
 - Digital infarcts

- Peripheral gangrene

History

HVS should be considered in the following patient:

- Any patient presenting with the classic symptom triad of bleeding, visual disturbance, and neurologic dysfunction.
- Any patient with an established immunoglobulin-producing hematologic disease that presents with signs or symptoms of microvascular end-organ damage or cardiac decompensation.
- Any patient with an established hypercellular hematologic disease who presents with signs or symptoms of microvascular end-organ damage or cardiac decompensation.

Physical-Exam

There are no specific physical exam findings unique to HVS. However, patient will exhibit findings based on the affected end organs. Mucosal bleeding, petechial rash or bruising, focal neurologic findings, signs of decompensated heart failure, and fundoscopic abnormalities have all been reported.

ESSENTIAL WORKUP

- Evaluate end-organ ischemia and bleeding.
- Measure serum or whole blood viscosity.
- Suspect diagnosis if the lab evaluation is hampered by serum stasis and increased viscosity causing analyzer blockage

DIAGNOSIS TESTS & NTERPRETATION

Lab

- CBC with WBC differential:
 - Anemia or erythrocytosis can be seen in HVS.
 - Anemia usually normocytic and normochromic
 - Rouleaux of erythrocytes on the peripheral smear is an important diagnostic clue
 - WBC for leukemia
- Electrolyte, BUN, creatinine, and glucose levels:
 - Renal dysfunction is commonly noted in HVS.
 - Hypercalcemia and pseudohyponatremia in multiple myeloma
- Urinalysis:
 - Proteinuria
 - Hematuria
 - Sterile pyuria
- Coagulation profile
- Serum and urine protein electrophoresis

- Measurement of serum viscosity (not routinely available in ED setting):
 - _ Ostwald viscosimeter
 - _ Normal range for the serum viscosity relative to water is 1.4–1.8.
 - _ Minimal viscosity at which symptoms develop is 4 centipoise (cp).
- Elevated leukocyte alkaline phosphatase, lactate dehydrogenase, and serum vitamin B₁₂ levels

Imaging

One should consider CT of head in patients with signs or symptoms of central neurologic dysfunction to exclude intracranial hemorrhage.

DIFFERENTIAL DIAGNOSIS

- Bleeding and clotting disorders:
 - _ Platelet disorders (qualitative and quantitative)
 - _ Hereditary factor deficiencies
 - _ Acquired disorders (vitamin K deficiency, liver disease)
 - _ Disseminated intravascular coagulation

TREATMENT

PRE HOSPITAL

IV fluid resuscitation with hemorrhage

INITIAL STABILIZATION/THERAPY

- Rehydrate with 0.9% NS IV fluid.
- Bleeding or end-organ ischemia may not be controlled by any treatment except plasmapheresis.
- In patients with anemia and a leukemic picture, avoid blood transfusion until plasmapheresis is performed to avoid exacerbation of HVS.

ED TREATMENT/PROCEDURES

- Hydration, supportive care, and early hematologist consultation are initial ED management.
- Phlebotomy or emergent plasma exchange: This temporizing measure can be performed in a patient with HVS and severe neurologic findings like coma or seizures:
 - _ Easily performed in the ED and is useful in acute severe cases if plasmapheresis not readily available
 - _ Simply draw off (100–200 mL) of whole blood and replace volume with isotonic saline.
 - _ Should be performed in consultation with hematologist when possible.
 - _ Treatment of choice in patients with polycythemia vera.

- Plasmapheresis/leukapheresis:
 - In stable patients: 40 mL/kg of body weight
 - In critical patients: 60 mL/kg of body weight
 - Side effects include hypocalcemia with use of a citrate-containing anticoagulant and dysrhythmia (rare).
 - Many patients require more than 1 plasmapheresis.
 - Definitive treatment for HVS. Should be performed in consultation with plasmapheresis/hematology team.
 - Leukapheresis is reserved as the initial treatment in patients with hyperleukocytosis (usually WBC > 100,000)
- ED physician can help in urgent situations by establishing or facilitating the establishment of large-bore central dialysis catheter, caution should be taken to avoid bleeding complications of this procedure

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with hyperviscosity and significant symptoms or any evidence of end-organ ischemia or hemorrhage should be admitted for treatment of the underlying hematologic disorder.
- ICU admission for the following:
 - Hemorrhage
 - Altered mental status
 - Acute MI

Discharge Criteria

Discharge after definitive treatment of the underlying disorder.

Issues for Referral

All patients with HVS should be referred to hematologist.

PEARLS AND PITFALLS

- Avoid diuretics in patients with HVS because they can increase blood viscosity.
- The classic triad of symptoms of HVS includes visual disturbances, bleeding, and neurologic manifestations.

- D75.1 Secondary polycythemia

HYPHEMA

Jamil D. Bayram • Sami H. Uwaydat

BASICS

DESCRIPTION

- Blood in anterior chamber (AC) of the eye (between iris and cornea).
- Hyphema: Grossly visible layering of blood.
- Microhyphema: Suspended RBCs visible by slit-lamp only.
- Genetics:
 - Genetic predisposition is related to hereditary blood dyscrasias (see below).

ETIOLOGY

- Blunt trauma: Most common (70–80%).
- Anteroposterior compression of the globe with simultaneous equatorial globe expansion causing rupture of iris stromal/ciliary body vessels
- Penetrating trauma: Direct injury to stromal vessels or sudden ocular decompression.
- Spontaneous: Less common, lower incidence of complications:
 - Tumors:
 - Melanoma
 - Retinoblastoma
 - Xanthogranuloma
 - Metastatic tumors
 - Blood dyscrasias:
 - Hemophilia
 - Leukemia
 - Thrombocytopenia
 - Von Willebrand disease
 - Blood thinners: Aspirin, Coumadin, heparin
 - Neovascularization of iris: In proliferative diabetic retinopathy, retinal vein occlusion, carotid stenosis.
 - Postsurgical: Cataract extraction, trabeculectomy, pars plana vitrectomy.

ALERT

In children with no history of trauma, suspect child abuse.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Photophobia

- Blurring of vision
- Decreased visual acuity
- Ocular pain
- Nausea/vomiting

History

- Previous visual acuity
- Prior eye surgery
- Prior glaucoma treatment.
- Past medical history (blood disorders including sickle cell disease).
- Mechanism of trauma.
- Exact time of injury and of visual loss.
- History of excessive tearing after injury.

ALERT

History of excessive tearing may indicate open globe injury.

Physical-Exam

- General physical exam with emphasis on associated bodily injuries.
- Periorbital ecchymosis
- Eyelid lacerations
- Enophthalmos (depression of the globe within the orbit)
- Limited ocular movement with diplopia (may indicate orbital floor fracture)
- Proptosis (may indicate retro-orbital hemorrhage)
- Ocular exam:
 - Visual acuity
 - Rule out open globe (positive Seidel sign, corneal laceration, diffuse subconjunctival hemorrhage, decreased ocular motility, prolapse of intraocular structures)
 - Pupillary reaction to light (check for afferent pupillary defect prior to using dilating drops)
 - Tonometry for intraocular pressure (IOP) measurement

ALERT

Exclude open globe injury before measuring IOP

- Slit-lamp exam; look for layer of blood in AC:
 - 4 grades of hyphema depending on percentage of AC occlusion by blood:
 - Grade I: $< 1/3$
 - Grade II: $1/3-1/2$
 - Grade III: $> 1/2$
 - Grade IV: Total (called 8-ball hyphema; blood is dark and filling 100% of AC)
 - High-grade hyphemas are:

- More likely to rebleed (25% of grade I compared with 67% of grade III)
- More likely to develop glaucoma and corneal staining
- Less likely to recover visual acuity
- _ Dilated fundus exam (avoid pressure on globe)

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Lab tests should be individualized depending on the case.
- Platelet count, PT/PTT, bleeding time if bleeding disorder is suspected, or if the patient is on anticoagulants.
- BUN, creatinine, and pregnancy test if aminocaproic acid is to be used (see below)
- Factor VIII assay if family history of hemophilia
- Sickle cell screen especially in African Americans and Mediterranean descent

Imaging

- CT orbits (1 mm cuts) if open globe injury, intraocular foreign body, or orbital wall fracture is suspected
- US biomicroscopy (B scan) if total hyphema and intraocular structures cannot be visualized.

ALERT

Do not perform B scan if open globe injury is suspected (pressure applied during this procedure may cause extrusion of intraocular contents).

ESSENTIAL WORKUP

- Exam: Visual acuity, status of globe, IOP, associated ocular/bodily injuries
- Labs: Platelet count, PT/PTT, and sickle cell screen if indicated
- Imaging: B scan or CT orbits if indicated

DIFFERENTIAL DIAGNOSIS

- Uveitis
- Endophthalmitis

TREATMENT

PRE HOSPITAL

Place eye shield in case of corneal perforation or suspected open globe injury.

INITIAL STABILIZATION/THERAPY

- Keep head upright to allow blood in AC to settle down.
- Limit activity; avoid bending, straining, or exertion.

- Place metal or plastic shield over involved eye until integrity of globe is confirmed.
- Do not patch affected eye (if eye is patched, patient cannot notice sudden loss of vision).
- Note that metal and plastic shields have holes that let patient see through whereas patch completely blocks patient's vision.

ED TREATMENT/PROCEDURES

- Mild analgesics (avoid NSAIDs because of antiplatelet effect)
- Antiemetics (associated N/V may worsen hyphema by increasing IOP)
- Cycloplegics decrease pain from iritis:
 - Atropine 1% or cyclopentolate 1% eye drops: BID–TID until hyphema resolves.
- Topical steroids may decrease inflammation from iritis:
 - Prednisolone acetate: 1% eye drops (or equivalent) 4–8 times per day until hyphema resolves (usually 7–10 days).
- Aminocaproic acid (antifibrinolytic):
 - Use in consultation with ophthalmologist:
 - Not commonly used because of frequent systemic side effects.
 - Stabilizes fibrin clot in AC and decreases incidence of rebleed, but has no effect on final visual outcome.
 - 50 mg/kg PO q4h for total of 5 days (do not exceed 30 g/day). Dose should be adjusted in renal failure.
 - May cause postural hypotension, nausea, vomiting, diarrhea.
 - New topical form is not yet FDA approved.
 - Do not use in pregnant women or in patients prone to thrombosis. It can also cause acute renal failure in patients with hemophilia.
- Oral prednisone:
 - Indications:
 - Hemophilia
 - Uncooperative children
 - Total hyphema
 - History of thrombotic disease
 - Dose: 0.6–0.75 mg/kg/24 hr in div. doses, up to 60 mg/day for 5 days
- For increased IOP:
 - For non-sickle cell patients, treat if IOP > 30 mm Hg.
 - For sickle cell patients, treat if IOP > 24 mm Hg.
 - Treat until IOP is controlled as indicated above.
 - Always start with 1 medication. Add another if unsuccessful in controlling pressure:
 - β -blockers—drug of choice: Timolol or Levobunolol 0.5% BID
 - α -agonist: Brimonidine 0.2% or apraclonidine 0.5% TID
 - Topical carbonic anhydrase inhibitors (CAI): Dorzolamide 2% or

brinzolamide 1% TID

- Oral CAI: Acetazolamide 500 mg PO q12h (peds: 8–30 mg/kg/24 hr q6–8h) or methazolamide 50 mg q8h.
- Mannitol (1–2 mg/kg IV over 45 min q24h) when all other eye drops fail to lower IOP to acceptable level.
- Avoid CAI and Mannitol in sickle cell patients, as they may cause acidosis and induce sickling.

– Allow 25–30 min for each eye drop to work. If after using all the drops and mannitol, IOP is still high, then surgical evacuation of blood clot is warranted (AC tap or washout).

- Drugs to avoid:

- Pilocarpine: Constricts pupil and prevents visualization of lens and retina
- Prostaglandin eye drops (e.g., Latanoprost): Increase inflammatory response

ALERT

Criteria for immediate consultation with ophthalmologist from the ED (If possible, consultation should be arranged within 24 hr.):

- Visual acuity worse than 20/200 at presentation.
- Sickle cell disease/trait with high IOP
- Large hyphema (filling >1/3 of AC).
- Medically uncontrolled IOP.
- Suspected open globe injury

MEDICATION

First Line

- Atropine: 1% TID
- Prednisolone acetate: 1% QID

Second Line

- Timolol 0.5% or levobunolol 0.5% BID
- Brimonidine 0.2% or apraclonidine 0.5% TID
- Dorzolamide 2% or brinzolamide 1% TID
- Acetazolamide: 500 mg PO q12h.

FOLLOW-UP

DISPOSITION

- Discharge patient on atropine, prednisolone, and any appropriate IOP-lowering medications.

- Continue aminocaproic acid if decision was made to start it in ED.
- Antiemetics if needed.
- Stool softeners to minimize straining during bowel movements.

Admission Criteria

- Hyphema size is not a criterion for discharge or admission; IOP control is the most important factor.
- Medically uncontrolled IOP requiring surgical intervention
- Ruptured globe
- Noncompliant patients
- Associated ocular or orbital injuries
- Children <7 yr of age:
 - Age group is usually at risk of amblyopia (also called lazy eye, which is irreversible visual loss secondary to visual deprivation in early childhood).
- Patients at risk of complications (sickle cell disease, hemophilia).

Discharge Criteria

Absence of any admission criteria with IOP <30 mm Hg for non-sickle patients and <24 mm Hg for patients with sickle cell disease/trait.

FOLLOW-UP RECOMMENDATIONS

Arrange for follow-up with ophthalmologist:

- Daily slit-lamp exam for 3 days after initial trauma to monitor for rebleeding, corneal staining, and increased IOP.
- Follow-up exam will determine length of treatment with atropine, prednisone acetate, and IOP-lowering eye drops.

PEARLS AND PITFALLS

- Rule out ruptured globe prior to checking IOP and prior to initiating treatment.
- IOP control is not immediate. Allow at least 30 min for any treatment to take effect:
 - Always check for sickle cell disease in African Americans.

- S05.12XA Contusion of eyeball and orbital tissues, left eye, init

HYPOCALCEMIA

Michelle J. Sergel • Damali N. Nakitende

BASICS

DESCRIPTION

- Hypocalcemia is defined as a total plasma calcium level < 8.7 mg/dL:
 - Ionized calcium may be normal and, therefore, have no clinical manifestations.
- Normal total serum calcium concentrations are 8.7–10.5 mg/dL.

ETIOLOGY

- Incidence in the general population is 0.6%.
- Mechanism:
 - From either increased loss of calcium from the circulation or decreased entry into the circulation
 - Intravascular calcium circulates in 3 forms:
 - Bound to proteins (mainly albumin): 45–50%
 - Bound to complexing ions (citrate, phosphate, carbonate): 5–10%
 - Ionized (free) calcium (physiologically active form): 45–50%
 - Serum levels of calcium are primarily controlled by 3 hormones:
 - Parathyroid hormone (PTH)
 - Decrease in calcium levels leads to an increase in PTH secretion (increasing bone resorption, renal absorption, intestinal absorption, urinary phosphate excretion).
 - Vitamin D (1,25-dihydroxyvitamin D):
 - Decrease in calcium level activates vitamin D (increasing bone resorption and intestinal absorption).
 - Calcitonin:
 - Causes a direct inhibition of bone resorption with increased calcium levels
- Hypoalbuminemia—the most common cause:
 - Each 1 g/dL decrease in serum albumin decreases protein-bound serum calcium by 0.8 mg/dL.
 - Ionized (free) calcium levels do not change.

Pediatric Considerations

- Children have higher values of normal calcium (9.2–11 mg/dL).
- Neonatal hypocalcemia: Total serum calcium concentrations < 7.5 mg/dL or serum-ionized calcium levels < 4 mg/dL
- Symptoms of hypocalcemia in infancy:

- Hyperactivity, jitteriness
- Tachypnea
- Apneic spells with cyanosis
- Vomiting

DIAGNOSIS

SIGNS AND SYMPTOMS

- Occur when ionized calcium < 3.2 mg/dL
- Dependent upon absolute calcium concentration and rate at which it falls
- Neuromuscular:
 - Paresthesias
 - Hyperreflexia
 - Muscle spasm
 - Tetany:
 - Neuromuscular irritability
 - Uncommon unless ionized calcium < 4.3 mg/dL
 - Latent tetany
 - Chvostek sign (finger taps of parotid gland over the facial nerve causes facial muscle spasm)
 - Trousseau signs (an inflated blood pressure cuff over the arm causes carpopedal spasm)
 - Laryngeal stridor
 - Seizures
 - Choreoathetosis
- Cardiovascular:
 - Dysrhythmias:
 - Torsades de pointes
 - Heart block
 - Hypotension
 - Impaired contractility (heart failure)
 - ECG changes:
 - Bradycardia
 - QT and ST prolongation
 - T-wave abnormalities
- Psychiatric:
 - Irritability/anxiety
 - Psychosis
 - Depression
 - Confusion
 - Delusions
 - Chorea

- Parkinsonisms
- Ocular:
 - Papilledema
 - Cataracts
 - May occur in patients with acute onset hypocalcemia

ESSENTIAL WORKUP

Serum-ionized calcium level confirms the diagnosis

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Arterial blood gas:
 - Change from normal pH of 0.1 U equals a reciprocal change in ionized calcium of ~ 1.7 mg/dL.
- Serum albumin
- Electrolytes, BUN/creatinine, glucose
- Magnesium
- Phosphate:
 - Increase in phosphate associated with hypoparathyroidism
 - Decrease in phosphate associated with vitamin D deficiency
- PTH:
 - Very high levels of PTH associated with pseudohypoparathyroidism
 - High levels of PTH associated with vitamin D deficiency
 - Low levels of PTH associated with hypoparathyroidism
- Serum calcidiol or calcitriol

Diagnostic Procedures/Surgery

ECG:

- Prolonged QT interval
- Heart block

DIFFERENTIAL DIAGNOSIS

- Impaired PTH action or secretion:
 - Parathyroid or thyroid surgery or radical neck surgery and/or irradiation for head and neck cancer
 - Autoimmune disease (typically presents in childhood)
 - Congenital hypoparathyroidism
 - Neonatal secondary to maternal hyperparathyroidism
 - Pseudohypoparathyroidism (resistance to PTH)
 - Infiltrative (amyloidosis, sarcoidosis, metastases, iron overload)
 - HIV infection
- Impaired vitamin D synthesis or action:

- Nutritional malabsorption or poor intake
- Renal disease
- Pronounced hypophosphatemia
- Sepsis or severe burns:
 - Impaired secretion of PTH and calcitriol
 - End-organ resistance to the action of PTH
- Calcium complex formation or sequestration:
 - Hyperphosphatemia
 - Ethylene glycol, ethylenediaminetetraacetic acid (EDTA), citrate (from transfusion)
 - Pancreatitis, rhabdomyolysis
 - Alkalosis (i.e., hyperventilation)
- Hypomagnesemia:
 - Causes end-organ PTH resistance
 - Decreased PTH secretion
 - Seen in chronic and/or critical illness
 - Must give magnesium to correct hypocalcemia
- Medications:
 - Mithramycin, plicamycin, phosphate, calcitonin, bisphosphonates
 - Phenobarbital, phenytoin
 - Cisplatin
 - Cadmium, colchicine
 - Fluoride, citrate, PPI
- Malignancies:
 - Prostate cancer
 - Breast cancer
 - Lung cancer
 - Chondrosarcoma
- “Hungry bone syndrome”:
 - After parathyroid removal
 - Rapid accretion of calcium as bone is remineralized

TREATMENT

INITIAL STABILIZATION/THERAPY

ABCs:

- Establish IV catheter access.
- Cardiac monitor

ED TREATMENT/PROCEDURES

- Acute management:
 - Treat symptomatic hypocalcemia as a medical emergency with parenteral

calcium administration.

- Calcium IV bolus:
 - Calcium gluconate 1–2 g in 50 mL of 5% dextrose
 - Infuse over 20 min
 - Faster IV rates can cause cardiac dysrhythmias
 - Calcium salts are irritating to veins.
 - IM calcium gluceptate or calcium gluconate if IV access not available
 - Bolus dose increases ionized calcium for only 1–2 hr, therefore, must be followed by an infusion
- Calcium infusion:
 - Calcium infusion rate: 0.5–1.5 mg/kg/hr
 - Do not mix with bicarbonate or phosphate or precipitation of salts may form.
 - Administer cautiously in patients taking digitalis—may initiate and exacerbate digitalis toxicity
- Response to therapy:
 - Individual responses vary.
 - Monitor calcium concentrations q1–4h during therapy.
 - Titrate treatment to symptoms or ECG changes.
 - Consider hypomagnesemia if the patient fails to respond to calcium therapy—correct hypomagnesemia with Mg 2 g IVPB 10% solution over 10 min
 - In the setting of acidosis, correct calcium 1st; alkalosis will further reduce ionized calcium.
 - Side effects of IV calcium include: Nausea, vomiting, hypotension, and dysrhythmias
- Chronic management:
 - Oral calcium supplementation
 - 1.5–2 g/day of Calcium in div. doses. May need up to 4 g/day in patients with malabsorption.
 - Vitamin D:
 - Enhances intestinal absorption
 - Initiate with calcium supplementation—alone not sufficient to restore calcium levels.
 - 600 IU for ages 19–50 yr
 - 600 IU for ages 51–70 yr
 - 800 IU for ages 71 and older
 - Multivitamins contain variable amounts of vitamin D
 - Vitamin D preparations:
 - Ergocalciferol: 125 µg/day
 - Dihydroxycholesterol: 100–400 µg/day
 - Calcifediol: 50–200 µg/day
 - Calcitriol: 0.25–0.5 µg/day: Rapid onset (preferred). Most active

Pregnancy Considerations

Calcitriol requirements may double or triple toward the end of pregnancy.

MEDICATION

- IV calcium:
 - Calcium chloride: 1 g in 10 mL (1 g = 360 mg [13.6 mEq] elemental calcium)
 - Calcium gluceptate (IV/IM): 1 g in 5 mL (1 g = 90 mg [4.5 mEq] elemental calcium)
 - Calcium gluconate: 1 g in 10 mL (1 g = 90 mg [4.5 mEq] elemental calcium)
- Oral calcium:
 - Calcium carbonate: 350–1,500 mg tablets (1 g = 400 mg)
 - Calcium citrate: 950 mg tablets (1 g = 211 mg elemental calcium)
 - Calcium glubionate: 18 g/5 mL of syrup (1 g = 65 mg elemental calcium)
 - Calcium gluconate: 500—1,000 mg tablets (1 g = 90 mg elemental calcium)
 - Calcium lactate: 350–1,000 mg tablets (1 g = 130 mg elemental calcium)

Pediatric Considerations

- Initial calcium bolus with 10% calcium gluconate should be 9–18 mg of elemental calcium/kg or 1–2 mL/kg not to exceed 5 mL in premature infants or 10 mL in term infants.
- Calcitriol dose in children ranges from 0.1–3 µg/day.
- MISCELLANEOUS:
 - Calcium content of common foods:
 - Milk or yogurt, 8 oz = 300 mg
 - Cheddar cheese, 1 oz = 200 mg
 - Calcium-fortified cereal, 1 cup = 300 mg
 - Calcium-fortified orange juice, 1 cup = 270 mg
 - Shrimp, 3 oz = 50 mg
 - Peanuts = 130 mg
 - Orange = 50 mg

FOLLOW-UP

DISPOSITION

Admission Criteria

- Symptomatic or severe ionized hypocalcemia (<3.2 mg/dL)
- Continuous IV calcium preparations necessary to maintain calcium levels

Discharge Criteria

- Asymptomatic hypocalcemia
- Ionized calcium > 3.2 mg/dL in healthy patients with no comorbid illness

FOLLOW-UP RECOMMENDATIONS

Close follow-up with an endocrinologist may be necessary for impaired PTH or vitamin D action or synthesis.

PEARLS AND PITFALLS

- Hypocalcemia has many causes
- Treatment of hypocalcemia varies with its severity and underlying cause
- Patients who are severely symptomatic require rapid correction with IV calcium therapy
- To effectively treat hypocalcemia with concurrent magnesium deficiency, magnesium must first be normalized

HYPOGLYCEMIA

Chadi I. Kahwaji • Matthew N. Graber

BASICS

DESCRIPTION

- Deficiency in counterregulatory hormones (glucagon, epinephrine, cortisol, growth hormone) or excessive insulin response
- Serum glucose < 70 mg/dL

RISK FACTORS

- Strict glycemic control with insulin
- Prior hypoglycemia episodes
- Hypoglycemia unawareness
- Decreased counterregulation
- <5 years of age or elderly
- Comorbid conditions:
 - Renal disease
 - Malnutrition
 - Coronary artery disease
 - Liver disease

Genetics

- Congenital metabolic and endocrine disorders that decrease gluconeogenic ability (e.g., hereditary fructose intolerance)
- Congenital hyperinsulinism
- Neonatal diabetes mellitus (often a mutation effecting an ATP-dependent potassium channel)

ETIOLOGY

- Increased insulin levels:
 - Overdose of oral hypoglycemic agent or insulin
 - Oral antihyperglycemics (i.e., α -glucosidase inhibitors, biguanides, and thiazolidinediones) do not cause hypoglycemia alone, but may enhance the risk when used with insulin or sulfonylureas.
 - Sepsis
 - Insulinoma
 - Autoimmune hypoglycemia
 - Alimentary hyperinsulinism
 - Renal failure (partially responsible for insulin metabolism)
 - Liver cirrhosis (responsible for significant insulin metabolism)

- Underproduction of glucose:
 - Alcohol (inhibitory effect on glycogen storage and gluconeogenesis)
 - Drugs
 - Salicylates
 - β -blockers (including eye drops)
 - SSRIs
 - Some antibiotics (e.g., sulfonyleureas, pentamidine)
 - Adrenal insufficiency
 - Malnutrition
 - Dehydration
- Cerebral edema
- Extremes of age
- Congestive heart failure
- Counterregulatory hormone deficiency
- Hypothyroidism or hyperthyroidism

Pregnancy Considerations

- 3rd-trimester pregnant patients risk relative substrate deficiency–induced hypoglycemia.
- The fetus is less likely to become hypoglycemic during mother’s hypoglycemic episode secondary to active glucose transport across placenta:
 - Oral hypoglycemic use in pregnancy may lead to profound and prolonged neonatal hypoglycemia.

Pediatric Considerations

Most common cause of hypoglycemia in the 1st 3 mo of life is persistent hyperinsulinemic hypoglycemia of infancy (PHHI) in mothers with diabetes.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Adrenergic caused by excessive counter-regulatory hormones (i.e., epinephrine):
 - Diaphoresis
 - Anxiety
 - Tachycardia/palpitations
 - Hunger
 - Paresthesias
 - Chest pain
 - Ischemic ECG changes
- Neuroglycopenic:
 - CVA mimic
 - Any focal or general neurologic change

- Dizziness
- Confusion
- Mood changes
- Hyperactive or psychotic behavior
- Slurred speech
- Cranial nerve palsies
- Seizures
- Hemiplegia
- Decerebrate posturing
- Neonatal presentation:
 - Asymptomatic
 - Limp
 - Bradycardia
 - Irritable
 - Tremulous
 - Seizures
 - Poor feeding

ALERT

Patients with “hypoglycemia unawareness” have reduced warning signals, do not recognize that their blood sugar is low, and instead may present with only late findings such as seizure, focal neurologic findings, altered mental status, and coma.

History

- Underlying diseases or conditions: Diabetes, renal failure, liver failure, alcohol use.
- Certain medications—long-acting insulin and oral hypoglycemic agents—are more concerning.
- Possible insulin or oral hypoglycemic overdose.

Physical-Exam

See Signs and Symptoms

ESSENTIAL WORKUP

- Diagnosis requires:
 - Demonstration of neuroglycopenic signs and symptoms as defined above
 - Lab evidence of hypoglycemia
 - Clearing of symptoms following glucose administration

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Blood glucose (initial and post-treatment)
- Electrolytes, BUN, creatinine

- Prothrombin time
- Urinalysis for possible infection
- Urine and other cultures as appropriate in evaluation for infection
- C-peptide if concern for exogenous insulin overdose

Imaging

CXR for:

- Possible aspiration during hypoglycemic episode
- Pneumonia as source of sepsis

Diagnostic Procedures/Surgery

- ECG if MI/ischemia owing to hypoglycemia or as cause of hypoglycemia suspected.
- Hypoglycemia may affect cardiac electrical conduction.

DIFFERENTIAL DIAGNOSIS

The differential diagnosis is extensive; see Altered Mental Status for a complete list.

Major concerns include:

- Neurologic:
 - Cerebral vascular accident/transient ischemic attack (CVA/TIA)
 - Seizure disorder
- Drug or alcohol intoxication
- Hypoxia
- Sepsis
- Metabolic derangements
- Endocrine derangements
- Environmental stressors
- Psychosis, depression, or anxiety

Pediatric Considerations

- Growth hormone deficiency
- Inborn errors of metabolism
- Ketotic hypoglycemia
- Reye syndrome
- Salicylate ingestion

TREATMENT

PRE HOSPITAL

- Diagnosis with finger stick glucose
- IV dextrose preferred
- Oral glucose-containing fluids in awake patient if unable to obtain IV

- Glucagon if unable to give IV glucose or oral glucose

INITIAL STABILIZATION/THERAPY

- ABCs with aspiration and seizure precautions
- Glucose:
 - Dextrose IV push (IVP)—this should always be given if possible.
 - Oral glucose in awake patient (with no IV) without risk of aspiration
 - Glucagon IM if unable to establish IV access

ED TREATMENT/PROCEDURES

- Administer D₅₀W 50 mL for decreased level of consciousness:
 - 2nd or 3rd amp may be necessary.
 - Complications include volume overload and hypokalemia.
- Administer octreotide:
 - If hypoglycemia refractory to glucose administration
 - If hypoglycemia secondary to sulfonylureas
 - Initiate continuous IV infusion of 5–20% glucose solution for persistent mild hypoglycemia or if patient cannot eat.
- Administer glucagon:
 - If hypoglycemia refractory to glucose
 - If IV access delayed
 - Ineffective in alcohol-induced hypoglycemia and significant liver disease
 - May repeat twice q20–30min
 - Administer hydrocortisone with glucagon for adrenal insufficiency.
 - Effective in 10–20 min

Geriatric Considerations

Elderly patients often have less hypoglycemic awareness and require significant time for resolution of symptoms, even after appropriate treatment of hypoglycemia.

MEDICATION

First Line

- D₅₀W: 1–2 amps (25 g) of 50% dextrose IVP
 - Zimmerman rule of 50: Adult 1 mL/kg of D₅₀W; child: 2 mL/kg D₂₅W; infants: 5 mL/kg D₁₀W)

Second Line

- Octreotide: 50 µg IV bolus then 50 µg IV/hr drip or 50 µg q12hSC/IV
- Glucagon: 0.5–2 mg IV/IM/SC:
 - Child: 0.03–0.1 mg/kg IV/IM/SC
 - Infant: 0.3 mg/kg IV/IM/SC

- May repeat in 4 hr
- Hydrocortisone: 100 mg (peds: 1–2 mg/kg) IV
- Oral glucose: 20 g orally equals ~12 oz nondiet fruit juice, 14 oz nondiet cola
 - Carbohydrate without fat or protein preferred

FOLLOW-UP

DISPOSITION

Admission Criteria

- Overdose of long-acting oral hypoglycemic agent (e.g., sulfonylureas) or long-acting insulin mandate observation for at least 24 hr.
- Failure of neuroglycopenic symptoms to improve with glucose administration suggests neurologic injury, pre-existing neurologic condition, or another cause for these symptoms.
- Recurrent hypoglycemic state in ED
- Patients unable to tolerate oral fluids or food
- Suicidal intentions
- Older patients may require several days for complete recovery from severe or prolonged hypoglycemia.

Discharge Criteria

- Discharge mild unintentional insulin overusage or failure to take oral calories if blood glucose normal, symptoms resolved, tolerating oral intake, and can be observed.
- Families of patient with recurrent hypoglycemia should be instructed in IM glucagon administration.
- Monitor blood glucose for at least 3 hr prior to discharge.

Issues for Referral

Refer to primary physician for consideration of medication or diet changes if recurrent hypoglycemic episodes.

FOLLOW-UP RECOMMENDATIONS

PMD follow-up for medication re-evaluation within 48 hr

PEARLS AND PITFALLS

- Administration of PO glucose or food may initially further decrease glucose level; therefore, IV dextrose always preferred if possible
- Multiple amps of D₅₀W commonly required
- Do not over rely on D10/D20 as even these concentrations contain relatively small

amounts of glucose.

- Hypoglycemia should be in the differential for all neurologic and psychiatric presentations.
- Recurrent hypoglycemia patients often require hours to days for full neurologic recovery

- P70.2 Neonatal diabetes mellitus

HYPOGLYCEMIC AGENT POISONING

Timothy J. Meehan

BASICS

DESCRIPTION

- Oral or parenteral agents that may cause hypoglycemia or other metabolic imbalances
- Hypoglycemic poisoning may be intentional or unintentional (accidental)

ETIOLOGY

- Insulin:
 - Enhances glucose uptake into cells
 - Limits glucose availability to the brain (most sensitive to hypoglycemia)
 - Influences potassium redistribution (hypokalemia)
- Sulfonylurea and Meglitinide agents:
 - Enhance insulin release from pancreatic β cells, reduce hepatic glucose production, and increase peripheral insulin sensitivity
 - Hypoglycemic effect enhanced by:
 - Polypharmacy (drug interactions)
 - Alcohol use and hepatic dysfunction (poor nutritional stores)
 - Renal insufficiency (decreased clearance)
- GLP1 modulators:
 - Exenatide is an analog of glucagon-like peptide 1 (GLP1)
 - Gliptins (sitagliptin and saxagliptin) inhibit DDP4 which normally inactivates GLP1
 - Net effects: Enhanced insulin secretion, delayed gastric emptying, and increased satiety
 - Unclear effects on glucose metabolism in overdose (data are lacking at this time)
- Biguanide agents (metformin):
 - Antihyperglycemic agents:
 - Decrease elevated serum glucose concentrations
 - Generally do not cause hypoglycemia in isolation.
 - In the presence of insulin, biguanides do the following:
 - Increase glucose uptake into cells
 - Limit glucose availability to the brain (most sensitive to hypoglycemia)
 - Influence potassium redistribution (hypokalemia)
 - Decrease GI glucose absorption
 - Decrease hepatic gluconeogenesis

- Metabolize glucose to lactate in intestinal cells, which may accumulate and lead to profound lactic acidosis
- Thiazolidinediones:
 - In the presence of insulin, thiazolidinediones increase glucose uptake and use and decrease gluconeogenesis
- α -glucosidase inhibitors:
 - Lower systemic glucose by decreasing GI absorption of carbohydrates

DIAGNOSIS

SIGNS AND SYMPTOMS

- Insulin or sulfonylureas:
 - Overdose causes hypoglycemia
 - Symptoms most often occur when glucose < 40–60 mg/dL (may occur at higher levels in diabetics)
 - Symptoms blunted by β -antagonists
 - Facial flushing, diaphoresis, pallor, piloerection
 - Hunger, nausea, abdominal cramping
 - Labored respirations, apnea
 - Headache, blurred vision
 - Paresthesias, weakness, incoordination, tremor
 - Anxiety, irritability, bizarre behavior, confusion, stupor, coma, seizures
 - Palpitations, tachycardia, bradycardia (late)
 - Hypertension
 - Hypothermia
- Biguanides:
 - Toxicity primarily owing to lactic acid accumulation
 - Nausea, vomiting, abdominal pain
 - Agitation, confusion, lethargy, coma
 - Kussmaul respirations
 - Hypotension, tachycardia

Pediatric Considerations

- Neonatal hypoglycemia may occur after maternal use of sulfonylureas during labor
- Ingestion of 1 sulfonylurea tablet may cause hypoglycemia in a child:
 - Death has been reported after ingestion of a single tablet
- Onset of symptomatic hypoglycemia may be delayed up to 8 hr

History

- Diagnosis of diabetes in patient
- Access to diabetic medications:
 - If occurring in a medical setting (hospital, nursing home), consider:

- Dosing error
- Malicious intent

Physical-Exam

- Vital signs:
 - Tachycardia (may be blunted if on β -blockers)
- Neurologic:
 - Confusion, obtundation, coma
 - Ataxia, other cerebellar signs

ESSENTIAL WORKUP

- Diagnosis based on clinical presentation and an accurate history
- Monitor serum glucose concentration
- Monitor vital signs and neurologic status
- Obtain serum electrolytes and lactate for biguanide ingestion
- Obtain liver function tests for thiazolidinedione ingestion

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Serum glucose before and after treatment
- Electrolytes:
 - Check for hypokalemia
 - Anion gap acidosis
- BUN, creatinine:
 - May reveal renal insufficiency, causing drug accumulation
- CBC
- Ethanol level
- Lactate level (especially if biguanide medications involved)
- Liver function tests
- Arterial blood gas
- Assays for immunoreactive insulin and C-peptide levels:
 - Confirms administration of exogenous insulin if insulin level is high and C-peptide is low in the setting of hypoglycemia
 - Do not correlate with severity of clinical symptoms

Imaging

- ECG: Sinus tachycardia, premature ventricular contractions (PVCs), atrial dysrhythmias
- EEG: Diffuse slowing without focal abnormalities
- CT scan: Cerebral edema if prolonged hypoglycemia
- Chest radiograph: Aspiration pneumonia or pulmonary edema

DIFFERENTIAL DIAGNOSIS

- Addison disease
- Panhypopituitarism
- Sepsis
- Insulinoma
- Neuroendocrine tumors
- Cirrhosis
- Chronic ethanol abuse
- Ethanol ingestion
- Salicylate ingestion
- β -antagonist ingestion
- Ackee fruit poisoning

TREATMENT

PRE HOSPITAL

Transport all medications, pills, and pill bottles involved in overdose for identification in ED

INITIAL STABILIZATION/THERAPY

- ABCs:
 - Airway control essential
 - Administer supplemental oxygen
 - IV access
 - Cardiac monitor and pulse oximetry
- Naloxone, thiamine, D₅₀ (or Accu-Chek) if altered mental status

ED TREATMENT/PROCEDURES

- Hypoglycemia:
 - D₅₀ bolus, then:
 - IV infusion D₅W or D₁₀W to maintain euglycemia or mild hyperglycemia
 - Food (if mental status improves or normalizes)
- Neuroglycopenia:
 - May persist shortly after serum glucose corrected
 - Persistent symptoms require further dextrose administration
- Decontamination:
 - Consider administration of activated charcoal for recent or large ingestion of oral agent (sulfonylurea or biguanide)
- Provide supportive care
- Hypotension:
 - 0.9% NS IV fluid bolus

- Pressor support with dopamine or norepinephrine as needed:
 - Pressors may increase lactate production
 - Use cautiously with biguanide-induced lactic acidosis
- Administer sodium bicarbonate for biguanide-induced lactic acidosis if pH < 7
- Administer benzodiazepines for seizures
- Inhibit insulin secretion for sulfonylurea overdose with recurrent hypoglycemia with:
 - Octreotide
 - Diazoxide (watch for hypotension)
- Early hemodialysis may be beneficial in cases of biguanide-induced lactic acidosis:
 - Corrects acid–base abnormalities
 - Enhances elimination of the drug

MEDICATION

- Activated charcoal: 1 g/kg PO
- Dextrose: 50–100 mL D₅₀ (peds: 2 mL/kg of D₂₅ over 1 min) IV; repeat if necessary
- Diazepam: 5–10 mg (peds: 0.2–0.5 mg/kg) IV q10–15min
- Diazoxide: 200 mg PO or 1–3 mg/kg IV (infant: 8–15 mg/kg/24 h q8–12hPO/IV; child: 3–8 mg/kg/24 h q8h PO/IV)
- Glucagon: 1–2 mg (peds: 0.03–0.1 mg/kg) IM/SC/IV
- Lorazepam: 2–4 mg (peds: 0.03–0.05 mg/kg) IV q10–15min
- Octreotide: 50–100 µg q8–12h SC/IV
- Thiamine (vitamin B₁): 100 mg (peds: 50 mg) IV or IM

FOLLOW-UP

DISPOSITION

Admission Criteria

- Hypoglycemia owing to sulfonylurea agents (may require several days of monitoring) or long-acting insulin preparations
- Any patient requiring a constant infusion of dextrose to maintain euglycemia
- Intentional overdose or self-injection of insulin warrants admission for 24 hr glucose monitoring
- All children with accidental ingestion of sulfonylureas
- Metabolic alterations owing to biguanide ingestion or accumulation

Discharge Criteria

- Accidental hypoglycemia owing to short-acting insulin injection in the setting of dietary insufficiency:
 - Must be tolerating oral intake
 - Ensure return to baseline mental status

- Discharge after glucose correction and a 4 hr period of observation

Issues for Referral

- Patients with unintentional (accidental) poisoning require poison prevention counseling
- Patients with intentional (e.g., suicide) poisoning require psychiatric evaluation

FOLLOW-UP RECOMMENDATIONS

Close primary care follow-up to help monitor blood sugar and adjust medication dosages

PEARLS AND PITFALLS

- Sulfonylureas can have markedly prolonged half-lives and long elimination times:
 - Delayed hypoglycemia and refractory hypoglycemia are common
 - Admit for observation, at a minimum
- Metformin must be held for 48 hr after any study requiring IV contrast media:
 - IV contrast can prolong renal clearance of biguanides
 - Can induce metformin-associated lactic acidosis

ICD10

T38.3X1A Poisoning by insulin and oral hypoglycemic drugs, acc, init

HYPOKALEMIA

David N. Zull

BASICS

DESCRIPTION

- Defined as a serum potassium level < 3.5 mEq/L:
 - _ Mild: 3–3.5 mEq/L
 - _ Moderate: 2.5–3 mEq/L
 - _ Severe: < 2.5 mEq/L
- Frequency:
 - _ Up to 20% of inpatients have documented hypokalemia (5% have levels < 3 mEq/L).
 - _ Up to 14% of outpatients are mildly hypokalemic (most are related to diuretics or GI loss).
 - _ 5% of geriatric patients have $K < 3$ mEq/L.
- Potassium is the major intracellular cation:
 - _ Gradient is maintained by Na–K ATPase activity (enhanced by insulin and β -agonists) and mineralocorticoids.
- Total body potassium is ~ 55 mEq/kg of body weight (98% ICF, 2% ECF).
- Electrophysiologic effects of hypokalemia:
 - _ Increase in the normal intracellular to extracellular potassium gradient:
 - Alters the depolarization threshold for muscles and nerves
 - Inhibits the termination of action potentials
 - _ Alterations in intracellular potassium directly affect cellular function.

ETIOLOGY

Renal Losses

- Diuretics (thiazides, loop diuretics, carbonic anhydrase inhibitors), usually associated with loss of other cations (Mg^{2+} , Ca^{2+} , P^{3+} , Na^{+})
- Renal tubular damage:
 - _ Primary renal tubular disorders (RTA type I and II)
 - _ Interstitial nephritis, analgesic nephropathy, drug toxicity (amphotericin, gentamicin, toluene, cisplatin), myeloma kidney
 - _ Overdose toxicity: Acetaminophen, NSAIDs, hydroxychloroquine
- Hyperaldosteronism:
 - _ Primary (primary hyperaldosteronism, Cushing, pituitary tumor-producing ACTH, congenital adrenal hyperplasia)
 - _ Secondary (volume depletion, CHF, cirrhosis, nephrotic)
 - _ Exogenous (steroids; fludrocortisone, glycyrrhizic acid [licorice]) hyperrenin

state in renal artery stenosis

- Hypomagnesemia (increased secretion)
- Polyuria:
 - Osmotic diuresis (mannitol, hyperglycemia)
 - Psychogenic polydipsia
- Congenital disorders:
 - Bartter and Gitelman syndromes—hypokalemic metabolic alkalosis and low BP
 - Liddle syndrome is the same but with hypertension.
- Delivery of nonreabsorbable anions such that sodium is reabsorbed and potassium is exchanged out and excreted:
 - Bicarbonate in metabolic alkalosis
 - β -hydroxybutyrate in DKA
 - Hippurate in toluene abuse
 - Penicillins—high dose IV therapy

GI Losses

- Diarrhea:
 - Proportional to volume and duration
 - Villous adenomas
 - Laxative abuse
- Vomiting and nasogastric suction result in volume depletion and metabolic alkalosis, which increases renal losses of potassium from bicarbonaturia and hyperaldosteronism.
- Ureterosigmoidostomy
- Intestinal fistulae, ileostomy
- Cystic fibrosis

Intracellular Shift of Potassium

- Alkalosis (metabolic or respiratory)
- Insulin:
 - Insulin administration
 - Stimulation of insulin release by IV glucose or massive sweetened beverage intake
 - Refeeding in prolonged starvation
- Adrenergic excess:
 - Severe stress (trauma, MI, sepsis)
 - Treatment of asthma (frequent β -agonists and theophylline toxicity)
 - Cocaine, amphetamines, caffeine excess
 - Dobutamine, dopamine, pseudoephedrine
- Hypokalemic periodic paralysis:
 - Familial

- Thyrotoxic
- B₁₂ administration in severely deficient patient
- Hypothermia
- Drugs: GM-CSF, quetiapine, risperidone

Poor Intake (Rare as a Sole Cause)

- Nutritional (poverty, pica, dementia)
- Eating disorders
- Dental problems/oral lesions
- Esophageal disease

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Neuromuscular:
 - Severe weakness (K < 2.5 mEq/L):
 - Begins in the lower extremities and progresses cephalad
 - May progress to paralysis if K < 2 mEq/L and rapid development
 - Muscle cramps, tetany, and tenderness
 - Rhabdomyolysis
 - Paresthesias
 - Generalized fatigue and malaise
- GI:
 - Constipation
 - Ileus
- Cardiovascular (heart disease increases risk):
 - Ventricular and atrial premature beats
 - AV block, atrial or junctional tachycardias
 - Ventricular tachycardia (VT) or fibrillation
 - Potentiation of digoxin toxicity
- Renal:
 - Impaired urinary concentrating ability resistant to ADH (polyuria, polydipsia)
 - Increased renal bicarbonate reabsorption and ammonia production (worsens alkalosis)

Physical-Exam

- HTN—renal artery stenosis, primary hyperaldosteronism, licorice, congenital adrenal hyperplasia, Liddle syndrome, glucocorticoid use
- Hypotension—GI losses, diuretic use, Bartter and Gitelman syndromes

- Neuromuscular—muscle weakness, decreased reflexes, muscle tenderness

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Electrolytes, BUN, creatinine, glucose:
 - High HCO_3 suggests diuretic abuse, vomiting, mineralocorticoid excess, Bartter, Gitelman.
 - Low HCO_3 suggests renal tubular disease or diarrhea
 - Low serum sodium suggests diuretic use or marked volume depletion from GI losses
 - High serum sodium suggests nephrogenic diabetes insipidus or primary hyperaldosteronism
- Urine K (spot sample):
 - < 20 mEq/L suggests GI loss, potassium shift into cells, poor intake.
 - > 20 mEq/L suggests renal loss.
- Urine K to creatinine ratio is more precise
 - < 13 mEq/g or 1.5 mEq/mmol (nonrenal)
 - > 13 mEq/g or > 1.5 mEq/mmol (renal loss)
- Urine Na:
 - < 20 mEq/L with elevated urine K suggests secondary hyperaldosteronism.
- Plasma renin if hypertensive:
 - High renin: Secondary hyperaldosteronism, renal artery stenosis
 - Low renin: Primary hyperaldosteronism
- TSH and free T4 if Asian male

ECG Findings

- Low-voltage T-waves
- Sagging of the ST segments
- U-waves:
 - In severe hypokalemia, the T disappears and the U-wave predominates, giving the illusion of dramatic QT prolongation.
- Diminutive P-waves (appears nodal)
- Dysrhythmias (very prevalent if underlying cardiomyopathy or digoxin toxic):
 - Atrial: Premature atrial contractions (PACs), atrial fibrillation (Afib)
 - Ventricular: Premature ventricular contractions (PVCs), VT, torsade

DIFFERENTIAL DIAGNOSIS

- Intrinsic cardiac disease with dysrhythmias
- Causes of muscular weakness:
 - Neuromuscular junction disease (myasthenia gravis, organophosphate poisoning, botulism)

- Spinal cord disease
- Polyneuropathies
- Primary acute myopathies
- Cataplexy

TREATMENT

INITIAL STABILIZATION/THERAPY

- Establish IV access/volume resuscitation
- ABCs
- Cardiac monitoring

ED TREATMENT/PROCEDURES

- Total body deficit is 200–300 mEq per 1 mEq/L decrement in serum potassium level.
- Rate of replacement and route dependent on presence of symptoms, severity of hypokalemia, and comorbidities.
- Complete replacement over several days
- Oral potassium preferable to IV therapy whenever possible
- Identify and prevent ongoing K losses:
 - Hold diuretics or laxatives
 - Treat vomiting or diarrhea
 - Minimize nasogastric suction losses by administering H2 blockers or PPIs
 - Avoid glucose-containing fluids

MEDICATION

- Oral potassium chloride:
 - Preferred replacement in almost all cases
 - Liquid (or powder dissolved in water or juice) is more bioavailable, but nausea may occur:
 - 10–40 mEq per dose
 - Rapid rise in K, but will drop after 4 hr from transcellular shift
 - Tablets (wax matrix and microencapsulated):
 - More palatable, more sustained effect
 - Slowly absorbed
 - Potential for small bowel ulceration.
 - Dosage for hypokalemia:
 - Mild to moderate: 10–20 mEq q6–12h
 - Moderate to severe: 40–60 mEq q8–12h
 - Continue until K remains 3–3.5 mEq/L
- Oral potassium gluconate or citrate:
 - Use in acidotic patients (e.g., RTA)

- Ineffective if accompanying metabolic alkalosis
- Less effective than KCl
- Can be used as prophylaxis of calcium oxalate renal stones or may dissolve uric acid stones
- IV potassium:
 - Recommended if neuromuscular symptoms, cardiac arrhythmias, ongoing GI losses, or severe hypokalemia
 - Potassium chloride is the preferred replacement:
 - Potassium phosphate is used only if accompanying severe hypophosphatemia.
 - Administration:
 - A potassium rider at 10 mEq/h piggybacked into maintenance 0.9 NS is safest and best tolerated (peds: 0.1–0.2 mEq/kg/h)
 - 15–20 mEq/h are feasible by peripheral vein but not recommended due to risk of phlebitis and pain
 - If K is added to maintenance fluids, the concentration should not be >40 mEq/L and dextrose solutions should be avoided
 - If sustained life-threatening dysrhythmias, 20–40 mEq/h by central line or 2 peripheral lines can be considered.
 - If cardiac arrest occurs in a patient with known severe hypokalemia, 20 mEq could be given IV over 2–3 min
 - Monitor serum potassium after every 40 mEq IV
 - Hypokalemic periodic paralysis and other situations in which there is significant transcellular K shifts (adrenergic excess):
 - Small amounts of K are effective (20 mEq IV).
 - More zealous administration may lead to rebound hyperkalemia.
- Electrolyte corrections:
 - Magnesium:
 - Consider if hypokalemia is resistant to K replacement.
 - Magnesium sulfate 2 g slow IV infusion
 - Chloride:
 - Hypokalemia with alkalosis is resistant to replacement unless volume depletion and hyponatremia is corrected by saline administration.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Need of IV potassium repletion
- Cardiac dysrhythmias
- Profound muscle weakness

- Ongoing K losses
- Serum potassium < 2.5 mEq/L
- Associated with significant hypotension or severe HTN
- Significant comorbidities or geriatric

Discharge Criteria

- Asymptomatic
- Able to replete deficiency with oral potassium
- Early follow-up available and reliable patient
- Repeat electrolyte determination in 2–3 days with the primary care doctor.
- Nephrology referral or consult if suspicion of renal wasting.
- Continue K replacement for 2–3 days if acute, self-limited loss, but ongoing therapy if the cause is not corrected (e.g., diuretic therapy, chronic diarrhea).

PEARLS AND PITFALLS

- If hypokalemia is accompanied by acidosis, correct hypokalemia 1st before treating the acidosis so as to avoid life-threatening hypokalemia from transcellular shifts.
- Minimize glucose administration when treating hypokalemia, since glucose will stimulate insulin release, which will lead to K movement into cells.
- Large doses of oral potassium can be given safely in patients with normal renal function, limited only by GI tolerance.
- Check for hypomagnesemia if hypokalemia is severe or resistant to replacement therapy.
- Relatively small amounts of IV potassium are required to reverse hypokalemia in periodic paralysis and states of adrenergic excess since transcellular shifts are transient.

HYPONATREMIA

Linda Mueller

BASICS

DESCRIPTION

- Sodium < 136 mEq/L
- Most common electrolyte disturbance (1–4% of hospitalized patients)

ETIOLOGY

Pseudohyponatremia

- Low measured serum sodium but normal measured serum osmolarity
- Occurs secondary to the displacement of sodium to aqueous phase of serum
- Seen with elevated lipids or proteins
- Lab or blood raw error
- Disease examples include:
 - Multiple myeloma
 - Hyperlipidemia

Hyponatremia with Normal Osmolarity and Fluid Overload

- Inappropriate retention of water
- Disease examples include:
 - CHF
 - Cirrhosis
 - Renal failure
 - Nephrotic syndrome

Hyponatremia with Normal Osmolarity and Euvolemia

- Patients tend to have increased total body water without marked edema
- Purest form of dilutional hyponatremia
- Disease examples include:
 - Endocrine abnormalities:
 - Hypothyroid
 - Stress
 - Syndrome of inappropriate antidiuretic hormone (SIADH)
 - Diseases that cause SIADH:
 - Pulmonary disease (tuberculosis, Legionella, Aspergillosis, COPD)
 - CNS disorders (malignancy, sarcoid, infection)
 - Cancer (small cell lung, pancreas, duodenum)
 - HIV infection

- Water intoxication (3–7% of institutionalized psychotic patients), can also occur in marathon runners
- Mineralocorticoid abnormalities
- Postoperative hyponatremia (particularly after transurethral prostatectomy)
- Consumption of large amounts of beer (beer potomania)
- MDMA (Ecstasy)

Hyponatremia with Normal Osmolarity and Hypovolemia

- Deficits in total body water and total body sodium
- Sodium deficits exceed water deficits
- Possible etiologies include:
 - GI losses
 - Sweating
 - Cerebral salt wasting (occurs after head injury or neurosurgical procedures)
 - Burns
 - Cystic fibrosis
 - Salt-wasting nephropathies
 - Diuretics

Drug Induced

- Drugs may stimulate antidiuretic hormone (ADH) and cause hyponatremia:
 - Amiodarone
 - Barbiturates
 - Bromocriptine
 - Carbamazepine
 - Clofibrate
 - Cyclophosphamide
 - Opiates
 - Oxytocin
 - Vincristine, vinblastine
- Drugs may increase sensitivity to ADH and cause hyponatremia:
 - Chlorpropamide
 - NSAIDs
- Drugs may stimulate thirst and cause hyponatremia:
 - Amitriptyline
 - Ecstasy
 - Fluoxetine
 - Fluphenazine
 - Haloperidol
 - Sertraline
 - Thiothixene

Hyponatremia with Hyperosmolarity

- Due to excessive osmotically active substances
- Possible etiologies include:
 - Elevated glucose (most common cause of hyponatremia)
 - Corrected $\text{Na}^+ = 0.016 \times (\text{measured glucose} - 100) + \text{measured sodium}$
 - Mannitol infusion
 - Maltose and glycine

Pediatric Considerations

- More prone to water intoxication
- High incidence of iatrogenic hyponatremia due to dilute formula or rehydration with water only
- If hyponatremia secondary to DKA, follow hydration per pediatric DKA recommendations

Pregnancy Considerations

Conivaptan and Tolvaptan are class C drugs in pregnancy.

Geriatric Considerations

- Tend to develop more symptoms
- Hyponatremia more common due to impaired water secretion and low sodium diets

DIAGNOSIS

SIGNS AND SYMPTOMS

- Mild: $\text{Na}^+ > 120 \text{ mEq/L}$:
 - Headache
 - Nausea
 - Vomiting
 - Weakness
 - Anorexia
 - Muscle cramps
 - Rhabdomyolysis
- Moderate: Na^+ between 110 and 120 mEq/L:
 - Impaired response to verbal stimuli
 - Decreased response to painful stimuli
 - Visual/auditory hallucinations
 - Bizarre behavior
 - Incontinence
 - Hyperventilation

- Gait disturbance
- Severe: $\text{Na}^+ < 110 \text{ mEq/L}$:
 - Signs of herniation
 - Decorticate/decerebrate posturing
 - Bradycardia
 - HTN
 - Altered temperature regulation
 - Dilated pupils
 - Seizure activity
 - Respiratory arrest
 - Coma/unresponsive

Chronic

May be asymptomatic

History

Review patient medication list.

Physical-Exam

- Assess volume status including skin turgor, neck veins, peripheral edema, and signs of ascites
- Perform a complete neurologic exam.

ESSENTIAL WORKUP

Serum sodium level:

- Recheck sodium to verify.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Electrolytes, BUN/creatinine
- Glucose:
 - Correct sodium value accordingly if severe hyperglycemia (add 1.6 Na for each 100 mg/dL of glucose above normal)
- Calculate osmolality:
 - Plasma osmolality = $[2 \times \text{NA (mEq L)} + \text{Glucose}/18 + \text{BUN}/2.8]$
- Urine sodium
- Serum and urine osmolality
- Thyroid function test
- Adrenal function tests
- CPK for possible rhabdomyolysis

Imaging

- CXR to rule out CHF, infection, and tumor
- CT of head, particularly if patient has AMS

DIFFERENTIAL DIAGNOSIS

- Pseudohyponatremia due to:
 - Hyperglycemia
 - Hyperlipidemia
 - Hyperproteinemia
 - Radiocontrast dye particularly in chronic renal insufficient patients

TREATMENT

PRE HOSPITAL

- Establish IV
- Supportive care

INITIAL STABILIZATION/THERAPY

- ABCs
- Initiate IV fluid with 0.9% NS.
- Naloxone, thiamine, D₅₀W (or Accu-Chek) for altered mental status

ED TREATMENT/PROCEDURES

- Depends on severity and chronicity of hyponatremia and underlying etiology
- Chronic hyponatremia is to be corrected slowly to minimize osmotic demyelination syndrome. Correction should be limited to 10–12 mmol/L in 24 hr
- Acute hyponatremia with severe CNS symptoms/actively seizing:
 - Goal:
 - Raise serum sodium by 8–10mEq/L in 4–6 hr or to level > 120–125 mEq/L with administration of hypertonic saline, slow or discontinue when seizure subsides.
 - 200–400 mL of 3% saline solution will be the approximate amount needed in most adults over the 1st 2 hr
 - OR may dose 1–2 mL/kg/hr of 3% saline solution
 - Calculate sodium deficit:
 - Na^+ deficit = 0.6 (weight in kg) (140 – Na^+)
 - Sodium contents:
 - 1 L 0.9% NS = 154 mEq of sodium
 - 1 L 3% saline = 513 mEq of sodium
- Hypovolemic hyponatremia:
 - Correct underlying cause
 - Replete volume with 0.9% NS IV.

- Primary goals to restore:
 - Extracellular fluid
 - Cardiac output
 - Organ perfusion
- Hypervolemic/euvolemic hyponatremia:
 - Water restriction to <1 L/day with high dietary salt intake
 - For faster correction of sodium:
 - Administer IV 0.9% NS with loop diuretic (furosemide).
 - Maximum rate of correction = 0.5 mEq/L/hr

MEDICATION

- Furosemide: 20–40 mg IV push
- Sodium replacement:
 - Calculate Na⁺ deficit
 - Replace no more than 1/2 of requirement over 8–12 hr

First Line

500 mL–1 L of saline for a fluid challenge

Second Line

- Conivaptan: Arginine vasopressin antagonist
- 20 mg IV loading dose over 30 min followed by 20 mg continuous IV infusion over 24 hr
- Tolvaptan: Selective vasopressin V2 receptor antagonist dose 15 mg/d PO and may increase in 24 hr to 30 mg
- Conivaptan and tolvaptan are for the treatment of euvolemic and hypervolemic hyponatremia only

FOLLOW-UP

DISPOSITION

Admission Criteria

- Symptomatic hyponatremia
- Sodium <120 mEq/L
- Asymptomatic, mild hyponatremia (Na⁺ 120–127 mEq/L), with comorbid factors

Discharge Criteria

- Sodium >130 mEq/L and asymptomatic
- Known chronic history of hyponatremia with no acute changes
- Asymptomatic, mild hyponatremia (Na⁺ 120–129 mEq/L) with no comorbid

factors; however, must have close outpatient follow-up.

FOLLOW-UP RECOMMENDATIONS

Have repeat serum sodium within a week, particularly if related to thiazide diuretics

PEARLS AND PITFALLS

- Too rapid correction may cause osmotic demyelination syndrome
- Females, alcoholics, malnourished patients, hypokalemia, and history of liver transplant are risk factors for osmotic demyelination syndrome.
- Repeat and document neurologic exam during correction.
- Beware of falsely low sodium when blood is drawn near an IV site with hypotonic fluid.
- Thiazide diuretics may cause persistent hyponatremia up to 2 wk after discontinuation.

HYPOPARATHYROIDISM

Rami A. Ahmed • Brad D. Gable

BASICS

DESCRIPTION

- Hypoparathyroidism occurs secondary to a deficiency in parathyroid hormone (PTH)
- Pseudohypoparathyroidism occurs secondary to end-organ unresponsiveness to PTH
- PTH:
 - _ Decreases urinary Ca^{2+} loss
 - _ Increases urinary PO_4 loss
 - _ Stimulates vitamin D conversion from 25(OH)-D to 1,25(OH)₂-D in kidney
 - _ Liberates Ca^{2+} and PO_4 from bone
- Hypocalcemia is the major metabolic derangement
- Calcitonin:
 - _ Promotes deposition of Ca^{2+} and PO_4 into bone (produced primarily in C cells in thyroid)
- Magnesium:
 - _ Cofactor in production of PTH
 - _ Essential for action of PTH in target tissues
- Hypoparathyroidism:
 - _ Primary failure of the parathyroid gland (may have associated Addison disease)
- Pseudohypoparathyroidism:
 - _ Tissue unresponsiveness with elevated PTH levels
 - _ Associated with hypothyroidism and hypogonadism
- Genetics:
 - _ Congenital absence
 - _ DiGeorge syndrome:
 - Hypoparathyroidism
 - Thymic dysplasia
 - Severe immunodeficiency
 - _ Wilson disease:
 - Destruction of gland owing to copper deposition
 - _ Autoimmune polyglandular syndrome type I
 - Hypoparathyroidism
 - Adrenal insufficiency

- Mucocutaneous candidiasis
- Albright syndrome (hereditary osteodystrophy):
 - Short stature
 - Obesity
 - Round face
 - Short neck
 - Short 4th and 5th metacarpals and metatarsals (type I pseudohypoparathyroidism)

ETIOLOGY

- Failure of parathyroid gland:
 - Autoimmune destruction
 - Surgical interruption of blood supply or gland removal
 - Radiation damage
 - Hypomagnesemia (PTH cofactor)
- End-organ unresponsiveness to PTH

DIAGNOSIS

SIGNS AND SYMPTOMS

ALERT

The most common symptomatic presentation is postoperatively after parathyroidectomy.

Pediatric Considerations

Neonates/infants:

- Transient hypoparathyroidism in 1st yr of life
- Below normal intelligence proportional to duration of hypocalcemia
- Dental hypoplasia

History

- Most common presentation is in the postoperative period after parathyroidectomy or thyroidectomy
- Prolonged severe hypomagnesemia, in the alcoholic or high-dose diuretic patient, is the next most common presentation and can be slow in onset; usually less symptomatic

Physical-Exam

- Related to severity, rapidity of onset, and duration of hypocalcemia
- General:
 - Weakness

- Malaise
- Neuromuscular:
 - Paresthesias (especially circumoral and extremities)
 - Carpal pedal spasm
 - Latent spasm elicited by:
 - Chvostek sign (twitching of circumoral muscles after tapping facial nerve in front of the tragus)
 - Trousseau sign (spasm after inflating BP cuff 20 mm above patient's systolic BP for 3 min)
 - Laryngospasm/bronchospasm
 - Blepharospasm
 - Muscle cramps
 - Tetany
 - Seizures (presenting symptom of 1/3 with hypoparathyroidism)
 - Increased intracranial pressure (ICP) with papilledema
 - Parkinson syndrome and other extrapyramidal disorders
 - Myelopathy
- Cardiovascular:
 - Prolonged QT interval (owing to ST-segment prolongation)
 - Heart block
 - CHF
 - Ventricular fibrillation (VFib)
 - Vasoconstriction
- Psychiatric:
 - Impaired memory
 - Confusion
 - Hallucinations
 - Dementia
- Dermatologic:
 - Brittle hair and nails
 - Psoriasis
- Hyperpigmentation:
 - Lenticular cataracts

ESSENTIAL WORKUP

- If *no hypocalcemic symptoms* with hypocalcemia, check albumin level:
 - If still low after correcting for hypoalbuminemia, check ionized Ca^{2+}
- If *hypocalcemic symptoms* with normal total Ca^{2+} , check pH for alkalosis:
 - If not alkalotic, check ionized Ca^{2+} (active form)
 - Metabolic or respiratory alkalosis increases the binding to albumin reducing the ionized Ca^{2+}
- If *hypocalcemic symptoms* with low ionized Ca^{2+} , check a PTH level:

- Low in primary hypoparathyroidism and in vitamin D deficiency
- Elevated in pseudohypoparathyroidism and hypocalcemia from renal failure

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Calcium: Correct for albumin using formula:
 - Corrected Ca^{2+} (mg/dL) = measured Ca^{2+} (mg/dL) + 0.8[4.0 – albumin (g/dL)]
- Ionized Ca^{2+} if symptomatic with low total calcium
- Electrolytes, BUN, creatinine, glucose
- Magnesium
- Arterial blood gas (ABG) if symptomatic with normal total Ca^{2+}
 - Elevation of 0.1 pH unit decreases the ionized Ca^{2+} by 3–8%.
- Phosphorus:
 - Elevated except when hypocalcemia caused by vitamin D deficiency
 - Metastatic calcification can cause hypocalcemia by tissue deposition when the calcium/phosphorus product is > 60.

Diagnostic Procedures/Surgery

ECG:

- Prolonged QT interval:
 - Owing to ST-segment prolongation from hypocalcemia

DIFFERENTIAL DIAGNOSIS

- Must differentiate from a variety of causes of hypocalcemia
- Lab artifact:
 - Low total calcium that is normal when corrected for albumin level with no symptoms of hypocalcemia
- Alkalosis:
 - Symptomatic hypocalcemia with a normal total calcium
- Hypomagnesemia (needed for PTH secretion)
- PTH resistance (congenital)
- Vitamin D deficiency (low Ca^{2+} + low PO_4):
 - Anticonvulsant use (decreased vitamin D absorption)
 - Liver disease
 - Resistance to vitamin D
 - Malabsorption or dietary deficiency
- Gram-negative sepsis
- Renal failure or nephrotic syndrome
- Chelation:

- Pancreatitis (fatty acids chelate calcium)
- Ammonium bifluoride (tire cleaner spray)
- Hydrofluoric acid
- Citrated blood
- Acute hyperphosphatemia:
 - o Fleet enemas
 - o Rhabdomyolysis
 - o Acute renal failure

TREATMENT

PRE HOSPITAL

- Administer calcium in refractory VFib or status epilepticus in addition to usual medications if known hypoparathyroidism or suspected hypocalcemia
- Stridor may herald laryngospasm

INITIAL STABILIZATION/THERAPY

- Airway, breathing, and circulation management (ABCs):
 - Manage airway if laryngospasm
- Administer IV calcium bolus (chloride or gluconate) if unstable cardiac rhythm or tetany:
 - Slow infusion much safer unless patient markedly symptomatic
- Prepare for ventricular dysrhythmias including VFib.
- Seizure precautions

ED TREATMENT/PROCEDURES

- Calcium replacement:
 - Calcium chloride 10% (27.2 mg elemental Ca^{2+} /mL):
 - o For life-threatening conditions: 10 mL (1 g) IV over 5 min OR
 - Calcium gluconate 10% (9 mg elemental Ca^{2+} /mL):
 - o For life-threatening conditions: 20–30 mL (2–3 g) over 3–5 min
 - For non-life-threatening conditions, administer calcium via slow infusion of 500–1,000 mg elemental Ca^{2+} over 6–24 hr (peds: 100 mg elemental Ca^{2+} /kg/24 hr)
 - Continuous cardiac monitoring
 - Stop infusion if bradycardia develops
 - Perform frequent checks of serum Ca^{2+} levels
 - Calcium administration may precipitate digitalis toxicity
 - Supplement to lowest possible Ca^{2+} level keeping the patient asymptomatic, then switch to oral replacement:
 - o Soft tissue calcification may occur with calcium/phosphorus product

of 60 (Ca × PO₄)

- Replace magnesium if low
- Bind phosphorus:
 - Aluminum hydroxide–containing antacids (Maalox, Mylanta, or Gelusil) if creatinine < 2
 - Calcium acetate (Phoslo) or calcium carbonate when concurrent renal failure if creatinine > 2
 - Sevelamer HCl or carbonate (Renagel, Renvela)
- Vitamin D supplementation
- Avoid carbonated beverages (high in phosphorus)
- Assess for associated endocrinopathies

MEDICATION

First Line

- Calcium gluconate: 10% (9 mg elemental Ca²⁺/mL): 20–30 mL over 3–5 min if life-threatening condition; otherwise, slow infusion (peds: 20 mg/kg of calcium gluconate 10% or 2 mg/kg elemental Ca):
 - Follow with slow infusion: Calcium gluconate 10 g in liter of 5% dextrose infused at 1–3 mg/kg/h in adults
 - Calcium gluconate has lower risk of venous irritation or extravasational injury compared to calcium chloride
- Magnesium sulfate: 2 g IV (peds: 25–50 mg/kg up to 2 g) over 2 hr—if severe, 6 g over 6 hr
- Calcium chloride 10% (27.2 mg elemental Ca²⁺/mL): 10 mL (1 g) IV over 5 min if life-threatening condition; otherwise, slow infusion

Second Line

- Calcium acetate: 667 mg (169 mg elemental Ca): 1 or 2 tabs TID with meals
- Calcium carbonate: 1,250 mg (500 mg elemental Ca): 1 or 2 tabs QID (2–4 g/d) (peds: 45–65 mg elemental Ca mg/kg/d div. QID)
- Sevelamer (Renagel, Renvela) 800 mg: 1 or 2 tabs TID with meals
- Magnesium oxide 400 mg: 1 tab daily or BID
- Vitamin D: 400 IU PO daily for supplement (if not responsive to standard supplement, then consider calcitriol (1,25(OH)₂-D) 0.25 µg daily; titrate to 0.5–2 µg/d):
 - Preferred over other long-acting vitamin D analogues due to patient availability and lower cost, quicker onset and offset of action
- Thiazide diuretics: HCTZ 25 100 mg daily

FOLLOW-UP

DISPOSITION

Admission Criteria

- Symptomatic hypocalcemia
- Abnormal ECG
- Inability to take vitamin D or calcium orally
- Corrected calcium < 5 mg/dL

Discharge Criteria

- Asymptomatic hypocalcemia
- Not meeting any admission criteria

FOLLOW-UP RECOMMENDATIONS

- Any patient requiring therapy or needing follow-up lab studies
- Repeat of calcium, phosphorus, magnesium levels in 1–2 days

PEARLS AND PITFALLS

- Rapid onset of symptoms following surgical excision of the parathyroid glands is the most common symptomatic presentation
- Symptoms often confused with hyperventilation or anxiety
- In the absence of surgery or severe hypomagnesemia, be sure that hypocalcemia is not due to sepsis or rhabdomyolysis
- With the exception of life-threatening presentations, avoid rapid IV administration of calcium salts

- D82.1 Di George's syndrome

HYPOTHERMIA

Jordan Moskoff

BASICS

DESCRIPTION

- Body temperature $< 35^{\circ}\text{C}$
- Risk factors:
 - Poor temperature regulation:
 - Very young
 - Advanced age
 - Comorbid condition
 - Intoxication
- Pathophysiology:
 - Loss of heat:
 - Radiation: Most rapid, 50% of heat loss
 - Conduction
 - Convection
 - Evaporation
 - Respiration
 - Heat production:
 - Shivering
 - Nonshivering thermogenesis
 - Increased thyroxine
 - Increased epinephrine

ETIOLOGY

- Dermal disease:
 - Burn
 - Exfoliative dermatitis
 - Severe psoriasis
- Drug induced:
 - Ethanol
 - Phenothiazines
 - Sedative–hypnotics
- Environmental:
 - Immersion
 - Nonimmersion
- Iatrogenic:
 - Aggressive fluid replacement
 - Heat stroke treatment

- Metabolic:
 - Hypoadrenalism
 - Hypopituitarism
 - Hypothyroidism
- Neurologic:
 - Acute spinal cord transection
 - Head trauma
 - Stroke
 - Tumor
 - Wernicke disease
- Neuromuscular inefficiency:
 - Age extreme
 - Impaired shivering
 - Lack of acclimatization
- Sepsis

Pediatric Considerations

Infants have a large body surface to mass ratio Child abuse.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Mild (35–32.2°C/95–90°F):
 - Initial excitation phase to combat cold:
 - HTN
 - Shivering
 - Tachycardia
 - Early tachycardia followed by bradycardia
 - Tachypnea
 - Vasoconstriction
 - Over time with onset of fatigue:
 - Apathy
 - Ataxia
 - Cold diuresis
 - Defect in distal tubular reabsorption of sodium and water
 - Impaired judgment
- Moderate (32.2–28°C/90–82.4°F):
 - Atrial dysrhythmias
 - Bradycardia:
 - Decreased spontaneous depolarization of pacemaker cells
 - Refractory to atropine
 - Decreased level of consciousness

- Decreased respiratory rate:
 - Progressive respiratory depression with CO₂ retention
- Dilated pupils
- Diminished gag reflex
- Extinction of shivering
- Hyporeflexia
- Hypotension
- J-wave (Osborn wave) on ECG
- Severe (< 28°C / < 82.4°F):
 - Apnea
 - Coma
 - Decreased or no activity on EEG (electroencephalography)
 - Nonreactive pupils
 - Oliguria:
 - Renal blood flow depressed 50%
 - Pulmonary edema
 - Ventricular dysrhythmias/asystole:
 - Cardiac cycle lengthens, resulting in increased intervals

History

Time of submersion for near drowning in cold water.

Physical-Exam

- May not be able to palpate pulse
- May not be able to obtain BP
- Pupils dilate < 26°C

ESSENTIAL WORKUP

Accurate core temperature confirms diagnosis.

DIAGNOSIS TESTS & NTERPRETATION

Lab

- Finger stick glucose
- ABG:
 - Temperature correction not needed
- CBC:
 - Hematocrit rises owing to decreased plasma volume.
 - Leukopenia does not imply absence of infection:
 - High-risk groups (e.g., neonate, immunocompromised) should receive empiric antibiotics.
- Electrolytes, BUN, creatinine:

- Vary during rewarming; recheck frequently, especially creatine phosphokinase (CPK) and potassium (K⁺)
- Serum lactate
- PT, PTT, and platelets:
 - Prolonged clotting times, thrombocytopenia common
- Toxicology screen:
 - Alcohol/drug ingestion common

Imaging

- CXR:
 - Pneumonia common complication
- EKG:
 - Tachycardia to bradycardia
 - Atrial fibrillation with slow response
 - Ventricular fibrillation
 - Asystole
 - Prolonged PR, QRS, QT intervals
 - J-wave (Osborn waves)
 - ST-elevation mimicking acute coronary syndrome

DIFFERENTIAL DIAGNOSIS

- Environmental
- Sepsis
- Primary CNS disorder
- Metabolic
- Drug induced

TREATMENT

PRE HOSPITAL

- Patient is not dead until “Warm and Dead”:
 - CPR recommended during transport:
- Prolonged palpation/auscultation for cardiac activity: 30–45 sec
 - Apparent cardiovascular collapse may be depressed cardiac output, often sufficient to meet metabolic demands.

INITIAL STABILIZATION/THERAPY

- ABCs:
 - Supplemental oxygen
 - Oral and nasotracheal intubation are safe.
 - Place nasogastric (NG) tube postintubation.
 - Cardiac monitor

- Warmed D5.9 NS preferred over lactated Ringer:
 - Shivering depletes glycogen.
- Remove wet clothing and begin passive external rewarming.
- Administer Narcan, D₅₀W (or Accu-Chek), and thiamine to a patient with altered mental status.
- Stress-dose steroids (Solu-Cortef 100 mg IV) for known adrenal insufficiency or treatment failure.
- Obtain accurate core temperatures using rectal thermometer.

ED TREATMENT/PROCEDURES

- Cardiac arrest resuscitation:
 - Most dysrhythmias correct with rewarming alone.
 - Ventricular fibrillation induction occurs with rough handling, chest compressions, hypoxia, and acid–base changes.
 - CPR is less effective owing to decreased chest wall elasticity.
 - Defibrillation is rarely successful at temperatures <28–30°C
 - Defibrillate 1–3 times and then again post rewarming.
 - Once >30°C, if ventricular fibrillation persists consider amiodarone.
 - Direct current results in myocardial damage.
- Dysrhythmia management:
 - Atrial fibrillation:
 - Commonly <32°C
 - Usually converts spontaneously
 - Malignant ventricular dysrhythmias:
 - Amiodarone drug of choice though limited proof of effectiveness.
- Rewarming techniques:
 - Faster rewarming rates (1–2°C/hr) generally have better prognosis than slower rewarming rates (<0.5°C/hr).
 - Active rewarming is necessary at core temperature of <32°C:
 - Internal thermogenesis insufficient to increase body temperature
 - Shivering extinguished
- Passive external rewarming:
 - Ideal technique for most healthy patients with mild hypothermia
 - Must have intact thermoregulatory mechanisms, normal endocrine function, and adequate energy stores
 - Cover the patient with dry insulating material.
 - Endogenous thermogenesis must generate an acceptable rate of rewarming:
 - Must increase 0.5–2°C/hr
 - Disadvantage: Core rises very slowly.
- Active external rewarming:
 - Delivers heat directly to the skin
 - Safe in previously healthy, young, acutely hypothermic victims
 - Requires intact circulation to remove peripherally rewarmed blood to core

- Associated with core temperature afterdrop
- Rewarming shock: Venous pooling in warmed extremities secondary to vasodilatation
- Cover trunk preferentially.
- Bair Hugger device provides forced warm air: Prevents shock or afterdrop.
- Active core rewarming techniques:
 - Airway rewarming (complete humidification at 40–45°C):
 - Administer to all patients.
 - Heated IV (40–42°C) D5.9 NS:
 - Administer to all patients.
 - High flow rates must be maintained.
 - Use blood warmer or calibrated microwave.
 - Heated gastric irrigation via NG or orogastric tubes:
 - Not recommended
 - Low amount of surface area
 - Aspiration risk if airway not secured
 - Pleural irrigation (0.9 NS at 30–42°C):
 - Use in severe hypothermia without cardiac activity.
 - 1–2 chest tubes; midaxillary and midclavicular bilaterally
 - Contraindicated in patients with cardiac rhythm because the chest tube may induce ventricular fibrillation
 - Heated peritoneal lavage (0.9 NS at 40–45°C):
 - Use in unstable hypothermic patients or stable patients with severe hypothermia whose rewarming rates are $< 1^{\circ}\text{C/hr}$.
 - 1–2 catheters
 - Advantageous in patients with overdose or rhabdomyolysis
- Extracorporeal rewarming:
 - Most effective rewarming method
 - Hemodialysis:
 - Initiate for patients with drug overdoses or severe electrolyte disturbances.
 - Continuous arteriovenous rewarming:
 - BP must be > 60 mm Hg.
 - Blood circulated through warmer from percutaneously inserted femoral arterial and contralateral venous catheters
 - Extracorporeal venovenous rewarming:
 - Blood is removed via central venous catheter, heated to 40°C, and returned via 2nd central or large peripheral venous catheter.
 - Cardiopulmonary bypass:
 - Treatment of choice in severe hypothermia with cardiac arrest
- Additional therapy:
 - Methylprednisolone or hydrocortisone for suspicion of adrenocortical insufficiency or steroid dependence

- Empiric treatment with levothyroxine only for myxedematous patients

MEDICATION

- Amiodarone: 300 mg IV push (IVP) for ventricular fibrillation followed by 1 mg/min infusion
- Dextrose: D₅₀W 1 amp—50 mL or 25 g (peds: D₂₅W 2–4 mL/kg) IV
- Hydrocortisone: 250 mg IVP
- Levothyroxine: 50–500 µg IV over several minutes
- Methylprednisolone: 30 mg/kg IVP
- Naloxone (Narcan): 2 mg (peds: 0.1 mg/kg) IV or IM initial dose
- Thiamine (vitamin B₁): 100 mg (peds: 50 mg) IV or IM

FOLLOW-UP

DISPOSITION

Admission Criteria

- Moderate to severe hypothermia ($< 32^{\circ}\text{C}$)
- Young, healthy patients with no comorbid illness who have mild accidental hypothermia ($> 32^{\circ}\text{C}$) that responds well to warming:
 - Admit to an observation area.
 - Discharge if asymptomatic after 8–12 hr and they remain asymptomatic.

Discharge Criteria

- Young, healthy patients with no comorbid illness
- Very mild accidental hypothermia ($> 35^{\circ}\text{C}$) that responds well to warming
- Safe, warm environment to go to after discharge

FOLLOW-UP RECOMMENDATIONS

Social work follow-up for homeless patients with cold exposure and hypothermia

PEARLS AND PITFALLS

- Defibrillation is rarely successful at temperatures $< 28\text{--}30^{\circ}\text{C}$:
 - Defibrillate 1–3 times and then again post rewarming.
- Atrial fibrillation usually converts spontaneously.
- Faster rewarming rates (1–2°C/hr) generally have better prognosis than slower rewarming rates ($< 0.5^{\circ}\text{C/hr}$).
- Afterdrop is the continued decline in core temp after removed from cold
 - Ongoing conduction of heat from core warming periphery prior to the core
- Rewarming shock
 - Hypovolemic shock secondary to failure to replete volume during

resuscitation.

HYPOTHYROIDISM

Rita K. Cydulka • Tammy L. Weiner

BASICS

DESCRIPTION

- Decreased level of effective circulating thyroid hormone leads to decreased metabolic rate and decreased sensitivity to catecholamines.
- More common in woman and the elderly
- Myxedema coma is a rare, extreme form of hypothyroidism characterized by altered mental status and defective thermoregulation triggered by a precipitating event in a patient with hypothyroidism.

ETIOLOGY

- Primary:
 - _ Idiopathic
 - _ Congenital
 - _ Autoimmune:
 - Thyroiditis
 - Hashimoto disease
 - _ Iatrogenic:
 - Postsurgical
 - External radiation
 - Radioiodine therapy
 - Drugs (iodides, lithium, amiodarone, sunitinib, bexarotene, interferons, narcotics, sedatives)
 - _ Neoplasm: Primary (carcinoma) or secondary (infiltration)
 - _ Infection: Viral (rarely aerobic or anaerobic bacteria)
 - _ Iodine deficiency (most common cause worldwide)
- Central (very rare):
 - _ Pituitary or hypothalamic disorder induced by drugs or severe illness
 - _ May have other associated hormone deficiencies
- Myxedema coma:
 - _ Critical decompensation of a patient with hypothyroidism due to a stress, often during winter months. Stressors include:
 - Infection
 - Hypothermia
 - Intoxication
 - Drugs
 - Cerebrovascular accident
 - Heart failure

- Trauma

Pregnancy Considerations

- Hypothyroid women require increased exogenous thyroid hormone replacement during pregnancy above baseline
- Postpartum thyroiditis occurs in up to 10% of women:
 - Usually 3–6 mo postpartum
 - Typically resolves without treatment

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Exhaustion
- Cold intolerance
- Headaches
- Diminished hearing
- Myalgias and muscle weakness
- Menorrhagia
- Infertility
- Carpal tunnel syndrome
- Constipation
- Weight gain
- Depression, hallucinations, or paranoia
- Cognitive impairment

Physical-Exam

- Periorbital edema
- Sparse, coarse hair and brittle nails
- Absent lateral 1/3 of eyebrows (Queen Anne sign)
- Husky or hoarse voice
- Goiter
- Prolonged relaxation phase of deep tendon reflexes (DTRs)
- Yellow, dry, pale, cool, coarse skin
- Myxedema (dry, waxy swelling of skin)
- Nonpitting edema of hands and feet
- Myxedema coma:
 - Altered mental status
 - Hypotension
 - Hypothermia
 - Respiratory failure

- Bradycardia

Pediatric Considerations

- Undiagnosed hypothyroidism in infants has largely been eliminated via universal screening at birth
- Hypothyroidism in childhood is usually due to Hashimoto disease.
- Children may manifest with retardation of mental developmental, linear growth, and sexual maturation

Geriatric Considerations

Typical symptoms of hypothyroidism may be confused with changes associated with aging.

ESSENTIAL WORKUP

Lab confirmation of the diagnosis of hypothyroidism/myxedema coma may not be available in the ED, and therapy should be initiated based on clinical suspicion.

DIAGNOSIS TESTS & INTERPRETATION

Search for the underlying cause of myxedema coma.

Lab

- Thyroid function studies:
 - Low total and free thyroxine (T₄)
 - Low total and free triiodothyronine (T₃)
 - Thyroid stimulating hormone (TSH):
 - Increased in primary hypothyroidism but normal or decreased in central pathology
- Anemia
- Hyponatremia
- Hypoglycemia
- Hypoxemia
- Hypercapnia
- Respiratory acidosis
- Elevated lactate dehydrogenase (LDH), creatine kinase (CK), cholesterol, creatinine

Imaging

CXR:

- Enlarged cardiac silhouette due to pericardial effusion

Diagnostic Procedures/Surgery

ECG:

- Sinus bradycardia, low voltage, PR interval prolongation, bundle branch blocks, QT interval prolongation and nonspecific ST-T-wave changes
- May see Osborn wave if profoundly hypothermic

DIFFERENTIAL DIAGNOSIS

- Chronic nephritis
- Chronic renal disease
- Heart failure
- Depression
- Hypoalbuminemia
- Pernicious anemia
- Nephrotic syndrome
- Sepsis

ALERT

- Euthyroid sick syndrome:
 - Illness, surgery, fasting may produce abnormal thyroid function test results
 - Thyroid function tests performed during acute nonthyroid illness may be abnormal and should be interpreted with caution

TREATMENT

INITIAL STABILIZATION/THERAPY

- ABCs:
 - Intubation and ventilation may be necessary
- Cardiac monitor
- Blood pressure support
- Supplemental oxygen to meet metabolic needs
- Correct hypothermia:
 - Initiate passive warming measures
 - Aggressive rewarming may precipitate hypotension from vasodilation

ED TREATMENT/PROCEDURES

- Mild hypothyroidism:
 - Refer for oral thyroid hormone replacement as an outpatient
- Myxedema coma:
 - Life-threatening condition
 - Initiate thyroid hormone replacement therapy if a high index of suspicion:
 - Prompt IV replacement improves survival
 - Controversy over regimen exists
 - Thyroxine (T₄) and triiodothyronine (T₃)
 - Reassess 4 hr after initial dose

- Use smaller doses of T₄ and avoid T₃ in the elderly or patients with cardiac disease to avoid precipitating ischemia
- Hydrocortisone to prevent Addisonian crisis
- Dextrose for hypoglycemia
- IV fluid bolus for hypotension:
 - Avoid pressors if possible, may precipitate dysrhythmias
 - Response to pressors is poor until thyroid replacement initiated
 - Thyroid hormone augments pressors
- Consider hypertonic saline for severe hyponatremia
- Correct the underlying precipitant

MEDICATION

First Line

Thyroid hormone therapy:

- Administer T₄, T₃, or a combination:
 - Combination therapy:
 - Thyroxine (T₄): 2 µg/kg (ideal body mass) load IV followed by 10–40 µg IV/PO daily
 - **PLUS**
 - Triiodothyronine (T₃): 10 µg load IV followed by 10 µg IV q8–12h until able to tolerate PO T₄
 - Thyroxine (T₄): 10–40 µg IV or IM daily
 - Triiodothyronine (T₃): 10–20 µg load IV followed by 10 µg IV q4h for 24 hr, then 10 µg IV q6h for 24–48 hr

Second Line

- Hydrocortisone: 100 mg (peds: 4 mg/kg/24h) IV q6–8h
- Dextrose: 50–100 mL D₅₀ (peds: 5 mL/kg of D₁₀) IV

FOLLOW-UP

DISPOSITION

Admission Criteria

All patients with myxedema coma require ICU admission.

Discharge Criteria

Hypothyroidism is managed in the outpatient setting.

Issues for Referral

- Primary care providers can generally manage hypothyroidism.
- Pregnant patients, elderly patients, and those with ischemic heart disease require special consideration when initiating thyroid hormone replacement.

FOLLOW-UP RECOMMENDATIONS

- Patients should be referred to a primary care provider for initiation of oral thyroid hormone replacement therapy.
- Severe untreated maternal hypothyroidism can negatively impact fetal brain development and cause obstetrical complications.

PEARLS AND PITFALLS

- Signs and symptoms of hypothyroidism are nonspecific and may be confused with other mental or physical disorders.
- Response to treatment for hypothyroidism may take weeks and is best initiated by the primary care physician.
- Consider myxedema coma in patients with altered mental status and underlying hypothyroidism.
- Myxedema coma has a high mortality rate and requires aggressive treatment. However, avoid parenteral T₃ in cardiac and elderly patients.

IDIOPATHIC THROMBOCYTOPENIC PURPURA

Matthew T. Keadey • Richard D. McCormick

BASICS

DESCRIPTION

- Idiopathic thrombocytopenic purpura (ITP) is thrombocytopenia without apparent cause or abnormalities in other celllines.
- Incidence is ~2–5/100,000/yr—may be an underestimate owing to undetected, subclinical cases.
- Acute ITP:
 - 1/2 of cases involve children.
 - 80% of children recover within 8 wk with or without therapy.
 - Adult recovery is delayed and requires specific therapy to achieve remission.
- Chronic ITP:
 - Occurs mostly in adults
 - Young women are most susceptible in adult onset ITP
 - Characterized by variable response to corticosteroids and other immune suppressants
 - 60–70% respond to splenectomy
- Chronic refractory ITP:
 - Platelet counts may often wax and wane.
 - Often do not respond to therapy
 - No clear optimal course of treatment
- Genetics:
 - ITP appears to run in families, as do variations in response to corticosteroids for treatment.

ETIOLOGY

- Autoantibodies produced by B cells and plasma cells cause immune-mediated destruction of circulating platelets
- Macrophages in spleen and liver mediate destruction of platelets via IgG autoantibodies
- IgM and IgA rarely have been seen
- Some patients do not possess autoantibodies, suggesting a role for T cell-mediated cytotoxicity.
- C3 and C4 complements have also been shown to play a role in patients that lack autoantibodies
- Poor platelet production may also play a role especially in chronic or refractory cases of ITP
- Eradication of *Helicobacter pylori* can sometimes be associated with platelet

recovery (unclear mechanism).

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Bleeding is the most common complaint:
 - Common:
 - Mucous membrane: Gingiva, epistaxis, conjunctival, menorrhagia
 - Rare (more common in coagulopathies):
 - GI bleeding, hemarthrosis, hematuria, and hematomas
- 84% of pediatric cases are 2–3 wk following a viral illness:
 - Small percentage found following vaccinations
- Most adult cases have an insidious onset:
 - Up to 28% of patients are asymptomatic and diagnosed on routine CBC
 - <5% present with life-threatening bleeding

Physical-Exam

- Mucosal bleeding often apparent in symptomatic cases
- Commonly may follow dental procedures, extraction or trauma
- Petechiae (nonblanching)
- Nonpalpable purpura
- Distinguishes ITP from Henoch–Schönlein purpura (HSP)
- Melena, bright red blood per rectum, or hemocult positive stools
- Spleen normal size in ITP:
 - Enlarged spleen may be found in leukemia or other platelet sequestration syndromes
- Neurologic deficits from intracranial hemorrhage (ICH):
 - ICH is the most common cause of death in ITP.
 - Risk of ICH in ITP increases with age:
 - Age <40 yr: 2%
 - Age >60 yr: 48%

ESSENTIAL WORKUP

- Diagnosis of exclusion—other causes of thrombocytopenia must be ruled out.
- CBC with differential
- PT and PTT if actively bleeding to exclude other forms of coagulopathy
- BUN and creatinine to evaluate renal function
- Liver function to exclude liver disease
- Type and screen if actively bleeding
- Pregnancy test if of childbearing age

- HIV testing should be considered

DIAGNOSIS TESTS & INTERPRETATION

Lab

CBC with differential and peripheral smear:

- Thrombocytopenia
- Increased mean platelet volume
- Normal WBC and RBC morphology and size
- Liver function, coagulation studies, and kidney function should all be within normal limits

Imaging

CT head without contrast to evaluate for ICH if clinically indicated by focal findings, headache, or head trauma.

Diagnostic Procedures/Surgery

Bone marrow biopsy:

- All adults > 60 yr to evaluate for malignancy
- Atypical symptoms and cases refractory to treatment
- Patients considering splenectomy
- Children with persistent thrombocytopenia > 6 mo
- Children unresponsive to intravenous immunoglobulin (IVIG)
- Antibody testing is of no clinical value

DIFFERENTIAL DIAGNOSIS

- Impaired bone marrow production:
 - Bone marrow fibrosis
 - Bone marrow infiltration owing to malignancy
 - Cytotoxic drugs used in chemotherapy
 - Congenital/acquired bone marrow abnormalities
- Splenic sequestration:
 - Portal hypertension
 - Neoplastic infiltration
 - Sickle cell disease
- Accelerated destruction of platelets:
 - Vasculitis
 - TTP/HUS
 - Disseminated intravascular coagulation (DIC)
 - HELLP syndrome
 - Cardiac valvular disease
- Drug induced:
 - Decreased platelet production:

- Chemotherapy
- Thiazide diuretics
- Ethanol
- Estrogen
- _ Increased destruction of platelets:
 - Aspirin
 - Heparin
 - Chlorpropamide
 - Chloroquine
 - Gold salts
 - Sulfonamides
 - Insecticides

TREATMENT

PRE HOSPITAL

Stabilize ABCs

- Significant oral or laryngeal bleeding may affect airway.
- CNS event may affect ability to control airway
- Establish IV access for cases of significant bleeding
- Control any bleeding with direct pressure

INITIAL STABILIZATION/THERAPY

- ABCs
- Stabilize life-threatening bleeding:
 - _ ICH:
 - Airway control
 - Neurosurgery consultation: Craniotomy not typically possible until platelet counts > 75 K
 - _ Hemorrhagic shock:
 - 2 large-bore IVs
 - Direct pressure for hemostasis
 - Resuscitation with blood transfusions and isotonic crystalloid
 - Medications and platelets for acute life-threatening episodes of bleeding:
 - IV high-dose dexamethasone or methylprednisolone
 - IVIG infusion
 - Platelet transfusions: 2–3 times the normal amount
 - _ Platelets typically infused after steroids and/or IVIG
 - _ Mucous membrane bleeding:
 - Topical agents
 - Other:

- IV Aminocaproic acid may be considered
- In rare cases, plasmapheresis has been proven helpful

ED TREATMENT/PROCEDURES

- Initial treatment options for ITP are based on:
 - _ Degree of thrombocytopenia
 - _ Severity of illness
 - _ Duration of symptoms
 - _ Age
 - _ Risk factors for bleeding (hypertension, peptic ulcer disease, vigorous lifestyle)
 - _ Hematologist preference
- Efficacy of treatment is demonstrated in terms of platelet recovery time and not morbidity or mortality.
- Specific treatment options:
 - _ Observation is recommended for children without bleeding complications or profound thrombocytopenia (< 20–30 K)
 - _ Profound thrombocytopenia (< 20 K):
 - High-dose corticosteroids: 75% response
 - IVIG: 80% response, but costly, so reserved in time critical emergencies
 - Anti-D IG: 70% response (used only in Rh⁺ patients)
 - _ Splenectomy:
 - 2nd-line therapy if inadequate response to a course of glucocorticoid therapy
 - Two-thirds of adult patients respond, three-fourths of pediatric patients respond.
 - No specific indications for emergent splenectomy

Pregnancy Considerations

- Differential diagnosis of thrombocytopenia during pregnancy:
 - _ Gestational thrombocytopenia (75%):
 - Usually of no clinical significance
 - Does not cause neonatal thrombocytopenia
 - Remits 1–2 wk after delivery
 - Platelets typically > 50 K
- HELLP syndrome (*hemolysis, elevated liver enzymes, and low platelets*)
- ITP (15%):
 - _ Platelets typically < 50 K
 - _ Maternal platelet count does not correlate to neonatal thrombocytopenia.
 - _ Treatment with steroids or IVIG does not alter incidence of neonatal thrombocytopenia.

- Degree of thrombocytopenia should not alter decision of vaginal birth vs. C-section.
- Measure neonatal CBC and check brain ultrasound for ICH.
- Treat neonatal thrombocytopenia with IVIG and steroids

MEDICATION

First Line

- Glucocorticoids (high dose over 2–3 wk):
 - Dexamethasone: 40 mg PO daily
 - Prednisone: 1–2 mg/kg/24 hr PO/day
 - Methylprednisolone: 1 g IV q8h (30 mg/kg/24 hr pediatric dose)
- IVIG: 1–2 g/kg IV × 1 dose and possibly repeated in 24 hr:
 - Used only for critical bleeding or when the need to acutely raise platelets is required such as emergency surgery
- Anti-D immunoglobulin: 50 µg/kg/24 hr IV:
 - Used only presplenectomy and in Rh⁺ patients

Second Line

- Chronic long-term suppression and steroid bolus therapy
- Immunosuppressive agents:
 - Azathioprine
 - Cyclosporin
 - Mycophenolate
 - Chemotherapeutic agents:
 - Vinca alkaloids
 - Cyclophosphamide
 - Combinational chemotherapy
- Other:
 - Rituximab: Monoclonal antibody directed against B cell antigens
 - Danazol: Antiandrogen
- Experimental:
 - Other monoclonal antibodies directed at B cells
 - Stem cell transplants
 - Thrombopoietin and thrombopoietin-like agonists

FOLLOW-UP

DISPOSITION

Admission Criteria

- Life-threatening bleeding regardless of platelet count

- Any bleeding with platelet count < 20 K
- Asymptomatic patient with platelet count < 20 K with issues of noncompliance or poor follow-up

Discharge Criteria

- Asymptomatic patients
- Patients with minor bleeding and platelets > 30 K

FOLLOW-UP RECOMMENDATIONS

Hematology referral is indicated in all cases (either outpatient or inpatient consultation)

PEARLS AND PITFALLS

- Before low platelet counts are evaluated, pseudothrombocytopenia should be excluded.
- Spontaneous bleeding usually does not occur until platelet counts are < 10 K.

ICD10

D69.3 Immune thrombocytopenic purpura

IMMUNIZATIONS

Garth D. Meckler

BASICS

DESCRIPTION

- Immunization enhances or initiates resistance to infectious diseases.
- Protection from immunization occurs through several mechanisms:
 - Passive immunization: Administration of purified antibodies or passive transfer of maternal antibodies through the placenta/breast milk.
 - Active immunization: Stimulates immune system, producing IgM antibodies after 7–10 days followed by IgG antibodies, peaking between 2 and 6 wk.
- Oral and nasal vaccines induce mucosal secretory IgA antibodies while parenteral vaccines may not. Improper administration (route, dose, bad storage, etc.) may result in decreased immunity.

ETIOLOGY

- Several types of vaccines are available:
 - Live attenuated (weakened) viruses (e.g., varicella [VZV]; measles, mumps, rubella [MMR]; rotavirus) replicate in the host and induce an immune response:
 - May cause serious infections in the immunocompromised.
 - Inactivated (or killed) vaccines (e.g., polio [IPV], hepatitis A [HepA], some influenza, pertussis) are safe in patients with compromised immune system.
 - Toxoid, subunit, or conjugate vaccines (e.g., diphtheria, tetanus, *Haemophilus influenzae b* [Hib], Human papilloma virus [HPV], Pneumococcus, Meningococcus) use antigenic portions of toxins, proteins, or carbohydrates from viruses or bacteria to induce immune response
 - Hepatitis B (HepB) vaccine uses recombinant DNA technology
- Several combination vaccines are also available but have an increased cost:
 - Pediarix (diphtheria and tetanus toxoids and acellular pertussis adsorbed [DTaP], HepB, and inactivated poliovirus vaccine [IPV] combined)
 - Comvax (HepB and Hib).
 - Pentacel (DTaP, IPV, and Hib).
 - Twinrix (HepA and HepB).
 - MMRV (MMR and varicella).

EPIDEMIOLOGY

- The incidence of several life-threatening illnesses has been markedly reduced with widespread immunization use:
 - Polio caused by wild-type viruses has been eliminated from the Western Hemisphere.

- Hib, diphtheria, and tetanus vaccines have nearly eliminated these invasive diseases among children in North America.
- The incidence of measles, rubella, and varicella has also declined; sporadic in unimmunized communities and foreign travelers to US.
- 7-valent and 13-valent conjugate pneumococcal vaccines (Prevnar 7 and Prevnar 13) have reduced invasive disease from 100–21 cases/100,000 for all types of pneumococcal infection and from 80–0.2/100,000 for vaccine serotypes (99% reduction).
- Rotavirus is a live oral vaccine
- Respiratory syncytial virus immune globulin given to high-risk patients
- Global surveillance of influenza activity allows for annual production of vaccines against seasonal influenza. Inactivated vaccines are available for IM administration and live attenuated virus vaccines can be given via the nasal route.
- Immunization recommendations and schedules are based on epidemiology, individual risks for disease and exposure, as well as vaccine safety and efficacy:
 - Infants and young children are vaccinated against common childhood diseases, but some vaccines are not immunogenic (e.g., pneumococcal capsular polysaccharide antigen vaccine) or may be dangerous (e.g., MMR, VZV) in infants.
 - Pregnant women are recommended to receive Tdap and inactivated influenza, but should not receive other live virus vaccines.
 - Specific recommendations exist for other at-risk groups including international travelers, the elderly, health care workers, and immunocompromised individuals.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Concern for vaccine-associated adverse events: The most common events associated with vaccination are mild and include local reactions (pain, swelling, erythema) and/or fever (usually within 7–10 days):
 - Local reactions can occur with almost any injected vaccine, but are particularly common with tetanus, diphtheria, and pertussis (particularly after repeat doses), Hib (can cause sterile abscesses in young infants), VZV, HPV, and pneumococcus.
 - Fever may follow immunization with rotavirus (40–43%), conjugate pneumococcus (24–35%), HPV (10–13%), MMR or MMRV (more common in the latter), and meningococcal vaccine. Influenza vaccine may cause fever 6–24 hr after administration.
 - Rash may be seen as a rare side effect of VZV and MMRV, MMR may cause transient rash or fever 6–12 days after immunization.

- Neurologic symptoms are rare but most commonly seen after DTP vaccines (fussiness, inconsolable crying, drowsiness, brief seizures without fever, hypotonic–hypo-responsive episodes, encephalopathy, and Guillain–Barré syndrome). Headache may follow vaccination with HepB or meningococcus; and MMR and MMRV are associated with febrile seizures in children and rare reports of encephalopathy. Guillain–Barré has also been linked to influenza vaccine in adults.
- Vomiting and diarrhea are rare adverse effects of rotavirus vaccine in infants.
- MMR has been associated with arthralgias in adult women, and rare hematologic adverse events such as thrombocytopenia.
- Live attenuated influenza (nasal) has been associated with mild respiratory symptoms in adults and asthma exacerbations in children with a history of asthma.

ESSENTIAL WORKUP

- ED visits for any reason present an opportunity to review immunization status and provide appropriate follow-up. Take a history of status of immunizations:
 - If incomplete, take a good history as to the reason why immunizations have not been administered.
- True contraindications to vaccination:
 - Anaphylactic reaction to a previous dose of the vaccine or:
 - Anaphylaxis to baker’s yeast is a contraindication to HepB vaccine.
 - Anaphylaxis to chicken or egg protein is a contraindication to influenza vaccine (but not MMR).
 - Anaphylaxis to neomycin or gelatin is a contraindication to MMR vaccine.
 - Anaphylaxis to neomycin, streptomycin, or polymyxin is a contraindication to IPV vaccine.
 - Specific reactions within 48 hr of vaccine of a previous vaccine:
 - Severe, inconsolable screaming for 3 hr
 - Distinctive high-pitched cry
 - Hypo-responsive episode
 - Temperature >40.5°C unexplained by other cause
 - Severe local reaction involving the circumference of the injected limb unless owing to inadvertent SC injection
 - Encephalopathy within 7 days of vaccine:
 - Severe acute neurologic illness with prolonged seizures and/or unconsciousness and/or focal signs
 - Progressive neurologic disease excluding epilepsy
- Reasons to defer vaccine administration:
 - Moderate or severe acute disease regardless of fever.
 - Congenital or acquired immunodeficiency (e.g., HIV,

malignancy/chemotherapy associated): Possible risk from live attenuated vaccines such as VZV, MMR, and influenza. Caution should be used when considering these vaccines for healthy individuals in close contact with the immunocompromised.

- Pregnancy is a contraindication to live attenuated virus vaccines including VZV and HPV; inactivated virus (influenza) and conjugate vaccines (DTaP) are thought to be safe.
- Recent convulsion is a relative contraindication to pertussis.
- Recent administration of immune globulin may lessen the efficacy of vaccinations
- Vaccines may be given with the following:
 - Mild acute illness with or without fever
 - Mild to moderate local reaction (i.e., swelling, redness, soreness), low-grade or moderate fever after previous dose
 - Current antimicrobial therapy
 - Convalescent phase of illness
 - Premature birth (HepB vaccine is an exception)
 - Recent exposure to an infectious disease
 - History of penicillin allergy, other nonvaccine allergies, relative with allergies, receiving allergen extract immunotherapy
 - HIV-infected children who are either asymptomatic or not severely immunocompromised should be vaccinated.

TREATMENT

PRE HOSPITAL

Attention should be focused on the airway, breathing, and circulation.

INITIAL STABILIZATION/THERAPY

Initial medications for anaphylactic reaction to vaccines include IM or IV epinephrine, diphenhydramine, albuterol for wheezing, and IV fluids for hypotension.

ED TREATMENT/PROCEDURES

- Treat anaphylaxis with epinephrine, antihistamines, albuterol and IV fluids as indicated.
- Treatment of potential exposure to infectious disease or contaminated wounds follows specific guidelines for active or passive immunization.
- Treatment of adverse reactions depend on symptoms:
 - Local reactions at the injection site can be treated with cold compresses, analgesics, or antipruritics. Control bleeding with a pressure dressing.
 - Treat fever, headaches, myalgias, and arthralgias with acetaminophen or ibuprofen.

- Treat ongoing seizures with benzodiazepines
- Consider prophylaxis with acetaminophen at the time of injection of vaccines and again 4–8 hr later:
 - Children who receive varicella vaccine should avoid salicylates for 6 wk post vaccination because of the association of varicella infection and salicylates to Reye syndrome.
- Specific discussion with the parents is required to review the risks and benefits of tetanus vaccination, particularly given the frequent occurrence of trauma and the need to provide both passive and active immunity at that time:
 - Document in the chart that the risks and benefits have been thoroughly discussed. A formal informed consent is used in some settings.
 - The National Childhood Vaccine Injury Act requires that a copy of the Vaccine Information Statements be provided before administering each dose of the vaccine.

MEDICATION

- Acetaminophen 15 mg/kg/dose q4–6h PO
- Ibuprofen 10 mg/kg/dose q6–8h PO

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with serious adverse reactions following immunization should be admitted.
- Patients with anaphylaxis and encephalopathy may require admission to a pediatric ICU.
- Unexpected adverse events should be reported to the Vaccine Adverse Event Reporting System.

Discharge Criteria

Patients may be discharged home after routine immunizations unless an immediate adverse reaction occurs. It is essential that follow-up with the primary care physician be arranged to complete immunizations.

PEARLS AND PITFALLS

- Failure to continue diphenhydramine for 48 hr following an allergic reaction. Steroids may also be considered.
- Failure to recognize egg allergy as a contraindication to influenza vaccine.

IMMUNOSUPPRESSION

Lara K. Kulchycki

BASICS

DESCRIPTION

Congenital or acquired deficiency in the ability to fight infection:

- Antibody production (B cell)
- Cellular immunity (T cell)
- Phagocytic dysfunction
- Complement deficiency
- Breach of skin/mucosal barriers

ETIOLOGY

- Congenital disorders
- Immunosuppressive medications
- Aging:
 - Immunosenescence
 - Poor circulation and wound healing
- Chronic (lung, kidney, or heart) disease
- HIV infection:
 - CD4 count determines susceptibility to pathogens
- Diabetes:
 - Hyperglycemia impairs immune response
 - Vascular insufficiency
- Malnutrition:
 - Poverty
 - Alcoholism and drug abuse
 - Eating disorders
- Asplenia:
 - Functional asplenia (sickle cell disease) or surgical splenectomy increases risk of infection with encapsulated organisms
- Organ transplantation:
 - Antirejection medications suppress immune response
 - Infections may be donor derived, recipient derived, or nosocomial
 - Increased risk of viral pathogens, such as cytomegalovirus, Epstein–Barr virus, and human herpes viruses
 - Time elapsed since transplantation is crucial, as different patterns of infection arise in early, intermediate, and late posttransplantation periods
- Malignancy
- Chemotherapy:

- Increased risk of infection with pyogenic bacteria and fungi
- Infection risk related to length and severity of neutropenia
- Neutropenia:
 - Defined as absolute neutrophil count (ANC) $< 500/\text{mm}^3$ or $< 1,000/\text{mm}^3$ with an anticipated nadir of $< 500/\text{mm}^3$
 - In US, gram-positive organisms are the leading etiology of infection
 - Gram-negative organisms are somewhat less common but often virulent
 - Polymicrobial infections are increasingly frequent
 - Anaerobic isolates remain relatively rare
 - The risk of fungal pathogens increases with prolonged neutropenia (> 1 wk), prior use of broad-spectrum antibiotics, or intense chemotherapy

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Fever may be the only symptom of a life-threatening infection in an immunocompromised host
- Perform a careful review of systems to identify any localizing symptoms
- Identify risk factors for nosocomial infections, such as recent hospitalization or nursing home residence
- Ask about close contacts with transmissible illnesses, such as influenza
- Review medications for the presence of immunosuppressive agents, such as steroids
- Recognize that prophylactic medicines, such as trimethoprim/sulfamethoxazole or fluconazole, may alter both the spectrum of likely pathogens and their resistance patterns

Physical-Exam

- Examine the patient from head to toe
- Some clinicians advise avoiding digital rectal exams in patients with febrile neutropenia
- Inflammation may be subtle or absent:
 - Surgical abdomen without peritoneal signs
 - Meningitis without nuchal rigidity
 - Infected wounds or indwelling lines without induration, erythema, or purulent discharge

ESSENTIAL WORKUP

- Choice of studies must be tailored to the patient and the presenting complaint
- Test interpretation may be difficult since inflammatory responses are often

blunted in immunosuppressed patients:

- Pneumonia without radiographic infiltrates
- UTIs without pyuria
- Meningitis without CSF pleocytosis

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC with differential:
 - Identify leukocytosis, left shift, bandemia, or neutropenia
 - Risk of infection begins to increase once ANC $< 1,000/\text{mm}^3$
- Blood cultures:
 - 2 sets of bacterial cultures
 - Draw 1 culture from an indwelling line, if present
 - Obtain fungal cultures if indicated
- Urinalysis/urine culture:
 - Obtain by clean catch, if possible, as catheterization may introduce infection
- Serum lactate:
 - Useful for identifying occult hypoperfusion in sepsis
- Arterial blood gas:
 - Useful in determining the need for steroids in suspected cases of *Pneumocystis jirovecii* pneumonia (PCP)
- Pregnancy testing in women of childbearing age

Imaging

- Chest x-ray recommended if patient is neutropenic, hypoxic, or has abnormal pulmonary signs
- Further imaging, such as CT or MRI, can be tailored to the patient's presentation and risk factors

Diagnostic Procedures/Surgery

- Lumbar puncture should be performed if there is a clinical suspicion for meningitis:
 - Check platelet counts and coagulation studies prior to procedure if thrombocytopenia or coagulopathy is suspected
 - Consider cryptococcal antigen testing even in the absence of CSF pleocytosis

DIFFERENTIAL DIAGNOSIS

- Infection:
 - Oropharynx
 - Sinuses
 - Lung

- GI tract
- Perineum/anus
- Urinary tract
- Skin/soft tissue
- Bone
- Indwelling catheters/devices
- Noninfectious etiology of fever:
 - Drug fever
 - Allograft rejection
 - Malignancy
 - Vasculitis
 - Rheumatologic disease
 - Pulmonary embolism
 - Thyroid dysfunction
 - Blood product transfusion

TREATMENT

PRE HOSPITAL

- Establish IV access
- IV fluid bolus

INITIAL STABILIZATION/THERAPY

- Aggressive fluid resuscitation for patients with hypovolemia
- Goal-directed therapy for patients with sepsis
- Ultrasound can be used to evaluate the IVC (caval index) to estimate volume status as well as screen for malignant pericardial tamponade
- Administer pressors for hypotension that fails to respond to IV fluids:
 - Dopamine 5–20 $\mu\text{g}/\text{kg}/\text{min}$ IV
 - Norepinephrine 2–12 $\mu\text{g}/\text{min}$ IV

ED TREATMENT/PROCEDURES

- Institute appropriate infection control precautions, such as neutropenic or contact precautions
- Rapidly collect appropriate cultures and administer broad-spectrum antibiotics
- Most patients with febrile neutropenia are admitted, but low-risk patients with fever may be candidates for outpatient treatment
- Low risk:
 - Age < 60 yr
 - Outpatient status at time of fever
 - ANC > 100 cells/mm³
 - Duration of neutropenia < 7 days

- Expected resolution of neutropenia < 10 days
- Well appearing
- Stable vital signs
- No change in mental status
- No dehydration
- Lack of significant comorbid conditions:
 - o Chronic pulmonary disease
 - o Diabetes
 - o Organ failure
- Disease in remission
- No history of fungal infections
- Normal chest x-ray

MEDICATION

- Treatment regimens should, if possible, be tailored to the patient
- Empiric therapy with broad-spectrum agents must be rapidly administered in febrile neutropenia or sepsis
- Oral antibiotic therapy:
 - Produces comparable results in low-risk adults with febrile neutropenia
 - Ciprofloxacin 750 mg PO BID + amoxicillin–clavulanate 875 mg PO BID
- Parenteral monotherapy options:
 - Ceftazidime: 2 g IV q8h (peds: 50 mg/kg IV q8h)
 - Cefepime: 2 g IV q8h (peds: 50 mg/kg IV q8h)
 - Imipenem–cilastatin: 500 mg IV q6h (peds: Dose based on age/weight)
 - Meropenem: 1 g IV q8h (peds: Dose based on age/weight)
 - Piperacillin–tazobactam: (Less well studied in neutropenia) 4.5 g IV q6h (peds: Dose based on age)
- For high-risk patients, consider adding an aminoglycoside (AG) for synergism:
 - Gentamicin: Dose based on Cr clearance (peds: Dose based on age)
 - AG use increases risk of adverse events, such as acute renal failure and ototoxicity
- Empiric vancomycin is usually not indicated:
 - Consider adding if suspected line sepsis or history of methicillin-resistant *Staphylococcus aureus*
 - Vancomycin: 1 g IV q12h (peds: Dose based on age/weight)
- Anaerobic coverage may be added if there is concern for oral or abdominal/perianal infections:
 - Clindamycin: 600–900 mg IV q8h (peds: Dose based on age)

FOLLOW-UP

DISPOSITION

Admission Criteria

- ANC < 100 cells/mm³
- Immunocompromised patients with infection who do not meet low-risk criteria
- Patients with inadequate access to outpatient medical care
- Maintain lower admission criteria for:
 - Elderly
 - Diabetics
 - Children

Discharge Criteria

- Low-risk patients that are well appearing and can tolerate oral antibiotics and fluids may be considered for outpatient management
- Discuss the disposition with the responsible hematology/oncology, infectious disease, or transplant physician prior to discharge

FOLLOW-UP RECOMMENDATIONS

24-hr follow-up must be available in order to reassess the patient and monitor culture results

PEARLS AND PITFALLS

- Failure to learn institutional/regional infection and antibiotic resistance patterns
- Failure to recognize that a vague symptom or isolated fever may be the sole warning sign of serious infection in an immunocompromised host
- Failure to administer broad-spectrum antibiotics rapidly in febrile neutropenia or sepsis
- Failure to review the patient's previous microbiology results
- Failure to involve the appropriate primary care and specialty physicians who are familiar with the patient and can help tailor therapy and ensure follow-up

- D84.1 Defects in the complement system
- D84.9 Immunodeficiency, unspecified

IMPETIGO

Irving Jacoby

BASICS

DESCRIPTION

- Impetigo is a common infection of the skin
- Primary infection:
 - Infection of minor breaks in the skin
- Secondary infection:
 - Infection of previously existing skin lesions, known as “impetiginization”
- Most prevalent in children aged 2–5 yr
- More common in summer months and warm and humid climates
- Predisposing factors:
 - Minor trauma, esp. around nose area
 - Burns
 - Insect bites
 - HIV infection
 - Diabetes mellitus
 - Existing skin disease
 - Varicella infection
- Complications:
 - Acute poststreptococcal glomerulonephritis
 - 1–5% in patients with nonbullous impetigo
 - Sepsis
 - Cellulitis
 - Endocarditis
 - Toxic shock syndrome
 - Staphylococcal scalded skin syndrome (SSSS)

ETIOLOGY

- Classic impetigo:
 - The result of bacteria entering through traumatic skin portal from scratch, abrasion, or insect bite
 - Caused by *Staphylococcus aureus*, group A β -hemolytic streptococci, or both
 - Often associated with poor hygiene
 - Treatment of both streptococci and *S. aureus*
- Bullous impetigo:
 - Caused by *S. aureus*, phage group II
 - Epidermal cleavage is caused by staphylococcal exfoliative toxins A, B, and D, which are serine proteases that bind and cleave desmoglein 1, an

Pregnancy Considerations

Zinc supplementation to mother during pregnancy may lead to decreased incidence in infants

DIAGNOSIS

SIGNS AND SYMPTOMS

- **Classic (nonbullous) impetigo:**
 - Begins as a single 2–4 mm erythematous macule or papule that may evolve into a vesicle or pustule, on a red base
 - Rupture of the vesicle, usually within 24 hr, leaves a honey-colored, dark brown, or reddish-black exudative crust
 - Highly contagious
 - Often pruritic, may be spread from the original site of infection by scratching
 - Mild lymphadenopathy may be seen, usually not lymphadenitis
 - Systemic manifestations are rare
 - Rheumatic fever does not occur following streptococcal skin infection
 - Skin infections with nephritogenic strains of group A streptococci are major antecedents of poststreptococcal glomerulonephritis
- **Bullous impetigo:**
 - Occurs most commonly in the neonate, but can occur at any age
 - Lesions begin as vesicles that turn into flaccid bullae with clear yellow fluid
 - Nikolsky sign is absent
 - Large, fragile bullae rupture quickly, leaving only a shiny, erythematous base with peeling edges

History

Fever and constitutional symptoms are uncommon

Physical-Exam

- **Common sites of infection:**
 - Face
 - Extremities
 - Scalp
- The diagnosis is made based on observation of the classic exam findings, especially appearance, and distribution

ESSENTIAL WORKUP

Cultures of fluid from bullae or pustules may be considered in those cases refractory to

traditional therapy or if methicillin-resistant *S. aureus* (MRSA) is of particular concern during an outbreak

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Antistreptolysin O titer after streptococcal impetigo is scant
- AntiDNase B response readily occurs; 90% of patients with nephritis complicating streptococcal skin infections have elevated titers
- Urinalysis to evaluate for hematuria or proteinuria which might suggest onset of poststreptococcal glomerulonephritis

Imaging

Not usually indicated

Diagnostic Procedures/Surgery

- Biopsy is generally not needed for diagnosis
- If biopsy is performed:
 - Subcorneal epidermal cleavage plane
 - Inflammatory infiltrate of neutrophils and lymphocytes in the upper dermis
 - Subcorneal blisters with occasional acantholytic cells
- Gram stain of blister fluid may show PMNs and gram-positive cocci in chains or clusters

DIFFERENTIAL DIAGNOSIS

- Herpes simplex
- Varicella zoster (shingles)
- Atopic dermatitis
- Contact dermatitis
- Dermatophytosis
- Erysipelas
- Candidiasis
- Scabies
- Folliculitis
- Pediculosis
- Pemphigus vulgaris
- Bullous pemphigoid
- Seborrheic dermatitis
- Thermal burns
- Stevens–Johnson syndrome
- Bullous erythema multiforme
- SSSS, caused by systemic spread of exfoliatin in susceptible individuals
- Pemphigus neonatorum (Ritter disease), or SSSS in the newborn

- Toxic epidermal necrolysis
- Cutaneous anthrax

TREATMENT

PRE HOSPITAL

- Apply dressings to cover for transport
- Gloves must be worn, as agents can be transmitted person to person
- Cautions:
 - _ Maintain universal precautions
 - _ Siblings of affected children in same household should be checked for lesions

INITIAL STABILIZATION/THERAPY

In healthy children or adults, classic or bullous impetigo is not a life-threatening condition and does not require resuscitative measures

ED TREATMENT/PROCEDURES

- Small nonbullous lesions may be treated with topical therapy alone
- Larger, widespread lesions, or presence of bullous impetigo, or presence of lymphadenopathy should be treated with systemic therapy
- Systemic treatment should include a β -lactamase-resistant penicillin, cephalosporin, or macrolide antimicrobial for 10 days:
 - _ If no response, check for MRSA and switch antibiotic to cover for MRSA
- Systemic antibiotic advisable during epidemics of acute poststreptococcal glomerulonephritis or in communities with widespread MRSA
- Local care should include cleansing, removal of crusts, and application of wet dressings to the affected areas

MEDICATION

- All treatment regimens are 10 days, except for topical retapamulin, which is used for 5 days and may enhance compliance, and oral azithromycin, which lasts 9 days when taken for 5 days
- Avoid use of erythromycin if high incidence of erythromycin resistance of streptococci or staphylococci in the community
- Oral:
 - _ Amoxicillin/clavulanic acid: 250 mg PO q8h (peds: 30 mg/kg/d PO in div. doses q8h)
 - _ Azithromycin: 500 mg PO on day 1; 250 mg PO days 2–5 (peds: 10 mg/kg PO on day 1; 5 mg/kg PO days 2–5)
 - _ Cephalexin: 500 mg PO QID (peds: 25–50 mg/kg/d PO in div. doses q8–12h)
 - _ Clarithromycin: 250 mg PO q12h (peds: 15 mg/kg in div. doses q12h)
 - _ Clindamycin: 150 mg PO TID (peds: 5 mg/kg TID)
 - _ Dicloxacillin: 250 mg PO q6h (peds: 25–50 mg/kg/d PO in div. doses q6h)

- Doxycycline: 100 mg PO q12h when MRSA suspected: (Peds over 8 yr and under 45 kg, give 4.5 mg/kg/d in div. doses q12h). Not recommended for children under 8 yr
- Erythromycin ethylsuccinate: 250 mg PO q6h (peds: 40 mg/kg/d PO in div. doses q6h)
- Trimethoprim–sulfamethoxazole DS: 1 tab PO BID for 10 days (peds: >2 mo; 4 mg/kg of trimethoprim component PO q12h for 10 days); Useful when MRSA suspected
- Linezolid: 600 mg PO BID—expensive, used only for multiallergic patients or MRSA (peds: Not approved for children)
- Topical:
 - Mupirocin (2% ointment [Bactroban]): Adult and peds: Apply topically to affected area TID (nonbullous impetigo only) for 10 days.
 - Retapamulin (1% ointment) (Altabax): Adult and peds >9 mo: Apply topically to affected areas BID for 5 days.

First Line

Topical:

- Mupirocin: (up to 46% of US 300 strain of Community-acquired MRSA carry gene encoding for resistance to mupirocin)

Second Line

• Topical:

- Retapamulin (package insert says not for MRSA due to not enough cases studied, but has shown effect on mupirocin-resistant MRSA)

• Oral antibiotics:

- Amoxicillin/clavulanic acid
- Cephalosporins
- Dicloxacillin
- Erythromycin
- Doxycycline

FOLLOW-UP

DISPOSITION

Admission Criteria

- Admission for impetigo alone is rarely necessary
- Patients with disease that is widespread, especially widespread bullae, or with larger areas of denuded skin, and dehydration, or refractory to outpatient therapy
- Toxic, ill-appearing, or immunocompromised patients require admission, as do neonates suspected of having sepsis

- Nephritis may already be present at time patients present for care if presentation is delayed > 4–5 days
- More typically, nephritis, if seen, occurs 2–4 wk after a streptococcal skin infection

Discharge Criteria

- Patients should not be toxic appearing
- Patients/caregivers should be able to comply with the recommended treatment regimen
- Follow-up for re-evaluation

Issues for Referral

Periorbital edema, leg swelling, or hematuria or proteinuria should suggest poststreptococcal glomerulonephritis and referral to nephrologist

FOLLOW-UP RECOMMENDATIONS

- Follow-up with primary care physician should be arranged to assure resolution without complications
- Return for failure of lesions to respond
- Return for development of hematuria, periorbital edema, or leg swelling

PEARLS AND PITFALLS

- Treat with systemic antibiotics in the presence of bullous impetigo or if lymphadenopathy is present
- Increasing antibiotic resistance continues to limit ability to use historic standard antibiotic protocols
- Mupirocin resistance exists, should be suspected in failures to respond and switch to retapamulin
- Cultures and sensitivity must be checked for recalcitrant lesions
- Relapse, representing reinfection, may occur if other affected family members are not treated at the same time

INBORN ERRORS OF METABOLISM

David A. Perlstein • David H. Rubin

BASICS

DESCRIPTION

- Defect in the type, amount, and toxicity of metabolites that accumulate due to an inherited abnormal pathway in children; result in a variety of clinical findings; > 400 human diseases are caused by inborn errors of metabolism
- Epidemiology:
 - Incidence:
 - Variable: 1:10,000–1:200,000 births
- Genetics:
 - Common inherited metabolic diseases:
 - Amino acid disorders
 - Urea cycle defects
 - Organic acidemias
 - Defects in fatty acid oxidation
 - Mitochondrial fatty acid defects and carnitine transport defects
 - Mitochondrial disease
 - Carbohydrate disorders
 - Mucopolysaccharidoses
 - Sphingolipidoses
 - Peroxisomal disorders
 - Protein glycosylation disorders
 - Lysosomal disorders
 - Rhizomelic chondrodysplasia punctata
- Pathophysiology:
 - Related to defect in a metabolic pathway

ETIOLOGY

Diverse group of disorders involving genetic deficiency of an enzyme of an intermediary metabolite or a membrane transport system.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Disorders may present with either a rapid decompensation or a chronic indolent course
- Neonates, initial presentation:
 - Asymptomatic

- Hypothermia (mitochondrial defects)
- Hypotonia/hypertonia (peroxisomal disorders)
- Apnea (urea cycle defects, organic acidosis)
- Seizures (peroxisomal disorders, glucose transporter defects)
- Coma (numerous)
- Vomiting (numerous)
- Poor feeding, growth (numerous)
- Jaundice (galactosemia, Niemann–Pick C)
- Hypoglycemia (galactosemia, maple syrup urine)
- Dysmorphic features (lysosomal storage disorders, congenital adrenal hyperplasia, Smith–Lemli–Opitz)
- Older children, untreated:
 - Failure to thrive (urea cycle defects)
 - Dehydration (organic acidosis)
 - Vomiting (urea cycle defects and others)
 - Diarrhea (numerous)
 - Food intolerance (lipid defects, amino acid defects)
 - Lethargy (urea cycle defects)
 - Ataxia (urea cycle defects)
 - Seizures (numerous)
 - Mental retardation (phenylketonuria and others)

History

Complete history of current and concomitant illness:

- Newborn screening
- Dietary
- Family
- Consanguinity
- Other

Physical-Exam

- Abnormal odor
- Altered mental status
- Tachypnea
- Abnormal facies
- Cataract
- Cardiomyopathy
- Hepatomegaly
- Splenomegaly
- Dermatitis
- Jaundice

ESSENTIAL WORKUP

Key is to consider in differential diagnosis:

- Deteriorating neurologic status
- Unexplained failure to thrive, with dehydration, persistent vomiting, or acidosis
- Shock unresponsive to conventional resuscitative measures

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Bedside glucose determination
- Electrolytes, BUN/creatinine, glucose
- CBC with differential
- Calcium level
- LFTs, fractionated bilirubin, PTT
- Arterial or venous blood gas
- Lactate and pyruvate level
- Uric acid
- Urinalysis
- Chemistries, as indicated:
 - Ammonia level
 - Quantitative serum amino acids
 - Urine organic and amino acids
- Cultures:
 - Blood
 - CSF

Imaging

- CT scan of head for altered mental status
- CXR

Diagnostic Procedures/Surgery

Lumbar puncture

DIFFERENTIAL DIAGNOSIS

- Often misdiagnosed as sepsis, dehydration, failure to thrive, toxic ingestion, or nonaccidental trauma
- Infection:
 - Sepsis
 - Meningitis
 - Encephalitis
- Metabolic:
 - Reye syndrome
 - Hepatic encephalopathy
 - Hyperinsulinemia

- Hormonal abnormality
- Renal:
 - Renal failure
 - Renal tubular acidosis
- Toxic ingestion
- CNS mass lesions
- Nonaccidental trauma

TREATMENT

PRE HOSPITAL

ALERT

- ABCs
- Bedside glucose
- IV glucose infusion takes precedence over fluid boluses unless patient in shock. Correction can occur concurrently.
- Avoid lactated Ringer solution.
- Keep child NPO.

INITIAL STABILIZATION/THERAPY

For altered mental status, administer Narcan, glucose (ideally after Accu-Chek and thiamine)

ED TREATMENT/PROCEDURES

- Establish airway, breathing, and circulation.
- For fluid boluses, use normal saline and avoid lactated Ringer and avoid hypotonic fluid.
- Initiate IV glucose at rate of 8–10 mg/kg/min to prevent catabolism:
 - Corresponds to D₁₀ at 1.5 times maintenance.
 - Do not delay glucose infusion to give a “bolus” of isotonic saline; may be given concurrently in a child in shock.
 - If patient is severely hypoglycemic, give IV glucose bolus of D₂₅.
- Rehydrate if patient is hypoglycemic:
 - Restore normal acid–base balance.
- Administer bicarbonate if pH is < 7.0:
 - Initiate dialysis if severe acidosis does not improve quickly.
- Increase urine output to help in removal of some toxins.
- Initially, stop all oral intake; amino acid metabolites may be neurotoxic.
- Treat severe hyperammonemia (≥ 500 –600 mmol/L) with immediate dialysis or with ammonia-trapping drugs such as:
 - Arginine hydrochloride

- Sodium benzoate
- Sodium phenylacetate
- Sodium phenylbutyrate
- Doses vary with disease; consult metabolic physician before use.
- Identify and treat intercurrent or precipitating infection/illness.
- Consult metabolic physician when any child presents with suspected inherited metabolic disease.

MEDICATION

- D₂₅: 2–4 mL/kg IV
- Sodium bicarbonate: 1–2 mEq/kg IV
- Other disease-specific drugs, including pyridoxine and levocarnitine as indicated

First Line

Glucose:

- 0.9% NS at 20 mL/kg

Second Line

Bicarbonate therapy for pH <7.0:

- Hemodialysis as needed

FOLLOW-UP

DISPOSITION

Admission Criteria

- Infants and children presenting with new onset of suspected inherited metabolic disease
- Significant urinary ketones or not tolerating oral intake
- ICU:
 - Significant altered mental status
 - Severe or persistent acidosis
 - Unresponsive hypoglycemia
 - Hyperammonemia
- Transfer to specialized pediatric center may be indicated.

Discharge Criteria

- Normal mental status
- Normal hydration with unremarkable labs
- No evidence of significant intercurrent illness
- Close follow-up arranged with primary care physician

Issues for Referral

Neurodevelopment:

- Diet
- Medications

FOLLOW-UP RECOMMENDATIONS

- Primary care physician
- Metabolic disease specialist

PEARLS AND PITFALLS

Watch for dehydration:

- Treat dehydration with normal saline fluid bolus:
 - _ Follow glucose level carefully; avoid hypoglycemia.
 - _ Use bicarbonate cautiously and only consider if pH < 7.0.
 - _ Hemodialysis may be necessary for hyperammonemia.

INFLAMMATORY BOWEL DISEASE

Shayle Miller

BASICS

DESCRIPTION

- Idiopathic, chronic inflammatory diseases of intestines, which can involve extraintestinal sites as well.
- Differentiation between ulcerative colitis (UC) and Crohn's is not always clear; intermediate forms of inflammatory bowel disease (IBD) exist.
- May present as initial onset of disease or exacerbation of existing disease.
- Maintain high index of suspicion owing to frequent, subtle presentation of Crohn's disease.
- Pediatric considerations:
 - Can occur in 1st few years of life.
 - Extraintestinal manifestations may predominate.
- Differences between Crohn's and UC:
 - Rectum almost always involved in UC with continuous inflammation proximally.
 - Small intestine is not involved in UC.
 - Crohn's can occur anywhere from mouth to anus, often with normal GI tract segments between affected areas.
 - Crohn's involves transmural inflammation, whereas UC is confined to submucosa.
- Similarities between Crohn's and UC:
 - Higher rate of colon cancer with disease > 10 yr.
 - Bimodal age distribution, with early peak between teens and early 30s and 2nd peak about age 60 yr.
- Crohn's disease clinical pattern:
 - Ileocecal: ~ 40%
 - Small bowel: ~ 30%
 - Colon: ~ 25%
 - Other: ~ 5%
- UC clinical pattern on presentation:
 - Pancolitis: 30%:
 - Most severe clinical course
- Proctitis or proctosigmoiditis: 30%:
 - Relatively mild clinical course
- Left-sided colitis (up to splenic flexure): 40%:
 - Moderate clinical course

ETIOLOGY

- Unknown
- Crohn's disease and UC are separate entities with common genetic predisposition.
- A positive family history is very common.
- Multifactorial origin involving interplay among the following factors:
 - Genetic
 - Environmental
 - Immune
- Pathogenesis:
 - Gut wall becomes unable to downregulate its immune responses, ultimately resulting in chronic inflammation.
- There is no definitive evidence for the etiologic role of infectious agents.
- Psychogenic factors may play a role in some symptomatic exacerbations.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Crohn's disease can present with any clinical correlates of chronic inflammatory, fibrostenotic, or fistulizing illness.
- UC may begin subtly or as catastrophic illness.
- Constitutional, GI, and extraintestinal manifestations are common with both Crohn's and UC.

History

- Constitutional:
 - Crohn's:
 - Low-grade fever
 - Night sweats
 - Weight loss
 - Fatigue
 - Pediatric: Growth or pubertal delay
 - UC:
 - Fever usually only in fulminant disease
 - Weight loss/fatigue
- GI:
 - Abdominal pain/tenderness—Crohn's disease:
 - Episodic
 - Periumbilical; may localize to right lower quadrant (RLQ) with ileal disease
 - Generalized with more diffuse intestinal involvement
 - Can localize to area of intra-abdominal abscesses or fistulous involvement

- Tenderness and distension suggest obstruction or toxic megacolon
- Abdominal pain/tenderness—UC:
 - More generalized than Crohn's disease
 - Often limited to predefecatory period
 - Tenderness with distension—suspect toxic dilation
- Stool:
 - Crohn's disease:
 - Mild, loose stool, rarely >5/day
 - ~50% bloody
 - UC:
 - Diarrhea is variable, can be severe.
 - Vast majority are bloody, sometimes with severe hemorrhage.
 - Mucus
 - Tenesmus and urgency are common.
- Nausea/vomiting:
 - Crohn's disease:
 - Obstruction common with ileocolonic disease
 - UC:
 - Obstruction rare
 - Diminished bowel sounds with toxic dilation
- Liver:
 - Sclerosing cholangitis can be seen.
 - Cholelithiasis can be seen in 35–60% of Crohn's.
- Renal:
 - Nephrolithiasis
 - Obstructive hydronephrosis
- Musculoskeletal:
 - Peripheral arthritis/artralgias—follows disease activity.
 - Pediatric—may be confused with juvenile rheumatoid arthritis, idiopathic growth failure, anorexia nervosa.

Physical-Exam

- Perianal:
 - Crohn's disease:
 - Perianal abscesses
 - Fissures—characteristically painless
 - Fistulas—seen in up to 50% of patients with colonic disease.
 - May present prior to other manifestations.
 - UC:
 - No perianal involvement
- RLQ pain/mass often mistaken for appendicitis.
- Severe toxicity/abdominal pain—must exclude toxic megacolon.
- Extraintestinal:

- Eye:
 - Uveitis
 - Episcleritis
 - Keratitis
- Oral:
 - Aphthous stomatitis
- Dermatologic:
 - Erythema nodosum
 - Pyoderma gangrenosum

ESSENTIAL WORKUP

- May present as initial onset of disease or exacerbation of existing disease.
- Maintain high index of suspicion because of subtle presentation of Crohn's disease.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Nothing diagnostic
- CBC:
 - Anemia secondary to chronic or acute blood loss
- Electrolytes, BUN/creatinine, glucose
- Stool exam:
 - Occult blood
 - *Clostridium difficile*
 - Fecal leukocytes may be present.
 - O & P and culture to rule out infectious cause of enteritis
- ESR is always elevated.
- Newer, investigational, serologic tests may have use as adjunctive diagnostic aids, screening tests, or predictors in therapy.

Imaging

- Lifetime radiation dose is cumulative and IBD patients have repeated exposure; consider MRI when available.
- Upright chest and abdominal radiographs for:
 - Toxic megacolon (>6 cm dilation)
 - Obstruction
 - Air in wall of colon (may indicate impending perforation)
 - Perforation—subdiaphragmatic air or free air outlining liver or gall bladder
- CT abdomen/MRI:
 - Distinguish abscess from localized inflammatory mass in Crohn's.
- Colonoscopy with biopsy can confirm diagnosis of UC or Crohn's:
 - Can be withheld with severe symptoms owing to perforation risk.
- Contrast imaging of small bowel, especially terminal ileum, may confirm diagnosis

of Crohn's.

- MRI can be useful in Crohn's perianal disease and avoids ionizing radiation.

DIFFERENTIAL DIAGNOSIS

- Infectious enteritis
- Pseudomembranous colitis (*C. difficile*)
- Appendicitis
- Diverticulitis
- Diverticulosis
- Functional bowel disease
- Lymphoma involving bowel
- Ischemic colitis
- Gonococcal or chlamydial proctitis
- HIV
- Colon cancer
- Vasculitis
- Amyloidosis

TREATMENT

PRE HOSPITAL

Vital sign stabilization as per BLS

INITIAL STABILIZATION/THERAPY

- IV 0.9% NS volume replacement if dehydrated
- Transfusion if significant blood loss

ED TREATMENT/PROCEDURES

- Nasogastric (NG) suction if obstruction or toxic dilation suspected
- Broad-spectrum antibiotics for fulminant UC or suspected perforation
- Consider steroid replacement if stress doses are required for those recently on oral steroids.
- Surgical evaluation indications:
 - Free perforation
 - Intestinal obstruction
 - Massive, unresponsive hemorrhage
 - Toxic dilation:
 - Not an absolute indication for surgery
 - Intensive medical management with small bowel decompression and close radiographic monitoring and surgical consultation
- Walled-off perforation with abscess:
 - Usually not an indication for emergent surgery
 - Careful observation for peritonitis

- **Medical therapy:**
 - Treatment is usually not initiated unless diagnosis is already established.
 - Refill or restart medications in patient with known disease.
 - ED-prescribed medical regimen should be individualized, and consultation with gastroenterologist strongly recommended:
 - Aminosalicylate (sulfasalazine/mesalamine) in mild to moderate case.
 - Antidiarrheal agent (diphenoxylate) is used—but withhold if severe disease or suspect toxic megacolon.
 - Steroid (prednisone, budesonide or hydrocortisone enema, ACTH) is used for moderate to severe disease.
 - Antibiotics (metronidazole and/or ciprofloxacin) aid in treatment of Crohn's with colon/perineal involvement.
 - Immunosuppressive agents (azathioprine, methotrexate) are used in severe disease.
 - Monoclonal antibodies neutralize cytokine tumor necrosis factor (TNF)- α and inhibit binding to TNF- α receptors (infliximab [Remicade]). Used as parenteral therapy in disease unresponsive to other modalities. Not an ED drug, but be aware of potential severe adverse reactions, infusion reactions, autoimmune diseases, and infections.

Pediatric Considerations

If nonaccidental trauma is suspected, prompt referral to appropriate child protective agencies is required along with medical treatment.

MEDICATION

- Ciprofloxacin: 500 mg (peds: 10–20 mg/kg q12) PO q12h
- Hydrocortisone enema: 60 mg per rectum
- Mesalamine enemas: 1–4 g retention enema—retain overnight. Adult.
- Mesalamine suppository: 500 mg per rectum BID. Adult.
- Mesalamine tablets:
 - Asacol 800 mg PO TID
 - Pentasa 1,000 mg PO QID
- Methylprednisolone: 125–250 mg IV load (peds: 2 mg/kg IV load, maintenance as adult), then 0.5–1 mg/kg/dose q6h for 5 days
- Metronidazole: 250–500 mg (peds: 30 mg/kg/24h) PO TID
- Prednisone: 40–60 mg (peds: 1–2 mg/kg) PO daily
- Sulfasalazine (Azulfidine): 500 mg (peds: 30 mg/kg) PO QID

FOLLOW-UP

DISPOSITION

Admission Criteria

- Surgical indication:
 - Massive, unresponsive hemorrhage
 - Perforation
 - Toxic dilation
 - Obstruction
- Severe flare-up:
 - Electrolyte imbalance
 - Severe dehydration
 - Severe pain
 - High fever
 - Significant bleeding

Discharge Criteria

- Initial presentation of diarrhea, mild pain, without toxicity, with close follow-up
- Mild to moderate exacerbation of known disease without obstruction, severe bleeding, severe pain, dehydration, with close follow-up, on renewed therapy or with addition of steroid

Issues for Referral

Extraintestinal manifestations

- Ocular
- Dermatologic

FOLLOW-UP RECOMMENDATIONS

Gastroenterologist or primary care as managing physician with surgical consultation as indicated

PEARLS AND PITFALLS

- With severe flare, rule out toxic megacolon.
- Consider Crohn's in children with growth/puberty delay.
- Consider Crohn's with perianal disease.
- Rule out *C. difficile* with flares; the incidence of *C. difficile* complicating IBD is increasing.
- Avoid antidiarrheals/spasmodic in severe UC.

- K52.9 Noninfective gastroenteritis and colitis, unspecified

INFLUENZA

Philip Shayne • Carli Blomquist

BASICS

DESCRIPTION

- Acute, usually self-limited, viral infection
- Transmission: By dispersion in small-particle aerosols created by sneezing, coughing, and talking
- Virus is deposited on respiratory tract epithelium and absorbed.
- Incubation period: 1–4 days (avg. 2)
- Mean duration in adults: 4 days
- Seasonal outbreaks most common in February.
- 2009 novel H1N1 pandemic peaked in fall and early winter of that year. Children and pregnant women had particularly high complication rates.
- Complications:
 - Primary influenza viral pneumonia
 - Secondary bacterial pneumonia
 - Exacerbations of COPD
 - Otitis and sinusitis in children
 - Reactive airway disease
 - Rare complications: Myositis, myocarditis, pericarditis, Guillain–Barré syndrome, and aseptic meningitis
 - ARDS and multisystem organ failure
- Key features:
 - Seasonal epidemics are spread by high attack rates in immunologically naive children.
 - Intermittent unpredictable pandemics
 - Mortality results largely from pulmonary complications.

Pediatric Considerations

- Children exhibit more lower respiratory involvement (croup, bronchitis, bronchiolitis, pneumonitis) and higher temperatures than adults.
- Children were particularly susceptible to complications of novel H1N1 influenza virus.
- Myalgias in the calf muscle
- Febrile convulsions occur in ~ 10% of children < 5 yr of age with influenza infection.
- Reye syndrome:
 - Influenza may be a predisposing factor.
 - Rare and severe complication associated with salicylate use (children taking

- aspirin chronically are recommended to get vaccinated)
- Acute liver and brain injury

ETIOLOGY

- Caused usually by 1 of 2 influenza types, A or B, the latter usually less severe.
- Influenza A subtypes are classified by hemagglutinin antigens H1, H2, or H3 and less importantly by the neuraminidase subtype.
- Vaccine targets the subtype antigen, which is also the target of natural immunity.
- Annual epidemics are seasonal:
 - Caused by *antigenic drift*—new variants from minor changes in surface protein
 - Duration of epidemic < 6 wk
- Pandemics:
 - Unpredictable
 - Caused by *antigenic shift*—major changes in virus structure
- Waterfowl reservoir of influenza virus
- Avian flu has proven difficult to transmit to humans and between humans, but infection is often very severe.
- The 3 most common strains in 2012 (most vaccinations cover) were influenza B viruses, influenza A (H1N1), and influenza A (H3N2)

DIAGNOSIS

- Complicated by similar acute infections caused by other respiratory viruses
- CDC defines influenza-like illness (ILI) as cough or sore throat in a patient with fever > 100°F and no alternative diagnosis.

SIGNS AND SYMPTOMS

- Local status of the epidemic (see CDC weekly status update <http://www.cdc.gov/flu/weekly/>) is by far the most important predictor of influenza in a patient with ILI.
- Despite poor discriminating properties of specific symptoms, a rise in ILI cases accurately predicts onset of the seasonal influenza epidemic.

History

- No single finding on history has much predictive power. Influenza can be asymptomatic or fatal.
- Fever and cough together is somewhat specific for influenza but insensitive.
- Specificity of findings depends on prevalence of other circulating viruses. E.g., RSV epidemics are also accompanied by high frequency of fever.

Physical-Exam

- Fever: Degree of fever is correlated with likelihood of influenza in randomized

trials of persons with ILI.

- There is no consistent relationship between physical findings and influenza positivity across multiple studies, but there are very few studies of ED patients.
- Many patients have evidence of reactive airway disease with bronchoconstriction.

Geriatric Considerations

Elderly may present with high fever, lassitude, and confusion without pulmonary complications.

ESSENTIAL WORKUP

Clinical diagnosis based on the signs and symptoms of influenza during the winter months in the setting of a known outbreak

DIAGNOSIS TESTS & NTERPRETATION

Lab

- CBC (optional):
 - _ WBC: Normal to mildly decreased
- Pulse oximetry/arterial blood gas for significant pulmonary symptoms

Imaging

CXR for prominent lower respiratory signs or symptoms:

- Normal (50–90%)
- Bilateral interstitial infiltration

Diagnostic Procedures/Surgery

- Culture of nasopharyngeal swab or aspirate is more sensitive than pharynx.
- Yield declines rapidly with duration of symptoms. Infrequently positive after day 2.
- Rapid influenza diagnostic tests and direct fluorescent antibody tests are inexpensive, rapid, and specific but often of very low sensitivity. Some are able to discriminate between A and B, but not subtypes of A.
- Polymerase chain reaction (PCR) tests have short turnaround time, are both sensitive and specific, and can discriminate H1 from H2 antigens; a combination of H1 negative and H2 negative is very specific for 2009 H1N1.
- Viral culture: Turnaround time too long for ED use, although OK for local surveillance.

DIFFERENTIAL DIAGNOSIS

- Other respiratory viruses
- Bronchitis
- Atypical pneumonia
- Epstein–Barr infection (infectious mononucleosis)

- Anthrax is very rare and much more likely to include dyspnea and nausea.

TREATMENT

PRE HOSPITAL

Vaccination and respiratory hygiene for EMS personnel during outbreaks

INITIAL STABILIZATION/THERAPY

Aggressive fluid resuscitation, supplemental oxygen, and positive-pressure ventilation as clinical circumstances dictate

ED TREATMENT/PROCEDURES

- Supportive and symptomatic:
 - Antipyretics (acetaminophen or NSAIDs)—avoid aspirin
 - Cough suppressants (rarely useful)
 - Rehydration
- Antivirals are effective if given within 48 hr of symptom onset:
 - Antiviral resistance patterns vary each season; confirm at CDC update page.
 - The neuraminidase inhibitors (NI) zanamivir and oseltamivir are generally active against types A and B.
 - The adamantanes amantadine and rimantadine are only effective against influenza A, but not current strains (currently not recommended for use due to resistance).
 - Antivirals reduce symptom duration by less than 1 day. Indirect evidence of benefit in severe disease.
 - Costly, except for amantadine
 - Recommended for:
 - Patient with severe illness
 - Immunocompromised patients
 - Patients at high risk for complications
- PREVENTION:
 - Inactivated, polyvalent influenza vaccine recommended annually for:
 - Adults > 50 yr
 - Residents of nursing homes and long-term care facilities
 - Children of age 6–4 yr
 - Children of age 6 mo–18 yr on chronic aspirin therapy
 - High-risk individuals (asthma, COPD, cardiovascular disease, immunocompromised, diabetics)
 - Health care workers
 - Morbidly obese (BMI > 40)
 - American Indians/Alaska natives
 - Caretakers of children < 6 mo old

- Women who will be pregnant during influenza season
- Attenuated-live intranasal vaccine (FluMist) is currently approved for healthy people of age 2–49 yr.
- Contraindicated for:
 - Pregnant women
 - Close contacts and health care workers for severely immunocompromised patients
 - Children < 5 yr with h/o recurrent wheezing
 - Children/adolescents receiving aspirin
 - Severe allergy to chicken eggs
 - People with comorbidities placing them in high risk for influenza complications
- Chemoprophylaxis in the following settings:
 - Postexposure prophylaxis for exposed family members, especially high risk
 - Short-term prophylaxis during outbreak of influenza A in high-risk patients who did not receive vaccine
 - In conjunction with vaccine in high-risk patients (including those with HIV infections) expected to respond poorly to vaccine
 - In lieu of vaccine when vaccine is contraindicated in high-risk individuals
 - In individuals providing care for high-risk persons
 - Extended duration, season-long prophylaxis of health care workers is effective but consumes large quantity of stockpiled drug.
 - Exceptions:
 - *Could interfere with live-virus vaccine*
 - Should not be started for at least 2 wk after inoculation
- Patients with evidence of bronchoconstriction and reduced breath sounds may benefit from bronchodilators such as albuterol.

Pregnancy Considerations

- Inactivated vaccine is recommended for women expected to be pregnant during influenza season.
- Live-attenuated virus is contraindicated in pregnancy.

MEDICATION

- Oseltamivir: 75 mg PO BID for 3–4 days:
 - Postexposure prophylaxis: 75 mg PO daily for 7–10 days
- Zanamivir: 10 mg nasal insufflation (2 inhalations) q12h for 3–5 days
- Amantadine: 200 mg PO initially, then 100 mg PO BID for 3–5 days (halve dose if age > 65 yr)
- Rimantadine: 200 mg PO initially, then 100 mg PO BID for 3–5 days
- Albuterol 2.5 mg in 3 mL by nebulizer or metered-dose inhaler with spacer

DISPOSITION***Admission Criteria***

- Hypoxia (pneumonia or reactive airway disease)
- Severe dehydration
- Alteration in mental status

Discharge Criteria

Most patients will have a short, self-limited course provided they are able to tolerate fluids and antipyretics.

Issues for Referral

Consultation with infectious disease specialist when uncertain of local disease status, diagnostic uncertainty, local antiviral resistance patterns

FOLLOW-UP RECOMMENDATIONS

Call back for PCR test result.

PEARLS AND PITFALLS

- Become familiar with online CDC weekly update since flu changes each season.
- In most patients, neither testing nor antiviral treatment is necessary.
- In patients with respiratory distress or hypoxia, consider concurrent reactive airway disease.
- ED policy: Institute respiratory hygiene:
 - Etiquette posters and alcohol hand soap available

INTRACEREBRAL HEMORRHAGE

Atul Gupta • Rebecca Smith-Coggins

BASICS

DESCRIPTION

Hemorrhage into brain parenchyma:

- Compression of brain tissues
- Secondary injury results from:
 - Cerebral edema
 - Increased intracranial pressure (ICP)
 - Potential of brain herniation

ETIOLOGY

Intracerebral hemorrhage can occur spontaneously or from trauma:

- Uncontrolled or acute HTN (most common)
- Vascular malformations:
 - Arteriovenous malformation
 - Venous angiomas
 - Ruptured cerebral aneurysms
- Neoplasm (particularly melanoma and glioma)
- Anticoagulant therapy (warfarin, heparin)
- Thrombolytic agents
- Illicit drugs (cocaine, amphetamines)
- Bleeding disorders (hemophilia)
- Cerebral amyloid angiopathy
- Traumatic hemorrhage secondary to blunt or penetrating injury

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Severe headache, typically sudden in onset
- Seizure
- Evidence of head injury
- Neck stiffness
- Vomiting
- Anticoagulation therapy
- Altered level of consciousness (may be comatose):
 - Altered mental status may occur as late as 24–48 hr after head injury

Physical-Exam

- HTN
- Nuchal rigidity
- Altered mental status
- Variable neurologic deficits depending on site of intracerebral hemorrhage:
 - Putamen hemorrhage (35%):
 - Contralateral hemiparesis
 - Contralateral hemisensory loss
 - Occasional dysphagia
 - Occasional neglect
 - Lobar hemorrhage (30%):
 - Variable signs depending on involved area
 - Cerebellar hemorrhage (15%):
 - Vomiting
 - Ataxia
 - Nystagmus
 - Thalamic hemorrhage (10%):
 - Similar to putamen, but may also have eye movement abnormalities
 - Caudate hemorrhage (5%):
 - Confusion
 - Memory loss
 - Hemiparesis
 - Gaze paresis
 - Pontine hemorrhage (5%):
 - Quadriplegia
 - Pinpoint pupils
 - Ataxia
 - Sensorimotor loss

ESSENTIAL WORKUP

- Manage airway if indicated
- Immediate noncontrast head CT:
 - Acute hemorrhage appears as high-density lesion

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Coagulation studies (PT/PTT, INR, platelets)
- Electrolytes; BUN, creatinine
- Pregnancy test in women of childbearing age
- EKG
- Consider toxicology screen

Imaging

- CT as above
- MRI may be useful but currently not as available or rapid as CT

Diagnostic Procedures/Surgery

- CT angiography:
 - Gaining increasing acceptance as a diagnostic tool in acute setting
 - Up to 15% of patients may show an underlying vascular etiology on CTA, potentially changing acute management
 - Contrast extravasation (spot sign) may represent ongoing bleeding
 - Highest risk of hematoma expansion with poor outcome and mortality

DIFFERENTIAL DIAGNOSIS

- Seizure:
 - Todd paralysis
- CNS infection
- CNS mass
- Electrolyte or acid–base abnormality
- Intoxication
- Wernicke encephalopathy
- Migraine headache
- Transient ischemic attack
- Nonhemorrhagic acute cerebrovascular accident
- Air embolism
- Differential diagnosis once bleed is seen on CT:
 - Spontaneous hemorrhage:
 - Hypertensive hemorrhage
 - Arteriovenous malformation
 - Neoplasm
 - Traumatic hemorrhage:
 - Subarachnoid hemorrhage
 - Subdural hematoma
 - Epidural hematoma

Pediatric Considerations

Additional differential diagnoses include:

- Moyamoya disease
- Acute infantile hemiplegia

TREATMENT

PRE HOSPITAL

- C-spine precautions if head or neck injury is suspected
- Elevation of head with C-spine control
- Initial pre-hospital responder must ascertain neurologic defect to be able to note progression of symptoms

INITIAL STABILIZATION/THERAPY

- Manage airway and resuscitate as needed:
 - _ Patients with depressed level of consciousness should be intubated immediately for controlled ventilation
- Early neurosurgical consultation

ED TREATMENT/PROCEDURES

- Prompt neurosurgery and/or neurology consultation
- BP management:
 - _ Must use caution in BP control because acute lowering of BP to normal in setting of increased ICP could reduce cerebral perfusion to ischemic levels
 - _ Use labetalol, nicardipine, esmolol, enalapril to lower diastolic BP initially by 10%
 - _ Normotensive levels should be achieved over 12–24 hr
 - _ May use nitroprusside, nitroglycerin, or hydralazine as an alternative
- Treatment of elevated ICP:
 - _ Controlled ventilation to PaCO₂ of 35 Torr
 - _ Fluid restriction; elevate head of bed 30°
 - _ Mannitol—osmotic diuresis
 - _ Use furosemide as an alternative
- Correct coagulopathies:
 - _ Consider fresh frozen plasma (FFP), platelets, prothrombin complex concentrates, vitamin K
- Consider anticonvulsants
 - _ Phenytoin, fosphenytoin

MEDICATION

- Esmolol: 0.5–1 mg/kg initial bolus IV, followed by 50–150 µg/kg/min infusion
- Enalapril: 1.25–5 mg q6h (risk of precipitous BP lowering, test dose 0.625 mg)
- FFP: 10–20 mL/kg IV
- Fosphenytoin: 15–20 mg/kg phenytoin equivalents (PE) at rate of 100–150 mg/min IV/IM
- Furosemide: 20–40 mg (peds: 0.5–1 mg/kg/dose) IV; may repeat as necessary
- Hydralazine: 10–40 mg (peds: 0.1–0.2 mg/kg/dose; max. 20 mg/dose) IV; may repeat as necessary
- Labetalol: 20 mg (peds: 0.3–1 mg/kg/dose; max. 20 mg/dose) IV; may give additional 40–80 mg IV q10min to max. 300 mg
- Mannitol: 1 g/kg IV

- Nicardipine: 5–15 mg/h infusion
- Nitroprusside: Start 0.25–10 µg/kg/min IV (max. 10 µg/kg/min); titrate to effect
- Phenytoin: 15–20 mg/kg/dose (peds: 15 mg/kg) at rate of < 40–50 mg/min
- Platelet: 1–2 U IV in consultation with neurosurgery
- Prothrombin complex concentrates: 500–1,000 IU IV
- Vitamin K: 5–10mg IV over 30 min

FOLLOW-UP

DISPOSITION

Admission Criteria

- To OR if surgical intervention is indicated
- To ICU if intubated, altered level of consciousness, or on IV infusion for BP control
- Admit to neurologic observation unit if normal neurologic exam without evidence of progression of bleed and hemodynamically stable

Discharge Criteria

All patients with intracerebral hemorrhage should be admitted

Issues for Referral

Rehabilitation is a key aspect of recovery

FOLLOW-UP RECOMMENDATIONS

- Treating HTN in the nonacute setting is the most important step to reduce the risk of intracerebral hemorrhage
- Discontinuation of smoking, alcohol use, and cocaine use prevents recurrence of intracerebral hemorrhage

PEARLS AND PITFALLS

- Brain imaging is a crucial part of emergent evaluation of patients with headache, HTN, and/or altered level of consciousness
- Cautious BP control because acute lowering of BP to normal in setting of ICP could reduce cerebral perfusion to ischemic levels
- Consider delayed intracranial bleed in patients on anticoagulation with head trauma

INTUSSUSCEPTION

Roger M. Barkin

BASICS

DESCRIPTION

- The proximal bowel invaginates into the distal bowel, producing infarction and gangrene of the inner bowel:
 - >80% involve the ileocecal region.
- Often occurs with a pathologic lead point in children >2 yr:
 - Hypertrophied lymphoid patches may be present in infants.
 - Children >2 yr: 1/3 of patients have pathologic lead point.
 - Children >6 yr: Lymphoma is the most common lead point.
 - Adults usually have a pathologic lead point.
- The most common cause of intestinal obstruction within the 1st 2 yr of life
- Epidemiology in US:
 - Most frequently between 5 and 9 mo of age
 - Incidence is 2.4 cases per 1,000 live births.
 - Male > female predominance of 2:1
 - Mortality <1%
- Morbidity increases with delayed diagnosis.

ALERT

Patients, particularly those in the pediatric age group, with a picture of potential intestinal obstruction, especially with hematest-positive stool or altered mental status, need to have intussusception considered.

ETIOLOGY

- Most cases (85%) have no apparent underlying pathology.
- Predisposing conditions that create a lead point for invagination, esp. in older children and adults:
 - Masses/tumors:
 - Lymphoma
 - Lipoma
 - Polyp
 - Hypertrophied lymphoid patches
 - Meckel diverticulum
 - Infection:
 - Adenovirus or rotavirus infection
 - Parasites
 - Foreign body
 - Henoch–Schönlein purpura

- Celiac disease and cystic fibrosis (small intestine intussusception)

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Classic triad (present in < 50% of patients):
 - Abdominal pain
 - Vomiting, often bilious
 - Stools have blood and mucus (“currant jelly” stools)
- Recurrent painful episodes accompanied by pallor and drawing up of the legs; intermittent fits of sudden intense pain with screaming and flexion of legs:
 - Occur in 5–20 min intervals
- Mental status changes:
 - Irritability
 - Lethargy or listlessness; child can be limp or have a rag doll appearance.
 - May precede abdominal findings.
- Stool variable:
 - Heme-positive (occult), bloody, or “currant jelly”
- Preceding illness several days or weeks prior to the onset of abdominal pain:
 - Diarrhea
 - Viral syndrome
 - Henoch–Schönlein purpura
- Recurrent intussusception occurs in < 10% of patients.

Physical-Exam

- Fever
- Abdomen distended and swollen:
 - A “sausage” mass may be palpated in the right upper quadrant.
 - May have absent cecum in right iliac fossa.
 - Peristaltic wave may be present.
 - Rectal exam may reveal bloody stool and palpable mass.
- Dependent on the time from onset to diagnosis; perforation with peritonitis and sepsis may be present.

ESSENTIAL WORKUP

- The diagnosis is suggested by the history and is proven radiographically.
- A heme-positive stool may aid in the diagnosis, particularly in the presence of lethargy or listlessness.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Serum electrolytes, BUN
- Type and cross-match

Imaging

- Abdominal radiograph:
 - Abnormal in 35–40% of patients
 - Decreased bowel gas and fecal material in the right colon
 - Abdominal mass
 - Apex of intussusceptum outlined by gas
 - Small bowel distention and air–fluid levels secondary to mechanical obstruction
 - May aid in excluding intestinal perforation.
- Enema:
 - Often both diagnostic and therapeutic. Reoccurrences do happen.
 - 74% successful if intussusception present ≤ 24 hr
 - 32% effective when present > 24 hr
 - The more distal the intussusception, the lower is the ability to reduce it radiographically.
 - Recurrent disease (up to 10%) has similar success to initial episode.
 - Complications include bowel perforation, reduction of necrotic bowel, incomplete reduction with delay in surgery, and overlooking pathologic lead point.
 - Hypovolemic shock reported following reduction secondary to endotoxins and cytokines.
 - Barium:
 - Traditional standard for diagnosis and treatment
 - Characteristic coiled-spring appearance
 - Air:
 - Fluoroscopic guidance
 - Avoids peritoneal contamination if perforation
 - Increasingly used for diagnosis and treatment
 - Contraindications:
 - Peritonitis
 - Perforation
 - Unstable patients secondary to sepsis or shock
- US is highly accurate and may be useful as a screening technique; operator dependent:
 - Typical appearance is a “donut” or “bull’s eye” structure, with hyperechoic core surrounded by hypoechoic rim of homogeneous thickness.

Diagnostic Procedures/Surgery

If enema is unsuccessful in reducing, surgery is required on an emergent basis.

DIFFERENTIAL DIAGNOSIS

- Infection
- Acute gastroenteritis
- Appendicitis
- Inflammatory bowel disease
- Infectious mononucleosis
- Pneumonia
- Pharyngitis/group A streptococcal
- Pyelonephritis
- Colic
- Intestinal obstruction/peritonitis
- Strangulated hernia
- Malrotation/volvulus
- Hirschsprung disease
- Trauma
- Intestinal vascular/hemorrhagic disorder
- Anal fissure/hemorrhoids
- Ulcer disease
- Vascular malformations
- Henoch–Schönlein purpura
- Polyp
- Protein-sensitive enterocolitis
- Diabetes mellitus
- Coagulopathy

TREATMENT

PRE HOSPITAL

- IV access
- IV bolus of 20 mL/kg of 0.9% NS or lactated Ringer (LR) if evidence of hypovolemia, abdominal distention, peritonitis, sepsis
- Diagnosis rarely confirmed in pre-hospital setting

INITIAL STABILIZATION/THERAPY

- IV access and initiation of 0.9% NS or LR at 20 mL/kg bolus
- Nasogastric tube

ED TREATMENT/PROCEDURES

- Stabilize patient hemodynamically.
- Surgical consultation

- Abdominal radiograph film series
- Interventional radiography for reduction if no contraindications:
 - Enemas are 75–80% successful at reduction, reflecting duration of condition.
 - Recurrences may also be reduced radiographically.
- Antibiotics:
 - Initiate if evidence of peritonitis, perforation, or sepsis.
 - Ampicillin, clindamycin, and gentamicin
 - Ampicillin/sulbactam
- Laparotomy:
 - Indications:
 - Enema is unsuccessful.
 - Enema is contraindicated.
 - Pathologic lead point
 - Multiple recurrences
 - Procedure:
 - Gentle milking of the intussusceptum
 - Resection of any nonviable bowel as well as any lead points that are identified

MEDICATION

First Line

- Ampicillin: 100–200 mg/kg/d q4h IV
- Clindamycin: 30–40 mg/kg/d q6h IV
- Gentamicin: 5–7.5 mg/kg/d q8h IV
- Ampicillin/sulbactam 100–200 mg/kg/d q6h IV

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients undergoing successful enema reduction should be observed for complications or recurrence.
- Patients undergoing surgery

Discharge Criteria

- May be considered after a *very prolonged* period of observation following successful enema reduction:
 - Stable patient with normal mental status
 - Symptomatic relief of abdominal pain during the postreduction period
 - Parents have appropriate understanding to watch for potential

reoccurrence, even after prolonged period observation

Issues for Referral

Surgeon should be aware of patients with potential diagnosis of intussusception.

PEARLS AND PITFALLS

Infants with intermittent abdominal pain, impaired mental status, and blood in stools should generally have intussusception considered.

ICD10

K56.1 Intussusception

IRITIS

Jessica Freedman

BASICS

DESCRIPTION

- Inflammation of anterior uveal tract
- Iritis and anterior uveitis are synonymous.
- Uveitis secondary to trauma is also called traumatic iritis.

ETIOLOGY

- Most cases are idiopathic, but may be traumatic or associated with numerous infectious and noninfectious systemic diseases.
- May be acute or chronic.
- Noninfectious systemic diseases include the following:
 - _ Ankylosing spondylitis
 - _ Reiter syndrome
 - _ Sarcoidosis
 - _ Behçet disease
 - _ Inflammatory bowel disease
 - _ Juvenile rheumatoid arthritis
 - _ Kawasaki syndrome
 - _ Interstitial nephritis
 - _ IgA nephropathy
 - _ Drug reactions
 - _ Sjögren syndrome
 - _ Psoriatic arthritis
- Infectious conditions include the following:
 - _ Viral:
 - Rubella
 - Measles
 - Adenovirus
 - Herpes simplex virus
 - Herpes zoster virus
 - HIV
 - Mumps
 - Varicella
 - Cytomegalovirus
 - West Nile virus
 - _ Bacterial:
 - Tuberculosis

- Syphilis
- Pertussis
- Brucellosis
- Lyme disease
- Chlamydia
- Rickettsia
- Gonorrhea
- Leprosy
- Fungal:
- Malignancies include the following:
 - Leukemia
 - Lymphoma
 - Multiple sclerosis
 - Malignant melanoma
- Other causes include the following:
 - Cocaine use
 - Exposure to pesticides
 - Corneal foreign body
 - Blunt trauma

DIAGNOSIS

SIGNS AND SYMPTOMS

- Acute presentation:
 - Ocular pain, red eye
 - Photophobia (consensual)
 - Lacrimation
 - Decreased visual acuity (usually mild)
 - Cells and flare in anterior chamber; hypopyon
 - Posterior synechiae (adhesions of iris to lens)
 - Miosis
 - Low intraocular pressure (occasionally may be high)
 - Injection of perilimbal vessels (ciliary flush)
- Chronic presentation:
 - Recurrent episodes
 - Few or no acute symptoms

ESSENTIAL WORKUP

- History and review of systems:
 - Up to 50% may be associated with systemic disease.
- Slit-lamp exam:
 - Inflammatory cells (leukocytes) or “flare” in the anterior chamber are diagnostic.

- Flare is a homogeneous fog secondary to protein leakage into aqueous humor.
- Use short, wide beam to best appreciate cells and flare.
- Cellular deposits with more severe inflammation
- Intraocular pressure measurement
- If topical anesthesia relieves pain, probably not iritis.

DIAGNOSIS TESTS & NTERPRETATION

- None usually indicated
- Tailored outpatient workup if history, signs, and symptoms point strongly to a certain cause (with referral to ophthalmology, rheumatology, or internal medicine)

Lab

- TB:
 - Purified protein derivative (PPD)
- Sarcoidosis:
 - PPD
- Ankylosing spondylitis:
 - ESR
 - HLA-B27
- Inflammatory bowel disease:
 - HLA-B27
- Reiter syndrome:
 - HLA-B27
 - Cultures of conjunctiva and urethra
- Psoriatic arthritis:
 - HLA-B27
- Lyme disease:
 - Immunoassays
- Juvenile rheumatoid arthritis:
 - Antinuclear antibody
 - Rheumatoid factor
- Sarcoidosis:
 - ACE
 - Serum lysozyme level
- STI:
 - Rapid plasma reagin or VDRL test
 - Fluorescent treponemal antibody absorption test
 - Appropriate cultures

Imaging

- Ankylosing spondylitis:
 - Sacroiliac spine radiograph

- Sarcoidosis:
 - CXR
- TB:
 - CXR

Diagnostic Procedures/Surgery

US biomicroscopy can be used to help to diagnose pathologies.

DIFFERENTIAL DIAGNOSIS

- Acute angle-closure glaucoma
- Conjunctivitis
- Corneal abrasion
- Corneal foreign body
- Episcleritis
- Intraocular foreign body
- Keratitis
- Posterior segment tumor

TREATMENT

INITIAL STABILIZATION/THERAPY

- Goal:
 - Reduce inflammation and prevent complications
- Cycloplegic agent (short-acting):
 - Decreases pain, photophobia
 - Prevents development of posterior synechiae

ED TREATMENT/PROCEDURES

- Cycloplegia
- Topical steroids if indicated:
 - Use with caution, in consultation with ophthalmologist.
 - May cause significant complications (i.e., progression of herpes simplex virus keratitis)
- Treat secondary glaucoma.
- Supportive measures:
 - Warm compresses
 - Dark glasses
 - Analgesia
- Identification of cause:
 - Initiate appropriate management.
- Ankylosing spondylitis:
 - Systemic anti-inflammatory agents

- Physical therapy
- Inflammatory bowel disease:
 - Systemic steroids
 - Sulfadiazine
 - Vitamin A
- Reiter syndrome:
 - Treat urethritis (and sexual contacts).
- Behçet disease:
 - Systemic steroids or immunosuppressive agents
- Infectious causes:
 - Appropriate management of underlying infection

MEDICATION

- Cycloplegic:
 - Cyclopentolate 1–2% for mild to moderate inflammation: 1 drop TID (lasts up to 24 hr)
 - Homatropine 2% or 5% for moderate inflammation: 1 drop TID (lasts up to 3 days)
 - Atropine 1% for moderate to severe inflammation (should only be used in consultation with ophthalmologist): 1 drop TID (lasts 7–14 days)
- Topical steroid (should only be used in consultation with ophthalmologist):
 - Prednisolone acetate 1%: 1 drop q1–6h, depending on severity
- Analgesic:
 - Tylenol or tylenol with codeine

Pediatric Considerations

- Cycloplegics not recommended in children <6 yr:
 - May cause systemic anticholinergic toxicity with blurred vision, flushing, tachycardia, hypotension, and hallucinations.

FOLLOW-UP

DISPOSITION

Admission Criteria

Not indicated unless significant systemic illness

Issues for Referral

- Iritis:
 - Refer to ophthalmologist within 24 hr for follow-up care and possible steroid therapy.
- Inflammatory bowel disease:

- Gastroenterology consult
- Reiter syndrome:
 - Rheumatology consult
- Psoriatic arthritis:
 - Rheumatology consult
- Juvenile rheumatoid arthritis:
 - Rheumatology consult

PEARLS AND PITFALLS

- If topical anesthesia relieves pain, probably not iritis.
- Must be differentiated from other, vision-endangering forms of eye pain:
 - Keratitis
 - Herpes simplex conjunctivitis
 - Bacterial conjunctivitis
 - Acute angle-closure glaucoma
 - Traumatic globe rupture

IRON POISONING

Sean M. Bryant

BASICS

DESCRIPTION

- Peak concentrations are 2–4 hr postingestion
- Serum concentrations not reliable if obtained > 4–6 hr after ingestion:
 - Enteric coated or sustained release—warrants serial levels
- Postabsorption: Iron redistributes into tissues, and fall in serum iron occurs as free iron shifts intracellularly resulting in cellular injury
- Injury patterns:
 - Corrosive injury to intestinal mucosa may result in profound fluid loss (shock), hemorrhage, and perforation
 - Liver receives largest load of iron because of portal venous circulation—(hemorrhagic periportal necrosis)
- Free iron:
 - Concentrates in mitochondria, disrupting oxidative phosphorylation; catalyzes lipid peroxidation and free radical formation, resulting in cell death; increases anaerobic metabolism and acidosis
 - Causes myocardial depression, venodilation, and cerebral edema
- Hydration of ferric form liberates 3 protons, resulting in acidemia

ETIOLOGY

Elemental iron ingestion:

- Nontoxic < 20 mg/kg
- Moderate to severe > 40 mg/kg
- Lethality possible > 60 mg/kg
- Elemental iron equivalents:
 - Ferrous sulfate, 20% (325 mg = 65 mg Fe)
 - Ferrous gluconate, 12%
 - Ferrous fumarate, 33%
- Prenatal vitamins vary from 60–90 mg elemental iron per tablet
- Children's vitamins may contain 5–18 mg elemental iron per tablet

Pediatric Considerations

- Historically notorious for the highest mortality rate among pediatric accidental exposures (adult iron products)
- Children's chewable iron products have been shown to be safe

DIAGNOSIS

SIGNS AND SYMPTOMS

- Classically divided into 5 stages:
 - **Stage 1: GI** (0.5–6 hr):
 - Abdominal pain
 - Vomiting
 - Diarrhea
 - Hematemesis
 - Hematochezia
 - **Stage 2: Latent/quiescent** (6–24 hr):
 - Resolution of GI symptoms
 - Deceptive phase (ongoing injury?)
 - Possible hypotension and acidosis
 - **Stage 3: Shock and organ failure** (6–72 hr):
 - Hypoperfusion
 - Metabolic acidosis
 - Coma
 - Coagulopathy
 - **Stage 4: Hepatic failure** (2–3 days):
 - Coagulopathy
 - Hypoglycemia
 - Jaundice
 - Elevated LFTs (transaminases) and bilirubin
 - **Stage 5: Obstruction** (2–4 wk):
 - Gastric outlet and small bowel obstruction
 - Abdominal pain, vomiting
- Patient may present in or skip any of the 5 stages
- If onset of stage 1 does not occur within 6 hr, likely not significant ingestion

ESSENTIAL WORKUP

Acute iron poisoning is a clinical diagnosis, regardless of lab results

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Serum iron levels (mg/dL):
 - Peak absorption 2–6 hr
 - 4 hr is most common time for peak
 - Delayed peak with enteric coated/sustained release
- Electrolytes, BUN/creatinine, glucose:
 - Anion gap metabolic acidosis
 - Hyperglycemia early
 - Hypoglycemia late
- Arterial blood gas:

- Metabolic acidosis
- CBC:
 - Anemia with significant hemorrhage
 - Leukocytosis
- Liver function
- Coagulation profile
- Lactate
- Type and screen if hemorrhage
- Total iron-binding capacity is not useful and not recommended

Imaging

Abdominal radiograph check for:

- Tablets (children's chewables rarely visible)
- Absence of pill fragment interpretation:
 - Patient did not ingest iron
 - Iron was in solution or has already dissolved
 - Patient ingested pediatric multivitamin product
 - Absence of radiopacities does not rule out significant or lethal ingestion
- Perforation

DIFFERENTIAL DIAGNOSIS

- Sepsis
- Acetaminophen toxicity
- Toxic ingestions causing anion gap acidosis:
 - Salicylate
 - Cyanide
 - Methanol
 - Ethylene glycol
- Mushrooms
- Heavy metals
- Theophylline toxicity
- GI bleed from other causes (alcoholic liver disease)

TREATMENT

PRE HOSPITAL

Collect prescription bottles/medications for identification in the ED

INITIAL STABILIZATION/THERAPY

- ABCs:
 - Intubate if profoundly unstable
 - Venous access and fluids for hypotension

- Cardiac monitor and pulse oximetry
- Naloxone, thiamine, dextrose (or Accu-Chek) as indicated for altered mental status

ED TREATMENT/PROCEDURES

- Decontamination:
 - Poorly adsorbed by activated charcoal
 - Gastric lavage has not been shown to change outcome
 - NaHCO₃, phospho soda, and oral deferoxamine are not recommended
 - If pill fragments are visualized on x-ray, or history of significant ingestion:
 - Consider whole bowel irrigation (with NG GoLytely: Peds: 10–15 mL/kg/h; adult: 1–2 L/h) while monitoring progression with radiograph (KUB).
 - Caution with GI bleed
 - Endoscopy or gastrotomy can remove bezoar formation after massive ingestions (> 240 mg/kg)
- Chelation with deferoxamine (DFO):
 - DFO is a highly specific chelator of parenteral iron
 - IV infusion results in more constant DFO levels and is route of choice:
 - Administer as soon as possible (< 24 hr)
 - Administration techniques:
 - Increase IV infusion rate to 15 mg/kg/h over 20 min, monitoring for hypotension
 - Decrease infusion rate if hypotension
 - Infusion rates as high as 45 mg/kg/h have been tolerated
 - Disregard manufacturer's recommendation of max. daily doses of 6 g in serious iron exposures
 - IM DFO challenge test is not advocated
 - Interpret serum levels cautiously:
 - Time since ingestion must be considered: Treatment may be indicated in patient who presents late, after distribution stage (> 8 hr postingestion), with serum iron level < 350 mg/dL
 - If serum iron levels are not readily available, base treatment decisions on clinical status
 - Length of infusion (controversial):
 - DFO–iron complex causes urine to turn *vin rose* color; this suggests continuing infusion until urine returns to normal
 - Resolution of signs and symptoms of significant toxicity is criterion for discontinuing DFO
 - Prolonged DFO therapy > 24–48 hr may precipitate adult respiratory distress syndrome
 - In severe cases with continued signs and symptoms, infusion may be continued cautiously at lower dose
 - Controversies:

- Safety of DFO infusions given for > 24 hr
- Maximal infusion rates and total amount
- Serum iron concentration warranting treatment
- Endpoint of treatment (best endpoint is resolution of poisoning, i.e., acidemia)
- Role of extracorporeal elimination
- Contact regional poison center for moderate to severe iron exposures
 - (1-800-222-1222)

MEDICATION

- Dextrose: D₅₀W 1 amp (50 mL or 25 g; peds: D₂₅W 2–4 mL/kg) IV
- Naloxone (Narcan): 2 mg (peds: 0.1 mg/kg) IV or IM initial dose
- Thiamine (vitamin B₁): 100 mg (peds: 50 mg) IV or IM

FOLLOW-UP

DISPOSITION

Admission Criteria

- GI symptoms or dehydration
- Altered mental status
- Hypotension, lethargy, metabolic acidosis, or shock
- Serum iron > 500 mg/dL
- Serum iron > 350 mg/dL *and* pills seen on KUB
- Rising serum iron levels
- Patients treated with deferoxamine
- ICU admission for coma, shock, metabolic acidosis, or iron levels > 1,000 mg/dL

Discharge Criteria

- Asymptomatic with negative radiograph
- Minimal to no symptoms after 6-hr observation
- Mild GI symptoms that have resolved without evidence of metabolic acidosis and serum iron < 350 mg/dL

Issues for Referral

Contact regional poison center for mild to moderate toxicity

FOLLOW-UP RECOMMENDATIONS

- Follow-up after discharge may be indicated in patients who are at risk of developing gastric outlet obstruction
- Psychiatric referral for patients with intentional overdose

PEARLS AND PITFALLS

- DFO may be indicated in patients who present late, after distribution stage (> 8 hr postingestion), or with serum iron level < 350 mg/dL and signs of intracellular poisoning (e.g., anion gap metabolic acidosis)
- Resolution of GI symptoms does not indicate that there is no ongoing toxicity that may progress over time

IRRITABLE BOWEL SYNDROME

Scott A. Miller

BASICS

DESCRIPTION

- Syndrome of abdominal pain or discomfort associated with altered bowel habits and no other pathology explaining symptoms
- Prevalence estimated to be 10–20%

ETIOLOGY

- Uncertain pathophysiology, but many possibilities
- Altered GI motility:
 - _ Increased gut sensitivity (visceral hyperalgesia):
 - Exaggerated response to normal GI physiology
- Mucosal inflammation:
 - _ Postinfectious:
 - After bacterial enteritis, 10% have persistent IBS symptoms
- Mucosal lymphocyte infiltration
- Altered microflora in small bowel or feces
- Food sensitivity is a possibility but not proven
- Psychosocial dysfunction:
 - _ More anxiety, somatoform disorders, and history of abuse in patients who seek care
 - _ No evidence of increased psychiatric illness in those who do not seek care

DIAGNOSIS

SIGNS AND SYMPTOMS

- Abdominal pain or discomfort:
 - _ Relief with defecation
- Altered stool frequency
- Altered stool consistency
- Bloating or distention
- Passage of mucus
- Feeling of incomplete emptying

ALERT

- Consider further diagnostic workup if any of the following “alarm” features are present:
 - _ Onset > 50

- Nocturnal symptoms
- Unintentional weight loss
- Iron-deficiency anemia
- Hematochezia
- Family history of colorectal cancer, inflammatory bowel disease, or celiac sprue

History

- Rome III diagnostic criteria: Recurrent abdominal pain or discomfort 3 days/mo in the last 3 mo associated with ≥ 2 of:
 - Improvement with defecation
 - Onset associated with a change in frequency of stool
 - Onset associated with a change in form (appearance) of stool
- Other symptoms consistent with IBS:
 - Abdominal distention or bloating
 - Passage of mucus in stools
 - Altered stool passage (straining, urgency, or feeling of incomplete evacuation)
 - Postprandial upper abdominal discomfort
 - Symptoms of gastroesophageal reflux
 - Flatulence
- Female < male, 1.5–2:1 overall, higher in those who seek care

Physical-Exam

- Usually well appearing with normal physical
- May have tender sigmoid or palpable sigmoid cord

ESSENTIAL WORKUP

Clinical diagnosis: Careful history crucial

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Typically no abnormalities found
- Labs to be considered (to exclude other pathology), but not required:
 - CBC:
 - Should not have leukocytosis or anemia
 - Normal ESR and CRP useful in excluding inflammatory conditions
 - Serum chemistry, thyroid studies unlikely to be useful
 - Stool for ova and parasites:
 - Most useful for diarrhea workup
 - Consider outpatient serum test for celiac

Imaging

Only necessary if excluding emergent pathology

Diagnostic Procedures/Surgery

Colonoscopy/flexible sigmoidoscopy for select patients (outpatient)

DIFFERENTIAL DIAGNOSIS

- Celiac disease
- Inflammatory bowel disease:
 - Ulcerative colitis/proctitis
 - Crohn's disease
- Infectious enteritis
- Small-intestinal bacterial overgrowth
- Lactose intolerance
- Colorectal cancer
- Diverticular disease
- Biliary disease
- Diabetic gastroparesis
- Pancreatitis
- Thyroid malfunction
- Obstruction
- Peptic ulcer disease
- Acute intermittent porphyria

TREATMENT

PRE HOSPITAL

No specific treatment required

INITIAL STABILIZATION/THERAPY

- Symptomatic treatment
- Pain control
- Administer fluids if dehydrated

ED TREATMENT/PROCEDURES

- Empathetic approach and therapeutic physician–patient relationship is most important.
- Exercise:
 - Improves gastric emptying and constipation
- Diet:
 - Many believe symptoms have a food trigger, but not yet proven.
 - Exclusion diets starting with gluten or lactose can be empirically considered.

- Avoid beans, cabbage, uncooked broccoli, other flatulent foods if symptomatic.
- Constipation symptoms:
 - High-fiber diet, fiber supplements
- Abdominal pain:
 - Antispasmodics like hyoscyamine and dicyclomine may be helpful short-term
- Probiotics:
 - Bifidobacteria appear more effective than lactobacilli
- Antidepressants:
 - TCAs and possibly SSRIs appear to be effective at relieving global IBS symptoms and reducing abdominal pain.
- Psychological therapies appear effective.

MEDICATION

First Line

- Dicyclomine: 10–20 mg PO q6h
- Hyoscyamine: 0.125–0.25 mg PO or sublingual not to exceed 12 tab/day

Second Line

- Amitriptyline: 25 mg PO at bedtime (or another TCA)
- Fluoxetine: 20 mg PO daily (or another SSRI)
- Bifidobacteria probiotic

FOLLOW-UP

DISPOSITION

Admission Criteria

Uncertain diagnosis with suspicion of an emergent abdominal condition

Discharge Criteria

Almost all patients can be managed as outpatients.

Issues for Referral

Some may benefit from GI or psychiatric referral.

FOLLOW-UP RECOMMENDATIONS

Most important is follow-up with primary care physician to foster a therapeutic physician–patient relationship.

PEARLS AND PITFALLS

- Beware of other emergent pathology.
- IBS is common, so it is likely the underlying cause of many abdominal workups done in the ED.

IRRITABLE INFANT

David H. Rubin

BASICS

DESCRIPTION

- Most children have some period of the day when they are most irritable, usually toward the evening:
 - Normal infant crying ranges from 1–4 hr by 6 wk of age.
 - During the 1st 6 mo of life, 1 mo olds have the highest prevalence of crying
- Irritability is based on a comparison with the child's normal behavior pattern
- Colic is the most common cause of inconsolable crying in infants, occurring in as many as 25% of healthy children:
 - Episodes of paroxysmal screaming accompanied by drawing up knees and oftentimes passage of flatus
 - Usually begins at 2–3 wk and may continue through 12 wk
 - Diagnosis of exclusion

ETIOLOGY

- Bites: Spider/insect bite
- Burn
- Cardiac (supraventricular tachycardia, congestive heart failure, aberrant left coronary artery, coarctation of the aorta, endocarditis, myocarditis)
- Child abuse
- Corneal abrasion/foreign body (eyelash) in eye
- Diaper pin
- Diphtheria, pertussis, and tetanus (DPT) and other vaccine reactions
- Endocrine/metabolic (inborn errors of metabolism, metabolic acidosis, hypernatremia, hypoglycemia, hypocalcemia, hyperthyroid—direct or by transplacental passage of maternal thyroid stimulating immunoglobulins)
- Foreign body, fracture, tourniquet (hair around digit or penis)
- GI (gastroenteritis, colic, gastroesophageal reflux, esophagitis, volvulus, malrotation constipation, cow's milk protein intolerance, anal fissure, intussusception, appendicitis)
- Genitourinary (incarcerated hernia, testicular torsion, genital tourniquets, urinary retention)
- Iron deficiency/anemia
- Medications/toxins: Aspirin, antihistamines, atropine, adrenergics, home remedies, new prescription, mercury)
- Meningitis
- Minor acute infections (upper respiratory infection, otitis media, thrush,

gingivostomatitis)

- Neurologic (increased intracranial pressure: Mass, hydrocephalus, intracranial hemorrhage, hematoma—subdural, epidural, skull fracture)
- Osteomyelitis
- Parental anxiety
- Pneumonia
- Sickle cell crisis
- Splinter
- Teething
- Trauma
- UTI
- Vascular

DIAGNOSIS

SIGNS AND SYMPTOMS

- Vital signs
- Chief complaint
- Chronology of events

History

Obtain complete history (including neonatal history) and information regarding routine feeding, crying.

Physical-Exam

- Assess vital signs including rectal temperature and pulse oximetry.
- Measure and plot for percentiles: Height, weight, and head circumference.
- Perform a thorough physical exam with infant completely undressed.

ESSENTIAL WORKUP

This is usually directed by a comprehensive history and physical exam. Specific studies may be obtained.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC, urinalysis, chemistries, and cultures as indicated by history and physical exam
- Stat blood glucose at bedside if indicated.
- Stool hemoccult test if GI signs or symptoms

Imaging

- Chest radiograph to exclude cardiopulmonary disease
- Skeletal survey, if indicated
- CT scan of the head, chest, etc. usually directed by history and physical exam
- Contrast radiograph studies such as barium enema for specific indications

Diagnostic Procedures/Surgery

- Fluorescein eye exam
- ECG

DIFFERENTIAL DIAGNOSIS

See etiology above. It is essential to distinguish benign, self-limited conditions from those that might be life threatening.

TREATMENT

PRE HOSPITAL

As determined by history, physical exam, and lab studies

INITIAL STABILIZATION/THERAPY

- Manage underlying conditions; stabilize airway, breathing, and circulation (ABCs).
- Immediate removal of hair tourniquets and/or splinters

ED TREATMENT/PROCEDURES

- Initial evaluation of the child focusing on parent–child interaction and then on potential underlying conditions
- Colic responds to soothing, rhythmic activities, avoiding stimulants (coffee, cola), minimizing daytime sleep:
 - Soy or hydrolyzed casein formula may be transiently beneficial.
 - Parents must reduce stress
 - No proven pharmacologic therapy
 - Probiotics may be useful
- Support, empathy, close follow-up
- Prolonged observation of the child is usually appropriate.

MEDICATION

Dependent on the underlying condition

First Line

Dependent on the underlying condition

Second Line

Dependent on the underlying condition

FOLLOW-UP

DISPOSITION

Admission Criteria

- Life-threatening underlying condition
- Significant parental stress secondary to crying infant

Discharge Criteria

- No serious condition
- Functional and supportive family
- Excellent follow-up is essential; parents must feel that their observations and concerns are not being ignored. Close follow-up and ongoing observation are mandatory to reevaluate the child and provide support to the family.

Issues for Referral

Determined by specific specialty related issues

FOLLOW-UP RECOMMENDATIONS

Long-term follow-up strongly recommended

PEARLS AND PITFALLS

- Address life-threatening/serious causes of irritability first:
 - Cardiovascular: Supraventricular tachycardia, congestive heart failure, endocarditis/myocarditis
 - Neurologic: Subdural/epidural, meningitis, intracranial hemorrhage, increased intracranial pressure, skull fracture
 - GI: Volvulus, intussusception, appendicitis, peritonitis
 - Metabolic: Metabolic acidosis, electrolyte disturbances
 - Genitourinary: UTI, torsion of testis, incarcerated hernia
 - Pulmonary: Foreign body, pneumothorax, pneumonia
 - Dermatologic: Strangulated digit
 - Toxicologic: Toxic ingestion, immunization reaction
 - Trauma
 - Ophthalmologic: Corneal abrasion, glaucoma
 - Other: Child abuse, transplacental passage of maternal medications that may cause irritability
- Detailed history and complete physical exam in the noncritically ill child is crucial before obtaining any lab or radiologic studies

IRRITANT GAS EXPOSURE

Patrick M. Whiteley • Sean M. Bryant

BASICS

DESCRIPTION

- An irritant is any noncorrosive substance that on immediate, prolonged, or repeated contact with respiratory mucosa will induce a local inflammatory reaction.
- Respiratory irritants are inhaled as gases, fumes, particles, or liquid aerosols.
- Inhaled irritants:
 - Pulmonary toxicity is determined primarily by their water solubility.
- Inhalation accidents frequently involve a mixture of irritant gases as well as chemical asphyxiants:
 - Carbon monoxide
 - Hydrogen cyanide
 - Hydrogen sulfide
 - Oxides of nitrogen
- Risk factors include exposure to potential irritants:
 - Occupational
 - Leisure
 - Intentional
 - Accidental
- Pathophysiology:
 - Cellular injury through interaction with respiratory mucosal water with subsequent formation of acids, alkalis, and free radicals

ETIOLOGY

- Settings:
 - Industrial: Chemical manufacturing, mining, plastics, and petroleum industries
 - Home: Improper use or storage of cleaning chemicals
 - Fires: Combustion yields toxic gases.
 - Civil Disturbance: Riot control agents.
- **Immediate onset** of upper airway inflammation with highly water-soluble irritant gases or with aerodynamic diameter > 5 mm:
 - Ammonia (fertilizers, refrigerants, dyes, plastics, synthetic fibers, cleaning agents):
 - Immediate symptoms range from mild edema and erythema to full-thickness burns and airway obstruction.
 - Sulfur dioxide (fumigants used on produce, bleaching, tanning, brewing,

- wine making, combustion of coal, and smelting of sulfide-containing ores):
 - Combines with water, forming sulfuric acid.
- Hydrogen chloride (formed during combustion of chlorinated hydrocarbons such as polyvinyl chloride):
 - Combines with water, forming hydrochloric acid.
- Chloramine (generated when ammonia and bleach are mixed):
 - When exposed to moist surfaces, releases hypochlorous acid.
- Acrolein (production of plastics, pharmaceuticals, synthetic fibers; formed during combustion of petroleum products, cellulose, wood, paper):
 - May cause protein damage via free radical production and sulfhydryl binding.
- Formaldehyde (production of plywood, particle board, insulation; combustion product of gas stoves and heaters):
 - Combines with water to form sulfuric acid and formic acid.
- Hydrogen fluoride (combustion of fluorinated hydrocarbons):
 - Depletes calcium stores, resulting in cell death.
- Riot control agents (Capsaicin [OC], Chlorobenzylidenemalononitrile [CS], and Chloroacetophenone [CN]):
 - Lacrimation agents which cause temporary ocular discomfort.
- **Latent period** of minutes to hours before onset of symptoms with irritant gases of intermediate water solubility or aerodynamic diameter of 1–5 mm:
 - Chlorine (product of chlorinated chemicals; bleaching agent):
 - Upper and lower airway damage after reacting with water to form hydrochloric and hypochlorous acids
- **Delayed onset** of symptoms up to 24 hr after inhalation with irritant gases of poor water solubility or aerodynamic diameter < 1 mm (with little or no warning of exposure):
 - Oxides of nitrogen produced:
 - In manufacture of dyes and fertilizers
 - By electric arc welding and gas blowing
 - By fermentation of nitrogen-rich silage (silo-filler's disease)
 - In combustion of nitrocellulose and polyamides
 - Phosgene/carbonyl chloride (arc welding and pesticide production: Combustion of chlorinated hydrocarbons and solvents)
 - Ozone (produced during arc welding)
 - Cadmium oxide (oxyacetylene welding and electroplating)

DIAGNOSIS

SIGNS AND SYMPTOMS

- Dependent on water solubility
- Highly water-soluble gases:

- Eye, nose, throat burning
- Shortness of breath
- Wheezing
- Cough
- Hoarseness
- Stridor
- Obstruction
- Intermediate water solubility:
 - Upper and lower tract involvement
 - Mucosal irritation
 - Bronchospasm
 - Dyspnea
 - Wheezing
 - Cough
 - Rales
 - Possible delayed pulmonary edema
- Other:
 - Dermal irritation
 - Headache
 - Nausea
 - Vomiting
 - Confusion
 - Seizures
 - Syncope

History

- Known exposures
- Type of chemical/industry
- Rapidity of symptom
- Material safety data sheet from exposure site
- Water solubility of agent

Physical-Exam

- HEENT:
 - Conjunctival injection
 - Lacrimation
 - Chemosis
- Respiratory
- Stridor
 - Voice changes
 - Dyspnea
 - Wheezing

- Cough
- GI:
 - Vomiting
- Dermatologic:
 - Skin erythema/irritation
 - Erythematous rash
- Neurologic:
 - Confusion
 - Seizure activity

ESSENTIAL WORKUP

History of exposure to irritant gases in addition to noted symptoms confirm diagnosis.

DIAGNOSIS TESTS & INTERPRETATION

ECG in the following patients:

- Elderly
- Cardiac history
- Evidence of significant pulmonary symptoms

Lab

- Arterial blood gas to assess:
 - Oxygenation
 - Ventilation status
 - pH
 - Pulse oximetry is unreliable.
- Carbon monoxide level:
 - If smoke inhalation with concomitant irritant gas inhalation (see “Carbon Monoxide Poisoning”)
- Methemoglobin level:
 - If oxides of nitrogen are suspected
- Serum calcium level:
 - If hydrogen fluoride is suspected
- Lactate:
 - Elevation may indicate cellular poisoning from carbon monoxide or cyanide.
- Pregnancy test in all females of childbearing age
- Rapid dextrose
- Cardiac enzyme levels if acute coronary syndrome suspected

Imaging

CXR:

- Frequently normal on initial presentation
- May take up to 24 hr to reveal pulmonary edema or evidence of diffuse injury.

Diagnostic Procedures/Surgery

- Spirometry:
 - Assess evidence suggesting airway narrowing and bronchoconstriction.
- Direct laryngoscopy:
 - Assess evidence of upper airway edema.
- Corneal fluorescein:
 - Assess evidence of corneal burns/injury.

DIFFERENTIAL DIAGNOSIS

- Asthma exacerbation
- Allergic stimuli (pollen)
- Physical stimuli (cold air)
- Bronchitis
- Pneumonia
- Occupational asthma
- Hypersensitivity pneumonitis
- Congestive heart failure

TREATMENT

PRE HOSPITAL

Rescuer's goal is to prevent self-contamination with use of protective clothing or equipment (self-contained breathing apparatus).

INITIAL STABILIZATION/THERAPY

- ABCs:
 - 100% oxygen through a tight-fitting, nonbreathing face mask
 - Early intubation may be necessary to protect airway from edema.
 - Mechanical ventilation
 - Continuous positive airway pressure or positive end-expiratory pressure may enhance oxygenation.
- Decontaminate by removing clothes and irrigating skin and ocular tissues.

ED TREATMENT/PROCEDURES

- Inhaled nebulized β_2 -adrenergic agonists (albuterol) for bronchoconstriction
- Inhaled/IV/PO corticosteroids: Beclomethasone, methylprednisolone, prednisone:
 - Controversial
 - No controlled trials that document benefit of acute corticosteroids after irritant gas inhalation.
- Nebulized sodium bicarbonate (3.75% solution) after chlorine gas exposure:
 - Reported to improve oxygenation in several case reports/series.
- Nebulized calcium gluconate after acute hydrogen fluoride inhalation:

- Reported, but with no proven benefit
- Hydroxocobalamin or cyanide antidote kit if hydrogen cyanide is suspected (see “Cyanide Poisoning”)
- Oxygen or hyperbaric oxygen therapy if carbon monoxide poisoning documented

MEDICATION

- Albuterol: 0.5 mL (peds: 0.03 mL or 0.15 mg/kg/dose) of 0.5% solution diluted in NS to 3 mL aerosolized
- Beclomethasone MDI: 1–2 sprays (40–80 µ/spray) BID
- Calcium gluconate: Nebulized (2.5–3% solution) prepared by adding 0.15 g of calcium gluconate to 6 mL of NS
- Methylprednisolone: 80–125 mg (peds: 1–2 mg/kg) IV
- Prednisone: 40–80 mg (peds: 1–2 mg/kg) PO
- Sodium bicarbonate: Nebulized (3 mL of 8.4% sodium bicarbonate mixed with 2 mL of NS to prepare 5 mL of 5% solution)

FOLLOW-UP

DISPOSITION

Admission Criteria

- ICU admission:
 - Intubated patients
 - Significant respiratory insufficiency or potential upper airway obstruction
- Persistently symptomatic with bronchospasm or oxygen requirement
- Exposure to irritant gases that affect peripheral airways:
 - Delayed pulmonary edema and respiratory failure may occur.
- Conservative treatment for children, pregnant women, elderly patients, or those with pre-existing chronic obstructive pulmonary or coronary disease

Discharge Criteria

- Mild exposures that respond well to supportive care and have no oxygen requirement or bronchospasm after 4–6 hr of observation
- Follow-up chest radiograph during observation and prior to discharge, especially if any symptoms are present or clinically worsening

Issues for Referral

Intensive care for patients with early evidence of acute lung injury

FOLLOW-UP RECOMMENDATIONS

- Occupational medicine referral for work-related exposures.
- Pulmonary follow-up for repeated symptomatic exposures.

PEARLS AND PITFALLS

- Beware of delayed onset of low-solubility agents. These exposures may require 23-hr observation for delayed respiratory symptoms.
- Avoid exposure of agent to first responders, with appropriate decontamination.

ISONIAZID POISONING

Sean M. Bryant

BASICS

DESCRIPTION

- Complexes with and inactivates pyridoxal-5 phosphate, the active form of pyridoxine (vitamin B₆)
- Inhibits pyridoxine phosphokinase, hindering the conversion of pyridoxine to its active form
- Yields a net decrease in γ -aminobutyric acid (GABA) production:
 - Depressed GABA causes cerebral excitability and seizures
- Inhibits lactate dehydrogenase, decreasing the conversion of lactate to pyruvate:
 - Contributes to the profound anion gap metabolic acidosis
- Chronic toxicity:
 - Interferes with synthesis of nicotinic acid (niacin)
 - May cause syndrome indistinguishable from pellagra after months of therapy (niacin deficiency)
- Some actions similar to the monoamine oxidase inhibitors:
 - Reports of a tyramine-like reaction to isoniazid (INH)
 - Rare cases of mania, diaphoresis, depression, obsessive–compulsive disorder, and psychosis
- Pharmacokinetics:
 - Rapidly absorbed, peak levels within 1–2 hr
 - Volume of distribution is 0.6 L/kg and protein binding is low (10%)
 - Renally excreted within 24 hr after acetylation in the liver
 - Half-life is < 1 hr in fast acetylators and 2–4 hr in slow-acetylating individuals

ETIOLOGY

- High-risk groups include:
 - Immigrants
 - Homeless
 - HIV infected
 - Alcoholics
 - Lower socioeconomic status populations
- Slow acetylators (60% of African Americans and Whites compared to 20% of Asians) are more prone to chronic effects/toxicity
- LD50 estimated at 80–150 mg/kg
- Ingestions < 1.5 g lead to mild toxicity, and those of 10 g or more often result in fatality

SIGNS AND SYMPTOMS

- Acute toxicity:
 - Neurologic:
 - Altered mental status
 - Seizures refractory to standard therapy
 - Agitation
 - Coma
 - Dizziness
 - Ataxia
 - Hyper-reflexia
 - Slurred speech
 - Hallucinations
 - Psychosis
 - GI:
 - Nausea
 - Vomiting
 - Renal:
 - Anuria
 - Oliguria
 - Cardiovascular:
 - Hypotension
 - Tachycardia
 - Shock
 - Cyanosis
 - Metabolic:
 - Profound anion gap metabolic acidosis (elevated lactate)
 - Hyperthermia
- Chronic toxicity:
 - Neurologic:
 - Peripheral neuropathy
 - Optic neuritis, optic atrophy
 - Psychosis
 - Insomnia
 - Vertigo
 - Pellagra
- GI hepatitis:
 - Liver failure, hepatitis
 - Nausea, vomiting, constipation
 - Anorexia

Without specific history of ingestion, initiate general workup for:

- Altered mental status
- Seizures
- Metabolic acidosis

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Arterial blood gas:
 - Profound metabolic acidosis
- Electrolytes, BUN/creatinine, glucose:
 - Elevated anion gap acidosis
 - Hyperglycemia
- CBC:
 - Acute toxicity:
 - Leukocytosis
 - Eosinophilia
 - Chronic toxicity:
 - Agranulocytosis
 - Eosinophilia
 - Hemolysis
 - Anemia

Imaging

- CXR:
 - Evidence of tuberculosis increases suspicion for ingestion/toxicity.
 - Evaluate for aspiration pneumonia.
- CT/lumbar puncture if indicated and questionable history

DIFFERENTIAL DIAGNOSIS

- Toxins:
 - Tricyclic antidepressants
 - Salicylates (aspirin)
 - Theophylline
 - Methanol/ethylene glycol
 - Lithium
 - Carbon monoxide
 - Cocaine/cyanide
 - Agents that cause metabolic acidosis
- CNS:
 - Cerebrovascular accident
 - Intracranial hemorrhage/mass/trauma/abscess
- Hypoglycemia

- Uremia
- Thyrotoxicosis

TREATMENT

PRE HOSPITAL

Collect prescription bottles/medications for identification in the ED

INITIAL STABILIZATION/THERAPY

- ABCs:
 - Supplemental oxygen
 - Intubate if necessary for airway protection
 - Secure IV access
 - Cardiac monitor
 - 0.9% NS access
- Naloxone, thiamine, D50W (Accu-Chek) if altered mental status

ED TREATMENT/PROCEDURES

- Vitamin B₆ (pyridoxine):
 - Specific antidotal treatment for INH toxicity
 - Goal: 1 g of pyridoxine for each gram of INH ingested (1 g q2–3min)
 - 5 g for unknown amount ingested
 - May repeat in 20 min for refractory seizures or persistent coma
 - If insufficient quantity of pyridoxine available, contact other hospital pharmacies and the regional poison control center to obtain more
 - If no parenteral pyridoxine available, crush tablets and give as a slurry via NG tube
- Seizure control:
 - Pyridoxine restores deficiency in GABA
 - Benzodiazepines are synergistic with pyridoxine
 - Phenytoin has no role
- Gastric decontamination after stabilization:
 - Consider gastric lavage only in life-threatening ingestions presenting within 1 hr with a protected airway (being aware of potential seizure activity and obtundation)
 - Activated charcoal (AC) dosed at 10:1 ratio (AC:drug)
- Hemodialysis:
 - Persistent symptoms despite adequate therapy
 - Renal insufficiency in symptomatic patients
- Sodium bicarbonate:
 - Acidosis usually resolves spontaneously after elimination of seizures

MEDICATION

- Dextrose: D50W 1 amp (50 mL or 25 g) (peds: D25W 2–4 mL/kg) IV
- Diazepam (benzodiazepine): 5–10 mg (peds: 0.2–0.5 mg/kg) IV
- Lorazepam (benzodiazepine): 2–6 mg (peds: 0.03–0.05 mg/kg) IV
- Naloxone (Narcan): 2 mg (peds: 0.1 mg/kg) IV/IM initial dose
- Pyridoxine (vitamin B₆): 1 g IV for each gram of INH ingested (see above)
- Thiamine (vitamin B₁): 100 mg (peds: 50 mg) IV/IM

FOLLOW-UP

DISPOSITION

Admission Criteria

- ICU admission for refractory seizures, severe acidosis, coma, altered mental status
- Uncontrolled nausea/vomiting, unclear history of ingestion, or suicidal
- Consult regional poison center:
 - (1-800-222-1222)

Discharge Criteria

- Symptoms are usually observed within 45 min of an acute overdose but may be delayed for ≥ 2 hr
- Discharge if asymptomatic after 6 hr

FOLLOW-UP RECOMMENDATIONS

Psychiatric referral for intentional overdoses or suicidal patients

PEARLS AND PITFALLS

- Inadequate appreciation and management of INH poisoning:
 - Refractory seizures to standard treatments is a fundamental clue to INH poisoning
 - Severe acidemia with elevated lactate in altered patients with seizures
- Never paralyze a seizing patient without the use of continuous EEG monitoring
- Goal of pyridoxine therapy is gram for gram of INH
- If pyridoxine adequately treats seizures, may give more if patient remains comatose

ADDITIONAL READING

- Minns AB, Ghafouri N, Clark RF. Isoniazid-induced status epilepticus in a pediatric patient after inadequate pyridoxine therapy. *Pediatr Emerg Care*. 2010;26:380–381.

- T37.1X4A Poisoning by antimycobacterial drugs, undetermined, init

ISOPROPANOL POISONING

Paul Kolecki

BASICS

DESCRIPTION

- CNS depressant effect of isopropanol is 2 to 3 times as potent as that of ethanol.
- Many products that contain isopropanol also contain methanol, ethylene glycol, and ethanol.
- Rapidly absorbed following oral ingestion
- Ketogenic, but does not cause significant acidosis
- Metabolized by alcohol dehydrogenase to acetone (a CNS depressant):
 - Concomitant ethanol ingestion doubles half-life of isopropanol but not that of acetone.
 - Acetone eliminated by lung and kidney
- Half-life:
 - Isopropanol: 3–16 hr
 - Acetone: 7.5–26 hr

ETIOLOGY

- Isopropanol (isopropyl alcohol): Clear, colorless, volatile liquid with faint odor of acetone and bitter taste
- Available as 70% rubbing alcohol solution:
 - May contain blue dye that was added to inhibit its abuse (“blue heaven”)
- Found in:
 - Various toiletries
 - Disinfectants
 - Window-cleaning solutions
 - Paint remover
 - Solvents
 - Jewelry cleaners
 - Detergents
 - Antifreeze
 - Hand sanitizers
- Typical adult patient: Chronic alcoholic who has been on drinking binge and recently depleted his or her ethanol supply
- Dermal and rectal administration can cause systemic toxicity.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Usually occur within 30–60 min of ingestion
- Neurologic:
 - Lethargy
 - Weakness
 - Headache
 - Inebriation
 - Vertigo
 - Ataxia
 - Apnea
 - Coma
 - Initial excitation phase seen with ethanol ingestion is absent.
- GI:
 - Nausea/vomiting
 - Abdominal pain
 - Gastritis
 - Hematemesis
- Cardiovascular:
 - Hypotension
 - Tachycardia
 - Myocardial depression
 - Peripheral vascular dilation
- Pulmonary:
 - Respiratory depression
 - Hemorrhagic tracheobronchitis
- Dermatologic:
 - Skin irritation
 - Burns
- Ocular:
 - Irritation
 - Lacrimation

Pediatric Considerations

- Accidental ingestions common in <6-yr olds.
- Rubbing alcohol sponge baths may cause inhalational toxicity.

ESSENTIAL WORKUP

- History of ingestion
- Odor of isopropanol or acetone on patient's breath

DIAGNOSIS TESTS & NTERPRETATION

Lab

- Electrolytes, BUN, creatinine (Cr), glucose:

- Hypoglycemia occurs.
- Does *not* produce significant acidosis unless accompanied by end-organ hypoperfusion.
- Acetone can produce false elevation of serum Cr:
 - o When acetone level > 40 mg/dL, Cr values rise at ~ 1 mg Cr/100 mg/dL acetone.
 - o Cr returns to baseline following acetone metabolism.
- CBC:
 - Decreased hematocrit with significant hemorrhagic gastritis
- Arterial blood gas:
 - Acidosis rare unless owing to hypoperfusion or coingestant.
- Urinalysis:
 - Ketones present.
- Serum ketones are present.
- Isopropanol level:
 - Coma with level > 150 mg/dL
- Serum osmolality:
 - Osmolar gap: Difference between measured and calculated osmolality
 - Calculated osmolality = $2 \text{ Na}^+ \text{ BUN}/2.8 + \text{glucose}/18 + \text{ethanol}/4.6$.
 - Osmolar gap is present if measured minus calculated osmolality is > 10.
 - Gap increases by 1 mOsm/kg for each 5.9 mg/dL of isopropanol and 5.5 mg/dL of acetone.

Imaging

- CXR: For aspiration pneumonia with altered mental status and vomiting
- CT head: Concomitant head injury occurs.

DIFFERENTIAL DIAGNOSIS

- For CNS depression and elevated osmolar gap includes:
 - Ethanol
 - Ethylene glycol
 - Methanol
 - Glycerol
 - Mannitol

Pediatric Considerations

Prone to hypoglycemia following exposure

TREATMENT

PRE HOSPITAL

Search for and transport all bottles and medications that may have been ingested by the

patient when an overdose is suspected.

INITIAL STABILIZATION/THERAPY

- ABCs:
 - Maintain airway and assist in ventilation if necessary.
- Hypotension:
 - Treat initially with 0.9% NS IV fluid bolus.
 - Initiate dopamine or norepinephrine infusion if hypotension persists.
 - Packed RBCs with significant hemorrhagic gastritis
- Place NG tube and irrigate for patients with hematemesis.
- Naloxone, thiamine, dextrose (or Accu-Chek) if altered mental status

ED TREATMENT/PROCEDURES

- Primarily supportive therapy—no specific antidote
- Irrigate skin/eyes for dermal or ocular exposure.
- Consider activated charcoal:
 - For coingestants
 - Large doses can absorb significant amounts of isopropanol.
- Do **not** treat with ethanol infusion or 4-methylpyrazole.
- Hemodialysis:
 - Effectively removes isopropanol and acetone.
 - Most managed with supportive care alone.
 - Indications:
 - Hemodynamic instability despite fluid replacement and use of pressors
 - Levels > 400 mg/dL (associated with severe hypotension and prolonged coma)

MEDICATION

- Activated charcoal slurry: 1–2 g/kg up to 90 g PO
- Dextrose: D50W 1 amp: 50 mL or 25 g (peds: D25W 2–4 mL/kg) IV
- Dopamine: 2–20 mg/kg/min IV
- Naloxone (Narcan): 2 mg (peds: 0.1 mg/kg) IV or IM initial dose
- Thiamine (vitamin B₁): 100 mg (peds: 50 mg) IV or IM

FOLLOW-UP

DISPOSITION

Admission Criteria

Moderate to severe isopropanol toxicity (altered mental status, hypotension)

Discharge Criteria

- Observe asymptomatic patients following ingestion for 2–4 hr before discharge.
- Mild intoxication that resolves over 4–6 hr

Issues for Referral

GI referral for endoscopy for patients with recurrent hematemesis.

FOLLOW-UP RECOMMENDATIONS

Alcohol detox or psychiatry referral for patients with intentional ingestion

PEARLS AND PITFALLS

- Supportive care is the primary treatment.
- Do **not** treat with ethanol infusion or 4-methylpyrazole.

- T52.8X1A Toxic effect of organic solvents, accidental, init

JAUNDICE

Andrew K. Chang • Albert Izzo

BASICS

DESCRIPTION

Yellow pigmentation of tissues and body fluids due to hyperbilirubinemia, usually present at levels of >2.5 mg/dL

ETIOLOGY

- Unconjugated (indirect) hyperbilirubinemia: Unconjugated bilirubin is the direct breakdown product of heme, is water insoluble, and is measured as indirect bilirubin:
 - Hemolytic:
 - Excessive production of unconjugated bilirubin
 - Hepatic:
 - Decreased hepatobiliary excretion of bilirubin by:
 - Defective uptake (drugs, Crigler–Najjar syndrome)
 - Defective conjugation (Gilbert syndrome drugs)
 - Defective excretion of bilirubin by the liver cell (drugs, Dubin–Johnson syndrome)
- Conjugated (direct) hyperbilirubinemia:
 - Conjugated bilirubin is water soluble and measured as direct bilirubin.
 - In conjugated hyperbilirubinemia, bilirubin is returned to the bloodstream after conjugation in the liver instead of draining into the bile ducts.
 - Hepatocellular dysfunction:
 - Hepatitis
 - Cirrhosis
 - Tumor invasion
 - Toxic injury
 - Intrahepatic (nonobstructive) cholestasis
 - Extrahepatic (obstructive) cholestasis

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Cholestasis:
 - Pruritus
 - Pale stools

- Dark urine
- Malignancy:
 - Anorexia
 - Weight loss
 - Malaise
- Abdominal pain

Physical-Exam

- Icterus of sclera and tongue base (levels > 2.5 mg/dL)
- Right upper quadrant tenderness:
 - Courvoisier rule:
 - Painless jaundice and a palpable, nontender gallbladder represent malignant common duct obstruction.
- Stigmata of cirrhosis:
 - Abdominal collateral circulation including caput medusae, hepatosplenomegaly, or hepatic atrophy
 - Ascites
 - Spider telangiectasia
 - Palmar erythema
 - Dupuytren contractures
 - Asterixis
 - Encephalopathy
 - Gynecomastia
- Palpable gallbladder
- Hepatomegaly
- Splenomegaly
- Abdominal mass
- Evidence of cachexia
- Excoriations (primary biliary cirrhosis, obstruction)
- Kayser–Fleischer rings:
 - Wilson disease

ESSENTIAL WORKUP

- History and physical exam, together with routine lab tests, will suggest the diagnosis in ~ 80% of patients with jaundice.
- Bilirubin level—severity may suggest cause:
 - Malignancy causes highest levels (10–30 mg/dL).
 - Choledocholithiasis rarely exceeds 15 mg/dL.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Urine dipstick is 74% sensitive for bilirubin.

- Alkaline phosphatase:
 - If no bone disease and not pregnant, then elevation suggests impaired biliary tract function.
 - 2X normal: Hepatitis and cirrhosis
 - 3X normal: Extrahepatic biliary obstruction (i.e., choledocholithiasis) and intrahepatic cholestasis (i.e., drug-induced and biliary cirrhosis)
- Aminotransferases—provide evidence of hepatocellular damage:
 - Alanine aminotransferase (ALT, SGPT): Primarily in the liver
 - Aspartate aminotransferase (AST, SGOT): Liver, heart, kidney, muscle, and brain
- γ -Glutamyl transpeptidase—throughout hepatobiliary system, pancreas, heart, kidneys, and lungs:
 - May be the most sensitive indicator of biliary tract disease.
 - Confirms hepatic origin of an elevated alkaline phosphatase.
- 5'-Nucleotidase—widespread tissue distribution:
 - Confirms hepatic origin of an elevated alkaline phosphatase level.
- Albumin: Decreased with severe liver disease
- PT: Elevation is an important prognostic indicator in patients with acute hepatitis.

Imaging

- US: Most effective initial imaging technique:
 - >90% effective in identifying cholelithiasis
 - Ductal dilation is a reliable indicator of extrahepatic obstruction:
 - A dilated common bile duct (CBD) and gallbladder suggest distal obstruction, whereas dilation of the intrahepatic ducts (without CBD dilation) suggests proximal obstruction.
- Tumors of the liver and head of pancreas are usually well visualized.
- Distinguishes solid liver tumors from cystic structures.
- Plain radiographs:
 - May show evidence of hepatic and splenic enlargement or biliary calcifications
- Hepatic nuclear scan (hepatobiliary iminodiacetic acid scan):
 - Accurate method of diagnosing acute cholecystitis or cystic duct obstruction
 - Time consuming (usually several hours)
- CT:
 - Superior to US in detecting pancreatic and intra-abdominal tumors.
 - Can help differentiate fluid-containing structures.

Diagnostic Procedures/Surgery

Endoscopic retrograde cholangiopancreatography (ERCP):

- Diagnostic:
 - Stones are seen as filling defects within bile duct lumen.

- Malignancies are seen as strictures.
- Therapeutic:
 - Extraction of CBD stones and insertion of stents to bypass malignant obstructions
 - Biopsy under direct vision

DIFFERENTIAL DIAGNOSIS

- Prehepatic:
 - Hemolysis (sickle cell, other hemoglobinopathies)
 - Ineffective erythropoiesis
 - Drugs
 - Gilbert syndrome: Usually benign inherited form of unconjugated hyperbilirubinemia
 - Crigler–Najjar syndrome
 - Prolonged fasting
- Hepatocellular:
 - Hepatitis (infectious, alcoholic, autoimmune, toxin, drug induced)
 - Cirrhosis
 - Postischemic
 - Hemochromatosis
- Intrahepatic cholestasis:
 - Idiopathic cholestasis of pregnancy
 - Drugs
 - Dubin–Johnson syndrome
 - Rotor syndrome
 - Benign recurrent cholelastia
 - Familial syndromes
 - Sepsis
 - Postoperative jaundice
 - Lymphoma
- Extrahepatic obstruction:
 - Common duct stone
 - Biliary stricture
 - Bacterial cholangitis
 - Sclerosing cholangitis
 - Carcinoma (ampulla, gallbladder, pancreas), cholangiosarcoma
 - Pancreatitis, pancreatic pseudocyst
 - Hemobilia
 - Duodenal diverticula
 - Ascariasis
 - Postlaparoscopic cholecystectomy complications
 - Congenital biliary atresia
 - Congenital choledochal cyst

Pediatric Considerations

Intrahepatic cholestasis:

- Cardiovascular (congenital heart disease, congestive heart failure, shock, asphyxia)
- Metabolic or genetic (α_1 -antitrypsin deficiency, trisomy 18 and 21, cystic fibrosis, Gaucher disease, Niemann–Pick disease, glycogen storage disease type IV)
- Infectious (bacterial sepsis, cytomegalovirus, enterovirus, herpes simplex virus, rubella, syphilis, TB, varicella, viral hepatitis)
- Hematologic (severe isoimmune hemolytic disease)

TREATMENT

INITIAL STABILIZATION/THERAPY

- Isotonic IV fluid therapy if dehydrated
- Toxic-appearing patients:
 - Supplemental oxygen, cardiac monitoring
 - Nasogastric suction and bladder catheterization

ED TREATMENT/PROCEDURES

- For bacterial cholangitis/sepsis, obtain blood cultures and administer parenteral antibiotics:
 - Ampicillin, gentamicin, and metronidazole *or*
 - Ticarcillin, or piperacillin, and metronidazole *or*
 - Cefoxitin and tobramycin
- Obstructive extrahepatic jaundice:
 - Surgical consult
- Choledocholithiasis:
 - ERCP papillotomy, balloon or basket retrieval, or open surgery
- Obstructive intrahepatic or nonobstructive jaundice:
 - Medical management:
 - Withdraw causative drug, ethanol
 - Interferon for chronic hepatitis B and C
 - Penicillamine and phlebotomy for Wilson disease and hemochromatosis
 - Corticosteroids for chronic hepatitis of autoimmune origin

Pediatric Considerations

- Exchange transfusion:
 - Emergent treatment of markedly elevated bilirubin (> 20 mg/dL in full-term infants) and for correction of anemia caused by isoimmune hemolytic disease
- Phototherapy—for neonatal jaundice when bilirubin = 17 mg/dL:

- Measure bilirubin once to twice daily and stop when bilirubin has been reduced by about 4–5 mg/dL.
- Phenobarbital: In sepsis and drug-induced causes; decreases conjugated bilirubin.
- Metalloporphyrins: Investigational inhibitors of heme oxygenase

MEDICATION

- Ampicillin: 2 g IV q6h (peds: 25 mg/kg IV q6–8h)
- Cefoxitin: 2 g IV q6h (peds: 40–160 mg/kg/d div. q6–12h)
- Gentamicin: 5–2 mg/kg IV q8h
- Metronidazole: 7.5 mg/kg IV q6h (peds: Same)
- Piperacillin/tazobactam: 3.375 g IV q6h (peds: 300 mg/kg/d div. q6h [> 2 mo of age])
- Ticarcillin/clavulanate: 3.1 g IV q6h (peds: 75–100 mg/kg/d div. q6h)
- Tobramycin: 1 mg/kg IV q6h (peds: Same)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Bacterial cholangitis
- Intractable pain
- Intractable emesis
- Associated pancreatitis
- Elevated PT

Discharge Criteria

- No evidence of infection (evaluate as outpatient)
- Tolerating liquids

CODES

ICD9

- 277.4 Disorders of bilirubin excretion
- 774.6 Unspecified fetal and neonatal jaundice
- 782.4 Jaundice, unspecified, not of newborn

ICD10

- E80.6 Other disorders of bilirubin metabolism
- P59.9 Neonatal jaundice, unspecified
- R17 Unspecified jaundice

KAWASAKI DISEASE

Adam Z. Barkin

BASICS

DESCRIPTION

- Acute inflammatory process involving multiple organs
- Leading cause of childhood-acquired heart disease in developed countries
- Vasculitis is most severe in medium-sized arteries
- Acute cardiac sequelae:
 - Coronary artery aneurysm:
 - Often lead to stenosis after healing
 - Giant aneurysm:
 - May rupture
 - Myocarditis
 - Pericarditis
- Stages:
 - Acute (lasts 1–2 wk):
 - Fever
 - Oral mucosal erythema
 - Conjunctival injection
 - Erythema and edema of hands and feet
 - Cervical adenopathy
 - Aseptic meningitis
 - Hepatic dysfunction
 - Diarrhea
 - Myocarditis
 - Pericardial effusion (20–40%)
 - No aneurysms by ECHO
 - Subacute (when fever, rash, and lymphadenopathy resolve until about 4 wk):
 - Anorexia
 - Irritability
 - Desquamation of hands and feet
 - Thrombocytosis
 - Coronary artery aneurysms (20% if untreated)
 - Risk for sudden death is highest
 - Convalescent phase (about 6–8 wk):
 - Clinical signs are absent
 - ESR normalizes
 - Epidemiology:

- 80% of cases occur in children < 4 yr old; peak at 1–2 yr; rare in infants < 3 mo old
- Adult cases have been reported
- Asians are at highest risk
- Males > females 1.5:1
- Genetics:
 - _ Possible genetic predisposition
- Risks for nonresponse to standard therapy (10–15%):
 - _ Elevated band count
 - _ Low albumin level
 - _ Abnormal initial ECHO
- Risks for development of coronary artery aneurysms:
 - _ Extremes of age
 - _ Male gender
 - _ Prolonged fever
 - _ Persistent fever after treatment
 - _ Delay in diagnosis
 - _ Increased WBC and/or band count
 - _ Low hematocrit
 - _ Significant increase in CRP and/or ESR

ETIOLOGY

- Unknown—believed to be infectious based on manifestations of disease, epidemics, and increased numbers of cases in winter and early spring
- Current theory:
 - _ Activation of immune system in response to infection
 - _ Genetically susceptible host
 - _ May explain why certain ethnicities have higher incidence of disease
 - More prominent in Asian countries

DIAGNOSIS

- Classic diagnostic criteria:
 - _ Fever for 5 days + 4 of the 5 following criteria:
 - Bilateral conjunctival injection
 - Changes in oral mucosa
 - Polymorphous erythematous rash
 - Changes in hands or feet—edema, erythema, desquamation
 - Cervical lymphadenopathy > 1.5 cm (least common)
- Atypical cases can be seen without meeting diagnostic criteria
 - _ Fever for > 5 days + 2 or 3 clinical criteria with ESR > 40 and CRP > 3
 - _ If > 3 of the below can diagnose incomplete Kawasaki disease
 - Albumin < 3

- Anemia for age
- ALT elevation
- WBC > 15,000
- Urine > 10 WBC per high power field
- Platelets > 450,000 after 7 days
- Thrombocytosis
 - Changes in hands or feet—edema, erythema, desquamation
 - Cervical lymphadenopathy > 1.5 cm (least common)

SIGNS AND SYMPTOMS

History

- Temperature > 38.5°C (often spiking) for at least 5 days:
 - Begins abruptly and may last > 2 wk
- Cardiac:
 - Shortness of breath
 - Chest pain
- HEENT:
 - Eyes:
 - Conjunctivitis
 - Photophobia
 - Mouth:
 - Erythema
 - Dry and fissured lips
- Skin rash
- Musculoskeletal:
 - Arthralgia, arthritis
- Neurologic:
 - Extreme irritability
- GI:
 - Diarrhea
 - Vomiting
 - Abdominal pain

Physical-Exam

- Cardiac:
 - Evidence of congestive heart failure
 - Evidence of pericarditis
 - Rub
 - Evidence of valvular disease
 - Murmur
- HEENT:
 - Eyes:

- Bilateral conjunctival injection without exudates
- Bulbar conjunctiva is more frequently involved than palpebral conjunctiva
- Usually within 2 days of onset of fever and lasting 1–2 wk
- Photophobia, uveitis, iritis
- Mouth:
 - Erythema, dry and fissured lips, strawberry tongue, pharyngeal erythema
- Lymph:
 - Cervical lymphadenopathy (node diameter >1.5 cm)
- Neurologic:
 - Irritability
 - Meningismus
- Skin:
 - Rash, primarily on the trunk
 - May be maculopapular, scarlatiniform, or erythema multiforme–like; erythroderma
 - Changes in the hands or feet—erythema, edema (acute phase); unwilling to bear weight
 - Desquamation (subacute phase) of the tips of fingers and toes 2–3 wk after onset of illness
- Genitourinary:
 - Urethritis
 - Meatitis
- GI:
 - Hydrops of the gallbladder

ESSENTIAL WORKUP

Must think of the diagnosis in a febrile child with rash

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - WBC—normally elevated with shift to left in acute phase
 - Normocytic anemia
 - Leukopenia and thrombocytopenia are rare
 - Suspect viral infection
 - Thrombocytopenia is a risk factor for development of coronary artery disease
- Urinalysis:
 - Sterile pyuria
 - Proteinuria

- ESR elevated from 1st wk until 4–6 wk
- Increased C-reactive protein
- CSF pleocytosis
- Cultures: Negative blood, urine, CSF, throat
- Increased transaminases and bilirubin

Imaging

- ECHO to evaluate for coronary artery aneurysm:
 - Acute phase (baseline)
 - 2–3 wk
 - 6–8 wk
- CXR

Diagnostic Procedures/Surgery

- ECG if concern about MI or pericarditis
- Slit-lamp exam—uveitis

DIFFERENTIAL DIAGNOSIS

- Viral infections:
 - Adenovirus
 - Enterovirus
 - Measles
 - Epstein–Barr virus
 - Rubella
 - Rubeola
 - Influenza
- Bacterial infection:
 - Scarlet fever (responds rapidly to penicillin)
 - Staphylococcal scalded-skin syndrome
 - Rickettsial disease, including Rocky Mountain Spotted Fever and leptospirosis
 - Cervical adenitis
- Immune-mediated:
 - Stevens–Johnson syndrome
 - Erythema multiforme
 - Serum sickness
 - Connective tissue disease (i.e., Lupus)
 - Other forms of vasculitis

TREATMENT

PRE HOSPITAL

- ABCs
- Oxygen

INITIAL STABILIZATION/THERAPY

ABCs with focus on cardiovascular system

ED TREATMENT/PROCEDURES

- Initiate IV gammaglobulin (IVIG) and aspirin therapy:
 - Do not generally need to monitor salicylate levels because of decreased absorption and increased clearance
- Treatment within the 1st 10 days of illness reduces cardiac sequelae from range of 20–25% to range of 2–4%.
- Cardiology consultation
- Treatment of MIs as in adults

MEDICATION

First Line

- IVIG: 2 g/kg IV over 10–12 hr; retreatment may be required for persistent (> 48–72 hr) or recrudescent fever:
 - Requires close cardiac monitoring
 - Should be started within the 1st 10 days of illness
 - 3–4% failure rate after 2 doses
- Aspirin: 80–100 mg/kg/d PO q6h until about day 14 when fever has resolved; then 3–5 mg/kg/d PO daily for 6–8 wk. Do not exceed 4g/24 h (peds: Do not exceed 120 mg/kg/24 h):
 - Anti-inflammatory
 - Antiplatelet
 - Potentiates the action of IVIG
 - Reduces the occurrence of aneurysms when given with IVIG
 - Alternative dosing at 30 mg/kg/d during acute and subacute phases

Second Line

If no response to 2nd dose of IVIG

- Corticosteroids:
 - Methylprednisolone 30 mg/kg over 3 hr
 - May improve outcome in conjunction with IVIG

May also consider:

- Infliximab
- Cyclosporine A
- Methotrexate

FOLLOW-UP

DISPOSITION

Admission Criteria

- Admit all patients who fulfill diagnostic criteria for Kawasaki disease
- Admit toxic-appearing patients who do not yet meet the criteria for Kawasaki disease

Discharge Criteria

- Nontoxic children who do not fulfill diagnostic criteria
- Close follow-up is required

Issues for Referral

Cardiology consultation for all patients

PEARLS AND PITFALLS

- Prompt diagnosis and therapy can prevent coronary aneurysms in 95%
- Aspirin and IVIG are mainstays of therapy
- Must consider the diagnosis in febrile children presenting to the ED for multiple visits
- Restrict steroids to children with 2 IVIG failures

KNEE DISLOCATION

Kelly Anne Foley

BASICS

DESCRIPTION

- Defined by the position of the tibia in relation to the distal femur:
 - _ Anterior dislocation:
 - Most common dislocation, accounts for 60%
 - Hyperextension of the knee
 - Rupture of the posterior capsule at 30°
 - Rupture of the posterior cruciate ligament (PCL) and popliteal artery (PA) occurs at 50°
 - _ Posterior dislocation:
 - Direct blow to the anterior tibia with the knee flexed at 90°, “dashboard injury”
 - Anterior cruciate ligament (ACL) is usually spared.
 - _ Medial dislocation:
 - Varus stress causing tear to the ACL, PCL, and lateral collateral ligament (LCL)
 - _ Lateral dislocation:
 - Valgus stress causing tear to the ACL, PCL, and medial collateral ligament (MCL)
- Associated injuries:
 - _ PA injury:
 - Occurs in 35% of dislocations.
 - Anterior dislocations place traction on PA and cause contusion or intimal injury, which may result in delayed thrombosis.
 - Posterior dislocations cause direct intimal fracture and transection of the artery with immediate thrombosis.
 - _ Peroneal nerve injury:
 - Less common than PA injury
 - If present, must rule out concomitant arterial insult
 - Medial dislocation causes injury by traction of the nerve.
 - Rotary injuries have a high incidence of traction and transection.

ETIOLOGY

High-energy injuries such as motor vehicle crashes, auto–pedestrian accidents, and athletic injuries (football most common)

DIAGNOSIS

SIGNS AND SYMPTOMS

- Grossly deformed knee
- Grossly unstable knee in AP plane or on varus/valgus stress
- Lack of distal pulse:
 - PA injury is primary concern.
- Signs of distal ischemia:
 - Pallor, paresthesia, pain, paralysis

History

Mechanism of injury with high level of suspicion

Physical-Exam

- Distal pulses
- Distal nerve function:
 - Hypesthesia of 1st web space, inability to dorsiflex foot
- Ligamentous laxity

ESSENTIAL WORKUP

- History of mechanism of injury
- Complete and careful physical exam:
 - Pulses—palpation, Doppler, ankle–brachial index (ABI), and cap refill
 - Neurologic—sensation to 1st web space and great toe, movement of toes, dorsiflexion of foot
- AP and lateral knee radiographs
- Documented repeat exam if any closed reduction is attempted

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- AP/lateral radiograph of knee:
 - Essential to rule out concomitant fractures
- MRI within 1 wk of injury to define ligamentous injury

Diagnostic Procedures/Surgery

- ABI—likelihood of significant arterial injury requiring surgery low if ≥ 0.9
- Peripheral vascular ultrasonography
- Arteriogram should be considered:
 - High suspicion of PA injury
 - Poor pulses or distal perfusion after reduction
 - Peroneal nerve injury
 - Ischemic symptoms despite normal pulses

DIFFERENTIAL DIAGNOSIS

- Tibial plateau fracture
- Supracondylar femoral fracture
- Ligamentous/tendonous avulsion fracture

TREATMENT

PRE HOSPITAL

- Management of ABCs
- Documentation of pulses and motor response essential
- Splint knee in slight flexion to prevent PA traction or compression.

INITIAL STABILIZATION/THERAPY

- ABCs especially when motor vehicle crash or auto-pedestrian accident
- Fluid resuscitation; hypotension may alter distal pulses and perfusion.
- Closed reduction immediately for any limb ischemia
- Early surgical consult in an open injury or high suspicion of arterial injury

ED TREATMENT/PROCEDURES

- Closed reduction by longitudinal traction and lifting femur into normal alignment without placing pressure on popliteal fossa
- Posterior leg splint/knee immobilizer with knee in 15–20° of flexion
- Repeat neurovascular exam after manipulation and at frequent intervals.
- IV analgesia for patient comfort
- Surgical consult (orthopedic and vascular): Open injury, PA injury, or unable to reduce

MEDICATION

First Line

- Narcotic analgesia IV
- Avoid PO meds, as surgery may be necessary.

FOLLOW-UP

DISPOSITION

Admission Criteria

All patients require admission for observation of limb perfusion and PA repair if necessary.

Discharge Criteria

All patients should be admitted.

Issues for Referral

Eventual repair of ligamentous injuries:

- Usually at 3 wk
- Arthroscopic surgery is contraindicated for 2 wk after injury to prevent compartment syndrome.

FOLLOW-UP RECOMMENDATIONS

- Orthopedics for ligamentous repair
- Vascular for PA injury

PEARLS AND PITFALLS

- Failure to revascularize PA within 6–8 hr: Amputation rate approaches 90%.
- Peroneal nerve injury:
 - Poor prognosis for recovery
- Delayed compartment syndrome may occur.

- S83.126A Posterior disloc of proximal end of tibia, unsp knee, init

KNEE INJURIES: ACL, PCL, MCL, MENISCUS

Ilona A. Barash

BASICS

DESCRIPTION

- Cruciate ligament injuries:
 - Anterior cruciate ligament (ACL):
 - From the posteromedial aspect of the lateral femoral condyle to the intraspinus area on the tibia
 - Prevents excessive anterior translation of the tibia, internal rotation of the tibia on the femur, or hyperextension of the knee.
 - Posterior cruciate ligament (PCL):
 - Twice as strong and twice as thick as the normal ACL, less commonly injured
 - From anterolateral aspect of medial femoral condyle to the posterior tibia
- Meniscal tears:
 - Medial meniscus injury most common
 - More firmly attached to the joint capsule and less mobile than lateral meniscus
 - Tears are the result of tensile or compressive forces between the femoral and tibial condyles
 - Extension of meniscal tear may result in a free segment that may become displaced into the joint, resulting in a true locked joint.
- Medial collateral ligament:
 - From the posterior aspect of medial femoral condyle to the tibia, distal to joint
 - Often accompanied by other injury:
 - Hyperextension with external rotation (ACL/PCL injured 1st)
 - Anterior stress (ACL injured 1st)

EPIDEMIOLOGY

Incidence and Prevalence Estimates

- ACL:
 - Most commonly injured knee ligament
 - 200,000 ACL injuries annually in US
 - 2/3 of all ACL injuries are noncontact
 - Female gender: 3× greater risk
- Associated injuries:

- ~50% ACL injuries are associated with meniscal tears
- ACL injuries commonly have chondral and subchondral injuries
- Meniscus:
 - Medial meniscus injury 10 × more common than lateral
 - True locked joint in only 30%

ETIOLOGY

- Cruciate ligament injuries:
 - ACL: Often deceleration with flexion and rotation, or hyperextension
 - Usually sports-related, especially skiing and football
 - Plant-and-pivot or stop-and-jump mechanism
 - PCL:
 - “Dashboard injury”: Flexed knee with posteriorly directed force to the anterior proximal tibia (motor vehicle crash or direct trauma)
 - Fall on flexed knee
- Meniscus Injury:
 - Sudden rotary motion of knee associated with squatting, pivoting, turning, and bending
 - Common in sports with low stance positions (wrestling/football) or kneeling position (carpet installers, plumbers)
- Medial collateral ligament injuries:
 - Direct trauma to lateral knee
 - Most common: Valgus stress with external rotation on flexed knee:
 - From catching a ski tip
 - Side tackle (football)

Pediatric Considerations

- The ACL is the most frequently injured knee ligament in children.
- Isolated MCL injury infrequent before growth plate closure (< 14-yr old)

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Cruciate ligament injuries:
 - Feeling knee “give way,” pop, tearing sensation
 - Most patients report immediate knee dysfunction, but some may ambulate despite complete ACL rupture because of stability from supporting structures.
 - Large, almost immediate effusion -- patients report significant swelling
- Medial collateral ligament:

- Tearing sensation and immediate pain in medial aspect of knee
- Medial pain and tenderness may be more pronounced with partial tears than with complete tears.
- Medial meniscus injury:
 - Patient may recall the knee “giving way”
 - Inability to fully extend knee is common
 - Effusion is found in 50% and usually occurs over 6–12 hr.
 - Pain is often intermittent and localized to the joint line
 - Unlike ligamentous injury, patients often report completion of activities at time of injury
 - Degenerative meniscal tears tend to have a more insidious, atraumatic presentation, with mild swelling, vague joint line pain, and sometimes with mechanical symptoms. Often associated with osteoarthritis.

Physical-Exam

- Ability to bear weight reduced with all injuries
- Palpate for pain on:
 - bony prominences for fracture
 - growth plates in children
 - medial and lateral joint line (meniscus and collateral ligament injury)
- Range of motion:
 - Locking: May occur with ACL (interposition of torn cruciate), meniscus injury, loose body (arthritis)
 - Pseudolocking may be present from pain, effusion, or spasm
- Effusion:
 - Immediate (within 2–3 hr) usually indicates a significant intra-articular injury including ACL
 - About 70% of acute knee hemarthroses are caused by ACL injury, but lack of effusion does not rule out ACL injury
 - MCL, meniscus, PCL injuries have more delayed effusion (12–24 hr)
 - Warmth, erythema: Consider infection
- Neurovascular exam:
 - Distal pulses
 - 1st dorsal web-space sensation (deep peroneal nerve)
 - Ankle/toe dorsiflexion
- Stress testing: *Always compare the injured to the uninjured side* (asymmetry is more reliable than absolute degree of laxity):
 - Pain and spasm can limit the utility of all stress testing in the acute phase
 - *Lachman test* is most reliable for ACL:
 - Knee flexed 20°, patient supine with thigh supported and hip slightly externally rotated. Quickly bring the tibia forward on the femur, 1 hand holding proximal tibia, the other stabilizing the femur just above the patella, evaluating for quality of the endpoint and degree of

- anterior translation of the tibia
- Pain with motion = partial tear or disruption
- Quantification of degree of movement less important than simply positive or negative interpretation of test
- *Pivot shift test*: More specific for ACL injury but unreliable without anesthesia and painful acutely. Not recommended routinely in the ED.
- *Anterior/posterior drawer sign*:
 - Knee flexed 90°, patient supine, hip flexed 45°, foot neutral and stabilized (sit on foot)
 - Observe for posterior sag of tibia, positive with PCL injury
 - Posterior drawer (PCL): Movement of tibia back with application of posterior pressure
 - Anterior drawer (ACL): Movement of tibia forward with anterior distraction force
- Quadriceps active test (PCL):
 - Patient supine, knee flexed at 90°, hip flexed at 45°
 - Patient attempts to extend knee against examiner's counterforce
 - Positive if the tibia translates anteriorly during quad activation
- Varus/valgus stress testing: Evaluate in extension and 20° flexion for MCL and LCL laxity
- Meniscus: Wait until acute pain is controlled:
 - *McMurray*: While palpating joint lines, extend the knee while internally and then externally rotating. Pain and click is positive.
 - *Apley*: With patient prone, flex knee to 90°, provide axial load and internally/externally rotate lower leg. Pain is positive.

Pediatric Considerations

- Children and adolescents show more laxity on exam than adults
- Examine hip and obtain radiograph if any concern for hip pathology (especially slipped capital femoral epiphysis)
- Have a high suspicion for epiphyseal growth plate injuries

DIAGNOSIS TESTS & INTERPRETATION

Lab

- If cause of knee effusion not clearly traumatic, synovial aspirate can be sent for cell count, Gram stain, culture, crystals
- Arthrocentesis is usually not indicated after trauma except to relieve symptoms from tense effusion

Imaging

- Ottawa knee rules (adults): Plain films required for patients with any of 5

findings:

- Age \geq 55
- Isolated tenderness of patella
- Tenderness at head of fibula
- Inability to flex 90°
- Inability to bear weight both immediately and in ED (4 steps)
- Standard radiography:
 - Obtain on all suspected ACL injuries due to high risk of fractures
 - Important in children to evaluate for tibial spine and growth plate fractures
 - Views: AP, lateral, oblique, notch
 - Special attention to avulsion fractures of the medial/lateral tibial spine and lateral tibial plateau, which can be seen with ACL/PCL injuries and may be more likely to be treated operatively
 - Fat–fluid level for fracture.
- MRI is around 95% sensitive for ACL tears and other intra-articular disorders (menisci, PCL, osteonecrosis, osteochondral lesions, occult fractures) and even more specific, but it is rarely indicated emergently.
- Arteriograms to evaluate vascular integrity for suspected dislocations
- US useful to diagnose cysts and popliteal artery aneurysms

Pediatric Considerations

Ottawa knee rules do not apply to children.

ESSENTIAL WORKUP

- Neurovascular evaluation
- Exclusion of fractures and infection
- Evaluate for multidirectional instability
- Valgus/varus stress at 20° of flexion
- Extensor mechanism function
- Lachman test for ACL injury

DIFFERENTIAL DIAGNOSIS

- Growth plate injury
- Tibial plateau bony injury, other fracture
- Transient knee dislocation
- Transient patellar dislocation
- Hip injury causing referred pain
- Nontraumatic causes of knee effusion and pain including septic joint, gout, osteoarthritis, rheumatoid arthritis

TREATMENT

PRE-HOSPITAL STABILIZATION AND INITIAL THERAPY

- ABC's, ATLS
- Immobilize knee
- Document neurovascular function
- Apply ice, elevate, analgesia

ED TREATMENT/PROCEDURES

- Reduce locked knee from meniscus injury within 1st 24 hr after injury:
 - With patient seated, hang extremity off edge of exam table at 90°: This with analgesia alone may reduce locked joint.
 - Assist with applying gentle traction and rotation of tibia
- Arthrocentesis may afford relief with large effusions and assist in reducing locked joint:
 - Follow with compressive dressing
- Treatment (if no fracture):
 - Rest, Ice, Compression, Elevation
 - Weight Bearing as Tolerated, crutches for comfort if needed
 - May provide knee immobilization for protection, but encourage motion out of brace as much as possible, especially if follow-up may be delayed

MEDICATION

- Pain control: NSAIDs preferred over opioids
- Ibuprofen: 400–600 mg (peds: 5–10 mg/kg) PO QID.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Isolated ACL, PCL, meniscus, or collateral ligament injury rarely requires emergent hospitalization
- Low threshold to admit possible knee dislocations for monitoring
- Fractures often need ORIF to limit post-traumatic arthritis

Discharge Criteria

Most patients can be managed as outpatients with appropriate referral.

Issues for Referral

- Re-exam is recommended at 48 hr if ED exam is inconclusive or if history suggests more significant injury than initial exam demonstrates (i.e., severe symptoms, hearing “pop”).
- Orthopedic referral within 1–2 wk if significant ligamentous injury is present.

- Surgical repair of all lesions may be considered for patients wishing to return to sports or active lifestyles.

PEARLS AND PITFALLS

- Do a careful neurovascular exam, and always examine 1 joint above and below the pain for associated injury or referred pain
- Have a high index of suspicion for a reduced total knee dislocation if patient has multidirectional knee instability or injuries to multiple ligaments
- Do not miss: Knee dislocation, fractures, septic joint, referred pain from hip, neurovascular injury

LABOR

Jonathan B. Walker • James S. Walker

BASICS

Labor denotes the sequence of physiologic occurrences that result in a fetus being transported from the uterus through the birth canal.

DESCRIPTION

- Labor brings about changes in the cervix to allow passage of fetus through birth canal
- Synchronous, coordinated contractions of the uterus
- Contractions progress in magnitude, duration, and frequency to produce dilation of the cervix and ultimate delivery
- Labor is divided into 3 stages:
 - Stage 1 (cervical stage): From onset of uterine contractions to full dilation of cervix
 - Stage 1 is further divided into latent and active phases:
 - In the *latent phase*, uterine contraction with little change in cervical dilation or effacement; contractions are mild, short (< 45 sec), and irregular
 - This is followed by the *active phase*, which begins around time of cervical dilation of 3–4 cm; contractions are strong, regular (every 2–3 min), and last longer (> 45 sec)
 - Stage 2: From onset of complete cervical dilation to time of delivery of infant
 - Stage 3: From time of delivery of baby to time of placental delivery
- Total duration of labor varies with each woman
- Generally, lengths of 1st and 2nd stages of labor are significantly longer for nulliparous woman:
 - Nulliparous: Mean length for 1st stage of labor is 14.4 hr and for 2nd stage of labor is 1 hr
 - Parous: Mean length of 1st stage of labor is 7.7 hr and for 2nd stage of labor is 0.2 hr
- Length of 2nd stage of labor is greatly influenced by “3 Ps”:
 - Passenger (infant size and presentation)
 - Passageway (size of bony pelvis and soft tissues)
 - Powers (uterine contractions)
- Problems with any of these 3 Ps can cause abnormal progression of labor:
 - Fetal malposition, uterine dysfunction, cephalopelvic disproportion
- False labor (Braxton Hicks contractions):
 - Irregular, nonsynchronous contractions of uterus several weeks to days

before onset of true labor, and do not cause cervical dilation

ETIOLOGY

- Premature labor occurs in 8–10% of pregnancies.
- 30–40% of premature labor is caused by uterine, cervical, or urinary tract infections
- Premature rupture of membranes is defined as rupture of amniotic/chorionic membranes at least 2 hr before onset of labor in patient before 37 wk gestation:
 - This occurs in only 3% of pregnancies but accounts for 30–40% of all premature births

DIAGNOSIS

SIGNS AND SYMPTOMS

- Symptoms of labor:
 - Intermittent low abdominal pain with or without low back pain
 - Occurring regularly at least every 5 min
 - Lasting 30–60 sec
- Preterm labor is of sufficient frequency and intensity to bring about changes in dilation or effacement of cervix before 37 wk
- Labor is not associated with vaginal bleeding:
 - Patients with 3rd-trimester abdominal pain or vaginal bleeding should raise suspicion of placenta previa or placental abruption
- Sudden release of clear fluid from vagina or feeling of constant perineal wetness can represent rupture of membranes:
 - This is not always associated with labor but often leads to onset of labor

History

- Gestational age
- Prenatal care
- Previous pregnancies:
 - Complications
 - C-section
- Recent infections

Physical-Exam

- Assess fundal height:
 - Centimeters from pubic bone to top of uterus
 - Correlates with number of weeks after 2nd trimester
 - Can help determine gestational age if unknown
- Sterile pelvic exam to assess cervical dilation and effacement

Do not perform a pelvic exam if vaginal bleeding is present.

ESSENTIAL WORKUP

- Patients presenting in possible labor should have *immediate sterile pelvic exam* to assess dilation, effacement of cervix, and possibility of imminent delivery.
- Bimanual pelvic exam should NOT be done in 3rd-trimester patient with vaginal bleeding until US can be done to assess for placenta previa or placental abruption.
- Patients with suspected rupture of membranes should have sterile speculum exam with visual exam of cervix and collection of fluid from vaginal area
- Suggestive of rupture of membranes:
 - _ Presence of *ferning* when fluid is allowed to dry on a slide
 - _ Presence of *pooling* of fluid in vagina
 - _ *Change of color of litmus paper* from yellow to blue
- Patients with preterm labor and cervical changes should have urinalysis with culture and cervical cultures
- Fetal monitoring should be initiated

DIAGNOSIS TESTS & INTERPRETATION

Lab

- If patient is in labor, CBC, type, and screen should be sent.
- Urinalysis for proteinuria
- In patients with no prenatal care, obtain Rh factor and antibody screen.
- Cervical cultures and urine culture in patients with preterm labor

Imaging

- Not generally needed
- 3rd-trimester patients with abdominal pain and vaginal bleeding should have emergent US to evaluate for placenta previa or abruption.

DIFFERENTIAL DIAGNOSIS

- Braxton Hicks contractions (false labor) are irregular uterine contractions without associated cervical changes:
 - _ Contractions can be every 10–20 min
- Round uterine ligament pain, musculoskeletal back pain
- Other common causes of abdominal pain, such as appendicitis, ovarian cyst, diverticulitis, nephrolithiasis, UTI

TREATMENT

PRE HOSPITAL

- Emergency medical services personnel should place patients in labor on oxygen

- and in left lateral recumbent position to maximize delivery of oxygen to uterus
- Maternal transport of high-risk obstetric patients before delivery results in improved outcomes instead of transfer of neonate after delivery
- Air transport of high-risk obstetric patients has been shown to be beneficial and cost effective
- Patients in labor who are transported by aircraft should have high-flow oxygen available in the event of cabin decompression at high altitudes

INITIAL STABILIZATION/THERAPY

If delivery is imminent (presenting part visible), prepare for immediate vaginal delivery in ED (see “Delivery, uncomplicated”)

ED TREATMENT/PROCEDURES

- Unless delivery is imminent, patient should be sent directly to the labor and delivery (L&D) unit
- If transport to L&D will be delayed, or if transfer to another facility is necessary, these steps should be taken:
 - Consider IV antibiotics for unknown group B Streptococcus status
 - IV hydration with 1 L NS or 5% dextrose in lactated Ringer over 30–60 min
 - Maternal monitoring
 - Fetal monitoring
 - If labor needs to be arrested (premature fetus), begin a tocolytic such as β -agonist terbutaline or magnesium sulfate:
 - Magnesium toxicity is suggested by loss of deep tendon reflexes
 - High doses of magnesium can cause cardiac dysrhythmias and respiratory depression.

MEDICATION

- Magnesium sulfate: 4–6 g IV over 30 min, followed by 2–6 g/hr
- Terbutaline: 0.25 mg SC; may repeat same dose in 30 min

ALERT

Consider antibiotic prophylaxis for patients with history of cardiac lesions.

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients in labor who are not at risk for imminent delivery should be admitted to L&D
- Preterm patients in labor demand immediate obstetric consultation and should be admitted to L&D for further treatment

Discharge Criteria

Patients with false labor may be discharged only after obstetric consultation, confirmation of fetal well-being, and close follow-up is arranged:

- False labor may progress to true labor

PEARLS AND PITFALLS

- If vaginal bleeding is present, must rule out placental abruption or previa
- Do not perform a digital exam if bleeding is present
- Pelvic exam must be sterile in a patient in labor
- False labor may progress to true labor

- Z34.90 Encntr for suprvsn of normal pregnancy, unsp, unsp trimester

LABYRINTHITIS

Amira M. Bass • Charles V. Pollack, Jr.

BASICS

DESCRIPTION

- Inflammatory disorder of the inner ear
- Inflammation decreases afferent firing from the labyrinth
 - CNS interprets the decreased signal as head rotation away from the diseased labyrinth
 - The imbalance in firing from the labyrinth results in spontaneous nystagmus with fast phase away from the pathologic side
- Form of unilateral vestibular dysfunction that typically cause balance disorders and vertigo, and may be associated with hearing loss and tinnitus
- Peak onset 30–60 yr old
- Associated with upper respiratory tract infection in 50% of patients
- Symptoms predominantly with head movement but can persist at rest
- Recovery phase gradual over weeks to months

ETIOLOGY

- 3 most common causes of peripheral vertigo include, benign paroxysmal positional vertigo (BPPV), Ménière disease, and labyrinthitis
- Labyrinthitis:
 - Serous: Viral or bacterial
 - Suppurative: Bacterial
 - Autoimmune: Wegener or polyarteritis nodosa
 - Vascular ischemia
 - Head injury or ear trauma
 - Medications:
 - Aminoglycosides, loop diuretics, antiepileptics (phenytoin)
 - Allergies
 - Chronic
- BPPV:
 - Dislodgement of otoconia debris:
 - Idiopathic: 49%
 - Post-traumatic: 18%
 - Sequela of labyrinthitis: 15%
 - Sequela of ischemic insult

Pediatric Considerations

- Suppurative and serous labyrinthitis:

- Usually secondary to acute otitis media, mastoiditis, or meningitis
- BPPV:
 - Onset 1–5 yr of age
 - Symptoms: Abrupt onset of crying, nystagmus, diaphoresis, emesis, ataxia
 - Recurrences for up to 3 yr
 - Migraine–BPPV complex is the most common etiology of pediatric vertigo
- Ménière disease:
 - Rare before 10 yr of age

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Vertigo:
 - Peripheral vertigo
 - Sudden onset
 - Associated with movement, head position
 - Sensation of room spinning or off balance
- Nausea and vomiting
- Episodes of hearing impairment:
 - Unilateral or bilateral
 - Mild or profound
 - Tinnitus (consider Ménière disease)
- Otorrhea (consider otitis media, tympanic membrane [TM] perforation)
- Otalgia (consider otitis media, mastoiditis, cholesteatoma)
- Associated with recent infections or sick contacts
- Predisposing factors include ear surgery, diabetes mellitus, stroke, migraine, and trauma
- Head/cervical spine trauma is a direct causal agent, as it dislodges inner ear particles
- Associated with family history of hearing loss or ear diseases

Physical-Exam

- Complete head and neck exam
- Inspect external ear (erythema, swelling, evidence of surgery), ear canal (otorrhea, vesicles), and TM and middle ear (perforation, cholesteatoma, middle ear effusion, or otitis media)
- Mastoid tenderness (mastoiditis)
- Ocular exam, including range of movements, pupillary response, and fundoscopy, to assess for papilledema
- Nystagmus:

- Augmented by head movement or rapid head shaking
- Positional
- Horizontal, frequently with rotational component
- Direction is constant
- Attenuates with fixation
- Fatigable
- Complete neurologic and cardiac exams:
 - Assess for other causes of symptoms
 - Cranial nerves, Romberg test, tandem gait, cerebellar function
 - Orthostatic vitals, carotid and vertebral bruits
- May be associated with facial weakness or asymmetry (consider stroke or Ramsay Hunt syndrome), neck pain or stiffness (consider meningitis), and visual changes (consider central cause of vertigo)
- Caloric testing:
 - Irrigate external ear canal with cold water for 20 sec (1st inspect to confirm absence of TM perforation).
 - Normal response causes horizontal nystagmus with the fast phase away from the irrigated ear
 - Labyrinthitis produces partial or complete loss of response
- Dix–Hallpike maneuver:
 - Tests for evidence of BPPV

ESSENTIAL WORKUP

- Careful neurologic exam to exclude central cause of vertigo
- Exclude underlying infections:
 - Acute otitis media, meningitis, mastoiditis, Ramsay Hunt syndrome (herpetic lesions on the TM)
- Orthostatics
- Auditory evaluation

DIAGNOSIS TESTS & INTERPRETATION

- Indicated only if evaluating patients for central vertigo or more unusual etiologies of peripheral vertigo
- Chemistry panel and electrolytes if significant or refractory nausea and vomiting
- Lumbar puncture if clinical suspicion for meningitis or subarachnoid hemorrhage

Lab

- Finger-stick glucose
- Syphilis screening
- Rheumatoid factor
- Chemistry panel and electrolytes

Imaging

- **Indications:**
 - Findings suggestive of central vertigo:
 - Acute or gradual onset
 - Not positional but may be exacerbated by head movements
 - Pure direction—vertical, horizontal, or torsional
 - Direction may change
 - Nonfatigable
 - High cardiovascular risk factors
 - Focal neurologic findings
- **Head CT:**
 - Fine cuts through the cerebellum
- **MRI and MRA:**
 - Evaluate the posterior fossa, the 8th cranial nerve, and the vertebrobasilar circulation
 - Imaging study of choice in patients suspected of central vertigo

ALERT

Consider brain imaging in patients >45 yr, children, and patients with cardiovascular risk factors.

Diagnostic Procedures/Surgery

- **Electronystagmography:** May help in diagnosing difficult cases
- **Infrared nystagmography:** Torsional eye movement can be demonstrated directly

DIFFERENTIAL DIAGNOSIS

- **Peripheral vertigo:**
 - Otitis media
 - Vestibular neuritis
 - Acoustic neuroma
 - Autoimmune inner ear disease
 - BPPV
 - Cholesteatoma
 - Ménière disease (associated tinnitus, “fullness,” or hearing loss)
 - Ootosyphilis
 - Ototoxic drugs (loop diuretics, aminoglycosides, streptomycin, salicylates, ethanol)
 - Herpes zoster (Ramsey Hunt syndrome)
 - Perforated TM
 - Perilymphatic fistula (symptoms accentuated with Valsalva)
 - Post-traumatic vestibular concussion
 - Suppurative labyrinthitis (toxic appearance)
 - Temporal bone fracture
- **Central vertigo—**often presents with symptoms indistinguishable from peripheral

vertigo because the labyrinth has a monosynaptic connection to the brainstem:

- Brainstem ischemia
 - Cerebellar hemorrhage
 - Inferior cerebellar ischemia
 - CNS lesions (tumors)
 - Chiari malformation
 - Multiple sclerosis (paresthesia, optic neuritis)
 - Partial seizures of temporal lobe
 - Vestibular–masseter syndrome (associated masseter muscle weakness)
 - Vestibular migraine (30% have vertigo independent of headaches)
 - Wallenberg syndrome (associated Horner's syndrome, crossed sensory signs)
- Cardiac arrhythmia (presyncopal symptoms)
 - Hypoglycemia (gradual onset, not positional)
 - Hypotension (exacerbated with standing)
 - Cervicogenic disease (onset with rotational neck movement)
 - Hypothyroidism
 - Alcohol or drug induced

TREATMENT

PRE HOSPITAL

- Cardiac monitor for arrhythmia
- Finger-stick glucose to exclude hypoglycemia
- Acute stroke assessment
- Antiemetics for nausea and vomiting
- IV fluids for dehydration
- Fall precautions

INITIAL STABILIZATION/THERAPY

- Bed rest and hydration
- Fall precautions

ED TREATMENT/PROCEDURES

- Medications are minimally beneficial for BPPV
- Avoid chronic use (up to 48 hr) to encourage development of vestibular compensation
- Medications for symptomatic relief:
 - Vestibular suppressants: Diazepam, meclizine, scopolamine
 - Antiemetics: Ondansetron, prochlorperazine, promethazine
 - Corticosteroids: Poor evidence for efficacy
- Debris repositioning is primary therapy for BPPV. Effective relief in 50–80% of patients:

- Epley maneuver
- Vestibular enhancement exercises
- Surgery for failed medical and physical therapy:
 - Posterior canal plugging to occlude canal
 - Nerve section

MEDICATION

- Diazepam (benzodiazepine): 2–10 mg IV; 5–10 mg (0.1–0.3 mg/kg/24 h) PO q6–12h
- Dimenhydrinate: 5 mg/kg/24 h PO, IM, IV, or PR
- Meclizine (antihistamine): 25 mg (50 mg/24 h for patient > 12 yr) PO q6h
- Lorazepam: 0.5–2 mg IV, IM, or PO q6h (peds: 0.05 mg/kg IV/PO q4–8h)
- Ondansetron: 4–8 mg IV, IM, or PO q8h (peds: 1 mo–12 yr and < 40 kg: 0.1 mg/kg IV; > 12 yr and > 40 kg: 4 mg IV)
- Prochlorperazine: 5–10 mg (peds: 0.3 mg/kg/24 h IM or PO for patient > 2 yr old) IV, IM, or PO q6–8h
- Promethazine: 12.5–25 mg (peds: 1.5–2 mg/kg/24 h) IV or PO q4–6h
- Scopolamine (anticholinergic, not approved in pediatrics): 0.4 mg PO q4–6h; 1.5-mg transdermal patch q3d

Pediatric Considerations

Bacterial labyrinthitis:

- Antibiotics IV
- Surgical debridement

Pregnancy Considerations

- Class D medication: Diazepam, lorazepam
- Class C medication: Prochlorperazine
- Class B medication: Famciclovir
- Class B medication: Corticosteroids

First Line

- Meclizine
- Ondansetron for nausea/vomiting

Second Line

- Diazepam or lorazepam
- Prochlorperazine or promethazine (beware dystonic or dysphoric reactions)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Symptoms concerning for an acute stroke or central etiology of vertigo
- Intractable nausea and vomiting
- Severe dehydration
- Unsteady gait

Discharge Criteria

- Tolerate oral fluids
- Steady gait
- Normal neurologic exam
- Avoid driving, heights, and operating dangerous equipment
- Fall precautions
- Arrange neurology or otolaryngology follow-up

Issues for Referral

- Recurrent symptoms
- Concern for cholesteatoma
- Possible severe underlying conditions such as vertebrobasilar ischemia or brainstem tumor will need consultation from neurologist or neurosurgeon

FOLLOW-UP RECOMMENDATIONS

- Vestibular rehabilitation for patients with persistent vestibular symptoms and chronic vertigo due to peripheral vestibular etiology
- Auditory brainstem response test is indicated in younger children.
- Surgical therapy in the form of labyrinthectomy/posterior canal occlusion/vestibular nerve section, etc., can be considered in cases of refractory vertigo and unsuccessful canalith repositioning procedure.

PEARLS AND PITFALLS

- Counsel patients regarding occupation, fall risk, and driving
- Failure to diagnose life-threatening conditions like meningitis, cerebrovascular ischemia, or brain tumors
- Take caution while performing physical maneuvers for BPPV, as violent hyperextension at cervical spine can cause vertebral artery dissection

LACERATION MANAGEMENT

Gordon S. Chew

BASICS

DESCRIPTION

- A laceration is a disruption in skin integrity most often resulting from trauma.
- May be single or multiple layered

ETIOLOGY

Multiple causes

DIAGNOSIS

SIGNS AND SYMPTOMS

Lacerations may be accompanied by:

- Bleeding
- Tissue foreign bodies
- Hematoma
- Pain or numbness
- Loss of motor function
- Diminished pulses, delayed capillary refill

History

- Mechanism and circumstances of injury
- Time of injury
- History of foreign body (glass, splinter, teeth)
- Tetanus immunization
- Comorbid condition or medications that may impede wound healing

Physical-Exam

- Evaluate nerve and motor function.
- Document associated neurovascular injury.
- Assess presence of devitalized tissue, debris from foreign materials, bone or joint violation, tendon injury:
 - Avoid digital exploration if the object is believed to be sharp.

ESSENTIAL WORKUP

- Consider repair in OR if unable to be performed safely within the ED, especially for children requiring deep sedation.
- Consider surgical consultation for complex lacerations, especially involving eyes

and face.

Pediatric Considerations

Assess for possible nonaccidental trauma.

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- Evaluation for possible foreign bodies
- Plain radiography:
 - Soft-tissue views may aid in visualization.
 - Objects with the same density as soft tissue may not be seen (wood, plants).
- US
- CT scan
- MRI with metal precautions

DIFFERENTIAL DIAGNOSIS

- Skin avulsion
- Contusion
- Abrasion

TREATMENT

PRE HOSPITAL

- Obtain hemostasis, or control of bleeding with direct pressure.
- Straighten any flaps of skin whose blood supply may be strangulated.
- Apply splint if needed.
- Universal precautions

INITIAL STABILIZATION/THERAPY

- Airway, breathing, and circulation management (ABCs)
- Control hemostasis.
- Remove rings or jewelry if needed. Swollen fingers with rings can become ischemic.

ED TREATMENT/PROCEDURES

- Time of onset:
 - Lacerations may be closed primarily ≤ 8 hr old in areas of poorer circulation.
 - Lacerations may be closed ≤ 12 hr old in areas of normal circulation.
 - On face, lacerations may be closed ≤ 24 hr if clean and well irrigated.
 - If not closed, wound may heal by secondary intention or by delayed primary closure (DPC) in 3–5 days.

- Analgesia and conscious sedation:
 - Adequate analgesia is crucial for good wound management.
 - Conscious sedation may be required (see “Conscious Sedation”).
- Local anesthetics:
 - Topical:
 - TAC (tetracaine, adrenaline, cocaine)
 - EMLA (eutectic mixture, lidocaine, prilocaine)
 - LET (lidocaine, epinephrine, tetracaine)
 - Local/regional:
 - Lidocaine, bupivacaine
 - Epinephrine will cause vasoconstriction and improve duration of action of anesthetic.
 - Avoid epinephrine in the penis, digits, toes, ears, eyelids, tip of nose, skin flaps (necrosis), and severely contaminated wounds (impairs defense).
 - For patient comfort, inject slowly with small-gauge needle; buffer every 9 mL of 1% lidocaine with 1 mL 8.4% sodium bicarbonate.
 - Consider a 1% diphenhydramine solution in the lidocaine-allergic patient.
- Exploration and removal of foreign body:
 - Indications for removal of a foreign body include:
 - Potential or actual injury to tendons, nerves, vasculature
 - Toxic substance or reactive agent
 - Continued pain
- Irrigation and debridement:
 - Surrounding intact skin may be cleaned with an antiseptic solution (povidone-iodine, chlorhexidine):
 - Do not use antiseptic solution within the wound itself because it may impair healing.
 - Scrub with a fine-pore sponge only if significant contamination or particulate matter.
 - Irrigation with ≥ 200 mL of normal saline (NS):
 - Optimal pressure (5–8 psi) generated with 30-mL syringe through 18–20G needle
 - Try to avoid shaving hair. Clip if necessary:
 - Increased skin infection rate after shaving
 - Never shave or clip eyebrow as it may not grow back with a normal appearance
 - Debride devitalized and contaminated tissue.
- Wound repair:
 - Universal precautions
 - Wounds that cannot be cleaned adequately should heal by secondary intention or DPC.

- Reapproximate all anatomic borders carefully (e.g., skin–vermilion border of lip).
- Consider tissue adhesive for wounds with clean borders, low tension.
- Single-layered closure:
 - Simple interrupted sutures:
 - Avoid in lacerations under tension.
 - Horizontal mattress sutures (running or interrupted):
 - Edematous finger and hand wounds
 - Ideal in skin flaps where edges at risk for necrosis
 - Vertical mattress:
 - For wounds under greater tension
 - 1 stitch that provides both deep and skin closure
 - Half-buried horizontal mattress sutures:
 - Ideal for closing the vertex of a v- or y-shaped laceration where ischemia is a concern
- Multiple-layered closure:
 - Closes deep tissue dead space
 - Lessens tension at the epidermal level, improves cosmetic result
 - Buried interrupted absorbable suture, simple or running nonabsorbable sutures for epidermis
- Dressing:
 - Dress wound with antibiotic ointment and nonadherent semiporous dressing.
 - Inform patient about scarring and risk for infection, use of sunscreen.
 - Apply splint if needed.
- Antimicrobial agents:
 - Uncomplicated lacerations do not need prophylactic antibiotics.
 - If antibiotics are used, initiate before wound manipulation or as early as possible.
 - Lacerations with high likelihood of infection:
 - Animal, human bites, especially to hand (see “Hand Infection”)
 - Contaminated with dirt, bodily fluids, feces
 - Tetanus immunization

MEDICATION

- See “Conscious Sedation.”
- Tetanus (Tdap/Td for adolescents–adults, DTap for peds): 0.5 mL IM
- Local anesthetics:
 - Topical, applied directly to wound with cotton, gauze:
 - EMLA (eutectic mixture, 5% lidocaine, and prilocaine): Apply for 60 min. Note: each g of EMLA contains 2.5 g of lidocaine, do not exceed 3 mg/kg lidocaine
 - TAC (0.5% tetracaine, 1:2,000 adrenaline, 11.8% cocaine): Apply for

- 20–30 min. Apply from 2–5 mL to wound
 - LET (4% lidocaine, 1:1,000 epinephrine, 0.5% tetracaine): Apply for 20–30 min. Apply 1–3 mL. Do not exceed 3 mg/kg lidocaine.
- Injected:
 - Bupivacaine (max.: 2 mg/kg; duration 3–10 hr)
 - Lidocaine (max.: 4.5 mg/kg; duration 1.5–3.5 hr)
- Suture materials:
 - Absorbable:
 - For use in mucous membranes and buried muscle/fascial layer closures
 - Natural: Dissolve < 1 wk, poor tensile strength, local inflammation: Plain gut, chromic gut, fast-absorbing gut (for certain facial lacerations where cosmesis is important)
 - Synthetic braided: Tensile strength diminishing over 1 mo, mild inflammation: Polyglycolic acid (Dexon), polyglactin 910 (Vicryl)
 - Synthetic monofilament: Tensile strength 70% at 1 mo: Polydioxanone (PDS), polyglyconate (Maxon)
 - Nonabsorbable:
 - Greatest tensile strength
 - Monofilament: Nylon (Ethilon, Dermalon), polypropylene (Prolene), polybutester (Novafil) can stretch with wound edema, polyethylene (stainless steel)
 - Multifilament: Cotton, Dacron, silk (local inflammation)
 - Needle types:
 - Cutting (cuticular and plastic) types are most often used in outpatient wound repair.
- Staples:
 - For linear lacerations of scalp, torso, extremities
 - Avoid in hands, face, and areas requiring CT or MRI.
- Adhesive tapes (Steri-Strips):
 - For lacerations that are clean, small, and under minimal tension
 - Avoid in wounds that have potential to become very swollen.
 - Pretreat wound edges with tincture of benzoin to improve adhesion.
- Tissue adhesives:
 - Good cosmetic results have been achieved in simple lacerations with low skin tension.
 - An alternative to sutures/staples, especially in children

FOLLOW-UP

DISPOSITION

Admission Criteria

- Few lacerations by themselves necessitate admission unless they require significant debridement or ongoing IV antibiotics, or are complicated by extensive wound care issues or comorbid processes (head injury, abdominal trauma).
- It is unsafe for a child to return home when nonaccidental trauma is suspected.

Discharge Criteria

- Wounds at risk for infection or poor healing require a wound check within 48 hr.
- Time of suture removal dependent on location and peripheral perfusion:
 - _ Scalp: 7–10 days
 - _ Face: 3–5 days
 - _ Oral: 7 days
 - _ Neck: 4–6 days
 - _ Abdomen, back, chest, hands, feet: 7–10 days
 - _ Upper extremity: 7–10 days
 - _ Lower extremity: 10–14 days
 - _ Overlying joints: 10–14 days

Issues for Referral

- Lacerations of the eye where tear duct injury is suspected require immediate referral.
- Complicated lacerations (tendon involvement) may require further repair in the outpatient surgical office.
- Be sure to discuss temporary skin closure and splinting with your surgical consultant.
- Specific follow-up should be arranged prior to patient discharge.

LARYNGITIS

Yi-Mei Chng

BASICS

DESCRIPTION

- Inflammation of the mucosa of the larynx
- The most common cause is viral upper respiratory infection
- Peaks parallel epidemics of individual viruses
- Most common during late fall, winter, early spring

ETIOLOGY

- Viral upper respiratory infections most common in acute laryngitis:
 - Influenza A and B
 - Parainfluenza types 1 and 2
 - Adenovirus
 - Coronavirus
 - Coxsackievirus
 - Respiratory syncytial virus
 - Measles
 - Rhinovirus
- Bacterial infections much less common:
 - β -Hemolytic streptococcus
 - *Streptococcus pneumoniae*
 - *Haemophilus influenzae* (HiB)
 - *Moraxella catarrhalis*
 - *Bordetella pertussis*
 - Diphtheria
 - Tuberculosis
 - Syphilis
 - Leprosy
- Laryngopharyngeal reflux (LPR) from gastroesophageal reflux disease (GERD) (especially in adults)
- Fungal infections (often associated with inhaled steroid use or immunocompromise)
- Allergic
- Voice abuse or misuse
- Inhalation or ingestion of caustic substances or other irritants
- Autoimmune (rheumatoid arthritis, relapsing polychondritis, Wegener granulomatosis, or sarcoidosis)
- Trauma

- Idiopathic

Pediatric Considerations

- Acute spasmodic laryngitis (spasmodic croup)
- More likely to be infectious.
 - Consider HiB, diphtheria, etc., if not immunized
- Consider foreign body

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Hoarseness
- Abnormal-sounding voice
- Throat swelling
- Throat tickling
- Feeling of throat rawness
- Constant urge to clear the throat
- Cough
- Fever
- Malaise
- Dysphagia

Physical-Exam

- Regional lymphadenopathy
- Stridor in infants
- Hoarse voice
- Pharyngeal erythema, exudates, and/or edema
- Asymmetrical breath sounds in case of foreign body

ESSENTIAL WORKUP

- Acute laryngitis:
 - In most cases, the history and inspection of the throat suffice to distinguish between infectious and noninfectious laryngitis:
 - Infectious laryngitis usually lasts about 7–10 days.
 - Have increased suspicion for epiglottitis in persons who have not had HiB vaccine
- Chronic laryngitis (> 3 wk):
 - The workup should be directed toward chronic infections, GERD, neurologic disorders, and tumors
 - Visualization of the larynx should be performed but may not need to be

done in the ED

- The patient should be referred to an ear–nose–throat specialist for further workup

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Blood tests are not generally indicated:
 - An elevated WBC count is not a reliable way to distinguish between bacterial and viral illness
- Throat culture:
 - Indicated when exam suggests a bacterial infection such as significant exudate in the throat or on the vocal folds

Imaging

Soft-tissue neck films:

- Rarely indicated because fiberoptic laryngoscopy provides a more comprehensive assessment
- Mostly used if epiglottitis or foreign body suspected, though high-risk patients should not be sent to radiology

Diagnostic Procedures/Surgery

Fiberoptic laryngoscopy:

- Red, inflamed vocal cords, with rounded edges
- Occasionally hemorrhage or exudates
- Endolaryngeal pus is more common in bacterial laryngitis than viral
- Demonstration of laryngeal pseudomembrane to distinguish diphtheria from other infectious forms of laryngitis

DIFFERENTIAL DIAGNOSIS

- Asthma
- Epiglottitis
- Esophageal reflux
- Vocal nodules
- Laryngeal or thyroid malignancy
- Croup/laryngotracheobronchitis
- Foreign-body inhalation or other trauma

TREATMENT

PRE HOSPITAL

Supportive care and ambulance transport are not generally indicated

ALERT

- Stridor can mean obstruction of the laryngeal or tracheal parts of the airway, particularly in children
- An otolaryngologist should evaluate laryngitis after trauma to the neck
- Beware of esophageal injuries in laryngitis associated with caustic ingestions
- If there are signs of respiratory distress, epiglottitis should be suspected:
 - Transport sitting up
 - Provide supplemental oxygen
 - Intubation may be difficult or impossible and should only be attempted in patients in extremis

INITIAL STABILIZATION/THERAPY

Stabilization is only required if the patient shows signs of respiratory distress:

- The patient should be managed for epiglottitis
- Supplemental oxygen via a nonrebreather mask
- Orotracheal intubation when time permits in the OR
- The neck should be prepped and the equipment ready for a surgical airway

ED TREATMENT/PROCEDURES

- Antibiotics are not 1st-line therapy in adults with acute laryngitis:
 - In a systematic review of randomized controlled trials investigating the use of antibiotics vs. placebo, antibiotics offered no objective improvement in symptoms over placebo
- Vocal rest (avoid whispering, as it promotes hyperfunctioning of the larynx):
 - If patient must speak, use a soft sighing voice
- Humidified air
- Increase fluid intake
- Analgesics
- Smoking cessation
- Symptoms usually resolve in 7–10 days, if viral cause
- Use of inhaled steroids for laryngitis is controversial and not part of current best practices.

MEDICATION

Depends on cause of laryngitis.

- Mucolytics like guaifenesin if related to upper respiratory infection or allergy
- Acetaminophen or NSAIDs for symptomatic relief if associated with viral syndrome
- Proton pump inhibitors for GERD-related laryngitis:
 - Esomeprazole magnesium: 20–40 mg (peds: 10 mg for patients 1–11 yr) PO daily
 - Omeprazole: 20 mg PO BID
- Diflucan for candidal laryngitis
- If caused by croup: Dexamethasone (0.6 mg/kg) PO or IM × 1

- Antihistamines can dry out the vocal cords, make it harder to clear secretions and exudate
- Cochrane Review found no benefit in using antibiotics to treat acute laryngitis
 - Antibiotics may be considered in high-risk patients or in cases where a positive Gram stain and culture has been obtained

FOLLOW-UP

DISPOSITION

Admission Criteria

- Tuberculous laryngitis:
 - Highly contagious requiring isolation
- Signs of epiglottitis, respiratory distress, neck trauma, or anaphylaxis
- Respiratory compromise

Discharge Criteria

Most patients with uncomplicated laryngitis can be discharged if they have no difficulty breathing and are able to keep adequately hydrated.

Issues for Referral

Refer patients with chronic laryngitis to otolaryngologist. Patients with >3 wk of laryngitis without obvious benign cause should be evaluated with laryngoscopy to rule out more serious conditions such as carcinoma.

FOLLOW-UP RECOMMENDATIONS

- With otolaryngology if not improved in 2–3 wk
- With primary care or gastroenterology if symptoms of GERD

PEARLS AND PITFALLS

- Most acute laryngitis is of viral origin
 - Antibiotics likely with no benefit
- Consider life-threatening causes of altered phonation such as epiglottitis
- Laryngitis not associated with upper respiratory infection may be related to GERD
- Patients with chronic or nonresolving laryngitis should follow up with otolaryngologist

CODES

ICD9

- 464.00 Acute laryngitis without mention of obstruction
- 464.01 Acute laryngitis with obstruction
- 476.0 Chronic laryngitis

ICD10

- J04.0 Acute laryngitis
- J05.0 Acute obstructive laryngitis [croup]
- J37.0 Chronic laryngitis

LARYNX FRACTURE

David Della-Giustina • Katja Goldflam

BASICS

DESCRIPTION

- Direct transfer of severe forces to the larynx
- Simple mucosal tears to fractured and comminuted cartilage:
 - Epiglottis, thyroid, arytenoid, cricoid, corniculate, and cuneiform cartilages

ETIOLOGY

- Rare: 1/5,000–1/42,000 ED visits
- <1% of all blunt trauma
- Directly related mortality is 2–15%
- Blunt or penetrating trauma to the anterior neck associated with motor vehicle or motorcycle crash, assault, or recreational activities.
- Typical mechanism is hyperextension of neck with a direct blow to the exposed anterior neck.
- “Clothesline” injury is a classic mechanism (victim struck in neck by cord, wire, or branch hung across path of travel).
- Iatrogenic injuries from intubation are becoming more common with an aging population.

Pediatric Considerations

Bicycle handlebars:

- Extended neck hits the bar, compressing structures between the bar and vertebral column.

DIAGNOSIS

SIGNS AND SYMPTOMS

- May be delayed for hours
- Blunt trauma recognition is most challenging
- Blood, cervical collar, or polytrauma may distract from subtle findings
- Neck tenderness
- Bruising or abrasions over the anterior neck
- Hoarseness or voice changes
- Hemoptysis
- Dysphonia
- Stridor
- SC or mediastinal emphysema

- Dyspnea
- Pneumothorax
- Loss of normal cartilaginous landmarks of neck
- Difficulty with mechanical ventilation

ESSENTIAL WORKUP

- Endoscopic evaluation should take precedence over radiography, as mucosal edema may contribute to airway compromise more than skeletal injury.
- Cervical spine imaging:
 - Plain radiographs are not very helpful and should not supplant cervical CT scan
- CXR:
 - Identify pneumothorax, SC emphysema, and pneumomediastinum
- CT scan (with IV contrast) of cervical spine with fine cuts of larynx:
 - Contrast may identify vascular injuries
 - Recommended unless the patient is going directly to surgery
 - Useful even in cases of apparently less severe symptoms and minor abnormalities on indirect laryngoscopy
- Pulse oximetry

ALERT

MRI has not gained acceptance:

- Length of time
- Physical demands on injured patient
- Less helpful for skeletal structures

DIAGNOSIS TESTS & INTERPRETATION

Lab

Arterial blood gas potentially useful if the patient is having respiratory difficulty:

- Identifies hypoxia, hypercarbia

Diagnostic Procedures/Surgery

- Fiberoptic laryngoscopy:
 - Visualization of injuries involving the airway, vocal cords, ideally with a nasopharyngoscope
- Angiography:
 - Penetrating injuries
 - Only when concern exists for possible vascular injuries
- CT angiogram offers advantages to conventional angiography:
 - Readily accessible and less invasive
 - Can be rapidly performed
 - Few complications

- Provides useful information on cervical soft tissues, aerodigestive tract, spinal canal, and spinal cord
- Fiberoptic bronchoscopy and esophagoscopy
- Surgery:
 - As indicated by severity of injury
 - Emergent surgical repair if necessary

DIFFERENTIAL DIAGNOSIS

Associated injuries:

- Intracranial injuries (13%)
- Open neck injuries (9%)
- Cervical spine injuries (8%)
- Esophageal injuries (3%)
- Carotid artery injury
- Phrenic nerve injury
- Hypoxic cerebral injury
- Airway edema
- Aspiration pneumonitis
- Air embolism

Pediatric Considerations

- The pediatric larynx is located higher in the neck and is more cartilaginous and mobile than in adults; thus, pediatric patients are more resistant to laryngeal fractures.
- Loosely attached submucosal tissue allows for greater soft-tissue trauma, massive edema, and hematoma formation:
 - With smaller airway diameter, airway compromise can occur rapidly.
- Symptoms can vary from neck tenderness or hoarseness to respiratory distress and stridor.
- CT imaging may not add much to the physical and fiberoptic exam of the child as fractures of the poorly mineralized larynx may not be visualized.

TREATMENT

PRE HOSPITAL

- Cautions:
 - Aggressive airway management may be necessary: Oxygen, suctioning
 - Cervical spine immobilization
 - Injury may be overlooked if patient is intubated pre-hospital for other injuries owing to loss of subjective complaints.
- Controversies:
 - Elective intubation is not advocated.

INITIAL STABILIZATION/THERAPY

Airway management is of primary concern:

- Severe injuries may require operative management.
- Early intubation to preclude progressive respiratory compromise.
- Formal tracheostomy under local anesthesia may be required rather than endotracheal intubation when more severe neck injury is present.
- *Avoid* repeated orotracheal intubation attempts:
 - Proceed to surgical airway.
- Cricothyrotomy for severe maxillofacial injuries and injuries cephalad to cricothyroid cartilage.
- *Avoid* cricothyrotomy if hematoma present over the cricothyroid membrane or there is evidence of cricotracheal disruption.
- Emergent tracheostomy may be the only option to secure an airway.

Pediatric Considerations

- Elective intubation is not recommended.
- Mandatory flexible fiberoptic laryngoscopy
- CT scan if management course is in doubt

ED TREATMENT/PROCEDURES

- Supplemental humidified oxygen
- Elevate head of bed to decrease cerebral and neck soft tissue edema
- Maintain NPO status
- Voice rest as much as possible
- Obtain IV access
- Consult otolaryngologist for surgical evaluation
- Positive end-expiratory pressure and volume-controlled ventilation for severe pulmonary injury associated with acute respiratory distress syndrome or aspiration pneumonitis

MEDICATION

- For laryngeal injury with SC emphysema:
 - Assume that the mucosa of the upper airway has communicated with the deep tissue of the neck:
 - Ampicillin/sulbactam: 1.5–3 g IV (peds: 50 mg/kg IV) q6h
 - Clindamycin: 600–900 mg IV q8h (peds: 25–40 mg/kg/24h IV)
 - Histamine-2 blockers to prevent irritation to mucosal injuries (e.g., ranitidine 150–300 mg IV; peds: 2–4 mg/kg/d div. q6h IV) or proton-pump inhibitors (e.g., pantoprazole 40 mg IV, no pediatric dosing)
- For laryngeal edema, steroids may be indicated:
 - Not routinely used, but may be used for massive edema.
 - Methylprednisolone 250 mg IV q4h (faster acting)
 - Dexamethasone 8–10 mg IV q8h (peds: 0.15–0.6 mg/kg/dose IV)

Pediatric Considerations

If stridor present, consider nebulized racemic epinephrine: 2.25% 0.25–0.5 mL in 2.5 mL NS.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with true laryngeal injuries must be admitted to a monitored setting for observation and airway management; prepare for emergent surgical repair of laryngeal defect.
- Patients with suspected laryngeal injury or highly suspicious mechanism must be admitted to a monitored setting for observation and serial flexible fiberoptic laryngoscopic exams.

Pediatric Considerations

Mandatory admission is recommended in all patients for oximetry, oxygen, and serial fiberoptic laryngoscopic exams.

Discharge Criteria

Patients without evidence of serious laryngeal injury or airway edema or compromise after an appropriate period of observation in the ED (usually 6 hr):

- Patients can appear deceptively normal for several hours after injury; if there is any doubt, admit to a monitored setting.

- S12.8XXS Fracture of other parts of neck, sequela

LEAD POISONING

Vinodinee L. Dissanayake

BASICS

DESCRIPTION

- Lead has multiple mechanisms of toxicity:
 - Binds sulfhydryl groups and affects multiple enzymatic processes
 - Resembles Ca^{2+} thereby interfering with Ca^{2+} -dependent processes, such as cell signaling
 - May have mutagenic potential and play a role in human carcinogenesis
- Distribution:
 - Up to 99% of lead is bound to erythrocytes after initial absorption.
 - Ultimately redistributed into bone:
 - 95% of total body lead in adults
 - 70% of total body lead in children
 - High lead levels in the serum compromise the blood–brain barrier and result in lead entry into the CNS and neurotoxicity.
- Often coexists with iron deficiency; this allows for increased lead absorption in the gut.
- Impairs heme synthesis, leading to elevated free erythrocyte protoporphyrin (FEP); these complex with zinc, resulting in elevated zinc protoporphyrin (ZPP).
- Levels correlate poorly with symptoms:
 - Associated with drops in intelligence quotient (IQ) and increase in violent behavior

ETIOLOGY

- Acute toxicity:
 - Most often due to inhalation of an environmental source or ingestion of substance containing lead
 - Pottery glaze
 - Certain folk remedies
 - Cosmetics
 - Jewelry
 - Weights
 - Home-distilled alcoholic beverages
 - Lead dust from ammunition and primer
- Chronic toxicity:
 - Occupational exposures (usually via inhalation):
 - Battery manufacturing/recycling
 - Bridge painting

- Construction workers
- De-leading
- Electronic waste recycling
- Firing range instructors
- Mining and smelting
- Pottery workers
- Welders
- Home exposures (pediatric poisoning):
 - Lead-based paint inhalation/ingestion from toys and walls
 - Contaminated water from old pipes
 - Lead dust from the clothing of a parent exposed at work
 - Imported foods
 - Folk medicines

DIAGNOSIS

SIGNS AND SYMPTOMS

- Neurologic:
 - Seizures (may be prolonged and refractory)
 - Encephalopathy
 - Learning disabilities
 - Psychiatric disturbances
 - Cerebral edema
 - Peripheral motor neuropathy (wrist drop), classic but rare finding in chronic toxicity
- GI:
 - Colicky abdominal pain (lead colic)
 - Ileus
 - Nausea/vomiting
 - Lead lines on gingival line (Burton lines) appear as bluish tint (indication of lifetime burden, not acute exposure).
 - Hepatitis/pancreatitis
- Cardiovascular:
 - HTN (generally secondary to renal failure)
 - Myocarditis and conduction defects
- Renal:
 - Chronic renal insufficiency with long-term exposure
- Hematologic:
 - Anemia (due to interference with globin chain synthesis)
 - Increases RBC fragility, so decreased RBC life span
- Musculoskeletal:
 - Lead lines from increased Ca^{2+} deposition at epiphyses (do not consist of

- lead itself)
- Decreased bone strength and growth

ESSENTIAL WORKUP

Blood lead level (BLL)

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Whole-BLL:
 - There is no normal BLL
 - In pediatric cases, educational interventions begin at BLL ≥ 10 $\mu\text{g}/\text{dL}$
 - In pediatric cases, chelation therapy is instituted at BLL ≥ 45 $\mu\text{g}/\text{dL}$
 - In adults, chelation therapy is usually considered at BLL ≥ 70 $\mu\text{g}/\text{dL}$
 - 100 $\mu\text{g}/\text{dL}$ may present with severe encephalopathy; cognitive effects increase with rising levels
 - Expect that BLL may rise after treatment is completed due to redistribution
- CBC:
 - For presence of anemia
 - RBC indices and iron studies
- Electrolytes, BUN, creatinine, glucose:
 - For renal insufficiency
- Transaminases, liver function tests prior to chelation administration
- FEP or ZPP

Imaging

- Plain abdominal radiographs to look for radiopaque foreign body
- Long-bone series to look for lead lines (specifically in children)
- Cranial CT and other studies as indicated by patient's condition

DIFFERENTIAL DIAGNOSIS

- Acute toxicity:
 - Acute appendicitis/colitis/gastroenteritis
 - Celiac disease
 - Cholera
 - Distributive shock
 - Encephalopathy
 - Toxic ingestions
 - *Amanita* mushroom poisoning
 - Cyclic antidepressants or other seizure-inducing toxins
 - Organophosphates
- Chronic toxicity:
 - Addison disease

- Guillain–Barré syndrome or other neuropathy
- Vitamin deficiency (B3, B6, or B12)
- Wernicke–Korsakoff syndrome

TREATMENT

PRE HOSPITAL

- Support airway/breathing and circulation
- Cardiac monitoring
- Seizure management

ALERT

- If possible to do so safely, bring containers in suspected overdose or poisoning.
- Decontaminate skin for obvious dermal exposures.

INITIAL STABILIZATION/THERAPY

- ABCs:
 - Cardiac monitor
 - Isotonic crystalloids as needed for hypotension; vasopressors for refractory hypotension
- Naloxone, thiamine, and dextrose (D50W) as indicated for altered mental status
- Cardiovascular:
 - Isotonic crystalloids to support BP
 - Vasopressors for refractory hypotension (rare)
- Neurologic:
 - Treat seizures with benzodiazepines.
 - Assist ventilation for respiratory failure due to neuromuscular weakness.
- Renal:
 - Hemodialysis for renal failure
- Alimentary:
 - Dextrose, enteral, or parenteral feeding may be beneficial

ED TREATMENT/PROCEDURES

- Decontamination:
 - If opacities are seen on upright abdominal film, institute whole-bowel irrigation at 1–2 L/hr of polyethylene glycol until abdominal films are clear
 - Activated charcoal is not effective.
- Evaluate need for chelation therapy:
 - BLL
 - Acuity of exposure
 - Clinical symptoms
 - Consultation with a medical toxicologist or poison center

Adult Considerations

- Most likely exposures are via inhalation and caused by occupational exposure or ethnic products
- Adults with encephalopathy or those with BLL: > 100 mg/dL may need chelation
 - Begin with dimercaprol (BAL) and continue for 5 days
 - Start edetate calcium disodium (CaNa₂ EDTA) after 2nd dose of BAL
- Asymptomatic patients with BLL of 70–100 µg/dL may be treated with an oral chelating agent, succimer (DMSA)
- Chelation is not indicated for asymptomatic adults with BLL < 70 µg/dL

Pediatric Considerations

- Currently, BLL ≥ 10 µg/dL require investigative and educational interventions:
 - Investigation into the cause of the exposure and repeat monitoring must occur
 - Parental education should be initiated
- BLL ≥ 45 µg/dL:
 - Chelation therapy is initiated
 - Asymptomatic children are treated with DMSA
 - Symptomatic children or those with BLL ≥ 70 µg/dL are treated with BAL and CaNa₂ EDTA
 - Consult with medical toxicologist/poison center when chelation therapy is considered

Pregnancy Considerations

- Much controversy about fetal lead toxicity
- Consult maternal–fetal medicine and medical toxicologist/poison center in pregnant patients with elevated BLL.

MEDICATION

- Chelating agents:
 - Dimercaprol (BAL), 3 mg/kg deep IM q4h for 3–5 days if mild to moderate symptoms; 4 mg/kg IM q4h for 5 days for severe symptoms (seizure, encephalopathy):
 - Caution: Contraindicated in patients with peanut allergies
 - Edetate calcium disodium (CaNa₂ EDTA), 50 mg/kg/d as continuous IV infusion (adults and peds) or 1 g/m²/d as continuous IV infusion
 - Treat for 5 days and start 4 hr after BAL
 - Succimer (DMSA):
 - Adults: 10 mg/kg PO q8h for 5 days, then q12h for 14 days
 - Peds: 350 mg/m² q8h for 5 days, then q12h for 14 days
- Dextrose 50%: 25 g (50 mL; peds: 0.5 g/kg D25W) IV for hypoglycemia

- Diazepam: 5–10 mg (peds: 0.1 mg/kg) IV for seizure control
- Lorazepam: 2–4 mg IV or IM
- Naloxone: 0.4–2 mg (peds: 0.1 mg/kg) IV
- Thiamine: 100 mg (peds: 1 mg/kg) IM or IV

FOLLOW-UP

DISPOSITION

Admission Criteria

- Symptomatic lead intoxication
- Children at high risk for re-exposure in their current environment
- Children with difficulty tolerating DMSA
- Pregnant patients with elevated lead levels—consult obstetrics and toxicology.

Discharge Criteria

- Asymptomatic patients not requiring IV chelation therapy
- Chronically exposed patients who do not require admission should be referred for outpatient evaluation
- Ensure home environment is safe for patient prior to discharge
- Ensure pediatric patients tolerate oral chelation therapy prior to discharge

FOLLOW-UP RECOMMENDATIONS

Follow up with medical toxicologist or primary care physician.

PEARLS AND PITFALLS

- Heel sticks may result in falsely elevated BLL; repeat positive blood tests for confirmation
- Secure social worker support to ensure safe home environment prior to discharge
- Inquire and test siblings or family members in a patient with lead toxicity
- Do not give BAL if patient has peanut allergy

LEGG–CALVÉ–PERTHES DISEASE

Sarah V. Espinoza

BASICS

DESCRIPTION

- Idiopathic avascular necrosis of the femoral head in children
- Genetics:
 - Increased frequency with factor V Leiden and anticardiolipin antibodies

Pediatric Considerations

Exclusively a pediatric disease

ETIOLOGY

- Successive vascular occlusions causing characteristic findings
- Growing evidence implicating hypercoagulable states
- May be multifactorial
- Risk factors include tobacco smoke, wood smoke, low birth weight, birth length < 50 cm
- Progression through 4 stages of disease:
 - Initial stage: Dense femoral head causing intermittent synovitis
 - Fragmentation: Femoral head becomes soft and deforms causing loss of motion
 - Healing: New bone grows into femoral head
 - Residual: Healed femoral head with some deformity
- More common in boys: Male > female, 4:1
- More common among Caucasians
- Most commonly occurs between ages of 3 and 7:
 - Range 18 mo–18 yr
- Bilateral in 10–15% of cases
- Associated with short stature, deprived populations, delayed & disproportionate growth

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Frequently insidious onset
- Limp often presenting complaint
- Pain:

- Aching in hip, groin, anteromedial thigh, or anteromedial knee
- May be mild
- Aggravated by activity, relieved by rest
- Muscle spasm common complaint early in course of disease

Physical-Exam

- Tenderness over anterior aspect of hip joint
- Joint stiffness:
 - Limitation of internal rotation seen earliest
 - Limited abduction
 - Contractures of adductors
- Muscle atrophy and shortening of leg on affected side are late findings
- Otherwise well appearing and afebrile
- May be asymptomatic

ESSENTIAL WORKUP

- Radiographs of hip most important study for diagnosis in ED
- Consider and exclude septic arthritis (usually an acute febrile illness)

DIAGNOSIS TESTS & INTERPRETATION

Lab

- No specific lab studies diagnostic of Legg–Calvé–Perthes (LCP)
- CBC, C-reactive protein (CRP), or ESR, if septic arthritis a concern

Imaging

- Characteristic imaging findings combined with consistent history and physical exam establish diagnosis
- Plain radiographs, MRI, and nuclear scintigraphy (bone scan) are the main diagnostic modalities used
- Hip radiographs:
 - AP & Frog lateral view of affected hip
 - Image both hips to detect contralateral disease
 - Assess stage, extent, and severity
 - Can be normal during 1st 3–6 mo
 - Usually abnormal at time of presentation
 - 5 stages seen in sequence:
 - Cessation of growth at the capital femoral epiphysis; smaller femoral head epiphysis and widening of articular space on affected side
 - Subchondral fracture
 - Resorption of bone
 - Reossification of new bone
 - Healed stage

- CT:
 - Shows precise information on anatomic relationship between femoral head and acetabulum
 - May have role in operative planning, staging
- MRI:
 - Sensitive in the diagnosis of LCP and provides good anatomic images
 - Detects abnormalities earlier than plain radiographs
 - Used to assess the extent of femoral head infarction
 - Variety of findings depending on imaging protocol used
- Bone scan:
 - Precedes x-ray changes by an average of 3 mo
 - Evaluates patterns associated with revascularization and recanalization
- US:
 - Shows effusion in the hip but is not specific for LCP
 - Evaluate for thickening of the synovial membrane
 - Evaluate deformity and containment of femoral head
- Arthrography:
 - Used to evaluate method of treatment

Diagnostic Procedures/Surgery

Arthrocentesis of hip definitive test to exclude septic arthritis if significant concern for this; may need orthopedic consultation

DIFFERENTIAL DIAGNOSIS

- Unilateral involvement:
 - Transient (a.k.a. toxic) synovitis
 - Septic arthritis
 - Osteomyelitis
 - Sickle cell anemia
 - Juvenile rheumatoid arthritis
 - Rheumatic fever
 - Trauma:
 - Femoral neck fracture
 - Hip dislocation
 - Slipped capital femoral epiphysis
 - Tuberculosis
 - Tumor
- Bilateral involvement:
 - Hypothyroidism
 - Epiphyseal dysplasia
 - Gaucher disease

TREATMENT

PRE HOSPITAL

Clinical course is subacute; less likely to present via ambulance

INITIAL STABILIZATION/THERAPY

Not a life-threatening condition; clinical instability mandates identification of alternative diagnosis

ED TREATMENT/PROCEDURES

- Main ED intervention is pain control
- Restrict from vigorous activity
- May need crutches if weight bearing painful

MEDICATION

First Line

Ibuprofen: 10 mg/kg/dose PO q6–8h PRN pain

Second Line

Diazepam: 0.1–0.2 mg/kg/dose (max. 5 mg) PO q6–8h PRN muscle spasm

FOLLOW-UP

DISPOSITION

Admission Criteria

Need for admission rare, indicated for:

- Severe pain or muscle spasm not controlled by PO medications
- Social considerations; bedrest/care at home not possible

Discharge Criteria

- Adequate pain control with PO medications
- Orthopedic follow-up arranged in 1–2 wk

Issues for Referral

- Age of onset shown to affect outcome; onset younger than 6 with better outcome, if older than 8, shown to have poorer outcome
- For more severe disease, a range of treatment options exists, including conservative treatment, orthotics, traction, and surgical osteotomy, determined by consulting orthopedist
- Degenerative arthritis and possible need of a replacement is the main long-term

complication

FOLLOW-UP RECOMMENDATIONS

Orthopedic consultation to determine further management; may be outpatient

PEARLS AND PITFALLS

Abrupt onset, presence of fever, unstable patient, or toxic appearance suggest diagnosis other than LCP.

CODES

ICD9

732.1 Juvenile osteochondrosis of hip and pelvis

ICD10

- M91.10 Juvenile osteochondrosis of head of femur, unspecified leg
- M91.11 Juvenile osteochondrosis of head of femur, right leg
- M91.12 Juvenile osteochondrosis of head of femur, left leg

LEUKEMIA

Linda Mueller

BASICS

DESCRIPTION

- Neoplasms of WBCs that have undergone a malignant transformation
- Hyperleukocytosis:
 - Occurs with WBC $> 100,000/\text{mm}^3$
 - Leads to occlusions of small vessels primarily in brain or lungs
 - Present with confusion, stupor, or shortness of breath

Chronic Myelogenous Leukemia

- Overproduction of granulocytic WBCs (neutrophils)
- Neutrophil function preserved
- Thrombocytosis
- Basophilia
- Philadelphia chromosome present in bone marrow of $> 95\%$

Chronic Lymphocytic Leukemia

- Most common leukemia in adults
- Overproduction of monoclonal lymphocytes
- Cells accumulate in lymph nodes, bone marrow, liver, spleen
- Particularly prone to herpes virus infections

Acute Leukemias

- Proliferation of undifferentiated immature cells:
 - Acute myelogenous leukemia (AML)—immature myeloid cells
 - Acute lymphocytic leukemia (ALL)—immature lymphoid cells (blasts)
- Rapidly fatal

ETIOLOGY

- Cause unknown
- Familial clustering in chronic lymphocytic leukemia (CLL)
- Increased incidence of AML, ALL, and chronic myelogenous leukemia (CML) with ionizing radiation

Pediatric Considerations

- Usually have ALL:
 - Most common pediatric cancer
- 60–80% remission in those who are standard risk

- Better overall prognosis, except if < 1 yr of age
- May develop leukostasis at lower levels
- Allopurinol dose is 3 mg/kg.
- Ceftazidime dose is 50 mg/kg.

Pregnancy Considerations

- 90% of leukemias are AML or ALL.
- Myeloid leukemias are more common.
- CLL is very rare in pregnancy.
- Chemotherapeutics may cause birth defects and/or preterm labor.
- Same prognosis as nonpregnant; do not delay therapy.
- Transfuse earlier than nonpregnant; keep hemoglobin > 9.8 mg/dL.

Geriatric Considerations

More likely to present with CLL and CML

DIAGNOSIS

SIGNS AND SYMPTOMS

Chronic Myelogenous Leukemia

- Asymptomatic
- Fatigue
- Weight loss
- Left upper quadrant pain, tenderness
- Abdominal fullness
- Splenomegaly (most common)
- Later stage:
 - Headaches
 - Bone pain
 - Arthralgias
 - Fever
 - Leukotactic symptoms:
 - Dyspnea
 - Drowsiness
 - Confusion

Chronic Lymphocytic Leukemia

- Asymptomatic
- Fatigue
- Lethargy
- Weight loss

- Lymphadenopathy
- Splenomegaly
- Hepatomegaly

Acute Myelogenous Leukemia

- Fever
- Fatigue
- Pallor
- Headache
- Angina
- Congestive heart failure, dyspnea on exertion
- Bone pain
- Granulocytic sarcoma (isolated mass of leukemic blasts)
- Easy bleeding (thrombocytopenia):
 - Petechiae
 - Ecchymosis
 - Epistaxis
 - Hemorrhage
- Infections (granulocytopenic)
- Organ involvement with advanced ALL:
 - Lymphadenopathy
 - Hepatomegaly
 - Splenomegaly
 - Leukemic meningitis:
 - Headache
 - Nausea
 - Seizures

History

- Radiation exposure
- Exposure to alkylating agents
- Recent viral infection, particularly Epstein–Barr

Physical-Exam

- Signs of bleeding (petechiae, purpura)
- Hepatomegaly and splenomegaly
- Presence of chloromas (AML blast tumors)
- Sausage-like hemorrhagic retinal veins are pathognomic for hyperviscosity.

ESSENTIAL WORKUP

- CBC/platelets:
 - CML:

- WBC range, 10,000–1 million/mm³
- Neutrophils predominate.
- Thrombocytosis in 50%
- CLL:
 - Absolute lymphocytosis >5,000
 - WBC range, 40,000–150,000/mm³
- Acute leukemia (AML/ALL):
 - Anemia
 - Thrombocytopenia
 - Elevation/depression of WBCs

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Electrolytes, BUN, creatinine, glucose, calcium
- Uric acid level:
 - Frequently elevated, especially in ALL
- Lactate dehydrogenase:
 - Increased in acute leukemias
- Coagulation profile:
 - PT/PTT, fibrinogen, fibrin-split products
 - If disseminated, suspect intravascular coagulation.
- Blood/urine cultures if fever
- Arterial blood gases/pulse oximetry for shortness of breath

Imaging

CXR for infectious workup

Diagnostic Procedures/Surgery

- Bone marrow biopsy:
 - Required to make diagnosis
 - CML—hypercellular with myeloid hyperplasia
 - CLL—lymphocytosis (30–100%)
 - Acute leukemia—hypercellular with blast cells, which replace normal marrow
- Leukocyte alkaline phosphatase test:
 - Decreased in neutrophils in CML
- Ph1 chromosome present in CML

DIFFERENTIAL DIAGNOSIS

- CML:
 - Lymphoma

- Myeloproliferative syndromes
- Systemic lupus erythematosus
- Infection—bacterial, fungal, mycobacterial
- CLL:
 - Pertussis
 - Infectious lymphocytosis
 - Cytomegalovirus
 - Epstein–Barr virus/mononucleosis
 - Hepatitis
 - Rubella
- Acute leukemia:
 - Aplastic anemia
 - Leukemoid reactions to infections

TREATMENT

INITIAL STABILIZATION/THERAPY

- 100% oxygen for hypoxia/shortness of breath
- IV access with 0.9% NS
- Initiate platelet transfusion for severe bleeding from thrombocytopenia.
- Begin broad-spectrum antibiotics for fever and granulocytopenia.
- Treat disseminated intravascular coagulation (see “Disseminated Intravascular Coagulation”).

ED TREATMENT/PROCEDURES

- Treat leukostasis:
 - Rehydrate with 500-mL bolus (20 mL/kg) IV 0.9% NS
 - Administer acetazolamide to alkalinize urine.
 - Initiate allopurinol.
 - Arrange for leukapheresis.
 - Whole-brain radiation or dexamethasone for CNS effects
 - Administer hydroxyurea for CML: 20–30 mg/kg single dose daily
- Transfuse packed RBCs for symptomatic anemia:
 - May require irradiated, filtered, and HLA-type–specific blood
- Post-ED treatment:
 - CLL:
 - Chemotherapy
 - Prednisone for immune-mediated thrombocytopenia
 - Radiation to localized nodular masses/enlarged spleen
 - CML:
 - Interferon therapy
 - Chemotherapy

- Bone marrow transplantation
- ALL:
 - Chemotherapy
 - CNS prophylaxis with intrathecal–methotrexate/cranial radiation
 - Bone marrow transplantation
- AML:
 - Chemotherapy
 - Bone marrow transplantation

MEDICATION

First Line

- Aggressive IVF, start with normal saline, then alkalinize
- Packed RBC and platelets as needed

Second Line

- Ceftazidime if febrile
- Allopurinol or rasburicase and diuretics if at risk for tumor lysis

FOLLOW-UP

DISPOSITION

Admission Criteria

- Newly diagnosed leukemia with:
 - Symptomatic anemia
 - WBC > 30,000
 - Thrombocytopenia
- ICU admission for unstable patients with disseminated intravascular coagulation, blast crisis, or bleeding

Discharge Criteria

Asymptomatic patients without significant lab abnormalities

Issues for Referral

Hematology for any patient presenting with new leukemia

PEARLS AND PITFALLS

- Monitor for tumor lysis and secondary hyperkalemia.
- Hyperleukocytosis may present as respiratory failure or hemorrhage.

- C92.10 Chronic myeloid leukemia, BCR/ABL-positive, not having achieved remission
- C95.90 Leukemia, unspecified not having achieved remission

LEUKOCYTOSIS

Sierra Beck • Steven M. Lindsey

BASICS

DESCRIPTION

Definition:

- Any elevation of total number of white blood cells (WBCs) beyond expected value
- Normal range for total WBCs ($/\text{mm}^3$):
 - Adults: 4,500–11,000
 - Children: WBC count decreases with age:
 - Infant, 1 wk old: 5,000–21,000
 - Toddler, 1 yr old: 6,000–17,500
 - Child, 4 yr old: 5,500–15,500
 - Pregnancy:
 - 1st trimester: 5,000–14,000
 - 2nd trimester: 5,000–15,000
 - 3rd trimester: 5,000–17,000
- Normal ranges shift upward with:
 - Exercise
 - Female gender
 - Smoking
 - Daytime hours
- Given wide range of normal values, numbers must be interpreted in clinical context
- Specific subsets
- Neutrophil predominance (neutrophilia):
 - Absolute neutrophil count $>7,500/\text{mm}^3$
 - Half of circulating neutrophils are adherent to blood vessel walls. They can be rapidly released (demarginate) in response to acute stressors. This can double the WBC count.
 - An additional pool of mature neutrophils, immature metamyelocytes, and band neutrophils are stored in the bone marrow. These can be released increasing the neutrophil count typically during inflammation or infection. Release of immature forms results in a “left shift.”
- Lymphocyte predominance (lymphocytosis)
 - Absolute lymphocyte count $>4,000/\text{mm}^3$
 - Stored in the spleen, lymph nodes, thymus, and bone marrow. They are typically released in response to foreign antigens or viral infections
- Hyperleukocytosis (WBC $>100,000/\text{mm}^3$):

- Seen primarily in hematologic malignancies
- Associated with leukostasis which can lead to cerebral infarction, pulmonary insufficiency, death

EPIDEMIOLOGY

- CBC most common test ordered from the emergency department
- Leukocytosis is one of the most commonly found lab abnormalities.
- Elevated WBC count can be found in 17% of ED patients in whom a CBC is checked (Callaham)

ETIOLOGY

- Neutrophil predominance:
 - Demargination/stress reaction:
 - Stress
 - Exercise
 - Surgery
 - Seizures
 - Trauma
 - Hypoxia
 - Pain
 - Vomiting
 - Inflammation:
 - Rheumatoid arthritis
 - Gout
 - Inflammatory bowel disease
 - Infection, generally bacterial
 - Lab error
 - Labor
 - Leukemoid reaction (TB, Hodgkin, sepsis, metastatic CA)
 - Medications:
 - β -Agonist (epinephrine, cocaine, parenteral albuterol)
 - Corticosteroids
 - Lithium
 - Granulocyte colony stimulating factor
 - Metabolic disorders:
 - DKA
 - Thyrotoxicosis
 - Uremia
 - Malignancy, nonhematogenous
 - Myeloproliferative disorders:
 - Chronic myeloid leukemia
 - Polycythemia vera
 - Pregnancy

- Rapid RBC turnover:
 - o Hemorrhage
 - o Hemolysis
- Tissue necrosis:
 - o Cancer
 - o Burns
 - o Infarction
- Lymphocyte predominance:
 - Infection, generally viral, early stages:
 - o Mononucleosis
 - o VZV
 - o CMV
 - o Viral hepatitis
 - Bacterial infection, specifically:
 - o Pertussis
 - o TB
 - o Syphilis
 - o Rickettsia
 - o Babesia
 - o Bartonella
 - Hypothyroidism
 - Immunologic responses:
 - o Immunization
 - o Autoimmune diseases
 - o Graft rejection
 - Lymphoproliferative disease:
 - o Acute lymphocytic leukemia
 - o Chronic lymphocytic leukemia
 - o Non-Hodgkin lymphoma
 - Splenectomy

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Depends upon presenting complaint
- Symptoms suggestive of infection:
 - Cough
 - Fever
 - Rash
 - GI symptoms

- Symptoms suggestive of long-term inflammation:
 - Joint pain
 - Rash
- Symptoms suggestive of malignancy:
 - Weight loss
 - Fatigue
 - Night sweats

Physical-Exam

- Focal signs of infection:
 - Cellulitis/abscess
 - Otitis
 - Pharyngitis
 - Pneumonia
- Signs of malignancy:
 - Hepatosplenomegaly
 - Lymphadenopathy
 - Pallor
 - Bleeding
- Signs of chronic inflammatory conditions:
 - Joint pain and swelling
 - Rash

DIAGNOSIS TESTS & INTERPRETATION

- Interpretation of leukocytosis:
 - Elevated WBC counts are highly nonspecific and rarely change management. They have equal chances of appropriately and inappropriately influencing care
 - Duration of leukocytosis:
 - Hours to days: More likely to be acute event (infection, acute leukemia)
 - Months to years: Chronic inflammatory states or hematologic malignancies (rheumatoid arthritis, solid organ tumors, chronic leukemias, lymphomas)
- Cell count and differential:
 - If obtained be sure to evaluate absolute cell counts, percentile counts will be spuriously elevated if other cell lines are low
 - Look for the presence of a “left shift” (immature cells in circulation). Normal ratio is 1 band cell for every 10 neutrophils in circulation. This may indicate acute infection, or malignancy. Demargination should not cause a left shift.
 - Differential rarely provides additional helpful information and cannot reliably distinguish between bacterial and viral infections.

- Manual differential or peripheral blood smear:
 - Can be ordered if concern for lab error. Nucleated RBCs, or clumped platelets may cause spurious results in automated tests.
- RBC and platelet counts:
 - Low counts may suggest malignancy or bone marrow infiltration
- Pediatrics:
 - Evaluation of young febrile children (< 36 mo):
 - WBC >15,000 is associated with a high risk of serious bacterial infection and in the appropriate clinical context should prompt clinicians to consider antibiotics, blood cultures, and possible admission.
 - Providers should not be reassured by only moderately elevated WBC counts 15–25,000
 - Conversely, the presence of a significantly elevated WBC count >25,000 does not signify more significant illness
 - Crying shown to elevate WBC count 113%

ESSENTIAL WORKUP

- Dependent upon clinical scenario
- Cell count differential with absolute cell counts may be helpful if the etiology is not apparent based on history and physical exam alone, or if hematologic malignancy is considered
- If hematologic malignancy is suspected patients will require peripheral blood smear and bone marrow biopsy following admission

DIFFERENTIAL DIAGNOSIS

See etiology. Narrow diagnosis based on corresponding clinical presentation.

TREATMENT

- Based on underlying disease process.
- Leukostasis secondary to the extremely high WBC counts of malignancy may require acute management with:
 - IV hydration
 - Transfusion
 - Allopurinol
 - Hydroxyurea
 - Hematology consult for leukapheresis

FOLLOW-UP

DISPOSITION

Dependent upon clinical scenario. Avoid making disposition decisions based solely on

the WBC count.

PEARLS AND PITFALLS

- Be aware that the decision making of health care providers is significantly influenced by the presence of a leukocytosis
- Increased admission rate
- Increased number of tests and cost
- Wide variety of conditions can cause a leukocytosis, including normal variants
- Poor sensitivity and specificity for predicting severity of illness
- Extremely high WBC counts typically in the setting of hematologic malignancy can be associated with leukostasis which can be life threatening and require emergent therapy

- D72.828 Other elevated white blood cell count
- D72.829 Elevated white blood cell count, unspecified

LIGHTNING INJURIES

Tarlan Hedayati • Sheila T. Wan

BASICS

DESCRIPTION

- Lightning is a discharge of energy that occurs cloud to cloud (90%) or cloud to ground (10%).
- Exposure to lightning:
 - Brief duration (1–100 msec)
 - Typically occurs during outdoor activity
 - Highest incidence in summer months, between 3 and 6 pm
 - Fatality rate of 8–10%

ETIOLOGY

- Mechanism of injury—electrical:
 - Direct strike (5%)
 - Contact potential (15–25%):
 - Current passes through an object the victim is touching.
 - Side splash (20–30%):
 - Current jumps from nearby object to the victim.
 - Earth potential rise/ground current (40–50%):
 - Current moves through the ground surface and may injure multiple victims.
 - Current moves through hard-wired telephone lines, metallic pipes, or a structure's electrical equipment, causing lightning injury to victims indoors.
 - Upward streamer (10–15%):
 - Negatively charged lightning strikes from a cloud and induces positive current from the ground to rise and meet it to complete the lightning channel.
- Mechanism of injury—trauma:
 - Barotraumas
 - Blunt trauma:
 - Muscle contractions can throw the victim and/or cause a fall.
 - Thermal burn

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Consider lightning strike in unwitnessed falls, cardiac arrests, or unexplained coma in an outdoor setting.
- Conscious patients may report:
 - Muscle aches and pains
 - Chest pain
 - Shortness of breath
 - Extremity pain or discoloration
 - Burns
 - Neurologic deficits including:
 - Paresthesia
 - Dysesthesias
 - Weakness or paralysis
 - Visual disturbance or blindness
 - Headache
 - Confusion or amnesia
 - Hearing loss or deafness
 - Dizziness

Physical-Exam

- HEENT:
 - Blunt head trauma
 - Ruptured tympanic membrane with ossicular disruption (up to 50%)
 - Ophthalmic injuries:
 - Cataracts
 - Corneal lesions
 - Intraocular hemorrhages
 - Retinal detachment
- Neck:
 - Cervical spine injury
- Cardiopulmonary injuries:
 - Primary cardiac arrest:
 - Cardiac asystole:
 - Due to direct current injury
 - May resolve spontaneously as the heart's intrinsic automaticity resumes.
 - Hypertension: Transient
 - Pulmonary contusion or hemorrhage
 - Respiratory arrest:
 - Caused by paralysis of medullary respiratory center
 - May persist longer than primary cardiac arrest and lead to hypoxia-induced secondary cardiac arrest and/or brain injury
- Extremities:

- Fractures/dislocations
- Muscle tears, contusions
- Compartment syndromes
- Mottled or cold:
 - Caused by autonomic vasomotor instability
 - Usually resolves spontaneously in a few hours
- Skin:
 - Burns:
 - May evolve over several hours after injury
 - Discrete entrance and exit wounds are uncommon.
 - Superficial in nature; deep burns uncommon
 - Direct thermal injury is uncommon due to the brevity of electrical currents.
 - Thermal burns can arise from evaporation of water on skin, ignited clothing, and heated metal objects (buckles, jewelry).
 - Feathering pattern of fernlike “burns” are pathognomonic of lightning injuries and resolve within 24 hr.
- Neurologic injuries:
 - Confusion, cognitive or memory defects
 - Altered level of consciousness (>70% of cases)
 - Flaccid motor paralysis
 - Seizures
 - Cerebrovascular accident
 - Fixed dilated pupils due to either serious head injury or autonomic dysfunction
- Shock:
 - Neurogenic (spinal injury)
 - Hypovolemic (trauma)

ESSENTIAL WORKUP

Confirmatory history from bystanders or rescuers of the circumstances of the injury

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Urinalysis for myoglobin (rare)
- Electrolytes for acidosis
- BUN, creatinine for renal function
- Troponin, creatine kinase, and cardiac enzymes for muscle/cardiac damage

Imaging

- CXR:

- Pulmonary edema
- Pulmonary contusion/hemorrhage
- Rib fractures
- Cervical spine radiograph
- Head CT for altered mental status or significant head trauma
- Relevant imaging for specific injuries

Diagnostic Procedures/Surgery

EKG:

- Prolonged QT (most common)
- Nonspecific ST changes
- Premature ventricular contractions
- Atrial fibrillation
- Ventricular tachycardia
- Acute MI (rare)

DIFFERENTIAL DIAGNOSIS

Other causes of coma, cardiac dysrhythmias, or trauma:

- Hypoglycemia
- Intoxication
- Drug overdose
- Cardiovascular disease
- Cerebrovascular accident
- Seizure
- Syncope

TREATMENT

PRE HOSPITAL

- Field triage should rapidly focus on providing ventilatory support to unconscious victims or those in cardiopulmonary arrest:
 - Prevents primary cardiac arrest from degenerating into hypoxia-induced secondary cardiac arrest
 - Conscious victims are at lower risk for imminent demise.
- Spine immobilization for:
 - Cardiopulmonary arrest (suspected trauma)
 - Significant mechanical trauma
 - Suspected loss of consciousness at any time
- Cover superficial burns with sterile saline dressings.
- Immobilize injured extremities.
- Rapid extrication to decrease risk for repeat lightning strikes

INITIAL STABILIZATION/THERAPY

- ABCs
- Standard advanced cardiac life support measures for cardiac arrest
- Diligent primary and secondary survey for traumatic injuries and other causes of collapse/injury:
 - Maintain cervical spine precautions until cleared.
- Treat altered mental status with glucose, naloxone, or thiamine as indicated.
- Hypotension requires volume expansion, blood products, and/or pressor agents.

ED TREATMENT/PROCEDURES

- IV access
- Cardiac monitor and pulse oximetry
- Clean and dress burns.
- Tetanus prophylaxis
- Treat myoglobinuria if present:
 - Diuretics, such as furosemide or mannitol
 - Alkalinize urine to a pH of 7.45 with IV sodium bicarbonate
- Volume expansion:
 - Do not follow burn treatment formulas because lightning burns are rarely the cause of fluid loss.
 - Occult deep burn injury is rare when compared with other types of electrical current injury.
 - Titrate volume administration to urine output.
 - Fluid loading may be dangerous if patient has concomitant head injury.
- Compartment syndrome:
 - Must be distinguished from vasospasm, autonomic dysfunction, and paralysis, which are usually self-limited phenomena.
 - Fasciotomy will rarely be necessary.
- NSAIDs and high-dose steroids have been proposed to reduce long-term neurologic and corneal damage.

MEDICATION

- Furosemide: 1 mg/kg IV slow bolus q6h
- Mannitol: 0.5 mg/kg IV, repeat PRN
- Sodium bicarbonate: 1 amp IV push (peds: 1 mEq/kg) followed by 2–3 amps/L D5W IV fluid

FOLLOW-UP

DISPOSITION

Admission Criteria

- Postcardiac arrest patients
- History of change in mental status/altered level of consciousness
- History of chest pain, dysrhythmias, or ECG changes:
 - May not resolve spontaneously
 - 24–48 hr observation period to identify potentially unstable cases
 - Myoglobinuria
 - Acidosis
 - Extremity injury with or at risk for compartment syndrome

Discharge Criteria

Asymptomatic patients with no injuries

FOLLOW-UP RECOMMENDATIONS

- Close follow-up with subspecialists may be required due to the risk for delayed sequelae:
 - Neurology:
 - Memory deficit
 - Attention deficit
 - Aphasia
 - Sleep disturbance
 - Prolonged paresthesia and dysesthesias
 - Ophthalmology
 - ENT
- Psychology/psychiatry:
 - Anxiety
 - Depression
 - Personality changes
 - Post-traumatic stress disorder

PEARLS AND PITFALLS

- Do not follow burn treatment formulas for lightning burns and injuries.
- Be diligent in the primary and secondary survey so as not to miss occult injuries.
- Have a low threshold to admit and monitor patients with cardiopulmonary complaints, as unstable dysrhythmias may occur 24–48 hr post injury.

- T75.09XA Other effects of lightning, initial encounter

LITHIUM POISONING

Sean M. Bryant

BASICS

DESCRIPTION

- GI absorption is rapid:
 - Regular release: Peak serum levels 2–4 hr
 - Sustained release: Peak serum levels 4–12 hr
- Half-life 24 hr
- Slow distribution (at least 6 hr)
- Volume of distribution 0.6–0.9 L/kg
- Elimination:
 - *Not* metabolized
 - Renal excretion (unchanged)
 - Reabsorbed in the *proximal* tubules by sodium transport mechanism
 - Elimination half-life (therapeutic) is 20–24 hr and prolonged in chronic users
- Therapeutic and toxic indices:
 - Therapeutic and toxic effects occur *only* when lithium is intracellular
 - Narrow toxic-to-therapeutic ratio
 - Therapeutic level 0.6–1.2 mEq/L (postdistribution)
 - Because of small size, renal handling is similar to sodium, potassium, and magnesium
- Risk factors:
 - Acute conditions increasing risk of toxicity:
 - Dehydration (larger percent reabsorbed)
 - Overdose
 - Chronic conditions:
 - Hypertension
 - Diabetes mellitus
 - Renal failure
 - Congestive heart failure
 - Advanced age
 - Dose change
 - Drug interactions
 - Lithium therapy
 - Low-salt diet
 - The following may result in increased serum lithium levels due to decreased renal clearance or exacerbated effects:
 - NSAIDs

- Thiazide diuretics
- ACE inhibitors
- Phenytoin
- Tricyclic antidepressants
- Phenothiazines

ETIOLOGY

- Acute or chronic conditions affecting lithium clearance
- Overdose

DIAGNOSIS

SIGNS AND SYMPTOMS

- Acute toxicity:
 - _ Less common/serious than chronic toxicity
 - _ Neurologic (mild):
 - Weakness
 - Fine tremor
 - Lightheadedness
 - _ Neurologic (moderate):
 - Ataxia
 - Slurred speech
 - Blurred vision
 - Tinnitus
 - Weakness
 - Coarse tremor
 - Fasciculations
 - Hyper-reflexia
 - Apathy
 - _ Neurologic (severe):
 - Confusion
 - Coma
 - Seizure
 - Clonus
 - Extrapyrarnidal symptoms
 - _ GI:
 - Very common
 - Nausea/vomiting
 - Diarrhea
 - Abdominal pain
 - _ Cardiac:
 - Prolonged QT, ST depression
 - T-wave flattening *most common* ECG abnormality

- U-waves
- Serious dysrhythmias (rare)
- Chronic toxicity:
 - _ Neurologic:
 - Most common
 - Same symptoms as acute
 - Severe toxicity includes parkinsonism, psychosis, and memory deficits
 - _ Renal:
 - Nephrogenic diabetes insipidus
 - Interstitial nephritis
 - Distal tubular acidosis
 - Direct cellular damage
 - _ Dermatologic:
 - Dermatitis
 - Ulcers
 - Localized edema
 - _ Endocrine:
 - Hypothyroidism
 - _ Hematologic:
 - Leukocytosis
 - Aplastic anemia

History

- Time of last dose ingested
- Ingestion history:
 - _ Acute (1-time overdose)
 - _ Chronic (scheduled dosing)
 - _ Acute on chronic (overdose in patients who regularly take lithium)

Physical-Exam

Perform complete neurologic exam

ESSENTIAL WORKUP

- Lithium level: Goal = postdistribution:
 - _ Because of prolonged distribution, repeat every 2 hr to ensure trend
- Stratify patient into 1 of 3 categories of toxicity to interpret level and predict toxicity: Acute, acute on chronic, chronic:
 - _ Acute toxicity:
 - Intentional overdose in patient not previously taking lithium
 - Poor correlation between lithium level and symptoms because intracellular distribution has not yet occurred
 - Toxic levels may appear in asymptomatic patients
 - Lithium level > 4 mEq/L may result in toxic sequelae because of

slowed clearance

- Acute on chronic toxicity:
 - Intentional or accidental overdose in patient on lithium therapy
 - Lithium level > 3 mEq/L usually associated with symptoms
- Chronic toxicity:
 - Patients on lithium therapy who progressively develop toxicity secondary to factors other than acute ingestion
 - Stronger correlation between lithium level and symptoms
 - Lithium level > 1.5 mEq/L may correlate with toxicity

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Electrolytes, BUN, creatinine, and glucose levels to determine electrolyte disturbances/renal function
- Aspirin and/or acetaminophen levels as indicated by history
- Urinalysis:
 - Specific gravity

DIFFERENTIAL DIAGNOSIS

- Consider lithium toxicity with altered mental status and fasciculations
- Endocrine:
 - Hypoglycemia
- Toxicologic:
 - Cholinergic substances
 - Heavy-metal poisoning
 - Neuroleptic overdose
 - Black widow/scorpion envenomation
 - Strychnine poisoning

TREATMENT

PRE HOSPITAL

- Transport all appropriate pill bottles to the hospital
- IV access, oxygen, and cardiac monitoring

INITIAL STABILIZATION/THERAPY

- ABCs
- Secure IV access with 0.9% NS
- Cardiac monitor
- Naloxone, thiamine, dextrose (or Accu-Chek) if altered mental status
- Benzodiazepines for seizures

ADDITIONAL TREATMENT

General Measures

- Correct electrolyte abnormalities
- Maintain well-hydrated state
- Continuous cardiac monitoring
- Observe for neurologic changes
- Prevent absorption:
 - Consider gastric lavage only if patient presents within 1 hr of acute life-threatening ingestion and has protected airway
 - Activated charcoal:
 - Lithium is not adsorbed by charcoal
 - Administer 1 dose of activated charcoal if possible coingestants
 - Whole-bowel irrigation:
 - Polyethylene glycol (PEG) solution (GoLytely)
 - Sustained-release lithium products
 - Flushes lithium through gut
 - Administer (2 L/hr per nasogastric tube) until rectal effluent is clear
 - Contraindications include bowel obstruction or perforation, ileus or hypotension, and unprotected airway in obtunded or seizing patient
- Enhance elimination:
 - IV fluids:
 - Rapidly correct any pre-existing fluid deficit with 0.9% NS at 150–300 mL/hr (or 2× maintenance)
 - Saline hydration improves glomerular filtration and decreases proximal tubule reabsorption of lithium
 - Maintain urine output, 1–2 mL/kg/hr
 - Limited value once glomerular filtration rate maximized
 - Sodium bicarbonate offers no additional advantage
 - Loop, thiazide, and osmotic diuretics not recommended:
 - Dehydration may result in worsening toxicity
 - No direct effect on renal reabsorption because lithium is reabsorbed in proximal tubules
 - Kayexalate (sodium polystyrene sulfonate):
 - Animal and human studies indicate some efficacy
 - Complications may include hypokalemia, hyperkalemia, fluid overload, and dysrhythmias
 - Dialysis:
 - Peritoneal dialysis is not recommended
 - Hemodialysis may be recommended for augmenting elimination (see below)
- Hemodialysis is recommended for severe cases or acute ingestions with high levels

indicating imminent toxicity:

- Controversial indications (validated criteria yet to be established):
 - o Severe and progressive neurologic abnormalities
 - o Renal insufficiency
 - o Altered mental status (e.g., placidly tolerating a rectal tube for GI effects would be considered substantial obtundation)
 - o Ventricular dysrhythmia/cardiogenic shock
 - o History of congestive heart failure or pulmonary edema
 - o Acute ingestions with levels $> 4\text{--}5$ mEq/L
 - o Chronic ingestions with levels $> 2.5\text{--}3$ mEq/L
- Endpoint is lithium level < 1 mEq/L
- Repeat lithium level 6 hr after dialysis checking for evidence of redistribution
- May need to repeat dialysis due to rebound effect (redistribution of intracellular lithium)
- May reduce the potential for developing permanent neurologic sequelae with chronic toxicity

MEDICATION

- Dextrose: D50 1 amp: 25 g (peds: D25W 4 mL/kg) IV
- Diazepam: 5 mg (peds: 0.2–0.4 mg/kg) IV q5min until seizures controlled
- Naloxone: 2 mg (peds: 0.1 mg/kg) IV or via endotracheal tube
- PEG solution: 2 L/hr (peds: 2 mL/kg/h) via nasogastric tube
- Thiamine: 100 mg IV

FOLLOW-UP

DISPOSITION

Admission Criteria

- Symptomatic
- Requiring hemodialysis
- Lithium level unchanged, increased, or > 2 mEq/L despite ED intervention
- Moderate to severe symptoms with chronic levels > 4 mEq/L warrant admission to ICU
- Intentional ingestion

Discharge Criteria

Decreasing lithium levels every 2–4 hr in *asymptomatic* patient *and* serum lithium level < 2 mEq/L (nonsuicidal patients)

Issues for Referral

Intentional overdose:

- Psychiatry consultation

FOLLOW-UP RECOMMENDATIONS

Psychiatry follow-up to ensure correct dosing regimen in those with chronic poisoning

PEARLS AND PITFALLS

- Erroneously interpreting a predistribution lithium concentration as “toxic” in patients without symptoms or history of overdose
- Aggressive hydration in patients with pulmonary edema, renal insufficiency, or mental status changes

ADDITIONAL READING

Paul Blackburn

BASICS

DESCRIPTION

-
- In a couple of places (concerning airway and oxygenation) I put one of the references in parentheses to direct the inquisitive to an article in *Annals of Emergency Medicine* that many will not have heard about. This is different than what the format usually directs, and these can very easily be cut.
- Also, following GlideScope and EZ-IO being mentioned, I followed the format seen in other publications of putting the company name and address in parentheses following first mention of the devices in the text. These can obviously be omitted
- Named for German physician Wilhelm Friedrich von Ludwig, who 1st described this in 1836 as a rapidly progressive, gangrenous cellulitis and edema of soft tissues of the neck, floor of the mouth
- Gangrene is serosanguineous infiltration with little or no frank pus or primary abscesses
 - _ Contiguous spread may encircle the airway or involve the mediastinum
 - _ Emergent interventions rarely include surgical or aspiration techniques
- Most deaths are due to airway compromise, occlusion, and resultant asphyxia
 - _ Mortality exceeded 50% in preantibiotic era, currently <8%

ETIOLOGY

- Odontogenic in 90% of adult cases, usually from 2nd, 3rd mandibular molars
- Less commonly: Mandibular fractures, oral lacerations, contiguous infections, errant drug injections, tongue piercings
- Polymicrobial: *β-hemolytic strep* commonly associated with anaerobes such as peptostreptococcus, pigmented bacteroides
 - _ Microbiologic analyses may guide therapy

Pediatric Considerations

- Frequently no clear etiology or site of origin
- Ideally, a destination facility will have specialty expertise available (surgery and subspecialties, anesthesia) and be properly equipped to provide emergent intervention

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Nonspecific constitutional symptoms: Fever, malaise, anxiety
- Pain: Tongue, throat, jaw, chest, neck stiffness
- Dysphagia, dysphonia
- Dentition, dental care suboptimal

Physical-Exam

- Febrile, toxic, tripod “sniffing” posture
- Stridor, “hot potato” voice
- HEENT:
 - Tongue progressively displaced upward in both posterior, anterior directions at unpredictable rate
 - Airway increasingly compromised
 - Drooling, salivary incontinence
 - Trismus impedes diagnosis and complicates treatment measures
- Physical exam findings beyond those of the head and neck area are often noncontributory or unrelated

ESSENTIAL WORKUP

- The diagnosis is usually clinically evident
 - No study or procedure needed to confirm the diagnosis
- Loss of airway patency can be unexpected, precipitous, and calamitous
- Securing airway patency and initiating treatment take precedent over workup considerations

DIAGNOSIS TESTS & INTERPRETATION

Lab

No test will establish the diagnosis; assess severity or direct therapy

Imaging

Contrast-enhanced CT:

- CT of the neck with IV contrast enhancement is the study of choice:
 - Standard cross-sectional imaging extends from skull base to aortic arch
 - Best for evaluating the mediastinum, deep space infection location and extent, degree of airway involvement.
 - Findings include streaky or “dirty” fat in areas of inflammation; adenopathy (submandibular, submental, anterior and posterior cervical chains); perhaps pus or gas formation
 - Potential limitations: Patient must remain supine for the study duration. Scanning location often away from optimal resuscitation, intervention capability.

Plain Radiographs:

- **Soft tissue lateral neck x-ray** may demonstrate altered anatomy, especially in the upper airway
- **Chest x-ray** of little utility, including detecting presence and extent of mediastinal involvement
- **Panorex** may detect odontogenic or mandibular pathology, but of no use imaging soft tissue

Contrast-enhanced MRI:

- Information obtained is the same, of no greater value than contrast-enhanced CT:
 - Potential limitations: patient must remain supine, motionless for the study duration. Scanning location often away from optimal resuscitation, intervention capability.

Ultrasound:

- Detects gas in tissues, abscesses, reactive lymphadenopathy
- May locate, outline the airway amongst edematous, distorted tissues of the anterior neck
- A guide for abscess or fluid aspiration

Diagnostic Procedures/Surgery

No surgery or invasive procedure will establish the diagnosis, assess severity, or direct therapy

DIFFERENTIAL DIAGNOSIS

- Infectious: Cellulitis, epiglottitis, tracheitis, peritonsillar abscess
- Traumatic: Penetrating injury, sublingual hematoma from fracture, soft tissue injury
- Angioneurotic edema
- Neoplasia

TREATMENT

PRE HOSPITAL

- Transport in position of comfort
 - Allow adult tripod “sniffing” position, to suction themselves
 - Allow pediatric transport, simple interventions (blow-by O₂, nebulizer treatments) on mother’s lap
- Maximize oxygenation:
 - FIO₂ of 100%
 - Consider concurrent O₂ delivery systems, such as facemask and nasal cannula
- Jet insufflation: An infrequently used temporizing rescue device for oxygenation
 - Potential limitations: Few experienced with device assembly or use.

- Newer rescue devices easier to place and use.

Pediatric Considerations

- Minimize patient upset, agitation
 - Allow transport, simple interventions (blow-by O₂, nebulizer treatments) in parent's embrace.
 - Question the necessity for any interventions: IV access, blood draws, O₂ mask, monitor leads.
 - Transport to facility best able to care for this complex patient if possible.

INITIAL STABILIZATION/THERAPY

Airway Measures

- Maximize oxygenation
- Maintain in position of comfort
- Gather supplies/personnel for back-up airway techniques
- See “Airway Management” below.

Vascular Access

- Vascular access: Provides rapid, titratable, predictable medication delivery
 - Intraosseus (IO) access useful with poor peripheral access, resuscitations, pediatric access, adverse prehospital conditions
 - Commercially available device provides IO access rapidly, effectively
- 2nd access recommended: Rescue backup, concurrent polypharmacy.

ED TREATMENT/PROCEDURES

- Immediate priorities are to secure the airway and to institute medical treatment. Diminishing consensus on need for acute surgical intervention other than airway related.
- Infrequently see treatable abscess formation, fluid collections on initial presentation.

Airway management:

- Rescue airway devices may be difficult to place, altered effectiveness due to anatomy distortion, trismus, excessive secretions
- Avoid blind intubation techniques to reduce laryngospasm, iatrogenic injury, bleeding, further tissue distortion
- Equipment considerations:
 - Smaller ET tubes
 - Prelubricate with gel or viscous lidocaine
 - Use stylet or bougie for tube support
 - Bend distal tube into “hockey stick” shape
- Rapid-sequence intubation (RSI) agents may cause abrupt loss of muscle tone, airway architecture, or precipitate airway compromise

- Concern for impending respiratory failure increases with stridor, voice change, trismus, tripod posture, sialorrhea

Definitive management:

- Traditional surgical gold standard: Tracheostomy using local anesthesia:
 - Potential difficulties: Surgeon, specialist availability, facility capabilities not uniform
- Traditional nonsurgical gold standard intubation using fiberoptic guidance:
 - Potential difficulties: Fiberoptic scopes expensive, fragile, require specific cleaning regimens. Short scopes often lack suction or irrigation ports, visualization easily impaired. Their use is not intuitive to the infrequent operator
- **Best management option “double setup”**
 - Patient in an operating theater equipped, prepared to establish surgical airway
 - Nonsurgical intervention attempted
 - Immediate surgical intervention if unsuccessful or clinical deterioration
- **Intubation:** Anticipate distorted anatomy:
 - Sitting, awake a preferred option
 - Sequential topical applications

MEDICATION

- **IV administration:** Preferred route of administration as previously outlined
- IO considerations:
 - Lidocaine flush reduces infusion pain
 - Flow rates same as IV for routine fluids, medication administration
 - Avoid hyperosmolar agents, potential marrow injury
- **Antibiotics:** Empiric use of broad-spectrum antibiotics justifiable, for use until return of culture and antibiogram results, which should direct further therapy:
 - Ampicillin/sulbactam: 1.5–3 g IM/IV q6h (peds: 300 mg/kg/d div. q6 if <1yr, <40 kg; 1.5–3 g IV q6h if >1 yr, >40 kg); max. 12 g/d
 - Cefoxitin: 1–2 g IV q6–8h (peds: 80–160 mg/kg/d div. q4–6h); max. 12g/d
 - Clindamycin: 600–900 mg IM/IV q8h (peds: 15–25 mg/kg/d div. q6–8h)
 - Piperacillin/tazobactam: 3.375 g IV q6h (peds: If >9 mo, <40 kg; 300 mg/kg/d IV div. q8h)
 - Ticarcillin/clavulanate: 3.1 g IV q4–6h (peds: If >3 mo, <60 kg; 200–300 mg/kg/d div. q4–6h)
- **Analgesia:** Pain control should be a primary concern
- **Antiemetics:** Proactive, prophylactic use for medication-related or condition-induced symptoms
- **Steroids:** Recommend empiric use of longer acting steroids to reduce:
 - swelling
 - inflammation
 - systemic stress dose replenishment

- **Hyperbaric oxygen:** Consider if mediastinitis or necrotizing fasciitis

FOLLOW-UP

DISPOSITION

Admission Criteria

- All are admitted:
 - Airway encroachment and obstruction can be progressive and unpredictable
- ICU or closely monitored setting due to unpredictable progression of symptoms

Issues for Referral

- This is a clinical diagnosis with unpredictable progression:
 - Early specialty consultation is necessary for possible assistance with airway management or drainage
- Early transfer to higher level of care if the illness acuity exceeds the clinician's level of expertise or if the facility is not adequately equipped for such management

Pregnancy Considerations

- Mother is susceptible to all aspects and complications as nongravid patients
- Focus: Airway management, oxygenation, treatment of sepsis if present

Geriatric Considerations

Chronic comorbid conditions, chronic medications, less physiologic reserve can all complicate the presentation and treatment

COMPLICATIONS

- Asphyxia
- Spread into thoracic cavity:
 - Empyema
 - Mediastinitis
 - Lung abscess
- Pericarditis
- Internal jugular vein thrombosis
- Carotid artery erosion and/or infection
- Sepsis/bacteremia
- Subphrenic abscess

PEARLS AND PITFALLS

Pearls:

- Prepare to manage airway immediately

- Consult appropriate medical specialists as soon as possible, whether for transfer to a higher level of care, or to the operating suite for “double setup” management
- Video laryngoscopy is intuitive and easy to use, provides rapid, safe, high probability intubation success

Pitfalls:

- Failure to appreciate the progressive nature, unpredictable rate, extent of advancement
- Diagnostic testing and/or imaging should not delay definitive airway management or other therapy

ICD10

K12.2 Cellulitis and abscess of mouth

LUNATE DISLOCATION

Emi M. Latham

BASICS

DESCRIPTION

- Dislocation of the lunate relative to the radius and distal row of metacarpals, most are volar but can be dorsal.
- Usually from high-energy hyperextension with ulnar deviation of the wrist.

ETIOLOGY

- Implies disruption of all 4 perilunate ligaments and radiocarpal ligament (Mayfield classification, stage IV)
- In volar dislocations, median nerve injury occurs in the carpal tunnel.
- Associated fractures of the radial styloid, scaphoid, capitate, and triquetrum are common and, if present, should raise suspicion of an occult perilunate ligamentous injury.

DIAGNOSIS

SIGNS AND SYMPTOMS

Frequently missed injury.

History

- Often from fall or motor vehicle accident.
- Pain and tenderness in the wrist.

Physical-Exam

- Mass or swelling in the wrist, either dorsally or volarly, depending on direction of dislocation.
- Gross deformity can be masked by swelling.
- May display signs of median nerve injury.

ESSENTIAL WORKUP

- Clinical exam is frequently not diagnostic.
- Assess skin integrity and neurovascular status, including 2-point discrimination.
- Radiographs as outlined below.

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- Radiographic imaging to include 3 views of the wrist.
- Lateral view most useful:
 - Disruption of the normal imaginary longitudinal line through the centers of the radius, lunate, and capitate indicates dislocation or subluxation.
 - In volar dislocations, the lunate is frequently tilted with the opening of the “cup” toward the palm (spilled teacup sign)
- Posteroanterior (PA) view:
 - The dislocated lunate has a triangular (as opposed to the usual quadrangular) appearance.
 - Disruption of a smooth and continuous arc formed by the radiocarpal row suggests lunate dislocation.

Pediatric Considerations

Radiograph can be difficult to interpret unless full ossification is present.

Geriatric Considerations

Other fractures are common.

DIFFERENTIAL DIAGNOSIS

- Lunate fracture.
- Perilunate dislocation.
- Scapholunate dissociation.
- Scaphoid fracture.

TREATMENT

PRE HOSPITAL

- Dress open wounds.
- Immobilize in neutral position.

INITIAL STABILIZATION/THERAPY

Immobilize in position of comfort with a volar or “sugar tongs” splint.

ED TREATMENT/PROCEDURES

- Identify multiple trauma or other injuries.
- Contact a hand surgeon for immediate reduction and possible operative intervention.
- Closed reduction can be difficult or unstable.
- Open reduction and internal fixation are frequently required.

Pediatric Considerations

Although serious injury is unusual, children with wrist pain should be splinted and

referred for ongoing evaluation of possible occult fractures.

MEDICATION

First Line

Analgesics:

- **Morphine:**
 - Pediatrics: 0.05–0.20 mg/kg IV up to 1.5 mg. Use preservative-free formulation q4h
 - Adults: 4–8 mg IV
- **Acetaminophen with hydrocodone:**
 - Pediatrics > 12 yo: 2.5–10 mg hydrocodone every 4–6 h to max 60 mg/24 h or 4 g acetaminophen/24 h.
 - Adults: 5–10 mg hydrocodone ever 4–6 h as needed not to exceed 60 mg/24 h or 4 g acetaminophen/24 h
- **Acetaminophen with codeine (adults):**
 - Pediatrics: 0.5–1 mg/kg/dose based on codeine content PO q4–6h; do not exceed 5 doses of 10–15 mg/kg/24 h of acetaminophen
 - Adults: 30–60 mg/dose PO q4–6h; do not exceed 4 g/24 h of acetaminophen
- **Hydrocodone and acetaminophen:**
 - Pediatrics < 12 yr old: 0.1–0.2 mg/kg based on hydrocodone content PO q4–6h; do not exceed 5 doses of 10–15 mg/kg/24 h of acetaminophen
 - Pediatrics > 12 yr old: 750 mg apap PO q4h, not to exceed 10 mg hydrocodone per dose
 - Adults: Do not exceed 4 g/24h of acetaminophen PO q4–6h

Second Line

NSAIDs:

- **Ibuprofen:**
 - Pediatrics: 5–10 mg/kg q6–8h, max. dose 40 mg/kg/d PO div. TID/QID
 - Adults: 600 mg PO q6h
- **Naproxen:**
 - Pediatrics > 2 yr old: 2.5 mg/kg/d PO BID (not to exceed 10 mg/kg/d)
 - Adults: 250–500 mg PO BID
- **Acetaminophen with codeine (pediatrics):**
 - Patients may metabolize codeine at variable speeds: poor metabolizers which may lead to under-response, or "ultra-fast" metabolizers which can lead to high levels of morphine, hence undesirable side effects such as apnea and death.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Admission is often necessary for definitive care.
- Open fracture, presence of multiple trauma, or other more serious injuries mandates admission.

Discharge Criteria

Patients with closed dislocations or fractures that have been adequately reduced and immobilized in the ED may be discharged with orthopedic follow-up.

FOLLOW-UP RECOMMENDATIONS

- For those reduced and discharged with splint, follow-up with orthopedics.
- No return to play until fully healed.

PEARLS AND PITFALLS

- Failure to diagnose wrist dislocations.
- Missed median nerve injury.
- Avascular necrosis of the lunate (Kienböck disease)
- Degenerative joint disease.

LYME DISEASE

Moses S. Lee

BASICS

DESCRIPTION

- Most common tick-borne illness in North America
- Endemic in Northeast, Upper Midwest, and northwestern California

ETIOLOGY

- Peak April–November; 80–90% in summer months
- Spirochete *Borrelia burgdorferi* introduced by Ixodes tick:
 - *Ixodes dammini* (deer tick) most common
- < 50% of patients recall tick bite.
- Pathogenesis—combination of:
 - Organism-induced local inflammation
 - Cytokine release
 - Autoimmunity
- No person-to-person transmission
- *Borrelia miyamotoi*, a spirochete related to *B. burgdorferi*, has recently been described as causing disease similar to Lyme disease.

DIAGNOSIS

SIGNS AND SYMPTOMS

Stage I (early):

- Onset few days to a month after tick bite (arthropod transmission)
- 30–50% of patients recall tick bite.
- Erythema chronicum migrans (ECM):
 - Pathognomonic finding:
 - Bull's-eye rash
 - Maculopapular, irregular expanding annular lesion:
 - Single or multiple
 - Central clearing with red outer border
 - Diameter > 5 cm
- Regional adenopathy
- Low-grade intermittent fever
- Headache
- Myalgia
- Arthralgias
- Fatigue

- Malaise

Stage II (secondary, disseminated):

- Days to weeks after tick bite
- Intermittent and fluctuating symptoms with eventual disappearance
- Triad of aseptic meningitis, cranial neuritis, and radiculoneuritis:
 - Facial (Bell) palsy most common cranial neuritis
 - May present without rash
 - Prognosis generally good
- Cardiac:
 - Tachycardia
 - Bradycardia
 - Atrioventricular block
 - Myopericarditis

Stage III (tertiary, late):

- Onset > 1 yr after disease onset
- Acrodermatitis chronica atrophicans:
 - Extensor surfaces of extremities, especially lower leg
 - Initial edematous infiltration evolving to atrophic lesions
 - Resembles scleroderma
- Arthritis:
 - Brief arthritis attacks
 - Monoarthritis
 - Oligoarthritis
 - Occasionally migratory
 - Most common joints (descending order):
 - Knee
 - Shoulder
 - Elbow

Other:

- GI:
 - Hepatitis
 - Right upper quadrant pain
- Ocular:
 - Keratitis
 - Uveitis
 - Iritis
 - Optic neuritis
- Jarisch–Herxheimer reaction:
 - Worsening of symptoms a few hours after treatment initiated
 - More common in patients with multiple ECM lesions
- Babesiosis occurs simultaneously in endemic areas.

Persistent Lyme disease:

- Articular and neurologic symptoms despite treatment:

– Chronic axonal polyneuropathy or encephalopathy

Recurrent Lyme disease:

- Relapse despite treatment
- 2nd episodes less severe

Pediatric Considerations

- More likely than adults to be febrile
- Only 50% of children with arthralgias have history of ECM.
- Facial palsy is accompanied by aseptic meningitis in 1/3.
- Asymptomatic cardiac involvement with abnormal ECGs
- Appropriately treated children have excellent prognosis for unimpaired cognitive functioning.
- Untreated children may have keratitis

Pregnancy Considerations

No clear evidence that Lyme disease during pregnancy causes harm to fetus

History

- History of tick bite in endemic areas
- Flu-like illness in the summer

Physical-Exam

- Rash
- Joint, cardiac, and neurologic findings in later organ involvement

ESSENTIAL WORKUP

- Clinical diagnosis:
 - Presence of ECM obviates serologic tests.
- Careful search for tick
- Lumbar puncture when meningeal signs
- Arthrocentesis for acute arthritis
- ECG

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - Leukocytosis
 - Anemia
 - Thrombocytopenia
- ESR:
 - > 30 mm/hr

- Most common lab abnormality
- Electrolytes, BUN, creatinine, glucose
- Liver function tests:
 - Elevated liver enzymes (γ -glutamyl transferase most common)
- Culture:
 - Low yield
 - Not indicated
- CSF:
 - Pleocytosis
 - Elevated protein
 - Obtain CSF spirochete antibodies.
- Special tests:
 - Serology:
 - Obtain ELISA, immunofluorescence assay, and western blot when disease is suggested without ECM lesion.
 - Antibodies may persist for months to years.
 - Positive serology or previous Lyme disease does not ensure protective immunity.
 - Polymerase chain reaction assay:
 - Highly specific and sensitive
 - Not available for routine use
 - Joint fluid:
 - Cryoglobulin increased 5-fold compared with serum
 - Joint films may show soft tissue, cartilaginous, osseous changes.

DIFFERENTIAL DIAGNOSIS

- Other tick-borne illnesses:
 - Deer tick usually larger (1 cm) than Ixodid ticks (1–2 mm)
 - Rocky Mountain spotted fever
 - Tularemia
 - Relapsing fever
 - Colorado tick fever
 - Tick-bite paralysis
- Rheumatic fever:
 - Rash of erythema marginatum
 - Temporomandibular joint arthritis more common than in Lyme disease
 - Valvular involvement rather than heart block
 - Chorea may be isolated finding.
- Viral meningitis
 - Syphilis
 - Septic arthritis
 - Parvovirus B19 infection—polyarticular arthritis
 - Infectious endocarditis

- Juvenile rheumatoid arthritis
- Reiter syndrome
- Brown recluse spider bite
- Fibromyalgia
- Chronic fatigue syndrome

TREATMENT

INITIAL STABILIZATION/THERAPY

- 20 mL/kg of 0.9% NS IV fluid bolus for dehydration
- IV access for neurologic and cardiac involvement
- Cardiac monitoring
- Temporary pacemaker for heart block

ED TREATMENT/PROCEDURES

- Remove tick:
 - Disinfect site.
 - With blunt instrument, grasp tick close to skin and pull upward with gentle pressure.
- Medications:
 - Aspirin as adjunctive therapy for cardiac involvement
 - NSAIDs for arthritis or arthralgias
- Vaccine (Lymerix) for prevention of disease:
 - A recombinant surface protein
 - For persons in high/moderate risk areas
 - For travelers to endemic areas
 - 3 doses (0–1 mo–2 mo)
- Stage I:
 - Amoxicillin, doxycycline (for those ≥ 8 yr of age), or cefuroxime (21 days)
 - Azithromycin (14–21 days)
 - Parenteral therapy in pregnant patients
- Stage II:
 - Oral therapy for isolated Bell palsy and mild involvement:
 - Amoxicillin with probenecid (30 days) or doxycycline (avoid if pregnant or ≥ 8 yr old; 10–21 days)
 - Parenteral therapy for more severe involvement (meningitis, carditis, severe arthritis):
 - Ceftriaxone, cefotaxime (14–21 days), or penicillin G (14–28 days)
- Stage III:
 - Parenteral therapy:
 - Penicillin G, cefotaxime (14–21 days), or ceftriaxone (14–28 days)

MEDICATION

First Line

- Amoxicillin: 500 mg (peds: 50 mg/kg/24 h) PO TID for those <8 yr of age or unable to tolerate doxycycline.
- Aspirin: 80–100 mg/kg/d (peds: 50–100 mg/kg/d in 6 div. doses) PO; do not exceed 4 g/24 h (peds: Do not exceed 120 mg/kg/24 h or 4 g/24 h)
- Doxycycline: 100 mg PO BID for 14–21 days for children ≥8 yr and adults (except if pregnant)
- Ceftriaxone: 2 g (peds: 100 mg/kg/24 h) IV daily (1st line for late-term disease)

Second Line

- Azithromycin: 500 mg PO daily
- Cefuroxime axetil, 500 mg BID (all ages)
- Cefotaxime: 2 g (peds: 100–150 mg/kg/24 h) IV q8h
- Penicillin G: 20–24 million U IV q4–6h
- Probenecid: 500 mg PO TID

FOLLOW-UP

DISPOSITION

Admission Criteria

- Meningoencephalitis
- Telemetry/ICU admission for carditis

Discharge Criteria

Patients treated with oral therapy

PEARLS AND PITFALLS

- Duration of treatment for later organ involvement will be ≥ 30 days.
- Be aware of coinfections with *Anaplasmosis* and *Babesiosis*.

- A69.21 Meningitis due to Lyme disease
- A69.23 Arthritis due to Lyme disease

LYMPHADENITIS

John Mahoney • Dolores Gonthier

BASICS

DESCRIPTION

- Lymph nodes may be swollen and tender as part of the systemic response to infection:
 - Become engorged with lymphocytes and macrophages
 - May be primarily infected
 - Infection in distal extremity may result in painful tender adenopathy proximally
- Acute suppurative lymphadenitis may occur after pharyngeal or skin infection

ETIOLOGY

- Most frequently caused by bacterial infection
- Most common organisms in pyogenic lymphadenitis:
 - *Staphylococcus aureus*—including resistant strains such as community-associated methicillin-resistant *S. aureus* (CA-MRSA):
 - CA-MRSA risk factors include prior MRSA infection, household contact of CA-MRSA patient, military personnel, incarcerated persons, athletes in contact sports, IV drug users, men who have sex with men
 - Different antibiotic susceptibility than nosocomial MRSA
 - CA-MRSA now sufficiently prevalent to warrant coverage in empiric treatment
 - Suspect CA-MRSA in unresponsive infections
 - Group A β -hemolytic *Streptococcus*
- Cervical lymphadenitis:
 - Usually pharyngeal or periodontal process
 - Streptococcus and anaerobes
- Axillary lymphadenitis:
 - *Streptococcus pyogenes* (group A β -hemolytic *Streptococcus*)
- Nosocomial MRSA:
 - Risk factors: Recent hospital or long-term care admission, surgery, injection drug use, vascular catheter, dialysis, recent antibiotic use, unresponsive infection
 - Resistant to most antibiotics (see “Treatment”)

Pediatric Considerations

- Acute unilateral cervical suppurative lymphadenitis:
 - Most common at age <6 yr

- Group A *Streptococcus*, *S. aureus*, and anaerobes are most common causes

DIAGNOSIS

SIGNS AND SYMPTOMS

- Painful swelling, inflammation/infection of lymph nodes
- Commonly presents simultaneously with acute cellulitis or abscess if pyogenic cause
- Axillary lymphadenitis:
 - Fever, axillary pain, and acute lymphedema of arms and chest, without features of cellulitis or lymphangitis; ipsilateral pleural effusion may be present

History

- Occupation
- Exposure to pets
- Sexual behavior
- Drug use
- Travel history
- Associated symptoms:
 - Sore throat
 - Cough
 - Fever
 - Night sweats
 - Fatigue
 - Weight loss
 - Pain in nodes
- Duration of lymphadenopathy

Physical-Exam

- Extent of lymphadenopathy (localized or generalized)
- Size of nodes:
 - Abnormal size by site:
 - General: > 1 cm
 - Epitrochlear: > 0.5 cm
 - Inguinal: > 1.5 cm
- Presence or absence of nodal tenderness
- Signs of inflammation over node
- Skin lesions
- Splenomegaly
- Enlargement of supraclavicular or scalene nodes is always abnormal

ESSENTIAL WORKUP

- Acute regional lymphadenitis is clinical diagnosis, often part of larger syndrome (cellulitis)
- History and physical exam to reveal infectious source

DIAGNOSIS TESTS & NTERPRETATION

Lab

- WBC is not essential:
 - Possible leukocytosis with left shift or normal
- CBC, Epstein–Barr virus (EBV), cytomegalovirus (CMV), HIV, and other serologies based on clinical findings

Imaging

US or CT in patients who do not improve or progress to suppuration

Diagnostic Procedures/Surgery

Consider percutaneous needle aspiration or surgical drainage in patients who do not improve or progress to suppuration

DIFFERENTIAL DIAGNOSIS

- Common infections:
 - Adenovirus
 - Scarlet fever
 - Cat scratch disease
 - Fungal
 - Herpes zoster
- Unusual infections:
 - Sporotrichosis (rose thorns)
 - Diphtheria
 - West Nile fever
 - Plague
 - Anthrax
 - Typhoid
 - Rubella
- Venereal infections:
 - Syphilis
 - Genital herpes
 - Chancroid
 - Lymphogranuloma venereum
- Other systematic infections causing generalized lymphadenitis:
 - HIV
 - Infectious mononucleosis (EBV or CMV)

- Toxoplasmosis
- Tuberculosis
- Infectious hepatitis
- Dengue
- Drug reaction:
 - Phenytoin
 - Allopurinol
- Silicone implants
- Malignancy
- Rheumatologic disorders
- Systemic lupus erythematosus
- Sarcoidosis
- Amyloidosis
- Serum sickness

Pediatric Considerations

- Kawasaki disease
- PFAPA syndrome (periodic fever, aphthous stomatitis, pharyngitis, cervical adenitis)

TREATMENT

INITIAL STABILIZATION/THERAPY

Ensure airway, breathing, and circulation management and hemodynamic stability

ED TREATMENT/PROCEDURES

- General principles:
 - Antibiotics based on involved primary organ/suspected pathogen (see also “Cellulitis”)
 - Consider local prevalence of MRSA and other resistant pathogens in addition to usual causes
 - Usual outpatient treatment: 7–10 days
 - Elevation
 - Application of moist heat
 - Analgesics
- Drainage of abscesses if present:
 - Obtain culture if drainage performed, especially to help identify resistant pathogens
- Skin origin:
 - Outpatient:
 - Oral cephalexin plus trimethoprim/sulfamethoxazole (TMP/SMX) (to cover CA-MRSA)

- Alternatives to cephalexin: Oral dicloxacillin, macrolide, or levofloxacin
- Alternatives to TMP/SMX: Clindamycin or doxycycline
- Inpatient:
 - IV nafcillin or equivalent, plus IV vancomycin (to cover CA-MRSA)
- Pharyngeal or periodontal origin:
 - Outpatient:
 - Oral penicillin VK
 - Alternatives: Oral clindamycin or amoxicillin/clavulanate
 - Inpatient:
 - IV penicillin G (aqueous) and IV metronidazole
 - Alternatives: IV ampicillin/sulbactam or IV clindamycin
- Axillary lymphadenitis:
 - Outpatient:
 - Oral penicillin VK
 - Alternatives: Oral macrolide or amoxicillin/clavulanate
 - Inpatient:
 - IV penicillin G (aqueous)
 - Alternatives: IV ampicillin/sulbactam
- Acute unilateral cervical suppurative lymphadenitis:
 - Outpatient:
 - Oral penicillin VK
 - Alternatives: Oral clindamycin or amoxicillin/clavulanate
- MRSA:
 - Nosocomial MRSA:
 - IV vancomycin or PO or IV linezolid
 - CA-MRSA:
 - PO: TMP/SMX, clindamycin or doxycycline
 - IV: Vancomycin or clindamycin

MEDICATION

- Amoxicillin/clavulanate: 500–875 mg (peds: 45 mg/kg/24 h) PO BID or 250–500 mg (peds: 40 mg/kg/24 h) PO TID
- Ampicillin/sulbactam: 1.5–3 g (peds: 100–300 mg/kg/24 h up to 40 kg; > 40 kg, give adult dose) IV q6h
- Cephalexin: 500 mg (peds: 50–100 mg/kg/24 h) PO QID
- Clindamycin: 450–900 mg (peds: 20–40 mg/kg/24 h) PO or IV q6h
- Dicloxacillin: 125–500 mg (peds: 12.5–25 mg/kg/24 h) PO q6h
- Doxycycline: 100 mg PO BID for adults
- Erythromycin base: (adult) 250–500 mg PO QID
- Linezolid: 600 mg PO or IV q12h (peds: 30 mg/kg/d divided q8h)
- Metronidazole: (adult) 15 mg/kg IV once, followed by 7.5 mg/kg IV q6h
- Nafcillin: 1–2 g IV q4h (peds: 50–100 mg/kg/24 h divided q6h); max. 12 g/24 h

- Penicillin VK: 250–500 mg (peds: 25–50 mg/kg/24 h) PO q6h
- Penicillin G (aqueous): 4 mIU (peds: 100,000–400,000 U/kg/24 h) IV q4h
- Rifampin: 600 mg PO BID for adults
- TMP/SMX: 2 DS tabs PO q12h (peds: 6–10 mg/kg/24 h TMP divided q12h)
- Vancomycin: 1 g IV q12h (peds: 10 mg/kg IV q6h, dosing adjustments required age <5 yr); check serum levels

FOLLOW-UP

DISPOSITION

Admission Criteria

- Toxic appearing
- History of immune suppression
- Concurrent chronic medical illnesses
- Unable to take oral medications
- Unreliable patients

Discharge Criteria

- Mild infection in a nontoxic-appearing patient
- Able to take oral antibiotics
- No history of immune suppression or concurrent medical problems
- Has adequate follow-up within 24–48 hr

Issues for Referral

- If not found in context of acute infection and not quick to resolve with course of antibiotics, evaluate for more serious underlying causes (e.g., malignancy)
- Lymph node biopsy may be helpful in the following circumstances:
 - Clinical findings indicate likely malignancy
 - Lymph node size > 1 cm
 - Supraclavicular location

FOLLOW-UP RECOMMENDATIONS

- Follow-up within 24–48 hr for response to treatment
- If symptoms worsen—including new or worsening lymphangitis, new or increasing area of redness over the node, worsening fever—patient should be instructed to return sooner

PEARLS AND PITFALLS

- Staph species are the most common cause of acute regional lymphadenitis due to pyogenic bacteria

- Empiric antibiotic coverage must extend to include CA-MRSA, in addition to coverage for other staph species and strep

LYMPHANGITIS

John Mahoney

BASICS

DESCRIPTION

- Lymphangitis is the infection of lymphatics that drain a focus of inflammation
- Histologically, lymphatic vessels are dilated and filled with lymphocytes and histiocytes:
 - Inflammation frequently extends into perilymphatic tissues and may lead to cellulitis or abscess formation

ETIOLOGY

- Acute lymphangitis:
 - Likely caused by bacterial infection
 - Most commonly group A β -hemolytic *Streptococcus*
 - Less commonly due to other strep groups, and occasionally *Staphylococcus aureus*, including resistant strains such as community-associated methicillin-resistant *S. aureus* (CA-MRSA):
 - CA-MRSA risk factors: Prior MRSA infection, household contact of CA-MRSA patient, military personnel, incarcerated persons, athletes in contact sports, IV drug users, men who have sex with men
 - Different antibiotic susceptibility than nosocomial MRSA
 - CA-MRSA now sufficiently prevalent to warrant empiric treatment
 - Suspect CA-MRSA in unresponsive infections or if multiple or recurrent abscesses
 - Other organisms:
 - *Pasteurella multocida* (cat or dog bite)
 - *Spirillum minus* (rat-bite fever)
 - *Wuchereria bancrofti* (filariasis): Consider in immigrants from Africa, Southeast Asia/Pacific, and tropical South America with lower-extremity involvement
- Chronic lymphangitis:
 - Usually caused by mycotic, mycobacterial, and filarial infections
 - *Sporothrix schenckii* (most common cause of chronic lymphangitis in US):
 - Inoculation occurs while gardening or farming (rose thorn)
 - Organism is present on some plants and in sphagnum moss
 - Multiple SC nodules appear along course of lymphatic vessels
 - Typical antibiotics and local treatment fail to cure lesion
 - *Mycobacterium marinum*:
 - Atypical Mycobacterium

- Grows optimally at 25–32°C in fish tanks and swimming pools
- May produce a chronic nodular, single wart-like or ulcerative lesion at site of abrasion
- Additional lesions may appear in distribution similar to sporotrichosis
- *Nocardia brasiliensis*
- *Mycobacterium kansasii*
- *W. bancrofti*

DIAGNOSIS

SIGNS AND SYMPTOMS

- Acute lymphangitis:
 - Warm, tender erythematous streaks develop and extend proximally from the source of infection
 - Regional lymph nodes often become enlarged and tender (lymphadenitis).
 - Peripheral edema of involved extremity
 - Systemic manifestations:
 - Fever
 - Rigors
 - Tachycardia
 - Headache
- Chronic (nodular) lymphangitis:
 - Erythematous nodule, chancreiform ulcer, or wart-like lesion develops in SC tissue at inoculation site
 - Often presents without pain or evidence of systemic infection
 - Multiple lesions possible along lymphatic chain

History

History and physical exam directed at discovering source of infection

Physical-Exam

- Fever
- Erythematous streaks from source of infection proceeding toward regional lymph nodes

ESSENTIAL WORKUP

Lymphangitis is a clinical diagnosis

DIAGNOSIS TESTS & NTERPRETATION

Lab

- WBC is unnecessary but often elevated

- Gram stain and culture of initial lesion to focus antimicrobial selection and reveal resistant pathogens (MRSA):
 - Aspirate point of maximal inflammation or punch biopsy
 - Essential if treatment failure
- If sporotrichosis or *M. marinum* infection is suspected, diagnosis should be confirmed by culture of organism from wound
- Blood culture may reveal organism

Imaging

- Imaging is not commonly performed
- Plain radiographs may reveal abscess formation, SC gas, or foreign bodies if these are suspected
- Extremity vascular imaging (doppler US) can help rule out deep venous thrombosis

DIFFERENTIAL DIAGNOSIS

- Thrombophlebitis; deep venous and superficial:
 - Differentiation from lymphangitis:
 - Absence of initial traumatic or infectious focus
 - No regional lymphadenopathy
- IV line infiltration
- Smallpox vaccination, normal variant of usual reaction to vaccination
- Phytophotodermatitis:
 - Linear inflammatory reaction, mimics lymphangitis
 - Lime rind, lime juice, and certain plants can act as photosensitizing agents

TREATMENT

INITIAL STABILIZATION/THERAPY

If patient is septic, manage airway and resuscitate as indicated

ED TREATMENT/PROCEDURES

- Antimicrobial therapy should be initiated with first dose in ED
- General principles:
 - Consider local prevalence of MRSA and other resistant pathogens in addition to usual causes
 - Usual outpatient treatment: 7–10 days
 - Elevation
 - Application of moist heat
- Acute lymphangitis, empiric coverage:
 - Outpatient:
 - Oral cephalexin plus trimethoprim/sulfamethoxazole (TMP/SMX) (to cover CA-MRSA)

- Alternatives to cephalexin: Oral dicloxacillin, macrolide, or levofloxacin
- Alternatives to TMP/SMX: Clindamycin or doxycycline
- Inpatient: IV nafcillin or equivalent
- Lymphangitis after dog or cat bite: IV ampicillin/sulbactam
- MRSA:
 - _ Nosocomial MRSA: IV vancomycin or PO or IV linezolid
 - _ CA-MRSA:
 - PO: TMP/SMX, clindamycin, or doxycycline
 - IV: Vancomycin or clindamycin
- Sporotrichosis:
 - _ Itraconazole or saturated solution of potassium iodide (SSKI)
- *M. marinum*:
 - _ Localized granulomas are usually excised
 - _ Antimicrobial therapy is usually reserved for more severe infections:
 - Limited data on what combination of agents should be used
 - Rifampin and ethambutol may be best choice

MEDICATION

- Ampicillin/sulbactam: 1.5–3 g (peds: 100–300 mg/kg/24 h up to 40 kg; > 40 kg, give adult dose) IV q6h
- Cephalexin: 500 mg (peds: 50–100 mg/kg/24 h) PO QID
- Clindamycin: 450–900 mg (peds: 20–40 mg/kg/24h) PO or IV q6h
- Dicloxacillin: 125–500 mg (peds: 12.5–25 mg/kg/24h) PO q6h
- Doxycycline: 100 mg PO BID for adults
- Erythromycin base: (Adult) 250–500 mg PO QID
- Itraconazole (adult): 200 mg PO daily, continue until 2–4 wk after all lesions resolve (usually 3–6 mo); peds: Not approved for use
- Levofloxacin: (Adult only) 500–750 mg PO or IV daily
- Linezolid: 600 mg PO or IV q12h (peds: 30 mg/kg/24 h div. q8h)
- Nafcillin: 1–2 g IV q4h (peds: 50–100 mg/kg/24 h div. q6h); max. 12 g/24 h
- Rifampin: 600 mg PO BID for adults
- TMP/SMX: 2 DS tabs PO q12h (peds: 6–10 mg/kg/24 h TMP div. q12h)
- Vancomycin: 1 g IV q12h (peds: 10 mg/kg IV q6h, dosing adjustments required for age <5 yr); check serum levels

FOLLOW-UP

DISPOSITION

Admission Criteria

- Toxic appearing

- History of immune suppression
- Concurrent chronic medical illnesses
- Unable to take oral medications
- Unreliable patients

Discharge Criteria

- Mild infection in a nontoxic-appearing patient
- Able to take oral antibiotics
- No history of immune suppression or concurrent medical problems
- Adequate follow-up within 24–48 hr

FOLLOW-UP RECOMMENDATIONS

- Follow-up within 24–48 hr
- Sooner if worsening symptoms, including worsening fever or other systemic symptoms
- Outline the border of erythema before discharge to aid in assessing response to therapy

PEARLS AND PITFALLS

Empiric antibiotic coverage must extend to include CA-MRSA, in addition to coverage for other staph species and strep.

LYMPHOGRANULOMA VENEREUM

Joel Kravitz

BASICS

DESCRIPTION

- Sexually transmitted disease
- Primary stage:
 - Painless papule, pustule, or ulcer
- Secondary stage:
 - Spread to regional lymph nodes
 - Fluctuant inguinal lymphadenopathy (buboes)
 - Lymphadenopathy may be unilateral or bilateral
- Responsive to antibacterial therapy
- Tertiary stage:
 - If untreated, significant tissue damage and destruction may result
- Endemic in Southeast Asia, Latin America, parts of Africa, and the Caribbean
- Increasing incidence among men who have sex with men
- Also known as:
 - Struma
 - Tropical bubo
 - Nicolas–Favre–Durand disease

ETIOLOGY

Chlamydia trachomatis serotypes L1, L2, and L3

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Primary genital lesions:
 - Incubation: 3–30 days after sexual exposure to *C. trachomatis*
 - Painless genital chancre lasts 2–3 days (rarely, a papule or vesicle)
 - Often transient and not noticed
 - May present as proctitis
- Secondary stage:
 - Systemic symptoms:
 - Fever and malaise
 - Myalgias
 - Lymphadenopathy; usually inguinal:

- May ulcerate and drain pus
- Proctitis:
 - Rectal bleeding
 - Tenesmus
 - Constipation
- Tertiary stage:
 - Symptoms mimic inflammatory bowel disease or proctocolitis
 - Elephantiasis
 - Strictures

Physical-Exam

- Primary stage:
 - Painless papule, pustule, or ulcer
 - Usually anogenital region
- Secondary stage:
 - Tender inguinal adenopathy:
 - Occurs 1–3 wk after initial inoculation
 - Adenopathy is unilateral in 2/3 of cases
 - Bubo (large inguinal lymph nodes) form in inguinal and femoral chains
 - Groove sign: Scarred or coalescent buboes above and below inguinal ligament give a linear depression parallel to the inguinal ligament (seen in 30%)
 - Anal-receptive patients may develop hemorrhagic proctocolitis
 - Perirectal lymphatic inflammation causes fistulae and strictures
- Tertiary disease (invasive if untreated):
 - Chronic proctocolitis:
 - Abdominal pain
 - Rectal bleeding
 - Genital strictures
 - Perineal and perianal fistulae
 - Elephantiasis of the ipsilateral leg

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Standard *Chlamydia* DNA probes *do not* test for lymphogranuloma venereum (LGV) strain
- False-positive VDRL in 20%
- Serologic testing and culture are the standard
- Complement fixation titers > 1:64 are consistent with LGV infection

Diagnostic Procedures/Surgery

Bubo aspiration—specific but expensive and impractical

DIFFERENTIAL DIAGNOSIS

- Genital herpes (ulcers usually not seen in LGV)
- Syphilis—nodes nontender, longer incubation
- Chancroid—multiple ulcers, no systemic symptoms
- Granuloma inguinale—lesions painless and bleed easily

TREATMENT

PRE HOSPITAL

No pre-hospital issues

INITIAL STABILIZATION/THERAPY

No field or ED stabilization required

ED TREATMENT/PROCEDURES

If large, buboes may need to be aspirated or drained to avoid or minimize scarring

MEDICATION

First Line

Doxycycline: 100 mg PO BID for 3 wk

Second Line

- Azithromycin: 1,000 mg PO weekly for 3 wk
- Erythromycin: 500 mg PO QID for 3 wk

Pregnancy Considerations

Erythromycin is the recommended regimen in pregnancy and during lactation

FOLLOW-UP

DISPOSITION

Admission Criteria

Hospitalization is rarely needed (i.e., severe systemic symptoms)

Discharge Criteria

Immunocompetent patient without systemic involvement

Issues for Referral

- Outpatient follow-up is required to confirm diagnosis and cure
- Rectal infection may require retreatment

FOLLOW-UP RECOMMENDATIONS

- Ensure that sexual partners are tested and treated
- Sexual contacts within 60 days should be tested and treated with antichlamydial therapy

PEARLS AND PITFALLS

- Diagnosis is based on clinical suspicion, epidemiologic patterns, and exclusion of other etiologies
- Consider this diagnosis in men who have sex with men
- Treat to avoid tertiary disease which is not responsive to antibiotic therapy alone
- Treatment course is at least 3 wk of antibiotics

ADDITIONAL READING

ICD10

A55 Chlamydial lymphogranuloma (venereum)

MALARIA

Jordan Moskoff

BASICS

DESCRIPTION

- Protozoan infection transmitted through the *Anopheles* mosquito
- Incubation period 8–16 days
- Periodicity of the disease is due to the life cycle of the protozoan:
 - Exoerythrocytic phase: Immature sporozoites migrate to liver, where they rapidly multiply into mature parasites (merozoites).
 - Erythrocytic phase: Mature parasites are released into circulation and invade RBCs.
 - Replication within RBCs followed 48–72 hr later by RBC lysis and release of merozoites into circulation, repeating cycle
 - Fever corresponds to RBC lysis.
- *Plasmodium falciparum*:
 - Cause of most cases and almost all deaths
 - Usually presents as an acute, overwhelming infection
 - Able to infect red cells of all ages:
 - Results in greater degree of hemolysis and anemia
 - Causes widespread capillary obstruction:
 - Results in end-organ hypoxia and dysfunction
 - More moderate infection in people who are on or who have recently stopped prophylaxis with an agent to which the *P. falciparum* is resistant
 - Post-traumatic immunosuppression may cause relapse of malaria in patients who have lived in endemic areas.
- *Plasmodium vivax* and *Plasmodium ovale*:
 - May present with an acute febrile illness
 - Dormant liver stages (hypnozoites) that may cause relapse 6–11 mo after initial infection
- *Plasmodium malariae*:
 - May persist in the bloodstream at low levels up to 30 yr

ETIOLOGY

- Transmission usually occurs from the bite of infected female *Anopheles* mosquito.
- North American transmission possible:
 - *Anopheles* mosquitoes on east and west coasts of US.
 - Transmission may also occur through infected blood products and shared needles.

Pediatric Considerations

- Sickle cell trait protective
- Cerebral malaria more common in children
- In highly endemic areas with minimal lab capability, all children presenting with febrile illness may be treated.

Pregnancy Considerations

Pregnant patients, especially primigravida, at higher risk

DIAGNOSIS

SIGNS AND SYMPTOMS

- **Timing:**
 - _ P. falciparum—exhibits within 8 wk of return
 - _ P. vivax—delayed several months
 - _ Most symptomatic within 1 yr
- **General:**
 - _ Malaise
 - _ Chills
 - _ Fever—usually $> 38^{\circ}\text{C}$
 - _ Classic malaria paroxysm:
 - 15 min to 1 hr of chills
 - Followed by 2–6 hr of nondiaphoretic fever $\leq 39\text{--}42^{\circ}\text{C}$
 - Profuse diaphoresis followed by defervescence
 - Pattern every 48 hr (P. vivax and P. ovale) or every 72 hr (P. falciparum)
 - Fever pattern may be varied; rare to have classical fever.
 - _ Orthostatic hypotension
 - _ Myalgias/arthralgias
 - _ Hematology
 - _ Hemolysis:
 - Blackwater fever; named from the dark color of the urine partially due to hemolysis in overwhelming P. falciparum infections
 - _ Jaundice
 - _ Splenomegaly:
 - More common in chronic infections
 - May cause splenic rupture
- **CNS—cerebral malaria:**
 - _ Headache
 - _ Focal neurologic findings
 - _ Mental status changes
 - _ Coma

- Seizures
- GI:
 - Emesis
 - Diarrhea
 - Abdominal pain
- Pulmonary:
 - Shortness of breath
 - Rales
 - Pulmonary edema
- Severe malaria:
 - One or more of the following:
 - >20% mortality even with optimal management
 - Prostration; unable to sit up by oneself
 - Impaired consciousness
 - Respiratory distress or pulmonary edema
 - Seizure
 - Circulatory collapse
 - Abnormal bleeding
 - Jaundice
 - Hemoglobinuria
 - Severe anemia

ESSENTIAL WORKUP

Oil emersion light microscopy of a thick-smear Giemsa stain:

- Demonstrates intraerythrocytic malaria parasites
- Cannot exclude diagnosis without three negative smears in 48 hr
- Only high degrees of parasitemia will be evident on a standard CBC smear.

DIAGNOSIS TESTS & NTERPRETATION

Lab

- CBC:
 - Anemia—25%
 - Thrombocytopenia—70% have < 150
 - Leukocytopenia
- Electrolytes, BUN, creatinine, glucose:
 - Renal failure
 - Hypoglycemia (rare)
 - Lactic acidosis
 - Hyponatremia
- Urinalysis
- Liver function tests:
 - Increased in 25%

- Increased bilirubin and lactate dehydrogenase are the signs of hemolysis

Imaging

Chest radiograph—for pulmonary edema

Diagnostic Procedures/Surgery

- Immunofluorescence assay, enzyme-linked immunosorbent assay, or DNA probes:
 - Differentiates the type of Plasmodium present
 - 5–7% will have mixed infections.
- Lumbar puncture/ CSF analysis:
 - Performed to distinguish cerebral malaria from meningitis
 - CSF lactate/protein elevated with malaria
 - CSF pleocytosis/hypoglycemia absent with malaria

DIFFERENTIAL DIAGNOSIS

- Meningitis
- Encephalitis
- Stroke
- Acute renal failure
- Acute hemolytic anemia
- Sepsis
- Hepatitis
- Viral diarrheal illness
- Hypoglycemic coma
- Heat stroke

TREATMENT

INITIAL STABILIZATION/THERAPY

- ABCs
- 0.9% NS fluid bolus for hypotension
- Immediate cooling if temperature $>40^{\circ}\text{C}$
- Acetaminophen
- Mist/cool-air fans
- Naloxone, D₅₀W (or Accu-Chek), and thiamine if altered mental status

ED TREATMENT/PROCEDURES

- Dependent on considering this diagnosis and identifying the type of malaria present and geographic area of acquisition
- Assume drug resistant until proven otherwise.
- To counter resistance Artemisinin combinations of antimalarials are recommended 1st line.

- Artemisinin-based combination therapy – choice is based on geographic region, check WHO database
 - Artemether + Lumefantrine
 - Artesunate + Amodiaquine
 - Artesunate + Mefloquine
 - Artesunate + Sulfadoxine–Pyrimethamine
- Severe falciparum—IV treatment:
 - Artesunate can be given IV or IM
 - Artemisinin can be given rectally
- Supportive therapy for complications
- Chemoprophylaxis: Must be based on region of travel, check WHO database
 - Malarone
 - Daily medication
 - Very well tolerated
 - Safe in children > 5 kg – pediatric dosing
 - Unsafe in pregnancy
 - 250/100 mg PO daily
 - Begin 1–2 days prior to entering malaria area and continue for 7 days after leaving area
 - Chloroquine:
 - Drug of choice for travelers who want weekly medication
 - Safe in pregnancy
 - 300 mg PO weekly
 - Begin 2 wk prior to departure and continue for 4 wk after return
 - Mefloquine:
 - Weekly medication
 - Safe in pregnancy; do not use with certain psychiatric conditions
 - 250 mg PO weekly
 - Begin 2 wk before departure and continue for 4 wk after return
 - Doxycycline:
 - Daily medication
 - Least expensive
 - Unsafe in pregnancy
 - Unsafe in children < 8 y/o
 - Risk with sun exposure
 - 100 mg PO daily
 - Begin 1 day prior to entering area and continue for 4 wk after return
 - Primaquine:
 - Daily medication
 - Cannot use in G6PD deficiency
 - Unsafe in pregnancy
 - 30 mg PO every day
 - Begin 1 day prior to entering area and continue 1 wk after return

- Vaccine is not available, but several are in field trials.

MEDICATION

- Acetaminophen: 500 mg (peds: 10–15 mg/kg) PO q4–6h; do not exceed 5 doses/24 h; max. 4 g/24 h
- Artemether (20 mg)–lumefantrine (120 mg): 6 dose regimen PO BID × 3 days
- Artesunate (50 mg) + Amodiaquine (153 mg): 3 dose regimen PO QD × 3 days
- Artesunate (50 mg) + Sulfadoxine
- Pyrimethamine (500/25): 3 dose regimen 1 tabs of Artesunate PO QD × 3 and 1 tab
- Sulfadoxine–Pyrimethamine PO QD × 1 day
- Artesunate (50 mg) + Mefloquine (250 mg): 3 dose regimen 1 tab of Artesunate PO QD × 3 days and Mefloquine PO split over 2–3 days.
- Dextrose: D₅₀W 1 amp—50 mL or 25 g (peds: D₂₅W 2–4 mL/kg) IV
- Naloxone (Narcan): 2 mg (peds: 0.1 mg/kg) IV or IM initial dose
- Thiamine (vitamin B₁): 100 mg (peds: 50 mg) IV or IM

FOLLOW-UP

DISPOSITION

Admission Criteria

- ICU admission for severe *P. falciparum* infection
- Suspected acute *P. falciparum* infection
- Severe dehydration
- Inability to tolerate oral solution/medication
- > 3% of RBC containing parasites

Discharge Criteria

- Non-*P. falciparum* infection
- Able to tolerate oral medications

PEARLS AND PITFALLS

Consider in patients with appropriate exposure/epidemiology and in exposed patients with fever and consistent signs and symptoms.

MALLORY-WEISS SYNDROME

Galeta C. Clayton

BASICS

DESCRIPTION

- Partial-thickness intraluminal longitudinal mucosal tear of distal esophagus or proximal stomach
- Sudden increase in intra-abdominal and/or transgastric pressure causes:
 - Mild to moderate submucosal arterial and/or venous bleeding:
 - May be related to underlying pathology
 - “Mushrooming” of stomach into esophagus during retching has been observed endoscopically.
 - Responsible for ~5% of all cases of upper GI bleeding

ETIOLOGY

- Associated with:
 - Forceful coughing, laughing, or retching
 - Lifting
 - Straining
 - Blunt abdominal trauma
 - Seizures
 - Childbirth
 - Cardiopulmonary resuscitation
- Risk factors:
 - Alcoholics:
 - Especially after recent binge
 - Patients with hiatal hernia
 - Hyperemesis gravidarum
- Greater bleeding associated with:
 - Portal hypertension
 - Esophageal varices
 - Coagulopathy

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Multiple bouts of nonbloody vomiting and/or retching followed by hematemesis:
 - Most bleeding is small and resolves spontaneously.

- Massive life-threatening hemorrhage can occur.
- Epigastric pain
- Back pain
- Dehydration:
 - Dizzy, light-headed; syncope

Physical-Exam

- Hematemesis
- Melena
- Postural hypotension
- Shock

ESSENTIAL WORKUP

- CBC
- Rectal exam for occult blood

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Prothrombin time (PT), partial thromboplastin time (PTT), INR
- Electrolytes, BUN, creatinine, glucose, LFTs
- Amylase/lipase if abdominal pain
- Type and cross-match:
 - At least 4 U of packed red blood cells (PRBCs) if bleeding is severe
- ECG if elderly or with cardiac history

Imaging

- Upright chest radiograph for free air from esophageal or gastric perforation
- Upper endoscopy (esophagogastroscopy):
 - Procedure of choice to locate, identify, and treat source of bleeding

DIFFERENTIAL DIAGNOSIS

- Nasopharyngeal bleeding
- Hemoptysis
- Esophageal rupture (Boerhaave syndrome)
- Esophagitis
- Gastritis
- Gastroenteritis
- Duodenitis
- Ulcer disease
- Varices
- Carcinoma
- Vascular-enteric fistula

- Hemangioma

TREATMENT

PRE HOSPITAL

- Airway control:
 - 100% oxygen or intubate if unresponsive or airway patency in jeopardy
- If hemodynamically unstable or massive hemorrhage:
 - Initiate 2 large-bore IV catheters.
 - 1 L bolus (peds: 20 mL/kg) lactated Ringer (LR) solution or 0.9% normal saline (NS)
 - Trendelenburg position

INITIAL STABILIZATION/THERAPY

- ABCs:
 - IV access with at least 1 large-bore catheter; more if unstable
 - Central catheter placement if unstable for more efficient delivery of fluids and monitoring of central venous pressure
 - IV fluids of either 0.9% NS (or LR) at 250 mL/h if stable; wide open if hemodynamically unstable
 - Dopamine for persistent hypotension unresponsive to aggressive fluid resuscitation
- Large-bore Ewald tube placement with evidence of large amount of bleeding:
 - Safe
 - Will not aggravate Mallory–Weiss tear
 - Lavage blood from stomach with water while patient is on side in Trendelenburg position.
- Nasogastric (NG) tube placement to check for active bleeding
- Transfuse O-negative red blood cells immediately if hypotensive and not responsive to 2 L of crystalloid.
- Most bleeding stops spontaneously with conservative therapy.

ED TREATMENT/PROCEDURES

- NPO
- Transfuse PRBCs if unstable or lowering hematocrit with continued hemorrhage.
- Place Foley catheter to monitor urine output.
- Monitor fluid status closely.
- With continuing hemorrhage, arrange for immediate endoscopy:
 - Control bleeding endoscopically via:
 - Electrocoagulation
 - Injection therapy (epinephrine)
 - Band ligation

- Hemoclips
- Application of blood-clotting agents
 - Esophageal balloon tamponade
 - Arterial embolization
- Intravenous vasopressin in massive bleeding and unavailable endoscopy
- In persistent/unresponsive hemorrhage, angiographic infusion of vasopressin
- Surgery—last but definitive treatment modality using techniques to oversew bleeding site or perform gastrectomy
- Failure of above may require gastric arterial embolization in patients of poor surgical risk.
- Antiemetics for nausea/vomiting
- Proton pump inhibitors or H₂ blockers for gastric acid suppression.
- Avoid Sengstaken-Blakemore tubes (especially in presence of hiatal hernia).

MEDICATION

- Dopamine: 2–20 µ/kg/min IV piggyback (IVPB)
- Ondansetron 4 mg IV
- Pantoprazole 20–40 mg IV
- Vasopressin: 0.1–0.5 IU/min IVPB titrating up to 0.9 IU/min as necessary

FOLLOW-UP

DISPOSITION

Admission Criteria

- ICU admission for:
 - Continued or massive hemorrhage
 - Hemodynamic instability
 - Extreme age
 - Poor underlying medical condition
 - Complications
- General floor admission for
 - Stable patients with minimal bleed on presentation that has since cleared
 - Patients with risk factors for rebleeding (portal HTN, coagulopathy)

Discharge Criteria

- History of minimal bleed that has stopped
- Hemodynamically stable
- Normal/stable hematocrit
- Negative or trace heme-positive stool
- Negative or trace gastric aspirate

Issues for Referral

Consult GI in ED if significant upper GI bleeding or if you suspect that requires urgent endoscopy.

FOLLOW-UP RECOMMENDATIONS

GI follow-up for outpatient endoscopy if clinically stable for discharge.

PEARLS AND PITFALLS

- Place 2 large-bore IVs for patients with upper GI bleed.
- For massive GI bleed, initiate blood transfusion early.
- Contact GI early for emergent endoscopy with significant bleeding.
- Active bleeding at the time of initial endoscopy and a low initial hematocrit is associated with a complicated clinical course.
- Rebleeding usually occurs within 24 hr, and is most common in patients with coagulopathies.

530.7 Gastroesophageal laceration-hemorrhage syndrome

ICD10

K22.6 Gastro-esophageal laceration-hemorrhage syndrome

MALROTATION

Moon O. Lee

BASICS

DESCRIPTION

- Incomplete rotation and fixation of intestine during embryogenesis during transition from extracolonic position during week 10 of gestation
- Risk factor:
 - Heterotaxia syndromes
- Associated conditions:
 - Gastrointestinal anomalies:
 - Duodenal stenosis, atresia, web
 - Meckel diverticulum
 - Intussusception
 - Gastroesophageal reflux
 - Omphalocele or gastroschisis
 - Congenital diaphragmatic hernia
 - Abdominal wall defect
 - Hirschsprung disease
 - Metabolic acidosis
 - Congenital cardiac anomalies; present in 27% of patients with malrotation; increases morbidity to 61%

ETIOLOGY

- Duodenojejunal junction remains right of midline
- Cecum remains in the upper left abdomen with abnormal mesenteric attachments
- Volvulus is complication of malrotation when small bowel rotates around superior mesenteric artery and vein resulting in vascular compromise to midgut
- Abnormal anatomy predisposes to obstruction and other conditions
- Usually found in combination with other congenital anomalies (70%): Cardiac, esophageal, urinary, anal
- Epidemiology:
 - 1 in 500 live births
 - High mortality in infants: Up to 24%
 - Necrotic bowel at surgery increases mortality by 25×.
 - Incidence:
 - In neonates, male-to-female ratio 2:1
 - 75% diagnosed newborn period
 - 90% diagnosed by age 1 yr of life
 - Can present during adulthood

SIGNS AND SYMPTOMS

- Neonates:
 - Bilious emesis
 - Abdominal distention
 - Bloody stools
 - Constipation/obstipation
 - Difficulty feeding
 - Poor weight gain
- > 1 yr: Abdominal pain followed by bilious emesis
- Older children and adolescents:
 - Chronic vomiting
 - Intermittent colicky abdominal pain
 - Diarrhea
 - Hematemesis
 - Constipation
 - May not exhibit abnormal physical findings at time of presentation (50–75%)
- Adults: Symptoms vague and nonspecific
- General:
 - Dehydration, acidosis
 - Peritonitis
 - Ischemic bowel
 - Sepsis, shock

History

- Vomiting in infant is the most common sign, but may or may not be bilious
- Signs of small bowel obstruction in early infancy
- Bilious vomiting associated with abdominal pain
- In older children and adults, the most common symptom is abdominal pain
- Other pertinent history—acute or chronic abdominal pain, poor feeding, lethargy, malabsorption, chronic diarrhea

Physical-Exam

- Abdominal exam may show distension from obstruction
- Blood in the stool indicates bowel ischemia
- Evaluate for congenital anomalies

ESSENTIAL WORKUP

Diagnosis is suggested by history and physical exam findings and is delineated by contrast radiography.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Venous blood gas
- Electrolytes, BUN, creatinine, glucose
- Urinalysis/urine culture
- Type and screen
- Prothrombin time, partial thromboplastin time, international normalized ratio
- Lactate

Imaging

- Plain abdominal radiographs:
 - _ Diagnostic in < 30%
 - _ Volvulus likely if accompanied by:
 - Duodenal obstruction
 - Gastric distention with paucity of intraluminal gas distal to volvulus in complete volvulus
 - Generalized distention of small-bowel loops
 - “Double-bubble sign” can be seen on upright film from partial duodenal obstruction causing distension of stomach and duodenum
- Upper GI contrast studies:
 - _ 95% sensitive and 86% accurate
 - _ Findings:
 - Absence of ligament of Treitz or on the right side of the abdomen with misplaced duodenum
 - Dilation of proximal duodenum with termination in conical or beak shape
 - Spiral or corkscrew appearance of duodenum with volvulus
 - Proximal jejunum on right side of abdomen (although readily displaced in neonates)
 - Thickening of small-bowel folds
- Contrast enema:
 - _ Can be useful to determine position of cecum in equivocal cases
 - _ Evaluates position of cecum in midline of upper abdomen or to left of midline
 - _ > 20% false-negative results
- Ultrasound:
 - _ US can be very sensitive in experienced hands
 - _ US shows abnormal relationship between superior mesenteric artery and vein in malrotation
 - _ “Whirlpool” sign on Doppler US of superior mesenteric artery and vein

twisting around the base of mesenteric pedicle seen in volvulus

– Normal ultrasound does not exclude malrotation

- CT:

– Little benefit in infants and children

– More likely to be used for diagnosis in adults

DIFFERENTIAL DIAGNOSIS

- Early life:

– Hirschsprung disease

– Necrotizing enterocolitis

– Intussusception

- Children with acute abdominal pain and peritoneal signs:

– Appendicitis

– Intussusception

– Overwhelming sepsis

- Older children and adults with vague abdominal pain:

– Irritable bowel syndrome

– Peptic ulcer disease

– Biliary and pancreatic disease

– Psychiatric disorders

TREATMENT

ALERT

Midgut volvulus may result in need for rapid volume and electrolyte replacement/resuscitation to correct severe hypovolemia and metabolic acidosis.

PRE HOSPITAL

Rapid transport to ED

INITIAL STABILIZATION/THERAPY

- ABCs
- NS (0.9%) IV fluid bolus (20 mL/kg) for shock, sepsis, or dehydration
- Consider nasogastric tube
- 2 IVs and/or CV catheter
- Initiate broad-spectrum antibiotics for signs of sepsis or peritonitis

ED TREATMENT/PROCEDURES

- Emergent surgical correction
- May require transfer to facility with pediatric surgical expertise when associated with midgut volvulus for:
 - Detorsion of volvulus
 - Restoration of intestinal perfusion

- Resection of obviously necrotic areas
- Replacement of long segments with questionable vascular integrity back into abdominal cavity for return evaluation and possible celiotomy in 36 hr
- Diet:
 - NPO

MEDICATION

- Broad-spectrum antibiotics prior to surgery
- Correct fluid and electrolyte abnormalities
- Vasopressors

FOLLOW-UP

DISPOSITION

Admission Criteria

- Acute abdomen
- Surgical intervention
- Significant dehydration
- Acidosis
- Sepsis
- Shock

Discharge Criteria

Stable, asymptomatic, incidental finding without associated condition, although patients are usually admitted

- Pediatric surgical evaluation prior to discharge

Issues for Referral

Diagnostic evaluation often requires tertiary care pediatric hospital with pediatric surgical and pediatric radiologic expertise.

FOLLOW-UP RECOMMENDATIONS

As dictated by pediatric surgical service

PEARLS AND PITFALLS

- Early recognition of child with acute abdomen
- Prompt treatment of acidosis and shock
- Prompt referral to appropriate facility

ICD10

Q43.3 Congenital malformations of intestinal fixation

MANDIBULAR FRACTURES

David W. Munter

BASICS

DESCRIPTION

- Typically due to a direct force
- The most common area fractured is the angle, followed by the condyle, molar, and mental regions.
- Because of its thickness, the mandibular symphysis is rarely fractured.
- Multiple fractures are seen in > 50% of cases owing to the ring-like structure of the mandible.
- Bilateral mandibular fractures most commonly result from motor vehicle accidents (MVAs).
- Open fractures are common, including lacerations of the gum overlying a fracture.

ETIOLOGY

- The mandible is the 3rd most common facial fracture following nasal and zygomatic fractures.
- MVAs, personal violence, contact sports, or industrial accidents
- Patients are often intoxicated and unable to give a clear history of events.
- Facial and head lacerations and facial fractures are the most commonly associated injuries.

Pediatric Considerations

- Mandibular fractures are uncommon in children < 6 yr of age; when they do occur, they are often greenstick fractures and can be managed with soft diet alone.
- Inform parents that because any fracture of the mandible may damage permanent teeth, follow-up with a specialty consultant is advisable.
- Refer pediatric patients to a specialist with experience in children due to issues with growth plates and permanent teeth.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Mandibular pain
- Facial asymmetry, deformity, and dysphagia
- Malocclusion, decreased range of motion of the temporomandibular joint (TMJ), trismus, or a grating sound conducted to the ear
- Gum laceration, subungual or gum hematoma

History

- Mechanism of injury
- Malocclusion, dental pain, associated injuries

Physical-Exam

- Inspect maxillofacial area for deformity, including ecchymosis or swelling.
- Malocclusion, trismus, or facial asymmetry
- Loose, fractured, or missing teeth; gross malalignment of teeth; separation of tooth interspaces, bleeding at the base of teeth; gum lacerations between teeth; and ecchymosis or hematoma of the floor of the mouth
- Step-off, bony disruption, or point tenderness with palpation along the entire length of the mandible
- Protrusion or lateral excursion of the jaw
- Interference with normal mandibular function, including decreased range of motion or deviation of the mandible with opening:
 - The examiner should be able to insert three fingers between the mandible and the maxilla.
 - Inability of the patient to hold a tongue depressor laterally between the teeth when pulled by the examiner, or attempted to be broken by twisting (positive tongue blade test)
- Paresthesia of the lower lip or gums indicates secondary damage to the inferior alveolar nerve.
- Inability to note motion of the mandibular condyles when palpated through the external ear canals suggests mandible fracture.
- Tenderness of the condyle at the TMJ

ESSENTIAL WORKUP

- Diagnosis of mandibular fractures requires radiographs – mandibular series or panorex.
- Panorex superior for evaluation of all of the mandible except condyles
- Low index for obtaining facial bone CT if associated injuries are suspected

DIAGNOSIS TESTS & INTERPRETATION

Lab

Only indicated if immediate operative intervention is indicated, or for evaluation of other injuries

Imaging

- Plain films or dental panoramic views should be obtained.
- Plain films including an anteroposterior (AP), bilateral obliques, and Towne view should be obtained:
 - Mandibular views are best for evaluating the condyles and neck of mandible

(most common site of fracture).

- Dental panoramic view may be obtained:
 - Panorex best evaluates the symphysis and body (less common fracture site).
- If condylar fracture is still suspected and not noted on initial radiographs, obtain CT of the condyles in the coronal plane.
- Missing teeth that cannot be found mandate a chest radiograph to rule out aspiration.
- Obtain cervical spine films if the neck cannot be cleared clinically
- Obtain facial bone CT if other injuries of the face suspected.

DIFFERENTIAL DIAGNOSIS

- Contusions
- Dislocation of the mandible:
 - If a single condyle is dislocated, the jaw will deviate away from the side of the dislocation.
 - If fractured, the jaw will deviate toward the fractured side.
- Isolated dental trauma

TREATMENT

PRE HOSPITAL

- Cautions:
 - Protect the airway.
 - Protect the cervical spine.
 - Preserve any avulsed teeth.

INITIAL STABILIZATION/THERAPY

- 20–40% of patients with mandibular fractures have associated injuries:
 - Treatment is directed toward immediate, potentially lethal injuries such as airway obstruction, aspiration, major hemorrhage, cervical spine injury, and intracranial injury.
- Airway must be protected.
- Cervical spine precautions
- If oral intubation cannot be performed, nasotracheal intubation should be performed unless associated facial injuries are present, in which case cricothyrotomy may be indicated.

ED TREATMENT/PROCEDURES

- With the exception of condylar fractures, many mandibular fractures are associated with mucosal, gingival, or tooth socket disruption and should be considered open fractures:
 - Antibiotics such as penicillin, clindamycin, amoxicillin, amoxicillin/clavulanate or azithromycin to cover intraoral anaerobic

pathogens

- Tetanus prophylaxis for open fractures
- Analgesia such as acetaminophen, ibuprofen, or narcotic medications
- Definitive care usually consists of reduction and fixation by wiring upper and lower teeth in occlusion for 4–6 wk or by ORIF:
 - Linear, nondisplaced, or greenstick fractures may be treated with soft diet without wiring.
- If mandible dislocation is present, while the jaw is open apply bilateral downward pressure on the occlusal surface of the posterior lower teeth while grasping the mandible:
 - The goal is to free the condyle from its anterior position to the eminence.
 - Reduction is facilitated by muscle relaxants (diazepam or midazolam) or anesthetic injection of mastication muscles.
 - A bite block should be used, or the examiner's fingers should be wrapped in gauze to prevent injury.

MEDICATION

- Acetaminophen: 500 mg (peds: 10–15 mg/kg, do not exceed 5 doses/24h) PO q4–6h, do not exceed 4 g/24h
- Amoxicillin/clavulanate: 500/125–875/125 mg PO BID (peds: 40 mg/kg/d of amoxicillin PO BID)
- Amoxicillin: 500 mg PO TID (peds: 40 mg/kg PO div. TID)
- Azithromycin: 500 mg PO day 1 followed by 250 mg day 2–4 (peds: 10 mg/kg day 1 followed by 5 mg/kg day 2–4)
- Clindamycin: 150–450 mg PO QID (peds: 10–20 mg/kg/24h)
- Diazepam: 5–10 mg (peds: 0.1–0.2 mg/kg) IV
- Ibuprofen: 600–800 mg (peds: 20–40 mg/kg/24h) PO TID–QID
- Midazolam: 2–5 mg (peds: 0.02–0.05 mg/kg/dose, max. dose 0.4 mg/kg total and not > 10 mg) IV over 2–3 min
- Penicillin VK: 250–500 mg (peds: 25–50 mg/kg/24h) PO QID

FOLLOW-UP

DISPOSITION

Admission Criteria

- Significant displacement or associated dental trauma—open fractures require urgent specialty consultation for possible admission.
- The severity of associated trauma may indicate admission.
- Any patient with the potential for airway compromise should be admitted.
- An unreliable patient with nondisplaced fractures should be admitted for definitive fixation.

- In the pediatric population, if the mechanism of injury is not appropriate to the injuries seen, pediatric or child protective services consultation should be obtained.

Discharge Criteria

Patients with nondisplaced, closed fractures may be discharged on analgesics and a soft diet.

FOLLOW-UP RECOMMENDATIONS

Oral or maxillofacial surgeon within 2–3 days for uncomplicated fractures

PEARLS AND PITFALLS

- The most sensitive sign of a mandibular fracture is malocclusion.
- Failure to recognize that a gum laceration overlying a mandibular fracture represents an open fracture which requires antibiotics.
- Missing mandibular condyle fractures when only a panorex film is obtained – if there is condyle tenderness or malocclusion, obtain plain films or CT.
- Missing teeth must be accounted for, if not found, obtain a chest x-ray to rule out aspiration.
- A nonfractured mandible should be able to hold a tongue blade between the molars tightly enough to break it off. There should be no pain in attempting to rotate the tongue blade between the molars.

MARINE ENVENOMATION

Armando Marquez, Jr. • Timothy B. Erickson

BASICS

DESCRIPTION

Marine envenomation refers to poisoning caused by sting or bite from a vertebrate or invertebrate marine species.

ETIOLOGY

- Sponges:
 - Contain sharp spicules with irritants that cause pruritic dermatitis
- Coelenterates (Cnidaria jellyfish):
 - Contain stinging cells known as nematocysts on their tentacles
 - Fluid-filled cysts eject sharp, hollow thread-tube on contact.
 - Thread-tube penetrates skin and envenomates the victim.
 - Box jellyfish can kill within minutes
- Starfish:
 - Sharp, rigid spines are coated with slimy venom.
- Sea urchins:
 - Hollow, sharp spines filled with various toxins
- Sea cucumbers:
 - Hollow tentacles secrete holothurin, a liquid toxin.
- Cone shells:
 - Venom injected through dart-like, detachable tooth.
 - Active peptides interfere with neuromuscular transmission.
 - Presents with puncture wounds similar to wasp stings.
- Stingrays:
 - Most common cause of human marine envenomations.
 - Tapered spines attached to tail inject venom into victim.
- Scorpion fish:
 - Lionfish usually mild; stonefish can be life threatening.
 - Sharp spines along dorsum and pelvis of fish
 - Often stepped on inadvertently
 - Neurotoxic venom
- Catfish:
 - Dorsal and pectoral spines contain venom glands.
- Sea snakes:
 - Hollow fangs with associated venom glands
 - Highly neurotoxic venom blocks neuromuscular transmission.

SIGNS AND SYMPTOMS

- Sponges:
 - Itching and burning a few hours after contact
 - Local joint swelling and soft tissue edema
 - Fever
 - Malaise
 - Dizziness
 - Nausea
 - Muscle cramps
 - In severe cases, desquamation in 10 days to 2 mo
- Coelenterates (Cnidaria jellyfish):
 - Mild envenomation:
 - Immediate stinging sensation
 - Pruritus
 - Paresthesia, burning sensation
 - Throbbing
 - Blistering/local edema/wheal formation
 - Moderate/severe:
 - Neurologic: Ataxia, paralysis, delirium, seizures
 - Cardiovascular: Anaphylaxis, hemolysis, hypotension, dysrhythmias
 - Respiratory: Bronchospasm, laryngeal edema, pulmonary edema, respiratory failure
 - Musculoskeletal: Muscle cramps or spasm, arthralgias
 - Gastrointestinal: Nausea, vomiting, diarrhea, dysphagia, hypersalivation/thirst
 - Ophthalmologic: Conjunctivitis, corneal ulcers, elevated intraocular pressure
- Echinodermata:
 - Starfish:
 - Immediate pain
 - Bleeding
 - Mild edema
 - Paresthesias, nausea, vomiting if severe
 - Sea urchins:
 - Intense pain and severe local muscle aches
 - Nausea, vomiting
 - Paresthesias, hypotension, or respiratory distress with multiple stings
 - Sea cucumbers:
 - Mild contact dermatitis
 - Corneal and conjunctival involvement: Severe reactions can lead to

blindness.

- Mollusks:
 - Cone shells:
 - Puncture wounds similar to wasp stings
 - Sharp burning and stinging
 - Paresthesias indicate severe envenomation.
 - Can evolve into muscular paralysis and respiratory failure, dysphagia, syncope, disseminated intravascular coagulation
- Stingrays:
 - Puncture wounds or jagged lacerations
 - Local, intense pain, edema, bleeding; necrosis if severe
 - Nausea, vomiting, diarrhea
 - Diaphoresis
 - Headache
 - Tachycardia
 - Seizures
 - Paralysis
 - Hypotension
 - Dysrhythmias
- Scorpion fish:
 - Intense local pain for 6–12 hr
 - Erythema may progress to cellulitis.
 - Headache
 - Nausea, vomiting, diarrhea
 - Pallor
 - Delirium
 - Seizures
 - Fever
 - Hypertension
- Catfish:
 - Local pain, ischemic appearance progressing to erythema
 - Swelling, bleeding, and edema
 - Local muscle spasms
 - Diaphoresis
 - Neuropathy, fasciculations, weakness, syncope
- Sea snakes:
 - Bite initially causes very little pain.
 - Pin-like pairs of fang marks
 - Onset from 5 min to 6 hr
 - Muscle pain, lower extremity paralysis, arthralgias
 - Trismus, blurred vision, dysphagia, drowsiness
 - Severe signs include:
 - Ascending paralysis

- Aspiration
- Coma
- Renal and liver failure
- _ If untreated, 25% mortality

History

- Time of envenomation
- Body part envenomated
- Activity when envenomated (scuba diving, swimming, surfing, fishing, boating, pet care)
- Type of water (salt water, fresh water, aquarium)
- Geographic location (resort, international, remote, local, aquarium, zoo, pet store)
- Onset of symptoms, pain
- Mental status changes
- Near drowning

Physical-Exam

- Vital signs
- Airway
- Mental status
- Cardiopulmonary exam
- Dermatologic exam, foreign bodies, cellulitis, blistering

ESSENTIAL WORKUP

- Careful history, repeated evaluation of wound sites
- Assessment of ABCs

DIAGNOSIS TESTS & NTERPRETATION

Lab

- CBC
- Electrolytes, BUN, creatinine, and glucose levels
- LFT
- Urinalysis
- Arterial blood gases if severe symptoms

Imaging

Soft tissue radiographs to detect foreign body

DIFFERENTIAL DIAGNOSIS

- Allergic reaction
- Cellulitis
- Gastroenteritis

- Aspiration pneumonia
- Near drowning

TREATMENT

PRE HOSPITAL

- Remove victim from water source.
- Control airway, breathing.
- Control hemorrhage.
- Detoxify venom with proper wound irrigation as discussed below.

INITIAL STABILIZATION/THERAPY

- Airway, breathing, and circulation management (ABCs)
- Establish IV access with 0.9% normal saline (NS).

ED TREATMENT/PROCEDURES

- General:
 - _ Prepare for anaphylactic reactions (epinephrine/steroids).
 - _ Prepare for intubation if needed.
 - _ Diphenhydramine for itch, burn, hives
 - _ Tetanus prophylaxis
 - _ Corticosteroids for severe local reactions
 - _ Narcotic analgesia for severe pain
 - _ Antibiotic prophylaxis for the following:
 - Large lacerations or burns
 - Deep puncture wounds
 - Grossly contaminated wounds
 - Elderly or chronically ill
 - _ Antibiotic choices:
 - Trimethoprim/sulfamethoxazole (TMP-SMX; Bactrim)
 - Tetracycline
 - Ciprofloxacin
 - 3rd-generation cephalosporin
- Sponges:
 - _ Gently dry skin and remove spicule:
 - Adhesive tape may aid in removal.
 - _ 5% acetic acid (vinegar) (or 40–70% isopropyl alcohol) soaks QID for 10–30 min
- Coelenterates (Cnidaria jellyfish):
 - _ Rinse wound with salt water or seawater:
 - Hypotonic (fresh or tap water solutions), trigger more nematocysts
 - _ Do not rub skin to avoid release of nematocysts.

- Inactivate toxin with 30-min soak of 5% acetic acid (vinegar)
- Remove remaining nematocysts with razor, clam shell.
- Apply topical anesthetics once nematocysts are removed.
- Sea Safe jellyfish sunblock products are available.
- Box-jellyfish sting envenomation (Australia) emergent cases:
 - Administer *Chironex* antivenin: 1 amp (20,000 U) IV diluted 1:5 with crystalloid.
- Corticosteroids for severe reactions
- Starfish:
 - Immerse in nonscalding hot water for pain relief.
 - Irrigate and explore all puncture wounds.
 - Prophylactic antibiotics for significant wounds
- Sea urchins:
 - Immerse in nonscalding hot water for pain relief.
 - Remove any remaining spines.
 - Prophylactic antibiotics for significant wounds.
- Sea cucumbers:
 - Immerse in nonscalding hot water for pain relief.
 - 5% acetic acid soaks
 - Ocular involvement:
 - Proparacaine for pain
 - Copious irrigation with NS
 - Careful slit-lamp exam
- Cone shells:
 - Hot water immersion for pain relief
 - Be prepared for cardiac or respiratory support.
- Stingrays:
 - Copious irrigation with removal of any visible spines
 - Local suction is controversial.
 - Hot water soaks for pain relief
 - Narcotics for pain control
 - High incidence of bacterial infection:
 - Administer prophylactic antibiotics for significant wounds.
- Scorpion fish:
 - Hot water soaks for pain relief and venom inactivation
 - Copious irrigation, removal of any visible spines
 - Local lidocaine or regional block for severe pain
 - Surgical exploration for deep penetration/foreign bodies
 - Stonefish antivenin for severe envenomations:
 - One 2-mL amp diluted in 50-mL saline IV slow
 - May cause serum sickness
- Catfish:
 - Hot water soaks for pain relief and venom inactivation

- Copious irrigation, removal of any visible spines
- Consider local lidocaine, regional block, or narcotics for severe pain.
- Surgical exploration for deep penetration, foreign bodies
- Leave puncture wounds open to heal.
- Consider prophylactic antibiotics for hand, foot, or deep wounds.
- Sea snakes:
 - Immobilize bitten extremity.
 - Apply pressure bandage for venous occlusion (pre-hospital).
 - Keep victim warm and still.
 - Polyvalent sea snake antivenin reduces mortality to 3%:
- May require 3–10 amps (1000 U each)
- Prepare early for assisted ventilation.

MEDICATION

- Cefixime: 400 mg (peds: 8 mg/kg/24h) PO daily
- Ciprofloxacin: 500 mg PO BID
- Epinephrine: 0.3–0.5 mL SC 1:1,000 (peds: 0.01 mL/kg)
- Tetracycline: 500 mg PO QID (caution with photosensitivity)
- TMP-SMX (Bactrim DS): 1 tab [peds: 5 mg liquid (40/200/5 mL)/10 kg per dose] PO BID (caution with photosensitivity)

FOLLOW-UP

DISPOSITION

Admission Criteria

Significant signs of systemic involvement or need for antivenom administration

Discharge Criteria

No signs of systemic illness after 8 hr of observation

Issues for Referral

Zoos, aquariums for available supplies of antivenom; poison control centers: 800-222-1222

PEARLS AND PITFALLS

- Most toxins are detoxified with either temperature change (hot water) or pH alteration (more acidic).
- Specific antivenoms for box jellyfish, stone fish, and sea snake envenomations are available but in limited supply; acquire early in treatment course.

CODES

ICD9

- 692.89 Contact dermatitis and other eczema due to other specified agents
- 989.5 Toxic effect of venom

ICD10

- T63.511A Toxic effect of contact with stingray, accidental (unintentional), initial encounter
- T63.621A Toxic effect of contact with other jellyfish, accidental (unintentional), initial encounter
- T63.691A Toxic effect of contact with other venomous marine animals, accidental (unintentional), initial encounter

MASTITIS

Hao Wang • Marco Coppola

BASICS

DESCRIPTION

- Infection of the breast causing pain, swelling, and erythema
- Most commonly in women who are breast-feeding
- Often with systemic symptoms also:
 - Malaise
 - Fever
- Incidence may be as high as 33% in lactating woman
- Onset typically 2–3 wk to months postpartum
- 75–95% occur before infant is 3 mo old
 - Rare during 1st postpartum week
- More common in advanced maternal age and patients with diabetes
- Complications:
 - Recurrence
 - Abscess
 - Sepsis
 - Necrotizing fasciitis
 - Fistula
 - Scarring
 - Breast hypoplasia

Pediatric Considerations

Can occur in full-term infants < 2 mo of age

ETIOLOGY

- *Staphylococcus aureus* most common
- Less common causes:
 - Coagulase-negative *Staphylococcus*
 - *Streptococcus* spp.
 - *Escherichia coli*
 - *Haemophilus influenzae*
 - *Candida albicans*
- Risk factors:
 - Cleft lip or palate
 - Cracked nipples
 - Infant attachment issues
 - Local milk stasis

- Nipple piercing
- Poor maternal nutrition
- Previous mastitis
- Primiparity
- Restriction from a tight bra
- Sore nipples
- Short frenulum in infant
- Use of a manual breast pump
- Yeast infection

DIAGNOSIS

SIGNS AND SYMPTOMS

- Fever and chills
 - Temperature usually $> 38.3^{\circ}\text{C}$ (101°F)
- General malaise
- Tachycardia
- Breast pain, induration, erythema, warmth; usually unilateral
- Onset typically 2–3 wk to months postpartum while breast-feeding
- Rare during 1st postpartum week

History

- Flu-like symptoms
- Fever, malaise, and myalgia
- Breast redness, swelling
- Breast pain
- Decreased milk outflow

Physical-Exam

- Breast is:
 - Warm
 - Tender
 - Indurated
 - Erythematous – often in a wedge-shaped pattern
- Usually unilateral breast involvement
- Purulent nipple discharge can occur
- Axillary lymph nodes may be enlarged

ESSENTIAL WORKUP

Physical exam with special attention to detecting abscess:

- Abscess is frequently difficult to detect, but is more common in periareolar area
- Purulent nipple discharge with palpation

Pediatric Considerations

- In neonates:
 - Consider the presence of abscess formation and systemic symptoms of infection (e.g., lethargy, poor feeding, fever)
 - Sepsis workup may be needed if neonates are febrile and ill appearing
 - A complete blood count (CBC) with differential and blood culture need to be considered before the initiation of antibiotics

DIAGNOSIS TESTS & INTERPRETATION

Lab

Breast milk culture is usually not required

Imaging

- Consider breast US if abscess is suspected
- Mammography is not indicated acutely

DIFFERENTIAL DIAGNOSIS

- Breast engorgement:
 - Transient fever $< 39^{\circ}\text{C}$ of 4–16 hr duration
 - Appearing 48–72 hr postpartum
 - Bilateral nonerythematous engorgement
- Carcinoma (inflammatory)
- Cyst, tumor
- Abscess formation

TREATMENT

PRE HOSPITAL

Generally no pre-hospital treatment needed

INITIAL STABILIZATION/THERAPY

No specific stabilization

ED TREATMENT/PROCEDURES

- Continue breast-feeding:
 - Child and mother are colonized with the same organisms
 - Milk from a breast with mastitis may be protective
 - If an infant does not like the taste of milk from a breast with mastitis, then encourage the mother to pump and discard
- Massage
- Hot/cold therapy
- Improve breast-feeding technique:

- May need a lactation consultant
- Maintain good maternal hydration.
- If mild symptoms and early in disease, antibiotics may not be necessary.
- Oral antibiotics for 7–14 days:
 - β -Lactamase-resistant penicillin (e.g., dicloxacillin)
 - 1st-generation cephalosporin (e.g., cefalexin)
 - Clindamycin or trimethoprim/sulfamethoxazole (TMP/SMX) or erythromycin if penicillin allergic
- Surgical consultation if evidence of abscess
- If considering methicillin-resistant *S. aureus* (MRSA), treat according to local susceptibility patterns:
 - Clindamycin
 - TMP/SMX
 - Vancomycin

ALERT

Vertical transmission of HIV (mother to infant) may be increased in mothers with mastitis.

MEDICATION

- Amoxicillin/clavulanate: 875 mg PO q12h
- Cephalexin: 500 mg PO q6h for 10 days
- Clindamycin: 300 mg PO q6h for 10 days
- Dicloxacillin: 500 mg PO q6h for 10 days (1st-line treatment)
- Erythromycin: 500 mg PO q6h for 10 days
- Mupirocin 2% ointment TID
- TMP/SMX: 160/800 mg PO q12h:
 - Avoid in compromised infants and healthy infants <2 mo old
- If MRSA positive: Vancomycin 1 g IV q12h

First Line

Dicloxacillin

Second Line

- Amoxicillin/clavulanate
- Cephalexin
- Erythromycin
- TMP/SMX

FOLLOW-UP

DISPOSITION

Admission Criteria

- Incision and drainage under general anesthesia may be necessary and require admission
- Immunocompromised or evidence of septicemia
- Patients with diabetes may account for 1/3 of mastitis cases
- Neonatal mastitis generally requires admission

Discharge Criteria

- Most patients may be managed in outpatient setting
- Most symptoms resolve within 48 hr of therapy
- In simple mastitis, breast-feeding may be continued, including using affected breast:
 - Gently massage to enhance drainage
 - Counsel that this will not harm baby
- Breast support, warm compresses, and analgesia for comfort
- In frank abscess, discontinue breast-feeding until purulent discharge resolves
- Follow-up should be arranged to exclude diagnosis of inflammatory carcinoma

FOLLOW-UP RECOMMENDATIONS

- Patients should follow up with primary care physician
- Lactation consultant may be helpful

PEARLS AND PITFALLS

- Most cases respond to lactation and warm compresses without antibiotics
- Cessation of breast-feeding will lead to increased milk stasis and increased risk for abscess formation
- One of the most common complications of mastitis is cessation of breast-feeding

ICD10

- N61 Inflammatory disorders of breast
- O91.23 Nonpurulent mastitis associated with lactation
- P83.4 Breast engorgement of newborn

MASTOIDITIS

Jonathan Fisher • Colby Redfield

BASICS

DESCRIPTION

- Inflammation of the mastoid air cells of the temporal bone, generally caused by direct extension of acute purulent otitis media
- Middle ear and mastoid air cells are contiguous via the aditus to mastoid antrum
- Fluid accumulation from closure of channel due to otitis media creates opportunity for infection
- Manifestation ranges from clinically insignificant inflammation of mastoid air cells to infection and destruction of the bone
- Acute mastoiditis:
 - Occurs to some degree in all cases of otitis media
 - Early signs and symptoms are those of acute otitis media
 - Usually secondary to contamination with infectious material trapped in the mastoid by inflammatory obstruction of the channel between middle ear and mastoid air cells
- Acute mastoiditis with periostitis:
 - As infection progresses, periosteum of the mastoid bone is involved, causing periostitis
 - Subperiosteal abscess may be present
- Acute mastoid ostitis (also called coalescent mastoiditis):
 - Progression of the infection within the mastoid air cells leads to destruction of the mastoid trabeculae, causing coalescence of bony trabeculae
 - Mastoid empyema or a draining fistula may be present
 - May progress to severe head and neck complications if untreated
- Masked mastoiditis:
 - Mastoid infection, which lingers after an acute otitis media has been treated
 - May progress to acute or coalescent mastoiditis
- Chronic mastoiditis:
 - Infection lasting > 3 mo
- Mastoiditis can be a complication of a primary disorder:
 - Leukemia
 - Mononucleosis
 - Sarcoma of the temporal bone
 - HIV
 - Kawasaki disease
- Mastoiditis used to be more common prior to the use of antibiotics for acute otitis media

- More common in young children and infants

ETIOLOGY

- Organisms in acute mastoiditis are similar to those in acute otitis media, but differ in frequency:
 - *Streptococcus pneumoniae*
 - Group A streptococcus
 - *Staphylococcus aureus*
 - *Haemophilus influenzae*
- Gram-negative enteric bacteria most common with chronic mastoiditis:
 - *Pseudomonas aeruginosa*
 - *Escherichia coli*
 - *Proteus mirabilis*
 - *Bacteroides* species
- Other less common causes:
 - *Mycobacterium tuberculosis*
 - *Aspergillus* species in immunocompromised states

Pediatric Considerations

- More frequently seen in the pediatric population due to strong association with otitis media
- *S. pneumoniae* is the most common cause in children

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Ear pain
- Otorrhea
- Mild to severe hearing loss
- Fever
- Headache
- History of irritability in a child
- History of recurrent otitis media

Physical-Exam

- Tenderness, edema, and erythema over the mastoid
- Lateral and inferior displacement of the auricle
- Loss of the postauricular crease
- Swelling of the posterior and superior ear canal wall
- Tympanic membrane abnormalities consistent with severe otitis media

- Purulent fluid drainage from the auditory canal
- Bulging tympanic membrane

ESSENTIAL WORKUP

Mastoiditis is a clinical diagnosis

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - Leukocytosis
- Cultures of drainage important owing to diversity of organisms:
 - If spontaneous drainage present or after surgical drainage
- Blood cultures if patient appears toxic

Imaging

- Mastoid plain radiographs:
 - Early stage of disease may show hazy or cloudy but intact mastoid
 - May reveal opacification or coalescence of the mastoid air cells or coalescence as disease progresses
 - Unreliable due to low sensitivity
- CT scan:
 - More useful, especially if abscess formation present
 - Can determine presence and extent of destruction of trabeculae as well as evaluate for the complications of mastoiditis
- MRI:
 - If intracranial involvement suspected but not confirmed by CT

Pediatric Considerations

- Conservative use of CT in children may be warranted
- The diagnosis can often be made on clinical grounds and avoids radiation exposure

Diagnostic Procedures/Surgery

Lumbar puncture:

- Cerebrospinal fluid evaluation for signs of meningitis

DIFFERENTIAL DIAGNOSIS

- Otitis media
- Cellulitis
- External otitis media
- Scalp infection with inflammation of posterior auricular nodes
- Rubella: Posterior auricular node enlargement
- Trauma to pinna or postauricular area

- Meningitis

TREATMENT

INITIAL STABILIZATION/THERAPY

- ABCs
- Airway management for signs of airway compromise
- 0.9% NS IV fluid bolus for hypotension/volume depletion

ED TREATMENT/PROCEDURES

- Initiate IV antibiotics
- Otolaryngologist consult for surgical drainage:
 - Drainage is the definitive therapy for acute or coalescent mastoiditis
 - Emergent drainage if the patient appears toxic
 - Types of surgical procedures:
 - Myringotomy drainage and tympanostomy tube placement
 - Mastoidectomy and drainage for severe extension (needed in ~ 50% of cases)

MEDICATION

- Initiate IV antibiotics:
 - Given increasing proportion of *S. aureus* as causative organism, consider including antistaphylococcal agent before culture results
 - Parenteral antibiotics can be switched to PO after patient afebrile for 36–48 hr
 - Consider antipseudomonal coverage when appropriate
- Administer pain medications:
 - NSAIDs
 - PO or parenteral narcotics

First Line

- Ceftriaxone: 1–2 g (peds: 50–75 mg/kg/24 h) IV q12–24 h
- Cefotaxime: 1–2 g (peds: 50–180 mg/kg/24 h) IV q4–6h

Second Line

- Ampicillin/sulbactam: 1.5–3 g IV q6h
- Chloramphenicol: 50–100 mg/kg/24 h IV or PO q6h
- Clindamycin: 600–2,700 mg/d IV div. q6–12h or 150–450 mg PO q6–8h (peds: 20–40 mg/kg/d IM/IV div. q6–8h or 10–25 mg/kg/d PO div. q6–8h)
- Ticarcillin/clavulanate: 3.1 g IV q4–6h
- Piperacillin/tazobactam: 3.375 g IV q6h
- Vancomycin: 1 g q8h (peds 40 mg/kg/24 h) IV q6–8h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Clinical suspicion of acute or coalescent mastoiditis
- Subperiosteal abscess
- Toxic appearing

Discharge Criteria

Patients with acute or coalescent mastoiditis should not be discharged

Issues for Referral

- Otolaryngologist consult for possible surgical drainage
- Audiography should be performed after resolution of mastoiditis to assess hearing loss

FOLLOW-UP RECOMMENDATIONS

Patients should follow up with otolaryngologist after discharge, if not admitted

COMPLICATIONS

- Bezold abscess:
 - Extension of infection to soft tissue below pinna or behind the sternocleidomastoid muscle of neck after erosion through the mastoid tip
- Petrositis:
 - Spread of the infection to the petrous air cells
- Osteomyelitis of the calvarium
- Intracranial complications:
 - Subperiosteal abscess
 - Subdural empyema:
 - Extension of infection to CNS with empyema around the tentorium
 - Sinus thromboses

Pediatric Considerations

Even with conservative management of otitis media, a 10-yr analysis did not show a significant increase in cases of acute mastoiditis.

PEARLS AND PITFALLS

- It is important to maintain a high index of suspicion for mastoiditis in setting of persistent or untreated acute otitis media.
- Failure to recognize meningitis or intracranial involvement, which require more

aggressive management, is a pitfall

- Drainage is the definitive therapy

MDMA POISONING

Mark B. Mycyk

BASICS

DESCRIPTION

- MDMA: 3,4-methylenedioxyamphetamine (“ecstasy”)
- Schedule I drug manufactured illegally
- Used recreationally:
 - Rave parties
 - Dance clubs
 - College campuses
- Onset of effects: 15–30 min after ingestion
- Duration of effects: 2–6 hr
- Pills commonly contain contaminants:
 - Caffeine
 - Ephedrine
 - Dextromethorphan
 - Ketamine
 - Related methylated amphetamines: 3,4-methylenedioxyamphetamine (MDA), 3,4-methylenedioxy-*N*-ethylamphetamine (MDEA), 3,4-methylenedioxy-*N*-butylamphetamine (MDBA), *para*-methoxyamphetamine (PMA)
- Pathophysiology:
 - Amphetamine-like structure stimulates catecholamine release.
 - Mescaline-like ring structure enhances serotonergic and dopaminergic activity.

ETIOLOGY

Deliberate or accidental ingestion of MDMA

DIAGNOSIS

SIGNS AND SYMPTOMS

- Overdose:
 - Altered mental status
 - Severe sympathomimetic symptoms
- Central nervous system:
 - Excitation
 - Coma
 - Seizures

- Cerebral edema
- Cardiovascular:
 - Hypertension (early)
 - Hypotension (late)
 - Palpitations
 - Ventricular tachycardia and ectopy
- Pulmonary:
 - Pulmonary edema
- Metabolic:
 - Hyponatremia
 - Hypoglycemia
 - Syndrome of inappropriate antidiuretic hormone
- Musculoskeletal:
 - Bruxism
 - Restlessness
 - Rigidity
- Renal:
 - Rhabdomyolysis
- Hepatic:
 - Jaundice
 - Hepatitis
- Hematologic:
 - Disseminated intravascular coagulation
- Gastrointestinal:
 - Vomiting
 - Diarrhea
 - Abdominal cramping
- Psychiatric:
 - Euphoria
 - Flight of ideas
 - Delirium/hallucinations
- Other:
 - Hyperthermia
 - Mydriasis
 - Nystagmus

ESSENTIAL WORKUP

- Diagnosis based on clinical presentation and an accurate history.
- Obtain core temperature.
- Exclude toxic coingestants or contaminants.

DIAGNOSIS TESTS & NTERPRETATION

Lab

- Electrolytes, BUN, creatinine, and glucose levels
- Prothrombin time, partial thromboplastin time, international normalized ratio
- Urine dip for blood and myoglobin
- Creatine phosphokinase level if rhabdomyolysis suspected
- Liver function tests for significant overdose or suspected hepatitis
- Urine toxicology screen to exclude coingestants:
 - May cause positive amphetamine and methamphetamine screen
- Quantitative MDMA levels rarely helpful

Imaging

- CXR if suspected aspiration pneumonia
- Head CT if suspected intracranial hemorrhage

Diagnostic Procedures/Surgery

ECG:

- Sinus tachycardia (most common)
- Dysrhythmias, conduction disturbances

DIFFERENTIAL DIAGNOSIS

- Cocaine overdose
- Amphetamine overdose
- Anticholinergic overdose
- Cathinone overdose (e.g., Bath salts)
- Serotonin syndrome
- Occult head injury
- Sepsis
- Thyroid storm
- Pheochromocytoma

TREATMENT

PRE HOSPITAL

- Transport all pills/pill bottles involved in overdose for identification in ED.
- Watch for MDMA paraphernalia:
 - Pacifiers
 - Glow sticks
 - Surgical masks

INITIAL STABILIZATION/THERAPY

ABCs:

- Airway control is essential.

- Administer supplemental oxygen.
- Intubate if indicated.
- IV access
- Naloxone, thiamine, dextrose (or Accu-Chek), if altered mental status

ED TREATMENT/PROCEDURES

- Supportive care
- Monitor core temperature and cardiac rhythm for at least 6 hr.
- Hydrate with 0.9% normal saline (NS) IV
- Hypertension:
 - _ Nitroprusside
 - _ Phentolamine
 - _ Esmolol
- Hypotension:
 - _ 0.9% NS IV bolus
 - _ Trendelenburg position
 - _ Pressors titrated to blood pressure
- Anxiety, restlessness, agitation:
 - _ Diazepam or lorazepam as needed
- Seizures:
 - _ Treat initially with benzodiazepines.
 - _ Phenobarbital for persistent seizures
- Rhabdomyolysis:
 - _ Hydrate aggressively with 0.9% NS IV
 - _ Consider sodium bicarbonate administration.
 - _ Hemodialysis if renal failure
- Hyperthermia:
 - _ Standard cooling measures
 - _ Treat agitation with benzodiazepines.

MEDICATION

- Diazepam: 5–10 mg (peds: 0.2–0.5 mg/kg) IV q10–15min
- Esmolol: 500 µg/kg IV bolus, then 50 µg/kg/min IV
- Lorazepam: 2–6 mg (peds: 0.05–0.1 mg/kg) IV q10–15min
- Naloxone: 0.4–2 mg (peds: 0.1 mg/kg; neonatal: 10–30 mg/kg) IV or IM
- Nitroprusside: 0.3 mg/kg/min to max. 10 µg/kg/min
- Phenobarbital: 10–20 mg/kg IV (loading dose)
- Phentolamine: 1–5 mg (peds: 0.02–0.1 mg/kg) IV bolus q5–10min
- Propofol: 0.5–1.0 mg/kg IV (loading dose), then 5–50 mg/kg/min (maintenance dose)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Altered mental status
- Seizures
- Persistent cardiovascular instability
- Rhabdomyolysis
- Loss of behavioral control
- Disseminated intravascular coagulation

Discharge Criteria

Asymptomatic 6 hr after oral overdose

FOLLOW-UP RECOMMENDATIONS

- Substance abuse referral for patients with recreational drug abuse
- Patients with unintentional (accidental) poisoning require poison prevention counseling.
- Patients with intentional (e.g., suicide) poisoning require psychiatric evaluation.

PEARLS AND PITFALLS

- Always obtain a core temperature.
- Concomitant recreational drugs might not be present on a routine hospital drug screen.
- For persistent altered mental status, assess electrolytes for hyponatremia.
- Consider nontoxicologic causes for altered mental status.

ICD10

- T43.621A Poisoning by amphetamines, accidental (unintentional), initial encounter
- T43.623A Poisoning by amphetamines, assault, initial encounter
- T43.624A Poisoning by amphetamines, undetermined, initial encounter

MEASLES

Austen-Kum Chai

BASICS

DESCRIPTION

- Vaccine preventable, primarily childhood, infectious disease characterized by fever, cough, coryza, conjunctivitis, and erythematous maculopapular rash
- Also known as rubeola
- Incidence is low secondary to widespread immunization

ETIOLOGY

- Rubeola is a *morbillivirus*, a negative-strand (RNA) paramyxovirus
- Humans are the only known reservoir
- Highly contagious. Respiratory isolation should be initiated when suspected. Outbreaks seen in nonimmunized or underimmunized

Pregnancy Considerations

- Increased risk of spontaneous abortion and premature contractions if infected during pregnancy.
- Does not appear to cause birth defects.
- Women should not be vaccinated with MMR or MMRV during pregnancy.

Geriatric Considerations

Those born before 1957 are generally considered immune. However, those in health care should receive vaccination if serologic testing reveals negative titer.

Pediatric Considerations

- Measles, mumps, and rubella ± Varicella (MMR or MMRV) vaccine should be administered to children on or after 12 mo of age. A 2nd dose is administered at the age of 4–6 yr, before start of school.
- Catch-up doses should be separated by at least 4 wk between vaccinations.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Incubation (10–12 days) before appearance of rash:
 - Transmission via direct contact or inhalation of infectious droplet
 - Children usually have incomplete or no immunization.
- Prodrome (1–7 days):
 - Fever, followed by mild respiratory illness, conjunctivitis, fever

- Koplik spots:
 - Small white to grayish-blue specks on buccal mucosa
 - Pathognomonic for rubeola
 - Transient. Appears 1–2 days before rash and disappears within 48 hr after onset of rash
- Active disease:
 - Cough, coryza, conjunctivitis (“three C’s”).
 - Fever of 101°F, usually higher. Fever beyond 3–4 days suggests measles related complication
 - Rash appears on day 3–7, lasting 4–7 days:
 - Begins on head and spreads centrifugally downward
 - Maculopapular blanching rash which becomes confluent. May have petechiae. Palm and soles rarely involved.
 - Clinical improvement seen in 48 hr of appearance of rash
 - Rash clears in 3–4 days and may desquamate as rash fades in order of appearance
- Complications:
 - Respiratory:
 - Cough may persist for 1–2 wk after measles infection.
 - Pneumonia (6%) seen most commonly in immunocompromised
 - Most common cause of fatality seen with measles
 - Laryngotracheobronchitis in patients <2 yr old
 - CNS:
 - Seizures <1%
 - Encephalitis
 - Encephalomyelitis:
 - *1–14 days after onset of rash. Due to post infection autoimmune response*
 - Fever, headache, vomiting, and stiff neck
 - Lethargy, stupor, and seizure followed by coma
 - Subacute sclerosing panencephalitis (SSPE):
 - *Very rare but serious complication that develops 7–10 yr after infection*
 - Insidiously progressive degeneration of CNS functions
 - Personality change, intellectual deterioration, motor and visual deficits, seizures, coma, and death
 - Cardiovascular:
 - Transient myocarditis, pericarditis, and conduction defects
 - Rarely clinically significant
 - Congestive heart failure in elderly patients
 - Thrombocytopenic purpura
 - Otitis media 7%
 - Sinusitis

- Diarrhea 8%, most common

ESSENTIAL WORKUP

- Diagnosis is based on clinical findings.
- Cough, coryza, and conjunctivitis with fever and subsequent rash

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CSF analysis for suspected encephalitis
- Viral isolation from blood, throat, nasopharynx, and urine for epidemiologic surveillance. Ideally within 7 and not more than 10 days of appearance of rash.
- Serologic tests for measles IgM and IgG titers, and PCR of measles virus RNA are available to confirm diagnosis

Imaging

Chest radiograph for suspected pneumonia

DIFFERENTIAL DIAGNOSIS

- Rubella
 - Milder course, postauricular nodes, pinker rash, no conjunctivitis
- Scarlet fever:
 - Sandpaper-textured rash, strawberry tongue, sore throat
- Infectious mononucleosis:
 - Serologic test available
- Roseola:
 - Rash appears after temperature falls.
- Erythema infectiosum (“fifth disease”):
 - No prodrome and without fever
 - Red, flushed cheeks with lace-like rash when fading
- Enterovirus:
 - No respiratory complaints
- Kawasaki disease:
 - Rash on palm and soles
- Secondary syphilis
- Toxic shock syndrome
- Drug reactions:
 - Usually without high fever and upper respiratory infection symptoms

TREATMENT

PRE HOSPITAL

Nonimmunized pre-hospital care personnel should be advised of potential risks described above.

- ABCs if indicated

ED TREATMENT/PROCEDURES

- Prevention with vaccination is cornerstone of therapy
- Antipyretics
- IV hydration if needed
- Isolate suspected cases
- Postexposure prophylaxis for the nonimmune:
 - _ Give MMR if <72 hr after exposure:
 - Avoid if pregnant or immunocompromised.
 - _ Immunoglobulin 0.25 mL/kg IM up to 15 mL (max.):
 - If given <6 days after exposure, may prevent or modify severity of symptoms
 - Indicated for susceptible household or other close contacts, particularly those <1 yr, pregnant women, or immunocompromised
 - For patients who receive immune globulin IV (IGIV) regularly, the usual dose of 400 mg/kg should be adequate for measles prophylaxis after exposure occurring within 3 wk of receiving IGIV.
 - Patients receiving IG should subsequently receive vaccine no sooner than 5–6 mo if not contraindicated.
- ABCs. Oxygenation and airway protection for:
 - _ Pneumonia
 - _ Encephalitis

MEDICATION

WHO recommends vitamin A once in a day for 2 days for children with measles where vitamin A deficiency is prevalent. It may reduce the risk of measles mortality:

- 50,000 IU for age <6 mo
- 100,000 IU for age 6–12 mo
- 200,000 IU for age >12 mo
- Parenteral and oral formulations are available in US

FOLLOW-UP

DISPOSITION

Admission Criteria

- Severe pneumonia
- Dehydration
- Encephalitis

- SSPE
- Immunocompromised patients:
 - AIDS
 - Immunosuppressive therapy
- Elderly patients with comorbid conditions

Discharge Criteria

Duration of infectivity:

- 4 days before symptoms and up to 4 days after onset of rash
- Immunocompromised are contagious for duration of illness

PEARLS AND PITFALLS

- One of the most highly communicable of infectious diseases; death occurs in 1–3/1,000 cases in US. Respiratory isolation in health care settings is a must
- Severely immunocompromised patients, those on immunotherapy, and pregnant patients should not receive MMR or MMRV vaccine.
- Characteristic rash may not develop in immunocompromised patients.

- B05.2 Measles complicated by pneumonia
- B05.9 Measles without complication

MECKEL DIVERTICULUM

Galeta C. Clayton

BASICS

DESCRIPTION

- Most common congenital abnormality of the GI tract
 - Results from incomplete obliteration of the omphalomesenteric duct
- True diverticula (contains all layers):
 - 50% contain normal ileal mucosa.
 - 50% contain either gastric (most common), pancreatic, duodenal, colonic, endometrial, or hepatobiliary mucosa.
- Rule of 2's:
 - 2% prevalence in general population
 - 2% lifetime risk for complications, decreasing with age
 - Symptoms commonly occur around 2 yr of age:
 - 45% of symptomatic patients < 2 yr old
 - Average length 2 in
 - Found within 2 ft of the ileocecal valve
- Male-to-female ratio approximately equal, but more often symptomatic in males
- Complications:
 - Obstruction and diverticulitis in adults
 - Hemorrhage and obstruction in children
 - Mean age 10 yr
 - Current mortality rate 0.0001%
 - Occurs more frequently in males
- Obstruction:
 - Diverticulum attached to the umbilicus, abdominal wall, other viscera, or is free and unattached, leading to:
 - Intussusception: Diverticulum is the leading edge.
 - Volvulus: Persistent fibrous band leads to bowel rotation.
- Diverticulitis:
 - Opening obstructed
 - Bacterial infection follows.
 - Presents like appendicitis (most common preoperative diagnosis with Meckel diverticulum)

Pediatric Considerations

- Most common cause of significant lower GI bleeding in children.
- Presents at age < 5 yr with episodic painless, brisk, and bright-red rectal bleeding.

ETIOLOGY

Remnant of the omphalomesenteric duct that typically regresses by week 7 of gestation.

DIAGNOSIS

SIGNS AND SYMPTOMS

- 3 different types of presentation:
 - *Rectal bleeding* due to hemorrhage, which results from mucosal ulcerations within the ectopic gastric tissue
 - *Vomiting* due to obstruction secondary to volvulus, intussusceptions, or intraperitoneal bands
 - *Abdominal pain* (appendicitis like) due to an inflamed or perforated diverticulum
- General:
 - Fever
 - Malaise
 - Weakness
 - Fatigue
- GI:
 - Classically painless rectal bleeding
 - Abdominal pain:
 - Location depends on cause
 - Appendicitis like
 - Vomiting
 - Distention
 - Changes in bowel movements
 - Hematochezia or melena (depending on briskness or location of diverticulum)
 - Peritonitis and septic shock (late complications)
- Cardiovascular:
 - Tachycardia (due to pain or blood loss)
 - Hypotension and shock (due to bleeding)

ESSENTIAL WORKUP

- May cause a variety of signs and symptoms:
 - < 10% diagnosed preoperatively
 - Consider in patients with recurrent nonspecific abdominal pain, nausea and vomiting, or rectal bleeding.
- History and physical exam narrow diagnosis, but will not give specific findings for Meckel diverticulum.
- Rectal exam mandatory
- Nasogastric (NG) tube placement to rule out upper GI bleed

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - _ Decreased hematocrit due to bleeding
 - _ Rarely a cause of chronic anemia
 - _ Leukocytosis with diverticulitis, perforation, or gangrene
- Electrolytes, BUN, creatinine, coagulation studies
- Type and screen/cross-match when significant GI bleeding.

Imaging

- CT abdomen/pelvis:
 - _ For suspected infection (appendicitis/diverticulitis) or bowel obstruction
- Abdominal radiographs:
 - _ Screening for bowel obstruction
 - _ Cannot diagnose Meckel diverticulum
- Tc-99m pertechnetate radioisotope scan (Meckel scan):
 - _ Noninvasive scan that identifies Meckel diverticulum containing heterotopic gastric mucosa
 - _ 90% accurate in children
 - _ 45% accurate in adults
- Small bowel enteroclysis:
 - _ 75% accuracy
 - _ Barium/methyl cellulose introduced through NG tube into distal duodenum or proximal jejunum
 - _ Increases the ability to detect Meckel diverticulum in adults
 - _ Diverticulum may be short and wide-mouthed, making diagnosis difficult.
- Barium enema:
 - _ Introduces fluid into distal small bowel
 - _ Look for diverticulum
- Angiogram for further evaluation of Meckel diverticulum if radioisotope scan and enteroclysis normal:
 - _ Blood supply is not always abnormal (vitelline artery).
- Ultrasound may be useful in nonbleeding presentations.
- Laparoscopic evaluation may provide both diagnosis and definitive treatment.
- ECG:
 - _ Eliminate myocardial ischemia as cause of abdominal pain.
- Colonoscopy:
 - _ Not useful in diagnosing Meckel diverticulum

DIFFERENTIAL DIAGNOSIS

- Adults:
 - _ Adhesions

- Appendicitis
- Arteriovenous malformation
- Bowel obstruction
- Diverticulitis
- Hemorrhoids
- Inflammatory bowel disease
- Internal hernias
- Intestinal polyps
- Intussusception
- Peptic ulcer disease
- Pseudomembranous colitis
- Volvulus
- Pediatric:
 - Adhesions
 - Anal fissures
 - Appendicitis
 - Atresia
 - Gastroenteritis
 - Hemolytic-uremic syndrome
 - Henoch–Schönlein purpura
 - Intestinal polyps
 - Intussusception
 - Malrotation
 - Milk allergy
 - Strictures
 - Volvulus

TREATMENT

PRE HOSPITAL

Establish IV access for patients with rectal bleeding or abdominal pain.

INITIAL STABILIZATION/THERAPY

- Stabilization followed by early surgical evaluation
- Hypotension:
 - Aggressive fluid resuscitation
 - Packed RBC (PRBC) transfusion with brisk rectal bleeding (more common in children)
 - Pressors for septic shock

ED TREATMENT/PROCEDURES

- GI bleeding:

- Fluid resuscitate and transfuse PRBC as indicated
- Foley to follow urine output
- NG tube to exclude brisk upper GI bleeding
- Surgical consult for surgical intervention as indicated
- Obstruction:
 - NG tube
 - Foley
 - Surgical consult
- Diverticulitis/perforation:
 - NPO
 - Preoperative antibiotics
 - Surgical consult
- Surgical intervention:
 - Symptomatic Meckel diverticula should be resected
 - Asymptomatic Meckel diverticula discovered incidentally at laparotomy in children should be resected

MEDICATION

- Ampicillin/sulbactam (Unasyn): 3 g (peds: 100–200 mg ampicillin/kg/24h) q8h IV
- Cefoxitin (Mefoxin): 1–2 g (peds: 100–160 mg/kg/24h) IV q6h
- Dopamine: 2–20 μ /kg/min IV

FOLLOW-UP

DISPOSITION

Admission Criteria

Presumptive diagnosis of Meckel diverticulum with diverticulitis, obstruction, intussusception, hemorrhage, or volvulus requires admission and surgical evaluation.

Discharge Criteria

None

FOLLOW-UP RECOMMENDATIONS

Postoperative surgical follow-up

PEARLS AND PITFALLS

- Painless, brisk, bright-red blood per rectum in an infant is often caused by Meckel diverticulum.
- Presents with a wide range of complications, including obstruction, intussusception, and hemorrhage.
- Often diagnosed in the OR for patients undergoing surgery for a presumptive

appendicitis.

- Rule of 2's:
 - 2% of the population
 - 2% risk of complications
 - Mostly <2 yr old
 - 2 in long
 - 2 ft from the ileocecal valve

MÉNIÈRE DISEASE

Amira M. Bass • Charles V. Pollack, Jr.

BASICS

DESCRIPTION

- Disease of the inner ear
- Classically unilateral ear involvement (may be bilateral in up to 40% of cases)
- Characterized by recurrent spontaneous and episodic vertigo, sensorineural hearing loss, “roaring” tinnitus, and aural fullness
- Estimated incidence about 15/100,000 in US
- Slight female > male (1.3:1)
- Positive family history up to 20%
- May develop at any age
 - Peak incidence is age 40–60 yr.
- Affects more Whites of Northern European descent than Africans or Blacks
- A benign disease without cure
- Can be associated with significant morbidity

ETIOLOGY

- Idiopathic
- Endolymphatic hydrops: Blockage of the endolymphatic sac and duct leading to endolymphatic outflow obstruction and increased hydraulic pressure within the endolymphatic system:
 - Increased pressure causes a break in the membrane that separates the perilymph (potassium [K]-poor extracellular fluid) and the endolymph (K-rich intracellular fluid)
 - The resultant chemical mixture bathes the vestibular nerve receptors, leading to a depolarization blockade and transient loss of function
- May be associated with structural abnormalities such as atrophy of the sac, hypoplasia of the vestibular aqueduct, narrowing of the endolymphatic duct, forwardly located lateral sinus causing compression, and obstruction of the endolymphatic sac
- Autoimmune processes suggested as an etiology, with immune complex deposition in endolymphatic sac and autoantibodies directed against endolymphatic sac
- Thought to have a genetic predisposition, leading to earlier age of onset and more severe symptoms
- Other proposed mechanisms are subclinical viral infection causing hydrops many decades later, and ischemia of the endolymphatic sac and the inner ear
- Need to differentiate Ménière syndrome from other disease processes that interfere with normal production or resorption of endolymph (e.g., thyroid disease, inner

ear inflammation due to syphilis, medication)

DIAGNOSIS

- Diagnosis based upon clinical symptoms and neurotologic evaluation
- Definitive diagnosis currently can only be made postmortem, though MRI holds potential for definitive diagnosis
- Diagnostic criteria (1995 American Academy of Otolaryngology guidelines):
 - At least 2 episodes of spontaneous and episodic vertigo, ≥ 20 min
 - At least 1 episode of hearing loss documented by audiogram
 - Tinnitus or aural fullness in the affected ear
 - Certain Ménière disease: Definite disease with histopathologic confirmation
 - Definite Ménière disease: 2 or more definitive episodes of vertigo with hearing loss, plus tinnitus, aural fullness, or both
 - Probable Ménière disease: Only 1 definitive episode of vertigo and the other symptoms and signs
 - Possible Ménière disease: Definitive vertigo with no associated hearing loss or hearing loss with nondefinitive disequilibrium

SIGNS AND SYMPTOMS

History

- Classical tetrad of symptoms:
 - Vertigo
 - Hearing loss
 - Tinnitus
 - Aural fullness
- Vertiginous attacks lasting minutes to hours, often associated with nausea and vomiting (96.2%)
- Sensorineural hearing loss is typically fluctuating and progressive
 - Low frequencies are affected more severely than high frequencies (87.7%)
 - Can result in permanent hearing loss at all frequencies
- Tinnitus is typically low pitch
- Aural fullness is described as pressure, discomfort, fullness sensation in unilateral ear
- Attacks reach maximum intensity within minutes, slowly subside over hours
- After the acute attack, patients generally feel tired, unsteady, and nauseated for hours to days
- Between episodes, some patients are completely symptom free
- Sudden, unexplained falls without loss of consciousness or associated vertigo may also occur
- Constellation of symptoms can vary from patient to patient
 - Auditory and vestibular symptoms may not be present simultaneously or in

the same pattern, particularly in the early phases of disease

- Close clustering of attacks may occur

Physical-Exam

- Exam results vary, depending upon the phase of disease
- During acute attack, patients are often in significant distress, diaphoretic, and pale
- Vital signs may show elevated blood pressure, pulse, and respiration
- Horizontal nystagmus
- Impaired hearing
- Pneumo-otoscopy may elicit symptoms or cause nystagmus
- Weber tuning fork test usually lateralizes away from the affected ear
- Rinne test usually indicates better air than bone conduction
- Positive Romberg test, with instability, especially when eyes are closed
- Must exclude central CNS lesion, peripheral pathology in ear (ruptured tympanic membrane, cholesteatoma, cerumen impaction, etc.)

ESSENTIAL WORKUP

- Complete history and neurologic exam
- Patients with central vertigo or focal neurologic findings require neuroimaging
- Focal findings include new unilateral hearing loss, usually with tinnitus

DIAGNOSIS TESTS & INTERPRETATION

Lab

When indicated:

- CBC
- Sedimentation rate
- Thyroid function
- Fasting lipid profiles
- Fasting blood glucose, hemoglobin A1c
- Treponemal antibody-absorption test
- Chemistry panel
- Urinalysis for proteinuria or hematuria

Imaging

- MRI with intratympanic gadolinium and views of internal auditory canal (typically outpatient)
- CT scan of temporal bone
- Standard lateral mastoid radiographs

Diagnostic Procedures/Surgery

- Audiometric assessment
- Bithermal caloric testing

- Transtympanic electrocochleography
- Electronystagmography

DIFFERENTIAL DIAGNOSIS

- Otologic:
 - Chronic suppurative otitis media
 - Benign positional vertigo
 - Acoustic neuroma
 - Vestibular neuronitis
 - Vestibular paroxysmia
 - Otosclerosis
 - Otic capsule dysplasia
 - Perilymphatic fistula
 - Labyrinthitis
- Systemic:
 - Vertebrobasilar insufficiency
 - Stroke and transient ischemic attack
 - Basilar artery thrombosis
 - Intracranial hemorrhage
 - Head trauma
 - CNS lesions (tumors)
 - Epilepsy
 - Multiple sclerosis
 - Paget disease
 - Diabetes
 - Concussive syndrome
 - Pseudotumor cerebri
 - Complex or vestibular migraine
 - Thyroid dysfunction
 - Drugs/medications
 - Autoimmune disorders (e.g., systemic lupus erythematosus)
 - Viral meningitis/encephalitis
 - Lyme disease
 - Neurosyphilis
 - Electrolyte imbalance
 - Panic attacks

TREATMENT

PRE HOSPITAL

- Vertigo and neurologic symptoms can represent a stroke
- Rapid transport to ED

- Protect patient from falling
- Maintain patient in comfortable position
- IV isotonic fluids for patients with vomiting
- Monitor for dysrhythmia

INITIAL STABILIZATION/THERAPY

- IV hydration with isotonic fluids
- IV benzodiazepines
- IV antiemetics

ED TREATMENT/PROCEDURES

Supportive therapy

MEDICATION

- Symptomatic:
 - Meclizine: 12.5–25 mg PO q8h
 - Diazepam: 5–10 mg PO/PR/IV
 - Lorazepam: 0.5–2 mg PO/IV/IM
 - Dimenhydrinate: 12.5–50 mg PO
 - Ondansetron: 4–8 mg IV/IM/PO
 - Metoclopramide: 10 mg IV/IM
 - Promethazine: 10–25 mg PO/PR/IV/IM
 - Prochlorperazine: 10 mg IV
- Therapeutic:
 - Hydrochlorothiazide: 25–50 mg PO daily
 - Triamterene: 100 mg PO daily
 - Acetazolamide: 250 mg PO daily
 - Furosemide: 20 mg PO daily
 - Prednisone: 1 mg/kg PO daily with taper over 7–14 days
 - Dexamethasone: 4 g/L transtympanic injection
 - Gentamicin transtympanic perfusion
 - Pressure pulse treatment
 - Surgery (surgical labyrinthectomy, vestibular neurectomy, sacculotomy)

First Line

- Diazepam or lorazepam
- Ondansetron for nausea, vomiting
- IV fluid

Second Line

- Meclizine
- Prochlorperazine

FOLLOW-UP

DISPOSITION

Admission Criteria

Patient refractory to acute control of vertigo and associated effects (e.g., dehydration from protracted vomiting)

Discharge Criteria

- Tolerate oral fluids
- Steady gait
- Normal neurologic exam
- Fall precautions
- Recurrent attacks are typical
- Dietary restrictions: Sodium, caffeine, chocolate, tobacco, and alcohol intake
- Patient needs to avoid driving, operating dangerous equipment, and working at heights until attacks have resolved and sedating medications have been withdrawn

Issues for Referral

- Persistent/intractable symptoms and medical treatment failures
- Presence of ear pathology

FOLLOW-UP RECOMMENDATIONS

- Proper education in terms of dietary control and avoidance techniques is helpful
- Vestibular rehabilitation can be helpful in teaching patients to cope with vertigo and imbalance
- Counsel regarding fall risks and avoiding dangerous tasks due to the unpredictable nature of the disease
- Refer to neurologist, otologist, and otolaryngologist for outpatient audiometry and electronystagmography testing

PEARLS AND PITFALLS

- Ménière disease typically presents with the classic tetrad of vertigo, hearing loss, tinnitus, and aural fullness
- Treatment focus is symptom relief, not cure
- Discharged patients should be referred to an outpatient neurologist, otologist, and otolaryngologist
- Inpatient care is generally unnecessary and is reserved for patients refractory to acute control of their symptoms or associated effects such as dehydration and vomiting
- Surgery is reserved for patients who fail medical therapy with intractable

MENINGITIS

Austen-Kum Chai • Patricia Shipley

BASICS

DESCRIPTION

CNS infection with inflammation of leptomeninges defined by an increased number of WBCs in the CSF often associated with fever, nuchal rigidity, headache, and altered mental status.

ETIOLOGY

- Bacterial:
 - Neonates: Group B *Streptococcus*, *Escherichia coli* and other enteric bacilli, *Listeria monocytogenes*
 - Children/adults: *Streptococcus pneumoniae*, *Neisseria meningitidis*, group B *Streptococcus* and gram-negative bacilli (< 3 yr)
 - Elderly/alcoholic: *S. pneumoniae*, gram-negative bacilli, *Listeria* spp.
 - Neurosurgical patients: *Staphylococcus* and gram-negative organisms
 - Transplant recipients and dialysis patients: Increased incidence of *Listeria* spp. infection
 - AIDS: Above, plus tuberculosis, fungal, syphilis
- Viral
- Fungal
- Chemical, drug, or toxin induced

DIAGNOSIS

SIGNS AND SYMPTOMS

- General:
 - Fever
 - Nuchal rigidity:
 - Kernig: Flexed knee resists extension (bilateral).
 - Brudzinski: Flexion of neck produces flexion at hips.
 - Kernig and Brudzinski signs are neither sensitive nor specific for meningitis.
 - Altered mental state, headache
 - Photophobia
 - Papilledema
 - Focal CNS abnormalities
 - Seizure, nonsimple
 - Petechial and palpable purpuric rash (meningococcal infection)

- Associated infections: Sinusitis, otitis media, pneumonia
- Infant/pediatric:
 - Fever or hypothermia
 - Lethargy
 - Weak suck
 - Vomiting
 - Dehydration
 - Respiratory distress
 - Apnea
 - Cyanosis
 - Bulging fontanel
 - Hypotonia
 - Meningismus often absent in < 1 yr old
- Elderly and immune compromised:
 - Confusion with or without fever
 - Less-striking symptoms overall

History

- Neonates: Prematurity, intrapartum complications as fever, prolonged rupture of membrane, antibiotic use, group B *Streptococcus* infection
- Adults: Recent travels
- Elderly: Pneumococcal vaccination status
- Immunologic incompetency suggested by frequent infections
- Recent trauma or ENT, facial, or neurologic surgery
- Shunt

ESSENTIAL WORKUP

- Treat immediately based on clinical suspicion
- Blood cultures. Give antibiotic therapy if at all possible after blood cultures but before other diagnostic procedures if patient is unstable.
- Routine CT before lumbar puncture (LP) not always required. Generally indicated with:
 - Immune deficiency/HIV
 - History of CNS disease (abscess, bleed, mass lesion, stroke, shunt)
 - History of seizure < 7 days
 - Focal neurologic deficit
 - Altered level of consciousness
 - Age > 60 yr
 - Papilledema
- LP: Every suspected meningitis patient unless contraindicated:
 - May delay LP when:
 - Risk for herniation (see above)
 - Unstable patient

- Thrombocytopenia or bleeding diathesis
- Spinal epidural abscess
- Overlying soft tissue infection
- CSF analysis:
 - _ Tube 1: Cell count and differential
 - _ Tube 2: Protein and glucose
 - _ Tube 3: Gram stain, culture, and sensitivity
- May add acid-fast bacillus smear, TB culture, India ink and fungal cultures, VDRL, cryptococcal antigen as needed
 - _ Tube 4: Repeat cell count or save for additional tests.
 - _ Check for elevated opening pressure: Normal up to 200 mm H₂O
 - _ Latex agglutination (optional):
 - Useful if other tests are not diagnostic
 - Best if urine and blood also tested
 - Detects: *Meningococcus*, *Pneumococcus*, group B *Streptococcus*, *Haemophilus influenzae*, *E. coli*, *Cryptococcus*
 - _ Polymerase chain reaction (optional):
 - Useful for virus (especially herpes simplex) and bacteria: *N. meningitidis*, *S. pneumoniae*, *H. influenzae* A and B
 - _ CSF interpretation:
 - Culture is diagnostic
 - >4 WBC/mL in CSF is highly sensitive for meningitis for age >3 mo and >9 WBC/mL for infants 29–90 days.
 - Cell count may be normal in HIV/AIDS.
 - Neonate: Up to 20–25 WBC/mL and protein up to 150 mg/dL in term and up to 100 mg/dL in preterm neonate may be normal.
 - _ Typical bacterial meningitis:
 - CSF glucose <40 mg/dL. Also ratio of CSF to blood glucose <0.6.
 - WBC >500/mL (usually 1,000–20,000). However, significantly fewer WBC count may be seen in the early course of the disease.
 - Differential >80% polymorphonuclear neutrophils (PMNs) is suggestive.
 - CSF protein >200 mg/dL. Normally <50 mg/dL.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Blood cultures (2 sets) before antibiotics
- Urine culture and urinalysis
- CBC with differential and platelets
- Electrolytes/glucose:
 - _ Calculate CSF glucose to serum glucose ratio

- Assess for metabolic acidosis, SIADH
- BUN/creatinine for medication dosing
- Prothrombin time, partial thromboplastin time, and platelet: Particularly in patients with petechiae or purpura:
 - Obtain before LP in severe sepsis or disseminated intravascular coagulation
- Toxicology studies as needed

Imaging

- CT: See essential workup section above.
- CXR: Pneumonia, TB if suspected

DIFFERENTIAL DIAGNOSIS

- Encephalitis
- Brain, spinal, epidural abscess
- Febrile seizure
- CNS/systemic lupus erythematosus cerebritis
- Intracranial bleed
- Primary or metastatic CNS malignancy
- Stroke
- Venous sinus thrombophlebitis
- Trauma
- Toxic/metabolic

TREATMENT

PRE HOSPITAL

- IV, O₂, and transport. ABCs
- Administer prophylactic antibiotics to any close personal contacts of patient diagnosed with meningococcal meningitis:
 - Adults:
 - Rifampin: 600 mg PO BID for 2 days; *or*
 - Ciprofloxacin: 500 mg PO single dose; *or*
 - Ceftriaxone: 250 mg IM (if pregnant)
 - Children:
 - Rifampin: 5 mg/kg if < 1 mo old and 10 mg/kg if > 1 mo old, BID for 4 doses

INITIAL STABILIZATION/THERAPY

- Isolate patient as appropriate.
- ABCs. Treat seizures.

ED TREATMENT/PROCEDURES

- Ideally perform LP and give antibiotic ± steroids promptly.
- If LP is delayed, give antibiotic ± steroids empirically before LP.
- If CT is indicated prior to LP, empiric antibiotic ± steroids should be given prior to CT.
- Steroids: If given, should be given prior to, or concurrently with, administration of antibiotics.
- Antibiotics:
 - _ Obtain blood cultures before antibiotics.
 - _ Do not delay giving antibiotics to obtain LP or CT unless absolutely necessary.
- IV (or IM) empiric antibiotics for presumed bacterial Infection:
 - _ Neonates:
 - 0–7 days old: Ampicillin 50–100 mg/kg q6h + gentamicin 2.5 mg/kg q8–12h
 - >7 days old: Ampicillin 50–100 mg/kg q6–8h; + cefotaxime 50 mg/kg q6h or gentamicin 2.5 mg/kg q8h
 - Add acyclovir 10–20 mg/kg q8h for suspected herpes simplex encephalitis.
 - _ Age 1–3 mo:
 - Ampicillin 50–100 mg/kg q6h; + ceftriaxone 75 mg/kg load, then 50 mg/kg q12h thereafter or cefotaxime 50 mg/kg q6h; + vancomycin 15 mg/kg q8h (if cephalosporin-resistant *S. pneumoniae* prevalent) ± dexamethasone (0.15 mg/kg q6h for 4 days)
 - _ Children > 3 mo:
 - Ceftriaxone 100 mg/kg/d or 50 mg/kg q12h or cefotaxime 50 mg/kg q6h + vancomycin 15 mg/kg q8h ± dexamethasone 0.15 mg/kg q6h for 4 days
 - Immune deficient: Add gentamicin 2.5 mg/kg q8h or amikacin 7.5 mg/kg q12h or 5 mg/kg q8h.
 - CNS surgery: Vancomycin 15 mg/kg q8h; + meropenem 40 mg/kg q8h or ceftazidime 50 mg/kg q8h or cefepime 50 mg/kg q8h
 - Penetrating head trauma: Vancomycin 15 mg/kg q8h; + cefepime 50 mg/kg q8h or ceftazidime 50 mg/kg q8h or meropenem 40 mg/kg; + gentamicin 2.5 mg/kg q8h or amikacin 5–10 mg/kg q8h
 - _ Adults:
 - Ceftriaxone 2 g q12h or cefotaxime 2 g q4–6h; + vancomycin 15–20 mg/kg q8–12h (not to exceed 2 g/dose or 60 g/kg/d); + dexamethasone (15 mg/kg) up to 10 g q6h IV, continue for 4 days if causative agent is *S. pneumoniae*
 - >50 yr: Add ampicillin 2 g q4h to above regimen for Listeria coverage
 - Immune impaired: Vancomycin 15–20 mg/kg q8–12h + ampicillin 2 g q4h; + meropenem 2 g q8h or cefepime 2 g q8h

- CNS surgery, shunt, head trauma: Vancomycin 15–20 mg/kg q8–12h; + meropenem 2 g
- Vancomycin dosing for patients with normal renal function: 50–89 kg (1 g q12h), 90–130 kg (1.5 g q12h), > 130 kg (2 g q12h)
- Other medication considerations:
 - _ Dexamethasone:
 - Benefits are not conclusive.
 - May be beneficial for children with *H. influenzae* meningitis and may be beneficial in children >6 wk and adults with *S. pneumoniae meningitis*. May reduce neurologic sequelae
 - Give before or with antibiotics in patient with altered mental status, focal neurologic deficit, papilledema, or CNS trauma, surgery, or space-occupying lesion. Give if CSF is cloudy, has positive Gram stain, or > 1,000 WBC/mm³.
 - _ Penicillin allergy (severe):
 - Aztreonam or chloramphenicol may be used in place of cephalosporins.
 - Do not delay therapy for lesser allergy history.
 - _ Vancomycin:
 - Add when concerned about penicillin-resistant pneumococcal infection.
 - _ Acyclovir if suspect herpes simplex virus encephalitis

MEDICATION

- Acyclovir: 30 mg/kg/d q8h IV (Neonate: 20 mg/kg/d q8h IV)
- Amikacin: Peds: 7.5 mg/kg q12h or 5 mg/kg q8h IV. Newborn: Load 10 mg/kg followed by 7.5 mg/kg q12h IV
- Ampicillin: 2 g q4h (peds: 50–100 mg/kg q6h–q8h) IV, max. 12 g/d
- Aztreonam: 2 g (peds: 30 mg/kg) q6–8h, max. 6–8 g/d IV
- Bactrim: 5–10 mg/kg trimethoprim q12h IV
- Cefepime: 2 g q8h, max. 6 g/d IV
- Cefotaxime: 2 g (peds: 50 mg/kg) q6h, max. 8–12 g/d IV
- Ceftazidime: 2 g q8h, max. 6 g/d IV
- Ceftriaxone: 2 g (peds: 50–75 mg/kg) q12h, max. 4 g/d IV
- Chloramphenicol: 1–1.5 g (peds: 12.5 mg/kg) q6h, max. 4–6 g/d IV
- Dexamethasone: 10 mg (peds: 0.15 mg/kg) q6h IV for 4 days
- Gentamicin: Peds: 2.5 mg/kg q8h IV
- Meropenem: 2 g (peds 40 mg/kg) q8h IV, max. 6 g/d
- Tobramycin: Peds: 2.5 mg/kg q8h IV
- Vancomycin: 1–2 g q8–12h IV (peds: 15 mg/kg q8h)
- Vancomycin and aminoglycosides: Adjust for renal function and serum concentration levels.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Known or suspected bacterial infection
- Immune-compromised host
- Any toxic-appearing patient

Discharge Criteria

- Clear viral infection. Controlled symptoms.
- Thorough and specific discharge instructions
- Careful follow-up plan discussed with primary care physician prior to discharge

PEARLS AND PITFALLS

- Meningitis generally does not present as uncomplicated febrile seizure in children.
- Failure to diagnose or delay in treatment of meningitis results in catastrophic outcome for patients, and not infrequently, negative medicolegal consequences for the physicians involved.

CODES

ICD9

- 320.2 Streptococcal meningitis
- 320.9 Meningitis due to unspecified bacterium
- 322.9 Meningitis, unspecified

ICD10

- G00.2 Streptococcal meningitis
- G00.9 Bacterial meningitis, unspecified
- G03.9 Meningitis, unspecified

MENINGOCOCCEMIA

Brian D. Euerle

BASICS

DESCRIPTION

- Bacterial illness caused by *Neisseria meningitidis*
- Several forms of illness may occur
- Mild meningococemia
- Overwhelming meningococcal sepsis
- Meningococcal meningitis
- Chronic/occult meningococemia
- Septic arthritis
- Acquired from close contact with an infected individual or an asymptomatic carrier
- Intimate kissing and cigarette smoking are independent risk factors.

ETIOLOGY

- *N. meningitidis*:
 - Serotypes A, B, C, D, H, I, K, L, X, Y, Z, 29E, and W135
 - Serotype B is most common in US
 - Majority of infections caused by A, B, C, X, Y, and W135
- Bacteria attach to and enter nasopharyngeal epithelial cells.
- Bacteria spread from the nasopharynx through the bloodstream via entry of vascular endothelium.
- Most circulating meningococci are eliminated by the spleen.
- Meningococci produce an endotoxin (lipooligosaccharide):
 - Involved in pathogenesis of the skin, adrenal manifestations, and vascular collapse
- Human oropharynx/nasopharynx is the only reservoir.
- Carrier usually has developed immunity to serotype-specific antibody (not immune to all serotypes):
 - Age < 5 yr: 1% carrier rate
 - Age 20–40 yr: 30–40% carrier rate
 - Lower rate of immunity in children, which is reflected by the higher rates of infection
- Most common in fall and spring
- Increased incidence in military recruits and close living conditions
- Epidemics—ages 5–9 yr most/earliest affected

DIAGNOSIS

SIGNS AND SYMPTOMS

- “Mild” meningococemia:
 - _ Most common
 - _ Preceded by upper respiratory infection
 - _ Fever, chills, myalgias/artralgias, malaise
 - _ Often self-limited, resolving in several days
 - _ Can progress to meningitis (mortality rate 2–10%) or overwhelming sepsis without meningitis
- Overwhelming meningococcal sepsis:
 - _ 10% of overall meningococemia cases
 - _ High mortality rate (20–60%)
 - _ Most deaths occur in 1st 48 hr
 - _ Sudden onset of illness and rapid progression of clinical course
 - _ Initial presentation may be mild:
 - Mild tachycardia
 - Mild tachypnea/respiratory symptoms
 - Mild hypotension
 - _ Fever, chills, vomiting, headache, rash, muscle tenderness
 - _ Toxic appearing
 - _ Infants: Lethargy, poor feeding, bulging fontanel
 - _ Rash:
 - Combination of purpura/ecchymosis
 - May later exhibit coalescence, necrosis/sloughing of the involved skin (purpura fulminans)
 - Petechiae (over skin, mucous membranes, conjunctivae) seen in 50–60%
 - Macules
 - Papules (scrapings of papules demonstrate the organism on Gram stain)
 - _ Deteriorate quickly over several hours:
 - Hypotension/shock
 - Acidosis
 - Acute respiratory distress syndrome (ARDS)
 - Disseminated intravascular coagulation (DIC)
 - _ Meningitis may or may not be present.
 - _ Waterhouse–Friderichsen syndrome:
 - Bilateral hemorrhagic destruction of adrenal glands
 - Vasomotor collapse
 - _ Acute renal failure:
 - From prolonged hypotension (low renal perfusion causing acute tubular necrosis)
- Chronic meningococemia:
 - _ Uncommon

- Well appearing
- Recurrent fevers, chills, arthralgias over weeks to months
- Intermittent rash—painful on the extremities
- Migratory polyarthritits
- Splenomegaly (20%)
- Meningococcal meningitis:
 - Headache
 - Fever
 - Neck stiffness
 - Confusion
 - Lethargy
 - Obtundation
- Septic arthritis:
 - Occurs during active meningococemia
 - Multiple joints involved
 - Joint pain, redness, swelling, effusion, fever, chills
 - Extremely limited or no range of motion
- Other meningococcal infections:
 - Occur with meningococcal infection elsewhere
 - Conjunctivitis—may occur alone
 - Sinusitis
 - Panophthalmitis
 - Urethritis
 - Salpingitis
 - Prostatitis
 - Pneumonia
 - Myocarditis/pericarditis:
 - Occurs late in onset
 - Usually associated with serogroup C

History

Progression of illness is variable and classifies illness into mild, overwhelming, and chronic.

Physical-Exam

- Tachycardia
- Hypotension, which may be mild initially
- Progressive, rapid deterioration
- Respiratory failure with ARDS picture
- Petechial rash 50–80%:
 - Involves axillae, flanks, wrists, ankles

ESSENTIAL WORKUP

- Do not allow workup (including delay in lumbar puncture) to postpone resuscitation and administration of antibiotics in suspected cases of meningococemia.
- Suspect diagnosis in setting of dramatic clinical presentation.
- Gram stain and culture of:
 - Peripheral blood, CSF, sputum, urine, joint aspirate, or petechial/papular scrapings
 - Gram stain: Intracellular or extracellular gram-negative diplococci

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - Elevated WBCs initially; later may be suppressed in severe disease
 - Decreased platelet count when large areas of purpura/petechiae or DIC
- Electrolytes, BUN, creatinine, glucose
- CSF:
 - Gram stain, culture, protein and glucose, cell count with differential
 - Consistent with bacterial infection in meningococcal meningitis
- Arterial blood gases for acidosis, hypoxia
- Fibrinogen levels, fibrin degradation products, prothrombin time, partial thromboplastin time if DIC suspected
- Throat/nasopharyngeal swab:
 - Positive swab does not establish the diagnosis of meningococemia.
- Analysis of buffy-coat layer of peripheral blood for bacteria if sepsis is suspected
- Blood culture:
 - Often negative with chronic meningococemia
 - Positive in mild and overwhelming meningococemia
- Immunoassays (beware false negatives)
- Polymerase chain reaction, especially useful when antibiotics given before specimen collection

Imaging

CXR: For ARDS/pneumonia

Diagnostic Procedures/Surgery

Amputations and débridement of necrotic tissue and/or extremities may be necessary.

DIFFERENTIAL DIAGNOSIS

- Viral exanthem
- Vasculitis
- Mycoplasma
- Rocky Mountain spotted fever

- Toxic shock syndrome
- Henoch–Schönlein purpura
- Idiopathic thrombocytopenic purpura
- Dengue fever
- Disseminated gonococcal infection
- Influenza
- *Streptococcus* group A and B
- Thrombotic thrombocytopenic purpura

TREATMENT

PRE HOSPITAL

Postexposure prophylaxis needed for pre-hospital personnel in close contact with patient

INITIAL STABILIZATION/THERAPY

- Wear mask and gloves, observe droplet precautions.
- Notify department of health.
- ABCs
- Immediate endotracheal intubation for severe acidosis, hypoxia, or decreased mental status:
 - Hyperventilate to treat acidosis (target PCO₂ about 25 mm Hg)
- Treat hypotension:
 - 0.9% normal saline bolus of 20 mL/kg; cautious rehydration with ARDS, CHF
 - Begin dopamine or norepinephrine (epinephrine if no response) if hypotensive after 2 L of IV fluids.
- Naloxone, thiamine, dextrose (Accu-Chek) for altered mental status
- Initiate IV antibiotics:
 - 1st line: High-dose penicillin (proven meningococemia) or 3rd-generation cephalosporin (broader coverage pending definitive diagnosis)
 - 2nd line: Ampicillin
 - 3rd line: Chloramphenicol (penicillin-allergic patients)

ED TREATMENT/PROCEDURES

- Overwhelming meningococcal sepsis
- Severe acidosis (pH <7–7.1 or serum HCO₃ <8–10):
 - Administer IV NaHCO₃ along with hyperventilation.
- Insert Foley catheter to monitor urine output.
- Place in respiratory isolation.
- High-dose steroids:
 - To protect against cranial nerve injury in the setting of ongoing infection

(controversial)

- Administer with adrenal gland injury.
- DIC treatment:
 - Administer fresh-frozen plasma and platelet transfusions.
 - Heparin is not indicated unless significant thrombotic complications are evident clinically (e.g., cyanosis or cold digits, low urine output despite adequate volume status, and blood pressure).
- Prophylaxis options for close contacts:
 - Ideally, prophylaxis should be given within 1st 24 hr.
 - 10-day window of observation
 - Serogroup-specific vaccine as adjunct only
- Vaccine:
 - Vaccine recommended in military recruits, travelers to endemic areas, complement-deficient or asplenic patients, 1st-year college dormitory residents
 - Vaccine recommended routinely for ages 11–18 yr

Pregnancy Considerations

The safety of meningococcal vaccine is unclear in pregnancy.

MEDICATION

First Line

- Cefotaxime: 2 g (peds: 50 mg/kg) IV q6h
- Ceftriaxone: 2 g (peds: 50 mg/kg) IV q12h
- Penicillin G: 4 MU (peds: 250,000 U/kg/24 h) IV q4h

Second Line

- Ampicillin: 2–3 g (peds: 200–400 mg/kg/24 h) IV q6h
- Chloramphenicol: 50–100 mg/kg/24 h IV q6h (max. 4 g/d)
- Prophylaxis:
 - Single-dose ceftriaxone:
 - 125 mg IM for age <15 yr
 - 250 mg IM for age >15 yr
 - Ciprofloxacin: 500 mg PO (adults)
 - Rifampin: 600 mg (peds: 5–10 mg/kg) PO BID for 2 days
 - Azithromycin 500 mg PO single dose (not routinely used)
- Dexamethasone: 0.15 mg/kg IV for pediatric meningitis
- Dopamine: 5–20 ug/kg/min IV titrate to blood pressure (BP)
- Epinephrine: 2–10 ug/min IV titrate to BP
- Heparin: 3,000–5,000 U (peds: 80 U/kg) IV bolus followed by 600–1,000 U/h (peds: 18 U/kg/h) IV drip

- Hydrocortisone (Solu-Cortef): 100 mg (peds: 2 mg/kg) bolus IV for adrenal insufficiency q8h
- Meningococcal polysaccharide 0.5 mL IM × 1
- Meningococcal vaccine 0.5 mL SC × 1
- Norepinephrine: 0.5–30 ug/min IV titrate to BP
- Sodium bicarbonate: 2–5 mEq/kg (peds: 0.5–1 mEq/kg) IV over 30 min to 4 hr

FOLLOW-UP

DISPOSITION

Admission Criteria

- ICU admission for overwhelming sepsis with respiratory isolation
- Respiratory isolation admission for mild meningococemia

Discharge Criteria

Prophylaxis for close patient contacts

Issues for Referral

- Consider transfer to tertiary care center, as multisystem organ failure is common.
- Late neurologic, cardiovascular, and orthopedic complications may necessitate follow-up with specialists.

FOLLOW-UP RECOMMENDATIONS

- Complete antibiotic course.
- Respiratory precautions may be discontinued after 24 hr.
- All close contacts need prophylaxis.

PEARLS AND PITFALLS

- Notify department of health in any suspected case.
- Watch for late development of pericardial tamponade.
- Do not wait to give antibiotics.

MERCURY POISONING

Keri L. Carstairs • David A. Tanen

BASICS

DESCRIPTION

Mercury:

- 3 forms: Elemental, inorganic salts, and organic
- Reacts with sulfhydryl groups, causing enzyme inhibition and alterations in cellular membranes
- Binds to phosphoryl, carboxyl, amide, and amine groups of enzymes

ETIOLOGY

- Exposure is usually through the GI tract and inhalation and less frequently dermal exposure.
- Exposure through manufacturing of chlorine and caustic soda, diuretics, antibacterial agents, antiseptics, thermometers, batteries, fossil fuels, plastics, paints, jewelry, lamps, explosives, fireworks, vinyl chloride, and pigments
- Exposure through taxidermy, photography, dentistry, mercury mining
- Contaminated seafood

DIAGNOSIS

SIGNS AND SYMPTOMS

- Naturally occurring mercury is converted into 3 primary forms, each with its toxicologic effects:
- Elemental mercury:
 - _ Symptoms from inhalation occur within hours:
 - Cough and dyspnea, which may progress to pulmonary edema
 - Metallic taste, salivation
 - Weakness, nausea, diarrhea, fever, headaches, visual disturbances
 - _ Subcutaneous deposits may present as granulomas or abscesses.
 - _ IV exposure presents with symptoms consistent with pulmonary embolization.
 - _ Relatively nontoxic from oral ingestion, although appendicitis has been reported
- Inorganic mercurial salt ingestion:
 - _ Caustic GI injury:
 - Abdominal pain with nausea, vomiting, and diarrhea
 - Metallic taste, sore throat
 - Hemorrhagic gastroenteritis with hematochezia and hematemesis

- Acute tubular necrosis
- Acrodynia (pink disease):
 - Idiosyncratic, occurs mainly in children
 - Painful extremities
- Pink discoloration with desquamation
- Organic mercury ingestion:
 - Historically, infants exposed in womb are most severely affected (e.g., Minamata Bay, Japan)
 - May see GI symptoms acutely
 - Delayed CNS toxicity predominates and may take weeks to months to manifest:
 - Paresthesias
 - Ataxia
 - Paralysis
 - Visual field constriction
 - Dysarthria
 - Hearing loss
 - Mental deterioration
 - Death

History

- Ask about possible workplace, environmental, or accidental exposure to mercurial products.
- Document the patient's ingestion of seafood over the last few weeks.

Physical-Exam

- Elemental mercury:
 - Cough progressing to respiratory distress if inhaled or intravenously injected
 - Ataxia
 - Subcutaneous nodules or granulomas if injected
- Inorganic mercury:
 - Oral burns
 - Abdominal tenderness
 - Heme-positive stools
- Organic mercury:
 - CNS abnormalities:
 - Progressive cognitive deterioration

ESSENTIAL WORKUP

- Good history for workplace or environmental exposure
- Physical exam looking for:
 - Respiratory distress

- Caustic GI injury
- Neuropsychiatric impairment
- Lab tests:
 - Renal failure
 - Urine and blood mercury levels:
 - Not reliable with recent seafood ingestion

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Inorganic mercury exposure:
 - CBC
 - Electrolytes, BUN, creatinine, glucose
 - 24-hr urine mercury collection:
 - Normal urine levels < 20 mg/dL
 - Whole-blood mercury level:
 - Normal blood < 10 mg/dL
- Organic mercury exposure:
 - CBC with peripheral smear
 - Electrolytes, BUN, creatinine, glucose
 - Whole-blood mercury level:
 - Normal blood < 10 mg/dL

Imaging

- Chest radiograph:
 - For noncardiac pulmonary edema
 - Evidence of IV mercury in pulmonary vascular tree
- Abdominal radiograph:
 - For presence of mercury with intentional oral ingestion
- Head CT:
 - May detect cerebellar atrophy

Diagnostic Procedures/Surgery

Lumbar puncture in the workup of altered mental status

DIFFERENTIAL DIAGNOSIS

- Multisystem involvement is often confused with other heavy-metal intoxications.
- Cerebrovascular accident
- Senile dementia, Alzheimer disease
- Parkinson disease
- Peptic ulcer disease
- Gastrointestinal bleeding
- Pancreatitis

- Sepsis
- Acute respiratory distress syndrome

TREATMENT

PRE HOSPITAL

- Remove from toxin exposure.
- Decontamination:
 - Wash exposed skin.
- For altered mental status:
 - Dextrose
 - Thiamine
 - Naloxone (Narcan)
 - Oxygen

INITIAL STABILIZATION/THERAPY

- Secure ABCs and monitoring.
- 0.9% NS
- IV fluid resuscitation for hypotension:
 - Blood transfusion for significant gastrointestinal hemorrhage
- Naloxone, D₅₀W, thiamine for altered mental status

ED TREATMENT/PROCEDURES

- Elemental mercury:
 - For inhalation exposure, observe closely for several hours for development of noncardiogenic pulmonary edema.
 - Ingested elemental mercury passes through normal intestinal tract with minimal absorption.
 - Consider chelation for symptomatic patients with oral dimercaptosuccinic acid (DMSA).
 - For subcutaneous nodules/abscess, perform an incision and drainage.
- Inorganic mercury salt ingestion:
 - Administer activated charcoal.
 - Aggressive 0.9% NS IV fluid resuscitation/blood products for hypovolemic shock:
 - Hydrate and maintain urine output (1 mL/kg/h).
 - Chelate symptomatic patients:
 - IM dimercaprol (British anti-Lewisite [BAL])
 - Oral DMSA efficacy may be limited secondary to caustic GI injury.
- Organic mercury:
 - Administer activated charcoal.
 - Chelate with oral DMSA.

MEDICATION

First Line

- Dextrose: D₅₀W 1 amp: 50 mL or 25 g (peds: D₂₅W 2–4 mL/kg) IV
- Dimercaprol (BAL): 5 mg/kg IM q4h for 48 hr, then 2.5 mg/kg q6h for 48 hr, then 2.5 mg/kg q12h for 7 days
- DMSA: 10 mg/kg PO q8h for 5 days, then q12h for 2 wk
- Naloxone (Narcan): 2 mg (peds: 0.1 mg/kg) IV/IM initial dose
- Thiamine (vitamin B₁): 100 mg (peds: 50 mg) IV or IM

Second Line

- D-penicillamine:
 - _ Adult: 250 mg PO QID for 7–14 days
 - _ Peds: 5–7 mg/kg PO QID for 7–14 days
- 2,3-Dimercapto-1-propanesulfonate:
 - _ IV or PO formulations. Contact your poison center at 1-800-222-1222 for availability.

FOLLOW-UP

DISPOSITION

Admission Criteria

Acutely symptomatic patients:

- Any evidence of respiratory compromise
- Ingestion of inorganic mercury salt that may lead to a caustic GI injury
- Renal impairment
- Any patient starting chelation therapy

Discharge Criteria

- Asymptomatic patient with history of ingestion of elemental mercury and intact intestinal tract
- Patient with history of inhalation exposure to elemental mercury who remain asymptomatic after 6 hr of observation

Issues for Referral

- Medical toxicology referral for symptomatic patients or where chelation is considered
- Gastroenterology for caustic GI injury
- Pulmonary/ICU care for patients with symptomatic inhalational injury
- Neurology in the evaluation of progressive cerebral deterioration

- Poison center for all suspected exposures

FOLLOW-UP RECOMMENDATIONS

- For discharged patients with possible workplace or environmental exposures, follow up with their primary care provider for results of 24-hr urine or whole-blood mercury levels.
- Outpatient referral to medical toxicology for suspected or confirmed cases
- For the asymptomatic patient, have the patient refrain from eating seafood for 2 wk before repeating the 24-hr urine for mercury.

PEARLS AND PITFALLS

- Obtain a good history for workplace, environmental or accidental exposure in patients with gastrointestinal and/or neuropsychiatric complaints.
- Monitor patients for at least 6 hr if they were exposed to inhalational elemental mercury.
- Ingestion of inorganic mercurial salts can lead to significant caustic GI injury.
- Lab tests may yield false positives especially in patients who eat seafood.

MESENTERIC ISCHEMIA

Rashid F. Kysia

BASICS

DESCRIPTION

- Decreased or occluded blood flow through the mesenteric vessels leading to ischemic or infarcted bowel
- Can be from arterial or venous blockage, or low flow states.
- 1 in 1,000 of all hospital admissions
- 1–2% of all admissions for abdominal pain:
 - Most cases occur in patients > 50 yr.
 - Mortality as high as 60–70%, particularly if diagnosis/presentation delayed > 24 hr

ETIOLOGY

- Acute mesenteric arterial embolism:
 - 50% of cases of acute mesenteric ischemia
 - Mean age 70 yr
 - Emboli most commonly arise in left atria or ventricle, from a dysrhythmia, valvular lesions, or ventricular thrombus from a prior MI
 - Typically lodge 3–10 cm distal to the origin of the superior mesenteric artery (SMA):
 - Preserves blood flow to proximal small and large bowel
 - Risk factors include dysrhythmia (especially atrial fibrillation), valvular heart disease, prior MI, aortic aneurysm, or dissection.
- Mesenteric artery thrombus:
 - SMA thrombus in 15% of cases of acute mesenteric ischemia
 - Rare in other vessels
 - Develops from plaque rupture of mesenteric atherosclerotic disease
 - 50–80% may have longstanding intestinal angina (chronic mesenteric ischemia).
 - Risk factors include age, atherosclerotic disease, HTN.
- Mesenteric venous thrombosis:
 - 5–15% of cases of acute mesenteric ischemia
 - Subacute/indolent presentation
 - 20–40% mortality
 - Typically occurs in younger patients with underlying hypercoagulable state
 - Risk factors include:
 - Hypercoagulable state (lupus, protein C and S deficiency)
 - Sickle cell disease

- Antithrombin III deficiency
- Malignancy (particularly portal)
- Pregnancy
- Sepsis
- Renal failure on dialysis
- Estrogen therapy
- Recent trauma or inflammatory conditions
- Nonocclusive mesenteric ischemia:
 - 20–30% of cases of acute mesenteric ischemia
 - Occurs in low cardiac output states with decreased mesenteric blood flow
 - Risk factors include CHF, sepsis, hypotension, hypovolemia, diuretic use, recent surgery (especially cardiac), or recent vasopressor requirement.
 - Poorer survival rates
- Chronic mesenteric ischemia:
 - “Intestinal angina”:
 - Postprandial, diffuse abdominal pain occurring ~1 hr after eating, lasts 1–2 hr
 - Patients may develop food aversions and eat small meals to avoid pain.
- Uncommon causes:
 - Spontaneous mesenteric arterial dissection
 - Median arcuate ligament syndrome—compression of the celiac axis or SMA by the arcuate ligament of the diaphragm
 - Extrinsic compression from tumors
 - Medications:
 - Digitalis
 - Ergotamine
 - Cocaine
 - Pseudoephedrine
 - Vasopressin

DIAGNOSIS

SIGNS AND SYMPTOMS

- Sudden-onset, severe, diffuse abdominal pain in acute ischemia:
 - Pain out of proportion to exam:
 - Patients may have relatively benign abdominal exam despite severe pain.
- Nausea
- Vomiting
- Diarrhea
- Occult GI bleeding

- Elderly patients can have nonspecific symptoms such as altered mental status, tachypnea, or tachycardia.
- Late findings:
 - _ Peritoneal signs owing to irreversible bowel ischemia
 - _ Abdominal distention
 - _ Hypoactive bowel sounds

History

Rapidity of onset of pain

Physical-Exam

Abdominal pain out of proportion to physical exam during the acute phase of illness

ESSENTIAL WORKUP

Maintain a high index of suspicion in patients >50 yr old with unexplained abdominal pain.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Often nonspecific and nondiagnostic
- CBC:
 - _ Elevated WBC count (90% > 15,000)
- Chemistry panel:
 - _ Approximately 50% have a metabolic acidosis.
- Amylase:
 - _ Elevated amylase found in 50% of cases
- Creatine phosphokinase (CPK) may be elevated.
- Lactate:
 - _ Elevated in 90% of patients
 - _ Indicative of advanced tissue damage, may not be elevated early in ischemic course.
 - _ High levels correlate with mortality.

Imaging

- Flat and upright abdominal radiographs:
 - _ Often obtained to rule out acute obstruction or perforation
 - _ Frequently normal
 - _ Late findings:
 - Thumbprinting from bowel wall edema and hemorrhage
 - Pneumatosis intestinalis: Air in bowel wall from tissue necrosis
 - Pneumobilia is a late finding associated with poor outcomes
- Abdominal CT scan:

- Can detect bowel wall edema, pneumatosis
- Newer helical and multidetector CT (MDCT) scanners can directly visualize mesenteric vascular anatomy and localize sites of occlusion
- MDCT angiography is more frequently the imaging modality of choice
- MRI:
 - Excellent images of mesenteric vasculature especially with MR angiography
 - Acquisition time and availability limits utility
- Angiography:
 - Historically the gold standard diagnostic modality, now being replaced by MDCT
 - Allows for direct visualization of emboli and administration of vasodilating or fibrinolytic agents
 - Invasive, time-consuming, and potentially nephrotoxic
- Doppler US:
 - Can detect decreased blood flow in SMA but more helpful in chronic mesenteric ischemia
 - For optimal results the patient should be NPO for 8 hr, limiting the utility of this study in the ED

DIFFERENTIAL DIAGNOSIS

- Bowel obstruction
- Volvulus
- GI malignancy
- Diverticulitis
- Inflammatory bowel disease
- Peptic ulcer disease
- Perforated viscus
- Cholecystitis
- Ascending cholangitis
- Pancreatitis
- Appendicitis
- Abdominal aortic aneurysm
- MI
- Renal stones

TREATMENT

PRE HOSPITAL

Initiate fluid replacement for dehydrated or hypotensive patients.

INITIAL STABILIZATION/THERAPY

- Airway, breathing, and circulation management (ABCs) with fluid resuscitation as

needed

- Caution:
 - Early diagnosis and intervention is critical to decrease mortality.

ED TREATMENT/PROCEDURES

- General measures:
 - Nasogastric suction to decompress the stomach and bowel
 - NPO
 - Electrolyte replacement as needed
 - Cardiac monitor for dysrhythmia
 - Consider invasive cardiac monitoring if patient is unstable
 - Monitor urine output
 - Analgesics
 - Broad-spectrum antibiotics to cover bowel flora (may need to adjust dose if concomitant renal failure):
 - Piperacillin/tazobactam
 - Ampicillin/sulbactam
 - Ticarcillin/clavulanate
 - Alternatives include imipenem, meropenem, 3rd-generation cephalosporins + metronidazole
 - Anticoagulation with heparin
 - Surgical consultation: All patients with peritoneal signs should have exploratory laparotomy.
- Specific therapies:
 - Papaverine 30–60 mg/h intra-arterial:
 - Phosphodiesterase inhibitor causes mesenteric vasodilatation.
 - Administered through angiography catheter
 - Intra-arterial thrombolytics can be used.
 - Surgical revascularization often indicated
- Caution:
 - Avoid vasoconstrictive medications, which may worsen ischemia:
 - If vasopressors are needed, use agents with less impact on mesenteric perfusion—consider dobutamine, low-dose dopamine, milrinone.

MEDICATION

- Ampicillin/sulbactam: 3 g IV q6h (peds: 100–200 mg/kg/d)
- Heparin sulfate: 80 U/kg IV bolus followed by 18 U/kg/h infusion
- Metronidazole: 1 g IV bolus followed by 500 mg IV q6h (peds: 12 mg/kg IV bolus, then 7.5 mg/kg IV q6h)
- Piperacillin/tazobactam: 3.375 g IV q6h (peds: 240–400 mg/kg/d)
- Ticarcillin/clavulanate: 3.1 g IV q4–6h

FOLLOW-UP

DISPOSITION

Admission Criteria

Admit all patients with mesenteric ischemia.

Discharge Criteria

None

FOLLOW-UP RECOMMENDATIONS

Surgical consultation

PEARLS AND PITFALLS

- Aggressive pursuit of diagnosis is mandatory.
- Mortality rises to 80% when the diagnosis is made > 24 hr after symptom onset.
- Early surgical evaluation for emergent operative intervention is mandatory.

- K55.1 Chronic vascular disorders of intestine

METACARPAL INJURIES

Davut J. Savaser • David Palafox

BASICS

DESCRIPTION

- Most metacarpal injuries are caused by crush injuries, a direct blow with hand vs. object, or burns.
- Most common fracture is boxer's fracture of distal 5th metacarpal neck.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Pain or swelling at the site of injury
- Deformity at the site of injury
- Malalignment of the distal tip of the finger on flexion indicates rotational deformity.
- Lines drawn down the longitudinal axis of each digit in flexion normally should converge on the scaphoid volarly.
- Limitation of movement secondary to pain and anatomic deformity

ALERT

Have a high suspicion for “fight bite.” This injury is the direct blow of a closed fist against a human tooth:

- Concern is violation of the extensor sheath, metacarpophalangeal (MCP) joint, or metacarpal head by a tooth, with subsequent infection by oral flora.

History

Not all patients are truthful as to cause of injury.

ESSENTIAL WORKUP

Exam should pay specific attention to skin integrity and alignment of the distal phalanges in flexion and extension.

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- Hand radiographs when fracture suspected, and/or to rule out opaque foreign body
- Special radiographic views (CT) of the proximal metacarpals and the carpometacarpal joints may be necessary for patients with a suggestive physical

exam and no definite fracture on a standard 3-view series.

DIFFERENTIAL DIAGNOSIS

Fracture of the metacarpal may be accompanied by dislocation of adjacent phalanges or carpal bones.

TREATMENT

PRE HOSPITAL

- Most do not require EMS transport solely for metacarpal injury.
- Cautions:
 - Metacarpal injuries should be splinted in position of comfort.

INITIAL STABILIZATION/THERAPY

- Other, more serious injuries should be treated 1st.
- Immobilize hand pending evaluation.
- Lacerations should be cleaned as soon as possible, and consideration should be given to the possibility of foreign body.
- Thermal burns are treated with early analgesia.

ED TREATMENT/PROCEDURES

- Elevation, rest, and intermittent application of ice for the 1st 24 hr are appropriate treatment for all hand injuries (RICE).
- Boxer's fractures usually have some volar flexion of the distal fragment:
 - Reduction should be attempted for volar angulation of 40° or more.
 - Fractures of the 4th and 5th metacarpals that are stable and with no significant rotational component can be treated with a padded ulnar gutter splint.
- Fractures of the index and middle finger metacarpals are more difficult to stabilize:
 - Radial gutter splint and early orthopedic referral
- Thumb metacarpal fractures are uniformly complicated and all should be referred early to a hand surgeon or orthopedist:
 - Place in thumb spica splint.
- Dislocations should be reduced immediately and splinted; metacarpal dislocations are rare and frequently need open reduction and pinning.
- Appropriate splinting position for the MCP joint is the intrinsic plus, or “cobra” position (20–30° wrist extension):
 - MCP joint as close to 90° of flexion as possible
 - Proximal interphalangeal (PIP) and distal interphalangeal (DIP) joints in extension
- Antibiotics for oral flora should be started early for any open injury to the metacarpals suspicious for injury against a tooth, and may require curettage of the impaction site in the operating room.

- Simple torus (buckle) fractures may be splinted and may be followed by a primary care physician.

MEDICATION

- Check for tetanus status and vaccinate per immunization schedule.
- Silvadene cream or bacitracin ointment is appropriate for thermal burn injury.
- Analgesics may be necessary; NSAIDs or hydrocodone is usually sufficient.
- For human bites or dirty wounds, administer amoxicillin/clavulanate (Augmentin), or:
 - A cephalosporin or other penicillinase-resistant antibiotic given parenterally is appropriate.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Open fractures or dislocations require urgent surgical intervention and should be admitted.
- All thumb metacarpal fractures or dislocations should be seen by an orthopedist or hand surgeon because of the special importance of the thumb in all activities of the hand.
- Infection from a bite wound requires prompt orthopedic consultation, admission for irrigation, débridement, and IV antibiotics.

Discharge Criteria

- Patients with a stable transverse or oblique fracture in a good splint may be discharged for early orthopedic follow-up.
- Metacarpal–carpal dislocations are usually unstable enough to require surgery even if reduction is achieved, but this may be semiurgent rather than emergent.
- If a metacarpal fracture produces impaired range of motion or misalignment of the finger, the patient will require surgical repair in the 1st several days after injury.

Pediatric Considerations

Epiphyseal injuries mandate orthopedic referral.

PEARLS AND PITFALLS

With all metacarpal injuries assure proper rotational alignment.

METHANOL POISONING

Michelle M. Troendle • Kirk L. Cumpston

BASICS

DESCRIPTION

- Colorless, volatile liquid
- Absorbed in 30–60 min
- Metabolized by liver
- Half-life 4–8 hr
- Mechanism:
 - Inebriating
 - Nontoxic
 - Metabolites of formaldehyde and formic acid produce toxic effects.
 - Inhibits cytochrome oxidase.
- Formic acid:
 - Determines degree of acidosis, visual symptoms, and mortality
 - Directly toxic to retinal and optic nerve tissue
- Methanol metabolism:
 - Step 1: Methanol is converted to formaldehyde by liver enzyme alcohol dehydrogenase.
 - Step 2: Formaldehyde is then rapidly converted by aldehyde dehydrogenase to formic acid.
 - Step 3: Formic acid is degraded to carbon dioxide and water by folate-dependent mechanism.
 - Steps 1 and 3 are rate-limiting steps.

ETIOLOGY

Common sources of methanol:

- Wood alcohol
- Windshield washer fluid (> 60% cases)
- Inhalational abuse of carburetor cleaners
- Fuel antifreeze solutions
- Formalin
- Gasoline
- Paint solvents
- Household cleaners
- Sterno cans
- Moonshine
- Model airplane fuel
- Photocopying fluid

- Perfumes

DIAGNOSIS

SIGNS AND SYMPTOMS

- GI:
 - Anorexia
 - Nausea/vomiting
 - Abdominal pain
- CNS:
 - Headache
 - Dizziness
 - Confusion
 - Inebriation
 - Coma
 - Seizures
- Ophthalmologic:
 - Blurry/hazy vision
 - Photophobia
 - “Snowfield vision”
 - Blindness
 - Central scotoma

History

- Intentional or unintentional methanol ingestion
- No history, but a patient with an unexplained high anion gap metabolic acidosis
- Elevated unexplained osmol gap

Physical-Exam

- Optic disc:
 - Hyperemia or pallor
 - Papilledema
- Afferent pupillary defect
- Tachypnea
- Altered mental status

ESSENTIAL WORKUP

- History of all substances ingested
- Inquire about visual symptoms.
- Funduscopic exam
- Drawn simultaneously:
 - Arterial blood gas

- Serum methanol, ethylene glycol, isopropyl alcohol, and ethanol levels
- Electrolytes, BUN, creatinine, and glucose
- Measured serum osmolality (by freezing-point depression is preferred)

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Calculate anion gap = $(\text{Na}^+) - (\text{Cl}^- + \text{HCO}_3^-)$:
 - Normal = 8–12.
- Determine serum osmol gap:
 - Osmol gap = measured osmolality – calculated osmolarity:
 - Calculated osmolarity = $2(\text{Na}^+) + \text{glucose}/18 + \text{BUN}/2.8 + \text{ethanol (in mg/dL)}/4.6$.
- Osmol gap:
 - Screens for methanol (methanol is osmotically active, toxic metabolites are not)
 - Most sensitive early in poisoning and normalizes as methanol is metabolized or with concurrent ethanol ingestion
 - Traditionally an osmol gap > 10 is considered indication for ruling out occult methanol ingestion. However, potentially toxic serum concentrations of methanol can be present with osmol gap < 10 .
 - A negative osmol gap DOES NOT rule out a methanol exposure.
 - Ethanol has higher affinity for alcohol dehydrogenase than methanol. With concurrent ethanol ingestion, osmol gap tends to be larger and acidosis tends to be less severe because relatively less methanol has been converted to acid-producing metabolites.
- Serum methanol concentrations *confirm* methanol poisoning:
 - Late after ingestion, no parent compound (methanol) may be detected and severe high anion gap metabolic acidosis will be present.
- Ethanol concentration may have clinical implications and is pertinent in interpreting lab tests.

Imaging

CT brain

DIFFERENTIAL DIAGNOSIS

- Increased osmol gap:
- *ME DIE A*:
 - Methanol
 - Ethanol
 - Diuretics/diluents (mannitol, glycerin, sorbitol, propylene glycol)
 - Isopropyl alcohol

- Ethylene glycol
- Acetone, ammonia
- Elevated anion gap metabolic acidosis: *A CAT MUDPILES:*
 - Alcoholic ketoacidosis
 - Cyanide, CO, H₂S, others
 - Acetaminophen
 - Antiretrovirals (NRTI)
 - Toluene
 - Methanol, metformin
 - Uremia
 - Diabetic ketoacidosis
 - Paraldehyde, phenformin, propylene glycol
 - Iron, INH
 - Lactic acidosis
 - Ethylene glycol
 - Salicylate, acetylsalicylic acid (ASA; aspirin), starvation ketosis

TREATMENT

PRE HOSPITAL

- Transport all possibly ingested substances.
- Dermal decontamination of a methanol spill by clothing removal, irrigation with soap and water
- Monitor airway and CNS depression.

INITIAL STABILIZATION/THERAPY

- Airway, breathing, and circulation (ABCs)
- Dextrose, naloxone, and thiamine for altered mental status
- Prevent further methanol absorption:
 - Gastric lavage with nasogastric tube:
 - Likely not helpful because of rapid absorption of methanol and delay in presentation > 1 hr
 - Activated charcoal:
 - For potential coingestants
 - Poorly adsorbs methanol
 - Aspiration risk for patients with altered mental status

ED TREATMENT/PROCEDURES

- Prevent methanol conversion to toxic metabolites with fomepizole (preferable) or ethanol infusion
- Fomepizole (4-MP, Antizol):
 - Competitive inhibitor of alcohol dehydrogenase

- Indications:
 - Intentional methanol ingestion
 - Accidental methanol ingestion of more than a sip
 - Altered mental status or visual symptoms associated with unexplained osmol gap and/or elevated anion gap metabolic acidosis
- Initiate before serum methanol level returns if intentional ingestion or more than a sip.
- Continue until methanol level is < 25 mg/dL.
- Advantages:
 - No need for continuous infusion
 - No inebriation/CNS depression
 - Ease of dosing
 - No hypoglycemia, no hyponatremia, no hyperosmolality
 - No checking serum concentrations
 - Reduced nursing care and monitoring
 - Occult methanol exposure can often be ruled out before 2nd dose is needed.
- Disadvantages:
 - Blurry vision
 - Transient elevation of liver function tests
- Ethanol therapy:
 - Not FDA approved for treatment of methanol
 - Ethanol has greater affinity than methanol for alcohol dehydrogenase:
 - Slows metabolism to formaldehyde and formic acid by competitive inhibition
 - Ethanol is the 2nd-choice antidote if fomepizole is not available.
 - Initiate before methanol level returns if potentially toxic ingestion is highly suspected or confirmed by history:
 - Therapeutic range is 100 mg/dL.
 - Continue until methanol level is < 25 mg/dL.
 - Indications for ethanol therapy:
 - Intentional methanol ingestion
 - Accidental methanol ingestion of more than a sip
 - Altered mental status or visual symptoms associated with unexplained osmol gap and or elevated anion gap metabolic acidosis
 - Advantages:
 - Easily accessible
 - Oral and IV routes
 - Disadvantages:
 - CNS depression especially in children
 - Respiratory depression
 - Hyponatremia or hypernatremia
 - Hypoglycemia

- Hyperosmolarity
- Continuous infusion
- Frequent lab testing
- Contraindicated in pregnancy
- Pancreatitis
- Gastritis
- Enhance elimination of methanol and toxic metabolites with hemodialysis:
 - _ Decreases elimination half-life of methanol
 - _ Removes formaldehyde and formic acid
 - _ Indications:
 - Ingestion of >1 mL/kg of 100% methanol
 - Ophthalmologic manifestations
 - Severe metabolic acidosis unresponsive to bicarbonate therapy
 - Persistent electrolyte or metabolic acidosis
 - Renal insufficiency
 - Serum methanol level >25 mg/dL
 - _ Continue hemodialysis until methanol level approaches <25 mg/dL and the metabolic acidosis has resolved.
- Folic acid and folinic acid (leucovorin):
 - _ Folic acid: Cofactor required for conversion of formic acid to carbon dioxide and water
 - _ Supplemental folate important in malnourished individuals (alcoholics)
- Correct acid–base abnormalities:
 - _ Sodium bicarbonate for severe acidosis (pH <7.1)
 - _ The goal of the sodium bicarbonate drip is to maintain a normal serum pH.

MEDICATION

- Activated charcoal: 1 g/kg PO
- Dextrose: D₅₀W 1 amp: 50 mL or 25 g (peds: D₂₅W 2–4 mL/kg) IV
- Fomepizole:
 - _ Loading dose: 15 mg/kg slow infusion over 30 min
 - _ Maintenance dose: 10 mg/kg q12h for 4 doses, then 15 mg/kg q12h until methanol levels reduced <25 mg/dL
 - _ Dosing related to hemodialysis:
 - Do not administer dose at beginning of dialysis if last dose was <6 hr previously.
 - Administer next dose if last dose was >6 hr previously.
 - Dose q4h during dialysis.
 - If time between last dose and end of dialysis was <1 hr from last dose, do not administer new dose.
 - If time between last dose and end of dialysis was 1–3 hr from last dose, administer 1/2 of next scheduled dose.
 - If time between last dose and end of dialysis was >3 hr from last

dose, administer next scheduled dose.

- Ethanol:
 - Oral: 50% ethanol solution (100-proof liquor) via nasogastric tube:
 - Loading dose 2 mL/kg
 - Maintenance dose 0.5 mL/kg/h
 - Maintenance dose during hemodialysis 1 mL/kg/h
 - IV: 10% ethanol in D₅W:
 - Loading dose 8 mL/kg over 30–60 min
 - Maintenance infusion 2 mL/kg/h
 - Maintenance infusion during hemodialysis 4 mL/kg/h
- Folic acid: 50 mg IV q4h for 24 hr
- Sodium bicarbonate: 1–2 mEq/kg in 1 L of D₅W with 40 mEq KCl at 250 mL/h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Significant historical methanol ingestion even if initially asymptomatic
- ICU admission for seriously ill patients
- Transfer to another facility if hemodialysis or antidote is indicated but not readily available.

Discharge Criteria

Asymptomatic patient with isolated methanol ingestion if serum methanol level is < 25 mg/dL; normal acid/base status and electrolytes.

FOLLOW-UP RECOMMENDATIONS

Psychiatric follow-up for suicidal/depressed patients

PEARLS AND PITFALLS

- An osmol gap < 10 mmol/L does not rule out a methanol exposure.
- If you have a patient with an elevated anion gap and methanol exposure is in the differential diagnosis, administer fomepizole immediately and confirm exposure with a serum concentration.
- If you cannot confirm a methanol exposure, or do not have hemodialysis capabilities 24/7, or have no antidote, transfer the patient to a facility that has all of these capabilities.
- Not all patients will have an elevated osmol and anion gap. Early presenters will have an osmol gap only, because methanol is osmotically active, and there are no toxic metabolites yet. Late presenters may have an anion gap only, because the

osmotically active parent compound has metabolized to the toxic acidotic metabolites. Patients who present in between will have a combination of an anion gap and an osmol gap.

CODES

ICD9

980.1 Toxic effect of methyl alcohol

ICD10

- T51.1X1A Toxic effect of methanol, accidental (unintentional), initial encounter
- T51.1X2A Toxic effect of methanol, intentional self-harm, initial encounter
- T51.1X4A Toxic effect of methanol, undetermined, initial encounter

METHEMOGLOBINEMIA

Navneet Cheema

BASICS

DESCRIPTION

- Iron molecule in hemoglobin is oxidized from ferrous (Fe^{2+}) to ferric (Fe^{3+}) state resulting in a form of hemoglobin that cannot transport oxygen.
- Oxygen-carrying capacity of blood is reduced and cyanosis is generally present with significant levels.
- Normal methemoglobin levels are $\leq 1\%$; symptoms usually occur with levels $> 20\%$.
- More serious with coexisting anemia
- Methemoglobin:
 - Decreases total oxygen-carrying capacity (functional anemia)
 - Shifts hemoglobin oxygen-dissociation curve to the left, impairing O_2 release to tissues
 - Maintained at physiologic level (1–2%) by nicotinamide adenine dinucleotide (NADH)-methemoglobin (cytochrome B_5) reductase in red blood cells (RBCs)
- Congenital methemoglobinemia:
 - NADH-methemoglobin (cytochrome B_5) reductase deficiency (homozygous or heterozygous)
 - Heterozygous hemoglobin M and other abnormal hemoglobins
- Acquired methemoglobinemia results from oxidant stress on RBCs:
 - Some methemoglobin-inducing agents are direct oxidants (e.g., nitrites)
 - Many substances produce oxidant injury via *N*-hydroxylamine metabolites.
 - Methemoglobinemia may be delayed relative to initial substance exposure.
- Many methemoglobin-inducing agents also cause Heinz body hemolytic anemia (HA):
 - Caused by oxidant injury of RBC proteins
 - Glucose-6-phosphate dehydrogenase (G6PD)–deficient patients have higher risk.
 - Patients with methemoglobinemia should be worked up for HA.
- Methemoglobinemia may serve as marker for genetic abnormalities:
 - Heterozygous NADH-methemoglobin (cytochrome B_5) reductase deficiency

ETIOLOGY

- Cyanide (CN) antidote kit:
 - Induces methemoglobinemia via amyl and sodium nitrite

- CN will preferentially complex with methemoglobin, which can then be chelated by sodium thiosulfate.
- Nitrates/nitrites:
 - Nitrites (NO₂)
 - Nitrates (NO₃) (e.g., nitroglycerine, via metabolic conversion to nitrites)
 - Nitric oxide (NO)
- Dyes:
 - Aniline dyes
 - Methylene blue (excessive)
- Antiparasitic drugs (high potential for MetHb formation):
 - Dapsone
 - Primaquine
 - Chloroquine
- Local anesthetics (high potential for MetHb formation):
 - Benzocaine
 - Lidocaine
 - Prilocaine
- Analgesics:
 - Phenazopyridine (Pyridium)
 - Phenacetin
- Antibiotics:
 - Nitrofurantoin
 - Sulfones
 - Sulfonamides
- Others:
 - Metoclopramide
 - Naphthalene (mothballs)
 - Paraquat (herbicide)
 - Arsine gas (AsH₃)
 - Chlorates (ClO₄)
 - Phenols (e.g., dinitrophenol, hydroquinone)

DIAGNOSIS

SIGNS AND SYMPTOMS

- Central cyanosis, refractory to oxygen administration:
 - Cyanosis evident at methemoglobin (MetHb) of 10–15% of total hemoglobin in nonanemic patient (or 1.5 g of MetHb/dL blood)
- Dyspnea/tachypnea
- Chest pain/dysrhythmias
- Syncope

- Altered mental status with levels > 50%

History

- Exposure to methemoglobin-inducing agent
- All substances ingested and time(s) of ingestion
- G6PD deficiency
- Medical conditions vulnerable to impaired oxygen delivery (e.g., coronary artery disease)

Physical-Exam

- Cyanosis
- Emphasis on mental status and cardiovascular findings
- Icterus or dark-colored urine with accompanying HA

ESSENTIAL WORKUP

- Pulse oximetry is *inaccurate* in methemoglobinemia:
 - MetHb interferes with pulse oximetry measurement of hemoglobin oxygen saturation.
 - Saturation decreases to ~ 85% with increasingly more severe methemoglobinemia.
 - Pulse oximetry cannot be used to guide management.
- ABG for:
 - Methemoglobin level
 - Carboxyhemoglobin level
 - PaO₂ and PaCO₂
- ECG

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Blood classically described as chocolate colored
- CBC with manual differential count and smear analysis for evidence of HA

Imaging

CXR to rule out other pulmonary pathology

DIFFERENTIAL DIAGNOSIS

- Hypoxia:
 - CHF
 - COPD
 - Pulmonary embolism
- Irritant gas exposure

- Blue discoloration:
 - Hypoxia
 - Sulfhemoglobinemia
 - CN poisoning
 - Hydrogen sulfide poisoning
 - Excess methylene blue administration
 - Tellurium toxicity
 - Skin contact/staining with blue dye

TREATMENT

PRE HOSPITAL

- Bring to hospital all substances patient may have ingested.
- Question witnesses and observe scene for household products and other potential coingestants:
 - Document and relay findings to emergency medical staff.
- Commercial or industrial sites:
 - Obtain relevant material safety data sheets (MSDSs) if available to identify commercial or chemical products.
 - Avoid dermal exposures.

INITIAL STABILIZATION/THERAPY

- ABCs:
 - Cardiac monitor
 - Isotonic crystalloids as needed for hypotension
- Naloxone, thiamine, and dextrose (D₅₀W) as indicated for altered mental status
- Supplemental oxygen

ED TREATMENT/PROCEDURES

- Decontamination:
 - If owing to acute ingestion/overdose within previous 1–2 hr, and protective airway reflexes are intact, administer 50–100 g of activated charcoal PO.
- Remove source of oxidant stress.
- Methylene blue:
 - Indications:
 - Asymptomatic with levels > 30%
 - Symptomatic patients with levels > 10–20%, especially if comorbid diseases are present
 - Expect transient worsening of saturations on pulse oximetry after methylene blue is administered:
 - Interferes with pulse oximetry measurement and no specific intervention required

- Use with caution in patients with glucose-6 pyruvate decarboxylase deficiency:
 - May cause hemolysis
- If no improvement with methylene blue, consider that source of oxidant stress is not eliminated, or that sulfhemoglobinemia is present:
 - Sulfhemoglobin is sulfur molecule bound to hemoglobin. Presents similar to methemoglobin, but is self-limited and not responsive to methylene blue.
- RBC transfusion:
 - May be necessary to increase blood oxygen-carrying capacity
 - Consider in the presence of HA.
- Exchange transfusion:
 - Especially with neonates/infants
- Hyperbaric oxygen therapy:
 - Increases oxygen delivery to tissues by allowing more oxygen to be dissolved in the blood, independent of hemoglobin.
 - Use in life-threatening methemoglobinemia if immediately available.

Pediatric Considerations

- Children may develop significant methemoglobinemia from apparently minor ingestions.
- Symptoms delayed several hours after ingestion, so prolonged observation necessary
- Neonates are also at higher risk of methemoglobinemia (owing to decreased stores of NADH methemoglobin reductase).

MEDICATION

- Dextrose 50%: 25 g (50 mL) (peds: 0.5–1 g/kg of dextrose) IV for hypoglycemia
- Methylene blue: 0.1–0.2 mL/kg 1% solution IV over 5 min (adults and peds)
 - May repeat if no improvement in 1 hr
 - Doses of 0.3 to 1 mg/kg IV have been effective in neonates. Has been used IO over 3–5 min.
- Naloxone: 0.4–2 mg (peds: 0.1 mg/kg) IV, may repeat up to 10 mg for suspected opioid intoxication
- Thiamine: 100 mg (peds: 1 mg/kg) IM or IV

FOLLOW-UP

DISPOSITION

Admission Criteria

- Severely symptomatic patients
- Patients requiring multiple doses of methylene blue

- Dapsone may cause prolonged recurrent methemoglobinemia

Discharge Criteria

Methemoglobin levels < 20% and falling with no symptoms or comorbid disease

Issues for Referral

Toxicology consult for significant exposures

FOLLOW-UP RECOMMENDATIONS

Occupational medicine referral for work-related exposures

PEARLS AND PITFALLS

- Pulse oximetry is *inaccurate* in methemoglobinemia.
- Obtain an ABG.
- Administer methylene blue for significant levels/symptoms.

A special thanks to Dr. Gerald Maloney who contributed to the previous edition.

- D74.9 Methemoglobinemia, unspecified

MITRAL VALVE PROLAPSE

Liudvikas Jagminas

BASICS

DESCRIPTION

- Bulging of 1 or both of the mitral valve leaflets into the left atrium during systole
- Occurs when the leaflet edges of the mitral valve do not coapt
- Commonly due to abnormal stretching of 1 of the mitral valve leaflets during systole:
 - Myxomatous proliferation of the spongiosa layer within the valve causing focal interruption of the fibrosa layer
 - Excessive stretching of the chordae tendineae, leading to traction on papillary muscles
- Theoretical explanations for associated chest pain:
 - Focal ischemia from coronary microembolism due to platelet aggregates and fibrin deposits in the angles between the leaflets
 - Coronary artery spasm
- Mitral regurgitation (MR) may occur in some patients.
- Age of onset is 10–16 yr
- Female > male (3:1)
- Typically benign in young women, whereas men > 50 yr tend to have serious sequelae and more often develop severe regurgitation requiring surgical intervention
- Can be identified by ECG in 2–4% of the general population and in 7% of autopsies
- A variety of neuroendocrine and autonomic disturbances occur in some patients
- Genetics:
 - Strong hereditary component
 - Sometimes transmitted as an autosomal dominant trait with varying penetrance

ETIOLOGY

- Marfan syndrome
- Relapsing polychondritis
- Ehlers–Danlos syndrome (i.e., types I, II, IV)
- Osteogenesis imperfecta
- Pseudoxanthoma elasticum
- Stickler syndrome
- Systemic lupus erythematosus
- Polyarteritis nodosa

- Polycystic kidney disease
- von Willebrand syndrome
- Duchenne muscular dystrophy

DIAGNOSIS

SIGNS AND SYMPTOMS

Separated into 3 categories:

- Symptoms related to autonomic dysfunction
- Symptoms related to the progression of MR
- Symptoms that occur as a result of an associated complication (i.e., stroke, endocarditis, or arrhythmia)

History

- Palpitations in up to 40% of cases:
 - Usually ventricular premature beats or paroxysmal supraventricular tachycardia
 - Up to 40% have symptoms of dysautonomia
- Chest pain occurs in 10%:
 - Sharp, localized, of variable duration, and nonexertional
 - Rarely may respond to nitroglycerin
- Panic attacks
- Anxiety
- Fatigue
- Depression in up to 70%
- Nervousness
- Migraine headaches
- Irritable bowel
- Syncope/presyncope:
 - Occurs in 0.9% of patients
- Orthostasis
- Dyspnea and fatigue relatively uncommon

Physical-Exam

- Mid to late systolic click at the cardiac apex:
 - Standing or Valsalva moves click closer to S1.
 - S1 may be accentuated when prolapse occurs early in systole.
 - Squatting moves click closer to S2.
- Late systolic murmur
- Skeletal abnormalities are observed in 2/3 of patients:
 - Asthenic body habitus: Height-to-weight ratio > normal
 - Arm span > height (dolichostenomelia)

- Scoliosis or kyphosis
- Pectus excavatum
- Arachnodactyly
- Joint hypermobility
- Hypomastia
- Cathedral palate

ESSENTIAL WORKUP

- History and auscultation of a midsystolic click are often sufficient to make the diagnosis.
- Echocardiography confirms the diagnosis when clinical information is insufficient.

DIAGNOSIS TESTS & INTERPRETATION

Lab

Not required to establish the diagnosis

Imaging

- EKG:
 - Usually normal
 - Occasionally ST-T wave depression and inversion in leads III and aVF
 - Prolonged QT interval or prominent Q waves
 - Premature atrial and ventricular contractions
- CXR:
 - Typically normal
 - If MR is present, may show both left atrial and ventricular enlargement
 - Calcification of the mitral annulus in patients with Marfan syndrome
- Echocardiography:
 - Classic MVP: The parasternal long-axis view shows > 2 mm superior displacement of the mitral leaflets into the left atrium during systole, with a leaflet thickness of at least 5 mm.
 - Nonclassic MVP: Displacement is > 2 mm, with a maximal leaflet thickness of < 5 mm.
 - Other ECG findings that should be considered as criteria are leaflet thickening, redundancy, annular dilatation, and chordal elongation.
 - Minor criteria:
 - Isolated mild to moderate superior systolic displacement of the posterior mitral leaflet
 - Moderate superior systolic displacement of both mitral leaflets

Diagnostic Procedures/Surgery

Cardiac studies may be indicated in patients with chest pain when the etiology is uncertain.

DIFFERENTIAL DIAGNOSIS

- MI/ischemia
- Hypertrophic cardiomyopathy with obstruction
- Idiopathic hypertrophic subaortic stenosis
- Tachyarrhythmias
- Atrial fibrillation/flutter
- Ventricular septal defect
- Papillary muscle dysfunction
- Hypokalemia
- Hypomagnesemia
- Valvular heart disease
- Pheochromocytoma
- Anemia
- Thyrotoxicosis
- Pregnancy
- Toxicity from cocaine, amphetamines, or other sympathomimetics
- Ventricular tachycardia
- WPW syndrome
- Rheumatic endocarditis
- Anxiety/panic disorder
- Stress
- Menopause

TREATMENT

PRE HOSPITAL

- ABCs
- IV access
- Supplemental oxygen
- Cardiac monitoring
- Pulse oximetry

INITIAL STABILIZATION/THERAPY

- Cardiac monitoring
- Supplemental oxygen
- IV catheter placement

ED TREATMENT/PROCEDURES

- Medications generally are not necessary. β -blockers may be helpful if palpitations are severe.
- Antiplatelet agents (aspirin, aspirin with extended-release dipyridamole, or clopidogrel) are indicated for patients with transient ischemic attack or stroke

symptoms.

- Orthostatic hypotension and presyncope symptoms may be treated with sodium chloride tablets; however, if this treatment is not successful, fludrocortisone may be used.
- Magnesium supplementation may improve symptoms of the classic MVP syndrome.
- Significant MR in the setting of HTN (systolic blood pressure > 140 mm Hg) may be improved with the use of ACE inhibitors.
- β -Blockers:
 - Patients with tachycardia or severely symptomatic chest pain
- Digoxin is an alternative for supraventricular tachycardia and prevention of chest pain and fatigue.
- Antibiotic prophylaxis:
 - When performing surgical procedures (e.g., contaminated wound repair, abscess incision and drainage)
 - Indicated in the following settings:
 - Presence of a murmur
 - Evidence of nontrivial MR on Echocardiogram
 - Men > 45 yr with valve thickening
 - Prophylaxis is not recommended for patients who have an isolated click without a murmur or for patients without evidence of MR on an echocardiogram or previous history of endocarditis.

MEDICATION

First Line

- Amoxicillin: 2 g PO 1 hr before the procedure (peds: 50 mg/kg PO 1 hr before procedure)
- Ampicillin: 2 g IV/IM 30 min before the procedure (peds: 50 mg/kg IV/IM 30 min before the procedure)
- Clindamycin: 600 mg PO 1 hr before procedure (peds: 20 mg/kg PO 1 hr before procedure; not to exceed 600 mg)
- Propranolol: 1–3 mg IV at 1 mg/min, 80–640 mg/d PO (peds: 1–4 mg/kg/d PO div. BID/QID)
- Isoproterenol: 0.02–0.06 mg IV \times 1, 0.01–0.02 mg IV or 2–20 mg/min infusion
- Atenolol: 0.3–2 mg/kg/d PO, max. 2 mg/kg/d

Second Line

- Digoxin: 0.5–1 mg IV/IM div. 50% initially then 25% \times 2 q6–12h or 0.125–0.5 mg/d PO
- Fludrocortisone: 0.05–0.10 mg/d PO

FOLLOW-UP

DISPOSITION

Admission Criteria

- Severe MR
- Severe chest pain with ischemic symptoms
- Syncope or near syncope
- Life-threatening dysrhythmias
- Cerebral ischemic events, including transient ischemic attack

Discharge Criteria

- Asymptomatic
- No lab abnormalities
- No significant MR or dysrhythmias

Issues for Referral

- Cardiology consultation is warranted in cases of ventricular dysrhythmia or risk of sudden death, as well as when symptoms of severe MR are present.
- Cardiothoracic surgery follow-up is recommended for consideration of valve replacement or repair
 - Symptomatic patients
 - Atrial fibrillation
 - Ejection fraction < 50–60%
 - Left ventricular end-diastolic dimension > 45–50 mm
 - Pulmonary systolic pressure > 50–60 mm Hg
- Valve repair rather than replacement is preferred to avoid the need for anticoagulation.
- Pilots with mitral valve prolapse may develop MR under positive G force and be at risk for dysrhythmia or syncope.

Pediatric Considerations

Dysrhythmias, sudden death, and bacterial endocarditis have been reported.

Geriatric Considerations

- Often present in an atypical manner:
 - More likely to have holosystolic murmurs and a greater degree of MR.
- Heart failure may be presenting symptom complex associated with ruptured chordae tendineae.

Pregnancy Considerations

MVP does not predispose women to any increased risk during pregnancy.

FOLLOW-UP RECOMMENDATIONS

- Repeat evaluations are necessary every 3–5 yr to identify any progression of disease.
- Infective endocarditis prophylaxis is indicated in patients with MVP and MR while undergoing at-risk procedures.
- Coronary artery anomalies should be excluded in patients with chest pain before they participate in sports.
- Patients with MVP and a murmur should avoid high-intensity competitive sports in the following settings:
 - Syncope associated with dysrhythmia
 - A family history of sudden death associated with MVP
 - Significant supraventricular or ventricular dysrhythmias
 - Moderate to severe MR

PEARLS AND PITFALLS

- The diagnosis of MVP should not be an excuse to terminate further diagnostic evaluation of patients with symptoms of chest pain, palpitations, dyspnea, or syncope.
- MVP is the 3rd most common cause of sudden death in athletes.

ICD10

I34.1 Nonrheumatic mitral (valve) prolapse

MOLLUSCUM CONTAGIOSUM

Evan Small • Deepi G. Goyal

BASICS

DESCRIPTION

- Molluscum contagiosum (MC) is a generally benign human disease characterized by multiple small, painless, pearly lesions.
- MC appears on epithelial surface and spreads through close contact or autoinoculation.
- Confined to the skin and mucous membranes
- 5–20% of patients with HIV have coinfection with MC.
- Found worldwide with an incidence of 2–8%, with higher distribution in tropical areas

ETIOLOGY

- MC is caused by a double-stranded DNA poxvirus of the *Molluscipox* genus
- Transmission in children is by direct skin-to-skin contact, fomites, or pool or bath water.
- Transmission in adults is most often by sexual contact; autoinoculation is common at any age.
- There are rare reports of transmission to infants during childbirth.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Incubation period: 14–50 days
- Patients are usually asymptomatic, with occasional pruritus or tenderness.
- 10–25% of patients may have eczematous reaction surrounding the lesions.
- Untreated lesions in immunocompetent hosts usually resolve within several months but can last up to 5 yr.

Physical-Exam

- Lesions are smooth-surfaced, firm, spherical papules 2–6 mm in diameter.
- May be flesh colored, white, translucent, or light yellow
- Lesions have a waxy, curd-like core composed of collagen–lipid-rich material containing large numbers of maturing virions
- Distinctive central umbilication in 25%
- Atypical presentations include nonumbilicated, persistent, disseminated, or giant

lesions, usually in the setting of immunosuppression.

- Distribution:
 - Children:
 - Face
 - Trunk
 - Extremities
 - Healthy adults:
 - Genitals
 - Lower abdomen
 - Occasionally perioral
 - Rarely on palms and soles
- MC is commonly seen with HIV infection, causing atypical involvement of face, neck, and trunk, lesions to 1.5 cm, and a progressive course. Lesions may also appear with initiation of highly active antiretroviral therapy (HAART) as a manifestation of the immune reconstitution inflammatory syndrome.
- Occasional intraocular or periocular involvement presenting as trachoma or chronic follicular conjunctivitis

ESSENTIAL WORKUP

- History and careful skin exam
- Skin biopsy for confirmation
- Lesions in adult men necessitate evaluation for an immunocompromised state.
- MC in children is rarely associated with immunodeficiency, and usually no further evaluation is needed.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Test for immunocompromised state if no clear etiology:
 - CBC with differential
 - HIV if indicated
- If anogenital lesions:
 - Consider syphilis, hepatitis C, HIV

Diagnostic Procedures/Surgery

Skin biopsy for confirmation

DIFFERENTIAL DIAGNOSIS

- Basal cell carcinoma
- Histiocytoma
- Keratoacanthoma
- Intradermal nevus
- Darier disease

- Nevoxanthoendothelioma
- Syringoma
- Epithelial nevi
- Sebaceous adenoma
- Atopic dermatitis
- Dermatitis herpetiformis
- Mycosis fungoides
- Jessner lymphocytic infiltration
- *Cryptococcus neoformans*

TREATMENT

PRE HOSPITAL

Maintain universal precautions.

INITIAL STABILIZATION/THERAPY

Not applicable in routine cases.

ED TREATMENT/PROCEDURES

- Aimed at destruction or removal of virus-infected epithelial cells and is indicated to prevent autoinoculation and transmission:
 - Intervention is not always indicated: Lesions are self-limited in immunocompetent hosts.
 - Untreated immunocompromised patients are at greater risk for secondary inflammation and bacterial infections
- If treatment is necessary, consider referral to dermatology.
- If dermatology referral is not an option, physical treatment modalities generally most effective:
 - Curettage after local anesthesia with EMLA (eutectic mixture, lidocaine, prilocaine) or ethyl chloride
 - Cryotherapy with liquid nitrogen
 - Podophyllin, trichloroacetic acid, cantharidin, tretinoin, and cidofovir applied topically are variably effective.
 - Repeatedly applying adhesive tape to the lesions as a means of removing the superficial epidermis
- Griseofulvin and methisazone orally for extensive disease have given mixed results.
- HAART has been effective in reducing incidence in HIV-infected patients.
- Topical imiquimod has shown effectiveness in several small studies.
- Examine sexual partners for MC and other sexually transmitted diseases:
 - Patients should avoid contact sports, swimming pools, shared baths and towels, scratching, and shaving until lesions have resolved.

- Re-examine treated patients for recurrence every 2–4 wk; 2–4 treatments are often needed to clear lesions completely.
- Discourage picking and scratching lesions, a common habit, as it may lead to scarring or pigment alteration.

MEDICATION

- Cantharidin 0.9% solution with equal parts of acetone and flexible collodion: Apply topically 1–3 treatments every 7 days or until resolution.
- Imiquimod 5%: Apply topically daily for 3–5 consecutive days for 16 wk.
- Podophyllin (podofilox 0.5%): Apply topically q12h for 3 days, withhold for 4 days; repeat 1-wk cycle up to 4 times until resolved.
- Tretinoin 0.1%: Apply topically q12h for 10 days or until resolution of lesions.
- Trichloroacetic acid (50–80%): Apply and cover with bandage 5–6 days.
- Oral cimetidine (40 mg/kg/d) in 2 div. doses for 2 mo has been used to treat extensive infections; however, further study is needed to determine efficacy.

FOLLOW-UP

DISPOSITION

Admission Criteria

Widespread disease with extensive superinfection in an immunocompromised host

Discharge Criteria

Patients without extensive superinfection may be safely treated as outpatients.

Issues for Referral

Consider referral to dermatology if treatment or confirmatory testing is necessary.

FOLLOW-UP RECOMMENDATIONS

Re-examine treated patient for recurrence every 2–4 wk.

PEARLS AND PITFALLS

- Active nonintervention is an option in immunocompetent hosts.
- Search for an immunocompromised state if no clear etiology.
- Physical destruction of lesions is often most effective treatment vs. medication.

MONOAMINE OXIDASE INHIBITOR POISONING

James W. Rhee

BASICS

DESCRIPTION

- Primarily for depression
- Selegiline, a selective monoamine oxidase B inhibitor, is sometimes used to treat Parkinson disease, and also comes in a transdermal preparation.
- Monoamine oxidase inhibitor (MAOI) pharmacologic actions:
 - Disruption of equilibrium between endogenous monoamine synthesis and degradation, resulting in:
 - Increased neural norepinephrine levels
 - Downregulation of several receptor types
 - Inhibition of irreversible (noncompetitive) enzyme
 - Inhibition of other B₆-containing enzymes
- MAO: Principal inactivator of neural bioactive amines:
 - MAO A:
 - Present in the gut and liver
 - Protects against dietary bioactive amines
 - MAO B:
 - Present in neuron terminals and platelets
 - Sympathomimetic amines: Types of bioactive amines

ETIOLOGY

- MAOI overdose:
 - Toxicopharmacology poorly understood
 - MAO inhibitors: Amphetamine-like in structure:
 - Early: Indirect sympathomimetic effect
 - Late: Sympatholytic response (hypotension)
- MAOI hypertensive crisis syndrome:
 - Results from impaired norepinephrine degradation and large norepinephrine release precipitated by an indirect- or mixed-acting sympathomimetic agent
 - Common precipitants: Tyramine, cocaine, amphetamines
- Serotonin syndrome (SS):
 - Commonly results from exposure to combinations of agents that affect serotonin metabolism or action
 - Increases serotonin synthesis: Tryptophan
 - Increase serotonin release:
 - Indirect- and mixed-acting sympathomimetic agents and dopamine

receptor agonists

- Decrease serotonin reuptake:
 - o Selective serotonin reuptake inhibitors
 - o Tricyclic antidepressants
 - o Newer antidepressants: Trazodone, nefazodone, venlafaxine
 - o Phenylpiperidine opioids: Meperidine, dextromethorphan, tramadol, methadone, propoxyphene
- Direct serotonin receptor agonists:
 - o Buspirone, sumatriptan, lysergic acid diethylamide
- Decrease serotonin breakdown:
 - o MAOIs
- Increases nonspecific serotonin activity:
 - o Lithium

DIAGNOSIS

SIGNS AND SYMPTOMS

- MAOI overdose:
 - Delayed onset (6–12 hr)
 - Initial hypertension with headache
 - Hyperadrenergic activity:
 - o Tachycardia
 - o Hypertension
 - o Mydriasis
 - o Agitation
 - Neuromuscular excitation:
 - o Nystagmus
 - o Hyperreflexia
 - o Tremor
 - o Myoclonus
 - o Rigidity
 - o Seizures
 - Hyperthermia
 - Associated complications:
 - o Rhabdomyolysis
 - o Renal failure
 - o Disseminated intravascular coagulation (DIC)
 - o Acute respiratory distress syndrome (ARDS)
- MAOI hypertensive crisis syndrome (MAOI interaction with drug or food):
 - Hypertension
 - Tachycardia or bradycardia
 - Hyperthermia

- Headache, usually occipital
- Altered mental status
- Intracranial hemorrhage
- Seizures
- SS:
 - Increased neuromuscular activity
 - Increased deep tendon reflexes:
 - Lower extremity may be greater than upper
 - Tremor
 - Myoclonus
 - Rigidity (when severe)
 - Autonomic nervous system hyperactivity:
 - Hyperthermia
 - CNS:
 - Agitation
 - Hallucinations
 - Delirium
 - Coma
 - Diarrhea
 - SS vs. neuroleptic malignant syndrome (NMS):
 - Both present along a spectrum of severity (mild to severe)
 - Onset: Hours (SS) vs. days (NMS)
 - Gastrointestinal symptoms: May be present (SS) vs. absent (NMS)
 - Only drug/medication history may differentiate in many cases

History

- Time of ingestion
- Bottle available
- Intentional or accidental
- Coingestions

Physical-Exam

- Neuromuscular hyperactivity:
 - Myoclonus
 - Rigidity
 - Tremors
 - Hyperreflexia
- Autonomic hyperactivity:
 - Tachycardia or bradycardia
 - Fever
 - Diaphoresis
- Altered mental status:

- Agitation, confusion, or excitement

ESSENTIAL WORKUP

- History of ingested substances
- Rectal temperature monitoring as indicated
- Blood pressure/cardiac monitoring

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Urinalysis:
 - Blood
 - Myoglobin
- Electrolytes, BUN/creatinine, glucose:
 - Hypoglycemia may contribute to altered mental status.
 - Acidosis may accompany severe toxicity.
 - Rhabdomyolysis may cause renal failure.
 - Hyperkalemia—life-threatening consequence of acute renal failure
- Coagulation profile to monitor for potential DIC:
 - INR, prothrombin time, partial thromboplastin time, platelets
- Creatinine kinase:
 - Markedly elevated in rhabdomyolysis
- Urine toxicology screen:
 - May be positive for amphetamines, given the structural similarities between some MAOIs and amphetamines
- Aspirin and acetaminophen levels if suicide attempt a possibility
- Arterial blood gas

Imaging

- Chest radiograph:
 - ARDS
- Head CT if significant headache or altered mental status or focal neurologic signs:
 - Subarachnoid hemorrhage, intracerebral bleed

Diagnostic Procedures/Surgery

Lumbar puncture for:

- Suspected meningitis (headache, altered mental status, hyperpyrexia)
- Suspected subarachnoid hemorrhage and CT normal

DIFFERENTIAL DIAGNOSIS

- Hyperthermia:
 - Infection
 - Hyperthyroidism

- Heat stroke
- Anatomic thalamic dysfunction
- NMS
- Malignant hyperthermia
- Malignant catatonia
- Ethanol or drug withdrawal
- Anticholinergic toxicity
- Sympathomimetic overdose
- Cocaine-associated delirium/rhabdomyolysis
- Salicylate toxicity
- Theophylline toxicity
- Nicotine toxicity
- Hypertension:
 - Hypoglycemia
 - Carcinoid syndrome
 - Pheochromocytoma
 - Accelerated renovascular hypertension
 - Ethanol or drug withdrawal
 - Sympathomimetic toxicity

TREATMENT

PRE HOSPITAL

- Patient may be uncooperative or violent.
- Secure IV access.
- Protect from self-induced trauma.

INITIAL STABILIZATION/THERAPY

- Airway, breathing, and circulation (ABCs)
- IV access and fluid resuscitation if hypotensive
- Oxygen
- Cardiac monitor
- Naloxone, thiamine, D50W (or Accu-Chek) if altered mental status

ED TREATMENT/PROCEDURES

- Gastrointestinal decontamination:
 - In potential life-threatening ingestions gastric lavage may be carefully considered if within *1 hr* of ingestion
 - Administer activated charcoal
- Hyperthermia:
 - Benzodiazepines if agitated
 - Active cooling if temperature > 40°C:

- Tepid water mist
 - Evaporate with fan
- Paralysis:
 - Indicated if muscle rigidity and hyperactivity contributing to persistent hyperthermia
 - Nondepolarizing agent (e.g., vecuronium)
 - Avoid succinylcholine
 - Intubation; mechanical ventilation
- Administer acetaminophen.
- Apply cooling blankets.
- Severe, malignant hypertension:
 - Nitroprusside (for MAOI overdose)
 - Calcium-channel blocker or phentolamine (for MAOI + food interaction)
 - Use short-acting IV agent that can be rapidly “turned off.”
- Hypotension:
 - Initially bolus with isotonic crystalloid solution
 - If no response, administer norepinephrine.
 - Dopamine may be ineffective
- Dysrhythmias (premorbid sign in MAOI overdose):
 - Treatment based on dysrhythmia
- Seizures:
 - Benzodiazepines
 - Barbiturates if benzodiazepines unsuccessful
 - Pyridoxine for refractory seizures
- Rigidity:
 - Benzodiazepines
 - Paralysis with vecuronium, endotracheal intubation, and mechanical ventilation
- ARDS:
 - Oxygen
 - Intubation and positive end-expiratory pressure as indicated
- DIC:
 - Fresh-frozen plasma
 - Platelets
 - Whole-blood transfusions
- Rhabdomyolysis:
 - IV isotonic crystalloid solution
 - Maintain hydration to ensure adequate urine output
- Specific treatment for SS:
 - Mainstay: Supportive care, discontinuation of offending agents
 - Nonselective serotonin antagonist:
 - Cyproheptadine

ALERT

Phentolamine *contraindicated in MAOI overdose* (results in unopposed β -agonist)

MEDICATION

- Activated charcoal: 1–2 g/kg PO
- Cyproheptadine: 4–8 mg PO/nasogastric tube q1–4h until therapeutic response; max. daily dose: 0.5 mg/kg (peds: 0.25 mg/kg/d; max. 12 mg/d; safety not established age < 2 yr)
- Dextrose: D50W 1–2 amp (50–100 mL or 25–50 g) (peds: D25W 2–4 mL/kg) IV push (IVP)
- Diazepam: 5–10 mg (peds: 0.1 mg/kg slowly) increments IVP
- Lorazepam: 1–2 mg increments IVP
- Nitroprusside: 0.3–10 μ /kg/min IV
- Norepinephrine: 2–4 μ /kg/min (peds: 0.05–0.1 μ /kg/min) IV
- Phentolamine: 5 mg (peds: 0.05–0.2 mg/kg/dose) increments IVP
- Sodium bicarbonate: Bolus 1–2 mEq/kg IVP; adult infusion: 3 amp (50 mEq per amp) sodium bicarbonate in 1,000 mL D5W at 2–3 mL/kg/h IV
- Vecuronium: 0.1 mg/kg IVP

FOLLOW-UP

DISPOSITION

ALERT

MAOI toxicity can occur in delayed fashion necessitating an extended observation period

Admission Criteria

- All MAOI overdose patients require admission to a monitored unit for 24 hr.
- ICU admission for seriously ill patients

Discharge Criteria

- Resolved mild hypertensive syndrome or resolved mild serotonin syndrome may be discharged after several hours of ED observation.

Issues for Referral

Intentional overdoses should receive a psychiatry consult for suicide attempt.

FOLLOW-UP RECOMMENDATIONS

Following significant MAOI toxicity, medications need to be reassessed to prevent future crises.

PEARLS AND PITFALLS

- Delayed onset of 6–12 hr prior to symptoms
- Linezolid and methylene blue are MAOIs.
- Phentolamine is contraindicated in MAOI overdose secondary to unopposed β -agonist.

MONONUCLEOSIS

Steven C. Rogers • Alberto Cohen-Abbo

BASICS

DESCRIPTION

- Results in most cases from infection with the Epstein–Barr virus (EBV) (a herpesvirus):
 - Non-EBV causes of infectious mononucleosis (IM):
 - Cytomegalovirus (CMV)
 - Adenovirus
 - Hepatitis A
 - Herpesvirus 6
 - HIV
 - Rubella
 - *Toxoplasma gondii*
 - Group A β -hemolytic streptococci
- > 90% of adults on serologic testing demonstrate prior infection with EBV:
 - Most do not recollect specific IM symptoms
- Mode of transmission is close or intimate contact particularly with saliva from “shedders” who may or may not be symptomatic:
 - Nickname “kissing disease”
 - Viral shedding in saliva can persist intermittently for life
 - May occur after transfusions/transplants
- Incubation period: 4–6 wk
- Immunologic response:
 - T-cells response:
 - T-cell response is responsible for an elevated absolute lymphocyte count and the associated clinical symptoms and complications
 - Subtype of the T-cell lineage, cytotoxic CD8 cells (Downey cells), contain eccentrically placed and lobulated nuclei with vacuolated cytoplasm: The “atypical lymphocytes” seen on differential
 - B-cell response:
 - EBV infects and replicates in B-cells
 - B-cells are then transformed into plasmacytoid cells that secrete immunoglobulins
 - IgM antibody secreted: The heterophile antibody which is reactive against red cell antigens
- Mortality from IM is rare, but may occur due to the following complications:
 - Airway edema
 - Neurologic complications

- Secondary bacterial infection
- Splenic rupture
- Hepatic failure
- Myocarditis
- EBV infection has also been strongly linked to African Burkitt lymphoma and nasopharyngeal carcinoma

Pediatric Considerations

- In children < 4 yr, infection with EBV is often asymptomatic
- In children who do become symptomatic, there is propensity toward atypical presentations:
 - Neutropenia, pneumonia, and varied rashes
 - Mesenteric lymphadenopathy and splenomegaly can cause the illness to present with abdominal pain and be confused with appendicitis.
 - Infants and toddlers can present with only irritability and failure to thrive so must be considered when no other source can be identified

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Typically an insidious onset over several days to weeks but may be abrupt onset
- Prodromal fatigue, malaise, arthralgias, and myalgias with a biphasic or “waxing and waning” course
- Prominent or “worst ever” sore throat and fever. Airway edema may be reported as difficulty breathing or respiratory distress.
- Swollen lymph nodes
- Headache
- Significant abdominal pain is uncommon but when present should raise concern about marked splenic enlargement or splenic rupture.
- Varied rashes can be seen in 18–34% of children and adolescents (not associated with antibiotics)
- Administration of ampicillin or amoxicillin in patients with IM is associated with development of a rash

Physical-Exam

- Malaise and/or fatigue (90–100%)
- Pharyngitis (65–85%) and tonsillar enlargement
- Fever (80–95%)
- Eyelid edema (15–35%)
- Symmetric tender lymphadenopathy (100%)

- Hepatomegaly (15–25%)
- Splenomegaly (50–60%)
- Nonspecific rashes
- Morbilliform rash can be seen if the patient has been given ampicillin or amoxicillin:
 - Typically develops 5–9 days after the onset of antibiotic therapy (should not be interpreted as a penicillin allergy)
- Petechia can occur on the skin or at the junction between the hard and the soft palate.
- Complications found on exam:
 - Airway compromise due to edema (1–5%)
 - Severe abdominal tenderness may be due to splenic rupture (may also cause referred pain to left shoulder)
 - Jaundice (~5%) due to hepatitis or hepatic failure
 - Hepatitis is the most common complication
 - Neurologic findings consistent with:
 - Encephalitis or cerebellitis
 - Aseptic meningitis
 - Guillain–Barré syndrome
 - Optic neuritis
 - Bell palsy
- Anemia (pallor): May be due to hemolytic anemia, thrombocytopenia, agranulocytosis, hemophagocytic lymphohistiocytosis (HLH)
- Orchitis
- Neck tenderness and/or limited range of motion due to pain: Secondary bacterial soft tissue infection such as retropharyngeal or peritonsillar abscesses
- Signs of shock: May be due to dehydration or a secondary anaerobic sepsis

DIAGNOSIS TESTS & INTERPRETATION

Lab

- WBC with differential:
 - Typically a modest elevation in total WBC between 10,000 and 20,000, which peaks during week 2 of the illness but occasionally can be 30,000–50,000
- Lymphocyte count—findings suggestive of IM:
 - >50% lymphocytes on differential
 - Absolute lymphocyte count >4,500
 - Elevated lymphocyte count with >10% atypical lymphocytes (up to 90% of patients)
- Liver function tests:
 - Elevated with transaminases up to 3 times normal found in 80–85% of patients in the 1st 2 wk

- Significant elevations in bilirubin to the point of causing clinical jaundice in ~5% of cases
- Monospot test detects presence of heterophile antibodies:
 - Moderately sensitive (85%) and highly specific (practically 100%)
 - Rarely false positives can occur with CMV, leukemia, lymphoma, rubella, hepatitis, HIV, or lupus
 - Most patients develop heterophile antibodies after ~1 wk of illness
 - Small percentage of patients (<10%) never develop heterophile antibodies
 - Heterophile antibodies peak at 2–5 wk and may persist for several months
 - Positive test relates to a titer >1:40
 - Results likely to be negative in children <4 yr old
- Testing does exist for EBV-specific antibodies but is expensive, time consuming, and rarely needed
 - Useful in patients with atypical/severe cases or when monospot testing is negative and confirmation of IM is desired
 - Acute infection is indicated by antibodies (IgG, IgM) against viral capsid antigens (VCAs) without antibodies against the Epstein–Barr nuclear antigen (EBNA) which are only present during the latency period 3–4 wk after onset of illness
 - Past infection indicated by negative IgM and positive EBNA

Imaging

Sonography or CT scan of abdomen for significant abdominal pain to identify splenic rupture and to ensure no signs of appendicitis

DIFFERENTIAL DIAGNOSIS

Divided into infectious and noninfectious causes:

- Infectious:
 - Adenovirus
 - CMV
 - Streptococcal pharyngitis
 - HIV
 - Rubella
 - Hepatitis A, B, C
 - Diphtheria in nonimmunized populations
 - Mumps
 - Toxoplasmosis
- Noninfectious:
 - Leukemia
 - Lymphoma
 - Medication-induced syndrome—phenytoin, sulfa drugs

TREATMENT

PRE HOSPITAL

ALERT

- Follow standard universal precautions
- ABCs. Assess airway patency
- Initiate IV hydration with normal saline if patient is dehydrated

INITIAL STABILIZATION/THERAPY

- ABC management. Airway edema may require intervention
- If possible, avoid placing patient in the same general area as post-transplant and other immunocompromised patients

ED TREATMENT/PROCEDURES

- Supportive therapy:
 - Hydration with IV or PO fluids
 - Antipyretics for fever control
 - Analgesics for pain of sore throat
- Steroids (methylprednisolone, prednisone, or dexamethasone) if there is significant pharyngeal/tonsillar edema with concern about impending airway obstruction. May also be considered for massive splenomegaly, myocarditis, hemolytic anemia, or HLH. Treatment is controversial and theoretically may be associated with increased risk of secondary infections or malignant disease
- Antiviral therapy has not been proven to effect clinical course but emerging research may suggest potential benefits
- Antibiotics if concerned for bacterial superinfection:
 - Avoid ampicillin because of associated rash
- Counsel patient on athletic activity limitations (*see follow-up recommendations*)

Pediatric Considerations

Advise parents of athletic activity limitations (*see follow-up recommendations*)

MEDICATION

- Methylprednisolone: 125 mg IV (peds: 2 mg/kg IV up to adult dose)
- Prednisone: 20–40 mg PO daily for 7 days (peds: 1 mg/kg up to adult dose) with subsequent tapering
- Dexamethasone: 12–16 mg PO (peds: 0.3 mg/kg up to adult dose)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Significant airway edema that represents any level of potential airway compromise
- Neurologic or severe hematologic/hepatic complications
- Inability to take PO
- Pain control

Discharge Criteria

- No airway compromise
- Mild hematologic complications or mild hepatitis
- Ability to take PO fluids
- Fever usually resolved within 10 days and lymph nodes and spleen within 4 wk; fatigue may continue for several weeks, although it may go on for 2–3 mo

Issues for Referral

- Infectious disease consultation may be useful if serology is not conclusive
- Significant complications or persistent symptoms

FOLLOW-UP RECOMMENDATIONS

- Contact sports, physical education, or other strenuous exercise should be avoided in the 1st 3 wk regardless of spleen size or current symptoms.
- After the initial 3-wk period patients need repeat outpatient evaluation to determine if they are able to return to full activity. Those with concerns of persistent symptoms including splenomegaly may require further studies (i.e., ultrasound) to determine when they are safe to return to full activity

PEARLS AND PITFALLS

- Although usually self-limited, significant complications occur and require consultation
- Treatment with steroids may be useful but is controversial due to potential increased risk of complications

MRSA, COMMUNITY ACQUIRED

Benjamin S. Heavrin

BASICS

DESCRIPTION

- Methicillin-resistant *Staphylococcus aureus* (MRSA) has historically been a pathogen endemic within healthcare settings, usually affecting the elderly and chronically ill. This strain of *S. aureus* has been termed “healthcare-associated MRSA” (HA-MRSA).
- Throughout the past decade, MRSA has become an increasingly common pathogen among younger, healthier populations who do not have a healthcare-related exposure history. This type of MRSA pathogen has been termed “community-acquired MRSA” (CA-MRSA).
- CA-MRSA is the most common cause of skin and soft tissue infections seen in the ED
- While CA-MRSA may cause skin and soft tissue infection, it may also lead to severe multisystem disease, including sepsis and necrotizing pneumonia

Geriatric Considerations

HA-MRSA (see below) is a different genotypic form of MRSA that frequently causes morbidity among the elderly, especially those living within extended-care facilities or those with healthcare-related exposures.

ETIOLOGY

- *S. aureus* is a gram-positive cocci frequently colonizing the skin
- MRSA refers to a specific strain of *S. aureus* that has resistance against the antimicrobial properties of numerous antibiotics, including methicillin
- Prisoners, athletes, soldiers, children in daycare, IV drug users, and those with prior treatment for MRSA or exposure to MRSA are at highest risk for colonization and subsequent infection.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Skin and soft tissue infections:
 - Increasing redness
 - Pain
 - Warmth

- Swelling
- Fever
- Chills
- Malaise
- Sepsis/pneumonia:
 - Weakness
 - Dyspnea
 - Fever
 - Rigors
 - Productive cough
 - Chest pain
- Inquire about prior diagnosis of MRSA infections, MRSA exposures, and family members or close contacts with a history of MRSA, as such a patient is at risk for CA-MRSA infection.

Physical-Exam

- Skin and soft tissue infections:
 - Abscess: Tender, raised boil with underlying induration and fluctuance
 - Cellulitis: Warm erythema possibly with lymphangitic streaking
- Sepsis:
 - Vital sign abnormalities including tachycardia and hypotension, respiratory failure, mental status changes, petechiae, systemic signs of toxicity
- Pneumonia:
 - Tachypnea, crackles, retractions, hypoxia
 - Alveolar opacities on chest radiographs

Pediatric Considerations

MRSA is the leading cause of skin and soft tissue infections among children presenting to the emergency department.

ESSENTIAL WORKUP

- Abscess:
 - I&D with packing and prompt follow-up is warranted for abscess
 - Microbiology often performed for antibiotic sensitivity given the changing antimicrobial resistance patterns
- Sepsis:
 - Source identification, including blood culture/urine culture, CXR, is indicated as resuscitation begins
- Pneumonia:
 - Chest radiographs and continuous vital sign monitoring is indicated

DIAGNOSIS TESTS & NTERPRETATION

Lab

- Skin and soft tissue infections:
 - Bacterial culture is often warranted to monitor for CA-MRSA resistance patterns
- Sepsis and pneumonia:
 - Blood, urine, and body fluid cultures. CBC, CMP to assess for organ dysfunction

Imaging

- Bedside US:
 - Abscess: Anechoic fluid collection
 - Cellulitis: “Cobblestoning” within the soft tissue
- CXR:
 - Indicated for patients with presumed sepsis, systemic illness, or pneumonia

Diagnostic Procedures/Surgery

Cultures of skin and soft tissue infections are frequently obtained to monitor microbiology and antimicrobial resistance patterns should a patient fail a course of therapy.

DIFFERENTIAL DIAGNOSIS

- Other skin and soft tissue infections:
 - Pathogens beyond MRSA which cause abscesses and cellulites should be considered (i.e., streptococcus)
- Necrotizing fasciitis
- Contact dermatitis
- Deep vein thrombosis
- Spider/insect bite
- Drug reaction

ALERT

Empiric antimicrobial treatment of skin and soft tissue infections should cover for common skin pathogens beyond MRSA (i.e., streptococcus)

TREATMENT

PRE HOSPITAL

- Contact precautions for all providers if MRSA is suspected
- IV access and fluid resuscitation if sepsis is suspected

INITIAL STABILIZATION/THERAPY

Begin resuscitation and administer early empiric antibiotics if pneumonia, fasciitis, or

sepsis is suspected:

- Include early coverage with antibiotics effective against MRSA

ED TREATMENT/PROCEDURES

- Skin and soft tissue infections:
 - Abscess:
 - I&D with packing
 - Antibiotics may not be necessary if there is no evidence for deep tissue infection or cellulitis
 - Cellulitis:
 - Cellulitis caused by CA-MRSA in a healthy, well-appearing patient may be treated with oral antibiotics in the outpatient setting
 - Ill appearing patients, patients with underlying medical conditions, and patients failing outpatient therapy require IV antibiotics with coverage against CA-MRSA
- Sepsis and pneumonia:
 - Early administration of broad-spectrum antibiotics that cover against MRSA should be given promptly if the patient is at risk for CA-MRSA

MEDICATION

ALERT

Review antimicrobial resistance patterns of CA-MRSA within your community prior to choosing a specific antibiotic regimen, as many antibiotics listed below may not be 100% effective against CA-MRSA.

First Line

- Bactrim:
 - Adults: Bactrim DS 160/800 PO BID
 - Children: 10 mg/kg PO BID
- Clindamycin:
 - Adults: 150–450 mg PO QID
 - Children: 5 mg/kg PO/IV TID–QID
- Doxycycline:
 - Adults: 100 mg PO BID
 - Children: 2.2 mg/kg PO BID
- Vancomycin:
 - Adults: 1 g IV q8–12h
 - Children: 15 mg/kg IV q8–12h

Second Line

- Rifampin:
 - Should not be used as monotherapy due to inducible resistance

- Adults: 300 mg PO BID
- Children: 10–20 mg/kg/d in 2 div. doses PO for 5 days; not to exceed 600 mg/d
- Linezolid:
 - Adults: 600 mg PO/IV q12h
 - Children: 10 mg/kg PO/IV q8h

Pregnancy Considerations

Avoid the use of tetracyclines in pregnancy

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with signs/symptoms of bacteremia, progressive infection, or systemic illness should be admitted:
 - Fever, chills, lymphangitic streaking
- Patients with underlying comorbid diseases such as diabetes or immunodeficiency should be admitted
- Individuals who have failed a course of outpatient therapy should be admitted and given IV antibiotics effective against MRSA

Discharge Criteria

Healthy, well-appearing patients with simple skin and soft tissue infections may be followed in the outpatient setting.

Issues for Referral

MRSA infection refractory to multiple medications may require infectious disease consultation.

FOLLOW-UP RECOMMENDATIONS

- All skin and soft tissue infections should be re-evaluated within 24–48 hr to monitor for clinical improvement.
- Individuals failing outpatient therapy require hospital admission and IV antibiotics.

PEARLS AND PITFALLS

- CA-MRSA is the most common cause of skin and soft tissue infections seen in the ED.
- CA-MRSA is a rare but serious cause of rapidly progressive pneumonia and sepsis.

- Antibiotic resistance patterns are dynamic and vary widely across geographic boundaries.
- Be cautious with long-term use of tetracyclines in children.

MULTIPLE MYELOMA

Nicole M. Franks

BASICS

DESCRIPTION

- Normal cells transform into myeloma cells at the hematopoietic stem cell level.
- Pathologic derangements:
 - Tumor cells within marrow lead to bone destruction and cytopenia.
 - Immunodeficiency develops secondary to suppression of normal immune functions.
 - Myeloma proteins lead to hyperviscosity and amyloidosis.
 - Multifactorial renal failure
- Plasma cell secretions activate osteoclasts, leading to:
 - Bone lysis, pathologic fractures, and neurologic impairment
 - Hypercalcemia (exacerbated by impaired renal function)
- Anemia due to marrow infiltration and renal insufficiency
- Immunocompromised due to:
 - Decrease in the number of normal immunoglobulins
 - Qualitative and quantitative defects in T- and B-cell subsets
 - Granulocytopenia
 - Decreased cell-mediated immunity
- Hyperviscosity secondary to protein accumulation:
 - Leads to high-output congestive heart failure
- Myeloma light chains accumulate in the renal epithelial cells and destroy the entire nephron.
- Clinical signs such as anemia, renal insufficiency, or lytic bone lesions
- Complications:
 - Pathologic fractures
 - Hypercalcemia
 - Renal failure
 - Recurrent infection
 - Anemia
 - Spinal cord compression (10% of all multiple myeloma [MM] patients)

ETIOLOGY

- Incidence: 4/100,000 population:
 - 1% of all cancers
 - 15% of all hematopoietic malignancies
 - 10,000 deaths/yr
- Mean age at diagnosis is 70 yr

- Slightly higher incidence in men and African Americans (reason unknown)

Pediatric Considerations

- Rarely seen in children.
- <2% in patients <40 yr of age

DIAGNOSIS

SIGNS AND SYMPTOMS

- Bone pain predominates (with secondary disuse or neurologic sequelae):
 - Ribs/sternum
 - Spine
 - Clavicle
 - Skull
 - Shoulder
 - Hip
- Constitutional symptoms:
 - Anemia
 - Weakness
 - Fatigue
 - Recurrent infection
 - Weight loss
- Asymptomatic (20%):
 - MM found on follow-up of routine blood screening
- Multiple bouts of sepsis secondary to the encapsulated organisms (*Streptococcus pneumoniae*, *Haemophilus influenzae*, and *Staphylococcus*).

ESSENTIAL WORKUP

- CBC, ESR, electrolytes, BUN, creatinine, urinalysis
- Plain radiographs related to bone pain:
 - Skeletal survey: Lateral skull, AP/lateral spine, AP of pelvis, humerus, and femur
- CT or MRI for persistent bone pain with negative plain radiographs
- Confirmation of diagnosis:
 - Serum and urine protein electrophoresis
 - Serum and urine protein immunofixation (diagnostic when electrophoresis is normal or nonspecific)
 - Vitamin D levels
 - Bone marrow biopsy

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - Normochromic, normocytic anemia
 - Thrombocytopenia
 - Leukocytosis
- “Rouleaux” formation on peripheral blood smear (stacks of red blood cells)
- Electrolytes, BUN, creatinine, glucose:
 - Renal insufficiency
- Serum calcium:
 - Hypercalcemia due to bone resorption
- Urinalysis:
 - Dipstick selects for albumin and not light-chain proteinuria.
 - False-negative screening urinalysis for Bence Jones protein is common.
- Elevated erythrocyte sedimentation rate (ESR)
- Urinary and serum electrophoresis show a monoclonal protein spike:
- Quantitative screening for light chain is diagnostic.

Imaging

- Plain radiographs demonstrate:
 - Lytic bone lesions
 - Pathologic fractures
- CT:
 - More sensitive for small lesions
 - Can differentiate malignant from benign vertebral compression fractures in non-MRI candidates
- MRI:
 - Preferred to detect spinal compression or soft-tissue plasmacytomas
- PET with MR or CT: May have future role in surveying response to treatment
- Technetium pyrophosphate bone scan:
 - Lights up bone deposition
 - False-negative scan with MM due to an uncoupling of bone absorption and deposition that results in a negative bone scan even when lytic lesions are present
- Bone marrow biopsy: Increase in plasma cells
- Cytogenetic screening may offer prognostic significance.

DIFFERENTIAL DIAGNOSIS

- Monoclonal gammopathy of undetermined significance
- Amyloidosis
- Chronic lymphocytic leukemia
- Non-Hodgkin lymphoma
- Waldenström macroglobulinemia
- Bone marrow plasmacytosis includes collagen vascular disease, cirrhosis, immune complex disease, viral illness, and papular mucinosis.

TREATMENT

PRE HOSPITAL

Immobilize appropriately patients with MM who present with back pain or neurologic symptoms:

- Presume to have a pathologic spinal fracture

INITIAL STABILIZATION/THERAPY

Recognition and treatment of:

- Hypercalcemia
- Renal failure
- Sepsis
- Spinal cord compression
- Anemia

ED TREATMENT/PROCEDURES

- Opiate analgesics are the mainstay of therapy in ED (NSAIDS may worsen renal insufficiency).
- Splint pathologic fracture; immobilize pathologic spine fractures.
- Aggressive normal saline hydration with bisphosphonate therapy for hypercalcemia
- Symptomatic anemia may be managed with transfusions or erythropoietin therapy.
- Hematology/oncology consultation for chemotherapy—administer on inpatient/outpatient basis:
 - Early or asymptomatic stages do not need treatment.
 - Chemotherapy in early stage shows no benefit.
 - Melphalan and prednisone combination chemotherapy is the most common treatment:
 - Symptom relief and decrease in M protein levels in up to 70% of patients
 - Alternative chemotherapy includes cyclophosphamide with or without prednisone or VAD (vincristine, doxorubicin [Adriamycin], and dexamethasone).
- Prolonged melphalan use may lead to a secondary leukemia.
- High-dose chemotherapy with stem cell transplantation has shown promise.
- Thalidomide is useful for salvage therapy.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Refractory pain requiring systemic analgesics
- Life-threatening complications of MM, including acute renal failure, hypercalcemia, sepsis, spinal cord compression, hyperviscosity, neutropenia, and cardiac tamponade

Discharge Criteria

Pain controlled with oral analgesics

Issues for Referral

- Oncology referral for all patients regardless of stage of disease discovery
- Neurosurgery and orthopedic referral for persistent vertebral pain that may require percutaneous vertebroplasty or kyphoplasty

PEARLS AND PITFALLS

- Infectious complications are the major cause of morbidity and mortality such that febrile illness should be treated with empiric therapy for common respiratory and urinary tract infections.
- Consider diagnosis of multiple myeloma for any persistent neurologic complaints or unknown mobility in the elderly.

CODES

ICD9

203.00 Multiple myeloma, without mention of having achieved remission

ICD10

C90.00 Multiple myeloma not having achieved remission

MULTIPLE SCLEROSIS

Richard S. Krause

BASICS

DESCRIPTION

- Pathophysiology: Recurrent episodes of CNS demyelination:
 - Signs and symptoms depend on location of lesions and timing of demyelination
- Multiple sclerosis (MS) occurs in distinct patterns:
 - *Relapsing recurring MS*: 2 or more episodes lasting ≥ 24 hr separated by ≥ 1 mo
 - *Primary progressive MS*: Slow or stepwise progression over at least 6 mo
 - *Secondary progressive MS*: Initial exacerbations and remissions followed by slow progression over at least 6 mo
 - *Stable MS*: No progression (without treatment) over at least 18 mo

ETIOLOGY

- MS is a chronic demyelinating disease of CNS:
 - Etiology is not well understood
- Presumed to be T cell-mediated autoimmune disease
- There is evidence for a viral trigger
- Plaques in white matter:
 - Characterized by infiltrate of T cells and macrophages
- Persons of northern European origin most often affected (in US)
- Increased prevalence is seen moving away from equator

DIAGNOSIS

SIGNS AND SYMPTOMS

- Initial attacks usually (~85%) represent single lesions, are abrupt in onset, and are seen in characteristic patterns (in order of decreasing frequency):
 - Optic neuritis:
 - Eye pain exacerbated by movement progressing to visual loss
 - Paresthesias (or changed sensory level) in 1 limb
 - Limb (usually leg) weakness
 - Diplopia:
 - Intranuclear ophthalmoplegia from lesion of medial longitudinal fasciculus
 - Results in unilateral or bilateral paralysis of adduction of eye on horizontal gaze

- Trigeminal neuralgia
- Urinary retention
- Vertigo
- Transverse myelitis:
 - Acute onset of motor and sensory findings at specific spinal cord level
 - Often associated with bladder or bowel incontinence
 - Can be early manifestation of MS
 - Unusual initial manifestations include psychosis, aphasia, etc.
 - Initial symptoms may be minor and only be recognized as due to MS in retrospect
- Symptoms typically develop abruptly (minutes to hours) and last 6–8 wk
- Most common in young women of Northern European descent:
 - Increased risk in 1st-degree relatives
 - Peak age: 30 yr
 - Female-to-male ratio: 2:1
- Pain is an uncommon symptom in MS:
 - Exceptions: Trigeminal neuralgia, early optic neuritis

Physical-Exam

Physical exam: Focused on “hard” neurologic signs:

- Focal neurologic deficits
- Afferent pupillary defect
- Internuclear ophthalmoplegia
- Sensory level or sphincter disturbance (transverse myelitis)

ESSENTIAL WORKUP

- MS is suspected based on history and physical exam
- Definitive diagnosis is not typically made in ED:
 - Requires observation over time and confirmatory testing

ALERT

Infection, especially with fever, is a common cause of MS exacerbation

DIAGNOSIS TESTS & INTERPRETATION

Lab

CSF analysis:

- CSF gel electrophoresis reveals “oligoclonal bands” not present in serum
 - Oligoclonal bands are found in $\geq 95\%$ of patients with clinically definite MS

Imaging

MRI most useful imaging test:

- Lesions appear as areas of high signal, in cerebral white matter or spinal cord on

T2-weighted images

- Abnormal in almost all patients who have clinically diagnosed MS
- McDonald diagnostic criteria for MS include specific MRI findings
- May also see plaques on CT (less sensitive)

Diagnostic Procedures/Surgery

Sensory-evoked potential testing:

- Not an ED test

DIFFERENTIAL DIAGNOSIS

- Signs and symptoms of MS are usually *focal*:
 - Diffuse symptoms (seizures, syncope, and dementia) are seldom due to MS
- Cerebrovascular accident and transient ischemic attack:
 - Usually older patients with risk factors for atherosclerotic disease or atrial fibrillation
- Systemic lupus erythematosus:
 - CNS involvement usually in setting of known disease and usually nonfocal
- Sarcoid:
 - CNS manifestations usually with known disease and lung involvement
- Lyme disease:
 - May mimic MS
 - Seek history of rash and tick exposure in geographic areas of high risk
 - Lyme titers may aid in diagnosis
- Psychiatric illness is diagnosis of exclusion
- Postinfectious or postimmunization demyelination may mimic MS, usually in children
- Guillain–Barré is usually ascending and symmetric and progresses over hours to days
- MS unlikely in patients with:
 - Normal neurologic exam
 - Abrupt hemiparesis (stroke)
 - Aphasia (stroke)
 - Pain predominating
 - Very brief symptoms (seconds to minutes)
 - Age < 10 or > 50 yr

TREATMENT

INITIAL STABILIZATION/THERAPY

Fever in MS patients is treated aggressively because it can worsen the manifestations of MS

ED TREATMENT/PROCEDURES

- Acute optic neuritis:
 - High-dose parenteral steroids
 - Oral steroids *relatively contraindicated* (has been reported to increase recurrence risk)
- Exacerbations:
 - High-dose IV methylprednisolone (up to 1 g/day) or other parenteral corticosteroid
 - High-dose oral steroids are sometimes used (except for optic neuritis)
- Symptomatic treatment:
 - Spasticity: Baclofen, tizanidine
 - Tremor: Clonazepam
 - Urinary symptoms:
 - Diagnose and treat infection
 - Self-catheterization
 - Oxybutynin may promote continence
 - Trigeminal neuralgia: Carbamazepine
 - Fatigue, general weakness: Amantadine, methylphenidate, and modafinil have been used
 - Depression: SSRIs are effective

MEDICATION

- Amantadine: 100 mg PO BID
- Baclofen: 10 mg PO TID initially; may increase to 25 mg PO TID
- Carbamazepine: 100 mg PO BID to 200 mg PO QID
- Clonazepam: 0.5 mg/d PO, increase in 0.5-mg increments and up to 3 times a day
- Methylprednisolone: 1 g IV daily (1st-line treatment)
- Modafinil: 100–200 mg PO daily in AM
- Oxybutynin: 5 mg PO BID to TID
- Tizanidine: 2–8 mg PO TID

FOLLOW-UP

DISPOSITION

Admission Criteria

- Acute exacerbation that requires IV therapy
- Patients unable to care for themselves due to severity of their illness
- Another condition requiring inpatient treatment cannot be effectively ruled out

Discharge Criteria

- *Suspected MS*: Patients may be referred for outpatient evaluation if their general

condition permits and other serious conditions requiring admission have been effectively ruled out

- *Complication of known MS*: Discharge if effective outpatient treatment is available for complication or exacerbating factor

FOLLOW-UP RECOMMENDATIONS

Patients with suspected MS should be referred to their primary care provider or a neurologist for further evaluation

PEARLS AND PITFALLS

- Signs and symptoms of MS are usually focal
- Diffuse symptoms are rarely MS
- Oral steroids are contraindicated
- Treat fever in MS patients aggressively

MUMPS

Austen-Kum Chai

BASICS

DESCRIPTION

Vaccine preventable infectious diseases characterized by swelling of salivary glands, in particular the parotid glands.

ETIOLOGY

- Rubulavirus, single stranded RNA virus, in the Paramyxovirus family
- Humans only known reservoir

Pediatric Considerations

- Mumps vaccine with measles and rubella \pm varicella (MMR or MMRV) should be administered to children on or after 12 mo of age. 2nd dose is usually administered at the age of 4–6 yr, before start of school.
- Catch-up vaccination should include 2 doses separated by at least 4 wk between vaccinations.
- Systemic symptoms and serious complications are less common in children when compared to adults with the infection.

Pregnancy Considerations

Infection during 1st trimester of pregnancy is associated with increased spontaneous abortion. Although mumps virus may cross the placenta, there is no evidence that mumps virus causes congenital malformation.

Geriatric Considerations

Adults born before 1957 are considered to have been exposed to mumps and are considered immune. However, during outbreaks, healthcare workers born before 1957 and without lab evidence of immunity to mumps should receive 2 doses of the MMR vaccine.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Incubation period from exposure to onset of symptoms (14–18 days):
 - Viral transmission is via respiratory droplets, saliva, contact with contaminated fomites
 - Replication in nasopharynx and regional lymph nodes
 - Viremia to glands as salivary, pancreas, testes, ovaries and also to meninges

- Contagious 1–7 days prior to onset of symptoms and 6 days afterward
- Often history of none or incomplete immunization
- Active illness (1–10 days):
 - Nonspecific prodromal symptoms such as low-grade fever, headache, malaise, myalgia, anorexia, otalgia, jaw pain up to 48 hr prior to presentation of parotitis
 - Up to 20% of infections are asymptomatic but still contagious
 - Up to 50% of cases have nonspecific symptoms of upper respiratory tract infection along with fever, malaise, anorexia, and headache without apparent salivary gland swelling.
 - *Parotitis* (30–40% of patients):
 - Most common manifestation of mumps. Present in 95% of symptomatic cases of mumps
 - Painful and tender unilateral or bilateral (90% of the time) enlargement of parotid gland
 - May begin as earache or pain at angle of jaw
 - Other salivary gland may be affected.
 - Stensen's duct is often edematous and erythematous and exudes a clear fluid.
 - Skin overlying swollen gland is nonerythematous.
 - Symptoms decrease after 1 wk and resolve by 10th day.
 - Considered contagious until swelling resolves
 - *Orchitis* (20–50% of postpubertal males):
 - Most common complication in postpubertal males
 - May occur alone, before, during, but most commonly, after parotitis
 - Unilateral or bilateral (up to 30%)
 - Abrupt, painful, tender swelling with nausea, vomiting, and fever
 - Pain and swelling resolve in 1 wk
 - Testicular atrophy in up to 50% of patients
 - Sterility rare
 - *Oophoritis* (5% of postpubertal females):
 - May mimic appendicitis if right-sided
 - Fertility not impaired
 - Pancreatitis (2–5%):
 - May occur without any other manifestations of mumps
 - Fever, nausea, vomiting, and epigastric pain
 - May see transient hyperglycemia
 - May be complicated by pseudocyst formation and shock
 - CNS involvement:
 - Aseptic meningitis (10–15% of patients)
 - Usually resolves without sequelae in 3–10 days
 - Encephalitis (very rare)
 - Sensorineuronal deafness (80% unilateral) with permanent hearing

- impairment
- Cerebellar ataxia
- Transverse myelitis
- Other:
 - Myocarditis (rarely with symptomatic involvement)
 - Glomerulonephritis
 - Polyarthralgia and arthritis
 - Thrombocytopenic purpura
 - Ocular complaints
 - Thyroiditis
 - Mastitis

ESSENTIAL WORKUP

Diagnosis is based on clinical findings of parotitis and associated signs, symptoms, and complications.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Lab tests as needed
- Cerebrospinal fluid (CSF) for symptomatic CNS involvement
- Hyperamylasemia usually due to parotitis and supports diagnosis
- Mumps RNA detection using PCR assays, mumps viral cultures, or enzyme immunoassays for mumps IgM antibody or significant rise in IgG titers between acute and convalescent specimens:
 - Provides definitive diagnosis
 - Viral culture may be from blood, throat swab, salivary gland secretions, CSF, or urine. PCR provides rapid confirmation of mumps in CSF
 - Not indicated unless need to confirm diagnosis in absence of parotitis

DIFFERENTIAL DIAGNOSIS

- Bacterial parotitis:
 - Commonly *Staphylococcus aureus*
 - Erythematous and tender parotid gland
 - Usually in elderly or immunocompromised
- Calculus parotid:
 - Stone may be palpable or may be seen on sialogram (CT)
- Cervical adenitis
- Tumors:
 - Older patients
 - History of indolent course
- Testicular torsion
- Bacterial epididymo-orchitis

- Other viral cause of parotitis; influenza A, parainfluenza, cytomegalovirus, coxsackieviruses, HIV

TREATMENT

PRE HOSPITAL

Nonimmunized pre-hospital care personnel exposed to mumps should be advised of potential risks.

INITIAL STABILIZATION/THERAPY

IV fluids for vomiting/dehydration

ED TREATMENT/PROCEDURES

- Prevention with mumps vaccination is cornerstone of therapy
- Supportive therapy:
 - Antipyretics
 - Analgesia:
 - Acetaminophen, NSAIDs, narcotics (for severe pain)
 - IV fluids and antiemetics for vomiting and dehydration
 - Ice pack
 - Scrotal support and bed rest for orchitis
- Isolation, droplet precaution, of infected patients

FOLLOW-UP

DISPOSITION

Admission Criteria

- Seriously ill who require supportive care
- Vomiting and dehydration
- Encephalitis, meningitis
- Severe pancreatitis
- Isolate admitted patients

Discharge Criteria

- Virtually all patients
- Contagious until about a week after onset of symptoms

PEARLS AND PITFALLS

- Mumps virus is the only cause of epidemic parotitis.
- Vaccines are highly effective, and when correctly given confer 90% immunity.

MMR should not be given to pregnant women or immunosuppressed or immunocompromised individuals.

- Mumps virus is endemic to many parts of the world and may pose a risk to travelers without immunity to mumps.

MUNCHAUSEN SYNDROME

Sophie Galson • Richard E. Wolfe

BASICS

DESCRIPTION

- A neurotic disorder in which the patient fakes signs or symptoms without tangible personal benefit other than to experience the sick role.
- Most dramatic form of chronic factitious disorder with a predominance of physical findings.
- The nature of the disorder resists rigorous study but possible risk factors include:
 - _ Males
 - _ Less severe factitious disorders are more common in women
 - _ Unmarried
 - _ Age in the forties
 - _ Personality disorder
 - _ A history of sadistic and rejecting parents
 - _ A history of chronic childhood illness

ETIOLOGY

- Factitious disorder:
 - _ 3 DSM-IV diagnostic criteria:
 - Intentional production of physical or psychological signs
 - Motivation to assume the sick role
 - Absence of external incentives
 - Predominance of symptoms rather than physical findings
- Classic Munchausen syndrome:
 - _ Most severe and chronic form of factitious disorders
 - _ Predominantly physical findings
- Clinical clusters:
 - _ Self-induced infection
 - _ Simulated specific illnesses with no actual disorder
 - _ Chronic wounds
 - _ Self-medication

Pediatric Considerations

- Munchausen by proxy:
 - _ The patient's illness is caused by the caregiver, not the patient
 - _ The motivation for the caregiver's behavior is to assume the sick role by proxy
 - _ The caregiver inflicts injury or induces illness in their charge, usually a child

- Commonly parents (mostly mothers)
- May simulate injury and disease in a number of ways:
 - Inflicts injury
 - Induces Illness
 - Fabricates symptoms
 - Exaggerates symptoms of the child's illness causing overaggressive medical interventions
- The perpetrator usually refuses to acknowledge the deception
- Cessation of the symptoms when the patient and caregiver are separated

Geriatric Considerations

Caregivers of elderly patients may also be perpetrators in Munchausen by proxy

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Inappropriate or bizarre use of the ED
- Frequent visits
- Numerous hospital admissions
- Peregrination: Travel from hospital to hospital
- Pseudologia fantastica:
 - Intricate and colorful stories associated with the presentation
- Alteration of biographical information:
 - Use of aliases
 - Change date of birth by 1 digit
- Escalating demands for diagnostic testing and therapeutic interventions
- Hostility toward the health care providers when questioned
- Evasiveness regarding details of the presenting complaint
- The patient provides excessive medical documentation
- Masochistic acceptance of painful procedures
- The patient appears more comfortable than is likely considering the disease
- The patient demonstrates unusually strong medical knowledge
- Frequent homelessness and significant wandering between cities and states
- An absence of close interpersonal relationships
- Self-medication
- Abdominal complaints with history of repeated negative laparotomies (laparotomaphilia migrans)
- Witnessed intentional acts to fake illness:
 - Inappropriate ingestion of medication to reproduce physical findings
 - Injection of contaminants (feces, bacteria, sputum, corrosives)

- Self-induced wounds
- Swallowing blood to simulate a GI hemorrhage
- Self-phlebotomy
- Instrument tampering

Physical-Exam

- Fever:
 - Factious from manipulation of thermometer
 - Induced from injection of contaminants
- Self-induced wounds
- Chronic wounds
- Multiple scars
- Foreign bodies in wounds, ear canals, urethra

ESSENTIAL WORKUP

- Diligent detective work is needed:
 - Retrieval of records from other hospitals
 - Call on family members to discuss past history for inconsistencies and excessive use
 - Call personal physician for background and to coordinate information
 - Search patient's room and belongings to establish the method of deception
- Conclusive proof of faking disease is needed to make the diagnosis

DIAGNOSIS TESTS & NTERPRETATION

Lab

- Direct observation of the patient when obtaining tests to prevent faking results
- Commonly faked lab results:
 - Hemocult positive stool
 - Hematuria (intentionally dripping blood into urine sample)
 - Hypoglycemia (self-administration of insulin)
- Abnormal results from self-medication:
 - Low hematocrit (ingestion of warfarin or self-phlebotomy)
 - Elevated INR (ingestion of warfarin)
 - Thyroid function tests (ingestion of thyroxine)
 - Low serum glucose (injection of insulin or ingestion of sulfonylurea)
- Evidence of intent to fake illness:
 - Testing stool for phenolphthalein may detect laxative abuse
 - Serum C-peptide with high insulin levels:
 - Low C-peptide: Exogenous administration of insulin
 - Elevated C-peptide: Endogenous hypoglycemia or sulfonylurea ingestion

Imaging

Do not rely on imaging brought by the patient

Diagnostic Procedures/Surgery

Avoid unless clear objective findings indicate the necessity of a procedure

DIFFERENTIAL DIAGNOSIS

- True illness:
 - Primary illness unrelated to a psychiatric disorder
- Secondary to a comorbid condition associated with factitious disorders:
 - Secondary to self-destructive acts in patients with dementia, psychotic disorders, or mental retardation
 - Secondary to diagnostic and therapeutic procedures
- Malingering:
 - Clear-cut secondary gain
- Conversion disorder:
 - Deficits of the voluntary motor or sensory neurologic system that are not consciously produced
- Somatization disorder (hysteria, Briquet syndrome):
 - Symptoms that involve multiple organs, that varies over time, and are not consciously produced
- Other neurotic disorders:
 - Anxiety
 - Depression

TREATMENT

PRE HOSPITAL

INITIAL STABILIZATION/THERAPY

Treatment should be limited to stabilization of life or limb threats caused by acts of self-harm

ED TREATMENT/PROCEDURES

- Identify objective physical illness and treat as appropriate
- Document history and findings suggestive of factitious illness
- List of all the aliases, addresses, and date of births that the patient is known to use
- Summarize the patient's known modus operandi (the factitious histories and behaviors that he or she has presented with)
- Ensure that the information will be communicated or available to all doctors who are likely to come into contact with the patient
- Confrontation of the patient in the ED is controversial and should only occur when

unambiguous evidence is gathered

- Report Munchausen syndrome by proxy to child protective services

MEDICATION

FOLLOW-UP

DISPOSITION

Admission Criteria

- Injuries and disease caused by self-harm
- Munchausen by proxy:
 - When the diagnosis is suspected but there is not enough evidence to have child protective services take custody
- Observation to collect evidence of faking disease:
 - May also allow setting to rule out rare organic etiologies
- To establish a long-term plan to prevent future self-harm and iatrogenic adverse events
- Psychiatric admission may be of benefit, but it is rarely accepted by the patient

Discharge Criteria

- Medical stability
- Not an active threat to harm self
- Appropriate referral for medical and psychiatric follow-up arranged

Issues for Referral

- May offer psychiatric referral as a method of dealing with stress caused by illness
- Psychiatric providers located directly in medical settings (e.g., primary care physician office) may be more accepted. Overall, this is a chronic illness with poor prognosis

FOLLOW-UP RECOMMENDATIONS

Maintain contact between the patient and an identified provider for that patient.

MUSHROOM POISONING

Michael E. Nelson • Timothy B. Erickson

BASICS

DESCRIPTION

- Amanitin/phalloidin:
 - Species:
 - *Amanita phalloides* (“death cap”)
 - *Amanita virosa/Amanita verna* (“destroying angel”)
 - *Galerina marginata, Galerina venenata*
 - Mechanism:
 - Cyclopeptide toxins inhibit RNA polymerase 2, which kills GI epithelium, hepatocytes, nephrocytes
- Gyromitrin:
 - Species:
 - *Gyromitra esculenta* (“false morels”)
 - Other *Gyromitra* spp.
 - Mechanism:
 - Inhibits pyridoxal phosphate
 - Damage to RBCs, hepatocytes, neurons
- Muscarine:
 - Species:
 - *Inocybe* (several species)
 - *Clitocybe* (several species)
 - Mechanism:
 - Parasympathomimetic
- Coprine:
 - Species:
 - *Coprinus atramentarius* (“inky caps”)
 - Mechanism:
 - Blocks acetaldehyde dehydrogenase
 - Causes disulfiram-like reaction if mixed with alcohol
- Ibotenic acid/muscimol:
 - Species:
 - *Amanita pantherina* (“the panther”)
 - *Amanita muscaria* (“fly agaric”)
 - Mechanism:
 - GABA agonists
- Psilocin/psilocybin:
 - Species:

- *Psilocybe* and *Panaeolus* spp. as well as others
- Mechanism:
 - Similar structure to lysergic acid diethylamide, effect serotonin receptor
- Gastric irritants:
 - Many various mushrooms, including those normally considered edible
- Orellanine:
 - Species:
 - *Cortinarius* (several species)
 - Mechanism:
 - Direct renal toxicity
- *Tricholoma equestre* (“man on horse”):
 - Rhabdomyolysis-inducing mushrooms
 - Unidentified myotoxin

DIAGNOSIS

SIGNS AND SYMPTOMS

- Amanitin/phalloidin:
 - Nausea
 - Vomiting
 - Abdominal cramps
 - Bloody diarrhea
 - Clinical course:
 - Onset of symptoms delayed 6–36 hr with development of GI symptoms
 - Transient latent phase may last 2 days (no pain/symptoms)
 - Can progress to hepatic or renal failure and death in 2–6 days
 - Most lethal mushroom toxins
- Gyromitrin:
 - 1st 5–10 hr:
 - Abdominal cramps
 - Nausea/vomiting
 - Watery diarrhea
 - Later symptoms:
 - Weakness
 - Cyanosis
 - Confusion
 - Seizures
 - Coma
- Muscarine:
 - Cholinergic symptoms include:

- Miosis
- Salivation
- Lacrimation
- Sweating
- Diarrhea
- Flushed skin
- Nausea
- Bradycardia
- Bronchoconstriction
- Onset usually within 1 hr (may be delayed)
- Coprine:
 - Disulfiram-like reaction within minutes to hours when combined with alcohol:
 - Flushing
 - Sweating
 - Nausea/vomiting
 - Palpitations
- Ibotenic acid/muscimol:
 - Relatively rapid onset of 30–120 min
 - GABA agonist effects include:
 - Hallucinations
 - Dysarthria
 - Ataxia
 - Somnolence/coma
 - Glutamatergic effects (mainly pediatrics):
 - Seizures
 - Muscle cramps/myoclonic movements
- Psilocin/psilocybin:
 - Rapid onset, usually resolves in 6–12 hr
 - Visual hallucinations
 - Alteration of perception
 - Mydriasis
 - Tachycardia
 - Fever and seizures in children
- Gastric irritants:
 - Group of toxins that cause nausea, vomiting, intestinal cramps, and watery diarrhea
 - Onset 30 min to 3 hr, usually resolved in 6–12 hr
- *Amanita smithiana*:
 - Nausea/vomiting
 - Headache
 - Sweating
 - Chills

- Low-back pain
- Polydipsia
- Clinical course:
 - May progress to oliguria and acute renal failure
 - Markedly delayed onset of symptoms (2–14 days)
- *T. equestre*:
 - Acute rhabdomyolysis:
 - Myalgias/arthralgias
 - Hematuria/dark urine
 - Decreased urine output
 - Dehydration

History

- Time of ingestion
- Time of symptom onset
- Quantity ingested
- Preparation: Raw or cooked
- Picked in the wild or store-bought
- Coingestants, other mushrooms
- Alcohol/drug use history
- Symptoms of family members, friends

Physical-Exam

- Vital signs
- Changes in mental status
- Pupillary response
- Cardiopulmonary exam
- Abdominal exam
- Neurologic exam

ESSENTIAL WORKUP

- Mushroom description:
 - Pileus (cap); margin shape
 - Stipe (stem)
 - Lamellae (gills)
 - Veil
 - Annulus (ring)
 - Volva
- Store mushroom in brown paper bag for future identification:
 - < 3% of cases result in an exact mushroom identification.
 - Digital photography and electronic image transfer to poison control center or regional mycologist

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Prothrombin time (PT), partial thromboplastin time (PTT)
- Electrolytes, BUN, creatinine, glucose
- Urinalysis
- LFTs, creatine phosphokinase (CPK)
- Imaging
- Spore print: Mycologist needed for specific genus/species interpretation

DIFFERENTIAL DIAGNOSIS

- Very broad differential
- Gastroenteritis
- Hepatitis/acetaminophen hepatotoxicity
- Acute renal failure (many causes)
- Rhabdomyolysis (many causes)
- Cholinergic syndrome (e.g., organophosphates)
- Anticholinergic syndrome
- Seizures (many causes)

TREATMENT

PRE HOSPITAL

Bring any unconsumed mushrooms or mushroom pieces to hospital to aid in diagnosis:

- Refrigerate specimens if possible, place in brown paper bag.

INITIAL STABILIZATION/THERAPY

- ABCs
- Establish IV 0.9% NS saline
- Monitor
- Naloxone, D₅₀W (or Accu-Chek), and thiamine for altered mental status

ED TREATMENT/PROCEDURES

General Measures

- Decontamination:
 - Activated charcoal (50–100 g)
 - Gastric decontamination if early after ingestion and patient:
 - Has not yet vomited.
 - Has normal mental and respiratory status
 - Is not undergoing hallucinations

- Fluid rehydration and electrolyte replacement as necessary
- Call local poison control center at 800-222-1222 and request mycologist—digital picture may be electronically sent for identification.
- Obtain specimens (vomit if needed) for identification.

Mushroom-specific Therapy

- Amanitin/phalloidin:
 - _ Administer activated charcoal PO q2–4h.
 - _ Hypoglycemia and elevated PT:
 - Signs of liver failure
 - Administer fresh-frozen plasma and vitamin K for coagulation disorders with active bleeding.
 - _ Administer calcium in presence of hypocalcemia.
 - _ Liver transplant for severe hepatic necrosis
 - _ Consider N-acetylcysteine, high-dose penicillin G, or silibinin if available (thioctic acid controversial)
- Gyromitrin:
 - _ Treat seizure with benzodiazepines.
 - Administer pyridoxine (vitamin B₆) in severely symptomatic patients.
 - _ Treat liver dysfunctions as outlined for amanitin/phalloidin group.
 - _ Dialysis for renal failure
- Muscarine:
 - _ Administer atropine in severe cases.
- Coprine:
 - _ Self-limited toxicity—supportive care
 - _ Avoid syrup of ipecac (contains alcohol)
 - _ β -Blockers for cardiac dysrhythmias
- Ibotenic acid/muscimol:
 - _ Usually self-limited toxicity
 - _ Provide supportive care
 - _ Monitor for hypotension
 - _ Treat moderate symptoms with benzodiazepines, if severe anticholinergic symptoms; consider physostigmine.
- Psilocin/psilocybin:
 - _ Self-limited toxicity
 - _ Dark, quiet room and reassurance
 - _ Benzodiazepines for agitation
 - _ External cooling measures if needed in children
- GI Irritants:
 - _ When poisoning from above groups not suspected, administer fluids and antiemetics.
 - _ Provide supportive care

- Orellanine and *A. smithiana*:
 - Closely monitor BUN, creatinine, electrolytes, and urine output.
 - Forced diuresis with Lasix contraindicated
 - Diuresis with alkalinization of urine with NaHCO₃ if signs of rhabdomyolysis
 - Hemodialysis/renal transplantation may be needed.
- *T. equestre* (“man on horse”):
 - Fluid hydration
 - Check and follow CPK.
 - Monitor urine output.

MEDICATION

- Activated charcoal slurry: 1–2 g/kg up to 100 g PO
- Atropine: 0.5 mg (peds: 0.02 mg/kg) IV; repeat 0.5–1 mg IV (peds: 0.04 mg/kg) q10min if secretions recur, to max. 1 mg/kg in children and 2 mg/kg in adults
- Dextrose: D₅₀W 1 amp: 50 mL or 25 g (peds: D₂₅W 2–4 mL/kg) IV
- Diazepam (benzodiazepine): 5–10 mg (peds: 0.2–0.5 mg/kg) IV
- Lorazepam (benzodiazepine): 2–6 mg (peds: 0.03–0.05 mg/kg) IV
- Naloxone (Narcan): 2 mg (peds: 0.1 mg/kg) IV or IM initial dose
- Physostigmine: 0.5–2 mg IM or IV in adults
- Propranolol: 1 mg (peds: 0.01–0.1 mg/kg) IV
- Pyridoxine: 25 mg/kg IV over 30 min
- Thiamine (vitamin B₁): 100 mg (peds: 50 mg) IV or IM

FOLLOW-UP

DISPOSITION

Admission Criteria

- All symptomatic patients:
 - Protracted vomiting, dehydration, liver or renal toxicity, or seizures
- Transfer to tertiary medical center for early signs of renal or hepatic failure.
- Symptomatic infants and young children found with mushrooms:
 - Assume ingestion.
- ICU admission for known ingestion of an amanitin-containing mushroom:
 - Early liver service consultation

Discharge Criteria

Asymptomatic during 6–8 hr with 24 hr of close home observation and close follow-up (if reliable caregivers)

Issues for Referral

Potential liver or renal transplantation

FOLLOW-UP RECOMMENDATIONS

Drug detoxification programs if chronic recreational use

PEARLS AND PITFALLS

- There are old mushroom pickers, and bold mushroom pickers; but there are no old, bold mushroom pickers.
- Symptoms with late onset (> 6 hr) generally indicate more lethal toxins.
- Lack of proper mycologic identification
- Timely organ transplant referrals when indicated

T62.0X1A Toxic effect of ingested mushrooms, accidental, init

MYASTHENIA GRAVIS

Douglas W. Lowery-North

BASICS

DESCRIPTION

- Antibody-mediated condition that results in painless, fatigable muscle weakness
- Ocular or generalized:
 - Ocular (eyelids and extraocular) muscle weakness:
 - Most common initial symptom (60%)
 - ~80% of myasthenia gravis (MG) patients who present with ocular weakness initially will progress to general weakness within 2 yr.
 - Generalized:
 - Usually affects proximal limbs, axial muscle groups such as neck, face, bulbar muscles
- Acute or subacute, with relapses and remissions
- Associated with thymoma in 15% and thymic hyperplasia in 65%
- Myasthenic crisis:
 - Respiratory failure or inability to protect airway due to weakness
 - Triggers:
 - Infection
 - Surgery
 - Trauma
 - Pregnancy
 - Medication changes (e.g., rapid tapering of steroids)
 - Difficult to distinguish from cholinergic crisis resulting from excessive doses of acetylcholinesterase (AChE) inhibitors:
 - Cholinergic crisis may also include muscarinic effects such as sweating, lacrimation, salivation, and GI hyperactivity in addition to weakness.

EPIDEMIOLOGY

- Pediatric MG is rare and distinct:
 - Congenital MG: Genetic defect
 - Juvenile MG: Autoimmune disorder
 - Transient neonatal MG: Postdelivery complication from placental transfer of maternal antibodies
- Adult MG has bimodal distribution:
 - 1st peak in 2nd and 3rd decades affecting mostly women
 - 2nd peak in 6th and 7th decades affecting men

ETIOLOGY

- Antibody-mediated attack on nicotinic acetylcholine receptors
- Up to 20% of patients may be acetylcholine receptor antibody (AChR Ab) negative
- Penicillamine can cause MG as well as other autoimmune conditions
- Many medications may worsen myasthenic weakness:
 - Aminoglycosides, macrolides, quinolones, antimalarials
 - Local anesthetics
 - Antidysrhythmics (propafenone, quinidine, procainamide)
 - β -Blockers, calcium-channel blockers
 - Anticonvulsants (phenytoin, carbamazepine)
 - Antipsychotics (phenothiazine, atypicals)
 - Neuromuscular blocking agents
 - Iodine-containing radiocontrast

DIAGNOSIS

SIGNS AND SYMPTOMS

Fluctuating focal weakness

History

- Symptoms worsen with repeated activity:
 - Improve with rest
- Ocular weakness:
 - Diplopia
 - Ptosis while driving or reading
- Bulbar and facial muscle weakness:
 - Trouble chewing, speaking, swallowing
 - Inability to keep jaw closed after chewing
 - Slurred, nasal speech
- Limb weakness:
 - Difficulty climbing stairs, rising from chair, reaching up with arms

Physical-Exam

- Ocular findings:
 - Ptosis, diplopia
 - Inability to keep eyelid shut against resistance
 - No pupillary changes
- Bulbar and facial findings:
 - Ask patient to count to 100; look for changes in speech.
 - Decreased facial expression
 - Head droop
- Limb findings:
 - Repetitive testing of proximal muscles or small muscles of hand results in

weakness.

- Reflex and sensory exam are normal.

ESSENTIAL WORKUP

- Assess for respiratory compromise
- Search for secondary triggers (e.g., infectious source)

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Electrolytes
- LFTs
- Thyroid function tests
- Anti-AChR Ab:
 - Positive in 90% with generalized disease
 - Positive in 50% with ocular disease
- Other tests for initial diagnosis:
 - Antistriated muscle antibody
 - Antinuclear antibody
 - Rheumatoid factor
 - ESR

Imaging

- Head CT or MRI to rule out compressive lesions causing cranial nerve findings
- Chest CT with contrast to look for associated thymoma
- CXR as needed to evaluate for infectious source

Diagnostic Procedures/Surgery

- Edrophonium (Tensilon) test:
 - Short-acting AChE inhibitor
 - A positive test produces rapid, short-lived (2–5 min) improvement in strength
 - Sensitivity 95% in generalized MG and 86% in ocular MG
 - False positives possible with Lambert–Eaton, Guillain–Barré, MS, botulism, and others
 - Keep patient on cardiac monitor during test.
 - Atropine at bedside for possible bradycardia
 - Suction at bedside for possible increased secretions
- Ice test:
 - Place ice on eyelid for 2 min.
 - Improvement in ptosis suggests MG.

DIFFERENTIAL DIAGNOSIS

- Amyotrophic lateral sclerosis
- Botulism
- Electrolyte abnormalities
- Graves disease
- Guillain–Barré syndrome
- Hyperthyroidism
- Inflammatory muscle disorders
- Intracranial mass lesions
- Lambert–Eaton syndrome
- Multiple sclerosis
- Periodic paralysis
- Tick paralysis

TREATMENT

PRE HOSPITAL

Attention to airway management

INITIAL STABILIZATION/THERAPY

Myasthenic crisis:

- Most important is early intubation and mechanical ventilation.
- Signs of impending failure:
 - Vital capacity < 20 mL/kg
 - Negative inspiratory pressure > -30 cm H₂O
 - Negative expiratory pressure < 40 cm H₂O
- Considerations regarding paralytics:
 - Decreased sensitivity to depolarizing agents may necessitate higher dose; consider doubling the usual dose of succinylcholine.
 - Nondepolarizing agents can cause extended paralysis; consider halving the usual dose.
 - Others recommend midazolam, etomidate, or thiopental instead.

ED TREATMENT/PROCEDURES

- Treat infections aggressively.
- Search for and remove triggers.
 - Careful medication history.
- Myasthenic crisis may require plasmapheresis or IV gamma globulin (IVIG).
 - Plasmapheresis: Remove 1–1.5 plasma volume each session \times 5 sessions
 - IVIG: 0.4 mg/kg/d \times 5 days
- Initiate high-dose corticosteroids.
- Discontinue AChE inhibitors while intubated.

- Atropine for AChE inhibitor effects (bradycardia, GI symptoms, increased bronchial or oral secretions)

MEDICATION

First Line

- Edrophonium (Tensilon): 2 mg IV over 15–30 sec; if no effect after 45 sec, can give 2nd dose of 3 mg IV. If still no response, final dose of 5 mg IV can be given (total 10 mg).
- Prednisolone 1 mg/kg/d for crisis
- Atropine for cholinergic crisis 0.5 mg IV or IM

Second Line

Other medications that may be initiated by neurologist:

- Prednisone, AChE inhibitors, azathioprine, mycophenolate, mofetil, cyclosporine, tacrolimus, rituximab

FOLLOW-UP

DISPOSITION

Admission Criteria

- New-onset myasthenic symptoms
- Diagnosis unclear, but myasthenia a possibility
- Myasthenic patients with worsening symptoms
- Myasthenic crisis or questionable respiratory status mandates admission to ICU.

Discharge Criteria

Myasthenic patients who are improving can be considered for discharge in consultation with neurology.

FOLLOW-UP RECOMMENDATIONS

Any discharged patient should have neurology follow-up arranged.

PEARLS AND PITFALLS

- Search for signs of myasthenic crisis in any MG patient who presents to the ED.
- Search carefully for secondary conditions in patients with worsening MG.
- Place patient on cardiac monitor and keep atropine and suction at bedside when performing edrophonium test.

- P94.0 Transient neonatal myasthenia gravis

MYOCARDIAL CONTUSION

Sean Patrick Nordt

BASICS

DESCRIPTION

- Also known as blunt cardiac injury
- Pathologically characterized by discrete and well-demarcated area of hemorrhage
- Usually subendocardial
- May extend in pyramidal transmural fashion
- Most commonly involves anterior wall of right ventricle or atrium due to anatomic location

ETIOLOGY

- Blunt trauma to chest:
 - High-speed deceleration accidents
 - May occur in accidents with speeds as low as 20–35 mph
- Auto–pedestrian injuries
- Falls
- Prolonged closed-chest cardiac massage
- Heart may be compressed between sternum and vertebrae.
- Heart strikes sternum during deceleration.
- Heart is damaged by abdominal viscera upwardly displaced by force on abdomen.
- Concussive forces (e.g., explosion)
- Associated conditions:
 - Life-threatening dysrhythmias
 - Cardiogenic shock/CHF
 - Hemopericardium with tamponade
 - Valvular/myocardial rupture
 - Intraventricular thrombi
 - Thromboembolic phenomena
 - Coronary artery occlusion from intimal tearing or adjacent hemorrhage and edema may rarely occur.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Clinical picture is varied and nonspecific:
 - Chest pain
 - Cardiogenic shock
 - Subtle EKG changes without clinical symptoms

- Most common sign is tachycardia out of proportion to degree of trauma or blood loss.
- Friction rub may occur rarely.
- Retrosternal chest pain unrelieved by nitroglycerin:
 - Often delayed up to 24 hr
 - May respond to oxygen
- Evidence of significant thoracic trauma:
 - Contusions, abrasions
 - Palpable crepitus
 - Sternal fracture alone with normal EKG and negative serial troponin I does not predict BCI
 - Visible flail segments
- Other injuries may mask signs and symptoms of myocardial contusion.

History

- Mechanism of injury (e.g., MVA, fall, explosion, missile to chest wall)
- Any syncope or loss of consciousness suggests possible dysrhythmia.
- Crush injury

Geriatric Considerations

Obtain and consider pre-existing cardiac disease and concurrent medications in elderly patients following blunt cardiac injury.

Pediatric Considerations

Due to increased compliance of pediatric chest wall, significant cardiac compression and contusion may be present with minimal or no external signs of trauma.

Physical-Exam

Complete physical exam as in any trauma patient:

- Evaluate for jugular venous distention (JVD)
- Decreased or muffled heart sounds
- Extra heart sounds
- Crepitus
- Pulsus paradoxus
- Evidence of chest wall trauma

ESSENTIAL WORKUP

- No single diagnostic study (other than autopsy findings!) confirms presence of myocardial contusion.
- EKG:
 - Best initial screening tool
 - Most common rhythm is sinus tachycardia (70%).

- Normal EKG does not rule out myocardial damage.
- EKG changes may be subtle or include nonspecific findings such as ST changes, right bundle branch block, and premature atrial and ventricular contractions.
- At least 1 repeat EKG is recommended because changes may occur over time.
- Serious dysrhythmias may result in hemodynamic instability:
 - Atrial fibrillation/atrial flutter
 - Ventricular tachycardia/ventricular fibrillation (commotio cordis)
- Troponin I is now the recommended screening lab test over CK-MB to be interpreted with EKG.
- Echocardiography should be performed on all patients with any EKG changes, elevated troponin I or troponin T.
- Transesophageal ECG (TEE) more sensitive than transthoracic ECG (TTE) but technically more difficult and time-consuming.
- Multidetector CT angiography or MRI may be of benefit.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Troponin I is the preferred lab test.
- Troponin T less sensitive than troponin I.
 - Levels should be sent on all patients where BCI suspected.
 - Should be repeated at 6–8 hr after injury.
 - Any elevation requires admission.
- Cardiac troponins are more specific than CK-MB for cardiac injury.
- CK-MB no longer routinely recommended.

Imaging

- Radiographs, CT, MRI detect associated injuries:
 - Pulmonary contusion
 - Rib or sternal fractures
 - Acute pulmonary edema
 - No specific findings in cardiac contusion
- Focused assessment with sonography for trauma (FAST) should be performed on all patients to assess pericardium and possible concurrent intra-abdominal injuries.
- ECG:
 - Generally regarded as best imaging study for detecting cardiac contusion
 - Detects wall-motion abnormalities and effusions
 - Allows direct visualization of cardiac chambers and valves
 - May not visualize small (possibly clinically insignificant) contusions
 - TEE preferable to TTE if patient stable enough for procedure.
 - TTE may be performed although may also visualize great vessels.

- Radionuclide ventriculography:
 - Has been largely abandoned owing to wide availability of ECG
- Thallium²⁰¹ scintigraphy (single photon emission CT [SPECT]):
 - Sensitive and specific to left ventricular injury
 - Unable to evaluate right ventricle, which is most commonly injured

Diagnostic Procedures/Surgery

- Pericardiocentesis:
 - For treatment of cardiac tamponade, preferably under US guidance
- Thoracotomy:
 - Consider in patient with acute cardiac arrest or decompensation in ED or after unsuccessful pericardiocentesis

DIFFERENTIAL DIAGNOSIS

- Cardiac rupture
- Tamponade
- Valvular damage
- Other traumatic chest wall injury
- Angina or MI

TREATMENT

PRE HOSPITAL

Pre-hospital personnel should convey accurate information to emergency department personnel:

- Mechanism of injury
- Motor vehicle status
- Steering wheel and dashboard damage
- Use of restraint devices
- Vehicle speed
- Patient position
- Time to extrication
- Any loss of consciousness

INITIAL STABILIZATION/THERAPY

Manage airway and resuscitate as indicated:

- Oxygen:
 - IV access
 - Cardiac monitoring

ED TREATMENT/PROCEDURES

- Dysrhythmias may be treated with same pharmacologic agents used for

nontraumatic dysrhythmias:

- Supraventricular tachycardia:
 - Adenosine or calcium channel blocker if patient not hypovolemic
- Bradycardia:
 - Atropine
 - Pacing
- Ventricular dysrhythmias:
 - Electrical conversion
 - Amiodarone
 - Lidocaine
 - Procainamide
- Cardiac arrest:
 - Epinephrine
 - Atropine
 - Other interventions as appropriate
- Rapid atrial fibrillation or flutter:
 - Diltiazem, or digoxin if patient not hypotensive
- Prophylactic treatment of dysrhythmias is not indicated.
- Cardiogenic shock caused by myocardial contusion:
 - Judicious fluid administration
 - Inotropic support (dopamine or dobutamine)
 - Intra-aortic balloon counterpulsation may be necessary.

MEDICATION

- Medications used in cardiac contusion are supportive for dysrhythmias or hemodynamic compromise secondary to injury.
- There is no primary therapy for cardiac contusion.
- Adenosine: 6 mg rapid IVP (peds: 0.05–0.1 mg/kg rapid IVP), may repeat 12 mg q1–2min twice if no response
- Amiodarone: Load 150 mg IV over 10 min (peds: 5 mg/kg), then 1 mg/min for 6 hr, then 0.5 mg/min (peds: 5 µg/kg/min)
- Atropine: 0.5–1 mg (peds: 0.02 mg/kg/ dose, min. 0.1 mg) IV or endotracheal tube (ET)
- Digoxin: Load 0.5 mg (peds: 0.02 mg/kg) IV, then 0.25 mg (peds: 0.01 mg/kg) IV q6h for 2 more doses
- Diltiazem: 0.25 mg/kg IV for both adults and peds over 2 min, may rebolus 0.35 mg/kg (adult and peds) 15 min later
- Dobutamine: 2–15 µg/kg/min (adults and peds)
- Dopamine: 2–20 µg/kg/min (adults and peds)
- Epinephrine: 1 mg (peds: 0.01 mg/kg) IV or ET for cardiac arrest (1:10,000 solution)
- Lidocaine: Load 1 mg/kg IV, then 0.5 mg/kg q8–10min to max. 3 mg/kg (adults and peds); infusion 1–4 mg/min (peds: 20–50 µg/kg/min) IV

- Procainamide: start at 3 to 6 mg/kg/dose over 5 minutes not to exceed 100 mg to a titrated maximum of 15 mg/kg/loading dose
- Verapamil: 0.1–0.3 mg/kg up to 5–10 mg IV over 2 min (not approved in children)

FOLLOW-UP

DISPOSITION

- Adverse outcomes, particularly dysrhythmias, are uncommon but generally occur within 1st 24 hr.
- No single test or combination of tests will accurately predict which patients can be discharged safely from ED:
 - All patients in whom diagnosis is seriously being entertained should be admitted to a monitored setting.

Admission Criteria

- EKG abnormalities
- Cardiac enzyme abnormalities
- Hemodynamic instability
- Other studies suggesting cardiac contusion
- Admit to monitored unit for close observation.

Discharge Criteria

Asymptomatic patients with no EKG abnormalities or dysrhythmia and with normal cardiac enzymes after 6–8 hr period may be discharged.

Issues for Referral

Immediate surgical consultation:

- Suspected myocardial wall rupture
- Suspected valve or papillary muscle rupture
- Suspected septal rupture
- Coronary artery thrombosis
- Pericardial effusion
- Cardiac tamponade

FOLLOW-UP RECOMMENDATIONS

Discharged patients:

- Should have follow-up within 24 hr of injury

PEARLS AND PITFALLS

- Obtain EKG in patients following chest wall trauma.
- Perform FAST exam on all patients to assess pericardium.

- External signs of chest wall trauma should increase concern of blunt cardiac injury.
- Pediatric patients may have little or no external signs of chest wall trauma.
- Do not administer thrombolytics to patients with ST elevation MI following trauma.
- Negative troponin I and normal EKG make significant blunt cardiac injury unlikely.

- S26.91XA Contusion of heart, unspecified with or without hemopericardium, initial encounter

MYOCARDITIS

Liudvikas Jagminas

BASICS

DESCRIPTION

- An inflammatory change in the heart muscle characterized by myocyte necrosis and subsequent myocardial destruction
- Direct cytotoxic effect of causative agent followed by a secondary immune response
- True incidence is unknown because many cases are asymptomatic.
- Autopsy studies have demonstrated evidence of myocarditis in 1–7% of cases and > 50% in HIV patients.
- Male > female (1.5:1)
- Average age of patients with myocarditis is 42 yr.
- Major cause of unexpected sudden death (15–20% of cases) < 40 yr old

ETIOLOGY

- Viral:
 - Enteroviruses (coxsackie B)
 - Adenovirus
 - Herpesvirus (including cytomegalovirus [CMV])
 - Hepatitis C
 - Influenza
 - Echovirus
 - Herpes simplex virus
 - Varicella-zoster
 - Epstein–Barr virus
 - Cytomegalovirus
 - Mumps
 - Rubeola
 - Variola/vaccinia
 - Yellow fever
 - Rabies
 - HIV
- Bacteria:
 - Diphtheria
 - Tuberculosis
 - Brucellosis
 - Psittacosis
 - Meningococcus

- Mycoplasma
- Group A streptococcus
- Protozoa:
 - Leishmaniasis
 - Malaria
 - Toxoplasmosis in the immunocompromised host
 - *Treponema cruzi* (Chagas disease):
 - Most common cause of heart failure and myocarditis worldwide
 - 20 million persons infected in Central and South America
 - Trichinosis
 - Trypanosomiasis
- Spirochetes:
 - *Borrelia burgdorferi*, the spirochete agent in Lyme disease
 - Syphilis
- Rickettsial:
 - Scrub typhus
 - Rocky Mountain spotted fever
 - Q fever
- Fungal:
 - Candidiasis
 - Aspergillosis
 - Cryptococcosis
 - Histoplasmosis
 - Actinomycosis
 - Helminthic
 - Trichinosis
 - Echinococcosis
 - Schistosomiasis
 - Cysticercosis
- Drugs:
 - Acetaminophen
 - Ampicillin
 - Chemotherapeutic agents (anthracyclines)
 - Cocaine
 - Hydrochlorothiazide
 - Lithium
 - Methyldopa
 - Penicillin
 - Sulfamethoxazole
 - Sulfonamides
 - Zidovudine
 - Radiation
 - Hypersensitivity

- Heavy metals
- Hydrocarbons
- Carbon monoxide
- Arsenic
- Autoimmune disorders:
 - Systemic lupus erythematosus (SLE)
 - Wegener granulomatosis
 - Kawasaki disease
 - Giant cell arteritis
 - Sarcoidosis
- Peripartum cardiomyopathy
- Bites/stings:
 - Scorpion
 - Snake
 - Black widow venom

DIAGNOSIS

SIGNS AND SYMPTOMS

Arrhythmias (18%), dyspnea (72%), and chest pain (35%)

History

- Fatigue
- Myalgias/arthralgias
- Malaise
- Fever
- Chest pain:
 - Reported in 35%
 - Most commonly pleuritic, sharp, stabbing, precordial
- Dyspnea on exertion is common.
- Orthopnea and shortness of breath if congestive heart failure (CHF) is present
- Palpitations are common
- Acute coronary syndrome due to local spasm & inflammation
- Syncope:
 - May signal high-grade aortic valve block or risk for sudden death from VT/VF

Physical-Exam

- Fever
- Tachypnea
- Tachycardia:
 - Often out of proportion to fever

- Cyanosis
- Hypotension:
 - Due to left ventricular dysfunction
 - Uncommon in the acute setting and indicates a poor prognosis when present
- Bibasilar crackles
- Rales
- Jugular venous distention (JVD)
- Peripheral edema
- Hepatomegaly
- Ascites
- S₃ or a summation gallop if significant biventricular involvement
- Intensity of S₁ may be diminished
- Murmurs of mitral or tricuspid regurgitation
- Pericardial friction rub if associated with pericarditis

Pediatric Considerations

- Most common cause of heart failure in previously healthy children
- Particularly infants, present with nonspecific symptoms:
 - Fever
 - Respiratory distress
 - Poor feeding or, in cases with CHF, sweating while feeding
 - New onset murmur
 - Cyanosis in severe cases

ESSENTIAL WORKUP

- Physical exam
- EKG
- CXR

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Cardiac enzymes
 - Troponin T: Low levels can be used to exclude myocarditis
 - Troponin I specificity is 89%; sensitivity is 34%
 - Creatinine kinase (elevated MB) may be elevated from myocardial necrosis
- Erythrocyte sedimentation rate (ESR) is elevated in 60% during the acute phase.
- Leukocytosis is present in 25%.
- Viral titers; cultures rarely positive
- Mycoplasma, antistreptolysin titers, cold agglutinin titer
- Hepatitis panels

- Lyme titer
- Monospot testing
- CMV serology
- Blood cultures

Imaging

- EKG:
 - Sinus tachycardia most frequent finding
 - Transient, nonspecific ST- and T-wave changes
 - Atrial and ventricular dysrhythmias
 - Heart block and conduction defects:
 - 20% have a conduction delay.
 - 20% have a left bundle branch block.
- CXR:
 - Normal cardiac silhouette
 - Pulmonary edema
 - Pleural effusion
- Echocardiogram:
 - Impairment of left ventricular systolic and diastolic function
 - Segmental wall motion abnormalities
 - Impaired ejection fraction
 - Pericardial effusion
 - Ventricular thrombus has been identified in 15% of patients
- Gallium⁶⁷ and Indium¹¹¹-labeled antimyosin antibody scans
- Gadolinium-enhanced MRI:
 - Indicate cardiac inflammation and myocyte necrosis
- Cardiac MRI:
 - Abnormal signal areas correlate with regions of myocarditis
 - Reported 76% sensitivity, 96% specificity, and 85% diagnostic accuracy
 - Considered in patients in whom the diagnosis is unclear and endocardial biopsy is planned

Diagnostic Procedures/Surgery

- Right ventricular endomyocardial biopsy:
 - Appropriate in heart transplant recipients
 - Polymerase chain reaction (PCR) amplification of viral genome in endomyocardial tissue
- PCR identification of a viral infection from pericardial fluid, or other body fluid sites

DIFFERENTIAL DIAGNOSIS

- Acute MI

- Acute and chronic pulmonary embolus
- Aortic dissection
- Adrenal insufficiency
- Environmental challenges
- Esophageal perforation/rupture/tear
- Hyperpyrexia
- Hypothermia
- Kawasaki disease
- Pericarditis
- Pneumonia
- Viral
- Bacterial
- Sepsis
- Severe hypothyroidism and hyperthyroidism
- Toxin-mediated disease

TREATMENT

ALERT

- Avoid sympathomimetic and β -blocker drugs.
- Patients presenting with Mobitz II or complete heart block require pacemaker placement.

INITIAL STABILIZATION/THERAPY

- ABCs
- Supplemental oxygen
- Cardiac monitor
- Pulse oximetry
- IV access

ED TREATMENT/PROCEDURES

- Treat dysrhythmias.
- Transthoracic or transvenous pacing for symptomatic heart block
- Supplemental oxygen
- ACE inhibitors (captopril):
 - _ Reduce afterload and inflammation.
- Digoxin:
 - _ CHF or atrial fibrillation
- Diuretics (furosemide, bumetanide)
- Hyperimmunoglobulin therapy in CMV-associated myopericarditis.
- NSAIDs contraindicated in early and acute-phase myocarditis
- Heparin and warfarin for patients with depressed LV function or intracardiac

thrombus

Pediatric Considerations

- IV immunoglobulin is an effective treatment option in pediatric viral myocarditis.
- Improved LV function and trend toward better survival

MEDICATION

- Captopril:
 - Adult dose: Initial dose 6.25 mg; can titrate to 50 mg/dose
 - Pediatric dose:
 - Infants: 0.15–0.3 mg/kg/dose (max. 6 mg/kg)
 - Children: 0.5–1 mg/kg/24h
- Digoxin:
 - Adult dose: Load: 0.4–0.6 mg IV, then 0.1–0.3 mg q6–8h. Maintain: 0.125–0.5 mg/d IV/PO
 - Pediatric dose:
 - < 2 yr: 15–20 µg/kg IV
 - 2–10 yr: 10–15 µg/kg IV
 - > 10 yr: 4–5 µg/kg IV
- Furosemide:
 - Adult dose: 20–80 mg/d PO/IV/IM; titrate up to 600 mg/d for severe edematous states
 - Pediatric dose: 1–2 mg/kg PO; not to exceed 6 mg/kg; do not administer > q6h 1 mg/kg IV/IM slowly under close supervision; not to exceed 6 mg/kg
- Immunoglobulin IV (Gamimune, Gammagard, Gammar-P, Sandoglobulin):
 - Adult dose: 2 g/kg IV over 2–5 days

FOLLOW-UP

DISPOSITION

Admission Criteria

Symptomatic patients with myocarditis:

- New-onset
- CHF
- Dysrhythmia
- Mobitz II or complete heart block
- Embolic events
- Cardiogenic shock

Discharge Criteria

Asymptomatic patient with no evidence of dysrhythmia or cardiac dysfunction

Issues for Referral

Cardiac transplant for patients with intractable CHF:

- Approximately 50% of patients die within 5 yr of diagnosis.
- Best prognosis for lymphocytic myocarditis

PEARLS AND PITFALLS

- Careful physical exam for signs of CHF and pericarditis is paramount.
- EKG should be obtained when considering the diagnosis and is especially sensitive for pediatric cases.
- Patients with evidence of dysrhythmia, CHF, or thromboembolism must be admitted.

NASAL FRACTURES

David W. Munter

BASICS

DESCRIPTION

- Fractures of nasal skeleton are the most common body fractures.
- Most nasal fractures are result of blunt trauma, frequently from motor vehicle crashes, sports injuries, and altercations.
- Lateral forces are more likely to cause displacement than straight-on blows.
- Characteristics that suggest associated injuries:
 - History of trauma with significant force
 - Loss of consciousness
 - Findings of facial bone injury
 - Frontal bone crepitus
 - CSF leak

ETIOLOGY

- The vast majority of nasal fractures are from direct trauma
- Altercations account for most nasal fractures in adults
- Direct blows, especially sports, account for most nasal fractures in children

DIAGNOSIS

SIGNS AND SYMPTOMS

- Nasal deformity, asymmetry, swelling, or ecchymosis
- Epistaxis
- Periorbital ecchymosis (“raccoon eyes”) from damage to branches of ethmoidal artery:
 - May indicate nasofrontoethmoid complex injury
- Palpable sharp edges, depressions, or other irregularities suggest nasal fracture.
- Crepitus or mobility of skeletal parts on palpation
- Septal hematoma:
 - Bluish fluid-filled sac overlying nasal septum
 - Critical to detect because it must be drained
 - Failure to drain can result in necrosis of the septum
- Flattening of nasal root and widening of intercanthal distance (telecanthus):
 - Indicative of serious nasofrontoethmoid complex injury
- Clear rhinorrhea indicates possible CSF leak:
 - Rhinorrhea may be delayed.
- Loss of sense of smell suggests significant injury.

- Tear duct injuries may be present with abnormal tearing.
- Associated eye injuries:
 - Subconjunctival hemorrhage
 - Hyphema
 - Retinal detachments

History

- Direct blow
- Associated injuries or symptoms
- Presence of epistaxis
- Changes in vision or smell

Physical-Exam

- Thorough physical exam with visual inspection and palpation is vital.
- It is critical to identify a septal hematoma:
 - Bluish bulging mass on nasal septum
- Septal deviation
- Epistaxis or intranasal laceration
- Examine closely for telecanthus:
 - Intercanthal width > 30–35 mm
 - Wider than width of 1 eye
 - May indicate nasofrontoethmoid fracture
 - Usually associated with depressed nasal bridge
- CSF rhinorrhea:
 - Indicates more serious underlying facial bone or skull fracture
 - CSF mixed with blood will often cause double ring sign when placed on filter paper, although this sign is not 100% reliable.

ESSENTIAL WORKUP

If concern for anything other than a simple nasal fracture:

- Evaluate nasolacrimal duct for patency:
 - Instill fluorescein into eye and look for it in nasopharynx under inferior turbinate.
 - Absence implies duct injury.
- Eyelash traction test:
 - Grasp eyelashes on eyelid and pull laterally:
 - If eyelid margin does not become taut or “bow string,” then medial portion of tendon has been disrupted.
 - This test is performed on both upper and lower eyelids.
 - Possible for only 1 portion of tendon to be selectively injured

DIAGNOSIS TESTS & NTERPRETATION

Lab

Coagulation studies if on anticoagulants with uncontrolled epistaxis

Imaging

- Nasal radiographs are rarely indicated:
 - _ Normally do not alter initial or subsequent management
 - _ Gross deformities will need referral.
 - _ Fractures without deformity will be treated conservatively regardless of radiographic findings.
 - _ Patients with associated facial bone deformity, crepitus, or tenderness may require radiographs.
- CT is test of choice if facial bone, nasofrontoethmoid, or depressed skull fractures are suspected; have low threshold for ordering CT if other injuries are suspected.

DIFFERENTIAL DIAGNOSIS

- Other facial injuries such as orbital, frontal sinus, maxillary sinus, or cribriform plate fractures
- Nasofrontoethmoid fracture

TREATMENT

PRE HOSPITAL

- Management of airway takes precedence.
- Nasotracheal intubation is contraindicated.
- Consider orotracheal intubation or cricothyroidotomy if definitive airway control is needed.
- Cervical spine precautions are indicated if there is associated trauma.
- Epistaxis can normally be controlled with direct pressure; pinch nares together.

INITIAL STABILIZATION/THERAPY

- Airway management with orotracheal intubation or cricothyroidotomy:
 - _ Nasotracheal intubation is contraindicated.
- Cervical spine precautions
- Other injuries take precedence.

ED TREATMENT/PROCEDURES

- Abrasions and lacerations:
 - _ Proper cleansing of facial wounds is essential.
 - _ Lacerations may be sutured.
- Epistaxis must be controlled if it does not stop spontaneously:
 - _ Anesthetize/vasoconstrict with topical cocaine, lidocaine, or neosynephrine spray.

- Identify bleeding source; cauterize anterior source if necessary.
- Pack nares with petroleum jelly, impregnated gauze, or any number of commercial packs.
- Posterior packs are rarely needed.
- Prophylactic antibiotics to prevent sinus infection are indicated if packed: Amoxicillin, amoxicillin/clavulanate, or trimethoprim–sulfamethoxazole or azithromycin in penicillin allergic patients.
- Displaced fractures do not need reduction in ED unless airway is compromised.
- Generally recommended to allow swelling to abate and reduce fracture in 3–5 days, although there are many specialists who recommend local anesthesia and immediate reduction.
- Septal hematoma must be drained immediately in ED:
 - Anesthetize with topical cocaine or lidocaine and vascular constriction with neosynephrine.
 - Attempt to aspirate with 18G to 20G needle on 3-mL syringe.
 - Rolling cotton swab down septum may facilitate drainage.
 - Holding mucosa down against cartilage must be done to prevent reaccumulation.
 - This can be done with petroleum jelly gauze packing.
 - Both nares should be packed to ensure adequate pressure:
 - Packing is left in place for 3–5 days or until follow-up with ear, nose, and throat (ENT).
 - Prophylactic antibiotics are prescribed.

MEDICATION

- Amoxicillin: 500 mg PO TID (peds: 40 mg/kg PO div. TID)
- Amoxicillin/clavulanate: 500/125–875/125 mg PO BID (peds: 40 mg/kg/d of amoxicillin PO BID)
- Azithromycin: 500 mg PO day 1 followed by 250 mg PO daily for 4 additional days (peds: 10 mg/kg PO day 1, followed by 5 mg/kg PO days 2–4)
- Cocaine: Topical 4%
- Lidocaine: 1–2% without epinephrine
- Neosynephrine nasal spray
- Trimethoprim–sulfamethoxazole: Double strength (DS) PO BID (peds: 40 mg/kg/d sulfamethoxazole PO BID)

IN PATIENT CONSIDERATIONS

Admission Criteria

- Most nasal fractures do not require admission.
- Admit patients with nasoethmoid fractures or more significant craniofacial injuries.

Discharge Criteria

- No evidence of significant head, neck, or other injuries.
- Epistaxis controlled
- Reliable companion or caregiver

Pediatric Considerations

- Follow up with specialist sooner because fibrous union begins in only 3–4 days
- Consider contacting child protective services if any suspicion of nonaccidental trauma:
 - History does not fit injury.
 - Always consider nonaccidental trauma as potential mechanism of injury.
- Fractures are rare in children; nasal injuries in children are more likely to be cartilaginous.
- Significant injuries in children are not always fully appreciated.

FOLLOW-UP

FOLLOW-UP RECOMMENDATIONS

- Follow up with ENT, plastic surgery, or oral maxillofacial (OMF) surgeon in 3–5 days for management:
 - Patients with septal hematoma should follow up in 24 hr for re-evaluation after drainage.
- Return for signs of clear rhinorrhea, difficulty breathing, fever, or signs associated with head injury.

PEARLS AND PITFALLS

- The absence of a septal hematoma must be documented in every case.
- Every patient discharged with nasal packing should be placed on antistaphylococcal antibiotics.
- Consider cribriform plate fractures in patients with clear rhinorrhea after nasal injury.
- Have a low threshold for ordering facial bone CT if there is suspicion for associated injuries or fractures.

NECK INJURY BY STRANGULATION/HANGING

David Della-Giustina • Karen Della-Giustina

BASICS

DESCRIPTION

- Strangulation:
 - Ligature: Material used to compress structures of neck
 - Manual: Physical force used to compress structures of neck
 - Postural: Airway obstruction from body weight (over an object) or position (typically in infants)
- Hanging is a form of strangulation:
 - Complete (judicial type): Victim's entire body is suspended off the ground
 - Incomplete (nonjudicial): Some part of victim's body contacts the ground
 - Typical: The point of suspension is placed centrally over the occiput.
 - Atypical: The point of suspension is in any position other than over the central occiput.
 - Intentional: Suicide, homicide, autoerotic, "the choking game"
 - Accidental: Often children or clothing caught in machinery
 - Near-hanging: Survival following nonjudicial hanging

ETIOLOGY

- Hanging (judicial):
 - Victim is dropped a distance at least equal to his or her height
 - Forceful distraction of head from torso results in a decapitation type of injury (fracture of cervical spine and transection of spinal cord)
- Hanging (nonjudicial):
 - Typically occurs from a lower height
 - Injuries mimic nonjudicial strangulation
- Strangulation:
 - External neck pressure causes cerebral hypoxia secondary to venous and arterial obstruction.
 - Pressure on neck structures may cause airway, soft tissue, and vascular injuries.
 - Cervical spine injuries are uncommon except with judicial-type hanging.
- Death:
 - Secondary to mechanical closure of blood vessels or airway
 - Secondary to cardiac arrest from extreme bradycardia due to increased vagal tone from carotid sinus pressure
 - Secondary to direct neurologic injury to the spinal cord
 - Secondary to pulmonary complications in near-hanging victims

- Secondary to cerebral hypoxia

COMMONLY ASSOCIATED CONDITIONS

- Cervical spine injury
- Hypoxic cerebral injury
- Arterial or venous dissection/thrombosis
- Hyoid bone fracture:
 - Typically seen in nonjudicial strangulation
- Cricoid cartilage disruption (rare)
- Thyroid cartilage disruption:
 - More common in nonjudicial strangulation deaths
- Phrenic nerve injury
- Airway edema
- Aspiration pneumonitis (may be late)
- Neurogenic pulmonary edema (may be late):
 - Due to massive central sympathetic discharge
- Postobstructive pulmonary edema (may be rapid onset):
 - Due to negative intrapleural pressure resulting from inspiration against an external airway obstruction
- Air embolism:
 - Consider when SC air and vascular injuries are present

DIAGNOSIS

SIGNS AND SYMPTOMS

- Airway disruption:
 - SC emphysema
 - Dyspnea
 - Dysphonia or stridor
 - Loss of normal cartilaginous landmarks
- Cervical spine injury:
 - Respiratory arrest
 - Paralysis
- Neurologic injury:
 - Hoarseness
 - Dysphagia
 - Altered mental status
 - Neurologic deficit
- Pulmonary sequelae:
 - Respiratory distress
 - Pulmonary edema, ARDS, pneumonia
- Soft tissue injury:
 - Abrasions, contusions, ecchymoses, ligature, or hand marks

- Vascular injuries:
 - Expanding hematoma
 - Pulse deficits or bruits
 - Evidence of cerebral infarction
 - Tardieu spots: Petechial hemorrhages of the skin, mucous membranes, and conjunctiva cephalad to the ligature marks

Pediatric Considerations

- Structures of neck are more cartilaginous and mobile than in adults
- More resistant to crush injuries and fractures
- Rapid airway compromise can occur with relatively little edema of soft tissues secondary to smaller airway diameter.

History

- Strangulation method:
 - Patient position:
 - To determine mechanism of strangulation
 - Predict potential injuries
 - Higher fall implies greater force:
 - Decapitation-type injury more common
 - Knot position:
 - Arterial occlusion more likely in typical hanging
 - Ligature material:
 - Elasticity limits force applied
 - Venous occlusion may still produce unconsciousness and death
- Circumstance:
 - Accidental, suicide/homicide, NAT, sexual, “choking game”

Physical-Exam

- ABCs:
 - Airway or respiratory compromise
 - C-spine precautions
- Disability:
 - Coma, AMS, neurologic deficit, paralysis
- Secondary survey:
 - Assess for traumatic injury to the neck:
 - Soft tissue, aero-digestive, vascular
 - Other traumatic injury due to fall, self-inflicted wounds (suicidal), injury sustained in conflict (homicidal/NAT)

ESSENTIAL WORKUP

- CT of the cervical spine through T1

- CT scan of the head:
 - For cerebral hemorrhage, subarachnoid hemorrhage, hematoma, edema, and evidence of hypoxic injury
- CT angiography of the neck:
 - For thrombosis and intimal dissection
- Plain radiography:
 - CXR to evaluate for SC emphysema, aspiration pneumonitis, and pulmonary edema
- Pulse oximetry
- Cardiac monitor

DIAGNOSIS TESTS & NTERPRETATION

Lab

- ABG (may be considered):
 - Evaluate for evidence of hypoxia or respiratory compromise.
- Hematocrit for significant blood loss
- Type and cross-match in anticipation of transfusion for vascular injuries.
- Coagulation profile for significant blood loss or coagulopathy
- Toxicology studies (ASA/APAP/ETOH):
 - Consider for suicide-related ingestions

Imaging

- MRI of the neck:
 - High sensitivity of MRI for soft tissue injury, bone and cartilaginous injury.
 - Superior to CT in diagnosis of soft tissue injury.
- Arteriography:
 - Definitive evaluation for potential vascular injuries

Diagnostic Procedures/Surgery

- Fiberoptic endoscopy:
 - Allows direct visualization for evaluation of aero-digestive injury
 - May aid in intubation
- Surgical exploration

DIFFERENTIAL DIAGNOSIS

Etiology of strangulation:

- Accidental, homicidal, suicidal, NAT, auto-erotic, choking game

TREATMENT

PRE HOSPITAL

- ABCs
- Early and aggressive airway management: Oxygen, suction, intubation, as indicated:
 - Remove ligature.
- Cardiac monitor
- Cervical spine stabilization:
 - Patient position, strangulation method, drop involved, knot location, signs of foul play

INITIAL STABILIZATION/THERAPY

- ABCs
- Aggressive airway management with cervical spine precautions is paramount:
 - Early intubation for respiratory compromise
 - Supplemental oxygen
 - Cricothyrotomy or tracheostomy may be required if severe maxillofacial injuries are present:
 - Avoid cricothyrotomy if hematoma over cricothyroid membrane or evidence of cricotracheal disruption is seen.
 - Arrange for emergent tracheostomy in above scenario (see Larynx Fracture).
- Control bleeding with application of direct pressure:
 - Do not explore in the ED

ED TREATMENT/PROCEDURES

- IV access
- Consult otolaryngologist or trauma surgeon in management of neck soft tissue injuries.
- Consult vascular surgery in management of vascular injuries.
- Consult neurology for suspected cerebral ischemic insults (thrombosis, embolism, dissection).
- Supportive care for suspected elevated intracranial pressure/cerebral edema:
 - Elevate head of bed.
 - Ensure adequate oxygenation and cerebral perfusion.
 - Prevent secondary neurologic injury/insult.
 - Consult neurosurgery for intracranial pressure monitoring and surgery as indicated.
- Neck injury with SC emphysema:
 - Assume that mucosa of upper airway communicates with deep tissues of neck.
 - Administer antibiotics.
- Laryngeal edema:
 - Consider steroids.
- Evaluate for associated injuries or harm:

- Consider ingestions in suicidal cases.
- Report suspected nonaccidental injuries in children.

MEDICATION

- Hypoxic brain injury:
 - Mannitol: 0.25–1 g/kg/dose IV (consider for elevated intracranial pressure; not routinely used in pediatric cases)
 - Hypertonic saline: Dosing regimens vary (consider for elevated intracranial pressure)
 - Phenytoin: 15–20 mg/kg IV (loading dose) as needed for seizures
- Neck injury with SC emphysema:
 - Ampicillin/sulbactam: 1.5–3 g (peds: 100–400 mg/kg/d) IV q6h
 - Clindamycin: 600 mg (peds: 25–40 mg/kg/d) IV q8h
- Airway edema:
 - Dexamethasone: 0.5–2 mg/kg/d (peds: 0.25–0.5 mg/kg) IV q6h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Admit patients with strangulation or hanging-mechanism injuries to a monitored setting to observe for airway or neurologic compromise (may have delayed onset).
- Surgical correction of laryngeal, esophageal, or vascular neck injuries
- Altered level of consciousness, new neurologic deficit, coma
- Respiratory distress:
 - Supportive care for pulmonary edema, ARDS, pneumonia
- All patients with suspected suicidal or homicidal strangulation injury should have psychiatric or social work consultation.
- For pediatric patients:
 - Suspected nonaccidental trauma, concern for safety in the home

Discharge Criteria

Only patients without strangulation or hanging injuries may be discharged after appropriate observation in the ED to ensure absence of airway compromise, vascular injury, neurologic deficit, and suicidal/homicidal ideation.

FOLLOW-UP RECOMMENDATIONS

- Neuropsychiatric evaluation:
 - Consider in evaluation for hypoxic encephalopathy
- Psychiatry/psychology:
 - Suicidal or homicidal patients

- Auto-erotic or “choking game” patients for medical/cognitive/behavioral therapy
- Surgical follow-up:
 - As indicated, based on injuries sustained

PEARLS AND PITFALLS

- Cervical spine injury is uncommon in nonjudicial hanging victims:
 - Cerebral hypoxia is the probable cause of death in the majority of victims.
- Aggressive airway management is paramount.
- Thoroughly evaluate for associated injuries.
- Consider admission for observation of all strangulation/hanging victims.
- Prognosis:
 - GCS on arrival does not predict prognosis.
 - Poor prognosis is suggested by:
 - Anoxic brain injury on head CT
 - Increased hanging time
 - Cardiac arrest at the scene AND on arrival to the ED

- T71.163A Asphyxiation due to hanging, assault, initial encounter

NECK TRAUMA, BLUNT, ANTERIOR

Alfred A. Joshua

BASICS

DESCRIPTION

- Blunt anterior neck trauma may result in various injuries to structures in the neck:
 - Vascular:
 - Carotid artery injury (internal, external, common carotid)
 - Vertebral artery injury
 - Intramural hematoma, intimal tear, thrombosis, and pseudoaneurysm
 - Hemorrhage or neck hematoma
 - Laryngotracheal:
 - Laryngeal injuries: Fracture of hyoid bone, thyroid cartilage, cricoid cartilage, cricotracheal separation
 - Vocal cord disruption
 - Dislocation of arytenoid cartilage
 - Tracheal injuries: Hematoma or transection
 - Pharyngoesophageal:
 - Pharynx: Hematoma, perforation
 - Esophagus: Hematoma, perforation
 - Nervous system:
 - Thoracic sympathetic chain wraps around carotid artery: Disruption can result in Horner's syndrome
 - Vagus nerve and recurrent laryngeal nerve
 - Cervical nerve roots and spinal cord
 - Cervical spine:
 - Fracture of vertebral body, transverse process, spinous process, etc.
 - Dislocation

ETIOLOGY

- Motor vehicle accidents (most common cause):
 - Unrestrained occupants involved in frontal collisions may strike neck on dashboard or steering wheel: “Padded dash syndrome”
 - Shoulder harness (seatbelt) can also cause shearing injury to anterior neck.
- Assault: Blows to anterior neck from fists, kicks, or objects
- “Clothesline injury”:
 - Motorcycle, snowmobile, jet ski, or all-terrain vehicle (ATV)
 - Drivers strike neck on cord or wire suspended between 2 objects.
- Strangulation

Pediatric Considerations

- Head is proportionally larger in children, increasing risk of acceleration–deceleration injury to neck
- Intraoral blow to soft palate may cause carotid thrombosis (popsicle in mouth of child who falls, pushing the object into soft palate).

DIAGNOSIS

SIGNS AND SYMPTOMS

- Presentation varies depending on mechanism of injury and structures involved:
 - Vascular injury:
 - Hemorrhage, ecchymosis, edema
 - Carotid bruit or thrill (pathognomic for vascular injury)
 - Neurologic deficits (often delayed)
 - Laryngotracheal injury:
 - Voice changes, hoarseness, aphonia
 - Dyspnea, inspiratory stridor, labored breathing, “air hunger”
 - SC emphysema, tenderness to palpation
 - Pharyngoesophageal injury (rarely isolated):
 - Dysphagia, odynophagia, hematemesis, blood in saliva
 - Tenderness to palpation
 - Infection, sepsis (delayed presentation)
 - Neurologic injury:
 - Central or peripheral nervous system deficits

History

- Detailed history (if patient is able to provide) based on signs and symptoms:
 - Cover all structures of the neck, as well as structures outside the neck (neck trauma usually associated with injures to chest, head, etc.)

Physical-Exam

- Ensure airway protection and patency.
- Inspect neck for hemorrhage, hematoma, ecchymosis, edema, or distortion of anatomy.
- Auscultate for carotid bruits, stridor.
- Palpate to detect tenderness or SC emphysema.
- Neurologic exam to detect evidence of ischemic event, spinal cord injury, or peripheral nerve damage
- Complete physical exam to detect associated injuries to the chest, abdomen, etc.

ESSENTIAL WORKUP

Depends on history and physical exam findings

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Type and cross-match
- Baseline CBC
- BUN/creatinine may be needed prior to radiologic testing (contrast with CT or MRI)

Imaging

- Cervical spine and lateral neck radiographs
- Limited value but may show subglottic narrowing, prevertebral soft tissue swelling, SC air, fractured calcified larynx
- CXR to rule out associated injury to thorax (pneumothorax, pneumomediastinum, etc.)
- Carotid duplex US is a noninvasive, rapid screening test for arterial injury:
 - Sensitivity as high as 92% in retrospective studies for dissection, operator-dependent, poor visualization above carotid bifurcation
- CT may be used in stable patients to evaluate laryngotracheal injury, cartilage disruption, or cervical spine injury.
- CT angiography:
 - Low sensitivity (50%) and high specificity (99%) on initial studies with early-generation CT scanner compared with angiography for carotid and vertebral artery injury, may have improved rates of detection with newer-generation CT scanners
- Magnetic resonance arteriography (MRA):
 - Low sensitivity (49%) and high specificity (99%) on initial studies with MRA compared with angiography for carotid and vertebral artery injury
 - 4-vessel angiography is considered gold standard for evaluation of arterial injury.
- Indications for angiography:
 - Presence of carotid bruit
 - Expanding neck hematoma
 - Neurologic deficit without intracranial pathology on CT
 - Horner's syndrome
 - Decreased level of consciousness

Diagnostic Procedures/Surgery

- Unstable patients must go directly to surgery.
- Laryngotracheal injuries:
 - Fiberoptic laryngoscopy can visualize subglottic airway, facilitate intubation, assess airway patency and injury.
- Esophageal injuries:

- Initial study of choice: Gastrografin swallow study (less pleural irritation with extravasation) or barium swallow study
- Indications for endoscopy:
 - Odynophagia
 - Hematemesis or blood in saliva
 - SC emphysema

DIFFERENTIAL DIAGNOSIS

- Peripheral or CNS injury
- Cervical spine injury
- Associated head or thoracic trauma

TREATMENT

PRE HOSPITAL

- Airway must be vigilantly monitored:
 - Edema or expanding hematoma can progress to airway compromise.
- Orotracheal intubation preferred 1st-line technique for airway control
- Clinical signs of respiratory distress:
 - Stridor
 - Air hunger
 - Labored breathing
 - Expanding neck hematoma
- Blind nasotracheal intubation should be avoided:
 - Owing to anatomy distortion and risk of hematoma rupture
- Cervical spine must be stabilized.

INITIAL STABILIZATION/THERAPY

Airway management with cervical spine control:

- Immediate intubation indicated for patients with signs of airway compromise or impending compromise
- Cricothyroidotomy or emergent tracheostomy may be needed if oral intubation is unsuccessful.
- Contraindicated if bruising or hematoma noted over thyroid/cricoid cartilage
- Bleeding into pharynx can be reduced by packing throat with heavy gauze after airway is secured by intubation.
- Unstable patients must go directly to OR.

ED TREATMENT/PROCEDURES

- Surgical consultation should be obtained for patients with suspicion of vascular, tracheal, or esophageal injury.
- Immediate surgical repair is required for symptomatic vascular injury, tracheal injury, pharyngeal, or esophageal injury.

- Laryngeal injury may not require immediate surgical repair.
- Anticoagulation is recommended for vascular injuries due to consequent luminal narrowing and thrombosis:
 - Results in improved neurologic outcomes
 - Requires surgical consultation prior to initiation of therapy

MEDICATION

- Anticoagulation (see above)
- Prophylactic antibiotics recommended in presence of an esophageal injury to prevent abscess formation (anaerobic coverage):
 - Cefoxitin: 2 g (peds: 80–160 mg/kg/d div. q6h) IV q8h *or*
 - Clindamycin: 600–900 mg (peds: 25–40 mg/kg/d div. q6–8h) IV q8h *or*
 - Penicillin G: 2.4 million U/d (peds: 150,000–250,000 U/kg/d) IV q4–6h, + metronidazole
 - Metronidazole: 1 g load, then 500 mg (peds: 30 mg/kg/d div. q12h) IV q6h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients who are symptomatic, have abnormal studies, or have significant blunt trauma mechanism must be admitted and observed for at least 24 hr.
- Patients with suspicion of airway or vascular injury must be admitted to ICU.

ALERT

Patients on anticoagulation medications should be observed in ED for 6 hr from injury to look for signs of delayed neck hematoma.

Discharge Criteria

Only patients with most trivial injuries who have negative studies may be discharged from ED after thorough evaluation.

FOLLOW-UP RECOMMENDATIONS

Patients should be given return precautions to the ED for delayed signs of vascular, tracheal, neurologic injury.

PEARLS AND PITFALLS

- Vascular injuries frequently have delayed presentation.
- Look for vascular injuries in blunt neck trauma patients with neurologic deficit and normal head CT.
- Always prepare for difficult airway and have specialty intervention (anesthesia,

ENT) on standby (if available).

CODES

ICD9

- 900.00 Injury to carotid artery, unspecified
- 900.89 Injury to other specified blood vessels of head and neck
- 959.09 Injury of face and neck

ICD10

- S15.009A Unspecified injury of unspecified carotid artery, initial encounter
- S15.109A Unspecified injury of unspecified vertebral artery, initial encounter
- S19.80XA Other specified injuries of unspecified part of neck, initial encounter

NECK TRAUMA, PENETRATING, ANTERIOR

Angela Pham

BASICS

DESCRIPTION

- Wound severity gauged by violation of platysma muscle
- Neck is divided into 3 zones
 - Zone I: Between clavicles and cricoid cartilage
 - Involves vessels, lungs, trachea, esophagus, thyroid
 - Penetrating trauma in this zone carries highest mortality owing to injury to thoracic structures.
 - Zone II: Between cricoid cartilage and angle of mandible
 - Involves vessels, trachea, esophagus, C-spine, and spinal cord
 - Injuries are most common in this zone due to it being most exposed region.
 - Zone III lies above angle of mandible to base of skull
 - Injuries are difficult to access surgically

Pediatric Considerations

Larynx is located higher in neck and receives better protection from mandible and hyoid bone.

ETIOLOGY

- Gunshot wounds
- Stab wounds
- Miscellaneous (e.g., glass shards, metal fragments, animal bites)

DIAGNOSIS

SIGNS AND SYMPTOMS

- Vascular:
 - Active/persistent hemorrhage or hematoma
 - Pulse deficit
 - Horner's syndrome (carotid injury)
 - Vascular bruit or thrill
 - Venous air embolism
- Aerodigestive:
 - Respiratory distress
 - Stridor
 - Hemoptysis

- Tracheal deviation
- SC emphysema
- Pneumothorax
- Sucking wound
- Hoarseness, aphonia, dysphonia
- Dysphagia/odynophagia
- Neurologic:
 - Central or peripheral nervous system deficits

History

- Wounds across midline increase injury significance
- Stab wound
 - Size of instrument
 - Mostly low-energy penetration
- Gunshot wound
 - Type of gun used
 - Long range vs. close range

Physical-Exam

- Careful exam of wound to determine extent of injury and whether it penetrates platysma
- Wounds should never be probed blindly:
 - May result in uncontrolled hemorrhage

ESSENTIAL WORKUP

- Platysma violation
 - No: Wound care, discharge
 - Yes:
 - Unstable: Emergent airway, OR
 - Stable: Workup depends on zone violation

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Type and cross-match.
- Baseline CBC, chem panel, coags

Imaging

- Lateral neck radiograph to evaluate soft tissue injury and detect foreign bodies
- Chest radiograph to detect hemopneumothorax, mediastinal air
- Zone I:
 - Angiography: Gold standard to evaluate vessel injury, invasive
 - Helical CT angiography: Speed, noninvasive

- Aware of streak artifact from shoulder, poor view of subclavian vessels
- Esophagram with water soluble contrast or dilute barium:
 - Low sensitivity
 - Combine with esophagoscopy to exclude injury.
 - Indications: Wound approaches/crosses midline, SC air
- Zone II:
 - Asymptomatic: Observation
 - Symptomatic: OR
- Zone III:
 - Symptomatic: Angiography or CT angiogram

Diagnostic Procedures/Surgery

- Bronchoscopy can be helpful in evaluating tracheal injury.
- Surgical consult for all wounds that penetrate platysma muscle
 - Surgical exploration:
 - Expanding or pulsatile hematoma
 - Active bleeding
 - Absence of peripheral pulses
 - Hemoptysis
 - Horner's syndrome
 - Bruit
 - SC emphysema
 - Respiratory distress
 - Air bubbling through wound

DIFFERENTIAL DIAGNOSIS

- Peripheral or CNS injury
- Cervical spine injury
- Associated head or thoracic trauma

TREATMENT

PRE HOSPITAL

- Frequent suctioning to clear airway of blood, secretions, or vomitus
- 2 large-bore IVs
- High-flow O₂ should be provided
- BVM should be avoided for potential distortion of neck anatomy and airway compromise due to forced air through tracheolaryngeal wound into tissues
- Airway must be vigilantly monitored, as edema or expanding hematoma can progress to airway compromise.
- Indications for early oral intubation:

- Clinical signs of respiratory distress
- Stridor
- Air hunger
- Labored breathing
- Expanding neck hematoma
- Nasotracheal intubation has not been proven to worsen penetrating wounds

ALERT

- Occlusive dressings should be applied to lacerations over major veins to prevent air embolism.
- Cervical spine immobilization in the absence of focal neurologic deficits is not indicated
 - Blocks direct visualization/palpation of neck; increases likelihood of missing life-threatening signs

INITIAL STABILIZATION/THERAPY

- Emergent intubation is indicated:
 - Patients who are in respiratory distress or comatose.
 - Be aware of voice change or odynophagia
 - Patients who are stable without evidence of respiratory distress may be managed aggressively with prophylactic intubation or observed closely with airway equipment at bedside.
 - Orotracheal intubation with rapid-sequence induction is method of choice for securing airway in penetrating neck trauma.
 - Blind nasotracheal intubation is contraindicated with apnea, severe facial injury, or airway distortion.
 - Fiberoptic bronchoscopic intubation is advantageous as patient may stay awake, allows direct visualization of vocal cords and injuries.
 - Percutaneous transtracheal ventilation may be useful when oral or nasotracheal intubation fails:
 - This is contraindicated in cases of upper airway obstruction.
 - May cause barotrauma
 - Cricothyroidotomy contraindicated if significant hematoma overlying cricothyroid membrane
 - Tracheostomy is warranted in this setting
 - Breathing:
 - Zone I injury can cause pneumothorax or subclavian vein injury and hemothorax:
 - May require needle decompression and tube thoracostomy
- Circulation:
 - External hemorrhage:
 - Control with direct pressure.
 - If failed, insert and inflate Foley catheter balloon within wound to

- tamponade bleeding
 - Blind clamping of vessels is contraindicated owing to risk of further neurovascular injury.
- Uncontrolled bleeding or hemodynamic instability: Send directly to OR.
- After intubation, throat can be packed with heavy gauze to tamponade bleeding.
- Hemothorax: Tube thoracostomy

ED TREATMENT/PROCEDURES

- Nasogastric tube should *not* be placed because of risk of rupturing pharyngeal hematoma.
- Prophylactic antibiotics are recommended (cefoxitin, clindamycin, penicillin G + metronidazole).
- Tetanus prophylaxis

MEDICATION

- Cefoxitin: 2 g (peds: 80–160 mg/kg/d div. q6h) IV q8h *or*
- Clindamycin: 600–900 mg (peds: 25–40 mg/kg/d div. q6–8h) IV q8h *or*
- Penicillin G: 2.4 million U/d (peds: 150,000–250,000 U/kg/d) IV q4–6h, + metronidazole
- Metronidazole: 1 g load, then 500 mg (peds: 30 mg/kg/d div. q12h) IV q6h

IN PATIENT CONSIDERATIONS

Admission Criteria

- All patients with penetrating neck trauma should be admitted and observed for at least 24 hr.
- Observation must take place in facility capable of providing definitive surgical care.
- Patients with injuries suggesting airway or vascular injury must be admitted to ICU.

Discharge Criteria

- Asymptomatic patients who have negative studies may be discharged after 24 hr of observation.
- Patients with wounds superficial to the platysma may be discharged directly from the ED

PEARLS AND PITFALLS

- Failure to anticipate difficulties in airway management
- Failure to recognize impending airway compromise

NECROTIZING SOFT TISSUE INFECTIONS

Adam Z. Barkin

BASICS

DESCRIPTION

- Necrotizing soft tissue infections (NSTI) are infections of any layer of the skin associated with necrotizing changes
 - Usually spreads rapidly along tissue planes
- Characterized by:
 - Widespread fascial and muscle necrosis with relative sparing of the skin
 - High mortality
 - Systemic toxicity
- Crepitant anaerobic cellulitis:
 - Necrotic soft tissue infection with abundant connective tissue gas
- Progressive bacterial gangrene:
 - Slowly progressive erosion affecting the total thickness of skin but not involving deep fascia
- Nonclostridial myonecrosis (synergistic necrotizing cellulitis):
 - Aggressive soft tissue infection of skin, muscle, SC tissue, and fascia
- Fournier gangrene:
 - Mixed aerobic–anaerobic soft tissue necrotizing fasciitis of the skin of the scrotum and penis in men and the vulvar and perianal skin in women
- *Necrotizing fasciitis*:
 - Progressive, rapidly spreading infection with extensive dissection and necrosis of the superficial and deep fascia
- Accounts for 500–1,500 cases per year in US
- Often difficult to recognize
- Incidence increases with:
 - Age
 - Smoking
 - Chronic systemic disease:
 - Diabetes
 - Obesity
 - Peripheral vascular disease
 - Alcohol abuse
 - IV drug use
- 24–34% mortality
- Also high morbidity:
 - Amputations
 - Renal failure

ETIOLOGY

- Conditions that lead to the development of NSTIs:
 - Local tissue trauma with bacterial invasion
 - Local ischemia and reduced host defenses:
 - More frequently in diabetics, alcoholics, immunosuppressed patients, IV drug users, and patients with peripheral vascular disease
- Type I NSTI:
 - Polymicrobial
 - Anaerobic and aerobic
 - Include Fournier gangrene and Ludwig angina
 - After surgical procedures
 - Existing diabetes, peripheral vascular disease, chronic kidney disease, alcohol abuse
 - Compromised immune system
 - Represent 80% of NSTIs
 - Strep species are most common aerobes
 - Also staph, enterococci, and gram-negative rods
 - Bacteroides are most common anaerobes
- Type II NSTI:
 - Monomicrobial
 - Typically aerobic Streptococcus
 - Often young, healthy patients
 - Most common cause of “flesh eating” disease
 - Methicillin-resistant Staphylococcus aureus (MRSA) species are becoming more common
- Type III NSTI
 - Least common NSTI (< 5%)
 - Rapidly progressive
 - Clostridial myonecrosis is an example
 - Usually following penetrating wounds or crush injuries
 - Also can be seen after black tar heroin injection, skin popping, intestinal surgery, obstetrical complications
- Bacteria involved include:
 - Group A β_2 -hemolytic streptococcus (GABHS)
 - Group B streptococcus
 - Staphylococci
 - Enterococci
 - Bacillus
 - Pseudomonas
 - *Escherichia coli*
 - Proteus
 - Klebsiella

- Enterobacter
- Bacteroides
- *Pasteurella multocida*
- Clostridium sp.
- Vibrio sp.
- Aeromonas sp.
- Fungi

Pediatric Considerations

- Neonates: Omphalitis and circumcision are predisposing factors.
- Risk factors for children:
 - Chronic illness
 - Surgery
 - Recent varicella infection (58-fold increased risk of GABHS NSTI)
 - Congenital and acquired immunodeficiencies

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Fever
- Altered mental status
- Chronic medical conditions
- IV drug use
- Skin:
 - Rapid progression of pain and swelling of involved area
 - In 1st 24 hr, rapid development of local swelling, heat, erythema, and tenderness
 - 24–48 hr: Purple and blue discoloration, blisters and bullae develop (often hemorrhagic)
 - Foul-smelling thin fluid (from necrosis of fat and fascia)

Physical-Exam

- Systemic toxicity:
 - Fever
 - Tachycardia
 - Tachypnea
 - Hypotension
 - Altered mental status
- Pain out of proportion to physical findings
- Skin:

- Erythema
- Tense edema
- Grayish or other discolored wound drainage
- Vesicles or bullae
- Necrosis
- Ulcers
- Crepitus (pathognomonic but present in only 10–37% of cases)
- Pain that extends past margin of infection

Pediatric Considerations

- Most common presenting symptoms
 - Localized pain (97%)
 - Rash (73%)
 - Hypotension, altered mental status, and other signs of shock are much less common

ESSENTIAL WORKUP

- Diagnosis can be difficult
- Careful exam for the aforementioned signs and symptoms in high-risk patients
- NSTIs must be suspected in patients who appear very ill and have pain out of proportion to physical findings
- Diagnosis may require incision and probing of tissue

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC with differential
- Electrolytes
- BUN and creatinine
- Disseminated intravascular coagulation panel
- Calcium level: Hypocalcemia can develop from extensive fat necrosis
- Gram stain and aerobic/anaerobic cultures of wound or tissue biopsy

Imaging

- X-rays to detect soft tissue gas: Pathognomonic, but present in only 39–57% of cases
- CT scan:
 - May be more helpful than plain x-rays in detecting SC air
 - May also identify deep abscess or other cause of infection
- MRI:
 - Can delineate extent of spread of the infection
- US:
 - Fascial thickening

- Fluid in the fascial plane
- SC soft tissue edema

ALERT

Imaging of any kind should never delay surgical debridement

Diagnostic Procedures/Surgery

- All patients with suspected NSTI must undergo surgical debridement
- Deep incisional biopsy and cultures are the gold standard for diagnosis

DIFFERENTIAL DIAGNOSIS

- Cellulitis
- Gas gangrene

TREATMENT

PRE HOSPITAL

- IV fluid resuscitation
- Manage airway as necessary.

INITIAL STABILIZATION/THERAPY

Manage airway and resuscitate as indicated:

- Rapid-sequence intubation as needed
- Supplemental oxygen, monitor, evaluate for acid–base disturbances
- IV access, CVP line may be needed
- Aggressive volume expansion including crystalloid, plasma, packed RBCs, and albumin

ED TREATMENT/PROCEDURES

- Antibiotics: Broad coverage of aerobic gram-positive and gram-negative organisms and anaerobes
- Acceptable combination therapy:
 - Penicillin or cephalosporin + an aminoglycoside or fluoroquinolone + anaerobic coverage with either clindamycin or metronidazole
- Treat methicillin-resistant Staphylococcus aureus (MRSA) until excluded:
 - Vancomycin
 - Linezolid
 - Daptomycin
- Surgical consultation:
 - Early debridement of all necrotic tissue with fasciotomy and drainage of fascial planes is paramount
- Hyperbaric oxygen as an adjunct:
 - Early transfer to hyperbaric facility may result in greater tissue salvage

- IV immunoglobulin (IVIG):
 - Controversial
 - May be beneficial in NSTI caused by group A streptococcal infection
- Observe for major complications including acute respiratory distress syndrome, renal failure, myocardial irritability, and DIC

ALERT

Clindamycin therapy should be initiated as soon as possible when group A strep infection is suspected

MEDICATION

- Ceftriaxone: 2 g (peds: 100 mg/kg/24 h; max. 4 g) IV q24h
- Ciprofloxacin: 400 mg IV q12h
- Clindamycin: 900 mg (peds: 40 mg/kg/d q6h) IV q8h
- Daptomycin: 4 mg/kg IV q24h
- Gentamicin: 2 mg/kg (peds: 2 mg/kg IV q8h) IV q8h
- Doxycycline: 100 mg IV q12h
- Imipenem/cilastatin: 250–1,000 mg IV q6–8h
- Levofloxacin: 750 mg IV q24h
- Linezolid: 600 mg PO/IV q12h (peds: 30 mg/kg/d PO/IV div. q8h)
- Meropenem: 1 g (peds: 20–40 mg/kg up to 2 g/dose) IV q8h
- Metronidazole: 500 mg (peds: Safety not established) IV q8h
- Penicillin G: 24 million U q24h (peds: 250,000 IU/kg/24h) IV q4–6h
- Piperacillin/tazobactam 3.375–4.5 g (peds: 240 mg/kg/d of piperacillin div. q8h) IV q6h
- Tigecycline: Start 100 mg IV × 1; 50 mg IV q12h
- Vancomycin: 10–15 mg/kg IV q12h (peds: 10–15 mg/kg IV q6–8h)

First Line

- Type I infections:
 - Piperacillin/tazobactam + clindamycin + ciprofloxacin/levofloxacin
 - Imipenem/cilastatin
 - Meropenem
- Type II infections:
 - Clindamycin + penicillin (or linezolid or vancomycin)
- Type III infections:
 - Clindamycin + penicillin
- Type IV infections:
 - Doxycycline

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with an NSTI *must be admitted* for surgical debridement and IV antibiotics
- Early hyperbaric oxygen therapy may be an important adjunct

Discharge Criteria

No patient with NSTI should be discharged

Issues for Referral

After stabilization with antibiotics and surgical debridement, consider referral for hyperbaric oxygen treatment as an adjunct.

PEARLS AND PITFALLS

- The clinician must have a high index of suspicion for NSTI, as initial skin findings may be unimpressive
- Pain out of proportion to exam may be a key finding
- Mortality will be near 100% if treatment is ONLY with antimicrobials
- Scoring systems for NSTI have limited utility
- 4 tenets of treating NSTI:
 - Fluid resuscitation and management of metabolic disturbances
 - Early antimicrobial therapy
 - Surgical debridement
 - Treating organ failure

NECROTIZING ULCERATIVE GINGIVITIS

Stephen K. Epstein • Laura B. Glicksman

BASICS

DESCRIPTION

- Periodontal disease
- Characterized by the “punched-out” appearance of the gingival papillae
- Synonym(s):
 - Acute necrotizing ulcerative gingivitis
 - Trench mouth
 - Vincent disease
 - Fusospirochetal gingivitis
- Not contagious
- Occurs most often in children and young adults in developing nations
- Mainly occurs in sub-Saharan Africa
- Rare; seen mostly in severely immunocompromised patients
- Males > females
- Can progress to more advanced disease:
 - Necrotizing stomatitis:
 - Similar to necrotizing ulcerative gingivitis with extension to the tongue and buccal mucosa
 - Necrotizing ulcerative periodontitis:
 - Similar to necrotizing ulcerative gingivitis with periodontal attachment loss and alveolar bone involvement
 - Orofacial gangrene

ETIOLOGY

- Caused by an overgrowth of oral flora
- *Prevotella intermedia*
- Spirochetes
- Predisposing factors (not required for diagnosis):
 - Poor oral hygiene/gingivitis
 - Immunodeficiencies (e.g., HIV)
 - Immunosuppression
 - Malnutrition
 - Smoking
 - Emotional and physical stress
 - Possible association with direct contact to certain chemicals (e.g., MDMA or ecstasy)

SIGNS AND SYMPTOMS

- Essential clinical features:
 - Painful gingival lesions
 - “Punched-out,” crater-like ulcers of the papillae
 - Ulcers bleed easily or spontaneously
- Nonessential clinical features:
 - “Pseudomembrane” of necrotic debris covering the ulcerated area
 - Foul breath
 - Fever/malaise

History

- Acute, generalized oral pain
- Bleeding gums:
 - Spontaneous or with minimal manipulation
- Foul breath
- Malaise
- Low-grade fever

Physical-Exam

- Loss of interdental papillae (key clinical feature)
- “Punched-out,” crater-like ulcers of the papillae
- Necrotic debris often present over ulcerated surfaces
- “Pseudomembrane” of inflammatory and necrotic cells
- Covers ulcerative lesions
- Leaves a bleeding surface when removed
- Lymphadenopathy, particularly submandibular
- Foul breath
- Low-grade fever

ESSENTIAL WORKUP

- Consider systemic disease:
 - Neutropenia
 - HIV
- Other reasons for immunosuppression or immunocompromise
- Rule out complications:
 - Progression to necrotizing stomatitis or ulcerative periodontitis
 - Lesions extending to periodontal ligament and alveolar bone
 - Alveolar bone destruction
 - Progression to orofacial gangrene (noma)

DIAGNOSIS TESTS & INTERPRETATION

Lab

Lab tests not clinically helpful

Imaging

Generally not indicated

DIFFERENTIAL DIAGNOSIS

- Other diseases rarely have the essential clinical feature of “punched-out” interdental papillae with ulcerations.
- Acute herpetic gingivostomatitis:
 - Affects entire gingival, not just papillae
 - Low-grade fever commonly present
 - Contagious
- Viral:
 - Viral infections: Epstein–Barr, varicella zoster virus
- Thrush
- Actinomycosis
- Streptococcal/gonococcal gingivitis/stomatitis
- Secondary syphilis
- Diphtheria
- Vesiculobullous disease
- Pemphigoid
- Pemphigus
- Oral lichen planus
- Systemic lupus erythematosus
- Trauma:
 - Toothpicks
 - Vigorous toothbrushing/flossing
- Immunocompromise:
 - Leukemia
 - Agranulocytosis (malignant neutropenia)
 - HIV

TREATMENT

INITIAL STABILIZATION/THERAPY

IV fluids for dehydration

ED TREATMENT/PROCEDURES

- Administer systemic and topical pain management:

- Narcotics rarely necessary
- Viscous lidocaine
- Debride pseudomembrane:
 - Use gauze or cotton-tipped applicator soaked in diluted H₂O₂
- Antibiotics (penicillin/metronidazole or clindamycin) when indicated:
 - Fever
 - Lymphadenopathy
 - Consider broad-spectrum antibiotics, antifungals, and antivirals in the immunosuppressed patient
- Institute outpatient therapy:
 - Remove predisposing factors
 - Dilute hydrogen peroxide rinses
 - Chlorhexidine gluconate (Peridex)
 - Antibiotics if indicated
 - Avoid irritants (spicy foods, hot beverages)
 - Analgesics for pain control
 - Improve oral hygiene with daily brushing and flossing of teeth

MEDICATION

First Line

- Oral rinses:
 - Chlorhexidine gluconate (Peridex): 15 mL swish/spit BID
 - Hydrogen peroxide (3% solution diluted in half): Rinse up to 12 times daily
- Viscous lidocaine
- Pain control:
 - NSAIDs (e.g., ibuprofen), acetaminophen

Second Line

- Metronidazole: 250–750 mg (peds: 30 mg/kg/24h) PO QID × 7 days
- Penicillin VK: 500 mg (peds: <12 yr, 25–50 mg/kg/24h) PO QID. × 10 days
- Clindamycin: 300 mg PO (peds: 6–8 mg/kg/24h) TID
- Narcotic pain control

FOLLOW-UP

DISPOSITION

Admission Criteria

- Extensive disease with systemic signs
- Severe dehydration/inability to tolerate PO fluids
- Evidence of orofacial gangrene (noma): Infection of mouth/face:

– 70% mortality with no treatment

Discharge Criteria

Able to maintain hydration

FOLLOW-UP RECOMMENDATIONS

Urgent referral to a dentist or periodontist for deep scaling and debridement

PEARLS AND PITFALLS

- Consider HIV or immunosuppression
- If untreated, can progress rapidly

CODES

ICD9

- 101 Vincent's angina
- 526.4 Inflammatory conditions of jaw
- 528.1 Cancrum oris

ICD10

- A69.0 Necrotizing ulcerative stomatitis
- A69.1 Other Vincent's infections
- M27.2 Inflammatory conditions of jaws

NEEDLESTICK

Gordon S. Chew

BASICS

DESCRIPTION

- Mechanisms of exposure to blood or body fluid:
 - Percutaneous
 - Mucous membrane
 - Skin
- General prevention:
 - Universal precautions
 - Avoid recapping of needles
 - Wear gloves: Decreases amount of blood exposure by 50%
 - Double gloving
 - Follow body–substance isolation protocols.
 - Hepatitis B virus vaccination
- Risk factors:
 - Risk of seroconversion from a single needlestick exposure without prior immunization:
 - Hepatitis B virus: 37–62% from HB_sAg-positive and HB_eAg-positive source, 23–37% from HB_sAg-positive and HB_eAg-negative source
 - Hepatitis C virus: 1.8%
 - HIV: Blood 0.3%, mucous membrane 0.09%
 - Infectiousness of various body fluids for HIV:
 - Plasma/serum: 10–5,000 ppm
 - CSF: 10–1,000 ppm
 - Semen: 10–50 ppm
 - Vaginal secretions, urine, saliva, tears, breast milk: <1 ppm
 - Factors affecting risk:
 - Viral load
 - Actual injection volume
 - Type and size of needle
 - Portal of entry (depth of inoculation)
 - Duration of contact
 - Level of disease in source patient
 - Host susceptibility
 - Barriers (e.g., through gloves)

DIAGNOSIS

SIGNS AND SYMPTOMS

History

Exposure to blood or body fluid:

- Date, time, circumstances, details of exposure, source
- Immunizations

DIAGNOSIS TESTS & INTERPRETATION

Women with body fluid exposure who are considering antiviral therapy must have serum or urine pregnancy testing.

Lab

To be done with occupational health if possible:

- Baseline serology for HIV (enzyme immunoassay, western blot), hepatitis B virus, hepatitis C virus (anti-HCV), ALT. Assess adequacy of hepatitis B virus vaccination.
 - HIV-Ab, HCV-Ab, HB_sAg, HB_sAb titer
- Obtain consent from source patient for HIV (consider rapid HIV-antibody test), hepatitis B virus, hepatitis C virus (anti-HCV) testing.
 - HIV-Ab, HCV-Ab, HB_sAg

Imaging

Not applicable unless concerned for retained tissue foreign body

DIFFERENTIAL DIAGNOSIS

Principally concerned with transmission of hepatitis B virus, hepatitis C virus, and HIV

TREATMENT

PRE HOSPITAL

ALERT

- Pre-hospital personnel should always maintain universal precautions to prevent needlestick or other body fluid exposure.
- Patients with exposure should be evaluated within hours for prophylactic therapy.

INITIAL STABILIZATION/THERAPY

- Copious cleaning, wound care
- Direct and immediate referral to occupational health, when available, to ensure strictest confidentiality in lab testing and treatment
- In the ED, after hours, patients with needlestick exposure must be triaged with high priority. It is important to initiate prophylactic therapy quickly after exposure.

ED TREATMENT/PROCEDURES

- If referral to occupational health is unavailable, initiate prophylactic therapy in ED.
- Tetanus prophylaxis if necessary
- HIV:
 - Begin basic vs. expanded antiretroviral prophylaxis regimen after considering HIV status of source and severity of exposure. Some organizations advocate only the expanded 3-drug regimen. Treat for 28 days.
 - CDC guidelines: For less severe percutaneous exposure, if source patient is:
 - HIV negative: No prophylaxis
 - Unknown source: Consider basic regimen
 - Patient with risk factors: Consider basic regimen
 - HIV positive, low viral load: Recommend basic regimen
 - HIV positive, high viral load: Recommend expanded regimen ≥ 3 drugs
 - CDC guidelines: For more severe percutaneous exposure, if source patient is:
 - HIV negative: No prophylaxis
 - Unknown source: Consider basic regimen
 - Patient with risk factors: Consider basic regimen
 - HIV positive, low viral load: Recommend expanded regimen 3 drugs
 - HIV positive, high viral load: Recommend expanded regimen ≥ 3 drugs
 - CDC guidelines: For less severe mucous membrane or nonintact skin exposure, if source patient is:
 - HIV negative: No prophylaxis
 - Unknown source: No prophylaxis
 - Patient with risk factors: No prophylaxis
 - HIV positive, low viral load: Consider basic regimen
 - HIV positive, high viral load: Recommend basic regimen
 - CDC guidelines: For more severe mucous membrane or nonintact skin exposure, if source patient is:
 - HIV negative: No prophylaxis
 - Unknown source: Consider basic regimen
 - Patient with risk factors: Consider basic regimen
 - HIV positive, low viral load: Recommend basic regimen
 - HIV positive, high viral load: Recommend expanded regimen ≥ 3 drugs
 - CDC preferred basic regimen:
 - Zidovudine (AZT) + lamivudine (3TC); sold as combination drug Combivir; *or*
 - Tenofovir DF (TDF) + emtricitabine (FTC);
 - Zidovudine (AZT) + emtricitabine (FTC); *or*

- Lamivudine (3TC) + tenofovir DF (TDF); *or*
- CDC alternative basic regimen:
 - Lamivudine (3TC) + stavudine (d4T); *or*
 - Emtricitabine (FTC) + stavudine (d4T) *or*
 - Lamivudine (3TC) + didanosine (ddI) *or*
 - Emtricitabine (FTC) + didanosine (ddI)
- CDC preferred expanded regimen: Basic regimen and:
 - Lopinavir/ritonavir (Kaletra)
- CDC alternative expanded regimen: Basic regimen and:
 - Atazanavir (ATV) ± ritonavir (RTV) *or*
 - Fosamprenavir ± ritonavir (RTV) *or*
 - Indinavir (IDV) ± ritonavir (RTV) *or*
 - Saquinavir (SQV) + ritonavir (RTV) *or*
 - Nelfinavir *or*
 - Efavirenz *or*
 - Consider others after expert consultation: These include abacavir, delavirdine, zalcitabine, nevirapine, enfuvirtide.
- Counseling to prevent secondary infection:
 - Safer sex advice
 - Avoid becoming pregnant
 - Do not donate blood/tissue.
 - Do not breast-feed.
- Hepatitis B virus:
 - Known HB_sAg-positive source:
 - Complete vaccination confirmed by titer: No prescription
 - Unvaccinated: Hepatitis B immune globulin ASAP, begin hepatitis B virus vaccine series.
 - Nonresponder to vaccine: Hepatitis B immune globulin ASAP, may repeat in 30 days; consider revaccination with 3-dose series.
 - Unknown responder to vaccine with inadequate titer: Hepatitis B immune globulin ASAP, vaccine booster
 - Known HB_sAg-negative source:
 - Vaccinated: No prescription
 - Unvaccinated: Begin hepatitis B virus vaccine series
 - Unknown source:
 - Complete vaccination confirmed by titer: No prescription
 - Unvaccinated: Begin vaccine series. If high-risk exposure, consider hepatitis B immune globulin
 - Nonresponder to vaccine: Hepatitis B immune globulin ASAP with revaccination 3-dose series. If high-risk exposure, repeat hepatitis B immune globulin in 30 days.
 - Unknown responder to vaccine with inadequate titer: Vaccine booster

and recheck titer in 1–2 mo

- Hepatitis C virus:
 - Use of immunoglobulins or antivirals (interferon, ribavirin) inconclusive as prophylaxis, but possibly beneficial if initiated early when infection evident

MEDICATION

- HIV:

- Zidovudine:
 - 300 mg PO BID or 200 mg PO TID
 - Side effects: GI symptoms, headache, fatigue, myalgias, marrow suppression, seizure
- Zidovudine should be taken in conjunction with lamivudine
- Lamivudine:
 - 300 mg PO QD or 150 mg PO BID
 - Side effects: GI symptoms, headache, fatigue, neuropathy, congestion, cough (caution with trimethoprim/sulfamethoxazole)
- Combivir (combination zidovudine + lamivudine) (300 mg + 150 mg tab):
 - 1 tablet PO BID
 - Side effects: See side-effect profiles of zidovudine and lamivudine
- Emtricitabine:
 - 200 mg/d PO
 - Side effects: Rash, hyperpigmentation
 - Emtricitabine must be taken in conjunction with efavirenz and zidovudine
- Tenofovir DF:
 - 300 mg/d PO
 - Side effects: GI symptoms, headache, fatigue, neuropathy, dizziness
 - Tenofovir must be taken in conjunction with efavirenz and emtricitabine
- Didanosine:
 - <60 kg 250 mg/d PO as delayed-release
 - Side effects: Pancreatitis, GI symptoms, lactic acidosis, neuropathy
- Stavudine:
 - 60 kg 40 mg PO BID or
 - If wt <60 kg, then 30 mg PO BID
 - Side effects: Peripheral neuropathy, GI symptoms, headache, pancreatitis, elevated liver function tests, neutropenia, anemia
- Lopinavir/ritonavir (Kaletra) (200 mg + 50 mg cap):
 - 2 capsules PO BID
 - Side effects: GI symptoms, hyperlipidemia
- Atazanavir:
 - 400 mg/d PO

- If used with tenofovir, then decrease to 300 mg/d PO and add ritonavir 100 mg/d PO
- Side effects: Be wary with medications that prolong PR interval, hyperbilirubinemia
- Fosamprenavir:
 - 1,400 mg PO BID
 - If used with ritonavir, then decrease to 1,400 mg/d PO or 700 mg PO BID
 - Side effects: GI symptoms, rash, drug interactions, depression
- Indinavir:
 - 800 mg + ritonavir 100 mg PO BID, in combination with (lamivudine + zidovudine) or (emtricitabine + zidovudine) or (lamivudine + tenofovir) or (emtricitabine + tenofovir);
 - If used with ritonavir, then decrease to 800 mg PO BID
 - Side effects: Nephrolithiasis, hyperbilirubinemia, GI symptoms
- Saquinavir:
 - 1,000 mg + ritonavir 100 mg PO BID
 - Side effects: GI symptoms, hepatitis
- Nelfinavir:
 - 1,250 mg PO BID
 - Side effects: Potential carcinogenic and teratogenic warning, GI symptoms, weakness, rash
- Efavirenz:
 - Alternate expanded regimen for HIV postexposure prophylaxis: 600 mg PO in combination with (lamivudine + zidovudine) or (emtricitabine + zidovudine) or (lamivudine + tenofovir) or (emtricitabine + tenofovir)
 - Side effects: Stevens–Johnson syndrome, rash, sleep disruption, dizziness, psychiatric, teratogen
- For some of the antiretroviral agents, the oncogenic and teratogenic effects are unknown.
- NRTIs and NtRTIs can result in lactic acidosis with hepatic steatosis.
- All can have serious drug interactions that lead to significant harm or death.
- Hepatitis B:
 - Hepatitis B immune globulin: 0.06 mL/kg IM
 - Hepatitis B virus booster: Unit-dose vial

FOLLOW-UP

DISPOSITION

Admission Criteria

Admission not necessary

Discharge Criteria

Manage as outpatients with appropriate follow-up in occupational medicine clinic

- Z20.6 Contact w and (suspected) exposure to human immunodef virus
- Z77.21 Contact w and exposure to potentially hazardous body fluids

NEONATAL JAUNDICE

Michele M. Chetham

BASICS

Produced by an imbalance between rates of bilirubin production and bilirubin elimination:

- Newborns have higher rate of bilirubin production than adults because of increased RBC mass and shorter RBC life span.
- Newborns, especially preterm infants, have rate limitations in hepatic conjugation and biliary excretion of bilirubin, increased enterohepatic circulation, and diminished bilirubin binding to albumin- and bilirubin-binding protein.

DESCRIPTION

- In most newborns, this represents *physiologic jaundice* and is not pathologic:
 - Bilirubin normally increases from 1.5 mg/dL in cord blood to a mean of 6.5 mg/dL on day 3, followed by a gradual decline to levels of <1.5 mg/dL by day 10 or 12 of life.
- Serum bilirubin may rise to levels exceeding neuroprotective defenses, causing bilirubin tissue binding in basal ganglia, hippocampus, brainstem nuclei, and cerebellum:
 - *Bilirubin-induced neurologic dysfunction (BIND)* caused by increasingly severe hyperbilirubinemia from mild dysfunction to acute bilirubin encephalopathy (ABE) and kernicterus.
 - *ABE* describes the acute manifestations of bilirubin toxicity seen in the 1st wk after birth.
 - *Kernicterus*: Chronic form of BIND, with significant mortality or permanent sequelae including choreoathetoid type of cerebral palsy, gaze abnormalities, hearing loss, and dental dysplasia.
 - Rate of progression of BIND depends on rate of increase of bilirubin levels, duration of hyperbilirubinemia, albumin-binding reserves, unbound bilirubin level, host susceptibility, and comorbidities.
 - Death is due to respiratory failure and progressive coma or intractable seizures.
- Risk factors for severe hyperbilirubinemia:
 - Jaundice observed in 1st 24 hr
 - Predischarge total serum bilirubin (TSB) or transcutaneous bilirubin (TcB) (see “Diagnosis”) in high-risk or high–intermediate-risk zone
 - Lower gestational age, 35–38 wk
 - Exclusive breastfeeding, especially if inadequate with excessive weight loss
 - Isoimmune or other hemolytic disease
 - Sibling with neonatal jaundice

- Cephalohematoma or excessive bruising
- Ethnicity: East Asian
- Severe hyperbilirubinemia is associated with perinatal factors: Low birth weight, macrosomia from maternal diabetes, infection, polycythemia
- Hyperbilirubinemia neurotoxicity risk factors:
 - Isoimmune hemolytic disease
 - G6PD deficiency
 - Asphyxia
 - Sepsis
 - Acidosis
 - Albumin < 3 mg/dL
- Postphototherapy (post-PT) bilirubin rebound to bilirubin levels of concern may occur:
 - At high risk are newborns < 37 wk gestation, patients with hemolytic disease, patients treated for < 72 hr.

ETIOLOGY

- Unconjugated hyperbilirubinemia:
 - Physiologic jaundice
 - Jaundice in breastfed infants:
 - *Breastfeeding failure jaundice*: Exaggeration of physiologic jaundice due to inadequate ingestion/production of sufficient volume of breast milk in the 1st wk of life
 - *Breast milk jaundice*: Begins days 3–5, peaks within 2 wk but lasts up to 8 wk; caused by increased β -glucuronidase in breast milk
 - May be exacerbated by dehydration
 - Specific hemolytic conditions:
 - Blood group isoimmunization due to ABO, Rh, and minor blood group incompatibility; ABO is most common: Rh disease is unusual (RhoGAM prevents).
 - Red cell enzyme deficiencies: G6PD deficiency
 - Red cell membrane defects: Hereditary spherocytosis and elliptocytosis
 - Sepsis: Bacterial, viral, or protozoal
 - Birth trauma:
 - Increased heme load from resolving cephalohematoma or ecchymosis
 - Polycythemia:
 - Caused by maternal–fetal transfusion
 - Fetal–fetal transfusion
 - Infants of diabetic mothers
 - Congenital hypothyroidism
 - Defective hepatic conjugation:
 - Gilbert syndrome (familial partial defect in glucuronyl transferase)

activity) is benign.

- Crigler–Najjar syndrome (congenital absence of glucuronyl transferase), lifelong unconjugated hyperbilirubinemia
- Intestinal obstruction such as ileus, functional or anatomic, increases enterohepatic circulation
- Conjugated hyperbilirubinemia:
 - Failure of hepatic excretion of conjugated bilirubin
 - Causes include neonatal hepatitis, congenital biliary atresia, extrahepatic biliary obstruction, shock liver from neonatal asphyxia, neonatal hemosiderosis

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Sleepiness, poor intake, and inadequate urine output may be present.
- Early phase of ABE:
 - Feeding difficulties with poor suck; decreased urine output
 - Fussiness, irritability, hypotonia
 - Lethargy with altered awake–sleep pattern
- Intermediate phase of ABE:
 - High-pitched cry, irritability
 - Increased tone with backward arching of neck (retrocollis) and trunk (opisthotonos) alternating with hypotonia
 - Fever
- Signs of advanced ABE:
 - Pronounced retrocollis–opisthotonos
 - Semicoma, seizures
 - Bicycling movements

Physical-Exam

- Yellowish discoloration of skin, sclera, and body fluids due to bilirubin deposition. Indicates elevated serum bilirubin level.
- Evidence of dehydration: Mottled, prolonged capillary refill
- Increasing levels of bilirubin affect skin color progressing in cephalocaudal direction:
 - Blanch skin with digital pressure to reveal underlying skin color
 - Face: Bilirubin levels > 6–8 mg/dL
 - Feet: Bilirubin levels > 12–15 mg/dL
 - Visual diagnosis of jaundice is unreliable, especially in darkly pigmented infants.

- Neurologic dysfunction is identified by abnormal tone—hypotonia, hypertonia, or variability; setting sun sign—sclera visible below upper eyelid.
- Clues to contributing conditions

ESSENTIAL WORKUP

- Clinical diagnosis considering risk factors
- TSB mandatory in any infant with suspected or obvious jaundice
- Initial TSB should be fractionated into indirect (unconjugated) and direct (conjugated) bilirubin

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Interpret TSB according to infant's age in hours, not days, to determine risk and need for treatment. Chart progression
- Identify TSB level or TcB
- TcB correlates well with TSB if available.
- Further evaluation is recommended for these newborns with jaundice:
 - _ Occurs in the 1st 24 hr of life
 - _ Persists beyond the 1st wk of life
 - _ TSB levels reach level to initiate *intensive* PT
 - _ Conjugated bilirubin is $> 10\%$ or > 2 mg/dL.
 - _ Any signs of ABE
- Serum albumin, electrolytes, BUN, Cr, calcium
- CBC with differential and RBC morphology
- Reticulocyte count
- Maternal and infant blood type
- Direct Coombs test on cord blood:
 - _ Hospital routines vary: Some will test newborns from all type O mothers.
 - _ If not available, direct Coombs test on infant's blood
- Sepsis evaluation in ill-appearing infant
- Further inpatient workup is directed at suspected cause:
 - _ Red cell enzyme assay: G6PD
 - _ Liver function tests
 - _ Urine-reducing substances
 - _ Metabolic or endocrine studies

Imaging

- Evaluation for obstructive liver disease (direct hyperbilirubinemia)
- MRI scan of brain with abnormal globus pallidus is pathognomonic of kernicterus; not indicated for emergency management.

DIFFERENTIAL DIAGNOSIS

- See “Etiology.”
- Essential to differentiate unconjugated from conjugated hyperbilirubinemia.

TREATMENT

ALERT

- Severe newborn hyperbilirubinemia with signs of encephalopathy requires immediate treatment, as outcome is related in part to duration of exposure.
- Initiate PT when TSB exceeds threshold level based on age-in-hours nomogram and risk factors.

INITIAL STABILIZATION/THERAPY

0.9% normal saline 20 mL/kg bolus if signs of volume depletion.

ED TREATMENT/PROCEDURES

- Treatment guidelines for infants ≥ 35 wk gestation based on TSB plotted vs. age in hours for infants by risk group (below).
- Higher risk are 35–37 6/7 wk + risk factors.
- Medium risk are ≥ 38 wk + risk factors, or 35–37 6/7 wk and well.
- Lower risk are ≥ 38 wk and well.
- Risk factors: Isoimmune hemolytic disease, G6PD deficiency, asphyxia, significant lethargy, temperature instability, sepsis, acidosis, albumin < 3 g/dL
- Depending upon the risk group, hospitalization for *intensive* PT is indicated when TSB (mg/dL) is above:

AGE	High	Medium	Low
12 hr	6	7.5	9
24 hr	7.5	9.5	11.5
36 hr	9.5	11.5	13
48 hr	11	13	15
60 hr	12.5	14.5	16.5
72 hr	13.5	15	18
96 hr	14.5	17	20
5–7 days	15	18	21

- BiliTool is an online calculator (<http://bilitool.org/>) for risk stratification.
- *Intensive* PT involves use of high level of irradiance delivered to as much of infant’s surface area as possible (overhead light source and *bili blanket* beneath) per light source manufacturer. Eyes must be shielded.

- *Intensive* PT should decrease TSB > 0.5 mg/dL/h. Begin as soon as possible.
- Indications for *exchange transfusions* (ET) are also determined by age in hours and risk stratification, and lack of response to PT in consultation with neonatology. Exchange requires irradiated blood and albumin infusion.
- *ET* is often recommended regardless of TSB level if infant shows signs of ABE. NICU admission and monitoring.
- If isoimmune hemolytic disease, consider IV immunoglobulin 0.5–1 g/kg over 2 hr if TSB level is nearing exchange criteria.
- If any delay in admission/transfer, initiate *intensive* PT in ED.
- Treat comorbid disease (sepsis, liver dysfunction, polycythemia, hypothyroidism)
- Encourage increased frequency of feeding with breast milk or formula; supplemental dextrose–water is not useful. May need to enter supplementation or IV fluids.
- *Breastfeeding failure and breast milk jaundice*:
 - Most infants can continue to breastfeed.
 - Encourage mothers to nurse at least 8–12 times per day for 1st several days.
 - Supplementation with formula and/or IV fluids may be temporarily required.
 - 2–3 day cessation of breastfeeding is recommended for infants with breast milk jaundice and levels not responding to PT.
 - Encourage mother to maintain lactation by use of breast pump or manual expression during period of cessation.
- *Physiologic jaundice*: Reassurance and arrange appropriate follow-up

MEDICATION

First Line

IV immunoglobulin 0.5–1 g/kg over 2 hr in isoimmune hemolytic disease if TSB level is nearing exchange criteria and not responding to intensive PT.

Second Line

- Phenobarbital increases bilirubin conjugation and excretion slowly; may adversely impact cognitive development; not routinely used
- Ursodeoxycholic acid increases bile flow and is useful in the treatment of cholestatic jaundice.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Infants requiring *intensive* PT

- Evidence of significant anemia, sepsis, dehydration, or evidence of obstructive liver disease requires hospitalization for diagnostic evaluation and treatment
- Rapid transport to NICU; transport PT if transport time > 30 min

Discharge Criteria

- Stable infant with hyperbilirubinemia not requiring PT
- Stable term infant with uncomplicated nonhemolytic hyperbilirubinemia with no risk factors and TSB 2–3 mg/dL below levels recommended for *intensive* PT; may have *home* PT arranged if appropriate timely follow-up can be ensured.
- Direct communication with primary care provider and neonatal consultant.

Issues for Referral

Breastfeeding failure: Lactation consultants are available at many hospitals.

FOLLOW-UP RECOMMENDATIONS

Follow-up with primary care provider:

- Within 12 hr: Stable infant with hyperbilirubinemia not requiring PT and with no risk factors
- Within 8 hr: Stable infant with uncomplicated nonhemolytic hyperbilirubinemia with home PT arranged

PEARLS AND PITFALLS

- TSB must be interpreted according to the newborn's age in hours, not days, and with regard for risk factors for severe hyperbilirubinemia.
- PT needs to be initiated when the TSB exceeds the threshold level.
- Infant feeding and hydration must be assessed and corrected.

- P59.9 Neonatal jaundice, unspecified

NEONATAL SEPSIS

Lazaro Lezcano

BASICS

DESCRIPTION

Mechanism

- Life-threatening infection of the newborn, rarely occurring as late as 3 mo of age
- Overwhelmingly bacterial:
 - Rarely viral or fungal infection
 - Organisms usually present in the maternal perineal flora
- Occurs in 3–5 newborns per 1,000 live births
- Risk factors:
 - Perinatal:
 - History of recent fever ($> 37.5^{\circ}\text{C}$)
 - UTI
 - Chorioamnionitis
 - Prolonged rupture of membranes (> 18 hr)
 - Foul lochia
 - Uterine tenderness
 - Intrapartum asphyxia
 - Neonatal:
 - Prematurity
 - Fetal tachycardia (> 180 beats/min)
 - Male
 - Twinning (especially 2nd twin)
 - Developmental or congenital immune defects
 - Administration of IM iron
 - Galactosemia
 - Congenital anomaly (urinary tract, asplenia, myelomeningocele, sinus tract)
 - Omphalitis

ETIOLOGY

Sepsis

- Bacterial:
 - Group B Streptococcus
 - *Escherichia coli*
 - *Listeria monocytogenes*

- Coagulase-negative Staphylococcus
- *Treponema pallidum*
- Viral:
 - Herpes simplex is a common viral etiology.
 - Enterovirus
 - Adenovirus
- Fungi:
 - *Candida* species
- Protozoa:
 - Malaria
 - *Borrelia*

Meningitis

- Bacterial:
 - Group B Streptococcus
 - *E. coli* type K1
 - *L. monocytogenes*
 - Other streptococci
 - Nontypeable *Haemophilus influenzae*
 - Coagulase-positive and coagulase-negative Staphylococcus
 - Less commonly: Klebsiella, Enterobacter
 - *Pseudomonas*, *T. pallidum*, and *Mycobacterium tuberculosis*
 - *Citrobacter diversus* (important cause of brain abscess)
 - *Additional pathogens: Mycoplasma hominis* and *Ureaplasma urealyticum*
- Viral:
 - Enteroviruses
 - Herpes simplex virus (type 2 more commonly)
 - Cytomegaloviruses
 - *Toxoplasma gondii*
 - Rubella
 - HIV
- Fungi:
 - *Candida albicans* and other fungi

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Nonspecific history:
 - “Not acting normal”
 - Feeding poorly

- Irritable or lethargic
- General:
 - Toxic appearing
 - Altered mental status: Irritable or lethargic
 - Apnea or bradycardia
 - Mottled, ashen, cyanotic, or cool skin

Physical-Exam

- Vital signs:
 - Hyperthermia/hypothermia
 - Tachypnea
 - Tachycardia
 - Prolonged capillary refill time
- Abdominal distention
- Jaundice
- Bruising or prolonged bleeding
- Sepsis syndrome in the neonate:
 - Septic shock
 - Hypoglycemia
 - Seizures
 - Disseminated intravascular coagulation (DIC)
 - If untreated, cardiovascular collapse and death

ESSENTIAL WORKUP

- Sepsis evaluation followed by empiric antibiotics and support
- Determine a source for the infection.
- Identify metabolic abnormalities.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Bedside glucose determination
- CBC:
 - WBCs elevated or suppressed
 - Shift to the left
 - Thrombocytopenia
- C-reactive protein (CRP)
- Urinalysis
- Cultures as soon as the diagnosis is entertained:
 - Blood, CSF, catheterized or suprapubic urine, stool
- Lumbar puncture:
 - May need to delay if hemodynamically unstable
 - Cell count, protein, glucose, culture, Gram stain

- Serum glucose needed to exclude hypoglycemia
- Arterial blood gas and oximetry
 - Metabolic acidosis is common.
- Electrolytes and calcium:
 - Hyponatremia
 - Hypocalcemia
- DIC panel:
 - Coagulopathy is a late complication.
 - Monitor PT, PTT and fibrinogen-split products

Imaging

CXR to rule out pneumonia

DIFFERENTIAL DIAGNOSIS

- Heart disease:
 - Hypoplastic left heart syndrome
 - Myocarditis
- Metabolic disorders:
 - Hypoglycemia
 - Adrenal insufficiency (congenital adrenal hyperplasia)
 - Organic acidoses
 - Urea cycle disorders
- Intussusception
- Child abuse
- CNS:
 - Intracranial hemorrhage
 - Perinatal asphyxia
- Neonatal jaundice
- Hematologic emergencies:
 - Neonatal purpura fulminans
 - Severe anemia
 - Methemoglobinemia
 - Malignancy (congenital leukemia)

TREATMENT

PRE HOSPITAL

Cautions

- Ventilatory support if obtunded, apneic, or respiratory distress
- IV access
- Continuous monitoring

ED TREATMENT/PROCEDURES

- Implement empiric treatment for neonatal sepsis if presentation at all consistent, particularly if any risk factors are present.
- Administer antibiotics:
 - Ampicillin and gentamicin or cefotaxime
 - Add vancomycin if the patient's condition continues to deteriorate or any suggestion of *Streptococcus pneumoniae*.
 - Cefotaxime may be substituted for gentamicin.
- Support for septic shock if present

MEDICATION

- Ampicillin: 200 mg/kg/d q6h IV/IM for infant > 2 kg birth weight and > 2 wk old; 150 mg/kg/d q8h if < 7 days old
- Cefotaxime: 150 mg/kg/d q6h IV/IM for infants > 2 kg birth weight and > 1 wk old; 150 mg/kg/d q8h IV/IM if 8–28 days old; 100 mg/kg/d IV/IM q12h if 0–7 days old
- Gentamicin: 2.5 mg/kg/dose q8h IV/IM if postconceptual age > 37 wk and > 7 days old; 2.5 mg/kg/dose q12h if < 7 days old
- Vancomycin: 15 mg/kg/dose IV q8h if postconceptual age > 37 wk and > 7 days old; 15 mg/kg IV q12h if < 7 days old

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with suspected sepsis are admitted to the hospital for supportive care, IV antibiotic therapy, and close monitoring.
- All children < 1 mo with a fever are generally admitted even in the absence of significant suspicion of sepsis. Older children are admitted based upon the clinical presentation.

Initial Stabilization

- Airway management indicated if obtundation, apnea, or respiratory distress
- IV access to administer fluids and pressors as needed
- Continuous monitoring

- P36.9 Bacterial sepsis of newborn, unspecified

NEPHRITIC SYNDROME

Maureen L. Joyner

BASICS

DESCRIPTION

- Acute glomerulonephritis (AGN) is acute inflammatory damage to glomerulus, associated with:
 - Abrupt onset of hematuria with or without RBC casts
 - Acute renal failure manifested by edema, hypertension, azotemia, decline in urine output
 - Variable proteinuria
 - Active urine sediment (RBC casts)
- Exact mechanism of AGN unclear:
 - Combination of autoimmune reactivity to specific antigens at renal glomeruli
 - Characterized by crescent formation secondary to nonspecific injury at the glomerular wall

ETIOLOGY

- Poststreptococcal glomerulonephritis (PSGN):
 - A postinfectious cause of acute nephritic syndrome, resulting from group A β -hemolytic streptococci
 - Considered a nonsuppurative complication (antibiotic treatment does not prevent this complication)
 - Occurs when immune complexes create hump-shaped subepithelial deposits in renal glomeruli
 - Most commonly affects patients between ages 3 and 15 yr but can occur at any age
 - Incidence of nephritis is 5–10% after pharyngitis and 25% after skin infections.
 - Consider PSGN in the setting of new-onset proteinuria, RBC casts, edema, and any recent infection.
 - Latent period between infection and onset of nephritis helps differentiate between PSGN and IgA nephropathy:
 - 1–3 wk in pharyngeal infection
 - 2–4 wk in cutaneous infection
 - Renal biopsy is usually not necessary for diagnosis.
 - Low complement (C3) for 6–8 wk
 - Can progress to severe renal failure if underlying infection goes untreated
 - Prognosis:

- Excellent; > 95% recover spontaneously with normalization of renal function within 6–8 wk, even with dialysis.
- Hematuria usually resolves in 3–6 mo.
- Transient nephrotic phase in 20% of patients during resolution of illness
- End-stage renal disease occurs < 5%
- Rapidly progressive glomerulonephritis (RPGN) is rare, occurring in < 1% cases.
- Most cases resolve spontaneously with no long-term sequelae.
- Other infectious sources of glomerulonephritis (GN):
 - Sepsis, pneumonia, endocarditis, viruses, HIV
 - Pulmonary, intra-abdominal, or cutaneous infections
 - Syphilis, leprosy, schistosomiasis, and malaria
 - Goal: Treat underlying infection.
- Hepatitis virus–related glomerular disease:
 - Can present with either nephritic or nephrotic symptoms
 - Causes membranoproliferative GN
 - Complements remain low indefinitely (compared to PSGN)
- Noninfectious causes of GN (due to immune complex formation):
 - Systemic lupus erythematosus, Henoch–Schönlein purpura, vasculitis, Wegener granulomatosis
 - Goodpasture syndrome
- IgA nephropathy (IgA-N)
 - Most common cause of AGN (> 25%) worldwide
 - Antibody–antigen causes immune complex deposition of IgA and C3
 - Complement levels are usually normal.
 - IgA-N has different presentations:
 - Gross hematuria following upper respiratory infection (URI)
 - Microscopic hematuria with proteinuria
 - Hematuria during viral illness or after exercise
 - Prognosis is related to serum creatinine, BP, and proteinuria.
 - 50% of patients with proteinuria may develop progressive renal disease.
 - ACE inhibitors or angiotensin-receptor blockers (ARBs) may help
- RPGN:
 - Certain patients with AGN may progress rapidly to renal failure.
 - Hallmarks are crescents on renal biopsy.
- Hereditary nephritis
 - Alport syndrome

SIGNS AND SYMPTOMS

- Hematuria:
 - Abrupt onset gross hematuria in 30–40% (coffee- or cola-colored urine)
- Edema:
 - Periorbital edema
 - Generalized edema more common in infants and children
- Infectious source or recent infection: Upper respiratory tract or skin common, e.g., PSGN
- Symptoms of congestive heart failure:
 - 40% occurrence in patients > 60 yr
 - Rare in children
- Arthritis, arthralgias, and various skin rashes: PSGN, systemic disease
- Nonspecific manifestations:
 - Malaise
 - Weakness
 - Anorexia
 - Nausea/vomiting

History

- Recent URI or skin or other infection
- Change in urine color

Physical-Exam

- Hypertension
- Edema

ESSENTIAL WORKUP

Urinalysis with sediment evaluation to detect:

- RBCs, proteinuria, and RBC casts
- RBC casts are diagnostic of an active glomerular inflammation.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - Anemia (seen in more chronic cases of GN or other systemic disease)
 - Acute leukocytosis (may suggest infectious process)
- Basic metabolic panel:
 - Assess baseline renal function
 - Check for electrolyte abnormalities
 - GFR will be normal or nearly normal
- Urinalysis:
 - RBCs +/- casts, protein

- Serum albumin
- Cultures (throat, skin, urine, blood):
 - As clinically suspected for infectious source
 - Streptozyme
- Serum complement level (C3): Decreased in infectious endocarditis, shunt nephritis, and PSGN
- Streptococcal antibodies:
 - Antistreptolysin (ASO), antistreptokinase (ASK), antideoxyribonuclease B (ADNase B), antinicotinyl adenine dinucleotidase (ANADase), and antihyaluronidase (AH)
 - ASO more reactive in pharyngeal infections
 - ADNase B, ANADase, and AH more reactive in cutaneous infections
 - ASK elevated in recent hemolytic Streptococcus infections
 - Titers do not correlate with prognosis of disease
- Urine osmolality, sodium, creatinine
- 24-hr urine collection:
 - Proteinuria initially present in 5% of children, 20% of adults with PSGN

Imaging

- Renal ultrasound: Kidney size abnormality
- Chest radiograph: Cardiomegaly, pulmonary edema, infection

Diagnostic Procedures/Surgery

Renal biopsy:

- Generally not done for PSGN, as symptoms typically resolve after a brief illness
- Recommended if atypical features of PSGN, persistently abnormal complement levels, persistent hypertension, and proteinuria > 3 g/d
- Facilitates diagnosis for other causes of nephritis

DIFFERENTIAL DIAGNOSIS

- (See “Glomerulonephritis” for further information on types of GN)
- Renal:
 - Primary glomerular disease
- Systemic:
 - Goodpasture syndrome
 - Vasculitis
 - Henoch–Schönlein purpura
- Other (rare):
 - Hemolytic-uremic syndrome
 - Thrombotic thrombocytopenic purpura
 - Acute hypersensitivity interstitial nephritis
 - Serum sickness

TREATMENT

PRE HOSPITAL

Support ABCs

INITIAL STABILIZATION/THERAPY

ABCs

ED TREATMENT/PROCEDURES

- Antibiotics for streptococcal infection:
 - Penicillin (erythromycin, if penicillin allergic)
- Restrict salt and fluid intake
- Administer loop diuretics (furosemide)
- Restore urine flow in oliguric patients:
 - Mannitol
- Treat pulmonary edema:
 - Oxygen
 - Morphine
 - Loop diuretics
- Stabilize BP to decrease proteinuria, retard progression of GN:
 - ACEIs, ARBs
 - Hypertensive emergency: Nitroprusside or other titratable antihypertensive medication
- Hemodialysis for:
 - Severe hyperkalemia
 - Fluid overload
 - Uremia
 - Severe acidosis
 - Correct electrolyte abnormalities

MEDICATION

- Erythromycin: 250–500 mg (peds: 30–50 mg/kg/d) PO q6h for 7–10 days
- Furosemide: 20–80 mg (peds: 1–6 mg/kg) PO daily/BID
- Lisinopril (ACEI): 10–40 mg (peds: > 6 yr: 0.07 mg/kg) PO daily
- Losartan (ARB): 25–100 mg (peds: > 6 yr: 0.7 mg/kg) PO daily
- Mannitol: 12.5–100 g (peds: 0.25–0.5 g/kg) IV:
 - May use single or repeat dosing; consider test dosing 1st.
- Morphine sulfate: 0.1 mg/kg/dose IV q4h
- Nitroprusside: 0.3–4 µg/kg/min IV
 - Titrate to goal mean arterial pressure for hypertensive emergency.
- Penicillin:
 - Benzathine penicillin: 1.2 million U (peds: 0.3–0.9 million U, based on weight) IM as single dose

- Penicillin VK: 250–500 mg (peds: < 12 yr 25–50 mg/kg/d) PO q6–8h for 10 days
- Other agents, including fish oil (ω -3 fatty acids for anti-inflammatory effects) and immunosuppressive agents (glucocorticoids, cyclophosphamide), may be used in consultation with specialists.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Evidence of infectious cause for GN
- Oliguria, anuria
- Uremia
- Elevated creatinine
- Edema
- Electrolyte abnormalities
- Severe hypertension
- CHF

Discharge Criteria

Mild cases of clinical nephritis in healthy patients with:

- No comorbid illness
- Strict supervision/monitoring of symptoms, diet, urine output, and medication
- Close follow-up with PMD and nephrology referral

Issues for Referral

Nephrology:

- Within 2–3 days

FOLLOW-UP RECOMMENDATIONS

- Adherence to antibiotic and antihypertensive therapy, as indicated
- Restrict salt and fluid intake.

PEARLS AND PITFALLS

- Diagnosis is confirmed by biopsy showing characteristic crescent formation within renal glomeruli.
- Must obtain thorough history of ongoing or recent infections as possible etiology of nephritis
- IgA nephropathy is most common cause of nephritis.
- Patients require aggressive management of BP and volume status.

ADDITIONAL READING

- Ikee R, Kobayashi S, Saigusa T, et al. Impact of hypertension and hypertension-related vascular lesions in IgA nephropathy. *Hypertens Res.* 2006;29(1):15–22.

CODES

ICD9

- 580.0 Acute glomerulonephritis with lesion of proliferative glomerulonephritis
- 580.9 Acute glomerulonephritis with unspecified pathological lesion in kidney
- 583.2 Nephritis and nephropathy, not specified as acute or chronic, with lesion of membranoproliferative glomerulonephritis

ICD10

- N00.9 Acute nephritic syndrome with unsp morphologic changes
- N01.9 Rapidly progr nephritic syndrome w unsp morphologic changes
- N05.9 Unsp nephritic syndrome with unspecified morphologic changes

NEPHROTIC SYNDROME

Maureen L. Joyner

BASICS

DESCRIPTION

- Diseases causing defect in glomerular filtration barrier, producing proteinuria:
 - Proteinuria > 3 g in 24 hr
 - Hypoalbuminemia (serum albumin < 3 g/dL)
 - Peripheral edema due to hypoalbuminemia
 - Hypogammaglobulinemia
 - Hyperlipidemia (fasting cholesterol > 200 mg/dL)
- Urine fat (oval fat bodies, fatty/waxy casts)
- Glomerular basement membrane altered by:
 - Immune complexes
 - Nephrotoxic antibodies
 - Nonimmune mechanisms
 - Result: More permeable glomerular membranes and excretion of albumin and large proteins

PATHOPHYSIOLOGY

- Proteinuria due to increased filtration within renal glomeruli
- Edema due to sodium retention and hypoalbuminemia
- Postural hypotension, syncope, and shock due to severe hypoalbuminemia
- Hyperlipidemia due to hepatic lipoprotein synthesis stimulated by decreased plasma oncotic pressure
- Cumulative thromboembolism risk increased if:
 - Hypovolemia
 - Low serum albumin
 - High protein excretion
 - High fibrinogen levels
 - Low antithrombin III levels

ETIOLOGY

- Due to primary renal or systemic diseases
- Membranous nephropathy:
 - Primary cause of nephrotic syndrome in adults
 - Other causes include chronic infection (hepatitis B virus, hepatitis C virus, autoimmune disorders).
 - Renal biopsy shows involvement of all glomeruli.
 - Women have better prognosis.
 - 30% may slowly progress to renal failure.

- Renal vein thrombosis causes sudden loss of renal function.
- Treat with steroids and cytotoxic agents in severe cases.
- Minimal change disease:
 - Most common cause (90%) of nephrotic syndrome in children
 - Other causes: Idiopathic, NSAIDs, paraneoplastic syndrome associated with malignancy (often Hodgkin lymphoma)
 - Best prognosis among all nephrotic syndromes
 - Good response to steroids
- Focal segmental glomerulosclerosis (FSGS):
 - Young patients (15–30 yr) with nephrotic syndrome
 - Presents with high BP, renal insufficiency, proteinuria, microscopic or gross hematuria.
 - Causes include HIV, heroin abuse, obesity, hematologic malignancies.
 - Primary FSGS responds to steroids.
 - Secondary FSGS treated with ACE inhibitors (ACEI)
 - Collapsing FSGS usually seen in HIV patients
- Membranoproliferative glomerulonephritis:
 - May present with nephrotic, non-nephrotic, or nephritic sediment
 - Complement levels are persistently low
 - Supportive care: Steroids may be helpful in children.
 - Aspirin and dipyridamole may slow progression.
- Diabetes mellitus/diabetic nephropathy:
 - Most common secondary cause of nephrotic range proteinuria in adults
 - Microalbuminuria (30–300 mg/24hr) is primary indicator of renal disease.
 - Worsening of renal function in 5–7 yr
 - Does not cause rapid decline in renal function
 - Strict control of blood sugar and ACEI therapy slow progression.
- Monoclonal gammopathies:
 - Include amyloidosis, multiple myeloma, and light-chain nephropathy
 - Renal manifestations include proteinuria, nephrotic syndrome, nephritic syndrome, and acute renal failure.
 - Lab findings include pseudo hyponatremia, low anion gap, hypercalcemia, and Bence Jones proteinuria.
 - Congo red stain of amyloid shows apple green birefringence in polarized light.
 - Supportive care: Steroids and melphalan have some benefit.
- Systemic lupus erythematosus (SLE):
 - Can present initially as a nephritic process, with progression to nephrotic syndrome
- HIV-associated nephropathy:
 - FSGS is most common nephropathy.
 - Collapsing glomerulopathy in seropositive HIV carriers with supernephrotic syndrome results in end-stage renal failure that is rapidly progressive

(months).

- Other causes include pre-eclampsia, hepatitis, and drug reactions (culprits include NSAIDs, gold, penicillamine).

DIAGNOSIS

SIGNS AND SYMPTOMS

- Many patients are asymptomatic.
- Proteinuria
- Peripheral edema:
 - Mild pitting edema to generalized anasarca with ascites
- Hyperlipidemia
- Lipiduria (urine fatty casts and oval fat bodies)
- Postural hypotension, syncope, shock
- Hypertension
- Hematuria:
 - Microscopic or gross hematuria (secondary to renal vein thrombosis)
- Renal insufficiency to acute renal failure in some cases
- Tachypnea, tachycardia, with or without hypotension:
 - Acute onset: Suggests pulmonary embolus (PE), secondary to renal or deep venous thrombosis and hypercoagulable state
 - Up to 30% occurrence of PE in membranous glomerulonephritis
 - Chronic or exertional tachypnea due to:
 - Pulmonary edema
 - Pleural effusions
 - Infection risk due to immunosuppressive treatment and frequent exposure to infections such as Pneumococcus
 - Ascites
- Protein malnutrition

History

- Systemic disease such as diabetes, SLE, HIV
- Use of NSAIDs, gold, or penicillamine
- History of unintentional weight gain (due to fluid retention)
- History of “foamy” appearance of urine

Physical-Exam

Varies depending on degree of hypoalbuminemia, hemodynamic status, and etiology of nephrotic syndrome:

- Edema
- Hypotension/hypertension
- Shock

ESSENTIAL WORKUP

Urinalysis:

- Dipstick protein largely positive:
 - Urine specific gravity > 1.025 lowers the diagnostic significance of proteinuria.
- Microscopic analysis for urinary casts and the presence of cellular elements:
 - Oval fat bodies
 - Free lipid droplets

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC + differential:
 - Anemia common
 - Leukocytosis: Infection
 - Leukopenia: Neoplastic disease or sepsis
 - Thrombocytopenia: Liver disease
- PT/PTT, international normalized ratio:
 - Coagulation profiles abnormal with concurrent liver disease
- D-dimer, fibrinogen, antithrombin III
 - Suspected thromboembolic event:
 - Often patients are asymptomatic with PE or renal vein thrombosis; therefore need high clinical suspicion.
- 24-hr urine protein, total protein to creatinine ratio
- Serum albumin: < 3 g/dL
- Serum total protein
- Basic metabolic panel with Ca, Mg, P
- Lipid profile: Elevated total cholesterol, LDL, and VLDL
- Additional lab tests may be necessary for systemic diseases:
 - Examples include antinuclear antibody, serum and urine protein electrophoresis, hepatitis profile, syphilis, cryoglobulins, complement levels

Imaging

Renal US:

- Used in suspected secondary causes of nephrotic syndrome

Diagnostic Procedures/Surgery

- Renal biopsy:
 - Definitive test for patients who do not respond to a short course of corticosteroids
 - Helps discern primary vs. secondary pathology
- Renal angiography, CT scan, or MRI for suspected renal vein thrombosis

DIFFERENTIAL DIAGNOSIS

Proteinuria resulting from other causes:

- Renal parenchymal disease:
 - Chronic renal disease
 - Mechanical nephropathy (outlet obstruction/reflux)
 - Acute pyelonephritis
 - Sickle cell disease
- Other causes:
 - CHF
 - Essential hypertension
 - Acute febrile illness
 - Pregnancy (pre-eclampsia)
 - Severe obesity

TREATMENT

PRE HOSPITAL

Support ABCs

INITIAL STABILIZATION/THERAPY

ABCs:

- Supplemental oxygen if respiratory distress
- IV fluids:
 - For decreased BP or orthostatic hypotension due to decreased intravascular volume
 - Active rehydration in the presence of severe hypotension, shock

ED TREATMENT/PROCEDURES

- Control edema:
 - Restrict sodium intake: 2 g NaCl/d
 - Loop diuretic (furosemide): Titrate dose until response seen
 - Thiazides and potassium-sparing diuretics
 - Goal: *Slow* diuresis:
 - Aggressive diuresis can precipitate acute renal failure due to hypovolemia and increase the risk of thromboembolic complications.
- Thromboembolic prevention/treatment:
 - Heparin: 80 IU/kg bolus followed by 18 IU/kg drip IV for thromboembolic event
 - Prophylactic anticoagulation now considered acceptable when level of hypoalbuminemia is extremely low (< 2.5 g/dL): Goal INR 1.8–2
 - Consider low-dose aspirin 81 mg
 - Support stockings

- Plasmapheresis, for severe cases
- Glucocorticosteroid: Mainstay of treatment for primary nephrotic syndrome
- ACEIs/ARBs: Decreases proteinuria, prevents worsening of renal function:
 - Adverse effects of ACEI include renal failure and hyperkalemia.
- Cholesterol-lowering agents/dietary manipulation (e.g., bile acid resin, statins)
- Other agents to be considered, under supervision of a specialist:
 - Cytotoxic agents/cyclosporine
 - Recombinant erythropoietin for anemia

MEDICATION

- Enoxaparin (Lovenox): 30–40 mg (peds: 0.5–0.75 mg/kg) SC q12h
- Furosemide: 20–80 mg (peds: 1–6 mg/kg) PO daily/BID
- Heparin: 80 IU/kg bolus followed by 18 IU/kg/h drip IV
- Lisinopril (ACEI): 10–40 mg (peds: > 6 yr: 0.07 mg/kg) PO daily
- Losartan (ARB): 25–100 mg (peds: > 6 yr: 0.7 mg/kg) PO daily
- Metolazone: 5–20 mg (peds: 0.2–0.4 mg/kg) PO daily
- Prednisone: 5–60 mg (peds: 0.5–2 mg/kg) PO daily

FOLLOW-UP

DISPOSITION

Admission Criteria

- Moderate to severe heart failure, ascites, respiratory compromise
- Signs of comorbid illness, such as undiagnosed malignancy, poorly controlled diabetes, immunocompromised patients
- Acute renal failure
- Evidence of thromboembolic event

Discharge Criteria

- Patients with no comorbid disease, normal vital signs, and normal blood work
- Close follow-up with a nephrologist for further evaluation and treatment is mandatory.

Issues for Referral

Nephrology:

- Routine follow-up for BP and disease management
- Renal biopsy for appropriate patients

FOLLOW-UP RECOMMENDATIONS

- In addition to nephrology, patients should follow up with rheumatology, infectious disease, hematology/oncology, or endocrine specialist (dependent on underlying

disorder contributing to nephritic syndrome).

- Strict BP control and attention to low-cholesterol diet allow for best prognosis in long-term disease management.

PEARLS AND PITFALLS

- Characterized by proteinuria, hypoalbuminemia, and peripheral edema
- Most common causes are minimal change disease in pediatric patients and diabetic nephropathy in adults.
- May present along spectrum from hypertensive to severe hypotension and shock; maintain high index of suspicion in the appropriate setting.
- Consider associated risks of thromboembolic disease.

NEUROLEPTIC MALIGNANT SYNDROME

Daniel L. Beskind

BASICS

DESCRIPTION

- Life-threatening neurologic disorder most often caused by an adverse reaction to a neuroleptic or antipsychotic medication.
- Mortality can be as high as 20%
- May develop any time during therapy with neuroleptics—from a few days to many years:
 - Most often occurs in the 1st mo of therapy
- Muscular rigidity and tremor resulting from dopamine blockade in the nigrostriatal pathway
- Hyperthermia due to central dopamine receptor blockage in the hypothalamus.
- More likely in the setting of benzodiazepine withdrawal
- May be indistinguishable from other causes of drug-induced hyperthermia (malignant hyperthermia, serotonin syndrome, anticholinergic toxins, or sympathomimetic poisoning)
- Most episodes resolve within 2 wk after cessation of offending agent.
- Diagnostic criteria:
 - Development of elevated temperature and severe muscle rigidity in association with use of antipsychotic/neuroleptic medication
 - 2 or more of the following:
 - Diaphoresis
 - Dysphagia
 - Tremor
 - Incontinence
 - Altered mental status (range from confusion to coma)
 - Mutism
 - Tachycardia
 - Elevated labile BP
 - Leukocytosis
 - Lab evidence of muscle injury
 - Symptoms are not caused by another disease process

ETIOLOGY

- Rare complication of treatment with neuroleptics:
 - Phenothiazines
 - Chlorpromazine (Thorazine)
 - Fluphenazine (Modecate)

- Prochlorperazine (Compazine)
- Promethazine (Phenergan)
- Metoclopramide (Reglan)
- Butyrophenones
 - Haloperidol
 - Droperidol
- Atypical antipsychotics
 - Risperidone (Risperdal)
 - Olanzapine (Zyprexa)
 - Quetiapine (Seroquel)
 - Clozapine (Clozaril)
 - Aripiprazole (Abilify)
- Occurs in ~1% of patients treated with neuroleptics (especially haloperidol)
- Has also been associated with abrupt withdrawal from dopamine agonists in Parkinson disease
- SSRIs or lithium along with neuroleptic medication may be associated with an increased risk
- Risk factors:
 - Rapid drug loading
 - High-dose antipsychotics
 - High-potency antipsychotics
 - IV administration of drug
 - Dehydration
 - Prior neuroleptic malignant syndrome (NMS)
 - Preceding extreme psychomotor agitation or catatonia
 - Infection or surgery

DIAGNOSIS

SIGNS AND SYMPTOMS

- Life-threatening condition
- Hallmarks of the disease:
 - Hyperthermia (temperature may be as high as 106–107°F, 41°C)
 - Altered level of consciousness—stupor
 - Significant skeletal muscle rigidity—”lead-pipe rigidity.”
 - Autonomic instability
 - Tachycardia
 - Labile BP
 - Tachypnea
 - Profuse sweating
 - Dysrhythmias

History

- Neuroleptic use
- Discontinuation of antiparkinsonian drugs
- Change in mental status

Physical-Exam

- Fever
- Tachycardia, labile BP
- Delirium
- Muscle rigidity
- Diaphoresis

ESSENTIAL WORKUP

- An accurate history (especially current medications) and physical exam confirm the diagnosis.
- Creatine phosphokinase, WBC determination, liver function tests, and iron level

DIAGNOSIS TESTS & NTERPRETATION

Lab

- Electrolytes, glucose
- BUN, creatinine
- PT/PTT, urinalysis, and urine myoglobin
- Creatine kinase
- LFTs (lactate dehydrogenase, aspartate transaminase, alkaline phosphatase, etc.)
- Venous blood gas (VBG)

Imaging

CT scan, EEG if the cause of altered level of consciousness is unclear

Diagnostic Procedures/Surgery

Lumbar puncture to rule out other causes of fever or altered mental status

DIFFERENTIAL DIAGNOSIS

Related disorders

- Malignant hyperthermia
- Serotonin syndrome
- Anticholinergic poisoning
- Sympathomimetic poisoning (cocaine, methamphetamine)
- Drug intoxication toxicity (PCP, ecstasy MDMA)
- Withdrawal from intrathecal baclofen therapy

Unrelated disorders

- CNS infection (meningitis, encephalitis)

- Tetanus
- Heat stroke
- Acute dystonia
- Strychnine poisoning
- Vascular CNS event
- Thyrotoxicosis
- Rabies
- Alcohol withdrawal
- Seizures
- Pheochromocytoma
- Acute porphyria
- Acute hydrocephalus
- Acute spinal cord injury
- Systemic infections (e.g., pneumonia, sepsis)

TREATMENT

PRE HOSPITAL

- Ventilation may be difficult because of chest wall rigidity
- Cool the patient and treat seizures if they occur
- Check fingerstick glucose

INITIAL STABILIZATION/THERAPY

- Airway intervention and circulatory support as needed
- IV, supplemental O₂, cardiac monitor
- Immediate IV benzodiazepines (diazepam, lorazepam, midazolam):
 - May require repeated large doses
- If symptoms are not controlled within a few minutes, rapid sequence intubation (RSI) and neuromuscular blockade are necessary:
 - Nondepolarizing neuromuscular blockers (vecuronium, rocuronium, pancuronium) are preferable to succinylcholine.
- Measures to control hyperthermia:
 - Ice packs
 - Mist and fan
 - Cooling blankets
 - Ice water gastric lavage
- Aggressive IV fluid therapy with lactated Ringer solution or normal saline

ED TREATMENT/PROCEDURES

- Relief of muscle rigidity
- Benzodiazepines are the drug of choice
- Bromocriptine is a dopamine agonist that may play a role in longer-term

management

- Dantrolene is a direct skeletal muscle relaxant that may play a role in longer-term management
- Neither bromocriptine nor dantrolene has a rapid onset and neither has been shown to alter outcome
- Amantadine has dopaminergic and anticholinergic effects and can be used as an alternative to bromocriptine
- Discontinue neuroleptics
- Recognize complications (rhabdomyolysis, respiratory failure, acute renal failure)

MEDICATION

First Line

- Diazepam: 5 mg IV q5min
- Lorazepam: 1 mg IV q5min
- Midazolam 1 mg IV q5min
- Rocuronium: 600–1,200 µg/kg IV × 1 for RSI
- Pancuronium: 60–100 µg/kg IV × 1 for intubation

Second Line

- Bromocriptine: 5–10 mg PO TID–QID (start 2.5 mg)
- Dantrolene: 1 mg/kg IV q4–6h × 24–48 hr
- Amantadine: 100 mg PO BID

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with NMS should be admitted
- Patients will often require intensive care

FOLLOW-UP RECOMMENDATIONS

Patients and families must be counseled on the future use of any drug that may trigger NMS

PEARLS AND PITFALLS

- Maintain high clinical suspicion for NMS in patients on neuroleptics with mental status changes, rigidity, fever, or dysautonomia
- Must rule out other causes of fever and altered mental status (i.e., meningitis, encephalitis)

- Medication history is essential when considering NMS
- Discontinuing causative agent is the key step in treatment
- Aggressive supportive care is essential

NEUROLEPTIC POISONING

Molly C. Boyd • Timothy D. Heilenbach

BASICS

DESCRIPTION

- Neuroleptics (antipsychotics) used for management of:
 - Psychotic disorders
 - Agitation
 - Dementia in the elderly
 - Autism and behavioral problems in children
 - Eating disorders
 - Antiemetic
 - Migraine headaches
- Acute overdose:
 - Symptoms usually mild to moderate
 - CNS and cardiovascular symptoms predominate
 - CNS depression, seizure, and coma possible
- Dystonic reactions (dystonia):
 - Most common adverse effect
 - Can occur at any time, often within 48 hr of starting medication
- Akathisia:
 - Patient has motor restlessness and feels a need to pace or move constantly
 - Occurs within hours to weeks of starting medication
- Neuroleptic malignant syndrome (NMS):
 - Idiosyncratic, life-threatening event
 - Can occur at any time but most commonly in overdose, dose increase, and during the 1st wk of usage
- Tardive dyskinesia:
 - Movement disorder usually affecting patients after years of taking neuroleptics
 - Treated by decreasing, discontinuing, or changing the drug

ETIOLOGY

- Typical neuroleptics (phenothiazines, butyrophenones) strongly antagonize dopaminergic receptors, these include:
 - Haloperidol (Haldol)
 - Chlorpromazine (Thorazine)
 - Prochlorperazine (Compazine)
 - Thioridazine (Mellaril)
 - Fluphenazine (Prolixin)

- Promethazine (Phenergan)
- Droperidol (Inapsine)
- Hydroxyzine (Atarax)
- Typical neuroleptics also have varying degrees of antagonism for histamine, muscarinic, and α -adrenergic receptors.
- Atypical neuroleptics have weaker dopaminergic antagonism and moderate serotonergic antagonism, these include:
 - Asenapine (Saphris)
 - Aripiprazole (Abilify)
 - Clozapine (Clozaril)
 - Paliperidone (Invega)
 - Risperidone (Risperdal)
 - Olanzapine (Zyprexa)
 - Quetiapine (Seroquel)
 - Ziprasidone (Geodon)

DIAGNOSIS

SIGNS AND SYMPTOMS

- Acute overdose:
 - Symptom onset within 6 hr, 9 hr with aripiprazole, up to 24 hr with extended-release formulations (paliperidone)
 - Can be delayed if anticholinergic symptoms predominate
 - CNS:
 - Ranges from mild sedation to coma
 - Anticholinergic delirium possible
 - Extrapyrarnidal symptoms (dystonia, akathisia)
 - Seizures
 - Cardiovascular:
 - Tachycardia (anticholinergic)
 - Hypotension (antiadrenergic)
 - QT prolongation
 - Torsade de pointes (rare)
 - Respiratory:
 - Respiratory depression
 - Loss of airway reflexes
 - GI:
 - Constipation
 - Dry mouth
 - Genitourinary:
 - Urinary retention
- Dystonic reactions:

- Involuntary muscle spasms of face, neck, back, and limbs
- Dramatic appearance is frightening to patient and family
- Laryngeal dystonia is a rare form that may cause stridor and dyspnea.
- NMS:
 - Occurs in < 1% of patients, 30% mortality
 - Severe hyperthermia
 - Skeletal muscle rigidity
 - Altered mental status
 - Autonomic dysfunction
 - Electrolyte disturbance
 - Rhabdomyolysis
- Agranulocytosis:
 - Seen with clozapine and olanzapine
 - Occurs with chronic treatment
- Diabetes:
 - Hyperglycemia, new-onset diabetes, and DKA have all been reported with initiation of neuroleptics.

ESSENTIAL WORKUP

- Monitor vital signs with significant ingestions.
- Cardiac monitor
- Pulse oximetry
- Core body temperature for hyperthermia

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Electrolytes, BUN, creatinine, glucose, LFTs
- CBC for clozapine overdose, WBC can be elevated in NMS
- Creatine phosphokinase (CPK) levels if NMS suspected, agitation, or prolonged immobilization
- Serum drug screen with drug levels for possible coingestions based on history:
 - Aspirin
 - Acetaminophen
 - Lithium
 - Valproate
 - Phenytoin
 - Phenobarbital
- Urine toxicologic screens are rarely helpful
 - False-negatives and false-positives can be misleading
- Quantitative levels are rarely available and not helpful in acute management

Imaging

- ECG:
 - QT prolongation
 - QRS prolongation (rare)
- Head CT:
 - Indicated for significant mental status change

DIFFERENTIAL DIAGNOSIS

- Serotonin syndrome
- Malignant hyperthermia (if recent anesthesia)
- Antidepressant overdose
- Anticholinergic crisis
- Sympathomimetic overdose
- Opioid overdose
- Occult head injury
- Endocrine disorder
- Sepsis
- Heat stroke

TREATMENT

PRE HOSPITAL

Bring medication bottles when transporting patient to hospital.

INITIAL STABILIZATION/THERAPY

Airway, breathing, and circulation management (ABCs):

- Administer supplemental oxygen.
- Consider naloxone, thiamine, D₅₀ (or check blood glucose) for altered mental status
- Intubate if respiratory depression

ED TREATMENT/PROCEDURES

- Supportive care is the mainstay of treatment
- Decontamination:
 - Administer single dose of activated charcoal if ingestion within 1 hr
 - Do not give charcoal to patient with unprotected airway
 - Use NG tube for charcoal only if pt is intubated
 - Consider whole bowel irrigation if large amounts of extended-release formulation ingested (paliperidone)
 - Hemodialysis unlikely to be helpful due to high degree of protein binding
 - Consider lipid emulsion therapy for cardiovascular collapse
- Hypotension:
 - 0.9% normal saline (NS) IV fluid bolus

- Treat resistant hypotension with norepinephrine or phenylephrine
- Dopamine may be ineffective
- Ventricular dysrhythmias:
 - Class IA, IB, and III antidysrhythmics can potentiate cardiotoxicity. Lidocaine can be used in refractory cases
 - Magnesium for prolonged QT
 - Cardioversion if hemodynamically unstable
 - Consider intralipid (20% lipid emulsion) for cardiovascular collapse
 - For asymptomatic QTc prolongation, replete potassium, calcium, and magnesium to normal levels
 - QRS prolongation (>120 msec) should be treated with sodium bicarbonate therapy
- Dystonic reactions:
 - Administer diphenhydramine or benztropine mesylate.
 - Treatment should be continued for 3 days to prevent recurrence.
- NMS:
 - Recognition and cessation of neuroleptics is critical.
 - Active cooling for hyperthermia
 - Aggressive benzodiazepines for agitation
 - Severe cases may require bromocriptine (dopamine agonist) or dantrolene (a direct-acting muscle relaxant)
 - Consider intubation and neuromuscular blockade
- Seizures:
 - Treat initially with diazepam or lorazepam.
 - Phenobarbital for persistent seizures
 - There is no role for phenytoin in toxin-induced seizures
- Anticholinergic delirium:
 - Benzodiazepines are 1st-line agents
 - Physostigmine can be used with caution
 - Physostigmine is contraindicated in a patient with dysrhythmias, heart block, or interval prolongation on EKG

MEDICATION

- Activated charcoal: 1–2 g/kg PO
- Benztropine mesylate: 1–2 mg IV or PO
- Bromocriptine: 2.5–10 mg q8h PO
- Dantrolene: 2–3 mg/kg/d as continuous infusion (10 mg/kg max.)
- Diazepam: 5–10 mg IV q10–15min
- Diphenhydramine: 25–50 mg IV (1 mg/kg)
- Lidocaine 1–2 mg/kg followed by infusion
- Lipid emulsion (20%) 1.5 mL/kg bolus followed by 0.25 mL/kg/min infusion for 30–60 min, may repeat bolus for persistent hemodynamic compromise
- Lorazepam: 2–4 mg (peds: 0.03–0.05 mg/kg) IV q10–15min

- Magnesium sulfate: 1–2 g IV over 5–15 min
- Norepinephrine: 1–2 µg/kg/min IV titrate to BP
- Phenobarbital: 10–20 mg/kg IV (loading dose); monitor for respiratory depression
- Physostigmine 0.5 mg IV q3–5min

FOLLOW-UP

DISPOSITION

Admission Criteria

- Overdose with CNS sedation, agitation, dysrhythmias, or vital sign abnormalities to monitored bed or ICU
- NMS require ICU care
- New-onset diabetes (secondary to neuroleptic use) with severe hyperglycemia and/or ketoacidosis.

Discharge Criteria

- Asymptomatic after 6 hr of observation
- Longer observation required for aripiprazole and paliperidone ingestion as well as ingestion of extended release formulations

Issues for Referral

- Patients with unintentional (accidental) poisoning require poison prevention counseling.
- Patients with intentional (e.g., suicide) poisoning require psychiatric evaluation.
- New-onset diabetes requires primary care/endocrine follow-up.

FOLLOW-UP RECOMMENDATIONS

- Psychiatric referral for intentional overdoses
- Primary care follow-up for accidental ingestions or medication side effect follow-up

PEARLS AND PITFALLS

- Neuroleptics represent a group of drugs with diverse indications and a wide range of toxicity.
- Most overdoses are mild, and CNS depression predominates.
- Dystonic reactions are the most common side effect of neuroleptics. These reactions are dramatic in appearance but easily treatable.
- NMS is a potentially fatal reaction that can be seen in acute or chronic usage of neuroleptics.
- Newer antipsychotics can have delayed onset up to 24 hr.

- Contact the poison control center for further guidance

NONCARDIOGENIC PULMONARY EDEMA

Rebecca B. Gilson

BASICS

DESCRIPTION

- Noncardiogenic pulmonary edema (NCPE) occurs secondary to accumulation of excess fluid and protein into the alveoli from factors other than increased pulmonary capillary pressure > 18 mm Hg
- Permeability pulmonary edema:
 - Functional disruption of the capillary–alveolar membrane allows protein and fluid to move freely from the intravascular space into the alveolar space
- Pulmonary parenchymal changes are similar to CHF
- Concomitant CHF may occur in up to 20% of patients with acute respiratory distress syndrome (ARDS)
- Distinction between NCPE and CHF:
 - Pulmonary capillary pressure ≤ 18 mm Hg
 - Often apparent from the clinical circumstances
 - The concentration of protein in the alveolar fluid is identical to that of the intravascular space in patients with NCPE
 - Cephalad redistribution of blood flow, pulmonary effusions, and cardiomegaly are usually not present
- Adult respiratory distress syndrome:
 - Clinical presentation caused by permeability pulmonary edema
 - Associated with severe physiologic impairment
- Typically, onset of the edema is within 1–2 hr of the noxious insult.
- ~ 250,000 cases occur each year in US

ETIOLOGY

- ARDS is the #1 cause:
 - Caused by:
 - Sepsis
 - Pneumonia
 - Nonthoracic trauma
 - Inhaled toxins
 - Disseminated intravascular coagulation (DIC)
 - Radiation pneumonitis
- High-altitude pulmonary edema (HAPE) neurogenic pulmonary edema
- Narcotic overdose
- Pulmonary embolus

- Eclampsia
- Transfusion-related acute lung injury (TRALI)
- Re-expansion of a collapsed lung in patient with a pneumothorax
- Salicylate intoxication
- Inhaled cocaine use
- Near drowning
- HCTZ
- Uremia
- S/p cardiopulmonary bypass; especially if patient taking amiodarone

DIAGNOSIS

SIGNS AND SYMPTOMS

- Shortness of breath
- Fatigue
- Weakness
- Cough
- Malaise

Physical-Exam

- Scattered rhonchi and rales
- Hypoxia
- Dyspnea
- Tachypnea
- Accessory muscle use
- Tachycardia
- Pink, frothy sputum
- You will *not* see the stigmata of left- and right-sided heart failure
 - Lower-extremity swelling
 - Cardiomegaly

ESSENTIAL WORKUP

- History and physical is usually enough to distinguish between cardiogenic and NCPE
- The CXR is essential in confirming the diagnosis and in assessing severity.

DIAGNOSIS TESTS & NTERPRETATION

Lab

General lab abnormalities are not specific to NCPE.

Imaging

CXR:

- Initially can be normal
- Classic butterfly pattern of pulmonary edema
- Lack of cardiomegaly

Diagnostic Procedures/Surgery

Pulmonary artery catheter:

- Pulmonary capillary wedge pressures normal or near-normal in contrast to elevated pressures with cardiogenic pulmonary edema

DIFFERENTIAL DIAGNOSIS

- Cardiogenic pulmonary edema
- Diffuse alveolar hemorrhage
- Diffuse dissemination of cancer such as with lymphoma or leukemia
- Chronic obstructive pulmonary disease exacerbation
- Pulmonary embolus
- Restrictive lung disease
- Pneumonia

TREATMENT

PRE HOSPITAL

- Patent airway
- Adequate oxygenation
- Cautions:
 - _ Patients will typically not respond to usual measures to treat CHF.

INITIAL STABILIZATION/THERAPY

- Supplemental oxygen (nasal cannula or nonrebreather)
- IV catheter
- Continuous cardiac monitor
- Continuous pulse oximetry

ED TREATMENT/PROCEDURES

- The treatment of NCPE is to treat underlying cause and give supportive care.
- Diuretics are *not* used.
- Noninvasive ventilatory support (BiPAP, CPAP) may be used if available and patient not in respiratory distress:
 - _ If oxygenation or ventilation not improving with noninvasive, intubation is required
- Endotracheal intubation is often necessary:
 - _ Improves oxygenation and ventilation

- Decreases work of breathing
- Use low tidal volumes of 6–8mL/kg to reduce barotrauma to the lungs
- Initially place on 100% O₂:
 - o Measure PO₂ and decrease FIO₂ accordingly.
- Positive end-expiratory pressure (PEEP) of 5–10 cm H₂O
- Steroids and cyclooxygenase inhibitors have not been proven effective.
- If at high altitude and concerned for HAPE, have the patient descend in elevation or put them in a hyperbaric chamber.
 - Nifedipine is adjunctive therapy to O₂ and descent.

FOLLOW-UP

DISPOSITION

Admission Criteria

All symptomatic patients should be admitted to ICU:

- Symptoms may worsen at any point for up to 3 days after noxious insult.

Discharge Criteria

Asymptomatic patients (especially narcotic overdose, HAPE, or aspiration):

- Observe in ED for 6–12 hr and then discharge with close follow-up scheduled if no evidence of pulmonary edema is present and adequate oxygenation is demonstrated.

FOLLOW-UP RECOMMENDATIONS

Patients, when discharged from the hospital, should seek medical follow-up within 48 hr.

PEARLS AND PITFALLS

- Utilizing diuretics in the acute setting may worsen patient condition.
- Failure to distinguish between cardiogenic and noncardiogenic etiologies is a pitfall as treatment is different.

CODES

ICD9

- 506.4 Chronic respiratory conditions due to fumes and vapors
- 508.1 Chronic and other pulmonary manifestations due to radiation
- 508.9 Respiratory conditions due to unspecified external agent

ICD10

- _ J68.1 Pulmonary edema due to chemicals, gases, fumes and vapors
- _ J70.0 Acute pulmonary manifestations due to radiation
- _ J70.9 Respiratory conditions due to unspecified external agent

NONSTEROIDAL ANTI-INFLAMMATORY POISONING

Michele Zell-Kanter

BASICS

DESCRIPTION

- Inhibit cyclooxygenase (COX), thereby blocking the conversion of arachidonic acid to prostaglandin.
- Typically morbidity is low when an NSAID is ingested
- Most literature on nonselective NSAID toxicity involves ibuprofen exposure likely due to its OTC availability.
- Fatalities have been reported with large ingestions.
- Greater potential for toxicity with underlying CHF or renal failure:
 - NSAIDs cause sodium and water retention and decrease renal blood flow.
 - Little overdose experience with the COX-2 inhibitors (celecoxib); treatment should be the same as for the traditional NSAIDs.
 - Patients may ingest rofecoxib and valdecoxib from stored supplies even though both are no longer available in US

ETIOLOGY

- Nonsteroidal medications are available by prescription and over-the-counter.
- NSAIDs include:
 - Diclofenac
 - Diflunisal
 - Etodolac
 - Fenoprofen
 - Ibuprofen
 - Indomethacin
 - Ketoprofen
 - Ketorolac
 - Meclofenamate
 - Meloxicam
 - Nabumetone
 - Naproxen
 - Oxaprozin
 - Piroxicam
 - Sulindac
 - Tolmetin

DIAGNOSIS

SIGNS AND SYMPTOMS

- GI:
 - Nausea
 - Vomiting
 - Epigastric pain
- CNS:
 - Drowsiness
 - Dizziness
 - Lethargy
 - Aseptic meningitis
 - Seizures
- Cardiovascular:
 - Hypotension
 - Tachycardia
- Pulmonary:
 - Eosinophilic pneumonia
 - Apnea
 - Hyperventilation
- Renal:
 - Acute renal failure, hyperkalemia
 - Acute tubular necrosis
 - Acute interstitial nephritis
- Liver:
 - Hepatocellular injury
 - Cholestatic jaundice
- Metabolic:
 - Mild, short-lived metabolic acidosis
- Hypersensitivity:
 - Aseptic meningitis
 - Asthma exacerbation
 - Angioedema, urticaria

ESSENTIAL WORKUP

- Generally, NSAID ingestion results in mild toxicity.
- Exact identification of drug helpful:
 - Subtle toxicologic differences among the NSAIDs
 - Aseptic meningitis more common with ibuprofen exposure
 - Liver toxicity more common with diclofenac and sulindac exposure

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Electrolytes, BUN/creatinine, glucose:

- Baseline renal function
- Check for metabolic acidosis.
- CBC
- Arterial blood gas for large overdoses
- PT/PTT:
 - False-positive bilirubin/ketone dipstick with etodolac ingestion
- Acetaminophen and salicylate level—patients often confuse salicylate, acetaminophen, and NSAID products thinking they are all the same.
- NSAID difficult to detect on toxicology screens and is not beneficial in management

DIFFERENTIAL DIAGNOSIS

Agents causing metabolic acidosis, altered mental status, and GI irritation:

- Salicylates
- Isoniazid
- Ethylene glycol
- Methanol
- Isopropanol

TREATMENT

PRE HOSPITAL

Collect prescription bottles/medications for identification in the ED.

INITIAL STABILIZATION/THERAPY

- ABCs
- Naloxone, thiamine, dextrose (or Accu-Chek) for altered mental status

ED TREATMENT/PROCEDURES

- Supportive care
- Administer activated charcoal.
- Extracorporeal methods to enhance elimination are not beneficial due to high degree of plasma protein binding.

MEDICATION

- Activated charcoal slurry: 1–2 g/kg up to 90 g PO
- Dextrose: D50W 1 amp (50 mL or 25 g; peds: D25W 2–4 mL/kg) IV
- Naloxone (Narcan): 2 mg (peds: 0.1 mg/kg) IV or IM initial dose
- Thiamine (vitamin B₁): 100 mg (peds: 50 mg) IV or IM

Pediatric Considerations

Piroxicam, naproxen, ketoprofen, and mefenamic acid have caused seizures in children.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Protracted vomiting, hematemesis
- CNS depression, seizure activity
- Metabolic acidosis
- CHF, hypotension, hypertension
- Renal failure

Discharge Criteria

Nontoxic ingestion in a patient who is asymptomatic 6–8 hr after ingestion

FOLLOW-UP RECOMMENDATIONS

Psychiatry follow-up/referral for intentional ingestion.

PEARLS AND PITFALLS

- Investigate for coingestions for all NSAID overdoses.
- Obtain acetaminophen and salicylate level on all patients who present with suspected NSAID ingestion.
- NSAID poisoning is generally benign, except with massive overdoses; patients with underlying CHF, coronary artery disease may be at higher risk of toxicity

NURSEMAID'S ELBOW

Neha P. Raukar • Daniel L. Savitt

BASICS

DESCRIPTION

The most common elbow injury in children <5 yr old.

ETIOLOGY

- Sudden traction of the distal radius leads to a portion of the annular ligament slipping over the radial head and becoming trapped between the radius and the capitellum. Traction can occur by swinging the child, wrestling, and lifting the child by the arms.
- By the time the child is 5 yr, the annular ligament is thick and strong and resists tearing and/or displacement.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Child refuses to use arm.
- Elbow is slightly flexed, with forearm held close to the trunk.
- Pain with flexion of the elbow
- Pain with forearm supination or pronation
- Absence of point tenderness
- Minimal to no swelling

History

- Child not using affected arm
- 50% report the classic history of pulling the arm.
- Can also be due to a fall, minor trauma to the elbow, or twisting of the forearm
- In children <6 mo, can be due to the child rolling onto the arm.

Physical-Exam

- Affected arm is held close to the body.
- Arm is usually pronated.
- Elbow is either fully extended or slightly flexed.
- Child will not use the elbow.
- Can be mildly tender over anterolateral radial head, but the rest of the elbow is nontender.
- Painless passive range of motion
- Painful with supination

ESSENTIAL WORKUP

Clinical diagnosis:

- Classic history, passive position of arm, and physical exam are sufficient for diagnosis.

DIAGNOSIS TESTS & INTERPRETATION

Imaging

Radiographs:

- Not routinely indicated
- Obtain to exclude or diagnose other injuries if any of the following are present:
 - Point tenderness
 - Soft tissue swelling
 - Deformity
 - Ecchymosis of the elbow
 - Failed reduction
 - Child continues to favor extremity after reduction maneuver.

DIFFERENTIAL DIAGNOSIS

- Humerus, radius, or ulna fracture
- Elbow dislocation
- Joint infection
- Osteomyelitis
- Tumor

TREATMENT

PRE HOSPITAL

Cautions:

- Place ice on the injured elbow to reduce pain and swelling.
- Immobilize in a sling or splint to facilitate transport and prevent further injury.
- Assess distal neurovascular status.

INITIAL STABILIZATION/THERAPY

Assess distal motor, sensory, and vascular function.

ED TREATMENT/PROCEDURES

- 2 common reduction techniques:
 - Supination/flexion:
 - More commonly used
 - Hyperpronation/extension:
 - Nurses and caretakers perceive this method to be less painful
 - More successful

- Supination/flexion technique:
 - Grasp child’s hand in handshake position and apply mild axial traction.
 - Stabilize injured elbow with the other hand with the thumb over the radial head exerting moderate pressure.
 - In 1 smooth, swift motion, fully supinate the forearm and flex the elbow.
- Hyperpronation/extension technique:
 - Grasp child’s hand in handshake position and apply mild axial traction.
 - Stabilize injured elbow with the other hand with the thumb over the radial head exerting moderate pressure.
 - Hyperpronate the arm and extend if arm is not already extended.
- Placing the examiner’s thumb over the radial head may allow palpation of a click.
- Child may cry during the reduction, but is frequently pain free using the arm shortly thereafter. Period of immobility may be some what prolonged if reduction delayed
- Attempt reduction a 2nd time if the child does not use arm 15 min after 1st attempt.
- 1 of the attempts should be the hyperpronation method.
- Consider opposing technique for 2nd reduction attempt.
- Radiographic studies indicated if the 2nd reduction attempt is unsuccessful, evaluate for fractures.
- Perform postreduction neurovascular assessment.

MEDICATION

- Usually unnecessary
- Acetaminophen: 10–15 mg/kg PO q4h; do not exceed 5 doses/24 hr
- Ibuprofen 10 mg/kg PO q6–8h

FOLLOW-UP

DISPOSITION

Admission Criteria

None

Discharge Criteria

- Discharge after child regains full, unrestricted use of the arm.
- Patient instructions:
 - Inform parents not to pull or lift the child by the hand, wrist, or forearm.
 - Recurrence rate of 27–39% until the child reaches 5 yr of age.

Issues for Referral

Unsuccessful reduction:

- If radiologic evaluation is also negative, child should be referred to an orthopedist.
- Place arm in a sling or a posterior splint for outpatient follow-up.
- No long-term sequelae have been reported with short delay in reduction

FOLLOW-UP RECOMMENDATIONS

- None required for successful reduction
- Orthopedics within 24 hr for unsuccessful reduction

PEARLS AND PITFALLS

- Suspect nursemaid's elbow with a classic history.
- Radiographs are not necessary unless the elbow is focally tender or swollen or history does not suggest nursemaid's elbow.
- Reduction attempt should include the hyperpronation method.
- 2 unsuccessful reductions should prompt radiographic evaluation.
- Unsuccessful reductions should be referred to the orthopedist after the arm is placed in a sling or posterior splint.

OCULOMOTOR NERVE PALSY

Adam Z. Barkin

BASICS

DESCRIPTION

- Typical presentation of a 3rd cranial nerve (CN) palsy:
 - Eyelid drooping
 - Blurred or double vision
 - Light sensitivity
 - May also have other neurologic signs/symptoms:
 - Hemiplegia
 - Ataxia
 - Tremor
- CN III controls elevation, adduction and depression of the eye. This nerve also raises the lid and mediates pupillary constriction and lens accommodation:
 - Medial rectus:
 - Moves eye medially toward nose (adduction)
 - Superior rectus:
 - Moves eye upward
 - Rotates top of eye toward nose
 - Slight adduction
 - Inferior rectus:
 - Moves eye inferiorly
 - Rotates top of eye away from nose
 - Slight adduction
 - Inferior oblique:
 - Rotates top of eye away from nose
 - Slight elevation and abduction
 - Levator palpebrae superioris:
 - Raises eyelid
- CN IV innervates the superior oblique:
 - Moves eye down when looking medially
 - Rotates eye internally
- CN VI innervates the lateral rectus:
 - Moves eye laterally (abduction)
 - Lesions categorized as:
 - Complete vs. incomplete
 - Pupil involving vs. pupil sparing
- Complete: Total loss of CN III function (“down and out”):
 - Compressive lesions:

- Aneurysms
- Tumors
- Brainstem herniation with compression
- Increased intracranial pressure
- Incomplete: Partial loss of CN III function:
 - Vascular infarction of vasa vasorum
- Pupil involving:
 - 95–97% of compressive lesions (aneurysm, tumor, etc.) involve the pupil
 - Parasympathetic fibers sit peripherally in CN III
- Pupil sparing:
 - Ischemic injury to nerve
 - Diabetics, uncontrolled hypertension

ETIOLOGY

- Intracranial or orbital tumor
- Aneurysm (particularly posterior communicating artery)
- Trauma
- Intracranial hemorrhage
- Diabetes mellitus
- Migraine headache
- Infection, meningitis
- Arteriovenous malformation or fistula
- Cavernous sinus thrombosis
- Neuropathy (e.g., myasthenia gravis, Guillain–Barré)
- Collagen vascular diseases (e.g., sarcoidosis)
- Idiopathic

Pediatric Considerations

Trauma is the most common cause of acquired oculomotor nerve palsies

DIAGNOSIS

SIGNS AND SYMPTOMS

A careful history and physical exam are vital to narrow down the differential diagnosis

History

History is of utmost importance in determining cause:

- Headache
- Pupillary dilation
- Eye pain
- Diplopia
- Blurry vision

- History of long-standing diabetes mellitus
- Head trauma, either recent or distant
- Unintentional weight loss
- Signs and symptoms of infection
- Sudden onset of severe headache, meningeal signs, photophobia
- Proptosis
- Lid swelling

Physical-Exam

- Ophthalmologic exam:
 - _ Extraocular movements
 - _ Fundoscopic exam for papilledema
 - _ Ipsilateral and contralateral pupillary reaction
 - _ Ptosis
 - _ Diplopia
 - _ Chemosis or conjunctival injection
 - _ Tenderness
 - _ Visual acuity
 - _ Exophthalmos
- Pupil sparing lesion:
 - _ Ptosis
 - _ Globe is “down and out”
 - _ No elevation, depression, or adduction
 - _ Normal pupil exam
 - _ CN IV, V, VI intact
 - _ Usually no other neurologic signs/symptoms
 - _ Most commonly caused by ischemia in adults
 - _ Also consider giant cell arteritis and trauma
- Pupil-involving lesion:
 - _ Anisocoria is present with a dilated pupil on affected side
 - _ Need to rule out compressive aneurysm
- Incomplete, 3rd CN palsy:
 - _ May have involvement of 1 or more extraocular muscle and may or may not involve pupil
- Look for associated symptoms:
 - _ Extremity weakness
 - _ Changes in speech
 - _ Dysfunction of other CNs
 - _ Gait or coordination

ESSENTIAL WORKUP

CT/MRI of brain, orbit, sinuses

DIAGNOSIS TESTS & INTERPRETATION

Lab

When indicated based on history and physical exam:

- CBC with differential
- ESR
- Antinuclear antibodies, rheumatoid factor to evaluate for vasculitis
- Lumbar puncture

Imaging

- MRI/MRA of brain and cerebral vessels particularly when pupil is involved
- CT angiogram
- Cerebral arteriogram: Has associated risk of neurologic morbidity and mortality
- Doppler imaging for arteriovenous malformations, dural sinus thrombosis

Diagnostic Procedures/Surgery

- Intraocular pressure to exclude glaucoma
- Slit-lamp exam:
 - _ Observe structural abnormalities of iris or anterior chamber

DIFFERENTIAL DIAGNOSIS

- Intracranial infections
- Malignancy
- Vasculitis
- Aneurysms
- Myasthenia gravis
- Botulism
- Orbital infections
- Trauma
- Lens pathology
- Retinal pathology
- Glaucoma
- MS

Pediatric Considerations

Consider congenital oculomotor nerve palsy

TREATMENT

PRE HOSPITAL

Without associated trauma, no specific pre-hospital care issues exist

INITIAL STABILIZATION/THERAPY

- Initial stabilization of trauma patient should concentrate on underlying injuries
- Any patient with evidence of herniation should have the following measures to control intracranial pressure:
 - Intubation using rapid-sequence induction and controlled ventilation to a PCO₂ level of 35–40 mm Hg
 - Elevate head of bed 30°
 - Mannitol

ED TREATMENT/PROCEDURES

- Differentiation between incomplete and complete oculomotor or pupil-involving vs. pupil-sparing nerve palsy guides focus of ED treatment
- All patients younger than 50 yr with any extent of 3rd nerve palsy should be evaluated for a compressive lesion
- If pupil is involved, neuroimaging is indicated as well as consultation to determine cause
- If pupil is spared and the patient has diabetes or other risk for an ischemic 3rd nerve, discharge is likely reasonable with outpatient follow-up:
 - If partial sparing or patient does not have these risk factors, consultation and neuroimaging is indicated
- Medication regimen determined by cause:
 - Aneurysm:
 - Control severe HTN.
 - Decrease intracranial pressure
 - Controlled ventilation
 - Elevation of head
 - Mannitol
 - Intracranial tumor: Control increasing intracranial pressure
 - Inflammation and edema: Decrease with IV steroids.
 - Meningitis:
 - Rapid administration of IV antibiotics
 - IV steroids may be useful to decrease inflammatory response and edema
 - Vasculitis and collagen vascular diseases: Decrease inflammatory cell infiltration with IV steroids
 - Neuropathy: Myasthenia gravis—edrophonium chloride test
- Neurosurgical consultation as appropriate

Pediatric Considerations

MRI/MRA is indicated for all children with a 3rd nerve palsy

MEDICATION

- Ceftriaxone: 1–2 g (peds: 50–100 mg/kg) IV

- Dexamethasone: 10 mg IV (peds: 0.15–0.5 mg/kg IV single dose in ED)
- Edrophonium chloride: 5–8 mg IV (peds: 0.15 mg/kg IV; 1/10 test dose given 1st)
- Mannitol: 1 g/kg IV (peds: Not routinely recommended)
- Methylprednisolone: Adults/peds: 1–2 mg/kg IV single dose in ED

FOLLOW-UP

DISPOSITION

Admission Criteria

- Complete oculomotor nerve palsy of any cause requires admission and emergency neurosurgical evaluation
- Incomplete oculomotor nerve palsy with abnormal CT or MRI, abnormal lab studies, or other focal neurologic or constitutional symptoms should receive prompt neurologic consultation and imaging

Discharge Criteria

- Incomplete oculomotor nerve palsy with negative CT or MRI, normal lab studies, and no other symptoms can be referred for urgent outpatient neurologic evaluation
- Complete pupil-sparing oculomotor palsy in patients with risk factors for microvascular disease (i.e., diabetic) can receive outpatient neurologic workup

FOLLOW-UP RECOMMENDATIONS

If the patient is being discharged, prompt neurologic follow-up is required

PEARLS AND PITFALLS

- Complete lesions must be assessed rapidly
- Patients < 50 yr old with any extent of CN III palsy should be evaluated for compressive lesions
- If the pupil is involved, compressive lesions are often the cause and immediate MRI/MRA is indicated

OPIATE POISONING

Amy V. Kontrick • Mark B. Mycyk

BASICS

DESCRIPTION

- Bind to μ , κ , and δ opiate receptors in the CNS and peripheral nervous system (PNS)
- Physical and psychological dependence occurs.
- Peak plasma levels:
 - PO: 1–2 hr
 - Intramuscular: 0.5–1 hr
 - Intravenous or intranasal: Seconds to minutes

ETIOLOGY

- Overuse or abuse of oral prescription analgesics for moderate to severe pain
- Street preparations of opiate analogs may contain adulterants:
 - Cocaine
 - Clenbuterol
 - Phencyclidine
 - Strychnine
 - Dextromethorphan
 - Quinine
 - Scopolamine

DIAGNOSIS

SIGNS AND SYMPTOMS

- CNS:
 - CNS depression
 - Coma
 - Seizures
- GI:
 - Nausea
 - Vomiting
 - Constipation
- Cardiovascular:
 - Hypotension
 - Bradycardia
 - Palpitations
- Pulmonary:

- Respiratory depression
- Bronchospasm
- Pulmonary edema
- Apnea
- Other:
 - Miosis
 - Hypothermia
- Withdrawal:
 - HTN
 - Tachycardia
 - Tachypnea
 - Abdominal cramps
 - Diarrhea
 - Piloerection
 - Yawning

Pediatric Considerations

- Neonatal withdrawal:
 - Infants born to addicted mothers
 - Onset: 12–72 hr after birth
 - Irritability, tremors, poor feeding, and dehydration
- Diphenoxylate (Lomotil): Toxicity more severe in children than adults and may be fatal

ESSENTIAL WORKUP

Monitor vital signs and pulmonary status with significant exposure:

- Pulse oximetry or arterial blood gases
- CXR if persistent hypoxia or possible aspiration
- Abdominal radiograph if body packing suspected
- Perform a complete exam for occult sticky patches (e.g., fentanyl).

DIAGNOSIS TESTS & NTERPRETATION

Lab

- Plasma opiate levels not clinically useful:
 - Treatment based on clinical presentation, not opiate level
- Urine toxicity screen for opiates may not identify some synthetic opioids (e.g., methadone).
- Acetaminophen level for overuse or abuse of oral prescription analgesic products

DIFFERENTIAL DIAGNOSIS

- Clonidine overdose
- Barbiturate overdose

- Benzodiazepine overdose
- γ -hydroxybutyrate (GHB) overdose
- Neuroleptic overdose
- Occult head injury

TREATMENT

PRE HOSPITAL

- Transport all pills/pill bottles involved in overdose for identification in ED.
- Provide respiratory support.
- Administer naloxone.

INITIAL STABILIZATION/THERAPY

- Check ABCs:
 - _ Airway control is essential.
 - _ Administer supplemental oxygen.
- Administer naloxone:
 - _ Reverses respiratory depression and coma in opiate overdoses
 - _ Intubate if naloxone does not reverse respiratory depression.

ED TREATMENT/PROCEDURES

- Naloxone administration:
 - _ Start with low doses for opiate-habituated patients.
 - _ High doses (10 mg) may be required to reverse the effects of propoxyphene, methadone, and fentanyl.
 - _ Administer repeated doses that reversed symptoms, as needed every 20–60 min.
 - _ For long-acting opioids, consider an hourly infusion of 2/3 of the dose needed to reverse symptoms.
- Decontamination:
 - _ Administer activated charcoal for oral ingestion.
 - _ Administer whole-bowel irrigation with polyethylene glycol for asymptomatic body packers.
- Treat opiate withdrawal with clonidine or methadone.
- Hypotension:
 - _ 0.9% normal saline IV fluid bolus
 - _ Trendelenburg test
 - _ Initiate dopamine for resistant hypotension.
- Seizures:
 - _ Treat initially with diazepam.
 - _ Administer phenobarbital for persistent seizures.

MEDICATION

- Activated charcoal: 1–2 g/kg PO
- Clonidine: 0.1–0.3 mg PO BID for 10 days; 0.1–0.2 mg/kg/d transdermal patch
- Diazepam: 5–10 mg IV (peds: 0.2–0.5 mg/kg IV) q10–15min
- Dopamine: 2–20 µ/kg/min; titrate to effect.
- Methadone: 15–40 mg/d
- Naloxone: 0.4–2 mg (peds: 0.1 mg/kg; neonate dose same as peds except if suspect neonatal withdrawal use 0.001 mg/kg IV) IV, IM, or nebulized
- Phenobarbital: 10–20 mg/kg IV (loading dose); monitor for respiratory depression
- Polyethylene glycol: 2 L/h until clear rectal effluent and/or passage of packets

ALERT

Opioid patches can be abused in various ways (transdermally, orally, smoked, injected). Even used patches still contain a significant dose of drug.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Symptomatic after oral overdose
- Repeated naloxone dosing or infusion needed to reverse symptoms
- Children <5 yr after diphenoxylate ingestion should be observed for 24 hr.
- Opiate body packers
- Persistent symptoms from concomitant toxin exposure (e.g., clenbuterol)

Discharge Criteria

- Asymptomatic 6 hr after oral overdose
- Asymptomatic 4 hr after naloxone administration
- Complete elimination of opiate packets

FOLLOW-UP RECOMMENDATIONS

- Substance abuse referral for patients with oral opiate abuse.
- Patients with unintentional (accidental) poisoning require poison prevention counseling.
- Patients with intentional (e.g., suicide) poisoning require psychiatric evaluation.

PEARLS AND PITFALLS

- Consider occult acetaminophen poisoning in chronic oral opioid-abusing patients.
- Buprenorphine may cause prolonged sedation in pediatric patients.
- Semisynthetic and synthetic opioids will not provide a positive opiate hospital drug screen result.

ICD10

- T40.1X1A Poisoning by heroin, accidental (unintentional), init encntr
- T40.3X1A Poisoning by methadone, accidental (unintentional), init
- T40.601A Poisoning by unsp narcotics, accidental, init

OPPORTUNISTIC INFECTIONS

Sandra E. Sicular • Colleen M. Rivers

BASICS

DESCRIPTION

Unusual infections that occur when host suffers a decrease in resistance against normally nonpathogenic organisms

ETIOLOGY

- Occurs in HIV patients when the CD4 T-lymphocyte count falls below 200 cells/mm³ or <14% of the total lymphocyte count:
 - *Pneumocystis jiroveci* pneumonia (PCP)
 - Disseminated tuberculosis
 - Cryptosporidiosis
 - Microsporidiosis
 - Isosporiasis
 - Toxoplasmosis
 - Histoplasmosis
 - Cryptococcosis
 - *Mycobacterium avium* complex
 - Tuberculosis pericarditis or meningitis
 - Cytomegalovirus
 - Human herpesvirus-8 (Kaposi sarcoma)
 - JC virus (progressive multifocal leukoencephalopathy)
 - Hepatitis B virus
 - *Penicilliosis marneffeii*
 - Bacterial species
- Cell-mediated deficiency:
 - Hematologic malignancies
 - Lymphoma
 - High-dose glucocorticoid therapy
 - Autoimmune disorders
 - Viral infections
 - Cytotoxic drugs/chemotherapy
 - Radiation therapy
 - Associated with:
 - *Legionella*
 - *Nocardia*
 - *Salmonella*
 - *Mycobacteria*

- Neutrophil impairment/depletion:
 - Cytotoxic drugs
 - Aplastic anemia
 - Drug reactions:
 - Dapsone
 - Neoplastic invasion of bone marrow
 - Arsenic
 - Penicillin
 - Chloramphenicol
 - Procainamide
 - Vitamin deficiencies
 - Associated with:
 - *Staphylococcus* and α -hemolytic *Streptococcus*
 - Enteric organisms and anaerobes
 - Invasive aspergillosis

DIAGNOSIS

SIGNS AND SYMPTOMS

- New or worsening fatigue
- Tachypnea
- Fever
- Chills
- Night sweats
- Pulmonary source of infection:
 - Cough
 - Congestion
 - Rales
- Genitourinary source of infection:
 - Dysuria
 - Increased frequency
 - Urinary retention
- GI source of infection:
 - Abdominal pain
 - Vomiting
 - Diarrhea
 - Bleeding
 - Jaundice
- CNS sources of infection:
 - Confusion
 - Focal neurologic deficits
 - Headache

- Seizure

History

- History for HIV/AIDS (recent CD4 count)
- History of malignancy with active treatment
- History of organ transplant
- History of autoimmune disorder
- Use of cytotoxic drugs
- Use of high-dose glucocorticoid therapy

Physical-Exam

- Complete, detailed physical exam indicated as signs of infection in the immunocompromised patient may be subtle.
- Signs of systemic inflammatory response syndrome:
 - Temperature $> 38^{\circ}\text{C}$ or $< 36^{\circ}\text{C}$
 - Heart rate > 90 bpm
 - Respiratory rate > 20 breaths per minute or $\text{PCO}_2 < 32$ mm Hg
- Septic shock
- Focal neurologic deficits
- New murmur
- Ambulatory hypoxia in PCP pneumonia
- Rales and/or rhonchi in pneumonia
- Skin/mucosa defects as a portal of entry.
- Oropharyngeal candidiasis as an indicator of immune suppression

ESSENTIAL WORKUP

Full workup indicated owing to impaired immunity:

- Signs of infection in the immunocompromised patient may not be present
- Can present with subtle signs with rapid deterioration
- Signs such as fever must lead to a full evaluation of patient
- Thorough physical exam is critical to search for source of infection

DIAGNOSIS TESTS & NTERPRETATION

Lab

- CBC with differential for neutropenia or leukocytosis:
 - WBC $> 12,000$ or $< 4,000$ are criteria for the systemic inflammatory response score
 - Neutropenia:
 - Absolute neutrophil count (ANC) $< 1,500/\mu\text{L}$
 - $\text{ANC} = \text{WBC (cells}/\mu\text{L)} \times \text{percent (PMNS + bands)}/100$
- Cultures (aerobic, anaerobic, fungal, viral as indicated):

- Urine
- Blood
- Wound
- Fecal
- CD4 count:
 - Absolute lymphocyte count (ALC) < 1,000/μL predicts CD4 < 200 if CD4 unknown
 - $ALC = WBC \text{ (cells/}\mu\text{L)} \times \text{percent lymphocytes/100}$
- Urinalysis for presence of WBC, nitrite, leukocyte esterase
- Electrolytes, BUN/creatinine, glucose; anion gap acidosis suggests severe infection
- VBG for acidosis
- Lactate level; elevated value suggests serious infection
- PT/PTT for evidence of disseminated intravascular coagulation
- Lactate dehydrogenase (LDH); elevated in patients with PCP

Imaging

- CXR:
 - Nonspecific for predicting a particular infectious etiology
 - Pneumonia:
 - Segmental or subsegmental infiltrate
 - Air bronchograms
 - Abscess
 - Cavitation
 - Empyema
 - Pleural effusion
 - PCP:
 - Classically reveals bilateral interstitial or central alveolar infiltrates
 - Radiograph normal in up to 25% of patients
- High-resolution chest CT:
 - Early studies show high sensitivity for PCP in HIV-positive patients
 - Reveals patchy ground-glass attenuation
 - Head CT: Contrast-enhancing lesions in *Toxoplasma gondii* encephalitis
- Abdominal and pelvic CT with contrast:
 - Indicated if a GI source of infection is suggested by the clinical exam

Diagnostic Procedures/Surgery

Lumbar puncture:

- CSF analysis if signs of CNS infection
- Diagnostic paracentesis:
- Immunocompromised liver patients for SBP

TREATMENT

INITIAL STABILIZATION/THERAPY

- Check airway, breathing, and circulation
- Initiate 0.9% normal saline IV 500 mL bolus for hypotension
- Oxygen
- Cardiac monitor for unstable vital signs
- Early initiation of antibiotic therapy

ED TREATMENT/PROCEDURES

- Strict isolation
- Antibiotics: Combination of expanded-spectrum penicillin (mezlocillin, ticarcillin, piperacillin) and aminoglycoside (amikacin, tobramycin):
 - Monotherapy with a 3rd-generation cephalosporin (ceftazidime, cefepime), fluoroquinolones (levofloxacin, gatifloxacin), or other broad-spectrum antimicrobials (imipenem/cilastatin) may be considered if aminoglycosides contraindicated
 - Vancomycin if there is a high prevalence of methicillin-resistant organisms in the area
 - Antifungals (amphotericin B, fluconazole) if patient is on adequate antibiotics for 1 wk
 - Trimethoprim/sulfamethoxazole for suspected PCP (alternatives: Pentamidine, clindamycin + primaquine)
- Steroids: Prednisone in PCP with hypoxemia

MEDICATION

- Amphotericin B: 0.25 mg/kg/d IV
- Cefepime: 1–2 q12h IV
- Ceftazidime:
 - Adults: 1–2 g IV q8–12h
 - Pediatric: 100–150 mg/kg/24h IV q8–12h
- Fluconazole: 400 mg 1st dose, then 200–400 mg/d IV (peds: 6–12 mg/kg/24h IV q12h)
- Gatifloxacin: 400 mg/d IV
- Imipenem/cilastatin: 500–1,000 mg IV q6–8h, max. 50 mg/kg/d or 4,000 mg/d
- Levofloxacin: 500 mg/d IV
- Vancomycin: 1–2 g IV q12h (peds: 10–50 mg/kg/24h IV q6h)
- Trimethoprim: 15–20 mg/kg + sulfamethoxazole: 75 mg/kg PO or IV div. q8h
- Prednisone: 40 mg PO BID × 5 days, then 40 mg PO QD × 5 days, then 20 mg PO QD × 11 days

*start within 72 hr of antimicrobials for PCP

FOLLOW-UP

DISPOSITION

Admission Criteria

Suspected or confirmed systemic infection

Discharge Criteria

Systemic infection excluded

Issues for Referral

Consider infectious disease consultation

FOLLOW-UP RECOMMENDATIONS

Patients with systemic opportunistic infections should be admitted to the hospital

PEARLS AND PITFALLS

- Signs of infection in the immunocompromised patient may not be present
- Can present with subtle signs with rapid deterioration

ICD10

- A19.9 Miliary tuberculosis, unspecified
- B59 Pneumocystosis
- B99.9 Unspecified infectious disease

OPTIC NEURITIS

Douglas W. Lowery-North

BASICS

DESCRIPTION

- Optic nerve dysfunction due to an inflammatory process, commonly associated with myelin destruction
- Highly associated with multiple sclerosis (MS); presenting feature in 15–20% of MS patients
- Grouped by site of inflammation:
 - Papillitis: Inflammation of the optic disk
 - Retrobulbar neuritis: Inflammation of the optic nerve proximal to the globe
- 5 yr risk for clinically definite MS following optic neuritis:
 - Normal MRI—16%
 - > 3 lesions on MRI—51%
- Recurrence is seen in 35% of patients.

RISK FACTORS

Genetics

High prevalence of A23, B7, and DR2 HLA alleles in patients with optic neuritis:

- Especially those that progress to clinically definite MS

ETIOLOGY

- Idiopathic:
 - Most common
 - Single isolated events
- MS:
 - 20–50% of patients with optic neuritis
- Viral infections:
 - Chicken pox
 - Measles
 - Mononucleosis
 - HSV and HZV
 - Encephalitis
- Postviral optic neuritis:
 - Usually occurs 4–6 wk after a nonspecific viral illness
- Granulomatous inflammation:
 - TB
 - Syphilis

- Sarcoidosis
- Cryptococcal infection
- SLE
- HIV:
 - Cytomegalovirus
 - Toxoplasmosis
 - Histoplasmosis
 - Cryptococcus
- Lyme disease
- Contiguous inflammation of meninges, orbit, sinuses, and intraocular inflammation
- Drug induced:
 - Amiodarone
 - Ethambutol
 - Tamoxifen

DIAGNOSIS

SIGNS AND SYMPTOMS

- Vision loss and pain most common symptoms
- Visual loss occurring over days (rarely over hours), peaks in 1–2 wk:
 - Adults usually unilateral (70%)
 - Bilateral visual loss more common in children
- Retrobulbar pain: Increased with movement of the affected eye
- Light, color vision, and depth perception loss more pronounced than visual acuity loss
- Afferent pupillary defect almost always occurs in unilateral cases if other eye is healthy.
- Visual field defects:
 - Usually characterized by central scotoma
 - Deficits resolve by 1 yr in 56% of patients, and 73% resolve by 10 yr
- Funduscopic exam usually reveals either swollen (papillitis) or normal disk
- Uhthoff sign:
 - Visual deficit occurring with exercise or increased body temperature
 - Unusual sign seen occasionally

History

- Age (typically women 18–45 yr)
- Pain on eye movement
- Speed of onset of symptoms
- Associated symptoms
- Previous episodes

- Family history of optic neuritis, MS

Physical-Exam

- Check BP.
- Complete ophthalmologic and neurologic exam, especially assessment of:
 - Pupillary function
 - Afferent pupillary defect
 - Visual field defect
 - Color vision (Ishihara color plates)
 - Evaluation of the vitreous body for cells
 - Dilated retinal exam (swollen optic disk)

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- ESR
- Rapid plasma reagin, fluorescent treponemal antibody-absorption (FTA-ABS)
- Lyme titer
- Antinuclear antibody
- Purified protein derivative
- HIV

Imaging

- CXR for TB, sarcoid
- CT scan or MRI of brain and orbits:
 - Inflammation of the retrobulbar optic nerve during the acute phase may appear as enlargement, thus falsely raising the issue of an optic nerve mass.
 - Optic nerve inflammation is seen in 95% of gadolinium-enhanced MRIs.
 - Visual field testing (preferably automated testing, such as Octopus or Humphrey)

DIFFERENTIAL DIAGNOSIS

- Acute papilledema
- Ischemic optic neuropathy
- Severe systemic hypertension
- Intracranial tumor compressing the afferent visual pathway
- Orbital mass compressing the optic nerve
- Toxic or metabolic neuropathy:
 - Heavy metal poisoning
 - Anemia
 - Malnutrition
 - Ethanol/Methanol

- Chloroquine
- Ethambutol
- Isoniazid
- Leber hereditary optic atrophy

Pediatric Considerations

In children, infectious and postinfectious causes should be considered.

Geriatric Considerations

In patients >50 yr, ischemic optic neuropathies (e.g., diabetes and giant cell arteritis) are more common, and appropriate workup should be obtained.

TREATMENT

ED TREATMENT/PROCEDURES

- Early ophthalmologic and neurologic consultations
- IV steroid pulse followed by oral steroids:
 - Recommended for those with ≥ 2 demyelinating lesions on MRI without a prior history of MS or optic neuritis, or severe vision loss
 - Decreases recurrence and progression to MS over 2 yr and shortens duration of visual impairment, but does not affect visual outcome at 1 yr nor rate of progression at 5 yr
 - Treatment should be individualized for those with 1 lesion on MRI.
 - Oral steroids used alone increases recurrence and should be avoided.

MEDICATION

Methylprednisolone: 250 mg IV q6h for 3 days, followed by oral prednisone (1 mg/kg/d) for 11 days with subsequent 4 day taper

FOLLOW-UP

DISPOSITION

Admission Criteria

- Bilateral vision loss
- If other sources of acute vision loss cannot be ruled out
- IV steroid pulse treatment needed

Discharge Criteria

- Unilateral visual impairment
- Good home support systems

- Neurology and ophthalmology follow-up arranged

Issues for Referral

Referral for interferon β -1a treatment as outpatient for high-risk patients (those with ≥ 2 demyelinating lesions on MRI):

- Reduces progression to MS

FOLLOW-UP RECOMMENDATIONS

Needs Ophthalmology referral

PEARLS AND PITFALLS

- Rule out space-occupying lesions before making the diagnosis of optic neuritis.
- Acute bilateral loss with a severe headache or diplopia should raise concern for pituitary apoplexy.
- The true benefit of corticosteroids in the treatment of optic neuritis is unclear, and emergency physicians should consult with appropriate specialists to determine the local standard of practice.
- Brain MRI is the most useful predictor of subsequent development of MS.

CODES

ICD9

- 377.30 Optic neuritis, unspecified
- 377.31 Optic papillitis
- 377.32 Retrobulbar neuritis (acute)

ICD10

- H46.00 Optic papillitis, unspecified eye
- H46.9 Unspecified optic neuritis
- H46.10 Retrobulbar neuritis, unspecified eye

ORGANOPHOSPHATE POISONING

Vinodinee L. Dissanayake

BASICS

DESCRIPTION

- Organophosphates (pesticides and nerve agents) irreversibly bind and deactivate cholinesterases, including acetylcholinesterase
- Acetylcholine accumulates at neural synapses, causing central and peripheral cholinergic overdrive
- Predominant effects (muscarinic, nicotinic, CNS) may vary and can overlap.
- Mortality is secondary to respiratory failure:
 - _ Weakness of respiratory muscles
 - _ Bronchorrhea and bronchoconstriction
 - _ Central depression of respiratory drive

Pediatric Considerations

- Symptoms are difficult to differentiate in toddlers
- Common symptoms: Miosis, salivation, and muscle weakness
- Seizure activity in 25% of pediatric cases:
 - _ Only 3% in adults

ETIOLOGY

- Exposure to insecticides (organophosphorus compounds)
- Exposure to chemical nerve agents (sarin, soman, tabun, VX)
- Extremely well absorbed from lung, GI tract, skin, mucosa, eyes

DIAGNOSIS

SIGNS AND SYMPTOMS

- Classic presentation: Cholinergic toxidrome:
 - _ DUMBELS:
 - *Diarrhea/diaphoresis*
 - *Urination*
 - *Miosis/muscle fasciculations*
 - *Bradycardia, bronchorrhea, bronchospasm*
 - *Emesis*
 - *Lacrimation*
 - *Salivation*
 - _ May have garlic odor
- Chronic intermittent exposure, nonspecific symptoms:

- Weakness
- Fatigue
- Malaise
- Anorexia
- Mild exposure:
 - CNS:
 - Headache
 - Dizziness
 - Tremors of tongue and eyelids
 - Weakness
 - GI:
 - Anorexia
- Moderate exposure:
 - CNS:
 - Muscle fasciculation then flaccid paralysis
 - Respiratory muscle weakness
 - Incoordination and ataxia
 - Agitation
 - Tremors
 - Confusion
 - Visual:
 - Pinpoint nonreactive pupils
 - Respiratory:
 - Respiratory muscle weakness
 - Bronchorrhea
 - Cardiovascular:
 - Bradycardia
 - GI:
 - Nausea/vomiting
 - Abdominal cramps
 - Exocrine glands:
 - Salivation
 - Lacrimation
- Severe exposure:
 - CNS:
 - Convulsions
 - Coma
 - Centrally mediated respiratory depression
 - Respiratory:
 - Bronchoconstriction
 - Wheezing
 - Dyspnea
 - Increased bronchial secretions

- Cardiovascular:
 - Bradycardia (tachycardia may follow pulmonary edema and hypoxia)
 - Heart block
 - Cyanosis
- GI:
 - Nausea, vomiting
 - Abdominal pain
 - Diarrhea, fecal incontinence
- Exocrine glands:
 - Diaphoresis
 - Salivation
 - Lacrimation
- Bladder:
 - Frequency
 - Urinary incontinence
 - Nicotinic manifestations

ESSENTIAL WORKUP

Inquire about possible exposure, occupation, recent insecticide at home, mislabeled, or poorly stored insecticides:

- Obtain original container if suicide attempt.
- Look for parasympathetic and CNS signs with muscle weakness or paralysis.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- RBC and plasma cholinesterase levels to confirm diagnosis:
 - RBC (true) cholinesterase level is best for synaptic inhibition (a send-out lab).
 - Plasma (pseudo)cholinesterase level not as reliable but more timely:
 - These are markers for poisoning
 - Depending on the agent and the patient, these levels may vary
 - Cholinesterase levels:
 - Latent exposure: > 50% of normal value
 - Mild exposure: 20–50% of normal value
 - Moderate exposure: 10–20% of normal value
 - Severe exposure: < 10% of normal value
 - Do not wait for cholinesterase results before administering treatment.
- CBC, electrolytes, glucose, BUN, creatinine
- ABG when respiratory symptoms are present

Imaging

- CXR if respiratory difficulty is present or suspect pulmonary edema:

- Pneumonitis from hydrocarbon aspiration
- ECG:
 - Dysrhythmias (atrial fibrillation, ventricular tachycardia, torsades de pointes, QT prolongation)
 - Bradycardia
 - Heart block
 - ST–T-wave abnormalities
- CT scan of head for altered mental status when diagnosis is uncertain

DIFFERENTIAL DIAGNOSIS

- Mild to moderate exposure:
 - Gastroenteritis
 - Asthma
 - Venomous arthropod bite (black widow, scorpion)
 - Progressive peripheral neuropathy (Guillain–Barré syndrome)
 - Carbon monoxide
- Severe exposure:
 - Narcotic overdose
 - Coma and miosis:
 - PCP, meprobamate, phenothiazine, clonidine
 - Muscarinic-containing mushrooms—cholinergic crisis without nicotinic symptoms
 - Nicotine poisoning
 - Metabolic and infectious:
 - Ketoacidosis, sepsis, meningitis, encephalitis
 - Hypoglycemia
 - Reye syndrome
 - Neurologic:
 - Cerebrovascular accident
 - Subdural or epidural hematoma
 - Postictal state

TREATMENT

PRE HOSPITAL

- Decontamination is initial priority:
 - Decontaminate, airway, breathing, circulation (DABC)
 - Remove all clothes and store as toxic waste (double bagged)
- Protection of health care workers of utmost importance:
 - Impenetrable gloves (neoprene, nitrile), gowns, eye protection
- Decontaminate skin with soap and water:
 - Shower or gentle scrubbing ideal if done before entrance into the ED

- Maintain airway and oxygenate.
- IV access and place on cardiac monitor

INITIAL STABILIZATION/THERAPY

- Decontaminate ABCs:
 - _ Decontamination and protection of staff
 - _ Maintain airway and oxygenate.
 - _ For unstable airway, intubate, and ventilate.
 - _ IV access with D₅W 0.9% NS
- Altered mental status: Administer thiamine, glucose, and naloxone (Narcan)

ED TREATMENT/PROCEDURES

- Atropine:
 - _ Blocks acetylcholine at muscarinic receptor sites.
 - _ No effect on nicotinic receptors
 - _ Onset of action is 1–4 min, peaks at 8 min.
 - _ Goal of therapy/end point:
 - Drying secretions of tracheobronchial tree
 - _ Administer test dose 1–2 mg IV/IM:
 - No clinical response: Double dose q5min until muscarinic findings subside
 - _ Dose: 1–4 mg IV q5min (peds: 0.05–0.2 mg/kg)
 - _ Common pitfalls in therapy:
 - Not giving enough atropine
 - Using pupillary findings (mydriasis) as end point of treatment
 - Mistaking dilated pupils or tachycardia as contraindications to atropine
- Pralidoxime (2-PAM):
 - _ Regenerates cholinesterase by reversing the phosphorylation of the enzyme.
 - _ Synergistic with atropine—muscarinic signs/symptoms will start to resolve in 10–40 min.
 - _ Side effects: Neuromuscular blockade with rapid infusion, respiratory arrest, HTN, nausea/vomiting, dizziness, blurred vision.
 - _ End point is resolution of muscle weakness and fasciculations.
 - _ Effective before enzyme aging occurs (permanent inactivation of cholinesterase)
 - _ Onset of aging varies among products
 - _ No restriction to its use even if 24–48 hr have passed
- Supportive care:
 - _ Dermal decontamination: Remove clothes and flush skin with water
 - _ Gastric lavage (early presentation of severe ingestion):
 - Gastric emptying with continuous suction via a nasogastric tube.
 - Handle contents with care—avoid direct contact to prevent personal

exposure.

– Respiratory difficulty:

- Frequent oropharyngeal suction
- Treat bronchospasm with atropine, not bronchodilators.
- Tachycardia may result from hypoxia (pulmonary secretions and bronchospasm).
- Atropine will dry secretions and paradoxically lower the heart rate.
- Intubate and ventilate if necessary.
- Avoid succinylcholine; may have prolonged duration as it is metabolized by cholinesterase.

MEDICATION

- Atropine: 1–2 mg (peds: 0.05–0.2 mg/kg) IV q5min (see the previous section for details)
- Dextrose: D₅₀W, 1 amp (25 g) of 50% dextrose (peds: 2–4 mL/kg D₂₅W) IV push
- Naloxone (Narcan): 2 mg (peds: 0.1 mg/kg) IV/IM
- Pralidoxime: 1–2 g (peds: 25–50 mg/kg) dissolved in 0.9% NS over 30 min IV; repeat in 1 hr if necessary, then q6h as needed:
 - Some propose continuous infusion (500 mg/h) for serum concentration of 4 mg/L.

FOLLOW-UP

DISPOSITION

Admission Criteria

- ICU admission for any exposure confirmed with atropine response.
- Any symptomatic patient should be admitted for monitoring.
- Avoid opioids, phenothiazines, and antihistamines; these may potentiate toxicity of organophosphates.

Discharge Criteria

- Asymptomatic for 6–12 hr after exposure
- Ensure close reliable follow-up and specific instructions when to return for evaluation.

Issues for Referral

Contact toxicologist or poison center for patients with significant exposures requiring repeat atropine administration.

FOLLOW-UP RECOMMENDATIONS

Psychiatry referral for intentional ingestions.

PEARLS AND PITFALLS

- Treatment failure often secondary to inadequate atropine dosing
- Recognize nicotinic manifestations (tachycardia, seizures).

OSGOOD–SCHLATTER DISEASE

Stephen R. Hayden

BASICS

DESCRIPTION

- Most frequent cause of knee pain in children aged 10–15 yr
- Pain and edema of the tibial tuberosity:
 - Tenderness at insertion site for patellar tendon just below the knee joint
- Extra-articular disease:
 - Pain is worse with activity and improves with rest
 - Caused by repetitive stress and is common in children participating in sports
- Benign, self-limited knee condition

ETIOLOGY

- Etiology is controversial
- Leading theory: Microfractures caused by traction on the apophysis
- Pain occurs during activities that stress the patellar tendon insertion onto tibial tubercle.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Pain and swelling over tibial tuberosity
- Pain exacerbated by running, jumping
- Pain relieved by rest

History

- Risk factors:
 - Age: 10–15 yr of age, associated with growth spurt in puberty
 - More common in boys
 - Sports: Activities with running, jumping, swift changes in direction (i.e., soccer, basketball, figure skating)
- Knee pain is worse with activity and improves with rest.
- Usually unilateral, with 20% occurring bilateral

Physical-Exam

- Prominence and soft tissue swelling over the tibial tuberosity
- Pain reproduced by extending the knee against resistance
- Tenderness over tibial tuberosity at patellar tendon insertion site

- Tight quadriceps and hamstrings compared to unaffected side
- Erythema of tibial tuberosity may be present.
- Knee joint exam is normal.

ESSENTIAL WORKUP

Diagnosis is clinical:

- Pain, swelling, and tenderness localized to the tibial tubercle

DIAGNOSIS TESTS & INTERPRETATION

Imaging

Knee x-ray:

- Irregular ossification and fragmentation at the tibial tuberosity may be seen.
- Ultrasound has the advantage of imaging surrounding soft tissues

DIFFERENTIAL DIAGNOSIS

- Patellar stress fracture
- Patellar or quadriceps tendonitis
- Prepatellar or infrapatellar bursitis
- Osteochondritis dissecans
- Osteomyelitis
- Patellofemoral pain syndrome
- Septic joint
- Inferior patellar pole traction apophysitis (Sinding-Larsen–Johansson disease)
- Fat pad impingement (Hoffa disease)
- Referred pain, especially from the hip

TREATMENT

INITIAL STABILIZATION/THERAPY

- Stabilize lower extremity in position of comfort.
- Apply ice to affected knee.

ED TREATMENT/PROCEDURES

- Rest from painful activities:
 - Limited activity for 6–8 wk
 - Avoid cutting and jumping sports, such as basketball, soccer, volleyball, etc.
- Ice affected area.
- Analgesic medications
- Stretch the quadriceps and hamstrings.
- Apply protective padding to knee during activities.
- Infrapatellar tendon strap may be worn for 6–8 wk.
- Avoid corticosteroid injections.

- Reassurance; it is a benign, self-limited condition.

MEDICATION

First Line

Analgesic medications:

- Ibuprofen: 10 mg/kg PO q6h
- Acetaminophen: 15 mg/kg PO q4h

FOLLOW-UP

DISPOSITION

Admission Criteria

No admission is necessary.

Discharge Criteria

Discharge home.

Issues for Referral

If patient fails nonoperative therapy, then refer to pediatric orthopedic surgery:

- Rarely, surgical excision is required but is delayed until after skeletal maturity.

FOLLOW-UP RECOMMENDATIONS

Rest from painful activities and follow-up with pediatrician in 2–3 wk for repeat exam.

PEARLS AND PITFALLS

- Diagnosis is clinical:
 - Pain, swelling, and tenderness at the tibial tuberosity:
 - Tenderness and pain worse during and after exercise
 - Risk factors:
 - 10–15 yr of age
 - Sports activities with running, jumping
- Treatment is conservative:
 - Treat with rest, ice, and NSAIDs
 - Avoid sports activities until pain resolves.

- M92.52 Juvenile osteochondrosis of tibia and fibula, left leg

OSTEOGENESIS IMPERFECTA

Daniel Davis • Chad M. Valderrama

BASICS

DESCRIPTION

- Inherited abnormality of procollagen amino acid sequence
- Bone hypomineralization and incomplete ossification result in brittle bones.
- Abnormal collagen affects all connective tissue to varying degrees.
- Time course is variable:
 - Most cases involve fractures during childhood followed by quiescence during adolescence and early adulthood.

ETIOLOGY

- Procollagen defects result in abnormalities of bone and connective tissue matrix.
- Defects in different sites on procollagen protein chain result in more severe forms.
- Defects are inherited, either autosomal recessive (generally milder) or autosomal dominant (more severe).
- Lethal cases involve sporadic or new mutations.
- Ehlers–Danlos syndrome involves mutations of the same procollagen protein in different locations.

Pediatric Considerations

- Most cases involve pathologic fractures during childhood.
- Multiple fractures often initiate evaluation for abuse, but the possibility of pathologic fractures also should be considered.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Multiple heritable defects that lead to brittle bones:
 - Often associated with other connective tissue abnormalities
- A suspected fracture with a relatively minor mechanism or a history of multiple fractures in a child suggests the diagnosis.
- Careful social history with consideration for the possibility of nonaccidental trauma
- Bones:
 - Multiple recurrent fractures (especially in long bones) are the hallmark of this disease.
 - Fractures may be present at birth or may recur in the elderly.
 - Shortened or bowed limbs, pectus excavatum, curving of long bones,

vertebral compression fractures, scoliosis, kyphosis, and abnormal skull shape

– All bones are affected to some extent (see Imaging/Special Tests).

- Eyes:

– *Blue sclerae* are another hallmark of this disease.

– No visual changes are reported.

- Ears:

– Hearing loss usually begins in adolescence; >90% of patients have some deficit by age 30 yr.

– Hearing loss is generally sensorineural, although some middle ear abnormalities have been demonstrated.

– Academic difficulties should raise suspicion of possible hearing deficits.

- Other:

– Discolored, fragile, and abnormal shape of teeth

– Shares several features with Ehlers–Danlos syndrome:

- Loose joints

- Valve problems

- Vascular abnormalities

- Thyroid abnormalities may be seen.

- Extreme cases may result in perinatal death.

ESSENTIAL WORKUP

- Diagnosis is usually made as combination of clinical and radiographic findings.

- History of repeated fractures or fractures with unimpressive mechanism

- Thorough search for other tender areas and evaluation of eyes, teeth, and joints is important for diagnosis.

- Careful exam of neurovascular status distal to fracture

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Evaluate for metabolic derangements such as hyperparathyroidism, vitamin C or D deficiencies, and calcium/phosphate abnormalities.

- DNA studies may be indicated for familial analysis, prenatal testing, and genetic counseling.

- Tissue biopsy is controversial but may help differentiate from tumors.

Imaging

- Radiographs of fracture sites:

– May reveal osteopenia (usually mild)

– Crumpled long bones (“accordion femora”)

– Incomplete ossification at physes

- Skeletal survey is mandatory, especially in children.

- Skull films may show wormian appearance of irregular ossification.
- Popcorn-like deposits on long-bone ends are poor prognostic finding.
- Formal audiologic testing as outpatient is required in older patients.

DIFFERENTIAL DIAGNOSIS

- Nonaccidental trauma in children
- Ehlers–Danlos syndrome
- Hypophosphatasia
- Achondroplasia
- Scurvy
- Congenital syphilis
- Celiac disease

TREATMENT

PRE HOSPITAL

Personnel should obtain information about mechanism or social factors that point toward pathologic fracture vs. nonaccidental trauma.

INITIAL STABILIZATION/THERAPY

- Airway management and resuscitation as indicated
- Fracture immobilization/splinting

ED TREATMENT/PROCEDURES

- Specific fracture management dictated by type and location of injury
- Orthopedic consultation regarding need for traction or operative fixation
- No specific treatment for osteogenesis imperfecta exists at present.

MEDICATION

- Pain medications as indicated
- Elderly women may benefit from calcium (1–1.5 g/d) and estrogen replacement (0.625 mg/d).

FOLLOW-UP

DISPOSITION

Admission Criteria

- Admission is determined by multiple trauma or operative needs for fracture repair.
- Pediatric patients may need admission to investigate possibility of nonaccidental trauma.

Discharge Criteria

- Patients may be considered for outpatient management if isolated fracture is present and appropriate home resources are available.
- Most patients should be discharged with orthopedic and primary physician follow-up.

Issues for Referral

- Orthopedic referral is driven by the acute injury.
- The presence of fractures in multiple locations or at different times also suggests nonaccidental trauma, which should prompt acute consultation and/or referral per local protocol.

FOLLOW-UP RECOMMENDATIONS

- Follow-up is generally driven by the acute injuries.
- Follow-up with the primary physician should be instituted to encourage treatment and monitoring of the disease.

PEARLS AND PITFALLS

- The most challenging aspect of caring for these patients is differentiating between pathologic fractures associated with osteogenesis imperfecta and nonaccidental trauma. With any questions, acute consultation and/or referral should be initiated per local protocol.
- It is a myth that children with osteogenesis imperfecta feel less pain than other patients.
- Predisposition to respiratory infections

OSTEOMYELITIS

Stephen R. Hayden

BASICS

DESCRIPTION

- Osteomyelitis (OM): Infection of bone with ongoing inflammatory destruction
- Usually bacterial, but fungal OM does occur
- Could be acute or chronic

ETIOLOGY

- Hematogenous OM:
 - _ Primarily in children, elderly, IV drug abuse (IVDA) patients
 - _ Seeding of bacteria to bone from remote site of infection via bloodstream
 - _ Children have acute OM and adults subacute or chronic.
 - _ Hematogenous OM of long bones rarely occurs in adults.
 - _ Most children with acute hematogenous OM have no preceding illness.
 - _ 1/3 have history of trauma to affected area.
 - _ *Staphylococcus aureus* is the most common cause of OM in all ages.
 - _ Neonates: *S. aureus*, *Enterobacteriaceae*, group A and B streptococci, and *Escherichia coli*
 - _ Children: *S. aureus*, group A streptococci, *Haemophilus influenzae*, *Enterobacteriaceae*
 - _ *Salmonella*: Common in sickle cell disease
 - _ Adults: *S. aureus*, *Enterobacteriaceae*, *Pseudomonas*, gram-negative rods, *Staphylococcus epidermidis*, gram-positive anaerobes, especially *Peptostreptococcus*
 - _ Illicit drug users: *Candida*, *Pseudomonas*, *Serratia marcescens*
 - _ Prolonged neutropenia: *Candida*, *Aspergillus*, *Rhizopus*, *Blastomyces*, coccidioidomycosis
- Hematogenous vertebral OM:
 - _ Uncommon
 - _ Most prevalent in adults >45 yr
 - _ Involves the disk and vertebra above and below
 - _ Often in the setting of long-term urinary catheter placement, IVDA, cancer, hemodialysis, or diabetes
 - _ IVDA: OM of pubic symphysis, sternoclavicular, and sacroiliac (SI) joints
 - _ Lumbar vertebrae most common, followed by thoracic, then cervical
 - _ Posterior extension leads to epidural/subdural abscess or meningitis.
 - _ Anterior extension may lead to paravertebral, retropharyngeal, mediastinal, subphrenic, retroperitoneal, or psoas abscess.

- Direct or contiguous OM:
 - Organism(s) directly seeded in bone due to trauma, especially following open fractures:
 - Spread from adjacent site of infection or from surgery
 - More common in adults and adolescents
 - *S. aureus*, *Enterobacteriaceae*, *Pseudomonas*
 - Normal vascularity:
 - *S. aureus* and *S. epidermidis*, gram-negative bacilli, and anaerobic organisms
 - Vascular insufficiency/diabetes:
 - Small bones of feet are common sites.
 - Infection resulting from minor trauma, infected nail beds, cellulitis, or skin ulceration
 - Polymicrobial, including anaerobes
 - Puncture wound through tennis shoe: *S. aureus*, *Pseudomonas*
 - Clavicular OM can occur as complication of subclavian vein catheterization.
- Chronic OM:
 - OM that persists or recurs
 - Distinguishing characteristic is necrotic bone (sequestrum) that must be débrided.
 - *S. epidermidis*, *S. aureus*, *Pseudomonas aeruginosa*, *S. marcescens*, and *E. coli*

DIAGNOSIS

SIGNS AND SYMPTOMS

Vary with duration of disease

History

- Mainly nonspecific symptoms
- Pain: Localized, deep, dull, and throbbing; occurs with and without movement
- Fever and chills; may be absent in chronic OM
- Malaise, nausea, vomiting
- Reluctance to use extremity
- Nonhealing ulcers despite proper therapy
- Consider OM as a cause of fracture nonunion
- Predisposing factors: DM, vasculopathy, IVDA, invasive procedures, trauma

Physical-Exam

- Tenderness to palpation, warmth, erythema, edema, decreased range of motion
- Drainage of sinus tract
- Deep ulcers and palpable bone (+ “probe to bone” test has very high positive predictive value)

- If ulcer size $> 2 \text{ cm}^2$ and $> 3 \text{ mm}$ in depth, bone involvement is likely.

ESSENTIAL WORKUP

- CBC
- ESR and C-reactive protein
- Radiographs
- Blood and wound cultures and sensitivities

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC; WBC may be elevated but often normal
- ESR; elevated in $> 90\%$ of cases
- C-reactive protein (usually elevated)
- Blood cultures (positive in $\sim 50\%$ of cases)

Imaging

- Plays a central role in evaluation
- Start with plain films; other tests often required
- Radiographs:
 - _ May be normal for the 1st 2–3 wk of symptoms
 - _ Earliest finding is periosteal elevation, followed by cortical erosions, then new bone formation.
 - _ 40–50% of focal bone loss needed to detect lucency on radiograph; fewer than 1/3 of cases have diagnostic findings at 10 days
 - _ Obtain CXR if TB suspected
- MRI:
 - _ Best modality to obtain detailed anatomy and extension of soft tissue and bone marrow involvement
 - _ Sensitivity and specificity of $\sim 90\%$
 - _ Reveals bone edema, cortical destruction, periosteal reaction, joint surface damage, and soft tissue involvement before x-rays
 - _ Effective in early detection (3–5 days from onset of infection)
 - _ Test of choice to identify vertebral OM and OM in diabetic foot ulcers
 - _ Occasional false-positive results in trauma, previous surgical procedures, or neuropathic joint disease
 - _ Negative study after 1 wk of symptoms rules out acute OM
- CT:
 - _ Modality of choice when MRI cannot be done
 - _ Reveals bone edema, cortical destruction, periosteal reaction, small foci of gas or foreign bodies, joint surface damage, and soft tissue involvement when plain films not helpful
 - _ Useful in OM of vertebrae, sternum, calcaneus, pelvic bones

- Useful to surgeons in guiding débridement and biopsy
- Bone scan:
 - Technetium 99m methylene diphosphonate ($^{99m}\text{Tc-MDP}$)
 - Measures increase in bone metabolic activity
 - ~95% sensitive but less specific than MRI
 - Bone scan abnormal after 2–3 days of symptoms
 - False-positive may occur in trauma, surgery, chronic soft tissue infection, tumor
 - High radiation burden, useful if suspect multifocal disease
- Leukocyte scintigraphy:
 - Indium 111 -labeled WBCs
 - More specific but less sensitive than bone scan
 - Difficult to distinguish bone inflammation from soft tissue inflammation (i.e., cellulitis, tumors, inflammatory arthritis)
- US:
 - An emerging modality for OM especially in children
 - Periosteal elevation or thickening, fluid collections adjacent to bone often seen
 - May show findings of OM days prior to plain films
 - Useful in guiding biopsy

Diagnostic Procedures/Surgery

- Gold standard for diagnosis is bone biopsy with histology and tissue Gram stains, including culture and sensitivities.
- Needle aspiration has lower sensitivity than open biopsy.
- Culture of sinus or drainage from wound can be misleading; correlates well with *S. aureus*, but not as reliable for other organisms.

Pediatric Considerations

- 70–85% of children have fever higher than 38.5°C.
- Neonates are commonly afebrile.
- Only ~1 in 3 of children will have leukocytosis.
- Blood cultures positive in ~50%
- US

DIFFERENTIAL DIAGNOSIS

- Cellulitis
- Paronychia/felon
- Bursitis, toxic synovitis, septic arthritis
- Extremity fracture
- Bone infarction in sickle cell patients
- Acute leukemia, malignant bone tumors

- Mechanical back pain
- Spinal epidural abscess
- Brucellosis, especially in SI joint
- TB, more common in thoracic spine (Pott disease)

TREATMENT

INITIAL STABILIZATION/THERAPY

Emergent stabilization if septic or if neurologic deficits from spine involvement

ED TREATMENT/PROCEDURES

- Empiric antibiotic treatment in ED
- Cultures should guide subsequent antibiotic regimen.
- Antibiotics: Depend on patient's age and organism (see Medications section)
- Orthopedic and infectious disease consultation
- Surgical intervention may be needed to optimize treatment (e.g., infected fracture or hardware, bone necrosis).
- Parenteral antibiotic treatment for 4–6 wk

MEDICATION

- Newborn–4 mo: Penicillinase-resistant synthetic penicillin (e.g., nafcillin: 37 mg/kg IV q6h) plus a 3rd-generation cephalosporin (e.g., ceftriaxone: 50–75 mg/kg/d IV); if suspect methicillin-resistant *S. aureus* (MRSA) then vancomycin (40–60 mg/kg IV q6h) plus a 3rd-generation cephalosporin. (Note: Doses are based on age > 28 days)
- Children (> 4 mo): Penicillinase-resistant synthetic penicillin (e.g., nafcillin: 37 mg/kg IV q6h to max. 8–12 g/d). If suspect MRSA, then vancomycin (40–60 mg/kg IV q6h to max. 2–4 g/d). Add 3rd-generation cephalosporin if suspicion for gram-negative rods, or presence on Gram stain noted (e.g., ceftriaxone: 50–75 mg/kg IV per day to max. 2–4 g/d)
- Adult: Penicillinase-resistant synthetic penicillin (e.g., nafcillin: 2 g IV q4h); if suspect MRSA, vancomycin (15 mg/kg IV q12h)
- Gram-negative (including pseudomonas) chronic OM: Ciprofloxacin 750 mg PO BID or Levofloxacin 750 mg PO QD
- Sickle cell anemia with OM: Ciprofloxacin 400 mg IV q12h, or levofloxacin 750 mg IV q24h (*not* in children); alternative: 3rd-generation cephalosporin
- Post nail puncture through tennis shoe: Ciprofloxacin 750 mg PO BID or Levofloxacin 750 mg PO q24h; alternative: Ceftazidime 2 g IV q8h
- Involving orthopedic prosthesis or hardware: Add rifampin (10 mg/kg/d PO/IV to max. of 600 mg/d) to regimen for *S. aureus*. Hardware removal generally required.
- Post-traumatic OM: Vancomycin and ceftazidime
- If vancomycin-resistant enterococcus present: Linezolid 600 mg IV q12h × 6 wk

Pediatric Considerations

Children with hematogenous OM may undergo short-course IV antibiotics and then be changed to oral for additional 1–2 mo.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with acute OM should be admitted.
- Patients with chronic OM usually require admission for surgical procedures, débridement, and obtaining bone cultures and histology.

Discharge Criteria

Subacute or chronic OM patients may be considered for outpatient management if home IV antibiotics arranged, bone specimens obtained, and necrotic bone débrided.

- Cases refractory to débridement and antibiotics benefit from hyperbaric oxygen as an adjunct to standard treatment.
- ~ 2/3 of these cases will demonstrate benefit.

PEARLS AND PITFALLS

- WBC may be normal in many cases.
- Radiographs may be normal in the 1st 2–3 wk of symptoms.
- Wound cultures are low yield in guiding antibiotic therapy.

- M86.10 Other acute osteomyelitis, unspecified site
- M86.60 Other chronic osteomyelitis, unspecified site

OSTEOPOROSIS

Daniel Davis • Marian Xu

BASICS

DESCRIPTION

- Overall decrease in skeletal mass, generally diffuse
- Trabecular bone (especially vertebrae and femur) affected more commonly and earlier
- Disease begins in adolescence, but fractures do not usually manifest until age ≥ 50
- Females affected much more commonly than males, especially after menopause

ETIOLOGY

- Overall increase in resorption over formation of new bone
- Advanced age is the most important risk factor
- Inadequate dietary calcium an important factor, especially early in life
- Sedentary lifestyle is a risk factor (weight bearing on bone favors new bone formation)
- Decrease in estrogen with menopause key factor in women
- Other risk factors include long-term steroid use, alcoholism, methotrexate, tobacco use, low body weight
- Familial or hereditary factor may coexist

Pediatric Considerations

Although disease appears to start in adolescence, pediatric patients are asymptomatic.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Usually asymptomatic until pathologic fractures occur
- Fractures with insignificant mechanism or recurrent fractures are hallmark
- Vertebral column most commonly involved
- Multiple compression fractures of vertebral column often lead to kyphosis and scoliosis
- Hip fractures (femoral neck and intertrochanteric fractures) also common

History

- A suspected fracture with a relatively minor mechanism or a history of multiple fractures suggests osteoporosis.
- A family history of osteoporosis is an important risk factor

Physical-Exam

Exam findings are related to the acute fracture rather than the disease itself.

ESSENTIAL WORKUP

- Fracture without significant mechanism and identification of risk factors is most important
- Careful neurovascular exam distal to femur or other extremity fracture
- Rectal tone and postvoid residual should be determined in patients with vertebral fractures
- Radiographs of suspected fracture may show osteopenia (late finding in disease)
- Spine films may show old compression fractures
- CT scan should be performed to better evaluate vertebral fractures:
 - Retropulsion, spinal canal compromise is not always apparent on plain films.
 - Make sure CT cuts extend full level above and below injuries on spine radiographs.

DIAGNOSIS TESTS & INTERPRETATION

Lab

Serum chemistries—such as calcium, parathyroid hormone, and alkaline phosphatase—may help differentiate this from other illnesses.

Imaging

- Plain films can identify fractures; however, age of each fracture may be difficult to determine
- Bone scan or CT can help determine age of fractures, especially in spine

Diagnostic Procedures/Surgery

Bone densitometry can provide prognostic information and help guide therapy. Dual-energy x-ray absorptiometry with BMD T-score ≤ -2.5 : Osteoporosis.

DIFFERENTIAL DIAGNOSIS

- Multiple myeloma or other metastatic tumor
- Osteogenesis imperfecta (usually apparent in childhood)
- Hyperparathyroidism
- Other demineralizing bone diseases

TREATMENT

PRE HOSPITAL

Cautions:

- Obtain pre-hospital information on mechanism to help diagnose pathologic fracture
- Avoid aggressive manipulation or movement of patient, as this may exacerbate bony injury

INITIAL STABILIZATION/THERAPY

Immobilize fractures

ED TREATMENT/PROCEDURES

- Fractures are treated with expectation of delayed or incomplete healing
- Prevention is far more effective than treatment
- Long-term therapy is beneficial (see Medication)
- Use of orthotic back braces and vests should be arranged in conjunction with orthopedic spine consultation
- Exercise is also helpful
- Balance must be achieved between osteoporosis risk and steroid or methotrexate therapy

MEDICATION

- Alendronate: 10 mg/d or 70 mg weekly, alternative is risedronate 5 mg/d, 35 mg weekly, or 150 mg monthly
- Zoledronic acid: 5 mg IV yearly
- Raloxifene (selective estrogen receptor modulator): 60 mg PO QD
- Calcium: 1,200 mg daily (total of diet + supplement)
- Vitamin D: 800 IU/d
- Calcitonin: Nasal spray 200 IU/d
- Denosumab (monoclonal antibody): 60 mg SC every 6 mo
- Parathyroid hormone 1–34: 20 µg SC daily
- Estrogen: 0.625 mg/d (with or without medroxyprogesterone)

Pediatric Considerations

Ensure adequate calcium in diet from early age.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Per normal orthopedic protocols, with special considerations for age and social situation
- Compression fractures are generally stable, but possibility of burst fracture with cord compression must be ruled out.

- Any cervical fracture or fracture with neurologic symptoms requires admission with emergent consultation with neurosurgery or orthopedics
- Admission may be necessary for pain control and because of decreased ambulation

Discharge Criteria

- Per normal orthopedic protocols with special considerations for age and social situation
- Patients with minimal injuries, able to care for themselves at home or with appropriate assistance, and adequate postoperative pain control may be discharged with orthopedic follow-up

Issues for Referral

Orthopedic referral is driven by the acute injury.

FOLLOW-UP RECOMMENDATIONS

- Follow-up is generally driven by the acute injuries
- Follow-up with the primary physician should be instituted to encourage treatment and monitoring of the disease to prevent recurrent fractures

PEARLS AND PITFALLS

- A history of recurrent fractures, particularly with a low-energy mechanism, suggests the possibility of osteoporosis
- Reduced bone density on plain radiographs is highly suggestive and warrants referral back to the PCP for further workup and treatment
- Bisphosphonates are 1st-line therapy for treatment

ADDITIONAL READING

OTITIS EXTERNA

Assaad J. Sayah

BASICS

DESCRIPTION

- Inflammation or infection of the auricle, auditory canal, or external surface of the tympanic membrane (TM):
 - Spares the middle ear
 - Affects 4/1,000 persons in US
- Also called “swimmer’s ear” due to the usual history of recent swimming:
 - Occasional cases after normal bathing
- Necrotizing (malignant) otitis externa:
 - Infection starts at the ear canal and progresses through periauricular tissue toward the base of the skull
 - Occurs in elderly, diabetic, or other immunocompromised patients
 - Caused by *Pseudomonas aeruginosa*
 - Can lead to cellulitis, chondritis, and osteomyelitis
 - Associated with 20% mortality

ETIOLOGY

- Often precipitated by an abrasion of the ear canal or maceration of the skin from persisting water or excessive dryness
- Predisposing factors include:
 - History of ear surgery or TM perforation
 - Narrow or abnormal canal
 - Humidity
 - Allergy
 - Eczema
 - Trauma
 - Abnormal cerumen production
- *P. aeruginosa*, *Staphylococcus aureus*, streptococcal species, and rarely fungi

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Recent swimming or prolonged water exposure
- History of diabetes
- History of chemotherapy, prolonged steroid use, HIV/AIDS, or other processes that

compromises immune system

- Itching of the external ear canal is usually the 1st symptom
- 1–2 day history of progressive pain
- Ear drainage
- Decreased auditory acuity
- Clogged sensation in ear

Physical-Exam

- Pain in ear or with motion of pinna/tragus
- Swollen, erythematous external ear canal
- Ear drainage
- Decreased auditory acuity
- Pain/swelling in preauricular area
- Necrotizing (malignant) otitis externa:
 - _ Pain, tenderness, swelling in periauricular area
 - _ Headache
 - _ Otorrhea
 - _ Cranial nerve palsy:
 - Facial nerve most affected

ESSENTIAL WORKUP

Clinical diagnosis with typical signs/symptoms:

- Pain in ear or with motion of pinna/tragus
- Otoscopic exam
- Swollen, erythematous external ear canal
- Ear drainage
- Cheesy white or gray-green exudate

DIAGNOSIS TESTS & INTERPRETATION

Lab

- None usually indicated, except when possibility of necrotizing otitis externa:
 - _ Signs of systemic toxicity or local spread of infection should be checked
- WBC count
- ESR
- Glucose (check for diabetes)
- Cultures

Imaging

CT/MRI to exclude mastoiditis if the patient has signs of toxicity or bone involvement

Diagnostic Procedures/Surgery

- Remove debris with a soft plastic curette or gentle irrigation with peroxide/water

mix

- Wick placement may be needed to facilitate medication delivery

DIFFERENTIAL DIAGNOSIS

- Necrotizing otitis externa
- Otitis media
- Folliculitis from obstruction of sebaceous glands
- Otic foreign bodies
- Herpes zoster infection of the geniculate ganglion
- Parotitis
- Periauricular adenitis
- Mastoiditis
- Dental abscess
- Sinusitis
- Tonsillitis
- Pharyngitis
- Temporomandibular joint pain
- Viral exanthems

Pediatric Considerations

Consider ear canal foreign bodies in children with purulent drainage from edematous, painful ear canals

TREATMENT

ED TREATMENT/PROCEDURES

- Clean external ear canal:
 - Remove the inflammatory debris by gentle curettage with a cotton-tipped wire applicator
 - Occasional suction with a Frazier suction tip may be necessary
- Insert a cotton or gauze wick 10–12 mm into the canal after cleansing if the ear canal is very edematous
- Management of otitis externa focuses on pain control, eradication of infection, and prevention of reoccurrence

MEDICATION

- Most cases respond well to topical treatment:
 - Antiseptic, anti-inflammatory, and drying otic drops eliminate the pathogenic bacteria and allow for rapid healing of the canal
 - Acetic acid solutions such as Domeboro otic (2% acetic acid): 4–6 drops q4–6h
 - Corticospirin otic (hydrocortisone 1%, polymyxin + neomycin) suspension:

- 4 drops to ear canal QID (use suspensions and not solutions with suspected TM perforation)
- Ofloxacin: 5 drops BID (drug of choice in perforated TM)
- Oral antibiotics:
 - Administer to patients with cellulitis of the face or neck, severe edema of the ear canal, concurrent otitis media, or when the TM cannot be visualized
 - Treat diabetics and other immunocompromised patients with oral ciprofloxacin and follow closely for symptoms of malignant otitis externa
 - Amoxicillin: 500 mg (peds: 40 mg/kg/d) PO TID
 - Ciprofloxacin: 500 mg PO BID
- IV antibiotics for patients with necrotizing otitis externa, severe cellulitis, or septic appearing
- Prophylaxis:
 - Apply rubbing alcohol or acetic acid (2%) to keep the external ear canal dry and prevent recurrence of infection
- Pain management with acetaminophen or NSAID. Consider opioids if severe pain
- Surgical débridement of granulation tissue and bone sequestration or drainage of associated abscess may be necessary in necrotizing otitis externa

COMPLICATIONS

- Mastoiditis
- Chondritis of the auricle
- Necrotizing otitis externa
- Osteomyelitis of the base of the skull
- CNS infections

FOLLOW-UP

DISPOSITION

Admission Criteria

- Necrotizing otitis externa
- Significant involvement of the pinna
- Signs of systemic illness

Discharge Criteria

- Most patients
- Close follow-up for patients at risk of otitis externa
- Patient instructions:
 - Avoid swimming and keep ears completely dry for 3–4 wk
 - Apply medications as directed
 - Return if worse pain, fever, hearing loss develops, or there is any change in

mental or neurologic status

- Follow up if symptoms are not improved within 2–3 days

Issues for Referral

Ear–nose–throat follow-up for:

- Perforated TM
- Worsening of symptoms
- Conductive hearing loss
- Failure of initial management

FOLLOW-UP RECOMMENDATIONS

Follow up with primary care physician or a return ED visit within 2–3 days for removal of the wick or if symptoms are worse.

PEARLS AND PITFALLS

- Concomitant and often erroneous diagnoses of acute otitis externa and otitis media are common because the TM in acute otitis externa is erythematous.
- Avoid ear canal lavage until tympanic integrity is documented.
- Regardless of the topical medications, penetration to the epithelium is key to therapy; any obstruction should be cleared.
- Recurrence can be largely prevented by counseling the patient and explaining how it can be avoided by minimizing ear canal moisture, trauma, or exposure to material that incites local irritation or contact dermatitis.
- Necrotizing otitis externa should be suspected in immunocompromised patients and diabetics who have severe otalgia, purulent otorrhea, and granulation tissue or exposed bone in the external auditory canal.

CODES

ICD9

- 380.10 Infective otitis externa, unspecified
- 380.14 Malignant otitis externa

ICD10

- H60.10 Cellulitis of external ear, unspecified ear
- H60.20 Malignant otitis externa, unspecified ear
- H60.90 Unspecified otitis externa, unspecified ear

OTITIS MEDIA

Assaad J. Sayah

BASICS

DESCRIPTION

- Inflammation of the middle ear
- Most commonly occurs in children 6–36 mo
- Rapid onset of local and/or systemic symptoms
- More than 1/3 of children experience >5 episodes by the age of 7 yr

ETIOLOGY

- Usually associated with (or as a result of) upper respiratory tract infections
- Viral:
 - Parainfluenza
 - Respiratory syncytial virus
 - Influenza
 - Adenovirus
 - Rhinovirus
- Bacterial:
 - *Streptococcus pneumoniae*
 - *Moraxella catarrhalis*
 - *Haemophilus influenzae*
 - *Streptococcus pyogenes*
 - *Mycoplasma pneumoniae*
- Associated with blockage of eustachian tube
- Predisposing factors:
 - Deficient mucus, cilia, or antibodies
 - Intubation, especially nasotracheal
 - American Indians, Eskimos
 - Down syndrome
 - Cleft palate
 - Diabetes
 - Vitamin A deficiency
 - HIV
- Risk factors
 - Family history
 - Daycare
 - Parental smoking
 - Pacifier use
 - Bottle-feeding

DIAGNOSIS

From the American Academy of Pediatrics 2013 Guidelines:

- Diagnose otitis media (OM) when:
 - Moderate to severe bulging of tympanic membrane (TM)
 - Mild bulging of TM *and* recent onset of ear pain (tugging, pulling, rubbing in nonverbal child)
 - New otorrhea not due to acute otitis externa
- Should *not* diagnose if no middle ear effusion (pneumatic otoscopy and/or tympanometry)
- Recurrent OM:
 - 3 episodes in 6 mo or
 - 4 episodes in the last year with 1 in the past 6 mo

SIGNS AND SYMPTOMS

History

- Ear pain (otalgia)
- Irritability
- Rhinitis
- Vomiting, diarrhea
- Poor feeding
- Fever
- Sensation of plugged ear
- Pulling at ear
- Vertigo, tinnitus
- Conjunctivitis

Physical-Exam

- TM inflammation, bulging, and limited mobility
- New onset otorrhea without evidence of otitis externa
- Decreased visibility of the landmarks of the middle ear

ESSENTIAL WORKUP

- Exclude associated conditions
- Consider full septic workup for sick patients with fever
- Otoscopic exam for appearance and mobility of TM:
 - Full visualization essential
 - Increased vascularity, erythema, purulence
 - Obscured landmarks—bony, light reflex
 - Pneumatic otoscopy—bulging, retracted, decreased mobility

DIAGNOSIS TESTS & INTERPRETATION

Lab

Cultures unhelpful unless done by tympanocentesis

Imaging

CT scan if associated mastoiditis is suspected

Diagnostic Procedures/Surgery

- Tympanocentesis—indications:
 - Severe pain or toxicity
 - Failure of antimicrobial therapy
 - Suspicion of suppurative complication
 - Sick neonate
 - Immunocompromised patient
- Tympanometry and acoustic otoscopy may be useful with difficult exams

DIFFERENTIAL DIAGNOSIS

- Infection:
 - Otitis externa
 - Mastoiditis
 - Dental abscess
 - Allergic rhinitis
 - Cholesteatoma
 - Peritonsillar abscess
 - Sinusitis
 - Lymphadenitis
 - Parotitis
 - Meningitis
- Trauma:
 - Perforation of the TM
 - Foreign body in ear
 - Barotrauma
 - Instrumentation
- Serous OM or eustachian tube dysfunction
- Impacted ear cerumen
- Impacted 3rd molar
- Temporomandibular joint dysfunction

TREATMENT

ED TREATMENT/PROCEDURES

- Most mild cases could resolve without antibiotics
- Antibiotics are indicated for:

- All infants < 6 mo
- Children < 2 yr with bilateral OM
- Bilateral OM in kids < 2 yr
- Children > 6 mo with severe infection (otalgia for > 48 hr or temperature 102.2°F or higher)
- Bilateral OM in kids < 2 yr
- Children > 6 mo with ruptured TM with drainage
- For otherwise normal healthy patients ≥ 6 mo with mild symptoms and/or uncertain diagnosis, consider no antibiotics and repeat evaluation in 2–3 days:
 - For reliable parents, may provide a prescription for oral antibiotics, which the family can fill if the child's symptoms get worse or persist after 2 days
- Considerations should include recurrent nature of OM, lack of clinical response, and resistance patterns in community
- Parenteral antibiotics are indicated in febrile toxic children < 1 yr or with immunocompromise
- Antihistamines, decongestants, and steroids have no proven efficacy
- Antipyretics and analgesics are important (avoid local analgesics in perforated TMs)

MEDICATION

- Antibiotics:
 - Amoxicillin: 500–875 mg PO q12h (peds: 80–90 mg/kg/d PO div. q12h) for 10 days
 - Amoxicillin–clavulanic acid: 500–875 mg PO q12h (peds: 90 mg/kg/d PO q12h) for 10 days
 - Azithromycin: 10 mg/kg PO day 1, then 5 mg/kg/d PO days 2–5
 - Cefuroxime: 500 mg PO q12h (peds: 30 mg/kg/d PO div. q12h)
- Analgesia:
 - Acetaminophen: 500 mg PO q6h (peds: 15 mg/kg per dose orally/rectally every 4–6 hr); not to exceed 4 g/24 h
 - Antipyrine/benzocaine (5.4%/1.4% solution): 2–4 drops in ear QID PRN
 - Ibuprofen: 400–600 mg PO q6–8h (peds: 10 mg/kg per dose orally every 6 hr)

FOLLOW-UP

DISPOSITION

Admission Criteria

Febrile toxic children who are:

- < 1 yr, immunocompromised
- Moderately or severely dehydrated

- Unable to tolerate oral fluids or medications
- Suspected or proven associated significant infection
- Suspected abuse
- Unreliable caretaker

Discharge Criteria

Children without any of the aforementioned criteria

FOLLOW-UP RECOMMENDATIONS

- Follow-up in 10–14 days to ensure resolution
- Indications for earlier follow-up:
 - Child does not get better in 24–48 hr
 - Any progression of signs or symptoms
 - New problems develop, including a rash
 - Any concerns arise

COMPLICATIONS

- Recurrent OM:
 - 3 episodes within 6 mo or
 - 4 episodes in 1 yr with the last within 6 mo
- Perforated TM
- Serous OM
- Hearing loss (conductive and sensorineural)
- Facial nerve injury
- Mastoiditis
- Cholesteatoma
- Meningitis
- Subdural empyema
- Labyrinthitis
- Epidural abscess
- Venous sinus thrombosis

PEARLS AND PITFALLS

For otherwise normal healthy patients ≥ 6 mo with mild symptoms and/or uncertain diagnosis, consider no antibiotics and repeat evaluation in 2–3 days.

- H66.90 Otitis media, unspecified, unspecified ear
- H68.109 Unspecified obstruction of Eustachian tube, unspecified ear

OTOLOGIC TRAUMA

David A. Pearson • Chelsea Kolshak

BASICS

DESCRIPTION

Pinna

- Ear cartilage has no blood supply and is nutritionally dependent on perichondrium
- Hematomas often disrupt perichondrium and cartilage
 - Can lead to:
 - Ischemia
 - Perichondritis
 - Necrosis
 - Cauliflower ear
- Penetrating injuries or bite wounds may lead to infection of cartilage

Middle Ear

- Air-space cavity containing ossicles; susceptible to injuries disrupting pressure (blast, diving)
- Bordered by medial cranial fossa (including temporal and mastoid bones)
- Traumatic fractures can lead to CSF leak (otorrhea/rhinorhea)
 - May disrupt enclosed vestibular system
- Facial nerve passes through cavity—injury to cavity may cause peripheral nerve paralysis

ETIOLOGY

- Blunt trauma:
 - Contact sports such as wrestling
 - Motorcycle helmets
- Penetrating trauma such as tympanic membrane (TM) perforation from cotton swabs
- Human or animal bites
- Blast injury
- Lightning injury:
 - TM and ossicular disruptions occur in 50% of lightning strikes
- Chemical exposure
- Thermal injury
- Diving injuries:
 - Inner ear barotrauma
 - TM rupture

Pediatric Considerations

Consider nonaccidental trauma

DIAGNOSIS

SIGNS AND SYMPTOMS

- Severe ear pain
- Bleeding
- *Signs of auricular deformity:*
 - Edema
 - Hematoma:
 - Bluish, fluctuant, or doughy swelling of auricle
 - Laceration
 - Amputation
 - Loss of contour of the pinna
- *Signs of middle ear trauma:*
 - Decreased hearing:
 - Partial loss suggests TM rupture
 - Complete loss suggests injuries to ossicles or inner ear
 - Tinnitus
 - Middle ear effusion or canal drainage
 - Peripheral facial nerve paralysis
 - Vestibular symptoms, i.e., nystagmus or vertigo:
 - May also result from inner ear injury
- *Signs of basilar skull fracture:*
 - Hemotympanum or serous effusion
 - Retroauricular hematoma (battle sign)
 - CSF otorrhea or rhinorrhea
 - Peripheral facial nerve paralysis

History

- Mechanism
- Associated injuries
- Past otologic history
- Medications and allergies

Physical-Exam

- Head
- Cranial nerves
- Vascular structures
- Pinna
- External ear canal

- TM
- Hearing
- Consider the Weber and the Rinne test to evaluate for conductive hearing loss due to TM rupture or perforation:
 - Rinne test: Place a struck tuning fork to mastoid tip, hold until patient no longer hears ringing, then place fork near external auditory opening:
 - Normal: Patient still hears ringing; air conduction > bone conduction
 - Abnormal: No sound heard; air conduction < bone conduction; implies a conductive hearing loss
 - Weber test: Place a struck tuning fork to center of forehead:
 - Normal: Equal sound perception in both ears
 - Abnormal due to neurosensory loss: Patient will have decreased sound perception in the impaired ear
 - Abnormal due to conductive loss: Increased sound perception in the impaired ear
- Be sure to evaluate for concomitant injuries

DIAGNOSIS TESTS & INTERPRETATION

Lab

Wound culture if signs of infection

Imaging

- Consider head and/or facial CT to evaluate for intracranial injury or bone fracture
- Consider CT temporal bone without contrast if evidence of serious middle ear injury

DIFFERENTIAL DIAGNOSIS

- Infection
- Hemangioma
- Foreign body in ear

TREATMENT

PRE HOSPITAL

If auricle is amputated, wrap in moist gauze and place in plastic bag

INITIAL STABILIZATION/THERAPY

- Check ABCs; full trauma evaluation; resuscitation as appropriate
- Sterile dressing to injured site

ED TREATMENT/PROCEDURES

- All injury types:

- Anesthesia:
 - Local anesthesia via nerve block to auriculotemporal branch of mandibular nerve, lesser occipital nerve, greater auricular nerve, and auricular branch of vagus nerve; use 1% lidocaine or 0.25% marcaine
 - Alternative: Inject ring of anesthetic around base of pinna
- Tetanus prophylaxis if necessary
- Specific injury types:
 - Auricular hematoma: Drainage imperative to reapproximate perichondrium to cartilage to prevent cartilage necrosis, ideally within 72 hr; however, no clearly defined best treatment
 - Antistaphylococcal antibiotics for 7–10 days
 - Aspiration: Preferred alternative if clot not yet formed; use 18G–20G needle for aspiration milk hematoma until totally evacuated; apply pressure dressing
 - Incision and drainage: More effective with larger and/or clotted hematomas; incise along curvature of pinna with no. 15 scalpel, evacuate, and irrigate; apply pressure dressing
 - Vaseline gauze pressure dressing: Place to fill crevices of pinna; place over and behind pinna; wrap soft gauze firmly around head
 - Alternative pressure dressing: Suture dental rolls into place over incised area
 - If patient has 2nd presentation due to reaccumulation, hematoma should be reaspirated and a wick placed for drainage
- Laceration:
 - Prophylactic antibiotics are controversial but for human and animal bites treat with amoxicillin–clavulanate
 - Clean and debride wound, anesthetize as necessary
 - Superficial abrasions: Clean, dress with antibiotic ointment
 - Simple lacerations: 5 or 6 monofilament nylon or polypropylene suture, then pressure dressing; may use absorbable suture to avoid having to bend ear for suture removal
 - Exposed auricular cartilage: Carefully debride jagged edges; completely cover cartilage to prevent perichondritis; can remove small amount of cartilage to allow skin coverage; approximate cartilage 1st with absorbable sutures at major landmarks; include anterior and posterior perichondrium in stitch
 - Avulsions:
 - < 2 cm total avulsions may be used as graft and survive
 - > 2 cm: Consult or urgently refer to otolaryngologist or plastic surgeon

MEDICATION

- Amoxicillin–clavulanate: Adults: 875/125 mg PO BID (peds: 40 mg/kg/d PO BID)

- Dicloxacillin: 250–500 mg PO QID (peds: 30–50 mg/kg/d PO div. q6h)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Concomitant serious traumatic injuries
- Need for IV antibiotics
- Immunosuppressed persons with serious infections, perichondritis, or chondritis

Discharge Criteria

- Able to tolerate oral antibiotics
- Able to arrange close follow-up

FOLLOW-UP RECOMMENDATIONS

- Follow up wound suture repair in 5 days
- Follow up hematomas in 24 hr to evaluate for reaccumulation

OVARIAN CYST/TORSION

René A. King • Lynne M. Yancey

BASICS

DESCRIPTION

- Ovarian cysts:
 - Generally asymptomatic until complicated by hemorrhage, torsion, rupture, or infection
 - Follicular cysts:
 - Most common
 - Occur from fetal life to menopause
 - Unilocular; diameter 3–8 cm
 - Thin wall predisposes to rupture, which usually causes minimal or no bleeding
 - Rupture during ovulation at midcycle is known as mittelschmerz
 - Corpus luteal cysts:
 - Most significant
 - Diameter 3 cm, but usually < 10 cm
 - Rapid bleeding from intracystic hemorrhage causes rupture
 - Rupture is most common just before menses begins
 - Can cause severe intraperitoneal bleeding
 - Gradual bleeding into cyst or ovary distends capsule and may cause pain without rupture
- Adnexal torsion:
 - 5th most prevalent surgical gynecologic emergency
 - Twisting of vascular pedicle of ovary, fallopian tube, or paratubal cyst
 - Causes adnexal ischemia leading to necrosis
 - Occlusion of lymphatics and venous drainage lead to rapid enlargement of adnexa
 - Greatest risk with cysts 8–12 cm

RISK FACTORS

Adnexal torsion:

- Reproductive-age women
- Ovarian cysts, especially > 5 cm
- Ovarian hyperstimulation
- Tumors: Serous cystadenoma most common; teratomas
- Pelvic surgery: Tubal ligation; hysterectomy
- Pregnancy
- History of pelvic inflammatory disease

Pregnancy Considerations

Torsion in pregnancy usually occurs in the 1st trimester, and in vitro fertilization or ovarian induction are risk factors.

Pediatric Considerations

15% of adnexal torsions occur in children

ALERT

- Anticoagulated patients at increased risk of:
 - _ Hemorrhagic corpus luteal cyst
 - _ Significant bleed from ruptured cyst, including with ovulation

ETIOLOGY

- Ovarian cyst:
 - _ Follicular cysts result from nonrupture of mature follicle or failure of atresia of immature follicle
 - _ Corpus luteal cysts result from unrestrained growth in early pregnancy or from normal intracystic hemorrhage days after ovulation
 - _ Other cysts:
 - Theca lutein
 - Cystic teratoma
 - Endometrioma (chocolate cyst)
- Adnexal torsion:
 - _ Right > left
 - _ Highest frequency in reproductive women

ALERT

Cysts found in postmenopausal women suggest carcinoma

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Ovarian cyst:
 - _ Abdominal pain
 - Sharp, unilateral
 - Intermittent vs. constant
 - Migration
 - Previous episodes
 - May occur with exercise, intercourse, trauma, or pelvic exam
 - _ Fever is rare
 - _ Irregular menses (may suggest polycystic ovary syndrome)

- Infertility
- Pregnancy status
- Previous STDs
- History of breast or GI cancer (may metastasize)
- Adnexal torsion:
 - Variable history
 - Abdominal pain:
 - Sudden, sharp, colicky
 - Localized vs. diffuse
 - Referred pain to groin or flank
 - May be chronic or recurring with torsion/detorsion
 - Fever
 - Nausea/vomiting
 - Vaginal bleeding
 - UTI symptoms

Physical-Exam

- Ovarian cyst:
 - Abdominal tenderness (mild to severe with peritonitis)
 - Adnexal tenderness
 - Pelvic mass
 - Hemorrhagic shock possible:
 - Usually from corpus luteal cyst rupture
 - Orthostasis, hypotension, tachycardia
- Adnexal torsion:
 - Abdominal tenderness (mild to severe)
 - Adnexal tenderness
 - Adnexal mass

ESSENTIAL WORKUP

- Pregnancy test essential to rule out ectopic pregnancy
- Rapid hemoglobin or hematocrit

DIAGNOSIS TESTS & NTERPRETATION

Lab

- Urine or serum human chorionic gonadotropin determination
- CBC
- Urinalysis
- If significant hemorrhage, type and cross packed RBCs
- Cervical cultures to rule out PID

Imaging

- Transvaginal US:
 - Adnexal cysts and masses:
 - Cystic masses <5 cm in premenopausal women generally benign
 - Should be re-evaluated at the end of menstruation
 - Pelvic free fluid
 - Enlarged, edematous ovary (suggests torsion)
- Doppler:
 - May show decreased flow with torsion
 - Important to document normal blood flow on Doppler in ED, even though does not rule out recent torsion of ovary
- MRI:
 - Consider in pregnant patients with right lower quadrant pain and nondiagnostic US and Doppler
- CT:
 - May demonstrate cysts or evidence of torsion or suggest alternative diagnosis
 - May provide enough information to proceed to laparoscopy if abnormal ovary and no other cause of pain identified
 - Uterus may be shifted to side of torted adnexa
 - Ascites may be present

ALERT

US sensitivity for diagnosis of ovarian torsion is not well established; continue workup if high clinical suspicion

Diagnostic Procedures/Surgery

- Culdocentesis:
 - No longer commonly done
 - May yield serosanguinous fluid with ruptured cyst
 - Hematocrit > 15% suggests significant hemoperitoneum
- Laparoscopy is gold standard for torted adnexa and definitive diagnosis

Pediatric Considerations

- Early detorsion of adnexa by laparoscopy is now advocated to preserve ovarian function
- Followed by frequent follow-up visits to monitor for malignancy

DIFFERENTIAL DIAGNOSIS

- Ectopic pregnancy
- PID
- Round ligament pain
- Endometriosis
- Neoplasm

- Torsion of uterus
- Appendicitis

FOLLOW-UP RECOMMENDATIONS

Ovarian cyst

- If pain is resolved and cyst is <4–5 cm, close follow-up is recommended with gynecology for further studies

PEARLS AND PITFALLS

Adnexal torsion:

- Torsion is a clinical diagnosis:
 - US may show flow to an ovary that has detorsed
- Symptoms can be varied and nonspecific
- Always include adnexal torsion in differential of abdominal pain

- N83.20 Unspecified ovarian cysts
- N83.51 Torsion of ovary and ovarian pedicle

PAGET DISEASE

Anna L. Waterbrook • Matthew C. Kostura

BASICS

DESCRIPTION

- Paget disease involves resorption of normal bone and its replacement with fibrous and sclerotic tissue
- Also known as osteitis deformans
- Usually focal, bones most frequently involved include:
 - Pelvis (70%)
 - Femur (55%)
 - Skull (42%)
 - Tibia (32%)
 - Spine (53%, lumbar spine)
 - Flat bones
- Usually found incidentally and generally asymptomatic
- Occurs in ~1–2% of patients >55 yr old
- Incidence increases with age
- Starts with resorptive or osteolytic phase, during which osteoclasts remove healthy bone
- Hypervascularity begins in resorptive phase:
 - Predisposes to hematoma and fracture
- Resorbed bone is eventually replaced by irregular, dense, disorganized trabecular bone in sclerotic or osteoplastic phase forming “mosaic pattern”
- Malignant transformation is rare:
 - Osteosarcoma is malignancy of concern
 - Usually malignant transformation occurs in 1%
- More common in men
- More common in European descent
- Less common in Asian or Scandinavian descent
- Typically involves 1 bone (monostotic)
- May involve a few bones (polyostotic)

ETIOLOGY

- Unknown
- Genetic component:
 - SQSTM1 mutation seen in many but not all cases
- Environmental influences may also play a role
 - Presence of nucleocapsids from measles, canine distemper, paramyxovirus, or respiratory syncytial virus may implicate viral cause

- Possible association with rural life and close contact with farm animals
- May represent vascular hyperplasia with subsequent inflammation
- Increased nucleoli and intranuclear inclusion bodies seen in osteoclasts on microscopy

Pediatric Considerations

Generally not seen in children

DIAGNOSIS

SIGNS AND SYMPTOMS

- Many patients are asymptomatic, with disease discovered by incidental radiographs or elevated alkaline phosphatase levels
- Deep, aching bone pain occurs late in the clinical course
- Pain with weight bearing if femur or tibia involvement
- Pain worse with rest in nonweight-bearing bones
- Acute (resorptive/osteolytic) phase:
 - Pathologic fractures
 - Pain from acute lysis, fracture, or resultant arthritis
 - Hypercalcemia or renal stones
 - Hypervascularity may result in significant bleeding if affected bone is fractured
 - Widespread disease:
 - Increased vascularity and blood flow may result in high-output cardiac failure
- Secondary (sclerotic/osteoplastic) phase:
 - Long-bone involvement may present with swelling or deformity and gait abnormality
 - Skull involvement may cause headaches or abnormal skull shape (change in hat size)
 - Severe skull or spine involvement may result in CNS compression
 - Hearing loss may result from nerve compression or ossicle involvement

ESSENTIAL WORKUP

- Diagnosis usually suggested by radiographs
- Thorough neurologic exam must be documented, especially with vertebral or pelvis involvement

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Alkaline phosphatase is the most dramatic marker of disease activity
- Calcium and phosphate levels should be checked as well, but are usually normal

- Hypercalcemia seen in immobilization or presence of a fracture, but if elevated in an ambulatory patient, suspect hyperparathyroidism
- EKG if suspect hypercalcemia and CXR with evidence of high-output cardiac failure
- Increased bone formation may lead to elevations in urine hydroxyproline or serum osteocalcin or procollagen fragments
- Alterations in parathyroid hormone (PTH) levels occur as secondary changes during resorptive/osteolytic phase (low PTH) and sclerotic/osteoplastic phase (high PTH)

Imaging

- Plain x-rays:
 - During resorptive phase, lytic lesions are often not seen, except in skull, where lesions are well demarcated (osteoporosis circumscripta)
 - Bowing of long bones may occur with resorption and strength loss
 - New bone initially appears irregular and spotty, and later becomes homogeneous and dense (“ivory pattern”)
 - Excess bone may be deposited along stress lines, leading to cortical irregularities and thickening
- CT or MRI defines margins and helps evaluate for neoplasm or hematoma:
 - Spiral CT to detect renal calculi
- Radionuclide bone scans useful to evaluate extent and activity of disease
- Plain films are usually all that is needed in acute setting to identify/manage fractures

DIFFERENTIAL DIAGNOSIS

- Primary hyperparathyroidism
- Multiple myeloma
- Hodgkin variants
- Acromegaly
- Osteosarcoma

TREATMENT

PRE HOSPITAL

- Pre-hospital personnel should obtain information about mechanism of injury or social factors that suggest pathologic fracture
- Adequate immobilization can limit excessive bleeding around fracture site

INITIAL STABILIZATION/THERAPY

- Airway management and resuscitation, as indicated
- High-output cardiac failure should be treated as outlined in CHF chapter
- Prompt immobilization of fractures will limit excessive bleeding around fracture

site

ED TREATMENT/PROCEDURES

- Analgesia for pain of lytic lesions, fractures, or arthritis includes acetaminophen and narcotics
- Fracture treatment is often more conservative, owing to difficulties with bleeding during operative repair
- Orthopedic consultation for severe arthritis and definitive fracture management
- Hypercalcemia may be treated with IV fluids, calcitonin, and/or bisphosphonates
- CNS compression requires emergent neurosurgical consultation and possible decompression

MEDICATION

Treatment indicated in patients with symptomatic disease or asymptomatic disease located in areas where complications can occur

First Line

- Nitrogen-containing bisphosphonates:
 - Pamidronate: 30 mg IV daily × 3 consecutive days; infuse over 4 hr
 - Alendronate: 40 mg PO daily for 6 mo
 - Risedronate: 30 mg PO daily for 2 mo
 - Zoledronic acid: 5 mg IV × 1; infuse over at least 15 min

Second Line

- Simple bisphosphonates and calcitonin:
 - Etidronate: 5 mg/kg PO daily for 6 mo
 - Tiludronate: 400 mg PO daily for 3 mo
 - Calcitonin: 50–100 U SC as tolerated; not for >6 mo
- Chemotherapy and simple bisphosphonates no longer recommended
- Use of calcitonin and simple bisphosphonates are limited to patients who cannot tolerate or who are allergic to the nitrogen-containing bisphosphonates
- Side effects of bisphosphonates include influenza like syndrome and jaw osteonecrosis
- Often need supplemental vitamin D and Ca to maintain normal Ca levels during treatment

FOLLOW-UP

Admission Criteria

- Admission as indicated for major trauma or injury, or excessive bleeding
- Orthopedic procedures
- Hypercalcemia

- CNS compressive symptoms, nerve entrapment requiring surgery

Discharge Criteria

- No evidence of significant bleeding, neurologic compromise, or hypercalcemia, and adequate pain control
- Appropriate fracture immobilization and orthopedic follow-up

Issues for Referral

- Referral is based upon any acute injuries
- May also consider referral to endocrinologist within 1–2 wk of discharge

FOLLOW-UP RECOMMENDATIONS

- Follow-up is generally driven by the acute injury that led to the radiographs on which the diagnosis of Paget disease was made
- Response to pharmacologic treatment aimed at correction of serum alkaline phosphatase levels
- Consider repeat pharmacologic treatment if rise in serum alkaline phosphatase, return of symptoms, or disease progression seen radiographically

PEARLS AND PITFALLS

- The diagnosis of Paget disease is usually made as an incidental finding on radiographic imaging
- Prompt immobilization of fractures will limit excessive bleeding around fracture site
- Consider Paget disease if elevation of alkaline phosphatase is present without any other explanation

PAIN (PRINCIPLES/MEDS/COMFORT CARE)

Vincent Bounes

BASICS

DESCRIPTION

Unpleasant sensory and emotional experience that may be secondary to actual or perceived damage to tissue, the somatosensory system, or a psychogenic dysfunction.

- It is an individual, subjective, multifactorial experience influenced by culture, medical history, beliefs, mood and ability to cope.

EPIDEMIOLOGY

Incidence and Prevalence Estimates

- Most common reason for seeking health care
- Up to 78% of visits to the emergency department.
- Pain is severe for 2/3rds of patients presenting with pain.
- Chronic pain is present in up to 35% of the population.
- Prevalence of neuropathic pain is 21.4% in emergency departments.

ETIOLOGY

- Different components of pain can be combined in a same patient.
- Nociceptive pain:
 - Stimulation of peripheral nerve fibers (nociceptors) that arises from actual or threatened damage to non-neural tissue.
 - Visceral pain:
 - Stimulation of visceral nociceptors
 - Diffuse, difficult to locate, and often referred to a distant, usually superficial, structure.
 - Sickening, deep, squeezing, dull.
 - Deep somatic pain:
 - Stimulation of nociceptors in ligaments, tendons, bones, blood vessels, fasciae, and muscles
 - Dull, aching, poorly localized pain.
 - Superficial pain:
 - Stimulation of nociceptors in the skin or other superficial tissue.
 - Sharp, well defined, and clearly located.
- Neuropathic pain:
 - Exacerbation of normally nonpainful stimuli (allodynia).
 - Paroxysmal episodes likened to electric shocks.
 - Continuous sensations include burning or coldness, “pins and needles”

sensations, numbness and itching.

- Psychogenic pain:
 - Pain caused, increased or prolonged by mental, emotional, or behavioral factors.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- A patient's self-report is the most reliable measure of pain.
- Obtain a detailed description of pain:
 - Onset
 - If caused by an injury, determine the mechanism of injury
 - Localization of pain
 - Severity of pain:
 - Mild pain from >0 to $\leq 3/10$
 - Moderate pain from >3 to $<6/10$
 - Severe pain $\geq 6/10$.
 - Type of pain
 - Duration of pain
 - Variations of pain:
 - Daily/weekly/monthly variations
 - Variations caused by physical activities
 - Effect of previous analgesic drugs taken before the consult.
- Acute vs. chronic pain:
 - Acute pain:
 - Transitory, usually <30 days
 - Lasting only until the noxious stimulus is removed or the underlying damage has healed
 - Resolves quickly
 - Subacute pain:
 - Lasting 1–6 mo
 - Chronic pain:
 - Lasts more than 3–6 mo
 - Pain that extends beyond the expected period of healing
- Numerical Rating Scale (NRS):
 - Patients estimate their pain intensity on a scale from 0 to 10
- Visual Analog Scale (VAS):
 - Patients indicate their pain by a position along a 10 cm continuous line between 2 end points, the left one representing no pain and the right one the worst pain they can imagine.

- Clinically relevant change varies from 13 to 19 mm on a VAS or 1.3–1.9/10 on an NRS.
- Faces Pain Scale:
 - Self-report measure of pain intensity developed for children (4–10 yr old).
- DN4 test:
 - Screening tool for neuropathic pain
 - The score ranges from 0 to 10
 - A score of 4 or more classifies the pain as neuropathic rather than nociceptive.
 - Pain characteristics:
 - Burning? (Yes = 1)
 - Painful cold (Yes = 1)
 - Electric shocks (Yes = 1)
 - Symptoms associated with the pain in the same area:
 - Tingling (Yes = 1)
 - Pins and needles (Yes = 1)
 - Numbness (Yes = 1)
 - Itching (Yes = 1)
 - Decrease in touch sensation (Yes = 1)
 - Decrease in prick sensation (Yes = 1)
 - Can the pain be caused or increased by brushing (Yes = 1)
- Remember to always use the same assessment tool for an individual patient.

Physical-Exam

- Observation needed to determine pain scale in nonverbal patients:
 - Vocalization, e.g., whimpering, groaning, crying, or moaning
 - Facial expression, e.g., looking tense, frowning, grimacing, looking frightened
 - Analgesic attitudes aimed to protect a body zone in rest position (seated or lengthened)
 - Careful movements, spontaneously or when asked.
- All aspects of the physical exam should be gently done.
- Posture, point tenderness, percussion tenderness, passive and active range of motion as well as active resistance.
- It is recommended to move smoothly between the different components of the exam while warning the patient about each phase.
- Always examine uninjured tissues first and avoid sudden movement.
- Repeat physical exam after pain relief.

DIAGNOSIS TESTS & INTERPRETATION

Perform any exam and lab or radiographic studies as indicated by the patient's condition.

ESSENTIAL WORKUP

- Obtain complete history of pain.
- When a person is nonverbal and cannot self-report pain, obtain history from caregivers/other relatives/friends/neighbors.

DIAGNOSIS TESTS & INTERPRETATION

As appropriate for medical condition(s)

Imaging

As appropriate for medical condition(s)

Diagnostic Procedures/Surgery

As appropriate for medical condition(s)

DIFFERENTIAL DIAGNOSIS

- Drug-seeking behavior in opioid dependent patients:
 - Frequent use of emergency facilities, moving from 1 provider to another without coordinated care.
 - Unclear history of illness, only subjective complaints (difficult to objectively verify).
 - Patients tend to be obsessive and impatient, and request repeatedly analgesic medications.
 - Some aspects of the physical exam should be inconsistent.
 - Lab and radiologic studies may remain normal.

TREATMENT

PRE HOSPITAL

- Nonpharmacologic measures are effective in providing pain relief in a pre-hospital setting.
- Nitrous oxide is an effective analgesic agent in pre-hospital situations.
- Morphine, fentanyl, and tramadol can be used in a pre-hospital setting.

INITIAL STABILIZATION/THERAPY

- ABCs
- Treat life-threatening medical/traumatic conditions as appropriate.
- Patients with severe pain should be triaged as a priority and dispatched in a rapid care sector, ensuring rapid pain control.

ED TREATMENT/PROCEDURES

- Nonpharmacologic measures are effective in providing pain relief and should be systematic:
 - Immobilization of injured extremities.

- Elevation of injured extremities.
- Ice.
- Opioids for severe pain:
 - Preferably IV or intraosseous if IV not possible
 - Wide interindividual variability in dose response and the delayed absorption with IM or SC routes
 - Oral opioids associated with acetaminophen represent reasonable alternatives for less severe pain:
 - Oxycodone 5–10 mg
 - Hydrocodone 5–10 mg
 - Codeine 30–60 mg
 - Tramadol 50–100 mg
- Nonsteroidal anti-inflammatory drugs:
 - Mild to moderate trauma pain
 - Musculoskeletal pain
 - Renal and biliary colic
 - Relatively high rate of serious adverse effects including GI bleeding and nephropathy.
- Acetaminophen provides safe and effective analgesia for mild to moderate pain with minimal adverse effects.
- Treat associated anxiety or emotion.
- Regional anesthesia should be considered for acute well-localized problems such as toothache, fractures, hand and foot injuries.

MEDICATION

- Acetaminophen: 500 mg (peds: 10–15 mg/kg, do not exceed 5 doses/24h) PO q4–6h, do not exceed 4 g/24h
- Codeine: 30–60 mg PO q4–6h prn
- Morphine:
 - Initial bolus of 0.05–0.1 mg/kg IV
 - 15–30 mg PO q4–6h
- Hydromorphone:
 - Initial bolus 1 mg IV
 - 2–4 mg PO q4–6h
- Oxycodone: 5–10 mg PO
- Hydrocodone: 5–10 mg PO
- Tramadol: 50–100 mg PO
- Hydrocodone/acetaminophen: 5/500 mg PO q4–6h
- Ibuprofen: 600–800 mg PO q6–8h (peds: 10 mg/kg q6h)
- Naproxen: 250–500 mg PO q12h

FOLLOW-UP

DISPOSITION

Admission Criteria

Disposition determined by medical condition and persistence of pain.

- Medical condition requiring admission.
- Uncontrolled pain.

Discharge Criteria

- Medical condition(s) addressed
- Pain relief defined as a final evaluation of pain $\leq 3/10$, or a decrease of pain $\geq 50\%$ from the baseline, or if the acceptable level of pain is reached for an individual patient.
- Physicians may control pain well in the ED with IV titration, but risk poor pain control after discharge with oral opioids:
 - Be aware of conversion rates between opioids.
 - Be aware of conversion from IV to oral dosing.
 - Opioids should be prescribed at fixed intervals to control pain, with additional as-needed doses as required.

Issues for Referral

Recurrence of pain despite adequate analgesic treatment or new unexpected pain requires a reassessment of the diagnosis and consideration of alternative causes for the pain.

FOLLOW-UP RECOMMENDATIONS

As appropriate for medical condition(s).

PEARLS AND PITFALLS

- In case of severe pain, initiate pain relief simultaneously with the primary assessment.
- Regular assessment of pain leads to improved pain management.
- Nonpharmacologic measures are effective in providing pain relief and should always be considered and used when possible.
- Titrating relatively high doses of opioid provides the best chance of delivering rapid and effective analgesia.

PANCREATIC TRAUMA

Stephen R. Hayden

BASICS

DESCRIPTION

- Direct epigastric blow compressing pancreas against vertebral column resulting in blunt trauma
- Injury to pancreas from penetrating object

Pediatric Considerations

- Trauma affects proportionately larger areas, leading to multisystem injuries.
- Children have less protective muscle and SC tissue.
- Malpositioned seat belts and child abuse need to be considered in small children.
- Children will less often present with hypotension.

ETIOLOGY

- Penetrating trauma: Most common mechanism
- Blunt trauma: Deep location of pancreas requires significant force to cause injury:
 - Steering wheel, seat belts, or bicycle handlebars to abdomen
 - In children, evaluate for nonaccidental trauma

COMMONLY ASSOCIATED CONDITIONS

90% of pancreatic injuries associated with injuries to adjacent structures:

- Liver, stomach
- Major arteries and veins
- Spleen, kidney
- Duodenum, colon, small bowel
- Common bile duct, gallbladder
- Spine: Chance fracture

DIAGNOSIS

ALERT

Extent of pancreatic injury may not be apparent on initial evaluation.

SIGNS AND SYMPTOMS

- Abdominal pain:
 - Diffuse or epigastric
 - Often out of proportion to physical exam and vital signs
- Soft-tissue contusion in upper abdomen

- Injury to lower ribs or costal cartilage
- Acute abdomen, often associated with other intra-abdominal injuries
- Concomitant splenic injury can present initially as dull back pain
- Hypotension
- Grey Turner sign:
 - Flank ecchymosis
- Cullen sign:
 - Periumbilical ecchymosis

History

Concise; details of incident especially important for blunt trauma

Physical-Exam

- Inspect for abrasions, contusions, penetrating wounds:
 - Must log roll patient for full inspection.
 - Look for seat belt-related injuries.
- Auscultate for presence or absence of bowel sounds.
- Palpate to determine location and severity of pain, presence of guarding, and rebound tenderness.
- Rectal exam for occult blood, vaginal exam, or penile exam
- Serial physical exams and vital signs for unidentified injuries

ALERT

Vascular injury is the most common cause of mortality related to pancreatic injury. Suspicion necessitates immediate evaluation and possible surgical exploration.

ESSENTIAL WORKUP

- Pace of workup is dictated by patient condition and other injuries.
- Abdominal CT with IV contrast is essential to evaluate for pancreatic trauma.
- MRCP is being used more frequently in trauma centers to better evaluate ductal injury.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Blood type, screen, or cross-match
- Hematocrit, WBC with differential, complete metabolic profile
- Amylase:
 - Not a reliable indicator of pancreatic trauma
 - Serial levels may increase sensitivity, but specificity still poor.
 - Elevated amylase may be early indicator of potential pancreatic injury.
 - Normal amylase does not rule out pancreatic injury.
 - More sensitive and specific if detected in diagnostic peritoneal lavage (DPL)

fluid

- Lipase:
 - No more specific for pancreatic injury
- Urinalysis
- Pregnancy test
- Alcohol and drug screening if indicated
- Prothrombin time/partial thromboplastin time, BUN, and creatinine

Imaging

- Note that all imaging tests may miss pancreatic injury.
- Cervical spine, CXRs, and pelvis films as for all blunt trauma patients
- Bedside US/FAST scan
- CT scan with IV contrast, helical/MDCT if available:
 - Shows better contrast enhancement of pancreatic parenchyma than standard scanning
 - MDCT is particularly useful in pediatric populations
- Magnetic retrograde cholangiopancreatography:
 - Noninvasive evaluation of injury to ductal components
- Endoscopic retrograde cholangiopancreatography:
 - Useful for patients with persistent hyperamylasemia
 - Unexplained abdominal symptoms
 - Some advocating early use to minimize complications
- Operative exploration and intraoperative cholangiogram remains the ideal diagnostic modality, particularly if patient is unstable.

Diagnostic Procedures/Surgery

DPL to identify intraperitoneal injuries:

- Check fluid for amylase level.
- May still miss significant pancreatic injury

DIFFERENTIAL DIAGNOSIS

Other or associated abdominal traumatic injuries

TREATMENT

PRE HOSPITAL

Transport to closest trauma center.

INITIAL STABILIZATION/THERAPY

- Airway management, resuscitation as indicated with crystalloids, colloids, or blood products
- Nasogastric-tube suction may be especially helpful in the setting of pancreatic

trauma.

GENERAL MEASURES

Follow standard trauma treatment for blunt abdominal trauma:

- Penetrating trauma:
 - Tetanus prophylaxis and broad-spectrum antibiotic therapy
- Intra-abdominal injury requiring operative intervention:
 - Broad-spectrum antibiotic therapy
- Must cover for colonic bacteria:
 - Aerobic: *Escherichia coli*, *Enterobacter*, *Klebsiella*, *Enterococcus*
 - Anaerobic: *Bacteroides fragilis*, *Clostridium*, *Peptostreptococcus*

ED TREATMENT/PROCEDURES

Follow ABCDE of trauma and resuscitate unstable patient with emergent surgical consultation or transfer to trauma center as indicated:

- Evaluate for associated abdominal injury.
- Choose imaging modality for rapid evaluation (CT and/or MRCP).
- Early identification of ductal injuries has been shown to reduce morbidity and mortality.
- Surgical: Pancreaticoduodenectomy, distal pancreatectomy, endoscopic stent (controversial), sump/closed suction drainage
- East Trauma Guidelines 2009
- Level III evidence: Grade I and II injuries: Drainage Grade III–V injuries: Resection and drainage

MEDICATION

- Adults:
 - Piperacillin/tazobactam 3.375 g IV OR
 - Cefotetan: 2 g IV + gentamicin 2 mg/kg IV OR
 - Cefoxitin: 2 g IV + gentamicin 2 mg/kg IV OR
 - Ceftriaxone: 1–2 g IV + Flagyl 15 mg/kg IV OR
 - Clindamycin: 600 mg IV + gentamicin 2 mg/kg IV
- Children:
 - Cefotetan: 20 mg/kg IV + gentamicin 2 mg/kg IV OR
 - Cefoxitin: 40 mg/kg IV + gentamicin 2 mg/kg IV OR
 - Ceftriaxone: 50 mg/kg per dose IV + Flagyl 15 mg/kg IV

First Line

Ceftriaxone and Flagyl or piperacillin/tazobactam or carbapenem:

- Goal is to choose broad-spectrum coverage with both aerobic and anaerobic coverage, particularly of enteric gram-negative organisms.

Second Line

Addition of an aminoglycoside, as it has good activity in an alkaline environment:

- Particularly useful if patient is unstable for broader gram-negative coverage

Adjunct Therapy

There is no good evidence to support the use of octreotide as studies still conflict on the benefits and adverse effects.

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with suspected pancreatic injuries must be admitted.
- Abdominal pain after blunt trauma requires serial exam and observation for 24–72 hr.
- Intoxicated trauma patient requires admission and serial exams for unidentified injury.

Discharge Criteria

Only for very minor trauma and with no evidence of pancreatic or any other intra-abdominal injury with appropriate follow-up and return precautions

Issues for Referral

- Patient with surgical drains or complications such as fistula formation may need further surgical, GI, and wound care evaluations.
- Most patients need close monitoring and follow-up within 1 wk.

FOLLOW-UP RECOMMENDATIONS

Delayed presentation of pancreatic injury is rare, but complications may arise and should be considered:

- Pancreatitis, pseudocysts, vascular aneurysms (such as splenic artery)
- Rare for exocrine or endocrine dysfunction to occur unless a majority of the pancreas is resected/destroyed:
 - Evaluate for glucose intolerance and digestive abnormalities

PEARLS AND PITFALLS

- Always consider pancreatic injury when evaluating abdominal or back trauma, both blunt and penetrating.
- Beware of nearby vascular injuries.
- Assess for related injuries.
- Choose the best imaging modality and obtain as rapidly as possible.

- Penetrating trauma or unstable patients should be rapidly prepared for surgical exploration.

- S36.239A Laceration of unspecified part of pancreas, unspecified degree, initial encounter

PANCREATITIS

Trevor Lewis

BASICS

DESCRIPTION

- Inflammation of pancreas due to activation, interstitial liberation, and digestion of gland by its own enzymes
- Acute pancreatitis:
 - Exocrine and endocrine function of gland impaired for weeks to months
 - Glandular function will return to normal.
- Chronic pancreatitis:
 - Exocrine and endocrine function progressively deteriorates with resultant steatorrhea and malabsorption.
 - Dysfunction progressive and irreversible
- Pancreatic pseudocyst:
 - Cystic collection of fluid with high content of pancreatic enzymes surrounded by a wall of fibrous tissue lacking a true epithelial lining
 - Localized in parenchyma of pancreas or adjacent abdominal spaces (lesser peritoneal sac)
 - Requires 4–6 wk to form from onset of acute pancreatitis

ETIOLOGY

- Gallstones and alcohol abuse most common causes of *acute pancreatitis* (75–80%)
- Alcohol abuse accounts for 70–80% of *chronic pancreatitis*.
- Acute:
 - Biliary tract disease
 - Chronic alcoholism
 - Obstruction of pancreatic duct
 - Ischemia
 - Medications
 - Infectious
 - Postoperative
 - Post-ERCP
 - Metabolic diseases
 - Trauma
 - Scorpion venom
 - Penetrating peptic ulcer
 - Hereditary
- Chronic:
 - Chronic alcoholism

- Obstruction pancreatic duct
- Tropical
- Hereditary
- Shwachman disease
- Enzyme deficiency
- Idiopathic
- Hyperlipedemia
- Hypercalcemia
- Pancreatic pseudocyst:
 - Complication in 5–16% of acute pancreatitis; 20–40% of chronic pancreatitis

Pediatric Considerations

Causes mainly viral, trauma, and medications

DIAGNOSIS

SIGNS AND SYMPTOMS

- Frequency:
 - Abdominal pain: 95–100%
 - Epigastric tenderness: 95–100%
 - Nausea and vomiting: 70–90%
 - Low-grade fever: 70–85%
 - Hypotension: 20–40%
 - Jaundice: 30%
 - Grey Turner/Cullen sign: <5%
 - Subcutaneous or SQ
- GI:
 - Severe, persistent epigastric pain radiating to back:
 - Colicky or rebound tenderness suggests nonpancreatic source.
 - Worse when supine
 - Nausea, vomiting, and anorexia
 - Bowel sounds usually decreased or absent
 - Significant GI bleed in patients with acute severe pancreatitis is uncommon.
 - Cullen sign:
 - Bluish discoloration at umbilicus secondary to hemorrhagic pancreatitis
 - Grey Turner sign:
 - Bluish discoloration at flank secondary to hemorrhagic pancreatitis
- Respiratory:
 - Pleuritic chest pain
 - Dyspnea

- Lung exam:
 - o Left pleural effusion (most common)
 - o Atelectasis
 - o Pulmonary edema
- Hypoxemia (30%)
- Cardiac:
 - Tachycardia
 - Hypotension
 - Shock
- Neurologic:
 - Irritability
 - Confusion
 - Coma
 - Chvostek and Trousseau signs are rare despite lab evidence of hypocalcemia.

Ranson Criteria

- Indicators of morbidity and mortality:
 - 0–2 criteria: 2% mortality
 - 3 or 4 criteria: 15% mortality
 - 5 or 6 criteria: 40% mortality
 - 7 or 8 criteria: 100% mortality
- Criteria on admission:
 - Age > 55 yr
 - WBC count > 16,000 mm³
 - Blood glucose > 200 mg/dL
 - Serum lactate dehydrogenase > 350 IU/L
 - AST > 250 IU/L
- Criteria during 1st 48 hr:
 - Hematocrit fall > 10%
 - BUN increase > 5 mg/dL
 - Serum calcium < 8 mg/dL
 - Arterial PO₂ < 60 mm Hg
 - Base deficit > 4 mEq/L
 - Estimated fluid sequestration > 6 L

ESSENTIAL WORKUP

Lab tests to confirm physical diagnosis

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Lipase:
 - Rises within 4–8 hr of pain onset
 - More reliable indicator of pancreatitis than amylase
- Amylase:
 - Rises within 6 hr of pain onset
 - Levels > 3 times limit of normal suggest pancreatitis.
 - Levels > 1,000 IU suggest biliary pancreatitis.
 - May be normal during acute inflammation due to significant pancreatic destruction
 - Secreted from various sources
- Electrolyte, BUN, creatinine, glucose:
 - Hypokalemia occurs with extensive fluid losses.
 - Hyperglycemia
- CBC:
 - Increased hematocrit with fluid losses
 - Hematocrit > 47% at risk for pancreatic necrosis
 - Decreased hematocrit with retroperitoneal hemorrhage
 - WBC count > 12,000 unusual
- Calcium/magnesium:
 - Hypocalcemia indicates significant pancreatic injury.
 - Hypomagnesemia occurs with underlying alcohol abuse.
- Liver function tests:
 - Useful for prognostic indicators if suspected biliary cause
- CRP:
 - Useful to measure severity at 24–48 hr after symptoms onset
- Pregnancy test
- Arterial blood gases:
 - Indicated if hypoxic (assess PO₂) or toxic appearing (assess base deficit)
- ECG:
 - Assess electrolyte imbalances, ischemia

Imaging

- Abdominal series radiograph:
 - Excludes free air
 - May visualize pancreatic calcifications
 - Most common finding is isolated dilated bowel loop (sentinel loop) near pancreas.
- Chest radiograph:
 - Pleural effusion
 - Atelectasis
 - Infiltrate
- US:

- Useful if gallstone pancreatitis suspected
- Abdominal CT indications:
 - High-risk pancreatitis (> 3 Ranson criteria)
 - Hemorrhagic pancreatitis
 - Suspicion for pseudocyst
 - Diagnosis in doubt

Diagnostic Procedures/Surgery

Endoscopic retrograde cholangiopancreatography (ERCP):

- Indicated for severe pancreatitis with cholangitis or biliary obstruction

DIFFERENTIAL DIAGNOSIS

- Mesenteric ischemia/infracton
- Myocardial infarction
- Biliary colic
- Intestinal obstruction
- Perforated ulcer
- Pneumonia
- Ruptured aortic aneurysm
- Ectopic pregnancy

TREATMENT

PRE HOSPITAL

- Initiate IV access in cooperative patients.
- Apply cardiac monitor.

INITIAL STABILIZATION/THERAPY

- ABCs
- Supplemental oxygen
- Cardiac monitor
- IV fluids

ED TREATMENT/PROCEDURES

- Airway management:
 - Pulmonary complaints necessitate supplemental oxygen.
 - Endotracheal intubation for adult respiratory distress syndrome or severe encephalopathy
- Fluid resuscitation:
 - Large fluid volumes (up to 5–6 L in 1st 24 hr) to compensate for fluid losses
 - Continuously assess vitals, urine output, and electrolytes to ensure rapid and adequate replacement of intravascular volume.

- Correct electrolyte abnormalities if present:
 - Hypocalcemia (Calcium gluconate)
 - Hypokalemia occurs with extensive fluid losses.
 - Hypomagnesemia occurs with underlying alcohol abuse.
- Blood products:
 - In hemorrhagic pancreatitis, transfuse to hematocrit level of 30%.
 - Fresh-frozen plasma and platelets if coagulopathic and bleeding
- Analgesia:
 - Opiate analgesia is the drug of choice.
- Nasogastric suction:
 - Not useful in cases of mild pancreatitis
 - Beneficial in severe pancreatitis or intractable vomiting
- Antiemetics
- Antibiotics:
 - Indicated if pancreatic necrosis >30% on abdominal CT

Geriatric Considerations

Consider central venous pressure monitoring when fluid overload is a concern.

MEDICATION

First Line

Analgesics, antiemetics:

- Morphine 2–4 mg IV
- Hydromorphone (Dilaudid) 1 mg IV/IM
- Ondansetron 4 mg IV/IM/PO

Second Line

Electrolyte replacement, antibiotics:

- Potassium chloride: 10 mEq/h IV over 1 hr
- Calcium gluconate 10%: 10 mL IV over 15–20 min
- Magnesium sulfate: 2 g IV piggyback
- Imipenem: 500 mg IV q6h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Acute pancreatitis with significant pain, nausea, vomiting
- ICU admission for hemorrhagic/necrotizing pancreatitis

Discharge Criteria

- Mild acute pancreatitis without evidence of biliary tract disease and able to tolerate oral fluids
- Chronic pancreatitis with minimal abdominal pain and able to tolerate oral fluids

Issues for Referral

- Surgical/GI consultation for ERCP in severe pancreatitis with cholangitis or biliary obstruction
- Emergent surgical consultation mandatory in cases of suspected ruptured pseudocyst or pseudocyst hemorrhage, as definitive treatment is emergent laparotomy

FOLLOW-UP RECOMMENDATIONS

All discharged mild pancreatitis should have scheduled follow-up within 24–28 hr.

PEARLS AND PITFALLS

- Gallstones and alcohol account for etiologies of 75–80% of acute pancreatitis.
- Early aggressive fluid therapy is essential to replace large volume losses.
- Nasogastric suction is not beneficial in routine pancreatitis.
- Consider early CT of abdomen when diagnosis in doubt or patient appears ill by clinical scoring scale (Ranson criteria ≥ 3).

CODES

ICD9

- 577.0 Acute pancreatitis
- 577.1 Chronic pancreatitis
- 577.2 Cyst and pseudocyst of pancreas

ICD10

- K86.1 Other chronic pancreatitis
- K85.2 Alcohol induced acute pancreatitis
- K85.9 Acute pancreatitis, unspecified

PANIC ATTACK

Juliana H. Chen • Bernie Vaccaro

BASICS

DESCRIPTION

- Characteristic, acute episodes of physical symptoms and intense fear that rapidly peak within 10 min and resolve in ~ 20 min
- There may be a nonfearful variant in medical patients.

Panic Disorder

- Recurrent, unexpected panic attacks with ≥ 1 mo of persistence:
 - _ Concerns about having another attack
 - _ Worry about the implications or consequences of the attacks
 - _ Behavioral change, such as phobic avoidance, related to the attacks
 - _ With or without agoraphobia = anxiety related to fear of escape
- Episodic, recurrent, or chronic attacks
- Frequently comorbid with depression, substance abuse, disability, suicidal tendency

Genetics

- Probably genetic
- Family history of panic or anxiety is common
- Altered serotonin- and benzodiazepine-receptor function

ETIOLOGY

Mechanism

Limbic system, norepinephrine release, other neurotransmitters (e.g., serotonin) implicated, leading to “fight-or-flight” response

RISK FACTORS

- Major life events in the year preceding onset
- Family history of panic or anxiety
- Childhood shyness or separation anxiety
- May develop in the course of predisposing physical illness or cocaine abuse:
 - _ May persist after the illness or substance use has resolved
- Twice as common in women

DIAGNOSIS

SIGNS AND SYMPTOMS

- Multiple systems suggest autonomic arousal
- Cardiac:
 - Palpitations
 - Tachycardia
 - Chest pain or discomfort
- Respiratory:
 - Shortness of breath
 - Smothering
 - Feeling of choking
- Neurologic:
 - Tremor
 - Dizziness
 - Lightheadedness
 - Feeling faint
 - Numbness
 - Tingling
 - Sweating
 - Chills
 - Flushing
 - Feelings of unreality or detachment
- GI:
 - Nausea
 - Cramps
 - Abdominal pain
- Intense fears:
 - Automatic, stereotypic
 - Imminent death
 - Having a heart attack
 - Humiliation
 - Loss of control—”going crazy”

History

- Known medical conditions
- All medications, including over the counter
- Herbal supplements
- Recreational drugs/alcohol use
- Caffeine consumption
- Age at onset
- Initiating life events or stressors
- Childhood antecedents
- Resultant avoidance
- Response to previous medication trials

- Family history of panic, anxiety
- Family history of drugs/alcohol use

Physical-Exam

- Thorough physical and neurologic exam
- Guided by particular symptoms

ESSENTIAL WORKUP

Detailed history, appropriate physical exam:

- Guided by presentation and initial findings
- May be minimal, depending on presentation

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Toxicology screen
- Consider tricyclic antidepressant (TCA) level
- CBC
- Electrolytes, BUN/creatinine, glucose
- Thyroid-stimulating hormone
- Pulse oximetry or arterial blood gases

Diagnostic Procedures/Surgery

- ECG for suspected mitral valve prolapse (MVP), to exclude underlying cardiac disease, or to monitor for QRS widening in patients on TCA:
 - Age > 40 yr
 - Cardiac symptoms
- Holter monitor:
 - If palpitations, near-syncope
- Sleep-deprived EEG if seizure suspected

DIFFERENTIAL DIAGNOSIS

- Consider organic causes if:
 - Panic presents late in life (> 50 yr)
 - No childhood antecedents or family history
 - No initiating or major life events
 - Without avoidance or significant fear
 - With a history of poor response to anxiolytic or antidepressant medication
- Medications:
 - Neuroleptics (akathisia)
 - Bronchodilators
 - Digitalis
 - Anticholinergic agents

- Psychostimulants
 - Diet pills
 - Herbal supplements
- Respiratory:
 - Asthma
 - Hyperventilation
 - Chronic obstructive pulmonary disease
 - Pulmonary embolus
 - Bacterial pneumonia
 - Costochondritis
- Cardiovascular:
 - Angina
 - Myocardial infarction
 - Arrhythmia
 - Anemia
 - MVP
- Substances:
 - Stimulant abuse
 - Withdrawal (alcohol, sedative–hypnotics)
 - Antidepressant discontinuation syndrome (with interruption, dose decrease, or discontinuation of SSRI or SNRI)
 - Excessive caffeine intake
- Endocrine:
 - Hyperthyroidism
 - Hypoglycemia
 - Hypoparathyroidism
 - Pheochromocytoma
- Other metabolic derangements:
 - Hypokalemia
 - Hypomagnesemia
 - Hypophosphatemia
- Neurologic:
 - Complex partial or limbic seizures (fear, physical symptoms, perceptual distortions)
 - Transient ischemic attack
 - Labyrinthitis
 - Benign positional vertigo
- Psychiatric:
 - Obsessive-compulsive disorder
 - Post-traumatic stress disorder
 - Specific phobia or social phobia
 - Somatoform disorder
 - Factitious disorder

- Acute grief
- Domestic violence

Pediatric Considerations

Tachycardia

TREATMENT

PRE HOSPITAL

- If diagnosis is supported by previous events, history and workup:
 - Reassurance and diversion
 - Does not require emergent care
- If 1st episode, treat and transport as appropriate to presentation

INITIAL STABILIZATION/THERAPY

- Be calm and reassuring.
- Most panic attacks resolve within 20–30 min without any treatment.
- Fear may trigger another panic attack.

ED TREATMENT/PROCEDURES

- Patient education, new cognitions:
 - Normal response to abnormal alarm
 - Physiologic explanations for symptoms
- High-potency benzodiazepines (*drugs of choice*):
 - Clonazepam:
 - Slow for emergency use
 - Long-acting without rapid onset/offset phenomena
 - Best choice in this class for maintenance therapy of recurrent panic attacks
 - Alprazolam:
 - Rapid onset
 - Rebound anxiety occurs due to short duration and rapid offset.
 - May lead to escalating doses with continued use
 - Lorazepam:
 - Quick onset
 - Advantage of sublingual (SL) use
 - Longer effect and less abrupt offset than alprazolam
- Avoid low-potency benzodiazepines:
 - Diazepam
 - Chlordiazepoxide
- Treat recurrent panic attacks and panic disorder with selective serotonin reuptake inhibitors (SSRIs) (or TCAs), with or without clonazepam:

- Will not work immediately
- Do not need to be started emergently, especially if there is no clear, established access to follow-up management
- There are a few small studies on the efficacy of atypical antipsychotics (e.g., olanzapine, risperidone) for treatment-resistant panic disorder. However, data to support this use is limited.
- Discharge therapy:
 - Several clonazepam tablets in case of repeated attacks

ALERT

Rapid offset (withdrawal) of alprazolam may trigger further attacks.

MEDICATION

First Line

- Clonazepam: 0.5 mg PO in the ED; 0.25–0.5 mg PO BID for initial outpatient therapy
- SSRI:
 - To be started as an outpatient
 - May require higher doses and longer time to therapeutic response for panic than for depression

Second Line

- Lorazepam: 1 mg PO or SL
- TCA:
 - To be started as an outpatient

Pregnancy Considerations

- Limit use of benzodiazepines.
- Risk/benefit discussion about the relative safety of SSRIs and less anticholinergic TCAs (e.g., nortriptyline, desipramine)
- Physiologic and autonomic effects of pregnancy and postpartum period may trigger attacks in predisposed women.

FOLLOW-UP

DISPOSITION

Admission Criteria

- As medically indicated to rule out organic cause
- Meets criteria for psychiatric admission (suicidal, homicidal)

Discharge Criteria

Most panic attacks do not require inpatient level of care.

Issues for Referral

- Managed care mental health carve-outs
- Psychopharmacologic and cognitive behavioral therapy evaluation for repeated attacks, or interepisode fear or avoidance
- Stigma
- Primary care follow-up may be an acceptable alternative to specialty, mental health/psychiatry referral.

FOLLOW-UP RECOMMENDATIONS

- Appointment with primary care physician or referral to mental health specialty treatment
- Avoid precipitants, e.g., caffeine, stimulants, alcohol.

PEARLS AND PITFALLS

- Panic is “contagious.” Try not to be infected by the patient’s sense of urgency to stop the symptoms; they will resolve spontaneously.
- Be calm so as not to add to the patient’s alarm, but diligent, so patient feels attended to and reassured.
- Cognitive–behavioral therapy (CBT) can start in the ED with brief explanation of the physiologic cause of symptoms.
- Be cautious not to start adolescents and young adults on a lifetime course of benzodiazepines; CBT (\pm SSRI therapy) is associated with good outcomes and fewer deleterious side effects.
- Avoid the use of alprazolam, especially for ongoing treatment.

PARAPHIMOSIS

Nicole M. Franks

BASICS

DESCRIPTION

- The entrapment of the retracted foreskin proximal to the glans of the penis
- Leads to lymphatic congestion and venous obstruction, which may result in arterial compromise to the glans
- Paraphimosis is a urologic emergency.

ETIOLOGY

- A number of conditions of the foreskin may predispose to paraphimosis, including:
 - Phimosis
 - Inflammation
 - Trauma
 - Sexually naive may be unaware of the need to reduce foreskin after intercourse
- Commonly iatrogenic, from failure to replace the foreskin after exam, catheterization, or cleaning

DIAGNOSIS

SIGNS AND SYMPTOMS

- Retracted prepuce (foreskin)
- Pain
- Swollen, edematous glans
- Local cellulitis
- Necrosis of glans in untreated cases

Physical-Exam

Exam of the genitalia should include a search for constricting foreign bodies or constricting bands.

ESSENTIAL WORKUP

- Paraphimosis is a clinical diagnosis with the clinical findings described earlier.
- Treatment must not be delayed pending diagnostic lab or radiographic studies.

DIAGNOSIS TESTS & INTERPRETATION

Imaging

If history suggests penile foreign body, radiographs may be obtained once the vascular compromise has been relieved.

DIFFERENTIAL DIAGNOSIS

- Foreign bodies constricting the penile shaft may mimic paraphimosis; these include:
 - Hair tourniquets
 - Wire, string, or other materials used for sexual enhancement or punishment
- Balanoposthitis
- Trauma (zipper injuries)
- Acute idiopathic penile edema

TREATMENT

PRE HOSPITAL

- Patients should be transported promptly; do not attempt reduction in the field.
- Pre-hospital personnel can be advised to apply an ice pack to the glans with adequate protection of the skin.
- Pain control

INITIAL STABILIZATION/THERAPY

- Ice can be applied to the glans while preparing to reduce the prepuce:
 - Use the thumb of a glove as an ice-filled condom to aid in direct application.
- The incarcerated foreskin must be released as soon as possible to prevent ischemia and necrosis of the glans.
- The pain associated with reduction techniques must be managed with some combination of conscious sedation, adequate analgesia, and local anesthesia.

ED TREATMENT/PROCEDURES

- Medical therapy for paraphimosis involves reassuring the patient, reducing the preputial edema, and restoring the prepuce to its original position and condition.
- The following sequence of procedures should be followed:
 - Paraphimosis can most frequently be reduced using a penile block and compressing the glans manually while applying traction on the foreskin.
 - Penile block is performed by infiltrating 5 mL of 1% lidocaine *without* epinephrine in the angle between the inferior rami of the symphysis pubis:
 - Then use another 5 mL to infiltrate a wheel along the sides of the penis.
 - This produces a block after 5 min.
 - Successful reduction requires steady circumferential pressure on the distal edema with simultaneous manual reduction of the foreskin.
 - In children, conscious sedation is usually required.

- If manual reduction is unsuccessful, then the technique of multiple punctures may facilitate reduction:
 - Make ~20 holes in the swollen foreskin with a small sterile needle (26G), allowing expression of edema fluid, then resume manual reduction.
- If this fails to return the foreskin to its original position, it will be necessary to incise the constricting ring of tissue with a dorsal longitudinal slit in the foreskin after sterile preparation:
 - If the incision made is too long, after reduction it may be necessary to suture the incision transversely with 3.0 absorbable sutures.
- If a delay is likely before the paraphimosis can be treated (e.g., NPO status), then applying a gauze swab soaked in 50% dextrose will reduce edema by osmosis and facilitate reduction.
- For patients who want to retain uncircumcised phallus steroid therapy can be attempted to reduce fibrose ring. Consult urology for close follow-up:
 - Triamcinolone cream 0.1% to affected area × 6 wk
 - If unsuccessful, circumcision may still be required.

MEDICATION

- Appropriate analgesics or anesthetics as required
- Antibiotics generally not required unless treating associated cellulitis or balanoposthitis.

FOLLOW-UP

DISPOSITION

Admission Criteria

Necrosis or cellulitis of the penis

Discharge Criteria

- Successful reduction with relief of symptoms
- Close urologic follow-up

Issues for Referral

- Urologic consultation is required.
- Subsequent circumcision to prevent recurrence is an area of clinical debate; historically, it has been common practice.

FOLLOW-UP RECOMMENDATIONS

- Education regarding importance of replacement of the foreskin after retraction for instrumentation or cleaning

- Emphasis on prepuce hygiene

PEARLS AND PITFALLS

- Goal is to reduce penile edema enough to allow the foreskin to return to original position over the glans.
- Generally, noninvasive reduction methods (at least 2 or 3 attempts) are successful and dorsal slit incision is mostly required only in severe cases.

CODES

ICD9

605 Redundant prepuce and phimosis

ICD10

N47.2 Paraphimosis

PARKINSON DISEASE

Adam Z. Barkin

BASICS

DESCRIPTION

- Gradual progressive neurologic disorder of middle or late life
- Degeneration of dopaminergic neurons in the substantia nigra
- Development of Lewy bodies in the residual dopaminergic neurons
- Accelerated cortical atrophy
- Can begin unilaterally, but generalizes to symmetric
- Affects 1% of people > 60 yr; 4% > 80 yr
- May have symptoms 20 yr prior to diagnosis
 - _ Nonspecific:
 - Fatigue
 - Constipation
 - Hyposomnia

ETIOLOGY

- Sporadic or idiopathic
- Disorders presenting with parkinsonism:
 - _ Drug induced:
 - Parkinsonism-hyperpyrexia syndrome (dopaminergic drug withdrawal)
 - Amphotericin B
 - Chemotherapeutic drugs
 - Neuroleptic treatment induced
 - _ Toxins:
 - Carbon monoxide
 - Methanol
 - Cyanide
 - Organophosphate poisoning
 - 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine
 - _ Brain lesions:
 - Basal ganglia stroke
 - Midbrain lesions
 - Hydrocephalus
 - _ Infections:
 - *Mycoplasma*
 - Viral encephalitis
 - _ Other:

- Central pontine myelinosis
- Encephalitis lethargica (autoantibodies against basal ganglia antigens)

DIAGNOSIS

SIGNS AND SYMPTOMS

- Nonmotor vs. motor symptoms:
 - _ Nonmotor:
 - Orthostatic hypotension
 - Constipation
 - Delayed gastric emptying
 - Dysphagia
 - Pain sensory dysfunction
 - Depression
 - Hallucinations
 - Dementia
 - Sleep disorders
 - Motor symptoms:
 - _ “Pill-rolling” resting tremor
 - _ “Cog-wheel” rigidity due to increased muscular tone
 - _ Stooped posture and instability of posture
 - _ Bradykinesia: Extreme slowness in movement
 - _ “Masked face” appearance

History

- Sudden change in baseline motor function or mental status:
 - _ May be the only indication of systemic disease such as infection
- Noncompliance (sudden withdrawal) of dopaminergic medications can lead to parkinsonism-hyperpyrexia syndrome:
 - _ Rigidity, pyrexia, reduced consciousness
 - _ Complications:
 - Acute renal failure
 - Venothrombosis
 - Disseminated intravascular coagulation
 - Rhabdomyolysis
 - Autonomic instability

Physical-Exam

- Cog-wheel rigidity:
 - _ Jerking movements when a muscle is passively stretched
- Stooped posture

- Pill-rolling tremor

ESSENTIAL WORKUP

- History is of primary importance:
 - Diagnosis is made based on clinical findings
- Important historical information includes:
 - Onset of symptom, whether gradual or sudden
 - History of potential causes of a Parkinson-like syndrome
 - Patients with established Parkinson disease (PD):
 - Sudden change in baseline motor function
 - Change in mental status
 - Should prompt workup for infectious process

DIAGNOSIS TESTS & INTERPRETATION

Lab

- No specific or recommended lab studies necessary to confirm the diagnosis
- Disorders presenting as PD may require directed lab studies as appropriate for suspected cause
- Directed labs if suspect parkinsonism-hyperpyrexia syndrome

Imaging

- CT and MRI are not required to diagnose PD but are often elements of evaluation for dementia
- CXR may be indicated for any signs of respiratory tract infection

DIFFERENTIAL DIAGNOSIS

- Benign familial tremor
- Major depression
- Wilson disease
- Huntington disease
- Alzheimer disease
- Creutzfeldt–Jakob disease
- Carbon monoxide poisoning
- B₁₂ deficiency
- Hydrocephalus
- Multi-infarct dementia
- Essential tremor disorders
- Hypothyroidism
- Dementia with Lewy bodies

TREATMENT

ED TREATMENT/PROCEDURES

- Treatment with antiparkinsonian medications can be initiated in the ED to alleviate symptoms
- Consultation with neurology for recommended medication regimens and ongoing support and monitoring is prudent
- For patients with mild disease, no medication may be required
- For moderate disease, anticholinergic medications and dopaminergic medications should be used
- Treat underlying infection, if present
- Treat parkinsonism-hyperpyrexia syndrome:
 - Replace levodopa or bromocriptine
 - Supportive
 - Treat complications

MEDICATION

- PD:
 - Amantadine: 100 mg BID
 - Stimulates dopamine release
 - Benztropine: 0.5–1 mg TID
 - Anticholinergic
 - Limited use in tremor-dominant PD
 - Carbidopa/levodopa: 25/100 mg TID
 - Carbidopa lessens peripheral side effects and increased levodopa CNS bioavailability
 - Levodopa is direct precursor to dopamine
 - Entacapone: 200 mg PO BID–QID
 - Adjunct therapy; should be administered concomitantly with carbidopa/levodopa
 - Increases CNS levodopa bioavailability
 - MAO inhibitors
 - May be used in mild disease as first-line therapy
 - Selegiline: 5 mg qam and noon
 - Rasagiline: 1–2 mg QD
 - Dopamine agonists:
 - Pramipexole: 0.5–1.5 mg PO TID
 - Ropinirole: 3–6 mg PO TID
 - Apomorphine: 0.2–0.6 mL SQ PRN
- Parkinsonism-hyperpyrexia syndrome:
 - Levodopa: 50–100 mg IV over 3 hr
 - Bromocriptine: 7.5–15 mg PO TID

First Line

Carbidopa/levodopa

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with previously diagnosed Parkinson with infections, trauma, cardiovascular emergencies, cerebrovascular emergencies, GI emergencies, electrolyte disturbances, altered mental status, or other medical problems
- Depression with intent to do self-harm
- Confirm diagnosis and levodopa responsiveness
- Medication complications (parkinsonism-hyperpyrexia syndrome)
- Management of motor fluctuations and dyskinesias
- Inability to go home secondary to elder abuse
- Complications from deep brain stimulation devices (e.g., headache, infection, mental status change)
- Failure to thrive

Discharge Criteria

- Mild to moderate disease without medications
- Moderate to severe disease with medications and urgent neurologic outpatient follow-up

FOLLOW-UP RECOMMENDATIONS

Discuss prevention strategies in disease management

PEARLS AND PITFALLS

- Diagnosis is often difficult; keep in mind other conditions commonly misdiagnosed as PD
- Sudden withdrawal of dopaminergic medications can result in parkinsonism-hyperpyrexia syndrome, a medical emergency

PARONYCHIA

Gene Ma

BASICS

DESCRIPTION

- Disruption of the seal between the nail plate and the nail fold may allow entry of bacteria into the eponychial space.
- Inflammation of the nail folds surrounding the nail plate

ETIOLOGY

- Acute paronychia: Predominantly *Staphylococcus aureus* but also streptococci, *Pseudomonas*, and anaerobes
- Chronic paronychia: Multifactorial due to allergens and irritants in addition to fungal etiologies, predominantly *Candida albicans*, which commonly coexist with *Staphylococcus* species

DIAGNOSIS

SIGNS AND SYMPTOMS

- Pain, warmth, and swelling to the proximal and lateral nail folds, often 2–5 days after trauma
- Symptoms must be present for 6 wk to meet criteria for a chronic paronychia.

History

- Acute paronychia: Nail biting, finger sucking, aggressive manicuring or manipulation, and trauma predispose to development.
- Chronic paronychia: Occupations with persistent moist hands; dish washers, bartenders; also increased in patients with peripheral vascular disease or diabetes

Pediatric Considerations

Frequently anaerobic mouth flora in children from nail biting

Physical-Exam

- Begins as swelling, pain, and erythema in the dorsolateral corner of the nail fold bulging out over the nail plate
- Progresses to subcuticular/subungual abscess
- Green nail coloration suggests *Pseudomonas*
- Nail plate hypertrophy suggests fungal source

ESSENTIAL WORKUP

- History and physical exam with special attention to evaluating for concomitant infections such as felon or cellulitis
- Assess tetanus status.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- No specific tests are useful.
- Cultures are not routinely indicated.
- Tzanck smear or viral culture if herpetic whitlow suspected.

Imaging

Soft tissue radiographs if foreign body is suspected; routine films if osteomyelitis suspected

Diagnostic Procedures/Surgery

Digital pressure test (opposing the thumb and the affected finger) may help identify the margins of an early subungual abscess

DIFFERENTIAL DIAGNOSIS

- Felon
- Herpetic whitlow
- Trauma or foreign body
- Primary squamous cell carcinoma
- Metastatic carcinoma
- Osteomyelitis
- Psoriasis
- Reiter syndrome
- Pyoderma gangrenosum
- Onychomycosis

TREATMENT

ED TREATMENT/PROCEDURES

Acute Paronychia

- Early paronychia without purulence may be managed with warm-water soaks 4 times a day with or without oral antibiotics; may also consider topical antibiotics and corticosteroids.
- Early superficial subcuticular abscess:
 - Elevation of the eponychial fold by sliding the flat edge of a no. 11 blade (18G needle or small clamps may be used) gently between the proximal nail

fold and the nail plate near the point of maximal tenderness

- A digital nerve block or local anesthesia may be necessary.
- Partial nail involvement:
 - If the lesion extends beneath the nail, remove a longitudinal section of the nail.
 - Petroleum jelly or iodoform gauze packing for 24 hr
- Runaround abscess:
 - If the lesion extends beneath the base of the nail to the other side, remove 1/4–1/3 of the proximal nail with 2 small incisions at the dorsolateral edges of the nail fold and pack eponychial fold with petroleum jelly or iodoform gauze to prevent adherence.
- Extensive subungual abscess:
 - Remove entire nail.
- Early paronychia without purulence present may be managed with warm soaks alone; beyond that, antibiotics are recommended if there is any apparent cellulitis, abscess, or systemic sign of infection.
- Trimethoprim–sulfamethoxazole, dicloxacillin, and amoxicillin–clavulanate are appropriate first-line agents, with treatment regimens ranging from 5–10 days, depending on severity.
- Clindamycin or amoxicillin–clavulanate if associated with nail biting or oral contact

Chronic Paronychia

- Avoidance of predisposing exposures and irritants/chemicals
- Topical steroids should be considered first-line therapy, with or without broad-spectrum topical antifungal agent
- Consideration for antistaphylococcal regimen
- For recalcitrant cases:
 - Eponychial marsupialization involving removal of a crescentic piece of skin just proximal to the nail fold, including all thickened tissue down to but not including germinal matrix
 - Oral antifungal therapy

MEDICATION

First Line

- Amoxicillin–clavulanate: 875 mg PO BID for 7 days (peds: 25 mg/kg/d PO q12h)
- Trimethoprim–sulfamethoxazole (Bactrim DS) BID for 7 days
- Dicloxacillin: 500 mg PO QID for 7 days (peds: 12.5–50 mg/kg/d PO q6h)

Second Line

- Clindamycin: 300 mg PO QID for 7 days (peds: 20–40 mg/kg/d div. q6h PO, IV,

IM)

- Topical antibiotics: Polymyxin B/Bacitracin, there is a high incidence of hypersensitivity to neomycin, mucipurin topical (Bactroban), or gentamicin TID for 5–10 days (0.1% ointment)
- Topical antifungal/steroid combination: nystatin–triamcinolone BID–TID until resolution, no longer than 1 mo
- For all topical antibiotics apply a small amount to affected areas TID–QID

FOLLOW-UP

DISPOSITION

Admission Criteria

Admission is not needed for paronychia alone.

Discharge Criteria

- Patients with uncomplicated paronychias may be discharged with appropriate follow-up instructions.
- Patients with packings should be re-evaluated in 24 hr.

Issues for Referral

Chronic paronychias refractory to treatment

PEARLS AND PITFALLS

- Acute paronychias respond well to decompression with or without antibiotics.
- Chronic paronychias are largely a result of chronic exposure to allergens/irritants.
- Reiter syndrome and psoriasis can mimic paronychia.
- Recurrent paronychia should raise suspicion for herpetic whitlow.
- Assess for felons.

PATELLAR INJURIES

Stacy M. Boore • Stephen R. Hayden

BASICS

DESCRIPTION

Dislocation

- Usually caused by sudden flexion and external rotation of tibia on femur, with simultaneous contraction of quadriceps muscle
- Direct trauma to patella is a less common cause
- Lateral dislocation of the patella is most common, with the patella displaced over the lateral femoral condyle
- Uncommon dislocations include superior, medial, and rare intra-articular dislocation

Fracture

- Direct trauma:
 - Most common mechanism
 - Direct blow or fall on patella
 - Usually results in comminuted or minimally displaced fracture, or open injury
- Indirect forces:
 - The result of excessive tension through the extensor mechanism during deceleration from a fall (can also cause patellar tendon rupture)
 - Avulsion injury from sudden contraction of the quadriceps tendon
 - Usually results in transverse or displaced fracture (often both)
- Types of patellar fractures:
 - Transverse: 50–80% (usually middle or lower 3rd of patella)
 - Comminuted (or stellate): 30–35%
 - Longitudinal: 25%
 - Osteochondral

Patellar Tendon Rupture

- Usually caused by forceful eccentric contraction of quadriceps muscle on a flexed knee during deceleration (e.g., jump landing and weight lifting)
- Often occurs in older athletes
 - Microtrauma from repetitive activity

Patellar Tendinitis

- Overuse syndrome from repeated acceleration and deceleration (jumping, landing)

ETIOLOGY

Dislocation

- Risk factors for patellar dislocation:
 - Genu valgum (knock-knee)
 - Genu recurvatum (hyperextension of knee)
 - Shallow lateral femoral condyle
 - Deficient vastus medialis
 - Lateral insertion of patellar tendon
 - Shallow patellar groove
 - Patella alta (high-riding patella)
 - Deformed patella
 - Pes planus (flatfoot)
- Common injury in adolescent athletes, especially girls
- The younger the patient at the time of initial dislocation, the greater the risk of recurrence

Fracture

- Male:female ratio 2:1
- Highest incidence in those 20–50 yr old

Patellar Tendon Rupture

- Peak incidence in 3rd and 4th decades:
 - Often in athletes
- Risk factors:
 - History of patellar tendinitis
 - History of diabetes mellitus, previous steroid injections, rheumatoid arthritis, gout, systemic lupus erythematosus
 - Previous major knee surgery

Patellar Tendinitis

- Microtears of tendon matrix from overuse
- Seen in high jumpers, volleyball and basketball players, runners

DIAGNOSIS

SIGNS AND SYMPTOMS

Dislocation

- History of feeling knee “go out”; popping, ripping, or tearing sensation
- Pain
- Inability to bear weight

- Obvious lateral deformity of patella
- Mild to moderate swelling
- Often reduces spontaneously before ED evaluation
- Tenderness along patella
- Positive apprehension test or Fairbanks sign:
 - Attempts to push the patella laterally elicits patient apprehension
 - Attempts to push patella medially do not

Fracture

- Pain over anterior knee
- Difficulty ambulating
- Increased pain with movement of patella
- Tenderness and swelling over patella
- Difficulty or inability to extend knee
- Palpable defect, crepitus, or joint effusion/hemarthrosis

Patellar Tendon Rupture

- Abrupt onset of severe pain
- Decreased ability to bear weight
- Occasionally hemarthrosis
- Proximally displaced patella
- Incomplete extensor function
- Inability to maintain knee extension against force

Patellar Tendinitis

- Pain in area of patellar tendon
- Pain worse from sitting to standing or going up stairs
- Point tenderness at distal aspect of patella or proximal patellar tendon

ESSENTIAL WORKUP

Radiographs essential

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- Anteroposterior (AP), lateral, and sunrise views of the knee should be obtained, pre- and postreduction
- Postreduction radiographs help exclude osteochondral fracture (in patellar dislocations)
- Bipartite patella (patella with accessory bony fragment connected to main body by cartilage) may be mistaken for fracture:
 - Comparison view may help differentiate
- For patellar tendon rupture, a high-riding patella (i.e., patella located superior to

level of intercondylar notch) is observed

- For patellar tendinitis, radiographic findings unlikely with symptom duration of < 6 mo

DIFFERENTIAL DIAGNOSIS

- Patellar subluxation
- Femoral or tibial fracture
- Traumatic bursitis
- Quadriceps tendon rupture

TREATMENT

PRE HOSPITAL

Patient should be transported in supine position with knee flexed and supported.

INITIAL STABILIZATION/THERAPY

Appropriate history and physical exam to identify any associated injuries (e.g., femoral fracture, hip fracture, posterior hip dislocation) and assess extensor mechanism

ED TREATMENT/PROCEDURES

Dislocation

- For simple lateral patellar dislocation, reduce dislocation by extending the knee gently to 180°:
 - Occasionally, simultaneous pressure may have to be applied over the lateral aspect of patella in a medial direction
- For other types of patellar dislocation (superior, medial, intra-articular), do not attempt reduction; consult orthopedics
- Aspiration of hemarthrosis with sterile technique is necessary if reduction is difficult
- If osteochondral fracture is present (28–50% of cases), obtain orthopedic consultation
- Although reduction is typically easy to accomplish, procedural sedation or parenteral analgesia may facilitate it
- Conservative (nonoperative) management of dislocations leads to recurrent instability in 60% of patients, but there is no evidence to support operative care in primary dislocations

Fracture

- Orthopedic consultation when patellar fracture is confirmed
- Nondisplaced fractures with intact extensor mechanism are managed nonsurgically
- Initial treatment often consists of long-leg bulky splint and subsequent operative

repair

Patellar Tendon Rupture

- Orthopedic consultation, with surgical repair within 2–6 wk

Patellar Tendinitis

- Rest, avoidance of inciting activity, heat, and NSAIDs

MEDICATION

- Fentanyl citrate: 0.5–1.5 µg/kg (peds: 0.5–1.0 µg/kg) IV
- Midazolam HCl: 1–2.5 mg (peds: 0.05–0.1 mg/kg, max. dose 6 mg) IV
- Morphine sulfate: 2–5 mg per dose (peds: 0.1–0.2 mg/kg per dose) IV
- Meperidine: 50–150 mg (peds: 1.1–1.8 mg/kg) IM q3–4h prn
- Ketorolac: 60 mg IM; 30 mg IV (peds: 0.5–1 mg/kg IV, max. 15 mg dose if <50 kg; max. 30 mg dose if >50 kg, IV)
- Methohexital: 1–1.5 mg/kg (1 mL q5sec) (peds: 0.5–1 mg IV) IV
- Propofol: 1–2 mg/kg IV (20 mg bolus q45sec) push slow IV to avoid dec BP (peds: 1 mg/kg not to exceed 40 mg)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with superior, medial, or intra-articular dislocation or in whom a lateral dislocation cannot be reduced require orthopedic consultation in the ED and possible admission
- Patellar dislocation associated with a fracture (osteochondral or lateral femoral condyle) requires orthopedic consultation in the ED
- Indications for operative intervention:
 - _ Fragments displaced > 4 mm
 - _ Unable to raise extended leg off bed
 - _ Articular step-off > 3 mm
- All open fractures require débridement and irrigation; such patients should be admitted.
- For patellar tendon rupture, discuss case with orthopedics.

Discharge Criteria

- Dislocation: Patients with successful reduction of lateral patellar dislocation and normal postreduction radiographs may be discharged with knee immobilization, crutches, and orthopedic follow-up.
- Fracture: If displaced < 3 mm and patient has full active knee extension:

- Knee immobilizer, or bulky long-leg splint, partial to full weight bearing as tolerated with crutches and orthopedic follow-up within a few days

PEARLS AND PITFALLS

- Lateral patella dislocations often reduce spontaneously prior to arrival in ED; do not dismiss patient's history of dislocation.
- In patella tendon ruptures, tendon defect may not be palpable if sufficient time has elapsed and swelling has occurred

PATENT DUCTUS ARTERIOSUS

Steven Lelyveld

BASICS

DESCRIPTION

- Patent vessel in the fetal heart connects the pulmonary trunk to the descending aorta.
- Shortly after birth, changes normally provoke contraction, closure, and fibrosis:
 - Sudden increase in the partial pressure of oxygen
 - Changes in the synthesis and metabolism of vasoactive eicosanoids
- In the preterm infant, persistent patency of the ductus may be a normal life-saving response.
- The patent ductus usually has a normal structural anatomy.
- Patency results from hypoxia and immaturity.
- In the full-term newborn, patency of the ductus is a congenital malformation.
- Deficiency of both the mucoid endothelial layer and the muscular media of the ductus
- As pulmonary vascular resistance falls, aortic blood is shunted into the pulmonary artery.
- Extent of the shunt reflects the size of the ductus and the ratio of the pulmonary to systemic vascular resistances.
- Up to 70% of the left ventricular output may be shunted through the ductus to the pulmonary circulation.
- Risk factors:
 - Premature birth
 - Coexisting cardiac anomalies
 - Conditions resulting in hypoxia
 - High altitude
 - Maternal rubella infection
 - Female-to-male ratio, 3:1

ETIOLOGY

- Prematurity
- Congenital anomaly
- Hypoxia
- Prostaglandins

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Isolated patent ductus arteriosus (PDA), an unanticipated event
- PDA, as part of a larger congenital cardiac anomaly, may be diagnosed by US during pregnancy.

Physical-Exam

- Asymptomatic when the PDA is small, but otherwise may present with a range of findings.
- Congestive heart failure (CHF), often in 1st day of life
- Wide pulse pressure
- Prominent apical impulse
- Thrill
- Systolic and continuous murmur.
- Sounds like a humming top or rolling thunder
- Begins soon after onset of the 1st sound, reaches maximal intensity at the end of systole, and wanes in late diastole
- Localized to the 2nd left intercostal space or radiates down the left sternal border toward the apex or to the left clavicle
- Recurrent pulmonary infections
- Retardation of physical growth

ESSENTIAL WORKUP

- Establish the diagnosis with imaging studies.
- Rule out complications such as heart failure and endocarditis.

DIAGNOSIS TESTS & NTERPRETATION

Lab

Unhelpful in making the diagnosis

Imaging

- CXR:
 - Usually normal in infants
 - In children and adults:
 - Increased intrapulmonary markings
 - Calcifications
 - Left ventricle and left atrial enlargement
 - Dilated ascending aorta
 - Dilated pulmonary arteries
- EKG:
 - Abnormal if the ductus is large:
 - Left ventricular hypertrophy
 - Right ventricular hypertrophy is a sign of greater severity.

- Echocardiography:
 - Normal if the ductus is small
 - Left atrial enlargement
 - Size of the ductus can be determined by scanning from the suprasternal notch.
 - Doppler studies will determine aortic to pulmonary artery flow during diastole.
- Cardiac catheterization:
 - Normal or increased right-sided pressure
 - Oxygenated blood in the pulmonary artery confirms left-to-right shunting.
 - Injection of contrast into the ascending aorta shows opacification of the pulmonary arteries.

DIFFERENTIAL DIAGNOSIS

- Venous hum:
 - Common insignificant bruit
 - Heard in the neck or anterior portion of the chest
 - Soft humming sound in systole and diastole
 - Decreased by light compression of the jugular venous system
- Total anomalous pulmonary venous connection to the innominate vein:
 - Continuous murmur like venous hum
- Aorticopulmonary septal defect:
 - Murmur is often only systolic.
 - Heard at the right sternal border
- Ruptured sinus of Valsalva
- Coronary arteriovenous fistulas
- Anomalous origin of left coronary artery from the pulmonary artery
- Absence or atresia of pulmonary valve
- Aortic insufficiency with ventricular septal defect
- Peripheral pulmonary stenosis
- Truncus arteriosus

TREATMENT

ALERT

Supplemental oxygen if CHF

PRE HOSPITAL

Monitoring and oxygen

INITIAL STABILIZATION/THERAPY

- Small, asymptomatic shunts may not need closure.
- Pulmonary support

- Supplemental oxygen

ED TREATMENT/PROCEDURES

- Sodium and fluid restriction
- Correction of anemia to hematocrit $> 45\%$
- Antibiotic prophylaxis for endocarditis
- Preterm infants:
 - Usually closes spontaneously
 - Varies with the magnitude of shunting and severity of respiratory distress syndrome
 - Pharmacologic inhibition of prostaglandin synthesis with indomethacin during the 1st 2–7 days of life
- Full-term infants and children:
 - Surgical closure is required, even in asymptomatic patients, as spontaneous closure is rare.
 - Ligation and division
 - Transfemoral catheter technique to occlude PDA with foam plastic plug or double umbrella

MEDICATION

Indomethacin: 0.2–0.25 mg/kg per dose; repeat q12–24h for 3 doses

FOLLOW-UP

DISPOSITION

Admission Criteria

- Heart failure
- Endocarditis
- Pulmonary hypertension

Discharge Criteria

- Asymptomatic
- Prophylactic antibiotics
- Close follow-up with plans for early surgical closure

Issues for Referral

A pediatric cardiologist/neonatologist should be involved in all patients who have any evidence of heart failure, particularly if pharmacologic management is being considered.

PEARLS AND PITFALLS

- CHF may cause decrease in glomerular filtration rate and urinary output.
- Indomethacin may cause GI bleeding.

ICD10

Q25.0 Patent ductus arteriosus

PEDIATRIC TRAUMA

Kevin M. Ban

BASICS

DESCRIPTION

- Pathophysiology and anatomy of adolescents and young adults are similar.
- 80% of pediatric trauma is blunt; 80% of multisystem trauma includes head injury.
- Trauma is the leading cause of death and disability in children > 1 yr in US and Europe.
- Most victims of child abuse are < 3 yr. 1/3 of these patients are < 6 mo.

ETIOLOGY

- Most cases of pediatric trauma are single-system, minor, blunt injuries.
- Common mechanisms of injury include motor vehicle collisions and bicycle accidents, struck by a vehicle as a pedestrian, and fall from height.
- Penetrating injuries are rare in younger children.
- Risk factors include inadequate supervision, developmental inadequacy of child to perform task, inadequate attention to task, risk taking, drugs, and alcohol.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- History is often straightforward and provided by the child, parents, witnesses, or paramedics. If inconsistent with injury, consider child abuse.
- Mechanism(s) of injury relatively poor predictor of injury severity, but may suggest type of injury.
- Variables that increase the likelihood of serious injuries include handlebar injuries, significant passenger space intrusion, and failure to use proper restraint during a motor vehicle collision or helmet when riding a bike or skateboard.
- AMPLE history includes *allergies, medications, past medical history, time of last meal, and events leading up to injury.*

Physical-Exam

- Primary survey:
 - For all children who have sustained a major trauma, a traditional stepwise ABCDE evaluation based on assessing the *airway, breathing, circulation, disability, and exposure* is appropriate.
- Secondary survey:

- General:
 - Mass-to-surface ratio may impact insensible water loss and increase the risk of hypothermia.
 - Compensatory mechanisms may delay signs of hypovolemia. Few findings may be present until loss of 25–30% of blood volume, at which time decompensation abruptly occurs.
 - Smaller total blood volume (80 mL/kg)
- Head:
 - Note bulging fontanel, scalp hematomas, midface instability, auricular and septal hematomas, lacerations, functional or cosmetic deformities to the face, and pupillary abnormalities.
 - Open sutures/fontanelles or multiple skull fractures may delay the onset of other signs and symptoms of increased intracranial pressure.
 - Large head/occiput causes cervical spine flexion when patient is supine on adult backboard.
- Eye/ears, nose, and throat exam:
 - Look for evidence of blood, trauma, hemotympanum, hyphema, and CSF fluid.
 - Large tongue and tonsillar hypertrophy may obstruct the airway.
- Neck:
 - Tracheal deviation and posterior neck step-offs are exceedingly unusual in children.
 - Shorter trachea increases risk of right mainstem intubation.
 - Cricoid cartilage is narrowest portion of airway in children < 8 yr.
 - Children with altered mental status cannot have their cervical spine precautions cleared in the ED. These children should remain in a cervical collar (and be taken off the spinal board) while in the ED.
 - Pseudosubluxation (anterior displacement of C-2 on C-3) occurs in 20% of patients.
 - The term spinal cord injury without radiologic abnormality (SCIWORA) is controversial in the MRI era.
- Chest:
 - Note the overall work of breathing, grunting, asymmetric breath sounds, posterior abrasions, chest wall deformities, and crepitus.
 - Flexible and compliant chest walls make pulmonary contusions more likely than rib fractures in young children. Rib fractures may be a sign of abuse.
 - Diaphragmatic breathing
- Abdomen:
 - Bruising, abrasions, and tenderness
 - Distention is usually caused by gastric air.
 - Liver and spleen relatively large
 - Rib cage covers less of abdomen.

- Bladder is intra-abdominal in children < 2 yr.
- Extremities:
 - Palpation and evaluation of joint stability and tenderness
 - Assess pulses and compartments.
 - Salter–Harris classification of fractures
 - Unique injuries: Greenstick and buckle fractures
- Neurologic exam:
 - Age-appropriate mental status assessment
 - Assess movement of the extremities.
- Skin:
 - Assess for prolonged capillary refill and pallor.
 - Bruising of the ears, dorsa of the feet, or genitalia may suggest nonaccidental trauma.
- Patterns of injury:
 - Car vs. pedestrian: Waddell triad (femur, torso, and head injuries)—uncommon
 - Bicycle handlebar injuries may impale child: Pancreatic or small bowel injury.
 - Lap belt syndrome: Abdominal ecchymoses and intestinal injury with or without lumbar spine fracture (chance fracture)
 - Minor trauma history with major injury: Consider child abuse

ESSENTIAL WORKUP

- History and age-appropriate physical exam are the only essential components to a workup for all children who present for an evaluation following trauma.
- Obtaining standard radiographic and lab “trauma panels” is not evidence based in children.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Lab tests should generally be individualized, reflecting the patient’s clinical presentation.
- A normal initial hemoglobin and hematocrit do not rule out a significant hemorrhage but will provide a baseline value for later comparison; tachycardia may be only sign of fluid/blood loss early in presentation, although it is nonspecific for blood loss.
- Initial electrolyte measurement is unnecessary.
- Routine amylase and lipase are not recommended because of the low incidence of pancreatic injuries; false-positive tests are common.
- Elevated LFTs should not be used as the sole determinant in deciding which children should undergo CT of the abdomen. Patients with AST > 200 IU/L or ALT > 125 IU/L who have sustained abdominal trauma should be considered for CT if

hemodynamically stable. Physical exam should guide imaging decision.

- Gross hematuria (> 50 RBC/HPF) is concerning for urinary tract injuries, but microscopic hematuria is not.
- Blood bank specimen for typing in appropriate patients
- A pregnancy test is indicated for teenage girls.
- Diagnostic peritoneal lavage is rarely indicated with availability of imaging modalities.

Imaging

- The traditional “c-spine, chest, pelvis” set of radiographs is no longer universally obtained; selective approach is more appropriate.
- Forgo cervical spine radiographs in children who are awake, alert, cooperative, neurologically intact without neck pain or midline tenderness on palpation of the neck, are without pain on range of motion testing, and are without distracting injury:
 - An unconscious child will not be able to have the cervical spine cleared in the ED and may later need MRI (less often CT) as an inpatient.
- Chest radiographs indicated for grunting respirations, hypoxia, asymmetric breath sounds, dyspnea, crepitus, endotracheal intubation, and thoracostomy tube or central venous catheter placement in the internal jugular or subclavian veins
- Pelvic radiographs are seldom indicated. Children with clinically significant pelvic pain or instability typically undergo CT of the abdomen and pelvis.
- CT of the head is indicated for abnormal mental status, focal neurologic deficit, prolonged loss of consciousness, bulging fontanel, temporal or parietal scalp hematoma, depressed skull fracture, and uncontrollable persistent vomiting.
- CT of the abdomen and pelvis is typically indicated for children with altered mental status, gross hematuria, abdominal bruising above the ileac crests, handlebar injuries, and abdominal tenderness with hemodynamic effect.
- US has limited utility since the presence of free fluid (i.e., blood) does not always indicate the need for laparotomy. The usefulness of focused abdominal sonography for trauma exam in young children needs further study.

DIFFERENTIAL DIAGNOSIS

Nonaccidental trauma should be considered when the history is inconsistent with the injury.

TREATMENT

PRE HOSPITAL

- Rapid transport to a facility capable of managing the child’s suspected injuries
- Priorities include stabilization of airway (intubation by paramedics in the pre-hospital setting is controversial), breathing, circulation.

- Immobilization of cervical spine and extremity fractures

INITIAL STABILIZATION/THERAPY

- Most traumatized children are stable throughout their ED course.
- Stabilization may require:
 - Cardiorespiratory and pulse oximetry monitoring
 - Early oxygen administration
 - Placement of 2 large-bore IVs and aggressive fluid resuscitation with normal saline
 - Pain control with morphine
 - Labs and radiographs as indicated
 - Administration of packed red blood cells if not responding to 2 crystalloid boluses
 - Endotracheal intubation:
 - Rapid sequence intubation should be performed with etomidate or ketamine and succinylcholine
 - Sedate patient with a benzodiazepine or propofol
 - Cervical spine immobilization
 - Thoracostomy tube as indicated
 - Urinary catheter (look for blood at the meatus)
 - Gastric decompression with a nasogastric or orogastric tube

ED TREATMENT/PROCEDURES

- Risk stratify based on history and physical exam.
- Acknowledge the limitations of using the mechanism of injury to predict its severity.
- Assess priorities; reassess frequently.
- Provide analgesia; sedate as appropriate.
- Clean wounds and splint fractures.
- Tetanus immunization if indicated
- Allow parents at the bedside during resuscitation and treatment.

MEDICATION

- Normal saline/lactated Ringer: 20 mL/kg boluses IV
- Packed red blood cells: 10 mL/kg U IV
- Etomidate: 0.3 mg/kg IV
- Morphine sulfate: 0.1 mg/kg IV
- Succinylcholine: 1.5 mg/kg IV
- Lorazepam: 0.1 mg/kg IV
- Propofol: 2 mg/kg IV
- Ketamine: 2 mg/kg IV (generally thought to raise intraocular and intracranial pressure—usually avoided when head injury is suspected)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Persistent altered mental status, endotracheal intubation, thoracostomy tube placement, intra-abdominal or intracranial injury identified on CT, pulmonary contusion, fractures requiring operative management, nonaccidental trauma
- Hemodynamic instability
- Airway concerns
- CT negative for intra-abdominal injury, but persistent abdominal pain as pancreatic or bowel injury is possible
- Failure to identify an appropriate adult to be responsible for the child (e.g., both parents are admitted to the hospital for their own injuries)

Discharge Criteria

- Most traumatized children with normal mental status and normal radiographic tests (if obtained) can be discharged home to a reliable caregiver.
- Post-traumatic stress syndrome may develop, and parents should be advised to seek appropriate counseling should concerns develop.

FOLLOW-UP RECOMMENDATIONS

- Specialists as indicated by injury
- Psychiatric evaluation may be indicated for evidence of post-traumatic stress.
- Neurologic assessment for evidence of residual from postconcussion syndrome.

- S09.90XA Unspecified injury of head, initial encounter
- T76.92XA Unspecified child maltreatment, suspected, initial encounter

PEDICULOSIS

Andrew B. Ziller

BASICS

DESCRIPTION

- Infestation by organisms that live in close association with host
- Bites are painless
- Signs and symptoms result from host response to saliva and anticoagulant injected during feeding
- Transmitted by direct contact and fomites (inanimate objects)
- Head lice are transmitted by head-to-head contact:
 - Combs
 - Pillows
 - Hats
- Head lice are more common in children and females
- Pubic lice are transmitted by sexual contact
- Obligate human parasites cannot survive away from hosts >7–10 days

ETIOLOGY

Infestation by:

- *Pediculus capitis* (head louse):
 - Most common
 - All socioeconomic groups
- *Pediculus corporis* (body louse):
 - Associated with poverty, poor hygiene, and overcrowding
 - Live in clothing and transfer to human host for feeding
 - Can live up to 30 days off of human
 - Related to bed bugs
- *Phthirus pubis* (pubic or crab louse)

Pediatric Considerations

Pubic lice may also indicate sexual abuse in children

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Head lice:
 - Dandruff

- Pruritus
- Often asymptomatic
- Body lice:
 - Pruritus
 - Excoriation particularly at belt lines or seams of clothing
- Pubic lice:
 - Intense pruritus, worse at night

Physical-Exam

- Examine hair for adult lice and nits:
 - Nits are cemented on hair shafts and are not easily removed
 - Head lice and pubic lice infestation is confirmed by differentiating nits from scales, hair casts, and other easily brushed-off artifacts
 - Empty nits are not diagnostic of active infection
- Scalp and posterior neck erythema, scaling, and excoriated papules:
 - May lead to pyoderma, posterior cervical lymphadenopathy, and bacterial superinfection
- Body lice are observed only in very heavy infestation; infestation is confirmed by finding nits in clothing seams:
 - Linear excoriations of neck and trunk
 - Pus or serum stains on clothing
- Pubic lice:
 - Occasional urticaria with typical flare/wheal formation
 - May infest eyelashes and scalp in children
 - Characteristic bluish macules (maculae ceruleae) appear infrequently on trunk and thighs
 - Prefer the perineum and pubic areas
 - Inguinal adenopathy

ESSENTIAL WORKUP

- Careful history and physical exam
- Universal precautions

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Nits may be visualized under low-power microscopy along hair shafts. They are <1 mm long:
 - Fluorescent under Wood lamp
- Mature lice are 3–4 mm long
- Pubic louse ~ 1 mm long but wider body than head or body louse

Imaging

No imaging indicated

DIFFERENTIAL DIAGNOSIS

- Scabies
- Contact or allergic dermatitis
- Seborrheic dermatitis
- Bed bugs (Cimicidae)

TREATMENT

PRE HOSPITAL

ALERT

Maintain universal precautions

INITIAL STABILIZATION/THERAPY

Not applicable for routine cases

ED TREATMENT/PROCEDURES

- Oral antihistamines and topical steroids may help pruritic symptoms of all lice infestations
- Head lice:
 - Topical pediculicidal agents:
 - Permethrin 1% cream rinse (Nix) is a reasonable agent; it has low toxicity and cost and is ovicidal; however, resistance is becoming more common
 - Pyrethrin (Rid) also has low toxicity but is less effective
 - All agents require reapplication in 7–10 days if further adult lice or nits noted
 - Remove nits with fine-toothed comb
 - Examine all members of household; treat infested individuals
 - Change clothing and machine wash and dry (using hot cycles) all clothing, towels, linens, and headgear:
 - Vacuum floors and furniture
 - Wash combs and brushes in hot water for 10–20 min or coat with pediculicide for 15 min and wash
 - Temperature $> 131^{\circ}\text{F}$ (55°C) for > 5 min kills eggs, nymphs, and mature lice
- Body lice:
 - Wash and dry bedding and clothing using hot cycles
 - Apply topical pediculicide cream or lotions from chin to toes
- Pubic lice:
 - Topical pediculicide applied to hairy areas of chest, axilla, and groin
 - Remove nits with fine-toothed comb

- Treat sexual contacts simultaneously
- Wash and dry bedding and clothing using hot cycles
- Treat eyelash involvement with topical petrolatum twice daily for 9 days

MEDICATION

First Line

- Antipruritics:
 - Diphenhydramine: 25–50 mg PO (peds: 5 mg/kg/d) q6h
 - Hydroxyzine: 25 mg PO q8h (peds: 12.5 mg/dose q6h)
- Pediculicides:
 - Permethrin 1% cream rinse (Nix): Apply to scalp and hair, rinse after 10 min; reapply in 7–10 days if needed
 - Pyrethrin/piperonyl butoxide (Rid): Apply to scalp and hair, wash after 10 min; repeat in 7–10 days; avoid in patients with ragweed allergies
 - Benzyl alcohol lotion 5% (Ulesfia lotion): Apply to scalp and hair, wash off after 10 min; repeat in 7 days
 - Mercuric oxide ophthalmic ointment 1%: Use for louse infestation of eyelids: Apply QID for 14 days

Second Line

- Pediculicides:
 - Ivermectin 0.5% lotion (Sklice): Apply to dry hair and scalp and rinse after 10 min
 - Spinosad 0.9% suspension (Natroba): Apply to dry hair and rinse after 10 min; repeat in 7 days if necessary
 - Ivermectin tablets (Stromectol): 200–400 µg/kg PO once; repeat in 7–10 days later
 - Use if 1st-line agents (Nix, Rid, Ulesfia) are not tolerated or effective
- Antihistamine:
 - Cetirizine (Zyrtec): Age > 12 yr, 5–10 mg PO (peds: 6–11 yr, 5–10 mg PO; 2–5 yr, 2.5 mg PO) daily

Pregnancy Considerations

- Nix is Class B and probably safe in lactation
- Rid is Class C and probably safe in lactation
- Ulesfia is Class B but should read package insert; safety unknown in lactation
- Ivermectin is Class C with safety unknown in lactation
- Spinosad is Class B but should read package insert for specifics; safety unknown in pregnancy

Pediatric Considerations

- Nix can be used in children > 2 mo
- Rid can be used in children > 2 yr
- Ulesfia can be used in children
- Ivermectin can be used in children > 6 mo
- Spinosad can be used in children > 4 yr

FOLLOW-UP

DISPOSITION

Admission Criteria

Extensive bacterial superinfection; systemic hypersensitivity reaction with cardiorespiratory compromise

Discharge Criteria

- Mild-to-moderate infestation with absence of significant superinfection or hypersensitivity reaction
- Children may return to school after initial treatment if repeat therapy is administered in 7–10 days
- Pubic lice are often associated with sexually transmitted diseases; prudent screening is recommended

FOLLOW-UP RECOMMENDATIONS

- Re-evaluation is necessary to observe if treatment has been successful
- Case management and/or social services may be required if concern for child well-being

PEARLS AND PITFALLS

- Diagnosed by direct visualization
- Most of the topical agents need to be reapplied in 7–10 days because unhatched eggs are not killed
- Clothing and bedding must be washed and dried at a high heat to eradicate the infestation
- Lindane is no longer recommended
- Resistance to *Nix* and *Rid* is increasingly more common
 - 2nd-line agents are more expensive

ADDITIONAL READING

PELVIC FRACTURE

Andrew T. LaFree • Theodore C. Chan

BASICS

DESCRIPTION

- 3% of all bony fractures
- Pelvis is made up of sacrum and 2 innominate bones:
 - The innominate bones consist of the ilium, ischium, and pubis
- Bony structures are stabilized by a network of ligaments, musculature, and other soft tissues in the pelvic area
- Anterior stability and support are provided by the symphysis pubis and pubic rami
- Posterior stability and support are provided by the sacroiliac (SI) complex and pelvic floor
- Pelvis provides protection for lower urinary tract; GI tract; gynecologic, and vascular, and nervous structures contained in the region:
 - Pelvic fractures have a high associated morbidity and mortality rate and require urgent diagnosis and therapy.
- Unstable pelvic fractures are high risk for associated injuries including:
 - Pelvic hemorrhage and hemorrhagic shock
 - Intra-abdominal and GI tract injuries
 - Genitourinary and urinary tract injuries
 - Uterine and vaginal injuries
 - Neurologic injuries
 - Arterial and venous plexus injuries

ETIOLOGY

- 65% of pelvic fractures are caused by vehicular trauma, including pedestrians struck by automobiles
- 10% caused by falls
- 10% caused by crush injuries
- The remainder caused by athletic, penetrating, or nontraumatic injuries
- Mortality rate from pelvic fractures is 6–19%:
 - Increases with open fractures or evidence of hemorrhagic shock
- Significant hemorrhage can occur in unstable, high-energy pelvic fractures (Tile type B and C fractures):
 - Bleeding most common with posterior injuries involving the vascular plexuses
 - Retroperitoneal hematoma may tamponade in the enclosed pelvic space

Tile Classification System

- Includes stable single bone and avulsion fractures as well as pelvic ring fractures
- Predicts need for operative repair
- Type A: Stable pelvic ring injuries:
 - A1: Avulsion fractures of the innominate bone (ischial tuberosity, iliac crest)
 - A2-1: Iliac wing fractures
 - A2-2: Isolated rami fractures; most common pelvic fracture
 - A2-3: 4-pillar anterior ring injuries
 - A3: Transverse fractures of sacrum or coccyx
- Type B: Partially stable pelvic ring injury (rotationally unstable, but vertically stable):
 - B1: Unilateral open-book fracture
 - B2: Lateral compression injury:
 - B2-1: Ipsilateral double rami fractures and posterior injury
 - B2-2: Contralateral double rami fractures and posterior injury (bucket-handle fracture)
 - B2-3: Bilateral type B injuries
- Type C: Unstable pelvic ring injury—rotationally and vertically unstable, *Malgaigne fracture*:
 - Anterior disruption of symphysis pubis or 2–4 pubic rami with posterior displacement and instability through sacrum, SI joint, or ileum:
 - C1: Unilateral vertical shear fracture
 - C2: Unilateral vertical shear combined with contralateral type B injury
 - C3: Bilateral vertical shear fracture
- Acetabular fractures (posterior lip, central/transverse, anterior column, or posterior column fractures)

Young Classification System

- Based on mechanism of injury
- Only fractures that result in disruption of pelvic ring included; no single bone, avulsion, or acetabular fractures
- Predicts chance of associated injuries and mortality risk:
 - LC: Lateral compression
 - APC: Anteroposterior compression
 - VS: Vertical shear
 - CM: Combination of injury patterns

Pediatric Considerations

- Children can have greater hemorrhage
- Nonaccidental trauma is a concern

Pregnancy Considerations

Gravid uterus may be at risk for injury, including uterine rupture.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Pain, swelling, ecchymosis, tenderness over hips, groin, perineum, and lower back
- Often presents with other traumatic injuries including neurologic, intra-abdominal, genitourinary, perineal, rectal, vaginal, and vascular injury
- Evidence of hemorrhagic shock
- Gross pelvic instability

History

- History of trauma (fall, vehicular trauma, crush injuries, athletic injuries)
- Pain on hip movement, ambulation, sitting, standing, defecation

Physical-Exam

- Ecchymosis, swelling, tenderness over bony prominences, pubis, perineum, pelvic region, lower back
- Lower extremities may be shortened or rotated
- Inability to actively or passively perform range of motion of involved hip
- Tenderness on LC of pelvis, palpation of symphysis pubis or SI joints
- Gross pelvic instability, deformity, asymmetry in lower extremity
- Wounds over pelvis or bleeding from rectum, vagina, or urethra may indicate open fracture
- In hemorrhagic shock:
 - Tachycardia, hypotension, narrowed pulse pressure
 - Altered mental status
 - Cool and pale extremities

ESSENTIAL WORKUP

- Pelvic radiograph is the most common initial test
- A single AP view of the pelvis can confirm diagnosis and should be obtained as early as possible when fracture suspected:
 - Most significant unstable pelvic fractures will be seen on the single AP view
- Other views include:
 - Inlet projection: 30° caudal view; allows visualization of posterior arch
 - Outlet projection: 30° cephalic angulation; allows visualization of sacrum
 - Judet oblique views: Allow evaluation of acetabulum

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Type and cross-match
- Hemoglobin/hematocrit, platelet count, and coagulation studies (prothrombin time, partial thromboplastin time)

Imaging

- CT may further delineate pelvic fracture(s), retroperitoneal hematoma, visceral injuries:
 - CT contrast angiography may delineate source of bleeding (particularly arterial), but should be considered only in hemodynamically stable patients
- Abdominal US focused abdominal sonography for trauma in patients with significant traumatic injury, but differentiation of intraperitoneal from extraperitoneal hemorrhage from pelvic fracture can be difficult
- MRI indicated for neurologic injury

Diagnostic Procedures/Surgery

- Although largely supplanted by US and CT, diagnostic peritoneal lavage (DPL) remains a rapid bedside evaluation for intraperitoneal hemorrhage
- Angiography and selective vessel embolization in the setting of pelvic hemorrhage:
 - Particularly for small-vessel arterial bleeding
- Surgery:
 - As indicated on the basis of clinical findings and orthopedic/surgical consult
 - Surgical stabilization with pelvic packing
 - Direct operative control of pelvic bleeding

DIFFERENTIAL DIAGNOSIS

- Normal variants (i.e., os acetabuli epiphyseal line can mimic type I fracture on radiograph)
- Ligamentous injury
- Spinal injury
- Intra-abdominal injury and hemorrhage

TREATMENT

PRE HOSPITAL

- IV fluid resuscitation as indicated
- Consider stabilization or immobilization measures for pelvis

INITIAL STABILIZATION/THERAPY

- ABCs of trauma care
- IV fluid resuscitation with blood or crystalloid, O-negative or type-specific blood if hemodynamically unstable:
 - Avoid using lower extremity IV sites

- Stabilize and immobilize the pelvis to prevent further injury and decrease bleeding:
 - Compression device: Folded sheet with clamp or commercial compression device wrapped circumferentially around greater trochanters to stabilize and compress pelvis
 - Pneumatic anti-shock garment (PASG): Use in ED is controversial, but allows rapid pelvic immobilization and pelvic compression to slow bleeding
 - External fixator: Requires more time to place than PASG but “splints” pelvis in a similar manner; contraindicated in severely comminuted pelvic fracture
 - Placement of a stabilization device should not interfere with further workup and care (e.g., US, DPL)

ED TREATMENT/PROCEDURES

- Determine which pelvic fractures are stable and which are unstable
- Type A fractures are generally stable
- Type B and C fractures are unstable
- Type A fractures:
 - Treated conservatively with bed rest, analgesics, and comfort measures; management decisions may be made in conjunction with orthopedics
 - For 4-pillar anterior ring injuries, CT should be obtained to evaluate the posterior pelvis
 - Ensure that there are no other breaks in the pelvic ring
- Type B and C fractures:
 - Immediate orthopedics consultation; patient should remain NPO
 - May require ED pelvic stabilization measures
 - Assess for pelvic hemorrhage
- Malgaigne fractures:
 - Anticipate significant hemorrhage and associated injuries
- Acetabular fractures:
 - Immediate orthopedics consultation; patient should remain NPO
- Pelvic hemorrhage:
 - Mechanical stabilization of unstable pelvic fractures (usually by application of external pelvic fixation)
 - Angiography and selective vessel embolization
 - Direct operative control of pelvic bleeding
- Prioritization of studies: CT, angiography, or surgery:
 - In the hemodynamically *unstable* patient:
 - Open B and C fractures: Surgical exploration
 - Closed fractures: DPL or US can help determine management in terms of need for immediate surgical exploration or selective angiography/embolization
- In the hemodynamically *stable* patient, the patient can go to CT for evaluation of the abdomen, pelvis, and retroperitoneum with external fixation as appropriate

MEDICATION

- Crystalloid fluids: 2 L IV bolus of normal saline or lactated Ringer (peds: 20 mL/kg)
- Blood products: 4–6 U cross-matched, type specific, or O-negative (peds: 10 mL/kg)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Hemodynamic instability, and pelvic hemorrhage to the ICU
- Type B or C pelvic fracture
- Acetabular fracture
- Other related injuries (e.g., genitourinary, intra-abdominal, neurologic)
- Intractable pain

Discharge Criteria

Type A pelvic fracture; hemodynamically stable with no evidence of other injuries

Issues for Referral

Close follow-up should be ensured for discharged patients.

FOLLOW-UP RECOMMENDATIONS

Discharged patients should be referred to an orthopedist for follow-up.

PEARLS AND PITFALLS

- Pelvic fractures can be a marker for high-energy traumatic mechanism and injury:
 - Assess for underlying abdominal/pelvic injuries including GI, genitourinary, vascular, and neurologic injuries
- In addition to initial resuscitation, immobilization and stabilization of the pelvis should be considered for unstable or open fractures or where hemorrhage is suspected
- Determination of diagnostic/therapeutic pathways including CT with or without angiography, selective IR angiography, and surgery are dictated by the patient's hemodynamic status, suspected underlying injuries, and type of pelvic fractures
- All patients with Malgaigne fractures should be admitted with consultation by trauma and orthopedic services

PELVIC INFLAMMATORY DISEASE

Erich Salvacion

BASICS

DESCRIPTION

- Pelvic inflammatory disease (PID) is an acute, community-acquired, sexually transmitted infection of the upper genital tract, including the uterus, fallopian tubes, ovaries, or adjacent structures
- Most frequent gynecologic cause for ED visits (350,000 per year)
- Represents a spectrum of infection:
 - No single diagnostic gold standard
 - Requires low clinical threshold for considering the diagnosis and starting empiric antibiotic therapy
- Progressive disease can lead to tubo-ovarian abscess (TOA)
- Fitz-Hugh–Curtis syndrome is a capsular inflammation of the liver associated with PID:
 - Sharp right upper quadrant abdominal pain
 - Worse with inspiration, movement, or coughing

ETIOLOGY

- Risk factors:
 - Age < 25 yr
 - Multiple or symptomatic sexual partners
 - Previous episode of PID
 - Nonbarrier contraception
 - Oral contraception
 - African American ethnicity
- Most common causes of PID are *Chlamydia trachomatis* and *Neisseria gonorrhoea*
- Other organisms include groups A and B streptococci, staphylococci, gram-negative rods (commonly *Klebsiella* spp., *Escherichia coli*, and *Proteus* spp.), and anaerobes

DIAGNOSIS

SIGNS AND SYMPTOMS

- Lower abdominal pain, usually bilateral
- Vaginal discharge
- Abnormal uterine bleeding
- Dysmenorrhea
- Dysuria
- Dyspareunia

- Nausea and vomiting
- Fever and chills
- Proctitis
- Lower abdominal tenderness
- Decreased bowel sounds
- Bilateral adnexal tenderness
- Cervical motion tenderness
- Purulent endocervical discharge
- Adnexal mass or fullness
- Right upper quadrant tenderness

History

- Lower abdominal pain is the most common symptom in PID, ranging from subtle to severe pain
- Abdominal pain that worsens during intercourse or onset of pain shortly after or during menses is suggestive of PID
- Abdominal pain is usually bilateral and usually present for ≤ 2 wk
- New vaginal discharge, urethritis, fever, and chills are common symptoms but are neither sensitive nor specific for the diagnosis

Pregnancy Considerations

PID is rare during pregnancy, but if present usually occurs during the 1st trimester before hormonal changes such as mucus plug formation can protect the uterus from ascending bacteria.

Physical-Exam

- Only 50% of patients with PID have fever
- Abdominal exam reveals diffuse tenderness worse in the lower quadrants, usually but not always symmetric
- Rebound tenderness and decreased bowel sounds are commonly found
- Right upper quadrant tenderness is suggestive of perihepatitis (Fitz-Hugh–Curtis syndrome) in the setting of PID
- Pelvic exam can reveal a purulent endocervical discharge, cervical motion tenderness, or adnexal tenderness
- If uterine or adnexal tenderness is not prominent, one must consider other diagnoses

ESSENTIAL WORKUP

- History and physical exam including pelvic exam
- Pregnancy test to rule out ectopic pregnancy or complications of an intrauterine pregnancy
- Cervical culture for *N. gonorrhoea* and *C. trachomatis*

- Minimum criteria for clinical diagnosis:
 - Lower abdominal tenderness *or*
 - Uterine/adnexal tenderness *or*
 - Cervical motion tenderness
- Supportive criteria for diagnosis:
 - Fever > 38.3°C (101°F)
 - Abnormal cervical/vaginal discharge
 - Intracellular gram-negative diplococci on endocervical Gram stain
 - Leukocytosis > 10,000/mm³
 - Elevated erythrocyte sedimentation rate (ESR) or C-reactive protein
 - WBCs or bacteria in peritoneal fluid obtained by culdocentesis or laparoscopy

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Gram stain of endocervix
- Urine polymerase chain reaction tests for *Chlamydia* and *Gonococcus*
- Microscopic exam of vaginal discharge in saline
- Liver enzymes may be elevated in Fitz-Hugh–Curtis syndrome
- Positive urinalysis or occult blood in stool decreases the probability of PID
- ESR or C-reactive protein may be elevated, but not routinely recommended

Imaging

- Patients with adnexal fullness or an adnexal mass on exam should have a transvaginal US to exclude TOA
- Consider obtaining a pelvic US in patients who use an intrauterine device, fail outpatient antibiotic therapy for PID, or who have inadequate pelvic exams due to pain or obesity

Diagnostic Procedures/Surgery

Laparoscopy may be useful in confirming PID in a patient with a high suspicion of competing diagnosis or who failed outpatient treatment for PID

DIFFERENTIAL DIAGNOSIS

- Ectopic pregnancy (must be excluded with a pregnancy test in any woman suspected of having PID)
- Acute appendicitis
- Adnexal torsion
- Endometriosis
- Cystitis

- Urolithiasis
- Ovarian tumor
- Adenomyosis uteri
- Chronic pelvic pain
- Benign ovarian cyst
- Diverticulitis
- Inflammatory bowel disease
- Mesenteric vascular disease
- Irritable bowel syndrome

TREATMENT

PRE HOSPITAL

- No specific pre-hospital considerations
- Appropriate pain management

INITIAL STABILIZATION/THERAPY

- Resuscitation rarely indicated
- Pain control

ED TREATMENT/PROCEDURES

Outpatient

- Ceftriaxone or cefoxitin/probenecid + doxycycline; with metronidazole when anaerobes are a particular concern
- Alternatives include ceftriaxone + azithromycin.
- Must evaluate and treat sex partner as appropriate

Inpatient

- Doxycycline + cefoxitin or cefotetan
- Alternatives include gentamicin + clindamycin; or ampicillin/sulbactam + doxycycline
- Continue parenteral antibiotic administration for 24 hr after clinical improvement, then switch to oral antibiotics to finish 14 day course
- Laparoscopy can be used to lyse adhesions in the acute and chronic stages of Fitz-Hugh–Curtis syndrome
- Add metronidazole when anaerobes are a particular concern

MEDICATION

- Ampicillin/sulbactam: 3 g IV q6h
- Azithromycin: 1 g PO once per week for 2 wk
- Cefotetan: 2 g IV q12h

- Cefoxitin: 2 g IM single dose (outpatient); 2 g IV q6h (inpatient)
- Ceftriaxone: 250 mg IM single dose
- Clindamycin: 450 mg PO QID for 14 days (outpatient); 900 mg IV q8h (inpatient)
- Doxycycline: 100 mg PO BID for 14 days (outpatient); 100 mg IV or PO q12h (inpatient)
 - Oral doxycycline is preferred due to pain of IV infusion
 - IV and oral doxycycline have similar bioavailability
- Gentamicin: 2 mg/kg loading dose followed by 1.5 mg/kg IV q8h. Single daily IV dosing of gentamicin may also be used.
- Metronidazole: 500 mg PO BID for 14 days (outpatient); 500 mg IV q8h (inpatient)
- Probenecid: 1 g PO single dose

First Line

- For outpatient:
 - Ceftriaxone or cefoxitin/probenecid + doxycycline
 - With metronidazole when anaerobes are a particular concern, in suspected *Trichomonas vaginalis* infection
 - Or in women with recent history of pelvic instrumentation
- Of note, oral cephalosporins are no longer a recommended treatment for gonococcal infections (CDC recommends combination therapy with single IM dose of ceftriaxone + oral azithromycin or doxycycline)
- For inpatient:
 - Doxycycline + cefoxitin or cefotetan

Second Line

- For outpatient:
 - Ceftriaxone + azithromycin with or without metronidazole
- For inpatient:
 - Gentamicin + clindamycin; or ampicillin/sulbactam + doxycycline

FOLLOW-UP

DISPOSITION

Admission Criteria

- Uncertain diagnosis and toxic appearance
- Suspected pelvic abscess, including TOA
- Pregnancy
- Immunodeficiency
- Severe illness (e.g., vomiting or severe pain)
- Failure of outpatient therapy

- Probable noncompliance with outpatient therapy (e.g., adolescents)
- Consider admission if appropriate clinical follow-up cannot be arranged

Discharge Criteria

- Patients who do not meet admission criteria may be treated as outpatients
- Recent studies have shown that in women with mild to moderate PID, there was no difference in reproductive outcomes between women randomized to inpatient vs. outpatient treatment

Issues for Referral

TOAs may require drainage or surgical intervention in addition to antibiotics

FOLLOW-UP RECOMMENDATIONS

- If outpatient therapy is selected, it is important to have follow-up in 48–72 hr to assess for clinical improvement
- If the patient has not defervesced by 72 hr, inpatient treatment and further evaluation should be considered

PEARLS AND PITFALLS

- PID represents a spectrum of disease from simple endometritis to fatal intra-abdominal sepsis
- Quinolones and oral cephalosporins are no longer recommended in US for the treatment of gonorrhea or associated conditions such as PID, due to increasing rates of resistance
- Patients with PID should have extensive counseling and testing for other STDs, including HIV
- Male sex partners of women with PID should be treated if they had sexual contact with the patient during the previous 60 days prior to the patient's onset of symptoms

CODES

ICD9

- 079.88 Other specified chlamydial infection
- 098.19 Other gonococcal infection (acute) of upper genitourinary tract
- 614.9 Unspecified inflammatory disease of female pelvic organs and tissues

ICD10

- A54.24 Gonococcal female pelvic inflammatory disease
- A56.11 Chlamydial female pelvic inflammatory disease
- N73.9 Female pelvic inflammatory disease, unspecified

PEMPHIGUS

Dustin G. Leigh • Deepi G. Goyal

BASICS

DESCRIPTION

- Autoantibody (IgG)-mediated blistering disease of the skin and mucous membrane:
 - Characterized by loss of cell-to-cell adhesion called acantholysis
- Median age 71 yr
 - Reports of disease occurring in neonates through elderly
- Rare; worldwide incidence 0.7/100,000
- Females > males, 66 vs. 34%
- *Pemphix* is Greek for bubble or blister
- Pemphigus, specific term for autoantibody disease against some portion of epidermis
- Pemphigoid: A term describing the group of syndromes that cause a separation of the epidermis from the dermis, typically more benign course
- Mortality is highest in those with mucocutaneous involvement
 - If untreated, mortality rates average 60–90%, with treatment this nears 5%
- 3 major subtypes exist:
 - Vulgaris; typically more serious with deeper mucocutaneous involvement:
 - Accounts for 70–80% of all pemphigus
 - Up to 70% with vulgaris present with oral lesions, which is often the presenting complaint
 - Autoantibodies to Dsg 1 and 3
 - Affects most races in middle age and elderly Ashkenazi Jews
 - Follicular; milder and more superficial cutaneous lesions:
 - Oral lesions and better prognosis
 - Autoantibodies to Dsg 1 only
 - Paraneoplastic pemphigus; often with severe mucocutaneous involvement
 - Most commonly seen in lymphoreticular malignancies

Pediatric Considerations

- Pemphigus is rare in neonates and children but may occur in adolescents
- Early diagnosis and treatment significantly impact growth, psychological, social, and cultural development
- Histopathology is identical to adult disease
- Neonates may develop the disease secondary to transplacental transfer of IgG
- Neonatal pemphigus spontaneously resolves in several weeks as the maternal antibodies are catabolized

Pregnancy Considerations

Effective treatment of maternal disease prior to conception lowers the risk of neonatal transmission and gestational complications

ETIOLOGY

- IgG autoantibodies are directed against desmosomal cadherins desmoglein 1 and desmoglein 3 found in all keratinocytes
- Autoantibodies cause histopathologic acantholysis, cytoskeletal derangements, and apoptosis
- Bullae formation is caused by the loss of cell–cell adhesion and separation of the keratinocytes
- Immunogenetic predisposition secondary to higher frequencies of specific human leukocyte antigen HLA haplotypes including DR4 and DRw6
- Drugs such as penicillamine, captopril, rifampin, piroxicam, and phenobarbital can trigger pemphigoid reactions
- Endemic pemphigus foliaceus (fogo selvagem), most common in South America, may be triggered or transmitted by bites from flying insects
- Pemphigoid reactions may occur in association with a neoplasm, usually lymphoma (paraneoplastic pemphigus)

DIAGNOSIS

SIGNS AND SYMPTOMS

- Generalized or focal flaccid bullae (blisters) of the skin and mucosa
- Painful skin erosions with shreds of detached epithelium
- Painful nonhealing oral, vaginal, or mucosal erosions
- Crusting, partially healing skin erosions from ruptured bullae
- Hypertrophic, hyperplastic erosive plaques with pustules in intertriginous areas (pemphigus vegetans)
- Moist, edematous, exfoliative erosions in seborrheic areas (pemphigus foliaceus)
- Erythematous, scaly, crusting skin lesions in a malar distribution (pemphigus erythematosus)
- Lesions usually persist without treatment:
 - May heal with post inflammatory hyperpigmentation

History

- Typically features mucocutaneous blisters followed by erosions
- Often appear 1st in mucous membranes with spread to cutaneous involvement; most commonly to scalp, chest, axillae, and groin
- Skin lesions are painful flaccid blisters that may appear anywhere

Physical-Exam

Nikolsky sign (separation of the epidermis with lateral pressure) is characteristic but not diagnostic:

- Poor sensitivity

ESSENTIAL WORKUP

- Suspected based on clinical presentation
- Biopsy with histologic and immunofluorescence testing is essential for definitive diagnosis (arrange with a dermatologist)

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Serum antibody titers, detected by indirect immunofluorescence, are often used as a marker of disease activity; however, the ED physician usually does not order these titers
- ELISA may be used to identify subtypes

Imaging

No diagnostic imaging test exists

Diagnostic Procedures/Surgery

Deep shave or punch biopsy

DIFFERENTIAL DIAGNOSIS

- Bullous pemphigoid
- Contact dermatitis
- Dermatitis herpetiformis
- Erythema multiforme
- Erysipelas
- Erythroderma
- Toxic epidermal necrolysis
- Epidermolysis bullosa
- Hand, foot, and mouth disease
- Systemic lupus erythematosus
- Systemic vasculitis
- Oral candidiasis
- Herpes simplex gingivostomatitis
- Erosive lichen planus
- Seborrheic dermatitis

TREATMENT

PRE HOSPITAL

- If severe disease:
 - IV access, pulse oximetry monitor, and cardiac monitor

INITIAL STABILIZATION/THERAPY

- If symptoms of hypotension or sepsis are present, IV fluid resuscitation should be guided by the Parkland burn formula
- If signs or symptoms of sepsis are present, initiate broad-spectrum antibiotic coverage
- In steroid-dependent patients, administer stress-dose steroids

ED TREATMENT/PROCEDURES

- Systemic corticosteroids are the mainstay of therapy
- *Mild-to-moderate disease* should receive PO prednisone, and intralesional triamcinolone acetonide may be used
- *Severe disease*: Conventional high-dose corticosteroids:
 - If severe symptoms are unresponsive to high-dose PO corticosteroids, consider pulse IV corticosteroids and admission for plasmapheresis
- Adjuvant immunosuppressive therapy may also be added to decrease the symptoms associated with high-dose systemic corticosteroids or in patients with contraindications to steroid therapy:
 - Dapsone, gold, azathioprine, cyclophosphamide, cyclosporine, methotrexate, mycophenolate, and IV immunoglobulins

MEDICATION

First Line

- Immune suppression:
 - Hydrocortisone: 100–300 mg/d IV stress-dose steroids adjusted based on patients known dosage and use habits
 - Methylprednisolone (pulse IV therapy; adults): 1 g IV over 3 hr daily
 - Prednisone: 1 mg/kg/d PO daily (adults); moderate-to-severe disease PO daily for 5–10 wk, then taper
 - Triamcinolone acetonide for limited intraoral involvement – 10 mg/mL 0.1-mL injection into each superficial lesion
- Pain:
 - Opiates, anti-inflammatory agents, acetaminophen
 - Biobrane synthetic dressing
 - Diphenhydramine and Maalox or Xylocaine oral wash

Second Line

- Usually performed as an inpatient for severe, refractory cases
- Immune suppression:

- IVIG: single cycle 400 mg/kg per day for 5 days
- Rituximab
- Triamcinolone acetonide: 10 mg/mL 0.1-mL injection into each superficial lesion
- Pain:
 - Gabapentin 300 mg daily titrated up to 300 mg TID over a month
- Other considerations: Patients on high-dose steroids should have diets high in vitamin D and calcium and may benefit from a proton-pump inhibitor or bisphosphonates.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Most acute flares are minor and can be managed with PO glucocorticoids and dermatology follow-up
- Admit 1st-time presentations of disease to facilitate treatment and definitive diagnosis with biopsy and rule out of high morbidity blistering skin disease
- Admit patients with extensive mucocutaneous involvement, intractable pain, coexisting bacterial skin infection, or signs of sepsis
- Admit to a floor bed if pulse parenteral steroid therapy or plasmapheresis is indicated
- Admit to the ICU or burn unit if any signs and symptoms of shock or sepsis are present because aggressive fluid resuscitation, wound care, and multiple medications will be required

Discharge Criteria

- Discharge if mild-to-moderate disease will not require aggressive steroid management, plasmapheresis, or aggressive pain control

FOLLOW-UP RECOMMENDATIONS

- A follow-up evaluation with dermatology is essential to monitor the course of the disease and to adjust treatment
- Rheumatology follow-up may be advantageous to assess risk of osteoporosis via bone scan if on high-dose steroids

PEARLS AND PITFALLS

- Mucocutaneous lesions often begin on face, head/scalp, or oral cavity
- Long-term management is the rule; ensure proper dermatology follow-up

- Glucocorticoids are the mainstay of therapy
- Paraneoplastic type often with severe oral mucosal involvement, consider associated lymphoproliferative disorder
- Patients on immunosuppressive treatment including steroids and immunomodulating agents are at very high risk of complications and may present in adrenal crisis, severe sepsis, or hyperosmolar nonketotic acidosis secondary to new-onset type 2 diabetes
- Patients with hypotension require aggressive fluid resuscitation

PENILE SHAFT FRACTURE

Ian R. Grover

BASICS

DESCRIPTION

- Traumatic rupture of the corpus cavernosum and the encompassing tunica albuginea
- May involve the corpus spongiosum and urethra
- Hematoma formation occurs at rupture site.
- Injury is usually unilateral and transverse.
- Most common fracture site is the proximal shaft of the penis.
- During erection, pressure within the corpus cavernosum is maximal, close to arterial pressure, increasing the volume in each corpus to maximum, which thins the tunica albuginea, making it susceptible to rupture.
- Penile erection stretches the spongiosum to the limit, which limits movement vertically while allowing lateral movements; this forms a bend at the base of the penis, making it vulnerable to lateral swing and rupture of corpus cavernosum.
- 25–30% have associated urethral injury, which may be partial or complete.
- Caused by blunt trauma to erect penis during:
 - Sexual intercourse
 - Manipulation
 - Fall on erect penis
 - Entanglement in clothing
 - “*Taghaandan*”—Middle Eastern practice of forcefully bending the erect penis to cause detumescence

ETIOLOGY

- Peyronie disease
- Urethritis in past
- Surgical procedure on corpus cavernosum or trauma to corpus cavernosum resulting in weak scar tissue

DIAGNOSIS

SIGNS AND SYMPTOMS

- Loud popping or crunching sound heard at the time of injury
- Immediate detumescence
- Severe penile pain
- Deviation of the penis away from the side of injury
- Penile swelling and ecchymosis

- There may be blood at the urethral meatus if there is a urethral injury.
- May have dysuria, inability to void, or an increase in the size of the swelling with voiding due to extravasation of urine

History

- Cause of the injury
- Sudden painful sensation in erect penis during sexual intercourse or soon after with loss of erection
- Blood at the urethral meatus after intercourse
- Problems with poor erections after the injury if presentation is delayed
- Penile deviation with erection
- Urinary retention or weak urinary stream

Physical-Exam

- Swelling and blue-black discoloration at base of penis, usually on one side
- Ecchymosis may also involve scrotum.
- Penis flaccid and edematous with angulation away from the side of tear
- Defect in the penile shaft may be palpable at the site of the tear.
- Blood at tip of penis or frank hematuria suggests an associated urethral injury.
- Urethrocavernous or urethrocutaneous fistulas may be present as late complications of a penile fracture.

ESSENTIAL WORKUP

- Urinalysis
- PT/PTT
- Retrograde urethrography if urethral trauma is suspected

DIAGNOSIS TESTS & INTERPRETATION

Lab

Urinalysis to evaluate urethral trauma:

- May have frank blood or microscopic hematuria
- PT/PTT if patient is on Coumadin or has a history of bleeding disorder

Imaging

- Retrograde urethrography—recommended in all cases of suspected urethral trauma:
 - Should be done with low pressure during injection, before urethral catheterization
- Cavernosography and MRI of penis may be needed to confirm diagnosis and site of tear.
- Ultrasonography may also be done to confirm a suspected tear.

Diagnostic Procedures/Surgery

Diagnostic exploration of the penis is recommended when cavernosography is negative but clinical suspicion of a fracture is high.

DIFFERENTIAL DIAGNOSIS

- Cellulitis of penis
- Contusion of penis
- Lymphangitis of penis
- Neoplasm of penis
- Paraphimosis
- Trauma because of constrictive ring or other structure
- Urethral injury
- Vasculature rupture, especially superficial or deep dorsal vein or dorsal artery

TREATMENT

PRE HOSPITAL

- Other injuries take precedence in the setting of multiple trauma.
- Local treatment: Ice packs to the penis; splinting of the penis with tongue blade
- Elevate the area to reduce swelling.

INITIAL STABILIZATION/THERAPY

- Pain control
- Needle suprapubic cystostomy in patients with urethral trauma and a full bladder to relieve patient discomfort

ED TREATMENT/PROCEDURES

- Combined efforts of ED physician and urologist are aimed toward restoration of normal shape of penis and sexual and urinary functions.
- ED treatment is directed to reducing hemorrhage, preventing further complications.
- Prophylactic antibiotic use is unnecessary.
- Urethral catheterization in all cases after excluding urethral trauma
- Urologic evaluation and early surgical treatment are essential to prevent complications such as erectile dysfunction, impotence, penile deformity, urethral stricture.
- All patients with suspected or definite diagnosis *must* have early urologic evaluation.

MEDICATION

- Diazepam: 2–5 mg IV q1–6h PRN anxiety
- Fentanyl: 0.05–0.2 mg IV q1h PRN pain
- Hydromorphone: 0.5–1 mg IV q1–2h PRN pain

- Lorazepam: 0.5–1 mg IV q1–6h PRN anxiety
- Morphine sulfate: 0.1 mg/kg IV q1h PRN pain

FOLLOW-UP

Admission Criteria

ALERT

All patients with penile fracture must be hospitalized for prompt surgery.

Issues for Referral

If immediate urologic consultation and treatment are unavailable, patient may be transferred to a suitable hospital after initial stabilization and transfer criteria have been met.

FOLLOW-UP RECOMMENDATIONS

Follow up with urologist to ensure adequate repair and return to normal sexual and urinary function.

PEARLS AND PITFALLS

- Penile fracture is not a rare occurrence.
- Coitus and penile manipulation are the most common causes.
- Delay in seeking treatment is the major cause of morbidity.
- Mainly a clinical diagnosis:
 - Cavernosography, MRI, and US may be used to confirm the diagnosis.
 - Early surgical repair is important.

ICD10

S39.840A Fracture of corpus cavernosum penis, initial encounter

PEPTIC ULCER

Yanina Purim-Shem-Tov

BASICS

DESCRIPTION

- Produced by breakdown in gastric or duodenal mucosal defenses
- Imbalance exists between production of acid and ability of mucosa to prevent damage.

ETIOLOGY

- *Helicobacter pylori*:
 - _ Gram-negative spiral bacteria that live in mucous layer
 - _ Responsible for 90–95% of duodenal ulcers and 80% of gastric ulcers
 - _ Increases antral gastrin production and decreases mucosal integrity
- NSAIDs:
 - _ Interfere with prostaglandin synthesis
 - _ Lead to break in mucosa
- Aspirin
- Cigarette smoking
- Alcohol
- Severe physiologic stress
- Hypersecretory states (uncommon)
- Genetics (> 20% have family history)

DIAGNOSIS

SIGNS AND SYMPTOMS

- Epigastric pain or tenderness (80–90%):
 - _ Burning, gnawing, aching pain
 - _ Location: midline, xiphoid, or umbilicus
- Duodenal ulcers:
 - _ Pain occurs 90 min -- 3 hr after meals
 - _ Usually awakens patient at night
 - _ Food and antacids relieve pain
- Gastric ulcers:
 - _ Pain worsens after meals
 - _ Nausea and anorexia
- Difficult to differentiate clinically between gastric and duodenal ulcers
- Relief of pain with antacids
- Heme-positive stools

- Complications of peptic ulcer disease (PUD):
 - Acute perforation:
 - Rigid, boardlike abdomen
 - Generalized rebound tenderness
 - Pain radiation to back or shoulder
 - Obstruction:
 - Pain with vomiting
 - Succussion splash from retained gastric contents and abdominal distention
 - Hemorrhage:
 - Hematemesis
 - Melena
 - Hypotension
 - Tachycardia
 - Skin pallor
 - Orthostatic changes

History

- NSAID, Aspirin
- Smoking
- Previous history of PUD
- Family history of stomach cancer
- Abdominal pain
- Diarrhea
- Weakness

Physical-Exam

- Abdominal pain
- Signs of anemia
- Guaiac-positive stool

ESSENTIAL WORKUP

- Careful physical exam including Hemoccult testing and vital signs with orthostatics
- For stable patients, oral GI cocktail typically relieves pain:
 - Antacid: 30 mL
 - Viscous lidocaine: 10 mL

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Normal lab values in uncomplicated ulcer disease
- CBC:
 - Low hematocrit with bleeding

- Leukocytosis with perforation/penetration
- Amylase/lipase:
 - Elevated with perforation/penetration
 - Pancreatitis in differential diagnosis
- Electrolytes, BUN/creatinine, glucose for critically ill
- Type and cross-match for significant blood loss
- *H. pylori* testing (urea breath test, *H. pylori* antibodies, IgG)

Imaging

- Chest radiograph/abdominal series:
 - Evaluate for perforations/obstructions

Diagnostic Procedures/Surgery

- ECG:
 - For elderly patients
 - Myocardial ischemia in differential diagnosis
- Endoscopy:
 - Procedure of choice
 - Outpatient unless significant hemorrhage
 - Allows for biopsies of gastric/duodenal ulcers for presence of *H. pylori*
 - Detects malignant gastric ulcers
- Upper GI series:
 - Single contrast barium diagnoses 70–80%
 - Double contrast diagnoses 90%
- Gastrin level is elevated in Zollinger–Ellison syndrome

DIFFERENTIAL DIAGNOSIS

- Gastroesophageal reflux
- Biliary colic
- Cholecystitis
- Pancreatitis
- Gastritis
- Abdominal aortic aneurysm
- Aortic dissection
- Myocardial infarction
- Subset with symptoms and no ulcer on endoscopy called *nonulcer dyspepsia*

TREATMENT

PRE HOSPITAL

- ABCs
- IV fluid resuscitation for hypotensive/shock patients

INITIAL STABILIZATION/THERAPY

- ABCs
- Identify ulcer complications (hemorrhage, perforation, obstruction)
- Treat hypotension with lactated Ringer/normal saline fluid bolus via 2 large-bore IVs
- Type and cross early
- Nasogastric tube (NGT) for gastric decompression/check for hemorrhage

ED TREATMENT/PROCEDURES

- Pain control with antacids (GI cocktail) or IV H₂ antagonists
- Avoid narcotics—may mask serious illness.
- Promotion of ulcer healing:
 - Antacids
 - H₂ antagonists (cimetidine, famotidine, ranitidine, nizatidine):
 - May continue for 2–5 yr for ulcer suppression therapy
 - Proton-pump inhibitors (PPIs; omeprazole, lansoprazole, or pantoprazole):
 - If H₂ antagonists have failed
 - Sucralfate
 - Prostaglandin congeners (misoprostol)
 - Sucralfate, H₂-receptor antagonists, and PPIs should not be combined because of lack of documented benefit
- Gastric outlet obstruction:
 - Decompress stomach with NGT
 - IV hydration
- Gastric hemorrhage:
 - IV fluid resuscitation
 - Blood transfusion depending on loss/hematocrit
 - Foley catheter to monitor volume status
 - GI consultation
- Perforation:
 - IV hydration
 - Foley catheter to monitor hydration status
 - Preoperative antibiotics
 - Emergency surgical consultation
- Treatment of *H. pylori* infection:
 - Invasive or noninvasive testing to confirm infection
 - Oral eradication antibiotic therapy options:
 - PPI (omeprazole 20 mg BID or lansoprazole 30 mg PO BID) and 2 antibiotics (clarithromycin 500 mg BID + metronidazole 500 mg BID) for 14 days
 - H₂ blocker, bismuth subsalicylate (Pepto-Bismol) + either amoxicillin

- 1,000 mg BID or tetracycline 500 mg QID in combination with either metronidazole 250 mg QID or clarithromycin 500 mg BID for 14 days
- Most common regimen: Omeprazole 20 mg or lansoprazole 30 mg + clarithromycin 500 mg and amoxicillin 1 g, all taken twice a day for 2 wk
- Stop NSAIDs
- Surgical therapy:
 - Refractory ulcer
 - Complications:
 - Bleeding
 - Perforation
 - Pyloric stenosis

MEDICATION

- Bismuth subsalicylate: 2 525 mg tabs PO
- Maalox Plus: 2–4 tabs PO QID
- Misoprostol: 100–200 mg PO QID
- Mylanta II: 2–4 tabs PO QID
- Sucralfate: 1 g PO QID for 6–8 wk
- Famotidine (H₂ blocker): 40 mg PO nightly at bedtime (peds: 0.5–0.6 mg/kg q12h) for 6–8 wk
- Nizatidine (H₂ blocker): 300 mg PO nightly at bedtime for 6–8 wk; 20 mg PO BID (peds: 0.6–0.7 mg/kg q12–24h) for 2 wk
- Ranitidine (H₂ blocker): 300 mg PO nightly at bedtime (peds: 5–10 mg/kg/24h given q12h) for 6–8 wk
- Cimetidine (H₂ blocker): 400 mg PO BID for 6–8 wk
- Lansoprazole (PPI): 30 mg PO BID for 2 wk
- Pantoprazole (PPI): 40 mg PO daily for 2 wk
- Omeprazole (PPI): 20 mg PO BID for 2 wk
- Rabeprazole (PPI): 20 mg PO daily for 6 wk
- Esomeprazole (PPI): 40 mg daily for 4 wk
- *H. pylori* therapy:
 - PPI (omeprazole 20 mg or lansoprazole 30 mg), clarithromycin 500 mg BID for 2 wk, amoxicillin 1 g BID for 2 wk
 - For penicillin-allergic patients: PPI + clarithromycin 500 mg BID + metronidazole 500 mg BID for 14 days
 - 4-drug therapy: H₂ blocker, bismuth subsalicylate (Pepto-Bismol) + either amoxicillin 1,000 mg BID or tetracycline 500 mg QID in combination with either metronidazole 250 mg QID or clarithromycin 500 mg BID for 14 days

H. pylori eradication regimes:

- PPI (omeprazole 20 mg or lansoprazole 30 mg), clarithromycin 500 mg BID for 2 wk, amoxicillin 1 g BID for 2 wk
- For penicillin-allergic patients: PPI + clarithromycin 500 mg BID + metronidazole 500 mg BID for 14 days
- Sequential 10 day therapy in high prevalence areas:
 - Double therapy for 5 days
 - PPI
 - Amoxicillin
 - Followed by triple therapy for 5 days
 - PPI
 - Clarithromycin
 - Metronidazole
- 4-drug therapy: H₂ blocker, bismuth subsalicylate (Pepto-Bismol) + either amoxicillin 1,000 mg BID or tetracycline 500 mg QID in combination with either metronidazole 250 mg QID or clarithromycin 500 mg BID for 14 days

Second Line

1 wk quadruple therapy:

- Bismuth subsalicylate 120 mg PO QID, tetracycline PO 500 mg QID, metronidazole 400 mg PO QID, esomeprazole 20 mg PO BID
- 80% eradication rate

FOLLOW-UP

DISPOSITION

Admission Criteria

- Gastric obstruction
- Perforation
- Active upper GI bleed
- Melena
- Uncontrolled pain
- Anemia requiring transfusion

Discharge Criteria

- Unremarkable physical exam with normal CBC and heme-negative stools
- If heme-positive stools, discharge if stable vital signs, normal hematocrit, and negative NGT aspiration for upper GI hemorrhage

Issues for Referral

FOLLOW-UP RECOMMENDATIONS

- High-risk patients include those with the following characteristics:
 - Bleeding with hemodynamic instability
 - Repeated hematemesis or any hematochezia
 - Failure to clear with gastric lavage
 - Coagulopathy
 - Comorbid disease
 - Advanced age
 - Patients with ulcer perforation or penetration require operative repair.
- All patients require primary care follow-up in 2–6 wk to evaluate efficacy of treatment.
- Patients > 55 yr and patients with severe symptoms should receive GI referral for endoscopy and testing for *H. pylori*.

PEARLS AND PITFALLS

- *H. pylori* is the most common cause of PUD.
- NSAID-induced PUD is frequently silent.
- Dyspeptic symptoms are nonspecific.
- Endoscopy is diagnostic and should include *H. pylori* screening.
- Treatment should include *H. pylori* eradication and H₂ blockers or PPIs.
- Complications include perforations, hemorrhage, anemia.
- Failure to follow up may result in failure to diagnose gastric cancer.

CODES

ICD9

- 531.30 Acute gastric ulcer without mention of hemorrhage or perforation, without mention of obstruction
- 532.30 Acute duodenal ulcer without mention of hemorrhage or perforation, without mention of obstruction
- 533.90 Peptic ulcer of unspecified site, unspecified as acute or chronic, without mention of hemorrhage or perforation, without mention of obstruction

ICD10

- K25.3 Acute gastric ulcer without hemorrhage or perforation
- K26.3 Acute duodenal ulcer without hemorrhage or perforation
- K27.9 Peptic ulc, site unsp, unsp as ac or chr, w/o hemor or perf

PERFORATED VISCUS

Rosaura Fernández • Jeffrey J. Schaidler

BASICS

DESCRIPTION

- Perforation/break in the containing walls of an organ with contents spilling into peritoneal cavity
- Inflammation/infection
- Ulceration
- Shearing/crushing or bursting forces in trauma
- Obstruction
- Chemical and/or bacterial peritonitis occurs as result of disruption of gastric or intestinal lining into peritoneal cavity.

ETIOLOGY

- Peptic ulcer disease:
 - Majority of cases caused by NSAIDS and *Helicobacter pylori*
- Esophageal
- Small bowel:
 - Ischemia, foreign body, neoplasms, inflammatory bowel disease
- Large bowel:
 - Diverticular disease, foreign body, neoplasms, inflammatory bowel disease
- Appendicitis
- Penetrating or blunt trauma
- Iatrogenic:
 - Endoscopy, colonoscopy
- Radiation enteritis and proctitis

Pediatric Considerations

- Trauma is the more common cause of rupture:
 - Neonates with difficult birth/child abuse/motor vehicle accidents and falls
- Jejunum is the most common site of rupture.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Sudden severe abdominal pain:
 - Initially local
 - Often rapidly becoming diffuse due to peritonitis
 - Consider persistent local pain due to abscess/phlegmon formation

- Rigidity
- Guarding
- Rebound tenderness
- Absent bowel sounds
- SIRS
- Hypovolemic or septic shock:
 - Hypotension
 - Tachycardia
 - Tachypnea

Geriatric Considerations

- 1/3 without complaints of PUD
- May not have dramatic pain/peritoneal findings on exam:
 - Less rebound and guarding due to less abdominal wall musculature
 - Chronic use of pain meds
- May present with altered mental status
- Hypothermic, suppressed tachycardia

ESSENTIAL WORKUP

Upright chest radiograph:

- Best demonstrates pneumoperitoneum
- When in upright position for 5–10 min, may detect as little as 1–2 mL of free air under diaphragm

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Electrolytes, BUN/creatinine, glucose
- Lipase
- Urinalysis
- Liver function test, coagulation panel
- ABG
- Lactate
- Consider type and cross match for blood

Imaging

- Upright CXR:
 - To detect air under diaphragm
 - Sensitivity ranges from 50% to 85%
- Abdominal radiographs:
 - Left lateral decubitus film more helpful than supine abdomen.
 - Double wall sign of perforated viscus:

- Air in intestinal lumen and peritoneal cavity allows for visualization of both serosal (not normally seen) and mucosal surfaces of intestine.
- Abdominal CT:
 - _ Detects small amounts of free air from perforated viscous
- ECG

DIFFERENTIAL DIAGNOSIS

- Pneumomediastinum with peritoneal extension
- Appendicitis/cholecystitis/pancreatitis
- Pneumonia
- DKA
- Intra-abdominal abscess
- Peptic ulcer disease
- Inferior wall myocardial infarction
- Obstruction

Geriatric Considerations

Atypical symptoms of pain, lack of fever, absence of leukocytosis more likely due to population's suppressed immunity, common comorbidities

- AAA
- Acute mesenteric ischemia
- Atypical presentations of conditions listed in DDx

Pregnancy Considerations

Rule out ectopic pregnancy

TREATMENT

PRE HOSPITAL

Initiate IV fluids for patients with history of vomiting or abnormal vital signs.

INITIAL STABILIZATION/THERAPY

Treat hypotension/tachycardia with 0.9% normal saline:

- Adults: 500 mL–1 L bolus:
 - _ Repeat bolus as necessary permitting patient can tolerate aggressive fluid resuscitation
 - _ Consider vasopressors if fluids not tolerated or not sufficient to maintain physiologic stability
- Pediatric: 20 mL/kg bolus:
 - _ Considerations similar as in adult population

ED TREATMENT/PROCEDURES

- Nasogastric tube
- Foley catheter
- Administer broad-spectrum antibiotics:
 - Cephalosporin/broad-spectrum penicillin +
 - Aminoglycoside/broad-spectrum penicillin/antianaerobe
- Immediate surgical consultation for operative intervention

MEDICATION

Broad coverage antibiotics should be given for enteric gram-negative aerobic and facultative bacilli and enteric gram-positive streptococci

- Metronidazole 500 mg IV (peds: 30–40 mg/kg/d q8h) in addition to 1 of the antibiotics below
- Carbapenem:
 - Meropenem 1 g IV q 8h (peds: 60 mg/kg/d in div. doses q8h)
 - Imipenem–cilastatin 500 mg IV q6h (peds: 60–100 mg/kg/d in div. doses q6h)
 - Doripenem 500 mg IV q8h
- β -lactamase inhibitor combination:
 - Piperacillin–tazobactam 3.375–4 g IV q4–6h (peds: 200–300 mg/kg/d of piperacillin component in div. doses q6–8h)
- Flouroquinolones (used only if hospital surveys indicate > 90% susceptibility of *Escherichia coli* to this class):
 - Ciprofloxacin 400 mg IV q12h
 - Levofloxacin 750 mg IV q24h
- Cephalosporin:
 - Ceftazidime 2 g IV q8h (peds: 150 mg/kg/d in div. doses q8h)
 - Cefepime 2 g IV q8–12h (peds: 100 mg/kg/d in div. doses q12h)
 - Ceftriaxone 1–2 g IV q12–24h (peds: 50–75 mg/kg/d in div. doses q12–24h)
- Morphine sulfate: 2–4 mg (peds: 0.1 mg/kg) IV q2–3h

FOLLOW-UP

DISPOSITION

Admission Criteria

Suspected or confirmed perforation requires admission and immediate surgical consultation.

Discharge Criteria

Discharge not applicable in this situation, as acute perforations are surgical emergencies

Issues for Referral

- General surgery consult for operative intervention
- Consider trauma consult/transfer if applicable

FOLLOW-UP RECOMMENDATIONS

Postoperative surgery follow-up

PEARLS AND PITFALLS

- Obtain upright CXR and abdominal radiographs for patients with suspected perforated viscous.
- CXR without free air does not rule out perforation
- If high clinical suspicion for perforation and plain films normal, obtain CT of abdomen to detect small perforation.
- Obtain immediate surgical consult for operative intervention.

Abdominal Pain

CODES

ICD9

- 533.50 Chronic or unspecified peptic ulcer of unspecified site with perforation, without mention of obstruction
- 562.11 Diverticulitis of colon (without mention of hemorrhage)
- 868.00 Injury to other intra-abdominal organs without mention of open wound into cavity, unspecified intra-abdominal organ

ICD10

- K27.5 Chronic or unsp peptic ulcer, site unsp, with perforation

- K57.20 Diverticulitis of large intestine with perforation and abscess without bleeding
- S36.99XA Other injury of unspecified intra-abdominal organ, initial encounter

PERICARDIAL EFFUSION/TAMPONADE

Louisa S. Canham • Carlo L. Rosen

BASICS

DESCRIPTION

- Pericardial effusion:
 - Pericardial sac usually contains 15–40 cc of fluid
 - Collection of additional fluid = effusion
- Pericardial tamponade:
 - Accumulation of pericardial fluid causes an elevation of pressure in the pericardial space, resulting in impairment of ventricular filling and decreased cardiac output.
 - Depends on size and speed of fluid accumulation
 - Increase of as little as 80–120 cc of fluid may lead to a rise in pericardial pressure.
 - Up to 70% present in “early tamponade” and appear clinically stable
 - Occurs in 2% of patients with penetrating chest trauma

ETIOLOGY

- Medical causes:
 - Pericarditis (20%):
 - 90% idiopathic or viral
 - Bacterial, fungal, parasitic, tuberculosis, HIV
 - Malignancy (13%):
 - Lymphoma, leukemia, melanoma, breast, lung
 - Metastatic disease, primary malignancy, postradiation
 - Postmyocardial infarction (8%):
 - Acute: 1–3 days after acute myocardial infarction (AMI)
 - Subacute (Dressler syndrome): Weeks to months after AMI
 - Incidence reduced with reperfusion therapy
 - End-stage renal disease, uremia (6%)
 - Autoimmune/collagen vascular disease (5%): Rheumatoid arthritis, systemic lupus erythematosus, scleroderma
 - Rheumatic fever
 - Radiation therapy
 - Myxedema
 - Congestive heart failure (CHF), valvular heart disease
 - Drug toxicity (isoniazid, doxorubicin, procainamide, hydralazine, phenytoin)
 - Idiopathic

- Surgical causes:
 - Penetrating chest trauma
 - Thoracic aortic dissection
 - Iatrogenic (cardiac catheterization, postcardiac surgery, central line placement)
 - Blunt trauma rarely causes pericardial effusion.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Beck's triad = classic presentation of cardiac tamponade:
 - Hypotension
 - Muffled heart sounds
 - Jugular venous distention
- Dressler syndrome: Pericarditis seen several weeks after a myocardial infarction:
 - Fever
 - Chest pain
 - Pericardial friction rub

History

- Past medical history is key:
 - History of malignancy?
 - Recent viral illness?
 - Connective tissue disorder?
 - Recent MI?
- History of the present illness:
 - Most are asymptomatic.
 - Pulmonary symptoms: Dyspnea, cough:
 - Dyspnea is the most common symptom seen in tamponade (87–88% sensitivity).
 - Chest pain is the most common symptom:
 - Usually sharp, pleuritic, relieved by sitting forward
 - Can be referred to scapula
 - Can also be dull, aching, constrictive
 - GI symptoms: Nausea or abdominal pain from hepatic and visceral congestion or dysphagia from esophageal compression
 - Generalized symptoms: Fatigue, malaise

Physical-Exam

- Signs of shock or right heart failure:
 - Tachycardia, hypotension
 - Jugular venous distention (may be absent if the patient is also hypovolemic)

- Pericardial friction rub (100% specific):
 - High-pitched “scratchy” sound
 - Best heard at left sternal border
 - Increased by leaning forward
 - Can be transient/intermittent
- Pulsus paradoxus:
 - Fall in systolic BP > 10 mm Hg with inspiration
 - When severe, this can manifest as lack of brachial or radial pulse during inspiration.
 - Sensitive but not specific
- Low-grade fever common; $> 38^{\circ}\text{C}$ is uncommon; if present, consider purulent pericarditis (can also result from autoimmune/connective tissue disease).
- Lungs should be clear; if not, consider CHF or pneumonia.

ESSENTIAL WORKUP

- ECG
- CXR
- US:
 - Echocardiography, including evaluation of aortic root
 - Shock US: Include focused assessment with sonography in trauma, aorta, pleural effusion, and pneumothorax views to rule out other causes of hypotension

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- ESR, C-reactive protein:
 - Usually elevated in pericarditis
- Cardiac enzymes:
 - Consider myocarditis if elevated
- Electrolytes:
 - BUN/creatinine in suspected uremic pericarditis
- Coagulation profile:
 - Especially in liver failure, anticoagulation, trauma
- Blood cultures if an infectious source is suspected

Imaging

- Chest radiograph:
 - Cardiomegaly is 89% sensitive for tamponade.
 - Can be normal even with effusion if developed quickly
- Echocardiography:
 - 97–100% sensitive, 90–97% specific

- Effusion: Can detect as little as 20–50 cc of pericardial blood/fluid:
 - Small effusions will only be seen posteriorly.
 - Anterior fat pad may mimic effusion; must also visualize posterior pericardial space for diagnosis of effusion.
- Tamponade:
 - Effusions large enough to cause tamponade should be circumferential.
 - Right atrial or ventricular bowing and eventual collapse
 - “Sniff” test: During inspiration, the inferior vena cava will not collapse in patients with tamponade.
- Chest CT for detecting hemopericardium
- Transesophageal echocardiography
- MRI with gadolinium (for stable patients only)

Diagnostic Procedures/Surgery

- ECG:
 - Low voltage
 - Electrical alternans: Alternating beat-to-beat variation of QRS amplitude (usually only seen with large effusions)
- Pericardiocentesis and fluid analysis:
 - Therapeutic for tamponade or large symptomatic effusion
 - Diagnostic for bacterial effusion (to guide antibiotics) or malignant effusion (for cytology)
- Central venous pressure (CVP) determination:
 - CVP > 15 cm H₂O suggests tamponade, but may be normal in the hypovolemic patient.

DIFFERENTIAL DIAGNOSIS

- Noncardiogenic shock:
 - Hypovolemic, septic, anaphylactic, spinal
- Other cardiac conditions:
 - Myocardial infarction—common misdiagnosis!
 - Pericardial constriction (due to pericardial fibrosis)
 - CHF
- Pulmonary conditions:
 - Pulmonary embolus
 - Tension pneumothorax
 - Hemothorax
- Other causes:
 - Air embolism
 - Aortic dissection
 - Ruptured abdominal aortic aneurysm

TREATMENT

PRE HOSPITAL

- 2 large-bore IV lines
- Start IV fluids.
- Supplemental O₂

INITIAL STABILIZATION/THERAPY

- Continue pre-hospital measures
- Continuous cardiac monitoring
- In tamponade:
 - IV fluid resuscitation with normal saline or blood
 - Pericardiocentesis for unstable patients to decompress the tamponade

ED TREATMENT/PROCEDURES

- Medical causes of tamponade in patients who are unstable:
 - Perform pericardiocentesis with placement of an indwelling catheter for continued drainage:
 - Site of drainage guided by maximum fluid collection
 - Subxiphoid: 2 cm below and 1 cm to the left of the xiphoid process, needle aimed at 30–45° angle toward the patient's left shoulder
 - Left parasternal approach: 5th intercostal space just lateral to sternum, needle inserted perpendicular to the skin
 - Remove fluid as needed to improve clinical condition.
- Traumatic pericardial tamponade:
 - Consult trauma surgeon immediately.
 - Definitive therapy is thoracotomy in the OR.
 - If patient is deteriorating despite resuscitation, ED thoracotomy with pericardotomy is an option.
- Bacterial pericardial effusion:
 - Initiate antibiotic therapy to cover gram-negative and anaerobic organisms and *Staphylococcus aureus*.
 - May ultimately require partial surgical resection of the pericardium
- Uremic pericardial effusion:
 - Arrange urgent dialysis.
- Dressler syndrome and postirradiation pericardial effusion:
 - Initiate aspirin
- Aortic dissection:
 - Immediate cardiothoracic surgical consultation for operative repair

MEDICATION

- Ibuprofen: 800 mg PO q8h

- Indomethacin: 75–150 mg PO daily
- Avoid NSAIDs in patients with CAD
- Steroids:
 - Only for refractory cases (more commonly associated with rebound when tapered)
 - Prednisone: 0.2–0.5 mg/kg, continued for at least 1 mo, slowly tapered

FOLLOW-UP

DISPOSITION

Admission Criteria

- ICU admission for acute, symptomatic pericardial effusion/tamponade
- New pericardial effusion
- Pericarditis with elevated troponin

Discharge Criteria

- Known or incidentally found small pericardial effusion in asymptomatic stable patient
- Pericarditis without evidence of tamponade in a young, healthy person whose pain is controlled with NSAIDs

Issues for Referral

- Trauma surgery:
 - Tamponade in setting of trauma: Will need to go to OR for thoracotomy (or from ED status post ED thoracotomy)
- Cardiothoracic surgery:
 - Tamponade/effusion in the setting of aortic dissection/other primary cardiac problem
 - Patients requiring pericardial window
 - Any patients who have had recent cardiac surgery
- Cardiology/interventional cardiology:
 - Dressler syndrome
 - Recent percutaneous intervention
 - Any patients who need pericardiocentesis

FOLLOW-UP RECOMMENDATIONS

Discharged patients need urgent primary care physician follow-up and repeat echo to evaluate for resolution of effusion.

PEARLS AND PITFALLS

- ECG changes associated with pericarditis include diffuse ST-elevation with PR-depression and eventual T-wave inversion. Should be contrasted with ECG findings of localized ST-elevation with reciprocal ST-depression in AMI.
- Relatively small effusions can cause tamponade if rapidly developing (conversely, large effusions can be relatively benign when they develop slowly).
- Cardiac output can be fluid dependent in tamponade—start fluids early.
- Use bedside US to look for pericardial effusion and other signs of tamponade in the setting of hypotension (including trauma).
- ED thoracotomy should not be employed if there is no OR readily available.

Cardiogenic Shock

CODES

ICD9

- 423.3 Cardiac tamponade
- 423.9 Unspecified disease of pericardium

ICD10

- I31.3 Pericardial effusion (noninflammatory)
- I31.4 Cardiac tamponade

PERICARDITIS

Terrance T. Lee • Shamai A. Grossman

BASICS

DESCRIPTION

- Inflammation, infection, or infiltration of the pericardial sac surrounding the heart:
 - Pericardial effusion may or may not be present.
- Acute pericarditis:
 - Rapid in onset
 - Potentially complicated by cardiac tamponade from effusion
- Constrictive pericarditis:
 - Results from chronic inflammation causing thickening and adherence of the pericardium to the heart

ETIOLOGY

- Idiopathic (most common)
- Viral:
 - Echovirus
 - Coxsackie
 - Adenovirus
 - Varicella
 - Epstein–Barr virus
 - Cytomegalovirus
 - Hepatitis B
 - Mumps
 - HIV
- Bacterial:
 - Tuberculosis
 - *Staphylococcus*
 - *Streptococcus*
 - *Haemophilus*
 - *Salmonella*
 - *Legionella*
- Fungal:
 - *Candida*
 - *Aspergillus*
 - Histoplasmosis
 - Coccidioidomycosis
 - Blastomycosis

- *Nocardia*
- Parasitic:
 - Amebiasis
 - Toxoplasmosis
 - Echinococcosis
- Neoplastic:
 - Lung
 - Breast
 - Lymphoma
- Uremia
- Myocardial infarction:
 - Dressler syndrome
- Connective tissue disease:
 - Systemic lupus erythematosus
 - Rheumatoid arthritis
 - Scleroderma
- Radiation
- Chest trauma
- Postpericardiotomy
- Aortic dissection
- Myxedema
- Pancreatitis
- Inflammatory bowel disease
- Amyloidosis
- Drugs:
 - Procainamide
 - Cromolyn sodium
 - Hydralazine
 - Dantrolene
 - Isoniazid
 - Penicillins
 - Doxorubicin/daunorubicin

DIAGNOSIS

SIGNS AND SYMPTOMS

- Chest pain
- Fever
- Mild dyspnea
- Cough
- Hoarseness
- Nausea

- Anorexia

History

- Chest pain:
 - _ Pain radiating to the ridge of the trapezius from phrenic irritation
 - _ Central or substernal pain
 - _ Sudden onset
 - _ Sharp
 - _ Pleuritic
 - _ Worse when supine or with cough
 - _ Improved with leaning or sitting forward
- Previous episodes of pericarditis
- History of fever or infection
- History of malignancy or autoimmune disease

Physical-Exam

- Tachypnea
- Tachycardia
- Odynophagia
- Friction rub:
 - _ Heard best at lower left sternal border
 - _ Very specific
 - _ Triphasic rub is classic
 - _ Can have any of these 3 components:
 - Presystolic
 - Systolic
 - Early diastolic
 - _ Intermittent and exacerbated by leaning forward
- Beck triad with the accumulation of pericardial fluid:
 - _ Muffled heart sounds
 - _ Increased venous pressure (distended neck veins)
 - _ Decreased systemic arterial pressure (hypotension)
- Ewart sign:
 - _ Dullness and bronchial breathing between the tip of the left scapula and the vertebral column
- Pulsus paradoxus:
 - _ Exaggerated decrease (> 10 mm Hg) in systolic pressure with inspiration
- Constrictive pericarditis:
 - _ Signs of both right- and left-sided heart failure
 - _ Pulmonary and peripheral edema
 - _ Ascites
 - _ Hepatic congestion

ESSENTIAL WORKUP

- ECG has 4 classic stages
- Stage 1:
 - Concave ST-elevations diffusely except aVR and V1
 - PR segment depressions with elevation in aVR
- Stage 2:
 - Normalization of ST and PR segments
 - T-wave flattening
- Stage 3:
 - Diffuse T-wave inversions
- Stage 4:
 - T-waves normalize, may have some persistent T-wave inversions
- Atypical changes may include localized ST-elevations or T-wave inversions
- Myocardial involvement suggested by intraventricular conduction delay, new bundle branch block, or Q-waves
- Pericardial effusion suggested by electrical alternans

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - May show leukocytosis
- Erythrocyte sedimentation rate and C-reactive protein:
 - May be elevated, can follow for resolution
- Cardiac enzymes:
 - Helpful in distinguishing pericarditis from myocardial infarction
 - May also be elevated in myopericarditis

Imaging

- CXR:
 - Most often normal
 - May show enlargement of the cardiac silhouette or calcification of pericardium
 - No change in heart size until >250 mL of fluid has accumulated in the pericardial sac
- Echocardiography:
 - Diagnostic method of choice for the detection of pericardial fluid
 - Can detect as little as 15 mL of fluid in the pericardial sac
 - Bedside US good screening tool
- Chest CT:
 - Useful for the detection of calcifications or thickening of the pericardium
 - Can help rule out other etiologies

Diagnostic Procedures/Surgery

Pericardiocentesis:

- Pericardial fluid can help determine underlying etiology.
- Fluid sent for protein, glucose, culture, cytology, Gram and acid-fast stains, and fungal smears

DIFFERENTIAL DIAGNOSIS

- Acute myocardial infarction
- Pulmonary embolism
- Pneumothorax
- Aortic dissection
- Pneumonia
- Empyema
- Cholecystitis
- Pancreatitis

TREATMENT

PRE HOSPITAL

- ABCs, IV access, O₂, monitor
- Consider fluid bolus if no crackles.

INITIAL STABILIZATION/THERAPY

- ABCs
- Emergent pericardiocentesis:
 - For hemodynamic compromise secondary to cardiac tamponade
 - Removal of a small amount of fluid can lead to a dramatic improvement.
 - US guidance if available

ED TREATMENT/PROCEDURES

- Treatment dependent on the underlying etiology
- Idiopathic, viral, rheumatologic, and post-traumatic:
 - NSAID regimens effective
 - Corticosteroids reserved for refractory cases
- Bacterial:
 - Aggressive treatment with IV antibiotics along with drainage of the pericardial space
 - Search for primary focus of infection.
 - Therapy guided by determination of pathogen from pericardial fluid tests
- Neoplastic:
 - Treat underlying malignancy.
- Uremic:

- Intensive 2–6 wk course of dialysis
- Caution should be used if using nonsteroidal medications.
- Expected course/prognosis:
 - Most patients will respond to treatment within 2 wk.
 - Most have complete resolution of symptoms.
- Few progress to recurrent episodes with eventual development of constrictive pericarditis or cardiac tamponade.

MEDICATION

- Ibuprofen 300–800 mg q6–8h for days to weeks depending on severity:
 - Can also be tapered to prevent recurrence
 - Improves coronary blood flow
 - GI prophylaxis with 20 mg omeprazole
- Aspirin 800 mg PO q6–8h × 7–10 days:
 - Taper off over 3–4 wk
 - Omeprazole as with ibuprofen
 - Colchicine 1–2 mg × 1 day, then 0.5–1 mg daily × 3 mo
- Colchicine alone: 1–2 mg × 1 day, then 0.5–1 mg daily × 3 mo:
 - Combination with aspirin decreased recurrence rate
 - Lower doses may also be effective.
- Indomethacin 25–50 mg q6h:
 - May restrict coronary blood flow
- Prednisone 0.2–0.5 mg/kg daily × 2–4 wk with taper:
 - Used for refractory cases
 - For use if aspirin/NSAIDs contraindicated
 - Associated with increased rate of recurrence
 - Also beneficial in uremic and autoimmune pericarditis

Pregnancy Considerations

- NSAIDs and aspirin are not teratogenic in 1st 20 wk of pregnancy
- Glucocorticoids may be used during pregnancy.
- Avoid aspirin and high-dose steroids when breast-feeding.
- Colchicine is generally contraindicated except with familial Mediterranean fever.

FOLLOW-UP

DISPOSITION

Admission Criteria

- ICU:
 - Hemodynamic instability
 - Cardiac tamponade

- Malignant dysrhythmia
- Status postpericardiocentesis
- Telemetry unit:
 - Suspicion of myocardial infarction
 - Severe pain
 - Suspicion of bacterial etiology
 - Any high-risk criteria
- High-risk criteria:
 - Large effusion (> 2 cm total)
 - Anticoagulant use
 - Malignancy
 - Temperature > 38°C
 - Traumatic pericarditis
 - Immunosuppression
 - Pulsus paradoxus
 - Slow onset

Discharge Criteria

- Mild symptoms in patients without any hemodynamic compromise
- Close follow-up
- Able to tolerate a regimen of oral medication
- Debate on need for ECG to evaluate for effusion prior to discharge

Issues for Referral

Follow-up with cardiology:

- Recurrent cases
- Admitted patients

FOLLOW-UP RECOMMENDATIONS

Follow up with primary care physician for re-evaluation and verification of resolution of symptoms and absence of complications in 1–2 wk.

PEARLS AND PITFALLS

- Classic history: Viral illness preceding development of sharp, positional chest pain
- Rub is very specific but not always audible.
- The challenge is distinguishing pericarditis from acute MI and other etiologies of chest pain.
- Mainstay of therapy is NSAIDs.

- I30.9 Acute pericarditis, unspecified
- I31.1 Chronic constrictive pericarditis

PERILUNATE DISLOCATION

Judson J. Merritt • Ian R. Grover

BASICS

DESCRIPTION

- Lunate remains located and in line with the radius but the distal carpal bones are displaced dorsally (~95% of the time) or volarly (~5% of the time)
- Early surgical treatment is recommended.
- This injury has a high incidence of post-traumatic arthritis.

ETIOLOGY

- Mechanism of injury is usually wrist hyperextension with ulnar deviation.
- These are high-energy injuries:
 - Falls from a height
 - Motor vehicle accidents
 - Industrial accidents
 - Sporting accidents

ALERT

Scaphoid is frequently fractured with perilunate dislocations.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Severe wrist pain
- Wrist swelling
- Diffuse wrist tenderness
- Paresthesias in the median nerve distribution

History

- History of a high-energy injury
- Any concomitant injuries
- Pain in the wrist
- May complain of paresthesias in the median nerve distribution

Physical-Exam

- Wrist swelling
- Possible deformity of the wrist
- Decreased range of motion of the wrist
- Possible decreased sensation in the median nerve distribution

- Special attention should be paid to skin integrity because open fractures are common.
- Neurovascular status should be monitored closely, including 2-point discrimination.
- Check closely for concomitant injuries, specifically of the upper extremity.

ALERT

Diagnosis is frequently missed on clinical exam.

ESSENTIAL WORKUP

Radiographs of the wrist

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- Radiographic imaging that includes 3 views of the wrist
- Perilunate dislocation visualized best on the true lateral view:
 - Distal carpal row, specifically the capitate, seen dorsally (95% of the time) or volarly (5% of the time) in relation to the lunate
 - Lunate is located and in line with the radius
- CT and MRI are not generally needed for diagnosis, but some orthopedists may request them for preoperative planning.

Pediatric Considerations

- Wrists are rarely sprained in children.
- Wrist radiographs are difficult to interpret in pediatric patients.
- Comparison view of the other wrist may be helpful.

DIFFERENTIAL DIAGNOSIS

- Lunate fracture
- Lunate dislocation:
 - Dislocation occurs between lunate and distal radius.
- Scapholunate dissociation and other similar ligamentous disruptions
- Distal radius fracture

Pediatric Considerations

Consider nonaccidental trauma.

TREATMENT

ALERT

Concern is for concomitant, more serious, injuries.

PRE HOSPITAL

- Assess for other injuries
- Immobilize
- Pain control
- Elevate

INITIAL STABILIZATION/THERAPY

- Identify other, more serious, associated injuries.
- Immobilize
- Elevate
- Ice

ED TREATMENT/PROCEDURES

- Pain control
- Procedural sedation for closed reduction:
 - Etomidate: 0.1–0.15 mg/kg IV
 - Methohexital: 1–1.5 mg/kg IV
 - Propofol: 40 mg IV every 10 sec until induction
- Closed reduction of the dislocation should be done emergently:
 - Arm is hung in traction for 10 min with 10–15 lb of counterweights and the fingers in traps.
 - The fingers are then removed from the traps and manual traction is continued.
 - One of the physician's thumbs is placed volarly over the lunate and then the injury is recreated with wrist extension.
 - Continued traction is applied to the wrist and then slow flexion of the wrist is performed, which usually locates the distal carpal bones.
- Operative fixation to reduce and maintain wrist stability is required.
- Immobilize wrist using a sugar-tong splint in neutral position. Obtain postreduction radiograph.

Pediatric Considerations

Although perilunate dislocation is unusual in pediatric patients, children with wrist pain should be splinted and referred to a pediatric hand surgeon.

MEDICATION

- Diazepam: 2–5 mg IV q2–4h (peds: Max. dose is 0.25 mg/kg q4h) PRN anxiety
- Fentanyl: 0.05–0.2 mg IV q1h PRN pain
- Hydromorphone: 0.5–1 mg IV q4–6h (peds: 0.015 mg/kg/dose q4–6h) PRN pain
- Lorazepam: 0.5–1 mg IV q1–6h (peds: 0.044 mg/kg q4–6h) PRN anxiety
- Morphine sulfate: 0.1 mg/kg IV q1h PRN pain

FOLLOW-UP

DISPOSITION

Admission Criteria

- Open dislocation, presence of multiple trauma, or other, more serious, injuries
- Inability to reduce dislocation or maintain reduction
- Neurovascular compromise

Discharge Criteria

- Closed injuries
- Adequate reduction
- No neurovascular involvement
- Orthopedic follow-up within 2–3 days

Issues for Referral

All patients with perilunate dislocations should be referred to a hand surgeon for surgical stabilization and ligament repair.

FOLLOW-UP RECOMMENDATIONS

- All patients with a perilunate dislocation must follow-up with a hand surgeon for surgical stabilization and ligament repair.
- Follow-up should be within 2–3 days.

PEARLS AND PITFALLS

- Up to 25% of these injuries are missed on initial presentation.
- In a patient with wrist pain, swelling, and limited range of motion, it is important to obtain adequate x-rays of the wrist and make sure that the lunate and capitate are located in their fossa on the lateral wrist x-ray.
- Late presentation of these injuries leads to a very poor outcome and often requires a salvage operation.
- Complications include median nerve injury, tendon problems, complex regional pain syndrome, wrist instability, and post-traumatic arthritis.
- Even with appropriate treatment, there is a high incidence of post-traumatic arthritis and loss of grip strength.

PERIODIC PARALYSIS

Kyle R. Brown • Jeffrey N. Siegelman

BASICS

DESCRIPTION

- Periodic paralysis (PP): Disorder of muscle metabolism usually inherited that leads to flaccid extremity weakness. Exacerbated by hyperkalemia, hypokalemia, thyrotoxicosis
- Primary: Familial AD mutation skeletal muscle calcium, sodium, or potassium channel
- Secondary: Thyrotoxic, hypokalemia, hyperkalemia

EPIDEMIOLOGY

Incidence and Prevalence Estimates

- Hypokalemic PP (HypoPP):
 - MC, 1:100,000 prevalence
 - 1/3 new AD mutations
- Hyperkalemic PP (HyperPP):
 - 1:200,000 prevalence
 - 90% of people with mutation will have clinical symptoms
- Thyrotoxic PP (ThyroPP):
 - Incidence 2% in patients with thyrotoxicosis
 - Higher in Asians
 - Subset of HypoPP, clinically identical
- Andersen–Tawil:
 - Subset of HypoPP
 - Rare
 - Prevalence unknown

ETIOLOGY

- Mutation of skeletal muscle Na channel gene:
 - SCN4A
 - HypoPP, HyperPP:
 - AD inheritance
 - Spontaneous mutation
- Mutation of skeletal muscle calcium channel gene CACN1A5:
 - HypoPP
- Mutation of KCNJ2 gene:
 - Andersen–Tawil:

- AD inheritance
- 50% spontaneous
- M > F
- Age of onset:
 - HypoPP:
 - 1st or 2nd decade
 - HyperPP:
 - 1st decade
 - Andersen–Tawil:
 - 1st or 2nd decade
 - ThyroPP:
 - 2nd–5th decade

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Intermittent weakness:
 - Can be isolated
 - Rapid onset
 - Common for attacks to recur and for weakness to persist between attacks
 - Frequency from single isolated to daily attacks
- Type of attack:
 - Spontaneous
 - At night or early morning
 - Provoked:
 - History of thyroid disease
 - Recent carbohydrate rich meal
 - Rest after strenuous exercise
 - Illness
 - Lack of sleep
 - Medications: Insulin, epinephrine, corticosteroids, β -agonists, diuretics
 - Cold environment
 - Menstruation
 - Reduced sleep
 - Pregnancy
 - Medications that induce thyroid disease
- Length of attack:
 - HypoPP: 1 hr–days
 - HyperPP: 15 min–4 hr

- ThyroPP: Same as HypoPP
- Andersen–Tawil: Variable
- Family history of episodes of weakness

Physical-Exam

- General:
 - ThyroPP:
 - Hyperthermia
- HEENT:
 - HypoPP and HyperPP:
 - Lid lag: Rare
 - Difficulty swallowing: Rare
 - ThyroPP:
 - Exophthalmos
 - Goiter
 - Andersen–Tawil:
 - Dysmorphic features: Short stature, low set ears, broad based nose, micrognathia
- Cardiac:
 - HypoPP and HyperPP:
 - Dysrhythmias possible
 - ThyroPP:
 - Tachycardia, dysrhythmia
 - Andersen–Tawil:
 - Cardiac dysrhythmia
- Pulmonary:
 - HypoPP:
 - Can affect respiratory muscles, rare
 - Severe hypokalemia
- M/S:
 - HypoPP, HyperPP, ThyroPP:
 - Symmetrical muscle weakness in 1 or more extremity
 - Legs > arms
 - Andersen–Tawil:
 - Periodic flaccid muscle weakness <1 hr
 - Proximal > distal
- Neuro:
 - Alert, conscious
 - Sensation intact
 - DTR reduced or absent
 - Skeletal muscle weakness, symmetrical
 - Sphincter normal
- Skin:

- ThyroPP:
 - o Warm, moist

ESSENTIAL WORKUP

Lab tests and EKG

DIAGNOSIS TESTS & NTERPRETATION

- EKG:
 - HypoPP:
 - o Sinus bradycardia
 - o Flattened T-wave
 - o ST-segment depressions
 - HyperPP:
 - o Rarely peaked T-waves
 - ThryoPP:
 - o Tall P-waves, wide QRS, decreased T-wave, AV block, ventricular fibrillation or asystole
 - Andersen–Tawil:
 - o Long QT, ventricular arrhythmias
 - o U-waves, prolonged T-wave downslope
 - o Differentiates Andersen syndrome from other long QT syndromes
- Electrolytes:
 - Potassium:
 - o HyperPP: Normal or increased
 - o HypoPP: Normal or decreased
 - o ThryoPP: Decreased during attacks
 - o Andersen–Tawil: Decreased, normal, or increased
 - Calcium:
 - o ThryoPP: Decreased during attacks
 - Phosphorus:
 - o ThryoPP: Decreased during attacks
- Thyroid Studies:
 - ThryoPP:
 - o TSH: Low
 - o T4: Elevated

Imaging

Not necessary for diagnosis

Diagnostic Procedures/Surgery

None in ED but specialists may consider the following:

- EMG:
 - HypoPP:

- No myotonia
- HyperPP:
 - Myotonia
- Andersen–Tawil
- Muscle biopsy
- Provocative testing:
 - HyperPP:
 - Potassium and epinephrine
 - HypoPP:
 - Insulin and glucose

DIFFERENTIAL DIAGNOSIS

Other causes of hypokalemia or hyperkalemia

- Hyperkalemia:
 - Drugs: Spironolactone, ACE inhibitors, NSAIDs, heparin
 - Hereditary: 21-hydroxylase deficiency, McArdle disease
 - GI:
 - Ileostomy with tight stoma
 - Renal:
 - Chronic renal failure
 - Endocrine:
 - Addison disease
- Hypokalemia:
 - Drugs:
 - Tocolytics, amphotericin B, diuretics, reduced potassium intake, malignant hyperthermia
 - GI:
 - Vomiting
 - Celiac and tropical sprue
 - Short bowel syndrome
 - Renal:
 - Conn syndrome
 - Bartter/Gitelman syndrome
 - Acute tubular necrosis
 - Renal tubular acidosis
 - Neuromuscular:
 - Andersen—Tawil
 - Myasthenia gravis
 - Endocrine:
 - Thyrotoxicosis
 - Hyperaldosteronism
 - DKA

TREATMENT

PRE HOSPITAL

- Supportive:
 - ABC, IV, O₂, monitor

INITIAL STABILIZATION/THERAPY

- Supportive care
- HyperPP:
 - Many attacks brief and do not need treatment
 - IV calcium gluconate may end attack
- HypoPP:
 - Potassium:
 - Preferred: Oral potassium 40 mEq
 - IV potassium 10 mEq 1 or 2 doses only
 - Watch for overcorrection
 - IV hydration can help correct potassium
- Andersen–Tawil:
 - Potassium unpredictable:
 - Could be helpful in hypokalemia
- ThyroPP:
 - Treat thyroid abnormalities:
 - Tachycardia: Nonselective β -blocker
 - Treat underlying abnormalities:
 - Same as in HypoPP
 - See the section on thyrotoxicosis

ALERT

HypoPP should avoid volatile anesthetics and depolarizing muscle relaxants which can cause an attack or malignant hyperthermia

FOLLOW-UP

DISPOSITION

- HypoPP or HyperPP:
 - Lifestyle modifications:
 - Avoid triggers: Ethanol, prolonged exercise, high potassium foods, fasting
- ThyroPP:
 - Depends on severity of underlying disease, if asymptomatic and controlled may consider discharge with consultation with neurologist and endocrinologist.

Admission Criteria

- HypoPP or HyperPP:
 - Consider if severe hypo- or hyperkalemia, still symptomatic, cardiac or respiratory compromise
- Andersen–Tawil:
 - Admit, risk of sudden cardiac death high

Discharge Criteria

- HypoPP, HyperPP, ThyroPP:
 - Resolved symptoms, referral to neurologist, no cardiac or respiratory compromise

Issues for Referral

- Neurology
- Endocrinology for ThyroPP
- Genetic counseling:
 - 50% risk of inheriting primary PP

FOLLOW-UP RECOMMENDATIONS

- Neurology specialist in metabolic myopathies
- Geneticist

PEARLS AND PITFALLS

- Admit Andersen–Tawil patients and all PP patients who remain symptomatic.
- Use caution with volatile anesthetics and depolarizing muscle relaxants in patients with all forms of PP

ICD10

G72.3 Periodic paralysis

PERIODONTAL ABSCESS

John E. Sullivan

BASICS

DESCRIPTION

- Collection of pus in supporting structures of teeth:
 - Periodontal ligament
 - Alveolar bone
- Periodontal pockets result from progression of periodontal disease and resultant bone loss:
 - Food and debris accumulate in periodontal pockets
 - Coronal epithelial tissues can reattach to tooth while bacteria and food debris remain trapped in pocket, impairing drainage
 - Food and debris become secondarily infected in the setting of impaired drainage
- Complications:
 - Osteomyelitis
 - Dentocutaneous fistula
 - Cavernous sinus thrombosis
 - Ludwig angina
 - Maxillary sinusitis
 - Mediastinitis
 - Tooth loss
 - Sepsis

Pediatric Considerations

- Periodontal abscess is rare in children
- Periapical abscess is more common:
 - Originates in pulp
 - Associated with caries

ETIOLOGY

- Anaerobic gram-negative rods
- Peptostreptococci
- Viridans group streptococci
- Neisseria species
- Usually polymicrobial

DIAGNOSIS

SIGNS AND SYMPTOMS

Periodontal abscess is a clinical diagnosis

History

- Dental pain
- Malaise
- Fever
- Facial swelling

Physical-Exam

- Focal swelling or fluctuance of gums and or face
- Tenderness to palpation
- Increased tooth mobility
- Parulis:
 - _ Pimple-like lesion on gingiva, representing terminal aspect of a sinus tract
 - _ May be seen in chronic abscess
- Expression of pus from sinus tract
- Heat sensitivity
- Lymphadenopathy
- Trismus is generally absent, unless infection has spread to muscles of mastication

ESSENTIAL WORKUP

This is a clinical diagnosis:

- Imaging and lab data are not essential for diagnosis

DIAGNOSIS TESTS & NTERPRETATION

Lab

Anaerobic culture of pus:

- Complicated abscess
- Immunocompromised patients

Imaging

- Panoramic, periapical, or occlusal radiographs
- Bedside US may also aid in confirming diagnosis
- CT may help visualize extension of abscess into adjacent structures
- Imaging can confirm and help define extent of abscess but is not essential to make diagnosis

Diagnostic Procedures/Surgery

Electric pulp testing:

- Performed by dental consultant to verify viability of tooth

- Performed during follow-up visit with dentist

DIFFERENTIAL DIAGNOSIS

- Periapical abscess
- Maxillary sinusitis
- Aphthous ulcers
- Oral herpes
- Salivary gland tumors
- Mumps
- Blocked salivary gland due to sialadenitis or dehydration
- Localized adenopathy due to oral infections
- Facial cellulitis
- Acute otitis media
- Peritonsillar abscess
- Pediatric consideration: Periapical abscess
- For asymptomatic parulis:
 - Fibroma
 - Pyogenic or peripheral ossifying granuloma
 - Kaposi sarcoma

TREATMENT

PRE HOSPITAL

Rarely associated with airway emergencies, but if any signs of airway compromise are present:

- Intubation equipment at bedside
- Transport in sitting position
- Supplemental oxygen
- Suction secretions as needed

INITIAL STABILIZATION/THERAPY

- Assess for airway patency
- Establish definitive airway via endotracheal intubation or cricothyrotomy/tracheostomy in the presence of:
 - Respiratory distress
 - Inability to handle secretions
 - Oropharyngeal tissue swelling that impairs or threatens airway

ED TREATMENT/PROCEDURES

- Analgesia with NSAIDs or opiates may be required
- Incision and drainage:
 - Anesthetize gingiva superficially with 2% lidocaine with 1:100,000 epinephrine until blanching occurs

- Make a 1 cm stab incision using a scalpel blade toward alveolar bone
- Blunt dissection using mosquito hemostat
- Irrigate cavity with saline
- If abscess cavity sufficiently large, place 1/4 in iodoform gauze drain or fenestrated Penrose drain for 24–48 hr:
 - To prevent its aspiration, secure gauze or drain with silk suture
- Antibiotics:
 - Indicated if abscess extensive or if systemic signs present
 - Penicillin considered first-line empiric therapy
 - Erythromycin, azithromycin, clindamycin for penicillin-allergic patients
 - Clindamycin for penicillin-allergic patients or patients not responding to penicillin
 - Ampicillin/sulbactam for severe infections
- Warm salt water rinses hourly while awake for 24–48 hr

MEDICATION

First Line

- Penicillin VK: 250–500 mg PO q6h (peds: 25–50 mg/kg/d PO div. q6h)
- Azithromycin: 500 mg (peds: 10 mg/kg) PO 1st day, then 250 mg (peds: 5 mg/kg) PO per day × 4 days (for penicillin-allergic patients)
- Clindamycin: 150–450 mg PO q6h (peds: 10–25 mg/kg/d div. PO q6h)
- Clindamycin: 300–900 mg IV q8h (peds: 15–25 mg/kg/d IV div. q8h)
- Erythromycin: 250–500 mg PO q6–8h (peds: 30–50 mg/d PO div. q6h)

Second Line

- Ampicillin/sulbactam IV: 1.5–3 g IV q6h (peds > 1 yr, < 40 kg: 300 mg/kg/d IV div. q6h)
- Amoxicillin/clavulanate: 875 mg PO q12h (peds: 25–45 mg/kg/d div. q12h) (oral conversion)
- Moxifloxacin: 400 mg PO or IV QD (not routinely recommended for pediatric use)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Severe infection or complication requiring parenteral antibiotics
- Necrosis or cellulitis involving areas with potential airway compromise
- Cavernous sinus thrombosis
- Osteomyelitis
- Outpatient therapy failure

- Immunocompromised patients:
 - Neutropenia
 - Uncontrolled diabetes
 - Advanced HIV
 - Cancer patients undergoing chemotherapy
- Ludwig angina
- Systemic involvement with significant dehydration
- Patients unable to handle secretions
- Patients unable to manage infection at home because of physical or mental disability or psychosocial factors

Discharge Criteria

- Uncomplicated cases
- Dental follow-up available in 24–48 hr

Issues for Referral

Dental follow-up useful for:

- Viability of affected tooth
- Dental extraction
- Root canal therapy
- Removal of Penrose drain or wic

FOLLOW-UP RECOMMENDATIONS

Dental follow-up in 24–48 hr:

- Lacking dental follow-up, patients should have alternative follow-up in 24–48 hr with provider familiar with disease process (oral surgeon, ED, urgent care, primary care)

PEARLS AND PITFALLS

Maxillary sinusitis may be incorrectly diagnosed without adequate oral exam:

- Dental follow-up is essential for short-term resolution of symptoms and long-term tooth viability and oral hygiene issues

- K04.7 Periapical abscess without sinus
- K05.21 Aggressive periodontitis, localized

PERIORBITAL AND ORBITAL CELLULITIS

Shari Schabowski

BASICS

DESCRIPTION

Periorbital Cellulitis

- An inflammatory, typically infectious condition affecting the eyelid(s)
- It is anatomically distinguished by its location, isolated to the tissues anterior to the orbital septum:
 - Orbital septum is the connective tissue extension of the orbital periosteum that is reflected into the upper and lower eyelids
 - Extension to the deep tissues is rare because the septum represents a nearly impenetrable barrier but it may be incomplete
- Most commonly presents as a complication of upper respiratory tract infection (URTI) and sinusitis:
 - Swelling is caused by inflammatory edema from vascular and lymphatic congestion
- May occur as a complication of a localized inflammation/infection in the eyelid or adjacent structures:
 - Blepharitis
 - Hordeolum
 - Dacryocystitis
 - Surrounding skin disruptions:
- Insect bites
- Minor trauma
- Impetigo or other dermatologic disorders

Orbital Cellulitis

- Inflammatory process in the structures deep to the orbital septum
- Typically occurs secondary to extension from an adjacent structure:
 - Sinusitis:
 - Most commonly ethmoiditis penetrating through the thin lamina papyracea
 - Dental abscess
 - Retained foreign body in the orbit
 - Puncture wounds
 - Orbital fracture
 - Postoperative infection
 - Hematogenous spread from a remote source due to valveless orbital veins

- Rare cause—direct extension of periorbital cellulitis

ETIOLOGY

Periorbital Cellulitis

- *Streptococcus pneumoniae*
- *Staphylococcus aureus*
- *Streptococcus pyogenes*
- *Moraxella catarrhalis*
- *Haemophilus influenzae*
- *Gonococcus* – rare
- Consider nonbacterial cause

Orbital Cellulitis

- Currently streptococcal and staphylococcal infections are the most common causes:
 - *S. pneumoniae*, *Streptococcus viridans*, *S. pyogenes*, *Streptococcus anginosus*, *S. aureus*
 - Anaerobes, Bacteroides, and gram-negatives may also be seen
- All forms of orbital cellulitis carry a risk of severe morbidity and possible mortality and are therefore a true emergency:
 - Permanent visual loss may occur
 - May extend to subperiosteal space with abscess formation
 - Cavernous sinus thrombosis and CNS infections may be life threatening
- Fungal infections are an uncommon but an even more lethal form particularly in the immunocompromised:
 - Cerebrorhino-orbital phycomycosis (CROP)
 - Rapidly fatal in 75% of cases:
 - 80% of cases occur in patients with a recent episode of diabetic ketoacidosis
 - Predisposing factor: Severe metabolic acidosis and immunocompromise
 - Begins in the paranasal sinuses and proliferates in the blood vessels causing thrombosis and necrosis
 - Bloody nasal discharge is common
 - May present with evidence of necrosis of the palate and/or nasal mucosa

Pediatric Considerations

- Routine vaccinations including Hib and Pneumococcus have dramatically decreased periorbital and orbital cellulitis, but infections may still occur with these organisms particularly in younger children and those without at least 2 Hib vaccines

- Periorbital cellulitis is overall 5 times more common and typically occurs in children <5 yr whereas orbital cellulitis is more common in children over 5 yr

DIAGNOSIS

SIGNS AND SYMPTOMS

Periorbital Cellulitis/Orbital Cellulitis

- Both present with a unilateral, red, swollen eye:
 - Lid swelling may be profound in both
- Differences include:
 - Source of inciting infection
 - Single vs. both lids involved
 - Toxicity, systemic and neurologic symptoms

Orbital Cellulitis

History

- Preceded by sinusitis in 60–90%, dental infection, trauma, puncture wound, or recent operation
- Swelling and redness surrounding eye in addition to eye pain, visual impairment, loss of color vision, restricted eye movements
- Headache, meningismus, and symptoms of systemic illness may occur
- Identify complicating medical problems:
 - Immunocompromise
 - Diabetes

Physical-Exam

- Toxic appearance:
 - Fever >39°C
- Restricted, painful extraocular movements (EOM)
- Afferent pupillary defect
- Conjunctival injection
- Chemosis
- Decreased visual acuity
- Diplopia
- Proptosis
- Meningismus and neurologic findings may be seen.

Periorbital Cellulitis

History

- Preceded by local skin injury, insect bite, URTI, or superficial ocular infection
- Ask about vaccination status in young children
- Low-grade fever
- Subacute presentation

Physical-Exam

- Red, swollen eyelid
- Often single lid involvement but can involve both
- Conjunctival injection common
- Low-grade fever common:
 - Rare systemic symptoms
- Normal visual acuity
 - No symptoms of deep ocular involvement

ESSENTIAL WORKUP

- Complete eye exam:
 - External exam
 - Visual acuity
 - EOM
 - Pupillary exam
 - Fundoscopic exam
 - Intraocular pressure measurement
- Complete neurologic exam

DIAGNOSIS TESTS & INTERPRETATION

Lab

Supportive but not diagnostic:

- CBC:
 - WBC < 15,000 for periorbital cellulitis
 - WBC > 15,000 may suggest bacteremic periorbital cellulitis or orbital cellulitis
- Blood culture
- Gram stain and culture of tissue aspirate or swab of draining purulent material:
 - Chocolate agar plate when gonorrhea suspected

Imaging

CT scan orbits with contrast:

- Indicated if:
 - CNS or systemic signs
 - Visual disturbances
 - Proptosis; restricted or painful EOM
 - Ophthalmoplegia

- Bilateral edema
- No improvement or deterioration at 24 hr
- Demonstrates extent of:
 - Orbital cellulitis
 - Sinusitis
 - Orbital emphysema
 - Subperiosteal abscess
 - Presence of foreign body
 - Cavernous sinus thrombosis

Diagnostic Procedures/Surgery

Lumbar puncture:

- Rule out CNS involvement in patients who appear toxic or manifest meningismus
- Surgery:
 - Evacuate abscess
 - Relieve sinusitis
 - Decompress optic nerve

DIFFERENTIAL DIAGNOSIS

- Allergic reaction
- Dacryoadenitis
- Dacryocystitis
- Graves disease
- Hordeolum
- Inflammatory orbital pseudotumor
- Insect bite
- Orbital rhabdosarcoma
- Periorbital ecchymosis
- Retrobulbar hemorrhage

TREATMENT

INITIAL STABILIZATION/THERAPY

IV fluids for vomiting, dehydration, toxic appearance, clinical need for parenteral antibiotics

ED TREATMENT/PROCEDURES

- Antipyretics
- Pain medication as needed
- Antibiotics

Periorbital Cellulitis

- Typically responds to oral antibiotics unless appears bacteremic or toxic:
 - Augmentin: 500 mg (peds: 45 mg/kg/24 h) PO TID
 - Cephalexin: 500 mg (peds: 100 mg/kg/24 h) PO QID
 - Clindamycin: 300 mg (peds: 20 mg/kg/24 h) PO QID
 - Dicloxacillin: 500 mg (peds: 100 mg/kg/24 h) PO QID
- Parenteral antibiotics:
 - Cefotaxime: 1–2 g (peds: 150 mg/kg/24 h) IV q6–8h
 - Clindamycin: 600 mg (peds: 40 mg/kg/24 h) IV q6h

Orbital Cellulitis

- Early administration of parenteral antibiotics
- Ophthalmologic consultation for any intraocular manifestations
- If sinusitis is the source, consider ENT consultation, and add decongestants to the treatment
- Emergent surgical intervention may be necessary:
 - If *Bacteroides* is suspected organism:
 - Surgical débridement
 - Vancomycin
 - Tetanus toxoid when appropriate
- If proptosis leaves the cornea exposed:
 - Lubricating drops (Lacri-Lube: 2 drops q2–4h PRN)
- If you suspect CROP:
 - Amphotericin B IV at highest tolerated dose
 - Topical amphotericin B (1 mg/mL) irrigation or nasal packing
 - Local debridement

MEDICATION

First Line

- Ceftriaxone: 1–2 g (peds: 100 mg/kg/24 h) IV q12–24h
- Erythromycin ophthalmologic ointment: Applied q4h to lower cul-de-sac

Second Line

Depending on suspected organism:

- Gentamicin: 5 mg/kg/24 h IV
- Metronidazole: 15 mg/kg IV load, then 7.5 mg/kg q6h
- Nafcillin: 1–2 g (peds: 100 mg/kg/24 h) IV q4h
- Vancomycin: 1 g (peds: 40 mg/kg/24 h) q12h

FOLLOW-UP

DISPOSITION

Periorbital Cellulitis

Discharge with oral antibiotics and prompt follow-up unless:

- Evidence of systemic toxicity, neurologic, visual or orbital findings
- Unable to tolerate PO antibiotics
- Progression of infection on oral antibiotics
- Unable to arrange follow up within 24–48 hr
- High-risk *H. influenzae* type B
- Complicating medical problems

Orbital Cellulitis

Admit for:

- IV antibiotics
- Observation for progression
- Specialist consultation
- Surgical incision and drainage

PEARLS AND PITFALLS

- Anytime a patient presents with a red swollen eye, consider the possibility of orbital cellulitis
- Take a careful history for:
 - _ Recent sinusitis
 - _ Recent puncture, history of trauma or surgical procedure
 - _ Recent dental infection—particularly a canine space abscess
 - _ History of immunocompromise or recent or current episode of DKA
 - _ Determine vaccination status in children
- Pay careful attention to exclude:
 - _ Systemic toxicity
 - _ Eye pain or visual impairment
 - _ Restriction of eye movements
 - _ Signs and symptoms of neurologic involvement

PERIPHERAL NEUROPATHY

Minh V. Le

BASICS

DESCRIPTION

Peripheral neuropathy is a general term for peripheral nerve disorders that may affect motor, sensory, or vasomotor nerve fibers and presents with marked muscle weakness, atrophy pain and numbness

ETIOLOGY

Variable, depending on presentation of symptoms; refer to Differential Diagnosis

DIAGNOSIS

SIGNS AND SYMPTOMS

- Sensory nerve dysfunction:
 - Numbness
 - Localized tingling
 - Paresthesias
 - Dysesthesias
 - Vibration and position sensations are decreased with large-fiber neuropathy
 - Pain and temperature sensation are decreased with small-fiber neuropathy
 - Deep tendon reflexes are decreased secondary to decreased sensation of afferent limb
- Motor nerve dysfunction:
 - Weakness:
 - Distal > proximal
 - Occasionally fasciculations
 - Muscle atrophy, diminished tone with long-standing motor nerve involvement
 - Loss of reflexes secondary to slowing of conduction along motor nerve efferent limb
- Autonomic nerve dysfunction:
 - Orthostasis
 - Constipation
 - Urinary retention
 - Impotence

History

- Duration of symptoms

- Symmetric or asymmetric symptoms
- Distal or proximal symptoms
- Motor, sensory, or mixed

Physical-Exam

- Thorough head-to-toe physical exam
- Focus on neurologic exam:
 - Motor weakness
 - Sensory loss typically in stocking-glove distribution

ALERT

Absence of reflexes early in course could represent demyelinating neuropathy such as Guillain–Barré syndrome (acute inflammatory demyelinating syndrome [AIDP]).

ESSENTIAL WORKUP

- Studies based on acuteness, severity of neuropathy, and most likely diagnosis
- Neurologic consult early if acute and severe symptoms

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Basic metabolic panel
- CBC
- Liver function tests
- Urinalysis
- Thyrotropin-stimulating hormone
- HIV or vitamin B₁₂ based on individual presentations
- Electrocardiogram

Imaging

- CXR if indicated
- Head CT if indicated

Diagnostic Procedures/Surgery

- Electromyographic studies, nerve conduction studies, and nerve biopsy per neurologic consult on admission or outpatient follow-up
- Lumbar puncture as appropriate for AIDP

DIFFERENTIAL DIAGNOSIS

- Focal:
 - Entrapment
 - Common sites of compression:
 - Carpal, ulnar tunnel

- Tarsal tunnel
 - Peroneal
- Myxedema
- Rheumatoid arthritis
- Amyloidosis
- Acromegaly
- Trauma
- Ischemic lesions
- Diabetes mellitus (DM)
- Vasculitis
- Leprosy
- Sarcoidosis
- Neoplastic infiltration or compression
- Multifocal (mononeuropathy multiplex):
 - DM
 - Vasculitis:
 - Polyarteritis nodosa
 - Systemic lupus erythematosus
 - Sjögren syndrome
 - Sarcoidosis
 - Leprosy
 - Malignancy related
 - HIV/AIDS
 - Hereditary predisposition to pressure palsies
- Symmetric:
 - Endocrine:
 - Most common is DM
 - Hypothyroidism
 - Medications:
 - Isoniazid
 - Lithium
 - Metronidazole
 - Phenytoin
 - Cimetidine
 - Hydralazine
 - Amitriptyline
 - Amiodarone
 - Nutritional diseases:
 - Alcoholism
 - B₁₂/folate deficiency
 - Thiamine
 - Critical illness neuropathy

- Hypophosphatemia
- Guillain-Barré syndrome (AIDP)
- Toxic neuropathy:
 - Carbon monoxide
 - Acrylamide
 - Carbon disulfide
 - Ethylene oxide
 - Organophosphate esters
 - Lead
- Myelopathy mimicking peripheral neuropathy
- Back pain
- Saddle anesthesia
- Lower extremity weakness

TREATMENT

PRE HOSPITAL

- Pain control as needed
- Airway protection as indicated

INITIAL STABILIZATION/THERAPY

Establish airway protection with severe acute peripheral neuropathy, such as Guillain-Barré syndrome

ED TREATMENT/PROCEDURES

- Variable depending on acuity of symptoms
- Discontinuation offending toxin or agent
- Treatment underlying systemic disease

MEDICATION

- Variable depending on underlying diagnosis
- Opioid analgesics
- Gabapentin 300 mg PO daily then BID on day 2, then TID on day 3 up to 1,800 mg/d div. TID
- Carbamazepine 100 mg PO BID for trigeminal neuralgia
- IV immunoglobulin for Guillain-Barré syndrome (AIDP)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Respiratory distress or acute gait disturbance
- Intractable pain

Discharge Criteria

Stable respiratory and gait status with outpatient follow-up

Issues for Referral

Neurology—based on duration, severity of presentation

FOLLOW-UP RECOMMENDATIONS

Primary care or neurology depending on etiology and severity of symptoms

PEARLS AND PITFALLS

Failure to diagnose Guillain–Barré syndrome (AIDP)

- R20.0 Anesthesia of skin
- R20.2 Paresthesia of skin

PERIPHERAL VASCULAR DISEASE

Sally A. Santen • Samantha R. Hauff

BASICS

DESCRIPTION

- Obstruction of ≥ 1 of the peripheral arteries secondary to embolism or thrombus
- Caused by atherosclerosis or embolus
- Patients with PAD may also have coronary artery and cerebrovascular disease.
- Epidemiology:
 - Risks factors (selected):
 - Age
 - Smoking
 - Diabetes
 - Hyperlipidemia
 - HTN
 - Associated with morbidity and mortality from other forms of atherosclerosis (coronary artery disease, stroke)
 - Complications:
 - Aneurysm
 - Thrombosis
 - Ulceration
 - Limb loss
- Chronic arterial insufficiency (CAI):
 - Progressive obstructing atherosclerotic disease causing subacute ischemia and pain (claudication)
 - 10% develop critical leg ischemia.
- Acute arterial insufficiency (AAI):
 - Caused by arterial thrombosis (50%) or embolism
 - Causes acute limb ischemia with signs and symptoms of the 6 Ps (below)
- Atheroembolism:
 - Caused by rupture or partial disruption of an atherosclerotic plaque (aorta, femoral, iliac)
 - Gives rise to cholesterol emboli that shower and obstruct arteriolar networks
 - May be precipitated by invasive arterial procedures such as cardiac catheterization

ETIOLOGY

- Obstruction by atherosclerotic plaques (CAI)
- Arterial thrombosis
- Arterial emboli:

- Cardiac emboli from dysrhythmias, valvular heart disease, or cardiomyopathy (80%)
- Aneurysms
- Infection
- Tumor
- Vasculitis or foreign body
- Thrombosis of plaques from pre-existing CAI
- Atheroembolism

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- CAI:
 - Claudication:
 - Aching pain in the calves (femoropopliteal occlusion) or buttocks and thighs (aortoiliac region)
 - Occurs with activity and slowly relieved by rest or dependent positioning
 - Classic claudication presents in about 1/2 of patients with PVD.
 - Severe disease presents with limb pain at rest:
 - Usually starting in the foot
 - Rapidly progressive claudication or ulceration
- AAI:
 - Extremity pain:
 - Sudden onset
 - Gradual increase in severity
 - Starts distally and moves proximally over time
 - Decrease in intensity once ischemic sensory loss occurs
- Atheroembolism:
 - Complaint of cold and painful fingers or toes
 - Small atherosclerotic emboli may affect both extremities.
 - Usually related to recent arteriography, vascular or cardiac surgery
 - Multiorgan involvement is common (renal, mesentery, skin, others)

Physical-Exam

ALERT

Sudden onset of pain and pallor in extremity is limb and life threatening.

- CAI:
 - Absent or decreased peripheral pulses

- Delayed capillary refill with cool skin
- Increased venous filling time
- Bruits
- Pallor and dependent rubor of the leg
- Muscle and skin atrophy
- Thickened nails and loss of dorsal hair
- Ulcerations (especially toes or heels) or gangrene with severe disease
- AAI:
 - 6 Ps:
 - Pain (1st, sometimes only symptom)
 - Pallor
 - Pulselessness
 - Poikilothermic
 - Paresthesias (late finding)
 - Paralysis (late finding)
 - Identification of a source of a possible embolic process is crucial (atrial fibrillation, cardiomegaly).
- Atheroembolism:
 - Ischemic and painful digits
 - “Blue toe syndrome”
 - Livedo reticularis

ESSENTIAL WORKUP

- CAI:
 - Ankle–brachial index (ankle systolic BP divided by higher arm systolic BP)
 - Bedside test to determine whether CAI is present (see NEJM video reference)
 - Ratio of <0.9 is abnormal and $<0.4-5$ indicates severe disease.
 - Calcific arteries (diabetes) can have false negative ABI or elevated ABI (>1.3).
- AAI:
 - Physical diagnosis using the 6 Ps
 - Those with acute-on-chronic arterial insufficiency tolerate limb ischemia better than those without CAI, due to well-developed collateral circulation.
- Atheroembolism:
 - Clinical diagnosis: Affected areas painful, tender, and may be either dusky or necrotic
 - Workup may investigate source of emboli with duplex US, CT angiogram, EKG.

DIAGNOSIS TESTS & NTERPRETATION

Lab

- CBC and platelets

- Electrolytes, BUN, creatinine, glucose
- Coagulation studies
- Creatine phosphokinase to evaluate for ischemia.
- Special tests for suspected etiologies:
 - Hold blood for hypercoagulable studies
 - Sedimentation rate, CRP for vasculitis
 - Blood cultures for endocarditis

Imaging

- Doppler US:
 - Visualizes both venous and arterial systems
 - Identifies level of arterial occlusion, as well as thrombosis and aneurysm
 - Sensitivity and specificity > 80–90% for occlusion of vessels proximal to the popliteal vessels
- Plethysmography/segmental pressure measurements:
 - Uses measurements of the volume and character of blood flow to detect areas of CAI
 - Less widely available than US, therefore requires an experienced technician
 - Approximates US in sensitivity and specificity
- Angiography:
 - Determines details about the anatomy, including the level of occlusion, stenosis, and collateral flow
 - Useful where the diagnosis of AAI is uncertain or before emergent bypass grafting
 - Advantage is intervention (atherectomy, angioplasty, or intraluminal thrombolytics) can be done at the time of diagnosis.
- CT angiogram:
 - CT is useful for diagnosis of occlusive aortic disease or dissection.
 - Rapidly available and reliable
 - Many centers have moved to CT angiogram as the 1st-line diagnostic tool. The decision for operative or angiographic intervention is based on the CT angiogram.
 - Requires contrast, therefore may not be 1st line for patients with renal insufficiency
- MRI:
 - Sensitive for evaluation of CAI and dissection
 - Disadvantages are that MRI is time consuming and expensive.

DIFFERENTIAL DIAGNOSIS

- Acute thrombosis or emboli
- Arterial dissection
- Deep venous thrombosis
- Venous insufficiency

- Compartment syndrome
- Buerger disease
- Spinal stenosis
- Neuropathy
- Bursitis
- Arthritis
- Reflex sympathetic dystrophy

TREATMENT

PRE HOSPITAL

- Maintain hemodynamic stability with fluids.
- Apply cardiac monitor.
- Place the ischemic limb at rest and in a dependent position.
- Provide oxygen if low oxygen saturation or pulmonary symptoms.

INITIAL STABILIZATION/THERAPY

- IV fluid bolus for hypotension
- EKG, monitor, pulse oximetry
- Supplemental oxygen
- Pain control
- Avoid temperature extremes

ED TREATMENT/PROCEDURES

- CAI:
 - Antiplatelet therapy with 75 or 325 mg of aspirin or clopidogrel (75 mg/day) may be used as 1st-line treatment. Dual therapy has not been shown to improve outcomes, although may be indicated in other forms of atherosclerosis.
 - Other approved drugs include: Cilostazol 100 mg BID, dipyridamole 200 mg BID, pentoxifylline 400 mg TID
 - Revascularization depending on the severity and location of obstruction:
 - Balloon angioplasty
 - Atherectomy
 - Bypass grafting
 - Risk-factor modification:
 - Tobacco cessation
 - Aggressive management of hyperlipidemia, HTN, diabetes
 - Exercise therapy
- AAI:
 - Limit further clot propagation with IV heparin.
 - Do not anticoagulate patients suspected of having an aortic dissection or

symptomatic aneurysm.

- Emergent consultation with vascular surgery or interventional radiology:
 - To determine which diagnostic study is best to make the diagnosis
 - To begin arrangements for possible operative therapy or other intervention
 - Options for operative therapy include thrombectomy, embolectomy, angioplasty, regional arterial thrombolysis, bypass grafting.
 - Blood flow to the affected limb must be re-established within 4–6 hr after onset of ischemic symptoms.
- Complications of AAI include:
 - Compartment syndrome
 - Irreversible ischemia requiring amputation
 - Rhabdomyolysis, renal failure
 - Electrolyte disturbances
- Atheroembolism:
 - Treat conservatively if a limited amount of tissue is involved and renal function is not significantly compromised.
 - No clear therapy for the ischemic digits besides supportive wound care and analgesia
 - Some studies have tried corticosteroids to decrease inflammation, statins to stabilize plaque, aspirin, or dipyridamole
 - Amputation for irreversibly necrotic toes
 - Vascular surgeon referral within 12–24 hr of ED visit
 - Prevent further embolic events by a thorough investigation and correction of the source of atheroemboli.

MEDICATION

- Aspirin: 81–325 mg/d
- Cilostazol: 100 mg BID
- Clopidogrel: 75 mg/d
- Heparin: 80 U/kg bolus IV followed by 18 U/h IV
- Pentoxifylline: 400 mg TID

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with AAI are admitted for evaluation and revascularization.
- CAI: Consider admission for rapidly progressive claudication or ischemic pain at rest:
 - To undergo heparinization and angiography to rule out an acute thrombosis

- Atheroembolism admission indicated with large areas involved, significant pain, infection, or renal compromise

Discharge Criteria

- Atheroembolism:
 - If they have small lesions, adequate pain control, no evidence of renal compromise or superinfection, and follow-up within 24 hr
- CAI:
 - No evidence of rapid progression, critical leg ischemia, gangrene, or infection

Issues for Referral

- CAI will need urgent referral to vascular surgery.
- Atheroembolism, depending on the origin of the emboli, may need referral to vascular surgery or to cardiology.

FOLLOW-UP RECOMMENDATIONS

CAI without acute ischemia and atheroembolism with minimal involvement should have close follow-up to evaluate the extent of their disease.

PERIRECTAL ABSCESS

James A. Nelson • Scott A. Miller

BASICS

DESCRIPTION

Localized infection and accumulation of purulent material adjacent to anus or rectum

ETIOLOGY

- Anal crypt gland infection, with spread to adjacent areas separated by muscle and fascia:
 - Perianal:
 - Most common
 - Usually with red bulge near anus
 - Ischiorectal:
 - Large potential space
 - May become very large before diagnosed
 - Can communicate posteriorly with other side forming “horseshoe” abscess
 - Intersphincteric:
 - Contained at primary site of origin between internal and external sphincters
 - Supralelevator:
 - Very deep above levator ani
 - Needs operative débridement under general anesthesia
 - Often systemic symptoms before diagnosis is made
- Bacterial cause is typically a mix of stool pathogens:
- Associated diseases:
 - Diabetes
 - Inflammatory bowel disease
 - Malignancy
 - Immunocompromised host

DIAGNOSIS

SIGNS AND SYMPTOMS

- Pain: Perianal, rectal, or pelvic
- Swelling, fluctuance, drainage, fever

History

- Perianal pain:

- Aggravated by defecation, sitting, coughing
- Dull deep pelvic or rectal pain:
 - Less pain if arises above dentate line (ischioanal and supralevator)
- Rectal or perirectal drainage
- Fever/chills
- Constipation

Physical-Exam

- Perianal swelling, erythema, induration, fluctuance, tenderness
- Inner cleft buttock abscess = red flag
 - Rectal abscess can track out to buttock
- Rectal exam is the most important diagnostic intervention
 - Rectal swelling or tenderness
 - Fistula can be probed, or palpated as a cord

ESSENTIAL WORKUP

- Careful history and physical exam with rectal exam are paramount in making diagnosis.
- Have high index of suspicion for any constant perirectal pain.

DIAGNOSIS TESTS & INTERPRETATION

No labs or imaging routinely indicated

Lab

- CBC: Leukocytosis with left shift
- Wound culture: Not typically indicated
- Blood cultures: Mainly for sepsis

Imaging

- CT (with IV contrast, +/- PO contrast)
- MRI (helpful with detecting fistulas)
- Endoanal US sometimes used

Diagnostic Procedures/Surgery

Incision and drainage (I&D) is the definitive management.

DIFFERENTIAL DIAGNOSIS

- Anal fissure
- Sentinel pile in the posterior midline or anterior midline
- Thrombosed or inflamed hemorrhoids
- Anal ulcer (i.e., HIV)
- Proctitis (i.e., gonococcal)
- Anorectal carcinoma

TREATMENT

INITIAL STABILIZATION/THERAPY

Pain medication

ED TREATMENT/PROCEDURES

- Delayed drainage may worsen outcome
- Bedside drainage:
 - Only if localized perianal abscess
 - Probe to rule out deeper tract
 - Radial incision close to anal verge
 - Explore cavity, breaking any loculations.
 - Irrigate liberally.
 - Loose packing removed at 48 hr.
- Operative debridement under general anesthesia:
 - If local anesthesia is inadequate, or deeper abscess
- Antibiotics rarely necessary:
 - Extensive cellulitis
 - Immunosuppression
 - Valvular heart disease
 - Systemic infection
 - Prosthetic device
 - PO:
 - Amoxicillin clavulanate or fluoroquinolone
 - Consider MRSA coverage
 - IV:
 - Cefoxitin
 - Ampicillin sulbactam
 - Combination therapy with ampicillin, gentamicin, and clindamycin or metronidazole
- Postoperative care:
 - Sitz baths TID 24 hr after I&D
 - High-fiber diet or bulking agent
 - Analgesic

MEDICATION

- Amoxicillin clavulanate: 875 mg PO q12h or 500 mg PO q8h
- Ampicillin sulbactam: 1.5–3 g IV q6h
- Cefoxitin: 1–2 g IV q6–8h
- Clindamycin: 600–900 mg IV div. q8h
- Gentamicin: 3–6 mg/kg/d IV div. q8h
- Metronidazole: 7.5 mg/kg IV q6h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Need for operative drainage
- Systemic toxicity/signs of sepsis

Discharge Criteria

Adequate I&D with complete drainage

Issues for Referral

All should be referred to surgeon in 24--48 hr

FOLLOW-UP RECOMMENDATIONS

Surgeon referral within 24–48 hr to evaluate for fistula:

- Fistulas develop in 25–50% of anorectal abscesses.

PEARLS AND PITFALLS

- Be certain of extent of abscess:
 - Thorough rectal exam and probing is mandatory.
 - Imaging adds insight into deeper areas not accessible to exam
- Deeper abscesses above dentate line have less pain and can present with isolated fever

ADDITIONAL READING

- K61.1 Rectal abscess
- K61.3 Ischiorectal abscess

PERITONSILLAR ABSCESS

Erik Adler • Maria E. Moreira

BASICS

DESCRIPTION

- Suppurative complication of tonsillitis where infection spreads outside the tonsillar capsule between the palatine tonsil and pharyngeal muscles
- Most common deep infection of the head and neck (incidence of 30/100,000 per year)
- In the US, 45,000 cases annually
- Occurs in all ages, more commonly in young adults (mean age 20–40 yr)
- Occurs most commonly Nov–Dec, April–May (coincides with highest incidence rates of streptococcal pharyngitis)
- Complications:
 - Airway compromise (uncommon)
 - Sepsis (uncommon)
 - Recurrence (12–15%)
 - Extension to lateral neck or mediastinum
 - Spontaneous perforation and aspiration pneumonitis
 - Jugular vein thrombosis (Lemierre syndrome)
 - Poststreptococcal sequelae (glomerulonephritis, rheumatic fever)
 - Hemorrhage from extension and erosion into carotid sheath
 - Severe dehydration
 - Intracranial extension (meningitis, cavernous sinus thrombosis, cerebral abscess)
 - Dural sinus thrombosis

ETIOLOGY

- 2 theories explain the development of peritonsillar abscess (PTA):
 - Direct bacterial invasion into deeper tissues in the patient with acute pharyngitis
 - Acute obstruction and bacterial infection of small salivary glands (Weber glands) in the superior tonsil
- Smoking may be a risk factor
- Most common pathogens:
 - *Group-A Streptococcus*
 - Staphylococcal species, including methicillin-resistant *Staphylococcus aureus* (MRSA)
 - Anaerobes (*Prevotella*, *Peptostreptococcus*, *Fusobacterium*)
 - Polymicrobial

SIGNS AND SYMPTOMS

History

- Sore throat
- Fever
- Voice change
- Odynophagia (difficulty swallowing)
- Drooling
- Headache
- Pain radiating to the ear
- Decreased PO intake
- Malaise

Physical-Exam

- Fever
- Trismus
- “Hot potato” voice
- Erythematous tonsils/soft palate
- Inferior and medial displacement of superior pole of tonsil on affected side
- Uvular deviation away from affected side
- Halitosis
- Cervical lymphadenitis
- Tenderness on ipsilateral side of neck at the angle of the jaw

ESSENTIAL WORKUP

- Evaluation for deep space infections beyond the PTA, either with additional imaging or physical exam that may require admission and surgery
- Evaluate and ensure airway patency: Look for stridor, tripod position, or inability to handle secretions
- Definitive management with either needle aspiration or incision and drainage (I&D), followed by a course of antibiotics

DIAGNOSIS TESTS & NTERPRETATION

- Usually a clinical diagnosis made by visually examining oropharynx
- May be difficult with severe trismus

Lab

- Throat culture and monospot (20% incidence of mononucleosis with PTA)
- CBC and culture of the abscess contents may be useful in some cases
- Basic metabolic panel may be useful in patients with decreased oral intake and

clinical signs of dehydration

Imaging

- Bedside intraoral US:
 - Using the high-frequency intracavitary US transducer with a lubricated latex cover can aid in identification and localization of the abscess
 - A cooperative patient can place the transducer at the point of maximum tenderness
- Transcutaneous cervical ultrasound is an option when the patient has too much trismus to use an intracavitary probe
- Soft-tissue lateral neck:
 - If suspicion for epiglottitis or retropharyngeal abscess exists
- Chest radiograph:
 - With severe respiratory symptoms or draining abscess
- CT scan of neck:
 - If suspicion exists for other deep space infection of the neck, CT may be indicated
 - CT also may be indicated if unable to obtain a good exam secondary to trismus
 - CT may locate abscess pocket after failed needle aspiration
- MRI may be useful to evaluate for complications of deep space infections (internal jugular vein thrombosis or erosion into the carotid sheath)

Diagnostic Procedures/Surgery

- Needle aspiration is diagnostic and often curative
- Bedside I&D

DIFFERENTIAL DIAGNOSIS

- Peritonsillar cellulitis
- Epiglottitis
- Retropharyngeal abscess
- Peripharyngeal abscess
- Tracheitis
- Meningitis
- Retropharyngeal hemorrhage
- Cervical osteomyelitis
- Cervical adenitis
- Epidural abscess
- Infectious mononucleosis
- Internal carotid artery aneurysm
- Lymphoma
- Foreign body
- Other deep space infections of the neck

TREATMENT

PRE HOSPITAL

Rarely associated with airway emergencies, but diagnosis is likely to be uncertain in transport, so suction and intubation equipment should be at the bedside:

- Pulse oximetry, supplemental oxygen
- Cardiac monitor
- IV access

Pediatric Considerations

- PTA occurs in children (< 18 yr) in 25–30% of reported cases (14 cases per 100,000 population)
- Young children may need sedation or general anesthesia if I&D or aspiration of the abscess is attempted
- Obtain soft-tissue lateral neck radiograph before oral exam in young children with symptoms of upper airway obstruction

INITIAL STABILIZATION/THERAPY

- Same as for pre-hospital
- Airway management may be necessary
- Equipment for intubation and cricothyroidotomy should be available

ED TREATMENT/PROCEDURES

- Antibiotics should be administered
- IV fluid should be given for dehydration
- Pain control is important
- A single dose of steroids may improve symptoms
- Adequate anesthesia prior to aspiration or I&D procedures is important:
 - Benzocaine spray
 - Lidocaine, 1% with 1:100,000 epinephrine
- No clear benefit for one drainage technique over another:
 - Needle drainage:
 - Successful 87–94%
 - Should be performed by a person experienced in drainage procedure and adept at advanced airway techniques
 - Less painful, less invasive than I&D
 - The internal carotid artery lies ~2.5 cm posterolaterally to the tonsil; sheathing the aspiration needle to prevent introduction of the needle to <0.5 cm is prudent
 - The superior pole of the tonsil is the most common place for maximal fluctuance (followed by the middle pole and then the inferior pole)
 - Repeat aspiration is necessary in 10%

- I&D:
 - Successful 90–92%
 - An 11- or 15-blade scalpel is used to make stab incision to area of fluctuance
 - Guard scalpel with trimmed plastic sheath leaving 1 cm of blade exposed
 - Avoid >0.5 cm depth
 - Medial and superior incisions are safer from the standpoint of potential injury to the carotid artery
 - Incision typically made superior to tonsil in area of soft palate. Incision in the tonsil itself causes excessive bleeding and may miss the abscess, which is located in the peritonsillar soft tissue of the soft palate.
 - Suction should be ready to remove purulent drainage and blood
 - Packing is *not* used
- Tonsillectomy (indications in children):
 - Upper airway obstruction
 - Previous episodes of severe recurrent pharyngitis or PTA
 - Failure of abscess resolution with other drainage techniques
 - Can be performed immediately or after resolution of acute infection

MEDICATION

- Length of antibiotic treatment should be 14 days (<10 day treatment course may be associated with recurrence)
- Adjunct with steroids can improve symptoms

Intravenous Antibiotics

- Ampicillin/Sulbactam (Unasyn), 3 gm q6h
- Penicillin G, 10 million U q6h + Metronidazole (Flagyl), 500 mg q6h
- If allergic to Penicillin, Clindamycin, 900 mg q8h

Oral Antibiotics

- Amoxicillin/Clavulanic acid (Augmentin), 875 mg BID
- Penicillin VK, 500 mg q6h + Metronidazole (Flagyl), 500 mg q6h
- Clindamycin, 600 mg BID or 300 mg q6h

Steroids

- Dexamethasone, 10 mg IV/IM/PO single dose
 - Pediatrics: 0.6 mg/kg; not to exceed 10 mg
- Methylprednisolone, 2 mg/kg; not to exceed 250 mg

FOLLOW-UP

DISPOSITION

Admission Criteria

- Airway compromise
- Sepsis
- Altered mental status
- Dehydration and inadequate PO intake
- Extension of infection beyond the PTA (i.e., deep space neck infections)

Discharge Criteria

- Most patients with PTA can be discharged home on oral antibiotics after abscess drainage
- Must be able to tolerate sufficient oral intake and antibiotics

Issues for Referral

- Referral to an otolaryngologist or surgeon should be provided
- Tonsillectomy is recommended 6–8 wk following treatment of the abscess

FOLLOW-UP RECOMMENDATIONS

Close follow-up recommended in 24–48 hr:

- Treatment failures and recurrences are relatively common

PEARLS AND PITFALLS

- Failure to secure the airway early in a severe infection
- Failure to recognize a more advanced, deep space infection of the neck
- Knowing the anatomy before performing needle aspiration or bedside I&D
- Bedside US is a useful adjunct in differentiating and identifying a PTA vs. peritonsillar cellulitis

ICD9

475 Peritonsillar abscess

ICD10

J36 Peritonsillar abscess

PERTUSSIS

Adam Z. Barkin

BASICS

DESCRIPTION

- Acute respiratory tract infection spread by small respiratory droplets
- Bacteria (fimbriae) attach to respiratory epithelial cells and proliferate, producing toxins:
 - Ciliary dysfunction, accumulation of cellular debris, increased mucus production, lymphocytic and granulocytic infiltration
- Bronchiolar congestion, obstruction, and necrosis
- Obstruction of the airway due to mucus plug, leading to hypoxia and hypoventilation
- Increased intrathoracic or intracranial pressure
- Secondary bacterial infection may exacerbate respiratory distress/failure.
- CNS injury caused by encephalitis, increased intracranial pressure, and/or hypoxia
- Uncomplicated cases last 6–10 wk; half of the cases last <6 wk.
- Mortality:
 - Mortality greatest in those <1 yr
 - 1.3% for patients <1 mo
 - 0.3% in children 2–11 mo
 - 90% of deaths are secondary to bacterial pneumonia
- Epidemiology:
 - Incubation period is 6–20 days, usually 7–10 days.
 - Mostly young children; 24% in children <6 mo
 - Increasing incidence in adolescents
 - Adults are the primary reservoir
 - Peak incidence is late summer/fall
 - Preventable with diphtheria–tetanus–pertussis (Tdap) vaccine

ETIOLOGY

Bordetella pertussis:

- A fastidious, gram-negative, pleomorphic bacillus

DIAGNOSIS

SIGNS AND SYMPTOMS

- Generally 3 recognized phases with progression:
 - Infants may have indistinct stages
- Catarrhal stage:

- 1–2 wk duration
- Rhinorrhea
- Mild cough
- Minimal fever
- Paroxysmal stage:
 - 1–6 wk duration
 - Classic “whooping” cough, increasing in severity:
 - Coughing spasm that ends with a sudden inflow of air—the whoop; unremitting paroxysms
 - Cyanosis with respiratory distress/failure
 - Apnea (infants < 6 mo)
 - Altered mental status secondary to hypoxia or encephalitis
- Convalescent stage:
 - 2–12 wk duration
 - Waning cough
 - Improving respiratory status
- Atypical presentations:
 - Often atypical in children < 6 mo
 - Partially immunized children have less severe disease
 - Adult manifestations are often only rhinorrhea, sore throat, persistent cough; often in family members

History

- Catarrhal phase:
 - Malaise
 - Low-grade fever
 - Rhinorrhea
 - Sore throat
- Paroxysmal phase:
 - “Whooping” cough
 - Post-tussive cyanosis
 - Post-tussive emesis
- “Whooping” sound during paroxysmal phase
- Catarrhal phase:
 - Persistent cough

Physical-Exam

- Catarrhal phase:
 - Low-grade fever
 - Rhinorrhea
 - Lacrimation
 - Dry cough (late phase)

- Conjunctival inflammation
- Paroxysmal phase:
 - Paroxysmal whooping cough
- Convalescent phase:
 - Occasional paroxysmal cough

ESSENTIAL WORKUP

- The ED diagnosis should be made on clinical grounds
- Attempt to establish a history of a contact
- Observe the paroxysmal cough with the characteristic whoop
- Use ancillary studies to further support the clinical diagnosis and exclude complications

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Polymerase chain reaction:
 - High sensitivity and specificity
 - High sensitivity leads to more false positives
 - Best practices for testing with PCR:
 - Test only those with symptoms
 - Testing after 4 weeks of cough or following antibiotics will increase false negative rate
 - Obtain samples via aspiration or posterior nasopharyngeal swab to maximize DNA recovery
 - Should be used in conjunction with culture
- Direct immunofluorescence assay of nasopharyngeal mucus:
 - High false-positive rate
- Culture of nasopharynx or cough plate on a Bordet–Gengou medium:
 - Takes 7–12 days
 - High specificity
 - Low sensitivity
 - Remains the gold standard test
- Serology:
 - Useful in later diagnosis
 - Perform testing 2–8 weeks after cough onset
- WBC count:
 - Leukocytosis (20,000–50,000 cells/mm³) with marked lymphocytosis
 - Normalizes during convalescent phase
 - Elevation of WBC and lymphocytosis parallels severity of cough
- Immunofluorescent and enzyme immunoassays to exclude respiratory syncytial virus
- Done on either nasal wash or nasopharyngeal swab (Dacron)

Imaging

CXR:

- Most often normal
- Perihilar infiltrates
- Atelectasis
- Occasionally characteristic “shaggy” right heart border
- Secondary bacterial pneumonia

DIFFERENTIAL DIAGNOSIS

- Infection:
 - Parallel whooping cough syndrome caused by *Bordetella parapertussis*, *Chlamydia trachomatis*, *Chlamydia pneumoniae*, *Bordetella bronchiseptica*, or adenovirus
 - Pneumonia:
 - Bacteria
 - *Mycoplasma*
 - *Mycobacterium*
 - Bronchiolitis:
 - Respiratory syncytial virus
 - Influenza
 - Other virus
- Reactive airway disease
- Foreign body
- Cystic fibrosis

TREATMENT

PRE HOSPITAL

- Oxygen
- Monitor airway
- Suction

INITIAL STABILIZATION/THERAPY

- Oxygen and respiratory support
- Suction mucous plugs

ED TREATMENT/PROCEDURES

- Universal precautions:
 - Specifically requires droplet precautions for 5 days after initiation of antimicrobial therapy
- Maintenance of adequate hydration
- Monitor oxygenation during paroxysms; supplement oxygen
- Airway management may be lifesaving in younger children

- **Antibiotics:**
 - Effective in the catarrhal stage
 - Prevent further transmission in the paroxysmal stage
 - Azithromycin is the first-line agent
 - Alternatively, clarithromycin, erythromycin, or trimethoprim–sulfamethoxazole may be used, although the efficacy is unproven; useful if erythromycin is not tolerated
- Corticosteroids and albuterol may reduce paroxysms of coughing, but further studies are required
- With increasing incidence of pertussis among adolescents and adults, emergency physicians can decrease incidence of pertussis by making vaccination routine when also vaccinating against tetanus:
 - Tetanus toxoid, reduced diphtheria toxoid, acellular pertussis (Tdap)

MEDICATION

Bronchodilators and steroids are generally not recommended for pertussis

First Line

- Azithromycin (adult): 500 mg PO day 1, then 250 mg PO QD for 4 days
- Azithromycin <5 mo: 10 mg/kg PO daily for 5 days
- Azithromycin 5 mo–adult: 10 mg/kg PO day 1 (max. 500 mg), then 5 mg/kg PO daily for 4 days (max. 250 mg daily)
- Tetanus toxoid, reduced diphtheria toxoid, Tdap vaccine: 0.5 mL IM:
 - Adacel: Approved for ages 11 and up
 - Boostrix: Approved for ages 10 and up

Pregnancy Considerations

- Advisory Committee on Immunization Practices (ACIP) recommends Tdap for pregnant patients during each pregnancy
- May be given anytime, but preference is between 27--36 weeks gestation

Second Line

- Clarithromycin: 15 mg/kg/d div. BID for 7 days (max. 1 g/d)
- Erythromycin: 40–50 mg/kg/d div. QID for 14 days (max. 2 g/d). Associated with risk of pyloric stenosis when administered in 1st 2 wk of life
- Trimethoprim–sulfamethoxazole: 8/40 mg/kg/d div. BID for 14 days (max. 320/1,600 mg/d):
 - Not for infants <2 mo

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients <1 yr
- Apnea
- Cyanosis during paroxysms of cough
- Significant associated pneumonia
- Encephalitis

Discharge Criteria

- Children without apnea, respiratory compromise, altered mental status, or complications and respiratory distress
- Warm liquids to reduce coughing spasm
- Remove thick secretions with bulb suction in infants
- Good hydration
- Avoid cough triggers: Cigarette smoke, pollutants, perfumes
- Postexposure prophylaxis is recommended to all persons with close contact (within 3 ft of a symptomatic person):
 - Antibiotic recommendations are the same as those with disease
 - Symptomatic children should be excluded from school or work; individuals with pertussis may return after 5 days of full treatment

FOLLOW-UP RECOMMENDATIONS

Children who are discharged need close follow-up to monitor hydration status and for respiratory compromise.

ALERT

Physicians are legally required to report cases of pertussis to state health department.

COMPLICATIONS

- Head, eyes, ears, neck, throat:
 - Epistaxis
 - Subconjunctival hemorrhage
- Respiratory:
 - Acute respiratory arrest
 - Pneumonia caused by secondary infection
 - Pneumothorax
 - SC or mediastinal emphysema with crepitus
 - Bronchiectasis
- GI:
 - Hernia: Inguinal or abdominal
 - Rectal prolapse
- Neurologic:
 - Seizures
 - Encephalitis

- Coma
- Intracranial hemorrhage
- Spinal epidural hemorrhage

ALERT

The child with pertussis may have significant respiratory distress or apnea

PEARLS AND PITFALLS

- Infants ≤ 1 yr need admission for pertussis
- Tdap should be given to eligible patients requiring tetanus prophylaxis
- Droplet precautions should be implemented for 5 days after implementation of effective antimicrobial therapy
- Chemoprophylaxis is recommended for all household contacts irrespective of age and immunization status

CODES

ICD9

- 033.0 Whooping cough due to bordetella pertussis [B. pertussis]
- 033.1 Whooping cough due to bordetella parapertussis [B. parapertussis]
- 033.9 Whooping cough, unspecified organism

ICD10

- A37.00 Whooping cough due to Bordetella pertussis without pneumonia
- A37.10 Whooping cough due to Bordetella parapertussis w/o pneumonia
- A37.90 Whooping cough, unspecified species without pneumonia

PHALANGEAL INJURIES, FOOT

Taylor Y. Cardall

BASICS

DESCRIPTION

- The phalanges of the foot are prone to injury.
- 5th (or small) toe most commonly affected

ETIOLOGY

- Usually the result of direct trauma
- Stubbing the toe, kicking a hard surface, or dropping a heavy object onto toes most common mechanisms of injury

DIAGNOSIS

SIGNS AND SYMPTOMS

History

History may predict the type of injury found and should include:

- Time of injury
- Mechanism
- History of previous trauma
- Status of tetanus immunization if laceration is present

Physical-Exam

- Tenderness, swelling, crepitus, and ecchymosis of affected digit
- Subungual hematomas are often present.
- Lacerations or crush-type wounds
- Document neurovascular status of the affected digit.

ESSENTIAL WORKUP

Radiographs of involved digit

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- Radiographs of involved digit
- Lateral view may be most sensitive.

DIFFERENTIAL DIAGNOSIS

- Fracture
- Contusion
- Abrasion/laceration
- Dislocation

TREATMENT

PRE HOSPITAL

- Ice to affected digit
- Direct pressure and dressing to any wounds

INITIAL STABILIZATION/THERAPY

- Ice to affected digit
- Direct pressure and dressing to any wounds

ED TREATMENT/PROCEDURES

- Fractures involving the proximal phalanx and interphalangeal (IP) joint of the hallux:
 - Nondisplaced, non–intra-articular fractures may be placed in a short-leg walking cast with toe extension for comfort.
 - Displaced, non–intra-articular fractures:
- Closed reduction with digital block anesthesia
- Longitudinal traction
- Placement in short-leg walking cast with toe extension:
 - Intra-articular fractures of the hallux merit orthopedic consult:
 - Frequently treated with open reduction and internal fixation
- Fractures involving the proximal phalanx and IP joint of the lesser toes:
 - Rarely cause long-term disability
- Nondisplaced fractures:
 - Treat with splinting or buddy taping
 - Gauze padding between the taped toes to prevent skin breakdown
- Displaced fractures:
 - Closed reduction by digital block anesthesia
 - Longitudinal traction
 - Buddy taping or splinting
 - Hard-sole shoe, weight bearing as tolerated
 - Oral analgesics for pain
 - Pain usually resolved by 2–3 wk
- IP joint dislocations:
 - Closed reduction by digital block anesthesia
 - Longitudinal traction with gentle downward pressure on distal phalanx
 - Buddy tape to adjacent toe

- Unstable or unsuccessful reductions require orthopedic consultation.
- Oral analgesics for pain
- Distal tuft fractures:
 - Subungual hematomas should be drained.
 - Nail-bed laceration repair may be necessary.
 - Buddy tape digit to adjacent toe.
 - Weight bearing as tolerated
 - Oral analgesics for pain
 - Pain usually resolved in 2–3 wk
- Open fractures:
 - Orthopedic consultation
 - Prophylactic antibiotics

MEDICATION

- NSAIDs are useful in treating acute pain:
 - Ibuprofen 800 mg (peds: 5–10 mg/kg) PO TID
- Narcotic analgesics may be required for severe pain
- Consider antibiotics for open wounds
 - Cefazolin: 1 g IM/IV in ED (peds: 50–100 mg/kg IM/IV in ED) for open fractures
 - Cephalexin 500 mg PO QID (peds 25–50 mg/kg/d in div. doses) for 7 days for dirty wounds.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Unstable or blocked dislocations
- Open fractures require orthopedic consultation in the ED.

Discharge Criteria

All other fractures may be discharged with orthopedic follow-up in 2–3 wk to evaluate healing.

Issues for Referral

Patient copies of any radiographs obtained may facilitate early follow-up.

FOLLOW-UP RECOMMENDATIONS

- Intra-articular fractures involving the proximal phalanx of the great toe require urgent orthopedic or foot and ankle surgery follow-up.
- Simple nondisplaced fractures of the small toes may often be followed by primary

care physicians.

PEARLS AND PITFALLS

Open, displaced, or intra-articular fractures, particularly involving the hallux, merit orthopedic consultation.

- S99.929A Unspecified injury of unspecified foot, initial encounter

PHALANGEAL INJURIES, HAND

Asia M.F. Takeuchi • Stephen R. Hayden

BASICS

DESCRIPTION

- 1/3 of all traumatic injuries affect the hand.
- Phalanges account for 1 of the most frequently fractured parts of the skeletal system with the distal phalanx being the most commonly fractured bone in the hand.
- Dorsal displacement of the proximal interphalangeal joint of the finger is the most frequent dislocation.

Pediatric Considerations

Injuries may be more difficult to diagnose in children who are unable to cooperate for a full exam.

ETIOLOGY

- Trauma (commonly work or sports related)
- Infectious sequelae:
 - Skin flora: *Staphylococcus aureus* and *Streptococci*
 - Cat/dog bites: *S. aureus* and *Pasteurella multocida*
 - Human bites: *Eikenella*
 - Thorns or woody plants puncture: Fungal
 - Fresh/salt water exposure: *Mycobacterium marinum* and *Pseudomonas aeruginosa*
- Overuse injury (e.g., “gamekeeper’s thumb”)

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Mechanism of injury:
 - Hyperextension injuries most commonly cause ligamentous injury (e.g., “Jersey finger” which is a rupture of the flexor digitorum profundus tendon from its distal attachment) or chip fractures.
 - Hyperflexion injury to the tip of digits may cause “Mallet finger” injury with avulsion fracture at the insertion of the extensor tendon on the distal phalanx.
 - Crush injuries most commonly cause fractures and diffuse soft-tissue injury.

- Handedness
- Occupation/hobbies
- Other factors may affect healing (e.g., age, diabetes, immune suppression, anticoagulation)

Physical-Exam

- Swelling and/or deformity (e.g., amputation, rotation, shortening, or angulation)
- Skin changes (e.g., ecchymosis, laceration, burn, pallor) or associated nail injury
- Decreased range of motion or weakness
- Pain or change in sensation in the area of injury

ALERT

Kanavel signs (*infectious* flexor tenosynovitis)

- Pain along the tendon with passive extension (early sign)
- Symmetric enlargement of the affected digit
- Slightly flexed finger at rest
- Tenderness along the course of the flexor sheath (later sign)
- Trigger finger (stenosing flexor tenosynovitis):
- *Noninfectious* inflammation of the flexor tendon sheath.
- Painful “snapping” sensation with flexion of the affected digit.
- May awaken with the finger locked in the palm, with gradual “unlocking” as the day progresses.

Pediatric Considerations

In an infant with a painful or swollen digit, it is important to consider a deeply embedded hair tourniquet that may not be readily obvious on superficial exam.

ESSENTIAL WORKUP

- Special attention directed at assessing individual tendon status, neurovascular integrity, and identifying rotational deformity:
 - Isolate and assess each individual joint (PIP, DIP, MCP); range with passive motion and against active resistance
 - Normal 2-point discrimination is ~4–5 mm
 - Malrotation can be evaluated by positioning the fingers with the MCP joints in flexion and the PIP and DIP in extension:
 - Normally, all fingers are directed toward the radius and there should be no overlap or rotation
- Exam conducted 1st to assess function, then under anesthesia, and finally with tourniquet if needed to allow a bloodless field for better exam of lacerated areas.

DIAGNOSIS TESTS & INTERPRETATION

Lab

Consider wound culture if signs of infection present or if there is concern for flexor tenosynovitis.

Imaging

- Plain radiography of involved digits should include AP, true lateral, and oblique views.
- US can help diagnose tendon tears.

Pediatric Considerations

Open epiphyses make radiographic interpretation less sensitive.

DIFFERENTIAL DIAGNOSIS

- Tendon laceration/rupture partial/complete
- Complicated open injuries may include several injuries, and the entire hand should be examined carefully.
- Beware of lacerations over dorsal metacarpal–phalangeal areas, which may be “fight bites” (human bites).

Pediatric Considerations

- Many fractures in children are torus (buckle) fractures of the phalanges.
- The growth plates are typically weaker than the surrounding ligaments, thus dislocations are commonly accompanied by Salter–Harris fractures.

TREATMENT

PRE HOSPITAL

- Reduction of a phalangeal dislocation at the scene SHOULD NOT be considered UNLESS there will be an unusually long transport time or there is vascular or neurologic compromise.
 - Reduction may be successful but prompt the physician to miss significant ligamentous injuries.
- Bleeding should be treated with appropriate direct pressure dressings.

ALERT

- Amputated digits or tissue should be placed in clean moist saline gauze, placed in plastic bag, and then placed in a separate bag with ice. *Do not place digit in direct contact with ice!*
- Indications for reimplantation in amputation:
 - Thumb
 - Single digit between PIP and DIP joints
 - Multiple digits
 - Amputation in a child

INITIAL STABILIZATION/THERAPY

- Remove all rings from injured hand.
- Immobilize the involved areas by proximal-to-distal splinting.
- Intermittent ice pack application with constant elevation for the 1st 24 hr.
- Dislocations or severely deformed fractures producing vascular compromise should be reduced immediately to a neutral position and immobilized.

ED TREATMENT/PROCEDURES

- Interphalangeal reduction:
 - Dorsal dislocation:
 - Provide longitudinal traction and gently hyperextend the joint while pushing the base of the dislocated phalanx into place.
 - Volar dislocation:
 - Provide longitudinal traction and gently hyperflex while pushing the base of the dislocated phalanx into place.
 - Lateral dislocation:
 - Provide longitudinal traction and gently hyperextend the joint while correcting the ulnar or radial deformity.
- Interphalangeal immobilization:
 - DIP dorsal or lateral finger dislocation:
 - Splint the DIP in full extension while allowing full range of motion of the PIP joint.
 - PIP dorsal or lateral finger dislocation:
 - Apply a dorsal splint with the PIP in 20–30° of flexion.
 - Volar finger dislocation:
 - Splint the PIP and DIP in full extension.
- Metacarpophalangeal dislocation:
 - Avoid excessive hyperextension or distraction. Gently distract the affected digit and apply volar pressure to the base of the dislocated proximal phalanx.
- Metacarpophalangeal immobilization:
 - Finger dislocation: Splint the digit in 90° of flexion at the MCP joint.
 - Thumb dislocation: Apply a thumb spica splint with the MCP joint in 20° of flexion.
- Open fracture:
 - Immediate referral to a hand surgeon for treatment within 4–6 hr after trauma.
 - Prophylactic antibiotics directed against gram-positive and gram-negative organisms should be administered parenterally within 6 hr.
- Closed fracture:
 - Distal phalanx:
 - Stable injuries may be splinted with the DIP in flexion and the PIP free; extend tip of splint beyond the end of the digit for added

protection; maintain for 3–4 wk.

– Middle phalanx:

- Nondisplaced stable fractures can be buddy taped to an adjacent digit.
- Displaced/angulated fractures may be reduced (using longitudinal traction with 3-point pressure to align the fragment) and immobilized (buddy tape and ulnar/radial gutter splint).
- Splinting should be done with the wrist in 20–30° of extension, the MCP joints in 70–90° of flexion, and the PIP and DIP joints flexed 5–10°.

– Proximal phalanx:

- A nondisplaced, nonangulated, stable injury can be buddy taped to an adjacent finger; ulnar/radial gutter or Burkhalter splint may be added for comfort.
- A displaced or angulated fracture may be reduced by flexing the MCP and PIP joints to 90°, then using a 3-point reduction technique to reduce the proximal fragment dorsally and the distal fragment volarly. Once reduced, the PIP joint should be extended (to avoid a flexion contracture), the MCP joint should remain in 70–90° of flexion and a radial or ulnar gutter splint should be placed with the fractured finger buddy taped to an adjacent finger.

ALERT

No more than 1 or 2 mm of displacement or shortening is acceptable. Up to 10° of angulation is acceptable but NO amount of rotation is permitted.

● Mallet finger:

- Immobilize the DIP joint in full extension or slight hyperextension (5–15°), while allowing full range of motion of the PIP joint.
- Do **not** attempt to reduce any displaced fractures before splinting because any reduction is unlikely to be maintained without surgery; refer for urgent orthopedic consult.

● Jersey finger:

- Apply an aluminum splint with the PIP joint and the DIP joint slightly flexed.
- DIP extension should be avoided until the digit can be evaluated by a hand specialist (definitive treatment of complete tendon rupture is surgery).

● Trigger finger:

- Immobilize by buddy taping to the adjacent finger for 4–6 wk.
- A metal or thermoplastic finger splint can be used if buddy taping is unsuccessful.

● Gamekeeper's thumb:

- Apply ice to the MP joint acutely.
- Immobilize with a thumb spica splint (MP joint is flexed to 20°) for 3 wk.

● Subungual hematoma:

- Nail trephination using a heated paper clip, electric cautery, or an 18G needle.
- This injury does not have to be treated as an open injury *unless* there is an underlying tuft fracture.
- Nail avulsions:
 - Clean and repair using fine (e.g., 6-0) absorbable suture.
 - Splint the eponychium and germinal matrix with the avulsed nail or small piece of gauze or foil to avoid adhesions.
- Open distal and volar directed fingertip wounds with no protruding bone and smaller than 1 cm may be allowed to heal by secondary intention.

MEDICATION

- Evaluate tetanus status and vaccinate per immunization schedule.
- Digital nerve block should be done with an anesthetic that does NOT contain epinephrine.
- Antibiotics:
 - Not indicated for simple clean wounds
 - For grossly contaminated injury, puncture wounds, or infectious tenosynovitis therapy should be tailored to specific pathogen exposure (e.g., skin flora, fresh water, bites)

FOLLOW-UP

DISPOSITION

- Patients with a stable injury, in an appropriate splint, may be discharged for orthopedic follow-up and possible repeat imaging in 1 wk time.

ALERT

Emergent orthopedic consult is required for:

- Amputation
- Open joint injuries or fractures
- Digital neurovascular compromise
- Signs of joint infection or infectious tenosynovitis
- High-pressure injection injury
- Urgent orthopedic consult:
 - Unstable fractures (rotational deformity, oblique or angulated fractures, joint involvement, epiphyseal injuries)
 - Any joint dislocation with tendon rupture
 - Digit dislocation that is irreducible
 - Unstable joint after attempted dislocation reduction

PEARLS AND PITFALLS

- Rotational deformity may not be apparent if finger is straight, exam under flexion is required.
- Jersey finger (FDP tendon rupture) is often misdiagnosed as a “jammed” or sprained finger, but requires more urgent management than these minor injuries.
- Always check for stability postreduction by having patient perform active range of motion and checking a postreduction x-ray.

ADDITIONAL READING

PHARYNGITIS

John C. Greenwood • Brian J. Browne

BASICS

DESCRIPTION

- Inflammation/infection of the pharynx
- 3rd most common complaint for physician visits
- 30 million cases diagnosed annually
- Group A β -hemolytic streptococcus (GAS):
 - *Streptococcus pyogenes*
 - Unusual in children < 3 yr old
 - Cause of 20–30% of childhood pharyngitis
 - Bimodal incidence, highest in ages 5–7 and 12–13 yr
 - Cause of 5–15% of adult pharyngitis
 - Peak months: January–May; also at the start of the school year

ETIOLOGY

- Viral (most common infectious cause):
 - Rhinovirus (20%)
 - Coronavirus (> 5%)
 - Adenovirus (5%)
 - Herpes simplex virus (4%)
 - Parainfluenza virus (2%)
 - Influenza virus (2%)
 - Coxsackievirus (< 1%)
 - Epstein–Barr virus (< 1%)
 - Acute human immunodeficiency virus (HIV)
- Bacterial:
 - GAS (*S. pyogenes* [15–30%])
 - *Fusobacterium necrophorum* (10%)
 - Group C & G β -hemolytic streptococcus (5%)
 - *Neisseria gonorrhoea* (< 1%)
 - *Corynebacterium diphtheriae* (< 1%)
 - *Arcanobacterium haemolyticum* (< 1%)
 - *Chlamydia pneumoniae*
 - *Mycoplasma pneumoniae* (< 1%)
 - Syphilis
 - Tuberculosis
- Fungal:
 - *Candida* (thrush)

- Chemical burns
- Foreign bodies
- Inhalants
- Postnasal drip
- Malignancy
- GERD

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Viral:
 - Cough
 - Rhinorrhea
 - Sore throat usually follows
 - Have a high suspicion for acute HIV in at-risk patients presenting with persistent pharyngitis despite treatment
- Bacterial:
 - Sudden-onset sore throat that usually precedes other symptoms
 - Odynophagia
 - Fever
 - Headache
 - Abdominal pain
 - Nausea and vomiting
 - Uncharacteristic symptoms:
 - Coryza
 - Hoarseness
 - Diarrhea

Physical-Exam

- High-risk features for a serious complication of pharyngitis:
 - Stridor, respiratory distress
 - Drooling
 - Dysphonia
 - Marked neck swelling
 - Neurologic dysfunction
- Viral:
 - Cough
 - Coryza
 - Rhinorrhea
 - Pharyngeal erythema

- Gingivostomatitis
- GAS:
 - Tonsillopharyngeal erythema/exudates
 - Soft palatal petechiae
 - Beefy red, swollen uvula
 - Anterior cervical lymphadenopathy
 - Scarletiform rash
 - Uncharacteristic signs:
 - Conjunctivitis
 - Anterior stomatitis
 - Discrete ulcerative lesions
- Mononucleosis:
 - Mistaken for GAS due to similar presentation:
 - Exudative pharyngitis
 - Tender cervical lymphadenopathy
 - Fever
 - Rash
 - Other possible exam findings:
 - Hepatosplenomegaly
 - Jaundice
- Diphtheria:
 - Consider in nonimmunized patients
 - Airway-threatening gray pharyngeal membrane
 - Myocarditis (2/3 of patients); clinically evident cardiac dysfunction (10–25%)
 - Cranial and peripheral neuropathies (5%)
- Gonococcal pharyngitis:
 - Can be asymptomatic
 - Always evaluate children for sexual abuse
 - Recurrent episodes of pharyngitis

ESSENTIAL WORKUP

Modified Center criteria for the diagnosis of GAS pharyngitis (most widely used decision rule):

- Criteria (points):
 - Absence of cough (+1)
 - Tonsillar exudates or swelling (+1)
 - Swollen and tender anterior cervical nodes (+1)
 - Temperature > 38°C (+1)
 - Age in years:
 - 3–14 (+1)
 - 15–44 (0)
 - > 45 (–1)

- Scoring:
 - < 1 should not be tested or treated
 - 3 is associated with a risk of 28–35%
 - > 4 is associated with a risk of 51–53%
- Patients with 3 criteria should receive a rapid antigen detection test (RADT)
- Presumptive treatment without testing has led to inappropriate use of antibiotics in about 50% of cases
- Some suggest that patients with a score > 4 should be treated empirically without a RADT

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Throat culture:
 - Gold standard
 - 24–48 hr for results, will delay treatment
 - Necessitates contacting patient/family
 - Obtain when *Gonococcus* is suspected
- GAS RADT:
 - Results are available within 30 min
 - Treat all patients with (+) RADT results
 - Technique: Performed by swabbing the tonsils or posterior pharynx:
 - Avoid contact with the tongue, buccal mucosa, and lips
 - Sensitivity 85–95%
 - Specificity 96–99%:
 - Confirm with conventional throat culture in children/adolescents with negative RADT
 - Optical immunoassay is extremely accurate; negative results do not require confirmatory culture
- Monospot:
 - Detects heterophil antibody:
 - Sensitivity:
 - < 2 yr old: < 30%
 - 2–4 yr old: 75%
 - > 5 yr old: 90%
 - CBC with peripheral smear: 50% lymphocytes, 10% atypical lymphocytes
 - Obtain rapid viral loads if HIV is suspected

Imaging

- Lateral neck radiograph for suspected epiglottitis, retropharyngeal abscess, or foreign body
- Contrast-enhanced CT of the neck is useful to identify complications such as peritonsillar abscess and retropharyngeal abscess

DIFFERENTIAL DIAGNOSIS

- Epiglottitis
- Peritonsillar/retropharyngeal abscess
- Diphtheria
- Mononucleosis
- Lemierre disease
- Ludwig angina
- *Candida* infection
- Gonorrhea
- Acute HIV infection
- Acute leukemia/lymphoma
- Oropharyngeal cancer
- Foreign body
- Inhalants and chemical burns
- Postnasal drip
- GERD

TREATMENT

PRE HOSPITAL

- Observe/manage airway for respiratory distress
- Normal saline (NS) hydration for hypotension/dehydration

INITIAL STABILIZATION/THERAPY

- ABCs
- Fluid resuscitation: 1 L (peds: 20 mL/kg) NS bolus for signs of volume depletion or if patient is unable to tolerate oral solutions

ED TREATMENT/PROCEDURES

- Antipyretics/analgesics:
 - Acetaminophen
 - Ibuprofen
 - Topical analgesics (e.g., Chloraseptic spray)
- GAS infection:
 - Often mild and self-limited:
 - Antibiotic therapy accelerates symptom relief (fever and pain) by 1–2 days
 - Goal of antibiotic treatment is to reduce the incidence of acute rheumatic fever, symptoms, and suppurative complications
- Antibiotics:
 - Penicillin V: Antibiotic of choice for GAS pharyngitis
 - Cephalosporins or macrolides are an acceptable alternative treatment for

nonresponders and penicillin-allergic patients

- Corticosteroids:
 - In conjunction with antibiotics, corticosteroids have a 3-fold increase in the likelihood of symptom resolution at 24 hr
 - Number needed to treat: 3.3–3.7
 - Avoid in diabetics and immunocompromised patients
- Potential complications of streptococcal infection:
 - Suppurative complications:
 - Peritonsillar/retropharyngeal abscess
 - Lemierre disease
 - Otitis media/mastoiditis
 - Nonsuppurative complications:
 - Acute rheumatic fever:
 - Rare in industrialized countries, but still the leading cause of cardiac death within 1st 5 decades of life
 - Sequelae of GAS; not proven in association with group C or G
 - Acute poststreptococcal glomerulonephritis
 - Sydenham chorea
 - Reactive arthritis
 - PANDAS: Pediatric autoimmune neuropsychiatric disorder associated with streptococcal infection:
 - Sudden onset of symptoms similar to obsessive–compulsive disorder
 - Caused by an autoimmune reaction affecting the basal ganglia
 - Uncommon and controversial
- Diphtheria:
 - Goals of therapy:
 - Prevent airway obstruction
 - Treat infection
 - Penicillin or macrolide antibiotic
 - Complications:
 - Exotoxin-mediated myocarditis and neuritis (cranial neuropathies)
- Gonococcal pharyngitis:
 - 3rd-generation cephalosporin plus macrolide for possible *Chlamydia* coinfection

MEDICATION

First Line

- Penicillin G:
 - < 27 kg: Benzathine penicillin G (Bicillin LA): 0.6 million U IM × 1
 - > 27 kg: Benzathine penicillin G (Bicillin LA): 1.2 million U IM × 1
- Penicillin V:

- <12 yr: 25–50 mg/kg/d PO div. q6–8h × 10 days
- >12 yr: 250–500 mg PO q6–8h × 10 days
- Amoxicillin:
 - 50 mg/kg PO QD, (max. 1 g) × 10 days

Second Line

- Macrolides:
 - Azithromycin: 20 mg/kg/d × 3 days (max. 500 mg per dose)
 - Erythromycin: 40–50 mg/kg PO div. q6h × 10 days (max. 500 mg per dose)
- Oral cephalosporins:
 - Cephalexin: 20 mg/kg/dose PO BID × 5 days (max. 500 mg per dose)
- Steroids:
 - Dexamethasone: 0.6 mg/kg IM/PO × 1 (max. 10 mg)
 - Prednisone: 40–60 mg PO × 1
- Special conditions:
 - Suspected gonococcal pharyngitis:
 - Ceftriaxone: 125–250 mg IM × 1

FOLLOW-UP

DISPOSITION

Admission Criteria

- Airway compromise
- Severe dehydration
- Suspected child abuse

Discharge Criteria

Able to tolerate oral intake

FOLLOW-UP RECOMMENDATIONS

- If symptoms do not improve within 72 hr
- Patients are no longer contagious after 24 hr of antibiotic treatment
- Mononucleosis patients should avoid contact sports

PEARLS AND PITFALLS

- Use the modified Centor criteria to make the decision to test for GAS pharyngitis
- Children with negative RADT need follow-up throat culture
- Acute rheumatic fever is a more common complication of GAS pharyngitis in nonindustrialized nations
- Evaluate for high-risk complications of bacterial pharyngitis (e.g., peritonsillar

abscess, retropharyngeal abscess, Lemierre disease)

PHENCYCLIDINE POISONING

Steven E. Aks

BASICS

DESCRIPTION

- Phencyclidine (PCP) is a dissociative anesthetic structurally related to ketamine:
 - Causes decreased perception of pain and agitation
- Half-life of 21–24 hr, but may be longer in overdose
- Enterohepatic recirculation—recirculated into the stomach

ETIOLOGY

- Drug of abuse:
 - Frequently encountered as an adulterant of marijuana
- Street names for PCP include:
 - Angel dust
 - Wicky stick
 - Wicky weed
 - Wacky weed
 - Wet
 - Illy
 - Embalming fluid
 - Sherman

Pediatric Considerations

Exposure in toddlers reported via passive exposure

DIAGNOSIS

SIGNS AND SYMPTOMS

- CNS:
 - Altered mental status
 - Agitation
 - Bizarre/violent behavior
 - Belligerence
 - Coma
 - Seizures
 - Nystagmus (vertical, horizontal, or rotatory)
- Cardiovascular:
 - HTN
 - Tachycardia

- Musculoskeletal:
 - Traumatic injury (decreased pain perception)
 - Rhabdomyolysis (due to vigorous muscular contraction)
- Vital signs:
 - Hyperthermia

History

How was the PCP consumed?

- Smoked with marijuana
- Ingested

Physical-Exam

- Agitation
- Coma
- Hypertension
- Tachycardia
- Diaphoresis
- Nystagmus (vertical, horizontal, or rotatory)
- Hyperthermia
- Vigorous muscular contraction

ESSENTIAL WORKUP

- Clinical diagnosis based on presentation supported by urine toxicology screen:
 - Dextromethorphan and ketamine may give false positive.
- Careful physical exam for occult trauma
- Exclude other causes of altered mental status.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Electrolytes, BUN/creatinine, glucose
- Urinalysis:
 - Dip for myoglobin (rhabdomyolysis)
- Creatine phosphokinase:
 - If urine dip for blood is positive
- Ethanol level

Imaging

- Chest radiograph for aspiration pneumonia
- Extremity/spine radiographs when there is associated trauma
- CT of the head when there is head trauma/altered mental status

DIFFERENTIAL DIAGNOSIS

- Drugs of abuse:
 - Cocaine
 - Amphetamines
 - Designer drugs:
 - Methcathinone (“Cat”)
 - “Ecstasy”
 - “Ice” (methamphetamine)
 - Alcohols
 - Ketamine
 - Sympathomimetics
- Drugs that cause nystagmus:
 - Lithium
 - Carbamazepine
 - Sedative–hypnotics
 - Alcohols
 - Phenothiazines
 - Dextromethorphan

TREATMENT

PRE HOSPITAL

ALERT

Use restraints/additional personnel to control combative patient.

INITIAL STABILIZATION/THERAPY

- ABCs
- IV
- Cardiac monitor
- Naloxone, thiamine, glucose (or Accu-Chek) if altered mental status
- Protect patient and staff from injury.

ED TREATMENT/PROCEDURES

- Maintain patient in a quiet place; avoid stimulation.
- Physical restraints for violent patient
- Sedation:
 - Benzodiazepines
 - Butyrophenones (haloperidol) theoretically can lower the seizure threshold.
- Activated charcoal if oral coingestants
- IV 0.9% normal saline for hydration, sodium bicarbonate/mannitol for rhabdomyolysis

MEDICATION

First Line

- Ativan (lorazepam): 2 mg IV increments
- Diazepam: 5 mg IV increments

Second Line

- Activated charcoal slurry: 1–2 g/kg up to 90 g PO
- Dextrose: D50W 1 amp: 50 mL or 25 g (peds: D25W 2–4 mL/kg) IV
- Mannitol: 25–50 g IV
- Naloxone (Narcan): 2 mg (peds: 0.1 mg/kg) IV or IM initial dose
- Sodium bicarbonate: 2 amps (50 mEq per amp) diluted in 1 L of D5W, given at 125–250 mL/h (for rhabdomyolysis) to urine pH of 7
- Thiamine (vitamin B₁): 100 mg (peds: 50 mg) IV or IM

FOLLOW-UP

DISPOSITION

Admission Criteria

- Prolonged altered mental status
- Significant traumatic injuries
- Rhabdomyolysis
- Hyperthermia

Discharge Criteria

Becomes lucid after a period of observation (6 hr)

FOLLOW-UP RECOMMENDATIONS

Psychiatry or social work referral for suicidal ideation or chronic drug use

PEARLS AND PITFALLS

- PCP poisoning can lead to traumatic injuries that can become life threatening.
- Adequate chemical restraints with benzodiazepines are needed to prevent excessive muscular activity leading to rhabdomyolysis.
- Dextromethorphan is a common cause for a false-positive PCP urine toxicology screen.
- Tramadol has been reported to cause a false-positive screen for PCP
- Ketamine abuse presents with similar signs and symptoms of PCP abuse.

ICD10

T40.991A Poisoning by oth psychodyslept, accidental, init

PHENYTOIN POISONING

Michele Zell-Kanter

BASICS

DESCRIPTION

- Phenytoin follows zero-order pharmacokinetics:
 - Small incremental increase in dose can result in a large increase in plasma concentration.
- Half-life in overdose prolonged; may be up to 70 hr
- Cardiovascular toxicity from IV administration likely due to the diluent propylene glycol
- Fosphenytoin, a prodrug for parenteral administration, is metabolized to phenytoin, its active moiety.

ETIOLOGY

- Phenytoin intoxication results from acute, chronic, or acute-on-chronic administration.
- If the cause of the intoxication is unclear in a patient receiving chronic phenytoin therapy, consider that there may have been a:
 - Change in the brand of phenytoin
 - Change in dosage form
 - Drug interaction
 - Change in serum albumin

DIAGNOSIS

SIGNS AND SYMPTOMS

- Level 20–40 $\mu\text{g/mL}$ (or mg/L):
 - Nystagmus
 - Dizziness
 - Ataxia
 - Drowsiness
 - Nausea/vomiting
 - Diplopia
 - Slurred speech
- Level 40–90 $\mu\text{g/mL}$:
 - Confusion
 - Disorientation
- Level >90 mg/mL :
 - Coma

- Respiratory depression
- Paradoxical seizures
- Hypotension/bradycardia with rapid IV administration:
 - Fosphenytoin injection does not contain propylene glycol
 - Hypotension/dysrhythmia unlikely with fosphenytoin
- Hypersensitivity reaction following chronic use:
 - Rash
 - Fever
 - Neutropenia
 - Agranulocytosis
 - Hepatitis
 - Cholangitis

ESSENTIAL WORKUP

- Determine the time, route, and amount of ingestion.
- Phenytoin level:
 - After oral overdose, the peak plasma concentration may not be reached until 24 hr or more post acute ingestion.
 - Absorption differs with various oral preparations and manufacturers
 - Repeat levels every 4 hr until levels have peaked and continue to steadily decline.
 - Once levels begin declining, check every 24 hr until $< 30 \mu\text{g/mL}$.
 - Free phenytoin level may be required in patients who are hypoalbuminemic or patients who are poor metabolizers.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Fosphenytoin level:
 - Measured as phenytoin
 - Measure fosphenytoin after conversion to phenytoin is complete (2 hr post IV infusion or 4 hr post IM injection).
 - Prior to complete conversion to phenytoin, immunoanalytic techniques may overestimate plasma phenytoin concentrations due to cross-reactivity with fosphenytoin.
- Electrolytes, BUN, creatinine, glucose:
 - Check for anion gap metabolic acidosis due to coingestant, seizure activity, from propylene glycol in the IV formulation
 - Determine glucose with altered mental status.

DIFFERENTIAL DIAGNOSIS

- Intoxication with other CNS depressants
- Guillain–Barré syndrome

- Botulism
- Posterior fossa tumor
- Acute cerebellitis

TREATMENT

PRE HOSPITAL

- Differentiate phenytoin-induced altered mental status from other potentially serious causes:
 - _ Head trauma common in seizure population
- Collect/transport prescription bottles and medications to aid in identification and quantification of ingestion

INITIAL STABILIZATION/THERAPY

- ABCs:
 - _ IV access
 - _ Cardiac monitor (with IV overdose)
- For altered mental status:
 - _ Accu-Chek.
 - _ Administer naloxone, dextrose, and thiamine as indicated.
- Treat hypotension with IV fluids and Trendelenburg position:
 - _ Dopamine for refractory hypotension
- Treat paradoxical seizures with diazepam.

ED TREATMENT/PROCEDURES

- Provide supportive care
- Activated charcoal
 - _ Administer single dose.
 - _ Multiple-dose activated charcoal may increase the clearance of phenytoin; does not correlate with clinical improvement in patients with phenytoin toxicity.

MEDICATION

- Activated charcoal slurry: 1–2 g/kg up to 90 g PO
- Dextrose: D50W 1 amp: 50 mL or 25 g (peds: D25W 2–4 mL/kg) IV
- Dopamine: 2–20 µg/kg/min IV titrated to desired BP
- Naloxone (Narcan): 2 mg (peds: 0.1 mg/kg) IV or IM initial dose
- Thiamine (vitamin B₁): 100 mg (peds: 50 mg) IV or IM

FOLLOW-UP

DISPOSITION

Admission Criteria

- Altered mental status, severe ataxia, increasing phenytoin level
- Level $> 25 \mu\text{g/mL}$
- ICU admission with intoxication from IV phenytoin
- Fall precautions

Discharge Criteria

- Level $\leq 25 \mu\text{g/mL}$
- Ambulatory without ataxia

FOLLOW-UP RECOMMENDATIONS

- Psychiatric referral for intentional ingestions/suicide attempts.
- Close primary care follow-up to check phenytoin levels.
- Anticipate altered pharmacokinetics and phenytoin levels with any change in manufacturer or dosage formulation

PEARLS AND PITFALLS

- Small incremental increases in dose of phenytoin can result in toxicity since phenytoin follows zero-order kinetics.
- Repeat phenytoin levels every 4 hr until declining.

ADDITIONAL READING

ICD10

T42.0X1A Poisoning by hydantoin derivatives, accidental, init

PHEOCHROMOCYTOMA

David N. Zull

BASICS

DESCRIPTION

- Pheochromocytoma (pheo) is a catecholamine-producing tumor arising from the chromaffin tissues of the sympathetic nervous system.
- Origin from the adrenal medulla or sympathetic ganglia:
 - 80% solitary adrenal (usually the right side)
 - 10% bilateral (usually inherited form)
 - 10% extra-adrenal in location:
 - Abdominal, within mesenteric ganglia (86%)
 - Thorax (10%), neck (3%), bladder (1%)
 - 10% malignant (usually inherited form)
- Incidence:
 - 0.2–0.4% of hypertensive patients, but higher proportion of patients with severe hypertension
 - 2–8/million population per year
 - Peaks in decades 3–5, 10% in children
 - Male = female
 - In about 1/2 of the cases, the diagnosis is made postmortem.
 - 10% asymptomatic, incidental on CT
- Genetics:
 - Inherited form 25%, autosomal dominant
 - Usually associated with multiple endocrine neoplasia (MEN) 2A, less so with MEN 2B or von Hippel–Lindau (VHL) disease:
 - MEN 2A (medullary thyroid carcinoma [CA], pheo, and hyperparathyroidism)
 - MEN 2B (medullary thyroid CA, pheo, oral mucosal neuromas, skeletal and bony abnormalities)
 - VHL (hemangioblastomas of retina and CNS, pancreas and renal cysts, and pheo)
 - Other associated diseases: Neurofibromatosis, tuberous sclerosis, Sturge–Weber syndrome, paragangliomas of the neck

ETIOLOGY

- The tumor synthesizes and stores catecholamines in the same manner as the normal adrenal medulla.
- Tumors predominantly secrete norepinephrine, and to a lesser extent epinephrine (some tumors are epinephrine predominant, in which hypotensive episodes are

characteristic)

- Paroxysmal release of catecholamines:
 - Spontaneously due to changes in blood flow or tumor necrosis
 - Direct pressure on the gland from external forces (trauma, exercise)
 - Precipitation of release (opiates, glucagon, metoclopramide, steroids, foods with tyramine, iodinated contrast media)
 - Augmentation of catecholamine effect (tricyclic antidepressants [TCAs], β -blockers, sympathomimetics)

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Hypertension, moderate to severe, refractory to treatment:
 - 40%: Paroxysms with normal BP between episodes
 - 30%: Sustained hypertension with paroxysms
 - 30%: Sustained hypertension without paroxysms
 - Sometimes normotensive in familial forms and small tumors: < 5%
- Paroxysmal symptoms
 - Sudden onset, gradual resolution
 - Duration: Minutes to hours (average 20 min)
 - Intervals: Hours to months (average weekly)
 - Increasing frequency, duration, and severity with time
- Clinical characteristics of paroxysms
 - Hypertensive crisis or urgency
 - Headache – abrupt, throbbing, bilateral
 - Tachycardia/palpitations
 - Profuse diaphoresis/pallor
 - Apprehension/anxiety/tremulous
 - Shock associated with trauma, surgery, parturition, anesthesia
- Acute crisis
 - Prolonged (> 24hr) severe paroxysm
 - Severe HTN or shock, hyperpyrexia
 - Multiorgan failure/lactic acidosis
 - Pulmonary edema due to cardiomyopathy (dilated, hypertrophic or Takotsubo)
 - Stroke (SAH, PRES, RCVS, embolic)
 - Severe headache/encephalopathy
 - Chest pain (MI/dissection)
 - Acute abdomen
 - Hemorrhagic tumor necrosis

- Mesenteric infarction

- Chronic symptoms
 - Chest pains/palpitations
 - Orthostasis (decreased plasma volume and blunted sympathetic reflexes)
 - Constipation can be severe, leading to ileus or pseudo-obstruction (catecholamines inhibit peristalsis)
 - Weight loss/fevers (increased metabolism)
 - Lethargy, fatigue (catecholamine withdrawal))
 - Polydipsia, polyuria (glucose intolerance)
 - Anxiety, tremors, heat intolerance

Physical-Exam

- Moderate to severe hypertension, often with orthostatic changes
- Tachycardic, diaphoretic, evidence of weight loss, low-grade fever
- Pallor, cold hands and feet (flushing not seen, except rarely after a paroxysm)
- Tremor, anxiety
- Mydriasis, hypertensive retinopathy
- Café au lait spots, neurofibromas, thyroid nodule
- No palpable masses (tumors tend to be small)

ESSENTIAL WORKUP

- Accurate BP determination with orthostatic BPs
- ECG to exclude ischemia or dysrhythmias

DIAGNOSIS TESTS & INTERPRETATION

- Overdiagnosis in > 20% from misinterpretation of borderline biochemical tests and overzealous imaging
- Underdiagnosis is common from failure to consider the diagnosis or ignoring adrenal masses on CT.

Lab

- CBC:
 - Elevated hemoglobin due to diminished plasma volume
 - Elevated WBC from demargination
- Electrolytes, BUN, creatinine, glucose:
 - Lactic acidosis
 - Renal failure secondary to hypertensive nephropathy
 - Hyperglycemia due to impaired response to insulin and effect of catecholamines
 - Hypercalcemia due to excess parathyroid hormone
- Urinalysis: Proteinuria and hematuria
- Plasma-free metanephrine (fractionated):
 - 96% sensitive, 85% specific—best screening test. Normal level excludes

- diagnosis, but many false positives
- Least likely to be interfered by medications or stress and no special prep for venipuncture
- 24 hr urine collection for free catecholamines and metanephrine (total and fractionated):
 - 99.7% combined specificity and 87.5% sensitivity (best test for confirmation)
 - Must include creatinine to verify adequate collection
 - Medications that interfere: Levodopa, methyldopa, monoamine oxidase inhibitors (MAOIs), labetalol, propranolol, radiographic contrast media, sympathomimetics, benzodiazepines, TCAs, caffeine, nicotine

Imaging

- CT sensitive for adrenal masses > 1 cm (IV contrast may pose a slight risk):
 - 5% of incidental adrenal tumors seen on CT are pheos.
- MRI or positron emission tomography more sensitive in identifying adrenal pheos as well as identifying extra-adrenal tumors
- Metaiodobenzylguanidine (radionuclear scintiscan: High specificity for localization, but not sensitive enough to exclude pheo)
- Chest radiograph for pulmonary edema
- CT head for CVA/intracranial bleed

Diagnostic Procedures/Surgery

- Clonidine suppression test if diagnosis uncertain (levels not suppressed if pheo)
- Provocative testing with glucagon is not recommended.
- Fine-needle aspiration is contraindicated.
- Laparoscopic resection is feasible in many cases.

DIFFERENTIAL DIAGNOSIS

- Alcohol withdrawal syndrome
- Autonomic hyperreflexia
- Cerebral vascular accident
- Cocaine or amphetamine intoxication
- Hypertensive crisis
- Migraines/subarachnoid hemorrhage
- Panic attack
- Postural tachycardia syndrome
- Paroxysmal supraventricular tachycardia
- Posterior reversible encephalopathy syndrome
- Serotonin syndrome
- Thyrotoxicosis
- Toxemia

TREATMENT

PRE HOSPITAL

- IV access, oxygen
- Continuous cardiac/BP monitoring
- Nitroglycerin 0.4 mg SL for chest pain and HTN

ED TREATMENT/PROCEDURES

Management of Hypertensive Paroxysm

- Phentolamine: α -blockade:
 - 1 mg IV test dose
 - 2.5–5 mg IV bolus given at 1 mg/min repeat bolus every 5–15 min to BP control. Follow by infusion
 - Infusion starting at 0.1 mg/min titrated up to 1 mg/min
 - Vigorous fluid resuscitation required as vasoconstriction is relieved
 - Traditional approach, but Nicardipine or Nitroprusside drip may be more practical
- β -blockade:
 - Add to α -blockade for further BP control
 - If tachycardia develops during induction of α -blockade
 - NEVER USE ALONE: Institution of β -blockade without prior α -adrenergic blockade may exacerbate hypertension by antagonizing β -mediated vasodilation in smooth muscle.
 - Esmolol: Load 500 μ g/kg over 1 min, followed by 50 μ g/kg/min for 4 min; if adequate therapeutic effect not achieved within 5 min, repeat loading dose and increase infusion to 100 μ g/kg/min; repeat loading dose and titrate infusion rate upward at 50 μ g/kg/min q4–q5min as needed; omit further loading doses once nearing therapeutic target.
 - Labetalol: Begin with 10–20 mg IV; BP falls within 5 min, maximum effect at 10 min; can double IV dose q15–q30min until target reached (α -blockade inadequate to be relied on as a single agent).
 - Metoprolol: 5 mg IV q15min until response
- Resistance to α - and β -blockade or 1st-line option if unfamiliar with Phentolamine:
 - Nitroprusside:
 - Start at 0.5 μ g/kg/min
 - Titrate by 0.5 μ g/kg/min increments
 - Maximum dose 10, average needed 3–4
 - Nicardipine:
 - Start infusion at 5 mg/hr
 - Titrate up by 2.5 mg/hr every 15 min
 - 15 mg/hr maximum dose

- Add β -blockade to vasodilator if needed
- Ventricular tachydysrhythmias:
 - Lidocaine:
 - 50–100 mg bolus
 - Repeat bolus q5min (5 mg/kg max.)
 - Esmolol 50–200 μ g/kg/min infusion

MEDICATION

First Line

- Phenoxybenzamine: Start at 10 mg BID orally, titrate up 10 mg every other day until desired effect (start at least 7 days preop).
- Other α -blockers (1st dose effect):
 - Doxazosin: 1–8 mg/d (start at 1 mg)
 - Terazosin: 1–10 mg/d (start at 1 mg)
- β -blocker added to control reflex tachycardia:
 - Metoprolol or atenolol: 25–100 mg/d

Second Line

- Calcium-channel blockers:
 - Amlodipine, nifedipine, or nifedipine
- Inhibition of catecholamine synthesis:
 - Metyrosine: 250–500 mg q6h

ALERT

The following medications can precipitate hypertensive crisis in pheo:

- β -blockers (if not pretreated with α -blocker)
- Glucagon
- Glucocorticoids
- Iodinated contrast media (ionic)
- Ketamine
- Metoclopramide
- Opiates
- Sympathomimetics, including over-the-counter decongestants

Pregnancy Considerations

- May be confused with toxemia, but proteinuria is usually absent
- MRI is the preferred imaging modality.
- Nitroprusside should not be used for hypertensive crisis, but all other BP medications are acceptable.
- Spontaneous vaginal delivery will likely precipitate hypertensive crisis, such that C-section should be planned.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Suspicion of pheo in an ill or toxic patient with labile swings in BP
- Hypertensive urgency or crisis
- Cardiac arrhythmias
- End organ compromise: Congestive heart failure, myocardial infarction, renal insufficiency, CVA, abdominal pain

Discharge Criteria

Stable patient with mild hypertension.

FOLLOW-UP RECOMMENDATIONS

- Obtain plasma-free metanephrine during a hypertensive episode.
- Consider initiating doxazosin or terazosin or a calcium-channel blocker for BP control.
- Arrange close follow-up

PEARLS AND PITFALLS

- Paroxysms of severe hypertension, headache, intense diaphoresis, and palpitations comprise a tetrad very suggestive of pheo.
- Pallor and sweating, not flushing, is typical of pheo crisis.
- Orthostasis is common in pheo and it is further aggravated by α -blockade, unless volume repletion is not done concomitantly.
- Consider pheo in unexplained shock, multisystem organ failure, cardiomyopathy, new glucose intolerance with weight loss.
- Never administer β -blockers (even labetalol) before α -blockade in patients with pheo
- Plasma-free metanephrine during an attack is very sensitive but not specific in the diagnosis

- D35.00 Benign neoplasm of unspecified adrenal gland

PHIMOSIS

Nicole M. Franks

BASICS

DESCRIPTION

- True phimosis is the pathologic inability to retract the foreskin over the glans of the penis as a result of scarring.
- The inability to retract a normal, supple foreskin is not true phimosis.
- The foreskin is rarely retractable at birth due to normal adhesions between the glans and the inner prepuce.
- ~90% are retractable by 3 yr of age, and 99% are retractable by 17 yr, as the epithelial cells that comprise smegma are shed.
- Parents should be instructed not to forcibly retract the foreskin.

ETIOLOGY

Possible causes of true phimosis include:

- Trauma from forcible retraction of the foreskin
- Repetitive bouts of diaper dermatitis
- Recurrent balanoposthitis
- Poor hygiene
- Poorly performed circumcision
- Congenital anomalies

DIAGNOSIS

SIGNS AND SYMPTOMS

- Dysuria, hematuria
- Poor urinary stream
- Whitish, narrowed preputial opening of the foreskin
- Edema, erythema, and tenderness of prepuce
- *Balanoposthitis* (inflammation of the glans and foreskin)
- Ballooning of foreskin on urination in severe cases

Physical-Exam

Exam should include an evaluation for potential complications:

- Obstruction and vascular compromise of glans
- Occur only in the most extreme cases

ESSENTIAL WORKUP

- In the majority of cases, no workup is necessary.

- In patients with severe stenosis, the complication of an *obstructive uropathy* may occur. This should be investigated by:
 - Evaluation of kidney function:
 - BUN and creatinine
 - Renal sonogram
- Phimosis secondary to recurrent balanoposthitis should prompt a workup for *diabetes mellitus*:
 - Urinalysis, serum glucose, or glycosylated hemoglobin (Hgb A1C)

DIFFERENTIAL DIAGNOSIS

- Preputial adhesions are normal in young children.
- Balanoposthitis without phimosis

TREATMENT

PRE HOSPITAL

- Pre-hospital personnel and family members should be instructed not to attempt retraction of the foreskin prior to medical evaluation.
- Unwarranted attempts may traumatize a normal, nonretractable prepuce or convert the situation to a more emergent *paraphimosis*.

INITIAL STABILIZATION/THERAPY

None required in most cases

ED TREATMENT/PROCEDURES

- Relieve obstructive uropathy, if present, with urethral catheterization or suprapubic aspiration.
- If vascular flow to the glans is compromised, a dorsal slit must be made in the foreskin:
 - Performed after achieving adequate penile block (see Paraphimosis for more detailed description of procedure)
 - This is rarely necessary in phimosis.
- Potent topical steroids for a multiweek course have been reported to successfully reduce phimosis:
 - Betamethasone dipropionate 0.05–0.1%: Apply to preputial orifice twice daily for 4–6 wk.

Pediatric Considerations

For foreskin incision, procedural sedation will likely be needed in place of penile block.

MEDICATION

Pain control as required

FOLLOW-UP

DISPOSITION

Admission Criteria

- Obstructive uropathy
- Severe balanoposthitis with ischemia or necrosis

Discharge Criteria

- Ability to urinate
- Adequate urologic follow-up

Issues for Referral

Urologic follow-up for response to steroid therapy, dilation of the preputial opening, operative repair, or elective circumcision as necessary

FOLLOW-UP RECOMMENDATIONS

Physiologic phimosis requires waiting for age-appropriate development and continued preputial hygiene.

PEARLS AND PITFALLS

- Foreskin is normally nonretractable from the neonatal period to age 3 yr.
- Do not forcibly retract foreskin especially in children 3–17 yr, as phimosis may still be physiologically normal.
- Vascular compromise of the glans penis requires a dorsal slit to the foreskin to prevent necrosis.

PITYRIASIS ROSEA

Benjamin S. Heavrin

BASICS

DESCRIPTION

- A self-limited skin exanthem of unknown origin primarily affecting children and young adults
- Skin findings often begin with an isolated “herald patch,” an ovoid erythematous raised lesion seen along the trunk and extremities
- A secondary eruption usually follows, where multiple smaller exanthems appear along the Langer lines of the trunk and proximal extremities in a symmetric “Christmas tree pattern”
- Nearly 80% of symptoms resolve within 2 mo

ETIOLOGY

- Unknown, although there is weak evidence for a viral etiology such as herpes 6 and 7
- Many medications have been associated with a pityriasis-like reaction:
 - Barbiturates
 - Captopril
 - Clonidine
 - Gold
 - Isotretinoin
 - Metronidazole
 - Bismuth
 - Hepatitis B vaccine
 - Gleevec
 - Interferon
- Eczema, asthma, and underlying malignancies may be weakly associated

DIAGNOSIS

SIGNS AND SYMPTOMS

Prodromal symptoms and characteristic skin findings are discussed below

History

Prodromal symptoms occur in 60–70% of patients:

- Malaise
- GI symptoms
- Respiratory symptoms

Physical-Exam

Dermatologic findings

- Herald patch:
 - Solitary, erythematous, slightly raised papule 2–10 cm in diameter
 - Seen in 50–90% of cases
- Secondary eruption:
 - Widespread salmon-colored, elliptic, finely scaling papules
 - Usually appear symmetrically along Langer lines in a “Christmas tree” pattern
 - Generally follows herald patch by 7–14 days
 - Lesions are concentrated on the trunk and proximal extremities
 - Pruritus is common
- Lesions concentrated on the face and distal extremities with minimal trunk involvement characterize *inverse pityriasis*

Pediatric Considerations

- Inverse pityriasis, lesions on the face and distal extremities characterize *inverse pityriasis* and may be seen more often in pediatric populations
- Rarely, pediatric presentations may have oral lesions, usually punctate hemorrhage and ulceration

ESSENTIAL WORKUP

Exclude other diagnoses, especially when a herald patch is not seen:

- Secondary syphilis can have similar skin findings. Consider RPR in a patient with STI risk factors
- KOH prep may diagnose tinea

DIAGNOSIS TESTS & NTERPRETATION

Lab

None required:

- KOH and RPR if other diagnoses are considered

DIFFERENTIAL DIAGNOSIS

- Herald patch:
 - Nummular eczema
 - Tinea corporis
- Secondary eruption:
 - Secondary syphilis
 - Drug eruption
 - Guttate psoriasis
 - Kaposi sarcoma
 - Lichen planus

- Occult malignancy
- Scabies
- Seborrheic dermatitis
- Tinea versicolor
- Dermatomyositis
- Cutaneous lymphoma
- Lupus

TREATMENT

INITIAL STABILIZATION/THERAPY

None required

ED TREATMENT/PROCEDURES

- Pityriasis is self-limiting
- Pruritus may improve after treatment with steroids, antihistamines, and, interestingly, erythromycin

MEDICATION

- Diphenhydramine: Adult: 25–50 mg PO QID (peds: 5 mg/kg/d div. QID)
- Erythromycin: 400 mg (peds: 10 mg/kg) PO QID
- Hydrocortisone: 1% cream TID
- Prednisone: 15–40 mg (peds 0.25–0.5 mg/kg) daily

First Line

- Diphenhydramine: Adult: 25–50 mg PO QID (peds: 5 mg/kg/d div. QID)
- Hydrocortisone: 1% cream TID

Second Line

- Prednisone: 15–40 mg (peds 0.25–0.5 mg/kg) daily
- Erythromycin: 400 mg (peds: 10 mg/kg) PO QID

FOLLOW-UP

DISPOSITION

Admission Criteria

Pityriasis rosea is a self-limited disease; admission is not required

Discharge Criteria

Patients with a clear diagnosis of pityriasis rosea may be discharged

Issues for Referral

Severe refractory pruritus may require dermatology follow-up

FOLLOW-UP RECOMMENDATIONS

- With primary care provider as needed
- Symptoms usually resolve over 1–2 mo

PEARLS AND PITFALLS

- Pityriasis is usually limited to the proximal extremities and trunk. Consider alternative diagnoses beyond *inverse pityriasis* in a patient with mucous membrane or distal extremity involvement.
- Consider alternative diagnoses in those patients who appear toxic or have atypical presentations.

696.3 Pityriasis rosea

ICD10

L42 Pityriasis rosea

PLACENTAL ABRUPTION

Rebecah W. Schwartz

BASICS

DESCRIPTION

- Hemorrhage at the decidual–placental interface leading to complete or partial separation of the normally implanted placenta before delivery of the fetus
- Incidence/prevalence:
 - ~ 1% of all pregnancies
 - 30% of bleeding episodes in the 2nd half of pregnancy
 - 15% of all fetal deaths
 - Neonatal death in 10–30% of cases
 - 6% of all maternal mortality
- Synonym(s): Abruptio placentae, accidental hemorrhage (in UK)

ETIOLOGY

- Primary cause unknown
- Vascular injury with dissection of blood into the decidua basalis or mechanical shearing between the placenta and uterus leading to bleeding and clot formation
- More severe cases lead to:
 - Development of disseminated intravascular coagulation (DIC)
 - Maternal–fetal compromise
- Research suggests that the majority of abruptions are due to chronic processes:
 - Inflammatory changes in the placenta
 - Manifestation of ischemic placental disease
- Acute abruption can occur due to:
 - Trauma
 - Rapid uterine decompression
 - Placenta implantation over a uterine anomaly or fibroid
- Multiple known risk factors:
 - Previous abruption (10–20% recurrence risk)
 - Maternal hypertension (> 140/90) and preeclampsia
 - Increased parity and maternal age
 - Multiple gestation
 - Fibroids or other uterine/placental abnormalities
 - Tobacco use
 - Cocaine abuse
 - Trauma
 - Premature rupture of membranes, particularly if associated with chorioamnionitis or oligohydramnios

- Rapid uterine decompression:
 - Polyhydramnios with membrane rupture
 - Rapid delivery of 1st twin
- Elevated 2nd trimester maternal serum α -fetoprotein
- Thrombophilias
- Maternal race:
 - More common among African American and Caucasian women
 - Incidence increasing more rapidly among African American women

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- 20+ wk of pregnancy
- Vaginal bleeding (> 80%, *usually painful*)
- Abdominal or back pain (> 50%)
- Uterine cramps, tenderness, frequent contractions, or tetany
- Nausea, vomiting
- Otherwise unexplained preterm labor
- History of recent trauma should be elicited
- Recent drug use, particularly cocaine or other sympathomimetics
- Prior abruption or other risk factors
- Estimated gestational age
- Prenatal care history

Physical-Exam

- Signs of *hypotensive shock* may be present
- Uterine tenderness frequently present
- Vaginal bleeding (absent in 20–25%)
- Petechiae, bleeding, and other signs of DIC
- Decreased fetal heart tones and movement
- Fetal bradycardia or nonreassuring fetal heart rate tracings

ALERT

- Sterile vaginal exam must be performed with caution to avoid tissue injury, especially if placenta previa suspected:
 - Assess for presence of amniotic fluid (nitrazine paper turns blue; ferning of fluid on glass slide)
 - Evaluate for vaginal or cervical lacerations

ESSENTIAL WORKUP

- Large-bore IV access

- Blood type, Rh, and cross-match
- Rapid hemoglobin determination
- Determine fetal heart tones by Doppler
- Fetal monitoring to detect signs of early fetal distress
- Uterine tocographic monitoring

DIAGNOSIS TESTS & INTERPRETATION

Diagnosis is primarily clinical, supportive tests include

Lab

- Blood type and Rh
- CBC
- PT/PTT
- Fibrinogen levels (normally 450 in latter half of pregnancy) and fibrin split products
- Fibrinogen < 200 mg/dL and platelets < 100,000/ μ L highly suggestive of abruption
- Kleihauer–Betke if mother Rh-negative (significant fetal-to-maternal hemorrhage more likely in traumatic abruption)

Imaging

- US demonstrates evidence of abruption in only 50% of cases (false-negative common)
- MRI sensitive but impractical
- If abdomen/pelvis CT scan done as part of maternal trauma evaluation, evidence of abruption may be visible (must ask the radiologist to evaluate specifically)

DIFFERENTIAL DIAGNOSIS

- Placenta previa
- Bleeding during labor
- Vaginal or cervical lacerations
- Uterine rupture
- Preterm labor
- Ovarian torsion
- Pyelonephritis
- Cholelithiasis/cholecystitis
- Appendicitis
- Other blunt intra-abdominal or pelvic injuries

TREATMENT

PRE HOSPITAL

- Patients with abruption may be in shock and need full resuscitative measures
- Transport in the left lateral recumbent position

INITIAL STABILIZATION/THERAPY

- Airway, breathing, circulation (ABCs), oxygen
- Cardiac monitor
- Placement of large-bore IVs
- IV crystalloid resuscitation

ED TREATMENT/PROCEDURES

- Maternal cardiac and tocographic monitoring
- Continuous fetal monitoring
- Transfuse PRBCs, fresh frozen plasma (FFP), cryoprecipitate, and platelets as indicated (may require massive transfusion protocol)
- Immediate OB/GYN consultation
- Foley catheter for close monitoring of urine output
- Tocolysis is generally contraindicated
- If abruption is suspected in the setting of trauma, maternal stabilization is of primary importance:
 - All indicated radiographs should be performed as needed

MEDICATION

First Line

- Rh-immunoglobulin in Rh-negative women:
 - 300 µg IM in women at ≥ 12 wk gestation
 - Higher doses if indicated by results of Kleihauer–Betke test
- Blood products as indicated

Second Line

Consider with obstetrician recommendation:

- Magnesium sulfate if tocolysis is indicated
- Steroids for fetal lung maturation if gestational age between 24 and 34 wk

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with placental abruption must be admitted for maternal and fetal monitoring
- Admit to ICU if DIC, amniotic fluid embolism, or significant hemorrhage (known

or suspected)

- Victims of multiple trauma with abruption should be admitted and managed in accordance with trauma protocols
- Transportation to higher trauma or obstetric level of care is appropriate if the patient is stable for transfer or appropriate care unavailable at existing facility

Discharge Criteria

- Trauma patients with no evidence of abruption or other significant injury may be discharged after 4–6 hr of normal maternal and fetal monitoring
- Discharge instructions include pelvic rest, no intercourse, no heavy lifting, no prolonged standing
- Discharge decision should be made in consultation with OB/GYN and include close follow-up

Issues for Referral

All cases of confirmed or suspected abruption require immediate obstetric consultation

PEARLS AND PITFALLS

- Primarily a clinical diagnosis: No single test reliably confirms or rules out placental abruption
- Hypotension typically occurs late in the course of hypovolemic shock in pregnancy
- Anticipate a consumptive coagulopathy and consider the need for blood products early in presentation
- Abruption may be associated with severe preeclampsia, causing a hypovolemic patient to be normotensive:
 - Maintain a high index of suspicion for preeclampsia in patients with severe abruption and no obvious cause

CODES

ICD9

- 641.20 Premature separation of placenta, unspecified as to episode of care or not applicable
- 641.21 Premature separation of placenta, delivered, with or without mention of antepartum condition
- 641.23 Premature separation of placenta, antepartum condition or complication

ICD10

- O45.90 Premature separation of placenta, unsp, unsp trimester
- O45.91 Premature separation of placenta, unsp, first trimester
- O45.92 Premature separation of placenta, unsp, second trimester

PLACENTA PREVIA

Roneet Lev

BASICS

DESCRIPTION

- Placental tissue overlying or proximate to the internal cervical os
- Uterine enlargement and cervical dilation cause placental vessels near the cervix to tear, resulting in vaginal bleeding
- >90% of placenta previa diagnosed before 20 weeks will migrate and have normal placental location at term
- If placenta covers the internal os by >20 mm, then previa is expected at birth
- Increased amount of placental overlap (>15–23 mm) predicts placenta previa present at birth
- Causes 20% of all antepartum hemorrhage
- Classifications:
 - Complete placenta previa: Cervical os is completely covered by placenta
 - Partial placenta previa: Cervical os is partially covered by placenta
 - Marginal placenta previa: Edge of placenta is at margin of cervical os
 - Low-lying placenta: Placenta edge is within 2 cm to cervical os

ETIOLOGY

- Unknown etiology
- Incidence: 4/1,000 births = 0.4% of pregnancies at term
- Maternal mortality: 0.03%
- Perinatal morbidity and mortality: Triple, due to preterm delivery
- Factors affecting location of implantation:
 - Increased number of curettages from spontaneous or induced abortions
 - Abnormal endometrial vascularization
 - Delayed ovulation
- Risk factors:
 - Multiparity (5% grand multiparous patients vs. 0.2% nulliparous)
 - Multiple gestation
 - Prior C-section (up to 3× increase, increases with number or prior C-sections)
 - Increased maternal age (0.7% age <19 yr, 1% age ≥35 yr)
 - Previous placenta previa (4–8% recurrence)
 - Smoking (2–4 times increase)
 - Male fetus (14% increase)
 - Assisted fertilization
 - Residence at higher altitude

- Asian maternal race
- Unexplained elevated maternal serum alpha fetal protein (MSAFP)
- Associated conditions:
 - Congenital anomalies
 - Abnormal fetal presentation
 - Preterm premature rupture of the membranes
 - Amniotic fluid embolism; associated with pathologies of the placenta
 - Vasa previa: Fetal vessels course through membranes and cover os
 - Placenta accreta, increta, percreta (growth of placenta into uterine wall) occur in 5–10% of patients with placenta previa; sustained bleeding may require C-section hysterectomy

DIAGNOSIS

SIGNS AND SYMPTOMS

Painless vaginal bleeding in pregnancy after 20 wk is placenta previa until proven otherwise

History

- Painless bright red vaginal bleeding in 70%
- Uterine contraction in 20%
- Common incidental finding on US in 2nd trimester (6% at 16–18 wk)
- 1st episode of bleeding typically occurs at 27–32 wk
- Bleeding may range from minor to massive; number of bleeding episodes does not correlate with degree of placenta previa
- Inciting factors—usually no cause; recent intercourse or heavy exercise may contribute
- Initial bleeding is often self-limited and not lethal, but often recurs

Physical-Exam

- Never do a digital exam or instrument probe of the cervix in 2nd-trimester vaginal bleeding until placenta previa is ruled out
- Sterile speculum exam can be safely performed prior to US to identify if blood is from the os, a vaginal lesion, or hemorrhoids
- Blood seen at patient's feet is a sign of heavy bleeding
- Hypotension and tachycardia may indicate hemorrhagic shock
- Fetal heart tones should be monitored along with other vital signs

ESSENTIAL WORKUP

Vaginal ultrasonography is the diagnostic procedure of choice

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC, platelets
- Type and screen; upgrade to cross-match if transfusion is indicated
- Kleihauer–Betke (KB)—detects > 5 mL of fetal cells in maternal circulation (it takes only 0.1 mL to sensitize mother if Rh negative)
- If coagulopathy suspected (rare): Prothrombin time/partial thromboplastin time, fibrin-split products, fibrinogen (< 300 mg/dL is abnormal)
- Rh status

Imaging

- Transabdominal US: 93–98% accurate:
 - _ False negative: Obesity, posterior or lateral placenta, fetal head over cervical os
 - _ False positive: Overdistended bladder
 - _ No sufficient accuracy for placenta previa position, need to obtain transvaginal US if placenta previa is detected or uncertain findings
- Transvaginal US: 100% accurate:
 - _ Vaginal probe does not exacerbate bleeding
- Color flow Doppler US: Used to determine placenta accreta
- MRI: May be useful in evaluating placental abnormalities such as accreta and percreta

DIFFERENTIAL DIAGNOSIS

- Placenta abruption (may occur concurrently)
- Uterine rupture
- Fetal vessel rupture
- Cervical/vaginal trauma
- Cervical/vaginal lesions
- Bleeding disorder
- Spontaneous abortion
- “Bloody show” of labor

TREATMENT

PRE HOSPITAL

- Patient with vaginal bleeding at > 24 wk should be transported to a facility that can handle high risk and premature delivery
- Place patient in left lateral recumbent position if hypotensive in 2nd half of pregnancy
- O₂ and IV as with other patients

INITIAL STABILIZATION/THERAPY

- Resuscitation for hemorrhagic shock as with any source with monitoring of fetus and higher cut off of blood transfusion
- ABCs
- 2 large-bore IVs with normal saline (NS) or lactated Ringer (LR) for resuscitation
- Left lateral recumbent position if hypotensive in 2nd half of pregnancy
- Fluid resuscitation
- Blood transfusion for hematocrit (Hct) < 30 or hypotension not responding to fluids
- Fresh-frozen plasma if coagulopathy
- Fetal monitoring (heart rate < 120 or > 160 bpm is abnormal)
- Immediate OB consultation for symptomatic patients

ED TREATMENT/PROCEDURES

- Emergent OB consultation for patients with active bleeding
- Volume resuscitation with 2 large-bore IVs with NS or LR
- Blood transfusion to keep Hct 30–35%
- RhoGAM if mother is Rh negative
- Fetal monitoring
- Keep NPO and on bed rest until considered stable by OB
- Magnesium sulfate only for contractions of preterm labor when delivery is not recommended
- Antenatal steroids (betamethasone) at 24–34 wk to stimulate prenatal lung maturity
- Emergency C-section or delivery for continued bleeding or fetal compromise

MEDICATION

- RhoGAM: 1 vial (300 µg) IM if not already given at 28 wk; may need > 1 vial if KB indicates > 15 mL of fetal RBS
- Magnesium sulfate: 6 g IV over 20 min, then 2–4 g/h; adjust to contractions
- Betamethasone: 12 mg IM q24h × 2 doses

FOLLOW-UP

DISPOSITION

Admission Criteria

- Active bleeding placental previa is a potential obstetric emergency, and all patients should be admitted
- Select patients may be managed on outpatient basis if bleeding is resolved. In consultation with OB

Discharge Criteria

- Asymptomatic patients
 - Bed rest is not necessary. Avoid strenuous physical activity. Report bleeding or contractions
 - <20 wk and placenta not over the os: No special follow up necessary
 - <20 wk and placenta 0–20 mm: Repeat US at 28 wk
 - Placenta >20 mm over os is unlikely to resolve. C-section at 36–37 wk
 - Pelvic rest (no intercourse or tampons in vagina) if placenta previa found after 28 wk or at any time if associated with bleeding
- 70% of patients will have a 2nd episode of bleeding

FOLLOW-UP RECOMMENDATIONS

Patients with incidental finding of placenta previa found at <20 wk will need outpatient US to determine migration of placenta

PEARLS AND PITFALLS

- Do not perform digital vaginal exam if suspect vaginal bleeding after 2nd trimester. Do US first
- Sterile speculum exam and transvaginal US are safe and do not increase bleeding
- Painless vaginal bleeding after 20 wk is placenta previa until proven otherwise
- Painful vaginal bleeding after 20 wk is placental abruption until proven otherwise
- The 2 above conditions can occur simultaneously

CODES

ICD9

- 641.00 Placenta previa without hemorrhage, unspecified as to episode of care or not applicable
- 641.01 Placenta previa without hemorrhage, delivered, with or without mention of antepartum condition
- 641.10 Hemorrhage from placenta previa, unspecified as to episode of care or not applicable

ICD10

- O44.00 Placenta previa specified as w/o hemorrhage, unsp trimester
- O44.03 Placenta previa specified as w/o hemorrhage, third trimester
- O44.10 Placenta previa with hemorrhage, unspecified trimester

PLANT POISONING

Patrick M. Lank

BASICS

DESCRIPTION

- Plant exposure is 1 of the most common reasons to contact the poison center
- Majority of cases involve unintentional ingestion in children <6 yr old.

ETIOLOGY

Identification of ingested plant species should be attempted whenever possible.

Plants with Anticholinergic Properties

- Genera include *Atropa*, *Datura*, *Hyoscyamus*, *Solandra*, and *Solanum*.
- Common names of anticholinergic plants include Jimson weed, deadly nightshade, henbane, and angel trumpet.
- Competitive antagonists of acetylcholine at the muscarinic acetylcholine receptor

Plants with Cardiac Glycosides

- Genera include *Digitalis*, *Nerium*, *Thevetia*, and *Helleborus*.
- Common names of cardiac glycoside plants include foxglove, oleander, yellow oleander, lily of the valley, and hellebore/Christmas rose
- Inhibit Na^+/K^+ -ATPase:
 - See separate chapter on Digoxin Poisoning

Plants with Nicotine-like Alkaloids

- Genera include *Nicotiana*, *Caulophyllum*, and *Conium*
- Common names of plants containing nicotine include tobacco, blue cohosh, and poison hemlock.
- Direct-acting agonists at the nicotinic acetylcholine receptor

Plants with Cyanogenic Compounds

- Genera include *Hydrangea*, *Malus*, *Prunus*, *Sambucus*
- Common names of plants containing cyanogenic compounds (in some part of the plant) include apricot, cherry, peach, plum, apple, cassava, and elderberry
- Metabolized to cyanide, which interferes with electron transport chain and leads to cellular poisoning

Plants with Calcium Oxalate Crystals

- Genera include *Alocasia*, *Dieffenbachia*, and *Philodendron* as well as many others
- Common names for calcium oxalate-containing plants include elephant's ear,

dumb cane, and mother-in-law's tongue

- Clinical manifestations occur after release of intracellular calcium oxalate crystals:
 - Local tissue exposure to calcium oxalate crystals leads to inflammatory response.

Plants with Pyrrolizidine Alkaloids

- Genera include Crotalaria, Heliotropium, Senecio, and Sesbania
- Common names of plants with pyrrolizidine alkaloids include scorpion's tail, ragwort, groundsel, and rattlebox
- Metabolized to highly reactive pyrroles, which are directly hepatotoxic acutely and lead to hepatic vascular proliferation and veno-occlusive disease chronically.

Plants with Sodium Channel Activity

- Genera include Aconitum, Delphinium, Leucothoe, Lyonia, Pernettya, Pieris, Rhododendron, Schoenocaulon, Veratrum, and Zigadenus
- Common names of plants with aconitine, veratrum alkaloids, and zygacine, all sodium channel openers, include: Aconite (monkshood, wolfsbane, delphinium), veratrum (false hellebore), and zygacine (death camas)
- Common names of plants with grayanotoxins, which have variable effects on sodium channels, include sweet bells, rhododendron, azalea, and lily-of-the-valley bush
- Variable sodium channel effects depending on toxin, although most lead to prolonged sodium channel influx.

Plants with Toxalbumins

- Genera include Abrus, Jatropha, Phoradendron, Ricinus, Robinia, Wisteria
- Common names of plants with toxalbumins include rosary pea, mistletoe, and castor bean
- Cause direct cellular toxicity by interfering with ribosomal function

DIAGNOSIS

SIGNS AND SYMPTOMS

Anticholinergic

- Dry, warm, and flushed skin
- Absent bowel sounds
- Urinary retention
- Agitated delirium

Cardioactive Steroids

- Digoxin-like toxicity

- Abdominal pain, nausea, vomiting
- Multiple cardiac effects, ranging from junctional bradycardia to v-tach/v-fib
- \pm hyperkalemia

Nicotine-like Alkaloids

- Hypertension
- Tachycardia \rightarrow bradycardia (late)
- Diaphoresis
- Salivation
- Vomiting
- Fasciculations
- Muscle weakness

Cyanogenic Compounds

- Potentially delayed (unlike cyanide gas)
- Initial symptoms:
 - Abdominal pain, nausea, vomiting
 - Lethargy
 - Diaphoresis
- Followed by:
 - Altered mental status
 - Lactic acidosis
 - Seizures
 - Cardiovascular collapse
 - Multiorgan system failure

Calcium Oxalate Crystals

- Oropharyngeal burning pain and swelling (after biting or chewing)
- Ocular exposure results in keratoconjunctivitis
- Dermal irritation after dermal contact

Pyrrolizidine Alkaloids

- Acutely causes hepatitis
- Chronic exposure may lead to hepatic veno-occlusive disease

Sodium Channel Activators

- Abdominal pain, nausea, vomiting
- CNS: Progress from paresthesias to depressed mental status, respiratory depression, coma, and seizures.
- CV: Bradycardia with atrioventricular blocks, progressing to tachydysrhythmias

Toxalbumins

- Effects depend on plant (e.g., mistletoe is rarely toxic, whereas ricin can be deadly) and route of exposure
- Gastroenteritis, diarrhea, or abdominal pain if ingested
- Localized pulmonary effects if inhaled
- Diffuse organ dysfunction if injected

Pediatric Considerations

- Often present with lip, tongue, and oropharyngeal irritation and swelling from oxalate crystal-containing plants:
 - Potential for airway compromise
- Usually consume leaves, seeds, and berries
- Nicotine group: 1 or 2 cigarettes potentially lethal
- Jimson weed:
 - Seeds highly concentrated
 - 100 seeds equal 6 mg of atropine
 - Lethal at 4–5 g of leaf
- Yellow oleander:
 - 2 leaves lethal in 12.5 kg child

ESSENTIAL WORKUP

- Identification of ingested material
- Workup depends on plant ingested

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Electrolytes, BUN, creatinine, glucose, liver function tests
- ABG/VBG for blood pH determination
- Digoxin level for cardiac glycoside plants
- Lactic acid for cyanogenic plants

Imaging

- ECG
- CXR

DIFFERENTIAL DIAGNOSIS

- Altered mental status:
 - Drug use/alcohol
 - Seizures
 - Trauma
 - Cerebrovascular accident
 - Hypoglycemia
- Digoxin toxicity

- Gastroenteritis
- Agents causing metabolic acidosis (see Acidosis chapter)
- Cardiotoxic drugs

TREATMENT

PRE HOSPITAL

- Examples of common nontoxic houseplants:
 - African violet
 - Bird of paradise
 - Ficus
 - Gardenia
 - Grape ivy
 - Orchids
 - Poinsettia (despite reputation)
 - Rubber tree
 - Spider plant
 - Wandering Jew
 - Wax plant
 - Zebra plant
- Collect seeds, leaves, spores in paper bag.
- Contact local botanist.
- Syrup of ipecac is not recommended

INITIAL STABILIZATION/THERAPY

- Airway, breathing, and circulation management (ABCs)
- 0.9% normal saline IV:
 - Aggressive volume replacement for dehydration/hypotension
 - Initiate pressors for hypotension unresponsive to fluids
- Cardiac monitoring
- Supportive care for most ingestions

ED TREATMENT/PROCEDURES

- Supportive care
- Rare plants necessitate focused/antidotal therapy

Anticholinergic

- Benzodiazepines for agitation
- Consider physostigmine for severe agitated delirium

Cardioactive Steroids

Digoxin-specific Fab indicated in:

- Significant bradycardia
- Tachydysrhythmia
- Hyperkalemia

Nicotine-like Alkaloids

- Parenteral short-acting antihypertensives such as nitroprusside for hypertensive crisis
- Treat seizures with benzodiazepines.

Cyanogenic Compounds

- Correction of electrolyte abnormalities
- Hydroxocobalamin or prepackaged cyanide antidote kit if severe lactic acidosis or hemodynamic compromise

Calcium Oxalate Crystals

- For mild symptoms, popsicles may decrease burning
- Viscous lidocaine and analgesics for more severe oral exposure
- Copious irrigation for ocular, oropharyngeal, and dermal exposure

Pyrrolizidine Alkaloids

- Supportive care
- Removal from source. Pyrrolizidine alkaloids have been found in herbal medication products as well as food contaminants
- Liver-specific management in conjunction with hepatologist

Sodium Channel Activators

- Atropine for bradycardia and atrioventricular blocks
- Normal saline bolus for hypotension, or vasopressor therapy if normal saline fails

Toxalbumins

Supportive care based on clinical symptoms: Replace GI losses with intravenous fluids, replete electrolytes.

MEDICATION

- Atropine: 0.5 mg (peds: 0.02 mg/kg) IV, repeat 0.5–1 mg IV
- Cyanide antidote kit:
 - Inhale amyl nitrite ampule for 30 sec every minute until sodium nitrite given.
 - Sodium nitrite: 10 mL of 3% solution or 300 mg IV over 3–5 min (peds: 0.15–0.33 mL/kg):
 - Monitor methemoglobin levels to keep < 30%.
 - Sodium thiosulfate: 50 mL IV of 25% solution or 12.5 g (peds: 1.65 mL/kg)

- Digoxin Fab fragments: Empiric dose 5–10 vials
- Hydroxocobalamin: 5 g IV for adults; 70 mg/kg not to exceed 5 g IV for pediatrics
- Magnesium: 2–4 g IV
- Physostigmine: 0.5–2 mg IV
- Sodium bicarbonate 8.4%: 1 amp IV push until narrowing of QRS complex

FOLLOW-UP

DISPOSITION

Admission Criteria

- Dysrhythmias for cardiac monitoring
- Intractable vomiting
- Refractory hypotension
- Evidence of end-organ damage (e.g., hepatic dysfunction, acidosis) or concern for potential for end-organ damage
- Altered mental status

Discharge Criteria

- Baseline mental status
- Tolerating oral fluids
- Normal cardiac activity
- Delayed sequelae not anticipated

Pediatric Considerations

Lower threshold to admit children:

- Tend to eat more concentrated parts of plants
- Lower lethal dose
- Symptoms less specific

FOLLOW-UP RECOMMENDATIONS

Follow-up with medical toxicologist or primary care physician

PEARLS AND PITFALLS

- Death from unintentional plant exposures is rare.
- Intentional exposures from herbal remedies, attempted abuse or therapeutic misadventures can be deadly.
- Contact your regional poison center if concerned about a patient ingesting a potentially poisonous plant: 1-800-222-1222

A special thanks to Dr. Harry Karydes, who contributed to the previous edition.

- Cyanide Poisoning
- Digoxin Poisoning

CODES

ICD9
988.2 Toxic effect of berries and other plants eaten as food

ICD10

- T62.1X1A Toxic effect of ingested berries, accidental, init
- T62.2X1A Toxic effect of ingested (parts of) plant(s), acc, init

PLEURAL EFFUSION

Sierra Beck • Steven M. Lindsey

BASICS

DESCRIPTION

- Normal conditions:
 - Pleural space contains 0.1–0.2 mL/kg (30 mL in an adult) of clear, low-protein fluid that facilitates movement of the pulmonary parenchyma within the thoracic space.
 - Fluid formation and reabsorption are governed by hydrostatic and oncotic forces.
 - Normally, the sum of these forces results in movement of fluid into the pleural space from the parietal surface and reabsorption at the visceral surface.
 - Lymphatics help remove any excess fluid.
- Alteration of any of the above factors results in abnormal fluid accumulation.
- Classification:
 - Transudative effusion:
 - An ultrafiltrate of serum, containing low protein and cells
 - Results from increase in hydrostatic pressure and/or decrease in oncotic pressure
 - Pleural surface is not involved in the primary pathologic process.
 - Exudative effusion:
 - Contains high protein and cells
 - Results from pathologic disease of the pleural surface leading to membrane permeability and/or disruption of lymphatic reabsorption

ETIOLOGY

- Transudative effusions:
 - Congestive heart failure (CHF)
 - Peritoneal dialysis
 - Cirrhosis with ascites
 - Pulmonary embolism
 - Acute atelectasis
 - Nephrotic syndrome
 - Myxedema
 - Hypoproteinemia
 - Superior vena cava syndrome
 - Meigs syndrome:
 - Triad of ascites, benign ovarian tumor, and pleural effusion

- Exudative effusions:
 - Pulmonary or pleural infection:
 - Bacterial, viral, fungal, tuberculosis (TB), parasitic
 - Primary lung cancer
 - Mesothelioma
 - Metastasis (often from breast cancer, ovarian cancer, or lymphoma)
 - Pericarditis
 - Pulmonary embolism
- Intra-abdominal disorders:
 - Pancreatitis, hepatitis, cholecystitis
 - Subdiaphragmatic abscess
 - Esophageal rupture
 - Peritonitis
 - Meigs syndrome
- Rheumatologic disease:
 - Systemic lupus erythematosus
 - Rheumatoid arthritis
 - Sarcoidosis
- Trauma:
 - Hemothorax
 - Chylothorax
- Drugs:
 - Drug-induced lupus
 - Nitrofurantoin, methysergide, dantrolene, amiodarone, bromocriptine
 - Crack cocaine

DIAGNOSIS

SIGNS AND SYMPTOMS

- Small effusions are often asymptomatic.
- Dyspnea, pleuritic chest pain, and/or cough
- Tachypnea, hypoxia, decreased breath sounds, and/or dullness to percussion

History

- Underlying primary pathologic process (CHF, pneumonia, pulmonary embolus, pancreatitis) is often the source of complaints.
- Dyspnea on exertion or at rest
- Cough with large effusion
- Pleuritic chest pain with inflammation of pleura
- Empyema: Fever, fatigue, weight loss

Physical-Exam

- Decreased breath sounds
- Decreased tactile fremitus
- Increased egophony for large effusions
- Dullness to chest percussion
- Pleural friction rub
- Examine for the primary cause of pleural effusion.

ESSENTIAL WORKUP

- Cardiac monitor and pulse oximetry
- CBC, comprehensive metabolic panel, coagulation panel
- Chest radiography
- Search for underlying cause

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Electrolytes, BUN/creatinine, glucose, serum lactate dehydrogenase (LDH), serum protein
- Pulse oximetry or arterial blood gas
- Coagulation panel
- Pleural fluid analysis to determine if transudative or exudative effusion:
 - _ Check pleural protein and LDH levels.
 - _ Light criteria: Fluid is likely exudative if 1 or more of the following criteria are met:
 - Pleural fluid protein/serum protein > 0.5
 - Pleural fluid LDH/serum LDH > 0.6
 - Pleural fluid LDH > 2/3 upper limit of normal serum LDH
- If effusion is transudative, no further fluid analysis is usually necessary.
- Determining etiology of exudative effusion:
 - _ Initial testing: Cell count with differential, Gram stain and culture, acid fast bacilli stain, pH, glucose, and cytology
 - _ Based on clinical scenario consider: Triglycerides, amylase, albumin, creatinine, adenosine deaminase, and tumor markers.
 - _ RBC and Hct:
 - 5,000–100,000/mm³ nonspecific
 - > 100,000/mm³ suggestive of malignancy, trauma, or pulmonary embolus
 - Pleural fluid Hct > 0.5 serum Hct is by definition a hemothorax.
 - Other causes: Malignancy, TB, aortic rupture
 - Heparinize and chill hemorrhagic samples to be sent for cytology.
 - _ WBC:

- 1,000–10,000/mm³ nonspecific
- >10,000/mm³ suggestive of parapneumonic effusion, empyema, pancreatitis, rheumatologic, malignancy, or TB
- Glucose:
 - Glucose < 60 mg/dL suggestive of complicated parapneumonic effusion/empyema, malignancy, esophageal rupture, or rheumatologic disease
- Triglyceride:
 - Triglycerides > 100 mg/dL suggestive of chylothorax, disruption of thoracic duct
- Amylase:
 - Amylase > 200 IU/L suggestive of pancreatitis, esophageal rupture, malignancy, TB, or empyema
- pH:
 - Send in a chilled heparinized arterial blood gas syringe.
 - pH < 7 suggests complicated parapneumonic effusion or empyema
- Cytology identifies malignant cells.

Imaging

- Chest radiograph:
 - Upright chest film:
 - Blunting of the costophrenic angle
 - Requires at least 200–250 mL of fluid
 - Presence of subpulmonic effusions may be indicated by loss of supradiaphragmatic vascular markings or an increased space between the gastric bubble and pulmonary parenchyma.
 - Lateral decubitus film:
 - Can identify as little as 5–10 mL of fluid.
 - Suspect a loculated effusion or alternative diagnosis if effusion fails to layer.
- US:
 - Has similar sensitivity to lateral decubitus film and can detect as little as 5–10 mL of fluid.
 - Can differentiate simple effusions from loculated fluid collections.
 - Improves patient safety and decreases risk of pneumothorax for thoracentesis
- CT chest with IV contrast:
 - Most sensitive study for detecting pleural fluid collections and identifying loculated effusions.
 - Useful for determination of underlying lung process such as masses and pleural thickening

ALERT

- Consider pulmonary embolism as a cause of unexplained pleural effusion
- Obtain lateral decubitus films, or bedside US prior to performing thoracentesis to avoid misdiagnosis and procedural complications.

Diagnostic Procedures/Surgery

Diagnostic/therapeutic ED thoracentesis:

- **Indication:**
 - _ Diagnose new effusion in a toxic patient.
 - _ Relieve symptomatic dyspnea caused by large effusions.
 - _ Diagnostic thoracentesis in a stable patient can be deferred until after the patient has been admitted.
- No absolute contraindications.
- Relative contraindications:
 - _ Platelets $< 50,000/\text{mm}^3$
 - _ Prothrombin and partial thromboplastin time $> 2 \times$ normal level
 - _ Serum creatinine > 6
- Correct coagulopathy if present.
- Position patient upright with arms crossed in front to elevate scapula.
- Identify superior border of effusion with US, percussion, or egophony.
- Mark area 1 interspace below this in the posterior axillary line or the midscapular line.
- Prepare area with Betadine, dry, and drape for sterile field.
- Anesthetize with 2% lidocaine.
- Attach 3-way stopcock between needle and syringe. Enter superior border of rib with needle bevel down, aspirating while advancing.
- Use 20G needle for diagnostic aspiration.
- Use 16G–18G needle/catheter (commercial kit) for therapeutic aspiration.
- Advance catheter once pleural space entered.
- Minimum of 100 cc required for basic studies (protein, LDH, cell count, Gram stain and culture)—more for cytology/additional studies.
- Avoid withdrawing $> 1,500$ cc to prevent re-expansion pulmonary edema.
- Intraprocedural chest pain may indicate trapped lung or pneumothorax; stop procedure and obtain chest radiograph.
- After obtaining fluid, withdraw needle, apply pressure, dress, and obtain post procedural chest radiograph for pneumothorax.
- Indications for tube thoracostomy:
 - _ Loculated effusion
 - _ Aspiration of pus
 - _ Complicated parapneumonic effusion with pH < 7 , or pleural glucose < 60 mg/dL, or positive pleural Gram stain or culture
 - _ Hemothorax

DIFFERENTIAL DIAGNOSIS

- Intraparenchymal densities:
 - Lobar collapse
 - Mass, tumor, infiltrative disease
 - Pneumonia
- Pleural densities:
 - Pleural scarring
 - Mesothelioma, metastatic disease
- Other:
 - Herniated abdominal contents
 - Paralyzed diaphragm

TREATMENT

PRE HOSPITAL

IV access, high-flow oxygen, cardiac monitor, and pulse oximeter.

INITIAL STABILIZATION/THERAPY

- ABCs
- High-flow oxygen for shortness of breath
- Emergent thoracentesis for significant respiratory compromise.

ED TREATMENT/PROCEDURES

- Identify and treat underlying pathologic process
- Surgical consult for tube thoracostomy if empyema found.
- Consult interventional radiology or pulmonology for loculated effusions.

MEDICATION

- CHF: Diuresis
- Parapneumonic effusion: Antibiotics
- Pulmonary embolism: Anticoagulation:
 - Bloody effusion is not a contraindication to anticoagulation.
- Rheumatologic disease: NSAIDs and steroids
- Loculated effusion: Injection of streptokinase or urokinase into pleural space by thoracic surgeon or pulmonologist

FOLLOW-UP

DISPOSITION

Admission Criteria

- Respiratory compromise

- Unknown cause of the effusion
- Primary process requires hospitalization
- Presence or suspected parapneumonic effusion or empyema
- Observation for 6 hr or admission for potential complications of thoracentesis:
 - Pneumothorax
 - Re-expansion pulmonary edema
- ICU admission for severe hemodynamic and respiratory compromise

Discharge Criteria

- Source of the pleural effusion is known.
- No evidence of respiratory compromise exists.
- Majority of effusions will resolve if the primary process is treated appropriately.
- Patient must be reliable and have access to a telephone, a supportive social environment, and adequate follow-up.

Issues for Referral

Arrange appropriate follow-up with oncologist or pulmonologist prior to discharge.

FOLLOW-UP RECOMMENDATIONS

Patients should be instructed to return to the ED for worsening dyspnea, fever/chills, or other symptoms of respiratory distress.

PEARLS AND PITFALLS

- The most common causes of pleural effusion are CHF, pneumonia, and malignancy.
- Identify and treat the underlying cause of the pleural effusion.
- Bedside US can help characterize the effusion and reduce the risk of pneumothorax with thoracentesis.
- Failure to identify fatal causes of pleural effusion such as pulmonary embolism, esophageal rupture, or hemothorax
- Failure to drain large effusions that are causing respiratory or circulatory compromise

CODES

ICD9

- 511.1 Pleurisy with effusion, with mention of a bacterial cause other than tuberculosis
- 511.9 Unspecified pleural effusion
- 511.89 Other specified forms of effusion, except tuberculous

ICD10

- J90 Pleural effusion, not elsewhere classified
- J91.0 Malignant pleural effusion
- J94.0 Chylous effusion

PNEUMOCYSTIS PNEUMONIA

Alan M. Kumar

BASICS

DESCRIPTION

- Originally called *Pneumocystis carinii* pneumonia, then renamed *Pneumocystis jirovecii* but still referred to as PCP
- Most common opportunistic infection in patients with HIV, even with PCP prophylaxis and antiretroviral therapy
- Believed to be transmitted by respiratory-aerosol route:
 - Cysts colonize respiratory tract.
 - Cysts rupture and multiple trophozoites release and form foamy exudate in alveoli.
- Most cases are believed to represent reactivation of latent disease, although person-to-person transmission suggested.
- Actual mode of transmission is unclear.

ETIOLOGY

- *Pneumocystis* is classified as a fungus.
- *Pneumocystis* occurs in hosts with altered cellular immunity:
 - HIV infection (most common, especially when CD4 count < 200 cells/mm³)
 - Cancer
 - Corticosteroid treatment
 - Organ transplantation
 - Malnutrition

Pediatric Considerations

PCP in children is typically more severe.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Subacute presentation
- Up to 7% of patients can be asymptomatic.
- Patients on inhaled pentamidine prophylaxis may have milder symptoms:
 - Increased incidence of pneumothorax
 - Increased incidence of extrapulmonary disease

History

- Fever

- Cough with none or minimal amount of white sputum
- Dyspnea on exertion or at rest:
 - Progressive over days (most common in non-HIV-immunocompromised hosts)
 - Indolent, developing over weeks to months (more common in HIV-positive hosts)
 - Oxygen desaturation with exercise
- Chills
- Fatigue
- Weight loss
- Chest pain

Physical-Exam

- Tachypnea
- Tachycardia
- Crackles and rhonchi on lung exam

ESSENTIAL WORKUP

- CBC
- Electrolytes
- Arterial blood gas (ABG)
- Lactate dehydrogenase (LDH)
- Blood cultures
- Chest x-ray

DIAGNOSIS TESTS & NTERPRETATION

Lab

- ABG:
 - Obtain in all cases of PCP.
 - Calculate the alveolar-arterial (A-a) gradient (usually increased).
 - Adjunctive corticosteroid therapy for A-a gradient > 35 mm Hg or $\text{PaO}_2 < 70$ mm Hg
- LDH:
 - Elevated in HIV-positive patients with PCP compared to non-PCP pneumonia
 - Higher levels correlate with poorer prognosis.

Imaging

- Chest radiograph:
 - Classically reveals bilateral interstitial or central alveolar infiltrates
 - Radiograph normal in up to 25% of patients with PCP

- Early or mild infection associated with decreased sensitivity
- Atypical presentations include:
 - Lobar infiltrates
 - Cysts
 - Pneumothoraces
 - Pleural effusions
 - Nodular infiltrates
- Prophylaxis with aerosolized pentamidine is a risk factor for developing predominantly upper lobe.
- Chest radiograph abnormalities can persist for months after treatment.
- High-resolution chest CT:
 - High sensitivity for PCP in HIV-positive patients.
 - Reveals patchy ground-glass attenuation

Diagnostic Procedures/Surgery

- Induced sputum:
 - Definitive diagnosis requires presence of *Pneumocystis* organisms in an appropriately stained respiratory specimen.
 - Specificity approaches 100%, but sensitivity depends on quality of induced sputum and lab expertise.
 - Less sensitive in patients on inhaled pentamidine prophylaxis and non-HIV-positive patients
- Bronchoalveolar lavage:
 - Perform if the induced sputum is nondiagnostic and the suspicion for PCP is still high.
 - Sensitivity 80–100%

DIFFERENTIAL DIAGNOSIS

Constellation of dyspnea, fever, diffuse radiographic infiltrates, minimal or nonproductive cough, and slow progressive course suggests atypical cause of the pneumonia:

- *Chlamydia pneumoniae*
- *Legionella*
- *Mycoplasma*
- Tuberculosis
- Viral pneumonia (especially cytomegalovirus)

TREATMENT

PRE HOSPITAL

Provide supplemental oxygen for symptomatic patients.

INITIAL STABILIZATION/THERAPY

- ABCs
- Provide adequate oxygenation with nasal cannula up to 100% nonrebreather.
- Perform endotracheal intubation in those with refractory hypoxemia despite maximal oxygenation or hypercarbic respiratory failure.
- At least 500–1,000 cc 0.9% normal saline IV bolus for hypotension, sepsis, dehydration

ED TREATMENT/PROCEDURES

- Initiate antibiotics:
 - _ IV Bactrim is the first-line agent.
 - _ IV pentamidine for those who cannot tolerate Bactrim
 - _ Oral therapy is an option for well-appearing patients.
 - _ Alternative regimens include trimethoprim–dapson, clindamycin–primaquine, and atovaquone.
 - _ Continue antibiotics for 21 days.
- Adjunctive corticosteroids in patients with A–a gradient > 35 mm Hg or $\text{PaO}_2 < 70$ mm Hg:
 - _ Must start within 1st 72 hr of treatment
- Isolate suspected PCP patients from others who are immunocompromised.

MEDICATION

- Atovaquone: 750 mg (peds: Dosing not established) PO q12h
- Clindamycin/primaquine: Clindamycin 900 mg (peds: Dosing not established) IV q8h or 300–450 mg PO q6h and primaquine 15–30 mg (peds: Dosing not established) PO per day
- Pentamidine: 4 mg/kg/24h IV over 1 hr (peds: 3–4 mg/kg IM or IV once/day for 21 days)
- Prednisone: 40 mg (peds: Dosing not established) PO q12h for 5 days, 40 mg PO per day for 5 days, then 20 mg PO per day for 11 days (IV methylprednisolone at 75% of the prednisone dose may be substituted)
- Trimethoprim/dapsone: Trimethoprim 15–20 mg/kg/d IV div. q8h + dapsone 100 mg PO per day (peds: Dosing not established)
- Trimethoprim/sulfamethoxazole (Bactrim): Trimethoprim 15–20 mg/kg/d IV div. q6h and sulfamethoxazole 100 mg/kg/d IV div. q6h (peds: Dosing same)

Pediatric Considerations

- Treatment of choice is IV trimethoprim/sulfamethoxazole, followed by IV pentamidine.
- Dosing for alternative medications not yet established (consult pediatric infectious disease specialist).

FOLLOW-UP

DISPOSITION

Admission Criteria

- Moderate to severe disease ($\text{PaO}_2 < 70$ mm Hg or A–a gradient > 35 mm Hg)
- Inability to digest medications
- Inability to return for careful follow-up

Discharge Criteria

- Nontoxic clinical appearance
- Mild disease state (no hypoxemia or A–a gradient)
- Ability to tolerate medications
- Close follow-up arranged
- If results of induced sputum are not available, add macrolide to empirical regimen.

FOLLOW-UP RECOMMENDATIONS

Close follow-up must be arranged with infectious disease specialist to allow for outpatient management.

PEARLS AND PITFALLS

- Include PCP in differential diagnosis in any patient presenting with shortness of breath who is immunocompromised or is suspected of having undiagnosed HIV.
- Patients considered for PCP are also more likely to have TB or atypical bacterial pneumonia.
- Well-appearing patients with low oxygen saturations are at higher risk for complications.

BASICS

DESCRIPTION

- Presence of free air or gas within the mediastinum (mediastinal emphysema)
- May originate from esophagus, lungs, or bronchial tree (*aerodigestive process*)
- May occur spontaneously (primary pneumomediastinum) or as result of trauma, surgery, or other pathologic processes (secondary pneumomediastinum)
- Spontaneous pneumomediastinum:
 - Caused by extrapleural tracheobronchial injury:
