Care has been taken to confirm the accuracy of the information presented and to describe generally accepted practices. However, the authors, editors, and publisher are not responsible for errors or omissions or for any consequences from application of the information in this book and make no warranty, expressed or implied, with respect to the currency, completeness, or accuracy of the contents of the publication. Application of the information in a particular situation remains the professional responsibility of the practitioner.

The authors, editors, and publisher have exerted every effort to ensure that drug selection and dosage set forth in this text are in accordance with current recommendations and practice at the time of publication. However, in view of ongoing research, changes in government regulations, and the constant flow of information relating to drug therapy and drug reactions, the reader is urged to check the package insert for each drug for any change in indications and dosage and for added warnings and precautions. This is particularly important when the recommended agent is a new or infrequently employed drug.

Some drugs and medical devices presented in the publication have Food and Drug Administration (FDA) clearance for limited use in restricted research settings. It is the responsibility of the health care provider to ascertain the FDA status of each drug or device planned for use in their clinical practice.

To purchase additional copies of this book, call our customer service department at (800) 638-3030 or fax orders to (301) 223-2320. International customers should call (301) 223-2300.

Rosen and Barkin's *5-Minute Emergency Medicine Consult* continues to reflect the evolving nature of our clinical emergency medicine practices. Emergency medicine provides unique challenges to the clinician; the remarkable breadth of clinical conditions encountered, the time constraints of an acute illness, environmental considerations, and the logistical demands of busy emergency departments. Time is of the essence, and this book is truly designed to meet the needs of clinicians working in settings providing urgent and emergent care. To look for a diagnosis, one must think of it, and the very nature of the emergency department (ED) makes prolonged deliberation difficult. Nevertheless, it must become instinctive to think about the statistically rare, but clinically serious entity, rather than to just reach for the statistically probable but nonlife-threatening diagnosis.

Rosen and Barkin's 5-Minute Emergency Medicine Consult provides concise formatted information allowing the busy clinician to respond to each patient appropriately. It is meant to be readily available in the ED, and frequently used in the trenches. Written and edited by practicing clinicians for their colleagues, the book is designed to synthesize a mountain of information into tightly formatted chapters that stimulate analysis and subsequent assessment.

We have attempted to integrate our authors' expertise, experience, and knowledge base onto the pages of this book. The chapters are not meant to be a diagnostic engine, but rather a place to confirm a diagnosis supported by clinical judgment and the subjective and objective evidence of a patient's presentation. Our authors attempt to provide a precise and clinically relevant summary useful in caring for the patient while also equipping students and residents with the structure needed to approach individual disease processes. We are indebted to our contributors for their commitment to this task.

The book is intended to be accurate, focused, and readily integrated into practice, rather than being definitive and all encompassing. As in the past, this new edition incorporates new information and approaches to management, while allowing us to modify topics that reflect some of the new challenges we face.

Our goal is to make *Rosen and Barkin's 5-Minute Emergency Medicine Consult* useful to both novices in emergency medicine and experienced clinicians. The information and organization is designed to be easily used within the "chaos" that surrounds our clinical settings.

Clinical acumen, judgment, and experience are the foundations for our clinical practice. It is our hope that this book will serve students, nurses, emergency medical personnel, residents, and practicing emergency physicians as a readily used resource in excellent patient care and knowledge acquisition.

ACKNOWLEDGMENTS

The dedication of our authors and the input of our readers is appreciated and forms the foundation for this book. Ashley Fischer of Lippincott Williams & Wilkins held our hands throughout the production.

To my wife Anna and sons Jacob and Isaac—thank you for your continued support and inspiration. Thanks to the Cook County Emergency Medicine Attendings and Residents for their contributions to the book and to enhancing my knowledge and understanding of our unique field.

J.J.S.

I am most appreciative for my family's support. Suzanne Barkin, MD is an exemplary clinician and has been a remarkable role model and teacher for the residents she has trained. Adam, Jill, Jacob, Eli, Michael, and Rachael remind us daily of the importance of our roles as clinicians and reaffirm our commitment to excellence.

It is also important to acknowledge and thank our colleagues nationally and internationally who continue to teach each of us on an ongoing basis and will hopefully find this book useful in their practices.

R.M.B.

To my wife Marina, and my children Connor, Maia, and Kenny; without your support and understanding, my involvement in academic emergency medicine and this book would be not possible. To my current residents and past graduates; I hope the information in this book helps guide your clinical decisions and prompts you to always maintain your intellectual curiosity.

S.R.H.

To my wife Alice whose unflagging support, patience, and humor provide the support for these efforts. To the faculty members at BIDMC who share the vision and high standards that this book strives to achieve. To Peter who has been a lifelong mentor and a role model.

R.E.W.

To Jill, Jacob, and Eli who provide so much joy, support, laughter, and love.

A.Z.B.

To my wife Helen for her unending patience, support, guidance, and understanding for her support in allowing me the freedom to work on this book. And to my sons Dylan and David for keeping me grounded to what really matters.

Pennsylvania Hospital
Philadelphia, Pennsylvania

Isam F. Nasr, MD, FACEP

Assistant Professor
Emergency Medicine
Rush Medical College

Attending Physician
Emergency Medicine
John H. Stroger, Jr. Hospital of Cook County
Chicago, Illinois

Erin Nasrallah, MD

Emergency Medicine Physician
Department of Emergency Medicine
Lutheran General Hospital
Park Ridge, Illinois

Sean-Xavier Neath, MD, PhD

Assistant Clinical Professor of Medicine
Department of Emergency Medicine

University of California
San Diego, California

James A. Nelson, MD

Assistant Clinical Professor
Department of Emergency Medicine
University of California
San Diego, California

Attending Physician
Emergency Department
Pioneers Memorial Hospital
Brawley, California

Michael E. Nelson, MD, MS

Medical Toxicology Fellow
Attending Physician
Department of Emergency Medicine
John H. Stroger, Jr. Hospital of Cook County
Chicago, Illinois

Edward Newton, MD

Professor of Emergency Medicine
Department of Emergency Medicine
Keck School of Medicine of University of Southern California

Professor of Emergency Medicine
Department of Emergency Medicine
LAC + USC Medical Center
Los Angeles, California

Sean Patrick Nordt, MD, PharmD

Assistant Professor of Clinical Emergency Medicine
Department of Emergency Medicine
Keck School of Medicine of University of Southern California

Director, Section of Toxicology
Department of Emergency Medicine
LAC + USC Medical Center
Los Angeles, California

Charles W. O'Connell, MD

Toxicology Fellow
Department of Emergency Medicine
University of California

Toxicology Fellow
Department of Emergency Medicine
UC San Diego Health System
San Diego, California

Neal P. O'Connor, MD, FACEP

Chief Medical Officer
CarePoint PC
Greenwood Village
Englewood, Colorado

Yasuharu Okuda, MD

Associate Professor
Emergency Medicine
University of Central Florida School of Medicine
National Medical Director
SimLEARN
Veterans Health Administration
Orlando, Florida

Jonathan S. Olshaker, MD

Professor and Chairman
Department of Emergency Medicine
Boston University School of Medicine
Chief
Department of Emergency Medicine
Boston Medical Center
Boston, Massachusetts

Ben Osborne, MD

Assistant Professor
Department of Emergency Medicine
Tufts University School of Medicine
Boston, Massachusetts
Residency Director
Department of Emergency Medicine
Baystate Medical Center
Springfield, Massachusetts

Jessica L. Osterman, MD

Assistant Professor
Assistant Program Director

Department of Emergency Medicine
LAC + USC Medical Center
Los Angeles, California

Carolyn Maher Overman, MD

Resident
Emergency Medicine
Emory University
Atlanta, Georgia

Leslie C. Oyama, MD

Associate Professor
Department of Emergency Medicine
University of California
San Diego, California

David Palafox, MD

Department of Emergency Medicine
Thomason General Hospital
El Paso, Texas

Lynne M. Palmisciano, MD

Assistant Professor (Clinical)
Emergency Medicine and Pediatrics
Warren Alpert Medical School of Brown University

Attending Physician
Pediatric Emergency Department
Hasbro Children's Hospital
Providence, Rhode Island

Peter S. Pang, MD

Associate Professor of Emergency Medicine
Associate Professor of Medicine-Cardiology
Emergency Medicine
Northwestern University Feinberg School of Medicine

Associate Chief
Emergency Medicine
Northwestern Memorial Hospital
Chicago, Illinois

Peter J. Park, MD

Chief Medical Informatics Officer
Healthcare Operations Directorate

Navy Medicine West
San Diego, California

Robert A. Partridge, MD, MPH

Adjunct Professor
Department of Emergency Medicine
Warren Alpert Medical School of Brown University
Providence, Rhode Island

Attending Physician
Department of Emergency Medicine
Emerson Hospital
Concord, Massachusetts

Matthew S. Patton, MD

Resident
Emergency Medicine
Northwestern University Feinberg School of Medicine
Chicago, Illinois

David A. Peak, MD

Assistant Professor
Emergency Medicine
Harvard Medical School

Assistant Residency Director
Harvard Affiliated Emergency Medicine Residency
Massachusetts General Hospital
Boston, Massachusetts

David A. Pearson, MD, MS

Assistant Professor
Department of Emergency Medicine
Carolinas Medical Center

Associate Residency Program Director
Department of Emergency Medicine
Carolinas Medical Center
Charlotte, North Carolina

Timothy C. Peck, MD

Clinical Fellow of Medicine
Division of Emergency Medicine
Harvard Medical School
Chief Resident

Department of Emergency Medicine
Beth Israel Deaconess Medical Center
Boston, Massachusetts

Bradley Peckler, MD, FACEP, FACEM

Director of Simulation
Department of Emergency Medicine
University of South Florida

Attending Physician
Emergency Medicine
Tampa General Hospital
Tampa, Florida

David A. Perlstein, MD, MBA

Assistant Professor
Department of Pediatrics
Albert Einstein College of Medicine

Senior Vice President
Medical Director
St. Barnabas Hospital
Bronx, New York

Marie-France Petchy, MD

Research Fellow
Department of Medicine
Harvard Medical School

Department of Emergency Medicine
Beth Israel Deaconess Medical Center
Boston, Massachusetts

Angela Pham, MD

Attending Physician
Department of Emergency Medicine
Kaiser Foundation Hospital/San Diego Medical Center
San Diego, California

Charles V. Pollack, Jr., MA, MD, FACEP, FAAEM, FAHA, FCPP

Professor
Department of Emergency Medicine
Perelman School of Medicine at University of Pennsylvania
Chairman
Department of Emergency Medicine

Pennsylvania Hospital
Philadelphia, Pennsylvania

Daniel A. Popa, MD, PhD

Resident Physician
Emergency Medicine
University of California
San Diego, California

William Porcaro, MD, MPH

Instructor
Department of Emergency Medicine
Harvard Medical School
Boston, Massachusetts

Attending Physician
Department of Emergency Medicine
Mount Auburn Hospital
Cambridge, Massachusetts

Yanina Purim-Shem-Tov, MD, MS, FACEP

Associate Professor
Medical Director of Clinical Practice
Director of Chest Pain Center
Department of Emergency Medicine
Rush University Medical Center
Chicago, Illinois

Nas N. Rafi, MD

Resident Physician
Emergency Medicine
University of California
San Diego, California

Vittorio J. Raho, MD, MPH

Attending Physician
Department of Emergency Medicine
Beverly and Addison Gilbert Hospital
Beverly, Massachusetts

Niels K. Rathlev, MD, FACEP

Chair and Professor
Department of Emergency Medicine
Tufts University School of Medicine

Boston, Massachusetts

Chair

Department of Emergency Medicine

Baystate Medical Center

Springfield, Massachusetts

Neha P. Raukar, MD, MS

Assistant Professor

Emergency Medicine

Warren Alpert School of Medicine of Brown University

Attending Physician

Emergency Medicine

Rhode Island Hospital/The Miriam Hospital

Providence, Rhode Island

Colby Redfield, MD

Emergency Medicine

Beth Israel Deaconess Medical Center

Boston, Massachusetts

Ian Reilly, MD, FACEP

Emergency Physician

Department of Emergency Medicine

Scripps Memorial Hospital La Jolla

La Jolla, California

James W. Rhee, MD

Departments of Emergency Medicine and Medical Toxicology

Loma Linda University Medical Center

Loma Linda, California

Christopher T. Richards, MD

Clinical Instructor

Department of Emergency Medicine

Northwestern University Feinberg School of Medicine

Attending Physician

Department of Emergency Medicine

Northwestern Memorial Hospital

Chicago, Illinois

James J. Rifino

Andrew Rinne, MD

Clinical Instructor
Department of Emergency Medicine
Harvard University
Boston, Massachusetts

Resident Physician
Beth Israel Deaconess Medical Center
Department of Emergency Medicine
Boston, Massachusetts

Jaime B. Rivas, MD

Medical Director
Department of Emergency Medicine
Palomar Health
Escondido, California

Colleen M. Rivers, MD

Assistant Professor
Department of Emergency Medicine
University of Medicine and Dentistry of New Jersey
New Jersey Medical School
Newark, New Jersey

Keri Robertson, DO, FACOEP

Clinical Associate Professor
Department of Emergency Medicine
Midwestern University
Downers Grove, Illinois
Attending Physician
Emergency Department
Swedish Covenant Hospital
Chicago, Illinois

Matthew T. Robinson, MD

Associate Professor
Medical Director
Department of Emergency Medicine
University of Missouri – Columbia
Columbia, Missouri

Colleen N. Roche, MD

Residency Director
Assistant Professor
Department of Emergency Medicine

George Washington University School of Medicine and Health Sciences

Attending Physician

Department of Emergency Medicine

George Washington University Hospital

Washington, DC

Steven C. Rogers, MD

Assistant Professor

Department of Pediatrics and Emergency Medicine

University of Connecticut School of Medicine

Farmington, Connecticut

Attending Physician and Assistant Director of Research

Division of Emergency Medicine

Connecticut Children's Medical Center

Hartford, Connecticut

Ernesto J. Romo, MD

Resident Physician

Department of Emergency Medicine

Rush Medical College

John H. Stroger, Jr. Hospital of Cook County

Chicago, Illinois

Genie E. Roosevelt, MD, MPH

Associate Professor

Pediatrics

University of Colorado School of Medicine

Aurora, Colorado

Attending Physician

Emergency Medicine

Denver Health Medical Center

Denver, Colorado

Carlo L. Rosen, MD

Associate Professor

Harvard Medical School

Program Director and Vice Chair for Education

Department of Emergency Medicine

Beth Israel Deaconess Medical Center

Boston, Massachusetts

Noah K. Rosenberg, MD

Adjunct Assistant Professor
Department of Emergency Medicine
Brown University
Providence, Rhode Island

Emergency Physician
Emergency Care Center
Sturdy Memorial Hospital
Attleboro, Massachusetts

Lawrence S. Rosenthal, PhD, MD, FACC, FHRS

Associate Professor
Department of Medicine
University of Massachusetts Medical School
Director, Section Cardiac Pacing and Electrophysiology
Director, EP Fellowship Program
Division of Cardiovascular Disease
University of Massachusetts Memorial Medical Center
Worcester, Massachusetts

Christopher Ross, MD, FRCPC, FACEP, FAAEM

Associate Professor
Emergency Medicine
Rush Medical Center
Associate Chair Professional Education and Associate Residency Director of Emergency
Medicine
Cook County Hospital (Stroger)
Chicago, Illinois

David H. Rubin, MD

Professor of Clinical Pediatrics
Pediatrics
Albert Einstein College of Medicine
Chairman
Pediatrics
Department of Pediatrics
St. Barnabas Hospital
Bronx, New York

Gary S. Sachs, MD

Department of Psychiatry
Harvard Medical School
Department of Psychiatry

Massachusetts General Hospital

Director

Bipolar Clinic and Research Program

Massachusetts General Hospital

Boston, Massachusetts

Charlotte A. Sadler, MD

Resident

Department of Emergency Medicine

University of California

San Diego, California

Roxanna A. Sadri, MD

Assistant Professor of Clinical Emergency Medicine

Department of Emergency Medicine

University of California

Associate Physician

Department of Emergency Medicine

University of California

San Diego, California

Anthony C. Salazar, MD

Department of Emergency Medicine

Kaiser Medical Center

San Diego, California

Erich Salvacion, MD

Attending Physician

Kaiser Permanente

Downey, California

Czarina E. S nchez, MD

Clinical Fellow

Harvard Medical School

Resident

Department of Emergency Medicine

Beth Israel Deaconess Medical Center

Boston, Massachusetts

Leon D. S nchez, MD, MPH

Associate Professor of Medicine

Harvard Medical School

Attending Physician
Department of Emergency Medicine
Beth Israel Deaconess Medical Center
Boston, Massachusetts

Arthur B. Sanders, MD, MHA

Professor
Emergency Medicine
University of Arizona

Attending Physician
Emergency Medicine
University of Arizona Health Network
Tucson, Arizona

John P. Santamaria, MD

Affiliate Professor of Pediatrics
Pediatrics
USF School of Medicine
Tampa, Florida

Sally A. Santen, MD, PhD

Assistant Dean for Educational Research and Quality Improvement in the Medical
School
Associate Chair of Education
Department of Emergency Medicine
University of Michigan Medical School
Ann Arbor, Michigan

Mary Saunders, MD

Staff Physician
Pediatric Emergency Department
Rocky Mountain Hospital for Children
Denver, Colorado

Davut J. Savaser, MD, MPH

Fellow Physician
Undersea and Hyperbaric Medicine
University of California
Emergency Medicine Physician
Department of Emergency Medicine
University of California San Diego Medical Center
San Diego, California

Daniel L. Savitt, MD

Associate Professor

Department of Emergency Medicine

Warren Alpert Medical School of Brown University

Vice Chair for Medical Development

Department of Emergency Medicine

Rhode Island Hospital and the Miriam Hospital

Providence, Rhode Island

Assaad J. Sayah, MD

Assistant Professor

Department of Medicine

Harvard Medical School

Boston, Massachusetts

Chief

Department of Emergency Medicine

Cambridge Health Alliance

Cambridge, Massachusetts

Shari Schabowski

Assistant Professor

Department of Emergency Medicine

Rush Medical College

Attending Physician

Department of Emergency Medicine

Cook County Health and Hospital System

Chicago, Illinois

Jeffrey J. Schaider, MD

Professor, Department of Emergency Medicine

Rush Medical College

Chairman, Department of Emergency Medicine

Cook County Health and Hospital System

Chicago, Illinois

FOURTH EDITION AUTHOR ACKNOWLEDGMENTS

The editors and authors of the 5th edition gratefully acknowledge the past contributions of the following previous edition authors:

John Bailitz

Todd Baumbacher

Jefferson D. Bracey

Colleen Campbell

Jamila Danishwar

Chirag A. Dholakia

Arunchalam Einstein

Tala R. Elia

David Feldman

Maggie Fernig

Steven Furer

Bret E. Ginther

Judd L. Glasser

Ian Greenwald

Mark A. Hostetler

Thea James

David Jerrard

Cade Lawrence

James M. Leaming

David Listman

Trevor J. Mills

Elizabeth L. Mitchell

Carol R. Okada

Janet M. Poponick

Marcelo Sandoval

Elaine Sapiro

Ghazala Q. Sharieff

Arash Soroudi

Vaishal M. Tolia

Karen B. Van Hoesen

Beth A. Zelonis

Contents

Preface

Acknowledgements

Contributors

Abdominal Aortic Aneurysm

Abdominal Pain

Abdominal Trauma, Blunt

Abdominal Trauma, Imaging

Abdominal Trauma, Penetrating

Abortion, Spontaneous

Abscess, Skin/Soft Tissue

Abuse, Elder

Abuse, Pediatric (Nonaccidental Trauma [NAT])

Acetaminophen Poisoning

Acidosis

Acromioclavicular Joint Injury

Acute Coronary Syndrome: Angina

Acute Coronary Syndrome: Coronary Vasospasm

Acute Coronary Syndrome: Myocardial Infarction

Acute Coronary Syndrome: Non-Q-Wave (Non-ST-Elevation) MI

Adrenal Insufficiency

Agitation

Airway Adjuncts

Airway Management

Alcohol Poisoning

Alcoholic Ketoacidosis

Alkalosis

Altered Mental Status

Amebiasis

Amenorrhea

Amphetamine Poisoning

Amputation Traumatic/Replantation

Amyotrophic Lateral Sclerosis

Anal Fissure

Anaphylaxis

Anemia

Angioedema

Ankle Fracture/Dislocation

Ankle Sprain

Ankylosing Spondylitis

Anticholinergic Poisoning

Antidepressant Poisoning

Aortic Dissection, Thoracic

Aortic Rupture, Traumatic (TAI)

Aphthous Ulcers

Apnea, Pediatric

Appendicitis

Arsenic Poisoning

Arterial Gas Embolism (AGE)

Arterial Occlusion

Arthritis, Degenerative

Arthritis, Juvenile Idiopathic

Arthritis, Monoarticular

Arthritis, Rheumatoid

Arthritis, Septic

Ascites

Asthma, Adult

Asthma, Pediatric

Asystole

Ataxia

Atrial Fibrillation

Atrial Flutter

Atrioventricular Blocks

Babesiosis

Back Pain

Bacterial Tracheitis
Barbiturates Poisoning
Barotrauma
Bartholin Abscess
Bath Salts – Synthetic Cathinones Poisoning
Bell's Palsy
Benzodiazepine Poisoning
Beta-Blocker Poisoning
Biologic Weapons
Bipolar Disorder
Bite, Animal
Bite, Human
Bladder Injury
Blow-Out Fracture
Boerhaave Syndrome
Botulism
Bowel Obstruction (Small and Large)
Bradyarrhythmias
Bronchiolitis
Bronchitis
Brugada Syndrome
Bundle Branch Blocks
Burns
Bursitis
Calcium Channel Blocker Poisoning
Candidiasis, Oral
Carbamazepine Poisoning
Carbon Monoxide Poisoning
Cardiac Arrest
Cardiac Pacemakers
Cardiac Testing
Cardiac Transplantation Complications
Cardiogenic Shock
Cardiomyopathy

Cardiomyopathy, Hypertrophic
Cardiomyopathy, Peripartum
Carpal Fractures
Carpal Tunnel Syndrome
Cauda Equina Syndrome
Caustic Ingestion
Cavernous Sinus Thrombosis
Cellulitis
Central Retinal Artery Occlusion
Central Retinal Vein Occlusion
Cerebral Aneurysm
Cerebral Vascular Accident
Cervical Adenitis
Cesarean Section, Emergency
Chancroid
Chemical Weapons Poisoning
Chest Pain
Chest Trauma, Blunt
Chest Trauma, Penetrating
Cholangitis
Cholecystitis
Cholelithiasis
Chronic Obstructive Pulmonary Disease
Cirrhosis
Clavicle Fracture
Coagulopathy Reversal (Nonwarfarin Agents)
Cocaine Poisoning
Colon Trauma
Coma
Compartment Syndrome
Congenital Heart Disease, Acyanotic
Congenital Heart Disease, Cyanotic
Congestive Heart Failure
Conjunctivitis

Rosen & Barkin's

5-Minute Emergency Medicine Consult

5TH EDITION

Rapid-Sequence Intubation*

1. Pre-oxygenate with 100% oxygen
2. Apply cricoid pressure
3. Induction: etomidate (0.3 mg/kg), propofol (0.5–2 mg/kg) or ketamine (2 mg/kg) IV push
4. Neuromuscular blockade: succinylcholine 1.5 mg/kg IV push
5. Wait 30–45 sec
6. Intubate when optimal conditions achieved

*Consider pretreatment with fentanyl (1–2 µg/kg) IV push (over 1–2 min) and lidocaine (1.5 mg/kg) IV push if concern for increased intracranial pressure or severe hypertension

*Consider defasciculating dose of paralytic if concern for increased intracranial pressure (see table for dosage)

*Atropine: 0.02 mg/kg IV push (for children < 1 y)

Neuromuscular Blocking Agents

Agent	RSI Dosage (paralytic)	Dosage (fas pro*)	Onset	Duration
Succinylcholine	RSI: 1–2 mg/kg		30–60 sec	4–6 min
Rocuronium	RSI: 0.6–1.2 mg/kg	0.06 mg/kg	2 min	30 min
Vecuronium	RSI: 0.015–0.25 mg/kg	0.01 mg/kg	2.5–5 min	25–40 min

*fas pro, fasciculation prophylaxis/defasciculating dose; RSI, rapid-sequence intubation.

Sedative and Induction Agents

Sedative	Dosage IVP	Onset	Duration
Etomidate	0.2–0.3 mg/kg	60 sec	3–5 min
Fentanyl	Induction: 2–10 µg/kg Sedation (titrate): 0.5–1 µg/kg	60 sec	30–60 min
Ketamine	2 mg/kg slow IVP (<0.5 mg/kg/min)	30–60 sec	15 min
Midazolam	Induction: 0.07–0.3 mg/kg Sedation (titrate): 0.02–0.04 mg/kg	2 min	1–2 h
Propofol	0.5–2 mg/kg IVP	30 sec	3–10 min
Thiopental	3–4 mg/kg	20–40 sec	5–10 min

Pediatric Vital Signs and Resuscitation Equipment Sizes

	Term	6 mo	1 yr	2 yr	5 yr	10 yr

ABDOMINAL AORTIC ANEURYSM

Daniel J. Henning • Jason C. Imperato • Carlo L. Rosen

BASICS

DESCRIPTION

- Focal dilation of the aortic wall with an increase in diameter by at least 50% (> 3 cm).
- 95% are infrarenal.
- Rapid expansion or rupture causes symptoms.
- Rupture can occur into the intraperitoneal or retroperitoneal spaces
- Intraperitoneal rupture is usually immediately fatal
- Average growth rate of 0.2–0.5 cm/yr
- Of ruptures:
 - 90% overall mortality
 - 80% mortality for patients who reach the hospital
 - 50% mortality for patients who undergo emergency repair

Geriatric Considerations

- Risk increases with advanced age.
- Present in:
 - 4–8% of all patients older than 65 yr
 - 5–10% of men 65–79 yr old
 - 12.5% of men 75–84 yr old
 - 5.2% of women 75–84 yr old

ETIOLOGY

- Risk factors:
 - Male gender
 - Age > 65 yr
 - Family history
 - Cigarette smoking
 - Atherosclerosis
 - HTN
 - Diabetes mellitus
 - Connective tissue disorders:
 - Ehlers–Danlos syndrome
 - Marfan syndrome
- Uncommon causes:
 - Blunt abdominal trauma
 - Congenital aneurysm

- Infections of the aorta
- Mycotic aneurysm secondary to endocarditis
- Rupture risk factors:
 - Size (annual rupture rates):
 - Aneurysms 5–5.9 cm = 4%
 - Aneurysms 6–6.9 cm = 7%
 - Aneurysms 6.9–7 cm = 20%
 - Expansion:
 - A small aneurysm that grows > 0.5 cm in 6 mo is at high risk for rupture.
 - Gender:
 - For aneurysms 4.0–5.5 cm, women have 4 × higher risk of rupture compared to men with similar sized aneurysms.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Abdominal, back, or flank pain:
 - Vague, dull quality
 - Constant, throbbing, or colicky
 - Acute, severe, constant
 - Radiates to chest, thigh, inguinal area, or scrotum
 - Flank pain radiating to the groin in 10% of cases
- Lower extremity pain
- Syncope, near-syncope
- Unruptured are most often asymptomatic

Physical-Exam

- Unruptured:
 - Abdominal mass or fullness
 - Palpable, nontender, pulsatile mass
 - Intact femoral pulses
- Ruptured:
 - Classic triad (only 1/3 of the cases):
 - Pain
 - Hypotension
 - Pulsatile abdominal mass
 - Systemic:
 - Hypotension
 - Tachycardia

- Evidence of systemic embolization
- Abdomen:
 - Pulsatile, tender abdominal mass
 - Flank ecchymosis (Grey Turner sign) indicates retroperitoneal bleed.
 - Only 75% of aneurysms > 5 cm are palpable.
 - Abdominal tenderness
 - Abdominal bruit
 - GI bleeding
- Extremities:
 - Diminished or asymmetric pulses in the lower extremities
- Complications:
 - Large emboli: Acute painful lower extremity
 - Microemboli: Cool, painful, cyanotic toes (“blue toe syndrome”)
 - Aneurysmal thrombosis: Acutely ischemic lower extremity
 - Aortoenteric fistula: GI bleeding

ESSENTIAL WORKUP

- Unstable patients:
 - Bedside abdominal US
 - Explorative surgery without further ancillary studies
- Stable, symptomatic patients:
 - Abdominal CT

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Type and cross-match blood
- CBC
- Creatinine
- Urinalysis
- Coagulation studies

Imaging

- Plain radiographs:
 - Abdominal or lateral lumbar radiographs
 - Only if other tests are unavailable
 - Curvilinear calcification of the aortic wall or a paravertebral soft-tissue mass indicates abdominal aortic aneurysm (AAA) in 75% of patients.
 - Cannot identify rupture
 - Negative study does not rule out AAA.
- Abdominal ultrasound:
 - 100% sensitive and 92–99% specific for detecting AAA prior to rupture
 - In emergent setting, useful to determine presence of AAA.

- Ultrasound findings consistent with AAA are enlarged aorta >3 cm or focal dilatation of the aorta.
- Sensitivity has been reported as low as 10% following rupture.
- Indicated in the unstable patient
- Abdominal CT scan:
 - Contrast is not necessary to make the diagnosis but CT angiogram is required for surgical planning for an endovascular approach
 - Will demonstrate both aneurysm and site of rupture (intraperitoneal vs. retroperitoneal)
 - Allows more accurate measurement of aortic diameter

DIFFERENTIAL DIAGNOSIS

- Other abdominal arterial aneurysms (i.e., iliac or renal)
- Aortic dissection
- Renal colic
- Biliary colic
- Musculoskeletal back pain
- Pancreatitis
- Cholecystitis
- Appendicitis
- Bowel obstruction
- Perforated viscus
- Mesenteric ischemia
- Diverticulitis
- GI hemorrhage
- Aortic thromboembolism
- Myocardial infarction
- Addisonian crisis
- Sepsis
- Spinal cord compression

TREATMENT

PRE HOSPITAL

- Establish 2 large-bore IV lines
- Rapid transport to the nearest facility with surgical backup
- Alert ED staff as soon as possible to prepare the following:
 - Operating room
 - Universal donor blood
 - Surgical consultation

INITIAL STABILIZATION/THERAPY

- 2 large-bore IV lines
- Crystalloid infusion
- Cardiac monitor
- Early blood transfusion

ED TREATMENT/PROCEDURES

For patients suspected of symptomatic AAA:

- Avoid over aggressive fluid resuscitation; this leads to increased bleeding
- Emergent surgical consult and operative intervention
- Laparotomy versus endovascular aortic repair (EVAR) by vascular surgeon
- Diagnostic tests should not delay definitive treatment.

FOLLOW-UP

DISPOSITION

Admission Criteria

All patients with symptomatic AAA require emergent surgical intervention and admission.

Discharge Criteria

Asymptomatic patients only

FOLLOW-UP RECOMMENDATIONS

- Close vascular surgery follow-up must be arranged prior to discharge
- Instructions to return immediately for:
 - Any pain in the back, abdomen, flank, or lower extremities
 - Any dizziness or syncope

PEARLS AND PITFALLS

- AAA should be on the differential for any patient presenting with pain in the abdomen, back, or flank.
- Symptomatic AAA requires immediate treatment. Do not delay definitive care for extra studies.
- A hemodynamically unstable (i.e., hypotensive) patient should not be taken for CT scan.

CODES

ICD9

ICD9

- 441.3 Abdominal aneurysm, ruptured
- 441.4 Abdominal aneurysm without mention of rupture

ICD10

- I71.3 Abdominal aortic aneurysm, ruptured
- I71.4 Abdominal aortic aneurysm, without rupture

ABDOMINAL PAIN

Saleh Fares

BASICS

DESCRIPTION

- **Parietal pain:**
 - Irritating material causing peritoneal inflammation
 - Pain transmitted by somatic nerves
 - Exacerbated by changes in tension of the peritoneum
 - Pain is sharp, well localized with abdominal, rebound tenderness and involuntary guarding
- **Visceral pain:**
 - Afferent impulses result in poorly localized pain based on the embryologic origin rather than true location of an organ.
 - Pain of foregut structures to the epigastric area
 - Pain from midgut structures to the periumbilical area
 - Pain from hindgut structures to the suprapubic region
 - Distention of a viscous or organ capsule or spasm of intestinal muscularis fibers
 - Pain is constant and colicky
 - **Inflammation:**
 - Focal tenderness develops once the inflammation extends to the peritoneum
 - **Ischemia from vascular emergencies:**
 - Pain is severe and diffuse
- **Referred pain:**
 - Felt at distant location from diseased organ
 - Due to an overlapping supply by the affected neurosegment
- **Abdominal wall pain:**
 - Constant, aching with muscle spasm
 - Involvement of other muscle groups

ETIOLOGY

- **Peritoneal irritants:**
 - Gastric juice, fecal material, pus, blood, bile, pancreatic enzymes
- **Visceral obstruction:**
 - Small and large intestines, gallbladder, ureters and kidneys, visceral ischemia, intestinal, renal, splenic
- **Visceral inflammation:**
 - Appendicitis, inflammatory bowel disorders, cholecystitis, hepatitis, peptic

ulcer disease, pancreatitis, pelvic inflammatory disease, pyelonephritis

- Abdominal wall pain
- Referred pain: (e.g., intrathoracic disease)

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Pain
 - Nature of onset of pain
 - Time of onset and duration of pain
 - Location of pain initially and at presentation
 - Extra-abdominal radiations
 - Quality of pain (sharp, dull, crampy)
 - Aggravating or alleviating factors
 - Relation of associated finding to pain onset
- Anorexia
- Nausea
- Vomiting (bilious, coffee-ground emesis)
- Malaise
- Fainting or syncope
- Cough, dyspnea, or respiratory symptoms
- Change in stool characteristics (e.g., melena)
- Hematuria
- Changes in bowel or urinary habits
- History of trauma or visceral obstruction
- Gynecologic and obstetric history
- Postoperative (e.g., cause ileus)
- Family history (e.g., familial aortic aneurysm)
- Alcohol use and quantity
- Medications: (e.g., aspirin and NSAIDs)

Physical-Exam

- General:
 - Anorexia
 - Tachycardia
 - Tachypnea
 - Hypotension
 - Fever
 - Yellow sclera (icterus)
 - Distal pulses and pulse amplitudes between lower and upper extremities

- Abdominal:
 - Distended abdomen
 - Abnormal bowel sounds:
 - High-pitched rushes with bowel obstruction
 - Absence of sound with ileus or peritonitis
 - Pulsatile abdominal mass
 - Rebound tenderness, guarding, and cough test for peritoneal irritation (e.g., appendicitis, peritonitis)
 - Rovsing sign, suggestive of appendicitis:
 - Palpation of left lower quadrant causes pain in right lower quadrant (RLQ).
 - Psoas sign suggests appendicitis (on right)
 - Pain on extension of thigh
 - Obturator sign suggests pelvic appendicitis (on the right only)
 - Pain on rotation of the flexed thigh, especially internal rotation
 - McBurney point tenderness associated with appendicitis:
 - Palpation in RLQ 2/3 distance between umbilicus and right anterior superior iliac crest causes pain.
 - Murphy sign, suggestive of cholecystitis:
 - Pause in inspiration while examiner is palpating under liver
 - Carnett sign indicates abdominal wall pain
 - Pain when a supine patient tenses the abdominal wall by lifting the head and shoulders.
 - Tender or discolored hernia site
 - Rectal and pelvic examination:
 - Tenderness with pelvic peritoneal irritation
 - Cervical motion tenderness
 - Adnexal masses
 - Rectal mass or tenderness
 - Guaiac positive stool
- Genitourinary:
 - Flank pain
 - Dysuria
 - Costovertebral angle tenderness
 - Suprapubic tenderness
 - Tender adnexal mass on pelvis
 - Testicular pain:
 - May be referred from renal or appendiceal pathology
- Referred pain:
 - Kehr sign (diaphragmatic irritation due to blood or other irritants) causes shoulder pain.
- Extremities:
 - Pulse deficit or unequal femoral pulses

- Skin:
 - Jaundice
 - Liver disease (caput medusa)
 - Hemorrhage
 - Grey Turner sign of flank ecchymosis
 - Cullen sign is ecchymotic area round the umbilicus
 - Herpes zoster
 - Cellulitis
 - Rash (Henoch–Schönlein purpura [HSP])

ESSENTIAL WORKUP

- For a woman in reproductive age group a pregnancy test is essential
- Where applicable for majority of cases, ultrasonography should be done with CT used in cases of negative or inconclusive ultrasonography.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Serum electrolytes, creatinine, and glucose
- ESR
- LFTs
- Lactic acid
- Serum lipase:
 - More sensitive and specific than amylase
- Urinalysis
- Stool analysis and culture
- Pregnancy testing (age reproductive women)

Imaging

- EKG:
 - Consider if risk factors for coronary artery disease are present
- Abdominal radiograph: Supine and upright
 - CT is superior for suspected visceral perforation and bowel obstruction.
- Upright CXR:
 - Pneumoperitoneum
 - Intrathoracic disease causing referred abdominal pain
- US:
 - Biliary abnormalities
 - Hydronephrosis
 - Intra-peritoneal fluid
 - Aortic aneurysm
 - Intussusception

- US (Doppler ultrasonography)
 - Volvulus and malrotation
 - Testicular and ovarian torsion
 - Hepatitis, cirrhosis, and portal vein thrombosis
- Abdominal CT:
 - Spiral CT without contrast:
 - Renal Colic
 - Retroperitoneal hemorrhage
 - Appendicitis
 - CT with intravenous contrast only:
 - Vascular rupture suspected in a stable patient (e.g., acute abdominal aortic aneurysm [AAA], aortic dissection)
 - Ischemic bowel
 - Pancreatitis
 - CT with IV and oral contrast:
 - Indicated when there is a suspicion of a surgical etiology involving bowel
 - History of inflammatory bowel disease
 - Thin patients (low BMI)
 - Diverticulitis
 - CT angiography:
 - Mesenteric ischemia
 - AAA
- IVP:
 - CT has replaced the use of intravenous urography in detection of ureteral stones
- Barium enema:
 - Intussusception
 - Treatment and confirmation of intussusception is with air contrast enema.
- MRI:
 - If concerns for radiation exposure or nephrotoxicity
 - Contraindicated in patients with metallic implants

Pregnancy Considerations

Ultrasonography and MRI should be preferred to prevent exposure of ionizing radiation to the fetus.

DIFFERENTIAL DIAGNOSIS

- AAA
- Abdominal epilepsy or abdominal migraine
- Boerhaave syndrome
- Adrenal crisis
- Early appendicitis

- Bowel obstruction
- Cholecystitis
- Constipation +/- fecal impaction
- Diabetic ketoacidosis
- Diverticulitis
- Dysmenorrhea
- Ectopic pregnancy
- Esophagitis
- Endometriosis
- Fitz-Hugh–Curtis syndrome
- Gastroenteritis
- Hepatitis
- Incarcerated hernia
- Infectious gastroenteritis
- Inflammatory bowel disease
- Irritable bowel syndrome
- Ischemic bowel
- Meckel diverticulitis
- Neoplasm
- Ovarian torsion
- Ovarian cysts (hemorrhagic)
- Pancreatitis
- Pelvic inflammatory disease
- Peptic ulcer disease
- Renal/ureteral calculi
- Renal Infarction
- Sickle cell crisis
- Spider bite (Black widow)
- Splenic infarction
- Spontaneous abortion
- Testicular torsion
- Tubo-ovarian abscess
- UTI
- Volvulus
- Referred pain:
 - Myocardial infarction
 - Pneumonia
- Abdominal wall pain:
 - Abdominal wall hematoma or infection
 - Black widow spider bite
 - Herpes zoster

Pediatric Considerations

- Under 2 yr:
 - Hirschsprung disease
 - Incarcerated hernia
 - Intussusception
 - Volvulus
 - Foreign body ingestion
- 2–5 yr:
 - Appendicitis
 - Incarcerated hernia
 - Meckel diverticulitis
 - Sick cell crisis
 - HSP
 - Constipation

TREATMENT

ED TREATMENT/PROCEDURES

- Nasogastric tube decompression and bowel rest
- IV fluids and electrolyte repletion
- Antiemetics are important for comfort.
- Narcotics or analgesics should not be withheld.
- Send for blood type and cross-match for unstable patient
- Surgical consultation based on suspected etiology

MEDICATION

- Fentanyl: 1–2 $\mu\text{g}/\text{kg}$ IV qh
- Morphine sulfate: 0.1 mg/kg IV q4h PRN
- Ondansetron: 4 mg IV
- Prochlorperazine: 0.13 mg/kg IV/PO/IM q6h PRN nausea; 25 mg PR q6h in adults
- Promethazine: 25–50 mg/kg IM/PO/PR

FOLLOW-UP

DISPOSITION

Admission Criteria

- Surgical intervention
- Peritoneal signs
- Patient unable to keep down fluids
- Lack of pain control
- Medical cause necessitating in-house treatment (MI, DKA)
- IV antibiotics needed

Discharge Criteria

No surgical or severe medical etiology found in patient who is able to keep fluid down, has good pain control, and is able to follow detailed discharge instructions

FOLLOW-UP RECOMMENDATIONS

The patient should return with any warning signs:

- Vomiting
- Blood or dark/black material in vomit or stools
- Yellow skin or in the whites of the eyes
- No improvement or worsening of pain within 8–12 hr
- Shaking chills, or a fever > 100.4°F (38°C)

PEARLS AND PITFALLS

- Elderly patients are more likely to present with atypical presentations and life threatening etiologies requiring admission.
- Do not consider constipation if stool is absent in the rectal vault.
- Etiology requiring surgical intervention is less likely when vomiting precedes the onset of pain.

- R10.84 Generalized abdominal pain

ABDOMINAL TRAUMA, BLUNT

Stewart R. Coffman

BASICS

DESCRIPTION

- Injury results from a sudden increase of pressure to abdomen.
- Solid organ injury usually manifests as hemorrhage.
- Hollow viscus injuries result in bleeding and peritonitis from contamination with bowel contents.

ETIOLOGY

- 60% result from motor vehicle collisions.
- Solid organs are injured more frequently than hollow viscus organs.
- The spleen is the most frequently injured organ (25%), followed by the liver (15%), intestines (15%), retroperitoneal structures (13%), and kidney (12%).
- Less frequently injured are the mesentery, pancreas, diaphragm, urinary bladder, urethra, and vascular structures.

Pediatric Considerations

- Children tend to tolerate trauma better because of the more elastic nature of their tissues.
- Owing to the smaller size of the intrathoracic abdomen, the spleen and liver are more exposed to injury because they lie partially outside the bony rib cage.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Spectrum from abdominal pain, signs of peritoneal irritation to hypovolemic shock
- Nausea or vomiting
- Labored respiration from diaphragm irritation or upper abdominal injury
- Left shoulder pain with inspiration (Kehr sign) from diaphragmatic irritation owing to bleeding
- Delayed presentation possible with small-bowel injury

ESSENTIAL WORKUP

- Evaluate and stabilize airway, breathing, and circulation (ABCs).
- Primary objective is to determine need for operative intervention.
- Examine abdomen to detect signs of intra-abdominal bleeding or peritoneal irritation.
- Injury in the retroperitoneal space or intrathoracic abdomen is difficult to assess

by palpation.

- Remember that the limits of the abdomen include the diaphragm superiorly (nipples anteriorly, inferior scapular tip posteriorly) and the intragluteal fold inferiorly and encompass entire circumference.
- Abrasions or ecchymoses may be indicators of intra-abdominal injury:
 - Roll the patient to assess the back.
 - Lap-belt abrasions can be indicative of significant intra-abdominal injuries.
- Bowel sounds may be absent from peritoneal irritation (late finding).
- Foley catheter (if no blood at the meatus, no perineal hematoma, and normal prostate exam) to obtain urine and record urinary output
- Plain film of the pelvis:
 - Fracture of the pelvis and gross hematuria may indicate genitourinary injury.
 - Further evaluation of these structures with retrograde urethrogram, cystogram, or IV pyelogram
- CT most useful in assessing need for operative intervention and for evaluating the retroperitoneal space and solid organs:
 - Patient must be stable enough to make trip to scanner.
 - Also useful for suspected renal injury
- Focused abdominal sonography for trauma (FAST) to detect intraperitoneal fluid:
 - US is rapid, requires no contrast agents, and is noninvasive.
 - Operator dependent
- Diagnostic peritoneal lavage (useful for revealing injuries in the intrathoracic abdomen, pelvic abdomen, and true abdomen) primarily indicated for unstable patients:
 - Positive with gross blood, RBC count of $>100,000/\text{mm}^3$, WBC count of $500/\text{mm}^3$, or presence of bile, feces, or food particles

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Hemoglobin/hematocrit, which initially may be normal owing to isovolemic blood loss
- Type and screen is essential. Cross-match PRBC units for unstable patients.
- Urinalysis for blood:
 - Microscopic hematuria in the presence of shock is an indication for genitourinary evaluation.
- ABG:
 - Base deficit may suggest hypovolemic shock and help guide the resuscitation.

Imaging

See “Essential Workup.”

Diagnostic Procedures/Surgery

See “Essential Workup”

DIFFERENTIAL DIAGNOSIS

Lower thoracic injury may cause abdominal pain.

TREATMENT

PRE HOSPITAL

- Titrate fluid resuscitation to clinical response. Target SBP of 90–100 mm Hg
- Normal vital signs do not preclude significant intra-abdominal pathology.

INITIAL STABILIZATION/THERAPY

- Ensure adequate airway:
 - Intubate if needed.
 - O₂ 100% by nonrebreather face mask
- 2 large-bore IV lines with crystalloid infusion
- Begin infusion of PRBCs if no response to 2 L of crystalloid.
- If patient is in profound shock, consider immediate transfusion of O-negative blood.

ED TREATMENT/PROCEDURES

- Continue stabilization begun in field.
- Nasogastric tube to evacuate stomach, decrease distention, and decrease risk of aspiration:
 - May relieve respiratory distress if caused by a herniated stomach through the diaphragm

MEDICATION

- Tetanus toxoid booster: 0.5 mL IM for patients with open wounds
- Tetanus immunoglobulin: 250 U IM for patients who have not had complete series
- IV antibiotics: Broad-spectrum aerobic with anaerobic coverage such as a 2nd-generation cephalosporin

Pediatric Considerations

- Crystalloid infusion is 20 mL/kg if patient is in shock.
- PRBC dose is 1 mL/kg.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Postoperative cases
- Equivocal findings on diagnostic peritoneal lavage, FAST exam, or CT
- Many blunt abdominal trauma patients benefit from admission, monitoring, and serial abdominal exams.

Discharge Criteria

No patient in whom you suspect intra-abdominal injury should be discharged home without an appropriate period of observation, despite negative exam or imaging studies.

PEARLS AND PITFALLS

- Do not delay blood products when patient is in obvious shock despite normal Hct.
- Avoid overaggressive resuscitation with crystalloids.
- Obtain a pregnancy test in all females of childbearing age.
- Do not transport unstable patients to CT for diagnostic imaging.

ABDOMINAL TRAUMA, IMAGING

Alfred A. Joshua

BASICS

DESCRIPTION

Diagnostic procedures: Use of these imaging and procedure modalities will be based on history and physical exam.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Abdominal trauma can be seen in a variety of patients ranging from those with isolated abdominal injury to multisystem trauma.
- Abdominal trauma is divided into blunt and penetrating injuries. Penetrating abdominal injuries can further be divided into stab wounds and gunshot wounds.
- Hemodynamic status should be the primary initial focus of evaluation. Most unstable patients will require early surgical management, while many stable patients with abdominal trauma may be managed nonoperatively.

History

- History should include mechanism of injury, restraint use and type, airbag or helmet use, prehospital vital signs, initial mental status, and change in mental status.
- AMPLE history (*allergies-to-medications and radiographic contrast agents, medications taken, past medical and surgical history, last meal, events leading up to the injury*)

Physical-Exam

- A comprehensive physical exam should start with ABCDE survey and include full exposure of the patient and careful palpation of all abdominal quadrants.
- Abdominal injury in only 45–50% of cases.
- The abdominal physical exam is frequently misleading in intoxicated, uncooperative, and multisystem trauma patients.

ESSENTIAL WORKUP

- See “Abdominal Trauma (Blunt)” and “Abdominal Trauma (Penetrating).”
- All trauma patients initially managed with:
 - ABCDE survey (Airway, Breathing, Circulation, Disability, Exposure)

DIAGNOSIS TESTS & NTERPRETATION

General approach to imaging in abdominal trauma:

- Unstable trauma patients:
 - Unstable patients should have a bedside ultrasound performed immediately as part of the primary survey (circulation). A positive FAST suggests that intra-abdominal bleeding is the source of hypotension. A negative FAST suggests either a retroperitoneal bleed, blood loss in the field, bleeding from an unstable pelvic fracture, or hemorrhage into another body cavity.
 - A surgeon should be consulted immediately to prepare for definitive operative care of the patient.
 - Stable trauma patients: The 3 main modes of diagnosing the extent of injury in hemodynamically stable abdominal trauma patients include:
 - US: Initial screening test of choice for hemodynamically stable patients. A positive US in the stable trauma patient warns the clinician about the possibility of impending hemodynamic deterioration. CT scan and surgical consult should be rapidly facilitated in this group of patients.
 - CT scan: The definitive test for stable abdominal trauma patients. CT scanning will diagnose both solid organ and retroperitoneal injuries better than ultrasound. CT imaging allows a determination of whether an embolization procedure is warranted for hemorrhage control. It is indicated in all stable patients with stab wounds. It is also indicated in patients with gross hematuria, to look for renal injury.
 - Diagnostic peritoneal lavage: Currently used infrequently.
- Local wound exploration: While frequently used in the past in penetrating abdominal trauma to look for violation of the fascia, it has now also been replaced with CT scanning in the majority of patients (see Diagnostic Tests & Interpretation).

Lab

- Blood type and screen
- CBC
- Electrolytes and creatinine
- Lipase
- UA
- EKG

Imaging

- Ultrasound: FAST exam focuses on dependent intraperitoneal areas where blood can accumulate which include: Hepatorenal space (Morison pouch), splenorenal space, suprapubic region (bladder and pouch of Douglas), pericardium
 - Advantages:
 - Rapid

- Noninvasive
- Can be performed at the patient's bedside concurrent with evaluation and initial resuscitation
- Does not require contrast agents or ionizing radiation
- Can be repeated in the case of changes in the patient's hemodynamic status or physical exam

– Disadvantages:

- Operator dependent
- Does not reliably identify solid organ (e.g., spleen and liver lacerations) or retroperitoneal injuries. May be negative with pelvic fractures despite significant hemorrhage. Not sensitive for bowel injury.

– Contraindications:

- Absolute: None
- Relative: Obesity; subcutaneous emphysema

– Positive test:

- Demonstration of free fluid or obvious solid organ injury. ~ 600 mL free fluid required in adults for a positive right upper quadrant Morison pouch view. ~ 150 mL is required for a positive pelvic/suprapubic view (optimally performed prior to Foley placement).
- Adequate exam includes visualization of the right upper quadrant, left upper quadrant, suprapubic/pelvis, and cardiac areas.

● CT scan:

– Advantages:

- Sensitivity of 85–98%, PPV (for detecting need for laparotomy) of 85%
- Provides specific and detailed organ injury information
- May aid in a nonoperative approach to solid organ injuries, which may be managed with observation or interventional radiology mediated embolectomy.
- Allows imaging of adjacent spinal structures to diagnose fracture.

– Disadvantages:

- Costly
- Possible risk: Up to 1 in 2,000 increase in risk of fatal cancer from radiation
- Requires IV contrast (with risk of acute contrast reactions and renal toxicity).
- Isolated diaphragmatic, pancreatic, bowel injuries may be missed, especially if performed immediately after injury.

– Indications:

- Hemodynamically stable patients

– Contraindications:

- Absolute: Pre-existing indication for exploratory laparotomy; hemodynamic instability; previous contrast reaction
- Considerations:
 - Many institutions now manage multisystem trauma patients with the “pan-scan,” which includes CT imaging of the head, C-spine, chest, and abdomen/pelvis in 1 session.
 - IV contrast is sufficient in the abdominal trauma patient. Oral and rectal contrast is not needed.
 - Angiography
 - Unstable patients and pelvic fractures
 - This approach can embolize vessels from pelvis, spleen, etc.

Diagnostic Procedures/Surgery

- Diagnostic peritoneal lavage:
 - Advantages:
 - Rapid
 - Helpful in detecting mesenteric and hollow organ injuries
 - May be considered in patients with pelvic fractures and hemorrhage
 - Relatively simple to perform
 - Sensitivity 87–92%, specificity 82%, PPV 52%, NPV 87%
 - Low complication rate
 - Disadvantages:
 - Invasive
 - Largely replaced by bedside US
 - Does not identify specific organ injury
 - 1–2% complication rate
 - May miss retroperitoneal injuries and intraperitoneal bladder rupture
 - High false-positive rates
- Possible indications:
 - Hemodynamically unstable patients
 - Patients requiring emergent surgery for other conditions (e.g., craniotomy for epidural hematoma)
 - Pelvic fractures
- Contraindications:
 - Absolute: Pre-existing indication for exploratory laparotomy
 - Relative: Previous abdominal surgery, severe abdominal distention, pregnancy, pediatric patients
- Considerations:
 - Foley catheter and nasogastric tube placement is recommended before beginning the procedure.
- Contraindications:
 - Blood at urethra
 - High riding prostate

- Positive test:
 - Aspiration of > 10 mL of blood, bile, bowel contents, or urine
 - Diagnostic peritoneal lavage fluid in the urine or chest tube
 - Blunt trauma with > 100,000 erythrocytes/mm³
 - Penetrating trauma > 1,000 erythrocytes/mm³

DIFFERENTIAL DIAGNOSIS

See “Abdominal Trauma (Blunt)” and “Abdominal Trauma (Penetrating).”

TREATMENT

PRE HOSPITAL

All patients with a significant mechanism of injury or suspicion of major trauma should be triaged to a designated trauma center (preferably a Level 1 Center)

Pediatric Considerations

- Pediatric patients should be triaged to a pediatric trauma center or to an adult trauma center equipped to manage children.
- CT scan should be considered the diagnostic test of choice in children.

INITIAL STABILIZATION/THERAPY

- In unstable patients, management of the airway, breathing, and circulation with resuscitation of hypovolemic shock and rapid control of major hemorrhage must take precedence.
- See “Abdominal Trauma (Blunt)” and “Abdominal Trauma (Penetrating).”

ED TREATMENT/PROCEDURES

- See “Abdominal Trauma (Blunt)” and “Abdominal Trauma (Penetrating).”
- Crystalloid IV therapy is generally warranted with significant abdominal injury.
- 2 large-bore IV catheters should be placed.
- Blood transfusion is indicated for all hemodynamically unstable abdominal trauma patients. O negative or O positive blood can be used in men/women beyond childbearing age.
- Hemodynamically unstable trauma patients with altered mental status and inability to protect airway will usually need endotracheal intubation prior to transfer to operating suite.

FOLLOW-UP

DISPOSITION

Admission Criteria

- All unstable trauma patients require admission to the hospital and most will require surgical management.
- Most multisystem trauma patients who also have abdominal trauma will need admission.
- Pregnant women > 24 wk gestation should be admitted for fetal–maternal monitoring.
- Stable trauma patients are divided into 3 classes:
 - Gun shot wounds to abdomen: Almost all will require admission. Rate of surgical exploration is high in this category due to elevated risk of organ injury.
 - Stab wounds to abdomen: Patients with penetration of fascia will require admission. US, CT, or physical exam will define patients who need operative management.
 - Blunt abdominal trauma: US, CT, or exam will define patients who need admission.

Discharge Criteria

- Patients with stable hemodynamics during their ED course with a negative evaluation and reliable follow-up may be considered for discharge.
- Patients with inability to travel back to the hospital or to contact EMS for aid in case of deterioration must be considered for admission.

FOLLOW-UP RECOMMENDATIONS

A small subset of discharged patients may have an undiagnosed injury (most commonly intestinal or pancreatic). Patients must be instructed to return to the ED with worsening abdominal pain, distention, vomiting, or rectal bleeding.

PEARLS AND PITFALLS

- US can be immediately performed at the bedside concurrent with initial stabilization.
- Consider serial US exams. This is especially important if there is a change in the patient's hemodynamic status or physical exam.
- Many stable adult and pediatric trauma patients are now being managed nonoperatively based on CT findings.
- “Pan CT scan” decreases missed injury rate but increases lifetime risk of cancer.
- With increased use of US and CT, DPL and local wound exploration have become less useful in the evaluation of abdominal trauma.
- Pitfalls include:
 - Not immediately sending type and screen or checking a pregnancy test
 - Sending pregnant women > 24 wk gestation home without fetal–maternal monitoring

ABDOMINAL TRAUMA, PENETRATING

Stewart R. Coffman • Stephen R. Hayden

BASICS

DESCRIPTION

- Solid organ injury usually results in hemorrhage.
- Hollow viscus injury can lead to spillage of bowel contents and peritonitis.
- Associated conditions:
 - Injury to both thoracic and abdominal structures occurs in 25% of cases.

ETIOLOGY

80% of gunshot wounds and 20–30% of stab wounds result in significant intra-abdominal injury. Commonly injured structures include:

- Liver (37%)
- Small bowel (26%)
- Stomach (19%)
- Colon (17%)
- Major vessel (13%)
- Retroperitoneum (10%)
- Mesentery/omentum (10%)
- Other:
 - Spleen (7%)
 - Diaphragm (5%)
 - Kidney (5%)
 - Pancreas (4%)
 - Duodenum (2%)
 - Biliary (1%)

DIAGNOSIS

SIGNS AND SYMPTOMS

- Penetrating wound from knife, gun, or other foreign object
- Spectrum of presentation ranging from localized pain to peritoneal signs:
 - High-velocity projectile can cause extensive direct tissue damage.
 - Secondary missiles and temporary cavitation of effected structures
 - Exit wound may be larger than entrance wound, but small entrance and exit wounds can conceal massive internal damage.
- Remember the borders of the abdomen: Superior from the nipples (anteriorly) or inferior tip of scapula (posteriorly) to inferior gluteal folds.

ESSENTIAL WORKUP

- Diagnosis of intra-abdominal injury from gunshot wounds to the abdomen are made by laparotomy in the operating room.
- Locally explore stab wounds to anterior abdomen:
 - If the wound penetrates the anterior fascial layer, the patient should undergo diagnostic peritoneal lavage or bedside US.
- Diagnostic laparoscopy is useful in diagnosing diaphragmatic injury and spleen and liver lacerations:
 - May help avoid unnecessary surgery.
- CT is useful in the evaluation of patients with a suspected retroperitoneal injury:
 - Not reliable for detection of hollow viscus or diaphragmatic injuries
- If 10,000 RBC/mm³ or more are found in the diagnostic peritoneal lavage fluid, the patient should undergo laparotomy.
- If <10,000 RBC/mm³ are present, the patient should be observed for 8–24 hr for the development of peritoneal signs.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Hemoglobin or hematocrit:
 - Repeated measurements to assess for ongoing hemorrhage
- Urinalysis for blood to assess for possible genitourinary tract damage
- ABG:
 - Base deficit may be helpful in assessing hypovolemia and guide volume resuscitation.
- Type and cross-match for all patients with significant intra-abdominal injuries.

Imaging

- Plain films:
 - Obtain after placement of markers for localization of foreign bodies, missiles, associated fractures, and free air.
- IV pyelogram:
 - For possible renal injury
- Bedside abdominal US (FAST: Focused abdominal sonography for trauma):
 - May reveal intraperitoneal blood or fluid
- CT with IV contrast in experienced facilities and with stable patients:
 - For possible retroperitoneal and solid organ injuries

DIFFERENTIAL DIAGNOSIS

- In cases of upper abdominal wounds, consider the possibility of intrathoracic injury.
- In cases of wounds to the lower thoracic area, consider the possibility of intra-

abdominal injury.

TREATMENT

PRE HOSPITAL

- Controversies:
 - Military antishock trousers (MAST) should not be used.
 - Titrate fluid resuscitation to clinical response.
- Caution:
 - Apply sterile dressings to open wounds and moistened sterile dressings to eviscerated bowel.
 - Secure impaled foreign objects in place; do not remove them.

INITIAL STABILIZATION/THERAPY

- 2 large-bore IV lines with crystalloid infusion
- If no response to 2 L of crystalloid, infuse 2–4 units packed red blood cells:
 - May use O negative blood initially if patient is unstable
 - Type-specific and cross-matched blood when it becomes available
- 100% oxygen by nonrebreather face mask

Pediatric Considerations

- Children in hypovolemic shock should receive 20 mL/kg boluses of crystalloid.
- Children in severe hypovolemic shock should receive 1 mL/kg of packed red blood cells.
- Age < 8 yr is a relative contraindication for diagnostic peritoneal lavage.

ED TREATMENT/PROCEDURES

- Nasogastric tube placement:
 - Will decrease aspiration risk
 - Place nasogastric tube before performing diagnostic peritoneal lavage to decompress stomach and reduce risk of iatrogenic injury.
 - May relieve respiratory distress in cases of diaphragmatic injury with herniated abdominal contents in the thorax
- Foley catheter placement:
 - Insert after ruling out urethral injuries
 - Facilitates rapid assessment of genitourinary injury
 - Assists in monitoring of urinary output
- Tetanus if appropriate; tetanus immunoglobulin if primary tetanus series not administered

MEDICATION

- Tetanus: 0.5 mL IM

- Tetanus immunoglobulin: 250 units IM for patients who have not had a complete series
- IV antibiotics: Antibiotics with coverage against gram-negative and anaerobic organisms:
 - Ampicillin/sulbactam:
 - Adults: 3 g q6h IV (peds: 50 mg/kg IV)
 - Cefotetan:
 - Adults: 2 g q12h IV (peds: 40 mg/kg IV)
 - Cefoxitin:
 - Adults: 2 g q6h IV (peds: 80 mg/kg q6h IV)
 - Piperacillin/tazobactam:
 - Adults: 3.375 g IV (peds: 75 mg/kg IV)
 - Ticarcillin/clavulanate:
 - Adults: 3.1 g IV (peds: 75 mg/kg IV)
- Additional anaerobic coverage:
 - Clindamycin:
 - Adults: 600–900 mg IV (peds: 10 mg/kg IV)
 - Metronidazole:
 - Adults: 1 g IV (peds: 15 mg/kg IV)
- Combination therapy:
 - Adults: Ampicillin 500 mg IV q6h, gentamicin 1–1.7 mg/kg IV, and metronidazole 1 g IV
 - Peds: Ampicillin 50 mg/kg IV q6h, gentamicin 1–1.7 mg/kg IV, and metronidazole 15 mg/kg IV

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients requiring abdominal surgery
- Observe the following patients for at least 8 hr:
 - Patients with negative findings on diagnostic peritoneal lavage, CT, or US. During hospitalization, the following are necessary:
 - Frequent abdominal exam
 - Repeated hematocrit levels at regular intervals

Discharge Criteria

Patients with stab wounds without fascial penetration may be discharged after observation in the ED.

PEARLS AND PITFALLS

Permissive hypotension is gaining support as a resuscitative principle:

- Avoid normal or near normal BP.
- Avoid overaggressive resuscitation with crystalloids.
- Completely exposing the patient will minimize overlooking an injury.
- Spinal immobilization is unnecessary unless there is an obvious spinal cord injury.

ABORTION, SPONTANEOUS

Ivette Motola • Aviva Jacoby Zigman

BASICS

DESCRIPTION

- Spontaneous termination of a < 20 wk intrauterine pregnancy
- Synonyms: Early pregnancy loss, miscarriage
- Occurs in up to 15–20% of recognized pregnancies (most common complication of early pregnancy)
- Vaginal bleeding in the 1st trimester seen in about 25% of pregnant patients:
 - 50% of these women will eventually mis-carry
- Definitions:
 - *Threatened abortion*: Vaginal bleeding, cervical os is closed, viable intrauterine pregnancy confirmed:
 - 50% of women seen in the ED for threatened abortion will eventually miscarry
 - *Inevitable abortion*: Vaginal bleeding, cervical os is open; products of conception (POC) have not been expelled
 - *Incomplete abortion*: Vaginal bleeding, cervical os is open with partial passage of some POC and some retained POC
 - *Complete abortion*: Vaginal bleeding, cervical os closed, complete passage of POC; no surgical or medical intervention
 - *Missed abortion*: Fetal demise with no uterine activity to expel
 - *Septic abortion*: Spontaneous abortion complicated by intrauterine infection
 - *Recurrent spontaneous abortion*: 3 or more consecutive pregnancy losses

ETIOLOGY

- Chromosomal abnormalities of the fetus
- Uterine abnormalities
- Risk factors include:
 - Increased age of both the mother and father
 - Increased parity
 - Alcohol use
 - Cigarette smoking
 - Cocaine use
 - Conception within 3–6 mo after delivery
 - Chronic maternal disease:
 - Poorly controlled diabetes
 - Autoimmune disease
 - Celiac disease

- Intrauterine device
- Maternal BMI < 18 or > 25 kg/m²
- Maternal infections:
 - Bacterial vaginosis
 - Mycoplasmosis
 - Herpes simplex
 - Toxoplasmosis
 - Listeriosis
 - Chlamydia/gonorrhea
 - HIV
 - Syphilis
 - Parvovirus B19
 - Malaria
 - CMV
 - Rubella
- Medications:
 - Misoprostol
 - Methotrexate
 - NSAIDs
- Multiple previous elective abortions
- Previous early pregnancy loss
- Toxins
- Uterine abnormalities (e.g., leiomyoma, uterine adhesions, congenital anomalies)

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Last menstrual period (LMP)
- Obstetric history:
 - Parity
 - Risk factors for pregnancy loss
 - Prenatal care
- Abdominal pain, cramping
- Vaginal bleeding:
 - Duration
 - Amount of bleeding (quantify by number of pads used, compare with normal menstrual period for patient)
 - Passage of clots
- Dizzy, syncope

Physical-Exam

- Determine hemodynamic status of patient:
 - Pregnant patients in late 1st trimester have an increased blood volume
 - Can lose substantial amount of blood before having abnormal vital signs
- Pelvic exam:
 - Determine whether the internal cervical os is opened or closed
 - Amount of bleeding
 - Presence of POC
 - Presence of adnexal tenderness or peritoneal irritation can be consistent with an ectopic pregnancy
- Bimanual exam to determine the size of the uterus:
 - Size of an orange: 6–8 wk
 - Fundus at the symphysis pubis: 12 wk
 - Fundus at the umbilicus: 16–20 wk

ESSENTIAL WORKUP

- Pregnancy test as below
- Imaging as below

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Confirm pregnancy with a urine or serum test:
 - Urine pregnancy test: Most are positive at β -hCG levels of 25–50 mIU/mL ~ 1 wk gestational age and remain positive 2–3 wk after induced or spontaneous abortions
- CBC
- Rapid hemoglobin determination: Type and Rh
- Type and cross-match for woman with low Hct or signs of active blood loss
- Quantitative β -hCG
- Any POC passed should be sent to pathology for confirmation

Imaging

- Transvaginal ultrasound (TVS):
 - Gestational sac seen at 5 wk
 - Cardiac activity seen at 6.5 wk
- Transabdominal ultrasound (TAS):
 - Gestational sac at 6 wk
 - Cardiac activity seen at 8 wk
- Discriminatory zone: Level of β -hCG where a normal IUP should be detected:
 - 1,500–2,000 for TVS
 - 6,500 for TAS

DIFFERENTIAL DIAGNOSIS

- Positive pregnancy test with vaginal bleeding:
 - Cervicitis
 - Ectopic pregnancy
 - Molar pregnancy
 - Pregnancy of unknown location (PUL)
 - Septic abortions
 - Subchorionic hemorrhage
 - Trauma
- 2nd- and 3rd-trimester vaginal bleeding:
 - Placenta previa
 - Placental abruption

TREATMENT

PRE HOSPITAL

- IV fluids, oxygen, and cardiac monitor
- Monitor vital signs and transport
- Cautions:
 - Patients with spontaneous abortion/vaginal bleeding can have severe hemorrhage and present in shock, especially at > 12 wk
 - BP drops during the 2nd trimester of pregnancy with an average of 110/70

INITIAL STABILIZATION/THERAPY

- Stable patients:
 - IV
 - Pelvic exam
- Unstable patients:
 - Oxygen, IV fluids via 2 large-bore IVs, cardiac monitor
 - Transfuse PRBC if patient does not stabilize after 2–3 L of crystalloid
 - Gynecologic consultation immediately
 - Oxytocin or methylergonovine may be necessary to control hemorrhage
 - These patients are at high risk for having ruptured ectopic pregnancies and may need emergent operative intervention

ED TREATMENT/PROCEDURES

- Threatened abortion:
 - Pelvic rest, close follow-up with obstetrics
 - Patients < 6.5 wk pregnant with no documented cardiac activity by vaginal US need to be followed with serial β -hCG to assess the viability of the fetus and to rule out ectopic pregnancy
- Inevitable and incomplete abortions:

- Expectant management:
 - o Successful in up to 85%
 - o Increased risk of unplanned surgical intervention and blood loss as compared to surgical management
- Medical management:
 - o Misoprostol
 - o Successful in up to 85%
- Surgical management:
 - o Dilation and curettage (D&C) or evacuation, removal of POC at the cervical os to help decrease bleeding and cramping
 - o Less unplanned hospital admissions, curettages, and blood transfusions
 - o The confirmation of POC by pathology rules out ectopic pregnancy
- Complete abortion:
 - May treat with methylergonovine or oxytocin if bleeding is heavy
 - If quantitative β -hCG is $< 1,000$ and the US is negative, may follow-up with obstetrics for serial β -hCG to confirm the levels are decreasing
- Missed abortion:
 - These patients are at risk for disseminated intravascular coagulation (DIC), especially if fetus is retained $> 4-6$ wk
 - Obtain CBC, PT/PTT, fibrin-split products (FSP), and fibrinogen levels
 - These patients may be followed closely as outpatients if stable with an early, confirmed IUP and no evidence of DIC
 - Patients may choose to have a D&C at a later date or miscarry at home with medication or no intervention; this decision should be made in consultation with OB/GYN

MEDICATION

First Line

- RHO immunoglobulin in Rh-negative women:
 - 50 μ g for women with threatened or complete abortion at < 12 wk
 - 300 μ g for women with threatened or complete abortion at ≥ 12 wk
- Patients need RhoGAM administration within 72 hr to prevent future isoimmunization
- Misoprostol 800 μ g vaginally if medical management is chosen in consultation with OB/GYN
- Repeat dose required in 48 hr

Second Line

Usually given in consultation with OB/GYN:

- Oxytocin: 20 IU in 1,000 mL of NS at a rate of 20 mIU/min titrated to decrease bleeding; may repeat for a max. dose of 40 mIU/min

- Methylergonovine: 0.2 mg IM/PO QID for bleeding

FOLLOW-UP

DISPOSITION

Admission Criteria

- Suspected unstable ectopic pregnancy (see “Ectopic Pregnancy”)
- Hemodynamically unstable patients with hypovolemia or anemia
- DIC
- Septic abortions
- Suspected gestational trophoblastic disease

Discharge Criteria

- D&Cs can be done in the ED for incomplete and inevitable abortions, and patients may be discharged home if stable after 2–3 hr
- Some early inevitable miscarriages can be discharged to complete their miscarriages at home without a D&C
- Discharge with pain medications and close OB/GYN follow-up
- Patients with threatened abortions should be told to avoid strenuous activity
- Pelvic rest (i.e., “nothing in the vagina” during active bleeding; may increase risk of infection)
- Patients should be instructed to return to the ED for any increase in bleeding, dizziness, or temperature $> 100.4^{\circ}\text{F}$
- Patients and their partners should be counseled that early pregnancy loss is common and that it is not anyone’s fault

FOLLOW-UP RECOMMENDATIONS

Patients with positive pregnancy tests and vaginal bleeding with or without abdominal pain should be followed by OB/GYN.

PEARLS AND PITFALLS

- Recognize the possibility of ectopic pregnancy
- Patients with spontaneous abortion may have clinically significant blood loss

ABSCESS, SKIN/SOFT TISSUE

Neal P. O'Connor

BASICS

DESCRIPTION

- A localized collection of pus surrounded and walled off by inflamed tissue. Abscesses can occur on any part of the body
- Furuncle:
 - Arises from infected hair follicle
 - Most common on back, axilla, and lower extremities
- Carbuncle:
 - Larger and more extensive than furuncle
- Dog/cat bite:
 - Usually polymicrobial
- Breast:
 - Puerperal:
 - Usually during lactation
 - Located in peripheral wedge
 - Usually staphylococci
 - Duct ectasia:
 - Caused by ectatic ducts
 - Periareolar location
 - Usually polymicrobial
- Hidradenitis suppurativa:
 - Chronic abscess of apocrine sweat glands
 - Groin and scalp
 - *Staphylococcus aureus* and *staphylococcus viridans* are common
 - *Escherichia coli* and *Proteus* may be present in chronic disease
- Pilonidal abscess:
 - Epithelial disruption of gluteal fold over coccyx
 - Staphylococcal species are most common
 - May be polymicrobial
- Bartholin abscess:
 - Obstruction of Bartholin duct
- Perirectal abscess:
 - Originates in anal crypts and extends through ischiorectal space
 - Inflammatory bowel disease and diabetes are predisposing factors
 - *Bacteroides fragilis* and *E. coli* are most common
 - Requires operative drainage
- Muscle (pyomyositis):

- Typically in the tropics
- *S. aureus* is most common
- IV drug abuse:
 - Staphylococcal species are most common
 - MRSA is common
 - May be sterile
- Paronychia:
 - Infection around nail fold
 - Usually *S. aureus*
- Felon:
 - Closed space abscess in distal pulp of finger
 - Usually *S. aureus*

ETIOLOGY

- Abscess formation typically occurs due to a break in the skin, obstruction of sebaceous or sweat glands, or inflammation of hair follicles. The collection may be classified as bacterial or sterile:
- Bacterial: Most abscesses are bacterial with the microbiology reflective of the microflora of the involved body part:
 - *S. aureus* is the most common causative organism
 - Community-acquired MRSA (CA-MRSA) common
- Sterile: More associated with IV drug abuse and injection of chemical irritants
- Risk factors for abscess formation:
 - Immunosuppression
 - Soft tissue trauma
 - Mammalian/human bites
 - Tissue ischemia
 - IV drug use
 - Chron's disease (perirectal)

DIAGNOSIS

SIGNS AND SYMPTOMS

- Local:
 - Erythema
 - Tenderness
 - Heat
 - Swelling
 - Fluctuance
 - May have surrounding cellulitis
 - Regional lymphadenopathy and lymphangitis may occur
- Systemic:
 - Often absent

- Patients with extensive soft tissue involvement, necrotizing fasciitis, or underlying bacteremia may present with signs of sepsis including:
 - Fever
 - Rigors
 - Hypotension
 - Altered mentation

History

- Previous episodes: Raise concern for CA-MRSA
- Immunosuppression
- Medications:
 - Chronic steroids, chemotherapy
- IVDU
- History of mammalian bite

Physical-Exam

- Location and extent of infection
- Presence of:
 - Associated cellulitis
 - Subcutaneous air
 - Deep structure involvement
- Involvement of specialty area:
 - Perirectal
 - Hand
 - Face/neck

ESSENTIAL WORKUP

- History and physical exam
- Gram stain unnecessary for simple abscesses in healthy patients
- Wound cultures:
 - Not indicated in simple abscesses
 - May help guide therapy if systemic treatment is planned
 - May be useful in confirming CA-MRSA in patients with recurrent abscesses
 - May guide specific therapy in a compromised host, abscesses of the central face or hand, and treatment failures

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Routine laboratory tests are not typically indicated.
- Glucose determination may be useful if:
 - Underlying undiagnosed diabetes is a concern
 - There is a concern for associated DKA

- For febrile patients who appear septic, systemically ill, or have recent IVDU the following labs are indicated:
 - Blood cultures
 - Lactate
 - Renal function
 - CK if myositis suspected

Imaging

- Bedside US can be helpful in distinguishing cellulitis from abscess
- CT/MRI can be helpful in determining deep tissue involvement
- Plain films may reveal gas in tissue planes

DIFFERENTIAL DIAGNOSIS

- Cellulitis
- Necrotizing fasciitis
- Aneurysm (especially with IV drug abusers)
- Cysts
- Hematoma

TREATMENT

PRE HOSPITAL

Caution: Septic patients may require rapid transport with IV access and volume resuscitation.

INITIAL STABILIZATION/THERAPY

Septic patient:

- Immediate IV access
- Oxygen
- Crystalloid volume resuscitation
- Blood cultures/lactate
- Early antibiotic therapy—broad spectrum to include MRSA coverage.
- Rapid source control (abscess drainage)
- If patient remains hypotensive after volume resuscitation consider:
 - Central venous pressure monitoring
 - Mixed venous sampling

ED TREATMENT/PROCEDURES

- Incision and drainage are the mainstays of treatment.
 - Incision should be deep enough to allow adequate drainage
 - Elliptical incision prevent early closure
 - Break loculations with gentle exploration

- Irrigate cavity after expressing all pus
- Loose packing of abscess cavity when:
 - Larger than 5 cm
 - Comorbid medical conditions
 - HIV
 - Diabetes
 - Malignancy
 - Chronic steroid use
 - Immunosuppressed
 - Abscess location: face, neck, scalp, hands/feet, perianal, perirectal, genital
 - Promote drainage and prevent premature closure
- For simple cutaneous abscesses (<5 cm) packing may not be routinely indicated.
- Routine antibiotics are not indicated.
- Antibiotics are indicated for the following conditions:
 - Sepsis/systemic illness
 - Facial abscesses drained into the cavernous sinus
 - Concurrent cellulitis (see “Medication”)
 - Mammalian bites
 - Immunocompromised hosts
- Perirectal abscess requires treatment in the operating room
- Hand infections that may require surgical intervention:
 - Deep abscesses
 - Fight bite abscesses
 - Associated tenosynovitis/deep fascial plane infection
- Loop drainage technique:
 - Less invasive
 - Simplifies wound care
 - Procedure:
 - Anesthetize locally
 - Incision made at outer margin of abscess
 - Use a hemostat to break loculations and manually express pus
 - Use hemostat to localize distal margin of abscess and use as guide for a second incision
 - Grasp silicone vessel loop with hemostat and pull through and then gently tie
 - Patient should move loop daily to promote drainage
 - No repeat ED visits generally required
 - Removal in 7–10 days is painless

Pediatric Considerations

Incision and drainage are painful procedures that often require procedural sedation and analgesia.

MEDICATION

ALERT

- Know your local susceptibility patterns
- Oral antibiotics (moderate associated cellulitis):
 - _ Amoxicillin/clavulanate:
 - Use: Mammalian bites/MSSA/Streptococcus species
 - Adult dose: 500–875 mg (peds: 40–80 mg/kg/d div q12h) PO q12h
 - _ TMP-SMX:
 - Use: MRSA
 - Adult dose: 160/800 mg (peds: 4–5 mg/kg) PO BID
 - _ Clindamycin:
 - Use: MRSA
 - Adult dose: 300–450 mg (peds: 4–8 mg/kg) PO q6h
 - _ Doxycycline:
 - Use: MRSA
 - Adult dose: 100 mg (peds: over 8 yr: 1.1 mg/kg) PO q12h
 - _ Cephalexin:
 - Use: MSSA/Strep species
 - Adult dose: 250 mg PO q6h or 500 mg PO q12h (peds: 25–50 mg/kg/d div q12h)
 - _ Erythromycin:
 - Use: MSSA/Streptococcus species
 - Adult dose: 250–500 mg (peds: 10 mg/kg) PO q6–8h
- IV antibiotics (systemic illness or extensive associated cellulitis):
 - _ Ampicillin/sulbactam
 - Uses: Human/mammalian bites and facial cellulitis
 - Adult dose: 1.5–3 g (peds: < 40 kg, 75 mg/kg; ≥ 40 kg, adult dose) IV q6h (max = 12 g/d)
 - _ Vancomycin:
 - Use: MRSA
 - Adult dose: 15 mg/kg IV q12h (peds: 10–15 mg/kg/d div q6–8 h) (max. = 2,000 mg/d)
 - _ Daptomycin:
 - Use MRSA
 - Adult dose: 4 mg/kg IV q24h
 - _ Linezolid:
 - Use: MRSA
 - Adult dose: 600 mg IV/PO q12h (peds: 30 mg/kg/d div q8h)
 - _ Clindamycin:
 - Use: MRSA
 - Adult dose: 600 mg (peds: 10–15 mg/kg) IV q8h

FOLLOW-UP

DISPOSITION

In accordance with abscess type and severity of infection

Admission Criteria

- Sepsis/systemic illness
- Immunocompromised host with moderate/large cellulitis
- Perirectal involvement
- Any abscess requiring incision and debridement in the operating room

Discharge Criteria

Most patients with uncomplicated abscesses can be treated with incision and drainage and close follow-up.

FOLLOW-UP RECOMMENDATIONS

- Recheck in 24–48 hr for packing removal and wound check.
- Warm soaks for 2–3 days after packing removal

PEARLS AND PITFALLS

- Consider CA-MRSA in recurrent abscesses
- Pain control is essential during incision and drainage of abscesses
- Beware of tenosynovitis and deep fascial space infections

ABUSE, ELDER

Helen Straus

BASICS

DESCRIPTION

Elder abuse may include the following:

- Emotional abuse:
 - Insults
 - Humiliation
 - Threats to institutionalize or abandon
- Physical and/or sexual abuse:
 - Hitting
 - Slapping
 - Pushing
 - Burning
 - Inappropriate restraining
 - Forced sexual activity
- Material exploitation:
 - Stealing or coercion involving patient money or property
- Neglect:
 - Behaviors by a patient or caregiver that compromise the patient's health or safety
 - Failure to provide adequate food, shelter, hygiene, and/or medical attention

EPIDEMIOLOGY

Incidence and Prevalence Estimates

- In the US., 1–2 million cases age 65 or older mistreated by someone on whom they depend (these numbers likely will increase in the near term as US age demographics shift):
 - 55% neglect
 - 14.6% physical mistreatment
 - 12.3% financial exploitation
 - 7.7% emotional mistreatment
 - 0.3% sexual abuse
 - 6.1% all other types
 - 4% unknown
- Family members, including partners and adult children, are perpetrators in approximately 90% of cases
- For every case of financial exploitation reported, 25 cases likely unreported

- Elder abuse (even modest abuse) is associated with a 300% greater risk of death as well as increased rates of additional health problems such as chronic pain, bone/joint, digestive or psychological disorders (compared to the non-abused)

ETIOLOGY

- Caregiver stress, dependency, or psychopathology
- Victim dependency or diminishment of ability to perform activities of daily living

DIAGNOSIS

SIGNS AND SYMPTOMS

Variable, possibly inconsistent, history or physical findings

History

- Not willing or able to obtain adequate food/clothing/shelter
- Not providing for personal hygiene/safety
- Delay in obtaining medical care/previously untreated medical condition
- Vague (or implausible/inappropriate) explanations
- Disparities between histories given by patient and caregiver
- Caregiver who insists on giving the patient's history
- Medication difficulties:
 - Incorrect doses
 - Lost medications
 - Unfilled prescriptions
- Altered interpersonal interactions:
 - Withdrawn
 - Indifferent
 - Demoralized
 - Fearful
 - Substance abuse
- Caregiver with:
 - Financial dependence on patient
 - Substance abuse or psychiatric or violence history
 - Controlling behavior (may refuse to leave elder alone with physician) or poor knowledge
 - Significant life stressors
 - Relationship issues
 - Financial difficulties
 - Legal problems

Physical-Exam

- Inconsistent findings:

- Patterns or variable-age bruises, burns, lacerations/abrasions
- Unusual sites of bruising (inner arm, torso, buttocks, scalp)
- Poor hygiene (inadequate care of skin, nails, teeth)
- Unexplained injuries:
 - Bruised or bleeding genital or rectal area
 - Wrist or ankle lesions suggestive of restraint use
- Findings that may be consistent with neglect or delay in seeking/obtaining medical attention:
 - Dehydration
 - Weight loss
 - Decubitus ulcer
 - Malnutrition

DIAGNOSIS TESTS & INTERPRETATION

Perform any exam and lab or radiographic studies as indicated by the patient's condition.

ESSENTIAL WORKUP

- Obtain history without family members/caregivers present:
 - Abused elders may fear institutionalization if they report caregivers.
 - Many may feel embarrassment and responsibility for abuse.
 - Frequently will not volunteer information
 - Ask patient specifically about abuse or neglect (in private)
- Patient's medical condition may influence quality of history obtained
- Obtain history from caregivers/other relatives/friends/neighbors
- Document a clear and detailed description of findings including the following:
 - Statements of the patient as they pertain to the abuse
 - Psychosocial history:
 - Family and other social relationships
 - Caregiver burdens/coping mechanisms
 - Drug/ethanol (Etoh) use
 - Prior adult protective services reports
 - Skin and other physical findings:
 - Photographic documentation
 - Safety assessment

DIAGNOSIS TESTS & INTERPRETATION

As appropriate for medical condition(s)

Imaging

As appropriate for medical condition(s)

Diagnostic Procedures/Surgery

As appropriate for medical condition(s)

DIFFERENTIAL DIAGNOSIS

- Patient may present with any chief complaint:
 - Potential differential diagnosis is nonspecific.
 - Abuse best identified by asking patient directly in a setting apart from caregivers/family and correlating with risk factors and provider findings
- Differentiate findings consistent with other disease entities from abuse/neglect:
 - Dehydration
 - Ill-fitting dentures
 - Burns
 - Ecchymosis
 - Insomnia
 - Medication noncompliance
 - Dementia
 - Depression

TREATMENT

PRE HOSPITAL

Observe details of the patient's environment that may not be immediately available to the hospital care team, including the following:

- Interpersonal interactions at the scene:
 - Embarrassment
 - Shame
 - Fear of reprisal, abandonment, and/or institutionalization
- Conditions in the physical environment that present a potential danger

INITIAL STABILIZATION/THERAPY

- ABCs
- Treat life-threatening medical/traumatic conditions as appropriate.

ED TREATMENT/PROCEDURES

- May require separation of the patient and the caregiver or family member
- Social work referral:
 - Safety planning
 - Respite planning for caregiver
 - Adult protective services referral
- Competent elder patients are free to accept or decline treatment or disposition despite risks they may incur.
- General measures appropriate to the medical/traumatic conditions identified, including:
 - Fluids

- Medications
- Surgery
- Diet
- Activity
- Nursing care
- Physical therapy

FOLLOW-UP

DISPOSITION

Admission Criteria

Disposition determined by medical condition and home environment:

- Medical condition requiring admission
- Abuse or neglect renders home conditions unsafe.
- Need for more information or time to enhance objective decision making and patient management

Discharge Criteria

- Medical condition(s) addressed
- Safe environment available
- Abuse or neglect successfully countered by social services and/or law enforcement

Issues for Referral

- Many states have mandatory reporting requirements:
 - Comply with area legal requirements.
- Alcohol/drug treatment as appropriate
- Notify adult protective services.

FOLLOW-UP RECOMMENDATIONS

As appropriate for medical condition(s)

PEARLS AND PITFALLS

- Entertaining the possibility of abuse or neglect in an elder patient offers the best possibility of diagnosis and successful intervention.
- Only ~ 1/3 of healthcare providers identified a case of elder abuse in the past year.
- Current data are inconclusive about the effectiveness of interventions for diminishing recurrence of elder abuse.
- Obtain the aid of social worker, physicians trusted by the patient, even an ethics consultant, should a vulnerable competent elder seek to decline an elder

abuse/neglect investigation.

- T74.91XA Unspecified adult maltreatment, confirmed, initial encounter

ABUSE, PEDIATRIC (NONACCIDENTAL TRAUMA [NAT])

Suzanne Z. Barkin

BASICS

DESCRIPTION

- Child abuse impacts up to 14 million or 2–3% of US children each year.
- 1,200–1,400 children die of maltreatment each year in the US. Of these, 80% < 5 yr and 40% < 1 yr.
- Mandated reporters of suspected abuse or neglect include all health care workers.
- Risk factors:
 - Child: Usually < 4 yr, often handicapped, retarded, or special needs (“vulnerable child”), premature birth, or multiple birth
 - Abusive parent: Low self-esteem, abused as child, violent temper, mental illness history, rigid and unrealistic expectations of child, or young maternal age
 - Family: Monetary problems, isolated and mobile, or marital instability
 - Poor parent–child relationship, unwanted pregnancy
 - Abuse crosses all religious and socioeconomic groups

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- History and mechanism inconsistent with the injury or illness:
 - Unexplained death, apnea, and injury
 - Unexplained ingestion or toxin exposure
 - Recurrent injury
 - Parent/caregiver reluctant to give information or denies knowledge of how injury occurred
 - Begin with open-ended questions about injury and mechanism
 - Discrepancy or inconsistencies among different caregivers
 - Developmentally, child unable to experience mechanism
 - Inappropriate response of care provider to injury or illness; delay in seeking care
 - If alleged anogenital/sexual abuse, history credible
- Munchausen by proxy:
 - Recurrent illness without medical explanation
 - Unexplained metabolic disorder suspicious for poisoning
- Failure to thrive:

- Inadequate caloric intake secondary to poor maternal bonding/neglect
- Review of past ED encounters and contact with the patient's primary care physician may be helpful.

Physical-Exam

- Injury not consistent with history
- Cutaneous bruising/contusions:
 - Regular pattern, straight line of demarcation, regular angles, slap marks from fingers, dunking burns (stocking or glove burns or doughnut shaped on buttock), bites, strap, buckle, cigarette burns
 - Location: Buttocks, hips, face (not forehead), arms, back, thighs, genitalia, or pinna
 - Aging:
 - Often different ages of bruises
 - Yellow bruises are older than 18 hr
 - Red, blue and purple, or black color may occur from 1 hr after injury to resolution
 - Red may be present irrespective of age
 - Bruises of identical age and cause on the same person may appear to be different.
- Skeletal trauma:
 - Usually multiple, unexplained, various stages of healing
 - Metaphyseal or corner (classic metaphyseal lesions) fractures (pathognomonic)
 - Skull fractures that cross suture lines
 - Posterior rib fractures (rib fractures almost never occur in infants from CPR)
 - Spiral fractures of long bones
 - Subperiosteal new bone formation
 - Uncommon fractures (vertebrae, sternum, scapula, spinous process) without significant mechanism
- CNS:
 - Altered mental status or seizure
 - Head trauma is leading cause of death in child abuse.
 - Skull fracture: Must consider child abuse in children <1 yr
 - Subdural hematoma, subarachnoid hemorrhage
 - Shaken baby syndrome with shearing and rotational injury
- Ocular findings:
 - Retinal hemorrhage or detachment:
 - 53–80% of abusive head injury has retinal hemorrhage (commonly bilateral) while present in only 0–10% severe accidental trauma
 - Rare in the absence of evidence of head trauma and normal neuroimaging
 - Hyphema

- Corneal abrasion/conjunctival hemorrhage
- Oral trauma
- Abdominal injuries:
 - Lacerated liver, spleen, kidney, or pancreas
 - Intramural hematoma (duodenal most common)
 - Retroperitoneal hematoma
- Anogenital/sexual abuse:
 - Contusion, erythema, open wounds, scarring, or foreign material (hair, debris, or semen)
 - Presence of STD or pregnancy in child <12 yr
- Death:
 - Unexplained death

ESSENTIAL WORKUP

- Formal oral and written report to appropriate child welfare agency
- Family and environmental evaluation, usually in cooperation with responsible child welfare agency
- Diagram or photograph of bruises is helpful.

ALERT

When suspected, health professionals have a legal obligation to report their suspicion to the appropriate authorities.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Bleeding screen if there is a history of recurrent bruising or bruising is the prominent manifestation; may usually be done electively: CBC, platelets, PT/PTT, or bleeding time (or PFA collagen epinephrine)
- If significant blunt trauma, CBC, LFT, amylase, and urinalysis
- Toxicology, chemistry, and metabolic screens in children with altered mental status
- Consider other differential considerations.

Imaging

- Global assessment:
 - Indicated for children <2 yr to exclude unsuspected injuries
 - In children 2–5 yr, in selected cases where physical abuse is strongly suspected
 - In older children, radiographs of individual sites of injury suspected on clinical grounds
 - Radiographic skeletal survey:
 - Anteroposterior (AP) and lateral skull
 - Lateral cervical spine

- AP and lateral thoracic and lumbar spine
- AP and obliques of chest
- AP pelvis
- AP humerus, forearm, and hands (bilateral)
- AP femur, tibia, and feet (bilateral)
- If fracture identified, get at least 2 views, 90° to original view.
- May need coned-down view of joints for visualization of classic metaphyseal lesions
- Skeletal scintigraphy provides adjunctive screening if suspicion exists beyond skeletal survey.
- Visceral imaging:
 - Suspected thoracoabdominal injury:
 - Abdominal CT scan with IV and possibly oral contrast
- Neuroimaging:
 - Nonenhanced head CT with brain, subdural, and bone windowing
 - MRI:
 - Adjunctive in evaluation of acute, subacute, and chronic intracranial injury; useful for shear injuries, evolving hemorrhage, contusion, or secondary hypoxic/ischemic injury

DIFFERENTIAL DIAGNOSIS

- General:
 - Trauma—accidental or birth/obstetrical
- Cutaneous:
 - Burn—accidental
 - Infection
 - Impetigo/cellulitis
 - Staphylococcal scalded skin syndrome
 - Henoch–Schönlein purpura
 - Purpura fulminans/meningococemia
 - Sepsis
 - Dermatitis: Contact or photo
 - Hematologic/oncologic disorder (idiopathic thrombocytopenic purpura [ITP], leukemia)
 - Bleeding diathesis (hemophilia, von Willebrand)
 - Nutritional deficiency: Scurvy
 - Cultural healing practices (coining, cupping)
- Skeletal:
 - Osteogenesis imperfecta
 - Nutritional (rickets, copper deficiency, or scurvy)
 - Menkes syndrome
 - Peripheral sensory impairment (indifference to pain)
- Ocular:

- Conjunctivitis
- Abdomen and GU tract:
 - GI disease (obstruction, peritonitis, or inflammatory bowel disease)
 - GU tract infection/anomaly
- CNS:
 - Intoxication, ingestion (CO, lead, or mercury)
- Infection:
 - Metabolic: Hypoglycemia
 - Epilepsy
- Death:
 - SIDS, apparent life-threatening event (ALTE)

TREATMENT

PRE HOSPITAL

- Diagnosis relies on physical evidence in child and inconsistency with the history and mechanism.
- Examination of the scene may be useful:
 - Evaluate validity of mechanisms
 - General appearance of home
 - Consistency of history by multiple caregivers
 - Evaluation of parent–child interaction

INITIAL STABILIZATION/THERAPY

As indicated by specific injury

ED TREATMENT/PROCEDURES

- Medical and trauma management as required
- Mandatory reporting to local child welfare agency of any suspected child abuse to determine appropriate social disposition:
 - This does *not* imply or require 100% certainty of abuse.
 - Expedited family, environmental, and social evaluation
 - Essential to be nonjudgmental
- Communication with family about report and primary concern is responsibility of child welfare.
 - Security may be required to protect child and staff.
- Siblings and other household children must be examined in appropriate time frame.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Observation and intervention for traumatic injury
- Concerns about disposition or lack of availability of child welfare receiving site, if required
- Goal must always be to ensure safety of child and siblings.

Discharge Criteria

- Adequate ED evaluation and medical follow-up
- Safe setting for child must determine disposition
- An abused child has a significant chance of further abuse so disposition must be determined in collaboration with social services and family evaluation
- Child (and siblings) may require placement in foster care.

Issues for Referral

- All patients require referral to the appropriate child welfare agency.
- Other family members may require evaluation before disposition is determined.

PEARLS AND PITFALLS

- A history inconsistent with the physical findings should lead to a suspicion of NAT.
- When child abuse is suspected, it must be reported.

ACETAMINOPHEN POISONING

Mark B. Mycyk

BASICS

DESCRIPTION

- Acetaminophen (APAP) is available alone, in combination with oral opiate, and in > 200 OTC cold remedies:
 - One of the most common drugs implicated in intentional and unintentional poisonings
 - The number 1 reason for hepatic transplantation in the US
- *N*-acetyl-*p*-benzoquinoneimine (NAPQI) produced when APAP metabolized by cytochrome P-450:
 - NAPQI normally detoxified by glutathione
 - In overdose, glutathione is quickly depleted and NAPQI causes hepatic damage.
 - *N*-acetylcysteine (NAC) replenishes the liver's glutathione stores.
- Increased risk of toxicity:
 - Patients with poor nutrition have decreased glutathione stores.
- Pharmacokinetics:
 - APAP half-life:
 - 2.5–4 hr in a nonoverdose setting
 - > 4 hr in overdose
- Toxic dose > 150 mg/kg acutely
- Probable toxic level is 140 $\mu\text{g}/\text{mL}$ at 4 hr postingestion (see Fig. 1 nomogram for acute intoxication).
- Therapeutic plasma concentration is 5–20 $\mu\text{g}/\text{mL}$.

Rumack–Matthew nomogram. (Adapted from Rumack BH, Matthew H. Acetaminophen poisoning and toxicity. *Pediatrics*. 1975;55:871–876.)

DIAGNOSIS

SIGNS AND SYMPTOMS

Acute overdose:

- Phase 1: 0.5–24 hr postingestion:
 - Nausea, vomiting, malaise
 - Occurs with large overdoses
 - May not be present with smaller toxic doses
- Phase 2: 24–72 hr postingestion:
 - Decreased GI symptoms

- Hepatic damage is occurring.
- Right upper quadrant pain and tenderness
- Elevation of liver enzymes, PT/INR, bilirubin
- Oliguria
- Prolonged (> 4 hr) APAP half-life implies hepatic toxicity.
- Phase 3: 72–96 hr postingestion:
 - Critical time period in the prognosis
 - Peak liver function abnormalities
 - Hepatic encephalopathy develops.
 - If the PT/INR continues to rise and/or renal insufficiency develops beyond the 3rd day postingestion, there is high likelihood that the patient will require hepatic transplantation.
- Phase 4: 96 hr to 10 days postingestion:
 - Resolution of hepatic injury or progression to complete hepatic failure

ESSENTIAL WORKUP

- Ingestion history of all APAP-containing products
- Time of ingestion
- APAP level:
 - Obtain 4 hr postingestion level or immediately on presentation if > 4 hr postingestion.
 - Use Rumack–Matthew nomogram as therapeutic guide for single acute overdose (see Fig. 1).
 - In chronic or very late ingestions (> 24 hr), obtain level, but do not use nomogram for therapeutic guidance.
- Call poison center ([800] 222-1222) or toxicologist.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- APAP level
- Electrolytes, BUN, creatinine, and glucose
- Liver enzymes:
 - Elevated AST is the first abnormality detected.
 - AST/ALT levels may rise > 10,000 in stage III of toxicity.
 - Bilirubin
- PT/INR
- Pregnancy test
- Toxicology screen

DIFFERENTIAL DIAGNOSIS

- Suspect APAP as coingestant with other drugs in overdose.
- Causes of acute onset hepatotoxicity:

- Infectious hepatitis
- Reye syndrome
- *Amanita* sp. mushrooms toxicity
- Herbal and dietary supplements
- Other drug ingestions

TREATMENT

PRE HOSPITAL

- Transport all pill bottles/pills involved in overdose for identification in ED.
- OTC cold remedies often contain APAP.

INITIAL STABILIZATION/THERAPY

- Airway, breathing, circulation (ABCs)
- Administer supplemental oxygen.
- Administer naloxone, thiamine, D₅₀ (or Accu-Chek) for altered mental status.

ED TREATMENT/PROCEDURES

- Supportive care:
 - IV fluids
 - Antiemetics
- Gastric decontamination:
 - Administer a single dose of activated charcoal if recent ingestion.

N-acetylcysteine (NAC) Administration

- Administer if toxic level detected as defined by Rumack–Matthew nomogram.
- NAC virtually 100% hepatoprotective if initiated within 8 hr of an acute overdose
- NAC available in oral form or IV form
- < 8 hr postingestion:
 - Check APAP level.
 - Initiate NAC if APAP level will not be available within 8 hr of ingestion and toxic ingestion suspected.
 - Discontinue NAC if APAP level nontoxic.
- ≥ 8 hr postingestion:
 - Initiate NAC immediately if suspected toxic ingestion.
 - Check APAP level.
 - Discontinue NAC if APAP level is nontoxic.
- > 24 hr postingestion or chronic repeated APAP ingestion
 - Initiate NAC if:
 - Ingestion > 150 mg/kg APAP
 - Symptomatic
 - Abnormal hepatic screening panel

- Discontinue NAC if APAP falls to nondetectable level and no AST elevation occurs by 36 hr postingestion.
- Call poison center ([800] 222-1222) or toxicologist for help.

NAC Preparations

- Oral NAC:
 - _ Poor taste and odor:
 - Dilute to 5% with fruit juice or soft drink to increase palatability.
 - _ Use antiemetics (metoclopramide or ondansetron) liberally to facilitate PO administration.
 - _ If the patient vomits NAC within 1 hr of administration, repeat the dose.
 - _ Administer NAC as a drip through nasogastric (NG) tube if vomiting continues.
 - _ Given q4h
- IV NAC (2 options):
 - _ Acetadote[®] infusion given per manufacturer's instructions
 - _ Oral NAC given by IV route if:
 - Oral form not tolerated because of vomiting
 - Acetadote[®] not available
 - Contact local poison center or toxicologist for help.

Pregnancy Considerations

- No teratogenicity with NAC
- NAC may be effective in protecting fetal liver:
 - _ Fetal liver metabolizes APAP to toxic NAPQI after 14 wk gestation.

ALERT

A shortened oral NAC protocol may be considered with poison center or toxicology consultation.

MEDICATION

- NAC: 140 mg/kg PO loading (adult and pediatric) followed by 70 mg/kg q4h for 17 additional doses
- Acetadote: 21 hr IV infusion: 150 mg/kg over 60 min, then 50 mg/kg over 4 hr, then 100 mg/kg over 16 hr for total dose 300 mg/kg (see package insert for additional guidance, especially for pediatric infusion dosing)
- Activated charcoal: 1–2 g/kg PO
- Dextrose: D₅₀W 1 amp (50 mL or 25 g; peds: D₂₅W 2–4 mL/kg) IV
- Metoclopramide: Start with 10 mg (peds: 1 mg/kg) IV (1 mg/kg max.)
- Naloxone (Narcan): 0.4–2 mg (peds: 0.1 mg/kg) IV or IM initial dose
- Ondansetron: > 80 kg, 12 mg; 45–80 kg, 8 mg (peds: 0.15 mg/kg) IV
- Thiamine (vitamin B₁): 100 mg (peds: 50 mg) IV or IM

Pregnancy Considerations

Treating the mother maximizes treatment for the fetus. NAC crosses the placenta and is considered safe PO or IV.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Hepatotoxic level of APAP requiring full course of NAC therapy (see “Treatment”)
- LFT abnormalities in the setting of chronic ingestion or late presentation
- Nontoxic suicide attempt requiring psychiatric treatment

Discharge Criteria

Asymptomatic patients with nontoxic ingestions not requiring full course of NAC therapy

Issues for Referral

Evidence of significant hepatotoxicity at time of ED arrival warrants early evaluation by hepatology and/or transplant service.

FOLLOW-UP RECOMMENDATIONS

- Substance abuse referral for patients with oral opiate abuse
- Patients with unintentional (accidental) poisoning require poison prevention counseling.
- Patients with intentional (e.g., suicide) poisoning require psychiatric evaluation.

PEARLS AND PITFALLS

- Consider occult APAP poisoning in patients evaluated for oral opiate abuse.
- Do not use the nomogram for patients with chronic ingestion or late presentation.
- Do not stop NAC therapy until nondetectable APAP level *and* improvement (or resolution) of laboratory and clinical evidence of hepatotoxicity.

ACIDOSIS

Matthew T. Robinson

BASICS

DESCRIPTION

Respiratory acidosis.

- Reduced pH owing to alveolar hypoventilation with elevated PaCO₂
- Defined as PaCO₂ >45 mm Hg or higher than expected for calculated respiratory compensation for metabolic acidosis
- Divided into 3 broad categories:
 - _ Primary failure in CNS drive to ventilate:
 - Sleep apnea
 - Anesthesia
 - Sedative overdose
 - _ Primary failure in transport of CO₂ from alveolar space:
 - COPD
 - Myasthenic crisis
 - Severe hypokalemia
 - Guillain–Barré syndrome
 - _ Primary failure in transport of CO₂ from tissue to alveoli:
 - Severe heart failure/pulmonary edema

Metabolic acidosis

- Process that reduces serum pH by decreasing plasma bicarbonate levels
- Primarily caused by:
 - _ Accumulation of a strong acid through ingestion or metabolism
 - _ Loss of bicarbonate from the body
- Metabolic acidosis is clinically evaluated by dividing into 2 main groups:
 - _ Elevated anion gap metabolic acidosis:
 - Bicarbonate reduced through buffering of added strong acid
 - Anion gap is increased due to retention of the unmeasured anion from the titrated strong acid.
 - _ Normal anion gap metabolic acidosis due to:
 - Kidneys fail to reabsorb or regenerate bicarbonate.
 - Losses of bicarbonate from GI tract (diarrhea)
 - Ingestion or infusion of substances that release hydrochloric acid
 - _ No anion gap is observed owing to the absence of any unmeasured anion of a titrated acid and secondary chloride retention with HCO₃⁻ loss.

ETIOLOGY

- Respiratory acidosis:
 - Inhibition of respiratory center:
 - Cardiac arrest
 - Drugs (opiates, benzodiazepines, etc.)
 - Meningitis/encephalitis
 - CNS lesions (mass, CVA)
 - Impaired gas exchange:
 - Pulmonary edema
 - Asthma/COPD
 - Pneumonia
 - Interstitial lung disease
 - Obesity
 - Pulmonary contusion
 - Neuromuscular disease:
 - Diaphragmatic paralysis
 - Guillain–Barré syndrome
 - Myasthenia gravis
 - Muscular dystrophy
 - Spinal cord injury
 - Hypokalemia/hypophosphatemia
 - MS
 - Obstructive:
 - Congenital lesions (laryngomalacia)
 - Foreign body aspiration
 - Vascular ring
 - Infectious (epiglottitis, croup, abscess)
- Anion gap acidosis: Mnemonic *A CAT PILES MUD*:
 - Alcohol ketoacidosis
 - Carbon monoxide or cyanide
 - Aspirin
 - Toluene
 - Paraldehyde
 - Iron/isoniazid
 - Lactic acidosis
 - Ethylene glycol
 - Starvation
 - Methanol
 - Uremia
 - Diabetic ketoacidosis
- Increased osmolar gap: Mnemonic *ME DIE*:
 - Methanol
 - Ethylene glycol
 - Diuretics (mannitol; no acidosis)

- Isopropyl alcohol (no acidosis)
- Ethanol
- Nonanion gap metabolic acidosis:
 - GI losses of bicarbonate:
 - Diarrhea
 - Villous adenoma
 - Removal of small bowel, pancreatic or biliary secretions
 - Tube drainage
 - Small bowel/pancreatic fistula
 - Anion exchange resins (i.e., cholestyramine)
 - Ingestion of calcium chloride or magnesium chloride
 - Type I renal tubular acidosis (distal): Hypokalemic hyperchloremic metabolic acidosis:
 - Decreased ability to secrete hydrogen
 - Serum $\text{HCO}_3^- < 15 \text{ mEq/L}$ when untreated
 - Potassium low
 - Renal stones common
 - Type II renal tubular acidosis (proximal): Hypokalemic hyperchloremic metabolic acidosis:
 - Decreased proximal reabsorption of HCO_3^-
 - Acidosis limited by reabsorptive capacity of proximal tubule for HCO_3^-
 - Serum HCO_3^- typically 14–18 mEq/L
 - Low/normal potassium
 - Type IV renal tubular acidosis (hypoaldosteronism): Hyperkalemic hyperchloremic acidosis:
 - Aldosterone deficiency or resistance causing decreased H^+ secretion
 - Serum bicarb $> 15 \text{ mEq/L}$
 - Normal/elevated potassium
 - Carbonic anhydrase inhibitors
 - Tubulointerstitial renal disease
 - Hypoaldosteronism
 - Addition of hydrochloric acid such as:
 - Ammonium chloride
 - Arginine hydrogen chloride
 - Lysine hydrogen chloride

DIAGNOSIS

SIGNS AND SYMPTOMS

- Nonspecific findings
- Vital signs:
 - Tachypnea or Kussmaul respirations with metabolic acidosis
 - Hypoventilation with respiratory acidosis
 - Tachycardia
- Somnolence
- Confusion
- Altered mental status (CO₂ narcosis)
- Myocardial conduction and contraction disturbances (dysrhythmias)

ESSENTIAL WORKUP

- Electrolytes, BUN, creatinine, and glucose:
 - Decreased bicarbonate with metabolic acidosis
 - Hyperkalemia and hypercalcemia with severe metabolic acidosis
- Arterial blood gases:
 - pH
 - CO₂ retention in respiratory acidosis
 - CO level

Check the degree of compensation by calculating the expected values and comparing them to the observed laboratory values as follows:

- Respiratory acidosis:
 - Acute: Expected HCO₃⁻ increased by 1 mEq/L for every 10 mm Hg increase in PaCO₂
 - Chronic: Expected HCO₃⁻ increased by 4 mEq/L for every 10 mm Hg increase in PaCO₂
- Calculate anion gap: Na⁺ – (HCO₃⁻ + Cl⁻):
 - Correct anion gap for hypoalbuminemia:
 - For every 1 g/dL decrease in albumin (from 4 g/dL), add 2.5 points to calculated anion gap.
 - Do not correct sodium concentration when calculating the anion gap in the setting of marked hyperglycemia because hyperglycemia affects the concentration of chloride and bicarbonate, as well as sodium.
 - Normal range = 5 – 12 ± 3 mEq/L
 - Anion gap > 25 mEq/L is seen only with:
 - Lactic acidosis
 - Ketoacidosis
 - Toxin-associated acidosis
- Calculate the degree of compensation:
 - Expected PaCO₂ = 1.5[HCO₃⁻] + 8

- If PaCO₂ inappropriately high, patient has a concomitant respiratory acidosis and/or inadequate compensation.
- Evaluate the delta gap (Δ Gap):
 - For every 1-point increase in anion gap, HCO₃⁻ should decrease by ~1 mEq/L in simple acid–base disorder.
 - As the volumes of distribution of the unmeasured anions and serum HCO₃⁻ are not in unity, a Δ Gap > 6 signifies a mixed acid–base disorder
- Evaluate Δ Gap by comparing the change in the anion gap (Δ AG) with the change in the HCO₃⁻ (Δ HCO₃⁻) from normal:
 - If Δ AG > Δ HCO₃⁻, then patient has a concomitant metabolic alkalosis.
 - If Δ HCO₃⁻ > Δ AG, then patient has concomitant nonanion gap acidosis.

DIAGNOSIS TESTS & NTERPRETATION

Lab

- ABG: See interpretation above.
- VBG:
 - Obvious benefit is less patient discomfort and ease in acquiring sample
 - pH varies by <0.04 units when compared to arterial sampling.
 - Correlation between venous pCO₂ lacking
 - Limited role in screening for hypercapnia. pCO₂ > 45 mm Hg is sensitive (but not specific) for detection of arterial pCO₂ > 50 mm Hg in hemodynamically stable patients
 - Useful in simple acid–base disorders
- Urinalysis for glucose and ketones
- Measure serum osmolality:
 - Calculated serum osmolality = 2 Na + glucose/18 + BUN/2.8
- Osmolar gap = difference between calculated and measured osmolality:
 - Normal = <10
 - Elevated osmolar gap may indicate toxic alcohol as etiology of acidosis.
 - Absence of an osmolar gap should never be used to rule out toxic ingestions:
 - Osmolar gap imprecisely defined
 - Delayed presentations may have normal gap
 - Large variance in gap among normal patients
- Toxicology screen:
 - Methanol, ethylene glycol, ethanol, and isopropyl alcohol if increased osmolality gap
 - Aspirin or iron levels for suspected ingestion
- Co-oximetry for CO exposure

- Serum ketones or β -hydroxybutyrate level
- Serum lactate

Imaging

CXR:

- May identify cardiomyopathy or CHF
- Underlying pneumonia

Diagnostic Procedures/Surgery

ECG:

- May identify regional wall motion abnormalities or valvular dysfunction
- Evaluate for conduction disturbances

DIFFERENTIAL DIAGNOSIS

- Anion gap acidosis:
 - _ Mnemonic *A CATPILES MUD*
- Increased osmolar gap:
 - _ Mnemonic *ME DIE*

TREATMENT

INITIAL STABILIZATION/THERAPY

Airway, breathing, and circulation (ABCs):

- Early intubation for severe metabolic acidosis with progressive/potential weakening of respiratory compensation
- Naloxone, D₅₀W (or Accu-Chek), and thiamine if mental status altered

ED TREATMENT/PROCEDURES

- Respiratory acidosis:
 - _ Treat underlying disorder
 - _ Provide ventilatory support for worsening hypercapnia
 - _ Identify and correct aggravating factors (pneumonia) in chronic hypercapnia.
- Metabolic acidosis:
 - _ Identify if concurrent osmolar gap.
 - _ Treat underlying disorder:
 - Diabetic ketoacidosis
 - Lactic acidosis
 - Alcohol ketoacidosis
 - Ingestion
 - _ Correct electrolyte abnormalities.
- IV fluids:

- Rehydrate with 0.9% normal saline if patient hypovolemic.
- Consider hemodialysis

MEDICATION

- Dextrose: D₅₀W 1 amp (50 mL or 25 g); (peds: D₂₅W 4 mL/kg) IV
- Naloxone (Narcan): 2 mg (peds: 0.1 mg/kg) IV or IM initial dose
- Thiamine (vitamin B₁): 100 mg (peds: 50 mg) IV or IM

FOLLOW-UP

DISPOSITION

Admission Criteria

Consider ICU admission if:

- pH < 7.1
- Altered mental status
- Respiratory acidosis
- Hemodynamic instability
- Dysrhythmias
- Electrolyte abnormalities

Discharge Criteria

Resolving or resolved anion gap metabolic acidosis

PEARLS AND PITFALLS

- Failure to appreciate acidosis in mixed acid–base disorders
- Failure to appreciate inadequate respiratory compensation for metabolic acidosis and need for ventilatory support
- Clues to the presence of a mixed acid–base disorder are normal pH with abnormal PCO₂ or HCO₃[−], when the HCO₃[−] and PCO₂ move in opposite directions, or when the pH changes in the direction opposite that expected from a known primary disorder.

ICD10

E87.2 Acidosis

ACROMIOCLAVICULAR JOINT INJURY

Aleksandr M. Tichter • Wallace A. Carter

BASICS

DESCRIPTION

- The acromioclavicular (AC) joint is formed by the articulation of the distal clavicle and the scapular acromion
- It is stabilized by the AC ligament, coracoclavicular (CC) ligament, and attachments from deltoid and trapezius muscles
 - AC ligament is responsible for horizontal stability
 - CC ligament is responsible for vertical stability
- Rockwood classification (sequential injury pattern):
 - Type I:
 - Sprained AC ligament (AC joint tender)
 - No CC ligament injury
 - No deltoid or trapezius injury
 - No radiographic abnormality (clinical diagnosis)
 - Type II:
 - Ruptured AC ligament (AC joint tender) (distal clavicle horizontally unstable)
 - Sprained CC ligament (CC ligament tender)
 - Minimal deltoid and trapezius injury
 - Radiographs show slight widening of AC joint (normal < 5 mm)
 - Normal CC space (11–13 mm)
 - Type III:
 - Ruptured AC ligament (AC joint tender) (distal clavicle horizontally unstable)
 - Ruptured CC ligament (CC ligament tender) (distal clavicle vertically unstable)
 - Detached deltoid and trapezius
 - Radiographs show widening of AC joint.
 - Increased CC space, with distal clavicle above superior aspect of acromion (100% displaced)
 - Types IV, V, and VI:
 - Cause more significant pain than Types I, II, and III.
 - Best visualized on lateral/axillary radiographs
 - All require operative treatment.
 - Greater risk for prolonged disability
 - Type IV:
 - Identical ligamentous/muscular injury pattern to Type III

- Clavicle is displaced *posteriorly* into trapezius muscle
- Posteriorly displaced clavicle may be palpable on exam
- May cause tenting of skin posteriorly
- Type V:
 - Rare
 - Identical ligamentous/muscular injury pattern to Type III
 - Clavicle is displaced *superiorly* above the trapezius (100–300% increase in CC space)
 - Shoulder droops severely
 - Clavicle may be palpated subcutaneously
 - May cause tenting, ischemia, or disruption of skin
- Type VI:
 - Usually associated with severe trauma
 - Identical ligamentous/muscular injury pattern to Type III
 - Clavicle is displaced *inferiorly* into subacromial or subcoracoid location.
 - Shoulder appears flattened
 - Associated neurovascular injury is common

ETIOLOGY

- Injury most commonly seen in young, active males during contact sports
- Most common mechanism is direct trauma to superior or lateral shoulder while arm is adducted, usually in the setting of a fall
 - acromion is displaced inferomedially
 - clavicle remains stabilized by sternoclavicular ligaments
- May also occur indirectly via a fall on an outstretched hand or elbow, with transmission of force to the AC joint

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Pain to anterior or superior aspect of the shoulder following trauma
- Pain exacerbated by moving arm across the chest, behind the back, or overhead
- Mechanism/force will dictate suspicion for and pattern of injury
- Associated neurovascular symptoms
- Cervical spine symptoms

Physical-Exam

- Exam in standing or sitting position, as supine position negates force of gravity which can mask joint instability

- Inspection: Ecchymosis, abrasion, swelling, symmetry, deformity of AC joint, skin tenting or laceration
 - prominence of clavicle with sagging of the acromion indicates rupture of AC joint (Rockwood Type II injury or greater)
- Palpation: Sequential exam of sternoclavicular joint, length of clavicle, AC joint, CC ligament, coracoid process, scapular spine, and proximal humerus
 - tenderness over AC joint indicates AC ligament injury (Rockwood Type I injury or greater)
 - horizontal instability of distal clavicle indicates AC ligament rupture (Rockwood Type II injury or greater)
 - tenderness over CC ligament indicates CC ligament injury (Rockwood Type II injury or greater)
 - vertical instability of distal clavicle indicates CC ligament rupture (Rockwood Type III injury or greater)
- Special tests
 - Cross-body adduction test:
 - Arm elevated to 90° with elbow flexed at 90°, and adducted across chest
 - Pain confirms AC injury by specifically compressing the joint
 - Sensitivity 77%, specificity 79%
 - O'Brien test
 - Arm elevated to 90° with elbow in extension, adduction of 10–15° and maximum forearm pronation
 - Examiner applies downward force against resistance
 - Pain over top of shoulder confirms AC injury
 - Sensitivity 16–93%, specificity 90–95%
- Complete distal neurovascular exam, including brachial plexus
- Careful cervical spine exam

ESSENTIAL WORKUP

- History to seek mechanisms that commonly cause AC joint injury and associated force
- Physical exam to evaluate for injury pattern, neurovascular compromise and exclude other causes of pain
- Radiographic evaluation as outlined below

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- Specific AC joint radiograph
 - Recommended if AC injury suspected
 - Should include bilateral AC joints (for comparison)
 - Standard shoulder views will over penetrate AC joint and may obscure

subtle injuries

- Stress views no longer recommended
- Zanca view (10–15° cephalic tilt) for limited initial views
- Axillary view for Type III–VI injuries to determine position of distal clavicle
- CT or MRI for further evaluation of surgical cases (Rockwood Types IV–VI)
 - Angiography may be used to evaluate associated neurovascular injuries
 - US if CT/MRI is not available

DIFFERENTIAL DIAGNOSIS

- Shoulder dislocation
- Fractures of acromion or clavicle
- Rotator cuff injury
- Tendinitis
- Capsulitis
- Cervical radiculopathy
- Osteoarthritis
- Osteomyelitis

Pediatric Considerations

- Pediatric clavicle encased in periosteal tube:
 - CC ligament within tube
 - AC ligament external to tube (more vulnerable)
- AC joint injury rarely occurs in isolation in the pediatric population
- When injury does occur, it is more often Type I or II
- Distal clavicular fractures through physis are more common than Type III AC joint dislocations

TREATMENT

PRE HOSPITAL

- Ice packs
- Sling immobilization
- Cervical spine immobilization if indicated

INITIAL STABILIZATION/THERAPY

- Ice packs
- Sling immobilization
- Cervical spine immobilization if indicated
- Analgesia (NSAIDs, other analgesics)

ED TREATMENT/PROCEDURES

- Types I and II:

- Rest, ice, analgesics
- Brief sling immobilization (typically 3–7 days)
- Range of motion (ROM) and strengthening exercises as soon as can be tolerated
- Resume normal activities once painless ROM and strength have returned (2–4 wk)
- Type III:
 - Rest, ice, analgesics
 - Sling immobilization and early (within 72 hr) orthopedic referral
 - Treatment plan is controversial
 - Insufficient evidence exists to favor one management strategy over the other (conservative vs. surgical)
 - Which approach is chosen may depend on general health of patient, level of activity, occupation, hand dominance, and risk for reinjury
- Types IV, V, and VI:
 - Rest, ice, analgesics
 - Sling immobilization and immediate orthopedic referral
 - Require early surgical intervention
- Special circumstance: Potential future complication of AC joint injury is arthritis of the joint

Pediatric Considerations

- Types I and II:
 - Conservative management (rest, ice, analgesics, sling)
 - Should heal without major sequelae
- Type III:
 - Age < 15 yr, conservative management
 - Age ≥ 15 yr may require more aggressive treatment.
- Types IV, V, and VI:
 - Operative repair

MEDICATION

- Ibuprofen: 600 mg (peds: 4–10 mg/kg) PO QID
- Ketorolac: 30 mg (peds: 0.5 mg/kg up to 30 mg if > 6 mo) IM/IV q6h (15 mg IM/IV q6h if > 65 yr or < 50 kg)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Open injury

- Types IV, V, and VI require admission for operative repair

Discharge Criteria

- Types I and II can be discharged with orthopedic referral
- Type III should have urgent orthopedic referral

FOLLOW-UP RECOMMENDATIONS

- Type I and II: Orthopedic follow-up within 2–4 wk
- Type III: Early (within 72 hr) orthopedic follow-up
- Type IV–VI: Immediate orthopedic referral
- All pediatric injuries should have prompt orthopedic follow-up, with Type IV–VI injuries requiring immediate referral

PEARLS AND PITFALLS

- Type I and II AC injuries:
 - No increase in CC space
 - Conservative management with rest, ice, sling, and ROM/strength exercises
- Type III injuries:
 - 100% superior displacement of distal clavicle
 - Management somewhat controversial
 - Require early orthopedic follow-up
- Type IV–VI injuries:
 - Identical ligamentous and muscular injuries to Type III
 - Difference according to position of distal clavicle
 - Operative management is standard of care

ACUTE CORONARY SYNDROME: ANGINA

Shamai A. Grossman • Margaret J. Lin

BASICS

DESCRIPTION

- Chest discomfort, due to imbalance of myocardial blood supply and oxygen requirements
- Canadian Cardiovascular Society classification for angina:
 - Class I: No angina with ordinary physical activity
 - Class II: Slight limitation of normal activity with angina occurring with walking, climbing stairs, or emotional stress
 - Class III: Severe limitation of ordinary physical activity with angina when walking 1–2 blocks on level surface or climbing 1 flight of stairs
 - Class IV: Inability to carry on any physical activity without discomfort or angina symptoms occur at rest
- Typically categorized as either stable or unstable
- Stable angina: Predictable, with exertion, and improves with rest
- Unstable angina (UA):
 - New onset
 - Increase in frequency, duration or lower threshold for symptoms
 - At rest
- UA associated with increased risk of transmural myocardial infarction and cardiac death

ETIOLOGY

- Cardiac risk factors:
 - Age
 - Men > 35 yr
 - Postmenopausal in women
 - Hypercholesterolemia
 - DM
 - HTN
 - Smoking
- Atherosclerotic narrowing of coronary vessels
 - Stable angina: Chronic and leads to imbalance of blood flow during exertion
 - UA: Acute disruption of plaque which can lead to worsening symptoms with exertion or at rest
- Vasospasm: Prinzmetal angina, drug related (cocaine, amphetamines)
- Microvascular angina or abnormal relaxation of vessels if diffuse vascular disease
- Arteritis: Lupus, Takayasu disease, Kawasaki disease, rheumatoid arthritis

- Anemia
- Hyperbarism, carboxyhemoglobin elevation
- Abnormal structure of coronaries: Radiation, aneurysm, ectasia

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Chest pain:
 - Substernal pressure, heaviness, tightness, burning or squeezing
 - Radiates to neck, jaw, left shoulder, or arm
- Poorly localized, visceral pain
- Anginal equivalents include:
 - Dyspnea
 - Epigastric discomfort
 - Weakness
 - Diaphoresis
 - Nausea/vomiting
 - Abdominal pain
 - Syncope
- Symptoms usually reproduced by exertion, eating, cold exposure, emotional stress
- Symptoms not usually positional or pleuritic
- Usually relieved with rest or nitroglycerin
 - Relief with nitroglycerin in nondiagnostic
- Lasts more than a few minutes but < 20 min
- Considered stable angina if no changes in pattern of frequency of symptoms

Geriatric Considerations

- Women, diabetics, ethnic minorities, and those > 65 yr often present with atypical symptoms
- Prognosis is worse for people with atypical symptoms

Physical-Exam

- “Levine Sign”: Clenched fist over chest, classic finding
- BP often elevated during symptoms
- Physical exam often uninformative
 - occasional S3/S4,
 - mitral regurgitation or new murmur (papillary muscle dysfunction)
 - diminished peripheral pulses

ESSENTIAL WORKUP

ECG:

- Standard 12 lead
 - Ideally should be obtained and read within 10 min of presentation for patients with acute chest pain
- Mostly helpful in detecting acute MI, less so UA
- Compare to prior ECG if available
 - If normal or unchanged, serial ECGs every 10–30 min
- New ST changes or T-wave inversion suspicious for UA
 - T-wave flattening or biphasic T-waves
 - ≤ 1 mm ST depression 80 msec from the J point, is characteristic in UA
 - Can see evidence of old ischemia, strain or infarct, such as old TWI, Q-wave, ST depression
 - Single ECG for acute MI is about 60% sensitive and 90% specific
- ECG can also be helpful to diagnose other causes of chest pain
 - Pericarditis: Diffuse ST elevations, then TW inversions and pulse rate depression
 - Pulmonary embolus S1Q3T3 pattern, unexplained tachycardia and signs of right heart strain

ALERT

- Patients with normal or nonspecific ECGs have a 1–5% incidence of AMI and 4–23% incidence of UA

DIAGNOSIS TESTS & INTERPRETATION

Lab

- For stable angina, cardiac enzymes not indicated, but if history suspicious for acute MI, should obtain.
- CK-MB and troponin I or T
 - $< 50\%$ of patient with UA will have low level troponin elevations
 - CK-MB peaks 12–24 hr, return to baseline in 2–3 days
 - Troponin peaks in 12 hr, return to baseline 7–10 days
- Hematocrit (anemia increases risk of ischemia)
- Coagulation profile
- Electrolytes, especially Cr and K⁺

Imaging

- CXR:
 - Usually nonrevealing
 - May show cardiomegaly, or pulmonary edema, CHF suggests UA or MI
 - May be helpful in identifying other etiologies such as pneumonia, pneumothorax, or aortic dissection
- Coronary CTA:

- Good for low-risk patients with no known CAD to rule out ischemia as cause of pain in patient if no coronary stenosis
- “Triple rule-out” for ACS, PE, and aortic dissection
- Bedside echo: To detect wall motion abnormalities and other etiologies of shock, pericardial effusion, pneumothorax
- Technetium Tc-99 sestamibi (rest): Radionucleotide whose uptake by myocardium is dependent on perfusion

Diagnostic Procedures/Surgery

- Exercise stress testing:
 - Not appropriate if active chest pain with moderate to high likelihood of ischemia
 - Imaging stress test (sestamibi, thallium, or echo) if baseline ECG abnormalities
 - Early positive (within 3 min) concerning for UA
- Coronary angiography:
 - Gold standard of diagnosis for CAD

DIFFERENTIAL DIAGNOSIS

- Anxiety and panic disorders
- Aortic dissection
- Biliary colic
- Costochondritis
- Esophageal reflux
- Esophageal spasm
- Esophagitis
- GERD
- Herpes zoster
- Hiatal hernia
- Mitral valve prolapse
- Musculoskeletal chest pain
- MI
- Myocarditis
- Nonatherosclerotic causes of cardiac ischemia
 - Coronary artery spasm
 - Coronary artery embolus
 - Congenital coronary disease
 - Coronary dissection
 - Valvular disease: AS, AI, pulmonary stenosis, mitral stenosis
 - Congenital heart disease
- Peptic ulcer disease
- Pericarditis
- Pneumonia

- Psychogenic
- Pneumothorax
- Pulmonary embolism

TREATMENT

PRE HOSPITAL

- IV access
- Aspirin
- Oxygen
- Vital signs and oxygen saturation
- Cardiac monitoring
- 12-lead ECG, if possible
- Sublingual nitroglycerin

INITIAL STABILIZATION/THERAPY

- IV access
- Oxygen
- Cardiac monitoring
- Vital signs and continuous oxygen saturation

ED TREATMENT/PROCEDURES

- All patients with chest pain in which cardiac ischemia is a consideration should receive an aspirin upon arrival to the ED
- Sublingual nitroglycerin: If symptoms persist after 3 sublingual doses, suggestive of UA, AMI, or noncardiac etiology
- Pain control
- Anticoagulation

MEDICATION

First Line

- Aspirin: 325 mg PO (chewed) or 81 mg × 4 (chewed)
- In patients with aspirin allergy: Clopidogrel (Plavix) 300--600 mg PO, also consider prasugrel 60 mg PO or 180 mg PO ticagrelor
- Dual antiplatelet therapy should be given to patients with UA at medium to high risk who have been selected to have invasive strategy such as catheterization or surgery
- Nitroglycerin:
 - 0.4 mg sublingual
 - 5–10 µg/min IV USE NON-PVC tubing, titrating to effect
 - 1–2 in of nitro paste

- Hold for low BP (can severely drop BP)
- Beware if pt has history of erectile dysfunction and use of phosphodiesterase inhibitors like sildenafil (Viagra) or tadalafil (Cialis) can last 48 hr
- Morphine
 - 4 mg IV, titrate to relief of pain assuming no respiratory depression and SBP > 90
- Consider beta blocker
 - Metoprolol: 25—50 mg PO or 5 mg IV q5–15min for refractory HTN and tachycardia
 - Contraindicated in reactive airway disease, active CHF, bradycardia, hypotension, heart block, cocaine use
 - Does not necessarily need to be given while patient is in ED, suggested benefit within 24 hrs of AMI

Second Line

Anticoagulation

- Does not alter mortality
 - Consider conferring with cardiology prior to anticoagulation
 - Heparin: 60 U/kg IV bolus, then 12 U/kg/hr (goal PTT 50–70)
 - Enoxaparin: 1 mg/kg SC q12 or q24 if Cr clearance < 30mL/min
- Glycoprotein IIb/IIIa inhibitors: Primary benefit en route to cath
 - Eptifibatide (Integrilin): 180 µg/kg bolus IV over 1–2 min, then 2 µg/kg/min up to 72 hr
 - Tirofiban (Aggrastat): 0.4 µg/kg/min for 30 min, then 0.1 µg/kg/min for 48—108 hr
 - Abciximab (Reopro): 0.25 mg/kg IV bolus, then 0.125 µg/kg/min, maximum dose 10 µg/min for 12 hr
 - Bilvalirudin, fondaparinux
- Patients at risk for high risk for bleeding include the elderly, female, anemic, chronic renal failure

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with UA require admission to the hospital
- Early intervention with cardiac catheterization likely decreases mortality in patients with elevations in cardiac enzymes, persistent angina or hemodynamic instability
- Patients with unclear diagnosis likely would benefit from admission to ED observation unit or hospitalization for serial cardiac enzymes, ECG and stress

Discharge Criteria

- Patients with stable angina
- Patients who are enzyme/stress testing or cath negative

FOLLOW-UP RECOMMENDATIONS

Patients with stable angina or workup negative chest pain should follow up with their PCP or cardiologist within several days of ED visit.

PEARLS AND PITFALLS

- History is the most important factor in differentiating unstable from stable angina or noncardiac pain
- All patients with chest pain or symptoms concerning for a cardiac etiology should have an immediate ECG
- If the initial ECG is normal or unchanged, do serial ECGs 10–30 min apart
- A single set of negative cardiac enzymes may not rule out ACS in a patient with chest pain
- Women, diabetics, ethnic minorities, and patients > 65 yr require a low threshold for ACS workup as they often have atypical presentations

ICD10

- I20.0 Unstable angina
- I20.1 Angina pectoris with documented spasm
- I20.9 Angina pectoris, unspecified

ACUTE CORONARY SYNDROME: CORONARY VASOSPASM

John W. Hardin • Shamai A. Grossman

BASICS

DESCRIPTION

- Spontaneous episodes of chest pain due to coronary artery vasospasm in the absence of increase in myocardial oxygen demand in either normal or diseased coronary vessels
- Also known as Prinzmetal angina or variant angina, originally described in 1959
- Most common in younger patients and men
- Usually occurs in patients without cardiac risk factors or coronary artery disease
- Risk factors:
 - Smoking (up to 75% of cases)
 - Hypertension
 - Hypercholesterolemia
 - Diabetes mellitus
 - Cocaine use

ETIOLOGY

- Abnormal vasodilator function in coronary arteries typically endothelial in origin
- High prevalence of microvascular and epicardial vessel involvement
- Defined by 3 types
 - Focal: Localized, often at or near a site of stenosis of a single artery
 - Multifocal: 2 or more segments of the same artery
 - Multivessel: Involving different coronary arteries
- Unopposed α sympathetic stimulation
- Sympathetic stimulation by endogenous hormones may cause vasoconstriction.
- Conversely, also associated with increased vagal tone or withdrawal from vagal tone as proven with acetylcholine provocative testing
- Hypersensitivity of coronary arteries due to mediators of vasoconstriction
- Endothelial dysfunction possibly from genetic mutations in nitric oxide synthase
- Newer research suggests potential increase ρ -kinase activity in smooth muscle cells

DIAGNOSIS

SIGNS AND SYMPTOMS

- Chest pain:
 - Retrosternal
 - Radiates to neck, jaw, left shoulder, or arm
 - Occurs at rest

– Occurs more frequently at night or in the morning

- Palpitations
- Presyncope or syncope
- Associated with migraine headaches and Raynaud disease in a minority of patients
- May occur during cold weather or stress
- May be prolonged in duration compared to typical angina
- May be elicited by hyperventilation
- May be elicited by exercise
- Circadian pattern, typically at night or early morning

History

May mimic angina, occurrences in the early morning should raise suspicion for vasospasm, but also ask about relationship to stress, exercise, and cold weather

Physical-Exam

Physical exam is typically nondiagnostic.

ESSENTIAL WORKUP

- Must include an ECG
- Use of other tests depends on history.

DIAGNOSIS TESTS & NTERPRETATION

- ECG:
 - Transient ST-segment elevation is characteristic, is typically quite pronounced
 - Often with reciprocal changes
 - May be followed by ST depression or T-wave inversion
 - May have associated dysrhythmia during coronary spasm
 - Heart block with right coronary artery spasm
 - Ventricular tachycardia with LAD spasm
 - In rare cases can present with sudden death during prolonged vasospasm period

Lab

- Troponin
- CK/CKMB fraction
- Toxicology screen:
 - Helpful if cocaine is suspected as etiology of chest pain

Imaging

- CXR:
 - May be helpful to rule out other etiologies such as pneumonia, pneumothorax, or aortic dissection

- Noninvasive coronary imaging (nuclear perfusion, coronary CTA, coronary MR):
 - Typically only helpful when combined with provocative testing

Diagnostic Procedures/Surgery

- Exercise stress testing:
 - Usually not helpful, but can help define those with true ischemic disease
- Noninvasive provocative hyperventilation
 - Highly specific, moderately sensitive, tends to favor those with increased disease activity
 - Paired with either EKG or EKG plus perfusion imaging
- Holter monitor:
 - Can be helpful in silent cases or dysrhythmia
- Coronary angiography:
 - Mild atherosclerosis is often the norm
 - Provocative test with acetylcholine is the gold standard

DIFFERENTIAL DIAGNOSIS

- Angina pectoris
- Anxiety and panic disorders
- Aortic dissection
- Cocaine chest pain
- Esophageal rupture
- Esophageal spasm
- Esophagitis
- GERD
- Mitral valve prolapse
- Musculoskeletal chest pain
- MI
- Peptic ulcer disease
- Pericarditis
- Pneumothorax
- Pulmonary embolism
- Takotsubo cardiomyopathy

TREATMENT

PRE HOSPITAL

Treat as any other acute coronary syndrome.

INITIAL STABILIZATION/THERAPY

- IV access
- Oxygen

- Cardiac monitoring
- Vital signs and oxygen saturation

ED TREATMENT/PROCEDURES

- All patients with chest pain in which cardiac ischemia is a consideration should receive an aspirin upon arrival to the ED:
 - Paradoxically may increase severity of Prinzmetal angina due to inhibition of biosynthesis of naturally occurring coronary vasodilator—prostacyclin
- Nitroglycerin should still be administered and usually will help relieve both ischemic and vasospastic chest pain.
- A trial of calcium-channel blockers is indicated if clinical history is consistent with coronary vasospasm.
- Heparin and β -blockers are not helpful in true coronary vasospasm:
 - β -blockers may be detrimental due to unopposed α -mediated vasoconstriction and should be avoided in suspected cocaine chest pain.

MEDICATION

- Aspirin: 325 mg PO
- Diltiazem: 30–60 mg PO (immediate release)
- Nitroglycerin, either:
 - 0.4 mg sublingual
 - 10–20 μ g/min IV USE NON-PVC tubing, titrating to effect
 - 1–2 in of nitro paste
- Verapamil: 40–80 mg PO (immediate release)

First Line

Diltiazem/verapamil:

- > 40% of patients will have recurrence of vasospastic angina despite calcium-channel blocker therapy

Long-acting nitrates

Second Line

- α -blocking agents
- Statin therapy
- Percutaneous intervention with stenting of fixed lesions in area of vasospasm controversial; can lead to spasm in other areas of coronary tree
- Pacemaker placement for patients with recurrent syncope or AV nodal block from vasospastic angina

FOLLOW-UP

DISPOSITION

Admission Criteria

- New-onset chest pain
- Rule-in with positive biochemical markers or provocative testing
- Rule-in with positive biochemical markers or stress testing
- Many patients previously admitted to the hospital can now be effectively evaluated in a chest pain observation unit or clinical decision unit

Discharge Criteria

- Stable (chronic chest pain)
- Negative ischemic workup

FOLLOW-UP RECOMMENDATIONS

Cardiology follow up within 7 days of ED evaluation

PEARLS AND PITFALLS

- 95% survival at 5 yr
- Typical patient will have no traditional coronary risk factors other than smoking.
- Calcium-channel blockers are 1st-line therapy.
- 30–40% of patients are refractory to treatment and will have repeat episodes.
- May present as STEMI, however true infarction is almost always relegated to patient with pre-existing coronary atherosclerotic disease
- β -blockers can lead to worsening of vasospasm due to unopposed α vasoconstriction.
- Patients with prolonged vasospasm can present with ST elevation MI, ventricular arrhythmias, and sudden death.

ACUTE CORONARY SYNDROME: MYOCARDIAL INFARCTION

Josh W. Joseph • Shama A. Grossman

BASICS

DESCRIPTION

- Imbalance in myocardial blood supply and oxygen requirement
- Acute coronary syndrome (ACS) encompasses a spectrum of disease processes:
 - Unstable angina pectoris
 - Acute myocardial infarction (AMI)
 - ST elevation myocardial infarction (STEMI)
 - Non-STEMI

ETIOLOGY

- Atherosclerotic narrowing of coronary vessels
- Vasospasm (Prinzmetal or variant angina)
- Microvascular angina or abnormal relaxation of vessels with diffuse vascular disease
- Plaque disruption
- Thrombosis
- Arteritis:
 - Lupus
 - Takayasu disease
 - Kawasaki disease
 - Rheumatoid arthritis
- Prolonged hypotension
- Anemia/stress ischemia:
 - Hemoglobin < 8 g/dL
- Carbon monoxide/elevations in carboxyhemoglobin
- Coronary artery gas embolus
- Thyroid storm
- Structural abnormalities of coronary arteries:
 - Radiation fibrosis
 - Aneurysms
 - Ectasia
- Cocaine- or amphetamine-induced vasospasm
- Cardiac risk factors include:
 - Hypercholesterolemia
 - DM
 - HTN

- Smoking
- Family history in a 1st-degree relative < 55 yr old
- Men, age > 55 yr
- Postmenopausal women

DIAGNOSIS

SIGNS AND SYMPTOMS

- Chest pain:
 - Most common presentation of MI
 - Substernal pressure
 - Heaviness
 - Squeezing
 - Burning sensation
 - Tightness
- Anginal equivalents (MI without chest pain):
 - Abdominal pain
 - Syncope
 - Diaphoresis
 - Nausea or vomiting
 - Weakness
- May localize or radiate to arms, shoulders, back, neck, or jaw
- Associated symptoms:
 - Dyspnea
 - Syncope
 - Fatigue
 - Diaphoresis
 - Nausea
 - Vomiting
- Symptoms are usually reproduced by exertion, eating, exposure to cold, or emotional stress.
- Symptoms commonly last 30 min or more.
- Symptoms may occur with rest or exertion.
- Often preceded by crescendo angina
- May be improved/relieved with rest or nitroglycerin
- Symptoms generally unchanged with position or inspiration
- Positive Levine sign or clenched fist over chest is suggestive of angina.
- BP is usually elevated during symptoms.

Physical-Exam

- Physical exam is usually unrevealing.
- Occasional physical findings include:

- S3 or S4 due to left ventricular systolic or diastolic symptoms
- Mitral regurgitation due to papillary muscle dysfunction
- Diminished peripheral pulses
- Physical findings of decompensated CHF

ESSENTIAL WORKUP

History is critical in differentiating MI from noncardiac etiologies.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Electrolytes
- Calcium, magnesium
- Cardiac enzymes
- Digoxin level

Imaging

- CXR:
 - May identify cardiomyopathy or CHF
 - Often abnormal in aortic dissection

Diagnostic Procedures/Surgery

- ECG:
 - Differentiate from nonischemic causes of ST elevation
 - Pericarditis
 - Benign early repolarization
 - Left ventricular hypertrophy with strain
 - Prior MI with left ventricular aneurysm
 - Hyperkalemia
- ECG criteria for STEMI
 - New ST elevation at J point in at least 2 contiguous leads of 2 mm (0.2 mV) in men or 1.5 mm (0.15 mV) in women in leads V2–V3 and/or of 1 mm (0.1 mV) in other contiguous chest leads or the limb leads
 - ST depression in leads V1–V2 may indicate posterior injury
 - New or presumably new LBBB has been considered an STEMI equivalent. Most cases of LBBB at time of presentation, are not old but prior ECG is unavailable
 - Sgarbossa criteria for MI in LBBB are diagnostic
 - Concordant ST elevation > 1 mm in leads with a positive QRS complex
 - Concordant ST depression > 1 mm V1–V3
 - Excessively discordant ST elevation > 5 mm in leads with a negative QRS complex

- Echo:
 - May identify regional wall motion abnormalities or valvular dysfunction

DIFFERENTIAL DIAGNOSIS

- Aortic dissection
- Anxiety
- Biliary colic
- Costochondritis
- Esophageal spasm
- Esophageal reflux
- Herpes zoster
- Hiatal hernia
- Mitral valve prolapse
- Peptic ulcer disease
- Psychogenic symptoms
- Panic disorder
- Pericarditis
- Pneumonia
- Pulmonary embolus

TREATMENT

PRE HOSPITAL

- IV access
- Aspirin
- Oxygen
- Cardiac monitoring
- Sublingual nitroglycerin for symptom relief
- 12-lead ECG, if possible, with transmission or results relayed to receiving hospital

INITIAL STABILIZATION/THERAPY

- IV access
- Oxygen
- Cardiac monitoring
- Oxygen saturation
- Continuous BP monitoring and pulse oximetry

ED TREATMENT/PROCEDURES

- STEMI requires reperfusion therapy as soon as possible:
 - Percutaneous coronary intervention (PCI) is preferred diagnostic and therapeutic modality if available.
- Goal is primary PCI within 90 min of 1st medical contact.
 - Thrombolytics should be given if PCI is not available within 120 min of 1st

medical contact (see “Reperfusion Therapy, Cardiac”).

- Aspirin should be administered 1st to all patients with suspected MI unless known allergy.
- Glycoprotein IIb/IIIa inhibitors (e.g., Abciximab) may be started at time of PCI
- Prasugrel or Clopidogrel should be started at the time of PCI
- Prasugrel should not be given to patients with history of prior stroke or TIA
- Clopidogrel is the recommended ADP receptor inhibitor for patients given fibrinolytics
 - Dose is reduced (age <75 yr: 300 mg, >75 yr: 75 mg)
- If BP is >90–100 mm Hg systolic, administer sublingual nitroglycerin, nitropaste, or IV nitroglycerin assuming no ECG criteria or clinical evidence of right ventricular infarct:
 - Symptoms that persist after 3 sublingual nitroglycerin tablets are strongly suggestive of AMI or noncardiac etiology.
- β -blockers should be initiated within 1st 24 hr if not contraindicated (e.g., heart block, heart rate <60, signs of heart failure, hypotension, or obstructive pulmonary disease) are present
 - No benefit of administration prior to PCI or in ED
- Morphine may be given to relieve pain, anxiety, and increase oxygen carrying capacity.
- Heparin (UFH) or Bivalirudin should be used in patients undergoing primary PCI. Bivalirudin is indicated in patients at high risk for bleeding.
- In patients undergoing thrombolysis, Heparin (UFH), Enoxaparin, or Fondaparinux are appropriate.
- If patient is in cardiogenic shock, patient should be transported to a cardiac catheterization laboratory for angioplasty and intra-aortic balloon pump as soon as possible (see “Congestive Heart Failure”).
- Ventricular dysrhythmias:
 - See “Ventricular Tachycardia”
- Bradydysrhythmia associated with hypotension should be treated with atropine or external pacing.
- Conduction disturbances:
 - 1st-degree atrioventricular (AV) block and Mobitz I (Wenckebach) are often self-limited and do not require treatment.
 - Mobitz II, complete heart block, new right bundle branch block (RBBB) in anterior MI, RBBB plus left anterior branch block or left posterior fascicular block, left bundle branch block plus 1st-degree AV block may require a temporary transvenous pacemaker.
- Accelerated idioventricular rhythm (AIVR) may present after reperfusion, appearing as a ventricular rhythm with rate below 120 bpm
 - Only if sustained treat with electrical cardioversion or sodium bicarbonate
 - Lidocaine and other antidysrhythmics may cause asystole

MEDICATION

- Aspirin: 162–325 mg PO
- ADP receptor inhibitors
 - Clopidogrel (Plavix): 600 mg PO
 - Prasugrel (Effient): 60 mg PO
 - Ticagrelor (Ticlid): 180 mg PO
- Bivalirudin: 0.75 mg/kg IV bolus, then 1.75 mg/kg/h infusion
- Enoxaparin (Lovenox): 1 mg/kg SC q12h
 - Fondaparinux: 2.5 mg IV
- Glycoprotein IIb/IIIa inhibitors:
 - Abciximab (ReoPro) for use prior to PCI only: 0.25 mg/kg IV bolus
 - Eptifibatide (Integrilin): 180 µg/kg IV over 1–2 min, then 2 µg/kg/min up to 72 hr
 - Tirofiban (Aggrastat): 0.4 µg/kg/min for 30 min, then 0.1 µg/kg/min for 48–108 hr
- Heparin: 60 units/kg IV bolus (max. 4,000 U), then 12 U/kg/h (max. 1,000 U/h)
- Metoprolol: 5 mg IV q5–15min followed by 25–50 mg PO starting dose as tolerated (note: β-blockers contraindicated in cocaine chest pain)
- Morphine: 2 mg IV, may titrate upward in 2 mg increments for relief of pain assuming no respiratory deterioration and SBP >90 mm Hg
- Nitroglycerin: 0.4 mg sublingual q5min for max. 3 doses
- Nitroglycerin: IV drip at 5–10 µg/min, USE NON-PVD tubing
- Nitropaste: 1–2 in transdermal
- Thrombolytics: See “Reperfusion Therapy, Cardiac,” for dosing

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with an AMI require hospital admission.
- If the diagnosis is unclear, admission to the hospital or an ED observation unit may be useful for serial cardiac enzymes, ECGs, and exercise stress testing and/or cardiac catheterization if needed.

Discharge Criteria

No patient with an AMI should be discharged from the ED.

Issues for Referral

- If PCI is unavailable at the treating institution, particularly if the patient is in cardiogenic shock, he should be transported to another hospital if PCI can be initiated within 120 min of 1st medical contact.

- Patients with failed reperfusion should be transported urgently to a PCI-capable facility
- Patients undergoing reperfusion therapy may benefit from transfer to a PCI-capable facility within 3–24 hr as part of an invasive strategy

PEARLS AND PITFALLS

- Goal of thrombolytic therapy is a 30 min door to needle time if PCI not possible.
- New or presumably new LBBB at presentation occurs infrequently, and should not be considered diagnostic of AMI in isolation

ACUTE CORONARY SYNDROME: NON-Q-WAVE (NON-ST-ELEVATION) MI

David F. M. Brown • Kenneth R. L. Bernard

BASICS

DESCRIPTION

- Non-ST-elevation myocardial infarction (NSTEMI) is a part of a clinical syndrome that also includes unstable angina and ST-elevation MI (STEMI).
- Caused by subtotal occlusion of coronary blood flow:
 - _ Often indicates an incomplete ischemic event
- Coronary plaque disruption:
 - _ Endothelial disruption exposes subendothelial collagen and other platelet-adhering ligands, von Willebrand factor (vWF), and fibronectin.
 - _ Release of tissue factors activates factor VII and extrinsic pathway.
- Thrombus generation:
 - _ Platelet adhesion via glycoprotein (GP) Ia/IIa to collagen; GP Ib to vWF:
 - Platelet activation: Release of ADP, thromboxane A₂, and serotonin alters the platelet GP IIb/IIIa receptor; also causes local vasoconstriction
 - Platelet aggregation: GP IIb/IIIa receptor binds fibrinogen, cross-links platelets, forming local platelet plug
 - _ Platelet stabilization: Thrombin converts fibrinogen to fibrin, provides fibrin mesh, stabilizes platelet aggregate
- Microembolization to downstream coronary arterioles may occur

ETIOLOGY

- Coronary thrombosis
- Coronary vasospasm, idiopathic or cocaine induced
- In situ thrombosis/hypercoagulable states
- Embolic event (e.g., endocarditis, paradoxical emboli through PFO)
- Arteritis

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Pain:
 - _ Pressure or tightness or heaviness

- Substernal, epigastric
- +/- radiation to arm, jaw, back
- More likely nonpositional, nonpleuritic, nonreproducible on palpation
- Nausea, vomiting
- Diaphoresis
- Cough
- Dyspnea
- Anxiety
- Light-headedness
- Syncope
- Recent cocaine or amphetamine use
- Family history of coronary disease
- Atypical presentations common, especially in women, diabetics, and the elderly

Geriatric Considerations

Geriatric patients may present with atypical symptoms or silent ischemia.

Physical-Exam

- Pallor or diaphoresis
- Hypertension or hypotension
- Arrhythmias
- S4 gallop
- Physical exam is often normal

ESSENTIAL WORKUP

ECG, cardiac biomarkers, CXR

DIAGNOSIS TESTS & NTERPRETATION

Lab

- Cardiac markers:
 - Troponins: Specific indicators of myocardial infarction, rises within 3–6 hr after MI, peaks at 9–10 days
 - Creatine kinase (CK): Rises within 4–8 hr, peaks at 18–24 hr, subsiding at 3–4 days; isoenzyme CK-MB more specific for cardiac origin
 - Myoglobin: Rises within 2–6 hr, returns to baseline within 24 hr, highly sensitive but very nonspecific
 - LDH: Rises within 24 hr, peaks at 3–6 days, returns to baseline at 8–12 days
- CBC
- Serum electrolytes including magnesium
- PT/PTT/INR for patients on warfarin
- NT-proBNP: Higher levels correlate with increased mortality in NSTEMI patients.

Imaging

- ECG:
 - ST-segment depression or transient elevation indicates increased risk.
 - T-wave inversion in regional patterns does not increase risk but helps differentiate cardiac pain from noncardiac pain.
 - Deep (> 2 mm) precordial T-wave inversion suggests cardiac ischemia.
- CXR:
 - To assess heart size, pulmonary edema/congestion or identify other causes of chest pain
- ECHO (generally not part of ED evaluation):
 - To identify wall motion abnormalities and assess ventricular function
- Radionuclide studies (if conservative management; generally not part of ED evaluation):
 - Sestamibi scan: Identify viable myocardium
 - Technetium 99: Identify recently infarcted myocardium

Diagnostic Procedures/Surgery

Coronary angiography (+/- PCI), typically as an inpatient, depending on patient's risk profile and comorbidities

DIFFERENTIAL DIAGNOSIS

- STEMI
- Pulmonary embolus
- Aortic dissection
- Acute pericarditis/myocarditis
- Pneumothorax
- Pancreatitis
- Pneumonia
- Esophageal spasm/gastroesophageal reflux
- Esophageal rupture
- Musculoskeletal pain/costochondritis

TREATMENT

PRE HOSPITAL

- IV access
- Oxygen administration
- 12-lead EKG, cardiac monitoring, and treatment of arrhythmias
- Aspirin, analgesia, anxiolytics

INITIAL STABILIZATION/THERAPY

- Oxygen administration

- IV access
- 12-lead EKG, cardiac monitoring, and treatment of arrhythmias

ED TREATMENT/PROCEDURES

- Anti-ischemic therapy to reduce demand and increase supply of oxygen to myocardium:
 - β -blockers: IV only if hypertensive with ongoing pain, else use orally within 24 hr; contraindicated in heart failure
 - Nitrates: Contraindicated with critical AS, suspicion of RV infarct or recent use of phosphodiesterase inhibitors (e.g., sildenafil)
 - Oxygen
 - Morphine sulfate
 - Calcium-channel blockers (nondihydropyridines—e.g., diltiazem, verapamil) may be used in patients with ongoing ischemia and contraindications to β -blockade. Contraindicated in heart failure
- Dual antiplatelet therapy to decrease platelet aggregation:
 - Aspirin: Only withhold if prior anaphylaxis
 - ADP Inhibitor: Clopidogrel (substitute for ASA if hypersensitivity), ticagrelor or prasugrel (if low bleeding risk, CABG unlikely, no history of CVA, age <75 yr)
- GP IIb/IIIa inhibitors (eptifibatide, tirofiban):
 - Only if ongoing ischemia, positive cardiac markers and PCI planned; can defer to inpatient administration
 - May omit if loading dose of clopidogrel administered at least 6 hr prior to PCI or bivalirudin used for anticoagulation
- Anticoagulation therapy to prevent thrombus propagation:
 - Unfractionated heparin or enoxaparin are 1st-line therapies.
 - Fondaparinux (factor Xa inhibitor) is a reasonable alternative, especially for medically managed patients; may have reduced bleeding risk.
 - Reserve bivalirudin (direct thrombin inhibitor) for patients with known heparin-induced thrombocytopenia
- Anxiolytics to suppress sympathomimetic release

MEDICATION

First Line

- Aspirin 162–325 mg PO per day
- β -blockers:
 - Atenolol: Start 5 mg IV over 5 min, then 5 mg IV 10 min later, then 50–100 mg PO per day (1–2 hr after IV doses)
 - Esmolol: 100 μ g/kg/min IV infusion (titrate by increasing 50 μ g/kg/min q15min until effect—to max. dose 300 μ g/kg/min)
 - Metoprolol: Start 5 mg IV q5min \times 3, after 15 min begin 25–50 mg PO BID

- Propranolol: 0.5–1 mg IV then 40–80 mg PO q6–8h
- Clopidogrel: 300–600 mg PO × 1, then 75 mg/d
- Heparins:
 - Enoxaparin: 1 mg/kg SC q12h, can give 30 mg IV bolus before SC dose (beware of enoxaparin in patients with renal dysfunction) *or*
 - Unfractionated heparin: 60 U/kg IV bolus then 12 U/kg/hr infusion (max. bolus 4,000 U, max. infusion rate 1,000 U/hr (goal is a PTT 50–75 s))
- Morphine sulfate: 1–5 mg IV q5–30min PRN pain
- Nitroglycerin: 0.3–0.6 mg SL or 0.4 mg by spray q5min followed by IV infusion beginning at 10–20 µg/min if pain persists (max. dose 200 µg/min)
- GP IIb/IIIa inhibitors:
 - Eptifibatide: 180 µg/kg IV bolus then 2 µg/kg/min infusion for 72–96 hr
 - Tirofiban: 0.4 µg/kg/min IV × 30 min, then 0.1 µg/kg/min infusion for 12–24h

Second Line

- Calcium-channel blockers:
 - Diltiazem: Start 0.25 mg/kg IV bolus, then 0.35 mg/kg IV after 15 min if needed then 30 mg PO q6h: immediate release
 - Verapamil: Start 5–10 mg IV, repeat after 30 min if needed, then 80–160 mg PO q8h: immediate release
- ADP blocker:
 - Ticagrelor 180 mg PO × 1 at time PCI or no later than 1 hr post-PCI then 90 mg PO BID
 - Prasugrel 60 mg PO × 1 at time of PCI or no later than 1 hr post-PCI then 10 mg/d
- Lorazepam: 1–2 mg IV PRN anxiety
- Anticoagulation (instead of unfractionated heparin or enoxaparin):
 - Fondaparinux: 2.5 mg SC once a day *or*
 - Bivalirudin (only prior to PCI): 0.75 mg/kg IV bolus, then 1.75 mg/kg/hr IV for up to 4 hr, then 0.2 mg/kg/hr IV for up to 20 hr

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with positive cardiac biomarkers, high risk for adverse outcomes by clinical prediction rules (TIMI, GRACE, PURSUIT), or significant clinical probability of acute coronary syndrome undergoing consideration for urgent or early invasive management 12–24 hr after presentation.
- Intensive care unit for monitoring unstable patients

Discharge Criteria

Only those who are ruled out for acute coronary syndrome/non-Q-wave infarction can be safely sent home.

FOLLOW-UP RECOMMENDATIONS

Only patients ruled out for acute coronary syndrome can be safely discharged:

- Discharged patients should follow up in 1–2 days with their primary care physician or cardiologist.
- Outpatient stress tests should be done within 72 hr.

PEARLS AND PITFALLS

- EKG should be done in all patients with chest pain on arrival to the ED, preferably within 10 min.
- Early medical therapy can reduce mortality in NSTEMI.
- Pitfalls:
 - Do not rule out infarction based on initial or single set of cardiac markers, particularly if the time from symptom onset is <4–6 hr.
 - Do not fail to ask about amphetamine or cocaine use.
 - Do not fail to ask about use of sildenafil, vardenafil, or tadalafil before giving nitroglycerin.

CODES

ICD9

- 410.70 Subendocardial infarction, episode of care unspecified
- 410.71 Subendocardial infarction, initial episode of care
- 410.72 Subendocardial infarction, subsequent episode of care

ICD10

- I21.4 Non-ST elevation (NSTEMI) myocardial infarction
- I24.9 Acute ischemic heart disease, unspecified

ADRENAL INSUFFICIENCY

Rita K. Cydulka • Joseph P. Tagliaferro

BASICS

DESCRIPTION

- Inadequate hydrocortisone secretion to meet body's stress requirement
- Adrenal deficiency:
 - Inadequate cortisol
 - Unresponsive to stimulation with adrenocorticotrophic hormone (ACTH)
- Functional hypoadrenalism:
 - Inadequate cortisol
 - Partial response to stimulation with ACTH
- Addisonian crisis (acute adrenal insufficiency):
 - Life-threatening emergency
 - Precipitated by intensification of:
 - Chronic adrenal insufficiency
 - Acute adrenal hemorrhage
 - Rapid steroid withdrawal
 - Treatment of hypothyroidism with unrecognized adrenal disease
 - Steroid-dependent patient under stress owing to pregnancy, surgery, trauma, infection, or dehydration

ETIOLOGY

Primary Adrenal Failure

- Adrenal dysgenesis/impaired steroidogenesis:
 - Congenital hypoplasia
 - Allgrove syndrome:
 - ACTH resistance
 - Achalasia
 - Alacrima
 - Glycerol kinase deficiency:
 - Psychomotor retardation
 - Hypogonadism
 - Muscular dystrophy
- Congenital adrenal hyperplasia:
 - 21-hydroxylase deficiency accounts for 95% of cases
- Aldosterone synthetase deficiency
- Mitochondrial disease
- Adrenal destruction:

- Autoimmune:
 - Autoimmune polyglandular syndrome types 1 and 2 (alopecia universalis, chronic mucocutaneous candidiasis, hypoparathyroid, thyroid autoimmunity, diabetes, celiac disease, pernicious anemia)
 - Adrenoleukodystrophy
- Infectious:
 - Granulomatous: TB
 - Protozoal and fungal: Histoplasmosis, coccidioidomycosis, and candidiasis
 - Viral: Cytomegalovirus, herpes simplex virus, and HIV
 - Bacterial
 - Fungal
- Metastatic tumor
- Infiltration:
 - Sarcoid
 - Hemochromatosis
 - Amyloidosis
 - Iron depletion
- Bilateral adrenalectomy
- Hemorrhage:
 - Sepsis: Particularly meningococemia (Waterhouse–Friderichsen syndrome), Pseudomonas infection
 - Birth trauma/anoxia
 - Pregnancy
 - Seizures
 - Anticoagulants
 - Rhabdomyolysis
- Pharmacologic inhibition:
 - Etomidate
 - Herbal medications
 - Ketoconazole
 - Metyrapone
 - Suramin

Secondary Adrenal Failure

- Pituitary insufficiency
- Sepsis
- Head trauma
- Hemorrhage
- Infarction (Sheehan syndrome)
- Infiltration: Neoplasm, amyloid, sarcoid, and hemochromatosis
- ACTH deficiency
- Pharmacologic: Glucocorticoid administration, herbal medications

Tertiary Adrenal Failure

- Hypothalamus insufficiency
- Sepsis
- Infiltrative: Neoplasm, amyloid, sarcoid, and hemochromatosis
- Head trauma

DIAGNOSIS

SIGNS AND SYMPTOMS

- Symptoms:
 - Depression
 - Weakness, tiredness, fatigue
 - Anorexia
 - Abdominal pain (can mimic acute abdomen)
 - Nausea or vomiting
 - Salt craving
 - Postural dizziness
 - Muscle or joint pains
 - Dehydration (found in primary adrenal insufficiency only)
- Signs:
 - Fever or hypothermia
 - Mental status changes
 - Hypotension (< 110 mm Hg systolic)
 - Tachycardia
 - Orthostatic BP changes or frank shock
 - Weight loss
 - Goiter
 - Hypogonadism
 - Hyperkalemia
 - Hypercalcemia
 - Sodium depletion
 - Azotemia
 - Eosinophilia
 - Hyperpigmentation (found in primary adrenal insufficiency only)
 - Vitiligo
- Addisonian crisis:
 - Hypotension and shock
 - Hyponatremia
 - Hyperkalemia
 - Hypoglycemia

ESSENTIAL WORKUP

- Lab confirmation of diagnosis not possible in emergency department

- Adrenal crisis: Life-threatening condition:
 - High degree of suspicion should prompt initiation of therapy before definitive diagnosis.
- Plasma cortisol level $< 20 \mu\text{g/dL}$ accompanied by shock suggests adrenal insufficiency.
- Stat electrolytes:
 - Potassium, sodium
- BUN, creatinine:
 - Elevated owing to dehydration
- Serum glucose levels may be low.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC with differential:
 - Anemia
 - Eosinophilia
 - Lymphocytosis
- Arterial blood gases:
 - Hypoxemia
 - Acidosis
- Cosyntropin stimulation test:
 - Adrenal deficiency:
 - Random serum cortisol $< 20 \mu\text{g/dL}$ (while stressed)
 - ACTH stimulation unresponsive
 - Functional hypoadrenalism:
 - Random serum cortisol $= 20 \mu\text{g/dL}$ (while stressed)
 - 60 min post ACTH stimulation $< 30 \mu\text{g/dL}$ or delta cortisol (60 min – baseline) $= 9 \mu\text{g/dL}$
- Normal anion gap metabolic acidosis due to aldosterone deficiency
- Search for underlying infection

Imaging

CXR:

- Look for infection or edema

Diagnostic Procedures/Surgery

ECG:

- Evaluate for electrolyte disturbances

DIFFERENTIAL DIAGNOSIS

- Sepsis
- Shock (any cause)

- Acute abdominal emergency

TREATMENT

INITIAL STABILIZATION/THERAPY

- Airway, breathing, and circulation management (ABCs)
- Cardiac monitor
- BP support for hypotension:
 - _ Normal saline (0.9%) IV fluids 500 mL–1 L (peds: 20 mL/kg) bolus
 - _ Avoid pressors (if possible):
 - May precipitate dysrhythmias
- Supplemental oxygen to meet metabolic needs
- Correct hyperthermia:
 - _ Initiate cooling measures.

ED TREATMENT/PROCEDURES

- Glucocorticoid replacement:
 - _ IV hydrocortisone or dexamethasone immediately
 - _ Use IM route if no IV access
 - _ Dexamethasone will not interfere with results of cosyntropin stimulation tests.
- Volume expansion:
 - _ NS (0.9%) or D₅NS at rate of 500–1,000 mL/hr for 1st 3–4 hr
 - _ Care should be taken to note patient's age, volume, and cardiac and renal function.
- For hypoglycemia:
 - _ D₅₀W
- Treat life-threatening dysrhythmias secondary to hyperkalemia with calcium, bicarbonate, and insulin/glucose.
- Identification and correction of underlying precipitant
- Should see BP improvement within 4–6 hr of therapy

MEDICATION

- Dexamethasone: 6–10 mg (peds: 0.15 mg/kg per dose) q12h
- Dextrose: 50–100 mL D₅₀ (peds: 2 mL/kg of D₁₀ over 1 min) IV
- Hydrocortisone: 100 mg (peds: 1–2 mg/kg per dose) IV q6h
- Insulin (regular): 10 U by IV push (for hyperkalemia)
- Sodium bicarbonate: 1–2 mEq/kg IV (for hyperkalemia)

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with acute adrenal insufficiency
- ICU admission for patients with unstable or potentially unstable cases

Discharge Criteria

- Normal lab evaluation with treated adrenal insufficiency
- Should speak with endocrinologist before discharge with chronic patients

FOLLOW-UP RECOMMENDATIONS

- Should have primary care physician follow-up within a few weeks depending on symptoms.
- May benefit from endocrinology referral.

PEARLS AND PITFALLS

- Acute adrenal insufficiency is a life-threatening emergency, and treatment should not be delayed in the ED while waiting for definite lab diagnosis.
- Cancer of any type can present with adrenal insufficiency; the most common being lung, melanoma, and breast.
- The benefit from steroids for relative adrenal insufficiency in septic shock is limited to the treatment of shock refractory to vasopressive (mortality benefit and clinical effect is questionable).
- The clinical consequence of a single dose of etomidate for rapid sequence intubation is controversial. Studies do show biochemical adrenal suppression which must be weighed against agents with other undesirable properties while performing a critical, life-saving procedure.

AGITATION

Maura Kennedy

BASICS

DESCRIPTION

Agitation, a state of extreme restlessness

- Characterized by increased verbal and motor activity
- Can be the presenting symptom of a variety of medical (organic) and psychiatric (functional) disorders
- Broad spectrum of severity
 - _ From excessive talkativeness to threatening or violent behavior
 - _ Includes excited delirium syndrome
 - Characterized by agitation, acidosis, hyperadrenergic autonomic dysfunction
 - Associated with sudden cardiac death, particularly after a violent struggle

EPIDEMIOLOGY

Incidence and Prevalence Estimates

- 6% of emergency visits are for behavioral disturbances
- ~1.7 million emergency visits annually in US involve agitated patients

ETIOLOGY

Medical (organic) etiologies:

- Infectious:
 - _ CNS infections
 - Encephalitis
 - Meningitis
 - Neurosyphilis
 - Abscess
 - _ Hyperactive or mixed delirium secondary to sepsis
- Metabolic derangements:
 - _ Electrolyte derangement
 - Hyponatremia
 - Hypocalcemia
 - Hypoglycemia
 - _ Renal failure
 - _ Acid/base disturbances
 - _ Hepatic encephalopathy

- Wernicke encephalopathy
- Wilsons disease
- Endocrinopathies:
 - Thyroid storm
 - Hyperparathyroidism
- Pulmonary etiologies:
 - Hypoxemia
 - Hypercarbia
- Toxicologic causes
 - Toxidromes:
 - Sympathomimetic
 - Anticholinergic
 - Cholinergic
 - Alcohol intoxication
 - Alcohol withdrawal
 - Neuroleptic malignant syndrome (NMS)
 - Serotonin syndrome (SS)
- Neurologic causes:
 - Tumors
 - CNS infections (see above)
 - Huntington disease
 - Ischemic cerebrovascular accident
 - Traumatic intracranial hemorrhage
 - Subarachnoid hemorrhage
 - Postseizure
- Psychiatric (functional) etiologies:
- Mania/agitated depression
- Psychotic illnesses such as schizophrenia
- Anxiety disorders

DIAGNOSIS

SIGNS AND SYMPTOMS

A detailed history and physical exam are critical in differentiating between medical and psychiatric causes of agitation.

History

- The HPI has a sensitivity of 94% in detecting medical illness in psychiatric patients.
 - If a detailed HPI is unattainable from the patient seek collateral information from family, friends, and pre-hospital providers
- Inquire about:

- Trauma
- Recent illness and fever
- Headache, loss of consciousness, neurologic deficits, or visual hallucinations
- Current medications
- History of:
 - Psychiatric illness
 - Substance abuse
 - HIV/immunosuppressed state
 - Cancer
 - Neurologic disorders, including epilepsy

Physical-Exam

A thorough exam is critical to differentiate between organic and functional causes

- Vital sign abnormalities should prompt a full evaluation for an organic cause
 - Hyperthermia may indicate an infectious etiology, NMS, SS, or excited delirium syndrome
- Perform a toxidrome-oriented exam, including
 - Pupillary assessment
 - Skin evaluation for diaphoresis or absence of sweat
 - Evaluation for urinary retention
- A detailed neurologic exam is mandatory
 - Any neurologic deficit requires a full evaluation for an underlying medical illness
 - Orientation, memory, and attention should be intact for patients with a functional cause of agitation
 - Alterations in orientation and memory are seen in delirium and dementia
 - Inattention, such as inability to recite the days of the week backward, should raise suspicion of delirium
 - Muscle tone and reflexes should be assessed
 - Muscle rigidity may indicate NMS
 - Hyperreflexia and clonus may indicate SS

DIAGNOSIS TESTS & INTERPRETATION

The diagnostic work up is directed by the history, physical exam, and underlying suspicion of for an organic etiology of the agitation.

ESSENTIAL WORKUP

At minimum all patients should have:

- A full set of vital signs
- A complete physical exam, including a detailed neurologic exam and tests of cognition and attention
- Blood glucose testing

DIAGNOSIS TESTS & INTERPRETATION

Diagnostic tests should be directed on the basis of the suspicion of an organic etiology for the patient's agitation, and history and physical exam findings.

Imaging

Head CT should be considered in trauma patients or those with neurologic deficits.

Diagnostic Procedures/Surgery

- Lumbar puncture should be considered in patients
 - with meningeal signs
 - where infection is suspected as etiology of agitation but no source is identified

DIFFERENTIAL DIAGNOSIS

Agitation may be the presenting symptom of an underlying medical illness, substance abuse or withdrawal, or a psychiatric illness.

TREATMENT

PRE HOSPITAL

Pre-hospital providers frequently encounter agitated or violent patients and should:

- Follow regional protocols regarding physical and chemical restraints
- Provide prenotification when transporting an agitated or violent patient so that the receiving hospital can mobilize necessary resources
- Obtain a fingerstick glucose if feasible

INITIAL STABILIZATION/THERAPY

- ABCs
- Treat life-threatening medical/traumatic conditions as appropriate
- Severely agitated patients may become violent and pose harm to staff and other patients
 - Patients should change into hospital gowns and be searched for weapons
 - Physical and parenteral chemical restraints should be used when necessary to ensure safety of patient(s) and staff

ED TREATMENT/PROCEDURES

- When an organic etiology is suspected or diagnosed
- Treatment should be directed at underlying cause
- When a functional etiology is suspected or diagnosed
- Emergency psychiatric referral is indicated
- Management of agitation
- Verbal de-escalation techniques are 1st line for mild or moderate agitation

- Chemical restraint options include
 - Benzodiazepines
 - 1st line therapy for alcohol withdrawal
 - May precipitate or worsen delirium in geriatric patients
 - Antipsychotics
 - 1st line for patients with functional etiology of agitation/psychosis
 - Low dose can be used in delirious geriatric patient when verbal de-escalation is unsuccessful
 - Monitor for QTc prolongation and extrapyramidal symptoms
 - Combination therapy of parenteral benzodiazepines and haloperidol
 - May produce more rapid sedation than monotherapy
 - Should be consider in highly agitated/violent patient
- Physical restraint use:
- Chemical sedation should be used to facilitate early discontinuation of physical restraints
- Physician and nurses must document use and rationale for usage
- Prolonged use can result in:
 - Hyperthermia
 - Rhabdomyolysis
 - Nerve injury if extremities are kept in same position for prolonged time
 - Excited delirium syndrome

FOLLOW-UP

DISPOSITION

Admission Criteria

Disposition is ultimately determined by the underlying cause of the agitation and whether the condition resolves.

Admission Criteria

Admission is warranted if there is an underlying medical or psychiatric condition that requires inpatient treatment

Discharge Criteria

Discharge should be limited to those individuals where the underlying cause resolves (e.g., substance use/abuse) and/or can be safely treated as an outpatient

Issues for Referral

- Psychiatric referral as appropriate
- Alcohol/drug treatment as appropriate

FOLLOW-UP RECOMMENDATIONS

Follow-up is determined by the causative medical or psychiatric condition(s).

PEARLS AND PITFALLS

Search for potential medical illnesses causing the agitation

- Factors suggestive of organic causes include:
 - New onset at age > 45
 - Abnormal vital signs
 - Focal neurologic abnormalities
 - Acute onset
 - Visual hallucinations
 - Abnormalities of memory or attention on cognitive testing
 - Trauma with evidence of head injury

Pitfalls:

- Not assessing for underlying organic cause of agitation
- Not undressing patients and searching for weapons
- Inadequate dosing of sedatives/antipsychotics
- Failure to adjust extremity position in restraints to prevent nerve complications
- Inadequate documentation of the need for restraint

ICD10

R45.1 Restlessness and agitation

AIRWAY ADJUNCTS

David W. Schoenfeld

BASICS

DESCRIPTION

- Airway adjuncts are devices used for management of the upper airway
- Often used as rescue techniques/devices when unable to intubate with standard techniques and difficult to mask ventilate
- Oral and nasopharyngeal airways:
 - Lift tongue off hypopharynx
 - Combined with positioning aid in airway patency
 - Nasopharyngeal airway may be used when gag reflex intact
 - Oropharyngeal airway placement requires absent gag reflex
- Extraglottic devices (EGD):
 - Supraglottic (SGD) class (i.e., LMA, PAXpress, CobraPLA, iGel, etc.)
 - These sit above and surround the glottis
 - Retroglottic (RGD) or infraglottic (IGD) class (i.e., Combitube, King tube, Ruch EasyTube, etc.)
 - RGD/IGD ventilate at the hypopharynx and occlude the esophagus
- Blind insertion technique (specific to device)
- Less protection from aspiration compared to ET tube
- High success rates for placement of EGDs

EPIDEMIOLOGY

- 95% success with 1st method of airway management
- 98% overall success of intubation
- 4% of ED airways are difficult

DIAGNOSIS

SIGNS AND SYMPTOMS

Physical Exam

- Predictors of difficult to bag-mask ventilate (MOANS)
 - M – Mask seal (beards/structural abnormality)
 - O – Obese or obstructed
 - A – Advanced age (> 55 yr)
 - N – No teeth
 - S – Stiff
- Predictors of difficult laryngoscopy and intubation (LEMON)

- L – Look externally
 - Micrognathia
 - Buck teeth
 - Large tongue
 - Short neck
- E – Evaluate 3-3-2
 - Mouth opens < 3 fingerbreadths
 - Horizontal length of mandible < 3 fingerbreadths
 - Thyromental distance < 2 fingerbreadths
- M – Mallampati score (increasing difficulty)
 - Class I: Soft palate, uvula, fauces, pillars visible
 - Class II: Soft palate, uvula, fauces visible
 - Class III: Soft palate visible
 - Class IV: Hard palate only visible
- O – Obstruction
 - Vocal changes/muffled voice
 - Difficulty managing secretions
 - Stridor
- N – Neck mobility (limited)
- Predictors of difficult cricothyrotomy (SHORT)
 - S – Surgery or disrupted airway
 - H – Hematoma or infection
 - O – Obese (access problem)
 - R – Radiation
 - T – Tumor
- Predictors of difficult EGD (RODS)
 - R – Restricted mouth opening
 - O – Obstruction
 - D – Disrupted or distorted airway anatomy
 - S – Stiff lungs or cervical spine

DIAGNOSIS TESTS & NTERPRETATION

- Pulse oximetry should rise or remain at high level with successful airway management
- Confirming correct placement:
- Fiberoptic bronchoscopy (gold standard)
- End tidal capnometry/capnography (> 99% reliable)
- Physical exam (common but unreliable)
- Chest rise/fall
- Auscultation of breath sounds with absence of sound over epigastrium
- Condensation inside the ETT
- Arterial blood gas is used to guide ventilator settings once airway established.

Imaging

CXR: Useful only in patients following endotracheal intubation to exclude mainstem bronchus intubation or pneumothorax and to adjust the position of the tube

ALERT

CXR does not rule out esophageal intubation

TREATMENT

PRE HOSPITAL

- Options for patients requiring prehospital airway management vary by region and include:
 - _ Bag-valve-mask ventilation \pm OPA or NPA
 - _ Orotracheal intubation (\pm RSI)
 - _ Nasotracheal intubation
 - _ EGD placement
 - _ Surgical airway

INITIAL STABILIZATION/THERAPY

- Maintain in-line cervical spine immobilization in trauma patients
- Oxygen (high flow via nonrebreather or BVM)
- Vascular access (for resuscitation and medication administration) IV or IO

ED TREATMENT/PROCEDURES

- Rapid sequence intubation
- Prepare
 - _ Suction, BVM, ETT, primary airway management modality, rescue airway management modality, medications
- Preoxygenate
 - _ NRB or BVM with 100% FiO₂ for 3 min
- Pretreatment
 - _ Minimize adverse responses to airway management
 - _ Suspected elevated ICP
 - _ Ischemic heart disease or major vessel dissection/rupture
 - _ Adults with significant reactive airways disease
 - _ Children up to 10 yr of age
- Paralysis with induction
 - _ Administration of induction agent
 - _ Rapid sequential administration of paralytic agent

ALERT

Paralysis is relatively contraindicated in anticipated difficult airway

- Positioning
 - _ Head extension
 - _ Cricoid pressure (Sellick maneuver)
- Placement of tube
- Postintubation
 - _ Confirm ETT placement
 - _ Sedation with benzodiazepines, opiates, propofol, or other agents
 - _ Continued paralysis as needed combined with adequate sedation
- Failed intubation
- Consider other intubation techniques in failed airway algorithm or use of airway adjunct
- Surgical airway as last resort

MEDICATION

- Induction
 - _ Etomidate: 0.3 mg/kg IV
 - _ Ketamine: 1--2 mg/kg IV or 4--7 mg/kg IM
 - _ Midazolam: 0.07--0.3 mg/kg IV
 - _ Propofol: 2--2.5 mg/kg IV
 - _ Thiopental: 3 mg/kg IV
- Paralysis
 - _ Succinylcholine: 1--1.5 mg/kg (peds: 2 mg/kg) IV, 2.5 mg/kg IM/SC
 - _ Rocuronium: 1 mg/kg IV (paralyzing dose); 0.1 mg/kg IV (defasciculating dose)
 - _ Pancuronium: 0.1 mg/kg IV (paralyzing dose); 0.01 mg/kg IV (defasciculating dose)
 - _ Vecuronium: 0.1 mg/kg IV (paralyzing dose); 0.01 mg/kg IV (defasciculating dose)

FOLLOW-UP

DISPOSITION

Admission Criteria

Almost all intubated patients should be admitted to an ICU or OR

Discharge Criteria

Rarely, ED patients who have been intubated may be extubated in the ED and discharged after a period of observation.

PEARLS AND PITFALLS

- Failure to ventilate is a life-threatening condition
- Assess every patient for the possibility of difficult mask ventilation or intubation
- Always formulate a back-up plan in case of a failed attempt
- Do not fixate on intubation but rather successful ventilation and oxygenation
- Move to alternate airway management techniques and consider surgical airway if unable to intubate or ventilate despite use of airway adjuncts

Pediatric Considerations

- Oro- and nasopharyngeal airways are available in infant+ sizes
- LMAs are available in infant+ sizes
- Combitube is only designed for patients >48 in in height
- Nasotracheal intubation is contraindicated in children under 10 yr of age

ADDITIONAL READING

CODES

ICD9

- 96.01 Insertion of nasopharyngeal airway
- 96.02 Insertion of oropharyngeal airway
- 96.05 Other intubation of respiratory tract

ICD10

0CHY7BZ Insertion of Airway into Mouth and Throat, Via Natural or Artificial Opening

AIRWAY MANAGEMENT

Scott G. Weiner • Carlo L. Rosen

BASICS

DESCRIPTION

- Techniques that ensure adequate oxygenation and ventilation
- Oral and nasopharyngeal airways:
 - Lift tongue off hypopharynx
 - Facilitate bag-valve-mask (BVM) ventilation
 - Insert when gag reflex is absent
- RSI:
 - Preferred method for ED oral intubation (minimizes aspiration risk)
 - Rapid induction of anesthesia and paralysis
 - Contraindicated in patients who should not be paralyzed
 - A preformulated backup strategy with alternative airway techniques is essential
 - Use of fiberoptic techniques maximizes success
- Oral awake intubation:
 - Oral intubation with sedation only
 - Use when paralysis is contraindicated
 - Ketamine is most commonly used
 - Use with benzodiazepines
- Gum elastic bougie:
 - Airway adjunct used when vocal cords are not well visualized
 - Placement confirmed by feeling bougie bump against tracheal rings
 - Slide endotracheal tube (ET) over bougie, then remove bougie
- Alternative airway devices:
 - Extraglottic devices:
 - Inserted blindly into oropharynx and inflated
 - Laryngeal mask airway (LMA) forms a seal around glottic structures in hypopharynx.
 - LMA offers less protection against aspiration than ET tube
 - Intubating LMA can be used to place an ET tube
 - Esophageal–tracheal tubes (e.g., Combitube, King LT) occlude the esophagus and ventilate the hypopharynx
 - Video laryngoscopes:
 - Fiberoptic camera on the tip of laryngoscope blade (e.g., Glidescope, C-MAC) or LMA to visualize tube placement
 - Fiberoptic intubating stylets:
 - Fiberoptic camera on the tip of a stylet which holds ET tube (e.g.,

Shikani)

- Classic fiberoptic intubation:
 - _ ET tube placed over bronchoscope
 - _ Nasotracheal or orotracheal approach
 - _ Indications:
 - Anatomic limitations to glottis visualization
 - Limited mobility of mandible or cervical spine
 - Unstable cervical spine injury
 - _ Contraindications:
 - Need for immediate airway management
 - Significant oropharyngeal blood
- Nasotracheal intubation:
 - _ Indications:
 - Oral access impaired
 - Unsuccessful oral intubation
 - Paralysis is contraindicated
 - Limited cervical mobility
 - _ Contraindications:
 - Apnea (only absolute contraindication)
 - Anticoagulation
 - Massive facial, nasal, or head trauma
 - Upper airway abscess
 - Epiglottitis
 - Penetrating neck trauma
- Cricothyrotomy:
 - _ Definitive treatment for a failed airway
 - _ Incision in cricothyroid membrane
 - _ Tracheostomy tube inserted percutaneously into the airway
 - _ Indications:
 - Crash airway when other airway attempts have failed
 - Massive facial trauma
 - Total upper airway obstruction
 - _ Contraindications:
 - Laryngeal crush injury
 - Tracheal transection
 - Relative: Expanding zone II or III hematoma
- Percutaneous translaryngeal ventilation (PTV):
 - _ Percutaneous placement of 12G or 14G catheter through cricothyroid membrane
 - _ Intermittent ventilation via high-pressure oxygen source
 - _ Indications:
 - Failed oral or nasal intubation until cricothyrotomy is complete
 - _ Contraindications:

- Upper airway obstruction preventing expiration

DIAGNOSIS

SIGNS AND SYMPTOMS

Clinical conditions requiring airway management:

- Failure to maintain or protect the airway:
 - Oropharyngeal swelling
 - Absent gag reflex
 - Inability to clear secretions, blood
 - Stridor
- Hypoxia or ventilatory failure:
 - Shortness of breath
 - Altered mental status
 - Status epilepticus
- Anticipated clinical course:
 - Ventilatory control for head injury or tricyclic overdose
 - Sedation for diagnostic or therapeutic procedures
 - Early management if the airway might become compromised

ESSENTIAL WORKUP

- Always be prepared with a difficult airway algorithm prior to beginning the procedure.
- Recognition of a difficult airway (LEMON)
 - LOOK for anatomic considerations:
 - Short mandible, thick neck, narrow mouth, large tongue, and protruding teeth
 - Congenital syndromes, acromegaly
 - Obesity
 - EVALUATE 3-3-2 rule (difficult airway if met):
 - Mouth opens < 3 fingerbreadths
 - Horizontal length of mandible < 3 fingerbreadths
 - Thyromental distance < 2 fingerbreadths
 - MALLAMPATI criteria (increasing difficulty):
 - Class I: Soft palate, uvula, fauces, pillars visible
 - Class II: Soft palate, uvula, fauces visible
 - Class III: Soft palate visible
 - Class IV: Hard palate only
 - OBSTRUCTION from underlying disease states:
 - Angioedema
 - Goiter
 - Laryngeal–tracheal tumors
 - History of radiation therapy to the neck

- Infections (epiglottitis, supraglottitis, croup, intraoral or retropharyngeal abscess, Ludwig angina)
- Profuse upper gastrointestinal hemorrhage
- Trauma (facial, neck, cervical spine, laryngeal–tracheal, burns)
- NECK mobility limitation:
 - Rheumatoid arthritis and other arthropathies that decrease cervical spine mobility
 - Spinal immobilization for trauma
- Verification of correct tube placement:
 - Visualization of tube passing through the vocal cords
 - Tracheal tube depth (tube tip to upper incisors):
 - 21 cm (women)
 - 23 cm (men)
 - Age (yr)/2 + 12 (children)
 - End-tidal CO₂ colorimetric device:
 - Changes color if CO₂ is present, indicating tracheal placement
 - Color change may not be seen in cardiac arrest
 - Auscultate over stomach, axillae, and anterior lung fields
 - Observe chest wall movement
 - Condensation in the tube during ventilation

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Pulse oximetry should rise after tracheal intubation
 - Continuous capnography used as adjunct
- Arterial blood gas to manage ventilator settings after intubation

Imaging

CXR:

- To exclude mainstem bronchus intubation or pneumothorax
- Does not rule out esophageal intubation

Diagnostic Procedures/Surgery

Direct visualization of the ET tube through the cords is gold standard.

DIFFERENTIAL DIAGNOSIS

- Esophageal intubation
- Right or left mainstem bronchus intubation
- Extratracheal placement through tear in pyriform sinus or trachea
- Pneumothorax

TREATMENT

PRE HOSPITAL

Options for patients in respiratory arrest for advanced life support (ALS) providers:

- Bag–valve management (BVM) ventilation followed by definitive airway management in the ED
- Orotracheal intubation
- Esophageal–tracheal tubes
- LMA

INITIAL STABILIZATION/THERAPY

- Maintain in-line cervical spine immobilization in trauma
- Oxygen, monitor, IV

ED TREATMENT/PROCEDURES

- RSI
 - Simultaneous administration of sedation (induction agent) and paralysis to provide optimal conditions for emergency airway management
- Prepare equipment:
 - Suction, BVM, various sizes of ET tubes and laryngoscope blades, stylets, medications, and backup devices.
- Preoxygenation:
 - 100% FIO₂ for 3 min
- Pretreatment:
 - Prevents physiologic sequelae of intubation
 - Performed 3 min prior to paralytic
 - Defasciculating dose of nondepolarizing agent
 - Fentanyl and lidocaine may minimize ICP rise and hemodynamic response to intubation in head-injured patients
 - Lidocaine and albuterol in reactive airway disease
- Paralysis with induction:
 - Administration of induction agent (e.g., etomidate, thiopental, midazolam, ketamine)
 - Rapidly followed by administration of paralytic agent (e.g., succinylcholine, rocuronium)
 - Succinylcholine is relatively contraindicated with anticipated difficult oral intubation, open globe injury, organophosphate poisoning, burns > 3 days old, denervation syndromes, myopathies, and suspected hyperkalemia
 - Nondepolarizing agents (e.g., rocuronium) can be used as an alternative to succinylcholine
- Positioning:

- Head extension, with midline cervical stabilization if trauma patient
- Cricoid pressure (Sellick maneuver) is controversial and optional
- Placement of tube:
 - After muscle tone is lost (45–60 sec after succinylcholine)
 - Use a stylet with the ET tube
 - Place tube through vocal cords
 - Inflate cuff
 - Begin ventilation
 - Confirm correct ET tube placement
- Postintubation:
 - Benzodiazepines, opiates, or propofol used for continued sedation
 - Vecuronium may be used for continued paralysis

Pediatric Considerations

- Estimation of ET tube size: $4 + \text{age}/4$
- Uncuffed ET tubes may be used in patients < 8 yr old
- Straight Miller blade is preferred in patients < 3 yr old
- Cricothyrotomy contraindicated in patients < 12 yr old; PTV is preferred
- Use atropine as pretreatment to reduce secretions and attenuate vagal effect
- A defasciculating neuromuscular blocking agent not necessary for children < 5 yr old

MEDICATION

- Atracurium: 0.4–0.5 mg/kg IV
- Atropine: 0.02 mg/kg IV
- Diazepam: 2–10 mg (peds: 0.2–0.3 mg/kg) IV
- Etomidate: 0.3 mg/kg IV
- Fentanyl: 3 µg/kg IV
- Ketamine: 1–2 mg/kg IV or 4–7 mg/kg IM
- Lidocaine: 1.5 mg/kg IV
- Midazolam: 1–5 mg IV (0.07–0.30 mg/kg for induction)
- Propofol: 2–2.5 mg/kg IV
- Pancuronium: 0.01 mg/kg IV (defasciculating dose); 0.1 mg/kg IV (paralyzing dose)
- Rocuronium: 1 mg/kg IV
- Succinylcholine: 1.5 mg/kg (peds: 2 mg/kg) IV; 2.5 mg/kg IM/SC
- Thiopental: 3 mg/kg IV
- Vecuronium: 0.01 mg/kg IV (defasciculating dose); 0.1 mg/kg IV (paralyzing dose)

FOLLOW-UP

DISPOSITION

Admission Criteria

Almost all intubated patients should be admitted to an ICU.

Discharge Criteria

Rarely, certain ED patients who have been intubated for airway protection or to facilitate diagnostic workup may be extubated in the ED after a period of observation and then discharged.

PEARLS AND PITFALLS

Respect the airway. Failure to intubate and ventilate is a life-threatening condition:

- Assess each patient for the possibility of difficult intubation.
- Prepare and familiarize yourself with all needed equipment and medications (including contraindications and side effects).
- ALWAYS formulate your backup plan in the case of a crash airway or failed standard orotracheal intubation before beginning the procedure.

0CHY7BZ Insertion of Airway into Mouth and Throat, Via Natural or Artificial Opening

ALCOHOL POISONING

Timothy J. Meehan

BASICS

DESCRIPTION

- Alcohol is the most commonly abused recreational agent among emergency department patients
- Alcohol is frequently associated with traumatic injuries

ETIOLOGY

- Alcohol intoxication:
 - Directly depresses CNS function
 - Blood alcohol levels drop by 15–40 mg/dL/hr depending on individual variables and chronicity of alcohol use
- Alcohol withdrawal:
 - Occurs in chronic alcohol abusers after partial or complete alcohol abstinence
 - May occur despite a serum alcohol level > 100 mg/dL (e.g., “intoxicated”)
 - Primarily due to loss of chronic CNS inhibition:
 - Profound CNS excitation
 - Increased catecholamine release and adrenergic tone

DIAGNOSIS

SIGNS AND SYMPTOMS

Acute Alcohol Intoxication

- CNS effects occur on a spectrum:
 - Relaxation
 - Euphoria
 - Sedation
 - Memory loss
 - Impaired judgment
 - Ataxia
 - Slurred speech
 - Obtundation/coma
- May also cause GI upset

Alcohol Withdrawal Syndrome

- Early or minor withdrawal:

- < 8 hr after last drink:
 - Symptoms of a hangover
 - Headache
 - Nausea/vomiting
- 12 hr after last drink:
 - Mild tremors/anxiety
 - Anorexia, nausea, vomiting
 - Weakness
 - Myalgias
 - Vivid dreams/nightmares
- 12–36 hr after last drink:
 - Irritability/agitation
 - Tachycardia/HTN
 - Tremors in hands and tongue
- 24–48 hr after last drink: Alcoholic hallucinosis:
 - Visual hallucinations most common (bug crawling)
 - Auditory hallucinations (buzz, clicks)
 - Present in minor and major withdrawal
- Alcoholic withdrawal seizures:
 - 8–12 hr after last drink
 - Brief, spontaneously abating tonic–clonic activity
 - Precedes delirium tremens (DTs)
- Late alcohol withdrawal or major withdrawal:
 - 48 hr after last drink
 - DTs:
 - Clouded consciousness and delirium
 - Confusion/disorientation
 - Agitation/combativeness
 - Tachycardia/HTN
 - Hyperpyrexia
 - Diaphoresis

History

- Often provided by EMS, family, or friends
- Beware the “frequent flyer” in the ED:
 - Can sometimes have other causes of AMS:
 - Hepatic disease/encephalopathy
 - Seizures (postictal)
 - Hypoglycemia
 - Head injury or intracranial bleeding

Physical-Exam

- Vital signs:
 - Acute intoxication: Normal or depressed
 - Withdrawal: Usually elevated
- Mental status:
 - Acute intoxication: Somnolent, obtunded, or comatose
 - Withdrawal: Hyperalert, agitated
- Signs of hepatic injury:
 - Jaundice
 - Icterus
 - Spider angiomas
 - Asterixis
 - Hepatomegaly
- Signs of malnutrition:
 - Alopecia
 - Poor dentition
 - Poor muscle mass
 - Abdominal wasting
 - Temporal wasting

ESSENTIAL WORKUP

- Obtain accurate alcohol ingestion and abstinence history
- Investigate for life-threatening causes of seizures:
 - Hypoglycemia (get rapid bedside glucose)
 - Intracranial hemorrhage
 - CNS infection
 - Electrolyte abnormalities
- Evaluate for occult trauma
- Monitor all vital signs frequently:
 - Hyperthermia predicts poorer outcomes

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Alcohol level if abnormal mental status
- Urine toxicology panel to screen for coingestants
- Electrolytes, BUN, creatinine, and glucose
- CBC
- Magnesium, calcium, and phosphate
- PTT, PT/INR if coagulopathy suspected
- LFTs if liver disease suspected
- Ammonia level if hepatic encephalopathy suspected
- Urinary ketones or serum acetone if alcoholic ketoacidosis suspected

Imaging

- CT of head if:
 - Alteration in mental status is out of proportion to expected AMS based on serum alcohol level
 - Suspected head trauma
 - Signs of increased intracranial pressure or focal findings on neurologic exams
 - New-onset seizure
 - Unimproved or deteriorating level of consciousness
- EEG differentiates alcohol withdrawal seizures from idiopathic epilepsy
- Chest radiograph if suspected aspiration or pneumonia

DIFFERENTIAL DIAGNOSIS

- Acute alcohol intoxication:
 - Hypoglycemia
 - Carbon dioxide narcosis
 - Mixed-drug overdose
 - Ethylene glycol, methanol, or isopropanol poisoning
 - Hepatic encephalopathy
 - Psychosis
 - Severe vertigo
 - Psychomotor seizure
- Alcohol withdrawal and seizures:
 - Sedative–hypnotic withdrawal
 - Acute intoxication or poisoning:
 - Carbon monoxide
 - Isoniazid (especially if prolonged seizures not responding to standard therapy)
 - Amphetamine
 - Anticholinergic
 - Cocaine
 - Secondary seizure disorders:
 - Infection
 - Meningitis
 - Encephalitis
 - Brain abscess
 - Trauma
 - Intracranial hemorrhage
 - CVA
 - Tumor
 - Anticonvulsant noncompliance
 - Thyroid disorder

TREATMENT

PRE HOSPITAL

- Administer benzodiazepines for seizures
- Give naloxone, oxygen, and dextrose for comatose individuals
- Intubate as necessary for airway protection to prevent aspiration
- C-spine immobilization if suspected trauma

INITIAL STABILIZATION/THERAPY

- Airway, breathing, circulation (ABCs)
- Evaluate C-spine if suspected trauma
- Initial IV rehydration with 0.9 NS, then D5 0.45 NS
- Administer naloxone, thiamine, and glucose (or Accu-Chek) if altered mental status
- Benzodiazepines if seizing (may require large doses)

Pediatric Considerations

- Young children have decreased hepatic glycogen reserves
- Cannot mount an appropriate response to increased glucose needs
- Rapid bedside glucose (Accu-Chek) is ESSENTIAL:
 - Administer dextrose if indicated with D5 (10 mL/kg), D10 (5 mL/kg), or D25 (2 mL/kg) depending on age and size

ED TREATMENT/PROCEDURES

- Alcohol intoxication:
 - Rehydrate with IV fluids
 - Correct electrolyte abnormalities:
 - Magnesium
 - Potassium
 - Folate
 - Thiamine
 - Multivitamins
- Alcoholic ketoacidosis:
 - Aggressive rehydration with D5 0.9 NS
 - Exclude other causes of wide anion-gap metabolic acidosis
- Alcohol withdrawal syndrome:
 - CIWA-Ar
 - Validated scale for assessing withdrawal severity
 - Guides initial pharmacotherapy
 - Gauges response to therapy and needs for repeat dosing (“symptom-triggered” therapy)
 - Benzodiazepines are the agent of choice:
 - Cross-tolerant with alcohol

- Increases GABA_A-mediated transmission
- Anticonvulsant effect
- Large, frequent doses required with significant withdrawal
- May halt progression to DTs
- Barbiturates (phenobarbital):
 - Useful if severe withdrawal or DTs refractory to large doses of benzodiazepines
- Propofol:
 - Agent of choice for intubated patients
 - Completely suppresses seizure activity
 - Requires intubation/ventilation
 - Caution if hypotensive
- β -blocker (labetalol, esmolol, or metoprolol):
 - Normalizes vital sign abnormalities
 - Does *not* treat CNS complications of alcohol use or withdrawal
- α -agonist (clonidine):
 - Centrally acting α_2 -adrenergic agonists
 - Normalizes vital sign abnormalities
 - Do *not* treat CNS complications of alcohol use or withdrawal
- Phenytoin:
 - Not indicated in seizures primarily due to alcohol withdrawal
 - Indicated if seizures secondary to idiopathic epilepsy, posttraumatic, or status epilepticus

MEDICATION

- Dextrose: D₅₀W 1 amp (50 mL or 25 g; peds: D₂₅W 2–4 mL/kg) IV
- Diazepam (Valium): 5–10 mg IV q5–10min until patient calm
- Lorazepam (Ativan): 0.5–4 mg IV/IM q5–10min until patient calm
- Naloxone (Narcan): 0.4–2 mg (peds: 0.1 mg/kg) IV or IM initial dose
- Phenobarbital: 10–20 mg/kg IV (loading dose) monitor for respiratory depression
- Phenytoin: 15–18 mg/kg not to exceed 25 mg/min:
 - May give Fosphenytoin at 15–20 mgPE/kg at a maximum rate of 150 mgPE/min
- Propofol: 25-75 μ /kg/min IV (loading dose) then 5–50 μ g/kg/min (maintenance dose)
- Thiamine (vitamin B₁): 100 mg (peds: 50 mg) IV or IM

FOLLOW-UP

DISPOSITION

Admission Criteria

- Inability to control seizures or withdrawal symptoms with oral medications
- Hepatic failure, infection, dehydration, malnutrition, cardiovascular collapse, cardiac dysrhythmia, or trauma
- Hallucinations, abnormal vital signs, severe tremors, or extreme agitation
- Wernicke encephalopathy
- Confusion or delirium

Discharge Criteria

- Clinically sober
- Seizure free for 6 hr (with negative workup if 1st seizure)

Issues for Referral

Discuss with social worker and/or police and/or department of family services for pediatric patients.

FOLLOW-UP RECOMMENDATIONS

Substance abuse referral for patients with recurrent alcohol intoxication/use

PEARLS AND PITFALLS

- Failure to appreciate AMS due to nonalcoholic causes in chronic alcoholics:
 - Serum levels should drop by 15–40 mg/dL/hr
 - If mental status not improving (or worsening) need to investigate further
- Failure to adequately treat with benzodiazepines:
 - May require massive doses (e.g., 200–300 mg of diazepam) to control
 - If unable to control, consider other GABAergic agents (phenobarbital, propofol)
- Failure to appreciate hypoglycemia as a common entity in these patients:
 - Can masquerade as “intoxication”
 - Can result in poor outcomes
 - Frequently occurs in chronic alcoholics and children

ALCOHOLIC KETOACIDOSIS

Charles Garcia

BASICS

DESCRIPTION

- Increased production of ketone bodies due to:
 - Dehydration (nausea/vomiting, ADH inhibition) leads to increased stress hormone production leading to ketone formation
 - Depleted glycogen stores in the liver (malnutrition/decrease carbohydrate intake)
 - Elevated ratio of NADH/NAD due to ethanol metabolism
 - Increased free fatty acid production
- Elevated NADH/NAD ratio leads to the predominate production of β -hydroxybutyrate (BHB) over acetoacetate (AcAc)

ETIOLOGY

- Malnourished, chronic alcohol abusers following a recent episode of heavy alcohol consumption:
 - Develop nausea, vomiting, or abdominal pain
 - Leading to the cessation of alcohol ingestion
- Presentation usually occurs within 12–72 hr

DIAGNOSIS

SIGNS AND SYMPTOMS

- Dehydration
- Fever absent unless there is an underlying infection
- Tachycardia (common) due to:
 - Dehydration with associated orthostatic changes
 - Concurrent alcohol withdrawal
- Tachypnea:
 - Common
 - Deep, rapid, Kussmaul respirations frequently present
- Nausea and vomiting
- Abdominal pain (nausea, vomiting, and abdominal pain are the most common symptoms):
 - Usually diffuse with nonspecific tenderness
 - Epigastric pain common
 - Rebound tenderness, abdominal distension, hypoactive bowel sounds uncommon

- Mandates a search for an alternative, coexistent illness
- Decreased urinary output from hypovolemia
- Mental status:
 - Minimally altered as a result of hypovolemia and possibly intoxication
 - Altered mental status mandates a search for other associated conditions such as:
 - Head injury, cerebrovascular accident (CVA), or intracranial hemorrhage
 - Hypoglycemia
 - Alcohol withdrawal
 - Encephalopathy
 - Toxins
- Visual disturbances:
 - Reports of isolated visual disturbances with AKA common

History

Chronic alcohol use:

- Recent binge
- Abrupt cessation

Physical-Exam

- Findings of dehydration most common
- May have ketotic odor
- Kussmaul respirations
- Palmar erythema (alcoholism)

ESSENTIAL WORKUP

- Presence of an increased anion gap metabolic acidosis secondary to the presence of ketones
- Differentiate from toxic alcohol ingestion and other causes of anion gap metabolic acidosis.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Acid–base disturbance:
 - Increased anion gap metabolic acidosis hallmark
 - Mixed acid–base disturbance common:
 - Respiratory alkalosis
 - Metabolic alkalosis secondary to vomiting and dehydration
 - Hyperchloremic acidosis
 - Mild lactic acidosis common
 - Due to dehydration and the direct metabolic effects of ethanol

- Profound lactic acidosis should prompt a search for other disorders such as seizures, hypoxia, and shock.
- Positive urine and serum nitroprusside reaction tests for ketoacids
 - May not reflect the severity of the underlying ketoacidosis, since BHB predominates and is not measured by this test.
 - May become misleadingly more positive during treatment as more AcAc is produced.
- Electrolytes:
 - Decreased serum bicarbonate
 - Hypokalemia due to vomiting
 - Hypocalcemia
 - Hypophosphatemia may worsen with Tx
 - Hypomagnesemia
 - Initially, can see hyperkalemia and/or hyperphosphatemia which will correct with treatment of the acidosis
- Glucose:
 - Usually mildly elevated
 - Should be monitored frequently as per DKA
 - Hypoglycemia may be present
- Alcohol level may be negative
- BUN and creatinine mildly elevated due to dehydration unless underlying renal disease.
- CBC:
 - Mild leukocytosis—neither sensitive nor specific
 - Thrombocytopenia and anemia commonly due to chronic alcoholism
- Urinalysis:
 - Ketonuria without glucosuria
- Amylase/lipase:
 - Elevated with associated pancreatitis
- LFTs:
 - May have mildly elevated LFTs
- Osmolal gap:
 - May be elevated
 - Elevation > 20 mOsm/kg should prompt evaluation for other ingestions (methanol and ethylene glycol)
 - Correct for ethanol level in osmolal gap by dividing ethanol level by 4.6

Imaging

- CXR if suspect associated pneumonia
- Abdominal films for free air if an acute abdomen is present
- CT scan of the head if associated trauma or unexplained altered mental status

DIFFERENTIAL DIAGNOSIS

- Elevated anion gap metabolic acidosis: *ACAAT MUDPILES*:
 - *Alcoholic* ketoacidosis
 - *Cyanide*, CO, H₂S, others
 - *Acetaminophen*:
 - Rare in acute ingestion
 - Rare in chronic ingestion
 - Fulminant hepatic failure
 - *Antiretrovirals* (NRTI)
 - *Toluene*
 - *Methanol*, metformin
 - *Uremia*
 - *Diabetic* ketoacidosis
 - *Paraldehyde*, phenformin, propylene glycol
 - *Iron*, INH
 - *Lactic* acidosis
 - *Ethylene glycol*
 - *Salicylate*, acetylsalicylic acid (ASA; aspirin), starvation ketosis
- Hypovolemia:
 - GI bleeding
 - Sepsis
- Abdominal pain, nausea, vomiting:
 - Pancreatitis
 - GI bleeding
 - Gastritis
 - Hepatitis
 - Perforated ulcer
 - Alcohol withdrawal
 - DKA
 - Viral illness
 - Obstruction/Ileus

TREATMENT

PRE HOSPITAL

- Supportive measures including IV access with 0.9 NS, oxygen, and cardiac monitoring
- Search for historical clues that may suggest other etiologies such as toxic ingestions or diabetic history, consider scene search
- Attend to other possible coexistent illnesses such as GI bleeding.

INITIAL STABILIZATION/THERAPY

- Cardiac monitor and supplement oxygen

- Naloxone, thiamine, and dextrose if altered mental status
- Initiate 0.9 NS IV fluids
 - _ 500 mL–1 L bolus
 - _ Fluid resuscitation as necessary
 - _ Promotes renal excretion of ketone bodies

ED TREATMENT/PROCEDURES

- Antiemetic for vomiting—ondansetron, promethazine, or prochlorperazine
- Benzodiazepines for symptoms of alcohol withdrawal
- Start dextrose containing solutions (D₅NS):
 - _ More rapid resolution of the metabolic abnormalities than saline alone
 - _ Rate higher than maintenance as tolerated until acidosis resolves
 - _ Avoid with significant hyperglycemia
 - _ Help replete glycogen stores
 - _ Decreases production of ketone bodies by stimulating the production of endogenous insulin
- Thiamine repletion (IV) prior to glucose administration to avoid precipitating Wernicke encephalopathy
- Sodium bicarbonate rarely indicated:
 - _ Consider in severe acidosis with associated cardiovascular dysfunction or irritability
- Electrolyte replacement:
 - _ Hypokalemia occurs with treatment and should be anticipated.
 - _ Hypophosphatemia may occur with treatment.
 - _ Magnesium replacement as indicated for both hypomagnesemia and hypokalemia
- Insulin is not indicated and may precipitate hypoglycemia.

MEDICATION

- D₅₀W: 1 ampule of 50% dextrose (25 g) IVP
- Lorazepam (benzodiazepine): 2 mg IV and titrate to effect
- Narcan: 2 mg IVP
- Ondansetron: 4–8 mg IVP
- Prochlorperazine: 5–10 mg IVP slowly (not > 5 mg/min)
- Promethazine: 12.5–25 mg IVP
- Thiamine: 100 mg IVP

FOLLOW-UP

DISPOSITION

Admission Criteria

- Persistent metabolic acidosis
- Persistent signs of hypovolemia
- Persistent nausea and vomiting
- Abdominal pain of uncertain etiology
- Comorbid illness requiring admission for treatment
- Need for monitored bed due to electrolyte abnormalities requiring continued treatment

Discharge Criteria

- Many patients can be managed in observation unit over 12–24 hr.
- Tolerating oral fluids well
- Resolution of metabolic abnormalities
- No other associated illnesses requiring additional therapy
- Most will warrant at least observation

FOLLOW-UP RECOMMENDATIONS

Counseling regarding alcohol cessation

PEARLS AND PITFALLS

- Aggressive volume repletion with dextrose containing fluid is key.
- Volume resuscitate with NS as necessary
- Thiamine repletion
- Monitor electrolytes before and after treatment.
- Unrecognized increased osmolal gap
- Inadequate monitoring of glucose levels
- Failure to recognize initial electrolyte abnormalities and electrolyte shifts caused by treatment.
- Must be placed on monitor:
 - Cases of sudden death in AKA:
 - Possible alcoholic cardiomyopathy
 - Dysrhythmias
 - Electrolyte derangements

E87.2 Acidosis

ALKALOSIS

Matthew T. Robinson

BASICS

DESCRIPTION

- Respiratory alkalosis:
 - Elevated serum pH secondary to alveolar hyperventilation and decreased PaCO₂
 - Hyperventilation occurs through stimulation of 2 receptor types:
 - Central receptors—located in the brainstem and respond to decreased CSF pH
 - Chest receptors—located in aortic arch and respond to hypoxemia
 - Increased alveolar ventilation secondary to:
 - Disorders causing acidosis
 - Hypoxemia *or*
 - Nonphysiologic stimulation of those receptors by CNS or chest disorders
 - Rarely life threatening with pH typically <7.50
- Metabolic alkalosis:
 - Primary increase in serum HCO₃⁻ secondary to loss of H⁺ or gain of HCO₃⁻
 - Pathogenesis requires an initial process that generates the metabolic alkalosis with a secondary or overlapping process maintaining the alkalosis.
- Generation occurs through 1 of the following mechanisms:
 - Gain of alkali through ingestion or infusion
 - Loss of H⁺ through the GI tract or kidneys
 - Shift of hydrogen ions into the intracellular space
 - Contraction of extracellular fluid (ECF) volume with loss of HCO₃⁻-poor fluids
- Renal maintenance is required to sustain a metabolic alkalosis secondary to the kidney's enormous ability to excrete HCO₃⁻. This occurs through the following:
 - Decreased GFR (renal failure, ECF depletion)
 - Elevated tubular reabsorption of HCO₃⁻ secondary to hypochloremia, hyperaldosteronism, hypokalemia, ECF depletion
- Mortality 45% if pH >7.55 and 80% if pH >7.65

ETIOLOGY

- Respiratory alkalosis:
 - _ CNS:
 - Hyperventilation syndrome
 - Pain
 - Anxiety/psychosis
 - Fever
 - Cerebrovascular accident (CVA)
 - CNS infection (meningitis, encephalitis)
 - CNS mass lesion (tumor, trauma)
 - _ Hypoxemia:
 - Altitude
 - Anemia
 - Shunt
 - _ Medications/drugs:
 - Progesterone
 - Methylxanthines
 - Salicylates
 - Catecholamines
 - Nicotine
 - _ Endocrine:
 - Hyperthyroidism
 - Pregnancy
 - _ Chest stimulation:
 - Pulmonary embolism
 - Pneumonia
 - Pneumothorax
 - _ Other:
 - Sepsis
 - Hepatic failure
 - Heat exhaustion
- Metabolic alkalosis:
 - _ GI loss of H⁺:
 - Vomiting
 - Nasogastric (NG) suctioning
 - Bulimia
 - Antacid therapy
 - Chloride-losing diarrhea (villous adenoma)
 - _ Renal loss:
 - Diuretics (loop and thiazide)
 - Post (chronic) hypercapnia
 - Mineralocorticoid excess
 - Hyperaldosteronism

- Drug/medication (carbenicillin)
- Glucocorticoid excess (Cushing disease)
- Gitelman syndrome
- Hypercalcemia
- Milk-alkali syndrome
- Low chloride intake
- Bartter syndrome
- Intracellular H^+ shift:
 - Hypokalemia
 - Refeeding
- Contraction alkalosis:
 - Diuretics
 - Sweat loss in CF
 - Gastric losses
- HCO_3^- retention:
 - $NaHCO_3$ infusion
 - Blood transfusions

DIAGNOSIS

SIGNS AND SYMPTOMS

- Signs and symptoms secondary to:
 - Arteriolar vasoconstriction
 - Hypocalcemia secondary to decreased ionized calcium from increased calcium binding to albumin
 - Associated hypokalemia
 - Underlying cause
- Weakness
- Seizures
- Altered mental status
- Tetany
- Chvostek sign
- Trousseau sign
- Arrhythmias
- Myalgias
- Carpal-pedal spasm
- Perioral tingling/numbness
- Hypoxemia
- Dehydration

ESSENTIAL WORKUP

- Electrolytes:
 - Elevated HCO_3^- with metabolic alkalosis
 - Evaluate for hypokalemia and hypocalcemia.
- BUN/creatinine:
 - Evaluate for renal failure or dehydration.
- Blood gas (arterial/venous):
 - pH
 - PCO_2 decreased in respiratory alkalosis
 - PO_2 for hypoxemia
 - Venous versus arterial blood gas
 - pH—good correlation within 0.03–0.04 units
 - pCO_2 —good correlation, although VBG may not correlate with severe shock
 - HCO_3^- —good correlation
 - Base excess—good correlation
- Calculate compensation to identify mixed acid–base disorders:
 - Acute respiratory alkalosis:
 - HCO_3^- decreases secondary to intracellular shift and buffering within 10–20 min.
 - Expected HCO_3^- decreased by 2 mEq/dL for each 10 mm Hg decrease in PCO_2 .
 - Chronic respiratory alkalosis:
 - HCO_3^- decreased secondary to renal secretion of HCO_3^-
 - Requires 48–72 hr for maximal compensation
 - Expected HCO_3^- decreased by 5 mEq/dL for each 10 mm Hg decrease in PCO_2 .
 - If HCO_3^- greater than predicted, concomitant metabolic alkalosis
 - If HCO_3^- less than predicted, concomitant metabolic acidosis
 - Metabolic alkalosis:
 - Expected $\text{PCO}_2 = 0.9 [\text{HCO}_3^-] + 9$
 - If PCO_2 greater than predicted, concomitant respiratory acidosis
 - If PCO_2 less than predicted, concomitant respiratory alkalosis
- Urine chloride:
 - More accurate marker than urine Na^+ for patient's volume status:
 - $\text{UCl}^- < 20$ mEq/L in volume depletion
 - $\text{UCl}^- > 40$ mEq/L in euolemia or edematous states

- Useful in therapy for determining saline-responsive vs. saline-resistant causes of metabolic alkalosis

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Glucose
- Ionized calcium
- Magnesium level
- Urine pregnancy
- Additional labs to evaluate underlying cause:
 - CBC, blood cultures for sepsis
 - LFT for hepatic failure
 - Aspirin level
 - Urine toxicology screen
 - Urine diuretics screen (bulimia)
 - Urine diuretic screen (surreptitious diuretic abuse)
 - Renin level
 - Cortisol level
 - Aldosterone level
 - TSH, T4
 - D-dimer

Imaging

CXR:

- May identify cardiomyopathy or CHF
- Underlying pneumonia

Diagnostic Procedures/Surgery

ECG:

- May identify regional wall motion abnormalities or valvular dysfunction
- Evaluate for conduction disturbances.

DIFFERENTIAL DIAGNOSIS

- Respiratory alkalosis:
 - It is essential to rule out organic disease prior to diagnosing hyperventilation syndrome or anxiety states.
- Metabolic alkalosis:
 - Saline responsive (urine $\text{Cl}^- < 20$ mEq/dL):
 - Loss of gastric secretions
 - Chloride-losing diarrhea
 - Diuretics

- Post (chronic) hypercapnia
- CF
- Saline resistant:
 - Hyperaldosteronism
 - Cushing syndrome
 - Bartter syndrome
 - Exogenous mineralocorticoids or glucocorticoids
 - Gitelman syndrome
 - Hypokalemia
 - Hypomagnesemia
 - Milk–alkali syndrome
 - Exogenous alkali infusion/ingestion
 - Blood transfusions

TREATMENT

INITIAL STABILIZATION/THERAPY

Airway, breathing, circulation (ABCs):

- Early intubation and airway control for altered mental status
- IV, oxygen, and cardiac monitor
- Naloxone, D₅₀W (or Accu-Chek), and thiamine for altered mental status

ED TREATMENT/PROCEDURES

- Respiratory alkalosis:
 - Treat underlying disorder.
 - Rarely life threatening
 - Sedation/anxiolytics for anxiety, psychosis, or drug overdose
 - Rebreathing mask bag for hyperventilation syndrome (used cautiously)
- Metabolic alkalosis: Examination of the urine chloride allows etiologies to be divided into saline-responsive or saline-resistant causes:
 - Urine chloride < 20 mEq/L indicates volume depletion:
 - Rehydration with 0.9% saline lowers serum HCO₃[–] by increasing renal HCO₃[–] excretion
 - Saline-responsive causes are associated with volume depletion.
 - Urine chloride > 20 mEq/L indicates saline-resistant etiology. Treat underlying disorder:
 - Potassium supplementation in hypokalemic states
 - Antagonism of aldosterone with spironolactone
 - Acetazolamide to increase renal HCO₃[–] excretion in edematous states
 - Other:

- Infusion of dilute HCl in severe cases of metabolic alkalosis
- Antiemetics for vomiting
- Proton pump inhibitors for patients with NG suction
- Follow ventilatory status closely.
- Correct electrolyte abnormalities.
- Consider hemodialysis for severe electrolyte abnormalities.

MEDICATION

- Dextrose: D₅₀W 1 amp (50 mL or 25 g; peds: 2% dextrose and water 2–4 mL/kg) IV
- KCl (K-Dur, Gen-K, Klor-Con): 20–120 mEq PO daily
- Naloxone: 2 mg (peds: 0.1 mg/kg) IV or IM initial dose
- Thiamine (vitamin B₁): 100 mg (peds: 50 mg) IV or IM
- 0.1–0.2 N HCl (100–200 mEq/L): Infuse over 24–48 hr at a rate not faster than 0.2 mmol/kg/h and through a central line to prevent sclerosing vein

FOLLOW-UP

DISPOSITION

Admission Criteria

- ICU admission if:
 - pH >7.55 or altered mental status
 - Dysrhythmias
 - Severe electrolyte abnormalities
 - Hemodynamic instability
- Coexisting medical illness requiring admission

Discharge Criteria

Resolving or resolved alkalosis

PEARLS AND PITFALLS

- Increased minute ventilation is the primary cause of respiratory alkalosis, characterized by decreased PaCO₂ and increased pH.
 - Metabolic alkalosis is usually caused by an increase in HCO₃⁻, reabsorption secondary to volume, potassium, or Cl⁻ loss.
 - Contraction alkalosis can result from extracellular volume reduction, with a consequent increase in the plasma HCO₃⁻ concentration.
 - Clues to the presence of a mixed acid–base disorder are normal pH with

abnormal PCO_2 or HCO_3^- , when the HCO_3^- and PCO_2 move in opposite directions, or when the pH changes in the direction opposite that expected from a known primary disorder.

ALTERED MENTAL STATUS

David F. M. Brown • David W. Schoenfeld

BASICS

DESCRIPTION

- Dysfunction in either the reticular activating system in the upper brainstem or a large area of 1 or both cerebral hemispheres
- Definitions:
 - Confusion: A behavioral state of reduced mental clarity, coherence, comprehension, and reasoning
 - Drowsiness: The patient cannot be easily aroused by touch or noise and cannot maintain alertness for some time.
 - Lethargy: Depressed mental status in which the patient may appear wakeful but has depressed awareness of self and environment globally; cannot be aroused to full function
 - Stupor: The patient can be awakened only by vigorous stimuli, and an effort to avoid uncomfortable or aggravating stimulation is displayed.
 - Coma: The patient cannot be aroused by stimulation and no purposeful attempt is made to avoid painful stimuli.
 - Delirium: Acute onset of fluctuating cognition with impaired attention and consciousness, ranging from confusion to stupor.

ETIOLOGY

- Hypoxic:
 - Severe pulmonary disease
 - Anemia
 - Shock
 - Intracardiac shunting (especially in pediatrics)
- Metabolic:
 - Hypoglycemia; hyperglycemia
 - Diabetic ketoacidosis
 - Nonketotic hyperosmolar coma
 - Hyponatremia; hypernatremia
 - Hypocalcemia; hypercalcemia
 - Hypomagnesemia; hypermagnesemia
 - Hypophosphatemia
 - Acidosis; alkalosis
 - Dehydration
 - Deficiency: Thiamine, folic acid, B₁₂, niacin
 - Hyperammonemia (hepatic encephalopathy)

- Uremia (renal failure)
- CO₂ narcosis
- Toxicologic:
 - Toxic alcohols
 - Salicylates
 - Sedatives and narcotics
 - γ -hydroxybutyrate (GHB)
 - Anticonvulsants
 - Psychotropics
 - Isoniazid
 - Heavy metals
 - Carbon monoxide
 - Cyanide
 - Toxic plants (jimsonweed, mushrooms, etc.)
 - Sympathomimetics
 - Anticholinergic, cholinergic
 - Antiemetics
 - Antiparkinsonian medications
 - Withdrawal (especially alcohol, sedatives)
- Infectious:
 - UTI (especially in elderly)
 - Pneumonia
 - Sepsis; bacteremia
 - Meningitis, encephalitis, brain abscess
- Endocrine;:
 - Myxedema coma
 - Thyrotoxicosis
 - Hypothyroidism
 - Addison disease
 - Cushing disease
 - Pheochromocytoma
 - Hyperparathyroidism
- Environmental:
 - Hypothermia
 - Hyperthermia; heat stroke
 - High-altitude cerebral edema
 - Neuroleptic malignant syndrome
 - Malignant hyperthermia
- Vascular:
 - Hypertensive encephalopathy
 - Cerebral vasculitis
 - TTP, DIC, hyperviscosity

- MI
- Primary neurologic:
 - Seizures, nonconvulsive status epilepticus, and postictal state
 - Head trauma, concussion
 - Diffuse axonal injury
 - Structural brain lesions:
 - Hemorrhage (subdural, epidural, subarachnoid, intraparenchymal)
 - Infarction
 - Tumors
 - Demyelination disorders
 - Intracranial hypertension (pseudotumor)
 - HIV-related encephalopathy
 - Autoimmune/inflammatory encephalitis
 - Carcinoid meningitis
 - Primary neuronal or glial disorders:
 - Creutzfeldt–Jakob disease
 - Marchiafava–Bignami disease
 - Adrenoleukodystrophy
 - Gliomatosis cerebri
 - Progressive multifocal leukoencephalopathy
- Trauma; burns
- Porphyria
- Psychiatric
- Multifactorial (especially in elderly)

DIAGNOSIS

SIGNS AND SYMPTOMS

Confusion

- Difficulty in maintaining a coherent stream of thinking and mental performance:
 - Remember to consider level of education, language, and possible learning disabilities.
- Inattention
- Memory deficit:
 - Inability to recall any of the following:
 - The date, inclusive of month, day, year, and day of week
 - The precise place
 - Items of universally known information
 - Why the patient is in the hospital
 - Address, telephone number, or Social Security number
- Impaired mental performance:
 - Difficulty retaining 7 digits forward and 4 backward

- Difficulty naming ordinary objects
- Serial calculations: 3-from-30 subtraction test
- Disorganized and rambling language:
 - May be mistaken for aphasia
- Fever:
 - Infectious etiologies, drug toxicities, endocrine disorders, heat stroke
- Severe hypertension and bradycardia
 - Cushing reflex suggests intracranial lesion
- Hypotension:
 - Infectious, toxicologic etiologies, decreased cardiac output
- Eye movements:
 - Ocular bobbing:
 - Cyclical brisk conjugate caudal jerks of the globes followed by a slow return to midposition
 - Seen in bilateral pontine damage, metabolic derangement, and brainstem compression
- Ocular dipping:
 - Slow, cyclical, conjugate, downward movement of the eyes followed by a rapid return to midposition
 - Seen in diffuse cortical anoxic damage
- Pupil exam:
 - Nearly all toxic and metabolic causes of coma leave the pupillary reflexes sluggish but bilaterally intact.
- Focal findings (indicative of CNS process):
 - Hemiparesis
 - Hemianopsia
 - Aphasia
 - Myoclonus
 - Convulsions
 - Nuchal rigidity
- Asterixis:
 - Arrhythmic flapping tremor (almost always bilateral)
 - Seen in hepatic failure or severe renal failure

History

- Ask witnesses, family, pre-hospital personnel
- Baseline mental status
- Medical history (immunosuppressed, liver failure, depression, or chronic conditions)
- Recent events: Trauma, fever, illness
- Detailed medication list
- Substance abuse history

Physical-Exam

- Vital signs
- Head: Signs of trauma, pupils
- Fundoscopic exam: Hemorrhage, papilledema
- Neck: Rigidity, bruits, thyroid enlargement
- Heart and lungs
- Abdomen: Organomegaly, ascites
- Extremities: Cyanosis
- Skin: Diaphoretic/dry, rash, petechiae, ecchymoses, splinter hemorrhages, needle tracks
- Neurologic exam
- Mental status exam

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Dextrostix and glucose
- CBC
- Electrolytes (including Ca, Mg, P)
- BUN, creatinine
- Toxicologic screen (including toxic alcohols)
- ECG
- Urinalysis
- Blood and urine cultures (suspected infection)
- PT, PTT (anticoagulated, liver failure patients)
- Consider LFTs, thyroid function tests, ammonia, serum osmolarity, arterial blood gas
- Consider B₁₂, folic acid, RPR, urine porphobilinogen, heavy metal screening

Imaging

- Head CT scan:
 - Noncontrast only to rule out hemorrhage and mass effect
- Chest radiograph: To diagnose pneumonia
- MRI (if available):
 - Indicated when suspicious of ischemic stroke or other CNS abnormality
 - May be deferred when admitting the patient as part of the inpatient work-up

Diagnostic Procedures/Surgery

- Lumbar puncture (LP):
 - Indicated when the etiology remains unclear after lab and CT scan
 - Empiric antibiotics should be given before LP in patients with suspected

meningitis.

- EEG (inpatient): For suspected seizure, nonconvulsive status epilepticus
- Caloric stimulation of the vestibular apparatus to assess unresponsive patients:

DIFFERENTIAL DIAGNOSIS

- Locked-in syndrome:
 - Rare disorder caused by damage to the corticospinal, corticopontine, and corticobulbar tracts resulting in quadriplegia and mutism with preservation of consciousness.
 - Communication may be established through eye movements (maintain vertical eye movements).
- Psychogenic unresponsiveness:
 - Conversion reactions
 - Catatonia
 - Malingering
 - Akinetic mutism (abulic state)
- Dementia:
 - Multiple progressive cognitive deficits
 - Attention is preserved in the early stages.

TREATMENT

PRE HOSPITAL

- Airway management if loss of airway patency
- IV access, supplemental oxygen, cardiac monitor
- Spine immobilization if possibility of trauma
- “Coma cocktail”:
 - Dextrose
 - Naloxone
 - Thiamine
- Look for signs of an underlying cause:
 - Medications, medic alert bracelets
 - Document a basic neurologic exam, GCS, pupils, extremity movements
 - Gross signs of trauma
- CONTROVERSIES
 - Empirical dextrose should not be withheld or delayed if Dextrostix is not available
 - Glucose can be safely administered before thiamine.

INITIAL STABILIZATION/THERAPY

- IV D₅₀
- Naloxone

- Thiamine

ED TREATMENT/PROCEDURES

- Consider empiric use of antibiotics for altered mental status of undetermined etiology:
 - Broad spectrum with good CSF fluid penetration such as ceftriaxone and vancomycin
- Empiric treatment if a toxic ingestion is suspected:
- Correct body temperature:
- Specific therapy directed at underlying cause

MEDICATION

- Ceftriaxone: 2 g (peds: 50–75 mg/kg/d q12–24h) IV q12–24h
- Dextrose: 1–2 mL/kg of D₅₀W (peds: 2–4 mL/kg D₂₅W) IV
- Diazepam: 0.1–0.3 mg/kg slow IV (max 10 mg/dose) q10–q15min × 3 doses
- Lorazepam: 0.05–0.1 mg/kg IV (max. 4 mg/dose q10–q15min)
- Mannitol: 0.5–1 g/kg IV
- Naloxone: 0.01–0.1 mg/kg IV/IM/SC/ET
- Thiamine: 100 mg IM or 100 mg thiamine in 1,000 mL of IV fluid wide open
- Vancomycin: 1 g (peds: 10 mg/kg q8–12h) IV q12h

FOLLOW-UP

DISPOSITION

Admission Criteria

All patients with acute and persistent changes in mental status require admission.

Discharge Criteria

- Treated hypoglycemia related to insulin therapy with resolved symptoms
- Chronic altered mental status (e.g., dementia) without change from baseline
- Acute drug intoxication with return of patient's mental status to baseline with observation and drug has no potential for delayed toxicity

FOLLOW-UP RECOMMENDATIONS

Primary care follow-up to manage etiology which led to altered mental status (i.e., adjust medication dosing, drug abuse treatment referral)

PEARLS AND PITFALLS

- Consider reversible causes
 - Hypoglycemia (check glucose, give dextrose)

- Opiate overdose (trial of naloxone)
- Thiamine deficiency (trial of thiamine)
- Consider head CT for any patient with unclear etiology or neurologic abnormality
- Consider empiric antibiotics in patients with fever or unclear etiology

- 780.97 Altered mental status

ICD10

- R41.0 Disorientation, unspecified
- R41.82 Altered mental status, unspecified

AMEBIASIS

Ben Osborne • Joel C. Miller

BASICS

DESCRIPTION

- Invasive parasitic infection with both intestinal and extraintestinal manifestations
- Endemic worldwide, especially areas with poor sanitation
- Populations at risk:
 - _ Travelers to, citizens of, and immigrants from endemic areas
 - _ Institutionalized persons
 - _ Practitioners of oral–anal sexual activity
 - _ Men who have sex with men (MSM)
 - _ HIV infected individuals
- Risk factors for increased severity of disease and complications:
 - _ Immunocompromised: Corticosteroid use, HIV infection, malnutrition, malignancy
 - _ Pregnancy/postpartum state
 - _ Extremes of age

ETIOLOGY

- *Entamoeba histolytica*, an anaerobic, nonflagellated protozoa
- Fecal–oral transmission:
 - _ Humans are sole reservoir.
- Ingested organisms cause invasive colitis.
- Extraintestinal spread is hematogenous.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Intestinal disease:
 - _ Onset 1 wk to 1 mo postexposure
 - _ Acute diarrhea (nondysenteric colitis):
 - 80% of cases
 - Afebrile
 - Occult blood in stool
 - Benign abdominal exam
 - _ Classic dysentery:
 - Bloody mucoid diarrhea
 - Abdominal pain/benign abdominal exam
 - Tenesmus

- Weight loss
- Fever (rare)
- Fulminant colitis:
 - Toxic-appearing patient
 - Rigid abdomen (25%)
 - Fever
 - Severe bloody diarrhea
 - Rapid progression to perforated bowel and frank peritonitis
 - >40% mortality
- Toxic megacolon:
 - Toxic-appearing patient
 - Profuse diarrhea (>10 stools per day)
 - Fever
 - Distended, tympanitic abdomen with signs of peritonitis
 - Associated with corticosteroid use
 - High mortality
- Ameboma:
 - Intraluminal granulated mass
 - Tender palpable mass on exam
- Amebic strictures:
 - Owing to chronic inflammation/scarring
 - Crampy abdominal pain
 - Nausea and vomiting (may be feculent)
 - Partial or complete bowel obstruction
- Chronic amebic colitis:
 - Mild recurrent episodes of bloody diarrhea, abdominal cramping, and tenesmus
 - Weight loss
 - May persist for years
- Extraintestinal disease:
 - Amebic liver abscess:
 - Most frequent extraintestinal manifestation (3–9% of cases)
 - Single abscess in right lobe (50–80%)
 - May develop months to years postexposure (median of 3 mo)
 - Fever
 - Right upper quadrant pain
 - Hepatomegaly with point tenderness
 - Rales at right lung base
 - Concurrent diarrhea unusual (20–33%)
 - Complication: Rupture into pleural cavity (10–20%), peritoneum, or pericardium (rare)
 - Increased risk of rupture if >5 cm in diameter or left lobe location
 - Extrahepatic amebic abscess:

- Brain
- Lung
- Perinephric
- Splenic
- Vaginal/cervical/uterine
- _ Cutaneous amebiasis:
 - Perineum and genitalia
 - Painful, irregularly shaped ulcers
 - Purulent exudate

Pediatric Considerations

Fulminant colitis is more likely

Pregnancy Considerations

Fulminant colitis is more likely

History

- Possible sources of exposure
- Membership in high-risk group

Physical-Exam

- Identify evidence of peritonitis, sepsis, or shock.
- Tender abdominal mass mandates workup for liver abscess or ameboma.
- Digital rectal exam shows gross or occult blood in >70% of patients.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - _ Leukocytosis in amebic liver abscess and peritonitis
- Alkaline phosphatase and ALT:
 - _ Elevated in amebic liver abscess
- Serum electrolytes, BUN/creatinine if prolonged diarrhea or evidence of dehydration
- Stool PCR is diagnostic gold standard:
 - _ 100% sensitive and specific
- Stool ELISA for *E. histolytica*-specific antigen:
 - _ 74–95% sensitive, 93–100% specific
- Serum for anti-*E. histolytica* antibodies:
 - _ Essential if suspecting liver abscess. These patients rarely shed parasites in stool
 - _ 90–100% sensitive in amebic liver abscess

- 70–90% sensitive in amebic colitis
- Stool microscopy is <60% sensitive and no longer the test of choice.
- Fecal leukocytes and culture:
 - Rule out infection of enteroinvasive bacteria;
 - Negative in amebiasis

Imaging

- Abdominal US:
 - 58–90% sensitive for liver abscess
 - Sensitivity influenced by size and location
 - Evaluate abscess for increased risk of rupture (>5 cm or located in left lobe)
- Abdominal CT or MRI:
 - Equivalent to US for delineating liver abscesses
 - Superior to US for detecting abscesses in other organs
- Head CT or MRI:
 - Suspect amebic brain abscess if patient with known amebiasis has altered mental status or focal neurologic findings.
 - Irregular nonenhancing lesions
- CXR:
 - Elevated right hemidiaphragm and/or right pleural effusion in liver abscess

Diagnostic Procedures/Surgery

- Colonoscopy with biopsy provides definitive diagnosis of amebic dysentery, colitis, ameboma, and amebic stricture.
- Percutaneous fine-needle aspiration of liver abscess to exclude bacterial abscess if nondiagnostic serology or antiamebic therapy fails
 - Not for primary treatment of liver abscesses

DIFFERENTIAL DIAGNOSIS

- Intestinal amebiasis:
 - Enteroinvasive bacterial infection (*Staphylococcus*, *E. coli*, *Shigella*, *Salmonella*, *Yersinia*, *Campylobacter*)
 - Inflammatory bowel disease
 - Ischemic colitis
 - Arteriovenous malformation
 - Abdominal aortic aneurysm
 - Perforated duodenal ulcer
 - Intussusception, diverticulitis
 - Pancreatitis
 - Colorectal carcinoma
- Amebic abscess:
 - Bacterial abscess

- Tuberculous cavity
- Echinococcal cyst
- Malignancy
- Cholecystitis
- Cutaneous amebiasis:
 - Carcinoma
 - STDs (condyloma acuminata, chancroid, syphilis)

TREATMENT

INITIAL STABILIZATION/THERAPY

- Airway, breathing, circulation (ABCs)
- IV 0.9% NS if signs of significant shock

ED TREATMENT/PROCEDURES

- Oral fluids if mild; IV if moderate/severe dehydration
- Avoid antidiarrheal agents.
- Correct serum electrolyte imbalances.
- Stool sample for *E. histolytica* PCR or ELISA, plus serology for anti-*E. histolytica* antibodies
- If stool or serum is positive for *E. histolytica*:
 - Metronidazole or tinidazole is 1st-line drug for systemic amebiasis (90% cure rate)
 - Chloroquine is an alternative systemic agent
 - Always follow systemic therapy with a luminal agent to eradicate intestinal colonization (erythromycin, iodoquinol, nitazoxanide, paromomycin, or tetracycline).
 - Do not use the luminal agents alone
- If stool or serum is negative for *E. histolytica*:
 - Refer to gastroenterologist for colonoscopy with biopsy.
 - Repeat serology in 7 days.
 - Consider empiric course of metronidazole if high suspicion for amebiasis and patient is critically ill.
- If evidence of peritonitis or sepsis:
 - Add IV antibiotic directed against anaerobic and gram-negative bacteria.
 - Surgery if toxic megacolon or perforation
- If liver abscess is suspected:
 - US or CT of hepatobiliary system with concurrent amebic serology
 - If imaging demonstrates an abscess but serology is negative, treat with amebicides and repeat serology in 7 days.
 - Consider abscess drainage by surgeon or interventional radiologist in conjunction with amebicidal therapy.

- If symptoms do not improve after 5–7 days of empiric amebicidal therapy, consider fine-needle aspiration to rule out bacterial abscess or hepatoma.

Pregnancy Considerations

- Use metronidazole with caution in 1st-trimester pregnancy, but do not withhold if patient has fulminant colitis or amebic abscess.
- Use erythromycin or nitazoxanide as intestinal amebicides along with metronidazole.
- Erythromycin or nitazoxanide may be used alone for mild dysentery in 1st-trimester pregnancy.
- Chloroquine, iodoquinol, paromomycin, tetracycline, and tinidazole are contraindicated.

MEDICATION

First Line

- Metronidazole: 500–750 mg (peds: 30–50 mg/kg/24 h) PO/IV q8h for 5–10 d
- Tinidazole: 2 g/d (peds: 50–60 mg/kg/d) PO for 3–6 d. For children older than 3 yr

Second Line

- Chloroquine: 1,000 mg/d PO for 2 d then 500 mg/d PO for 14 d; or 200 mg IM for 10–12 d
- Erythromycin: 250–500 mg (peds: 30–50 mg/kg/24 h) PO q6h for 10–14 d
- Iodoquinol: 650 mg PO q8h for 20 d
- Nitazoxanide: 500 mg PO q12. for 3 d (10 d if liver abscess) for children > 12 yr
- Paromomycin: 500 mg (peds: 25–30 mg/kg/24 h) PO q8h for 5–10 d
- Tetracycline: 250–500 mg (peds[> 12 yr]: 25–50 mg/kg/24 h) PO q6h for 10 d

Pediatric Considerations

- Chloroquine and iodoquinol are contraindicated.
- Tetracycline contraindicated in children < 8 yr

Pregnancy Considerations

Use erythromycin or nitazoxanide only.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Shock, sepsis, or peritonitis
- Hypotension or tachycardia unresponsive to IV fluids

- Children with > 10% dehydration
- Severe electrolyte imbalance
- Patients unable to maintain adequate oral hydration:
 - Extremes of age, cognitive impairment, significant comorbid illness
- Fulminant colitis or toxic megacolon
- Bowel obstruction
- Extraintestinal abscesses
- Failure of outpatient regimen

Discharge Criteria

- Nontoxic presentation of acute or chronic dysentery
- Able to maintain adequate oral hydration and medication compliance
- Dehydration responsive to IV fluids

Issues for Referral

Consult surgery if evidence of peritonitis, toxic megacolon, colonic perforation, or liver abscess.

FOLLOW-UP RECOMMENDATIONS

- Gastroenterology and infectious disease follow-up in 7 days for repeat serology and possible endoscopic evaluation.
- Physical exam in 14 days to assess for treatment effectiveness and for development of complications or extraintestinal disease.

PEARLS AND PITFALLS

- Avoid antidiarrheal medications
- Always give double therapy with both a systemic amebicidal (metronidazole, tinidazole, or chloroquine) plus an intestinal amebicidal (erythromycin, iodoquinol, nitazoxanide, paromomycin, or tetracycline) unless contraindicated.
- Always be vigilant for high-mortality complications such as fulminant colitis or extraintestinal disease.

- A06.1 Chronic intestinal amebiasis
- A06.9 Amebiasis, unspecified

AMENORRHEA

Andrew J. French

BASICS

DESCRIPTION

- Absence of menstruation
- Primary amenorrhea:
 - No spontaneous uterine bleeding by age 16 yr or within 5 yr of breast development, which should occur by age 13.
- Secondary amenorrhea:
 - Absence of uterine bleeding for 3 mo in a woman with prior regular menses or for 9 mo in a woman with prior oligomenorrhea
 - More common than primary amenorrhea
 - Pregnancy is the most common cause.

ETIOLOGY

- Primary:
 - Gonadal failure
 - Hypothalamic-pituitary disorder
 - Chromosomal abnormalities
 - Imperforate hymen
 - Turner syndrome
- Secondary:
 - Pregnancy, breast-feeding, or postpartum
 - Asherman syndrome (intrauterine adhesions)
 - Dysfunction of the hypothalamic-pituitary-ovarian axis
 - Polycystic ovarian syndrome (PCOS)
 - Endocrinopathies
 - Obesity, starvation, anorexia nervosa, or intense exercise
 - Drugs:
 - Oral contraceptives
 - Antipsychotics
 - Antidepressants
 - Calcium channel blockers
 - Chemotherapeutic agents
 - Digitalis
 - Marijuana
 - Autoimmune disorders
 - Ovarian failure
 - Menopause

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Menarche and menstrual history
- Sexual activity
- Exercise, weight loss
- Chronic illness
- Medications
- Previous CNS radiation or chemotherapy
- Family history
- Infertility

Physical-Exam

- Low estrogen:
 - Atrophic vaginal mucosa
 - Mood swings, irritability
- High androgen:
 - Truncal obesity
 - Hirsutism
 - Acne
 - Male-pattern baldness
- Thyroid exam
- Pelvic/genital exam
- Tanner staging

ESSENTIAL WORKUP

Pregnancy test

DIAGNOSIS TESTS & INTERPRETATION

Lab

- If pregnancy test is negative, no further testing is needed emergently.
- May send TSH, prolactin, LH, FSH for follow-up by gynecology or primary care physician

Imaging

None needed emergently unless concern for ectopic pregnancy or other emergency as directed by patient's presentation

Diagnostic Procedures/Surgery

None needed emergently

DIFFERENTIAL DIAGNOSIS

Pregnancy

TREATMENT

PRE HOSPITAL

If amenorrhea is the result of pregnancy, stabilize patient as appropriate for pregnancy.

ED TREATMENT/PROCEDURES

Reassurance and referral for follow-up

MEDICATION

Defer for gynecology evaluation.

FOLLOW-UP

DISPOSITION

Admission Criteria

No need for admission unless concern for ectopic pregnancy

Discharge Criteria

Discharge with appropriate referral.

Issues for Referral

Referral to gynecology

FOLLOW-UP RECOMMENDATIONS

Gynecology follow-up is recommended.

PEARLS AND PITFALLS

- Pregnancy is the most relevant etiology of amenorrhea in the emergency department.
 - Urine pregnancy test (UPT) may give false negative with low urine specific gravity.
 - UPT sensitivity for β -HCG level may vary depending on type/manufacturer. High concern for amenorrhea due to pregnancy, specifically an ectopic, may warrant a qualitative serum pregnancy test
- Anorexia nervosa is an important consideration in patients with amenorrhea,

particularly in adolescents.

AMPHETAMINE POISONING

James W. Rhee

BASICS

DESCRIPTION

- Increased release of norepinephrine, dopamine, and serotonin
- Decreased catecholamine reuptake
- Direct effect on α - and β -adrenergic receptors

ETIOLOGY

- Prescription drugs:
 - _ Amphetamine (Benzedrine)
 - _ Dextroamphetamine (Dexedrine)
 - _ Diethylpropion (Tenuate)
 - _ Fenfluramine (Pondimin)
 - _ Methamphetamine
 - _ Methylphenidate (Ritalin)
 - _ Phenmetrazine (Preludin)
 - _ Phentermine
- “Designer drugs”:
 - _ Variants of illegal parent drugs
 - _ Often synthesized in underground labs
 - _ “Crystal,” “Ice”:
 - Crystalline methamphetamine hydrochloride
 - Smoked, insufflated, or injected
 - Rapid onset; duration several hours
 - _ “Crank”
 - _ “Ecstasy” (3,4-methylenedioxymethamphetamine, MDMA, XTC, E):
 - Often used at dances and “rave” parties
 - Dehydration can lead to hyperthermia, hyponatremia, fatality
 - _ MDA (3,4-methylenedioxyamphetamine)
 - _ Methcathinone (“cat,” “Jeff,” “mulka”):
 - Derivative of cathinone, found in the evergreen tree *Catha edulis*
 - Frequently synthesized in home labs
 - Does not show up on urine toxicology screens
 - _ Mephedrone
 - May be contained in “bath salts”

DIAGNOSIS

SIGNS AND SYMPTOMS

- CNS:
 - Agitation
 - Delirium
 - Hyperactivity
 - Tremors
 - Dizziness
 - Mydriasis
 - Headache
 - Choreoathetoid movements
 - Hyperreflexia
 - Cerebrovascular accident
 - Seizures and status epilepticus
 - Coma
- Psychiatric:
 - Euphoria
 - Increased aggressiveness
 - Anxiety
 - Hallucinations (visual, tactile)
 - Compulsive repetitive actions
- Cardiovascular:
 - Palpitations
 - Hypertensive crisis
 - Tachycardia or (reflex) bradycardia
 - Dysrhythmias (usually tachydysrhythmias)
 - Cardiovascular collapse
- Other:
 - Rhabdomyolysis
 - Myoglobinuria
 - Acute renal failure
 - Anorexia
 - Diaphoresis
 - Disseminated intravascular coagulation (DIC)

History

- Determine the type, amount, timing, and route of amphetamine exposure
- Assess for possible coingestions
- Evaluate for symptoms of end organ injury:
 - Chest pain
 - Shortness of breath
 - Headache, confusion, and vomiting

Physical-Exam

- Common findings include:
 - Agitation
 - Tachycardia
 - Diaphoresis
 - Mydriasis
- Severe intoxication characterized by:
 - Tachycardia
 - HTN
 - Hyperthermia
 - Agitated delirium
 - Seizures
 - Diaphoresis
- Hypotension and respiratory distress may precede cardiovascular collapse
- Evaluate for associated conditions:
 - Cellulitis and soft tissue infections
 - Diastolic cardiac murmurs or unequal pulses
 - Examine carefully for trauma
 - Pneumothorax from inhalation injury
 - Focal neurological deficits

ESSENTIAL WORKUP

- Vital signs:
 - Temperature > 40°C:
 - Core temperature recording essential
 - Peripheral temperature may be cool
 - Indication for urgent cooling
 - Ominous prognostic sign
 - BP:
 - Severe hypertension can lead to cardiac and neurologic abnormalities.
 - Late in course, hypotension may supervene due to catecholamine depletion
- ECG:
 - Signs of cardiac ischemia
 - Ventricular tachydysrhythmias
 - Reflex bradycardia

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Urinalysis:
 - Blood
 - Myoglobin

- Electrolytes, BUN/creatinine, glucose:
 - Hypoglycemia may contribute to altered mental status.
 - Acidosis may accompany severe toxicity.
 - Rhabdomyolysis may cause renal failure.
 - Hyperkalemia—life-threatening consequence of acute renal failure
- Coagulation profile to monitor for potential DIC:
 - INR, PT, PTT, platelets
- Creatine phosphokinase (CPK):
 - Markedly elevated in rhabdomyolysis
- Urine toxicology screen:
 - For other toxins with similar effects (e.g., cocaine)
 - Some amphetamine-like substances (e.g., methcathinone) may not be detected.
- Aspirin and acetaminophen levels if suicide attempt is a possibility
- Arterial blood gas (ABG)

Imaging

- Chest radiograph:
 - Adult respiratory distress syndrome
 - Noncardiogenic pulmonary edema
- Head CT for:
 - Significant headache
 - Altered mental status
 - Focal neurologic signs
 - For subarachnoid hemorrhage, intracerebral bleed

Diagnostic Procedures/Surgery

Lumbar puncture for:

- Suspected meningitis (headache, altered mental status, hyperpyrexia)
- Suspected subarachnoid hemorrhage and CT normal

DIFFERENTIAL DIAGNOSIS

- Sepsis
- Thyroid storm
- Serotonin syndrome
- Neuroleptic malignant syndrome
- Pheochromocytoma
- Subarachnoid hemorrhage
- Drugs that cause delirium:
 - Anticholinergics:
 - Belladonna alkaloids
 - Antihistamines
 - Tricyclic antidepressants

- Cocaine
- Ethanol withdrawal
- Sedative/hypnotic withdrawal
- Hallucinogens
- Phencyclidine
- Drugs that cause HTN and tachycardia:
 - Sympathomimetics
 - Anticholinergics
 - Ethanol withdrawal
 - Phencyclidine
 - Caffeine
 - Phenylpropanolamine
 - Ephedrine
 - Monoamine oxidase inhibitors
 - Theophylline
 - Nicotine
- Drugs that cause seizures:
 - Carbon monoxide
 - Carbamazepine
 - Cyanide
 - Cocaine
 - Cholinergics (organophosphate insecticides)
 - Camphor
 - Chlorinated hydrocarbons
 - Ethanol withdrawal
 - Sedative/hypnotic withdrawal
 - Isoniazid
 - Theophylline
 - Hypoglycemics
 - Lead
 - Lithium
 - Local anesthetics
 - Anticholinergics
 - Phencyclidine
 - Phenothiazines
 - Phenytoin
 - Propoxyphene
 - Salicylates
 - Strychnine

TREATMENT

PRE HOSPITAL

- Patient may be uncooperative or violent.
- Secure IV access.
- Protect from self-induced trauma.

INITIAL STABILIZATION/THERAPY

- ABCs
- Establish IV 0.9% NS access.
- Cardiac monitor
- Naloxone, dextrose (or Accu-Chek), and thiamine if altered mental status

ED TREATMENT/PROCEDURES

- Decontamination:
 - _ Administration of activated charcoal
 - _ Whole-bowel irrigation with polyethylene glycol solution for body packers
- Hypertensive crisis:
 - _ Initially administer benzodiazepines if agitated.
 - _ α -blocker (phentolamine) as second-line agent
 - _ Nitroprusside for severe, unresponsive hypertension
 - _ Avoid β -blockers, which may exacerbate hypertension.
- Agitation, acute psychosis:
 - _ Administer benzodiazepines.
- Hyperthermia:
 - _ Benzodiazepines if agitated
 - _ Active cooling if temperature $> 40^{\circ}\text{C}$:
 - Tepid water mist
 - Evaporate with fan.
 - _ Paralysis:
 - Indicated if muscle rigidity and hyperactivity contributing to persistent hyperthermia
 - Nondepolarizing agent (e.g., vecuronium)
 - Avoid succinylcholine.
 - Intubation; mechanical ventilation
 - _ Apply cooling blankets.
- Rhabdomyolysis:
 - _ Administer benzodiazepines.
 - _ Hydrate with 0.9% NS.
 - _ Maintain urine output at 1–2 mL/min.
 - _ Hemodialysis (if acute renal failure and hyperkalemia occur)
- Seizures:
 - _ Maintain airway.
 - _ Administer benzodiazepines.
 - _ Phenobarbital if unresponsive to benzodiazepines

- Phenytoin contraindicated
- Hypotension:
 - May be late finding due to catecholamine depletion
 - Initially bolus with isotonic crystalloid solution
 - If no response, administer norepinephrine.
 - Dopamine may not be effective

MEDICATION

- Activated charcoal: 1–2 g/kg up to 100 g PO
- Dextrose: D₅₀W 1 amp: 50 mL or 25 g (peds: D₂₅W 2–4 mL/kg) IV
- Diazepam (benzodiazepine): 5–10 mg (peds: 0.2–0.5 mg/kg) IV
- Lorazepam (benzodiazepine): 2–6 mg (peds: 0.03–0.05 mg/kg) IV
- Nitroprusside: 1–8 µg/kg/min IV (titrated to BP)
- Phenobarbital: 15–20 mg/kg at 25–50 mg/min until cessation of seizure activity
- Phentolamine: 1–5 mg IV over 5 min (titrated to BP)
- Vecuronium: 0.1 mg/kg IVP

FOLLOW-UP

DISPOSITION

Admission Criteria

- Hyperthermia
- Persistent altered mental status
- Hypertensive crisis
- Seizures
- Rhabdomyolysis
- Persistent tachycardia

Discharge Criteria

- Asymptomatic after 6 hr observation
- Absence of the above admission criteria

FOLLOW-UP RECOMMENDATIONS

Patients may need referral for chemical dependency rehab and detoxification.

PEARLS AND PITFALLS

- Admit patients with severe or persistent symptoms.
- Monitor core temperature:
 - Hyperthermia > 40°C may be life threatening.
 - Treat with aggressive sedation and active cooling.

- Recognize rhabdomyolysis and hyperkalemia.
- Avoid physical restraints in agitated patients if possible.
- Consider associated emergency conditions:
 - Patients with chest pain should be evaluated for acute coronary syndromes and treated accordingly.
 - Consider infection in altered patients with fever and history of IV drug use.
 - Methamphetamine abuse frequently associated with traumatic injury
- Benzodiazepines are 1st-line therapy in symptomatic methamphetamine intoxication

- T43.631A Poisoning by methylphenidate, accidental, init

AMPUTATION TRAUMATIC/REPLANTATION

Charlotte A. Sadler

BASICS

DESCRIPTION

- Partial amputations have tissue connecting the distal and proximal parts and are treated by revascularization.
- Complete amputations have no connecting tissue and may be treated by replantation.
- Both of the above are treated the same from an emergency standpoint.

ETIOLOGY

Traumatic amputations may result from machinery, powered hand tools, household appliances, lawnmowers, getting caught between objects, motor vehicle collisions, crush injuries, blast injuries, gunshot wounds, knives, degloving injuries to digits (ring avulsions), and animal bites.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Exact time of injury is critical, as ischemia time predicts success for replantation:
 - Irreversible muscle necrosis begins at 6 hr of ischemia.
 - The temperature and amount of muscle present in the tissue predicts the tolerable ischemia time.
 - Amputated digits have little muscle and can tolerate more ischemia time:
 - Warm ischemia time of 8–12 hr
 - Cool ischemia time of as much as 24 hr
 - Amputated limbs have more muscle mass and can tolerate less ischemia time:
 - Warm ischemia time of 4–6 hr
 - Cold ischemia time of 10–12 hr
- Mechanism of injury:
 - Clean-cut or “guillotine” amputations have better prognosis for replantation than crush or avulsion injuries.
- Comorbid illnesses that hinder successful replantation:
 - Diabetes, peripheral vascular disease, rheumatologic disease, smoking
- Handedness
- Social history, including occupation and major hobbies

Physical-Exam

- Assessment and documentation of injured extremity is crucial.
- Signs of neurologic compromise:
 - Loss of sensation and 2-point discrimination
 - Loss of active range of motion
- Signs of vascular compromise in partial amputations:
 - Distal part dusky or cyanotic
 - Delayed capillary refill (> 2 sec)
 - Diminished or absent pulses (Doppler or palpation)
 - Ribbon sign (twisting of the artery in the amputated digit or limb)
 - Use Allen test in hand injuries.
 - Pulse oximetry may be helpful.
- Soft tissue: Assess skin, muscle, tendon, and nail bed integrity.
- Identify exposed bone and fractures (gross deformity, tenderness, crepitus).

ESSENTIAL WORKUP

ED workup includes obtaining an accurate history and physical exam, stabilizing the patient and injured part, and consultation or transfer if replantation is an option.

DIAGNOSIS TESTS & INTERPRETATION

Lab

Preoperative lab studies, cultures from wounded area

Imaging

Radiographs of both amputated part and stump are important, but should not delay transport.

Diagnostic Procedures/Surgery

Determined by surgical consultant for replantation

DIFFERENTIAL DIAGNOSIS

- Involves neurologic, vascular, and soft tissue integrity and potential for replantation/revascularization
- Do not miss other major injuries with concurrent trauma.

TREATMENT

PRE HOSPITAL

- Collect all amputated body parts, including pieces of bone, tissue, and skin.
- See “Initial Stabilization” for care of amputated parts during transport.
- Transport patient and body parts to the nearest microvascular replantation center

unless other major injuries require transport to the nearest trauma center:

- Air transport from remote locations should be considered if ischemia time is of concern.

INITIAL STABILIZATION/THERAPY

- Consult surgical specialist as early as possible.
- Establish IV access.
- Limit blood loss:
 - Elevate injured limb.
 - Direct pressure using bulky pressure dressing or pressure points if ineffective.
 - Use tourniquet if above methods fail to give desired hemostasis (BP cuff 30 mm Hg > systolic BP [SBP]).
 - Partial amputations bleed more because of lack of both retraction and spasm of blood vessels.
- Avoid further damage to injured part:
 - Avoid vascular clamps, cautery, vessel ligation, or debridement.
 - Avoid repeated exams of the stump or amputated part.
- Care of amputated part (complete and partial):
 - Remove gross contamination/foreign material.
 - Gently irrigate with saline (avoid antiseptics).
 - Wrap in gauze moistened with saline.
 - Place in clean, dry plastic bag or specimen cup.
 - Place sealed bag/cup in ice water (half water, half ice) or refrigerate at 4°C.
 - Never place directly onto ice or into ice water.
 - Avoid dry ice to prevent freezing.
- Care of the stump:
 - Irrigate with saline and cover with saline dampened gauze.
 - Splint if necessary; keep partial amputations as near anatomic position as possible.
 - Keep any fragments of tissue (even if seemingly insignificant) because they may be used for skin, bone, or nerve grafting
 - If limb amputation, may cannulate proximal artery with 18G cannula and irrigate with tissue preservation formula, but this should be at the discretion of the surgeon
- Maintain normal blood volume with IV fluids or blood products if necessary.

ED TREATMENT/PROCEDURES

- Tetanus prophylaxis
- Adequate IV analgesia
- Patient NPO
- Prophylactic antibiotics if devitalized tissue, exposed bone, or contamination:
 - Cover *Streptococcus*, *Staphylococcus aureus*, and *Clostridium perfringens*

- All patients are candidates for surgical repair until a specialist deems otherwise.
- Limit ischemia time of the amputated part (i.e., early transfer if necessary).
- Patient considerations in decision to replant:
 - Age
 - Occupation/handedness
 - Degree of motivation
 - General physical condition and underlying diseases, particularly diabetes mellitus, peripheral vascular disease
- Indications for replantation (no absolute indications):
 - Thumb, any level (supplies 40% of hand function)
 - Multiple digits
 - Hand amputations through the palm and distal wrist
 - Individual digit distal to flexor digitorum superficialis tendon insertion and proximal to distal interphalangeal joint (DIP)
 - Some single-digit ring avulsion injuries
 - Arm proximal to midforearm (if sharp or moderately avulsed)
 - Virtually all pediatric amputations (younger patients have lower success rates but better functional outcomes)
- Contraindications to replantation:
 - Severely crushed or mangled parts
 - Injuries at multiple levels
 - Psychotic patients who willfully self-amputated the part
 - Single-digit amputations proximal to the flexor digitorum superficialis muscle insertion
 - Amputated parts with tendons avulsed from musculotendinous junctions
 - Lower extremities rarely attempted and usually in children
 - Unstable patients secondary to other serious injuries or diseases
 - Older patients or those with contraindications to general anesthesia
 - Inappropriately prolonged ischemia time
- Fingertip amputations: Most common type of upper extremity amputation:
 - Distal to DIP joint
 - Primary goals of treatment:
 - Maintenance of length
 - Good soft-tissue coverage
 - Painless fingertip with durable and sensate skin
 - Nail preservation
 - Better dorsal prognosis than ventral
 - No exposed phalanx:
 - Irrigate with saline, apply petrolatum-soaked gauze and allow to heal by secondary intention (best result in wounds < 1 cm²).
 - Small amount of exposed phalanx:
 - Shorten bone with rongeur below level of the tissue and close by

- primary intention or allow to heal by secondary intention.
 - Any bone left exposed requires additional operative procedures and consultation.
 - Replantation is an option for cosmetic reasons or for occupational consideration (e.g., musicians).
 - Considered open fractures if phalanx exposed, thus antibiotics are indicated.
 - Preserve nail bed and nail to optimize function and cosmesis.
 - Treat subungual hematomas.
 - Splint to prevent trauma to healing fingertip.
 - Consultation required if significant loss of bone or soft tissue for possible graft or flap
- Nonlimb amputations (penis, ear, nose): Amputated parts should be cared for similarly as above and emergently referred to a specialist for replantation:
 - Penile amputations: Most often secondary to self-mutilation and psychiatric illness
 - Successful replantation unlikely beyond 24 hr of cold ischemia or 6 hr of warm ischemia
 - Ear amputations: Should be considered for replantation by appropriate specialist
 - Nose amputations: Replantation has been successfully performed with variable results.

Pediatric Considerations

- All pediatric amputations considered for replantation
- Fingertip amputations often left to heal by secondary intention:
 - Spontaneous regeneration of fingertip occurs in children even with volar fingertip amputations.
 - Pediatric fingertip amputations distal to the lunula of the fingernail can be successfully replanted (unlike adults).

Geriatric Considerations

Advanced age not an absolute contraindication to replantation; however, underlying medical problems often make older patients poor surgical candidates.

MEDICATION

- First Line: Cefazolin: 0.5–1.5 g IV or IM q6–q8h (peds: 25–100 mg/kg/d divided q8h, max. 6 g/d)
- Second Line: Vancomycin 15–20 mg/kg IV q12h
- If concerned about clostridia, consider using Piperacilin/Tazobactam 80 mg/kg IV q8h

FOLLOW-UP

DISPOSITION

Admission Criteria

Hospitalization is required for all patients undergoing replantation or revascularization.

Discharge Criteria

- Mild fingertip amputations or mild degloving injuries with adequate repair and stable vasculature
- Close surgical or orthopedic follow-up is required.

Issues for Referral

- Know exact mechanism and time of injury
- Refer as early as possible
- Transfer imaging and amputated parts with patient, stored in appropriate medium

FOLLOW-UP RECOMMENDATIONS

Patients discharged but with significant skin loss should be considered for skin grafting and have close surgical follow-up.

PEARLS AND PITFALLS

- Every effort should be made to minimize ischemia time
- Expeditious consultation or transfer to appropriate surgeon and team is paramount.
- Avoid any direct contact of the amputated part with ice
- Perform thorough ATLS survey to avoid missing other less obvious, but potentially life threatening, injuries

CODES

ICD9

- 885.0 Traumatic amputation of thumb (complete)(partial), without mention of complication
- 886.0 Traumatic amputation of other finger(s) (complete) (partial), without mention of complication
- 887.4 Traumatic amputation of arm and hand (complete) (partial), unilateral, level not specified, without mention of complication

ICD10

- S68.019A Complete traumatic metacarpo-phalangeal amputation of unspecified thumb, initial encounter
- S68.119A Complete traumatic metacarpo-phalangeal amputation of unspecified finger, initial encounter
- S68.129A Partial traumatic metacarpophalangeal amputation of unspecified finger, initial encounter

AMYOTROPHIC LATERAL SCLEROSIS

Richard S. Krause

BASICS

DESCRIPTION

- Progressive, incurable disease of adults
- Neurodegenerative disease of the motor system at all levels
- Some patients have associated dementia
- Manifestations:
 - Muscle weakness
 - Wasting
 - Fasciculations
 - Babinski sign
 - Hyperreflexia
- Variants with predominately upper or lower motor neuron manifestations also occur
- May begin with bulbar symptoms of dysphagia and dysarthria
- Also known as “Lou Gehrig Disease” after the famous baseball player who was affected
- Eventually leads to respiratory compromise secondary to weakness of diaphragm and other muscles of respiration
- 80% of cases begin between ages 40 and 70 yr
- Death (usually from respiratory paralysis) typically occurs within 3–5 yr of the diagnosis
- 50% die within 3 yr
- ~ 10% ALS patients live 10 yr or more
- Males > females

ETIOLOGY

- Etiology of amyotrophic lateral sclerosis (ALS) is unknown
- ~ 10% of affected patients have another affected family member
- Cigarette smoking and heavy metal exposure may be risk factors
- There is a disease cluster in the western Pacific
- Pathologically, there is loss of both upper and lower motor neuron cells
- Predilection for the motor system and sparing of other neurons

DIAGNOSIS

SIGNS AND SYMPTOMS

- Asymmetric limb weakness is the most common presentation of ALS (80%)

- May begin in either the arms (cervical onset) or the legs (lumbar onset):
 - Later all limbs are affected
- Bulbar ALS:
 - Usually presents with dysarthria or dysphagia
 - 2nd most common presentation
- Both lower motor neuron (weakness and wasting with fasciculation) and upper motor neuron signs (Babinski sign with hyperreflexia) occur
- Respiratory muscles and the vocal cords are affected late
- Muscle fasciculation is common, but may not be apparent to the patient
- Extraocular muscles, sphincters, cognition, and sensation are spared

History

- Most ED patients with ALS will present with an established diagnosis
- History should focus on clues regarding acute medical issues and functional decline
- When ALS is suspected due to a complaint of “weakness” consider that this occurs with many illnesses including:
 - Pulmonary disease
 - Cardiac disease
 - Anemia
 - Endocrine disorders
 - Toxidromes
 - Diseases of muscles or joints
 - Spinal cord abnormalities
 - Depression
- Differentiate true weakness from: Shortness of breath, chest pain, joint pain, fatigue, poor exercise tolerance, etc.
- True weakness often leads to complaints of inability to perform specific tasks:
 - Bulbar palsy:
 - Facial weakness
 - Weakness and fasciculation of tongue
 - Dysarthria
 - Cervical onset ALS:
 - Difficulty with washing hair, using comb
 - Impaired pincer grip
 - Lumbar onset ALS:
 - Frequent trips secondary to foot drop
 - Difficulty walking up stairs

Physical-Exam

- A detailed and thorough neurological exam is the key to diagnosis but is not typically performed in the ED
- Upper motor neuron disease causes slow uncoordinated movements and stiffness

- Lower motor neuron disease causes weakness accompanied by atrophy and muscle cramps are common
- Common findings:
 - _ Brisk reflexes
 - _ Fasciculations
 - _ Muscle wasting
- Exam should focus on excluding or confirming other conditions

ESSENTIAL WORKUP

- Previously undiagnosed ALS:
 - _ Diagnosis of ALS is clinical and rarely made in the ED:
 - Recognition of the possibility of this disease is sufficient and mandates referral for workup
 - _ If ALS is suspected, forced vital capacity (FVC) should be performed
- Known ALS patient:
 - _ Patients with known disease and progressive symptoms:
 - Evaluate potentially treatable complications with lab and imaging studies
 - _ FVC is a sensitive indicator of respiratory muscle weakness:
 - FVC < 50% of predicted is considered a sign of advanced disease
 - FVC < 50% usually requires ventilatory support
 - Start with noninvasive positive pressure ventilation when possible
 - Compare with the patient's previous baseline
 - _ CXR may reveal aspiration or pneumonia or comorbid conditions such as CHF
 - _ Pulse oximetry and blood gas analysis aid in the diagnosis of respiratory failure
 - _ Electrolytes and other blood chemistry tests may reveal a treatable cause of increasing weakness

DIAGNOSIS TESTS & INTERPRETATION

Lab

- In cases of undifferentiated weakness, consider CPK measurement along with blood chemistry:
 - _ Elevated CPK is associated with myopathy
- Electrolyte abnormalities such as hypokalemia, hypercalcemia, etc. may cause generalized weakness but this is typically in association with other signs and symptoms
- CBC, UA may be indicated to look for source of infection

Imaging

Cervical spine, other skeletal radiography, or head CT may be needed in case of falls

(common in ALS) or to rule out other conditions

Diagnostic Procedures/Surgery

- Check FVC
- Electromyography (EMG) may help confirm the diagnosis (not usually an ED test)

DIFFERENTIAL DIAGNOSIS

- Cervical cord compression:
 - Similar symptoms but usually acute onset with pain and sensory changes
 - Spinal MRI or myelography for diagnosis
- Thyrotoxicosis may mimic ALS:
 - Usually marked systemic symptoms
- Heavy metal poisoning (lead, mercury, arsenic)
- Syphilis and Lyme disease
- Lymphoma may have an associated lower motor neuron syndrome, which mimics ALS
- Bulbar ALS:
 - Esophageal cancer
 - Myasthenia gravis

TREATMENT

- There is no specific therapy for ALS
- The drug riluzole, a glutamate release inhibitor, has been shown to extend survival in ALS patients for an average of a few months
- Treatment issues in the ED revolve around symptomatic therapy and identification and treatment of complications

PRE HOSPITAL

Controversies:

- Many patients will have advanced directives:
 - Unless immediate intervention is essential, intubation should be avoided until directives have been ascertained
 - Noninvasive means of ventilatory support may be tried first

INITIAL STABILIZATION/THERAPY

- Respiratory insufficiency or failure:
 - Ascertain any advanced directives
 - Noninvasive ventilatory support
 - Intubation as indicated
- Weaning off the ventilator is very difficult:
 - Average survival after institution of ventilation is 19 mo

ED TREATMENT/PROCEDURES

- Sedation and pain control as indicated:
 - Joint pain may respond to NSAIDs
- Insomnia from pressure pain (owing to immobility) may respond to diphenhydramine or amitriptyline
 - Insomnia may also be treated with benzodiazepines
- Aspiration or drooling may be treated with amitriptyline, atropine, or hyoscyamine (dries secretions)
- Muscle cramps may respond to baclofen or tizanidine
- Constipation is related to immobility and diet:
 - Treated with laxatives, stool softeners, and dietary changes

MEDICATION

- Amitriptyline: 25–100 mg PO QHS
- Atropine: 0.4 mg PO q4–6h
- Baclofen: 10–25 mg PO TID
- Diphenhydramine: 25–50 mg PO nightly at bedtime
- Tizanidine 2–4 mg PO BID

FOLLOW-UP

DISPOSITION

Admission Criteria

- Need for respiratory support
- Dehydration
- Unable to be cared for at home owing to progression of illness
- Complications (e.g., infection) or other diagnosis that requires admission

Discharge Criteria

- *Suspected ALS*: Refer for outpatient evaluation if general condition permits and other serious conditions requiring admission are ruled out
- *Complication of known ALS*: Discharge if outpatient treatment available and stable respiratory status

FOLLOW-UP RECOMMENDATIONS

If considering diagnosis of ALS, prompt follow-up with a neurologist should be arranged

PEARLS AND PITFALLS

- ALS is a progressive neurodegenerative disease affecting all components of the motor system
- Many patients with ALS have advanced directives—*inquire prior to any aggressive*

intervention

- FVC <50% usually requires ventilatory support.

ICD10

G12.21 Amyotrophic lateral sclerosis

ANAL FISSURE

Julia H. Sone

BASICS

DESCRIPTION

- Hard stool passes and “cuts” anoderm
- Linear tear extends from dentate line to anoderm:
 - Posterior midline 95%
 - Anterior midline 5%
 - Externally: Forms skin tag or sentinel pile
 - Internally: Forms hypertrophied anal papilla
 - Chronic fissure may reveal fibers of internal sphincter with sentinel pile.

ETIOLOGY

- Stress or an overly tight anal sphincter leads to local ischemia of posterior anoderm.
- Diarrhea or hard bowel movement tears anoderm.
- Local trauma from anal intercourse or sexual abuse may be the cause.
- Lateral fissures indicate underlying causative systemic disease:
 - Crohn's disease
 - Anal cancer
 - Leukemia
 - Syphilis
 - Previous anal surgery

DIAGNOSIS

SIGNS AND SYMPTOMS

- Bright red blood per rectum usually on toilet paper
- Sharp, cutting, throbbing or burning pain with bowel movement:
 - May last for hours
- Constipation; unable to pass stool owing to pain:
 - Hard, nondeformable stools

History

- Passage of hard stool or constipation
- Episode(s) of diarrhea
- Bright red blood on toilet paper

Physical-Exam

Anal exam:

- Gently retract buttocks and have patient bear down to visualize the fissure.
- Severe pain usually prevents a manual or digital exam:
 - Use lidocaine jelly or ELA-Max5, a topical lidocaine ointment, before attempting digital rectal exam.
 - Need to exclude abscess or tumor

Pediatric Considerations

A clear test tube may be used as an anoscope to visualize the anal canal/fissure.

ESSENTIAL WORKUP

Careful rectal exam

DIAGNOSIS TESTS & INTERPRETATION

Lab

Hematocrit if severe bleeding by history

Imaging

CT pelvis:

- To exclude anal rectal abscess/tumor if palpable mass on rectal exam

DIFFERENTIAL DIAGNOSIS

- Crohn's disease
- Chronic ulcerative colitis
- Anorectal carcinoma
- Perirectal abscess
- Thrombosed hemorrhoid
- Sexual abuse
- TB
- Syphilis
- Lymphoma
- Leukemia
- Previous anal surgery

TREATMENT

PRE HOSPITAL

Establish IV access for patients with significant rectal bleeding.

INITIAL STABILIZATION/THERAPY

Administer pain medications for patients with significant pain.

ED TREATMENT/PROCEDURES

- IV/IM/PO pain medications:
 - NSAIDs
 - Acetaminophen
 - Muscle relaxants to relieve sphincter spasm:
 - Cyclobenzaprine
 - Diazepam
 - Diltiazem 2% ointment
 - Nifedipine ointment 0.3%
- Topical anesthetics:
 - ELA-Max5
 - Lidocaine jelly 2%
- Sitz baths (with warm water) to relieve sphincter spasm

Diet

- High-fiber diet instruction:
 - Fiber/bran: 20 g/d
 - Psyllium seeds (Metamucil or Konsyl): 1–2 tsp (peds: 0.25–1 tsp/d) PO q24h
- Encourage consumption of 10–12 oz glasses of water per day.

MEDICATION

- Cyclobenzaprine (Flexeril): 10 mg (peds: Not indicated) PO TID
- Diazepam (Valium): 5 mg (peds: 0.12–0.8 mg/kg/d) PO TID PRN for spasm
- Diltiazem 2% ointment: Apply to fissure BID
- Docusate sodium (Colace): 50–200 mg (peds: younger than 3 yr, 10–40 mg/d; 3–6 yr, 20–60 mg/d; 6–12 yr, 40–150 mg/d) PO q12h
- ELA-Max5 (5% lidocaine anorectal cream): Apply to perianal area q4h PRN pain (pediatric dose: Not for those younger than 12 yr)
- Ibuprofen: 400–600 mg (peds: 40 mg/kg/d) PO q6h
- Nifedipine ointment 0.3%: Apply to fissure TID with Q-tip (peds: Not indicated)
- Nitroglycerin ointment 0.2%: Apply a small pea-sized dot to fissure BID—TID with cotton swab. (peds: Not indicated)

FOLLOW-UP

DISPOSITION

Admission Criteria

Severe abdominal pain/distention due to fecal impaction

Discharge Criteria

- Initial treatment is conservative therapy for acute anal fissures as an outpatient.

- Operative referral for chronic fissures

FOLLOW-UP RECOMMENDATIONS

Colorectal or GI follow-up for patients with symptomatic fissures

PEARLS AND PITFALLS

- Perform a careful physical exam of rectal area to delineate fissures and exclude other pathology.
- Provide combination of pain relief and muscle relaxants for patients with significant pain.
- Provide discharge medications/instructions to prevent constipation.

- K60.2 Anal fissure, unspecified

ANAPHYLAXIS

Sean-Xavier Neath

BASICS

DESCRIPTION

- An acute, widely distributed form of shock that occurs within minutes of exposure to antigen in a sensitized individual
- ~500–1,000 deaths are attributed annually in the US to anaphylaxis. There are ~10,000 ER visits per month for anaphylaxis in the US
- Involves release of bioactive molecules such as histamine, leukotrienes, and prostaglandins from inflammatory cells:
 - Mediator release results in increased vascular permeability, vasodilation, smooth-muscle contractions, and increased epithelial secretion.
 - Physiologically, this is manifested in a decrease in total peripheral resistance, venous return, and cardiac output, as well as intravascular volume depletion.

ETIOLOGY

- IgE mediated:
 - Antibiotics, particularly penicillin family
 - Venoms, especially bee and wasp
 - Latex
 - Vaccines
 - Foodstuffs (shellfish, soybeans, peanuts, tree nuts, wheat, milk, eggs, nitrates/nitrites)
 - Monoclonal antibody therapeutics
- Non-IgE mediated:
 - Iodine contrast media
 - Opiates
 - Vancomycin

Pediatric Considerations

In children, foods are an important trigger for IgE-mediated anaphylaxis:

- Milk, egg, wheat, and soy (MEWS) are the most common food allergens.
- Peanut allergies are increasingly common and can be more potent; children can develop anaphylaxis from residual peanut in a candy bar.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Symptoms begin within seconds to minutes after contact with an offending antigen.
- Anaphylactic reactions almost always involve the skin or mucous membranes. > 90% of patients have some combination of urticaria, erythema, pruritus, or angioedema.
- Some patients may have an initial sensation of impending doom followed by more clearly definable symptomatology:
 - Respiratory: From sneezing and nasal congestion to frank bronchospasm and laryngeal edema
 - Cardiovascular: Hypotension, dysrhythmias, myocardial ischemia
 - Gastrointestinal: Nausea, vomiting, diarrhea
 - Ocular: Eye itching and tearing, conjunctival injection
 - Hematologic: Activation of intrinsic coagulation pathway sometimes leading to disseminated intravascular coagulation, thrombocytopenia
 - Neurologic: Seizures

History

- Anaphylaxis is a clinical diagnosis.
- A brief history should include previous history of allergy or anaphylaxis, as well as exposure to potential new triggers.

Physical-Exam

- Usually will include alterations in a combination of any 2 or more of the following systems: Cutaneous, respiratory, gastrointestinal, or cardiovascular system
- Hypotension or airway compromise is not always present at onset.

ESSENTIAL WORKUP

- Diagnosis is made based on clinical symptoms.
- It is important not to underestimate the potential severity of an allergic reaction in its early stages.
- ECG should be done in patients with previous cardiac history or ischemic symptoms; consider routinely in the elderly.

DIAGNOSIS TESTS & NTERPRETATION

Lab

The diagnosis of anaphylaxis is made on clinical grounds; laboratory tests are usually not useful in aiding diagnosis in the acute setting. Tryptase levels remain elevated after an attack and can be useful for later confirmation of a suspected anaphylactic episode.

Imaging

Hyperinflation can be seen on CXR.

DIFFERENTIAL DIAGNOSIS

- Pulmonary embolism
- Acute MI
- Airway obstruction
- Asthma
- Tension pneumothorax
- NSAID reaction
- Vasovagal collapse
- Hereditary angioedema
- Serum sickness
- Systemic mastocytosis
- Foreign body aspiration
- Hypoglycemia
- Pheochromocytoma
- Carcinoid syndrome

TREATMENT

PRE HOSPITAL

- IV access, O₂, cardiac and pulse oximetry monitoring
- Early intubation based on the initial progression of disease and response to treatment:
 - Laryngeal edema and spasm can progress rapidly.
 - Laryngeal edema can be managed with racemic epinephrine prior to intubation.
- IM epinephrine can be administered en route even prior to establishment of an IV.

ALERT

Note that current guidelines advocate the use of IM over SC epinephrine

INITIAL STABILIZATION/THERAPY

- ABCs
- Assure adequate ventilation
- Airway management:
 - Orotracheal intubation is the airway technique of choice.
 - If laryngeal edema, spasm, or soft tissue swelling present; consider using advanced airway adjuncts when available.
 - Consider blind nasotracheal intubation if soft tissue swelling prohibits an oral approach and there is absence of stridor.
 - Transtracheal jet insufflation or cricothyrotomy may be necessary to control the airway.
- Epinephrine IM/IV or endotracheal administration:

– Direct injection into the venous plexus at the base of the tongue is an option.

- Volume resuscitation with crystalloids or colloids

ED TREATMENT/PROCEDURES

- Continuous cardiac and vital sign monitoring until stable
- Persistent bronchospasm can be treated with β_2 -agonist bronchodilators.
- Hypotension should be treated with volume repletion. Vasopressors can provide additional support.
- Antihistamines (both H_1 and H_2 blockers) have been shown to be helpful in preventing histamine interactions with target tissues.
- Corticosteroids help prevent the progression or recurrence of anaphylaxis.
- Glucagon is particularly useful in epinephrine-resistant anaphylaxis from β -adrenergic blocking agents.

MEDICATION

ALERT

A patient's concomitant use of a β -blocker may antagonize the effects of epinephrine. For these patients consider glucagon as it increases intracellular cyclic adenosine monophosphate levels by a mechanism that does not depend upon β -receptors.

First Line

- Diphenhydramine: Adults—50 mg IV; (peds: 1–2 mg/kg, not to exceed 50 mg/dose) slow IVP
- Epinephrine: 0.3–0.5 mg; use 1:1,000 dilution for IM route and 1:10,000 for IV route (peds: epinephrine 0.01 mg/kg SC/IV)
- Hydrocortisone: Adults—500 mg IV (peds: 4–8 mg/kg/dose IV) OR
- Methylprednisolone: Adult—125 mg IV (peds: 1–2 mg/kg IV) OR
- Prednisone: Adult—60 mg PO (peds: 1 mg/kg PO)
- Albuterol: 0.5 mL of 0.5% solution in 2.5 mL of isotonic saline by nebulizer

Second Line

- Racemic epinephrine: 2.25% solution (0.5 mL placed in a nebulizer in 2.5 mL of normal saline)
- Glucagon: Adults—1–2 mg IV/IM/SC
- Ranitidine: Adult—50 mg IV (peds: 1 mg/kg) *or* cimetidine 300 mg IV

FOLLOW-UP

DISPOSITION

Admission Criteria

- Intubated patients or patients in respiratory distress should be admitted to an intensive care unit setting.
- A monitored inpatient bed may be necessary for the patient who has not had substantial response to initial therapy.
- Patients with significant generalized reactions and persistent symptoms should be admitted for observation for 24 hr. Biphasic or late phase reactions are known to occur.

Discharge Criteria

Patients with complete resolution of symptoms may be discharged after several hours of ED observation.

Issues for Referral

- Consultation with an allergist/immunologist is appropriate when desensitization to an antibiotic is being considered for the treatment of an infectious process.
- When a patient at high risk for contrast reaction needs a contrast study, consultation with the radiologist regarding pretreatment and choice of contrast agent is appropriate.

FOLLOW-UP RECOMMENDATIONS

- Patients with allergic reactions should have a follow-up within 48 hr of discharge to evaluate effectiveness of outpatient therapy.
- Refer patients who are treated and released from the ED after an episode of anaphylaxis, angioedema, or urticaria to an allergist for follow-up skin testing and consideration for desensitization.
- Patients should be advised to carry some type of treatment that can be self-administered in the event of future reactions such as the prefilled syringe EpiPen.
- Patients with a known trigger should be counseled on strict avoidance of that trigger.

PEARLS AND PITFALLS

- Failure to consider anaphylaxis early in presentation can lead to devastating hemodynamic compromise and airway collapse.
- Epinephrine given early is the most important intervention.
- Patients with a history of anaphylaxis should be educated about trigger avoidance and instructed in the correct use of epinephrine auto-injector pens.

ANEMIA

Stevan A. Vuckovic • Paul J. Allegretti

BASICS

DESCRIPTION

- Reduction below normal in the mass of RBCs
- Measured by 1 or more of the major RBC components:
 - Hemoglobin (Hgb): Concentration of the major oxygen-carrying component in whole blood
 - Hematocrit (Hct): Percent volume of whole blood occupied by intact RBCs
 - RBC count: RBCs contained in a volume of whole blood
- Adult female: Hgb < 12 g/dL or Hct < 37%
- Adult male: Hgb < 14 g/dL or Hct < 42%
- Normal blood count values depend on age:
 - Birth: Hgb 16.5, Hct 51
 - 1 yr: Hgb 12, Hct 36
 - 6 yr: Hgb 12.5, Hct 37
 - Adult male: Hgb 14, Hct 42
 - Adult female: Hgb 12, Hct 37
- Hgb/Hct depend on oxygen pressure:
 - Increased in neonates and people living above 4,000 ft
- Hgb, Hct, and RBC count are concentrations:
 - Dependent on RBC mass and plasma volume
 - Values decrease if RBC mass decreases or plasma volume increases.
- Anemia is an indication of an underlying disorder or deficiency.

ETIOLOGY

- Never a normal variant:
 - May be the first manifestation of a systemic disorder
 - Always seek a cause.
- Excessive blood loss (most common cause):
 - Trauma
 - GI bleed
 - Menstruation
- Hemolysis (increased RBC destruction, RBC lifespan < 100 days):
 - Hypersplenism
 - Autoimmune hemolytic anemia
 - Mechanical trauma (prosthetic heart valves, vasculitis, thrombotic thrombocytopenic purpura [TTP], hemolytic uremic syndrome [HUS], or disseminated intravascular coagulation [DIC])

- Toxins
- Infections (malaria, babesiosis)
- Membrane abnormalities
- Intracellular RBC abnormalities (G6PD, sickle cell anemia, or thalassemia)
- Decreased RBC synthesis:
 - Classified by measurement of RBC size
 - Hypochromic/microcytic:
 - Iron deficiency
 - Thalassemia
 - Sideroblastic
 - Chronic disease
 - Normochromic/macrocytic:
 - Hypothyroidism
 - Folate deficiency
 - Vitamin B₁₂ deficiency
 - Liver disease
 - Myelodysplasia
 - Certain leukemias
 - Normochromic/normocytic:
 - Aplastic anemia
 - Chronic renal failure
 - Malignancy
 - Adrenal insufficiency
 - Hyperparathyroidism
 - Alcohol abuse
 - Acute blood loss

DIAGNOSIS

SIGNS AND SYMPTOMS

Depends on:

- Rapidity of onset:
 - Hypovolemia if acute
 - Asymptomatic if mild and chronic

History

- Underlying disease
- Severity and type of anemia
- Fatigue
- Decreased exercise intolerance
- Shortness of breath
- Dyspnea on exertion

- Chest pain/angina
- Syncope
- Blood in stool/tarry black stools
- Irregular or heavy menses
- Easy bruising or history of excessive bleeding

Physical-Exam

- Cardiovascular:
 - _ Tachycardia, cardiomegaly, or murmurs
 - _ Postural hypotension
- Dermatologic:
 - _ Skin:
 - Cool
 - Pallor
 - Jaundice
 - Purpura
 - Telangiectasia
 - Petechiae
 - Ecchymosis
 - _ Spoon-shaped nails (koilonychia)
- Neurologic:
 - _ Neuropathy
 - _ Altered mental status
- Bone (especially sternal) or joint pain (sickle cell disease)
- Hepatomegaly, splenomegaly
- Lymphadenopathy
- Findings reflect underlying disease

ESSENTIAL WORKUP

- CBC
- Vital signs/orthostatics
- Determine if:
 - _ Bleeding
 - _ Increased RBC destruction
 - _ Bone marrow suppression
 - _ Iron deficient

DIAGNOSIS TESTS & NTERPRETATION

Lab

- Type and crossmatch or type and screen
 - _ Depends on severity
- CBC

- RBC indices:
 - Mean corpuscular volume (MCV; normal: 80–100 μm^3)
 - Mean corpuscular hemoglobin (MCH; normal: 27–34 pg/cell)
 - Mean corpuscular hemoglobin concentration (MCHC; normal: 33–36%)
- Platelet count
 - Thrombocytosis suggests:
 - Iron deficiency
 - Myeloproliferative disorders
 - Inflammation
 - Infection
 - Neoplasm
 - Thrombocytopenia suggests:
 - Bone marrow malignancy
 - Hypersplenism
 - Sepsis
 - Vitamin B₁₂ or folate deficiency
 - Autoimmune disorders
- Reticulocyte (retic) count:
 - Normal 0.5–1.5% (retics/1,000 RBCs)
 - Increased retic count: Increased erythropoietic response to continued blood loss or hemolysis
 - Stable anemia with low retic count: Impaired RBC production
 - Active hemolysis or blood loss with low retic count: Concurrent disorder
 - Low retic count with pancytopenia: Aplastic anemia
 - Low retic count with normal WBC and platelets: Pure RBC aplasia
- Reticulocyte index (RI): $\text{Retic count (\%)} \times (\text{patient Hct}/\text{normal Hct})$:
 - RI < 2% implies inadequate RBC production.
 - RI > 2% implies increased RBC production with excessive RBC destruction or loss.
- WBC with differential and peripheral smear:
 - Leukopenia with anemia suggests bone marrow suppression, hypersplenism, or deficient vitamin B₁₂/folate
- Stool for occult blood
- Electrolytes, BUN, creatinine, glucose:
 - Chronic renal failure
- Urinalysis:
 - Hematuria
 - Hemoglobinuria in hemolytic anemia
- Workup strategy:
 - Hypochromic/microcytic anemias:
 - Iron

- Total iron-binding capacity
- Transferrin saturation
- Ferritin
- Macrocytic anemias:
 - Folate
 - Vitamin B₁₂
 - LFT
 - Thyroid function tests
- Hemolytic anemia:
 - Rapid fall in Hgb
 - Reticulocytosis
 - Fragmented RBCs
 - Increased LDH
 - Increased indirect bilirubin
 - Decreased serum haptoglobin
 - Coombs positive
- Special tests:
 - Peripheral smear:
 - Helmet cells/schistocytes—microangiopathic hemolysis
 - Teardrop cells—myelofibrosis
 - Spherocytes—autoimmune hemolysis
 - Leukoerythroblastic pattern—bone marrow replacement
 - Bite cells—oxidative hemolysis
 - RBC parasites—malaria or babesiosis
 - Target cells—liver disease
 - Burr cells—uremia
 - Sideroblasts—alcoholism or myelodysplasia
 - Howell–Jolly bodies—asplenia
 - Hgb electrophoresis for sickle cell/thalassemia
 - Iron, iron-binding capacity, transferrin saturation, ferritin:
 - Iron deficiency
 - Iron—decreased
 - Iron-binding capacity—increased
 - Transferrin saturation—decreased
 - Ferritin—decreased
 - Chronic disease:
 - Iron—decreased
 - Iron-binding capacity—decreased
 - Transferrin saturation—decreased/normal
 - Ferritin—normal/increased
 - Thalassemia:
 - Iron—normal

- Iron-binding capacity—normal
- Ferritin—normal
- Sideroblastic anemia:
 - Iron—increased
 - Iron-binding capacity—normal
 - Ferritin—increased

Diagnostic Procedures/Surgery

Bone marrow biopsy evaluates:

- Aplastic anemia
- Myelodysplasia
- Bone marrow malignancy
- Myeloproliferative disorders

DIFFERENTIAL DIAGNOSIS

- Acquired versus inherited anemia
- Anemia of chronic disease
- Blood loss
- CHF
- Dilutional anemia
- Hemolysis
- Malignancy
- Nutritional deficiency/malabsorption
- Toxic bone marrow suppression

Pediatric Considerations

- Hemolytic anemia of the newborn:
- Rh antibody crosses placenta when Rh-negative mother has Rh-positive child.

Pregnancy Considerations

- Physiologic or dilutional anemia in 3rd-trimester pregnancy:
- 25% increase of RBC mass and 50% increase in plasma volume

Geriatric Considerations

- Values for Hgb/Hct in healthy elderly are generally lower than in younger adults.
- This lower “normal” must be a diagnosis of exclusion.

TREATMENT

PRE HOSPITAL

Ongoing blood loss requires close assessment and rapid transport:

- Control bleeding to include wound packing and use of tourniquets if needed.

- Two large-bore IVs

INITIAL STABILIZATION/THERAPY

- Airway, breathing, circulation (ABCs)
- Oxygen
- IV fluid resuscitation with 0.9% NS if ongoing loss/hypotension

ED TREATMENT/PROCEDURES

- Depends on severity of anemia and acuteness of onset
- Transfusion for hemorrhage with unstable vital signs not responding to crystalloid resuscitation.
- Most anemias seen in ED are chronic and do not require immediate intervention.
- Therapy for specific anemia:
 - _ Iron deficiency:
 - FeSO₄: 300 mg PO TID
 - Investigate underlying cause.
 - Increased Hgb expected in 2–3 wk
 - _ Renal failure:
 - Endogenous erythropoietin is diminished.
 - Replace with recombinant erythropoietin
 - _ Autoimmune hemolytic anemia:
 - Corticosteroids (prednisone 60 mg/day until response)
 - Immunosuppressive agents
 - Plasmapheresis
 - Splenectomy if splenic sequestration
 - _ Drug-induced hemolytic anemia: Stop offending agent.
 - _ Anemia of chronic disease: Treat underlying disease.
 - _ Vitamin B₁₂ deficiency:
 - Vitamin B₁₂: 1,000 µg IM daily for 1 wk, then weekly for 1 mo, then monthly
 - Hematologic parameters normalize within 2 mo.
 - Neurologic symptoms present >6 mo may be permanent.
 - _ Folate deficiency:
 - Folic acid: 1 mg PO daily
 - _ Aplastic anemia
 - _ Antithymocyte globulin
 - _ Bone marrow transplantation:
 - Sickle cell anemia
 - Supportive care with oxygen, rehydration, analgesia
 - Treat precipitating cause.
 - _ Leukemia:
 - Bone marrow replacement

MEDICATION

- Iron supplements
- Erythropoietin for renal failure
- Corticosteroids for autoimmune
- Vitamin B₁₂
- Folic acid (B₉)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Unstable vital signs
- Ongoing blood loss
- Symptomatic anemia—angina/dyspnea/syncope/neurologic symptoms
- Need for transfusion
- Need for aggressive evaluation
- Severe anemia
 - Initial, unexplained Hgb < 8 g/dL
 - Major difficulty in obtaining outpatient care for patients whose Hgb are significantly low or when comorbidity is present

Discharge Criteria

Discharge vast majority of stable patients for outpatient workup.

FOLLOW-UP RECOMMENDATIONS

Newly diagnosed anemic patients need to be worked up:

- If stable for discharge from the ED, provide follow-up options for workup

PEARLS AND PITFALLS

- Anemia is an indication of an underlying disorder or deficiency.
- Severe or life-threatening cases require immediate correction via blood transfusion.
- Most cases seen in the ED are chronic and do not require immediate intervention.

ANGIOEDEMA

Sean-Xavier Neath

BASICS

DESCRIPTION

- Nonpruritic, well-demarcated, nonpitting edema of the dermis
- Due to the release of inflammatory mediators that cause dilation and increased permeability of capillaries and venules:
 - Mast cell mediated
 - Kinin related from the generation of bradykinin and complement-derived mediators
- Similar in pathologic basis to urticaria except that affected tissue lies deeper:
 - Urticaria affects superficial tissue and causes irritation to mast cells and nerves in the epidermis leading to intense itching.
 - Angioedema occurs in deeper layers, which have fewer mast cells and nerves, therefore causing less itching.
 - Angioedema can affect tissues other than the skin, for example, the gut.
 - Angioedema may be seen in a mixed picture along with urticaria
- Hereditary and acquired etiologies are due to deficiencies in the quantity and/or function of C1-INH rather than classic hypersensitivity reactions
- Hereditary angioedema (HAE):
 - An autosomal dominant disorder caused by a deficiency of C1-INH
 - The prevalence of HAE is estimated to range from 1:10,000 to 1:150,000.
 - C1-INH has a regulatory role in the contact, fibrinolytic, and coagulation pathways.
 - Deficiency results in unregulated activity of the vasoactive mediators bradykinin, kallikrein, and plasmin.
 - More than 100 mutations of the C1-INH gene have been reported.
 - Type 1: Decreased expression of C1-INH
 - Type 2: Normal plasma levels of C1-INH but the protein is dysfunctional
 - Type 3: Mutation in coagulation factor XII resulting in increased kinin production:
 - Symptoms increased by estrogen-containing medications
 - Episodes occur in all 3 types when inflammation, trauma, or other factors lead to depletion of C1-INH.
- Acquired angioedema:
 - Normal quantities and function of C1-INH
 - Type 1 is associated with lymphoproliferative diseases and caused by consumption of the C1-INH protein by malignant cells.
 - Type 2 is autoimmune caused by circulating antibodies that inactivate C1-

INH.

- ACE inhibitor–induced angioedema:
 - Accounts for 2030% of all angioedema cases presenting to ER reported in 0.1–2.2% of patients taking ACE inhibitors
 - Usually occurs during the 1st mo of taking the medication, however the 1st event may occur spontaneously after many years.

ETIOLOGY

- Kinin-related etiologies:
 - HAE
 - Acquired angioedema:
 - Lymphoproliferative
 - Autoimmune
 - ACE inhibitor induced
- Mast cell–mediated etiologies:
 - Food allergies:
 - Additives
 - Nuts
 - Eggs/milk
 - Shellfish
 - Soy/wheat
 - Drug allergies:
 - Aspirin
 - NSAID
 - Antihypertensives
 - Narcotics
 - Oral contraceptives
 - Insect stings
 - Physically induced:
 - Cold/heat
 - Exercise/trauma/vibrations
 - Stress
 - UV light
- Hypereosinophilic syndromes such as Gleich syndrome
- Thyroid autoimmune disease
- Idiopathic recurrent AE

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- A family history or history of recurrent episodes can be useful in the diagnosis. Use of culprit foodstuffs or medications, especially ACEIs should increase index of suspicion
- Abdominal pain associated with nausea, vomiting, and diarrhea
- Attacks of HAE are not associated with hives or itching
- Emotional stress or physical trauma can trigger attacks.

Physical-Exam

- The lesions of angioedema are large, swollen, and nonpitting wheals.
- The eyelids and lips are frequently involved.
- Involvement of the pharynx and larynx may cause airway obstruction.
- Lesions are often asymmetric and do not typically involve gravitationally dependent areas

ESSENTIAL WORKUP

- Diagnosis is made of clinical grounds based on the presentation of large nonpitting, nonpruritic wheals.
- A family history need not be present: 25% of HAE patients have a new mutation and may not have a positive family history.

DIAGNOSIS TESTS & NTERPRETATION

Lab

- CBC with differential, ESR, ANA, rheumatoid factor, C4 and C3 levels.
- Skin biopsy if an urticarial lesion is accessible

Diagnostic Procedures/Surgery

Measurement of C1-INH levels (not routinely available in EDs):

- Patients affected with HAE type 1 have very low levels; carriers will have half-normal levels.
- C4 and C2 levels are low during attacks in both hereditary and acquired forms.

DIFFERENTIAL DIAGNOSIS

- Edema:
 - SVC syndrome
 - Right heart failure
 - Constrictive pericarditis
 - Renal failure
 - Nephrotic syndrome
- Allergic contact dermatitis
- Blepharochalasis
- Facial cellulitis
- Facial lymphedema

- Edema secondary to autoimmune disorders:
 - Dermatomyositis
 - Lupus
 - Polymyositis
 - Sjögren syndrome
- Hypothyroidism

Pediatric Considerations

Recurrent angioedema presenting around puberty should raise suspicion of HAE.

TREATMENT

PRE HOSPITAL

- Establish IV access
- Early intubation may be necessary due to the rapid progression of laryngeal swelling.
- Administration of H1 blocker when available
- Epinephrine to be considered for laryngeal edema especially if itching or other signs of a mast cell etiology with histamine release is suspected.

INITIAL STABILIZATION/THERAPY

- Active airway management and supportive measures are the primary goals of emergency treatment.
- Intubation may be necessary in severe cases:
 - Orotracheal intubation is the technique of choice but may be difficult because of laryngeal edema, spasm, or soft-tissue swelling.
 - Consider advanced airway adjuncts such as the gum elastic bougie to assist in securing endotracheal tube placement.
 - Blind nasotracheal intubation if soft tissue swelling prohibits an oral approach
 - Transtracheal jet insufflation or cricothyrotomy may be necessary to control the airway.
- Epinephrine, antihistamines, and steroids in obstructive airway swelling, although patient response can be variable.

ED TREATMENT/PROCEDURES

- Acute angioedema with features of a type 1 hypersensitivity reaction:
 - Treat similarly to an allergic reaction with H1 and H2 blockers along with corticosteroids.
 - Epinephrine should be used in refractory cases where the benefits outweigh the risks.
 - For abdominal attacks consider the addition of parenteral pain relief,

antiemetics, and IV fluid replacement.

- HAE and acquired angioedema:
 - C1-INH
 - Fresh frozen plasma (FFP) may be used as an alternative to C1-INH.
 - The kallikrein inhibitor ecallantide (Kalbitor) was approved in 2009 for the treatment of acute attacks of HAE.
 - Tranexamic acid (Cyklokapron), an antifibrinolytic agent, is not as effective for acute attacks and is used primarily in prevention.

ALERT

- C1 inhibition has been standard therapy in Europe for many years; however, the US FDA has only recently been approving these medications for use in the US, therefore clinician and pharmacist recognition of the utility of these drugs may be limited.
- Therapy with FFP (as a source of nonpurified C1-INH) is advised with caution as it may paradoxically worsen some attacks due to its high concentration of complement components.
- Attenuated androgens, such as the anabolic steroids and gonadotropin inhibitor danazol, are used in the long-term prophylactic treatment. They may not have any effect for 24–48 hr in the acute setting.
- Angioedema associated with ACE inhibitors occurs in 0.1–0.2% of cases and requires immediate withdrawal of the ACE inhibitor. ACE inhibitor–related angioedema usually occurs within a week after starting ACE inhibitor therapy, but may occur much later.

MEDICATION

General principles of pharmacologic treatment are based on suspected underlying cause:

- Suspected HAE:
 - C1-INH
 - Ecallantide
 - Icatibant
- Non-HAE:
 - H1 blockers
 - H2 blockers
 - Corticosteroids
- C1 esterase inhibitor replacement proteins (C1-INHP):
 - In the US currently only plasma-derived products:
 - Cinryze: 20 U/kg IV slow IV infusion
 - Berinert: 20 U/kg IV slow IV infusion with additional doses if no improvement in 2 h, sooner if worsening or if laryngeal symptoms
 - In the EU recombinant C1-INHP is also available (at this time not yet approved by US FDA)
 - Ruconest (not yet FDA approved) 50 U/kg, generally does not require

repeat dosing

- Cimetidine: 300 mg IV
- Danazol: 400–600 mg PO up to 1 g/d. *Contraindicated in children and pregnancy.*
- Diphenhydramine: Adult: 50 mg IV; peds: 1–2 mg/kg slow IVP
- Ecallantide (kallikrein inhibitor available US only): 30 mg SC given as 3 separate injections (about 1 mL each anatomically distant from AE affected area)
- Epinephrine: 0.3–0.5 mg (use 1:1,000 dilution for SC route, and 1:10,000 for IV route); peds: 0.01 mg/kg SC/IV
- Racemic epinephrine: 2.25% solution (0.5 mL placed in a nebulizer in 2.5 mL of NS)
- FFP (if C1-INH is unavailable): Adult: 2 U
- Hydrocortisone: Adult: 500 mg IV; peds: 4–8 mg/kg/dose IV.
- Icatibant (bradykinin B2 receptor antagonist): 30 mg SC once
- Methylprednisolone: Adult: 125 mg IV; peds: 1–2 mg/kg IV
- Prednisone: Adult: 60 mg PO; peds: 1 mg/kg PO
- Ranitidine: Adult: 50 mg IV
- Stanazolol: 2 mg PO up to 16 mg/d:
 - Discontinued in the US
 - Contraindicated in children and in pregnancy
- Tranexamic acid: 1 g PO q3–4h for up to 48 h if necessary

Pediatric Considerations

Safety and efficacy of newer HAE treatment agents (such as C1-INH Cinryze and Berinert) have not been established in children as of this writing. Dosing for adolescents is suggested to be weight based at 20 U/kg.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with systemic symptoms that do not resolve completely will need to be hospitalized for observation.
- A monitored bed is recommended for those with airway involvement.

Discharge Criteria

- Patients presenting with minor symptoms of angioedema without progression after 4–6 hr of observation may be safely discharged home on a short course of steroids and antihistamines.
- Patients should be provided with an EpiPen and instructions on its use.

Issues for Referral

Patients should be evaluated by an allergist/immunologist after the initial presentation, especially if there is a family history of angioedema, or if the angioedema is accompanied by abdominal pain, or triggered by trauma.

FOLLOW-UP RECOMMENDATIONS

Patients without systemic symptoms who are stable for discharge should be seen in outpatient follow-up in a few days.

PEARLS AND PITFALLS

- Early measures should be employed to maintain the patient's airway.
- Consider use of newer agents in HAE patients (e.g., C1-INH and Kallikrein inhibition).

ANKLE FRACTURE/DISLOCATION

Sarah V. Espinoza • Leslie C. Oyama

BASICS

DESCRIPTION

Common mechanisms and injury patterns of the ankle:

- Mechanism of injury:
 - Inversion injury: Lateral ankle distraction and medial ankle compression
 - Avulsion fracture of the lateral malleolus
 - Oblique fracture of the medial malleolus
 - Eversion injury: Medial ankle distraction and lateral ankle compression
 - Avulsion fracture of medial malleolus
 - Oblique fracture of the fibula
 - External rotation injury:
 - Disruption of the tibiofibular syndesmosis, or a fibular fracture above the plafond
 - Anterior or posterior tibial fracture with separation of the distal tibia and fibula (unstable fracture)
 - Inversion and external rotation (Maisonneuve fracture):
 - Medial malleolus avulsion fracture or deltoid ligament tear
 - Disruption of the tibiofibular syndesmosis
 - Oblique fracture of the proximal fibula
 - Inversion and dorsiflexion (snowboarders' fracture):
 - Fracture of the lateral process of the talus
- Epidemiology
 - Most ankle fractures are malleolar
 - Common in young male and 50–70 yr old female
 - Associated with cigarette use and high BMI

Pediatric Considerations

- Ankle fractures in children often involve the physis (growth plate):
 - May result in angular deformity from growth plate injury
 - Associated with sports requiring sudden changes in direction and obese children
 - In children < 10 yr old, growth plate is weaker than epiphysis
- *Tillaux fracture*: Salter–Harris type III injury of the anterolateral tibial epiphysis external rotation of the foot
- *Triplane fracture*: Uncommon fracture of distal tibia with fracture lines in 3 distinct planes (coronal, transverse, sagittal)

SIGNS AND SYMPTOMS

- History of trauma
- Local ankle pain, swelling, deformity
- Inability to bear weight
- Soft tissue injury, swelling, ecchymosis, skin tenting, skin blanching
- Neurovascular compromise:
 - _ Diminished capillary refill
 - _ Diminished posterior tibialis (PT) or dorsalis pedis (DP) pulses
- Limited range of motion

History

- Discover the position of the ankle at the time of injury and area of most significant pain
- Determine if patient was able to bear weight immediately or if he or she needed assistance to walk afterward
- Ask if the patient heard audible “pop” or “snap,” as this may indicate partial or full tendon rupture

Physical-Exam

- *Ottawa Ankle Rules* (OAR), 100% sensitive: Decision tool for ordering radiographs in patients with suspected injury to the ankle and midfoot:
 - _ Malleolar zone (if any finding is present, then *ankle* radiographs are indicated):
 - Bony tenderness at the posterior edge or distal 6 cm of either malleoli (points A and B)
 - Inability to bear weight for 4 consecutive steps both immediately after the injury and in ED
 - _ Midfoot zone (if either finding is present, then *foot* radiographs are indicated):
 - Bony tenderness at the base of the 5th metatarsal (point C)
 - Bony tenderness of the navicular (point D)
 - Inability to bear weight for 4 consecutive steps both immediately after the injury and in ED
 - _ Considered a reliable tool in children > 5 yr
- Assess the skin for swelling, ecchymosis, skin tenting, disruption, or ischemia
- Careful evaluation of distal neurovascular status:
 - _ Capillary refill
 - _ Palpation or Doppler of DP and PT pulses
- Palpate proximal fibula for tenderness, especially when medial malleolus or deltoid ligament tenderness is present:

- Peroneal nerve is at risk for injury with a Maisonneuve fracture:
 - Wraps around the fibular head
 - Test anterior tibialis and extensor hallucis longus
 - Assess sensation in the 1st web space

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- Radiography:
 - Evaluate the mortise view for widening: Distance between talus to the medial and lateral malleoli should be uniform
- Unstable ankle fractures or dislocations require post reduction radiographs in all 3 planes after splinting
 - Anteroposterior (AP), lateral, and mortise (AP with a 20° lateral angle)
- AP and lateral radiographs of the tibia and fibula are indicated if a Maisonneuve fracture is suspected clinically
- Stress testing of the ligaments in a painful ankle is unnecessary in the ED if the patient will be re-examined in 3–7 days
- Stress radiographs of the ankle are usually unnecessary acutely
- CT scan or MRI:
 - Assess the degree of injury to the tibial plafond and associated ligamentous injury

Diagnostic Procedures/Surgery

N/A

DIFFERENTIAL DIAGNOSIS

- Ankle sprain
- Achilles tendon injury
- Os trigonum fracture
- 5th metatarsal fracture (Jones fracture)
- Peroneal tendon dislocation or injury
- Talar fractures
- Talar dome fracture/lesion
- Subtalar dislocations
- Calcaneal fractures
- Foot fractures
- Ankle diastasis
- Rattlesnake envenomation

Pediatric Considerations

- Injury to the growth plates may not be apparent on plain radiographs
- Consider splint immobilization, nonweight-bearing status, and orthopedic referral

- if clinical suspicion warrants, even in the setting of negative radiographs
- CT scan or MRI may be warranted to delineate the extent of the injury
- Inform parents of the possibility of growth abnormalities in patients with injury to the physis

TREATMENT

PRE HOSPITAL

- Immobilize with soft splint to reduce pain, bleeding, and further injury
- Cautions:
 - _ Traction devices are usually unnecessary:
 - Contraindicated with open injuries
 - _ Protruding bone should not be reduced; the wound should be covered with a clean dressing

INITIAL STABILIZATION/THERAPY

- Nonweight bearing
- Ice
- Compression
- Elevation

ED TREATMENT/PROCEDURES

- Ankle fracture:
 - _ All ankle fractures or dislocations require orthopedic referral
 - _ Open ankle fractures:
 - Remove contaminants
 - Apply moist sterile dressing
 - Assess tetanus immunity
 - Antibiotics
 - Emergent orthopedic consultation
 - _ Closed ankle fractures:
 - Dislocations should be reduced promptly to prevent complications
 - Apply *posterior splint* to immobilize foot in 90° angle with the application of bulky dressings and covered by a volar posterior and coaptation (U-shaped stirrup) splint
 - Sugar tong (coaptation) can be added for mediolateral support
 - _ *Stable injury*: (one-sided nondisplaced malleolar fracture without ligamentous injury)
 - Isolated injury to the lateral malleolus without medial involvement is virtually always stable
 - Apply posterior splint
 - _ *Unstable injury*: (both sides of the ankle are injured i.e., bi- or trimalleolar

fractures)

- Urgent orthopedic consultation
- Posterior splint as in stable injuries
- May require open reduction and internal fixation (ORIF) emergently before significant swelling develops
- *Neurovascular injury* requires emergent orthopedic consultation
- Ankle dislocations:
 - Closed reduction should be performed as rapidly as possible to minimize ischemia to the skin and reduce the risk of avascular necrosis of the talus
 - Skin tenting and evidence of neurovascular compromise are indications for immediate reduction, even prior to radiographs
 - Most ankle dislocations require ORIF
 - After reduction, place a posterior splint

MEDICATION

- Closed fractures:
 - Primarily analgesics (opioids)
- Dislocations or displaced fractures requiring closed reduction consider:
 - Short-acting benzodiazepine (midazolam 0.05–0.1 mg/kg IV) or barbiturate (methohexital 1–1.5 mg/kg IV) with opioid analgesic
- Open fractures:
 - Cefazolin: 2 g loading dose (peds: 50 mg/kg) IV
 - Gentamicin: 5–7 mg/kg q24h (peds: 2.5 mg/kg q8h) IV
 - Vancomycin: 1 g loading dose (10 mg/kg in children) if penicillin allergic
 - Tetanus toxoid if indicated

FOLLOW-UP

DISPOSITION

Admission Criteria

- Unstable ankle fractures require urgent orthopedic consultation and may require admission
- Open ankle fractures and dislocations should be admitted for debridement, irrigation, and IV antibiotics
- Ankle dislocations that are treated with either open or closed reduction
- Concern for compartment syndrome or neurovascular injury

Discharge Criteria

Simple nondisplaced stable ankle fractures without neurovascular compromise may be splinted for immobilization and discharged

FOLLOW-UP RECOMMENDATIONS

- Splinting
- Elevation of affected lower extremity
- Fitted for crutches and shown how to use them
- Placed on nonweight-bearing status of affected joint, until seen by orthopedist

PEARLS AND PITFALLS

- To reduce a dislocated ankle, partial flexion of knee of affected limb will decrease tension on Achilles tendon and ankle
- Differentiate between ankle fracture and subtalar fracture on physical exam: While the latter is rare, it is also rarely reducible
- Remember to look for other injuries including lumbar spine, hip, tibia, fibula, especially the proximal fibular neck, and foot

ANKLE SPRAIN

Taylor Y. Cardall

BASICS

DESCRIPTION

- Injuries to ligamentous supports of the ankle
- Ankle joint is a hinge joint composed of the tibia, fibula, and talus.
- Injuries may range from stretching with microscopic damage (grade I) to partial disruption (grade II) to complete disruption (grade III).

ETIOLOGY

- Forced inversion or eversion of the ankle
- Forceful collisions
- 85–90% of ankle sprains involve lateral ligaments:
 - Anterior talofibular (ATFL)
 - Posterior talofibular (PTFL)
 - Calcaneofibular (CFL)
 - Usually the result of an inversion injury
 - The ATFL is the most commonly injured.
 - If the ankle is injured in a neutral position, the CFL is often injured.
 - The PTFL is rarely injured alone.
- Injury to the deltoid ligament (connecting the medial malleolus to the talus and navicular bones) is usually the result of an eversion injury:
 - Often associated with avulsion at the medial malleolus or talar insertion
 - Rarely found as an isolated injury
 - Suspect associated lateral malleolus fracture or fracture of the proximal fibula (Maisonneuve fracture).
- Syndesmosis sprains (injury to the tibiofibular ligaments or the interosseous ligament of the leg):
 - Occur most commonly in collision sports
 - Syndesmosis injuries (“high ankle sprains”) have a higher morbidity and potential for long-term complications.

Pediatric Considerations

- Children <10 yr with traumatic ankle pain and no radiologic evidence of fracture most likely have a Salter–Harris I fracture.
- The ligaments are actually stronger than the open epiphysis.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

History may predict the type of injury found and should include:

- Time of injury
- Mechanism
- The presence of a “pop” or “crack”
- History of previous trauma
- Relevant medical conditions (e.g., bone or joint disease)
- Treatments attempted prior to arrival
- Ability to bear weight subsequent to the injury at scene and ED

Physical-Exam

- Aimed at detecting joint instability and any associated injuries:
 - Note the presence or absence of bony tenderness at posterior edge of medial and lateral malleoli as well as at the base of the 5th metatarsal.
- Document neurovascular status distal to the injury.
- Assess range of motion and compare it with the uninjured side.
- Stress testing in the ED is often limited by pain and may impair detection of ligament injury.
- The squeeze test helps identify syndesmosis injuries:
 - Squeeze tibia and fibula together at the midcalf; pain felt in the ankle indicates a positive test.

ESSENTIAL WORKUP

- The Ottawa Ankle Rules, a selective strategy for obtaining ankle radiographs in adults, suggest that foot or ankle radiographs are unnecessary except when any of the following are present:
 - Bony tenderness at the posterior edge of the distal 6 cm or tip of either malleolus
 - Bony tenderness along the base of the 5th metatarsal or navicular bone
 - Inability to take 4 unassisted steps both immediately after the injury and in the ED
- The rules have been prospectively validated by the original authors as well as independently by groups in the US, the UK, France, and other countries.

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- Ankle injuries should be radiographed if there is concern for fracture.
- Stress radiographs are rarely useful in the ED and should not be routinely ordered unless requested by a consultant.

DIFFERENTIAL DIAGNOSIS

- Ankle fracture (lateral, medial, or posterior malleolus) or dislocation
- Achilles tendon injury
- Maisonneuve fracture
- Os trigonum fracture
- 5th metatarsal fracture (Jones fracture)
- Transchondral talar dome fracture
- Peroneal tendon dislocation or injury

TREATMENT

PRE HOSPITAL

Immobilize ankle as necessary.

INITIAL STABILIZATION/THERAPY

- Prevent further injury; avoid weight bearing if painful.
- RICE (rest, ice, compression, elevation)

ED TREATMENT/PROCEDURES

- The goal of treatment is reduction of pain and return to normal activity without long-term pain or joint laxity.
- Existing evidence supports early mobilization and functional treatment:
 - Unstable ankles (i.e., grade III) or those with severe pain may benefit from brief immobilization followed by early return to functional treatment.
- Grade I or II sprains can be treated with functional support (elastic bandage, air splint, gel splint, etc.):
 - Recent evidence suggests an elastic bandage dressing coupled with an air stirrup splint is superior to other forms of immobilization.
- Grade III sprains can be treated by immobilization (sugar tong with posterior splint or elastic bandage dressing coupled with air stirrup splint) and early orthopedic consultation or referral.
- Crutches may be needed initially for comfort, but encourage weight bearing as tolerated for grades I and II.
- Once acute pain and swelling have resolved, strengthening exercises and proprioceptive training (e.g., balance board, small circle walking) improve ankle strength and function and prevent reinjury.
- Full sports activities may be resumed only when running and turning are pain free.
- Ankle taping, air splints, or gel splints reduce the risk of recurrent injury in high-risk sports such as basketball, volleyball, soccer, and running.

MEDICATION

- NSAIDs are useful in treating acute pain:

- Ibuprofen: 800 mg (peds: 5–10 mg/kg) PO TID
- Topical NSAIDs have been shown to control pain and shorten healing time with acute ankle sprain:
 - Diclofenac sodium 1% gel: Apply 4g to affected area QID
- Narcotic analgesics may be required for severe pain.

FOLLOW-UP

DISPOSITION

Admission Criteria

An isolated ankle sprain should not require admission.

Discharge Criteria

An isolated ankle sprain may be safely discharged from the ED with appropriate treatment, prescriptions, aftercare instructions, and referrals.

Issues for Referral

Patient copies of any radiographs obtained may facilitate early follow-up.

FOLLOW-UP RECOMMENDATIONS

- Patients with grade I and II sprains should be instructed to follow up with the primary care physician in 1–2 wk.
- Patients with grade III sprains and syndesmosis injuries should be referred to an orthopedic surgeon or sports medicine specialist within 7–10 days.

PEARLS AND PITFALLS

- The Ottawa Ankle Rules may decrease the need for radiographs.
- Immobilization with an elastic bandage dressing coupled with an air stirrup splint followed by early functional therapy may shorten healing time.

- S93.499A Sprain of other ligament of unspecified ankle, init encntr

ANKYLOSING SPONDYLITIS

Daniel R. Lasoff • Brian K. Snyder

BASICS

DESCRIPTION

- Chronic inflammatory disease, primarily affects the axial skeleton with predilection toward the spine and sacroiliac (SI) joints:
 - SI joints 100%
 - Cervical spine 75%
 - Thoracic spine 70%
 - LS spine 50%
 - Hip joints 30%
 - Shoulder joints 30%
- *Spondylitis* (inflammation of vertebrae) of ankylosing spondylitis (AS) begins at the insertions of the outer fibers of the annulus fibrosus (enthesitis) of the vertebrae:
 - Ossification (syndesmophyte formation) may lead to complete fusion, *ankylosis*, of the vertebrae.
 - Extensive spinal involvement causes the radiographic appearance of the brittle “bamboo spine.”
- Onset 15–35 yr of age
- Male to female ratio is between 2:1 and 3:1.

ALERT

AS patients are at 4 times the risk for fracture and paralysis compared to the general population. They are 11 times more likely to have spinal cord injuries.

RISK FACTORS

Genetics

Strong genetic component. HLA-B27 is present in 80–90% of patients with AS.

ETIOLOGY

Disease is likely triggered by environmental factors such as infection in genetically predisposed individuals.

DIAGNOSIS

SIGNS AND SYMPTOMS

- **Spinal:** Low back pain with sacroiliitis is the most common presentation:
 - Inflammatory back pain, improving with movement and exercise.

- Higher risk for serious injury from milder traumatic mechanisms.
- Extraspinal inflammatory conditions (which may precede spinal symptoms):
 - Ocular (the most common):
 - Uveitis (25–40% occurrence). Usually acute and unilateral in onset. Can alternate eyes.
 - Cardiac:
 - Slight increased risk of CAD
 - Increased risk for valvular incompetence with prolonged course of AS.
 - Pulmonary:
 - Progressive restrictive lung disease due to limited expansion and fibrosis
 - GI:
 - 5–10% of patients with inflammatory bowel disease.
 - GU:
 - Risk for IgA nephropathy or amyloidosis. Also increased risk for NSAID nephropathy from anti-inflammatory use.
 - Enthesitis (inflammation at tendon or ligament insertion):
 - Often Achilles tendonitis or plantar fasciitis

History

- Patients <40 yr of age with insidious onset of low back pain >3 mo, radiating into gluteal areas from SI region, and progressing to involve the entire spinal region:
 - Worse with rest and improved with mild activity. Pain in 2nd half of night waking patient from sleep
 - Women may have more cervical and extraspinal manifestations than men.
- Possible prior history of uveitis, restrictive pulmonary disease, inflammatory bowel disease, enthesitis, or migrating or polyarthritis.

Physical-Exam

- Tenderness over SI joints elicited with direct pressure over both of patient's ASIS simultaneously.
- Dactylitis or enthesitis.
- Flattening of the normal lumbar lordosis
- Exaggeration of thoracic kyphosis
- Limitation of spinal movement
- Reduction in chest expansion

Pediatric Considerations

- Patients with juvenile ankylosing spondylitis (JAS) may commonly be misdiagnosed as recurrent sprains
- Onset of JAS is late childhood or adolescence (between 8 and 12 yr, before age

20); primarily boys.

- JAS has a much greater predilection for extraspinal joints and entheses of the lower extremities; in addition to SI tenderness, examine for:
 - Asymmetrical pauciarthritides of the joints of the lower extremities
 - Enthesitis of the ankle, knee, or tarsal bones. Plantar fasciitis and Achilles tendonitis are often common findings.

ESSENTIAL WORKUP

- Exclude fracture and neurologic injury in any patient with suspected AS for any new spinal pain (even without trauma).
- Exclude sepsis or septic joint if clinically indicated.
- Evaluate for sacroiliitis with pelvic rock test (compression) or Patrick test (downward pressure on the knee of a flexed and externally rotated leg and the contralateral ASIS causing sacral distraction).

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC may show mild leukocytosis with slight to moderate anemia and thrombocytosis.
- BUN, creatinine, and electrolytes may be useful to assess renal involvement.
- Erythrocyte sedimentation rate (ESR) or C-reactive protein (CRP) may be elevated, but are of limited use in the ED.
- HLA-B27 testing can be performed by a specialist. A negative result does not rule out AS.

Imaging

- Pelvic radiograph: Should be done in any adult patient suspected of undiagnosed ankylosing spondylitis:
 - Sacroiliitis is essential to the diagnosis of AS; this is seen initially as subchondral bony erosions on the iliac side of the SI joint, which later manifest as bony proliferation and sclerosis.
 - If plain films are negative for sacroiliitis, MRI should be considered.
- Lumbar, thoracic, and cervical spine radiographs to exclude fracture for complaint of new pain to these areas with or without trauma
- CT should be performed to further evaluate possible fractures on plain radiographs.
- MRI should be performed emergently on any patient with neurologic deficit.
- Chest radiograph may show patchy inflammatory infiltrates or apical fibrosis.

Diagnostic Procedures/Surgery

- Electrocardiogram indications:
 - Symptoms of acute coronary syndrome (slightly increased risk compared to

general population for CAD)

- Symptomatic arrhythmia:
 - o AV block
- Echocardiogram indications:
 - New murmur: Increased predilection for aortic insufficiency with AS
 - Evidence of new heart failure.

DIFFERENTIAL DIAGNOSIS

- **JAS:**
 - Onset before age 20
 - More enthesitis and extraspinal joint involvement.
- **Reactive arthritis (formerly Reiter syndrome):**
 - Arthritis, urethritis, and conjunctivitis beginning about 1 mo after an episode of urethritis or enteritis.
- **Enteropathic arthritis:**
 - Crohn's disease or ulcerative colitis
 - Primarily involves knee, elbow, ankle, or wrist, and usually exacerbated by flares of the bowel disease
- **Psoriatic arthritis:**
 - Psoriasis rash
 - Much greater predilection for the hands and feet with higher incidence of dactylitis.
- **Septic arthritis:**
 - Exclude with arthrocentesis if clinically suspected in single joint involvement.
- **Mechanical low back pain:**
 - Improved with rest and exacerbated by exercise without signs of systemic inflammatory process.
- **Spinal epidural abscess:**
 - More constant, unremitting, and typically associated with fever and history of IVDA or immunosuppression.
- **Neoplastic low back pain:**
 - Typically in patients older than 40, more constant and unremitting, and more characteristically at night.

TREATMENT

PRE HOSPITAL

ALERT

- High risk of spinal injury from minor trauma.
- Spinal immobilization must avoid creating further injury:

- Cushion stabilization and scoop board in position of comfort may be a better approach than cervical collar and/or backboard.
- Intubation difficulty
 - Cervical and TMJ restriction may limit success in all but fiberoptic techniques.
 - Consider alternative airway approaches such as LMA or bag valve mask with oral airway until definitive airway can be achieved safely (usually fiberoptic).
- Ventilation difficulty
 - Chest wall restriction from deformity and pulmonary fibrosis
- CPR may carry a higher likelihood of rib fractures

ED TREATMENT/PROCEDURES

- Exclude cord compression if clinically suspected (MRI is the study of choice).
- Exclude spinal fracture for any new spinal pain (CT may be necessary).
- Exclude infection if clinically suspected with laboratory analysis and arthrocentesis.
- Control pain and inflammation with NSAIDs

MEDICATION

- Nonselective NSAIDs:
 - Ibuprofen: 35 mg/kg/d divided QID, max. 50 mg/kg/d (adult: 300–800 mg PO TID or QID)
 - Indomethacin: 1–2 mg/kg/d divided BID or QID, max. 4 mg/kg/d (adult: 25 mg PO BID or TID)
 - Not well tolerated, especially at higher doses because of GI and CNS effects
 - Naproxen: 10 mg/kg/d divided BID, max. 1,000 mg/d (adult: 250–500 mg PO BID)
- COX 2 inhibitors:
 - Celecoxib (adult: 100 mg–200 mg PO BID)
- TNF- α inhibitors:
 - Adalimumab (adult: 40mg SubQ q2wk)
 - Etanercept (adult: 50mg SubQ qwk)

Pregnancy Considerations

- NSAIDs should be avoided in pregnancy.
 - Acetaminophen is 1st line
 - Opioids are 2nd line

Geriatric Considerations

NSAID use may increase risk in the elderly for cardiovascular disease, GI bleeding, renal function, and hypertension. Although effective in select patients, close follow-up is

prudent.

ALERT

- NSAIDs:
 - _ GI bleeding risks
 - Elderly, history of PUD, concurrent use of glucocorticoids, anticoagulants, aspirin, smoking, alcohol.
 - Consider celecoxib or adding an H2 blocker or PPI if patient is at higher risk for GI bleeding.

Second Line

Consider if NSAIDs or acetaminophen are ineffective at appropriate doses:

- Opioid analgesics, muscle relaxants, or low-dose steroids.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Acute neurologic impairment
- Intractable pain
- Sepsis or septic joint cannot be excluded.

Discharge Criteria

- No serious injuries or neurologic deficit
- Pain is manageable to the patient

Issues for Referral

- The patient should be encouraged to obtain a medical alert bracelet.
- Rheumatology:
 - _ Patients with evidence of a new diagnosis of AS should be considered for early referral to a specialist in rheumatology for immunomodulative therapy.
- Physical medicine and rehabilitation:
 - _ Resting splints for inflamed joints
 - _ Orthoses for enthesitis (such as heel cushion inserts to rest Achilles tendon attachment)

FOLLOW-UP RECOMMENDATIONS

- Routine primary care re-evaluation within 1–2 wk to assess response to treatment.
- Referral to a rheumatologist for immunomodulating medications.
- Earlier follow-up in any patient with higher risk for adverse response to NSAIDs:

- Elderly, hypertensive patients, and patients with higher GI bleeding risks.

PEARLS AND PITFALLS

- Intubation is likely to be difficult and should avoid neck repositioning due to risk of C1 subluxation.
 - Consider airway adjuncts (such as LMA) until a definitive airway (usually fiberoptic) can be safely assured.
- Immobilization must avoid creating additional injury
 - Consider cushion/tape stabilization in position of comfort rather than standard cervical collar and backboard
- Minor traumatic injuries in AS can result in spinal fracture and possible cord injury. Maintain a high clinical suspicion.

CODES

ICD9

720.0 Ankylosing spondylitis

ICD10

- M45.2 Ankylosing spondylitis of cervical region
- M45.8 Ankylosing spondylitis sacral and sacrococcygeal region
- M45.9 Ankylosing spondylitis of unspecified sites in spine

ANTICHOLINERGIC POISONING

Patrick M. Whiteley

BASICS

DESCRIPTION

- Central and peripheral cholinergic blockade
- Depending on the drug involved, antagonism occurs at muscarinic (most common), nicotinic, or both receptors.
- Onset of activity: 15–30 min after ingestion
- Duration of effect: 2–24 hr

ETIOLOGY

- Many drugs contain anticholinergic properties:
 - Mild at therapeutic doses
 - Life threatening in overdose
- Anticholinergic substances:
 - Antihistamines
 - Belladonna alkaloids and synthetic congeners
 - Antiparkinsonian drugs
 - Cyclic antidepressants
 - Antipsychotics (neuroleptics)
 - Mydriatics
 - Skeletal muscle relaxants (orphenadrine, cyclobenzaprine)
 - Antispasmodics
 - Mushrooms—*Amanita muscaria*, *Amanita pantherina*
 - Plants—deadly nightshade, mandrake, henbane
 - Jimson weed—smoked or ingested

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Onset and duration of symptoms
- Type and extent of ingestion/exposure

Physical-Exam

- Classic toxidrome:
 - “**Mad as a hatter**”—altered mental status
 - “**Hot as a hare**”—hyperthermia

- “*Red as a beet*”—flushed skin
- “*Dry as a bone*”—dry skin and mucous membranes
- “*Blind as a bat*”—blurred vision secondary to mydriasis
- General:
 - Hyperthermia
 - Altered mental status
- Ocular:
 - Unreactive mydriasis
 - Inability to accommodate
- Cardiovascular:
 - Sinus tachycardia
 - Dysrhythmias (rare except in massive ingestions)
 - Hypotension/HTN
 - Cardiogenic pulmonary edema
- Pulmonary:
 - Tachypnea
 - Respiratory failure
- GI:
 - Decreased/absent bowel sounds
 - Dysphagia
 - Decreased GI motility
 - Decreased salivation
- Genitourinary (GU):
 - Urinary retention
- Integument:
 - Decreased sweating
 - Flushed skin
 - Dry skin and mucous membranes
- CNS:
 - Altered mental status
 - Auditory or visual hallucinations
 - Coma
 - Seizures

ESSENTIAL WORKUP

Diagnosis based on clinical presentation and an accurate history

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Urine toxicologic screen if clinically indicated
- Electrolytes, BUN, creatinine, and glucose
- CBC

- Creatine phosphokinase (CPK) if suspected rhabdomyolysis
- Urinalysis
- Acetaminophen and salicylate levels:
 - _ Detects occult ingestion (e.g., Tylenol PM)

Imaging

ECG:

- Sinus tachycardia most common
- QRS prolongation
- AV blockade
- Bundle branch block pattern
- Dysrhythmias

DIFFERENTIAL DIAGNOSIS

- Sympathomimetic intoxication
- Withdrawal syndrome
- Acute psychiatric disorders
- Sepsis
- Thyroid disorder

TREATMENT

PRE HOSPITAL

Transport all pills/pill bottles involved in overdose for identification in ED.

INITIAL STABILIZATION/THERAPY

- Airway, breathing, and circulation (ABCs):
 - _ Airway control essential
 - _ Administer supplemental oxygen.
 - _ IV access
 - _ Cardiac monitor and pulse oximetry
- Naloxone, thiamine, D₅₀ (or Accu-Chek) if altered mental status

ED TREATMENT/PROCEDURES

- Supportive care:
 - _ IV rehydration with 0.9% NS
 - _ Standard aggressive cooling measures for hyperthermia
 - _ Use benzodiazepines for treatment of agitation:
 - Avoid phenothiazines owing to anticholinergic effects.
 - _ Treat seizures with benzodiazepines and barbiturates.
 - _ Dysrhythmias:
 - Use standard antidysrhythmics.

- Avoid class Ia antidysrhythmic owing to the quinidine-like effect of many anticholinergic drugs.
- Sodium bicarbonate boluses may reverse the quinidine-like effects.
- Decontamination:
 - Administer activated charcoal for oral ingestions if within 1 hr.
 - Ocular lavage for eyedrop exposure
- Physostigmine (Antilirium):
 - Reversible acetylcholinesterase inhibitor that crosses the blood–brain barrier
 - Short-term reversal of both central and peripheral anticholinergic effects
 - Indicated in the presence of peripheral anticholinergic signs and the following:
 - Seizures unresponsive to conventional therapy
 - Uncontrollable agitation
 - Use with caution if prolonged QRS is present on ECG owing to risk of dysrhythmias (especially asystole), seizures, and cholinergic crises:
 - Place on cardiac monitor.
 - Observe for cholinergic symptoms.
 - Contraindications:
 - Cyclic antidepressant overdose (potentiates toxicity)
 - Cardiovascular disease
 - Asthma/bronchospasm
 - Intestinal obstruction
 - Heart block
 - Peripheral vascular disease
 - Bladder obstruction

MEDICATION

- Activated charcoal: 1 g/kg PO
- Dextrose: 50–100 mL D₅₀ (peds: 2 mL/kg of D₂₅ over 1 min) IV; repeat if necessary
- Diazepam: 5–10 mg (peds: 0.2–0.5 mg/kg) IV every 10–15 min
- Dopamine: 2–20 µg/kg/min IV with titration to effect
- Lorazepam: 2–4 mg (peds: 0.03–0.05 mg/kg) IV every 10–15 min
- Physostigmine: 0.5–2.0 mg (peds: 0.02 mg/kg) IV over 5 min; repeat if necessary in 30–60 min
- Phenobarbital: 10–20 mg/kg IV (loading dose); monitor for respiratory depression
- Thiamine (vitamin B₁): 100 mg (peds: 50 mg) IV or IM

First Line

Lorazepam or Diazepam

Second Line

Physostigmine (use with caution and consult with medical toxicologist)

FOLLOW-UP

DISPOSITION

Admission Criteria

- ICU admission for moderate to severe anticholinergic symptoms (agitation control, temperature control, and observation for seizures or dysrhythmias)
- Any patient receiving physostigmine

Discharge Criteria

Mild and improving symptoms of anticholinergic toxicity after 6–8 hr of ED observation

Issues for Referral

- Substance abuse referral for patients with recreational anticholinergic abuse
- Patients with unintentional (accidental) poisoning require poison prevention counseling.
- Patients with intentional (e.g., suicide) poisoning require psychiatric evaluation.

FOLLOW-UP RECOMMENDATIONS

Appropriate psychiatric referral for intentional ingestions

PEARLS AND PITFALLS

- Aggressively treat hyperthermia.
- Antipyretic medications are not effective in toxic hyperthermia.
- Use physostigmine cautiously and consult with medical toxicologist when available.

ANTIDEPRESSANT POISONING

Patrick M. Lank

BASICS

DESCRIPTION

- Antidepressants are the most commonly prescribed psychiatric medications in US.
- Patients who overdose on antidepressants may be on various antidepressants, divided into SSRIs, SNRIs, and atypical. Concomitant usage of atypical antipsychotics and mood stabilizing medications, some of which are FDA approved for the treatment of depressive disorders, is common.
- Antidepressants may be prescribed for multiple other indications, including chronic pain syndromes, anxiety, eating disorders, substance abuse, and sleep disorders.
- Tricyclic antidepressants (TCAs) are covered in a separate chapter

ETIOLOGY

Mechanism

- SSRIs:
 - Increase serotonin at the synapse by preventing the reuptake of serotonin by the presynaptic neuron.
 - SSRIs include paroxetine, fluoxetine, sertraline, citalopram, and escitalopram
- SNRIs
 - Similar to SSRIs, but also inhibit reuptake of norepinephrine.
 - Developed because said to have fewer side effects than SSRIs at therapeutic dose, although not true for toxicity.
 - SNRIs include venlafaxine, desvenlafaxine, and duloxetine.
- Atypical antidepressants:
 - Have variable effects on serotonin, norepinephrine, and dopamine.
 - Include mirtazapine, trazodone, and bupropion
- Atypical antipsychotics:
 - Most antipsychotics have activity at dopamine receptors, although variable agonism/antagonism depending on medication and dopamine receptor.
 - Additional activity at serotonin, α -adrenergic, histamine, and muscarinic receptors.
- Psychiatric medications also have variable potassium and sodium channel blockade, leading to cardiotoxicity (QT and QRS prolongation, respectively).

DIAGNOSIS

SIGNS AND SYMPTOMS

- SSRIs:
 - Traditional SSRIs (fluoxetine, paroxetine, sertraline):
 - Sedation
 - Serotonin syndrome
 - In single substance overdose, rarely will cause severe medical effects
 - Citalopram/Escitalopram:
 - Somnolence, vomiting, tachycardia
 - QTc prolongation
 - Seizures (more common in citalopram)
 - Exhibit *delayed* toxicity (up to 12 hr after ingestion)
- SNRIs:
 - Duloxetine:
 - Somnolence, vomiting, tachycardia
 - Seizures rare
 - Venlafaxine/Desvenlafaxine:
 - Seizures
 - QTc prolongation
- Atypical antidepressants:
 - Bupropion
 - Sedation
 - Seizures
 - QRS & QTc prolongation
 - Trazodone:
 - Sedation
 - QTc prolongation
 - Hypotension
 - Priapism
 - Mirtazapine:
 - Sedation
 - QTc prolongation
 - Possible neutropenia in chronic dosing
- Atypical antipsychotics:
 - Variable dopamine receptor activity
 - Developed for fewer extrapyramidal symptoms (EPS), particularly tardive dyskinesia, than typical antipsychotics
 - Most common symptoms in overdose include sedation, tachycardia, and miosis
 - Clozapine:
 - Agranulocytosis (in up to 1% taking chronically)
 - Sialorrhea
 - Cardiomyopathy
 - Anticholinergic delirium

- Olanzapine:
 - Anticholinergic delirium
 - QTc prolongation
- Quetiapine:
 - Hypotension from significant α_1 -antagonism
 - QTc prolongation
 - Anticholinergic delirium
- Ziprasidone:
 - Sedation
 - QTc prolongation → increased risk of torsade
- Aripiprazole:
 - No QTc prolongation
 - Hypotension
 - Prolonged CNS dysfunction

ESSENTIAL WORKUP

- Determine agents ingested, dose, and time of ingestion:
 - Investigate for coingested drugs.
- Rapid bedside glucose if altered mental status

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Specific drug levels rarely available and do not guide emergent management
- ECG:
 - For evaluation of QTc and QRS width
- Urine pregnancy:
 - In females of childbearing age
- Electrolytes, BUN, creatinine, glucose
- Urine drug of abuse screening:
 - Rarely changes clinical management
- Salicylate and acetaminophen concentrations
 - Very common coingestants in suicidal patients
- Serum ethanol:
 - To evaluate ethanol intoxication as contributing to altered mental status

Imaging

- CT of brain to evaluate for other causes of depressed mental status
- CXR if intubated or hypoxic

DIFFERENTIAL DIAGNOSIS

- TCA overdose
- Ethanol overdose

- Isoniazid overdose
- Hypoglycemia
- Hypoxemia
- Hyponatremia
- Hypocalcemia
- Withdrawal syndromes
- Serotonin syndrome
- Head trauma
- Opioid intoxication
- Sedative–hypnotic overdose
- Mood stabilizer/antiepileptic overdose
- DKA

TREATMENT

PRE HOSPITAL

- In cases of suspected overdose, bring all medication bottles to hospital with patient.
- ABCs
- 0.9% NS IV fluids as needed for hypotension
- Benzodiazepines as needed for seizures

INITIAL STABILIZATION/THERAPY

- ABCs:
 - Administer oxygen.
 - Place on cardiac monitor and measure pulse oximetry.
 - Establish IV access
 - Intubate as needed for airway protection or respiratory status.
- Rapid bedside glucose measurement
- Naloxone or D₅₀W as indicated for altered mental status and rapid clinical evaluation
 - Flumazenil is not recommended for mixed-overdose patients, patients with underlying seizure disorder, or patients chronically on benzodiazepines.
- May give diphenhydramine 25–50 mg IM/IV or Cogentin 1 mg IV for EPS

ED TREATMENT/PROCEDURES

- GI decontamination:
 - Do not attempt decontamination in a patient who cannot protect their airway.
 - Intubation solely for decontamination purposes, however, is not recommended.
 - Activated charcoal may be beneficial in early presenting overdoses.

- For QRS widening, administer sodium bicarbonate IV bolus.
 - Sodium bicarbonate infusion (i.e., “bicarb drip”) is NOT appropriate for use with QRS widening, as it is ineffective and potentially limits ability to provide sodium bicarbonate boluses.
- Treat hypotension unresponsive to IV fluids with norepinephrine rather than dopamine owing to α_1 receptor antagonism.
- Treat seizures with:
 - Initial therapy: Benzodiazepines
 - For refractory seizures: Barbiturates
- Treat symptoms of serotonin syndrome (fever, AMS, tachycardia, rigidity, hyperreflexia) with benzodiazepines and active cooling

MEDICATION

- Activated charcoal: 50–75 g PO initial dose; better to give 10g charcoal per 1g ingested xenobiotic as tolerated up to 100g PO
- Benzotropine 1 mg PO/IV
- Diazepam: 5–10 mg IV bolus (peds: 0.1 mg/kg IV bolus or 0.5 mg/kg rectal)
- Diphenhydramine 25–50 mg IM/IV (peds 1 mg/kg)
- Lorazepam: 2–4 mg (peds: 0.1 mg/kg) IV bolus
- Naloxone: 0.4–2 mg (peds: 0.1 mg/kg) initial bolus; may repeat up to a total of 10 mg
- Norepinephrine: 0.5–2 μ g/kg IV infusion
- Phenobarbital: 15–20 mg/kg IV max. dose is 2 g; caution: Likely to develop respiratory depression with IV loading doses
- Sodium bicarbonate: 1 mEq/kg IV bolus (adult 8.4%; peds: < 50 kg, 4.2%)

FOLLOW-UP

DISPOSITION

Admission Criteria

- 24 h telemetry admission for ingestions of the following: Citalopram, escitalopram, venlafaxine, desvenlafaxine, bupropion
 - Asymptomatic patients 6 hr after ingestion of other antidepressant medications do not require medical admission
- Coma
- Altered mental status
- Symptoms of NMS
- Hemodynamic compromise
- ECG changes
- Suicidal patients should be on a 1:1 observation

Discharge Criteria

- Asymptomatic patients of less toxic antidepressants > 6 hr after ingestion may be medically cleared for psychiatric admission.
- Discharge only asymptomatic patients who are not suicidal.

FOLLOW-UP RECOMMENDATIONS

Psychiatry referral for patients with intentional overdose

PEARLS AND PITFALLS

- For QRS widening, administer sodium bicarbonate IV bolus.
- Overdose with citalopram, venlafaxine, and bupropion have the possibility of being more severe than overdoses with other SSRIs and SNRIs and should prompt medical observation prior to clearance for psychiatric hospitalization.
- For any overdose, call your regional poison center at 1-800-222-1222

AORTIC DISSECTION, THORACIC

Jeffrey I. Schneider • Jonathan S. Olshaker

BASICS

DESCRIPTION

- Aortic dissection begins when there is an intimal tear.
- Blood then dissects through the media under aortic systolic pressure.
- It is thought that hypertension is a major factor in the dissection process.
- Dissections can start proximally at the root and dissect distally to involve any or all branches of the aorta, such as the carotid and subclavian arteries.
- The dissection process can also proceed proximally to involve the aortic root, the coronary ostia, and the pericardium.
- Dissection that progresses proximally may lead to occlusion of the coronary ostia, aortic valve incompetence, or cardiac tamponade.
- Classification related to portion of aorta involved:
 - Stanford classification:
 - Type A: Ascending aorta
 - Type B: Distal to ascending aorta
 - DeBakey classification:
 - DeBakey I: Intimal tear in aortic arch or root
 - DeBakey II: Ascending aorta
 - DeBakey III: Distal to takeoff of left subclavian artery
- Peak age for occurrence:
 - Proximal dissection: 50–55 yr
 - Distal dissection: 60–70 yr

Pregnancy Considerations

Risk of dissection increases in the presence of pregnancy:

- In women < 40 yr of age, 50% of dissections occur during pregnancy.

ETIOLOGY

Any process that affects the mechanical properties of the aortic wall can lead to dissection:

- Hypertension (72% of patients in the Registry of Acute Aortic Dissection)
- Congenital heart disease (bicuspid aortic valve, coarctation)
- Aortic wall connective tissue abnormalities (cystic medial necrosis)
- Connective tissue disease (Marfan disease, Ehlers–Danlos syndrome)
- Pregnancy
- Infectious/inflammatory conditions that can cause vasculitis (lupus, syphilis, endocarditis, giant cell arteritis, rheumatoid arthritis, Takayasu arteritis)

- Previous cardiac surgery including CABG, aortic valve repair
- Tobacco use

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Chest pain:
 - May be absent in as many as 15% of patients
 - Substernal if type A dissection
 - Intrascapular if descending thoracic dissection
 - Lumbar if abdominal aorta involved
 - Starts abruptly
 - Usually described as sharp
 - Most severe at onset
- Back pain:
 - Commonly interscapular or lumbar
- Combination of chest, back, and abdominal pain
- Neurologic complaints:
 - Visual changes
 - Stroke symptoms
- Aortic dissection may present with atypical symptoms that can result in a delay of diagnosis
 - Abdominal pain
 - Chest pressure
 - Leg pain
 - Syncope
 - Fever
 - Nausea, vomiting

Geriatric Considerations

Elderly are less likely to undergo surgery and have a higher mortality rate

- Elderly are less likely to describe their pain as abrupt in onset, have a pulse deficit, or have aortic insufficiency

Physical-Exam

- HTN:
 - 35–40% may be normotensive.
- Pulse deficits:
 - Discrepancies in BP between limbs
 - Usually in upper extremities

- Neurologic/spinal cord deficits
- Murmur of aortic regurgitation:
 - Occurs in up to 31% of patients
 - Musical, vibrating quality with variable intensity
 - Heard best along right sternal border
- Shock
 - If pericardial rupture or myocardial infarction (MI) from dissection into a coronary artery
- Atypical presentations
 - Ischemic lower extremity
 - Altered mental status
 - Congestive heart failure

ESSENTIAL WORKUP

ECG:

- Useful in ruling in or out ST-elevation MI or ischemia
- Dissection may involve coronary ostia and cause MI:
 - Inferior MI (right coronary artery lesion) is more common than left coronary artery territory.
- Useful for evaluating the presence of left ventricular hypertrophy
- A normal ECG in the presence of severe, acute-onset chest/back pain should heighten one's suspicion of an aortic dissection.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Leukocytosis
- Hematuria
- Elevated BUN and creatinine
- Elevated amylase secondary to bowel ischemia
- Elevated cardiac enzymes due to myocardial ischemia
- D-dimer < 500 ng/mL makes the diagnosis of dissection unlikely

Imaging

- CXR:
 - Useful in excluding other etiologies such as pneumothorax and pneumonia
 - In dissection, there may be a widened mediastinum or abnormal aortic contour.
 - An enlarged heart secondary to pericardial fluid (blood) may be present.
 - May be completely normal in as many as 12–18% of cases
- Echo—transthoracic or transesophageal:
 - Transthoracic:
 - Not very helpful in the diagnosis of aortic dissection

- May be used to evaluate for complications of a known dissection such as tamponade, valvular incompetence, or MI (from ostial occlusion)
- Transesophageal:
 - May be performed in the ED
 - Patients may require intubation.
 - Provides information regarding extent of dissection and complications
- CT:
 - Very useful in defining extent of dissection
 - May also be used in diagnosing clinical entities such as pulmonary embolism
 - Has a high sensitivity for the diagnosis of aortic dissection and is the diagnostic modality of choice in many centers
- MRI:
 - Highly sensitive and specific
 - Requires patient transport out of ED for extended period of time
 - Lack of immediate availability may be a problem
 - Study of choice in those with renal insufficiency or dye allergy
- Aortography:
 - High sensitivity and specificity
 - Useful for preoperative planning
 - Difficult to obtain in many centers
- Cardiac catheterization:
 - Due of overlap of symptomatology with cardiac ischemia, some patients may have diagnosis made by cardiac catheterization when an intimal flap is visualized.

DIFFERENTIAL DIAGNOSIS

- MI/ischemia
- Unstable angina
- Pneumothorax
- Esophageal rupture
- Pulmonary embolism
- Pericarditis
- Pneumonia
- Musculoskeletal pain

TREATMENT

PRE HOSPITAL

- Monitor
- IV access
- Oxygen

INITIAL STABILIZATION/THERAPY

- 2 large-bore IV lines
- Continuous cardiac monitoring
- Pulse oximetry
- Oxygen
- Type and cross

ED TREATMENT/PROCEDURES

- BP reduction to reduce shearing forces on aortic wall and slow down the dissection process
- Medications: IV β -blockade and nitroprusside
 - Medications are used to control HTN and cardiac contractility and decrease shearing forces.
 - Esmolol (IV) or labetalol (IV):
 - Contraindications: Bradycardia, COPD, hypotension
 - Nitroprusside (commonly used in conjunction with IV β -blocker)
 - Caution when using the above together: To prevent an initial increase in shear forces, β -blocker therapy should be started prior to the addition of nitroprusside therapy
- Emergent surgery:
 - Treatment of choice for type A dissection
 - Treatment for type B dissections in those who have failed medical therapy
- Medical management:
 - Treatment of choice for stable type B dissections

ALERT

Symptoms of aortic dissection may be similar to those of cardiac ischemia/infarction and pulmonary embolus. Treatment with thrombolytics and anticoagulants may be harmful and potentially fatal if aortic dissection is present.

MEDICATION

- Esmolol: 500 μ g/kg IV bolus, then 25--50 μ g/kg/min drip
- Labetalol: 10–20 mg IV over 2 min q10–15min. Then 2–4 mg/min IV drip. Total dose not to exceed 300 mg.
- Nitroprusside: 0.5 μ k/kg/min IV and titrate upward to desired effect. Dose should be based on IBW.

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with acute aortic dissection should be admitted to the intensive care

unit.

- Emergency cardiothoracic surgery consultation should be obtained, especially in cases of type A dissection.

Discharge Criteria

None

FOLLOW-UP RECOMMENDATIONS

Close follow-up with cardiology and/or cardiothoracic surgery is of paramount importance.

PEARLS AND PITFALLS

- Untreated, nearly 75% of patients with ascending aortic dissection can be expected to die within 2 wk, with a mortality of 1–3%/hr in the 1st 48 hr.
- Majority of patients present with pain (90%) of severe intensity (90%) that occurred suddenly (84%).
- Although some recent literature has suggested a role for D-dimer testing, there is insufficient evidence to support its use as the sole screening test for aortic dissection.
- Should consider the diagnosis in patients with chest pain in whom conventional therapy (nitrates, β -blockers) are ineffective, and in those who have chest pain in addition to another complaint (extremity weakness, back pain, paresthesias, abdominal pain).
- Identification of risk factors is critical. These include:
 - HTN
 - Male gender
 - Cocaine use
 - Advanced age
 - Pregnancy
 - Connective tissue disorders, such as Marfan syndrome or cystic medial necrosis
 - Bicuspid aortic valve
 - Turner syndrome
 - Family history
 - Previous cardiac or valvular surgery

ICD9

441.01 Dissection of aorta, thoracic

ICD10

I71.01 Dissection of thoracic aorta

AORTIC RUPTURE, TRAUMATIC (TAI)

Stephen R. Hayden

BASICS

DESCRIPTION

- Traumatic aortic rupture (also referred to as traumatic aortic injury or TAI) is the cause of death in an estimated 20% of lethal motor vehicle collisions.
- An estimated 85% of patients with TAI die before reaching the hospital.
- Patients surviving to the ED usually have a contained rupture as aortic blood is tamponaded by the adventitia.
- Without proper treatment, of the 15% that survive the initial event, 49% will die within the 1st 24 hr, and 90% within 4 mo.
- Mean age of patients sustaining aortic rupture is 33 yr, and 70% are male.
- Most tears are transverse, not longitudinal.
- Tears may be partially or completely circumferential.

ETIOLOGY

- Most commonly results from motor vehicle collisions > 30 mph
- Unrestrained passengers, driver seat occupants (injuries from steering column and instruments), and ejected occupants.
- Other mechanisms: Auto versus pedestrian, airplane crashes, falls from height > 10 ft, crush and blast injuries, direct blow to chest
- Proposed mechanisms of aortic injury:
 - Shear forces arising from unequal rates of deceleration of the relatively fixed descending aorta and the more mobile arch
 - “Bending” stress at the aortic isthmus may cause flexion of the aortic arch on the left mainstem bronchus and pulmonary artery.
 - Twisting of the arch forces it superiorly and causes it to stretch.
 - Osseous structures (e.g., medial clavicles, manubrium, 1st rib) cause pinching of the trapped aorta as they strike the vertebral column.
 - “Waterhammer” fluid wave causes explosive rupture of aorta just distal to the aortic valve.

DIAGNOSIS

SIGNS AND SYMPTOMS

ALERT

Despite the severe nature of the injury, clinical manifestations are often deceptively subtle or nonexistent as patients frequently present with multiple coexisting injuries.

1/3–1/2 of these patients do not have external signs of chest trauma.

History

- Substernal chest pain is the most common symptom, but only present in ~25% of cases.
- Dyspnea, hoarseness, and stridor (tracheal compression from expanding hematoma) are less common.

Physical-Exam

- Neither sensitive nor specific for aortic injury
- Generalized HTN may occur from stimulation of sympathetic afferent nerves located near aortic isthmus.
- Harsh precordial or midscapular systolic murmur (1/3 of patients)
- Ischemic pain in lower extremities, oliguria/anuria, paraplegia from decreased aortic blood flow distal to aortic arch
- Swelling of base of neck (extravasation of blood)
- Acute coarctation syndrome (1/3 of patients): Upper extremity HTN with decreased pressures in low extremities, caused by periaortic hematoma compressing aortic lumen

ESSENTIAL WORKUP

Plain CXR is the primary screening tool with ~90% sensitivity, but low specificity.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Chemistry
- Prothrombin time/partial thromboplastin time
- Type and cross-match (6–8 units PRBC)

Imaging

- Plain CXR:
 - Findings suggestive of mediastinal hemorrhage, hematoma, or associated injuries:
 - Widening of the superior mediastinum at the level of aortic arch (defined as >8 cm on a supine film, >6 cm in an upright PA film, or >0.25 mediastinum-width to chest-width ratio) is the most sensitive sign.
 - Obscuration of the aortic knob is also a sensitive sign.
 - More specific, but less sensitive, signs include opacification of the aortopulmonary window, rightward displacement of nasogastric tube, widened paratracheal stripe, and widened right paraspinal interface.

- 7–10% false-negative rate with normal mediastinum on x-ray; consider use of helical chest CT with high-speed deceleration mechanisms.
- In pediatric patients: The most common findings are a left apical cap, pulmonary contusion, aortic obscuration, and mediastinal widening.
- Helical chest CT angiography:
 - Preferred confirmatory study in stable patients
 - Nearly 100% sensitivity and specificity for detecting aortic rupture with improved CT technology
 - Has largely eliminated need for aortography
 - Advantages over aortography include noninvasive, provides information on other thoracic structures, more rapid
- Aortography:
 - Still considered by some to be the gold standard for diagnosis of TAI
 - Provides precise anatomic localization of aortic tears, useful for aorta injured at > 1 site (15–20% of cases)
 - Risk of further damage to aorta from catheter
 - Need for this modality is declining given advances in CT imaging quality.
- Transesophageal Echo (TEE):
 - Can be done rapidly in the ED
 - Can detect associated cardiac injuries (contusion, effusion, etc.)
 - Reported 87–100% sensitivity and 98–100% specificity
 - Contraindicated in patients with cervical, maxillofacial, or esophageal injuries
- MRI:
 - High accuracy
 - Lengthy study time and difficulty monitoring patients limit use
- Intravascular US:
 - Newer modality, availability is limited
 - Preliminary data suggest high sensitivity and specificity.

Pediatric Considerations

Presence of large thymus may make diagnosis of widened mediastinum difficult.

DIFFERENTIAL DIAGNOSIS

- Supine CXR can lead to false positive for widened mediastinum; obtain upright PA if possible.
- Mediastinal hematoma owing to other causes
- Mediastinal lymphadenopathy or tumor
- Redundant aorta resulting from HTN

TREATMENT

PRE HOSPITAL

Important information to retrieve at scene of injury:

- Vehicular speed
- Patient in driver or passenger seat
- Damage to steering column if driver is patient
- Ejection or use of seat belt

INITIAL STABILIZATION/THERAPY

- Follow advanced trauma life support protocols.
- Life-threatening intracranial, peritoneal, and retroperitoneal injuries take precedence.

ED TREATMENT/PROCEDURES

- Immediate trauma surgery consultation
- Immediate cardiothoracic or vascular surgery consultation (institution dependent)
- Avoid maneuvers that may result in a Valsalva-like response (e.g., gagging, straining)
- Aggressive pharmacologic treatment of BP and heart rate, as emerging data suggest delaying surgical repair may lead to improved outcomes
- Goal of medical therapy is to target heart rate 60 ± 5 bpm, systolic BP 100–120 mm Hg, and mean arterial BP 70–80 mm Hg to decrease risk of sudden free rupture and exsanguination:
 - β -blockers such as esmolol and labetalol are 1st-line agents
 - Calcium-channel blockers in patients with contraindications to β -blockade (CHF, COPD, 2nd- or 3rd-degree atrioventricular block)
 - Add vasodilator (nitroprusside) if needed to reach target BP and heart rate goals.
 - Antihypertensives are relatively contraindicated in acute coarctation syndrome.
- For significant hypotension, initiate rapid volume expansion, including blood.
- Vasopressors for refractory hypotension; norepinephrine and phenylephrine are preferred
- Central venous and arterial catheters

ALERT

Only administer vasodilator after initiating negative inotrope (β -blocker or calcium-channel blocker), as vasodilator alone can cause an increase in shearing forces on the intact aortic adventitia.

MEDICATION

- Esmolol: 500 μ g/kg bolus IV (peds: 100–500 μ g/kg bolus), then 50–150 μ g/kg/min IV infusion (peds: 25–100 μ g/kg/min IV infusion)
- Labetalol: 20 mg IV, followed by additional doses of 40 mg and 80 mg (peds: 0.2–

- 10 mg/kg per dose, max. 20 mg per dose) IV q10–15min, to 300 mg IV total; start infusion at 2 mg/min and titrate up to 10 mg/min (peds: 0.4–3 mg/kg/h infusion)
- Diltiazem: 20 mg (0.25 mg/kg) IV over 2 min; 2nd bolus 25 mg (0.35 mg/kg) in 15 min if needed; infusion 5–15 mg/h
- Norepinephrine: Start with 0.5–1 µg/min and titrate to desired response; 8–30 µg/min is usual dose (peds: Start 0.05–0.1 µg/kg/min, max. 2 µg/kg/min)
- Phenylephrine: 0.1–0.5 mg IV boluses q10–15min, initial dose not to exceed 0.5 mg (peds: 5–20 µg/kg/dose q10–15min); 100–180 µg/min or 0.5 µg/kg/min titrated to desired effect (peds: 0.1–0.5 µg/kg/min, titrated to desired effect)

FOLLOW-UP

DISPOSITION

Admission Criteria

All patients with aortic injuries must be admitted to the ICU if not taken directly to the OR.

FOLLOW-UP RECOMMENDATIONS

All patients with TAI are admitted to the hospital.

PEARLS AND PITFALLS

- Maintain a high degree of suspicion for TAI in patients with injuries from significant deceleration mechanisms.
- Clinical signs and symptoms may be subtle or nonexistent, necessitating some reliance on radiologic imaging for diagnosis.
- Special attention should be given to assessment of the mediastinum on CXR in trauma patients.
- Early pharmacologic control of BP and heart rate is of utmost importance when diagnosis is confirmed.

APHTHOUS ULCERS

Matthew R. Berkman

BASICS

DESCRIPTION

Painful ovoid or round ulcerations on the mucous membranes of the mouth, tongue or genitals:

- Commonly referred to as “canker sores”

ETIOLOGY

- Unknown
- Etiology likely multifactorial with some correlation with:
 - Immunologic dysfunction; alteration of cell-mediated immune system
 - Infection
 - Food hypersensitivities (i.e., gluten)
 - Vitamin deficiency
 - Pregnancy
 - Menstruation
 - Trauma
 - Stress
 - Ethnicity
 - Immunodeficiency
 - Medications: β -blockers, anti-inflammatory
- Epidemiology: Usually occurs in children and young adults (Peak age of onset: Between 10 to 19 yr old)
 - Most common inflammatory ulcerative condition of the oral cavity (20-40% of general population)
 - More common in women
 - May be familial

DIAGNOSIS

SIGNS AND SYMPTOMS

- Minor aphthous ulcers:
 - 70–90% of all aphthae
 - <5 mm in diameter; up to 5 appear at a time
 - Painful, shallow ulcers with necrotic centers
 - Raised, circumscribed margins and erythematous halos
 - Gray-white pseudomembrane
 - Affect nonkeratinized mucosa of anterior oral cavity

- Labial and buccal mucosa
- Floor of mouth
- Ventral surface of tongue
- Rarely found on dorsum of tongue, hard palate, or gingiva
- Last for 10–14 days; do not scar
- Fever/constitutional symptoms rarely associated
- Major aphthous ulcers or Sutton disease:
 - 10–15% of all aphthae
 - Similar in appearance but more painful than minor form
 - >5 mm in diameter; 1–10 ulcers at a time
 - Deeper than minor form
 - Involve all areas of oropharynx including pharynx, soft/hard palate, lips
 - Last for weeks to months, may scar
 - Onset after puberty
 - Often associated with underlying disease
 - Fever is rarely associated
- Herpetiform aphthous ulcers:
 - 7–10% of all aphthae
 - Multiple small clusters
 - <5 mm in diameter, 10–100 at any time, may coalesce into plaques
 - Herpetiform in nature, but herpes simplex virus cannot be cultured from lesions.
 - Predisposition for women
 - Last for 7–30 days; scarring can occur

History

- Prodrome of burning or pricking sensation of oral mucosa 1–2 days prior to appearance of ulcers
- Inquire about patient or family history of:
 - Systemic lupus erythematosus (SLE)
 - Inflammatory bowel disease (IBD)
 - Behçet disease
 - Reiter disease
 - Gluten sensitivity
 - Cancer
 - HIV
- Inquire about patient sexual history of syphilis or herpes virus
- Inquire about current medications:
 - NSAIDs
 - β -blockers

Physical-Exam

- See “Signs and Symptoms.”
- Look for signs of dehydration:
 - Vital signs should be within normal limits.
 - Evaluate mucus membranes.
- Evaluate for signs of secondary infection.
- Evaluate for signs of systemic causes of ulcers (see “History”).

ESSENTIAL WORKUP

- Diagnosis is made by history and clinical presentation.
- Rule out oral manifestation of systemic disease:
 - More likely if persists > 3 wk or associated with constitutional symptoms
- Focus on symptoms of eyes, mouth, genitalia, skin, GI tract, allergy, diet history and physical exam

DIAGNOSIS TESTS & INTERPRETATION

Lab

Routine lab testing not indicated:

- Needed only when systemic etiologies causing ulcers are suspected
- Biopsy should be considered for ulcers lasting more than 3 wk
- Should be guided by history and physical exam:
 - CBC series
 - Rapid plasma reagin (RPR) (syphilis)
 - Fluorescent treponemal antibody-absorption test
 - Antinuclear antibody test
 - Tzanck stain: Inclusion giant cells (herpes virus)
 - Biopsy: Multinucleated giant cells (cytomegalovirus)
 - Fungal cultures

Diagnostic Procedures/Surgery

An outpatient biopsy should be considered for any ulcer > 3 wk

DIFFERENTIAL DIAGNOSIS

- Trauma:
 - Biting
 - Dentures
 - Braces
- Drug exposure:
 - NSAIDs
 - Nicorandil
 - β -blockers
- Infection:
 - Herpes virus:

- Vesicular lesions
- Ulcers on attached mucosa
- Cytomegalovirus:
 - Immunocompromised patient
- Varicella virus:
 - Characteristic skin lesions
- Coxsackievirus:
 - Ulcers preceded by vesicles
 - Hand, foot, and buttock lesions
- Syphilis:
 - Other skin or genital lesions
- Erythema multiforme:
 - Lip crusting
 - Lesions on attached and unattached mucosa skin lesions
- *Cryptosporidium* infection, mucormycosis, histoplasmosis
- Necrotizing gingivitis
- Underlying disease:
 - Behçet syndrome:
 - Genital ulceration
 - Uveitis
 - Retinitis
 - Reactive arthritis (Reiter syndrome):
 - Uveitis
 - Urethritis
 - HLA-B27-associated arthritis
 - Sweet syndrome:
 - Fever
 - Erythematous skin plaques/nodules
 - In conjunction with malignancy
 - IBD:
 - Bloody or mucous diarrhea
 - GI ulcerations
 - Weight loss
 - Gluten-sensitive enteropathy:
 - Weight loss
 - SLE:
 - Malar rash
 - ANA positive
 - Bullous pemphigoid/pemphigus vulgaris:
 - Vesiculobullous lesions on attached and unattached mucosa
 - Diffuse skin involvement
 - Cyclic neutropenia:
 - Periodic fever

- Squamous cell carcinoma:
 - o Chronic
 - o Head/neck adenopathy
- Immunocompromised patient:
 - HIV
 - Agranulocytosis
 - Malignancy

TREATMENT

ED TREATMENT/PROCEDURES

- Treatment guided by severity and duration of symptoms
- Goal is for symptomatic pain relief and reduction of inflammation.

MEDICATION

- Mild to moderate disease:
 - Avoid oral trauma/acidic foods
 - Topical anesthetic
 - o Magnesium hydroxide/diphenhydramine hydrochloride 5 mg/5 mL in 1/1 mix swish and spit
 - o Viscous lidocaine 2–5%: Applied to ulcer QID after meals until healed
 - Protective bioadhesives
 - o Topical OTC preparations (Orabase, Anbesol): Applied to ulcer QID after meals until healed
 - Topical anti-inflammatory
 - o Amlexanox 5% paste (Aphthasol): applied to ulcer QID after meals until healed
 - Antimicrobial mouthwash
 - o Chlorhexidine gluconate aqueous mouthwash 0.12% (Peridex): Mouth rinse QID after meals until healed
- Severe disease:
 - Prednisone tablets: 30–60 mg PO per day × 7 d
 - Thalidomide: 50–200 mg PO per day × 4 wk

FOLLOW-UP

DISPOSITION

Admission Criteria

- Unable to eat or drink after appropriate analgesia
- Abnormal vital signs or evidence of dehydration

Discharge Criteria

- Tolerating fluids
- Adequate analgesia
- Normal vital signs

Issues for Referral

Follow up with primary care physician if lesions have not resolved within 2 wk.

FOLLOW-UP RECOMMENDATIONS

- Avoid oral trauma (hard foods) or acidic foods.
- Referral to a specialist if underlying disease suspected

PEARLS AND PITFALLS

- The vast majority of aphthous ulcers are benign, self-limited, and treated symptomatically
- ED physicians must consider underlying systemic cause of ulcers.

APNEA, PEDIATRIC

Sarah M. Halstead

BASICS

DESCRIPTION

- Absence of respiratory airflow for a period of 20 sec, with or without decreased heart rate:
 - Central apnea:
 - Disruption in the generation or propagation of respiratory signals in the brainstem and descending neuromuscular pathways
 - Obstructive apnea:
 - Respiratory effort is present, but there is no airflow
 - Structural airway obstruction, often with paradoxical chest wall movement
 - Functional obstruction from airway collapse
 - Mixed
- Apparent life-threatening event (ALTE):
 - Episode that is associated with a combination of apnea, color change, change in tone, choking, or gagging
 - A clinical presentation, not a diagnosis

ETIOLOGY

- Infection:
 - Sepsis
 - Meningitis or encephalitis
 - Pneumonia
 - Pertussis/chlamydia
 - RSV and other viral respiratory infections
- Respiratory:
 - Obstructive airway lesions
 - Enlarged tonsils and adenoids
 - Vocal cord dysfunction
 - Laryngotracheomalacia
 - Vascular ring
 - Foreign body
 - Craniofacial abnormality
 - Choanal atresia or stenosis
 - Functional obstruction from airway collapse
 - Infection
 - Immaturity/prematurity

- Abnormal ventilatory response to hypoxia/hypercarbia
- Neurologic:
 - Seizure
 - Intracranial hemorrhage
 - Increased intracranial pressure
 - Tumor
 - Arnold–Chiari or other CNS malformation
 - Ingestion
 - Toxin
 - Carbon monoxide
 - Hypoxic injury
 - Neuromuscular disorder
 - Central hypoventilation syndrome
- Cardiac:
 - Dysrhythmia
 - Congenital heart disease
 - CHF
 - Myocarditis
 - Cardiomyopathy
- GI:
 - GERD
 - Volvulus
 - Intussusception
- Child abuse
- Endocrine/metabolic:
 - Hypoglycemia
 - Electrolyte disorders
 - Inborn errors of metabolism
- Other:
 - Transient choking episode
 - Laryngospasm
 - Periodic breathing
 - Breath-holding spell

DIAGNOSIS

ALERT

If the patient is apneic, treatment must commence at once.

SIGNS AND SYMPTOMS

Apnea may be current, historical, or impending.

History

- Duration of apnea
- State:
 - Asleep, awake, crying
 - Relationship to feeds and position (supine, prone)
- Respiratory effort:
 - None, shallow breathing, increased work of breathing, struggling to breathe, choking
- Presence and location of any color change
- Position of eyes
- Description of movements and muscle tone
- Interventions done by the caregiver
- Antecedent symptoms such as fever or cough
- Antecedent trauma
- Past medical history, including prematurity, cardiopulmonary, GI, or neurologic conditions
- Any past history of ALTEs in this patient or family members

Physical-Exam

- Vital signs with temperature
- Growth parameters:
 - Weight pattern
 - OFC (head circumference) pattern
- Pulse oximetry
- Exam of airway and lungs:
 - Assess impending apnea
 - Stridor or other evidence of upper airway obstruction
 - Fast or slow respirations
 - Use of accessory muscles
 - Adventitial lung sounds
- Exam of heart:
 - Irregular rhythm
 - Murmur
 - Evidence of CHF
- Neurologic exam:
 - Assess mental status
 - Assess for trauma, seizure, or toxidrome
 - Muscle tone and reflexes
 - Funduscopic exam

ESSENTIAL WORKUP

- Complete history and physical exam
- The historical factors and exam will direct the diagnostic evaluation and treatment

- Check/clear out upper airway as appropriate.
- Remove or suction any obstruction as appropriate
- Ensure proper head positioning with special consideration for occult trauma

DIAGNOSIS TESTS & INTERPRETATION

Lab

Perform as appropriate for presentation:

- Dextrostix
- CBC
- Urinalysis
- CSF studies
- Blood, urine, and CSF cultures
- Electrolytes (including calcium)
- BUN, creatinine
- Blood gas
- RSV and respiratory viral studies
- Pertussis and chlamydia tests
- Consider toxicologic screen (including toxic alcohols and acetaminophen)
- Consider LFTs and ammonia

Imaging

Perform as appropriate for presentation:

- CXR
- Head CT or MRI
- ECG
- UGI or swallowing study
- Polysomnography in follow-up in patient with suspected central or obstructive sleep apnea
- EEG in follow-up
- 0 Bone survey and other studies as indicated

DIFFERENTIAL DIAGNOSIS

- Multiple etiologies as previously noted
- Special considerations:
 - _ Breath-holding spells:
 - Reflexive cessation of respiratory effort during expiration
 - Cyanotic and pallid types
 - Paroxysmal event occurring in 0.1–5% of healthy children 6 mo–6 yr of age
 - _ Periodic breathing may be seen in neonates:
 - 3 or more respiratory pauses lasting > 3 sec with < 20 sec of respiration between pauses

- May be normal event

ALERT

In a neonate, strongly consider occult sepsis.

TREATMENT

PRE HOSPITAL

- Respiratory support as indicated
 - _ High-flow oxygen if breathing resumes
 - _ Check/clear out upper airway
 - _ Bag-mask ventilation
 - _ Endotracheal intubation if continued apnea
- IV access, cardiac monitoring
- Look for signs of an underlying cause:
 - _ Medications
 - _ Document a basic neurologic exam:
 - GCS
 - Pupils
 - Extremity movements
 - _ Gross signs of trauma
 - _ Talk with family/pre-hospital personnel for information

INITIAL STABILIZATION/THERAPY

- Establish unresponsiveness
- Check/clear out upper airway
- Remove or suction any obstruction
- Ensure proper head positioning

ED TREATMENT/PROCEDURES

- If currently apneic, ventilate with the bag-valve-mask device and high-flow oxygen
- Endotracheal intubation is required if apnea persists
- Resuscitation medications and antibiotics as indicated
- Support and counseling if breath holding suspected

MEDICATION

- Antibiotic doses in ED
 - _ Ceftriaxone: 50 mg/kg IV
 - _ Vancomycin: 15 mg/kg IV
 - _ Neonates:
 - Ampicillin: 50 mg/kg IV
 - Gentamicin: 2.5 mg/kg IV
- Dextrose: 2–4 mL/kg D₂₅W IV or 5-10 mL/kg D₁₀W IV

- Neonates: 1 mo 2–4 mL/kg D₁₀W IV
- Naloxone: 0.01–0.1 mg/kg IV/IM/SC/ET
 - Caution: May precipitate withdrawal symptoms in patients with chronic opiate use

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients who were or may become apneic should be admitted to an inpatient unit for appropriate monitoring. Those with persistent abnormal vital signs need intensive care monitoring.
- Variables that identify most children requiring admission include those with an obvious need for admission including abnormal vital signs or a medical history, or >1 apparent ALTE event in 24 hr.
- Recommend referral for pediatric evaluation and follow-up as indicated. Interventions may include further studies (i.e., EEG), antireflux medications or caffeine, and home monitoring.

Discharge Criteria

In patients without true apnea who are low risk and have no abnormalities noted during the period of observation and evaluation, discharge may be considered, assuming that parents are compliant and comfortable with their child and follow-up and support are definitively established.

Issues for Referral

Primary care physician and subspecialist, reflecting suspected etiology

PEARLS AND PITFALLS

- Consider occult sepsis, especially in a neonate
- Consider occult trauma

CODES

ICD9

- 327.23 Obstructive sleep apnea (adult)(pediatric)
- 770.81 Primary apnea of newborn
- 786.03 Apnea

ICD10

- G47.33 Obstructive sleep apnea (adult) (pediatric)
- P28.4 Other apnea of newborn

APPENDICITIS

Colleen N. Hickey • Jennifer L. Kolodchak

BASICS

DESCRIPTION

- Most common abdominal emergency
- Acute obstruction of appendiceal lumen results in distension followed by organ ischemia, bacterial overgrowth, and eventual perforation of the viscus
- Pain migration:
 - Periumbilical pain: Appendiceal distension stimulates stretch receptors, which relay pain via *visceral* afferent pain fibers to 10th thoracic ganglion.
 - RLQ pain: As inflammation extends to surrounding tissues, pain occurs owing to stimulation of *parietal* nerve fibers and localizes to position of appendix.

Pediatric Considerations

- 28–57% misdiagnosis in patients <12 yr (nearly 100% in patients <2 yr)
- 70–90% perforation rate in children <4 yr
- Perforation correlates strongly with delayed diagnosis.

Geriatric Considerations

- Decreased inflammatory response
- 3 times more likely to have perforation owing to anatomic changes
- Diagnosis often delayed owing to atypical presentations

Pregnancy Considerations

- Slightly higher rate in 2nd trimester compared to 1st/3rd/postpartum periods
- Increased perforation rate (25–40%), highest in 3rd trimester
- RLQ pain remains the most common symptom
- 7–10% fetal loss, up to 24% in perforated appendicitis

ETIOLOGY

- Luminal obstruction of appendix
- Appendiceal lumen becomes distended, inhibiting lymphatic and venous drainage.
- Bacterial invasion of wall, with edema and blockage of arterial blood flow
- Perforation and spillage of contents into peritoneal cavity, causing peritonitis (usually 24–36 hr from onset)
- May wall off and form abscess
- Gram-negative rods and anaerobic organisms predominate

SIGNS AND SYMPTOMS

History

- **Abdominal pain: Primary symptom:**
 - Normal location:
 - RLQ pain
 - 35% of patients have appendix located within 5 cm of “normal” location.
 - Retrocecal appendix (28–68%):
 - Back pain
 - Flank pain
 - Testicular pain
 - Pelvic appendix (27–53%):
 - Suprapubic pain
 - Urinary or rectal symptoms
 - Long appendix (< 0.2%):
 - Inflamed tip may cause pain in RUQ or LLQ.
 - Anorexia
 - Vomiting
- **Change in bowel habits: Diarrhea (33%), constipation (9–33%)**
- **Classic presentation (< 75% adults):**
 - Initially periumbilical pain
 - Followed by anorexia (1st symptom in 95%) and nausea
 - Localizes to RLQ (1–12 hr after onset)
 - Finally, vomiting with fever

Pediatric Considerations

- **Presentations often nonspecific and difficult to localize (< 50% have classic presentation)**
- **Anorexia, vomiting, and diarrhea more common (half-eaten meal hours before complaints of pain may more accurately indicate duration of symptoms)**
- **Observe child before exam for subtle indicators of local inflammation:**
 - Limping gait
 - Hesitation to move or climb
 - Flexed right hip

Physical-Exam

- **Vital signs:**
 - Often normal
 - Fever: Normal to mild elevation (< 1°F) initially, increases with perforation

- Abdominal exam:
 - Tenderness at McBurney point (1/3 of distance from right anterior iliac spine to umbilicus)
 - Guarding:
 - Voluntary guarding early owing to muscular resistance to palpation
 - Involuntary guarding (rigidity) later as inflammation progresses and perforation occurs
 - Rebound:
 - Pain with any rapid movement of peritoneum (e.g., bumping stretcher)
 - Specific signs (less useful in pediatrics):
 - *Rovsing sign*: Pain in RLQ when palpating LLQ
 - *Psoas sign*: Increased pain on extension of right hip with patient lying on her or his left side, owing to inflamed appendix touching iliopsoas muscle.
 - *Obturator sign*: Pain with passive internal rotation and flexion of right hip
- Rectal exam:
 - Limited value: May localize tenderness/mass
- Pelvic exam:
 - Important to differentiate gynecologic disease
 - Vaginal discharge and/or adnexal tenderness or mass suggests gynecologic disease.
 - Cervical motion tenderness when present suggests PID, but can be seen in up to 25% of women with appendicitis
- Patient position:
 - Supine or decubitus with legs (particularly the right) drawn up
 - Prefer not to move
- Shuffling gait—known as “appy walk”

Pediatric Considerations

Almost all children have generalized abdominal tenderness with some rigidity.

Pregnancy Considerations

- Enlarging uterus displaces appendix upward and laterally.
- Hyperemesis gravidarum and other nonsurgical causes of vomiting should not cause abdominal tenderness.

Geriatric Considerations

Typical signs of peritonitis may be absent in elderly.

ESSENTIAL WORKUP

- Suggestive history and physical exam sufficient to establish preoperative diagnosis and warrant surgical consultation
- Tests listed below may be used to assist in diagnosis
- Atypical cases: Repeat serial exams in conjunction with some of the tests listed below is effective, with decreased rates of negative appendectomies and no increase in rates of perforation

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - WBC > 10,000, with left shift (80%)
 - Normal WBC does *not* exclude diagnosis
- C-reactive protein:
 - Overall sensitivity 62%, specificity 66%
 - May not be elevated early (< 12 hr)
 - Increased sensitivity with serial measurements
- Urinalysis:
 - Generally normal
 - Mild pyuria, bacteriuria, or hematuria (25–30%)
 - Pyuria present if inflamed appendix lies near ureter or bladder
- Pregnancy test for females of child-bearing age

Imaging

- Unnecessary when diagnosis is clear
- Most helpful in female patients of child-bearing age where diagnosis is often unclear
- Abdominal radiographs—not recommended
- US: Sensitivity 86–90%; specificity 92–95%:
 - Noncompressible appendix 6 mm anteroposterior (AP) diameter
 - Presence of appendicolith
 - Periappendiceal fluid/mass
 - Limited by obesity, bowel gas, retrocecal appendix, and operator
 - Negative study of limited use
- CT: Sensitivity 91–100%; specificity 94–97%:
 - Highest yield using oral and rectal contrast with focused appendiceal technique (5 mm cuts from 3 cm above cecum extending distally 12–15 cm)
 - Fat stranding (100%)
 - Appendix 6 mm in diameter (93%)
 - Focal cecal apical thickening
 - Defines appendiceal masses (phlegmon vs. abscess)
 - Best study for finding alternative diagnoses
 - Nonvisualized appendix does not rule out appendicitis

- MRI: Sensitivity 97–100%, specificity 92–94%:
 - Appendix 7 mm in diameter
 - Periappendiceal fat stranding
 - Advantages: Lack of ionizing radiation, excellent safety profile of gadolinium contrast agents
 - Disadvantages: High cost, limited availability, lengthy exam, lack of radiologist familiarity in appendicitis
 - No gadolinium in early pregnancy (class C drug)

Pediatric Considerations

American College of Radiology recommends US followed by CT as needed for suspected appendicitis

Diagnostic Procedures/Surgery

- Laparoscopy:
 - Diagnostic and therapeutic use
 - Gross pathology may be absent with positive microscopic findings
- Open appendectomy
- Percutaneous drainage

DIFFERENTIAL DIAGNOSIS

- Gastroenteritis
- Meckel diverticulum
- Epiploic appendicitis
- Crohn's disease
- Diverticulitis
- Volvulus
- Abdominal aortic aneurysm
- Intestinal obstruction
- UTI
- Pyelonephritis
- PID
- Ectopic pregnancy
- Ovarian cyst/torsion
- Tubo-ovarian abscess
- Endometriosis
- Renal stone
- Testicular torsion
- Mesenteric adenitis
- Henoch–Schönlein purpura
- Diabetic ketoacidosis
- Streptococcal pharyngitis (children)
- Biliary disease

TREATMENT

INITIAL STABILIZATION/THERAPY

- Airway, breathing, and circulation management (ABCs)
- Fluid resuscitation with LR or 0.9% NS

ED TREATMENT/PROCEDURES

- IV fluids, correct electrolyte abnormalities
- Immediate surgical consult for convincing history and physical exam:
 - Laparoscopic versus open technique
 - Negative appendectomy rate of 10% in males and 20% in females
 - Percutaneous drainage, IV antibiotics, bowel rest and possible interval appendectomy in 6–8 wk in appendiceal abscesses
- Perioperative antibiotics
- NPO
- Order CT if palpable mass is present in RLQ to define phlegmon versus abscess
- If diagnosis is uncertain, send serial labs, observe, and repeat exams (6–10% negative appendectomy rate with observation protocols)
- Analgesics:
 - Administration of analgesics, including narcotics, does not adversely affect abdominal exam or mask pathology

MEDICATION

- Ampicillin/sulbactam: 3 g (peds: 100–200 mg ampicillin/kg/24 h) IV q6h
- Cefoxitin: 2 g (peds: 80–100 mg/kg/24 h) IV q6h
- Ceftriaxone: 1 g (peds: 50–100 mg/kg) IV q24h
- Ciprofloxacin: 400 mg (peds: 20–40 mg/kg) IV q12h
- Ertapenem: 1 g IM/IV q24h
- Metronidazole: 500 mg (peds: 30–50 mg/kg/24 h) IV q8–12h
- Morphine sulfate: 3–5 mg (peds: 0.1–0.2 mg/kg per dose q2–q4h) IV, every 15 min titrated to effect
- Piperacillin/tazobactam: 3.375 g (peds: 150–300 mg/kg/d if < 6 mo; 240–400 mg/kg/d if > 6 mo) IV q6h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Surgical intervention of acute appendicitis
- Observation or further diagnostic workup if diagnosis is uncertain

Discharge Criteria

Patients with abdominal pain thought not to be appendicitis may be discharged if they meet the following criteria:

- Resolved or resolving symptoms
- Minimal or no abdominal tenderness
- No lab/radiologic abnormalities
- Able to tolerate PO intake
- Adequate social support and able to return if symptoms worsen

FOLLOW-UP RECOMMENDATIONS

24–48 hr recheck for patients discharged from the ED with abdominal pain of unclear etiology

PEARLS AND PITFALLS

- Pediatric and geriatric patients present atypically and have increased perforation rates
- Imaging is not required in a classic presentation of acute appendicitis
- Appendicitis cannot be ruled out on any imaging modality if the appendix is not visualized

ADDITIONAL READING

- K37 Unspecified appendicitis

ARSENIC POISONING

Vinodinee L. Dissanayake

BASICS

DESCRIPTION

- Acute toxicity:
 - Caused by intentional ingestion, malicious poisoning, or medication error
- Minimal lethal ingested dose ~ 2 mg/kg
- Chronic toxicity:
 - Resulting from occupational exposures, water or food contamination, or use of folk remedies containing arsenic
- Ingestion is the primary route of exposure
- Inhalational toxicity is possible from arsine gas exposure

ETIOLOGY

- Most cases seen in the ED result from intentional ingestion or malicious poisoning
- Sodium arsenate, found in ant killer, is the most common acute exposure in the US
- Contaminated food and water supplies are the most common cause worldwide
- Inorganic arsenic trioxide has been recently approved as a chemotherapeutic agent for acute myelogenous leukemia (AML)
- Melarsoprol, an organic arsenical, has been used to treat trypanosomiasis since 1949
- Found in pesticides, certain folk remedies (herbal balls), industrial wood preservatives
- May be released as arsine gas from combustion of zinc- and arsenic-containing compounds

Mechanism

- Arsenic exists in several forms—gas (arsine, or lewisite), organic, elemental, and inorganic
- Inorganic forms (pentavalent and trivalent arsenic) are most frequently involved in toxic exposures:
 - Pentavalent arsenic uncouples oxidative phosphorylation
 - Most pentavalent arsenic is converted to the more toxic trivalent arsenic in the body
 - Trivalent arsenic binds sulfhydryl groups and interferes in hemoglobin production
 - Some trivalent arsenic may be methylated into species of varying toxicity
 - The more reactive species are DNA damaging and genotoxic

DIAGNOSIS

SIGNS AND SYMPTOMS

- CNS:
 - Altered mental status/encephalopathy
 - Neurodevelopmental deficits in children
 - Peripheral neuropathy
 - Acute: Sensory neuropathy
 - Subacute: Sensorimotor neuropathy
 - Peripheral dysesthesias
 - Headache
 - Seizures
- Cardiovascular:
 - Prolonged QTc interval
 - Hypotension (acute) or hypertension (chronic)
 - Dysrhythmias, primarily ventricular
 - Nonspecific ST segment changes
 - Noncardiogenic pulmonary edema
- Pulmonary:
 - Inhalational exposure increases lung cancer risk and respiratory mortality
 - Large acute ingestion (8 mg/kg) may lead to severe respiratory distress
 - Pulmonary edema, hemorrhagic bronchitis, and bronchopneumonia
- GI:
 - Nausea, vomiting after ingestion and possibly inhalation
 - Protracted and may be refractory to antiemetics at usual doses
 - Can have hemorrhagic gastroenteritis; corrosive to GI tract
 - Rice water diarrhea
 - Abdominal pain
 - Garlic odor to breath, vomit, stools
 - Causes acute hepatitis; chronically, can cause portal HTN
 - A possible association with diabetes mellitus in chronic exposure
- Miscellaneous (usually associated with chronic exposure)
 - Acute rhabdomyolysis
 - Blackfoot disease in Taiwan: Gangrene from loss of circulation to extremities
 - Dermatitis, such as toxic erythroderma and hyperkeratotic, hyperpigmented lesions
 - Hemolytic anemia (more pronounced with arsine gas exposure)
 - Hypothyroidism (antagonizes thyroid hormone)
 - Increased risk of carcinoma (liver/basal cell/squamous cell of skin/bronchogenic)
 - Leukopenia (after several days)

- Mees lines (white bands across the nails owing to growth arrest caused by arsenic)
- Patchy alopecia
- Raynaud phenomenon and vasospasticity

ESSENTIAL WORKUP

- Spot urine arsenic level
- CBC

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Spot urine arsenic level $> 1,000 \mu\text{g/L}$ may confirm diagnostic suspicion:
 - Peaks 10–50 hr postingestion
- Definitive test is 24 hr urine collection with speciation into organic and inorganic types of arsenic.
- Blood levels not routinely helpful owing to short half-life in serum (~ 2 hr)
- CBC to evaluate for anemia, leukopenia, basophilic stippling
- Electrolytes, BUN/creatinine, and glucose
- Urinalysis to look for evidence of hemolysis/rhabdomyolysis
- Liver function tests
- Total creatine phosphokinase (CPK) for rhabdomyolysis
- Hair and nail arsenic levels:
 - Do not help in acute setting
 - May help determine chronicity of exposure in select populations

Imaging

- Plain abdominal radiographs to look for radiopaque foreign body
- Cranial CT/other studies as indicated by patient's condition

DIFFERENTIAL DIAGNOSIS

- Acute toxicity:
 - Acute appendicitis/colitis/gastroenteritis
 - Celiac disease
 - Cholera
 - Distributive shock
 - Encephalopathy
 - Toxic ingestions
 - *Amanita* mushroom poisoning
 - Cyclic antidepressants or other seizure-inducing toxins
 - Organophosphates
- Chronic toxicity:
 - Addison disease

- Guillain–Barré syndrome or other neuropathy
- Raynaud phenomenon
- Thromboangiitis obliterans, or other vasculitides
- Vitamin deficiency (B₃, B₆, or B₁₂)
- Wernicke–Korsakoff syndrome

TREATMENT

PRE HOSPITAL

ALERT

- If possible to do so safely, bring containers in suspected overdose/poisoning.
- Decontaminate skin.
- Support airway/breathing/circulation.
- Cardiac monitoring

INITIAL STABILIZATION/THERAPY

- ABCs:
 - Cardiac monitor
 - Isotonic crystalloids as needed for hypotension
- Naloxone, thiamine, and dextrose (D50W) as indicated for altered mental status
- Cardiovascular:
 - Vasopressors if refractory hypotension is present
 - Central venous pressure monitoring to prevent pulmonary/cerebral edema
 - Avoid type IA, IC and III antidysrhythmic agents, which worsen QTc prolongation
 - Continuous cardiac monitoring for QTc prolongation
- Neurologic:
 - Treat seizures with benzodiazepines
 - Assist ventilation for respiratory failure from neuromuscular weakness
- Renal:
 - Hemodialysis for renal failure
- Alimentary:
 - Dextrose, enteral or parenteral feeding may be beneficial

ED TREATMENT/PROCEDURES

- Decontamination:
 - Orogastric lavage or aspiration may be helpful within the 1st hr of ingestion
 - Activated charcoal does not bind arsenic
 - If opacities are seen on abdominal film, administer whole bowel irrigation (polyethylene glycol) at 1–2 L/hr until repeat radiographs are clear
 - If dermal exposure, decontaminate skin as 1st step in management

- Ensure that no one else is contaminated and environment is evaluated
- Ensure that electrolytes such as calcium, magnesium, and potassium are replaced
- Evaluate need for chelation therapy, based on levels, acuity of exposure, clinical symptoms:
 - Consult with medical toxicologist/poison center
 - Agents
 - Dimercaprol (British anti-Lewisite)
 - DMSA (succimer)
- Elimination:
 - Hemodialysis not routinely effective
 - Consider for patient with renal failure or other hemodialysis indications
 - Continue chelation throughout hemodialysis sessions

MEDICATION

- Dimercaprol (British anti-Lewisite): 3 mg/kg deep IM q4h for 24 h, then q6h for the next 24 h, then q12h until able to tolerate PO
 - Caution: Contraindicated in patients with peanut allergies
- Dextrose 50%: 25 g (50 mL) (peds: 0.5 g/kg D₂₅W) IV for hypoglycemia
- DMSA (succimer): 10 mg/kg PO q8h for 5 d, then q12h for 14 d
- Sodium bicarbonate: 1 mEq/kg IV bolus, followed by infusion of 150 mEq in 1 L of D₅W at 150 mL/h
 - Used to treat rhabdomyolysis
 - Ensure that potassium and other electrolytes are monitored and replaced during infusion
- Naloxone: 0.4–2.0 mg (peds: 0.1 mg/kg) IV, may repeat up to 10 mg for suspected opioid intoxication
- Thiamine: 100 mg IM or IV (peds: 1 mg/kg)
- Vasopressors after sufficient fluids
 - Dopamine 5 µg/kg/min, increase by 5–10 µg/kg/min (q10–30min) Max.: 20 µg/kg/min
 - Norepinephrine 0.01–3 µg/kg/min, start at 2 µg/min, titrate to MAP 65–90 mm Hg
- Max.: 20 µg/min

FOLLOW-UP

DISPOSITION

Admission Criteria

Symptomatic arsenic exposures should be admitted to an intensive care setting.

Discharge Criteria

- Asymptomatic patients with a spot urinary arsenic level < 50 µg/L may be discharged
- Suspected chronic exposures who do not require admission should be referred for outpatient evaluation and 24 hr urine collection
- Ensure that home environment is safe for patient prior to discharge

FOLLOW-UP RECOMMENDATIONS

- Psychiatric follow-up for intentional overdoses
- Primary care follow-up for cancer screening and monitoring

PEARLS AND PITFALLS

- Arsenic poisoning results in a myriad of signs and symptoms
 - Suspect acute arsenic poisoning when patients present with gastrointestinal distress and neurologic findings.
 - Suspect chronic arsenic poisoning in patients who present with neurologic deficits, nonspecific wasting, and hyperkeratotic skin lesions.
- Consult a medical toxicologist/poison center regarding the need for chelation therapy.

A special thanks goes to Dr. Gerald Maloney Jr, who contributed to the previous edition.

CODES

ICD9

985.1 Toxic effect of arsenic and its compounds

ICD10

- T57.0X1A Toxic effect of arsenic and its compounds, accidental (unintentional), initial encounter
- T57.0X2A Toxic effect of arsenic and its compounds, intentional self-harm, initial encounter
- T57.0X3A Toxic effect of arsenic and its compounds, assault, initial encounter

ARTERIAL GAS EMBOLISM (AGE)

Nicole L. Lunceford • Catherine M. Visintainer • Peter J. Park

BASICS

DESCRIPTION

- Results when air bubbles enter the pulmonary venous return from ruptured alveoli, then propagate through the systemic vasculature:
 - Clinical manifestations depend on location of air bubbles in systemic vasculature system.
- Also known as dysbaric air embolism or cerebral air embolism
- Caused by overpressurization of lung tissue, causing pleural tear with air entering the vascular circulation:
 - Trapped air (in lungs with closed glottis) expands on diver ascent.
 - Boyle law: At a constant temperature, pressure (P) is inversely related to volume (V):
 - $PV = K$ (constant) or $P_1V_1 = P_2V_2$
 - As pressure increases/decreases, volume decreases/increases.

ETIOLOGY

- Pulmonary atrioventricular (AV) shunts, or as paradoxical embolism via a patent foramen ovale
- Breath holding during ascent:
 - Symptoms attributable to a shower of bubbles and multiple blood vessel involvement
- Iatrogenically during placement of central venous pressure (CVP) lines, cardiothoracic surgery, or hemodialysis
- Penetrating injuries to heart, with emergent repair of cardiac wound

DIAGNOSIS

SIGNS AND SYMPTOMS

- Cerebral:
 - Rapid onset:
 - Almost all cases of AGE present within 1st 5 min of surfacing, although most often symptoms are evident in 1st 2 min
 - Dive-related stroke
 - 2 main presentations:
 - Apnea and full cardiopulmonary arrest
 - Any combination of neurologic deficits
 - Presentation depends on arterial distribution of gas embolism:

- Stupor or confusion (24%)
- Coma without seizure (22%)
- Coma with seizures (18%)
- Unilateral motor deficits (14%)
- Visual disturbances (9%)
- Vertigo (8%)
- Unilateral sensory deficits (8%)
- Bilateral motor deficits (8%)
- Collapse (4%)
- Spontaneous improvement minutes after initial deficits may occur:
 - High incidence of relapse
 - Improvement may be transiently related to postural changes that affect distribution of bubbles flowing to brain.
- Pulmonary:
 - Dyspnea
 - Hemoptysis, pleuritic chest pain
 - Subcutaneous air
- Cardiac:
 - MI owing to air in coronary vessels
 - Reduced cardiac output owing to air trapped in ventricle
 - Hamman sign: Crepitus on auscultation of heart
- Renal:
 - Renal infarction owing to air embolism

History

Elicit time of symptom onset in relation to dive surfacing (almost all symptoms occur within the 1st 10 min).

Physical-Exam

Careful neurologic exam owing to the wide variety of neurologic manifestations

ESSENTIAL WORKUP

- Clinical diagnosis: Recognize risk factors and various clinical presentations.
- Inquire as to unusual circumstances during ascent:
 - Breath holding
 - Panic/out-of-air situation
- Thorough neurologic exam must carefully document the extent of the deficits to the motor, sensory, cerebellar, and cranial nerves.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Serum creatinine kinase activity:

- Marker of the severity of cerebral AGE
- CBC
- Electrolytes, BUN, creatinine, glucose
- ABG when respiratory symptoms are present

Imaging

- CXR:
 - For evidence of pneumothorax or mediastinal emphysema (both rare)
- Chest CT
 - For evidence of local lung injury or hemorrhage
- Ventilation Perfusion Scan
 - For evidence consistent with pulmonary emboli
- EKG
- Echo:
 - Looking for evidence of patent foramen ovale
- CT head:
 - For altered mental status
 - Do not delay recompression for CT when AGE almost certain clinically.

DIFFERENTIAL DIAGNOSIS

- Cerebrovascular accident (CVA) from causes unrelated to gas embolism
- Neurologic deficits owing to decompression sickness

TREATMENT

PRE HOSPITAL

- Cautions:
 - Patients who experience sudden neurologic recovery can relapse quickly as bubble positions change.
 - Recognize AGE as a potential diagnosis.
- Altered mental status within 10 min of surfacing from compressed air dive
- Sudden neurologic decompensation following placement of central line
- Controversies:
 - Trendelenburg positioning patients with suspected AGE is not effective:
 - Hypothesized that elevation of legs could cause air bubbles to migrate away from cerebral circulation and that increased hydrostatic pressure in brain will shrink bubbles
 - Trendelenburg positioning may in fact increase injury by increasing intracerebral pressure.

INITIAL STABILIZATION/THERAPY

ABCs:

- 100% oxygen by tight-fitting mask
- Intubation for ventilation/protection of airway required
- IV access with volume augmentation

ED TREATMENT/PROCEDURES

- Hyperbaric oxygen recompression therapy (see “Hyperbaric Oxygen Therapy”):
 - _ For all AGE
 - _ Arrange transportation to nearest hyperbaric facility.
 - _ Aircraft capable of cabin pressurization below 1,000 feet barometric pressure best suited for transfers
 - _ Prophylactic chest tube for simple pneumothorax to prevent conversion to tension pneumothorax during recompression
 - _ Fill endotracheal and Foley catheter balloons with water or saline to avoid shrinkage/damage during recompression.
- Divers alert network (DAN):
 - _ Based at Duke University Medical Center
 - _ Provides 24 hr emergency hotline for medical consultation on treatment of dive-related injuries and for referrals to hyperbaric chambers (telephone: [919] 684-8111)

FOLLOW-UP

DISPOSITION

Admission Criteria

Admit all following initial hyperbaric therapy for observation and re-exam.

Discharge Criteria

No AGE patients should be discharged from the ED.

FOLLOW-UP RECOMMENDATIONS

Hyperbaric oxygen referral for patients with arterial gas embolisms

PEARLS AND PITFALLS

- Symptoms occur during ascent or within 10 min of reaching the surface.
- Patients who experience sudden neurologic recovery can relapse quickly as bubble positions change.
- Fill endotracheal and Foley catheter balloons with water or saline to avoid shrinkage/damage during recompression.

ICD10

T79.0XXA Air embolism (traumatic), initial encounter

ARTERIAL OCCLUSION

Richard E. Wolfe

BASICS

DESCRIPTION

Immediate and severe compromise of the blood supply to a limb, threatening its viability, secondary to the sudden blockage of a peripheral artery

- Arterial embolization
 - Thrombus or plaque
 - Originates from aneurysms or atherosclerotic lesions
 - Emboli typically lodge where there is an acute narrowing of the artery
 - 75% of emboli involve an axial limb vasculature
 - Femoral 28%
 - Arm 20%
 - Aortoiliac 18%
 - Popliteal 17%
 - Visceral and other 9%
- Thrombosis
- Arterial dissection
- Trauma
 - Crush injuries
 - Compression
 - Arterial contusion and thrombosis
 - Arterial transection
- Limb ischemia >6 hr usually results in functional impairment or limb loss.
 - If acute on chronic, collateral circulation may preserve tissue beyond 6 hr.

ETIOLOGY

- Embolus:
 - Atrial fibrillation
 - Myocardial infarction
 - Valvular disease
 - Endocarditis
 - Atrial myxoma
 - Aneurysm
 - Atherosclerotic plaques
 - Paradoxical embolus
 - Patent foramen ovale
- Thrombosis
 - Vascular grafts

- Atherosclerosis
- Thrombosis of an aneurysm
- Entrapment syndrome
- Blood clotting disorders
- Low flow state
- Heparin-induced thrombosis
- Arterial dissection
- Arterial injury:
 - Intimal flap
 - Dissection
 - Pseudoaneurysms
 - Iatrogenic
 - Catheterization
 - Arteriography
 - Balloon angioplasty
 - Complication of arterial puncture
 - Penetrating trauma
 - Gunshot, stab wounds, shotgun, shrapnel
 - IV drug use
 - Blunt trauma
 - Joint displacement
 - Fracture
 - Compartment syndrome

DIAGNOSIS

SIGNS AND SYMPTOMS

- Sudden onset of a cold, painful leg
- The 6 Ps:
 - Pain
 - Gradual, initially increasing in severity then decreasing with progressive sensory loss
 - Distal progressing proximally
 - Sudden onset with embolization
 - Pallor
 - Paresthesias
 - Paralysis
 - Pulseless (late finding)
 - Polar (Cold)
- Progressive peripheral nerve dysfunction
 - Early loss of proprioception and light touch
 - Loss of sensation and weakness follows

- Blue toe syndrome:
 - Development of blue or violaceous discoloration in one or more toes
 - The affected digits are often painful.
 - The cyanosis initially blanches with pressure or leg elevation.
- Signs of severe obstruction and poor prognosis
 - Absent capillary flow
 - Skin marbling
 - Loss of distal pulses
 - Paralysis

History

- Time of onset
- History of claudication or cramps
 - Reproducible discomfort of a defined group of muscles that is induced by exercise and relieved with rest
- Past medical history to identify risk factors for thrombosis or embolus

Physical-Exam

- Sensory loss
- Muscle weakness
- Skin color changes
- Loss of pulse
- Signs of chronic arterial insufficiency:
 - Hair loss
 - Atrophic skin
- Ankle-brachial pressure index measurement
 - Measure arm systolic pressure with the Doppler flowmeter for accuracy
 - Record pressure in both arms and both tibial arteries at the ankle.
 - Ratio of systolic BP in the lower legs to the brachial pressure in the arm:
 - Place cuff above malleoli to measure pressure in lower legs
 - Use Doppler at posterior tibial or dorsalis pedis artery
 - Chronic PVD < 0.9
 - Acute arterial occlusion < 0.5
- Demarcation of the warm part of the extremity to the cold part to estimate level of the obstruction

ESSENTIAL WORKUP

ALERT

Elevation, cool compress or ice, or warm compress to the affected extremity is contraindicated.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Electrolytes/anion gap
- BUN
- Creatinine
- CBC
- Creatine phosphokinase

Imaging

- The utility of imaging in the ED is limited as most of the decision making is based on the clinical presentation
- Duplex US
 - _ Provides a “roadmap” of stenosis of the arteries of the lower extremities
- CT angiography
 - _ With multidetectors, performance is similar to angiography
 - _ Like angiography it requires IV contrast bolus and exposure to radiation
- MRI
 - _ Viable alternative to angiography.
 - _ Noninvasive
 - _ Does not required contrast material
- Angiography

Classification

- Class 1: Viable
 - _ Pain but no paralysis or sensory loss
 - _ Needs attention, not in immediate danger
- Class 2: Threatened but salvageable
 - _ 2A: Some sensory loss, no paralysis: No immediate threat.
 - _ 2B: Sensory and motor loss: Needs immediate treatment
- Class 3: Irreversible/nonviable:
 - _ Sensory loss, paralysis, absent capillary flow, skin marbling, absent arterial Doppler flow
 - _ Will require amputation

DIFFERENTIAL DIAGNOSIS

- Lumbar spine disorders
- Back pain, mechanical
- Decreased cardiac output owing to advanced atherosclerotic disease
- Frostbite
- Peripheral neuropathy
- Aneurysm, abdominal
- Ankle injury, soft tissue
- Deep venous thrombosis
- Septic thrombophlebitis

- Superficial thrombophlebitis
- Trauma, peripheral vascular injuries

TREATMENT

PRE HOSPITAL

- Early recognition and rapid transport to an emergency department
- Place the limb in a dependent position
- Keeping the limb warm
- Oxygen by nasal cannula
- Aspirin

ED TREATMENT/PROCEDURES

- Prompt consultation with vascular surgeon
- Heparin bolus followed by an infusion
- Class 1: Viable
 - _ Most often due to thrombosis
 - _ Intra-arterial thrombolytic agents versus surgical revascularization or endovascular repair depending on viability of limb
- Class 2: Threatened but salvageable
 - _ Immediate surgical revascularization
 - _ Embolectomy if indicated
 - _ Angiography and oral anticoagulation post op
- Class 3: Nonviable
 - _ Prompt amputation
 - _ Clinical assessment, imaging usually not required
- Pain control

MEDICATION

- Heparin: Weight-based protocol anticoagulation with typical 80 U/kg loading bolus; 18 U/kg/h IV

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with clinical diagnosis of acute arterial occlusion or (ABI < 0.5) should be admitted after an emergency consultation with a vascular surgeon.

Discharge Criteria

- Patients with chronic occlusive disease, resolved pain, and stable ABI

measurements

- No other acute medical issues (e.g., new atrial fibrillation)
- Vascular surgical follow-up can be ensured.
- Patients should be instructed to return for any recurrent or progressive symptoms.

Issues for Referral

- PVD patients in which illness is not severe or acute as to require inpatient treatment may be discharged with appropriate follow-up with a vascular surgeon.
- Potential effects of various activities and medications on the course of their illness should be discussed.
- Education on smoking cessation, temperature extremes, and vasoconstricting medications should be considered.

ARTHRITIS, DEGENERATIVE

Patrick H. Sweet

BASICS

DESCRIPTION

- Degenerative arthritis or osteoarthritis (OA) is the most common progressive joint disease, with 20–30 million cases in the US
- Found almost exclusively in the elderly

ETIOLOGY

- Mechanism
- Repetitive stress to synovial joints associated with age
- May be seen in younger patients secondary to joint trauma
- Articular cartilage destruction:
 - Reactive changes in joint margin bone and subchondral sclerosis
- Risk factors include age, obesity, trauma, genetics, sex, and environment.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Chronic progressive joint pain:
 - Worse with weight bearing, improved with rest
- Asymmetric joint involvement:
 - Involves hand, foot, knee, hip, and spine joints
- Morning joint stiffness usually < 30 min
- Joint deformity late in presentation with limited range of motion
- Heberden nodes at the distal interphalangeal joints
- Bouchard nodes at the proximal interphalangeal joints
- Absence of systemic symptoms
- Crepitus common

ESSENTIAL WORKUP

- Thorough joint exam with assessment of range of motion and functional ability
- Radiographic exam: Typical findings in OA are decreased joint space, irregular bone at the joint margin, and osteophytes.
- Synovial fluid analysis in the setting of effusion may be therapeutic and diagnostic (see below), but is absolutely necessary if presents with warmth and erythema so as to rule out a septic joint or gout.
- ESR, CRP, and CBC if infection is in the differential as arthrocentesis may be indicated if a more superficial infection cannot be ruled out (e.g., septic bursitis,

cellulitis, etc.).

DIAGNOSIS TESTS & INTERPRETATION

Lab

Synovial fluid exam typically reveals the following:

- Clear
- Elevated leukocyte cell count, but $< 4,000/\text{mm}^3$
- $< 25\%$ polymorphonuclear leukocytes
- Glucose level similar to blood levels (95–100%)

Imaging

- Radiographs
- Joint space narrowing
- Osteophyte formation
- Marginal bone erosion
- Subchondral sclerosis

DIFFERENTIAL DIAGNOSIS

- Gout or pseudogout
- Septic arthritis
- Rheumatoid arthritis
- Charcot joint
- Hemarthrosis
- Overlying bursitis or soft tissue infection

TREATMENT

The general goal of treatment is to provide relief from symptoms. A patient may have significant radiographic evidence of disease but have very few symptoms. Therefore the treatment regimen is tailored to the patient's symptomatology.

PRE HOSPITAL

Immobilization of affected joint may be indicated until fracture is excluded.

INITIAL STABILIZATION/THERAPY

- Pain management acutely
- Begin a daily medication that can be managed on follow-up with primary care physician.
- Instructions for gentle strengthening exercises
- Avoidance of unnecessary joint immobilization

ED TREATMENT/PROCEDURES

Intra-articular (IA) arthrocentesis and injection:

- Ultrasound (US) guidance is recommended when expertise and instrument is available
- Shown to be an effective low-risk intervention for OA with or without effusion
- Though relatively rare in larger joints, dry tap is a possible finding due to anatomic features of joint and periarticular soft tissue (e.g., fat pad).
 - US very useful in this case
- Careful attention must be given to aseptic technique while joint is in proper position to reduce muscle tension, exposing joint space.
- Vapor coolant or lidocaine 1% or 2% can be used for local anesthesia.
- Usually 1.5 in or greater 22G or 18G hypodermic needle should be used with 1 syringe for arthrocentesis and another for IA corticosteroid injection.
- If septic joint cannot be ruled out, corticosteroids should not be administered after arthrocentesis.

Corticosteroid dosing equivalents:

- Small joints—wrist and foot:
 - Methylprednisolone 10–20 mg, triamcinolone 10 mg, betamethasone 0.75–1.5 mg
- Medium-sized joints—elbow and ankle:
 - Methylprednisolone 40–80 mg, triamcinolone 20 mg, betamethasone 3–6 mg
- Large joints—knee and shoulder:
 - Methylprednisolone 80–120 mg, triamcinolone 40 mg; betamethasone 6–9 mg
- Some studies show triamcinolone to be more efficacious than other corticosteroids; the author recommends this, if available.

MEDICATION

General guidelines:

- Acetaminophen is drug of choice initially as it has a safer medication profile compared with NSAIDs and has been shown to be as efficacious in some patients.
- If one class fails, consider another class (e.g., salicylates vs. COX-2 inhibitors).
- The 2 alternative medications below have been shown to have a small but positive effect by meta-analysis of recent studies and can be considered adjuncts.
- Postprandial administration is recommended for all these. Patients at increased risk for GI bleeding (e.g., history of peptic ulcer disease, etc.) should be placed on COX-2 inhibitors or alternatively a proton pump inhibitor can be given with a nonselective COX inhibitor.
- NSAIDs:
 - Celecoxib (reversible COX-2-selective) 400 mg PO q24:
 - Note: Contraindicated in sulfonamide allergy
 - Ibuprofen (reversible nonselective COX): 400–600 mg PO q6h
 - Naprosyn (reversible nonselective COX): 500 mg PO q12h

- Meloxicam (reversible nonselective COX): 7.5 mg PO q12h or 7.5–15 mg PO q24h
- Analgesics:
 - Acetaminophen: 500 mg (peds: 10–15 mg/kg, do not exceed 5 doses/24 h) PO q4–6h, do not exceed 4 g/24 h
 - Tramadol: 50 mg PO q4–6h:
 - Note: Use cautiously in elderly, patients with seizure disorders, concurrently using antidepressants, or in hepatic or renal dysfunction.
 - Other opioid narcotics rarely used
- Alternative therapies (separate or in combination):
 - Glucosamine: 500 mg PO q8h
 - Chondroitin: 1200 mg PO q24h
- Lifestyle modification:
 - Weight loss for the obese
 - Strengthening exercises

FOLLOW-UP

DISPOSITION

Admission Criteria

Rarely indicated in the absence of fracture

Discharge Criteria

- Ambulatory and capable of activities of daily living
- Improvement in symptoms (i.e., pain)

Sports Medicine Follow-up

- Consider referral to sports medicine clinic for definitive management

ARTHRITIS, JUVENILE IDIOPATHIC

Kathleen A. Kerrigan • Kenneth G. Christian

BASICS

DESCRIPTION

- Previously called JRA
- JIA comprises persistent, unexplained arthritis lasting >6 wk, occurring <17 yr of age, and affecting a heterogeneous group of children.
- Prevalence up to 1 in 1,000 children
- Girls > boys for most forms
- Classified into 7 subgroups: Systemic onset, polyarticular RF⁺, polyarticular RF⁻, pauciarticular, psoriatic, enthesitis, other or unclassified.
- Subtypes are based on number, type, and symmetry of joints involved; presence of systemic symptoms; skin involvement; family history; and lab values.
- Up to 20% of JIA patients remain unclassified or are classified in multiple categories.
- Natural course of the disease depends on the subtype (pauciarticular with overall best prognosis), but full resolution occurs in <50% of JIA patients.
- Many will have a fluctuating course and ongoing disease through adulthood.

ETIOLOGY

Believed to be an autoimmune disease triggered by an unknown environmental trigger in a genetically susceptible host

DIAGNOSIS

Subtypes

- Systemic onset:
 - 10% of cases, girls = boys
 - Associated fever and arthritis:
 - Fever: Diurnal (>39°C) of >2 wk duration, child looks ill during temperature spike
 - Arthritis: May involve any number of joints and may appear only weeks to months after onset of fever
 - In addition there must be 1 of the following:
 - Maculopapular, salmon-colored rash on trunk and axillae
 - Lymphadenopathy
 - Hepatosplenomegaly
 - Serositis
 - Most acute, ill appearing of subtypes

ALERT

- Systemic onset JIA patients are at risk for macrophage activation syndrome (MAS).
- MAS is a proliferation of macrophages causing a DIC-like picture with resultant fever, mucosal bleeding, neurologic changes and multisystem failure.
- ESR may be normal in active MAS
- MAS mortality is 8–22%.
- Pauciarticular:
 - 50% of cases of IJA
 - 80% girls, peak incidence 2–4 yr olds
 - Insidious onset and child appears healthy
 - ≤ 4 joints involved at 6 mo:
 - Involves larger joints, (89% knee) *hip rarely affected*
 - Joints swollen, mildly tender, with decreased range of motion (ROM), possible leg-length discrepancy
 - Uveitis in about 20%; no other systemic signs
 - Subset termed *extended* pauciarticular progresses to greater joint involvement after 6 mo and has worse prognosis
- Polyarticular:
 - 10–30% of cases, girls > boys, bimodal peaks: 2–5 and 10–14 yr
 - > 4 joints involved at 6 mo:
 - Arthritis often symmetrical, small or large joints—commonly knees, wrists, and ankles
 - Decreased ROM of cervical and lumbar spine and temporomandibular joint (TMJ)
 - Systemic involvement rare except for fatigue and anemia
 - Older girls with RF⁺ often go on to develop typical adult rheumatoid arthritis (RA) and are placed in a separate subtype.
- Psoriatic:
 - Arthritis; asymmetric large joints of lower extremities and back
 - Psoriatic rash in patient or 2 of the following: Dactylitis, nail pitting, psoriatic rash in 1st-degree relative
 - Enthesitis-related (*enthesitis* means pain at the insertion of a muscle or tendon)
 - Arthritis; asymmetric large joints of lower extremities
 - Boys > girls, age usually > 6 yr
 - Sacroiliac (SI) joint pain
 - Limited flexion of lumbar spine
 - Uveitis
 - Often FH
- Otherwise unclassified:

– Arthritis not fitting into any distinct category

History

- Findings based on specific subtype
- Classic presentation is insidious arthritis, worse in AM and with periods of immobility, improved with ROM.
- New-onset systemic subtype most likely to use ED because they appear acutely ill, whereas other subtypes have a more insidious onset.

ALERT

- Child with severe pain and red-hot joint probably does not have new-onset JIA.
- Rapid onset of polyarticular joint involvement is atypical for JIA; infectious or reactive cause of arthritis should be ruled out.
- Beware of occult infection in patients on immunosuppressants.

Physical-Exam

- Determine if child is systemically ill: Search for fever, rash, or other nonarthritic involvement.
- Do careful joint evaluation, documenting the number of joints involved and noting whether they are red, warm, and swollen or have limited ROM.

ESSENTIAL WORKUP

- Rule out septic joint and malignant bone tumor.
- Rule out other identifiable causes of joint inflammation.
- Rule out complications from long-term drug therapy.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC, ESR; if ill appearance, add blood cultures
- Other labs if suspicious of specific subtype: rheumatoid factor (RF), antinuclear antibodies (ANA), HLA-B27, LFTs:
 - Systemic—ESR often elevated, leukocytosis, thrombocytosis, anemia, minor AST/ALT elevations, positive RF or ANA rarely seen, MAS may be associated with elevated LFTs and abnormal clotting factors but will often have normal ESR
 - Pauciarticular—common to have positive ANA in young girls; other labs usually normal; if anemic or elevated ESR, are probably misclassified or pauciarticular extended subtype
 - Polyarticular—may be anemic; if positive RF more likely to go on to adult RA, ESR may be elevated
 - Enthesitis—more likely positive HLA; presence of positive RF or positive ANA specifically excludes enthesitis subtype

- Psoriatic arthritis—usually seronegative RF
- Unfortunately, RF and ESR may also be elevated in acute infection unrelated to JIA.

ALERT

Consider adding Lyme titer if new joint swelling in endemic area.

Imaging

- Joint radiograph:
 - Early presentation: Soft tissue swelling, joint effusion
 - Late presentation: Osteoporosis, joint destruction, early growth plate closure
- Ultrasound:
 - Evaluate for small effusion, especially if tap considered.

Diagnostic Procedures/Surgery

Arthrocentesis if concern for septic arthritis: 5,000–8,000 WBC/mm³ with negative Gram stain and culture typical for JIA

DIFFERENTIAL DIAGNOSIS

- Trauma
- Infection:
 - Septic arthritis, viral infection (especially parvovirus), Lyme disease, rheumatic fever, tuberculosis, subacute endocarditis, malaria, *Neisseria gonorrhoeae* infection
- Other rheumatic/connective tissue diseases:
 - Systemic lupus erythematosus, polyarteritis nodosa, Henoch–Schönlein purpura, sarcoid
 - Legg–Calvé–Perthes disease/slipped capital femoral epiphysis
- Neoplasm:
 - Be suspicious of neoplasm in a severely uncomfortable child with midshaft bone pain.
- Hematologic disease:
 - Sickle cell disease, hemophilia
- Drug reactions

TREATMENT

INITIAL STABILIZATION/THERAPY

Toxic-appearing children: IV access, O₂

ED TREATMENT/PROCEDURES

- ED treatment is directed toward ruling out a septic joint and other causes of acute arthritis
- If the diagnosis of JIA is already established and the child presents with an acute flare, a treatment plan/medication adjustment should be coordinated with the child's rheumatologist.

MEDICATION

- Medication in children with JIA is geared toward eliminating clinical signs of active disease, maximizing joint function, and preserving growth. (Chronic inflammation can make affected limb slightly longer.)
- Efficacy depends on JIA subtype and disease severity.
- Most pauciarticular JIA responds to NSAIDs and joint injections; polyarticular and systemic JIA usually require disease-modifying antirheumatic drug (DMARD) therapy and/or biological agents.
- Antibiotics are indicated only if the joint is infected.

ALERT

As early aggressive therapy may prevent some of the long-term complications of JIA, it is now common for children to be placed on DMARDs and biological agents early in the disease course. These medications have serious potential side effects, including:

- Immunosuppression
- Decreased vaccine response (live vaccinations are contraindicated)
- Increased potential for malignancy
- NSAIDs:
 - _ Responsiveness differs within NSAID subtype
 - _ Used alone in mild JIA subtype or with other medications
 - _ Ibuprofen: 30–45 mg/kg divided TID–QID
 - _ Naproxen: 10–20 mg/kg divided BID; maximum daily dose 1,000 mg
 - _ Side effects: Gastritis, hepatitis, renal, headache, dermatitis
 - _ Intra-articular steroids: Triamcinolone hexacetonide: 1 mL/mg of 20 mg/mL solution
 - _ Often provide long-term (6–18 mo) relief
- DMARDs:
 - _ Include corticosteroids, methotrexate, sulfasalazine
 - _ Corticosteroids
 - _ Use judiciously because of long-term complications, but high-dose pulse therapy may be needed in acute attack.
 - _ Prednisone: 0.5–2 mg/kg PO
 - _ Methylprednisolone: 30 mg/kg daily IV up to 1 g for 1–5 days for high-dose pulse steroids
 - _ Side effects: Gastritis, adrenal suppression, osteopenia, Cushing syndrome, infection
 - _ Methotrexate: 5–15 mg/m² PO/SC or IM per week

- Considered 1st-line DMARD, as most will respond
- Side effects: GI, nausea, liver toxicity, teratogenic
- Sulfasalazine: 30 mg/kg/d divided QID
- Poorly tolerated in up to 30%
- Side effects: GI, rash, anorexia
- Biological agents—engineered to target specific key cytokines, very expensive
- Tissue necrosis factor binders
- Etanercept: 0.8 mg/kg SC once a week
 - Adalimumab: < 30 kg: 20 mg, > 30 kg: 40 mg given SC administered every other week
 - Side effects: Infection, injection-site reactions, inhibit T-cell activation
 - Abatacept: 10 mg/kg infusion q4wk
 - Side effects: Infusion reaction, HA, cough, nausea, infection
- Non-FDA–approved therapies:
- Remicade, rituximab, anakira, leflunomide IL-1 and IL-6 blockers
- Stem cell transplants are used rarely for severe cases unresponsive to medical treatment:
 - Treatment for MAS is nonstandardized but may include high-dose steroids, cyclosporine, cyclophosphamide, or intravenous immunoglobulin

FOLLOW-UP

DISPOSITION

Admission Criteria

Unclear diagnosis in ill-appearing child or if concern of secondary joint infection

Discharge Criteria

- No evidence of septic joint, systemic infection, or organ failure from drug therapy
- Patient appears comfortable.
- Appropriate follow-up has been arranged.

Issues for Referral

- Orthopedics if septic joint suspected
- Rheumatologist if meds need adjustment

FOLLOW-UP RECOMMENDATIONS

- Children need long-term consults with a rheumatologist.
- Children with JIA need frequent eye exams to rule out uveitis (which is often asymptomatic until permanent damage has occurred).

PEARLS AND PITFALLS

- Rule out acute joint infection (always consider Lyme disease in the appropriate geographic context).
- Consider systemic onset JIA in child with prolonged diurnal febrile illness that is unresponsive to antibiotics.
- Consider MAS in systemic onset JIA patients who appear septic.
- Review patient's medications to identify potential side effects or immunosuppression.

- M08.90 Juvenile arthritis, unspecified, unspecified site

ARTHRITIS, MONOARTICULAR

Paul Blackburn

BASICS

DESCRIPTION

- Localized to 1 joint, not migratory
- 1 etiology does not exclude another
- *Infectious (septic) arthritis*: Rapidly destructive process causes significant disability
 - Contiguous extension (cellulitis, osteomyelitis), hematogenous spread, direct inoculation
 - Predisposing factors:
 - Local pathology (inflammatory arthritis, trauma, prosthetic joint)
 - Immunosuppression
 - IV drug use
- *Crystalline*:
 - *Gout*: Uric acid overproduction or underexcretion, deposited within and around joints.
 - *Pseudogout*: Calcium pyrophosphate
- *Noninflammatory conditions*
 - Osteoarthritis (DJD), trauma (fractures, hemarthrosis), autoimmune disorders
 - Progressive joint destruction; mechanical dysfunction
 - Bone reactive changes (spurring)
 - Subchondral bony erosions

ETIOLOGY

- *Infectious (septic)*
 - Most common organisms nongonococcal
 - Gram-positives: *Streptococcus*, *Staphylococcus* (80%)
 - Some associations:
 - *Staphylococcus aureus*: (trauma, IV drug use)
 - *Neisseria gonorrhoea* (STD)
 - Salmonella (sickle cell) but most common causes in sickle cell same (*Staphylococcus*, *Streptococcus*)
 - Less common: Fungal (chronic), spirochete (Lyme), viral (polyarticular), mycobacteria (TB)
- *Crystalline*:
 - *Gout*: Uric acid overproduction, underexcretion within, around joints
 - *Tophi*: Crystal deposits near recurrent flare sites. Progressive enlargement, may ulcerate “spit out” (discharge) crystals

- Negatively birefringent crystals
- *Pseudogout*: Calcium pyrophosphate
- Positively birefringent crystal
- Bariatric surgery: Postoperative gout flares common, frequent, significant. Prophylactic treatment effective, recommended
- *Inflammatory*
 - Diligent search for underlying cause, resultant conditions: arthritides (rheumatoid, psoriatic), inflammatory bowel disease, Reiter syndrome
- *Noninflammatory conditions*
 - Osteoarthritis or degenerative joint disease (DJD), overuse, overload (obesity)
 - Trauma (fractures, hemarthrosis)
 - Hemorrhagic disorders
 - Neuropathic disorders (Charcot joint)

Pediatric Considerations

- *Infectious (septic) arthritis*
 - Low incidence, high morbidity, sepsis (8%)
 - Most common: *S. aureus*, hip > knee, 50% coexisting osteomyelitis
 - Present like adults: Joint swollen, painful, worsened with weight bearing, movement; constitutionally ill (fever, lassitude)
 - Immediate aspiration, empiric treatment, admission mandatory
- *Inflammatory*
 - A diagnosis only after septic joint excluded; then considerations same as adults
- *Noninflammatory:*
- Orthopedic considerations to not overlook:
 - Salter–Harris epiphyseal plate fractures
 - Congenital hip dysplasia
 - Slipped capital femoral epiphysis (SCFE)
 - Overweight adolescents
 - Legg–Calve–Perthes:
 - Osteonecrosis femoral head
 - Age 4–9
 - Bleeding disorders, hemorrhage

DIAGNOSIS

Early accurate diagnosis allows directed therapy, earlier resumption of function, activities of daily living (ADL); longer-term morbidity lessened

SIGNS AND SYMPTOMS

- Isolated to 1 joint, not migratory

- Acute pain, swelling, redness, warmth
- Decreased range of motion, nonweight bearing (effusion, pain, osteomyelitis)
- *Infectious (septic) arthritis*:
 - Constitutionally ill, fever, chills
 - Larger joints swollen, painful range motion
 - Knee > hip = shoulder > ankle > wrist
 - *N. gonorrhoea*: Urethral discharge painful, purulent (males)
 - Lyme disease:
 - Spirochete *Borrelia burgdorferi*
 - Deer tick (*Ixodes dammini*)
 - Circular expanding, centrally clearing, eruption (*erythema chronicum migrans*)
 - Knees, shoulders most common
- *Crystalline*:
 - Sudden, severe pain, swelling, erythema
 - Recurrent, self-limited flares
 - *Gout*: Great toe joint (“podagra”) > ankle > tarsal joints > knee
 - *Tophi*: Crystal granulomas overlying affected joints; ulcerate, drain crystals
 - *Pseudogout*: Knee > wrist > ankle = elbow
- *Inflammatory*:
 - Protean manifestations, findings related to systemic conditions
 - Individual, multiple, combination organ system involvement. Example: Reiter syndrome: Iritis, urethritis, arthritis
- *Noninflammatory conditions*
 - Osteoarthritis (DJD):
 - Stiffness AM (inactivity), after activity (synovial gelling), relieved with rest
 - Trauma: Acute or distant, gradual swelling episodes, pain pattern same as DJD
 - Neuropathic: Charcot joint (“bag of bones”), little or no pain—chronic neuropathy
 - Hemarthrosis, hemorrhagic disorders

History

- See “Description,” “Etiology,” “Pediatric Considerations,” and “Signs and Symptoms.”
- Complete, meticulous history: Joint issues or involvement (recent, remote), systemic conditions (direct, local, remote manifestations), immune status (HIV, medications, disease process), STD (history, exposure, treatment type and duration), IV drug use.

Physical-Exam

See “Description” and “Signs and Symptoms.”

ESSENTIAL WORKUP

- Meticulous history and physical exam
- Condition—related diagnostic studies
- Arthrocentesis for synovial fluid analysis is the definitive diagnostic procedure.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Blood testing never the key diagnostic studies of choice for monoarticular arthritis; provides ancillary, corroborative, exclusionary information.
- Arthrocentesis for synovial fluid aspiration and analysis the definitive diagnostic procedure and studies.
- Synovial fluid culture the definitive synovial study regarding infection, but results not immediate (inherent nature of the test)
- Fluid appearance: Clear versus turbid, serous versus bloody, viscosity (“string sign”), volume removed, associated pain (levels, trends)
- Synovial fluid white blood cells (WBC), polymorphonuclear (PMN) predominance suggests septic etiology
 - WBC $> 50,000/\text{mm}^3$ increases likelihood of septic arthritis
- Synovial glucose: Most useful compared to concurrent blood glucose levels
 - Synovial glucose less than half blood value indicates likely septic process
- *Gram stain (positive stain)*: Directs initial antibiotic selection, administration
 - Gram + cocci: Vancomycin
 - Gram – cocci: Ceftriaxone
 - Gram – rods: Ceftazidime
- *Gram stain (negative stain)*: Clinical suspicion for septic joint: Empiric vancomycin + ceftazidime or aminoglycoside
- Viscosity: “String sign”
 - Slowly drip fluid off needle or syringe, noting the length of the “stringing.”
 - Noninflammatory fluid has longer strings
 - Inflammatory fluid will drip like water
- Crystal analysis: Polarized light microscopy for birefringent crystals: Gout (negative), pseudogout (positive)
- Rheumatologic “screening panel” for suspected disease: Uric acid, C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), rheumatoid factor (RF), anticyclic citrullinated peptide (ACCP)
- Lyme testing (anti-*Borrelia* titers or “Lyme titers”) for monoarticular arthritis presenting in endemic areas
- Fat globules in bloody aspirate: Suspect fracture with marrow (fat globules), synovial space communication

Imaging

- *Plain films* reasonable cost-effective choice:
 - Joint surfaces: Chondral, subchondral erosions, joint margin destruction or reactive bone formation (osteophytes, “spurring”), loose bodies, fractures
 - *Infectious*: As above plus soft-tissue swelling, joint capsule distortion
 - *Crystalline*: As above plus soft-tissue calcification, tophi usually located on or near frequent, repetitive joint flares
- *Ultrasound*: Detects joint fluid, tissue and vascular perfusion, periarticular structures, foreign bodies (especially if small, superficial organic composition of tissue density)
 - Guides aspiration attempts
- *MRI* detects bone necrosis, subtle fractures
- Bone or gallium scans do not distinguish Infectious versus inflammatory, especially chronic

Diagnostic Procedures/Surgery

See “Diagnostic Tests & Interpretation” above.

- Arthrocentesis for synovial fluid aspiration, analysis the definitive diagnostic procedure and laboratory studies.

DIFFERENTIAL DIAGNOSIS

See “Etiology” and “Signs and Symptoms” “Pediatric Considerations” above.

TREATMENT

PRE HOSPITAL

Alluding to subsequent headings containing all pertinent consideration.

INITIAL STABILIZATION/THERAPY

- Joint immobilization, position of comfort
- Vascular access for rapid, titratable, predictable medication effects
- Symptom control: Pain, nausea, vomiting, fluid replenishment
- Joint aspiration as soon as practicable; analysis directs therapy, disposition

ED TREATMENT/PROCEDURES

- See “Diagnostic Procedures” above
- *Septic arthritis*:
 - Urgent empiric IV bactericidal antibiotics: Ceftriaxone, vancomycin for *Staphylococcus*, *Streptococcus*, gonococcal arthritis
 - Subsequent outpatient antibiotics (PICC line, oral) therapy duration variable, multifactorial: Joint involved, organism, underlying health, patient compliance, medical costs

- Surgical irrigation considerations (“washouts”): Joint involved, open versus closed, single versus multiple sequential, comorbid conditions, patient compliance, medical costs
- *Crystalline*:
 - Treatment goals: (1) Quell the acute flare: NSAIDs (indomethacin, naproxen), colchicine, steroids; (2) only after acute exacerbation quelled:
 - Prophylaxis with flare prevention medications (colchicine, naproxen), begin urate-lowering therapy (allopurinol, febuxostat)
 - Febuxostat as effective or greater than allopurinol for gout flares, tophus area, uric acid levels.
 - Probenecid: Efficacious long-term uricosuric, alone or in conjunction with allopurinol
- *Noninflammatory*:
 - NSAIDs, analgesics
 - Physical therapy, rehabilitation
 - Orthopedic trauma: Immobilize, pain control, ensure neurovascular status intact
 - Hemorrhagic causes: Correction of factor levels, component replacement

FOLLOW-UP

DISPOSITION

Admission Criteria

- Unable to perform ADL
- Evidence systemic illness, metabolic derangement (sepsis, DKA)
- Any joint requiring surgical intervention (including serial washouts)
- Intractable pain
- *All septic arthritis*
 - General medical/surgical bed
 - Intensive care unit if generalized sepsis, metabolic derangement
- *Crystalline*:
 - Intractable nausea, vomiting, diarrhea
 - Septic joint superimposed on other arthritis

Discharge Criteria

- Symptoms (including pain) controlled, comorbid conditions stable, managed appropriately
- Medication compliance: Can obtain medications (economically, logistically), understands dosages, time intervals.
- Timely follow-up possible

Issues for Referral

Immediate consultation, admission for infectious etiologies, intractable pain, poorly controlled comorbid illnesses, interference with ADL

FOLLOW-UP RECOMMENDATIONS

- As soon as practicable, with health care providers best suited, capable of treating the condition in question.
- If unable to acquire the appropriate care in a timely manner, return to ED (safety net).

PEARLS AND PITFALLS

- Joint aspiration with Gram stain of fluid is the most important aspect of securing a diagnosis, directing initial management
- Suspect septic arthritis in the presence of Intra-articular corticosteroid administration, diabetes, drug abuse, trauma, injections through cellulitis and extra-articular infection

- M10.00 Idiopathic gout, unspecified site
- M19.90 Unspecified osteoarthritis, unspecified site

ARTHRITIS, RHEUMATOID

Charles F. Lanzillo • Stephen R. Hayden

BASICS

DESCRIPTION

- Chronic systemic inflammatory disorder that attacks the joints:
 - Nonsuppurative, proliferative synovitis
 - Destruction of the articular cartilage
 - Ankylosis of the joint
- Involvement of knee is common.
- Baker cysts may be seen in chronic disease.
- Involvement of spine is limited to cervical region:
 - May cause atlantoaxial subluxation
 - Rarely results in cord compression

Pediatric Considerations

Juvenile rheumatoid arthritis (JRA) is a distinct entity (see “Arthritis, Juvenile Idiopathic”).

- Genetics:
 - Genetic predisposition related to HLA-DR4
 - Female-to-male ratio is 3:1.
 - Typical age of onset is between 30 and 50.

ETIOLOGY

- Etiology is unknown.
- Possible triggers include infection and autoimmune response.
- Prevalence is about 1% of both US and world population.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Malaise, fatigue
- Generalized musculoskeletal pain
- After weeks to months, patients develop swollen, warm, painful joints.
- Often worse in morning
- Joint involvement usually symmetric and polyarticular
- Starting in small joints of hands and feet:
 - Later wrists, elbow, and knees
- Distal interphalangeal (DIP) joints of hand generally not involved:
 - Presence of swelling in these joints should suggest another type of arthritis.

- Synovitis is typically gradual.
- Classic joint findings in long-standing disease:
 - Metacarpophalangeal (MCP) swelling with ulnar deviation
 - Swan neck and boutonniere deformities
- Extra-articular complications:
 - SC nodules
 - Vasculitis
 - Pericarditis or myocarditis
 - Pulmonary fibrosis
 - Pneumonitis
 - Sjögren syndrome
 - Mononeuritis multiplex
- Evidence of mild pericarditis on echocardiogram is found in up to 1/3 of patients.
- Consider ECG evaluation in these patients
- Patients usually present to ED owing to exacerbations of the disease or complication in other organ systems:
 - Airway obstruction from cricoarytenoid arthritis or laryngeal nodules
 - Heart block, constrictive pericarditis, pericardial effusion with possible tamponade or myocarditis
 - Pulmonary fibrosis, pleuritis, intrapulmonary nodules, or pneumonitis
 - Hepatitis
- Neurologic findings may result from cervical spine subluxation or ocular manifestations such as scleritis and episcleritis.
 - Can also have retinal vasculitis in periphery, and recurrent iritis—consider in patients with photophobia, red eye, and decreased vision. These patients need ophthalmologic evaluation
- Complications of chronic steroid use:
 - Infections
 - Steroid-induced osteopenia and fractures
 - Insulin resistance
 - Glaucoma or IOP elevation, accelerated cataracts
- Patients may present with side effects related to chronic salicylate or NSAID use such as GI bleeding.
- Drugs such as methotrexate, gold, or d-penicillamine also have toxic side effects, most commonly GI but also neuropathic.

ESSENTIAL WORKUP

- Primary diagnosis of rheumatoid arthritis (RA) is rarely made in the ED.
- Synovitis should be present for at least 6 wk; a minimum of 4 of the following 7 criteria as established by the American Rheumatism Association must be met to make the diagnosis:
 - Stiffness of the involved joints in the morning for at least 1 hr
 - Arthritis in 3 or more joints with effusion or soft tissue swelling

- Arthritis of joint in hand (wrist, MCP, or proximal interphalangeal [PIP] joint)
- Symmetric arthritis
- Rheumatoid nodules on extensor surfaces or juxta-articular surfaces
- Significantly elevated rheumatoid factor
- Characteristic radiographic changes include erosions and decalcification (not attributable to osteoarthritis).
- Other pertinent history: Malaise, weakness, weight loss, myalgias, bursitis, tendonitis, fever of unknown cause
- Initial workup should focus on demonstrating that other causes of arthritis are not present, especially septic arthritis, reactive arthritis, or gout.
- Arthrocentesis of a joint effusion may be required.

DIAGNOSIS TESTS & INTERPRETATION

ECG, chest radiograph, C-spine or extremity radiograph, and hemoglobin testing are helpful if patient presents with complications of RA.

Lab

- CBC: Mild anemia with leukocytosis and thrombocytosis
- Erythrocyte sedimentation rate (ESR): Often > 30 . Guide for elevation is $\text{age}/2$ in men, $(\text{age} + 10)/2$ in women. Consider GCA in patients with elevated markers and RA with vision loss that is acute.
- C-reactive protein correlates with erosive disease
- Antinuclear antibodies (ANA) 30–40% positive screening tool
- Rheumatoid factor: Elevated in $\sim 70\%$ of cases
- Joint fluid analysis:
 - Typically between 4,000 and 50,000 white cells
 - Neutrophil predominance
 - Microscopic Gram stain of fluid should show no organisms and no crystals.
- ECG: Conduction defects are rare, but heart block may be seen. May see evidence of pericarditis.

Imaging

- Joint radiograph:
 - Joint effusion
 - Juxta-articular erosions and decalcification
 - Narrowing of joint space
 - Loss of cartilage
- MRI of joints can detect early inflammation before plain radiograph
- CXR reveal pulmonary fibrosis, pleural changes, nodular lung disease, or pneumonitis:
 - Cardiac silhouette may show changes related to myocarditis.
- Cervical spine radiograph:

- Atlantoaxial joint subluxation may occur.

DIFFERENTIAL DIAGNOSIS

- Osteoarthritis
- Septic arthritis
- Reactive arthritis
- Gonococcal arthritis
- Lyme disease
- Gout
- Connective tissue disorders
- Systemic lupus erythematosus (SLE), dermatomyositis, polymyositis, vasculitis, Reiter syndrome, and sarcoid
- Rheumatic fever
- Malignancy

TREATMENT

PRE HOSPITAL

Cervical spine immobilization and airway support as indicated

INITIAL STABILIZATION/THERAPY

- ABCs:
 - Manage airway with attention to C-spine immobilization during intubation.
- Treat complications of RA as appropriate.

ED TREATMENT/PROCEDURES

- Salicylates or NSAIDs are 1st-line treatment for RA:
 - If 1 NSAID fails, another NSAID from a different chemical class may work better.
- Early treatment of RA is important as joint changes may be most progressive during the 1st 18 mo.

MEDICATION

- Glucocorticoids, methotrexate, and other 2nd-line therapies should be initiated by a rheumatologist.
- Aspirin (ECASA): Adult: 900 mg PO QID (2.6–5.4 g/d); peds: 60–90 mg/kg/d QID up to 3.6 g

Note: Enteric coated aspirin has delayed absorption and its analgesic effects will be delayed compared to regular aspirin. Doses of aspirin needed for anti-inflammatory effect approach toxic doses. Patients should be closely monitored and dose carefully titrated to avoid toxicity.

- Auranofin: 3–9 mg/d (peds: 0.15 mg/kg/d up to 9 mg) divided BID
- Celecoxib (Celebrex): 100–200 mg PO BID; peds: N/A

- Hydroxychloroquine: Adult: 200–600 mg/d divided BID
- Ibuprofen (Ibuprofen, Advil, Motrin): 200–800 mg (peds: 10 mg/kg) PO q6h
- Leflunomide: 100 mg PO daily for 3 d, then maintenance dose of 10–20 mg PO daily; peds: N/A
- Methotrexate: 7.5 mg once/wk
- Prednisone: Maintenance: 5–10 mg PO daily; acute exacerbations: 20–50 mg PO daily; peds: Maintenance: 0.1 mg/kg/d PO, acute exacerbations: 2–5 mg/kg/d PO
- Sulfasalazine: Adult: 500–1,000 mg PO BID; peds: 30–60 mg/kg/d BID. up to 2 g
 - Not recommended in children <6 yr
- NSAIDs and Tramadol for breakthrough pain.
- Newer DMARDs and monoclonals need to be dosed by a rheumatologist and should likely not be prescribed in the ED: Abatacept, Adalimumab, Anakinra, Etanercept, Infliximab, Rituximab, Tocilizumab.

ALERT

Recent studies have shown possibly increased risk of cardiovascular event with NSAID medications, particularly with COX-2 inhibitors.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with severe or life-threatening presentations of RA and its complications should be admitted to hospital.
- Admission is warranted when diagnosis is unclear and serious illnesses such as septic joint or systemic vasculitis may be present or cannot be ruled out.
- Admission may be required for pain control.
- Admission may be required if patient has inadequate social support and is unable to maintain activities of daily living.
- Pediatric patients with fever and arthritis should be strongly considered for admission.

Discharge Criteria

Patients without serious complications may be managed as outpatients with appropriate medications and follow-up.

Issues for Referral

All patients should have primary physician for further therapy and care as well as appropriate specialty care referral such as rheumatologists, cardiologists, and orthopedics.

PEARLS AND PITFALLS

- Recognize that symmetric arthritis is more consistent with RA.
- Even patients with RA can get septic arthritis.
- Consult rheumatologist rather than initiate steroids or TNF antagonists from ED.

- M06.079 Rheumatoid arthritis w/o rheumatoid factor, unsp ank/ft

ARTHRITIS, SEPTIC

Amin Antoine Kazzi • Elie R. Zaghrini

BASICS

DESCRIPTION

- Bacteria can be introduced into a joint by:
 - Hematogenous spread (most common)
 - Invasive procedures
 - Contiguous infection (e.g., osteomyelitis, cellulitis)
 - Direct inoculation such as plant thorns or nails
- Acute inflammatory process results in migration of WBCs into joint.
- Synovial hyperplasia, cartilage damage, and formation of a purulent effusion
- Irreversible loss of function in up to 50%
- Mortality rate reported as high as 11%

Pediatric Considerations

- Hip infections are most common:
 - Often in patients with otitis media, upper respiratory tract infections or history of femoral venipuncture
 - Complications of septic arthritis (SA) of hip in children: Avascular necrosis, epiphyseal separation, pathologic dislocation, and arthritis
- 50% occur in children < 3 yr old.
- Infants present with irritability, fever, and loss of appetite.
- Older children present with fever, and a limp or refusal to bear weight or use joint.

ETIOLOGY

- Risk factors:
 - Old age, infancy
 - Rheumatoid arthritis and degenerative joint disease
 - Intravenous drug user (IVDU), endocarditis
 - Females (gonococcal [GC] infection)
 - Immunosuppression (AIDS, diabetes, chemotherapy, steroid therapy)
 - Repeated joint injections, pre-existing joint diseases, trauma, or prosthesis
 - Skin infection, cutaneous ulcers
- No bacterial pathogen is identified in 10–20%.
- Most common organisms:
 - *Staphylococcus aureus* in adults, hip infections (80%), and patients with rheumatoid arthritis or diabetes
 - *Multidrug-resistant S. aureus (MRSA)* has been noted in some studies to be the most common organism in community-onset adult SA.

- *Neisseria gonorrhoeae* most common in young, healthy, sexually active patients (incidence has decreased over the past decades due to a decrease in the incidence of mucosal GC infections)
- Other pathogens: Group A β -hemolytic and group B, C, and G streptococci:
 - Gram-negative rods (e.g., *Pseudomonas aeruginosa*, *Escherichia coli*) in 10% of cases
 - *Neisseria meningitidis* (12% of patients with meningococcal meningitis)
- Common in old age, infancy, immunosuppression, and IVDU (*Pseudomonas*)
- Anaerobes: Diabetes, prosthetic joints
- Mycobacterial and fungal causes: Atypical (e.g. in advanced HIV); more indolent course

DIAGNOSIS

SIGNS AND SYMPTOMS

- Presents abruptly as a single painful, swollen, warm, tender joint
- Common findings include:
 - Fever
 - A separate source of infection (e.g., skin)
 - Extremely painful joint motion in all planes
 - A joint effusion (less evident in sacroiliac, hip, and shoulder)
- Any joint can be involved:
 - Typically a single joint is involved.
 - Most commonly knee, then hip, shoulder, and ankle
- Commonly seen in IVDUs: Sacroiliac costochondral and sternoclavicular joints:
 - Vertebral involvement such as lumbar facets possible
- Human and animal bites, plant thorns, local steroid therapy, and trauma may lead to infection in atypical locations.
- Polyarticular involvement in 10–20%:
 - Mostly with rheumatoid arthritis; delay in diagnosis from low suspicion and more subtle presentations (fever in only 50%)
 - Patients with sepsis
- GC SA features:
 - Develops in 1–3% of untreated gonorrhea and in 42–85% of disseminated GC infection:
- Typically monoarticular but commonly polyarticular
- Migratory polyarthralgia, tenosynovitis (present in 20% of patients with arthritis), and dermatitis:
 - Involves small joints (e.g., fingers, wrist, elbow, ankle)
- Signs of urethral or vaginal GC infection may be present.
- Painless maculopapular lesions on trunk, arms, legs, and around affected joint

ESSENTIAL WORKUP

Arthrocentesis

- Perform joint aspiration in any suspected case.
- Send fluid for protein and glucose, cell count, Gram stain, and culture.
- Typical SA findings:
 - A turbid, purulent, or serosanguineous fluid
 - A leukocytosis (50,000–150,000/mm³) with a polymorphonuclear predominance (>75%)
 - Often a decreased glucose and elevated protein level
- Appearance of crystals does not rule out SA.
- Use special stain or culture media when indicated (e.g., GC, anaerobes, fungus, mycobacterium)
- Intra-articular lidocaine reduces the sensitivity of subsequent cultures; immediate emptying of aspirated sample into a blood culture flask increases the yield.
- In non-GC SA, Gram stain and culture are positive in 50% and 90% of cases, respectively:
 - Drops to nearly 10% and 50% in GC SA, respectively
- Real-time PCR can detect bacterial pathogen DNA in many culture-negative aspirates.
- Fluoroscopic, sonographic, or CT guidance can be used in technically difficult aspirations.
- CT scan and MRI may aid in the diagnosis for joints such as the sacroiliac joint.
- Arthrocentesis is contraindicated whenever there is an underlying joint prosthesis or an overlying skin infection:
 - If cellulitis present, use an alternate approach through normal skin.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Nonspecific serum leukocytosis (more common in children), left shift, and C-reactive protein (CRP) and ESR elevation are usually present.
- Procalcitonin can be a helpful aid to rule in rather than rule out SA
- UA and culture can reveal a urologic source for the pathogen.
- Blood cultures may be useful: Positive in 50–70% of non-GC SA.
- Culture any potential focus of infection (pharynx, urine, cervix, or anus), particularly when suspecting GC.

Imaging

- Plain radiographs to identify:
 - Effusion
 - Baseline status of the joint
 - Contiguous osteomyelitis
 - Concurrent rheumatologic diseases

- Fractures or foreign body
- Joint loosening (a late nonspecific sign)
- US, CT, and MRI are more sensitive:
 - US may be used to guide aspiration of some joints (e.g., hip) and to detect joint effusions.
- Scintigraphic techniques are sensitive and specific in diagnosis of SA. However, they are often not available through ED.
- Other tests:
 - Bacterial DNA amplification techniques in rapid detection and identification of organisms

DIFFERENTIAL DIAGNOSIS

- Viral arthritis
- Rheumatoid arthritis
- Gout or pseudogout
- HIV-associated arthritis
- Reactive arthritis
- Lyme disease
- Osteomyelitis
- Endocarditis
- Septic bursitis
- Trauma
- In children:
 - Juvenile idiopathic arthritis
 - Slipped capital femoral epiphysis
 - Legg–Calvé–Perthes disease
 - Metaphyseal osteomyelitis
 - Transient synovitis

Pediatric Considerations

- Because of vaccine, *Haemophilus influenzae* is no longer the most common agent.
- *S. aureus* is most common.
- Group B streptococcus, enterobacteria, and gram-negative rods in the newborn

TREATMENT

PRE HOSPITAL

No specific considerations

INITIAL STABILIZATION/THERAPY

- Patient may be septic and require resuscitation.
- If patient is toxic, do not delay antibiotics for aspiration results.

ED TREATMENT/PROCEDURES

- Promptly aspirate joint fluid.
- Obtain cultures.
- Start empiric antibiotics based on Gram stain (if available) and age group or risk factors—consider staphylococcal, streptococcal, and gram-negative coverage; and MRSA in the appropriate setting. Recommended duration of treatment is 2–4 wk. Intra-articular antibiotics are contraindicated.
- No risk factors for atypical organisms:
 - Use Flucloxacillin or equivalent 2 g QDS IV. Local policy may be to add gentamicin IV.
 - If penicillin allergic, clindamycin 450–600 mg QDS IV or 2nd or 3rd generation cephalosporin IV.
- High risk of gram-negative sepsis (elderly, frail, recurrent UTI, and recent abdominal surgery):
 - 2nd or 3rd generation cephalosporin for example, cefuroxime 1.5 g TDS IV. Local policy may be to add flucloxacillin IV to 3rd generation cephalosporin.
 - Gram stain may influence antibiotic choice.
- MRSA risk (known MRSA, recent inpatient, nursing home resident, leg ulcers or catheters, or other risk factors determined locally):
 - Vancomycin IV + 2nd or 3rd generation cephalosporin IV
- Suspected gonococcus or meningococcus:
 - Ceftriaxone IV or similar
 - Dependent on local policy or resistance
- IVDUs: Discuss with microbiologist
- ICU patients, known colonization of other organs (e.g., cystic fibrosis): Discuss with microbiologist
- Early orthopedic consultation to evaluate eligibility for surgical drainage
- Pain control: Narcotics and moderately flexed splinting
- Immunologic therapies are experimental.
- Prosthesis: Some may try to preserve the limb unless it is loose on plain films.
- Patients should be at rest with joint maintained in optimal position to prevent damage.

MEDICATION

- Cefazolin: 1–2 g IV q6h
- Ceftazidime: 1–2 g IV q8h
- Cefotaxime: 2 g IV q8h; peds: 50 mg/kg q12h
- Ceftriaxone: 2 g IV QD; peds: 50 mg/kg
- Ciprofloxacin: 400 mg IV q12h
- Flucloxacillin: 2 g QD IV
- Gentamicin: 2–5 mg/kg IV load
- Nafcillin: 2 g IV q4h; peds: 25 mg/kg q6h

- Tobramycin: 1 mg/kg IV q8h; peds: 2.5 mg/kg q8h
- Vancomycin: 1 g IV q12h; peds: 10 mg/kg q6h

Pediatric Considerations

- Open surgical drainage is the method of choice in pediatric hip SA.
- Cover *H. influenzae* type B if prior immunization cannot be established.

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with suspected SA should be admitted until SA is ruled out.
- May undergo drainage of joint, as indicated, by serial aspirations, arthroscopy, or arthrotomy

Discharge Criteria

Cases where suspected SA has been adequately ruled out

PEARLS AND PITFALLS

- CRP and ESR can be used to follow up response to treatment
- It can be difficult to distinguish SA from toxic synovitis or crystal arthropathy; have a low threshold for arthrocentesis.

- M00.059 Staphylococcal arthritis, unspecified hip

ASCITES

Paul J. Allegretti • Keri Robertson

BASICS

DESCRIPTION

- Pathologic accumulation of serous fluid in the peritoneal cavity
- Portal hypertension (> 12 mm Hg) starts fluid retention.
- Avid sodium retention state
- Retained sodium and water increases plasma volume.
- Water excretion becomes impaired.
- Increased release of antidiuretic hormone (ADH)
- Urinary sodium retention, increased total body sodium, and dilutional hyponatremia
- Degree of hyponatremia correlates with disease severity; prognostic factor.
- Decreased plasma oncotic pressure from hypoalbuminemia
- Peritoneal irritation owing to infection, inflammation, or malignancy

ETIOLOGY

- Parenchymal liver disease:
 - Cirrhosis and alcoholic hepatitis:
 - 80% of adult patients
 - Fulminant hepatic failure
- Hepatic congestion:
 - CHF
 - Constrictive pericarditis
 - Veno-occlusive disease and Budd–Chiari syndrome
- Malignancies:
 - Peritoneal carcinomatosis
 - Hepatocellular carcinoma or metastatic disease
- Infections:
 - TB, fungal, or bacterial peritonitis
- Hypoalbuminemic states:
 - Nephrotic syndrome
 - Malnutrition; albumin < 2.0 g/dL
- Other conditions:
 - Pancreatic ascites
 - Biliary ascites
 - Nephrogenous ascites
 - Ovarian tumors
 - Chylous ascites from lymphatic leak

- Connective tissue disease
- Myxedema
- Granulomatous peritonitis

Pediatric Considerations

Most pediatric cases owing to:

- Malignancy (Burkitt lymphoma, rhabdomyosarcoma)
- Nephrotic syndrome
- Malnutrition

DIAGNOSIS

SIGNS AND SYMPTOMS

- Abdominal distention, discomfort
- Weight gain; sometimes weight loss
- Dyspnea
- Orthopnea
- Edema
- Abdominal hernias
- Muscle wasting
- Shifting dullness, flank fullness, fluid wave, puddle sign
- Signs and symptoms of underlying disease
- Stigmata of chronic liver disease

History

- Risk factors for liver disease
- Description of onset of symptoms:
 - Distinguishes ascites from obesity
 - Patients less tolerant of rapid accumulation of ascitic fluid
- New-onset ascites in known cirrhotic signifies 1 of the following:
 - Progressive liver disease
 - Superimposed acute liver injury (alcohol, viral hepatitis)
 - Hepatocellular carcinoma

Physical-Exam

- Detection difficult in obese patients
- Flank dullness is a prominent physical finding:
 - 500 mL for flank dullness
 - Fluid wave
 - Shifting dullness

ESSENTIAL WORKUP

- Search for liver disease, CHF, TB, malignancy, and other systemic disorders.
- Abdominal paracentesis:
 - Necessary for:
 - New ascites
 - Worsening encephalopathy
 - Fever
 - Abdominal pain/tenderness
- Determine if fluid infected or presence of portal hypertension
- Test ascitic fluid for:
 - Cell count and differential:
 - Most helpful to determine infection quickly
 - Order on every specimen
 - Albumin
 - Protein
 - Gram stain
 - Culture twice in blood culture bottles with 10 mL of fluid
 - Lactate dehydrogenase (LDH)
 - Glucose
 - TB culture
 - Amylase
 - Triglyceride
 - Cytology
 - Bilirubin
 - Carcinoembryonic antigen
- Spontaneous bacterial peritonitis (SBP):
 - Ascitic fluid infection without an intra-abdominal surgically treatable source
 - Fever, abdominal pain/tenderness, altered mentation
 - Polymorphonuclear neutrophils (PMNs) > 250 cells/mm³
 - Ascitic fluid protein < 1 g/dL
 - Low concentration of opsonins
- Secondary bacterial peritonitis:
 - Bacterial peritonitis from a surgically treatable intra-abdominal source
 - Gut perforation or intra-abdominal abscess (i.e., perinephric abscess)
 - PMNs > 250 cells/mm³ with multiple micro-organisms on Gram stain + 2 of the following found with secondary bacterial peritonitis:
 - Total protein > 1 g/dL
 - Glucose < 50 mg/dL
 - LDH greater than the upper limit of normal for serum

DIAGNOSIS TESTS & INTERPRETATION

- CBC
- Basic chemistry
- LFTs
- PT, PTT, INR
- Arterial blood gas (ABG) or pulse oximeter
- Urinalysis
- Urine sodium
- Hepatitis panel
- Amylase/lipase
- α -fetoprotein
- TSH

Imaging

- US:
 - _ Confirm ascites, especially if < 500 mL
 - _ Evaluate liver, pancreas, spleen, and ovaries
 - _ Guides paracentesis
- Doppler study: Evaluate hepatic blood flow
- CT scan
- CXR: CHF, effusions, cavitory, or mass lesion
- ECG

Diagnostic Procedures/Surgery

- Peritoneoscopy: Ascites of unknown cause; especially TB
- Paracentesis:
 - _ Clinical diagnosis of SBP without paracentesis is inadequate.
 - _ Safety of paracentesis:
 - 70% of ascitic patients have coagulopathy.
 - Benefits of a diagnostic paracentesis outweigh the risks.
 - Paracentesis is still indicated unless disseminated intravascular coagulation (DIC) is present.
 - Transfusion of plasma or platelets prior to paracentesis is not supported.

DIFFERENTIAL DIAGNOSIS

- 1 of the 5 “F” causes of abdominal swelling:
 - _ Fluid (including cysts)
 - _ Fat
 - _ Flatus
 - _ Fetus
 - _ Feces
 - _ Other: Organomegaly
- Serum-ascites albumin gradient (SAAG) = serum albumin – ascitic albumin:

- Replaced ascitic fluid total protein in the differential diagnosis of ascites
- SAAG ≥ 1.1 g/dL:
 - 97% accurate in predicting portal hypertension
 - Cirrhosis
 - Alcoholic hepatitis
 - Cardiac
 - Liver metastases
 - Fulminant hepatic failure
 - Portal vein thrombosis
 - Veno-occlusive disease
 - Myxedema
 - Budd—Chiari
 - Fatty liver of pregnancy
 - SBP
- SAAG < 1.1 g/dL:
 - Peritoneal carcinomatosis
 - TB
 - Pancreatic ascites
 - Nephrotic syndrome
 - Bowel obstruction or infarction
 - Vasculitis
 - Postoperative lymphatic leak

TREATMENT

PRE HOSPITAL

Symptomatic hypotension:

- Airway, breathing, circulation (ABCs), IV 0.9 NS

INITIAL STABILIZATION/THERAPY

Sudden increase in abdominal girth, pain, or fever requires urgent evaluation for possible complicating factor such as:

- Infection
- Hepatoma
- Obstruction of hepatic outflow
- Decompensated liver function

ED TREATMENT/PROCEDURES

- Successful treatment depends on accurate diagnosis of underlying cause.
- Treat underlying cause.
- Minimize ascitic fluid and peripheral edema without causing intravascular volume depletion.

- Early detection of complications is necessary:
 - SBP:
 - High degree of suspicion
 - Low threshold for paracentesis
 - Prompt therapy
 - Tense ascites and hydrothorax:
 - Supplemental oxygen
 - Therapeutic paracentesis or thoracentesis for respiratory distress
 - Abdominal hernias:
 - Watch for incarceration, ulceration, or rupture.
 - Therapeutic paracentesis
 - Surgical consultation
 - Persistent leak at paracentesis site:
 - Remove more fluid.
 - Stomal barrier device
 - Meralgia paresthetica:
 - Owing to pressure on the lateral femoral cutaneous nerve
 - Relieve the pressure by paracentesis or diuresis.
- Large-volume paracentesis:
 - 5–10 L (100 mL/kg)
 - Performed safely in the ED with stable hemodynamics
 - Consider replacement with IV albumin (5–10 g/L fluid removed) if >5 L removed.
 - Monitor the patient for 8 hr prior to discharge.
- Nonparacentesis reduction of ascites:
 - Strict sodium restriction:
 - <2 g/day
 - Restrict water if serum sodium <120–125 mEq/L
 - Spironolactone:
 - Works best for cirrhotic ascites
 - Alternatives: Amiloride or triamterene
 - Furosemide:
 - Works best for other causes of ascites
 - Add to spironolactone in cirrhotics at spironolactone/furosemide ratio of 100 mg/40 mg.
 - Add metolazone for less responsive cases.
 - Diuretic principles:
 - Administer diuretics as single morning dose.
 - Obtain spot-urine sodium to evaluate response.
 - Patients with urinary Na >10 mEq/L are more responsive to diuretics.
 - Diuretic-induced weight loss should not exceed 2 lb/day in patients without edema and 5 lb/day in patients with edema.

- Monitor electrolytes and renal function.
- Avoid hypokalemia since hypokalemia enhances renal ammonia production, precipitating hepatic encephalopathy.
- Refractory ascites:
 - Accounts for 10% of patients
 - Ensure compliance with diet and medications.
 - Treated with peritoneovenous shunt—transjugular intrahepatic portosystemic shunt
 - Liver transplantation
- Avoid NSAIDs:
 - Diminish response to diuretics
 - Decrease renal plasma flow and GFR.
 - Cause sodium retention/reduces urinary Na excretion
- Treat underlying cause of ascites owing to conditions other than cirrhosis:
 - TB, CHF

MEDICATION

First Line

- Albumin: 5–10 g/L of fluid removed if >5 L removed
- Cefotaxime: 2 g IV q8h
- Spironolactone: 100–400 mg/d (peds: 1–6 mg/kg) PO in 2 divided doses per day
- Furosemide: 40–160 mg/d (peds: 1–3 mg/kg) PO

Second Line

- Amiloride: 5–20 mg/d PO
- Metolazone: 5 mg/d
- Triamterene: 100–300 mg/d PO in 2 divided doses per day

FOLLOW-UP

DISPOSITION

Admission Criteria

- Fulminant liver failure
- Hepatic encephalopathy
- SBP
- Hepatorenal syndrome
- GI bleeding
- Tense ascites not responding to ED treatment

Discharge Criteria

Patients responding to ED management

FOLLOW-UP RECOMMENDATIONS

- GI for all new cases
- Primary doctor or GI for previously established cases

PEARLS AND PITFALLS

- New cases need full workup and GI consultation for management.
- SBP symptoms are frequently vague.
- Must have a high suspicion and low threshold for paracentesis when considering SBP
- Benefits of confirming SBP outweigh risks of bleeding in a coagulopathic patient undergoing paracentesis.
- US guidance is helpful when performing paracentesis in lower-volume ascites.

CODES

ICD9

- 789.5 Ascites
- 789.51 Malignant ascites
- 789.59 Other ascites

ICD10

- R18 Ascites
- R18.0 Malignant ascites
- R18.8 Other ascites

ASTHMA, ADULT

Melissa H. White • Carolyn Maher Overman

BASICS

DESCRIPTION

- Increased expiratory resistance:
 - Airway inflammation
 - Bronchospasm
 - Mucosal edema
 - Mucous plugging
 - Smooth muscle hypertrophy
- Consequences:
 - Air trapping
 - Airway remodeling
 - Increased dead space
 - Hyperinflation
- Status asthmaticus refers to disease that does not respond to therapy within 30–60 min
- Risk factors for life-threatening disease:
 - Prior intubations
 - Intensive care unit admissions
 - Chronic steroid use
 - Hospital admission for asthma during the past year
 - Inadequate medical management
 - Increasing age
 - Ethnicity (African Americans)
 - Lack of access to medical care
 - Multiple comorbidities

ETIOLOGY

- Inflammatory process of the airways evidenced by episodic and reversible airflow obstruction and hyper-responsiveness with many cells and cellular elements contributing to the disease:
 - Neutrophils
 - Mast cells
 - Eosinophils
 - Macrophages
 - T lymphocytes
 - Epithelial cells
 - Cytokines

- Triggers:
 - Pollen
 - Dust mites
 - Molds
 - Animal dander
 - Other environmental allergens
 - Viral upper respiratory infections
 - Occupational chemicals
 - Tobacco smoke
 - Environmental change
 - Cold air
 - Exercise induced
 - Emotional factors
 - Menstrual associated
 - Drugs:
 - Aspirin
 - NSAIDs
 - β -blockers

DIAGNOSIS

SIGNS AND SYMPTOMS

- Wheezing
- Dyspnea
- Chest tightness
- Cough
- Tachypnea
- Tachycardia
- Respiratory distress:
 - Posture sitting upright or leaning forward
 - Use of accessory muscles
 - Inability to speak in full sentences
 - Diaphoresis
 - Poor air movement
- Impending failure:
 - Altered mental status
 - Worsening fatigue
- Pulsus paradoxus > 18 mm Hg

ESSENTIAL WORKUP

- Primarily a clinical diagnosis
- Measure and follow severity with peak expiratory flow rate (PEFR)
- Assess for underlying disease

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Arterial blood gas:
 - _ Not helpful during the initial evaluation
 - _ The decision to intubate should be based on clinical criteria.
 - _ Mild-moderate asthma: Respiratory alkalosis
 - _ Severe airflow obstruction and fatigue: Respiratory acidosis and $\text{PaCO}_2 > 42$
- Pulse oximetry:
 - _ $< 90\%$ is indicative of severe respiratory distress.
 - _ Patients with impending respiratory compromise may still maintain saturation above 90% until sudden collapse.
- WBC:
 - _ Leukocytosis is nonspecific
 - _ Pneumonia
 - _ Chronic steroid use
 - _ Stress of an asthma exacerbation
 - _ Demargination occurs after administration of epinephrine and steroids.

Diagnostic Procedures/Surgery

- PEFR:
 - _ Estimates the degree of airflow obstruction:
 - Normal peak flow (adult) is 400–600.
 - 100–300 indicates moderate airway obstruction.
 - < 100 is indicative of severe airway obstruction.
 - Use serially as an objective measure of the response to therapy
- Forced expiratory volume (FEV):
 - _ More reliable measure of lung function than PEFR
 - _ Difficult to use as a screening tool
 - _ Often unavailable in the ED
 - _ Severe airway obstruction: $\text{FEV}_1 < 30\text{--}50\%$
- CXR:
 - _ Indications:
 - Fever
 - Suspicion of pneumonia
 - Suspicion of pneumothorax or pneumomediastinum
 - Foreign body aspiration
 - 1st episode of asthma
 - Comorbid illness: For example: Diabetes, renal failure, CHF, AIDS, cancer
 - Not responding to treatment
 - _ Typical findings:

- Hyperinflation
- Scattered atelectasis
- ECG:
 - _ Indicated in patients at risk for cardiac disease:
 - Dysrhythmias
 - Myocardial ischemia
 - _ Transient changes in severe asthma:
 - Right axis deviation
 - Right bundle branch block
 - Abnormal P-waves
 - Nonspecific ST–T-wave changes

DIFFERENTIAL DIAGNOSIS

- Allergic reaction
- Angioedema
- Bronchiolitis
- Bronchitis
- Carcinoid tumors
- Chemical pneumonitis
- Chronic cor pulmonale
- Chronic obstructive pulmonary disease
- CHF
- Croup
- Foreign body aspiration
- Immersion injury
- Myocardial ischemia
- Pneumonia
- Pulmonary embolus
- Smoke inhalation
- Upper airway obstruction
- Venous air embolus

TREATMENT

PRE HOSPITAL

- Recognize the “quiet chest” as respiratory distress.
- Supplemental oxygen
- Continuous nebulized β -agonist
- Administration of IM/SC epinephrine

INITIAL STABILIZATION/THERAPY

- Immediate initiation of inhaled β -agonist treatment

- Intubate for fatigue and respiratory distress.
- Steroids

ED TREATMENT/PROCEDURES

- Oxygen:
 - _ Maintain an oxygen saturation > 90%
- β -adrenergic agonist:
 - _ Selective β_2 -agonists (albuterol)
 - Mild–moderate asthmatic: Administer every 20 min
 - Severe asthmatic: Continuous nebulized treatment
 - _ SC β -agonist (terbutaline and epinephrine):
 - Severe exacerbations
 - Limited inhalation of aerosolized medicine
 - More side effects because of systemic absorption
 - Terbutaline—longer acting β -2 agonist with bronchodilating effects equivalent to epinephrine in acute asthma.
 - Relative contraindication: Age > 40 yr and coronary disease
- Corticosteroids:
 - _ Reduce airway wall inflammation
 - _ Administered early
 - _ Onset of action may take 4–6 hr
 - _ Administer IV or PO
 - _ IV Solu-Medrol in the treatment of severe asthma exacerbation
 - _ Mild–moderate exacerbations may be treated with oral prednisone burst or Depo-Medrol IM
 - _ Inhaled corticosteroids are currently not recommended as initial therapy.
- Anticholinergic agents:
 - _ If minimal response to initial β -agonist treatment
 - _ Severe airflow obstruction
 - _ Inhaled anticholinergic agents should be used in conjunction with β -agonists.
- Magnesium sulfate:
 - _ No benefit in mild–moderate asthma
 - _ May have a benefit in severe asthma
- Aminophylline:
 - _ Rare utility in acute management
- Leukotriene inhibitors:
 - _ Not currently recommended for acute exacerbation
- Heliox:
 - _ Mixture of helium and oxygen (80:20, 70:30, 60:40)
 - _ Less dense than air
 - _ Decrease airway resistance.
 - _ Decrease in respiratory exhaustion

- Not currently recommended for routine use
- Consider in severe asthma
- Noninvasive positive pressure ventilation:
 - CPAP and BiPAP
 - May improve oxygenation and decrease respiratory fatigue
 - Can only be used in an alert patient
 - Should not replace intubation
 - Not currently recommended for routine use
 - Consider in severe asthma
- Ketamine:
 - Bronchodilator and an anesthetic agent
 - Useful as an induction agent during intubation
 - Contraindications:
 - HTN
 - Coronary disease
 - Preeclampsia
 - Increased intracranial pressure
- Halothane:
 - Inhalation anesthetics are potent bronchodilators.
 - Refractory asthma in intubated patients
- Intubation of the asthmatic patient:
 - Rapid sequence intubation
 - Lidocaine to attenuate airway reflexes
 - Etomidate or ketamine as an induction agent
 - Succinylcholine should be administered to achieve paralysis.
 - A large endotracheal tube >7 mm should be used to facilitate ventilation.
 - May need to mechanically exhale for the patient
 - Permissive hypercapnia

MEDICATION

- β -agonists
 - Albuterol: 2.5 mg in 2.5 mL NS q20min inhaled (peds: 0.1–0.15 mg/kg/dose q20min [min. dose 1.25 mg])
 - Epinephrine: Adult: 0.3 mg (1:1,000) SC q0.5h–q4h \times 3 doses (peds: 0.01 mg/kg up to 0.3 mg SC)
 - Terbutaline: 0.25 mg SC q0.5h \times 2 doses (peds: 0.01 mg/kg up to 0.3 mg SC)
- Corticosteroids:
 - Methylprednisolone: 60–125 mg IV (peds: 1–2 mg/kg/dose IV or PO q6h \times 24 h)
 - Prednisone: 40–60 mg PO (peds: 1–2 mg/kg/d in single or divided doses)
 - Depo-Medrol 160 mg IM
- Anticholinergics

- Ipratropium bromide: 0.5 mg in 3 mL NS q1h × 3 doses
- Magnesium: 2 g IV over 20 min (peds: 25–75 mg/kg)
- Aminophylline: 0.6 mg/kg/h IV infusion
- Rapid sequence intubation:
 - Etomidate: 0.3 mg/kg IV, *or* ketamine: 1–1.5 mg/kg IV
 - Lidocaine: 1–1.5 mg/kg IV
 - Succinylcholine: 1.5 mg/kg IV

FOLLOW-UP

DISPOSITION

Admission Criteria

Medical Wards

- PEFR < 40% and minimal air movement
- Persistent respiratory distress:
 - Factors that should favor admission:
 - Prior intubation
 - Recent ED visit
 - Multiple ED visits or hospitalizations
 - Symptoms for more than 1 wk
 - Failure of outpatient therapy
 - Use of steroids
 - Inadequate follow-up mechanisms
 - Psychiatric illness

Observation Unit

- PEFR > 40% but < 70% of predicted
- Patients without subjective improvement
- Patients with continued wheeze and diminished air movement
- Patients with moderate response to therapy and no respiratory distress

Discharge Criteria

- PEFR > 70% should be > 300
- Patient reports subjective improvement
- Clear lungs with good air movement
- Adequate follow-up within 48–72 hr

FOLLOW-UP RECOMMENDATIONS

Encourage patients to contact their PMD or pulmonologist for asthma related problems over the next 3–5 days.

PEARLS AND PITFALLS

- Altered mental status in asthma equals ventilatory failure.
- Patients should be able to demonstrate the correct use of their inhaler or nebulizer:
 - Discharge with a peak flow meter
- If no signs or symptoms of dehydration, no evidence that IVF will clear airway secretions.
- Antibiotics should generally be reserved for patients with purulent sputum, fever, pneumonia, or evidence of bacterial sinusitis.

ICD9

- 493.90 Asthma, unspecified type, without mention of status asthmaticus
- 493.91 Asthma, unspecified type, with status asthmaticus
- 493.92 Asthma, unspecified type, with (acute) exacerbation

ICD10

- J45.901 Unspecified asthma with (acute) exacerbation
- J45.902 Unspecified asthma with status asthmaticus
- J45.909 Unspecified asthma, uncomplicated

ASTHMA, PEDIATRIC

Nathan Shapiro

BASICS

DESCRIPTION

- 2.7 million children (<18 yr) affected in US
- 850,000 ED visits per year in US
- Inflammatory events, usually viral, lead to bronchoconstriction:
 - Compounded by hyper-reactivity of airways
 - Mediators of the inflammatory cascade exacerbate symptoms
- Airway obstruction produces increased airway resistance and gas trapping:
 - Mucosal edema
 - Bronchospasm
 - Mucous plugging
- Infants more vulnerable to respiratory failure:
 - Increased peripheral resistance
 - Decreased elastic recoil with early airway closure
 - Unstable rib cage
 - Mechanically disadvantaged diaphragm
- Family history of allergy
- Medical history of early injury to airway (bronchopulmonary dysplasia, pneumonia, intubation, croup, reflux, passive exposure to smoking), reactions to foods and drugs, other allergic manifestations
- Environmental exposures such as pets, smoke, carpets, or dust may trigger or exacerbate

ETIOLOGY

Precipitating/Aggravating Factors

- Infection:
 - Viral
 - Bacterial
- Allergic/irritant:
 - Environment: Pollens, grasses, mold, house dust mites, and animal dander
 - Occupational chemicals: Chlorine, ammonia—food and additives
 - Irritants: Smoke, pollutants, gases, and aerosols
 - Exercise
 - Cold weather
 - Emotional: Stress, phobia
 - Intoxication: β -blockers, aspirin, NSAIDs

SIGNS AND SYMPTOMS

General

- Fatigue, somnolence
- Diaphoresis, agitation
- Hypoxia, cyanosis
- Tachycardia
- Dehydration
- Pulsus paradoxus

Respiratory

- Wheezing, rales, rhonchi
- Cough, acute or chronic
- Tachypnea
- “Tight chest”
- Dyspnea, shortness of breath with prolonged expiratory phase
- Retractions, accessory muscle use, nasal flaring
- Hyperinflation
- Often a history of recurrent episodes and chronic restrictions
- Complications:
 - Recurrent pneumonia, bronchitis
 - Atelectasis
 - Pneumothorax, pneumomediastinum
 - Respiratory distress/failure/death

History

- Precipitating events or known triggers
- Chronicity of symptoms
- Comorbid illnesses
- History of disease:
 - Previous hospitalizations for asthma
 - Previous intubations and intensive care
 - Regular and sporadic medications

Physical-Exam

- Vital signs, including oximetry and respiratory status
- Wheezing: Absence of wheezing may be associated with markedly impaired air movement and decreased breath sounds
- Signs of hypoxia
- Skin and nail bed color bluish

- Signs of respiratory fatigue, distress, or failure:
 - Use of accessory muscles of respirations or retractions
 - Lethargy or confusion

ESSENTIAL WORKUP

- Clinical diagnosis based primarily on physical exam and history; assess ventilation by observation for retractions and use of accessory muscles as well as auscultating for air exchange.
- Follow response to bronchodilator therapy with present illness and past episodes.
- Exclude other differential considerations.
- Pulse oximetry:
 - Initial SaO₂ < 91% (sea level) associated with significant illness: Admission, relapse, prolonged course
- Peak flow meters in cooperative patients (usually > 5 yr old)
 - < 50–70% predicts moderate to severe obstruction.
 - > 70–90% associated with mild to moderate obstruction
 - > 90% considered normal

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Arterial blood gas (ABG) may be an adjunct to pulse oximetry to measure oxygenation and clinical exam to assess ventilation; not mandatory or routinely done.
- CBC as a nonspecific marker of infection
- Theophylline level: Only for patients on theophylline (not recommended)

Imaging

Chest radiograph considered in the following patients, esp. focusing on the presence of infiltrates, bronchial wall thickening, or hyperexpansion.

- < 1 yr of age to exclude foreign body or atelectasis
- First episode of significant wheezing (suggested to assess chronicity of illness and assist in excluding other conditions)
- Increasing respiratory distress or minimal response to therapy
- Respiratory distress/failure
- Shortness of breath in the absence of wheezing

Diagnostic Procedures/Surgery

Peak flow measurement (see above)

DIFFERENTIAL DIAGNOSIS

- Infection/inflammation:
 - Bronchiolitis: Clinically difficult to differentiate except by age and clinical

- history.
- Pneumonia: Viral, bacterial, chemical, or hypersensitivity
- Aspiration
- Retropharyngeal/mediastinal abscess/mass
- Anaphylactic reaction
- Anatomic:
 - Pneumothorax
 - Foreign body
- Vascular disorder:
 - Compression of trachea by vascular anomaly
 - Pulmonary embolism
 - CHF
- Congenital disease:
 - Cystic fibrosis
 - Tracheoesophageal fistula
 - Bronchogenic cyst
 - Congenital heart disease
- Intoxication: Metabolic acidosis
- Neoplasm
- Vocal cord dysfunction (VCD)
- Pulmonary edema—cardiogenic or noncardiogenic
- Gastroesophageal reflux

TREATMENT

PRE HOSPITAL

- Oxygen and oxygen saturation monitoring
- Nebulized β -adrenergic agonist: Albuterol
- Intubate for respiratory failure or severe fatigue.
- IV fluids if evidence of dehydration
- Rapid transport and good communication with ED

INITIAL STABILIZATION/THERAPY

- Maintain $\text{SaO}_2 > 90\text{--}95\%$.
- β -adrenergic nebulizer(s): Albuterol
- Intubate for respiratory failure.
- 20 mL/kg 0.9% NS bolus if evidence of dehydration.

ED TREATMENT/PROCEDURES

- Assess patient for signs of potential respiratory failure:
 - Cyanosis
 - Severe anxiety or irritability

- Lethargy, somnolence, fatigue
- Persistent tachypnea
- Poor air entry, ventilation
- Severe retractions
- Monitor oxygenation; titrate oxygen saturation to $\text{SaO}_2 > 95\%$ (sea level).
- β -adrenergic nebulizer: Albuterol:
 - Frequent or continuous for severe asthma
 - Levalbuterol may require less frequent dosing and may be associated with less side effects.
- Ipratropium bromide may be added as adjunct to β -adrenergic agonists. Most effective when combined with 1st 3 doses of β -adrenergic agent in moderate to severely ill children
- Steroid therapy:
 - Oral for moderate exacerbations in those able to take oral meds
 - IV for severe exacerbations or in those unable to take oral meds
 - 1 dose of dexamethasone may be equivalent to traditional steroids
- SC epinephrine or terbutaline for severe or refractory asthma (rarely used)
- Magnesium sulfate may be useful in severe disease following standard therapy.
- Intubate for respiratory failure:
 - Ketamine is a useful induction agent.
- 20 mL/kg of 0.9% NS bolus if evidence of dehydration
- Heliox (oxygen and helium) may be useful but studies are inconclusive

MEDICATION

- Albuterol (0.5% solution or 5 mg/mL):
 - Nebulizer: 0.15 mg/kg per dose, up to 5 mg per dose, q15–30min PRN
 - Metered-dose inhaler (MDI) (with spacer) (90 μg /puff): 2 puffs q5–10min, max. 10 puffs
 - Also available for nebulizer as 0.083% solution or 2.5 mg/3 mL
- Dexamethasone 0.3 mg/kg/dose (max.: 16 mg)
- Epinephrine (1:1,000) (1 mg/mL): 0.01 mg/kg SC, up to 0.35 mL per dose, q20min for 3 doses
- Ipratropium bromide: Nebulizer (0.02% inhaled sol 500 μg /2.5 mL), 250–500 μg per dose q6h
- Ketamine (for intubation): 1–2 mg/kg IV as induction agent
- Levalbuterol (0.63 and 1.25 mg vials): q6–8h by nebulizer
- Magnesium sulfate: 25 mg/kg per dose IV over 20 min; max. 1.2–2 g per dose
- Methylprednisolone: 1–2 mg/kg per dose IV q6h; max. 125 mg per dose
- Prednisolone: 1–2 mg/kg per dose PO q12h (available as 15 mg/5 mL)
- Prednisone: 1–2 mg/kg per dose PO q6–12h; max. 80 mg per dose
- Terbutaline/ (available as 1 mg/1 mL) (0.01%): 0.01 mL/kg SC q15–20min up to 0.25 mL per dose, q20min for 2 doses

First Line

- Albuterol
- Steroids
- Ipratropium

Second Line

- Epinephrine or terbutaline
- Magnesium sulfate

FOLLOW-UP

DISPOSITION

Admission Criteria

- Need to individualize based upon subjective and objective assessment
- Persistent respiratory difficulty:
 - Persistent wheezing
 - Increased respiratory rate/tachypnea
 - Retraction and use of accessory muscles
- $\text{SaO}_2 < 93\%$ (sea level) on room air
- Peak expiratory flow rate (PEFR) $< 50\text{--}70\%$ predicted levels
- Inability to tolerate oral medicines or liquids
- Prior ED visit in last 24 hr
- Comorbidity:
 - Congenital heart disease
 - Bronchopulmonary dysplasia
 - CF
 - Neuromuscular disease
- Concomitant illness:
 - Pneumonia or severe viral infection

Intensive Care Unit Criteria

- Severe respiratory distress
- $\text{SaO}_2 < 90\%$ or $\text{PaO}_2 < 60$ mm Hg on 40% oxygen
- $\text{PaCO}_2 > 40$ mm Hg
- Significant complications:
 - Pneumothorax
 - Dysrhythmia

Discharge Criteria

- Good response to therapy. Observe in ED 60 min after last treatment before

discharging:

- PEFR > 70% predicted based on age/height
- SaO₂ > 93% on room air (sea level)
- Respiratory rate normal
- No retractions
- Clear or minimal wheezing
- No or minimal dyspnea
- Good follow-up and compliance. Reduce exposure to irritants (smoking) or allergens
- Discharge treatment:
 - Intensive β -adrenergic regimen for 3–5 days
 - Short course (3–5 days) of steroids (2 mg/kg/day) for those presenting with moderate symptoms with consideration of ongoing therapy using nebulized or MDI routes. Patients with moderate or severe exacerbations should have arrangements made for inhaled steroids over a 1–2 mo period such as fluticasone, budesonide, or beclomethasone
 - Follow-up appointment 24–72 hr
 - Instructions to return for shortness of breath refractory to home regimen
 - Long-term therapy should be considered for children with recurrent episodes, persistent symptoms, or activity limitations.

FOLLOW-UP RECOMMENDATIONS

Primary care physician for maintenance therapy, often including nebulized or MDI steroid therapy and education about acute rescue management.

PEARLS AND PITFALLS

- Rapid treatment with continuous re-evaluation to detect any progression of disease is essential.
- When admitting patients, assure that β -adrenergic agent therapy is not interrupted.

ASYSTOLE

David F. M. Brown • Calvin A. Lee

BASICS

DESCRIPTION

Absence of ventricular electrical activity

ETIOLOGY

- An end-stage rhythm, sometimes degrading from:
 - Prolonged bradycardia
 - Prolonged ventricular fibrillation (VF)
 - Prolonged pulseless electrical activity
- Patient is extremely unlikely to survive when asystole occurs outside the hospital:
 - ~40% will have return of spontaneous circulation and survive to hospital admission, but <15% survive to hospital discharge.
- Prognosis is similarly poor for those patients who develop asystole after countershock for ventricular tachycardia/VF; <10% survive to hospital discharge.
- Potentially reversible causes include:
 - Hypoxia
 - Hypovolemia (blood loss)
 - Acidosis
 - Hyperkalemia
 - Hypokalemia
 - Drug overdose
 - Hypothermia
 - Pulmonary embolism
 - Myocardial infarction
 - Tension pneumothorax
 - Cardiac tamponade

DIAGNOSIS

SIGNS AND SYMPTOMS

- Unresponsive patient
- Pulseless
- Agonal or absence of spontaneous respirations

ESSENTIAL WORKUP

- Confirm asystole in 2 limb leads to exclude VF.
- Confirm lead and cable connections.

- Confirm monitor power is on.
- Confirm monitor gain is up.
- Identify reversible causes (see above)

DIAGNOSIS TESTS & INTERPRETATION

Lab

Arterial blood gas (potassium and hemoglobin)

Imaging

Cardiac US to exclude pericardial tamponade

DIFFERENTIAL DIAGNOSIS

“Fine” VF (which may be mistaken for asystole)

TREATMENT

PRE HOSPITAL

- No intervention should be made for a patient with a valid Do Not Resuscitate document.
- No intervention if patient can be verified as dead:
 - Rigor mortis
 - Dependent livedo
 - Injury incompatible with life (e.g., decapitation)

INITIAL STABILIZATION/THERAPY

- Initiate CPR, with emphasis on minimally interrupted, high-quality chest compressions
- Confirm asystole with cardiac monitor
- Place airway device (ETT preferred, but BVM acceptable), confirm placement, and provide 100% inspired oxygen and a slow ventilation rate (6–12 breaths/minute). Minimize interruption in chest compressions during airway placement
- Establish IV or IO access.
- Apply continuous waveform capnography to optimize quality of chest compressions (PETCO₂ correlates with cardiac output and myocardial blood flow during CPR)
- Epinephrine every 3–5 min.
- Consider and treat potentially reversible causes (see above)
- Sodium bicarbonate if hyperkalemia or drug overdose suspected
- No proven benefit to an empiric single countershock
- No proven benefit to electrical pacing
- Provide defibrillation without delay, IF the patient develops VF or VT

ED TREATMENT/PROCEDURES

- Initiate induced hypothermia in comatose patients with return of spontaneous circulation
- Consider termination of resuscitation efforts if the following conditions are met:
 - High-quality chest compressions performed for a period of time
 - Tracheal intubation to ensure normal oxygenation
 - Fine VF excluded
 - Reversible causes corrected or excluded
 - Bedside US without pericardial effusion
 - No tension pneumothorax clinically

MEDICATION

- Epinephrine: 1 mg (peds: 0.01 mg/kg) IV q3–5min
- Sodium bicarbonate: 1 mEq/kg IV only if:
 - Pre-existing acidosis
 - Hyperkalemia
 - Tricyclic antidepressant overdose is suspected.

FOLLOW-UP

DISPOSITION

Admission Criteria

All patients with return of spontaneous circulation

Discharge Criteria

None—all patients with return of spontaneous circulation need admission to an ICU for post-arrest care

FOLLOW-UP RECOMMENDATIONS

A permanent pacemaker may be considered only if asystole is found to be due to primary heart block

Patient Monitoring

ICU for cardiac monitoring and induced hypothermia as appropriate

PEARLS AND PITFALLS

- Emphasis on high-quality, minimally uninterrupted chest compressions while considering reversible causes of asystole
- Resuscitation is likely to be successful only if reversible causes are found and corrected immediately

ICD10

- I46.2 Cardiac arrest due to underlying cardiac condition
- I46.8 Cardiac arrest due to other underlying condition
- I46.9 Cardiac arrest, cause unspecified

ATAXIA

Lara K. Kulchycki

BASICS

DESCRIPTION

- Inability to perform coordinated movements
- Caused by a disorder of the cerebellum or its connections:
 - Ipsilateral signs with lateral cerebellar lesions
 - Truncal ataxia with midline lesions

ETIOLOGY

Usually cerebellar in origin, but may occur with sensory, motor, or vestibular dysfunction:

- Trauma
- Mass lesions
- Vascular disorders
- Infections or postinfectious processes
- Toxins/drugs
- Metabolic/endocrine derangements
- Demyelinating diseases
- Congenital malformations
- Hereditary disorders:
 - Inborn errors of metabolism
 - Progressive degenerative ataxias
- Nutritional deficiencies

DIAGNOSIS

SIGNS AND SYMPTOMS

- Gait disturbance:
 - Ataxia often presents with unsteady gait
 - Initial sense of insecurity while walking
 - Problems with special skills (bicycling, skiing, climbing)
 - Sense of imbalance
 - Wide base stance and staggering gait
 - Test tandem gait to identify subtle ataxia
- Limb ataxia:
 - Incoordination
 - Intention tremors
 - Clumsiness with writing, picking up objects, buttoning

- Dysmetria: Under- or overshooting on finger-to-nose and heel-to-shin testing
- Dysdiadochokinesis: Difficulty with rapid alternating movements
- Truncal ataxia:
 - Head tremors
 - Truncal instability
 - Titubation: Swaying of the head/trunk while at rest
- Dysarthria and bulbar symptoms:
 - Slurred speech
 - Staccato, scanning speech
 - Choking from incoordination of swallowing
- Visual abnormalities:
 - Blurry vision
 - Vertigo:
 - Distinguish central from peripheral vertigo
 - Peripheral vertigo is often severe, triggered by movement, and may be accompanied by ear pain, hearing loss, or tinnitus
 - Nystagmus:
 - Gaze-evoked nystagmus: Repetitive drifts to the midline followed by fast phase to the eccentric side
 - Rebound nystagmus
- Abnormalities of muscle tone and strength:
 - Isometrataxia: Difficulty sustaining constant force during hand use:
 - Ask patient to hold slight, steady pinching pressure against examiner's finger (examiner will feel irregular pressure)
 - True muscle weakness or hypotonia uncommon in cerebellar disease
- Sensory ataxia:
 - Paresthesias
 - Numbness
 - Cautious, steppage gait
 - Marked worsening of coordination with eyes closed:
 - A positive Romberg sign is the classic finding in sensory ataxia
 - Loss of position/vibration sense
 - Difficulty with fine motor skills

History

- A careful history is essential since gait changes may be caused by pain, weakness, lightheadedness, vertigo, or incoordination
- Onset:
 - Hours–days: Acute
 - Weeks–months: Subacute
 - Months–years: Chronic
- Symmetric or focal symptoms
- Presence of fever, mental status changes, weakness, sensory loss, or urinary

incontinence

- Recent viral illness or immunizations
- History of trauma or toxic ingestion
- Family history of movement disorder

Physical-Exam

- Perform a complete physical exam, including neurological and gait testing
- Assess for signs or symptoms of acute, life-threatening disorders such as hemorrhage, stroke, or CNS infection:
 - Altered mental status
 - Headache
 - Focal neurological deficits
 - Elevated intracranial pressure:
 - Bradycardia, HTN, abnormal respiratory pattern
 - Papilledema
 - Bulging fontanelles
 - Fever
 - Meningismus
 - Nystagmus
 - Nausea/vomiting
 - Examine ears and perform provocative testing for nystagmus (Dix–Hallpike)
- Note the presence of intoxication or toxidromes in patients with suspected ingestion

ESSENTIAL WORKUP

A detailed history and physical exam will help determine which tests are necessary

DIAGNOSIS TESTS & NTERPRETATION

Lab

- Blood glucose level
- Serum electrolytes
- Toxicology screen:
 - Standard panels may not include the drugs of interest in the ataxic patient
- Thyroid function testing
- Target additional testing to likely exposures, such as anticonvulsants

Imaging

- CT:
 - Head CT can identify mass, hemorrhage, subacute infarct, or hydrocephalus
 - Consider CT with and without IV contrast if mass suspected
 - CT angiography can be performed to evaluate for vascular disease
- MRI:

- Excellent study to evaluate for acute ischemia, mass, demyelinating lesions, and vascular abnormalities
- Superior for imaging the posterior fossa
- MR angiography of head/neck may be indicated if vascular abnormality is suspected
- EKG:
 - Not indicated as part of ataxia workup, but may be useful in evaluation of nonspecific dizziness

Diagnostic Procedures/Surgery

- Lumbar puncture:
 - Indicated if infection or Guillain–Barré suspected

DIFFERENTIAL DIAGNOSIS

- Acute symmetric ataxia:
 - Head trauma
 - Drug use/toxic ingestion:
 - Alcohol
 - Lithium
 - Phenytoin
 - Barbiturates
 - Carbamazepine
 - Phenobarbital
 - Valproic acid
 - Benzodiazepines
 - Diphenhydramine
 - Dextromethorphan
 - Acute viral cerebellitis
 - Meningitis/encephalitis
 - Hydrocephalus
 - Postinfectious syndrome
 - Hypoglycemia
 - Hyponatremia
 - Severe heat stroke
- Acute focal ataxia:
 - Posterior circulation infarction
 - Anterior cerebral artery syndrome
 - Vertebrobasilar insufficiency (VBI)
 - Cerebellar hemorrhage
 - Subdural hematoma
 - Cerebellar abscess
 - Acute disseminated encephalomyelitis
 - Complicated migraine

- Atypical seizure
- Subacute symmetric ataxia:
 - Drug use/toxic ingestion:
 - Mercury
 - Lead
 - Hydrocarbons
 - Glue sniffing
 - Cytotoxic chemotherapy
 - Organophosphates
 - Vitamin B₁ or B₁₂ deficiency
 - Paraneoplastic syndromes:
 - Breast/ovarian cancer
 - Hodgkin lymphoma
 - Neuroblastoma
 - Lyme disease
 - Toxoplasmosis
 - Creutzfeldt–Jakob disease
- Subacute focal ataxia:
 - Cerebellar glioma
 - Metastatic tumors
 - Lymphoma
 - Multiple sclerosis
 - Guillain–Barré syndrome
 - AIDS-related progressive multifocal leukoencephalopathy
 - Syringomyelia
 - Cervical spondylosis
- Chronic ataxia:
 - Alcohol-related cerebellar degeneration
 - Stable gliosis
 - Inherited disorders:
 - Spinocerebellar ataxias
 - Friedreich ataxia
 - Ataxia telangiectasia
 - Niemann–Pick disease
 - Hypothyroidism
 - Vitamin E deficiency
 - Tabes dorsalis
 - Congenital malformation:
 - Arnold—Chiari
 - Dandy–Walker
- Disease states that cause peripheral vertigo can mimic the gait findings in ataxia:
 - Benign paroxysmal positional vertigo

- Acute labyrinthitis
- Ménière disease

Pediatric Considerations

- May present with a refusal to walk
- Acute ataxia in children is usually a benign, self-limited process:
 - 60% of cases caused by acute cerebellar ataxia or drug ingestion
- Acute cerebellar ataxia:
 - Postinfectious cerebellar demyelination
 - Usually occurs in children 2–5 yr old
 - Onset 1–3 wk after triggering illness
 - Over 1/4 of cases occur after varicella, but linked to many viral infections and immunizations
 - Normal mental status
 - No fever, focal deficits, or seizures
 - Mild cases may be managed at home, but require injury prevention counseling
 - Most children recover completely within 3 mo without intervention
- Drug/toxic ingestions:
 - Expect mental status changes
 - Assess access to medications and order appropriate toxicological testing
- Guillain–Barré syndrome:
 - 15% present with sensory ataxia
 - Miller-Fisher variant: Clinical triad of ataxia, areflexia, and ophthalmoplegia
- Neoplasm:
 - More than 50% of childhood brain tumors occur in the brainstem or cerebellum
 - Opsoclonus-myoclonus-ataxia syndrome:
 - Paraneoplastic autoimmune syndrome affecting cerebellum
 - Over 50% due to neuroblastoma
- Stroke:
 - Rare in children, but can occur in patients with sickle cell disease or hypercoagulable states

Geriatric Considerations

- Gait disorders in the elderly are often multifactorial
- Underlying cognitive deficits may make it difficult to distinguish presyncope, weakness, vertigo, and incoordination
- Posterior circulation cerebrovascular syndromes, like VBI and stroke, are more common in the elderly and may present with vague symptoms, like dizziness
- Evaluate for signs of orthostasis or extrapyramidal disorders, like Parkinsonism

TREATMENT

PRE HOSPITAL

ALERT

- Acute onset of ataxia may be due to stroke or hemorrhage
- Deterioration in mental status may warrant field endotracheal intubation

INITIAL STABILIZATION/THERAPY

- ABCs
- IV access
- Supplemental oxygen
- Cardiac monitor
- Fingertick blood glucose:
 - _ Administer dextrose if hypoglycemic
 - _ Consider thiamine in alcoholics and malnourished patients

ED TREATMENT/PROCEDURES

- Institute fall precautions
- Treatment must be tailored to the patient's presentation and underlying pathology
- Cerebellar infarction can lead to significant edema with mass effect and herniation:
 - _ Neurosurgery consultation may be needed for decompressive craniectomy

MEDICATION

- Dextrose: D₅₀W 1 amp (50 mL or 25 g) (peds: D₂₅W 2–4 mL/kg) IV
- Thiamine (vitamin B₁): 100 mg IV

FOLLOW-UP

DISPOSITION

Admission Criteria

- Acute and subacute ataxia, particularly if a benign etiology cannot be established
- Patients who cannot ambulate safely
- Admit patients with cerebellar hemorrhage or mass effect to the ICU

Discharge Criteria

- Reversible or mild symptoms
- Normal mental status
- Able to ambulate safely

FOLLOW-UP RECOMMENDATIONS

Follow up with primary care or neurology depending on likely etiology of symptoms

PEARLS AND PITFALLS

- Failure to distinguish true ataxia from other causes of gait instability
- Failure to note trauma in intoxicated patients
- Failure to realize the limitations of CT scan in evaluating the posterior fossa
- Failure to recognize the risk of herniation in cerebellar lesions, including stroke

CODES

ICD9

- 334.2 Primary cerebellar degeneration
- 334.3 Other cerebellar ataxia
- 781.3 Lack of coordination

ICD10

- G11.1 Early-onset cerebellar ataxia
- G11.9 Hereditary ataxia, unspecified
- R27.0 Ataxia, unspecified

ATRIAL FIBRILLATION

Edward Ullman • Terrance T. Lee

BASICS

DESCRIPTION

- Dysrhythmia characterized by seemingly disorganized atrial depolarizations without effective atrial contraction
- Caused by multiple re-entrant waveforms within the atria
- Atrial rate ranges from 350–600 beats per minute (bpm).
- Results in loss of organized atrial contractions and rapid ventricular rate:
 - Decrease in cardiac output
 - Prone to embolus formation
- Most common clinical arrhythmia:
 - Prevalence increasing with age
 - Men are at higher risk

ETIOLOGY

- Systemic disease:
 - HTN
 - Hyperthyroidism
 - Chronic pulmonary disease
 - Infection
 - Pulmonary embolus
 - Hypoxia
 - Drugs (e.g., sympathomimetics)
 - Acute alcohol ingestion (holiday heart syndrome)
 - Obesity
 - Electrolyte disturbance
 - Thyroid disease
- Underlying cardiac disease:
 - Cardiomyopathy
 - CAD
 - Valvular disease, especially mitral
 - Pericarditis
 - Sick sinus syndrome
 - Myocardial contusion
 - CHF
 - Congenital heart disease
- Idiopathic:
 - Absence of any known etiologic factor

- No clinical or echocardiographic evidence of heart disease

DIAGNOSIS

SIGNS AND SYMPTOMS

- Palpitations
- Decreased cardiac output:
 - Weakness
 - Light headedness
 - Syncope
 - Hypotension
 - Angina
 - Pulmonary edema
 - Altered mental status
 - Lower extremity edema
 - Hepatojugular reflex
- Embolus formation:
 - Acute neurologic injury
 - Mesenteric ischemia

History

- Onset of symptoms
- Duration
- Inciting factors
- Prior episodes of fibrillation
- Prior heart disease

Physical-Exam

- Palpitations
- Irregularly irregular pulse
- Absence of A- waves in the jugular venous pulse
- Pulse deficit with more rapid ventricular rates:
 - The auscultated or palpated apical rate is faster than the rate palpated at the wrist

ESSENTIAL WORKUP

- History and physical exam:
 - Assess for instability and need for immediate cardioversion
 - Duration of symptoms > 48 hr or < 48 hr
 - Evidence of systemic disease or underlying cardiac disease
- ECG: Signs of congestive heart failure
 - Absent P-waves replaced by fibrillatory (f) waves, 350–600 bpm

- F-waves vary in amplitude, morphology, and intervals
- R-R intervals are irregularly irregular
- Absence of an isoelectric baseline
- Ventricular rate ranges from 80–150 bpm:
 - If rate > 200 associated with wide-irregular QRS, consider bypass tract
- Slower rate suggests abnormal AV node or presence of AV nodal blocking medication
- Usually narrow QRS complexes unless:
 - Functional aberration
 - Pre-existing bundle branch
 - Pre-excitation with an accessory pathway

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Electrolytes
- Cardiac enzymes—if ischemia is a concern
- Thyroid function
- Digoxin level—if patient is taking
- Anticoagulation parameters
- Urine drug screen

Imaging

- CXR
- ECG

DIFFERENTIAL DIAGNOSIS

- Atrial flutter with variable AV block
- Multifocal atrial tachycardia
- Sinus rhythm with frequent premature atrial contractions
- Atrial tachycardia with variable AV block

TREATMENT

PRE HOSPITAL

- IV access
- Monitor
- Oxygen
- Cardioversion:
 - In settings where patient is unstable

INITIAL STABILIZATION/THERAPY

- IV
- Oxygen
- Monitor
- Immediate synchronized electrical cardioversion starting at 200 J if the patient is unstable

ED TREATMENT/PROCEDURES

- Hemodynamically unstable and life threatening:
 - _ Myocardial infarction, pulmonary edema, heart failure that does not respond promptly to pharmacological measures
 - _ Synchronized electrical cardioversion
 - Biphasic: Start at 100 J, higher success rate
 - Monophasic: Start at 200 J
 - Sx duration < 48 hr: Consider IV heparin bolus prior.
 - Sx duration > 48 hr: IV heparin, transesophageal echo to exclude atrial clot, cardioversion. Anticoagulate for 4 wk. Do not delay echo if life-threatening arrhythmia.
 - Consider pretreatment with antiarrhythmic drugs and use anterior-posterior pad placement to increase likelihood of success
 - _ Chemical cardioversion:
 - Choice of drug depends on history of CHF, high BP, LV hypertrophy, and CAD
 - Medications may be proarrhythmic and should be used with caution
 - As with electrical cardioversion, appropriate anticoagulation will be necessary depending on the duration and presence/absence of clot
 - Ibutilide
 - Procainamide
 - Flecainide
 - Propafenone
 - Sotalol
- Hemodynamically stable, mildly symptomatic:
 - _ Treat underlying cause if 1 is identified.
 - _ Identify if symptoms are < 48 hr. If so consider synchronized cardioversion.
 - _ > 48 hr: Rhythm control does not offer mortality benefit over rate control
 - _ Use procainamide to treat stable patients with a suspected bypass tract
 - _ Rate control:
 - Not necessary if rate < 100 bpm or if rhythm spontaneously converts to sinus
 - AV nodal blockers (calcium channel blockers, β -blockers, and digoxin) contraindicated if bypass tract suspected such as WPW
 - Calcium channel blockers: Consider in patient with pulmonary disease. Use cautiously in patient with uncompensated CHF and 2nd-

- or 3rd-degree heart block
 - β -blockers: Consider in patient with coronary artery disease (CAD). Use cautiously in patient with uncompensated CHF, 2nd- or 3rd-degree heart block, and pulmonary disease
 - Digoxin: Consider in patient with pre-existing CHF.
 - Amiodarone: Consider in refractory atrial fibrillation
- Rhythm control and prophylaxis:
 - Includes procainamide, sotalol, amiodarone, dofetilide
 - Amiodarone: Only agent with strong data to support initiation for outpatient treatment
- Elective cardioversion:
 - Oral anticoagulation with therapeutic levels for 3 wk prior to and 4 wk after
- Stable patients with atrial fibrillation and WPW can be treated with procainamide or ibutilide, although cardioversion may be preferred
- Anticoagulation determined by CHADS2 scoring:
 - 1 point for each of the following:
 - History of cardiac failure
 - History of HTN
 - Age ≥ 75 yr
 - Diabetes
 - 2 points for a history of stroke or TIA
 - Score of 0:
 - 81–325 mg/day of aspirin
 - Score of 1:
 - Either 81–325 mg/day of aspirin or adjusted-dose warfarin with a target INR of 2.5
 - Score > 1 :
 - Adjusted-dose warfarin with a target INR of 2.5 (range 2–3)
 - Adjusted annual stroke rate increases from 1.9% for a CHADS2 score of 0 to 18.2% for a CHADS2 score of 6
 - Aspirin:
 - Patients with contraindications to anticoagulation and unreliable individuals
 - Patients with low stroke risk

MEDICATION

- Metoprolol:
 - 5–10 mg slow IV push at 5 min intervals to total of 15 mg
 - 25 mg–100 mg oral BID
- Diltiazem:
 - 0.25 mg/kg IV over 2 min; if unsuccessful, repeat in 15 min as 0.35 mg/kg IV over 2 min; maintenance infusion of 5 mg/h usually started to maintain

- rate control.
 - 120–300 mg oral daily
- Digoxin:
 - 0.5 mg IV initially, then 0.25 mg IV q4h until desired effect
- Esmolol:
 - 0.5 mg/kg over 1 min; maintenance infusion at 0.05 mg/kg/min over 4 min
- Propranolol:
 - 0.1 mg/kg IV divided into equal doses at 2–3 min intervals
- Verapamil:
 - 2.5–5 mg IV bolus over 2 min; may repeat with 5–10 mg q15–30min to max. of 20 mg
 - 120–300 mg PO daily
- Amiodarone:
 - 5–7 mg/kg over 30–60 min, then 1.2–1.8 g/d continuous infusion or in divided PO doses until 10 g total
 - 600–800 mg/d divided dose until 10 g total, then 200–400 mg/d maintenance
- Procainamide: 15–18 mg/kg loading dose administered as a slow infusion over 30 min. Max.: 1 g. Then 2–6 mg/min infusion.
- Quinidine gluconate: 324–648 mg PO q8–12h: (extended release tabs)
- Ibutilide: 1 mg IV for patients >60 kg; 0.01 mg/kg IV for patients <60 kg infused over 10 min; can be repeated once if sinus rhythm not restored within 10 min. Requires normal QTc, no history of torsades, no hypokalemia. Patients must be monitored for 4 h for QT prolongation, Torsades de Pointes, and ventricular tachycardia.
- Flecainide: 2 mg/kg IV at 10 mg/min PO. Do not give in patients with structural heart disease.
- Propafenone: 1–2 mg/kg IV at 10 mg/min
- Sotalol: 75 mg infused IV over 5 h BID if CrCl > 60 mL/min. Give QD if CrCl 40–60 mL/min
- Heparin: Load 80 U/kg IV; infusion at 18 U/kg/h. Dosage adjustment required in obese patients
- Low-molecular-weight heparin: 1 mg/kg SQ BID
- Warfarin sodium: 2.5–5 mg/d PO, dosage adjustments based on INR
- Aspirin: 50–325 mg/d

ALERT

IV form for flecainide, propafenone, and sotalol not approved for use in US; *must be infused slowly.*

FOLLOW-UP

DISPOSITION

Admission Criteria

- Unstable AF:
 - Inability to control rate
- High risk for stroke:
 - Prior cardiovascular accident
 - CHF
- Associated medical problems contributing to the AF that require inpatient management

Discharge Criteria

- Conversion to sinus rhythm if symptoms < 48 hr
- Chronic AF with appropriate ventricular rate control and anticoagulation
- New-onset AF with rate control and anticoagulation

Issues for Referral

- Cardiology or an electrophysiologist
- Evaluation for outpatient cardioversion

FOLLOW-UP RECOMMENDATIONS

- INR check if placed on warfarin
- The patient should return to the ED if feeling faint, dizzy, numbness or weakness of the face or limbs, or trouble seeing or speaking

PEARLS AND PITFALLS

- If hemodynamically unstable and life threatening, synchronized cardioversion is warranted
- Rate or rhythm control is an individualized option for stable atrial fibrillation using β -blockers, calcium channel blockers, or antiarrhythmics
- Do not mistake F-waves or U-waves as P-waves. Can misdiagnose AF as a sinus rhythm.
- Do not use channel blockers, β -blockers, or digoxin in AF with a wide complex AF in a patient with an underlying bypass tract

- I48.91 Unspecified atrial fibrillation

ATRIAL FLUTTER

Liesl A. Curtis

BASICS

DESCRIPTION

- Atrial dysrhythmia
- 200,000 new cases each year
- A macroreentrant circuit in the right atrium is thought to be the underlying mechanism.
- Most sensitive rhythm to cardioversion
- Seldom occurs in the absence of organic heart disease
- Less common than supraventricular tachycardia (SVT) or atrial fibrillation
- Typically paroxysmal, lasting seconds to hours
- Occurs in ~ 25–35% of patients with atrial fibrillation
- Untreated, may promote cardiomyopathy

ETIOLOGY

- Alcoholism
- Cardiomyopathies and myocarditis
- CHF
- Electrolyte abnormalities
- Ischemic heart disease
- Pulmonary embolus and other pulm diseases
- Valvular heart diseases
- Post op following cardiac surgery (often in 1st postoperative week)
- Thyrotoxicosis

Pediatric Considerations

- Occurs in children but is often asymptomatic
- Associated mortality is highest in the neonatal period.
- Associated with:
 - Congenital heart disease
 - Infectious etiologies, such as rheumatic fever or myocarditis
- Be sure to consider potential toxic ingestions in pediatric patients with new AV block

DIAGNOSIS

SIGNS AND SYMPTOMS

- Palpitations

- Syncope/presyncope
- Chest pain
- Fatigue
- Dyspnea
- Poor exercise capacity
- Tachycardia—HR > 150 bpm:
- Hypotension
- Heart failure

Pediatric Considerations

- Infants do not tolerate atrial flutter well.
- The aortic valve (AV) node is capable of very rapid conduction.
- Extremely rapid ventricular rates can lead to shock or CHF.
- Atrial flutter can occur in the fetus and young infants without associated cardiac defects:
 - _ Often does not recur beyond neonatal period
- Most older children have an underlying cardiac abnormality
 - _ More likely to recur and difficult to control

ESSENTIAL WORKUP

- EKG
- Labs
- CXR

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Electrolytes and mineral panel
- Cardiac enzymes
- Digoxin level
- PT/PTT

Imaging

- CXR:
 - _ May identify cardiomyopathy or CHF
- Echo:
 - _ May identify regional wall motion abnormalities or valvular dysfunction

DIFFERENTIAL DIAGNOSIS

- SVT
- Sinus tachycardia
- Atrial fibrillation
- Multifocal atrial tachycardia

- Ventricular tachycardia (VT)

TREATMENT

PRE HOSPITAL

- Oxygen, monitor, IV access
- Unstable patients should be cardioverted in the field:
 - _ Immediate synchronized cardioversion
 - _ Start with 100 J

INITIAL STABILIZATION/THERAPY

- Oxygen, monitor, IV access
- Immediate synchronized cardioversion if unstable
 - _ Current guidelines recommend starting at 150–200 J min to improve initial success and to limit cumulative energy doses.

ED TREATMENT/PROCEDURES

- Rate control:
 - _ Rate control should be instituted prior to giving an antidysrhythmic to avoid risk of a 1:1 AV conduction ratio and hemodynamic collapse.
 - _ May be difficult to achieve
- Anticoagulation:
 - _ Same guidelines as for atrial fibrillation:
 - INR 2–3 for 3 wk prior to cardioversion if > 48 hr or unknown duration
 - Recommended even if negative transesophageal echo
 - Risk of thromboembolism ranges from 1.7–7%.
 - _ CHADS₂ score: Used for decision regarding anticoagulation
 - CHF history (1 point)
 - Hypertension history (1 point)
 - Age ≥ 75 (1 point)
 - DM history (1 point)
 - Stroke symptoms or TIA history (2 points):
 - Score 0: Aspirin is sufficient prophylaxis
 - Score 1: Oral anticoagulants preferred
 - Score 2 or more: Oral anticoagulants strongly recommended
 - _ Patients at higher thromboembolism risk:
 - Valvular heart disease
 - Fluctuating a fib/flutter rhythms
 - Left ventricular (LV) dysfunction
 - Prior stroke or thromboembolism
 - Longer symptom duration (> 48 hr)

- Antiarrhythmic drugs:
 - Adenosine:
 - Unlikely to break atrial flutter
 - May aid in the diagnosis of atrial flutter by unmasking the flutter waves
 - Amiodarone:
 - Rate control in patients with pre-excited atrial arrhythmias (i.e., WPW)
 - Preferable antiarrhythmic agent for patients with severely impaired heart function
 - Major adverse effects are hypotension and bradycardia, slower infusions can prevent this.
 - Calcium channel blockers:
 - Rate control
 - Verapamil has higher incidence of symptomatic hypotension than diltiazem.
 - Verapamil should only be used in narrow-complex arrhythmias
 - β -blockers:
 - Rate control
 - Added benefit of cardioprotective effects for patients with ACS
 - Magnesium sulfate:
 - Rate control
 - Low-level evidence
 - Digoxin:
 - Rate control
 - 3rd-line drug
 - Has inotropic properties so may be useful in patients with ventricular dysfunction
 - Longer onset to therapeutic effect
 - Procainamide:
 - Rhythm control
 - Drug of choice for patients with known pre-excitation syndromes (i.e., WPW) and preserved ventricular function
 - Caution if patient has QT prolongation
 - Sotalol:
 - Rhythm control
 - Not a 1st-line drug
 - For use in WPW and preserved ventricular function if duration of arrhythmia is ≤ 48 hr
 - Ibutilide:
 - Rhythm control
 - For acute pharmacologic rhythm conversion in patients with preserved ventricular function (EF > 30%) if duration of arrhythmia

- is ≤ 48 hr
 - Correct potassium and magnesium before use
 - Contraindicated if QTc > 440 msec or in patients with severe structural heart disease
 - Efficacy rate of 38–76%
 - Mean time to conversion is 30 min.
 - Incidence of sustained polymorphic VT 1.2–1.7%
 - Observe for 4–6 hr after administration for QT prolongation or VT.
- Cardioversion:
 - 100–360 J
 - Sedation when possible
 - Safest and most effective means of restoring sinus rhythm
- Maintenance of sinus rhythm after cardioversion:
 - High recurrence rate: $\sim 50\%$ at 1 yr; however, difficult to determine rate because data combines atrial fibrillation with atrial flutter
 - Amiodarone most effective
- Percutaneous catheter ablation:
 - Acute success rates exceed 95%.
 - 5–10% recurrence in 1–2 yr of follow-up
 - Low complication rate
 - Candidates include:
 - Recurrent episodes of drug-resistant atrial flutter
 - Patients who are drug intolerant
 - Patients who do not desire long-term drug therapy

Pediatric Considerations

- Verapamil is not recommended in infants and young children as it is associated with a low cardiac output and serious cardiovascular compromise.
- Digoxin is the 1st-line drug therapy for pediatric atrial flutter.
- Consider cardioversion as 1st-line therapy in neonates.

MEDICATION

- Amiodarone: 150 mg IV over 10 min, then continuous infusion at 1 mg/min for 6 hr, then 0.5 mg/min infusion over 18 hr; supplemental 150 mg infusions can be dosed PRN to a max. daily dose of 2.2 g (peds: 5 mg/kg IV loading dose over 20–60 min, may repeat to max. of 15 mg/kg/d IV)
- Adenosine: 6 mg IV $\times 1$. May give 12 mg IV q1–2min $\times 2$ if no conversion. Give all doses IV push
- Atenolol: 5 mg IV over 5 min, may repeat in 10 min if tolerated, then 50 mg PO q12h
- Digoxin: Loading dose 8–12 U μ g/kg lean body weight, half of which is administered initially over 5 min, and remaining portion at 25% fractions at 4–8 hr intervals (peds: 8–12 μ g/kg)

- Diltiazem: 0.25 mg/kg IV over 2 min followed in 15 min by 0.35 mg/kg IV over 2 min, maintenance infusion of 10–15 mg/h titrated to heart rate
- Dofetilide: CrCl > 60 mL/min and QTc 440 msec or less) initial dose 500 µg ORALLY twice daily; determine QTc 2–3 h after 1st dose; if QTc increases by more than 15% OR is > 500 msec (550 msec in patients with ventricular conduction abnormalities), reduce dose to 250 µg ORALLY twice daily; MAX. dose 500 µg ORALLY twice daily
- Esmolol: 0.5 mg/kg over 1 min; maintenance infusion at 0.05 mg/kg/min; can repeat loading dose and increase in increments of 0.05 mg/kg/min q4min up to 0.3 mg/kg/min
- Flecainide: A single dose of flecainide 300 mg (body weight 70 kg or greater), and flecainide 200 mg (body weight < 70 kg) [3]; prior to antiarrhythmic initiation, a β-blocker or nondihydropyridine calcium channel antagonist should be administered to prevent rapid AV conduction if atrial flutter occurs
- Ibutilide: 1 mg IV over 10 min for patients > 60 kg; 0.01 mg/kg IV for patients < 60 kg infused over 10 min; dose can be repeated once if normal sinus rhythm not restored within 10 min after infusion
- Magnesium sulfate: 1–2 g diluted in D5W over 5–60 min; slower rate preferable if patient is stable.
- Metoprolol: 5 mg IV push over 5 min at 5 min intervals to total of 15 mg, then 50 mg PO BID
- Procainamide: 20 mg/min until arrhythmia suppressed, hypotension, QRS prolongation of 50%, or total of 17 mg/kg; may be given at rate up to 50 mg/min (peds: 15 mg/kg IV over 30 min, then 20–80 µg/kg/min continuous infusion)
- Propranolol: 0.5–1 mg over 1 min, repeated after 2 min up to a total dose of 0.1 mg/kg (peds: 0.01–0.15 mg/kg/dose slow IV push over 5 min, max. 1 mg/dose)
- Sotalol: 1–1.5 mg/kg over 5 min (US packaging recommends infusion over 5 h)
- Verapamil: 2.5–5.0 mg IV bolus over 2 min; may repeat with 5–10 mg q15–30min to a max. of 20–30 mg.

FOLLOW-UP

DISPOSITION

Admission Criteria

- New-onset atrial flutter requiring antidysrhythmics, rate control
- Symptomatic (i.e., chest pain that warrants a rule out or cardioversion)
- CHF

Discharge Criteria

- New-onset atrial flutter who meet these criteria:
 - _ Rate or rhythm has been controlled

- Underlying cause has been investigated and addressed
- Anticoagulation has been initiated
- Appropriate follow-up is arranged
- Chronic atrial flutter with good rate control and appropriate anticoagulation

FOLLOW-UP RECOMMENDATIONS

Cardiologist: Radiofrequency ablation of atrial flutter emerging as treatment of choice for patients with symptomatic atrial flutter without identifiable reversible cause

PEARLS AND PITFALLS

- Be aware of WPW:
 - Do not use adenosine, β -blockers, calcium channel blockers, and digoxin (Class III can be harmful).
 - Can cause increased ventricular response, which can deteriorate to ventricular fibrillation
- Do not delay cardioversion in an unstable patient for IV placement.
- Use β -blockers with caution in patients with pulmonary disease or CHF.
- 4 major treatment issues:
 - Rate control
 - Prevention of systemic embolization
 - Reversion to sinus rhythm
 - Maintenance of sinus rhythm

ICD10

- I48.3 Typical atrial flutter
- I48.4 Atypical atrial flutter
- I48.92 Unspecified atrial flutter

ATRIOVENTRICULAR BLOCKS

Colleen N. Roche

BASICS

DESCRIPTION

- Impaired conduction between the atrium and the ventricle through the AV node or His–Purkinje system
- 1st-degree AV block:
 - Prolonged conduction through the AV node
 - Ventricular impulses are not lost.
 - Generally benign, and occurs in 1.6% healthy adults.
- 2nd-degree AV block:
 - Marked by a failure of some atrial impulses to reach ventricles
 - Mobitz Type I (Wenckebach):
 - Usually secondary to conduction deficit in AV node.
 - Progressive prolongation of the pulse-rate (PR) interval until a nonconducted P-wave and a dropped QRS complex occur
 - Generally benign, but may be a complication of an inferior wall MI
 - Mobitz Type II:
 - Conduction deficit is usually below the level of the AV node.
 - PR intervals are constant until single or multiple beats are abruptly dropped.
 - High likelihood of progression to complete heart block
 - Worse prognosis if associated with an acute MI
 - Less common than Type I
- 3rd-degree AV block:
 - Also known as complete heart block
 - All atrial impulses are unable to reach the ventricular conducting system; a ventricular escape pacemaker then takes over, resulting in AV dissociation.
 - Constant PP and RR intervals with variable PR intervals because PP and RR intervals are independent of each other.
 - More severe symptoms occur when the block is lower in the conducting system.
 - If secondary to toxicologic agents, often resolves upon omission of offending toxin
 - Never a benign condition

ETIOLOGY

- Essentially due to:
 - A structural lesion

- Increase in inherent refractory period
- Marked shortening of the supraventricular cycle
- MI:
 - 1st-degree block and Type I 2nd-degree AV block may be associated with an inferior wall MI:
 - These blocks are transient.
 - AV conduction usually returns to normal with no increased morbidity or mortality.
 - Type II 2nd-degree AV block may be associated with an anterior wall MI:
 - 5% anterior wall MIs are associated with AV blocks.
 - Increased mortality secondary to ventricular arrhythmias and left-heart failure
- Coronary artery disease:
 - Chronic ischemic injury can lead to fibrosis around the AV node
- Toxicologic:
 - Digoxin
 - β -blockers
 - Calcium-channel blockers
 - Amiodarone
 - Procainamide
 - Class 1C agents: Propafenone, encainide, flecainide
 - Clonidine
- Congenital
- Valvular heart disease
- Surgical trauma:
 - S/P coronary artery bypass graft or valvular replacement
- Increased vagal tone
- Infectious:
 - Syphilis
 - Diphtheria
 - Chagas disease
 - TB
 - Toxoplasmosis
 - Lyme disease
 - Myocarditis
 - Endocarditis
 - Rheumatic fever
 - Abscess formation in interventricular septum
- Collagen vascular diseases
- Infiltrative diseases:
 - Sarcoidosis
 - Amyloidosis
 - Hemochromatosis

- Cardiomyopathy
- Electrolyte disturbances:
 - Hyperkalemia
- Myxedema
- Hypothermia

Pediatric Considerations

- Occurs in children, but is often asymptomatic
- Associated mortality is highest in the neonatal period.
- Associated with:
 - Congenitally acquired maternal antibodies
 - Congenital heart disease
 - Infectious etiologies, such as rheumatic fever or myocarditis
- Be sure to consider potential toxic ingestions in pediatric patients with new AV block

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- 1st-degree AV block:
 - Asymptomatic
- Type I 2nd-degree AV block:
 - Pulse irregularities
- Type II 2nd-degree AV block and 3rd-degree block:
 - Exercise intolerance
 - Palpitations
 - Chest pain
 - Presyncope/syncope
 - Altered mental status
 - Dyspnea, orthopnea

Physical-Exam

- 1st-degree AV block:
 - No discrete physical exam findings
- Type I 2nd-degree AV block:
 - Regularly irregular pulse
- Type II 2nd-degree AV block and 3rd-degree block:
 - Irregular pulse
 - Hypotension
 - Mental status changes

- Signs of heart failure:
 - o Rales
 - o Cyanosis
 - o Jugular venous distention

ESSENTIAL WORKUP

- A 12-lead EKG to determine the type of block and identify evidence of infarction
- 1st-degree AV block:
 - PR interval > 0.20 sec
- 2nd-degree AV block:
 - Type I: Progressive prolongation of PR interval until there is a nonconducted P-wave and a dropped QRS complex; occurs in repeated cycles; QRS is usually narrow.
 - Type II: PR interval remains constant; atrial impulses are not conducted intermittently, giving the appearance of an occasionally dropped ventricular beat; QRS may be prolonged depending on the level of the lesion.
- 3rd-degree AV block:
 - P-waves occur at consistent intervals.
 - QRS complexes occur independently from P-waves but also at consistent intervals.
 - QRS complexes are usually narrow unless there is an infranodal conduction disturbance or a ventricular escape rhythm.

DIAGNOSIS TESTS & INTERPRETATION

Additional studies aid in confirming the etiology of the identified AV block.

Lab

- Electrolytes
- Calcium, magnesium
- Cardiac enzymes:
 - Especially for Type II 2nd-degree and 3rd-degree blocks
- Digoxin level, if patient has been exposed to this medication

Imaging

- CXR:
 - May identify cardiomyopathy or CHF
- ECG:
 - May identify regional wall motion abnormalities or valvular dysfunction

DIFFERENTIAL DIAGNOSIS

- Accelerated junctional rhythm
- Idioventricular rhythm

- Sinus bradycardia
- SA block

TREATMENT

PRE HOSPITAL

- Transcutaneous pacing for unstable Type II 2nd- or 3rd-degree block
- Atropine:
 - _ Avoid with Type II 2nd-degree block because it may precipitate complete heart block
 - _ Contraindicated in 3rd-degree heart block with a widened QRS complex
- Attempts should be made to prevent increases in vagal tone.

INITIAL STABILIZATION/THERAPY

- Transcutaneous pacemaker:
 - _ Necessary for the unstable patient with signs of hypoperfusion:
 - Hypotension
 - Chest pain
 - Dyspnea
 - Mental status changes
- Atropine:
 - _ Can be administered in:
 - Complete heart block with a narrow QRS
 - Symptomatic sinus bradycardia

ED TREATMENT/PROCEDURES

- 1st-degree AV block:
 - _ No treatment required
 - _ Avoid AV nodal blocking agents
 - _ Evaluate for associated MI, electrolyte abnormalities, medication excess in the appropriate clinical scenarios
- Type I 2nd-degree AV block:
 - _ Usually no treatment needed
 - _ If symptomatic, atropine will enhance AV conduction
- Type II 2nd-degree AV block:
 - _ Temporary transcutaneous or transvenous pacemaker
 - _ Atropine is not effective and should be avoided
- 3rd-degree AV block:
 - _ 1st line of treatment: Emergent pacemaker
 - _ May transiently respond to atropine with narrow QRS complexes
 - _ If block is identified to be toxin-mediated, specific treatments include:
 - Digoxin-specific antibodies (digoxin overdose)

- Glucagon and calcium (β -blocker or calcium-channel blocker overdose)

MEDICATION

- Atropine: 0.5–1.0 mg (peds: 0.01–0.03 mg/kg) IV q5min as necessary
- Digoxin-specific antibodies: 10 vials (380 mg) is an appropriate loading dose if digoxin toxicity is strongly suspected:
 - _ Serum level \times weight (kg) = number of vials to be administered
- Glucagon: 5–10 mg (peds: 50 μ g/kg) IV over 5 min
- Calcium chloride: 250–500 mg (peds: 20 mg/kg) IV

FOLLOW-UP

DISPOSITION

Admission Criteria

Monitored bed:

- Type II 2nd-degree block
- 3rd-degree block

Discharge Criteria

Asymptomatic 1st-degree and Type I 2nd-degree blocks: Ensure follow-up for further outpatient workup.

FOLLOW-UP RECOMMENDATIONS

Asymptomatic 1st-degree and Type I 2nd-degree blocks can follow-up with a cardiologist on a routine outpatient basis.

PEARLS AND PITFALLS

- Obtaining an EKG rapidly in symptomatic patients is paramount.
- Once a high-degree AV block has been diagnosed, initiate transcutaneous pacing immediately.
- Obtain a complete history from all available resources; it may help you identify an offending toxin rapidly.
- Common pitfalls:
 - _ Failure to interpret EKG properly
 - _ Failure to diagnose AV block appropriately
 - _ Failure to initiate transcutaneous pacing in a timely fashion
 - _ Failure to consult cardiology for permanent pacemaker in a timely fashion

BABESIOSIS

Philip D. Anderson

BASICS

DESCRIPTION

- Tick-borne, infectious disease caused by intraerythrocytic protozoa of the genus *Babesia*, infects wide array of vertebrate animals, causes lysis of host RBCs
- Asymptomatic to severe, life-threatening infection depending on the species of *Babesia* and the immune status of the patient
 - Asymptomatic infection:
 - 50% of children and 25% of adults with infection have no symptoms
 - Mild–moderate disease:
 - Usually immune competent patients
 - Infections typically self-limited or resolve with antibiotic therapy
 - Mortality usually <5%
 - Severe disease:
 - Defined as hospitalization >2 wk, ICU stay >2 days, or ending in death
 - Typically associated with immune compromise: Splenectomy; cancer; HIV; hemoglobinopathy; chronic heart, lung, or liver disease
 - Other groups at higher risk for severe disease: Neonates, >50 yr old, on immune-suppressive drugs (e.g., rituximab or anticytokine therapy [e.g., etanercept, infliximab])
 - Mortality can be as high as 21% among immune-suppressed patients
- Complications develop in approximately one-half of the hospitalized patients:
 - ARDS, DIC most common
 - Can also see CHF, coma, liver failure, renal failure, splenic rupture
- Co-occurrence with other tick-borne diseases should be considered in endemic regions under the following conditions:
 - Lyme disease (*Borrelia burgdorferi*) – associated rash
 - Human granulocytic anaplasmosis (*Anaplasma phagocytophilum*) – protracted symptoms with leukopenia

ETIOLOGY

- *Babesia*:
 - Species causing human disease:
 - *Babesia microti* – Northern and Midwestern US (most common cause of disease in US)
 - *Babesia divergens* – Europe
 - *Babesia duncani* – Northern US Pacific coast

- Case reports of Babesiosis in Asia, Africa, Australia, and South America
- Animal reservoirs:
 - *B. microti* – white-footed mouse, white-tailed deer
 - *B. divergens* – cattle, rats
- Transmission via *Ixodes* tick vector:
 - Most common vector for transmission of babesiosis to humans
 - *Ixodes* requires blood meal from a vertebrate host to pass through each stage of life cycle (larva, nymph, adult)
 - Most cases result from nymphal tick bites in late spring through summer, adult ticks can also transmit disease
- Pathogen life cycle, pathogenesis:
 - Protozoa pass from tick salivary glands to mammalian bloodstream where they penetrate erythrocytes, mature and divide.
 - Mature protozoa exit from RBC resulting in membrane damage, lysis, hemolytic anemia, and hemoglobinuria.
 - Damaged RBCs become less deformable, enhancing removal by spleen; however, asplenic patients less able to clear infected RBCs, leading to more severe disease.
 - Damaged RBCs may result in microvascular stasis with secondary ischemic organ injury to liver, spleen, heart, kidney, or brain.
- Transmission via transfusion of RBCs, platelets:
 - > 150 cases since 1979, 75% of these since 2000
 - *B. microti* is the most common pathogen
 - Low-level parasitemia may not be visible on donor blood smears, yet can still transmit disease
 - Often results in severe cases as recipients of blood products often immune compromised or have significant comorbidities

Pediatric Considerations

Transmission can occur in utero and during delivery; youngest reported case was a 4-wk-old infant.

DIAGNOSIS

SIGNS AND SYMPTOMS

Gradual onset of malaise and fatigue, associated with fever as high as 105°F (40.6°C), 1–4 wk after tick bite, or 1–9 wk after transfusion with contaminated blood products

- Common symptoms include chills and sweats, headache, anorexia, nonproductive cough, arthralgia, and nausea
- Less common symptoms include vomiting, sore throat, abdominal pain, conjunctival injection, photophobia, weight loss, emotional lability, depression, and hyperesthesia

History

- Febrile, flu-like illness in patients who
 - live in, or traveled to an endemic area within past 2 mo (especially during spring, summer)
 - have had blood product transfusions within past 6 mo
- Shock or sepsis presentation in patients with above history, especially in presence of risk factors for severe disease (see above)

Physical-Exam

- Fever (most common finding)
- Hepatosplenomegaly
- Pharyngeal erythema
- Jaundice
- Retinopathy with splinter hemorrhages
- Retinal infarcts
- Rash may be seen:
 - Petechiae, ecchymosis
 - Erythema chronicum migrans (suggests concurrent Lyme disease)
- Severe disease:
 - Tachypnea
 - Hypoxia
 - Hypotension
 - Altered mental status

ESSENTIAL WORKUP

- Microscopy of thin blood smear with Giemsa or Wright staining to demonstrate *Babesia* organisms
- When smears are negative, polymerase chain reaction (PCR) assay can be used
- Indirect immunofluorescent antibody testing can be used to recognize babesial antigens when microscopy and PCR assays are negative

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Microscopy:
 - Intraerythrocytic parasites can be round, oval, or pear shaped.
 - Parasites in budding tetrad formation (Maltese cross) are pathognomonic for babesiosis, but not commonly seen.
 - Most common finding is intraerythrocytic round or oval (pyriform) rings with pale blue cytoplasm and red-staining nucleus.
 - Extracellular parasites may be seen with high levels of parasitemia.
 - Parasitemia levels are generally between 1% and 10%, but can be as high as 80%; may be <1% in early stages of disease.

- Ring forms may appear similar to *Plasmodium falciparum* (malaria); in babesiosis there are no pigment deposits (hemozoin) that are usually seen with malaria.
- PCR:
 - Amplification of babesial 18s rRNA gene is more sensitive than microscopy
 - Results can be available within 24 hr
 - Useful in cases with low levels of parasitemia
- Serology:
 - Indirect immunofluorescent antibody testing may be useful when microscopy and PCR testing are negative.
 - IgM antibody usually detectable 2 wk after onset of illness
 - IgG titers $\geq 1:256$ suggest active or recent infections; IgM titers $\geq 1:64$ suggest acute infection.
- Nonspecific lab abnormalities that may be seen in babesiosis:
 - Mild-to-moderate hemolytic anemia (low hematocrit/hemoglobin, low haptoglobin, elevated reticulocyte count, elevated lactate dehydrogenase, elevated total bilirubin)
 - Thrombocytopenia is common
 - LFTs (elevated alkaline phosphatase, transaminases, lactate dehydrogenase, bilirubin)
 - Urinalysis (hemoglobinuria, proteinuria)
 - Elevated BUN, creatinine suggests renal insufficiency
 - Hyperkalemia may result from massive hemolysis

DIFFERENTIAL DIAGNOSIS

- Malaria
- Other tick-borne diseases:
 - Lyme disease
 - Human granulocytic anaplasmosis
 - Ehrlichiosis
 - Rocky Mountain spotted fever
 - Colorado tick fever
 - Q fever
 - Tularemia
 - Relapsing fever
- Typhoid fever
- Acute hemolytic anemia

TREATMENT

PRE HOSPITAL

- Ensure a patent airway in patients with respiratory distress.

- Provide supplemental oxygen and ventilatory assistance as needed.
- If patient presents in shock, establish IV access and administer a fluid bolus of 0.9% NS 500 mL (peds: 20 mL/kg) IV.

INITIAL STABILIZATION/THERAPY

- Airway management, ventilatory support for patients with acute respiratory distress
- IV access should be established in patients with evidence or risk factors for severe disease.
- IV fluids, pressor support for patients in shock
- Cardiac monitor: Patients with severe disease may develop cardiac ischemia, arrhythmias.

ED TREATMENT/PROCEDURES

- Antipyretics for fever
- Start antibiotic therapy in symptomatic patients after confirming diagnosis on microscopy or PCR
- Mild–moderate disease:
 - Oral atovaquone + azithromycin for 7–10 days is the regimen of choice.
 - Clindamycin + quinine is an effective alternative, but associated with significant side effects (tinnitus, vertigo, gastroenteritis) that may require reduced dosing or stopping medication in up to one-third of patients.
- Severe disease:
 - IV clindamycin + oral quinine for 7–10 days is regimen of choice (IV quinine may be used, but may cause ventricular arrhythmias and requires QT monitoring)
 - RBC exchange transfusion is indicated in patients with parasitemia > 10%; hemoglobin < 10 g/dL; or pulmonary, renal, or hepatic complications.
 - Persistent or relapsing disease may be seen in immunocompromised patients; these patients should receive antibiotic therapy for at least 6 wk, continuing for 2 wk after the last positive blood smear; can use standard combinations (see above).
- Asymptomatic infection:
 - Antibiotics are not indicated unless parasitemia on blood smears persists > 3 mo.

MEDICATION

- Acetaminophen: 500 mg (peds: 10–15 mg/kg, do not exceed 5 doses/24 h) PO q4–6h, do not exceed 4 g/24 h
- Atovaquone: 750 mg (peds: 20 mg/kg; max. 750 mg/dose) PO BID for 7 days
- Azithromycin: 500 mg (peds: 10 mg/kg; max. 500 mg) PO on day 1, followed by 250 mg (peds: 5 mg/kg; max. 250 mg) PO per day: 6 days
- Clindamycin: 300–600 mg (peds: 7–10 mg/kg q6–8h) IV q6h; 600 mg (peds: 7–10

- mg/kg q6–8h) PO q8h for 7–10 days
- Ibuprofen: 400 mg (peds: 20–40 mg/kg/d) PO q6–8h PRN
- Quinine: 650 mg (peds: 25 mg/kg/d) PO q8h for 7–10 days

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with parasitemia > 4%, severe anemia (hemoglobin < 10 g/dL), significant symptoms or complications, or need for exchange transfusion require admission:
 - Respiratory distress
 - Hypotension or shock
 - New renal insufficiency or hepatic failure
 - Altered mental status
 - Severe hemolysis (jaundice, hematuria)
- Admission should also be considered in patients without any of the above, but who have risk factors for developing severe disease (see above):
 - Elevated alkaline phosphatase, elevated WBC counts, and male gender were predictive of more severe outcomes

Discharge Criteria

- Patients with asymptomatic, mild, or moderate disease
- Parasitemia < 4%
- Intact spleen, immune competent
- Able to tolerate oral medications

Issues for Referral

Immunodeficient patients are more likely to have persistent or relapsing disease following initial treatment and should be referred for infectious disease consultation.

FOLLOW-UP RECOMMENDATIONS

Patients diagnosed with babesiosis should follow up with their primary care physician or infectious disease specialist for monitoring of parasitemia levels following completion of antibiotic course in symptomatic patients and at 3 mo in asymptomatic patients.

PEARLS AND PITFALLS

- Babesiosis can be a life-threatening disease in asplenic patients.
- Consider babesiosis as a potential cause of respiratory distress/shock in patients with a travel history to an endemic area.

- Microscopy findings may not be present in early stages of disease when parasitemia levels are low.

B60.0 Babesiosis

BACK PAIN

James Willis • Eric Legome

BASICS

DESCRIPTION

- Low back pain (LBP):
 - Refers to pain in the area between the lower rib cage and the gluteal folds, often with radiation into the thighs
- Sciatica:
 - Pain in the distribution of the lower lumbar spinal roots
 - May be accompanied by neurosensory and motor deficits
- Pain classification:
 - Acute: < 6 wk
 - Subacute: 6–12 wk
 - Chronic: > 12 wk

ETIOLOGY

- Nonspecific musculoligamentous source (great majority) (e.g., muscle, ligament, fascia)
- Herniation of the nucleus pulposus
- Degenerative joints or discs
- Spinal stenosis
- Anatomic abnormalities—especially spondylolisthesis
- Fractures from trauma and osteoporosis
- Underlying systemic diseases (minority):
 - Neoplasm
 - Infections
 - Vascular (dissection, aneurysm, and thrombosis)
 - Renal
 - GI
 - Pelvic organ pathology

DIAGNOSIS

SIGNS AND SYMPTOMS

- Musculoligamentous:
 - Poorly localized and dull back/gluteal pain without radiation past the knee.
 - Usually no objective neurologic signs.
 - Back spasm is a variable and poorly reproducible finding.
- Sciatica:

- Sharp, shooting, well-localized pain
- Leg complaints often greater than back
- May present with
 - asymmetric deep tendon reflexes
 - decreased sensation in a dermatomal distribution
 - objective weakness
- Massive central disc herniation (cauda equina):
 - Decreased perineal sensation
 - Urinary retention with overflow incontinence
 - Fecal incontinence
- Infectious processes:
 - Fever
 - Localized percussion tenderness of the vertebral bodies
- Bony lesion:
 - Continuous pain that does not change with rest
 - Constitutional symptoms
- Vascular etiology:
 - Severe, often “ripping or tearing” pain
 - May be associated with cold or insensate extremities

History

- Can assist with focusing and narrowing differential diagnosis. Helps rule out concerning pathology for pain:
 - Intensity
 - Quality
 - Location and radiation
 - Onset
 - Exacerbating or remitting factors
 - Social or psychological factors
 - Response to previous therapy
- Risk factors for serious disease:
 - Fever
 - Constitutional symptoms
 - Trauma
 - Age >60 yr
 - History of cancer:
 - Especially those that metastasize to bone
 - Chronic steroid use
 - IV drug use
 - Recent instrumentation or bacteremia
 - Night pain

Physical-Exam

- Fever
- Spasm or soft tissue tenderness is a poorly reproducible finding:
 - Vertebral tenderness sensitive but nonspecific for infection
- Straight leg raise—elevating the leg while supine reproduces sciatic symptoms:
 - Ipsilateral raise highly sensitive but not specific
 - Crossed leg raise highly nonspecific but insensitive
- Ankle and great toe dorsiflexion and ankle plantar flexion (L5, S1 nerve roots)
- Ankle deep tendon reflexes (S1)
- Dermatomal sensory exam:
 - Assess for saddle anesthesia
- Rectal sphincter tone

ESSENTIAL WORKUP

- Thorough history and physical exam, including detailed neurologic and vascular exam
- No specific tests are needed for uncomplicated musculoligamentous or sciatic pain
- Rapid diagnostic testing and vascular consultation concerning aortic etiology

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Urinalysis for suspected:
 - UTI/pyelonephritis
 - Prostatitis
- ESR:
 - Highly sensitive, though nonspecific for infectious or inflammatory etiologies
 - Used for screening to help rule out disease

Imaging

- Lumbosacral radiograph:
 - Significant trauma
 - Age > 50–60 yr
 - History or signs/symptoms of cancer
 - Fever
 - IV drug user
 - Pain at rest
 - Suspicion of inflammatory etiology
 - Pain that does not improve after 4 wk
- Bedside US:
 - Full bladder suggests urinary retention
 - Abdominal aortic aneurysm (AAA)

- Abdominal CT if patient stable
- MRI:
 - Suspicion of abscess:
 - Fever, immunocompromised, IVDA, history of bacteremia
 - Suspicion of metastatic tumor:
 - Systemic cancer, weight loss
 - Suspicion of hematoma:
 - Anticoagulation, recent spinal anesthesia
 - Rapidly progressing neurologic symptoms
 - Urinary retention or fecal incontinence associated with back pain
- CT:
 - Secondary modality for diagnosis of abscess, cancer, or massive disc when MRI unavailable
 - Test of choice in imaging potential unstable fractures
 - Excellent sensitivity to evaluate vascular etiology in stable patient

DIFFERENTIAL DIAGNOSIS

- Spinal origins—in the majority of patients no precise anatomic site is discovered:
 - Musculoligamentous (majority)
 - Discogenic
 - Fracture
 - Spondylolisthesis
 - Ankylosing spondylitis
 - Osteomyelitis
 - Epidural abscess/hematoma
 - Neoplasm
- Nonspinal causes:
 - AAA
 - Prostatitis
 - Upper UTI
 - Abdominal neoplasm
 - Renal colic
 - Aortic dissection

TREATMENT

PRE HOSPITAL

- Immobilization is not generally recommended for nontraumatic pain.
- Rapid transport for vascular concerns

ED TREATMENT/PROCEDURES

- NSAIDs:

- Musculoligamentous pain
- Renal colic
- Similar benefits as APAP but less optimal side-effect profile
- APAP: Considered 1st-line therapy for mild-to-moderate pain
 - Moderate but conflicting evidence for benefit of NSAID and acetaminophen combination over each individually in postoperative pain
 - APAP and NSAIDs not effective for sciatica pain
- Muscle relaxants:
 - Cyclobenzaprine, methocarbamol, carisoprodol, or tizanidine
 - Benefits must be balanced by side effects, mostly sedation, dizziness, and dry mouth
- Benzodiazepines:
 - No clear difference from skeletal muscle relaxants
 - Likely higher risk profile for addiction
- Narcotics:
 - A reasonable (3–5 days) course may be given for severe pain not relieved by anti-inflammatory or APAP. Effective for neuropathic pain
 - Risk benefit profile should be considered and discussed with patient
- Corticosteroids:
 - No benefit in radicular or nonradicular back pain
- Spinal manipulation:
 - A short course (< 2 wk) may be helpful in acute LBP without sciatica
- Physical therapy/exercise:
 - No clear consensus for indications
 - May be helpful in symptomatic relief, preventing further episodes and teaching patients
- Acupuncture:
 - Controversial, probable benefit for chronic musculoskeletal pain
 - No clear benefit over other modalities
 - Trigger point therapy with minimal to no evidence of benefit for chronic LBP not studied for acute
- Massage:
 - May be beneficial when combined with exercises and education
- Heat/cold therapy:
 - Limited evidence to support that heat wrap therapy may help reduce pain and disability for patients with back pain < 3 mo. Improved as adjunct to exercise.
- Bed rest:
 - Unhelpful to speed recovery and may impede improvement. If patient requires bed rest acutely or is symptomatically improved, 1 or 2 days may be recommended.
- Back exercises:
 - Unlikely to be useful in acute phase; may assist with prevention of future

episodes

- Expected recovery to pain-free state:
 - Conflicting data, mostly in non-ED setting
 - ~33% within 1 wk
 - ~90% within 6–8 wk
 - Low SES, female sex, baseline disability and chronic LBP significant for worse functional outcome at 1 and 3 wk
 - Newer ED data suggests functional limitation in 50% of patients with pain at 3 mo.
- Recurrence is common: ~40%

MEDICATION

First Line

- Acetaminophen: 500 mg (peds: 10–15 mg/kg, do not exceed 5 doses/24h) PO q4–6h, do not exceed 4 g/24h
- Hydrocodone/acetaminophen: 5/500 mg PO q4–6h
- Ibuprofen: 600–800 mg PO q6–8h (peds: 10 mg/kg q6h)
- Naproxen: 250–500 mg PO q12h
- Oxycodone/acetaminophen: 5/500 mg PO q4–6h

Second Line

- Cyclobenzaprine: 5–10 mg PO TID. Caution patient regarding drowsiness.
- Methocarbamol: 500–1,500 PO q6h. Caution patient regarding drowsiness.
- Valium: 5–10 mg PO q8h
- You may combine 1st- and 2nd-line therapies but side-effect profile will increase

FOLLOW-UP

DISPOSITION

Admission Criteria

- Severe pain with inability to ambulate
- Pain unresponsive to ED management
- Progressive neurologic deficits
- Signs of cauda equina syndrome
- Infectious, vascular, or neoplastic etiologies

Discharge Criteria

Uncomplicated presentation with ability to control pain and ambulate

Geriatric Considerations

- Maintain a high suspicion for serious disease including vascular etiology, neoplasm, or infection.
- Have a low threshold for imaging or diagnostic testing.
- Follow up patients on NSAIDs or opioids more carefully for complications or adverse events related to therapy.

Pediatric Considerations

- Back pain is unusual in the pediatric patient; a high suspicion for an infectious etiology must be maintained.
- For musculoligamentous pain, a single trial found that Ibuprofen provides good pain control with a low side-effect profile.

Pregnancy Considerations

Limited evidence suggests that strengthening and pelvic tilt exercises combined with routine prenatal care may have benefit in treating back pain; unclear if they prevent pain

Issues for Referral

Urgent neurosurgical or orthopedic consultation for definite diagnosis or high suspicion for abscess or lesion (disc, neoplasm, or other) with rapidly progressive objective neurologic findings

FOLLOW-UP RECOMMENDATIONS

- Uncomplicated back pain: PCP in 1–2 wk
- New sciatica without neurologic findings: PCP or specialist in 7–10 days
- Complicated with sensory findings only or minimal motor symptoms: 24–48 hr
- Marked or rapidly progressive motor symptoms, or bowel/bladder findings warrant specialist consultation in the ED or transfer if unavailable.

PEARLS AND PITFALLS

- Consider MRI for history of IVDA to rule out epidural abscess or if concerns of nonbony spinal metastases.
- Elderly with minimal trauma may sustain fractures.
- Consider vascular etiology in elderly patients with 1st-time presentation of back pain.
- Advise patients that this is often a prolonged course and they should not expect rapid resolution.
- Opioids should be limited to a short course from the ED.

BACTERIAL TRACHEITIS

Noah K. Rosenberg • Gary Bubly

BASICS

DESCRIPTION

- A tracheal infection potentially causing acute airway obstruction. Also known as bacterial croup and laryngotracheobronchitis. Exudative tracheitis can refer to a less severe form of disease
- Usually secondary bacterial infection of trachea, complicating antecedent viral infection, or less commonly, instrumentation
- Fatal in 0–20%
- Tracheal membrane formation, purulent discharge, subglottic edema, erosions, with normal epiglottis
- Classically presents with prodrome similar to croup followed by rapid deterioration and loss of airway patency
- Mean age 5 yr; rarely occurs in adults
- More common in children than epiglottitis, presumably due to success of *Haemophilus influenzae* immunization
- More frequent August–December

ALERT

Patients may present with a fairly benign course, followed by rapid deterioration, with respiratory distress, toxic appearance, and acute airway obstruction.

ETIOLOGY

- *Staphylococcus aureus* (with occ. methicillin-resistant *S. aureus* [MRSA])
- *Moraxella catarrhalis*
- *Streptococcus pneumoniae*
- Group A streptococcal species
- *Pseudomonas aeruginosa*
- *H. influenzae* type B
- *Escherichia coli*
- Anaerobes
- *Klebsiella pneumoniae*
- *Nocardia*
- Associated with influenza A (including H1N1) and B, parainfluenza, adenovirus, and RSV viral infections
- *Aspergillus*, HSV in immunocompromised hosts (HIV)

DIAGNOSIS

SIGNS AND SYMPTOMS

History

Usually preceding viral infection with acute deterioration in course of illness

Physical-Exam

- Fever
- Cough
- Retractions
- Inspiratory/expiratory stridor
- Toxic appearance
- Hoarseness
- Cyanosis
- Nasal flaring
- Sore throat/neck pain
- Dysphonia (drooling uncommon)
- Complications:
 - Respiratory:
 - Airway obstruction
 - Subglottic stenosis
 - Pulmonary edema
 - Pneumothorax
 - ARDS
 - Endotracheal tube (ETT) plugging
 - Infection:
 - Septic shock
 - Toxic shock syndrome (TSS)
 - Pneumonia
 - Retropharyngeal cellulitis
 - Cardiopulmonary arrest
 - Renal failure

ESSENTIAL WORKUP

- Clinical assessment and management of airway takes priority over diagnostic workup; secure airway, optimally in operating room under controlled conditions.
- Ensure adequate oxygenation before proceeding:
 - Pulse oximetry

DIAGNOSIS TESTS & INTERPRETATION

Lab

- WBC variably elevated
- Blood cultures usually negative

- Request tracheal cultures from endoscopist/surgeon.

Imaging

Radiographs of neck soft tissue:

- If done, perform in ED; accompany and monitor at all times.
- Tracheal margin irregularities
- Subglottic narrowing
- Clouding of tracheal air column
- Irregular intratracheal densities
- Normal epiglottis

Diagnostic Procedures/Surgery

- Flexible fiberoptic laryngoscopy:
 - Permits direct visualization of epiglottis
 - Mucosal edema
 - Subglottic edema, secretions, membrane
- Bronchoscopy:
 - Direct visualization of trachea
 - Laryngotracheal inflammation and erosions
 - Mucopurulent secretions
 - Membranes
 - Therapeutic stripping of membranes
 - Enables direct culture of material

DIFFERENTIAL DIAGNOSIS

- Infection:
 - Croup (failure to respond to treatment, older age, rapid deterioration or toxic appearance should raise suspicion for bacterial tracheitis rather than croup.)
 - Epiglottitis
 - Peritonsillar abscess
 - Retropharyngeal abscess
 - Uvulitis
 - Laryngeal diphtheria
- Angioedema
- Intraluminal obstruction:
 - Foreign body aspiration
- Caustic ingestion
- Trauma

TREATMENT

PRE HOSPITAL

- Assess airway/breathing:
 - Supplemental oxygen
 - Racemic epinephrine aerosol if easily tolerated
 - Reassurance; avoid agitating child
- Bag-valve-mask (BVM) ventilation if in respiratory failure
- Intubate if unable to maintain airway with BVM and other measures.
- Immediate transport
- Notify receiving ED of airway status.

INITIAL STABILIZATION/THERAPY

Airway management:

- Anticipate difficult airway
- Intubation required in ~75% (40–100%) of patients. More frequently required in younger patients. Active airway management ensures stable airway and facilitates suctioning.
- Intubation should ideally be performed in the operating room with surgical airway backup.
- Select an ETT 1–2 sizes smaller than usual for age/size.
- Meticulous ETT care and suctioning
- If BVM ventilation needed, use appropriately sized mask with 2-hand seal.
- Supplemental humidified oxygen

ED TREATMENT/PROCEDURES

- Continue monitoring of ventilation and oxygenation.
- IV fluids, bolus, as necessary
- Bronchoscopy if not rapidly deteriorating:
 - Assess need for intubation
 - Therapeutic stripping of membranes
- IV antibiotics to cover typical pathogens:
 - Ceftriaxone and nafcillin or vancomycin
 - Vancomycin or clindamycin for penicillin-allergic patients
 - Consider corticosteroid therapy

MEDICATION

- Ceftriaxone: 50 mg/kg IV, max. 2 g
- Nafcillin: 50 mg/kg IV; max. 2 g
- Ampicillin/sulbactam: 50 mg/kg IV; max. 3 g
- Vancomycin: 15 mg/kg IV; max. 1 g
- Clindamycin: 10 mg/kg IV; max. 1 g
- Racemic epinephrine: 2.25% solution diluted 1:8 with water in doses of 2–4 mL via aerosol
- Dexamethasone: 0.6 mg/kg IV

First Line

Ceftriaxone plus nafcillin

Second Line

Vancomycin or clindamycin:

- Consider if penicillin allergic, and in areas of high prevalence of MRSA

FOLLOW-UP

DISPOSITION

Admission Criteria

All patients with suspected or documented bacterial tracheitis:

- Admit to PICU.
- PICU length of stay varies from 3–9 days.

Discharge Criteria

None

Issues for Referral

Critical care, otolaryngologist, or pulmonologist should be consulted.

FOLLOW-UP RECOMMENDATIONS

Few long-term complications

PEARLS AND PITFALLS

- Consider in patients with croup-like illness who rapidly deteriorate.
- May be more severe in younger patients due to narrower tracheal diameters.

BARBITURATES POISONING

Shaun D. Carstairs • David A. Tanen

BASICS

DESCRIPTION

- Class of sedative–hypnotic agents
- Derivatives of barbituric acid
- Mechanism:
 - Enhances activity of γ -aminobutyric acid (GABA)
 - At high levels, directly opens GABA-A associated chloride channel
 - Leads to inhibition of vascular smooth muscle tone
 - May lead to direct myocardial depression

ETIOLOGY

Overdose of barbiturates:

- Intentional or nonintentional

DIAGNOSIS

SIGNS AND SYMPTOMS

- CNS:
 - Lethargy
 - Slurred speech
 - Incoordination
 - Ataxia
 - Coma (can mimic brain death)
 - Loss of reflexes
- Cardiovascular:
 - Hypotension
 - Bradycardia
- Ophthalmologic:
 - Miosis (generally associated with deep coma)
 - Nystagmus
 - Dysconjugate gaze
- Other:
 - Respiratory depression
 - Hypothermia
 - Bullae or “barb blisters”

History

- Determine if there was an intentional overdose:
 - _ Pill bottles at the scene
 - _ History of depression or suicidal ideation
- Determine if there was a medication error:
 - _ What other medications was the patient taking?
 - _ Were there any recent changes in dose?
- Estimate how long the patient may have been unresponsive.

Physical-Exam

- CNS abnormalities:
 - _ Ataxia to coma
- Respiratory depression
- Cardiovascular:
 - _ Bradycardia and hypotension
- Ophthalmologic:
 - _ Miosis
 - _ Nystagmus
 - _ Dysconjugate gaze
- Hypothermia
- Bullae or “barb blisters”

ESSENTIAL WORKUP

- Fingerstick glucose
- Oxygen saturation monitor
- Monitor BP

ALERT

Barbiturate poisoning can mimic brain death:

- Cannot pronounce a patient brain dead until barbiturate poisoning has been ruled out

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Electrolytes, BUN/creatinine, glucose:
 - _ Calculate anion gap
 - _ Assess for renal failure
- Urinalysis:
 - _ For myoglobin
 - _ For crystalluria (Primidone)
- Creatine phosphokinase for evidence of rhabdomyolysis
- Urine toxicology screen
- Obtain serum phenobarbital level (if suspected)

- Acetaminophen and salicylate levels if suspected suicide attempt
- Thyroid function tests

Imaging

- CT scan of head for altered mental status
- CXR for evidence of aspiration

Diagnostic Procedures/Surgery

- Noncontrast head CT
- Lumbar puncture

DIFFERENTIAL DIAGNOSIS

- Sedative–hypnotic poisoning (including γ -hydroxybutyrate [GHB] and its precursors)
- Carbon monoxide poisoning
- CNS infections
- Space-occupying lesions of the head
- Hypoglycemia
- Uremia
- Electrolyte imbalance (i.e., hypermagnesemia)
- Postictal state following seizure
- Hypothyroidism
- Liver failure
- Psychiatric illness

TREATMENT

PRE HOSPITAL

- Moderate to severe poisonings require paramedic transport.
- Intubation is often necessary because of respiratory depression or loss of gag reflex.
- IV access and supplemental oxygen:
 - IV fluid bolus for hypotension

INITIAL STABILIZATION/THERAPY

- ABCs:
 - Administer supplemental oxygen.
 - Severe poisonings usually require endotracheal intubation.
- 0.9% NS:
 - Hypotensive patients require at least 1–2 L IV fluid resuscitation.
 - Pressor support may be necessary for refractory hypotension.
- Activated charcoal effectively binds barbiturates and may decrease systemic

absorption.

ED TREATMENT/PROCEDURES

- Administer 1 dose of activated charcoal:
 - Utility greatest if given within 1 hr of ingestion
 - Ensure patient is awake and alert (or airway protected) prior to administration.
 - Consider “gut dialysis” with repeated dose activated charcoal (without sorbitol) given q2–4h (as long as bowel sounds are present).
- Rewarm patient if hypothermic (see “Hypothermia” chapter).
- Treat hypotension resistant to IV fluid bolus with vasopressors (dopamine, norepinephrine, epinephrine).
- Treat hyperkalemia (from muscle breakdown) with calcium, sodium bicarbonate, insulin and glucose, and/or potassium-binding agents.
- Repeat phenobarbital level in 2–4 hr to determine whether level is increasing.
- Consider hemodialysis if patient has
 - decreased or no renal function
 - prolonged coma
 - serum phenobarbital level > 100 mg/dL
 - refractory hypotension
- There is no role for urinary alkalinization

MEDICATION

First Line

- Activated charcoal: 1 g/kg PO
- Dopamine: 5–10 µg/kg/min titrating to desired effect (to max. of 20 µg/kg/min)
- Norepinephrine: 2–4 µg/min titrating to desired effect (to max. of 10 µg/min)

Second Line

Epinephrine: 0.1 µg/kg/min titrating to desired effect (to max. of 1 µg/kg/min)

FOLLOW-UP

DISPOSITION

Admission Criteria

ICU admission for:

- Coma
- Respiratory depression
- Hypotension
- Hypothermia

- Rhabdomyolysis

Discharge Criteria

Asymptomatic after a minimum of 6 hr of observation with 2 consecutive subtoxic phenobarbital levels before discharge

Issues for Referral

- If intentional overdose, will require psychiatric evaluation
- For nonintentional overdose, referral for adjustment in medications

FOLLOW-UP RECOMMENDATIONS

For nonintentional overdose, may need referral for adjustment in medications or change of medications to agents with a greater therapeutic window.

PEARLS AND PITFALLS

- Hypothermia may be pronounced:
 - Ensure accurate core temperature is measured.
- Check for rhabdomyolysis, since the patient may have been down for a while.
- Barbiturate poisoning can cause prolonged coma:
 - Ensure medication effects have resolved prior to making diagnosis of brain death.

BAROTRAUMA

Catherine M. Visintainer • Nicole L. Lunceford • Peter J. Park

BASICS

DESCRIPTION

Injury resulting from the expansion or contraction of gases in an enclosed space

ETIOLOGY

- Tissue damage results when a gas-filled space does not equalize its pressure with external pressure.
- Boyle's law: At a constant temperature, pressure (P) is inversely related to volume (V):
 - _ $PV = K$ (constant) or $P_1V_1 = P_2V_2$
 - _ As pressure increases/decreases, volume decreases/increases.
- Solid and liquid-filled spaces distribute pressure equally.
- Volume changes are greatest in the few feet nearest the surface.
- Gas-filled cavities in the body are subject to expansion/contraction:
 - _ External objects:
 - Air pockets in dive suit/mask expand and contract.
 - _ Paranasal sinus:
 - Barotrauma of descent
 - Pressure equalization impaired through nasal ostia resulting in negative pressure in sinus cavity
 - Frontal sinus most commonly affected
 - _ External ear:
 - Barotrauma of descent
 - Blockage of external auditory canal results in trapped air leading to a vacuum
 - _ Middle ear:
 - Barotrauma of descent
 - Most common type of barotraumas
 - Seen in 30% of inexperienced divers and 10% of experienced divers
 - Eustachian tube provides sole route of pressure equalization for middle ear.
 - Inadequate clearance via eustachian tube leads to increasingly negative pressure gradient across tympanic membrane (TM).
 - _ Inner ear:
 - Barotrauma of descent
 - Results from rapid development of pressure differential across middle and inner ear (Valsalva, Frenzel maneuvers, rapid descent)

- Increased pressure in inner ear may cause round or oval window to rupture.
- Frequently associated with middle ear barotrauma
- Teeth:
 - Entrapped gas within or around tooth
- GI:
 - Barotrauma of ascent
 - Swallowed air in GI tract expands as external pressure decreases.
- Pulmonary:
 - Barotrauma of ascent
 - Expansion of gas trapped in lungs (closed glottis, bronchospasm) leads to distention of alveoli
 - Can lead to alveolar rupture
 - Most common is pneumomediastinum
 - Potential arterial gas embolism (AGE) (see “Arterial Gas Embolism”)
 - Divers with decreased lung compliance/increased lung volumes at increased risk (chronic obstructive pulmonary disease [COPD], asthma)

DIAGNOSIS

SIGNS AND SYMPTOMS

- Facial:
 - Occlusive dive mask: Conjunctival hemorrhage, facial edema, and swelling
- Extremities:
 - Tight-fitting dive suit: Edema and erythema of the skin at locations of air pockets
- Paranasal sinuses (barosinusitis):
 - Sinus congestion, pain, epistaxis
 - Pain in maxillary teeth
 - Cheek/lip numbness from CN V neuropraxia
- External ear:
 - May result from tight-fitting hood, earplug, or earwax occluding canal
 - Auditory canal mucosa becomes edematous, then hemorrhagic, and ultimately tears
- Middle ear (barotitis media):
 - Begins as clogged sensation
 - Increasingly painful as pressure differential increases across TM
 - Progresses to rupture of TM
 - TM appearance:
 - Progresses from normal appearance to edema to hemorrhage to TM rupture (Teed classification)

- Inner ear:
 - Tinnitus, hearing loss, and vertigo
 - Similar symptoms to inner ear decompression illness (usually less vertigo)
- Teeth (barodontalgia):
 - Severe tooth pain: Possible air trapped in fillings
- GI (aerogastralgia):
 - Excessive belching
 - Flatulence
 - Abdominal distention
- Pulmonary (pulmonary barotrauma [PBT], or pulmonary overpressurization syndrome):
 - Localized pulmonary injury
 - Chest pain, cough, hemoptysis
 - Subcutaneous emphysema
 - Pneumomediastinum
 - Chest pain, neck fullness
 - Pneumothorax
 - Chest pain (pleuritic), dyspnea
 - Delayed symptoms include bull neck appearance, dysphagia, changes in voice character

History

Thorough dive history and timing of symptoms in relation to dive (ascent, descent, delayed)

Physical-Exam

- HEENT for tympanic membrane trauma/rupture
- Chest wall/neck exam for subcutaneous emphysema
- Lung exam for pneumothorax
- Neurologic exam for imbalance/ataxia representing inner ear pathology

ESSENTIAL WORKUP

Clinical diagnosis: Meticulous physical exam (as above) and thorough history should direct any workup

DIAGNOSIS TESTS & INTERPRETATION

Lab

ABG for pulmonary symptoms

Imaging

- Sinus imaging:
 - CT

– Plain films

- CXR for PBT
- Abdominal series (upright, decubitus) for free air from a ruptured viscus

DIFFERENTIAL DIAGNOSIS

- Decompression sickness
- Otitis media
- Otitis externa
- Sinusitis

TREATMENT

PRE HOSPITAL

- For barotrauma of *descent*, unless air-filled cavity has ruptured, no progression of disease on return to normal atmospheric pressure is to be expected.
- If patient requires air evacuation, maintain air cabin pressure at 1 atm or fly below 1,000 feet to avoid aggravating barotraumas.

INITIAL STABILIZATION/THERAPY

Airway, breathing, and circulation management (ABCs):

- 100% oxygen for ill-appearing patients
- Intubation for patients with subcutaneous emphysema of neck
- Immediate needle thoracostomy for evidence of tension pneumothorax

ED TREATMENT/PROCEDURES

- Establish IV access for unstable patients.
- Control bleeding from ear or nose.
- Tube thoracostomy for large pneumothorax
- Decongestants for middle ear or sinus congestion
- Antibiotics with TM or sinus rupture
- Analgesics

MEDICATION

- Amoxicillin: 250–500 mg (peds: 40 mg/kg/24h) PO TID
- Trimethoprim–sulfamethoxazole (Bactrim DS): 1 tablet double-strength (160 mg/800 mg) (peds: 40 mg/200 mg/5 mL, 5 mL/10 kg/dose) PO BID
- Oxymetazoline (Afrin) 0.05%: 2 or 3 drops/sprays per nostril BID for 3 days
- Pseudoephedrine (Sudafed): 60 mg (peds: 6–12 yr, 30 mg; 2–5 yr, 15 mg/dose) PO q4–6h

FOLLOW-UP

DISPOSITION

Admission Criteria

- PBTs
- Inner ear barotrauma with round window rupture or severe vertigo

Discharge Criteria

- Most non-PBT
- ENT follow-up for severe TM or sinus pathology

FOLLOW-UP RECOMMENDATIONS

ENT referral for ruptured TM or inner ear–related signs/symptoms

PEARLS AND PITFALLS

- Watch closely for development of decompression sickness in patients who present with barotraumas.
- Perform careful lung exam for signs of pneumothorax.
- Perform careful history in patients with PBT, any history of neurologic symptoms indicates AGE.

BARTHOLIN ABSCESS

Marilyn Althoff • Mark Mandell

BASICS

DESCRIPTION

- The Bartholin glands are located inferiorly on either side of vaginal opening:
 - _ Ducts open on sides of labial vestibule.
- Obstruction of duct produces a usually painless cyst:
 - _ Infection of cyst results in abscess formation.

EPIDEMIOLOGY

Prevalence

Most common in women aged 20–40 yr

ETIOLOGY

- Anaerobic and aerobic microflora normally found in vagina:
 - _ *Bacteroides* species
 - _ *Peptostreptococcus* species
 - _ *Escherichia coli*
 - _ Other gram-negative organisms
- Occasionally *Neisseria gonorrhoeae* and *Chlamydia trachomatis*

DIAGNOSIS

SIGNS AND SYMPTOMS

- Swollen, painful labia
- Tender, fluctuant mass on posterolateral margin of vestibule of vagina
- Warmth, erythema

History

Acute onset:

- Painful, unilateral labial swelling
- Pain with sitting, walking
- Dyspareunia

Physical-Exam

- Bartholin abscess:
 - _ Tender, fluctuant, unilateral labial mass
 - _ Surrounding erythema, warmth

- Fever uncommon
- Bartholin cyst:
 - Painless, unilateral labial mass

ESSENTIAL WORKUP

Diagnosis based on findings of tender, localized, fluctuant mass in region of Bartholin gland

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Culture material from abscess for gonorrhea and chlamydia.
- Culture cervix for gonorrhea and chlamydia.

Imaging

Generally not indicated

DIFFERENTIAL DIAGNOSIS

- Bartholin cyst
- Carcinoma of Bartholin gland (rare)
- Perineal hernia

TREATMENT

ED TREATMENT/PROCEDURES

- Prompt incision and drainage using local anesthesia with patient in lithotomy position
- Narcotic analgesia for patient comfort
- Alternative approaches include:
 - Simple incision and drainage
 - Word catheter method
 - Marsupialization
- Simple incision and drainage:
 - After local anesthesia, palpate abscess between thumb and index fingers.
 - Spread vulva apart and make stab incision on *mucosal* surface of abscess, parallel to hymenal ring.
 - When incising abscess, 2 tissue layers must be penetrated:
 - 1st the labial mucosa
 - Then abscess wall
 - Free flow of pus indicates penetration of abscess wall.
 - Pack wound with gauze.
 - Follow-up in 24–48 hr for removal of packing.

- Start sitz baths after 24 hr.
- Consider referral for marsupialization to avoid recurrence.
- Word catheter method:
 - Use small, inflatable, bulb-tipped Word catheter to treat abscess.
 - May avoid recurrence and make marsupialization unnecessary
 - Stab wound is made as with simple incision and drainage:
 - It should be just large enough to easily admit catheter so that balloon does not fall out after inflation.
 - After inserting bulb tip of catheter, inflate balloon by injecting 2–4 mL water using 25G needle (to minimize size of puncture):
 - Overinflation may cause patient discomfort
 - Remedied by withdrawing some water from balloon
 - Sitz baths may be started after 24 hr.
 - Follow-up in 2–4 days.
 - Leave catheter in place for 6–8 wk until epithelialization is complete; after device is removed, gland resumes normal function.
 - Common for catheter to fall out prematurely:
 - If this occurs, catheter may be reinserted or abscess can heal as with simple incision and drainage.
- Marsupialization:
 - Procedure allows for a permanent fistula by suturing wound edges of abscess cavity to edges of labial mucosa:
 - Technically more challenging in ED and better reserved for specialist.
 - Excise an ellipse of labial mucosa that overlays cyst cavity.
 - Incision and drainage of abscess
 - Evert edges of abscess and suture them to labial epithelium using absorbable suture:
 - Opening will shrink but remain patent.
 - Packing is not needed.
 - Start sitz baths in 24–48 hr.
 - Follow-up within 1 wk.
- Antibiotics not necessary after incision and drainage:
 - If mild cellulitis present or patient immunocompromised, broad-spectrum coverage may be started.
 - If sexually transmitted disease (STD) suspected, treat with antibiotics.

MEDICATION

First Line

Broad-spectrum coverage:

- Amoxicillin/clavulanic acid: 500–875 mg PO BID for 5 days with metronidazole 500 mg PO q8h for 5 days
- Ciprofloxacin: 500 mg PO BID for 5 days with metronidazole 500 mg PO q8h for 5

days

Second Line

Treat for STD if indicated

FOLLOW-UP

DISPOSITION

Admission Criteria

- Sepsis
- Significant cellulitis
- Evidence of necrotizing infection

Discharge Criteria

Well-appearing patients may be discharged with designated follow-up plan.

Issues for Referral

Patients should have gynecologic follow-up:

- Follow-up in 24–48 hr for removal of packing.
- Follow-up in 2–4 days after insertion of Word catheter.

FOLLOW-UP RECOMMENDATIONS

Continue sitz baths for at least 72 hr.

PEARLS AND PITFALLS

- Do not mistake a nontender Bartholin cyst, which does not require immediate treatment, for an inflamed abscess.
- Consider malignancy as an alternative cause of a mass, particularly in women > 40 yr.
- Incision should be on mucosal surface of abscess.

BATH SALTS – SYNTHETIC CATHINONES POISONING

Jami L. Hickey • Jenny J. Lu

BASICS

DESCRIPTION

“Bath salts”:

- General term for “designer drugs” containing synthetic cathinones:
 - 3,4 methylenedioxypropylamphetamine (MDPV) is most common in US
 - Also mephedrone, methylone, and many others
- Sold under numerous names including
 - Aura, Bliss, Bolivian Bath, Cloud 9, Ivory Snow, Ivory Wave, Vanilla Sky, White Dove, White Rush
 - Labeled “not for human consumption” to evade regulatory control
 - Falsely marketed as plant food, insect repellents, “bath salts”
- Substances may be powders, tablets, or crystals:
 - Ranging in color from white, yellow, brown, or gray
- May be ingested, snorted, smoked, injected
- Highly addictive CNS stimulant, often with hallucinogenic properties:
 - Many effects similar to cocaine, methamphetamine, or ecstasy
 - Severe delirium, psychosis, violence, multiorgan failure, DIC, myocardial infarction, stroke, and deaths have been reported

EPIDEMIOLOGY

Incidence and Prevalence Estimates

- 1st use in US reported in 2010
 - MDPV and mephedrone noted in Europe since 2004
- Called “America’s new drug problem” in 2011
 - Thousands of cases reported to poison control centers nationwide
- Immediate temporary classification (Fall 2011) as a DEA schedule I controlled substance
- Still available at retail shops or through the internet

ETIOLOGY

- MDPV is structurally similar to cathinone, an alkaloid derived from the khat plant (chewed socially and abused for centuries in East Africa and Arabian Peninsula)
- Drug chemical formulas change regularly to evade detection, compound identification, and classification as “illegal”
- Principal toxicity derives from effects on dopamine, norepinephrine, and serotonin receptors

- Effects from potential adulterants and contaminants in the drugs remain unknown

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Often unobtainable or incomplete
 - Friends, family, bystanders may provide information about patient behavior
 - High index of suspicion when signs and symptoms are present with no satisfactory alternative explanation

Physical-Exam

- No pathognomonic signs or symptoms
- Sympathomimetic toxidrome:
 - Hyperthermia
 - Tachycardia
 - Hypertension
 - Dysrhythmias
 - Diaphoresis
 - Mydriasis
 - Rhabdomyolysis
 - Respiratory distress
 - Hyperreflexia
 - Seizures
- Mental status and behavioral effects:
 - Psychomotor agitation
 - Hallucinations
 - Physical aggression
 - Psychosis
 - Paranoia
 - Excited delirium
 - Suicidal ideation
 - Panic attacks
 - Insomnia

ESSENTIAL WORKUP

Primarily focused on assessing severity of intoxication and excluding other medical or toxicologic causes of altered mental status

DIAGNOSIS TESTS & INTERPRETATION

Lab/Imaging

- No tests in current routine ED use to detect MDPV:
 - Samples of ingested substance, serum, or urine can be sent to reference labs
 - Results not available in ED setting
- Labs:
 - Urine and serum toxicology screens may detect coingestants
 - CBC, BMP, liver profile, PT/PTT
 - Lactate, pH
 - Total CK
 - Blood/urine culture if infectious process suspected
- Imaging:
 - Consider CT head if appropriate (e.g., trauma)
- ECG:
 - Evaluate QRS/QT intervals, dysrhythmias

DIFFERENTIAL DIAGNOSIS

- Other intoxications:
 - Cocaine
 - Amphetamines
 - Anticholinergic agents
 - Ecstasy
 - Ethanol
- Acute psychosis
- Serotonin syndrome
- Delirium from infectious or metabolic process

TREATMENT

PRE HOSPITAL

- Stabilize airway
- Vital signs
- IV access
- Fingertick glucose
- Oxygen administration if needed

INITIAL STABILIZATION/THERAPY

- Stabilize airway, establish IV, vital signs, cardiac monitoring
- Benzodiazepines are 1st-line medications
- Judicious use of physical restraints, if necessary, for prevention of harm to patient and staff

ED TREATMENT/PROCEDURES

- Supportive care is mainstay of treatment with continuous cardiac and temperature

monitoring:

- Fluid resuscitation
- Oxygen
- Benzodiazepines are 1st-line medications
- Aggressive cooling measures for hyperthermia:
 - Ice packs, cool mists, fans, cooling blankets, cool intravenous fluids
- Severe symptoms may necessitate intubation in rare cases:
 - Propofol for sedation
- Caution with antipsychotic administration which may lower seizure threshold, cause extrapyramidal symptoms, and dysrhythmias
- Poison Control Center/toxicology guidance (1-800-222-1222)

MEDICATION

- Ativan 2–4 mg increments IM or IV
- Valium 10–30 mg increments IM or IV

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with symptoms should be admitted for monitoring
- Severe symptoms including uncontrollable hypertension, altered mental status, cardiovascular instability, and hyperthermia require ICU monitoring

Discharge Criteria

Only asymptomatic patients who remain asymptomatic after an adequate observation period (half-life of MDPV estimated at 1.88 hr with 6–8 hr duration of action) may be discharged; exact timing will vary on each case (consult your poison control center)

FOLLOW-UP RECOMMENDATIONS

Follow up with primary care after discharge

PEARLS AND PITFALLS

- A sympathomimetic toxidrome with delirium/psychosis should arouse suspicion for “bath salts” intoxication
- Severe hyperthermia should be aggressively controlled
- Focused supportive care is the mainstay of treatment, with benzodiazepines as initial therapy

BELL'S PALSY

Robert F. McCormack • Richard S. Krause

BASICS

DESCRIPTION

- Acute, *idiopathic* peripheral CN VII (facial nerve) palsy
- Complete recovery in 85% of cases without treatment
- Degree of deficit correlates with prognosis:
 - Complete lesions have poorest prognosis
 - Partial lesions often have excellent results
- Recovery usually begins within 2 wk (often taste returns 1st) and is complete by 2–3 mo:
 - Advanced age and slow recovery are poor prognosticators
- Affects men and women equally
- Age predominance between the 3rd and 5th decade (may occur at any age)
- Diabetes and pregnancy increase risk
- Incidence 15–40 per 100,000 per year
- The most common cause of facial nerve palsy in children

ETIOLOGY

- Idiopathic by definition, but viral cause (particularly herpes simplex) suspected
- Lyme disease, infectious mononucleosis (Epstein–Barr virus [EBV] infection), varicella-zoster infections, and others may cause peripheral 7th nerve palsy
- Mechanism: Edema and nerve degeneration within stylomastoid foramen
- Innervation to each side of forehead is from both motor cortices:
 - Unilateral cortical processes do *not* completely disrupt motor activity of forehead
- Only peripheral or brainstem lesion can interrupt motor function of just 1 side of forehead

DIAGNOSIS

SIGNS AND SYMPTOMS

History

Sudden onset of unilateral facial droop, incomplete eyelid closure, and loss of forehead muscle tone:

- Maximal deficit by 5 days in almost all cases (2 days in 50%)
- Tearing (68%) or dryness of eye (16%) and less frequent blinking on affected side
- Subjective “numbness” of the affected side

- Abnormal taste, drooling
- Hyperacusis (sensitivity to loud sounds)
- Fullness or pain behind mastoid
- Viral prodrome frequently reported

Physical-Exam

- Unilateral facial palsy including the forehead
- If forehead muscle tone is *not* lost, a central lesion is strongly implied (i.e., this is *not* Bell's palsy)
- Motor weakness isolated to 7th nerve distribution:
 - _ Involves both upper and lower face
- An otherwise normal neurologic exam including all cranial nerves and extremity motor function
- The Bell phenomenon (upward rolling of the eye on attempted lid closure) may be seen

ESSENTIAL WORKUP

Diagnosis is clinical and based on history and physical exam

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Not helpful in diagnosis of Bell's palsy
- Lyme titers are useful when Lyme disease is suspected or in endemic area
- Tests for mononucleosis (CBC, monospot) if EBV infection suspected

Imaging

- Not helpful in diagnosis of Bell's palsy unless a parotid tumor, mastoiditis, etc. are suspected

DIFFERENTIAL DIAGNOSIS

- Brainstem events (mass, bleed, infarct) affecting CN VII almost always involve CN VI (abnormal EOM) and may affect long motor tracts:
 - _ There have been (*rare*) case reports of *isolated* CN VII palsy from brainstem disease.
- Lyme disease: History of tick bite, erythema migrans rash, or endemic area
- Zoster (Ramsay Hunt syndrome): Look for herpetic vesicles, inquire about tinnitus or vertigo
- Infectious mononucleosis: Look for pharyngitis, posterior cervical adenopathy
- Tumors: Parotid, bone, or metastatic masses, acoustic neuroma (deafness)
- Trauma: Skull fracture or penetrating facial injury may damage CN VII
- Middle ear or mastoid surgery or infection, cholesteatoma
- Meningeal infection

- Guillain–Barré syndrome: Other neurologic deficits are present (e.g., ascending motor weakness or diminished deep tendon reflexes [DTRs])
- Basilar artery aneurysm; other CN deficits should be present
- Bilateral peripheral CN VII palsy: Consider multiple sclerosis, sarcoidosis, leukemia, and Guillain–Barré. Idiopathic (Bell's) palsy may be bilateral in rare cases
- Early HIV infection
- Bell's palsy may reoccur; treatment is unchanged

TREATMENT

PRE HOSPITAL

None

INITIAL STABILIZATION/THERAPY

Patients with an isolated peripheral CN VII palsy are stable.

ED TREATMENT/PROCEDURES

- Corneal damage may result from incomplete eyelid closure:
 - Lubricating and hydrating ophthalmic preparations are often needed
 - Eye patching at night
- Oral steroids may hasten recovery if started within 1 wk of onset (preferably w/in 72 hr):
 - Complications of therapy are rare
- Antiviral therapy (acyclovir or valacyclovir) with steroids may be effective in improving functional nerve recovery:
 - Initiate within 72 hr of symptom onset
 - No clear proven benefit
 - May be indicated for severe palsy
- Suspected Lyme disease should be treated with doxycycline or amoxicillin
- Surgical decompression may be indicated for complete lesions that do not improve; this is controversial

MEDICATION

First Line

- Lacri-Lube or artificial tears: At bedtime and PRN; dryness/irritation in affected eye (or equivalent)
- Prednisone: 30–40 mg PO BID for 7 days, (peds: 2 mg/kg/d PO [max. 60 mg])

Second Line

Valacyclovir 1 g PO TID for 7 days (peds: 20 mg/kg TID) may be useful in severe cases.

FOLLOW-UP

DISPOSITION

Admission Criteria

Isolated peripheral CN VII palsy does not require admission.

Discharge Criteria

Isolated peripheral CN VII palsy may be treated on outpatient basis.

FOLLOW-UP RECOMMENDATIONS

Follow-up should be within 1 wk.

PEARLS AND PITFALLS

- Motor weakness isolated to 7th nerve distribution:
 - _ Involves both upper and lower face
 - _ If tone is NOT lost on the forehead, it is *not* Bell's palsy.
- Otherwise normal neurologic exam including all cranial nerves and extremity motor function
- Protect the eye
- Steroids beneficial, antivirals controversial

CODES

ICD9

351.0 Bell's palsy

ICD10

G51.0 Bell's palsy

BENZODIAZEPINE POISONING

Michael E. Nelson

BASICS

DESCRIPTION

- Potentiates the activity of γ -aminobutyric acid (GABA), the major inhibitory neurotransmitter, by binding to its own specific site
- Also facilitates GABA binding to its site
- Results in chloride influx, membrane hyperpolarization, and inhibition of cellular excitation:
 - Benzodiazepines (BZDs) increase the frequency of chloride channel opening.
 - Depresses spinal reflexes and reticular activating system
- Rapidly absorbed from GI tract:
 - Highly protein bound
 - Large V_d
 - Hepatic metabolism
 - Duration of action is inversely proportional to lipophilicity with highly lipophilic drugs penetrating the CNS more rapidly.
 - Duration of lorazepam > diazepam > midazolam.
 - Synergistic with other sedative–hypnotic medications (e.g., ethanol, barbiturates, propofol)

DIAGNOSIS

SIGNS AND SYMPTOMS

- CNS:
 - Sedation/drowsiness
 - Slurred speech
 - Midrange or small pupils
 - Delirium
 - Coma
- Neuromuscular:
 - Incoordination
 - Slowed voluntary movements
 - Ataxia
 - Hypotension
 - Hyporeflexia/areflexia
- Cardiovascular:
 - Mild depression
 - Rarely lethal if ingested alone

- Respiratory:
 - Mild depression but less than barbiturates
 - Short acting and IV have higher depression
- GI:
 - Nausea, vomiting, diarrhea
- Other:
 - Hypothermia
 - Complications may include cerebral hypoxia, rhabdomyolysis, pressure-induced neuropathies.
 - No long-term organ toxicity

Pediatric Considerations

Rarely may cause paradoxical restlessness and agitation

ESSENTIAL WORKUP

Diagnosis based on:

- History of ingestion or recent injection
- Clinical findings associated with CNS depression
- No response to naloxone

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Pulse oximetry
- Electrolytes, BUN, creatinine, serum glucose
- Thyroid studies
- Urinalysis (UA) for myoglobin if coma present or down for prolonged period of time
- ABG
- Qualitative urine screen:
 - May confirm exposure, but does not indicate or measure intoxication or correlate clinical state.
 - False-negative test results reported
 - Qualitative immunoassays detect only BZDs that are metabolized to oxazepam.
 - BZDs that do not produce this metabolite (clonazepam, lorazepam, midazolam, alprazolam) are not detected on qualitative screen.
 - Serum levels not acutely practical
 - Clinical signs and symptoms more important than theoretic LD₅₀ or serum levels
- Alcohol(s) level
- Barbiturate level (e.g., Phenobarbital)

- Acetaminophen and salicylate levels
- Pregnancy test

Imaging

- EKG
- CXR for aspiration pneumonia
- Consider CT head

Diagnostic Procedures/Surgery

Core body temperature

DIFFERENTIAL DIAGNOSIS

- Drugs and toxins causing decreased level of consciousness:
 - Hypoglycemics
 - Other sedative–hypnotics (barbiturates, chloral hydrate, GHB, bromides)
 - Antidepressant–antipsychotics
 - Narcotics
 - Anticonvulsants
 - Carbon monoxide/cyanide
 - Alcohols
- Nontoxic medical conditions:
 - Hypoxemia
 - Hypothermia
 - Head trauma (intracranial bleeding)
 - Infection (meningitis or encephalitis)
 - Electrolyte and metabolic abnormalities

TREATMENT

PRE HOSPITAL

- Attention to airway and breathing
- Cardiac monitor
- IV access
- Rapid glucose determination
- Obtain pill bottles/pills in suspected overdose

INITIAL STABILIZATION/THERAPY

- ABCs:
 - Secure airway and assist ventilation with supplemental oxygen to prevent hypoxemia and shock.
 - IV access with 0.9% NS
 - Cardiac monitor

- Administer naloxone, thiamine, and dextrose if altered mental status/comatose.

ED TREATMENT/PROCEDURES

- Consider gastric lavage when presenting within 1 hr of life-threatening ingestion with protected airway but should be done cautiously
- Activated charcoal (AC) PO or via nasogastric tube (NGT) if airway protected
- No role for diuresis, dialysis, or charcoal hemoperfusion
- Flumazenil (FZ):
 - _ Competitive BZD-receptor inhibitor
 - _ Rapidly reverses BZD-induced coma
 - _ Onset within 1–2 min; peak at 6–10 min; duration 1–2 hr (repeated dosing may be indicated)
 - _ Efficacy dependent on dose of BZD being antagonized and dose of FZ used
 - _ Do not administer empirically as part of “coma cocktail” or unknown ingestion
 - _ May help avert need of airway intubation but has not consistently reversed respiratory depression
 - _ May be beneficial in shortening hospital stay or as diagnostic maneuver
 - _ Indications include isolated BZD overdose in nonhabituated user with CNS depression, normal EKG, normal vital signs, and normal neurologic exam.
 - _ Most useful to reverse iatrogenic poisoning (conscious sedation)
 - _ Contraindications include:
 - Coingestions that might lower seizure threshold (tricyclic antidepressants [TCAs])
 - Seizure history or activity
 - Allergy
 - Neuromuscular blockade
 - Do not use if hypotension, hypoxia, dysrhythmias, or increased intracranial pressure is present.
 - May precipitate withdrawal state including seizures, for which BZDs can no longer be used to treat

MEDICATION

- AC: 1 g/kg PO/NG (ideal is 10:1 ratio of AC:dose of drug)
- Dextrose: D₅₀W 1 ampule: 50 mL or 25 g (peds: D₂₅W 2–4 mL/kg) IV if hypoglycemic
- FZ (Romazicon):
 - _ Initial: 0.2 mg IV over 30 sec (adult)
 - _ If no response: 0.3 mg IV after 30 sec
 - _ If still no response: 0.5 mg IV and repeat q1min if needed, to max. dose of 3 mg
 - _ Continuous infusion at 0.1–1 mg/h if multiple repeated doses required to maintain response. Continuous infusion not FDA approved

- Pediatric dosing: Titrate to max. cumulative dose of 0.05 mg/kg/d. Continuous infusion at 0.005–0.01 mg/kg/h has been used.
- Only use in selected patients (see above) as may precipitate seizures or dysrhythmias
- Monitor after use for re sedation (occurs between 20 and 120 min after use)
- Naloxone (Narcan): 0.4–2 mg (peds: 0.1 mg/kg) IV or IV initial dose
- Thiamine (vitamin B₁): 100 mg IV/IM

FOLLOW-UP

DISPOSITION

Admission Criteria

- Persistent or profound CNS depression
- Cardiovascular or respiratory compromise
- Coingestants with potential delayed toxicity

Discharge Criteria

- Can discharge after 4-hr observation period if no signs or symptoms of BZD poisoning.
- If FZ administered, observe for additional 2–4 hr for recurrent sedation.

Issues for Referral

Psychiatry consultation for intentional overdoses.

FOLLOW-UP RECOMMENDATIONS

Habituated patients may experience BZD withdrawal after cessation:

- Autonomic instability, tremor, paresthesias, seizures

PEARLS AND PITFALLS

IV formulations of certain BZDs (e.g., lorazepam) may contain propylene glycol diluent that can produce elevated osmolar gap and anion gap metabolic acidosis.

BETA-BLOCKER POISONING

Christopher S. Lim • Steven E. Aks

BASICS

DESCRIPTION

Normal Physiology

- Cardiovascular: β_1 -receptors:
 - ATP converted to cAMP by adenylyl cyclase with stimulation of β -receptors.
 - cAMP activates protein kinase, which phosphorylates proteins of the sarcoplasmic reticulum.
 - Sarcoplasmic reticulum releases calcium.
 - Excitation–contraction coupling occurs.
- Effects of β -blockers:
 - Cardiovascular:
 - Decreased excitation/contraction
 - Membrane stabilizing activity
 - Sodium channel blockade causes a prolongation of the QRS complex (with some agents).
 - Prolongation of QTc interval leading to ventricular dysrhythmias (with some agents)
 - Intrinsic sympathomimetic activity
 - Partial agonist properties (with some agents)
 - Neurologic:
 - CNS effects with the lipophilic agents (propranolol, metoprolol, labetalol)

DIAGNOSIS

SIGNS AND SYMPTOMS

- Cardiovascular:
 - Hypotension
 - Bradycardia
 - Cardiac conduction delays
 - Heart block
 - Heart failure
 - Electrical mechanical dissociation
 - Loss of β -selectivity in overdose settings
- Neurologic:
 - Coma

- Seizures
- Pulmonary:
 - Bronchospasm
 - Pulmonary edema
- Metabolic:
 - Hypoglycemia

History

- Inquire about risk of medication error.
- Inquire about risk of suicidal ideation with intent.
- Inquire about possible exposure to medications with a pediatric patient.

Physical-Exam

- Hypotension
- Bradycardia
- Dysrhythmias

ESSENTIAL WORKUP

- With unknown ingestion: Suspect β -blocker poisoning with bradycardia/hypotension.
- ECG:
 - Conduction delays
 - 1st-, 2nd-, or 3rd-degree heart block
 - Bradycardia

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Electrolytes, BUN, creatinine, glucose
- Toxicology screen if coingestants suspected

DIFFERENTIAL DIAGNOSIS

- Calcium-channel blocker toxicity
- Clonidine toxicity
- Digitalis toxicity
- Acute myocardial infarction with heart block

TREATMENT

PRE HOSPITAL

- Transport pills and pill bottles when overdose suspected.

INITIAL STABILIZATION/THERAPY

- ABCs:
 - Airway protection as indicated by mental status
 - Supplemental oxygen as needed
 - 0.9% NS IV access
 - Close hemodynamic monitoring
- Naloxone and thiamine if altered mental status
- Bedside glucose determination, treat hypoglycemia with D₅₀W
- Treat prolonged seizures with benzodiazepines

ED TREATMENT/PROCEDURES

Goals

- Heart rate > 60 beats per minute
- Systolic BP > 90 mm Hg
- Adequate urine output
- Improving level of consciousness

GI Decontamination

- Syrup of ipecac: Contraindicated in the prehospital and ED setting.
- Consider lavage with Ewald tube if ingestion within 1 hr:
 - Propranolol may cause esophageal spasm producing difficulty with passage and removal of gastric lavage tube.
- Activated charcoal helpful especially in the presence of coingestants.

Bradycardia/Hypotension

- Atropine:
 - Initial agent
 - Low success rate
- Glucagon:
 - Initial drug of choice for β -blocker-induced hemodynamic instability
 - Administer if atropine does not increase heart rate.
 - Promotes cAMP production through a receptor site other than the β -receptor
 - May cause nausea and vomiting
 - Mix with NS or D₅W
- IV fluids:
 - Administer cautiously in the hypotensive patient
 - Swan-Ganz catheter or central venous pressure (CVP) monitoring to help follow volume status
- Amrinone:
 - Selective phosphodiesterase inhibitor
 - Indirectly increases cAMP leading to increased inotropy

- Use in conjunction with glucagon to treat symptomatic sustained bradycardia.
- Vasopressor agents:
 - Initiate when symptomatic hypotension/bradycardia persists after atropine/glucagon.
 - Use invasive monitoring to help guide therapy.
 - Utility may be limited owing to β -blockade:
 - Higher doses may be required.
 - Isoproterenol (nonselective β -agonist):
 - Titrate for BP and heart rate.
 - Epinephrine (potent α - and β -receptor agonist):
 - BP increases as a result of direct myocardial stimulation, increase in heart rate, and vasoconstriction.
 - Use if no BP response with isoproterenol
 - High-dose dopamine
- Sodium bicarbonate:
 - In theory, this is used if there is evidence of prolongation of QRS > 100 ms owing to some of the β -blockers also causing sodium channel blockade leading to a prolonged QRS.
 - Not routinely administered for all β -blocker toxicities
- Electrical pacing: When other treatment options have failed

Experimental Treatment Options

- Consult with local poison center
- High-dose insulin:
 - Promotes more efficient myocardial metabolism
 - Hypoglycemia commonly seen in β -blocker overdose, will require frequent monitoring of glucose concentration
 - Perform in consultation with local poison center
- IV fat emulsion therapy (20% intralipid)

Enhanced Elimination

- Hemodialysis helpful with water-soluble β -blocking agents:
 - Nadolol
 - Atenolol
 - Sotalol
- IV fat emulsion (20% Intralipid):
 - Potential treatment in the future

MEDICATION

- Activated charcoal: 1 g/kg PO
- Amrinone: Loading dose 0.75 mg/kg; maintenance drip 2–20 μ g/kg/min; titrate for effect

- Atropine: 0.5 mg (peds: 0.02 mg/kg) IV; repeat 0.5–1 mg IV (peds: 0.04 mg/kg)
- Dopamine: 2–20 µg/kg/min IV
- Dextrose: D₅₀W 1 ampule (50 mL or 25 g; peds: D₂₅W 2–4 mL/kg) IV
- Epinephrine: 2 µg/min (peds: 0.01 mg/kg [0.1 mL/kg 1:10,000]); titrate to effect
- Glucagon: 3–5 mg IV over 1–2 min (peds: 0.03–0.1 mg/kg) bolus followed by 70 µg/kg/h infusion
- Insulin (regular insulin): 1 IU/kg bolus IV followed by 0.5–1 IU/kg/h titrated to clinical response (be sure to supplement with dextrose)
- Isoproterenol: 5 µg/min IV and titrate for heart rate effect
- Norepinephrine: Start 2–4 µg/min IV, titrate up to 1–2 µg/kg/min IV
- Sodium bicarbonate: 1 mEq/kg IVP

First Line

- IV fluids
- Glucagon
- Vasopressor agents

Second Line

- Sodium bicarbonate
- Hemodialysis

FOLLOW-UP

DISPOSITION

Admission Criteria

- ICU admission for decreased level of consciousness or hemodynamic instability (bradycardia, conduction delays, hypotension)
- Observation and monitoring for 24 hr for long-acting or sustained-release preparations owing to the potential delay in symptoms

Discharge Criteria

Asymptomatic 8–10 hr after ingestion of short- or immediate-release preparation

FOLLOW-UP RECOMMENDATIONS

- Psychiatric evaluation for all suicidal patients
- Poison prevention guidance for parents of pediatric accidental ingestion

PEARLS AND PITFALLS

- Consider β-blocker toxicity in patients who present with hypotension and bradycardia.

- Wide complex QRS dysrhythmias should be treated with sodium bicarbonate.

BIOLOGIC WEAPONS

Brigham R. Temple

BASICS

DESCRIPTION

- Defined as naturally occurring organisms or toxins that are purified and prepared for mass dissemination with intent of causing mass morbidity, mortality, and social disruption.
- Organisms include bacteria, viruses, and fungi.
- Over 400 potential or actualized etiologic agents capable of being used as biologic weapon:
 - Characterized by their relatively low cost compared with other weapons of mass destruction (WMD), high potency, and their ability to be delivered in a stealthy manner
 - Stealth quality of biologic weapons comes from organism's natural incubation period.
- Easy to conceal and difficult to detect:
 - Agents often invisible to naked eye, odorless, and tasteless
- Patients typically present to various health care facilities with host of common complaints, adding to delay in recognition of covert release of biologic weapon.
- Victims of biologic warfare agents are exposed either via direct cutaneous contact with agent, respiratory inhalation of aerosolized agent, or via GI tract after poisoning of food or water source.

ETIOLOGY

- Bacteria:
 - Anthrax: *Bacillus anthracis*
 - Plague: *Yersinia pestis*
 - Cholera: Infection from *Vibrio cholerae*:
 - Presents with severe GI symptoms and rapidly leads to profound dehydration
 - Tularemia: *Francisella tularensis*
 - Brucellosis: Organism in the *Brucella* genus
 - Q fever: *Coxiella burnetii*
- Viruses:
 - Smallpox: Variola virus
 - Viral encephalitides: Members of *Alphavirus* genus (Venezuelan equine encephalitis, Eastern equine encephalitis, and Western equine encephalitis)
 - Viral hemorrhagic fevers: From 4 families of viruses, includes illnesses such as Ebola, Marburg, Lassa, and dengue fever

- Toxins:
 - Ricin
 - Staphylococcal enterotoxin B
 - Botulinum toxin
 - Mycotoxins

DIAGNOSIS

SIGNS AND SYMPTOMS

- Health care providers need to be alert to detect illness patterns and diagnostic clues that indicate biologic weapon release.
- Indications of intentional release of agent include:
 - Geographic clustering of illnesses with individuals who live, work, or attended event in close proximity (if multiple people who work in same office develop pneumonia, it could potentially represent respiratory pathogen release)
 - Unusual age distribution for common illness (chickenpox-like illness among adult patients could represent smallpox release)
 - ≥ 2 patients presenting with similar unexplained illnesses (2 patients presenting with flaccid paralysis could represent botulinum toxin release)
 - Single case of illness caused by uncommon agent (smallpox, inhalational anthrax)
 - High volume of patients with similar presentation of symptoms associated with escalating morbidity and mortality

Anthrax

- Inhalational anthrax:
 - Fever
 - Chills
 - Fatigue, malaise, lethargy
 - Cough, usually dry or minimally productive
 - Nausea or vomiting
 - Dyspnea
 - Diaphoresis
 - Chest pain
 - Myalgias
 - Tachycardia
 - Fever
 - Meningeal signs
- Cutaneous anthrax:
 - Skin lesion:
 - Painless pruritic papule

- Turning into vesicle that ruptures forming necrotic ulcer
- Black eschar
- Surrounding gelatinous nonpitting edema

Plague

- Abrupt onset
- Fever, chills
- Cough, hemoptysis, dyspnea
- Headache
- Vomiting
- Swollen tender lymph nodes (buboes)
- Skin lesions at site of inoculation (i.e., flea bite)
- Confusion
- Abdominal pain
- Oliguria
- Obtundation
- Extensive ecchymosis
- Acral gangrene (digits, nose, penis)

Tularemia

- See “Tularemia” chapter.
- Typhoidal:
 - Most likely form of disease when weaponized and delivered by aerosol
 - Fever, headache, malaise
 - Nonproductive cough
 - 35% mortality if untreated

Q fever

- Incubation period 10–40 days
- Flu-like symptoms and pleuritic chest pain for 2–10 days
- CXR shows patchy infiltrates
- Definitively diagnosed serologically
- Mortality:
 - <1% even if untreated

Brucellosis

- Incubation period 3–60 days
- Flu-like symptoms and neuropsychiatric symptoms (headache, depression, fatigue, and irritability)
- Focal infection of joints and GU tract may cause localized pain, particularly back pain.
- Diagnosis by combination of serologic testing and cultures of blood or bodily

fluids.

- Mortality: < 2%

Smallpox

- Incubation period 7–17 days (average is 12 days)
- Flu-like symptoms (fever, fatigue, myalgias, headache) for ~ 2–3 days followed by characteristic rash:
 - Progresses from macules to papules to pustular lesions and crusted lesions
 - Starts on face and extremities (including palms/soles) and spreads to trunk in 1 wk
 - Scabs over in 1–2 wk
- Mortality:
 - 30% if untreated

Hemorrhagic Fevers

- See “Hemorrhagic Fever” chapter
- Incubation period 1–3 wk
- Starts as flu-like syndrome with fever, malaise, myalgias, headache, and sore throat
- Afterward, infectious gastroenteritis syndrome, rash, and renal/hepatic dysfunction
- Finally, hemorrhagic symptoms develop around the 5th day followed by shock and death:
 - Mortality in 50–90% for Ebola if untreated

ESSENTIAL WORKUP

Suspect bioterrorism if:

- Multiple cases of relatively young, healthy patients who present with flu-like syndrome and within days deteriorate rapidly
- Typical cutaneous lesions appear

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Electrolytes, BUN, creatinine
- ABG
- Cerebrospinal fluid (CSF):
 - Anthrax: 50% with inhalation anthrax develop hemorrhagic meningitis.
- Coagulation studies:
 - Plague: Disseminated intravascular coagulation (DIC)
- Blood cultures
- Wound cultures

- Alert lab personnel to potential concerns of clinicians.

Imaging

CXR:

- Anthrax: Mediastinal widening, pulmonary infiltrate/consolidation, pleural effusion
- Plague: Bronchopneumonia

DIFFERENTIAL DIAGNOSIS

- Anthrax:
 - Influenza
 - Bacterial pneumonia, bacterial meningitis
 - Brown recluse spider bite
 - Tularemia
 - Streptococcal/staphylococcal skin infection
- Plague:
 - Tularemia, catscratch disease
 - Lymphogranuloma venereum, chancroid
 - Tuberculosis
 - Streptococcal adenitis
 - Meningitis, encephalitis, sepsis
- Smallpox:
 - Varicella
 - Rash starts centrally on trunk and spreads outward:
 - Lesions in different stages of development
 - Rarely involves palms or soles
 - Disseminated molluscum contagiosum
 - Monkeypox, drug eruptions
- Toxins:
 - Staphylococcal enterotoxin B:
 - Most common cause of food poisoning
 - Can be aerosolized in addition to being placed in food or water reservoir
 - When inhaled, produces febrile type of illness that can progress to septic shock picture
 - Ricin:
 - Plant protein derived from castor beans
 - Causes rapid progression from upper respiratory congestion to cardiopulmonary collapse
 - Ingestion is less toxic because GI tract does not absorb it well, but it can lead to local cytotoxic death, shock, and death.
 - Botulinum toxin:
 - Initially symptoms include cranial nerve dysfunction with descending

paralysis that leads to respiratory failure.

– **Mycotoxins:**

- Highly toxic compounds produced by certain species of fungus
- Dermal, respiratory, or GI contact can rapidly lead to multiorgan system failure and death.

TREATMENT

PRE HOSPITAL

Universal precautions with N-95 mask

INITIAL STABILIZATION/THERAPY

- ABCs
- 0.9% NS fluid bolus for hypotension
- Supplemental oxygen for hypoxemia
- Vasopressors for persistent hypotension
- Respiratory and contact isolation for suspected cases

ED TREATMENT/PROCEDURES

- All treatments include:
 - Control fever with acetaminophen.
 - Initiate therapy for specific disease.
- Anthrax:
 - Initiate antibiotics:
 - IV for inhalational or severe cutaneous
 - Antibiotic choice depends on susceptibility.
 - Antibiotic options:
 - Ciprofloxacin: 1st line
 - Doxycycline
 - Rifampin
 - Clindamycin
 - Vancomycin
- Plague:
 - Antibiotics initiated within 24 hr minimizes mortality.
 - 1st-line agents: Streptomycin or gentamicin
 - Add chloramphenicol if signs of meningitis or unstable patient
 - Prophylaxis: Doxycycline or ciprofloxacin
- Brucellosis:
 - Supportive therapy
 - Start doxycycline 100 mg PO BID for 6 wk with the addition of streptomycin 1 g per day IM for the 1st 2–3 wk or rifampin 900 mg per day for 6 wk.
- Q fever:

- Recovery occurs within 2 wk without treatment.
- Doxycycline shortens duration of illness.
- Smallpox:
 - Supportive therapy
 - Vaccine given within 4 days of initial exposure decreases chances of contracting smallpox or developing severe symptoms.
 - Vaccinate medical staff caring for patient.
 - Treat secondary bacterial infection.
- Tularemia:
 - See “Tularemia.”
- Hemorrhagic fevers:
 - See “Hemorrhagic Fever.”

MEDICATION

- Chloramphenicol: 25 mg/kg IV q6h
- Ciprofloxacin: 400 mg IV q12h or 500 mg PO BID (peds: 15 mg/kg BID PO)
- Clindamycin: 900 mg IV q12h
- Doxycycline: 100 mg (peds: ≥ 45 kg, 100 mg; if weight ≤ 45 kg, 2.2 mg/kg IV) PO/IV q12h
- Gentamicin: 5 mg/kg IM or IV q24h (peds: 2.5 mg/kg IV/IM q8h)
- Rifampin: 10 mg/kg IV not to exceed 600 mg/d
- Streptomycin: 1 g (peds: 20–40 mg/kg) IM q12h
- Vancomycin: 1 g IV q12h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Decision to treat patient as inpatient vs. outpatient will have to be made in context of overall disaster.
- Toxic or hypoxic patients require admission.
- Respiratory isolation

Discharge Criteria

Mild, noncontagious illness

Issues for Referral

- Contact local and state health departments for suspected or confirmed illness related to biologic weapons.
- Infectious disease and toxicology consult for suspected illness

FOLLOW-UP RECOMMENDATIONS

- Postexposure prophylaxis and vaccinations should be continued based on the causative agent.
- Exposed staff should have follow-up with employee health and infection control prior to returning to work.

PEARLS AND PITFALLS

- Early diagnosis is difficult, and a high index of suspicion is required.
- Failing to use personal protective equipment to protect self and staff is a pitfall.
- Suspect biologic weapons etiology when there is geographic clustering of patients who live, work, or attended an event in close proximity.
- Initiate therapy or prophylaxis early in suspected illness.

CODES

ICD9

- V01.0 Contact with or exposure to cholera
- V71.82 Observation and evaluation for suspected exposure to anthrax
- V71.83 Observation and evaluation for suspected exposure to other biological agent

ICD10

- Z03.818 Encounter for observation for suspected exposure to other biological agents ruled out
- Z20.09 Contact with and (suspected) exposure to other intestinal infectious diseases
- Z20.810 Contact with and (suspected) exposure to anthrax

BIPOLAR DISORDER

Paul H. Desan • Gary S. Sachs

BASICS

DESCRIPTION

- **Mania:**
 - Presentation is diverse and may be difficult to recognize as mania:
 - Simple irritability
 - Cheerfulness
 - Psychosis
 - Delirium
 - Agitation
 - Full extent of pathology often revealed only by outside informants
 - Onset gradual or acute, duration several weeks or months; rarely may be chronic
- **Hypomania:**
 - Milder symptoms without marked impairment
- **Mixed mood:**
 - Simultaneous symptoms of mania and depression
 - Treat in ED as for mania
- **Bipolar disorder:**
 - Formerly manic depressive disorder
 - Defined as one or more episodes of hypomanic, manic, or mixed mood
 - Possibly with episodes of depressed mood
 - Bipolar II is used to denote cases where hypomania has occurred in the course of the disorder but never mania.
 - Typically begins in the teens or 20s
 - Episodes of abnormal mood may be mild or severe, brief or prolonged, infrequent or chronic, chiefly elevated or chiefly depressed in character.
 - Bipolar disorder may be readily responsive to treatment or nearly intractable.
- **Schizoaffective disorder:**
 - Characterized by episodes of altered mood, but psychotic features present even when mood is normal

ETIOLOGY

- Typically, a primary psychiatric disorder, with genetic association
- May be secondary to medical disorder (e.g., drug toxicity, endocrine, neurologic process)
- Particularly likely to be secondary if

- 1st episode
- patient > 40 yr
- atypical or mixed presentation
- abnormal sensorium

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- **Psychiatric history:**
 - Recent symptoms of mania (often collateral sources critical): Elevated, expansive, or irritable mood; increased energy and activity; decreased need for sleep; irresponsibility, disregard for negative consequences of actions; talkativeness; distractibility; fast thoughts; grandiosity, overconfidence
 - Past mania or depression
 - Noncompliance with mood stabilizer
 - Recent initiation or discontinuation of antidepressant
 - Recent substance abuse
 - Bipolar family history
- **Medical history:**
 - Endocrine, metabolic, or neurologic disorders
 - Current or recent medications

Physical-Exam

- **Appearance:**
 - Hyperactive, if not agitated
 - Talkative, often with loud, rapid, or “pressured” speech
- **Affect:**
 - Irritable, argumentative, often multiple recent arguments or fights
 - Less commonly euphoric or expansive
 - Often labile with depressed or tearful intervals (may confound diagnosis)
 - Patient likely to describe mood as tense, irritable, or depressed rather than euphoric
- **Neurovegetative:**
 - Increased energy, engaged in multiple goal-directed activities many hours per day
 - Racing thoughts
 - Decreased sleep
- **Thought process:**
 - Rapid, distractible, may be incoherent, delirious
- **Thought content:**

- Psychosis possible, either mood congruent (e.g., delusions of grandeur or power) or mood incongruent (may be indistinguishable from other psychotic disorders)
- Judgment:
 - Inflated self-esteem, perhaps to grandiose or psychotic extent
 - Uncharacteristic, irresponsible behavior, such as financial or sexual indiscretions, with inability to recognize negative consequences of actions.
 - Substance abuse is frequent during mania.
- Sensorium:
 - Typically normal
 - Confusion or delirium possible

ESSENTIAL WORKUP

- Physical and neurologic exam; vital signs
- Mania may present as delirium and need workup of full differential diagnosis of delirium.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Toxicology screen (urine or serum)
- Blood alcohol level
- Electrolytes
- Blood glucose
- CBC
- TSH
- Lithium, carbamazepine, valproate serum levels, if relevant
- Other tests as suggested by history or physical exam

Imaging

CT head only with suspicion of neurologic etiology

DIFFERENTIAL DIAGNOSIS

- Primary mania of bipolar or schizoaffective disorder
- Psychosis
- Agitated depression
- Personality disorders:
 - Borderline
 - Narcissistic
 - Antisocial
- Attention deficit disorder
- Conduct or intermittent explosive disorders
- Organic brain syndrome

- Intoxication or withdrawal from alcohol or sedative hypnotics
- Intoxication with cocaine, amphetamines, phencyclidine, or other sympathomimetics
- Accidental or deliberate toxic overdose
- Treatment with antidepressants or electroshock therapy in susceptible individuals
- Recent discontinuation of antidepressant medication
- Corticosteroid or thyroid hormones
- Anticholinergics
- Treatment of Parkinson disease
- Cyclobenzaprine (Flexeril)
- Endocrine or metabolic disorders (particularly thyroid disease)
- Encephalitis
- Meningitis
- Postictal states
- MS
- Postcerebrovascular accident
- CNS tumors
- CNS vasculitis
- General paresis

TREATMENT

INITIAL STABILIZATION/THERAPY

- High violence potential:
 - Quiet environment
 - Prompt evaluation
 - Nonconfrontational manner
 - Adequate security backup
 - Physical restraint and sedation, as needed
- For cooperative, but agitated patient:
 - PO neuroleptics (e.g., haloperidol, consider olanzapine or chlorpromazine as alternate) or PO benzodiazepines (e.g., lorazepam)
- For uncooperative agitated patient:
 - Synergistic combination of IM, IV, or PO haloperidol and lorazepam widely used (some authorities favor monotherapy with benzodiazepine or neuroleptic):
 - Bzotropine for prevention of acute dystonic reaction to haloperidol is not usually required when concurrent benzodiazepine is given.
 - Consider lorazepam, olanzapine, ziprasidone, or chlorpromazine IM as alternative.

ED TREATMENT/PROCEDURES

- Outpatient management:
 - Neuroleptics for symptomatic treatment, on temporary or continuing basis
 - Agents for sleep
 - Discontinuation of antidepressant if related to present hypomania or mania
 - Initiation or restart of mood-stabilizer therapy:
 - Action of mood-stabilizing agents requires days or weeks, even after full serum level attained.
- Inpatient management:
 - Sedation or initiation of mood stabilizer in consultation with admitting psychiatrist

MEDICATION

- Acute agitation:
 - Lorazepam: 2 mg PO/IM (lower dose in mild agitation or in frail or elderly); may repeat q30min, generally not to exceed 12 mg/24h
 - Haloperidol: 5 mg PO (lower dose in mild agitation or in frail or elderly); may repeat q30min, generally not to exceed 20 mg/24h
 - Synergistic combination of haloperidol, 5 mg IM/IV/PO + lorazepam 1–2 mg IM/IV/PO, repeat q30min, as required (doses may be smaller in elderly or frail patients)
 - Olanzapine 10 mg IM, ziprasidone 10 mg IM, aripiprazole 9.75 mg IM or chlorpromazine 50 mg IM may be useful parenteral alternatives, perhaps at a lower dose in frail or elderly (avoid chlorpromazine in hypotension; ziprasidone may have more QT prolonging effect than other neuroleptics but the clinical relevance of such effect at this dose is unclear).
- Typical outpatient medications:
 - Aripiprazole: 5–20 mg PO QD
 - Benztropine: 1 mg PO BID
 - Carbamazepine: 400–2,000 mg/d (often in div. doses or in sustained-release dose forms)
 - Clonazepam: 0.5–2 mg PO QHS or 0.5–2 mg PO BID
 - Haloperidol: 0.5–5 mg PO BID
 - Lamotrigine: 25–200 mg/d in 1 or 2 div. doses (typically up to 100 mg/d in patients taking valproate, up to 500 mg/d in patients taking carbamazepine or certain other cytochrome inducers, but not valproate)

ALERT

- Lamotrigine must be started by a gradual dose escalation schedule specified by manufacturer to avoid increased risk of severe dermatologic reactions; if resumed after discontinuation for more than 5 half-lives (about 5 days), the gradual dose escalation schedule must be used again (half-life is shorter with certain antiepileptics, OCPs, rifampin; see prescribing literature).
 - Lithium: 600–3,000 mg/d (often in div. doses or in sustained-release dose

- forms; in acute mania, initiate at 300 mg PO TID)
- Olanzapine: 1.25–30 mg/d, QHS or in div. doses
- Perphenazine: 4–32 mg/d PO QHS or in div. doses
- Quetiapine: 50–400 mg PO QHS or 100–400 PO BID; quetiapine XR PO 50–800 mg QHS
- Risperidone: 0.5–6 mg/d PO QHS or in div. doses
- Valproate (e.g., Depakote): 750–3,000 mg/d (often in div. doses; in acute mania, initiate at 250 mg PO TID)

Pregnancy Considerations

The safety of psychotropic medications in pregnancy is a complex issue: Lithium, valproate, and carbamazepine are Pregnancy Category D and pose particular risks, highest in early pregnancy.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Involuntary hospitalization is required by danger to self:
 - Suicidal risk, especially if mixed or labile mood or psychotic
 - Unsafe behaviors due to impaired judgment
 - Medically unstable
 - Hospitalization diagnostically required
- Involuntary hospitalization also required by:
 - Risk of behaviors dangerous to others
 - Inability to care for self (unable to obtain basic needs, such as food, clothing, or shelter)

Discharge Criteria

- Patients with mild symptoms may be discharged on medications noted above if:
 - necessary supports to ensure safety are in place.
 - patient is compliant with treatment plan.
 - consultation with outpatient psychiatrist is available within 1–3 days.
- Some patients who are not legally committable may refuse treatment; explain availability of future treatment to patient and any involved friends or family.

PEARLS AND PITFALLS

- Manic patients are more likely to appear dysphoric or irritable, rather than “happy.”
- Patients presenting with depression should be asked about features suggesting

mania and hypomania; 70% of bipolar patients have previously been misdiagnosed.

- Individuals with bipolar disorder are at high risk for addiction, further complicating treatment.
- Prompt recognition of the earliest signs of mania may allow prevention of a full episode.
- Bipolar disorder in children frequently manifests as behavioral disinhibition or irritability.

BITE, ANIMAL

Daniel T. Wu

BASICS

DESCRIPTION

- Most bites are from provoked animals.
- Dog bite wounds:
 - Large dogs inflict the most serious wounds (pit bulls cause the most human fatalities).
 - Most fatalities in children (70%) due to bites to face/neck
 - Dogs of family or friends account for most bites.
- Cat bite wounds:
 - Majority from pets known to victim
 - 50% infection rate in those seeking care
 - Puncture wounds most frequent due to sharp thin teeth causing deep inoculation of bacteria
- Catscratch disease (CSD):
 - 3 of the following 4 criteria:
 - Cat contact, with presence of scratch or inoculation lesion of the skin, eye, or mucous membrane
 - Positive CSD skin test result
 - Characteristic lymph node histopathology
 - Negative results of lab studies for other causes of lymphadenopathy
- Rat bite wounds:
 - Occur in lab personnel or children of low socioeconomic class
 - Rat-bite fever (RBF), rare in US but high mortality rate
 - Rat bites rarely transmit rabies, and prophylaxis not routine

ETIOLOGY

- Dog and cat bites:
 - *Pasteurella multocida* is the major organism in both:
 - Twice as likely to be found in cat bites than dog bites
 - Gram-negative aerobe found in up to 80% of cat infections
 - Infection appears in < 24 hr
 - *Staphylococcus* or *Streptococcus*:
 - Infection appears in > 24 hr
 - Other organisms include anaerobes and *Capnocytophaga canimorsus* (dogs).
- Catscratch disease:
 - Caused by *Bartonella henselae*
- Rat bites:

- Caused by *Spirillum minus* and *Streptobacillus moniliformis* (RBF)

DIAGNOSIS

SIGNS AND SYMPTOMS

- Distribution of mammalian bites:
 - Dog bites represent 80–90% of all bites.
 - Cat bites represent 5–15% of all bites.
 - Human bites represent 2–5% of all bites (see “Human Bite” chapter).
 - Rat bites represent 2–3% of all bites.
- Dog bites:
 - Appearance:
 - Crush injuries (most common), tears, avulsions, punctures, and scratches
 - Low rates of infection compared with cat and human bites
 - Infections usually present with:
 - cellulitis
 - malodorous gray discharge
 - fever
 - lymphadenopathy
- Cat bites:
 - Appearance:
 - Puncture wounds (most common)
 - Abrasions
 - Lacerations
 - High infection rates (30–50%) due to deeper puncture wounds
- Catscratch disease:
 - From the bite/scratch of a cat, dog, or monkey
 - Small macule or vesicle that progresses to a papule:
 - Begins several days (3–10) after inoculation
 - Resolves within several days or weeks
 - Regional lymphadenopathy occurs 3 wk postinoculation
 - Tender
 - Nonsuppurative
 - Resolves after 2–4 mo
 - Low-grade fever, malaise, headache
- Rat-bite fever:
 - Does not have to involve a bite. Can occur from handling of rats
 - *S. moniliformis*:
 - Begins several days (2–10) after exposure
 - Common in US
 - Fever, rigors, migratory polyarthralgias, headaches, nausea, and

vomiting

– *S. minus*

- Incubation period from 1–3 wk
- More common in Asia
- Arthritis not common

History

- Animal's behavior, provocation, location, ownership
- Time since attack
- Past medical history: Conditions compromising immune function, allergies, and tetanus status

Physical-Exam

- Record the location and extent of all injuries.
- Document any swelling, crush injuries, or devitalized tissue.
- Note the range of motion of affected areas.
- Note the status of tendon and nerve function.
- Document any signs of infection, including regional adenopathy.
- Document any joint or bone involvement.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Aerobic and anaerobic cultures from any infected bite wound
- Cultures not routinely indicated if wounds not clinically infected
- Catscratch disease:
 - Presence of elevated titers of *B. (Rochalimaea) henselae*, or
 - Positive reaction to catscratch antigen (CSA):
 - Inject 0.1 mL CSA IM
 - Induration at the site 48–72 hr later equal to or exceeding 5 mm is positive

Imaging

Plain radiograph indications:

- Fracture
- Suspect foreign body (e.g., tooth)
- Baseline film if a bone or joint space has been violated in evaluating for osteomyelitis
- For infection in proximity to a bone or joint space

DIFFERENTIAL DIAGNOSIS

- Human bite injuries: Human teeth cause crush injuries and animal teeth cause more punctures and lacerations.

- Bite injuries from other animals
- CSD-caused lymphadenopathy:
 - Reactive hyperplasia (leading cause of lymphadenopathy in children <16 yr)
 - Infection, chronic lymphadenitis, drug reaction, malignancy, and congenital conditions

TREATMENT

PRE HOSPITAL

Apply pressure to any bleeding wound

INITIAL STABILIZATION/THERAPY

- Achieve hemostasis on any bleeding wound.
- Airway stabilization if bite located on face or neck

ED TREATMENT/PROCEDURES

- Wound irrigation:
 - Copious volumes of normal saline irrigation with an 18G plastic catheter tip aimed in the direction of the puncture.
 - Avoid injection of saline through tissue planes due to force of irrigation.
- Débridement:
 - Remove foreign material, necrotic skin tags, or devitalized tissues.
 - Do not débride puncture wounds.
 - Remove any eschar present so underlying pus may be expressed and irrigated.
- Wound closure:
 - Closing wounds increases risk of infection and must be balanced with scar formation and effect of leaving wound open to heal secondarily.
 - Do not suture infected wounds or wounds > 24 hr after injury.
 - Repair of wounds > 8 hr: Controversial
 - Close facial wounds (warn patient of high risk of infection).
 - Infected wounds, those presenting > 24 hr after the event, and deep hand wounds should be left open.
 - May approximate the wound edges with Steri-Strips and perform a delayed primary closure.
- Antibiotic indications:
 - Infected wounds
 - Cat bites
 - Hand injuries
 - Severe wounds with crush injury
 - Puncture wounds

- Full-thickness puncture of hand, face, or lower extremity
- Wounds requiring surgical débridement
- Wounds involving joints, tendons, ligaments, or fractures
- Immunocompromised patients
- Wounds presenting > 8 hr after the event
- Elevate injured extremity
- Tetanus prophylaxis
- Rabies immunoprophylaxis:
 - Not required if rabies not known or suspected
 - Rodents (squirrels, hamsters, rats, mice) and rabbits rarely transmit the disease.
 - Skunks, raccoons, bats, and foxes represent the major reservoir for rabies.
 - See “Rabies” chapter for treatment guidelines.
- Catscratch disease:
 - Analgesics
 - Apply local heat to affected nodes.
 - Avoid lymph node trauma.
 - Disease usually self-limiting
 - Antibiotics controversial, consider if severe disease is present or immunocompromised victim
- Rat-bite fever:
 - High mortality (10%)
 - IV penicillin or doxycycline

MEDICATION

First Line

- Amoxicillin/clavulanic acid (Augmentin): 500/125 mg (peds: 40 mg/kg/24h) q8h PO
- Ampicillin–sulbactam (Unasyn): 3 g q6h IV
- Penicillin 1–2 million units q6h IV (peds 20,000–50,000 U/kg/d div. q4h IV)
- Piperacillin–Tazobactam (Zosyn): 4.5 g q8h IV
- Ticarcillin–clavulanate (Timentin): 3.1 g q4h IV
- Ceftriaxone (Rocephin): 1 g/d plus Metronidazole (Flagyl): 500 mg q8h

Second Line

- 2 drug therapy: 1 of the following below + anaerobic coverage:
 - Trimethoprim–sulfamethoxazole (Septra DS): 1 tablet q12h (peds: 8 mg/kg trimethoprim and 40 mg/kg sulfamethoxazole per day divided into 2 daily doses) PO
 - Penicillin (Penicillin VK): 500 mg (peds: 50 mg/kg/24h) PO q6h
 - Ciprofloxacin (Cipro): 500–750 mg q12h PO or 400 mg q12h IV
 - Doxycycline: 100 mg PO BID

- + (anaerobic coverage):
 - Clindamycin (Cleocin): 150–450 mg (peds: 8–20 mg/kg/24h) PO q6h or 600–900 mg (peds: 20–40 mg/kg/24h) IV q8h
 - Metronidazole (Flagyl): 500 mg PO TID (peds: 10 mg/kg/dose TID)

FOLLOW-UP

DISPOSITION

Admission Criteria

- All bites:
 - Infected wounds at presentation
 - Severe/advancing cellulitis/lymphangitis
 - Signs of systemic infection
 - Infected wounds that have failed to respond to outpatient (PO) antibiotics
- Catscratch disease:
 - Prolonged fever, systemic symptoms, and/or marked lymphadenopathy

Discharge Criteria

- Healthy patient with localized wound infection:
 - Discharge on antibiotics with 24-hr follow-up.
- Noninfected wounds:
 - 48-hr follow-up

FOLLOW-UP RECOMMENDATIONS

- Hand specialist referral/follow-up for infected hand wounds.
- Healthy patient with localized wound infection: Discharge on antibiotics with 24-hr follow-up.
- 48-hr follow-up for noninfected wounds

PEARLS AND PITFALLS

Animal bites must be reported to authorities in many localities.

BITE, HUMAN

Daniel T. Wu

BASICS

DESCRIPTION

- 3rd most common bite (after dogs and cats)
- Most bites (up to 75%) occur during aggressive acts.
- 15–20% are related to sexual activity (love nips).
- 2 types of bites:
 - Occlusional bites: Laceration or crush injury to affected body part:
 - Occurs when human teeth bite into the skin
 - More prone to infection than animal bites
 - Clenched-fist injuries (CFIs) (CFIs; most serious type): Present as small wounds over metacarpophalangeal joints in dominant hand (fight bites):
 - Sustained from a clenched fist striking the mouth and teeth of another person
- With joint relaxation from the clenched position:
 - Puncture site sealed
 - Oral bacteria inoculated in the anaerobic setting within the joint
 - Bacterial inoculation carried by the tendons deeper into the potential spaces of the hand
 - Increases chances for a more extensive infection

ETIOLOGY

- Aerobic and anaerobic organisms:
 - Most common:
 - *Streptococcus*
 - *Staphylococcus*
 - Others:
 - *Eikenella corrodens*
 - *Haemophilus influenzae*
 - *Peptostreptococcus*
 - *Corynebacterium*
 - *E. corrodens* exhibits synergism with *Streptococcus*, *Staphylococcus aureus*, *Bacteroides*, and gram-negative organisms
- Although rare, case reports of viral transmission via bites (hepatitis, HIV, and herpes)

DIAGNOSIS

SIGNS AND SYMPTOMS

- Location:
 - Upper extremities (60–75%)
 - Head and neck (15–20%)
 - Trunk (10–20%)
 - Lower extremities (~ 5%)
- Frequent complications:
 - Cellulitis
 - Serious deep-space infections (septic arthritis and osteomyelitis)
 - Fractures and tendon injuries
 - Hand bites have highest rates of infection.

History

- Time of injury
- Patient allergies
- Relevant medical history (immune status)
- Last tetanus shot
- HIV, hepatitis B status of person inflicting bite

Physical-Exam

- Record the location and extent of all injuries.
- Document any swelling, crush injuries, or devitalized tissue.
- Note the range of motion of affected areas.
- Note the status of tendon and nerve function.
- Document any signs of infection, including regional adenopathy.
- Document any joint or bone involvement.

ESSENTIAL WORKUP

Careful physical exam for involvement of deep structures and foreign bodies:

- Examine the deepest part of clenched-fist bites while putting the fingers through full range of motion to check for extensor tendon lacerations and joint violation.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Aerobic and anaerobic cultures from any infected bite wound
- Cultures not indicated if wounds not clinically infected
- CBC if signs of significant infection.
- Electrolytes, glucose, BUN, and creatinine:
 - For diabetic patients or those with significant infections

Imaging

- Generally not helpful

- Plain radiograph indications:
 - Fracture
 - Suspect foreign body (e.g., tooth)
 - Baseline film if a bone or joint space has been violated in evaluating for osteomyelitis
 - For infection in proximity to a bone or joint space
- Ultrasound can be useful in differentiating abscess from cellulitis

DIFFERENTIAL DIAGNOSIS

Bite injuries from animals:

- Sharper teeth cause more punctures and lacerations than human teeth, which usually cause more crush-type injuries.

Other Considerations

- In suspected sexual abuse:
 - Check for a central area of bruising or “hickey” from suction
- Linear abrasions or bruises on both the dorsal and palmar/plantar surfaces of the hand or foot:
 - Highly suggestive of bite marks
 - Lesions on one extremity should prompt a search for lesions on the other extremities.
- An intercanine distance of > 3 cm indicates permanent dentition (present only if the attacker is > 8 yr)
- If abuse suspected:
 - Rub a saline-moistened swab in the wound to collect any saliva and then place in a paper envelope for analysis.
 - Obtain photographs.
 - Notify authorities.

TREATMENT

PRE HOSPITAL

Control bleeding with direct pressure.

INITIAL STABILIZATION/THERAPY

ABCs: Ensure patent airway and adequate peripheral tissue perfusion

ED TREATMENT/PROCEDURES

- Wound irrigation:
 - Copious volumes of normal saline irrigation with an 18G needle or plastic catheter tip aimed in the direction of the puncture
 - Care should be taken not to inject fluid into the tissues.

- Débridement:
 - Remove any foreign material, necrotic skin tags, or devitalized tissues.
 - Do not débride puncture wounds.
 - Remove any eschar present so that underlying pus may be expressed and irrigated.
- Clenched-fist injuries:
 - Immobilize
 - Splint in a position of function that maintains the maximal length of ligaments and intrinsic muscles.
 - Use a bulky hand dressing
 - Consultation with hand surgeon regarding operative irrigation/exploration of wound
 - Elevation for several days until any edema resolved
 - Sling for outpatients
 - Place the hand in a tubular stockinette attached to an IV pole for inpatients.
 - Administer antibiotics
- Do not perform primary repair of avulsion wounds.
- Wound closure:
 - Closing wounds increases risk of infection and must be balanced with scar formation and effect of leaving wound open to heal secondarily.
 - Do not suture infected wounds or wounds > 24 hr after injury.
 - Repair of wounds > 8 hr after bite: Controversial.
 - Close facial wounds up to 24 hr after bite (warn patient of high risk of infection).
 - Infected wounds and those presenting > 24 hr should be left open.
 - May approximate the wound edges with Steri-Strips and perform a delayed primary closure.
 - Do not suture CFIs.
- Prophylactic antibiotics controversial for low-risk bites
- Antibiotics for outpatients with:
 - Moderate to severe injuries with crush injury or edema
 - Involvement of the bone or a joint
 - Hand bites
 - Wounds near a prosthetic joint
 - Underlying disease (diabetes, prior splenectomy, or immunosuppression) that increases the risk of developing a more serious infection
- Tetanus prophylaxis
- Refer for possible testing/surveillance for HIV infection.

MEDICATION

First Line

- Amoxicillin/clavulanic acid (Augmentin): 500/125 mg (peds: 40 mg/kg/24h) q8h

PO

- Ampicillin–sulbactam (Unasyn): 3 g q6h IV
- Piperacillin–Tazobactam (Zosyn): 4.5 g q8h IV
- Ticarcillin–clavulanate (Timentin): 3.1 g q4h IV
- Ceftriaxone (Rocephin): 1 g/d plus Metronidazole (Flagyl): 500 mg q8h

Second Line

- 2 drug therapy: 1 of the following below + anaerobic coverage:
 - Trimethoprim–sulfamethoxazole (Septra DS): 1 tablet q12h (peds: 8 mg/kg trimethoprim and 40 mg/kg sulfamethoxazole per day divided into 2 daily doses) PO
 - Penicillin (Penicillin VK): 500 mg (peds: 50 mg/kg/24h) PO q6h
 - Ciprofloxacin (Cipro): 500–750 mg q12h PO or 400 mg q12h IV
 - Doxycycline: 100 mg PO BID
- + (anaerobic coverage):
 - Clindamycin (Cleocin): 150–450 mg (peds: 8–20 mg/kg/24h) PO q6h or 600–900 mg (peds: 20–40 mg/kg/24h) IV q8h
 - Metronidazole (Flagyl): 500 mg PO TID (peds: 10 mg/kg/dose TID)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Infected wounds at presentation
- Severe/advancing cellulitis/lymphangitis
- Signs of systemic infection
- Infected wounds that have failed to respond to outpatient (PO) antibiotics

Discharge Criteria

- Healthy patient with localized wound infection:
 - Discharge on antibiotics with 24-hr follow-up.
- Noninfected wounds
 - 48-hr follow-up

Geriatric Considerations

- Human bite marks rarely occur accidentally; good indicators of inflicted injury.
- Consider elder abuse.

Pediatric Considerations

- Human bite marks rarely occur accidentally; good indicators of inflicted injury.
- If intercanine distance > 3 cm, bite likely from an adult. Consider child abuse.

Issues for Referral

Suspected child abuse

FOLLOW-UP RECOMMENDATIONS

- Hand specialist referral/follow-up for infected hand wounds
- Healthy patient with localized wound infection: Discharge on antibiotics with 24-hr follow-up.
- 48-hr follow-up for noninfected wounds

PEARLS AND PITFALLS

- Examine the deepest part of clenched-fist bites while putting the fingers through full range of motion to check for extensor tendon lacerations and joint violation.
- Obtain hand consultation for operative irrigation for all patients with clenched-fist lacerations due to the high rate of infection.
- An intercanine distance of > 3 cm indicates permanent dentition (present only if the attacker is > 8 yr).

BLADDER INJURY

Mary E. Johnson

BASICS

DESCRIPTION

- Blunt trauma is the most common mechanism.
- 10% of pelvic fractures have serious bladder injury.
- 80–90% of bladder ruptures have pelvic fracture.
- Mortality: 17–22% overall; 60% if combined intraperitoneal/extraperitoneal rupture

ETIOLOGY

- Mechanism:
 - Trauma, 82%
 - Blunt trauma: Motor vehicle accident (MVA; 87%), falls (7%), assault (6%)
 - Penetrating: Gunshot wound (GSW) (85%), stabbings (15%)
 - Iatrogenic 14%: TURP and urologic procedures, gynecologic procedures, obstetric procedures, abdominal procedures, hernia repair, intrauterine device (IUD), orthopedic hip procedures, biopsies, indwelling Foley
 - Intoxication 2.9%
 - Spontaneous <1%
- Classification:
 - Extraperitoneal bladder rupture (62%):
 - Associated with pelvic fractures
 - Caused by blunt force or fracture fragments
 - Intraperitoneal bladder rupture (25%):
 - Direct compression of distended bladder
 - Caused by rupture of the dome of the bladder
 - Combined extraperitoneal and intraperitoneal rupture (12%):
 - Highest mortality owing to associated injuries
 - Bladder contusion:
 - Damage to endothelial lining or muscularis layer with intact bladder wall
 - Gross hematuria after extreme physical activity (long-distance running)
 - Gross hematuria with normal imaging
 - Usually resolves without intervention

Pediatric Considerations

- In children, the bladder is an intra-abdominal organ and descends into the pelvis

by age 20 yr.

- Intraabdominal rupture is more common in children than adults because the bladder is an abdominal organ.
- Bladder injury is more common in children than in adults because the pediatric bony pelvis is less rigid and transmits more force to adjacent structures.

DIAGNOSIS

SIGNS AND SYMPTOMS

Triad:

- Gross hematuria
- Suprapubic pain
- Difficulty voiding

History

Establish potential mechanism.

Physical-Exam

Evaluate urethral meatus—if blood is present, do not insert Foley catheter until retrograde urethrogram (RUG) is performed (concomitant urethral and bladder injuries occur in 10–29% of patients).

ESSENTIAL WORKUP

- History of trauma or procedures
- Evaluate urethral meatus for blood.
- Urinalysis (UA)
- Retrograde cystography

DIAGNOSIS TESTS & INTERPRETATION

Lab

- UA:
 - Gross hematuria in 95–100% of patients with significant bladder or urethral trauma
 - Microscopic hematuria in 5%
- BUN and creatinine:
 - The BUN can be elevated from resorption of urine within the peritoneum.
- Electrolytes:
 - Hyperkalemia and hyponatremia may result from resorption of urine within the peritoneum.

Imaging

- Retrograde cystography and retrograde CT cystography are the methods of choice to diagnose a ruptured bladder. Both studies have reported sensitivity and specificity of 95% and 100% respectively.
- If urethral injury is suspected, the cystogram is performed after a RUG.
- Cystography technique:
 - Kidneys/ureter/bladder (KUB) scout film
 - Infuse 100 mL of diluted contrast via Foley into bladder. Contrast material needs to be diluted: 30% or 6:1 saline; otherwise it is too dense.
 - Plain film is repeated to evaluate early extravasation.
 - If initial film is normal, fill rest of bladder with diluted contrast:
 - Min. 300–350 mL total for adult
 - 3–5 mL/kg or 60 mL + (age in yr × 30) for children or until discomfort
 - It is essential to have a bladder full of contrast for diagnosis; it is not sufficient to place contrast and clamp Foley in antegrade fashion.
 - Cystogram films taken in AP, lateral, and oblique views (oblique may be difficult in trauma and CT is often used)
 - Empty bladder and obtain a postdrainage film unless CT cystography obtained.
 - Postdrainage film is essential without CT cystography—10% of bladder ruptures are seen only on postdrainage film; a distended bladder may hide extravasation.
- Cystography interpretation:
 - Extraperitoneal rupture: Tear drop- or star-shaped form
 - Intraperitoneal rupture: Outlining of bowel or contrast within the paracolic gutters

Diagnostic Procedures/Surgery

- FAST scan:
 - Free pelvic fluid should raise concern for bladder injury.

DIFFERENTIAL DIAGNOSIS

- Peritoneal trauma
- Urethral trauma
- Renal or ureteric trauma

TREATMENT

PRE HOSPITAL

Do not attempt bladder catheterization in the field.

INITIAL STABILIZATION/THERAPY

- ABCs
- Early urologic consultation

ED TREATMENT/PROCEDURES

- Urologic consultation is needed when bladder rupture is diagnosed.
- Extraperitoneal nonpenetrating ruptures may be managed by catheter drainage:
 - 20F Foley or larger for 14 days
 - 80% of lacerations will seal in 3 wk.
 - If patient is undergoing abdominal or pelvic surgery for other injury, surgical repair is recommended.
- Intraperitoneal ruptures require surgical exploration.
- Bladder contusions do not need any specific interventions.

MEDICATION

Broad-spectrum antibiotics for intraperitoneal rupture

FOLLOW-UP

DISPOSITION

Admission Criteria

- Concurrent major trauma requiring admission or observation
- Surgical intervention required

Discharge Criteria

- Bladder contusion with no rupture or other major trauma requiring admission
- Most cases of bladder rupture will require admission; discharge only after clearance by urology and no other associated injuries.

Issues for Referral

Any bladder injury managed as an outpatient should have urologic referral.

FOLLOW-UP RECOMMENDATIONS

Follow-up to be arranged with urology:

- Extraperitoneal bladder rupture with Foley catheter management will have Foley removal in 14 days.

PEARLS AND PITFALLS

- Any free fluid on CT or US exam should raise suspicion for bladder injury.
- Unresponsive, altered, and intoxicated patients warrant careful exam.
- Penetrating injuries to lower abdomen with any degree of hematuria warrant cystography.

CODES

ICD9

- 665.50 Other injury to pelvic organs, unspecified as to episode of care or not applicable
- 867.0 Injury to bladder and urethra, without mention of open wound into cavity
- 867.1 Injury to bladder and urethra, with open wound into cavity

ICD10

- S37.20XA Unspecified injury of bladder, initial encounter
- S37.23XA Laceration of bladder, initial encounter
- S37.29XA Other injury of bladder, initial encounter

BLOW-OUT FRACTURE

Shari Schabowski

BASICS

DESCRIPTION

- Defined as an orbital floor fracture without orbital rim involvement
- Results from sudden blunt trauma to the globe:
 - Typically caused by the force of a projectile $>$ half the size of the fist
- Force transmitted through the noncompressible structures of the globe to the weakest structural point: The orbital floor
- Transmitted force “blows out” or fractures the orbital floor.
- Orbital floor serves as roof to air-filled maxillary and ethmoid sinuses:
 - Communication between the spaces results in orbital emphysema.
- Orbit contains fat, which holds the globe in place:
 - Orbital floor fracture may result in herniation of the fat on the inferior orbital surface into the maxillary or ethmoid sinuses.
 - Leads to enophthalmos owing to orbital volume loss and sinus congestion; fluid collection may occur secondary to edema and bleeding.
- Infraorbital nerve runs through the bony canal 3 mm below the orbital floor:
 - Injury may result in hypoesthesia of the ipsilateral cheek and upper lip.
 - To distinguish facial hypoesthesia related to local swelling from nerve injury: Test for sensation on the ipsilateral gingiva, which is within the infraorbital nerve distribution.
- Inferior rectus and the inferior oblique muscle run along the orbital floor:
 - Restriction of these extraocular muscles may occur because of entrapment within the fracture, contusion, or cranial nerve dysfunction.
 - Typically manifests as diplopia on upward gaze
 - Inability to elevate the affected eye normally on exam
- Medial rectus located above the ethmoid sinus:
 - Less commonly entrapped
 - Diplopia on ipsilateral lateral gaze

ETIOLOGY

Caused by a projectile which strikes the globe. The force is transmitted through the noncompressible structures of the globe to the weakest structural point: the orbital floor resulting in a blow out fracture.

Pediatric Considerations

- Orbital roof fractures with associated CNS injuries more common in children
- Orbital floor fractures: Unlikely before 7 yr of age:

- Orbital floor is not as weak a point in the orbit due to lack of pneumatization of the paranasal sinuses.
- Unfortunately fractures can occur in children and may result in unrecognized entrapment of the rectus muscle labeled the “white-eyed” fracture:
 - These children may present with marked nausea, vomiting, headache, and irritability suggestive of a head injury that commonly distracts from the true diagnosis.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Periorbital tenderness, swelling, and ecchymosis
- Impaired ocular mobility or diplopia:
 - Restricted upward gaze owing to inferior rectus entrapment
 - Restricted ipsilateral lateral gaze with medial rectus entrapment
- Infraorbital hypoesthesia:
 - Caused by compression/contusion of infraorbital nerve
 - May extend to upper lip
- Enophthalmos:
 - Globe set back owing to orbital fat displaced through fracture
- Periorbital emphysema:
 - From the ethmoid or maxillary sinus
- Epistaxis
- Normal visual acuity:
 - If not, consider more extensive injuries
- No orbital rim step off

Associated Severe Injuries

- Ocular injuries:
 - Ruptured globe:
 - Incidence up to 30% of blow-out fractures
 - Ophthalmologic emergency
 - Retrobulbar hemorrhage
 - Emphysematous optic nerve compression
- Cervical spine or intracranial injuries
- Commonly associated injuries:
 - Subconjunctival hemorrhage
 - Corneal abrasion/laceration
 - Hyphema
 - Traumatic mydriasis
 - Traumatic iridocyclitis (uveitis)
- Less common:

- Iridodialysis
- Retinal detachment
- Vitreous hemorrhage
- Optic nerve injury
- Associated fractures:
 - Nasal bones
 - Zygomatic arch fracture
 - Le Fort fracture
- Late complications:
 - Sinusitis
 - Orbital infection
 - Permanent restriction of extraocular movement
 - Enophthalmos

History

Struck in the eye with a projectile. Paintball, handball, racquetball, baseball, rock, or possibly fist. Larger-sized projectiles will likely be blocked by the orbital rim. Seen frequently after MVCs which are the most common cause of maxillofacial trauma.

Physical-Exam

- Thorough ophthalmologic exam:
 - Palpate bony structures of the orbit for evidence of step off.
 - Careful attention not to place pressure on the globe until ruptured globe excluded:
 - Desmarres lid retractors may be necessary to evaluate the eye with swollen lid.
- Document pupillary response
- Visual acuity (should not be affected):
 - Handheld visual acuity Rosenbaum card is most useful with injuries.
- Test extraocular movements for disconjugate gaze or diplopia.
- Test sensation in inferior orbital nerve distribution.
- Examine lid and adnexa:
 - Orbital emphysema may be present.
- Slit-lamp and fundoscopic exam to identify associated injuries.
- Full physical exam to identify associated injuries and neurologic impairment.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Preoperative lab studies if indicated
- Pregnancy testing prior to radiography

Imaging

- If CT unavailable or contraindicated, plain radiographs will provide important information:
 - _ Facial films
 - _ Orbits
 - _ Waters view and exaggerated Waters view:
 - Classic “teardrop sign” illustrates herniated mass of orbital contents in the ipsilateral maxillary sinus.
 - Opacification of or air–fluid level in the ipsilateral maxillary sinus (less specific)
 - Orbital floor bony fracture
 - Lucency in orbits consistent with orbital emphysema
- CT-preferred modality:
 - _ Defines involved anatomy
 - _ Obtain axial and coronal 1.5-mm cuts:
 - Reconstruction of coronals not preferred but acceptable if positioning impossible

Diagnostic Procedures/Surgery

Forced duction test:

- Distinguishes nerve dysfunction from entrapment
- Topical anesthesia applied to the conjunctiva on the opposite side, and the globe is pulled away from the expected point of entrapment; if the globe is not mobile, the test is positive—defining physical entrapment.

Pediatric Considerations

- Orbital CT: Study of choice:
 - _ Plain films less helpful
- Essential to identify entrapment early as long-term outcome will likely be affected if left undiagnosed:
 - _ Early surgical intervention for entrapment may significantly improve outcome.

DIFFERENTIAL DIAGNOSIS

- Cranial nerve palsy
- Orbital cellulitis
- Periorbital cellulitis
- Periorbital contusion/ecchymosis
- Retrobulbar hemorrhage
- Ruptured globe

TREATMENT

PRE HOSPITAL

- Metal protective eye shield if possible globe injury
- Place in supine position.

INITIAL STABILIZATION/THERAPY

Initial approach and immediate concerns:

- Assess for associated intracranial or cervical spine injuries.
- Rule out ruptured globe.
- Test visual acuity:
 - _ Decreased visual acuity suggestive of associated with more extensive injuries

ED TREATMENT/PROCEDURES

- After globe rupture is excluded, apply cool compresses for the 1st 24–48 hr to decrease swelling to minimize or reverse herniation and avoid surgical intervention.
- Avoid Valsalva maneuvers and nose blowing to prevent compressive orbital emphysema.
- Prophylactic antibiotics to prevent infection
- Nasal decongestants if no contraindication
- Analgesics as needed
- Tetanus prophylaxis

MEDICATION

- Antibiotics are recommended prophylactically to prevent sinusitis and orbital cellulitis:
 - _ Cephalexin 250 mg q6h for 10 days
- Systemic corticosteroids have been advocated to speed up the resorption of edema in order to more accurately assess any muscle entrapment and orbital damage:
 - _ Prednisone (60–80 mg/d) within 48 hr of the injury and continued for 5 days
- Nasal decongestants may be beneficial if not contraindicated:
 - _ Phenylephrine nasal spray: BID for 2–4 days

FOLLOW-UP

DISPOSITION

Admission Criteria

- Rarely indicated
- 85% resolve without surgical intervention.
- Consultation with facial trauma service in ED and consideration for admission if:
 - _ 50% of floor fractured
 - _ Diplopia or entrapment is identified

- Particularly in children
- Enophthalmos > 2 mm or more

Discharge Criteria

In most cases, observe for 10–14 days until swelling resolves, then follow up with facial trauma surgeon to determine need for surgical intervention.

FOLLOW-UP RECOMMENDATIONS

Symptoms should improve over time:

- If at any point patient develops increased swelling, tenderness, redness, or pain around the eye, they should return to ED for re-evaluation.
- If any visual disturbance, visual loss, or increased eye pain return to ED for re-evaluation.

PEARLS AND PITFALLS

- Be hypervigilant in checking pupillary response and visual acuity:
 - Abnormal results may be the 1st sign of serious complications:
 - Globe rupture
 - Optic nerve injury possibly stemming from emphysematous or retrobulbar compression
- Careful evaluation for entrapment:
 - Essential for all, but particularly children, to exclude white-eyed fracture and its long-term complications
- The oculocardiac (Aschner) reflex may be associated with this injury. It manifests as a decrease in pulse rate associated with traction applied to extraocular muscles and/or compression of the eyeball:
 - May be seen more commonly in children
 - Treated by release of pressure and in some cases may require atropine

BOERHAAVE SYNDROME

Lauren M. Smith • Edwin R. Malone

BASICS

DESCRIPTION

- Spontaneous esophageal rupture from sudden combined increase in intra-abdominal pressure and negative intrathoracic pressure
 - Causes complete, full-thickness (transmural), longitudinal tear in esophagus
- Esophagus has no serosal layer (which normally contains collagen and elastic fibers):
 - Results in weak structure vulnerable to perforation and mediastinal contamination
 - Esophageal wall is further weakened by conditions that damage mucosa (i.e., esophagitis is of various causes).
- Majority of perforations occur at left posterolateral wall of the lower third esophagus.
- Significant morbidity/mortality (most lethal GI tract perforation):
 - Owing to explosive nature of tear
 - Owing to almost immediate contamination of mediastinum with contents of esophagus
 - Overall mortality can approach 20%
 - Mortality can double if treatment is delayed > 24 hr from rupture
 - Cervical rupture associated with the lowest mortality, followed by abdominal and thoracic rupture, respectively

ETIOLOGY

- Associated with:
 - Forceful vomiting and retching (most common)
 - Heavy lifting
 - Seizures
 - Childbirth
 - Blunt trauma
 - Induced emesis
 - Caustic ingestions
 - Laughing
 - History of Barrett ulcer
 - History of HIV/AIDS
 - History of pill esophagitis
- Common in middle-aged men
- Medical procedures cause over 50% of all perforations.

Pediatric Considerations

- Described in female neonates but rarely seen
- Consider caustic ingestions

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Often no classic symptoms
- Most common symptoms:
 - Chest or epigastric pain after vomiting/retching
- Mackler triad:
 - Vomiting/retching
 - Chest pain
 - Subcutaneous emphysema
- Retrosternal chest pain present in most patients:
 - Often pleuritic
 - Radiates to back or left shoulder
 - Worsens with swallowing
- Odynophagia
- Swallowing may precipitate coughing
- Frequently, a history of alcoholism or heavy alcohol ingestion may be elicited

ALERT

The vague nature of symptoms often lead to a delay in outcome and poorer prognosis

Physical-Exam

- Dyspnea
- Diaphoresis
- Subcutaneous emphysema in neck and chest wall
- Mediastinal crackling on auscultation (Hamman crunch)
- Pleural effusions
- Tachypnea
- Fever
- Shock, in more severe cases
- If untreated, mediastinitis will develop and abscesses will form.
- Not usually associated with bleeding

ESSENTIAL WORKUP

- Upright chest radiographs (preferably posteroanterior and lateral views if tolerated) evaluating for:
 - Pneumomediastinum

- SC emphysema
- Pleural effusion (left side)
- Pneumothorax
- Widened mediastinum
- Hydropneumothorax
- Empyema
- Free peritoneal air
- Naclerio “V” sign:
 - V-shaped radiolucency seen through the heart (air in left lower mediastinum)
- Contrast esophagram identifies leak in esophagus:
 - Aids in decision of which type of surgical approach
 - Controversy exists regarding contrast use, water-soluble vs. barium
 - Water-soluble contrast material was thought to be less toxic if extravasated into the mediastinum; however, if aspirated may cause necrotizing pneumonitis and has a higher rate of false negatives
 - Barium, more sensitive for diagnosing perforation, but more irritating to the mediastinum
 - If esophagus is intact, use barium contrast for better detail

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- PT/PTT/INR
- Blood cultures
- Pleural effusion:
 - Amylase content
 - pH (< 6)
 - Undigested food particles
- ECG

Imaging

- CXR
- Endoscopy:
 - Controversial because this may extend perforation and/or introduce air into mediastinum
- CT chest:
 - Sensitive for identifying free air, periesophageal fluid, mediastinal widening, air or fluid in pleural spaces; however, does not isolate lesion
 - Indicated if esophagram cannot be obtained
 - Evaluates other intrathoracic structures

DIFFERENTIAL DIAGNOSIS

- Cholecystitis
- Dissecting aortic aneurysm
- Intestinal obstruction
- Lung abscess
- Mesenteric thrombosis
- Myocardial infarction
- Pneumothorax
- Pericarditis
- Pneumonia
- Pancreatitis
- Pulmonary thromboembolism
- Ruptured abdominal viscus
- Spontaneous pneumomediastinum (clinically benign)

TREATMENT

PRE HOSPITAL

- Airway control must be established if patient unresponsive or airway patency in jeopardy.
- Establish 2 large-bore intravenous catheters and treat hypotension with 0.9% NS.
- Avoid opiates until patient is in ED to avoid complication of hypotension.

INITIAL STABILIZATION/THERAPY

- ABCs
- Airway control: 100% oxygen or intubate patient if unresponsive or airway patency is in jeopardy.
- Establish intravenous access and treat hypotension:
 - Administer 1 L (20 mL/kg) bolus with 0.9% NS (or lactated Ringer solution).
 - Initiate dopamine if blood pressure does not respond to fluids.
 - Central catheter placement if condition of patient remains unstable for more efficient delivery of fluids and monitoring of central venous pressure

ED TREATMENT/PROCEDURES

- NPO
- Careful placement of a nasogastric tube to decompress the stomach
- Bladder catheter to monitor urine output
- Expedient diagnosis to decrease incidence of morbidity/mortality
- Prompt surgical consultation
- Definitive treatment:
 - Surgical repair
 - Endoscopic stent placement, considered in appropriate patients

- Conservative management, may be considered in patients with a contained perforation
- Initiate broad-spectrum antibiotics directed against oral microflora and gastrointestinal pathogens:
 - Ampicillin/sulbactam + gentamicin
 - Imipenem/Cilastatin

MEDICATION

- Ampicillin/sulbactam: 3 g IV q6h
- Dopamine: 2–20 $\mu\text{g}/\text{kg}/\text{min}$ IV per bolus
- Gentamicin: 2 mg/kg load, then 1.7 mg/kg IV q8h or 5–7 mg/kg IV QD (assuming normal renal function)
- Imipenem/cilastatin: 250–500 IV q6h

FOLLOW-UP

DISPOSITION

Admission Criteria

All cases of Boerhaave syndrome must be admitted to surgical ICU:

- Cervical esophageal perforations may be treated by drainage alone.
- All thoracic and abdominal perforations require surgical intervention.

Discharge Criteria

None

Issues for Referral

Thoracic or general surgeon must be consulted for admission and possible operative intervention.

FOLLOW-UP RECOMMENDATIONS

As per surgeon recommendations

PEARLS AND PITFALLS

- Chest radiographs done immediately after injury may be normal.
- Left pleural space involvement is usually associated with a distal esophageal perforation.
- Right pleural space involvement is usually associated with proximal esophageal perforations.
- If esophagram is negative and there is high suspicion, repeat with patient in left and right decubitus positions.

- Immediate surgical consultation is the keystone of management.
- Significant increases in mortality are seen with delay in diagnosis and management.

ICD10

K22.3 Perforation of esophagus

BOTULISM

Philip Shayne • Jean Wheeler

BASICS

DESCRIPTION

- Rare in US, causing < 200 cases/yr; however, has significant bioterrorism potential.
- Caused by a polypeptide, heat-labile exotoxin produced by *Clostridium botulinum*:
 - Most potent poison known
- Toxin blocks neuromuscular transmission in cholinergic nerve fibers.
- Symptoms occur by inhibition of acetylcholine release from presynaptic nerve membranes:
 - Damage is permanent.
 - Recovery is by formation of new synapses through sprouting from the axon.
- Onset: 12–72 hr after exposure; may be up to 1 wk after exposure:
 - Death can occur 24 hr after onset of symptoms.
- Slow recovery; symptoms often persist for months
- Mortality:
 - Untreated: 60–70%
 - With supportive care: 3–10%
- 3 major types: Food-borne botulism, wound botulism, and infantile botulism (see “Pediatric Considerations”). Absorbed through mucosal surfaces or nonintact skin
- Food-borne botulism:
 - Occurs by ingestion of preformed toxin; from improperly canned food, improper refrigeration
 - Conditions required for exposure:
 - Food product contaminated with *C. botulinum* bacilli or spores
 - Proper conditions for germination of spores exist.
 - Time and conditions permit production of toxin before eating.
 - Food not heated sufficiently to destroy botulism toxin
 - Toxin-containing food ingested by susceptible host
- Wound botulism:
 - Clinical evidence of botulism after trauma with a resultant infected wound and no history suggestive of food-borne illness
 - Botulinum isolated in about 50%
 - Wounds usually contaminated with soil
 - Majority of US cases from IV drug use
- Other types:
 - Adult intestinal toxemia botulism:
 - Seen in adults with functional or structural GI abnormalities, are

- immunocompromised or with prolonged antibiotic use
- Predisposes to *Clostridial* colonization
- May have sporadic or recurrent botulism with no known source and even after immunoglobulin treatment
- Iatrogenic botulism:
 - Doses found in cosmetic applications are insufficient to cause systemic symptoms.
 - No known recent cases from medical use.
 - Symptoms would be expected to be classic.
- Inhalation botulism:
 - Aerosolization of toxin may have bioterrorism applications. Last reported naturally occurring case in 1962 from the disposal of animal remains.

Pediatric Considerations

- Infantile botulism occurs from the ingestion of *C. botulinum* spores, which germinate in the gut and produce the toxin.
- Accounts for 50–76% of botulism cases
- 90% occur in children <6 mo:
 - Associated with patient or family exposure to soil, dust, or agricultural industry.
 - May also be associated with weaning from breast milk, which may alter intestinal flora and increase susceptibility to *Clostridia* infection.
- Usually presents with change in stool pattern or constipation, progressing over several days to symptoms of bulbar weakness, then descending flaccid paralysis.
- Slower onset is attributed to the toxin being produced locally as opposed to being ingested in 1 dose.
- *C. botulinum* spores found in honey:
 - Honey not recommended for children <1 yr.

ETIOLOGY

- *C. botulinum* is a large spore-forming, usually gram-positive, strictly anaerobic bacilli ubiquitous in nature.
- Each strain produces antigenically distinct toxins, designated types A to G:
 - Types A, B, E, and rarely F are responsible for most human cases.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Ingestions/food history for previous 4–5 days:

- Exposures traditionally from home-processed fruit or vegetable products
- In prison populations ingestion of “pruno” (alcohol product created by prisoners using leftover food products)
- Immune status (AIDS, cancer, chronic illness)
- IV drug use

Physical-Exam

- Food-borne botulism (classic botulism):
 - Bulbar weakness is invariably the initial presentation: Diplopia, dysphagia, dysarthria, and dysphonia
 - Subsequent symmetric, descending weakness or paralysis of the extremities (hallmark of the disease)
 - No sensory deficit
 - May have progressively diminishing deep tendon reflexes
 - Patient remains awake/alert; mentation unaffected.
 - Ventilatory insufficiency from weakness of respiratory muscles
 - Autonomic dysfunction (sympathetic and parasympathetic):
 - Dry mouth
 - Blurred vision
 - Orthostatic hypotension
 - Constipation
 - Urinary retention
 - Nausea and vomiting with food-borne botulism only
 - Afebrile
- Wound botulism:
 - Finding similar to food-borne botulism
 - May be febrile as a result of soft-tissue infection
- Infantile botulism:
 - Constipation
 - Weakness
 - Poor suck
 - Weak cry
 - Lethargy
 - Hypotonia
 - Flaccid facial expression
 - Respiratory difficulty
- Inhalation botulism:
 - Similar to food-borne botulism with absence of GI symptoms

ESSENTIAL WORKUP

- Diagnosis is entirely clinical.
- Workup focuses on differentiation from other conditions causing general paralysis.
- If diagnosis is suspected, immediately notify state health department or CDC (770-

488-7100 for adults or 1-510-231-7600 for infant cases).

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Electrolytes, BUN/creatinine, and glucose:
 - Check for hypokalemia.
- Arterial blood gas (ABG):
 - For signs of respiratory insufficiency
- Confirmatory testing via mouse assay performed by select state and federal labs, using samples from:
 - Blood
 - Feces
 - Gastric contents
 - Suspected food and containers
 - Takes between 6–96 hr for results
- Anaerobic blood cultures:
 - May detect bacterium
- Nasal swab for ELISA test:
 - For inhalation botulism, as less reliably detected in sera and stool than other forms
 - Sample needs to be collected within 24 hr of exposure

Imaging

CT/MRI of brain:

- Normal

Diagnostic Procedures/Surgery

- CSF testing:
 - Normal
 - Helps differentiate from Guillain–Barré syndrome (which has markedly elevated CSF protein)
- Electrophysiologic studies:
 - Normal nerve conduction with diminished evoked muscle action potential
- Edrophonium testing may be positive, but not to the degree seen in myasthenia gravis.

DIFFERENTIAL DIAGNOSIS

- Myasthenia gravis (less acute)
- Lambert–Eaton myasthenic syndrome (less acute)
- Polio (fever and asymmetric)
- Guillain–Barré (simultaneous sensory findings and elevated spinal fluid protein)

- Tick paralysis
- Magnesium intoxication
- Hypokalemic periodic paralysis
- Diphtheritic neuropathy
- Rare basilar stroke syndromes with bulbar palsy

Pediatric Considerations

- Often misdiagnosed as dehydration, sepsis, or Reye syndrome
- Other diagnoses include inborn errors of metabolism, Guillain–Barré syndrome, and spinal muscle atrophy.

TREATMENT

ALERT

Death is invariably from progressive ventilatory failure:

- Intubate as soon as respiratory insufficiency noted, clinically and/or in conjunction with ABG.
- May require several weeks of ventilatory support

PRE HOSPITAL

- Transcutaneous pacing for unstable type II 2nd- or 3rd-degree block
- Atropine:
 - Avoid with type II 2nd-degree block because it may precipitate complete heart block
 - Contraindicated in 3rd-degree heart block with a widened QRS complex
- Attempts should be made at preventing increases in vagal tone.

INITIAL STABILIZATION/THERAPY

- Early intubation and ventilatory support is the key to survival.
- Respiratory difficulties occur rapidly.

ED TREATMENT/PROCEDURES

- Bivalent AB antitoxin:
 - IV administration as soon as the diagnosis is made and initial samples are collected, without waiting for lab confirmation
 - Before use assess hypersensitivity with skin test using horse serum or antitoxin
 - Using recommended dose < 1% will have hypersensitivity reaction
- With wound botulism perform wound débridement even if it appears to be healing.
- Antibiotics for specific infectious complications
- Standard precautions only; no evidence of person-to-person transmission
- If environmental exposure, wash clothing and skin with soap and water

MEDICATION

- ABE antitoxin formulations no longer used because of declines in titer to type E toxin
- 1st-line treatment:
 - Baby BIG human-derived antitoxin to types A and B licensed by USFDA for treatment of infant botulism and distributed by CA Dept. of Public Health (510-231-7600). www.infantbotulism.org/
 - Heptavalent antitoxin (H-Bat) available from CDC as an investigational use drug protocol and emergency therapeutic use. Not for infant botulism.

Pediatric Considerations

- Baby BIG halves average hospital stay from 6–3 wk:
 - Adult equine antitoxin should not be used on pediatric patients
- Antibiotics:
 - Ineffective in eradicating organism from the intestine
 - Release of toxin in the gut through bacterial cell lysis may worsen neurologic symptoms.

Second Line

Pentavalent toxoid for lab workers

FOLLOW-UP

DISPOSITION

Admission Criteria

Admit patients with suspected botulism poisoning to monitored bed:

- ICU admission for any respiratory deficiency

Discharge Criteria

Clinical course of botulism poisoning is unpredictable; it can become rapidly progressive and fatal:

- Discharge patients only after a prolonged period of progressive recovery from symptoms.

FOLLOW-UP RECOMMENDATIONS

- Physical medicine and rehabilitation:
 - Residual weakness can last for up to 1 yr
- Mental health:
 - Patients and their families often experience stress and depression with the prolonged recovery.

PEARLS AND PITFALLS

- Botulism is a public health emergency; early consultation with state and federal health departments is required.
- Suspect botulism if there are more than 2 cases; other conditions in the differential do not produce outbreaks.
- Antitoxin does not reverse paralysis but only halts its progression. Therefore, administer antitoxin once diagnosis is suspected. Do not wait until signs of respiratory compromise are present.
- Initial signs of respiratory distress may not be clinically apparent secondary to paralysis.
- Bulbar palsy at presentation may be mistaken for altered mental status.

BOWEL OBSTRUCTION (SMALL AND LARGE)

Jenny J. Lu

BASICS

DESCRIPTION

- Obstruction of normal intestinal flow from mechanical or nonmechanical causes
- Small-bowel obstruction (SBO):
 - 20% of acute surgical admissions
 - Adhesions: Most common cause (60%)
 - Neoplasms
 - Hernias
 - Strictures: Inflammatory bowel disease
 - Trauma: Bowel wall hematoma
 - Miscellaneous (e.g., ascaris infection)
- Large-bowel obstruction (LBO):
 - Disease primarily of the elderly
 - Carcinoma (60%)
 - Diverticular disease (20%)
 - Volvulus (5%)
 - Colitis (e.g., ischemic, radiation)
 - Crohn's disease
 - Foreign bodies
- Functional, nonmechanical:
 - Paralytic ileus (e.g., electrolyte abnormalities, injury)
 - Pseudo-obstruction (i.e., Ogilvie syndrome [e.g., operative and nonoperative trauma] 11%)

ETIOLOGY

- Obstruction leads to proximal dilatation of intestines due to swallowed air and accumulated GI secretions, leading to increased intraluminal pressures.
- Retrograde peristalsis causes vomiting.
- Distended bowel becomes progressively edematous, and additional intestinal secretions cause further distention and 3rd spacing of fluid into the intestinal lumen.
- Obstruction may lead to intestinal wall ischemia (strangulated obstruction), resulting in increased aerobic and anaerobic bacteria, and methane and hydrogen production. Peritonitis, sepsis, and death may follow.
- Mortality is 100% in untreated strangulated obstruction, 8% if treated surgically within 36 hr, but 25% if surgery delayed after 36 hr.

SIGNS AND SYMPTOMS

History

- Previous surgery, malignancy, hernias, colonoscopy history, significant family history
- Abdominal pain:
 - Intermittent when early
 - Symptoms may be vague in elderly or altered patients
 - Constant with strangulated obstruction
- Vomiting:
 - Bile-stained emesis with proximal obstruction
 - Feculent emesis with distal obstruction
- Obstipation, constipation, diarrhea
- Stool caliber changes, weight loss

Physical-Exam

- Vital signs:
 - Tachycardia, hypotension with significant volume depletion
 - Fever with strangulation or perforation
 - Hypothermia with sepsis
- Abdominal exam:
 - Distention
 - Variable tenderness, often diffuse
 - Hyperactive and high-pitched bowel sounds when early; hypoactive when late
 - Consider ischemic or gangrenous bowel if pain out of proportion to exam.
 - Peritoneal signs indicate strangulation or perforation.
- Hernia (ventral, inguinal, femoral)
- Digital rectal exam:
 - Rectal mass
 - Blood in stool, gross or occult

Geriatric Considerations

- Abdominal pain variable in elderly, may be vague
- Nausea/vomiting and abdominal pain are common symptoms in elderly patients with acute myocardial infarctions:
 - Abdominal distention, obstipation, and colicky pain suggest GI cause.

Pediatric Considerations

- Intussusception:

- Leading cause of intestinal obstruction in infants
- Most common between 3 and 12 mo of age
- Incarcerated inguinal/umbilical hernia
- Malrotation with volvulus:
 - Can occur as early as 3–7 days of age
 - “Double bubble” sign seen on plain radiograph owing to partial obstruction of duodenum, resulting in air in stomach and in 1st part of duodenum
- Pyloric stenosis:
 - Progressive, projectile, nonbilious postprandial vomiting
 - Male/female ratio: 5:1 incidence
 - Onset usually 2–5 wk of age
- Other causes include duodenal atresia, Hirschsprung, and imperforate anus.

ESSENTIAL WORKUP

Careful history and physical exam

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - Leukocytosis common
- Electrolytes, BUN/creatinine, glucose:
 - Hypokalemia
 - Hypochloremic metabolic alkalosis
 - Prerenal azotemia
- Lactate
- Amylase/lipase
- Liver enzymes/function to exclude hepatic/biliary pathology
- Stool heme test
- Urinalysis
- Type and crossmatch
- PT/PTT
- ECG in patients at risk of coronary artery disease

Imaging

- Upright CXR:
 - Evaluate for pulmonary pathology.
 - Check for free air beneath diaphragm.
- Plain abdominal radiographs, supine and upright (75% sensitivity; 53% specificity):
 - Distended loops of bowel (normal small bowel < 3 cm in diameter)
 - Distended cecum > 13 cm indicates potential for perforation.
 - Air–fluid levels

- “String of pearls” sign if small bowel loops nearly completely fluid filled
- Less helpful for distinguishing strangulation
- Abdominal CT:
 - Sensitivity:
 - 90% for SBO; 91% for LBO
 - Detects neoplastic causes and stages malignancy
 - Effective in defining location of obstruction
 - More helpful than plain radiographs in identifying early strangulation (with IV contrast)
 - Exclude other incidental findings/causes
 - Has decreased use of contrast enemas due to ease of use
- MRI:
 - Sensitivity approached that of CT
 - Availability variable
- US:
 - More sensitive and specific than plain films for SBO but not as accurate as CT

Diagnostic Procedures/Surgery

Upper GI/barium enemas/endoscopy:

- If carcinoma or mass lesion suspected as cause
- Use decreased with availability of CT scan
- May be painful or difficult in sick patients

DIFFERENTIAL DIAGNOSIS

- Paralytic ileus
- Pseudo-obstruction (Ogilvie)
- Perforated ulcer
- Pancreatitis
- Cholecystitis
- Colitis
- Mesenteric ischemia

TREATMENT

PRE HOSPITAL

Establish IV access for patients with dehydration, vomiting, or significant abdominal pain.

INITIAL STABILIZATION/THERAPY

- ABCs
- 0.9% normal saline (NS) or lactated ringers (LR) IV fluid resuscitation for

significant volume depletion and strangulated or perforated bowel:

- Adults: 1 L bolus
- Peds: 20 mL/kg bolus
- Correct electrolyte abnormalities, especially hypokalemia.

ED TREATMENT/PROCEDURES

- IV fluids (isotonic saline or lactated Ringer's)
- Nasogastric tube (NGT)
- Foley catheter to monitor urine output
- Surgical consultation
- Antibiotics for suspected strangulated/perforated bowel:
 - Antibiotic choices should cover gram-negative aerobic and anaerobic organisms:
- Analgesics
- Antiemetics
- Treat underlying etiology, appropriate steroids for inflammatory bowel disease, radiation enteritis

MEDICATION

- Antibiotic choices (broad spectrum, for suspected ischemia):
 - Combination therapy:
 - Metronidazole (Flagyl): 1 g IV, then 500 mg IV q6h (peds: 7.5–30 mg/kg/24h IV div. q6–8h)
 - Ciprofloxacin (Cipro): 400 mg IV q12h
 - Ceftriaxone (Rocephin): 1–2 g (peds: 25–75 mg/kg/d IV up to 2 g div. q12–24h) IV q24h
 - Single therapy:
 - Piperacillin–tazobactam (Zosyn): 3.375 g (peds: 150–400 mg/kg/24h IV div. q6–8h) IV q4–6h
 - Ampicillin–sulbactam (Unasyn): 1.5–3 g (peds: 100–400 mg/kg/24h IV div. q6h) IV q6h
 - Meropenem (Merrem): Adult: 1 g (peds: 60–120 mg/kg/24h IV q8h) IV q8h
 - Imipenem–cilastatin (Primaxin): 250–1,000 mg (peds: 50–100 mg/kg/24h IV q6–12h) IV q6–8h
- Analgesics:
 - Morphine: 2–10 mg/dose (peds: 0.1–0.2 mg/kg IV/IM/SC q2–4h) IV/IM/SC q2–6h PRN
- Antiemetics:
 - Ondansetron (Zofran): 4 mg (peds: 0.1 mg/kg IV div. q8h) IV q4–8h PRN
 - Promethazine (Phenergan): 12.5–25 mg (peds: > 2 yr: 0.25–1 mg/kg/d IV/IM/PR div. q4–6h PRN) IV/IM/SC q4h

FOLLOW-UP

DISPOSITION

Admission Criteria

All patients with suspected/confirmed intestinal obstruction should be admitted with early surgical consultation.

Discharge Criteria

Normal lab/radiology results with resolution of symptoms and no further suspicion for intestinal obstruction.

Issues for Referral

Surgery consult for patients with suspected bowel obstruction

FOLLOW-UP RECOMMENDATIONS

Discharged patients:

- Normal lab and radiologic studies
- Timely appointment for re-evaluation
- Explicit instructions detailing signs/symptoms to return to emergency department

PEARLS AND PITFALLS

- Carefully examine patient with history of vomiting for incarcerated hernias.
- Failure to diagnose strangulated bowel obstruction:
 - Symptoms potentially vague in very old and very young and in altered patients
- Failure to adequately replete fluid losses and electrolyte imbalances

BRADYARRHYTHMIAS

Benjamin S. Heavrin

BASICS

DESCRIPTION

- Ventricular heart rate < 60 beats/ min:
 - Sinus bradycardia can be normal variant.
 - All other rhythms are pathologic.
- May be asymptomatic or have hypotension, altered mental status, fatigue, nausea, syncope.
- Treatment varies based on ECG findings and clinical status.

ETIOLOGY

- Idiopathic:
 - Healthy athletes
- Intrinsic cardiac disorders:
 - Sinus node dysfunction such as sick sinus syndrome (may alternate with tachycardia)
 - Atrioventricular block:
 - Junctional or ventricular escape rhythm
 - Infiltrative disease:
 - Amyloidosis, sarcoidosis, hemochromatosis
 - Collagen vascular disease:
 - Systemic lupus erythematosus (SLE), scleroderma, rheumatoid arthritis
 - Anatomic abnormalities:
 - Congenital, postsurgical, post-transplant, postradiation
 - Muscular disorders:
 - Myotonic muscular dystrophy
 - Trauma with myocardial contusion
- Extrinsic disorders:
 - Cardiac injury and infarction:
 - RCA infarction can cause sinus bradycardia.
 - LAD infarction can cause high-grade block.
 - Acidemia
 - Medication and toxin effects:
 - β -Blockers, calcium channel blockers, digoxin, clonidine, antiarrhythmics, lithium, organophosphate
 - Electrolyte abnormalities:
 - Hypo-/hyperkalemia, hypoglycemia, hypo-/hypercalcemia, hypermagnesemia

- Vital sign abnormalities:
 - Hypoxia, hypothermia, hypotension, HTN
- Endocrine abnormalities:
 - Hypothyroidism
- Infectious disease:
 - Lyme disease, Chagas disease, diphtheria, endocarditis, myocarditis
- Neurologic disorders:
 - Increased intracranial pressure, increased vagal tone, carotid sinus hypersensitivity, spinal cord injury
 - Can be triggered by micturition, defecation, coughing, vomiting, ocular pressure, or other Valsalva maneuvers

Pediatric Considerations

Hypoxia is the most common etiology in children.

Pregnancy Considerations

Maternal SLE can result in congenital complete heart block.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Often asymptomatic
- Lightheadedness, confusion, fatigue, decreased level of consciousness
- Dyspnea, cyanosis, pallor
- Chest pain/pressure, diaphoresis
- Hypotension
- Syncope
- Hypothermia
- Cardiac arrest

History

- Medication changes, especially cardiac
- Urine output:
 - Hypokalemia with diuretics
 - Hyperkalemia with renal failure
- Trauma:
 - Intracranial injury
 - Myocardial contusion
- Activity at time of symptom onset:
 - Increased vagal tone

Physical-Exam

- Respiratory status
- Perfusion status, pulses
- Regular vs. irregular cardiac rhythm
- Mental status, thorough neuro exam
- Body habitus, skin/hair/nails
- Temperature

ESSENTIAL WORKUP

- ECG and continuous cardiac monitoring
- Pulse oximetry
- BP monitoring
- Glucose and electrolytes

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Serum glucose
- Serum electrolytes
- BUN and creatinine
- Cardiac enzymes
- Digoxin level
- Thyroid function tests
- ANA, RF, other rheumatologic testing
- Lyme titers
- Iron levels

Imaging

- CXR
- CT head if patient has altered mental status

Diagnostic Procedures/Surgery

EKG:

- Sinus bradycardia:
 - P wave before every QRS, QRS after every P wave, usually narrow QRS
- Sinoatrial block: Abnormal conduction between sinus node and atrium
- Sinus arrest:
 - No sinus activity, no P waves
- Atrioventricular block: Abnormal conduction between atria and ventricles:
 - 1st degree: PR > 0.2 sec, every P wave conducts a QRS complex
 - 2nd-degree type I, Mobitz I, Wenckebach: Progressive prolongation of PR interval with eventual dropped QRS, grouped beats
 - 2nd-degree type II, Mobitz II: Stable PR interval and intermittent dropped QRS, high risk of degeneration into 3rd-degree block

- 3rd-degree, complete heart block: Complete dissociation of atrial and ventricular activity, constant P-P interval and constant R-R interval, but no relation between the 2, unstable rhythm
- Junctional rhythm:
 - Loss of atrial conduction, AV pacemaker “escapes” at 40–60 bpm
 - Retrograde P waves may occur before, during, or after QRS, and QRS can be any duration
- Idioventricular rhythm:
 - Loss of both SA and AV nodal activity, bundle of His or Purkinje network takes over at 30–40 bpm
 - QRS always > 0.12 sec
 - Preterminal rhythm

DIFFERENTIAL DIAGNOSIS

- Normal variant
- Cardiac ischemia
- Medication toxicity
- Pacemaker malfunction
- Hypoxia
- Hypothermia
- Electrolyte abnormality
- Renal failure
- Hypothyroidism
- Infection
- Rheumatologic disease
- Neuromuscular disease
- Increased intracranial pressure
- Myocardial contusion

TREATMENT

PRE HOSPITAL

- Treat the patient, not the heart rate
- Oxygen:
 - For all patients, especially children
- If hypothermic, warm the patient and give magnesium:
 - Do NOT pace; move patient gently as rough handling can induce v-fib.
- Atropine or epinephrine:
 - Only with hypotension or altered mental status
 - Often ineffective or harmful in 3rd-degree block
- Transcutaneous pacing:
 - If other measures ineffective

INITIAL STABILIZATION/THERAPY

- ABCs
- Oxygen therapy
- Apply pacing pads and continuous cardiac monitoring
- IV access

ED TREATMENT/PROCEDURES

- Asymptomatic bradycardia:
 - Monitor while continuing workup
- Symptomatic or unstable bradycardia:
 - Oxygen
 - Atropine:
 - Symptomatic sinus bradycardia and symptomatic 1st- and 2nd-degree type I AV blocks
 - Usually ineffective for high-grade AV blocks
 - Epinephrine
 - Transcutaneous pacing
 - Transvenous pacing if transcutaneous pacing unsuccessful
- Find and treat underlying cause:
 - Hypoglycemia:
 - D50
 - Hypocalcemia:
 - Calcium gluconate
 - Hypercalcemia:
 - NS +/- Lasix
 - β -Blocker or calcium channel blocker overdose:
 - Glucagon, calcium gluconate, insulin, D50, intralipid emulsion
 - Hyperkalemia:
 - IV calcium, insulin with D50, albuterol, bicarb if acidotic, Lasix, Kayexalate, dialysis
 - Hypokalemia:
 - Potassium
 - Digoxin toxicity:
 - Digibind (Digoxin immune Fab)
 - MI:
 - ASA, Plavix, heparin, statin, cath lab
 - Hypothyroidism:
 - Levothyroxine
 - Hypothermia:
 - Warm O₂, warm IVF, Bair Hugger, blankets, warming lights, consider warm bladder and gastric irrigation, cardiopulmonary bypass
 - Infection:
 - Targeted antibiotics, antivirals, or antifungals

- Myocardial contusion:
 - Supportive care
- Increased intracranial pressure:
 - Mannitol, neurosurgical consult
- Pacemaker malfunction:
 - Interrogate pacemaker, cardiology consult
- Idiopathic:
 - Cardiology consult for ICU admission and pacemaker placement

MEDICATION

- Atropine: 0.5–1 mg (peds: 0.02 mg/kg; min. 0.1 mg) IV q3–5 min; max. 3 mg or 0.04 mg/kg
- Calcium gluconate: 1,000 mg (peds: 60 mg/kg) IV q3–5min, max. 3 g
- D50: 1–2 amps (peds: D10 or D25 2–4 mL/kg) IV
- Digoxin immune Fab: Dose varies with amount of digoxin ingested, average 6 vials (peds: Average dose, 1 vial) IV bolus; see package insert
- Epinephrine: 0.1–0.5 mg (peds: 0.01–0.03 µg/kg/min) IV q3–5min; infusion 2–10 µg/min (peds: 0.1–1 µg/kg/min) IV
- Glucagon: 3–5 mg (peds: 0.05 mg/kg) IV, can repeat once; infusion 1–5 mg/h (peds: 0.07 mg/kg/h) IV for BB or CCB overdose
- Insulin regular: 10 U (peds: 0.1 U/kg) IV × 1 with glucagon for BB or CCB overdose. Higher doses may be appropriate after tox. consult.

First Line

Atropine, epinephrine, pacing

Second Line

Treatment for specific disorders

FOLLOW-UP

DISPOSITION

Admission Criteria

- ICU:
 - Hemodynamically unstable bradycardia
 - 2nd-degree type II or 3rd-degree block
 - Transcutaneous or transvenous pacer
 - Pressors
 - Acute myocardial infarction or ischemia
- Telemetry:
 - Hemodynamically stable bradycardia

Discharge Criteria

Asymptomatic sinus bradycardia

Issues for Referral

- All patients without existing primary care physicians should be referred to a generalist for follow-up as needed.
- 1st- and 2nd-degree type I AV block need cardiology referral.
- Severe endocrine, rheumatologic, infectious, renal, or neurologic disorders require appropriate specialty referral.

FOLLOW-UP RECOMMENDATIONS

- Minor lab abnormalities that do not require admission require PCP follow-up.
- All patients except asymptomatic sinus bradycardia require cardiology follow-up.
- Specific disorders require appropriate specialty follow-up.

PEARLS AND PITFALLS

- Asymptomatic sinus bradycardia is the ONLY potentially “normal” bradycardia. All others require treatment or follow-up.
- O₂, O₂ sat, IV, ECG, cardiac monitor for all patients.
- Pediatric bradycardia is likely secondary to hypoxia.
- Have pacing pads available for all symptomatic patients.
- The most important treatment targets the underlying cause.

- I49.8 Other specified cardiac arrhythmias

BRONCHIOLITIS

Suzanne Schuh

BASICS

DESCRIPTION

Lower respiratory tract infection by airway inflammation and bronchoconstriction with wheezes/tachypnea and respiratory distress and upper respiratory prodrome

ETIOLOGY

- Respiratory syncytial virus (RSV) in 85–90% of cases
- Influenza
- Parainfluenza
- Adenovirus
- Normally occurs during the winter months

DIAGNOSIS

SIGNS AND SYMPTOMS

- Age < 2 yr (usually 1 yr or younger)
- Nasal congestion, often with marked rhinorrhea
- Cough, sometimes associated with vomiting
- Wheezing
- Crackles, rhonchi
- Respiratory distress manifested by tachypnea, nasal flaring, retractions, grunting. Often progressive over a period of 1–3 days
- Fever usually < 39.5°C
- Hypoxemia may be present (usually mild). Cyanosis rare
- Decreased fluid intake common, frank dehydration uncommon
- Apnea may occur, particularly in young infants with history of prematurity
- Synagis, an RSV specific immunoglobulin, may be administered IM monthly during winter months in high-risk children. This reduces risk of RSV infection.

ESSENTIAL WORKUP

- Clinical diagnosis
- Defining viral cause may be useful for cohorting in hospital if admitted.
- Assess ventilation clinically.
- Pulse oximetry:
 - Confirms proper oxygenation on continuing basis
 - Follows trends over the course of illness

DIAGNOSIS TESTS & NTERPRETATION

Lab

- Most patients need no specific tests beyond oximetry.
- Nasopharyngeal aspirate/wash:
 - Viral cultures
 - Fluorescent antibodies
 - Commercial kits are available.
 - Consider when:
 - Clinical symptoms suggestive of other cause (pertussis, chlamydia)
 - Critically ill child
 - Febrile child < 3 mo old with bronchiolitis (consider UTI as coexistent cause of fever)
 - Coexisting signs suggesting significant bacterial infection (positive aspirate does not exclude coexisting significant bacterial infection but such infections are uncommon)
 - Bronchopulmonary dysplasia or chronic lung disease
 - Coexistent cardiac disease
 - Prematurity
 - Other conditions warranting antiviral therapy (rare)

Imaging

CXR:

- Usually hyperinflation, airway disease, atelectasis, variable infiltrate:
 - Atelectasis in young infants indicates more severe disease.
- Minority have airway + airspace disease; pneumonia usually viral
- Rarely changes management acutely
- Consider when:
 - Need to exclude other diagnoses such as CHF, aspiration, congenital airway anomaly (rare)
 - Chronic course with lack of resolution over 2–3 wk
 - Critically ill infants with impending respiratory failure
 - Atypical presentation in toxic or deteriorating child
 - Not routinely indicated in typical clinical presentation

Diagnostic Procedures/Surgery

- Septic workup in febrile bronchiolitis < 28 days of age if respiratory status permits
- In febrile infants 1–3 mo of age, consider catheterized urine culture
- Oximetry during significant distress

DIFFERENTIAL DIAGNOSIS

- Asthma/recurrent virus-induced wheezing: Severe bronchiolitis requiring hospitalization, and family history of atopy are risk factors for future asthma.
- Pertussis: No respiratory distress between coughing spasms, no wheezing
- Bacterial pneumonia: Often toxic appearance, no wheezing, isolated airspace

- disease (consolidation) with no airway abnormality on chest radiograph
- Foreign body: Sudden onset of symptoms, usually afebrile
- CHF: Pre-existing clinical red flags (failure to thrive [FTT], feeding problems)

TREATMENT

PRE HOSPITAL

ALERT

- Young infants have limited respiratory reserve and decompensate rapidly with little warning.
- Monitor cardiorespiratory status and oxygenation.
- Supplemental oxygen if saturation $< 90\text{--}92\%$ (sea level) and/or severe distress
- Watch for apneic pauses:
 - Greatest risk of developing high-risk outcomes in children < 7 wk, weight < 4 kg, respiratory rate $> 80/\text{min}$, heart rate $> 180/\text{min}$, comorbidities, premature
 - Bag-mask ventilation if recurrent apneas

INITIAL STABILIZATION/THERAPY

- Pediatric advanced life support: Airway, ventilation, and fluid hydration
- Emergent intubation if recurrent apneas, impending respiratory failure

ED TREATMENT/PROCEDURES

- Supplemental oxygen if oxygen saturation $< 90\text{--}92\%$ (sea level)
- Parenteral hydration if dehydration or severe respiratory distress. Many children may improve their intake once respiratory status has improved.
- Many children with bronchiolitis do not benefit from pharmacotherapy.
- Bronchodilators (albuterol, racemic epinephrine, l-epinephrine, levalbuterol):
 - Should not routinely be used alone without determination of efficacy
 - Some clinicians administer on trial basis with 2–3 consecutive treatments in those with moderate to severe distress and continue as part of management if there is a clear decrease in the work of breathing.
 - Often utilized in significantly ill children
- Steroids:
 - On their own do not change clinical course or hospitalizations in the majority of patients without prior atopic or family history.
 - 2 doses of 1:1,000 l-epinephrine 30 min apart in the ED + 6 daily doses of oral dexamethasone may be useful in moderate to severe distress—reduces admissions by 35% by day 7, shortens time to discharge and duration of symptoms
 - Conflicting evidence with another recent dexamethasone trial showing no benefit when used alone—synergy between steroids and epinephrine likely

critical for efficacy

- Often used empirically in children with past or family history of atopy. Prednisolone common for this usage.
- Albuterol–dexamethasone combination efficacy not confirmed in a big trial.
- Bronchodilators alone after discharge not effective unless there was demonstrated effectiveness prior to discharge.
- Antibiotics:
 - Not generally indicated since viral etiology
 - Consider if associated signs of focal bacterial disease (otitis, focal pneumonia), radiographic evidence of isolated lobar consolidation without airway disease (usually bacterial pneumonia rather than bronchiolitis), significant toxicity, sepsis
- Ribavirin:
 - No role in ED management and rarely used in the inpatient setting

MEDICATION

- Albuterol: 2.5 mg/3 mL, 2–3 doses via nebulizer or 400 mcg via MDI/spacer 20–30 min apart in the ED. A therapeutic trial can be considered but continue only if there is a clear improvement in the work of breathing. Does not change overall disease outcomes.
- Levalbuterol: 1.25 mg/dose, 2–3 doses via nebulizer, 20–30 min apart in the ED (see above).
- l-epinephrine: 3 mL (1:1,000 solution), 2 doses via nebulizer 30 min apart in the ED or with
- Dexamethasone: 1 mg/kg/dose PO in the ED, then 0.15 mg/kg daily for 5 days
- Prednisolone (15 mg/5 mL): 1–2 mg/kg/d PO BID/3–5 d
- Comment 1: Most children require no medications. Bronchodilators alone rarely change outcomes. Initial trial of albuterol should be extended only if clear clinical improvement. Epinephrine–dexamethasone combination shown to decrease hospitalizations by day 7 of illness and may warrant consideration.
- Comment 2: Although no trial to date has identified any pharmacotherapeutic agent to change the course of the disease, a recent meta-analysis found that (a) inhaled epinephrine alone and epinephrine + oral dexamethasone appear to have half the odds of hospitalization compared to placebo and (b) salbutamol does not reduce hospitalizations in bronchiolitis.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Need for supplemental oxygen (oxygen saturation on room air is < 90–92% at sea

level)

- Some institutions have developed protocols that allow full-term, stable children >6 months of age, who are well hydrated, have compliant parents, and good follow-up to be discharged on minimal oxygen after a prolonged period of observation in the ED.
- Inability to self-hydrate
- Marked increase work of breathing (tachypnea with retractions or accessory muscle use)
- Apnea
- Severe underlying chronic lung disease or cardiac disease
- Persistent marked respiratory distress 4 hr after a trial of epinephrine and dexamethasone
- Significant comorbidity/suspicion of alternative diagnosis/underlying systemic disease/immunodeficiency or immunosuppressive therapy
- Strongly consider in infants <7 wk, weight <4 kg, respiratory rate >80/min, heart rate >180/min, comorbidities, or prematurity
- Caretaker noncompliant or unable to monitor child closely

Discharge Criteria

- Feeding reasonably well
- Acceptable room air saturation (see above)
- Absence of significant respiratory distress
- Follow-up available within 24 hr
- Compliant home environment
- Discharge instructions:
 - Symptoms may persist for 2–3 wk
 - Frequent small feeds
 - Bronchodilators after discharge not uniformly beneficial

FOLLOW-UP RECOMMENDATIONS

Because of the progressive nature of bronchiolitis close follow-up is required, particularly early in the illness alerting parents to the likelihood of worsening respiratory distress, dehydration, and apnea.

PEARLS AND PITFALLS

Infants with bronchiolitis often present with respiratory distress associated with hypoxia, dehydration, and/or apnea. Aggressive monitoring may be warranted.

- J21.1 Acute bronchiolitis due to human metapneumovirus
- J21.9 Acute bronchiolitis, unspecified

BRONCHITIS

Robin R. Hemphill

BASICS

DESCRIPTION

- Hyperemia and edema of the mucous membranes
- Production of mucopurulent exudates
- Impairment of the productive function of the cilia, lymphatics, and phagocytes
- Airway obstruction from:
 - Edema
 - Secretions
 - Bronchial muscle spasm

ETIOLOGY

- Viral infections are the primary cause of bronchitis:
 - Parainfluenza
 - Influenza A and B
 - Respiratory syncytial virus
 - Human metapneumovirus
 - Echovirus
 - Coronavirus
 - Adenovirus
 - Coxsackievirus
 - Rhinovirus
 - Measles and herpes viruses (can cause severe viral bronchitis)
- Particularly severe or long-lasting bronchitis:
 - *Mycoplasma pneumoniae*
 - *Chlamydia pneumoniae*
 - *Bordetella pertussis*:
 - Rates of pertussis are increasing, even in the fully immunized population (little protection remains after 10 yr).
- Other bacteria have not been conclusively proven to cause bronchitis except in those with chronic lung disease.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Complaints that may precede upper respiratory tract infection (URTI) symptoms:

- Malaise
- Chills
- Myalgias
- Coryza (rhinitis)
- Sore throat
- Onset of URTI symptoms:
 - Mild dyspnea
 - Cough, initially dry and nonproductive
 - Cough, later becomes mucoid or mucopurulent
 - Chest pain or burning related to cough
 - Initial symptoms improve after 3–5 days, with 1–3 wk of residual cough and malaise

Physical-Exam

- Fever, not usually above 102°F (38.5°C)
- Tachypnea
- Mild hemoptysis
- Ronchi (wheezing)
- Rales (crackles)

ESSENTIAL WORKUP

- Influenza A and B testing if identification of these organisms is required for treatment or reporting
- Evaluate for pertussis:
 - Acute cough illness lasting 14 days or more in a person with paroxysmal cough, post-tussive vomiting, or inspiratory whoop
 - 14 days or more of cough within an outbreak setting

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Influenza A and B testing may help immediately confirm clinical suspicion.
- In most cases, no specific test will help make the diagnosis immediately.
- Viral or bacterial cultures are rarely helpful.
- CBC may show leukocytosis, but is a nonspecific finding.
- Pertussis may be confirmed using PCR testing, but diagnosis will be delayed.

Imaging

CXR:

- No evidence of consolidation
- Indications:
 - Shortness of breath
 - Hypoxia

- Chest pain
- Heart rate > 100 beats/min
- Respiratory rate ≥ 24 breaths/min
- Temperature ≥ 38°C
- Focal findings on chest exam
- Elderly patient with multiple comorbid conditions
- Hypoxia
- 14 days or more of cough

Diagnostic Procedures/Surgery

Pulmonary function tests are frequently abnormal.

DIFFERENTIAL DIAGNOSIS

- Acute and subacute < 8 wk:
 - Pneumonia
 - Reactive airway disease
 - Aspiration
 - Acute sinusitis
 - Bacterial tracheitis
 - Occupational exposure
- Chronic > 8 wk:
 - Asthma
 - GERD
 - Chronic bronchitis
 - Bronchiectasis
 - ACE inhibitor use
 - Bronchogenic carcinoma
 - Carcinomatosis
 - Sarcoidosis
 - Left ventricular failure
 - Aspiration syndrome
 - Psychogenic/habit

TREATMENT

PRE HOSPITAL

- Maintain adequate oxygenation
- Bronchodilators if wheezing is present

INITIAL STABILIZATION/THERAPY

- Aggressive initial management of these patients is seldom required.
- Administer oxygen if the patient is hypoxic.

- Fluids may be administered if the patient is dehydrated.

ED TREATMENT/PROCEDURES

- Bronchitis is usually a viral process, but may be bacterial and there is no practical test to distinguish between the 2:
 - Because this is usually a viral process, treatment is symptomatic:
 - Cough suppressants may be considered.
 - β -Adrenergic inhaler for patients with evidence of airflow obstruction
- Amantadine may be used in known outbreaks of influenza A, although local patterns of resistance should be reviewed.
- Oseltamivir (Tamiflu) and zanamivir (Relenza) may be considered in patients with recent onset of influenza.
- Antibiotics:
 - Generally, antibiotics are not indicated (even when secretions are purulent).
 - In healthy patients with no underlying lung disease, antibiotics may help some patients get better slightly faster, but weighed against the many people it does not help, cost, side effects, and resistance, antibiotics are not recommended.
 - Consider use in those patients who have recurrence of fever after initial improvement.
- Symptomatic control with antipyretics and analgesics
- Although patients should be encouraged to stop smoking, the use of tobacco is not an indication for antibiotics unless the patient has a known history of emphysema.

ALERT

Be aware that respiratory viruses can cause significant morbidity in immunocompromised patients and their care should be discussed with their primary care physician.

Pediatric Considerations

- Aggressive initial management of these patients is seldom required.
- Administer oxygen if the patient is hypoxic.
- Fluids may be administered if the patient is dehydrated.
- Repeated bouts in children should lead to referral for complete evaluation of the respiratory tract.

MEDICATION

- Albuterol Inhaler may be used for those with evidence of airflow obstruction.
- Amantadine: 100 mg/d PO, must be given within 48 hr of symptom onset
- Oseltamivir (Tamiflu) and zanamivir (Relenza) within 48 hr of symptom onset for influenza-related bronchitis:
 - Zanamivir: 10 mg inhalation q12h (peds: >7 yr 10 mg or 2 inhalations q12h) \times 5 d

– Oseltamivir: 75 mg PO BID (peds: 2 mg/kg) × 5 d

- Erythromycin should be given to proven cases of pertussis and to household contacts of those with proven pertussis.
- Yearly influenza vaccinations should be encouraged in health care providers and in the high-risk populations (elderly, immunocompromised, chronic lung disease).

Geriatric Considerations

- Use of acetaminophen rather than aspirin for analgesia
- Antibiotic considerations are the same as in adults.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Underlying significant cardiopulmonary compromise
- Significant hypoxia
- Ill patient with unclear diagnosis

Discharge Criteria

- No pulmonary compromise should be present.
- Instruct patients, particularly high-risk patients, to return if no improvement or worsening of symptoms occurs.
- Bed rest
- Fluids
- Aspirin or acetaminophen

FOLLOW-UP RECOMMENDATIONS

- No follow-up is needed in those patients that improved.
- Patients should be instructed to return to the ED for onset of shortness of breath and should see their doctor if not improved after 2–3 wk.

PEARLS AND PITFALLS

Patients with high fever or significant pulmonary symptoms should be evaluated for pneumonia.

BRUGADA SYNDROME

Edward Ullman • John W. Hardin

BASICS

DESCRIPTION

- Inherited heart disease due to mutations of cardiac Na⁺ channels without structural abnormalities
- Very high risk of sudden cardiac death in the form of ventricular fibrillation
- 2-yr mortality ~ 30%
- Suspected in 40–60% of what was previously known as idiopathic ventricular fibrillation
- Higher prevalence in men of Southeast Asian descent, but all ages, genders, races can be affected

ETIOLOGY

- Inherited:
 - Autosomal dominant in 50%
 - Variable penetration
- Cardiac Na⁺ channel:
 - >70 described mutations
 - Variable penetrance
 - SCN5A mutations account for 20%

DIAGNOSIS

SIGNS AND SYMPTOMS

- Most commonly presents as episodes of sudden death (in ventricular fibrillation) or as syncope or near-syncope in self-terminating episodes of polymorphic ventricular tachycardia

History

- HPI:
 - Episodes of syncope or near-syncope
 - Palpitations
 - Cardiac arrest
 - Concomitant illness, fever, metabolic, or electrolyte disorders
 - Cocaine use
 - TCA and psychotropic drugs
 - Nocturnal agonal respirations
- Family history:

- History of drowning due to syncope or dysrhythmias while submerged
- History of early and/or sudden cardiac death
- Known relatives with Brugada syndrome

Physical-Exam

- Complete physical exam, with special attention to other causes of syncope or dysrhythmia:
 - Abnormal heart sounds
 - Pectus excavatum (normal variant EKG changes)
 - Athletes
 - Pacemaker in situ

ESSENTIAL WORKUP

- A 12-lead EKG is imperative
- Detailed HPI and family history
- Toxicology screen

DIAGNOSIS TESTS & INTERPRETATION

EKG Diagnostic Criteria

- Basic:
 - Right bundle branch block (RBBB) or Incomplete right bundle branch block (IRBBB) with ST-segment elevation in the right precordial leads only
- Morphology of QRS-T in V1–V3
 - ST-elevation
 - Sometimes only in V1 and very rarely in V3
- Type 1 (coved pattern):
 - Initial ST-elevation ≥ 2 mm, slowly descending, concave with respect to the isoelectric line
 - Negative symmetric T-wave
 - No clear r'
 - QRS duration mismatch between V1 and V6
- Type 2 (saddle back pattern):
 - High r' take-off is ≥ 2 mm with respect to the isoelectric line
 - Followed by ST-elevation – convex with respect to the isoelectric line
 - QRS duration mismatch between V1 and V6

Lab

- Serum:
 - Chemistries to rule out underlying electrolyte causes of dysrhythmia or syncope
 - Cardiac biomarkers (troponin, CK-MB) for ischemia
 - D-dimer in the appropriate population (Wells, PERC) if considering

- pulmonary embolism
- CBC for evaluation of syncope

Imaging

- CXR:
 - Evaluate for cardiomegaly
- CT-angiogram of the chest:
 - If considering pulmonary embolism as a cause

Diagnostic Procedures/Surgery

- Electrophysiology lab
 - Drug challenge with sodium channel blockers (type 1a and 1c)
- AICD placement
 - Mortality reduced to 0% in this group

DIFFERENTIAL DIAGNOSIS

- Syncope:
 - Primary cardiogenic
 - Vasovagal
 - Neurogenic
 - Hypovolemia
 - Pregnancy
- Dysrhythmias:
 - Paroxysmal atrial fibrillation
 - Atrial fibrillation with rapid ventricular response
 - Wolff–Parkinson–White syndrome
 - Lown–Ganong–Levine syndrome
 - Ventricular tachycardia
 - Multifocal atrial tachycardia
 - Spontaneously terminating ventricular fibrillation
 - Symptomatic bradycardia
 - High-grade heart blocks
 - Long QT syndromes
 - Overdose especially TCA
- EKG mimics:
 - Isolated RBBB
 - Athletes
 - Septal hypertrophy
 - Pectus excavatum
 - Arrhythmogenic right ventricular dysplasia
 - STEMI
- Other systemic illness:
 - Electrolyte disturbances

- Pericarditis
- Myocarditis
- Myopericarditis
- Pulmonary embolism

TREATMENT

PRE HOSPITAL

- Airway, breathing, and circulation management
- ACLS protocol for arrest/dysrhythmias

INITIAL STABILIZATION/THERAPY

- Airway, breathing, and circulation management
- Start or continue ACLS algorithms

ED TREATMENT/PROCEDURES

- Cardiac monitoring at all times
- Cardiology consult:
 - For electrophysiology evaluation
- Defibrillator/pacing pads
- Correct underlying disease processes:
 - Replete electrolytes
 - Correct metabolic derangements
 - Asymptomatic patients' management controversial. Current consensus states EP evaluation but not supported in literature.

MEDICATION

- ACLS medications per protocol
- Antiarrhythmics usually not helpful

Pediatric Considerations

- PALS/defibrillation
- Appropriate weight-based medication and energy (joule) adjustments

FOLLOW-UP

DISPOSITION

Admission Criteria

- EKG findings concerning for Brugada in the appropriate clinical setting
- Unexplained syncope
- Inability to obtain rapid cardiology follow-up

- Ongoing dysrhythmias even if they are spontaneously terminating

Discharge Criteria

- Hemodynamically stable
- Asymptomatic
- Cardiology clearance
- Appropriate AICD intervention after an event
 - After interrogation of AICD

FOLLOW-UP RECOMMENDATIONS

- All patients with concerning EKG findings and history should be referred to EP for additional evaluation

PEARLS AND PITFALLS

- Consider in any episodes of sudden cardiac death or syncope, especially in the setting of family history of the same
- The EKG is diagnostic showing RBBB or IRBBB with ST-segment elevation in the right precordial leads only
- Beware of EKG mimics which can have similar presentation – typically mimics will have concordant QRS duration in V1 and V6 whereas Brugada QRS changes should be isolated to V1–V3
- Have a low threshold for cardiology consultation given high risk of death
- AICD implantation is definitive treatment, almost eliminating risk of sudden cardiac death
- Antiarrhythmic agents have not been found to be helpful
- The Brugada pattern may be “unmasked” in systemic illness, even if resolution of the EKG occurs, the patient should still have EP follow-up

ICD9

746.89 Other specified congenital anomalies of heart

ICD10

- I49.8 Other specified cardiac arrhythmias
- Q24.8 Other specified congenital malformations of heart

BUNDLE BRANCH BLOCKS

Annette Dorfman • James Scott

BASICS

DESCRIPTION

- Blockage of intraventricular electrical impulses through the right and left bundles
- Complete bundle branch block:
 - Absence or delay of conduction down one bundle, with normal conduction down the other bundle
 - Affected ventricle depolarizes from muscle to muscle in a slower and more disorganized fashion.
 - Quasi-random signal (QRS) complex at 120 msec or longer
- Incomplete bundle branch block:
 - Delayed depolarization, but less than complete bundle branch block
 - QRS complex duration 100–120 msec
- Right bundle branch block (RBBB):
 - Delayed depolarization of the right ventricle
- Left bundle branch block (LBBB):
 - Delayed depolarization of the left ventricle
 - LBBB can be caused by delay of conduction in main left bundle or delay in both fascicles of the left bundle.
 - Causes early activation of the right side of the septum and the right ventricular myocardium (so explaining loss of “septal Q” on ECG)
 - Left bundle branches into 2 fascicles:
 - Left anterior fascicle: Initial septal activation proceeds inferiorly, anteriorly, and to the right.
 - Left posterior fascicle: Isolated blockage rare; activation begins in the midseptum and finishes in inferior and posterior walls.
- Bifascicular block:
 - RBBB with concomitant block of the left anterior or left posterior fascicle

ETIOLOGY

- Myocardial infarction
- Cardiomyopathy
- Hypertension
- Age-related fibrosis of Purkinje fibers
- Valvular disease
- Exercise induced
- Congenital/atrial septal defect
- Brugada syndrome (RBBB): Cause of sudden cardiac death in otherwise healthy

patients.

- Chagas disease (especially Central/South America)
- Postoperative, following cardiac surgery
- Drugs:
 - β -Blockers
 - Calcium blockers
 - Tricyclic antidepressants
 - Type Ia and Ic antiarrhythmics
 - Digitalis

DIAGNOSIS

SIGNS AND SYMPTOMS

- Asymptomatic
- RBBB: Split S_2 that persists with expiration
- LBBB: Reversed/paradoxical split S_2
- Syncope
- Chest pain

ESSENTIAL WORKUP

ECG:

- RBBB:
 - Complete: QRS complex ≥ 0.12 sec
 - Incomplete: QRS complex duration 0.10–0.12 sec
 - rsr' , rsR' , rSR' in V_1 or V_2 (*M* shape)
 - Wide and deep S-wave in V_5 – V_6
 - Brugada syndrome: RBBB and ST-segment elevation in V_1 – V_3
- LBBB:
 - Broad slurred R-waves in leads V_5 – V_6 , aVL, and I
 - Small/absent R-wave in V_1 – V_2 and deep S-waves
 - Absence of normal Q-waves in leads V_5 – V_6 and I
- Left anterior fascicular block:
 - QRS complex < 120 msec, axis 45° – 90°
 - Deep S-wave in leads II, III, aVF, qR in leads aVL and I
- Left posterior fascicular block:
 - QRS < 120 msec, axis $\geq 120^\circ$
 - RS-waves in leads I and aVL, qR in leads II, III, and aVF
 - Exclusion of other things causing right axis deviation (right ventricle overload, right ventricular hypertrophy, lateral infarction)

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Electrolytes if hyperkalemia, hypercalcemia are suspected
- Cardiac enzymes if ischemia is suspected

Imaging

- CXR:
 - May reveal cardiac enlargement or CHF
- Electrophysiologic testing:
 - Especially for unexplained syncope in patient with structural heart disease, as part of inpatient workup

DIFFERENTIAL DIAGNOSIS

- Ventricular tachycardia
- MI:
 - Criteria for diagnosing MI with LBBB (Sgarbossa criteria) include any of the following:
 - ST-segment elevation ≥ 1 mm concordant with QRS
 - ST-segment elevation ≥ 5 mm discordant with QRS
 - ST-segment depression ≥ 1 mm in leads V_1 – V_3
- Hyperkalemia
- Ventricular hypertrophy
- Drug effects (see “Etiology” section)

TREATMENT

PRE HOSPITAL

Cautions:

- Monitor: Difficult to diagnose from single lead
- Avoid confusing with ventricular tachycardia or ischemia, use.
- Treat patient; bundle branch block requires no specific therapy.

INITIAL STABILIZATION/THERAPY

- Standard treatment for symptoms of ischemia, dyspnea, and syncope
- Symptomatic bifascicular block and high-degree atrioventricular block:
 - Apply transcutaneous pacing pads to back and chest.
 - IV sedation and analgesia
 - Gradually increase current until capture is achieved.

ED TREATMENT/PROCEDURES

- Asymptomatic: None
- Thrombolysis or cardiac catheterization for symptoms suggestive of myocardial infarction and new bundle branch block

- Transvenous pacemaker indications:
 - Bifascicular block and type II 2nd- or 3rd-degree atrioventricular block
 - Alternating LBBB and RBBB

FOLLOW-UP

DISPOSITION

Admission Criteria

- Suspected myocardial ischemia
- Syncope
- Dysrhythmias
- Bundle branch block with high-degree atrioventricular block

Discharge Criteria

Asymptomatic or incidental finding of bundle branch block

Issues for Referral

At discharge, patient should be referred to cardiologist for evaluation of underlying disease.

FOLLOW-UP RECOMMENDATIONS

- Reassure patients that usually no treatment is needed.
- Instruct patient to return or call for help if:
 - Dizziness
 - Fainting
 - Palpitations

PEARLS AND PITFALLS

- Myocardial ischemia should be considered in all patients who develop new conduction abnormalities.
- Specific criteria can be used to diagnose cardiac ischemia in patients with a bundle branch block.

ADDITIONAL READING

- I45.4 Nonspecific intraventricular block
- I45.10 Unspecified right bundle-branch block

BURNS

Gabriel Wardi • Anthony J. Medak

BASICS

DESCRIPTION

Burns represent an acute injury to the flesh.

ETIOLOGY

Burns can be classified into 7 categories

- Scalds: Hot liquids, grease, or steam
- Contact: Hot or cold surfaces
- Thermal: Fire or flames
- Radiation burns
- Chemical burns
- Electrical burns
- Friction burns: Road rash, rope burns

DIAGNOSIS

SIGNS AND SYMPTOMS

- Most burns will have external signs of trauma to the skin
- Inhalation injury
 - _ Facial burns, pharyngeal injection
 - _ Singed nasal hair/eyelashes
 - _ Carbonaceous sputum
 - _ Change in respiratory mechanics (wheezing, coughing, tachypnea)
- Electrical and chemical burns may have minimal external findings (entry/exit wounds)

History

- AMPLE history, source of fire (plastic, wood, chemical, etc.), the location and surroundings, any explosions
- Medical/surgical/social history, medications, allergies, tetanus immunization status
- Carbon monoxide (CO) poisoning (most common cause of death in fires) from exposure to wood-based fires/combustion:
 - _ Pulse oximetry unreliable in CO poisoning
- Cyanide poisoning from burning wool, silk, nylon, and polyurethane found in furniture/paper

Physical-Exam

- Focus on airway 1st, then secondary survey for concurrent injuries
- Evaluate the face, oropharynx, and nares for signs of inhalation injury
- Assess need for immobilization of cervical spine (explosion or falls)
- Eye exam for corneal burns
- Estimate severity of partial- and full-thickness burns by assessing size/depth of burn

Pediatric Considerations

Specific patterns of injury may indicate nonaccidental injury (immersion wounds, cigarette burns, etc.)

ESSENTIAL WORKUP

- Severity of the burn should be assessed by determining the size and depth of the burn
- Size is reported as percent involvement of total body surface area (TBSA) in 1 of 3 ways:
 - 1: Rule of nines (applies only to adults)
 - TBSA of body parts is estimated by multiples of 9%
 - Adult estimates of percentage of TBSA
 - Head and neck: 9
 - Arms: Right, 9; left, 9
 - Legs: Right, 18; left, 18
 - Trunk: Front, 18; back, 18
 - Perineum, palms: 1
 - In infants and children, the head contributes more to the percentage of TBSA and legs contribute less.
 - Infants/children
 - Head and neck: 18
 - Arms: Right, 9; left, 9
 - Legs: Right, 14; left, 14
 - Trunk: Front, 18; back, 18
 - 2: Lund and Browder chart; divides body into areas and assigns percentage of BSA based on age; produces more reliable results than rule of 9s
 - 3: Palm surface area; patient's palm and fingers represent ~1% of TBSA
 - Helpful in assessing irregular/scattered burns
 - Superficial or 1st-degree (epidermis only) when: Local erythema, minimal swelling/pain, no initial blisters (may occur in 2–3 days); healing occurs in several days, no scar
 - Partial-thickness or 2nd-degree burns (epidermis and dermis): Superficial partial-thickness or deep partial-thickness burns:
 - Superficial partial-thickness burns (epidermis and superficial dermis)
 - Often seen in scald burns

- Generally with blister formation, underlying skin is pink, moist, painful, good capillary refill, sensation intact
- Heals in 14–21 days, generally no scars
- Deep partial-thickness burns (epidermis and deep dermis)
 - Skin may be blistered, with white to yellow dermis; absent capillary refill/pain sensation
 - Heals via epithelialization within 3–12 wk, although may cause severe scarring and contractures requiring surgery
- Full-thickness or 3rd-degree burns (through epidermis and dermis)
 - Skin is charred, leathery, and pale, no blisters, sensation is absent
 - Will not heal spontaneously; will require surgical repair and skin grafting
- Full-thickness burns or 4th-degree burns (damage to underlying structures)
 - Full-thickness + involvement of underlying fascia, muscle, bone, and other tissues
 - Requires extensive débridement/grafting
 - Resultant disability

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Severe burns: CBC, serum electrolytes, glucose, BUN, creatinine, PT/PTT, type and crossmatch, and pregnancy test (if indicated)
- Blood gas with CO level for closed space or suspected inhalation exposures
- Cyanide level (if indicated)

Imaging

CXR

Diagnostic Procedures/Surgery

- Bronchoscopy to assess for inhalation injury
- ECG, especially in electrical burns, elderly patients

DIFFERENTIAL DIAGNOSIS

- Electrical injury
- Chemical injury
- Associated trauma or intoxication

TREATMENT

PRE HOSPITAL

- Stop the burning process, remove smoldering/contaminated clothes/jewelry
- Keep patient warm, cool affected areas

- Establish patent airway, frequent reassessment, start 100% oxygen
 - Early intubation for respiratory distress
- Early IV fluid therapy, especially if >20% TBSA
- Institute pain relief, with narcotics if possible
- Protect the wound with clean sheets
- Transport to burn center (for major burns) if transport time <30 min
- Spinal immobilization if mechanism is concerning

INITIAL STABILIZATION/THERAPY

- Airway control is paramount
 - Early intubation for patients with signs of upper airway involvement, significant nasolabial burns, or circumferential neck burns
- IV access, supplemental 100% oxygen, monitor, pulse oximetry
- Evaluation for concurrent injuries
- Provide adequate analgesia
- Early fluid resuscitation is essential

ED TREATMENT/PROCEDURES

- Fluid resuscitation: Partial- and full-thickness burns (>20% TBSA)
 - Parkland formula (not for pediatric patients): 4 mL of lactated Ringer solution (preferred) or normal saline (NS) per kilogram per percentage of BSA burned
 - 1/2 in the 1st 8 hr and the remaining 1/2 over the next 16 hr
 - Example: 70-kg patient with a 40% TBSA burn requires $4 \text{ mL} \times 70 \text{ kg} \times 40\% = 11,200 \text{ mL}$ over 24 hr, with 5,600 mL over 1st 8 hr or 700 mL/hr
 - After the initial resuscitation, burns with >20% TBSA should have IV fluid therapy guided by invasive hemodynamic monitoring or urine output
 - Maintain urine output of 0.5 mL/kg/hr for adults and 1 mL/kg/hr for children
- Escharotomy
 - Circumferential burn eschar may lead to vascular or respiratory compromise
 - Indications: Circulatory compromise of limb that does not improve with elevation, or respiratory compromise in circumferential chest wall burn
 - Extremities: Incisions on extremities should be made medially and laterally along the long axis of the limb just superficial to the subcutaneous fat layer through the entire length of the burn eschar
 - Chest wall: Make longitudinal incisions at anterior axillary line from the 2nd rib to the level of the 12th rib; connect with 2 transverse incisions across the chest
- Wound care:
 - Cover the wounds with Polysporin or bacitracin ointment and nonadherent

- dressings
- Use silver sulfadiazine in contaminated/dirty wounds (avoid if transferring to burn center as interferes with later assessment of burn)
- Do not delay transfer to burn unit for wound care
- Prophylactic antibiotics not indicated
- Outpatient management of minor burns
 - Sterile technique for cleansing and débridement
 - Pain control is almost always needed
 - Remove loose, necrotic skin; débride broken, tense, or infected blisters
 - Topical antibacterial agents (e.g., silver sulfadiazine, bacitracin, mafenide acetate) recommended in deep partial-thickness or full-thickness burns only
 - Consider collagenase (Santyl) in partial thickness wounds with eschar present; no need in 3rd-degree wounds; this lacks antibiotic properties
 - 3-layer burn dressings should keep the wound moist and absorb exudate
 - Inner layer should be nonadherent porous mesh gauze saturated with nonpetroleum-based lubricant, or a mild ointment (bacitracin or Polysporin) under a nonadherent porous gauze
 - 2nd layer should be fluffed coarse-mesh gauze
 - Outer wrap should keep the dressing in place without constricting
 - Dressings should be changed at least daily
 - Silver wound dressings (Silverlon and Acticoat)
 - Thin coating of metallic silver applied to knitted fabric backing
 - Requires dressing to remain moist
 - May leave in place for up to 3 days
 - Even minor burns need tetanus if indicated

Pediatric Considerations

- Parkland formula underestimates fluid requirements in children; the Galveston formula is more accurate
 - $5,000 \text{ mL/m}^2 \text{ BSA burned} + 2,000 \text{ mL/m}^2$
- Use 5% dextrose in lactated Ringer solution IV over the 1st 24 hr; give 1/2 in the 1st 8 hr and the other 1/2 over the next 16 hr
 - Titrate to goal urine output of 1 mL/kg/hr
- Consider nonaccidental trauma, particularly with burns on the back of hands or feet, buttocks, perineum, or legs
- Avoid hypothermia
 - Children have greater body surface area/mass ratio and lose heat more rapidly
- Avoid hypoglycemia
 - Children are more prone to hypoglycemia due to limited glycogen stores

Pregnancy Considerations

- Significant morbidity to mother and child
- Fluid requirements may exceed estimations
- Fetal monitoring and early obstetric consultation recommended

MEDICATION

- Bacitracin ointment: Apply 1–4 times per day
- Mafenide (Sulfamylon) acetate cream: Apply 1 or 2 times per day
- Narcotics, especially for débridement of blisters and larger, severe burns
- Silverlon and Acticoat: Cut sheet to size of burn; moisten with sterile water
- Silver sulfadiazine cream: Apply 1–2 times per day
- Tetanus toxoid or immunoglobulin: 0.5 mL IM; 250 U IM once along with toxoid
 - Santyl: apply to eschar/wound bed once daily

FOLLOW-UP

DISPOSITION

Admission Criteria

- Injuries requiring admission
 - Partial-thickness burns of noncritical areas (excludes eyes, ears, face, hands, feet, or perineum) involving 10–20% of BSA in adults (>10 yr and <50 yr)
 - Partial-thickness burns of noncritical areas involving 5–10% of BSA in children <10 yr
 - Suspicion of nonaccidental trauma
 - Patients unable to care for wounds in outpatient setting (e.g., homeless patients)
- Injuries requiring transfer/admission to a burn center
 - Partial-thickness or full-thickness burns involving $\geq 10\%$ of BSA
 - Full-thickness burns involving $> 5\%$ of BSA
 - Partial-thickness and full-thickness of face, hands, feet, genitalia, perineum, or major joints
 - Electrical burns, including lightning injury
 - Significant chemical burns
 - Inhalation injury
 - Patients with pre-existing illness that could complicate management
 - Patients with concomitant trauma or social barriers

Discharge Criteria

Partial-thickness burns of $< 10\%$ of BSA in adults ($< 5\%$ in children or the elderly) involving noncritical areas only. Patients must be reliable, able to manage wounds as outpatients and obtain follow-up.

Issues for Referral

Maintain low threshold for referral to burn specialist whenever there is raised concern regarding cosmesis, involvement of hands/face/eyes/perineum, or if burn is overlying a joint.

FOLLOW-UP RECOMMENDATIONS

1–2 days after the injury to assess for early infection, saturation of dressings, pain control

PEARLS AND PITFALLS

- Early IV fluid rehydration is essential
- Intubate early for signs of respiratory distress; must recognize potential for airway involvement
- Early pain control in all burns
- Monitor for hypoglycemia in children

CODES

ICD9

- 949.0 Burn of unspecified site, unspecified degree
- 949.1 Erythema [first degree], unspecified site
- 949.2 Blisters, epidermal loss [second degree], unspecified site

ICD10

- T20.00XA Burn of unsp degree of head, face, and neck, unsp site, init
- T30.0 Burn of unspecified body region, unspecified degree
- T30.4 Corrosion of unspecified body region, unspecified degree

BURSITIS

Patrick H. Sweet

BASICS

DESCRIPTION

- Bursae are synovial fluid-filled sacs:
 - ~150 are located between bones, ligaments, tendons, muscles, and skin.
- They provide lubrication to reduce friction during movement.
- Bursitis is inflammation of a bursa caused by trauma and overuse, infection, crystal deposition, or systemic disease.
- Chronic bursitis can lead to proliferative changes in the bursa.
- Commonly affected sites:
 - Shoulder (subacromial)
 - Elbow (olecranon): Usually secondary to trauma
 - Hip (greater trochanter, ischial, iliopsoas): More common in elderly
 - Knee (prepatellar and pes anserine): Secondary to trauma or arthritis
 - Foot (calcaneal): Almost always secondary to improperly fitting shoes/heels

ETIOLOGY

- Trauma (most common cause):
 - Specific traumatic event or repetitive use of associated joints
- Infection: Secondary to direct penetration; may be obvious or microscopic:
 - Higher risk with diabetes, chronic alcohol abuse, uremia, gout, immunosuppression
 - 90% caused by *Staphylococcus* spp.
- Crystal deposition: Calcium phosphate, urate
- Systemic disease: Rheumatoid arthritis, gout, ankylosing spondylitis, psoriatic arthritis, lupus, rheumatic fever

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Acute or chronic
- History of trauma, overuse, or prolonged pressure
- Pain with increased activity at respective joint or with pressure
- Functional complaints (e.g., limping)
- History of localized swelling
- Screen for symptoms of systemic disease

- History of gout or pseudogout or rheumatologic disease
- History of recent procedure at bursa (e.g., aspiration, injection, etc.)

Physical-Exam

- Tenderness to palpation is minimal to mild in aseptic bursitis.
- Localized pain with movement
- Often reduced active range of motion (ROM) with preserved passive ROM
- Localized swelling, particularly with superficial bursae
- Skin trauma overlying bursa
- Warmth and erythema*
- May be febrile in septic bursitis

*NB: The constellation of erythema, warmth, swelling, and exquisite tenderness are common in septic bursitis.

ESSENTIAL WORKUP

- Full assessment of adjacent musculoskeletal structures
- Any suspicion of infection warrants aspiration of bursae (especially olecranon and prepatellar bursae).
- Lateral approach to prevent a needle tract directly over lines of tension of the joint
- Aspiration of hip and other deep bursae may be guided in ED by US or deferred to consultants.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Serum labs:
 - Suspected infection: CBC with differential
 - Evaluation of related systemic disease (e.g., uric acid level for gout); ESR and CRP in rheumatologic disease
 - Send serum glucose if bursal fluid aspiration is done
- Bursal fluid analysis:
 - Send fluid for complete cell count with differential, glucose, total protein, crystal determination, Gram stain, and culture.
 - Cultures must always be sent.
 - Normal fluid: Fluid is clear yellow with 0–200 WBCs, 0 RBCs, low protein, and glucose is same as serum.
 - Traumatic bursitis: Fluid is bloody/xanthochromic with < 1,200 WBCs, many RBCs, low protein, and normal glucose.
 - Septic bursitis: Fluid is cloudy yellow with > 50,000 WBCs, few RBCs, slightly increased protein, and decreased glucose; bacteria on Gram stain.
 - Rheumatoid and microcrystalline inflammation (aseptic bursitis): Fluid is yellow, sometimes turbid, and has 1,000–40,000 WBCs, few RBCs, slightly

increased protein, and variable glucose; microscopic exam for crystals.

Imaging

- Radiographs may demonstrate soft tissue swelling or adjacent chronic arthritic changes or calcium deposits:
 - Especially recommended when trauma is involved to rule out fracture or foreign body
- MRI and US may aid in diagnosis of deep bursitis and in defining the extent of septic bursitis.
- CT scans can also help differentiate septic from nonseptic bursitis.

DIFFERENTIAL DIAGNOSIS

- Arthritides: Septic, inflammatory, rheumatoid and degenerative joint (osteoarthritis)
- Gout and pseudogout
- Tendonitis, fasciitis, epicondylitis
- Fracture, tendon/ligament tear, contusion, sprain
- Osteomyelitis
- Nerve entrapment
- Also in hips: Neuritis, lumbar spine disease, sacroiliitis

TREATMENT

PRE HOSPITAL

May be difficult to distinguish from fractures; suspicious joints should be immobilized, particularly in the setting of trauma.

INITIAL STABILIZATION/THERAPY

- Immobilize joint if pain is severe.
- Shoulders should not be immobilized for >2–3 days because of the risk of adhesive capsulitis.

ED TREATMENT/PROCEDURES

- Nonseptic bursitis:
 - Rest and removal of aggravating factors (e.g., avoid direct pressure and repetitive use; protective padding where necessary)
 - Ice affected areas for 10 min, 4 times a day until improved; may alternate with heat.
 - NSAIDs for at least 7 days; best if continued for 5 days after improvement to help prevent recurrence
 - If fluctuant, then aspirate and place compression dressing
 - If no improvement within 5–7 days and infection has been ruled out (by

culture), injection of lidocaine and corticosteroids may be considered:

- Mix 2 mL of 2% lidocaine with appropriate depo-corticosteroid (see below) and inject 1–3 mL of this mixture into the bursa using sterile technique.
- Steroid injections should not be repeated until 4 wk have passed, and no > 2 injections per bursa should be performed without consultation.
- Septic bursitis:
 - Superficial bursae: Aspiration and antibiotics may be sufficient with close follow-up.
 - Other major bursae: Antibiotics and drainage of bursae (leaving in perforated drainage catheter can reduce period of treatment and avoid eventual bursectomy)
 - Febrile patients may need IV antibiotics.
 - Base antibiotic choice on the Gram stain when available or empiric coverage based on local susceptibilities:
 - Penicillinase-resistant penicillins may be used if Gram stain shows gram-positive cocci in chains but should be broadened for MRSA coverage if cocci in clusters are seen
 - If gram-negative organisms are found, blood cultures should be done and another primary source for the infection should be sought.
- Antibiotics should be continued for 5–7 days beyond resolution of signs of infection (thus may require follow-up)
- Treat associated diseases as needed (e.g., gout).

MEDICATION

- NSAIDs (many choices; a few are listed here):
 - Naprosyn: 500 mg PO q12h
 - Ibuprofen: 600 mg PO q6h (peds: 5–10 mg/kg PO q6h)
 - Ketorolac: 30 mg IV/IM q6h or 10 mg PO q4h–q6h
 - Meloxicam: 7.5 mg PO q12h or 15 mg PO daily
- Corticosteroids for intrabursal injection:
 - Triamcinolone acetonide: 20–40 mg (1st choice)
 - Methylprednisolone acetate: 20–40 mg
 - Dexamethasone acetate/sodium: 8 mg

FOLLOW-UP

DISPOSITION

- Most patients may be treated as outpatients.
- Most patients respond to therapy in 3–4 days and may follow-up within 1 wk or PRN.
- Septic bursitis requires repeated bursal aspiration every 3–5 days until sterile.

Admission Criteria

- Patients with systemic inflammatory response syndrome (SIRS), large surrounding cellulitis, unable to take PO antibiotics, failed outpatient therapy, or immunosuppressed
- Unusual organisms, extrabursal primary site, or deep bursal involvement

Discharge Criteria

- Able to tolerate pain
- Septic bursitis are safe to discharge if appropriately treated and close follow-up is secure

Issues for Referral

Rheumatology or orthopedic referral is recommended for patients who do not respond to intrabursal steroids or recurrent bursitis or need operative management.

FOLLOW-UP RECOMMENDATIONS

- Close follow-up for septic bursitis
- PRN to the emergency department for worsening symptoms but otherwise follow-up with primary care physician.

PEARLS AND PITFALLS

- Exam alone may be unreliable in distinguishing between traumatic and septic bursitis:
 - Aspiration and fluid analysis may be the only method of distinguishing.
- Beware of risk for GI hemorrhage associated with PO NSAIDs and for nephrotoxicity with ketorolac
- If presents with the 4 signs of infection—*humor, dolor, rubor, and calor*—then it is likely septic but still needs an aspiration and culture
- Beware of the potential of seeding organisms to adjacent joints when aspirating septic bursae.

CALCIUM CHANNEL BLOCKER POISONING

Christopher S. Lim • Steven E. Aks

BASICS

DESCRIPTION

- 3 classes of calcium channel blockers (CCBs):
 - Phenylalkylamines (verapamil):
 - Vasodilation resulting in a decrease in BP
 - Negative chronotropic and inotropic effects: Reflex tachycardia not seen with a drop in BP.
 - Dihydropyridine (nifedipine):
 - Decreased vascular resistance resulting in a drop in BP
 - Little negative inotropic effect: Reflex tachycardia occurs
 - Benzothiazepine (diltiazem):
 - Decreased peripheral vascular resistance leading to a decrease in BP
 - Heart rate (HR) and cardiac output initially increased
 - Direct negative chronotropic effect, which leads to a fall in HR
- Effects of calcium channel blockade
 - Calcium plays key role in cardiac and smooth muscle contractility
 - CCBs prevent
 - the entry of calcium, resulting in a lack of muscle contraction
 - the normal release of insulin from pancreatic islet cells, resulting in hyperglycemia

DIAGNOSIS

SIGNS AND SYMPTOMS

- Cardiovascular:
 - Hypotension
 - Bradycardia
 - Reflex tachycardia (dihydropyridine)
 - Conduction abnormalities/heart blocks
- Neurologic:
 - CNS depression
 - Coma
 - Seizures
 - Agitation
 - Confusion
- Metabolic:
 - Hyperglycemia

History

- Inquire about risk of medication error.
- Inquire about risk of suicidal ideation with intent.
- Inquire about possible exposure to medications with a pediatric patient.

Physical-Exam

- Hypotension
- Bradycardia
- Skin may be warm instead of cool and clammy.

ESSENTIAL WORKUP

ECG:

- Bradycardia (reflex tachycardia with nifedipine)
- Conduction delays: QRS complex prolongation
- Heart blocks

DIAGNOSIS TESTS & NTERPRETATION

Lab

- Ionized calcium level when administering calcium
- Digoxin level if patient taking digoxin (dictate safety of calcium administration)
- CBC
- Electrolytes, BUN, creatinine, glucose
 - Strongly consider CCB overdose in the setting of bradycardia, hypotension, and hyperglycemia
 - Degree of hyperglycemia may correlate with severity of CCB poisoning in nondiabetics
- Toxicology screen if coingestants suspected

DIFFERENTIAL DIAGNOSIS

- β -Blocker toxicity
- Clonidine toxicity
- Digitalis toxicity
- Acute myocardial infarction with heart block

TREATMENT

PRE HOSPITAL

- Transport pill/pill bottles to ED
- Calcium for bradycardic/unstable patient with confirmed CCB overdose

INITIAL STABILIZATION/THERAPY

- ABCs:

- Airway protection, as indicated
- Supplemental oxygen, as needed
- 0.9% NS IV access
- Hemodynamic monitoring

ED TREATMENT/PROCEDURES

Goals

- HR > 60 beats/min
- Systolic BP > 90 mm Hg
- Adequate urine output
- Improving level of consciousness

GI-Decontamination

- Syrup of ipecac: Contraindicated in the pre-hospital and ED setting
- Activated charcoal:
 - May be helpful, especially in the presence of coingestants

Calcium

- Usually only transiently effective
- Calcium gluconate (10%):
 - Contains 0.45 mEq Ca²⁺/mL
 - Does not cause tissue necrosis as calcium chloride does
 - Calcium gluconate: Preferred agent in an acidemic patient
- Calcium chloride (10%):
 - Contains 1.36 mEq Ca²⁺/mL (3 times more calcium than calcium gluconate)
 - Can cause tissue necrosis and sloughing with extravasation
 - Very irritating to veins
- Follow serum calcium levels if repeated doses of calcium administered.
- Contraindicated in known digoxin toxicity because calcium may cause serious adverse effects in this setting

Bradycardia/Hypotension

- IV fluids:
 - Administer cautiously in the hypotensive patient.
 - Swan-Ganz catheter or central venous pressure (CVP) monitoring to help follow volume status
- Atropine usually ineffective
- High-dose insulin (HDI):
 - CCBs cause myocardial insulin resistance and inhibit insulin release from pancreatic islet cells
 - Results in inefficient fatty acid metabolism

- HDI promotes more efficient myocardial carbohydrate metabolism and has been shown to improve hemodynamic function
- Vasopressor agents:
 - No clear evidence that 1 agent is more effective than another
 - Institute invasive monitoring to help guide treatment.
 - Dopamine:
 - β_1 -Receptor agonist at low doses, which causes a positive inotropic effect on the myocardium
 - α -Receptor agonist at higher doses, which leads to vasoconstriction
 - Epinephrine:
 - Potent α - and β -receptor agonist
- Amrinone:
 - Selective phosphodiesterase inhibitor
 - Indirectly increases cAMP leading to increased inotropy
- Electrical pacing: When other treatment options have failed
- Potential future therapies:
 - Hypertonic sodium bicarbonate
 - IV fat emulsion (20% intralipid)

MEDICATION

- Amrinone: Loading dose 0.75 mg/kg; maintenance drip 2–20 $\mu\text{g}/\text{kg}/\text{min}$; titrate for effect
- Atropine: 0.5 mg (peds: 0.02 mg/kg) IV; repeat 0.5–1 mg IV (peds: 0.04 mg/kg)
- Calcium chloride: 5–10 mL of 10% solution slow IVP (peds: 0.2–0.25 mL/kg; repeat in 10 min if necessary) followed by infusion 20–50 mg/kg/h
- Calcium gluconate: 10–20 mL of 10% solution slow IVP (peds: 1 mL/kg; may repeat in 10 min if necessary)
- Dextrose: 50 mL of 50% solution (peds: 0.25 g/kg of 25% solution)
- Dopamine: 2–20 $\mu\text{g}/\text{kg}/\text{min}$; titrate to effect
- Epinephrine: 1–2 $\mu\text{g}/\text{min}$ (peds: 0.01 mg/kg or 0.1 mL/kg 1:10,000); titrate to effect
- Norepinephrine: Start 2–4 $\mu\text{g}/\text{min}$ IV; titrate up to 1–2 $\mu\text{g}/\text{kg}/\text{min}$ IV
- Potassium: 40 mEq PO or IV

High-dose Insulin Treatment Protocol

- Should be considered if response to fluid resuscitation is inadequate
- Insulin (regular insulin): 1 IU/kg bolus IV followed by 0.5–1 IU/kg/h titrated up to clinical response
- Administer dextrose if blood glucose < 200 mg/dL
- Administer potassium if serum potassium < 2.5 mEq/L
- Monitor serum glucose and potassium concentrations every 30 min for the 1st 4 hr
- Approximate 24-hr insulin requirement: 1,500 U of regular insulin for adult

patient

First Line

- IV fluids
- Calcium
- HDI
- Vasopressor agents

Second Line

- Amrinone
- IV fat emulsion

FOLLOW-UP

DISPOSITION

Admission Criteria

- Admit symptomatic patients to a monitored bed for hemodynamic monitoring.
- Admit all patients who ingested sustained-release CCBs for 24-hr observation and monitoring owing to the potential delay in symptoms.

Discharge Criteria

Discharge asymptomatic patients 8 hr after ingestion of immediate-release preparation.

FOLLOW-UP RECOMMENDATIONS

- Psychiatric evaluation for all suicidal patients
- Poison prevention guidance for parents of pediatric accidental ingestion

PEARLS AND PITFALLS

- Consider CCB toxicity in patients presenting hypotensive and bradycardic.
- Consider suicidal gesture in patients presenting with CCB toxicity.
- Consider HDI with dextrose and potassium if fluid resuscitation not rapidly effective.

CANDIDIASIS, ORAL

Derrick D. Fenchel • Deepi G. Goyal

BASICS

DESCRIPTION

- Infection of oral mucosa with any species of *Candida*
- Up to 80% of isolates are *Candida albicans* (most common), *Candida glabrata*, and *Candida tropicalis*.
- *Candida* normally present as oral flora in 60% of the healthy population.
- Variations include:
 - Pseudomembranous (thrush)
 - Chronic and acute atrophic candidiasis
 - Angular cheilitis
 - Hyperplastic candidiasis
- More common in neonates, elderly, and immunosuppressed individuals
- Usually benign course in healthy patients
- In immunocompromised patients, more likely to be recurrent and a non-*albicans* species
- May represent an early manifestation of AIDS in HIV-infected patients
- Typically localized
- Risk factors for systemic infection:
 - AIDS
 - Diabetes
 - Hospitalization
 - Immunosuppressive therapy
 - Malignancy
 - Neutropenia
 - Organ transplantation
 - Prematurity

ETIOLOGY

- Usually overgrowth of *C. albicans* from alterations in intraoral environment
- May be medication induced—commonly antimicrobials, inhaled or systemic steroids, chemotherapy, immunosuppressive agents
- Immunocompromised patients
- Alterations or impairment of salivary flow:
 - Anticholinergic or psychotropic medications
 - Sjögren disease
 - Head or neck radiation
- Presence of dentures or other orthodontics:

- Occurs in up to 50–65% of denture wearers
- Common etiology for chronic atrophic candidiasis
- Interruption of epithelial barrier (cheek biting)
- Endocrinopathies (diabetes, hypothyroidism)

Pediatric Considerations

- Acute pseudomembranous candidiasis (thrush) is common in infancy likely because of immaturity of their immune system and lack of mature oral flora
- Initial presentation may be feeding difficulty secondary to dysphagia
- May have concurrent Candida diaper rash
- Consider maternal treatment if breastfeeding:
 - Maternal breast colonization may be cause for persistent thrush. Query maternal nipple pain, burning, itching, or cracked skin

Geriatric Considerations

- Candida organisms are normally present as oral flora from 65–88% of elderly or those in long-term care facilities
- Dentures can lead to Candida overgrowth
- Angular cheilitis more common in the elderly secondary to facial wrinkling

DIAGNOSIS

SIGNS AND SYMPTOMS

- Pseudomembranous candidiasis (thrush):
 - Painless white mucosal plaques
 - Adherent but removable plaques
 - Erythematous base
 - May become confluent and curdlike
 - Anorexia, dysphagia
- Acute atrophic candidiasis:
 - Also referred to as erythematous candidiasis
 - Burning sensation in mouth or on tongue
 - Erythematous with few, if any white patches usually on the palate or dorsum of tongue
 - Tongue may be bright red in color—similar to nutritional deficiency
- Chronic atrophic candidiasis:
 - Also referred as denture stomatitis
 - Irritation around denture-bearing mucosa
- Angular cheilitis:
 - Cracking or erythema at the corners of mouth
 - Lesion can be asymptomatic, pruritic, or painful
 - Superinfection with Staphylococcus or Streptococcus is common

- Hyperplastic candidiasis:
 - Chronic, invasive ulcers
 - Typically on lateral borders of tongue or buccal mucosa
 - High incidence of malignant degeneration in tobacco users

ESSENTIAL WORKUP

- Minimal workup needed in otherwise healthy infant. Diagnosis can be made clinically.
- Determine whether there is a cause for a breakdown of host factors
- If no reason is found, evaluate for possible HIV infection or diabetes
- Exclude a systemic infection

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Clinical diagnosis often sufficient
- CBC if suspect severe infection
- Glucose testing
- Periodic acid-Schiff stain/KOH/fungal culture:
 - Branching, thread-like hyphae, spores or pseudohyphae may be seen
 - Obtain culture and sensitivity if failed first line treatment or high-risk individuals (HIV/AIDs, neutropenic, AIDs, transplant, etc.)

DIFFERENTIAL DIAGNOSIS

- Hairy leukoplakia
- Lichen planus
- Squamous cell carcinoma
- Adherent food/milk

TREATMENT

ED TREATMENT/PROCEDURES

- IV fluids if dehydration and/or unable to tolerate PO fluids
- Topical analgesia: “Magic mouthwash”:
 - Mixture of equal parts of 2% viscous lidocaine, Maalox, and diphenhydramine elixir
 - Swish for 1–2 min, then expectorate
- Topical antifungal medications:
 - Suspension, troches, lozenges
 - Ointments (angular cheilitis)
- Systemic agents reserved for those with severe disease or resistant to topical therapy

- Provide oral hygiene education:
 - Instruct those using steroid inhalers to rinse mouth immediately after use
 - Denture and orthodontic care

MEDICATION

Pediatric Considerations

- Dissolve troche in bottle nipple
- Mix suspensions with fruit juice and freeze into popsicle
- Apply suspensions to affected areas with a cotton-tipped swab
- Instruct parents to disinfect or replace toothbrushes, pacifiers, bottle nipples

Geriatric Considerations

- Angular cheilitis: Treat with topical nystatin ointment
- Dentures: Remove, brush, and soak nightly. Consider overnight rinse with 2% chlorhexidine

First Line

- Nystatin: Oral suspension; neonates 100,000 U; older infants: 200,000 U; children/adults: 400,000–600,000 U. Swish and swallow QID for 7–14 days
- Nystatin pastilles: 200,000 U PO QID for 7–14 days
- Clotrimazole troches: 10 mg PO dissolved slowly 5 times per day for 7–14 days (children > 3 yr)

Second Line

- Oral fluconazole: Loading dose of 200 mg (peds: 6 mg/kg) on day 1, followed by 100 mg (peds: 3 mg/kg) PO daily for 7–14 days
- Itraconazole solution: 200 mg (peds: > 5 yr, 2.5 mg/kg BID, not FDA approved) PO daily for 7–14 days
- Posaconazole 100 mg (peds: > 13 yr refer to adult dosing) PO BID on day 1, then 100 mg PO daily for 13 days
- Systemic Amphotericin B (0.3 mg/kg) daily is the treatment of choice for candidiasis in pregnant women

FOLLOW-UP

DISPOSITION

Admission Criteria

- Inability to tolerate oral intake
- Newly diagnosed immunocompromised state
- Systemic infection

Discharge Criteria

If the candidiasis does not threaten patient's hydration status, discharge

FOLLOW-UP RECOMMENDATIONS

Additional workup for immunodeficiency is warranted in older children and adults with unexplained candidiasis.

PEARLS AND PITFALLS

- Failure to recognize immunodeficiency
- Failure to recognize other intraoral pathology such as squamous cell carcinoma

ADDITIONAL READING

- 771.7 Neonatal Candida infection

ICD10

- B37.0 Candidal stomatitis
- P37.5 Neonatal candidiasis

CARBAMAZEPINE POISONING

James W. Rhee

BASICS

DESCRIPTION

- Therapeutic uses of carbamazepine:
 - Anticonvulsant
 - Treatment of chronic pain
 - Migraine prophylaxis
 - Mood stabilizer
- Mechanism:
 - Anticholinergic
 - Similarities to phenytoin and tricyclic antidepressants (TCAs)
 - Sodium channel blocker
 - Decreases synaptic transmission

ETIOLOGY

Toxicity may occur from:

- Suicide attempt
- Accidental ingestion
- Supratherapeutic dosing
- Drug–drug interaction

DIAGNOSIS

SIGNS AND SYMPTOMS

- Neurologic manifestations common
- Cardiotoxicity rare, except in massive overdose
- CNS:
 - Ataxia
 - Dizziness
 - Drowsiness
 - Nystagmus
 - Hallucinations
 - Combativeness
 - Coma
 - Seizures
- Respiratory system:
 - Respiratory depression
 - Aspiration pneumonia

- Cardiovascular system:
 - Hypotension
 - Conduction disturbances (mostly in elderly)
 - Supraventricular tachycardia
 - Sinus tachycardia or bradycardia
 - ECG changes:
 - Prolongation of PR, QRS, and QTc intervals
 - T-wave changes

Pediatric Considerations

Higher incidence of neurologic manifestations

History

- Overdose of carbamazepine or extended-release versions
- Time of ingestion
- Is the bottle available
- Accidental or intentional ingestion
- Coingestions

Physical-Exam

- May present with seizures or altered mental status
- May be combative or drowsy
- Sinus tachycardia (massive carbamazepine overdose)
- Bradydysrhythmia (often seen in elderly with mild increase in carbamazepine level)
- Anticholinergic manifestations:
 - Decreased bowel sounds
 - Mydriasis
 - Flushing
 - Urinary retention
- Neuromuscular changes:
 - Tremor
 - Slurred speech
 - Myoclonus
 - Choreiform and choreoathetoid movements

ESSENTIAL WORKUP

- Continuous cardiac monitor
- Serum carbamazepine level:
 - Therapeutic, 6–12 µg/L
 - Levels > 25–40 µg/mL associated with serious toxicity:
 - Coma

- Seizures
- Respiratory failure
- Conduction defects
- Serum levels do not clearly predict clinical toxicity:
 - Active metabolite carbamazepine 10, 11 epoxide not measured
 - Neurologic manifestations depend on CNS (not serum) level
- Serial levels may be needed owing to erratic absorption of carbamazepine.
- ECG:
 - Conduction delays:
 - Increased QRS interval
 - Increased PR interval
 - QTc prolongation
 - Dysrhythmias
- Serum acetaminophen level (to evaluate for coingestion in a suicide attempt)

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - Leukopenia or leukocytosis
- Electrolytes, BUN/creatinine, glucose:
 - Hyperglycemia
 - Hypokalemia
 - Hyponatremia
- Arterial blood gases (ABGs)
- Urinalysis:
 - Glucosuria
 - Ketonuria
- Pregnancy test
- ALT, AST, bilirubin, alkaline phosphatase:
 - May be mildly elevated
 - Usually not clinically significant

Imaging

CXR:

- Aspiration pneumonia
- Pulmonary edema

DIFFERENTIAL DIAGNOSIS

- Drugs that cause decreased mental status:
 - Alcohol
 - Anticholinergics
 - Barbiturates

- Benzodiazepines
- Lithium
- Opiates
- Phenothiazines
- Drugs that cause seizures:
 - Alcohol withdrawal
 - Anticholinergics
 - Camphor
 - Isoniazid
 - Lithium
 - Phenothiazines
 - Sympathomimetics:
 - Amphetamine
 - Cocaine
 - TCAs
- Drugs that cause abnormal movement:
 - Antihistamines
 - Butyrophenones
 - Caffeine
 - Cocaine
 - Levodopa
 - Meperidine
 - Phencyclidine
 - Phenothiazines
 - Phenytoin
 - TCAs

TREATMENT

PRE HOSPITAL

- Do *not* administer ipecac.
- Intubate if significant respiratory depression or airway compromise.
- Secure IV access.
- Get complete information about all products potentially ingested.

INITIAL STABILIZATION/THERAPY

- ABCs
- IV access and fluid resuscitation if hypotensive
- Oxygen
- Cardiac monitor
- Naloxone, thiamine, D₅₀W (or Accu-Chek) if altered mental status

ED TREATMENT/PROCEDURES

- General management:
 - Activated charcoal:
 - Administer sorbitol with 1st dose (only) of activated charcoal.
 - Administer with caution if GI activity is decreased.
 - Contraindicated if bowel sounds are absent
 - Multidose activated charcoal:
 - Decreases mean half-life of carbamazepine
 - Binds unabsorbed drug in GI tract
 - Interrupts enterohepatic circulation
 - Do not give additional sorbitol
 - Charcoal hemoperfusion/hemodialysis:
 - Removes small to moderate amount of ingested dose
 - Patients usually do well with supportive care without hemoperfusion or dialysis
 - Indicated in cases of clinical deterioration or lack of improvement with good supportive care
- Respiratory depression:
 - Intubation
 - Ventilatory support
- Hypotension:
 - Bolus with IV isotonic crystalloid solution
 - Norepinephrine if unresponsive to IV fluids
- Seizures:
 - Diazepam (drug of choice)
 - Phenobarbital (if diazepam ineffective)
 - Phenytoin not effective in most toxic seizures
- Cardiac conduction delay:
 - QRS widening (> 100 msec):
 - Sodium bicarbonate (to overcome sodium channel blockade)
- Psychiatric consultation if suicide attempt

MEDICATION

First Line

- Activated charcoal (initial bolus): Slurry 1–2 g/kg up to 100 g PO
- Multidose activated charcoal: 25 g (peds: 0.25 g/kg) q2h PO after bolus dose (above); can also use 50 g q6h PO/NG

Second Line

- Dextrose: D₅₀W 1 ampule: 50 mL or 25 g (peds: D₂₅W 2–4 mL/kg) IV
- Diazepam: 5–10 mg (peds: 0.2–0.5 mg/kg) IV

- Naloxone (Narcan): 2 mg (peds: 0.1 mg/kg) IV/IM initial dose
- Norepinephrine: 2–4 µg/min (peds: 0.05–0.1 µg/kg/min) IV titrated to effect
- Sodium bicarbonate: 1 or 2 amps IV push (peds: 1–2 mEq/kg)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Decreased mental status at any time, even if resolving (tends to recur with fluctuating drug levels):
 - _ Observe at least 24 hr for late relapse.
- Seizures
- Cardiac dysrhythmias
- Lack of psychiatric clearance after suicidal ingestion

Discharge Criteria

- Asymptomatic after 6 hr of observation
- Normal mental status
- Normal or baseline ECG
- GI motility present
- Psychiatric clearance (after suicidal ingestion)

Issues for Referral

Suicidal patients need psychiatric evaluation referral.

FOLLOW-UP RECOMMENDATIONS

Supratherapeutic dosing will need ongoing monitoring by physician treating underlying disorder.

PEARLS AND PITFALLS

- Carbamazepine levels commonly rebound to higher levels during treatment. Obtain serial measurements for severe ingestions.
- Monitor closely for arrhythmias.
- Multidose charcoal may be needed for more serious ingestions.
- Paradoxical seizures may occur, use benzodiazepines to treat initially (diazepam is the drug of choice).

CARBON MONOXIDE POISONING

Trevonne M. Thompson

BASICS

DESCRIPTION

- Carbon monoxide (CO) is a colorless, odorless, nonirritating gas.
- Binds to hemoglobin to form carboxyhemoglobin:
 - Decreases O₂-carrying capacity
- Direct cellular toxin
- Impairs cellular O₂ utilization

ETIOLOGY

- Endogenous:
 - Result of normal metabolism
- Incomplete combustion of carbonaceous fossil fuel:
 - Internal combustion engines
 - Natural gas
 - Heaters
 - Indoor grills
 - Fireplaces
 - Furnaces
 - Accidental fires
 - Tobacco smoke
- Methylene chloride:
 - Found in some solvents for paint removal and furniture stripping
 - Converted in vivo to CO after exposure
 - Peak carboxyhemoglobin levels delayed after exposure
 - Half-life is ~ 2 times that of inhaled CO

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- CNS:
 - Headache
 - Dizziness
 - Ataxia
 - Confusion

- Syncope
- Seizures
- GI:
 - Nausea
 - Vomiting
- Cardiovascular:
 - Chest pain
 - Palpitations
- Respiratory:
 - Dyspnea
- Ophthalmologic:
 - Decreased visual acuity

Physical-Exam

- CNS:
 - Acute encephalopathy
 - Seizures
 - Coma
- Cardiovascular:
 - Tachycardia
 - Premature ventricular contractions
 - Dysrhythmias
 - Myocardial ischemia/infarction
- Respiratory:
 - Tachypnea
 - Noncardiogenic pulmonary edema
- Ophthalmologic:
 - Retinal hemorrhage
- Other:
 - Respiratory alkalosis
 - Rhabdomyolysis
 - Lactic acidosis

ESSENTIAL WORKUP

- History:
 - Maintain a high index of suspicion
 - Symptoms may be mild, nonspecific
 - Inquire about the following:
 - Similar symptoms in other household members
 - Malfunctioning furnaces
 - Use of space heaters, open ovens for supplemental heat
 - Ill pets
- Arterial blood gas:

- Normal PaO₂
- Normal calculated O₂ saturation
- Low measured O₂ saturation
- Metabolic acidosis in severe cases
- Carboxyhemoglobin level:
 - Measure as soon as possible
 - Level may not reflect clinical severity:
 - Patient may be critically ill despite unimpressive carboxyhemoglobin level.
 - May be misleadingly low if significant time has passed since exposure
 - Normal range is 0–3% (up to 10% in smokers).

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Pulse oximetry:
 - Falsely elevated SaO₂ reading
 - Pulse oximeter cannot distinguish oxyhemoglobin from carboxyhemoglobin.
- Electrolytes:
 - Metabolic acidosis and elevated anion gap associated with increased clinical severity
- Cardiac enzymes:
 - When myocardial ischemia/infarction suspected
- Pregnancy test
- ECG:
 - CO may precipitate myocardial ischemia/infarction.
 - Dysrhythmias
 - Nonspecific ST-segment and T-wave abnormalities

Imaging

- Chest radiography:
 - Pulmonary edema
- CT scan of the head:
 - To evaluate for intracranial causes of altered mental status when indicated
 - Bilateral globus pallidus low-density lesions may be clue to CO poisoning in unclear cases.

DIFFERENTIAL DIAGNOSIS

- Viral illness/viral syndrome
- Meningitis/encephalitis
- Intracranial hemorrhage
- Gastroenteritis

- Migraine headache
- Tension headache
- Ethanol intoxication
- Sedative–hypnotic overdose
- Cyanide poisoning
- Salicylate overdose
- Toxic alcohol exposure

TREATMENT

PRE HOSPITAL

Administer 100% O₂

INITIAL STABILIZATION/THERAPY

- ABCs
- Establish IV access
- 100% oxygen
- Cardiac monitor

ED TREATMENT/PROCEDURES

- Oxygen:
 - Administer 100% normobaric O₂:
 - Via face mask or endotracheal tube
 - Continue O₂ therapy until carboxyhemoglobin level <10%.
 - Half-life of carboxyhemoglobin:
 - ~300 min in ambient air
 - ~90 min in 100% normobaric O₂
 - ~20 min at 3 atm (hyperbaric O₂)
- Hyperbaric O₂:
 - Dose:
 - 100% O₂ at 3 atm
 - May be repeated
 - Benefits:
 - May reduce delayed neurologic sequelae
 - Decreases half-life of carboxyhemoglobin
 - Potential adverse effects:
 - Tympanic membrane rupture
 - Pneumothorax
 - Seizure
 - Decompression sickness

- Pulmonary edema
- Use of hyperbaric O₂ remains controversial
- Indications for consulting hyperbaricist:
 - Altered mental status/coma
 - Focal neurologic deficits
 - Seizures
 - Cardiovascular compromise (infarction, persistent dysrhythmia)
 - Persistent metabolic acidosis
 - Carboxyhemoglobin level > 25%
 - Pregnancy with carboxyhemoglobin level > 10%

Pregnancy Considerations

- Fetal hemoglobin has higher affinity for CO than adult hemoglobin.
- Fetal carboxyhemoglobin levels 10–15% higher than maternal levels
- Delayed clearance of fetal carboxyhemoglobin compared with maternal

FOLLOW-UP

DISPOSITION

Admission Criteria

- Persistent symptoms after 4 hr of treatment with 100% oxygen
- Evidence of myocardial ischemia or cardiac instability
- Seizures
- Persistent metabolic acidosis
- Syncope

Discharge Criteria

- Asymptomatic after 4 hr of observation
- Absence of aforementioned admission criteria
- Psychiatric clearance if suicidal exposure

Issues for Referral

Need for hyperbaric oxygen therapy

FOLLOW-UP RECOMMENDATIONS

Contact local fire department in cases of CO home exposures.

PEARLS AND PITFALLS

- Suspect CO poisoning in patients who present with headaches when home heaters are initiated.

- Suspect CO poisoning when family members living in the same enclosed space have similar symptoms.
- Administer 100% O₂ and transfer to hyperbaric facility if the above-described criteria is met.

CARDIAC ARREST

Michael W. Donnino • Brandon Giberson • Michael N. Cocchi

BASICS

ALERT

- NOTE: The following information is based on 2010 Advanced Cardiac Life Support (ACLS) Guidelines. Any revisions made by the American Heart Association since then are not available at time of publication.
- Major ACLS Changes for the 2010 revision include:
 - Change in the BLS sequence of treatment from A–B–C (airway, breathing, circulation) to C–A–B (circulation, airway, breathing) to emphasize early chest compressions
 - Emphasis on postcardiac arrest care, particularly implementation of targeted temperature management
 - Removal of atropine from PEA/asystole ACLS algorithms

DESCRIPTION

- Sudden cardiac arrest is characterized by:
 - Unresponsiveness
 - Pulselessness
 - Little to no respiratory effort
- Factors affecting survival:
 - Initial rhythm
 - Total down time
 - Time to successful defibrillation (as indicated)
 - Time to basic life-support interventions

ETIOLOGY

Contributing factors to cardiac arrest are outlined by the American Heart Association as:

- Hypovolemia
- Hypoxia
- Hydrogen ion (acidosis)
- Hypo-/hyperkalemia
- Hypothermia
- Toxins
- Tamponade, cardiac
- Tension pneumothorax
- Thrombosis
- Trauma

Pediatric Considerations

- Sudden cardiac arrest in children is often of a respiratory rather than cardiac etiology
- Follow current ACLS guidelines for pediatric cardiac arrest. Major differences between adult and pediatric cardiac arrest management include:
 - Depth of compressions for pediatric populations should be ~1/3 to 1/2 the depth of the chest
 - For 2 rescuer CPR, a 15:2 compression to ventilation rate is recommended
 - Drug dosage differences: See “Medications” section

Pregnancy Considerations

Follow current ACLS guidelines for management of the pregnant cardiac arrest patient:

- Awareness that airway may be difficult
- Compressions should be performed at a higher location than conventional CPR, slightly above the center of the sternum
- Follow Adult ACLS guidelines for defibrillation
- Pre- or postcardiac arrest pregnant patients should be placed in the left lateral recumbent position; during arrest, perform manual left uterine displacement
- To ensure a best possible outcome for the fetus, all efforts must be geared toward maternal survival
- In the event of a failed maternal resuscitation, an emergent cesarean delivery may be considered

DIAGNOSIS

SIGNS AND SYMPTOMS

- Unresponsiveness
- Pulselessness
- Shallow, gasping respirations may persist for a few minutes
- Occasionally preceded by:
 - Chest pain
 - Dyspnea
 - Palpitations
 - Seizure activity
- Immediately prior to arrest:
 - Shock or hypotension
 - Impaired mentation

ESSENTIAL WORKUP

- Assess circulation, airway, breathing
- Determine shockable vs. nonshockable rhythm and treat accordingly, per ACLS guidelines

DIAGNOSIS TESTS & INTERPRETATION

Lab

Indicated only when successful return of spontaneous circulation (ROSC) is achieved:

- Electrolytes
- BUN/creatinine
- Creatinine kinase with isoenzymes, cardiac troponin
- ABG
- CBC
- Therapeutic drug levels
- Toxicologic testing
- Lactic acid levels

Imaging

- EKG:
 - _ Evaluate for STEMI or ACS
- CXR:
 - _ Endotracheal tube position
 - _ Pneumothorax
 - _ Pulmonary etiology of arrest
- Echocardiogram:
 - _ Pericardial effusion
 - _ Wall motion abnormality
 - _ Valvular dysfunction
- Head CT scan (postresuscitation):
 - _ Rule out bleed/neurologic source

Diagnostic Procedures/Surgery

- Suspected cardiac etiology:
 - _ Cardiac catheterization lab
 - _ Possible cardiac output augmentation device placement
- EEG (postresuscitation)
 - _ Identify and treat seizures

DIFFERENTIAL DIAGNOSIS

Sudden loss of consciousness with a palpable pulse:

- Syncope
- Seizure
- Acute stroke
- Hypoglycemia
- Acute airway obstruction
- Head trauma

- Toxins

TREATMENT

PRE HOSPITAL

- Prompt initiation of standard CPR
- Confirm underlying rhythm
- Early defibrillation of pulseless ventricular tachycardia (VT) or ventricular fibrillation (VF)
- Secure airway and provide adequate respirations. Advanced airway should be deferred if placement interrupts BLS measures
- Postresuscitation care:
 - _ Identify cause of arrest
 - _ 12-lead EKG
 - _ Monitor vital signs
 - _ Fluid bolus and/or vasopressors for hypotension
- Transport to the closest facility that is capable of handling postarrest patients:
 - _ Consider transport to center equipped for interventional cardiac care and those specializing in postarrest care
 - _ Pediatric critical care center for children

INITIAL STABILIZATION/THERAPY

- Initiate ACLS
- Perform standard CPR as long as no pulse is palpable:
 - _ Stop CPR only briefly to check pulse, cardiac rhythm, or defibrillate
- Secure the airway
- Obtain IV/IO access
- Cardiac monitor
- Therapy is based on the underlying rhythm, according to ACLS protocols

ED TREATMENT/PROCEDURES

- Pulseless VT or VF:
 - _ Immediate defibrillation with 1 countershock:
 - Energy selection based on type of defibrillator for biphasic (if unknown use 200 J) or 360 J monophasic
 - _ If defibrillation is unsuccessful, continue CPR for 2 min and re-evaluate rhythm. When IV/IO access is established, and after second rhythm check then consider:
 - Epinephrine
 - Vasopressin
 - _ If refractory to defibrillation and epinephrine, consider:
 - Amiodarone

- Lidocaine
- Magnesium for *torsade de pointes*
- Asystole:
 - Confirm in ≥ 2 leads
 - Epinephrine
 - May substitute vasopressin to replace 1st or 2nd dose of epinephrine
- Pulseless electrical activity:
 - Epinephrine
 - Treat for reversible cause of pulseless electrical activity/asystole
- Postresuscitation:
 - Treat the underlying cause of the arrest.
 - EKG to establish presence of acute coronary syndrome:
 - Immediate catheterization for STEMI
 - Consider catheterization for suspected cardiac etiology without STEMI
 - Ventilatory support
 - Correct electrolyte abnormalities
 - Initiate volume resuscitation and provide vasopressors/inotropic support as needed
 - Targeted temperature management for eligible patients
 - Continuous EEG to rule out seizures

MEDICATION

Medication administration should never interrupt CPR:

- Amiodarone: 300 mg (peds: 5 mg/kg to max. 15 mg/kg) IVP
- Epinephrine: 1 mg (peds: 0.01 mg/kg) IVP q3–5min
- Lidocaine: 1–1.5 mg/kg 1st dose (peds 1 mg/kg) IVP, then 0.5–0.75 mg/kg (peds: 20–50 $\mu\text{g}/\text{min}$) IV, up to 3 mg/kg
- Magnesium: 1–2 g (peds: 25–50 mg/kg max. of 2 g) slow IV
- Vasopressin: 40 U IVP (as replacement for dose 1 or 2 of epinephrine in adult arrest)
- Sodium bicarbonate: 1 mEq/kg (peds: 1 mEq/kg) slow

FOLLOW-UP

DISPOSITION

Admission Criteria

ROSC:

- Intensive care unit
- Postresuscitation care
- Treatment of underlying cause of arrest

Discharge Criteria

None

Issues for Referral

May consider referral to regional cardiac arrest center

FOLLOW-UP RECOMMENDATIONS

Admission to ICU

PEARLS AND PITFALLS

- Provide targeted temperature management in comatose post arrest patients.
- Expect recurrent cardiac arrest and provide close monitoring and appropriate postresuscitative treatment, which may consist of fluids and vasopressors.
- Get a cardiology consultation to determine if patient is candidate for cardiac catheterization.

427.5 Cardiac arrest

ICD10

I46.9 Cardiac arrest, cause unspecified

CARDIAC PACEMAKERS

Susan P. Torrey

BASICS

DESCRIPTION

- A device that uses electrical impulses to contract the heart muscles and provide an adequate pulse
- Methods of cardiac pacing:
 - Transcutaneous pacing:
 - 2 pads are placed on the chest in the anterior-lateral or anterior-posterior position.
 - The pacing current is gradually increased until electrical capture occurs with a pulse.
 - Emergency therapy used only until transvenous pacing or another therapy can be applied
 - Temporary transvenous pacing:
 - A pacemaker wire is placed through central venous access into the right atrium (RA) or right ventricle (RV) and connected to an external generator outside of the body.
 - Used as a bridge until a permanent pacemaker can be placed or there is no longer a need for a pacemaker
- Permanent, implanted pacemaker has 3 components:
 - A battery-powered energy source:
 - Lithium batteries last 7–10 yr
 - Generator:
 - A sophisticated computer with many programmable parameters
 - Leads connected to the RV/RA:
 - Typically sense intrinsic electrical activity of the heart and pace the myocardium as needed
- Pacemaker magnet:
 - Placed over pacemaker generator
 - Converts pacer to asynchronous mode
 - Useful if pacer spikes not present on ECG
 - A depleted battery will result in decrease in magnet rate by ~10%.

Pacemaker Terminology

- Fixed mode:
 - The pacemaker is set to fire at a set rate regardless of patient's underlying rhythm.
 - Rarely seen

- Demand mode:
 - The pacemaker fires only when necessary.
 - It senses the underlying rhythm.
 - It will only pace if the intrinsic rhythm is absent or less than a set rate.
- Sensing:
 - Pacemaker's ability to determine whether the heart has an intrinsic rhythm
- All pacemakers have a 5-letter code to describe their function.
- For ED purposes, only the 1st 3 letters of the code are necessary:
 - 1st letter in code indicates chamber being sensed by pacemaker:
 - A: Atria
 - V: Ventricle
 - D: Dual (both chambers)
 - 2nd letter in code indicates chamber that can be paced:
 - A: Atria
 - V: Ventricle
 - D: Dual (both chambers)
 - 3rd letter in code describes pacemaker's response to sensed intrinsic complex:
 - T: Trigger (a sensed beat results in a pacing response as when a sensed atrial beat provokes a subsequent ventricular beat)
 - I: Inhibit (a sensed beat precludes pacemaker function)
 - D: Dual (a pacemaker is capable of both functions)
 - O: No response
 - The most common pacemakers are VVI (single lead) and DDD (two leads).

ETIOLOGY

- Pacemaker-associated infection:
 - Infection of pacemaker components often associated with endocarditis
 - *Staphylococcus epidermidis* and *Staphylococcus aureus* account for > 90% of infections.
 - Transesophageal echo is the preferred diagnostic method.
- Venous thrombosis:
 - Very common (overall incidence 30–50%)
 - Symptomatic, acute obstruction is rare (< 3%).
 - Pulmonary embolism is rare.
- Pacemaker failure to discharge impulse
 - Component failure is rare.
 - Battery depletion is rare with routine checks; it is not abrupt.
 - Lead fracture or disconnection
 - Oversensing of muscular activity or external electrical interference
- Pacemaker failure to capture myocardium:
 - Lead dislodgment is common.
 - Twiddler's syndrome:

- Unintentional manipulation of pacemaker generator causing lead to be dislodged from myocardium
- Elevated myocardial threshold:
 - Hyperkalemia
 - Ischemia
- Change in cardiac (QRS) morphology
- Pacemaker-mediated tachycardia:
 - Occurs with dual-chamber pacemakers
 - A re-entry rhythm using generator and intrinsic conduction system
 - Max. rate typically 140 bpm due to built-in safeguards
- Runaway pacemaker:
 - Rare; triggered by battery depletion or component failure
 - Often rapid rates (> 200 bpm) with hemodynamic compromise

DIAGNOSIS

SIGNS AND SYMPTOMS

- Pacemaker failure:
 - Bradycardia
 - Syncope
 - Hypotension, progressive to shock and hemodynamic collapse
 - Fatigue and weakness
 - Dyspnea on exertion or shortness of breath secondary to CHF
 - Ischemic chest pain
 - Altered level of consciousness
- Pacemaker-induced tachycardia:
 - Dyspnea
 - Ischemic chest pain
 - Lightheadedness
 - Syncope
- Pacemaker syndrome:
 - Symptoms related to asynchronous chamber contractions (typical with VVI pacer)
 - Lightheadedness
 - Dyspnea
 - Palpitation
 - Weakness or exercise intolerance
 - Syncope

History

- Date of placement pacemaker
- Compliance with follow-up (battery checks)

- Type of pacemaker

Physical-Exam

General cardiac exam:

- Heart exam for murmurs
- Lung exam for CHF
- Chest wall exam at generator site

ESSENTIAL WORKUP

- 12-lead EKG to assess whether there is any obvious evidence of pacemaker failure
- Metabolic workup to determine whether an acquired medical condition led to an elevated myocardial threshold
- EKG with pacer magnet:
 - Assess magnet rate.
 - Particularly useful when the baseline EKG does not reveal pacer spikes
 - The magnet activates asynchronous pacing mode.
 - Produces pacer spikes at a preprogrammed rate, regardless of the intrinsic rhythm
 - If the magnet rate equals the preprogrammed rate set at implantation, the pacer is okay.
 - If the magnet rate is > 10% slower than at implantation, the battery is depleted.
 - If there are no pacer spikes, there is significant pacemaker malfunction.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Serum potassium
- ABG
- Serum levels of antidysrhythmic drugs

Imaging

CXR:

- Evaluate integrity of pacer lead(s) and position.
- Fractured lead
- Lead dislodgment:
 - Perforation through septum
 - Tip of lead moved (e.g., in pulmonary artery)

TREATMENT

PRE HOSPITAL

Record rhythm strips for analysis

INITIAL STABILIZATION/THERAPY

- Oxygen administered via 100% nonrebreather
- Intubation as needed
- IV access
- Advanced cardiac life support drugs as per usual protocol (especially for bradycardia)
- Defibrillation: Avoid placing paddles over generator.
- Transcutaneous pacemaker in hemodynamically unstable patients with pacemaker failure

ED TREATMENT/PROCEDURES

- Pacemaker failure:
 - Transcutaneous pacemaker
 - Temporary transvenous pacemaker:
 - Obtain central IV access with a Cordis introducer (right IJ preferred)
 - Perform the procedure under fluoroscopy if possible.
 - Set the pulse generator to asynchronous mode.
 - Turn the output dial all the way up.
 - Advance the catheter through the central venous access Cordis until you see a QRS complex on the monitor.
 - Check the femoral pulse.
 - If you have a pulse and see a QRS complex, the pacer is “capturing.”
 - Slowly turn the output dial down until you lose the QRS complex (capture threshold).
 - Turn the output dial up to 2 or 3 times the capture threshold.
 - Continuous EKG monitoring facilitates correct placement.
- Treat hyperkalemia (see “Hyperkalemia”).
- Runaway pacemaker:
 - AV node blocking or reprogramming
 - In extreme situation, may need to disconnect lead from generator surgically

MEDICATION

Adenosine: 6 mg IV bolus

FOLLOW-UP

DISPOSITION

Admission Criteria

- Permanent pacemaker failure or malfunction
- Suspicion of infection involving pacemaker components

Discharge Criteria

- Asymptomatic pacemaker malfunction
- A cardiologist has interrogated the pacemaker

FOLLOW-UP RECOMMENDATIONS

Refer to cardiologist and/or pacemaker clinic

PEARLS AND PITFALLS

- Always consider pacemaker failure in evaluation of cardiac decompensation, bradycardia, or syncope.
- Utilize pacemaker magnet to evaluate function.

CARDIAC TESTING

Steve R. Grosse • Shamai A. Grossman

BASICS

DESCRIPTION

- Cardiac testing is indicated for emergency patients at risk for heart failure (HF) or acute coronary syndrome (ACS).
- These pathologies may be thought of as a spectrum: Unstable angina can evolve into MI, which in turn can cause HF:
 - ~20% of ED malpractice claims are due to missed diagnosis of ACS.
 - ~2% of patients with ACS are inappropriately discharged from an ED.
 - History, physical exam, and ECG are the critical elements in working up chest pain and ACS/HF.
 - History, physical, and ECG nevertheless miss 1–4% of all heart attacks.
 - Additional tools include imaging modalities and blood tests (e.g., cardiac biomarkers).

ETIOLOGY

ACS is caused by atherosclerotic narrowing of coronary vessels or by coronary vasospasm.

Pregnancy Considerations

In the pregnant patient with chest pain and ischemic changes on ECG, also consider spontaneous coronary artery dissection.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Anginal symptoms usually are produced by bodily stresses, including exertional and emotional events, and relieved by rest.
- ACS is less likely when chest pain is sharp, stabbing, pleuritic, or reproducible with palpation.
- Ischemia is still diagnosed in 13% of pleuritic chest pain and in 7% of chest pain reproducible with palpation.
- Nitroglycerin may relieve cardiac ischemia, but can also relieve pain in GI and aortic pathology.
- A “GI cocktail” of lidocaine and Maalox, or a proton-pump inhibitor such as omeprazole, may relieve GI pathology, but can also relieve cardiac ischemia.

- Anginal symptoms often last < 20 min but > 5 min
- AMI and UA should be considered if symptoms last > 20 min.

Physical-Exam

Often unremarkable

ESSENTIAL WORKUP

EKG:

- Per ACC/AHA guidelines, a 12-lead ECG should be performed on a patient with chest pain within 10 min of arrival to the ED:
 - A single ECG will miss ~ 50% AMI.
 - Hyperacute T-waves (tall, broad-based, especially in anterior leads) may be the earliest and only sign of AMI.
 - During an MI, the ECG may evolve. Continuous ECG monitoring can identify an additional 16% of acute MIs not seen on initial ECGs. Absent continuous monitoring, consider a repeat EKG 15–60 min after the initial ECG.
 - New ST-segment changes or T-wave inversions are suspicious for ischemia.
 - ST depressions of 1 mm are characteristic of ischemia; or, could be reciprocal changes, so check other leads.
 - STEMI: ST-elevation of > 1–2 mm in ≥ 2 contiguous leads.
 - New left bundle branch block (LBBB) is suggestive of AMI:
 - Old LBBB makes diagnosing AMI difficult: Apply Sgarbossa criteria: AMI is likely if LBBB and > 1 mm ST-elevation concordant with QRS, or ST depression > 1 mm in leads V1, V2, or V3.
 - Current ACCF/AHA guidelines advise that LBBB “not known to be old” in isolation is not diagnostic of AMI, and should be further evaluated with serum biomarkers and immediate cardiac consultation for consideration of echocardiography and invasive angiography.
- Additional-lead EKGs: Standard 12 leads often miss infarcts in the posterior, right, and high lateral walls.
 - Right-sided EKG:
 - Move lead V4 to the right side of chest, midclavicular line, 5th intercostal space, and repeat EKG, to capture infarct in right ventricle.
 - A right-sided EKG is often performed in the setting of a STEMI in inferior leads (II, III, aVF) to diagnose a right ventricular (RV) infarct.
 - Posterior EKG:
 - Leads V7, V8, V9 are placed posterior thorax along 5th intercostal space: V7 at posterior axillary line, V8 at inferior angle of scapula, V9 paraspinous.
 - Performed in setting of inferior or lateral wall MI; or if ST depression in V1–V3. May identify a lateral or left circumflex infarct.

- EKG may be helpful in diagnosing other etiologies of chest pain:
 - Pericarditis is suggested by diffuse ST-elevations followed by T-wave inversions and P-R depression.
 - Pulmonary embolism is suggested by unexplained tachycardia, signs of right heart strain (RVH, RBBB, “p” pulmonale), new-onset atrial fibrillation, or rarely with S1, Q3, T3 pattern.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Cardiac biomarkers:
 - Indicated if the history is suspicious for ACS.
 - Should not be elevated in stable angina and may be normal in unstable angina.
- Troponin T and I: Starts to rise 2–3 hr after onset of chest pain of ACS and peaks in 8–12 hr. Remains elevated 7–14 days:
 - A single troponin has low sensitivity for ACS (1 study of low-risk chest pain in patients with negative initial troponin: 2.3% rate of AMI and 1% rate of death at 30 days).
 - Timing of biomarker testing is critical: ACEP endorses with “moderate clinical certainty” that a single negative troponin can rule out AMI if drawn 8–12 hr after onset of symptoms. However, uncertainty in time of symptom onset, unreliable history, and possibility of preinfarction angina complicates utilizing single troponin.
 - Newer, more sensitive assays may in the future eliminate the need for a 2nd troponin.
 - Minor troponin elevations may occur with renal failure, structural heart disease, CHF (acute or chronic), cardiac pacing, pulmonary embolism, sepsis, stroke.
 - Lack of standardization between assays (particularly with troponin I) means values from 1 lab cannot always be simply compared to values from another.
- CK/CK-Mb: Less sensitive than troponin, rises more slowly. Little gained by using both CK-Mb and troponin assays. Obtain CK-Mb if
 - Renal failure is present (Tn less accurate)
 - Recent prior infarct
- Myoglobin: Rises faster than standard troponin assays and thus able to detect AMI sooner, but max. sensitivity is 70%.
- B-type natriuretic peptide (BNP):
 - Release and synthesis activated by diastolic ventricular stretch.
 - Useful for detecting HF.
 - A cutoff of > 100 pg/mL diagnosed HF with a sensitivity of 90% and specificity of 76%.

- Unclear significance of elevated BNP in setting of ACS.

Imaging

- CXR:
 - Usually normal
 - May show cardiomegaly
 - May show pulmonary edema
 - May identify other etiologies of chest pain, such as pneumonia or widened mediastinum of aortic dissection.
- Rest echocardiography:
 - May identify ACS or AMI based on wall motion abnormalities; also can detect pump failure and valvular abnormalities.
 - Rest echo has a sensitivity of 70% and specificity of 87% for ACS.
 - Rest echo has a sensitivity of 93% and specificity of 66% for AMI.
- Technetium 99m sestamibi:
 - Radioactive IV dye taken up by myocardium, and detected by single photon emission CT (SPECT) imaging. (Also known as myocardial perfusion imaging.)
 - Can be imaged at rest to detect low- or no-flow areas of myocardium; can also be imaged after exercise or pharmacologic stress.
 - Per 2009 AHA/ACC guidelines, reserve for intermediate- to high-risk patients.
 - Has a sensitivity of 81% and specificity of 73% for ACS.
 - Has a sensitivity of 92% and specificity of 67% for AMI.
- CT coronary angiography (CTCA):
 - Imaging to evaluate degree of coronary artery stenosis and calcium deposits
 - Negative predictive value between 97% and 100%, accuracy comparable to stress testing
 - Recent NEJM article suggests CTCA decreases ED length of stay but leads to further downstream testing, radiation exposure, and no decrease in cost of care.
- Exercise stress testing (ETT):
 - May help establish diagnosis of angina, provide prognostic information.
 - 1-mm depression of the ST-segment in 3 consecutive beats and 2 consecutive leads is characteristic of cardiac ischemia.
 - Early positive (within 3 min) stress tests are worrisome for unstable angina.
 - 6 min of exercise using a standard Bruce protocol suggests an excellent prognosis.
 - Exercise stress testing with EKG alone has a sensitivity of 68% and specificity of 77%.
 - Exercise stress testing with echo has a sensitivity of 85% and specificity of 77%.

- Exercise stress testing with technetium^{99m} sestamibi has a sensitivity of 87% and specificity of 64%.
- Cardiac catheterization:
 - Considered the gold standard for evaluating coronary arteries.
 - A history of a recent negative catheterization does not fully exclude AMI, i.e., in cases of vasospasm or cocaine use.

Diagnostic Procedures/Surgery

EKG, cardiac enzymes, echo, stress testing

DIFFERENTIAL DIAGNOSIS

See ACS chapters.

TREATMENT

PRE HOSPITAL

- Cardiac monitoring
- Out-of-hospital EKG:
 - Alone has a sensitivity of 76% and specificity of 88% for ACS.
 - Alone has a sensitivity of 68% and specificity of 97% for AMI.

INITIAL STABILIZATION/THERAPY

- Cardiac monitoring
- Oxygen saturation

ED TREATMENT/PROCEDURES

- See “Acute Coronary Syndrome: Stable Angina”; “Acute Coronary Syndrome: Unstable Angina”; and “Acute Coronary Syndrome: MI” for more detail.
- Guidelines for cardiac testing
- History suggestive of ACS:
 - Obtain ECG and 1st troponin (or other cardiac biomarkers).
- ECG or 1st troponin abnormal:
 - Admit; consider cardiology consult.
- Ongoing chest pain or pressure:
 - Obtain sestamibi or echo.
 - Consider serial EKGs
- Sestamibi, serial EKG or echo abnormal:
 - Admit or cardiology consult.
- Second troponin (or other cardiac biomarkers) abnormal:
 - Admit; consider cardiology consult.
- Ancillary testing:
 - For low- to moderate-risk patients: standard exercise testing (ETT).

- If low-risk patient with good follow-up, ACC/AHA guidelines allow for outpatient stress testing within 72 hr.
- Per 2007 AHA/ACC guidelines CTCA “reasonable alternative” to stress testing.
 - For abnormal or uninterpretable EKG: Stress echo or sestamibi.
 - For patient unable to exert self: Pharmacologic ETT (i.e., dobutamine stress or dipyridamole sestamibi).
 - Ancillary testing abnormal:
 - Cardiology consult or admit.

MEDICATION

Patient should not be started on new antianginal medication before stress testing in the ED.

FOLLOW-UP

DISPOSITION

Admission Criteria

- History suggestive of cardiac etiology for chest pain and ED observation for serial testing unavailable
- Abnormal or changed EKG and ED observation unavailable
- Positive cardiac biomarkers
- Positive rest imaging
- If the diagnosis is unclear, admission to the hospital or an ED observation unit may be useful for serial cardiac biomarkers, EKGs, and further ancillary testing.
- Early positive stress test:
 - If the patient has a positive stress test, the decision for admission should be made in consultation with the primary care physician or cardiologist.

Discharge Criteria

Patients who meet the following criteria are safe to discharge:

- History not suggestive of cardiac etiology for chest pain
- Normal ECG
- Normal cardiac testing

FOLLOW-UP RECOMMENDATIONS

- Abnormal stress test will require close follow-up with cardiology or PCP.
- Undifferentiated CP should have ED stress testing unless clear follow-up is available.

PEARLS AND PITFALLS

- Normal EKG or enzymes do not rule out CAD.
- Repeat EKG or additional leads improve sensitivity in detecting AMI.
- Most ED patients with undifferentiated chest pain will need some form of additional testing.

- I24.9 Acute ischemic heart disease, unspecified

CARDIAC TRANSPLANTATION COMPLICATIONS

Jarrold Mosier • Samuel M. Keim

BASICS

DESCRIPTION

- Cardiac transplant recipients are a unique population with increased risk for cardiac ischemia, heart failure, as well as general risks as an immunocompromised host.
- 1,900–2,300 cardiac transplants per yr in US
- 1-yr survival 85–90%; 5-yr survival ~75%
- Typical immunosuppressive therapy to control rejection is a “triple-drug” regimen often including steroids.
- Frequent biopsies are used initially to evaluate rejection; echocardiography often used in children.
- Complications occur most commonly in the 1st 6 wk after cardiac transplantation

Geriatric Considerations

- The proportion of elderly patients on the transplant list, and receiving transplants are increasing.
- Due to changes in immune system with age, elderly transplant recipients are at increased risk of life-threatening infections, and acute rejection.

Pregnancy Considerations

- Pregnancy after cardiac transplant is becoming more common. Between 1988 and 2010, 63 women received either heart or heart–lung transplants. They have reported 108 pregnancies, all progressing to live births.
- Most common complications include hypertension, pre-eclampsia, and rejection.
- Physiologic changes that occur with pregnancy do not relate to increased rate of heart failure in transplant patients.
- Special attention should be paid to these patients regarding rejection and infection given their immunosuppression.

ETIOLOGY

- Rejection
 - Hyperacute rejection
 - Occurs within minutes of transplantation
 - Rare, due to ABO or other graft/host major incompatibility
 - Aggressive and immediately fatal to graft
 - Acute rejection
 - Lymphocyte infiltration and myocyte destruction

- Most common in 1st 6 wk
- May occur at any time
- 75% prevalence
- Chronic rejection
 - Fibrosis and graft vascular disease
 - Long-term complication
 - Incompletely understood etiology
 - No effective therapy
- Cardiac allograft vasculopathy
 - Analogous to accelerated coronary artery disease in native hearts
 - Limits long-term survival, leading cause of mortality after 1 yr
- Immune-mediated atherosclerosis
 - Form of chronic rejection
- Infections
 - 1st mo
 - Bacterial infections are the most common cause of mortality during this high-risk time period
 - Pneumonia (*Pseudomonas*, *Legionella*, other gram-negative organisms)
 - Mediastinitis
 - Wound infection
 - UTI
 - 1st yr
 - Opportunistic and conventional infections
 - Cytomegalovirus (CMV)
 - Herpes simplex virus (HSV)
 - *Legionella*
 - Fungal infections
 - *Pneumocystis carinii*
- Medication toxicity
 - Cyclosporine, Neoral (2nd-generation cyclosporine), tacrolimus:
 - Nephrotoxicity (30% incidence)
 - Hepatotoxicity
 - Neurotoxicity
 - Hyperlipidemia, diabetogenic
 - Azathioprine, mycophenolate mofetil:
 - Bone marrow suppression
 - Leukopenia
 - Sirolimus:
 - Hyperlipidemia
 - Wound healing
 - Steroids
 - Osteoporosis

- Cushing disease
- Neoplasms
 - Secondary to immunosuppression
 - 10–100 times more common vs. general population
 - Skin and lip cancer
 - Lymphomas
 - Kaposi's sarcoma
 - Solid organ neoplasms

Pediatric Considerations

- If the patient is not on steroids, bacteremia risk is similar to that in the general population.
- High incidence of pneumonia
- Patients on steroids may not show meningeal signs

DIAGNOSIS

SIGNS AND SYMPTOMS

- Acute rejection
 - Nonspecific symptoms predominate because the heart is usually denervated
 - Fatigue
 - Dyspnea
 - Low-grade fever
 - Nausea
 - Vomiting
 - May be difficult to differentiate between infection and acute rejection
- Heart failure
 - Tachypnea
 - Rales
 - Hypoxia
 - S3
 - Murmur
 - Edema
- Allograft vasculopathy
 - As early as 3 months after transplantation (20–50% incidence by 5 yr)
 - Denervated hearts do not present with typical angina.
 - Insidious onset
 - Fatigue
 - Cough
 - Dyspnea
 - Acute onset
 - Heart failure

- Sudden death
- Infarction
- Infection (Opportunistic and conventional)
 - Fever
 - Skin lesions (zoster)
 - CMV
 - Mild (flu-like illness)
 - Fever
 - Nausea
 - Malaise
 - Pneumonitis (13–50% mortality)
 - Hepatitis
 - Gastroenteritis
 - Profound leukopenia

Pediatric Considerations

- Higher risk for post-transplant lymphoproliferative disease with Epstein–Barr virus seroconversion
- Like adults, at risk for allograft vasculopathy and its associated cardiac ischemia

ESSENTIAL WORKUP

- Assess for signs of rejection, cardiac dysfunction, and infarction:
 - ECG
 - Cardiac enzymes
 - Chest radiograph
 - Echocardiography
- Possible rejection requires biopsy, consult transplant team.

Pediatric Considerations

Normal fever workup + chest radiograph and ECG; if on steroids, perform LP

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Electrolytes:
 - Cyclosporine effects:
 - Increased blood urea nitrogen, creatinine
 - Hyperkalemia
 - Metabolic acidosis
 - Hyponatremia
- CBC:
 - Relative eosinophilia may indicate rejection over infection
- Blood and urine culture if febrile

- Lumbar puncture if seizures, altered mental status, or severe headache
- BNP (expect baseline elevation)
- CMV titers
- Urine antigen test
- Cyclosporine trough level

Imaging

- ECG
 - Tachycardia
 - 20% decrease in total voltage (nonsensitive)
 - Note that normal rhythm for denervated heart is sinus 90–110 bpm
 - Depending on transplant surgical technique, may see 2 P-waves (native and donor heart):
 - Native P-waves do not correspond to quasi-random signal
- Chest radiograph
 - Cardiomegaly
 - Pulmonary edema
 - Pleural effusions
 - Compare with previous (healthy donor heart may appear large in small recipient)
- Echocardiography
 - Decreased mitral deceleration time
 - Initial diastolic dysfunction
 - Biventricular enlargement
 - Mitral/tricuspid regurgitation

DIFFERENTIAL DIAGNOSIS

- Rejection
- Infection
- Ischemia
- CMV
- Viral illness
- Malignancy
- Cyclosporine toxicity

TREATMENT

PRE HOSPITAL

Adenosine should not be given to patients who have had a heart transplant as the effects may be prolonged and unpredictable.

INITIAL STABILIZATION/THERAPY

- IV access
- Oxygen
- Monitor
- Intubation
- Defibrillation/pacing
- Vasopressors as required
- Arrhythmias
 - Advanced cardiac life support
 - Bradycardia does not respond to atropine; use isoproterenol

ED TREATMENT/PROCEDURES

- Hemodynamically significant rejection
 - Methylprednisolone
 - May also require OKT3 or other anti-T-cell antibody therapy
- Infarct/vasculopathy
 - Aspirin
 - Heparin
 - Possible angioplasty
 - Likely need retransplantation
- CMV
 - Empiric IV ganciclovir
- HSV
 - Oral or IV acyclovir
- Gastroenteritis
 - Search for CMV infection with culture, serology
- Fever without a source
 - Consult infectious disease or transplantation team
- Headache
 - Threshold for CT scan and lumbar puncture should be low (meningitis, abscess)
- Serious illness/trauma/operation
 - Steroid burst
 - Limit NSAID use because risk for renal insufficiency from cyclosporine and tacrolimus.

MEDICATION

- Acyclovir: 5–10 mg/kg IV q8h calculate dose on IBW; genital herpes: 400 mg PO TID × 7–10 days; varicella: 20 mg/kg up to 800 mg PO QID for 5 days
- Ceftriaxone: 50 mg/kg IV q12–24h
- Cyclosporine, CellCept, tacrolimus, sirolimus, Neoral, azathioprine, mycophenolate mofetil: Per transplantation team
- Ganciclovir: Insert IV; 5 mg/kg BID for 2–3 wk (adjust for renal function)
- Isoproterenol: 1–4 µg/min, titrate to effect; max. 10 µg/min

- Methylprednisolone: 1 g IV; peds: 10–20 mg/kg IV
- OKT3, daclizumab or other antibody therapy: Per transplant team

IN PATIENT CONSIDERATIONS

Admission Criteria

- Hemodynamically significant rejection
- Vasculopathy/ischemia
- New dysrhythmia
- Poorly controlled hypertension
- Congestive heart failure
- Dyspnea
- Hypoxia
- Temperature > 38°C in adult or child on steroids
- Suspected CMV (unexplained fever, gastroenteritis, or interstitial pneumonitis)
- Not tolerating oral medicines
- Syncope

Discharge Criteria

- Mild rejection
- Only in consultation with transplantation team
- Fever in nontoxic child:
 - Do not give children stress-dose steroids

CARDIOGENIC SHOCK

Nadeem Alduaij

BASICS

DESCRIPTION

- Persistent hypotension and tissue hypoperfusion due to cardiac dysfunction in the presence of adequate intravascular volume and left ventricular (LV) filling pressure
- Most common cause of death in hospitalized patients with acute MI (AMI)
- Underlying mechanisms in AMI:
 - Pump failure:
 - $\geq 40\%$ LV infarct
 - Infarct in pre-existing LV dysfunction
 - Reinfarction
 - Mechanical complications:
 - Acute mitral regurgitation
 - Ventricular septal defect
 - LV rupture
 - Pericardial tamponade
 - Right ventricular (RV) infarction
- 5–8% of patients with STEMI develop cardiogenic shock
- Role for a systemic inflammatory response syndrome via excess nitric oxide in the pathophysiology of cardiogenic shock
- Role of initial treatment with β -blockers, ACEI, and high-dose diuretics in cardiogenic shock development

ETIOLOGY

- AMI
- Sepsis
- Myocarditis
- Myocardial contusion
- Valvular disease
- Cardiomyopathy
- Left atrial myxoma
- Drug toxicity:
 - β -blocker
 - Calcium channel blocker
 - Adriamycin

DIAGNOSIS

SIGNS AND SYMPTOMS

- ABCs and vital signs:
 - Patent airway (early)
 - Labored breathing and tachypnea (early); respiratory failure (late)
 - Diffuse crackles or wheezing
 - Hypoxia
 - Hypotension:
 - Systolic BP < 90 mm Hg
 - Decline by at least 30 mm Hg below baseline level
 - Tachycardia
 - Weak pulses
- General:
 - Cyanosis
 - Pallor
 - Diaphoresis
 - Dulled sensorium
 - Decrease in body temperature
 - Urine flow of < 20 mL/hr
- Neck:
 - Jugular venous distention
- Cardiac:
 - Ischemic chest pain
 - Systolic apical blowing murmur
 - Gallop rhythm:
 - S3 reflects severe myocardial dysfunction.
 - S4 is present in 80% patients in sinus rhythm with AMI.
 - Systolic click:
 - Suggests rupture of the chordae tendineae
- Abdominal:
 - Epigastric pain
 - Nausea and vomiting
- Neurologic:
 - Obtundation

History

- Obtain history from patient, family, or EMS for clues to possible etiology
- Medications history

Physical-Exam

- Perform rapid survey and stabilize ABCs
- Distended neck veins and cool extremities distinguish cardiogenic shock from distributive and hypovolemic shock

- Careful heart and lung exam

ESSENTIAL WORKUP

Ancillary studies further define the type and degree of cardiac injury and determine the indications for emergent catheterization or surgical intervention.

DIAGNOSIS TESTS & INTERPRETATION

ECG:

- Normal ECG does not rule out AMI.
- Findings of AMI (ST-elevations in 2 or more contiguous leads)
- May occur in non-ST-elevation acute coronary syndrome
- Dysrhythmias
- LV hypertrophy

Lab

- B-type natriuretic peptide (BNP):
 - Diagnostic and prognostic value
- Creatine kinase (CK), CK-MB, troponin
- Electrolytes and renal function:
 - Acute renal failure is a strong predictor of mortality.
- CBC:
 - Identify anemia or elevated WBC.
- Drug levels (e.g., digoxin)

Imaging

- CXR:
 - Pulmonary congestion
 - Pleural effusion
 - Cardiomegaly
 - Pneumonia
 - Pneumothorax
 - Pericardial effusion
- Emergent echocardiography:
 - Transthoracic echocardiography (TTE) with color Doppler
 - LV contractility looking for hypokinesis, akinesis, or dyskinesis
 - Acute mitral regurgitation or septal defects
 - RV dilatation, tricuspid insufficiency, high pulmonary artery and RV pressures suggest pulmonary embolism
 - RV hypokinesis or akinesis, RV dilatation, normal pulmonary pressures suggest RV infarction
 - Pericardial effusion, right atrium or RV diastolic collapse suggest cardiac tamponade

DIFFERENTIAL DIAGNOSIS

- Obstructive shock:
 - Tension pneumothorax
 - Cardiac tamponade
 - Pulmonary embolism
 - Spontaneous esophageal rupture
 - Air embolus
- Distributive shock:
 - Sepsis
 - Anaphylaxis
 - Addisonian crisis
 - Neurogenic shock
- Hypovolemic shock:
 - Hemorrhage
 - GI losses
 - Dehydration
 - Burns

TREATMENT

PRE HOSPITAL

- ABCs, IV access, O₂, monitor
- Consider fluid bolus if no crackles
- Aspirin
- Nitroglycerin or morphine sulfate for chest pain in absence of hypotension
- Transport AMI patients to facility with 24-hr cardiac revascularization capability

INITIAL STABILIZATION/THERAPY

- ABCs
- 2 large-bore peripheral IV lines
- Cardiac monitor
- Endotracheal intubation for airway compromise:
 - Consider etomidate for induction (minimal effect on BP)
- Fluid challenge (100–250 mL normal saline) in absence of pulmonary congestion
- Foley catheter to monitor urine output

ED TREATMENT/PROCEDURES

- AMI:
 - Aspirin
 - Heparin
 - Thrombolysis if percutaneous coronary intervention or bypass surgery not available

- GP IIb/IIIa inhibitors prior to percutaneous coronary intervention
- Hypotension:
 - Norepinephrine is 1st-line vasopressor
 - Consider dopamine in absence of NE
- Normotensive patient:
 - Dobutamine may be used with NE or dopamine; combine with nitroprusside in acute mitral regurgitation
 - Milrinone may be considered in conjunction with dobutamine or dopamine
- Pulmonary edema:
 - Nitroglycerin drip or furosemide in the normotensive patient
- Prompt cardiology consultation is crucial for the initiation of the following therapies:
 - IABP independently improves survival in experienced centers
 - Early revascularization is the single most important life-saving measure

MEDICATION

- Dobutamine: 3–5 $\mu\text{g}/\text{kg}/\text{min}$, titrate to 20–50 $\mu\text{g}/\text{kg}/\text{min}$ as needed IV
- Dopamine: 3–5 $\mu\text{g}/\text{kg}/\text{min}$, titrate to 20–50 $\mu\text{g}/\text{kg}/\text{min}$ as needed IV
- Furosemide: 40–80 mg/d (peds: 1 mg/kg IV or IM, not to exceed 6 mg/kg) IV or IM
- Milrinone: 50 $\mu\text{g}/\text{kg}$ loading dose, 0.375–0.75 $\mu\text{g}/\text{kg}/\text{min}$ continuous infusion IV
- Nitroglycerin: 10–20 $\mu\text{g}/\text{min}$ (peds: 0.1–1 $\mu\text{g}/\text{kg}/\text{min}$) IV, USE NON-PVC tubing
- Nitroprusside: 0.3 $\mu\text{g}/\text{kg}/\text{min}$, titrate to a max. of 10 $\mu\text{g}/\text{kg}/\text{min}$ IV
- Norepinephrine: 2 $\mu\text{g}/\text{min}$, titrate up as needed IV

FOLLOW-UP

DISPOSITION

Admission Criteria

All patients in cardiogenic shock require admission to a critical care unit.

PEARLS AND PITFALLS

- Cardiogenic shock is the leading cause of death in inpatient AMI.
- Early recognition of preshock states is essential.
- Early revascularization offers better outcomes.

CARDIOMYOPATHY

David T. Chiu • Edward Ullman

BASICS

DESCRIPTION

Diseases of the myocardium associated with cardiac dysfunction:

- Dilated:
 - Idiopathic in 25% of all cases of heart failure
- Hypertrophic
- Restrictive
- Arrhythmogenic right ventricular (RV)
- Unclassified cardiomyopathy
- Specific cardiomyopathy:
 - Heart muscle disease associated with a systemic disease or condition

Pediatric Considerations

- Genetic: 20–30%
- Acquired
- Idiopathic

ETIOLOGY

- Dilated:
 - Idiopathic
 - Viral
 - Genetic/toxic
 - Immune
 - Familial
- Hypertrophic:
 - Familial disease with autosomal dominance
- Restrictive:
 - Idiopathic
 - Amyloid
- Arrhythmogenic RV:
 - Familial disease with dominant and recessive patterns
- Specific infectious:
 - Lyme disease
 - Viral
 - Chagas disease
 - HIV
- Toxic agents:

- Alcohol
- Chemotherapeutic agents
- Peripartum
- Metabolic:
 - Hyperthyroidism
 - Pheochromocytoma
 - Takotsubo (stress catecholamine)
- General system diseases:
 - Lupus
 - Scleroderma
 - Neuromuscular diseases
 - Amyloidosis

Pediatric Considerations

- Idiopathic
- Genetic:
 - Inborn errors of metabolism
 - Malformation syndromes
 - Neuromuscular disease
 - Familial isolated cardiomyopathy disorders
- Acquired:
 - Vitamin and/or trace mineral deficiencies
 - Electrolyte disturbances
 - Endocrine disorders
 - Toxins
 - Collagen vascular disease
 - Immunologic disease
 - Malignancy
 - Morbid obesity
 - Myocarditis
 - Pulmonary disease
 - Kawasaki disease
 - Infection
 - Radiation
 - Congenital heart disease
 - Asphyxia

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Antecedent illness or exposure:
 - Chemotherapy
 - HIV
 - Lyme disease
 - Viral
- Underlying systemic condition:
 - Hemochromatosis
 - Sarcoidosis
 - Pregnancy
- Substance abuse history
- Family history:
 - Familial sudden death
- Exertional complaints (syncope, dyspnea)
- Dizziness
- Near syncope and syncope
- Palpitations
- Sudden death
- Ventricular arrhythmias
- CHF

Pediatric Considerations

- Irritability
- Hepatomegaly
- Generalized muscle weakness
- Acute biochemical crisis
- Hypoglycemia
- Metabolic acidosis
- Hyperammonemia
- Cyanosis
- Encephalopathy
- Dysmorphic features

Pregnancy Considerations

See Cardiomyopathy, Peripartum.

Physical-Exam

- Vital signs
- Cardiopulmonary exam
- Abdominal organomegaly
- Edema
- Other:
 - Rash

- Goiter
- Systemic illness

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Chemistry panel
- Liver function tests, thyroid function tests
- Cardiac biomarkers
- Brain (B-type) natriuretic peptide: Level > 100 pg/mL
- Serologies: Not useful in the ED

Imaging

- CXR:
 - Dilated cardiomyopathy:
 - Cardiomegaly
 - Pulmonary congestion
 - Pleural effusions
 - Hypertrophic cardiomyopathy (HCM):
 - See Cardiomyopathy, Hypertrophic.
 - Restrictive cardiomyopathy:
 - Normal cardiac silhouette
 - Pulmonary congestion
- Emergency transthoracic 2D echocardiography by emergency physician:
 - Depressed LV ejection fraction (EF)
 - Excludes pericardial tamponade
- Formal echocardiography:
 - Study of choice
 - Identification of underlying disease
- Nuclear scintigraphy:
 - When ECG is indeterminate
 - Determination of the thickness of the septum and free wall
 - Alternatives to echocardiography
- CT and MRI distinguish between constrictive pericarditis and restrictive cardiomyopathy.
- MR comprehensive assessment of heart failure: Assess myocardial anatomy, regional and global function, and viability. Allows assessment of perfusion and acute tissue injury (edema and necrosis), and nonischemic heart failure, fibrosis, infiltration, and iron overload can be detected.

Diagnostic Procedures/Surgery

EKG:

- HCM:
 - Left ventricle (LV) hypertrophy
 - Q-waves in leads II, III, aVF, V5, and V6 in the early teenage years (most specific)
- Dilated, Lyme, Chagas, and toxic cardiomyopathies:
 - Atrial fibrillation
 - Heart block
 - Conduction abnormalities
 - Pseudoinfarct pattern with pathologic Q-waves in anterior and inferior leads without coronary artery disease

ALERT

Takotsubo (stress cardiomyopathy) can mimic STEMI (ST-elevation MI).

- Cardiac catheterization:
 - Suspicion of ischemia
 - Treatable systemic disease
- HCM:
 - Assessment of hemodynamic abnormalities
 - Endomyocardial biopsy
 - Evaluation for myocarditis or define etiology
- Cardiac CT or MRI

Pediatric Considerations

- Electrolytes
- pH
- Glucose
- Ammonia level
- Cardiac output
- Dysmorphic evaluation
- EKG
- Echocardiogram:
 - Genetic workup; see individual causes

DIFFERENTIAL DIAGNOSIS

- Other causes of dyspnea:
 - Chronic obstructive pulmonary disease
 - Anemia
 - Asthma
 - Interstitial lung disease
 - Pulmonary embolism
 - Pericardial tamponade
 - Valvular heart disease

- Ischemic heart disease
- Hypothyroidism
- Constrictive pericarditis, commonly confused with restrictive cardiomyopathy
- Other causes of syncope:
 - Hypovolemia
 - Heat disorder
 - Hypoglycemia
 - Arrhythmia
 - Cardiac ischemia

TREATMENT

PRE HOSPITAL

- Monitor
- Oxygen
- Avoid or use a lower dose of nitroglycerin in suspected HCM
- Decompensated heart failure:
 - Nitroglycerin
 - Noninvasive positive-pressure ventilation

INITIAL STABILIZATION/THERAPY

Airway, breathing, and circulation:

- Control airway as needed.
- Supplemental oxygen
- Noninvasive positive-pressure ventilation

ED TREATMENT/PROCEDURES

- Anticoagulation:
 - Dilated cardiomyopathy
 - Standard treatment of atrial fibrillation
 - Systemic embolization
- Limited ED experience with agents effective in HCM:
 - Disopyramide to reduce obstruction
 - Amiodarone to convert and maintain sinus rhythm
- Standard treatment of CHF
- Standard treatment of dysrhythmias

ALERT

- Keep NPO until inborn errors of metabolism ruled out.
- IV fluids:
 - D10 should be given until defects in the protein or fatty acid metabolism pathways are ruled out.

- IV fluids need to be given slowly and judiciously to avoid rapid fluid shifts to the extravascular space.

ALERT

Do not give any products with lactate to avoid worsening any metabolic acidosis or lactic acidemia:

- Antioxidants and vitamin cofactors
- L-Carnitine to increase mitochondrial energy metabolism
- Standard treatment of CHF
- Sodium dichloroacetate (DCA) acutely lowers acetic acid levels in patients with mitochondrial disorders.

MEDICATION

- Amiodarone: 5 mg/kg over 10 min
- Carnitine: (Peds: 50–300 mg/kg/d PO or IV)
- Digoxin: Start 0.125 mg IV
- Diltiazem IV: 0.25 mg/kg actual body weight over 2 min (average adult dose: 20 mg); repeat bolus dose (may be administered after 15 min if the response is inadequate): 0.35 mg/kg actual body weight over 2 min (average adult dose: 25 mg); continuous infusion 10 mg/hr; rate may be increased in 5 mg/hr increments up to 15 mg/hr as needed
- Disopyramide: 100–200 mg PO q6h
- Esmolol IV: Loading dose: 500 µg/kg over 1 min; follow with a 50 µg/kg/min infusion for 4 min; infusion may be continued at 50 µg/kg/min or, if the response is inadequate, titrated upward in 50 µg/kg/min increments (increased no more frequently than q4min) to a max. of 200 µg/kg/min
- Furosemide: 20–40 mg IV to a max. of 200 mg on subsequent doses (peds: 1 mg/kg IV q12–24h)
- Heparin: Load 80 IU/kg IV; then 18 IU/kg/hr
- Metoprolol IV: 2.5–5 mg q2–5min (max. total dose: 15 mg over a 10–15-min period)
- Milrinone: Bolus 50 µg/kg IV over 10 min, then 0.375–0.75 µg/kg/min IV
- Nesiritide: Bolus 2 µg/kg IV, then 0.01 µg/kg/min IV with a max. of 0.03 µg/kg/min
- Nitroglycerin: 5 µg/min IV titrate to SBP

Geriatric Considerations

Use caution in geriatric dosing.

FOLLOW-UP

DISPOSITION

Admission Criteria

- New or suspected cardiomyopathy
- Syncope in which dysrhythmias or HCM are possible etiologies
- Familial history of premature sudden death
- Cardiogenic shock

Discharge Criteria

- Diagnosed cardiomyopathy with mild CHF that improves with ED therapy
- Restrictive cardiomyopathy or HCM
- Cardiology consultation for discharge planning

Issues for Referral

Patients with EF < 35% may require referral for:

- Single-chamber implantable cardioverter defibrillator
- Atrial-synchronized biventricular pacing
- Ventricular assist devices
- Heart transplant

FOLLOW-UP RECOMMENDATIONS

- Primary care
- Cardiology
- Genetic testing may be indicated.

PEARLS AND PITFALLS

- Emergency physician bedside echocardiography is a useful tool for patients with syncope or exertional symptoms
- Obtaining family history in suspected cardiomyopathy

CARDIOMYOPATHY, HYPERTROPHIC

L. Kristian Arnold

BASICS

DESCRIPTION

- Hypertrophic cardiomyopathy (HCM):
 - Genetic disorder affecting the sarcomere:
 - Various mutations
 - Many phenotypic variations
 - Hypertrophied (regionally or globally), nondilated left or, rarely, right ventricle in the absence of another cause of degree of hypertrophy observed, such as hypertension or aortic stenosis
 - 2 general types:
 - Nonobstructive (HCM)—75% of patients. Estimated around 1% annual mortality
 - Obstructive (HOCM)—25% of patients. More severe—estimated 2% annual mortality
 - Manifests at all ages, from neonate to elderly:
 - Most manifest in childhood and adolescence—pubertal growth spurt
 - Usually more severe when diagnosed at younger age
 - Small percent progress to reduced LV function
 - Clinical presentation in mid and late life not uncommon
 - May initially be misdiagnosed as asthma, COPD, deconditioning or sleep apnea
 - Lethal arrhythmias more common in younger patients
 - Most common cause of atraumatic death in young (<35 yo) athletes
 - Supraventricular arrhythmias common with incidence increasing with age
 - Atrial fibrillation both common and poorly tolerated
- Prevalence ~ 1 in 500 adults general population:
 - Based on echocardiographic diagnosis
- Structural pathology:
 - Irregular, marked ventricular wall thickening with disarray of myofibrils in the thickened regions and fibrin deposition:
 - Affects higher-pressure LV more than right and, in obstructive form, if obstruction removed, hypertrophy decreases
 - Some phenotypes have progressive wall thinning with age—usually associated with thicker wall early
 - Thickening usually asymmetric involving the septum to a greater extent than the free ventricular wall
 - Atrial dilatation secondary to diastolic filling stiffness

- Impaired microvascular dilation associated with intimal thickening and perivascular collagen deposition
- Outpatient long-term management
 - Avoidance of volume depletion and elevated cardiac demand—depending on degree and location of hypertrophy
 - Pharmacologic
 - β -Blockers or verapamil to slow and control rate, thus prolonging diastole
 - Implantable cardiac defibrillator
 - In patients with history of syncope, cardiac arrest, family member with sudden death, asymptomatic nonsustained ventricular tachycardia (VT), abnormal BP response to exercise, massive hypertrophy
 - Alcohol ablation of hypertrophic outflow-obstructing septal tissue
 - Surgical septal myectomy—improving statistics with more centers performing

RISK FACTORS

Genetics

- 1st cardiac disorder for which genetic basis identified (1989)
- Autosomal-dominant inheritance:
 - > 10 associated genes found:
 - Most encode proteins for sarcomere
 - >700 distinct mutations recognized
 - High penetrance
 - Variable phenotypic expression
 - Some genotypes significantly more lethal:
 - Routine screening impractical at present
 - Increasing complexity with more understanding of interplay between primary sarcomere abnormalities and other genetic and nongenetic factors
 - Some mutations affect cell wall pumps—thus, association with dysrhythmias.

ETIOLOGY

See “Genetics.”

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Obstructive symptoms correlate with exertion or suddenly assuming upright position—activities that decrease venous return or ventricular filling.
 - Severity depends on the location and degree of ventricular wall thickening.
- Shortness of breath
- Dyspnea on exertion
- Exertional or postprandial angina
- Presyncope
- Syncope
- CHF
- Cardiovascular collapse
- Dysrhythmias:
 - Paroxysmal atrial fibrillation:
 - Often leads to significant, rapid clinical deterioration when present with CHF
 - Elevated CVA risk from clots
 - Supraventricular tachycardia
 - Nonsustained VT
 - Bradydysrhythmia rare
 - VT or ventricular fibrillation may lead to sudden death.
- Prior therapy for known HCM might include surgery or alcohol injection to reduce septal bulk:
 - Potential for conduction blocks
 - Potential septal rupture
- Known cases with higher risk of arrhythmia may have implanted defibrillators.
- Family history of sudden death without apparent cause or known HCM

Pediatric Considerations

Due to potential increasing severity in adolescence, any young child with syncope without clear cause, or in association with exercise, should have more extensive, focused history for familial sudden death (standard is 3 generations) and possible referral for evaluation.

Physical-Exam

- No or subtle physical findings
- Most findings in patients with outflow tract obstruction, variably:
 - Loud, left-sided S4
 - Double apical cardiac impulse at the mid to upper sternum
 - Murmur:
 - Crescendo–decrescendo midsystolic murmur at the left sternal edge
 - Radiation to aortic and mitral areas, not to neck or axilla
 - Increasing in intensity with Valsalva maneuver or standing up
 - Quieter with recumbency, squatting, or handgrips

- Frequent associated mitral regurgitation
- With more severe obstruction, a more apparent murmur with radiation to the left sternal border
- Radiation to the axilla if there is associated mitral insufficiency

DIAGNOSIS TESTS & INTERPRETATION

ECG findings:

- Abnormal in >90% pts with HCM
- T-wave inversion >1 mm 2 or + leads V2-V6, II and aVF, or I and aVL or deep TWI in V4-V6 in non-African-Caribbean descent athletes >16 yo
- ST-segment depression >0.5 mm in 2 or more leads requires further investigation
- Q-waves >3 mm in depth or >40 ms duration in at least 2 leads other than III & aVR
- P-wave >120 ms leads I or II with negative portion ≥ 1 mm and ≥ 40 ms in lead V1
- Nonspecific IVCD >140 ms

Lab

- Clinical lab testing is of no assistance.
- Genetic testing may help in outpatient workup, but not in ED.

Imaging

- CXR:
 - Normal in the vast majority
 - Bulge along left heart border representing hypertrophy of free wall of LV
 - Right or left atrial enlargement
 - Pulmonary vascular redistribution
- Transthoracic cardiac echo/Doppler:
 - LV wall >15 mm, with normal or small LV cavity (13–14 mm with other features; e.g., family history in adults), in children ≥ 2 times standard deviation above mean for age, sex, size
 - Systolic outflow obstructions
 - Diastolic filling abnormalities
- Cardiovascular magnetic resonance (CMR)
 - Supplements ECHO
 - Allows more structural detail for evidence of fibrosis
- Stress thallium and PET evaluate ischemia.

Diagnostic Procedures/Surgery

No ED-based procedures are of diagnostic utility.

DIFFERENTIAL DIAGNOSIS

- Vagal and other causes of syncope and presyncope

- Heatstroke
- Aortic stenosis
- Pulmonic stenosis
- Ventricular septal defect
- Mitral regurgitation
- Mitral valve prolapse
- Arteriosclerotic coronary vascular disease
- Differentiate in patients presenting with CHF or angina:
 - _ More ominous in the setting of HCM

TREATMENT

ALERT

Consider HCM in patients who decompensate during standard treatments for CHF, ischemia, or supra-VT, and in young athletes who collapse during or just after exertion—rule out heat stroke. HCM patients may decompensate with IV fluids due to diastolic stiffness.

INITIAL STABILIZATION/THERAPY

- ABCs
- IV catheterization
- Supplemental oxygen
- Cardiac monitor
- Pulse oximetry

ED TREATMENT/PROCEDURES

- Depends on type of presentation: Dysrhythmia, cardiac failure, chest pain or ischemia
- Underlying principle to understand sensitivity to any situation that may impair cardiac filling.
- Patient may need to remain supine.
- Standard CHF or anginal vasodilator therapy may lead to cardiovascular collapse; if this occurs, treat with fluid bolus.
- Attention to any hypovolemia as small degree may significantly impair cardiac output.
- Control rate and improve diastolic filling (underlying principle in treating HCM-associated CHF and angina):
 - _ β -Blockers:
 - Mainstay of therapy
 - Decrease dysrhythmias and lower elevation of pressure gradient across the LV outflow tract
 - _ Calcium channel blockers:

- Verapamil reduces obstruction by decreasing contractility and improving diastolic relaxation and filling.
- Nifedipine relatively contraindicated due to vasodilatation
- Dysrhythmia management:
 - β -Blockers and calcium channel blockers 1st line for supraventricular dysrhythmias
 - Amiodarone:
 - Drug of choice for ventricular dysrhythmias
 - Used when β -blockers and calcium channel blockers fail
 - Electrical cardioversion:
 - Use early in HCM with new atrial fibrillation and CHF

MEDICATION

All medications must be assessed for effect in face of possible outflow track restriction

- Amiodarone: 150 mg over 10 min, then 360 mg over 6 hr, then 540 mg over next 18 hr (peds: 5 mg/kg IV rapid IV/IO bolus, off-label use per manufacturer, but class IIb for VT with a pulse and class indeterminate for VF and pulseless VT, per American Heart Association. Do not use in infants.)
- Propranolol: 1–3 mg (peds: 0.01–0.1 mg/kg slow IV push over 10 min; not to exceed 1 mg/dose) slow IV bolus
- Verapamil: 2.5 mg (peds: > 1 yr: 0.1–0.2 mg/kg/dose over 2 min; repeat q10–30min as needed; not to exceed 5 mg/dose [1st dose] or 10 mg/dose [2nd dose]) IV bolus over 1–2 min, may repeat as 5 mg in 15–30 min
- Phenylephrine: 0.1–0.2 mg (peds: 1–20 μ g/kg) IV slow bolus for severe hypotension (shock) not responding to fluid bolus. Repeat in 10–15 min as needed or start IV drip to titrate to BP; or other pure vasoconstrictor (i.e., no inotropic effect). Maintenance dose: 0.05 μ g/kg/min (peds: 0.1–0.5 μ g/kg/min) IV

First Line

N/A

Second Line

Diltiazem: 0.25 mg/kg (peds: Contraindicated < 12 yr old) IV over 2 min; may repeat in 15 min at 0.35 mg/kg

FOLLOW-UP

DISPOSITION

Admission Criteria

- Unexplained syncope, especially in younger adults.
- ICU admission:

- Syncopal episodes
- CHF
- Angina
- Hemodynamically significant tachydysrhythmia

Discharge Criteria

When increased myocardial wall thickness is an incidental finding during the ED evaluation for another presentation with:

- No history of familial sudden death (proposed guidance—3 generations to rule out in face of suspicion) or personal history of syncope
- Need urgent follow-up with a cardiologist
- Counsel against any activities that may decrease diastolic filling pending follow-up:
 - Counsel against physical exertion until evaluated by cardiologist

Issues for Referral

See “Discharge Criteria.”

FOLLOW-UP RECOMMENDATIONS

See “Discharge Criteria.”

PEARLS AND PITFALLS

- Increasing awareness of genetic and phenotypic variants with implications in definition of “normal variant”:
 - Some authors advocate cardiac ECHO screening for any youth participation in sports.
 - Some authors advocate AICD at diagnosis.
- If HCM is considered in a patient with syncope, it must be ruled out because it is much more likely to be fatal with repeat episodes.

CARDIOMYOPATHY, PERIPARTUM

David W. Callaway

BASICS

DESCRIPTION

- Dilated cardiomyopathy occurring during the last month of pregnancy up to 5 mo following the delivery
- Diagnostic criteria (all required):
 - Onset of myocardial failure during last month of pregnancy or 1st 5 mo after delivery
 - Absence of a specific cause
 - Absence of prior cardiac disease
- Diagnosis requires strict criteria of echocardiographic dysfunction
- Incidence: 3–5/10,000 live births
- ~50% of cases resolve spontaneously
- Mortality: 18–56%
- Risk factors:
 - Older women (> 30 yr)
 - Multiparous women
 - Multiple gestations
 - Prolonged tocolytic therapy (> 4 wk)
 - Obesity
 - Preeclampsia
 - African American
- Systemic and pulmonary embolism more frequent than with other forms of cardiomyopathy
- Factors indicating a poor prognosis:
 - Lower left ejection fraction at 6 mo postpartum
 - Onset > 2 wk postpartum
 - Age > 30 yr
 - African American descent
 - Multiparity

ETIOLOGY

Various causes are suggested but remain unproved:

- Viral infection leading to myocarditis in presence of immunosuppression during pregnancy (*most likely*)
- Immunologic response to an unknown maternal or fetal antigen
- Maladaptive response to the hemodynamic stresses of pregnancy
- Stress-activated cytokines

- Prolonged tocolysis
- Selenium deficiency

DIAGNOSIS

SIGNS AND SYMPTOMS

- Dyspnea
- Dizziness
- Chest pain
- Orthopnea
- Cough
- Paroxysmal nocturnal dyspnea
- Anorexia
- Fatigue
- Arrhythmias

History

- Onset and duration of symptoms
- Unexplained persistent cough
- Excessive weight gain:
 - >2–4 lb/wk
- Prior cardiac disease
- Prior pregnancies and complications

Physical-Exam

- Palpitations
- Jugular venous distention
- Gallop rhythm
- Mitral regurgitation murmur
- Loud P2
- Pulmonary rales
- Peripheral edema (especially rapid onset)
- Hepatomegaly
- Hepatojugular reflux

ESSENTIAL WORKUP

- CXR views:
 - Pulmonary venous congestion
 - Cardiomegaly (can be difficult to differentiate with pregnancy)
 - Pleural effusions
- EKG:
 - Nonspecific

- Left ventricular hypertrophy
- Left atrial enlargement
- T-wave flattening or inversion
- Arrhythmias
- Ventricular ectopy (40%)
- Atrial fibrillation (20%)

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Electrolytes:
 - Generally normal
- BUN, creatinine
- CBC:
 - Mild postpartum anemia may contribute to fatigue and dyspnea.
- Creatine kinase with muscle and brain fraction
- β -Natriuretic peptide (BNP):
 - Useful for distinguishing between heart failure due to diastolic and/or systolic dysfunction and a pulmonary cause of dyspnea
 - BNP > 100 pg/mL diagnosed heart failure with a sensitivity of 90%, a specificity of 76%, and a predictive accuracy of 83%. BNP of \leq 50 pg/mL has a high negative predictive value.

Imaging

- CXR:
 - Cardiomegaly
 - Effusions (usually right sided)
 - 3 phases of pulmonary findings:
 - Stage I: Pulmonary redistribution to upper lung fields (cephalization)
 - Stage II: Interstitial edema with Kerley B lines
 - Stage III: Alveolar edema
 - Bilateral confluent perihilar infiltrates leading to classic butterfly pattern
 - May be asymmetric and mistaken for pneumonia
- Echo:
 - Demonstrates global dilation, cardiac wall thinning, and decreased ejection fraction
 - Criteria for the diagnosis were established by Hibbard et al.:
 - Ejection fraction < 45% or M-mode fractional shortening of < 30%
 - End-diastolic dimension > 2.72 cm/m²
 - Exclude valvular pathology and cardiac tamponade.

Diagnostic Procedures/Surgery

Endomyocardial biopsy:

- Indicated to assess for myocarditis and steroid therapy

DIFFERENTIAL DIAGNOSIS

- Other causes of dilated cardiomyopathy:

- Ischemia
- Infarction
- Valvular rupture or disease
- Chronic HTN
- Familial
- Toxins:
 - Ethanol, anthracyclines, cocaine, drug allergy
- Metabolic:
 - Thiamine
 - Selenium
 - Hypothyroidism
 - Thyrotoxicosis
 - Hypophosphatemia
- Infectious:
 - Viral
 - Parasitic or rickettsial
 - Bacterial
 - Fungal
- Systemic disorders:
 - Sarcoidosis
 - Scleroderma
 - Systemic lupus erythematosus
- Eosinophilic myocarditis
- Neuromuscular dystrophies
- Mitochondrial cardiomyopathies

- Other causes of shortness of breath or edema:

- Pulmonary embolism
- Pneumonia
- Asthma
- Cardiac ischemia
- Anemia
- Hyperthyroidism
- Constrictive pericarditis
- Pericardial tamponade
- Nephrotic syndrome
- Cirrhosis

TREATMENT

PRE HOSPITAL

Differentiate pulmonary edema from acute reactive airway disease.

INITIAL STABILIZATION/THERAPY

ABCs:

- Prompt evaluation of respiratory and hemodynamic status
- Control airway as needed
- Supplemental oxygen
- Continuous positive airway pressure, as needed
- Preload and afterload reduction

ED TREATMENT/PROCEDURES

- Antepartum therapy:
 - _ Nitrates
 - _ Hydralazine
 - _ IV furosemide
 - _ Amlodipine: A dihydropyridine calcium channel blocker that has been shown to improve survival in nonischemic cardiomyopathy patients
 - _ Digoxin to control rate due to atrial fibrillation
 - _ Carvedilol (antepartum and not in acute decompensated phase)
 - _ LMWH if EF < 35%
 - _ Fetal monitoring
- Invasive cardiac monitoring if unstable
- Postpartum therapy:
 - _ Consider adding ACE inhibitors (enalapril) or ARBs.
 - _ Anticoagulation therapy often recommended:
 - 30% of cases complicated by systemic or pulmonary embolism
 - During pregnancy, use SC or IV heparin rather than warfarin, which causes birth defects.
- For severe symptoms or lack of response to standard therapy:
 - _ Dobutamine
 - _ Dopamine
 - _ Nitroprusside
 - _ Assist devices
 - Intra-aortic balloon pump
 - LV assist device
 - Extracorporeal membrane oxygenation
 - _ Immunosuppressive therapy:
 - Advocated for patients who fail to improve within 2 wk of standard medical therapy

- Prednisone with cyclosporine or azathioprine
- Immunoglobulin therapy remains controversial

MEDICATION

- Amlodipine: 2.5–10 mg/d PO
- Bumetanide: 0.5–2 mg IV
- Digoxin: 0.5 mg IV, then 0.25 mg IV q4h for 2 doses; 0.125–0.375 mg/d PO
- Milrinone: 50 µg/kg over 10 min
- Dobutamine: 2–10 µg/kg/min IV
- Dopamine: 2–20 µg/kg/min IV
- Enalapril: 0.625–1.25 mg IV; 2.5–20 mg/d PO
- Furosemide: 20–100 mg IV
- Metoprolol: 12.5 mg PO BID
- Morphine sulfate: 2–4 mg IV q5min
- Nitroglycerin: 0.4 mg sublingual; 1–2 in of nitroglycerin paste; 5–20 µg/min IV, max. of 100–200 µg/min IV. USE NON-PVC tubing
- Nitroprusside: 0.5–10 µg/kg/min IV

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with pulmonary edema, cardiogenic shock, or evidence of ischemia should be admitted to the ICU.
- All symptomatic patients with new onset of peripartum cardiomyopathy should be admitted.

Discharge Criteria

- Mild left ventricular dysfunction
- Established history of peripartum cardiomyopathy:
 - Mild fluid overload attributable to excessive salt intake
 - Complete resolution of symptoms following ED treatment
 - No evidence of cardiac ischemia
- Close follow-up arranged

Issues for Referral

Close follow-up with a cardiologist

FOLLOW-UP RECOMMENDATIONS

- Drink 6–8 glasses of liquid each day.
- Limit salt intake.

- Avoid alcohol because it may worsen cardiomyopathy.
- Support socks may help decrease the swelling in legs and prevent clot formation.
- Daily weights:
 - Weight gain can be a sign of extra fluid in the body.
 - Call doctor if gain of >2 lb in a day.
- Return for shortness of breath, feeling faint, palpitations.

PEARLS AND PITFALLS

- Remember high rates of thromboembolism in pregnancy and peripartum cardiomyopathy.
- Utilize multidisciplinary approach with cardiology and obstetrics consultations.

ICD10

O90.3 Peripartum cardiomyopathy

CARPAL FRACTURES

Mary R. Mulcare • Wallace A. Carter

BASICS

DESCRIPTION

- Most commonly injured region of upper extremity
 - Most commonly fractured carpals are the scaphoid (68%) and triquetrum (18%)
- Carpal bone fractures commonly occur with other wrist injuries:
 - Capitate fractures along with scaphoid (scaphocapitate syndrome) sometimes occur with perilunate dislocations
 - Hamate fractures associated with injuries to 4th and 5th CMC and metacarpals concurrent with distal radius fractures

ETIOLOGY

- Fall on outstretched hand (FOOSH) with a hyperextended or hyperflexed wrist
- Direct blow
- Axial loading
- Chronic use injury

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- FOOSH or direct blow
 - Hyperflexion → dorsal avulsion fracture
 - Hyperextension → volar avulsion fracture
- Hook of hamate fractures:
 - Associated with a forceful swing of a racquet or club

Physical-Exam

- Pain, swelling, decreased range of motion
- Individual palpation of each carpal bone is possible with correct positioning of wrist
- Scaphoid fractures:
 - Snuffbox tenderness is sensitive but not very specific
 - Specificity improved with pronation and ulnar deviation of wrist
 - Scaphoid compression test (axial loading thumb causes pain) is also not very specific

- Tenderness of tubercle on palmar aspect at distal wrist crease with wrist in extension
- More specific than snuffbox tenderness

ESSENTIAL WORKUP

- A complete physical exam of the entire upper extremity and shoulder girdle:
 - Evaluate for associated injuries
- Neurovascular exam is essential
- Hamate fractures may be associated with ulnar nerve or artery injuries

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- Anterior–posterior, lateral, oblique views of the hand and wrist
- Special views (e.g., scaphoid views) may be obtained for most of the carpals if physical exam is suspicious
- CT scan has superior sensitivity for fractures
- MRI can diagnose ligamentous injuries

DIFFERENTIAL DIAGNOSIS

- Metacarpal base fractures
- Distal radius or ulna fractures
- Lunate or perilunate dislocations

Pediatric Considerations

Be wary of epiphyseal injuries of the distal radius: Children rarely get simple sprains or fractures of the wrist.

TREATMENT

PRE HOSPITAL

- Prevent contamination of any lacerations overlying the area
- Patients with swelling or significant pain at the wrist or hand:
 - Elevate extremity and apply ice
 - Remove jewelry, watches
 - Immobilize extremity with padded board splints to reduce further injury

INITIAL STABILIZATION/THERAPY

As in any trauma, assess for other more serious injuries.

ED TREATMENT/PROCEDURES

- Isolated carpal bone fractures can be initially managed with splinting
 - Goal to obtain and maintain normal alignment

- Thumb spica:
 - Scaphoid and trapezium fractures
 - Wrist held in slight extension
- Sugar tong splint:
 - Capitate and lunate fractures
 - Extends from MCP joint on dorsal side of hand, wrapping around the elbow, ending at midpalmar crease
 - Wrist neutral
- Volar splint:
 - Triquetrum, pisiform, trapezoid, hamate fractures
 - Extends from midpalmar crease to below the elbow
 - Wrist in slight extension
 - Splint suspected fractures (especially scaphoid) based on physical exam despite negative radiographs
- Open carpal fractures:
 - Requires extensive, high-pressure irrigation
 - Parenteral antibiotics against *Staphylococcus aureus*, with gram-negative coverage in Grade III (involving significant soft tissue damage) open fractures
 - Monitor neurovascular status
 - Tetanus prophylaxis
 - Immediate orthopedic consultation

MEDICATION

- Mild oral analgesics, oral narcotics, NSAIDs for patient comfort
- Proper splinting will relieve most of the pain for these injuries

FOLLOW-UP

DISPOSITION

Admission Criteria

- Open fractures are admitted for early operative irrigation and débridement
- Patients with injuries requiring surgical management (open reduction, unstable displaced fractures) sometimes are admitted for early intervention

Discharge Criteria

Closed, nondisplaced carpal fractures treated with adequate splinting may be discharged to have orthopedic follow-up in 7–10 days.

FOLLOW-UP RECOMMENDATIONS

- Confirmed fractures are referred to orthopedics for definitive casting and further

management

- Missed fractures or improper splinting can lead to long-term complications and disability:
 - Untreated scaphoid, capitate, and lunate fractures lead to high rates of nonunion and avascular necrosis
 - Splinting is crucial for long-term function and mobility
 - Immobilize any injury with significant pain and refer for repeat radiographs in 7–10 days or more advanced imaging (CT or MRI)

PEARLS AND PITFALLS

- Carpal fractures may not be apparent on initial radiographs and may lead to long-term disability if not treated appropriately
- Splint all suspected fractures and refer for repeat radiographs or consider CT scanning in ED or outpatient setting
- Most (90%) scaphoid fractures are isolated injuries:
 - All other carpal fractures are more often associated with other wrist or hand injuries
- Adequate treatment involves splinting in position of function and referral for definitive casting and management

CARPAL TUNNEL SYNDROME

Matthew T. Spencer • Linda L. Spillane

BASICS

DESCRIPTION

- Carpal tunnel syndrome is caused by compression of the median nerve as it passes through the carpal tunnel.
- The carpal tunnel is the area bound by the carpal bones and the transverse carpal ligament.
- The median nerve, flexor digitorum profundus, flexor digitorum superficialis (FDS), and flexor pollicis longus are located in the carpal tunnel.
- Carpal tunnel syndrome can be classified as acute or chronic.

ETIOLOGY

- Acute:
 - Trauma
 - Infection
 - Snake bite
 - Hemorrhage
 - High-pressure injection injury
- Chronic:
 - Occupational/overuse syndromes—high impact, repetitive motion
 - Pregnancy, birth control pills
 - Granulomatous disease: Tuberculosis, sarcoidosis
 - Mass lesions with median nerve compression
 - Osteophytes
 - Amyloid
 - Multiple myeloma
 - Rheumatoid arthritis
 - Endocrine disorders: Hypothyroidism, diabetes mellitus, acromegaly
 - Chronic hemodialysis
 - Idiopathic

Pediatric Considerations

Idiopathic causes are rare in children; most cases have a correctable cause including:

- Trauma
- Mucopolysaccharidosis
- Hamartoma of the median nerve
- Anomalous FDS
- Hemophilia with hematoma

SIGNS AND SYMPTOMS

History

- Acute or chronic onset
- Numbness/paresthesia in a median nerve distribution:
 - Thumb, index, middle, and radial aspect of ring finger
- Pain:
 - Location: Wrist or hand, sometimes radiating to elbow, forearm, or shoulder
 - Often worse at night—relieved by “shaking out” the hand
 - Exacerbated by repetitive wrist movement and by activities in which the wrist is flexed (e.g., driving)

Physical-Exam

- Weakness of the abductor pollicis brevis and opponens muscles:
 - Innervated by the recurrent branch of the median nerve
 - Patient may complain of dropping things or having decreased fine motor control.
- Loss of 2-point discrimination:
 - Late finding, highly specific
- Atrophy of thenar muscles:
 - Late finding, highly specific

ESSENTIAL WORKUP

- History of characteristic nocturnal pain and paresthesia in the median nerve distribution.
- Muscle weakness and thenar wasting are later findings.
- Provocative testing:
 - Overall poor sensitivity and specificity
 - Phalen test:
 - Wrist flexion for 60 sec produces numbness or tingling in the median nerve distribution.
 - Tinel sign:
 - Gentle tapping over the median nerve at wrist produces tingling in the fingers in the median nerve distribution.
 - Carpal compression test:
 - Direct pressure applied over the proximal carpal ligament for 30 sec produces tingling in the fingers in the median nerve distribution.
 - Tourniquet test:
 - BP cuff inflated to just above the patient’s systolic BP for 2 min produces paresthesia in the median nerve distribution.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Not indicated in most cases
- Thyroid function studies; rheumatoid factor and immune panel if indicated by history and physical exam

Imaging

- Wrist radiograph if trauma or degenerative arthritis suspected
- CT in select cases (not routine):
 - May show encroachment of carpal tunnel
- MRI displays the soft tissues well but not recommended for routine diagnosis:
 - Findings: Palmar bowing of transcarpal ligament, flattened median nerve, median nerve or synovial swelling, fluid in carpal tunnel, signal abnormality of median nerve
- Ultrasound can be diagnostic:
 - Sensitivity of 44–95%; specificity of 57–100%
 - Findings: Median nerve swelling at proximal canal, median nerve flattening at distal canal, bowing of transcarpal ligament

Diagnostic Procedures/Surgery

Nerve conduction studies and electromyography are criterion standard tests.

DIFFERENTIAL DIAGNOSIS

- Cervical nerve root compression:
 - Origin of median nerve is at the 6th and 7th cervical roots.
 - Symptoms are aggravated by erect posture and neck movement.
- Hand–arm vibration syndrome:
 - Characterized by Raynaud, numbness and tingling in ulnar and median nerve distributions when exposed to cold or vibration, weakened grip, and upper extremity myalgias
 - Associated with prolonged exposure to vibration
- Thoracic outlet obstruction
- Osteoarthritis of the 1st carpometacarpal joint
- Brachial plexitis
- Generalized neuropathy
- Syringomyelia
- Multiple sclerosis

TREATMENT

INITIAL STABILIZATION/THERAPY

None necessary

ED TREATMENT/PROCEDURES

- Acute:
 - Hand surgery consultation for surgical release of transverse carpal ligament using either open or endoscopic technique
- Chronic:
 - Analgesics
 - Oral corticosteroids
 - Local corticosteroid injection
 - Avoidance of repetitive wrist movement
 - Splint wrist in neutral position (0°):
 - Worn at night until follow-up
 - Yoga
 - Referral:
 - Primary care physician
 - Occupational medicine for ergometric testing if caused by repetitive motion, and tendon gliding, nerve gliding, or carpal bone mobilization exercises
 - Hand surgeon for evaluation of surgical intervention

MEDICATION

- Analgesics:
 - There are many choices
 - NSAIDs have not been shown to improve long-term outcome
- Oral corticosteroids—short-term benefit:
 - Prednisone: 20 mg daily × 7 days, 10 mg daily × 7 days
 - Prednisolone: 20–25 mg daily, tapered over 2–4 wk
- Local corticosteroid injection—transient relief in 2/3 of patients (many different regimens):
 - Hydrocortisone: 20 mg
 - Methylprednisolone: 15–40 mg
 - Triamcinolone: 20 mg
 - Usually combined with 0.15–0.5 mL 2% lidocaine

FOLLOW-UP

DISPOSITION

Admission Criteria

Acute carpal tunnel syndrome requiring surgical decompression

Discharge Criteria

Chronic carpal tunnel syndrome after adequate pain control

FOLLOW-UP RECOMMENDATIONS

Primary care physician or directly to a specialist in occupational medicine or hand surgery within 1–2 wk

CAUDA EQUINA SYNDROME

Daniel F. Morris

BASICS

DESCRIPTION

Compression of lumbar and sacral nerve fibers in cauda equina region:

- Nerve fibers below conus medullaris
- Fibers end at L1–L2 interspace.

RISK FACTORS

- Neoplasm
- IV drug use
- Immunocompromised state
- Trauma

ETIOLOGY

- Herniated disc most common:
 - _ L4–L5 discs > L5–S1 > L3–L4
 - _ Most common in 4th and 5th decades of life
- Mass effect from:
 - _ Myeloma, lymphoma, sarcoma, meningioma, neurofibroma, hematoma
 - _ Spine metastases (breast, lung, prostate, thyroid, renal)
 - _ Epidural abscess (especially in IV drug users)
- Blunt trauma
- Penetrating trauma
- Spinal anesthesia

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Low back pain
- Sciatica/radicular pain (unilateral or bilateral)
- Lower-extremity numbness or weakness
- Difficulty ambulating owing to weakness or pain
- Bladder or rectal dysfunction:
 - _ Retention or incontinence

Physical-Exam

- Lumbosacral (LS) tenderness
- Lower-extremity sensory or motor deficits:
 - May be asymmetric
- Decreased foot dorsiflexion strength
- Decreased quadriceps strength
- Decreased deep tendon reflexes
- Saddle hypalgesia or anesthesia
- Decreased anal sphincter tone

ESSENTIAL WORKUP

- Neurologic exam most essential:
 - Straight-leg raise
 - Lasègue sign:
 - With patient supine, flex hip and dorsiflex foot.
 - Pain or spasm in posterior thigh indicates nerve irritation.
 - Perineal sensation
 - Rectal tone
 - Anal wink: Reflex contraction of external anal sphincter with gentle stroking of skin lateral to anus
- Postvoid residual volume:
 - Estimate by bladder catheterization or using US.
 - >50–100 mL is considered abnormal.
 - Residual increases with age.
 - Diagnosis unlikely if normal

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Based on differential diagnoses
- CBC, urinalysis, ESR, and C-reactive protein (CRP)

Imaging

- Radiographs of LS spine
- MRI of spine is definitive study.
- CT myelogram if MRI unavailable

DIFFERENTIAL DIAGNOSIS

- Osteoarthritis, LS strain, sciatica
- Vertebral fracture (pathologic and nonpathologic)
- Osteomyelitis
- Spinal epidural abscess
- Conus medullaris or higher cord compression
- Ankylosing spondylitis, spinal stenosis

- Abdominal aortic aneurysm dissection
- Vascular claudication
- Hip pathology
- Acute transverse myelitis

TREATMENT

PRE HOSPITAL

- Manage airway and traumatic injuries as indicated.
- If evidence of trauma, patient should be transported with full spine immobilization.

ALERT

Even in nontrauma patient, consider spinal immobilization given possibility of unstable lesion.

INITIAL STABILIZATION/THERAPY

- Spine immobilization if trauma or unstable spine lesion suspected
- Analgesia
- NPO until evaluated by neurosurgery

ED TREATMENT/PROCEDURES

- Repeat neurologic exams to detect progression.
- For acute spinal cord trauma (< 8 hr), begin high-dose methylprednisolone protocol.
- Immediate neurosurgical consultation in all cases
- Initiate antibiotics for epidural abscess in consultation with neurosurgery.
- Controversy exists regarding urgency of decompression:
 - Recommendations range from within 6 hr of onset to within 24 hr.

MEDICATION

- Methylprednisolone (high-dose steroid protocol): 30 mg/kg IV bolus, then 5.4 mg/kg/h infusion over next 23 hr. Should be started within 8 hr of injury.

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with acute cauda equina syndrome must be admitted to neurosurgical service.
- Patients have good prognosis with rapid surgical decompression.

- Treatment should not be delayed.
- Patients presenting late (> 48 hr) also benefit from surgical decompression.

Discharge Criteria

Patients with established cauda equina syndrome with prior complete evaluation and no new neurologic deficits may be discharged with close follow-up with their neurosurgeon.

PEARLS AND PITFALLS

Ideally, diagnose patients in early phase before irreversible neurologic dysfunction:

- Back pain out of proportion
- Fever and back pain
- Back pain in high-risk groups; screen with ESR/CRP when infection suspected

CAUSTIC INGESTION

Paul Kolecki

BASICS

DESCRIPTION

- Alkalis:
 - Dissociate in the presence of H_2O to produce hydroxy (OH^-) ions, which leads to liquefaction necrosis
 - Postingestion—mainly damages the esophagus:
 - Gastric damage can occur (see “Acids”).
 - Esophageal damage (in the order of increasing damage) consists of:
 - Superficial hyperemia
 - Mucosal edema
 - Superficial blisters
 - Exudative ulcerations
 - Full-thickness necrosis
 - Perforation
 - Fibrosis with resulting esophageal strictures
 - Do *not* directly produce systemic complications.
- Acids:
 - Dissociate in the presence of H_2O to produce hydrogen (H^+) ions, which leads to a coagulation necrosis with eschar formation
 - Postingestion—damages the stomach because of rapid transit time through esophagus:
 - Esophageal damage can occur (see “Alkalis”).
 - Gastric damage (in the order of increasing damage) consists of:
 - Edema
 - Inflammation
 - Immediate or delayed hemorrhage
 - Full-thickness necrosis
 - Perforation
 - Fibrosis with resulting gastric outlet obstruction
 - Well-absorbed and can cause hemolysis of RBCs and a systemic metabolic acidosis

ETIOLOGY

- Direct chemical injuries
- Injuries occur secondary to acid and alkali exposures.
- Many caustic agents (acids and alkalis) are found in common household and

industrial products.

- Caustic substances:
 - Ammonia hydroxide
- Glass cleaners:
 - Formaldehyde:
 - Embalming agent
 - Hydrochloric acid:
 - Toilet bowl cleaners
 - Hydrofluoric acid:
 - Glass etching industry
 - Microchip industry
 - Rust removers
 - Iodine:
 - Antiseptics
 - Phenol:
 - Antiseptics
 - Sodium hydroxide:
 - Drain cleaners
 - Drain openers
 - Oven cleaners
 - Sodium borates, carbonates, phosphates, and silicates:
 - Detergents
 - Dishwasher preparations
 - Sodium hypochlorite
 - Bleaches
 - Sulfuric acid:
 - Car batteries
 - Button batteries

DIAGNOSIS

SIGNS AND SYMPTOMS

- Oropharyngeal:
 - Pain
 - Erythema
 - Burns
 - Erosions
 - Ulcers
 - Drooling
 - Hoarseness
 - Stridor
 - Aponia

- Absence of visible lesions in the oropharynx does not exclude visceral injuries.
- Pulmonary:
 - Tachypnea
 - Cough
 - Pneumonitis if aspirated
- GI:
 - Pain
 - Emesis or hematemesis
 - Melena, dysphagia
 - Odynophagia
 - Esophageal or gastric perforation
 - Peritonitis owing to perforation
- Cardiovascular:
 - Tachycardia
 - Hypotension
 - Orthostatic changes
- Hematologic:
 - Acid ingestion can cause RBC hemolysis.
- Dermatologic:
 - Pain
 - Erythema
 - 1st-, 2nd-, or 3rd-degree burns
- Ocular:
 - Pain
 - Erythema
 - Injection
 - Corneal burns
 - Full-thickness corneal damage
- Metabolic:
 - Metabolic acidosis

ESSENTIAL WORKUP

- History of or signs and symptoms of an exposure
- Absence of oropharyngeal lesions does *not* exclude visceral injury.

DIAGNOSIS TESTS & NTERPRETATION

Lab

- CBC
- Electrolytes, BUN, creatinine, glucose
- Arterial blood gas
- Blood cultures:

- If mediastinitis or peritonitis suspected
- Type and cross-match

Imaging

Chest and abdominal radiographs for:

- Esophageal or gastric perforation

Diagnostic Procedures/Surgery

- Esophageal and gastric endoscopy:
 - For symptomatic patients to determine the extent of injury
 - Perform within the 1st 12–24 hr after ingestion.
 - Not recommended in the presence of respiratory distress without proper airway management
 - Not recommended in the presence of severe pharyngeal damage
- Radiographic oral contrast imaging not recommended acutely:
 - May be used in follow-up for assessment for strictures

DIFFERENTIAL DIAGNOSIS

- Chemical injuries from corrosives, acids, alkalis, desiccants, vesicants, and oxidizing and reducing agents
- Foreign body ingestion
- Upper airway infection or angioedema

TREATMENT

PRE HOSPITAL

- For oral burns or symptoms: Rinse mouth liberally with water or milk.
- Water or milk can be given to following patients:
 - Able to drink
 - Not complaining of significant abdominal pain
 - Do not have airway compromise or vomiting
- Copious irrigation for ocular or dermal exposure

INITIAL STABILIZATION/THERAPY

- ABCs:
 - Prophylactic intubation if there is any evidence of respiratory compromise
 - Blind nasotracheal intubation contraindicated
- Treat hypotension with 0.9% NS IV fluid resuscitation.

ED TREATMENT/PROCEDURES

- Decontamination:
 - Dermal or ocular exposure:

- Immediate and thorough irrigation with water or 0.9% NS until physiologic pH attained
- Alkalis typically require more irrigation than acids.
- Ipecac, activated charcoal, gastroesophageal lavage (large-bore or an NG tube), and a neutralizing acid or base are all contraindicated with caustic ingestions.
- Dilution:
 - Water or milk in the 1st 30 min of ingestion:
 - Especially useful for solid caustic alkali ingestions
 - Excessive intake may induce vomiting and worsen esophageal damage.
 - If respiratory distress, intubate before dilution.
 - Contraindicated if esophageal or gastric perforation suspected
- Keep patient NPO if oral exposure.
- Broad-spectrum antibiotics if mediastinitis or peritonitis suspected
- Antiemetics for nausea and vomiting
- Treat dermal exposures according to standard burn recommendations.
- Detailed exam for ocular exposures
- IV proton pump inhibitors or H₂ blockers for symptomatic relief
- Gastroenterology and surgical consultation
- Benefit of corticosteroids following esophageal damage is controversial:
 - May prevent the formation of esophageal stricture
 - May promote bacterial invasion, immune suppression, and tissue softening
 - The decision to initiate corticosteroids requires input from entire team caring for patient.
 - Initiate broad-spectrum antibiotics if corticosteroids are given.
- Laparoscopy or laparotomy for perforation and full-thickness necrosis
- Topical hydrofluoric acid exposure (options depend on severity and location):
 - IM injection of 5% calcium gluconate (0.5 mL/cm² of skin with 30G needle)
 - Intra-arterial infusion of 10 mL of 10% calcium gluconate in 40 mL D₅W over 4 hr

MEDICATION

- Methylprednisolone: 40 mg q8h IV (peds: 2 mg/kg/d IV); the course of therapy is 14–21 days followed by a corticosteroid taper.
- Ondansetron: 4 mg (peds: 0.1–0.15 mg/kg) IV
- Pantoprazole: 40 mg IV
- Prochlorperazine (Compazine): 5–10 mg IV (peds: 0.13 mg/kg per dose IM)
- Ranitidine (Zantac): 50 mg IV q6–8h

FOLLOW-UP

DISPOSITION

Admission Criteria

- All symptomatic patients
- Nonaccidental ingestion

Discharge Criteria

- Asymptomatic patients who accidentally ingested and are able to swallow without difficulty
- Minimal oropharyngeal pain with a corresponding visible lesion; no drooling; no respiratory compromise; no deep throat, chest, or abdominal pain; and able to swallow without difficulty

FOLLOW-UP RECOMMENDATIONS

Psychiatric referral for intentional ingestion

PEARLS AND PITFALLS

- Dilute with milk or water at home or in the ED within the 1st 30 min.
- Perform copious irrigation of ocular or dermal exposure:
 - _ Alkalis require more irrigation than acids.

CAVERNOUS SINUS THROMBOSIS

Joanna W. Davidson

BASICS

DESCRIPTION

- Thrombosis of a branch of the major intracerebral venous drainage system
- Most commonly infectious
- Spreads from facial, odontogenic, or sinus infection
- Less frequently occurs with hypercoagulable state

Anatomy

3 primary sites of thrombosis:

- Cavernous sinus—Most common:
 - Drainage from superficial venous system
- Superolateral to the sphenoid sinus and surrounds the sella:
 - Cranial nerves (CN) III, IV, V1, and V2 traverse the lateral wall of the sinus.
 - CN VI and the internal carotid artery occupy the medial portion of the sinus.
- Can also involve transverse sinus and superficial sagittal sinus

PATHOPHYSIOLOGY

- Hematogenous spread of facial, otic, or neck infection into venous drainage system
- Contiguous spread directly from infected sinus cavities (sphenoid, ethmoid > frontal)
- Bacterial overgrowth leads to inflammation and coagulation, resulting in thrombosis.
- Venous engorgement of cavernous sinus can affect adjacent structures:
 - Ophthalmoplegia from inflammation of CN III, IV, or VI
 - Pupillary fixation from CN III
 - Sensory deficits or paresthesia of forehead or cheek from CN V1 and V2

ETIOLOGY

- Septic:
 - *Staphylococcus aureus* accounts for 70%
 - *Streptococcus pneumoniae*, gram-negative bacilli, and anaerobes also seen
 - Fungi less common; include *Aspergillus* and *Rhizopus* species
- Aseptic:
 - Less common
 - Granulomatous conditions (TB)
 - Inflammatory disorders

- From mass effect (tumors at base of skull, aneurysms)
- Hypercoagulable states

Pediatric Considerations

- Children may present with nonspecific symptoms such as decreased energy, vomiting, fever.
- Have high level of suspicion for any child with recent otitis or pharyngitis with worsening symptoms, declining mental status, or signs of increased intracranial pressure (ICP):
 - HTN, bradycardia, lethargy, vomiting, gait instability
- More common in the neonatal period, when diagnosis can be extremely difficult to make

DIAGNOSIS

SIGNS AND SYMPTOMS

- Symptoms:
 - Headache occurs in 90% of patients.
 - Fever
 - Ocular or retrobulbar pain
 - Facial swelling
 - Visual disturbance
 - Facial dysesthesia
 - Lethargy or altered mental status
- Signs:
 - Periorbital edema is earliest sign
 - Chemosis with retinal vein engorgement
 - Ptosis, proptosis
 - Ophthalmoplegia
 - CN palsies:
 - Lateral gaze palsy (CN VI)
 - Hypo/hyperesthesia of V1 and V2 (CN V)
 - Meningismus
 - Altered level of consciousness or coma
 - Seizures
 - Sepsis with cardiovascular instability or collapse

History

High-risk historical factors include:

- A history of trauma
- Previous ear/nose/throat (ENT) or neurosurgical instrumentation
- History of central face furuncle that was manipulated

- Diabetes or immunocompromised state (HIV, steroid use, cancer) may increase risk

ESSENTIAL WORKUP

- Clinical diagnosis: Venous engorgement, ocular symptoms, unilateral symptoms that become bilateral, rapidly progressive
- Labs nonspecific
- Imaging findings can be subtle

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Neither sensitive nor specific
- CBC:
 - _ Leukocytosis
 - _ Bandemia
- PT/PTT/INR
- ESR and D-dimer usually elevated
- Lumbar puncture/CSF: Parameningeal inflammation or frank meningitis

Imaging

- CT scan:
 - _ Can be normal early in disease course
 - _ Noncontrast can show increased density
 - _ Contrast can show filling defect
 - May identify original source of infection (e.g., sinusitis)
 - Dilated superior ophthalmic vein
 - Associated intracranial hemorrhage
 - Signs of increased ICP: Small ventricles, loss of sulci
- MRI with MR angiography (MRA)/MR venography (MRV):
 - _ Diagnostic modality of choice
 - _ Direct visualization of intracranial vessels and sinuses
 - _ Capable of visualizing thrombus at any stage

DIFFERENTIAL DIAGNOSIS

- Meningitis/encephalitis
- Intracranial abscess
- Periorbital and orbital cellulitis
- Internal carotid artery aneurysm or fistula
- Pseudotumor cerebri
- Acute angle-closure glaucoma
- Intracranial hemorrhage
- Tolosa–Hunt syndrome: Rare granulomatous inflammation of cavernous sinus

ALERT

- Extremely difficult diagnosis to make.
- Maintain a high level of suspicion in toxic-appearing patients with recent ENT infections or in patients with refractory headache and risk factors for hypercoagulability or intracranial infection.

TREATMENT

PRE HOSPITAL

ALERT

- Patients can be altered and unstable.
- May require rapid assessment and stabilization of airway, breathing, and circulation (ABCs)

INITIAL STABILIZATION/THERAPY

- Careful assessment of mental status with intubation for airway protection as needed
- Aggressive fluid resuscitation for cardiovascular instability

ED TREATMENT/PROCEDURES

- Broad-spectrum antibiotics with multiple drug regimens:
 - Cover for gram positives, gram negatives, as well as anaerobes.
 - Nafcillin or vancomycin (for methicillin-resistant *S. aureus* [MRSA]) + ceftriaxone:
 - Add metronidazole or clindamycin in significant infections.
- Heparin:
 - Attenuates clot propagation and decreases morbidity/mortality.
 - Controversial in transverse and sagittal thrombosis owing to higher risk of subsequent hemorrhage
 - Administer only after ruling out bleed on CT scan.
 - Questionable superiority of LMWH over IV heparin
 - Endovascular TPA in severe refractory cases
- Systemic steroids:
 - Believed to be of benefit with concomitant pituitary insufficiency, and with infectious or inflammatory etiologies
- Appropriate management of increased ICP as needed
- Surgical consultation for drainage of primary site of infection (e.g., dental abscess or sinusitis)

MEDICATION

- Ceftriaxone: 2 g/d IV (peds: 80–100 mg/kg/d to q12h)
- Clindamycin: 300–900 mg IV q6–12h (neonates: 10–20 mg/kg/24h IV divided q6–

- 12h; peds: 25–40 mg/kg/24h divided q6–8h)
- Metronidazole: 500 mg IV q6h (neonates: 7.5–30 mg/kg/24h IV divided q12–24h; peds: 30 mg/kg/24h IV divided q6h)
- Nafcillin: 1–2 g IV q4h (peds: 50–75 mg/kg/24h IV divided q8–12h depending on age)
- Vancomycin: 1 g IV q12h (peds: 10–20 mg/kg IV q8–12h depending on age)

First Line

- Broad-spectrum antibiotics
- Anticoagulation

Second Line

- Dexamethasone or hydrocortisone IV
- Endovascular thrombolytics in selected cases

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with sinus thrombosis warrant admission to a monitored setting.
- Consider ICU admission.

Discharge Criteria

None

FOLLOW-UP RECOMMENDATIONS

Neurologic and neurosurgical consultation

COMPLICATIONS

- Blindness
 - 1/6 left with visual impairment
- CN palsies
- Meningitis or intracranial abscess
- Seizures, especially in superior sagittal sinus thrombosis
- Pituitary necrosis and insufficiency from local invasion
- Septic emboli
- Sepsis and shock
- 30% mortality

PEARLS AND PITFALLS

- Diagnosis is made on clinical evaluation and confirmatory lab evidence. Maintain a high index of suspicion.
- Noncontrast head CT is often negative or nonspecific. MRI/MRV is the diagnostic imaging modality of choice and should be pursued in high-risk individuals.
- Administer IV antibiotics early, especially in any ill-appearing patient with ENT or neurologic complaints.
- Hypercoagulable states result in *both* central and peripheral venous thrombosis. Workup and management decisions must include consideration of systemic thromboembolism.

CODES

ICD9

- 325 Phlebitis and thrombophlebitis of intracranial venous sinuses
- 437.6 Nonpyogenic thrombosis of intracranial venous sinus

ICD10

- G08 Intracranial and intraspinal phlebitis and thrombophlebitis
- I67.6 Nonpyogenic thrombosis of intracranial venous system

CELLULITIS

John Mahoney • Dolores Gonthier

BASICS

DESCRIPTION

- Acute, spreading erythematous superficial infection of skin and SC tissues:
 - Variety of pathogens
 - Extension into deeper tissues can result in necrotizing soft tissue infection
- Progressive spread of erythema, warmth, pain, and tenderness
- Predisposing factors:
 - Lymphedema
 - Tinea pedis
 - Open wounds
 - Pre-existing skin lesion (furuncle)
 - Prior trauma or surgery
 - Retained foreign body
 - Vascular or immune compromise
 - Injection drug use

ETIOLOGY

- Simple cellulitis:
 - Group A streptococci
 - *Staphylococcus aureus*—including resistant strains such as community-associated methicillin-resistant *S. aureus* (CA-MRSA; see below):
 - CA-MRSA risk factors include: Prior MRSA infection, household contact of CA-MRSA patient, daycare contact of MRSA patients, children, soldiers, incarcerated persons, athletes in contact sports, IV drug users, men who have sex with men
 - Different antibiotic susceptibility than nosocomial MRSA
 - CA-MRSA now sufficiently prevalent to warrant empiric treatment
 - Suspect CA-MRSA in unresponsive infections
- Nosocomial MRSA:
 - Risk factors: Recent hospital or long-term care admission, surgery, injection drug use, vascular catheter, dialysis, recent antibiotic use, unresponsive infection
 - Resistant to most antibiotics (see “Treatment”)
- Extremity cellulitis after lymphatic disruption:
 - Nongroup A β -hemolytic streptococci (groups C, B, G)
- Cellulitis in diabetics:
 - Can be polymicrobial with *S. aureus*, streptococci, gram-negative bacteria,

and anaerobes, especially when associated with skin ulcers

- Periorbital cellulitis:
 - *S. aureus*
 - Streptococcal species
- Buccal cellulitis:
 - *Haemophilus influenzae* type B
 - Anaerobic oral flora, associated with intraoral laceration or dental abscess
- Less common causes:
 - Clostridia
 - Anthrax
 - *Pasteurella multocida*—common after cat and dog bites
 - *Eikenella corrodens*—human bites
 - *Pseudomonas aeruginosa*:
 - Hot-tub folliculitis—self-limited
 - Foot puncture wound
 - Ecthyma gangrenosum in neutropenic patients
 - Erysipelothrix species—raw fish, poultry, meat, or hide handlers
 - *Aeromonas hydrophila*—freshwater swimming
 - *Vibrio* species—seawater or raw seafood

Pediatric Considerations

- Facial cellulitis in children:
 - *Streptococcus pneumoniae*
 - *H. influenzae* type B, although incidence declining since introduction of HIB vaccine
- Perianal cellulitis:
 - Group A streptococci
 - Associated or antecedent pharyngitis or impetigo
- Neonates:
 - Group B streptococci

DIAGNOSIS

SIGNS AND SYMPTOMS

- Common to all syndromes:
 - Pain, tenderness, warmth
 - Erythema
 - Edema or induration
 - Fever/chills
 - Tender regional lymphadenopathy
 - Lymphangitis
 - Accompanying SC abscess possible

- Suspect deep abscess especially if treatment failure on initial antibiotic
- Superficial vesicles
- Buccal cellulitis:
 - Odontogenic cases more serious:
 - Toothache, sore throat, or facial swelling
 - Progressive extension into soft tissues of neck with fever, erythema, neck swelling, and dysphagia

Pediatric Considerations

- Facial cellulitis in children:
 - Erythema and swelling of the cheek and eyelid
 - Rapidly progressive
 - Usually unilateral
 - Upper respiratory tract symptoms
 - Risk for cavernous sinus thrombosis and permanent optic nerve injury
- Perianal cellulitis:
 - Erythema and pruritus extending from the anus several centimeters onto adjacent skin
 - Pain on defecation
 - Blood-streaked stools

History

Patients often incorrectly attribute CA-MRSA infection with spontaneous abscess to a spider bite

Physical-Exam

In simple cellulitis, physical findings can suggest the etiology and help narrow empiric antibiotic coverage:

- Staph etiology: Focal abscess or pustule with: Fluctuance, yellow or white center, central point or “head,” or draining pus, indolent progression
- Strep etiology: Sharply demarcated borders, lymphangitis, pre-existing lymphedema, concomitant nausea from toxin

ESSENTIAL WORKUP

- Cellulitis is a clinical diagnosis.
- Physical exam to reveal infection source

DIAGNOSIS TESTS & INTERPRETATION

Lab

- WBC generally unnecessary
- Gram stain and culture to focus antimicrobial selection and reveal resistant pathogens (MRSA):

- Aspirate point of maximal inflammation or punch biopsy if there is no wound to culture
- Perform in treatment failures and consider in admitted patients
- Blood culture:
 - Usually negative in uncomplicated cellulitis
 - May identify organism in patients with:
 - Lymphedema
 - Buccal or periorbital cellulitis
 - Saltwater or freshwater source
 - Fever or chills

Imaging

- Plain radiographs may reveal abscess formation, SC gas, or foreign bodies:
 - Extension to bone (osteomyelitis) not visualized early on plain radiographs
- Extremity vascular imaging (Doppler US) can help rule out deep venous thrombosis (DVT).
- US useful for diagnosing abscess if physical exam is equivocal or if there is a broad area of cellulitis
 - In cellulitis may see characteristic “cobblestone” appearance and thickening of SC layer, both due to edema
- CT or MRI can help rule out necrotizing fasciitis

DIFFERENTIAL DIAGNOSIS

- Necrotizing fasciitis
- Lymphangitis or lymphadenitis
- Thrombophlebitis or DVT:
 - Differentiation from cellulitis:
 - Absence of initial traumatic or infectious focus
 - No regional lymphadenopathy
 - Presence of risk factors for DVT
- Insect bite
- Allergic reaction
- Acute gout or pseudogout
- Ruptured Baker cyst
- Herpetic whitlow
- Neoplasm
- Phytophotodermatitis
- Erythema chronicum migrans lesion of Lyme disease
- Differential diagnosis of facial cellulitis:
 - Allergic angioedema
 - Conjunctivitis
 - Contusion

Pediatric Considerations

Differential diagnosis of perianal cellulitis:

- **Candida intertrigo**
- **Psoriasis**
- **Pinworm infection**
- **Child abuse**
- **Behavioral problem**
- **Inflammatory bowel disease**

TREATMENT

INITIAL STABILIZATION/THERAPY

Airway compromise possible with deep extension of facial or neck cellulitis

ED TREATMENT/PROCEDURES

- **General principles:**
 - Consider local prevalence of resistant pathogens in addition to usual causes
 - In simple cellulitis, periorbital cellulitis, and diabetic patients, need to include CA-MRSA coverage in empiric therapy
 - Usual outpatient treatment: 7–10 days
 - Cool compresses for comfort
 - Analgesics
 - Extremity elevation
 - Treat predisposing tinea pedis with topical antifungal such as clotrimazole
- **Simple cellulitis:**
 - **Outpatient:**
 - Oral Cephalexin + TMP/SMX (to cover CA-MRSA)
 - Alternatives to cephalexin: Oral dicloxacillin, macrolide, or levofloxacin
 - Alternatives to TMP/SMX: Clindamycin or Doxycycline
 - **Inpatient:**
 - IV nafcillin or equivalent, + IV vancomycin (to cover CA-MRSA)
- **Extremity cellulitis after lymphatic disruption:**
 - Same as simple cellulitis
- **Cellulitis in diabetics:**
 - **Outpatient:**
 - Amoxicillin/clavulanate + TMP/SMX (to cover CA-MRSA), or clindamycin
 - **Inpatient:**
 - IV ampicillin/sulbactam or imipenem cilastatin or equivalent; + IV vancomycin (to cover CA-MRSA)
- **Periorbital cellulitis in adults:**

- Outpatient: Oral dicloxacillin or azithromycin; + TMP/SMX (to cover CA-MRSA)
- Inpatient: IV vancomycin
- Buccal cellulitis in adults:
 - Outpatient: Oral amoxicillin/clavulanate
 - Inpatient: IV ceftriaxone
 - Odontogenic source:
 - Drainage essential
 - Coverage for anaerobes: Clindamycin
- Facial cellulitis in children:
 - IV ceftriaxone
- Perianal cellulitis:
 - Outpatient: Oral penicillin VK
 - Inpatient: IV penicillin G (aqueous)
- Animal or human bite:
 - Oral amoxicillin/clavulanate
- Foot puncture wound:
 - Oral or IV ciprofloxacin or IV ceftazidime
- MRSA:
 - Nosocomial MRSA: IV vancomycin or oral or IV linezolid
 - CA-MRSA:
 - PO: TMP/SMX, clindamycin or doxycycline
 - IV: Vancomycin or clindamycin

MEDICATION

- Amoxicillin/clavulanate: 500–875 mg (peds: 45 mg/kg/24h) PO BID or 250–500 mg (peds: 40 mg/kg/24h) PO TID
- Ampicillin/sulbactam: 1.5–3 g (peds: 100–300 mg/kg/24h up to 40 kg; over 40 kg give adult dose) IV q6h
- Azithromycin: (Adults and peds) 10 mg/kg up to 500 mg PO on day 1, followed by 5 mg/kg up to 250 mg PO daily on days 2–5
- Ceftazidime: 500–1,000 mg (peds: 150 mg/kg/24h; max. 6 g/24h; use sodium formulation in peds) IV q8h
- Ceftriaxone: 1–2 g (peds: 50–75 mg/kg/24h) IV daily
- Cephalexin: 500 mg (peds: 50–100 mg/kg/24h) PO QID
- Ciprofloxacin: (Adult only) 500–750 mg PO BID or 400 mg IV q8–12h
- Clindamycin: 450–900 mg (peds: 20–40 mg/kg/24h) PO or IV q6h
- Dicloxacillin: 125–500 mg (peds: 12.5–25 mg/kg/24h) PO q6h
- Doxycycline: 100 mg PO BID for adults
- Erythromycin base: (Adult) 250–500 mg PO QID
- Imipenem cilastatin: 500–1,000 mg (peds: 15–25 mg/kg) IV q6h; max. 4 g/24h or 50 mg/kg/24h, whichever is less
- Levofloxacin: (Adult only) 500–750 mg PO or IV daily

- Linezolid: 600 mg PO or IV q12h (peds: 30 mg/kg/24h div. q8h)
- Nafcillin: 1–2 g IV q4h (peds: 50–100 mg/kg/24h divided q6h); max. 12 g/24h
- Penicillin VK: 250–500 mg (peds: 25–50 mg/kg/24h) PO q6h
- Penicillin G (aqueous): 4 mU (peds: 100,000–400,000 U/kg/24h) IV q4h
- Trimethoprim/sulfamethoxazole (TMP/SMX): 2 DS tabs PO q12h (peds: 6–10 mg/kg/24h TMP div. q12h)
- Vancomycin: 1 g IV q12h (peds: 10 mg/kg IV q6h; dosing adjustments required younger than age 5 yr); check serum levels

FOLLOW-UP

DISPOSITION

Admission Criteria

- Toxic appearing
- Tissue necrosis
- History of immune suppression
- Concurrent chronic medical illnesses
- Unable to take oral medications
- Unreliable patients

Discharge Criteria

- Mild infection in a nontoxic-appearing patient
- Able to take oral antibiotics
- No history of immune suppression or concurrent medical problems
- No hand or face involvement
- Has adequate follow-up within 24–48 hr

FOLLOW-UP RECOMMENDATIONS

- Follow-up within 24–48 hr
- Sooner if worsening symptoms, including new or worsening lymphangitis, increasing area of redness, worsening fever
- Outline the border of erythema before discharge to aid in assessing response to therapy

PEARLS AND PITFALLS

- Strep and staph are most common causes
- CA-MRSA now significant cause of cellulitis, frequent enough to warrant including coverage in empiric treatment
- Clinicians not accurate at identifying MRSA at the bedside
- A deep abscess may be misclassified as cellulitis

- Use clinical suspicion and ultrasound to avoid missing an abscess

- L03.119 Cellulitis of unspecified part of limb

CENTRAL RETINAL ARTERY OCCLUSION

Yasuharu Okuda • Braden Hexom

BASICS

DESCRIPTION

- Obstruction of the central retinal artery associated with sudden painless loss of vision
- Usually occurs in persons 50–70 yr of age
- Ophthalmic artery is 1st branch of carotid.
- Risk factors include HTN, atherosclerotic disease, sickle cell disease, vasculitis, valvular heart disease, lupus, trauma, and coronary artery disease.
- Incidence of 1–10/100,000
- Often described as a “stroke of the eye”

ETIOLOGY

- Embolic:
 - Occlusion by intravascular material from a proximal source:
 - Atherosclerotic disease (majority)
 - Carotid artery stenosis
 - Valvular heart disease (cardiogenic emboli)
 - Atrial myxoma
 - Dissection of the ophthalmic artery
 - Carotid artery dissection
- Thrombotic:
 - Obstruction of flow from the rupture of a pre-existing intravascular atherosclerotic plaque
 - Hypercoagulable states (sickle cell)
- Inflammatory:
 - Due to temporal arteritis, lupus, vasculitis
- Arterial spasm:
 - Associated with migraine headaches
- Decreased perfusion:
 - Low-flow conditions such as in severe hypotension or high-pressure situations seen in acute angle-closure glaucoma or retrobulbar hemorrhage

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Sudden, painless, monocular loss of vision
- Prior episodes of sudden visual loss:
 - May last a few seconds to minutes (amaurosis fugax)
 - Caused by transient embolic phenomena or decreased ocular blood flow

Physical-Exam

- Significantly decreased visual acuity
- Afferent pupillary defect usually present
- Retinal appearance:
 - Emboli visualized within vascular tree of the retina
 - Appears as glinting white or yellow flecks (Hollenhorst plaques) within the vessels
 - Ischemic edema visible within 15–20 min of occlusion
 - “Cherry-red spot” remains over the fovea (only area where there is very thin retina allowing the vascular choroids to show through).
 - Affected arteries empty or showing dark red stationary or barely pulsatile segmented rouleaux (“box-carring”)
 - Within 1–2 hr opacification of the usually transparent infarcting retinal nerve layer occurs.
- Partial field deficits:
 - Occur only if branch of central retinal artery involved

ESSENTIAL WORKUP

- Visual acuity and visual field testing
- Fundoscopic exam
- Intraocular pressure measurements
- Emergent ophthalmologic consultation

DIAGNOSIS TESTS & INTERPRETATION

Lab

Directed toward evaluating underlying etiology of occlusion:

- CBC with differential and platelet count
- PT/PTT
- Electrolytes, BUN/creatinine, glucose
- Electronic spin resonance for giant cell arteritis (in patients > 55 yr old)
- ANA, RF, CRP, ESR
- Rapid plasma reagin (RPR)
- Hemoglobin electrophoresis
- Serum protein electrophoresis

Imaging

Directed toward evaluating underlying etiology of occlusion:

- Carotid artery ultrasound/Doppler
- Possibly echocardiography
- Fluorescein angiography or electroretinography to confirm the diagnosis

DIFFERENTIAL DIAGNOSIS

- Acute angle-closure glaucoma
- Central retinal vein occlusion
- Giant cell arteritis (temporal arteritis)
- Optic neuritis
- Retinal detachment

TREATMENT

ALERT

Initiate treatment immediately because irreversible visual loss occurs at 90 min:

- Only immediate treatment may help to salvage or restore sight to the affected eye.
- Goals of therapy include dislodging or dissolving the embolus, arterial dilation to improve forward flow, and reduction of intraocular pressure to improve the perfusion gradient.

ED TREATMENT/PROCEDURES

- Immediate global massage in an attempt to dislodge the embolus:
 - _ Lay patient flat and apply digital global massage bolus.
 - _ On closed eyelid, apply constant pressure for 15 sec and remove for 15 sec. Repeat for 5 cycles.
- Initiate high-flow oxygen via 100% nonrebreather:
 - _ Consider transfer to a facility capable of providing hyperbaric oxygen (HBO) if < 24 hr from symptom onset
 - _ May use inhaled carbogen (a mixture of carbon dioxide and oxygen gas) if available
- Administer IV acetazolamide to decrease intraocular pressure.
- Apply topical timolol maleate to reduce intraocular pressure.
- Administer aspirin and IV heparin for prevention of clot propagation.
- Obtain emergent ophthalmology consultation for:
 - _ Anterior chamber paracentesis to help reduce intraocular pressure
 - _ Possible intra-arterial fibrinolysis for clot lysis
- Administer high-dose systemic steroids in suspected cases of inflammatory arteritis.

MEDICATION

First Line

- Acetazolamide: 500 mg IV or PO

- Carbogen: Inhalation of 95% oxygen and 5% carbon dioxide mixture
- Heparin: 80 U/kg IV bolus then 18 U/kg/h continuous infusions (rate adjusted based on PTT level)
- Timolol maleate 0.5% solution: 1 drop topically to affected eye

Second Line

- Methylprednisolone: 250 mg IV in suspected cases of inflammatory arteritis
- Aspirin: 325 mg PO
- Mannitol
- Sublingual nitroglycerin

FOLLOW-UP

DISPOSITION

Admission Criteria

Required for workup of proximal cause in acute cases (source of embolism, thrombosis, or inflammatory)

Discharge Criteria

Chronic retinal artery occlusion with no evidence of active disease can be worked up as an outpatient.

Issues for Referral

All suspected cases warrant emergent ophthalmology consultation.

FOLLOW-UP RECOMMENDATIONS

Most cases will require carotid ultrasound to exclude atherosclerotic disease.

PEARLS AND PITFALLS

- Amaurosis fugax (transient, possibly resolved retinal artery occlusion) is a sentinel event and may lead to complete occlusion or stroke. Do not ignore these symptoms and urgent workup is required.
- Retinal artery occlusion is a medical emergency requiring immediate treatment to prevent loss of the eye.
- It is important to document a full eye exam including visual acuity and evaluation of the optic fundus.

- H34.11 Central retinal artery occlusion, right eye
- H34.12 Central retinal artery occlusion, left eye

CENTRAL RETINAL VEIN OCCLUSION

Lisa Jacobson • Yasuharu Okuda

BASICS

DESCRIPTION

Disease characterized by decreased visual acuity resulting from venous occlusion of any etiology

ETIOLOGY

- Ischemic CRVO:
 - _ 20–25% of cases
 - _ Blocked venous return leads to backflow in capillaries, hemorrhage, and macular edema.
 - _ Limited space at lamina cribrosa predisposes to thrombosis due to slow flow and vessel wall changes
 - _ Theorize that arteriosclerotic changes in the adjacent artery may impinge upon the vein.
 - _ Blood viscosity also thought to play a role
- Nonischemic CRVO:
 - _ Milder, incomplete occlusion

DIAGNOSIS

SIGNS AND SYMPTOMS

Classic description:

- Acute, unilateral, painless vision loss
- “Blood and thunder” appearance on fundoscopy

History

- Painless, unilateral vision loss
- If nonischemic, may be incomplete and intermittent vision loss

Physical-Exam

- Decreased visual acuity:
 - _ Usually worse than 20/200
- Afferent pupillary defect
- Dilated tortuous veins
- Retinal hemorrhages:
 - _ If central, findings in all 4 quadrants
 - _ Extensive hemorrhages give a dramatic look to fundus classically described

as “blood and thunder appearance.”

- Disk edema
- Cotton wool spots

ESSENTIAL WORKUP

- BP
- Visual acuity:
 - Hand movements typically is all that is seen.
- Visual fields
- Fundoscopy
- Tonometry:
 - Normal pressures are between 10 and 21 mm Hg.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- PT/PTT
- ESR
- ANA
- Serum protein electrophoresis

Imaging

Fluorescein angiography:

- Ophthalmologists use this to map areas of nonperfusion.
- Differentiates between ischemic and nonischemic

Diagnostic Procedures/Surgery

Gonioscopy:

- Measure iris or angle neovascularization.

DIFFERENTIAL DIAGNOSIS

- Amaurosis fugax/transient ischemic attack
- Cavernous sinus thrombosis
- DM
- HTN/hypertensive retinopathy
- Hyperviscosity syndromes:
 - Sickle cell, polycythemia, leukemia, multiple myeloma
- Hysterical blindness
- Ocular ischemia syndrome
- Papilledema
- Retinal artery occlusion
- Retinal detachment

- Severe anemia with thrombocytopenia
- Temporal arteritis
- Vitreal hemorrhage

TREATMENT

PRE HOSPITAL

No specific interventions need occur prior to arrival at the hospital in regard to the eye.

INITIAL STABILIZATION/THERAPY

- Initiate steps to lower intraocular pressure (IOP) if it is elevated.
- Treat underlying medical problems.

ED TREATMENT/PROCEDURES

- Recognition and prompt ophthalmologic referral is the cornerstone of ED treatment.
- Though not proven, the following may be tried in consultation with an ophthalmologist:
 - Aspirin
 - Anti-inflammatory agents
 - Systemic steroids
 - Systemic anticoagulation
 - Fibrinolytics (controversial)
 - Laser chorioretinal anastomosis

MEDICATION

There is no proven treatment for CRVO, ophthalmologists may treat with the following:

- Intravitreal triamcinolone
- Antivascular endothelial growth factor:
 - Bevacizumab

Considerations in Prescribing

Use of oral contraceptives can increase the risk of CRVO.

FOLLOW-UP

DISPOSITION

Admission Criteria

Patients may be admitted for surgical intervention, depending upon the ophthalmologist.

Discharge Criteria

Patients can be discharged from the ED as long as they have immediate follow-up with an ophthalmologist.

Issues for Referral

- If no ophthalmologist is available, treatment should be initiated for concomitant conditions and patient transferred to nearest hospital with ophthalmologic consultation.
- Ophthalmologists often perform panretinal photocoagulation if neovascularization is found.

FOLLOW-UP RECOMMENDATIONS

- Patients with ischemic CRVO need prolonged follow-up to catch neovascularization and glaucoma that typically develop.
- Patients with CRVO likely have other vascular diseases and need complete medical workups.
- Patients should also follow with an internist to manage comorbidities and risk factors.

PEARLS AND PITFALLS

- Increased IOP resulting from neovascularization and edema can cause vascular insufficiency and with delayed treatment vision loss can be permanent.
- When patients present with bilateral CRVOs or CRVO at a young age, workup must search for hyperviscosity syndromes.

CEREBRAL ANEURYSM

Veronique Au • Rebecca Smith-Coggins

BASICS

DESCRIPTION

- Abnormal, localized dilation or outpouching of cerebral artery wall:
 - Occurs in 5–10% of population
- Rupture of saccular aneurysms account for 5–15% of strokes
- Of those that rupture:
 - 40% occur at anterior communicating artery (ACA)
 - 30% at internal carotid (IC)
 - 20% in middle cerebral artery (MCA)
 - 5–10% in vertebrobasilar artery (VBA) system

ETIOLOGY

- Asymptomatic in 3.2% of population
- “Congenital,” saccular, or berry aneurysms most common (90%):
 - Develop at weak points in arterial wall and bifurcations of major cerebral arteries
 - Incidence increases with age
 - Multiple in 20–30%
 - Increased incidence:
 - Polycystic kidney disease
 - Cerebral arteriovenous malformation
 - Type III collagen deficiency
 - Fibromuscular dysplasia
 - Ehlers–Danlos syndrome
 - Marfan syndrome
 - Pseudoxanthoma elasticum
 - Neurofibromatosis
 - Moyamoya syndrome
 - Coarctation of the aorta
 - Tuberous sclerosis
 - Sickle cell disease
 - Osler–Weber–Rendu syndrome
 - α 1-Antitrypsin deficiency
 - Systemic lupus erythematosus
 - Glucocorticoid remediable hyperaldosteronism
- Arteriosclerotic, fusiform, or dolichoectatic (7%):
 - More common in peripheral arteries

- Inflammatory (mycotic):
 - 10% of patients with bacterial endocarditis
- Traumatic, associated with severe closed head injury
- Neoplastic, embolized tumor fragments
- Familial correlation: 1st-degree relative with history of aneurysm essentially doubles lifetime risk

Pediatric Considerations

- Although rare in children, more likely to be giant (> 25 mm)
- Occur in the posterior circulation

DIAGNOSIS

SIGNS AND SYMPTOMS

- Commonly asymptomatic before rupture
- Sentinel headaches occur in 30–60% of patients before rupture:
 - Can be unilateral
- Seizures, syncope, or altered level of consciousness

History

- Onset of headache
- Family history
- Altered mental status
- Focal neurologic deficits
- Rupture results in subarachnoid hemorrhage:
 - Headache: Severe (“worst headache ever”) with sudden onset (“thunderclap”)
 - Different from prior headaches
 - Classically without focal deficits
 - Nuchal rigidity (most common sign) secondary to blood in CSF

Physical-Exam

Compression of adjacent structures may cause neurologic symptoms:

- ACA aneurysms:
 - Optic tract: Altitudinal field cut or homonymous hemianopsia
 - Optic chiasm: Bitemporal hemianopsia
 - Optic nerve: Unilateral amblyopia
- Aneurysms at IC–posterior communicating artery junction:
 - Oculomotor nerve: Fixed and dilated pupil, ptosis, diplopia, and temporal deviation of eye with inability to turn eye upward, inward, or downward
- Aneurysms in cerebral cortex may produce focal deficits including:
 - Hemiparesis

- Hemisensory loss
- Visual disturbances
- Aphasia
- Seizures

ESSENTIAL WORKUP

- Complete neurologic examination
- Emergent noncontrast head CT scan will diagnose 90–95% of subarachnoid hemorrhages
- Lumbar puncture with CSF analysis if CT scan is negative

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Coagulation studies
- Baseline CBC with platelets and differential
- Electrolytes
- Renal and liver function tests
- Arterial blood gas

Imaging

- CXR for pulmonary edema
- 4-vessel cerebral angiography remains gold standard
- MRA
- Helical CT scanning may be useful in detecting aneurysms > 3 mm
- Transcranial Doppler US may be useful in detecting vasospasm.

Diagnostic Procedures/Surgery

Lumbar puncture if suspect aneurysmal leak or rupture with normal head CT

DIFFERENTIAL DIAGNOSIS

- Neoplasm
- Arteriovenous malformation
- Optic neuritis
- Migraine
- Meningitis
- Encephalitis
- Hypertensive encephalopathy
- Hyperglycemia or hypoglycemia
- Temporal arteritis
- Acute glaucoma
- Subdural hematoma
- Epidural hematoma

- Intracerebral hemorrhage
- Thromboembolic stroke
- Air embolism
- Sinusitis

TREATMENT

PRE HOSPITAL

- Cautions:
 - _ Neurologic examination in the field can be extremely helpful
 - _ Assess:
 - Level of consciousness
 - Glasgow coma scale score
 - Gross motor deficits
 - Speech abnormalities
 - Gait disturbance
 - Facial asymmetry
 - Other focal deficits
- Patients with subarachnoid hemorrhage may need emergent intubation for rapidly deteriorating level of consciousness
- Patients must be transported to a hospital with emergent CT scanning and intensive care unit (ICU)-level treatment

INITIAL STABILIZATION/THERAPY

- ABCs:
 - _ Supplemental oxygen
 - _ Rapid-sequence intubation may be required for airway protection or for controlled ventilation
 - _ Continuous cardiac monitoring and pulse oximetry
- For altered mental status:
 - _ Check blood glucose immediately, give D₅₀ (if glucose is low)
 - _ Naloxone
 - _ Thiamine
- Reversal of anticoagulation
- Prevention of acute increases in intracranial pressure from vomiting should be accomplished with antiemetics
- Seizures should be managed acutely with IV benzodiazepines and fosphenytoin/phenytoin
- Seizure prophylaxis is controversial and not recommended

ED TREATMENT/PROCEDURES

Following initial stabilization, the major goals of early treatment of ruptured or leaking

aneurysms are to prevent re-rupture, cerebral vasospasm, and hydrocephalus (see “Subarachnoid Hemorrhage”).

SURGERY/OTHER PROCEDURES

- Optimal timing for angiography and surgery remain controversial, but trend is toward early surgery to decrease incidence of rebleeding and cerebral vasospasm
- Early placement of ventriculostomy in appropriate patients may allow for direct intracranial pressure monitoring and often decreases systemic hypertension

Pediatric Considerations

Aneurysms in children have a high rate of hemorrhage and should be repaired early

MEDICATION

First Line

- Labetalol: 20–30 mg/min IV bolus, then 40–80 mg q10min max. 300 mg; follow with continuous infusion 0.5–2 mg/min
- Nimodipine: 60 mg PO/nasogastric q4h
- Ondansetron: 4 mg PO/SL/IV q4h PRN (peds: 0.1 mg/kg IV; max. 4 mg/dose)
- Prochlorperazine: 5–10 g IV/IM q6–8h (peds: 0.2 mg/kg/d IM in 3 or 4 div. doses); max. 40 mg/d

Second Line

- Diazepam: 5–10 mg IV q10–15min max., 30 mg (peds: 0.2–0.3 mg/kg q5–10min max. 10 mg)
- Docusate sodium: 100 mg PO BID
- Fosphenytoin: 15–20 mg/kg phenytoin equivalents (PE) at rate of 100–150 mg/min IV/IM
- Hydralazine: 10–20 mg IV q30min
- Lorazepam: 2–4 mg IV q15min PRN (peds: 0.03–0.05 mg/kg/dose; max. 4 mg/dose)
- Nicardipine: 5 mg/h IV infusion, increase by 2.5 mg/h q5–15min max. 15 mg/h (peds: Dosing unavailable)
- Phenytoin: 15–20 mg/kg IV load at max. 50 mg/min; max. 1.5 g (adult and peds); maintenance 4–6 mg/kg/d IV/IM

FOLLOW-UP

DISPOSITION

Admission Criteria

- Any patient with acute aneurysmal subarachnoid hemorrhage should be admitted,

preferably to ICU

- Any patient with symptomatic unruptured aneurysm should receive admission and urgent neurosurgical consultation, given high rate of rupture

Discharge Criteria

- Patients with incidentally discovered asymptomatic intracranial aneurysms may be discharged with close neurosurgical follow-up
- Note that overall risk of rupture is 1–2%/yr and that critical size at which risk for rupture outweighs risk for surgery is controversial (classically 10 mm, but probably in the 4–8-mm range).

FOLLOW-UP RECOMMENDATIONS

- Neurosurgery
- Neurology
- Primary care

PEARLS AND PITFALLS

- CT scan alone is not sufficient to exclude subarachnoid hemorrhage
- Vasospasm is typically seen on day 3 after bleed or surgery
- Nimodipine can prevent or treat vasospasm but should never be administered IV
- Nitroprusside and nitroglycerine should be avoided due to tendency to increase cerebral blood volume and thereby intracranial pressure

Subarachnoid Hemorrhage

CODES

ICD9

- 430 Subarachnoid hemorrhage
- 437.3 Cerebral aneurysm, nonruptured
- 747.81 Anomalies of cerebrovascular system

ICD10

- I60.7 Nontraumatic subarachnoid hemorrhage from unspecified intracranial artery
- I67.1 Cerebral aneurysm, nonruptured
- Q28.3 Other malformations of cerebral vessels

CEREBRAL VASCULAR ACCIDENT

Veronique Au • Rebecca Smith-Coggins

BASICS

DESCRIPTION

Interruption of blood flow to a specific brain region:

- Neurologic findings are determined by specific area affected
- Onset may be sudden and complete, or stuttering and intermittent
- Responsible for 1 in 18 deaths in US
- 610,000 new strokes every year in US

RISK FACTORS

- Diabetes
- Smoking
- HTN
- Coronary artery disease, dysrhythmias
- Peripheral vascular disease
- Oral contraceptive use
- Polycythemia vera
- Sickle cell anemia
- Deficiencies of antithrombin III, protein C or S

ETIOLOGY

- May be ischemic (thrombotic, embolic, or secondary to dissection/hypoperfusion) or hemorrhagic
- Thrombotic stroke is caused by occlusion of blood vessels:
 - Clot formation at an ulcerated atherosclerotic plaque is most common
 - Sludging (sickle cell anemia, polycythemia vera, protein C deficiency)
- Embolic stroke is caused by acute blockage of a cerebral artery by a piece of foreign material from outside the brain, including:
 - Cardiac mural thrombi associated with mitral stenosis, atrial fibrillation, cardiomyopathy, CHF, or MI
 - Prosthetic or abnormal native valves
 - Atherosclerotic plaques in the aortic arch or carotid arteries
 - Atrial myxoma
 - Ventricular aneurysms with thrombi
- Arterial dissection:
 - Carotid artery dissection
 - Arteritis (giant cell, Takayasu)
 - Fibromuscular dysplasia
- Global ischemic or hypotensive stroke is caused by an overall decrease in systemic

BP: Sepsis, hemorrhage, shock

- Hemorrhagic stroke:
 - Intracranial hemorrhage
 - Subarachnoid hemorrhage

Pediatric Considerations

- Usually attributable to an underlying disease process, such as sickle cell anemia, leukemia, infection, or a blood dyscrasia
- Younger children often present with seizures and/or altered mental status

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Time of onset (or time last seen at baseline)
- Trauma/surgery
- Medications
- Altered mentation/confusion
- Headache
- Vertigo/dizzy
- Focal neurologic deficits

Physical-Exam

- General:
 - Cheyne–Stokes breathing, apnea
 - HTN
 - Cardiac dysrhythmias, murmurs
- Anterior cerebral artery:
 - Contralateral hemiplegia (lower/upper)
 - Hemisensory loss
 - Apraxia
 - Confusion
 - Impaired judgment
- Middle cerebral artery:
 - Contralateral hemiplegia (upper/lower)
 - Hemisensory deficits
 - Homonymous hemianopsia
 - Dysphasia
 - Dysarthria
 - Agnosia
- Posterior cerebral artery:

- Cortical blindness in half the visual field
- Visual agnosia
- Altered mental status
- Impaired memory
- 3rd-nerve palsy
- Hemiballismus
- Vertebrbasilar system:
 - Impaired vision, visual field defects, nystagmus, diplopia
 - Vertigo, dizziness
 - Crossed deficits: Ipsilateral cranial nerve deficits with contralateral motor and sensory deficits
- Basilar system:
 - Quadriplegia
 - Locked-in syndrome
 - Coma
- Watershed area (boundary zone between anterior, middle, and posterior circulation):
 - Cortical blindness
 - Weakness of proximal upper and lower extremities with sparing of face, hands, and feet

ESSENTIAL WORKUP

- Detailed neurologic exam; consider calculating National Institutes of Health stroke scale (NIHSS).
- Emergent noncontrast head CT scan to distinguish ischemic from hemorrhagic events:
 - May be normal in 1st 24–48 hr
 - GOALS:
 - CT completed within 25 min of arrival
 - CT read by a radiologist within 45 min
 - Thrombolytics administered within 1 hr of presentation
- If CT is normal and subarachnoid hemorrhage is suspected, emergent lumbar puncture is indicated
- EKG to evaluate for dysrhythmias or presence of MI
- Oxygen saturation measurement
- Rapid glucose determination

DIAGNOSIS TESTS & NTERPRETATION

Lab

- Baseline CBC, electrolytes, renal function tests, liver function test, prothrombin time, partial thromboplastin time
- Urinalysis:

- Hematuria can be seen in subacute bacterial endocarditis with embolic stroke.
- Sedimentation rate:
 - Elevated in subacute bacterial endocarditis, vasculitis, hyperviscosity syndromes
- Consider additional tests: Cardiac enzymes, urine pregnancy test, drug screen, alcohol level, ABG, and blood cultures.

Imaging

- Noncontrast head CT
- MRI can detect ischemia < 2 hr after onset
- CXR
- Carotid US

Diagnostic Procedures/Surgery

- EKG to evaluate for arrhythmia
- Lumbar puncture if subarachnoid hemorrhage is suspected and head CT nondiagnostic

DIFFERENTIAL DIAGNOSIS

- Intracranial bleeding
- Hypoglycemia
- Seizure disorder; Todd paralysis
- Panic attacks, depression, conversion reaction
- Transient global amnesia
- Meningoencephalitis
- Peripheral neuropathy
- Intracranial abscess
- Migraine
- Air embolism
- Transient ischemic attack
- Encephalopathy
- Neoplasm
- Giant cell/Takayasu arteritis
- Multiple sclerosis
- Compressive myelopathy
- Vestibulitis
- Medication effect/toxidrome

TREATMENT

PRE HOSPITAL

- Patients may have difficulty moving or communicating after cerebral vascular accident
- Neurologic exam in field is helpful:
 - Should include assessment of consciousness level, Glasgow coma scale score, gross motor deficits, speech abnormalities, gait disturbance, facial asymmetry, and other focal deficits
- Check fingerstick glucose

INITIAL STABILIZATION/THERAPY

- Manage airway:
 - Supplemental oxygen 2–4 L
 - Rapid-sequence intubation may be required for airway protection or controlled ventilation to decrease intracranial pressure
- For altered mental status, give naloxone and thiamine and check blood glucose

ED TREATMENT/PROCEDURES

- Treat elevated BP with labetalol, nicardipine, nitroprusside, or hydralazine:
 - Systolic BP >220 mm Hg or diastolic BP >120 mm Hg on repeated measurements
 - If indicated for other concurrent problems (MI, aortic dissection, CHF, hypertensive encephalopathy)
 - Initial goal is systolic BP <180 mm Hg, diastolic <110 mm Hg
- Control seizures with benzodiazepines, then fosphenytoin/phenytoin
- Maintain euvolemia and normothermia.
- Thrombolytics:
 - Ischemic stroke only; administer within 4.5 hr of symptom onset
 - Contraindications:
 - Any history of intracranial hemorrhage
 - Recent stroke or head trauma <3 mo ago
 - Major surgery <14 days ago
 - Systolic BP >185 mm Hg; diastolic BP >110 mm Hg
 - Bleeding diathesis
 - Noncompressible arterial puncture <7 days ago
 - MI <3 mo ago
 - Anticoagulation: INR >1.7, PT >15 sec, or prolonged PTT; use of heparin within 48 hr
 - Platelets <100,000
 - Intracranial neoplasm
 - Seizure at stroke onset
 - Minor or rapidly improving symptoms
 - Pregnancy
 - Internal bleed (GI/GU) <3 wk ago
 - Blood glucose <50

- Age < 18 yr
 - Avoid anticoagulants and antiplatelet drugs for 24 hr
- Treat increased intracranial pressure and cerebral edema:
 - Elevate head of bed 30°
 - Controlled ventilation to keep partial pressure of carbon dioxide 35–40 mm Hg
 - Mannitol
- Urgent neurosurgical decompression may be required with brainstem compression in cases of vertebrobasilar stroke or hemorrhage.
- In patients with completed or minor strokes, aspirin may prevent recurrence.
- For focal embolic/thrombotic strokes:
 - Recannulation
 - US-enhanced thrombolysis
 - Intra-arterial thrombolysis or clot retrieval

ALERT

For patients presenting between 3 and 4.5 hr of onset, there are additional exclusion criteria:

- Age > 80 yr
- Oral anticoagulant use (regardless of INR)
- NIH-SS > 25 or > 1/3 MCA territory involved
- History of previous stroke *and* diabetes

MEDICATION

First Line

- Alteplase (tPA): 0.9 mg/kg IV; max. 90 mg, with 10% of dose given as bolus and remainder infused over 60 min
- Aspirin: 81–325 mg PO/PR
- Labetalol: 10–20 mg IV bolus, repeat q10min max. 300 mg; follow with continuous infusion 0.5–2 mg/min

Second Line

- Clopidogrel: 75 mg PO daily
- Diazepam: 5 mg IV q5–10min max. 20 mg
- Enalapril: 0.675–1.25 mg IV
- Hydralazine: 10–20 mg IV q30min
- Mannitol (15–25% solution): 0.5–2 g/kg IV over 5–10 min, then 0.5–1 g/kg q4–q6h
- Nicardipine: 5 mg/h IV, increase by 2.5 mg/h q5–15min max. 15 mg/h
- Nitroprusside: 0.25–10 µg/kg/min IV
- Trimetaphan: 1–4 mg/min IV

Pediatric Considerations

- Heparin or low-molecular-weight heparin is often used in children with ischemic stroke
- May call 1-800-NOCLOTS for pediatric stroke consultation and guidance

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with acute cerebral vascular accident should be admitted to hospital
- Indications for ICU:
 - _ Severely decreased level of consciousness
 - _ Hemodynamic instability
 - _ Life-threatening cardiac dysrhythmias
 - _ Significantly increased intracranial pressure
 - _ Administration of alteplase

Discharge Criteria

- Patients who present with completed strokes that are days to weeks old may be discharged if they are able to function independently or have adequate social support
- Patients with multiple prior strokes who experience relatively minor new episodes may also be treated on outpatient basis if similar criteria are met and stroke is completed

FOLLOW-UP RECOMMENDATIONS

- Neurology
- Primary care
- Speech therapy/occupational therapy

PEARLS AND PITFALLS

- Always note pre-hospital observations
- Onset of symptoms is crucial to determining treatment with tPA
 - _ Include additional exclusion criteria between 3 and 4.5 hr
- Avoid aggressive BP correction due to risk of hypoperfusion and extension of stroke
- Door to needle goal is <60 min

CERVICAL ADENITIS

Julie Zeller

BASICS

DESCRIPTION

- Acute bacterial infection of a cervical lymph node
 - Often arising after a prior bacterial infection of the head or neck area
- Primarily a pediatric disease:
 - Becoming more common in adults owing to immunocompromised disease states (HIV, cancer, transplant patients)
- Any cervical node can become infected:
 - >80% of childhood cervical lymphadenitis involves the submandibular or deep cervical nodes
 - Jugulodigastric node located just below the angle of the mandible is common site
 - Cervical nodes act as the final common pathway for lymphatic drainage of all areas of the head and neck
 - Initial lymphadenopathy results after bacterial invasion of regional areas of the head and neck
 - Local lymph nodes swell secondary to hyperplasia of sinusoidal cells and infiltration of lymphocytes
 - If the infection is not contained, the bacteria enter the lymph system and proliferate (lymphadenitis)
 - Pus forms when neutrophils are incited, and an abscess develops when host defenses are unable to clear infection
 - Clinically manifests as warm, tender, swollen, erythematous node

ETIOLOGY

- ~70% of cases are a result of group A β -hemolytic Streptococcal infection
 - 20% Staphylococcal infection
 - 10% related to viral infection or other bacteria
- Infections secondary to community-acquired MRSA (CA-MRSA) have increased in frequency
- Children have one of the highest rate of CA-MRSA colonization and invasive disease
- Mycobacteria TB:
 - Scrofula or tuberculous lymphadenitis
 - Rarely seen
 - Usually a chronic lymphadenitis in the posterior cervical nodes
 - Purified protein derivative (PPD) is usually strongly reactive

- Treatment is nonsurgical
- Atypical mycobacteria (nontuberculous) *Mycobacterium avium* complex:
 - More commonly seen
 - Usually a chronic lymphadenitis in the submandibular or anterior cervical nodes
 - PPD test results are unreliable
 - Treatment is primarily surgical
- *Bartonella henselae* (cat scratch disease):
 - Subacute lymphadenitis
 - Fever and mild systemic symptoms occur in only ~ 3% of patients
 - Has indolent course but usually spontaneously resolves after 4–6 wk
- Anaerobes:
 - Consider when associated with infections of the teeth or gingiva
- Rare organisms:
 - Gram-negative bacilli
 - *Yersinia pestis*
 - Group B streptococcus
 - *Francisella tularensis*
 - *Alpha-streptococcus*
 - Anthrax

Pediatric Considerations

- One of the most common causes of a neck mass in a child
- Overall, group A Streptococcus and *Staphylococcus aureus* most common causes
- In neonates, group B Streptococcus and *S. aureus* most common
- Group B *Streptococcal cellulitis*–adenitis syndrome:
 - Infants are usually 3–7 wk of age, male, febrile, with submandibular or facial cellulitis, and an ipsilateral otitis media
 - 94% incidence of concurrent bacteremia
- *S. aureus* associated with more indolent course and higher frequency of suppuration
- Viral infections generally result in bilateral lymphadenopathy

Geriatric Considerations

- Consider malignancy over infection in this population, especially in the absence of fever, leukocytosis, etc.
- Fixed, nontender, hard node most likely not cervical adenitis

DIAGNOSIS

SIGNS AND SYMPTOMS

- Enlarged, tender cervical lymph node

- Usually unilateral and solitary
- Warmth and erythema of overlying skin
- Early in course, node is firm but may become fluctuant later
- With or without fever
- Malaise
- Irritability in infants and children
- Usually a concurrent head and neck infection:
 - Pharyngitis, tonsillitis, peritonsillar abscess
 - Otitis media, otitis externa
 - Dental infection
 - Impetigo, scalp infection

History

- Time of onset of symptoms
- Associated symptoms: Fever, weight loss, rash
- Exposures/travel history
- Comorbidities/birth history for infants

Physical-Exam

Complete evaluation of head and neck with attention to airway and patient's clinical appearance

ESSENTIAL WORKUP

- Cervical adenitis is a clinical diagnosis
- Identify primary source of infection in head and neck area (e.g., otitis media, tonsillitis)
- If no primary inflammatory source of infection in head and neck:
 - Address possible TB exposure with PPD
 - Look for signs of systemic disease and viral illness

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Unnecessary if a treatable primary source of infection confirmed
- Blood cultures for toxic-appearing patients
- Sepsis workup in neonates
- If cause unclear, the following lab tests may help to discern a nonbacterial cause (see “Differential Diagnosis”):
 - Leukocyte count with differential
 - Monospot
 - Throat cultures
 - Antibody titers (Epstein–Barr virus, CMV, toxoplasmosis)

Imaging

- CXR study, lateral neck, or Panorex:
 - Helpful if source of infection unclear or to rule out a deep space infection
 - Chest radiograph study to screen for TB
- CT or MRI of neck:
 - Helpful to exclude deep space infections or delineating embryonic developmental masses
- US:
 - Can differentiate cystic from solid structures, but other findings nonspecific
 - Can identify deep-cavity abscess if not palpable on exam
- Excisional biopsy

Diagnostic Procedures/Surgery

- Needle aspiration:
 - All fluctuant nodes should be aspirated
 - Send for Gram stain and acid-fast stains, aerobic and anaerobic cultures, mycobacteria, and fungi
 - If any suspicion of tuberculous lymphadenitis, the node should not be aspirated owing to risk for sinus development and chronic drainage
- Intradermal skin testing:
 - Mycobacteria, catscratch disease

DIFFERENTIAL DIAGNOSIS

- Lymphadenopathy (inflammation of node but no bacterial infection) can be a sign of many systemic diseases; usually these nodes are multiple and bilateral
- Viral infections are a common cause:
 - Respiratory viruses (adenoviruses, rhinoviruses, enteroviruses)
 - Epstein–Barr virus, herpes simplex virus, varicella-zoster virus, CMV
 - Mumps, rubella, rubeola
- Specific pediatric diseases with cervical adenitis in their diagnostic criteria:
 - Kawasaki disease
 - Kikuchi disease
 - Periodic fever, aphthous stomatitis, pharyngitis, and cervical adenitis known by mnemonic PFAPA (seen in preschool-aged children)
- Toxoplasmosis
- Congenital cysts:
 - Brachial cleft cysts, thyroglossal duct cysts, cystic hygromas
- Malignancies:
 - Leukemia, lymphoma, rhabdomyosarcoma, thyroid carcinoma
 - Rare cause of a nonspecific lump in children (< 2% overall)
- Other systemic diseases:
 - Lupus, sarcoidosis

TREATMENT

INITIAL STABILIZATION/THERAPY

- Oxygen, monitor airway for any signs of compromise
- Universal precautions

ED TREATMENT/PROCEDURES

- Treatment directed toward the primary source of infection in the head and neck:
 - If unsure of cause, treat for group A Streptococcus and *S. aureus*
 - Consider MRSA if symptoms not improving on standard antibiotic therapy
- Aspirate all fluctuant nodes
- Many oral antibiotics are effective:
 - Cephalexin
 - Cefadroxil
 - Amoxicillin/clavulanic acid
- Patients with suspected dental, periodontal, or anaerobic causes of illness:
 - Clindamycin
 - Amoxicillin/clavulanic acid
- CA-MRSA:
 - Clindamycin (many isolates are now resistant)
 - Bactrim
 - Vancomycin or Linezolid if toxic and requiring inpatient care
- Treatment should be for at least 10 days, even if symptoms resolve sooner
- Warm, moist compresses
- Analgesics, as needed

MEDICATION

First Line

- Cefadroxil: 500 mg (peds: 30 mg/kg/24 h) PO q12h
- Cephalexin: 250–500 mg (peds: 25–50 mg/kg/24 h) PO q6h
- Amoxicillin/clavulanic acid: 250–500 mg (peds: 20–40 mg/kg/24 h) PO q8h
- Clindamycin: 300 mg (peds: 8–25 mg/kg/24 h) PO q6h
- TMP-SMX (Bactrim): DS (160/800) 2 tabs PO BID (peds: 40 mg/200 mg/10 kg/PO BID)

Second Line

- Cefazolin: 1–2 g (peds: 25–50 mg/kg/24 h) IV q8h
- Nafcillin: 1–2 g (peds: 50–200 mg/kg/24 h) IV q4–6h
- Clindamycin: 600–900 mg (peds: 20–40 mg/kg/24 h) IV q8h
- Ampicillin–sulbactam: 1.5–3 g (peds: 200 mg/kg/d) q6h
- Vancomycin: 10–15 mg/kg IV Q12h (peds: 40–60 mg/kg/d div q8h)

- Linezolid (alternative to Vancomycin): 600 mg IV BID for children >12 or 30 mg/kg/8 h with max. dose of 1,200 mg for children <12 yr

FOLLOW-UP

DISPOSITION

Admission Criteria

- Neonates
- Airway compromise
- Patient appears ill
- Immunocompromised
- Inability to take PO
- Not improving on oral antibiotics

Discharge Criteria

- Most patients can be discharged on PO antibiotics
- Close follow-up with a recheck in 2–3 days
- Ability to take PO antibiotics and fluids
- Return to the ED if:
 - Symptoms worsen
 - Abscess develops
 - Voice changes
 - Dyspnea develops
 - Systemic symptoms develop

Issues for Referral

Clinical exam concerning for malignancy or congenital abnormality (brachial cleft/thyroglossal duct cyst)

FOLLOW-UP RECOMMENDATIONS

- Mandatory recheck in 48 hr to ensure improvement
- Referral to dentist or ENT depending on source of infection

PEARLS AND PITFALLS

- Cervical adenitis is a clinical diagnosis
- Unilateral warm, tender, swollen, erythematous lymph node
- Most common bacteria responsible for infection are group A *Strep* and *S. aureus*.
- Consider group B *Strep* in infants and MRSA for infections not improving on standard antibiotics
- Disposition should be influenced by patient's clinical status

CESAREAN SECTION, EMERGENCY

Jonathan B. Walker • James S. Walker

BASICS

ALERT

- The sole indication for ED physician to perform emergency perimortem cesarean section is a gravid female (>24 wk gestation) in cardiopulmonary arrest who has not responded to initial resuscitative measures, regardless of cause
- The most important predictor of fetal survival is length of time between maternal cardiac arrest and cesarean delivery:
 - _ Cesarean section should begin within 4 min of maternal arrest
 - _ Goal is delivering fetus within 1 min
- Obtain immediate consultations from obstetrics, pediatrics (and surgery, if trauma related):
 - _ Do not defer or delay performing procedure until arrival of consultants
- Do not perform emergent cesarean section if patient is <24 wk gestation

ETIOLOGY

- Trauma (penetrating or blunt):
 - _ Major cause of maternal mortality
- Pulmonary embolus:
 - _ Thromboembolism is most common cause of nontraumatic maternal mortality
- Cerebral vascular accident
- Amniotic fluid embolism
- DIC
- Placenta previa
- Eclampsia
- Miscellaneous medical disorders:
 - _ Asthma
 - _ CHF
 - _ MI
 - _ Drug overdose

DIAGNOSIS

SIGNS AND SYMPTOMS

History

Gravid female (>24 wk gestation determined by uterine fundal height) who is in

cardiopulmonary arrest

Physical-Exam

Patient is determined to be >24 wk gestation if uterus is at least 4 finger breadths above umbilicus

ESSENTIAL WORKUP

- Physical exam for apnea and pulselessness in obviously gravid female:
 - Quickly evaluate for reversible causes of cardiopulmonary arrest:
 - Hypoxia
 - Hypovolemia
 - Hydrogen ion (acidosis)
 - Hypokalemia/hyperkalemia
 - Hypoglycemia
 - Hypothermia
 - Trauma
 - Thromboembolism
 - Toxins/poisons
 - Tension pneumothorax
 - Tamponade (pericardial)
 - Supine hypotension syndrome (compression of inferior vena cava by enlarged uterus)
- Assess gestational age by uterine fundal height
 - Distance from pubis to fundus in centimeters is roughly equivalent to gestational age in weeks, i.e., 24 cm = 24 wk
- US is beneficial if *immediately* available to assess fetus.

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- None necessary to establish cardiopulmonary arrest
- Do *not* use valuable time attempting to determine fetal heart tones

DIFFERENTIAL DIAGNOSIS

Cardiopulmonary arrest is final common pathway:

- Evaluate for underlying cause

TREATMENT

PRE HOSPITAL

Cautions:

- Minimal scene time, “scoop and run”

- Place the patient in the left lateral decubitus position to avoid compression of inferior vena cava (supine hypotension syndrome)
- Trauma patient requiring spinal immobilization:
 - Uterus can be manually displaced to left
 - Backboard can be wedged to keep right hip elevated 45°

INITIAL STABILIZATION/THERAPY

- Standard resuscitation measures:
 - Emergency intubation
 - Use a smaller endotracheal tube (0.5–1 mm less in internal diameter compared to that used for nonpregnant women)
 - High-flow oxygen
 - Cardiac and BP monitoring
 - 2 large-bore peripheral IV lines:
 - Fluid resuscitation
 - O-negative blood if indicated
- Fetal survival correlates with maternal survival and adequacy of initial maternal resuscitation
- If patient is at <24 wk gestation, use advanced cardiac life support (ACLS) and advanced trauma life support protocols directed at maternal resuscitation
 - Do *not* perform emergent cesarean section
- If patient is >24 wk gestation, use 4-min rule:
 - Perform ACLS or advanced trauma life support for 4 min
 - If no response, proceed to immediate emergency cesarean section
 - Goal is to deliver fetus within 1 min
 - If it is obvious there is no chance for maternal survival, begin perimortem cesarean section immediately

ED TREATMENT/PROCEDURES

- Call for immediate obstetric, surgical, and pediatric consultations:
 - Do *not* delay performing procedure while waiting for consultants
- Ensure a Foley catheter has been inserted to decompress bladder, but do not delay procedure
- Perform cesarean section:
 - Use linea nigra as landmark for vertical midline incision
 - Incise abdominal wall from pubic hairline to 5 cm above umbilicus.
 - This incision should pass through fascial and peritoneal layers
 - Retract urinary bladder inferiorly against pubic symphysis
 - Make small vertical incision in lower uterine segment, just cephalad to urinary bladder
 - Extend incision cephalad with scissors:
 - Insert your free hand into uterus
 - Lift uterine wall away from fetus to avoid fetal injury

- Deliver fetus
- Clamp umbilical cord in 2 places and cut between the 2 clamps
- Manually deliver placenta
- Perform neonatal resuscitation, as indicated
- Immediately reassess maternal vital signs because occasionally spontaneous circulation may return
- Continue maternal resuscitation as appropriate
- Suture uterus with running lock stitch using no. 0 polyglactin suture
- Suture fascia and peritoneum with running stitch using no. 0 polyglactin suture
- Close the skin with staples or suture
- Administer broad-spectrum antibiotics
- If maternal return of circulation is obtained, consider starting therapeutic hypothermia protocol

MEDICATION

First Line

Resuscitative measures/ACLS medications directed at mother:

- Treatment of underlying cause

Second Line

Neonatal resuscitation should be anticipated:

- Oral tracheal intubation

FOLLOW-UP

DISPOSITION

Admission Criteria

- The infant should be admitted to NICU
- If maternal resuscitation is successful, patient should be admitted to appropriate ICU

Discharge Criteria

Neither infant nor mother should be discharged from ED

PEARLS AND PITFALLS

- Only females > 24 wk pregnant in cardiopulmonary arrest qualify for the procedure.
- Decision to perform perimortem cesarean section must be made quickly (within 4

- min of maternal cardiopulmonary arrest)
- Procedure must be done quickly (<1 min).

CHANCROID

Norbert Elsner

BASICS

DESCRIPTION

- Sexually transmitted genital ulcerative disease:
 - Increased risk for HIV infection
- A common cause of genital ulceration in Africa, southeast Asia, and Latin America:
 - Uncommon in US where herpes simplex virus (HSV) > syphilis > > chancroid, but likely underreported

ETIOLOGY

Causative agent: *Haemophilus ducreyi*

- Highly infectious bacterium

DIAGNOSIS

SIGNS AND SYMPTOMS

- Begins as a single erythematous papule or pustule:
 - Quickly erodes into painful chancres (1–20 mm)
 - Soft and friable with ragged, irregular borders
- Primary ulcer usually excavated
- Moist, granulation tissue at base
- Purulent or hemorrhagic exudate
- Location:
 - Male:
 - Penile shaft, glans, internal surface of foreskin, anus
 - Female:
 - Cervix, vagina, vulva, perineum, anus
- Occurs 4–7 days (median) after exposure
- Incubation period 3–10 days (range 1–35 days)
- Inguinal adenopathy:
 - In ~50% of men; less common in women
 - Appears 3–14 days after initial ulcer
 - Unilateral (usually)
 - Painful
 - Suppurative large nodes (buboes)
 - May rupture and form chronic draining sinuses
- Dysuria, dyspareunia secondary to contact with lesions
- Variants:

- Phagedenic:
 - Secondary superinfection (especially fusospirochetal) and rapid extensive tissue destruction
- Giant chancroid:
 - Very large single ulcer
- Serpiginous ulcer:
 - Rapidly spreading, indolent, shallow ulcers in groin or thigh
- Follicular:
 - Multiple small ulcers with perifollicular distribution

ESSENTIAL WORKUP

Clinical diagnosis based on appearance is often inaccurate, and lab tests difficult or unavailable, so consider:

- CDC case definitions:
 - Definite: Positive culture of *H. ducreyi*
 - Probable: Typical signs, symptoms of chancroid + negative dark-field exam for *Treponema pallidum* + negative syphilis serology + negative culture for HSV (or clinical exam atypical for herpes)

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Gram stain unreliable (positive in 50–80%):
 - Gram-negative coccobacilli
 - Linear or “school-of-fish” pattern
- Culture extremely difficult (positive in 0–80%); requires complex media:
 - Obtain specimen from:
 - Base of ulcer
 - Needle aspiration of inguinal node by placing needle through normal skin (to avoid formation of fistula)
- Polymerase chain reaction (PCR) assay:
 - Sensitive and specific, but not widely available
- RPR:
 - Coinfection with syphilis is common
 - Part of CDC guidelines for probable clinical diagnosis of chancroid
- HSV culture:
 - Part of CDC guidelines for probable clinical diagnosis of chancroid
- HIV testing

DIFFERENTIAL DIAGNOSIS

- Infectious:
 - Syphilis (*T. pallidum*):
 - Chancre usually painless, indurated, clean

- Herpes genitalis (*HSV*):
 - Vesicular, multiple, recurrent
- Granuloma inguinale (donovanosis) (*Klebsiella granulomatis*):
 - Ulcer margins elevated; + induration
- Lymphogranuloma venereum (*Chlamydia trachomatis*):
 - Often single lesion; tender, fluctuant, unilateral lymphadenopathy
- Noninfectious:
 - Drug eruption
 - Less common:
 - Pyoderma gangrenosum
 - Behçet disease

TREATMENT

INITIAL STABILIZATION/THERAPY

Usual precautions for patient exam and handling of specimens

ED TREATMENT/PROCEDURES

Antibiotics:

- Azithromycin: Single PO dose
- Ceftriaxone: Single IM dose (pregnancy: 1st line)
- Ciprofloxacin: PO × 3 days:
 - NOT for pregnant/lactating patients
- Erythromycin base: PO × 7 days:
 - Pregnancy: 2nd line
- Needle aspiration of suppurative nodes (> 5 cm diameter):
 - To prevent chronic sinus drainage from spontaneous rupture
 - Use 18G needle through lateral intact skin.
 - May require repetition
- Recommend concurrent HIV, syphilis, HSV testing, *and* follow-up testing in 3 mo if initially negative

MEDICATION

First Line

- Azithromycin: 1 g PO × 1
- Ceftriaxone: 250 mg IM × 1

Second Line

- Ciprofloxacin: 500 mg PO BID for 3 days
- Erythromycin base: 500 mg PO QID for 7 days

FOLLOW-UP

DISPOSITION

Admission Criteria

- Sexual abstinence or condom use until lesions healed
- Clinical course:
 - Symptoms improve within 2 days of treatment
 - Ulcers improve within 3–7 days
 - Possible delayed resolution in those HIV-positive or uncircumcised

FOLLOW-UP RECOMMENDATIONS

- Examine and treat sexual partners (regardless of presence/absence of symptoms) if contact within 10 days of symptom onset
- HIV-positive patients require assured follow-up if using single-dose therapy (higher treatment failure rate)

PEARLS AND PITFALLS

- Initiate treatment if probable CDC case guidelines met; do not wait for culture results
- Higher risk of treatment failure in HIV-infected patients
- Presumptive treatment of sexual contacts
- Treatment failure: Consider drug resistance, medication noncompliance, coinfection (syphilis).

CHEMICAL WEAPONS POISONING

Patrick M. Whiteley

BASICS

DESCRIPTION

Chemical agents that affect CNS, pulmonary, cardiovascular, dermal, ocular, or GI systems when exposed to victims

ETIOLOGY

- **Blood agents: Cyanide:**
 - Inhibition of cellular respiration by binding to ferric ion in cytochrome oxidase a-a3 and uncoupling oxidative phosphorylation
- **Blister agents: Sulfur mustard, nitrogen mustard, lewisite, phosgene oxime:**
 - Alkylation and cross-linking of purine bases of DNA and amino acids resulting in change in structure of nucleic acid, proteins, and cellular membranes
- **Lacrimators and riot control agents: 1-chloroacetophenone (CN; Mace), o-chlorobenzylidene malononitrile (CS), oleoresin capsaicin-pepper spray (OC), chloropicrin, adamsite (DM):**
 - Mucous membrane irritators
- **Pulmonary irritants (choking agents):**
 - High water solubility: Ammonia:
 - Mucous membrane irritation of eyes and upper airway
 - Intermediate water solubility: Chlorine:
 - Forms hydrochloric acid, hydrochlorous acids, which form free radicals causing upper airway and pulmonary irritation
 - Low water solubility: Phosgene:
 - Mild irritant effects initially, then delayed pulmonary edema as late as 24 hr
 - Direct pulmonary damage after hydrolysis in lungs to hydrochloric acid
- **Nerve agents:**
 - Anticholinesterase inhibitors—causes cholinergic overstimulation at muscarinic, nicotinic, and CNS sites
- **Incapacitating agents: 3-quinuclidinyl benzilate (BZ):**
 - Anticholinergic (antimuscarinic)

DIAGNOSIS

SIGNS AND SYMPTOMS

History

Multiple victims, house fire, known exposure (agent determines history findings)

Physical-Exam

- Blood agents (cyanide and cyanogens):
 - Vital signs:
 - Tachypnea and hyperpnea (early); respiratory depression (late)
 - Hypertension and tachycardia (early); hypotension and bradycardia (late)
 - Death within seconds to minutes
 - CNS:
 - Headache
 - Mental status changes
 - Seizures
 - Pulmonary:
 - Dyspnea
 - Noncardiogenic pulmonary edema
 - Cyanosis uncommon
 - GI:
 - Odor of bitter almonds (sometimes)
 - Burning in mouth and throat
 - Nausea, vomiting
- Blister agents (mustards, lewisite):
 - General:
 - Mortality, 2–4%
 - Dermatologic:
 - Skin erythema, edema, pruritus can appear 2–24 hr after exposure.
 - Necrosis and vesiculation appear 2–18 hr after exposure.
 - Head, eyes, ears, nose, and throat (HEENT):
 - Airway occlusion from sloughing of debris
 - Laryngospasm, sore throat, sinusitis
 - Eye pain, photophobia, lacrimation, blurred vision, blepharospasm, periorbital edema, conjunctival edema, corneal ulceration
 - Pulmonary:
 - Bronchospasm, tracheobronchitis
 - Respiratory failure
 - Hacking cough
 - GI:
 - Nausea, vomiting
 - Hematologic:
 - Leukopenia
- Lacrimators and riot control agents (tear gases):
 - HEENT:

- Eye pain
- Lacrimation
- Blepharospasm
- Temporary blindness
- Dermatologic:
 - Skin irritation
 - Papulovesicular dermatitis (tear gas)
 - Superficial burns
- Pulmonary:
 - Cough
 - Chest tightness
 - Dry throat
 - Sensation of suffocation
 - Pulmonary edema when exposed to high concentrations without ventilation
- Pulmonary irritants (choking agents):
 - HEENT:
 - Eye pain, lacrimation, blepharospasm
 - Temporary blindness
 - Dermatologic:
 - Skin irritation, dry throat, nasal irritation
 - Pulmonary:
 - Shortness of breath, cough, bronchospasm
 - Chest pain
 - Pulmonary edema as late as 24 hr from exposure (phosgene)
- Nerve agents (sarin, tabun, soman, VX):
 - *SLUDGE* syndrome:
 - Salivation
 - Lacrimation
 - Urination
 - Defecation
 - GI cramps
 - Emesis
 - *Bronchorrhea, bronchoconstriction, bradycardia (most life threatening)*
 - Abdominal upset
 - Miosis
 - HEENT:
 - Miosis
 - Hypersecretion by salivary, sweat, lacrimal, and bronchial glands
 - CNS:
 - Irritability, nervousness
 - Giddiness
 - Fatigue, lethargy, depression

- Ataxia, convulsions, coma
- Pulmonary:
 - Bronchoconstriction
 - Bronchorrhea
- GI:
 - Nausea, vomiting, diarrhea
 - Crampy abdominal pains
 - Urinary and fecal incontinence
- Musculoskeletal:
 - Fasciculations, skeletal muscle twitching
 - Weakness
 - Flaccid paralysis
- Incapacitating agents (BZ):
 - Anticholinergic (antimuscarinic) toxidrome:
 - Hot as a hare
 - Dry as a bone
 - Red as a beet
 - Blind as a bat
 - Mad as a hatter
 - Hypertension
 - Tachycardia
 - Hyperpyrexia
 - Urinary retention
 - Decreased bowel sounds

ESSENTIAL WORKUP

- History and symptoms key to type of agent exposure
- Physical exam:
 - Cyanide (bitter almonds, comatose, hypotensive, metabolic acidosis)
 - Mustard (faint, sweet odor of mustard or garlic, blisters, sloughing of skin, dyspnea)
 - Check for SLUDGEABAM syndrome.
 - Lacrimators (eye irritation, lacrimation, blepharospasm)
 - Choking agents (dyspnea, bronchospasm)

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Arterial blood gases:
 - Cyanide:
 - Decreased atrioventricular (AV) oxygen saturation gap
 - Lactic acidemia with high anion gap metabolic acidosis
 - Arterialization of venous blood

- Cyanide levels cannot be performed in clinically relevant timeframe.
- CBC:
 - Leukopenia, thrombocytopenia, anemia with significant mustard exposure
- Electrolytes, BUN, creatinine, glucose
- Urinalysis
- Creatine phosphokinase (CPK)
- Lactate for cyanide
- Erythrocyte cholinesterase activity for nerve agents

Imaging

CXR for pulmonary edema

DIFFERENTIAL DIAGNOSIS

- Asthma/COPD
- Stevens–Johnson syndrome
- Toxic epidermal necrolysis
- Pemphigus vulgaris
- Scalded skin syndrome
- Organophosphate or carbamate pesticide poisoning
- Botulism
- Radiation poisoning
- CHF
- Anaphylactoid reaction

TREATMENT

PRE-HOSPITAL

- Avoid contamination of environment and clinicians:
 - Use level A or level B personal protective equipment.
 - Decontamination:
 - Dermal wet decontamination primarily for nerve and blistering agents
 - Dry decontamination (removal of clothing and jewelry) for other agents
- Administer atropine even if patient is tachycardic because condition may result from hypoxia.

INITIAL STABILIZATION/THERAPY

- ABCs
- Patient decontamination:
 - Brush off powder from chemical.
 - Irrigate skin and eyes with copious amounts of water or saline.

- Remove and dispose of clothing in double bags.
- Protection for health care workers:
 - Level A or B personal protective suit
 - Chemical-resistant suit
 - Heavy rubber gloves and boots, neoprene gloves
- Administer oxygen, place on cardiac monitor, and measure pulse oximetry.
- Establish IV access with 0.9% NS.

ED TREATMENT/PROCEDURES

- Decontamination: Reduce secondary exposure
- Blood agents:
 - High flow 100% NRB oxygen
 - Benzodiazepines for seizures
 - Hydroxocobalamin (1st line)
 - Cyanide antidote kit (2nd line), may be repeated.
- Blister agents:
 - Supportive care
 - Standard burn management
 - Atropine to relieve eye pain
 - Monitor fluids, electrolytes, complete blood chemistry.
 - Monitor CBC for nadir.
 - Supportive care for sepsis, anemia, hemorrhage
 - Granulocyte colony-stimulating factor (G-CSF) for neutropenia
- Choking agents, lacrimators, riot control agents:
 - Supportive care, bronchodilators
 - Eye irrigation
 - CXR and careful monitoring for respiratory complications
 - Phosgenes require monitoring for delayed pulmonary edema for 24 hr
- Nerve agents:
 - Supportive care:
 - 100% oxygen
 - Frequent airway suctioning
 - Atropine 2 mg IV q5min until reversal of bronchorrhea, bronchoconstriction, and hypoxemia:
 - Antagonizes muscarinic effects and some CNS but no effect on skeletal muscle weakness or respiratory failure
 - Pupillary response and heart rate are not useful measures of adequate atropinization.
 - Stop atropine after patient regains consciousness and spontaneous ventilation (may need for periodic relapses); give as much as it takes to reverse respiratory compromise.
 - Pralidoxime chloride (2-PAM or Protopam):
 - Regenerates cholinesterase by reversing phosphorylation (unless

- aging has occurred)
- Reduces abnormal skeletal muscle movements, improves skeletal muscle weakness, and reverses flaccid paralysis
- May repeat 1st dose or start on continuous infusion
- If improvement from 1st dose, repeat 60–90 min later.
- Diazepam: Administer for seizures.
- Incapacitating agents (BZ):
 - Supportive care
 - Aggressive IV fluid hydration
 - Benzodiazepines for agitation and increased muscular activity
 - Consider physostigmine in consultation with a poison center.

MEDICATION

- Albuterol using nebulizer: 2.5 mg in 2.5 mL NS (peds: 0.1–0.15 mg/kg/dose)
- Atropine: 2 mg IM or IV (5–6 mg in severely poisoned adults; peds: 0.02–0.08 mg/kg), then q5–10min titrate to clinical effect
- Cyanide antidote kit:
 - Inhale amyl nitrite ampule for 30 sec qmin until sodium nitrite given.
 - Sodium nitrite: 10 mL of 3% solution or 300 mg IV over 3–5 min (peds: 0.15–0.33 mL/kg):
 - Monitor methemoglobin levels to keep < 30%.
 - Sodium thiosulfate: 50 mL IV of 25% solution or 12.5 g (peds: 1.65 mL/kg)
- Diazepam: 5–10 mg IV over 3–5 min (peds: 0.2–0.4 mg/kg up to 10 mg over 2–3 min)
- Hydroxocobalamin: 5 g IV
- Pralidoxime chloride (2-PAM, Protopam): 1–2 g IV over 20–30 min or 600 mg IM (diluted with water or saline to concentration of 300 mg/mL) given with 1st 3 atropine doses (peds: 25–50 mg/kg/dose IV), repeat in 2 hr if muscle weakness has not been relieved, and in 4–6-hr intervals if necessary. Continuous infusion of 500 mg/h has been used for organophosphate poisoning

FOLLOW-UP

DISPOSITION

Admission Criteria

- ICU admission for symptomatic patients with significant exposure
- Hospital admission to monitor for developing complications for blister, choking, lacrimating agents, incapacitating agents

Discharge Criteria

Riot control exposures:

- Observe in ED for 6 hr and discharge if symptoms resolve.

PEARLS AND PITFALLS

Must perform adequate decontamination

CHEST PAIN

Josh W. Joseph • Edward Ullman

BASICS

DESCRIPTION

- One of the most frequent chief complaints in the ED
- Often the presenting symptom of a high-risk etiology:
 - Acute coronary syndrome
 - Pulmonary embolism
 - Aortic dissection
- Assume life threatening until proven otherwise.
- Categorization may suggest the underlying etiology, but the presentation of chest pain can be extremely variable and vague.
- Thoracic pain:
 - May involve the myocardium, pericardium, the ascending aorta, pulmonary artery, mediastinum, and esophagus
 - Pain is deep, visceral, and poorly localized.
 - Characteristics vary from severe and crushing to mild, burning, or indigestion.
- Epigastric pain:
 - May involve the descending aorta, diaphragmatic muscles, gallbladder, pancreas, duodenum, and stomach
 - Pain is generally referred to the xiphoid region and in the back.
- Pleuritic pain:
 - Inflammation or trauma to the ribs, cartilage, muscles, nerves, pleural or pericardial surface
 - Pain increased by breathing, laughing, coughing, sneezing
 - Tenderness to palpation may be present.
 - Diaphragmatic pleurisy:
 - Sharp shooting pains in the epigastrium, lower retrosternal area, or shoulder intensified by thoracic movement
- Chest wall pain:
 - Inflammation of skin and SC structures of the chest wall
 - Pain is reproduced by:
 - Palpation
 - Horizontal flexion of the arms
 - Extension of the neck
 - Vertical pressure on the head

ETIOLOGY

- Thoracic:
 - Acute coronary syndrome
 - Pericarditis
 - Myocarditis
 - Stress-induced cardiomyopathy
 - Cardiac syndrome X
 - Stimulant use
 - Thoracic aortic dissection
 - Esophagitis
 - Esophageal spasm
 - GERD
 - Esophageal hyperalgesia
 - Abnormal motility patterns and achalasia
 - Esophageal rupture and mediastinitis
- Epigastric:
 - Dissection of the descending aorta
 - Peptic ulcer disease
 - Pancreatitis
 - Cholecystitis
 - Splenic rupture
 - Hepatic injury
 - Subdiaphragmatic abscess
- Pleuritic pain:
 - Pulmonary embolism
 - Pneumothorax
 - Pneumonia
 - Costochondritis
- Diaphragmatic pleurisy:
 - Splenic rupture
 - Hepatic injury
 - Subdiaphragmatic abscess
- Esophageal rupture
- Intercostal myositis
- Intercostal neuralgia
- Pectoralis minor strain
- Pericarditis
- Pleuritis
- Pneumonitis
- Rib fractures
- Acute chest syndrome of sickle cell
- Chest wall twinge syndrome:
 - Brief episodes of sharp anterior chest pain lasting 30 sec–3 min, aggravated by deep breathing and relieved by shallow respirations

- Chest wall pain:
 - Chest wall hematoma
 - Chest wall laceration
 - Herpes zoster
 - Thrombophlebitis of the thoracoepigastric vein
 - Xiphisternal arthritis
 - Adiposis dolorosa
 - Breast abscess, fibroadenosis, carcinoma

DIAGNOSIS

SIGNS AND SYMPTOMS

- Coronary artery disease:
 - Pressure
 - Squeezing pain
 - Radiation to arm, jaw
 - Shortness of breath
 - Diaphoresis
 - Nausea
 - Vomiting
 - Weakness
 - Fatigue especially in women or elderly
 - Signs of CHF
 - Anxiety
- Aortic dissection:
 - Sudden onset of pain with maximal intensity early
 - Tearing pain
 - Radiation to back and/or flank
 - HTN
 - Diastolic murmur of aortic insufficiency
 - Difference in upper-extremity pulses
 - Syncope
 - Nausea
 - Vomiting
 - Associated neurologic changes (i.e., visual changes)
- Pulmonary embolism:
 - Pleuritic pain
 - Shortness of breath
 - Anxiety
 - Diaphoresis
 - Tachypnea
 - Tachycardia

- Low-grade fever
- Syncope
- Localized rales
- Wheezing
- Acute pericarditis:
 - Substernal pain
 - Varies with respiration
 - Increased with recumbency
 - Relieved by leaning forward
 - Anxiety
 - Anorexia
 - Fever
 - Pericardial friction rub
- Pneumothorax:
 - Pleuritic pain
 - Shortness of breath
 - Anxiety
 - Tachypnea
 - Decreased unilateral breath sounds
 - Can be spontaneous (young), or associated with very minor trauma (elderly)

History

- The history is the most important tool to distinguish between the various etiologies.
- Have the patient define the key features:
 - Duration
 - Location:
 - Retrosternal
 - Subxiphoid
 - Diffuse
 - Frequency:
 - Constant
 - Intermittent
 - Sudden vs. delayed onset
 - Precipitating factors:
 - Exertion
 - Stress
 - Food
 - Respiration
 - Movement
 - Timing:
 - Context of onset of pain (i.e., at rest, exertional)

- Duration of pain
- Quality:
 - Burning
 - Squeezing
 - Dull
 - Sharp
 - Tearing
 - Heavy
- Associated symptoms:
 - Shortness of breath
 - Diaphoresis
 - Nausea
 - Vomiting
 - Jaw pain
 - Back pain
 - Radiation
 - Palpitations
 - Syncope
 - Fever
 - Weakness: Generalized vs. focal
 - Fatigue

Physical-Exam

- Cardiac exam for murmurs, rub, decreased heart sounds, or extra heart sounds
- Chest exam for decreased breath sounds, rales, wheezing
- Extremity exam for decreased pulses, pulsus paradoxus
- Skin exam for lesions of herpes zoster
- Abdominal exam for tenderness, rebound, guarding

DIAGNOSIS TESTS & INTERPRETATION

EKG:

- Inexpensive and available
- Obtain and interpret within 10 min of arrival
- Serial EKG can be useful in patients with high concern for ACS and a negative initial EKG.
- See specific etiologies.

Lab

- Lab testing should be individualized to the patient and the presentation, based on the risk of potential life threats.
- See “Cardiac Testing.”
- D-Dimer:

- Sensitive but poor specificity for physical exam
- Indicated for low-risk patient if there is an indication to rule out pulmonary embolus
- Controversial use as a screening test for aortic dissection

Imaging

- CXR:
 - Pneumothorax
 - Pneumonia
 - CHF
 - Aortic dissection:
 - Widened mediastinum seen in ~ 55–62% of patients
 - A pleural effusion is found in ~ 20% of patients.
 - Apical capping
 - Aortic knob obliteration
 - A normal chest radiograph is found in 12–15% of patients.
 - Acute pericarditis:
 - Usually normal unless massive effusion enlarges cardiac silhouette
 - Esophageal rupture:
 - Usually will show mediastinal air
 - May have left pleural effusion
- Helical CT scan:
 - Pulmonary embolism
 - Sensitive for aortic dissection
- Ventilation/perfusion scan:
 - Useful in pulmonary embolus
 - Must have normal CXR
- Angiography:
 - Pulmonary embolism; although rarely done
 - Useful in dissection, especially in stable patients
- US:
 - Test of choice for pericardial and valvular disease
 - Transesophageal Echo can be used in diagnosis of aortic dissection, especially in unstable patients and those unable to tolerate contrast.
 - Right ventricular dilation and hypokinesia is suggestive for pulmonary embolus and can be used to guide therapy
 - Bedside transthoracic Echo can be used to quickly discover significant pericardial effusion, pneumothorax, and pleural effusion

DIFFERENTIAL DIAGNOSIS

See “Etiology.”

TREATMENT

PRE HOSPITAL

- Therapeutic interventions should be guided by the patient's presentation, risk factors, and past history.
- If a cardiac life threat is suspected:
 - IV access
 - Cardiac monitoring
 - EKG
 - Oxygen
 - Baby aspirin/Full aspirin
 - Pain control:
 - Nitrates
 - Morphine

INITIAL STABILIZATION/THERAPY

As guided by the patient's presentation:

- ABCs
- IV
- Oxygen
- Cardiac monitoring

ED TREATMENT/PROCEDURES

- IV, oxygen, and monitoring
- EKG
- Treatment varies based on suspected etiologies.

MEDICATION

Dependant on etiology

FOLLOW-UP

DISPOSITION

Admission Criteria

Dependent on the risk for life-threatening cardiopulmonary etiologies

Discharge Criteria

Safe if patient is deemed to have low-risk etiology of chest pain

Issues for Referral

Follow-up with primary care physician on low-risk chest pain for outpatient assessment

FOLLOW-UP RECOMMENDATIONS

Patient should be instructed to return if:

- Chest discomfort lasts > 5 min
- Chest discomfort gets worse in any way
- History of angina, and discomfort not relieved by usual medicines
- Shortness of breath, sweats, dizziness, vomiting, or nausea with chest pain or chest discomfort
- Chest discomfort moves into your arm, neck, back, jaw, or stomach

PEARLS AND PITFALLS

- Caution in only ordering a single biomarker
- Using response to medications as a diagnostic tool
- Not using serial EKG in patients with suspected ACS or repeating EKGs when patients have recurrent chest pain

ICD10

- R07.2 Precordial pain
- R07.9 Chest pain, unspecified
- R07.89 Other chest pain

CHEST TRAUMA, BLUNT

Lisa G. Lowe Hiller

BASICS

DESCRIPTION

- Significant source of morbidity and mortality in US
- ~12 thoracic trauma victims per million population per day
- ~33% of these injuries require hospital admission.
- Directly responsible for 20–25% of all deaths attributed to trauma
- Contributing cause of death in 25% of patients who die from other traumatic injuries

ETIOLOGY

- Common mechanisms of injury include:
 - Motor vehicle collisions (70–80%)
 - Motorcycle collisions
 - Pedestrians struck by a motor vehicle
 - Falls from great heights
 - Assaults
 - Blast injuries
 - Sports-related injuries
- Injuries can result from direct blunt force to the chest or from forces related to rapid deceleration.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Obvious contusion, wound, or other defect of the chest wall
- Paradoxical chest wall movement suggests flail chest segment.
- Usually occurs in combination with other injuries
- Hypotension
- Some patients with severe intrathoracic injuries, such as traumatic aortic disruption, may have *no* visible external signs of trauma.

History

- Time of injury
- Mechanism of injury
- Estimates of motor vehicle accident (MVA) velocity and deceleration
- Loss of consciousness
- Chest pain

- Pain with deep inspiration or cough
- Dyspnea

Physical-Exam

- Unilaterally absent breath sounds
- Crepitus or subcutaneous air in the chest wall
- Decreased or absent breath sounds
- Tenderness to palpation on the chest wall
- Jugular venous distention
- Tracheal deviation away from midline
- Hyper-resonance to percussion on involved side

ESSENTIAL WORKUP

- Check airway, breathing, and circulation (ABCs) to determine the patient's stability
- Focused exam of the chest:
 - Respiratory effort and rate
 - Chest wall excursion
 - Crepitus
 - Subcutaneous air
 - Breath sounds and heart sounds
 - Presence of jugular venous distention
- Obtain a supine CXR immediately:
 - Avoid an upright CXR because of potential for other injuries (especially spinal injuries)
- ECG and monitor to detect myocardial ischemia or dysrhythmias
- Consider use of US for detecting small pneumothoraces, especially given the poor sensitivity of supine CXR in detecting such injuries.

DIAGNOSIS TESTS & NTERPRETATION

Lab

- Baseline hemoglobin
- Pulse oximetry
- ABG
- Serum lactate
- Type and cross-match
- Coagulation profile
- Cardiac enzymes when indicated
- Periodic chemistry panel for patients receiving significant fluid resuscitation

Imaging

- CXR is the initial radiologic study of choice:

- If CXR reveals widened mediastinum and patient hemodynamically stable, repeat film in upright position.
- Chest CT is more specific for pneumothoraces and pulmonary contusions/occult injuries.
- Thoracic US can be efficiently used for detecting pneumothoraces and pericardial injuries. The sensitivity, specificity, and overall accuracy in the ED setting for such injuries is >90%.
- Chest CT with contrast, or aortic angiogram, is useful in identifying aortic and large-vessel injuries.
- Esophagoscopy for direct endoscopic visualization if esophageal injury suspected
- Contrast esophagogram (with water and then barium) for possible esophageal injuries if esophagoscopy negative, but patient at risk for esophageal injury (e.g., pneumomediastinum)
 - Combination of these 2 tests in sequence (each 80–90% sensitive individually) reaches close to 100% sensitivity
- ECG if sternal tenderness is present or abnormalities on cardiac monitor

Diagnostic Procedures/Surgery

- If patient's condition is unstable, emergency thoracotomy may be necessary to repair a traumatic aortic disruption.
- If there are signs of cardiac tamponade, and patient is stable, perform an echocardiogram urgently:
 - Pericardial effusions, wall motion defects, aortic injuries, valvular or other intracardiac pathology may also be identified.
- If there are signs of cardiac tamponade and the patient is unstable, consider emergent pericardiocentesis, followed by immediate transport to the OR for a pericardial window.
- Bronchoscopy often indicated for possible upper airway injuries (e.g., a large persistent air leak after chest tube)

Pregnancy Considerations

- In pregnant patients, remember to use the least amount of radiation available and to shield the uterus during imaging when possible.
- Take note of the differences in anatomy of the thoracic cavity in pregnant patients, as well as differences in lab values, intravascular volume, and cardiovascular physiology.
- See “Pregnancy,” “Trauma in,” for details.

DIFFERENTIAL DIAGNOSIS

- Simple pneumothorax
- Tension pneumothorax
- Open pneumothorax
- Hemothorax

- Rib fractures
- Flail chest
- Sternoclavicular fractures/dislocations
- Pulmonary contusion
- Myocardial contusion
- Myocardial rupture
- Cardiac (pericardial) tamponade
- Traumatic aortic disruption
- Esophageal injury
- Large vascular injury (subclavian artery, pulmonary artery)
- Tracheobronchial injury
- Diaphragmatic injury

Pediatric Considerations

The rib cage is highly elastic in children and can withstand significant forces without overt signs of external trauma and can underestimate even major intrathoracic injuries.

Geriatric Considerations

Elderly patients have been shown to have greater respiratory complications, including ARDS and pneumonia, than younger patients in the setting of blunt chest trauma. This is especially true in those >85 yr of age.

TREATMENT

PRE HOSPITAL

- All patients with any signs of life in the field should be transported to a trauma center.
- Full spinal precautions should be employed.
- Needle decompression is indicated for tension pneumothorax:
 - Unilaterally absent breath sounds
 - Hypotension
 - Jugular venous distention
 - Hyper-resonance to percussion
- If large, open pneumothorax exists, tape an occlusive dressing on 3 sides only to prevent causing a tension pneumothorax.
- Do not delay transport to hospital for IV access.

INITIAL STABILIZATION/THERAPY

- ABCs management; intubate patient early if signs of respiratory insufficiency, shock, or altered mental status exist.
- Resuscitation attempts should be initiated only in patients who arrive in the ED with vital signs.

- Any patient who presents in blunt traumatic arrest is not likely to survive a thoracotomy in the ED, and it is therefore generally not indicated in this group.
- If the patient's condition is unstable and clinically shows signs of a tension pneumothorax, perform needle thoracostomy and place a chest tube immediately afterward.
- Do not wait to obtain a CXR.
- Place chest tube on the affected side or bilaterally if injury site is unclear.
- Deliver oxygen by nonrebreather face mask for stable patients.
- Obtain vascular access, preferably 2 large-bore IV lines (> 18G).
- Maintain spinal immobilization.

ED TREATMENT/PROCEDURES

- Tube thoracostomy if pneumothorax or hemothorax is identified:
 - 36F chest tube in an adult
 - In children, use the largest tube that the intercostal space will accommodate.
- Provide resuscitation with isotonic fluids and blood products as necessary:
 - Aggressive fluid resuscitation may be harmful if severe pulmonary contusions exist (consider permissive hypotension).
- Workup for associated intra-abdominal injuries (e.g., with abdominal US, abdominal CT scan, less commonly diagnostic peritoneal lavage):
 - Patients with chest trauma frequently have concomitant intra-abdominal injuries.

MEDICATION

- Tetanus booster if indicated
- Consider methylprednisolone (for signs of spinal cord injury): 30 mg/kg IVI over 1 hr, followed by a continuous drip of 5.4 mg/kg/h for next 23 hr

ALERT

- This practice is under debate and becoming less utilized, so know your hospital's protocol.
- Judicious doses of short-acting analgesics (fentanyl 1–2 µg/kg IV, morphine 0.1 mg/kg IV) as needed for pain control.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with conduction blocks, frequent ectopy, or ischemic changes visible on EKG should be admitted to a monitored setting for possible myocardial contusion.

- Hemodynamically unstable patients should go to the OR on an emergency basis for thoracotomy or laparotomy.
- >1,000–1,500 mL of blood drawn out of the chest tube on initial insertion indicates need for thoracotomy/operative management.
- >200 mL of blood per hour from chest tube for several hours suggests the need for operative intervention.
- Patients with significant rib fractures should be admitted for pain control:
 - Consider epidural catheter for analgesia.
- Patients who lose vital signs in the ED should undergo rapid open thoracotomy.

Discharge Criteria

Patients with clinically insignificant chest wall contusions and an initial negative upright CXR may be observed for 6 hr in the ED and often be discharged if a repeat radiograph at that time reveals no pneumothorax, hemothorax, or pulmonary contusion, the patient is able to breathe deeply and to cough, remains clinically stable, and has no other significant injuries.

Issues for Referral

- Notify trauma surgeon promptly about patients with significant injuries requiring surgical intervention or admission.
- Indications for emergent surgical referral:
 - Traumatic thoracotomy with loss of chest wall integrity
 - Blunt diaphragmatic injuries
 - Massive air leak following chest tube insertion
 - Massive hemothorax or continued high rate of blood loss via the chest tube (i.e., 1,500 mL on insertion of tube or continued loss of 200–300 mL/hr)
 - Radiographically or endoscopically confirmed tracheal, major bronchial, or esophageal injury
 - GI tract contents recovered on chest tube placement
 - Cardiac tamponade
 - Radiographic confirmation of a great-vessel injury
 - Embolism or missile into pulmonary artery, great vessel, or heart

FOLLOW-UP RECOMMENDATIONS

- Patients should be closely followed by trauma or cardiothoracic surgeons after hospital discharge, as indicated, depending upon the injuries discovered and treatment rendered.
- Patients with thoracostomy tubes should have a CXR and routine wound care follow-up within 48 hr to remove the dressing and reassess clinical status.

PEARLS AND PITFALLS

- Blunt chest trauma is responsible for up to 1/4 of all trauma-related deaths.

- Trauma patients arriving at a nontrauma center should be stabilized and transferred to facilities that can provide definitive care as soon as possible.
- Open thoracotomy in the ED has not been shown to improve survival in patients found to be in cardiopulmonary arrest after blunt trauma and is generally only indicated if the patient arrives in the ED with vital signs present.
- The extent of injury is not always clinically obvious upon initial presentation. This is particularly true in pediatric patients.

- S22.5XXA Flail chest, initial encounter for closed fracture
- S29.9XXA Unspecified injury of thorax, initial encounter

CHEST TRAUMA, PENETRATING

Jean C.Y. Lo

BASICS

ETIOLOGY

- Gunshot wounds or stab wounds most common
- Impalement on a sharp object from a fall can occur.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Object impaled in the chest wall
- Obvious wound in the chest wall with or without bleeding
- Chest pain
- Dyspnea
- Respiratory distress
- Altered mental status from hypoxemia
- Absent or altered breath sounds on 1 or both sides
- Hypotension
- Jugular venous distention

ESSENTIAL WORKUP

- Perform routine assessment of airway, breathing, and circulation.
- Rapid exam:
 - Respiratory effort and rate
 - Chest excursion
 - Crepitus
 - Subcutaneous air
 - Breath sounds and heart sounds
- Upright CXR is preferred for identifying a pneumothorax:
 - Supine CXR should be taken 1st if spinal precautions must be maintained.
- Baseline hemoglobin
- Pulse oximetry
- ABG
- Serum lactate
- Type and screen

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Perform echocardiogram if signs of tamponade present or if wound is close to the heart:
 - In stab wound to precordium and pericardial sac, hemopericardium may decompress into hemothorax, thus not apparent on initial echo:
 - Repeat pericardial US is recommended after tube thoracostomy decompression of the hemothorax.
 - Residual hemothorax represents pericardial injury or cardiac laceration.
- ECG

Imaging

- With gunshot wounds, other areas (abdomen, pelvis) should be imaged:
 - Total number of wounds and bullets must be the same.
- Arteriogram of aortic arch, carotid arteries, or subclavian artery if great vessel injury is suspected
- Esophageal Gastrografin swallow or endoscopy to identify esophageal perforation
- Bronchoscopy to identify tracheobronchial injuries

DIFFERENTIAL DIAGNOSIS

- Simple pneumothorax
- Tension pneumothorax
- Open pneumothorax
- Hemothorax
- Rib fractures
- Flail chest
- Pulmonary contusion
- Myocardial contusion
- Myocardial rupture
- Pericardial tamponade
- Traumatic aortic disruption
- Esophageal injury
- Large vessel injury
- Tracheobronchial injury
- Diaphragmatic injury
- Intra-abdominal injury
- Spinal cord injury

TREATMENT

PRE HOSPITAL

- Cautions:
 - All patients with signs of life in the field according to reports from EMS

- personnel should be transported to a trauma center.
- Full spinal immobilization if spinal injury suspected
- Never remove objects impaled in the chest because exsanguination may follow.
- Needle decompression may be necessary if tension pneumothorax suspected:
 - Unilaterally absent breath sounds, hypotension, jugular venous distention
- If large open pneumothorax exists, occlusive dressing taped on 3 sides:
 - A totally occlusive dressing may produce a tension pneumothorax.
- Controversies:
 - Do not delay transport to hospital to obtain IV access:
 - IV access may be established en route.
 - Do not delay transport to hospital by applying full spinal immobilization to patients who do not have clear clinical signs of spinal injury.

INITIAL STABILIZATION/THERAPY

- Airway, breathing, and circulation management:
 - Intubate for signs of serious chest injury, obvious respiratory distress, or hypotension.
- Oxygen by nonrebreather face mask for patients in stable condition
- Obtain vascular access, 2 peripheral large-bore IV lines (> 18G), and fluid resuscitation as needed:
 - Restrictive fluid resuscitation is associated with shorter hospital length of stay and lower overall mortality.
 - In penetrating aortic trauma, permissive hypotension at systolic BP 90 mm Hg until definitive surgical control prevents further hemorrhage.
- For tension pneumothorax, perform a needle thoracostomy and place a chest tube immediately.
- Do not wait to get a CXR.
- Sonogram has demonstrated higher sensitivity than CXR in diagnosing pneumothorax.
- For pericardial tamponade, perform an emergency pericardiocentesis:
 - Follow by rapid transport to the operating room for a pericardial window
- Maintain spinal immobilization if indicated.

ED TREATMENT/PROCEDURES

- Notify trauma surgeon about patient's arrival.
- Tube thoracostomy if a pneumothorax or hemothorax is identified:
 - 36G chest tube in an adult
 - In children, use largest tube the intercostal space will accommodate.
- Fluid resuscitation as necessary:
 - Contused lung parenchyma will have leaky capillary beds, and aggressive crystalloid resuscitation may aggravate pulmonary dysfunction.

- Any wound with an entry or exit site below the nipple or the posterior tip of the scapula is concerning for an intra-abdominal injury:
 - Workup with a diagnostic peritoneal lavage (DPL), US, CT scan, exploratory laparotomy, or laparoscopy
 - DPL positive with 5,000 RBC
- Describe the nature of wounds accurately:
 - Retain any bullet fragments, clothes, or tissue removed from the wound.
- Probing a chest wound is contraindicated because it can create a pneumothorax or worsen hemorrhage.
- Impaled objects should be removed only in the operating room.
- Tetanus booster if indicated

MEDICATION

- Methylprednisolone (for spinal cord injury): 30 mg/kg IV over 1 hr, followed by a continuous drip of 5.4 mg/kg/h for 23 hr
- Small doses of short-acting analgesics (fentanyl, 1–2 µg/kg IV, morphine 0.1 mg/kg IV) or sedatives (midazolam, 0.05 mg/kg IV) as needed for pain control and sedation
- Treat with IV antibiotics if wound grossly contaminated (e.g., cephalexin 1 g IV).

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with penetrating chest trauma should be admitted.
- In penetrating torso trauma, resuscitative thoracotomy in the ED demonstrates survival when pre-hospital CPR does not exceed 15 min.
- A patient who has signs of life in the field but no BP on arrival in the ED should have an emergency thoracotomy performed by the most experienced person present:
 - If the source of bleeding is controlled and there are signs of cardiac activity, the patient should go to the operating room for formal operative repair.
- Hemodynamically unstable patients should go immediately to the operating room.
- Any patient with intrathoracic penetration should have a chest tube placed and should be admitted to a monitored setting.
- > 1,000–1,500 mL of blood drawn out of the chest tube on initial insertion indicates the need for thoracotomy.
- > 200 mL/hr of blood from a chest tube for several hours suggests the need for surgical intervention.
- Patients with large, persistent air leaks usually require surgery.
- Patients with significant rib fractures should be admitted and have an epidural

catheter placed for pain control and pulmonary toilet.

Discharge Criteria

Patients with isolated minor chest wounds and a normal CXR can be observed for 3 hr in the ED and have a repeat radiographic study; if no intrathoracic penetration is suspected, the patient can be discharged:

- CT chest may be an alternative to CXR, if no intrathoracic penetration is suspected; patient can be discharged without repeat radiograph.

CHOLANGITIS

Robert G. Buckley

BASICS

DESCRIPTION

- Partial or complete obstruction of the common bile duct owing to gallstones, tumor, cyst, or stricture
- Increased intraluminal pressure in biliary tree
- Bacterial multiplication results in bacteremia and sepsis.
- Purulent infection of biliary tree, which may involve the liver and gallbladder
- Mirizzi syndrome is defined as common bile duct obstruction owing to extrinsic compression from gallbladder or cystic duct edema or stones.

ETIOLOGY

- Bacterial sources of infection include:
 - Ascending duodenal source
 - Gallbladder infection
 - Portal venous seeding
 - Hematogenous spread with hepatic secretion
 - Lymphatic spread
- Bacterial organisms include:
 - Anaerobes (*Bacteroides* and *Clostridium* species)
 - Intestinal coliform (*Escherichia coli*)
 - Enterococcus
- AIDS sclerosing cholangitis characterized by:
 - Papillary stenosis
 - Sclerosing cholangitis
 - Extrahepatic biliary obstruction
 - Cytomegalovirus (CMV), *Cryptosporidium*, and microsporidia isolated, but causal role not established

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Charcot triad:
 - Classic presentation of fever and chills; right upper quadrant (RUQ) pain and jaundice found in only 50–70%
- Addition of shock and altered mental status denotes a more advanced form of

biliary sepsis known as *Reynolds pentad*.

- Abdominal pain present in >70%—localizing to RUQ.
- AIDS sclerosing cholangitis presents with similar symptoms but with more chronic indolent course and near-normal serum bilirubin levels.

Physical-Exam

- Fever found in >90%
- Peritoneal findings found in 30%
- Clinically apparent jaundice may be absent in up to 40%.

ESSENTIAL WORKUP

- ECG in patients at risk for coronary artery disease
- CBC
- LFT
- Amylase, lipase
- Urinalysis
- Blood cultures
- Gallbladder US or hepatiminodiacetic acid (HIDA) scan

DIAGNOSIS TESTS & NTERPRETATION

Lab

- CBC:
 - Leukocytosis with left shift unless immunocompromised or severe sepsis
- LFTs consistent with cholestasis:
 - Elevated direct bilirubin and alkaline phosphatase
- Minimal elevation of transaminases (<200 IU/mL)
- Changes may lag symptom onset by 24–48 hr.
- Amylase and lipase normal or mildly elevated
- Urinalysis positive for bilirubin

Imaging

- US detects the level of ductal obstruction and the presence of gallstone etiology.
- Radionuclide scanning (HIDA):
 - Indicates obstruction when tracer not found in duodenum within 1 hr
 - More sensitive than US in detecting obstruction in the 1st 24–48 hr before ductal dilation occurs
- CT scan and CRX:
 - Useful to rule out intestinal obstruction, perforation, or pneumonia
 - 20% gallstones radiopaque
- Magnetic resonance cholangiopancreatography (MRCP) is highly accurate for biliary obstruction but unnecessary if endoscopic retrograde cholangiopancreatography (ERCP) will be performed.

Diagnostic Procedures/Surgery

Emergency invasive biliary imaging and drainage by ERCP (or surgical/percutaneous if not available), if no response to medical treatment in 12–24 hr

DIFFERENTIAL DIAGNOSIS

- Acute cholecystitis
- Hepatitis or hepatic abscess
- Acute pancreatitis
- Right pyelonephritis
- Right lower lobe pneumonia or pulmonary embolism
- Perforated duodenal ulcer
- Appendicitis
- Sepsis with nonspecific elevation of LFTs
- Fitz-Hugh and Curtis syndrome

TREATMENT

PRE HOSPITAL

Stabilize septic shock.

INITIAL STABILIZATION/THERAPY

- Immediate IV fluid resuscitation for dehydration, hemodynamic compromise, and sepsis
- 80% respond to IV antibiotics within 1st 24 hr
- Vasopressors (dopamine) for hypotension refractory to volume replacement

ED TREATMENT/PROCEDURES

- Broad-spectrum antibiotics for coliforms, anaerobes, and enterococcus such as:
 - Ampicillin/sulbactam + aminoglycoside (e.g., gentamicin)
 - Imipenem–cilastatin
 - Piperacillin/tazobactam + aminoglycoside (e.g., gentamicin)
 - For penicillin allergy:
 - Adults—use levofloxacin (Levaquin) and metronidazole
 - Pediatrics—use clindamycin and metronidazole
- Substitute aztreonam for aminoglycoside in renal insufficiency.
- NPO
- Nasogastric (NG) suctioning if protracted vomiting or ileus
- IV fluid (0.9% NS) replacement and maintenance
- Narcotic analgesia if hemodynamically stable and diagnosis reasonably established
- Immediate surgical and GI consultation
- Emergency invasive biliary drainage procedure (surgical, percutaneous, or ERCP) if no response to medical treatment in 12–24 hr

MEDICATION

- Ampicillin/sulbactam: 3 g (peds: 200 mg/kg/24 h) IV piggyback (IVPB) q6h
- Aztreonam: 2 g (peds: 120 mg/kg/24 h) IVPB q6h
- Clindamycin: 600–900 mg (peds: 25–40 mg/kg/24 h) IVPB q6–8h
- Dopamine: 2–20 µg/min IVPB; titrate to maintain BP
- Gentamicin: 1.5–2 mg/kg (peds: 6–7 mg/kg/24 h) IVPB q8h; follow levels
- Imipenem–cilastatin: 500 mg (Peds 60–100 mg/kg/24 h) q6h
- Levaquin: 500 mg IVPB q24h; contraindicated in peds
- Hydromorphone: 0.5–2 mg IV (0.01–0.02 mg/kg), titrated to pain relief.
- Metronidazole: 500 mg (peds: 30 mg/kg/24 h) IVPB q6h
- Piperacillin/tazobactam: 3.375 mg (peds: 300 mg/kg/24 h) IVPB q6h
- Ondansetron: 4–8 mg IV, (0.15–0.3 mg/kg) IV (not to exceed 8 mg/dose IV), q4h PRN vomiting

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with acute cholangitis should be admitted with immediate surgical and gastroenterologic consultation.
- Admit patients with signs of septic shock to the ICU.

Discharge Criteria

None

Issues for Referral

Surgery/GI consultation

FOLLOW-UP RECOMMENDATIONS

Admission to hospital for IV antibiotic and possible biliary drainage procedure.

PEARLS AND PITFALLS

- Aggressively fluid resuscitate patients.
- Administer antibiotics.
- Obtain GI and surgical consultations.

K83.0 Cholangitis

CHOLECYSTITIS

Robert G. Buckley

BASICS

DESCRIPTION

Cholecystitis is defined as inflammation of the gallbladder.

ETIOLOGY

- **Acute calculous cholecystitis:**
 - Owing to bile stasis secondary to prolonged obstruction by a gallstone (see “Cholelithiasis”) in the gallbladder neck, cystic duct, or common bile duct
 - Leads to increased intraluminal pressure and mucosal damage
 - Release of inflammatory mediators results in distention, edema, and increased vascularity.
 - Coliforms and anaerobes lead to infection—primary causal role is controversial.
- **Acalculous cholecystitis:**
 - 10% of cases
 - Underlying critical illness leads to biliary stasis and mucosal ischemia.
 - Subsequent mucosal inflammation and infection

Pediatric Considerations

- *Acute calculous cholecystitis* extremely rare in childhood (see “Cholelithiasis”)
- *Acalculous cholecystitis* more common than calculous form in children:
 - Associated with systemic bacterial infections, scarlet fever, Kawasaki disease, and parasitic infections

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- **Acute calculous cholecystitis:**
 - Dull, aching, epigastric, or right upper quadrant (RUQ) pain
 - Radiation to tip of right scapula, acromion, or thoracic spine
 - Duration > 6 hr more suggestive of cholecystitis than uncomplicated biliary colic
 - As inflammation progresses, parietal peritoneal irritation leads to sharp, localized pain.
 - Nausea, vomiting, fever, and chills often reported, but absent in most cases

- Jaundice in 20%
- History of prior attacks of biliary colic or known gallstones favors diagnosis.
- Acalculous cholecystitis:
 - Occurs in critically ill patients (burns, sepsis, trauma, or postoperative)
 - Localized pain and tenderness frequently absent
 - Often presents with symptoms of generalized sepsis of unknown source

Physical-Exam

- Localized parietal peritoneal signs:
 - Percussion tenderness
 - Rebound
 - Found as the disease progresses
- Murphy sign:
 - Inspiratory arrest with gentle palpation of RUQ owing to increased pain
 - Found in most cases

ESSENTIAL WORKUP

- ECG in patients at risk for coronary artery disease
- CBC
- LFT
- Amylase, lipase
- Urinalysis
- Human chorionic gonadotropin (hCG)
- Gallbladder US or HIDA scan

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - WBC $> 12,000$ cells/mm³ supports diagnosis, but may be normal in more than half of cases
- LFTs:
 - Transaminases, bilirubin, amylase, and lipase may be minimally elevated, but are generally normal.
 - Disproportionate elevation of direct bilirubin and alkaline phosphatase compared with transaminases suspicious for common duct obstruction or cholangitis

Imaging

- US:
 - Generally the 1st-line imaging procedure

- Positive findings include gallbladder wall thickening (>5 mm) or pericolic fluid—sensitivity, 90%; specificity, 80%.
- Optimal if patient NPO >8 hr
- Radionuclide scanning (HIDA):
 - Most useful when clinical suspicion remains high despite equivocal findings on US or when acalculous cholecystitis suspected
 - Positive when tracer seen in small bowel but inflamed gallbladder fails to visualize
 - Sensitivity, >95%; specificity, 90%
 - False-positive results increase in nonfasting state.
 - Addition of IV morphine induces Sphincter of Oddi contraction which improves gallbladder filling and reduces false-positive scan results.
- CT scanning:
 - Exclude intestinal perforation or obstruction
 - Air in the gallbladder wall consistent with emphysematous cholecystitis
 - Gallstones radiopaque in up to 20%

DIFFERENTIAL DIAGNOSIS

- Biliary colic
- Hepatitis or hepatic abscess
- Cholangitis
- AIDS sclerosing cholangitis
- Pancreatitis
- Intestinal perforation
- Peptic ulcer disease
- Gastritis
- Duodenal perforation
- Right lower lobe pneumonia, pleurisy, or pulmonary infarction
- MI
- Abdominal aortic aneurysm
- Appendicitis
- Fitz-Hugh and Curtis syndrome
- Pyelonephritis

TREATMENT

PRE HOSPITAL

Establish IV access for patients with vomiting or severe pain.

INITIAL STABILIZATION/THERAPY

- IV, oxygen, cardiac monitoring until myocardial ischemic cause excluded
- Initiate IV fluid therapy for dehydration, hemodynamic compromise, or sepsis.

ED TREATMENT/PROCEDURES

- Broad-spectrum antibiotics for coliforms, anaerobes, and enterococcus:
 - Ampicillin/sulbactam
 - Piperacillin/tazobactam
 - Add aminoglycoside if sepsis or cholangitis suspected (see “Cholangitis”).
- Alternative antibiotics for penicillin allergic:
 - Adults: Levofloxacin (Levaquin) and metronidazole
 - Peds: Clindamycin with aminoglycoside
- NPO
- IV fluid replacement and maintenance
- Antiemetics (ondansetron) if vomiting
- Nasogastric (NG) suctioning if refractory vomiting or ileus
- Narcotic analgesics (hydromorphone) with antiemetic (ondansetron):
 - Administer for refractory pain once diagnosis is reasonably established.
 - Morphine sulfate may lead to spasm at sphincter of Oddi (clinical significance not well established).
- Anticholinergics (glycopyrrolate) of no proven benefit for acute biliary pain.
- Surgical consultation

MEDICATION

- Ampicillin/sulbactam: 3 g (peds: 200 mg/kg/24h) IV piggyback (IVPB) q6h
- Clindamycin: 600–900 mg (peds: 25–40 mg/kg/24h) IVPB q6–q8h
- Gentamicin: 1.5–2 mg/kg (peds: 6–7 mg/kg/24h) IVPB q8h; follow levels
- Levaquin: 500 mg IVPB q24h; contraindicated in peds
- Hydromorphone: 0.5–2 mg IV (0.01–0.02 mg/kg), titrated to pain relief.
- Metronidazole: 500 mg (peds: 30 mg/kg/24h) IVPB q6h
- Piperacillin/tazobactam: 3.375 mg (peds: 300 mg/kg/24h) IVPB q6h
- Ondansetron: 4–8 mg IV (peds: 0.15–0.3 mg/kg) IV (not to exceed 8 mg/dose IV), q4h PRN vomiting

FOLLOW-UP

DISPOSITION

Admission Criteria

- All cases of cholecystitis should be admitted for parenteral antibiotics, analgesia, fluid replacement, and cholecystectomy in 24–72 hr.
- Unstable patients (gallbladder perforation or sepsis) require immediate surgery.

Discharge Criteria

None

Issues for Referral

General surgery consult for patients with cholecystitis. GI consult if choledocholithiasis or cholangitis suspected.

FOLLOW-UP RECOMMENDATIONS

Inpatient admission for antibiotics and surgical evaluation.

PEARLS AND PITFALLS

- US is the 1st-line imaging procedure.
- Perform a radionuclide scanning (HIDA) when clinical suspicion is high with equivocal US or when acalculous cholecystitis suspected.

CHOLELITHIASIS

Robert G. Buckley

BASICS

DESCRIPTION

- Symptoms arise when gallstones pass through the cystic or common bile ducts leading to impedance of normal bile flow and gallbladder spasm.
- Biliary dyskinesia produces symptoms identical to biliary colic in the absence of stones.
- Choledocholithiasis (common bile duct stones), may lead to prolonged pain, elevated LFTs and bilirubin, and to more complications like cholangitis or pancreatitis.

ETIOLOGY

- Cholesterol stones:
 - Most common type of gallstone
 - Form when solubility exceeded
- Pigment stones:
 - 20%
 - Composed of calcium bilirubinate
 - Associated with clinical conditions such as hemolytic anemias that lead to increased concentration of unconjugated bilirubin
- Incidence increases with age and favors females to males 2:1. Other risk factors include Hispanic ethnicity, obesity, pregnancy, rapid weight loss, and drugs that induce biliary stasis (e.g., ceftriaxone and oral contraceptives).
- Gallstones are exceedingly rare in childhood and are most commonly associated with sickle cell disease, hereditary spherocytosis, or other hemolytic anemias that result in pigment stone formation.
- Biliary sludge:
 - Nonstone, crystalline, granular matrix
 - Associated with rapid weight loss, pregnancy, ceftriaxone or octreotide therapy, and organ transplantation
 - May develop symptoms identical to cholelithiasis and its complications
- “Porcelain gallbladder” from mucosal precipitation of calcium salts owing to recurrent obstruction of cystic duct.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Dull, aching epigastric or right upper quadrant (RUQ) pain:
 - Arising over 2–3 min, continuous (rather than colicky), and lasting from 30 min–6 hr before dissipating
 - May radiate to the tip of right scapula, acromion, or thoracic spine
 - Often correlated with ingestion of large, fatty meal
- Anorexia
- Nausea and vomiting
- Afebrile:
 - Fever and chills suggest cholecystitis or cholangitis

Physical-Exam

- Tenderness to deep palpation but without rebound
- Murphy sign (inspiratory arrest during deep palpation of the RUQ) may be present during the episode of colic, but should resolve when symptoms pass.

ESSENTIAL WORKUP

- Obtain ECG on those whose pain may be owing to myocardial ischemia.
- CBC
- LFTs
- Amylase, lipase
- Urinalysis
- Human chorionic gonadotropin (hCG)

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - WBC count usually normal, but may elevate after vomiting
 - Leukocytosis suggestive of cholecystitis or cholangitis
- LFTs:
 - Usually normal
 - Elevation suggests common duct obstruction, cholangitis, cholecystitis, or hepatitis.
- Amylase/lipase
 - Normal or minimally elevated with passage of gallstone
 - Elevation in context of severe persistent epigastric pain suggests pancreatitis.
- Urinalysis:
 - Exclude nephrolithiasis or pyelonephritis.
 - Bilirubinuria suggests common duct obstruction or hepatitis.

Imaging

- US:
 - Detects gallstones with sensitivity and specificity > 90%
 - Dilation of common bile duct > 10 mm indicates obstruction, but no dilation may be present with acute obstruction.
 - Gallbladder wall thickening > 5 mm or pericolic fluid 90% sensitive and 80% specific for cholecystitis
 - Accuracy enhanced in fasting patient (> 6 hr) with noncontracted gallbladder
- Radionuclide scanning (HIDA):
 - Cannot detect gallstones
 - Passage of tracer into small intestine without visualization of gallbladder highly diagnostic of cystic duct obstruction and cholecystitis:
 - Sensitivity and specificity roughly 95%
 - Failure of tracer to pass into duodenum suggests common bile duct obstruction. Accuracy enhanced by morphine injection during scan causing sphincter of Oddi spasm and improving gallbladder filling.
- CT scanning:
 - Less sensitive than US to detect gallstones:
 - Only 20% radiopaque.
 - Most useful to exclude other causes of upper abdominal pain such as aortic aneurysm, perihepatic abscess, or pancreatic pseudocyst
 - Detects rare complications such as air in gallbladder wall in emphysematous cholecystitis, air-filled gallbladder in biliary-enteric fistula or a “Porcelain gallbladder.”
- Plain radiographs:
 - Most useful for diagnosis of intestinal obstruction or rare abnormalities such as air in gallbladder wall in emphysematous cholecystitis, air-filled gallbladder in biliary-enteric fistula or a “Porcelain gallbladder.”

DIFFERENTIAL DIAGNOSIS

- MI
- Abdominal aortic aneurysm
- Acute cholecystitis, cholangitis, or choledocholithiasis
- Renal colic or pyelonephritis
- Duodenal ulcer perforation
- Acute pancreatitis
- Intestinal obstruction
- Peptic ulcer disease, gastritis, or GERD
- Right lower lobe pneumonia, pleurisy, or pulmonary infarction
- Hepatitis or hepatic abscess
- Fitz-Hugh and Curtis syndrome

TREATMENT

PRE HOSPITAL

Initiate IV access for patients with nausea or vomiting.

INITIAL STABILIZATION/THERAPY

IV fluid bolus if vomiting or hypotensive

ED TREATMENT/PROCEDURES

- IV hydration with 0.9% NS if vomiting
- NPO
- Parenteral NSAIDs (ketorolac) may lessen biliary spasm, but may exacerbate peptic causes of pain.
- Narcotic analgesics (hydromorphone) with antiemetic (ondansetron):
 - Administer for refractory pain once diagnosis is reasonably established.
 - Morphine sulfate may lead to spasm at sphincter of Oddi (clinical significance not well established).
- Anticholinergics (glycopyrrolate) have no proven benefit in the treatment of acute biliary pain.

MEDICATION

- Ketorolac: 60 mg IM or 30 mg (peds: Start 0.5 mg/kg for 1st dose up to 1 mg/kg/24h) IV q6h. In elderly: 30 mg IM or 15 mg IV
- Hydromorphone: 0.5–2 mg IV (0.01–0.02 mg/kg), titrated to pain relief.
- Ondansetron: 4–8 mg IV (0.15–0.3 mg/kg) IV (not to exceed 8 mg/dose IV), q4h PRN vomiting.

FOLLOW-UP

DISPOSITION

Admission Criteria

Admission and surgical or gastroenterologic consultation for evidence of:

- Acute cholecystitis
- Acute cholangitis
- Common duct obstruction
- Gallstone pancreatitis

Discharge Criteria

- Lack of clinical, lab, or radiographic evidence of cholecystitis, cholangitis, common duct obstruction, or pancreatitis
- Resolution of all pain and tenderness

- Ability to tolerate oral fluids

Issues for Referral

- General surgery referral for all cases of biliary colic with documented cholelithiasis or for radiographic finding of a “Porcelain gallbladder” (due to increased risk of gallbladder carcinoma).
- GI referral for choledocholithiasis.

FOLLOW-UP RECOMMENDATIONS

Surgical follow-up for patients with symptomatic gallstones

PEARLS AND PITFALLS

- Alternative causes of upper abdominal pain may be falsely attributed to incidental finding of gallstones.
- An ultrasound is more sensitive and specific for cholelithiasis.
- Radionuclide scanning (HIDA) is highly diagnostic of cystic duct obstruction and cholecystitis.
- CT scans may miss gallstones if the stones are not radiopaque.

CHRONIC OBSTRUCTIVE PULMONARY DISEASE

Adam Z. Barkin

BASICS

DESCRIPTION

- 3rd leading cause of death in US
- A disease characterized by airflow obstruction due to several processes:
 - Emphysema: Irreversible alveolar destruction with loss of airway elastic recoil. Represents accelerated aging of the lung
 - Chronic bronchitis: Airway inflammation without alveolar destruction
 - Reactive airway disease: Reversible bronchospasm, mucous plugging, and mucosal edema
- COPD affects ~10% of the population and 50% of smokers.
- Increased incidence of hypertension, diabetes, heart failure, and cardiovascular disease in those with COPD
- Frequent exacerbations lead to:
 - Greater mortality
 - Faster decline in lung function
 - Worse quality of life
 - Increased risk of hospitalization
- Medical Research Council (mMRC) dyspnea scale
 - Grade 0: Only breathless with strenuous exercise
 - Grade 1: Short of breath when hurrying or walking up a slight hill
 - Grade 2: Walk slower than people of same age due to dyspnea or have to stop for breath when walking on level ground
 - Grade 3: Stop for breath after 100 m on level ground
 - Grade 4: Too breathless to leave the house or breathless when dressing/undressing
- GOLD guidelines
 - Group A
 - No more than 1 exacerbation/yr
 - FEV1 > 80% predicted
 - mMRC of 0 or 1
 - Group B
 - mMRC of 2 or more
 - FEV1 50–80% of predicted
 - Group C
 - mMRC < 2
 - ≥ 2 exacerbations/yr
 - FEV1 30–49% of predicted

- Group D
 - High symptom burden
 - mMRC \geq 2
 - High risk for exacerbations
 - FEV1 < 30% of predicted

RISK FACTORS

Genetics

α_1 -Antitrypsin deficiency

ETIOLOGY

- Smoking is the overwhelming cause:
 - COPD develops in 15% of smokers.
- Air pollution
- Airway hyper-responsiveness
- α_1 -Antitrypsin deficiency
- Autoimmunity may play a role
- Acute exacerbations:
 - Viral infections
 - >50% of exacerbations associated with recent cold symptoms
 - Decreased immunity may make the host more susceptible to a COPD exacerbation
 - Rhinovirus
 - Respiratory syncytial virus (RSV)
 - Bacterial infections
 - Bacteria isolated in 40–60% of sputum during acute exacerbation
 - Most common:
 - *Haemophilus influenzae*
 - *Moraxella catarrhalis*
 - *Streptococcus pneumoniae*
 - More likely if:
 - Increased dyspnea
 - Increased sputum volume
 - Purulent sputum
 - Pollutants
 - Changes to immunity
 - Increased airway inflammation
 - Seasonal variations
 - More common and more severe in winter

SIGNS AND SYMPTOMS

History

- Dyspnea on exertion
- Cough
- Sputum production
- Fatigue
- Wheezing
- Orthopnea
- Altered mental status

Physical-Exam

- Wheezing
- Retractions
- Decreased air movement
- Cyanosis
- Prolonged expiratory phase
- Barrel chest
- Lower-extremity edema
- Jugular venous distension
- S3 and S4 gallops
- Altered mental status secondary to carbon dioxide narcosis

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - _ Elevated hematocrit may indicate chronic hypoxemia.
 - _ Increased neutrophils and elevated WBC may indicate infection.
- Arterial blood gas:
 - _ Retaining carbon dioxide
 - _ Acidosis
 - _ Oxygenation
- β -Natriuretic peptide:
 - _ Differentiate between COPD and CHF
- Sputum sample
- Theophylline level as needed

Imaging

- CXR:
 - _ Pneumothorax
 - _ Pneumonia

- CHF
- Lobar collapse
- Chest CAT scan:
 - When needed to evaluate for pulmonary embolus or further characterize disease

Diagnostic Procedures/Surgery

- Pulse oximetry
- ECG
- Pulmonary function tests
- Echocardiography:
 - To diagnose left or right ventricular failure or strain

DIFFERENTIAL DIAGNOSIS

- Pneumothorax
- CHF
- Pneumonia
- Pulmonary embolus
- Upper airway obstruction
- Asthma
- Restrictive lung disease
- ARDS
- Pleural effusions
- Acute coronary syndrome
- Pericardial effusion
- Metabolic derangement

TREATMENT

PRE HOSPITAL

Supplemental oxygenation:

- 100% via nonrebreather
- Do not withhold for fear of CO₂ retention.
- Initiate nebulized bronchodilator therapy.

INITIAL STABILIZATION/THERAPY

- Oxygen therapy:
 - Maintain oxygen saturation > 90–92%.
 - Patients at risk for CO₂ narcosis are those with slow respiratory rate.
 - Monitor closely for ventilation suppression.
- Noninvasive ventilation:
 - Treatment of choice in hypercapneic respiratory failure if ventilatory

support required

- May prevent intubation
- May help resolve hypercarbia
- Intubation for airway control:
 - Clinical tiring
 - Altered mental status
 - Inability to comply with emergent therapy
 - Ineffective ventilation
 - CO₂ narcosis

ED TREATMENT/PROCEDURES

- Continuous ECG and pulse oximetry monitoring
- Bronchodilator therapy
- β -Agonists:
 - Albuterol
- Anticholinergics:
 - Ipratropium bromide
- Corticosteroids:
 - Anti-inflammatory effects
 - Reduce relapses
 - Methylprednisolone or prednisone
- Antibiotics:
 - Fever, increased sputum production, and/or dyspnea
 - Macrolides also may have anti-inflammatory effects unrelated to their antibacterial role
- Methylxanthines
 - Theophylline
- Ventilator settings:
 - Allow sufficient expiratory time to minimize air trapping and subsequent barotrauma.
 - Permissive hypercapnia

MEDICATION

- Albuterol: 2.5 mg nebulized q10–30min
- Azithromycin: 500 mg PO/IV once, then 250 mg/d PO for 4 days
- Ceftriaxone: 1 g IV q24h
- Ipratropium bromide: 0.5 mg nebulized q6h
- Levofloxacin: 500 mg PO/IV q24h
- Methylprednisolone: 125 mg IV q6h
- Prednisone: 40–60 (1–2 mg/kg) mg/d PO for 5 days
- Terbutaline: 0.25 mg SC q30min

First Line

- Albuterol
- Ipratropium bromide
- Prednisone or methylprednisolone

FOLLOW-UP

DISPOSITION

Admission Criteria

- ICU admission:
 - Intubated patients
 - CO₂ narcosis with oxygen saturation < 90%
 - Clinical tiring in the ED
 - Severe acidosis
 - Concomitant cardiac or pulmonary disease
 - Acute coronary syndrome
 - Arrhythmia
 - CHF
 - Pulmonary embolism
- Regular hospital bed:
 - COPD patients with an additional pulmonary insult:
 - Pneumonia
 - Lobar collapse
 - Increased work of breathing
- Exercise intolerance
- Failure to improve in ED
- Failed outpatient treatment
- 3 criteria can predict mortality at admission:
 - Age > 70 yr
 - Number of clinical signs of severity:
 - Cyanosis, accessory muscle use, etc.
 - Dyspnea at baseline

Discharge Criteria

- Mild flare
- Resolution in ED
- Ambulatory oxygen saturation > 92%

FOLLOW-UP RECOMMENDATIONS

- Smoking cessation
- Ensure vaccinations are up-to-date (influenza annually, pneumococcal at least once).

- Identify and avoid triggers (e.g., cold air, perfumes)
- Possible referral for lung volume reduction surgery

PEARLS AND PITFALLS

- Noninvasive positive pressure ventilation is the therapy of choice when optimal medical therapy is insufficient
- Nebulized steroids may be used more for acute exacerbation of COPD in the future.
- Patients with COPD are at increased risk for diabetes, hypertension, and cardiovascular disease.
- Consider routine influenza and pneumococcal vaccinations for those with COPD.

CIRRHOSIS

Ahmed Nadeem • Paul J. Allegretti

BASICS

DESCRIPTION

- Progressive process of inflammation, cellular injury and necrosis, diffuse fibrosis, and formation of regenerative nodules
- Loss of lobular and vascular architecture
- Irreversible in advanced stages
- Intrahepatic portal hypertension owing to increased resistance at the sinusoid, compression of the central veins, and anastomosis between the arterial and portal systems
- 10th leading cause of death in US

ETIOLOGY

- Chronic alcohol abuse (most common cause in US)
- Chronic viral hepatitis, B or C (2nd most common cause in US)
- Autoimmune hepatitis
- Biliary cirrhosis, primary (PBC) or secondary (sclerosing cholangitis)
- Metabolic:
 - Hereditary hemochromatosis
 - Wilson disease
 - Porphyrria
- Drugs:
 - Acetaminophen
 - Methotrexate
 - Amiodarone
 - Methyl dopa
- Hepatic congestion:
 - Right-sided heart failure
 - Pericarditis
 - Budd–Chiari syndrome (hepatic venous outflow obstruction)
- Infiltrative:
 - Sarcoidosis
 - Amyloidosis
 - Nonalcoholic steatohepatitis (NASH)
 - Hepatocellular carcinoma, diffusely infiltrating
- Infections:
 - Brucellosis
 - Echinococcosis

- Tertiary syphilis
- Schistosomiasis

Pediatric Considerations

- Congenital
- Arteriohepatic dysplasia, biliary atresia, cystic fibrosis, α_1 -antitrypsin deficiency
- Metabolic
- Fructosemia, tyrosinemia, galactosemia, glycogen storage diseases
- Infectious
- Congenital hepatitis B

DIAGNOSIS

SIGNS AND SYMPTOMS

- May be silent
- Insidious onset with nonspecific findings:
 - Malaise
 - Fatigue
 - Anorexia
 - Nausea and vomiting
 - Weight loss
 - Pruritus
 - Hyperpigmentation
- Jaundice
- Abdominal collateral circulation including caput medusae
- Hepatomegaly
- Splenomegaly
- Abdominal discomfort or tenderness
- Fever
- Feter hepaticus
- Asterixis
- Hypotension
- Cruveilhier–Baumgarten murmur
- Renal insufficiency
- Spider telangiectasias
- Palmar erythema
- Dupuytren contractures
- Parotid and lacrimal gland enlargement
- Terry nails
- Muehrcke lines
- Clubbing
- Feminization:

- Testicular atrophy
- Impotence
- Loss of libido
- Gynecomastia
- Amenorrhea
- Complications:
 - When complications develop, patient is considered to have decompensated disease.
 - Ascites
 - Spontaneous bacterial peritonitis (SBP)
 - Hepatic encephalopathy (HE)—may be precipitated by:
 - GI bleed
 - Infections
 - Increased dietary protein
 - Hypokalemia
 - Sedatives
 - Constipation
 - Azotemia
 - Alkalosis
 - Variceal hemorrhage:
 - 1/3 of patients with variceal bleed.
 - Each bleeding episode carries a 33% mortality rate.
 - Hepatic venous pressure gradient > 12 mm Hg increases risk of bleed.
 - Portal hypertensive gastropathy or peptic ulcer disease
 - Hepatorenal failure:
 - Caused by decreased renal perfusion during severe decompensated cirrhosis
 - May be iatrogenic: Secondary to diuretics, NSAIDs, IV contrast, aminoglycosides, large-volume paracentesis
 - High mortality rate
 - Hepatopulmonary syndrome:
 - Intrapulmonary vascular dilation and hypoxia
 - Results in increased alveolar–arterial gradient

ESSENTIAL WORKUP

Detailed history and physical exam to search for clues to liver disease

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - Anemia
 - Macrocytosis

- Leukopenia and neutropenia
- Thrombocytopenia
- Impaired liver function:
 - High bilirubin
 - Low albumin
 - High globulins
 - Prolonged PT
 - Varying degrees of DIC
 - Hypoglycemia
- Increased liver enzymes:
 - Aspartate alanine aminotransferase (AST, SGOT), alanine aminotransferase (ALT, SGPT)—reflect injury
 - Ratio of AST:ALT ≥ 2 in alcoholic liver disease
 - Alkaline phosphatase and 5'-nucleotidase reflect cholestasis.
 - γ -Glutamyltranspeptidase (GGT)
 - May be normal in inactive cirrhosis
- Electrolytes, BUN, and creatinine
- Hyponatremia:
 - Renal dysfunction and hepatorenal syndrome
- Arterial blood gases or pulse oximeter for:
 - Suspected pneumonia
 - CHF
 - Hepatopulmonary syndrome
- Search for cause:
 - Hepatitis B surface antigen
 - Hepatitis C antibody
 - Antinuclear antibody (ANA) and antismooth muscle antibody (autoimmune hepatitis)
 - Antimitochondrial antibody (PBC)
 - Serum iron, transferrin saturation, and ferritin (hemochromatosis)
 - Ceruloplasmin (Wilson disease)
 - α_1 -Antitrypsin deficiency
 - Serum immune electrophoresis (high IgM in PBC)
 - Cholesterol (chronic cholestasis)
 - α -Fetoprotein (hepatocellular cancer)

Imaging

- US for liver architecture, biliary obstruction, ascites, portal vein thrombosis, splenomegaly
- CT scan to explore abnormal finding on ultrasound
- CXR for pleural effusion, cardiomegaly, and CHF

Diagnostic Procedures/Surgery

- Esophagogastroduodenoscopy (EGD) indicated for upper GI bleeding or variceal surveillance
- Variceal ligation or endoscopic sclerotherapy
- Paracentesis for significant ascites or SBP

DIFFERENTIAL DIAGNOSIS

- Ascites:
 - Increased right heart pressure
 - Hepatic vein thrombosis
 - Peritoneal malignancy/infection
 - Pancreatic disease
 - Thyroid disease
 - Lymphatic obstruction
- Upper GI bleeding:
 - Peptic ulcer disease
 - Gastritis
- Encephalopathy:
 - Metabolic
 - Toxic
 - Intracranial process

TREATMENT

PRE HOSPITAL

- Naloxone, dextrose (or Accu-Chekk), and thiamine for altered mental status
- Reverse hypotension with IV fluids to prevent acute ischemic hepatic injury.

INITIAL STABILIZATION/THERAPY

Treat complications such as GI bleeding or HE.

ED TREATMENT/PROCEDURES

- For suspected variceal bleed:
 - IV proton pump inhibitors
 - IV octreotide-splanchnic vasoconstrictor
 - Reverse coagulopathy:
 - Fresh-frozen plasma 1 IU/hr until bleeding is controlled
 - Desmopressin (DDAVP)—improves bleeding time and prolonged PTT
 - Balloon tamponade with Sengstaken–Blakemore tube or a variant for variceal compression (rarely used anymore, prophylactic intubation recommended)
 - Emergent endoscopic sclerotherapy
- Initiate broad-spectrum antibiotics in suspected sepsis or SBP:

- Cefotaxime
- Ticarcillin–clavulanate
- Piperacillin–tazobactam
- Ampicillin–sulbactam
- Treat complicating conditions such as ascites, HE, SBP.
- Treat pruritus with:
 - Diphenhydramine 25–50 mg IM/IV q4h
 - Cholestyramine, ursodeoxycholic acid, or rifampin
 - Naloxone infusion 0.2 µg/kg/min for temporary relief for extreme cases
- β-Blocker (propranolol) for esophageal varices:
 - Titrated to pulse rate of 60 or 25% reduction of resting pulse
 - With or without isosorbide dinitrate
 - Decreases rebleeding rate
 - May delay or prevent occurrence of 1st bleed
- Relieve biliary obstruction (e.g., stricture) by endoscopic, radiologic, or surgical means.
- Provide nutritious diet, high in calories and adequate in protein (1 g/kg), unless there is complicating HE
- Consult transplantation coordinator whenever postliver transplantation patient presents to the ED with liver dysfunction, suspected sepsis, or possible treatment-related complication.

SPECIAL THERAPY

- Hemochromatosis: Phlebotomy or deferoxamine (iron-chelating agent)
- Autoimmune hepatitis: Prednisone with or without azathioprine
- Chronic hepatitis B or C: α-Interferon (avoid in decompensated cirrhosis)
- PBC: Ursodeoxycholic acid
- Wilson disease: Penicillamine
- The only cure for most advanced cirrhosis is liver transplantation.

MEDICATION

- Azathioprine: 1–2 mg/kg PO daily
- Cefotaxime: 1–2 g q6–8h (peds: 50–180 mg/kg/d q6h) IV
- Cholestyramine: 4 g PO 1–6 times per day
- Desmopressin (DDAVP): 0.3 µg/kg in 50 mL saline infused over 15–30 min
- Dextrose: D₅₀W 1 amp (50 mL or 25 g; peds: D₂₅W 2–4 mL/kg) IV
- Naloxone: 0.2–2 mg (peds: 0.1 mg/kg) IV or IM initial dose
- Lactulose: 15–30 mL TID—goal is 2–3 stools per day
- Octreotide: 25–50 µg IV bolus followed by 50 µg/hr IV infusion
- Piperacillin–tazobactam: 3.375 g IV q6h (peds: 100–400 mg/kg/d div. q6–8h; renal dosing required)
- Prednisone: 40 mg (peds: 1–2 mg/kg) PO daily
- Propranolol: 40 (initial) to 240 mg (peds: 1–5 mg/kg/d) PO TID

- Rifampin: 600 mg (peds: 10–20 mg/kg) PO daily
- Thiamine: 100 mg (peds: 50 mg) IV or IM
- Ursodeoxycholic acid: 8–10 mg/kg/d TID

FOLLOW-UP

DISPOSITION

Admission Criteria

- Acute decompensation or complicating conditions
- 1st presentation with clinically evident cirrhosis, unless close outpatient workup is possible
- Advanced grades HE, sepsis, active GI bleed, and hepatorenal and hepatopulmonary syndromes require ICU.
- Advanced stages of hepatocellular carcinoma

Discharge Criteria

Most patients with compensated cirrhosis can be treated as outpatients.

FOLLOW-UP RECOMMENDATIONS

GI for all new cases

PEARLS AND PITFALLS

- Prognosis is highly variable.
- Patients present with a wide variety of signs and symptoms related to end-stage liver disease.
- New cases need full workup and GI consultation for management.
- Any complication puts patient in decompensated state.
- SBP symptoms are frequently vague:
 - Must have a high suspicion and low threshold for paracentesis when considering SBP

- K74.60 Unspecified cirrhosis of liver

CLAVICLE FRACTURE

Sean Patrick Nordt

BASICS

DESCRIPTION

- Clavicular fractures account for 5% of all fractures in all age groups.
- 80% of clavicular fractures involve the middle 3rd.
- 15% occur in the distal 3rd.
- 5% occur in the medial 3rd.

Classification

- Group I: Middle-3rd fractures
- Group II: Distal-3rd fractures:
 - Type I: Coracoclavicular ligaments are intact (nondisplaced).
 - Type II: Severing of the coracoclavicular ligaments (conoid)
 - Type III: Articular surface involvement of the acromioclavicular joint
- Group III: Medial (proximal)-3rd fractures

ETIOLOGY

Mechanism:

- Direct trauma to the clavicle
- Fall on the lateral shoulder
- Fall on the outstretched hand

Pediatric Considerations

- Most common of all pediatric fractures
- May occur in newborns secondary to birth trauma

Geriatric Considerations

Geriatric patients who sustain a clavicular fracture may have difficulty performing activities of daily living. The patient's social and living situations should be assessed to determine a safe discharge plan that may require additional assistance at home.

Pregnancy Considerations

Clavicular fractures are the result of direct trauma. Patients who are pregnant should be appropriately worked up for other injuries but also should receive fetal monitoring to ensure the health of the fetus. Even minor injuries can result in trauma or harm to the fetus.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Local pain, tenderness, and swelling over the fracture site
- Crepitus is often present owing to the clavicle's SC position
- Arm held in adduction against the chest wall with resistance to motion
- Shoulder displaced anteriorly and inferiorly

Physical-Exam

- Palpate the clavicle for tenderness, crepitus, and swelling.
- Examine the humerus and shoulder joint for other fractures, dislocations, or subluxations.
- Determine whether the fracture is open or closed.
- Evaluate for associated injuries (often serious and life threatening) that must be excluded:
 - Skeletal injuries:
 - 1st rib fracture with underlying aortic injury
 - Sternoclavicular joint separation/fracture-dislocation
 - Acromioclavicular joint separation/fracture-dislocation
 - Cervical spine injuries

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- AP radiographs of both clavicles are mandatory and must include:
 - Upper 3rd of the humerus
 - Shoulder girdle (rule out other fractures)
 - Upper lung fields (rule out pneumothorax)
- Oblique and apical lordotic views:
 - May be helpful, especially for medial and distal clavicle fractures that are not easily visualized on the AP view
 - Stress views (weight bearing) for distal clavicle fractures are no longer routinely recommended.
- Angiography:
 - Should be performed if there is any evidence or suspicion of vascular injuries (most commonly subclavian vessels)

DIFFERENTIAL DIAGNOSIS

- Distal fractures: Consider acromioclavicular separation.
- Medial fractures: Consider sternoclavicular separation.
- Shoulder fracture–dislocation

TREATMENT

PRE HOSPITAL

- Ice packs to affected area
- Pain management using either narcotics or NSAIDs
- Immobilize affected side in a sling.

INITIAL STABILIZATION/THERAPY

Airway management and resuscitate as indicated

ED TREATMENT/PROCEDURES

- Open fracture: Uncommon occurrence, but usually requires open débridement and internal fixation (obtain immediate orthopedic referral)
- Closed fracture: If severely displaced, attempt closed reduction and immobilize depending on type of fracture:
 - _ Middle 3rd:
 - If nondisplaced, a sling or shoulder immobilizer is enough to provide support.
 - Controversy exists as to whether closed reduction is necessary because the alignment is rarely maintained regardless of splinting technique.
 - To perform a closed reduction, 1% lidocaine should be injected into the fracture hematoma. The shoulders are pulled upward, outward, and backward, and the fracture is then manipulated into place.
 - Sedation may be given to alleviate pain or anxiety.
 - A figure-of-eight splint or shoulder immobilizer is then applied.
 - Ice should be applied for the 1st 24 hr.
 - Analgesia (narcotics or NSAIDs) for pain
 - _ Distal 3rd type I:
 - Ice for the 1st 24 hr.
 - Immobilization with a sling or shoulder immobilizer
 - Orthopedic referral
 - Analgesia (narcotics or NSAIDs) for pain
 - Early range of motion
 - _ Distal 3rd type II:
 - Ice for the 1st 24 hr.
 - Immobilization with a sling or shoulder immobilizer
 - Orthopedic referral (may require operative repair)
 - Analgesia (narcotics or NSAIDs) for pain
 - _ Distal 3rd type III: Same as type II
 - _ Medial (proximal) 3rd:
 - Ice for the 1st 24 hr.
 - Immobilization in a sling or shoulder immobilizer for support

- Analgesia (narcotics or NSAIDs) for pain
- Orthopedic follow-up
- Reassess neurovascular status after all splints are applied.

Pediatric Considerations

- Children who do not cooperate with the figure-of-eight splint should be referred to an orthopedic surgeon for possible shoulder spica placement.
- Most children will tolerate a shoulder immobilizer best.

MEDICATION

- Acetaminophen: 650 mg to 1000 mg (peds: 10--15 mg/kg) PO q6h prn. Do not exceed 3 g/24 hr
- Ibuprofen: 600–800 mg PO q6h PRN with meals (peds: 10 mg/kg PO q6h PRN)
- Adults: Hydrocodone/Acetaminophen 5 mg/325 mg one to two tablets PO q6h prn. Do not exceed 3 g/24 hr of acetaminophen. Avoid concomitant use of acetaminophen-containing medications
- Hydrocodone, oxycodone, and codeine-containing medications should be avoided in pediatric patients

FOLLOW-UP

DISPOSITION

Admission Criteria

- Open fracture
- Associated injuries that are potentially life threatening

Discharge Criteria

- Isolated closed clavicle fracture without other injuries
- Appropriate support services at home (especially for elderly patients)
- Orthopedic follow-up
- Adequate pain management

Issues for Referral

Open fracture, complex injury, signs of neurovascular injury require immediate orthopedic referral.

FOLLOW-UP RECOMMENDATIONS

Follow-up with an orthopedic surgeon:

- Seek medical care immediately with any changes in neurologic function, sensation, or motor strength.

PEARLS AND PITFALLS

- Always be wary of associated injuries that can be life threatening including cervical spine injury, aortic injury, and other cardiopulmonary injuries:
- Always assess for any neurologic deficits associated with the fracture.

COAGULOPATHY REVERSAL (NONWARFARIN AGENTS)

Susanne M. Hardy • John P. Lemos

BASICS

DESCRIPTION

- Patient on anticoagulant medications with minor, major, or clinically significant bleeding needing close monitoring +/- anticoagulant reversal
- Anticoagulant medication
 - _ Indirect inhibitors of thrombin
 - Unfractionated heparin (UFH)
 - Low-molecular-weight heparin (LMWH)
 - Enoxaparin
 - Dalteparin
 - Tinzaparin
 - _ Anti-platelet agents
 - Aspirin
 - Clopidogrel hydrogen sulfate (Plavix)
 - _ Factor Xa inhibitors (FXa inhibitors)
 - Fondaparinux (Arixtra)
 - Rivaroxaban (Xarelto)
 - _ Direct thrombin inhibitors (DTIs)
 - Argatroban
 - Bivalirudin (Angiomax)
 - Dabigatran (Pradaxa)
 - Hirudin derivatives
 - Desirudin
 - Lepiruden (Refludan)

Pediatric Considerations

- Heparin and LMWH are the most commonly utilized anticoagulants beyond warfarin
- Routine use of DTIs is being studied

Geriatric Considerations

Excretion primarily renal with FXa inhibitors, Dabigatran, and Hirudin derivatives necessitating caution with impaired renal function

EPIDEMIOLOGY

Incidence and Prevalence Estimates

- Indirect inhibitors of thrombin
 - Up to 1/3 patients develop bleeding complication
 - 2–6% of bleeding is major
- Anti-platelet agents
 - > 300 over-the-counter medications contain aspirin
 - Conflicting studies regarding increased hematoma expansion and mortality
- FXa Inhibitors
 - Unknown
- DTIs
 - Unknown

ETIOLOGY

- Indirect inhibitors of thrombin
 - Combines with antithrombin III to inactivate activated FXa and also inhibits thrombin
 - LMWH has a reduced ability to inactivate thrombin
 - Half-life is dose dependent (30–150 min), can be up to 8 hr with LMWH
- Anti-platelet agents
 - Inactivates cyclooxygenase-1 (COX-1) preventing formation of thromboxane A₂, which inactivates platelets
 - Single dose suppresses for 1 wk
 - New platelet production recovers 10%/day
 - Patients may manifest normal hemostasis with as few as 20% platelets with normal COX1 activity
 - Aspirin half-life 15–30 min
 - Clopidogrel half-life 8 hr
- FXa inhibitors
 - Binds to antithrombin III, catalyzing FXa inhibition
 - No direct inhibitory effect on thrombin
 - Half-life 12–21 hr in normal renal function
- DTIs
 - Competitively targets active site of thrombin +/- exosite (substrate binding site)
 - Half-life long with dabigatran (14–17 hr) and short with others (20–45 min)

DIAGNOSIS

- Patient on anticoagulants with active bleeding
- Indications for reversal
 - Serious or life-threatening bleeding
 - Trauma
 - GI bleeding
 - Intracerebral hemorrhage (ICH)

- Procedural

SIGNS AND SYMPTOMS

History

- Type of anticoagulant
- Last anticoagulant use
- Length of anticoagulant
- Recent injury or trauma
- Bleeding location
- Symptoms (fatigue, lightheadedness, headache, abdominal pain)

Physical-Exam

- VS +/- orthostatics
- Search for hemorrhage locations/signs of trauma
- Comprehensive neurologic exam
- Rectal with stool guaiac test

ESSENTIAL WORKUP

- CBC
- PT/INR
- PTT
- Stool guaiac test
- +/- Fibrinogen/DIC panel

DIAGNOSIS TESTS & INTERPRETATION

- Indirect inhibitors of thrombin
 - PTT
 - Anti-FXa
 - High is > 0.8 U/mL
- Anti-platelet agents
 - Bleeding time
- FXa inhibitors
 - Anti-FXa
 - PT, PTT minimally helpful
 - Fondaparinux level (institution specific)
- DTIs
 - PTT minimally helpful
 - Dabigatran level aka dilute thrombin time (institution specific)

DIFFERENTIAL DIAGNOSIS

- Disseminated intravascular coagulopathy
- Inherited coagulation disorders

- Platelet dysfunction:
 - _ TTP/HUS
 - _ HIT
 - _ ITP

TREATMENT

PRE HOSPITAL

- Pressure to hemorrhage (if possible)
- 2 large-bore IVs
- IV fluids

INITIAL STABILIZATION/THERAPY

- Same as pre-hospital
- Hold anticoagulants

ED TREATMENT/PROCEDURES

- Indirect inhibitors of thrombin
 - _ Level bleeding
 - Minor: Observe PTT, anti-FXa
 - Major: Protamine (Class II for UFH and Class III for LMWH)
 - _ Protamine
 - 1 mg IV neutralizes 100 U UFH administered in prior 3–4 hr
 - If < 30 min since UFH, use 1 mg/100 U UFH
 - If 30–120 min, use 0.5 mg/100 U UFH
 - If > 120 min, use 0.25 mg/100 U UFH
 - Give slowly IV over 1–3 min not to exceed 50 mg in any 10-min period
 - Short half-life, may need to re-dose
 - Protamine reversal effectiveness is compound specific for LMWH (does not reverse enoxaparin completely)
 - 1 mg for each 1 mg/100 IU LMWH given in last 8 hr
 - If 8–12 hr since LMWH, use 0.5 mg for each 1 mg/100 IU LMWH
 - If > 12 hr since LMWH, no protamine suggested
 - For LMWH, if PTT remains prolonged, may repeat with half of the 1st dose
 - High or excessive dosing can have a paradoxical anticoagulant effect
 - Rapid administration can cause hypotension, bradycardia, and anaphylaxis
 - Anaphylaxis is more likely with a fish allergy or prior exposure to protamine and if concerned, can premedicate with corticosteroids and antihistamines

- Anti-platelet agents
 - Level bleeding
 - Minor: Observe bleeding
 - Major: DDAVP +/- platelet transfusion(s) (class III)
 - Desmopressin (DDAVP)
 - Induces the release of von Willebrand factor and factor VIII
 - 0.3 µg/kg IV over 15 min
 - Effect is immediate
 - Multiple doses associated with tachyphylaxis, hyponatremia, and seizures
 - Platelets
 - Transfuse to increase count by 50,000/µL (on average, 1 U increases platelet count by 10k)
 - May need to repeat transfusions daily
 - Risks include infection transmission, acute lung injury, and allergic reactions
- FXa inhibitors
 - Level bleeding
 - Minor: Observe bleeding
 - Major: PCC or rFVIIa (Class III), consider hemodialysis (HD) for fondaparinux, consider charcoal if rivaroxaban and ingested in previous 2 hr
 - Prothrombin complex concentrates (PCCs)
 - 3 factor: Contains factors II, IX, X and low concentrations of nonactivated factor VII + anticoagulant protein C, protein S, antithrombin III
 - 4 factor: Contains II, IX, X, activated VII
 - Factor 4 is now available widely in the US
 - FDA approved for bleeding episodes in patients with hemophilia B
 - Dose 25–50 U/kg not to exceed 2 mL/min
 - Give 1–2 U FFP for factor VIIa component
 - Effect in < 30 min
 - Limited data to support use in trauma
 - Vary widely in composition
 - Several contain heparin
 - Long-term safety has not been assessed
 - Associated with risk of thrombosis
 - Allergic reactions may occur
 - Recombinant activated factor VII (rFVIIa)
 - FDA approved for bleeding episodes in patients with hemophilia A and B
 - Off-label use for life-threatening bleeding
 - Dose 15–90 µg/kg (suggested 40 µg/kg) IV over 3–5 min

- Effect in < 30 min
- May repeat in 2 hr if continued bleeding
- Associated with risk of thrombosis
- Ultrafiltration/HD
 - For fondaparinux, may remove 20%
- Activated charcoal
 - If ingestion within 1–2 hr of rivaroxaban
- DTIs
 - Level bleeding
 - Minor: Observe bleeding (DTIs have short half-life except dabigatran, which is 14–17 hr), IV fluids to improve renal clearance
 - Major: PCC or rFVIIa (no strong evidence for either), consider DDAVP, activated charcoal if within 1–2 hr ingestion, consider HD (especially if dabigatran)
 - PCC
 - Dose 25–50 U/kg not to exceed 2 mL/min
 - Give 1–2 U FFP if using 3 factor
 - rFVIIa
 - Dose 100 µg/kg IV over 3–5 min
 - May repeat in 2 hr if continued bleeding
 - DDAVP
 - Dose 0.3 µg/kg IV over 15 min
 - Demonstrated effectiveness with hirudin
 - Ultrafiltration/HD
 - Consider early in course for dabigatran and major bleeding
 - Activated charcoal
 - If ingestion within 1–2 hr

FOLLOW-UP

DISPOSITION

Admission Criteria

- Clinically significant bleeding
- Utilization of reversal agents

Discharge Criteria

- Insignificant bleeding that is controlled without the use of anticoagulant reversal
- Discussion with outpatient hematologist or primary care physician (PCP) is ideal for follow-up

Issues for Referral

- Blood bank reversal medication availability
- Surgical/Interventional Radiology specialty availability to control hemorrhage

FOLLOW-UP RECOMMENDATIONS

Close follow-up and monitoring is paramount

PEARLS AND PITFALLS

- Prophylactic heparin dosing does not typically confer an increased risk of major bleeding
- LMWH is not always reversed with protamine—it is compound specific
- If > 12 hr have elapsed since LMWH administration, protamine may not be necessary
- Single-dose aspirin suppresses COX1 for 1 wk
- Caution is needed with renal impairment if utilizing FXa inhibitors, dabigatran, or hirudin derivatives
- FFP as 1st-line replacement has to be weighed against extensive volume expansion

CODES

ICD9

- 286.6 Defibrination syndrome
- 286.9 Other and unspecified coagulation defects
- V58.61 Long-term (current) use of anticoagulants

ICD10

- D65 Disseminated intravascular coagulation
- D68.9 Coagulation defect, unspecified
- Z79.01 Long term (current) use of anticoagulants

COCAINE POISONING

Steven E. Aks

BASICS

DESCRIPTION

- Sympathomimetic
- Inhibits neurotransmitter reuptake at the nerve terminal
- Metabolism:
 - Hepatic degradation
 - Nonenzymatic hydrolysis
 - Cholinesterase metabolism

ETIOLOGY

- IV, nasal, oral administration of cocaine
- Oral ingestion:
 - Body stuffers:
 - Ingest hastily wrapped packets in attempt to evade police.
 - Body packers:
 - Ingest cocaine packets to smuggle the drug using couriers' oral, rectal, and vaginal cavities.
 - Cocaine is wrapped carefully in packets containing large amounts of drug.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Sympathomimetic toxidrome
- Cardiovascular:
 - HTN
 - Tachycardia
 - Chest pain (angina)
- Respiratory:
 - Tachypnea
 - Pleuritic chest pain:
 - Pneumomediastinum
 - Pneumothorax
 - Bronchitis
 - Pulmonary infarction
 - Cough
- CNS:

- Agitation
- Tremulousness
- Coma
- Seizures
- Stroke
- Miscellaneous:
 - Hyperthermia (poor prognosis)
 - Limb ischemia (inadvertent intra-arterial injection)
 - Corneal ulcerations (heavy crack smokers):
 - Owing to local chemical and thermal irritation that disrupts corneal epithelium
 - Rhabdomyolysis

History

For body packers and stuffers:

- Time since ingestion
- Route of ingestion (oral, rectal, vaginal)
- Number of packets ingested
- Material and method of packing

Physical-Exam

Sympathomimetic toxidrome:

- HTN
- Tachycardia
- Tachypnea
- Hyperthermia
- Diaphoresis
- Mydriasis
- Neuromuscular hyperactivity

ESSENTIAL WORKUP

- Recognition of the sympathomimetic toxidrome caused by cocaine:
 - Distinguish from anticholinergic toxidrome.
- Toxidrome recognition:
 - Sympathomimetic:
 - Heart rate (tachycardia)
 - BP (increased)
 - Moist skin
 - Bowel sounds present
 - Temperature (increased)
 - No urinary retention
 - Anticholinergic:
 - Heart rate (tachycardia)

- BP (increased)
- Dry skin
- Bowel sounds diminished
- Temperature (increased)
- Urinary retention present

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Electrolytes, BUN, creatinine, glucose
- Urinalysis dip for myoglobin
- Cardiac enzymes (troponin, creatine phosphokinase [CPK]) for:
 - Anginal chest pain
 - Abnormal results on ECG
- CPK for evidence of myoglobinuria
- Toxicology screen

Imaging

- ECG:
 - For anginal chest pain
 - Consider possibility of myocardial infarction with cocaine-related chest pain.
- CXR:
 - For chest pain or shortness of breath
 - Check for pneumomediastinum, pneumothorax, aortic rupture.
- Abdominal radiograph:
 - For body packers/stuffers
 - Usually produces negative result for stuffers because drug is loosely packed in cellophane
 - Positive for packers because drug is densely packed and usually radiopaque
- CT of the abdomen with contrast:
 - When unreliable history of body packers/stuffers and nothing visualized on abdominal frontal radiograph
- CT brain scan:
 - For altered mental status or severe headache
 - Detects cerebral ischemia or hemorrhage

DIFFERENTIAL DIAGNOSIS

Other agents with sympathomimetic effects

- Theophylline
- Caffeine
- Amphetamines

- Albuterol
- Tricyclic antidepressants
- Antihistamines
- Phencyclidine (PCP)
- Thyrotoxicosis
- Neuroleptic malignant syndrome
- Hallucinogens

TREATMENT

PRE HOSPITAL

- Establish IV access
- Cardiac monitor:
 - Chest pain may be ischemic.
 - Benzodiazepine therapy to control agitation
- When drug is used as a “speedball” (combination of heroin and cocaine), administer naloxone in increments to reverse coma.

INITIAL STABILIZATION/THERAPY

- ABCs
- Establish IV access.
- Establish cardiac monitor.
- Provide therapy with naloxone (Narcan), thiamine, dextrose (or Accu-Check) for altered mental status

ED TREATMENT/PROCEDURES

- Supportive care for mildly symptomatic patients
- Benzodiazepines:
 - For agitation and tremor
 - Initial agents for hypertension and tachycardia
- Cooling measures for hyperthermia:
 - Evaporative–convective method
- Treat rhabdomyolysis:
 - Hydrate with 0.9% NS
 - Alkalinization with IV bicarbonate in severe cases
- Cardiac chest pain:
 - Aspirin
 - Nitrates
 - Oxygen
 - Opiates
 - Avoid β -blockers because of unopposed α -stimulation
 - Angiography/angioplasty/thrombolysis for acute myocardial infarction

- HTN/tachycardia:
 - Benzodiazepine initial agent
 - Use α -blocking agent (phentolamine) as sole agent or combine with β -blocker (propranolol, esmolol) if unresponsive to benzodiazepine.
 - Use labetalol cautiously (does not have equal α - and β -blocking properties).
 - IV nitroglycerin/nitroprusside for severe unresponsive hypertension
- Body packer/stuffers:
 - Treat asymptomatic or minimally symptomatic body packers and body stuffers:
 - Single-dose activated charcoal is appropriate for asymptomatic or minimally symptomatic body stuffers
 - Whole-bowel irrigation with polyethylene glycol electrolyte lavage solution (efficacy unknown)
 - Consult with surgeons for symptomatic body packers and stuffers.
 - If toxicity is not easily managed with previously suggested pharmacologic therapy, remove the drug packets intraoperatively.

MEDICATION

First Line

- Diazepam: 5 mg incremental doses IV
- Lorazepam: 2 mg incremental doses IV

Second Line

- Activated charcoal slurry: 1–2 g/kg up to 90 g PO
- Dextrose: D₅₀W 1 ampule (50 mL or 25 g) (peds: D₂₅W 2–4 mL/kg) IV
- Esmolol: 50–200 μ g/kg/min IV infusion titrated to effect
- Naloxone (Narcan): 2 mg (peds: 0.1 mg/kg up to 2 mg) IV or IM initial dose
- Nitroglycerin: 10–100 μ g/min IV infusion
- Nitroprusside: 0.3 μ g/kg/min IV (titrate to effect up to 10 μ g/kg/min)
- Phentolamine: 5 mg IV q15–24min (titrate to clinical effect)
- Polyethylene glycol (GoLYTELY): 1–2 L PO/hr until packet passage (efficacy controversial)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Altered mental status
- Abnormal vital signs: Heart rate > 100 bpm, diastolic BP > 120 mm Hg, or hypotension

- Hyperthermia
- Cocaine-induced myocardial ischemia
- Body stuffers and body packers
- ICU admission for moderate to severe toxicity

Discharge Criteria

- Mental status and vital signs normal after 6 hr of observation
- Body packers or stuffers with confirmed expulsion of packets and no clinical signs of toxicity
- Stuffers may be discharged if uncomplicated packets were ingested and if asymptomatic for 12–24 hr.

PEARLS AND PITFALLS

- Benzodiazepines are the 1st-line treatment for the sympathomimetic toxidrome from cocaine.
- Avoid β -blockers in the hyperdynamic cocaine intoxicated patient.
- Consider a broad differential in cocaine-associated chest pain.
- An abdominal flat plate radiograph will be of some value in a body packer, but of no value in imaging packets in a body stuffer.

COLON TRAUMA

Stephen R. Hayden

BASICS

DESCRIPTION

- Trauma that perforates the colon inflames the cavity in which it lies.
- Peritoneal inflammation from hollow viscus perforation often requires hours to develop.
- Mesenteric tears from blunt trauma cause hemorrhage and bowel ischemia.
- Delayed perforation from ischemic or necrotic bowel may occur.
- Peritonitis and sepsis may develop from the extravasated intraluminal flora.
- Ascending and descending colon segments are retroperitoneal.
- The left colon has a higher bacterial load than the right.
- Morbidity and mortality increase if the diagnosis of colon injury is delayed.

ETIOLOGY

- Penetrating abdominal trauma:
 - The colon is the 2nd most commonly injured organ in penetrating trauma.
 - Gunshot wounds have the highest incidence.
 - Transverse colon is most commonly injured.
 - Often presents with peritonitis
- Blunt abdominal trauma:
 - Colon rarely injured in blunt trauma
 - Burst injury occurs from compression of a closed loop of bowel.
 - Intestine may be squeezed between a blunt object (lap belt) and vertebral column or bony pelvis.
 - Sudden deceleration may produce bowel–mesenteric disruption and consequent devascularization.
 - With deceleration, the sigmoid and transverse colon are most vulnerable.
- Transanal injury:
 - Iatrogenic endoscopic or barium enema injury
 - Foreign bodies used during sexual activities may reach and injure the colon.
 - Compressed air under high pressure such as at automobile repair facilities can perforate the colon even if the compressor nozzle is not fully inserted anally.
 - Swallowed sharp foreign bodies (toothpick) may penetrate the colon, particularly the cecum, appendix, and sigmoid:
 - Most foreign bodies pass without complications.

Pediatric Considerations

Unlike adults, children have an equal frequency of blunt and penetrating colon injuries.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Colon trauma is generally associated with other intra-abdominal and extra-abdominal injuries, commonly to the small intestine.
- Injuries of significant severity may have minimal early findings.
- It is uncommon to determine specific organ injury on physical exam.
- Assess on exam:
 - Abdomen for peritoneal signs
 - Ecchymosis or hematoma on lower abdomen from lap-belt compression
 - Ecchymosis on epigastric region from steering-wheel compression
 - Grey Turner sign (flank hematomas) resulting from retroperitoneal bleeding.
 - Foreign bodies or blood on digital rectal exam (be careful if sharp object suspected)
 - Note: Abdominal wall ecchymosis or hematoma is not always present despite existing injury.
 - Note: Bowel sounds are not helpful.

ESSENTIAL WORKUP

- Serial abdominal exam because inflammation takes time to develop
- Abdominal CT with contrast is the best diagnostic study in stable patients.
- US and diagnostic peritoneal lavage (DPL) are helpful in the potentially unstable patient.

DIAGNOSIS TESTS & INTERPRETATION

- No individual test or combination of currently available diagnostic modalities is adequate to exclude blunt colonic injury.
- Signs of peritoneal irritation owing to intestinal injury typically develop hours after the event.

Lab

- Electrolytes
- Calcium, magnesium

Imaging

- CT is more useful for detecting penetrating vs. blunt colon injury.
- CT with triple contrast allows intraperitoneal and retroperitoneal visualization.
- Oral contrast is not essential in blunt abdominal trauma CT evaluation.
- Although CT may miss colon injuries, abnormal findings are typical.
- CT is only moderately sensitive at identifying hollow viscus injury.

- Hollow viscus injury—associated CT findings include extraluminal gas or contrast, mesenteric fat streaking, and free fluid without solid organ injury.
- Water-soluble enema with fluoroscopy is useful if other test results are inconclusive.
- Plain abdominal radiographs can show indirect signs such as intraperitoneal and retroperitoneal free air.
- FAST US exam does not evaluate for enteric injury and retroperitoneal hemorrhage.
- See “Abdominal Trauma, Blunt”; “Abdominal Trauma, Imaging.”

Diagnostic Procedures/Surgery

- DPL or ultrasound in addition to CT will increase sensitivity.
- In blunt trauma, DPL will often not detect retroperitoneal injuries and enteric injury as intra-abdominal bleeding is limited.
- Fecal or vegetable material on DPL analysis indicates hollow viscus injury.
- Lavage white cell response may be negative secondary to delayed peritoneal inflammation.
- In hollow viscus injury, lavage WBC count: RBC ratio is higher than that seen with solid organ injuries.

DIFFERENTIAL DIAGNOSIS

- Other intra-abdominal injuries
- A fractured pelvis may present similarly to intraperitoneal injuries in children.

TREATMENT

PRE HOSPITAL

- Cautions:
 - _ Follow standard pre-hospital guidelines for trauma management (ABCs).
 - _ Do not remove penetrating foreign bodies.
 - _ Do not attempt to replace eviscerated bowel; cover with moist saline dressings.
 - _ Obtain history regarding mechanism of injury, vehicular damage, and seat belt use.
- Controversies:
 - _ Use of intravenous crystalloid resuscitation is still considered the standard of care.

INITIAL STABILIZATION/THERAPY

- Refer to topic on abdominal trauma.
- ABCs should precede abdominal evaluation.
- Aggressive management with IV crystalloid resuscitation and blood replacement as

needed.

ED TREATMENT/PROCEDURES

- Early surgical consultation; surgery is definitive treatment.
- Cover eviscerated bowel in moist saline gauze, in a nondependent position.
- Administer broad-spectrum antibiotics to cover gram-negative aerobic and anaerobic bacteria.
- The efficacy of multiple-agent and single-agent antibiotic regimens is similar.
- Ensure tetanus prophylaxis.

MEDICATION

- Ampicillin: 2 g (peds: 50 mg/kg) IV q6h + gentamicin 2 mg/kg (peds: 2.5 mg/kg) IV q8h + metronidazole 500 mg IV q6h (peds: Use clindamycin 25–40 mg/kg IV q24h div. q6–q8h)
- Aztreonam: 2 g IV q8h (peds: 90–120 mg/kg IV q24h div. q6–q8h) + clindamycin 900 mg IV q8h (peds: Use clindamycin 25–40 mg/kg IV q24h div. q6–q8h)
- Cefoxitin: 2 g IV q8h (peds: 40 mg/kg IV q6h)
- Piperacillin/tazobactam: 4.5 g (peds: 75 mg/kg) IV q8h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Colon injuries require admission for surgical repair or monitoring.
- All penetrating foreign bodies must be removed to prevent sepsis.
- Patients with abdominal ecchymosis require hospital admission and observation because of potential for undiagnosed hollow viscus injury.

Discharge Criteria

- Patients in whom serious abdominal injury is not suspected and with completely normal abdominal exam, normal hemodynamic status, and no other injury may be considered for discharge with appropriate precautions.
- If there is any doubt about the possibility of colon injury, the patient should be admitted and observed.

PEARLS AND PITFALLS

Patients may initially present with paucity of symptoms:

- Observation and serial exams are indicated if mechanism suggests significant blunt abdominal trauma.

COMA

Gregory D. Jay • Linda C. Cowell

BASICS

DESCRIPTION

- Light coma:
 - _ Responds to noxious stimuli
- Deep coma:
 - _ Does not respond to pain
- Unresponsiveness:
 - _ Loss of either arousability or cognition:
 - Loss of arousal
 - Arousal is primarily a brainstem function.
 - Impairment of the reticular activating system
 - Loss of cognition
 - Requires dysfunction of both cerebral hemispheres
 - _ Stupor:
 - Deep sleep, although not unconsciousness
 - Exhibits little or no spontaneous activity
 - Awaken with stimuli
 - Little motor or verbal activity once aroused
- Obtundation:
 - _ Mental blunting with mild or moderate reduction in alertness
- Delirium:
 - _ Floridly abnormal mental status
 - _ Irritability
 - _ Motor restlessness
 - _ Transient hallucinations
 - _ Disorientation
 - _ Delusions
- Clouding of consciousness:
 - _ Disturbance of consciousness
 - _ Impaired capacity to think clearly or perceive, respond to, and remember current stimuli

ETIOLOGY

- Diffuse brain dysfunction (69%):
 - _ Lack of nutrients:
 - Hypoglycemia
 - Hypoxia

- Poisoning:
 - Ethanol
 - Isopropyl alcohol
 - Ethylene glycol
 - Methanol
 - Salicylates
 - Sedative-hypnotics
 - Narcotics
 - Anticonvulsants
 - Isoniazid
 - Heavy metals
 - Opiates
 - Benzodiazepines
 - Anticholinergics
 - Lithium
 - Phencyclidine
 - Cyanide
 - Carbon monoxide
 - Isoniazid
- Infection:
 - Bacterial/tuberculous/syphilitic meningitis
 - Encephalitis
 - Falciparum meningitis
 - Typhoid fever
 - Rabies
- Endocrine disorders:
 - Myxedema coma
 - Thyrotoxicosis
 - Addison disease
 - Cushing disease
 - Pheochromocytoma
- Metabolic disorders:
 - Hepatic encephalopathy
 - Uremia
 - Porphyria
 - Wernicke encephalopathy
 - Aminoacidemia
 - Reye syndrome
 - Hypercapnia
- Electrolyte disorders:
 - Hypernatremia, hyponatremia
 - Hypercalcemia, hypocalcemia
 - Hypermagnesemia, hypomagnesemia

- Hypophosphatemia
- Acidosis, alkalosis
- Temperature regulation:
 - Hypothermia
 - Heat stroke
 - Neuroleptic malignant syndrome
 - Malignant hyperthermia
- Uremia
- Postictal state, status epilepticus
- Psychiatric
- Shock
- Fat embolism
- Hypertensive encephalopathy
- Supratentorial lesions (19%):
 - Hemorrhage (15%):
 - Intraparenchymal hemorrhage
 - Epidural hematoma
 - Subdural hematoma
 - Subarachnoid hemorrhage
 - Infarction (2%):
 - Thrombotic arterial occlusion
 - Embolic arterial occlusion
 - Venous occlusion
 - Tumor or abscess (2%):
 - Hydrocephalus
 - Herniation
 - Hemorrhage from erosion into adjacent blood vessels
- Subtentorial lesions (12%):
 - Infarction
 - Hemorrhage
 - Tumor
 - Basilar migraine
 - Brainstem demyelination

Pregnancy Considerations

Eclampsia

DIAGNOSIS

SIGNS AND SYMPTOMS

History

Ongoing disturbance of consciousness

Physical-Exam

- No spontaneous eye opening
- Lack of response to painful stimuli
- No motor activity
- Regular cardiorespiratory function
- Glasgow Coma Scale (GCS) scoring:
 - Eye opening (E):
 - Spontaneously: 4
 - To verbal command: 3
 - To pain: 2
 - No response: 1
 - Best motor response (M) to verbal command:
 - Obeys: 6
 - Best motor response to painful stimulus:
 - Localizes to pain: 5
 - Withdraws to pain: 4
 - Flexion—abnormal: 3
 - Extension—abnormal: 2
 - No response: 1
 - Best verbal response (V):
 - Oriented and converses: 5
 - Disoriented and converses: 4
 - Verbalizes: 3
 - Vocalizes: 2
 - No response: 1
 - $GCS = E + M + V$
- Hypothermia:
 - Infection, hypoglycemia, myxedema coma, alcohol and sedative-hypnotic poisoning
- Fever:
 - Infection, thyrotoxicosis, anticholinergics, sympathomimetics, neuroleptic malignant syndrome, hypothalamic hemorrhage
- HTN
- Structural lesion, hypertensive encephalopathy
- Hypotension
- Mydriasis:
 - Organophosphates
- Miosis:
 - Narcotics
 - Anticholinergics
 - Pontine lesion

- Loss of pupillary reflexes or unequal pupils:
 - Structural lesions
- Evidence of head trauma
- Nuchal rigidity:
 - Meningitis
 - Subarachnoid hemorrhage
- Decorticate posturing:
 - Flexion of elbows and wrists
 - Adduction and internal rotation of shoulders
 - Supination of the forearms
 - Suggests severe damage above the midbrain
- Decerebrate posturing:
 - Extension of elbows and wrists
 - Adduction and internal rotation of shoulders
 - Pronation of the forearms
 - Suggests damage at the midbrain or diencephalon
- Asymmetric movements:
 - Structural lesions
 - Persistent twitching of an extremity:
 - Status epilepticus

ESSENTIAL WORKUP

- Detect and treat reversible causes.
- Immediate exclusion of comalike states:
 - Noting resistance to passive opening of eyelids, fluttering of eyelids when stroked, abrupt eyelid closure, eye movements by saccadic jerks (rather than roving), or finding the eyes rolled back
 - Provocation of nystagmus with ice-water caloric testing
 - Before paralyzing a patient for intubation, an attempt should be made to detect a locked-in syndrome.
 - Demonstrating that the patient is able to blink on verbal command will establish this diagnosis.
 - Intubation is still indicated to prevent aspiration.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Dextrostix
- CBC
- Electrolytes
- Blood and urine toxicologic screen

Imaging

Head CT:

- Diagnosis of hemorrhage and midline shift
- CT angiography for suspected cerebrovascular accident

Diagnostic Procedures/Surgery

- Lumbar puncture:
 - _ All patients with coma of unknown etiology, particularly if fever is present
 - _ Antibiotics may be administered for as long as 48 hr before lumbar puncture.
 - _ CT should be performed before lumbar puncture if there is evidence of increased intracranial pressure, a mass lesion, pre-existing trauma, or focal findings.
- Risk of tonsillar herniation in patients with a mass lesion is very small.
- EEG:
 - _ Performed to rule out suspected seizure activities
 - _ Little use in the emergency evaluation
 - _ Unlike EEG studies performed in a lab, lighting will cause artifacts.

DIFFERENTIAL DIAGNOSIS

- Locked-in syndrome
- Psychogenic unresponsiveness
- Stupor
- Catatonia
- Akinetic mutism

TREATMENT

PRE HOSPITAL

- Airway management if loss of airway patency
- Endotracheal intubation if no response to coma cocktail
- IV access
- Dextrose or Dextrostix
- Narcan
- Monitor
- Look for signs of an underlying cause:
 - _ Medical alert bracelets
 - _ GCS
 - _ Pupils
 - _ Extremity movements

INITIAL STABILIZATION/THERAPY

- Airway management

- Empiric use of naloxone
- Empiric dextrose:
 - Administer if serum glucose cannot be measured at the bedside
 - Can safely be administered before thiamine
 - Does not worsen outcome in patients with stroke

ED TREATMENT/PROCEDURES

- Specific therapy directed at underlying cause once identified
- Consider empiric use of antibiotics for coma of undetermined etiology:
 - Broad-spectrum with good cerebrospinal fluid penetration such as ceftriaxone
- Stop seizure activity with benzodiazepines, phenytoin, and phenobarbital.
- Empiric treatment for a toxic ingestion:
 - Activated charcoal
- Correct body temperature:
 - Aggressive rewarming for patients with core temperature between 32°C and 35°C and invasive rewarming for <32°C
 - Ice packs and forced air movement over exposed wetted skin if severe hyperthermia

MEDICATION

- Ceftriaxone: 100 mg/kg IV
- Dextrose: 1–2 mL/kg of D₅₀W IV; neonate 10 mL/kg D₁₀W IV; peds 4 mL/kg D₂₅W IV
- Diazepam: 0.1–0.3 mg/kg slow IV (max. 10 mg/dose) q10–15min × 3 doses
- Flumazenil: 0.20 mg IV qmin × 1–5 doses
- Fomepizole: 15 mg/kg IV
- Lorazepam: 0.05–0.1 mg/kg IV (max. 4 mg/dose q10–15min)
- Mannitol: 0.25–1 g/kg IV over 20 min
- Naloxone: 0.01 mg/kg to 0.01–0.1 mg/kg
- Phenobarbital: 10–20 mg/kg IV, monitor for respiratory depression
- Phenytoin: Infuse at <50 mg/min; 18–20 mg/kg IV/IO or fosphenytoin 15–20 mg/kg IV/IO
- Physostigmine: 0.5–2 mg IV
- Thiamine: 100 mg IM or 100 mg thiamine in 1,000 mL of IV fluid wide open
- Pyridoxine: 70 mg/kg IV (Max. 5 g on a 1:1 basis with INH overdose)

FOLLOW-UP

DISPOSITION

Admission Criteria

Patients who do not have a readily identifiable and completely reversible cause of coma should be admitted.

Discharge Criteria

Comatose patients with correctable hypoglycemia and opiate toxicity who respond completely to aggressive ED treatment can be discharged.

Issues for Referral

Further delineation or prevention of possible adverse medication reaction

FOLLOW-UP RECOMMENDATIONS

- If discharged, urgent PCP F/U is needed.
- Consideration of adverse medication reaction
- Supervision for 24 hr postdischarge

PEARLS AND PITFALLS

- Rapid medical stabilization
- Neuroimaging for structural lesions
- Metabolic and toxicologic assessment
- Identification of unusual causes of coma
- Dischargeable patients require period of ED observation.

COMPARTMENT SYNDROME

Chester D. Shermer

BASICS

DESCRIPTION

- Elevated tissue pressure in closed spaces that compromises blood flow through capillaries
- Normal tissue pressure is < 10 mm Hg.
- Capillary blood flow in a compartment is compromised at pressures > 20 mm Hg.
- Muscles and nerves can develop ischemic necrosis at pressures > 30 mm Hg.
- When distal pulses are diminished on exam, muscle necrosis is probably present.
- The 4 compartments of the leg are most frequently involved, but compartment syndrome can occur in the arm, forearm, hand, foot, shoulder, buttocks, and thigh.

ETIOLOGY

- Decreased compartment size: Circumferential cast, burn eschar, or military antishock trousers (MAST)
- Increased compartment contents: Compression of the compartment from edema or hematoma caused by direct trauma, fracture, overexertion of muscles, contrast extravasation, injection of recreational drugs, postischemic time, or limb compression during prolonged recumbency

DIAGNOSIS

ALERT

- Keep the extremity at the level of the heart to promote arterial flow but not diminish venous return.
- Do not use ice if compartment syndrome is suspected—it may compromise microcirculation.

SIGNS AND SYMPTOMS

- Severe, constant pain over the compartment that is disproportionate to extent of injury
- Pain increases with active contraction and passive stretching.
- Muscle weakness
- Hypesthesia
- 6 P's: Pain, pressure, paresis, paresthesia, and pulses present

History

- Elicit above symptoms in proper clinical setting.

- 6 P's

Physical-Exam

- Tenderness of muscle compartment
- Assess motor and neurologic function.

DIAGNOSIS TESTS & INTERPRETATION

Imaging

Radiographs should be performed if fracture is suspected.

Diagnostic Procedures/Surgery

- Measurement of compartment pressures with a system such as the Stryker IC pressure monitor system (Stryker Surgical, 2825 Airview Boulevard, Kalamazoo, MI 49002. www.stryker.com), using an 18G needle or continuous pressure monitoring with the attachment for an indwelling catheter
- Technique is as follows:
 - Prep overlying skin with antiseptic solution.
 - Local anesthetic can be infiltrated into the *SC tissue only*, taking care not to inject intramuscularly.
 - The needle used for pressure measurements is advanced through the skin until a popping sensation is felt when the fascia is pierced.
 - 0.2 mL of saline is injected to clear the lumen of the needle, and the intracompartmental pressure measurement is then read.
 - To ascertain correct placement of the needle within the compartment, external pressure may be applied over the muscle compartment, or the muscles can be passively stretched to increase the intracompartmental pressure transiently; once these maneuvers are discontinued, the pressure should drop to baseline and stabilize.

DIFFERENTIAL DIAGNOSIS

- Chronic compartment syndrome
- Fascial hernia
- Stress fracture
- Arterial occlusion
- Neurapraxia
- Deep venous thrombosis
- Cellulitis
- Osteomyelitis
- Tenosynovitis
- Synovitis

TREATMENT

INITIAL STABILIZATION/THERAPY

- Acutely injured extremities that are casted should have the cast univalved and spread and underlying cast padding should be cut.
- Keep the extremity at the level of the heart.

ED TREATMENT/PROCEDURES

- Acute compartment syndrome is a surgical emergency.
- Mainstay of treatment is fasciotomy, particularly for compartment pressures $> 30\text{--}40$ mm Hg.

MEDICATION

- Medications are not helpful, including steroids or vasodilators, in the treatment of compartment syndrome.
- Pain medication is essential after diagnosis is made or consultant evaluation is begun.

First Line

IV narcotic analgesics may provide some relief, although the pain is frequently so severe that only decompression in the OR can provide relief.

Second Line

Oral narcotic analgesics and nonsteroidal agents are of very little benefit acutely.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Emergent orthopedic or surgical consultation for compartment pressures > 30 mm Hg
- For compartment pressures > 20 mm Hg but < 30 mm Hg, surgical consultation should be sought and the patient admitted.
- For compartment pressures between 15 and 20 mm Hg, serial measurement of pressures should be taken; if the patient cannot be relied on to return for repeat measurements, the patient should be admitted.

Discharge Criteria

Compartment pressure $< 10\text{--}15$ mm Hg: Patients should be given symptomatic treatment and instructed to return for increased pain, swelling, development of

paresthesia.

Issues for Referral

If the clinician suspects chronic compartment syndrome, then prompt referral to orthopedic surgeon is necessary. Direct communication is best to express your concerns.

PEARLS AND PITFALLS

- Must measure compartment pressures or arrange transfer to higher level of care if capability is lacking.
- Care must be taken when measuring compartment pressures to avoid injury to tendons, nerves, and blood vessels.
- Must consider concomitant rhabdomyolysis in crush-type injuries.

CONGENITAL HEART DISEASE, ACYANOTIC

Lynne M. Palmisciano • William J. Lewander

BASICS

DESCRIPTION

Abnormality in the cardiocirculatory system that is present at birth but does not cause mixing of deoxygenated and oxygenated blood:

- L→R shunting lesions:
 - Ventricular septal defect (VSD)
 - Atrial septal defect (ASD)
 - Patent ductus arteriosus (PDA)
 - Endocardial cushion defects (AV canal)
- Ventricular outflow obstructions:
 - Coarctation of aorta (LV)
 - Aortic stenosis (LV)
 - Pulmonic stenosis (RV)
 - Hypoplastic left-heart syndrome (HLHS)
- Ductal dependent: Symptoms as DA closes:
 - Coarctation of aorta
 - Critical aortic stenosis
 - Critical pulmonic stenosis
 - HLHS

ETIOLOGY

For most forms, cause is unknown:

- Genetic: Down (AV canal), Turner (coarct)
- Environmental: Congenital rubella (PDA, AS)

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Many asymptomatic
- Lethargy, poor feeding, and failure to thrive
- Dyspnea on exertion
- Recurrent respiratory infections

Physical-Exam

- VSD and AV canal:

- Dusky color, hepatomegaly
- Holosystolic and diastolic murmurs + thrill
- Hyperdynamic precordium, displaced PMI
- ASD:
 - Fixed, split S2
 - Systolic ejection and diastolic murmurs
- PDA:
 - “Machine-like” murmur and bounding pulses
- Coarctation:
 - Differential cyanosis (pink only upper 1/2)
 - BP upper extremities > BP lower extremities
 - ↓ or absent lower-extremity pulses
- AS:
 - Harsh systolic murmur, thrill, aortic click
- PS:
 - Systolic ejection murmur, thrill, pulmonic click
 - Widely split S2
 - Jugular venous A-waves
- HLHS:
 - Dusky, listless, tachypneic, ↓ pulses
 - Single heart sound, systolic ejection murmur

ESSENTIAL WORKUP

- Oxygen saturation (pre- and postductal)
- ABG, CBC, basic chemistries, and glucose
- Sepsis evaluation
- CXR to assess pulmonary blood flow
- EKG (axis, hypertrophy, conduction delays)
- 4-extremity BPs
- Cardiology consult with ECG

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- CXR:
 - L→R shunting lesions all show cardiomegaly (specific chambers) and ↑ pulmonary markings
 - ASD (RA, RV), VSD (RV, LA), PDA (LA, LV)
 - AV canal (globular; all chambers enlarged)
- Obstructive lesions: Normal to cardiomegaly

Diagnostic Procedures/Surgery

EKG:

- ASD: Right axis deviation:
 - RVH or right bundle branch block (RBBB)
- VSD–LAH, LVH (if large, also RVH):
 - Notched or peaked P-waves (large VSD)
- PDA: Biventricular hypertrophy (large PDA)
- AV canal: Superior axis, LVH, RVH:
 - RBBB and prolonged PR interval
- AS: Normal to LVH (severe cases)
- PS: Normal to RVH, RAE (severe cases):
 - RBBB
- Coarctation of aorta: RVH or RBBB
- HLHS: RAE, RVH, peaked P-waves

DIFFERENTIAL DIAGNOSIS

- CHF
- Hypertrophic cardiomyopathy
- Cardiogenic shock
- Aortic dissection
- Myocarditis
- Bronchopulmonary dysplasia
- Pulmonary HTN
- Pneumonia/bronchiolitis
- Hypoglycemia
- Adrenal insufficiency, CAH
- Glycogen storage diseases
- Sepsis
- Shock

TREATMENT

INITIAL STABILIZATION/THERAPY

- Maintain warmth and oxygenation.
- Treat hypoglycemia and acidosis.
- Establish IV access.
- Prepare for endotracheal intubation.

ALERT

High oxygen tensions promote ductal closure.

ED TREATMENT/PROCEDURES

- Administer prostaglandin E₁ (PGE₁) to dilate or reopen the ductus arteriosus:
 - Continuous IV infusion 0.05–0.1 µg/kg/min

- Complications include apnea, bradycardia, hypotension, and seizures.
- Evaluate and treat alternate causes:
 - Septic workup and empiric antibiotics
 - Maintain normoglycemia
- Circulatory collapse from CHD:
 - Fluid resuscitation (increments of 10 mL/kg)
 - Inotropes
 - Aggressive treatment of acidosis
- CHF:
 - Digoxin and diuretics

MEDICATION

- Ampicillin 50 mg/kg IV
- Digoxin dosing requires extreme caution:
 - Range 25–40 µg/kg IV
- Dobutamine: 5–20 µg/kg/min IV
- Dopamine: 2–20 µg/kg/min IV
- Epinephrine: 0.1–2 µg/kg/min IV
- Furosemide: 1 mg/kg IV
- Gentamicin: 4 mg/kg/d IV or 2.5 mg/kg/dose
- Milrinone 0.25–1 µg/kg/min
- PGE₁: 0.05–0.1 µg/kg/min
- Sodium bicarbonate: 1–2 mEq/kg IV

FOLLOW-UP

DISPOSITION

Admission Criteria

- All newborns with suspected CHD:
 - Admit to pediatric ICU.
- CHD with acute worsening of cyanosis or CHF
- CHD with pneumonia or bronchiolitis

Discharge Criteria

Determine in consult with cardiologist

Issues for Referral

Primary care physician to coordinate care with cardiologist and cardiothoracic surgery

FOLLOW-UP RECOMMENDATIONS

Plan for follow-up should be made in consult with the pediatric cardiologist.

PEARLS AND PITFALLS

- Acyanotic lesions presenting at 2–12 wk:
 - Coarctation as DA closes
 - Septal defects as pulmonary vascular resistance drops
- Classic ECG in AV canal: Superior QRS axis
- Classic CXR in coarctation: Rib notching (late)

CONGENITAL HEART DISEASE, CYANOTIC

Lynne M. Palmisciano • William J. Lewander

BASICS

DESCRIPTION

- Aberrant embryonic development results in mixing of deoxygenated and oxygenated blood returning to systemic circulation by 2 mechanisms:
 - Right-to-left intracardiac shunt
 - Anatomic defects of the aortic root
- Subtypes: 5 T's, 2 E's, single ventricle:
 - Tetralogy of Fallot (TOF):
 - Ventricular septal defect (VSD)
 - Right ventricular (RV) outflow obstruction
 - Overriding aorta
 - RV hypertrophy (RVH)
 - Transposition of the great arteries (TGA):
 - Aorta arises from RV and pulmonary artery from left ventricle (LV)
 - Tricuspid atresia:
 - No outlet from right atrium to RV
 - Obligatory atrial level connection
 - Truncus arteriosus:
 - Single arterial trunk for systemic, pulmonic, and carotid circulations
 - Total anomalous pulmonary venous return (TAPVR):
 - Pulmonary veins drain into systemic venous circulation
 - Supracardiac, cardiac, infracardiac, or mixed
 - Ebstein anomaly of tricuspid valve:
 - Abnormal and displaced tricuspid valve divides RV resulting in poor RV function
 - Eisenmenger syndrome:
 - Complication in longstanding acyanotic heart disease with L→R shunts
 - Pulmonary vascular resistance reaches suprasystemic levels; R→L shunt
 - Single ventricle physiology:
 - Total mixing of systemic and venous return

ETIOLOGY

For most forms, cause is unknown

DIAGNOSIS

- Most common initial ED presentations of cyanotic congenital heart disease (CHD):
 - Cyanosis
 - CHF
 - Circulatory collapse
- Physiologic stress triggers cyanosis in older patients with CHD:
 - Cardiac shunt obstruction
 - Pulmonary disease
 - Decreased systemic vascular resistance
 - Fever
 - Dehydration

SIGNS AND SYMPTOMS

- Central cyanosis:
 - Visible in lips, nail beds, mucosa
 - Increases with cry or agitation
 - Minimal change with 100% O₂
- CHF:
 - Rales, gallop, hepatomegaly, scalp edema
- Hypercyanotic spells or “Tet spells”:
 - Restless and hyperpneic then increased cyanosis then syncope
 - Follows reductions in already compromised pulmonary blood flow:
 - Wakening, feeding, vigorous cry, exercise
- Older child may compensate by squatting.
- Temporary reduction or absence of systolic ejection murmur during spell

History

- Family history of CHD:
 - If parent or sibling: Increased risk of CHD
 - If 2 relatives: Risk of CHD triples
- Prenatal history:
 - Exposure to teratogens
 - Abnormal fetal ultrasound
- TOF:
 - Often asymptomatic at birth; symptoms develop as RV infundibulum hypertrophies
 - Severe RV outflow obstruction; neonatal cyanosis (duct-dependent lesion)
 - Cyanosis during crying or feeding (Tet spells) in toddlers
 - Older, uncorrected patients:
 - Dyspnea on exertion and growth delay
- Tricuspid atresia:
 - Usually cyanotic from birth
 - Feeding difficulties

- Older patients show dyspnea on exertion and easy fatigability
- Ebstein anomaly:
 - Teens may present with dysrhythmias.
- TGA:
 - Presents in 1st hr to days of life
- TAPVR:
 - Neonatal presentation; severely ill:
 - Cyanosis
 - Does not improve with mechanical ventilation
 - Infantile presentation; heart failure:
 - Mild cyanosis
 - If no obstruction to pulmonary venous return:
 - Asymptomatic or mild cyanosis
 - Frequent pneumonias
 - Growth problems
- Truncus arteriosus:
 - Mild cyanosis in newborn
 - Heart failure in older infants

Physical-Exam

- TOF:
 - Loud systolic murmur left sternal border (LSB)
 - Systolic thrill in 50%
 - +/- Continuous murmur of PDA
 - Loud, single 2nd heart sound (S2)
 - RV prominence/bulge
 - Older, uncorrected patients:
 - Dusky, blue skin
 - Clubbing of digits
 - Retinal engorgement
- Tricuspid atresia:
 - Tachypnea
 - Regurgitant murmur from VSD at LSB
 - +/- continuous PDA murmur
 - Single S2
 - Prominent LV impulse
- Ebstein anomaly:
 - Holosystolic murmur of tricuspid regurgitation
 - Many have diastolic murmur
 - Gallop
- TGA:
 - Single, loud S2
 - Severe hypoxemia

- TAPVR:
 - Neonatal; severe tachypnea and cyanosis
 - Infantile; heart failure:
 - Tachycardia
 - Systolic ejection murmur at LSB
 - Mid-diastolic murmur at lower LSB
 - Gallop
 - Fixed, split S2
 - Hepatomegaly
- Truncus arteriosus:
 - Newborn:
 - Mild cyanosis
 - Regurgitant systolic murmur at LSB
 - Single S2
- Older infants; heart failure:
 - Hyperdynamic precordium
 - Bounding pulses
 - Wide pulse pressure
 - Loud, single S2
 - Systolic ejection murmur and thrill
 - Mid-diastolic murmur

ESSENTIAL WORKUP

- Oxygen saturation
- ABG
- CBC, glucose
- Sepsis evaluation
- CXR to assess pulmonary blood flow
- EKG to assess for hypertrophy and QRS axis
- Cardiology consult and ECG

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Decreased room air oxygen saturation
- Hyperoxia test:
 - ABG in room air and after several minutes 100% oxygen:
 - $\text{PaO}_2 > 150$ in O_2 ; no intracardiac shunt
 - $\text{PaO}_2 < 100$ in O_2 ; highly suspicious of cyanotic CHD
- CBC: Erythrocytosis with chronic cyanosis

Imaging

- CXR:
 - Decreased pulmonary blood flow:
 - TOF (enlarged RV)
 - Tricuspid atresia (enlarged LV)
 - Single ventricle physiology
 - Increased pulmonary flow:
 - Transposition of the great vessels (large RV)
 - TAPVR (large RV)
 - Truncus arteriosus (large LV and RV)
 - Classic CXR descriptions:
 - Boot-shaped heart: TOF; large and upturned RV looks like toe of boot
 - Egg on a string: TGA; narrow mediastinum, great vessels anterior/posterior position
 - Snowman sign: Supracardiac TAPVR; upper portion formed by pulmonary veins

Diagnostic Procedures/Surgery

EKG:

- TOF:
 - Right axis deviation (RAD)
 - RVH
- TAPVR:
 - RAD
 - RVH and right atrial enlargement (RAE)
- Transposition of the great vessels:
 - RAD
 - RVH
- Tricuspid atresia:
 - Superior axis
 - LVH, RAE, LAE
- Truncus arteriosus:
 - RVH, LVH
- Ebstein anomaly:
 - Right bundle branch block
 - Often Wolff–Parkinson–White

DIFFERENTIAL DIAGNOSIS

- Pulmonary:
 - Pneumothorax/hemothorax
 - Bronchopulmonary dysplasia
 - Congenital lung hypoplasia/dysplasia
 - Pulmonary hemorrhage
 - Pulmonary embolus

- Pulmonary HTN
- Diaphragmatic hernia
- Foreign body/anatomic obstruction
- Cardiac:
 - Cyanotic CHD
 - CHF
 - Cardiogenic shock
- Infectious:
 - Pneumonia, bronchiolitis
 - Sepsis
- Neurologic:
 - Seizure
 - Neuromuscular disease
 - Drug-induced respiratory depression
- Other:
 - Polycythemia
 - Methemoglobinemia
 - Dehydration
 - Hypoglycemia

TREATMENT

INITIAL STABILIZATION/THERAPY

- Maintain warmth (cold \uparrow O_2 consumption).
- Treat hypoglycemia and acidosis.
- Maintain oxygenation.
- Establish IV access.
- Prepare for endotracheal intubation.

ALERT

- High oxygen tensions promote ductal closure.
- Place air filters on all IV lines to avoid paradoxical emboli through R \rightarrow L shunt.

ED TREATMENT/PROCEDURES

- Administer prostaglandin E_1 (PGE_1) to dilate or reopen the ductus arteriosus:
 - Continuous IV infusion 0.05–0.1 $\mu\text{g}/\text{kg}/\text{min}$
 - Complications include apnea, bradycardia, hypotension, and seizures:
 - Generally intubate prior to transport
 - Not effective for obstructed TAPVR:
 - May require ECMO awaiting surgery
 - Overall benefits far outweigh potential risks
- Evaluate and treat alternate causes of cyanosis:

- Septic workup and empiric antibiotics
- Fluid resuscitate (increments of 10 mL/kg)
- Maintain normoglycemia
- Patients with Tet spells:
 - Provide a calming environment.
 - Place child in knee-chest position.
 - Supplemental O₂ if not agitating to patient
 - IV or IM morphine
 - For severe cases not responding to above:
 - IV bicarbonate to treat severe acidosis
 - IV phenylephrine to ↑systemic vascular resistance and reduce R→L shunt
 - IV propranolol for β-adrenergic blockade
- Cyanosis in the older patient with known CHD:
 - 10–20 mL/kg NS IV if dehydration likely
 - Supplemental O₂ if suspicious for pulmonary diseases
 - Antipyretics for fever
 - Antibiotics for pneumonia/infectious process
- Circulatory collapse from CHD:
 - Fluid resuscitation
 - Inotropes: Dobutamine, dopamine, milrinone
 - Aggressive treatment of acidosis

MEDICATION

- Acetaminophen: 15 mg/kg PO or PR
- Ampicillin: 50 mg/kg IV
- Dobutamine: 5–20 µg/kg/min IV
- Dopamine: 5–20 µg/kg/min IV
- Gentamicin: 4 mg/kg/d IV or 2.5 mg/kg/dose
- Ibuprofen: 10 mg/kg PO (>6 mo)
- Milrinone: 0.25–1 µg/kg/min
- Morphine sulfate: 0.1 mg/kg SC, IM, or IV
- Phenylephrine: 0.5–5 µg/kg/min IV
- Propranolol: 0.1 mg/kg IV
- PGE₁: 0.05–0.1 µg/kg/min
- Sodium bicarbonate: 1–2 mEq/kg IV

FOLLOW-UP

DISPOSITION

Admission Criteria

- All newborns with suspected CHD:
 - Admit to pediatric ICU.
- CHD with acute worsening of cyanosis or CHF
- CHD with symptomatic pneumonia or respiratory syncytial virus

Discharge Criteria

- Determine in consult with cardiologist
- Patients who respond to minimal intervention (i.e., TOF patients treated noninvasively)
- Ensure close follow-up.

Issues for Referral

- Primary care physician to coordinate care
- Cardiologist for diagnosis, medical management, and ongoing monitoring
- Cardiothoracic evaluation for surgery

FOLLOW-UP RECOMMENDATIONS

- Plan for follow-up should be determined in consult with the pediatric cardiologist.
- Clear instructions for return visits, as any physiologic stress may worsen condition.

PEARLS AND PITFALLS

- Visual appearance of cyanosis requires $> 3\text{--}5$ mg/dL deoxygenated hemoglobin.
- Duct-dependent lesions:
 - Present at 2–3 wk of age
 - Sudden cyanosis or cardiovascular collapse
 - Treat with PGE1:
 - Beware apnea and hypotension

CONGESTIVE HEART FAILURE

Naomi George • Robert A. Partridge

BASICS

DESCRIPTION

- A clinical syndrome in which the heart fails to maintain adequate circulation for metabolic needs, characterized by chronic debility, acute decompensation, and high mortality.
- Acute Decompensated Heart Failure (ADHF) is a rapidly progressive failure state (hr–days)
 - Common reason for presentation to the ED
 - Usually caused by a precipitating event in which the heart does not have the reserve to compensate for the added burden
- Chronic HF is a progressive failure state (mo–yr) characterized by cardiac remodeling and neurohormonal changes, with multiple subclasses:
 - Systolic heart failure
 - Impaired contractile or pump function causing decreased ejection fraction
 - Diastolic heart failure
 - Impaired ventricular relaxation resulting in decreased cardiac filling
 - Low-output failure
 - Decreased cardiac output
 - High-output failure:
 - Normal or increased cardiac output, but insufficient to meet metabolic demands
 - Left-sided failure
 - Systolic or diastolic (or both) dysfunction of the left ventricle
 - Resultant pulmonary congestion
 - Right-sided heart failure
 - Due to either intrinsic dysfunction or secondary to left heart failure or pulmonary hypertension (cor pulmonale)
 - Hepatic enlargement, JVD, and dependent edema can occur
- CHF affects ~5.8 million Americans.
- Estimated 2012 cost of CHF is \$40 billion
- ADHF is the leading Medicare diagnosis for hospitalized patients ≥ 65 yr old.

ETIOLOGY

Underlying causes and acute precipitants

- Decreased myocardial contractility:
 - Myocardial ischemia/infarction

- Cardiomyopathy (including, alcoholic and pregnancy-related)
- Myocarditis
- Dysrhythmias
- Decreased contractile efficiency:
 - Drug related (negative inotropes)
 - Metabolic disorders
- Pressure overload states:
 - HTN
 - Valvular abnormalities
 - Arrhythmia
 - Congenital heart disease
 - Pulmonary embolism
 - Primary pulmonary hypertension, sleep apnea syndromes (right heart failure)
- Restricted cardiac output:
 - Myocardial infiltrative disease
- Volume overload:
 - Dietary indiscretion (sodium overload)
 - Drugs leading to sodium retention (glucocorticoids, NSAIDs)
 - Overload due to transfusion or IV fluid
- High demand states:
 - Hyperthyroidism, thyrotoxicosis
 - Pregnancy
 - A-V fistula
 - Beriberi (thiamine deficiency)
 - Paget disease
 - Severe anemia
 - Aortic insufficiency
- Pediatric etiologies: Volume/pressure overload lesions vs. acquired HD:
 - 1st 6 mo: VSD and PDA
 - Older children: Subvalvular aortic stenosis, coarctation
 - Acquired dysfunction: Nonspecific age of onset, including myocarditis, valvular disease, and cardiomyopathies; cocaine/stimulant abuse in adolescents

DIAGNOSIS

SIGNS AND SYMPTOMS

- Poor perfusion:
 - Fatigue, somnolence, lightheadedness
 - Palpitations, or irregular pulse
 - Shortness of breath

- Cool extremities
- Worsening renal function
- Congestion
 - Dyspnea, cough
 - Orthopnea
 - Paroxysmal nocturnal dyspnea
 - Evidence of sleep disordered breathing
 - Decreased exercise tolerance
 - Elevated JVD or abdominojugular reflex
 - Dependent edema (poor sensitivity and specificity)
 - Rales and/or wheezing, (absent in 80% with chronically elevated filling pressure due to compensatory lymphatic drainage)
 - Pleural effusion, dullness at lung bases
 - S3 gallop and/or S4.
 - Laterally displaced apical impulse
 - Hepatic enlargement/tenderness
 - Nausea
 - Ascites
- ADHF with hemodynamic instability:
 - Confusion, anxiety, syncope
 - Tachypnea
 - Tachycardia
 - Hypotension
 - Cool, pale or cyanotic extremities
 - Narrow pulse pressure or pulsus alternans
 - Cheyne–Stokes respirations

ESSENTIAL WORKUP

- The CXR is important in confirming the diagnosis and assessing severity.
- 12-hr radiographic lag from onset of symptoms may occur.
- Radiographic findings may persist for several days despite clinical improvement.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Chemistry/electrolytes:
 - Establish baseline renal function when initiating diuretics, or ACE inhibitors
 - Hyperkalemia possible with low output
 - Hyponatremia associated with poor prognosis
- CBC:
 - Anemia can cause or exacerbate failure
 - Infection can cause or exacerbate failure
- Liver function tests:

- Increase suggests hepatic congestion, or ischemia.
- Thyroid function tests:
 - Specifically in patients >65 yr old or in a-fib
- Cardiac enzymes:
 - Evaluate for ischemia or infarction
- ANA and rheumatoid factor: Suspected lupus
- Viral panel: Suspected myocarditis
- BNP:
 - Useful for distinguishing cardiac vs. pulmonary cause of dyspnea
 - BNP >500 pg/mL, HF likely (ppv 90%)
 - BNP <100 pg/mL, HF unlikely, (npv 90%)
 - BNP 100–500 pg/mL, consider PE, cor pulmonale, renal failure, or stable underlying HF.
 - REDHOT II Study: BNP levels are better than physicians at predicting which patients are more likely to have bad outcomes
 - EPs were blinded to BNP values. 78% of patients discharged from ED had BNP >400.
 - Of those discharged with a BNP >400, 90-day mortality was 9%
 - BNP levels rise with age and are affected by gender, comorbidity, and drug therapy and should not be used in isolation
 - BNP levels may be low in acute pulmonary edema (<1–2 hr) and obesity (BMI >30).
- NT-proBNP: Cleavage product of prohormone.
 - NT-proBNP >1,000 pg/mL predictive of HF
 - NT-proBNP <300 pg/mL unlikely to be HF

Imaging

- CXR:
 - Cardiomegaly (sensitive)
 - Specific signs of CHF:
 - Cephalization (vascular prominence in the upper lungs due to fluid overload)
 - Interstitial edema/Kerley B lines
 - Alveolar edema
 - Effusions (usually right sided)
 - Bilateral confluent perihilar infiltrates leading to classic butterfly pattern:
 - May be asymmetric and mistaken for pneumonia
- EKG:
 - Underlying cardiac ischemia
 - Presence of dysrhythmias
 - Left-ventricular hypertrophy
 - Heart block
 - Normal EKG has high negative predictive value for systolic dysfunction.

- 2-D Cardiac Echo:
 - Ejection fraction
 - Acute valvular pathology
 - Pericardial tamponade
 - Pericardial thickening in constrictive pericarditis
 - Ventricle dilation, or hypertrophy
 - Regional wall motion abnormalities

DIFFERENTIAL DIAGNOSIS

- Left-sided CHF:
 - Acute exacerbation of COPD
 - Asthma exacerbation
 - Acute respiratory distress syndrome
 - Pneumonia, bronchitis
 - Constrictive pericarditis
 - Anemia, malnutrition
 - Pericardial tamponade
 - Coarctation of aorta
- Right-sided HF:
 - Nephrotic syndrome, chronic renal failure
 - Cirrhosis
 - Left-side heart failure
 - Pulmonary embolism
 - Sleep disordered breathing
 - Venous stasis

TREATMENT

PRE HOSPITAL

- IV access
- Supplemental oxygen
- Cardiac monitor and pulse oximetry
- EKG
- Sublingual nitrates for active chest pain without hypotension
- Furosemide
- Endotracheal intubation may be required.

INITIAL STABILIZATION/THERAPY

- IV access
- Supplemental oxygen
- Cardiac monitor and pulse oximetry
- EKG

- Elevate head of bed to reduce venous return.
- Control airway as needed:
 - Noninvasive positive pressure ventilation
 - CPAP vs. BiPAP
 - Reduce work of breathing, improve oxygenation, decrease need for intubation, possible mortality benefit
 - Some studies report higher incidence of MI with BiPAP over CPAP in acute CHF; studies not conclusive
 - Intubation for impending respiratory failure

ED TREATMENT/PROCEDURES

- General: Oxygenate, ventilate, treat underlying condition when possible
- Congestion with adequate perfusion: Reduce preload, consider fluid restriction
 - Rapidly reduce preload in acute pulmonary edema:
 - Sublingual or IV nitroglycerin
 - Nitro paste
 - IV diuretics (less rapid/effective in patients with poor renal perfusion)
 - Avoid preload reduction in ADHF when suspected etiology is aortic stenosis, HOCM, or pulmonary hypertension.
 - Cautious afterload reduction in ADHF: Avoid ACEi and ARBs in cases of hypotension, acute renal failure, and hyperkalemia.
 - Nesiritide
 - Limited benefit, may cause hypotension
- Poor perfusion with hypotension:
 - Agents that increase contractility:
 - Dobutamine
 - Dopamine
 - Milrinone
 - Avoid vasodilators (nitrates, morphine)
 - Initiate diuretics after inotropes.
- Initiate venous thromboembolism prophylaxis in those with ADHF without contraindications

Pediatric Considerations

- Neonates (1st weeks of life):
 - Suspect ductal-dependent cardiac lesions if clinical CHF and no improvement with O₂:
 - PGE1 to maintain patent ductus
- Children:
 - IV furosemide, and dopamine or milrinone
 - IV nitroglycerin for pulmonary edema

MEDICATION

- Aspirin: 325 mg PO/PR if AMI is suspected
- Bumetanide (Bumex): 1–3 mg IV, max. 10 mg/day
- Dobutamine: 2–10 µg/kg/min IV, max. of 40 µg/kg/min
- Dopamine: 2–20 µg/kg/min IV, max. of 50 µg/kg/min
- Enalapril: 0.625–1.25 mg IV; 2.5–20 mg/d PO
- Furosemide (Lasix): No prior use: 40 mg IVP; prior use: Double 24-hr dose (80–180 mg IV); no effect in 30 min: Redouble dose
- Milrinone: 50 µg/kg IV load; 0.375–0.75 µg/kg/min IV
- Nesiritide: 2 µg/kg bolus, then infusion of 0.01 µg/kg/min
- Nitroglycerin: 0.4 mg sublingual; 1–2 in of nitro paste; 5–20 µg/min IV, max. of 100–200 µg/min IV. USE NON-PVC tubing.
- Nitroprusside: 0.3–10 µg/kg/min IV (starting dose), max. of 10 µg/kg/min

Pregnancy Considerations

ACEi and ARBs are associated with multiple fetal abnormalities and should be held

- Oxygen
- Nitroglycerin
- Furosemide

FOLLOW-UP

DISPOSITION

Admission Criteria

- ICU:
 - Pulmonary edema
 - Cardiogenic shock
 - Concomitant MI or ischemia
- Medical wards:
 - New-onset CHF
 - Symptoms not relieved by ED therapy

Discharge Criteria

- Mild exacerbation of chronic CHF:
 - Responds to ED treatment
 - No other cardiac and pulmonary findings
- Close follow-up should be arranged with continuation of diuretic, vasodilator, or ACE inhibitor therapy and patient lifestyle education.

Issues for Referral

Consider ICD and/or BV pacer in advanced HF

- Shown to decrease mortality and hospitalization rates in select patient groups

FOLLOW-UP RECOMMENDATIONS

- Close follow-up within 1 wk of discharge
- Medication and dietary compliance
- Frequent home monitoring of body weight
- Monitor electrolytes and renal function during chronic diuretic therapy

PEARLS AND PITFALLS

- BNP may be useful if CHF diagnosis uncertain.
- In severe CHF, NIPPV can improve impending respiratory compromise.
- Be vigilant in searching for and treating the underlying cause of the heart failure exacerbation (e.g., MI, PE, valvular pathology).

CONJUNCTIVITIS

Jessica Freedman

BASICS

DESCRIPTION

Inflammation of the conjunctiva arising from a broad group of etiologies. Commonly referred to as “pink eye.”

ETIOLOGY

- Bacterial:
 - *Staphylococcus aureus*
 - *Streptococcus pneumoniae*
 - *Haemophilus influenzae*
 - Gonococcal:
 - Ophthalmic emergency
 - Chlamydia:
 - Transmission occurs via autoinoculation from genital secretions.
 - Often occurs in newborns
- Viral:
 - Adenovirus most common
 - Epidemic keratoconjunctivitis (EKC) is caused by adenovirus subtypes.
 - Frequently associated with upper respiratory infections or exposure to someone with a red eye
 - Most commonly referred to as “pink eye”
 - Herpes simplex virus (HSV)
 - Recurrent ocular infection occurs in 25% patients within 2 yr.
 - Use of steroids is contraindicated:
 - Allergic
 - Frequent history of allergy, atopy, nasal symptoms
 - Contact related
 - May be due to chemical irritation, hypersensitivity from preservatives, medications, shampoo, chlorine, dust, smoke
 - Pseudomonas commonly implicated organism:
 - May be found in patients using saliva to clean contact lenses

DIAGNOSIS

SIGNS AND SYMPTOMS

- General:
 - Red eye (conjunctival irritation)

- Gritty, foreign body sensation
- Sensation of eyes burning
- Discharge
- Eyelid sticking (worse upon awakening)
- Conjunctival edema (chemosis) and eyelid edema
- Itchy eyes
- Increased tearing
- Bacterial:
 - Mucopurulent or purulent discharge
- Gonococcal:
 - Hyperacute, copious purulent discharge:
 - Discharge starts 12 hr after inoculation.
 - Severe chemosis
 - Eyelid swelling
 - Preauricular lymphadenopathy typically absent
 - Invades intact conjunctiva and cornea within 24 hr and causes ulcerations, scarring, and perforations leading to blindness
- Chlamydia:
 - Lacrimation
 - Mucopurulent discharge
 - With or without photophobia
 - Concomitant genital infection (> 50%)
 - Transmission occurs via autoinoculation from genital secretions
- Viral—general:
 - Preauricular adenopathy
- Viral syndrome:
 - Watery, mucous discharge, lacrimation
 - Gritty feeling or foreign body sensation in eye
 - Spreads to other eye in 24–48 hr
 - Pinpoint subconjunctival hemorrhages:
 - Tarsal conjunctiva may have a bumpy appearance.
- EKC:
 - Conjunctival hyperemia
 - Chemosis
 - Corneal infiltrates
 - Decreased vision
- HSV:
 - Acute follicular conjunctival reaction
 - Skin lesions or vesicles along eyelid margin or periocular skin
 - Corneal involvement—dendritic lesion
- Herpes zoster virus (HZV):
 - Associated with pain or paresthesia of the skin
 - Rash or vesicles involving the distribution of cranial nerve V1

- Dendritic characters on cornea
- Rarely vesicles or ulcers form on the conjunctiva.
- Allergic:
 - Hallmark: Itching
 - Red conjunctiva
 - Watery discharge
 - Papillary hypertrophy
 - Frequent history of allergy, atopy, nasal symptoms
- Contact related:
 - Acute symptoms result of corneal ulceration
 - Normal visual acuity and intraocular pressures

ESSENTIAL WORKUP

- History for:
 - Onset of inflammation
 - Environmental or work-related exposure
 - Ill contacts
 - Sexual activity, discharge, rash
 - Use of over-the-counter medicines or cosmetics
 - Systemic diseases
- Careful physical exam including slit-lamp exam including fluorescein staining

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Bacteriologic studies:
 - Not indicated in routine cases
 - Indications:
 - Ophthalmia neonatorum (except chemical)
 - Suspected gonococcal ophthalmia
 - Compromised host
 - Signs and symptoms of systemic disease
 - Refractory to treatment within 48–72 hr (with good compliance)
- Positive Gram stain for gram-negative intracellular diplococci:
 - Sufficient to initiate systemic and topical treatment for gonococcal disease
- Rapid plasma reagent (RPR):
 - For suspected cases of sexually transmitted disease

DIFFERENTIAL DIAGNOSIS

- Acute angle-closure glaucoma (most serious cause)
- Allergies or hypersensitivity
- Anterior uveitis
- Corneal abrasion

- Dry eye
- Foreign body
- Keratitis
- Nasolacrimal obstruction
- Scleritis or episcleritis
- Subconjunctival hemorrhage

TREATMENT

INITIAL STABILIZATION/THERAPY

- Initiate empiric antibiotic therapy with broad-spectrum topical agent.
- Systemic therapy for gonococcal, chlamydial, and meningococcal conjunctivitis, ophthalmia neonatorum, and all severe infections regardless of cause
- Manage herpetic eye infections in consultation with an ophthalmologist.

ED TREATMENT/PROCEDURES

- Remove discharge from the eye(s):
 - _ Contact lens wearers should discontinue use and throw away affected contact lenses.
 - _ Contact lens wearers should discontinue use until:
 - Eye is white.
 - Antibiotic therapy is completed.
 - No discharge for 24 hr
 - _ Frequent handwashing
 - _ No sharing of towels, tissues, cosmetics, linens
 - _ Frequent warm soaks until lashes and eyes free of debris
- Bacterial conjunctivitis:
 - _ Antibiotics—topical:
 - _ Can use ointment or drops
 - _ Continue therapy for 48 hr after clearing of symptoms.
 - _ Discontinue therapy and obtain cultures if no improvement in 48–72 hr (with good compliance).
- Antibiotics—systemic:
 - _ Parenteral therapy mandatory for gonococcal infection
 - _ Chlamydia requires systemic treatment of sexual partners and parents of neonates.
- Viral conjunctivitis:
 - _ No specific antiviral therapy
 - _ Limited use of topical antihistamine or decongestant
- EKC may require steroids and should be prescribed in consult with ophthalmology.
- Allergic conjunctivitis (there may be a lag time of up to 2 wk for improvement with these agents):

- Antihistamine or decongestant drops (naphazoline [Naphcon-A])
- Mast cell stabilizer/antihistamine or NSAID ophthalmic drops as 2nd line
- Artificial tears
- Noninfectious:
 - Eye lubricant drops or ointment
- Empiric treatment:
 - Topical antibiotic ointment or drops

MEDICATION

- General:
 - All contact lens wearers require pseudomonal coverage.
 - Bacterial:
 - Bacitracin ophthalmologic ointment (no pseudomonal coverage)
 - Ciprofloxacin: 0.35% 1 drop q1–6h (has antipseudomonal properties; may be used in children)
 - Erythromycin: 0.5% ointment
 - Gentamicin: 0.3% ointment q3–4h or drops q1–4h (has antipseudomonal coverage)
 - Sulfacetamide: 10% 1 drop q1–6h (lacks pseudomonal coverage)
 - Tobramycin ointment
- Chlamydia:
 - Doxycycline: 100 mg PO BID for 3 wk
 - Erythromycin: 250–500 mg PO QID for 3 wk (peds: 50 mg/kg/d PO in 4 div. doses for 14 days)
 - Sulfisoxazole 500–1,000 mg QID for 3 wk
- Gonococcal:
 - Adults:
 - Ceftriaxone: 1 g IV or IM daily for 3–5 days or PRN
 - Erythromycin: 500 mg PO QID for 2–3 wk or doxycycline 100 mg PO BID for 2–3 wk
 - + topical antibiotics as above
 - Neonates:
 - Penicillin G 100,000 U/kg/d in 4 div. doses for 7 days or ceftriaxone 25–50 mg/kg/d IV for 7 days
- Viral:
 - Artificial tears
 - Naphcon-A or Visine AC 1 or 2 drops QID PRN for no more than 1 wk
- HSV or HZV:
 - Trifluorothymidine: 1% 5 times per day
 - Vidarabine: 3% ointment 5 times per day
- Allergic:
 - Naphazoline (Naphcon-A): 1 drop BID–QID or Visine AC
 - Acular: 1 or 2 drops BID

- Cromolyn sodium 4% (Crolom): 1 drop QID
- Noninfectious and nonallergic:
 - Eye lubricant drops or ointment: Artificial tears or Lacri-Lube
- Empiric treatment:
 - Erythromycin ointment 0.5% (half in QID)
 - Sulfacetamide 10% ophthalmic drops (1 or 2 drops QID) for 5–7 days

Pediatric Considerations

- Often a manifestation of systemic disease in infants
- Conjunctivitis in the 1st 36 hr of life usually chemically induced caused by silver nitrate applied at birth.
- Neonates become infected during passage through the birth canal.
- Gonococcal, herpetic, chlamydial organisms most common
- Ophthalmia neonatorum is conjunctivitis within the 1st 4 wk of life.
- Chlamydia trachomatis is not eradicated by silver nitrate.
- Some newborns treated with erythromycin still develop conjunctivitis.
- Ointment is preferred over drops because of difficulty with administration of drops.

FOLLOW-UP

DISPOSITION

Admission Criteria

Known or suspected gonococcal infection (any age group)

Discharge Criteria

Close follow-up for all cases

Issues for Referral

Diagnosis of EKC and bacterial conjunctivitis requires ophthalmology referral.

FOLLOW-UP RECOMMENDATIONS

All patients with bacterial conjunctivitis require ophthalmology follow-up.

PEARLS AND PITFALLS

- Be sure to disinfect slit lamp and chair used for patients to avoid contamination.
- Conjunctivitis is extremely contagious.
- Viral conjunctivitis contagious for up to 2 wk.
- EKC is especially contagious.
- Extreme caution should be taken when using corticosteroids, as they may worsen

an underlying HSV infection.

CODES

ICD9

- 077.99 Unspecified diseases of conjunctiva due to viruses
- 372.03 Other mucopurulent conjunctivitis
- 372.30 Conjunctivitis, unspecified

ICD10

- B30.9 Viral conjunctivitis, unspecified
- H10.029 Other mucopurulent conjunctivitis, unspecified eye
- H10.9 Unspecified conjunctivitis

CONSTIPATION

Julia H. Sone

BASICS

DESCRIPTION

Rome Criteria for the diagnosis of constipation requires 2 or more of the following for at least 3 mo:

- Straining > 25% of the time
- Hard stools > 25% of the time
- Incomplete evacuation > 25% of the time
- 2 or fewer bowel movements per wk

Pediatric Considerations

- 3% of pediatric outpatient visits are because of defecation disorders.
- Children with cerebral palsy often develop functional constipation.
- Can be classified into subgroups:
 - Constipation with anatomical origins (anal stenosis/strictures, ectopic anus, imperforate anus, sacrococcygeal teratomas)
 - Colonic neuromuscular disease (Hirschsprung disease)
 - Defecation disorders (functional constipation and nonretentive fecal soiling)
 - Function fecal retention
- Most common cause of fecal retention and soiling in children is functional fecal retention:
 - Caused by fears associated with defecation
 - Associated with irritability, abdominal cramps, decreased appetite, early satiety

ETIOLOGY

- Metabolic and endocrine:
 - Diabetes
 - Uremia
 - Porphyria
 - Hypothyroidism
 - Hypercalcemia
 - Pheochromocytoma
 - Panhypopituitarism
 - Pregnancy
- Functional and idiopathic:
 - Colonic irritable bowel syndrome
 - Diverticular disease

- Colonic inertia
- Megacolon/megarectum
- Pelvic intussusception
- Nonrelaxing puborectalis
- Rectocele/sigmoidocele
- Posthysterectomy syndrome
- Descending perineum
- Pharmacologic:
 - Analgesics
 - Anesthetics
 - Antacids
 - Anticholinergics
 - Anticonvulsants
 - Antidepressants
 - Antihypertensives
 - Calcium channel blockers
 - Diuretics
 - Ferrous compounds
 - Laxative abuse
 - MAOIs
 - Opiates
 - Paralytic agents
 - Parasympatholytics
 - Phenothiazines
 - Psychotropics
- Neurologic:
 - Central Parkinson disease
 - Multiple sclerosis
 - Cerebrovascular accidents
 - Spinal cord lesions/injury
 - Peripheral Hirschsprung disease
 - Chagas disease
 - Neurofibromatosis
 - Autonomic neuropathy
- Mechanical obstruction:
 - Neoplasm
 - Stricture
 - Hernia
 - Volvulus

SIGNS AND SYMPTOMS

- Constipation is a symptom, not a disease.
- Passage of hard stool
- Straining/difficulty passing stool
- Infrequent bowel movements
- Abdominal distention/bloating
- Firm/hard stool on digital rectal exam:
 - May have empty rectal vault
- Diarrhea (liquid stool passes around firm feces)

History

- Age of onset of symptoms
- Diet and exercise regimen
- Stool size, caliber, consistency, frequency, ease of defecation
- Medical and surgical history:
 - Medications that can slow colonic transit like β -blockers, high-dose calcium channel blockers, narcotics
- Use of enemas, laxatives, and digital manipulation to facilitate defecation
- Associated pelvic floor dysfunction:
 - Urinary symptoms
 - Rectocele

Physical-Exam

- Abdominal exam may reveal a mass due to stool
- Rectal exam to assess for outlet obstruction:
 - Ability to squeeze and relax the sphincter
 - Is there a rectocele or cystocele?
 - Assess firmness of stool

ESSENTIAL WORKUP

Thorough history and physical exam:

- Medical, surgical, and psychiatric investigation and date of onset
- Note abdominal distention, hernias, tenderness, or masses
- Complete anorectal exam for anal stenosis, fissure, neoplasm, sphincter tone, perineal descent, tenderness, spasm

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Only necessary when considering metabolic/endocrine disorders
- CBC if inflammatory or neoplastic origin
- Electrolytes and calcium indicated if at risk of:
 - Hypokalemia

- Hypocalcemia
- Thyroid function test if patient appears to be hypothyroid

Imaging

- Rarely indicated unless an underlying process suspected
- Abdominal radiograph:
 - Large amount of feces in colon
 - Dilated colon that needs decompression
- CT scan of abdomen/pelvis to r/o perforation in elderly, constipated patient with abdominal pain/fever
- Barium/Gastrografin enema study:
 - Diverticulosis
 - Megarectum
 - Megacolon
 - Hirschsprung disease
 - Stricture from inflammation or tumor

DIFFERENTIAL DIAGNOSIS

- See “Etiology.”
- Bowel obstruction

TREATMENT

PRE HOSPITAL

Establish IV access for patients with significant abdominal pain.

INITIAL STABILIZATION/THERAPY

IV fluids for dehydrated/hypotensive patients

ED TREATMENT/PROCEDURES

- Clean out colon:
 - Enemas, suppositories
 - Manual disimpaction of hard stool
 - Laxatives
- Maintain bowel regimen:
 - Increase noncaffeinated fluids (8–10 cups per day).
 - Increase dietary fiber intake (20 g/day).
 - Stool softeners
 - Exercise
 - Change medications causing constipation.

MEDICATION

- Enemas:

- Fleet: 120 mL (peds: 60–120 mL) per rectum (PR)
- Mineral oil: 60–150 mL (peds: 5–11 yr old, 30–60 mL; older than 12 yr, 60–150 mL) PR daily
- Tap water: 100–500 mL PR
- Fiber supplements:
 - Methylcellulose: 1 tbs in cup water PO daily to TID
 - Psyllium: 1–2 tsp in cup of water/juice (peds: Younger than 6 yr, 1/4–1/2 tsp in 2 oz water or juice; 6–11 yr, 1/2–1 tsp in 4 oz water or juice; older than 12 yr, 1–2 tsp in cup water or juice) PO daily to TID
- Laxatives (osmotic):
 - Lactulose: 15–30 mL (peds: 1 mL/kg) PO daily to BID
 - Polyethylene glycol: 17 g (peds: 0.8 g/kg/d dissolved in 4–8 oz of liquid) PO daily dissolved in liquid
 - Milk of magnesia: 2400–4800 mg Mg hydroxide po (peds 6 mo–1 yr: 40 mg/kg Mg hydroxide; 2–5 yr: 400–1200 mg Mg hydroxide; 6–11 yr: 1200–2400 mg Mghydroxide; over 12 yrs: 2400–4800 mg Mg hydroxide) QD or divided bid–qid prn
- Laxatives (stimulant):
 - Bisacodyl: 10–15 mg PO daily (peds: Younger than 3 yr, 5 mg PR daily; 3–12 yr, 5–10 mg PO/PR daily; older than 12 yr, 5–15 mg PO daily or 10 mg PR daily)
 - Senna: 2 tabs PO daily to BID (peds: 2–6 yr, 1/2–1 tab PO daily to BID; 6–12 yr, 1–2 tabs PO daily to BID; older than 12 yr, 2–4 tabs PO daily to BID)
- Stool softeners:
 - Docusate sodium: 100 mg (peds: 3–5 mg/kg/d in div. doses) PO daily to BID
 - Mineral oil: 15–45 mL (peds: 5–15 mL) PO daily
- Suppositories:
 - Glycerin: 1 adult (peds: Infant, 1 infant suppository) PR PRN

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with severe abdominal pain, nausea, and emesis
- Neurologically impaired, elderly, morbidly obese who cannot be cleaned out in the ED or home
- Bowel obstruction/peritonitis

Discharge Criteria

- No co-morbid illness requiring admission
- Pain free

- Adequately cleaned out

Issues for Referral

GI follow-up for further evaluation and treatment

FOLLOW-UP RECOMMENDATIONS

Primary care or GI follow-up for patients with longstanding constipation

PEARLS AND PITFALLS

- Advise patients regarding appropriate dietary and lifestyle changes to decrease incidence of constipation.
- Perform thorough history and physical exam to exclude significant medical or surgical etiologies for constipation.

- K59.8 Other specified functional intestinal disorders

CONTACT DERMATITIS

Erik Adler • Jeffrey Druck

BASICS

DESCRIPTION

- Irritant:
 - Immediate eczematous eruption (superficial inflammatory process primarily in epidermis)
 - Most common type of dermatitis
 - Trigger substance itself directly damages the skin resulting in nonimmunologic inflammatory reaction with erythema, dryness, cracking, or fissuring
 - Usually owing to repeated exposure to mild irritant (e.g., water, soaps, heat, friction)
 - Lesions itch or burn:
 - Usually gradual onset with indistinct borders
 - Most often seen on hands
 - May see vesicles or fissures
 - Dry, red, and rough skin
 - Common irritants include cement, hair dyes, wet diapers, rubber gloves, shampoos, frequent hand washing
- Allergic:
 - Delayed (type IV) hypersensitivity reaction (requires prior sensitization)
 - Allergen-induced immune response
 - Local edema, vesicles, erythema, pruritus, or burning
 - Usually corresponds to exact distribution of contact (e.g., watchband)
 - Onset usually within 12–48 hr with prior sensitization; may take 14–21 days for primary exposure
 - Common sources: Nickel, gold, neomycin, bacitracin, preservatives, fragrances, dyes, poison ivy
- Photocontact:
 - Interaction between an otherwise harmless substance on the skin and UV light
 - Common sources: Shaving lotions, sunscreens, sulfa ointments, perfumes.

Pediatric Considerations

- Allergic contact dermatitis is less frequent in children, especially infants, than in adults
- Major sources of pediatric contact allergy:
 - Metals, shoes, preservatives, or fragrances in cosmetics, topical medications,

and plants

- Diaper dermatitis: Prototype for irritant contact dermatitis in children
- Circumoral dermatitis: Seen in infants and small children; may result from certain foods (irritant or allergic reaction)

ETIOLOGY

- Irritant (80% of contact dermatitis), e.g.:
 - Soaps, solvents
 - Chemicals
 - Certain foods
 - Urine, feces
 - Diapers
 - Continuous or repeated exposure to moisture (hand washing)
 - Course paper, glass, and wool fibers
 - Shoe dermatitis: Common; identify by lesions limited to distal dorsal surface of foot usually sparing the interdigital spaces
- Allergic:
 - Plants, poison ivy, oak, sumac (rhus dermatitis):
 - Most common form of allergic contact dermatitis in North America
 - Direct: Reaction to oleoresin urushiol from plant
 - Indirect: Contact with pet or clothes with oleoresin on surface or fur or in smoke from burning leaves
 - Lesions may appear up to 3 days after exposure with prior sensitization (12–21 days after primary exposure) and may persist up to 3 wk
 - Fluid from vesicles is not contagious and does not produce new lesions
 - Oleoresin on pets or clothes remains contagious until removed
 - Cement (prolonged exposure may result in severe alkali burn)
 - Metals (especially nickel)
 - Solvents, epoxy
 - Chemicals in rubber (e.g., elastic waistbands) or leather
 - Lotions, cosmetics
 - Topical medications (e.g., neomycin, hydrocortisone, benzocaine, paraben)
 - Some foods
 - Ability to respond to certain antigens is probably genetically determined
- Photodermatitis:
 - Inflammatory reaction from exposure to irritant (frequently plant sap) and sunlight
 - Typically no response in absence of sunlight

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Date of onset
- Time course
- Pattern of lesions
- Relationship to work
- Pruritic or not
- Mucosal involvement
- Exposure to new products (e.g., lotions, soaps, and cosmetics), foods, medications, and jewelry

Physical-Exam

- Special attention to character and distribution of rash
- *Acute lesions*: Skin erythema and pruritus:
 - May see edema, papules, vesicles, bullae, serous discharge, or crusting
- *Subacute*: Vesiculation less pronounced
- *Chronic lesions*: May see scaling, lichenification, pigmentation, or fissuring with little to no vesiculation; may have characteristic distribution pattern

DIAGNOSIS TESTS & INTERPRETATION

Lab

No specific tests in ED are helpful.

Imaging

No specific tests in ED are helpful

Diagnostic Procedures/Surgery

- Patch testing:
 - Generally not done in ED; refer to allergist/immunologist
- When tinea is suspected, may use Wood lamp for fluorescence

DIFFERENTIAL DIAGNOSIS

- Atopic dermatitis: Associated with family history of atopy
- Seborrheic dermatitis: Scaly or crusting “greasy” lesions
- Nummular dermatitis: Coin-like lesions
- Intertrigo: Dermatitis in which skin is in apposition (axillae, groin area)
- Infectious eczematous dermatitis: Dermatitis with secondary bacterial infection, usually *Staphylococcus aureus*
- Cellulitis: Warm, blanching, painful lesion
- Impetigo: Yellow crusting

- Scabies: Intensely pruritic, frequently interdigital with tracks
- Psoriasis: Silvery adherent, scaling, lesions well delineated, affecting extensor surfaces, scalp, and genital region
- Herpes simplex: Groups of vesicles, painful, burning
- Herpes zoster: Painful, follows dermatomal pattern
- Bullous pemphigoid: Diffuse bullous lesions
- Tinea: Maximal involvement at margins, fluoresces under Wood lamp
- Pityriasis alba: Discrete, asymptomatic, hypopigmented lesions
- Urticaria: Pruritic raised lesions (wheal) frequently with surrounding erythema (flare)
- Acrodermatitis enteropathica: Vesiculobullous lesion of hands and feet, associated with failure to thrive, diarrhea, and alopecia
 - Due to zinc deficiency
- Dyshidrotic dermatitis (eczema)
 - Drug rash
 - Stevens–Johnson syndrome (SJS)
 - Toxic epidermal necrolysis (TEN)
 - Erythema nodosum (EN)

TREATMENT

INITIAL STABILIZATION/THERAPY

Rarely required in absence of concomitant pathology

ED TREATMENT/PROCEDURES

General:

- Primarily symptomatic
- Wash area with mild soap and water
- Remove or avoid offending agent (including washing clothes)
- Cool, wet compresses; especially effective during acute blistering phase
- Antipruritic agents:
 - Topical:
 - Calamine lotion, corticosteroids (do not penetrate blisters); avoid benzocaine or hydrocortisone-containing products, which may further sensitize skin
 - Systemic: Antihistamines, corticosteroids
- Aluminum acetate (Burrows) solution: Weeping surfaces

Irritant dermatitis:

- Remove offending agent
- Wash well with soap and warm water
- Decrease wet/dry cycles (hand washing)
 - Alcohol-based cleansers decrease repetitive trauma

- Bland emollient
- Topical steroids for severe cases (ointment preferred), medium to high potency (hands), BID for several weeks

Allergic dermatitis:

- Topical steroids (ointment preferred) BID for 2–3 wk:
 - Face: Low potency
 - Arms, legs, and trunk: Medium potency
 - Hands and feet: High potency
- Oral steroids for severe cases

Rhus dermatitis:

- Follow general measures plus:
 - Wash all clothes and pets that have come in contact with the plant; oil persists and is contagious
 - Oatmeal baths can provide soothing relief
 - Aseptic aspiration of bullae may relieve discomfort
 - Severe reaction (>10% TBSA): Systemic corticosteroids for 2–3 wk with gradual taper:
 - Premature termination of corticosteroid therapy may result in rapid rebound of symptoms

Shoe dermatitis:

- Follow general measures plus:
 - Wear open-toe, canvas, or vinyl shoes.
 - Control perspiration: Change socks, use absorbent powder.

Diaper dermatitis:

- Follow general measures plus:
 - Topical zinc oxide, petrolatum ointment, or aquaphor
 - Change diapers after each soiling

MEDICATION

Systemic:

- Antihistamine (H₁-receptor antagonist, 1st and 2nd generation):
 - Cetirizine: Adults and children >6 yr, 5–10 mg PO daily (peds: Age 2–6 yr, 2.5 mg PO daily BID)
 - Diphenhydramine hydrochloride: 25–50 mg IV/IM/PO q6h PRN (peds: 5 mg/kg/24h div. q6h PRN)
 - Fexofenadine: 60 mg PO BID or 180 mg PO daily (peds: Age 6–12 yr, 30 mg PO BID)
 - Hydroxyzine hydrochloride: 25–50 mg PO IM up to QID PRN (peds: 2 mg/kg/24h PO div. q6h or 0.5 mg/kg IM q4–6h PRN)
 - Loratadine: 10 mg PO BID
 - For refractory pruritus: Doxepin: 75 mg PO daily may be effective.
- Corticosteroid:
 - Prednisone: 40–60 mg PO daily (peds: 1–2 mg/kg/24h, max. 80 mg/24h)

div. daily/BID

- For refractory pruritis:
 - Doxepin: 75 mg PO daily may be effective.

Topical:

- Aluminum acetate (Burrows) solution: Apply topically for 20 min TID until skin is dry.
- Calamine lotion: q6h PRN
- Topical corticosteroid: Triamcinolone ointment 0.025, 0.1%; cream 0.025, 0.1%; lotion 0.025, 0.1% TID or QID daily
 - Caution: Do not apply to face or eyelids

First Line

- Topical steroids
- Oral antihistamines

Second Line

Oral steroids

FOLLOW-UP

DISPOSITION

Admission Criteria

Rarely indicated unless severe systemic reaction or significant secondary infection

Discharge Criteria

- Symptomatic relief
- Adequate follow-up with primary care physician or dermatologic specialist

FOLLOW-UP RECOMMENDATIONS

- Follow up with primary care physician in 2–3 days for recheck
- Return to ED for: Facial swelling, difficulty breathing, mucosal involvement causing decreased PO intake

PEARLS AND PITFALLS

- Remove offending agent
- Beware of progression to systemic anaphylaxis (e.g., latex allergy)
- Watch out for concurrent bacterial infections
- Rhus dermatitis wounds are no longer contagious after washed with soap and water:
 - Be sure to wash all clothes and animals that have come in contact with

plant as oil remains contagious.

COR PULMONALE

Richard E. Wolfe

BASICS

DESCRIPTION

Right ventricular hypertrophy (RVH) or dilation caused by elevated pulmonary artery pressure. RVH due to a *systemic* defect or congenital heart disease is not classified as cor pulmonale.

- Acute cor pulmonale:
 - Right ventricle is dilated and muscle wall stretched thin
 - Overload due to acute pulmonary hypertension (HTN)
 - Most often caused by massive pulmonary embolism
- Chronic cor pulmonale:
 - RVH with eventual dilation and right-sided heart failure
 - Caused by an adaptive response to chronic pulmonary HTN
 - Predominately occurs as a result of alveolar hypoxia
- The pulmonary circulation is a low-resistance, low-pressure system:
 - The pulmonary arteries are thin walled and distensible
 - Mean pulmonary arterial pressure is usually 12–15 mm Hg
 - Normal left arterial pressure is 6–10 mm Hg
 - The resulting pressure difference driving the pulmonary circulation is only 6–9 mm Hg
- 3 factors affect pulmonary arterial pressure:
 - Cardiac output
 - Pulmonary venous pressure
 - Pulmonary vascular resistance
- Pulmonary HTN can arise through a number of mechanisms:
 - A marked increase in cardiac output
 - Left-to-right shunt secondary to congenital heart disease
 - Hypoxia:
 - The most common cause of increased pulmonary vascular resistance
 - Hypoxic pulmonary vasoconstriction is an adaptive vasomotor response to alveolar hypoxia
 - A compensatory rise in pressure is seen in the pulmonary arterial system, so flow is maintained across the pulmonary vascular bed.
 - Pulmonary embolus causes a similar change by increasing resistance to pulmonary blood flow
 - Dramatic rises in blood viscosity or intrathoracic pressure also impede blood flow
- Pulmonary HTN is classified into 5 groups

- Group 1: Pulmonary arterial HTN
- Group 2: Pulmonary HTN owing to left heart disease
 - o RV dysfunction in this category is not considered cor pulmonale
- Group 3: Pulmonary HTN owing to lung diseases and/or hypoxia
- Group 4: Chronic thromboembolic pulmonary HTN
- Group 5: Pulmonary HTN with unclear multifactorial mechanisms

EPIDEMIOLOGY

Incidence

- ~86,000 patients die from COPD each yr:
 - Associated RV failure is a significant factor in many of these cases, and accounts for 10–30% of heart failure admissions in US.
- In patients >50 yr with COPD, 50% develop pulmonary HTN and are at risk of developing cor pulmonale.
- The course of cor pulmonale is generally related to the progression of the underlying disease process.
- Once cor pulmonale develops, patients have a 30% chance of surviving 5 yr.

ETIOLOGY

- Chronic hypoxia
 - COPD
 - High-altitude dwellers
 - Sleep apnea
 - Chest deformities
 - o Kyphoscoliosis
- Pulmonary embolism
- Interstitial lung disease
 - Scleroderma
 - Systemic lupus erythematosus
 - Mixed connective tissue disease
 - Sarcoidosis
 - Pulmonary Langerhans cell histiocytosis
 - Neurofibromatosis type
 - Lymphangioleiomyomatosis
- Cystic fibrosis
- Severe anemia
- Obesity
- Pulmonary veno-occlusive disease
- Pulmonary vascular obstruction secondary to tumors or adenopathy
- Increased blood viscosity:
 - Polycythemia vera
 - Leukemia

- Increased intrathoracic pressure:
 - Mechanical ventilation with positive end-expiratory pressure
- Idiopathic primary pulmonary HTN

DIAGNOSIS

SIGNS AND SYMPTOMS

- Exertional dyspnea
- Easy fatigability
- Weakness
- Exertional syncope
- Cough
- Hemoptysis
- Exertional angina even in the absence of coronary disease
- Anorexia
- Right upper quadrant discomfort
- Wheezing
- Hoarseness
- Weight gain
- Hepatomegaly
- Ascites
- Peripheral edema

End-stage cor pulmonale

- Cardiogenic shock
- Oliguria
- Cool extremities
- Pulmonary edema secondary to intraventricular septum impairing left ventricular diastolic function

History

- Exercise intolerance
- Palpitations
- Chest pain
- Lightheadedness
- Syncope
- Swelling of the lower extremities

Physical-Exam

- Jugular venous distention:
 - Prominent A- and V-waves
- Increase in chest diameter
- Crackles and/or wheezes

- Left parasternal heave on cardiac palpation
- Splitting of the 2nd heart sound or murmurs of the pulmonary vasculature may be heard.
- Hepatojugular reflex and pulsatile liver
- Pitting edema of the lower extremities

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Pulse oximetry or ABG:
 - Resting PO₂ 40–60 mm Hg
 - Resting PCO₂ often 40–70 mm Hg
- Hematocrit:
 - Frequently elevated
- B-natriuretic peptide:
 - When elevated, is sensitive for moderate to severe pulmonary HTN, and may be an independent predictor of mortality
 - Elevated level alone is not enough to establish diagnosis of cor pulmonale.
- Other lab tests are not generally useful.

Imaging

- CXR:
 - Signs of pulmonary HTN:
 - Large pulmonary arteries (> 16–18 mm)
 - An enlarged RV silhouette
 - Shows abnormalities in > 90% of patients in the detection of cor pulmonale, but does not indicate the severity of disease
 - Pleural effusions do not occur in the setting of cor pulmonale alone.
- EKG:
 - Right-axis deviation
 - Right bundle branch block
 - RVH
 - Dominant R-wave in V1 and V2
 - Prominent S-wave in V5 and V6
 - Small R-waves and deep S-waves across the precordium
 - Right atrial enlargement
 - Tall, peaked P-waves (P pulmonale)
 - S1Q3 pattern with acute cor pulmonale
 - Transient changes due to hypoxia
 - Right precordial T-wave flattening
- Echocardiography
 - The noninvasive diagnostic method of choice

- RV dilation or RVH
- Assessment of tricuspid regurgitation
- Doppler quantization of pulmonary artery pressure, RV ejection fraction
- Chest CT, ventilation/perfusion scans, or pulmonary angiography:
 - Useful in the setting of acute cor pulmonale
- Magnetic resonance imaging
 - Superior to echocardiography for assessment of right ventricular size and function
- Pulmonary function tests
 - Impaired diffusion capacity due to pulmonary HTN
- Right-heart catheterization:
 - The most precise estimate of pulmonary vascular hemodynamics
 - Gives accurate measurements of pulmonary arterial pressure and pulmonary capillary wedge pressure

DIFFERENTIAL DIAGNOSIS

- Primary disease of the left side of the heart
 - Mitral stenosis
- Congenital heart disease
 - Eisenmenger syndrome
 - Left to right shunt caused by a congenital heart defect in the fetal heart causes increased flow through the pulmonary vasculature, causing pulmonary HTN
- Hypothyroidism
- Cirrhosis

TREATMENT

PRE HOSPITAL

- Supportive therapy:
 - Supplemental oxygen
 - To an endpoint of 90% arterial saturation
- - IV access
 - Cardiac monitoring
 - Pulse oximetry
- Treat bronchospasm from associated respiratory disease:
 - β -Agonist nebulizers
- Caution:
 - Vasodilators and diuretics do not have a role in the field.
 - Severely hypoxic patients may require endotracheal intubation.

INITIAL STABILIZATION/THERAPY

ED therapy is directed at the underlying disease process and reducing pulmonary HTN.

ED TREATMENT/PROCEDURES

- Supplemental oxygen sufficient to raise arterial saturation to 90%:
 - Improving oxygenation reduces pulmonary arterial vasoconstriction and RV afterload.
 - The improved cardiac output enhances diuresis of excess body water.
 - Care must be taken to monitor the patient's ventilatory status and PCO_2 , as hypercapnia may reduce respiratory drive and cause acidosis.
- Diuretics, such as furosemide, may be added cautiously to reduce pulmonary artery pressure by contributing to the reduction of circulating blood volume:
 - Be wary of volume depletion and hypokalemia
- Patients should be maintained on salt and fluid restriction.
- There is no role for digoxin in the treatment of cor pulmonale.
- Bronchodilators:
 - Bronchodilator therapy is particularly helpful for those patients with COPD
 - Selective β -adrenergic agents such as terbutaline 0.25 mg SC may be useful.
 - Bronchodilator affects and reduces ventricular afterload.
 - Theophylline may play a role to improve diaphragmatic contractility and reduce muscle fatigue.
 - Anticoagulation may be considered for those at high risk for thromboembolic disease.
- Acutely decompensated COPD patients:
 - Early steroid therapy
 - Antibiotic administration
- In general, improvement in the underlying respiratory disease results in improved RV function.

MEDICATION

- Furosemide: 20–60 mg IV (peds: 1 mg/kg may increase by 1 mg/kg/q2h not to exceed 6 mg/kg)
- Terbutaline: 0.25 mg SC

FOLLOW-UP

DISPOSITION

Admission Criteria

- New-onset hypoxia
- Anasarca
- Severe respiratory failure

- Admission criteria for the underlying disease process

Discharge Criteria

Patients without hypoxia or a stable oxygen requirement

Issues for Referral

- Close follow-up as long as the underlying etiology has responded to acute management
- The need for a sleep study to assess for sleep apnea should be coordinated by the patient's physician.

FOLLOW-UP RECOMMENDATIONS

Ensure home oxygenation in patients with chronic hypoxia

PEARLS AND PITFALLS

- The physical exam is unreliable for detecting cor pulmonale in patients with COPD, as hyperinflation of the chest obscures the classic findings.
- Vasodilator therapy should only be considered after conventional therapy and oxygenation have failed.

CODES

ICD9

- 415.0 Acute cor pulmonale
- 416.9 Chronic pulmonary heart disease, unspecified

ICD10

- I26.09 Other pulmonary embolism with acute cor pulmonale
- I27.81 Cor pulmonale (chronic)

CORNEAL ABRASION

Denise S. Lawe

BASICS

DESCRIPTION

- Any tear or defect in the corneal epithelium
- May be traumatic, spontaneous, due to foreign body, or contact lens related

ETIOLOGY

- Traumatic:
 - Human fingernail
 - Branches
 - Hairbrushes/combs
 - Sand/stones
 - Snow
 - Pens/pencils
 - Toys
 - Chemical burn
 - Airbag deployment
 - Pepper spray
 - Paper/cardboard
 - Make-up applicator
 - Animal paws
- Foreign body related:
 - Wood
 - Glass
 - Metal
 - Rust
 - Plastic
 - Fiberglass
 - Vegetable matter
 - Eyelid foreign body
- Contact lens related:
 - Over-worn
 - Improperly fitting or cleaned
- Spontaneous:
 - Usually previous traumatic corneal abrasion or an underlying defect in the corneal epithelium

DIAGNOSIS

SIGNS AND SYMPTOMS

- Severe ocular pain
- Gritty (scratchy) discomfort
- Tearing
- Blepharospasm
- Foreign body sensation
- Photophobia (particularly if secondary traumatic iritis present)
- Conjunctival injection
- Diminished or blurred vision
- Headache

History

- Any direct trauma to the globe
- Any known or potential foreign body
- Contact lens use
- Any history of previous corneal abrasion
- Ocular/periocular surgery
- Pre-existing visual impairment
- Time of onset
- Associated symptoms or concomitant injury
- Treatment before visit
- Use of safety glasses (pounding, drilling, grinding metal) or eyeglasses
- Systemic disease (diabetes, autoimmune disorders)
- Tetanus status

Pediatric Considerations

- Signs and symptoms may differ:
 - Excessive crying
- Younger than 12 mo:
 - Frequently no history of eye trauma
 - Might present as the crying inconsolable infant
 - In 1–12 wk old may be an incidental finding and not the cause of their irritability or crying
- Older than 12 mo:
 - More often will have history of minor eye trauma
 - Positive eye signs

Physical-Exam

- If indicated, evaluate for other life-threatening injuries with attention to the primary survey.
- Complete eye exam:
 - Focus is to evaluate for evidence of penetrating injury and/or infection

- Gross visual inspection
- Visual acuity
- Penlight exam to evaluate for conjunctival injection, the pupil shape/reactivity, and for any evidence of corneal infiltrate or opacity
- Evert upper lids to check for retained foreign body
- Slit-lamp exam to evaluate for anterior chamber reaction, infiltrate, corneal laceration, and penetrating trauma
- Fluorescein dye to identify size and location of corneal epithelium defect

DIAGNOSIS TESTS & INTERPRETATION

Pediatric Considerations

Handheld slit-lamp and Wood lamp: Helpful in exam of pediatric eye

DIFFERENTIAL DIAGNOSIS

- Conjunctivitis, viral, or bacterial
- Corneal ulcer
- Glaucoma
- Herpes zoster
- Keratitis, viral or bacterial, or ultraviolet induced
- Recurrent corneal erosion syndrome
- Uveitis
- More extensive pathology than corneal abrasion:
 - Laceration of cornea
 - Perforation of cornea
 - Hyphema
 - Iris prolapse
 - Lens disruption

TREATMENT

INITIAL STABILIZATION/THERAPY

Instill topical anesthetic (proparacaine/tetracaine).

ED TREATMENT/PROCEDURES

- Removal of superficial foreign body:
 - A residual rust ring does not need emergent removal. It can be removed at 24–48 hr
- Oral pain control:
 - Oral narcotics or NSAID or acetaminophen
- Topical pain control:
 - Studies have demonstrated efficacy; however, there are scattered reports of

- adverse effects
 - Avoid in patients with other ocular surface disease and in postoperative patient
 - Topical diclofenac or ketorolac
- Cycloplegic (optional):
 - Cyclopentolate (mydriasis 1–2 days)
 - Tropicamide (mydriasis 6 hr)
 - Homatropine 5%
- Topical antibiotic:
 - This practice has not been rigorously studied.
 - Concern is for superinfection
 - Ointment better than drops because also a lubricant
 - Discontinue antibiotics once symptom free for 24 hr
 - Contact lens wearers must have anti-Pseudomonal coverage:
 - Ciprofloxacin
 - Erythromycin
 - Gentamicin
 - Sulfacetamide
 - Tobramycin/Tobradex
 - Polytrim
- Eye patch:
 - Does not appear to improve healing or reduce pain particularly in the 1st 24 hr
 - Not recommended for small abrasions
 - Never patch the patient who wears contact lens
 - Never patch infection-prone injury (organic matter is at high risk)
 - More research needed to evaluate efficacy of patching in abrasions > 10 mm
- Contact lens
 - No contact lens wear till abrasion healed and eye feels normal for a wk without medication
 - Might consider bandage contact lens in severe pain. Be certain no infection and will need daily follow-up
- Tetanus prophylaxis:
 - Routine tetanus not necessary
 - Update tetanus if abrasion caused by or contaminated with organic matter or dirt
- Emergent ophthalmologic consultation required for retained intraocular foreign body, penetrating injury to globe (or other more serious injury) and any patient with a corneal infiltrate, white spot, or opacity

MEDICATION

- Ciprofloxacin: 0.35% 1 drop QID

- Cyclopentolate: 0.5%, 1%, or 2% drops (mydriasis 1 or 2 drops TID)
- Diclofenac: 0.1% drops 1 drop QID
- Erythromycin: 0.5% ointment QID
- Gentamicin: 0.3% ointment QID
- Gentamicin: 0.3% 2 drops q6h
- Homatropine: 5% solution 2 drops BID
- Ketorolac: 0.5% drops 1 drop QID
- Proparacaine: 0.5% 1 drop once
- Sulfacetamide: 10% drops 2 drops QID
- Sulfacetamide: 10% ointment QID
- Tobradex: Suspension 0.1%/0.3% 2 drops q4–6h
- Tobramycin: 0.3% drops 2 drops q6h
- Tobramycin: 0.3% ointment q6h
- Tropicamide: 0.5%, 1% drops (mydriasis 6 hr) 1 drop q4h

FOLLOW-UP

DISPOSITION

Admission Criteria

Associated injuries requiring admission

Discharge Criteria

All simple corneal abrasions

Issues for Referral

No studies on optimal follow-up. Practice recommendations however dictate all corneal abrasions require follow-up to ensure healing without infection or scarring.

FOLLOW-UP RECOMMENDATIONS

- Follow-up with ophthalmologist for re-exam and ongoing care in 24 hr if in contact lens wearer, the eye has been patched or bandage contact lens applied
- Follow-up with ophthalmologist if central or large abrasion in 24 hr; otherwise follow-up can be in 48–72 hr

PEARLS AND PITFALLS

- Always diligently evaluate for penetrating trauma to the globe.
- Always diligently evaluate for evidence of infection.
- Do not discharge the patient with any topical anesthetic. It is felt to be toxic to the epithelium and retards healing, although a recent small study indicated it might be safe to discharge with dilute proparacaine.

- Do not use a mydriatic agent on a patient with a history of glaucoma.
- Do not recommend return to contact use until followed up and cleared by ophthalmology.

CORNEAL BURN

Matthew A. Wheatley • Ryan A. Stroder

BASICS

DESCRIPTION

- Inappropriate exposure of cornea to chemicals, heat, cold, electrical, or radiant energy causing damage to the cornea and often extending to adjacent structures
- Severity of injury related to duration of exposure, type of agent, anion concentration, pH level of solution
- Alkalis:
 - Cause immediate rise in pH level
 - Highly soluble in lipids, so rapidly penetrate the eye, causing severe corneal injury and continue to penetrate over time if no intervention undertaken
 - Penetration can occur in < 1 min.
 - Exception: Calcium alkalis penetrate relatively poorly secondary to soap formation; can cause corneal opacification, so may appear worse but actually have better prognosis than other alkali burns.
- Acids:
 - Immediately coagulate proteins of corneal epithelium
 - Cause opacification
 - Coagulation produces barrier to deeper penetration
 - Exception: Lipophilicity of hydrofluoric (HF) acid causes it to act similar to a base with more rapid penetration
- Thermal burns:
 - Affect eyelids more than globe due to reflex blinking and Bell phenomenon (eyes roll up and outward)
 - Cause direct injury to cornea
 - Damage primarily depends on duration and intensity of heat
- Electrical injury:
 - Occurs with current flow through head, with input at or near eye
- Radiation injury:
 - Due to ultraviolet light exposure to cornea

ETIOLOGY

- Alkalis:
 - Ammonia:
 - Fertilizer, refrigerant, household ammonia, cleansing agents
 - Potassium hydroxide:
 - Caustic potash
 - Magnesium hydroxide:

- Sparklers, flares, fireworks
- Lye: NaOH:
 - Caustic soda, drain cleaners
- Lime: CaOH₂ or MgOH₂:
 - Fresh lime, quicklime, calcium hydrate, slaked lime, hydrated lime, plaster, mortar, cement, whitewash
- Nonspecific alkali:
 - Motor vehicle airbag on inflation releases alkali.
- Acids:
 - Sulfuric acid: H₂SO₄:
 - Car battery acid, toilet cleaner
 - Sulfurous acid: H₂SO₃:
 - Preservatives (fruit and vegetable)
 - Acetic acid: CH₃CO₂H:
 - Vinegar
- Bleach
- Refrigerants:
 - HF acid:
 - Etching silicon/glass
 - Cleaning brick
 - Electropolishing metals
 - Control of fermentation in breweries
 - Commercial/household rust removal
- Thermal:
 - Hot liquids, molten metal
 - Flames
 - Hot smoke/gases
 - Flash burn
 - Steam
 - Cigarette burns
- Radiation:
 - Sun lamps
 - Tanning booths
 - High-altitude sunlight
 - Reflection off snow/water
 - Arc welding

Pediatric Considerations

Consider child abuse or neglect.

SIGNS AND SYMPTOMS

- Severe ocular pain
- Photophobia
- Lacrimation
- Foreign body sensation
- Conjunctival injection
- Corneal edema
- Corneal opacification
- Impaired visual acuity
- Limbal blanching
- Lens opacification
- Vesicles clear fluid (hypothermal injury)
- Vesicles hemorrhagic fluid
- Necrosis of iris, ciliary body

History

- Type of exposure:
 - _ Inspect any bottles accompanying the patient for active and inactive ingredients
- Vehicle of exposure:
 - _ Aerosol: Common
 - _ Propellant: May result in intraocular foreign body/perforation
- Duration of exposure
- Time of onset
- Time irrigation initiated
- Pre-existing visual impairment
- Protective eyewear
- Contact lens use
- Treatment before arrival

Physical-Exam

Complete eye exam (after irrigation):

- Visual acuity
- Bright white light for visual inspection of cornea/conjunctivae/limbus
- Slit-lamp to evaluate anterior segment inflammation
- Fluorescein stain:
 - _ Corneal epithelial damage:
 - Punctate corneal lesions with discrete lower border from inferior lid seen in UV radiation burns
 - _ Perforation (Seidel test)
- Check for lenticular clarity
- Fundus exam

- Measure intraocular pressure (especially in delayed presentation)
- Lid/eyelash exam
- Check pH with acid/alkali burns with litmus paper or pH indicator on urine dipstick

DIAGNOSIS TESTS & INTERPRETATION

Diagnostic Procedures/Surgery

- Fluorescein stain
- Check pH

DIFFERENTIAL DIAGNOSIS

- Infection:
 - Viral keratitis
 - Corneal ulcer
- Corneal erosion syndrome:
 - Corneal foreign body
 - Corneal abrasion
 - Hypothermal injury

Pediatric Considerations

Handheld slit-lamp and Wood lamp helpful in exam of child's eye

TREATMENT

PRE HOSPITAL

- Irrigate at scene 15–30 min unless other coexisting life-threatening conditions require immediate transfer
- Bring bottle of substance to hospital
- Continuous irrigation en route to hospital with NS or water

INITIAL STABILIZATION/THERAPY

- Chemical exposure:
 - Suspect acid or alkali in all exposures to unknown substances
 - Irrigate with any available diluting substance but preferably water or NS
- Thermal exposure:
 - Cool-moist dressing with overlying ice packs

ED TREATMENT/PROCEDURES

- Chemical exposure: Alkalis/acids/mace:
 - Continuous irrigation to achieve pH 7.3–7.5 (1–2 L via a Morgan lens > 30–60 min):
 - Measure pH every 30 min

- Dip pH paper in inferior conjunctival fornix
 - Topical anesthetic (proparacaine) may be necessary during irrigation
 - pH should be evaluated at 5 and 30 min after irrigation to ensure normalization of pH
 - Evaluate fornices in detail and eye in full range of motion to ensure removal of all particulate chemical substance
 - Antibiotic prophylaxis for Staphylococcus/Pseudomonas until epithelialization is complete:
 - Gentamicin ointment + erythromycin *or*
 - Bacitracin
 - Cycloplegics to minimize posterior synechiae formation:
 - Cyclopentolate 1%
 - Atropine 1%
 - Oral analgesics
 - If increased intraocular pressure:
 - Immediate ophthalmologic consultation
 - Administer acetazolamide 125 mg PO QID and timolol 0.5% drops BID
- Topical steroids to control anterior uveitis (consult ophthalmology)
- Eye patch (consult ophthalmology)
- May require surgical intervention if frank corneal penetration
- Ophthalmologic consultation by phone in mild injuries
- Immediate ophthalmologic consultation in all moderate to severe injuries; if unavailable at your hospital, arrange transfer to closest eye center
- HF acid:
 - Treat as above, + 1% calcium gluconate eyedrops
 - Systemic analgesia for 24 hr
- Thermal exposure:
 - Frequent moist dressing changes
 - Antibiotics drop QID
 - Generous lubricant application
 - Moisture chamber when extensive injury to eyelid
 - Steroids (consult ophthalmologist; do not use for > 1 wk)
 - Ophthalmology consultation for any 2nd- or 3rd-degree burn to eyelids
 - Cigarette ash and hot liquid splashes usually result in corneal epithelial injury:
 - Treat as corneal abrasion
- Electrical injury:
 - Irrigation
 - Wound care
 - Antibiotic ointment
 - Cycloplegic (if anterior uveitis)
 - Analgesia

- Radiation injury:
 - Topical anesthetic
 - Short-acting cycloplegic
 - Antibiotic ointment
 - Consider oral opioids for pain control

Pediatric Considerations

- Patching poorly tolerated
- May require systemic analgesia for complete exam

MEDICATION

- Artificial tears
- Atropine: 0.5%, 1%, 2% drops (cycloplegia 5–10 days, mydriasis 7–14 days) 1 drop TID
- Bacitracin ointment: QID
- Ciprofloxacin: 0.35% 1 drop QID
- Cyclopentolate: 0.5%, 1%, 2% drops (cycloplegia 1–2 days, mydriasis 1–2 days) 1 drop TID
- Erythromycin: 0.5% ointment QID
- Gentamicin: 0.3% ointment QID
- Gentamicin: 0.3% drops 1 drop q6h
- Homatropine: 5% drops 1–2 drop BID–TID
- Proparacaine: 0.5% drops 1 drop
- Sulfacetamide: 10% ointment QID
- Sulfacetamide: 10% drops QID
- Tetracaine: 0.5% drops 1–2 drops
- Tobramycin: 0.3% ointment q6h
- Tobramycin: 0.3% drops q6h
- Tropicamide: 0.5%, 1% drops (cycloplegia none; mydriasis 6 hr) 1 drop

FOLLOW-UP

DISPOSITION

Admission Criteria

- Intractable pain
- Increased intraocular pressure
- Corneal penetration requiring immediate surgical intervention
- HF acid burn; admit for 24 hr of systemic analgesia
- Suspected child abuse

Discharge Criteria

All mild corneal burns

FOLLOW-UP RECOMMENDATIONS

Mandatory follow-up with ophthalmologist in 12–24 hr; arrange before patient discharge

PEARLS AND PITFALLS

- In chemical exposures, delay exam until eye has been irrigated
- All patients with epithelial defects need 12–24 hr ophthalmology follow-up
- Do not prescribe topical anesthetics for discharged patients

CORNEAL FOREIGN BODY

Ian C. May • Carl G. Skinner

BASICS

DESCRIPTION

- Foreign material on or in the corneal epithelium
- Corneal epithelium disrupted:
 - Abrasion if only epithelium disrupted
 - Scar if deeper layers of cornea involved

ETIOLOGY

- Foreign material causes inflammatory reaction:
 - May develop conjunctivitis, corneal edema, iritis, necrosis
- Poorly tolerated:
 - Organic material (plant material, insect parts)
 - Inorganic material that oxidizes (iron, copper)
- Well tolerated:
 - Inert objects (paint, glass, plastic, fiberglass, nonoxidizing metals)

DIAGNOSIS

SIGNS AND SYMPTOMS

- Foreign body (FB) sensation
- Eye pain
- Conjunctiva and sclera injection
- Tearing
- Blurred or decreased vision
- Photophobia
- Visible FB or rust ring
- Iritis

History

Common complaint: Something fell, flew, or otherwise landed in my eye:

- Hot, high-speed projectiles may not produce pain initially.

Physical-Exam

- Complete eye exam:
 - Visual acuity
 - Visual fields
 - Extraocular movements

- Lids and lashes
- Pupils
- Sclera
- Conjunctiva
- Anterior chamber
- Fundi:
 - Slit-lamp
 - Fluorescein exam
 - Perform Seidel test (visualization of flow of aqueous through corneal perforation during fluorescein slit-lamp exam)
 - Intraocular pressure if no evidence of perforation

ESSENTIAL WORKUP

- Injury history to determine type of FB and likelihood of perforation
- Exclude intraocular FB:
 - Suspect intraocular FB with high-speed mechanisms, such as machine operated or hammering metal on metal, or positive Seidel test.

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- Orbital CT scan or B-mode US when suspect intraocular FB
- Orbital plain radiograph to screen for intraocular metallic FB

ALERT

Avoid MRI for possible metallic FBs.

DIFFERENTIAL DIAGNOSIS

- Conjunctival FB
- Corneal abrasion
- Corneal perforation with or without intraocular FB
- Corneal ulcer
- Keratitis

TREATMENT

PRE HOSPITAL

Place a Fox shield and position the patient upright.

INITIAL STABILIZATION/THERAPY

Apply topical anesthetic to stop eye discomfort and assist in exam.

ED TREATMENT/PROCEDURES

- Deep FBs:
 - Refer those penetrating the Bowman membrane (next layer under epithelium) to an ophthalmologist, because permanent scarring may occur.
- Superficial FBs:
 - Irrigation removal technique
- Apply topical anesthetic
- Try to wash FB off cornea by directing a stream of 0.9% NS at an oblique angle to cornea:
 - 25G needle or FB spud removal technique:
 - Using slit-lamp to immobilize patient's head and allow good visualization
 - Hold needle (bevel up) with thumb and forefinger, allowing other fingers to be stabilized on the patient's cheek.
 - Lift FB off cornea, keeping needle parallel to corneal surface.
- Rust rings removal:
 - Within 3 hr, iron-containing FBs oxidize, leaving a rust stain on adjacent epithelial cells.
 - Removal recommended as rust rings delay healing and act as an irritant focus
 - Remove with needle or pothook burr either at same time as FB or delayed 24 hr
- Postremoval therapy:
 - Recheck Seidel test to exclude corneal perforation.
 - Treat resultant corneal abrasion with antibiotic drops or ointment.
 - Initiate cycloplegic agent when suspect presence of keratitis.
 - Update tetanus.
 - Initiate analgesia (nonsteroidal anti-inflammatory drug [NSAID] or acetaminophen with oxycodone).

Pediatric Considerations

May require sedation to facilitate exam and FB removal

MEDICATION

- Cycloplegics:
 - Cyclopentolate 1–2%: 1 drop TID (lasts up to 2 days)
 - Homatropine 2% or 5%: 1 drop daily (lasts up to 3 days)
- Topical antibiotics for 3 to 5 days: Often used but unproven benefit:
 - Erythromycin ointment: Thin strip q6h
 - Sulfacetamide 10%: 1 drop q6h
 - Ciprofloxacin: 1 drop q6h
 - Ofloxacin: 1 drop q6h
 - Polymyxin/trimethoprim: 1 drop q6h
- Topical NSAIDs:

- Ketorolac: 1 drop q6h
- Diclofenac: 1 drop q6h

FOLLOW-UP

DISPOSITION

Admission Criteria

Globe penetration

Discharge Criteria

All corneal FBs

Issues for Referral

- Consult ophthalmologist for:
 - Vegetative material removal owing to risk of ulceration
 - Any evidence of infection or ulceration
 - Multiple FBs
 - Incomplete FB removal
- Ophthalmology follow-up in 24 hr for:
 - Abrasion in the visual field
 - Large abrasion
 - Abrasions that continue symptomatic or worsen the next day
 - Rust ring removal

FOLLOW-UP RECOMMENDATIONS

Return or follow-up with a physician if symptoms continue or worsen in 1 or 2 days.

PEARLS AND PITFALLS

- Consider intraocular FB, especially with history of high-projectile objects or industrial tools.
- Clinical evidence does not support eye patching for pain or healing.
- After removal, most corneal FBs can be treated as an abrasion and usually do well without further treatment.
- Topical anesthetics should not be prescribed for home use.

COUGH

Alison Sisitsky Curcio

BASICS

DESCRIPTION

- A sudden spasmodic contraction of the thoracic cavity resulting in violent release of air from the lungs and usually accompanied by a distinctive sound:
 - Deep inspiration
 - Glottis closes
 - Expiratory muscles contract
 - Intrapulmonary pressures increase
 - Glottis opens
 - Air expiration at high pressure
 - Secretion and foreign material excretion
 - Vocal cord vibration with tracheobronchial walls, lung parenchyma, and secretions
- Defense mechanism to clear the airway of foreign material and secretions:
 - Voluntary or involuntary
 - Involuntary coughing regulated by the vagal afferent nerves:
 - Voluntary coughing under cortical control allowing for inhibition or voluntary cough
 - Because of cortical control, placebos can have a profound effect on coughing.
 - Reflex involves respiratory tissue receptor activation of afferent neurons to the central cough center followed by efferent output to the respiratory muscles.
 - Mechanical receptors in larynx, trachea, and carina sense touch and displacement.
 - Chemical receptors in larynx and bronchi are sensitive to gases and fumes.
 - Activated by irritants, mucus, edema, pus, and thermal stimuli
- Complications of severe coughing:
 - Epistaxis
 - Subconjunctival hemorrhage
 - Syncope
 - Pneumothorax
 - Pneumomediastinum
 - Emesis
 - Hernia
 - Rectal prolapse
 - Incontinence

- Seizures
- Encephalitis
- Intracranial hemorrhage
- Spinal epidural hemorrhage
- Clubbing
- Pruriginous rash

ETIOLOGY

- Acute (< 3 wk):
 - Pneumonia
 - Acute bronchitis
 - Sinusitis
 - Pertussis
 - Tuberculosis
 - Upper respiratory tract infection
 - Cough variant asthma
 - COPD exacerbation
 - Bronchiectasis
 - Pulmonary embolism
 - Left ventricular failure
 - Airway obstruction (food, pills)
 - GERD
 - Allergies
 - Bronchospasm
- Subacute (3–8 wk):
 - Postinfectious cough
 - Pertussis
 - Bronchitis
 - Bacterial sinusitis
 - Asthma
 - GERD
 - Pulmonary embolism
- Chronic (> 8 wk):
 - Postnasal drip
 - Asthma
 - GERD
 - Chronic bronchitis
 - Tuberculosis
 - Bronchiectasis
 - Eosinophilic bronchitis
 - ACE inhibitor use
 - Bronchogenic carcinoma
 - Carcinomatosis

- Sarcoidosis
- Left ventricular failure
- Aspiration syndrome
- Psychogenic/habit

Pediatric Considerations

- Most frequent causes:
 - Asthma
 - Viral illness
 - Acute bronchitis
 - Pneumonia
 - Sinusitis
 - GERD
- Less common causes:
 - Tracheobronchomalacia
 - Mediastinal tumor
 - Acyanotic congenital heart disease
 - Ventricular septal defect
 - Patent ductus arteriosus
 - Pulmonary stenosis
 - Tetralogy of Fallot
 - Lodged foreign body
 - Chronic aspiration of milk
 - Environmental exposure
- Consider:
 - Neonatal history
 - Feeding history
 - Growth and developmental history
 - Allergies
 - Eczema
 - Sleep disorders
- Indications for CXR:
 - Suspicion of foreign body ingestion
 - Suspect aspiration

DIAGNOSIS

SIGNS AND SYMPTOMS

- Sputum production:
 - Frothy (pulmonary edema)
 - Mucopurulent
 - Suggestive of bacterial pneumonia or bronchitis but also seen with viral

- infections
 - Rust colored (pneumococcal pneumonia)
 - “Currant jelly” (Klebsiella pneumonia)
 - Hemoptysis
- Post-tussive syncope or emesis (suggests pertussis)
- Shortness of breath
- Chest pain
- Chills/fever
- Night sweats
- Wheezing
- GERD:
 - Heartburn
 - Dysphagia
 - Regurgitation
 - Belching
 - Early satiety
- Malignancy:
 - Weight loss
 - Poor appetite
 - Fatigue

History

- Duration of cough to classify into acute, subacute, and chronic
- Description of sputum, if present, including hemoptysis
- Post-tussive emesis or syncope and paroxysmal cough suggests pertussis.
- History of GI symptoms pointing to GERD
- Weight loss and night sweats suggestive of tuberculosis in chronic cough

Physical-Exam

- Vital signs
- Abnormal breath sounds:
 - Absence or decreased: Reduced airflow vs. overinflation
 - Rales (crackles): Popping or rattling when air opens closed alveoli:
 - Moist, dry, fine, coarse
 - Rhonchi: Snoring-like sounds when large airways are obstructed
 - Wheezes: High-pitched sounds produced by narrowed airways
 - Stridor: Upper airway obstruction
- Evidence of respiratory distress:
 - Use of accessory muscles
 - Abdominal breathing

ESSENTIAL WORKUP

- Complete medical history:

- Duration
- Associated symptoms
- Sick contacts
- Smoking exposure
- ACE inhibitor use
- HIV/immunocompromised state
- Potential exposure to tuberculosis
- EKG:
 - History of cardiac disease
 - Associated chest pain or abnormal vital signs
 - Lack of infectious symptoms

DIAGNOSIS TESTS & INTERPRETATION

Lab

Order according to presenting signs and symptoms:

- WBC count with differential
- Sputum gram stain, cultures, and sensitivities
- Acid fast bacilli (AFB) culture
- CD4 count
- Pertussis titers
- D-Dimer
- Flu swab (for high-risk patients or those to be admitted)

Imaging

- CXR:
 - For immunosuppressed patient
 - At least 1 of the following in healthy patients with acute cough and sputum production:
 - Heart rate > 100 bpm
 - Respiratory rate > 24 breaths/min
 - Oral body temperature of > 38°C
 - Chest exam findings of focal consolidation, egophony, or fremitus
 - Ill appearing
 - Change in chronic cough
 - Continued cough after discontinuation of ACE inhibitor
- CT of chest:
 - Abnormal CXR
 - Assess for pulmonary embolism

Diagnostic Procedures/Surgery

- Peak flow

- **Bronchoscopy:**
 - For unknown mass on chest radiograph
 - Hemoptysis
 - Suspected cancer

DIFFERENTIAL DIAGNOSIS

See “Etiology.”

TREATMENT

INITIAL STABILIZATION/THERAPY

Assess airway, breathing, and circulation.

ED TREATMENT/PROCEDURES

Specific treatment related to cause:

- **Respiratory infection:** Consider antibiotics, antivirals (flu), decongestants, and antitussives.
- **Asthma:** Inhaled β_2 -agonist and steroids
- **GERD:** H₂-blockers, proton pump inhibitors, and antacids
- **Suspicion of pertussis:** Macrolide and 5 days isolation
- **Exacerbation of chronic bronchitis:** Inhaled β_2 -agonist and steroids
- **Malignancy:** Supportive care

MEDICATION

- **Antibiotics:**
 - Pick appropriate coverage for suspected bacteria.
- **Antivirals:**
 - Tamiflu: 75 mg (peds: 30–75 mg PO BID × 5 days) PO daily
- **Antitussives:**
 - Codeine: 10–20 mg (peds: 1–1.5 mg/kg/d) PO q4–6h
 - Dextromethorphan: 10–20 mg (peds: 1 mg/kg/d) PO q6–8h
 - Hydrocodone: 5–10 mg (peds: 0.6 mg/kg/d q6–8h) PO q6–8h
- **Bronchodilators:**
 - Albuterol: 2.5 mg in 2.5 NS (peds: 0.1–0.15 mg/kg/dose q20min) q20min inhaled
 - Ipratropium: 0.5 mg in 3 mL NS (peds: Nebulizer 250–500 μ g/dose q6h) q3h
- **Decongestants:**
 - Chlorpheniramine: 4–12 mg (peds: 2 mg PO q4–6h) PO q4–12h
 - Phenylpropanolamine: 25–50 mg (peds: 6.25–12.5 mg PO q4h) PO q4–8h
- **Mucolytics:**
 - Guaifenesin: 200–400 mg (peds: 2–5 yr 50–100 mg PO, 6–11 yr 100–200 mg) PO q4h PRN

- Steroids:
 - Dexamethasone: 2 sprays/nostril BID
 - Methylprednisolone: 60–125 mg IV (peds: 1–2 mg/kg/dose IV/PO q6h)
 - Prednisone: 40–60 mg (peds: 1–2 mg/kg/d q12h) PO

FOLLOW-UP

DISPOSITION

Admission Criteria

- Hypoxemia or critical illness
- Suspected tuberculosis with positive chest radiograph result
- Immunocompromised with fever
- Risk of bacteremia or sepsis

Discharge Criteria

- Oxygenation at baseline for patient
- Oral medications
- Safe environment at home

Issues for Referral

Close follow-up by primary care physician for outpatient management

FOLLOW-UP RECOMMENDATIONS

- Stop smoking, avoid being around smokers or other harmful substances such as asbestos.
- Change diet:
 - Avoid coffee, tea, and soda.
 - Avoid eating for at least 4 hr prior to sleeping.
- Use pillows to keep head elevated at night.
- Seek care immediately with:
 - Chest pain
 - Coughing blood
 - Shortness of breath
 - Fainting

PEARLS AND PITFALLS

- For patients fitting the clinical profile for cough due to GERD, it is recommended that treatment be initially started in lieu of testing.
- For patients with a presumed diagnosis of acute bronchitis, routine treatment with antibiotics is not justified and should not be offered.

CODES

ICD9

- 306.1 Respiratory malfunction arising from mental factors
- 786.2 Cough
- 786.30 Hemoptysis, unspecified

ICD10

- F45.8 Other somatoform disorders
- R04.2 Hemoptysis
- R05 Cough

CROUP

Dale W. Steele

BASICS

DESCRIPTION

- Viral infection of the upper respiratory tract
- Most commonly presents in children 6 mo–3 yr:
 - Laryngotracheitis/laryngotracheobronchitis
 - Inspiratory stridor owing to extrathoracic airway obstruction
 - Expiratory wheeze suggests lower airway involvement.
 - Inflammatory edema of subglottic region
 - Narrowest part of pediatric airway
- May progress to respiratory failure

ETIOLOGY

- Parainfluenza types 1, 2, and 3
- Human coronavirus NL63
- Influenza A and B
- Adenoviruses
- Respiratory syncytial virus
- Measles
- *Mycoplasma pneumoniae*
- Herpes simplex

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Nonspecific upper respiratory prodrome with or without fever
- Duration of illness
- History of tracheal intubation
- Possibility of foreign body aspiration
- Previous episodes
- History of wheeze
- Immunization status (*Haemophilus influenzae* type b [HIB]; diphtheria, pertussis, and tetanus [DPT]), influenza

Physical-Exam

- Rarely toxic appearing

- Cyanosis (not present in majority of patients. If present, suggests severe disease)
- Prefer upright position
- Quality of cry/voice
- Drooling/trismus/limited *neck extension*
- *Mental status*
- Stridor at rest, increased work of breathing
- Hydration status
- Westley croup score (max. total points: 17):
 - Stridor (inspiratory or biphasic):
 - 0 = None
 - 1 = Audible with stethoscope at rest
 - 2 = Audible without stethoscope at rest
 - Retractions:
 - 0 = None
 - 1 = Mild
 - 2 = Moderate
 - 3 = Severe
 - Air entry:
 - 0 = Normal
 - 1 = Decreased
 - 2 = Severely decreased
 - Cyanosis:
 - 0 = None
 - 4 = With agitation
 - 5 = At rest
 - Level of consciousness:
 - 0 = Normal
 - 5 = Altered

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Continuous pulse oximetry
- Other tests are not routinely indicated.

Imaging

Anteroposterior (AP) and lateral neck radiographs:

- Steeple sign indicates narrowing of subglottic trachea.
- Imaging not routinely indicated, unless atypical presentation or clinical course
- Subject to misinterpretation and should not be used as sole means to exclude epiglottitis
- Should not delay definitive visualization and intubation in OR in child with concern for epiglottitis or bacterial tracheitis

- Monitor child during imaging, if done.

DIFFERENTIAL DIAGNOSIS

- Infection:
 - Bacterial tracheitis
 - Retropharyngeal or parapharyngeal abscess
 - Epiglottitis
 - Peritonsillar abscess
 - Diphtheria
- Foreign body (airway or esophageal)
- Angioedema
- Congenital airway anomaly:
 - Laryngomalacia, tracheomalacia, laryngeal cleft
- Acquired subglottic stenosis
- Vocal cord paralysis
- Thermal or chemical injury to upper airway
- Hemangioma
- Laryngeal papillomatosis
- Vocal cord dysfunction (VCD) (adolescents)

TREATMENT

PRE HOSPITAL

- Allow child to maintain position of comfort.
- Defer interventions that may distress child such as:
 - IV access
 - IM injections
- If severe distress:
 - Immediate nebulized epinephrine

INITIAL STABILIZATION/THERAPY

- Nebulized racemic epinephrine or l-epinephrine if distress or stridor at rest:
 - l-epinephrine containing only the active isomer; has been shown to be therapeutically equivalent to racemic epinephrine
- Oxygen (via blow-by) for suspected or documented hypoxia suggesting severe disease
- Mist therapy often used, but no evidence for efficacy
- Dexamethasone:
 - Reduces need for intubation, shortens length of stay, and reduces admissions and return visits and may have effects within 30 min
 - Effective even in mild croup (Westley croup score ≤ 2)
- If poor response to nebulized racemic epinephrine or l-epinephrine:

- Consider trial of heliox:
 - Heliox, when available, has been used to decrease the work of breathing in patients with an incomplete response to epinephrine.
- If impending or existing respiratory failure despite aforementioned therapy:
 - Tracheal intubation by most experienced person available
 - Use uncuffed endotracheal tube (ETT) 0.5--1 mm smaller than usual size.
- If epiglottitis or foreign body suspected:
 - Ideally, to OR for inhalational anesthesia, direct laryngoscopy, and intubation
 - Surgeon standing by for emergent tracheostomy

ED TREATMENT/PROCEDURES

See “Initial Stabilization.”

MEDICATION

- Racemic epinephrine 2.25%: 0.25–0.5 mL nebulized in 2.5 mL NS
- l-epinephrine 1:1,000: 5 mL (5 mg) nebulized
- Dexamethasone: Single dose of 0.6 mg/kg (max. 10 mg) PO (use crushed tablet) or IV preparation (4 mg/mL) PO with flavored syrup. Equally effective when given PO, IV, or IM. Lower doses may be effective.
- Heliox (70% helium: 30% oxygen mixture administered via face mask or tent house)
- Antibiotics: Not indicated

FOLLOW-UP

DISPOSITION

Admission Criteria

- Young infants, pre-existing upper airway obstruction
- Persistent or recurrent stridor at rest unresponsive to nebulized epinephrine, or recurring during 2–3 hr observation
- Pediatric intensive care unit:
 - Persistent severe obstruction
 - Need for frequent epinephrine treatments and/or heliox
 - Tracheal intubation with assisted ventilation

Discharge Criteria

- Normal oxygenation in room air
- No stridor at rest after brief observation
- Children initially given epinephrine who no longer have stridor at rest should be observed for a min. of 2–3 hr

- Reliable caretaker, communication, and transport

Issues for Referral

- Concern for underlying anatomic abnormality (young age, history of intubation, frequent recurrence)
- Infants <1 year with stridor unassociated with laryngotracheobronchitis may require endoscopic evaluation

FOLLOW-UP RECOMMENDATIONS

- Most children with croup do not require specific follow-up.
- Patients who have had prolonged stridor, or acute worsening of stridor should seek care with their primary care physician or return to the ED.

PEARLS AND PITFALLS

- Beware young infants with stridor
- High incidence of congenital abnormalities
- Mild and early epiglottitis or bacterial tracheitis may mimic croup

Epiglottitis

CODES

ICD9

- 464.4 Croup
- 464.20 Acute laryngotracheitis without mention of obstruction

ICD10

- J04.2 Acute laryngotracheitis
- J05.0 Acute obstructive laryngitis [croup]

CUSHING SYNDROME

Rami A. Ahmed • Stephen L. Chesser

BASICS

DESCRIPTION

- Cushing disease: Pituitary adenoma producing excess adrenocorticotrophic hormone (ACTH)
- Cushing syndrome: Excessive glucocorticoid effects

RISK FACTORS

Genetics

- Multiple endocrine neoplasia type I
- Carney complex (pigmented lentigines, atrial myxoma, germ-cell tumors with Cushing disease)

ETIOLOGY

- Most commonly exogenous administration of glucocorticoids either therapeutically or surreptitiously
- Pituitary adenoma secreting ACTH
- Adrenal production of cortisol from adenoma, carcinoma, or micronodular disease
- Tumor-producing ectopic ACTH:
 - Small cell lung carcinoma:
 - Most common
 - Uterine cervical carcinoma
 - Islet cell tumor of pancreas:
 - Multiple endocrine neoplasia (MEN) I-type syndrome
 - Medullary thyroid cancer
 - Pheochromocytoma
 - Ganglioneuroma
 - Melanoma prostate carcinoma
 - Carcinoid tumor:
 - Lung
 - Pancreas
 - GI tract
 - Thymus
 - Ovary

DIAGNOSIS

SIGNS AND SYMPTOMS

ALERT

- The most important aspect of Cushing syndrome in the ED is recognizing the potential for Addisonian (adrenal) crisis during periods of stress.
- Although nonemergent, the early recognition of Cushing syndrome may prevent morbidity and mortality.

Pediatric Considerations

Suspect if increasing in obesity while failing to maintain height on the growth chart

Pregnancy Considerations

Cushing syndrome rarely complicates pregnancy, but has been associated with severe pre-eclampsia and HELLP syndrome (*hemolysis, elevated liver function, and low platelets*)

History

- Cushing disease previously diagnosed
- Prior use of corticosteroids
- Characteristic appearance should lead to questions concerning change in weight, facial appearance, hirsutism, or psychiatric symptoms

Physical-Exam

- Diagnosis suggested by:
 - _ Abnormal fat deposition with moon facies
 - _ Buffalo hump
 - _ Central obesity with thin extremities
 - _ Supraclavicular fat deposition:
 - Above findings raise suspicion in a stressed patient of potentially developing Addisonian (adrenal) crisis
- Cardiovascular:
 - _ Uncontrolled hypertension
- Neurologic:
 - _ Atherosclerotic or embolic stroke
 - _ Pseudotumor cerebri (primarily with exogenous glucocorticoid administration):
 - Check fundi
- Spinal lipomatosis with cord or nerve-root compression
- Gastroenterologic:
 - _ Peptic ulcers
 - _ GI hemorrhage
 - _ Pancreatitis (primarily with exogenous glucocorticoid administration)

- Fatty liver
- Psychiatric:
 - Toxic psychosis
 - Mood disorders (40%)
 - Depression
 - Memory impairment
 - Euphoria
- Musculoskeletal:
 - Myopathy (proximal weakness)
 - Pathologic fractures
 - Osteoporosis
 - Aseptic necrosis humeral or femoral heads (primarily with exogenous glucocorticoid administration)
- Endocrine:
 - Glucose intolerance
 - Hyperlipidemia
 - Amenorrhea, female with male pattern balding, or hirsutism
- Hematologic:
 - Increased neutrophils
 - Decreased lymphocytes and eosinophils
 - Opportunistic infections
- Ophthalmologic:
 - Cataracts (primarily with exogenous glucocorticoid administration)
 - Glaucoma (primarily with exogenous glucocorticoid administration)
- Dermatologic:
 - Purple striae > 1 cm in diameter
 - Hyperpigmentation: Especially of buccal mucosa (from excess ACTH production)
 - Facial plethora
 - Thin skin
 - Impaired wound healing
 - Ecchymoses
 - Acne
 - Hyperhidrosis

ESSENTIAL WORKUP

- Cannot confirm diagnosis in ED
- Anticipate impending Addisonian (adrenal) crisis:
 - Most frequent and common problem with Cushing syndrome is its recognition with concurrent illness to prevent acute Addisonian crisis
- Search for life-threatening conditions:
 - MI
 - Stroke

- Sepsis
- Pathologic fracture
- Uncontrolled DM
- Psychiatric emergency necessitating admission

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Electrolytes, BUN, creatinine, glucose:
 - Hypokalemia
 - 10% with metabolic alkalosis
 - Diminished glucose tolerance (75%)
 - 20% overt DM
- Urinalysis:
 - 50% have glycosuria
- CBC:
 - Increased WBCs
 - Decreased eosinophils

Imaging

- ECG for myocardial ischemia
- CXR for tumor-causing ectopic ACTH
- Plain films if suspect possible pathologic fractures:
 - Delayed bone age

Diagnostic Procedures/Surgery

Nonemergent testing:

- MRI for pituitary tumor
- CT for adrenal carcinoma, adenoma, or hyperplasia
- Dexamethasone-suppression test (follow-up study with primary physician):
 - If suspicion of endogenous Cushing syndrome exists
 - Low-dose (screening test): 1 mg at 11:00 pm with an 8 am cortisol level drawn:
 - Low specificity
- False-positive results from alcohol, estrogens, spironolactone, phenytoin, barbiturates, and rifampin:
 - High-dose dexamethasone-suppression test needed to confirm the diagnosis:
 - 2 mg QID of dexamethasone with cortisol level 6 hr later
 - Compare day 2 urine-free cortisol and 17-hydroxyketosteroids with baseline levels.

DIFFERENTIAL DIAGNOSIS

- Alcohol-induced pseudo-Cushing syndrome

- Obesity
- Psychiatric states:
 - Depression
 - Obsessive–compulsive disorder
 - Panic disorder
- Physiologic states:
 - Chronic stress
 - 3rd-trimester pregnancy
 - Chronic strenuous exercise

TREATMENT

PRE HOSPITAL

- Acute addisonian (adrenal) crisis under stress may develop with iatrogenic Cushing syndrome
- Patients may have extremely labile behavior with violent behavior
- Leading causes of death in untreated Cushing syndrome are:
 - Infection
 - Stroke
 - MI

INITIAL STABILIZATION/THERAPY

- Anticipate addisonian (adrenal) crisis.
- Initiate treatment for associated complications:
 - MI
 - Stroke
 - Psychiatric stabilization

ED TREATMENT/PROCEDURES

- IV rehydration
- Glucose-lowering agents for hyperglycemia
- Appropriate cultures and antibiotics for suspected infection
- Antihypertensive agents for uncontrolled BP
- Administer steroids (hydrocortisone) with iatrogenic Cushing if patient under stress to prevent addisonian crisis.
- Medications to lower cortisol levels (bromocriptine, ketoconazole, aminoglutethimide, metyrapone):
 - Used rarely with severe symptoms in patients awaiting surgery
 - Institute under the direction of an endocrinologist.
 - Definitive therapy:
- Iatrogenic:
 - Taper steroids as rapidly as possible

- Calcium, vitamin D, and estrogen supplementation if possible
- Pituitary Cushing:
 - Transsphenoidal surgery
 - Radiation for surgical failures and a few select patients
- Adrenal adenoma/carcinoma:
 - Adrenal resection with medical therapy for metastatic lesions not resectable
- Ectopic ACTH:
 - Tumor resection (if possible) with medical therapy for metastatic lesions not resectable

MEDICATION

First Line

ONLY if in adrenal crisis: Hydrocortisone: 100 mg (peds: 1–2 mg/kg) IV q6h

Second Line

- In consultation with an endocrinologist
- SYMPTOMATIC TREATMENT ONLY as adjunctive therapy in patients awaiting surgery or refractory to other treatment
- Steroidogenic inhibitors:
 - Ketoconazole 200 mg PO BID
 - Methyrapone 0.5–1 g/d PO in 4 div. doses
 - Aminoglutethimide 250 mg PO q6h
 - Mifepristone 300 mg PO daily
- Adrenolytics:
 - Mitotane 500 mg PO daily
- ACTH release inhibitors:
 - Cyproheptadine 4 mg PO BID
 - Bromocriptine 2.5–30 mg/d
- Other:
 - Pasireotide 0.6 mg SQ initial
 - Spironolactone for symptomatic relief of HTN or hypokalemia

FOLLOW-UP

DISPOSITION

Admission Criteria

- Complications that require admission such as:
 - MI
 - Stroke
 - Sepsis

- Pathologic fracture
- Uncontrolled DM
- Psychiatric emergency
- Impending Addisonian (adrenal) crisis

Discharge Criteria

Well-appearing, stable patient without admission criteria

Issues for Referral

- Any patient suspected of Cushing syndrome for further evaluation
- Conditions secondary to Cushing requiring treatment

FOLLOW-UP RECOMMENDATIONS

Follow-up testing to confirm diagnosis

PEARLS AND PITFALLS

- Keep a high index of suspicion in the physiologically stressed patient by history or from body habitus and for the need to prevent against Addisonian crisis
- Suspect Cushing disease when there are supraclavicular fat pads

CODES

ICD9

255.0 Cushing's syndrome

ICD10

- E24.0 Pituitary-dependent Cushing's disease
- E24.2 Drug-induced Cushing's syndrome
- E24.9 Cushing's syndrome, unspecified

CYANIDE POISONING

Paul E. Stromberg • Kirk L. Cumpston

BASICS

DESCRIPTION

- Toxicity through inhalation, or GI tract absorption
- Intracellular toxin that inhibits aerobic metabolism through interruption of oxidative phosphorylation:
 - _ Leads to decreased O₂ utilization and ATP production
- Detoxification:
 - _ Rhodanese: Hepatic mitochondrial enzyme responsible for the metabolism:
 - Combines cyanide (CN) with sulfur (rate-limiting step) covalently (irreversible) to form less toxic and water-soluble thiocyanate (T-CN)
 - Forms less toxic reversible cyanhemoglobin when combined with hemoglobin (Fe 3+)
 - Forms nontoxic cyanocobalamin (B₁₂) when combined with hydroxocobalamin (B_{12a})
 - Rate of CN removal requires adequate bioavailability of sulfur compounds (thiosulfate [TS]).

ETIOLOGY

- Fires:
 - _ Combustion by-product of natural and synthetic products
- Industry:
 - _ Metal plating, microchip manufacturing
 - _ Chemical synthesis
 - _ Plastic manufacturing
 - _ Pesticides
- Solvents:
 - _ Artificial nail remover
 - _ Metal polishes
- By-product of nitroprusside metabolism (nonenzymatic)
- By-product of *Pseudomonas aeruginosa* and pyocyanus infections
- Amygdalin (converted by intestinal flora to CN), CN-containing plants (apricot and peach pits, apple and pear seeds, and cassava)
- Jewelry making

DIAGNOSIS

SIGNS AND SYMPTOMS

- Heart and brain—most sensitive organs—1st to show manifestation of toxicity
- CNS:
 - Headache
 - Confusion
 - Syncope
 - Seizures
 - Coma
- Cardiovascular:
 - Dyspnea
 - Chest pain
 - Cardiorespiratory collapse and death
- Other:
 - Nausea/vomiting
- Oral exposure: Can be caustic, 50 mg has caused death.
- Inhalational exposure:
 - 50 ppm causes anxiety, palpitations, dyspnea, headache.
 - 100–135 ppm < 1 hr is lethal.

ESSENTIAL WORKUP

- History of exposure:
 - Smoke inhalation
 - Industrial exposure
 - Intentional suicide
 - Intentional homicide
- Clinical clues (frequently absent):
 - Peculiar odor of bitter almonds
 - Bright red (arterialization) retinal vessels
 - Abrupt onset and/or deteriorating toxic effects
 - Lactic acidosis
 - High venous O₂ saturation (secondary to blocked cellular O₂ consumption); arterialization of venous blood gases

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Electrolytes, BUN, creatinine, glucose:
 - Anion gap acidosis
- Liver profile
- Creatine phosphokinase (CPK)
- Carboxyhemoglobin (CO) level
- Methemoglobin (MH) level

- CN level:
 - Send out lab that is not usually available in a clinically relevant time period.
 - Levels > 0.5–1 mg/L: Toxic
 - Levels 2.5–3 mg/L: Fatal
- Blood gas determinations:
 - Elevated mixed venous O₂: MvO₂ (normal about 35–40)
 - Elevated mixed venous O₂ saturation (co-oximeter): SmvO₂ (normal about 75%)
 - Decreased arteriovenous O₂ difference: AVO₂D (normal about 3–4.8 mL/dL)
- Elevated lactate level > 8 mmol/L:
 - An elevated lactate is a surrogate marker for the presence of CN with the appropriate history and physical exam.

Imaging

CXR

DIFFERENTIAL DIAGNOSIS

- Carbon monoxide
- Hydrogen sulfide
- Methemoglobinemia
- Sulfhemoglobinemia
- Inert gases “asphyxiants”
- Other causes of high anion gap metabolic acidosis

TREATMENT

PRE HOSPITAL

- Remove source of CN.
- Prevent others from becoming contaminated.
- Remove and bag all contaminated clothing and wash affected areas copiously with soap and water if a liquid exposure. If vapor contamination, removal of the patient from the CN environment may be all that is necessary.

INITIAL STABILIZATION/THERAPY

- ABCs:
 - Administer 100% oxygen:
 - Even in presence of normal PaO₂
 - Acts synergistically with antidotes
- Gastric decontamination for oral ingestions if within 1 hr:
 - Perform gastric lavage and administer activated charcoal (AC) if ingestion

of solid CN or CN-containing products and no contraindications.

– Do not induce emesis.

- Dermal exposure: Standard decontamination

ED TREATMENT/PROCEDURES

- Hydroxocobalamin (B_{12a}) Cyanokit®:

– Administer if manifesting significant CN toxicity with persistent high anion gap metabolic acidosis and hyperlactatemia, with any syncope, seizures dysrhythmias, and hypotension.

– Administration often instituted empirically; CN levels not immediately available

– Binds to CN:

- Forms nontoxic cyanocobalamin (B₁₂); renally excreted

– Advantages:

- No MH induction
- Does not cause hypotension
- Intracellular distribution

– Limitations:

- Cost

– Incompatible in the same IV line with:

- Diazepam
- Dobutamine
- Dopamine
- Fentanyl
- Nitroglycerin
- Pentobarbital
- Propofol
- Sodium thiosulfate
- Sodium nitrite
- Ascorbic acid
- Blood products

– Side effects of hydroxocobalamin:

- HTN
- Red skin and all secretions
- Interference of colorimetric assays of AST, ALT, total bilirubin, creatinine, Mg, iron

- CN antidote kit:

– Administer if manifesting significant CN toxicity with persistent high anion gap metabolic acidosis, hyperlactatemia with any syncope, seizures dysrhythmias, and hypotension.

– Administration often instituted empirically; CN levels not immediately available

- Contents: Amyl nitrite pearls, sodium nitrite, and sodium thiosulfate
- Nitrite action:
 - o Induce a CN-scavenging MH by oxidizing hemoglobin (Fe^{2+} to Fe^{3+}), which attracts extracellular CN away from the mitochondria-forming CN-MH, which is less toxic.
 - o Do not administer empirically or prophylactically.
- Sodium thiosulfate action:
 - o Substrate for the enzyme rhodanese
 - o Combines with CN to form a less toxic T-CN
- Hyperbaric oxygen therapy:
 - Can be used to treat CN exposures
 - Maximizes tissue oxygenation despite toxic MH level

MEDICATION

AC: 1 g/kg PO

First Line

Hydroxocobalamin (B_{12a}):

- 70 mg/kg IV, max. 5 g
- The kit contains either two 2.5 grams/bottle or one 5 gram/bottle. The starting dose is 5 grams.
- Reconstitute the powder by gently rolling the bottle after filling with 100 mL of 0.9% NS.
- Infuse each 2.5 gram bottle over 7.5 minutes, or one 5 gram bottle over 15 minutes. The 5 gram dose can be repeated.

Consider adjunctive use of sodium thiosulfate

Second Line

- CN antidote kit: Amyl nitrite, sodium nitrite, and sodium thiosulfate:
- Amyl nitrite pearls:
 - Crush 1 or 2 ampules in gauze and hold close to nose, in lip of face mask, or within Ambu bag.
 - Inhale for 30 sec–1 min until IV access obtained.
- Sodium nitrite (NaNO_2): 10 mL (300 mg) (peds: 0.15–0.33 mL/kg) IV as 3% solution over 5–20 min:
 - May repeat once at half dose within 30–60 min
 - Keep MH level < 30%.
 - Dilute; infuse slowly if hypotensive.
- Sodium thiosulfate: 50 mL: 12.5 g (peds: 0.95–1.65 mL/kg) IV over 10–15 min of 25% solution:
 - 1/2 initial dose may be given after 30–60 min.

Pregnancy Considerations

- Hydroxocobalamin is class C.
- Amyl nitrite is class X.
- Sodium nitrite is unknown.
- Sodium thiosulfate is class C.

Geriatric Considerations

- ~ 50 known or suspected CN victims aged 65 or older received hydroxocobalamin and it had similar safety and efficacy as younger patients.
- Hydroxocobalamin is renally excreted unchanged in the urine so renal impairment could prolong the elimination half-life.
- The safety and effectiveness of hydroxocobalamin is unknown in hepatic impairment.
- Sodium thiosulfate is metabolized in the liver and excreted by the kidney. Impairment in either organ may prolong elimination.
- The nitrites are short acting. Hepatic or renal impairment may prolong elimination.

Pediatric Considerations

The safety and effectiveness of hydroxocobalamin has not been established in children, but the 70 mg/kg dose has been used.

ALERT

- Sodium nitrite has weight-based dosing for children.
- Sodium nitrite dosing can be based on serum hemoglobin when the clinical scenario does **NOT** require life-saving administration of the antidote before lab testing:

Hgb Nitrite (mg/kg) Nitrite (mL/kg)

7	5.8	0.19
8	6.6	0.22
9	7.5	0.25
10	8.3	0.27
11	9.1	0.30
12	10.0	0.33
13	10.8	0.36
14	11.6	0.39

FOLLOW-UP

DISPOSITION

Admission Criteria

ICU admission of all symptomatic exposures

Discharge Criteria

- Asymptomatic patients after at least 4 hr of observation
- Survival after 4 hr of acute exposure usually associated with complete recovery

Issues for Referral

Psychiatry referral for intentional overdose and suicidal patients

PEARLS AND PITFALLS

- In a patient with hypotension, high anion gap metabolic acidosis, hyperlactatemia, seizures, syncope, altered mental status consider CN in the differential diagnosis and treat presumptively.
- Use serum lactate as a surrogate marker for CN exposure.
- Victims of smoke inhalation may have combination of:
 - _ CN toxicity
 - _ MH
 - _ CO toxicity
 - _ If the COHgb concentration is extremely elevated, considered a concomitant CN exposure as well
 - _ To avoid further reduction in oxygen transport; initially treat with hydroxocobalamin or sodium thiosulfate, without sodium nitrite to avoid methemoglobinemia.

CODES

ICD9

- 987.7 Toxic effect of hydrocyanic acid gas
- 989.0 Toxic effect of hydrocyanic acid and cyanides

ICD10

- T65.0X1A Toxic effect of cyanides, accidental (unintentional), initial encounter
- T65.0X2A Toxic effect of cyanides, intentional self-harm, initial encounter
- T65.0X4A Toxic effect of cyanides, undetermined, initial encounter

CYANOSIS

Michael S. Murphy

BASICS

DESCRIPTION

Abnormal bluish discoloration of the skin or mucous membranes

- Caused by abnormal elevations of deoxygenated hemoglobin or hemoglobin derivatives in the capillaries:
 - Deoxygenated hemoglobin > 5 g/dL
 - Methemoglobin > 1.5 g/dL
 - Sulfhemoglobin > 0.5 g/dL
- The absolute amount of deoxygenated hemoglobin is the pigment that creates the bluish tint
 - The amount of oxyhemoglobin does not affect the blood's color
 - Cyanosis is more common in patients with polycythemia and less common in patients with anemia.
- Cyanosis varies based on skin thickness or pigment
- Accumulation of deoxygenated hemoglobin may be systemic producing central cyanosis or localized producing peripheral cyanosis
 - Central cyanosis
 - Hypoxemia
 - Anatomic right to left shunts
 - Abnormal hemoglobin derivatives
 - Peripheral cyanosis
 - Tissue extracts more than normal amounts of O₂ from the blood
 - Hypoperfusion
 - Vasoconstriction to cold air or water
 - Arterial insufficiency
 - Venous insufficiency
 - Acrocyanosis: Painless, symmetrical, cyanosis in distal parts of body, the pathophysiologic cause of which is not known

ETIOLOGY

Central cyanosis

- Impaired pulmonary function:
 - Hypoventilation:
 - Pneumonia
 - Chronic obstructive pulmonary disease
 - Pulmonary edema
 - Ventilation/perfusion mismatch:

- Asthma
- Pulmonary embolus
- Diffusion problems:
 - Interstitial lung disease
 - Anatomic shunts
- Pulmonary arteriovenous fistula:
 - Hereditary hemorrhagic telangiectasia
- High-altitude related, with decreased atmospheric pressure at 16,000 ft
- Cardiac abnormalities with right to left shunt
 - Eisenmenger syndrome
 - Pulmonary hypertension
 - Longstanding intracardiac shunt (VSD, patent ductus arteriosus, ASD)
 - Reversal of flow through detected when pulmonary artery pressure exceeds threshold
- Abnormal hemoglobin
 - Low-oxygen affinity hemoglobin mutants:
 - Hb Kansas
 - Hb Beth Israel
 - Hb St. Mandé
 - Congenital methemoglobinemia:
 - Cytochrome *b5* reductase deficiency
 - Hemoglobin M disease
 - Acquired methemoglobinemia:
 - Aniline dyes
 - Chloroquine, primaquine
 - Dapsone
 - Local anesthetic agents such as lidocaine
 - High doses of methylene blue
 - Naphthalene
 - Nitrites, nitroglycerine
 - Sulfonamides
 - Fava beans
 - Sulfhemoglobin:
 - Generally benign
 - Irreversible alteration of hemoglobin
 - Caused by many medications
 - Dimethyl sulfoxide
 - Paint
 - Phenacetin
 - Phenazopyridine
 - Phenylenediamine
 - Phenylhydroxylamine
 - Sulfanilamide

- Sulfapyridine
- Sulfathiazole
- Sulfur compounds

Peripheral cyanosis

- Shock
- Exposure to cold
- Arterial insufficiency
- Venous insufficiency
- Raynaud phenomenon
- Acrocyanosis

Pediatric Considerations

- Cardiac:
 - _ Cyanotic congenital defects:
 - Tetralogy of Fallot
 - Transposition of great vessels
 - Truncus arteriosus
 - Pulmonary and tricuspid atresia
 - Ebstein anomaly
 - Pseudocoarctation
 - Patent ductus arteriosus
 - _ Total anomalous pulmonary venous return
- Pulmonary stenosis:
 - _ Any right-to-left shunting
- Respiratory:
 - _ Upper airway disorders:
 - Croup
 - Bacterial tracheitis
 - Epiglottitis
 - Retropharyngeal abscess
 - Foreign body
 - _ Lower airway disorders:
 - Asthma
 - Bronchiolitis
 - Pneumonia
 - Cystic fibrosis
 - Pulmonary edema/CHF
 - Pulmonary embolism
- Neurologic:
 - _ Breath holding

SIGNS AND SYMPTOMS

- A bluish discoloration of the skin and mucous membranes that blanches with pressure:
 - Chocolate color:
 - Methemoglobinemia
 - Slate gray color:
 - Methemoglobinemia, sulfhemoglobin
 - Reddish blue
 - Venous stasis

History

- Establish timing of onset of cyanosis
- Associated symptoms
 - Pain
 - Dyspnea
 - Fatigue
 - Headache
 - Changes in mental status
- Medication list
- Occupational exposure or use of chemicals or drugs

Physical-Exam

- General appearance and vital signs for shock and respiratory distress
- Does the discoloration blanch with pressure?
 - Distinguishes cyanosis from abnormal skin pigmentation
- Location of discoloration
 - Symmetrical involving extremities and mucus membranes
 - Central cyanosis
 - Face, neck, and upper extremities
 - Superior vena cava syndrome
 - Lower extremities with upper extremities unaffected
 - Differential cyanosis
 - Pseudocoarctation and patent ductus arteriosus
 - Inferior vena cava syndrome
 - Single extremity
 - Arterial or venous insufficiency
 - Symmetrical, painful, involving extremities
 - Raynaud phenomenon
 - Symmetrical, painless, involving extremities and face with hyperhidrosis
 - Acrocyanosis
- Clubbing
 - Chronic hypoxemia

- Pulmonary exam
- Cardiac exam
- Extremities for edema, pulses, and temperature

ESSENTIAL WORKUP

- Assess airway and ventilation as 1st priority:
 - _ Stabilize airway and provide adequate ventilation.
- Investigate hypoxemia causes:
 - _ Cardiac and respiratory most common
 - _ Consider methemoglobinemia

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Pulse oximetry:
 - _ Does not assess ventilation
 - _ Results inaccurate with:
 - Abnormal hemoglobins
 - Nail polish
 - Pigmented skin
 - Hypoperfusion
 - Use of vital dyes
- Arterial blood gas:
 - _ Oxygen tension
 - _ Measured hemoglobin saturation
 - _ Cyanosis in face of normal PO₂, think methemoglobinemia
 - _ Blood in methemoglobinemia is chocolate color.
 - _ Methemoglobin level
- Complete blood chemistry:
 - _ Check hemoglobin.
- Hyperoxia test for congenital cyanosis of newborn:
 - _ If PO₂ fails to increase to 100 mm Hg after 100% O₂, suspect congenital heart disease.

Imaging

- CXR to investigate respiratory or cardiac pathology:
 - _ Inspiratory/expiratory views if foreign body
 - _ Expiratory view if occult pneumothorax suspected
- Radiograph of neck for upper airway disorders:
 - _ Foreign body
 - _ Steeple sign (croup)
 - _ Prevertebral swelling (retropharyngeal abscess)

- Epiglottic swelling
- EKG:
 - Dysrhythmia, injury, or ischemia
- Echo:
 - Bubble study if septal defect/shunt suspected
 - Wall motion/valvular abnormalities
 - Pericardial fluid

DIFFERENTIAL DIAGNOSIS

- Abnormal skin pigmentation (fails to blanch with pressure)
 - Amiodarone
 - Minocycline
 - Chronic high-dose chlorpromazine
 - Argyria (silver deposits)
 - Arsenic
 - Alkaptonuria
 - Chrysiasis (secondary to parenteral administration of gold salts)
 - Tattoos
- Chromhidrosis
 - Rare condition characterized by the secretion of colored sweat

TREATMENT

PRE HOSPITAL

- Assess and establish patent airway.
- Correct any airway obstruction.
- Recognize an incorrectly placed airway.
- 100% O₂ using a nonrebreathing device
- Ensure adequate ventilation.
- Recognize need to establish definitive airway.
- Protect cervical spine if trauma suspected.
- IV line, monitor, pulse oximetry
- Albuterol nebulizer for bronchospasm
- Racemic epinephrine nebulizer for severe croup
- Management of pulmonary edema per protocol

INITIAL STABILIZATION/THERAPY

- Oxygen supplied through a 100% nonrebreathing device
- Immediately assess and address airway issues.

TREATMENT GENERAL MEASURES

- Recognize and manage cardiopulmonary disorders.

- Methylene blue for methemoglobinemia exceeding 30%:
 - _ Do not use if patient has G6PD deficiency.

MEDICATION

- Albuterol nebulized: 0.03 mL/kg (5 mg/mL)
- Dexamethasone: (For croup) 0.75–9 mg/d in div. doses q6–12h
- Furosemide: 0.5 mg/kg IV over 1–2 min. May double the dose after 1 hr if unsatisfactory response.
- Magnesium: 2 g IV over 10 min (40 mg/kg IV over 20 min)
- Methylene blue: 1–2 mg/kg IV of 1% solution over 5 min
- Methylprednisolone: 1–2 mg/kg IV q6h
- Morphine: 2–4 mg IV (0.05–0.1 mg/kg IV q2h PRN)
- Nitroglycerine: USE NON-PVC tubing. 5 µg/min, titrate up by 5 µg/min every 3–5 min until desired effect
- Prostaglandin E₁: 0.05–0.1 µg/kg/min IV; max. 0.4 µg/kg/min
- Racemic epinephrine nebulized: 0.25–0.75 mL of 2.25% solution diluted in 2 mL NS

FOLLOW-UP

DISPOSITION

Admission Criteria

- Most affected patients should be admitted to the hospital.
- ICU admission is required for any instability or cyanosis.

Discharge Criteria

Reversible causes of hypoxia:

- Reactive airway disease responsive to β-agonists
- Pulmonary edema in patient with known CHF but no suspicion of myocardial injury and diuresis

PEARLS AND PITFALLS

- First assume hypoxemia and immediately assess airway and breathing
- Chocolate-colored blood or unchanging oxygen saturation despite aggressive administration of oxygen: Think methemoglobinemia.

ADDITIONAL READING

CODES

ICD9

- 770.83 Cyanotic attacks of newborn
- 782.5 Cyanosis

ICD10

- P28.2 Cyanotic attacks of newborn
- R23.0 Cyanosis

CYSTIC FIBROSIS

Joseph Kahn

BASICS

DESCRIPTION

- Defect of the cystic fibrosis transmembrane conductance regulator (CFTR)
- CFTR functions as an ATP-regulated chloride channel that regulates the activity of chloride and sodium channels on the cell surface:
 - Abnormal electrolyte transport in exocrine glands and secretory epithelia
 - Decreased exocrine pancreatic function with malabsorption
 - Thickened mucus, recurrent pulmonary infections, and progressive obstructive damage to the lungs
 - Recurrent sinus disease
- Occurs in 1:3,600 live births in White population, 1:29,000 in African American population; 1:6,500 in Hispanic population
- 30% of cases diagnosed by newborn screening
- 75% cases diagnosed in the 1st 2 yr of life
- ~ 30,000 children and young adults in US have CF.
- Median life expectancy in US about 40 yr.
- 40% of CF patients are older than 18 yr.
- 10 million Americans are unknown, asymptomatic carriers of the defective gene.
- 16% of lung transplants in US due to CF

RISK FACTORS

Genetics

Recessively inherited genetic disease, involving the CFTR gene on the long arm of chromosome 7:

- Different mutations; variable phenotypes.
- Classic disease: Homozygous DF508 mutation.
- Most common lethal genetic disease in US

ETIOLOGY

Common organisms in patients with pneumonia; often multiple drug resistance:

- *Staphylococcus aureus*:
 - MSSA/MRSA
- *Pseudomonas aeruginosa*:
 - Prevalence increases with age; >70% of adults are chronically infected.
- *Haemophilus influenzae*
- *Stenotrophomonas maltophilia*

- *Burkholderia cepacia*:
 - Prevalence 3%
 - Associated with rapid clinical deterioration
- *Achromobacter xylosoxidans*
- Mycobacteria (nontuberculous):
 - *Mycobacterium avium* complex, *Mycobacterium abscessus*
- *Aspergillus*

DIAGNOSIS

SIGNS AND SYMPTOMS

- General:
 - Failure to thrive
 - Recurrent respiratory tract infections
 - Anasarca in infancy
 - Salty taste of skin
- Head, ears, eyes, nose, and throat (HEENT):
 - Nasal polyps; severe headaches due to sinusitis; otitis media
- Pulmonary:
 - Persistent cough. Initially dry, then productive
 - Recurrent pneumonitis or bronchiolitis in 1st yr of life
 - Wheezing
 - Hemoptysis
 - Pneumonia
 - Chronic bronchitis
 - Bronchiectasis
 - Respiratory distress
 - Pneumothorax
 - Pneumomediastinum
 - Most common cause of CF hospitalization
- Cardiac:
 - CHF
 - Cor pulmonale; pulmonary hypertension
- GI:
 - Abdominal pain
 - Meconium ileus
 - Distal intestinal obstructive syndrome (DIOS) or “meconium ileus equivalent”
 - Gastroesophageal reflux
 - Cholelithiasis
 - Pancreatitis/pancreatic insufficiency
 - Ileocecal intussusception

- Foul smelling, fatty stools
- Jaundice/cirrhosis
- Rectal prolapse
- Hematemesis
- Small intestine bacterial overgrowth
- Extremities:
 - Bone pain
 - Edema/joint effusions
 - Decreased thickness of cortical bone
- Recurrent venous thrombosis
- Cardiorespiratory failure is most common cause of death.

ESSENTIAL WORKUP

- Sweat chloride test
- DNA analysis if sweat test equivocal
- Nasal potential difference if DNA inconclusive

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Sweat chloride test:
 - Chloride concentration > 60 mEq/L
 - With classic signs and symptoms, a positive test result confirms the diagnosis.
- Stool sample:
 - Decreased elastase, trypsin, or chymotrypsin
 - Increased fat in 72-hr fecal fat excretion
- Immunoreactive trypsin (IRT):
 - Defines increased risk and/or diagnosis
 - May be falsely positive or negative
- DNA analysis:
 - Indicated if symptoms are highly suggestive, but sweat test result is negative
 - 90% of CF chromosomes identified
 - Positive if 2 abnormal genes present
 - Genotyping cannot establish the diagnosis.
 - 1,300 CFTR mutations listed
 - Ameliorating or neutralizing 2nd mutation may be present.
- CBC:
 - Thrombocytopenia
- Serum electrolytes:
 - Hyponatremic, hypochloremic alkalosis
- Serum glucose:
 - Hyperglycemia and new-onset diabetes in adolescents and adults;

ketoacidosis is rare.

- Liver function tests and PT:
 - Obtain if hematemesis or hemoptysis or signs of liver failure
- ABG:
 - Hypoxemia. Metabolic alkalosis
- Sputum culture:
 - May have pseudomonal colonization.
- Studies indicated in high-risk patients with unclear diagnosis:
 - Nasal potential-difference measurements:
 - Complex and time-consuming study
 - Semen analysis:
 - Azoospermia

Imaging

- Chest radiograph:
 - Hyperaeration
 - Peribronchial thickening
 - Atelectasis
 - Hilar lymphadenopathy
 - Pneumothorax/pneumomediastinum
 - Bronchiectasis
 - Blebs
 - Chest CT identifies blebs/bronchiectasis
- Abdominal radiographs and/or CT:
 - Indicated if abdominal pain, vomiting, or abdominal distention
 - Distal intestinal obstruction syndrome
 - Intussusception
- Barium enema:
 - Indicated if suspicion of intussusception
- Sinus films:
 - Limited use because routine sinus films are always cloudy
 - CT scan is needed to assess sinuses for pre-operative planning.

Diagnostic Procedures/Surgery

Bronchoalveolar lavage:

- High percentage of neutrophils and absolute neutrophil count
- Unnecessary if obvious pulmonary symptoms

DIFFERENTIAL DIAGNOSIS

- Respiratory:
 - Asthma
 - Recurrent pneumonia
 - Bronchiectasis

- Pertussis
- Immunodeficiency
- Foreign body aspiration
- α_1 -Antitrypsin deficiency
- Ciliary agenesis
- GI:
 - Chronic diarrhea
 - Gastroenteritis
 - Milk allergy
- Elevated electrolyte levels in sweat:
 - Fucosidosis
 - Glycogen storage disease type I
 - Mucopolysaccharidosis
 - Hypothyroidism
 - Vasopressin-resistant diabetes insipidus
 - Adrenal insufficiency
 - Familial cholestasis
 - Familial hypoparathyroidism
 - Malnutrition
 - Ectodermal dysplasia
 - Atopic dermatitis
 - Infusion of prostaglandin E₁

TREATMENT

PRE HOSPITAL

- Transcutaneous pacing for unstable type II 2nd- or 3rd-degree block
- Atropine:
 - Avoid with type II 2nd-degree block because it may precipitate 3rd-degree block.

ED TREATMENT/PROCEDURES

- Stabilize airway, breathing, and circulation:
 - Correct fluid, respiratory, electrolyte, and glucose abnormalities.
 - Bronchodilators/steroids if wheezing.
- Pneumothorax:
 - Observe if <5–10%.
 - Thoracostomy
- Consultation with the primary CF physician or pulmonary specialist
- Right heart failure:
 - Diuretics
- Hemoptysis:

- Blood products as indicated (check INR)
- Ventilatory support
- DIOS:
 - Usually requires surgery
- Hematemesis:
 - Packed RBCs
 - Blood products for coagulation abnormalities
 - Early consultation with endoscopist
- Intussusception:
 - Correct with barium/air enema
 - May require surgery
- Rectal prolapse:
 - Manual reduction
 - Consider surgical consult
- Respiratory care:
 - Pulmonary toilet/physical therapy
 - Mucous thinning inhaled agents
- Antibiotics for pneumonia:
 - Based on culture and sensitivity
 - *S. aureus* (MSSA):
 - Cephalothin or Nafcillin
 - *S. aureus* (MRSA):
 - Vancomycin or linezolid
 - *P. aeruginosa*:
 - (Tobramycin or amikacin or colistin) + (piperacillin/tazobactam or ticarcillin/clavulanate or ceftazidime or imipenem/cilastatin or meropenem)
 - *S. aureus* (MSSA) and *P. aeruginosa*:
 - (Piperacillin/tazobactam or ticarcillin/clavulanate or cefepime or imipenem/cilastatin or meropenem) + (tobramycin or amikacin or colistin)
 - *S. aureus* (MRSA) and *P. aeruginosa*:
 - (Vancomycin or linezolid) + coverage for Pseudomonas alone
 - *B. cepacia*:
 - Trimethoprim–sulfamethoxazole and/or meropenem and/or cipro and/or minocycline and/or chloramphenicol
 - *H. influenzae*:
 - Cefotaxime or ceftriaxone
 - Sinusitis
 - Based on cultures and sensitivities

Note: Ciprofloxacin may replace the aminoglycoside if sensitive pseudomonas

- CFTR modulation: Ivacaftor
 - Repair of protein function

- Restore airway surface liquid:
 - Nebulized hypertonic saline
- Mucous alteration:
 - Dornase alpha to thin mucus in lungs
- Future directions:
 - Gene therapy: Compacted DNA
 - Anti-inflammatory: High-dose ibuprofen
 - Anti-infective agents:
 - Inhaled tobramycin, aztreonam, colistin
 - Continuous vancomycin infusion
 - Transplantation: Inhaled cyclosporine
 - Nutrition and exercise

MEDICATION

- Amikacin: 7.5–10 mg/kg IV q8h
- Cefazolin: 100 mg/kg/d IV (max.: 6 g/d)
- Cefepime: 50 mg/kg IV q8h (max.: 2 g/8hr)
- Ceftazidime: 50 mg/kg IV q8h (max.: 6 g/d)
- Colistin: 2.5–5 mg/kg/d IV, div. BID–QID
- Imipenem/cilastatin: 15–25 mg/kg IV q6h
- Meropenem: 40 mg/kg IV q8h (max.: 2 g/8hr)
- Nafcillin: 25–50 mg/kg IV q6h (max. 2–3 g q6h)
- Piperacillin/tazobactam: 350–450 mg/kg/d IV (max.: 4.5 g q6h)
- Ticarcillin/clavulanate: 300–400 mg/kg/d IV q6h
- Tobramycin: 2.5–3.3 mg/kg/dose IV q8h
- TMP–SMX: 5–10 mg/kg IV q12h (max.: 160 mg TMP q12h)
- Vancomycin: 15 mg/kg q6h (max.: 1 g q6h)
- Note: Because many patients are undernourished, pharmacokinetics of antibiotics (especially aminoglycosides, penicillins, and cephalosporins) may be altered, requiring careful monitoring.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Pulmonary exacerbation with significant deterioration from baseline, hypoxemia, resistant bacteria, failure of outpatient therapy
- Pneumothorax
- Hemoptysis
- Hematemesis
- Intussusception or unexplained abdominal pain or bowel obstruction

- Hyperglycemia

Discharge Criteria

- Close follow-up to verify the sensitivities of culture results and change therapy as needed
- Avoid hot weather.
- Oral salt supplement when profuse sweating

Issues for Referral

All patients followed by a pediatric pulmonary center. Consultation during acute exacerbations.

FOLLOW-UP RECOMMENDATIONS

- Team approach of specialists
- Breathing treatments, chest PT, exercise programs, antibiotics, replacement of pancreatic enzymes

PEARLS AND PITFALLS

- With CF patients in respiratory distress, always consider pneumothorax: Obtain CXR.
- For CF patients with abdominal pain/vomiting, always consider DIOS and intussusception

- E84.9 Cystic fibrosis, unspecified
- E84.19 Cystic fibrosis with other intestinal manifestations

DACRYOCYSTITIS AND DACRYOADENITIS

Shari Schabowski

BASICS

DESCRIPTION

- Dacryoadenitis and dacryocystitis are inflammatory conditions affecting the lacrimal system of the eye:
 - Dacryoadenitis is inflammation or infection of the lacrimal gland from which tears are secreted.
 - Dacryocystitis is an infection within the lacrimal drainage system.
- Dacryoadenitis may be a primarily inflammatory condition or an infectious process resulting from contiguous spread from a local source or systemic infection.
- Dacryocystitis is a suppurative infection involving an obstructed lacrimal duct and sac.

EPIDEMIOLOGY

Dacryoadenitis is an uncommon disorder more commonly seen on the left:

- Acquired:
 - Uncommon

Dacryocystitis is a more common disorder most often occurring in adult females > 30 yr old but may be seen in infants

Etiology—Dacryoadenitis

- Most commonly caused by systemic inflammatory conditions:
 - Autoimmune diseases
 - Sjögren syndrome
 - Sarcoidosis
 - Crohn's disease
 - Tumor
- Infectious causes may be primary or may occur secondary to contiguous spread from bacterial conjunctivitis or periorbital cellulites
- Acute, suppurative:
 - Bacteria most common cause in adults:
 - *Staphylococcus aureus*
 - *Streptococci*
 - *Chlamydia trachomatis*
 - *Neisseria gonorrhoea*
- Chronic dacryoadenitis:
 - Nasal flora > ocular flora

Pediatric Considerations

- Viruses most common cause in children:
 - Mumps
 - Measles
 - Epstein–Barr virus
 - Cytomegalovirus
 - Coxsackievirus
 - Varicella-zoster virus
- Slowly enlarging mass may be dermoid

Etiology—Dacryocystitis

- Under normal conditions, tears drain via pumping action at the lacrimal duct, moving tears to lacrimal sac and then into middle turbinate/sinuses.
- Symptoms begin when duct to lacrimal sac becomes partially or completely obstructed:
 - In acquired form, chronic inflammation related to ethmoid sinusitis is a commonly implicated cause but many nasal and systemic inflammatory conditions have been correlated with this process:
 - May also occur secondary to trauma, a dacryolith, after nasal or sinus surgery or by any local process that might obstruct flow
 - Stasis in this conduit results in overgrowth of bacteria and infection.
 - Infection may be recurrent and may become chronic:
 - Most common bacteria: Sinus > ocular flora
 - *S. aureus* is the most common organism

Complications may include formation of draining fistulae, recurrent conjunctivitis, and even abscesses or orbital cellulitis

Pediatric Considerations

- In congenital form, presentation occurs in infancy as a result of dacryocystoceles
- High morbidity and mortality associated with this form:
 - Caused by systemic spread of infectious process or bacterial overgrowth in a partially obstructed gland
- The most common organism is *Streptococcus pneumoniae*.

DIAGNOSIS

Both will present as a unilateral, red, painful eye.

SIGNS AND SYMPTOMS

Dacryoadenitis

May present as an acute or indolent swelling and erythema of upper eyelid

- Swelling and tenderness greatest in temporal aspect of upper lid under orbital rim:
 - S-shaped lid
- Mass may be palpable

- May be associated with:
 - Extensive cellulitis
 - Conjunctival injection and discharge
 - Increase or decrease in tear production
 - Ipsilateral conjunctival injection and chemosis
 - Ipsilateral preauricular adenopathy
 - Systemic toxicity may be present
- Normal visual acuity, slit-lamp, and funduscopy exams
- May cause pressure on the globe or globe displacement:
 - Visual distortion may occur.
- Chronic form: Slowly progressive, painless swelling

ALERT

Promptly determine clinical probability of spread *from N. gonorrhoea* conjunctivitis:

- Morbidity very high:
 - Visual loss likely
 - Systemic illness probable
- Treatment differs significantly from other causes.

Dacryocystitis

Presents as an acutely inflamed, circumscribed mass extending inferiorly and medially from inner canthus:

- Epiphora or excessive tearing—hallmark symptom:
 - Tear outflow is obstructed.
- Discharge from punctum:
 - Pressure on the inflamed mass may result in purulent material from the punctum.
 - This may be diagnostic.
- Cellulitis extending to lower lid may be present
- Low-grade fever may be present, but patient rarely appears toxic.

ESSENTIAL WORKUP

Complete eye exam, including visual acuity, extraocular movements, slit-lamp, and funduscopy exam:

- Flip lids
- Examine nasal passages

Pediatric Considerations

Careful inspection for evidence of extension to orbital cellulitis or meningitis is essential.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Tests of expressed material (used to help direct specific antibiotic treatment):
 - Gram stain
 - Culture and sensitivity
 - Chocolate agar plating if GC suspected
- CBC and blood cultures

Imaging

CT of orbit/sinus to evaluate deep-tissue extension or possible underlying disorder in dacryoadenitis particularly with recurrent cases or in children at risk for orbital cellulitis extending from dacryocystitis.

DIFFERENTIAL DIAGNOSIS

- Dacryoadenitis:
 - Autoimmune diseases
 - Lacrimal gland tumor
 - Hordeolum
 - Periorbital cellulitis
 - Severe blepharitis
 - Orbital cellulitis
 - Insect bite
 - Traumatic injury
 - Orbital or lacrimal gland tumor
- Dacryocystitis:
 - Insect bite
 - Traumatic injury
 - Acute ethmoid sinusitis
 - Periorbital cellulitis
 - Acute conjunctivitis

TREATMENT

ED TREATMENT/PROCEDURES

- Early diagnosis and initiation of treatment will reduce risk of extension of infection to adjacent structures and systemic infection.
- Topical antibiotics may be considered to treat or avoid conjunctivitis.

Dacryoadenitis

- Cool compresses to decrease inflammation and nonsteroidal pain medication
- Viral etiology:
 - Typically self-limited inflammation
- Bacterial etiology:

- Antibiotics
- Oral for mild infection:
 - Cephalexin
 - Amoxicillin/clavulanate
- IV for severe infection:
 - Cefazolin
 - Ticarcillin/clavulanate
- Tetanus toxoid if necessary
- Incision and drainage rarely necessary except in very severe cases:
 - Perform with consultation to facial surgery service or ophthalmology

Pediatric Considerations

- Cool compresses
- Analgesics
- If cause unclear, treat with antibiotics as with adults

Dacryocystitis

- Drainage of infected sac is essential:
 - Warm compresses and gentle massage to relieve obstruction
 - May facilitate outflow from obstructed tract with nasal introduction of vasoconstricting agent
 - Incision and drainage only in severe cases:
 - Typically done by ophthalmology
 - Avoid in ED when possible
 - May result in fistula formation
 - Duct instrumentation to facilitate drainage is not indicated in acute setting:
 - Reserve instrumentation for nonacute setting, if necessary at all
 - Manipulation while duct is inflamed may cause injury to duct and permanent obstruction from scarring and stenosis.
 - Topical ophthalmic antibiotic drops to prevent secondary conjunctivitis
- Systemic antibiotics to resolve infection and prevent spread to adjacent structures:
 - Oral for mild infection
 - Intravenous when febrile or severe infection
- Analgesics

Pediatric Considerations

- Newborns respond well to massage and topical antibiotics in ~95% of cases.
- If no resolution in 1st yr of life, may require probing of duct by ophthalmologist
- Children <4 yr old who develop dacryocystitis:
 - At increased risk for *Haemophilus influenzae* infection, if not immunized:
 - Given typical age of presentation, complete immunization is unlikely at primary presentation.

- Recommended schedule 2, 4, 6, and 12–15 mo
- *H. influenzae* type B carries high risk for bacteremia, septicemia, and meningitis.
- Treat afebrile, well-appearing children with responsible parent with oral cefaclor or amoxicillin/clavulanate.
- Administer cefuroxime IV in acutely ill patients.

MEDICATION

- Amoxicillin/clavulanate (Augmentin): 500 mg (peds: 20–40 mg of amoxicillin/kg/24h) PO q8h
- Cefaclor: 500 mg (peds: 20–40 mg/kg/24h) immediate release PO TID
- Cefazolin: 500–1,000 mg (peds: 50–100 mg/kg/24h) IV q6–8h
- Cefuroxime: 750–1,500 (peds: 50–100 mg/kg/24h) mg IV q8h
- Cephalexin: 500 mg (peds: 25–100 mg/kg/24h) PO QID
- Erythromycin ophthalmic ointment: 2 drops QID to affected eye
- Tetracaine and phenylephrine topical solution single-dose nasal spray
- Ticarcillin/clavulanate: 3.1 g (peds: 200–300 mg of ticarcillin/kg/24h) IV q4–6h
- Trimethoprim-polymyxin ointment: 2 drops QID to the affected eye

FOLLOW-UP

DISPOSITION

Admission Criteria

- Adults:
 - Febrile or toxic appearance
 - Concomitant medical problems including diabetes or immunosuppression
 - Extensive cellulitis
 - Suspicion of adjacent spread with deep tissue involvement or meningitis or *Neisseria meningitidis*
- Children:
 - Acutely ill appearance
 - Concomitant medical problems
 - Extensive cellulitis
 - High risk for *H. influenzae* (nonvaccinated)
 - If reliable follow-up within 24 hr cannot be arranged

Issues for Referral

Dacryoadenitis and dacryocystitis should be referred promptly to ophthalmology:

- Patients with dacryocystitis require further evaluation to confirm complete drainage of sac and to assess need for further intervention to avoid recurrence.
- Availability of follow-up should be confirmed and ophthalmologic consultation

should be completed prior to discharge.

PEARLS AND PITFALLS

- In cases of red eye with lid swelling, specifically examine the lacrimal structures for evidence of involvement.
- Skin incision and drainage of dacryocystitis should be avoided whenever possible to avoid fistula formation:
 - Intranasal vasoconstricting agents should be used primarily to facilitate drainage.

DECOMPRESSION SICKNESS

Catherine M. Visintainer • Nicole L. Lunceford • Peter J. Park

BASICS

DESCRIPTION

Multisystemic disease process resulting from escape of inert gas bubbles (nitrogen) out of solution into body fluids and tissues

ETIOLOGY

Mechanism:

- Pathophysiology:
 - Increases in ambient pressure cause increase in partial pressure of nitrogen inspired (as per Henry law, below).
 - Nitrogen accumulates in tissues in increasing concentrations the longer ambient pressures remain elevated.
 - Decompression sickness (DCS) results when ambient pressure keeping nitrogen in solution decreases too rapidly (on ascent), preventing gradual removal of excess body burden of nitrogen.
 - As the nitrogen removal gradient is overwhelmed, tissues become supersaturated and bubble formation occurs.
- Henry law:
 - Amount of gas that will dissolve in a solution at a given temperature is directly proportional to partial pressure of that gas.
 - Increases in partial pressure result in larger amount of gas dissolved in tissue.
 - Decreases in partial pressure result in gas coming out of solution.
- Bubbles are viewed as foreign material by body inciting inflammatory and coagulation responses
 - Leads to increased vascular permeability and decreased intravascular volume and hemoconcentration
- Bubble location determines clinical effects:
 - Blood flow and lymphatic obstruction leading to ischemia, infarction, or lymphedema
 - Mechanical distention of tissues leading to pain
- Risk factors for DCS:
 - Dive factors:
 - Greater depth
 - Longer bottom time
 - Multiple dives in a day
 - Rapid ascent

- Cold water
- Human factors:
 - Obesity
 - Intercurrent illness
 - Pulmonary disease
 - Dehydration
- Proper use of dive tables and computers does *not* eliminate risk for DCS.
- Pre-dive vigorous exercise may reduce risk
- 50% of patients develop symptoms in 1 hr, 90% develop symptoms within 6 hr.
- Airplane flight following diving can precipitate DCS owing to lower cabin pressure.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Cutaneous:
 - Scarlatiniform, erysipeloid, or mottled rash:
 - Mottling (*Cutis marmorata*) often indicates more severe disease
 - Peau d'orange appearance owing to lymphatic obstruction
- Musculoskeletal (the bends):
 - Pain:
 - Dull, deep muscular aching
 - Often in a joint (elbow and shoulder most common)
 - Typically not exacerbated by movement or reproduced with palpation
- GI:
 - Nausea and vomiting
 - Abdominal pain
- Pulmonary (the chokes):
 - Pulmonary vasculature obstruction from bubble burden (venous gas embolism)
 - Acute respiratory distress
 - Substernal chest pain/pressure
 - Cough
 - Dyspnea
 - Hypoxia
- CNS:
 - Weakness and fatigue
 - Numbness and paresthesia
 - Agitation
 - Headache
 - Dizziness
 - Vertigo

- Convulsion
- Bladder and/or bowel incontinence
- Lethargy
- Visual disturbances
- Most commonly affects spinal cord (lower thoracic and lumbar regions)
- Inner ear (the staggers):
 - Vestibular damage
 - Dizziness, vertigo, tinnitus, nausea
 - Similar symptoms to inner ear barotrauma but with worse prognosis

History

Meticulous dive history including time at depth, ascent history, and onset of symptoms.

Physical-Exam

Thorough physical exam including a detailed neurologic exam

ESSENTIAL WORKUP

- Clinical diagnosis: Recognize risk factors and various clinical presentations.
- Careful neurologic exam to document possible waning symptoms
- Trial of pressure:
 - Rapid relief of symptoms upon recompression in a hyperbaric chamber may be the only way to diagnose DCS conclusively.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - Increased hematocrit secondary to hemoconcentration
- Electrolytes, BUN, creatinine, glucose
- Urinalysis
 - Increased specific gravity may indicate intravascular volume depletion
- ABG and pulse oximetry:
 - Monitor oxygenation

Imaging

- CXR:
 - Concomitant pulmonary barotrauma
 - Noncardiogenic pulmonary edema from DCS
- Extremity x-ray
 - Rule out trauma as cause of pain
- Head CT when altered mental status or neurologic deficit

DIFFERENTIAL DIAGNOSIS

- Musculoskeletal injury unrelated to bubble formation
- Inner or middle ear barotraumas
- Arterial gas embolism
- Cerebrovascular accident (CVA)
- Trauma

TREATMENT

PRE HOSPITAL

- Cautions:
 - _ Recognize DCS:
 - Postdive extremity pain often attributed to muscle strain
 - Serious neurologic complaints often minimized because diver does not consider DCS
 - _ If air evacuation required:
 - Limit altitude to less than 1,000 ft or use pressurized aircraft
- Controversies:
 - _ In-water recompression:
 - Return injured diver/patient to depth where symptoms are ameliorated.
 - Extremely difficult
 - Need large amount of surface support

INITIAL STABILIZATION/THERAPY

- Airway, breathing, and circulation management (ABCs)
- Provide normobaric (100%) oxygen via mask or endotracheal tube (ETT):
 - _ Increases inert gas (nitrogen) elimination from tissues, reducing gas bubble size
 - _ Increases oxygen delivery to injured tissue
- Maintain patient in supine position to prevent further cerebral involvement
- Early recompression in hyperbaric chamber

ED TREATMENT/PROCEDURES

- IV rehydration with 0.9% normal saline (NS) to maintain goal urine output of 1–2 mL/kg/h:
 - _ Diver usually dehydrated owing to diuretic effect of pressure, exercise, breathing dry compressed air, and increased vascular permeability
 - _ Increased fluid assists with gas removal and dissolution of nitrogen
- Hyperbaric oxygen recompression therapy (see Hyperbaric Oxygen Therapy):
 - _ Arrange transportation to nearest hyperbaric facility.
 - _ Prophylactic chest tube for simple pneumothorax to prevent conversion to tension pneumothorax in chamber

- Fill endotracheal and Foley catheter balloons with water or saline to avoid shrinkage/damage during recompression.
- Recompression therapy protocols found in US Navy diving manual
- Divers Alert Network (DAN):
 - Provides 24-hr emergency hotline for medical consultation on treatment of dive-related injuries and for referrals to hyperbaric chambers ([919] 684-9111)
- Analgesics and antiemetics
- Diazepam (Valium) for severe vertigo
- Adjunctive therapy with NSAIDs and/or heliox may reduce number of recompression treatments required

FOLLOW-UP

DISPOSITION

Admission Criteria

Refer all patients with suspected or diagnosed DCS for hyperbaric therapy.

Discharge Criteria

- Stable patients with mild symptoms may be discharged posthyperbaric oxygen treatment.
- Air travel may exacerbate symptoms as ambient pressure decreases.

FOLLOW-UP RECOMMENDATIONS

Hyperbaric referral

PEARLS AND PITFALLS

- Difficult to distinguish musculoskeletal DCS from musculoskeletal pain
- Significant fatigue may be the only symptom of DCS
- Even minor symptoms or resolving symptoms suspected of being DCS should be treated with hyperbaric recompression therapy
- Do not delay recompression therapy for lab testing and imaging when DCS is most likely diagnosis
- Avoid in-water recompression therapy.

DEEP VEIN THROMBOSIS

Sarah K. Flaherty

BASICS

DESCRIPTION

- A constant balance exists between intravascular clot formation and clot dissolution, clot forming when the former overpowers the latter.
- Clot can be superficial (to the fascia) or deep. The latter is called deep vein thrombosis (DVT).
- Pulmonary embolism (PE) and DVT are different ends of the clinical spectrum of the same disease process (venous thromboembolism, VTE).
- DVT can be upper or lower extremity, as well as distal or proximal (to the popliteal vein)
- Incidence is ~2 1st time VTE episodes per 1,000 person yr.
- Prevalence increases with advancing age
- Common in both medical and surgical hospitalized patients
- Diagnosis is more accurate using active surveillance rather than clinical suspicion.

Pediatric Considerations

DVT in children is unusual, but when cases do occur, search for an underlying reason for hypercoagulability. Also, upper-extremity DVT is associated with central IV lines in children.

ETIOLOGY

- Clot formation/dissolution is an intricately balanced system which can be influenced by many factors which must be considered
- Hypercoagulable states:
 - Cancer
 - Myeloproliferative disorders
 - Nephrotic syndrome
 - Sepsis
 - Inflammatory conditions:
 - Ulcerative colitis
 - Increased estrogen:
 - Pregnancy
 - Exogenous hormones (OCPs, HRT)
 - Antiphospholipid syndrome
 - Protein S, C, and antithrombin III deficiencies, factor V Leiden, prothrombin gene mutations, lupus, others
- Stasis:

- Prolonged bed rest
- Immobility (such as from a cast)
- Long plane, car, or train rides
- Neurologic disorders with paralysis
- CHF
- Obesity
- Vascular concerns/damage:
 - Trauma
 - Surgery
 - Anatomic anomalies (May–Thurner syndrome)
 - Central lines:
 - Especially with upper extremity DVT
- Multifactorial issues:
 - Advancing age
 - Medications (hydralazine, procainamide, phenothiazines)
 - Tobacco use
 - Prior DVT or PE
- Genetics:
 - Important with respect to some of the risk factors; ask about family history of clotting.
 - There is no consensus about which patients with VTE to test for inherited thrombophilias

Pregnancy Considerations

Pregnancy is a risk factor for DVT, especially in the 3rd trimester up to the 2nd wk postpartum.

Geriatric Considerations

Age in and of itself is a risk for DVT (and PE). As with many diseases, the presentation may be atypical in the elderly.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Leg swelling:
 - > 1 cm difference is usually significant.
- Leg warmth and redness
- Leg pain and tenderness
- Palpable cord
- In superficial thrombophlebitis, a red pipe cleaner–like cord may be visible and palpable.
- Arm swelling, warmth, or tenderness:

- Upper extremity or subclavian vein involved
- Phlegmasia cerulea dolens:
 - Cold, tender, swollen, and blue leg (secondary arterial insufficiency, venous gangrene)
- In phlegmasia alba dolens:
 - Cold, tender, and white leg (secondary arterial insufficiency)

ESSENTIAL WORKUP

- Determination of a patient's clinical (pretest) risk is a key step in a workup for DVT.
- A careful history and physical exam, interpreted in the context of the risk-factor profile, is the most important driver of subsequent diagnostic evaluation as individual clinical findings are poorly predictive in isolation.
- Consider further evaluation for underlying malignancy when appropriate as VTE may be initial manifestation.

DIAGNOSIS TESTS & INTERPRETATION

Lab

D-dimer testing:

- D-dimer, a byproduct of endogenous clot formation, is becoming increasingly used in evaluation of patients for DVT and PE.
- *Only useful when the result is negative* (to exclude DVT). Positive D-dimer does not make the diagnosis; it only mandates further testing.
- Methods of measuring D-dimer levels:
 - Latex agglutination (1st-generation tests) and microlatex agglutination (2nd-generation) are generally insufficient.
 - Whole-blood latex agglutination (SimpliRED) is valuable if negative in low probability patients (using Wells criteria).
 - Enzyme-linked immunosorbent assay (ELISA) testing gives a quantitative result and has been validated in large clinical studies in ED patients; particularly when combined with assessment of pretest probability

Imaging

- Contrast venography:
 - Once the imaging test of choice; now rarely performed because it is invasive, expensive, and has complications.
 - Involves injection of contrast medium into a leg vein, which can cause thrombophlebitis in patients undergoing the procedure; as well as contrast dye reactions and possible renal damage
- Compression US:
 - Standard 1st-line diagnostic test

- Venous study. Normal veins compress; those with clots do not.
- Color Doppler can be useful for identifying the vein but does not add substantially to accuracy. Duplex scanning refers to the combination of compression B-mode US and color Doppler.
- Has a sensitivity in the high 90% range
- Should be repeated (or followed up with contrast venography) in high-risk patients with negative US.
- Other tests include radionuclide venography and impedance plethysmography; however, these are not commonly used in clinical practice

DIFFERENTIAL DIAGNOSIS

- Superficial thrombophlebitis
- Cellulitis
- Torn muscle and/or ligaments (including plantaris and gastrocnemius tears)
- Ruptured Baker cyst
- (Bilateral) edema secondary to heart, liver, or kidney disease
- Venous valvular insufficiency
- Drug-induced edema (calcium channel blockers)
- (Unilateral) edema from abdominal mass (gravid uterus or tumor) or lymphedema
- Postphlebotic syndrome (from prior thrombophlebitis)

TREATMENT

INITIAL STABILIZATION/THERAPY

In cases of phlegmasia cerulea, or alba dolens:

- IV access
- Supplemental oxygen
- Surgical or vascular consultation

ED TREATMENT/PROCEDURES

- Systemic anticoagulation:
 - In patients without contraindications as PE will occur in ~50% of untreated DVT
 - Use either unfractionated heparin or low-molecular-weight heparin (LMWH), fondaparinux or adjusted dose subcutaneous heparin
 - Carefully selected patients can be primarily treated with as outpatients
- Warfarin:
 - Started shortly after a heparin has been administered
 - Not before heparin because of the theoretic risk for inducing a transient hypercoagulable state
 - Insufficient evidence exists to safely recommend other oral anticoagulants (e.g., dabigatran, rivaroxaban, apixaban)

- Vena cava filters:
 - Two main indications:
 - Contraindications to systemic anticoagulation
 - New thromboembolic event while on adequate anticoagulation
 - Vena cava filters can be placed transcutaneously, usually by a vascular or trauma surgeon or radiologist.
 - Empiric filter placement may be useful in certain settings:
 - Ongoing risk such as cancer, polytrauma.
 - Risk for a recurrent PE could be fatal because of poor cardiopulmonary reserve or a recent PE.
 - Randomized data suggest that filter placement is no more effective than anticoagulation.
 - Filters can also be deployed in the superior vena cava in the setting of upper-extremity DVT.
- Thrombolysis:
 - Rarely indicated
 - Roughly a 3-fold increase in bleeding complications
 - Catheter-administered lytic therapy is used more commonly in upper-extremity DVT
- Thrombectomy (surgical or percutaneous):
 - Occasionally recommended for patients with extensive disease
 - Consult a vascular surgeon
- Septic thrombophlebitis:
 - Surgical excision of the vein or IV antibiotics

MEDICATION

- Maintain treatment with IV or SQ therapy until INR has been therapeutic for 2 consecutive days.
- Warfarin: 5 mg/d starting dose with a prothrombin time being checked on the 3rd day.
- Heparin (unfractionated): 80 U/kg bolus followed by an 18 U/kg/h drip, with the activated partial thromboplastin time (aPTT) titrated 1.5–2.5 times normal.
- LWMH (enoxaparin): 1 mg/kg SC BID for outpatients (alternative: 1.5 mg/kg SCQD).
- Tinzaparin: 175 U/kg/d SC.
- Dosing regimens are based on total body weight; however, in obese patients alternative dosing should be considered.
- Treatment usually maintained for at least 3 mo, total length is individualized.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with DVT unable to receive LMWH as an outpatient or poor follow-up
- Patients with concomitant PE or other serious diseases (i.e., renal failure)
- Patients thought to be at especially high bleeding risk
- Patients with phlegmasia

Discharge Criteria

- Outpatient treatment with an LMWH:
 - No serious concomitant disease that requires hospitalization.
 - Patient has means of communication and transportation to return to the hospital if needed, as well as appropriate follow-up.
 - Patient (or family member) is willing and able to inject the medication.
 - aPTT does not need to be checked.
 - Heparin-induced thrombocytopenia is less common with the LMWH but still occurs.
- Patients with superficial or distal thrombophlebitis can be discharged with close follow-up.

Issues for Referral

- Consult vascular surgery if there is any question about arterial insufficiency.
- Consider need for inferior vena cava filter in patients who have contraindications to full anticoagulation or form new clots on adequate anticoagulation.

ALERT

When the clinical suspicion is high but the US is negative, remember to advise the patient to follow-up with his or her primary care physician, and to have a follow-up US in ~1 wk.

FOLLOW-UP RECOMMENDATIONS

Outpatient treatment with an LMWH:

- Patient needs hematocrit, platelet count, and INR checked in 2–3 days.
- INR needs to be checked at about day 3.

PEARLS AND PITFALLS

- Do not use a negative Homans sign to exclude the diagnosis of DVT.
- Use some measure (whether clinical gestalt or a formal scoring system such as the Wells score) to determine pretest probability for DVT.
- In high pretest probability patients, do not rely on D-dimer testing; instead, perform venous imaging, generally compression US.
- In medium-risk patients with a negative D-dimer or negative US, arrange or recommend a repeat study in 1 wk.

DEFIBRILLATORS, IMPLANTABLE

Robert D. Sidman • Lawrence S. Rosenthal

BASICS

DESCRIPTION

- An implantable cardiac device (ICD) is a small battery-powered electrical impulse generator implanted SC in patients at risk of cardiac arrest from cardiac arrhythmias.
- Lead(s) are positioned via venous return to heart and are endocardial (RA and RV) or epicardial (LV via coronary sinus).
- The device is able to detect and convert ventricular and atrial arrhythmias to sinus rhythm with electric shocks delivered between the ICD can and coil(s) in the RV (single coil) and the SVC/RA juncture (dual coil).
- Similar method of implantation as a pacemaker
- Newly released devices (S-ICD) no longer have endocardial leads reducing the risk of blood infection.
- 450,000 individuals experience sudden cardiac death yearly in US:
 - >100,000 devices implanted in US each year
 - ICDs have been shown to reduce mortality more effectively than antiarrhythmic drug therapy in patients with left ventricular dysfunction:
 - Absolute risk reduction of mortality of 7% in the 1st 2 yr
 - Benefit over antiarrhythmic drug therapy is limited to patients with ejection fractions of <35%
 - Effective in reducing mortality in hypertrophic cardiomyopathy
 - Both ischemic and nonischemic dilated cardiomyopathy patients show survival benefit with ICD
- Immediate postimplant complications:
 - Pneumothorax
 - Vascular perforation
 - Acute lead dislodgement
- Appropriate shocks:
 - 5% a year for primary prevention
 - 20% a year for secondary prevention
- Electrical storm:
 - ≥ 2 appropriate shocks delivered within a 24-hr period
- Inappropriate shocks:
 - 10–20% of ICD recipients
 - Oversensing
 - Inappropriate classification of rapid supraventricular tachycardia
- Device infection:

- 1–12% of patients
- Acute 1–30 days—think staph
- Subacute > 30 days—think *Staphylococcus epidermidis* or gram negatives
- 31–66% mortality if the device is left in place
- Infection may involve the skin, the generator, the defibrillation pocket, or the leads.
- Coagulase-negative staphylococci (42%)
- Methicillin-sensitive staphylococci (25%)
- MRSA (4%)
- Gram-negative bacilli (9%)
- Pocket hematoma do not aspirate
- Vascular occlusion

ETIOLOGY

- Electrical storm: (≥ 2 appropriate shocks delivered within a 24-hr period)
 - Unknown
 - Decompensated heart failure
 - Acute ischemia
 - Metabolic disturbances
 - Drug proarrhythmia
 - Thyrotoxicosis
 - Fever with dilated cardiomyopathy
 - Genetic channelopathies, Brugada syndrome, Long QT, catecholaminergic polymorphic VT, arrhythmogenic RV cardiomyopathy
 - Postcardiac surgery
 - ICD induced from left ventricular or T-wave pacing
- Inappropriate shocks:
 - Oversensing:
 - QRS, T-wave, P-wave, myopotential, electromagnetic interference (EMI)
 - Frequent nonsustained ventricular dysrhythmias
 - Lead fracture
 - Loose setscrew
 - Chatter between leads
 - Header (device circuitry) problem
 - Inappropriate classification of rapid supraventricular tachycardia:
 - Atrial fibrillation
 - Sinus tachycardia
 - Atrial flutter
 - Other supraventricular tachycardias (SVT)
- Device/site-related:
 - Wound infection:
 - *Staphylococcus aureus* (most aggressive and seen early)

- *S. epidermidis* (more indolent and later)
- *Escherichia coli*, *Pseudomonas* species, and *Streptococcal* species (less common)
- Pocket hematomas
- Vascular (venous thrombosis/embolism secondary to impedance of venous flow as a result of the ICD lead[s])

DIAGNOSIS

SIGNS AND SYMPTOMS

- Felt bad before shock and good after: Likely appropriate therapy
- Felt good before and after shock: Likely inappropriate therapy
- Felt bad before and after shock: Consider ongoing arrhythmia or ischemia
- Appropriate shocks:
 - Syncope or near syncope
 - Lightheadedness or dizziness
 - Shortness of breath
 - Palpitations (non-SVT)
 - Chest discomfort or pain
 - Diaphoresis
- Inappropriate shocks:
 - Palpitations (SVT)
 - No symptoms (Lead-related fractures, inappropriate sensing)
- Device infection:
 - Fever
 - Chills
 - Malaise
 - Anorexia
 - Nausea
 - Diaphoresis
 - Hypotension
 - Heart murmur
 - Wound infection:
 - Pain
 - Erythema
 - Purulent drainage
 - Warmth
 - Fluctuance
 - Skin erosion
- Hematoma at the insertion site (pocket hematoma):
 - Pain (mild)
 - Swelling

- Vascular (thromboembolic phenomena):
 - Unilateral swelling in upper extremity
 - Superficial varicosities

History

- Therapy-related:
 - Recent angina, heart failure
- Device-related:
 - Recent implant (<14 days)
 - Skin trauma to wound
 - Lead-related:
 - Repetitive arm motions
 - “Twiddler’s syndrome” (inadvertent manipulation of the device)
 - Vascular:
 - Recent implant
 - Multiple leads

Physical-Exam

- Vital signs
- Evidence of heart failure/acute coronary syndrome:
 - Displaced point of maximal impulse
 - Left ventricular heave
 - Presence of an S3 or S4
 - Presence of basilar rales
 - Dullness to percussion
 - Determination of jugular venous pressure
 - Hepatojugular reflex
 - Peripheral edema
- Device/site-related:
 - Exam of wound/pocket:
 - Demarcation of pocket (erythema)
 - Purulent drainage
 - Exam of affected upper extremity

ESSENTIAL WORKUP

- Following ICD therapy:
 - ICD interrogation will determine whether therapy was appropriate and can determine lead fracture if present.
 - EKG (transient ST-segment changes and elevations of the cardiac enzymes may be seen after shock delivery and do not necessarily indicate myocardial damage)
 - CXR may diagnose lead fracture.
- Device/site-related:

- Signs and symptoms of local vs. systemic infection
- Upper-extremity swelling suggests venous thrombosis.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Therapy-related:
 - 12-lead EKG
 - Cardiac enzymes
- Device-related:
 - CBC with differential
 - Blood cultures
 - Do not aspirate pocket

Imaging

- PA and lateral chest radiograph:
 - Lead fractures
 - Lead dislodgement
- Vascular US of upper extremity
- MRI absolutely contraindicated:
 - Magnetic field may damage ICDs and cause heating at lead tip.

Diagnostic Procedures/Surgery

- Therapy-related:
 - Device interrogation by electrophysiologist/cardiologist
 - Application of magnet inhibits tachy therapies (does not affect brady support pacing).
- Device/site-related (pocket hematoma/infection):
 - Referral to surgeon/electrophysiologist
 - Electrocautery should generally be avoided in patients with ICDs unless device is deactivated with programming or with magnet application.
- External defibrillation is safe, but avoids shocking directly over ICD (see below).

DIFFERENTIAL DIAGNOSIS

- Appropriate therapies:
 - Single shock following an episode of VT or VF with restoration of normal rhythm
- Inappropriate therapies:
 - Usually due to SVT (afib), lead fracture, or EMI
- Phantom shocks:
 - Patient awakened from sleep by a perceived shock(s)

TREATMENT

PRE HOSPITAL

Following an ICD electrical discharge:

- IV access
- Continuous EKG monitoring
- Advanced cardiac life support (ACLS) protocols

INITIAL STABILIZATION/THERAPY

- ACLS protocols
- Magnet application inhibits ICD therapies.
- Device-related:
 - _ Pain management
 - _ Elevation of affected extremity (upper-extremity thrombosis)

ED TREATMENT/PROCEDURES

- Patients with devices should receive treatment according to standard ACLS protocols.
- Electrical storm may require IV antiarrhythmic agents such as amiodarone.
- Inappropriate therapies:
 - _ Treatment of supraventricular dysrhythmia to prevent ICD shocks with β -blockers or calcium channel blockers
- Lead-related problems may require further surgical intervention or device reprogramming; magnet application will inhibit tachy therapies.
- Device infections:
 - _ Broad-spectrum antibiotics
 - _ Obtain blood cultures 1st

MEDICATION

- Amiodarone 150 or 300 mg IVP followed by an infusion 1 mg/kg/h for 6 hr, then reduce to 0.5 mg/kg/h. Can rebofus (150 mg) as often as required
- Metoprolol: 5 mg IV as needed to control heart rate
- Diltiazem: 5–20 mg IV, then a maintenance drip to control heart rate
- Cefazolin: 1 g IV q8h
- Vancomycin: 1 g IV q12h
- Cephalexin: 500 mg PO QID
- Warfarin for documented venous occlusion, INR 2–3 for 3 mo

FOLLOW-UP

DISPOSITION

Admission Criteria

- Therapy-related:
 - Ongoing/suspected cardiac ischemia or heart failure
 - Multiple ICD shocks and initiation of antiarrhythmic agents for VF/VT or other SVT
 - Treat underlying process and consult with electrophysiologist to determine if immediate interrogation is warranted.
- Device/site-related:
 - Skin erosion
 - Wound dehiscence
 - Systemic infection/endocarditis
 - Need for lead revision
 - Expanding pocket hematoma
 - Upper-extremity thrombosis

Discharge Criteria

- Therapy-related:
 - If patient is hemodynamically stable without evidence of active ischemia or heart failure, interrogation usually not required:
 - Single-shock, appropriate therapy
 - Consult with electrophysiologist and arrange appropriate follow-up.
 - Device reprogrammed to avoid inappropriate therapy
- Device/site-related:
 - Localized infection
 - No signs of skin erosion
 - Pocket not expanding:
 - Prophylactic antibiotics are not indicated for pocket hematomas.
 - Wound stable

FOLLOW-UP RECOMMENDATIONS

- Therapy-related:
 - Cardiologist or electrophysiologist
- Device-related:
 - Surgeon or cardiologist/electrophysiologist

PEARLS AND PITFALLS

- Aspiration of device pocket is not recommended.
- Care should be taken not to deliver external shocks directly over the device, as it may shunt energy away from the heart.

DELIRIUM

Lori A. Stolz • Arthur B. Sanders

BASICS

DESCRIPTION

- Delirium is a clinical syndrome characterized by acute changes in awareness, cognition, and perception with a waxing and waning course.
- Delirium is a syndrome secondary to an underlying medical condition.
- Pathophysiology unknown:
 - Diffuse cerebral dysfunction
 - Derangements of cerebral acetylcholine
 - CNS dopamine, γ -aminobutyric acid, and serotonin may be involved.
- Frequently missed by emergency medicine physicians due to atypical chief complaints.
- Associated with increased mortality for inpatients and increased length of stay.

ETIOLOGY

- Neurologic:
 - Meningitis or encephalitis
 - Seizure
 - Wernicke encephalopathy
 - Hypoxia and hypoperfusion of the brain
 - Intracranial bleed or mass
- Pulmonary:
 - Pneumonia
 - Other pulmonary etiology of hypoxia
- Cardiovascular:
 - Hypertensive crisis
 - Acute coronary syndromes
 - Arrhythmia
- GI:
 - Hepatic encephalopathy
 - Dehydration
- Renal:
 - UTI
 - Acute renal failure
- Endocrine:
 - Hypoglycemia
 - Hyperglycemia
 - Hypothyroid

- Rheumatologic:
 - Collagen vascular disorder
- Toxicologic:
 - Environmental toxins
 - Medications
 - Withdrawal from barbiturates or alcohol
- Other:
 - Electrolyte abnormalities
 - Vitamin deficiencies
 - Hypothermia
 - Hyperthermia
 - Trauma

Geriatric Considerations

- Common presentation in older ED patients
- Up to 10% of older ED patients may have delirium.
- Many patients will present with subtle symptoms and vague chief complaints:
 - Fall, dizzy, or not feeling well
- Waxing and waning symptoms
- Cause may be life-threatening condition.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Disturbed consciousness:
 - Hyperalert:
 - Combative
 - Agitation
 - Hypoactive:
 - Lethargic
 - Stupor
 - Coma
 - Can have mixed hyperalert and hypoactive state with rapid oscillations
- Cognitive changes:
 - Disorientation
 - Impaired memory
 - Disorganized thinking and speech
 - Misperceptions, illusions, delusions, and hallucinations
- Reduced awareness of environment
- Inattention:
 - Difficulties in focusing, shifting, and maintaining attention
 - Restlessness

- Distractibility
- Lability

History

- History from caregivers is essential.
- Time course:
 - Hours to days
 - Fluctuating course
- Medications:
 - Prescribed, over-the-counter and illicit drugs
 - Dosing
 - Recently added medications
 - Recently discontinued medications
- Associated signs, symptoms, pre-existing conditions that would indicate underlying etiology

Physical-Exam

- Vital signs
- Complete neurologic exam:
 - Careful attention to changes in mental status
 - Orientation
 - Focal deficits
 - Hallucinations
- Psychiatric exam
- Cardiovascular, pulmonary, GI systems.
- Use physical exam to determine possible underlying medical illness and to focus further workup, especially sources of infection and sepsis.
- Several screening tools are available to evaluate for delirium:
 - Confusion assessment method consists of 4 key features:
 - 1: Acute onset or fluctuating course
 - 2: Inattention
 - 3: Disorganized thinking
 - 4: Altered level of consciousness
 - Diagnosis is made when features 1 and 2 are present with either 3 or 4
 - Mini-mental state exam:
 - Can be administered serially and will fluctuate; formal cognitive assessment may be difficult to accomplish due to patient cooperation.

ESSENTIAL WORKUP

- Awareness of delirium as syndrome is key.
- Workup should be broad to determine underlying organic disease.
- Ancillary studies as determined by history, physical, and initial workup

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Initial testing:
 - Electrolytes, calcium
 - Renal function
 - Hepatic function
 - Glucose
 - CBC
 - Urinalysis with culture and sensitivity
 - Toxicology screens
- Further studies based on signs and symptoms:
 - Arterial blood gas
 - Thyroid-stimulating hormone
 - Cardiac enzymes

Imaging

- ECG
- Head CT scan
- CXR
- Other imaging based on history, physical exam, and possible etiologies

Diagnostic Procedures/Surgery

- As indicated by potential underlying cause
- Lumbar puncture if indicated
- EEG if indicated by potential seizure activity

DIFFERENTIAL DIAGNOSIS

- Other disease processes that should be distinguished from delirium include:
 - Psychiatric illness:
 - Symptoms do not have fluctuating course that is typical of delirium.
 - Usually there are no changes in level of consciousness.
 - Delirium is classically associated with visual hallucinations and psychiatric illness with auditory hallucinations.
 - Dementia:
 - Delirium has rapid onset, while dementia has a slowly progressive, insidious course without fluctuation of symptoms.
 - Dementia is not associated with acute changes in consciousness.
- Once identified as delirium, the differential for the underlying cause is quite extensive.

TREATMENT

PRE HOSPITAL

- IV access:
 - Pulse oximetry to monitor respiratory status:
 - Glucose measurement
 - ECG monitoring
- Naloxone if associated respiratory insufficiency
- Monitor patient:
 - Advanced life support (ALS) transport with all medications
- Look for signs of an underlying cause:
 - Medications
 - Medical alert bracelets
- Document basic neurologic exam:
 - Glasgow coma scale score
 - Pupils
 - Extremity movements

ED TREATMENT/PROCEDURES

- When delirium is identified, seek the underlying cause intensely.
- Treatment should be targeted at underlying medical condition.
- IV line access
- Oxygen if indicated by hypoxia
- Cardiac, pulse oximetry, and BP monitoring
- Thiamine should be administered to alcoholic and malnourished patients.
- In patients who are significantly agitated, chemical treatment of agitation may help facilitate ED workup.

MEDICATION

- Treatment of delirium should be aimed at underlying condition.
- Benzodiazepines should be 1st line for patients with alcohol or benzodiazepine withdrawal.
- Benzodiazepines should be avoided in patients with all other causes of delirium, if possible.

First Line

- Assess the patient for prolonged QT syndrome before administering antipsychotic agents. Haloperidol: 5–10 mg IV or IM:
 - Lower doses (0.5–2 mg) are appropriate for elderly patients.
- Recent studies show that atypical antipsychotics may be equally effective to typical antipsychotics.
- Thiamine: 100 mg IV, IM, or PO

Second Line

- Alprazolam: 0.25–0.5 mg PO

- Lorazepam: 0.5–2 mg IV, IM, or PO

FOLLOW-UP

DISPOSITION

Admission Criteria

- When cause is unclear, admit.
- If delirium has not resolved, admit.

Discharge Criteria

Patient could be discharged if:

- Treatable cause is found and treated
- Mental status clears while in the ED
- Reliable caregivers are available
- Follow-up is ensured

FOLLOW-UP RECOMMENDATIONS

- Follow-up depends on underlying condition.
- When delirium has resolved within ED stay, close follow-up with primary care provider, preferably in <2 days.
- Patients and caregivers should be counseled carefully regarding return precautions:
 - Any recurrence of delirium should prompt a return to the ED.
 - Delirium can be a life-threatening condition.

PEARLS AND PITFALLS

- Identify underlying cause
- Delirium is often missed by emergency physicians and maintaining an awareness of delirium as a syndrome is critical.

CODES

ICD9

- 291.0 Alcohol withdrawal delirium
- 293.0 Delirium due to conditions classified elsewhere
- 780.09 Other alteration of consciousness

ICD10

- F05 Delirium due to known physiological condition
- F10.231 Alcohol dependence with withdrawal delirium
- R41.0 Disorientation, unspecified

DELIVERY, UNCOMPLICATED

Jonathan B. Walker • James S. Walker

BASICS

ETIOLOGY

- Delivery in ED is rare:
 - Incidence of ED deliveries in US is not known.
 - Health care systems in which patients have little prenatal care tend to have greater incidence of ED deliveries.
- ED deliveries usually occur in 1 of the following 3 scenarios:
 - Multiparous patient with history of prior rapid labor
 - Nulliparous patient who does not recognize symptoms of labor
 - Patients with lack of prenatal care, lack of transportation, or premature labor

DIAGNOSIS

SIGNS AND SYMPTOMS

- True labor presents as uterine contractions occurring at least every 5 min and lasting 30–60 sec.
- Significant vaginal bleeding with labor demands immediate assessment for placenta previa or abruption.

History

- Last menstrual period and estimated gestational age (EGA)
- Recent infections
- Pregnancy history, complications
- Prior C-section
- Prenatal care
- Abdominal/pelvic cramping
- Ruptured membranes (amniotic sac)
- May report incontinence
- Urge to push or have a bowel movement
- Bloody show—loss of mucous plug

Physical-Exam

- Signs of imminent delivery:
 - Fully effaced and dilated cervix (~ 10 cm in term infant)
 - Palpable fetal parts
 - Bulging of perineum

- Widening of vulvovaginal area
- Try to determine fetal position and presenting part by palpation of the uterus

ESSENTIAL WORKUP

- *Sterile* bimanual pelvic exam is the most useful tool to assess presence of labor and possibility of imminent delivery:
 - Assess dilation, station, and effacement
 - No pushing until full dilation
 - Bimanual exam should *not* be done with vaginal bleeding until ultrasound (US) can rule out placenta previa.
- Fetal heart tones (FHTs) should be obtained by Doppler

DIAGNOSIS TESTS & INTERPRETATION

Lab

- If patient is in active labor, CBC, blood typing, and Rh screen should be sent:
 - Kleihauer-Betke testing should be ordered after delivery if Rh-negative mother gives birth to Rh-positive child
 - Rh immunoglobulin can be administered to mother within 72 hr of delivery
- Urinalysis if there is concern about urinary tract infection or preeclampsia

Imaging

- Imaging studies are not needed for uncomplicated vaginal deliveries
- 3rd-trimester vaginal bleeding should have emergent US to evaluate for placental abruption or placenta previa
- If time permits, US can help locate the position and anatomy of the placenta

DIFFERENTIAL DIAGNOSIS

- Braxton Hicks contractions:
 - Irregular uterine contractions that do not result in cervical dilation or effacement
- Muscular low back pain
- Round uterine ligament pain
- Other causes of abdominal pain, such as torsion of the ovary, appendicitis, nephrolithiasis

TREATMENT

PRE HOSPITAL

- Place patients in left lateral recumbent position
- Emergency medical services (EMS) personnel should be adequately trained and have proper equipment available for delivery

- EMS transportation of high-risk obstetric patients *before* delivery:
 - Lower neonatal morbidity and mortality
 - Faster and less expensive when compared with transportation of neonate *after* delivery
- Use of air transport for obstetric patients has been shown to be safe and effective:
 - Altitude during flight can result in hypoxia for fetus; pregnant patients should be placed on supplemental oxygen

INITIAL STABILIZATION/THERAPY

- Immediate sterile pelvic exam to assess for cervical dilation, effacement, station, or presenting parts (if no vaginal bleeding)
- Patients in active labor should be transferred to labor and delivery immediately unless delivery is imminent
- If patient is completely dilated and fetal parts are on perineal verge, prepare for ED delivery

ED TREATMENT/PROCEDURES

- Obstetrician should be notified that delivery will be occurring in ED
- Pediatrician or neonatologist and NICU should be notified
- Prepare for neonatal resuscitation
- Place patient in supine position or Sims position
- Begin IV saline or D5NS and supplemental oxygen, and place patient in lithotomy position
- Assemble obstetric (OB) pack:
 - Bulb syringe
 - 2 sterile Kelly clamps
 - Sterile Mayo scissors
 - Umbilical clamp
- Neonatal resuscitative equipment should also be available
- If time permits, sterilize vaginal area with povidone-iodine (Betadine)
- Uncomplicated vaginal delivery should occur as follows:
 - As crowning occurs, deliver head in controlled fashion, guiding it through introitus with each contraction.
 - Routine episiotomy is not necessary; however, if perineum is tearing, perform midline episiotomy by placing 2 fingers behind perineum and make straight incision toward (but not including) rectum with sterile Mayo scissors.
 - After fetal head is delivered, quickly suction nasopharynx, then feel around neck for nuchal cord:
 - If present, manually reduce over head
 - If nuchal cord is too tight, double clamp, cut cord, and deliver infant immediately
 - Apply gentle downward pressure on fetal head with uterine contractions:

- Deliver anterior shoulder
- Posterior shoulder and remainder of infant will rapidly deliver
- After delivery, infant should be held at level of uterus and oropharynx suctioned again
- Double clamp cord with sterile Kelly clamps and cut between them
- Infant should be stimulated, warmed, and dried:
 - If cyanosis is present, infant should be given oxygen and resuscitated
 - Follow neonatal resuscitation protocols if necessary
- Place umbilical clamp
- Placenta will spontaneously deliver in 20–30 min:
 - Observe mother closely for postpartum hemorrhage
- Uterine massage can aid in separation of placenta from uterus and limit uterine atony:
 - Avoid placing traction on umbilical cord because this can lead to inversion of uterus or rupture cord
- If patient has severe bleeding and placenta is not passing spontaneously, patient should be taken immediately to operating room
- After delivery of placenta, it should be examined for any irregular or torn areas suggestive of retained placental products
- In uncomplicated delivery, use of drugs is not necessary:
 - Massage of uterus is all that is needed to facilitate cessation of bleeding after placenta has been delivered
- Postpartum uterine bleeding is common:
 - Uterus, vagina, and perineum should be inspected for laceration
 - If no laceration is found, assume uterine atony
 - If uterus does not contract in response to uterine massage, administer oxytocin IV
 - Continued massage of uterus may be helpful if bleeding still persists; then give methylergonovine maleate (Methergine) IM
 - If bleeding is not responding to these measures, then carboprost tromethamine (Hemabate) can be administered IM

MEDICATION

- Carboprost tromethamine (Hemabate): 0.25 mg IM q15–60min (up to 2 doses)
- Methylergonovine maleate (Methergine): 0.2 mg IM
- Oxytocin: 20–40 U IV in 1 L of normal saline infused at 250–500 mL/h IV

FOLLOW-UP

DISPOSITION

Admission Criteria

- All women with uncomplicated deliveries and no significant postpartum bleeding should be admitted to labor and delivery or postpartum unit for care and monitoring
- Obtain pediatric or neonatal consultation and admit to neonatal ICU:
 - All infants with respiratory distress
 - Gestational age < 36 wk
 - Weight < 5 lb
 - Low Apgar scores
- Term infants with none of above complications may be admitted to the nursery or with mother to combined maternal–fetal unit
- If transferring the mother and infant after delivery, consider using 2 ambulances

Discharge Criteria

- After adequate recovery from delivery, patient can be taken labor and delivery or postpartum unit
- Patient should not be discharged home from ED

PEARLS AND PITFALLS

- Be ready for complications such as cord prolapse, shoulder dystocia, breech delivery
- Be prepared to treat 2 patients after delivery—mother and infant

- O62.3 Precipitate labor

- O80 Encounter for full-term uncomplicated delivery

DEMENTIA

Gabriel Wardi

BASICS

DESCRIPTION

- Progressive deterioration in cognition, behavior, or both without impaired consciousness that is severe enough to interfere with activities of daily living due to alteration in cortical brain function. A chronic and progressive form of organic brain syndrome.
- Over 50 different causes, but > 60% caused by Alzheimer disease
 - Involves increased neurofibrillary tangles and elevated beta amyloid plaques
- Prevalence 1% at age 60 yr to 30–50% by age 85 yr
- Characterized by gradual decline in cognitive functioning:
 - Generally evolves over period of years
 - Course is highly variable, months to years in duration
 - Rapid decline indicative of other causes, or rare rapid onset causes of dementia (prion diseases, progressive supranuclear palsy)
- Variable hereditary
 - Increased risk of Alzheimer disease in 1st-degree relatives of patients with Alzheimer
 - Apolipoprotein ε4 is the only well-established mutation with late-onset Alzheimer

ETIOLOGY

- Primary dementia:
 - Cortical (Alzheimer disease, frontotemporal dementia)
 - Subcortical (Huntington disease, Parkinson disease, progressive supranuclear palsy)
- Secondary dementia:
 - Cerebrovascular disease (multi-infarct dementia)
 - Toxic, metabolic, nutritional derangements
 - Prion disorders (Creutzfeldt-Jakob or bovine spongiform encephalopathy and variants)
 - Infectious agents (HIV, syphilis, encephalitis)
 - Vasculitis (systemic lupus erythematosus, thrombotic thrombocytopenic purpura)
 - Traumatic (chronic subdural hematomas, pugilistic dementia)
 - Structural (normal pressure hydrocephalus, brain masses)
 - Binswanger disease

- Reversible (~15%) causes include normal pressure hydrocephalus, medications, intracranial masses, and alcohol abuse syndromes
- Pseudodementia:
 - Depression in elderly can present with dementia-like symptoms
 - Common in mildly demented patients, look for pin-point event with short duration of symptoms
 - Generally with history of psychiatric conditions, emphasis on failures and disabilities

DIAGNOSIS

SIGNS AND SYMPTOMS

- Insidious onset, with initial complaints of anxiety, depression, frustration, increased forgetfulness
- Generally preceded by “mild cognitive impairment,” an intermediate state of cognitive function between normal aging and those meeting criteria for dementia
- Can be grouped into 3 categories:
 - Early: Difficulty concentrating, memory deficits, difficulty with complex tasks, social withdrawal
 - Moderate: Major memory difficulties, need assistance with activities of daily living
 - Severe: Minimal ability to speak or communicate, difficulty eating, loss of psychomotor skills
- Diagnostic criteria (from American Psychiatric Association):
 - Development of multiple cognitive deficits manifested by both:
 - Memory impairment
 - One (or more) of the following cognitive disturbances: Aphasia, apraxia, agnosia, disturbance in executive functioning
 - Cognitive deficits that cause significant impairment in social or occupational functioning and are a decline from prior levels of functioning
 - Deficits do not occur during course of delirium

History

- Must include input from family and friends
- Complete list of medications
- Comorbid diseases
- Prior history of similar behavior
- Onset and progression
- Consider use of Montreal Cognitive Assessment, Short Test of Mental Status (alternative to mini-mental status exam)

Physical-Exam

Full and complete physical exam:

- Head-to-toe evaluation, all organ systems
- Meticulous neurologic exam:
 - _ Mental status evaluation
 - _ Cranial nerves
 - _ Reflexes
 - _ Motor, sensory, cerebellar, gait

ESSENTIAL WORKUP

- Must eliminate acute reversible or exacerbating factors
- Extent of workup is related to history and course of illness:
 - _ Extensive evaluation for new diagnosis
 - _ Directed evaluation for sudden change of dementia
 - _ Limited evaluation for stable disease previously assessed
- Must be able to identify signs and symptoms of the reversible causes of dementia

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Extent of evaluation dependent on patient condition and suspected cause
- New diagnosis or sudden deterioration:
 - _ CBC
 - _ ESR/CRP
 - _ CMP
 - _ Ammonia
 - _ Urinalysis
 - _ Toxicology screen
 - _ Thyroid-stimulating hormone
 - _ Vitamin B₁₂ level
 - _ Syphilis serology (RPR)
 - _ HIV
 - _ Blood cultures if fever present
 - _ Urine cultures if fever present
 - _ Antinuclear antibody if SLE suspected
- Established diagnosis with stable disease: No tests may be required.

Imaging

- New diagnosis or sudden deterioration in established dementia:
 - _ CXR if infection considered
 - _ Head CT, without and with contrast
 - _ EEG if suspicion of seizure disorder
 - _ Brain MRI/MRA in selected cases

- More advanced imaging (PET, etc.) should be reserved for use by specialists
- Established diagnosis with stable disease: Studies may not be required.

Diagnostic Procedures/Surgery

- Lumbar puncture and CSF analysis, syphilis serology
- EEG if seizure suspected

DIFFERENTIAL DIAGNOSIS

- Toxic, metabolic, nutritional abnormalities:
 - Narcotics, sedatives, hypnotics
 - Alcohol
 - Heavy metals
 - Dehydration
 - Electrolyte abnormalities
- Pseudodementia
- Delirium (high suspicion for UTI and pneumonia in febrile patients)
- Senescent aging

TREATMENT

PRE HOSPITAL

- Obtain history from friends, family
- Provide for patient and staff safety
- Manage agitation
- Attentiveness to comorbid conditions
- Treat acute toxic and metabolic disorders:
 - Hypoglycemia
 - Hypothermia
 - Hyperthermia

INITIAL STABILIZATION/THERAPY

- Ensure adequate airway
- Administer O₂ if hypoxic
- Ensure normal vital signs
- Establish IV access if required
- In agitated patients, provide for patient and staff safety

ED TREATMENT/PROCEDURES

- Must determine if patient presents with acute change in mental status
- Consider full differential diagnosis—evaluate and treat appropriately:
 - Treat hypoglycemia with PO or IV dextrose.
 - Treat narcotic overdose or excess with naloxone.

- Rewarm if hypothermic.
- Antipyretic for hyperthermia
- IV fluids for dehydration
- Correct electrolyte abnormalities
- Administer antibiotics for infection:
 - UTI and pneumonia most common occult infections; look for wounds and decubitus ulcers
- Treat seizures:
 - Lorazepam, other agents as needed
 - Long-term management in conjunction with neurology
- Sedation for agitation:
 - Start with low doses and increase as necessary to achieve clinical result.
 - Neuroleptics: Haloperidol, risperidone, ziprasidone
 - Benzodiazepines: Lorazepam, midazolam
- Soft restraints if chemical sedation ineffective
- Attempt to limit number of medications:
 - Reduced likelihood of toxicity
 - Reduced likelihood of drug–drug interaction
 - If agitation not an issue, eliminate all sedative-hypnotics
- Treat depression

MEDICATION

- Alzheimer’s agents: Always start at lowest dose:
 - Donepezil: 5–10 mg PO at bedtime
 - Rivastigmine: 1.5–6 mg PO BID
 - Galantamine: 4–12 mg PO BID
 - Above 3 anticholinergics without clear superior agent, watch for side effects including nausea, vomiting, diarrhea
 - Consider memantine (NMDA receptor antagonist) in those with poor response to anticholinergics: 5 mg PO QID–10 mg PO BID
 - Effects generally modest, best started, and changed by primary provider
 - Numerous trials showing inconsistent or negative benefit of anti-inflammatory agents, estrogens, and statins for Alzheimer
- Antidepressants: Start with lowest dose:
 - Oversedation a problem
 - May worsen dementia
 - Useful in patients who cannot sleep
- Sedative agents: Always start with lowest dose
 - Droperidol: 0.625–2.5 mg IV—advantage, rapid onset; disadvantage, risk for QT prolongation
- Haloperidol: 0.5–2 mg PO BID; start with lowest dose 0.5–2.5 mg IM or IV if rapid onset required
- Lorazepam: 0.5–1 mg IV, 0.5–2 mg PO

- Midazolam: 0.5–2 mg IV slow push
- Naloxone: 0.4–2 mg IVP
- Risperidone: 0.5–2 mg PO BID; start with lowest dose
- Ziprasidone: 20–80 mg PO BID, 10–20 mg IM q4h; start with lowest dose

FOLLOW-UP

DISPOSITION

Admission Criteria

- Unstable vital signs
- Significant comorbid condition requiring parenteral medications:
 - Pneumonia
 - UTI
 - Fluid and electrolyte disorder
- Uncertain diagnosis requiring evaluation and management that is not suitable for outpatients
- Inadequate home support coupled with inability to arrange suitable placement from ED

Discharge Criteria

- Stable vital signs
- No significant unstable comorbid conditions
- Secure diagnosis or elimination of life-threatening organic disease
- Adequate home support, watch for caregiver burnout
- Reliable access to follow-up care

Issues for Referral

- Patients may need assistance with transportation, finances, etc.
- Patients with other comorbidities need referral to appropriate specialists.

FOLLOW-UP RECOMMENDATIONS

- Primary care
- Geriatrician
- Psychiatrist
- Neurologist

PEARLS AND PITFALLS

- Primary dementia is characterized by slow, steady progression:
 - Course is generally 5–10 yr from diagnosis to death.
- Can fluctuate as consequence of intervening illness and comorbid conditions

- Cholinesterase medications can improve functional status in patients with Alzheimer disease.
- Careful attention to medications, secondary illnesses, and prompt intervention for infections can improve quality of life and longevity.
- Death is generally consequence of infection, cardiovascular disease, or injury.

CODES

ICD9

- 294.10 Dementia in conditions classified elsewhere without behavioral disturbance
- 294.20 Dementia, unspecified, without behavioral disturbance
- 331.0 Alzheimer’s disease

ICD10

- F02.80 Dementia in other diseases classified elsewhere without behavioral disturbance
- F03.90 Unspecified dementia without behavioral disturbance
- G30.9 Alzheimer’s disease, unspecified

DENGUE FEVER

Jessica Freedman

BASICS

DESCRIPTION

- Dengue fever occurs secondary to dengue viral infection.
- Most prevalent mosquito-borne viral infection.
- Poorly understood immunopathologic response causes dengue hemorrhagic fever (DHF) and dengue shock syndrome (DSS).
- DHF and DSS usually occur in patients with previous exposure to dengue virus.
- Hemorrhagic manifestations occur after defervescence of fever.
- Vascular permeability increases.
- Plasma extravasates into extravascular space, including pleural and abdominal cavities.
- Bleeding tendency
- Shock may ensue.
- Disseminated intravascular coagulation (DIC) may develop.
- Dengue fever, DHF, and DSS are all self-limited.
- World Health Organization—required criteria for the diagnosis of DHF:
 - Fever
 - Bleeding evidenced by one of the following: Positive tourniquet test, petechiae, ecchymosis, purpura, GI tract bleeding, injection site bleeding
 - Increased vascular permeability and plasma leakage as evidenced by an elevated hematocrit ($> 20\%$), decreased hematocrit $> 20\%$ after volume replacement or pleural effusions, ascites or hypoproteinemia
 - Thrombocytopenia ($< 100,000/\text{mm}^3$)
- World Health Organization—required criteria for diagnosis of DSS:
 - All 4 criteria of DHF +
 - Rapid and weak pulse
 - Narrow pulse pressure or hypotension for age
 - Cold, clammy skin
 - Restlessness

ETIOLOGY

- Occurs in tropical and subtropical regions: Asia, Africa, Central and South America, and the Caribbean
- Caused by dengue virus serotypes 1–4
- Transmitted by mosquitoes: *Aedes aegypti* and *Aedes albopictus*
- Incubation period of 3–14 days
- There is only transient and poor cross protection among the 4 serotypes

DIAGNOSIS

SIGNS AND SYMPTOMS

- Fever:
 - Abrupt in onset rising to 39°C or higher
 - 2–7 days duration
 - Biphasic (“saddleback”) curve, returning to almost normal after 2–7 days
 - Associated with frontal or retro-orbital headache
- Rash:
 - Generalized maculopapular rash occurs with onset of fever in 50% of patients.
 - After 3–4 days, rash becomes diffusely erythematous.
 - Faded areas appear.
 - Areas of desquamation may appear.
 - After defervescence of fever, scattered petechiae may develop over trunk, extensor surfaces of limbs, and axillae.
 - Palms and soles spared
- Musculoskeletal:
 - Arthralgias and myalgias after onset of fever
 - Severe lumbar back pain
- GI:
 - Anorexia
 - Nausea and vomiting
 - Abdominal pain (sometimes severe)
 - Altered taste
 - Hepatomegaly/ascites
 - GI bleeding
- Miscellaneous:
 - Epistaxis
 - Gingival bleeding
 - Hemoptysis
 - Hypotension
 - Narrowed pulse pressure (< 20 mm Hg)
 - Retro-orbital pain

ESSENTIAL WORKUP

- Primarily a clinical diagnosis
- Suspect in endemic areas
- Suspect in patients with history of travel

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - Thrombocytopenia
 - Elevated hematocrit
- Electrolytes, BUN, creatinine:
 - Elevated BUN
 - Hyponatremia
- Liver function tests:
 - Elevated aspartate transaminase (AST; or serum glutamic-oxaloacetic transaminase [SGOT])
- Coagulation profiles:
 - Prolonged INR, prothrombin time (PT), and partial thromboplastin time (PTT)
 - Low fibrinogen:
 - D-dimer
 - Virus isolation or detection of dengue virus–specific antibodies (available in only a few labs) through hemagglutination inhibition (HI) assay

Imaging

CXR:

- Pleural effusions

Diagnostic Procedures/Surgery

Tourniquet test:

- Inflate BP cuff to median BP in patient's extremity.
- Test is positive when 3 or more petechiae appear per square centimeter.

DIFFERENTIAL DIAGNOSIS

- Viral illness, nonspecific
- Influenza
- Rubella
- Measles
- Malaria
- Rocky Mountain spotted fever
- Typhoid
- Kawasaki disease
- Scarlet fever
- Erythema infectiosum
- Mononucleosis
- Roseola infantum
- Secondary syphilis
- Enterovirus
- West Nile virus

- HIV
- Leptospirosis
- Chikungunya fever
- Toxic shock syndrome
- Hepatitis
- Appendicitis
- Meningitis

TREATMENT

INITIAL STABILIZATION/THERAPY

- IV access
- IV crystalloids for hypotension
- O₂ and monitor for unstable patients

ED TREATMENT/PROCEDURES

- Treatment is supportive.
- IV fluids
- Acetaminophen (Tylenol) for fever
- Analgesics for pain
- Platelet transfusion for severe thrombocytopenia
- DIC therapy, if necessary

Pediatric Considerations

- Neonatal dengue can occur by vertical transmission if mother infected 0–8 days before delivery:
 - Infants may develop DHF or DSS because of passive maternal immunity.
- DHF and DSS most common in children 7–12 yr of age

FOLLOW-UP

DISPOSITION

Admission Criteria

- ICU admission for the following:
 - Hypotension
 - DIC
 - Thrombocytopenia
 - Hemoconcentration
- Regular admission for the following:
 - 15 yr of age or younger

- All patients with previous dengue exposure
- Any patient where close follow-up is not available

Discharge Criteria

- Close follow-up guaranteed
- Tolerating PO
- Pain controlled

PEARLS AND PITFALLS

- Consider dengue in patients presenting with fever and rash who recently traveled to endemic regions.
- Chikungunya fever is an emerging infectious disease also seen in travelers and must be considered in the differential:
 - Found in Asia and Africa

ICD10

A90 Dengue fever [classical dengue]

DENTAL TRAUMA

Brian N. Corwell

BASICS

DESCRIPTION

- Primary teeth:
 - Eruption begins between 6–10 mo of age and concludes by 30 mo
 - Eruption is bilaterally symmetric
 - 20 total teeth
- Permanent teeth:
 - Begin to erupt at age 6
 - 32 total (4 central and 4 lateral incisors, 4 canines, 8 premolars, 12 molars)
 - Number from 1–32 starting with upper right 3rd molar (1) to upper left 3rd molar (16) and lower left 3rd molar (17) to lower right 3rd molar (32)
 - Better and often easier to describe the involved tooth anatomically
- Most commonly injured teeth:
 - Maxillary central incisors, maxillary lateral incisors, and the mandibular incisors
- Tooth fractures:
 - Fractures of the crown are classified as uncomplicated (involve only the enamel or both the enamel and dentin) or complicated (involves the neurovascular pulp)
 - Fractures can be classified using the *Ellis classification system*
 - Class I fracture (uncomplicated fracture):
 - Involves only the superficial enamel
 - Fracture line appears chalky white
 - Painless to temperature, air, percussion
 - Class II fracture (uncomplicated fracture):
 - Involves enamel and dentin
 - Fracture line will appear ivory or pale yellow compared to whiter enamel
 - May be sensitive to heat, cold, or air
 - Not tender
 - Class III fracture (complicated fracture):
 - True dental emergency
 - Involves enamel, dentin, and pulp
 - Pulp has pinkish, red, fleshy hue
 - Frank bleeding or a pink blush after wiping tooth surface indicates pulp violation
 - May be exquisitely painful or desensitized (with associated

neurovascular disruption)

- Luxation injuries
 - Involve the supporting structures
 - Includes the periodontal ligament (PDL) and alveolar bone
- Several types of injuries exist:
 - Concussed teeth:
 - Tooth neither loose nor displaced
 - Sensitivity with chewing or percussion
 - Subluxed teeth:
 - Tooth is loose but not displaced
 - Bleeding from gingival sulcus
 - Sensitivity with chewing or percussion
 - PDL is damaged
 - Intrusion:
 - Tooth is driven into socket
 - Alveolar socket fractured
 - PDL compressed
 - Avulsed tooth:
 - Total displacement from alveolar ridge
 - PDL severed
 - Extrusion:
 - Partial central dislocation from socket
 - PDL damaged
 - Lateral luxation:
 - Nonaxial displacement of the tooth
 - PDL damaged
 - Associated with alveolar socket fracture
- Alveolar bone fractures:
 - Fractures of tooth-bearing portions of mandible or maxilla
 - Bite malocclusion, painful bite, tooth mobility en bloc
 - Diagnosed clinically or radiographically

ETIOLOGY

- Nearly 50% of children sustain a dental injury
- Age periods of greatest predilection:
 - Toddlers (falls and child abuse)
 - School-aged children and preteens (falls, bicycle, and playground accidents)
 - Adolescents (athletics, altercations, MVCs)
 - Mouth guard use greatly reduces sport-associated dental injury
- Assault, domestic violence, or multiple trauma
- Motor vehicle, motorcycle, bicycle accidents
- Child abuse
 - Frequently associated with orofacial injury

- Laryngoscopy
- Certain predisposing anatomic factors increase risk:
 - Anterior overbite >4 mm increases risk for traumatic injury 2–3 times
 - Short or incompetent upper lip, mouth breathing, physical disabilities, use of fixed orthodontic appliances

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Tooth mobility, avulsion or laxity
- Bite malocclusion or trismus
- Exacerbating factors (may indicate pulp exposure or PDL damage):
 - Chewing or drinking
 - Extremes of temperature
 - Pain on palpation
- Mechanism:
 - Sufficient mechanism necessitates complete evaluation for multiple trauma and associated local injuries (e.g., jaw fracture)
- Exact time of injury:
 - May affect treatment and prognosis

Physical-Exam

- Examine all teeth for trauma or fracture
- Examine fractured teeth for pulp exposure:
 - Dry the tooth with gauze; observe for frank bleeding or pink blush
- Inspect each tooth surface and percuss for mobility, sensitivity, or fracture
- Assess for malocclusion and midface stability
- Account for all missing teeth
 - Tooth fragments and prostheses may have been swallowed, aspirated, embedded into adjacent soft tissue or impacted into alveolus
- Inspect oral cavity carefully:
 - Adjacent soft tissue or bone injuries
 - Suspect a mandible fracture in those unable to open mouth >5 cm or with a positive tongue blade bite test
 - Associated injuries:
 - Salivary glands, ducts, blood vessels
 - Mental and infraorbital nerves

ESSENTIAL WORKUP

- Thorough physical exam

- Imaging as necessary
- Stabilization and proper referral

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- Plain dental radiograph:
 - Complicated fractures
- Panorax indications:
 - Foreign bodies
 - Displacement of teeth
- CT indications:
 - Trauma with malocclusion or trismus
 - Suspected alveolar or mandibular fracture
- CXR:
 - Indicated for missing teeth or fragments
 - Teeth visualized below the diaphragm do not require removal
- Bronchoscopy:
 - Indicated removal of aspirated tooth

DIFFERENTIAL DIAGNOSIS

Rule out other significant concurrent facial or systemic injuries.

TREATMENT

PRE HOSPITAL

- Avulsed teeth:
 - Only replace avulsed secondary teeth
 - Rinse tooth with cold running water
 - Immediate attempt to reimplant permanent tooth into socket by 1st capable person:
 - *Time is tooth:* Each minute tooth is out of socket reduces tooth viability by 1%
 - Best chance of success if reimplant done within 5–15 min
 - Poor tooth viability if avulsed for >1 hr
 - If unsuccessful, place tooth in a transport solution (from most to least desirable):
 - Hanks balanced salt solution (HBSS)
 - Balanced pH culture media available commercially in the Save-A-Tooth kit
 - Effective hours after avulsion
 - Cold milk:

- Best alternative storage medium
- Place tooth in a container of milk that is then packed in ice (prevents dilution)
- _ Saliva:
 - Store in a container of child's saliva
- _ Never use tap water or dry transport

INITIAL STABILIZATION/THERAPY

- Ensure patent airway
- Have patient bite on gauze to control bleeding
- Account for all teeth and tooth fragments
- Reimplant avulsed tooth immediately

ED TREATMENT/PROCEDURES

- General considerations:
 - _ Splint before attempting laceration repair
 - _ Occlusion is always the best guide to proper tooth position
 - _ Tetanus prophylaxis:
 - Consider as a nontetanus-prone wound
 - Indicated for dirty wounds, deep lacerations, avulsed teeth, intrusion injuries, bone fracture
 - _ Antibiotic indications:
 - Open dental alveolar fractures
 - Treatment of secondary infection
 - Persons at risk for subacute bacterial endocarditis
 - Not indicated for infection prophylaxis
 - _ Dental fracture management:
 - Determined by patient age and extent of associated trauma
- Ellis class I:
 - _ No emergency treatment indicated
 - _ File/smooth sharp edges with an emery board:
 - Prevents further injury to soft tissue
 - _ Dental referral for elective cosmetic repair
- Ellis class II:
 - _ Treatment goal is to prevent bacterial pulp contamination through exposed dentin
 - _ Cover exposed surface with calcium hydroxide paste or similar barrier agent
 - Dry tooth surface prior to application
 - Use cyanoacrylate tissue adhesive if no such agent exists
 - _ Next, cover and wrap tooth with dental foil
 - _ Liquid diet until follow-up
 - _ Pain control
 - _ Dental referral within 48 hr

- Ellis class III:
 - Immediate referral to dentist or endodontist
 - If dentist/oral surgeon is not available:
 - Cover exposed surface and wrap with dental foil as with class II injuries
 - For brisk bleeding, have patient bite into gauze soaked with topical anesthetic and epinephrine or inject solution into pulp
 - Pain control
- Concussed tooth:
 - No splinting required
 - Soft diet
 - Follow-up with dentist as needed
- Subluxed tooth:
 - Splinting only required for excess laxity
 - Soft diet for 1 wk
 - Follow-up with dentist
- Extrusion:
 - Reposition with digital pressure
 - Splinting for 2 wk
 - Soft diet for 1 wk
 - Follow-up with dentist
- Lateral luxation:
 - Repositioning may be forceful/traumatic
 - May need to disengage from bony lock
 - May require local anesthetic
 - Use 2-finger technique:
 - 1st finger guides the apex down and back while 2nd finger repositions crown
 - Soft diet for 2 wk
 - Splinting usually required for up to 4 wk
 - Follow-up with dentist
- Intrusion:
 - Do not manipulate
 - Pain control
 - Dental follow-up within 24 hr
- Partial tooth avulsion:
 - May require local anesthetic
 - Carefully reduce to normal position
 - Consider manual removal of extremely loose teeth in neurologically impaired patients to prevent aspiration
- Avulsed tooth:
 - Never replace avulsed primary teeth
 - Handle the tooth only by the crown

- Avoid touching the root
- Remove debris by gentle rinsing in saline or tap water
- Do not wipe, scrub, curette, or attempt to disinfect tooth
- Administer local anesthesia if needed
- Gently irrigate or suction clots
 - Use care not to damage socket walls
- Manually reimplant tooth with firm but gentle pressure
 - Tooth should “click” into place
- Once tooth inserted, have patient bite gently onto folded gauze pad to help maneuver into proper position
- Splinting may be required
 - Apply to anterior or both anterior and posterior surfaces of the avulsed tooth/gingiva and adjacent 2 teeth
- Attempt reimplant regardless of time avulsed
- Liquid diet until follow-up
- Definitive stabilization by a dentist
- If tooth reimplanted pre-hospital:
 - Assure correct position and alignment
- Alveolar bone fracture:
 - Oral surgery/dental consultation for reduction and fixation (arch bar)
 - Pain control
 - Prophylactic antibiotics
 - Liquid diet, avoid straws

MEDICATION

- Acetaminophen with codeine: 30–60 mg/dose 1–2 tabs PO q4–6h PRN (peds: Codeine: 0.5–1 mg/kg/dose [max. 30–60 mg] PO q4–6h)
- Acetaminophen with oxycodone: 1–2 tabs PO q4–6h PRN (peds: Oxycodone: 0.05–0.15 mg/kg/dose [max. 5 mg/dose] PO q4–6h)
- Penicillin V: 250–500 mg PO q6h (peds: 25–50 mg/kg/24h [max. 3 g] PO q6h)
- Clindamycin (use if penicillin allergic): 150–300 mg PO q6h (peds: 10–25 mg/kg/24h PO q6h)
- Tetanus prophylaxis: 0.5 mL IM

ALERT

The dose of acetaminophen and all acetaminophen products should not exceed 4 g/24h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Admission for other associated injuries
- Suspected child or elder abuse and those with no available safe environment

Discharge Criteria

All hemodynamically stable patients with dental injury without associated traumatic injury

Issues for Referral

- Ellis III injuries: Immediate dental referral
- Loose, displaced, or missing teeth
- Document recommendations and arrangements for dental follow-up care

FOLLOW-UP RECOMMENDATIONS

All patients with avulsions and Ellis II and III injuries should see dentist within 24 hr

PEARLS AND PITFALLS

- Avulsed teeth should never be transported in a dry medium or in tap water
- Occlusion is the best guide to proper tooth position after reimplantation
- Warn patients with dental trauma of risks of tooth resorption, color change, potential tooth loss, and/or need for future root canal

Tooth Pain

CODES

ICD9

- 525.8 Other specified disorders of the teeth and supporting structures
- 525.11 Loss of teeth due to trauma
- 873.63 Open wound of tooth (broken) (fractured) (due to trauma), without mention of complication

ICD10

- K03.81 Cracked tooth
- S02.5XXA Fracture of tooth (traumatic), init for clos fx
- S03.2XXA Dislocation of tooth, initial encounter

DEPRESSION

Jonathan Florman

BASICS

DESCRIPTION

Major depression:

- Depressed mood and associated signs and symptoms lasting more than 2 wk
- Significant morbidity and mortality, including risk of suicide
- Often coexists with other medical illness

ETIOLOGY

- Biologic illness associated with derangements in several neurotransmitter systems including serotonin, norepinephrine, and dopamine
- Contributing factors:
 - _ Genetic predisposition
 - _ Medical illness
 - _ Medication effects
 - _ Psychosocial stress: Depression may follow adverse life event, trauma, loss of important relationship, or life role
- Higher prevalence in women. (Women make more suicide attempts; men are more likely to complete suicide successfully)

DIAGNOSIS

SIGNS AND SYMPTOMS

- 5 or more symptoms for at least 2 wk. (One of the symptoms must be depressed mood or loss of interest or pleasure):
 - _ Depressed mood
 - _ Diminished interest or pleasure
 - _ Change in appetite, weight loss/gain
 - _ Sleep disturbance
 - _ Fatigue or loss of energy
 - _ Diminished concentration
 - _ Feeling of worthlessness or guilt
 - _ Recurrent thoughts of death or suicide
 - _ Psychomotor agitation or retardation
- Subtypes: Psychotic features, melancholic, catatonic, atypical, postpartum, seasonal
- May be anxious/agitated or withdrawn
- Associated somatic complaints:

- Weakness, malaise
- Weight loss
- Headache, back pain

History

- Time course, acuity, stressors
- Review depressive symptoms (see above)
- Past medical history
- Past psychiatric history
- Medications (prescribed and over-the-counter)
- Substance use
- Family history
- Social and occupational history; losses, transitions, trauma, and other major life events
- Safety assessment:
 - Suicide risk
 - Risk of violence to others
 - Assess ability to care for self, nutrition
- Collateral from family or outpatient providers
- Cultural and language differences may complicate evaluation; use interpreter when appropriate

Physical-Exam

- Vital signs
- Neurologic exam:
 - Motor exam: Station, gait, strength, tone, abnormal movements
 - Cognitive exam: Orientation, attention, memory, language, executive function
- Mental status exam: Affect and mood, thought form and content

Pediatric Considerations

- Depression may be difficult to diagnose in children and adolescents. Indicators of major depression in children may include:
 - Changes in school, home, and social functioning
 - Changes in sleep
 - Social withdrawal
 - Somatic complaints
- Consult with a child psychiatrist

ALERT

Rule-out bipolar disorder: May require different treatment (mood stabilizers, antipsychotics), also antidepressants may precipitate mania in bipolar patients

ESSENTIAL WORKUP

- Identify signs and symptoms of major depression (see “Signs and Symptoms”)
- Use history and physical exam to guide further workup
- Rule-out associated or coexisting psychiatric and medical conditions, substance use
- Safety assessment

DIAGNOSIS TESTS & INTERPRETATION

Lab

- 1st line:
 - CBC; chemistries including electrolytes, BUN/creatinine, glucose, calcium, liver function tests
 - Urinalysis
 - Serum and urine toxicology screen
 - Thyroid function tests
 - B₁₂ and folate
- 2nd line, guided by history and initial findings:
 - HIV testing
 - RPR
 - ESR/CRP/ANA

Imaging

- Brain imaging: Recommended for atypical presentation or if focal neurologic findings
- MRI brain preferred over CT for detecting tumors, cerebrovascular accident, white matter changes

DIFFERENTIAL DIAGNOSIS

- Psychiatric illnesses:
 - Dysthymic disorder
 - Adjustment disorder
 - Bipolar disorder
 - Anxiety disorders, including acute stress reactions, PTSD
 - Schizophrenia, schizoaffective disorder
 - Personality disorder
 - Eating disorder
 - Substance-induced mood disorder
- Medical conditions that may cause or mimic depression:
 - Drug induced:
 - Antihypertensives
 - Oral contraceptives
 - Steroids

- Sedative-hypnotics
- Opioids
- Psychostimulants (in withdrawal phase)
- β -Blockers
- Metoclopramide
- Endocrine disorders:
 - Hypothyroidism
 - Adrenal insufficiency
 - Diabetes mellitus
 - Postpartum, perimenopausal, and premenstrual syndromes
- Tumors:
 - Pancreatic
 - Lung
 - Brain
- Neurologic disorders:
 - Dementia (early phase or frontal type)
 - Epilepsy
 - Parkinson disease
 - Multiple sclerosis
 - Huntington disease
 - Stroke
 - Head trauma; subdural hematoma
 - Normal pressure hydrocephalus
- Infections:
 - Hepatitis
 - HIV
 - Mononucleosis
- Nutritional disorders:
 - Folate deficiency
 - Pellagra
 - Vitamin B₁₂ deficiency
- Electrolyte disturbances
- End-stage renal, hepatic, pulmonary, and cardiovascular diseases
- Obstructive sleep apnea
- Chronic pain syndromes

TREATMENT

PRE HOSPITAL

- Ensure safety of patient and providers
- Understand local laws for involuntary commitment to hospital

INITIAL STABILIZATION/THERAPY

- Safety: Assess risk of suicide, violence
- General medical evaluation
- Management:
 - 1-to-1 observation and suicide precautions when appropriate
 - Work up potential medical causes

ED TREATMENT/PROCEDURES

- Psychological management:
 - Listen empathically to understand context and relevant stressors
 - Reassurance and education (e.g., depression is a treatable condition)
- Initiate medications:
 - Antidepressant medication may be initiated for some patients with clear diagnosis and established follow-up
 - Usually takes weeks for antidepressant medications to resolve major depression
 - Low-dose benzodiazepines or neuroleptics may be used for associated agitation, insomnia, or psychosis
- Choice of drug determined by:
 - Indications, efficacy
 - Side-effect profile and risks
 - Convenience, cost, availability
- Selective serotonin reuptake inhibitors (SSRIs: fluoxetine, paroxetine, sertraline, citalopram, escitalopram):
 - Well tolerated
 - Side effects may include:
 - Mild nausea
 - Headache
 - Anxiety, restlessness, insomnia
 - Somnolence
 - Sexual dysfunction
 - Weight gain
 - Minimal overdose risk
- Serotonin norepinephrine reuptake inhibitors (SNRIs: venlafaxine, duloxetine):
 - Well tolerated
 - May be helpful for some pain syndromes
 - Side effects similar to SSRIs
- Dopamine norepinephrine reuptake inhibitor (bupropion):
 - Agitation, insomnia
 - Tremor
 - Decreased seizure threshold
 - Well-tolerated; no sexual side effects
- Norepinephrine serotonin modulator (mirtazapine):

- Weight gain
- Sedation
- Orthostasis
- Constipation
- Tricyclic antidepressants (amitriptyline, imipramine, nortriptyline, clomipramine):
 - Anticholinergic effects
 - Weight gain
 - Postural hypotension
 - Sedation
 - Decreased seizure threshold
 - Cardiac risk; overdose can be fatal
 - Nortriptyline is best tolerated
- Monoamine oxidase inhibitors (phenelzine, tranylcypromine, selegiline transdermal):
 - Dietary and other medication restrictions to avoid hypertensive crisis
 - Dangerous in overdose

MEDICATION

Medication dosage ranges are for adults.

Dose may be titrated over weeks as indicated.

- Amitriptyline: Initial 25–50 mg/d PO
- Bupropion: 75–400 mg/d PO
- Citalopram: 20–40 mg/d PO
- Desvenlafaxine: 50 mg/d PO
- Duloxetine: 30–120 mg/d PO
- Escitalopram: 10–20 mg/d PO
- Fluoxetine: 20–60 mg/d PO
- Imipramine: Initial 25–50 mg/d PO
- Mirtazapine: 15–45 mg/d PO
- Nortriptyline: Initial 25 mg/d PO
- Paroxetine: 20–40 mg/d PO
- Phenelzine: 15–90 mg/d PO
- Sertraline: 50–200 mg/d PO
- Tranylcypromine: 10–60 mg/d PO
- Venlafaxine: 75–300 mg/d PO

First Line

SSRIs, SNRIs, bupropion, mirtazapine

Second Line

- Tricyclics and monoamine oxidase inhibitors
- Use with caution in geriatric or medically ill
- Consider ECT for severe or treatment-resistant depression, psychotic depression, or

Geriatric Considerations

- Older patients may require lower dose; pay careful attention to potential drug interactions
- Caution with orthostatic hypotension and cholinergic blockade

Pediatric Considerations

FDA “Black box” warning: Antidepressants may increase risk of suicidal thinking and behavior in some children, adolescents, or young adults with depression

Pregnancy Considerations

In pregnant or breast-feeding women pay special attention to risks and benefits of medication treatments—consider consultation with a specialist in perinatal psychiatry

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patient is suicidal or at high risk for suicide. See “Suicide, Risk Evaluation”
- Minimal or unreliable social supports
- Symptoms so severe that continual observation or nursing supportive care is required
- Psychotic features
- *Civil commitment* for psychiatric hospitalization is necessary if the patient is refusing treatment and is at risk to harm self or others

Discharge Criteria

- Low suicide risk
- Adequate social support
- Close follow-up available

Issues for Referral

- Outpatient mental health appointments and/or partial (day) hospital for patients not admitted
- Insurance carrier may determine inpatient disposition and options for other levels of care
- Case management or social services in ED may be helpful for disposition issues
- Communicate and coordinate care with other providers including primary care

FOLLOW-UP RECOMMENDATIONS

Follow-up depends on severity of illness and risk:

- If not admitted, patients with significant symptoms should follow up in 1–2 wk
- When medication is initiated, patient should be seen in follow-up in 1–2 wk
- More stable patients or those with minor symptoms may be seen with less urgency

PEARLS AND PITFALLS

- Patients with depression experience significant morbidity and may present a risk of self-harm
- Consider other conditions that mimic depression; also coexisting psychiatric and medical conditions, substance use
- Know hospitalization and involuntary commitment criteria in your area

- F32.9 Major depressive disorder, single episode, unspecified

- F33.9 Major depressive disorder, recurrent, unspecified

DERMATOMYOSITIS/POLYMYOSITIS

Sean-Xavier Neath

BASICS

DESCRIPTION

- Dermatomyositis (DM) and polymyositis (PM) are systemic inflammatory myopathies, which represent the largest group of acquired and potentially treatable causes of skeletal muscle weakness
- Patients experience a marked progression of muscle weakness over weeks to months
- Can lead to respiratory insufficiency from respiratory muscle weakness
- Aspiration pneumonia can occur owing to a weak cough mechanism, pharyngeal muscle dysfunction, and esophageal dysmotility
- Cardiac manifestations include myocarditis, conduction defects, cardiomyopathy, and congestive heart failure (CHF)
- Arthralgias of the hands, wrists, knees, and shoulders
- Ocular muscles are not involved but facial muscle weakness may be seen in advanced cases

ETIOLOGY

- The exact cause is unknown, although autoimmune mechanisms are thought to be largely responsible
- Incidence ~ 1:100,000 with a female preponderance
- Association with HLA-B8 and HLA-DR3
- There may be an association between PM and certain viral, bacterial, and parasitic infections
- DM/PM occurs with collagen vascular disease about 20% of the time
- In DM, humoral immune mechanisms are implicated, resulting in a microangiopathy and muscle ischemia
- In PM, a mechanism of T-cell-mediated cytotoxicity is posited. CD8 T cells, along with macrophages surround and destroy healthy, non-necrotic muscle fibers that aberrantly express class I major histocompatibility complex (MHC) molecules
- Deposition of complement is the earliest and most specific lesion, followed by inflammation, ischemia, microinfarcts, necrosis, and destruction of the muscle fibers

Pediatric Considerations

- Although DM is seen in both children and adults, PM is rare in children
- Similar to adult DM, juvenile DM (JDM) primarily affects the skin and skeletal muscles

- Juvenile form may include vasculitis, ectopic calcifications (calcinosis cutis), and lipodystrophy
- The juvenile form may be associated with coxsackievirus

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- PM is distinguished from DM by the absence of rash
- Patients with PM present with muscle pain and proximal muscle weakness
- DM presents with skin rash, muscle pain, and weakness
- Constitutional symptoms include weight loss, fever, anorexia, morning stiffness, myalgias, and arthralgias
- Patients often note fatigue doing customary tasks:
 - Brushing hair, climbing stairs, reaching above the head, rising from a chair
 - May also complain of dysphagia, dyspnea, and cough
- Progressive weakness of the proximal limb and girdle muscles is seen early; distal muscle weakness can occur late in the disease

Physical-Exam

- General:
 - Fatigue
 - Fever
 - Weight loss
- Dysphagia
- Progressive muscle weakness:
 - Involves proximal muscles primarily
 - Symmetrical
- Skin findings of DM:
 - Skin rash occurs with or precedes muscle weakness
 - Heliotrope rash (lilac discoloration) on the upper eyelids associated with edema
 - Gottron sign: Violaceous or erythematous papules over the extensor surfaces of the joints, particularly knuckles, knees, and elbows
 - Shawl sign: A V-shaped erythematous rash occurring on the back and shoulders
 - Periungual telangiectasias: Nail-bed capillary changes that include thickened irregular and distorted cuticles
 - “Machinist hands”: Darkened horizontal lines across the lateral and palmar aspects of the fingers

ESSENTIAL WORKUP

- Assess airway and breathing for any signs of aspiration or compromise
- Assess for any signs of cardiac involvement and complications

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Serum muscle enzymes:
 - Creatine phosphokinase (CPK) is elevated, other muscle enzymes such as aldolase, can also be elevated
- Diagnostic criteria established in 1975 by Bohan and Peter:
 - Symmetric proximal muscle weakness with dysphagia and respiratory muscle weakness
 - Elevation of serum muscle enzymes
 - Electromyographic features of myopathy
 - Muscle biopsy showing features of inflammatory myopathy
 - Confidence limits for diagnosis (typical rash must be seen for diagnosis of DM):
 - Definite diagnosis: 3 or 4 criteria
 - Probable diagnosis: 2 criteria
 - Possible diagnosis: 1 criterion
- Newer diagnostic criteria using autoantibody profiles (Anti-Jo-1, Anti-SRP, Anti-Mi-2) or immunohistologic characterization may prove to be more specific for diagnosis of specific disease subgroups

Imaging

- Chest radiograph may show interstitial lung disease, evidence of aspiration pneumonia, CHF, or cardiomyopathy
- EMG studies show myopathic potentials that may support the diagnosis but are not specific for DM/PM
- Increasing role for MRI in determining regions of inflammation best suited for biopsy

Diagnostic Procedures/Surgery

- Muscle biopsy is the definitive test:
 - In PM, inflammatory infiltrates are often endomysial, although they may be perivascular
 - In DM, inflammatory infiltrates are mostly perivascular and include a high percentage of B cells
- Renal biopsies of patients may show focal proliferative glomerulonephritis
- Pulmonary function tests are useful in following the progression of interstitial lung disease

DIFFERENTIAL DIAGNOSIS

- Collagen vascular diseases
- Muscular dystrophies
- Spinal muscular atrophy
- Myasthenia gravis
- Amyotrophic lateral sclerosis
- Poliomyelitis
- Guillain–Barré syndrome
- Hypothyroidism
- Hyperthyroidism
- Cushing syndrome
- Drug-induced:
 - Colchicine
 - Zidovudine (AZT)
 - Penicillamine
 - Ipecac
 - Ethanol
 - Chloroquine
 - Corticosteroids
- Infection:
 - Toxoplasmosis
 - Trichinosis
 - Coxsackievirus
 - HIV, influenza
 - Epstein–Barr virus
- Electrolyte disturbances:
 - Hypokalemia
 - Hypercalcemia
 - Hypomagnesemia
- Vasculitis
- Paraneoplastic neuromyopathy
- Hypereosinophilic myalgia syndrome

TREATMENT

PRE HOSPITAL

- Assess ABCs
- Transport with elevation of head of bed

INITIAL STABILIZATION/THERAPY

- Intubation and mechanical ventilation as required
- Nasogastric (NG) suction to prevent aspiration

- Pneumothorax has been described as a rare occurrence in childhood DM

ED TREATMENT/PROCEDURES

- Elevate head of the bed to prevent aspiration
- Begin high-dose corticosteroids to suppress inflammation and improve muscle weakness
- Avoid triamcinolone and dexamethasone because they may cause a drug-associated myopathy
- Efficacy of prednisone determined by objective increase in muscle strength, not change in CK levels
- Some clinicians start glucocorticoid sparing immunosuppressive medications at onset, others reserve these agents for failure to respond to corticosteroids
- Azathioprine and methotrexate are used with limitations based on side-effect profiles
- Cyclosporine and monoclonal antibody therapies have been used but with limited success
- Do not base treatment decisions solely upon CPK level

MEDICATION

First Line

- Prednisone: 60 mg/d PO (peds: 1–2 mg/kg/d PO) (in severe illness consider methylprednisolone pulse 1,000 mg/d for 3 days):
 - Length of treatment and taper individualized to clinical response and normalization of CK

Second Line

- Methotrexate: 15–25 mg PO per week (peds: 15 mg/m²/wk PO not > 25 mg)
- Azathioprine: Start at 50 mg/d then in 2 wk, increase by 50 mg until a dose of 1.5 mg/kg/d.
 - After 3 mo, may increase dose to 2.5 mg/kg/d if tolerated
- Intravenous immunoglobulin (IVIG), plasmapheresis, and cyclosporine are also used by some rheumatologists

FOLLOW-UP

DISPOSITION

Admission Criteria

- Respiratory insufficiency
- Aspiration pneumonia
- Profound muscle weakness

- Weakened cough mechanisms
- Pharyngeal dysfunction
- CHF

Discharge Criteria

- Well-appearing patients with no respiratory dysfunction and no risk for aspiration
- Patients who can take oral corticosteroids and immunosuppressive agents as outpatients

Issues for Referral

Consultation with a rheumatologist should be made when the diagnosis is suspected for assistance with definitive diagnosis and further treatment.

FOLLOW-UP RECOMMENDATIONS

- Compared to the general population, the incidence of malignant conditions appears to be increased in patients with DM (but not in those with PM)
- A complete annual physical exam with pelvic, breast, and rectal exams; urinalysis; CBC; blood chemistry tests; and a chest film are often recommended for cancer surveillance in patients with a history of DM

PEARLS AND PITFALLS

- The diagnosis of an inflammatory myopathy is largely clinical supported by selected lab testing and muscle biopsy
- Most patients improve with therapy, and many make a full functional recovery, which is often sustained with maintenance therapy
- Up to 30% may be left with some residual muscle weakness
- It is important to keep in mind that relapses may occur at any time despite successful response to therapy

DIABETES INSIPIDUS

Melissa H. White • Carolyn Maher Overman

BASICS

DESCRIPTION

- Disorder in which large volumes of dilute urine are excreted (polyuria) as an inappropriate response to arginine vasopressin (AVP)
- Polyuria defined as >3 L in 24 hr
- Often characterized by excessive fluid intake (polydipsia)
- 2 types:
 - Central diabetes insipidus (DI, CDI; failure or deficiency of AVP release):
 - 4 types:
 - No AVP to release (loss or malfunction of posterior pituitary neurons)
 - Defective osmoreceptors—release AVP only in response to severe dehydration
 - Elevated threshold for AVP release
 - Subnormal amount of AVP released
 - Familial cases have been reported (autosomal dominant).
 - Nephrogenic DI (lack of renal response to AVP):
 - Differentiate from primary polydipsia.
 - Some cases are X-linked recessive in males.

ETIOLOGY

- Central DI:
 - Any condition that disrupts the osmoreceptor-hypothalamus-hypophyseal axis:
 - Highest incident in ages 10–20 yr
 - Trauma (skull fractures, hemorrhage)
 - Pituitary or hypothalamic surgery
 - CNS neoplasm: DI can be considered a tumor marker:
 - Pituitary adenomas
 - Craniopharyngiomas
 - Germinomas
 - Pinealomas
 - Meningiomas
 - Metastatic tumors:
 - Leukemia/lymphoma
 - Granulomatous:
 - Histiocytosis

- Sarcoidosis
 - Congenital CNS defects
 - CNS infections (e.g., meningitis, encephalitis)
 - Pregnancy (Sheehan syndrome)
 - Idiopathic (autoantibodies, occult tumor)
 - Wolfram syndrome (DI, DM, optic atrophy, deafness)
 - Ethanol
- Nephrogenic DI:
 - Any condition that disrupts the kidney:
 - Congenital renal disorders
 - Obstructive uropathy
 - Renal dysplasia
 - Polycystic kidney disease
 - Systemic disease with renal involvement
 - Sickle cell disease
 - Sarcoidosis
 - Amyloidosis
 - Drugs:
 - Amphotericin
 - Phenytoin
 - Lithium (most common and persists past discontinuation of drug)
 - Aminoglycosides
 - Methoxyflurane
 - Demeclocycline
 - Electrolyte disorders:
 - Hypercalcemia
 - Hypokalemia

Pregnancy Considerations

- Transient in the 2nd trimester:
 - Unclear etiology, but there is an increase of circulating vasopressinase.
 - Leads to a decrease in AVP and transient DI
 - Watch patient closely during anesthesia and periods of water restriction.
 - Typically clears after 2–6 wk after delivery
 - Desmopressin (DDAVP) resists this vasopressinase.
- Sheehan syndrome may cause DI.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Polyuria (up to 16–24 L/d of urine):
 - Note the voiding frequency.
- Polydipsia (often craves cold fluids):
 - Note the amount of PO fluid intake per day.
- Drug ingestion
- Signs and symptoms of hypothalamic tumors:
 - Headache
 - Visual disturbances
 - Growth disturbances
 - Obesity
 - Hyperpyrexia
 - Sleep disturbances
 - Sexual precocity
 - Emotional disturbances

Physical-Exam

- Dehydration
- Cachexia
- Head trauma
- Visual field defects
- Seizures

Pediatric Considerations

- Polyuria and polydipsia may not be recognized by caregivers until symptoms of dehydration develop.
- In neonates:
 - Often present at birth
 - If unrecognized, dehydration and hypernatremia may cause permanent CNS damage.
- In infants:
 - Irritability
 - Poor feeding/weight loss
 - Constipation
 - Growth failure
 - Intermittent high fever
 - Abnormal behavior (hyperactivity, restlessness, excessive crying)
- In children:
 - Enuresis
 - Difficulty with toilet training

ESSENTIAL WORKUP

- Clinical diagnosis in the ED:

- Elevated serum sodium concentration
- Copious amounts of dilute urine
- History:
 - Usually an increased amount of PO fluid intake per day
 - Voiding frequency
 - Medication use history
- Physical exam
- Labs below

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Urinalysis:
 - Specific gravity will be low.
- Serum and urine osmolality:
 - High serum osmolality
 - Low urine osmolality
- Electrolytes, BUN, creatinine, and glucose:
 - Hyponatremia
 - Hypercalcemia
 - Hypokalemia
- CBC:
 - Anemia may be a sign of a neoplasm.
- Serum and urine AVP tests are expensive and unnecessary in the ED.

Imaging

- As needed to evaluate for trauma or search for neoplasm
- CXR
- CT of brain
- MRI of pituitary axis is usually outpatient.

Diagnostic Procedures/Surgery

Water deprivation test (dehydration test):

- Unnecessary in the emergency setting
- Can be dangerous in cases of hypotension or small children
- Performed as a confirmatory test for those receiving treatment
- Measures urine and plasma osmolality after fluid restriction
 - Urine osmo < 300 is significant for DI
 - Desmopressin is administered
 - Central DI—urine osmo increased by $> 50\%$
 - Nephrogenic DI—urine osmo increased by $< 50\%$
 - Further testing is needed if urine osmo 300–800

- Primary polydipsia if urine osmo > 800

DIFFERENTIAL DIAGNOSIS

- Primary water deficit:
 - Inadequate access to free water
 - Increased insensible water loss (e.g., premature infants)
 - Inadequate breast-feeding
- Primary sodium excess:
 - Excessive sodium bicarbonate during resuscitation
 - Hypernatremic enemas
 - Ingestion of seawater
 - Hypertonic saline administration
 - Accidental substitution of salt (sodium chloride) for glucose in infant formulas
 - Intentional salt poisoning
 - High breast milk sodium
- Primary polydipsia (psychogenic polydipsia):
 - Solute-induced polyuria
 - Diuretic use
 - Resolving acute renal failure
 - Osmotic diuresis
 - Uncontrolled *DM*

TREATMENT

PRE HOSPITAL

- ABCs
- Immobilize if trauma is suspected.
- Serum blood glucose
- IV access and fluids if signs of dehydration exist
- Control seizures according to medical direction guidelines.

INITIAL STABILIZATION/THERAPY

- Manage ABCs.
- Manage traumatic injuries accordingly.
- High index of suspicion for head trauma

ED TREATMENT/PROCEDURES

- Correction of hypotension:
 - Use of 0.9% NaCl is indicated for shock.
 - Intravascular losses represent only about 1/12 of total water losses.
- Central DI (vasopressin deficient):
 - AVP (aqueous vasopressin):

- Half-life is too short.
- May induce coronary vasospasm
- Used only for dehydration test
- Lysine vasopressin (lypressin):
 - Can be given intranasally
 - Frequent instillation needed
- Desmopressin:
 - Drug of choice to control symptoms
 - Administer intranasally, SC, IV, or PO in 2 divided doses as necessary to control polyuria or polydipsia.
 - Caution in postoperative patients as cerebral edema may develop
- Chlorpropamide (Diabinese):
 - Enhances effect of vasopressin at renal tubule
 - May stimulate AVP release
 - Useful only in partial CDI
 - Clofibrate stimulates the release of endogenous vasopressin.
- Nephrogenic DI:
 - Diuretics:
 - Induce natriuresis
 - Thiazides 1st line
 - Amiloride often used in combination with thiazides
 - Dietary sodium restriction
 - Restrict solutes and avoid excessive drinking to prevent water intoxication.
 - Avoid alcohol (especially beer) intake.
 - Check daily weights.
 - NSAIDs (indomethacin)
- Parenteral correction of initial water deficit in cases where PO is not an option:
 - Usually only in symptomatic hypernatremic cases
 - For fluid replacement, refer to “Hypernatremia.”

MEDICATION

- Aqueous AVP: 5–10 U SC in the unconscious patient from head trauma or postoperative
- Amiloride: 2.5–10 mg PO BID
- Chlorpropamide (Diabinese): 200–500 mg PO daily
- Clofibrate (Atromid-S): 500 mg PO q6h
- Desmopressin: 10–20 µg/d intranasally; 1–3 µg/d SC or IV; 0.1–1.2 µg/d PO
- Hydrochlorothiazide (HCTZ): 50 mg PO daily (peds: 2–4 mg/kg QD–BID)
- Lypressin nasal spray: 1–2 nasal spray TID–QID as needed

FOLLOW-UP

DISPOSITION

Admission Criteria

- AMS
- Seizure
- Severe dehydration
- Electrolyte abnormalities
- Associated trauma
- Patients requiring DDAVP testing or a trial of water restriction

Discharge Criteria

- Known diagnosis of DI
- Stable electrolytes
- Adequately hydrated

FOLLOW-UP RECOMMENDATIONS

Referral to specialist depends on underlying etiology of DI.

PEARLS AND PITFALLS

- Check urine osmolality and consider DI in polyuria.
- Central DI will typically respond to desmopressin.
- Nephrogenic DI will not respond to ADH:
 - Treat the underlying electrolyte abnormality, discontinue concerning drugs, and consult nephrology for further management.

- N25.1 Nephrogenic diabetes insipidus

DIABETES MELLITUS, JUVENILE

Madeline M. Joseph

BASICS

DESCRIPTION

- Decrease in effective circulating insulin
- Increase in counter regulatory hormones including glucagon, catecholamines, cortisol, and growth hormone
- Hyperglycemia owing to:
 - Decreased peripheral glucose utilization
 - Increased hepatic gluconeogenesis
- Hyperosmolality and osmotic diuresis due to hyperglycemia
- Ketoacidosis produced by increased lipolysis, with ketone body (β -hydroxybutyrate, acetoacetate) production, causes ketonemia and metabolic acidosis, which is augmented with lactic acidosis from poor tissue perfusion
- Potassium deficit:
 - Intracellular shifts into extracellular space owing to hydrogen ion exchange
 - Loss from osmotic diuresis

ETIOLOGY

Mechanism:

- Immune-mediated pancreatic islet β -cell destruction
- The overall incidence has been increased worldwide by 2–5% over the past 20 yr.
- Precipitating events leading to diabetic ketoacidosis (DKA):
 - Infection, often minor acute illness such as virus, group A streptococcal pharyngitis, or UTI
 - Stress
 - Endocrine: Pregnancy, puberty, hyperthyroidism
 - Psychiatric disorders, including eating disorders
 - Medication noncompliance, inappropriate interruption of insulin pump therapy, or treatment error
- Risk factors for cerebral edema:
 - Attenuated rise in measured serum sodium during DKA therapy (unrelated to the volume or sodium content of IV fluid or rate of change in serum glucose)
 - Bicarbonate treatment for acidosis correction
 - Hypocapnia
 - Increased serum urea nitrogen
 - No association with degree of hyperglycemia
 - Demographic factors that have been associated with an increased risk of

cerebral edema include younger age, longer duration of symptoms, and new onset diabetes mellitus. These factors are also associated with increased risk of severe DKA.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Polydipsia
- Polyuria (may have good urine output despite dehydration)
- Nocturia
- Polyphagia
- Malaise, weight loss
- DKA:
 - Initial presentation in 20–40% of patients
 - Often associated with tachypnea (Kussmaul respiration), tachycardia, orthostatic BP changes
 - Nausea
 - Vomiting
 - Abdominal pain, often resolving with reduction in ketosis/acidosis
 - Hyperpnea
 - Fruity breath secondary to ketones
- Rapid onset of DKA can occur within 7–8 hr with the use of insulin pump therapy if there is an infusion set or insulin delivery malfunction. This is due secondary to lack of long acting insulin to provide a safety net (more commonly seen in female > 10 yr of age).
- Findings with more advanced disease
 - Dehydration, drowsiness, altered mental status, and ultimately, late stage coma and shock
- Cerebral edema:
 - The incidence ranges from 0.87–1.1%.
 - Cerebral edema accounts for 57–87% of all DKA deaths.
 - It typically occurs 4–12 hr after treatment is initiated, but can be presenting (subclinical) before treatment has started.
 - Headache
 - Change in neurologic status, such as drowsiness, irritability, or specific neurologic deficit, such as pupillary responses or cranial nerve palsies
 - Inappropriate slowing in pulse rate
 - Increase in BP
- Hyperglycemic hyperosmolar nonketotic coma:
 - Glucose level of 800–1,200 mg/dL
 - Rare in children; more common in adults

ESSENTIAL WORKUP

For DKA:

- The International Society for Pediatric and Adolescent Diabetes (ISPAD) defines DKA as blood bicarbonate level <15 mmol/L or venous pH <7.3 and hyperglycemia (>200 mg/dL) with related ketonemia or ketonuria.
- DKA classification:
 - Mild DKA: Venous pH <7.2 – 7.3 or $\text{HCO}_3^- <10$ – 15 mmol/L
 - Moderate DKA: Venous pH <7.1 – 7.2 or $\text{HCO}_3^- <5$ – 10 mmol/L
 - Severe DKA: Venous pH <7.1 or $\text{HCO}_3^- <5$ mmol/L
- Hourly vital signs and neurologic checks
- Frequent blood chemistries
- ECG monitoring (in severe DKA) to assess T-waves for evidence of hyperkalemia or hypokalemia
- Accurate fluid input and output. Consider urinary catheterization in patients with impaired level of consciousness.

DIAGNOSIS TESTS & INTERPRETATION

Lab

For DKA:

- Glucose, serum: Hyperglycemia
- Urinalysis:
 - Glycosuria
 - Ketonuria
 - Exclude UTI
- Blood chemistries every 2–4 hr until acidosis has resolved (more frequent as clinically indicated in the more severe cases)
- Electrolytes and venous pH
- Anion gap metabolic acidosis:
 - Potassium—high or normal (artifactual owing to extracellular shift)
 - Serum potassium rises 0.5 mEq/L for each 0.1 decrease in pH
 - Sodium—low or normal (may be artifactual owing to hyperglycemia)
 - Corrected Na (mEq/L) = [measured serum Na (mEq/L) + plasma glucose (mg/dL) – 100] \times 0.016
 - Bicarbonate—low
 - Calculation: $\text{Na} - (\text{Cl} + \text{HCO}_3^-)$
- Serum ketones—elevated. β -hydroxybutyrate (BHOB) is a quantitative test that is available to replace the classic nitroprusside test for serum ketones
- Serum osmolality
- CBC:
 - WBC often elevated owing to stress or infection
- Calcium
- Phosphate

- Cultures as indicated: Group A streptococcal pharyngeal swab, urine, etc.
- Pregnancy test if indicated
- ECG if potassium markedly abnormal

Imaging

- CXR if any suggestion of pneumonia
- Head CT if there are concerns about cerebral edema

DIFFERENTIAL DIAGNOSIS

- Infection (may precipitate):
 - UTI
 - Gastroenteritis
 - Appendicitis
 - Sepsis
- Ingestion (salicylates, alcohols, glycols)
- Diabetes insipidus

TREATMENT

PRE HOSPITAL

For DKA:

- ABCs
- Airway protection
- Establish IV access and initiate fluid therapy.

INITIAL STABILIZATION/THERAPY

For DKA:

- Oxygen
- Cardiac monitor
- IV access and volume resuscitation

ED TREATMENT/PROCEDURES

- For DKA:
 - Fluid replacement:
 - Assume fluid deficit of 10% of body weight.
 - Initial volume expansion with 10–20 mL/kg of 0.9% NaCl or lactated Ringer; may repeat to achieve hemodynamic stability
 - Correct 50% of fluid deficit over 1st 8 hr, remainder over 24–48 hr.
 - Do not give $> 3 \text{ L/m}^2$ over 1st 24 hr.
 - Begin IV insulin infusion after ketoacidosis confirmed:
 - Initial rate of continuous infusion (regular insulin) 0.1 U/kg/h IV
 - Adjust rate to drop serum glucose 50–100 mg/dL/h.

- Add dextrose to infusion fluid when serum glucose < 300 mg/dL.
 - Change to SC insulin when no longer significantly acidotic and able to eat.
- Some clinicians prefer IM route, commonly initially using regular insulin at a dose of 0.1–0.2 U/kg/h.
- Replace potassium and phosphate losses:
 - Verify adequate urine output.
 - Add to fluids as K-acetate (or KCl if acetate not available) and K_3PO_4 in equal amounts.
 - Large doses of K^+ may be necessary; guide therapy by frequent monitoring of K^+ .
- Monitor serum sodium:
 - Risk for cerebral edema if Na^+ fails to rise as glucose falls
- Bicarbonate therapy:
 - Not recommended in most cases since generally it does not alter outcome and it increases risk for cerebral edema with its use
 - Use it with caution in patients with severe acidosis (pH < 6.9) in whom peripheral vasodilation and decreased cardiac contractility may further impair tissue perfusion and in potentially life-threatening hyperkalemia.
- Cerebral edema:
 - Treat cerebral edema as soon as the condition is suspected due to its high mortality and morbidity rates: 21–25% and 10–26%, respectively.
 - Decrease fluid administration rate.
 - Mannitol (0.25–1 g/kg over 20 min): No large studies to date demonstrate definitive beneficial or detrimental effects. Consider its use in patients with signs of cerebral edema before impeding respiratory failure. Dose can be repeated in 2 hr if there is no initial response.
 - Endotracheal intubation and ventilation: Avoid aggressive hyperventilation since it has been associated with poor outcome in DKA-related cerebral edema (similar to that found in head trauma).

MEDICATION

- Insulin drip: Start regular insulin 0.1 U/kg/h IV (some clinicians prefer the IM dosing and route).
- Mannitol: 0.25–1 g/kg IV

FOLLOW-UP

DISPOSITION

Admission Criteria

For DKA:

- ICU:
 - Altered mental status
 - Shock or cardiac dysrhythmia
 - Initial glucose > 700 mg/dL
 - Initial pH < 7
 - Risk factors for cerebral edema (age < 5 yr, prolonged symptoms, high BUN)
- Inpatient unit:
 - Stable new-onset diabetic patients requiring intensive education
 - Patients with ketoacidosis not meeting requirements for ICU care
 - Compliance concerns or other social issues

Discharge Criteria

- Known diabetic patients who respond well to therapy with normalization of glucose, pH, and ketosis
- Tolerating oral fluids
- Reliable parents
- Reliable follow-up within 24 hr including appropriate education

Issues for Referral

- Critically ill
- Persistent abnormal mental status
- Poorly controlled diabetes

FOLLOW-UP RECOMMENDATIONS

- Close follow-up with the primary care physician is important even after the resolution of DKA to ensure appropriate management of the patient's diabetes to prevent further occurrence of DKA.
- Many children with diabetes are followed at comprehensive diabetes centers in collaboration with primary care physician.

PEARLS AND PITFALLS

- Mortality from DKA is predominately related to the occurrence of cerebral edema. Therefore, early and appropriate treatment is of most importance in managing children with DKA.
- In children, avoid using an insulin bolus since it increase the risk of cerebral edema. Recently, some data suggest that starting insulin drip at 0.05 U/kg/h may reduce the risk for rapid fluid shifts and theoretically for cerebral edema.

- 250.03 Diabetes mellitus without mention of complication, type I [juvenile type], uncontrolled
- 250.11 type I diabetes mellitus [insulin dependent type] [IDDM] [juvenile type], not stated as uncontrolled, with ketoacidosis

ICD10

- E10.9 Type 1 diabetes mellitus without complications
- E10.10 Type 1 diabetes mellitus with ketoacidosis without coma

- E10.65 Type 1 diabetes mellitus with hyperglycemia

DIABETIC KETOACIDOSIS

Joseph M. Weber

BASICS

DESCRIPTION

Insulin deficiency and excess of counterregulatory hormones (catecholamines, glucagon, growth hormone, and cortisol) resulting in:

- Dehydration (osmotic, hyperglycemic, diuresis, and decreased oral intake)
- Acidosis (anion gap metabolic acidosis)
- Ketone formation (unrestrained lipolysis and ketogenesis)
- Hyperglycemia (unrestrained glycogenolysis and gluconeogenesis)
- Electrolyte disturbances (hypokalemia, hypo/hyponatremia, hypophosphatemia)

ETIOLOGY

- Medication noncompliance (> 50%)
- New-onset diabetes (type I or II)
- Underlying medical illness (increased counterregulatory hormones and insulin resistance):
 - Infectious process
 - MI
 - GI bleed
 - CNS event
- Pregnancy (relative insulin deficiency and counterregulatory hormone excess)
- Medications (protease inhibitors and atypical antipsychotics: Olanzapine, clozapine)
- Alcohol abuse

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Medication noncompliance
- Polyuria, polydipsia
- Weakness
- Abdominal pain, nausea, vomiting
- Altered mental status
- Chest pain
- Febrile illness

Physical-Exam

- Tachycardia
- Hypotension (dehydration, sepsis)
- Tachypnea (hyperpnea)
- Kussmaul respirations
- Hyperthermia/hypothermia (coexisting infection)
- Dehydration:
 - Poor skin turgor
 - Dry mucous membranes
- Odor of ketones on breath
- Diffuse abdominal tenderness

ESSENTIAL WORKUP

- Diagnostic criteria:
 - pH < 7.3 with ketonemia
 - Bicarbonate < 15 mEq/L
 - Glucose > 250 mg/dL
- Bedside glucose measurement
- Venous blood gas
- Urine dip for ketones
- Serum electrolytes, glucose, BUN/creatinine
- Search for precipitating cause

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Serum glucose measurement:
 - Confirm bedside test.
- Electrolyte measurement:
 - Increased anion gap metabolic acidosis: $[\text{Na} - (\text{Cl} + \text{HCO}_3)] > 12$
 - Sodium:
 - Pseudohyponatremia (from hyperglycemia) correction factor; add 1.6 mEq/L to the measured sodium for every 100 mg/dL of blood glucose > 100 mg/dL.
 - Potassium:
 - Initial serum level may be normal to high owing to extracellular shift as compensation for acidosis.
 - Total body deficit usually 3–5 mEq/kg
 - As acidosis improves, for every 0.1 increase in the pH, serum potassium decreases 0.5 mEq/L.
 - Can drop precipitously with insulin and fluids
 - Bicarbonate:
 - Usually < 15 mEq/L

- May be higher owing to coexisting volume contraction alkalosis
- BUN/creatinine:
 - Usually shows prerenal azotemia owing to dehydration
- Serum ketones:
 - Must be present to make diagnosis of DKA.
 - β -Hydroxybutyrate is the predominant ketoacid, but acetoacetate and acetone are also present:
 - β -Hydroxybutyrate is not measured by most hospital serum and urine ketone tests (nitroprusside reaction measures only acetoacetate and acetone), thus there is a theoretical risk of missing the presence of ketones using these tests.
 - Urine ketone dip test (UKDT) is 97% sensitive for presence of serum ketones and a negative UKDT has a negative predictive value of 100% in ruling out the presence of DKA.
 - Point-of-care capillary testing for β -hydroxybutyrate is 98% sensitive for serum ketones:
 - May be used with capillary glucose testing in triage to detect DKA early in the ED course.
- Urinalysis:
 - Ketonuria, glucosuria
 - Pregnancy (UhCG)
- Venous blood gas:
 - Essential to assess patient's pH
 - pH correlates well with arterial pH
 - Avoids need for repeated arterial sticks
 - ABG should be performed if oxygenation/ventilation needs assessment.
- Serum osmolarity:
 - May be measured in the lab and calculated
 - Calculated: $2(\text{Na}) + \text{glucose}/18 + \text{BUN}/2.8$ (normal 285–300 mOsm/L)
 - Significant hyperosmolarity > 320
- CBC:
 - Leukocytosis may be present without infection.
 - If left shift in differential, suspect infection.
- Other lab tests:
 - Amylase: Elevation is nonspecific in DKA
 - Lipase: Elevation specific for pancreatitis
 - Calcium, Mg, Phosphate: All usually decreased as is K^+

Imaging

- CT head to rule out other causes of altered mental status.
- CXR if pneumonia suspected as precipitant or hypoxia present
- EKG to rule out ischemia as a precipitant and look for signs of hyper/hypo K^+

DIFFERENTIAL DIAGNOSIS

- Other causes of anion gap acidosis
- Use ACAT MUD PILES mnemonic:
 - _ Alcoholic ketoacidosis
 - _ Carbon monoxide/cyanide
 - _ Aspirin
 - _ Toluene
 - _ Methanol
 - _ Uremia
 - _ Diabetic ketoacidosis
 - _ Paraldehyde
 - _ Iron/isoniazid
 - _ Lactic acidosis
 - _ Ethylene glycol
 - _ Starvation/sepsis
- Hyperglycemic hyperosmolar nonketotic syndrome

TREATMENT

PRE HOSPITAL

- Fluid bolus often initiated in field
- Quantify amount given by paramedics to guide further ED fluids.

INITIAL STABILIZATION/THERAPY

- ABCs for patients with altered mental status
- Coma cocktail for AMS: Naloxone, thiamine, blood sugar
- 0.9% NS bolus for hypotension/tachycardia

ED TREATMENT/PROCEDURES

- Cardiac monitor and pulse oximetry for patients with abnormal vitals
- Fluids:
 - _ Average adult water deficit is 100 mL/kg (5–10 L).
 - _ Initial 1–2 L bolus of 0.9% NS to restore intravascular volume over 1st hr.
 - _ If corrected serum sodium is low, continue with 0.9% NS, giving 1–2 more liters over the next 2–4 hr.
 - _ If corrected serum sodium is normal or elevated, use 0.45% NS giving 1–2 more liters over next 2–4 hr.
 - _ Be careful to avoid fluid overload in patients with cardiac disease.
 - _ Avoid precipitous falls in serum sodium/osmolality, as this may contribute to cerebral edema.
 - _ Total fluid replacement should take 24–36 hr.
- Insulin:

- Reverses ketogenic state and down-regulates counterregulatory hormones
- Administered as continuous IV infusion of regular insulin at 0.1 U/kg/h:
 - Adjust infusion in response to changes in glucose and anion gap
- Continue until pH >7.3 and resolution of anion gap
- Serum glucose will fall sooner than resolution of acidosis and should be kept >250 mg/dL with glucose-containing fluids such as D₅ 45% NS.
- Potassium:
 - Administration is essential.
 - Total body deficit of 3–5 mEq/kg
 - Will drop precipitously with administration of fluid and insulin
 - Administer KCl, 10 mEq/h IV once renal function is established and K⁺ is known to be <5.5 mEq/L.
 - May need to give up to 20–40 mEq/h IV in cases where initial K⁺ is <3.5 mEq/L
 - In hypokalemic patients, insulin therapy should be delayed until K⁺ is >3.5 mEq/L.
 - Should measure q1–2h during 1st 4–6 hr of therapy
- Bicarbonate:
 - No studies have shown clinical benefit in DKA, and its routine use is not advocated.
 - Complications include hypokalemia, alkalosis, cerebral acidosis, and edema.
 - Some advocate its use for pH <6.9 with cardiac instability.
- Phosphate:
 - Not routinely replaced during initial ED therapy
 - May supplement if <1 mg/dL and symptomatic muscle weakness.
 - Administer as potassium phosphate.
- Magnesium:
 - May supplement if <1.2 mg/dL
 - Administer 2 g MgSO₄ IV over 1 hr.
- Identify and treat precipitating cause.

Pediatric Considerations

- Fluids:
 - Average fluid deficit is 100 mL/kg.
 - Initial 10–20 mL/kg bolus of 0.9% NS to restore intravascular volume
 - May repeat once in severely dehydrated children
 - Should not exceed 40–50 mL/kg of fluid in 1st 4 hr of therapy
 - Replace remainder of deficit at 1.5–2 times maintenance over 24–36 hr.
 - Overzealous fluid administration is thought to contribute to cerebral edema.
- Cerebral edema:
 - Occurs in 1–2% of children with DKA

- Causes 31% of deaths associated with DKA
- Exact causes unclear
- Suspect with coma, fluctuating mental status, bradycardia, HTN, severe headache, decreased urine output, or quickly falling corrected Na^+ or osmolality to below normal levels
- Mannitol: 0.25–1 g/kg IV over 30 min should be given immediately and can be repeated hourly.
- Fluid rate should be decreased and other supportive measures instituted.

MEDICATION

- D_{50} : 1 amp (25 g) of 50% dextrose IVP (peds: 2–4 mL/kg D_{25})
- Insulin (100 U regular insulin in 100 mL NS) run at 0.1 U/kg/h
- MgSO_4 : 2 g of 20% solution

FOLLOW-UP

DISPOSITION

Admission Criteria

- ICU admission for pH < 7, altered mental status, serious comorbid illness, and extremes of age (< 2 yr or > 60 yr)
- Monitored unit for moderate DKA (pH 7.01–7.24) with CHF or cardiac history
- General floor (nurses skilled with insulin infusions) for moderate DKA without comorbidities
- Observation unit (< 23 hr admission) for mild DKA (pH 7.25–7.30) without precipitating illness

Discharge Criteria

- Resolution of anion gap acidosis
- Tolerating PO fluids
- No evidence of precipitating event
- Clear instructions on home insulin regimen
- Close primary care follow-up arranged

PEARLS AND PITFALLS

- Decreasing or discontinuing insulin drip when glucose normalizes is a pitfall. Insulin should only be stopped when pH improves and anion gap normalizes.
- Failure to replete potassium is a pitfall.

DIALYSIS COMPLICATIONS

Christopher B. Colwell

BASICS

DESCRIPTION

Dialysis complications may be:

- Vascular access related (infection, bleeding)
- Nonvascular access related (hypotension, hyperkalemia)
- Peritoneal (abdominal pain, infection)

ETIOLOGY

- Vascular access related:
 - _ Infections:
 - Infections (largely access related or peritonitis) are a major cause of death in dialysis patients.
 - Often caused by *Staphylococcus aureus*
 - Can present with signs of localized infection or systemic sepsis
 - Can also present with minimal findings
 - _ Thrombosis or stenosis:
 - Often presents with loss of bruit or thrill over access site
 - Must be addressed quickly (within 24 hr) to avoid loss of access site
 - _ Bleeding:
 - Can be life-threatening
 - Aneurysm
- Nonvascular access related:
 - _ Hypotension:
 - Most common complication of hemodialysis
 - After dialysis: Often owing to acute decrease in circulating blood volume
 - During dialysis: Hypovolemia (more commonly) or onset of cardiac tamponade owing to compensated effusion suddenly becoming symptomatic after correction of volume overload
 - MI, sepsis, dysrhythmias, hypoxia
 - Hemorrhage secondary to anticoagulation, platelet dysfunction of renal failure
 - _ Shortness of breath:
 - Volume overload
 - Development of dyspnea *during* dialysis owing to tamponade, pericardial effusion, hemorrhage, anaphylaxis, pulmonary embolism, air embolism

- Chest pain:
 - Ischemic:
 - Dialysis patients are often at high risk for having atherosclerotic disease
 - Dialysis is an acute physiologic stressor with transient hypotension and hypoxemia that increases myocardial oxygen demand.
 - Pleuritic:
 - Pericarditis, pulmonary embolism
- Neurologic dysfunction: Disequilibrium syndrome:
 - Rapid decrease in serum osmolality during dialysis leaves brain in comparatively hyperosmolar state.
- Peritoneal:
 - Peritonitis:
 - Owing to contamination of peritoneal dialysate or tubing during exchange
 - *S. aureus* or *Staphylococcus epidermidis* (70%)
 - Perforated viscus with abdominal pain that can be severe, fever, brown or fecal material in effluent, or localized tenderness
 - Fibrinous blockage of catheter resulting from infection or inflammation

DIAGNOSIS

SIGNS AND SYMPTOMS

- Vascular access related:
 - Bleeding from puncture sites
 - Loss of bruit in graft
 - Local infection, cellulitis, fever
 - Decreased sensation and strength distal to access
 - New or increasing size mass adjacent to access site
- Nonvascular access related:
 - Hypotension before, during, or after procedure
 - Palpitations
 - Syncope
 - Chest pain:
 - Ischemic
 - Pleuritic
 - Hemorrhage:
 - GI
 - Pleural
 - Retroperitoneal
 - Shortness of breath:

- Neurologic symptoms (disequilibrium syndrome):
 - Headache
 - Malaise
 - Seizures
 - Coma
- Peritoneal:
 - Abdominal pain
 - Cloudy dialysis effluent
 - Nausea and vomiting
 - Exudates or inflammation at insertion site of Tenckhoff catheter

ESSENTIAL WORKUP

- Careful physical exam:
 - Complete set of vital signs including auscultated BP, pulse, respiratory rate, accurate temperature, and pulse oximetry
 - Careful physical exam for occult infectious sources (odontogenic, perirectal abscess)
 - Auscultation of lungs for evidence of infection (rhonchi) or volume overload (rales)
 - Search for other evidence of volume overload (edema)
 - Careful cardiac exam including listening for murmurs or rubs
- EKG: Look for signs of electrolyte balance or conduction disturbances.
- Infection:
 - Blood and wound cultures
 - Cell count, Gram stain, culture of peritoneal fluid
- Bleeding:
 - CBC to evaluate anemia and platelet count
 - Coagulation studies
- Chest pain or shortness of breath:
 - Chest radiograph
 - ABG
 - EKG, cardiac enzymes (if appropriate, based on history)
- Neurologic dysfunction: CT of brain for intracranial hemorrhage

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Glucose, electrolytes, BUN, and creatinine
- CBC

Imaging

- ECG for suspected:
 - Hyperkalemia

- Pericarditis
- Effusion
- Tamponade
- US of access for possible clotted graft or fistula
 - ECHO to assess for pericardial effusion/tamponade
- Peritoneal cathetergram for blockages
- CT scan for pulmonary embolism:
 - Dialysis patients are at risk for both bleeding and clotting problems.
 - Problematic in renal insufficiency owing to contrast dye load:
 - Can be done in renal failure, but contrast is then a fluid bolus and may need to be dialyzed off
 - Communicate contrast load to renal team, as dialysis may need to occur for longer-than-normal duration.

DIFFERENTIAL DIAGNOSIS

- Hypotension:
 - Sepsis
 - Cardiogenic shock, acute MI, tamponade, primary dysrhythmias
 - Electrolyte abnormalities leading to dysrhythmias (hyperkalemia and hypokalemia)
 - Embolism: Air or pulmonary
 - Hypovolemia
 - Vascular instability: Autonomic neuropathy, drug related, dialysate related
- Neurologic complications:
 - Cerebrovascular accident
 - Disequilibrium syndrome
 - Hyperglycemia or hypoglycemia
 - Hyponatremia or hypernatremia
 - Hypoxemia
 - Intracranial bleed
 - Meningitis or abscess
 - Uremia
- Peritoneal complications:
 - Peritonitis
 - Hernia incarceration
 - Perforated viscus
 - Acute abdominal process: Appendicitis, cholecystitis

TREATMENT

PRE HOSPITAL

ALERT

- Do not perform IV access and BP measurement in extremity with functioning AV graft or fistula.
- Run IV fluids slowly and keep to min., if possible.
- Administer furosemide in pulmonary edema (anuric patients: Use high doses ≤ 200 mg).

INITIAL STABILIZATION/THERAPY

- Check airway, breathing, and circulation.
- Vascular access related:
 - Bleeding:
 - Firm pressure to site(s)
 - Do not totally occlude access; may cause clotting.
 - Will likely need pressure applied for at least 5–10 min to stop even minor bleeding
 - Document presence or absence of thrill after pressure was applied.
 - Apply Gelfoam.
- Nonvascular access related:
 - Hypotension:
 - Search for underlying cause.
 - Vasopressors, fluids
 - Shortness of breath:
 - Preload and afterload reduction with nitrites and ACE inhibitors.
 - Attempt diuresis if fluid overload is suspected cause.
 - Arrange for dialysis.
 - Hyperkalemia:
 - Administer IV calcium, bicarbonate, insulin, and glucose when appropriate (see “Hyperkalemia”).
 - Monitor cardiac rhythm.
 - Administer ion-exchange resin (Kayexalate).
 - Arrange for dialysis.
 - Neurologic complications:
 - Administer naloxone, thiamine, dextrose (or Accu-Chek) for altered mental status.
 - Control seizures with benzodiazepines.

ED TREATMENT/PROCEDURES

- Vascular access related:
 - Infection:
 - Initiate antistaphylococcal IV antibiotics.
 - Clotted access:
 - Analgesia
 - Warm compresses

- Vascular surgery consult
- Hemorrhage:
 - Control bleeding.
 - Correct coagulopathies.
 - Administer IV fluids and blood products.
- Nonvascular access related:
 - Electrolyte imbalances:
 - Treat hypercalcemia or hypermagnesemia with saline infusion if tolerated (dilution).
 - Diuresis with furosemide after preload and afterload reduction (nitroglycerin, enalapril)
 - Arrange for dialysis.
 - Volume overload:
 - Attempt diuresis with nitrites and furosemide.
 - Arrange for dialysis.
 - Pericardial effusion or tamponade:
 - Emergent pericardiocentesis may be necessary in unstable patient.
 - Arrange for dialysis.
 - Acute MI:
 - Thrombolytics or angioplasty if patient is appropriate candidate
 - Nitrates to decrease myocardial workload
 - Disequilibrium syndrome:
 - Rule out other causes of altered mental status.
 - Generally resolves over time
- Peritoneal:
 - Peritonitis: IV or intraperitoneal antibiotics
 - Culture catheter or tunnel infection, visible exudates:
 - Oral antibiotics (antistaphylococcal)
 - If recurrent or tunnel, may need to be unroofed
 - Meticulous site care
 - Perforated viscous:
 - IV antibiotics
 - Surgical consultation

MEDICATION

- Calcium gluconate: 1 g slowly IV (cardioprotective in hyperkalemia with widened QRS complex)
- Cefazolin: 1 g IV or IM followed by 250 mg/2 L bag for 10 days (peritonitis)
- Captopril: 25 mg sublingually
- Dextrose D₅₀W: 1 amp: 50 mL or 25 g (peds: dextrose D₂₅W: 2–4 mL/kg)IV
- Dopamine: 2–20 µg/kg/min IV
- Enalapril: 1.25 mg IV
- Furosemide: 20–100 mg IV (may require doses of ≥ 30 mg to effect diuresis in

chronic renal failure)

- Insulin: 5–10 U regular insulin IV (with D₅₀ for hyperkalemia)
- Naloxone (Narcan): 2 mg (peds: 0.1 mg/kg) IV or IM initial dose
- Nitroglycerin: 0.4 mg sublingually; 5–20 µg/min IV
- Sodium bicarbonate: 1 mEq/kg up to 50–100 mEq IV PRN
- Sodium polystyrene sulfonate (Kayexalate): 1 g/kg up to 15–60 g PO or 30–50 g retention enema q6h PRN (for hyperkalemia)
- Thiamine (vitamin B₁): 100 mg (peds: 50 mg) IV or IM
- Tobramycin: 1.7 mg/kg IV or IM followed by 10 mg/2 L bag for 10 days (peritonitis)
- Vancomycin: 1 g IV or IM followed by 50 mg/2 L bag for 10 days (peritonitis)

FOLLOW-UP

DISPOSITION

Admission Criteria

- ICU admission:
 - Severe hyperkalemia
 - Pulmonary edema
 - Volume overload
 - Persistent hypotension
 - Uncontrolled seizures
 - Acute MI
 - Cardiovascular accident
 - Pericarditis
 - Sepsis
 - Peritonitis with toxic or systemic symptoms
- Regular admission:
 - Fever
 - Vomiting
 - Peritonitis without toxic or systemic symptoms
 - Non–life-threatening electrolyte disturbances
 - Inability to provide self-care for continuous ambulatory peritoneal dialysis with antibiotics

Discharge Criteria

- Mild infections of access site
- Same-day surgery for some thrombectomy procedures
- Hemostasis at puncture sites

FOLLOW-UP RECOMMENDATIONS

Most patients on dialysis are followed closely by their nephrologists.

PEARLS AND PITFALLS

- Consider cardiac tamponade in dialysis patients, even when they don't exhibit classic symptoms.
- Always consider hyperkalemia in dialysis patients.
- Infections can have very subtle presentations in dialysis patients and are a common cause of morbidity and mortality
- Early vascular surgery consultation is important for patients with clotted or ruptured access sites

- T80.90XA Unsp comp following infusion and therapeutic injection, init
- T82.9XXA Unspecified complication of cardiac and vascular prosthetic device, implant and graft, initial encounter

DIAPER RASH

Francesco Mannelli

BASICS

DESCRIPTION

- Very common dermatologic disorder of infancy
- Most common in 1st month of life and again at 12–24 mo
- Incidence in adult incontinent patients is reported from 5.7% to more than 42% and appears to be strongly associated with age
- Primary irritant/contact dermatitis:
 - Outer skin layers are broken down, leading to inflammation, impairment of normal skin microflora, and loss of protective barrier function.
 - Increased skin moisture encourages growth of microorganisms on the surface of the skin.
 - Secondary fungal or bacterial infection can cause more severe forms of diaper dermatitis.
- Also known as irritant diaper dermatitis

ETIOLOGY

- Irritants:
 - Moisture:
 - Prolonged overhydration owing to infrequent diaper changes, poorly absorbing diapers or cloth diapers, urinary or faecal incontinence in adults
 - Friction:
 - Diaper rubbing on skin or loose-fitting diaper
 - Chemicals:
 - Prolonged exposure to stool enzymes and urine
 - Scents or moisturizers in wipes or soap
 - Diaper material or adhesive used to hold diaper in place
- Infection:
 - *Candida albicans*:
 - Isolated in up to 80% of infants
 - Overgrowth common after systemic antibiotic use
 - Bacterial
 - Often complication of other causes of dermatitis:
 - *Staphylococcus aureus*, *Streptococcus*, *Escherichia coli* are common; *Peptostreptococcus* and *Bacteroides* may also be encountered.
- Seborrheic diaper dermatitis
- Atopic diaper dermatitis (contact dermatitis)

- Risk factors:
 - Oral thrush
 - Number of previous episodes of diaper rash
 - Duration of use of diapers
 - Diarrhea

DIAGNOSIS

Diagnosis often empiric based on appearance of rash

SIGNS AND SYMPTOMS

History

Child may cry with diaper changes or wiping diaper area or may be irritable.

Physical-Exam

- Irritant:
 - Beefy-red confluent patches with distinct borders at diaper edges, typically sparing skin folds
- Infectious:
 - *Candida*—demarcated erythematous rash with satellite pustules or papules, typically involves skin folds
 - Bacterial—superficial erosions with yellow crust and occasionally bullae
- Seborrheic diaper dermatitis:
 - Lesions with erythematous base and greasy yellow or gray scale
 - Infant will likely have similar lesions on other body surfaces, especially scalp.
- Atopic diaper dermatitis:
 - Similar appearance to irritant dermatitis, but lesions also on other body surfaces such as the face.
- Variations include:
 - Jacquet form—erosive variant with ulcers or erosions with elevated margins usually seen with persistent diarrhea or adult urinary incontinence.
 - Psoriasiform—erythema, silvery surface scales and spared skin folds; also likely to have similar lesions on other body surfaces.
 - Granuloma gluteale infantum—violaceous papules and nodules on the buttocks and in the groin with a self-limited course, resolving in weeks or months, often with residual scarring.

ESSENTIAL WORKUP

- Inquire about diaper-changing habits and urinary and fecal habits.
- Examine other body areas to identify associated rashes.
- Consider child abuse or neglect:

- Child's overall hygiene
- Burns or other trauma

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Lab evaluation usually not necessary for management of diaper dermatitis.
- Bacterial cultures usually not indicated except in complicated cases.
- Skin surface scrapings with KOH prep and/or culture may help distinguish between *Candida* and atypical seborrheic dermatitis:
 - Look for budding yeast and/or pseudohyphae.

DIFFERENTIAL DIAGNOSIS

- Child abuse or neglect
- Infection:
 - Impetigo
 - Scabies
 - Herpes simplex
 - Varicella
 - Congenital syphilis
- Psoriasis
- Atopic dermatitis
- Seborrheic dermatitis
- Papular urticaria
- Bullous pemphigoid
- Epidermolysis bullosa
- Acrodermatitis enteropathica
- Acrodermatitis enteropathica–like eruption
- Langerhans cell histiocytosis

TREATMENT

ED TREATMENT/PROCEDURES

The management of diaper dermatitis should include reducing moisture in the diaper area, minimizing contact with urine and feces and eradicating infectious microorganism

- Environmental adjustments:
 - Education of parents and caregivers is essential:
 - Cleanse skin frequently using cotton balls and water.
 - Wet wipes and talcum powders are not recommended.
 - Frequent diaper changes, up to q1h for neonates and q3–4h for infants and adults.
 - Gentle rinsing of affected area with warm water or saline.

- Avoid harsh soaps or alcohol wipes.
- Leave area uncovered as much as possible; allow time to air dry.
- Highly absorbant diapers have less incidence of diaper rash than cloth diapers.
- Cloth diapers are not recommended for patients with irritant diaper dermatitis.
- New diapers that are “breathable” or contain top sheet of zinc oxide/petroleum and stearyl alcohol lining have been shown to decrease incidence.
- Barrier creams:
 - Many preparations available containing zinc oxide, petroleum, lanolin.
 - Should be applied after each diaper change and continued after rash resolves to minimize recurrence
 - A substantial negative relationship exists between barrier cream use and number of previous episodes of diaper dermatitis.
 - If *Candidal* infection present, apply over antifungal medication.
- Corticosteroids:
 - For moderate to severe cases not responding to other therapy
 - Should not be stronger than 1% hydrocortisone: Anything stronger can cause serious side effects.
 - Discontinue after 3–5 days.
- Antifungals:
 - Nystatin cream, powder, or ointment:
 - Expect improvement in 1–2 days.
 - Ointment best tolerated on macerated skin.
 - Clotrimazole applied topically after diaper change.
 - Miconazole applied topically after diaper change.
 - Lotion is preferred in intertriginous areas.
 - Cream should be applied sparingly to avoid maceration effects.
 - Ciclopirox applied topically after diaper change.
 - Generally continue 1–2 days after clearing
 - Antifungal agent also found to have some antibacterial activity and anti-inflammatory properties.
 - Consider oral agent if concurrent cutaneous or oral candidiasis is present or in recalcitrant case because stool may be colonized with *C. albicans*.
- Antibacterials:
 - Typically concurrent with other therapies if suspicion of bacterial infection
 - Mupirocin (Bactroban) applied after diaper changes
 - Systemic antibiotics rarely needed

MEDICATION

- Ciclopirox 0.77% cream, gel, or suspension: Applied topically BID after diaper change

- Clotrimazole 1% cream: Applied topically BID after diaper change
- Hydrocortisone 0.5–1% topical cream: Applied BID
- Miconazole topical 2% cream: Applied BID after diaper change
- Miconazole nitrate 0.25% ointment: Apply after diaper change and bathing
- Mupirocin 2% ointment or cream (Bactroban): Applied topically 3–5 times daily after diaper changes (for infants > 3 mo of age)
- Nystatin 100,000 U/g cream, powder, or ointment: Apply BID after diaper change

FOLLOW-UP

DISPOSITION

Admission Criteria

- Evidence of child abuse or neglect
- Evidence of sepsis

ICD10

L22 Diaper dermatitis

DIAPHRAGMATIC TRAUMA

Jennifer Cullen

BASICS

DESCRIPTION

- Penetrating injury:
 - Violation of the diaphragm by penetrating object (most commonly stab and gunshot wounds)
 - May involve any portion of diaphragm
 - Smaller defect compared with blunt injuries (more likely to be missed)
- Blunt injury:
 - Increased intra-abdominal or intrathoracic pressure is transmitted to diaphragm, causing rupture.
 - Usually due to motor vehicle crashes
 - Injuries are more commonly left-sided:
 - Left hemidiaphragm has posterolateral embryologic point of weakness.
 - Right hemidiaphragm is protected by liver.
 - Injuries are larger than with penetrating injury (frequently between 5 and 15 cm in length).
- Diaphragmatic defects do not heal spontaneously because of pleuroperitoneal pressure gradient:
 - May exceed 100 cm H₂O during maximal respiratory effort
 - Promotes herniation of abdominal contents through rent in diaphragm and into chest

EPIDEMIOLOGY

Incidence

Uncommon; <1% of all traumatic injuries

ETIOLOGY

- Lateral torso impact is 3 times more likely to result in ipsilateral diaphragmatic rupture than frontal impact.
- Suspect diaphragmatic injury:
 - Penetrating trauma to thoracoabdominal area
 - Injuries that cross plane of the diaphragm

DIAGNOSIS

ALERT

In acute phase, there may be no abdominal visceral herniation:

- This injury may even be missed on initial laparotomy or laparoscopy.

SIGNS AND SYMPTOMS

- Vary depending on whether phase is acute, latent, or obstructive:
 - _ Acute:
 - Tachypnea
 - Hypotension
 - Absent or diminished breath sounds
 - Abdominal distention
 - Bowel sounds in chest
 - _ Latent:
 - Abdominal discomfort from intermittent herniation of abdominal contents into thorax
 - Abdominal pain that is worse postprandially
 - Exacerbated by lying supine
 - Pain radiating to left shoulder
 - Nausea, vomiting, or belching
 - _ Obstructive:
 - Severe abdominal pain
 - Obstipation
 - Nausea, vomiting
 - Abdominal distention
- Strangulated abdominal organs may perforate and spill abdominal contents into chest
- Respiratory compromise, sepsis, and death
- Obstructive injuries may present in delayed fashion

ESSENTIAL WORKUP

CXR may reveal herniated loops of bowel or other abdominal viscera in thorax:

- Pathognomonic finding is presence of nasogastric tube above diaphragm.
- Findings are often nonspecific:
 - _ Elevated hemidiaphragm
 - _ Irregular diaphragmatic contour
 - _ Mediastinal shift away from affected side
 - _ Unilateral pleural thickening or pleural effusion
 - _ Areas of atelectasis or consolidation at bases
 - _ Small hemothorax or pneumothorax
- 50% of initial CXRs may be normal.
- Diagnosis may be difficult in latent phase because of intermittent nature of herniation.
- Contrast studies of GI tract may be helpful.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- If diagnostic peritoneal lavage (DPL) is performed:
 - Red blood cell count of 1,000 RBC/mm³ is considered positive for diaphragmatic injury after penetrating trauma.
 - May provide false-negative result in up to 40% of patients with isolated diaphragmatic injury
- No lab studies confirm or rule out presence of diaphragmatic injury.

Imaging

- CXR is diagnostic in 90% of cases in which herniation is present, but sensitivity is limited in absence of acute hernia.
- GI contrast studies are the most useful in diagnosing chronic herniation of abdominal contents through diaphragm.
- US may be used, particularly on right side with accompanying hepatic herniation.
- Conventional CT is rarely diagnostic and has poor sensitivity.
- New helical and multidetector CT (MDCT) modalities have much more success in diagnosing subtle diaphragmatic injuries.
- MRI is useful in its ability to visualize the diaphragm as a discrete structure, but is not practical in acute settings.

Diagnostic Procedures/Surgery

- Diagnostic pneumoperitoneography:
 - Air is injected through DPL catheter.
 - Pneumothorax on subsequent CXR is diagnostic of diaphragmatic injury.
 - Poorly tolerated by unstable patients and may require chest tube placement.
- Thoracoscopic and laparoscopic exploration may be indicated
 - Especially when suspicion is high despite negative imaging results
 - Facilitates minimally invasive repair

DIFFERENTIAL DIAGNOSIS

- Atelectasis
- Hemothorax
- Pneumothorax
- Pulmonary contusion
- Gastric dilation, intra-abdominal fluid
- Traumatic pneumatocele
- Subdiaphragmatic abscess
- Intrathoracic cyst
- Empyema
- Congenital eventration of the diaphragm

TREATMENT

ALERT

- Herniation of abdominal contents into chest wall may mimic hemothorax or tension pneumothorax
- Bowel sounds in chest may help distinguish
- Be suspicious of diaphragmatic injury with lateral compression of chest:
 - _ Be cautious in placement of needle or tube thoracostomies.
- Fecal thorax has been reported with bowel rupture.

INITIAL STABILIZATION/THERAPY

- Follow advanced trauma life support (ATLS) protocols.
- If respiratory distress is present, immediate placement of a nasogastric tube may decompress herniated abdominal contents.

ED TREATMENT/PROCEDURES

- Palpate within the chest cavity for visceral organs before inserting a chest tube.
- Patients with visceral perforations are septic and need aggressive resuscitation and antibiotic therapy.
- Empiric broad-spectrum antibiotics are indicated in the case of perforated viscera.
- Early surgical intervention is paramount.
- Minimally invasive repair may be possible in selected circumstances

MEDICATION

- Gram-negative aerobes:
 - _ Gentamicin: Adults/peds: 2–5 mg/kg IV initial dose
- Gram-negative anaerobes:
 - _ Clindamycin: 900 mg (peds: 20–40 mg/kg/24h) IV q8h
 - _ Metronidazole: 1 g (peds: 15 mg/kg) IV load, then 500 mg (peds: 7.5 mg/kg) IV q6h
- Both aerobic and anaerobic:
 - _ Ampicillin/sulbactam: 1.5–3 g (peds: 100–400 mg/kg/24h) IV q6h
 - _ Cefotetan: 2 g (peds: 40–80 mg/kg/24h) IV q12h
 - _ Cefoxitin: 2 g (peds: 80–160 mg/kg/24h) IV q12h
 - _ Ticarcillin/clavulanate: 3.1 g (peds: 50 mg/kg/dose) IV q6h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with suspicion for diaphragmatic injury must be admitted to trauma

surgery.

- Patients should be admitted to the monitored or ICU setting.

Discharge Criteria

Patients with diaphragmatic injury or any significant suspicion for it must not be discharged from ED.

FOLLOW-UP RECOMMENDATIONS

Patients with diaphragmatic injuries s/p repair must be followed by trauma surgeon to monitor for recurrence.

Pediatric Considerations

- Pediatric anatomic differences predispose to diaphragmatic injury via less severe mechanisms:
 - Thinner abdominal wall
 - More horizontal orientation of diaphragm
 - Greater cartilaginous rib component
- Incidence of right- and left-sided injury is equal.
- More likely to be isolated injury

PEARLS AND PITFALLS

- Overall mortality is 18–40% depending on mechanism.
- Highly associated with concomitant severe injuries to spleen and liver, hemothorax, pneumothorax, and pelvic fractures.
- Must have high suspicion for diaphragmatic injury with left-sided upper abdominal and lower thoracic penetrating trauma.
- Delayed diagnosis is associated with increased risk for herniation and strangulation of abdominal organs.
- Always obtain chest imaging.

DIARRHEA, ADULT

Isam F. Nasr

BASICS

DESCRIPTION

Bowel movements characterized as frequent ($> 3/\text{day}$), loose, and watery owing to an infectious or toxin exposure

ETIOLOGY

- Viruses:
 - 50–70% of all cases
- Invasive bacteria:
 - *Campylobacter*:
 - Contaminated food or water, wilderness water, birds, and animals
 - Most common bacterial diarrhea
 - Gross or occult blood is found in 60–90%.
 - *Salmonella*:
 - Contaminated water, eggs, poultry, or dairy products
 - Typhoid fever (*Salmonella typhi*) characterized by unremitting fever, abdominal pain, rose spots, splenomegaly, and bradycardia
 - *Shigella*:
 - Fecal or oral route
 - *Vibrio parahaemolyticus*:
 - Raw and undercooked seafood
 - *Yersinia*:
 - Contaminated food (pork), water, and milk
 - May present as mesenteric adenitis or mimic appendicitis
- Bacterial toxin:
 - *Escherichia coli*:
 - Major cause of traveler's diarrhea
 - Ingestion of food or water contaminated by feces
 - *Staphylococcus aureus*:
 - Most common toxin-related disease
 - Symptoms 1–6 hr after ingesting food
 - *Bacillus cereus*:
 - Classic source—fried rice left on steam tables
 - Symptoms within 1–36 hr
 - *Clostridium difficile*:
 - Antibiotic-associated enteritis linked to pseudomembranous colitis
 - Incubation period within 10 days of exposure or initiation of

antibiotics

- *Aeromonas hydrophila*:
 - Aquatic sources primarily
 - Affects children < 3 yr of age
 - Fecal leukocytes absent
- *Cholera*:
 - Caused by enterotoxin produced by *Vibrio cholerae*
 - Profuse watery stools with mucus (classic appearance of rice-water stools)
- Protozoa:
 - *Giardia lamblia*:
 - Most common cause of parasite gastroenteritis in North America
 - High-risk groups: Travelers, children in day care centers, institutionalized people, homosexual men, and campers who drink untreated mountain water
 - *Cryptosporidium parvum*:
 - Commonly carried in patients with AIDS
 - *Entamoeba histolytica* (entamebiasis):
 - 5–10% extraintestinal manifestations (hepatic amebic abscess)

Pediatric Considerations

- Most are viral in origin and self-limited.
- Rotavirus accounts for 50%.
- *Shigella*: Infections associated with seizures
- Focus evaluation on state of hydration.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Loose, watery bowel movements
- Bloody stools with mucus
- Abdominal pain and cramps, tenesmus, flatulence
- Fever, headache, myalgias
- Nausea, vomiting
- Dehydration, lethargy, and stupor

Physical-Exam

- Dry mucous membranes
- Abdominal tenderness
- Perianal inflammation, fissure, fistula

ESSENTIAL WORKUP

- Digital rectal exam to determine presence of gross or occult blood
- Fecal leukocyte determination:
 - Present with invasive bacteria
 - Absent in protozoal infections, viral, toxin-induced food poisoning

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC—indications:
 - Significant blood loss
 - Systemic toxicity
- Electrolytes, glucose, BUN, creatinine—indications:
 - Lethargy, significant dehydration, toxicity, or altered mental status
 - Diuretic use, persistent diarrhea, chronic liver, or renal disease
- Stool culture—indications:
 - Presence of fecal leukocytes
 - Historical markers: Immunocompromised, travel, homosexual
 - Public health: Food handler, day care or health care worker, institutionalized
- Blood cultures—indications:
 - Suspected bacteremia or systemic infections
 - Ill patients requiring admission
 - Immunocompromised
 - Elderly patients and infants

Imaging

Abdominal radiographs:

- No value unless obstruction or toxic megacolon suspected

DIFFERENTIAL DIAGNOSIS

- Ulcerative colitis
- Crohn's disease
- Mesenteric ischemia
- Diverticulitis, anal fissures, hemorrhoids
- Irritable bowel syndrome
- Milk and food allergies
- Malrotation with midgut volvulus
- Meckel diverticulum
- Intussusception
- Appendicitis
- Drugs and toxins:
 - Mannitol

- Sorbitol
- Phenolphthalein
- Magnesium-containing antacids
- Quinidine
- Colchicine
- Mushrooms
- Mercury poisoning

TREATMENT

PRE HOSPITAL

- Difficult IV access with severe dehydration
- Avoid exposure to contaminated clothes or body substances.

INITIAL STABILIZATION/THERAPY

- ABCs
- IV fluid with 0.9% normal saline (NS) resuscitation for severely dehydrated

ED TREATMENT/PROCEDURES

- Oral fluids for mild dehydration (Gatorade/Pedialyte)
- IV fluids for:
 - Hypotension, nausea and vomiting, obtundation, metabolic acidosis, significant hypernatremia or hyponatremia
 - 0.9% NS bolus: 500 mL–1 L (peds: 20 mL/kg) for resuscitation, then 0.9% NS or D₅W 0.45% NS (peds: D₅W 0.25% NS) to maintain adequate urine output
- Bismuth subsalicylate (Pepto-Bismol):
 - Antisecretory agent
 - Effective clinical relief without adverse effects
- Kaolin-pectin (Kaopectate):
 - Reduces fluidity of stools
 - Does not influence course of disease
- Antimotility drugs: Diphenoxylate (Lomotil), loperamide (Imodium), paregoric, codeine:
 - Appropriate in noninfectious diarrhea
 - Initial use of sparse amounts to control symptoms in infectious diarrhea
 - Avoid prolonged use in infectious diarrhea—may increase duration of fever, diarrhea, and bacteremia and may precipitate toxic megacolon
- Antibiotics for infectious pathogens:
 - *Campylobacter*: Quinolone or erythromycin
 - *Salmonella*: Quinolone or trimethoprim–sulfamethoxazole (TMP-SMX)
 - *Typhoid fever*: Ceftriaxone

- *Shigella*: Quinolone, TMP-SMX, or ampicillin
- *V. parahaemolyticus*: Tetracycline or doxycycline
- *C. difficile*: Metronidazole or vancomycin
- *E. coli*: Quinolone or TMP-SMX
- *G. lamblia*: Metronidazole or quinacrine
- *E. histolytica* (entamebiasis): Iodoquinol or metronidazole

MEDICATION

- Ampicillin: 500 mg (peds: 20 mg/kg/24h) PO or IV q6h
- TMP-SMX (Bactrim DS): 1 tab (peds: 8–10 mg TMP/40–50 mg SMX/kg/24h) PO or 4–5 mg/kg TMP IV BID
- Ceftriaxone: 1 g (peds: 50–75 mg/kg/12h) IM or IV q12h.
- Ciprofloxacin (quinolone): 500 mg PO or 400 mg IV q12h (> 18 yr)
- Doxycycline: 100 mg PO or 100 mg IV q12h
- Erythromycin: 500 mg (peds: 40–50 mg/kg/24h) PO QID
- Iodoquinol: 650 mg (peds: 30–40 mg/kg/24h not to exceed 2 g daily) PO TID
- Metronidazole: 250 mg (peds: 35 mg/kg/24h) PO TID (> 8 yr)
- Quinacrine: 100 mg (peds: 6 mg/kg/24h) PO TID
- Tetracycline: 500 mg PO or IV q6h
- Vancomycin: 125–500 mg (peds: 40 mg/kg/24h) PO q6h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Hypotension, unresponsive to IV fluids
- Significant bleeding
- Signs of sepsis or toxicity
- Intractable vomiting or abdominal pain
- Severe electrolyte imbalance or metabolic acidosis
- Altered mental status
- Children with > 10–15% dehydration

Discharge Criteria

- Mild cases requiring oral hydration
- Dehydration responsive to IV fluids

Issues for Referral

Cases of prolonged diarrhea may be referred to a gastroenterologist for further workup.

FOLLOW-UP RECOMMENDATIONS

Since diarrhea is self-limiting, follow-up is optional.

PEARLS AND PITFALLS

- Avoid prolonged use of antimotility drugs in infectious diarrhea.
- TMP-SMX (Bactrim DS), ciprofloxacin, doxycycline, and tetracycline are contraindicated in pregnancy. Metronidazole may be used in the 3rd trimester.
- Health care providers and food handlers with documented infectious diarrhea may need clearance to return to work from their local health department.
- Infectious diarrhea with *C. difficile* is on the rise, especially in nursing home patients.

DIARRHEA, PEDIATRIC

Rajender Gattu • Richard Lichenstein

BASICS

DESCRIPTION

- One of the most common pediatric complaints; 2nd only to respiratory infections in overall disease frequency for ED visits
- Leading cause of illness and death in children worldwide
- Acute infectious enteritis (AIE):
 - Vomiting and diarrhea
 - Children <5 yr in US typically have 2 episodes annually.
 - Responsible for ~10% of all pediatric ED visits and hospital admissions
- Acute change in the “normal” bowel pattern that leads to increased number or volume of stools and lasts <7 days; World Health Organization (WHO) defines case as 3 or more loose or watery stools per day.
 - Chronic if the diarrhea persists for >2 wk

ETIOLOGY

- Acute enteritis:
 - Infectious:
 - Viruses: 70–80% of cases:
 - Rotavirus most common
 - Enteric adenovirus
 - Norovirus (foodborne outbreaks)
 - Bacteria: 10–20%:
 - *Escherichia coli*, *Yersinia*, *Clostridium difficile*
 - *Salmonella*, *Shigella*, *Campylobacter*
 - *Vibrio*
 - *Aeromonas*
 - Parasites 5%:
 - Cryptosporidiosis (waterborne)
 - *Giardia lamblia*
 - Noninfectious:
 - Postinfectious
 - Food allergies and intolerance:
 - Cow’s milk protein
 - Soy protein
 - Methyl xanthines
 - Lactose intolerance
 - Chemotherapy/radiation induced

- Drug induced:
 - Antibiotics, laxatives, antacids
- Ingestion of heavy metals—copper, zinc
- Ingestion of plants—hyacinth, daffodils, amanita species
- Vitamin deficiency: Niacin, folate
- Vitamin toxicity: Vitamin C
- Associated with other infections
 - Otitis media, UTI, pneumonia, meningitis, appendicitis.
- Chronic diarrhea:
 - Dietary factors: Excessive consumption of sorbitol or fructose from fruit juices
 - Enteric infections in immunocompromised
 - Malnutrition
 - Endocrine: Thyrotoxicosis, pheochromocytoma
 - Inflammatory bowel diseases: Crohn's disease, ulcerative colitis
 - Malabsorption syndromes (cystic fibrosis, celiac disease)
 - Irritable bowel syndrome

DIAGNOSIS

SIGNS AND SYMPTOMS

- Frequent, loose stools
- Signs of dehydration:
 - Watery
 - Bloody
 - Mucoïd
 - Sometimes abdominal pain, fever, anorexia
 - Tenesmus
- Signs of dehydration reflect degree of loss of total body water and vary with the degree of dehydration: Mild < 5%, moderate 5–10%, severe > 15%
- Severe dehydration:
 - Mental status change: Often depressed with significant dehydration associated with impaired muscle tone
 - Mucous membrane: Dry
 - Skin turgor: Decreased
 - Anterior fontanel: Depressed
 - Blood pressure: Decreased
 - Pulse: Tachycardia
 - Capillary refill: Prolonged (> 2 sec)
 - Urine output: Decreased
 - Eyes: Sunken and absent tears
 - Thirst

History

- Onset and duration
- Mental status and muscle tone
- Fever and associated symptoms (e.g., abdominal pain, emesis)
- Stool frequency and character with blood and mucus
- Urine output
- Feeding
- Recent antibiotics
- Recent travel
- Possible ingestions
- Immunodeficiency
- Underlying intestinal anomalies (e.g., Hirschsprung disease)

Physical-Exam

- Abnormal capillary refill > 2 sec
- Absent tears
- Dry mucus membranes
- 3 best exam signs for determining dehydration in children are an abnormal respiratory pattern, abnormal skin turgor, and prolonged capillary refill time:
 - Clinical dehydration scales based on a combination of physical exam findings are better predictors than individual signs.

ESSENTIAL WORKUP

Majority of children with acute diarrhea do not require any lab tests. Consider workup if:

- Temperature > 103°F
- Systemic illness
- Bloody diarrhea
- Prolonged course > 2 wk
- Tenesmus
- Dehydration greater than mild, usually requiring parenteral therapy
- Diarrhea with blood or mucus suggests an enteroinvasive inflammatory or cytotoxin-mediated process (*Salmonella*, invasive *E. coli*).

DIAGNOSIS TESTS & NTERPRETATION

Lab

- CBC with differential, blood culture, urine culture, and UA—if any signs of systemic infection
- Basic metabolic panel including electrolytes, BUN, creatinine, bicarbonate, for any child treated with IV hydration for severe dehydration or with those patients with abnormal physical signs:
 - Recent evidence suggests that serum bicarbonate is particularly helpful in

- detecting moderate dehydration.
- Stool pH <5.5 or positive stool-reducing substances are positive in lactose intolerance.
- Stool occult blood
- Stool microscopy:
 - >5 fecal leucocytes per high-power field are suggestive of invasive bacterial infection:
 - *Shigella*
 - *Salmonella*
 - *Campylobacter*
 - *Yersinia*
 - Invasive *E. coli*
- Stool culture:
 - Unnecessary in most cases unless there is a high likelihood of identifying bacterial pathogens (positive guaiac and/or fecal leucocytes) for which the clinical course and period of contagion may be altered by antibiotic therapy
- Consider urine culture in febrile children ≤12 mo.

Imaging

Imaging is usually not indicated. Abdominal x-ray or ultrasound may be useful if the clinical suspicion is high for other diagnoses such as intussusception, ileus, appendicitis.

Diagnostic Procedures/Surgery

Usually not indicated unless high clinical suspicion for other diagnoses based on history and physical exam

DIFFERENTIAL DIAGNOSIS

- Postinfectious:
 - Follows acute or bacterial or viral gastroenteritis; often associated with malabsorption, especially lactose
- *C. difficile* following use of antibiotics.
- Milk allergy
- Malrotation with midgut volvulus
- Inflammatory bowel disease
- Intussusception
- Malabsorption syndromes
- Extra intestinal infections
- Medications altering intestinal flora such as antibiotics (e.g., amoxicillin—clavulanate)

TREATMENT

INITIAL STABILIZATION/THERAPY

- For severely dehydrated children in shock or near shock, IV or intraosseous access with 20 mL/kg 0.9% NS and 1 g/kg dextrose if hypoglycemic
- Alternatively, fluids can be subcutaneously administered using recombinant hyaluronidase human injection using strict protocols
- Pulse oximetry
- Endotracheal intubation may be required for children in shock.

ED TREATMENT/PROCEDURES

- For mild to moderate dehydration, correct dehydration using oral rehydration therapy (ORT), 50 mL/kg and 100 mL/kg, respectively, over a 4-hr period:
 - Replace ongoing losses with 10 mL/kg of ORT for each stool.
 - Ideal ORT solution has a low osmolarity (210–250), glucose of about 2 g/dL, and sodium content of 50–60 mmol/L.
- For moderate to severe dehydration, correct dehydration using parenteral fluids combining maintenance and deficit requirements.
- If diarrhea is not associated with dehydration, use 10 mL/kg of ORT for each stool alone.
- Antibiotics only for defined acute enteritis: Routine use is not recommended; use only in either severe or invasive disease or patients who are immunocompromised or who have significant underlying GI conditions
 - Erythromycin for *Campylobacter jejuni*
 - TMP-SMX for:
 - *Salmonella*—complicated (infant <6 mo old, disseminated, bacteremia, immunocompromised host, enteric fever)
 - *Shigella*
 - *Yersinia*
 - *E. coli*—enteroinvasive
 - Metronidazole or vancomycin for:
 - *C. difficile* (severe and/or prolonged enteritis)
 - Neomycin for *E. coli*—enteroadherent
 - Furazolidone or metronidazole for *G. lamblia*
- Antidiarrheal agents *not* recommended
- Probiotics: *Lactobacillus GG*
 - Probiotics degrade and modify dietary antigens and balance the anti-inflammatory response to cytokines. They reduce the duration of diarrhea
- Post-ED diet:
 - While rehydrating, feed children with diarrhea age-appropriate diets.
 - Well-tolerated foods:
 - Rich in complex carbohydrates (rice, potatoes, bread)
 - Lean meats
 - Yogurt
 - Fruits

- Vegetables
- Full-strength milk and formula unless there is a strong suspicion of lactose intolerance
- Avoid fatty foods and foods high in simple sugars.

MEDICATION

- Ampicillin: 50–200 mg/kg/24h IV/PO q6h
- Erythromycin: 40 mg/kg/24h PO q6h; 10–20 mg/kg/24h IV q6h
- Metronidazole: 30 mg/kg/24h PO divided QID × 7 d
- Neomycin: 50–100 mg/kg/24h PO q6–8h
- TMP-SMX: 8–10 mg/kg/24h as TMP PO divided BID
- Vancomycin: 40–50 mg/kg/24h PO q6h
- Loperamide (not for use in children <6 yr old or in those with heme-positive stools): Age 6–8 yr, 2 mg PO div. BID; age 8–12 yr, 2 mg PO div. TID
- Cefixime: 8 mg/kg/d PO per day for 7–10 days
- Ceftriaxone: 50 mg/kg/d IV/IM for 7–10 days
- *Lactobacillus GG* and *Saccharomyces boulardii*: 5 billion doses/d
- Zinc: 10–20 mg/d for 10–14 days (children <5 yr)

First Line

- TMP-SMX for *Salmonella* and *Shigella* sp.
- Doxycycline for *Vibrio cholerae*
- Metronidazole for *C. difficile*

Second Line

- Ceftriaxone and Cefotaxime for *Salmonella* and *Shigella* sp.
- Erythromycin for *V. cholerae*.
- Vancomycin for resistant *C. difficile*

FOLLOW-UP

DISPOSITION

Admission Criteria

- Surgical abdomen
- Inability to tolerate oral fluids
- 10% dehydration or greater
- Suspected complicated *Salmonella* enteritis
- Toxic-appearing child

Discharge Criteria

- Improvement in the patient's condition

- Caregivers of child can follow through with appropriate ORT and diet.
- Caregivers able to identify signs and symptoms of dehydration

Issues for Referral

- Immunocompromised host
- Conditions associated with complications such as seizures
- Underlying bowel disorders

FOLLOW-UP RECOMMENDATIONS

Follow-up care depends on the length and severity of diarrhea, age of the child, and caregiver's ability to comply with instructions:

- Uncomplicated diarrhea does not typically need follow-up.
- Neonates require strict follow-up care in a few days.

PEARLS AND PITFALLS

- History and PE assists in differentiating uncomplicated diarrhea from other, often more serious conditions in children.
- Vast majority of children with acute diarrhea do not need extensive lab tests, which are unlikely to affect the management.
- Treatment with antidiarrheals and antibiotics has very limited role in childhood diarrhea.
- Diagnoses like appendicitis, intussusception, UTI, and sepsis may need to be considered.

CODES

ICD9

- 008.8 Intestinal infection due to other organism, not elsewhere classified
- 008.61 Enteritis due to rotavirus
- 787.91 Diarrhea

ICD10

- A08.0 Rotaviral enteritis
- A08.4 Viral intestinal infection, unspecified
- R19.7 Diarrhea, unspecified

DIGOXIN, POISONING

Michelle M. Troendle • Kirk L. Cumpston

BASICS

DESCRIPTION

- Acute digitalis effects (elevated levels in children and intentional overdose):
 - Inhibits sodium-potassium ATPase pump in cell membranes
 - Allows more calcium ions to enter cell and cardiac cells to contract more strongly
 - Increases K^+ extracellularly
 - Increases vagal tone
 - Slows atrioventricular (AV) node conduction (vagotonic)
 - Increases automaticity and conduction system refractory period
 - Bradydysrhythmias
- Chronic digitalis effects (therapeutic to toxic levels in elderly patients):
 - Inhibits sodium-potassium ATPase pump in cell membranes
 - Increases intracellular calcium
 - Increases vagal tone
 - Bradydysrhythmias
 - Increases automaticity
 - Usually hypokalemic secondary to diuretic use
 - Tachydysrhythmias

ETIOLOGY

- Digoxin/digitoxin pharmaceuticals
- Plants and animals containing cardiac glycosides:
 - Foxglove
 - Oleander (white and yellow)
 - Lily of the valley
 - Dogbane
 - Red squill
 - Cane toad, Colorado River toad

DIAGNOSIS

SIGNS AND SYMPTOMS

- Toxicity onset: 2 hr after PO ingestion and 15 min following IV
- Toxicity:
 - Occurs with normal digoxin levels (chronic)
 - May be absent with elevated digoxin levels (acute)

- Cardiovascular:
 - Dysrhythmias:
 - Paroxysmal atrial tachycardia (PAT) with AV block
 - Bidirectional ventricular tachycardia (VT) is pathognomonic
 - Premature ventricular contractions (PVCs) most common
 - Nonparoxysmal accelerated junctional tachycardia
 - VT
 - Ventricular fibrillation
 - Atrial fibrillation/flutter
 - Bigeminy
 - Bradycardia
 - Nonparoxysmal atrial tachycardia
 - AV blocks
 - Sinus arrhythmia
 - Premature atrial contraction
 - CHF exacerbation
 - Hypotension
 - Shock
 - Cardiovascular collapse
 - Syncope
- CNS:
 - Mental status changes:
 - Agitation
 - Lethargy
 - Psychosis
- Visual perception:
 - Blurred
 - Scotoma
 - Green to yellow halo
 - Photophobia
 - Color perception changes
- GI:
 - Anorexia, nausea, vomiting, abdominal pain

History

- Accidental adult or pediatric overdose of a known amount
- Intentional acute overdose in a patient not taking digoxin chronically
- Intentional acute or chronic overdose in a patient taking digoxin chronically
- Unintentional chronic ingestion of digoxin in which renal clearance decreases or the dose chronically increases
- Unintentional toxicity from recent antibiotic use (esp. macrolides) that alter GI flora, primarily by decreasing *Eubacterium lentum*, increasing absorption

Physical-Exam

- Altered mental status
- Bradycardia
- Tachycardia
- Irregular rhythm
- Hypotension

ESSENTIAL WORKUP

- ECG:
 - For dysrhythmia
- Digoxin level:
 - Normal range: 0.5–2 ng/mL
 - Distribution after oral intake not complete until 6 hr; therefore, >6-hr level is most accurate steady state concentration.
 - False elevations possible with spironolactone use, pregnancy, hyperbilirubinemia, chronic renal failure, liver failure, CHF
 - May be falsely elevated after digoxin-specific Fab fragments given

DIAGNOSIS TESTS & NTERPRETATION

Lab

- Electrolytes, BUN, creatinine, glucose:
 - Hypokalemia contributes to digitalis toxicity.
 - Hyperkalemia seen in acute toxicity and correlates with acute digitalis mortality better than digoxin serum levels.
 - Follow K⁺ serially
- Calcium, magnesium

ALERT

Serum digoxin concentration (SDC) should not be obtained after digoxin-specific antibody Fab fragments have been administered because it will be inaccurate.

DIFFERENTIAL DIAGNOSIS

- Overdoses:
 - Calcium channel blockers
 - β -Blockers
 - Quinidine, procainamide
 - Clonidine
 - Organophosphates
 - Antidysrhythmics
 - Other antihypertensives
- Primary cardiac dysrhythmias
- Acute gastroenteritis

TREATMENT

PRE HOSPITAL

- Establish IV access
- Continuous cardiac monitoring
- Apply pads for potential cardioversion

ALERT

- If cardioversion is necessary for tachydysrhythmias, use low levels (50 J)
- May precipitate refractory tachydysrhythmias

INITIAL STABILIZATION/THERAPY

ABCs:

- IV, oxygen, monitor:
 - IV fluid bolus if hypovolemic
- Administer naloxone, thiamine, dextrose for altered mental status.

ED TREATMENT/PROCEDURES

- Cardiac arrest resuscitation:
 - Defibrillate for ventricular fibrillation, pulseless VT.
 - Standard advanced cardiac life support (ACLS) protocol
 - Administer digoxin-specific antibody Fab fragments (Digibind), up to 5–20 vials IV push (IVP).
 - MgSO₄, 2 g IVP
 - Continue resuscitation for 30 min after digoxin-specific antibody Fab fragments.
- General measures:
 - Activated charcoal if acute ingestion
 - Replenish magnesium.
 - Treat hyperkalemia with insulin, dextrose, bicarbonate, sodium polystyrene sulfonate.
 - Calcium can probably be used to treat hyperkalemia, but because other safer alternatives exist it is not recommended, unless life-saving membrane stabilization is needed secondary to hyperkalemia, in the unstable patient.
 - If the patient has hyperkalemia from digoxin toxicity treatment with digoxin-specific Fab fragments are indicated 1st in the hemodynamically stable patient.

DYSRHYTHMIA MANAGEMENT

- 1st choice: Digoxin-specific antibody Fab fragments (Digibind, DigiFab)
 - Indications:
 - SDC ≥ 15 ng/mL at any time or ≥ 10 ng/mL at steady state (6 hr)

- Ingestion of >10 mg in adults or 0.2 mg/kg or 4 mg in children
- Hyperkalemia >5–5.5 mEq/L
- Hemodynamically unstable or life-threatening dysrhythmias
- VT, ventricular fibrillation
- Atrial tachycardia
- Variable AV block
- Bradycardia with no response to atropine
- Hypotension
- Onset: 20–30 min
- Digoxin levels may increase, decrease, or stay in therapeutic range after therapy owing to Fab digoxin complexes and redistribution.
- Renal clearance of drug–antibody complexes:
 - Too large to be removed by dialysis
- 2nd dose if rebound toxicity
- Complications:
 - Exacerbation of CHF
 - Hypokalemia
 - Atrial fibrillation with rapid ventricular response
- If digoxin-specific antibody Fab fragments not immediately available initiate the following:
 - Lidocaine:
 - For ventricular dysrhythmias without AV block
 - Not harmful but not very effective
 - For bradydysrhythmias:
 - Atropine
 - Pacing for symptomatic bradydysrhythmia
 - MgSO₄ for ventricular dysrhythmias with torsades de pointes
 - Quinidine, procainamide contraindicated
- Cardioversion is last resort for severe, life-threatening tachydysrhythmia:
 - Start at low energy 10–50 J, then increase to high levels if ineffective.
 - Safe if digoxin level <2 ng/mL

MEDICATION

- Activated charcoal slurry:
 - 1 g/kg if within 1 hr
- Digoxin-specific antibody Fab fragments:
 - 40-mg vial neutralizes 0.5 mg of digoxin.
 - If amount ingested known:
 - Number of vials needed to treat equals [amount ingested (mg)/0.5 (mg/vial)]
 - If steady serum level known:
 - Number of vials needed equals [SDC (ng/mL) × weight (kg)]/100
 - If neither amount ingested nor serum level known:

- Acute toxicity: 5–10 vials adults or children
- Chronic toxicity: 1--2 vials in adults or children
- Bolus digoxin-specific antibody Fab fragments for cardiac arrest
- Additional doses as needed
- Standard treatment for hyperkalemia and bradycardia (calcium only if necessary)

Geriatric Considerations

- Dosage is based on weight and serum concentration. There is no change in the setting of renal or hepatic dysfunction.
- Recrudescence of toxicity has been reported in patients with concomitant renal failure. Redosing of digoxin-specific antibody Fab fragments should be used again when indicated.

Pediatric Considerations

- Weight-based dosing for children is the same as it is for adults.
- On some occasions, accidental dose ingested by a child is known and the number of vials is indicated by the amount of digoxin bound by each vial. See dosing.

Pregnancy Considerations

Digoxin-specific Fab fragments are pregnancy class C.

FOLLOW-UP

DISPOSITION

Admission Criteria

- ICU:
 - Unstable cardiovascular status in acute or chronic toxicity
- Telemetry:
 - Asymptomatic or mildly symptomatic dysrhythmia
 - High risk for developing toxicity

Discharge Criteria

Acute/chronic ingestion:

- Digoxin level < 2 ng/mL
- Asymptomatic for 6 hr and no ECG abnormalities

FOLLOW-UP RECOMMENDATIONS

Psychiatric referral for stable patients who are suicidal

PEARLS AND PITFALLS

When it is known that the patient is on digoxin and presents with cardiovascular instability, and/or hyperkalemia, treatment should begin with the antidote: Digoxin-specific Fab fragments.

- T46.0X4A Poisoning by cardi-stim glycos/drug similar act, undet, init

DIPLOPIA

Jonathan A. Edlow

BASICS

DESCRIPTION

- Double vision
 - Simultaneous perception of 2 images
 - Can be oriented horizontally, vertically, or diagonally from one another.
- Diplopia is usually due to abnormal movement of the extraocular muscles (EOMs), which are innervated by 3 cranial nerves (CNs):
 - CN 3 – superior, inferior, and medial rectus and inferior oblique muscles
 - CN 4 – superior oblique muscle
 - CN 6 – lateral rectus muscle
- Brainstem lesions can damage CN nuclei or their connections (medial longitudinal fasciculus, MLF), causing an internuclear ophthalmoplegia (INO)
- CN dysfunction
 - Compression as they traverse the subarachnoid space and venous sinuses
 - Inflammation
 - Elevation (or reduction) of CSF pressure can cause CN 6 palsy
- Disease affecting the orbits and the bony skull can cause restriction of motion of one or both eyes or EOMs

ETIOLOGY

- Traumatic diplopia
 - Orbital fracture
 - Contusions
 - Hematoma
 - Rarely brainstem contusion or hematoma
- Monocular diplopia
 - Nearly always due to an intrinsic eye problem
 - Corneal surface keratoconus
 - Subluxation of the lens
 - Structural defect within the eye
 - Functional disorders such as conversion disorder, factitious disorder, or somatization.
- Nontraumatic binocular diplopia
 - Brain and brainstem dysfunction
 - Stroke
 - Multiple sclerosis
 - Cerebral cortical problems (e.g., migraine) are rare

- CN dysfunction
 - Aneurysm of posterior communicating artery (CN 3 palsy)
 - Chronic lymphocytic meningitis (multiple CN deficits)
 - Pseudotumor cerebri (CN 6 palsy)
 - Low pressure (spontaneous intracranial hypotension) (CN 6 palsy)
- Bony skull and orbits:
 - Tumor
 - Thyroid disease
 - Inflammation (Tolosa-Hunt)
- Neuromuscular junction (NMJ) of EOMs:
 - Myasthenia gravis (MG)

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Determine if the diplopia is following head injury, if it is constant or intermittent and its duration.
- Determine if diplopia is monocular or binocular.
- Ask about HA or other neurologic or visual symptoms.
- Are the 2 images aligned horizontally, vertically, or diagonally?

Physical-Exam

- Differentiate monocular from binocular:
 - If the diplopia goes away with covering either eye, it is binocular
 - If it persists in one eye, it is monocular (problem in the eye with diplopia)
- Differentiate traumatic and nontraumatic diplopia
- Monocular diplopia
 - Careful ocular exam
 - Visual acuity
- Binocular diplopia:
 - Examine the eye completely (is there ptosis, anisocoria, limitation of EOMs, proptosis, exophthalmos?). Is VA normal?
 - CN 3 – pupil involving – diagonal diplopia with ptosis and dilated pupil
 - CN 3 – pupil sparing – diagonal diplopia with normal lids and pupils
 - CN 4 – vertical or diagonal diplopia, least common of all
 - CN 6 – horizontal diplopia; images separate more as gaze goes out laterally on affected side.
 - Do a complete neurologic exam
- Traumatic diplopia:
 - Facial anesthesia

- Anisocoria
- Proptosis
- Decreased visual acuity

ALERT

- Patients may appear well with benign exams; one must look carefully for neurologic or ophthalmologic findings.
- Do a systematic physical exam to try to localize the site of the lesion
- If CN 3 palsy, differentiate a pupil-sparing (usually microvascular infarct) from a pupil-involving palsy (usually aneurysmal). This is often due to an expanding but unruptured aneurysm.
- If facial numbness (CN 5) with diplopia, consider cavernous sinus or superior orbital fissure syndromes
- If decreased vision, suspect orbital or superior orbital fissure syndrome

ESSENTIAL WORKUP

Accurate history and physical exam are the cornerstones of diagnosis. Establishing a history of trauma is key. In spontaneous cases, the physical exam should be directed at establishing:

- Is the diplopia isolated or not?
- If isolated, which CN is involved?
- If other neurologic deficits exist, try to localize the site of the lesion.
- Some form of cerebral angiography (CTA, MRA, DSA) if there is a CN 3 palsy and dilated pupil.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Lab testing in the ED is not generally useful:
 - Occasionally, thyroid function tests are helpful. Other serologic tests (e.g., for myasthenia) are not necessary in the ED).

Diagnostic Procedures/Surgery

- If MG is possible, consider an edrophonium (Tensilon) test or an ice test.
- Lumbar puncture – if considering SAH, chronic lymphocytic meningitis, high or low CSF pressure.
- Brain and cerebrovascular imaging – if considering mass lesion, aneurysm, stroke, MS. Specific tests depend on the specific differential diagnosis.

DIFFERENTIAL DIAGNOSIS

- Post-traumatic diplopia:
 - Orbital fracture/hematoma with direct damage to CNs or hematoma limiting EOM excursions

- Rarely, brainstem contusion affecting CN nuclei or MLF
- Monocular diplopia:
 - Nearly any ocular problem (corneal, lens, iris, retinal problems, and refractive error)
 - Rarely, bilateral monocular diplopia due to cortical dysfunction
- Binocular diplopia:
 - Brain and brainstem
 - Stroke or MS involving the brainstem, often with a nuclear CN palsy or an INO. This pattern is rarely seen after head injury and contusion
 - Wernicke encephalopathy
 - Rare: “Cortical” diplopia from migraine or irritative lesion and botulism
 - CN lesions
 - CN palsy due to stretch, contusion, ischemia, CSF inflammation, or abnormal pressure
 - CN 3 – KEY to differentiate pupil involving (must r/o aneurysm) vs. pupil sparing (microvascular infarct from diabetes/hypertension).
 - CN 6 palsy is a nonlocalizing finding.
 - When multiple CNs are involved, think about MG, lymphocytic meningitis, cavernous sinus pathology.
 - When medial rectus is involved (decreased adduction) but there is no clear CN 3 palsy, consider INO
- Skull and orbits:
 - Infiltrative disorders of orbit (thyroid, tumor, abscess, and Tolosa-Hunt)
- NMJ:
 - MG and botulism

TREATMENT

INITIAL STABILIZATION/THERAPY

The vast majority of patients with diplopia do not require stabilization. Initial steps are entirely based on the etiology in an individual patient.

ED TREATMENT/PROCEDURES

- Lumbar puncture:
 - In cases of possible lymphocytic meningitis, pseudotumor cerebri, spontaneous intracranial hypotension, do LP. ALWAYS measure the opening pressure.
- Edrophonium test:
 - In cases of possible MG, consider performing an edrophonium test (see reference Scherer et al. for technique).
- Eye patch:

- Consider eye patch in discharged patients for symptom control

Pediatric Considerations

Same differential diagnosis.

Pregnancy Considerations

- Pregnant women with hyperemesis gravidarum can get Wernicke encephalopathy or orbital hemorrhage, both of which can present with diplopia.
- Postpartum women can develop diplopia due to cavernous sinus thrombosis, postdural puncture headache, or orbital hemorrhage.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Admission is predicated upon the cause.
- Many patients are admitted to facilitate a rapid workup for serious causes (including advanced brain and vascular imaging and specialty consultation).

Discharge Criteria

Most patients with monocular diplopia or with traumatic diplopia whose cause is *clearly established* and does not require urgent surgery can be safely discharged.

FOLLOW-UP RECOMMENDATIONS

All patients who are discharged with diplopia will require some form of follow-up, usually with either a neurologist or ophthalmologist.

PEARLS AND PITFALLS

- Diplopia can present as “blurred vision” if the 2 images are not far off from one another.
- Never assume diplopia is an isolated cranial neuropathy without doing a very careful neurologic exam.
- Check pupils to avoid missing a cerebral aneurysm. Aneurysmal CN 3 palsies are often due to *unruptured* aneurysm (CT and LP normal).
- MG can present with intermittent diplopia. The pupils are *always* normal.
- Test facial sensation; hypoesthesia and diplopia localize the lesion to the cavernous sinus or superior orbital fissure.
- Test vision; decreased VA and diplopia are often an orbital or superior orbital fissure lesion (may be surgical emergency!)

ICD10

H53.2 Diplopia

DISSEMINATED INTRAVASCULAR COAGULATION

Steven H. Bowman • Ernesto J. Romo

BASICS

DESCRIPTION

- Normal coagulation: Series of local reactions among blood vessels, platelets, and clotting factors
- Disseminated intravascular coagulation (DIC) is systemic activation of coagulation and fibrinolysis by some other primary disease process.
- Coagulation system activation results in systemic circulation of thrombin and plasmin.
- Role of thrombin in DIC:
 - Tissue factor/factor VIII(a) activate the extrinsic pathway, leads to thrombin formation.
 - Thrombin circulates and converts fibrinogen to fibrin monomer.
 - Fibrin monomer polymerizes into fibrin (clot) in the circulation.
 - Clots cause microvascular and macrovascular thrombosis with resultant peripheral ischemia and end organ damage.
 - Platelets become trapped in clot with resultant thrombocytopenia.
- Role of plasmin in DIC:
 - Plasmin circulates systemically converting fibrinogen into fibrin degradation products (FDPs).
 - FDPs combine with fibrin monomers.
 - FDP-monomer complexes interfere with normal polymerization and impair hemostasis.
 - FDPs also interfere with platelet function.
- Role of impaired anticoagulation in DIC.
 - Failure of physiologic anticoagulation is necessary for DIC to occur.
 - Antithrombin III, protein C system, and tissue factor pathway inhibitor all impaired.
- Acute DIC—uncompensated form:
 - Clotting factors used more rapidly than body can replace them
 - *Hemorrhage* predominant clinical feature, which overshadows ongoing thrombosis
- Chronic DIC—compensated form:
 - Body able to keep up with pace of clotting factor consumption
 - *Thrombosis* predominant clinical feature

ETIOLOGY

- Precipitated by many disease states

- Complications of pregnancy:
 - Retained fetus
 - Amniotic fluid embolism
 - Placental abruption
 - Abortion
 - Eclampsia
 - HELLP syndrome
- Sepsis:
 - Gram negative (endotoxin-mediated meningococemia)
 - Gram positive (mucopolysaccharide-mediated)
 - Other microorganisms (e.g., viruses, parasites)
- Trauma:
 - Crush injury
 - Severe burns
 - Severe head injury
 - Fat embolism
- Malignancy:
 - Solid tumor or metastatic disease
 - Hematologic malignancy (e.g., leukemia)
- Intravascular hemolysis:
 - Transfusion reactions
 - Massive transfusion
- Organ destruction:
 - Severe pancreatitis
 - Severe hepatic failure
- Vascular abnormalities:
 - Kasabach–Merritt syndrome
 - Large vascular aneurysm
- Thrombocytopenia:
 - Thrombotic thrombocytopenic purpura
 - Idiopathic thrombocytopenic purpura
- Miscellaneous:
 - Snake bites
 - Recreational drugs

DIAGNOSIS

SIGNS AND SYMPTOMS

- Excessive bleeding:
 - Petechiae
 - Purpura
 - Hemorrhagic bullae

- Wound bleeding
- Bleeding from venipuncture/arterial lines
- Epistaxis
- Hemoptysis
- GI bleeding
- Excessive thrombosis:
 - Large vessels
 - Microvascular thrombosis and end organ dysfunction
 - Cardiac, pulmonary, renal, hepatic, CNS
 - Thrombophlebitis
 - Pulmonary embolus
 - Nonbacterial thrombotic endocarditis
 - Gangrene
 - Ischemic infarcts of kidney, liver, CNS, bowel
- Acute DIC:
 - Hemorrhagic complications predominate.
- Chronic DICL:
 - Thrombotic complications predominate.

History

- Previous history of bleeding disorder
- Pregnancy/last menstrual period
- History of malignancy or immunocompromised

Physical-Exam

- Neurologic:
 - Altered MS, confusion, lethargy
- Cardiovascular:
 - Hypotension, tachycardia
- Respiratory:
 - Tachypnea, rhonchi, rales
- GI:
 - Upper or lower GI bleeding, abdominal distension
- GU:
 - Oliguria, hematuria
- Skin:
 - Petechiae, purpura, jaundice, necrosis

ESSENTIAL WORKUP

- Depends on precipitating illness
- Diagnosis generally not made in ED

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Platelet count:
 - Important to note rapid decrease
 - $< 100,000/\text{mm}^3$
 - May be normal in chronic DIC
- Prothrombin time (PT)/partial thromboplastin time (PTT):
 - Increased
 - May be normal in chronic DIC
- Fibrinogen:
 - Decreased
 - $< 150 \text{ mg/dL}$ in 70%
 - Low sensitivity, as levels can remain normal
 - May be normal in chronic DIC
- FDPs:
 - Increased
 - $> 40 \mu\text{g/mL}$
- D-dimer increased
- CBC/peripheral smear:
 - Red cell fragments
 - Low platelets
 - Peripheral smear confirms disease in chronic DIC
- Electrolytes, BUN, creatinine, glucose:
 - Elevated BUN, creatinine owing to renal insufficiency
- ABGs:
 - Oxygen, acid–base status
- ISTH scoring system
 - Underlying disorder associated with DIC
 - no = 0, yes = 2
 - Platelet count
 - $> 100 = 0$, $< 100 = 1$, $< 50 = 2$
 - Fibrin markers (D-dimer, FDP)
 - Normal = 0, moderate increase = 1, strong increase = 2
 - Prolonged PT
 - $< 3 = 0$, > 3 but $< 6 = 1$, $> 6 = 2$
 - Fibrinogen
 - $1 \text{ g/L} = 0$, $< 1 \text{ g/L} = 1$
 - Score > 5 overt DIC, associated with increased mortality.

Imaging

- CXR for suspected pneumonia
- Head CT for altered mental status
- OB US in pregnant patients

DIFFERENTIAL DIAGNOSIS

- Inherited coagulation disorders:
 - Factor deficiencies
- Other acquired coagulation disorders:
 - Anticoagulant therapy
 - Drugs
 - Hepatic disease
 - Vitamin K deficiency
 - Massive blood loss
- Platelet dysfunction:
 - TTP/HUS
 - HIT
 - ITP
- Platelet dysfunction:
 - TTP/HUS
 - HI

TREATMENT

INITIAL STABILIZATION/THERAPY

- Airway management and resuscitation measures:
 - Control bleeding
 - Establish IV access
 - Restore and maintain circulating blood volume.
- Initiate therapy of precipitating disease:
 - Antibiotics in sepsis
 - Evacuate uterus of retained products of conception
 - Chemotherapy in malignancy
 - Débridement of devitalized tissue in trauma

ED TREATMENT/PROCEDURES

- Therapy of DIC is controversial and should be individualized based on:
 - Age
 - Hemodynamic status
 - Severity of hemorrhage
 - Severity of thrombosis
- Involve admitting service before initiating specific DIC therapy.
- Replace depleted blood components:
 - Fresh frozen plasma (FFP):
 - For prolonged PT
 - Provides clotting factors and volume replacement
 - Dose: 2 U or 10–15 mL/kg

- Platelets:
 - If platelet count < 20,000 or platelet count < 50,000 with ongoing bleeding
 - Dose: 1 U/10 kg body weight
- Cryoprecipitate:
 - Higher fibrinogen content than whole plasma
 - For severe hypofibrinogenemia (< 50 mg/dL) or for active bleeding with fibrinogen < 100 g/dL
 - Dose: 8 U
- Recombinant factor VIIa
 - Successful use reported, benefit and safety unknown.
- Washed packed cells
- Albumin
- Nonclotting volume expanders
- Inhibit intravascular clotting with heparin:
 - Use is controversial.
 - Consider when thrombosis predominates.
 - May be effective in mild to moderate DIC
 - Efficacy undetermined in severe DIC. Possible indications:
 - Purpura fulminans (gangrene of digits, extremities)
 - Acute promyelocytic leukemia
 - Dead fetus syndrome—several weeks after intrauterine fetal death
 - Thromboembolic complications of large vessels
 - Before surgery with metastatic carcinoma
 - Administer activated protein C (controversial):
 - No mortality benefit.
 - Antithrombin
 - No mortality benefit found in patients also receiving heparin.
 - Lack of evidence to support use at this time.
- Inhibit fibrinolysis:
 - Block secondary compensatory fibrinolysis that accompanies DIC
 - Use complicated by severe thrombosis
 - Use only when DIC accompanied by primary fibrinolysis:
 - Promyelocytic leukemia
 - Giant hemangioma
 - Heat stroke
 - Amniotic fluid embolism
 - Metastatic carcinoma of prostate
 - Initiate in extreme cases only:
 - Profuse bleeding not responding to replacement therapy
 - Excessive fibrinolysis present (rapid whole blood lysis/short euglobulin lysis time)
 - E-aminocaproic acid (EACA)

- Tranexamic acid

MEDICATION

Specific DIC treatment is usually not initiated in the ED. Underlying precipitating diseases should be treated initially:

- Heparin:
 - Low-dose regimen: 5–10 U/kg/h IV for causes where thrombosis predominates.

FOLLOW-UP

DISPOSITION

Admission Criteria

Severe precipitating illness in combination with DIC requires ICU admission.

Discharge Criteria

None

FOLLOW-UP RECOMMENDATIONS

Follow-up involves following platelets and coagulation factors.

PEARLS AND PITFALLS

- Suspect DIC as a complicating factor in severe, life-threatening illness.
- Establish early clinical suspicion since the sequelae of DIC can be devastating.
- Remember to consider treating the underlying cause of DIC when the thromboembolic and bleeding complications of the process seem to be dominating the clinical picture.

D65 Disseminated intravascular coagulation

DISULFIRAM REACTION

Timothy J. Meehan • Sean M. Bryant

BASICS

DESCRIPTION

- Inhibits various enzymes and its active metabolites exert additional effects.
- Disulfiram–ethanol reaction:
 - Usually occurs 8–12 hr after taking the drug; should not be observed > 24 hr after dosing
 - Competitively and irreversibly inactivates aldehyde dehydrogenase
 - Ethanol metabolism is blocked, resulting in accumulation of acetaldehyde
 - Acetaldehyde produces release of histamine resulting in vasodilation and hypotension
 - Severe reactions may occur in drinkers with ethanol levels of 50–100 mg/dL
 - Severity and duration of reaction is proportional to amount of ethanol ingested
- Disulfiram blocks dopamine β -hydroxylase and limits synthesis of norepinephrine from dopamine:
 - Relative excess of dopamine may contribute to altered behavior
 - Relative depletion of norepinephrine may contribute to hypotension
- Disulfiram metabolite (carbon disulfide) interacts with pyridoxal 5-phosphate:
 - Diminishes concentration of pyridoxine available for formation of γ -aminobutyric acid (GABA) in CNS
 - Potentially lowers seizure threshold
 - Carbon disulfide is also cardiotoxic, hepatotoxic, and inhibits cytochrome P-450 (CYP2E1)
- Disulfiram metabolites may chelate important metals (copper, zinc, iron) essential in various enzyme systems
- Disulfiram metabolites may cause peripheral neuropathies that are dose and duration dependent

ETIOLOGY

- Disulfiram is used as a deterrent in the treatment of chronic ethanol abuse
- Many users of the medication wear a medical alert bracelet
- Other agents producing disulfiram-like reactions:
 - Antibiotics:
 - Metronidazole
 - Cephalosporins (with nMTT side chain)
 - Cefoperazone, Cefotetan, Cefmetazole
 - Nitrofurantoin

- Oral hypoglycemics:
 - o Sulfonylureas
- Industrial agents:
 - o Carbon disulfide
 - o Hydrogen sulfide
- Mushrooms:
 - o *Coprinus atramentarius*
 - o *Clitocybe clavipes*

DIAGNOSIS

SIGNS AND SYMPTOMS

- Disulfiram–ethanol reaction:
 - Hypotension, tachycardia, tachypnea
 - Flushing of face, neck, torso
 - Pruritus, diaphoresis, sensation of warmth
 - Nausea, vomiting, abdominal pain, diarrhea
 - Headache, ataxia, confusion, anxiety, dizziness
 - Dyspnea, pulmonary edema, chest pain, dysrhythmias, myocardial infarction
- Disulfiram overdose:
 - Symptoms rare with < 3 g ingested
 - 10–30 g may be lethal
 - May mimic shock and/or sepsis
 - Tachycardia, hypotension, tachypnea
 - Abdominal pain, diarrhea, garlic, or rotten-egg breath
 - Agitation, irritability, ataxia
 - Dysarthria, hallucinations
 - Lethargy, coma, seizures, flaccidity
 - Parkinsonism

History

Ingestion of disulfiram or agents listed above may provide essential clues to diagnosis

Physical-Exam

- Vital signs:
 - Hypotensive, tachycardic, tachypneic
- Cardiovascular:
 - Tachycardia, arrhythmias
- Pulmonary:
 - Pulmonary edema, dyspnea
- Abdominal:

- Diffuse abdominal pain, nausea, vomiting
- Skin:
 - Flushed, diaphoretic
- Neurologic:
 - Dysphoria, confusion, signs of cerebellar dysfunction, seizures

ESSENTIAL WORKUP

Suspect disulfiram–ethanol reaction with the following:

- Typical signs and symptoms are present
- Treatment for chronic ethanol abuse in conjunction with recent ethanol ingestion, or exposure to ethanol-containing foods or medications, including mouthwash

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Ethanol level
- Electrolytes, BUN, creatinine, and glucose
- Liver function tests if hepatitis is suspected
- Creatine phosphokinase (CPK) if considering rhabdomyolysis in light of seizures or agitation
- Urinalysis (myoglobin)
- Serum levels of offending agent are NOT clinically useful

Imaging

- ECG to assess cardiac ischemia or dysrhythmia
- CT scan or MRI:
 - Indicated with altered mental status/seizure
 - Basal ganglia ischemia and infarction have been reported
- EEG:
 - Diffuse slowing without focal abnormalities has been seen in cases of acute toxicity with coma

DIFFERENTIAL DIAGNOSIS

- Sepsis
- Meningitis, encephalitis
- Cardiogenic shock secondary to acute coronary syndrome
- Anaphylactoid/anaphylactic reaction
- Gastroenteritis/pancreatitis with dehydration
- Ethanol withdrawal

Pediatric Considerations

- Acute poisonings yield mainly severe CNS toxicity
- Ataxia, weakness, lethargy, seizures

- Reye syndrome-like encephalopathy in severe cases
- Adult symptoms may also be present

TREATMENT

PRE HOSPITAL

- ABCs, IV access
- Begin resuscitation with IVF if no signs or symptoms of pulmonary edema
- Rapid glucose determination (Accu-Chek)

INITIAL STABILIZATION/THERAPY

- ABCs:
 - Airway protection if necessary
 - Supplemental oxygen
 - Mechanical ventilation as needed
 - Resuscitation with 0.9% NS IV for hypotension
- Pressor support with norepinephrine for refractory hypotension

ED TREATMENT/PROCEDURES

- Management is primarily supportive with aggressive, appropriate care:
 - No specific antidote available
- GI decontamination:
 - Activated charcoal in cases of disulfiram overdose:
 - Caution if mental status depression
 - Caution if vomiting (potential for aspiration)
 - Do not intubate solely to give activated charcoal
 - Gastric lavage is unnecessary
 - Whole-bowel irrigation is not indicated
- Alleviation of flushing:
 - Antihistamines (H₁ and H₂ antagonists)
 - Prostaglandin inhibitors (indomethacin, ketorolac)
- Antiemetics for intractable vomiting (ondansetron, metoclopramide)
- Seizures:
 - Benzodiazepines (diazepam, lorazepam)
 - Pyridoxine (vitamin B₆)
 - 4-methylpyrazole:
 - Inhibits ethanol metabolism at alcohol dehydrogenase enzyme
 - Not indicated for routine disulfiram–ethanol reactions or mild disulfiram overdose
 - May improve the hemodynamic profile in moderate to severe overdoses
- Hemodialysis:

- Consider after massive ingestion of disulfiram and ethanol with refractory hypotension
- No studies documenting beneficial effect

MEDICATION

- Diazepam: 5–10 mg (peds: 0.2–0.5 mg/kg) IV
- Diphenhydramine: 25–50 mg (peds: 1–2 mg/kg) IV
- Indomethacin: 50 mg PO (peds: 0.6 mg/kg PO for age > 14 yr)
- Lorazepam: 2–6 mg (peds: 0.03–0.05 mg/kg) IV
- Metoclopramide: 10 mg (peds: 1–2 mg/kg) IV
- Norepinephrine: 4 mL in 1,000 mL of D₅W, infused at 0.1–0.2 µg/kg/min
- Ondansetron: 4 mg (peds: 0.1 mg/kg for > 2 yr old) IV
- Pyridoxine: 1 g (peds: 500 mg) IV, repeat PRN

FOLLOW-UP

DISPOSITION

Admission Criteria

- ICU admission for mechanical ventilation, coma, refractory hypotension requiring pressors, cardiac ischemia, refractory seizures, and severe agitation
- Persistent vomiting, abdominal pain, or flushing
- Elderly patients or those who have pre-existing cardiac disease

Discharge Criteria

- Mild reactions that resolve with supportive care after observation period of 8–12 hr:
 - Symptoms may recur on rechallenge with ethanol up to 7–10 days after last dose of disulfiram or agents that cause disulfiram-like reactions
 - Abstain from ethanol use until at least 2 wk after last dose of such agents
- Appropriate follow-up needed to assess development of hepatic or neurologic sequelae

FOLLOW-UP RECOMMENDATIONS

- Psychiatry follow-up for intentional overdose with disulfiram
- Detox follow-up for patients with disulfiram–ethanol reactions

PEARLS AND PITFALLS

- Educate patients who are prescribed medications with potential for disulfiram-like reactions to avoid ALL alcohol
 - Includes: Mouthwash, alcohol-based hand gels, alcohol-based aftershave,

some cough syrups, and elixir-based liquid medications

- Recommend abstinence for 3 days longer than the course of treatment to ensure low likelihood of reaction

- T50.6X5A Adverse effect of antidotes and chelating agents, initial encounter

DIVERTICULITIS

Ronald E. Kim

BASICS

DESCRIPTION

- Micro- or macroscopic perforation of diverticulum
 - Uncomplicated (75%) vs. complicated
- Incidence increasing
 - Obesity is a risk factor

ETIOLOGY

- Fecal material in diverticulum hardens, forming fecalith, increasing intraluminal pressure
- Erosion of diverticular wall leads to inflammation
- Focal necrosis leads to perforation
- Microperforation: Uncomplicated diverticulitis:
 - Colonic wall thickening
 - Inflammatory changes (fat stranding on CT)
- Macroperforation: Complicated diverticulitis:
 - Abscess
 - Bowel obstruction
 - Fistulas after recurrent attacks
 - Colovesical fistula (most common) presents with dysuria, frequency, urgency, pneumaturia, and fecaluria.
 - Peritonitis

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Symptoms typically develop over days
 - Almost 50% have had prior episodes of pain
- Left lower quadrant pain in 70% of cases in Western countries
 - Initially vague, then localizes
 - RLQ in 75% of Asian patients
- Nausea/vomiting, constipation, diarrhea, urinary symptoms (in decreasing order)

Physical-Exam

- +/- low-grade fever

- Tenderness at left lower quadrant with occasional (20%) mass palpated (phlegmon):
 - *Phlegmon*—inflamed bowel loops or abscess
- Abdominal distension
- Bowel sounds variable
- Rectal tenderness with heme-positive stool:
 - Massive gross rectal bleeding (rare)
- Peritoneal signs if:
 - Perforation has occurred
- Unremarkable exam if:
 - Elderly
 - Immunocompromised
 - Taking corticosteroids

ESSENTIAL WORKUP

- CBC
- UA
- Blood cultures and lactate
 - If showing signs of sepsis
- CT of abdomen/pelvis
 - Preferred diagnostic modality
 - Ability to diagnose nondiverticular causes of abdominal pain
 - Accuracy enhanced with use of IV and PO/PR contrast
 - Gastrografin PO/PR (per rectum) contrast may be used; avoid barium, especially when perforation is suspected
- Plain radiographs: Chest/abdomen

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
 - Leukocytosis common, but absence does not exclude diagnosis
- UA
 - Sterile pyuria is possible
 - Colonic flora (bacteria) suggests colovesical fistula

Imaging

- Abdominal (supine and upright) and chest radiographs
 - Perforation indicated by free air
 - Obstruction indicated by air–fluid levels
- CT
 - Diagnostic criteria include:
 - Wall thickening >5 mm

- Inflammation of pericolic fat
- Pericolic abscess
- Nondiagnostic criteria include:
 - Stricture
 - Diverticula
 - Fistula
- CT-guided percutaneous needle aspiration of localized abscesses avoids further surgery.
- Endoscopy
 - Not necessary to diagnose acute illness
 - Rigid sigmoidoscopy aids in diagnosing nondiverticular causes of abdominal pain (spasm, stricture, edema, pus, or peridiverticular erythema).
- US
 - For diagnosing colonic wall thickening, inflammation, mass, abscess, or fistula
 - Greatly operator dependent
 - Not reliable in presence of intestinal gas
- Barium enema
 - Indicated after resolution of acute illness to rule out fistula or other colonic pathology (e.g., carcinoma)

DIFFERENTIAL DIAGNOSIS

- Colon carcinoma with perforation
- Ischemic colitis
- Bacterial colitis
- Appendicitis
 - Left-sided pain if peritonitis from ruptured appendix
 - Right-sided diverticular pain with cecal diverticulum (rare) or redundant sigmoid colon
- Inflammatory bowel disease
- Irritable bowel syndrome
- Ruptured or torsed ovarian cyst
- Pancreatic disease
- Pelvic inflammatory disease
- Peptic ulcer disease
- Renal colic

TREATMENT

PRE HOSPITAL

IV fluids

INITIAL STABILIZATION/THERAPY

- Fluid resuscitation with 0.9% normal saline
- Bowel rest
 - NPO or clear liquid diet
 - Nasogastric tube (NG) tube if persistent vomiting or bowel obstruction suspected

ED TREATMENT/PROCEDURES

- Uncomplicated diverticulitis
 - Most respond to medical therapy, but 30% may require surgery
- Complicated diverticulitis
 - Most require percutaneous drainage or surgery
- Analgesia
 - Anticholinergics (dicyclomine):
 - Reduces colonic spasm
 - Does not mask underlying pathology
 - Opiates for more aggressive pain management (theoretically increase intraluminal pressure, leading to perforation)
 - Do not use if hemodynamically unstable
- Antibiotics to cover gram-negative aerobic and anaerobic bacteria:
 - Mild, uncomplicated cases (peridiverticulitis) for outpatient management:
 - Ciprofloxacin or levaquin + metronidazole or clindamycin
 - Trimethoprim/sulfamethoxazole (TMP/SMX) DS + metronidazole
 - Amoxicillin/clavulanate
 - Duration of therapy is 10–14 days
 - Moderate uncomplicated and mild complicated cases for inpatient management:
 - Ceftriaxone or other 3rd-generation cephalosporin + metronidazole or clindamycin
 - Ampicillin/sulbactam
 - Piperacillin/tazobactam
 - Ticarcillin/clavulanate
 - Ciprofloxacin or levaquin + metronidazole or clindamycin
 - Aztreonam
 - Complicated cases (with peritonitis from perforation), consider:
 - Imipenem/cilastatin
 - Meropenem
 - Aztreonam + metronidazole or clindamycin
 - Gentamicin + metronidazole or clindamycin ± ampicillin
 - Trovafloxacin (alternative)
- Surgery:
 - Emergent surgery:
 - Indicated for generalized peritonitis from perforation

- 2-stage procedure with resection of diseased segment of colon and proximal colostomy followed later with reanastomosis
- Elective surgery:
 - Indicated for multiple recurrent attacks (>2) without generalized peritonitis (controversial); fistula formation; intractable pain; unresolved obstruction; failure of medical therapy; single serious attack in patient <50 yr of age (controversial)
 - 1-stage procedure following resolution of inflammation from medical therapy
 - Nonoperative management may be considered for complicated diverticulitis.
- Peridiverticular abscess drainage:
 - Indicated if well circumscribed and easily accessible
 - Accomplished by CT- or ultrasound-guided percutaneous needle aspiration
- Outpatient therapy:
 - Clear liquids with follow-up in 2–3 days
 - When acute condition has resolved:
 - High-fiber, low-fat diet to decrease recurrence of attacks

MEDICATION

- Amoxicillin/clavulanate: 500/125 mg PO TID or 875/125 mg PO BID
- Ampicillin: 2 g IV q6h
- Ampicillin/sulbactam: 3 g IV q6h
- Cefotetan: 2 g IV q12h
- Cefoxitin: 2 g IV q8h
- Ciprofloxacin: 400 mg IV q12h or 500 mg PO BID
- Dicyclomine: 20 mg PO QID (up to 40 mg PO QID) or 20 mg IM q6h (*not* for IV use)
- Gentamicin: Multiple daily dose (MDD) regimen, 2 mg/kg load, then 1.7 mg/kg IV q8h, or once-daily dose (OD) regimen, 5–7 mg/kg IV q24h (assuming normal renal function)
- Imipenem/cilastatin: 500 mg IV q6h
- Meropenem: 1 g IV q8h
- Metronidazole: 1 g (15 mg/kg) IV load then 500 mg IV q8h or 500 mg PO q8h
- Piperacillin/tazobactam: 3.375 g IV q6h or 4.5 g IV q8h
- Ticarcillin/clavulanate: 3.1 g IV q6h
- Trimethoprim/sulfamethoxazole DS: 1 tablet PO BID
- Trovafloxacin: 300 mg IV for 1st dose, then 200 mg IV/PO daily

First Line

- Uncomplicated diverticulitis (outpatient), 10–14 days
 - Amoxicillin–clavulanate 875/125 mg PO BID

- Trimethoprim/sulfamethoxazole DS 1 tablet PO BID AND metronidazole 500 mg PO q6h
- Ciprofloxacin 500 mg PO BID AND metronidazole 500 mg PO q8h
- For patients intolerant of metronidazole, consider clindamycin
- Complicated diverticulitis
 - Ticarcillin/clavulanate: 3.1 g IV q6h or
 - Ampicillin/sulbactam: 3 g IV q6h or
 - Ceftriaxone 1 g IV q24h AND metronidazole 500 mg IV q8h
 - Levofloxacin 500 mg or 750 mg IV q24h (or ciprofloxacin 400 mg IV q12h) AND metronidazole 1 g IV q12h
 - Imipenem 500 mg IV q6h or meropenem 1 g IV q8h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Intractable pain and/or vomiting
- High fever
- Peritonitis
- Failure to respond to outpatient management
- Severe disease on CT scan
- Significant leukocytosis
- Immunocompromised or steroid-dependent patients
- Recurrent episodes
- Comorbidities: Renal insufficiency, liver dysfunction, COPD, diabetes with end-organ damage
- Extremes of age
- Uncertainty of diagnosis

Discharge Criteria

- Mild cases (low-grade fever, mild discomfort) of known diverticular disease
- Minimal comorbidities
- Tolerating PO

Issues for Referral

Massive diverticular bleeding requiring GI or surgical consultation

FOLLOW-UP RECOMMENDATIONS

- Clear liquids
- Clinical improvement should be seen in 3 days, after which diet can be advanced
- Advise patients to call for increasing pain, fever, or inability to tolerate PO

- Colonoscopy (or contrast enema x-ray with flexible sigmoidoscopy) should be obtained after resolution of initial episode
- Patients do NOT need to avoid seeds and nuts

PEARLS AND PITFALLS

- CT scanning differentiates diverticulitis as complicated or uncomplicated:
 - Surgery reserved for complicated cases, but nonoperative management becoming more prevalent
- Most cases of uncomplicated diverticulitis rarely progress to complicated disease
 - Multiple attacks do not seem to lead to increased complications.
- Diverticulitis does not seem to be a progressively worsening process
 - Acute episodes can present at any stage.
- Severe disease on initial CT scan
 - Increased risk of failure of medical therapy
 - High risk of secondary complications

Diverticulosis

CODES

ICD9

- 562.11 Diverticulitis of colon (without mention of hemorrhage)
- 562.13 Diverticulitis of colon with hemorrhage

ICD10

- K57.20 Diverticulitis of large intestine with perforation and abscess without bleeding
- K57.32 Diverticulitis of large intestine without perforation or abscess without bleeding
- K57.92 Diverticulitis of intestine, part unspecified, without perforation or abscess without bleeding

DIVERTICULOSIS

Ronald E. Kim

BASICS

DESCRIPTION

- Single (diverticulum) or multiple (diverticula) colonic wall outpouchings from colonic muscle dysfunction, usually acquired
- Sequence:
 - Insufficient amounts of dietary fiber cause diminished stool bulk
 - Increased colonic contractions to propel stool through colon cause increase in intraluminal pressure
 - Increased pressure forces mucosa and submucosa to herniate through muscularis propria at its weakest point, where vasa recta penetrate

ETIOLOGY

- Occurs anywhere in GI tract, although generally a colonic disease:
 - Left sided 95% (Western countries)
 - Right sided 70% (Asian countries)
 - Sigmoid colon most common site
- Pseudodiverticula:
 - Outpouchings of mucosa and submucosa only
 - Most common form of colonic diverticula
 - True congenital diverticula (uncommon) contain all bowel wall layers.
- Common in Western society, owing to refined diet and low intake of fiber
- Prevalence is age-dependent
 - 30% by 50 yr old, 65% by 85 yr old
- Complications
 - 70% are asymptomatic
 - 15–25% develop diverticulitis
 - 5–15% develop bleeding; obesity is a risk factor
 - Bleeding stops spontaneously in 75% of cases
 - Inflammation (diverticulitis)
 - Massive arterial bleeding usually from right colon:
 - Fecalith (dry, hard stool) erodes through arterial branch.
 - Perforation
 - Abscess
 - Obstruction

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Chronic or intermittent abdominal pain
 - _ Often precipitated by eating
 - _ Sometimes relieved by flatulence or bowel movement
- Change in bowel pattern
 - _ Constipation or diarrhea
- Dyspepsia
- Painless hematochezia; 75% self-limiting
 - _ Left colon origin: Bright red
 - _ Right colon origin: Dark or maroon colored, mixed with stool
- Diverticulitis and diverticular bleeding are separate entities and rarely coexist.

Physical-Exam

- Afebrile
- Abdomen typically benign, but presentation variable
 - _ Tenderness in left lower quadrant
 - _ Firm sigmoid colon in left lower quadrant
- Rectal exam variable
 - _ Heme-negative stool
 - _ Blood if diverticular bleed

ESSENTIAL WORKUP

Thorough history and physical exam essential to avoid excessive workup

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Asymptomatic diverticulosis
 - _ Requires no workup
- Recurrent uncomplicated painful disease
 - _ Requires no workup
- New onset uncomplicated painful disease
 - _ Requires workup to rule out carcinoma (if weight loss, anorexia, heme-positive stool)
 - _ CBC for leukocytosis or anemia
 - _ Urinalysis to exclude hematuria or pyuria
- Hemorrhagic diverticulosis
 - _ CBC
 - _ Electrolytes, BUN, creatinine, glucose, calcium
 - _ Type and cross for 4 units of packed RBCs
 - _ PT, PTT, INR

- ECG

Imaging

- Uncomplicated painful diverticulosis—outpatient options
 - Flexible sigmoidoscopy, then barium enema
 - Sigmoidoscopy: Rule out carcinoma (before barium studies for optimal visualization)
 - Barium enema: Search for classic diverticula and exclude carcinoma or polyps
 - Colonoscopy
- Hemorrhagic diverticulosis
 - Anoscopy
 - If mild bleeding, to rule out hemorrhoids
 - Massive bleeding from hemorrhoids is rare
 - Proctosigmoidoscopy
 - If no blood in stool above rectum, assume rectal bleed
 - Colonoscopy
 - Cannot perform if bleeding excessive (difficult to visualize pathology)
 - Allows for therapeutic intervention
 - Usually done prior to radionuclide imaging or angiography
 - Radionuclide imaging
 - Safe, no bowel prep needed
 - Poor localization of bleeding site
 - Ideal for detecting intermittent bleeding, owing to long half-life of radioisotope (24–36 hr)
 - No potential for therapeutic intervention, but helpful prior to angiography
 - Angiography
 - Helpful if bleeding site cannot be identified by colonoscopy; must be actively bleeding at least 0.5 mL/min
 - Localizes site of bleeding (more exact after radionuclide scanning)
 - Allows for therapeutic intervention
 - Risk of intestinal infarction
 - Barium enema
 - Rarely indicated, but most sensitive for diagnosis
 - Identifies diverticula but not bleeding (can hinder visualization of other imaging techniques)

DIFFERENTIAL DIAGNOSIS

- Painful diverticulosis
 - Irritable bowel syndrome (almost identical clinical presentation)
 - Diverticulitis
 - Colon carcinoma

- Crohn's disease
- Urologic (renal colic)
- Gynecologic (ruptured or torsed ovarian cyst)
- Hemorrhagic diverticulosis
 - Hemorrhoids
 - Anal fissure
 - Proctitis
 - Colitis
 - Carcinoma
 - Polyps
 - Ischemic enteritis
 - Angiodysplasia
 - Amyloidosis
 - Vascular-enteric fistula
 - Upper GI source

TREATMENT

PRE HOSPITAL

- Avoid opiates in abdominal pain when underlying cause is uncertain.
- Establish 2 large-bore IV lines
- For significant bleeding or hypotension:
 - 1–2 L (20 mL/kg) bolus 0.9% NS intravenously
 - Trendelenburg position

INITIAL STABILIZATION/THERAPY

- Hemorrhagic diverticulosis (massive):
 - Airway control (100% O₂ or intubate if unresponsive)
 - Intravenous access with at least 1 large-bore catheter or 2 if unstable
 - 0.9% NS bolus 1–2 L (20 mL/kg) for hypotension
 - Central catheter placement if unstable following initial fluid resuscitation for more efficient delivery of fluids and monitoring of central venous pressure
 - Consider nasogastric tube to rule out upper GI bleed
 - Bladder catheter to monitor urine output
 - Transfuse O-negative RBCs immediately if arrest is impending
 - Consult surgeon for persistent bleeding, impending hemorrhagic shock (most diverticular bleeding stops spontaneously)

ED TREATMENT/PROCEDURES

- Uncomplicated symptomatic diverticulosis
 - High-fiber diet and/or hydrophilic bulk laxative (i.e., psyllium)

- Warm compresses to abdomen
- Reassurance
- Avoid cathartic laxatives
- No evidence to support use of antispasmodic (dicyclomine)
- Hemorrhagic diverticulosis (massive):
 - Initial stabilization (see above)
 - Colonoscopy is diagnostic and potentially therapeutic
 - Radionuclide scan; sensitive and noninvasive, but requires active bleeding
 - Selective angiography with injection of vasopressin to control bleeding
 - Embolization, interventional radiology; consider before surgery
 - Surgical intervention for segmental colectomy

MEDICATION

- Dicyclomine: 20 mg PO/IM QID (not for IV use)
- Propantheline: 15 mg PO 30 min ac/qhs

FOLLOW-UP

DISPOSITION

Admission Criteria

- ICU if unstable with massive hemorrhagic diverticulosis
- Mild or intermittent hemorrhagic diverticulosis that is otherwise stable so as to determine site of bleeding and evaluate need for definitive treatment

Discharge Criteria

- Uncomplicated, symptomatic diverticulosis
- Stable with trace heme-positive stool, negative gastric aspirate, no anemia, and no other complaints

Issues for Referral

GI follow-up for colonoscopy

FOLLOW-UP RECOMMENDATIONS

- Colonoscopy within 48 hr of initial presentation for stable patients
- Discontinue aspirin and NSAIDs
- Increase intake of dietary fiber
- No evidence for avoidance of nuts, corn, popcorn

PEARLS AND PITFALLS

- 15% with hematochezia have an upper GI source

- Most cases (75–95%) resolve spontaneously or with conservative management
- Massive blood loss seen in 9–19% of patients, especially those with comorbid diseases or advanced age
- Colonoscopy is the initial diagnostic procedure of choice in stable patients

- K57.31 Dvrtclos of lg int w/o perforation or abscess w bleeding
- Q43.8 Other specified congenital malformations of intestine

DIZZINESS

Michael Bouton • Jonathan A. Edlow

BASICS

DESCRIPTION

- Patients' descriptions of symptom quality (vertigo, lightheadedness, disequilibrium, or "other") are frequently misleading and should not be the basis of clinical decision making.
- An approach based on associated symptoms, timing and triggers of the dizziness followed by a targeted physical exam looking for telltale signs is less prone to subjective errors of language and possibly more likely to yield a specific diagnosis.
- There are 4 "timing and triggers" categories:
 - Acute vestibular syndrome (AVS)
 - Abrupt onset of persistent dizziness
 - Episodic vestibular syndrome (EVS)
 - Spontaneous episodes of dizziness lasting many minutes to hours
 - Positional vestibular syndrome (PVS)
 - Very brief episodes (usually lasting 20–50 sec) that are triggered by head or body position movement
 - Chronic vestibular syndrome (CVS)
 - Gradual onset of dizziness lasting weeks to months or longer

ETIOLOGY

- General medical (49%):
 - Arrhythmia
 - Hypoglycemia and other toxic metabolic causes
 - Hypovolemia of any cause
 - Sepsis and infections
 - Low cardiac output states of any cause
- Otologic/vestibular (33%):
 - Benign paroxysmal positional vertigo (BPPV)
 - Labyrinthitis and vestibular neuritis
- Neurologic (11%):
 - Stroke and transient ischemic attack (TIA)
 - Vestibular migraine
- Psychiatric (7%):
 - Anxiety and depression

DIAGNOSIS

SIGNS AND SYMPTOMS

History

Define the timing and triggers category and determine if the ROS suggests a particular serious diagnosis:

- Is the dizziness abrupt or gradual in onset?
- Is the dizziness intermittent or persistent?
- If intermittent, how long do episodes last?
- If intermittent, are the episodes triggered by head or body position movement?
- Are there any hearing or neurologic symptoms?
- Has the patient had recent head injury or started any new medications?
- Does the ROS suggest an acute medical issue; not an encyclopedic list, but examples include:
 - Headache – stroke, dissection, or tumor
 - Ear pain – mastoiditis, otitis media
 - Hearing changes – Ménière disease or labyrinthitis
 - Neck pain – vertebral dissection
 - Fever – systemic infection
 - Dyspnea – pulmonary embolism, pneumonia, or anemia
 - Chest pain – ACS or pulmonary embolism
 - Fluid losses – orthostatic hypotension, hypovolemia
 - Pregnancy – ectopic pregnancy, pre-eclampsia

ALERT

Exacerbation of dizziness with head motion occurs with both central and peripheral causes. However, new dizziness with head motion in a patient who is entirely asymptomatic at rest suggests a peripheral cause.

Physical-Exam

- Vital signs
- Stand patient to test for clinical signs of orthostatic hypotension
- Otoscopic evaluation
- Cardiac exam – is there a murmur or S3?
- Neurologic exam
 - CN II-XII. In particular, is there nystagmus, and if so, what type (see below)?
 - Observe gait
 - Cerebellar exam (finger to nose/heel to shin)
 - Dix-Hallpike maneuver only for intermittent symptoms
- HINTS exam (only for patients with AVS)
 - This is a 3-part more detailed oculomotor exam (head impulse test, nystagmus testing, and test for skew deviation)
 - For acute (< 48 hr) of symptoms this exam has been shown to be more

sensitive than MRI. If exam is concerning obtain MRI or neurology consultation.

- Head impulse testing (vestibulo-ocular reflex)
 - Patient fixes gaze on examiner's nose
 - Move patient's heads rapidly about 20° in the horizontal plane
- If reflex is intact their eyes will stay fixed on your nose (vestibulo-ocular reflex is intact) and a central cause such as cerebellar stroke may be at play. If there is a corrective saccade (eye moves with head and then snaps back toward your nose), this suggests a peripheral cause (vestibular neuritis or labyrinthitis)
- Nystagmus
 - Have patient track your finger to all visual fields.
 - Does the direction of horizontal nystagmus change with change in direction of gaze? (i.e., when patient looks left, is fast component beating to left; when patient looks right, is fast component toward the right)?
 - Direction-changing, vertical or torsional nystagmus (in a patient with the AVS) strongly suggests a central cause.
 - Direction-fixed nystagmus (always in same direction independent of direction of gaze) suggests peripheral cause.
- Tests of skew
 - Alternating cover test
 - Have the patient look at your nose and cover one of their eyes with your hand
 - Rapidly uncover the 1st eye; cover the other one and observe if there is a rapid vertical eye movement (the amplitude can be quite small).
 - Continue to alternately cover and uncover each eye (focusing on 1 eye) in rapid succession.
 - A rapid vertical corrective saccade (up or down) strongly suggests a central process.

ALERT

Each of the components of HINTS individually is not sufficiently sensitive to rule out a central cause. If any one of them is worrisome, assume stroke. Remember that it is the negative head impulse test (no corrective saccade) that is worrisome in patients with AVS.

ESSENTIAL WORKUP

The only mandatory workup is history and physical exam. Using these, one can often make a specific diagnosis.

- Triage: Identify abnormal vital signs, changes in mentation or gross focal deficits in primary survey
 - Focused history to elicit other complaints such as chest pain, headache, and change in hearing that will guide evaluation

- **Timing:** Distinguish between intermittent and chronic symptoms considering relevant conditions for each
- **Triggers:** For intermittent symptoms consider the immediate context of episodes
- **Telltale signs:** HINTS exam for acute dizziness

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Serum glucose
- Hematocrit, if suspected anemia/blood loss
- Electrolytes and renal function
 - VBG if considering CO poisoning or CO₂ narcosis
- UA to evaluate for infection
- Toxicologic screen, if suspected exposure

Imaging

- CT head if acute bleed suspected
 - CT only ~ 40% sensitive for ischemic posterior circulation stroke
- MRI if no other etiology found and HINTS exam concerning in a patient with the AVS

Diagnostic Procedures/Surgery

- Dix-Hallpike maneuver, head thrust maneuver, and test for skew deviation.
- EKG to detect arrhythmia, MI
- Lumbar puncture in setting of unexplained infectious signs or headache

DIFFERENTIAL DIAGNOSIS

Each of the timing and triggers categories has its own differential diagnosis. Here are the common and the dangerous causes:

- **AVS – acute vestibular syndrome**
 - Benign
 - Viral labyrinthitis (hearing involved)
 - Vestibular neuritis (hearing not involved)
 - Dangerous
 - Stroke, particularly brainstem or cerebellar
 - Occasionally low cardiac output state (e.g., PE, ACS)
- **EVS – episodic (spontaneous) vestibular syndrome**
 - Benign
 - Vestibular migraine
 - Dangerous
 - TIA
 - Rarely, brief low cardiac output state (e.g., arrhythmia, PE that

breaks up and migrates)

- **PVS – positional (triggered) vestibular syndrome**
 - Benign
 - BPPV
 - Orthostatic hypotension (if benign cause)
 - Dangerous
 - Orthostatic hypotension (if serious cause)
 - Rarely, CPPV (central paroxysmal positional vertigo) caused by a posterior fossa mass
- **CVS – chronic vestibular syndrome**
 - Benign
 - Psychiatric causes (anxiety and depression)
 - Benign medication side effects
 - Dangerous
 - Rarely a posterior fossa mass

TREATMENT

INITIAL STABILIZATION/THERAPY

- Abnormal vital signs clinically managed
- Stabilization should be determined by more specific classification of dizziness based on the history, physical exam, and ancillary studies.

ED TREATMENT/PROCEDURES

Symptomatic control until diagnosis established

If BPPV suspected perform Epley maneuver

MEDICATION

- Ondansetron: 4 mg IV or ODT
- Diazepam: 2.5–5 mg IV or 2–10 mg PO
- Diphenhydramine: 25–50 mg IV, IM, or PO
- Meclizine: 25 mg PO (no more than 2–3 days)
- Promethazine: 12.5 mg IV q6h or 25–50 mg PO, IM, or PR q6h

Note: These medications are for symptom relief; response has no etiologic implications.

FOLLOW-UP

DISPOSITION

Admission Criteria

Admission or discharge of patients with dizziness should be based on the underlying etiology or associated symptoms.

Discharge Criteria

- Admission or discharge of patients with dizziness should be based on the underlying and the patient's ability to function safely at home.
- If patient has isolated complaint of dizziness with normal neurologic and oculomotor testing as described above, consider discharge with follow-up instructions

Issues for Referral

Refer for completion of workup as an outpatient to a primary care physician, ENT, or neurologist depending upon likely cause.

FOLLOW-UP RECOMMENDATIONS

- The patient should be instructed:
 - Not to drive or operate machinery if he is feeling dizzy
 - To get up slowly after sitting or lying down
- Patient should return to the ED or see his doctor right away if:
 - Symptoms of neurologic problem (worsening headache, confusion, memory loss, new motor or sensory loss)
 - Symptoms of an infection (stiff neck, fevers, or chills)
 - Symptoms of acute cardiovascular or pulmonary problem (new acute abdominal chest or back pain, new dyspnea, or hemoptysis)
 - Symptoms of fluid losses (intractable emesis or stools, GI or vaginal bleeding)

PEARLS AND PITFALLS

- Use the “timing and triggers” technique to diagnose dizzy patients.
- Advanced age and traditional stroke risk factors increase the likelihood of acute stroke as cause of dizziness.
- Noncontrast CT is NOT sensitive for acute cerebellar stroke.
- Patients with cerebellar stroke can present with isolated dizziness.
- It is a “negative” head impulse test (lack of corrective saccade) that is worrisome; a “positive” test suggests a peripheral vestibular etiology.
- The treatment for BPPV is an Epley maneuver, NOT meclizine.

ICD10

- H81.10 Benign paroxysmal vertigo, unspecified ear
- H83.09 Labyrinthitis, unspecified ear
- R42 Dizziness and giddiness

DOMESTIC VIOLENCE

Laura G. Burke

BASICS

DESCRIPTION

- Intimate partner violence (IPV) is the physical, sexual, or psychological abuse by a current or former partner.
- Occurs in adult and adolescent intimate relationships across the socioeconomic spectrum.

ETIOLOGY

- Most victims are women injured by male perpetrators
- Men and individuals in same-sex relationships may also be victims.
- Risk factors for IPV include female sex, young age (20–24) and being separated from partner/spouse.

DIAGNOSIS

Asking specifically about IPV increases likelihood of identifying victims.

SIGNS AND SYMPTOMS

- Traumatic injuries:
 - Wide variety of presentations
 - Unwitnessed head, neck, facial injuries are common
 - Forearm bruises or fractures suggesting a defensive posture
 - Injuries in various stages of healing
- Psychiatric:
 - Chronic pain syndromes
 - Depression
 - Somatization
 - Anxiety
 - Suicidality
 - Substance abuse

ALERT

Clinical clues:

- Discrepancy between history and physical findings
- Partner refusing to allow patient to be alone with provider
- Delay in seeking care
- Any injury during pregnancy
- Interaction between patient and partner that suggests interpersonal problems

- Multiple symptoms without obvious physical findings

History

- Screening questions for IPV may be useful in identifying victims of domestic violence.
- Controversial as to whether available evidence demonstrates that screening improves health outcomes.
- IPV screening is required by the Joint Commission and supported by some professional medical organizations.
- Screening should be direct, nonjudgmental, supportive, and private.
- There is some evidence for effectiveness of computer-based screening of ED patients for IPV.
- Consider IPV in patients with substance abuse/intoxication as they may be at greater risk and less likely to be identified.

Physical-Exam

- Careful exam for traumatic injuries
- Mental status exam

ESSENTIAL WORKUP

- After identification of IPV, a directed workup for traumatic injuries and acute medical or behavioral health illnesses is warranted.
- Assess patient's risk for future injury/victimization

DIFFERENTIAL DIAGNOSIS

Important to maintain high index of suspicion for IPV in patients with traumatic injuries, behavioral health problems, and medical complaints (e.g., GU, GYN, multiple somatic complaints)

TREATMENT

PRE HOSPITAL

- Customary trauma evaluation and treatment
- An accurate description of events by EMS should be incorporated into the medical record.

INITIAL STABILIZATION/THERAPY

- Provide timely and appropriate medical attention.
- Provide appropriate emotional support throughout workup and treatment

ED TREATMENT/PROCEDURES

- Interview the patient in a private, secure location without any family members present

- Use a medical interpreter (not family members) to conduct in an interview when there is a language barrier.
- Provide complete, careful documentation including use of the patient's exact words, as they are admissible in court.
- Carefully document extent and location of injuries. Diagrams or photographs are particularly useful.
- If stable for discharge, assess situation for lethality
 - Risk factors include violence that is increasing in frequency and severity, threats of homicide or suicide by the partner, or the availability of a lethal weapon.
 - Work with the patient to develop optimal discharge plan that is consistent with his/her wishes.
- Arrange referrals and follow-up:
 - Outpatient victim services
 - Emergency shelter information
 - Hotlines
 - Restraining order information
 - Legal services
- Mandatory reporting requirements vary among states:
 - Reporting requirements for IPV vary by state.
 - Mandatory reporting may place the victim in more danger and create ethical dilemmas for the physician when the victim does not want the case reported to police or social service agencies.
 - Inform victims of any requirement to report to authorities and possible outcomes of reporting.

MEDICATION

- Acetaminophen: 650–975 mg PO
- Morphine sulfate: 0.1 mg/kg/dose IV or IM

FOLLOW-UP

DISPOSITION

Admission Criteria

- Use appropriate admission guidelines depending on degree of trauma sustained.
- A patient who is medically stable for discharge but whose safety is at imminent risk may require hospitalization until a safe discharge plan is developed.

Discharge Criteria

A victim whose safety is ensured and whose injuries can be managed as an outpatient may be discharged.

Issues for Referral

Availability of advocacy services varies considerably.

FOLLOW-UP RECOMMENDATIONS

Provide information regarding outpatient services and emergency shelter information.

PEARLS AND PITFALLS

- Failure to consider IPV in the differential diagnosis of the patient's chief complaint.
- Failure to provide thorough, objective documentation of the details of the assault and physical exam findings.
- Failure to adequately assess patient's safety upon discharge and provide appropriate referrals
- Mandatory reporting laws remain controversial and may cause unintended consequences for the patient.

DROWNING

Colleen N. Hickey

BASICS

DESCRIPTION

- Definitions:
 - Drowning: “A process resulting in primary respiratory impairment from submersion or immersion in a liquid medium”
 - Fatal drowning: Death at any time as a result of drowning
 - Nonfatal drowning: If the victim is rescued at any time and the process of drowning is interrupted
 - Water rescue: Any submersion or immersion incident without evidence of respiratory impairment
- Scenario of drowning:
 - Now thought all drowning victims aspirate some amount of liquid
 - Previously classified as “wet” and “dry” drowning:
 - “Wet” drowning (90%): Aspiration of small amount of liquid into the lungs
 - “Dry” drowning (10%): Laryngospasm secondary to the presence of liquid in the oropharynx or larynx
 - End result: Hypoxia
 - No significant difference between freshwater and saltwater submersion
- Pathophysiology:
 - Aspiration:
 - Small volume of water
 - Decreased lung compliance causing ventilation/perfusion mismatch and intrapulmonary shunting
 - No significant electrolyte changes
 - Grossly contaminated water: Risk for pulmonary infection
 - Hypoxemia:
 - Metabolic lactic acidosis
 - Multisystem organ dysfunction
 - Noncardiogenic pulmonary edema
 - Myocardial dysfunction (arrhythmias)
 - Coagulation abnormalities (disseminated IV coagulation)
 - Renal failure (usually acute tubular necrosis)
 - Cerebral hypoxia: Cerebral edema, increased intracranial pressure

Pediatric Considerations

- Hypothermia:

- More common in young children
- Larger body surface-to-mass ratio
- Decreases the metabolic rate
- Survival with full recovery is possible (neuroprotective)
- Diving reflex:
 - Young children are more susceptible
 - Triggered by submersion of face in cold water
 - Bradycardia ensues: Redistribution of blood flow to the heart and brain
 - Delays onset of hypoxia-related damage

ALERT

Risk factors:

- Lack of proper supervision
- Alcohol or other drug abuse
- Limited swimming ability or exhaustion
- Trauma
- Seizure disorder
- Risky behavior
- Pre-existing medical problem
- Attempted suicide
- Poor education

DIAGNOSIS

SIGNS AND SYMPTOMS

- Cardiopulmonary arrest
- Cyanosis
- Dyspnea
- Copious pulmonary secretions
- Loss of consciousness
- Cerebral edema/injury
- Evidence of trauma:
 - Intracranial hemorrhage
 - Cervical spine injury rare (< 0.5%)
- Hypothermia

ESSENTIAL WORKUP

- Information from witnesses or emergency medical services personnel at the scene
- Early airway management and CPR
- Rectal temperature for hypothermia

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Arterial blood gas (pH)
- CBC
- Electrolytes, BUN, creatinine, glucose:
 - Usually normal (>85%)
 - Hyponatremia or hyponatremia
- Alcohol and toxicology screen

Imaging

- CXR:
 - Diffuse or focal infiltrates, acute respiratory distress syndrome
 - May be normal initially
- ECG:
 - Long QT interval
 - Sinus bradycardia
 - Sinus tachycardia
 - Atrial fibrillation
- CT scan:
 - Brain: Abnormality at any time during hospitalization is associated with poor neurologic outcome
 - Cervical spine: Traumatic injury

DIFFERENTIAL DIAGNOSIS

- Consider reason for submersion:
 - Dysrhythmia (long QT syndrome, familial polymorphic ventricular tachycardia)
 - Myocardial infarction
 - Seizure
 - Syncope
 - Trauma
 - Suicide attempt

Pediatric Considerations

Consider child abuse/neglect:

- Especially infants in bathtub near drowning

TREATMENT

PRE HOSPITAL

- Attention to ABCs:
 - Avoid further aspiration
 - Secure airway—intubate

- Early CPR
- Cervical spine precautions if injury suspected or concerning mechanism
- Early rewarming attempts
- 90% survival with appropriate intervention
- All drowning victims need ED evaluation
- Abdominal thrust to remove water *not* recommended:
 - Useful only if foreign body in airway
 - Increases risk for aspiration
 - Delays effective CPR

INITIAL STABILIZATION/THERAPY

- ABCs
- Core temperature:
 - Initiate rewarming (see “Hypothermia”)
 - Remove wet clothing

ED TREATMENT/PROCEDURES

- Correct hypoxemia:
 - Titrate to oxygen saturation
 - Intubate and provide mechanical ventilation with positive end-expiratory pressure
- Evaluate and treat traumatic injuries
- Correct acidosis
- Cardiopulmonary arrest:
 - Initiate advanced cardiac life support measures
 - Continue rewarming efforts:
 - Passive: Blankets, insulators
 - Active external: Warm blankets, radiant heat, warm baths
 - Active internal: Pleural or peritoneal lavage, cardiopulmonary bypass
 - Continue resuscitation until core temperature $> 32^{\circ}\text{C}$ or until spontaneous pulse and respirations return
- No value to steroids
- Poor prognostic signs:
 - Prolonged submersion time
 - Severe acidosis ($\text{pH} \leq 7.0$)
 - Need for CPR
 - Low oxygen saturation
 - Low Glasgow Coma Score (GCS)

MEDICATION

- Epinephrine: 1 mg (peds: 0.01 mg/kg) IV
- Vasopressin: 40 U (peds: 0.04 U/kg) IV
- Lidocaine: 1 mg/kg IV

- Sodium bicarbonate: 1 mEq/kg IV

Pediatric Considerations

- Hypothermia may be protective:
 - Aggressive rewarming
 - Aggressive resuscitation
- Evaluate for abuse/neglect
- Family history: Sudden death, similar episode:
 - Long QT syndrome
 - Familial polymorphic ventricular tachycardia
- Prevention is key to treatment:
 - Supervision around water
 - Empty pails and buckets

ALERT

Controversial: Therapeutic hypothermia

- Widely accepted in adult population after cardiac arrest with return of spontaneous circulation, still controversial in pediatrics
- Optimize neurologic outcome
- Suppress reperfusion injury

FOLLOW-UP

DISPOSITION

Admission Criteria

- Delayed symptomatology occurs:
 - Pulmonary edema (up to 12 hr later)
 - Neurologic abnormalities
- ICU:
 - Patients who required CPR or artificial ventilation
 - Abnormal chest radiograph
 - Arterial blood gas abnormalities
 - GCS < 13
- Admit observation status:
 - All symptomatic patients
 - Submersion for > 1 min
 - History of cyanosis or apnea
 - Patients who required brief assisted ventilation

Discharge Criteria

- Questionable history of submersion:

- Observe in ED for 8 hr:
 - No respiratory distress
 - No neurologic impairment
- Discharge to reliable home
- Home-going instructions:
 - Return for shortness of breath or mental status changes

FOLLOW-UP RECOMMENDATIONS

Close primary care follow-up for all patients discharged from ED

PEARLS AND PITFALLS

- All patients with drowning incident require at least 8 hr of observation
- Indicators of poor prognosis:
 - Acidemia (pH <7.1 on presentation)
 - Age <3 yr
 - Submersion >10 min
 - Time to basic life support care >10 min
 - GCS ≤ 5
 - Long transportation time to ED
 - Persistent apnea or need for cardiopulmonary resuscitation in the ED
 - Water temperature >10°C

DUODENAL TRAUMA

Christanne H. Coffey

BASICS

DESCRIPTION

- Characteristics of duodenum:
 - 12 in long
 - C-shaped
 - From pylorus to ligament of Treitz
 - Divided into 4 sections:
 - Last 3 sections retroperitoneal along with distal portion of 1st section
 - Lies mostly over 1st 3 lumbar vertebrae
 - 2nd section is most commonly injured
- Types of injury:
 - Duodenal wall hematoma
 - Wall perforation
 - Hemorrhage, including retroperitoneal
 - Crush
- Incidence of duodenal injury is 3–5% of all traumatic abdominal injuries
- Penetrating trauma accounts for ~75% of duodenal injuries:
 - Mortality ranges from 13–28%
 - Associated with exsanguination
- Blunt duodenal trauma has a higher mortality due to greater force of injury and often delayed diagnosis due to retroperitoneal location:
 - If injury is diagnosed in < 24 hr, mortality rate is about 11%
 - If > 24 hr, mortality rate approaches 40%
 - Late mortality usually from sepsis

Pediatric Considerations

- Majority secondary to recreational injuries (e.g., bicycle handlebar injuries)
- Intramural duodenal hematomas may occur in nonaccidental trauma:
 - If suspected, prompt referral to appropriate child protective agency is required
- In children, hematoma is most commonly seen in 1st portion of duodenum

Pregnancy Considerations

- Retroperitoneal hemorrhage more common due to increased pelvic and abdominal vascularity
- Large uterus serves as protection from bowel injury.
- Peritoneal irritation is blunted in the pregnant patient; therefore, greater index of

suspicion

ETIOLOGY

- Blunt trauma:
 - Shear strain: Abrupt acceleration/deceleration at point of attachment (most common retroperitoneal injury with rapid deceleration)
 - Tensile strain: Direct compression or stretching of tissue
- Penetrating trauma:
 - Most common cause of injury
 - Creates cavitations, can lead to infection

DIAGNOSIS

SIGNS AND SYMPTOMS

- Complaints may be minimal with vague abdominal, flank, and back pain
- High GI obstruction may be seen with duodenal hematomas

History

Penetrating or blunt abdominal trauma

Physical-Exam

- Retroperitoneal: Often subtle, RUQ pain, nausea, vomiting, tachycardia, fever
- Intraperitoneal: Peritonitis

ESSENTIAL WORKUP

- Basic labs including amylase
- Acute abdominal series or CT
- Diagnostic peritoneal lavage (DPL) or ex lap if unstable, high suspicion

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Lab tests are of little value
- 50% of patients with duodenal injuries have elevated serum amylase
- An increasing leukocytosis may suggest undiagnosed duodenal injury

Imaging

- Focused assessment with sonography in trauma (FAST)
 - Validated for hemoperitoneum
 - Not reliable for duodenal injury
 - 1/3 retroperitoneal injuries with normal FAST
- Upright chest and abdominal radiographs:

- Intraperitoneal air
- Retroperitoneal air
- Air in biliary tree
- Scoliosis to the right
- Loss of psoas shadow
- Air around right kidney
- Injecting air into nasogastric tube may demonstrate retroperitoneal air more clearly
- Intramural hematomas without leakage may have coiled-spring appearance
- CT with oral and IV contrast:
 - Best imaging diagnostic test that shows small amounts of retroperitoneal gas and extravasated contrast material
 - Duodenal wall thickening, periduodenal fluid, “sentinel clot” adjacent to injury
 - Sausage-shaped mass in duodenal wall strongly suggests hematoma

Diagnostic Procedures/Surgery

- Ex lap is the ultimate diagnostic test when high suspicion remains, even after other diagnostic tests are negative
- DPL:
 - Often positive for blood, bile, or bowel content
 - Negative lavage does not exclude injury (65% false-negative rate)

DIFFERENTIAL DIAGNOSIS

- Injury to hollow organs (stomach, small and large intestines)
- Liver and biliary tree injuries
- Vascular injuries (aortic and mesenteric arteries as well as venous injuries)
- Postoperative complications from prior duodenal surgery or injury repair, such as infection and suture line dehiscence

TREATMENT

PRE HOSPITAL

- Follow trauma protocols
- Important to have pre-hospital personnel provide clear description of mechanism of injury and to transport to appropriate facility

INITIAL STABILIZATION/THERAPY

- Airway management, resuscitation as needed
- Aggressive fluid therapy with warmed normal saline or lactated Ringer solution if patient hypotensive; transfuse as indicated
- Central line may be needed for unstable patients

- Nasogastric decompression
- Early trauma surgical consultation

ED TREATMENT/PROCEDURES

- Tetanus and antibiotic prophylaxis for penetrating wounds
- Definitive treatment involves laparotomy with exploration of duodenum for injuries
- Low-grade (I or II) blunt duodenal injuries usually managed nonoperatively – 10% fail
- Broad-spectrum antibiotics to prevent sepsis in patients with perforation

MEDICATION

- Cefoxitin: 2 g (peds: 40 mg/kg) IV q6h or
- Levofloxacin 750 mg or Ciprofloxacin 400 mg q24h + Metronidazole 500 mg IV q8h

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with duodenal injuries need admission to trauma surgical service
- Minor duodenal hematomas that do not require immediate surgery may require nasogastric decompression for obstruction (up to 7 days) and observation for possible expansion or rupture of the hematoma

Discharge Criteria

- No patient with identified traumatic duodenal injury should be discharged from the ED
- Complications: Intra-abdominal abscess, duodenal fistula, pancreatic fistula, sepsis

Issues for Referral

- Duodenal organ injury scale (DIS) by American Association for the Surgery of Trauma:

Grade Duodenal Injury Description

- | | |
|----|---|
| I | Hematoma: Single portion
Laceration: Partial thickness, no perforation |
| II | Hematoma: > 1 portion
Laceration: Disrupts < 50% circumference, spares duct
Lacerations only: |

III --Disrupts 50—75% circumference D2

--Disrupts 50—100% circumference

D1, D3, D4

Lacerations only:

IV --Disrupts >75% circumference D2

--Involves ampulla or CBD

V Laceration: Massive disruption duodenopancreatic complex Vascular-devascularization

- Majority injuries Grade II or Grade III
- 80% primary repairs

FOLLOW-UP RECOMMENDATIONS

- All patients with diagnosed duodenal injury should be admitted
- If diagnostic studies are negative, recommend follow-up with PMD within 24–48 hr
- Diet: Clear liquids, advance as tolerated

PEARLS AND PITFALLS

- Significant morbidity and mortality with delayed or missed diagnosis
- Physical exam can be misleading due to retroperitoneal location
- If continued high suspicion despite negative diagnostic tests, get surgical consult

- S36.420A Contusion of duodenum, initial encounter
- S36.430A Laceration of duodenum, initial encounter

DYSFUNCTIONAL UTERINE BLEEDING

Andrew J. French

BASICS

DESCRIPTION

- Abnormal uterine bleeding is an alteration in pattern or volume of normal menses
 - Typical blood loss during a normal menstrual cycle is 30–80 mL
 - Normal interval between menses 28 (+/– 7) days
- 2 classifications
 - **Dysfunctional uterine bleeding (DUB)**
 - Hormonally related
 - Anovulatory and ovulatory categories
 - Not due to organic or iatrogenic causes
 - Diagnosis of exclusion
 - **Organic uterine bleeding**
 - Bleeding related to systemic illness or disease of the reproductive tract

ETIOLOGY

- Anovulatory (most common):
 - Unopposed estrogen stimulation of proliferative endometrium
 - Alteration of neuroendocrine function due to:
 - Polycystic ovarian syndrome (PCOS)
 - Very low calorie diets, rapid weight change, intense exercise, anorexia
 - Psychological stress
 - Obesity
 - Drugs
 - Hypothyroidism
 - Primary hypothalamic dysfunction
- Ovulatory:
 - Inadequate uterine PGF₂ α
 - Increased uterine contractility
 - Excessive uterine prostacycline
 - Diminishes platelet function and increases uterine vasodilation

Pediatric Considerations

Anovulatory bleeding common in adolescence owing to immaturity of the hypothalamic–pituitary–ovarian axis

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Abnormal uterine bleeding in the absence of systemic or structural disease
- Most common in perimenarcheal, perimenopausal women
- Typically painless
- Anovulatory presentations:
 - Metrorrhagia:
 - Irregular bleeding between periods
 - Menorrhagia:
 - Regular periods with excess flow (> 80 mL) or >7 days of bleeding
 - Oligomenorrhea:
 - Periods with intermenstrual cycles > 35 days
 - Menometrorrhagia:
 - Excessive bleeding with and between menses

Physical-Exam

- Acne, hirsutism, obesity suggest PCOS
- Mild to moderate bleeding on pelvic exam
- Pallor, tachycardia, hypotension, orthostasis in severe cases
- Evaluate for trauma, foreign bodies

ALERT

It is rare for women to be hemodynamically unstable simply from DUB; if such instability is present, concern is for ectopic pregnancy or other cause for hemorrhage.

ESSENTIAL WORKUP

Pregnancy test

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Pregnancy test, CBC, PT/PTT
- May send iron studies, TSH, LH, FSH, prolactin level, cervical cultures for routine follow-up by primary medical doctor (PMD)/gynecology

Imaging

Pelvic ultrasound may show uterine, tubal, or ovarian abnormality; may be needed to rule out other organic or iatrogenic causes on differential diagnoses.

Diagnostic Procedures/Surgery

- Dilation and curettage (D&C) may be required for heavy bleeding unresponsive to other interventions

- Refer for endometrial biopsy if > 35 yr of age

DIFFERENTIAL DIAGNOSIS

Organic/Iatrogenic

- Pregnancy complications:
 - Threatened, incomplete, or spontaneous abortion
 - Ectopic pregnancy
 - Molar pregnancy
- Infectious:
 - Vaginitis
 - Cervicitis
 - Pelvic inflammatory disease (PID)
- Coagulopathies:
 - von Willebrand disease
 - Idiopathic thrombocytopenic purpura
 - Platelet defects
 - Thalassemia
- Medications:
 - Warfarin
 - Aspirin
 - Oral contraceptives
 - Tricyclic antidepressants
 - Major tranquilizers
- Systemic illness:
 - Adrenal, hepatic, renal or thyroid dysfunction, diabetes mellitus, other endocrinopathies
- Anatomic lesions:
 - Fibroids
 - Endometriosis
 - Polyps
 - Endometrial hyperplasia
 - Neoplasm
- Intrauterine devices
- Trauma

Hormone related

See anovulatory and ovulatory etiologies

TREATMENT

PRE HOSPITAL

IV crystalloid boluses as needed for hypotension, tachycardia secondary to heavy bleeding

INITIAL STABILIZATION/THERAPY

ABCs:

- Packed RBCs for significant bleeding unresponsive to crystalloids

ED TREATMENT/PROCEDURES

- Observation usually adequate if bleeding mild
- IV crystalloid, packed RBCs for continued bleeding, or hemodynamic instability
- Gynecology consultation if bleeding is severe and unresponsive to crystalloids, medications:
 - D&C may be necessary for hemodynamic instability
 - Endometrial ablation or hysterectomy for continued heavy bleeding unresponsive to other measures

MEDICATION

- Conjugated estrogen (Premarin) for heavy bleeding, hemodynamic instability:
 - 2.5 mg PO q6h
 - 25 mg IV, repeat in 3 hr if needed
- Ibuprofen 400–800 mg PO q8h (reduces prostaglandin synthesis)
- IV dosing has not been shown to be superior to oral route:
 - Medroxyprogesterone acetate 5–10 mg/d PO is added when bleeding subsides
- Oral contraceptive pills:
 - Ethinyl estradiol 35 µg and norethindrone 1 mg PO QID for 1 wk
- Antifibrinolytic agents:
 - Tranexamic acid: 1,300 mg PO TID × 5 days
 - May be used in conjunction with OCPs
 - Use limited by GI effects and allergy
- Medications may be deferred in mild cases with referral to gynecology
- Transdermal or long-acting estrogens are other options

FOLLOW-UP

DISPOSITION

Admission Criteria

- Significant blood loss
- Continued bleeding
- Hemodynamic instability requiring aggressive resuscitation and/or operative intervention

Discharge Criteria

Most patients can be discharged with gynecology referral once bleeding is controlled and patient is hemodynamically stable.

Issues for Referral

Endometrial biopsy if > 35 yr old:

- Follow-up with either gynecologist or primary care physician is necessary for patients with DUB
- Must evaluate for ongoing blood loss or potential malignancy as cause

PEARLS AND PITFALLS

- DUB is a diagnosis of exclusion
- Only 2% of endometrial carcinoma occur before age 40 yr
- If hemodynamic instability, unlikely diagnosis of DUB

CODES

ICD9

- 626.2 Excessive or frequent menstruation
- 626.6 Metrorrhagia
- 626.8 Other disorders of menstruation and other abnormal bleeding from female genital tract

ICD10

- N92.0 Excessive and frequent menstruation with regular cycle
- N92.1 Excessive and frequent menstruation with irregular cycle
- N93.8 Other specified abnormal uterine and vaginal bleeding

DYSPHAGIA

Laura G. Burke

BASICS

DESCRIPTION

- Difficulty swallowing
- Can be neuromuscular or mechanical

ETIOLOGY

- Oropharyngeal (transfer) dysphagia:
 - Difficulty transferring from the mouth to the proximal esophagus (difficulty initiating a swallow)
 - Easier to swallow solids vs. liquids
 - Immediate, within seconds of swallowing
 - Associated with nasal or oral regurgitation, coughing, or choking
 - Usually a neuromuscular disorder resulting in bulbar muscle weakness or impaired coordination
- Esophageal (transport) dysphagia:
 - Failure of normal transit through the esophagus
 - Retrosternal sticking sensation seconds after swallowing
 - Nocturnal regurgitation/aspiration
 - Drooling or regurgitation of undigested food and liquid (characteristic of esophageal obstruction)
 - Motility disorder vs. mechanical obstruction
- Functional dysphagia:
 - Diagnosis of exclusion
 - Full workup without evidence of mechanical or neuromuscular pathology
 - Symptoms > 12 wk
- Odynophagia:
 - Pain with swallowing
 - Separate, but often related, entity
- Pain pattern:
 - Overall poor ability to localize pain with dysphagia, although oropharyngeal source is better
 - Somatic nerve fibers in the upper esophagus; better pain localization
 - Visceral pain from the lower esophagus is poorly localized and may be difficult to distinguish from that of acute coronary syndrome.

Pediatric Considerations

- Pediatric dysphagia:

- Common causes in infants/newborns include prematurity, congenital malformations, neuromuscular disease, infection (e.g., candidiasis), inflammation
- Always consider foreign body aspiration in a child presenting with dysphagia
- Other common causes in children include caustic ingestions, infections, and neurologic disorders including sequelae from head injury
- Acquired tracheoesophageal fistula in children may result from ingestions (disk battery, caustic ingestions) or prior surgery
- Other life-threatening causes of dysphagia include epiglottitis, retropharyngeal abscess, CNS infection, botulism, esophageal perforation, diphtheria

DIAGNOSIS

SIGNS AND SYMPTOMS

- Difficulty initiating swallowing
- Sensation of food stuck after swallowing
- Cough/choke after eating
- Impairment of gag reflex and ability to clear bolus
- Voice change/dysphonia
- Drooling
- Dysarthria
- Chest pain

History

- Is there difficulty swallowing solids, liquids, or both?
 - Solids and liquids suggest a neuromuscular disorder.
 - Solids only or progression from solids to liquids suggests a mechanical abnormality.
- How long after swallowing do symptoms occur?
 - Immediate onset of symptoms suggests oropharyngeal cause
 - Delay (seconds after swallowing) suggests esophageal cause
- Are symptoms intermittent or progressive?
 - Intermittent symptoms suggest rings or webs.
 - Progressive symptoms suggest peptic or malignant strictures.
 - Motility disorders can be intermittent or progressive.
- How long have the symptoms been present?
 - Acute onset is more concerning for acutely life-threatening etiology
 - Food impaction is the most common cause of acute-onset dysphagia
 - Malignancy may also progressive relatively quickly
- Are there other associated symptoms?

- e.g., nasal regurgitation, choking, heartburn, weight loss

Physical-Exam

- Often unremarkable
- Oropharyngeal inspection
- Pulmonary and cardiac auscultation
- Neurologic exam with emphasis on cranial nerves (esp. V, VII, IX, X, XII)

ESSENTIAL WORKUP

- Adequate airway evaluation
- Thorough neurologic exam

DIAGNOSIS TESTS & INTERPRETATION

EKG:

- Consider cardiac etiology for chest discomfort

Lab

No specific studies are indicated.

Imaging

- CXR:
 - Achalasia food dilating the esophagus may be seen as widened mediastinum, air–fluid level in posterior mediastinum
 - Aspiration pneumonitis
 - Extrinsic compressing mass
- Soft tissue lateral neck radiograph
- Modified barium swallow (with solid bolus) or videofluoroscopy:
 - Defines esophageal anatomy
 - Assesses function
 - Do not perform if endoscopy anticipated
- CT/MRI of the head:
 - Indicated for new-onset neuromuscular dysphagia

Diagnostic Procedures/Surgery

- Often performed in the outpatient setting
- Upper endoscopy:
 - Indicated to relieve obstruction and inspect the esophageal anatomy
 - Biopsy possible if indicated
- Esophageal manometry
- Fiberoptic nasopharyngeal laryngoscopy

DIFFERENTIAL DIAGNOSIS

- Oropharyngeal:

- Infectious:
 - Botulism
 - CNS infections
 - Mucositis
 - Lyme disease
- Mechanical:
 - Congenital
 - Malignancy
 - Pharyngeal pouch
- Medications:
 - Antibiotics (especially doxycycline)
 - Aspirin and NSAIDs
 - Bisphosphonates
 - Ferrous sulfate
 - Potassium chloride
 - Quinidine
- Neuromuscular:
 - Amyotrophic lateral sclerosis
 - Cerebrovascular accident
 - Guillain–Barré syndrome
 - Cranial nerve palsy
 - Huntington chorea
 - Multiple sclerosis
 - Myasthenia gravis
 - Parkinson disease
 - Traumatic brain injury
- Psychological/behavioral
- Esophageal:
 - Mechanical:
 - Diverticula
 - Esophageal webs
 - Foreign body
 - Neoplasm
 - Peptic esophageal stricture
 - Postsurgical (laryngeal, spinal)
 - Radiation injury
 - Schatzki ring
 - Motor:
 - Achalasia
 - Chagas
 - Cushing syndrome
 - Diffuse esophageal spasm
 - Hyperthyroidism/hypothyroidism

- Nutcracker esophagus
- Scleroderma
- Vitamin B₁₂ deficiency
- Inflammatory:
 - Eosinophilic esophagitis
 - Pill esophagitis
- Extrinsic:
 - Cardiovascular abnormalities (vascular rings, thoracic aneurysm, left atrial enlargement, aberrant subclavian artery)
 - Cervical osteophytes
 - Mediastinal mass

TREATMENT

PRE HOSPITAL

- Vigilant airway attention
- Position of comfort with suction available

INITIAL STABILIZATION/THERAPY

- Vigilant airway attention
- Position of comfort with suction available
- NPO
- 0.9% NS 500 mL (peds: 20 mL/kg) IV fluid bolus for significant dehydration
- Evaluate for life-threatening causes of dysphagia including
 - Retropharyngeal hematoma/abscess
 - Epiglottitis
 - Foreign body
 - Upper airway obstruction
 - Cardiovascular causes (thoracic aortic aneurysm)

ED TREATMENT/PROCEDURES

- Nitroglycerin for esophageal spasm
- Glucagon for impacted foreign body
- Treat complications:
 - Airway obstruction
 - Aspiration, pneumonia, lung abscess
 - Dehydration, malnutrition
- Endoscopy
- Dietary modifications:
 - Thickened liquids for neuromuscular disorder
 - Thin liquids for mechanical disorders

MEDICATION

First Line

- Glucagon for food impaction: 1 mg IV followed by 2nd dose of 1 mg after 5 min if there is no improvement in symptoms (0.02–0.03 mg/kg in children, not to exceed 0.5 mg):
 - Success rates vary from 12–50%, which may not be better than spontaneous passage.

Second Line

Calcium channel blockers and nitrates may be used in motility disorders (e.g., achalasia and nutcracker esophagus)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Esophageal obstruction persists despite treatment
- Compromised fluid or nutrition status
- Inability to protect airway
- Unable to tolerate own secretions

Discharge Criteria

- Well-hydrated patient
- Urgent neurology, otolaryngology, or gastroenterology referral arranged for further evaluation and treatment

Issues for Referral

Next day follow-up with PCP or ENT/GI

FOLLOW-UP RECOMMENDATIONS

- Clear liquid diet prior to ENT follow-up
- Return if SOB, chest pain, or unable to tolerate own secretions.

PEARLS AND PITFALLS

- Consider foreign-body aspiration in children presenting with dysphagia.
- Dysphagia is a common presentation in stroke.
- Consider in patients with recurrent pneumonia.
- Assess for life-threatening causes of dysphagia before deferring definitive diagnosis to outpatient setting.

DYSPNEA

Matthew M. Hall

BASICS

DESCRIPTION

Inability to breathe comfortably

- Describes a symptom of many possible underlying diseases
- Is different from signs of increased work of breathing
- Usually an unconscious activity, dyspnea is the subjective sensation of breathing, from mild discomfort to feelings of suffocation.
- Dyspnea comes from the Greek word for “hard breathing.”
- Often described as “shortness of breath”
- Common presenting complaint seen in 3.5% of ED visits
- Caused by difficulties in maintaining homeostasis with respect to gas exchange and acid–base status
- Dyspnea usually reflects an impairment in ventilation, perfusion, metabolic function, or CNS drive.
- Mechanisms that control breathing:
 - Control centers:
 - Brainstem and cerebral cortex affect both automatic and voluntary control of breathing.
 - Chemo, stretch, and irritant sensors:
 - CO₂ receptors located centrally and PO₂ receptors located peripherally.
 - Mechanoreceptors lie in respiratory muscles and respond to stretch.
 - Intrapulmonary mechanoreceptors respond to chemical irritation, engorgement, and stretch.
 - Effectors of respiratory center output are in the respiratory muscles and respond to central stimulation to move air in and out of the thoracic cavity.
 - Motor–sensory control of the diaphragm and muscles of respiration are controlled by C3–C8 nerves and T1–T12 nerves.
- Derangements of any of these neurosensory pathways produces dyspnea:
 - Many etiologies for the sensation of dyspnea are due to the complex nature of mechanisms that control breathing.

ETIOLOGY

- Upper airway:
 - Epiglottitis
 - Laryngeal obstruction
 - Tracheitis or tracheobronchitis

- Angioedema
- Pulmonary:
 - Airway mass
 - Asthma
 - Bronchitis
 - Chest wall trauma
 - CHF
 - Drug-induced conditions (e.g., crack lung, aspirin overdose)
 - Effusion
 - Emphysema
 - Lung cancer
 - Metastatic disease
 - Pneumonia
 - Pneumothorax
 - Pulmonary embolism
 - Pulmonary HTN
 - Restrictive lung disease
- Cardiovascular:
 - Arrhythmia
 - Coronary artery disease
 - Intracardiac shunt
 - Left ventricular failure
 - Myxoma
 - Pericardial disease
 - Valvular disease
- Neuromuscular:
 - CNS disorders
 - Myopathy and neuropathy
 - Phrenic nerve and diaphragmatic disorders
 - Spinal cord disorders
 - Systemic neuromuscular disorders
- Metabolic acidosis:
 - Sepsis
 - DKA
 - AKA
 - Renal failure
 - Profound thiamine deficiency
- Toxic:
 - Methemoglobinemia
 - Salicylate poisoning
 - Cellular asphyxiants:
 - Carbon monoxide
 - Cyanide

- Hydrogen sulfide
- Sodium azide
- Toxic alcohols
- Abdominal compression:
 - Ascites
 - Pregnancy
 - Massive obesity
- Psychogenic:
 - Hyperventilation
 - Anxiety
- Other:
 - Altitude
 - Anaphylaxis
 - Anemia

Geriatric Considerations

- Most common diagnoses in elderly patients presenting to the ED with dyspnea:
 - Decompensated heart failure
 - Pneumonia
 - COPD
 - Pulmonary embolism
 - Asthma

Pediatric Considerations

- Common conditions in differential diagnosis for age <2 yr:
 - Asthma
 - Croup
 - Congenital anomalies of the airway
 - Congenital heart disease
 - Foreign-body aspiration
 - Nasopharyngeal obstruction
 - Shock

DIAGNOSIS

SIGNS AND SYMPTOMS

- Difficult, labored, or uncomfortable breathing
- Upper airway:
 - Stridor
 - Upper-airway obstruction
- Pulmonary:
 - Tachypnea

- Accessory muscle use
- Wheezing
- Rales
- Asymmetric breath sounds
- Poor air movement
- Prolonged expiratory phase
- Cardiovascular:
 - S3 gallop
 - Murmur
 - Jugular venous distention
- CNS:
 - Altered levels of consciousness
- General:
 - Diaphoretic/cool vs. hot/dry skin
 - Pallor
 - Upright patient position
 - Clubbing
 - Cyanosis
 - Edema
 - Ketotic breath odor

History

- Previous history of dyspnea
- Time course, abruptness of onset, triggers, and severity
- History of stridor or wheezing
- Exercise (activity) tolerance
- Medications and recent compliance
- Exposure to allergens
- Past medical history
- Associated symptoms:
 - Chest pain
 - Fever
 - Cough
 - Hemoptysis

Physical-Exam

- Signs of acute distress:
 - Altered mental status
 - Cyanosis
 - Respiratory rate
 - Retractions suggest severe disease
- Listen for abnormal lung sounds:

- Stridor
- Rales
- Wheezing
- Decreased breath sounds

ESSENTIAL WORKUP

- Pulse oximetry:
 - May be falsely elevated due to increased ventilation or carbon monoxide
- End tidal CO₂:
 - Quickly gives hint of PaCO₂
 - Waveform can give clue to etiology
- CXR:
 - For diagnosis of pulmonary conditions
 - Assess heart size and evidence of CHF
- ABG:
 - Oxygenation
 - Calculate arterial–alveolar gradient:
 - A–a (at sea level) = $150 - (PO_2 - PCO_2)/0.8$, normal 5–20
 - Assess degree of acidosis

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - Evaluation for anemia
 - Neutrophil count helpful in evaluation of infectious processes
- Electrolyte, BUN, creatinine, glucose:
 - Consider when specific metabolic derangements are suspected
 - B-type natriuretic peptide may be elevated in CHF
- Toxicology screen
- Methemoglobin/carboxyhemoglobin level
- Thyroid function tests
- D-dimer (ELISA):
 - Useful for excluding pulmonary embolus if normal

Imaging

- Chest x-ray for infiltrate, effusion, pneumothorax, or vascular consolidation
- Ventilation–perfusion scan or CT pulmonary angiogram for suspected pulmonary embolism
- Soft tissue neck radiograph or fiberoptic visualization for suspected upper airway obstruction

Diagnostic Procedures/Surgery

- EKG for suspected myocardial ischemia, CHF, suspected pericardial effusion/tamponade
- Peak expiratory flow/spirometry to assess for reactive-airway disease
- Tensilon test for suspected myasthenia gravis

DIFFERENTIAL DIAGNOSIS

- Anticholinergic or adrenergic toxidrome
- Thyroid storm
- Munchausen syndrome

TREATMENT

PRE HOSPITAL

- Place all patients on supplemental oxygen, pulse oximetry, end tidal CO₂, and cardiac monitor.
- Initiate therapy for suspected cause of dyspnea when indicated:
 - Asthma
 - COPD
 - CHF
- Utilize advanced airways in the face of impending respiratory failure.

INITIAL STABILIZATION/THERAPY

- ABCs
- Immediate intubation for impending respiratory arrest:
 - Altered mental status
 - Unstable vital signs
- BiPAP in alert patients:
 - Contraindications:
 - Cardiac instability
 - Suspicion of upper airway obstruction
 - Inability to protect airway
 - Upper GI bleeding
 - Status epilepticus

ED TREATMENT/PROCEDURES

- Based on underlying etiology
 - Antibiotics and fluid for pneumonia
 - CPAP and diuretics for CHF
 - Bronchodilators and steroids for asthma
 - Aspirin, heparin, and lyrics/cath lab for MI
 - Other treatments as necessary for other etiologies

- Palliative care with opiates is indicated for the relief of dyspnea in terminally ill patients.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Assisted ventilation
- Hypoxia
- A-a gradient > 40
- Medical condition requiring hospital therapy

Discharge Criteria

- Adequate oxygenation
- Stable medical illness that can be managed as outpatient
- Adequate ambulatory pulse ox

Issues for Referral

Based on suspected underlying etiology

FOLLOW-UP RECOMMENDATIONS

- Patients should be told not to smoke while short of breath and to try to quit to help with some of the causes, as well as to prevent others from getting worse.
- The patient should return for any of the following problems:
 - No improvement or worsening in 24 hr
 - New chest pain, pressure, squeezing, or tightness
 - Shaking chills, or a fever > 102°F
 - New or worsening cough or wheezing
 - Abdominal (belly) pain, vomiting, severe headache
 - Dizziness, confusion, or change in behavior
 - Any serious change in symptoms, or any new symptoms that are of concern

PEARLS AND PITFALLS

- Altered mental status is an indication for immediate airway management in a patient with severe dyspnea.
- Dyspnea can and should be quantified.
- Dyspnea and tachypnea may occur without a respiratory etiology because of metabolic derangement or a catastrophic CNS event.

DYSTONIC REACTION

Kenneth Jackimczyk

BASICS

DESCRIPTION

- Normal pattern of CNS neurotransmission maintained by balance between dopaminergic and cholinergic receptors:
 - Certain drugs antagonize dopamine receptors in the basal ganglia resulting in an imbalance of dopaminergic and cholinergic stimulation
 - This imbalance leads to acute involuntary muscle spasms of the face or neck (the trunk, pelvis, or extremities can also be affected)
- Although the spasms are uncomfortable and frightening, they are not life threatening except in very rare cases when laryngeal muscles are involved
- Usually occurs within hours of ingestion:
 - Almost always within 1st wk after exposure to offending drug
- Risk factors:
 - Children and young adults are at higher risk
 - Rarely occurs in patients over 45 yr of age
 - Males more often affected
 - Prior episodes of dystonia significantly increase risk
 - Recent cocaine use increases risk

ETIOLOGY

- Usually occurs after patient has taken antipsychotic, antiemetic, or antidepressant drug
- Incidence of dystonic reactions varies widely (2–25%) depending on the potency of the agent
- Higher with more potent drugs (haloperidol, fluphenazine)
- Lower with less potent drugs (chlorpromazine, thioridazine)
- Lowest with atypical antipsychotics (quetiapine, olanzapine, risperidone)
- Antiemetic agents:
 - Metoclopramide (Reglan)
 - Prochlorperazine (Compazine)
 - Promethazine (Phenergan)
 - Droperidol (Inapsine)
- Other agents:
 - Cyclic antidepressants
 - H₂ blockers
 - Some antimalarial agents
 - Antihistamines

- Some anticonvulsants
- Doxepin
- Lithium
- Phencyclidine

Pediatric Considerations

Children are particularly vulnerable to dystonic reactions when dehydrated or febrile

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Ingestion of neuroleptic, antiemetic, or other drug within week of symptom onset
 - May occur in patients on neuroleptic agents who increase their dose of neuroleptics or reduce medications (anticholinergic agents) used to treat extrapyramidal symptoms
- Difficulty with vocalization
- Completely alert and able to answer questions, although facial muscle involvement may make speech difficult.
- Involuntary muscle contractions or spasms usually involving the face or neck (see “Physical Exam”):
 - Muscles of the trunk, pelvis, or extremities can also be involved

Physical-Exam

- Characteristic involuntary muscle spasms occur
- Oculogyric crisis
 - Involves eye and periorbital muscles
 - Evolves into painful upward or lateral deviation of the eyes
- Blepharospasm
 - Involuntary eyelid closure
- Buccolingual crisis
 - Involves facial muscles and the tongue
 - May have difficulty speaking
 - Facial grimacing
 - Trismus
 - Tongue protrusion
 - Dysphagia
- Spasmodic torticollis
 - Twisting of the neck
- Torticopelvic crisis
 - Abdominal wall muscle spasm

- Opisthotonos
 - Involves muscles of trunk and back
 - Twisting and arching of spine
- Laryngeal dystonia
 - Very rare but potentially life threatening
 - May develop airway obstruction due to laryngospasm
 - Presents as dysphonia or stridor

ESSENTIAL WORKUP

- Clinical diagnosis is based on characteristic signs and symptoms with history of possible drug exposure
- Diagnosis is confirmed by response to treatment
 - Lack of response to treatment should lead one to consider alternative diagnosis

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Lab testing not routinely indicated
- If no response to treatment, hypocalcemia should be considered and calcium level obtained

Imaging

No imaging studies needed

DIFFERENTIAL DIAGNOSIS

- Tardive dyskinesia:
 - Complication of chronic antipsychotic therapy
 - Usually choreiform movements
 - Does not rapidly improve with administration of anticholinergic drug
- Akathisia:
 - Involuntary motor restlessness
 - May appear agitated
- Seizure:
 - History of prior seizures
 - Not responsive to verbal stimuli
 - Tonic-clonic-type motor movements rather than spasm
- Hysteria or pseudoseizure:
 - History of precipitating emotional event
 - Tonic-clonic motor activity rather than sustained spasm
- Tetanus
- Strychnine poisoning
- Chronic dystonias:

- Cerebral palsy, familial choreas
- Usually history of dystonia is associated with chronic neurologic process
- Scorpion envenomation:
 - Oculogyric crisis and opisthotonos are common manifestations of scorpion envenomation
 - Patient lacks history of drug exposure.
- Meningitis and encephalitis may present with atypical seizures that mimic dystonic reaction
- Mandible dislocation
- Hypocalcemia

TREATMENT

PRE HOSPITAL

- Rarely life threatening
- Direct attention toward spasm of larynx and tongue to be sure dystonic reaction is not causing respiratory compromise
- Ask family and friends about ingestions of antipsychotic medications, antiemetics, and recreational drugs
- Transport pill bottles

INITIAL STABILIZATION/THERAPY

Stabilize airway to prevent spasm of larynx or tongue from causing respiratory compromise.

ED TREATMENT/PROCEDURES

- Administer diphenhydramine (Benadryl) or benztropine mesylate (Cogentin):
 - Rapid resolution of muscular spasm by restoring cholinergic–dopaminergic balance in CNS
 - IV administration is preferred route of treatment
 - Onset of relief in 2–5 min
 - Complete resolution of symptoms in 30 min
 - IM administration is alternate route of treatment
 - Begins to work in 15–30 min
 - Continue oral administration for 3 days to prevent redevelopment of symptoms
- Diazepam (Valium):
 - Administer in cases of dystonia unresponsive to adequate doses of anticholinergic medications
 - Failure to respond to standard treatment should lead physician to consider other diagnoses

MEDICATION

- Benztropine mesylate (Cogentin): 1–2 mg either IV (over 2 min) or IM followed by 1–2 mg PO BID for 3 days:
 - Not to be used in children < 3 yr old
 - For children > 3 yr old: 0.02 mg/kg IV (over 2 min) or IM followed by 0.02 mg/kg PO BID for 3 days
- Diphenhydramine (Benadryl): 1–2 mg/kg up to 100 mg either IV (over 2 min) or IM followed by 25–50 mg (peds: 1–2 mg/kg) PO q6–8h for 3 days, *or*
- Diazepam: 5–10 mg IV followed by 5 mg PO q4–6h as necessary for 3 days

First Line

Diphenhydramine (Benadryl)

Second Line

Benzotropine mesylate (Cogentin):

- Not to be used in children < 3 yr old
- Diazepam

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients are not admitted unless symptoms do not resolve with treatment, there are concerns about maintaining the airway, or the diagnosis is not certain
- If the dystonic reaction causes laryngospasm patient should be observed for 12–24 hr after symptoms resolve

Discharge Criteria

- Discharge after resolution of symptoms
- The offending agent should be discontinued
- Patient should not drive or perform tasks that require full alertness while taking sedating medications

FOLLOW-UP RECOMMENDATIONS

Patients should follow-up with the prescribing physician of the causative agent

PEARLS AND PITFALLS

- The diagnosis of acute dystonia is made based on the history of ingestion coupled with complete resolution of the symptoms after appropriate treatment
- 1st line of therapy is diphenhydramine
- Failure to respond should lead you to consider other diagnoses

ICD10

- G24.01 Drug induced subacute dyskinesia
- G24.02 Drug induced acute dystonia
- G24.09 Other drug induced dystonia

EATING DISORDER

Rohn S. Friedman

BASICS

DESCRIPTION

Anorexia Nervosa (AN)

- Restriction of intake, leading to markedly low body weight for age, height, and/or developmental trajectory
- Intense fear of gaining weight or becoming fat, or behavior that prevents weight gain
- Severe body image disturbance, undue influence of body weight and shape on self-evaluation, or denial of seriousness of low body weight
- Lifetime prevalence: 0.5% of females in US
- Typical age of onset for AN is bimodal at 13–14 yr and 17–18 yr

Bulimia Nervosa (BN)

- Recurrent episodes of binge eating characterized by:
 - Eating an unusually large amount of food in a discrete period of time
 - A sense of loss of control over eating during the episode
- Recurrent inappropriate compensatory behaviors used to prevent weight gain:
 - Self-induced vomiting
 - Misuse of laxatives or enemas
 - Diuretics
 - Diet pills
 - Fasting
 - Excessive exercise
- Bingeing and compensation occur on average at least once a week for 3 mo
- Self-evaluation that is excessively influenced by weight or body shape
- Lifetime prevalence: 2% of females in US
- Commonly onset in late adolescence or early adulthood.

Binge Eating Disorder (BED)

- Recurrent episodes of binge eating characterized by:
 - Eating a larger than usual amount of food in a discrete period of time
 - A sense of loss of control over eating during the episode
- Binge eating episodes associated with 3 or more of the following:
 - Eating much more rapidly than normal
 - Eating until feeling uncomfortably full
 - Eating large amounts of food when not feeling physically hungry

- Eating alone because of embarrassment about how much one is eating
- Feeling disgusted with oneself, depressed, or very guilty after overeating
- Marked distress over binge eating
- Occurs on average at least once a week for 3 mo
- No compensatory behavior
- Lifetime prevalence: 3.5% of females and 2% males in US
- Onset in late adolescence or early adulthood.

ETIOLOGY

- Twin studies have supported a strong genetic component.
- Cultural emphasis on thinness as a valued attribute has been implicated
- Temperament or personality attributes of perfectionism, anxiety, and behavioral rigidity have been described
- Family conflict or stress is a frequent element
- Neurochemical (serotonin) and neuroendocrinologic (leptin, HPA axis) abnormalities have been reported
- Dieting is a frequent immediate precipitant

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Rapid or sustained weight loss
- Typical detailed day's eating pattern shows restricting and/or bingeing behavior
- Purging (vomiting, laxatives, diuretics, enemas)
- Excessive exercise
- Dizziness, syncope
- Bloating (gastroparesis), constipation, abdominal pain
- Fatigue, lethargy
- Palpitations
- Cold intolerance
- Amenorrhea, loss of libido
- Family history of eating disorders and obesity
- Comorbid psychiatric disorder (e.g., mood disorder, substance abuse, personality disorder)

Physical-Exam

- Weight < 85% IBW or BMI < 17.5 for AN
- Hypothermia
- Hypotension, orthostasis
- Bradycardia, arrhythmia

- Skin: Dry skin, lanugo (soft downy body hair on chest and arms), carotenoderma
- Breast atrophy
- Parotid swelling, submandibular swelling
- Abnormal dentition
- Abrasions of dorsum of hand
- Skin breakdown, poor wound healing
- Peripheral edema
- Muscle weakness

ESSENTIAL WORKUP

- History
- Physical exam
- Lab testing
- Nutritional assessment
- Psychiatric interview:
 - Concurrent psychiatric illness
 - Suicide risk assessment
 - Explore psychosocial context
- Family evaluation when patient lives with his or her family

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC (anemia, leukopenia, thrombocytopenia)
- Electrolytes, BUN, creatinine, glucose (hyponatremia, hypokalemia, hypoglycemia, dehydration, metabolic alkalosis)
- Calcium, magnesium, phosphorus, albumin (hypocalcemia, hypomagnesemia, hypophosphatemia, hypoalbuminemia)
- LFTs (hepatic dysfunction)
- UA including specific gravity
- Toxic screen
- β -hCG
- Amylase (salivary hyperamylasemia if vomiting, pancreatitis)
- Lipase (more accurate than amylase in predicting pancreatitis)
- Consider checking thyroid-stimulating hormone.

Imaging

Specific tests may be useful in making differential diagnoses, e.g., MRI (rule out brain tumor), abdominal CT (rule out obstruction)

Diagnostic Procedures/Surgery

- ECG (QTc prolongation, arrhythmia)
- Consider cardiac echo if substantial weight loss (cardiomyopathy from AN or

ippecac)

- Bone mineral density (osteoporosis)

DIFFERENTIAL DIAGNOSIS

- Medical conditions:
 - GI disease (e.g., Crohn's Disease, IBD, celiac disease)
 - Endocrine disorder (e.g., DM, thyroid disorder, adrenal insufficiency)
 - Cancer
- Psychiatric conditions
 - Borderline personality disorder
 - Mood disorders
 - Obsessive-compulsive disorder
 - Substance abuse

TREATMENT

INITIAL STABILIZATION/THERAPY

- ABCs
- Careful fluid resuscitation for dehydration to avoid precipitating peripheral or pulmonary edema
- Replete phosphate and thiamine since both may drop with refeeding
- Correct hypokalemia, hypomagnesemia, hypocalcemia
- Correct hypoglycemia
- Warming blankets for severe hypothermia

ED TREATMENT/PROCEDURES

- Initial workup
- Medical stabilization
- Psychiatric consultation (including assessment of suicide risk and psychiatric comorbidities)

MEDICATION

First Line

- No medication has been demonstrated to be of benefit for AN per se
 - Small trials have suggested possible benefit from atypical antipsychotics, particularly olanzapine 2.5–10 mg PO QD
 - It may be helpful to treat psychiatric comorbidities
- Only fluoxetine 20–60 mg PO QD has FDA indication for the treatment of BN, though other SSRIs are frequently used. There is also evidence for tricyclic antidepressants as well as topiramate
- There is evidence for imipramine, sertraline, citalopram/escitalopram, and

FOLLOW-UP

DISPOSITION

Admission Criteria

- Medical risk:
 - Extremely low weight ($< 75\%$ IBW)
 - Rapid weight loss
 - Serum electrolyte imbalance (K < 3 , glucose < 60)
 - Bradycardia < 40
 - BP $< 90/60$
 - Orthostasis (> 20 bpm or > 20 mm Hg/10 mm Hg)
 - Hypothermia $< 97^{\circ}\text{F}$
 - Arrhythmia or heart failure
 - Hepatic or renal dysfunction
- Psychiatric risk:
 - Severe depression, psychosis, or other comorbid psychiatric diagnosis
 - Suicidality
 - Lack of motivation or cooperation with treatment
 - Failure of outpatient treatment
 - Severe impairment in functioning
 - Toxic family environment

Discharge Criteria

- Medically and psychologically safe enough to be managed on an outpatient basis
- Multimodal, multidisciplinary team in place to manage medical, nutritional, and psychological issues

Issues for Referral

- Outpatient treatment requires a team approach composed of a:
 - Psychiatrist and/or psychologist
 - Nutritionist, preferably one who specializes in eating disorders
 - Pediatrician or internist
 - Family therapist
 - Group therapist
 - Dentist
- Prognosis:
 - AN and BN:
 - 20% chronic course
 - 30% improve

- 50% recover
- Mortality rate 5.6% per decade for AN
- Outcomes improved with early diagnosis and treatment

FOLLOW-UP RECOMMENDATIONS

- For outpatient treatment the team must establish modest goals and clear parameters, including expected weight gain for anorexic patients and compliance with follow-up appointments.
- Internist/pediatrician: Monitor vital signs, weight, BMI, electrolytes, and ECG.
- Nutritionist: Monitor diet, calorie intake, and exercise.
- Psychotherapy:
 - Cognitive behavioral therapy and interpersonal psychotherapy are the most effective forms of psychotherapy for BN.
 - Cognitive behavioral therapy, family therapy, and psychodynamic therapies are all useful for AN.
 - Family-based treatment is the preferred therapy for teenagers with AN, and it is promising for teenagers with BN as well.
- Pharmacotherapy:
 - Only indicated within the context of psychotherapy, especially with comorbid psychopathology.
 - No accepted pharmacologic treatment of AN.
 - Case studies suggest that 2nd-generation antipsychotics may be helpful in AN.
 - There is no clear evidence for specific treatment of osteoporosis in AN apart from weight restoration and nutritional calcium supplementation.
 - Antidepressant medications are shown to significantly reduce bingeing and purging behaviors:
 - Fluoxetine is the best studied

PEARLS AND PITFALLS

- Eating disorders are associated with high medical risk and risk of suicide; prioritize safety assessment
- Rapid restoration of nutrition, volume resuscitation, and/or failure to replete vitamins and electrolytes can result in potentially fatal refeeding syndrome
- Avoid trying to “out-obsess” the obsessional patient
- Coordinate care with PCP and other members of a multidisciplinary team

ECTOPIC PREGNANCY

Ivette Motola • Aviva Jacoby Zigman

BASICS

DESCRIPTION

- Implantation of fertilized ovum outside of uterus:
 - Most commonly fallopian tube (93–97%)
- Abdominal and peritoneal implantations:
 - Associated with higher morbidity
 - Difficulty in diagnosis
 - Tendency to bleed
- Occurs in 2–2.6% of pregnancies
- Accounts for 6% of all maternal deaths (leading cause of 1st-trimester pregnancy-related death)
- 60% of women with ectopic pregnancy are subsequently able to have a normal pregnancy

ETIOLOGY

- Risk factors include:
 - Woman > 35 yr old
 - African American
 - Previous fallopian tube damage from infections, such as pelvic inflammatory disease (PID)
 - Previous tubal surgery (i.e., tubal ligation)
 - Previous ectopic pregnancy
 - Intrauterine device (IUD) use:
 - 25–50% of pregnancies with IUD are ectopic
 - Diethylstilbestrol (DES) exposure
 - In vitro fertilizations
 - Being a current smoker
- More than half of women with ectopic pregnancies have no risk factors

DIAGNOSIS

SIGNS AND SYMPTOMS

Classic triad of amenorrhea, vaginal bleeding, and abdominal pain are present in only 15% of women with ectopic pregnancies:

- Amenorrhea (75–95%)
- Abdominal pain (80–100%):
 - Frequently unilateral

- Abnormal vaginal bleeding (50–80%)
- Symptoms of pregnancy (10–25%)
- Orthostatic hypotension, dizziness, and syncope (5–35%)
- Abdominal tenderness (55–95%)
- Adnexal tenderness (75–90%)
- Adnexal mass (35–50%)
- Cervical motion tenderness (43%)

History

- Last menstrual period (LMP):
 - Majority of ectopics present 5–8 wk after LMP.
- Gestation and parity history
- Vaginal bleeding
- Location, nature, and severity of pain
- History of pelvic surgery, prior ectopic, IUD
- History of fertility treatments

Physical-Exam

- Evaluate for signs of peritoneal irritation
- Pelvic exam:
 - Note uterine size
 - Adnexal size, mass
 - Adnexal tenderness
 - Presence of tissue in vaginal vault
 - Cervical motion tenderness
 - Cervical OS open or closed

ESSENTIAL WORKUP

- Pregnancy testing:
 - Women of potential childbearing age with vaginal bleeding or abdominal pain *must* have urine or serum pregnancy test
 - Include testing of patients with history of recent elective or spontaneous abortion, tubal ligations, or IUD use
 - Quantitative β -human chorionic gonadotropin (β -hCG) in patients with positive qualitative test
- Vital signs unstable:
 - 2 large-bore IVs
 - Type and cross-match, hemoglobin (Hg)/hematocrit (Hct)
 - Bedside ultrasound (US), if immediately available, simultaneous with resuscitation (transvaginal preferred)
 - Consult obstetrics/gynecology (OB/GYN) and prepare for immediate surgical intervention
- Vital signs stable:

- Rapid Hg/Hct determination
- Type and Rh
- US (transvaginal preferred)

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Urine pregnancy tests can detect β -hCG levels of 25–50 mIU/L
- Serum can detect β -hCG levels of 25 mIU/L
- Quantitative serum β -hCG; for diagnosis and follow-up:
 - Doubles every 2 days in normal early pregnancy (early pregnancy < 10,000 β -hCG mIU/L, 8 days–7 wk)
 - β -hCG increases less in ectopic pregnancy
 - Correlation with vaginal US increases predictive value

Imaging

- Ultrasonographic evidence of IUP makes ectopic pregnancy less likely:
 - Heterotopic pregnancies are possible
- Positive IUP is indicated by double-ringed gestational sac, yolk sac, or fetal pole, and heartbeat seen in uterus
- Transvaginal US; visualization of gestational sac at 5 wk, cardiac activity at 6.5 wk
- Transabdominal US; visualization of gestational sac at 5–6 wk, cardiac activity at 8 wk
- Complex adnexal mass and fluid in cul-de-sac seen in 22% of ectopics and has 94% positive predictive value when present
- Positive pregnancy test with no confirmed IUP and fluid in pelvis; high risk for bleeding ectopic pregnancy

Diagnostic Procedures/Surgery

- US in conjunction with quantitative β -hCG
- Patients with β -hCG levels > 6,500 mIU/L and no intrauterine gestational sac seen on US have 100% chance of having ectopic pregnancy
- Patients with β -hCG levels > 6,500 mIU/L with intrauterine gestational sacs present have 94% chance of having normal pregnancy
- Patients with β -hCG < 2,000 mIU/L are too early to have gestational sac seen by abdominal US and thus cannot be ruled out for ectopic pregnancy
- Patients with β -hCG > 2,000 and < 6,500 mIU/L should have IUP visualized on transvaginal US; suspect ectopic pregnancy if IUP is absent
 - Discriminatory hCG value for transvaginal US is between 1,500 and 3,000 mIU/mL
- Culdocentesis to evaluate for intraperitoneal blood if US is unavailable

DIFFERENTIAL DIAGNOSIS

- Positive pregnancy test with vaginal bleeding:
 - Spontaneous abortion
 - Cervicitis
 - Trauma
- Positive pregnancy test with no evidence of IUP:
 - Completed spontaneous abortion
 - Early threatened abortion
- Positive pregnancy test with evidence of IUP, abdominal pain, or adnexal tenderness:
 - Septic abortion
 - Threatened abortion
 - Ruptured corpus luteal or ovarian cyst
 - Ovarian torsion
 - UTI
 - Nephrolithiasis
 - Gastroenteritis
 - Appendicitis
 - Heterotopic pregnancy (IUP + ectopic)
 - PID

TREATMENT

PRE HOSPITAL

Cautions: Female patients of childbearing age presenting in shock may have unrecognized ruptured ectopic pregnancy

INITIAL STABILIZATION/THERAPY

- Vital signs unstable:
 - Airway management, resuscitate as needed
 - Fluid therapy with 2 large-bore IVs, oxygen, and monitor
 - Type specific, or O-negative blood if hypotensive after initial fluid bolus
 - Consult gynecology and transport to OR immediately for surgery
- Vital signs stable:
 - Evidence of ectopic pregnancy on US:
 - Obstetric–gynecologic evaluation for surgery vs. outpatient methotrexate treatment
 - For patients in whom future fertility is desired, methotrexate is the best option; otherwise surgery is the definitive treatment
 - No evidence of ectopic pregnancy (pregnancy of unknown location [PUL]: Early IUP vs. early ectopic):
 - Desired pregnancy: Serial β -hCG every 48 hr in stable, reliable

- patients and in conjunction with obstetrician
- Undesired pregnancy: Dilation and curettage to evacuate uterus and confirm presence of products of conception

ED TREATMENT/PROCEDURES

Methotrexate: Initiated only in conjunction with obstetric consultant and close follow-up:

- Reliable patients with unruptured ectopic pregnancies < 3.5 cm
- β -hCG levels < 6,000–15,000
- Contraindications:
 - Breast-feeding
 - Immunodeficiency
 - Pre-existing blood dyscrasia
 - Clinically significant anemia
 - Known sensitivity to methotrexate
 - Active pulmonary disease
 - Peptic ulcer disease
 - Hepatic dysfunction
 - Renal dysfunction
 - Alcoholism
 - Alcoholic liver disease
 - Ectopic mass > 3.5 cm (relative contraindication)
 - Embryonic cardiac motion (relative contraindication)
- Most common dosing, single dose (50 mg/m²); serial β -hCG on days 2, 4, and 7
 - If < 25% decline in β -hCG from day of 1st injection, 2nd dose is given
- Multidose treatment is associated with less treatment failure
- Common side effects:
 - Worsening abdominal pain
 - Nausea, vomiting, and diarrhea
- Worsening abdominal pain usually occurs 3–7 days after methotrexate initiation.
 - These are usually tubal miscarriages
 - Follow-up USs are essential to rule out ectopic rupture
- Most common complication, tubal rupture in 4%
- Factors associated with methotrexate treatment failure:
 - Initial hCG > 5,000 mIU (5,000–9,999 mIU/mL—13% failure rate, > 15,000 mIU/mL failure rate as high as 32%)
 - Moderate to large free peritoneal fluid on US
 - Presence of fetal cardiac activity
 - Pretreatment increase in serum hCG level of more than 50% over a 48 hr period

MEDICATION

- Methotrexate: 50 mg/m² IM/IV × 1
- RhoGAM in Rh-negative women: 50 µg IM in women ≤12 wk pregnant; 300 µg IM in women >12 wk pregnant

FOLLOW-UP

DISPOSITION

Admission Criteria

- Any patient with confirmed ectopic pregnancy who is hemodynamically unstable
- Unreliable patients with increased risk factors, no available US, β-hCG >6,500 with no evidence of IUP should be admitted for observation and serial β-hCG tests

Discharge Criteria

- Decision for outpatient management should be made in conjunction with OB/GYN
- Hemodynamically stable and reliable patients with workup that cannot rule out ectopic pregnancy:
 - Strict follow-up for serial β-hCG tests every 2 days
 - Patients should be recorded in logbook with phone numbers to ensure follow-up
- *Ectopic precautions:* Patients should return to emergency room immediately for:
 - Increasing abdominal pain
 - Vaginal bleeding
 - Syncope or dizziness
 - Patients should not be left alone until diagnosis of ectopic pregnancy can be safely ruled out
 - Family and friends should also be instructed on warning signs and symptoms of ruptured/bleeding ectopic pregnancies

Issues for Referral

Phone consultation (at a minimum) with OB/GYN is essential when discharging a possible ectopic pregnancy

FOLLOW-UP RECOMMENDATIONS

All patients with positive pregnancy tests and unconfirmed IUP must be followed by an OB/GYN

PEARLS AND PITFALLS

- Always obtain a pregnancy test on women of childbearing age
- Obtain serum hCG and transvaginal ultrasonography in all women with positive pregnancy test presenting with abdominal pain or vaginal bleeding

- Recognize the possibility of heterotopic pregnancies, especially in women undergoing fertility treatment
- Secure close follow-up for any patient being evaluated and discharged for ectopic pregnancy

ECZEMA/ATOPIC DERMATITIS

James A. Nelson

BASICS

DESCRIPTION

- Atopic dermatitis is the most common cause of eczema and the terms are often used synonymously.
 - Associated with allergic diseases such as asthma and allergic rhinitis
- Eczema literally means “out boil” and refers to spongiosis, the process where microvesicles form and rupture, leaving erythema, edema, crusting, and oozing
- Pruritus is highly characteristic
 - Patient rub and scratch skin breakdown with oozing and crusting
 - Chronically this causes epidermal hyperplasia and hyperkeratosis
- 90% of patients colonize with *Staphylococcus aureus*, and are prone to episodes of superinfection

RISK FACTORS

Genetics

- Family history of atopy (asthma, allergic rhinitis) typical
- Mutation of the filaggrin protein, part of the epidermal barrier, is strongly associated

ETIOLOGY

Atopic dermatitis is caused by a deficit in epidermal integrity that allows foreign substances to enter and trigger immune responses.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Rash, pruritus, and atopy traditionally prompt the diagnosis
- UK diagnostic criteria = pruritus and 3 of the following:
 - Flexural distribution
 - Atopic history (asthma or allergic rhinitis)
 - History of dry skin
 - Onset age < 2 yr
 - Objective signs of flexural dermatitis
- Additional findings:

- Cutaneous infections
- Itch when sweating
- Intolerance to wool and lipid solvents
- Triggered by stress

Physical-Exam

Dermatitis, located on areas of trauma or motion such as hands and feet and flexural areas

- Epidermal compromise:
 - Dry skin
 - Weeping
 - Oozing
 - Finally crusting
- Inflammation:
 - Maculopapular erythema
 - Edema
- Scratching leads to:
 - Excoriation
 - Cracking
 - Lichenification
 - Hyperkeratosis
- Additional findings:
 - Ichthyosis, palmar hyperlinearity, keratosis pilaris
 - Hand or foot dermatitis
 - Nipple eczema
 - Cheilitis
 - Dennie–Morgan infraorbital fold
 - Orbital darkening
 - Facial pallor or facial erythema
 - Pityriasis alba
 - Perifollicular accentuation
 - White dermographism or delayed blanch

Pediatric Considerations

- 70% of all cases begin during the 1st 5 yr of life
- Only 10% of cases start in adulthood
- 30% of children with atopic dermatitis develop asthma, 35% develop allergic rhinitis
- Infant distribution is classically extensor surfaces and head and face

ESSENTIAL WORKUP

History and physical exam

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Clinical diagnosis
- IgE commonly elevated but does not usually need to be tested

Diagnostic Procedures/Surgery

Generally reserved for settings outside of the ED:

- Radioallergosorbent test (RAST) sometimes used to identify allergic triggers
- Patch testing used if contact dermatitis is suspected

DIFFERENTIAL DIAGNOSIS

- Seborrheic dermatitis
- Neurodermatitis (lichen simplex chronicus)
- Allergic contact dermatitis
- Irritant dermatitis
- Psoriasis
- Dyshidrosis
- Ichthyosis
- Scabies

TREATMENT

ED TREATMENT/PROCEDURES

- Mild disease or disease of the head and neck:
 - Low-potency corticosteroids such as hydrocortisone 1–2.5%
 - Eucerin cream: Apply to affected areas BID
- Moderate or severe disease of the trunk and extremities:
 - Higher-potency corticosteroids such as triamcinolone 0.1% (moderate potency) or fluocinonide 0.05% ointment (high potency)
- Severe disease of the head and neck:
 - Topical calcineurin inhibitors such as pimecrolimus and tacrolimus
- 1st-generation antihistamines:
 - Diphenhydramine, hydroxyzine are used for relief of itching but are only weakly effective
- Behavioral interventions:
 - Avoid excessive bathing
 - Use of tepid water and mild soaps
 - Frequent use of emollients (Eucerin cream, Aquaphor ointment)
- Bacterial superinfection: Cephalexin, cefazolin:
 - Consider MRSA

MEDICATION

- Aquaphor ointment: Apply to affected areas BID
 - Contains lanolin alcohol
- Cephalexin: 500 mg (peds: 25–100 mg/kg/24h) PO q6h
- Diphenhydramine: 25–50 mg (peds: 5 mg/kg/24h) PO or IV q6h
- Eucerin cream: Apply to affected areas BID
 - Contains lanolin alcohol
- Fluocinonide 0.05% ointment: Apply to affected areas of body BID for the duration of the flare (high potency)
- Hydrocortisone 2.5% ointment: Apply to affected areas of body/face BID for the duration of the flare (low potency)
- Hydroxyzine: 25–100 mg (peds: 2 mg/kg/24h) PO q4–6h
- Pimecrolimus 1% cream: Apply to affected areas BID (peds: > 2 yr of age) for the duration of the flare
- Tacrolimus ointment: 0.1% (peds: > 2 yr of age: 0.03%) apply to affected areas BID for the duration of the flare
- Triamcinolone 0.1% ointment: Apply to affected areas of body BID for the duration of the flare (mid potency)

First Line

- Hydrocortisone 2.5% ointment: Apply to affected areas of body/face BID for the duration of the flare (low potency)
- Aquaphor ointment: Apply to affected areas BID

Second Line

- Triamcinolone 0.1% ointment: Apply to affected areas of body BID for the duration of the flare (mid potency)
 - Avoid the face and eyelids
- Fluocinonide 0.05% ointment: Apply to affected areas of body BID for the duration of the flare (high potency)
 - Avoid the face and eyelids
- Tacrolimus ointment: 0.1% (peds: > 2 yr of age: 0.03%) apply to affected areas BID for the duration of the flare
 - Can be used on the face
- Pimecrolimus 1% cream: Apply to affected areas BID (peds: > 2 yr of age) for the duration of the flare
 - Can be used on the face

FOLLOW-UP

DISPOSITION

Issues for Referral

Dermatology referral for problematic cases

FOLLOW-UP RECOMMENDATIONS

- Patients should be warned of adverse consequences of treatment:
 - High-potency steroids can cause thinning of the skin
 - Tacrolimus and pimecrolimus cause a stinging sensation for the 1st wk of therapy. Long term use can increase risk of cancer

PEARLS AND PITFALLS

- Consider secondary cellulitis, as 90% of patients with atopic dermatitis are eventually colonized with *S. aureus*
- Use tacrolimus and pimecrolimus for moderate to severe disease of the head and neck
- Consider in any patient with a severely pruritic rash
- Lotions have low lipid content and can cause drying
 - Heavy creams are preferred
- Do not use triamcinolone or fluocinonide on face or eyelids

EDEMA

Laura J. Macnow

BASICS

DESCRIPTION

- Clinically apparent accumulation of extravascular fluid due to a derangement in the balance of oncotic and hydrostatic forces:
 - Increase in venous/capillary hydrostatic pressure
 - Decrease in plasma oncotic pressure
 - Increase in interstitial oncotic pressure
 - Increase in capillary permeability
 - Increase in lymphatic pressure due to obstruction
 - Combination of these factors
- Generalized, as with CHF or nephrotic syndrome
- Localized, as with deep vein thrombosis
- Increased venous hydrostatic pressure or decreased oncotic pressure results in pitting edema
- Protein-rich extravasated fluid results in nonpitting edema
- In certain disorders, there is no clear relation to Starling forces:
 - Idiopathic (cyclic) edema:
 - Worsened with heat
 - More common in women
 - Not necessarily related to menses

ETIOLOGY

- Generalized:
 - Heart failure
 - Cor pulmonale
 - Cardiomyopathies
 - Constrictive pericarditis
 - Pulmonary HTN:
 - Sleep apnea
 - COPD
 - Acute glomerulonephritis
 - Renal failure
 - Medication related (often secondary to salt retention):
 - Steroids/estrogens/progestins
 - NSAIDs
 - Antihypertensives (especially vasodilators)
 - Lithium

- Cyclosporine
- Insulin
- Thiazolidinediones (glitazones)
- Growth hormone
- Interleukin-2
- MAOIs
- Pramipexole
- Docetaxel
- Minoxidil
- Acute withdrawal of diuretics
- Idiopathic (cyclic) edema
- Myxedema
- Cirrhosis
- Nephrotic syndrome
- Protein-losing enteropathy/malabsorption
- Starvation
- Pregnancy
- Localized:
 - Deep vein thrombosis
 - Venous insufficiency
 - Thrombophlebitis
 - Chronic lymphangitis
 - Cellulitis
 - Baker cyst
 - Vasculitis
 - Angioedema:
 - Allergic
 - Acquired
 - Hypothyroidism (myxedema)
 - Mechanical trauma
 - Thermal injuries
 - Radiation injuries
 - Chemical burns
 - Hemiplegia
 - Reflex sympathetic dystrophy
 - Compressive or invasive tumor
 - Postsurgical resection of lymphatics
 - Postirradiation
 - Filariasis

SIGNS AND SYMPTOMS

- Weight gain of several kilograms
- Discomfort in the affected areas
- Swelling
- Tenderness
- Pitting edema:
 - Increased venous hydrostatic pressure or decreased oncotic pressure
- Nonpitting edema:
 - Protein-rich extravasated fluid
- Generalized edema (anasarca):
 - Edema is most prominent in dependent areas:
 - Feet
 - Sacrum
 - Bilateral lower extremities
 - Face/periorbital (especially in the morning)
 - Cardiac:
 - Dyspnea
 - Orthopnea
 - Paroxysmal nocturnal dyspnea
 - Increased jugular venous pressure
 - Rales
 - S3 gallop
 - Renal:
 - Anorexia
 - Puffy eyelids
 - Frothy urine
 - Oliguria
 - Dark urine
 - Hematuria
 - HTN
 - Hepatic:
 - Jaundice
 - Spider angiomas
 - Palmar erythema
 - Gynecomastia
 - Testicular atrophy
 - Ascites
 - Myxedema:
 - Pretibial nonpitting edema
 - Dry waxy swelling of skin and SC tissues
 - Periorbital most common (puffy eyes)
 - Nondependent areas
 - Fatigue

- Cold intolerance
- Weight gain
- Constipation
- Slowed deep-tendon reflex relaxation
- Idiopathic:
 - Diurnal weight gain/loss
- Localized:
 - Chronic venous insufficiency:
 - Chronic pitting
 - Skin discoloration (hemosiderin deposits)
 - Dermatitis/ulceration
 - Varicose veins
 - History of trauma:
 - Mechanical, thermal, radiation
 - Infectious/inflammatory:
 - Chills
 - Fever
 - Erythema
 - Increased warmth
 - Allergic:
 - Pruritus
 - Hives
 - Involvement of the lips and the oral mucosa

Pregnancy Considerations

- Common secondary to hormonally mediated fluid retention
- When involving hands and face, may be early sign of preeclampsia
- Dependent edema:
 - Usually in late pregnancy
 - From impedance of venous return
- Diuretics contraindicated

ESSENTIAL WORKUP

Diagnostic studies should be directed by the underlying etiology suggested by the history and physical exam.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Cardiac etiology suspected:
 - BNP or NT-proBNP
- Deep vein thrombosis suspected:
 - d-dimer (for patients with low clinical probability to rule out DVT)

- Renal etiology suspected:
 - Electrolytes
 - BUN and creatinine
 - Urinalysis
 - Urine electrolytes and protein
 - Serum lipids
- Hepatic etiology suspected:
 - Serum albumin
 - Liver function tests
 - Prothrombin time and partial thromboplastin time
- Myxedema suspected:
 - Thyroid function tests

Imaging

- Cardiac etiology suspected:
 - EKG
 - CXR
 - ECG
- Localized edema to an extremity:
 - US (duplex scanning) or contrast venography
- High suspicion for abdominal or pelvic malignancy:
 - Abdominal/pelvic CT

DIFFERENTIAL DIAGNOSIS

- Cellulitis
- Contact dermatitis
- Diffuse SC infiltrative process
- Lymphedema
- Obesity

TREATMENT

INITIAL STABILIZATION/THERAPY

See “ED Treatment.”

ED TREATMENT/PROCEDURES

- Treatment should be directed toward the underlying cause.
- Diuretics are usually indicated in cases of generalized edema but are not required emergently.
- Diuretics may be deleterious in patients with cirrhosis and ascites, as rapid fluid shifts may precipitate hepatorenal syndrome.

MEDICATION

- Amiloride: 5–10 mg PO daily
- Captopril: 6.25–100 mg PO TID (max. 450 mg/d)
- Furosemide: 20–80 mg IV/PO QID (max. 600 mg/d)
- Hydrochlorothiazide: 25–100 mg PO BID
- Spironolactone: 25–200 mg PO BID

FOLLOW-UP

DISPOSITION

Admission Criteria

- Base the decision to admit the patient on the underlying etiology.
- Concomitant cardiovascular or pulmonary compromise
- Inability to ambulate without adequate home support
- Hypoxia

Discharge Criteria

- Patient should be advised to decrease salt intake.
- Elastic support stockings
- Elevation of involved limbs

Issues for Referral

- Patients > 45 yr with chronic edema, or whose symptoms suggest a cardiopulmonary etiology require follow-up EKG.
- Patients with pulmonary HTN of unknown cause should be referred for a sleep study to evaluate for sleep apnea.
- A negative US in a patient at high risk for DVT requires urgent repeat study in 5–7 days.

FOLLOW-UP RECOMMENDATIONS

Patients with chronic edema may follow-up with primary care doctor for continued workup and treatment.

PEARLS AND PITFALLS

- Classify edema as generalized vs. localized, pitting vs. nonpitting.
- Pitting edema is caused by “protein-poor” extravasated fluid (by increased hydrostatic pressure or decreased oncotic pressure).
- Nonpitting edema is caused by “protein-rich” extravasated fluids (lymphedema or increased capillary permeability).
- Generalized or bilateral leg edema necessitates workup of systemic disease.

- Acute unilateral leg edema requires evaluation for DVT.
- Consider preeclampsia in pregnant patients.

EHRlichiosis

Roger M. Barkin • Jonathan A. Edlow

BASICS

DESCRIPTION

- Tick-borne human infection presenting as a nonspecific febrile illness
- Several forms of ehrlichiosis exist; 2 predominate in North America
 - Human monocytic ehrlichiosis (HME), 1st described in 1987:
 - Vector tick: *Amblyomma americanum* (lone star tick)
 - Geographic range: Central, southern, and mid-Atlantic states, with range expanding to parts of New England
 - Human granulocytic ehrlichiosis or human granulocytic anaplasmosis (HGE or HGA), 1st described in 1994:
 - Vector tick: *Ixodes scapularis* (deer tick)
 - Geographic range: East Coast, mid-Central States, and Pacific Northwest (same areas as Lyme disease which is more common in US than HME)
- All are tick borne but have different vectors and geographic ranges. Other species have been reported, but at present HME and HGE are the important ehrlichial human pathogens.

ETIOLOGY

- 2 distinct species of obligate intracellular organisms
- The taxonomy of these pathogens has changed in recent years as more DNA and ribosomal RNA data become available.
- HME is caused by the organism *Ehrlichia chaffeensis*.
- HGE/HGA is caused by *Anaplasma phagocytophila* (a new name as of 2002).
- The vasculitis found in Rocky Mountain spotted fever (RMSF) is usually not present.
- A 3rd type may also be encountered, caused by *Ehrlichia ewingii*, which has the tick vector of the lone star tick. Clinically similar to HME.
- Compared with RMSF, older individuals are usually affected, commonly >40 yr of age.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Signs and symptoms of HME and HGE/HGA are similar.
- Many patients who are infected undergo asymptomatic seroconversion.
- The spectrum reported may overrepresent the more severely affected patients.

- With any tick-borne infection, patients can be coinfecting by more than 1 pathogen from the same tick bite:
 - May have a complicated presentation of 2 different diseases
- 1/4 of children have severe disease.

History

- The season and other epidemiologic factors are important in diagnosing tick-borne diseases:
 - Most commonly present from April to October
 - Variability is likely owing to changes in weather patterns from year to year and from region to region.
- Symptom onset from 1–2 wk (median 9–10 days) following the tick bite:
 - Bite of the larger lone star tick is more likely to be recalled by the patient than that of the smaller deer tick.
- Abrupt onset of:
 - Fever
 - Chills
 - Headache
 - Myalgias
 - Malaise
- Rash:
 - HME (35–60% of cases)
 - HGE or HGA (~5–10% of cases)
 - Often delayed and may be variable
- Symptoms may relate to complications of ehrlichiosis, such as:
 - ARDS
 - Renal failure
 - Hypotension and shock
 - Rhabdomyolysis
 - GI disturbances
 - CNS or peripheral nervous system (PNS) involvement, such as encephalopathy and meningitis as well as seizures
 - DIC
 - Immunocompromised patients have more severe complications.

Physical-Exam

- Fever
- Rash:
 - May be macular, maculopapular, or petechial
 - May be absent during 1st wk of illness
 - Usually involves trunk and spares hands and feet
- Lymphadenopathy

- Hepatosplenomegaly
- Neurologic findings:
 - Abnormal mental status
 - Meningismus
 - Nystagmus
- Pulmonary findings (rales, rhonchi) depending on pulmonary complications

Pediatric Considerations

- Fever, headache, and rash present in 48%
- Lymphadenopathy in 45%

ALERT

- Ehrlichiosis is a potentially fatal tick-borne illness that is usually diagnosed clinically.
- Consider this diagnosis in all patients with nonspecific febrile illnesses, especially during the warm months of the year, and definitely if there is a history of tick bite.
- The Centers for Disease Control and Prevention (CDC) define the illness as fever with 1 or more of the following: Headache, myalgia, anemia, leukopenia, thrombocytopenia, or elevation of serum transaminase; + serologic evidence of 4-fold change in IgG specific antibody by IFA or detection of specific target by PCR assay, demonstration of antigen on biopsy/autopsy sample, or isolation of organism in cell culture.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - Leukopenia
 - Thrombocytopenia
 - Anemia
- Hepatic transaminases:
 - Often elevated 2–6 times normal
- Indirect immunofluorescence antibody test, specific for HME and HGA
 - Usual test available
 - Threshold for a positive test is usually made by the individual lab testing the serum.
 - 94–99% sensitive when 2nd sample obtained over 14 days from onset of illness
- Wright stain of peripheral blood:
 - Morula may be seen:
 - Small intracytoplasmic ehrlichial DNA inclusion bodies
 - Diagnostic
 - Sensitivity of seeing morulae depend on who is looking, for how long,

and the immunologic competence of the patient.

- Found more commonly in HGE/HGA (~50%) than in HME (~10–15%)
- Culture and PCR for HEM and HGA
 - Not routinely available
- Antibody titer tests:
 - Not available in real time
- Lumbar puncture
 - Pleocytosis with predominance of lymphocytes and increased total protein

Imaging

- Head CT for encephalopathy
- CXR for fever/dyspnea

DIFFERENTIAL DIAGNOSIS

- Most tick-borne illnesses:
 - RMSF
 - Lyme disease
 - Babesiosis
- Many viral and bacterial infections and numerous other infectious diseases, especially early in their course, can initially present with an undifferentiated febrile illness similar to ehrlichiosis.
- Mononucleosis
- Thrombotic thrombocytopenia purpura
- Hematologic malignancy
- Cholangitis
- Pneumonia

TREATMENT

INITIAL STABILIZATION/THERAPY

ABCs

ED TREATMENT/PROCEDURES

- Initiate antibiotics:
 - Doxycycline:
 - Drug of choice
 - Children who are affected should also receive doxycycline. 14 days of treatment does not appear to cause significant discoloration of permanent teeth. The risks and benefits in children <9 yr old should be specifically discussed with parents.
 - Treatment should be continued for at least 3 days past defervescence

for a min. total course of 7 days. Severe or complicated disease requires a longer course.

– Rifampin for:

- Pregnant patients
 - Allergy to doxycycline
 - Mildly affected children < 9 yr of age
 - Patients who are pregnant, allergic to doxycycline, or mildly affected can be given rifampin for 7–10 days.
- Initiate therapy for other tick-borne diseases that may have been cotransmitted.

MEDICATION

Doxycycline:

- Adults: 100 mg IV/PO q12h for 10 days or for 3–5 days after defervescence.
- Children (severely affected): 4 mg/kg q12h IV/PO up to max. of adult dose; older children can be dosed as adult.

Pediatric Considerations

Despite the fact that doxycycline is generally contraindicated in patients < 9 yr old, it is the drug of choice in young children who are severely affected by ehrlichiosis. In less affected children, rifampin has been used successfully.

Pregnancy Considerations

Rifampin can be used to treat pregnant women with ehrlichiosis. When life-threatening disease is present, doxycycline may be considered.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Significant comorbidities/severely affected
- Cannot take PO antibiotics
- Immunosuppressed patients
- *E. chaffeensis* (HME) has a case fatality rate up to 3%.

Discharge Criteria

- Healthy appearing
- Symptoms typically last 1–2 wk; recovery occurring without sequelae.
- Long-term neurologic complications have been reported.

Issues for Referral

Severe disease or presence of complications

- A77.49 Other ehrlichiosis

ELBOW INJURIES

Christian M. Sloane

BASICS

DESCRIPTION

Bony Injuries

- Supracondylar fracture:
 - Most common in children
 - Peak ages 5–10 yr, rarely occurs > 15 yr
 - Extension type (98%): Fall on outstretched *hand* (FOOSH) with fully extended or hyperextended arm:
 - Type 1: Minimal or no displacement
 - Type 2: Slightly displaced fracture; posterior cortex intact
 - Type 3: Totally displaced fracture; posterior cortex broken
 - Flexion type: Blow directly to flexed elbow:
 - Type 1: Minimal or no displacement
 - Type 2: Slightly displaced fracture; anterior cortex intact
 - Type 3: Totally displaced fracture; anterior cortex broken
- Radial head fracture:
 - Usually indirect mechanism (e.g., FOOSH)
 - Radial head driven into capitellum

Soft Tissue Injuries

- Elbow dislocation:
 - 2nd only to shoulder as most dislocated joint
 - Most are posterior.
- Medial/lateral epicondylitis:
 - Overuse injuries usually related to rotary motion at elbow
 - Involving attachment points of hand and wrist flexor/extensor groups to elbow
 - Plumbers, carpenters, tennis players, golfers
 - Pain made worse by resisted contraction of particular muscle groups

Pediatric Considerations

- Subluxed radial head (nursemaid's elbow)
- 20% of all upper extremity injuries in children
- Peak age 1–4 yr; occurs more frequently in females than males
- Sudden longitudinal pull on forearm with forearm pronated

ETIOLOGY

- Mechanism aids in determining expected injury.
- Trauma predominates.
- Most elbow injuries caused by indirect trauma are transmitted through bones of forearm (e.g., FOOSH)
- Direct blows account for very few fractures or dislocations.

DIAGNOSIS

SIGNS AND SYMPTOMS

How patient carries arm may give clues to diagnosis.

Bony Injuries

Supracondylar fracture:

- Flexion type:
 - Patient supports injured forearm with other arm and elbow in 90° flexion.
 - Loss of olecranon prominence
- Extension type:
 - Patient holds arm at side in S-type configuration.

Soft Tissue Injuries

- Elbow dislocations:
 - Posterior: Abnormal prominence of olecranon
 - Anterior: Loss of olecranon prominence
- Radial head subluxation:
 - Elbow slightly flexed and forearm pronated, resists moving arm at elbow
- Medial/lateral epicondylitis:
 - Gradual onset of dull ache over inner/outer aspect of elbow referred to forearm
 - Pain increases with grasping and twisting motions.

ESSENTIAL WORKUP

- Radiographs
- Assess wrist and shoulder for associated injury.
- Evaluate neurovascular status of limb.
- Assess skin integrity.
- Examine for compartment syndrome, which is more common in supracondylar fractures.

ALERT

- Injuries to ipsilateral upper limb, particularly fractures to midshaft humerus and distal forearm, are common.
- Evaluate for associated neurovascular injuries (up to 20%).

DIAGNOSIS TESTS & INTERPRETATION

Lab

None specific for elbow injuries

Imaging

- Not usually necessary if overuse injury suspected
- Routine anteroposterior (AP) and lateral; add oblique for assessment of subtle injuries to radial head/distal humerus.
- Fat pad sign:
 - Seen with intra-articular injuries
 - Normally, anterior fat pad is a narrow radiolucent strip anterior to humerus.
 - Posterior fat pad is normally *not* visible.
 - *Anterior fat pad sign* indicates joint effusion/injury when raised and becomes more perpendicular to anterior humeral cortex (sail sign).
 - *Posterior fat pad sign* indicates effusion/injury:
 - In adults, posterior fat pad sign without other obvious fracture implies radial head fracture.
 - In children, it implies supracondylar fracture.

Pediatric Considerations

- Fractures in children often occur through unossified cartilage, making radiographic interpretation confusing.
- A line drawn down the anterior surface of humerus should always bisect the capitellum in lateral view.
- If any bony relationships appear questionable on radiographs, obtain comparison view of uninvolved elbow.
- Suspect nonaccidental trauma if history does not fit injury.
- Ossification centers: 1st appear:
 - Capitellum: 3–6 mo
 - Radial head: 3–5 yr
 - Medial epicondyle: 5–7 yr
 - Trochlea: 9–10 yr
 - Olecranon: 9–10 yr
 - Lateral epicondyle: 9–13 yr

DIFFERENTIAL DIAGNOSIS

- Sprain/strain
- Effusion
- Contusion
- Bursitis

- Arthritis

TREATMENT

PRE HOSPITAL

Appropriate splinting

INITIAL STABILIZATION/THERAPY

Immobilization to prevent further injury before taking radiographs is essential.

ED TREATMENT/PROCEDURES

- Orthopedic consultation is recommended for all but nondisplaced, stable fractures, which can generally be splinted with 24–48 hr orthopedic follow-up.
- Fractures generally requiring orthopedic consultation:
 - _ Transcondylar, intercondylar, condylar, epicondylar fractures
 - _ Fractures involving articular surfaces such as capitellum or trochlea
- Supracondylar fractures:
 - _ Type 1 can be handled by ED physician with 24–48 hr orthopedic follow-up.
 - _ Elbow may be flexed and splinted with posterior splint.
 - _ Types 2 and 3 require immediate orthopedic consult.
 - _ Reduce these in ED when fracture is associated with vascular compromise.
- Anterior dislocation:
 - _ Reduce immediately if vascular structures compromised.
 - _ Then flex to 90° and place posterior splint.
- Posterior dislocation:
 - _ Reduce immediately if vascular structures compromised.
 - _ Then flex to 90° and place posterior splint.
- Radial head fracture:
 - _ Minimally displaced fractures may be aspirated to remove hemarthrosis; instill bupivacaine (Marcaine) and immobilize.
 - _ Other types should have orthopedic consult.
- Radial head subluxation:
 - _ In 1 continuous motion, supinate and flex elbow while placing slight pressure on radial head.
 - _ Hyperpronation technique is possibly more effective—while grasping the patient's elbow the wrist is hyperpronated until a palpable click is felt.
 - _ Often will feel click with reduction
 - _ If exam suggests fracture but radiograph is negative, splint and have patient follow up in 24–48 hr for re-evaluation.
- Medial/lateral epicondylitis:
 - _ Severe cases can be splinted.
 - _ Rest, heat, anti-inflammatory agents

ALERT

- Neurovascular injuries to numerous structures that pass about the elbow, including anterior interosseous nerve, ulnar and radial nerves, brachial artery
- Volkmann ischemic contracture is compartment syndrome of forearm.

MEDICATION

- Conscious sedation is often required to achieve reductions; see Conscious Sedation.
- Ibuprofen: 600–800 mg (peds: 5–10 mg/kg) PO TID
- Naprosyn: 250–500 mg (peds: 10–20 mg/kg) PO BID
- Tylenol with codeine no. 3: 1 or 2 tabs (peds: 0.5–1 mg/kg codeine) PO q4–6h; Do not exceed acetaminophen 4 g/24h
- Morphine sulfate: 0.1 mg/kg IV q2–6h
- Hydromorphone 5 mg/Acetaminophen 300 mg
- Acetaminophen do not exceed 4 g/24h
- Vicodin: 1–2 tabs PO q4–6h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Vascular injuries, open fractures
- Fractures requiring operative reduction or internal fixation
- Admit all patients with extensive swelling or ecchymosis for overnight observation and elevation to monitor for and decrease risk for compartment syndrome.

Discharge Criteria

- Stable fractures or reduced dislocations with none of the above features
- Splint and arrange orthopedic follow-up in 24–48 hr.
- Uncomplicated soft tissue injuries

PEARLS AND PITFALLS

- Failure to appreciate that a posterior fat pad sign is abnormal.
- Always check for neurovascular injury with injuries about the elbow, especially with dislocations, pre- and postreduction.
- Always educate parents of a child with a supracondylar fracture about the signs and symptoms of compartment syndrome.

ELECTRICAL INJURY

Marilyn M. Hallock

BASICS

DESCRIPTION

- Electricity is the flow of electrons through a conductor, across a gradient, from high to low concentration
- Nature and severity of electrical injuries depend on the voltage, current strength and type, resistance to flow, and duration of contact
- Ohm law: Voltage (V) = current (I) × resistance (R):
 - Voltage is directly proportional to current and is inversely proportional to resistance.
 - High-voltage (> 600 V) and low-voltage sources:
 - Telephone lines: 65 V
 - Household general circuit: 110 V
 - Electrical range or dryer: 220 V
 - Household power lines: 220 V
 - Subway 3rd rail: 600 V
 - Residential trunk line: 7,620 V
 - Industrial electrical power line: 100,000 V
 - Household devices can contain a transformer stepping up a seemingly low-voltage source to high voltage:
 - Microwave, television, computer
 - Resistance (R) is determined by the current's pathway through the body:
 - Nerves, muscles, blood vessels have low resistance and are better electrical conductors than are bone, tendon, fat
 - Water and sweat on skin decrease resistance; calloused skin increases resistance
 - More resistance means less flow, and more conversion to heat
 - Current is measured in amperes (I) and is a measure of the amount of energy flowing through an object:
 - “Let go” current is the max. current a person can grasp and release before muscle tetany inhibits letting go
 - Household general circuit: 15–30 A
 - Tingling sensation/perception: 0.2–2 mA
 - Pain: 1–4 mA
 - Average child “let go” current: 3–5 mA
 - Adult “let go” current: 6–9 mA; higher for men than women
 - Skeletal muscle tetany current: 16–20 mA
 - Respiratory muscle paralysis: 20–50 mA

- Ventricular fibrillation: 50–120 mA
- Alternating current (AC):
 - Electron flow rhythmically reverses direction:
 - Homes and offices in US use standard 60 Hz
 - Can produce continuous tetanic muscle contraction, loss of voluntary control of muscles, prolonged contact
 - More dangerous than direct current (DC)
 - More likely to result in ventricular fibrillation at household current level:
 - Stimulation can continue through T-wave period of cardiac cycle
- DC:
 - Continuous electron flow in 1 direction
 - Defibrillators and pacemakers, industrial sources
 - Large, single muscle spasm tends to throw victim from source:
 - Increased risk of traumatic blunt injuries
 - Shorter duration of exposure
 - More likely to result in asystole
- Trimodal distribution of electrical injuries:
 - Toddlers (household outlets and cords)
 - Teenagers (risk-taking behavior)
 - Adults (work-related injuries)

ETIOLOGY

Types of electrical injury:

- Direct contact causing tissue destruction:
 - Electrothermal burn may cause skin or deep tissue coagulation necrosis
 - Minor visible injuries may be misleading for extensive deep tissue injury
 - Location of damage is point of contact with source and point of contact with ground
- Flame:
 - Burns from burning clothing or other substances
- Electrical arc indirect contact:
 - Burns from the heat of a high-voltage arc (a flash burn) that passes electricity through air
 - May cause thermal and flame burns
 - Flash burns usually result in superficial partial-thickness burns
- Primary electrical phenomena:
 - Cardiac arrhythmias
 - Muscle contractions and tetany
- Secondary injury from trauma:
 - Supraphysiologic muscle contraction
 - Fall or being thrown

SIGNS AND SYMPTOMS

- **Head/neck/ENT:**
 - Common entry site for high-voltage injuries:
 - Facial and corneal burns
 - Perforated tympanic membranes
 - Cataracts and optic nerve atrophy may present initially, or delayed 4–6 mo
 - Intraocular hemorrhage, uveitis
 - Cervical spine injury
- **Cardiovascular:**
 - Cardiac arrest, asystole, and ventricular fibrillation are leading causes of death
 - Other arrhythmias and EKG findings: Sinus tachycardia, atrial fibrillation, premature ventricular contractions, transient ST-elevation, reversible QT-prolongation:
 - Sometimes delayed up to 12 hr
 - Usually resolve spontaneously
 - Myocardial damage occurs rarely:
 - Generally epicardial, not transmural
 - Damage does not follow distribution of coronary arteries
 - EKG will not show standard injury patterns
- **Respiratory:**
 - Brain injury causing respiratory center inhibition
 - Tetanic contraction/paralysis of chest wall/diaphragm muscles:
 - May cause respiratory arrest
 - Postcardiac arrest, respiratory arrest
 - Traumatic lung injury
 - Lung tissue itself appears resistant to electrical injury, probably owing to air content.
- **Neurologic:**
 - Respiratory arrest
 - Amnesia, transient confusion
 - Loss of consciousness, altered mental status, seizures, coma
 - Spinal cord injury:
 - May result from blunt trauma or DC effects (hand-to-hand flow)
 - Localized paresis up to/including quadriplegia
 - Long-term neurologic complications:
 - Seizures, peripheral nerve damage, spinal cord syndromes, psychiatric problems
- **Vascular:**

- Muscle necrosis and compartment syndromes
- Thrombosis in slow-moving venous system owing to coagulation
- Intimal injury in fast-moving arterial system may lead to acute or delayed arterial malfunction.
- Renal failure secondary to myoglobinuria
- Skeletal system/orthopedics:
 - Supraphysiologic tetanic muscle contractions from electrostimulation
 - Classically described injuries:
 - Vertebral column fracture
 - Posterior shoulder dislocation
 - Femoral neck fracture
- Dermatologic:
 - Contact/ground wounds: Hands, feet, and head most common and most severe sites
 - “Kissing” burns from current exit and re-entry on flexor surfaces

Pediatric Considerations

Mouth burn most common < 4 yr; sucking/biting on household electrical cord:

- Cosmetic deformity risk if commissure involved
- Delayed bleeding (3–5 days) from labial artery when eschar separates
- Risk of damage to developing dentition

Pregnancy Considerations

Fetus much less resistant to electrical shock than mother:

- Obstetric consult or referral for all pregnant patients regardless of symptoms:
 - Risk of placental abruption or threatened miscarriage
 - Fetal monitoring if > 20 wk gestation

History

- Determine whether exposure was high or low voltage, the duration and location of contact, or concomitant trauma
- If unwitnessed respiratory arrest or ventricular fibrillation in patient, consider electrical injury

Physical-Exam

Search the skin for entry/exit wounds and kiss/arch wounds at flexor surfaces

ESSENTIAL WORKUP

- Urinalysis for myoglobin
- EKG and cardiac enzymes for high-voltage victims, and low-voltage victims with cardiorespiratory complaints
- Cardiac monitoring indications:

- Cardiac arrest
- Loss of consciousness
- Chest pain
- Hypoxia
- Abnormal EKG
- Dysrhythmia in pre-hospital or ED setting
- History of cardiac disease
- Significant risk factors for coronary artery disease
- Suspicion of conductive injury
- Concomitant injury severe enough to warrant admission
- Prolonged monitoring is probably unnecessary in asymptomatic patients with normal EKG, no dysrhythmias, and exposure to < 240 V

DIAGNOSIS TESTS & NTERPRETATION

Lab

- For most exposures to household current, no testing is indicated:
 - Low-voltage burns can still cause dysrhythmias, seizures, and other complications if contact is near the chest or head
- Urinalysis for myoglobinuria
- Creatinine kinase, electrolytes, BUN, creatinine:
 - Positive urine myoglobin and/or high-voltage exposure
 - Provides baseline renal function, possible presence of hyperkalemia and metabolic acidosis
- Cardiac markers in:
 - Abnormal EKG or dysrhythmia
 - High-voltage exposures or low-voltage victims with cardiorespiratory complaints

Imaging

Dictated by clinical indications

DIFFERENTIAL DIAGNOSIS

- Thermal burns from electrical arcing flash burn vs. deep electrothermal injury
- Instability owing to traumatic injuries vs. electrical burns

TREATMENT

PRE HOSPITAL

- Secure scene; turn off power source for high-voltage incident
- Assume traumatic injury in unstable or unconscious patient:
 - Spinal immobilization

- Standard basic life support/advanced cardiac life support care
- Early CPR in postelectric shock arrest may allow time for heart to restart
- Splint fractures and dislocations
- Cover burns with clean, dry dressings

ALERT

Care must be exercised at scene to ensure that rescuers do not contact live electrical sources

INITIAL STABILIZATION/THERAPY

- ABCs
- Local wound care for thermal burns
- Immobilize/reduce fractures and dislocations

ED TREATMENT/PROCEDURES

- IV fluid resuscitation:
 - Larger fluid volumes may be required owing to extensive 3rd spacing in injured muscle.
 - Rapid administration to reach urine output of 1 mL/kg/hr
 - Foley catheter
- Evaluate for myoglobinuria and prevent renal failure:
 - Maintain good urine output
 - IV sodium bicarbonate increases solubility of myoglobin in urine
 - Consider furosemide/mannitol
 - Monitor renal function
- Tetanus prophylaxis
- Pain control as required

MEDICATION

- Bicarbonate: 1 ampule (50 mEq) IV, then add 2 ampules to 1 L of D₅W to maintain urine pH >7.45
- Furosemide: 0.5 mg/kg IV
- Mannitol: 25 g (ped: 0.25–0.5 mg/kg) IV bolus, then 12.5 mg/kg/h IV titrated to urine flow > 1 mL/kg/h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Documented loss of consciousness
- Dysrhythmias, abnormal EKG, or evidence of myocardial damage

- Suspicion of deep tissue damage
- Myoglobinuria or acidosis
- Burn criteria for admit or transfer to burn center
- Traumatic injuries requiring admission
- Pregnant patients > 20 wk gestation

Discharge Criteria

- Minor, low-voltage injury (< 240 V) with no associated injuries, normal physical exam, and asymptomatic
- Cutaneous burns or mild persistent symptoms with normal EKG and no urinary heme pigment
- Stable in ED after period of observation
- Discharge 1st-trimester patient with threatened miscarriage instructions
- Pediatric patients with isolated oral burns and close adult care

Issues for Referral

- Burn wound care
- Persistence of current symptoms or new delayed symptoms:
 - Neurology for delayed weakness, paresthesias
- Obstetrics for pregnant patients
- Dental or reconstructive surgery for pediatric oral burns

FOLLOW-UP RECOMMENDATIONS

Ophthalmology for delayed cataracts in significant electrical current injuries

PEARLS AND PITFALLS

- Prolonged cardiac monitoring is probably unnecessary in asymptomatic patients with normal EKG, no dysrhythmias, and exposure to < 240 V
- With significant electrical burn injuries, administer enough IV fluid to maintain adequate urine output and to stabilize the vital signs:
 - Extensive 3rd spacing may occur

ENCEPHALITIS

Mary Saunders

BASICS

DESCRIPTION

- Acute inflammation of the brain
- 20,000 cases in US annually
- Mortality: 10%
- Inflammatory reaction occurs within brain parenchyma with destruction of neurons, parenchymal edema, and petechial hemorrhages
- Route of CNS infection usually hematogenous
 - Respiratory or GI tract
 - Blood transfusion
 - Organ transplant
- Neural migration occurs with rabies, herpes simplex virus (HSV), and varicella zoster virus (VZV) encephalitis

ETIOLOGY

- Viral is most common
- Noninfectious
 - Autoimmune, paraneoplastic, collagen vascular disease
- 50% of cases have no identifiable cause

Specific Viruses

- HSV:
 - 10–20% of all encephalitides
 - Primary or reactivation
 - Early treatment improves prognosis
- Arbovirus:
 - 10–15% of all encephalitides
 - Zoonotic transmission (mosquitoes, ticks) in warm months
 - Eastern equine causes fulminant encephalitis:
 - Tropism for the hippocampus
 - Abrupt onset of headache, fever, vomiting progressing to coma
 - Western equine occurs mostly in the western 2/3 of US:
 - Often preceded by nonspecific upper respiratory/GI tract symptoms
 - Japanese—most prevalent arboviral encephalitis worldwide:
 - Indolent course of fever, headache, myalgias, and fatigue followed by confusion, delirium, masklike facies, and parkinsonism, seizures, brainstem dysfunction, coma, and death

- **Flavivirus:**
 - West Nile virus—increased incidence in North America:
 - Found in mosquitoes and birds
 - Febrile illness, often with rash
 - Headache
 - Lymphadenopathy
 - Polyarthropathy
 - Increased morbidity/mortality in elderly patients
 - Flaccid paralysis can lead to respiratory failure with 50% mortality
- **Enteroviral:**
 - Occurs mainly in children < 10 yr old
 - Relatively benign course with little or no long-term sequelae
- **Measles encephalitis:**
 - Occurs several days to 2–3 wk after primary infection and rash, or after years of latent infection
 - Abrupt onset and rapid progression to coma
 - Seizures common (50–60%)
 - Postimmunization incidence of 1 per 1 million vaccinated
- **HIV encephalitis:**
 - Lower CD4 counts predispose to encephalitis
 - Typical features include motor spasticity and dementia
 - Involvement of white matter with extensive neural degeneration
- **Rhabdovirus: Rabies**
 - CNS infection in the absence of systemic infection

Nonviral

- *Mycoplasma pneumoniae*
- *Toxoplasma gondii*
- *Rickettsia rickettsii*
- *Mycobacterium tuberculosis*
- *Borrelia burgdorferi*
- *Bartonella henselae*

Immunocompromised/HIV Patients

- Histoplasma
- *Cryptococcus neoformans*
- VZV
- *Listeria monocytogenes*
- Cytomegalovirus (CMV)
- *T. gondii*
- Human herpesvirus type 6 (HHV-6)

Autoimmune

- Anti-LGI1 encephalitis
- Anti-N-methyl-D-aspartate receptor (anti-NMDAR) encephalitis

DIAGNOSIS

SIGNS AND SYMPTOMS

- Often begins with a preceding flulike illness over a few days:
 - _ Mild headache, fever, sore throat, reduced appetite, myalgias
- Altered level of consciousness, drowsiness, coma
- Impaired cognitive ability and personality change, hallucinations, psychosis
- Restlessness, agitation, irritability, delirium
- Rash:
 - _ Lyme disease
 - _ Rocky Mountain spotted fever
 - _ Varicella
 - _ HSV
- Seizures
- Fever, headache, vomiting, possible meningismus
- Focal neurologic deficits, tremor, ataxia, cranial nerve palsies (more common than meningitis)
- Papilledema on funduscopy
 - _ Autonomic dysfunction can lead to hypotension and cardiac arrhythmias
- Clinical picture varies from mild headache and mild cognitive/emotional lability to severe agitation, seizures, coma, permanent neurologic sequelae, and death
- Clinical course of symptoms may be slow moving or rapidly progressive

History

Arboviruses (eastern equine, western equine, St. Louis, and West Nile virus) cause disease when mosquitoes are active, whereas HSV can occur at any time

Physical-Exam

- Patients with encephalitis have an altered mental status ranging from subtle deficits to complete unresponsiveness
- Other findings reflect neurologic involvement

ESSENTIAL WORKUP

- Lumbar puncture
- Cell count/chemistry:
 - _ Elevated WBC, predominantly lymphocytes
 - _ Elevated protein
 - _ Glucose (normal in viral disease)

- Gram stain with or without India ink for suspected/confirmed HIV
- Viral and bacterial cultures (fungi if indicated by history)
- Antigen assays for:
 - HSV
 - Cryptococcus
 - Toxoplasmosis
 - Other viral antigen and antibody assays if available (enterovirus, adenovirus, CMV, mumps, varicella zoster)

DIAGNOSIS TESTS & NTERPRETATION

Lab

- CBC:
 - WBC usually elevated; however, a normal WBC does not exclude infection
- Electrolytes, glucose, BUN, creatinine
- Bacterial and viral blood cultures
- Liver function tests, ammonia level if hepatic failure suspected
- Carboxyhemoglobin level if CO poisoning suspected
- Toxicology screen if ingestion suspected in differential
- Polymerase chain reaction (PCR):
 - Confirm viral nucleic acids in CSF
 - HSV, varicella, enteroviruses, others
 - West Nile virus IgM serology

Imaging

- CT scan:
 - To rule out trauma, hemorrhagic conditions, and mass lesions
 - Cerebral edema may be the only finding consistent with encephalitis
 - HSV may show parenchymal hemorrhagic areas of the frontal and temporal lobes, along with edema
- MRI:
 - Hypodense temporal lobes in HSV

Diagnostic Procedures/Surgery

EEG may be useful in the presence of proven or suspected seizures

DIFFERENTIAL DIAGNOSIS

- Meningitis
- Brain abscess
- Sepsis
- Stroke (hemorrhagic or ischemic)
- Head injury
- Subarachnoid hemorrhage

- Encephalopathy (hepatic, uremic)
- Epilepsy
- Acute disseminated encephalomyelitis (ADEM)
- Metabolic:
 - Electrolyte abnormalities (Na^+ , K^+ , Cl^- , Ca^{2+} , Mg^{2+} , phosphate)
 - Hypoglycemia
 - Hyperglycemic nonketotic coma
- Neoplastic
- Drugs/toxins
- Carbon monoxide (CO) inhalation

TREATMENT

PRE HOSPITAL

Stabilize. Treat seizures

INITIAL STABILIZATION/THERAPY

- ABCs:
 - Intubate patients who are obtunded/comatose/absent gag reflex
- Naloxone, thiamine, glucose (or Accu-Chek) for altered mental status
- For signs of raised intracranial pressure on funduscopy or CT:
 - Hyperventilate to PCO_2 of 25–30 mm Hg
 - Administer mannitol
 - Neurosurgical consult for suspected hydrocephalus
- Run IV saline at KVO or half maintenance to avoid cerebral edema

ED TREATMENT/PROCEDURES

- Seizure control:
 - Abort with lorazepam or diazepam
 - Initiate antiseizure medication (fosphenytoin or phenobarbital) if more than 1 seizure has occurred
- No specific treatment for most viral encephalitides:
 - Steroid use controversial
- Treat HSV encephalitis with acyclovir IV:
 - Initiate if considered likely based on clinical grounds, CT, and CSF findings.
- Initiate ganciclovir and foscarnet for suspected immunocompromised-related infections (CMV, HHV-6).
- Administer antibiotic to cover for meningitis if diagnosis uncertain, especially when rash present (e.g., meningococemia, rickettsia)

MEDICATION

- Acyclovir: 10 mg/kg IV div. q8h, max. 30 mg/kg/d (peds: 20 mg/kg IV div. q8h up

to age 12 yr)

- Lorazepam: 2–4 mg per dose slow IV (peds: 0.05–0.1 mg/kg) per dose
- Diazepam: 5 mg IV per dose (peds: 0.1–0.2 mg/kg IV or 0.2–0.5 mg/kg per rectum)
- Fosphenytoin: Loading dose 20 mg/kg IV to a max. 1 g
- Ganciclovir: 5 mg/kg IV div. q12h
- Foscarnet: 90 mg/kg IV div. q12h or 60 mg/kg IV q8h
- Mannitol: 0.5–1 g/kg of a 20% solution to run IV over 20–30 min
- Phenobarbital: Load 15–20 mg/kg to 300–800 mg IV at 25 mg/min. Monitor respirations

FOLLOW-UP

DISPOSITION

Admission Criteria

All patients

PEARLS AND PITFALLS

Empiric treatment for HSV-1 infection with acyclovir should always be initiated as soon as possible if the patient has encephalitis without apparent explanation to decrease morbidity/mortality

ENDOCARDITIS

Michael S. Murphy

BASICS

DESCRIPTION

An inflammation of the endothelial surface of the heart

- Various cardiac structures may be involved:
 - _ Native heart valves (most common)
 - _ Prosthetic valves
 - _ Interventricular septum
 - _ Chordae tendineae
 - _ Mural endocardium
 - _ Intracardiac devices
- Characterized by a vegetation (a thrombus with superimposed microorganisms)
 - _ Bacterial colonization of the initially sterile vegetation composed of fibrin and platelets
 - _ Bacterial growth enlarges the vegetation, further impeding blood flow and inciting inflammation.
 - _ Propagation of the infection through systemic emboli
- Almost always secondary to bacterial infection
- Rare noninfectious causes
 - _ Nonbacterial thrombotic endocarditis or marantic endocarditis
 - Often due to a hypercoagulable state
 - Small sterile vegetations
 - _ Libman–Sacks endocarditis
 - Complications of lupus erythematosus
 - Due to the deposition of immune complexes that cause an inflammatory reaction
 - Small vegetations

EPIDEMIOLOGY

- More common in men (ratios from 3.2 to 9.1)
 - _ M: 8.6–12.7 cases/100,000 person-yr
 - _ F: 1.4–6.7 cases/100,000 person-yr
- Risk factors:
 - _ Older patients
 - _ Poor dental hygiene
 - _ Comorbidities
 - Rheumatic heart disease
 - Prosthetic valve

- Hemodialysis
- Diabetes
- IV drug abuse (IVDA):
 - Greater risk than rheumatic heart disease or prosthetic valves
 - Predilection for right-sided heart valves
- Septic embolization
 - Cerebral complications
 - Cerebral embolism
 - Intracranial hemorrhage
 - Cerebral abscess
 - Extracerebral embolic events
 - Pulmonary
 - Splenic
 - Renal
 - Mycotic aneurysms (aorta, renal artery, splenic artery, hepatic artery, mesenteric arteries, etc.)
 - Hepatic
 - Coronary
- Risk factor for recurrent endocarditis:
 - Structural heart disease serves as common vegetative site due to altered intracardiac flow:
 - Mitral valve prolapse
 - Aortic valve dysfunction
 - Congenital heart disorders in the pediatric populations:
 - Tetralogy of Fallot
 - Aortic stenosis
 - Patent ductus arteriosus
 - Ventricular septal defects
 - Aortic coarctation
 - Prosthetic valves
 - Indwelling catheters
 - Any mechanical device may serve as a portal of entry or attachment for microorganisms.

ETIOLOGY

- Major categories:
 - Bacterial endocarditis
 - Prosthetic valve endocarditis
 - Nonbacterial thrombotic endocarditis:
 - Malignancy
 - Uremia
 - Burns
 - Systemic lupus erythematosus

- Common organisms:
 - *Staphylococcus aureus* (most common pathogen):
 - Seen in all populations, especially IVDA and toxic illness
 - Sometimes metastatic
 - *Streptococcus viridans*:
 - Found in oropharynx, common agent in native valve endocarditis
 - *Streptococcus bovis*:
 - Common association with colonic polyps or GI malignancy
 - *Streptococcus pneumoniae*:
 - Causes rapid valvular destruction, abscess, and CHF
 - Risk factor: Alcoholism
 - *Staphylococcus epidermidis*
 - Enterococci:
 - Seen in young women and old men following instrumentation or infection
 - Candida and Aspergillus:
 - Found in IVDA, prosthetic valves, or immunocompromised patients
 - HACEK (Haemophilus sp.)
 - Culture-negative endocarditis (Q fever, psittacosis, Bartonella, brucellosis)

DIAGNOSIS

SIGNS AND SYMPTOMS

- Fever:
 - Present in 86% of patients
 - May be absent in certain settings:
 - Elderly
 - CHF
 - Severe debility
 - Chronic renal failure
 - Flulike illness
 - Chills
 - Sweats
 - Rigors
 - Malaise
- Head, eyes, ears, nose, and throat:
 - Retinal hemorrhages or Roth spots
- Respiratory:
 - Dyspnea
 - Cough
 - Heart failure
- Cardiac:

- A new or changing murmur in 80–85% of patients
- Abdominal:
 - Abdominal or back pain
 - Splenomegaly (15–50%)
- Extremities:
 - Myalgias
 - Arthralgias
 - Digital clubbing
- Neurologic:
 - Altered mental status
 - Septic embolization (stroke or mycotic aneurysm)
- Skin:
 - Cutaneous vasculitic lesions:
 - Mucosal and conjunctival petechiae
 - Splinter hemorrhages
 - Osler nodes: Erythematous, painful tender nodules
 - Janeway lesions: Erythematous or hemorrhagic, macular or nodular lesions, a few millimeters in diameter on the hands and feet

History

- Fever duration and pattern
- Risk factors:
 - Prior cardiac disease
 - Source of bacteremia:
 - Indwelling intravascular catheters
 - IV drug use
 - Poor dental hygiene

Physical-Exam

- Heart and lung exam:
 - New cardiac regurgitant murmur
 - Heart failure
- Assess for splenomegaly.
- Assess for septic emboli:
 - Fundi, skin, nail beds
 - Careful neurologic exam for small focal deficits

ESSENTIAL WORKUP

- Identify risk factors for endocarditis in patients with fever of unknown etiology.
- Blood cultures
- ECG is needed to confirm the diagnosis.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - Anemia (sometimes hemolytic)
 - Leukocytosis (with granulocytosis and bandemia)
- Blood cultures:
 - Multiple sets (3 sets over a time period) should be obtained before antibiotic administration:
 - 5–10% with endocarditis have false-negative cultures
 - Consider culture of catheter device
- Elevated sedimentation rate and C-reactive protein (lacks specificity)
- Urinalysis:
 - Microscopic hematuria

Imaging

- CXR:
 - CHF
 - Septic pulmonary emboli, which may be seen in right-sided endocarditis
- EKG
 - Arrhythmia, new heart block
- Echocardiogram
 - Acute valvular pathology
 - Abscess
 - Vegetations
 - Transesophageal echo provides greater sensitivity.
- CT scan
 - May provide comprehensive information and valvular abnormalities

DIFFERENTIAL DIAGNOSIS

- Rheumatic fever
- Atrial myxoma
- Acute pericarditis
- MI
- Aortic dissection with regurgitant valve
- Thrombotic thrombocytopenic purpura
- Systemic lupus erythematosus
- Occult neoplasm with metastasis
- Septicemia
- Cotton fever

TREATMENT

INITIAL STABILIZATION/THERAPY

- Monitor for signs of heart failure.
- Operative repair if:
 - Severe valvular dysfunction causing failure
 - Unstable prosthesis
 - Perivalvular extension with intracardiac abscess
 - Antimicrobial therapy failure
 - Large or fungal vegetations
- Antibiotic therapy:
 - IV, bactericidal, and empiric, pending culture results
 - Native valve or congenital abnormality:
 - Penicillin G + nafcillin + gentamicin
 - Vancomycin + gentamicin
 - Prosthetic valve or history of IVDA:
 - Vancomycin + gentamicin + rifampin
 - Nafcillin + gentamicin + rifampin (if methicillin-resistant *S. aureus* [MRSA] is not suspected)
 - If MRSA vancomycin failure/intolerant consider daptomycin or quinupristin–dalfopristin
 - Vancomycin resistant
 - *Enterococcus faecium* consider quinupristin–dalfopristin
 - Enterococcal: Penicillin G + gentamicin; vancomycin + gentamicin
 - Enterococcal (gentamicin resistant): Penicillin G + streptomycin
 - Fungal:
 - Amphotericin B
 - HACEK:
 - Ceftriaxone

MEDICATION

- Amphotericin B:
 - Test dose 0.1 mg/kg up to 1 mg slow IV
 - Wait 2–4 hr.
 - If tolerated, begin 0.25 mg/kg IV and advance to 0.6 mg/kg IV QID
- Ceftriaxone: 2 g/d IV (peds: 100 mg/kg/24h)
- Daptomycin: 4 mg/kg/d U IV
- Gentamicin: 1 mg/kg IV q8h (peds: 3 mg/kg/24h in 3 equally div. doses)
- Nafcillin: 2 g IV q4h
- Penicillin G: 4 million IU IV q4h (peds: 300,000 U/kg/d div. into 4 equal doses)
- Quinupristin–dalfopristin: 7.5 mg/kg IV q8h (peds: 7.5 mg/kg/12h)
- Rifampin: 600 mg PO QID
- Streptomycin: 15 mg/kg/24h IV/IM in 2 equally div. doses (peds: 20 mg/kg/24h IV in 2 equally div. doses)
- Vancomycin: 15 mg/kg IV q12h (peds: 40 mg/kg/24h in 2–3 equally div. doses)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with risk factors who exhibit pathologic criteria or clinical findings
- All IV drug users with fever
- Admit patients with cardiovascular instability to an intensive care unit/monitored setting.

Discharge Criteria

None

FOLLOW-UP RECOMMENDATIONS

- Expected course:
 - Most patients will defervesce within 1 wk.
- Complications:
 - Cardiac: CHF, valve abscess, pericarditis, fistula
 - Neurologic: Embolic stroke, abscess, hemorrhage
 - Embolization: CNS, pulmonary, ischemic extremities
 - Mycotic aneurysms: Cerebral or systemic
 - Renal: Infarction, nephritis, abscess
 - Metastatic abscess: Kidney, spleen, tissue

PEARLS AND PITFALLS

- Fever, new or changing murmur
- 50% of cases occur in patients with no known history of valve disease
- Recent health care exposure/device consider as risk factor
- Common complications; watch for stroke, embolization, heart failure, intracardiac abscess
- Admit IV drug abusers presenting with fever to rule out endocarditis.
- Empiric therapy for acutely ill after 2–3 sets of blood cultures from separate venipuncture sites.

ENDOMETRIOSIS

Francis L. Counselman

BASICS

DESCRIPTION

- Presence of endometrial tissue and glands outside uterus
- An estrogen-dependent chronic inflammatory disease
- Affects 6–10% of women of reproductive age and 50–60% of women/teenage girls with pelvic pain
- Endometrial tissue found anywhere in pelvic cavity, on ovaries, uterine ligament (due to retrograde menstruation) and distant sites, including bowel and lungs

ETIOLOGY

- Unknown

Pediatric Considerations

Not prior to menarche

RISK FACTORS

- Anatomic obstruction of menstrual outflow
- Early menarche
- Short menstrual cycles
- Genetic component suggested by twin and family studies

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Dysmenorrhea (50–90%)
- Deep pelvic pain
- Dyspareunia
- Dysfunctional uterine bleeding
- Lower abdominal pain
- Nausea, abdominal distention
- Infertility (30–50%)

Physical-Exam

- Focal pain or tenderness on pelvic exam
- Tenderness along uterosacral ligament

- Retroverted uterus
- Rectovaginal nodularity
- Pelvic mass
- Physical exam can vary depending on location of endometrial tissue
- Catamenial pneumothorax occurs during menses due to pleural endometriosis

ESSENTIAL WORKUP

- Pregnancy test
- GC/chlamydia testing
- Other tests as directed by history and physical exam
- Rarely diagnosed in ED

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Pregnancy test
- GC/chlamydia testing
- Hematocrit if bleeding
- Type and screen if significant bleeding
- Other labs as directed by history and physical exam

Imaging

- Ultrasound (11% sensitivity)
- Doppler ultrasound
- CT scan (15% sensitivity)
- MRI (69% sensitivity; 75% specificity)
- Typically not helpful in ED

Diagnostic Procedures/Surgery

Laparoscopy usually required for definitive diagnosis

DIFFERENTIAL DIAGNOSIS

- Appendicitis
- Dysfunctional uterine bleeding
- Ectopic pregnancy
- Inflammatory bowel disease
- Irritable bowel disease
- Menstrual cramps/mittelschmerz
- Ovarian cyst
- Ovarian torsion
- Pelvic inflammatory disease
- Tubo-ovarian abscess

TREATMENT

PRE HOSPITAL

- Stabilize as needed.
- Pain control as necessary

INITIAL STABILIZATION/THERAPY

- Treat hypotension or tachycardia from blood loss with isotonic IV fluids
- May need to transfuse packed red blood cells (PRBCs) if significant bleeding

ED TREATMENT/PROCEDURES

- Analgesia
- Oral contraceptive (i.e., medroxyprogesterone acetate) or gonadotropin-releasing hormone agonist (i.e., leuprolide acetate) in consultation with gynecologist or primary care physician
- Gynecology consultation for significant bleeding, pain, or serious complication

MEDICATION

- Ibuprofen: 400–800 mg PO q6–8h (max. 3.2 g/d)
- Acetaminophen: 325–650 mg PO q4–6h (max. 4 g/d)
- Ketorolac: 15–30 mg IV or 30–60 mg IM
- Morphine: 4–8 mg IM/IV or equivalent analgesic

First Line

- Ibuprofen: 400–800 mg PO q6–8h (max. 3.2 g/d)
- Acetaminophen: 325–650 mg PO q4–6h (max. 4 g/d)
- Ketorolac: 15–30 mg IV or 30–60 mg IM

FOLLOW-UP

DISPOSITION

Admission Criteria

- Intractable pain
- Significant bleeding
- Unclear diagnosis
- Need for further workup and treatment
- Peritoneal signs

Discharge Criteria

Most patients with suspected endometriosis can be discharged with pain control and gynecology referral

FOLLOW-UP RECOMMENDATIONS

Suspected cases of endometriosis should be referred to a gynecologist for evaluation and treatment

PEARLS AND PITFALLS

- Occurs in 6–10% of women of reproductive age
- Endometriosis frequently causes cyclical pelvic pain
- Rarely diagnosed initially in ED; delay between symptom onset and diagnosis frequently years
- Rule out other emergency medical conditions and treat symptoms as needed
- Endometriosis is a chronic condition that necessitates outpatient monitoring by a gynecologist or primary care physician

CODES

ICD9

- 617.1 Endometriosis of ovary
- 617.3 Endometriosis of pelvic peritoneum
- 617.9 Endometriosis, site unspecified

ICD10

- N80.1 Endometriosis of ovary
- N80.3 Endometriosis of pelvic peritoneum
- N80.9 Endometriosis, unspecified

EPIDIDYMITIS/ORCHITIS

Matthew D. Cook • Kevin R. Weaver

BASICS

DESCRIPTION

Epididymitis

- **Definition:** Inflammation or infection of the epididymis
- Rare in prepubertal boys
- **Pathogenesis:**
 - Initial stages:
 - Cellular inflammation begins in vas deferens, descends to epididymis
 - Acute phase:
 - Epididymis is swollen and indurated in upper and lower poles.
 - Spermatic cord thickened
 - Testis may become edematous owing to passive congestion or inflammation.
 - Resolution:
 - May be complete without sequelae
 - Peritubular fibrosis may develop, occluding ductules.
- **Complications:**
 - 2/3 of men have atrophy due to partial vascular thrombosis of testicular artery.
 - Abscess and infarction rare (5%)
 - Incidence of infertility with unilateral epididymitis unknown:
 - 50% with bilateral epididymitis

Orchitis

- **Definition:** Inflammation or infection of the testicle:
 - Usually from direct extension of the same process within the epididymis
 - Isolated testicular infection is rare:
 - Can result from hematogenous spread of bacteria or following mumps infection
- **Categories:**
 - Pyogenic bacterial orchitis secondary to bacterial involvement of epididymis
 - Viral orchitis:
 - Most commonly due to mumps
 - Rare in prepubertal boys; occurs in 20–30% of postpubertal boys with mumps.
 - Occurs 4–6 days after parotitis but can occur without parotitis.
 - Unilateral in 70% of patients

- Usually resolution in 6–10 days
- 30–50% of testes involved have residual atrophy; rarely affects fertility
- Granulomatous orchitis:
 - Syphilis
 - Mycobacterium and fungal diseases
 - Usually occurs in immunocompromised host

ETIOLOGY

Epididymitis

- Children:
 - Most common in children < 1 yr or between the ages of 12–15 yr
 - Etiology identified in only 25% of prepubertal boys
 - Coliform or pseudomonal UTI
 - Sexually transmitted diseases rare in prepubertal males
 - Associated with predisposing abnormalities of lower urinary tract
- Young men, age < 35 yr:
 - Usually sexually transmitted
 - *Chlamydia trachomatis* (28–88%) with severe inflammation with minimal destruction
 - *Neisseria gonorrhoea* (3–28%)
 - Coliform bacteria (7–24%):
 - Highly destructive with tendency for abscess
 - Coliform bacteria more common in insertive partners in anal intercourse
 - *Ureaplasma urealyticum* (sole organism in only 6% of cases)
- Older men, age > 35 yr:
 - Commonly associated with underlying urologic pathology (benign prostatic hypertrophy, prostate cancer, strictures)
 - May have acute or chronic bacterial prostatitis
 - Coliform bacteria more common (23–67%), especially after instrumentation
 - *C. trachomatis* (8–80%)
 - Klebsiella and Pseudomonas species
 - *N. gonorrhoea* (15%)
 - Gram-positive cocci
- Drug related:
 - Amiodarone-induced epididymitis:
 - Usually with amiodarone levels > therapeutic levels
- Granulomatous:
 - Etiology maybe related to mycobacterial, syphilis, or fungal infections:
 - *Mycobacterium tuberculosis* is the most common cause of granulomatous disease affecting the epididymis

- Suspect in HIV patients
- Urine cultures often negative for *M. tuberculosis*
- Vasculitis:
 - Polyarteritis nodosa
 - Behçet disease
 - Henoch–Schönlein purpura

Orchitis

- Pyogenic bacterial orchitis:
 - *Escherichia coli*
 - *Klebsiella pneumoniae*
 - *Pseudomonas aeruginosa*
 - Staphylococci
 - Streptococci
- Viral orchitis:
 - Mumps:
 - 20% may develop epididymo-orchitis.
 - Rarely associated with live-attenuated mumps vaccine
- Coxsackie A and lymphocytic choriomeningitis virus
- Granulomatous orchitis: Syphilis, mycobacterial and fungal diseases:
 - Suspect in HIV patients
- Fungal orchitis:
 - Blastomycosis in endemic regions
 - Invasive candidal infections in immunosuppressed hosts
- Post-traumatic orchitis: Inflammation

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Gradual onset of mild to moderate testicular or scrotal pain, usually unilateral
- Progressive scrotal swelling
- Dysuria (30%):
 - Recent UTI
 - History of abnormal bladder function
- Urethral discharge:
 - Of patients with gonococcal epididymitis, 21–30% did not complain of urethral discharge.
 - No demonstrable urethral discharge in 50%
- Fever (14–28%)
- Recent urethral instrumentation or catheterization

Physical-Exam

- Tenderness in groin, lower abdomen, or scrotum
- Scrotal skin commonly erythematous and warm
- Early:
 - May feel swollen, indurated epididymis
- Later:
 - May not be able to distinguish epididymis from testis
 - Spermatic cord may be edematous.
- Intact cremasteric reflex
- Prehn sign:
 - Pain relief with testicular elevation
 - Commonly observed but not specific
- Coexistent prostatitis is rare (8%).
- Pyogenic bacterial orchitis:
 - Patients usually are acutely ill.
 - Fever
 - Intense discomfort, swelling of testicle
 - Often reactive hydrocele

ESSENTIAL WORKUP

- Must differentiate from testicular torsion
- Early consultation with urologist if strong suspicion of testicular torsion

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - Often leukocytosis in the range of 10,000–30,000/mm³
- Urinalysis and culture:
 - Positive leukocyte esterase on first-void urine or >10 WBC per high-power field on first-void urine sediment
 - 15–50% of patients with epididymo-orchitis have pyuria.
 - 24% of patients have positive urine bacterial cultures.
- Urethral swab (50–73% have demonstrable urethritis despite minority of symptoms)
 - Gram stain and culture or DNA amplification for *C. trachomatis*/*N. gonorrhoea*
 - Avoid bladder emptying within 2 hr of tests (lowers sensitivity).
 - Especially for postpubertal and sexually active
- Blood culture if systemically ill

Imaging

- US: Color Doppler imaging:

- 82–100% sensitivity, 100% specificity in detecting testicular torsion or decreased blood flow
- Epididymo-orchitis:
 - Hyperemia
 - Increased vascularity and blood flow
- Advantages:
 - Can evaluate for epididymitis or other causes of scrotal pain
 - 70% sensitivity, 88% specificity for epididymitis
- Disadvantages:
 - Highly examiner dependent
 - Difficult in infants or children
- Testicular scintigraphy:
 - Radionuclide study to assess perfusion
 - 90–100% sensitivity, 89–97% specificity in detecting testicular torsion
 - Inflammatory processes have increased flow and uptake.
 - Not routinely available at many institutions

Diagnostic Procedures/Surgery

Surgical exploration indications:

- Scrotal abscess
- If torsion cannot be excluded
- Suspected or proved ischemia caused by severe epididymitis
- Patient with solitary testicle
- Scrotal fixation: Indicates severe inflammation and potential suppuration

DIFFERENTIAL DIAGNOSIS

- Testicular torsion
- Testicular tumor
- Torsion of testicular appendages
- Trauma to scrotum
- Acute hernia
- Acute hydrocele

TREATMENT

PRE HOSPITAL

- IV access
- IV fluids, especially if systemically ill

INITIAL STABILIZATION/THERAPY

- IV access
- IV fluids, especially if systemically ill

ED TREATMENT/PROCEDURES

- **Antibiotics:**
 - Cover for chlamydial and gonococcal etiologies if adult or presumed sexually transmitted
 - Cover for coliform etiology:
 - Child, or adult > 35 yr of age
 - Insertive partner in anal intercourse
 - Presumed nonsexually transmitted
- Bed rest, scrotal support, ice packs
- Analgesics and anti-inflammatories

MEDICATION

- Age < 35 yr or sexually active postpubertal males:
 - Ceftriaxone 250 mg IM once + doxycycline 100 mg PO BID for 10 days:
 - May substitute azithromycin 1 g PO once for doxycycline if tetracycline allergy
 - Quinolones no longer recommended if suspect *N. gonorrhoea*
- Age > 35 yr or insertive partners in anal intercourse or negative culture/DNA amplification for *C. trachomatis*/*N. gonorrhoea* or allergy to cephalosporins/tetracyclines:
 - Ofloxacin 300 mg PO BID or levofloxacin 500 mg/d PO for 10 days

Pediatric Considerations

- Bacterial epididymitis is uncommon in prepubertal boys and antibiotic regimens are not well established.
- If concurrent UTI:
 - TMP–SMX: 4 mg/kg TMP and 20 mg/kg SMX BID for 10 days
- Avoid quinolones and tetracyclines in children

FOLLOW-UP

DISPOSITION

Admission Criteria

- Surgical indications present
- Older age group if it is the only way to ensure appropriate workup:
 - Many will have underlying urologic pathology.
- Systemically ill, fever, nausea, vomiting
- Scrotal abscess
- Intractable pain

Discharge Criteria

- Fails to meet admission criteria
- Patient with good follow-up
- Able to take oral antibiotics

Issues for Referral

- Children need workup for urologic abnormalities:
 - Voiding cystourethrography, renal US
- If bacteriuria present, exam of lower tract with cystoscopy after treatment completed

FOLLOW-UP RECOMMENDATIONS

- Failure to improve within 3 days of commencing antibiotics warrants urologic evaluation.
- Persistence of symptoms after full antibiotic course warrants search for other causes of epididymitis:
 - TB or fungal epididymitis, scrotal abscess, tumor, infarction.
- Sexual partners of patients with suspected or confirmed *C. trachomatis*/*N. gonorrhoea* should be tested/treated.
- Children need urology consult for evaluation of structural urogenital abnormalities.

PEARLS AND PITFALLS

- Testicular torsion should be ruled out in all cases of new-onset testicular pain.
- Epididymitis usually due to STD in sexually active men < 35 yr
- Epididymitis usually due to coliform bacteria in men > 35 yr
- Antibiotic treatment is started immediately and empirically based on clinical picture.

- 604.99 Other orchitis, epididymitis, and epididymo-orchitis, without mention of abscess

ICD10

- N45.1 Epididymitis
- N45.2 Orchitis
- N45.3 Epididymo-orchitis

EPIDURAL ABSCESS

Richard S. Krause

BASICS

DESCRIPTION

- A rare pyogenic infection of the spinal epidural space
 - 2–25/100,000 admissions
- Most common in thoracic spine, followed by lumbar and cervical

ETIOLOGY

- Focus of infection is present followed by either hematogenous spread (~50%) or direct extension
 - No focus identified in ~1/3
- Most common source is skin infection:
 - Any pyogenic infection may be source
- *Staphylococcus aureus* accounts for >50% of cases:
 - Many are MRSA
 - Streptococcus is 2nd most common
- *Haemophilus influenzae*, gram-negative bacilli, mycobacteria, anaerobic, coagulase-negative Staphylococcus, fungal, and mixed infections also occur
- Complication of epidural catheter or spinal surgery
- Unusual complication of lumbar puncture (usually follows multiple attempts)

Pediatric Considerations

- Children present similar to adults with back pain, fever, and neurologic signs as well as nonspecific systemic symptoms
- Infants may exhibit only fever, irritability, and associated meningitis
- Sphincter disturbance is frequently seen
- Usually secondary to hematogenous spread
- Location and bacteriology similar to adults

DIAGNOSIS

SIGNS AND SYMPTOMS

- Fever and severe back pain represent “red flag” for potentially serious condition:
 - If pain is radicular or there is neurologic disturbance, likelihood of epidural abscess is increased
- Classic presentation:
 - Severe, progressive back pain (often radicular)
 - Fever

- Neurologic deficit:
 - Weakness or paralysis
 - Sensory level
 - Sphincter disturbance
 - May present with signs and symptoms of sepsis without prominent back pain
- Occurs at all ages including infants:
 - Peak is at ages 60–70 yr
- Most patients have predisposing condition:
 - IV drug abuse (IVDA)
 - Diabetes
 - Malignancy
 - Chronic steroids
 - Chronic alcoholism
 - Instrumentation or spinal surgery
 - Indwelling vascular catheter
- May occur in the absence of identifiable predisposing factors

History

- Back pain
- Fever
- Neurologic deficit:
 - Weakness
 - Paresthesias
 - Incontinence

Physical-Exam

- Fever
- Localized spinal tenderness and/or erythema
- Neurologic deficit
- Evidence of IV drug use or other predisposing factors

ESSENTIAL WORKUP

- History should include predisposing conditions when this diagnosis is suspected
- Physical exam for source of infection, localized spinal tenderness, and neurologic findings:
 - Decreased sphincter tone
 - Saddle anesthesia
 - Lower extremity weakness
- Postvoid residual or sonography
- Younger adults should have < 50 mL postvoid residual urine:
 - Older adults may have residual of 100 mL
- Erythrocyte sedimentation rate (ESR) as below

- MRI with and without gadolinium contrast is the diagnostic test of choice:
 - CT with IV contrast or myelography if MR not available
 - Suspected epidural abscess is an emergency and requires emergent imaging

DIAGNOSIS TESTS & INTERPRETATION

Lab

- ESR is almost always elevated (~100%), but is nonspecific:
 - Normal ESR makes diagnosis much less likely
- C-reactive protein nearly always elevated
- Blood cultures often positive (~60%)
- Leukocytosis with left shift is common (~70%)
- CSF often abnormal, but nondiagnostic; routine lumbar puncture should be avoided when epidural abscess is primarily suspected (may cause meningitis)

Imaging

- MRI is at least 90% sensitive:
 - Shows high-intensity lesion on T2 imaging
- CT with IV contrast if MR or myelography not available
- Myelography and CT myelography are also sensitive, but risk dissemination
- Plain films are often abnormal but nonspecific

DIFFERENTIAL DIAGNOSIS

- Diagnosis is difficult owing to rarity of condition and nonspecific symptoms:
 - Multiple physician encounters commonly precede diagnosis
 - Most common initial diagnosis is benign musculoskeletal pathology: Muscular or ligamentous pain, degenerative arthritis, compression fracture, discogenic pain
- Back pain with fever, systemic signs, and symptoms:
 - Vertebral osteomyelitis
 - Spinal tumor (usually there is a known primary)
 - Meningitis (cervical epidural abscess may mimic, but bacterial meningitis usually associated with abnormal mental status)
 - Discitis (usually postinstrumentation)
 - Pyelonephritis
- Back pain with neurologic signs and symptoms:
 - Cord compression
 - Cord ischemia
 - Disc herniation

Pediatric Considerations

Fever and back pain should be urgently investigated with MRI when epidural abscess is suspected

TREATMENT

PRE HOSPITAL

Spinal immobilization if trauma suspected or other cause of fracture suspected

INITIAL STABILIZATION/THERAPY

Broad-spectrum parenteral antibiotics early

- Must include coverage for *S. aureus*, Streptococci, and gram-negative rods
- Vancomycin (for possible MRSA) and a 3rd-generation cephalosporin (for gram-negative coverage) are appropriate initial antibiotics
- Cover *Pseudomonas* if IVDA
- 1 suggested regimen includes vancomycin, ceftazidime, and metronidazole (for anaerobes)

ED TREATMENT/PROCEDURES

- Urgent imaging essential when diagnosis is considered
- Delay in treatment is associated with poorer outcome
- If unable to localize lesion on physical exam, consider imaging entire spine
- Urgent neurosurgical consultation or transfer for definitive therapy (surgical decompression) after diagnosis and antibiotic administration:
 - Conservative treatment (prolonged [6 wk] antibiotic therapy) may be successful

MEDICATION

- Ceftazidime: 2 g (peds: 50 mg/kg)
- Vancomycin: 15 mg/kg IV loading dose (peds: 10–15 mg/kg q6–8h) q12h
- Metronidazole: 500 mg IV

First Line

- Ceftazidime
- Vancomycin
- Metronidazole if anaerobes suspected

FOLLOW-UP

DISPOSITION

Admission Criteria

Patients with epidural abscess should be admitted; MRI is needed emergently; transfer patient if necessary

Discharge Criteria

Patients with definite or strongly suspected epidural abscess should not be discharged

Issues for Referral

Patients with spinal epidural abscess require admission to facility with neurosurgical capability:

- Transfer usually indicated if a neurosurgeon or MRI is unavailable:
 - Administer antibiotics and obtain blood cultures (positive in ~ 60%) prior to antibiotics unless this results in a delay

PEARLS AND PITFALLS

- Successfully treated epidural abscess may reoccur, especially in the setting of decreased immunity
- Patients with Staphylococcal bacteremia and back pain or neurologic signs/symptoms should be investigated for epidural abscess
- Failure to order images that include the involved area:
 - Careful physical exam for areas of spinal tenderness and level of neurologic deficit may help avoid this pitfall:
 - Consider both thoracic and lumbar imaging for a problem suspected in the mid back and cervical and thoracic imaging for upper back and neck pathology
 - If unable to localize lesion on physical exam, consider imaging entire spine

CODES

ICD9

324.1 Intraspinal abscess

ICD10

G06.1 Intraspinal abscess and granuloma

EPIDURAL HEMATOMA

Stephen R. Hayden

BASICS

DESCRIPTION

- Direct skull trauma
- Inward bending of calvarium causes bleeding when dura separates from skull:
 - Middle meningeal artery is involved in bleed > 50% of time.
 - Meningeal vein is involved in 1/3.
- Skull fracture is associated in 75% of cases, less commonly in children.
- > 50% have epidural hematoma (EDH) as isolated head injury:
 - Most commonly associated with subdural hematoma (SDH) and cerebral contusion
- Classic CT finding is lenticular, unilateral convexity, usually in temporal region.
- It usually does not cross suture lines, but may cross midline.

ETIOLOGY

- Accounts for 1.5% of traumatic brain injury (TBI)
- Male/female incidence is 3:1.
- Peak incidence is 2nd–3rd decade of life.
- Motor vehicle accidents (MVAs), assault, and falls are most common causes:
 - Of all blunt mechanisms, assault has highest association with intracranial injury requiring neurosurgical intervention.
- Uncommon in very young (< 5 yr) or elderly patients
- Mortality is 12% and is related to preoperative condition.

Pediatric Considerations

- Head injury is the most common cause of death and acquired disability in childhood.
- Falls, pedestrian-struck bicycle accidents are most common causes:
 - Most severe head injuries in children are from MVA.
 - Always consider possibility of nonaccidental trauma.
- < 50% have altered level of consciousness (LOC):
 - If EDH in differential diagnosis (DD), CT should be obtained.
- Bleeding is more likely to be venous.
- Good outcome in 95% of children < 5 yr

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Altered or deteriorating LOC
- LOC: 85% will have at some point in course:
 - Only 11–30% will have a lucid interval.
- Nausea and vomiting: 40%

Pediatric Considerations

- Many times the only clinical sign is drop in hematocrit (Hct) of 40% in infants.
- Bulging fontanel with vomiting, seizures, or lethargy also suggests EDH in infants.
- <50% of children have LOC at time of injury.
- Posterior fossa lesions are seen more commonly in children.

Physical-Exam

- Pupillary dilation: 20–40%:
 - Usually on same side as lesion (90%)
- Hemiparesis > 1/3:
 - Usually on opposite side from lesion (80%)

ESSENTIAL WORKUP

Head imaging, as below

DIAGNOSIS TESTS & INTERPRETATION

Lab

- ABG, CBC, chemistry, PT/PTT
- Blood ETOH and drug screen as appropriate

Imaging

- Noncontrast CT of head:
 - Admission perfusion CT may help predict prognosis.
 - Lenticular, biconvex hematoma with smooth borders may be seen.
 - Mixed density lesion may indicate active bleeding.
 - Most commonly seen in temporal parietal region
- Plain films may show skull fractures:
 - CT with bone windows is more often used.
- Spine series
- Further workup of trauma as indicated

Pediatric Considerations

US may be used for diagnosis in infants with open fontanels.

DIFFERENTIAL DIAGNOSIS

- History of recent head trauma lends itself to the diagnosis:

- Trauma may be minor in infants and toddlers.
- Consider other diagnosis:
 - SDH
 - Cerebral concussion/contusion
 - Intracerebral bleed
 - Diffuse axonal injury
 - Subdural hygroma
 - Shaken baby syndrome
 - Toxic, metabolic, or infectious causes

TREATMENT

PRE HOSPITAL

- Head-injured patients have 25% improved mortality when triaged to regional trauma centers.
- Spinal immobilization is essential.
- Ensure adequate oxygenation throughout transport:
 - Intubation and airway protection may be necessary.

INITIAL STABILIZATION/THERAPY

- Prevent hypoxia and hypotension:
 - Rapid-sequence intubation for signs of deterioration or increased intracranial pressure (ICP)
 - Controlled ventilation to PCO_2 of 35–40 mm Hg
 - Avoid hyperventilation unless signs of brain herniation are present.
 - Avoid induction agents, which may increase ICP (e.g., ketamine).
- Elevate head of bed 20° – 30° after adequate fluid resuscitation.
- Perform rapid neurologic assessment:
 - Glasgow coma scale (GCS) score:
 - 14–15; minor head injury
 - 9–13; moderate head injury
 - < 8; severe:
 - Reflexes; pupils, corneal, gag, brainstem reflexes
- Secondary survey will reveal coexisting injury in >50%.

ED TREATMENT/PROCEDURES

- Early surgical intervention (< 4 hr) in comatose patients with EDH improves meaningful survival:
 - Burr hole is placed at fracture site or side with ipsilateral pupillary dilation.
 - Rapid craniectomy is occasionally performed if bleeding is not controlled at site of burr hole.
- Nonsurgical intervention in asymptomatic patients is associated with high rate of

deterioration; > 30% require surgical intervention.

- Maintain euvoemia with isotonic fluids.
- Continuous end tidal CO₂ monitoring:
 - Arterial line placement for close monitoring of MAP, PO₂, PCO₂
 - Foley catheter to monitor input/output (I/O) status
- Control ICP:
 - Prevent pain, posturing, and increased respiratory effort:
 - Sedation with benzodiazepines
 - Neuromuscular blockade with vecuronium or rocuronium in intubated patients
 - Etomidate is a good induction agent.
 - Barbiturate coma should be initiated for refractory increased ICP in neurosurgical ICU.
 - Mannitol may be used once euvolemic:
 - Shown to increase MAP greater than coronary perfusion pressure (CPP) and cerebral blood flow (CBF), as well as decrease ICP
 - Keep osmolality between 295 and 310.
 - Use furosemide (Lasix) as adjunct only if no risk of hypovolemia.
- Treat HTN:
 - Labetalol or hydralazine
- Treat hyperglycemia if present:
 - Associated with increased lactic acidosis and mortality in patients with TBI
- Treat and prevent seizures:
 - Diazepam and Dilantin
- Not considered helpful:
 - Steroids
 - Antibiotic prophylaxis
 - Hyperventilation in the absence of herniation
 - Fluid restriction
 - Calcium channel blockers
- Factors associated with poor outcome:
 - Age > 40 yr
 - Increased admission base deficit
 - Large hematoma with rapid expansion
 - Increased midline shift
 - Lower admission GCS or unconsciousness at presentation
 - Postoperative ICP > 3
 - Prolonged anisocoria
 - Associated brain injuries or concomitant trauma injuries

Pediatric Considerations

Hemodynamically significant blood loss can result from scalp lacerations and subgaleal

hematomas: Direct pressure and control of bleeding is indicated.

MEDICATION

- Diazepam: 5–10 mg (peds: 0.1–0.2 mg/kg) IV
- Dilantin: Adult/peds: Load 18 mg/kg at 25–50 mg/min
- Etomidate: 0.3 mg/kg IV
- Fentanyl: 2–4 U μ g/kg IV
- Furosemide (Lasix): Adults/peds: 0.5 mg/kg IV
- Hydralazine: 10 mg/h IV (peds: 0.1–0.5 mg/kg IV) q3–4h PRN
- Labetalol: 15–30 mg/h IV (peds: 0.4–1 mg/kg/h IV continuous infusion; max. 3 mg/kg/h)
- Levetiracetam: 1,500 mg IV/PO q12h
- Lidocaine: As preinduction agent, 1.5 mg/kg IV
- Mannitol: Adults/peds: 0.25–1 g/kg IV q4h
- Midazolam: 1–2 mg (peds: 0.15 mg/kg IV \times 1) IV q10min PRN
- Pentobarbital: 1–5 mg IV q6h
- Prothrombin complex concentrate 50 U/ kg IV
- Rocuronium: 1 mg/kg IV
- Thiopental: As induction agent, 20 mg/kg IV

Pediatric Considerations

- Hypertonic saline has been shown to be beneficial in some pediatric studies (1.7–3%).
- NaCl 3%: 2–6 mL/kg IV. Infusion 0.1–1 mL/kg/h

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with CT abnormality or altered LOC should be admitted to ICU setting with frequent neurologic assessment.
- Patients should have repeated CT exam in 12–24 hr or if clinical deterioration occurs.
- Patients at increased risk of deterioration include those with rapid bleeds, associated skull fracture, or lower GCS or neurologic deficits.

Discharge Criteria

Admission is necessary for all patients with EDH.

EPIGLOTTITIS, ADULT

Jonathan Fisher • Colby Redfield

BASICS

DESCRIPTION

- Rapidly progressive inflammation of the epiglottis and surrounding tissues leading to airway compromise
- May be more indolent in adults than pediatrics; rapid progression to total airway occlusion still seen in adults
- Although the incidence of pediatric epiglottitis has been decreasing, the incidence in adults is increasing
- Inflammation of supraglottic structures:
 - Epiglottis:
 - Edema is the primary airway concern
 - May be primary or secondary from adjacent structures
 - Vallecula
 - Arytenoids
- Incidence is 1–4:100,000 adults per year and rising
- More common in men: 3:1
- Adult mortality rate is 7% (<1% in children)
- Most common in 5th decade of life
- Immunocompromised patients may be particularly fulminant, with minimally associated symptoms and unusual pathogens, such as *Candida* and *Pseudomonas aeruginosa*
- Complications:
 - Total airway obstruction
 - Retropharyngeal abscess
 - Acute respiratory distress syndrome
 - Pneumonia
 - Empyema

ETIOLOGY

- Infectious causes:
 - *Haemophilus influenzae B*, also type A and nontypeable strains
 - *Haemophilus parainfluenzae*
 - *Streptococcus pneumoniae*
 - *Staphylococcus aureus*
 - Group A Streptococcus
 - *Neisseria meningitis*
 - Herpes simplex

- Cytomegalovirus
- *P. aeruginosa*
- Numerous other uncommon agents
- Physical agents:
 - Chemical and thermal burns
 - Toxic or illicit drug inhalation
- Trauma, instrumentation

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- General:
 - Fever
- Upper respiratory tract infection symptoms
- Prodrome absent in significant number of cases
- Head, eyes, ears, nose, throat:
 - Dysphagia
 - Muffled voice
 - Voice change:
 - “Hot potato” voice
 - Hoarseness
 - Foreign body sensation in throat
 - Drooling
 - Associated tonsillar, peritonsillar, uvular findings
- Respiratory:
 - Subjective sense of obstructed airway
 - Short of breath

Physical-Exam

- General:
 - Fever
 - Toxic appearing
 - Sitting up in “tripod” stance
- Head, eyes, ears, nose, throat:
 - “Cherry red” epiglottitis is classic, may be pale and edematous in up to 50%
 - Hyoid/thyroid cartilage tender to gentle palpation
 - Tracheal rock: Pain with movement of the larynx from side to side
 - Lymphadenopathy
- Respiratory:
 - Stridor

- Sudden loss of airway
- Respiratory distress with accessory muscle use

ALERT

Patients with respiratory distress are at high risk for rapid progression to complete airway obstruction. Surgical airway management may be required.

ESSENTIAL WORKUP

If significant respiratory distress:

- Avoid invasive diagnostic procedures
- Manage empirically with antibiotics and control of airway prior to further diagnostic evaluation

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC with differential
- Blood cultures
- Cultures of pharynx:
 - Only if no signs of respiratory distress

Imaging

- In patients with moderate to severe respiratory distress, the airway should be managed prior to imaging
- Portable lateral soft tissue x-ray:
 - Epiglottic “thumb” sign:
 - Thickening of the epiglottis
 - “Vallecula” sign:
 - The vallecula is normally well-delineated, deep, and roughly parallel to the pharyngotracheal air column
 - Absence of a deep and well-defined vallecula, approaching the level of the hyoid bone
 - Swelling of the arytenoids and aryepiglottic folds
 - Prevertebral soft tissue swelling
 - Significant false-negative with imaging
 - If suspected with negative film results, rule out with indirect visualization
- CT:
 - Indicated when a laryngoscopic evaluation cannot be performed or if coexistent soft tissue complications are suspected

Diagnostic Procedures/Surgery

- Avoid prior to airway management if any signs of respiratory distress are present, including stridor

- Nasopharyngoscopy (mini-fiberoptic scope)
- Indirect laryngoscopy

DIFFERENTIAL DIAGNOSIS

- Croup
- Airway foreign body
- Anaphylaxis
- Paradoxical vocal cord dysfunction
- Angioedema
- Laryngitis
- Pharyngitis
- Oropharyngeal abscess (peritonsillar or retropharyngeal)
- Bacterial tracheitis
- Congenital anomaly
- Meningitis

TREATMENT

PRE HOSPITAL

- Transport patients in position of comfort
- Supplemental oxygen as tolerated; avoid increasing anxiety
- Intubation indicated only if patient is in severe respiratory distress:
 - Likely difficult airway and significant chance of exacerbating compromise with laryngoscopy attempts
- Inhaled agents, racemic epinephrine, and β -agonists have no demonstrated value.

INITIAL STABILIZATION/THERAPY

- ABCs
- Be prepared with all equipment on hand for definitive airway management, including a surgical airway, from presentation until diagnosis is ruled out or transport to intensive care setting
- Exam of the airway can trigger airway obstruction
- Orotracheal intubation in patients with signs of obstruction or significant respiratory distress:
 - Respiratory distress/airway failure may develop precipitously
 - Consider ear-nose-throat/surgical consult if patient's condition permits for possible difficult/surgical airway
- Needle jet insufflation may be a life-saving temporizing measure if a surgical airway is not immediately attainable with failed intubation

ED TREATMENT/PROCEDURES

- Humidified oxygen support
- IV access, hydration as indicated

- Begin antibiotic coverage empirically
- Corticosteroids are controversial

MEDICATION

First Line

- Cefotaxime: 2 g IV q8h
- Ceftriaxone: 2 g IV q24h

Second Line

- Ampicillin/sulbactam: 3 g IV initially, then 200–300 mg/kg/d in 4 div. doses + vancomycin 1 g IV q12h
- Trimethoprim–sulfamethoxazole: 320 mg IV initially, then 4–5 mg/kg IV q12h
- Consider adding increased coverage against *S. aureus*:
 - Nafcillin: 150–200 mg/kg IV per day in 4 div. doses
 - Clindamycin: 600–900 mg IV q8h
- Rifampin prophylaxis:
 - Adults: 600 mg/d PO for 4 days
 - > 1 mo of age: 20 mg/kg/d PO for 4 days
 - < 1 mo of age: 10 mg/kg/d PO for 4 days

FOLLOW-UP

DISPOSITION

Admission Criteria

Any patient with a suspected or confirmed diagnosis of epiglottitis should be admitted to an ICU setting for IV antibiotics and airway management

Discharge Criteria

- Patients should not be discharged unless the diagnosis has been ruled out by visualization of the supraglottic structures by a physician familiar with physical appearance of the disease
- Close contacts should receive prophylactic treatment with rifampin

Issues for Referral

ENT consultation should be obtained

PEARLS AND PITFALLS

- Failure to manage the airway in a timely manner
- Avoid any unnecessary intervention until airway is secured

- Mortality is 7% in adults with epiglottitis

- J05.11 Acute epiglottitis with obstruction

EPIGLOTTITIS, PEDIATRIC

Beverly Bauman

BASICS

DESCRIPTION

- Inflammation of the epiglottis and surrounding supraglottic region, which is potentially life threatening due to progressive airway obstruction
- Children are at greater risk of upper airway obstruction owing to:
 - Decreased cross-sectional area of the upper airway (resistance is proportional to the inverse of the radius to the 4th power)
 - Loose attachment of mucosal surface and increased vascularity of mucosa allows for edema
 - Dynamic collapse of the airway
- A precipitous decline in the incidence of childhood epiglottitis since the introduction of the *Haemophilus influenzae* vaccination has occurred, although vaccine failure may result in rare cases among children who have been immunized
- In the post-Hib vaccine era, the mean age for this disease has increased, and it is now more commonly seen in adolescents and adults than in toddlers or young school-aged children.
- May occur throughout the year

ALERT

All patients with suspected epiglottitis require intensive monitoring and intervention. Rapid progression of airway obstruction may occur.

ETIOLOGY

- Infection:
 - *H. influenzae* type B
 - *Streptococcus pneumoniae*
 - Group A β -hemolytic
 - Streptococcus
 - *Staphylococcus aureus*
 - Viruses
 - Less common infections include Klebsiella, Pseudomonas, Candida
- Caustic
- Thermal
- Traumatic
- Post-transplant lymphoproliferative disorder
- Hereditary angioedema

SIGNS AND SYMPTOMS

History

- Usually fulminant presentation without prodromal illness
- General:
 - Irritability, throat pain (often described as patient's worse sore throat), fever, noisy breathing
 - Progressive toxicity and respiratory distress
 - Adults have often been previously seen by a physician 1 or more times before diagnosis is made. Adults may present with the “worst sore throat of my life.”

Physical-Exam

- General:
 - Toxic appearing
 - High fever is typical.
 - Rapid onset and progression
- Throat:
 - Drooling
 - Dysphagia
 - Muffled “hot potato” voice
 - Older patients often have very painful throat.
- Respiratory:
 - Rapidly progressive respiratory distress (dyspnea in only 1/3 of adults)
 - Children usually prefer to sit upright, leaning forward with open mouth (“tripod sniffing position”) to maximize air entry.
 - Subtle stridor that may progress to severe stridor (stridor in only 10% of adults)
- Complications:
 - Airway obstruction is the most severe complication.
 - Epiglottic abscess
 - Associated pneumonia and atelectasis

ESSENTIAL WORKUP

- Epiglottitis is a clinical diagnosis.
- Indirect laryngoscopy or any attempts to directly visualize the epiglottis are not indicated in children with suspected epiglottitis unless performed in a controlled environment. (In adolescents or adults, use of fiberoptic nasopharyngoscope may be indicated for patients without impending airway obstruction.)
- If infection is suspected, obtain cultures of the epiglottis during laryngoscopy after

airway is secure.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Avoid lab tests until airway is controlled.
- Throat cultures after control of airway
- Blood cultures after airway is secure:
 - Often positive if *H. influenzae* is the pathogen

Imaging

- Radiographs of the soft tissue lateral neck:
 - Usually not necessary to make the diagnosis
 - Creates additional risk by delaying stabilization of the airway, promoting airway obstruction by agitating the patient, and often removing the child from the ED to an uncontrolled environment. Children should never go unaccompanied to radiology. Personnel and equipment to control airway must always be available.
- Variable findings:
 - Normal
 - Swelling of the epiglottis (“thumbprint sign”) and often supraglottic region
 - Ballooned hypopharynx
 - Obliteration of vallecula
 - EW/C3W (epiglottic width to 3rd cervical vertebral body width) ratio of >0.5

Diagnostic Procedures/Surgery

Laryngoscopy:

- In a controlled environment whenever possible
- Cultures of the epiglottis during laryngoscopy after the airway is secured may help identify pathogens and direct treatment.
- Epiglottis will appear swollen, inflamed, reddened.

DIFFERENTIAL DIAGNOSIS

- Other infectious processes:
 - Bacterial tracheitis
 - Retropharyngeal abscess
 - Peritonsillar abscess
 - Croup (laryngotracheobronchitis)—primarily in younger children, but there is a significant overlap in the ages of presentation.
 - Pertussis
 - Mononucleosis
 - Ludwig angina

– Diphtheria

- Anaphylactic reaction with angioedema
- Hereditary angioedema
- Foreign body in upper airway
- Laryngeal trauma
- Laryngospasm
- Inhalation or aspiration of toxins (e.g., hydrocarbons)
- Airway burns (have been related to crack cocaine)
- Hyperventilation
- CNS disorders

TREATMENT

PRE HOSPITAL

Degree and mode of intervention must reflect degree of obstruction, time and means of transport, capability of care providers, etc. Consult and notify receiving hospital.

INITIAL STABILIZATION/THERAPY

- Airway management if patient is in extremis
- Bag-valve-mask ventilation with 100% O₂ with cricoid pressure often provides adequate ventilation and time to prepare for intubation and move to a controlled setting such as the operating room.
- Oral intubation:
 - Use an endotracheal tube (ETT) size that is 1 or 2 sizes smaller than indicated by age or length.
 - Direct compression of the anterior neck in the glottic region may help visualize air bubbles at the opening of the swollen glottis.
 - Instruments used for difficult airways may be adjunctive devices.
- If oral intubation fails:
 - Emergent cricothyrotomy or needle cricothyrotomy if age older than 10–12 yr
 - Needle cricothyrotomy if age younger than 10–12 yr

ED TREATMENT/PROCEDURES

- 100% O₂ as tolerated by patient
- Allow child to remain in position of comfort and do not force child to lie down, which may worsen airway obstruction.
- Although not proven, racemic epinephrine or L-epinephrine by nebulizer may temporize symptoms while plans for a definitive airway are rapidly arranged. It must be done with caution to avoid agitating the child.
- Avoid procedures that agitate the child such as IV access and blood draws.
- Empiric invasive airway management may be indicated:

- Patients with rapidly progressive respiratory difficulty, tachypnea, worsening throat pain, tachycardia, or hypoxemia
- Patients at high risk of acute obstruction (e.g., children with immunodeficiency disorders)
- Intubate in operating room or controlled environment by most skilled person.
- Use inhalational anesthesia before intubation.
- Have appropriate ETTs of various diameters of available to accommodate the inflamed supraglottic region.
- Surgical backup is required in case intubation is not possible; then emergency tracheotomy or cricothyrotomy can be performed.
- Equipment for intubation and for a surgical airway or needle cricothyrotomy must be available at the bedside.
- Administer IV antibiotics: 2nd- or 3rd-generation cephalosporins are active against β -lactamase-producing *H. influenzae*.
- Steroids are controversial but frequently administered, particularly in patients with chemical or thermal epiglottitis.

MEDICATION

First Line

- Ampicillin/sulbactam: 200–300 mg/kg/24h q6h IV
- Cefotaxime: 150 mg/kg/24h q6–8h IV
- Ceftriaxone: 100 mg/kg/24h q12h IV

Second Line

- Ampicillin: 100–200 mg/kg/24h q6h IV given with chloramphenicol
- Chloramphenicol: 75–100 mg/kg/24h q6h IV
- Meropenem: 120 mg/kg/24h q8h max. dose 6 g/24h
- Decadron: 0.6 mg/kg/d (max. 10 mg) IV.
 - Steroid use is controversial
- Epinephrine, racemic: 0.05 mL/kg (max. 0.5 mL) q30min in 2.5 mL normal saline (NS) via nebulizer
- L-epinephrine, 1:1,000: 0.5 mL/kg (max. 5 mL) q30min via nebulizer
- Rifampin for household contact prophylaxis: 20 mg/kg (max. 600 mg) daily for 4 days
- If hereditary angioedema is the suspected cause of epiglottitis, C1 esterase inhibitor concentrate (alternatively, if C1-INH is not available, consider fresh frozen plasma). Expert consultation recommended

FOLLOW-UP

DISPOSITION

Admission Criteria

Patients with suspected or proven epiglottitis should be admitted to ICU after stabilization of airway and administration of antibiotics and fluids.

Discharge Criteria

- Rifampin prophylaxis may be indicated for close contacts of *H. influenzae* epiglottitis. If the household has children younger than 12 mo of age or children who are unimmunized, incompletely immunized, or immunosuppressed, prophylaxis is indicated for nonpregnant household contacts. Child care center contacts should receive prophylaxis when 2 or more cases of Hib invasive disease have occurred within 60 days.
- All cases of invasive *H. influenzae* disease should be reported to the local or state public health department.

Issues for Referral

Critical care or pulmonary consult on all patients

PEARLS AND PITFALLS

True airway emergency. Patient must be monitored and accompanied at all times by someone with airway stabilization capabilities.

EPIPHYSEAL INJURIES

Neha P. Raukar • Daniel L. Savitt

BASICS

DESCRIPTION

- Fractures through the physis accounts for 21–30% of pediatric long bone fractures with 30% of these leading to a growth disturbance:
 - Most frequently seen in the distal radius and ulna, distal tibia and fibula, and the phalanges
 - More common than ligamentous injury in children:
 - Tensile strength of pediatric bone is less than adjacent ligaments.
 - Physis is the weakest part of pediatric bone.
 - Similar injury in an adult usually causes a sprain.
- Most common during peak growth:
 - Females: Age 9–12
 - Males: Age 12–15
 - Much less common in infancy and early childhood because epiphysis is not ossified and acts as a shock absorber
- Twice as common in males because female bones mature earlier
- Salter–Harris (SH) classification (introduced in 1963, simplest and most commonly used classification system):
 - Type I:
 - Fracture line confined to physis
 - Complete epiphyseal separation from metaphysis through the physis
 - If periosteum remains intact, epiphysis will not displace.
 - Clinical diagnosis made with focal tenderness over the physis
 - Most common example is SCFE.
 - Growth disturbance is rare.
 - Type II:
 - Accounts for ~ 80% of physeal fracture patterns
 - Fracture propagates along physis, and fragment from metaphysis accompanies the displaced epiphysis (Thurston–Holland sign)
 - Periosteum torn opposite metaphyseal fragment
 - Growth is rarely disturbed.
 - Type III:
 - Rare
 - Fracture through a portion of physis extending through the epiphysis
 - Distal tibia most commonly affected
 - If displaced, requires reduction to maintain anatomic alignment
 - Growth disturbance may occur despite anatomic reduction because

blood supply can be affected.

- Type IV:
 - Fracture originates at articular surface.
 - Extends through physis and into metaphysis
 - Distal humerus most commonly affected
 - Also has Thurston–Holland fragment
 - Anatomic reduction essential and displaced fractures require ORIF
 - Growth arrest is common even with optimal treatment.
- Type V:
 - Results from severe crush injury to physis
 - No immediately visible radiographic alteration so almost impossible to diagnose initially
 - Compression forces lead to physeal injuries and inevitable growth disturbances.
 - Often found in retrospect
- Ogden modified the SH system to include injuries to the surrounding anatomy—periosteum, perichondrium, and zone of Ranvier:
 - Ogden Type VI: Involves the peripheral perichondrium including the zone of Ranvier
 - Ogden Type VII: Involves epiphysis only
- Peterson classification system, 1994:
 - Result of a 10 yr retrospective study
 - Showed that 16% of physeal injuries could not be classified by the SH system
 - Includes 2 different fracture patterns:
 - Peterson Type I—transverse fracture through the metaphysis with 1 or more longitudinal extensions into the physis (this is similar to SH II except most of the energy is transmitted through the metaphysis, leading to a fracture, and not the physis; there is very little growth plate disturbance, this was actually the most common fracture pattern found)
 - Peterson Type VI—a part of the epiphysis, physis, and metaphysis are missing due to an open injury, classically by a lawnmower. Severe growth disturbance.
 - Peterson Types II–V are similar to the SH II–V.

ETIOLOGY

- Competitive and recreational injuries
- Traumatic injuries
- Child abuse
- Extreme cold
- Radiation injury
- Genetic, neurologic, and metabolic disease

SIGNS AND SYMPTOMS

History

- Most commonly occurs after a fall
- Extreme cold and radiation can injure the physeal plate.

Physical-Exam

- Focal tenderness
- Swelling
- Limited mobility
- If lower extremity involved, patient may be nonweight bearing
- Joint laxity:
 - _ Can be due to physeal injury and not ligamentous injury

ESSENTIAL WORKUP

- Radiographs to classify the extent of the injury
- Assess pulses and capillary filling distal to injury.
- Evaluate distal motor and sensory function.
- Verify integrity of skin overlying injury.
- Address and manage coexisting injuries.

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- Plain radiography of injured extremity:
 - _ Type I fractures:
 - Usually normal
 - May appreciate a slightly separated physis or an associated joint effusion
 - Consider comparison views of contralateral joint to detect small defects.
 - Callus may be present on follow-up films.
 - _ Types II–IV: Films diagnostic of fracture
 - _ Type V:
 - Initial film often normal
 - Subsequent radiographs may reveal premature bone arrest.
- Ultrasound can be helpful in infants whose cartilage has not ossified.
- CT scan: Helpful in assessing orientation of comminuted fragments
- MRI:
 - _ Most accurate in the acute phase of injury

- Can identify physal arrest lines
- Recommended if diagnosis remains equivocal and identification of a specific fracture would alter management

DIFFERENTIAL DIAGNOSIS

- Strain
- Sprain
- Contusion

TREATMENT

PRE HOSPITAL

- Immobilize limb in position found if no compromise in vascular status
- Apply ice or cold packs to injury.
- Assess injured extremity for neurologic and vascular function.
- Consider concomitant injuries.

INITIAL STABILIZATION/THERAPY

- Analgesia
- Apply sterile dressings to open wounds.
- Control bleeding of open wounds.

ED TREATMENT/PROCEDURES

- Reduction/alignment required in displaced fractures:
 - Need to achieve anatomic alignment
- Vascular or neurologic compromise distal to injury requires immediate intervention.
- Immobilization of all suspected or radiographically confirmed physal injuries:
 - Splint must immobilize joint proximal and distal to injury in anatomic alignment and neutral position.
 - Limit activity of the injured limb.
- Open fractures:
 - IV antibiotics for *Staphylococcus aureus*, group A streptococcus, and potential anaerobes depending on mechanism and after cultures are obtained
 - Copious irrigation with saline
 - Sterile dressing
 - Orthopedic consultation
- Consultation:
 - Open fractures
 - Type II with displacement and Types III and higher

MEDICATION

First Line

Pain management:

- Fentanyl: 2–3 µg/kg IV; transmucosal lollipops 5–15 µg/kg, max. 400 mg; contraindicated if <10 kg
- Morphine: 0.1 mg/kg IV/IM

If open:

- Cefazolin: 25–50 mg/kg/d IV/IM q6–8h
- Penicillin G: 100,000–300,000 U/kg/24 h IM, or IV in 4–6 div. doses—has better strep and corynebacterium coverage—for farm injuries
- Gentamicin: 5–7.5 mg/kg/d—for obviously contaminated injuries

FOLLOW-UP

DISPOSITION

Admission Criteria

- Open fractures
- Open surgical reduction required
- Consider with Type III and IV fractures

Discharge Criteria

- Low-grade fractures and fractures with higher grade if follow-up is definite
- Splint
- Analgesics
- Ice packs
- Elevation of affected limb
- Orthopedic follow-up within 1 wk

Issues for Referral

All injuries involving the physis should follow-up with a musculoskeletal specialist.

FOLLOW-UP RECOMMENDATIONS

Usually necessary, especially with higher-grade injuries, to monitor limb length:

- Involves periodic physical exam and radiographic evaluation

PEARLS AND PITFALLS

- Long-term complications:
 - Limb length discrepancy if entire growth plate affected
 - Angulation if only a part of the physis is affected
- In patients with suspected SH fracture and negative radiograph, immobilization with follow-up in a few days is appropriate.

EPISTAXIS

Richard E. Wolfe • Christopher M. McCarthy II

BASICS

DESCRIPTION

- Nosebleeds are a common emergency presentation that is usually minor and self-limited but rarely may be life threatening:
 - _ Lifetime incidence of ~60%:
 - The incidence decreases with age, with most cases seen in children <10 yr.
 - Male > female
 - Severe bleeds requiring surgical intervention are more common in patients >50 yr.
 - Occurs more frequently with low humidity during the winter, in northern climates, and at high altitude
- The nasal cavity is supplied with blood vessels originating from both the internal and external carotid arteries.
- Location of the hemorrhage determines therapy:
 - _ Anterior epistaxis (90% of cases): Bleeding can be visualized in anterior nose.
 - Most commonly bleeding is located at Kiesselbach plexus, an anastomotic network of vessels on the anteroinferior nasal septum.
 - Rarely, bleeding is found on the posterior floor of the nasal cavity or the nasal septum.
- Posterior epistaxis (10% of cases): Bleeding source not within range of direct visualization.
 - _ Posterolateral branch of sphenopalatine artery

ETIOLOGY

- Idiopathic:
 - _ Dry nasal mucosa (low humidity)
- Nasal foreign body:
 - _ Children, mentally retarded patients, psychiatric patients
- Infection:
 - _ Rhinitis
 - _ Sinusitis
 - _ Nasal diphtheria
 - _ Nasal mucormycosis
- Allergic rhinitis
- Trauma:

- Nose picking
- Postoperative
- Facial trauma
- Barotrauma
- Environmental irritants:
 - Ammonia
 - Gasoline
 - Sulfuric acid
 - Glutaraldehyde
- Intranasal neoplasia: Most commonly Papilloma
- Coagulopathy:
 - Hemophilia A or B
 - Von Willebrand disease
 - Thrombocytopenia: Liver disease, leukemia, chemotherapy viral illness, or autoimmune disease.
 - Platelet dysfunction: Renal impairment or chronic alcohol consumption
- Drug induced:
 - Salicylates
 - NSAIDs
 - Heparin
 - Coumadin
- Hereditary hemorrhagic telangiectasia (Osler–Weber–Rendu disease)
- Atherosclerosis of nasal vasculature
- Endometriosis

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Laterality of the bleeding
- Intensity and amount of bleeding from the nares
- Recurrence of epistaxis and history of prior episodes
- Nasal obstruction and the duration of this symptom
- Complaints of vomiting or coughing blood
- Known tumors or coagulopathy
- Unusual bleeding or easy bruising suggests an underlying coagulopathy.
- Presence of systemic disease exacerbated by blood loss (coronary artery disease, chronic obstructive pulmonary disease)

Physical-Exam

- Evaluate vitals for hemorrhagic shock

- Careful exam for signs of coagulopathy:
 - Bruises
 - Petechiae and purpura
- Nasopharyngeal inspection:
 - Anesthetize nasopharynx prior to exam with cotton swab soaked in anesthetic and vasoactive agent.
- Attempt to identify bleeding source with nasal speculum
- Blood in mouth or oropharynx

ESSENTIAL WORKUP

- Assess stability: Airway compromise, hypovolemia.
- Determine source (anterior vs. posterior).
- Consider underlying coagulopathy.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Consider for severe bleeding or suspected coagulopathy:
 - CBC, type and cross-match, PT/INR, PTT, BUN

Diagnostic Procedures/Surgery

Direct visualization of nasal mucosa with nasal speculum:

- Pretreat with topical vasoconstricting agent and anesthetic.
- Ensure adequate lighting (i.e., headlamp) and suction.

DIFFERENTIAL DIAGNOSIS

- Hematemesis
- Hemoptysis

Pediatric Considerations

- Posterior epistaxis is rare in children; consider further workup for bleeding diatheses.
- Consider nasal foreign bodies or neoplasm, such as juvenile angiofibroma or papilloma.
- 4 wk of topical antiseptic ointment decreases incidence of recurrent epistaxis.

TREATMENT

PRE HOSPITAL

- Stable patients: Patient should bend forward at the waist; pinch nares closed, and spit out blood rather than swallow it.
- Unstable patients:

- Intubation, if airway is compromised
- IV access
- Crystalloid resuscitation, if signs of hypovolemia

INITIAL STABILIZATION/THERAPY

- Secure the airway in patients who are unconscious, have major facial trauma, or are otherwise at risk of obstruction or aspiration.
- Treat hypotension with crystalloids and blood products, if necessary, and ensure adequate IV access.

ED TREATMENT/PROCEDURES

- Universal precautions against blood/fluid contamination
- Anterior source:
 - Have patient apply direct pressure by pinching nares closed for 15 min. This may control bleeding and assist with visualization.
 - If bleeding persists, use bayonet forceps to place cotton pledgets soaked in vasoconstricting and anesthetic agents into affected nares.
 - If view is obstructed by blood have patient blow nose, or clear blood from view with irrigation and suction.
 - Visualize source of bleeding and cauterize limited area with silver nitrate.
 - Consider Gelfoam or Surgicel packing over cauterized site.
- Anterior nasal packing:
 - Indicated when cautery has failed to control bleeding
 - Associated with significant discomfort and infectious risk of sinusitis and toxic shock
 - Anterior nasal balloon:
 - Check the integrity of the balloons before insertion.
 - Cover with water-based lubricant or viscous lidocaine
 - Insert the device and inflate it slowly to avoid discomfort.
 - Use saline for the inflation if the balloon is to remain in place > a few hours.
 - Preformed nasal tampons:
 - Adequate anesthesia of the nasal passage should be ensured before placing the tampon.
 - Lubricate the tip of the sponge tampon with antibiotic ointment.
 - Insert it at a 45° angle ~1–2 cm into the nasal cavity.
 - Rotate the long axis of the tampon into a horizontal plane and push it firmly back into the nasal cavity.
 - If the pack does not fully expand from the blood, then use saline to complete the expansion.
 - Secure the drawstring to the cheek.
 - Petroleum-jelly–impregnated gauze:
 - Add an antibiotic ointment to the gauze.

- Ensure that a free end remains outside the nose.
- Place the gauze as far back as possible, starting on the floor of the nose.
- Repeat while securing the placed gauze with the speculum until the nose is fully packed.
- After anterior packing, persistent new bleeding may be a sign of inadequate packing or posterior source.
- Always treat patients with nasal packing with antibiotics to prevent sinusitis and prevent or limit *Staphylococcus aureus* infections that can lead to toxic shock syndrome (TSS).
- Posterior source:
 - Early endoscopic visualization and cautery of bleeding source may prevent need for posterior packing and admission.
 - Posterior packing may be accomplished with commercially available devices such as Nasostat or Epistat.
 - If commercial packs are unavailable, a Foley catheter may be directed into posterior nasopharynx until the tip visible in mouth. The balloon is then inflated and the catheter retracted until the balloon is lodged in the posterior nasopharynx. The catheter is then held in place by umbilical clamp.
 - Posterior pack should not be left in > 3 days due to infectious risk. Patient should be admitted and on telemetry while pack in place due to risk of vagal response.
- Complications of posterior packing:
 - Pressure necrosis of posterior oropharynx (do not overfill balloon)
 - Nasal trauma
 - Vagal response with reflex bradycardia
 - Aspiration
 - Infection/TSS
 - Hypoxia

MEDICATION

- Vasoactive solutions:
 - 4% cocaine
 - 1:1 mixture of 2% tetracaine and epinephrine (1:1,000)
 - 1:1 mixture of oxymetazoline 0.05% (Afrin) and lidocaine solution 4%
 - Phenylephrine (Neo-Synephrine)
- Antibiotics: For use while packing in place.
 - Amoxicillin–clavulanate potassium: 250 mg PO q8h
 - Cephalexin: 250 mg PO q6h
 - Clindamycin: 150 mg PO q6h
 - Trimethoprim–sulfamethoxazole: 160/800 mg PO q12h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Severe blood loss requiring transfusion
- Severe coagulopathy that places the patient at risk of further blood loss
- Posterior nasal packing: Otolaryngology consult and admission for telemetry, supplemental oxygen, possible sedation, and observation; possible further surgical intervention (e.g., arterial ligation or embolization)
- Patients with anterior packing who do not have reliable follow up within 48 hr.

Discharge Criteria

Stable patients:

- Use Afrin nasal spray for 2 days.
- Lubricate nares with an antibiotic ointment.
- Humidify air.
- Avoid nose picking.
- All patients with nasal packing in place should be prescribed an antistaphylococcal antibiotic (amoxicillin–clavulanate, cephalexin, trimethoprim–sulfamethoxazole) for the duration that the packing remains in place for prevention of both acute sinusitis and TSS.

Issues for Referral

- Refer all patients with packing to a specialist within 48 hr.
- Patients with nonvisualized source, suspicious-appearing lesions, recurrent same-side bleeding, or nasal obstruction should be referred to an ORL specialist for an exam to rule out a neoplastic etiology or a foreign body.

FOLLOW-UP RECOMMENDATIONS

- Return to ED for bleeding not controlled by pressure, fever, difficulty breathing, or vomiting.
- Avoid any nose blowing for 12 hr after the bleeding stops.
- Avoid nose picking or putting anything into the nose.
- If the bleeding starts again, sit up and lean forward, pinch the soft part of the nose tightly for 10 min without letting go.
- Avoid lifting heavy objects or doing too much work right away.
- If there is no packing in the nose, put a small amount of petroleum jelly or antibiotic ointment inside the nostril 2 times a day for 4–5 days.
- Use a humidifier or vaporizer at home.

PEARLS AND PITFALLS

- Foreign bodies should be suspected in any unilateral nasal bleeding in small children, psychiatric patients, and patients with mental retardation.
- Avoid covering anterior nasal balloons with antibiotic ointment, as petroleum-based materials may cause a delayed rupture of the balloon.
- Avoid overinflating nasal balloons or placing a pack too tightly, as it can cause necrosis and eschars.
- Patients with packings should receive prophylactic antibiotics

R04.0 Epistaxis

ERYSIPELAS

Irving Jacoby

BASICS

DESCRIPTION

- Superficial bacterial infection of the skin with prominent lymphatic involvement
- Leukocytosis is common
- Positive blood cultures in 3–5%

ETIOLOGY

- Group A β -hemolytic streptococcus is the causative organism (uncommonly, group C or G streptococci)
- Portals of entry:
 - Skin ulcers
 - Local trauma
 - Abrasions
 - Psoriatic or eczematous lesions
 - Fungal infections

Pediatric Considerations

- *Haemophilus influenzae* type b (HIB) causes facial cellulitis in children that may appear similar to erysipelas:
 - Should be considered in unimmunized children
 - Many will be bacteremic and require admission
 - Cefuroxime or other appropriate *H. influenzae* coverage is important
 - *H. influenzae* is much less common since widespread use of the HIB vaccine
- Group B streptococci can cause erysipelas in the newborn
- Can develop from infection of umbilical stump

Pregnancy Considerations

- Erythema of the breast in puerperal mastitis is often caused by Staphylococcus organisms, hence methicillin-resistant *S. aureus* (MRSA) should be covered
 - See Mastitis

DIAGNOSIS

SIGNS AND SYMPTOMS

- Most common sites of involvement are the face (5–20% of cases), lower legs (70–80% of cases), and ears
- Skin has an intense fiery red color, hence the name “Saint Anthony’s fire”

- Often bilateral on the face, but unilateral elsewhere
- Predilection for infants, children, and the elderly
- Systemic symptoms may include malaise, fever, chills, nausea, and vomiting
- Traumatic portal of entry on skin is not always apparent
- Rarely there may be an associated periorbital cellulitis or cavernous sinus involvement

History

- Facial erysipelas may follow a nasopharyngeal infection or trauma
- Predilection for areas of lymphatic obstruction:
 - _ Particularly in the upper extremity following radical mastectomy
 - _ Increased frequency after saphenous vein harvesting or stripping
 - _ May be a marker for previously undiagnosed lymphatic obstruction, or patients with congenital lymphedema (such as Milroy disease)
- 30% recurrence rate within 3 yr, owing to lymphatic obstruction caused by an episode of erysipelas

Physical-Exam

- Involved skin is:
 - _ Edematous
 - _ Indurated (peau d'orange)
 - _ Painful
 - _ Well-circumscribed plaque with sharp, clearly demarcated edges
- Classical butterfly rash on cheeks and across nose when affecting face
- Vesicles and bullae may be present in more serious infections

ESSENTIAL WORKUP

- The diagnosis is clinical:
 - _ Based on the characteristic skin findings and the clinical setting
- Needle-aspirate wound cultures are seldom positive and not indicated

DIAGNOSIS TESTS & NTERPRETATION

Lab

- Swabs of the skin are not indicated for culture, as they will show only skin organisms
- CBC with differential, and blood cultures should be performed in diabetics and other high-risk populations, or in patients with hypotension and those who require admission:
 - _ Blood cultures more likely to be positive in patients with lymphedema
- Check glucose in diabetics as infection may disrupt control
- Urinalysis: To check for proteinuria, hematuria, and red cell casts
 - _ Would suggest diagnosis of post-streptococcal glomerulonephritis (PSGN)

- If it occurs, usually around 2 wk after onset of skin infection
- Antistreptolysin O (ASL-O), anti-DNase B and streptolysin antibody serial titer changes are useful in diagnosing post-streptococcal immunologic entities such as rheumatic fever or glomerulonephritis,
 - Do not add anything to the diagnosis and management of uncomplicated erysipelas
 - Should not be routinely ordered unless there are already manifestations of such complications

Imaging

- There is no standard imaging for classical erysipelas
 - If deeper infection such as myositis is suspected, plain films of an extremity or CT scan may be performed to assess for the presence of gas
- Ultrasound may be useful to evaluate for an abscess if this is suspected, or in the leg to r/o deep vein thrombophlebitis DVT

DIFFERENTIAL DIAGNOSIS

- Abscess
- Acute bacterial sinusitis
- Allergic inflammation
- Cellulitis
- Contact dermatitis
- DVT
- Diffuse inflammatory carcinoma of the breast
- Familial mediterranean fever
- Herpes zoster, second division of cranial nerve V
- Impetigo
- Inflammatory dermatophytosis
- Mastitis
- Necrotizing fasciitis
- Periorbital cellulitis
- Systemic lupus erythematosus (SLE) with butterfly rash
- Streptococcal or staphylococcal TSS (sunburn-like rash)
- Venous stasis dermatitis
- Viral exanthem

TREATMENT

PRE HOSPITAL

Wearing gloves, followed by hand washing when managing patients, to decrease risk of transmission of streptococcal carriage

INITIAL STABILIZATION/THERAPY

Patients may be toxic and in need of intravenous fluid resuscitation or pressure support

ED TREATMENT/PROCEDURES

- Appropriate antibiotic therapy; treatment should be for 10 days:
 - Patients with extensive involvement should be admitted for parenteral antibiotic treatment
 - May switch to oral antibiotics when patient is stable and showing signs of response
- Mild cases: Patients can be discharged on oral therapy if nontoxic appearing, good compliance, and close follow-up can be ensured
- Penicillin is the drug of choice when symptoms are consistent with erysipelas
- If there is difficulty in distinguishing from cellulitis, staphylococcal coverage should be added:
 - Use penicillinase-resistant penicillin or 1st-generation cephalosporin
 - If in community with high incidence of MRSA, use vancomycin, or other anti-MRSA coverage
 - Reports of vancomycin-resistant Staphylococci are occurring
- Acetaminophen for fever
- Isolation while in hospital
 - Contagious

MEDICATION

OUTPATIENT

- Penicillin V: 500 mg PO q6h (peds: 25–50 mg/kg/d div. q6–8h) for 10 days.
- Amoxicillin: 500 mg PO q8h (peds: 50 mg/kg/d div. TID) for 10 days.
- Clindamycin: 300 mg PO QID (peds: 8–25 mg/kg/d suspension PO div. TID or QID) for 10 days.
- Dicloxacillin: 500 mg PO q6h (peds: 30–50 mg/kg/d PO div. q6h) for 10 days
- Erythromycin: 250–500 mg PO q6h (peds: 40 mg/kg/d PO in div. doses q6h) for 10 days
- Cephalexin: 500 mg PO q6h (peds: 40 mg/kg/d PO div. q8h) for 10 days
- Cefuroxime: 250–500 mg PO BID (peds: 30 mg/kg/d PO div. q12h) for 10 days.

INPATIENT

- Penicillin G: 2 million U q4h IV (peds: 25,000 U/kg IV q6h).
- Penicillin G, procaine: 600,000 U q12h IM
- Clindamycin: 600 mg q8h IV (peds: 20–40 mg/kg/d IV div. q8h)
- Vancomycin: 1 g IV q12h given over 1.5–2 hr to decrease risk of red man syndrome (peds: 10–15 mg/kg IV q6h)

First Line

- Oral or IV: Penicillin or 1st-generation cephalosporin
- Clindamycin for penicillin-allergic individuals

Second Line

Oral: Erythromycin

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with extensive involvement, fever, toxic appearance, or in whom orbital or periorbital cellulitis is suspected
- Patients who live alone or are unable or unreliable to take oral medications will require admission for IV antibiotics
- Children more often require admission
 - Blood cultures
 - Intravenous antibiotics, including coverage for *H. influenzae*, should be initiated for patients who have not been immunized with HIB vaccine

Discharge Criteria

- Minimal facial involvement
- Nontoxic appearance
- Not immunosuppressed
- Able to tolerate and comply with oral therapy
- Adequate follow-up and supervision
- Diagnosis certain

Issues for Referral

- Refer to nephrologist for evaluation and treatment for PSGN if:
 - Hematuria, proteinuria, and red cell casts are noted on UA
 - Particularly in children between the ages of 5 and 15
- Infectious disease consultation for infection in immunocompromised patients who are at risk for unusual organisms

FOLLOW-UP RECOMMENDATIONS

- Use of pressure stocking on leg in the presence of lymphedema may reduce incidence of relapses
- Following erysipelas of legs, use of topical antifungal cream or ointment to treat underlying tinea pedis when present

PEARLS AND PITFALLS

- Failure to respond, or pain out of proportion to findings, might suggest deeper level of infection and require further workup to rule out necrotizing fasciitis, or

mixed aerobic/anaerobic necrotizing cellulitis

- Treatment of underlying lymphedema is associated with reduced incidence of relapses
- Presence of micropustules would suggest staphylococcal infection/cellulitis rather than erysipelas, and antibiotic coverage would need to be broader
- Presence of crepitus in skin should prompt search for alternate diagnosis
- Since infection is likely to have entered skin through traumatic skin break, remember to check for tetanus immunization status and update if necessary
- Consider prophylaxis for patients with frequent relapses

A46 Erysipelas

ERYTHEMA INFECTIOSUM

Benjamin S. Heavrin

BASICS

DESCRIPTION

- Characteristic viral exanthem also known as 5th disease:
 - 5th most common childhood rash historically described
 - Measles (1st), scarlet fever (2nd), rubella (3rd), Duke disease (4th), roseola (6th)
- Common symptoms: Viral prodrome followed by slapped-cheek rash and subsequent diffuse reticular rash +/- arthropathy
- Most common in school-aged children <14 yr
- Usually self-limited with lasting immunity
- Rare complications and chronic cases in patients with congenital anemias or immunosuppression
- Potential for severe complications to fetus if infection acquired during pregnancy
- Possible link to encephalopathy, epilepsy, meningitis, myocarditis, dilated cardiomyopathy, autoimmune hepatitis, HSP, ITP

ETIOLOGY

- Caused by human parvovirus B19, small SS-DNA virus:
 - Infects human erythroid progenitor cells, suppressing erythropoiesis
- Most common in late winter and spring
- Transmitted via respiratory droplets and blood products as well as vertical maternal-fetal transmission
- Incubation period 4–21 days
- Most contagious during the week PRIOR to rash onset
- Majority of adults have serologic evidence of prior infection

DIAGNOSIS

SIGNS AND SYMPTOMS

- “Slapped-cheek” appearance most common in young children
- Fever
- Malaise
- Delayed symptoms 4–14 days later:
 - Diffuse, pruritic, lacy rash (absent in most adults), most pronounced in extremities
 - Symmetric polyarthropathy, most common in middle-aged women:
 - Small joints involved in adolescents and adults

- Knees most commonly involved in children
- Secondary to immune-complex deposition
- However, most patients remain asymptomatic or only develop mild, nonspecific viral symptoms

History

- Mild constitutional symptoms (fever, headache, nasal congestion, nausea, sore throat)
- Contagious only until facial rash appears

Physical-Exam

- Stage 1:
 - “Slapped-cheek” rash of coalescent, warm, erythematous, edematous papules with circumoral pallor in young children
- Stage 2:
 - Nonspecific, diffuse, pruritic, maculopapular, reticular eruption
 - 4–21 days after facial rash, lasts up to 6 wk
 - More prominent on extremities
 - Usually spares palms and soles
- Stage 3:
 - Rash fades but recurs with exposure to sunlight, stress, exercise, and heat
- Usually complete resolution without scarring

ESSENTIAL WORKUP

Clinical diagnosis based on characteristic signs and symptoms.

DIAGNOSIS TESTS & INTERPRETATION

- Usually not necessary
- CBC and reticulocyte count if concern for aplastic crisis
- Confirm diagnosis if immunocompromised or pregnant:
 - Viral DNA PCR now available
 - IgM antibody confirms acute infection and persists for 2–3 mo
 - IgG presence confers lasting immunity
- In pregnancy, ultrasound to detect hydrops fetalis

DIFFERENTIAL DIAGNOSIS

- Allergic reaction
- Collagen vascular disease
- Coxsackie virus
- Drug eruptions
- Enterovirus
- Erysipelas
- Infectious mononucleosis

- Measles
- Nonspecific viral illness
- Rheumatoid arthritis
- Roseola
- Rubella
- Scarlet fever
- Sunburn

TREATMENT

Erythema infectiosum is usually self-limited and does not require treatment

PRE HOSPITAL

ABCs for severe cases and septic patients

INITIAL STABILIZATION/THERAPY

- ABCs, supplemental oxygen if indicated
- IVF with associated severe dehydration
- Severe anemia may also cause hypotension and hypoxia, transfuse PRBCs as indicated
- Pain control with acetaminophen, NSAIDs, or opiates as needed for severe arthropathy

ED TREATMENT/PROCEDURES

- No specific antiviral treatment or vaccine is available
- Send appropriate labs (CBC, reticulocytes, antibody testing) for severe cases
- Symptomatic treatment as needed:
 - _ IVF for severe dehydration
 - _ NSAIDs for arthropathy if no underlying renal insufficiency
 - _ Consider diphenhydramine for pruritus, caution parents about possible AMS
 - _ Antipyretics for fever
- PRBC transfusion for severe anemia
- ID consult: IVIG may have benefit for immunocompromised patients with chronic symptoms and red cell aplasia
- Hematology consult for severe cases
- Hospitalization and respiratory isolation for aplastic crisis

MEDICATION

- Acetaminophen: 500 mg (peds: 15 mg/kg/dose) PO q6h PRN fever for up to 5 days
 - _ Dose not to exceed 4 g/24h
- Diphenhydramine: 25 mg (peds: 1–2 mg/kg/dose) PO q6h PRN itching for up to 5 days
- Ibuprofen: 400 mg (peds: 10 mg/kg/dose) PO q8h PRN pain for up to 5 days
- IVIG only in consultation with ID specialist

DISPOSITION***Admission Criteria***

- Aplastic crisis or severe anemia
- Severely immunocompromised
- Hydrops fetalis
- Toxic appearance
- Severe arthritis

Discharge Criteria

- Nearly all patients
- Normal CBC, O₂ sat, and BP
- Patients are no longer contagious following appearance of facial rash and may return to day care, school, or work

Issues for Referral

- All patients without existing primary care physicians should be referred to a generalist for follow-up as needed
- Patients with hereditary anemias should be referred to hematology for follow-up in 1–2 days
- All immunocompromised patients require prompt subspecialty follow-up
- Pregnant patients with new infection should have immediate follow-up with OB/GYN for further monitoring and ultrasound

FOLLOW-UP RECOMMENDATIONS

- Pregnant women with new parvovirus B19 infection may need serial ultrasounds for 10–12 wk.
- Patients at risk for aplastic crisis should follow-up with the appropriate specialties 1–2 days after ED discharge for repeat CBC

PATIENT EDUCATION**Prevention:**

- No vaccine available
- Frequent handwashing helps prevent spread
- No current recommendations to keep children out of school, since most children are no longer contagious by the time the diagnosis is made.
- Pregnant women may choose to stay away from a workplace outbreak, but no current official recommendation exists

COMPLICATIONS

- Transient aplastic crisis in patients with anemias: Sick cell disease, hereditary spherocytosis, thalassemia, iron-deficiency, or other conditions with shortened red cell lifespan:
 - Usually full recovery within 2 wk
- Persistent infection with severe anemia if immunocompromised and unable to mount antibody response, especially with HIV
- Arthritis or hypersensitivity dermatitis in adults:
 - May have transient rheumatoid factor positivity, but no true association with rheumatoid arthritis and no joint destruction
- Association with papular, purpuric gloves, and socks syndrome in adults:
 - Symmetric, painful progressive rash and edema of hands and feet
 - Erythema progresses to petechiae, purpura, and occasionally bullae
 - This syndrome is also associated with many other viruses and drugs
- Extremely rare – hepatosplenomegaly, heart failure, CVA, thrombocytopenia, leukopenia

Pregnancy Considerations

- Risk of hydrops fetalis in pregnancy
- 60% of pregnant women are susceptible to new infection
- 30% risk of transplacental infection with new maternal infection
- Affects fetal liver (main site of erythropoiesis), leading to anemia, CHF, myocarditis, IUGR
- 2–6% risk of fetal loss, highest in 2nd trimester

PEARLS AND PITFALLS

- Parvovirus B19 is usually a self-limited, mild illness.
- Common symptoms include “slapped-cheeks” rash with subsequent diffuse lacy rash and arthropathy
- Patients are no longer contagious when the rash appears and aplastic crisis resolves
- Evaluate all patients with history of hereditary or iron-deficiency anemia for aplastic crisis
- Evaluate all patients with history of immunosuppression for chronic infection with persistent anemia
- Confirm diagnosis in all pregnant patients. If no proven immunity, monitor for fetal complications and refer for follow-up

057.0 Erythema infectiosum (fifth disease)

ICD10

B08.3 Erythema infectiosum [fifth disease]

ERYTHEMA MULTIFORME

Gregory W. Hendey

BASICS

DESCRIPTION

- A rash caused by a hypersensitivity reaction:
 - May occur in response to various medications, infections, or other illness
- Erythema multiforme (EM) minor:
 - Typical target lesions
 - Edematous papules
 - Usually distributed peripherally
 - Benign, self-limited rash generally not associated with acute, serious illness
- EM major
 - Also called bullous EM
 - Target lesions
 - Edematous papules
 - Also with peripheral distribution
 - Involves 1 or more mucous membranes
 - <10% total body surface area of epidermal detachment
- Differentiate from:
 - Stevens–Johnson syndrome (SJS):
 - Also <10% TBSA epidermal detachment
 - Often widespread blisters over trunk and face
 - Mucosal involvement
 - Toxic epidermal necrolysis (TEN)
 - >30% TBSA epidermal detachment
 - EM is now considered a different entity from SJS and TEN
- Most often affects children and young adults (>50% younger than 20 yr)
- Males are affected more often than females.

ETIOLOGY

- Hypersensitivity reaction, probably transient autoimmune defect
- *Herpes simplex virus* (HSV) is the most common precipitant (>70%).
- Other causes include:
 - Idiopathic
 - Medications
 - Penicillin
 - Sulfur based
 - Phenytoin
 - Barbiturates

- NSAIDs
- Vaccines
 - Diphtheria—tetanus
 - Hepatitis B
 - Smallpox
- Malignancy
- Infection
 - HIV
 - CMV
 - Hepatitis C
 - Mycoplasma infections

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Prodrôme: Infrequent systemic symptoms (mild fever/malaise), antecedent HSV in most cases (within 3 wk)
- Usually not associated with severe systemic illness

Physical-Exam

Characteristic rash:

- Lesions:
 - Symmetric dull red macules and papules
 - Evolve into round, well-demarcated target lesions with central clearing
 - *No epidermal necrosis* with EM minor
- *Multiforme* refers to the evolution of the rash through various stages at different times.
- Distribution:
 - Extremities
 - Dorsal hands and feet
 - Extensor surfaces
 - Elbows and knees.
- 1 of the few rashes that may involve palms and soles
- Spread: From extremities toward trunk
- Mucosal involvement: Minor blistering or erosions of 1 mucosal surface (lips/mouth)
- Duration: Usually 1–4 wk, but may become chronic or recurrent

ESSENTIAL WORKUP

Complete history and physical exam, with special attention to the skin, genitourinary

system, recent infectious symptoms, and recent medications

DIAGNOSIS TESTS & NTERPRETATION

Lab

No specific lab tests needed

Imaging

No specific imaging is helpful.

Diagnostic Procedures/Surgery

- Skin biopsy reveals mononuclear cell infiltrate around upper dermal blood vessels, without leukocytoclastic vasculitis and necrosis of epidermal keratinocytes.
- Biopsy is not necessary in most cases.

DIFFERENTIAL DIAGNOSIS

- Systemic lupus erythematosus
- Fixed drug eruption
- Pityriasis rosea
- Secondary syphilis
- Erythema migrans
- Urticaria
- SJS
- TEN
- Vasculitis
- Viral exanthem

TREATMENT

PRE HOSPITAL

Not contagious and does not require isolation or postexposure prophylaxis for exposed personnel

INITIAL STABILIZATION/THERAPY

Generally benign and self-limited, requiring no initial stabilization

ED TREATMENT/PROCEDURES

- Attempt to identify, treat, or remove underlying cause or precipitant.
- Symptomatic: Cool compresses, antipruritics

MEDICATION

- Antiviral agents:
 - _ Acute EM

- Treat within 48 hr of onset
- May not impact clinical course
 - Acyclovir: 400 mg PO TID
- Prevention of recurrent EM
 - Acyclovir 400 mg PO BID
 - Valacyclovir 500 mg PO BID
 - Famciclovir 250 mg PO BID
- Antipruritic agents:
 - Cetirizine (Zyrtec): 10 mg/d (peds: 2.5–5 mg) PO
 - Diphenhydramine: 25–50 mg (peds: 5 mg/kg/24h) PO q6–8h
 - Hydroxyzine: 25 mg PO q6–8h (peds: 2 mg/kg/24h div. q6–8h)
- Anesthetic for oral lesions
 - Magic mouthwash
- Oral corticosteroids:
 - Reserved for severe mucosal disease
 - Prednisone 40–60 mg PO QD tapered over 2–3 wk
- Medium-potency topical corticosteroids:
 - Triamcinolone 1% apply BID–QID
 - Do not use on face or eyelids
- Low-potency topical corticosteroids
 - For face or intertriginous regions
 - Hydrocortisone 1% apply BID–QID

First Line

- Topical corticosteroids (low to medium potency)
- Antipruritics

Second Line

- Antivirals
- Oral corticosteroids

FOLLOW-UP

DISPOSITION

Admission Criteria

- Admission is not needed unless required for another concurrent disorder.
- Unable to take PO fluids secondary to mucosal lesions

Discharge Criteria

EM is generally a benign disorder that does not require admission.

Issues for Referral

- Patients should be referred to a dermatologist if the diagnosis is uncertain or the rash is atypical or severe.
- Refer immediately to ophthalmologist if ocular involvement

FOLLOW-UP RECOMMENDATIONS

- Follow-up with primary care physician within 1 wk to assess:
 - Further evaluation of underlying conditions (infection, medications, malignancy, etc.)
 - Progression or resolution of rash
- Follow-up with a dermatologist within 1 wk if the diagnosis is uncertain.

PEARLS AND PITFALLS

- In patients with severe systemic illness, a more serious diagnosis should be considered, such as SJS or TEN.
- Most patients with EM have underlying HSV infection.
- Secondary syphilis may produce similar lesions on the palms and soles.
- Reassure patients that the rash of EM is benign and self-limited.

ERYTHEMA NODOSUM

Herbert G. Bivins

BASICS

DESCRIPTION

- Erythema nodosum (EN) is characterized by multiple symmetric, nonulcerative tender nodules on the extensor surface of the lower extremities, typically in young adults.
- Peak incidence in 3rd decade
- More common in women (4:1)
- Nodules are round with poorly demarcated edges and vary in size from 1 to 10 cm.
- Skin lesions are initially red, become progressively ecchymotic appearing as they resolve over 3–6 wk.
- Lesions are caused by inflammation of the septa between SC fat nodules (septal panniculitis).
- Spontaneous regression of lesions within 3–6 wk
- Major disease variants include:
 - EN migrans (usually mild unilateral disease with little or no systemic symptoms)
 - Chronic EN (lesions spread via extension, and associated systemic symptoms tend to be milder)

ETIOLOGY

- Immune-mediated response
- 30–50% of the time etiology is idiopathic
- Often a marker for underlying disease; specific etiologies include:
 - Drug reactions:
 - Oral contraceptives
 - Sulfonamides
 - Penicillins
 - Infections including:
 - *Streptococcal pharyngitis*
 - *Mycobacterium tuberculosis* (TB)
 - Atypical mycobacteria
 - Coccidioidomycosis
 - Hepatitis
 - Syphilis
 - Chlamydia
 - Rickettsia
 - Salmonella

- Campylobacter
- Yersinia
- Parasites
- Leprosy
- Systemic diseases:
 - Sarcoidosis
 - Inflammatory bowel disease
 - Behçet disease
 - Connective tissue disorders
- Malignancies such as lymphoma and leukemia
- Catscratch disease
- HIV infection
- Rarely can be caused by vaccines for hepatitis and TB (BCG)

Pediatric Considerations

Typically, EN begins 2–3 wk after onset of *S. pharyngitis*.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Tender erythematous nodules symmetrically distributed on extensor surface of lower legs
- Lesions occasionally occur on fingers, hands, arms, calves, and thighs.
- In bedridden patients, dependent areas may be involved.
- Fever, malaise, leukocytosis, arthralgias, arthritis, and unilateral or bilateral hilar adenopathy with any form of the disease

History

- General symptoms may precede or accompany the rash:
 - Fever
 - General malaise
 - Polyarthralgias
- GI symptoms with EN may be a marker for:
 - Inflammatory bowel disease
 - Bacterial gastroenteritis
 - Pancreatitis
 - Behçet disease
 - A history of travel is important, as there are regional variations in etiology.

Physical-Exam

- A careful exam is important, as underlying etiology varies by region.
- Lesions are most common on the pretibial area but may occur on the thigh, upper

- extremities, neck and, rarely, the face.
- Absence of lesions on the lower extremities is atypical, as are ulcerated lesions.
- Lower-extremity edema may occur.
- Adenopathy should be evaluated.

ESSENTIAL WORKUP

Careful history and physical exam directed at detecting precipitating cause

DIAGNOSIS TESTS & NTERPRETATION

Lab

- CBC
- Throat culture/ASO titer
- ESR
- Appropriate chemistry tests
- Liver function tests
- Serologies for coccidioidomycosis in endemic regions
- TB skin testing in endemic regions

Imaging

CXR: Hilar adenopathy may be evidence of sarcoidosis, coccidioidomycosis, tuberculosis, or other fungal infections.

Diagnostic Procedures/Surgery

Definitive diagnosis made by deep elliptical biopsy and histopathologic evaluation (punch biopsy may be inadequate): Usually indicated for atypical cases or when TB is being considered

DIFFERENTIAL DIAGNOSIS

- EN migrans and chronic EN
- Any type of panniculitis can resemble EN.
- Differences can be determined histopathologically.
- Other disorders include:
 - Periarteritis nodosum
 - Migratory thrombophlebitis
 - Superficial varicose thrombophlebitis
 - Scleroderma
 - Systemic lupus erythematosus
 - α_1 -antitrypsin deficiency
 - Behçet syndrome
 - Lipodystrophies
 - Leukemic infiltration of fat
 - Panniculitis associated with steroid use, cold, and infection

TREATMENT

Pediatric Considerations

- Rare in children, *S. pharyngitis* is the most likely etiology.
- Cat scratch disease should be considered.

PRE HOSPITAL

Maintain universal precautions

INITIAL STABILIZATION/THERAPY

Airway, breathing, and circulation (ABCs); IV, oxygen, monitoring as appropriate

ED TREATMENT/PROCEDURES

- Treatment should be directed at underlying disease.
- Supportive therapies include rest and analgesics.
- Corticosteroids and potassium iodide may hasten resolution of symptoms.
- Systemic corticosteroids are contraindicated in the presence of certain underlying infections such as TB or coccidioidomycosis, which may disseminate with their use.
- Potassium iodide is contraindicated in hyperthyroid states.

MEDICATION

- Aspirin: 650 mg PO q4–6h PRN (peds: contraindicated)
 - _ Do not exceed 4 g/24 h
- Ibuprofen: 400–800 mg PO q8h (peds: 5–10 mg/kg PO q6h)
- Indomethacin: 25–50 mg PO q8h
- Potassium iodide/SSKI (used for resistant disease; contraindicated in hyperthyroidism): 900 mg PO daily for 3–4 wk
- Systemic corticosteroids (prednisone): 40 mg/d PO; duration determined by primary physician

First Line

- Rest/supportive care
- NSAIDs
- Treatment of underlying disease

Second Line

- Potassium iodide
- Steroids

FOLLOW-UP

DISPOSITION

Admission Criteria

Dictated by the severity of symptoms and the etiologic agent

Discharge Criteria

- Nontoxic patients, able to take PO fluids without difficulty
- Scheduled follow-up should be arranged.

Issues for Referral

- EN is usually self-limited and resolves in 3–6 wk.
- Atypical cases may need excisional biopsy.
- Steroid and potassium therapy needs primary physician monitoring.

FOLLOW-UP RECOMMENDATIONS

- Follow-up to assess for resolution with primary care physician or dermatologist.
- Evaluation of underlying etiology may require specialist referral.

PEARLS AND PITFALLS

- EN is usually idiopathic but may be the 1st sign of systemic disease.
- Lesions may recur if underlying disease is not treated.
- Atypical and chronic lesions may indicate an alternative diagnosis and need biopsy.
- Patients taking potassium or steroids need close follow-up.

- L52 Erythema nodosum

ESOPHAGEAL TRAUMA

Susan E. Dufel

BASICS

DESCRIPTION

- Adult esophagus is ~25–30 cm in length in close proximity to mediastinum with access to pleural space.
- It begins at hypopharynx posterior to larynx at level of cricoid cartilage.
- On either side of this slit are piriform recesses:
 - May be site for foreign body to lodge
- Sites of esophageal narrowing:
 - Cricopharyngeal muscle (upper esophageal sphincter)
 - Crossover of left main stem bronchus and aortic arch
 - Gastroesophageal junction (lower esophageal sphincter)
 - Areas of disease (cancer, webs, or Schatzki ring)
- Upper 3rd of esophagus is striated muscle:
 - Initiates swallowing
- Middle portion is mixture of striated and smooth.
- Distal portion is smooth muscle.
- It is a fixed structure, but can become displaced by other organs:
 - Goiter
 - Enlarged atria
 - Mediastinal masses

ETIOLOGY

Mechanism

- External forces or agents (30%):
 - Penetrating: Leading to tears:
 - Stab wounds
 - Missile wounds
 - Perforation:
 - Foreign bodies via direct penetration
 - Pressure necrosis
 - Chemical necrosis
 - Radiation necrosis from selective tissue ablation
 - Instrumentation
 - Blunt: Motor vehicle accident
- Internal forces or agents:
 - Caustic ingestions/burns:

- Acid pH < 2, alkali pH > 12 accidental or intentional
- Alkali (42%): Liquefaction necrosis causing burns, airway edema or compromise, perforation, chronic stricture, and cancer
- Acid (32%): Coagulation necrosis, thermal injury, and dehydration causing perforation, ulceration, and infection, more likely to perforate than alkali
- Chlorine bleach (26%): Mucosal edema, superficial erythema
- Infections:
 - Viruses (CMV, HPV, and HSV) or fungi in immunocompromised patients
- Drugs:
 - Less common but case series reported
 - Alendronate, Doxycycline, NSAIDs
 - Mycophenolate mofetil
 - May cause esophageal erosion or esophagitis
- Swallowed agents:
 - Food bolus impaction:
 - Coins, bones, buttons, marbles, pins, button batteries
 - Most common type is meat.
- In adults: Prisoners, psychiatric patients, intoxicated patients, or edentulous patients
- Iatrogenic (55%):
 - Perforation secondary to instrumentation, endoscopy most common cause
 - Nasotracheal intubation/nasogastric (NG) tube most common cause in emergency department
- Increased gastric pressure (15%):
 - Large pressure differences between thorax and intra-abdominal cavity:
 - May lead to lacerations or perforation
 - Mallory–Weiss syndrome:
 - Longitudinal tears in distal esophageal mucosa with bleeding
 - Boerhaave syndrome:
 - Spontaneous esophageal rupture
 - Full-thickness rupture of distal esophagus
 - Classically after alcohol or large meals and vomiting

Pediatric Considerations

- Foreign bodies
 - Accounts for 75–80% of swallowed foreign bodies:
 - Typically in infants ages 18–48 mo
 - Entrapment usually at upper esophageal sphincter
 - Perforations
 - Commonly iatrogenic with NG insertion, stricture dilation, and endotracheal intubation

- Caustic ingestions
 - More common in children <5 yr
 - Button batteries highly alkaline and need removal if lodged in esophagus within 4–6 hr
 - Packets of single use laundry/dishwasher detergents are prevalent with AAPCC issuing safety warning

DIAGNOSIS

SIGNS AND SYMPTOMS

General

- Dysphagia: Difficulty swallowing
- Odynophagia: Pain with swallowing
- Chest pain: Angina like, often pleuritic, severe, and unrelenting
- Hoarseness
- Dyspnea
- Tears or perforations:
 - Bleeding
 - Hematemesis
- Ingestions/foreign bodies:
 - Drooling or excessive salivation
 - Choking, gagging, vomiting, stridor, or wheezing
 - Inability of food or liquid to pass
- Caustic ingestions:
 - Oral pain
 - Abdominal pain
 - Vomiting
 - Drooling

History

- History of ingestions (type, time, amount)
- History of protracted vomiting
- History of inability to swallow after eating, foreign body sensation in throat
- History of penetrating trauma
- History of cancer therapy

Physical-Exam

- Tears or perforations:
 - SubQ air at base of neck
 - Hamman crunch:
 - Systolic crunching sound secondary to air in mediastinum

- Shock
- Septicemia
- Peritonitis
- Penetrating trauma:
 - Associated neck, chest, or abdominal injury with trauma:
 - Most commonly trachea
 - Associated with penetrating/blunt trauma
- Caustic ingestions:
 - Airway edema leading to stridor
 - Oral burns

ESSENTIAL WORKUP

High level of suspicion and early diagnosis are key:

- Mortality <5% for perforation if repaired within 24 hr; 75% if delayed
- Early endoscopy for caustic ingestions
- Chest/lateral neck radiograph

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC in cases of GI bleeding
- TXC for any extensive bleeding/OR candidate
- Coagulation studies
- Electrolytes for protracted vomiting or prolonged foreign body retention
- Arterial blood gas (ABG) for acid ingestions

Imaging

- CXR for foreign body or perforation:
 - Pneumomediastinum
 - Widened mediastinum
 - Pneumothorax
 - Pleural effusion
- Lateral cervical spine films for foreign body or perforation:
 - Retropharyngeal air or fluid
 - Cervical emphysema
- Fiberoptic nasopharyngoscopy for foreign body removal
- Esophagram for foreign bodies or suspected perforation:
 - 10–25% false-negative rate
 - Current recommendations for water-soluble contrast (Gastrografin) 1st if perforation likely
 - Barium may limit visibility for later endoscopy:
 - More irritating if extravasates into mediastinum
 - Water-soluble contrast provides better visibility:

- Less reaction if extravasates into mediastinum
- May cause chemical pneumonitis if aspirated
- Nonionic contrast may be safest but more expensive
- Endoscopy for suspected perforation, caustic ingestions, and esophageal foreign body removal
 - Severity of injury in caustic ingestions
 - 1st degree: Superficial mucosal damage, focal or diffuse, erythema, edema, mucosa sloughs without scar
 - 2nd degree: Mucosal and submucosal damage, ulcers and vesicles, granulation tissue and scar formation, stricture possible
 - 3rd degree: Transmural with deep ulcers, black discoloration, and wall perforation
- CT scanning with dilute oral contrast may be useful in diagnosis of perforations.

DIFFERENTIAL DIAGNOSIS

- Pulmonary:
 - Tracheal injury
 - Pneumothorax
- Cardiovascular:
 - Myocardial infarction
 - Aortic dissection
 - Spontaneous pneumomediastinum
- Other esophageal emergencies:
 - Peptic stricture
 - Esophageal neoplasm
 - Schatzki ring
 - Diverticula
 - Achalasia
 - Diffuse esophageal spasm
 - Nutcracker esophagus
 - Gastroesophageal reflux
 - Esophagitis
 - esophagitis esp. tetracycline

TREATMENT

PRE HOSPITAL

ALERT

- Chest pain should be presumed cardiac.
- Airway protection, frequent suctioning
- Intravenous crystalloid if patient is hypotensive, vomiting, or if hematemesis is

present

- Pain management
- Avoid neutralizing agents in caustic ingestions as that may worsen injury.
- Avoid copious amounts of oral fluids in caustic ingestions to prevent emesis.

INITIAL STABILIZATION/THERAPY

- Manage airway and resuscitate as needed
- Intravenous access, monitoring
- Early intubation for penetrating neck and chest wounds
- Frequent suctioning of copious secretions
- Fluid replacement

ED TREATMENT/PROCEDURES

- Foreign bodies/food impaction:
 - 80% pass, 20% need endoscopy, <1% need surgery
 - Glucagon may be tried: 1 mg IV and repeated in 20 min. Carbonated beverage in combo may be more effective
 - Nitroglycerin or nifedipine may be tried.
 - Diazepam may be of benefit in the upper (striated muscle) esophagus.
 - GI consultation and endoscopic extraction if not relieved
- Caustic ingestions:
 - Emesis/lavage contraindicated
 - Immediate decontamination with milk
 - Avoid neutralizing agents as they may cause exothermic reaction.
 - GI consultation for early endoscopy to provide prognostic information
 - No role for corticosteroids and may be harmful
- Tears/perforations:
 - Partial-thickness tears usually heal spontaneously.
 - GI consultation may be needed for diagnosis (endoscopy).
 - Perforation requires surgical consultation for thoracotomy and primary repair; some patients may be managed nonoperatively.
 - Broad-spectrum parenteral antibiotics for perforation

Pediatric Considerations

- Certain swallowed foreign bodies require GI consultation and endoscopic removal:
 - Sharp objects: Fish bones, straight pins, razor blades, pencil
 - Caustic objects: Button batteries
- Objects may pass on their own:
 - Coins, buttons, marbles
 - Open safety pins may pass spontaneously if blunt end forward.
- Consult pediatric GI specialist.

MEDICATION

- Foreign bodies/food impactions:
 - Glucagon: 1–2 mg (peds: 0.02–0.03 mg/kg) IV; may repeat once in 20 min
 - Nitroglycerin: 0.4 mg sublingually
 - Diazepam: 5–10 mg (peds: 1–2 mg) IV
- Perforation:
 - Cefoxitin: 1–2 g (peds: 100–160 mg/kg/24 h) IV q6–8h
 - Gentamicin: 1–1.7 mg/kg (peds: 1.5–2.5 mg/kg/24 h) IV q8h
 - Steroids not indicated in caustic ingestions

FOLLOW-UP

DISPOSITION

Admission Criteria

- Caustic ingestion
- Sharp foreign bodies
- Airway compromise
- Penetrating neck or chest trauma
- Evidence of sepsis, mediastinitis, or esophageal perforation
- Significant bleeding
- Inability to tolerate oral fluids

Discharge Criteria

- Self-limited bleeding from partial-thickness tear
- Foreign body or food impaction that has passed lower esophageal sphincter

PEARLS AND PITFALLS

Factors to predict outcomes in esophageal injuries:

- Time to diagnosis and definitive therapy: 24 hr decreases mortality by half.
- Location of injury: Cervical less than thoracic or abdominal
- Mechanism of injury: Spontaneous perforation has highest mortality 30–40%; iatrogenic 15–20%, and direct trauma 5–10%.

ETHYLENE GLYCOL POISONING

Paul E. Stromberg • Kirk L. Cumpston

BASICS

DESCRIPTION

- Peak serum concentration in 1–4 hr
- Half-life, 2.5–4.5 hr
- <20% excreted unmetabolized by kidneys
- Pathophysiology:
 - Metabolized by hepatic alcohol dehydrogenase and aldehyde dehydrogenase ultimately to oxalic acid
 - Results in aldehyde and acid metabolites
 - Directly toxic to CNS, heart, and kidneys

ETIOLOGY

- Ethylene-glycol-containing products:
 - Antifreeze
 - Solvents
- Min. reported lethal dose is 30 mL of 100% ethylene glycol.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Cardiovascular:
 - Tachycardia/bradycardia/other dysrhythmias
 - Hypertension/hypotension
- CNS:
 - Inebriation/irritability
 - Ataxia
 - Obtundation
 - Coma
 - Cerebral edema
 - Convulsions
 - Peripheral nervous system
 - Cranial nerve abnormalities
- GI:
 - Nausea/vomiting
 - Abdominal pain
- Pulmonary:
 - Hyperventilation/tachypnea/Kussmaul respiration

- Pulmonary edema
- Renal:
 - Acute renal failure
 - Crystalluria
- 3 stages (may overlap):
 - 1st stage: 1–12 hr after ingestion:
 - CNS depression
 - GI symptoms
 - Worsening acidosis
 - Coma
 - Convulsions
 - Cerebral edema
 - Tetany and myoclonus secondary to hypocalcemia
 - 2nd stage: 12–36 hr after ingestion:
 - Cardiopulmonary symptoms
 - When most deaths occur
 - 3rd stage: 36–72 hr after ingestion:
 - Oliguria
 - Flank pain
 - Acute renal failure

History

- Intentional or unintentional ethylene glycol ingestion
- No history but a patient with an unexplained high anion gap metabolic acidosis
- Elevated unexplained osmol gap

Physical-Exam

- Tachypnea
- Altered mental status

ESSENTIAL WORKUP

- History of all substances ingested
- Drawn simultaneously:
 - Arterial blood gas
 - Serum ethylene glycol, methanol, isopropyl alcohol, and ethanol serum concentration
 - Electrolytes, BUN/creatinine, glucose
 - Measured serum osmolality (by freezing point depression)
 - Serum calcium, phosphorus, magnesium

DIAGNOSIS TESTS & NTERPRETATION

Lab

- Determine the anion gap:
 - _ Anion gap = $(\text{Na}^+) - (\text{Cl}^- + \text{HCO}_3^-)$
 - _ Normal anion gap is 8–12.
- Determine osmol gap:
 - _ Osmol gap = measured osmolality – calculated osmolarity
 - _ Increased osmol gap: > 10
 - _ Calculated osmolarity = $2(\text{Na}^+) + \text{glucose}/18 + \text{BUN}/2.8 + \text{ethanol (mg/dL)}/4.6$
 - _ Calculated to screen for ethylene glycol ingestion because toxic alcohol serum concentration are not commonly available in timely manner from most clinical labs
 - _ Most useful early in course of ethylene glycol poisoning or with concurrent ethanol ingestion
 - _ With concurrent ethanol ingestion, osmol gap tends to be larger and acidosis tends to be less severe because relatively less ethylene glycol has been converted to acid-producing metabolites.
 - _ Normal osmol gap does not rule out ethylene glycol ingestion.
 - _ Late presentation after ethylene glycol ingestion may manifest itself with only an elevated anion gap without a significant osmol gap.
- Ethylene glycol, methanol, isopropyl alcohol serum concentration
- Ethanol serum concentration:
 - _ Measured to determine amount of ethanol bolus necessary to attain therapeutic serum concentration, and to determine coingestants
- Urinalysis:
 - _ Envelope-shaped oxalate crystals: Insensitive but specific finding.
 - _ Absence of urine calcium oxalate crystals does not rule out ethylene glycol exposure.
 - _ Ketones may be due to isopropyl alcohol ingestion, starvation, or diabetic ketoacidosis.

Diagnostic Procedures/Surgery

Wood lamp inspection of urine or gastric contents:

- Detects presence of fluorescein, a common antifreeze additive
- Insensitive and not specific marker of antifreeze ingestion
- Absence of urinary fluorescence does not rule out ethylene glycol exposure.

DIFFERENTIAL DIAGNOSIS

- Increased osmol gap:
 - _ Methanol
 - _ Ethanol
 - _ Diuretics (mannitol, glycerin, propylene glycol, sorbitol)
 - _ Isopropyl alcohol

- Ethylene glycol
- Acetone, ammonia
- Propylene glycol
- Elevated anion gap metabolic acidosis: *A CAT MUDPILES:*
 - Alcoholic ketoacidosis
 - Cyanide, CO, H₂S, others
 - Acetaminophen
 - Antiretrovirals (NRTI)
 - Toluene
 - Methanol, metformin
 - Uremia
 - Diabetic ketoacidosis
 - Paraldehyde, phenformin, propylene glycol
 - Iron, INH
 - Lactic acidosis
 - Ethylene glycol
 - Salicylate, acetylsalicylic acid (ASA; aspirin), starvation ketosis

TREATMENT

PRE HOSPITAL

- Bring containers of all possible substances ingested.
- Monitor airway and CNS depression.
- Dermal decontamination of an ethylene glycol chemical spill by removal of clothing and jewelry and irrigation with soap and water

INITIAL STABILIZATION/THERAPY

- ABCs
- Supplemental oxygen, cardiac monitor, secured IV line with 0.9% NS
- D₅₀W (or Accu-Check), naloxone, and thiamine for altered mental status

ED TREATMENT/PROCEDURES

- Prevent further ethylene glycol absorption:
 - Gastric lavage with nasogastric tube:
 - If < 1 hr since ingestion, if patient is in coma, or if history of large ingestion
 - Initial dose of activated charcoal for potential coingestants, but unlikely to help if only ethylene glycol:
 - Activated charcoal adsorbs ethylene glycol poorly.
- Prevent ethylene glycol conversion to toxic metabolites with fomepizole:
 - Fomepizole (4-MP, Antizol):
 - Initiate before ethylene glycol serum concentration returns, if

accidental ingestion greater than a sip or intentional ingestion
oraltered mental status associated with unexplained osmol gap or
elevated anion gap acidosis.

- Competitive inhibitor of alcohol dehydrogenase

– Disadvantages:

- Blurry vision
- Transient elevation of LFTs

– Advantages:

- Easy dosing
- No need for continuous infusion
- No inebriation/CNS depression
- No hypoglycemia, hyponatremia, or hyperosmolality
- Not necessary to check ethanol serum concentration
- Reduction in degree of nursing care and monitoring

● Ethanol therapy:

- 2nd choice antidote if fomepizole is not available
- Not FDA approved for treatment of ethylene glycol
- Initiate before ethylene glycol serum concentration returns, if potentially toxic ingestion is suspected.

– Ethanol: Greater affinity than ethylene glycol for alcohol dehydrogenase:

- Slows conversion to toxic metabolites

– Indications:

- History of accidental ethylene glycol ingestion of greater than a sip or intentional ethylene glycol ingestion
- Altered mental status associated with unexplained osmol gap or elevated anion gap metabolic acidosis

– Goal: Serum ethanol serum concentration of 100–150 mg/dL

- Continue ethanol therapy until ethylene glycol serum concentration is 25 mg/dL.

● Administer thiamine, pyridoxine, and magnesium:

- Cofactors in metabolism of ethylene glycol that may promote conversion to nontoxic metabolites.
- No human data supporting this theory

● Hemodialysis:

- Decreases elimination half-life of ethylene glycol and removes toxic metabolites
- Indications: Severe acidosis or osmol gap; persistent electrolyte or metabolic acidosis; renal insufficiency; pulmonary edema; cerebral edema; serum ethylene glycol serum concentration > 25 mg/dL
- Continue hemodialysis until ethylene glycol serum concentration approaches 25 mg/dL and metabolic acidosis resolves.

● Correct secondary disorders:

- Ensure adequate urine output via IV fluids.

- Sodium bicarbonate therapy for acidemia with pH < 7.1:
 - The goal is to maintain a serum pH in the normal range.
- Monitor/replace calcium:
 - Deposition of calcium into tissues can result in hypocalcemia.

Pregnancy Considerations

- Fomepizole is class C in pregnancy.
- Ethanol is not recommended in pregnancy. Class D/X

Pediatric Considerations

Ethanol can cause serious CNS depression and hypoglycemia when administered to children.

MEDICATION

- Activated charcoal: 1 g/kg PO
- Dextrose: D₅₀W 1 ampule: 50 mL or 25 g (peds: D₂₅W 2–4 mL/kg) IV
- Ethanol:
 - PO: 50% ethanol solution (100-proof liquor) via nasogastric tube:
 - Loading dose: 1.5 mL/kg
 - Maintenance dose: 0.2–0.4 mL/kg/h
 - Maintenance dose during hemodialysis: 0.4–0.7 mL/kg/h
 - IV: 10% ethanol in D₅W:
 - Loading dose: 8 mL/kg over 30–60 min
 - Maintenance infusion: 1–2 mL/kg/h
 - Maintenance infusion during hemodialysis: 2–4 mL/kg/h
- Fomepizole:
 - Loading dose: 15 mg/kg slow infusion over 30 min
 - Maintenance dose: 10 mg/kg q12h for 4 doses, then 15 mg/kg q12h until ethylene glycol serum concentration are reduced to < 25mg/dL
 - Dosing related to hemodialysis:
 - Do not administer dose at beginning of dialysis if last dose was < 6 hr previously.
 - Administer next dose if last dose was > 6 hr previously.
 - Dose q4h during dialysis.
 - If time between last dose and end of dialysis was < 1 hr from last dose, do not administer new dose.
 - If time between last dose and end of dialysis was 1–3 hr from last dose, administer 1/2 of next scheduled dose.
 - If time between last dose and end of dialysis was > 3 hr from last dose, administer next scheduled dose.
- Magnesium: 25–50 mg/kg IV 1 dose up to 2 g
- Naloxone: 2 mg (peds: 0.1 mg/kg) IV or IM initial dose

- Pyridoxine: 100 mg/d for 2 days
- Sodium bicarbonate: 1–2 mEq/kg in D₅W IV
- Thiamine: 100 mg (peds: 50 mg) IV or IM per day for 2 days

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with significant ethylene glycol ingestion, even if initially asymptomatic
- ICU admission for seriously ill patients, metabolic acidosis, and renal failure
- Transfer to another facility if hemodialysis or fomepizole is indicated but not readily available.

Discharge Criteria

Asymptomatic patient with isolated ethylene glycol ingestion, if serum ethylene glycol serum concentration is undetectable and no metabolic acidosis

FOLLOW-UP RECOMMENDATIONS

Psychiatric referral for suicidal patients.

PEARLS AND PITFALLS

- An osmol gap <10 mmol/L does not rule out an ethylene glycol exposure.
- Administer fomepizole immediately and confirm exposure with a serum concentration for patients with an elevated anion gap and ethylene glycol exposure in the differential diagnosis.
- If you cannot confirm an ethylene glycol exposure, or do not have hemodialysis capabilities 24/7, or no antidote, transfer the patient to a facility which has all of the above capabilities.
- Not all patients will have an elevated osmol and anion gap. Early presenters will have an osmol gap only, and late presenters may have an anion gap only.
- Do not use the absence of urine crystals or fluorescence of the urine to rule out an ethylene glycol exposure.

EXTERNAL EAR CHONDRITIS/ABSCESS

Assaad J. Sayah

BASICS

DESCRIPTION

Inflammation and/or infection of the pinna

ETIOLOGY

- Mechanism:
 - Cartilage of the external ear is easily damaged due to:
 - Lack of overlying subcutaneous tissue
 - Relative avascularity
 - Exposed position
 - Chondritis:
 - Most commonly a secondary complication of otic trauma and burns
 - Onset is often insidious and may be delayed until apparent healing has occurred.
- Improper management may cause disfiguration of the pinna secondary to cartilage avascular necrosis:
 - Ranges from being a shriveled, cauliflower-like ear to complete loss of the external ear and possible stenosis of the auditory meatus.
- Causes:
 - Common causes of chondritis include:
 - Chemical or thermal burns
 - Frostbite
 - Hematoma formation
 - Trauma
 - Human/insect bites
 - Deep abrasions
 - External otitis
 - High piercing of the ear lobe especially with poor technique, hygiene, and aftercare.
 - Bacteria involved:
 - *Pseudomonas aeruginosa*
 - Staphylococcus
 - Proteus

DIAGNOSIS

SIGNS AND SYMPTOMS

- Initially a dull pain that increases in severity
- Fever
- Chills

History

- Ear trauma
- Ear piercing

Physical-Exam

- Pinna:
 - _ Painful
 - _ Exquisite tenderness
 - _ Erythematous
 - _ Warmth
 - _ Loss of contours caused by edema often with sparing of the lobule.
- Increase of the auriculocephalic angle
- Fluctuant areas develop with eventual breakdown and suppuration.

ESSENTIAL WORKUP

Clinical diagnosis:

- Typical physical findings in combination with aforementioned causes

DIAGNOSIS TESTS & INTERPRETATION

Lab

Only if systemic signs of infection:

- CBC
- Blood cultures
- Local cultures for chondritis and abscess drainage

DIFFERENTIAL DIAGNOSIS

- Allergic reaction
- Mastoiditis
- Dermatitis
- Hematoma

TREATMENT

ED TREATMENT/PROCEDURES

General postinjury preventive measures:

- Prevention of chondritis is of utmost importance:
 - _ Difficult management and disfiguring potential

- Avoid pressure to the injured ear.
- Minimize active débridement of eschars and crusts.
- Gentle washing twice daily with antibacterial soap and water followed by complete drying and application of topical antibiotics
- Keep hair away from the ear.
- Oral antibiotics for minor cases of early ear-lobe inflammation
- Parenteral antibiotics and early surgical drainage for patients with chondritis

MEDICATION

- Ciprofloxacin: 500 mg PO BID (adult)
- Cephalexin: 500 mg (peds: 50 mg/kg/d) PO QID
- Dicloxacillin: 500 mg (peds: 25 mg/kg/d) PO QID
- IV antibiotics for severe infection
- Apply topical antibiotics when there is a break in skin barrier.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Edema, erythema, and significant ear tenderness
- Toxic patient with fever and chills
- Immunocompromised patient

Discharge Criteria

Stable patient without systemic signs with close ear, nose, and throat (ENT) follow-up

Issues for Referral

ENT consult:

- For chondritis, abscess, and necrosis of the involved cartilage
- Early surgical drainage for chondritis and abscess

PEARLS AND PITFALLS

Aggressive early management may prevent gross ear deformity:

- Antibiotic regimen should cover for *Pseudomonas*.

EXTREMITY TRAUMA, PENETRATING

Gary M. Vilke

BASICS

DESCRIPTION

Penetrating injury to extremity

ETIOLOGY

- Stab or puncture
- Gunshot
- Laceration
- Bite
- High-pressure injection injury

DIAGNOSIS

SIGNS AND SYMPTOMS

- Entry and exit wound (if present), lacerations
- High-muzzle-velocity gunshot wounds:
 - _ Produce shock wave that results in significant tissue injury
 - _ Often exit wound demonstrates more tissue damage than entrance wound.
- Vascular injury:
 - _ Arterial injury:
 - Decreased or absent distal pulse
 - Distal ischemic changes
 - Expanding hematoma
 - Bruit or thrill over injury
 - _ Presence of distal pulse does not exclude proximal vascular injury.
- Neurologic injury:
 - _ Paresthesias
 - _ Decreased or absent motor function
 - _ Diminished sensation distal to injury
- Musculoskeletal injury:
 - _ Visible deformity
 - _ Ligamentous laxity in joints adjacent to injury suggests tendon injury.
 - _ Effusion in adjacent joint indicates fracture or ligamentous injury.
- Compartment syndrome:
 - _ Suggested by severe and constant pain over involved compartment
 - _ Pain on active and passive extension or flexion of distal extremity
 - _ Weakness, pain on palpation of compartment

- Hypesthesia of nerves in compartment
- Pulselessness and pallor are late findings.

History

- Mechanism of injury
- Age of wound
- Circumstances of wounding:
 - Assault
 - Self-inflicted wound
 - Domestic violence
- Comorbid conditions:
 - Immunosuppression or diabetes
 - Valvular heart disease
 - Asplenia
 - Peripheral vascular disease

Physical-Exam

- Note location, length, depth, and shape of primary wound and exit wound, if present.
- Vascular injury:
 - Compare distal pulses by palpation and with Doppler study.
 - Assess capillary refill:
 - Abnormal if > 2 sec
 - Ankle-brachial index (ABI):
 - Take BP in calf and arm (involved extremity).
 - Systolic pressure difference of > 10 mm Hg suggests vascular injury.
 - Expanding hematoma, bruit, or thrill over injury also indicates vascular injury.
- Neurologic injury:
 - Assess distal motor function and sensory function:
 - 2-point discrimination
 - Light touch
 - Proprioception
- Musculoskeletal injury:
 - Note associated crush, tendon, or ligamentous injury and bony deformity.
 - Examine adjacent joints for range of motion.
 - Assess for compartment syndrome.
- Explore wound for foreign body (FB).

ESSENTIAL WORKUP

- Physical exam
- Imaging if findings suggestive of bony injury or possible FB

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Culture of acute wounds is not indicated.
- Wounds with signs of infection may be cultured to guide antibiotic choice.

Imaging

- Radiograph to evaluate for radiopaque FB or underlying fracture:
 - _ Min. AP and lateral views
- Radiolucent FBs may be located by US, fluoroscopy, or CT.

Diagnostic Procedures/Surgery

Arteriogram is indicated when vascular injury is suspected and immediate vascular surgery not required.

DIFFERENTIAL DIAGNOSIS

Any medical condition that presents with findings consistent with extremity trauma or a wound

TREATMENT

PRE HOSPITAL

Cautions:

- Control hemorrhage with direct pressure over site.
- Elevate extremity.
- Evaluate neurovascular status.
- Leave impaled objects in place and stabilize in current position.
- Pain control

INITIAL STABILIZATION/THERAPY

- Manage airway and resuscitate as indicated.
- Expose wound completely and remove constricting clothing or jewelry.
- Control hemorrhage with direct pressure.
- Blind clamping within wound and prolonged tourniquet use are not recommended.

ED TREATMENT/PROCEDURES

- Pain control
- Complete neurologic assessment before local anesthesia
- Prolonged soaking of wounds, particularly with cytotoxic agents, is *not* recommended.
- Remove any visible debris and débride devitalized tissue.
- Most important is copious high-pressure irrigation with saline.

- Tetanus prophylaxis
- Stab wounds and gunshot wounds should receive single dose of cefazolin in ED.
- Immobilize extremity if there is suspicion of significant vascular injury, tendon injury, fracture, or joint violation.
- Loss of pulse or distal ischemia requires emergent surgery:
 - Do not delay surgical management for arteriogram.
- Lacerations may be closed if they have been adequately cleaned, have minimal tissue loss, and are seen within 6–8 hr of injury:
 - Delayed primary closure is an alternative for older or contaminated wounds.
- Puncture or gunshot wounds should *not* be closed primarily.
- Special considerations:
 - Plantar puncture wounds:
 - Examine wound carefully under bright light.
 - Remove any foreign material.
 - Clean wound carefully.
 - Coring wound is controversial and should be reserved for removal of devitalized tissue or imbedded debris:
 - Probing or high-pressure irrigation of puncture wound will only force particulate matter further into wound.
 - Prophylactic antibiotics are not recommended (unless patient is diabetic or immunocompromised or if the wound is highly contaminated or delayed in presentation).
 - If not treated with aggressive debridement, can lead to osteomyelitis
 - High-pressure injuries of hand:
 - Orthopedic evaluation in ED is essential because wounds that appear trivial on surface may have product track up tendon sheaths into more proximal aspects of hand.
 - Some paints and other products are radiopaque, and plain radiographs may demonstrate extent of spread.
 - Soft tissue FBs:
 - Small inert FB in wound, including bullets, not easily retrievable and not in close proximity to joint, tendon, vessel, or nerve can be left in place with close follow-up.
 - FB in hands and feet should be referred to specialist as they often migrate and become or remain symptomatic.
 - Organic materials (thorns, wood, spines, clothing) should be removed as they are very reactive.

MEDICATION

- Tetanus prophylaxis: TDap 0.5 mL IM (TD only if > 65 yr
- Wounds > 12 hr old, especially of hands and lower extremities, crush wounds with devitalized tissue, contaminated wounds

First Line

- Cefazolin: 1 g IV/IM (peds: 20–40 mg/kg IV/IM single dose in ED)
- Cephalexin: 500 mg PO (peds: 25–50 mg/kg/d) QID for 7 days *or*
 - Amoxicillin/clavulanate: 875/125 mg PO (peds: 25 mg/kg/d) BID for 7 days
- Erythromycin: 333 mg PO TID (peds: 40 mg/kg/d q6h for 7 days)
- Contaminated wounds in patients with pre-existing valvular heart disease:
 - Cefazolin: 1 g IV/IM, then cephalexin 500 mg PO QID for 7 days
- Plantar through shoe at risk for *Pseudomonas*:
 - Ciprofloxacin 500 mg BID for 7–10 days *or*
 - Levofloxacin 500 mg QD for 7–10 days

Second Line

If penicillin allergic:

- EES: 800 mg PO, then 400 mg PO q6h for 7 days *or*
- Clindamycin: 300 mg PO q6–8h for 7 days

FOLLOW-UP

DISPOSITION

Admission Criteria

- Emergent surgical consultation and admission are required for any penetrating wounds with potential for vascular compromise, associated compartment syndrome, and joint penetration.
- High-muzzle-velocity penetrating gunshot wounds
- Diabetic or immunocompromised patients with contaminated wounds

Discharge Criteria

Penetrating extremity injuries not requiring surgical intervention may be discharged after appropriate wound care with instructions to elevate extremity, keep wound clean, and to return for recheck in 24–48 hr or for any signs of infection.

Issues for Referral

- Plantar puncture wounds: Close follow-up is necessary to assess for infection from unseen FB.
- Delayed primary closure is alternative for older or contaminated wounds.
- Wounds at high risk for infection should have close 1–2 day follow-up.

FOLLOW-UP RECOMMENDATIONS

Return to the ED for increasing pain, numbness, tingling, redness, swelling drainage, fevers or other changes in clinical presentation.

PEARLS AND PITFALLS

- Presence of distal pulse does not exclude proximal vascular injury.
- High-pressure injuries of hand may have wounds that appear trivial on surface but track up tendon sheaths into more proximal aspects of hand.
- Plantar surface puncture wounds through shoes or socks have relatively high risk of retained foreign material – patients should be told of this possibility.
- Post-puncture wound infections failing to respond to antibiotics should be suspected of having retained FB.

FACIAL FRACTURES

David W. Munter

BASICS

DESCRIPTION

- Typically blunt trauma from motor vehicle accidents, direct blows including assaults, or falls.
- Consider physical assault and domestic violence, especially in women and children.
- Open fractures common.
- Many facial fractures are complex and are not easily classified.

ETIOLOGY

- Le Fort fractures involve the maxilla and are classified as:
 - Le Fort I: Transverse fracture of maxilla below nose but above teeth through lateral wall of maxillary sinus to lateral pterygoid plate.
 - Le Fort II: Pyramidal fracture from nasal and ethmoid bones through zygomaticomaxillary suture and maxilla, often involving maxillary sinuses and infraorbital rims.
 - Le Fort III: Craniofacial disjunction with elongated, flattened face owing to fractures through frontozygomatic suture, orbit, base of nose, and ethmoid bone.
 - Le Fort IV: Includes frontal bone in addition to Le Fort III.
 - A patient may have different level Le Fort fractures on each side of the face.
- Zygomatic arch fractures often occur in 2 or 3 places and can involve the orbit and maxilla (tripod fracture).
- Inner plate frontal sinus fractures are associated with CSF leaks and ocular injuries.
- Orbital fractures most commonly involve the orbital floor (blow-out fracture), and are commonly associated with ocular injuries but can involve the medial and lateral orbital walls.

Geriatric Considerations

- Falls most common cause.
- Zygoma most common bone fractured.
- Beware of associated cervical and intracranial injuries.

Pediatric Considerations

- Maxillofacial fractures rarely seen in children younger than 6 yr; suspect nonaccidental trauma.

- Falls and motor vehicle accidents account for most cases.
- Over 50% have severe associated injuries, high incidence of associated head injury.
- Fractures of the orbit are the most common facial fracture in children (excluding nose)

DIAGNOSIS

SIGNS AND SYMPTOMS

- Most post-traumatic deformities of the face represent underlying fractures.
- Pain, swelling, ecchymosis, and deformity.
- CSF rhinorrhea, facial hemorrhage, epistaxis, raccoon eyes.
- Facial anesthesia with nerve entrapment or injury.
- Associated injuries; tooth, mandible, eye, tear duct, skull, and neck.
- Bluish fluid-filled sac overlying nasal septum is a septal hematoma and is critical to detect.

History

- Mechanism of injury.
- Associated injuries.

Physical-Exam

- Immediately assess airway.
- Most important:
 - _ Palpate entire face for tenderness, step-offs, depressions, and crepitus.
 - _ Check for mandibular injuries or malocclusion.
 - _ Nasal speculum exam for septal hematoma or CSF leak.
 - _ Assess for areas of facial anesthesia.
 - _ Careful eye exam including funduscopic exam; obtain a visual acuity; assess for telecanthus (intercanthal width $> 30\text{--}35$ mm), upward dysconjugate gaze (indicative of ocular muscle entrapment in an orbital floor blow-out fracture).
- Le Fort fractures are assessed by placing thumb and index finger of 1 hand on the bridge of the nose and pulling upper teeth with other hand:
 - _ Le Fort I: Movement of hard palate and maxillary dentition only (your hand on the nose will not feel movement).
 - _ Le Fort II: Movement of hard palate, maxillary dentition, and nose (your hand on the nose will feel movement).
 - _ Le Fort III: Movement of entire midface.

Pediatric Considerations

- Sedation may be needed to perform an adequate exam.

ESSENTIAL WORKUP

- After airway is secured, other injuries take precedence.
- Radiologic studies in all cases of suspected facial fractures.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Indicated for evaluation of associated injuries or if needed for preoperative reasons.

Imaging

- Facial bone CT scanning with reconstructions is the imaging modality of choice for suspected facial injuries.
- Plain films such as a Waters view are less helpful.
 - May show fractures, asymmetry, or blood in the sinuses, or the classic teardrop opacity in the maxillary sinus representing an orbital floor blow-out fracture.
- Jug-handle views (submental vertex) may visualize zygomatic arch fractures.

DIFFERENTIAL DIAGNOSIS

- Nasal fracture.
- Zygoma fractures (arch or tripod fracture).
- Le Fort fracture.
- Skull fractures including frontal sinus fractures and cribriform plate fractures.
- Nasofrontoethmoid complex fractures.
- Mandibular fractures.
- Orbital fracture including blow-out fracture
- Associated injuries to teeth, neck, and brain.
- Contusions or lacerations without underlying fractures.

TREATMENT

PRE HOSPITAL

ALERT

- Airway control takes precedence:
 - Attempt chin lift, jaw thrust, and suctioning first.
 - Underlying injuries may make these attempts as well as use of bag/valve/mask (BVM) device unsuccessful.
 - Severe facial fractures may preclude oral intubation.
 - Nasotracheal intubation contraindicated in massive facial or nasal trauma.
 - Cricothyroidotomy performed if intubation using rapid-sequence induction

(RSI) cannot be performed.

- If associated injuries are present, protect cervical spine.

INITIAL STABILIZATION/THERAPY

- Aggressively manage airway if not patent, patient requires airway protection, or ongoing swelling or bleeding threatens airway. RSI is initial airway management of choice in facial injuries; use etomidate or midazolam and vecuronium, rocuronium, or succinylcholine for RSI.
- Surgical airway (cricothyroidotomy or needle cricothyroidotomy) may be required if RSI is unsuccessful.
- Nasotracheal intubation is contraindicated in most facial fractures.
- Protect cervical spine until clinically or radiographically cleared.
- Once airway is secure, other major injuries take precedence over facial injuries.
- Bleeding may be difficult to control and may require posterior packing if direct pressure does not work.

ED TREATMENT/PROCEDURES

- Consult ear, nose, throat specialist; plastic surgery; or oral surgery for complex fractures, including all Le Fort fractures, and neurosurgery for frontal sinus fractures involving the posterior table.
- Antibiotics (cefazolin or clindamycin in penicillin-allergic patients) for open fractures and CSF leak.
- Tetanus prophylaxis.
- Parenteral pain medication (morphine or fentanyl).
- A septal hematoma must be drained in the ED:
 - Anesthetize, aspirate with an 18G–20G needle, and pack both nares with Vaseline gauze.
 - Discharge on amoxicillin or erythromycin with recheck in 24 hr by ear, nose, and throat specialist.
- Nondisplaced zygomatic fractures can be discharged with analgesics (acetaminophen or ibuprofen); refer displaced zygoma and tripod fractures that are otherwise stable for outpatient reduction in 2–3 days after swelling is reduced.
- Overlying lacerations with simple fractures can be sutured in the emergency department; if patient is discharged, treat with amoxicillin or azithromycin.
- Patients discharged with facial fractures with blood in the sinus should be treated with amoxicillin or azithromycin.

Pediatric Considerations

- Surgical cricothyroidotomy should not be performed in children younger than 8 yr:
 - Needle cricothyroidotomy with jet ventilation may be performed.
- Children are at high risk of associated injuries.
- Repair of facial fractures should not be delayed more than 3–4 days (rapid healing of facial fractures and the risk of malunion and cosmetic deformity).

MEDICATION

- Acetaminophen: 500 mg (peds: 10–15 mg/kg, do not exceed 5 doses/24 h) PO q4–6h, do not exceed 4 g/24 h
- Amoxicillin: 250 mg (peds: 40–80 mg/kg/24 h) PO q8h
- Azithromycin: 500 mg PO day 1 followed by 250 mg PO days 2–4 (peds: 10 mg/kg PO day 1 followed by 5 mg/kg days 2–4)
- Cefazolin: 1 g (peds: 50–100 mg/kg/24 h) IV or IM
- Clindamycin: 600–900 mg (peds: 25–40 mg/kg/24 h) PO q8h
- Diazepam: 5–10 mg (peds: 0.1–0.2 mg/kg) IV
- Etomidate: 0.2–0.3 mg/kg (peds: 0.2–0.3 mg/kg) IV (not recommended in children <10 yr)
- Fentanyl: 2–10 µg/kg (peds: 2–3 µg/kg) IV
- Ibuprofen: 600–800 mg (peds: 20–40 mg/kg/24 h) PO TID–QID
- Ketamine: 1–2 mg/kg (peds: 1–2 mg/kg) IV
- Midazolam: 2–5 mg (peds: 0.02–0.05 mg/kg per dose, max. dose 0.4 mg/kg total and not >10 mg) IV over 2–3 min
- Morphine sulfate: 0.1–0.2 mg/kg (peds: 0.1–0.2 mg/kg) IV q1–4h titrated
- Rocuronium: 0.6–1.2 mg/kg (peds: 0.6 mg/kg) IV
- Succinylcholine: 1–1.5 mg/kg (peds: 1–2 mg/kg) IV
- Vecuronium: 0.1–0.3 mg/kg (peds: 0.1–0.3 mg/kg) IV

FOLLOW-UP

DISPOSITION

Admission Criteria

- Significant associated trauma.
- Airway compromise.
- Le Fort II and III fractures.
- CSF leak.
- Posterior table frontal sinus fractures.
- Most open fractures, excluding simple nasal fractures with lacerations.

Discharge Criteria

- No evidence of significant head, neck, or other injuries.
- Closed fractures of the zygoma, orbit, sinus, or anterior table of the frontal sinus with appropriate follow-up in 24–36 hr.
- Septal hematomas that have been drained in the emergency department require follow-up in 24 hr.
- Refer displaced zygoma and tripod fractures that are otherwise stable for outpatient reduction in 2–3 days after swelling is reduced.

Issues for Referral

- ENT, plastic surgery, or neurosurgery may all handle facial fractures, actual referral depends on practice patterns at your institution. If there is no CSF leak or involvement of the posterior table of the frontal sinus, it is reasonable to initially consult ENT.

PEARLS AND PITFALLS

- Facial fractures and injuries can be very dramatic in appearance.
 - Airway management always takes precedence. Avoid nasotracheal intubation.
 - After the airway is secured as necessary, evaluation of other injuries takes precedence—do not miss life-threatening injuries.
 - Cervical spine.
 - Pulmonary or thoracic.
 - Intra-abdominal injuries.
- Have a low threshold for obtaining facial bone CT for evaluation of facial injuries.
- Facial fractures are frequently associated with ocular injuries. Perform a thorough eye exam.
- Always assess for a nasal septal hematoma.
- Missing teeth must be accounted for, obtain a CXR to rule out aspiration.

FAILURE TO THRIVE

Roger M. Barkin

BASICS

DESCRIPTION

- Not a single disease, but a description of a group of symptoms
- Inadequate physical growth:
 - Usually diagnosed earlier than age 2 yr
- Broadly divided into:
 - Organic (underlying medical condition)
 - Nonorganic (no underlying medical condition)
- Found in all socioeconomic groups
- Poverty increases risk of failure to thrive (FTT)
- May result in long-term growth, behavioral, and developmental difficulties, particularly in children who fail to thrive in the first few months of life

ETIOLOGY

Many diseases with unique causes resulting in 1 or more of:

- Inadequate caloric intake
- Inadequate caloric absorption, malabsorption
- Excessive caloric expenditure
- These may be secondary to underlying chronic disease

DIAGNOSIS

SIGNS AND SYMPTOMS

- No universally accepted definition
- Failure to achieve or maintain a growth rate appropriate for age
- Weight less than 2 standard deviations below normal for age (corrected for prematurity) and sex
- Weight that crosses downward through 2 major percentiles (major percentiles are 5th, 10th, 25th, 50th, 75th, and 90th percentiles) on standard growth chart (see Additional Reading below)
- There is an associated change in the velocity of growth of 1 or more growth parameters. Any of the 3 routinely monitored growth parameters may be impaired initially:
 - Weight loss initially followed by impaired growth in length/height and finally head circumference usually caused with caloric inadequacy.
 - Primary length/height fall-off often associated with endocrinology problem
 - Impairment in growth of head circumference commonly caused by CNS

primary condition.

- Although the pattern is usually one of slow decrease in growth velocity, an abrupt change may occur, usually indicative of an organic origin.
- Can manifest as:
 - Reduced muscle mass
 - Loss of subcutaneous fat
 - Alopecia
 - Dermatitis
 - Chronic disease
 - Marasmus
 - Kwashiorkor
 - Associated endocrinologic findings
 - Abnormal neurologic exam and development
 - Decreased immunologic function and increased risk of infection

History

- Detailed feeding history:
 - Breast-feeding:
 - Prior breast-feeding experience
 - Frequency of feedings
 - Length of feedings
 - Family support for breast-feeding
 - Formula:
 - Type of formula (milk, soy, elemental, preemie)
 - How formula is prepared (ready to feed, powder, liquid concentrate)
 - Frequency of feedings
 - Volume per feeding
 - Solid foods
 - Vomiting associated with feeds
 - Urine and stool output:
 - Blood in stool
- Gestational history:
 - Maternal medical complications
 - Drug or alcohol use
- Birth history:
 - Complications, intrauterine growth retardation, prematurity
 - Birth weight
 - Congenital anomalies
 - Intrauterine exposures/infections
- Developmental history:
 - Achievement of appropriate milestones
 - Child's perceived temperament
- Psychosocial history:

- Family composition
- Family/social support
- Stresses
- Maternal depression
- Abuse or neglect

Physical-Exam

- Weight, length/height, head circumference:
 - Plotted on appropriate growth chart:
 - Include as many prior growth points as possible
- Dysmorphic features:
 - Cardiac disorders
 - Pulmonary disorders
 - GI disorders
- Skin exam to include signs of child abuse

ESSENTIAL WORKUP

- Detailed history and physical exam
- Growth parameters plotted on appropriate growth charts
- Observation of family–child interaction
- Direct observation of feeding
- CBC, CRP, electrolytes, urinalysis and urine culture, and if indicated, lead level

DIAGNOSIS TESTS & NTERPRETATION

Lab

- CBC:
 - Anemia
 - Infection
 - Leukemia/malignancy
 - Lead level
 - Lead poisoning
- Chemistry panel (electrolytes, BUN, creatinine, glucose, liver function, protein, albumin, calcium, phosphate, magnesium):
 - Hydration and acidosis
 - Metabolic and endocrinologic disorders including thyroid disease. Often checking the routine newborn screening (NBS) is useful
 - Diabetes mellitus
 - Renal disease
 - Blood gas analysis
 - Renal tubular acidosis
 - Inborn errors of metabolism
- Urinalysis with culture:

- Renal disease
- Infection
- HIV
- Stool studies including occult blood, culture, and ova and parasites

Imaging

- CXR:
 - TB
 - Pneumonia
 - Cardiomegaly
- Bone age

Diagnostic Procedures/Surgery

- pH probe:
 - Gastroesophageal reflux
- Sweat chloride test:
 - Cystic fibrosis (may be part of NBS)
- Tuberculin skin testing

DIFFERENTIAL DIAGNOSIS

- Organic causes:
 - GI:
 - Malabsorption syndromes
 - Celiac disease
 - Cystic fibrosis
 - Food allergy
 - Inflammatory bowel disease
 - Hepatobiliary disease
 - Hepatitis
 - Cirrhosis
 - Biliary atresia
 - Obstructive disease
 - Pyloric stenosis
 - Malrotation
 - Hirschsprung disease
 - Pancreatitis
 - Short gut syndrome
 - Gastroesophageal reflux
 - Vitamin deficiencies
 - Cardiac:
 - Congenital heart disease
 - Cyanotic
 - Congestive

- Acquired heart disease
- Pulmonary:
 - Bronchopulmonary dysplasia
 - Obstructive sleep apnea
 - Chronic lung disease
 - Cystic fibrosis
- Hematologic/oncologic:
 - Iron-deficiency anemia
 - Thalassemia
 - Lead poisoning
 - Leukemia
- Renal:
 - Chronic renal insufficiency
 - Renal tubular acidosis
 - Recurrent UTIs
- Neurologic/CNS:
 - Hydrocephalus
 - Hypertonia/hypotonia
 - Generalized weakness (i.e., spinal muscular atrophy)
 - Oromotor dysfunction
- Immunologic:
 - AIDS
- Endocrine:
 - Diabetes mellitus
 - Thyroid/parathyroid disease
 - Adrenal disease
 - Growth hormone deficiency
 - Hypopituitarism
 - Hypophosphatemic rickets
- Infectious:
 - TB
 - Parasite
 - UTI
- Genetic/congenital:
 - Fetal alcohol syndrome
 - Smith–Lemli–Opitz syndrome
 - Cleft lip/palate
 - Inborn errors of metabolism
 - Many genetic syndromes can contribute.
- Toxic
- Nonorganic causes:
 - Parent–child dysfunction:
 - Mother–infant bonding problems

- Maternal mental illness/substance abuse
- Inexperienced mother
- Breast-feeding difficulties
- Improper formula preparation
- Inadequate availability of formula
- Chaotic family environment
- Child abuse or neglect
- Munchhausen syndrome by proxy

TREATMENT

INITIAL STABILIZATION/THERAPY

- Check for hypoglycemia
- Fluid resuscitation when dehydrated
- Supportive/nonjudgmental environment

ED TREATMENT/PROCEDURES

- Recognize/identify child with FTT
- Rule out organic abnormalities:
 - Organic causes may have specific treatments.
- Social services consult
- Breast-feeding consult:
 - Advise on appropriate feeding.

MEDICATION

Dependent on underlying cause

FOLLOW-UP

DISPOSITION

Admission Criteria

- Organic cause requiring medical admission
- Nonorganic causes to observe caregiver–child interaction
- Nonorganic causes to observe weight while monitoring oral intake. This is particularly appropriate in children < 3–6 mo of age because of the potential impact upon cognitive development
- Suspected child abuse/neglect
- Severe dehydration, malnutrition, or electrolyte imbalance

Discharge Criteria

- Case appropriately managed by primary care physician

- Follow-up is adequate to provide close monitoring of intake and growth.

Issues for Referral

Subspecialty referral depending on cause

- R62.51 Failure to thrive (child)

FATIGUE

Matthew B. Mostofi

BASICS

DESCRIPTION

- A subjective state of overwhelming, sustained exhaustion and decreased capacity for physical and mental work that is not relieved by rest
- Fatigue occurs with or without objective findings on physical exam.
- Fatigue is a common complaint in people with and without systemic disease, which makes this complaint a challenge to practicing physicians.

ETIOLOGY

- The specific mechanisms of fatigue are unknown.
- Hematologic:
 - Anemia
 - Leukemia
- Endocrine:
 - Thyroid disorders
 - Adrenal insufficiency
 - Diabetes
 - Pregnancy
- Malignancy:
 - Paraneoplastic syndromes
- Psychiatric:
 - Chronic pain
 - Emotional distress
 - Depression
 - Eating disorders
 - Chemical dependency
 - Withdrawal syndromes
- Sleep disorders:
 - Insomnia
 - Sleep apnea
- Cardiac and pulmonary disorders
- Infections acute and chronic
- Rheumatic and autoimmune disorders
- Nutritional deficiencies including electrolyte abnormalities
- Physical inactivity and deconditioning
- Medications
- Chronic fatigue syndrome:

- Symptom complex defined by the CDC
- Severe chronic fatigue lasting >6 mo
- Not explained by any medical or psychiatric diagnosis
- Presence of 4 or more of the following 8 symptoms:
 - Headache
 - Arthralgias
 - Sleep disturbances
 - Lymphadenopathy
 - Exercise intolerance
 - Myalgias
 - Impaired memory/concentration
 - Sore throat

DIAGNOSIS

SIGNS AND SYMPTOMS

- Fatigue is a subjective complaint of exhaustion or tired sensation that interferes with normal activities of life, and symptoms do not resolve with sleep.
- There are no specific signs of fatigue, but frequently physical signs may hint at the underlying cause of complaint.

History

- Onset, pattern, duration of fatigue
- Associated symptoms: Fever, night sweats, weakness, dyspnea, weight loss/gain, sleep patterns
- Past medical and surgical history
- Psychiatric history: Emotional and mental stressors, depression
- Social history: Alcohol, drug use, major life events
- Medications
- Full review of systems

Physical-Exam

- A complete physical exam should be focused on trying to identify an underlying cause for patient's symptoms. No physical findings are specific to fatigue.
- A partial list of physical exam findings which may suggest an underlying cause include:
 - Vital signs
 - HEENT
 - Pupils for evidence of toxidrome
 - Sclera for icterus in liver disease
 - Conjunctiva pale in anemia
 - Thyroid for enlargement, pain, or nodule that would suggest

dysfunction

- Heart: Murmurs or S3 may suggest LV dysfunction.
- Lung: Abnormal AP diameter or breath sounds may suggest chronic or acute lung disease.
- Abdomen: Tenderness or masses should be investigated.
- Skin: Rash may suggest infectious or autoimmune disease, lack of turgor may suggest dehydration, hyperpigmentation in Addison disease.
- Neurologic: True weakness or areflexia may suggest neuromuscular disorder, all new focal weakness should be investigated.
- Musculoskeletal: Indwelling IV lines or dialysis catheters should prompt investigation of electrolyte abnormality or occult bacteremia.

ESSENTIAL WORKUP

- Because fatigue is a subjective complaint, the essential workup is directed at identification of an underlying cause.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Lab evaluation should be directed by findings of history and physical exam.
- CBC:
 - Screen for anemia or leukemia.
- Serum glucose:
 - Both hyperglycemia and hypoglycemia can present with fatigue.
- Pregnancy test
- Electrolytes with BUN/creatinine
- Thyroid-stimulating hormone:
 - Screen for hypothyroidism.
- Urine drug screen

Imaging

Imaging/special test: Special tests are reserved for evaluation of abnormal physical exam findings or history suggesting further evaluation.

Diagnostic Procedures/Surgery

Any diagnostic procedures considered should be reserved for evaluation of abnormal physical exam findings or history suggesting further evaluation.

DIFFERENTIAL DIAGNOSIS

- Infection:
 - Bacteremia
 - Urosepsis
 - Pneumonia

- Viral syndromes
- Abscess
- Epstein–Barr virus, monospot
- Cytomegalovirus
- HIV
- Human herpesvirus 6
- Immunologic/connective tissue:
 - Rheumatologic (rheumatoid arthritis, systemic lupus erythematosus, juvenile rheumatoid arthritis)
 - Osteoarthritis
 - Fibromyalgia
 - Myasthenia gravis
 - Lambert–Eaton syndrome
- Neoplastic:
 - Solid or hematologic cancers
- Metabolic:
 - Electrolyte abnormalities
 - Mitochondrial diseases
 - Bromism
- Hematologic:
 - Anemia
 - Hypovolemia
 - Hemoglobinopathy
- Endocrine:
 - Hyperthyroid or hypothyroid
 - Adrenal insufficiency
 - Diabetes
 - Hypoglycemia
- Neurologic:
 - Multiple sclerosis
 - Cerebrovascular accident
 - Amyotrophic lateral sclerosis
- Cardiovascular:
 - MI
 - Cardiomyopathy
 - CHF
- Pulmonary:
 - Pneumonia
 - Chronic obstructive pulmonary disease
 - Asthma
 - Sleep apnea
- GI:
 - Reflux

- Peptic ulcer disease
- Liver disease
- Autonomic dysfunction
- Lifestyle:
 - Excessive or insufficient exercise
 - Obesity
- Psychiatric:
 - Major depression
 - Anxiety
 - Grief
 - Stress
- Medication related:
 - Drug interactions
 - Commonly caused by BP, cardiovascular, psychiatric, and narcotic medications
- Dehydration

TREATMENT

PRE HOSPITAL

Evaluate vital signs:

- Collect relevant information that could help psychosocial evaluation.

INITIAL STABILIZATION/THERAPY

- ABCs
- Administer supplemental oxygen for hypoxia.
- IV fluid bolus for signs of dehydration

ED TREATMENT/PROCEDURES

- Treatment should be directed to correction of the underlying cause of fatigue:
 - Identify and treat any infectious process.
 - Correct metabolic and hematologic disturbances.
 - Diagnose progressive neurologic disease and acute psychiatric crisis.
 - Initiate workup for endocrine and neoplastic disease.
 - Stop any offending medications or toxins.
- Most cases will not have identifiable cause, so reassurance and close follow-up is required.
- Recommend appropriate diet, exercise regimen, and consistent sleep cycles.

MEDICATION

First Line

Medication should be reserved for treatment of the underlying cause of symptoms.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Underlying disease requiring IV medication or monitoring
- Failure to thrive as outpatient
- Unable to provide for self

Discharge Criteria

- Able to care for self
- Serious disturbances have been excluded.
- Adequate follow-up is arranged.

Issues for Referral

Most patients who are evaluated for fatigue in the ED should be referred:

- When the cause of a patient's fatigue symptoms have been clearly identified, referral should be directed to the appropriate specialist.
- When the cause of a patient's fatigue symptoms are not clearly identified, a primary care referral is indicated.

PEARLS AND PITFALLS

- Fatigue is a subjective symptom complex, and a complete history and physical exam are needed.
- Beware of patients with unreliable history and physical exam. The elderly, children, intoxicated, and those with decreased mental ability may all have life-threatening disease and present with a complaint of fatigue.

- R53.83 Other fatigue

FEEDING PROBLEMS, PEDIATRIC

Richard Gabor • Niels K. Rathlev

BASICS

DESCRIPTION

- Problems may present in 1 or several of the components of “feeding”:
 - Getting food into oral cavity: Appetite, food-seeking behavior, ingestion
 - Swallowing food: Oral and pharyngeal phases
 - Ingestion and absorption: Esophageal swallowing, GI phase
- Acute feeding problems may be a component of acute systemic disease:
 - Infection, bowel obstruction
- Chronic feeding problems may result from underlying neuromuscular, cardiovascular, or behavioral issues:
 - Cerebral palsy, prematurity, congenital heart disease, chronic neglect
- Minor feeding difficulties reported in 25–50% of normal children:
 - Mainly colic, vomiting, slow feeding, and refusal to eat
- More severe problems observed in 40–70% of infants born prematurely or children with chronic medical conditions.

ETIOLOGY

- Several distinct areas of pathology—but overlap is common
- Structural abnormalities:
 - Naso-oropharynx:
 - Cleft lip/palate
 - Choanal atresia
 - Micrognathia and/or Pierre Robin sequence
 - Macroglossia
 - Tonsillar hypertrophy
 - Retropharyngeal mass or abscess
 - Larynx and trachea:
 - Laryngeal cleft or cyst
 - Subglottic stenosis
 - Laryngo- or tracheomalacia
 - Tracheoesophageal fistula
 - Esophagus:
 - Esophageal strictures, stenosis, or web
 - Tracheoesophageal compression from vascular ring/sling
 - Esophageal mass or tumor
 - Foreign body
- Neurologic conditions:

- Cerebral palsy
- Muscular dystrophies
- Mitochondrial disorders
- Arnold–Chiari malformation
- Myasthenia gravis
- Brainstem injury
- Pervasive developmental disorder (autism spectrum disorders)
- Infant botulism
- Brainstem glioma
- Polymyositis/dermatomyositis
- Prematurity
- Immune disorders:
 - Allergy
 - Eosinophilic esophagitis
 - Celiac disease
- Congenital heart disease:
 - Precorrection: Fatigue, respiratory compromise, increased metabolic needs
 - Postcorrection: Any/all of the above, recurrent laryngeal nerve injury
- Chronic aspiration
- Conditioned dysphagia:
 - Gastroesophageal reflux (GER)
 - Prolonged tube or parenteral feeding early in life
- Metabolic disorders:
 - Hypothyroidism
 - Inborn errors of metabolism
- Acute illness or event:
 - Sepsis
 - Pharyngitis
 - Intussusception
 - Malrotation
 - Shaken baby syndrome
- Behavioral issues:
 - Poor environmental stimulation
 - Dysfunctional feeder–child interaction
 - Selective food refusal
 - Rumination
 - Phobias
 - Conditioned emotional reactions
 - Depression
 - Poverty (inadequate food available)

SIGNS AND SYMPTOMS

Common presentations:

- Caregiver concerns regarding feeding or postfeeding behavior
- Poor weight gain/failure to thrive
- Recurrent or chronic respiratory illness

History

- Onset of problem
- Length of meals (often prolonged)
- Food refusal/oral aversion
- Independent feeding (if >8 mo):
 - Neuromuscular problems decrease ability to get food to the mouth
- Failure to thrive/poor weight gain
- Recurrent pneumonia/respiratory distress:
 - Most aspiration episodes are silent in infants
 - Recurrent pneumonia or wheezing may be primary symptoms of chronic aspiration
 - Chronic lung disease
- Recurrent vomiting or gagging:
 - If yes, when
- Diarrhea, rectal bleeding
- Onset of irritability or lethargy during feeding, colic
- Duration of feeding highly variable, especially in breast-fed infants—for all ages, feeding times > 30 min on a regular basis is cause for concern:
 - Full-term healthy infant usually has 2–3 oz of formula every 2–3 hr.
 - Breast-fed baby eats 10–20 min on each breast every 2–3 hr.
 - As child gets older, duration and frequency may decrease.
 - 1 mo old normally eats 4 oz every 4 hr.

Physical-Exam

- Vital signs, including oximetry
- Weight, length, head circumference:
 - Comparison with prior measurements; plotting growth curve
 - Slow velocity of growth
 - Impaired nutritional status. Severe cases may show emaciation, weakness, apathy.
- General physical exam—especially note:
 - Affect and social responsiveness
 - Dysmorphism (facial asymmetry, tongue and jaw size, etc.)
 - ENT—oropharyngeal inflammation, infection, or anatomic abnormality
 - Cardiovascular status (murmur, tachycardia, tachypnea, retractions)
 - Pulmonary—tachypnea, color change, evidence of aspiration

- Abdominal exam—bowel sounds, distension, tenderness, masses
- Neurologic—tone, coordination, alertness
- Skin: Allergic rash or atopy:
 - Loss of subcutaneous fluid or fat is often most apparent around the eyes, which will appear “sunken” in most dehydrated or malnourished infants
 - Edema, however, may occur with protein deficiency (kwashiorkor).
- Observation of feeding: Neuromuscular tone, posture, position; patient motivation; oral structure and function; efficiency of oral intake:
 - Ability to handle oral secretions
 - Pace of feeding
 - Noisy airway sounds after swallowing
 - Gagging, coughing, or emesis during feeding
 - Respiratory distress with feeding
 - Oximetry during feeding may be helpful
 - Onset of fatigue or irritability
 - Duration of feeding

ESSENTIAL WORKUP

- A well-hydrated, comfortable child with a normal physical exam and recent history of good weight gain may not need any ED workup beyond assuring good follow-up.
- Children who show evidence of distress, dehydration, discomfort, respiratory distress, or poor weight gain require further evaluation.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Initial assessment if child failing to thrive or appears malnourished:
 - CBC, urinalysis, electrolytes, BUN, glucose, erythrocyte sedimentation rate (ESR) and/or CRP, thyroid functions, LFTs, total protein, and albumin
- Cultures of blood, urine, if concern of infection—CSF analysis and culture if concern for meningitis
- Serum NH₃, urine for organic acids, and blood for inborn errors or metabolism if concern for metabolic disorders

Imaging

- CXR if suspected cardiopulmonary concerns
- EKG if cardiac disease suspected
- Referral or admission for ultrasound and other imaging studies as indicated. Fiberoptic or videofluoroscopic evaluation of swallowing may be needed.
- MRI if concerns for brainstem, skull base, or spinal problems

Diagnostic Procedures/Surgery

- May need a multidisciplinary evaluation involving speech pathologist, pediatrician, and potentially an otolaryngologist.
- Surgical correction of specific pathology

DIFFERENTIAL DIAGNOSIS

Feeding disorder encompasses symptoms observed as a final pathway for many disorders.

Specific clues to the etiology may include:

- Prolonged feeding, fatigue:
 - Consider cardiac disease.
- Recurrent pneumonias:
 - Consider chronic aspiration.
- Stridor with feeds:
 - Consider glottic or subglottic anomalies.
- Suck–swallow–breathing coordination:
 - Consider nasal congestion, choanal atresia.
- Vomiting, diarrhea, abdominal pain, colic:
 - Consider allergy or GER.

TREATMENT

PRE HOSPITAL

- Assess vital signs and hydration; resuscitate as necessary.
- Assess for and treat hypoglycemia.

INITIAL STABILIZATION/THERAPY

- Cardiovascular/respiratory/fluid resuscitation as needed
- Assess for and treat hypoglycemia if suspected.

ALERT

- Certain inborn errors of metabolism (glycogen storage diseases) can cause profound hypoglycemia if unable to take PO feeds—if known or suspected, IV dextrose should be started immediately
- Bilious vomiting in a young infant may be a sign of malrotation with volvulus causing intestinal ischemia—this requires emergent surgical consultation.

ED TREATMENT/PROCEDURES

- Treat dehydration if present:
 - Oral rehydration if practical
 - IV if PO contraindicated, not tolerated, or impractical
- Ondansetron for acute vomiting
- Treat respiratory distress if present:

- Nasal suction to clear secretions prior to feeding may be very helpful in young infants with URI/bronchiolitis symptoms
- Oxygen and other interventions as needed
- Treat infection if suspected.

ALERT

Patients with severe malnutrition are at risk for sepsis AND may have blunted physiologic responses—a high index of suspicion for infection is warranted in severely malnourished patients.

MEDICATION

Ondansetron: 0.1 mg/kg IV or PO q8h PRN nausea or vomiting—min. oral dose 2 mg, max. dose 4 mg:

- Monitor if patient at risk of QT prolongation
- For short-term use (2–3 doses) in patients >6 mo.
- Review FDA black box warning re QT prolongation

FOLLOW-UP

DISPOSITION

Admission Criteria

- Suspected systemic infection
- Inability to maintain hydration
- Sustained hypoxia during feeding
- Significant failure to thrive:
 - Particularly in infants <3 mo
- Decompensated cardiopulmonary disease
- Symptomatic anemia or endocrine dysfunction
- Negligent or overwhelmed caretaker

Discharge Criteria

- Demonstrated ability to tolerate oral feedings
- Weight gain if failure to thrive
- Reliable caretaker and follow-up

Issues for Referral

- Specific referrals based on source of problem
- For complex or chronic feeding problems, a multidisciplinary approach is often needed.
- Chronic disease process may interfere with feeding AND increase caloric needs:
 - Nonoral nutrition such as percutaneous endoscopic gastrostomy (PEG) tubes

are often needed to address these issues.

FOLLOW-UP RECOMMENDATIONS

- When available, a primary provider is the most important resource for follow-up.
- In the case of complex problems, a multidisciplinary approach is often needed—the primary provider is often in the best position to coordinate this.

PEARLS AND PITFALLS

- Successful feeding in infants requires coordinated, effective interaction of complex physiologic, developmental, and environmental factors.
- The factors are interdependent—disruption of 1 often leads to disruption of others:
 - Premature infant gavage fed for immature suck–swallow coordination, misses critical period for developing this reflex—develops aversion to oral stimulus because of recurrent noxious stimuli.
- Feeding problems of recent, acute onset are likely to have a single identifiable cause:
 - Gastroenteritis, pyloric stenosis, pharyngitis, sepsis
- In an infant with upper respiratory symptoms the answer may be as simple as vigorously suctioning the nose to effectively clear it immediately before feeding
- More chronic, long-term problems are more likely to have multifactorial and/or subtle causes:
 - Feeding is an essential part of the parent–child interaction:
 - Dysfunctional interaction may be the cause of or a response to a feeding problem.
- Chronic feeding issues of medical origin may result in continued behavioral feeding difficulties even after the medical problem is corrected.
- Swallowing disorders and aspiration are frequently occult.

FEEDING TUBE COMPLICATIONS

Colleen N. Hickey • Jennifer L. Kolodchak

BASICS

DESCRIPTION

- Extubation:
 - Accidental or intentional
 - More common with nasoenteric tubes compared with percutaneous endoscopic gastrostomy (PEG) tubes, gastrostomy tubes (G tubes), or jejunostomy tubes (J tubes)
- Occlusion:
 - Small diameter:
 - Most common with nasoenteric tubes
 - Pill fragments
 - Inadequate flushing
 - Physical incompatibilities between formula and medications:
 - Adherence of formula residue to inner wall
 - Essential to rule out malposition, fracture, and dislodgment
- Peristomal wound infections:
 - Risk factors:
 - Malnutrition
 - Stomal leak
 - Local irritation
 - Poor wound care
 - Immunosuppression
 - Diabetes mellitus
 - Poor wound healing
 - Obesity
 - Excessive traction on tube:
 - Leads to delayed maturation of gastrocutaneous tract
 - Increases stomal leakage
- Stoma leak:
 - Problematic with distal obstruction (mechanical or dysmotility); more common with high gastric residual
 - Excessive tube motion
- Aspiration pneumonia:
 - At risk:
 - Impaired cough/gag reflex
 - Delayed gastric emptying from ileus
 - Obstruction

- Gastroparesis
- Gastroesophageal reflux (frequent with large nasoenteric tube)
- Diarrhea:
 - _ Medication induced:
 - Antibiotics
 - Promotility agents
 - _ Overgrowth of *Clostridium difficile*, other bacteria, or *Candida*
 - _ High osmolar formula
- Feeding intolerance:
 - _ High residual suggests GI motility dysfunction
 - _ Delivery is too rapid
 - _ High osmolarity formula
 - _ Lactose or fat intolerance
 - _ Low serum albumin
- Uncommon complications:
 - _ Abdominal wall hematoma
 - _ Fistulas:
 - Hepatogastric
 - Gastrocolic
 - Colocutaneous
 - _ Perforation (usually with placement)
 - _ Pressure sores/ulcerations
 - _ GI bleeding
 - Esophagitis, gastric pressure ulcers, concomitant PUD
 - _ Gastric outlet obstruction
 - Partial or complete obstruction at the pylorus or duodenum by part of tube or Foley catheter balloon used for temporary replacement
 - _ Buried bumper syndrome
 - Rare but potentially serious
 - Bumper becomes lodged between the gastric wall and skin due to gastric ulceration from excessive tension
 - _ Bowel volvulus around PEG tube

Pediatric Considerations

Increased risk of aspiration:

- Delayed gastric emptying
- Immaturity of lower esophageal sphincter

DIAGNOSIS

SIGNS AND SYMPTOMS

- Extubation:

- Tube removed from source
- Occlusion:
 - Unable to pass liquid through tube
- Tube migration:
 - Distal displacement of PEG tube
 - Obstruction at or distal to pylorus
 - Dumping syndrome
 - Ischemia
 - Intussusception
 - Evidence of distal prolapse on external tube (if marked)
- Peristomal wound infections:
 - Cellulitis
 - Abscess formation
 - Necrotizing fasciitis
- Stoma leak:
 - Leakage of feedings/GI tract contents around stoma
- Aspiration pneumonia:
 - Cough
 - Dyspnea
 - Hypoxia
 - Food particulate in pulmonary secretions
 - Fever
- Misplacement of nasoenteric tube in pulmonary tree:
 - Pneumothorax
 - Hydrothorax
 - Pleural effusion
 - Bronchopleural fistula
 - Pneumonia
- Diarrhea:
 - Frequent loose stools
 - Dehydration
- Intolerance to enteral nutrition:
 - High residuals
 - Associated with increased risk of aspiration

ESSENTIAL WORKUP

- Carefully examine the tube site and position of feeding tube within wound
- For suspected tube migration, obtain a water-soluble contrast radiography of the tube to establish the tube position within the abdomen/stomach/intestine

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Peristomal wound infections:
 - CBC for significant infections
 - Blood culture if systemically ill
- Aspiration pneumonia:
 - Pulse oximetry or arterial blood gas
 - CBC
 - Electrolytes, BUN/creatinine, glucose
 - Blood and sputum culture
- Diarrhea:
 - Stool for white blood cells/culture/*C. difficile* toxin
- GI bleeding
 - Serial CBC

Imaging

- CXR:
 - Nasoenteric tube position
 - Aspiration pneumonia
- Water-soluble contrast radiography for suspected tube migration

Diagnostic Procedures/Surgery

Endoscopy to evaluate for tube migration

TREATMENT

PRE HOSPITAL

ALERT

If extubation of tube has occurred, transport tube with patient to facilitate easier replacement

INITIAL STABILIZATION/THERAPY

- ABCs
- IV fluid resuscitation for dehydration/sepsis

ED TREATMENT/PROCEDURES

Extubation

- Nasoenteric tube:
 - Replace in emergency department
 - Confirm position by radiograph before use
- PEG tube and gastrojejunal (G-J) tube:
 - Takes 4–6 wk for gastrocutaneous tract/fistula to mature

- Improper or aggressive attempt at tube replacement could lead to disruption of gastrocutaneous tract and subsequent peritonitis
- PEG tube in place >4 wk:
 - Replace in emergency department (may use a Foley catheter of equivalent size)
 - Confirm by water-soluble radiographic study
 - Secure catheter to abdominal wall to prevent distal migration
- PEG tube in place <4 wk:
 - Do not replace in ED
 - Risk of intraperitoneal placement
 - May need hospital admission and endoscopic tube replacement
- Surgical G tube or J tube:
 - Management similar to that for PEG tube
 - Early dislodgment within 1st 3 days requires emergency surgical consult and antibiotic coverage for peritonitis
 - May need endoscopic replacement if <4 wk old

Occlusion

- Attempt gentle irrigation with NS, water, carbonated soda, pancreatic enzymes
- If irrigation fails, replace tube
- Do not use meat tenderizer

Tube Migration

- If retraction of tube is possible and well tolerated:
 - Secure tube externally
 - Discharge home after brief trial of tube feeding
- If feeding is not tolerated, or if there are signs of persistent obstruction or peritonitis:
 - Admit with consult to appropriate service (surgical/GI).
- If external tube is cut (accidental or intentional) and the inner tube is within the abdomen:
 - Inner bumper usually passes through GI tract
 - Cases of obstruction, subsequent perforation, and peritonitis have been reported, especially in children

Peristomal Wound Infections

- Local wound care
- Antibiotics:
 - 1st-generation cephalosporin (cefazolin or cephalexin)
 - Ampicillin/sulbactam
 - Amoxicillin/clavulanic acid
 - Clindamycin (penicillin allergic)

- Outpatient management for milder cases
- More severe cases require surgical consult for possible drainage/debridement and inpatient care
- Prophylactic use of antibiotic (cefazolin) before tube placement decreases wound infection (3% vs. 18%)

Peristomal Leak

- Change from intermittent to continuous delivery
- Decrease rate of infusion
- Optimize nutritional status
- Relieve excess tension on tube
- Administer prokinetic agents (e.g., metoclopramide)
- Do NOT place larger tube
- Local care:
 - _ Keep site clean and dry
 - _ Barrier creams

Aspiration Pneumonia

- Stop enteral feeding
- Administer oxygen and broad-spectrum antibiotics
- Endotracheal intubation with mechanical ventilation for respiratory failure and airway protection when indicated
- Prevent by:
 - _ Elevation of head of bed
 - _ Monitoring gastric residual
 - _ Use of continuous infusion at graduated rate
 - _ Use of prokinetic agent

Diarrhea

- Manage cause
- Correct fluid and electrolyte imbalance
- Try isotonic, hypotonic, or fat- or lactose-free formulas
- High-fiber formula if above measures fail
- Antimotility agents:
 - _ Loperamide
 - _ Kaopectate
 - _ Cholestyramine

Formula Intolerance

Prokinetic agents promote gastric emptying

MEDICATION

- Amoxicillin/clavulanic acid (Augmentin): 500–875 mg (peds: 25–45 mg/kg/24 h) PO q12h
- Ampicillin/sulbactam: 1.5–3 g (peds: 100–200 mg/kg/24 h) IV q6h
- Cefazolin (Ancef, Kefzol): 500 mg–1 g (peds: 25–100 mg/kg/24 h) IV q6h
- Cephalexin (Keflex): 250–500 mg (peds: 25–50 mg/kg/24 h) PO q6h
- Cholestyramine: 2–4 g (peds: >6 yr 80 mg/kg q8h) PO q6–12h
- Clindamycin: 150–300 mg (peds: 5–10 mg/kg) IV q6h
- Kaopectate: 30 mL (peds: 3–6 yr old, 7.5 mL; 6–12 yr old, 15 mL) PO after each loose bowel movement up to 7 times per day
- Loperamide (Imodium): 4 mg initially, then 2 mg (peds: 1 mg q8h if 13–20 kg; 2 mg q12h if 20–30 kg; 2 mg q8h, if >30 kg not to exceed 9 mg/d) PO up to 16 mg/d
- Metoclopramide: 5–10 mg (peds: 0.1–0.2 mg/kg to max. 0.8 mg/kg/d) PO/IV/IM q6h (30 min before feeds and every night)

FOLLOW-UP

DISPOSITION

Admission Criteria

- PEG tube extubation within 1 wk of placement
- Surgical G tube or J tube extubation within 3 days of placement
- Significant peristomal wound infection
- Aspiration pneumonia
- Diarrhea associated with dehydration
- Active GI bleeding
- Peritonitis

Discharge Criteria

Successful replacement of extubated feeding tube

Issues for Referral

GI consult or surgical consult for feeding tube replacement when cannot be placed successfully in the emergency department

FOLLOW-UP RECOMMENDATIONS

Primary care or GI follow-up for recurrent feeding tube complications

PEARLS AND PITFALLS

- Radiography should be used to confirm placement of all feeding tubes
- Do not attempt replacement of a newly placed PEG tube, G tube, or J tube in the

FEMUR FRACTURE

Alexander D. Miller

BASICS

DESCRIPTION

Fractures classified according to:

- Location:
 - Proximal 3rd (subtrochanteric region)
 - Middle 3rd
 - Distal 3rd (distal metaphyseal–diaphyseal junction)
- Geometry:
 - Spiral
 - Transverse
 - Oblique
 - Segmental
- Extent of soft tissue injury:
 - Open
 - Closed
- There are 2 commonly accepted classification systems of femoral fractures: The AO/OTA and the Winquist and Hansen.
- Degree of comminution: Winquist and Hansen classification:
 - Grade I: Fracture with small fragment < 25% width of femoral shaft; stable lengthwise and rotationally
 - Grade II: Fracture with 25–50% width of femoral shaft; stable lengthwise; may or may not have rotational stability
 - Grade III: Fracture with > 50% width of femoral shaft; unstable lengthwise and rotationally
 - Grade IV: Circumferential loss of cortex; unstable lengthwise and rotationally

ETIOLOGY

- Usually requires major, high-energy trauma
- Patients are mostly young adults with high-energy injuries (motor vehicle accidents [MVAs], gunshot wounds [GSWs], falls):
 - Spiral fractures with falls from height
- Consider pathologic fracture if minor mechanism
- Can occasionally be due to stress fracture from repetitive activity
- Complications include compartment syndrome, fat embolism, adult respiratory distress syndrome (ARDS), hemorrhage.

Geriatric Considerations

- Atypical femur fractures have been associated with use of bisphosphonate medications.

Pediatric Considerations

- 70% of femoral fractures in children < 3 yr old are the result of nonaccidental trauma (NAT).
- Spiral fractures of the femur strongly suggest NAT.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Thigh pain, deformity, swelling, shortening
- Patient unable to move hip or knee
- Commonly presents as multitrauma:
 - _ Chest, abdominal, pelvic, hip, knee injury, including dislocation

Physical-Exam

- Rarely open fracture, unless injury is due to penetrating trauma
- Patient may be hypotensive due to hemorrhage into the thigh.
- Patient may have impaired circulation in the distal leg due to vascular compromise, compartment syndrome.

ESSENTIAL WORKUP

- Radiographs (see Imaging)
- Assess distal pulses, palpate compartments, evaluate sensation and motor function.
- If pulses are not equal or palpable, bedside Doppler or angiography may be necessary.
- Search for associated injuries with multisystem trauma.
- In suspected NAT, obtain skeletal survey or bone scan.

DIAGNOSIS TESTS & INTERPRETATION

Lab

CBC, type and cross-match

Imaging

- AP pelvis, true lateral of the hip, AP and lateral views of the femur, complete knee series

- Baseline CXR, other films as indicated by trauma protocols

DIFFERENTIAL DIAGNOSIS

- Hip fracture or dislocation
- Knee fracture or dislocation
- Thigh contusion or hematoma

TREATMENT

PRE HOSPITAL

- Immobilization of the extremity and application of a traction splint can be important for tamponade of further blood loss into the thigh:
 - _ Backboard immobilization, rigid splinting, support of extremity for position of comfort
- Contraindications to traction:
 - _ Fractures close to the knee
 - _ Fracture or dislocation of the ipsilateral hip
 - _ Fractures of the pelvis
 - _ Fractures of the lower leg
- Do not attempt to reduce open fractures in the field; cover open wounds with sterile dressings.
- Monitor closely for development of hemorrhagic shock, as thigh can contain 4–6 U of blood.

INITIAL STABILIZATION/THERAPY

- Airway, chest, abdominal injuries take precedence.
- Monitor BP continuously for signs of hemorrhagic shock.

ED TREATMENT/PROCEDURES

- Maintain lower extremity stability.
- Remove splint and clothing.
- Pain control:
 - _ Isolated femur injuries: Parenteral analgesia
 - _ Multitrauma or pediatric patients: Femoral nerve block
- Orthopedic consultation necessary for all femur fractures:
 - _ Emergent if neurovascular compromise
 - _ Open fractures must go directly to the OR for irrigation and débridement.
- Antibiotics:
 - _ Fractures requiring surgery: Cefazolin if open fracture with laceration (clindamycin if allergic to cephalosporins). If extensive soft tissue damage or contamination: Consider gentamicin/tobramycin, tetanus.
 - _ If highly contaminated wound: Consider penicillin G to cover clostridial species.

- Femur fractures with diminished or absent distal pulses, an expanding hematoma, or a palpable pulsatile mass require immediate angiography or femoral artery exploration.
- Skeletal traction should be applied if the patient will not go to the OR immediately.

MEDICATION

- Antibiotics:
 - First line:
 - Cefazolin: 2 g IM/IV q6–8h (peds: 50–100 mg/kg IM/IV divided q6–8h max. 1 g)
 - Second line:
 - Clindamycin: 450–900 mg IM/IV q6–8h; max. dose: 4.8 g/d (peds: 20–40 mg/kg/d IM/IV in 3–4 divided doses)
- Moderate sedation:
 - Etomidate: 0.1–0.3 mg/kg IV once (not recommended for <12 yr)
 - Fentanyl: 50–100 µg IV over 1–2 min once (peds: >6 mo 1–2 µg/kg IV once)
 - Ketamine: Caution in adults due to potential for emergence reaction (peds: 0.2–1 mg/kg IV, 0.5–4 mg/kg IM once)
 - Midazolam: 0.07 mg/kg IM or 1 mg slow IV q2–3min up to 5 mg max. (peds: 0.25–0.5 mg/kg PO once to a max. of 20 mg PO; 6 mo–5 yr: 0.05–0.1 mg/kg IV titrate to max. of 0.6 mg/kg; 6–12 yr: 0.025–0.05 mg/kg IV titrate to max. of 0.4 mg/kg)
 - Propofol: 40 mg IV q10sec until induction; 5–60 µg/kg/min IV continuous infusion
- Pain control:
 - Hydromorphone: 0.5–2 mg IM/SC/slow IV q4–6h PRN; titrate for pain control (peds: 0.015 mg/kg per dose IV q4–6h PRN)
 - Morphine: 2–10 mg IV q4h; titrate for pain control (peds: 0.1 mg/kg IV q4h; titrate for pain control to max. 15 mg/dose)

Pediatric Considerations

- Assess markers for NAT:
 - Delay in presentation
 - History of mechanism inconsistent with the injury
 - Isolated trauma to the thigh, associated burns, bruises, or linear abrasions
- Assess for dislocation of the femoral capital epiphysis.
- Depending on the age of the patient and the fracture type, pediatric femoral fractures may not require operative treatment.

FOLLOW-UP

DISPOSITION

Admission Criteria

- All femur fractures must be admitted except as noted below in Discharge Criteria.
- Any suspicion of NAT in children

Discharge Criteria

In certain rare circumstances of pathologic fracture or femur fractures in patients who are not ambulatory and would not undergo operative fixation, discharge can be considered in consultation with orthopedics if adequate pain control can be achieved and proper follow-up ensured.

FOLLOW-UP RECOMMENDATIONS

Follow-up will likely be determined by operating surgeon based on clinical course.

PEARLS AND PITFALLS

- Due to the high-energy mechanism required to incur a femoral fracture, other associated traumatic injuries must be ruled out.
- Document neurovascular function on initial assessment and frequently reassess.
- Depending on the age of the patient and the fracture type, pediatric femoral fractures may not require operative treatment.

FEVER, ADULT

Matthew L. Wong

BASICS

DESCRIPTION

- Fever is an elevation of core body temperature caused by an increase in the body's thermoregulatory set point.
- Prostaglandin E2 (PGE2) synthesis in the anterior hypothalamus controls the thermostat, and is the target of antipyretics.
- Core temperature is regulated to $37^{\circ}\text{C} \pm 2^{\circ}\text{C}$.
- Autonomic discharge from hypothalamus can raise core temperature through shivering and dermal vasoconstriction.
- Normal circadian variation in core temperature occurs with nadir in early morning and peaks in late afternoon.
- Fever is not synonymous with hyperthermia or hyperpyrexia.
- Hyperthermia is an elevated temperature with normal thermostat set point; caused by excessive endogenous heat production or endogenous production (e.g., malignant hyperthermia or heat stroke).
- Hyperpyrexia is extreme fever $> 41.5^{\circ}\text{C}$ usually from CNS hemorrhages.
- Both exogenous and endogenous factors can raise the body's set thermoregulatory point:
 - Endogenous pyrogens include PGE2, IL-1, IL-6, TNF, IFN- γ .
 - Exogenous pyrogens include lipopolysaccharide (LPS) endotoxin and other TLR ligands, and toxic shock syndrome toxin (TSST-1) and other MHC II ligands.
- Patients on anticytokine medications or glucocorticoids have impaired fever response.
- Fever of unknown origin (FUO):
 - Fever $> 38.3^{\circ}\text{C}$ for at least 3 wk as an outpatient and 3 days of inpatient evaluation or 3 outpatient visits without determining etiology.

ETIOLOGY

- Infectious processes:
 - CNS, chest and lung, gastrointestinal, genitourinary, skin, soft tissue and bone, vascular and endocardial
 - Iatrogenic: Catheters, implants, hardware, recent surgical sites.
- 1° CNS processes such as CVA, trauma, seizures
- Neoplastic fevers
- Drug fever:
 - Most drugs can cause elevated temperatures by a wide variety of

mechanisms

- Toxidromes (e.g., adrenergic, anticholinergic, dopaminergic, salicylate overdose, serotonin toxicity)
- Hypersensitivity:
 - Allergic reaction
 - Serum sickness
- Jarisch–Herxheimer reaction
- Local phlebitis from irritant drugs
- Severe withdrawal:
 - Alcohol
 - Benzodiazepines
- Systemic rheumatologic and inflammatory diseases (e.g., familial Mediterranean fever, rheumatoid arthritis, sarcoidosis, systemic lupus erythematosus, temporal arteritis)
- Endocrine:
 - Hyperthyroidism, pheochromocytoma
- Miscellaneous:
 - Alcoholic cirrhosis
 - Acute inhalation exposures (e.g., metal fume fever)
 - Cotton fever:
 - Febrile reaction from an injected contaminant when IV drug abusers strain drug through cotton
 - Sickle cell disease
 - Hemolytic anemia
 - Pulmonary embolus
- Common causes of FUO:
 - Infectious:
 - Abdominal and pelvic abscesses
 - Cardiac (endocarditis, pericarditis)
 - Cat scratch disease
 - Cytomegalovirus
 - Epstein–Barr virus
 - TB (miliary, renal, or meningitic)
 - Typhoid enteric fevers
 - Visceral leishmaniasis
 - Neoplastic:
 - Colon adenocarcinoma
 - Hepatocellular carcinoma and metastases
 - Myeloproliferative disorders
 - Leukemia and lymphoma
 - Renal cell carcinoma

SIGNS AND SYMPTOMS**History**

- Chills, shivering, and rigors:
 - Rigors may suggest bacteremia
- Weight loss:
 - Suggestive of neoplastic, chronic infectious, or endocrine disorders
- Night sweats:
 - Suggestive of neoplastic, chronic inflammatory disease, or TB
- Specific fever patterns:
 - Daily morning temperature spikes:
 - Miliary TB, typhoid fever, polyarteritis nodosa
 - Relapsing fevers: Febrile episode with alternating afebrile intervals:
 - Seen in malaria, *Borrelia* infections, rat-bite fever, and lymphoma
 - Remittent fever: Temperature falls daily but does not return to normal:
 - Seen in TB and viral diseases
 - Intermittent fevers: Exaggerated circadian rhythm:
 - Seen in systemic infections, malignancy, and drug fever
 - Double quotidian fever:
 - Common pattern of 2 temperature spikes in 24 hr
 - In FUO, consider miliary TB, visceral leishmaniasis, and malarial infections
- High-risk features:
 - Anticytokine therapy (e.g., TNF- α monoclonal antibodies, calcineurin inhibitors)
 - Glucocorticoid use
 - Immunosuppressed states
 - Incomplete vaccination status
 - IV drug use
 - Pregnancy and peripartum patients
 - Rash
 - Recent chemotherapy
 - Recent travel
 - Splenectomy

Physical-Exam

- Elevated core temperature:
 - Temperature $>38^{\circ}\text{C}$ (100.4°F) rectally or 37.5°C (99.5°F) orally
 - Lower thresholds in patients older than 65 yr, as the febrile response is not as strong

- Diaphoresis:
 - Absence of diaphoresis with severe hyperthermia suggests anticholinergic poisoning or heat stroke.
- Tachycardia:
 - For each degree of elevation in temperature in Fahrenheit, there should be a 10 bpm increase in pulse.
 - Relative bradycardia (Faget sign):
 - Associated with malaria, typhoid fever, CNS disorders, lymphoma, drug fever, brucellosis, ornithosis, Legionnaire disease, Lyme disease, and factitious fevers
- Muscle rigidity, clonus, and hyper-reflexia:
 - Associated with specific toxidromes and medical conditions
- Changes in mental status:
 - Toxic–metabolic encephalopathy vs. primary CNS disorder
- Rash:
 - Lesion type, distribution, and progression can offer important clues to diagnosis.
 - Petechia, purpura, vesicles, mucosal, or palm and sole involvement require special note
- Signs of hyperthyroidism:
 - Goiter
 - Exophthalmos

ESSENTIAL WORKUP

- Core temperature is most acutely measured rectally.
- Careful history and physical exam (PE) necessary to determine need for further diagnostic testing:
 - History should elicit any sick contacts, previous infections, occupational exposures, recent travel, medications, animal or tick exposure, and immunization status.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - Important in determining neutropenia in patients with risk factors
 - Neutrophilia and bandemia suggestive of bacterial infection
 - Lymphocytosis suggestive of typhoid, TB, brucellosis, and viral disease
 - Atypical lymphocytosis seen in mononucleosis, cytomegalovirus, HIV, rubella, varicella, measles, and viral hepatitis
 - Monocytosis suggestive of TB, brucellosis, viral illness, and lymphoma
- Lactate:
 - Initial and repeat measurements useful for screening for sepsis, risk

stratification, and management decisions

- Urinalysis and urine culture
- Blood cultures:
 - Obtain for all systemically ill patients, and patients at risk for bacteremia
- Thick and thin blood smears and malaria antigen testing in at-risk individuals for parasitic and intraerythrocytic infections
- Stool culture and *Clostridium difficile* assay for suspected individuals.
- Heterophile antibody testing in select patients.
- Erythrocyte sedimentation rate and C-reactive protein generally not useful:
 - Very high values suggestive of endocarditis, osteomyelitis, TB, and rheumatologic conditions.

Geriatric Considerations

- Decreased immunocompetence, increased risk of systemic spread, increased exposure to health care settings, may have comorbid conditions.
- If institutionalized consider the infectious implications of multiple potential sick contacts.

Imaging

- CXR:
 - In patients with PE finding of cardiopulmonary disease and patients with unclear fever source
- CT or MRI may be indicated if lumbar puncture or osteomyelitis is considered, respectively.

DIFFERENTIAL DIAGNOSIS

- The differential diagnosis is very broad as listed above, but is generally categorized as infectious vs. noninfectious, and by immunocompetency.

TREATMENT

PRE HOSPITAL

- No specific field interventions required
- Monitoring and IV access should be obtained in the field for unstable patients or patients with altered mental status.

INITIAL STABILIZATION/THERAPY

- ABCs for unstable patients.
- Initiate early broad-spectrum antibiotics for patients with suspected sepsis or unstable vital signs, particularly those who are at high risk for serious bacterial infection.

ED TREATMENT/PROCEDURES

- Antipyretics:
 - Generally either acetaminophen or NSAIDs
 - Inhibit the cyclooxygenase enzyme, thereby blocking synthesis of prostaglandins.
- Empiric antibiotics for neutropenic patients:
 - Combination therapy:
 - Extended spectrum β -lactam (ceftazidime, piperacillin) with an aminoglycoside
 - Monotherapy:
 - Cefepime
 - Ceftazidime
 - Imipenem
- Empiric antibiotics for asplenic patients for encapsulated bacteria
- Empiric antiviral therapy for patients with encephalitis and potential disseminated viral infections (e.g., recent organ or bone marrow transplant patients, AIDS patients)
- External cooling mechanism rarely indicated

MEDICATION

- Antipyretics:
 - Acetaminophen: 650–1,000 mg PO/PR q4–6h; do not exceed 4 g/24h
 - Aspirin: 650 mg PO q4h; do not exceed 4 g/24h
 - Ibuprofen: 800 mg PO q6h
- Antibiotics:
 - Cefepime: 2 g IV q12
 - Ceftazidime: 2 g IV q8
 - Gentamicin or tobramycin (D): 2 mg/kg IV load then 1.7 mg/kg q8h + piperacillin/tazobactam (B) 3.375 g IV q4h or ticarcillin/clavulanate (B) 3.1 g IV q4h
 - Imipenem/cilastatin: 500–1,000 mg IV q8h
 - Meropenem (B): 1 g IV q8h
 - Ciprofloxacin: 750 mg PO BID + amoxicillin/clavulanate (B) 875 mg PO BID
- Antivirals:
 - Herpes simplex virus and varicella-zoster virus (VZV):
 - Acyclovir 10–15 mg/kg IV q8h
 - Influenza A and B:
 - Oseltamivir 75 mg PO q12h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with unstable vital signs require ICU admission.
- When identified, the underlying source of the fever usually determines the disposition.
- Certain high-risk groups who have fever without an identifiable source:
 - Neutropenic patients
 - Immunosuppressed or immunocompromised patients
 - Asplenic patients
 - IV drug abusers
- Lower thresholds for admission in patients older than 60 yr and diabetics

Discharge Criteria

Immunocompetent patients with stable vital signs and an identified source of fever or a high suspicion of a nonthreatening viral infection may be safely discharged.

Issues for Referral

The suspected etiology of the fever determines the referral to a primary care physician or a specialist.

FOLLOW-UP RECOMMENDATIONS

Appropriate outpatient treatment and follow-up for further outpatient assessment of the suspected etiology.

PEARLS AND PITFALLS

- Screening lactates for sepsis.
- Early, empiric, and broad-spectrum antibiotic coverage for all septic patients.
- Consider all potential sources of infection.
- Careful consideration for the immunosuppressed, elderly, and IV drug users.

CODES

ICD9

- 780.60 Fever, unspecified
- 780.61 Fever presenting with conditions classified elsewhere

ICD10

- R50.2 Drug induced fever
- R50.9 Fever, unspecified
- R50.81 Fever presenting with conditions classified elsewhere

FEVER, PEDIATRIC

Nathan W. Mick • David A. Peak

BASICS

DESCRIPTION

- Fever is defined as a temperature of 38°C (100.4°F) rectally:
 - Oral and tympanic temperatures are generally 0.6°C–1°C lower.
- Tympanic temperatures are not accurate in children younger than 6 mo.
- Axillary temperatures are generally unreliable.
- Children who are afebrile but have a reliable history of documented fever should be considered to be febrile to the degree reported.

ETIOLOGY

- Bacteremia (*Haemophilus influenzae* type B, *Streptococcus pneumoniae*), viral illness, often accompanied by exanthem (varicella, roseola, rubella), coxsackievirus (hand-foot-and-mouth disease), abscess:
 - *H. influenzae* type B and *S. pneumoniae* vaccines have reduced incidence of Haemophilus and pneumococcal disease
- CNS: Meningitis, encephalitis
- Head, eyes, ears, neck, and throat (HEENT): Otitis media, facial cellulitis, orbital/periorbital cellulitis, pharyngitis (group A β -hemolytic streptococcus, herpangina, adenovirus pharyngoconjunctival fever), viral gingivostomatitis (herpes and coxsackievirus), cervical adenitis, sinusitis, mastoiditis, conjunctivitis, peritonsillar/retropharyngeal abscess
- Respiratory: Croup (paramyxovirus), epiglottitis, bronchiolitis (respiratory syncytial virus [RSV]), pneumonia, empyema, influenza
- Cardiovascular: Purulent pericarditis, endocarditis, myocarditis
- Genitourinary (GU): Cystitis, pyelonephritis
- GI: Bacterial diarrhea, intussusception, appendicitis, hepatitis
- Extremity: Osteomyelitis, septic arthritis, cellulitis
- Miscellaneous: Herpes simplex virus infection in the neonate, Kawasaki disease, vaccine (DPT) reaction, heat exhaustion/stroke, factitious, familial dysautonomia, thyrotoxicosis, collagen vascular disease, vasculitis, rheumatic fever, malignancy, drug induced, overbundling (uncommon, recheck 15 min after unbundling)

DIAGNOSIS

SIGNS AND SYMPTOMS

- Clinical appearance must be evaluated. Airway, breathing, and circulation (especially dehydration with impaired perfusion/color) need specific evaluation.

- Toxicity associated with lethargy, delayed capillary refill, hypoventilation/hyperventilation, weak cry, decreased PO intake; purpuric or petechial rash, and/or hypotonia. Initial observation is crucial in this evaluation.
- Tachycardia or tachypnea may be the only finding in children with serious underlying condition.
- Fever with a temperature $>38^{\circ}\text{C}$ can raise a child's heart rate by 10 bpm for each degree Fahrenheit.
- Temperature $>40^{\circ}\text{C}$ have been associated with an elevated bacteremia rate in children <24 mo.
- Altered mental status:
 - Lethargy presenting with decreased level of consciousness
 - Irritability
 - Impaired interaction with environment, parents, physician, toys
- Physical exam (PE) to search for underlying condition
- Tachypnea and low oximetry are the most sensitive signs for pneumonia. Also useful are rales, hypoxemia, cough >10 days, and fever >5 days.
- Risk factors for occult UTI include female sex, uncircumcised boys, fever without source, and fever $>39^{\circ}\text{C}$.
- Febrile seizures
- Temperatures $>42^{\circ}\text{C}$ often have a noninfectious cause.
- Serious infection may occur in the absence of fever.
- Antipyretics may change findings without impacting underlying disease. This may be useful in evaluation of patient, esp. with respect to mental status
- $\sim 20\%$ of children will have fever without definable source after history and PE.

ESSENTIAL WORKUP

- Oxygen saturation as mandatory 5th vital sign
- Resuscitate as appropriate.
- Determine duration of illness, degree, pattern and height of fever, use of antipyretics, past medical history, drug allergies, immunization status and history, recent medications/antibiotics, birth history if younger than 6 mo of age, exposures, feeding, activity, urine/bowel habits, travel history, and relevant review of systems.
- Search for underlying condition.
- Initiate antipyretic therapy.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC with differential
- Urinalysis (UA) and culture in all male infants younger than 6 mo, uncircumcised male infants younger than 12 mo, and females younger than 2 yr. Urines for culture should be obtained by catheterization or suprapubic techniques.

- Blood culture:
 - The development of automated blood culture systems has led to more rapid detection of bacterial pathogens.
- CSF for cell counts, Gram stain, culture, protein, and glucose for toxic children and those 0–28/30 days of age; consider for nontoxic-appearing children 28–90 days of age as well as older ones in whom meningitis must be excluded.
- Stool for WBCs and culture when diarrhea present and suggestion of bacterial process
- C-reactive protein (CRP) elevation is commonly found and provides confirmatory data related to the presence of infection. The sedimentation rate (ESR) is also an adjunctive measure.
- Procalcitonin is being used in some settings as additional confirmatory information.

Imaging

- CXR to exclude pneumonia if patient tachypneic or hypoxic
- Other studies as indicated to evaluate for specific underlying infection

DIFFERENTIAL DIAGNOSIS

See “Etiology.”

TREATMENT

PRE HOSPITAL

- Resuscitate as appropriate.
- Begin cooling with antipyretics.

INITIAL STABILIZATION/THERAPY

- Treat any life-threatening conditions.
- Antipyretic therapy
- Evaporative cooling techniques, such as sponge bath, have minimal role.

ED TREATMENT/PROCEDURES

- Focal infections require evaluation and treatment.
- Toxic children require prompt septic workup and appropriate antibiotics.
- All potential life-threatening conditions must be excluded before treating a minor acute illness, which is more common.
- Infants 0–28 days old need a full sepsis workup: CBC, UA, cultures (blood, urine, CSF), lumbar puncture. A CXR should be obtained if there is suspicion for pneumonia:
 - Antibiotics: Ampicillin and either gentamicin or cefotaxime; consider acyclovir for infants at risk for HSV

- Admit
- Well-appearing infants 29–90 days old need workup, selective antibiotic use (ceftriaxone), and re-evaluation within 24 hr:
 - *H. influenzae* type B and *S. pneumoniae* incidence has declined significantly with widespread vaccination.
 - It is currently reasonable to perform CBC, UA, blood culture, and urine culture with selective lumbar puncture, coupled with ceftriaxone IM in low-risk patients (see definition under Disposition) if re-evaluation in 24 hr is ensured. Well-appearing infants 60–90 days of age may be managed without LP or antibiotics selectively.
 - While lumbar puncture is optional in this setting, treatment with empiric antibiotics (ceftriaxone) without lumbar puncture may compromise subsequent re-evaluation.
 - Presence of RSV or influenza in this age group decreases but does not eliminate the risk of bacteremia and meningitis, but the rate of UTI is still appreciable.
- Children 3 mo–3 yr of age are evaluated selectively; those with recognizable viral syndrome (croup, stomatitis, varicella, bronchiolitis) generally do not require workup unless there is toxicity; antibiotic use is individualized for specific identifiable infections and pending appropriate cultures:
 - Well-appearing children with a temperature $> 39^{\circ}\text{C}$ and no identifiable infection should prompt a UA and culture in all male infants younger than 6 mo, uncircumcised male infants younger than 12 mo, and females younger than 2 yr. Urine for culture should be obtained by catheterization or suprapubic techniques
 - Obtaining blood work or performing a lumbar puncture on a child 6 mo–3 yr of age is a clinical decision. Mandatory lumbar puncture in this age group based solely on the presence of fever has not been shown to be cost-effective and is not routinely recommended
 - Children 3–6 mo of age who are incompletely immunized and have WBC $> 15,000/\text{mm}^3$ and no identifiable infection may benefit from empiric antibiotics until preliminary blood cultures are available because of the risk of bacteremia.
 - Widespread immunization for *Pneumococcus* and *H. influenzae* have decreased the incidence of invasive infections by these bacteria.
- Immunocompromised children need aggressive evaluation, as do children with fever and petechiae/purpura or sickle cell disease.
- If methicillin-resistant *S. aureus* is considered, clindamycin or trimethoprim-sulfamethoxazole may be useful.
- Patients with underlying malignancy, central venous catheters, or ventricular peritoneal shunts may have few findings other than fever.

MEDICATION

First Line

- Cefotaxime: 100–150 mg/kg/d IV divided q8h
- Ceftriaxone: 50–100 mg/kg/d IV/IM divided q12h
- Vancomycin: 40–60 mg/kg/d IV divided q6–8h if *S. pneumoniae* suspected until sensitivities defined
- Ampicillin: 150 mg/kg/d IV divided q4–6h
- Gentamicin: 5 mg/kg/d IV divided q8–12h

Second Line

- Acetaminophen: 15 mg/kg per dose PO/PR (per rectum) q4–6h; do not exceed 5 doses/24 h
- Ibuprofen: 10 mg/kg per dose PO q6–8h
- Specific antibiotics for identified or specific conditions

FOLLOW-UP

DISPOSITION

Admission Criteria

- All toxic patients
- Infants 0–28 days of age with temperature $> 38^{\circ}\text{C}$
- Nontoxic infants 29–90 days of age with temperature $> 38^{\circ}\text{C}$ who do not meet low-risk criteria (see definition under Discharge Criteria)
- Patients with fever and petechiae/purpura are generally admitted unless there is a specific nonlife-threatening cause.
- Immunocompromised children
- Poor compliance or follow-up

Discharge Criteria

- Infants 29–90 days of age meeting low-risk criteria:
 - No prior hospitalizations, chronic illness, antibiotic therapy, prematurity
 - Reliable, mature parents with home phone, available transport, thermometer, and living in relative proximity to ED
 - No evidence of focal infection (except otitis media); nontoxic appearing; normal activity, perfusion, and hydration with age-appropriate vital signs
 - Normal WBC ($5\text{--}15,000/\text{mm}^3$), urine (negative Gram stain of unspun urine or leukocyte esterase or < 5 WBC/high power field [HPF]), stool (< 5 WBC/HPF) if performed, and CSF (< 8 WBC/ mm^3 and negative Gram stain) if performed
- Infants 3–36 mo of age who are nontoxic and previously healthy with good follow-up:

– Antipyretics

- Follow-up by phone in 12–24 hr and re-evaluate in 24–48 hr with parental instructions to return if concerns develop or patient worsens.

FOLLOW-UP RECOMMENDATIONS

Patients discharged with fever require close follow-up, usually by their primary care provider and guidelines of when to return with any change or worsening of signs or symptoms.

PEARLS AND PITFALLS

- Fever is the most common presenting complaint in children. It may reflect a life-threatening condition.
- Children under 28 days of age are generally treated empirically, pending culture results.
- Older children need close follow-up and specific discharge instructions.
- Subtle findings such as tachycardia, tachypnea, or altered mental status may be indicative of significant underlying infection.

- R50.9 Fever, unspecified
- R50.81 Fever presenting with conditions classified elsewhere

FIBROCYSTIC BREAST CHANGES

Ryan E. Christensen • David A. Pearson

BASICS

DESCRIPTION

- Generalized term for benign breast changes that are poorly defined
- No longer considered a pathologic disease process as they are found in the majority of healthy women
- Most common of all benign breast conditions
- Changes include:
 - Benign cysts
 - Breast pain (mastalgia or mastodynia), which may or may not be cyclic
 - Diffuse and focal nodularity
 - Palpable fibroadenomas
 - Nipple discharge—may be green or brownish, though usually nonbloody
- Spontaneous, persistent discharge warrants further evaluation
- Occurs in ~60% of women
- Symptoms of pain and tenderness become progressively worse until menopause
- Pain is often most prominent during the premenstrual phase and improves with the onset of menses
 - Breast pain alone is a rare symptom of cancer and accounts for only 0.2–2% of cases
- Synonyms: Adenosis, benign breast disease, cystic mastitis, cystic disease of the breast, fibroadenosis, fibrocystic disease, mammary dysplasia.

ETIOLOGY

- Mechanism of development not well understood
- Likely an enhanced or exaggerated reaction of breast tissue to cyclic levels of female reproductive hormones:
 - May be caused by imbalance of the estrogen to progesterone ratio
 - May occur secondary to increased daily prolactin production
- Most common in women 30–50 yr old
- Pain is most likely caused by rapid expansion of simple cysts
- Symptoms may continue into menopause secondary to hormone replacement therapy
- Incidence is decreased in women taking oral contraceptives
- Risk factors include:
 - Family history of fibrocystic changes
 - Oral contraceptives
 - Hormone replacement therapy

- Increasing age
- Diet (high fat intake; caffeine/methylxanthines)

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Mastalgia and tenderness:
 - Persistent or intermittent
 - Often occurs during premenstrual phase of normal menstrual cycle
 - Usually bilateral
 - Pain may radiate to shoulders and upper arms
- Lumpiness, nodularity:
 - May be localized or generalized
- Increased engorgement and breast density:
 - Breasts described as being dull and heavy
 - Caused by fluctuations in the size of the cystic areas
- Spontaneous or expressible nipple discharge
- Abnormal nipple sensations, including pruritis
- Family history of cysts is common

Physical-Exam

- Palpate the 4 breast quadrants while patient is sitting and then while lying down
- Note any changes from normal, including overlying erythema and warmth that may suggest an alternative diagnosis
- Examine for regional nodes (axillary, clavicular, etc.)
- Fibrocystic changes feel doughy with vague nodularity
- Nodules are typically discrete and mobile
- Usually more marked in the superior and lateral quadrants
- Small groups of cysts often described as palpating a “plate full of peas”
- Large cysts have consistency of a balloon filled with water
- Breast exam is most sensitive 7–9 days after 1st day of menses when the breasts are least congested

DIAGNOSIS TESTS & INTERPRETATION

Lab

- A detailed lab evaluation is usually not necessary in the emergency department
- Prolactin and thyroid-stimulating hormone may be helpful if galactorrhea is present

Imaging

- Ultrasound if < 30 yr old
- Mammography if > 30 yr old
- Ultrasound:
 - Can differentiate cystic from solid masses
 - Benign cysts:
 - Typically demonstrate a uniform outer margin without asymmetry or irregular thickness of the cyst wall
 - Have no central echoes
 - Posterior wall enhancement is normal
 - Can assist in aspiration of deep and nonpalpable cysts
 - Also used to conservatively follow cyst size
 - Performed at a specialized breast center with trained techs and interpreting radiologists
- Mammography:
 - Benign changes may falsely appear malignant
 - Difficult to interpret in women < 30 yr old due to breast tissue density
 - Should be performed either before aspiration or 7–10 days afterward to avoid artifact

Diagnostic Procedures/Surgery

- Fine needle aspiration:
 - Usually performed by a specialist
 - May be performed therapeutically for symptomatic or large masses
 - Allows differentiation between cystic and solid masses
 - Obtain cytology studies to evaluate for malignancy
- Excisional biopsy:
 - Performed by surgeon
 - Indicated for solid lumps that are not proven benign

DIFFERENTIAL DIAGNOSIS

- Benign breast masses:
 - Breast abscess
 - Duct ectasia
 - Mastitis
 - Simple fibroadenomas
 - Solitary papillomas
- Malignant breast masses:
 - Atypical hyperplasia
 - Complex fibroadenomas
 - Diffuse papillomatosis
 - Ductal hyperplasia without atypia
