 - Increased intra-alveolar pressure, low perivascular pressures, or both
 - Terminal alveolar rupture into the lung interstitium and bronchovascular tissue sheath
 - Dissection of air into the hilum and subsequently the mediastinum along a pressure gradient
 - Mediastinal air then dissects into the fascial planes, most commonly into the tissues of the neck.
 - Often in setting of a Valsalva maneuver, forceful vomiting, in association with bronchospasm or inhalational drug use
 - Men > women (2:1 in some series)
 - Young > old (most common in 2nd/3rd decades of life in most series)
 - Pediatric patients have a bimodal age distribution of peak incidence (<7 and 13–17 yr)
- Relatively rare, 1/30,000–50,000 hospital admissions

ETIOLOGY

- Primary or spontaneous pneumomediastinum:
 - Associated with forced Valsalva maneuvers:
 - Forceful vomiting
 - Forceful straining during exercise
 - Straining during defecation
 - Coughing/sneezing
 - Intense screaming
 - Labor and delivery
 - Playing wind instruments
 - Pulmonary function testing
 - Anorexia nervosa
 - Obesity
 - Pre-existing lung disorders (interstitial lung disease, pulmonary

- fibrosis, pneumonitis)
 - Illicit inhalation drug use (marijuana, cocaine, methamphetamine)
 - Tobacco abuse
- A majority of cases will have no identified precipitating event/cause
- Has been rarely described after dental extraction/procedures.
- Secondary pneumomediastinum:
 - Secondary to thoracic barotrauma
 - Common traumatic mechanisms:
 - Motor vehicle collision
 - Fall
 - Blows to chest or neck
 - Recent esophageal/tracheobronchial instrumentation
 - Positive-pressure ventilation
 - Esophageal rupture (Boerhaave syndrome)
 - In association with mediastinal infection caused by gas-forming organisms
- Tension pneumomediastinum:
 - Rare but life-threatening event
 - Usually in patients on positive-pressure ventilation
- May be associated with pneumopericardium and/or extension of a pneumothorax/tension pneumothorax

DIAGNOSIS

SIGNS AND SYMPTOMS

- Chest pain (most common symptom in multiple series):
 - Sharp
 - Pleuritic
 - Retrosternal
 - Radiating to back and arms
 - Often positional
- Dyspnea
- Neck pain:
 - Occurs in association with dissection of air into soft tissues of neck
 - Often described as “neck swelling,” “neck pain,” “throat pain,” or “difficulty swallowing”
- SC emphysema:
 - Most commonly located at the supraclavicular area and anterior neck
- Dysphagia/odynophagia
- Dysphonia/hoarseness
- Hamman crunch: Presence of a precordial crinkling or crepitation during systole:
 - Uncommon but pathognomonic
 - Best heard with patient in left lateral decubitus position

- Meckler triad (esophageal rupture): Vomiting, lower chest pain, and cervical SC emphysema following overindulgence of food or alcohol

History

- Inhalational drug use
- Asthma exacerbation
- Pre-existing lung disorders
- Forceful vomiting (such as in diabetic ketoacidosis [DKA], or hyperemesis)
- Preceding strenuous athletic activity

Physical-Exam

- SC emphysema
- Hamman crunch

ESSENTIAL WORKUP

- Exclude secondary causes, notably esophageal rupture.
- Chest radiography
- Chest CT (if high index of suspicion)

DIAGNOSIS TESTS & INTERPRETATION

Lab

CBC if there is suspicion of mediastinitis (the most concerning consequence of esophageal rupture, with high morbidity and mortality)

Imaging

- CXR:
 - Most valuable initial test
 - Important to include lateral view because mediastinal air is often missed on posterior–anterior view
 - Aids in excluding pneumothorax, pneumopericardium
 - Identification of a pleural effusion or parenchymal infiltrate may suggest an esophageal rupture.
 - Negative in up to 30–35% of cases
 - Spinnaker sail sign or “angel wing” sign (produced by air lifting the thymus off the heart and major vessels)
 - Continuous diaphragm sign (air collecting between the diaphragm and the pericardium)
 - SC or superior mediastinal emphysema
- Chest CT:
 - Imaging test of choice if suspicion is high but CXR is negative (CXR has high false-negative rate)
- Esophagram with water-soluble contrast material:

- Study of choice to exclude diagnosis of esophageal rupture

Diagnostic Procedures/Surgery

- Esophagoscopy:
 - Limited usefulness (overutilized)
 - May be used to further delineate injuries identified with CT and/or esophagram
- Laryngoscopy/bronchoscopy:
 - Limited usefulness (overutilized)
 - May be used to exclude diagnosis of laryngeal/tracheobronchial injury
- Pericardiocentesis:
 - Only in the setting of tension pneumopericardium in the crashing patient
- Tube thoracostomy:
 - Only in the setting of concomitant pneumothorax of sufficient size, or one that is rapidly progressing

DIFFERENTIAL DIAGNOSIS

- Aortic dissection
- Coronary ischemia
- Esophageal diverticula
- Esophageal webs
- Mediastinitis
- Myocarditis
- Pericarditis
- Pneumonia
- Pneumopericardium
- Pneumothorax/tension pneumothorax
- Pulmonary embolus
- Schatzki rings

TREATMENT

PRE HOSPITAL

- Resuscitation of the acutely ill patient (as in the patient with septic mediastinitis)
- In the appropriate setting, standard care of the trauma patient
- Withhold PO intake
- Rapid patient evolution and transport to an appropriate facility

INITIAL STABILIZATION/THERAPY

- IV access
- Oxygen
- Cardiac monitoring

- Pulse oximetry

ED TREATMENT/PROCEDURES

- Spontaneous pneumomediastinum:
 - Usually a benign, self-limiting condition
 - Does not require specific treatment
 - Efforts should focus on pain relief and reassurance once diagnosis is confirmed.
 - High-flow oxygen may facilitate the reabsorption of nitrogen and provide comfort.
 - Withhold PO intake if suspected esophageal source (pending diagnostic studies)
 - Condition is self-limiting and may be expected to resolve over 2–5 days.
- Secondary pneumomediastinum:
 - Once diagnosis is made, direct invasive diagnostic modalities toward the most likely underlying cause (esophagoscopy, laryngoscopy, bronchoscopy).
 - Direct therapy toward underlying cause.

MEDICATION

- Treat underlying cause aggressively (e.g., asthma exacerbation or DKA).
- Oxygen 15 L via nonrebreather mask
- Analgesia (non-narcotic and narcotic as necessary)
- Antibiotics have limited use, but in the setting of concern for mediastinitis use broad-spectrum coverage to include GI flora, resistant organisms, and *Pseudomonas*:
 - Vancomycin 10–15 mg/kg IV q12h *and*
 - Piperacillin/tazobactam 3.375–4.5 g IV q6h *and*
 - Clindamycin 600–900 mg IV q8h *or* Metronidazole 500 mg IV q8h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Secondary pneumomediastinum
- Associated pneumothorax
- Possibility of esophageal rupture has not been excluded
- Abnormal vital signs
- Ill/toxic-appearing patient
- Intractable pain
- Underlying disorder requires admission (asthma exacerbation, exacerbation of lung disorder, DKA).

- Social situation prevents compliance or follow-up
- Extremes of age (pediatric and elderly)
- Immunosuppression
- Failure of outpatient management

Discharge Criteria

- Spontaneous pneumomediastinum
- Normal vital signs
- No pneumothorax
- No significant comorbidities
- Period of observation in the ED with resolution of symptoms
- Close outpatient follow-up

FOLLOW-UP RECOMMENDATIONS

- Patients should be followed up for re-evaluation of clinical symptoms and imaging for resolution of the process.
- Recurrent spontaneous pneumomediastinum may warrant cardiothoracic consultation for further diagnostic evaluation (invasive studies).

PEARLS AND PITFALLS

- Ensure that underlying causes are excluded.
- Be aware of typical presenting features (chest pain, dyspnea, and neck swelling), pre-existing conditions, and precipitating factors associated with pneumomediastinum.
- Hamman crunch is pathognomonic but not commonly seen.
- Remember Meckler triad:
 - Vomiting
 - Lower chest pain
 - Cervical SC emphysema

PNEUMONIA, ADULT

Jason C. Imperato

BASICS

DESCRIPTION

- Epidemiology:
 - 7th leading cause of death and leading cause from infectious disease in US
- Highest mortality in elderly and patients with the following coexisting conditions:
 - Chronic heart, lung, liver, and kidney disease
 - Diabetes mellitus
 - Alcoholism
 - Malignancy
 - Asplenia
 - Immunosuppression
 - Use of antimicrobials within last 3 mo
- Classifications:
 - Source based:
 - Community acquired (CAP)
 - Health care associated (HCAP)
 - Hospital acquired (HAP)
 - Ventilator associated (VAP)
 - Symptom based:
 - Typical
 - Atypical
- Complications:
 - Bacteremia
 - Sepsis
 - Abscess
 - Empyema
 - Respiratory failure

ETIOLOGY

- CAP (typicals):
 - *Streptococcus pneumoniae*
 - *Haemophilus influenzae*
 - *Klebsiella pneumoniae*
 - *Moraxella catarrhalis*
 - *Streptococcus pyogenes*
 - *Staphylococcus aureus*
- CAP (atypicals):

- *Mycoplasma pneumoniae*
- *Chlamydophila pneumoniae*
- *Legionella pneumophila*
- Viral
- HCAP/HAP/VAP:
 - Gram negatives (*Pseudomonas*, *Stenotrophomonas*)
 - Methicillin-resistant *S. aureus* (MRSA)
- Immunosuppressed:
 - *Mycobacterium tuberculosis*
 - *Pneumocystis jirovecii*
- Aspiration:
 - Chemical pneumonitis ± oral and gastric anaerobes

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Typical:
 - Acute onset
 - Fever
 - Chills
 - Rigors
 - Cough
 - Purulent sputum
 - Shortness of breath
 - Pleuritic chest pain
- Atypical:
 - Subacute onset
 - Viral prodrome
 - Nonproductive cough
 - Low-grade fever
 - Headache
 - Myalgias
 - Malaise
 - Absence of pleurisy and rigors

Physical-Exam

- Vital signs:
 - Tachypnea
 - Tachycardia
 - Hypoxia

- Fever
- Pulmonary exam:
 - Dullness to percussion
 - Tactile fremitus
 - Egophony
 - Rales
 - Rhonchi
 - Decreased breath sounds
- Note that pneumonia may be present in the absence of the above signs of consolidation.

Geriatric Considerations

- Elderly patients have higher morbidity and mortality from pneumonia.
- Atypical presentations are more common.

ESSENTIAL WORKUP

Combination of clinical and radiographic diagnosis

DIAGNOSIS TESTS & INTERPRETATION

Lab

- General:
 - CBC with differential
 - Serum chemistry
- Others:
 - Blood cultures (ICU only)
 - Sputum cultures and Gram stain (ICU only)
 - Urine antigen tests for *S. pneumoniae* & *Legionella*
 - C-reactive protein possibly helpful
 - Lactate may be helpful
 - Influenza viral test

Imaging

Chest radiograph:

- General:
 - Findings are nonspecific for particular infectious etiologies.
 - May be deferred in young, healthy patients receiving empiric outpatient management.
 - Negative imaging should not preclude antimicrobial therapy in patients with clinical diagnosis.
- Suggestive findings:
 - Silhouette sign (R. heart border = RML, L. heart border = lingula, R. hemidiaphragm = RLL, L. hemidiaphragm = LLL)

- Air bronchograms
- Segmental or subsegmental consolidation
- Diffuse interstitial opacities
- Pleural effusion
- Empyema
- Abscess
- Cavitation

Diagnostic Procedures/Surgery

Thoracentesis:

- For large effusions, enigmatic pneumonia, and patients who fail to respond to standard therapy

DIFFERENTIAL DIAGNOSIS

- Asthma
- Bronchitis
- CHF
- COPD
- Foreign-body aspiration
- Occupational or environmental exposure
- Pneumothorax
- Pulmonary embolism
- Tumor

TREATMENT

PRE HOSPITAL

- IV access
- Supplemental oxygen
- Cardiac monitor
- Consider inhaled bronchodilators.
- Consider endotracheal intubation in cases of severe respiratory distress.

INITIAL STABILIZATION/THERAPY

- IV access and fluid resuscitation as needed
- Supplemental oxygen
- Cardiac monitor
- Inhaled bronchodilators
- Endotracheal intubation in cases of severe respiratory distress as indicated

ED TREATMENT/PROCEDURES

- American Thoracic Society guidelines for empiric therapy:

- Outpatient:
 - Previously healthy, no coexisting conditions:
 - Macrolide (azithromycin) OR doxycycline
 - Significant coexisting conditions (see above):
 - Combination β -lactam (ceftriaxone, cefuroxime, cefpodoxime, high-dose amoxicillin, Augmentin) PLUS macrolide (azithromycin) OR
 - Respiratory fluoroquinolone (levofloxacin, moxifloxacin) alone
- Inpatient:
 - Noncritical care:
 - Combination β -lactam PLUS macrolide OR
 - Respiratory fluoroquinolone alone
 - Critical care:
 - Combination β -lactam PLUS macrolide OR respiratory fluoroquinolone
 - For *Pseudomonas*, consider adding antipseudomonal agent (piperacillin/tazobactam, imipenem, meropenem, cefepime) PLUS antipseudomonal fluoroquinolone (high-dose levofloxacin) OR antipseudomonal agent (see above) PLUS aminoglycoside (gentamicin) PLUS macrolide (azithromycin).
 - For MRSA, consider adding vancomycin OR linezolid.
 - For aspiration, consider adding clindamycin OR metronidazole.
 - For drug-resistant *S. pneumoniae*, consider adding vancomycin.

MEDICATION

- Amoxicillin–clavulanate (Augmentin): 500 mg PO q12h
- Ampicillin–sulbactam (Unasyn): 1.5–3 g IV q6h
- Azithromycin: 500 mg PO on day 1 and 250 mg PO on days 2–5 OR 500 mg PO daily for 3 days OR 500 mg IV daily
- Aztreonam: 1–2 g IV q12h
- Cefepime: 2 g IV q12h
- Cefotaxime: 1–2 g IV q8h
- Cefpodoxime: 200 mg PO q12h
- Ceftazidime: 2 g IV q12h
- Ceftriaxone: 1–2 g IV daily
- Cefuroxime: 0.75 and 1.5 g IV q8h
- Doxycycline: 100 mg PO/IV q12h
- Ertapenem: 1 g IV daily
- Levofloxacin: 500–750 mg PO/IV daily
- Linezolid: 600 mg PO/IV daily
- Imipenem: 500 mg IV q6h
- Meropenem: 1 g IV q8h
- Moxifloxacin: 400 mg IV daily
- Piperacillin–tazobactam (Zosyn): 3.375–4.5 g IV q6h
- Vancomycin: 1 g IV q12h

First Line

- Outpatient:
 - Healthy:
 - Azithromycin 500 mg PO day 1, 250 mg PO days 2–5 OR 500 mg PO daily for 3 days
 - Comorbidities:
 - Levofloxacin 750 mg PO daily for 5 days
- Inpatient:
 - Non-ICU:
 - Levofloxacin 750 mg IV daily
 - ICU:
 - Ceftriaxone 1 g IV daily AND levofloxacin 750 mg IV daily ± piperacillin–tazobactam 4.5 g IV q6h ± vancomycin 1g IV q12h

Second Line

Aztreonam may be substituted for β -lactams in confirmed penicillin-allergic patients for the above ICU regimens.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Based on severity of illness, coexisting conditions, ability of home care, and follow-up
- Clinical decision-making rules may aid in stratifying patients but should not supersede clinical judgment.
- CURB-65 rule:
 - Criteria:
 - Confusion (Abbreviated Mental Test ≤ 8)
 - Urea >7 mmol/L OR BUN >19
 - Respiratory rate ≥ 30 /min
 - BP with SBP <90 mm Hg, DBP <60 mm Hg
 - Age ≥ 65 yr
 - Interpretation:
 - 0–1: Outpatient treatment
 - 2: Close outpatient vs. brief inpatient
 - 3–5: Inpatient with ICU consideration
- Pneumonia Severity Index:
 - Demographics:
 - If Male: + age (yr)
 - If Female: + age (yr) – 10

- If nursing home resident: +10
- Comorbid illness:
 - Neoplastic disease: +30
 - Liver disease: +20
 - Congestive heart failure: +10
 - Cerebrovascular disease: +10
 - Renal disease: +10
- Physical exam findings:
 - Altered mental status: +20
 - Pulse ≥ 125 /min: +20
 - Respiratory rate > 30 /min: +20
 - SBP < 90 mm Hg: +15
 - Temperature $< 35^\circ\text{C}$ or $\geq 40^\circ\text{C}$: +10
- Lab and radiographic findings:
 - Arterial pH < 7.35 : +30
 - BUN ≥ 30 mg/dL: +20
 - Sodium < 130 mmol/L: +20
 - Glucose ≥ 250 mg/dL: +10
 - Hematocrit $< 30\%$: +10
 - PaO₂ < 60 mm Hg: +10
 - Pleural effusion: +10
- Interpretation:
 - 0: Class I (outpatient)
 - < 70 : Class II (outpatient vs. short observation)
 - 71–90: Class III (home with IV antibiotics vs. short observation)
 - 91–130: Class IV (inpatient)
 - > 130 : Class V (inpatient)
- Additional considerations:
 - Previous hospitalization within last year for pneumonia
 - Failed outpatient therapy
 - Social conditions preventing safe outpatient disposition

Discharge Criteria

- Age < 65 yr
- No comorbid illnesses
- Nontoxic appearance
- Normal vital signs
- Normal lab studies
- Primary care follow-up within 72 hr

Issues for Referral

Follow-up with primary care within 72 hr

FOLLOW-UP RECOMMENDATIONS

Primary care follow-up within 72 hr

PEARLS AND PITFALLS

- Delayed initiation of antibiotics in ill-appearing patients
- Failure to recognize pneumonia in patients assumed to have exacerbations of underlying lung conditions
- Failure to question patients regarding TB and HIV risk factors
- Elderly and immunocompromised patients may not exhibit any classic symptoms of pneumonia when ill.

ICD10

- J13 Pneumonia due to Streptococcus pneumoniae
- J18.9 Pneumonia, unspecified organism
- J69.0 Pneumonitis due to inhalation of food and vomit

PNEUMONIA, PEDIATRIC

Gary D. Zimmer • Karen P. Zimmer

BASICS

DESCRIPTION

- Mechanism is often unknown.
- Source is oropharyngeal aspiration (most common) or hematogenous.
- Distribution depends on the organism: Interstitial (*Mycoplasma pneumoniae*, virus), lobar (*Streptococcus pneumoniae*), abscesses (*Staphylococcus aureus*), or diffuse (*Pneumocystis carinii*)

ETIOLOGY

- < 2 wk:
 - Group B *Streptococcus* species
 - Enteric gram-negative organisms
 - Respiratory syncytial virus (RSV)
 - Herpes simplex virus
 - *S. aureus*
- 2 wk–3 mo:
 - *Chlamydia trachomatis*
 - Parainfluenza virus
 - RSV
 - *S. pneumoniae*
 - *S. aureus*
 - *H. influenza*
 - *Bordetella pertussis*
- 3 mo–8 yr:
 - Viral (predominate):
 - RSV
 - Parainfluenza virus
 - Influenza virus
 - Adenovirus
 - *S. pneumoniae*
 - *H. influenza* in unimmunized children
 - Group A streptococcus
 - *S. aureus*
 - *B. pertussis*
- > 8 yr:
 - *M. pneumoniae* most common
 - Viral

- *S. pneumoniae*
- Recent immigrants from developing countries:
 - *Mycoplasma tuberculosis*
 - *H. influenza*
 - *B. pertussis*
- Immunocompromised (e.g., HIV, cancer):
 - *P. carinii*
 - *Mycoplasma avium* complex
 - *M. tuberculosis*
 - *Klebsiella pneumoniae*
 - *Pseudomonas aeruginosa*
- Less common:
 - Fungal (coccidioidomycosis, histoplasmosis)
 - *Rickettsia* (Q fever)

DIAGNOSIS

SIGNS AND SYMPTOMS

- General (in all ages):
 - Cough
 - Rales
 - Fever
 - Hypoxia
 - Tachycardia
 - Tachypnea, retractions, grunting
 - Rash (up to 10% of cases); usually maculopapular
 - Nonspecific symptoms of toxicity
 - Pulmonary exam:
 - Decreased breath sounds, ventilation
 - Dullness to percussion
 - Wheezing, ronchi, rales
- Infants < 6 mo:
 - Altered behavior: Listless, irritable
 - Apnea (esp. RSV in premature infants)
 - Conjunctivitis (*Chlamydia* < 1 mo old)
 - Cyanosis
 - Grunting
 - Poor feeding
 - Temperature instability (hypothermia/hyperthermia)
 - Vomiting, often with coughing
 - Cough
 - Nasal congestion

- Nasal flaring
- Wheezing
- Staccato cough (*Chlamydia*)
- Children >5 yr:
 - Pleuritic chest pain
 - Productive cough
 - Rigors, chills

History

- Immunization history
- Past medical history include immune status
- Exposures
- Progression of signs and symptoms

Physical-Exam

- Pulmonary exam may be helpful, particularly in children >5 yr.
- Peripheral and central cyanosis should be assessed.
- Evidence of respiratory compromise, distress, failure

ESSENTIAL WORKUP

- Pulse oximetry
- Chest radiograph:
 - Gold standard for diagnosis
 - Should be ordered for patients with signs of lower respiratory tract infection and patients <36 mo old with marked leukocytosis or neutrophilia (WBC >15,000 or absolute neutrophil count [ANC] >9,000).
 - Much overlap between viral and bacterial findings
 - Viral and *M. pneumoniae* tend to show interstitial infiltrates, often perihilar and peribronchial.
 - Bacterial pneumonias may show focal lobar consolidation, focal alveolar infiltrates, and possibly effusion or pneumatocele.
 - Round pneumonia pathognomonic of *S. pneumonia*
 - Lateral decubitus films may aid in demonstrating effusion.

DIAGNOSIS TESTS & NTERPRETATION

Lab

- CBC with differential:
 - Patients with bacteremia tend to have leukocytosis with left shift.
 - Sensitivity and specificity are poor.
 - Patients with WBC $\geq 20,000$ or ANC >9,000 are at increased risk of pneumococcal bacteremia.
 - *B. pertussis* usually has elevated WBC with lymphocytosis.

- Blood culture:
 - Low yield (< 10–20%)
 - Recommended in children < 36 mo
 - Probably worthwhile in toxic patients requiring hospitalization
- Arterial blood gas may be useful in determining degree of respiratory insufficiency in critically ill patients.
- Electrolytes to exclude syndrome of inappropriate antidiuretic hormone secretion and in hypotensive children
- Sputum for Gram stain and culture may be obtained in older children with suspected bacterial infection.
- *Mycoplasma* IgM or cold agglutinin titers:
 - Useful if suspecting this organism
 - More likely positive with severe illness
- Nasopharyngeal washes for direct fluorescent antibody and culture:
 - Identify RSV, *C. trachomatis*, and *B. pertussis* infections

Imaging

Chest radiographs are still the imaging modality of choice:

- Posteroanterior and lateral films should be obtained whenever possible.
- CT provides additional detail and better identification of underlying lung pathology but adds little as an initial testing modality.

Diagnostic Procedures/Surgery

Pleural fluid (if present) for culture, Gram stain, protein, glucose, and cell counts

DIFFERENTIAL DIAGNOSIS

- Reactive airway disease (asthma, bronchiolitis [age < 2 yr])
- Aspiration:
 - Gastroesophageal reflux
 - Vascular ring
 - H-type tracheoesophageal fistula
 - Foreign body
 - Hydrocarbon
- Congestive heart failure
- Congenital:
 - Cystic fibrosis
 - Sequestered lobe
 - Congenital lobe absence
 - Hemangioma
- Neoplasm

TREATMENT

PRE HOSPITAL

- Pulse oximetry
- Administer high-flow oxygen for respiratory distress.
- IV fluids (0.9% normal saline [NS] 20 mL/kg initial bolus) for volume depletion, hypotension
- Support and intubation for respiratory failure

INITIAL STABILIZATION/THERAPY

- If moderately or severely ill:
 - Secure airway, as appropriate; intubate for clinical respiratory failure. Children with severe sepsis or septic shock benefit from aggressive airway management.
 - High-flow oxygen
 - IV hydration (0.9% NS 20 mL/kg initial bolus) and resuscitation if in shock or hypovolemia
- Monitor
- Ongoing pulse oximetry
- Arterial blood gas if inadequate ventilation
- Check bedside glucose in severely ill-appearing infants and toddlers:
 - If hypoglycemic, administer glucose D25 at 2 mL/kg IV for toddlers or D10 at 5 mL/kg IV for neonates.

ED TREATMENT/PROCEDURES

- Continue pre-hospital and initial stabilization therapy.
- Early antibiotic therapy should be broad enough to address local resistance patterns in your area.
- Often have concurrent reactive airway disease that needs specific treatment with bronchodilator (albuterol or levalbuterol)
- Perform thoracentesis if pleural effusion is compromising respiratory function or for diagnostic tests.

MEDICATION

- Empiric therapy with oral antibiotics for most well-appearing children ≥ 6 mo:
 - Infants < 2 mo:
 - Outpatient treatment generally not recommended unless child has no respiratory distress or associated conditions or issues.
 - Children 3 mo–5 yr:
 - Amoxicillin
 - Amoxicillin—clavulanate
 - Trimethoprim—sulfamethoxazole
 - Erythromycin—sulfisoxazole
 - Macrolide (azithromycin or clarithromycin)
 - Children 5–18 yr:

- Macrolide (azithromycin or clarithromycin)
- Initiate IV antibiotic therapy for moderate to severely ill children who require admission:
 - _ Neonate:
 - Ampicillin, and cefotaxime or gentamicin
 - Azithromycin for suspected *C. trachomatis* or *B. pertussis* pneumonia
 - _ Infants 1–2 mo:
 - Ampicillin and cefotaxime
 - Azithromycin or erythromycin for suspected *C. trachomatis* or *B. pertussis*
 - _ Children ≥ 3 mo:
 - Cefotaxime, cefuroxime, or ceftriaxone
 - Vancomycin for suspected or confirmed penicillin-resistant *S. pneumoniae*
 - Macrolide (i.e., azithromycin) for suspected *M. pneumoniae*
 - Clindamycin if group A strep suspected in patient with severe disease
- Unusual organisms require specific therapy in coordination with infectious disease consultation.
- Albuterol (0.5% solution or 5 mg/mL): Nebulizer 0.015 mg (0.03 mL)/kg per dose up to 5 mg per dose q10–20min as needed; metered dose inhaler (with spacer; 90 mg per puff) 2 puffs q10–20min up to total of 10 puffs
- Amoxicillin: 80 mg/kg/24 h q12h PO
- Amoxicillin–clavulanate: 30 mg/kg/24 h q12h PO
- Ampicillin: 100–150 mg/kg/24 h q6h IV
- Azithromycin: 10 mg/kg/24 h daily for 1 day, then 5 mg/kg/24 h daily for 4 days
- Cefotaxime: 50–75 mg/kg/24 h q8h IV, max. 2 g q8h
- Ceftriaxone: 100 mg/kg/24 h q12–24 h IV, max. 2 g q12h
- Cefuroxime: 100 mg/kg/24 h q8h IV, max. 2 g q8h
- Clarithromycin: 15 mg/kg/24 h q12h PO, max. 500 g q12h
- Clindamycin 30–40 mg/kg/24 h q6–8h IV
- Erythromycin–sulfisoxazole: 40 mg/kg/24 h as erythromycin q8h PO, max. 2 g/d
- Gentamicin: 5–7.5 mg/kg/24 h q8–12h IV
- Trimethoprim–sulfamethoxazole: 8–10 mg/kg/24 h as TMP q12h PO
- Vancomycin: 10–15 mg/kg/24 h q8–12h IV; max. 1,000 mg

FOLLOW-UP

DISPOSITION

Admission Criteria

- Toxic appearance
- Respiratory distress or failure

- Dehydration/vomiting
- Apnea
- Infants < 2 mo
- Infants < 6 mo with lobar pneumonia
- Hypoxia (O₂ saturation < 92% on room air [sea level])
- Pleural effusion
- Poor response to outpatient oral therapy
- Immunocompromised children
- Concern about noncompliant parents

Discharge Criteria

- Most cases are mild and can be discharged home if no evidence of hypoxia, significant work-of-breathing, dehydration, vomiting, or noncompliance.
- Ensured follow-up within 1–2 days

Issues for Referral

Respiratory failure, effusion, toxicity

FOLLOW-UP RECOMMENDATIONS

Clinical resolution should be ensured through follow-up.

PEARLS AND PITFALLS

- Early, aggressive airway management for patients with severe sepsis and septic shock
- Delays to antibiotic therapy should be avoided.
- Discharged patients should have clear evidence of good support, follow-up, and lack of toxicity.
- Local patterns of drug resistance should be known and empiric therapy should take these resistance patterns into consideration.

CODES

ICD9

- 483.0 Pneumonia due to mycoplasma pneumoniae
- 486 Pneumonia, organism unspecified
- 507.0 Pneumonitis due to inhalation of food or vomitus

ICD10

- J15.7 Pneumonia due to Mycoplasma pneumoniae
- J18.9 Pneumonia, unspecified organism
- J69.0 Pneumonitis due to inhalation of food and vomit

PNEUMOTHORAX

William Porcaro

BASICS

DESCRIPTION

- Presence of free air in the intrapleural space
- Spontaneous pneumothorax is due to atraumatic rupture of alveolus, bronchiole, or bleb.
- Primary spontaneous pneumothorax (2/3 of incidences):
 - No underlying pulmonary pathology present
 - Rupture of small subpleural cyst or bleb
 - Primarily young, healthy patients (20–40 yr old) with tall, thin body habitus
 - Risk factors: Smoking, family history, Marfan syndrome, homocystinuria, thoracic endometriosis
- Secondary spontaneous pneumothorax from underlying pulmonary pathology (see Etiology)
- Tension pneumothorax:
 - Air continues to enter pleural space through bronchoalveolar disruption and becomes trapped via “ball-valve” mechanism.
 - Intrapleural pressure increases.
 - Venous return to right heart decreases, resulting in decrease in cardiac output.
 - Mediastinum shifts toward uninvolved side, mechanically interfering with right atrial filling.
 - Ventilation compromise and ventilation/perfusion mismatch result in hypoxemia

ETIOLOGY

- Idiopathic
- Airway disease:
 - Chronic obstructive pulmonary disease (COPD)
 - Asthma
 - Cystic fibrosis
- Infections:
 - Necrotizing bacterial pneumonia
 - TB
 - Fungal pneumonia
 - *Pneumocystis carinii*
- Neoplasm
- Interstitial lung disease:

- Sarcoidosis
- Idiopathic pulmonary fibrosis
- Lymphangiomyomatosis
- Tuberosus sclerosis
- Pneumoconioses
- Connective tissue diseases
- Pulmonary infarction
- Endometriosis
- Blunt chest trauma
- Penetrating trauma to neck or trunk
- Iatrogenic:
 - Central line placement
 - Other vascular access procedures

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Severity of symptoms is generally proportional to size of the pneumothorax.
- Chest pain on the ipsilateral side:
 - Sharp, pleuritic pain
 - Sudden onset
 - Dull ache in delayed presentations
- Shortness of breath
- Rarely cough, asymptomatic, or generalized malaise

Physical-Exam

- Tachypnea
- Heart rate < 120 bpm generally seen in simple spontaneous pneumothoraces
- Jugular venous distention and tracheal deviation to the contralateral side may be evident in tension pneumothorax.
- Cardiac and pulmonary exam:
 - Asymmetric decreased breath sounds
 - Hyperresonance to percussion of ipsilateral side
- Tension pneumothorax:
 - Hypotension
 - Tachycardia, heart rate > 120 bpm
 - Diaphoresis
 - Cyanosis
 - Cardiovascular collapse
 - Tracheal deviation

ESSENTIAL WORKUP

- Imaging is mainstay of the workup
- DO NOT delay chest decompression if the patient is hemodynamically unstable and there is sufficient clinical evidence of pneumothorax.

DIAGNOSIS TESTS & INTERPRETATION

Lab

Arterial blood gas offers little over oxygen saturation.

Imaging

- Chest radiograph:
 - Upright chest radiograph
- Patients unable to tolerate upright chest radiograph can be taken in decubitus position with the suspected side up:
 - Absence of lung markings distal or peripheral to the visceral pleural white line
 - Displacement of mediastinum or anterior junction line
 - Deep sulcus sign
- On frontal view, larger lateral costodiaphragmatic recess than on opposite side
- Diaphragm may be inverted on the side with deep sulcus:
 - A rough estimate of pneumothorax size is sufficient to make clinical decisions.
- Expiratory film:
 - May demonstrate small pneumothorax but has not been shown to increase yield of detection
- Chest CT:
 - Very sensitive for small pneumothorax but has little practical advantage over chest radiograph
- US:
 - User experience required
 - Rapid at bedside
 - Lack of lung sliding and comet-tail artifact signifies pneumothorax.
 - M-mode confirms pneumothorax with smooth lines above and below pleural line.
 - With experience, sensitivity surpasses chest radiograph

Diagnostic Procedures/Surgery

ECG:

- Often necessary to rule out cardiac etiologies of chest pain
- Nonspecific changes include T-wave inversion, left axis deviation, and decreased R-wave amplitude.

DIFFERENTIAL DIAGNOSIS

- Acute abdominal processes
- Aortic aneurysm or dissection
- Asthma exacerbation
- Chest wall pain
- COPD exacerbation
- Myocardial infarction
- Pericarditis
- Pleuritis
- Pneumomediastinum
- Pulmonary embolus

TREATMENT

PRE HOSPITAL

ALERT

Unstable patients with a suspected tension pneumothorax require immediate needle thoracostomy.

INITIAL STABILIZATION/THERAPY

- Cardiac monitor
- Pulse oximetry
- Oxygen 100% via nonrebreather face mask
- IV access
- Suspected tension pneumothorax requires either immediate needle thoracostomy or tube thoracostomy.
- Needle thoracostomy:
 - _ Immediate placement indicated in unstable patients with a tension pneumothorax
 - _ 14G–18G angiocatheter in the 2nd intercostal space at midclavicular line or 4th or 5th intercostal space at anterior axillary line
 - _ NOTE: The length of most standard angiocatheters is too short to penetrate the pleural cavity in moderate to large framed patients – longer, purpose-specific catheters may be required

ED TREATMENT/PROCEDURES

- Nontraumatic pneumothorax estimated at < 15% collapse and no cardiovascular or respiratory compromise:
 - _ Observe with 100% oxygen support for 4–6 hr.
 - _ Repeat chest radiograph and discharge if unchanged.
- Simple aspiration:
 - _ Indications:

- Simple pneumothorax with only 15–30% collapse
 - Increase in size of a small pneumothorax during observation
- Placement of aspiration catheter (typically 8F) with 3-way stopcock
- Aspirate air until resistance or 3 L of air aspirated.
 - If the pneumothorax is no longer visible on 2 subsequent chest radiographs at 4 hr intervals, remove catheter.
 - If a final chest radiograph is normal 2 hr after the catheter is removed, the patient may be discharged.
 - A 2nd aspiration may be attempted if the pneumothorax does not resolve.
- Heimlich valve:
 - Indicated when < 30% collapse after failure of aspiration
 - Attach Heimlich valve to aspiration catheter or chest tube.
- Suction:
 - Indicated when the Heimlich valve fails
 - Attach aspiration catheter to suction at 20 cm H₂O.
 - Observe in ED for 1 hr.
- Tube thoracostomy:
 - Indications:
 - Suspicion of a tension pneumothorax
 - Gunshot wound to the chest
 - Clinical evidence of a pneumothorax following blunt chest trauma or penetrating chest trauma
 - Presence of a pneumothorax of any size in patient receiving positive-pressure ventilation
 - Pneumothorax with > 30% collapse
 - Most cases of secondary pneumothorax
 - Definitive therapy after needle thoracostomy
 - Tube size:
 - Small-caliber (7–14F) tube for primary spontaneous pneumothoraces
 - 20–28F for secondary spontaneous pneumothorax
 - 28F when there is detectable pleural fluid or an anticipated need for mechanical ventilation
 - Check for tube kinks by fully rotating the inserted tube.
 - All side holes in the tube must be within the chest wall to avoid leak.
 - Following insertion, the tube should be connected to a water-seal device.
 - A Heimlich valve may be used instead of a water-seal device in stable patients without a pleural effusion.
 - Re-expansion edema is a rare complication requiring supportive care.
- Possible complications:
 - Intercostal vessel bleeding
 - Inadequate drainage:
 - Kinked tube

- Clogged tube
- Communication outside of pleural cavity with leak
- Re-expansion pulmonary edema:
 - Treatment with fluid resuscitation

MEDICATION

- Local anesthetic:
 - 1% lidocaine with epinephrine 1:100,000
 - Max. dose: 7 mg/kg–500 mg
- Consider procedural sedation in stable awake patients
- No indication for antibiotics in a clean procedure

FOLLOW-UP

DISPOSITION

Admission Criteria

- Tension pneumothorax
- Chest tube required

Discharge Criteria

- <15% collapse, no expansion while in the ED or successful aspiration with catheter removed:
 - Discharge with follow-up in 24 hr and 1 wk for chest radiograph to assure re-expansion.
- Reliable patients with the thoracic vent and successful aspiration or secured catheter and Heimlich valve:
 - Discharge with 24 and 48 hr follow-up.
 - At 48 hr follow-up:
 - Clamp catheter, observe for 2 hr, and repeat chest radiograph.
 - Remove thoracic vent or catheter if no re-expansion.
 - Observe for 2 hr and repeat chest radiograph.
 - If no re-expansion, discharge with 24 hr and 1 wk follow-up.
- Discharge instruction should include prompt return for new onset of chest pain or dyspnea.
- Patients without re-expansion at 1 wk require a cardiothoracic surgery consult.

FOLLOW-UP RECOMMENDATIONS

Pulmonary medicine and/or chest surgery

PEARLS AND PITFALLS

- Delay in chest decompression in the unstable patient leading to rapid

hemodynamic compromise

- Avoid poor tube placement involving kinks or improper depth, which may necessitate repeating the procedure.
- Avoid placement of catheter or tube too low on the lateral chest wall, which may lead to iatrogenic abdominal injuries.
- Failure to detect associated mediastinal or lower neck injuries
- If pneumomediastinum is detected, evaluate for esophageal pathology

- J93.11 Primary spontaneous pneumothorax

POISONING

Mark B. Mycyk

BASICS

DESCRIPTION

- Poisoning may be intentional or unintentional.
- Patients with change in mental status without clear cause should have poisoning (intoxication, overdose) considered in differential diagnosis.

ETIOLOGY

- Intentional:
 - Depression
 - Suicide
 - Homicide
 - Recreational drug abuse
- Unintentional (accidental):
 - Common cause in children
 - Therapeutic error (e.g., double dose)
 - Recreational drug experimentation

Pediatric Considerations

- Accidental ingestions—typically young children (1–5 yr)
- Consider child abuse if inconsistent or suspicious history.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Neurologic:
 - Lethargy
 - Agitation
 - Coma
 - Hallucinations
 - Seizures
- Respiratory:
 - Tachypnea, bradypnea, apnea
 - Inability to protect airway
- Cardiovascular:
 - Dysrhythmias
 - Conduction blocks
- Vital signs:

- Varies depending on toxic substance
- Hyperthermia, hypothermia
- Tachycardia, bradycardia
- Hypertension, hypotension

Selected Toxidromes (see Poisoning, Toxidromes)

- **Anticholinergic:**
 - Altered mental status (confusion, delirium, lethargy)
 - Dry skin and mucous membranes
 - Fixed dilated pupils
 - Tachycardia
 - Hyperthermia
 - Flushing
 - Urinary retention
- **Cholinergic:**
 - Secretory overdrive (salivation, lacrimation, urination, diaphoresis)
 - Miosis
 - Bronchospasm, wheezing
- **Opiate:**
 - CNS and respiratory depression
 - Miosis
- **Sympathomimetic:**
 - CNS excitation
 - Seizures
 - Tachycardia
 - Hypertension
 - Diaphoresis

ESSENTIAL WORKUP

- A complete set of vital signs, including core temperature
- A complete physical exam, including eyes, skin, odors

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Electrolytes, BUN/creatinine, glucose
- Calculate anion gap: $Na + (Cl + HCO_3)$:
 - Normal anion gap: 8–12
 - Use mnemonic *A CAT MUD PILES* for elevated anion gap acidosis:
 - Alcoholic ketoacidosis
 - Cyanide, carbon monoxide
 - Aspirin, other salicylates
 - Toluene
 - Methanol, metformin

- Uremia
- Diabetic ketoacidosis
- Paraldehyde, phenformin
- Iron, isoniazid
- Lactic acidosis from other causes
- Ethylene glycol
- Starvation ketosis
- Serum osmol gap:
 - Calculate osmol gap if elevated anion gap acidosis from potential toxic alcohol.
 - Most sensitive *early* in poisoning
 - Normal osmol gap does not completely rule out toxic alcohol ingestion.
 - Calculated osmolality = $2(\text{Na}^+) + \text{glucose}/18 + \text{BUN}/2.8 + \text{ethanol (in mg/dL)}/4.6$.
 - Osmol gap = measured osmolality – calculated osmolality.
 - Use mnemonic *ME DIE A* when osmol gap > 10:
 - Methanol
 - Ethanol
 - Diuretics (mannitol, glycerin, sorbitol)
 - Isopropyl alcohol
 - Ethylene glycol
 - Acetone
- Pregnancy test
- Acetaminophen level for suicidal ingestions
- Toxicology screen

Imaging

- ECG for dysrhythmias or QRS/QT changes
- CT of head for altered mental status not clearly due to toxin
- Chest radiograph if suspected aspiration or pneumonia

DIFFERENTIAL DIAGNOSIS

- Causes of altered mental status
- Intracranial mass, bleeding
- Infection, sepsis
- Endocrine abnormalities
- Hypothermia
- Hypoxia
- Metabolic abnormalities
- Psychogenic

TREATMENT

PRE HOSPITAL

- Search for clues at scene:
 - Pills/pill bottles
 - Drug paraphernalia
 - Witnesses
 - Transport all drugs and pill bottles for identification.
- Restrain uncooperative patients for patient and health care giver protection.
- Consider comorbid conditions:
 - Trauma
 - Medical illness
 - Environmental exposure
- Pre-hospital administration of activated charcoal may optimize decontamination if prolonged transport time.

INITIAL STABILIZATION/THERAPY

- ABCs:
 - Endotracheal intubation as needed for airway protection, oxygenation, ventilation, and orogastric lavage
 - Supplemental oxygen for hypoxia
 - Pulse oximetry
 - Cardiac monitor
 - IV access
- Hypotension:
 - Administer 0.9% normal saline IV fluid bolus.
 - Trendelenburg
 - Vasopressors for persistent hypotension
- Bradycardia:
 - Atropine
 - Cardiac pacing
- If altered mental status, administer coma cocktail: Thiamine, D50W (or Accu-Chek), naloxone

ED TREATMENT/PROCEDURES

- Decontamination:
 - See Poisoning, Gastric Decontamination.
 - Prevents systemic absorption of ingested toxin
- Orogastric lavage:
 - Consider in potentially lethal ingestions without known antidote within 1 hr of ingestion.
 - Protected airway *essential* prior to lavage
- Activated charcoal:
 - Most effective within a few hours of most toxic ingestions
 - Contraindicated if caustic ingestion, unprotected airway, or bowel

obstruction

- Drugs not effectively bound to charcoal: Metals (borates, bromide, iron, lithium), alcohols, potassium
- Whole-bowel irrigation:
 - Polyethylene glycol (Colyte, GoLyteLy) evacuates bowel without causing electrolyte disturbances.
 - Consider in toxins not well adsorbed by charcoal (e.g., iron and lithium), body packers/stuffers, sustained-release ingestions.
 - Contraindicated if bowel obstruction, perforation, or hypotension
- Enhanced elimination:
 - Enhances removal of systemically absorbed toxin
- Multiple-dose activated charcoal:
 - Theophylline
 - Carbamazepine
 - Phenobarbital
- Urinary alkalization:
 - Salicylates
 - Phenobarbital
- Hemodialysis/hemoperfusion:
 - Lithium
 - Salicylates
 - Theophylline
 - Toxic alcohols
 - Valproate
- Seizures
 - Treat initially with diazepam or lorazepam.
 - For persistent seizures, consider phenobarbital.
 - Phenytoin *not* indicated in toxicologic seizures:
 - Indicated only if seizures secondary to idiopathic epilepsy, post-traumatic, or status epilepticus
- Antidotes:
 - Acetaminophen: N-acetylcysteine
 - Anticholinergic: Physostigmine
 - Benzodiazepines: Flumazenil
 - β -blockers: Glucagon
 - Calcium-channel blockers: Calcium chloride/gluconate, insulin
 - Carbon monoxide: Oxygen, hyperbaric oxygen
 - Coumadin: Vitamin K₁
 - Cyanide: Cyanide antidote kit, hydroxocobalamin
 - Digoxin: Digibind
 - Ethylene glycol: Ethanol, 4-methylpyrazole
 - Iron: Deferoxamine

- Isoniazid: Pyridoxine (vitamin B₆)
- Methanol: Ethanol, 4-methylpyrazole
- Methemoglobinemia: Methylene blue
- Opiates: Naloxone
- Organophosphates: Atropine, pralidoxime
- Tricyclic antidepressants: NaHCO₃

MEDICATION

- Activated charcoal slurry: 1–2 g/kg PO
- Dextrose: D50W 1 amp: 50 mL or 25 g (peds: D25W 2–4 mL/kg) IV
- Diazepam: 5–10 mg (peds: 0.2–0.5 mg/kg) IV every 10–15 min
- Lorazepam: 2–6 mg (peds: 0.05–0.1 mg/kg) IV every 10–15 min
- Naloxone (Narcan): 0.4–2 mg (peds: 0.1 mg/kg) IV or IM initial dose
- Thiamine (vitamin B₁): 100 mg (peds: 50 mg) IV or IM

FOLLOW-UP

DISPOSITION

Admission Criteria

- Altered mental status
- Cardiopulmonary instability
- Suicidal
- Lab abnormalities
- Potential for decompensation from delayed acting substance

Discharge Criteria

- Psychiatrically clear
- Detoxified
- Hemodynamically stable

Issues for Referral

- Patients with unintentional (accidental) poisoning require poison prevention counseling.
- Patients with intentional (e.g., suicide) poisoning require psychiatric evaluation.
- Consider substance abuse referral for patients.

Pregnancy Considerations

In general, treating the mother is also the best treatment strategy for the fetus.

FOLLOW-UP RECOMMENDATIONS

- Consider substance abuse referral for patients with recreational drug abuse.
- Patients with unintentional (accidental) poisoning require poison prevention counseling.
- Patients with intentional (e.g., suicide) poisoning require psychiatric evaluation.

PEARLS AND PITFALLS

- Do not forget to consider nontoxicologic etiologies for altered mental status.
- Do not rely on the urine drug screen to make a diagnosis: It only provides screening tests for a limited number of drugs.
- Call a toxicologist or a poison center for help: 800-222-1222.

POISONING, ANTIDOTES

Suzan S. Mazor

TREATMENT

N-ACETYLCYSTEINE (NAC)

- Indications: Acetaminophen overdose
- Warnings:
 - _ Unpleasant odor, nausea, vomiting
 - _ Most effective if given in 1st 8 hr postingestion
- Dose:
 - _ PO: 140 mg/kg, then 70 mg/kg q4h for 17 doses
 - _ IV (consult poison center): 150 mg/kg in 200 mL D₅W over 60 min, then 50 mg/kg in 500 mL D₅W over 4 hr, then 100 mg/kg in 1,000 mL D₅W over 16 hr

Pediatric Considerations

This volume of D₅W will need to be reduced in dosing pediatric patients to avoid fluid overload/hyponatremia. Discuss with pharmacy.

ATROPINE

- Indications:
 - _ Bradycardia owing to drugs
 - _ Organophosphate insecticides
- Warnings:
 - _ Myasthenia gravis, narrow-angle glaucoma, HTN, coronary ischemia, and urinary obstruction
- Dose:
 - _ Adult: 1–2 mg IV
 - _ Pediatric: 0.02 mg/kg (min. 0.1 mg) IV
 - _ Large repeated doses needed in organophosphate poisoning

BENZTROPINE (COGENTIN)

- Indications: Acute dystonic reactions
- Warnings: Carbamates, myasthenia gravis, narrow-angle glaucoma, HTN, coronary ischemia, and urinary obstruction
- Dose:
 - _ Adult: 1–2 mg IV (for acute reaction) or PO (to prevent reaction)
 - _ Pediatric: 0.02 mg/kg IV (for acute reaction) or PO (to prevent reaction)

BENZODIAZEPINE

- Indications: Agitation, stimulant drugs, seizures
- Warnings: Respiratory/CNS depression
- Dose:
 - Midazolam:
 - Adult: 1 mg IV/IM every 2–3 min PRN
 - Pediatric: 0.1 mg/kg IV/IM
 - Diazepam:
 - Adult: 2–5 mg IV/IM, repeat in 10–15 min
 - Pediatrics: 0.1 mg/kg IV/IM

BICARBONATE, SODIUM

- Indications: Cyclic antidepressant poisoning, metabolic acidosis, urinary alkalinization
- Warnings: May cause CHF, excessive alkalosis, hypokalemia
- Dose:
 - Serum alkalinization:
 - 1 mEq/kg IVP
 - Urine alkalinization:
 - 100–150 mEq in 1 L DW at 2–3 mL/kg/h IV, goal urine pH 7–8

BLACK WIDOW SPIDER ANTIVENIN (LACTRODECTUS MACTANS)

- Indications: Severe HTN, muscle spasms not alleviated by analgesics and muscle relaxants; consider in extremes of age (<5 or >65 years), pregnant women with threatened abortion
- Warnings:
 - Equine serum derived: Immediate hypersensitivity, serum sickness 10–14 days
 - Premedicate for anaphylaxis if know equine serum hypersensitivity.
- Dose: 1–2 vials IM or IV slowly over 15–30 min; dilute 1 vial in 50 mL saline for IV

BOTULIN ANTITOXIN TRIVALENT A, B, E

- Indications: Clinical botulism, prior to onset of paralysis
- Warnings:
 - Binds only free toxins
 - Not for infant botulism
 - Equine serum derived: Immediate hypersensitivity, serum sickness 10–14 days
 - Premedicate for anaphylaxis if know equine serum hypersensitivity.
 - Administer slow IV push.
- Dose: 1–2 vials IV q4h for 4 or 5 doses; reconstitute 1 vial with 2 mL sterile water. Administer 0.5 mL/kg/h IV. Double rate after 15 min if no ill effects.

CALCIUM

- **Indications:**
 - Hyperkalemia with cardiac toxicity
 - Hydrofluoric acid burn
 - Calcium channel blocker overdose
 - Citrate, oxalate, phosphate poisoning
- **Warnings:**
 - Avoid in digoxin toxicity, hypercalcemia
 - Calcium chloride (CaCl) corrosive to skin, SC tissue
 - Incompatible with certain IV solutions
 - Administer slow IV push.
- **Dose:**
 - Adult: 5–10 mL of 10% CaCl, or 10–20 mL of 10% Ca gluconate
 - Pediatric: 0.1–0.2 mL/kg of 10% CaCl, or 0.2–0.3 mL/kg of 10% Ca gluconate

CALCIUM EDTA (EDETATE DISODIUM)

- **Indications:** Lead, chromium, nickel, manganese, zinc toxicity
- **Warnings:** Nausea, vomiting, chill, nephrotoxicity, hypercalcemia
- **Dose:** 1 g/m²/day IV over 8–12 hr for 5 days, skip 2–4 days, then repeat. Follow lead (Pb) level

CORAL SNAKE ANTIVENIN (MICRURUS FULVIUS)

- **Indications:** Eastern or Texas coral snake
- **Warnings:**
 - Equine serum derived: Immediate hypersensitivity, serum sickness 10–14 days
 - Premedicate for anaphylaxis if we know the equine serum hypersensitivity.
- **Dose:** 4–10 vials slow IV push over 15–30 min

CYANIDE ANTIDOTE KIT

- **Indications:** Cyanide poisoning
- **Warnings:** Hypotension, methemoglobinemia
- **Dose:**
 - Amyl nitrite: 1–2 amp crushed, inhaled
 - Use amyl nitrite only until IV access is established
 - Sodium nitrite:
 - Adult: 300 mg in 10 mL IV over 5 min
 - Pediatric: 0.3 mL/kg of 3% solution IV
 - Sodium thiosulfate:
 - Adult: 12.5 g IV, may repeat in 1 hr
 - Pediatric: 50 mg/kg IV

HYDROXOCOBALAMIN

- Indications: Cyanide poisoning
- Warnings: Erythema, HTN
- Dose:
 - Adult: 5 g IV over 15 min; may repeat a 2nd 5 g dose depending on severity of poisoning and clinical response. Max. 10 g. Reconstitute each 2.5 g vial with 100 mL 0.9% NaCl
 - Pediatric: Safety and efficacy have not been established in children. Suggested initial dose: 70 mg/kg IV.

DANTROLENE

- Indications:
 - Malignant hyperthermia
 - Neuroleptic malignant syndrome
 - Serotonin syndrome
 - Muscle rigidity
- Warnings: Muscle weakness, respiratory depression, hepatitis
- Dose: 1–2 mg/kg IV bolus, repeat q10–15 min PRN, max. 10 mg/kg

DEFEROXAMINE (DESFERAL)

- Indications: Iron toxicity
- Warnings:
 - Do not treat for > 24 hr, risk for delayed adult respiratory distress syndrome (ARDS).
 - Hypotension if > 15 mg/kg/h, flushing, urticaria
- Dose: 10–15 mg/kg/h IV, may increase in severe iron (Fe) poisoning

DIGOXIN ANTIBODY (DIGIBIND)

- Indications: Digoxin, digitoxin toxicity
- Warnings:
 - Falsely elevated digoxin levels after use
 - Development of CHF/atrial fibrillation in patients requiring digoxin
- Dose:
 - 1 vial (40 mg) binds 0.6 mg digoxin.
 - Number of vials = digoxin level (ng/mL) × weight (kg)/100
 - Dose estimate: Acute overdose 10–20 vials, chronic overdose 4–6 vials

DIMERCAPROL (BAL)

- Indications: Arsenic, gold, mercury, lead-induced encephalopathy
- Warnings: Renal toxicity, fever, nausea, vomiting, urticaria, cholinergic symptoms
- Dose:
 - 3 mg/kg deep IM q4h for 2 days, then q12h for 7 days; follow metal levels
 - For Pb level > 100 µg/dL: 4–5 mg/kg IM q4h until Pb < 50 µg/dL, in

conjunction with EDTA

DIPHENHYDRAMINE (BENADRYL)

- Indications: Antihistamine, acute dystonic reaction
- Warnings: Sedation, excitation in children, anticholinergic symptoms
- Dose:
 - Adult: 25–50 mg IV/IM/PO q4–6h
 - Pediatric: 0.5–1 mg/kg IV/IM/PO q4–6h

SUCCIMER, CHEMET

- Indications: Pediatric lead poisoning
- Warnings:
 - Caution in renal impairment—urinary elimination
 - Nausea, vomiting diarrhea
- Dose: 10 mg/kg PO q8h for 5 days, then q12h for 14 days, then reassess blood lead levels

EPINEPHRINE

- Indications: Angioedema, anaphylaxis, acute asthma, spinal shock, β -blocker overdose
- Warnings: Dysrhythmias, HTN, tremor, anxiety
- Dose:
 - Hypotension/shock:
 - Adult: 1–4 μ g/min IV infusion
 - Pediatric: Start IV infusion at 0.1 μ g/kg/min.
 - Anaphylaxis
 - Adult: 0.3–0.5 mg IM/SC
 - Pediatric: 0.01 mg/kg IM/SC

ETHANOL

- Indications: Methanol or ethylene glycol toxicity
- Warnings:
 - Disulfiram reaction, CNS sedation
 - Hypoglycemia in pediatric population
 - Increase dose during dialysis, for chronic alcoholics.
- Dose:
 - IV: 10 mL/kg load as 10% solution over 1 hr, then 1 mL/kg/h maintenance
 - PO: 1.5 mL/kg as 100-proof solution, then 0.3 mL/kg/h maintenance
 - Goal: Ethanol level of 100–150 mg/dL

FLUMAZENIL (ROMAZICON)

- Indications: Benzodiazepine overdose
- Warnings:

- Contraindicated in tricyclic antidepressant (TCA) overdose
- Lowers seizure threshold
- Induces benzodiazepine withdrawal
- Dose:
 - Adult: 0.2 mg IV slow, repeat q2–3min to 1 mg max.
 - Pediatric: 0.01–0.05 mg/kg IV over 30 min–1 hr

FOMEPIZOLE (4-MP, ANTIZOL)

- Indications: Methanol or ethylene glycol toxicity
- Warnings: Nausea, dizziness, headache
- Dose: 15 mg/kg load IV, then 10 mg/kg q12h for 4 doses, then 15 mg/kg q12h

GLUCAGON

- Indications:
 - β -blocker or calcium channel blocker overdose with bradycardia/hypotension
 - Hypoglycemia
- Warnings:
 - Nausea, vomiting, hyperglycemia
 - Hypotension from diluent (phenol containing)
- Dose:
 - β -blocker or calcium channel blocker overdose:
 - Adult: 5–10 mg IV over 1 min
 - Pediatric: 0.15 mg/kg IV over 1 min
 - Hypoglycemia:
 - Adult: 0.5–1 mg IM/IV/SC
 - Pediatric: 0.025–0.1 mg/kg IM/IV/SC (max. 1 mg per dose)

INSULIN/GLUCOSE

- Indications:
 - Calcium channel blocker overdose with severe hypotension/symptomatic bradycardia refractory to other therapies
 - Hyperkalemia
- Warnings:
 - Experimental therapy: Consult a poison control center/medical toxicologist.
 - Follow serum glucose q15min for 1 hr after the 1st bolus or after any increase in dose, then q1h
- Dose:
 - Bolus:
 - 0.5–1 IU/kg regular insulin, followed by 25 g glucose (1 amp D₅₀)
 - Maintenance:
 - Insulin 0.5 IU regular insulin per kg/hr, titrate to 1 IU regular insulin per kg/hr

- Glucose D₁₀ start at 100 mL/h (10 g/h) and titrate to keep glucose ≥ 100 mg/dL

INTRALIPIDS

- Indications:
 - Cardiac arrest due to local anesthetic toxicity, most commonly bupivacaine, however may be useful for other lipid-soluble drugs
- Warnings:
 - Experimental therapy: Consult a poison control center/medical toxicologist.
- Dose:
 - Intralipid 20% bolus; 1.5 mL/Kg over 1 min followed by infusion 0.25 mL/kg/min.
 - Repeat bolus in 3–5 min if circulation not restored.

METHYLENE BLUE

- Indications: Methemoglobinemia with dyspnea or > 25%
- Warnings: G6-PD deficiency
- Dose: 1–2 mg/kg slow IV as 1% solution, repeat in 1 hr

NARCAN

- Indications:
 - Opiate poisoning, empiric treatment of coma
- Warnings:
 - Acute opiate withdrawal, severe agitation
- Dose:
 - Adult: 0.4–2 mg IV or IM, repeat to 10 mg
 - Pediatric: 0.1 mg/kg IV or IM

OCTREOTIDE

- Indications: Sulfonylurea overdose with hypoglycemia
- Warnings: Use with caution in diabetic patients.
- Dose:
 - Adult: 50 µg SC q6h
 - Pediatric: 4–5 µg/kg/d SC div. q6h

OXYGEN, HYPERBARIC

- Indications: Carbon monoxide (CO) poisoning
- Warnings:
 - Tympanic membrane (TM) perforation, seizures owing to oxygen toxicity
 - Difficulty monitoring patient
- Dose: 100% oxygen at 2–3 atm

PENICILLAMINE

- Indications: Arsenic, copper, lead, mercury with/following BAL or EDTA
- Warnings: Contraindicated in penicillin allergy, renal insufficiency
- Dose:
 - _ Lead:
 - Adult: 250–500 mg per dose PO q8–12h
 - Pediatric: 25–40 mg/kg/d PO in 3 div. doses
 - _ Arsenic: 100 mg/kg/d PO div. in 4 doses for 5 days (max. 1 g/d)
 - _ Mercury:
 - Adult: 250 mg PO QID
 - Pediatric: 20–30 mg/kg/d PO in 4 div. doses

PHENTOLAMINE

- Indications:
 - _ Hypertensive crisis: Stimulants, sympathomimetics, MAO–tyramine reaction, and extravasated pressors
 - _ Reversal of cocaine-mediated vasospasm
- Warnings: HTN, tachycardia, dysrhythmias
- Dose:
 - _ HTN (HTN):
 - Adult: 1–5 mg IV bolus
 - Pediatric: 0.02–0.1 mg/kg bolus
 - _ Extravasation:
 - Adult: 5 mg diluted in 10–15 mL saline SC
 - Pediatric: 0.1 mg/kg diluted in 10–15 mL saline SC

PHYSOSTIGMINE

- Indications: Severe anticholinergic syndrome
- Warnings: Contraindicated in TCA overdose
- Dose:
 - _ Adult: 0.5–1 mg IV, repeat in 10 min PRN
 - _ Pediatric: 0.02 mg/kg IV, repeat in 10 min PRN

PRALIDOXIME (2-PAM, PROTOPAM)

- Indications:
 - _ Organophosphate toxicity
 - _ Reversal of nicotinic effects
 - _ Reactivates enzyme
 - _ Use in conjunction with atropine
- Warnings:
 - _ Myasthenic crisis if myasthenia gravis
 - _ Nausea, headache, dizziness, laryngospasm, muscle rigidity
- Dose:
 - _ Adult: 1–2 g IV in 100 mL NaCl over 15 min, repeat in 1 hr PRN, repeat in 6

hr if nicotinic symptoms return

- Pediatrics: 25–50 mg/kg over 15 min, repeat in 1 hr PRN, repeat in 6 hr if nicotinic symptoms return

PROTAMINE

- Indications: Reversal of heparin anticoagulation
- Warnings:
 - Hypersensitivity in patients with fish allergy
 - Avoid benzyl alcohol diluent in neonates.
- Dose: 1 mg for each 100 IU heparin, 1/2 dose if 30–60 min; 1/4 dose if 2 hr after heparin bolus;
 - 25–50 mg slow IV over 15 min. Initial dose should not be > 50 mg

PYRIDOXINE (VITAMIN B₆)

- Indications:
 - Isoniazid-induced seizures
 - *Gyromitra* mushroom
- Warnings: None, nontoxic
- Dose:
 - Isonicotinic acid hydrazide (INH)–induced seizures:
 - Unknown ingested amount: 5 g for adult or 1 g for pediatrics
 - Dose (mg) = amount INH ingested (mg)
 - *Gyromitra*: 25 mg/kg IV over 30 min–1 hr

RATTLESNAKE ANTIVENIN (CROTALINE)

- Indications: Significant envenomation by *Crotaline* species: Rattlesnake, cottonmouth, water moccasin, pit viper
- Warnings:
 - Ovine-derived products: Immediate hypersensitivity, serum sickness 10–14 days
 - Premedicate for anaphylaxis if we know the equine/ovine serum hypersensitivity.
- Dose:
- Ovine derived (CroFab):
 - 4–6 vials slowly; may repeat dose of 4–6 vials if control of envenomation not achieved, then 2 vials q6h for 3 doses
 - Reconstitute each vial with 25 mL sterile water. Dilute in 250 mL 0.9% NaCl and infuse over 1 hr.

VITAMIN K (PHYTONADIONE, AQUA MEPHYTON)

- Indications: Reversal of Coumadin anticoagulation
- Warnings: Hypersensitivity from IV administration
- Dose:

- 2–10 mg SC/slow IV, may repeat in 8 hr
- 2–10 mg PO, may repeat in 12–48 hr

CODES

ICD9

ICD10
T65.91XA Toxic effect of unspecified substance, accidental (unintentional), initial encounter

POISONING, GASTRIC DECONTAMINATION

Frank LoVecchio

BASICS

DESCRIPTION

Modalities to decontaminate the GI tract of poisons

TREATMENT

ALERT

- Ipecac is contraindicated in ambulance setting.
- Controversies:
 - _ Home use of ipecac in general is not recommended.
 - _ In extremely rare cases (e.g., very prolonged transit times, protecting airway), consider ipecac administration only after consultation with regional poison control center.
 - _ Decreased time to activated charcoal administration when given in pre-hospital setting

INITIAL STABILIZATION/THERAPY

- Airway, breathing, and circulation management (ABCs):
 - _ Secure airway for decreased mental status/inability to protect airway.
 - _ IV access
 - _ Cardiac monitor
- With altered mental status from overdose:
 - _ Naloxone
 - _ Thiamine
 - _ Dextrose (or Accu-Chek)

ED TREATMENT/PROCEDURES

- Activated charcoal:
 - _ General:
 - Prepared by treating heated wood pulp, which creates a large surface area to bind toxins
 - Mainstay of gastric decontamination
 - Effective when contents have reached small intestine
 - _ Dose:
 - 1–2 g/kg of body weight or an activated charcoal-to-drug ratio of 10:1; often mixed with sorbitol (see below)
 - Oral or nasogastric tube administration

- Indications:
 - Administer in every toxic ingestion (see below for exceptions).
 - Optimal for toxic ingestions presenting within 1 hr of ingesting a drug that is absorbed by charcoal in a patient with a patent airway
- Adverse effects:
 - Vomiting and constipation
 - Charcoal aspiration and subsequent charcoal pneumonitis
- Contraindications:
 - Caustic ingestions
 - Unprotected airway
 - Bowel obstruction or ileus
- Drugs not effectively bound to charcoal:
 - Metals (borates, bromide, iron, lithium)
 - Alcohols
 - Potassium
 - Potassium cyanide (poorly absorbed)
 - Hydrocarbons
 - Caustics
- Pediatric considerations:
 - Mix with palatable substance (cola or juice) to facilitate intake or administer via gastric tube.
- Controversies:
 - Randomized, controlled trials have shown a slightly worse outcome and higher complication rate when *asymptomatic* patients received charcoal vs. nothing.
 - An extremely small minority of patients are likely to benefit from gastric lavage.
- **Multiple-dose activated charcoal:**
 - General:
 - Used in toxic ingestions that are well absorbed by charcoal and undergo enterohepatic circulation
 - Dose:
 - 1 g/kg followed by 0.5 g/kg q2–6h
 - Never use cathartics in conjunction with multiple-dose activated charcoal.
 - Indications:
 - Salicylates
 - Theophylline
 - Multiple-dose activated charcoal may decrease area under the curve for drugs such as phenobarbital, phenytoin, and carbamazepine but has not been proven to improve outcome.
- **Cathartics:**
 - General:

- Used in combination with activated charcoal to prevent constipation and to enhance GI transit time
- Limited data available to demonstrate any decreased absorption when a cathartic (sorbitol) is added to activated charcoal
- Cathartics alone are of no proven benefit and should be avoided.
- *Never* use cathartics in conjunction with multiple-dose activated charcoal.

– Dose:

- Magnesium citrate: 10% solution: 250 mL (peds: 4 mL/kg)
- Magnesium sulfate: 15–20 g (peds: 250 mg/kg)
- Sorbitol: 0.5–1 g/kg to a max. 100 g of 70% solution (peds: > 1 yr old: 0.5–1 g/kg as a 35% solution to a max. 50 g) PO mixed in the activated charcoal slurry—use only in 1st dose.

– Adverse effects:

- Dehydration
- Hypermagnesemia
- Diarrhea
- Abdominal discomfort

– Contraindications:

- Pre-existing dehydration
- Renal disease (cathartics containing magnesium)
- Avoid in children

– Controversies:

- No proven benefit and some cases of harm reported

● **Whole-bowel irrigation:**

– General: Cleansing of bowel

– Indications:

- Toxins not well absorbed by charcoal, such as toxic iron and lithium ingestions
- Toxins in sealed containers (body packers) without signs of GI perforation
- Toxic, sustained-release product ingestions

– Dose:

- Polyethylene glycol (Colyte, GoLytely)
- Solution at 2 L/hr in adults (0.5 L/hr in children) until rectal excretions clear
- Administer via nasogastric tube with activated charcoal via continuous or bolus method as indicated.

– Adverse effects:

- Bloating
- Rectal irritation
- Frequent bowel movements

– Contraindications:

- Mechanical or pharmacologic ileus
- Bowel obstruction
- Hypotension
- Intestinal perforation
- Unprotected airway
- **Orogastric lavage:**
 - General:
 - Placement of large-bore tube (32F–36F) in stomach for removal of ingested toxins
 - Effectiveness of orogastric lavage depends on time since ingestion, timing of last meal, and toxin ingested.
 - Protected airway is essential prior to any attempts at orogastric lavage.
 - Indications:
 - Currently, rarely performed
 - Presentation within 1 hr of taking a potentially lethal ingestion with no known antidote
 - Poisoned intubated patient arriving within ~ 1 hr
 - Adverse effects:
 - Intubation of respiratory tree
 - Esophageal or gastric perforation
 - Charcoal aspiration
 - Patient discomfort
 - Contraindications:
 - Large pills (limited by lavage-tube port size) ingestion
 - Caustics (acids and alkali) ingestion
 - Hydrocarbon ingestion
 - Ingestion of agents that rapidly depress mental status
 - Unprotected airway
 - Pediatric considerations:
 - Avoid in children
 - Unlikely to result in any clinically significant pill extraction secondary to smaller-bore orogastric tube (i.e., 18F)
 - Risk of aspiration increased in children
 - Controversies: Several randomized, controlled trials have documented no benefit when lavage plus activated charcoal is compared with activated charcoal alone.
- **Ipecac:**
 - General:
 - Rarely used
 - Derived from the roots of the plant *Cephaelis acuminata*
 - Exerts emetic action by direct gastric irritation and centrally mediated chemoreceptive trigger-zone stimulation

- Delays administration of activated charcoal
- Offers no advantage over activated charcoal alone when both treatments are potentially effective
- Dosage:
 - >12 yr: 30 mL
 - 1–12 yr: 15 mL
 - 6 mo–1 yr: 5–10 mL + 15 mL clear fluid
- Indications:
 - No utility in ED
- Adverse effects:
 - Vomiting may complicate and worsen clinical presentation.
 - Delay to administration of activated charcoal or oral antidotes
- Contraindications:
 - Caustics (acids and alkali) ingestion
 - Hydrocarbon ingestion
 - Ingestion of agents that rapidly depress mental status
 - Patient actively vomiting

PEARLS AND PITFALLS

- Ipecac has no utility in the ED.
- Administer activated charcoal in almost every toxic ingestion that presents within 1 hr with a patent airway
- Never use multiple doses of cathartic in conjunction with multiple-dose activated charcoal.

POISONING, TOXIDROMES

Michael S. Wahl

BASICS

DESCRIPTION

- A toxidrome is the constellation of signs and symptoms that result from the effects of a particular toxin (toxic syndrome)
- Mechanism of action varies with each class of toxin to which the patient may be exposed and the target receptors.

DIAGNOSIS

SIGNS AND SYMPTOMS

Toxidromes

- There are multiple toxidromes:
 - Anticholinergic
 - Cholinergic
 - Sympathomimetic
 - Hallucinogenic
 - Opiate
 - Sedative–hypnotic
 - Withdrawal syndromes
 - Serotonin syndrome
 - Malignant neuroleptic syndrome
- **Anticholinergic:** Mnemonic: *“Blind as a bat, mad as a hatter, red as a beet, hot as a hare, dry as a bone, the bowel and bladder lose their tone, and the heart runs alone”*:
 - Hyperthermia (“hot as a hare”)
 - Dry, flushed skin (“dry as a bone” and “red as a beet”)
 - Dilated pupils (“blind as a bat”)
 - Delirium (“mad as a hatter”)
 - Tachycardia (“the heart runs alone”)
 - Hypertension
 - Hyperthermia
 - Urgency retention (“bowel and bladder lose their tone”)
 - Decreased bowel sounds (“bowel and bladder lose their tone”)
 - Seizures
 - Mental status changes
 - Somnolence
- **Cholinergic:** Mnemonic: *DUMBELS for the muscarinic component*:
 - Muscarinic signs:

- Diarrhea, diaphoresis
- Urination
- Miosis
- Bradycardia, bronchorrhea, bronchospasm (the killer Bs)
- Emesis
- Lacrimation
- Salivation
- Nicotinic signs:
 - Mydriasis
 - Tachycardia
 - Weakness
 - Hypertension
 - Fasciculations
- **Sympathomimetic:** Similar to anticholinergic presentation except for skin and bowel differences (diaphoresis and increased bowel sounds may be present in sympathomimetic presentations):
 - Diaphoresis
 - Mydriasis
 - Tachycardia
 - Hypertension
 - Hyperthermia
 - Seizures
 - Increased peristalsis
- **Hallucinogenic:** May have significant overlap with sympathomimetic toxidrome as many sympathomimetic drugs have hallucinogenic properties (e.g., MDMA/ecstasy, cathinones, hallucinogenic amines). Other hallucinogens include LSD, psilocybin, peyote, mescaline:
 - Disorientation
 - Hallucinations
 - Anxiety
 - Panic
 - Seizures
- **Opiate:**
 - Classic triad:
 - Miosis
 - Hypoventilation
 - Coma
 - May also present with:
 - Bradycardia
 - Hypotension
 - Hypothermia
 - Decreased bowel sounds
- **Sedative–hypnotics and alcohol:**

- Sedation
- Mental status changes (confusion, delirium, hallucinations)
- Vision changes (blurred vision, diplopia)
- Slurred speech
- Ataxia
- Nystagmus
- **Withdrawal** (alcohol, benzodiazepine, barbiturates):
 - Mydriasis
 - Tachycardia
 - Hypertension
 - Hyperthermia
 - Increased respiratory rate
 - Diaphoresis
 - Increased bowel sounds
 - Tremor
 - Agitation
 - Anxiety
 - Hallucinations
 - Confusion
 - Seizures
- **Withdrawal** (opioid):
 - Nausea
 - Vomiting
 - Diarrhea
 - Abdominal cramps
 - Increased bowel sounds
 - Mydriasis
 - Piloerection
 - Tachycardia
 - Lacrimation
 - Salivation
 - Hypertension
 - Yawning
- **Neuroleptic malignant syndrome:**
 - Recent treatment with typical and atypical antipsychotic medications:
 - Generally occurs from hours to several weeks of starting or increasing the dose of a medication, but can occur at any time.
 - Hyperthermia
 - Muscular rigidity
 - Diaphoresis
 - Mental status changes
 - Hypertension or hypotension may be seen
 - Sialorrhea

- Tremor
- Incontinence
- Increased creatinine phosphokinase
- Leukocytosis
- Metabolic acidosis
- **Serotonin syndrome:**
 - Occurs soon after the increase in dose or addition of serotonergic medications.
 - Syndrome with variable presentation
 - Following are most common, seen 25–57% of the time:
 - Mental status changes (confusion, agitation, hypomania, lethargy)
 - Seizures
 - Myoclonus
 - Hyperreflexia
 - Muscle rigidity
 - Tremor
 - Nystagmus
 - Hyperthermia
 - Diaphoresis
 - Tachycardia
 - Hypertension
 - Mydriasis

Physical-Exam

- **Bradycardia:**
 - α_2 -adrenergic agonists (e.g., clonidine)
 - β -blockers
 - Calcium-channel blockers
 - Digoxin and related substances
 - Cholinergics
 - Opioids
- **Tachycardia:**
 - Sympathomimetics
 - Anticholinergics
 - Methylxanthines
 - Tricyclic antidepressant
 - Withdrawal
 - Phenothiazines
 - Atypical antipsychotics
 - α_1 -blockade with reflex tachycardia
 - Phosphodiesterase type 5 inhibitor (e.g., Sildenafil)
- **Hyperthermia:**

- Anticholinergics
- Sympathomimetics
- Serotonin syndrome
- Neuroleptic malignant syndrome
- Malignant hyperthermia
- Dinitrophenol
- Salicylates
- Withdrawal
- **Hypothermia:**
 - Carbon monoxide
 - Oral hypoglycemics
 - Opiates
 - Ethanol
 - Sedative–hypnotics
 - α_2 -adrenergic agonists
- **Hypertension:**
 - Sympathomimetics
 - Anticholinergics
 - Nicotine
 - Phencyclidine (PCP)
 - Ergot alkaloids
- **Hypotension:**
 - α_2 -agonists
 - α_1 -antagonists
 - β -blockers
 - Calcium-channel blockers
 - Angiotensin converting–enzyme inhibitors
 - Methylxanthines
 - Nitrates
 - Opioids
 - Phenothiazines
 - Phosphodiesterase type 5 inhibitors
 - Sedative–hypnotics
 - Ethanol
 - Tricyclic antidepressants
 - Atypical antipsychotic medications
- **Miosis:**
 - Cholinergics
 - Clonidine
 - Reserpine
 - Phenothiazines
 - Atypical antipsychotics

- **Mydriasis:**
 - Anticholinergics
 - Sympathomimetics
 - Withdrawal (esp. opioids)
 - Botulism
- **Seizures:** *Mnemonic with a limited list of causes for toxic seizures OTIS CAMPBELL:*
 - Organophosphates
 - Tricyclic antidepressants
 - Isoniazid, insulin
 - Sympathomimetics, salicylates
 - Camphor, cocaine, citalopram
 - Amphetamines, anticholinergic agents
 - Methylxanthines (theophylline, caffeine), mushrooms (*Gyromitra*: monomethyl hydrazine group), meperidine
 - PCP, propoxyphene, plants (nicotine, water hemlock)
 - Benzodiazepine withdrawal, bupropion
 - Ethanol withdrawal
 - Lithium, lidocaine
 - Lead, lindane
- **Diaphoresis:**
 - Sympathomimetics
 - Cholinergics
 - Salicylates
 - Withdrawal
 - Serotonin syndrome
- **Bradypnea:**
 - Opiates
 - Sedative–hypnotics
 - Ethanol
 - γ -hydroxybutyric acid and congeners
 - Botulism
 - Muscular receptor blockade
- **Tachypnea:**
 - Paraquat (and other drugs that cause pneumonitis)
 - Salicylates
 - Sympathomimetics
 - Dinitrophenol
 - Methylxanthines
 - Drugs that cause acidosis

Dermatologic

- **Mees lines:**
 - Arsenic
 - Thallium

- Chemotherapy agents
- Radiation
- Bullae:
 - Barbiturates
 - Carbon monoxide
 - Captopril
- Flushed or red appearance:
 - Anticholinergics
 - Disulfiram reactions
 - Niacin
 - Boric acid
 - Scombroid poisoning
 - Monosodium glutamate
 - Carbon monoxide (frequently postmortem)
 - Cyanide (rare)
 - Vancomycin
- Blue skin:
 - Ergotamines
 - Methemoglobinemia from:
 - Nitrite
 - Nitrate
 - Dapsone
 - Aniline dye
 - Phenazopyridine
 - Benzocaine
 - Chloroquine
 - Pseudocyanosis from:
 - Chlorpromazine
 - Amiodarone
 - Minocycline
 - Silver (argyria)
 - Gold (chrysiasis)

ESSENTIAL WORKUP

Depends on ingested substance:

- CBC
- Electrolytes, BUN, creatinine, glucose
- Urinalysis
- Arterial blood gas, venous blood gas
- Carboxyhemoglobin, methemoglobin levels
- Toxicology screen
- Aspirin and Acetaminophen level
- Prothrombin time

- Liver function tests

DIAGNOSIS TESTS & INTERPRETATION

- **Anion gap acidosis:** Mnemonic: *A CAT MUD PILES* (encompasses a limited number of common causes):
 - Alcohol ketoacidosis
 - CO/cyanide
 - Acetaminophen in fulminant hepatic failure
 - Toluene
 - Methanol
 - Uremia
 - Diabetic ketoacidosis
 - Paraldehyde, phenformin/metformin
 - Iron, isoniazid
 - Lactic acidosis
 - Ethylene glycol
 - Salicylates, sodium azide, hydrogen sulfide
- **Increased osmolar gap:**
 - Methanol
 - Ethylene glycol
 - Isopropyl alcohol
 - Ethanol
 - Acetone
 - Glycerol
 - Mannitol
 - Glycine

TREATMENT

INITIAL STABILIZATION/THERAPY

ABCs

ED TREATMENT/PROCEDURES

Depends on ingested substance (see Poisoning; Poisoning, Gastric Decontamination)

PEARLS AND PITFALLS

- Obtain appropriate lab tests.
- Recognize signs and symptoms and lab clues to the toxidromes.

POLIO

Philip Shayne • Marie Carmelle Tabuteau

BASICS

DESCRIPTION

- Caused by poliovirus infection
- Incubation period 7–14 days
- Duration < 1 wk
- Clinical manifestations are defined as follows:
 - Subclinical (i.e., not apparent) 90–95%
 - Abortive poliomyelitis 4–8%:
 - Clinically indistinct from many other viral infections (fever, myalgias, malaise)
 - Only suspected to be polio during an epidemic
 - Nonparalytic poliomyelitis 1–2%:
 - Differs from abortive poliomyelitis by the presence of meningeal irritation
 - Course similar to any aseptic meningitis
 - Paralytic poliomyelitis 0.1%, which is further subdivided:
 - Spinal paralytic poliomyelitis (frank polio)
 - Bulbar paralytic poliomyelitis (10% of paralytic polio): Paralysis of muscle groups innervated by cranial nerves; involves the circulatory and respiratory centers of the medulla with high mortality
 - Mixed bulbospinal poliomyelitis
 - Postpoliomyelitis syndrome:
 - New onset of increased muscle weakness, pain, and focal or generalized atrophy
 - Occurs 8–70 yr after the active illness, usually in the previously affected limb
 - Risk factors include age at time of infection, extent of recovery and female sex (increased risk with better recovery)
 - Gradual progression

ETIOLOGY

- Polioviruses:
 - Picornaviruses
 - Small, nonenveloped RNA viruses of the enterovirus genera
 - 3 subtypes: 1, 2, 3
- Fecal–oral route transmission
 - Enters through oral cavity

- Replicates in pharynx, GI tract, and lymphatics
- Humans are the only natural host and reservoir
- Poliovirus selectively destroys motor and autonomic neurons
- Natural (wild) virus has been completely eliminated in US since 1979
- Oral poliovirus vaccine (OPV):
 - Accounts for only poliomyelitis seen in US
 - 8–10 cases/yr of vaccine-associated paralytic poliomyelitis (VAP): Neurovirulent conversion of vaccine virus; decreased since widespread use of inactivated poliovirus vaccine (IPV)
 - VAP occurs in poorly immunized regions by acquiring properties of wild-type virus.
 - There has been a recent increase in some third world countries

DIAGNOSIS

SIGNS AND SYMPTOMS

- Primarily asymptomatic
- Viral symptoms: Fever, headache, malaise. Respiratory symptoms: Sore throat, fatigue GI symptoms: Nausea, vomiting
- Nonparalytic aseptic meningitis: Stiff neck, and or back
- Muscle pain and weakness
- Progressive weakness for < 1 wk:
- Dysphagia and dysarthria with bulbar involvement

History

- Vaccination history
- History of prior polio infection
- Recent exposure to individual vaccinated with OPV
- Recent travel to endemic countries (Nigeria, Pakistan, India, Afghanistan)
- Comorbid conditions affecting immunocompetence especially B-lymphocyte disorders (e.g., hypogammaglobulinemia and agammaglobulinemia)

Physical-Exam

- Fever (37°C –39°C)
- Headache, photophobia
- Nuchal rigidity
- Neurologic changes:
 - Muscle soreness that becomes severe muscle spasm, progressing rapidly to spotty flaccid weakness and paralysis
 - Asymmetric paralysis more prominent in the lower than the upper extremities
 - Urinary retention (50% of paralytic cases)

- Reflexes initially hyperactive, then absent
- Apprehensive and irritable, occasionally drowsy
- No sensory loss associated with the motor deficit

Pediatric Considerations

More likely to have a biphasic acute course:

- Viral-type syndrome for 1–2 days
- Symptom-free period of 2–5 days
- Then an abrupt onset of the major illness

ESSENTIAL WORKUP

- Clinical diagnosis
- Differentiate from other causes of acute paralysis.
- Notify public health officials when diagnosis suspected.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - WBC normal or mildly elevated
- Diagnosis confirmed by:
 - Comparing acute with convalescent sera for antigen titers
 - Isolation of virus from blood, CSF, stool, throat secretions (within week 1 of infection)

Diagnostic Procedures/Surgery

- Lumbar puncture/CSF analysis:
 - Abnormalities typical of aseptic meningitis (increased lymphocytes and elevated protein)
 - Poliovirus rarely isolated from the CSF
- Electrodiagnostics:
 - Normal to slow motor function
 - Sensory function intact

DIFFERENTIAL DIAGNOSIS

- Abortive poliomyelitis is similar to many viral illnesses.
- Nonparalytic poliomyelitis is indistinguishable from any viral, aseptic meningitis.
- Paralytic poliomyelitis:
 - Amyotrophic lateral sclerosis
 - Guillain–Barré (not febrile, symmetric, not ill appearing)
 - Acute transverse myelitis
 - Spinal cord compression/infarction
 - Multiple sclerosis

- Rhabdomyolysis
- Acute intermittent porphyria
- West Nile virus
- Diphtheria
- Botulism
- Tick paralysis
- Encephalitis

TREATMENT

ALERT

Rare fatal cases come from respiratory insufficiency, which requires prompt ventilatory support.

INITIAL STABILIZATION/THERAPY

Aggressive pulmonary toilet and early intubation mandated for respiratory insufficiency

ED TREATMENT/PROCEDURES

- Supportive and symptomatic management
- Analgesics for severe muscle pain and spasm
- Bed rest to prevent augmentation or extension of paralysis
- Paralytic poliomyelitis tends to localize to a limb that has been the site of intramuscular injection or injury within 2–4 wk prior to the onset of infection:
 - Avoid any unnecessary tissue damage in suspected cases
 - No antiviral agents available
 - Prevention
- Prevention
- IPV:
 - Costly
 - Painful
 - No conferred immunity
 - No VAP, which previously accounted for all poliomyelitis cases in US
- OPV:
 - Accounted for only poliomyelitis seen in US (8–10 cases/yr)
 - Incidence of VAP: 1/900,000 (immunocompromised: 1/1,000):
 - Most at risk are the underimmunized young and their caretakers.
 - Confers immunity to unvaccinated contacts by fecal–oral spread.
 - Inexpensive
 - No longer available in US
 - Still remains the vaccine recommended by WHO Expanded Program on Immunization

FOLLOW-UP

DISPOSITION

Admission Criteria

All acute-phase paralytic poliomyelitis for strict bed rest and observation for respiratory symptoms:

- Isolate from nonvaccinated personnel.

Discharge Criteria

No evidence of nervous system involvement and no danger of contact with nonvaccinated population:

- Deterioration of muscle strength usually ends after 3–5 days

FOLLOW-UP RECOMMENDATIONS

Physical therapy:

- Only 1/3 of the people with acute flaccid paralysis regain full strength
- Lamotrigine may decrease pain, improve symptoms and quality of life.
- IV immunoglobulin (IVIg) may improve muscle strength, has not been proven to decrease pain or improve quality of life.

PEARLS AND PITFALLS

- Most cases are asymptomatic, with symptoms ranging from viral illness to acute flaccid paralysis.
- IPV is the only vaccine available in US; however OPV is still the vaccine of choice for global eradication.
- Diagnosis is primarily clinical and is confirmed by virus isolation from blood, CSF, stool, or throat secretions.
- Treatment is supportive; all acute-phase paralytic poliomyelitis patients should be admitted for observation with close monitoring of the respiratory system.
- If the patient survives the acute stage, paralysis of respiration and deglutition usually recovers completely.
- Paralytic poliomyelitis may occur decades after initial infection and manifests with neurologic and non-neurologic symptoms.

POLYCYTHEMIA

David N. Zull

BASICS

DESCRIPTION

- Increase in hemoglobin (Hgb) above the normal range:
 - _ Men: Hgb > 17.5 g/dL, hematocrit (Hct) > 52%
 - _ Women: Hgb > 16 g/dL, Hct > 48%
- Symptoms are related to blood viscosity, which increases exponentially at Hct > 60%.

ETIOLOGY

- Relative (apparent) polycythemia:
 - _ Resulting from decrease in plasma volume
 - _ Acute: Dehydration
 - _ Chronic: Gaisbock syndrome (stress polycythemia): Obese, hypertensive, middle-aged smokers
- Primary erythrocytosis:
 - _ Polycythemia vera (PV): A stem cell disorder characterized by panhyperplasia of all bone marrow elements leading to increased production of RBCs, WBCs, and platelets. Erythrocytosis is the most prominent feature:
 - Mutation in the tyrosine kinase (JAK2), which acts in signaling pathways of the EPO-receptor, rendering those cells hypersensitive to erythropoietin
 - Median age 60, 5% < 40, peak in 70s
 - Higher in Ashkenazi Jews and lower in Asians and African Americans.
 - May progress to myelofibrosis or acute leukemia
- Secondary polycythemia:
 - _ Central hypoxia increasing erythropoietin:
 - Chronic pulmonary disease
 - Sleep apnea (5–10% have high Hgb)
 - Obesity hypoventilation syndrome (Pickwickian syndrome)
 - Congenital heart disease (right-to-left shunt)
 - High altitude (chronic)
 - Smoker's erythrocytosis
 - Carbon monoxide poisoning (chronic)
 - Chronic methemoglobinemia
 - _ Renal-mediated causes of increased erythropoietin production:
 - Renal cell carcinoma

- Renal artery atherosclerotic narrowing
- Focal glomerulonephritis
- Postrenal transplant with or without rejection
- Chronic hydronephrosis
- Polycystic kidney disease and renal cysts
- Inappropriate autonomous erythropoietin production:
 - Hepatomas
 - Cerebellar hemangioblastoma
 - Wilms tumor
 - Parathyroid carcinoma and adenoma
 - Ovarian tumors
 - Adrenal adenomas and carcinomas (pheochromocytoma, Cushing)
 - Uterine leiomyomata
- Blood doping:
 - Recombinant erythropoietin abuse
 - Autologous transfusions
- Drug abuse:
 - Chronic cocaine abuse
 - Androgenic steroids
- Genetic disorders with polycythemia:
 - High-affinity Hgb variants
 - Bisphosphoglycerate deficiency
 - von Hippel–Lindau syndrome
 - Chuvash polycythemia
 - Erythropoietin-receptor mutations
 - Congenital methemoglobinemia
- Infections:
 - Viral hepatitis, AIDS

Diagnostic Criteria for Polycythemia Vera

- Major criteria:
 - Hgb > 18.5 g/dL in men, > 16.5 g/dL in women
 - Presence of JAK2 mutation by polymerase chain reaction (PCR) – clinches the dx
 - Oxygen saturation > 92% and no other cause for secondary erythrocytosis
- Minor criteria:
 - Low serum erythropoietin level
 - Bone marrow aspirate and biopsy revealing panhyperplasia
- Adjuncts to diagnosis:
 - Platelets > 400,000/mm³
 - ANC > 10,000 (WBC > 12,000/mm³)
 - Splenomegaly on exam or by CT

- Leukocyte alkaline phosphatase elevation
- B₁₂ >900 pg/mL; unbound vitamin B₁₂-binding capacity >2,200 pg/mL

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- General:
 - Dyspnea
 - Weakness/fatigue
 - Excessive sweating
 - Epistaxis/gingival bleeding
 - Pruritus (40% of PV):
 - Generalized
 - Exacerbated by warm bath or shower
 - Excoriations common in PV
 - Gouty arthritis and tophi
- Neurologic (hyperviscosity):
 - Headache
 - Vertigo/dizziness/tinnitus
 - Lethargy/confusion
 - Paresthesias
 - Cerebrovascular accident/TIAs
- Visual (hyperviscosity):
 - Amaurosis fugax
 - Scotoma/blurred vision
 - Ophthalmic migraine
- Cardiovascular:
 - CHF
 - Angina/myocardial infarction
 - Deep vein thrombosis (DVT)
 - Hypertension
- Extremities:
 - Erythromelalgia:
 - Secondary to capillary sludging
 - Burning pain in the feet or hands
 - Warmth, erythema/cyanosis and puffiness of hand and feet
 - Acral paresthesias
 - Worse at night
 - Relief with cooling and aspirin
 - Pulses intact

- Painful ulcers of fingers and toes (digital ischemia)
- GI (unique to PV):
 - Hepatomegaly/splenomegaly
 - Sudden spleen enlargement in known PV suggests development of myelofibrosis
 - Epigastric discomfort/early satiety
 - Peptic ulcer disease/GI bleed
 - Budd–Chiari syndrome (hepatic vein thrombosis): Ascites and peripheral edema

Physical-Exam

- Hypertension
- Conjunctival suffusion
- Fundus: Venous engorgement
- Ruddy complexion/plethora
- Erythema/rubor of hands, feet, nail beds
- Skin excoriations from severe pruritus
- Splenomegaly (75% in PV)
- Hepatomegaly (30% in PV)
- Thrombotic complications:
 - 2/3 arterial, 1/3 venous
 - Cumulative risk of 2–5% per year
 - TIAs, stroke, MI, digital infarcts
 - Unusual venous thrombosis:
 - Splenic or mesenteric veins
 - Hepatic vein and IVC clot with subsequent cirrhosis/ascites (Budd–Chiari syndrome)
 - Cerebral sinus thrombosis
 - DVT, PE
- Complications of hyperviscosity:
 - Lethargy/confusion
 - Headaches, dizziness, vision changes
 - Crackles/findings of CHF
- Hemorrhagic complications:
 - Ecchymosis
 - Epistaxis
 - Gingival bleeding

ESSENTIAL WORKUP

CBC with platelets

DIAGNOSIS TESTS & NTERPRETATION

Lab

- 1st priority: Distinguish relative from true erythrocytosis:
 - Volume repletion IV or PO, then repeat CBC
- 2nd priority: Evaluate for secondary causes:
 - Pulse oximetry with $pO_2 < 92\%$
 - Carboxyhemoglobin level
 - Erythropoietin level (normal or elevated if secondary)
 - CXR, chest CT, pulmonary function tests
 - Sleep study
 - Hgb electrophoresis
- RBC mass:
 - Cr-51–labeled RBCs by nuclear medicine
 - Concomitant plasma volume with I-131–labeled albumin
 - Not necessary if Hgb > 18.5 in men, or > 16.5 in women
 - Red blood cell mass < 35 mg/kg (males) or < 31 mg/kg (females) is normal.
 - Decreased plasma volume with normal RBC mass verifies relative erythrocytosis.
 - Elevated RBC mass suggests PV or secondary polycythemia.
 - Falsely low if iron deficient or obese
- PV suspected if:
 - Hgb > 18.5 g/dL (men), 16.5 g/dL (women)
 - Absolute neutrophil count $> 10,000$
 - Platelet count $> 400,000$
 - Pulse oximetry $> 92\%$
 - Low erythropoietin level – a major clue
 - Vitamin B₁₂ level elevated in 30% (unbound vitamin B₁₂-binding capacity elevated in 75%)
 - Uric acid elevated in 40%
 - Leukocyte alkaline phosphatase elevated in 70%
 - PCR for JAK2 gene mutation diagnostic of PV (seen in 97%)

Imaging

Abdominal US or CT can detect a splenomegaly

DIFFERENTIAL DIAGNOSIS

See Etiology.

TREATMENT

INITIAL STABILIZATION/THERAPY

ABCs with emphasis on fluid resuscitation if no evidence of CHF

ED TREATMENT/PROCEDURES

Emergency Management of Hyperviscosity Syndrome or Hct > 60%

- Fluid resuscitation to achieve hemodilution:
 - Withhold if evidence of CHF
- Emergency phlebotomy of 250–500 mL of blood over 1–2 hr replacing with an equal amount of 0.9% normal saline (NS)
- Removal of 1,000–1,500 mL of blood over 24 hr with a goal of Hct < 60 or relief of symptoms:
 - Keep Hct > 45.
 - Replace with an equal amount of 0.9% NS.
- Phlebotomize the elderly and those with cardiovascular disease more slowly:
 - Every-other-day phlebotomy
- Emergent surgery with polycythemia:
 - Phlebotomize to Hct of 45 to avoid thrombotic complications postoperatively.
- Thrombocytosis therapy:
 - Administer aspirin if platelet count is 500,000–1,500,000/mm³ and there are no hemorrhagic complications.
- Treat pruritus with diphenhydramine.

Long Term Management

- Phlebotomy: Maintain Hct at 45% for men and 42% for women.
- Aspirin 81 mg daily if thrombocytosis
- Interferon- α (normalizes CBC in 80%):
 - Especially helpful for refractory pruritus and painful splenomegaly
 - Suggested in symptomatic patients < 60 yr
- Anagrelide:
 - Specific for thrombocytosis
 - No risk of leukemia, ideal for younger patients with postphlebotomy thrombocytosis
 - Effective alone and can decrease need for or frequency of chemotherapy
- Hydroxyurea:
 - Mainstay of therapy, especially for patients > 60 yr, with frequent phlebotomy requirements, thrombotic episodes, or refractory thrombocytosis
- Aldylating agents: Busulfan:
 - Severe refractory disease in the elderly
 - High risk of leukemic transformation

Pregnancy Considerations

Temporary remission during pregnancy, no treatment usually needed

Pediatric Considerations

- In the neonate, defined as a peripheral venous Hct > 65%, Hgb > 22 g/dL:
 - Sample must be obtained > 6 hr post delivery.
 - Capillary Hgb and Hct are 10% higher than venous (always rely on venous)
 - 1–5% of neonates
 - Up to 50% of neonates with intrauterine growth retardation
- Etiology:
 - Maternal–fetal hypoxemia secondary to maternal heart or lung disease, diabetes, preeclampsia, hypertension, or smoking
 - Delayed clamping of the umbilical cord with increase cord transfusion
- Symptoms and signs (most asymptomatic):
 - Acrocyanosis/plethoric
 - Tachypnea/respiratory distress
 - Irritable, lethargic, jittery, poor feeding
- Hypoglycemia and hyperbilirubinemia common
- Treatment:
 - Observation and serial CBCs
 - 0.9 NS 100 mL/kg per day (symptomatic)
 - Partial exchange transfusion: Remove 20 mL/kg blood and infuse equal amount of saline (persistent or severe symptoms)
 - Dextrose solutions if hypoglycemia

Geriatric Considerations

Caution with speed of phlebotomy and fluid resuscitation as noted

FOLLOW-UP

DISPOSITION

Admission Criteria

- New diagnosis of polycythemia
- Hct > 60% without symptoms
- Symptoms of hyperviscosity
- Unstable vital signs/significant comorbidities

Discharge Criteria

- Previous diagnosis of polycythemia, Hct < 60, and asymptomatic
- Stable vital signs

Issues for Referral

All patients should be referred to a hematologist or primary care physician.

PEARLS AND PITFALLS

- Criteria for phlebotomy in polycythemia secondary to hypoxemia is not clear. While phlebotomy will decrease viscosity, it may decrease oxygen-carrying capacity.
- It is critical to distinguish PV from secondary causes of erythrocytosis since PV carries a high risk of thrombotic complications.
- Pruritus with water contact and erythromelalgia (pain, paresthesia and rubor in hands/feet) are unique features of PV.

- D75.1 Secondary polycythemia

POLYNEUROPATHY

Sandra A. Deane

BASICS

DESCRIPTION

A peripheral nerve disorder in which many nerves throughout the body malfunction simultaneously:

- Acute polyneuropathy causes:
 - Infectious (toxin producing bacteria, viruses)
 - Autoimmune (Guillain–Barré)
 - Toxic (heavy metals):
 - Lead
 - Mercury
 - Drugs:
 - Anticonvulsants (phenytoin)
 - Antibiotics (chloramphenicol, nitrofurantoin, sulfonamides)
 - Chemotherapy (vinblastine, vincristine)
 - Sedatives (hexobarbital and barbital)
 - Cancer (multiple myeloma)
- Chronic polyneuropathy causes:
 - Diabetes (most common)
 - Alcohol abuse
 - Nutritional deficiencies (Thiamine, B₁₂)
 - Hypothyroidism
 - Liver failure
 - Kidney failure
 - Lung cancer
 - Chronic inflammatory demyelinating polyneuropathy (CIDM)

EPIDEMIOLOGY

Incidence and Prevalence Estimates

- In US, the prevalence of polyneuropathy is ~2% in the general population
- It is 8% in patients >55 yr of age
- The most common cause in US is diabetes and it occurs in ~50% of diabetics on insulin

ETIOLOGY

- Myelin dysfunction:
 - Parainfectious immune response triggered by antigens that cross-react with

- antigens in the peripheral nervous system:
 - Encapsulated bacteria (*Campylobacter* sp., diphtheria)
 - Viruses (enteric or influenza viruses, HIV)
 - Vaccines (influenza)
- Guillain–Barré syndrome:
 - Acute onset due to myelin dysfunction
 - Rapidly progressive weakness and may lead to respiratory failure
- CIDM:
 - Chronic illness of myelin dysfunction
 - Symptoms may recur or progress over months and years
- Vasa nervosum compromise:
 - Vascular supply to nerves compromised leading to nerve infarction
 - Causes:
 - Chronic atherosclerosis
 - Vasculitis
 - Infections
 - Hypercoagulable states
 - Axonopathy
 - Primary dysfunction of the axon
 - Most often the result of toxic–metabolic disorders:
 - Diabetes
 - Nutritional deficiencies
 - Drugs/chemicals

DIAGNOSIS

SIGNS AND SYMPTOMS

- May be acute or chronic
- May be predominately sensory, motor, combined sensory–motor, or autonomic dysfunction

History

- More commonly affects lower extremities than upper extremities and begins distally
- Typical complaints:
 - Dysaesthesias – numbness, burning, or tingling of the extremities
 - Weakness of extremities
 - Difficulty walking
 - Autonomic symptoms:
 - Constipation
 - Loss of bowel/bladder control
 - Sexual dysfunction

- Orthostatic dizziness
- Dry skin
- Decreased sweating

Physical-Exam

- Typically, findings are bilateral symmetrical and stocking glove distribution
- Typical findings:
 - Decreased sensation
 - Decreased vibratory and position sense
 - Decreased motor function
 - Decreased reflexes
 - Muscle atrophy
 - Fasciculations
 - Paralysis
- Findings in specific types of polyneuropathy:
 - Myelin dysfunction (Guillain–Barré – acute and CIDP – chronic):
 - Muscle weakness greater than expected for degree of atrophy
 - Paresthesias
 - Greatly diminished reflexes
 - Proximal and distal symptoms
 - Ischemia to nerve (atherosclerosis, vasculitis, infectious, hypercoagulable):
 - Painful, burning sensory disturbances
 - Decreased pain and temperature sensation
 - Muscle weakness proportional to atrophy
 - Reflexes spared
 - Usually spares proximal nerves
 - Cranial nerve involvement rare
 - Primary axon dysfunction (toxic-metabolic disorders):
 - Have symptoms of either myelin dysfunction, ischemia, or combined
 - Painful
 - Distally symmetrical
 - Stocking glove
 - Lower extremities before upper

ESSENTIAL WORKUP

- Thorough past medical history and physical exam should be obtained to guide testing
- Initial lab testing:
 - CBC
 - Electrolytes
 - Glucose
 - Renal and liver function
 - TSH

- ESR
- ANA
- Vitamin B₁₂
- Folate
- RPR
- HIV
- Hepatitis B and C
- Lyme
- CPK
- Serum protein electrophoresis
- Subsequent lab testing based on history:
 - Heavy metal levels (history of exposure)
 - Genetic testing for genetic neuropathies
 - Serum antibody testing for immune-mediated neuropathies

DIAGNOSIS TESTS & INTERPRETATION

Imaging

Should be guided by history and physical findings

Diagnostic Procedures/Surgery

- Electromyography (EMG)
- Nerve conduction studies
- Lumbar puncture:
 - Increased CSF protein level abnormal
 - Diagnostic of Guillain-Barré syndrome and CIDP
- Skin or nerve biopsy

DIFFERENTIAL DIAGNOSIS

- Primarily to differentiate between various causes of polyneuropathy:
 - Endocrine disease (diabetes)
 - Infections (Guillain-Barré, Lyme disease, HIV, syphilis)
 - Vitamin deficiency
 - Cancer/paraneoplastic
 - Toxins
 - Liver disease
 - Renal failure
 - Genetic disorders
 - Amyloidosis
- Other diseases with similar presentations:
 - Polio
 - Porphyria

- Spinal muscular atrophy
- Catecholamine disorders
- Psychological disorders

TREATMENT

PRE HOSPITAL

Primarily supportive care for ABCs

INITIAL STABILIZATION/THERAPY

- ABCs
- Respiratory support for respiratory failure

ED TREATMENT/PROCEDURES

- Pain control:
 - Parenteral or oral narcotics
 - Tricyclic antidepressants (amitriptyline)
 - Anticonvulsants (gabapentin)
- Plasma exchange or IV immune globulin for acute myelin dysfunction
- Corticosteroids or antimetabolite drugs for chronic myelin dysfunction
- Supportive care for autonomic dysfunction (IVF, pressors)
- Measure Negative Inspiratory Force (NIF) if concerned about respiratory compromise (Normal is \sim -60 cm H₂O)

FOLLOW-UP

DISPOSITION

Admission Criteria

Determined by medical condition and acuity of onset necessitating rapid diagnostic testing:

- Respiratory failure
- BP instability
- Inability to walk or care for self
- Inadequate pain control
- Poor control of underlying disease process
- Rapidly progressing symptoms

Discharge Criteria

- Underlying medical condition stabilized
- No evidence or low risk of respiratory failure or autonomic instability

- Able to care for self
- Adequate pain control
- Access to outpatient follow-up for further testing or management

Issues for Referral

All patients require referral to primary care physician or neurology for ongoing testing and/or management

FOLLOW-UP RECOMMENDATIONS

- Primary care physician
- Neurology
- Physical therapy

PEARLS AND PITFALLS

- Understanding that the potential causes of polyneuropathy are broad and a comprehensive search for the underlying cause will aid in management
- Recognizing those few causes that are at risk for respiratory failure or autonomic instability
- For most causes, treatment consists of controlling underlying disease process

- G62.9 Polyneuropathy, unspecified
- G63 Polyneuropathy in diseases classified elsewhere

POSTPARTUM HEMORRHAGE

AJ Kirk • Marco Coppola

BASICS

DESCRIPTION

- Postpartum hemorrhage (PPH) after 20 wk gestation
- Primary: Hemorrhage occurring ≤ 24 hr after delivery
 - Also known as early PPH
- Secondary: Hemorrhage occurring > 24 hr after delivery (but < 12 wk):
 - Also known as delayed PPH
- Definitions:
 - > 500 mL after vaginal delivery
 - $> 1,000$ mL after C-section
- Occurs in 4% of vaginal deliveries
- Occurs in 6% of C-sections
- Leading cause of death in pregnancy worldwide
 - Accounts for 25% of pregnancy-related deaths
 - $\sim 50\%$ of postpartum deaths are due to PPH
- 95% of PPH caused by:
 - Uterine atony (50–60%)
 - Retained placenta (20–30%)
 - Cervical/vaginal lacerations (10%)
- Complications:
 - Hypovolemic shock
 - Blood transfusion
 - Acute respiratory distress syndrome
 - Renal and/or hepatic failure
 - Sheehan syndrome
 - Loss of fertility
 - Disseminated intravascular coagulopathy (DIC)

ETIOLOGY

- 4 Ts:
 - Tone
 - Tissue
 - Trauma
 - Thrombin
- Immediate:
 - Uterine atony
 - Lower genital lacerations

- Retained placental tissue
- Placenta accreta
- Uterine rupture
- Uterine inversion
- Puerperal hematoma
- Coagulopathies
- Delayed:
 - Retained products of conception
 - Postpartum endometritis
 - Withdrawal of exogenous estrogen
 - Puerperal hematoma
- Coagulopathies:
 - Pre-existing idiopathic thrombocytopenic purpura
 - Thrombotic thrombocytopenic purpura
 - Von Willebrand disease
 - DIC
- Associated conditions:
 - If bleeding is present at other sites, consider coagulopathy
- Risk factors:
 - Prior PPH
 - Advanced maternal age
 - Multiple gestations
 - Prolonged labor
 - Polyhydramnios
 - Instrumental delivery
 - Fetal demise
 - Anticoagulation therapy
 - Placental abruption
 - Fibroids
 - Prolonged use of oxytocin
 - C-section
 - Placenta previa and accreta
 - Chorioamnionitis
 - General anesthesia

DIAGNOSIS

SIGNS AND SYMPTOMS

- Ongoing blood loss, usually painless
- Significant hypovolemia, resulting in:
 - Tachycardia
 - Tachypnea

- Narrow pulse pressure
- Decreased urine output
- Cool, clammy skin
- Poor capillary refill
- Altered mental status
- Maternal tachycardia and hypotension may not occur until blood loss > 1,500 mL

History

- Condition is typically recognized by obstetrician soon after delivery
- Delayed PPH presents as copious vaginal/perineal bleeding
- Key historical elements:
 - Complications of delivery
 - Episiotomy
 - Prior clotting disorders
- Symptoms of hypovolemia:
 - Decreased urine output
 - Lightheaded
 - Syncope
 - Pale skin

Physical-Exam

Thorough exam of perineum, cervix, vagina, and uterus:

- External inspection
- Speculum exam
- Bimanual exam

ESSENTIAL WORKUP

- Abdomen and pelvic exam to assess for uterine atony, retained products, or other anatomic abnormality
- Type and cross-match for packed red blood cells
- Rapid hemoglobin determination

DIAGNOSIS TESTS & INTERPRETATION

Diagnosis is chiefly based on clinical suspicion and exam

Lab

- CBC, platelets
- PT, PTT
- Fibrinogen level
- Type and cross-match

Imaging

US to evaluate for retained products in delayed PPH or for evaluation of fluid

concerning intrauterine or intra-abdominal hemorrhage

Diagnostic Procedures/Surgery

Manual exam preferred over ultrasonography:

- Greater sensitivity
- Both diagnostic and therapeutic

DIFFERENTIAL DIAGNOSIS

- Consider puerperal hematomas if perineal, rectal, or lower abdominal pain in conjunction with tachycardia and hypotension
- Retained products of conception

TREATMENT

ALERT

- Patients with PPH may be hemodynamically unstable
- IV access, and active resuscitation is important, considering both crystalloid and blood product resuscitation and closely following BP and mental status

PRE HOSPITAL

- Monitor hemodynamics
- Aggressive IV fluids to maintain BP

INITIAL STABILIZATION/THERAPY

- Attempt to simultaneously control bleeding and stabilize hemodynamic status
- Manage airway and resuscitate as indicated:
 - Supplemental oxygen
 - Cardiac monitor
- IV fluid resuscitation with normal saline or lactated Ringer solution
- Foley catheter

ED TREATMENT/PROCEDURES

- Management of uterine atony:
 - Bimanual massage
 - Oxytocin (Pitocin) administered IV/IM
 - Methylergonovine (Methergine) or ergonovine (Ergotrate) IM if oxytocin fails:
 - Avoid if known hypertensive
 - Onset in minutes
 - 15-methyl prostaglandin F^{2α} (PGF^{2α}; Hemabate) IM if above fails:
 - Relatively contraindicated in asthma
 - Surgery if medical intervention fails

- Inspect closely for genital tract laceration:
 - Repair required if ≥ 2 cm
 - Use 00 or 000 absorbable suture; continuous, locked recommended
- Management of uterine inversion (acute):
 - Reposition uterus using Johnson maneuver or Harris method:
 - Use left hand on abdominal wall to stabilize fundus of uterus
 - Place right hand with fingers spread into vagina and push steadily on inverted part to reduce
 - If unsuccessful, give terbutaline IV or magnesium sulfate to produce cervical relaxation, and reposition
 - Surgery if unsuccessful or if subacute or chronic inversion
- Management of coagulopathies in childbirth:
 - Fresh-frozen plasma, platelets, cryoprecipitate as indicated
 - Careful attention to volume status
 - Continuous reassessment
 - Active over expectant management
 - Immediate administration of uterotonics after delivery
 - Cord clamping and cutting without delay
 - Cord traction/uterine countertraction (Brandt–Andrews maneuver)
- Uterine tamponade
 - Can be used for atony or continued bleeding
 - Temporizing measures only
 - Balloon or packing can be used
 - May use a foley catheter, Rusch catheter, Sengstaken–Blakemore tube or
 - Surgical Obstetric Silicone (SOS) Bakri tamponade balloon
 - Specifically designed for control of PPH

MEDICATION

- Uterotonics—stimulate uterine contraction to control bleeding:
 - Ergonovine (Ergotrate): 0.2 mg IM; avoid if known hypertensive
 - Methylergonovine (Methergine): 0.2 mg IM; 0.2 mg PO q6h; avoid if known hypertensive
 - 15-methyl PGF^{2 α} (Hemabate): 0.25 mg IM; may repeat in 15–60 min
 - Oxytocin (Pitocin): 10 U IM or 20–40 U IV in 1 L normal saline; titrate to achieve uterine contractions
- Cervical relaxation agents facilitate uterine inversion reduction:
 - Magnesium sulfate 20%: 2 g IM bolus over 10 min
 - Terbutaline: 0.25 mg IV; avoid if hypotensive

First Line

- Uterotonics
- Oxytocin

- Methylergonovine

Second Line

- Surgical intervention:
 - Hysterectomy is required in management of PPH in 1/1,000 deliveries
- Radiologic embolization

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with immediate PPH require admission to a closely monitored setting
- Early obstetrics consultation is recommended
- Early surgical intervention is dependent on cause
- ICU setting if DIC or evidence of hemodynamic compromise
- Patients with endometritis should be admitted for parenteral antibiotics

Discharge Criteria

- Delayed PPH that is easily controlled without excessive bleeding
- Outpatient management with methylergonovine 0.2 mg PO every 6 hr may be considered in consultation and close follow-up with obstetrician

FOLLOW-UP RECOMMENDATIONS

- Close follow-up with obstetrician
- Seek immediate care if bleeding recurs

PEARLS AND PITFALLS

- Active over expectant management
 - Most deaths are due to delayed diagnosis and/or inadequate resuscitation with blood products
- Uterotonics are the first line of treatment
- Aggressive use of fluid and blood products for resuscitation
- Manual exam is the preferred diagnostic approach
- Immediate obstetric consult

- O72.2 Delayed and secondary postpartum hemorrhage

POSTPARTUM INFECTION

Noah White • Yvonne C. Chow • Marco Coppola

BASICS

DESCRIPTION

- Postpartum endometritis (PPE):
 - Early PPE
 - Develops within 48 hr
 - Most often complicating C-section
 - Occurs in 1–3% of uncomplicated vaginal deliveries
 - Classic triad: Fever, lower abdominal pain with uterine tenderness, foul-smelling lochia
 - Late PPE
 - Develops 3 days–6 wk after delivery
 - Usually follows vaginal delivery
 - Risk of PPE as high as 85–95% in high-risk nonelective C-section patient
- Complications of PPE: All are more common after C-section:
 - Pelvic thrombophlebitis
 - Pelvic abscess
 - Bacteremia
- Risk factors for PPE:
 - C-section
 - Prolonged labor
 - Prolonged rupture of membranes
 - Increased number of vaginal exams
 - Use of internal fetal monitoring
- Septic pelvic thrombophlebitis is a diagnosis of exclusion with 2 distinct clinical presentations, either of which may present with postpartum pulmonary embolus:
 - Acute thrombosis:
 - Most common in right ovarian vein
 - Usually occurs in 1st 48 hr as acute, progressive lower abdominal pain
 - Enigmatic fever: “Picket fence” spiking fevers and tachycardia
- Septic abortion:
 - Uncommon in developing countries
 - Usually an ascending infection through an open cervical os
 - Associated with:
 - Nonsterile techniques, instruments
 - Retained products of conception
- Mastitis:

- Ranges from mild breast redness to fever, systemic illness, and abscess
- Common (1–30% of postpartum patients)
- Occurs within the 1st 3 mo postpartum
- Peaks at 2–3 wk
- Recurs in 4–8%
- UTI/pyelonephritis:
 - Along with mastitis accounts for 80% of postpartum infections

ETIOLOGY

- PPE:
 - Polymicrobial infection result of ascending spread from lower genital tract
 - Anaerobic (up to 80%) and aerobic (~70%):
 - Gram-positive aerobes:
 - Group A, B streptococci
 - Enterococci
 - *Gardnerella vaginalis*
 - Gram-negative aerobes:
 - *Escherichia coli*
 - *Enterobacter*
 - Anaerobes:
 - *Bacteroides*
 - *Peptostreptococcus*
 - Other genital mycoplasmas common in late PPE:
 - *Ureaplasma urealyticum*
 - *Mycoplasma hominids*
 - *Chlamydia trachomatis*
- Septic abortion:
 - Usually polymicrobial
 - *E. coli*
 - *Bacteroides*
 - Anaerobic gram-negative rods
 - Group B streptococci
 - Staphylococcus
 - STD:
 - Gonorrhoea
 - *C. trachomatis*
 - *Trichomonas*
- Mastitis
 - *Staphylococcus aureus*
 - Group A and B hemolytic streptococci
 - *E. coli*
 - *Bacteroides*

SIGNS AND SYMPTOMS***History***

- Careful birth history:
 - C-section
 - Length of labor
 - Complications
 - Exposure to STDs
- Pre-existing immunocompromise or disease
- Endometritis:
 - Fever and chills
 - Abdominal pain
 - Foul-smelling lochia
- Septic abortion:
 - Similar to endometritis
 - Fever
 - Abdominal pain
 - May present with symptoms of shock including:
 - Dyspnea (acute respiratory distress syndrome [ARDS], pulmonary edema)
 - Bruising, bleeding (disseminated intravascular coagulation [DIC])
- Mastitis:
 - Fever
 - Breast pain, engorgement, redness
- Other sources of infection:
 - Wound infection:
 - Redness, pain, swelling
 - UTI/pyelonephritis:
 - Fever, dysuria, frequency, flank pain

Physical-Exam

- Abdominal and/or uterine tenderness
- Foul-smelling lochia
- Unilateral tender, engorged, erythematous breast in cases of mastitis
- Examine episiotomy infections
- Suprapubic or costovertebral angle tenderness in cases of UTI/pyelonephritis

ESSENTIAL WORKUP

- Abdominal and pelvic exam
- Cervical cultures for *Chlamydia*

- Transcervical endometrial cultures

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Urinalysis and culture
- Blood cultures

Imaging

- CT or MRI for ovarian vein thrombosis
- US is sensitive for abscess or retained products of conception
- Plain x-rays may show retained foreign bodies or free air in septic abortion.

DIFFERENTIAL DIAGNOSIS

- Fever from other sources
- < 6 hr:
 - Early streptococcal infection
 - Transfusion reaction
 - Thyroid crisis
- < 48 hr:
 - Atelectasis
- < 72 hr:
 - UTI
 - Pneumonia
- 3–5 days:
 - Mastitis
 - Breast engorgement
 - Necrotizing fasciitis
- 3–7 days:
 - Mastitis
 - Septic thrombophlebitis
- 7–14 days:
 - Abscess
- > 2 wk:
 - Mastitis
 - Pulmonary embolism

TREATMENT

PRE HOSPITAL

- ABCs

- IV and IV fluids if signs of shock or impending shock

INITIAL STABILIZATION/THERAPY

Manage airway and resuscitate as indicated:

- Prompt evaluation of respiratory and hemodynamic status
- Supplemental oxygen, cardiac monitor, and pulse oximetry, as needed
- Venous access; support circulatory status with crystalloid and pressors, if needed

ED TREATMENT/PROCEDURES

- IV antibiotics and close observation
- Septic abortion is usually treated with dilatation and curettage and removal of any inciting agents
- Monitor for signs of impending shock, circulatory failure, ARDS, and/or sepsis.
- Heparin if suspicion or evidence of thrombophlebitis
- Infected wound or abscess should be opened to establish drainage
- Necrotizing fasciitis requires wide surgical débridement, parenteral antibiotics, and adjunctive hyperbaric oxygen therapy
- Peritonitis requires imaging to evaluate cause

MEDICATION

Per underlying infection. See corresponding chapters for complete list (consider safety in breast-feeding)

Endometritis

- Cefoxitin: 2 g IV q6h *or*
- Cefotetan: 2 g IV q12h *or*
- Piperacillin/tazobactam: 3.375 g IV q6–8h *or*
- Ampicillin/sulbactam: 1.5–3 g IV q6h *or*
- Clindamycin: 600–900 mg IV q8h +
- Gentamicin: 2 mg/kg load, then 1–1.5 mg/kg IV q8h

Septic Abortion

- Triple antibiotics
- Gram-positive coverage:
 - Ampicillin/sulbactam: 1.5–3 g IV q6h *or*
 - Cefoxitin: 2 g IV q6h *or*
 - Cefotetan: 2 g IV q12h
- Gram-negative coverage:
 - Gentamicin: 2 mg/kg load, then 1–1.5 mg/kg IV q8h
- Anaerobic coverage:
 - Clindamycin: 600–900 mg IV q8h *or*
 - Metronidazole: 500 mg IV q8h

Mastitis

- Dicloxacillin: 250 mg q6h PO for 10 days
- Mupirocin 2% ointment TID
- Cephalexin: 500 mg q6h PO for 10 days
- Clindamycin: 300 mg q6h PO for 10 days
- Erythromycin: 500 mg q6h PO for 10 days
- If MRSA positive: Vancomycin 1 g IV q12h

UTI/Pyelonephritis (Inpatient)

- Ciprofloxacin: 400 mg IV q12h *or*
- Ceftriaxone: 1–2 g IV q24h *or*
- Piperacillin/tazobactam: 3.375 g IV q6–8h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with endometritis or suspicion for septic pelvic thrombophlebitis should be admitted
- Septic abortion

Discharge Criteria

Nontoxic, mildly symptomatic patient may be considered for outpatient management in consultation and close follow-up with obstetrics

FOLLOW-UP RECOMMENDATIONS

Close follow-up with obstetrician and/or primary care physician to evaluate treatment

PEARLS AND PITFALLS

- Mastitis and UTI account for 80% of postpartum infections
- C-section increases risk for PPE
- Entertain broad differential with regard to source of infection
- Early broad-spectrum antibiotics are often indicated

PREECLAMPSIA/ECLAMPSIA

Adam Z. Barkin

BASICS

DESCRIPTION

- Hypertension in pregnancy:
 - 1% of all pregnancies
 - 16% of maternal deaths
- Gestational hypertension (GH)
 - Hypertension associated with pregnancy
 - Resolves with delivery
 - 6–7% of all pregnancies
- Preeclampsia
 - GH PLUS proteinuria
 - 2.2–6.3% of all pregnancies
- Eclampsia
 - Preeclampsia with seizure
- Postpartum preeclampsia
 - Occurs within 6 wk of delivery
 - Usually no history of hypertension
 - Occurs in 5% patients
 - Most women are African American
- HELLP syndrome
 - May occur in women with preeclampsia or eclampsia
 - Hemolysis
 - Elevated liver function tests
 - Low platelets
- Superimposed preeclampsia
 - Preeclampsia in the setting of chronic hypertension
 - Complicates pregnancy in up to 25% of women with chronic hypertension
 - Risk factors:
 - African American
 - Antihypertensive medication use
- Chronic hypertension
 - Systolic BP (SBP) > 140 or diastolic BP (DBP) > 90
 - Measured twice prior to 20 wk gestation or lasting > 12 wk after delivery

ETIOLOGY

- Preeclampsia
 - Incomplete placental implantation and underperfusion

- Leads to decreased angiogenic growth factor and increased maternal placental debris in circulation
- Eclampsia
 - 1/3 of patients with eclampsia did not have hypertension prior to seizure
- Risk factors:
 - Extremes of reproductive age
 - Primigravida
 - Multiple gestations
 - Molar pregnancy, hydatidiform mole
 - Smoking
 - Increased body mass index
 - Diabetes, collagen vascular diseases
 - Pre-existing hypertension or renal disease
 - History of preeclampsia with prior pregnancies (7.5–10% increased risk)
 - Independent risk factors for eclampsia
 - Nulliparity
 - Maternal age
 - GH

DIAGNOSIS

- GH
 - Normotensive prior to 20 wk gestation
 - SBP > 140 or DBP > 90 on 2 separate measurements
 - Severe: SBP > 160 and DBP > 110
- Preeclampsia
 - GH and proteinuria
 - 300 mg protein on 24 hr urine
 - 1+ protein on urinalysis
 - Mild:
 - SBP < 160 mm Hg or
 - DBP < 110 mm Hg
 - Normal platelets
 - Normal liver function tests
 - No cerebral symptoms
 - Severe:
 - SBP > 160 or DBP > 110
 - 5 g protein on 24 hr urine
 - 3+ proteinuria on 2 occasions
 - Oliguria
 - Thrombocytopenia
 - Right upper quadrant pain
 - Impaired liver function

- Cerebral symptoms
- Intrauterine growth restriction
- Vision changes
- Pulmonary edema
- HELLP Syndrome
 - Hemolysis
 - Elevated liver enzyme
 - Low platelets
 - May present with:
 - Pulmonary edema
 - Renal failure
 - Liver failure
 - Sepsis
 - Pulmonary disease
 - Stroke

SIGNS AND SYMPTOMS

History

- History of preeclampsia
- Parity
- Weight gain
- Leg swelling
- Abdominal pain
- Nausea/vomiting
- Shortness of breath
- Headache
- Visual changes
- Jaundice
- Stroke symptoms

Physical-Exam

- Check serial BP
- Palpate abdomen carefully, especially RUQ
- Assess extremities for edema
- Perform neurologic exam:
 - Deep tendon reflexes
 - Mental status changes
 - Visual acuity

ESSENTIAL WORKUP

- Serial BP measurements
- Urinalysis

- CBC, LFTs, BUN/creatinine, uric acid
- US
- Fetal monitoring
- Head CT depending on severity of presentation

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Urinalysis:
 - Protein > 1+ correlates to 30 mg/dL
 - > 1+ requires 24 hr urine collection
 - Urine sediment for RBC, WBC, casts
- CBC
- LFTs
- BUN/creatinine
- Uric acid
- LDH
- d-dimer
- Fibrinogen levels
- Coagulation studies

Imaging

- US:
 - Gestational age
 - Fetal viability/distress
 - Oligohydramnios
- Fetal monitoring, nonstress test
- Head CT: Rule out mass or hemorrhage

Diagnostic Procedures/Surgery

- Lumbar puncture: Rule out infection or subarachnoid hemorrhage
- Urine toxicology: Rule out substance abuse:
 - Cocaine
 - Methamphetamine

DIFFERENTIAL DIAGNOSIS

- Essential hypertension
- Renal or collagen vascular disease
- Hydatidiform mole, hydrops fetalis
- Drug abuse
- Epilepsy
- Encephalitis
- Meningitis

- Encephalopathy
- Brain tumor
- Intracranial hemorrhage

TREATMENT

PRE HOSPITAL

- ABCs
- Oxygen
- Place patient in left lateral decubitus position

INITIAL STABILIZATION/THERAPY

- ABCs
- 100% oxygen
- Left lateral decubitus position (reduces pressure on inferior vena cava, enhancing cardiac return/output)
- Maternal cardiopulmonary monitoring
- Magnesium sulfate (MgSO_4) for seizures

ED TREATMENT/PROCEDURES

- Make arrangements for emergent C-section
- MgSO_4 for seizure treatment and prophylaxis
- Hydralazine or labetalol for BP control
 - Goal is to lower BP by 25% initially and then to $<160/100$ over subsequent hours
- Mg toxicity:
 - Hypotension
 - Loss of patellar reflex
 - Respiratory depression
 - Decreased urine output
 - Elevated creatinine
 - Calcium gluconate to reverse
- Intubate for airway protection/hypoxia or if seizures refractory to interventions
- Tocographic and fetal monitoring
- OB consult:
 - All cases along GH–preeclampsia–eclampsia spectrum
 - Expectant management if <30 wk gestation
 - Delivery >30 wk
 - Emergent delivery for severe symptoms: Induction vs. C-section

MEDICATION

First Line

- MgSO_4 : 10 g IM or 4 g IV; followed by 1–2 g/hr IV infusion:
 - MgSO_4 bolus should not exceed 1 g/min
 - Serum Mg goal: 4–7 mEq/L
- Hydralazine: 5–20 mg IV
- Labetalol: 10 mg IV initially, then 5–10 mg increments for desired effect

Second Line

- Valium: 5–10 mg IV if no response to MgSO_4
- Fosphenytoin: 15–20 mg phenytoin equivalents (PE) IV \times 1 (max. 150 mg PE/min IV)
- Phenytoin: 15–18 mg/kg IV, not to exceed 25–50 mg/min, for persistent seizure activity
- Calcium gluconate: 1 g IV

FOLLOW-UP

DISPOSITION

Admission Criteria

- Preeclampsia
- Eclampsia
- HELLP syndrome
- ICU, labor and delivery, OR

Discharge Criteria

- Isolated hypertension with workup negative for preeclampsia
- Asymptomatic
- Close obstetric follow-up assured

FOLLOW-UP RECOMMENDATIONS

- Follow-up with OB as above
- Return to ED:
 - Headache
 - Abdominal pain
 - Leg swelling
 - Decreased urination
 - Shortness of breath

PEARLS AND PITFALLS

- Delivery is the definitive treatment for preeclampsia and eclampsia
- BP of 130/80 mm Hg in a pregnant woman requires investigation
- Postpartum presentation: Consider preeclampsia/eclampsia in patient up to 30 days postpartum presenting with:
 - Edema
 - Shortness of breath
 - Headache
 - Seizure
- Airway considerations in preeclamptic or eclamptic patients:
 - Reduced internal diameter of airways due to engorgement
 - Airway edema may be present
 - Use smaller-diameter endotracheal tube
 - Use fiberoptic guidance if available
 - High risk for aspiration

CODES

ICD9

- 642.40 Mild or unspecified pre-eclampsia, unspecified as to episode of care
- 642.60 Eclampsia complicating pregnancy, childbirth or the puerperium, unspecified as to episode of care
- 642.64 Eclampsia, postpartum condition or complication

ICD10

- O14.90 Unspecified pre-eclampsia, unspecified trimester
- O15.2 Eclampsia in the puerperium
- O15.9 Eclampsia, unspecified as to time period

PREGNANCY, TRAUMA IN

Amin Antoine Kazzi • Ali F. Maatouk

BASICS

DESCRIPTION

- Fetal and maternal injury after the 1st trimester:
 - Increased rate of fetal loss, but not maternal mortality
- Likelihood of fetal injury increases with the severity of maternal insult
- Physiologic hypervolemia of pregnancy may lead to an underestimation of blood loss:
 - Clinical shock may be apparent only after a 30% maternal blood loss
- Abdominal findings are less evident in the gravid patient
- Minor trauma can also lead to fetal injuries (at least 50% of fetal losses)
- An Injury Severity Score >9 is associated with a worse outcome
- Less frequent bowel injury
- More frequent retroperitoneal hemorrhage due to the engorgement of pelvic organs and veins
- Increased morbidity and mortality with pelvic fractures due to pelvic and uterine engorgement
- Fetal or uterine trauma includes:
 - Placental abruption
 - Fetal–maternal hemorrhage (FMH)
 - Premature labor
 - Uterine contusion or rupture
 - Fetal demise
 - Premature membrane rupture
 - Hypoxemic or anatomic fetal injury (skull fracture)
- Abruption occurs in up to 60% of severe trauma and 1–5% of minor injuries:
 - Accounts for up to 50% of fetal loss
 - May occur with no external bleeding (20%)
 - Occurs after 16 wk of gestation
 - Can present with abdominal pain, cramping and/or vaginal bleeding
 - Hallmark is uterine contractions
- Uterine rupture:
 - Usually in patients with prior C-section
 - Nearly universal mortality
 - 10% maternal mortality
- Pelvic fracture:
 - May be an independent predictor of fetal death
 - Fatal insults to fetus can occur in all trimesters

- 10% fetal mortality in patients with minor injuries
- FMH occurs in > 30% of severe trauma:
 - Isoimmunization of Rh-negative mothers (with as little as 0.03 cc of FMH)
- Penetrating trauma results in direct injury to fetus, maternal shock, and premature delivery
- Falls and slips occur in 1 out of 4 pregnant women and may cause:
 - 4.4 fold increase in preterm birth (PTB)
 - 8 fold increase in placental abruption
 - 2.1 fold increase in fetal distress
 - 2.9 fold increase in fetal hypoxia
- Burns: If BSA involved is > 40% the maternal and fetal mortality approaches 100%
- Intentional trauma and domestic violence (DV) increases the risk for PTB 2.7 fold and low birth weight 5.3 fold
- Electrocution is a significant cause of fetal mortality

ETIOLOGY

- Trauma occurs in ~7% of all pregnancies
- Most common cause of nonobstetric morbidity and mortality in pregnancy
- Rate of fetal loss 3.4–38%
- Motor vehicle accidents (MVA; 48–84%)
- Domestic violence (DV)
- Falls
- Direct abdominal trauma
- Penetrating (stab or gunshot)
- Electrical or burn
- Higher rate in younger woman
- Substance abuse is a common accompaniment of MVA and DV
- Suicide and exposure to toxins

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Mechanism of injury
- Last menstrual period
- Abdominal pain
- Uterine contraction
- Vaginal bleeding or leakage of fluid
- Previous pregnancies, C-sections
- Substance use/abuse

Physical-Exam

- Perform with patient in left lateral recumbent position if possible
- Primary survey
- Secondary survey
- Tertiary survey
- Placental abruption:
 - Uterine tenderness
- Uterine rupture:
 - Uterine tenderness and variable shape
 - Palpation of fetal body parts
- Determine the gestational age (EGA) to assess viability:
 - Estimate last menstrual period
 - EGA = fundal height (FH; distance from pubic bone to top of uterus in cm after week 16)
- Vaginal exam to assess for:
 - Blood
 - Amniotic fluid
 - Cervical dilation and effacement

ESSENTIAL WORKUP

- Maintain spinal immobilization
- Identify maternal condition 1st:
 - Airway management and resuscitate as indicated
- Determine the EGA to assess viability:
 - EGA = FH after week 16
 - Doppler fetal heart tones
 - Sonography (may miss small abruptions)
- Fetal/maternal monitoring for > 4–6 hr:
 - Only monitor viable fetuses (typically with an EGA > 24 wk)
 - Abruption unlikely if no contractions during 1st 4 hr of monitoring
 - > 8 contractions/hr over 4 hr is associated with adverse outcome
 - If > 1 contraction every 10 min, there is a 20% incidence of abruption
 - The occurrence of bradycardia, poor beat-to-beat variability, or type II “late” deceleration indicates fetal distress
 - An abnormal tracing has a 62% sensitivity and 49% specificity for predicting adverse fetal outcomes
 - A normal tracing combined with a normal physical exam has a negative predictive value of nearly 100%

DIAGNOSIS TESTS & NTERPRETATION

Lab

- CBC, urinalysis

- Blood gas and electrolyte panel
- Type, Rh, and screening of blood
- The Kleihauer–Betke (KB) stain:
 - Identifies FMH in vaginal fluid or blood
 - Indicated when quantification of FMH is important

Imaging

- Shield the uterus if possible, but obtain necessary maternal radiographs
- *Inform the mother of the potential risks of radiation exposure*
- No definite evidence of increased risk for congenital malformation or intrauterine death
- Cancer risk is debated
- Radiation <1 rad (10 mGy) believed to carry little risk
- Increased risk of fetal malformation at 5–10 rad
- The radiation exposure is estimated at the following:
 - CXR (2 views): Minimal
 - Pelvis (anteroposterior): 1 rad
 - Cervical spine x-ray: Minimal
 - Thoracic spine x-ray: Minimal
 - Lumbar spine x-ray: 0.031–4.9 rads
 - CT head: <0.05 rads
 - CT thorax: 0.01–0.59 rads
 - CT abdomen: 2.8–4.6 rads
 - CT pelvis: 1.94–5 rads
- Ultrasonography:
 - Focused assessment with sonography for trauma (FAST) exam
 - Evaluate for solid-organ injury or hemoperitoneum
 - Fetal heart activity
 - Gestational age
 - Amount of amniotic fluid (amniotic fluid index)
 - Misses 50–80% of placental abruptions
- Test vaginal fluid with Nitrazine paper (turns blue) and for ferning
 - Likely rupture of membranes and presence of amniotic fluid
- With stable penetrating trauma, triple-contrast CT is advocated, particularly with stab wounds

Diagnostic Procedures/Surgery

As indicated by traumatic injury

DIFFERENTIAL DIAGNOSIS

Differential diagnosis is broad and should include careful exam for occult traumatic injuries

TREATMENT

PRE HOSPITAL

- Maintain spinal immobilization
- Patients in late 2nd and 3rd trimesters should be transported to a trauma center
- Advise trauma center early of pregnancy and EGA to facilitate mobilization of appropriate resources
- Place patient (while on backboard) in the left lateral recumbent position to avoid supine hypotension (after 20 wk EGA or earlier in multiple gestations)
- Mast suit inflation over the abdomen is contraindicated

INITIAL STABILIZATION/THERAPY

- Direct therapy to the mother with no delays due to pregnancy:
 - Manage airway and resuscitate as indicated
- Cardiac, pulse oximetry, and cardiotocographic monitoring
- Tilt patient or board 15–30° to the left (or manually displace uterus to the left)

ED TREATMENT/PROCEDURES

- Lactated Ringer preferred for IV fluids:
 - Large volumes of normal saline may induce hyperchloremic acidosis
- Replace estimated blood loss in a 3:1 ratio:
 - O-negative packed red blood cells if type-specific blood is not available
- In cases of severe hemorrhage transfusion of fresh frozen plasma, platelets and packed RBC at 1:1:1 ratio lowers the rate of coagulopathy and may improve survival
- Resort to transfusions after 1 L of estimated blood loss or if hypovolemia persists after 2 L of crystalloid
- Nasogastric tube decompression (higher risk of aspiration in pregnancy)
- Foley catheterization to assess urinary output
- Tube thoracostomy:
 - Use a higher intercostal space to avoid diaphragm
- Rapid sequence intubation:
 - Safe and preferred method
 - Avoid aspiration and deoxygenation
- If diagnostic peritoneal lavage is necessary, use supraumbilical open technique
- Use tocolytic therapy only for hemodynamically stable patients:
 - Contraindicated if cervix dilated > 4 cm or if FMH and abruption have not been reasonably ruled out
 - Use tocolytics only when > 8 contractions/hr have lasted > 4 hr
- A perimortem cesarean delivery may be attempted within 4–5 min of cardiopulmonary arrest. See Cesarean Section, Emergency.
- In minor trauma after week 20, fetal and maternal monitoring is best done in the

labor and delivery area

- If burns are $>50\%$ BSA + fetus in the 2nd or 3rd trimester consider delivery
- RhoGAM in all Rh-negative women (within 72 hr):
 - 50 μg IM in women <12 wk pregnant
 - 300 μg IM in women >12 wk pregnant
- 24 hr recheck for ongoing FMH:
 - Repeat Rh immune globulin if needed (if FMH >30 mL)
- Tocolytics: Magnesium sulfate 4 g IV
- Avoid aspirin, hypnotics, nonsteroidals, vasopressors when possible

FOLLOW-UP

DISPOSITION

Admission Criteria

- Vaginal bleeding or amniotic fluid leakage
- Fetomaternal hemorrhage
- Abdominal pain
- Uterine contractions
- Evidence of fetal distress
- Abruptio placenta
- Hemoperitoneum or visceral or solid-organ injury
- Fetal survival begins at week 24 (9.9%):
 - Survival becomes significant after week 26 (54.7%)

Discharge Criteria

- All the following criteria must be met:
 - No uterine contractions for >4 hr of tocodynamometry
 - No evidence of fetal distress
 - No vaginal bleeding or amniotic fluid leakage
 - No abdominal pain or tenderness
 - Timely obstetric follow-up
- Specific instructions to return if any of the above symptoms occur
- Discharge only in consultation with obstetrics.

FOLLOW-UP RECOMMENDATIONS

A pregnant trauma patient being discharged after appropriate evaluation and observation needs prompt follow-up with obstetrician.

PEARLS AND PITFALLS

- Minor trauma can lead to maternal and/or fetal death

- Stabilization of the mother is 1st priority
- Maternal stress may not occur until 1,500–2,000 mL of blood loss

PREGNANCY, UNCOMPLICATED

Jonathan B. Walker • James S. Walker

BASICS

DESCRIPTION

- Pregnancy is not a disease process but rather a physiologic state. It involves severe metabolic stresses on the mother to facilitate the growth and development of the fetus.
- All women of reproductive age with abdominal pain are considered pregnant until proven otherwise even with history of sterilization.
- The changes in pregnancy occur from the production of large amounts of placental hormones:
 - Placental progesterone and estrogen

Pediatric Considerations

- Range for menarche in US is 11–15 yr old
- Pregnant adolescents who present to the ED may be either unaware of the pregnancy or reluctant to admit it:
 - Assume pregnancy in adolescents, regardless of the chief complaint
 - Pediatric pregnancies have an increased risk of obstructive labor

ETIOLOGY

- Preceding signs and symptoms can be explained by elevations in various hormone levels or changes in anatomy that are a function of the progression of the pregnancy.
- Placental human chorionic gonadotropin (hCG):
 - Prevents the normal involution of the corpus luteum at the end of the menstrual cycle
 - Causes the corpus luteum to secrete even larger quantities of estrogen and progesterone
 - Elevated hCG levels are responsible for nausea and vomiting.
- Placental progesterone:
 - Causes decidual cells in the endometrium to develop and provide nutrition for the early embryo
 - Decreases contractility of the gravid uterus and risk of spontaneous abortion
 - Helps estrogen prepare the breasts for lactation
- Placental estrogen:
 - Responsible for enlargement of uterus, breasts, and mammary ducts
 - Enlargement of female external genitalia, relaxation of pelvic ligaments, symphysis pubis, and sacroiliac joints

DIAGNOSIS

The diagnosis of pregnancy and some of its potential complications focus on 3 diagnostic tools:

- History and physical exam
- Hormonal assays
- Ultrasonography

SIGNS AND SYMPTOMS

- Amenorrhea accompanied by nausea and vomiting in a sexually active woman
- Amenorrhea:
 - _ Most common cause of secondary amenorrhea in a woman of reproductive age is pregnancy
- Nausea and vomiting (morning sickness)
- Breast tenderness (mastodynia)
- Urinary frequency
- Headache
- Low back pain
- Pica
- Edema of feet and ankles
- Weight gain
- Easy fatigability, generalized malaise
- Increase in abdominal girth
- Constipation
- Heartburn
- Excessive eructation
- Skin darkening

History

- Determine 1st day of last menstrual period (FDLMP)
- 40% of women cannot accurately remember their FDLMP

Physical-Exam

Pelvic exam:

- Estimate expected date of delivery by determining uterine fundal height
- Centimeters from pubic bone to top of uterus approximates gestational age after 16 wk
- Detect abnormal pelvic pain or masses

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Pregnancy tests:

- β -subunit of hCG
- Quantitative hCG normally doubles every 2 days until 6–7 wk gestation
- Progesterone
- Measurement of β -hCG:
 - Most urine pregnancy tests have sensitivity at 25 mIU/mL:
 - False-negative tests with dilute urine and high vitamin C intake
 - Home pregnancy tests are not that accurate:
 - Detect pregnancy 9–12 days post conception
 - Positive home pregnancy tests should be confirmed by serum hCG levels.
 - Serum level of hCG:
 - Detectable 8–11 days post conception
 - hCG levels may remain detectable up to 60 days after an abortion.
- Serum progesterone level is an indicator of the viability of the pregnancy and may be used to predict the outcome of the pregnancy:
 - A serum progesterone level of < 5 ng/mL is indicative of a nonviable pregnancy (spontaneous abortion or ectopic pregnancy).
 - Progesterone level 25 ng/mL denotes a viable pregnancy.

Imaging

- Ultrasonography is used to confirm pregnancy in the setting of abdominal pain, vaginal bleeding, or some other potential obstetric complication:
 - Can estimate gestational age
 - Confirm intrauterine or ectopic pregnancy
 - Evaluate fetal viability
 - Identify fetal abnormalities
- Transabdominal US vs. transvaginal US:
 - Transvaginal US is more sensitive but more difficult to perform.
 - Intrauterine pregnancy seen at 4–5 wk in transvaginal US
 - Gestational sac seen at 5.5–6 wk in transabdominal US
 - Transvaginal US is contraindicated in the setting of premature rupture of membranes and 3rd-trimester bleeding.
- When used in combination with hCG levels, US is a very helpful tool in detecting abnormal/problem pregnancy.
- MRI: No significant side effects have been documented.
 - Often the study of choice to evaluate for appendicitis in pregnancy
- Plain radiography and CT:
 - Dose-dependent teratogen
 - Slight increase in risk of childhood cancer
 - Goal is to not exceed 5,000 mrad fetal dose of radiation:
 - CXR with abdominal shield: < 1 mrad
 - Abdominal plain film: 240 mrad
 - Chest CT: < 10 mrad
 - Head CT: < 10 mrad

- Abdominal CT with and without contrast: 2,000 and 1,000 mrad
- Cardiac catheterization: 1,300 mrad
- VQ scan: < 50 mrad

DIFFERENTIAL DIAGNOSIS

Any woman who is of the age to be sexually active who presents to the ED should be assumed to be pregnant until proven otherwise.

TREATMENT

PRE HOSPITAL

- Assume the patient is pregnant
- Administer medications only when necessary to avoid teratogenic side effects or placental–fetal compromise (e.g., epinephrine)
- If > 24 wk gestation, transport in left lateral recumbent position

INITIAL STABILIZATION/THERAPY

- Advanced cardiac life support, advanced trauma life support measures as needed: Oxygen, cardiac monitor, IV access, and fluids:
 - 1st objective is to resuscitate mother
- If > 24 wk gestation, place in the left lateral recumbent position

ED TREATMENT/PROCEDURES

The goal is to optimize maternal condition to improve fetal condition.

MEDICATION

- 1st trimester is when organogenesis is occurring.
- Fetal malformation continues beyond the 1st trimester.
- Before using any drug, refer to its Food and Drug Administration safety classification in pregnancy:
 - This classification system categorizes drugs as A, B, C, D, and X, with category A being the safest and category X being the most toxic.
- Analgesics: Acetaminophen is the preferred OTC analgesic
- Aspirin and NSAIDs are not teratogenic but are best used in consultation with an obstetrician
- Oxycodone, codeine, hydrocodone, meperidine, and morphine have no known teratogenic affect and can be used for the control of severe pain in pregnancy for short periods of time (3–4 days).
- Antibiotics: Selecting the right antibiotic in a gravid female depends on 3 factors:
 - Maternal drug allergies
 - Gestational age
 - Type of infections and associated pathogens
- Consider placing patient on prenatal vitamins

- Pain control:
 - Acetaminophen: 500 mg PO q6h; do not exceed 4g/d
- Antiemetic:
 - Ondansetron: 4 mg IM/IV q8h
 - Vitamin B₆ 25 mg TID or ginger can also help

FOLLOW-UP

DISPOSITION

Admission Criteria

- Pregnant women with the following obstetric complications should be admitted to the hospital:
 - Hyperemesis gravidarum with inability to tolerate oral fluids
 - Complicated UTI
 - Ectopic or molar pregnancy
 - Septic abortion
 - Preterm labor
 - Premature rupture of membranes
 - Preeclampsia/eclampsia
 - Severe pregnancy-induced HTN
- Pregnant women with medical conditions that would warrant admission in a nongravid female.

Discharge Criteria

Women without the above conditions may be discharged from the ED.

FOLLOW-UP RECOMMENDATIONS

Need OB follow up for prenatal care by 6–8 wk gestation

PEARLS AND PITFALLS

- All women are considered to be pregnant until proven they are not
- Review all medications' pregnancy safety classifications before administering or prescribing
- Minimize radiation exposure to fetus to <5,000 mrad

PRIAPISM

David Barlas

BASICS

DESCRIPTION

- Penile erection (engorgement of corpora cavernosa) in the absence of sexual arousal that is prolonged and frequently painful
- Low-flow priapism:
 - _ Most common mechanism
 - _ Poor venous outflow
 - _ Usually painful
 - _ Ischemia and thrombosis from stagnant, hypoxic blood can occur after a few hours.
 - _ Fibrosis and erectile dysfunction are late sequelae.
- High-flow priapism:
 - _ Rare
 - _ Penile arterial laceration with uncontrolled inflow of arterial blood
 - _ Usually painless
 - _ Presentation may be later than in low-flow priapism.
 - _ Ischemia and erectile dysfunction are uncommon.

ETIOLOGY

- Idiopathic
- Pharmacologic agents:
 - _ Intracavernosal injectables for the treatment of erectile dysfunction:
 - Prostaglandin E1
 - Papaverine
 - Phentolamine
 - _ Psychotropics:
 - Phenothiazines
 - Butyrophenones
 - Trazodone
 - Sedative–hypnotics
 - Selective serotonin uptake inhibitors
 - _ Antihypertensives:
 - Prazosin
 - Hydralazine
 - Phenoxybenzamine
 - Guanethidine
 - _ Rarely implicated agents:

- Phosphodiesterase inhibitors: Sildenafil (Viagra), tadalafil (Cialis), vardenafil (Levitra)
- Anticoagulants
- Cocaine
- Marijuana
- Ethanol
- Androstenedione
- Toxins (Black Widow, Scorpion)
- Hematologic disorders predisposing to sludging of blood:
 - Sickle cell anemia (most common cause)
 - Leukemia
 - Multiple myeloma
 - Polycythemia
- Penile and perineal trauma (arterial laceration and high-flow priapism)
- Spinal trauma (loss of inhibitory adrenergic tone)
- Rare causes:
 - Pelvic neoplasms and infections
 - Infiltrative diseases (e.g., amyloidosis)
 - Dialysis
 - Parenteral nutrition solutions containing a fat emulsion

Pediatric Considerations

Sickle cell anemia is the cause of most priapism in children.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Type of priapism may be determined by history:
- Low-flow priapism:
 - Painful
 - Predisposing condition or medication
- High-flow priapism:
 - Painless
 - Penile trauma

Physical-Exam

- Diagnosis is clinically apparent.
- Check for penile implants.
- Evaluate trauma (i.e., urethral, rectal injuries).
- Urinary retention

ESSENTIAL WORKUP

Lab tests and imaging should not delay urologic consultation and definitive management.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Coagulation studies
- Sickle cell evaluation may be indicated.

Imaging

- Duplex Doppler US can verify and localize the arterial laceration in high-flow priapism.
- Angiography enables localization and embolization of the arterial laceration in high-flow priapism.

Diagnostic Procedures/Surgery

Intracavernosal blood gas analysis can help differentiate type of priapism if unsure:

- Because of the possibility of penile arterial injury, a urologist should perform this procedure.
- High-flow priapism: Near-normal values
- Low-flow priapism: Acidosis and hypoxia (pH <7.25; O₂ <30 Torr)

DIFFERENTIAL DIAGNOSIS

- Penile erection from sexual arousal is usually painless and transient.
- Penile implants are a benign cause of “priapism.”

TREATMENT

PRE HOSPITAL

- IV
- O₂
- Analgesia

INITIAL STABILIZATION/THERAPY

- O₂
- Analgesia and sedation
- IV hydration

ED TREATMENT/PROCEDURES

- Urgent urologic consultation

- Management of specific causes should begin concurrently with specific therapy outlined below:
 - Sickle cell anemia:
 - Packed RBC or exchange transfusion
 - Hyperbaric oxygen if other measures fail
 - Leukemia:
 - Chemotherapy
 - Arterial injury:
 - Expectant management is an option
 - Angiographic localization and embolization
- Terbutaline (β -agonist):
 - May be administered to initiate treatment of low-flow priapism, but may not be effective alone.
- Intracavernosal injection/aspiration is often required for low-flow priapism despite the above measures:
 - Ideally performed by urologist, but the ED physician may perform the procedure as follows if specialty care is not immediately available:
 - Sterile prep area
 - Consider IV sedation and analgesia
 - Administer local anesthesia, or perform a pudendal nerve block or penile nerve block (inject plain lidocaine around the base of the penis)
 - Position yourself to the right of the patient and grasp the penile shaft with your left hand
 - Enter the corpus cavernosum with a 19G butterfly needle and 10 mL syringe inserted laterally at 2- or 10-o'clock position and 45° angle to avoid the ventral urethra and the dorsal neurovascular bundle
 - Aspirate blood *slowly* while “milking” the penile shaft until arterial blood is obtained, often after 30–50 mL. Irrigation with saline may be necessary.
 - Aspirating both corpora cavernosa is unnecessary as they are connected by shunts.
 - Phenylephrine (preferred to limit systemic effects), or epinephrine may be injected through the butterfly needle if retumescence occurs. Monitor cardiac rhythm and BP if these agents are used and avoid in patients with cardiovascular or cerebrovascular disease, hypertension, or those taking monoamine oxidase inhibitors because of the risk of hypertensive crisis.
 - Repeated injections may be needed 5–15 min apart for 1 hr.
 - Surgical shunt (i.e., corpus cavernosum to spongiosum) may be necessary if the above measures fail.

First Line

- Terbutaline: 0.25–0.5 mg SC (may repeat in 15 min) or 5 mg PO
- Phenylephrine: Dilute 1 mg in 100 mL saline; inject 10 mL boluses in the corpus cavernosum.

Second Line

- Epinephrine: Dilute 1 mg in 100 mL saline; inject 1–3 mL boluses in the corpus cavernosum, up to 10 mL.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Persistent priapism despite noninvasive treatments
- Serious underlying disease (sickle cell anemia, leukemia)

Discharge Criteria

- Detumescence is complete and has not recurred after several hours of observation
- Urologic consultation has been obtained

Issues for Referral

Arrange short-term follow-up with a urologist for all patients.

FOLLOW-UP RECOMMENDATIONS

- Ensure underlying conditions are addressed.
- Discontinue offending medication(s).
- Advise patient to return to the ED if tumescence recurs.

PEARLS AND PITFALLS

- Intracavernosal injection of vasoactive medications during partial tumescence increases the risk of a systemic bolus and adverse effects.
- Management of underlying conditions should not delay timely direct therapy to reduce the risk of subsequent erectile dysfunction.
- Always document and warn of the possibility of subsequent complete erectile dysfunction even when timely and successful treatment has occurred.

PROCEDURAL SEDATION

Christopher Ross • Theresa Schwab

BASICS

Administration of agents with or without analgesia to induce a state that allows diagnostic and therapeutic procedures to be performed successfully without significant pain and/or anxiety while maintaining cardiorespiratory function.

Preparation

- Obtain consent
- Equipment
 - Breathing masks, bag-valve ventilation device, oropharyngeal and nasal airways, laryngoscopes, endotracheal tubes, and stylets appropriate for size of patient
 - Defibrillator/automated external defibrillator
 - Suction
 - Emergency cart with all available medications if resuscitation needed
 - Flumazenil and naloxone
- Apply cardiorespiratory monitor, pulse oximeter, and BP monitor
- Gather medicines that will be used in procedure, label (preferably color-coded) syringes, and place at bedside.
- Apply oxygen delivery device (cannula or mask) and keep oxygen saturation > 95%.

Sedation Agents and Techniques

- Can be administered by various means
- Administer local or regional anesthesia if applicable.
- Perform the procedure.
- Closely observe and monitor patient during entire course of procedure as well as the recovery period afterward.
- Monitor patient until awake, alert, and back to baseline function.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

Past medical history, anesthesia history, medications, allergies, review of systems and last meal.

Physical-Exam

- BP, heart rate, respiratory rate, pulse oximetry, cardiopulmonary and neurologic exams.

- Airway assessment:
 - _ Difficult bag-valve mask ventilation:
 - Beards
 - Abnormal facial contour
 - Morbid obesity
 - No teeth
 - Patients with COPD/asthma/congestive heart failure)
 - _ Difficult airway management:
 - Short neck
 - Large tongue
 - Small mandible
 - Mallampati scoring
 - Evidence of airway obstruction (stridor, drooling, and dysphagia).

TREATMENT

MEDICATION

ALERT

Many sedative and analgesic medications can cause dose-dependent respiratory depression. Combination of 2 or more of these agents may have a synergistic effect on respiratory depression that can lead to hypoxia and apnea.

- Painless procedures (single agents):
 - _ Methohexital
 - _ Choral hydrate (children)
 - _ Etomidate
 - _ Barbiturates (pentobarbital)
 - _ Benzodiazepines (midazolam)
 - _ Ketamine
- Painful procedures:
 - _ Ketamine (\pm barbiturates [midazolam] to reduce emergence reactions)
 - _ Ketamine and propofol (ketofol)
 - _ Opiates (fentanyl/remifentanyl) and midazolam
 - _ Nitrous oxide
 - _ Propofol and opiates (fentanyl)
 - _ Etomidate and opiates (fentanyl)
 - _ Dexmedetomidine
- Methohexital:
 - _ A short-acting barbiturate with rapid recovery that produces a state of unconsciousness and profound amnesia but has no analgesic properties
 - _ Dosage (IV): 0.75–1 mg/kg with subsequent titration at 0.5 mg/kg every 2

min to required effect

- Onset: < 1 min
- Duration of action: 10 min
- Side effects:
 - Respiratory depression with potential apnea
 - Hypotension due to myocardial depressant effect (caution with underlying myocardial disease)
- Pentobarbital:
 - A short-acting barbiturate used only for *painless* procedures as a sole agent for diagnostic modalities:
 - Dosage (IV): 2–5 mg/kg for children, and adults have a loading dose of 100 mg slow bolus repeated/titrated q3–5min to max. of 200–500 mg.
 - Dosage (IM): 4 mg/kg
 - Duration of action: 30–60 min
 - Onset: IV mode acts within 30 sec, and patient is appropriately sedated within 5 min.
 - Side effects: Central nervous system, respiratory depression, and bronchospasm (contraindicated in asthma/COPD)
- Benzodiazepines:
 - Commonly used for minimal sedation as it causes anxiolysis and amnesia
- Midazolam:
 - Short-acting agent that is lipophilic that allows penetration of the blood–brain barrier quickly
 - Provides anxiolysis and amnesia but not analgesia, so should not be the sole agent for painful procedures
 - Dosage (IV): 0.02–0.05 mg/kg (usual starting adult dose is 0.5–1 mg) with subsequent incremental doses at 3 min intervals to desired effect (single max. dose, 2.5 mg)
 - Dosage (IM): 0.05–0.2 mg/kg
 - Dosage (PO): 0.5–0.75 mg/kg (max. of 15 mg)
 - Dosage (nasal): 0.2–0.5 mg/kg (max. of 5 mg)
 - Onset/duration:
 - IV: Fairly rapid onset (1–2 min) and short duration of action (10–40 min)
 - IM, PO, and nasally: Slower onset and longer duration of action
 - Cautions for benzodiazepines:
 - Respiratory depression
 - Hypotension
 - Excessive sedation
 - Effects augmented by opioids, so reduce dose by 30–50% if opioid therapy utilized simultaneously
 - Effects may be reversed with flumazenil: 200 µg every 1–2 min, to effect
- Chloral hydrate:

- To be used in procedural sedation in children (< 2 yr old) undergoing painless diagnostic studies
- Dosage (PO): 50–100 mg/kg with usual dose of 50–75 mg/kg (max. 2 g)
- Dosage for rectal administration: Not recommended due to erratic absorption Max. dose 1 g in infants, 2 g noninfants
- Onset: 30–45 min
- Duration of action: 2–4 hr (effects can recur up to 24 hr)
- Side effects:
 - Nausea and vomiting
 - Respiratory depression
 - Prolonged sedation
 - Rarely paradoxical excitation
- **Dexmedetomidine:** A short-acting, rapidly cleared α_2 -adrenergic agonist with sedative, anxiolytic, and analgesic properties:
 - Dosage IV: 1 μ g/kg loading dose over 5–10 min followed by infusion at 0.2–1 μ g/kg/h (use half dose for elderly or less invasive procedures)
 - Onset: Progressive during loading dose cycle
 - Duration: 6 min after cessation of infusion
 - Side effects:
 - Moderate BP and heart rate reductions should be expected, but alternative agent should be used if bradycardia and/or severe heart block.
- **Etomidate:** Unique class of sedative–hypnotic:
 - Produces amnesia and sedation but *not* analgesia
 - Minimal cardiovascular and respiratory effects
 - Dosage IV: 0.1–0.15 mg/kg
 - Onset: < 1 min
 - Duration: 5 min
 - Side effects:
 - Myoclonus that seems to be related to dose and speed of administration
 - Nausea and vomiting
 - Hypotension and respiratory depression when combined with opioid or benzodiazepine
 - Adrenocortical suppression
- **Ketamine**
 - Produces analgesia, amnesia, and sedation due to its dissociative effect while maintaining spontaneous respirations and airway reflexes
 - Dosage (IV): 0.5–1 mg/kg (use midazolam 0.05 mg/kg and atropine 0.01 mg/kg concurrently) with onset of action 5–10 min
 - Dosage (IM): 2–4 mg/kg (combine atropine and midazolam in same syringe) with onset of action 15–25 min

- Dosage (PO): 5–10 mg/kg (use midazolam 0.5 mg/kg and atropine 0.02 mg/kg PO as well) with onset of 30–45 min
- Duration of action: IV 15–45 min; IM 30–90 min; PO 60–120 min
- Side effects:
 - Hypertension and tachycardia
 - Increases intracranial and intraocular pressure
 - Stimulates salivary and tracheobronchial secretions
 - Emergence reactions with hallucinations reported, but are less frequent in children <10 yr; the incidence can be reduced by premedication with midazolam in adults.
- Nitrous oxide
 - Inhalational agent administered in 50% nitrous oxide/oxygen concentration:
 - Excellent agent for quick procedures, as it provides analgesia, anxiolysis, and sedation without the need for IV placement
 - Onset of action: 30–60 sec
 - Duration of action: 3–5 min after ceasing inhalation
 - Side effects are rare but can cause deep sedation with respiratory depression (especially if concurrent narcotic) as well as nausea and vomiting.
 - Contraindications: Pregnancy, pneumothorax, and bowel obstruction
- Fentanyl
 - Ultra-short acting synthetic opioid
 - Analgesic properties but minimal sedative and no amnestic properties
 - Dosage (IV): 1–4 µg/kg (titrate)
 - Onset (IV): 30–60 sec with peak at 1–3 min
 - Transmucosal 10–15 µg/kg with onset in 15–20 min:
 - Oral lozenge (Oralet) allows patient to suck on drug, which then can be removed by physician or patient when adequate sedation achieved.
 - Duration of action: 30 min
- Remifentanyl
 - Potent ultra-short-acting synthetic with potent sedative and analgesic properties.
 - Dosage (IV): 0.5–1 µg/kg every 2 min titrated to effect
 - Onset (IV): <1 min
 - Duration of action: 5 min
 - Side effects of fentanyl and remifentanyl:
 - Respiratory depression with potential apnea
 - Hypotension
 - Chest wall rigidity is a rare complication when large doses given quickly.
 - Use <1/3 dose in children <6 mo.
 - Emesis with transmucosal preparation
- Propofol: Rapid onset and short duration make for excellent ED agent for

procedural sedation:

- Produces amnesia and sedation but *not* analgesia
- Onset of action: 15–45 sec
- Dosage (IV): 0.5–1 mg/kg bolus (usually given as 20 mg boluses every 10 sec in adults until desired effect is obtained) followed by infusion of 50–75 µg/kg/min; effective total dose for adults 20–150 mg
- Duration of action: < 2 min
- Side effects:
 - Dose-related respiratory depression with occasional apnea (care with COPD)
 - Hypotension (care with cardiomyopathy or hypovolemia)
 - Pain at injection site
- Care with patients in renal failure due to accumulation of active metabolite leading to prolonged sedation

Reversal agents

- **Naloxone:** Opioid antagonist:
 - For reversal of respiratory depression, apnea, and severe hypotension
 - Dosage: 0.1–0.2 mg/kg IV/IM in incremental doses (to total of 2 mg) q1–2min to the desired reversal effect; usual adult dose of 1–2 mg effective
 - Duration of action: 20–45 min

ALERT

Naloxone may induce severe opioid withdrawal (nausea and vomiting, agitation, abdominal pain with diarrhea) for those on chronic opioid therapy.

- **Flumazenil:** Benzodiazepine antagonist:
 - Reverses CNS depression and some degree of respiratory depression
 - Dosage (IV): 0.01 mg/kg per dose (max. initial dose 0.2 mg) repeated at 1-min intervals to desired effect or max. 0.05 mg/kg or 1 mg
 - Duration of action: 20–45 min

ALERT

Flumazenil may induce severe benzodiazepine withdrawal (seizures, agitation, psychosis, nausea and vomiting, and muscle spasm) for those on chronic benzodiazepine therapy.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Postprocedural sedation

- Inability to walk
- No responsible adult to accompany patient home
- Reason for undergoing conscious sedation still present
- Postprocedure complication

Discharge Criteria

- Patient is awake, alert, and at baseline
- Procedure was of sufficiently low risk that additional monitoring for complications is unnecessary
- Stable hemodynamically
- Ambulatory 30 min before discharge
- Able to urinate
- Able to retain oral fluids
- Pain controlled
- Under observation of a responsible person and have transportation from the hospital

PEARLS AND PITFALLS

- All airway adjuncts should be readily available in case of respiratory compromise.
- All reversal agents should be readily available in case of inadvertent overdose of medications.
- Patients must have continuous cardiorespiratory monitoring during and after procedural sedation.

PROSTATITIS

Nicole M. Franks

BASICS

DESCRIPTION

- Acute (bacterial) prostatitis:
 - Acute febrile illness
 - Systemic symptoms may appear days before localizing urinary symptoms appear.
 - Patients may appear toxic and usually have a concurrent cystitis.
- Prostatic abscess:
 - Once common after acute prostatitis, now rare except in immunocompromised patients
 - Fever, rectal pain, and leukocytosis despite treatment
 - Fluctuant mass on rectal exam
- Chronic bacterial prostatitis:
 - ~10% of cases of prostatitis
 - Most common cause of recurrent UTI in men
 - WBC and bacteria may be present in expressed prostatic secretions (EPS).
- Chronic nonbacterial prostatitis (also called prostaticitis):
 - Same symptoms as chronic bacterial prostatitis but unable to culture organisms from urine or EPS
- Chronic pelvic pain syndrome (CPPS):
 - Symptoms referable to the prostate
 - No inflammatory cells are found
 - No bacteria cultured from the urine or EPS

ETIOLOGY

- Usually a single-organism bacterial infection of the prostate
- Acute prostatitis:
 - Age < 35 yr:
 - *Neisseria gonorrhoeae* and *Chlamydia trachomatis* are usual etiologies.
 - Age ≥ 35 yr:
 - Enterobacteriaceae or *Escherichia coli* (usual), *Klebsiella*, *Pseudomonas*, *Enterococcus*, and *Proteus* also seen
 - Rarely may be caused by *Salmonella*, *Clostridia*, tuberculosis, or fungi.
 - *Cryptococcus neoformans* in AIDS patients
- Chronic bacterial prostatitis:
 - Enterobacteriaceae (80%), *Enterococcus* (15%), and *Pseudomonas aeruginosa*
- Chronic nonbacterial prostatitis:

- Possible role for *Chlamydia*, *Ureaplasma urealyticum*, *Trichomonas vaginalis*, and *Mycoplasma hominis*

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Irritative voiding symptoms:
 - Frequency, urgency, dysuria
- Low back pain
- Perineal, suprapubic, or testicular pain
- Bladder outlet obstruction and urinary retention
- Ejaculatory symptoms such as hematospermia
- Acute prostatitis:
 - Fever, chills
 - Malaise
 - Arthralgias or myalgias
- Primary symptom in chronic prostatitis is relapsing dysuria.

Physical-Exam

- Acute prostatitis:
 - Exquisitely prostate tenderness
 - Warm, swollen
 - Firm or boggy prostate
 - Acutely inflamed prostate should not be massaged because that may precipitate hematogenous spread of organisms.
- In chronic prostatitis, the exam is usually normal.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Urinalysis (with microscopy) and culture
- Acute prostatitis:
 - CBC, electrolytes, and blood cultures may be helpful in the acutely ill patient.
 - If < 35 yr old or suspected sexual transmission, test for syphilis:
 - Venereal Disease Research Lab or rapid plasma reagin
- Chronic prostatitis/CPPS:
 - Prostatic massage between voiding may be used to capture EPS for Gram stain and culture if organism or white cells not present in the urine.

Imaging

- Not indicated in acute prostatitis
- If prostatic abscess suspected, transrectal US or pelvic CT with IV and rectal contrast will confirm diagnosis.

Diagnostic Procedures/Surgery

Not applicable in ED

DIFFERENTIAL DIAGNOSIS

- Benign prostatic hyperplasia
- Cystitis
- Epididymitis
- Orchitis
- Perirectal/perianal abscess
- Proctitis
- Prostatic carcinoma
- Prostatic infarction
- Pyelonephritis
- Seminal vesiculitis
- Urethritis
- Urolithiasis
- Vesicular calculi
- Other causes of lower back pain (strain, disc disease, sacroiliac joint disease, etc.)

TREATMENT

INITIAL STABILIZATION/THERAPY

Initial resuscitative measures as indicated

ED TREATMENT/PROCEDURES

- Prostatic abscess requires urgent urologic consultation and transrectal US-guided aspiration.
- Antibiotic therapy should be initiated in ED (see Medications).
- Urinary tract instrumentation should be avoided:
 - If patient has painful urinary retention in acute prostatitis, suprapubic needle aspiration or suprapubic catheter placement should be performed.
- Many patients will benefit from IV fluid.
- Pain control with NSAIDs and narcotic analgesics as needed
- Stool softeners
- Bed rest
- Irritative voiding symptoms may persist for months after antibiotic therapy and may be treated with NSAIDs.

MEDICATION

- Analgesia:
 - Narcotic, analgesic combinations such as hydrocodone/acetaminophen: 1–2 tabs PO q4h
 - NSAIDs such as ibuprofen: 800 mg PO TID
- Parenteral antibiotic therapy for acute prostatitis:
 - Levofloxacin: 750 mg IV daily
 - Ampicillin/sulbactam: 3 g IV q6h
 - Cefotaxime: 2 g IV q8h
 - Ceftriaxone: 2 g IV daily
 - Ciprofloxacin: 400 mg IV BID
 - Ofloxacin: 200 mg IV BID
 - Piperacillin/tazobactam: 3.375 g IV q6h or 4.5 g IV q8h
 - Ticarcillin/clavulanate: 3.1 g IV q6h
- Antibiotics for outpatient treatment of acute (≤ 35 yr old) prostatitis, suspected etiology *N. gonorrhoeae* or *C. trachomatis*:
 - Ceftriaxone: 250 mg IM, then doxycycline: 100 mg PO BID \times 10–14 days
 - Levofloxacin: 500 mg PO every day for 10–14 days
 - Ofloxacin: 400 mg PO \times 1, then 300 mg PO BID \times 10–14 days
- Antibiotics for outpatient treatment of acute (> 35 yr old) prostatitis, suspected etiology Enterobacteriaceae (coliforms); some authorities recommend 3–4 wk of therapy:
 - Ciprofloxacin: 500 mg PO BID \times 14 days
 - Levofloxacin: 500 mg PO every day for 14 days
 - Ofloxacin: 200 mg PO BID \times 14 days
 - Trimethoprim/sulfamethoxazole: 1 double-strength (DS) tab or 2 regular-strength tabs PO BID \times 28 days
- Outpatient therapy for chronic bacterial prostatitis (Enterobacteriaceae, *Enterococcus*, or *P. aeruginosa*):
 - Ciprofloxacin: 500 mg PO BID for 4 wk
 - Levofloxacin: 500 mg PO every day for 4 wk
 - Ofloxacin: 300 mg PO BID for 6 wk
 - Trimethoprim/sulfamethoxazole DS: 1 tab PO BID for 1–3 mo
- CPPS:
 - Tamsulosin: 0.4 mg PO every day
 - Doxazosin: 1 mg PO (immediate release) every day
 - Peripheral β -adrenergic blocking agents have been used with some success; consult a urologist.
 - Prazosin: 1 mg PO BID/TID
 - Terazosin: 1 mg PO qhs

FOLLOW-UP

DISPOSITION

Admission Criteria

- Acute prostatitis:
 - Patients who appear ill or toxic
 - Hypotension
 - Urinary retention
- Chronic prostatitis:
 - Admission generally not warranted unless patient has signs or symptoms of acute prostatitis.

Discharge Criteria

- Acute prostatitis:
 - Patient must be nontoxic.
 - Able to take fluids and oral medications (analgesia and antibiotics)
 - Urinate without difficulty
 - Immunocompetent
 - Relatively free of concurrent underlying disease
 - Have appropriate follow-up care
- Chronic prostatitis: Appropriate follow-up care should be available.

Issues for Referral

Patient with either acute or chronic prostatitis should be referred to an urologist.

PEARLS AND PITFALLS

- Obtain a good history to distinguish acute from chronic prostatitis, as longer antibiotic therapy may be warranted.
- Consider this diagnosis even in sexually active adolescent males.
- Acutely ill males with antibiotic treatment failure for prostatitis should be evaluated for abscess regardless of immunocompetence.

CODES

ICD9

- 601.0 Acute prostatitis
- 601.1 Chronic prostatitis
- 601.9 Prostatitis, unspecified

ICD10

- N41.0 Acute prostatitis
- N41.1 Chronic prostatitis
- N41.9 Inflammatory disease of prostate, unspecified

PRURITUS

Christine Tsien Silvers

BASICS

DESCRIPTION

- Unpleasant sensation that provokes a desire to scratch
- Mediated by unmyelinated C fibers in upper portion of dermis:
 - Transmitted to dorsal horn of spinal cord
 - Via spinothalamic tract to cerebral cortex
- Peripheral mediators (e.g., histamine and peptides such as substance P that release histamine) stimulate C fibers and induce itching
- Prostaglandins (PGE₂, PGH₂) lower threshold to pruritus
- Opiates cause pruritus by acting on central receptors
- No single pharmacologic agent effectively treats all causes of pruritus
- “Itch–scratch–itch” cycle:
 - Itching triggers scratching
 - Scratching damages skin and stimulates nerve endings, thereby producing even greater itching

ETIOLOGY

4 categories in proposed itch classification:

- Pruritoceptive: Generated in the skin from localized irritation or inflammation
- Neurogenic: Generated in the CNS due to circulating pruritogens
- Neuropathic: Due to CNS or PNS lesions
- Psychogenic

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Onset:
 - Shortly after freshwater bathing in swimmer’s itch
 - More intense at night with scabies
 - Paroxysmal with multiple sclerosis
 - With sudden changes in temperature in polycythemia vera
- Character: Paroxysmal, burning, pricking
- Time of occurrence, duration
- Severity; impact on quality of life
- With or without skin lesions

- Anatomic area (e.g., exposed skin only)
- Exacerbating or alleviating factors (e.g., water, heat, dryness, dampness, coolness)
- Medications
- New products (e.g., soap, cosmetics, laundry detergents, fabric softeners)
- Age
- Family history of atopic dermatitis or skin disease
- Personal history of allergies or asthma
- Pruritus in other family members
- Systemic or associated symptoms (e.g., night sweats, fever, tremors, weight loss, fatigue, jaundice, anemia, neurologic symptoms)
- Sexual history, history of HIV or AIDS
- Social: Occupation, hobbies, pets, travel

Physical-Exam

- Dermatologic:
 - _ Absence of rash
 - _ Diffuse or localized rash
 - _ Location: Genitals, interdigital webs, axilla, wrists, etc.
 - _ Generalized morbilliform eruptions
 - _ Discrete weeping patches with vesicles
 - _ Dry skin
 - _ Jaundice
 - _ Follicular (around the hair)
 - _ Nonfollicular (e.g., insect bites, scabies)
 - _ Primary lesions:
 - Papular, pustular, urticarial, or polymorphic
 - _ Secondary lesions:
 - Excoriations
 - Lichenification
 - Hyperpigmentation
 - Prurigo papules: Thickened papular areas of skin from constant rubbing
- Psychogenic: Constant rubbing in areas patient can readily reach

ESSENTIAL WORKUP

- Detailed history is key in the ED workup
- Physical exam to characterize skin lesions
- Look for evidence of systemic disease

DIAGNOSIS TESTS & INTERPRETATION

Lab

Indications for specific studies (e.g., CBC and differential, ESR, CRP, BUN/creatinine,

glucose, LFTs, TSH, free T4, HIV, RPR, cancer screening, CXR, abdominal ultrasound, CT/MRI) vary based on the clinical presentation and should be guided by clinical judgment.

Diagnostic Procedures/Surgery

- Skin scrapings for scabies and dermatophytoses
- Skin biopsy performed by dermatologist at follow-up visit
- Skin culture for bacterial, viral, or fungal infection

DIFFERENTIAL DIAGNOSIS

Dermatologic

- Xerosis (dry skin)
- Insect infestations:
 - Scabies: Vesicles and burrows on intertriginous areas
 - Pediculosis (lice)
- Insect bites: Localized clusters of papules
- Dermatitis:
 - Atopic dermatitis
 - Contact dermatitis (e.g., poison ivy contact)
 - Nummular dermatitis: Round eczematous or vesicular eruption
- Drug induced (suspect when no rash):
 - Opiates and derivatives
 - Aspirin/NSAIDs
 - Quinidine; amiodarone
 - Certain antibiotics, antifungals, antimalarials
 - Phenothiazines
 - Estrogens, progestins, testosterone
 - Statins
 - Others
- Lichen planus: Lichenification, hyperpigmentation, skin thickening
- Urticaria
- Bullous pemphigoid
- Eosinophilic folliculitis
- Psoriasis
- Dermatitis herpetiformis: Burning itch
- Sunburn
- Aquagenic pruritus
- Fiberglass dermatitis
- Seborrheic dermatitis: Scaly plaques on sebaceous gland-bearing areas
- Swimmer's itch, schistosome cercarial dermatitis, or schistosomiasis:
 - Repeated freshwater exposure
 - Itching starts as water evaporates

- Highly pruritic papules develop hours later
- Miliaria rubra (prickly heat)

Pregnancy Considerations

- Polymorphic eruption of pregnancy
- Pemphigoid gestationis
- Intrahepatic cholestasis of pregnancy
- Atopic eruption of pregnancy

Infectious

- HIV
- Parasites:
 - Ankylostomiasis/helminthiasis (hookworm)
 - Onchocerciasis/river blindness (nematode)
 - Ascariasis (roundworm)
 - Trichinosis (roundworm)

Cholestatic

- Obstructive biliary disease
- Primary biliary cirrhosis
- Hepatic cholestasis secondary to drugs
- Intrahepatic cholestasis of pregnancy
- Extrahepatic biliary obstruction
- Chronic hepatitis, especially hepatitis C

Hematologic

- Polycythemia vera
- Iron-deficiency anemia
- Paraproteinemia
- Waldenström macroglobulinemia
- Mastocytosis

Neoplastic

- Lymphoma, including Hodgkin lymphoma
- Mycosis fungoides
- Leukemia
- CNS tumors
- Multiple myeloma
- Carcinoid
- Visceral malignancies (breast, stomach, lung)

Metabolic-Endocrine

- Uremia
- Hyperthyroidism
- Hypothyroidism
- Hyperparathyroidism
- Diabetes mellitus
- Carcinoid

Neurologic

- Multiple sclerosis: Paroxysmal itching
- Notalgia paraesthetica: Local itch of back, medial shaft scapula
- Brain abscess
- CNS infarct
- Cerebral tumor
- Creutzfeldt-Jakob disease

Renal

- Chronic renal failure
- Chronic hemodialysis

Rheumatologic

- Sjögren syndrome
- Dermatomyositis

Psychiatric

- Stress, anxiety, neurotic excoriation
- Delusions of parasitosis
- Psychogenic pruritus

TREATMENT

ED TREATMENT/PROCEDURES

- Start with antihistamines for pruritus of undetermined etiology
- Emollients indicated for dry skin
- Coolants to alleviate itching, for neural modulation: Menthol, camphor, eucalyptus oil, calamine lotion, ice, topical anesthetics
- Substance P evacuators (capsaicin) block C fibers:
 - Burning sensation during 1st weeks of use
 - Anesthetic can be applied prior
- Topical glucocorticoids for contact dermatitis
- Permethrin cream for scabies and lice when rash is suggestive
- Topical antihistamines (e.g., doxepin) for eczema, urticaria, bites
- Swimmer's itch:

- Control with antihistamines, cool compresses, calamine lotion
- Topical steroids to suppress intense inflammation
- Towel dry immediately after leaving water as preventive measure
- Discontinue medications that may cause allergic reaction
- UV light for uremic pruritus
- Treat the underlying cause for pruritus associated with a systemic disease

MEDICATION

- Oral antihistamines:
 - Chlorpheniramine 4 mg (peds: 0.35 mg/kg/24h div. q 4–6h PRN; 2–6 yr max. 4 mg/24h; 6–12 yr max. 12 mg/24h) PO q4–6h PRN; max. 24 mg/24h
 - Diphenhydramine 25–50 mg (peds: 5 mg/kg/24h div. q6h PRN; 2–5 yr max. 37.5 mg/24h; 6–11 yr max. 150 mg/24h; > 12 yr max. 400 mg/24h) PO q4–6h PRN; max. 400 mg/24h
 - Hydroxyzine 25–100 mg (peds: 2 mg/kg/24h div. q6h PRN) PO q6–8h PRN; max. 600 mg/24h
- Topical treatments:
 - Capsaicin 0.025%, 0.075% cream: Apply TID–QID
 - Doxepin 5% cream: Apply QID for up to 8 days (to max. of 10% of the body)
 - EMLA (2.5% lidocaine + 2.5% prilocaine): Apply prior to capsaicin
 - Hydrocortisone 0.5%, 1%, 2.5%: Up to QID
 - Permethrin 5% cream (for scabies):
 - Apply from neck down after bath
 - Wash off thoroughly with water in 8–12 hr
 - May repeat in 7 days
 - Permethrin 1% cream rinse (for lice):
 - Shampoo, rinse, towel dry, saturate hair and scalp (or other affected area), leave on 10 min, then rinse
 - May repeat in 7 days
 - White petroleum emollients: Apply after short bath/shower in warm (not hot) water
- Other treatments for specific diseases

FOLLOW-UP

DISPOSITION

Admission Criteria

- Anaphylaxis
- Generalized exfoliating lesions
- Manifestations of systemic diseases requiring admission

Discharge Criteria

Vary by etiology

Issues for Referral

- Refer patients with skin lesions to primary care physician or dermatologist
- Stable patients with pruritus without skin lesions should be discharged on antipruritic medication and referred to a physician for an underlying systemic illness

FOLLOW-UP RECOMMENDATIONS

- Practical recommendations for dry skin:
 - Take baths with baking soda, bath oils, or colloidal oatmeal
 - Use moisturizers frequently during day and immediately after bathing
- Avoid:
 - Dry air (humidity < 40%)
 - Contact irritants (e.g., wool, cleansers)
 - Alkaline soaps and overwashing
 - Alcohol, caffeine, peppery foods
 - Overexposure to heat, hot water

PEARLS AND PITFALLS

- Detailed history is key in the ED workup
- Pruritus can be indicative of systemic illness
- No single treatment for all causes of pruritus

ADDITIONAL READING

PSEUDOTUMOR CEREBRI

Ian Reilly

BASICS

DESCRIPTION

- Buildup of CSF pressure without mass lesion or clear etiology
- Also known as idiopathic intracranial hypertension
- 2 proposed mechanisms:
 - Increased abdominal pressure or intracranial venous stenosis may decrease venous drainage from the head
 - Vitamin A levels above the saturation of the liver can damage cell membranes in the arachnoid granulations
- Associated with obesity
- Average age of onset 30 yr
- Female predominance (7:1)
- Uncommon, ~1–5 cases per 100,000

ETIOLOGY

Proposed causative agents:

- Obesity
- Obstruction of intracranial venous drainage
- Hypervitaminosis A
- Steroids/steroid withdrawal
- Tetracycline antibiotics
- Oral contraceptive pills
- Hypertension
- Recent weight gain
- Chronic carbon dioxide retention with elevated intracranial pressure

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Headache:
 - Typically described as constant, bilateral
 - Pressure like
 - Worse in the morning
 - Worse with Valsalva maneuver
- Nausea and vomiting

- Tinnitus or pulsatile intracranial noise
- Diplopia
- Dizziness
- Scotoma
- Transient visual obscurations lasting seconds
- Blind spots
- Constriction of vision

Physical-Exam

- Visual field defects (in up to 90%):
 - Typically inferior nasal visual field loss
- Papilledema
- Lumbar puncture improves symptoms
- 6th cranial nerve palsy
- Loss of visual acuity
- Otherwise normal neurologic exam except:
 - Visual changes
 - Abducens palsy
 - Rarely 7th cranial nerve palsy

Pediatric Considerations

- Usually presents with strabismus as opposed to headache and visual field loss
- Also associated with obesity and medications (tetracycline antibiotics, steroids)

ESSENTIAL WORKUP

- Thorough history and physical exam
- Detailed neurologic assessment and fundoscopic exam

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Lumbar puncture: CSF normal or low protein with a normal cell count
- Opening pressure > 25 cm H₂O or > 20 cm H₂O in nonobese, relaxed patient
- Consider CBC, coagulation studies prior to lumbar puncture
- Improvement of symptoms with lumbar puncture

Imaging

- Head CT/MRI to rule out mass lesions (prior to lumbar puncture)
- Classically, the head CT will demonstrate slitlike frontal horns of the lateral ventricles
- MRI recommended in the full workup:
 - Can be done as an outpatient

- Cerebral venous thrombosis can mimic pseudotumor cerebri in all regards including normal head CT

Diagnostic Procedures/Surgery

- Modified Dandy criteria for diagnosis:
 - Symptoms of raised intracranial pressure
 - No localizing symptoms with exception of 6th nerve palsy
 - Patient is awake and alert
 - Normal CT/MRI findings without evidence of thrombosis
 - Lumbar puncture opening pressure > 25 cm H₂O (some suggest > 20 cm H₂O in nonobese, relaxed patients)
- Lumbar puncture
 - Opening pressure should be performed in lateral decubitus position with neck and legs straight
 - Observing respiratory variation ensures good transmission of pressure
 - Improvement of symptoms may occur with lumbar puncture

DIFFERENTIAL DIAGNOSIS

- Migraine headache
- Hypertensive headache
- Anoxic headache
- Tension headache
- Cluster headache
- Subarachnoid hemorrhage
- Aneurysm/arteriovenous malformation
- Meningitis/encephalitis
- Subdural hematoma
- Epidural hematoma
- Tumor
- Abscess
- Trigeminal neuralgia
- Giant cell/temporal arteritis
- Sinusitis
- Glaucoma
- Central retinal vein/artery occlusion
- Congenital optic nerve head elevation
- Optic nerve drusen
- Labyrinthitis
- Optic neuritis
- Cerebral venous thrombosis
- Chronic carbon dioxide retention

TREATMENT

PRE HOSPITAL

Pain control as appropriate

INITIAL STABILIZATION/THERAPY

- Airway and circulation management as indicated
- IV fluid hydration

ED TREATMENT/PROCEDURES

- Large-volume lumbar puncture of 20–30 mL of CSF:
 - Only if confident of correct diagnosis and head CT demonstrates open basilar cisterns and 4th ventricle
- Acetazolamide
- Pain control
- Neurology consult
- Ophthalmology consult
- Neurosurgery consult for acute or impending visual loss unresponsive to diuretics (for lumboperitoneal shunt)
- Optic nerve fenestration is another surgical option
- Venous sinus stenting if stenosis is present
- Weight loss
- Discontinue any drugs that could be causative
- Typically resolves spontaneously

MEDICATION

- Acetaminophen: 500 mg PO (peds: 10–15 mg/kg; do not exceed 5 doses/24 h) PO q6h; do not exceed 4 g/24 h
- Acetazolamide: 500 mg slow-release PO BID (peds: 25 mg/kg/d div. TID/QID) PO/IV
- Ibuprofen: 600–800 mg (peds: 10 mg/kg) PO q8h
- Lasix: 0.5–1 mg/kg IV/PO
- Morphine: 0.1 mg/kg IV/IM
- Prednisone: Helpful when severe visual symptoms present, 5-day course recommended (longer treatment not recommended)

First Line

- Acetazolamide
- NSAIDs

Second Line

Topiramate has been suggested as a 2nd-line agent but is not FDA approved for this use

FOLLOW-UP

DISPOSITION

Admission Criteria

Acute or impending visual loss

Discharge Criteria

- Consultation obtained from neurology and ophthalmology
- Appropriate follow-up arranged
- Tolerating oral diuretics
- Pain under control

Issues for Referral

Timely referral and return precautions:

- Visual loss
- Focal neurologic deficit
- Worsening headache

FOLLOW-UP RECOMMENDATIONS

Follow-up is recommended with neurology and ophthalmology

PEARLS AND PITFALLS

- Consider this diagnosis in younger patients with chronic headache
- Consider measuring opening pressure when performing lumbar puncture for headache
- Measure opening pressure with neck and legs straight in lateral decubitus position
- Visual changes can portend visual loss

G93.2 Benign intracranial hypertension

PSORIASIS

Allison Tadros • Erica B. Shaver

BASICS

DESCRIPTION

- Chronic, noncontagious, inflammatory skin condition
- Disease of hyperproliferation
- Recently classified as an autoimmune disease
- Presents with erythematous plaques with silver scaling
- Most commonly affects the elbows, knees, lumbar area, gluteal cleft, and glans penis
- Up to 1/3 of patients develop associated arthritis and 10% have ocular manifestations
- Course is unpredictable; marked variability in severity over time and remissions may be seen
- Exact cause unclear: triggers may be infectious, stressors, medications, or trauma
- Tends to show improvement in summer months, possibly related to UV exposure
- Associated with metabolic syndrome
- Caucasians and atopics most affected
- 2 peaks of onset: between ages 20–30 and 50–60
- Affects 2.2% of US population, slightly higher incidence in females
- Rare cause of mortality, but at least 100 deaths annually in US related to severe disease and/or treatment adverse effects
- Several clinical presentations:
 - Plaque-type psoriasis (psoriasis vulgaris):
 - Most common form (75–80%) with erythematous, raised plaques with well-demarcated borders distributed over the scalp, back, and extensor side of the knees and elbows
 - Guttate psoriasis:
 - Abrupt appearance of multiple, discrete, salmon-colored, “drop-like” papules with a fine scale in a patient with no prior history of psoriasis
 - Most commonly seen on the trunk and proximal extremities
 - Often preceded by a streptococcal infection and resolves spontaneously
 - Pustular psoriasis:
 - Occasionally isolated to the palms and soles, but can present as widespread erythema, scaling, and sheets of superficial pustules with erosions
 - Patient may appear toxic and have other systemic symptoms, like

- malaise, fever, and diarrhea
 - Potentially severe and life threatening and treated as an inpatient if generalized
- Erythrodermic psoriasis:
 - Generalized erythema and pruritis with a fine scale
 - Increased risk for infection, dehydration
 - Often treated as inpatients
- Nail psoriasis
 - Pitting over the nail plate or change in nail bed
 - Nail changes in up to 50% of patients
- Inverse flexural psoriasis:
 - A variant that causes lesions in flexural areas and in skin folds that do not exhibit scaling due to moisture in these areas
- HIV-induced psoriasis:
 - May be the first manifestation of AIDS, more frequent and severe in HIV population
- Genetics:
 - There is a genetic predisposition and gene loci have been identified
 - 40% of patients with psoriasis have a family history in a 1st degree relative

ETIOLOGY

- Typical findings of erythema and scaling are the result of increased number of epidermal stem cells and keratinocyte hyperproliferation, shortened cell cycles, inflammatory infiltrates, and vascular changes
- Triggers include:
 - Drugs:
 - Lithium
 - β -blockers
 - Antimalarials
 - Steroid withdrawal
 - NSAIDs
 - Alcohol
 - Potassium iodide
 - Infections:
 - Streptococcal pharyngitis
 - HIV
 - Staph
 - Local trauma:
 - Frostbite
 - Sunburn
 - Recent skin trauma (Koebner phenomenon)
 - Stress: Emotional and physical
 - Winter:

- Low light exposure
- Dry weather
- Cigarette smoking
- Elevated BMI

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Long standing area of scaling erythema
- May give a history of previous diagnosis of psoriasis
- May be mildly pruritic
- May relate to one of the above triggers
- Specific location of lesions
- Family history of the disease
- History of improvement with sun exposure, or if recurrent, success of prior regimens
- Systemic symptoms like fevers or joint pains

Physical-Exam

- The classic skin lesion is a round, red patch with a central plaque of silvery, white scale that appears on extensor surfaces
- Redness and scaling around the umbilicus is highly suggestive of psoriasis
- Positive Auspitz sign:
 - Erythema and punctate bleeding when scales are removed
- In dark-skinned patients lesions may be grey
- Scalp lesions may be confused with seborrhea:
 - Lesions that extend beyond the hair borders indicate psoriasis
- Stippling and pitting of nail and onycholysis:
 - Yellow or brown band across the nail may help differentiate psoriasis (+ band) from onychomycosis (– band)
- Patients with plaque psoriasis may have concomitant psoriatic arthritis:
 - Often affects the DIP joints of the hands and feet
- Asymmetric oligoarticular arthritis:
 - Present in 70% of these patients
 - Swelling of the juxta-articular tissue
 - “Sausage-shape” to the affected digits

ESSENTIAL WORKUP

- The diagnosis is clinical
- Rarely, a biopsy is necessary to confirm the diagnosis or rule out other conditions

DIAGNOSIS TESTS & INTERPRETATION

Lab

- No lab test confirms the diagnosis
- Elevated sedimentation rate in erythrodermic and pustular forms
- Positive streptococcal cultures and titers with guttate psoriasis
- Hypocalcemia and leukocytosis in pustular disease
- Negative rheumatoid factor
- Uric acid may be elevated
- If starting medications, consider checking baseline CBC, LFTs, and renal function, as well as TB screening

Imaging

- Plain radiographs of the hands or feet may be abnormal with psoriatic arthritis
- Sacroiliitis and ankylosing spondylitis may also be seen on radiographs

DIFFERENTIAL DIAGNOSIS

Best thought of by region

- Scalp: Seborrhea
- Flexure creases:
 - Candidiasis
 - Intertrigo
 - Eczema
- Nails: Onychomycosis
- Trunk and extremities:
 - Nummular eczema
 - Pityriasis rosea or rubra pilaris
 - Tinea
 - Systemic lupus erythematosus
 - Syphilis
 - Lichen simplex chronicus
 - Atopy, drug eruption
 - Mycosis fungoides
 - Squamous cell carcinoma

TREATMENT

PRE HOSPITAL

- Maintain universal precautions
- IV access and pain control as necessary

INITIAL STABILIZATION/THERAPY

- General resuscitation efforts aimed at correcting fluid and electrolyte abnormalities
- Treating sepsis if present:
 - Cultures of lesions, blood, and urine
- Systemic steroids should not be used as they may predispose to severe complications

ED TREATMENT/PROCEDURES

- Patients should be educated on the chronic nature of psoriasis and that there is no cure even with treatment
- Treatments can be expensive and compliance is often poor
- Some patients may decline treatment in milder cases
- 3 basic types of treatment for psoriasis:
 - Topical therapy
 - Systemic therapy
 - Phototherapy
- Topical therapy is the most commonly prescribed treatment modality from the ED
- Systemic therapy is usually employed only after failure of topical and phototherapy and in conjunction with a dermatologist
- Exceptions where systemic therapy may be used:
 - Generalized pustular psoriasis
 - Very active psoriatic arthritis
 - Psoriasis that is considered severely disabling
- Phototherapy is not an ED treatment modality
- Dermatology consult should be obtained in severe cases

MEDICATION

- Mild to moderate disease:
 - Usually topical treatment only
 - No single topical agent works best for all patients.
 - Emollients:
 - Works well for limited plaque psoriasis
 - Greasier choices work best, but may be poorly tolerated by patients.
 - Topical steroids
 - Major form of therapy for those with limited disease
 - Can be used as monotherapy, 1–2 times a day, or in combination with emollients
 - Once improvement is achieved, consider tapering use
 - May need to rotate drugs
 - Occlusive dressing improves efficacy
 - Salicylic acid
 - Topical keratolytic agent
 - Precaution if already on systemic aspirin

- Coal-tar preparations:
 - Usually used with topical steroids
 - Newer forms are less messy
- Vitamin D analogs:
 - Calcipotriene and calcitriol
- Tazarotene
 - Topical retinoid, 0.1% cream
 - Pregnancy class X
- Tacrolimus
 - Topical treatment for inverse psoriasis or facial lesions
- Is steroid sparing and reduces risk of atrophy from steroids
- Moderate to severe disease:
 - The above-named agents may be employed along with phototherapy and systemic medications
 - Phototherapy:
 - UV radiation is thought to have antiproliferative and anti-inflammatory effects
 - Ultraviolet B light is usually combined with ≥ 1 topical agents and has reports of 80% remission
 - Ultraviolet B may be used alone in guttate psoriasis
 - Psoralen ultraviolet A (PUVA) light therapy combines a systemic agent (psoralen) that sensitizes the skin to UVA light
 - Therapy is usually given 2–3 times per week
 - Systemic agents: May be used in various combinations with the above modalities:
 - Should not be initiated without dermatology consultation
 - Methotrexate (immunosuppressant): Assess renal, liver, and hematologic function prior to therapy; not to be used during pregnancy
 - Retinoids: May cause dryness, scaling, redness, and tenderness of the skin
 - Systemic corticosteroids: Not favorable due to iatrogenic Cushing syndrome; it may have a role in acute erythrodermic psoriasis if patient is extremely ill
 - Cyclosporine: Use in conjunction with dermatology consult
 - Injectable immunosuppressants: Etanercept and Alefacept

FOLLOW-UP

DISPOSITION

Admission Criteria

ALERT

Acute erythroderma and acute pustular psoriasis warrant admission for supportive therapy and systemic treatment, as noted above.

Discharge Criteria

- Advise patients that the disease is not contagious
- Warn patients to avoid skin trauma and sunburns
- Educate the patient on avoiding medications that trigger relapses
- Refer patients to the National Psoriasis Foundation, www.psoriasis.org

Pediatric Considerations

- About 10–15% of cases occur \leq age 10
- Involvement of face and flexural areas more common; pustular and erythrodermic less common
- May have significant psychosocial impact on this population

Pregnancy Considerations

Many of the drugs used to treat psoriasis are contraindicated in pregnancy

Issues for Referral

- Referral to dermatology is indicated for most patients with psoriasis
- Patients with psoriasis may also need referral to primary care doctor and/or psychiatry to cope with impaired quality of life

FOLLOW-UP RECOMMENDATIONS

Follow-up with dermatology and/or primary care doctor to evaluate efficacy of treatment

PEARLS AND PITFALLS

- Patients with pustular psoriasis are at risk for severe systemic infections
- Patients with erythrodermic psoriasis are at risk for dehydration and may need to be treated similarly to a major burn patient
- Improvement occurs in weeks, not days

PSYCHIATRIC COMMITMENT

Danielle B. Kushner • Rohn S. Friedman

BASICS

DESCRIPTION

- Psychiatric “civil commitment”: The state-sanctioned *involuntary* hospitalization of mentally disordered individual
- Voluntary psychiatry hospitalization: Voluntary psychiatric admission of competent adult who agrees to hospitalization
- Commitment criteria (review specific laws in your state):
 - Individual is mentally ill (many states exclude mental retardation, antisocial behavior, medical illness, and substance abuse)
 - Likelihood of serious harm defined as:
 - Substantial risk of physical harm to self
 - Substantial risk of physical harm to other persons
 - “Gravely disabled”: Inability to care for basic needs, including food, clothing, shelter, medical care, and safety
 - No less-restrictive alternative to hospitalization would attenuate risk
- 2 stages of commitment:
 - Emergency detention and admission (sometimes called emergency hold)—an emergency admission with minimum of legal process. Usually 72 hr
 - Longer-term commitment—requires judicial approval of continued confinement in an adversarial proceeding where patient may have legal representation

ETIOLOGY

- Underlying genetic/biologic predisposition to psychiatric illness
- Precipitating psychosocial events can trigger onset or worsening of symptoms
- Substance abuse can worsen symptoms or lead to disinhibition causing worsening safety concerns

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Recent change in behavior or thinking
- Psychotic symptoms
 - Hallucinations
 - Delusions

- Disorganized thought
- Panic, anxiety, or agitation
- Depressed mood
- Neurovegetative symptoms (disturbance of sleep, appetite, libido, energy, concentration, energy, psychomotor state)
- Manic symptoms (elevated or irritable mood, grandiosity, racing thoughts, excessive involvement in pleasurable activities at high potential risk)
- Specific evidence of commitment criteria:
 - Actual or threatened violence toward self
 - Actual or threatened violence toward others
 - Inability to care for self or protect self in the community
- Past psychiatric diagnoses, treatment, hospitalizations, history of harm to self or others
- Medication compliance
- Drugs of abuse: Amount and time of last use
- Access to weapons

Physical-Exam

- Signs of toxidromes/overdose
 - Slurred speech, ataxia (alcohol intoxication)
 - Tremor, nystagmus, diaphoresis, tachycardia (alcohol withdrawal)
 - Dilated pupils, piloerection, rhinorrhea (opiate withdrawal)
 - Hyperreflexia, myoclonus, diaphoresis, dilated pupils (serotonin syndrome)
- Signs of self-injury (scars, fresh wounds)
- Hypoactivity, rigidity, catalepsy, posturing (catatonia, NMS)
- Mental status exam
 - Expansive, irritable, or depressed mood
 - Disordered thought process, loose associations
 - Hallucinations
 - Delusions
 - Suicidal ideation (active vs. passive), intent, or plan
 - Homicidal ideation (identified target, intent, plan)
 - Impaired cognition (delirium, dementia)

ESSENTIAL WORKUP

- Thorough medical evaluation to rule out medical causes of change in thinking or behavior
- Psychiatric evaluation to clarify diagnosis and need for hospital level of care

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Basic screening labs for medical clearance as indicated by history and physical:

- Electrolytes, BUN, creatinine, glucose
- Liver function tests
- CBC and differential
- Toxicology screens and medication levels
- Urinalysis if infection suspected
- TFTs

Imaging

CT or MRI of head if injury or structural CNS pathology suspected

Diagnostic Procedures/Surgery

- EEG if seizure/postictal state suspected
 - Repetitive pattern
 - Aura usually somatosensory psychiatric autonomic symptoms
 - Postictal period of either confusion or dysphasia
- LP
 - Fever or nuchal rigidity
 - Seizures

DIFFERENTIAL DIAGNOSIS

- Substance intoxication or withdrawal
- Delirium
- Dementia
- Traumatic brain injury/subdural
- Temporal lobe seizures
- Encephalitis
- Meningitis
- Antisocial behavior (patient feigning psychiatric symptoms, homicidal or suicidal ideation to obtain medications or shelter or avoid arrest)

TREATMENT

PRE HOSPITAL

- Patient or concerned family may call the ED and describe an emergency circumstance
- Depending on state, police, social worker, psychologist, or psychiatrist can send patient to ED for emergent assessment and possible involuntary hospitalization
- EMTs can restrain and bring patient to hospital involuntarily with appropriate legal paperwork

INITIAL STABILIZATION/THERAPY

- Ensure patient and staff safety

- Make sure patient does not have weapon or medications
- Room without hazards (sharps, medications, etc)
- Constant observation to prevent elopement
- Assess for overdose or self-injury requiring immediate treatment
- Ensure that proper legal paperwork is in place to hold patient in the ED

ED TREATMENT/PROCEDURES

- Medical workup and clearance
- Psychiatric consultation, if available
- Determine if patient requires psychiatric hospitalization.
- Restrain patients at risk of harming themselves or others, using least restrictive means required to maintain safety:
 - Nurse or security guard standing outside room
 - Pharmacologic restraint given PO, IM, or IV
 - Physical restraints
- Continue patient's confirmed home medications if appropriate
- Offer symptomatic medications such as antianxiety, antipsychotic, or sleep aid as needed
- Treat alcohol or drug withdrawal as needed

MEDICATION

- First line is Olanzapine 5--10 mg PO/IM OR haloperidol 5 mg IM with lorazepam 2 mg IM and benztropine 1 mg IM.
- First Line for EtOH/BZP withdrawal:
 - Diazepam 5–10 mg PO q1h prn (monitored with standardized symptoms assessment such as CIWA scale)
- 1st line for delirium not associated with alcohol withdrawal or anticholinergic excess:
 - Haloperidol 1–2 mg PO/IM/IV
- 1st line for agitation not associated with psychosis, delirium, or alcohol withdrawal:
 - Lorazepam 1 mg PO/IM/IV

FOLLOW-UP

DISPOSITION

Admission Criteria

- Danger to self
- Danger to others
- Severely disabled and unable to care for self/protect self in community
- Follow commitment process for your state

Discharge Criteria

- Patients may be discharged after medical and psychiatric evaluation if they:
 - _ Can care for themselves adequately *and*
 - _ The risk of harm to self or others is assessed to be safely manageable in a less-restrictive alternative, such as a partial hospital, a crisis stabilization/observation unit, or outpatient treatment

Issues for Referral

- Patient with acute psychiatric illness who does not meet the criteria for hospitalization usually requires 1 or more of the following:
 - _ Crisis stabilization or observation unit
 - _ Partial hospitalization, day program, or intensive outpatient program referral
 - _ Psychiatrist and/or therapist follow-up appointment within 3–5 days
 - _ Crisis Line phone number
- Patient may need to call insurer for list of or referral to outpatient providers covered by his or her insurance and may need a prior authorization

FOLLOW-UP

FOLLOW-UP RECOMMENDATIONS

Patient instructed to return to ED if feels unsafe, has increasing suicidal/homicidal thoughts, or other symptoms worsen

PEARLS AND PITFALLS

- Psychiatric civil commitment involves involuntary hospitalization due to mental illness and 1 of the following:
 - _ Substantial risk of harm to self
 - _ Substantial risk of harm to others
 - _ Inability to care for/protect self
- The details vary by state, so you need to know the specifics of your jurisdiction:
 - _ Mental retardation, antisocial behavior, organic causes such as dementia or delirium, and substance abuse may not qualify as a mental illness for which a person can be committed
 - _ The definition of the 3rd criterion for commitment (“gravely disabled,” unable to care for or protect self, or in need of treatment) varies
 - _ Time frames and procedures differ
- Need to complete thorough psychiatric and medical evaluation to evaluate causes of change in patient’s behavior
- Physician must weigh the ethical considerations inherent in involuntary hospitalization, balancing patient rights against the safety of patient or others.

PSYCHOSIS, ACUTE

Celeste N. Nadal • Serena A. Fernandes

BASICS

DESCRIPTION

- Disorder of brain function characterized by loss of contact with reality, abnormal perceptions, disorganization of emotions, thought, and behavior
- Dopamine pathways are strongly implicated
- May be secondary to psychiatric or medical, nonpsychiatric causes
- Medical causes of psychosis can be secondary to focal or systemic medical insults, neurologic impairment, or pharmacologic agents

ETIOLOGY

Medical, Nonpsychiatric

- Neurologic disease:
 - Head injury (history of)
 - Dementias (Alzheimer, Lewy body)
 - Cerebrovascular accident
 - Seizures
 - Space occupying lesions (neoplasm, malignancy, abscesses, cysts)
 - Hydrocephalus
 - Migraines
 - Demyelinating diseases (multiple sclerosis)
 - Neuropsychiatric disorders (Parkinson, Huntington, Wilson disease)
- Infectious disease:
 - Any focal infection (UTI, PNA, cellulitis)
 - HIV infection
 - Neurosyphilis
 - Lyme disease
 - Encephalitis, meningitis or cerebritis:
 - Bacterial (TB, Lyme)
 - Viral (HSV, CMV, EBV)
 - Fungal (Cryptococcus)
 - Prion diseases
- Metabolic:
 - Electrolyte imbalance
 - Hypoxia
 - Hypoglycemia
 - Hypercarbia

- Porphyria
- Intoxication or withdrawal syndrome
- Organ failure:
 - Liver (hepatic encephalopathy)
 - Renal
 - Cardiac (CHF, arrhythmias)
- Endocrine:
 - Thyroid disease
 - Parathyroid disease
 - Cushing syndrome
 - Addison disease
- Nutritional deficiencies:
 - Niacin
 - Thiamine
 - Vitamin B₁₂ and folate
- Autoimmune disease:
 - SLE
 - Paraneoplastic syndrome
 - Myasthenia gravis

Pharmacologic

- Medications:
 - All medications can cause psychosis
 - Sedative–hypnotics: Benzodiazepines (lorazepam, diazepam, alprazolam), barbiturates (butalbital), other (zolpidem)
 - Anticholinergic and antihistaminergic agents (diphenhydramine, cimetidine)
 - Steroids (prednisone)
 - Antiepileptic agents
 - Antiparkinsonian agents (amantadine, levodopa)
 - Cardiovascular agents (digoxin, reserpine)
 - Anti-infectious medications: Antibiotics (isoniazid, rifampin, fluoroquinolones, TMP/SMX), antivirals (oseltamivir, interferon), antiparasitics (metronidazole)
 - Chemotherapeutic agents (vincristine)
 - Muscle relaxants (dicyclomine, carisoprodol)
- Substances associated with intoxication:
 - Alcohol
 - Amphetamines
 - Cocaine
 - Opioids
 - Hallucinogens
 - Cannabis

- Sedative–hypnotics
- Other: LSD, MDMA, PCP, ketamine
- Substances associated with withdrawal:
 - Alcohol and sedative–hypnotics
- Toxins (heavy metals, organophosphates, carbon monoxide)

Psychiatric

- Brief psychotic disorder:
 - Abrupt onset, usually due to psychosocial stressors, lasting < 1 mo
- Delusional disorder:
 - Circumscribed delusions
- Schizophreniform disorder:
 - Symptoms present 1–6 mo
- Schizophrenia
- Schizoaffective disorder
- Mood disorder with psychotic features
- Postpartum psychosis

DIAGNOSIS

SIGNS AND SYMPTOMS

- Delusions are fixed, false beliefs that are:
 - Impervious to outside logic
 - Often persecutory, religious, or somatic content
- Hallucinations:
 - Sensory experiences in the absence of external stimuli
 - Can involve any sensory modality; auditory and visual are most common.
- Thought disorder:
 - Disorganized speech ranging from odd, idiosyncratic logic (loose associations) to incoherence (neologisms, word salad) or poverty of content
- Disorganized or catatonic behavior:
 - Odd, stereotyped behavior (waxy flexibility, echopraxia)
- Negative symptoms:
 - Flattened affect
 - Apathy
 - Anhedonia
 - Social isolation
- Features suggesting a nonpsychiatric etiology:
 - Sudden onset
 - > 30 yr old
 - Fluctuating course
 - Focal neurologic symptoms

- Abnormal vital signs
- Visual, olfactory, gustatory or tactile hallucinations
- Impairment of orientation, attention, or cognitive function

History

- Screen for psychosis, including onset, duration, triggers, and content:
 - Delusions:
 - “Do you feel anyone is trying to harm you or that you are being followed?”
 - “Is anyone trying to send you messages, steal, control, or block your thinking?”
 - Hallucinations:
 - “Do you ever see or hear things that other people cannot see or hear?”
 - “Do you ever hear voices telling you to do things such as to harm yourself or to harm others?”
- Suicidal or homicidal behavior or threats
- Past medical and psychiatric history
- Social situation and ability to care for self
- Recent use, increase or cessation of medications, drugs, or alcohol
- Obtain history from friends, family, and treaters

Physical-Exam

Look for signs of a medical etiology:

- Vital signs
- Eye exam (pupils, EOM, fundi)
- General exam with particular attention to the signs and symptoms of endocrine, liver, and renal disease
- Neurologic exam, including cognitive exam
- Careful assessment for signs of delirium

ESSENTIAL WORKUP

The workup is case specific and primarily based on the suspected etiology

DIAGNOSIS TESTS & NTERPRETATION

Lab

- Electrolytes, BUN, creatinine, glucose, calcium
- Toxicology screen
- CBC with differential
- TSH
- Urinalysis
- Further specific studies should be guided by the suspected underlying etiologies

Imaging

Consider head imaging for new-onset psychotic symptoms of unclear etiology, especially in setting of focal neurologic symptoms.

Diagnostic Procedures/Surgery

When clinically warranted consider:

- Lumbar puncture
- EEG
- EKG (monitor QT)

DIFFERENTIAL DIAGNOSIS

See Etiology.

TREATMENT

PRE HOSPITAL

- Patients can display unpredictable and violent behavior toward themselves and others
- Patients may require police presence or restraints to maintain safety
- Local laws vary regarding involuntary restraint

INITIAL STABILIZATION/THERAPY

- Safety of patient and staff is paramount and may require presence of security
- Behavioral interventions should be used first
 - Provide a calm, containing environment
 - Remove all potentially dangerous items
 - Use a reassuring voice and calm demeanor to set boundaries and verbally redirect
- If safety is a concern, patient needs to be under constant observation
- Physical or chemical restraints as necessary

ED TREATMENT/PROCEDURES

- If a nonpsychiatric etiology is suspected, identify and treat underlying medical condition
- If a psychiatric etiology is suspected, consider psychiatric consultation or referral
- Acute agitation is reduced with antipsychotics:
 - Encourage voluntary PO medications prior to IM administration
 - Avoid polypharmacy
- Rapid tranquilization may be achieved with the addition of a benzodiazepine
- Monitor for and treat adverse effects from antipsychotic medications:
 - Extrapyramidal symptoms (dystonia, akathisia, pseudoparkinsonism, and tardive dyskinesia)

- Neuroleptic malignant syndrome is a life-threatening complication:
 - o Characterized by hyperthermia, muscle rigidity, autonomic instability, and altered consciousness

MEDICATION

- 1st line antipsychotics:
 - Haloperidol: 2–10 mg PO/IV/IM, repeat q20–60min prn to max. 100 mg/d; elderly 0.5–2 mg/dose
 - o Commonly augmented with lorazepam
- 2nd line antipsychotics:
 - Aripiprazole: 2–15 mg PO/IM, may repeat q2h prn to max. 30 mg/d
 - Chlorpromazine: 25 mg PO/IM, repeat 25–50 mg q60min prn to max. 1,000 mg/d. Caution: Sedating, postural hypotension, do not use in elderly
 - Olanzapine: 2.5–20 mg PO/IM, may repeat dose q2–4h prn to max. 20 mg/d; elderly 2.5–5 mg/dose. Caution: Concurrent use of IM olanzapine and IV benzodiazepines may increase risk of cardiopulmonary collapse
 - Risperidone: 1–2 mg PO, may repeat 2 times; elderly 0.25–0.5 mg/dose. Caution: Orthostatic hypotension
 - Quetiapine: 25–50 mg PO BID, increase by 100 mg/d to max. 800 mg/d; elderly 12.5–25 mg/dose, increase by 25–50 mg/d
 - Ziprasidone: 20–40 mg PO BID, max. 80 mg PO BID; 10 mg IM q2h or 20 mg IM q4h prn to max. 40 mg/d IM, no more than 3 days. Caution: Monitor QT
- Benzodiazepines:
 - Lorazepam to augment tranquilization: 1–2 mg PO/IM/IV; elderly 0.25–0.5 mg PO/IM/IV

Geriatric Considerations

Black box warning: Elderly patients with dementia-related psychoses treated with antipsychotic drugs are at increased risk of death.

FOLLOW-UP

DISPOSITION

Admission Criteria

- If nonpsychiatric etiology, admit to appropriate medical service
- If psychiatric etiology and patient is medically stable, patient may require admission to a psychiatric hospital if patient:
 - Is a danger to self or others
 - Is gravely disabled and unable to care for self due to psychosis
 - Has new-onset psychosis and medical etiology has been ruled out

- Criteria for involuntary hospitalization vary

Discharge Criteria

- Patient is not a danger to self or others and is able to perform activities of daily living
- Psychotic symptoms resolved after causative medical issue addressed and patient is medically stable for discharge

Issues for Referral

Consider psychiatric consultation for complicated cases or for psychiatric admission.

FOLLOW-UP RECOMMENDATIONS

- Plan appropriate outpatient medical follow-up
- In patients with psychiatric disorders not requiring admission, plan outpatient psychiatric follow-up within 1 wk
- Consider referral for detoxification in patients with problems related to substance use

PEARLS AND PITFALLS

- Psychotic symptoms should be evaluated for treatable medical causes and not assumed to be solely psychiatric in nature even in patients with known mental illness
- Visual, olfactory, gustatory, or tactile hallucinations should prompt medical workup
- Avoid using IM olanzapine with IV benzodiazepines as this increases risk for cardiopulmonary collapse
- Patients who have recently started or increased their antipsychotics who present with fever, rigidity, autonomic instability, and mental status changes should be assessed for neuroleptic malignant syndrome

PSYCHOSIS, MEDICAL VS. PSYCHIATRIC

Richard E. Wolfe

BASICS

DESCRIPTION

Mental derangement involving hallucinations, delusions, or grossly disorganized behavior resulting in loss of contact with reality

- Complex and poorly understood pathophysiology
- An excess in dopaminergic signaling may be a contributing factor
- Psychosis ranges from a relatively mild derangement to catatonia
- CNS impairment leading to a psychotic presentation may be due to:
 - _ Neurologic disorders
 - _ Metabolic conditions
 - _ Toxins or drug effects
 - _ Infections
- Higher risk for underlying psychiatric disorder:
 - _ Hallucinations and illusions incorporated into delusional system
 - _ Late adolescence/early adulthood
 - _ Normal orientation
- Higher risk for underlying medical disorder:
 - _ Middle- to late-life presentation
 - _ Acute onset
 - _ History of substance abuse
 - _ No pre-existing psychiatric history
 - _ Absence of a family history of major mental illness
 - _ Presence of pre-existing medical disorders
 - _ Lower socioeconomic level
 - _ Recent memory loss
 - _ Disorientation or distractibility
 - _ Abnormal vital signs
 - _ Visual hallucinations:
 - Delirium
 - Dementia
 - Migraines
 - Dopamine agonist therapy (i.e., carbidopa)
 - Posterior cerebral infarcts
 - Narcolepsy

ETIOLOGY

- Neurologic:

- Head trauma
 - Space-occupying lesions
 - Cerebrovascular accident
 - Seizure disorders
 - Hydrocephalus
- Neuropsychiatric disorders: (Parkinson, Huntington, Alzheimer, Pick, Wilson disease)
- Infectious:
 - Focal infections in the elderly (UTI, pneumonia)
 - HIV
 - Neurosyphilis
 - Encephalitis
 - Lyme disease: Neuroborreliosis
 - Parasites:
 - Cerebral malaria
 - Neurocysticercosis
 - Schistosomiasis
 - Toxoplasmosis
 - Trypanosomiasis
- Metabolic:
 - Electrolyte imbalance
 - Hypoglycemia
 - Hypoxia
 - Porphyria
 - Withdrawal syndromes
- Endocrine:
 - Thyroid disorders
 - Parathyroid disorders
 - Diabetes mellitus
 - Pituitary abnormalities
 - Adrenal abnormalities
- End-organ failure:
 - Cardiac/respiratory
 - Renal
 - Hepatic
- Nutritional deficiencies:
 - Pernicious anemia
 - Wernicke–Korsakoff syndrome
 - Pellagra
 - Pyridoxine deficiency
- Autoimmune disorders:
 - Systemic lupus erythematosus
 - Sarcoidosis

- Myasthenia gravis
 - Paraneoplastic syndromes
- Demyelinating disease:
 - Multiple sclerosis
 - Leukodystrophies
- Postoperative states:
 - Delirium
- Intoxicants:
 - Alcohol
 - Benzodiazepines
 - Barbiturates
 - Stimulants (cocaine, amphetamines)
 - Hallucinogens
 - Opiates
 - Anticholinergic compounds
 - Inhalants
 - Cannabis
- Toxins:
 - Bromide
 - Carbon monoxide
 - Heavy metals
 - Organic phosphates
- Medication side effects:
 - Corticosteroids
 - Anticholinergics
 - Sedative–hypnotics
- Psychiatric:
 - Antidepressants
 - Antipsychotics
 - Lithium carbonate
- Antiparkinsonian drugs
- Anticonvulsants
- Antibiotics (quinolones, isoniazid)
- Antihypertensive agents
- Cardiac (digitalis, lidocaine, propranolol, procainamide)
- Interferon
- Muscle relaxants
- Over-the-counter medications:
 - Pseudoephedrine
 - Antihistamines
- Psychiatric:
 - Schizophrenia
 - Schizoaffective disorder

- Delusional disorder
- Bipolar disorder with psychotic features
- Major depression with psychotic features
- Stress reactions including post-traumatic stress disorder
- Narcolepsy (hallucinations at edge of sleep/wake cycle)
- Postpartum psychosis

DIAGNOSIS

SIGNS AND SYMPTOMS

- Psychosis characterized by:
 - Impaired reality testing
 - Inappropriate affect
 - Poor impulse control
- Focal and diffuse CNS impairment may result in derangements of:
 - Perception
 - Thought content
 - Thought process
- Hallucinations:
 - Sensory perception that has the compelling sense of reality of a true perception without external stimulation of the relevant sensory organ
- Delusions
 - Beliefs held with certainty, incorrigibility, and impossibility
 - Categorized by type and theme:
 - Bizarre or nonbizarre
 - Mood congruent or neutral
 - Persecutory or grandiose
 - Primary or secondary
- Thought disorder
- Affective symptoms may include mania, depression, or catatonia.

History

- Time course: Acute, episodic, chronic
- Collateral from family or outpatient providers
- Substance use
- Medications and medication adherence
- Family history
- Associated symptoms: Fever, weight loss, appetite, recent surgery and trauma

Physical-Exam

- Vital signs
- Neurologic exam:

- Cognitive exam: Attention and orientation
- Motor exam: Tone, abnormal movements

ESSENTIAL WORKUP

Detailed history and physical exam, including neurologic exam

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Low likelihood of clinically significant findings if there is a past history of psychosis, a benign history, and normal physical exam
- 1st line:
 - CBC
 - Electrolytes including calcium, BUN/creatinine, glucose
 - Urine and serum toxicology screen
 - Urinalysis
 - Liver function tests
 - Thyroid function tests
 - Vitamin B₁₂ and folate
- 2nd line guided by history and physical findings:
 - Ammonia level
 - HIV testing
 - Fluorescent treponemal antibody absorption (to rule out neurosyphilis; rapid plasmin reagin not sufficient as screen)
 - Ceruloplasmin
 - Urine heavy metals
 - ESR, C-reactive protein, antinuclear antibody

Imaging

- Routine CT or MRI scans are of little benefit
- Indications:
 - History or exam suggests a neurologic disorder
 - 1st-episode psychosis, 50 yr and older
- No clear clinically relevant benefit for MRI over CT

Diagnostic Procedures/Surgery

- EKG with attention to corrected QT interval
- Not recommended for routine screening:
 - Lumbar puncture
 - EEG

DIFFERENTIAL DIAGNOSIS

- Martha Mitchell effect:

- Process by which a clinician mistakes the patient's perception of real events as delusional
- Locked-in syndrome
- Periodic paralysis
- Conversion disorder

TREATMENT

PRE HOSPITAL

- Ensure safety of patient, bystanders, and medical personnel.
- Monitor vital signs, check finger stick.

INITIAL STABILIZATION/THERAPY

- Safety
- Evaluation
- Check O₂ saturation and serum glucose
- If uncooperative and dangerous, control behavior

ED TREATMENT/PROCEDURES

- Treat underlying medical illness or substance abuse disorder.
- Control psychotic behavior with psychotropic medications
- Check for prolonged QT before administering neuroleptic agents
- Haloperidol in combination with lorazepam:
 - Safe, fast; least disruptive of ongoing medical exam of patient
- Atypical neuroleptics:
 - Few extrapyramidal side effects
 - Olanzapine and ziprasidone can be given IM
 - Olanzapine (Zydis) and Risperdal M-tab are available in dissolving wafer preparations.
 - Avoid IM lorazepam with IM olanzapine due to risk of respiratory depression.

MEDICATION

First Line

- Haloperidol 2–10 mg IM or IV with lorazepam 0.5–2 mg IM or IV

Second Line

- Neuroleptics:
 - Olanzapine: 5–10 mg PO, SL, or IM
 - Risperidone: 1–2 mg PO or SL
 - Quetiapine: 25–100 mg PO

- Benzodiazepines:
 - Diazepam: 5–10 mg IV

Geriatric Considerations

- Increased mortality risk in patients > 65 yr on typical and atypical antipsychotics
- Start with lower doses (Haloperidol 2 mg IV), Olanzapine 2.5–5 mg PO, SL, or IM).
- Use benzodiazepines cautiously, given risk of disinhibition; avoid in delirious patients.

Pregnancy Considerations

Best evidence of safety of antipsychotic use in pregnancy is for 1st-generation (typical) antipsychotics such as haloperidol.

FOLLOW-UP

DISPOSITION

Admission Criteria

- If primarily medical etiology, admission to medical service, criteria dictated by specific medical condition
- If primarily psychiatric etiology (e.g., schizophrenia), admit to psychiatric service if:
 - Danger to self or others
 - Inability to care for self
 - Deranged thought pattern that can be threat to self or others
 - 1st episode: Evaluation and stabilization
 - Laws for involuntary hospitalization vary by state.

Discharge Criteria

- Stable medical condition
- Not suicidal/homicidal
- Able to care for self
- Capable of making medical decisions

Issues for Referral

- Insurance coverage determines inpatient and outpatient psychiatric disposition options.
- Case management or social services necessary for psychiatric disposition.

FOLLOW-UP RECOMMENDATIONS

- If psychosis is primarily psychiatric, confirm follow-up appointment with mental health provider within 1–2 wk.

- Reassess risk/benefit of continuing on antipsychotic medication at follow-up.

PEARLS AND PITFALLS

- Patients with psychosis may not be able to explain their symptoms in a typical way. Get collateral and maintain a high degree of suspicion.
- Important to rule out organic causes prior to ascribing psychosis to a psychiatric disorder.

PULMONARY CONTUSION

Douglas W. Lowery-North

BASICS

DESCRIPTION

- Transfer of kinetic energy to the lung, causing direct damage to the lung parenchyma, resulting in both hemorrhage and edema in the absence of a pulmonary laceration
- Mortality rate is 10–25%.
- Independent risk factor for:
 - Acute respiratory distress syndrome
 - Pneumonia
 - Long-term respiratory dysfunction

PATHOPHYSIOLOGY

- Development of pulmonary contusion:
 - Takes place in 2 stages:
 - 1st stage, which is related to the direct injury, results in disruption of the alveolocapillary membrane, which leads to extravasation of blood into the interstitial and alveolar space.
 - 2nd stage is related to the indirect worsening of the injury as a result of measures that occur during the resuscitation of the patient, in particular, administration of IV fluids.
- Leads to:
 - Increased intrapulmonary shunting
 - Increased resistance to airflow
 - Decreased lung compliance
 - Increased respiratory work
 - Hypoxemia and acidosis
 - Respiratory failure

ETIOLOGY

- Blunt or penetrating thoracic trauma
- Sudden deceleration–compression
- Fall from height
- Motor vehicle accident
- Assault
- Missile

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Blunt or penetrating thoracic trauma by any mechanism
- Mechanism as described by patient, family or emergency medical services personnel:
 - Seat belt use
 - Steering wheel damage
 - Air bag deployment
- Chest pain
- Dyspnea
- Hemoptysis

Physical-Exam

- Auscultation:
 - Initially normal or diminished breath sounds
 - Progresses to crackles, rales, absent breath sounds
- Localized ecchymosis, edema, erythema, and tenderness of chest wall
- Bony deformities, crepitus, point tenderness, and paradoxical movements associated with rib fractures
- Ecchymosis from seat belt, aka “seat belt sign”
- Ecchymosis from steering wheel impact
- Splinting respirations
- Cyanosis, tachycardia, hypotension
- Dyspnea, tachypnea

ALERT

Insidious onset increasing 6–12 hr post injury

ESSENTIAL WORKUP

CXR:

- Radiographic findings may not appear until 6–12 hr post injury.
- Patchy alveolar infiltrates to frank consolidation.
- Associated intrathoracic injury:
 - Rib fractures
 - Pneumothorax, hemothorax
 - Widened mediastinal silhouette

DIAGNOSIS TESTS & NTERPRETATION

Lab

Arterial blood gas may reveal hypoxemia and elevated alveolar–arterial gradient.

Imaging

- Chest radiograph:
 - Percentage of contusion can help predict the need for intubation:
 - <18%: Usually will not need intubation
 - >28%: Usually leads to intubation
- Thoracic CT is useful in detecting pulmonary injury and associated intrathoracic injuries not identified on CXR:
 - Studies that have shown injury size on CT can also assist with prognosis.
 - >20% of the total lung volume is predictive of the need of assisted ventilation.
- US has been studied and could prove to be a fast, sensitive method for diagnosing pulmonary contusion.

DIFFERENTIAL DIAGNOSIS

- Adult respiratory distress syndrome
- CHF
- Hemothorax
- Noncardiogenic causes of pulmonary edema
- Pneumonia, abscess, or other infectious process
- Pneumothorax
- Pulmonary laceration, infarction, or embolism

TREATMENT

PRE HOSPITAL

Thoracic trauma with significant mechanism or pre-existing pulmonary disease should be routed to the nearest available trauma center.

INITIAL STABILIZATION/THERAPY

- Manage airway and resuscitate as indicated.
 - Stabilize associated chest wall injuries (open chest, flail chest)
- IV line, O₂, continuous cardiac monitoring, and pulse oximetry
- Control airway:
 - Endotracheal intubation indications:
 - Severe hypoxemia (PaO₂ <60 mm Hg on room air, <80 mm Hg on O₂)
 - Significant underlying lung disease
 - Impending respiratory failure
 - Early intubation and institution of positive end expiratory pressure:
 - Correct hypoxemia and acidosis.
 - Decrease the work of breathing.

ED TREATMENT/PROCEDURES

- Maintain adequate oxygenation and ventilation.
- Monitor O₂ saturation and respiratory rate.
- In conscious and alert patients, O₂ administration via face mask is 1st-line therapy.
- If patient cannot maintain a PaO₂ > 80 mm Hg on high-flow oxygen:
 - _ Continuous positive airway pressure via mask
 - _ Nasal bilevel positive airway pressure (BiPAP)
 - _ Early endotracheal intubation and mechanical ventilation
- In patients with severe unilateral injuries with significant hemoptysis or air leaks, consider selective bronchial intubation.

ALERT

- Avoid excessive fluid administration:
 - _ IV crystalloid administration needed for resuscitation must be balanced with the risk of increasing interstitial pulmonary edema.
- Frequent re-exam and serial chest radiographs are required to monitor alveolar fluid accumulation.
- Mental status must be appropriate and patient must be alert and cooperative for BiPAP/CPAP:
 - _ Often this is only a temporizing intervention and should not delay intubation in worsening patients.

MEDICATION

- Adequate pain control is key for optimal outcome.
- Steroids have no proven benefit.
- Prophylactic antibiotics are not indicated.

Pediatric Considerations

Increased pliability of the chest wall increases the frequency of pulmonary contusions.

Geriatric Considerations

- Suboptimal cardiopulmonary reserve in combination with large-volume fluid resuscitation increases the likelihood of worsening of pulmonary contusions in the elderly.
- Pulmonary contusion has been identified as a marker for bad outcomes in elderly patients with isolated blunt chest trauma.

FOLLOW-UP

DISPOSITION

Admission Criteria

Patients with pulmonary contusion must be admitted to the hospital for observation in anticipation of delayed-onset respiratory compromise.

Discharge Criteria

- Patients with minimal chest trauma
- No evidence of respiratory distress or hypoxemia:
 - Normal respiratory rate
 - Reassuring pulse oximetry
 - Negative chest radiograph
- Strict return criteria should be discussed with the patient prior to discharge:
 - Shortness of breath
 - Hemoptysis
 - Inadequate pain control or increased pain
 - Cough

PEARLS AND PITFALLS

- Avoid underestimating the severity of pulmonary injury based on initial chest x-ray.
- Failure to recognize this injury in the ED can lead to unexpected deterioration.
- Comorbid conditions such as chronic lung disease and renal failure increase the likelihood of requiring mechanical ventilation.
- Careful monitoring and reassessment is key.

- S27.329A Contusion of lung, unspecified, initial encounter

PULMONARY EDEMA

Timothy C. Peck • Shamai A. Grossman

BASICS

DESCRIPTION

Imbalance in Starling forces causes an accumulation of alveolar fluid secondary to leakage from pulmonary capillaries into the interstitium and alveoli of the lungs.

- **Cardiogenic:**
 - Abnormality in cardiac function leading to inadequate tissue perfusion
 - Acute decompensated cardiac failure: Acute fluid overload in the setting of chronic HF
 - Acute vascular failure: Decreased contractility and increased vascular resistance
- **Noncardiogenic:**
 - Increased alveolar–capillary membrane permeability, and accumulation of fluid in the alveoli without a cardiac etiology
 - Acute lung injury: Lower severity
 - Acute respiratory distress syndrome (ARDS): $\text{PaO}_2/\text{FiO}_2$ ratio of ≤ 200 mm Hg
- **New York Heart Association classification:**
 - Class I: Not limited in normal physical activity by symptoms
 - Class II: Ordinary physical activity results in fatigue, dyspnea, or other symptoms
 - Class III: Marked limitation in normal activity
 - Class IV: Symptoms at rest or with any activity
- **Epidemiology:**
 - 5.8 million patients in US
 - Increases with increasing age and affects 10% of population >75 yr.
 - 30–40% of patients with HF are hospitalized every year.
 - 11% 1 mo mortality after AHF admission

ETIOLOGY

- **Cardiogenic etiologies:**
 - Contractile dysfunction:
 - Ischemic heart disease
 - Idiopathic cardiomyopathy
 - Myocarditis
 - Systolic pressure overload:
 - Aortic stenosis
 - Systemic hypertension

- Systolic volume overload:
 - Aortic regurgitation
 - Mitral regurgitation
- Restricted diastolic filling:
 - Mitral stenosis
 - Left atrial myxoma
 - Hypertrophic cardiomyopathy
- High-output states:
 - Hyperthyroidism
 - Anemia
 - Arteriovenous fistula
 - Wet beriberi
- Congenital heart disease
- Endocarditis
- Rheumatic heart disease
- Noncardiogenic etiologies:
 - Sepsis
 - Acute pulmonary infection, aspiration
 - Inhalation injuries
 - Aspiration
 - Near drowning
 - Disseminated intravascular coagulation
 - Pancreatitis
 - Pulmonary contusion
 - Severe (nonthoracic) trauma
 - Cardiopulmonary bypass
 - Uremia
 - High-altitude pulmonary edema
 - Neurogenic pulmonary edema
 - Narcotic overdose
 - Salicylate overdose
 - Pulmonary embolism
 - Fat embolism
 - Transfusion-related acute lung injury

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Risk factors:
 - Prior CHF diagnosis

- History of coronary artery disease or myocardial infarction
- Diabetes
- Severe systemic illness
- Symptoms:
 - Dyspnea on exertion progressing to dyspnea at rest
 - Orthopnea
 - Peripheral edema
 - Paroxysmal nocturnal dyspnea
 - Acute weight gain
 - Weakness/fatigue
 - Cough

Physical-Exam

- Vital signs
 - May be hypertensive or hypotensive
 - Tachypnea
 - Low oxygen saturation
- General
 - Diaphoresis
 - Cold, ashen, or cyanotic skin
- Respiratory:
 - Rales
 - Wheezes
 - Accessory muscle use
- Cardiovascular
 - Tachycardia
 - Jugular venous distention
 - Increased P2, S3, S4
 - Hepatojugular reflex
- Extremities
 - Peripheral edema
- Noncardiogenic
 - Similar pulmonary but rarely peripheral signs

ESSENTIAL WORKUP

- ECG to evaluate for cardiac ischemia and dysrhythmias.
- Chest x-ray to confirm the diagnosis and assessing illness severity.
- Labs: B-type natriuretic peptide (BNP), cardiac enzymes, and creatinine

DIAGNOSIS TESTS & NTERPRETATION

Lab

- BNP:

- Lab parameter for the detection and follow-up of heart failure:
 - <100 pg/mL: CHF unlikely
 - 100–500 pg/mL: Indeterminate
 - >500 pg/mL: Most consistent with CHF
- May not be elevated in very acute CHF or ventricular inflow obstruction
- May be falsely elevated in patients with renal failure undergoing dialysis due to LVH
- N-terminal pro-BNP:
 - Similar test characteristics to BNP
- Cardiac troponins:
 - May be elevated due to myocardial ischemia causing AHF or as result of AHF's effects on cardiac myocytes
 - Elevated in 20% of AHF episodes
 - Strong negative prognostic factor
- Serum chemistry panel:
 - Creatinine elevation:
 - Predicts all-cause mortality in chronic heart failure
 - Indication of acute end-organ hypoperfusion
 - Indication for admission or observation
 - Hyponatremia: Marker of severe HF
 - Electrolyte abnormalities are common due to various HF treatments.
- Elevated alanine aminotransferase, aspartate aminotransferase, or bilirubin suggests congestive hepatopathy.
- Serum lipase if pancreatitis is suspected as the underlying cause
- Arterial blood gas: Evaluates hypoxemia, ventilation/perfusion mismatch, hypercapnia, and acidosis.

Imaging

- CXR:
 - Pulmonary redistribution: Cephalization of vessels
 - Cardiomegaly: Cardiac silhouette >50% of thoracic width on PA exam only
 - Interstitial edema:
 - Pleural effusions
 - Kerley B lines
 - Bilateral perihilar alveolar edema producing a characteristic butterfly pattern
 - Noncardiogenic: Bilateral interstitial or alveolar infiltrates in a homogeneous pattern, typically without enlarged heart shadow
 - Radiographs are often normal in the 1st 12 hr of the disease process.
- ECG:
 - Assess for underlying cardiac disorders:
 - Acute dysrhythmias
 - Signs of acute coronary syndromes

- Signs of electrolyte abnormalities
- Atrial fibrillation occurs in 30–42% of patients admitted for acute heart failure.
- Both tachy- and bradydysrhythmias can lead to decreased cardiac output.
- Echocardiography:
 - Evaluates left ventricle function
 - Assesses acute valvular or pericardial pathology
 - Measures cardiac output
- Bedside ultrasonography:
 - Bilateral B-lines: Comet-tail artifacts arising from pleural line extending to the far field without a decrease in intensity on both the left and the right thorax

DIFFERENTIAL DIAGNOSIS

- COPD exacerbation
- Pneumonia
- Asthma
- Pulmonary embolism
- Pericardial tamponade
- Pneumothorax
- Pleural effusion
- Anaphylaxis
- Acidosis
- Hyperventilation syndrome

TREATMENT

PRE HOSPITAL

- IV access
- Supplemental oxygen
- 100% nonrebreather mask
- Cardiac monitor
- Pulse oximetry
- Sublingual nitrates
- If bag valve mask is needed, should use PEEP valve if available
- Endotracheal intubation in severe cases.

INITIAL STABILIZATION/THERAPY

- Assess and gain control of airway, breathing, and circulation.
- Noninvasive ventilation or endotracheal intubation for impending respiratory failure.

- IV access
- Supplemental oxygen
- Cardiac monitor
- Pulse oximetry
- Place patient in an upright position.
- Inotropic therapy for hypotensive patient with signs of end-organ dysfunction

ED TREATMENT/PROCEDURES

- Treatment decisions should be based on the underlying cause of pulmonary edema.
- Supplemental O₂
- Volume restriction
- Urine output monitoring with or without urinary catheter
- BiPAP/CPAP:
 - _ Improves oxygenation, reduces respiratory work, decreases left ventricular afterload
 - _ Reduces need for intubation, length of stay, and mortality
 - _ Efficacy of BiPAP = CPAP
- Noncardiogenic causes: Frequently require positive-pressure ventilation:
 - _ Low-volume ventilation recommended (6 mL/kg)
- Positive-end expiratory pressure: Most useful strategy for oxygenation
- Hypotensive patients:
 - _ Avoid nitrates, angiotensin-converting enzyme inhibitors (ACEIs), and morphine.
 - _ Initiate inotropes:
 - Dobutamine, Dopamine, Norepinephrine, or Milrinone
 - _ Direct cardioversion for new onset unstable atrial fibrillation
- Normotensive or hypertensive patients:
 - _ Nitrates (nitroglycerin vs. nitroprusside)
 - _ Diuretics (furosemide vs. bumetanide) may be most effective after initial stabilization
- Noncardiogenic: Treat underlying cause.

MEDICATION

- Aspirin: 325 mg PO/PR if myocardial infarction suspected
- Bumetanide: 1–3 mg IV
- Captopril: 6.25 mg SL
- Dobutamine: 2–10 µg/kg/min IV, titrate. May lower BP due to vasodilatory effects.
- Dopamine: 2 × 20 µg/kg/min IV; titrate
- Enalapril: 0.625–1.25 mg IV
- Furosemide: 20–80 mg IV
- Torsemide: 10–20 mg IV
- Milrinone: 50 µg/kg IV; titrate; inotropic effects comparable to dobutamine
- Nitroglycerin: 0.4 mg SL; 1–2 in; 5–20 µg/min IV and titrate; Nitropaste is not

- preferred as it is more difficult to titrate and to use in diaphoretic patients.
- Nitroprusside: 0.25–0.3 µg/kg/min, titrate up by 0.5 µg/kg/min q2–3 min until desired effect
- Norepinephrine: 2–12 µg/min IV; titrate

FOLLOW-UP

DISPOSITION

Admission Criteria

- ICU:
 - Positive-pressure ventilation
 - Inotropic support
 - Acute cardiac ischemia or infarction
 - ARDS
- Monitored unit:
 - New-onset pulmonary edema
 - Electrocardiographic changes
 - Patients presenting with risk factors for mortality, including advanced age, renal dysfunction, hypotension, digoxin use, and anemia

Discharge Criteria

- Most patients with pulmonary edema should be admitted or observed for 24 hr.
- Patients with mild underlying disease and a mild exacerbation that responds fully to ED management and have no risk factors for in-house mortality (see above) may be discharged.
- Ensure close outpatient follow-up.

FOLLOW-UP RECOMMENDATIONS

- Contact patient's primary physician and/or cardiologist to establish close follow-up.
- Continue diuresis.
- Low-salt diet
- Daily weights

PEARLS AND PITFALLS

- Nitrates, SL and IV, are 1st-line therapy to reduce preload.
- BNP can reliably differentiate between AHF syndromes and other causes of dyspnea.
- AHF chest radiography findings can be absent early in disease course.
- Aggressive, early treatment of normotensive and hypertensive patients with

nitrates, diuretics, and ACEIs can rapidly reverse the clinical course.

- Positive-pressure ventilation is an essential intervention in noncardiogenic pulmonary edema and can reduce rates of intubation and mortality in AHF.

- J81.0 Acute pulmonary edema

PULMONARY EMBOLISM

Alan M. Kumar

BASICS

DESCRIPTION

- The majority of pulmonary embolisms (PEs) arise from thrombi in the deep veins of the lower extremities and pelvis.
- Thrombi also originate in renal and upper extremity veins.
- After traveling to lungs, the size of the thrombus determines signs and symptoms.

ETIOLOGY

- Most patients with PE have identifiable risk factor:
 - Recent surgery
 - Pregnancy
 - Previous deep vein thrombosis (DVT)/PE
 - Stroke or recent paraplegia
 - Malignancy
 - Age > 50 yr
 - Obesity
 - Smoking
 - Oral contraceptives
 - Major trauma
- Hematologic risk factors:
 - Factor 5 Leiden
 - Protein C or S deficiency
 - Antithrombin III deficiency
 - Antiphospholipid antibody syndrome
 - Lupus anticoagulant

Pediatric Considerations

- Thromboembolic disease is quite rare.
- Risk factors in children:
 - Presence of central venous catheter
 - Immobility
 - Heart disease
 - Trauma
 - Malignancy
 - Surgery
 - Infection

DIAGNOSIS

SIGNS AND SYMPTOMS

- Variability in signs and symptoms make diagnosis difficult
- Most common:
 - Dyspnea
 - Pleuritic chest pain
 - Tachypnea
- General:
 - Fevers (rarely $> 102^{\circ}\text{F}$)
 - Diaphoresis
- Pulmonary:
 - Cough
 - Hemoptysis (rarely massive)
 - Rales
- Cardiovascular:
 - Tachycardia
 - Syncope
 - Murmur
- Extremities:
 - Cyanosis
 - Evidence of thrombophlebitis
 - Lower-extremity edema
- Abdominal pain
- Symptoms similar in elderly but typically more subtle if age < 40 yr

ESSENTIAL WORKUP

- Routine labs are nonspecific.
- CXR:
 - Used to rule out other causes
 - Most common findings with PE:
 - Normal
 - Nonspecific parenchymal abnormality
 - Atelectasis
 - Other findings with PE:
 - Pleural effusions
 - Pleural-based opacities (Hampton hump)
 - Elevated hemidiaphragm
 - Local oligemia (Westermark sign)
- ECG:
 - To rule out cardiac etiology
 - Usually normal in PE
 - Other findings include:

- Nonspecific ST–T-wave changes (most common abnormality)
- Sinus tachycardia
- Left axis deviation
- Right bundle branch block pattern
- S1Q3T3 pattern is uncommon and not specific enough to rule in/out diagnosis.
- Modified Wells criteria:
 - Popular decision rule that can assist with risk stratification in combination with d-dimer
 - Each criterion is given numeric value and if total value <4, along with negative d-dimer, risk of PE is <2%:
 - Clinical signs/symptoms of DVT: 3 pts
 - PE is no. 1 diagnosis: 3 pts
 - Heart rate >100 bpm: 1.5 pts
 - Surgery or immobilization for 3 days within last 4 wk: 1.5 pts
 - Previous PE or DVT: 1.5 pts
 - Hemoptysis: 1 pt
 - Malignancy with treatment within last 6 mo: 1 pt
- Pulmonary Embolism Rule-out Criteria (PERC)
 - Useful in low prevalence setting (ED) in combination with low clinical suspicion.
 - Age <50 yr
 - Heart rate <100 bpm
 - O₂ saturation ≥95%
 - No hemoptysis
 - No estrogen use
 - No prior DVT or PE
 - No unilateral leg swelling
 - No surgery or trauma requiring hospitalization within the past 4 wk
 - <1% risk for PE/DVT in 45 days if PERC score 0

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Arterial blood gas:
 - Can show hypoxemia, hypocapnia, respiratory alkalosis, or increased alveolar–arterial (A–a) gradient
 - PE still possible with normal A–a gradient
 - Does not aid in diagnosis of PE
- CBC:
 - Anemia may be contributing factor to dyspnea.
- d-dimer enzyme-linked immunosorbent assay:

- d-dimers are detectable at levels > 500 ng/mL in nearly all patients with PE.
- High sensitivity (close to 100%) with low specificity for PE
- Almost always elevated in patients with malignancy or surgery within the last 3 mo
- Multiple studies confirm that negative enzyme-linked immunosorbent assay d-dimer in combination with low clinical suspicion effectively rules out PE.

Imaging

- **Spiral chest CT with IV contrast:**
 - Has ability to also detect alternative pulmonary abnormalities
 - Accurate for identifying PE in proximal pulmonary tree:
 - In patients with high pretest probability, positive predictive value of 96%
 - In patients with low pretest probability, negative predictive value of 96%
- **Ventilation–perfusion scan (V/Q):**
 - Results reported in probabilities and correlated to clinical suspicion
 - Probability of PE with V/Q results:
 - Normal or near normal V/Q scan: 4% probability for PE
 - Low-probability V/Q scan with low clinical suspicion: 4% probability for PE
 - Low-probability V/Q scan with high clinical suspicion: 16–40% probability for PE
 - Intermediate V/Q scan: 16–66% probability for PE
 - High-probability V/Q scan with low clinical suspicion: 56% probability for PE
 - High-probability V/Q scan with high clinical suspicion: 96% probability for PE
- **Lower-extremity duplex US:**
 - Used in patients who would otherwise require pulmonary angiogram
 - Presence of DVT requires same anticoagulation as PE.
 - Negative lower-extremity duplex does not rule out PE.
- **Echocardiogram:**
 - Used to assess for right heart strain or patent foramen ovale when thrombolysis is a possibility

Diagnostic Procedures/Surgery

Pulmonary angiogram:

- Gold standard for diagnosis
- Used when diagnosis not confirmed or excluded
- Higher complication rate than other modalities

DIFFERENTIAL DIAGNOSIS

- Anxiety disorder
- Aortic dissection
- Asthma
- Cardiac dysrhythmias
- Costochondritis
- Myocardial infarction
- Pericarditis
- Pneumonia
- Pneumothorax
- Rib fracture

TREATMENT

PRE HOSPITAL

- Initial supplemental oxygen
- Establish IV access
- Cardiac monitor

INITIAL STABILIZATION/THERAPY

- Airway, breathing, and circulation
- Provide supplemental oxygen to maintain adequate oxygen saturation.
- Intubate if unable to provide adequate oxygenation.
- Administer IV fluids carefully for hypotensive patients:
 - _ Excessive fluid expansion may worsen right heart failure.
- IV vasopressor therapy is indicated if hypotension does not resolve with IV fluids.

ED TREATMENT/PROCEDURES

- Anticoagulation:
 - _ Prevents additional thrombus from forming
 - _ Stabilizes existent clot to prevent migration
 - _ Risk of minor/major bleeding with therapy
- Unfractionated heparin:
 - _ Dose titration fraught with difficulty leading to inadequate therapy
 - _ Goal to maintain partial thromboplastin time test between 1.5 and 2.5 times the control value (60–80 sec)
- Low-molecular-weight heparin:
 - _ At least as effective as unfractionated heparin in multiple prospective randomized trials
 - _ Therapeutic goal automatic with weight-based dosing
 - _ Easier administration and monitoring than heparin with some cost benefit
- Warfarin:

- Oral therapy for long-term anticoagulation
- Goal is international normalized ratio (INR) of 2–3
- Rivaroxaban:
 - Oral factor 10a inhibitor
 - Recently approved for treatment of PE
 - Does not require lab monitoring
 - Not recommended in renal/hepatic insufficiency or pregnancy
 - No specific antidote but has short half-life in case of bleeding
- Thrombolysis:
 - Initiate in hemodynamically unstable patients with confirmed PE.
 - Consider in stable patients with PE and severe hypoxemia, massive PE, or right ventricular dysfunction.
- Inferior vena cava filter:
 - Indicated in patients who have contraindications to anticoagulation or have been therapeutic on anticoagulation but failed prevention of PE
- Surgical or catheter embolectomy:
 - Consider in those with thrombolysis contraindications or failure, or deemed unstable for medical management.
 - Case-by-case basis

MEDICATION

- Alteplase: 100 mg (peds: N/A) IV over 2 hr
- Enoxaparin: 1 mg/kg (peds: 0.75 mg/kg) SC q12h
- Reteplase: 10 U (peds: N/A) IV bolus q30min × 2
- Streptokinase: 250,000 U (peds: 3,500–4,000 U/kg) IV bolus over 30 min, then 100,000 U (peds: 1,000–1,500 U/kg) IV maintenance over 24 hr
- Unfractionated heparin:
 - Bolus: 80 U/kg (peds: 75 U/kg) IV over 10 min
 - Maintenance: 18 U/kg (peds: 20 U/kg) IV drip
 - Do not use TBW to calculate dose in obese patients.
- Warfarin: 5 mg (peds: 0.05–0.34 mg/kg/d) PO per day, adjust for INR goal 2–3
- Rivaroxaban: 15 mg BID × 3wks then 20mg QD

FOLLOW-UP

DISPOSITION

Admission Criteria

- Admit all patients with PE for continued anticoagulation and observation.
- Clinically stable patients with a high suspicion for PE, no contraindication to anticoagulation, and a lack of V/Q scanning or angiographic availability may be anticoagulated and studied when resources are available in the morning.

PEARLS AND PITFALLS

- Clinical presentation is variable and nonspecific, making diagnosis difficult in many cases.
- Patients with malignancy are at higher risk for Coumadin failure and recurrent PE even with therapeutic INR.

- O88.219 Thromboembolism in pregnancy, unspecified trimester

PURPURA

Richard E. Wolfe • Ashley L. Greiner

BASICS

DESCRIPTION

- Skin lesions caused by extravasation of blood into the skin or subcutaneous tissue
- Can be caused by fragile capillaries, poor dermal support, and/or platelet dysfunction
- The resultant lesions do not blanch completely with pressure (as seen when pressing down through a glass slide)
- Nomenclature varies by the size of the lesions:
 - Petechiae (≤ 4 mm)
 - Purpuric lesions (5–10 mm)
 - Ecchymoses (> 10 mm)
- Color determined by depth and time of onset:
 - Red if superficial and recent onset
 - Purple if deep
 - Deep purple, brown, orange, or blue-green with later presentations
- Nonpalpable purpura:
 - Simple hemorrhage or microvascular occlusion with ischemic hemorrhage
 - Generally due to a platelet disorder:
 - Diminished production
 - Altered distribution
 - Increased destruction
 - Abnormal function
- Palpable purpura:
 - Generally due to vasculitis:
 - Autoimmune, small-vessel leukocytoclastic vasculitis
 - Hypersensitivity to various antigens
 - Formation of circulating immune complexes deposited in walls of postcapillary venules; activate complement that is chemotactic for polymorphonuclear leukocytes
 - Released enzymes damage vessel walls and cause leakage of blood
 - Vasculitic lesions may not be palpable in immunocompromised patients

ETIOLOGY

- Nonpalpable purpura:
 - Viral:
 - Echovirus

- Coxsackie
- Measles
- Parvovirus B19

– Drugs:

- Acetaminophen
- Allopurinol
- Anticoagulants
- Aspirin
- Digoxin
- Furosemide
- Gold salts
- Lidocaine
- Methyldopa
- Nonsteroidal anti-inflammatory drugs
- Penicillin G
- Phenylbutazone
- Quinidine
- Quinine
- Rifampin
- Steroids
- Sulfonamides
- Thiazides

– Nutritional deficiencies:

- Vitamin K deficiency
- Vitamin C deficiency (Scurvy)

– Bone marrow disease

– Hypersplenism

– Idiopathic thrombocytopenic purpura (ITP)

– Disseminated intravascular coagulation (DIC)

– Thrombotic thrombocytopenic purpura

– Liver or renal insufficiency

– Thrombocytopenia ($< 50,000$ plt/cc)

– Thrombocytosis ($> 1,000,000$ plt/cc)

– Spiking elevations of intravascular pressure (childbirth, vomiting, paroxysmal coughing)

– Hemophilia

– Solar purpura (only on sun-exposed areas)

– Post-transfusion

● Palpable purpura:

– Viral:

- Echovirus type 9
- Coxsackie
- Hepatitis B

- *Streptococcal pharyngitis*
- Drugs:
 - Allopurinol
 - Anti-influenza vaccines
 - Cephalosporins
 - Gold
 - Heparin
 - Hydralazine
 - Iodides
 - Levamisole
 - Metoclopramide
 - Penicillin G
 - Phenylbutazone
 - Phenytoin
 - Quinidine
 - Quinine
 - Streptomycin
 - Sulfonamides
 - Thiazides
 - Ticlopidine
- Malignancies
- Autoimmune and connective tissue diseases
- *Gonococcus*
- *Meningococcus*
- *Pseudomonas* (ecthyma gangrenosum)
- Rocky Mountain spotted fever
- In immunocompromised hosts: *Candida*, *Aspergillus*
- Occlusion due to organisms living in vessels (generally immunocompromised hosts): Mucormycosis, aspergillosis, and disseminated strongyloidiasis
- Occlusion due to microvascular platelet plugs (heparin necrosis)
- Cold-related gelling or agglutination (cryoglobulinemia)
- Local or systemic coagulation abnormalities: Scarlet fever, *Vibrio vulnificus* bacteremia; “malignant chickenpox” and “black measles” (both rare in US); Coumadin necrosis
- Embolization: Cholesterol, crystal, thrombus (atrial myxoma, septic endocarditis, multiple myeloma)

Pediatric Considerations

- Henoch–Schönlein purpura
- Hemolytic uremic syndrome
- Kawasaki disease
- Neonatal:

- Extramedullary erythropoiesis in rubella and cytomegalovirus (blueberry muffin baby)
- Purpura fulminans (protein C and S deficiency)
- Maternal ITP
- Wiskott–Aldrich syndrome

DIAGNOSIS

SIGNS AND SYMPTOMS

- Palpable or nonpalpable, nonblanching lesions
- Size:
 - Petechiae (≤ 4 mm)
 - Macular (5–10 mm)
 - Ecchymoses (> 1 cm)
- Shape:
 - Round lesions: Caused by leukocytoclastic emboli
 - Irregular (retiform) lesions: Caused by infectious emboli
 - Annular or erythema multiforme (target lesions)
- Distribution:
 - Generalized: Consider DIC and meningococemia
 - Dependent: Most common. Seen in the lower extremities (increased hydrostatic force)
 - Acral: Found in the extremities only
 - Oral/mucous membranes: Consider ITP
- Hypotension
- Altered mental status
- Gingival hemorrhage
- Epistaxis
- Hematuria
- Fever
- Malaise
- Arthralgias/hemarthroses
- Myalgias
- Purpura fulminans:
 - Large, irregular ecchymoses
 - Fever
 - Shock
 - DIC
- *Pseudomonas* (ecthyma gangrenosum):
 - Begins as edematous, erythematous papules
 - Bullae formation in girdle region
- Disseminated gonococcal infection:

- Usually < 10 lesions, purpuric papules, or vesicopustules on the extensor surface of hands, dorsal aspect of ankles and toes
- Fever
- Arthralgias
- Meningococemia:
 - Small areas of skin infarction cause retiform purpura
 - May involve head, palms, soles, mucous membranes, including conjunctivae
 - Fever
 - Headache
- Rocky Mountain spotted fever:
 - After 4–7 days of generalized symptoms, erythematous macules on distal extremities including palms and soles, then petechial
 - Fever
 - Headache
- Henoch–Schönlein purpura:
 - Appears on extensor aspects of lower extremities and buttocks
 - Fades in about 5 days
 - Fever
 - Arthralgias
 - Abdominal pain
 - Hematuria
- Kawasaki disease:
 - Purpura is rare
 - Fever, plus 4 of the following: Polymorphous exanthem, peripheral extremity changes, bilateral conjunctivitis, changes of lips and mouth, unilateral cervical lymphadenopathy
- Levamisole adulterated cocaine:
 - Retiform, necrotic purpura involving the ears/face but can occur anywhere
 - Neutropenia
 - Recurrent symptoms with continued abuse

ESSENTIAL WORKUP

- Obtain a complete medical history
- Previous bleeding problems
- Deep venous thrombosis/pulmonary embolism suggesting factor V Leiden mutation
- Splenectomy
- Alcohol and drug abuse
- Family history of bleeding disorders
- High-risk medications

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Platelet count: Abnormal counts must be verified by manual exam of a peripheral smear
- DIC screen: Indicated when patient appears toxic
- PT/PTT
- Chemistry panel including liver function tests
- Rapid strep test
- Urinalysis
- Studies for outpatient management:
 - Bleeding time
 - Hepatitis B and C serologies
 - Strep throat culture or anti-streptolysin O titer
 - Antinuclear antibodies
 - Cryoglobulins
 - Platelet function studies
 - Serum complements
 - Serum protein electrophoresis
 - von Willebrand disease screen

DIFFERENTIAL DIAGNOSIS

- Disorders with telangiectasias:
 - Cherry angiomas
 - Hereditary hemorrhagic telangiectasia
 - Chronic actinic telangiectasia
 - Scleroderma
 - CREST syndrome
 - Ataxia-telangiectasia
 - Chronic liver disease
 - Pregnancy-related telangiectasia
- Kaposi sarcoma and other vascular sarcomas
- Fabry disease
- Neonatal extramedullary hematopoiesis
- Angioma serpiginosum

TREATMENT

PRE HOSPITAL

- IV access
- Monitor for:
 - Fever
 - Hypotension
 - Altered mental status

INITIAL STABILIZATION/THERAPY

- For fever, hypotension, altered mental status, or generalized ecchymoses:
 - Airway support
 - IV access
 - Fluid resuscitation
 - IV antibiotics as soon as possible

ED TREATMENT/PROCEDURES

- Presumptive treatment of infectious etiology:
 - *Meningococcus*: Ceftriaxone (Prophylaxis: Rifampin or Ciprofloxacin)
 - *Pneumococcus*: Ceftriaxone, consider penicillin
 - *Rickettsia rickettsii*: Doxycycline, Chloramphenicol in pregnancy

MEDICATION

- Ceftriaxone: 2 g (peds: 100 mg/kg/24h) IV BID
- Ciprofloxacin (prophylaxis): 500 mg PO once
- Chloramphenicol: 75 mg/kg/24h PO or IV QID
- Doxycycline 100 mg (peds: 4 mg/kg/24h) PO or IV BID
- Penicillin G: 4 million U (peds: 240,000 U/kg/24h) IV q4h
- Rifampin (prophylaxis): 600 mg PO BID for 2 days
- Neonatal sepsis: Ampicillin 100 mg/kg/24h IV q6h *and* gentamicin 7.5 mg/kg/24h IV q8h (or cefotaxime 200 mg/kg/24h IV q6h)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Unstable vital signs
- Altered mental status
- Fever

Discharge Criteria

Exclusion of life-threatening etiologies:

- Serious bacterial infections
- Critical thrombocytopenia

Issues for Referral

- Serious hematologic, rheumatologic features and malignancies require an in-depth outpatient assessment if the patient is not admitted
- No contact sports or antiplatelet agents until cleared by a physician

FOLLOW-UP RECOMMENDATIONS

- Appropriate close follow-up scheduled
- Consider follow-up with dermatology (skin biopsy) and hematology

PEARLS AND PITFALLS

Consider empiric antibiotics to cover for meningococemia, Rocky Mountain Spotted fever, and/or sepsis if any doubt of underlying infection

ICD9

- 287.0 Allergic purpura
- 287.2 Other nonthrombocytopenic purpuras
- 287.31 Immune thrombocytopenic purpura

ICD10

- D69.0 Allergic purpura
- D69.2 Other nonthrombocytopenic purpura
- D69.3 Immune thrombocytopenic purpura

PYELONEPHRITIS

Matthew D. Bitner

BASICS

DESCRIPTION

- Complication of a lower UTI by bacterial ascension into the upper urinary tract
- Primarily a clinical diagnosis
- Incidence lower in males in every age group
- Male/female ratio:
 - _ 1:10 in 1st years of life
 - _ 1:5 in children
 - _ 1:50 in reproductive years
 - _ 1:1 in 5th decade and later
- Bilateral infection in up to 25% of cases, hence no lateralizing signs (in some studies)

ETIOLOGY

- Bacteriology:
 - _ *Escherichia coli* 80–95% predominates
 - _ Uropathogens:
 - *Klebsiella* species
 - *Citrobacter* species
 - *Enterobacter* species
 - _ Others:
 - *Staphylococcus saprophyticus* 5–15%
 - *Proteus mirabilis*
 - *Serratia* species
 - *Pseudomonas* species
 - *Staphylococcus aureus* (increasing)
- Predisposing factors (consider complicated infections):
 - _ Recent instrumentation:
 - Catheterization
 - Cystoscopy
 - _ Urinary retention:
 - Mechanical (see Obstruction below)
 - Medications (e.g., anticholinergics)
 - Other infections (e.g., herpes simplex)
 - _ Urinary obstruction:
 - Stricture
 - Renal calculi

- Prostatic hypertrophy
- Anatomic abnormalities:
 - Hypospadias
 - Ureteral ectopia
 - Bifid ureter
 - Renal scarring
 - Ureterovesicular reflux (UVR)
 - Posterior urethral valves
- Neurologic conditions:
 - Neurogenic bladder
 - Spinal cord injury
- Abnormal urodynamics
- Previous UTIs (in childhood, > 3 in last year)
- Recent pyelonephritis (within 1 yr)
- Diabetes mellitus
- Immunosuppression
- Pregnancy

DIAGNOSIS

SIGNS AND SYMPTOMS

- Dysuria, urgency, frequency
- Back, flank, or abdominal pain
- Fever, chills
- Arthralgias, myalgias, malaise
- Nausea and/or vomiting
- Costovertebral angle/suprapubic tenderness
- Ill/toxic appearing
- Dehydration
- Occult pyelonephritis:
 - Invasion of upper urinary tract without clinical symptoms:
 - Suspect in lower UTI that does not resolve with standard treatment.

Pediatric Considerations

- Fever, irritability, lethargy, poor feeding, or jaundice may be only symptom in infants.
- Enuresis in previously toilet-trained child
- Common cause of a serious bacterial infection (SBI) in neonates, young children, and the immunocompromised (hematogenous spread)
- Renal scarring:
 - More common sequelae in young children than in adults
- Group B streptococci

- Etiologic agents in neonates

Geriatric Considerations

Commonly present atypically:

- Absence of classic dysuria/frequency
- Instead nausea/vomiting, diarrhea, fever, or altered mental status may predominate.

ESSENTIAL WORKUP

- Urinalysis (UA):
 - Clean-catch or catheterized urine specimen; catheterized specimen if:
 - Vaginal discharge or bleeding
 - Contaminated specimen
 - Pyuria: 5–10 WBCs, plus leukocyte esterase, plus nitrites:
 - If not present, consider alternate diagnosis.
 - Nitrite represents a gram-negative pathogens are present that is converting dietary nitrates to nitrites.
 - Note that some uropathogens such as *Pseudomonas*, *Enterococcus*, and *S. Saprophyticus* are not nitrate reducers
 - Hematuria:
 - White cell cast: Renal origin of pyuria
- Urine culture and sensitivity:
 - Obtain in:
 - Suspected pyelonephritis
 - Unclear diagnosis
 - Treatment failures, recurrent infections
 - High clinical suspicion, with negative UA
 - >100,000 colony-forming units (CFU)/mL is positive.
 - 10^2 – 10^4 CFU considered positive in:
 - Early infection
 - Clinical scenario consistent with UTI
 - Catheter or suprapubic specimen
 - Males

DIAGNOSIS TESTS & NTERPRETATION

Lab

- CBC:
 - Leukocytosis
 - Does not rule in or out upper tract infection
- Blood cultures:
 - Not needed unless patient is septic; positive cultures do not correlate with

more severe disease.

– Bacteria identified more readily on urine culture

- **Chemistries:**

– For patients with significant risk for electrolytes abnormalities (severe nausea/vomiting, or medication use)

Imaging

- Imaging is required to differentiate pyelitis (no parenchymal involvement) and pyelonephritis (parenchymal involvement); however, this typically does not alter ED treatment.

- **Bedside renal US:**

– Limited value for characterization except for detecting hydro/pyonephrosis/obstruction

- **Helical CT:**

– Superior to renal US in detecting abnormalities/characterizing extent of disease

– Consistent or concerning findings:

- Stranding or inflammation and edema of parenchyma

- Perinephric fluid

- Calculi, obstruction

- Renal/perinephric abscess

- Intraparenchymal gas formation (emphysematous pyelonephritis)

- **MRI:**

– Useful in:

- Pregnant patients (lack of radiation)

- Renal failure (lack of iodinated contrast)

– Cost/availability limit usefulness in the ED

– Obtain imaging if:

- Concomitant stone/obstruction

- At risk for emphysematous pyelonephritis/abscess (diabetes mellitus, immunocompromised, elderly)

- Elective evaluation of genitourinary tract in males with pyelonephritis

Pediatric Considerations

- **Obtain catheter urine specimen:**

– Vast majority of bag urine specimens will result in positive cultures (contaminants).

– Helpful only for excluding disease if culture is negative

– Catheterized or suprapubic specimen with > 1,000 CFU is positive.

- Blood cultures usually performed for children < 1 yr of age (due to risk for SBI)

- All children with 1st episode of pyelonephritis should have urinary tract imaging

performed later to evaluate for UVR.

- Renal US:
 - Within 48 hr if no clinical improvement
 - Within 3–6 wk if clinical improvement

Diagnostic Procedures/Surgery

Suprapubic bladder aspiration:

- When urethral catheterization is not successful, or not possible (phimosis, urethral stricture, etc.)
- Contraindicated when there is an overlying infection, a known anatomic abnormality (tumor), recent complete voiding/micturition

DIFFERENTIAL DIAGNOSIS

- Abdominal aortic aneurysm or dissection
- Appendicitis
- Cholecystitis
- Cystitis
- Diverticulitis
- Cervicitis/pelvic inflammatory disease
- Endometritis/salpingitis
- Inferior pneumonia
- Prostatitis/epididymitis
- Nephrolithiasis
- Renal/perinephric abscess
- Urethritis

TREATMENT

PRE HOSPITAL

IV access for the ill/toxic-appearing patient with appropriate fluid resuscitation

INITIAL STABILIZATION/THERAPY

Treat shock with 0.9% normal saline 500 mL–1 L (peds: 20 mL/kg) IV fluid bolus

- While shock needs to be treated aggressively, be cognizant of fluid overload in patients with comorbidities (renal failure, congestive heart failure).

ED TREATMENT/PROCEDURES

- Parental antibiotics for:
 - Inability to tolerate oral therapy
 - Extremes of age, immunosuppression, and pregnancy
 - Failure of oral/outpatient therapy
 - Urinary obstruction

- Suspected antibiotic-resistant organisms
- Empiric IV antibiotics:
 - Fluoroquinolones (not approved in children)
 - Aminoglycoside (gentamicin) plus ampicillin
 - 3rd-generation cephalosporin (ceftriaxone)
 - In pregnancy:
 - 3rd-generation cephalosporin
 - Gentamicin/ampicillin
 - Cefazolin
 - Aztreonam
- Outpatient oral antibiotics:
 - For nontoxic and otherwise healthy patient:
 - Fluoroquinolone: 7–14 day course
 - May administer 1 dose of parenteral antibiotics prior to oral antibiotics:
 - Ensures prompt cessation of bacterial proliferation
 - No literature addressing efficacy
- Antiemetics and analgesics

MEDICATION

- Oral antibiotics:
 - Ciprofloxacin: 500 mg PO BID
 - Ciprofloxacin ER: 1,000 mg PO daily.
 - Levofloxacin: 750 mg PO daily (5 days)
 - Ofloxacin: 200 mg PO BID
 - Amoxicillin/clavulanic acid: 875 mg/125 mg PO BID
- IV antibiotics:
 - Ceftriaxone: 1 g IV q24h
 - Ciprofloxacin: 400 mg IV q12h
 - Ampicillin/sulbactam: 3 g IV q6h
 - Cefazolin: 1–1.5 g IV q8h
 - Gentamicin: 3–5 mg/kg IV load
 - Levofloxacin: 500 mg IV daily
 - Piperacillin–tazobactam: 3.375 g IV q8h

Pediatric Considerations

- Oral antibiotic liquid preparations for children:
 - Amoxicillin: 30–50 mg/kg/24h PO TID
 - Amoxicillin/clavulanic acid: 45 mg/kg/24h PO TID
 - Cefixime: 8 mg/kg PO daily
 - Cefpodoxime: 10 mg/kg/24h PO BID
 - Cephalexin: 50–75 mg/kg/24h PO QID
 - Erythromycin/sulfisoxazole: 50 mg erythromycin/kg/24h PO QID
- Parenteral antibiotics for admitted children:

- Age 0–3 mo:
 - Cefotaxime (50–180 mg/kg/d TID) + ampicillin (50–100 mg/kg/d QID)
 - Gentamicin (1–2.5 mg/kg/d TID) + ampicillin
- Age > 3 mo:
 - May substitute ceftriaxone (50–100 mg/kg/d BID to daily) for cefotaxime

FOLLOW-UP

DISPOSITION

Admission Criteria

- Sepsis, ill/toxic appearance
- Inability to tolerate oral therapy
- Intractable nausea/vomiting
- Social situation prevents compliance.
- Pregnancy
- Indwelling urinary catheter
- Urinary obstruction/anatomic abnormalities
- Proximal obstruction,
- Immunosuppression/diabetes mellitus
- Extremes of age (children < 2–6 mo)
- Failure of outpatient therapy/recent antibiotics

Discharge Criteria

- Clinical course improving in ED
- Ability to maintain oral hydration
- Pain controlled with oral analgesic
- Normal renal function
- Follow-up in 48–72 hr

FOLLOW-UP RECOMMENDATIONS

- Uncomplicated cases in patients without comorbidities can safely follow up with their primary care physicians.
- If cultures were obtained, patient will need to follow up on results for possible therapy change once antibiotic sensitivities are known.
- Pediatric patients all need to follow up with their pediatrician for required imaging for anatomic abnormalities
- Pregnant patients need repeat UA to assess for resolution/recurrence and possible suppressive therapy.
- Patients with recurrent infections and those with identified unusual or resistant

organisms require close follow-up with urologic and/or infectious disease consultation.

PEARLS AND PITFALLS

- Primarily a clinical diagnosis with minimal lab work required
- Treat young, old, immunosuppressed, and pregnant patients aggressively.
- Consider other diagnoses (e.g., gynecologic etiologies, abdominal aortic aneurysm)

PYLORIC STENOSIS

Roger M. Barkin

BASICS

DESCRIPTION

- Postnatal hypertrophy and hyperplasia of the circular smooth muscle cell layer causing a thickened pylorus and antrum leading to progressive gastric outlet obstruction
- Neuronal nitric oxide synthase (NOS-1) may be a genetic susceptibility locus.
- Administration of erythromycin in infants during 1st 2 wk of life may increase risk of hypertrophic pyloric stenosis.
- Jaundice due to transient glucuronyl transferase deficiency
- Adult: Caused by peptic ulcer disease

ETIOLOGY

- Most common cause of GI obstruction in infants; incidence 1/150 males, 1/750 females (average: 3/1,000 live births)
- Males affected 5× more commonly than females; firstborn most common
- Familial, 15%:
 - Child of affected parent has 7% incidence.
 - Recurrence risk in subsequent male children is 10%; 2% in females.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Vomiting:
 - Gradual onset, usually beginning at around 3–6 wk of age; rarely after 12 wk of age
 - Progressive, usually becoming projectile
 - Nonbilious
 - May be blood tinged (secondary to esophagitis, gastritis, gastric ulceration)
 - Progressively worsening
 - Postprandial
- Represents the hypertrophied pylorus:
 - Confirms diagnosis
- Constipation or small amount of stools
- “Lean and hungry” infant early in course; dehydrated and uninterested in feeding late in course; failure to thrive

- Variable dehydration and wasting depending on duration of symptoms
- Jaundice in 8% of children
- Adult presents with vomiting, anorexia, early satiety, and epigastric pain.

Physical-Exam

- Often normal unless a relaxed abdomen
- May feel olive-shaped mass at lateral margin of the right rectus abdominis muscle in the right upper quadrant (80% of patients), often after vomiting:
 - Best felt immediately after vomiting or after the stomach is emptied via gastric suction as the dilated body of the stomach overlies the pylorus
 - Represents the hypertrophied pylorus:
 - Helps confirm diagnosis
 - Peristaltic waves moving from the left to right in the left upper quadrant, seen best after feeding or just prior to vomiting

ESSENTIAL WORKUP

If “olive” palpable, further diagnostic evaluation may be unnecessary and surgical consultation should be sought; otherwise, imaging studies are indicated.

DIAGNOSIS TESTS & NTERPRETATION

Lab

- Electrolytes, BUN/creatinine, glucose:
 - Hypokalemic, hypochloremic metabolic alkalosis
 - Normal electrolytes do not exclude the diagnosis.
- Bilirubin elevated, usually unconjugated
- CBC if blood in emesis
- Urinalysis for hydration

Imaging

- Abdominal US:
 - Study of choice
 - US diagnosis hinges on identification and measurement of pyloric muscle mass (3 mm ring thickness, 1.5 cm pylorus channel or muscle length, and 10–14 mm pylorus diameter) and observation of fluid movement through the pylorus.
 - Positive predictive value approaches 100%; 19% false negatives.
 - Serial US for equivocal or negative study
- Upper GI series:
 - String sign representing contrast passing through a narrowed gastric outlet
 - 95% accurate
 - Remove contrast from the stomach after the study to prevent aspiration.
- Supine abdominal film:

- Not diagnostic; rarely helpful
- Dilated stomach and no air distal to the pylorus
- Most useful with other views to begin evaluation for other abdominal pathology

DIFFERENTIAL DIAGNOSIS

- GI anatomic/functional disorder:
 - Gastroesophageal reflux
 - Hiatal hernia
 - Obstruction/atresia
 - Gastric or duodenal web
- Infection:
 - Gastroenteritis
 - UTI
 - Sepsis
- Metabolic:
 - Adrenal insufficiency
 - Inborn error of metabolism
- Feeding problems:
 - Psychosocial: Poor maternal interaction or stress
 - Chhalasia
 - Formula intolerance
 - Overfeeding
- Drug withdrawal
- Increased intracranial pressure

TREATMENT

PRE HOSPITAL

Fluid resuscitation if significant volume deficit

INITIAL STABILIZATION/THERAPY

- IV access
- Rapid bedside glucose test to exclude hypoglycemia
- Correct volume deficit with 20 mL/kg bolus of 0.9% normal saline IV; may repeat.

ED TREATMENT/PROCEDURES

- Correct electrolyte abnormalities.
- Hydrate with dextrose-containing solution after fluid resuscitation at 1–1.5 × maintenance rate:
 - Add potassium after ensuring adequate urine output.
- Insert nasogastric tube to decompress the stomach.
- Restrict oral intake.

- Consult pediatric surgeon for pyloromyotomy.
- Adult: Proton pump antagonist (lansoprazole or omeprazole)

MEDICATION

Adults

- Lansoprazole: 30 mg daily PO
- Omeprazole: 20 mg daily PO

FOLLOW-UP

DISPOSITION

Admission Criteria

- All pediatric patients should be admitted to the hospital for rehydration and surgical correction with either an umbilical pyloromyotomy or laparoscopic pyloromyotomy.
- Adult patients: Admit as necessary for rehydration; may be scheduled for elective pyloromyotomy if proton pump inhibitors fail to improve this condition.

Discharge Criteria

None

Issues for Referral

Surgical consultation concurrent with correction of electrolytes and fluid deficits

FOLLOW-UP RECOMMENDATIONS

Follow growth pattern after surgery.

PEARLS AND PITFALLS

Suggestive clinical presentation combined with lab evaluation should lead to imaging and correction of electrolyte abnormalities.

QT SYNDROME, PROLONGED

Jason A. Tracy

BASICS

DESCRIPTION

A disorder of myocardial repolarization characterized by a prolonged QT interval on the electrocardiogram

- The pathophysiology is complex and incompletely understood:
 - Alteration in cardiac sodium, potassium, or calcium ion flow
 - Imbalance in the sympathetic innervation of the heart
- Prolonged ventricular repolarization results in lengthening of QT interval on surface ECG:
 - “Pause-dependent” lengthening due to short–long–short sequence in which a sinus beat is followed by an extrasystole (short), then a postextrasystolic pause (long), concluding with a ventricular extrasystole (short)
 - “Adrenergic-dependent” pauses found in congenital cases
- Symptoms often preceded by vigorous exercise, emotional stress, or loud noise.
- Nocturnal bradycardia can lengthen QT interval, causing sleep-related symptoms.
- Re-entrant rhythm can lead to torsades de pointes, ventricular tachycardia, and ventricular fibrillation.
- Hemodynamic compromise following dysrhythmia leads to syncope or death.
- Independent risk factor for sudden cardiac death.

RISK FACTORS

Genetics

- 10 genes linked to long QT syndrome:
 - Autosomal recessive form associated with deafness (Jervell and Lange–Nielsen syndromes)
 - Autosomal dominant form not associated with deafness (Romano–Ward syndrome)
 - Adrenergic stimulation (fright, exertion, delirium tremens, and loud auditory stimulus) becomes prodysrhythmic in certain genotypes, while sleep-related symptoms are found in others.
- 10–15% of carriers have baseline normal QTc.
- Death occurs in 1–2% of untreated patients per year.
 - Drug-induced QT prolongation may also have a genetic background.
 - Congenital form occurs in 1 in 3,000–5,000, with mortality of 6% by age 40 yr.

Pediatric Considerations

- Diagnosis suspected in the young with syncope, cardiac arrest, or sudden death
- Syncope following emotional stress or exercise suggestive
- Death occurs without preceding symptoms in 10% of pediatric patients.

ETIOLOGY

- Drugs:
 - Complete list at www.QTDrugs.org
 - Class Ia antidysrhythmics—quinidine, procainamide, disopyramide
 - Class III antidysrhythmics—sotalol, ibutilide, amiodarone
 - Antibiotics—erythromycin, pentamidine, chloroquine, trimethoprim-sulfamethoxazole
 - Antifungal agents—ketoconazole, itraconazole
 - Psychotropic drugs—phenothiazines, haloperidol, risperidone, STCAs
 - Cisapride
 - Antihistamines
 - Organophosphates
 - Narcotics—methadone
- Electrolyte abnormalities
 - Hypokalemia
 - Hypomagnesemia
 - Hypocalcemia
- Cardiac
 - Bradyarrhythmias
 - Arteriovenous block
 - Mitral valve prolapse
 - Myocarditis
 - Myocardial ischemia
- CNS
 - Subarachnoid hemorrhage
 - Stroke
- Congenital (idiopathic)
- Other
 - Protein-sparing fasting
 - Anorexia nervosa
 - Hypothyroidism
 - Hypothermia

DIAGNOSIS

SIGNS AND SYMPTOMS

- Palpitations
- Light-headedness

- Dizziness

History

- Syncope
- Near syncope
- Seizure
- Family history of syncope or sudden death
- Congenital deafness
- Medication use

ESSENTIAL WORKUP

Cardiac monitor:

- ECG
- QTc (QT corrected for heart rate) > 0.44 sec in men and > 0.46 sec in women
- QT measured from beginning of quasi-random signal to end of T wave:
 - Measured best in the limb leads and should be averaged over 3–5 beats
 - There is no expert consensus on best heart rate correction (QTc) formula.
 - Bazett formula (QT divided by square root of RR interval) is most commonly used
 - Increase in QT variability
- T-wave abnormalities (T-wave alternans, biphasic)
- Appearance of U waves
- Ventricular tachycardia
- Ventricular fibrillation
- Torsades de pointes

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Full electrolytes including calcium and magnesium
- Toxicology screen

Imaging

Echocardiography to exclude other cardiac causes

Diagnostic Procedures/Surgery

- ECG stress testing to induce a prolonged QT interval in suspected cases
- Holter monitoring of QTc
- Genetic counseling/testing in suspected congenital forms
- Familial ECG testing

DIFFERENTIAL DIAGNOSIS

- Myocardial infarction

- Hypertrophic cardiomyopathy
- Valvular defect

TREATMENT

PRE HOSPITAL

- Supplemental oxygen
- IV access
- Monitor

ALERT

- Stable patients with prolonged QT transported without intervention
- Cardioversion for unstable patients with confirmed torsades de pointes
- Magnesium sulfate for stable patients with evidence of torsades de pointes

INITIAL STABILIZATION/THERAPY

- IV access
- Monitor
- Determine hemodynamic stability
- Unstable patients require immediate cardioversion

ED TREATMENT/PROCEDURES

- IV magnesium sulfate for torsades de pointes
- IV potassium to serum levels of 4.5–5 mEq/L
- Temporary transvenous cardiac pacing (rates from 100–120 beats/min) for recurrences of torsades de pointes refractory to magnesium sulfate therapy (shortens QTc)
- IV isoproterenol for refractory cases or hemodynamically unstable patients with acquired long QT (ineffective in congenital cases) who do not respond to transvenous pacing
- Remove any offending medications and correct metabolic derangements.
- Consult with cardiology in those with symptomatic long QT regarding use of β -blockers at maximum doses.
- No ED treatment needed (in consultation with cardiology) for those with suspected idiopathic long QT and no history of syncope, family history of sudden cardiac death, or ventricular arrhythmias.
- Pacemaker or defibrillator placement with or without cervicothoracic stlectomy (to reduce adrenergic stimulation) may be required in high-risk patients.
- β -Blockers prevent 70% of cardiac events in congenital cases.

MEDICATION

First Line

- Magnesium sulfate: 2 g (peds: 25–50 mg/kg) IV bolus over 2–3 min followed by IV infusion at 2–4 mg/min
- Isoproterenol: 1 µg/min (peds: 0.05–0.1 µg/kg/min) IV continuous infusion, titrate for effect, up to 10 µg/min

Second Line

Propranolol: 2–3 mg/kg/d (peds: 2–3 mg/kg/d) PO (in consultation with cardiology)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Symptomatic prolonged QT
- Syncope
- Cardiac dysrhythmia
- Possible cardiac or ischemic event
- Metabolic abnormality

Discharge Criteria

Asymptomatic prolonged QT in consultation with cardiology

FOLLOW-UP RECOMMENDATIONS

Follow-up recommended in all patients with a new diagnosis of prolonged QT

PEARLS AND PITFALLS

- Suspect prolonged QT in patients with syncope
- Prolonged QT is an independent risk factor for sudden cardiac death.
- Correct electrolyte abnormalities and discontinue offending drugs in those with prolonged QT.
- Magnesium sulfate followed by pacing for torsades de pointes.

RABIES

Herbert Neil Wigder • Ashley Alwood • Matthew A. Kippenhand

BASICS

DESCRIPTION

CNS infectious disease of mammals caused by the rabies virus:

- Highest case fatality rate of any known infectious disease

ETIOLOGY

- Epidemiology:
 - _ 30,000–70,000 people die/yr worldwide
 - _ Especially common in Southeast Asia, Philippines, Africa, South America, and Indian subcontinent
 - _ US has 2–3 human cases per year.
 - _ Most clinical cases in US from foreign travel and bat exposures
 - _ Raccoons, skunks, foxes, bats, dogs, woodchucks, groundhogs are reservoirs.
 - _ In US bats are the most common reservoir while abroad dogs are more common.
 - _ Squirrels, rats, mice, hamsters, guinea pigs, gerbils, chipmunks, and rabbits can also be infected but there has never been a reported case of human transmission.
- Pathophysiology:
 - _ Negative-stranded RNA genome, family Rhabdoviridae, genus Lyssavirus
 - _ Mode of transmission:
 - Contact with infected saliva of host
 - Bite: Most common
 - Nonbite: Saliva or bat aerosol exposure to an open wound or mucous membrane
 - Transplant procedures are the only well-documented person-to-person transmission
 - Not considered a transmission risk: Petting rabid animal or contact with the blood, urine, or feces of a rabid animal
 - _ Progression after infection:
 - Virus multiplies in local tissue and is taken up into muscle through n-acetylcholine receptors.
 - Virus enters peripheral nerves and is transported to CNS via retrograde axoplasmic flow at ~1--4 inches per day
 - Once in CNS, rapid replication and dissemination cause encephalitis.
 - Centrifugal spread of virus to peripheral nerves, including salivary glands

SIGNS AND SYMPTOMS

- Once a patient exhibits clinical signs course is almost universally fatal.
- 5 stages: Incubation, prodrome, encephalitis, coma, death (or recovery):
 - _ Incubation: 1–3 mo (range 10 days to 1 yr):
 - Virus amplifies in peripheral tissues
 - Time depends on amount inoculated and proximity to CNS, thus shorter incubation for head or neck bites
 - _ Prodrome: 1–7 days:
 - Nonspecific symptoms: Fever, headache, malaise, myalgias, anorexia, sore throat, nausea, and vomiting
 - Paresthesias or fasciculations around bite site give clue to diagnosis.
 - _ Encephalitis (classic form): 2–7 days:
 - Anxiety, agitation, hallucinations, confusion or delirium, muscle spasms, opisthotonos, and seizure
 - Aerophobia (pathognomonic): Pharyngeal spasm from draft of air
 - Hydrophobia (pathognomonic): Violent involuntary muscle contraction of diaphragm, pharyngeal, laryngeal, and accessory respiratory muscles when attempting to swallow (seen in up to half of cases)
 - Dysrhythmias, myocarditis, autonomic instability, and fevers
 - Brainstem involvement: Diplopia, facial paralysis
 - _ Coma:
 - Apnea from respiratory center involvement, vascular collapse, flaccid paralysis, adult respiratory distress syndrome, syndrome of inappropriate diuretic hormone
 - Most die within 2 wk
 - _ Death (or recovery):
 - Almost universally fatal if no pre- or postexposure prophylaxis (PEP) given
 - Rare case reports of survival without prophylaxis
 - Known survivors have some residual neurologic deficits
- 3 manifestations of disease:
 - _ Classic or encephalitic rabies accounts for ~80% of cases. See above.
 - _ Paralytic rabies (~20%): Ascending paralysis mimicking Guillain–Barré syndrome
 - _ Atypical rabies (<1%): Seen with bat-associated rabies. Characterized by neuropathic pain, sensory or motor deficits, choreiform movements, myoclonus, and seizures

- Bite wound or other known exposure
- Bat found in room with person unable to give history (e.g., child or intoxicated): Assume exposure
- Travel to endemic areas with associated dog exposure
- Rabid animals more likely to attack unprovoked. Any handling of the animal prior to bite is considered a provoked attack.

Physical-Exam

- Fever
- A bat bite wound often not visible on exam
- Altered mental status, seizures, encephalopathy
- Percussion myoedema: Muscle mounds at percussion site
- Autonomic manifestations: Dilated pupils, perspiration, hypersalivation, orthostatic hypotension

ESSENTIAL WORKUP

- Saliva:
 - Rabies RNA by reverse transcription polymerase chain reaction (RT-PCR)
 - Virus isolation in cell culture
- Serum:
 - Rabies antibodies are diagnostic only if not vaccinated.
 - Earliest positive, day 6
- CSF:
 - Mildly elevated WBC and protein, normal glucose
 - Virus isolation
 - Rabies antibodies in CSF are diagnostic, even if immunized.

DIAGNOSIS TESTS & NTERPRETATION

Lab

- CBC: May have leukocytosis
- Electrolytes, BUN, creatinine, glucose
- Blood cultures/urinalysis:
 - Search for other infection/illness
- Neck biopsy: RT-PCR, immunofluorescent staining for viral antigen

Imaging

- CT head: Usually normal but may show cerebral edema, evaluate for other causes of symptoms
- Chest radiograph: Other infectious etiologies

Diagnostic Procedures/Surgery

Lumbar puncture

DIFFERENTIAL DIAGNOSIS

- Other causes of encephalitis:
 - Herpesviruses: HSV1, VZV
 - Enterovirus (Coxsackie, echovirus, poliovirus)
 - Arboviruses (West Nile, eastern/western equine encephalitis, St. Louis)
- Tetanus
- Delirium tremens
- Psychosis
- Paralytic form:
 - GBS
 - Polio
 - Tick-bite paralysis
 - Immune-mediated polyneuritis
 - Botulism

TREATMENT

PRE HOSPITAL

- Thoroughly wash wound with soap and water.
- If safely able, capture wild animal for sacrifice and testing.

INITIAL STABILIZATION/THERAPY

- Airway, breathing, and circulation
- Intubation as needed
- Treatment of seizures

ED TREATMENT/PROCEDURES

- Wound cleansing and irrigation
- Tetanus immunization
- Determine if exposure requires prophylaxis:
 - Consult local health department
 - Domestic animal bite:
 - Home monitoring of animal for 10 days
 - If animal displays no signs of illness, patient does not need PEP.
 - Wild animal bite:
 - Rabies testing of sacrificed animal head-Negri bodies are diagnostic
 - Start PEP and stop if test is negative
 - Treat if animal not captured.
 - Unprovoked attacks should be assumed high risk for exposure.
- PEP:
 - Passive immunization with human rabies immune globulin (HRIG)
 - HRIG: 20 IU/kg:

- Majority infiltrated in and around wound
- Remainder given IM (gluteus)
- Active immunization with rabies vaccine
- Rabies vaccine: 1 mL (2.5 IU) IM days 0, 3, 7, 14, add day 28 if immunocompromised
- 3 vaccines approved in US:
 - Imovax–human diploid cell culture
 - RabAvert–chick embryo cell culture
 - Rabies vaccine adsorbed–inactivated virus, for US military
- Administration location:
 - Deltoid in adults or anterior thigh in small children or infants
- For those with pre-exposure prophylaxis and rabies exposure:
 - Do not require HRIG
 - Need vaccine booster on days 0 and 3
- If care delayed after rabies exposure:
 - HRIG not indicated > 7 days after exposure
 - Vaccine should be administered as usual
- Pre-exposure prophylaxis:
 - Rabies vaccine on days 0, 7, 21, 28
 - Target groups: Veterinarians, animal handlers, virus lab workers, foreign travelers in endemic regions

Pediatric Considerations

Treat as in adults.

Pregnancy Considerations

Treatment considered safe during pregnancy.

FOLLOW-UP

DISPOSITION

Ensure adequate access for subsequent vaccine administration post rabies exposure.

Admission Criteria

Patient with clinical signs of rabies

Discharge Criteria

- Stable patient
- No evidence of reaction to vaccine

Issues for Referral

Public health and CDC for suspicious cases

FOLLOW-UP RECOMMENDATIONS

- Ensure access to subsequent vaccine doses
- Patient should follow up with animal control if source animal has been sacrificed or is being observed.

PEARLS AND PITFALLS

- PEP is only proven treatment after exposure.
- PEP should be given in all high-risk exposures regardless of timing
- Vaccine should only be given in deltoid in adults: Treatment failures reported with inadvertent SC administration in gluteus injections.

- Z20.3 Contact with and (suspected) exposure to rabies

RADIATION INJURY

Robert J. Feldman

BASICS

DESCRIPTION

- *Radiation* in this chapter refers to ionizing radiation.
- *Alpha* (α)—*helium nucleus; does not penetrate skin*
- *Beta* (β)—*electron; penetrates tissue a few cm*
- *Gamma* (γ)—*photon; penetrates body*
- *Neutron*—*very penetrating; not detected by Geiger counter, but neutron emitters also emit γ radiation*
- *Radioisotope/radionuclide*—*chemical element that emits radiation from its nucleus:*
 - Radioactivity cannot be destroyed, only relocated or shielded.
 - Being radioactive does not change element's other chemical and physical properties, such as heavy metal toxicity.
- *Exposure/irradiation*—*patient has been in presence of ionizing radiation:*
 - Whole body or only certain areas may be exposed.
- *Contamination*—*radioactive material where it is not desired:*
 - Internal—within body (e.g., lung)
 - External—outside body (skin, hair, clothing)
- *Dose*—*amount of radiation energy absorbed by tissue:*
 - Units and conversions:
 - 1 gray (Gy) = 100 rad
 - 1 sievert (Sv) = 100 rem
 - For β and γ radiation:
 - 1 Gy = 1 Sv = 100 rad = 100 rem

ALERT

Contact regional or federal authorities for guidance if radiation incident is suspected.

Pediatric Considerations

- Children are more sensitive to radiation injury.
- Potassium iodide is most protective for children and should be given promptly if contamination with radioactive iodine (I-131) is suspected.

Pregnancy Considerations

- Developing fetus is very sensitive to radiation.
- Pregnant staff should not care for radioactively contaminated patients.

ETIOLOGY

- Ionizing radiation leads to cellular injury.
- Damage to blood vessels leads to endarteritis and loss of tissue blood supply.
- Higher rates of cell division within an organ make it more sensitive to radiation:
 - Bone marrow and GI tract are very sensitive.
 - Skin and nerve are less sensitive.
- *Acute radiation syndrome* (ARS) occurs in stages following whole-body exposure:
 - Prodromal: Acute radiation injury leads to acute inflammation (0–48 hr).
 - Latent: If the acute phase of injury is survived, inflammation and symptoms subside (0–2 wk).
 - Manifest illness: At higher radiation doses, organ failure then develops.
 - Recovery or death (usually from infection) follows.
- Sources of radiation include medical devices, therapeutics, nuclear weapons, and industry.

DIAGNOSIS

- Diagnosing contamination is fairly easy.
- Diagnosing and quantifying exposure is more difficult and probably require expert consultation.

SIGNS AND SYMPTOMS

- Vary based on dose; see: <http://www.afrrri.usuhs.mil/outreach/pdf/AFRRI-Pocket-Guide.pdf> for quick reference.
- Overall:
 - Whole-body exposure: Syndrome similar to high-dose chemotherapy toxicity
 - ARS progresses more rapidly the higher the absorbed dose.
- Local exposure:
 - Early resembles thermal or UV burn
 - Later resembles ischemic ulcer

History

- Recognized exposure:
 - Occupational, medical, transportation accident
- Unrecognized or clandestine exposure:
 - Radiologic dispersal device (RDD), concealed or unrecognized source
 - Industrial and medical radiography sources may be pellets, only a few millimeters in diameter and are highly radioactive.
 - Suspect if multiple patients present with symptoms of ARS at any stage, burns without history of thermal exposure, or ischemic ulcers in unusual locations (e.g., hand from handling unrecognized source, hip from placing source in pocket).

Physical-Exam

- Whole-body exposure:
 - Nausea, vomiting:
 - Within 3–6 hr for >100 rad exposure; sooner with higher exposures
 - Vomiting within 1 hr of exposure indicates potentially lethal injury (>600 rad).
 - Confusion and weakness (>200 rad)
 - Fever:
 - Acutely, from inflammation
 - During manifest illness, from infection
 - Hair loss, hemorrhage, diarrhea may develop with doses >300 rad.
- Dermal exposure:
 - Initial erythema
 - Blistering and ischemic necrosis may follow.

ESSENTIAL WORKUP

- *Survey for radiation* using a *Geiger counter*, which can be found in any nuclear medicine or radiation therapy department:
 - Any probe style is acceptable for survey.
 - Cover probe with exam glove:
 - Prevents contamination of probe
 - Blocks α radiation but detects β/γ
 - Measure background radiation away from patient.
 - Move probe slowly over patient's skin:
 - 1–2 cm from skin
 - Move probe only 2–3 cm/sec.
 - Contamination is $>2 \times$ background radiation level.
 - Note any contaminated areas.
 - Follow systematic pattern to avoid missing areas.
 - Remember to survey palms, soles, hair.
- *Absolute lymphocyte count (ALC)* is the best indicator of severity of ARS:
 - $<1,000/\text{mm}^3$: Moderate exposure, 200–600 rad
 - $<500/\text{mm}^3$: Severe exposure, >600 rad

DIAGNOSIS TESTS & NTERPRETATION

Lab

- CBC with differential every 4–6 hr (for 24 hr or until stable)
- Swab both nares and survey swab for inhaled contaminants.
- Type and cross-match blood.
- 24-hr stool for radioassay if GI contamination suspected
- 24-hr urine for radioassay if any internal contamination is suspected

Imaging

- Diagnostic imaging as clinically indicated
- Whole-body gamma camera (without collimator) is best for ruling out internal contamination with low levels of radioisotopes, if suspicion is high and survey with Geiger counter is negative.

Diagnostic Procedures/Surgery

Cytogenetics allows more accurate dose assessment:

- 10 mL blood in lithium-heparin tube (ethylenediaminetetraacetic acid also acceptable)
- Draw 24 hr postexposure.
- Refrigerate (4°C) and ship cold to Radiation Emergency Assistance Center/Training Site (REAC/TS).
- Only limited number of samples can be processed due to resources required.

DIFFERENTIAL DIAGNOSIS

- Systemic illness: Lymphopenia, weakness, nausea:
 - Psychological effects are common in both exposed and unexposed patients and may mimic ARS:
 - Radiation casualty with vomiting from ARS should have falling ALC; if ALC normal and stable, consider psychological stress reaction or other type of illness.
 - Hematologic malignancy
 - Chemical warfare agents (blister/mustard)
 - HIV disease, immunosuppression
- Skin injuries:
 - Ischemic ulcer
 - Brown recluse spider bite
 - Pyoderma gangrenosum

TREATMENT

Personal protective equipment (PPE):

- Must provide protection from dust (particulate respirator; e.g., N-95, gown, gloves, hair, and shoe covers)
- Radiography aprons are of no value—they do not protect against most γ radiation.

PRE HOSPITAL

- Treat life threats (airway, breathing, and circulation management [ABCs]).
- Assess any bombing scene for radioactive contamination (RDD).
- Removing clothing will eliminate about 80% of external contamination.
- Survey for residual contamination:
 - No contamination: Patient may be cared for as usual.

- If contamination is present, assess medical condition:
 - Stable: Proceed with decontamination.
 - Unstable: Provide necessary care and transport; use sheets to control contamination.

INITIAL STABILIZATION/THERAPY

- ABCs
- Assess for contamination.
- If patient condition permits, perform decontamination before patient enters (and contaminates) facility.
- Minimize staff exposure:
 - *Time*: Limit time in contaminated area, remove contaminated material often.
 - *Distance*: Use long-handled instruments to handle contaminated material.
 - *Shielding*: Place contaminated material in a lead container (available in nuclear medicine department); radiography lead aprons are not effective.

ED TREATMENT/PROCEDURES

- Hospital issues:
 - Activate hospital disaster plan, if indicated, to mobilize resources.
 - Designate contaminated and “clean” treatment areas.
 - Appoint a temporary radiation safety officer (RSO) for incident to survey all patients and staff and all materials leaving treatment area
 - Any staff member who is trained to use Geiger counter and dosimeters may fill RSO role initially if necessary.
 - Patients and materials that are not contaminated do not need decontamination or containment.
 - Call for expert assistance: Hospital RSO, local department of nuclear safety, health department, or REAC/TS.
- Staff issues:
 - Provide PPE and psychological support as described above.
 - Assign pregnant personnel to “clean” areas only.
- Decontamination:
 - *Priorities*: Wounds > mucous membranes > intact skin
 - Use fenestrated drapes to shield adjacent skin.
 - Use soap and water; no harsh chemicals.
 - Diaper wipes work well for intact skin; wipe from edges of area to center, then lift away.
 - Irrigate wounds—collect and survey runoff, avoid splashing.
 - Resurvey frequently to assess effectiveness of decontamination.
 - Do not abrade skin.
 - If contamination cannot be removed, cover area to prevent spread and move on—residual contamination can be controlled.

- RDD:
 - Necessary surgery must be done immediately (36–48 hr), or else delayed 1–2 mo, with exposure > 200 rad.
 - Any bombing victim must be assessed for radioactive contamination until RDD is ruled out by assessment of scene.
 - Preserve evidence for criminal investigation.
- Treat vomiting and dehydration:
 - Antiemetics (ondansetron)
 - IV fluids
- Decorporation agents for internal decontamination are specific to each radionuclide:
 - Contact REAC/TS for guidance (see below).
- Cytokines and transfusions may be needed with doses > 200 rad.
- Potassium iodide:
 - Useful only to prevent thyroid uptake of radioactive iodine (found in nuclear reactors), and only if given within 4 hr after contamination. See www.remm.nlm.gov/potassiumiodide.htm for more information.

MEDICATION

- Ondansetron 8 mg IV (or equivalent 5-HT₃ serotonin antagonist)
- Potassium iodide:
 - Adults: 130 mg PO per day
 - Children:
 - 3–18 yr: 65 mg PO per day
 - 1 mo to 3 yr: 32 mg PO per day
 - <1 mo: 16 mg PO per day

FOLLOW-UP

DISPOSITION

Admission Criteria

- Lymphocyte count < 1,000 at 24–48 hr postexposure
- Lymphocyte count decreased 50% at 24–48 hr
- Suspect acute exposure > 200 rad
- Significant trauma or other illness
- Uncontrolled vomiting
- When in doubt, admit for serial CBC and obtain consultation

Discharge Criteria

- No residual contamination
- No evidence of acute exposure > 100 rad

- Tolerating oral fluids

Issues for Referral

- Internal contamination: Contact REAC/TS for guidance.
- 24-hr emergency number: 865-576-1005
- External contamination that cannot be removed
- Any patient with radiation exposure requires dose assessment and risk counseling.

PEARLS AND PITFALLS

- Emergency medical care takes precedence over decontamination:
 - _ No known case where a live, contaminated patient was so radioactive as to be an immediate hazard to emergency personnel
- Do not underestimate psychological impact of any incident involving “radiation”
- ALC can help differentiate ARS from psychosomatic illness: If vomiting is due to ARS, ALC should be low and falling over 4–8 hr

- Z77.123 Cntct w & expsr to radon & oth naturally occuring radiation

BASICS

DESCRIPTION

- Morphology, distribution, associated systemic symptoms, and the evolution of a rash are important clinical considerations in identifying a dermatologic emergency
- Presentations of erythroderma, blistering/desquamation, purpura, and skin pain with systemic symptoms are warning signs of a potential emergency
- Abnormal skin lesions due to an inflammatory reaction that can be classified into patterns with distinctive clinical features
- Vesiculobullous lesions:
 - Fluid-filled swelling of the skin or sloughing due to disruption of epidermal/dermal integrity
- Purpura and petechiae:
 - Failure of normal vascular integrity/hemostatic mechanisms
 - Do not blanch on palpation
- Erythema:
 - Erythroderma when covering $\geq 90\%$ of the skin surface
 - Vascular dilatation of the superficial vessels leading to red macular lesions
 - Blanches on palpation
 - Figurate erythema:
 - Erythema classified by its particular annular or arcuate shape
- Papulosquamous:
 - Papules and scaly desquamation of the skin
 - Lesions may also be red and macular
 - Classified into psoriasiform, pityriasiform, lichenoid, annular, and eczematous
- Nodules:
 - Secondary to prolonged inflammatory response, cyst, or infiltrative process
 - Granulomatous lesions:
 - “Apple jelly” appearance when pressed with glass slide

ETIOLOGY/DIFFERENTIAL DIAGNOSES

- Vesiculobullous lesions:
 - Toxic epidermal necrolysis (mucosal and $> 30\%$ body surface area involvement)
 - Stevens–Johnson syndrome (mucosal and $\leq 10\%$ body surface area involvement)
 - Pemphigus vulgaris

- Bullous pemphigoid
- Disseminated herpes simplex
- Herpes zoster
- Varicella
- Smallpox
- Vaccinia
- Allergic contact dermatitis
- Purpura and petechiae:
 - Meningococemia
 - Gonococemia
 - Purpura fulminans/disseminated intravascular coagulopathy (DIC)
 - Rocky Mountain spotted fever (RMSF):
 - Pronounced prodrome of fever, headache, myalgia, rash, peripheral moves to palms/soles
 - Ecthyma gangrenosum:
 - *Pseudomonas* infections in critically ill and immunocompromised patients
 - Babesiosis: Similar to RMSF, rash less often, frequent coinfection with Lyme
 - Vasculitis
 - Multiple systemic illnesses (see chapter on Purpura)
- Erythroderma:
 - Toxic shock syndrome
 - Drug-induced
 - Psoriasis
 - Seborrheic dermatitis
 - Mycosis fungoides
 - Lymphoma of the skin
- Erythematous rashes:
 - Localized:
 - Cellulitis
 - Early necrotizing fasciitis with concomitant skin pain
 - Diffuse:
 - Staphylococcal scalded skin syndrome
 - Toxic shock syndrome
 - Drug-induced, including drug reaction with eosinophilia and systemic symptoms (DRESS)
 - Viral exanthema
- Figurate erythema:
 - Erythema chronicum migrans (large red ring that arises around a tick bite):
 - Lyme disease
 - Erythema multiforme:
 - *Mycoplasma pneumoniae*
 - Herpes simplex

- Drug reaction leading to Steven–Johnson syndrome
- Urticaria:
 - Allergic reaction from drugs, food, infection, pressure, heat, or cold
- Papulosquamous:
 - Psoriasiform:
 - Psoriasis
 - Seborrheic dermatitis
 - Drug-induced
 - Pityriasiform:
 - Pityriasis rosea
 - Secondary syphilis
 - Tinea versicolor
 - Lichenoid:
 - Lichen planus
 - Drug-induced
 - Annular:
 - Tinea
 - Figurate erythema (see below)
 - Eczematous:
 - Atopic dermatitis
 - Allergic contact dermatitis
 - Irritant dermatitis
- Nodules:
 - Granulomatous disease:
 - Sarcoid
 - Granuloma annulare
 - Infectious: Leprosy, tuberculosis, deep fungal infection
 - Panniculitis:
 - Erythema nodosum
 - Lymphoma of the skin
 - Cysts
 - Tumors and metastatic disease

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Age of patient
- Immune status (HIV, chemotherapy, diabetes, steroids)
- Chronologic and physical evolution
- Previous episodes/prior history of lesions/reactions

- Associated symptoms:
 - Pruritus
 - Fever
 - Abdominal pain
 - Myalgias/arthralgias
- Prodromal symptoms:
 - Fever
 - Headache
 - Cough
 - Odynophagia
 - Rhinorrhea
- Environmental exposure:
 - Tick bite
 - Unusual flora
 - Diet
 - Travel
 - Physical trauma (cold, heat, sun)
- Sick contacts
- Recent change in medication
- Family history

Physical-Exam

- Associated signs/symptoms:
 - Fever with infection/drug reaction/systemic inflammatory response
 - Skin pain out of proportion to the clinical picture is a worrisome sign of possible impending skin necrosis
 - Lymphadenopathy may be a symptom of DRESS
 - Pruritus associated with allergic reactions, systemic and contact
- Assess severity of systemic signs:
 - Abnormal vital signs, respiratory distress, hemodynamic instability
- Primary lesion appearance:
 - Vesicles:
 - Small, raised, clear fluid-filled lesions (<5 mm)
 - Bullae:
 - Large, raised, clear fluid-filled lesions (>5 mm)
 - Macule:
 - Nonraised areas of distinct coloration
 - Papule:
 - Raised, palpable lesions <5 mm in diameter, not fluid-filled
 - Pustules:
 - As vesicles and bullae, but containing purulent fluid
 - Nodule:
 - Solid, raised lesion >5 mm seated in deeper layer of skin and tissue

- Distribution of the rash:
 - Characterized as central/peripheral, confluent/scattered, mucosal/nonmucosal, presence of palm/sole involvement
- Secondary changes:
 - Scaling, lichenification, excoriation, fissuring all result from manipulation/scratching or proliferation/shedding of epidermal cells.
 - Erosions/ulcers from varying degrees of tissue loss due to loss of vascular supply/tissue integrity

ESSENTIAL WORKUP

- Identify systemic illness.
- Signs/symptoms of local infectious source
- Categorize the lesion morphology and distribution

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Presence of fever, systemic symptoms, or possible infection warrants blood work:
 - CBC with differential, electrolytes, BUN/creatinine
 - Blood cultures, viral cultures
 - Gram stain and culture of purulent lesions
 - Polymerase chain reaction (PCR) or Direct fluorescent antibody (DFA) of suspected viral lesions
- Rapid plasma reagin (RPR) or fluorescent treponemal antibody (FTA) for suspected syphilis
- Suspected autoimmune disorders:
 - CBC
 - ESR, CRP
 - Particular assays in consultation with a rheumatologist (ANA, antineutrophil cytoplasmic antibody)
- Petechiae/purpura:
 - CBC with platelets
 - Partial thromboplastin time, prothrombin time, INR
 - DIC screen: Fibrinogen, fibrin split products, haptoglobin, LDH
 - Urinalysis for suspected renal involvement in vasculitis

Diagnostic Procedures/Surgery

- In febrile and seriously ill patients, suspected septic lesions may be incised and drained and sent for cultures.
- Nikolsky test: Expansion of bullous lesion with lateral stress at margin indicates epidermal/dermal disruptive process
- Scrapings: Indicated to rule out topical fungal infections and parasites:
 - Potassium hydroxide preparation from edge of lesion reveal hyphae

- Plain mineral oil to rule out scabies in pruritic linear lesions of hands
- Biopsy under dermatologic consultation to differentiate allergic/autoimmune/infectious processes

DIFFERENTIAL DIAGNOSIS

See Etiology.

TREATMENT

PRE HOSPITAL

Universal precautions, masks if infectious etiology suspected

INITIAL STABILIZATION/THERAPY

Aggressive, presumptive management of potentially lethal presentations:

- Petechial lesions
- Disseminated erythematous or vesicobullous lesions
- Purpura with systemic symptoms
- Erythroderma with systemic symptoms

ED TREATMENT/PROCEDURES

- Treatment directed by underlying cause
- Immediate empiric antibiotics targeted toward meningococemia and RMSF in unstable patients with fever and purpura
- Treat disseminated bullous or exfoliative disease as a severe thermal burn.
- Symptomatic treatment of pruritus (diphenhydramine or hydroxyzine)
- Steroid therapy reserved for clear allergic reactions, relapse of known steroid responsive disease, or in consultation with dermatologist
- Allergic reactions:
 - H₁-blocker
 - H₂-blocker
 - Steroids
 - Epinephrine if respiratory compromise

MEDICATION

- Prednisone: 1 mg/kg (max. 60 mg/d)
- Diphenhydramine: 25–50 mg PO/IM/IV q6h
- Hydroxyzine: 25–100 mg PO q6h
- Methylprednisolone: 125 mg IV q24h
- Topical steroids: Classes 3–5 depending on location and severity

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with significant bullous/exfoliative disorders
- Associated systemic symptoms

Discharge Criteria

- Limited lesions
- Viral exanthems
- Absence of systemic signs or symptoms
- Stable, chronic presentation

Issues for Referral

Discharge to follow up with primary care physician or dermatologist

FOLLOW-UP RECOMMENDATIONS

- Reassure patients that rashes that cannot be diagnosed in the ED are often due to a mild viral illnesses or allergic reactions
- Stress the importance, however, of a follow-up visit with their physician or a dermatologist to obtain the best possible outcome.
- The patient should see his doctor quickly or return to the ED if the condition worsens:
 - _ Spreading redness from the rash
 - _ Increasing pain from the rash
 - _ Joint pain
 - _ Spreading of the rash with crusting
 - _ Fever
 - _ Severe headache
 - _ Confusion
 - _ Signs of a life-threatening allergic reaction:
 - Feeling dizzy or faint
 - Trouble breathing or swallowing
 - Swelling of the tongue

PEARLS AND PITFALLS

- Rapid evolution of a rash with systemic symptoms can indicate a dermatologic emergency
- Treat rapidly with empiric antibiotics in patients with purpura and fever to cover for meningococemia and RMSF.
- Treat rapidly with empiric antibiotics in patients with erythroderma, fever, and hypotension to cover toxic shock syndrome.
- Hyperpigmented scaly papules on the palms and soles require that secondary

syphilis be ruled out.

Purpura

CODES

ICD9

782.1 Rash and other nonspecific skin eruption

ICD10

R21 Rash and other nonspecific skin eruption

BASICS

DESCRIPTION

- Lesion morphology:
 - Macule:
 - Localized nonpalpable changes in skin color
 - Purpura or petechiae (nonblanching with pressure)
 - Maculopapule:
 - Slightly elevated lesions with localized changes in skin
 - Papule:
 - Solid, elevated lesions < 5 mm in diameter
 - Keratotic (rough-surfaced lesion)
 - Nonkeratotic (smooth lesion)
 - Palpable purpura (nonblanching with pressure)
 - Plaque:
 - Solid, elevated lesions > 5 mm in diameter
 - Often results from a confluence of papules
 - Nodule:
 - Solid, elevated lesions extending deep into the dermis or SC tissue > 5 mm in diameter
 - Wheal:
 - Circular, irregular lesions varying from red to pale
 - Vesicle:
 - Clear, fluid-filled lesions < 5 mm in diameter
 - Bullae:
 - Clear, fluid-filled lesions > 5 mm in diameter
 - Pustules:
 - Pus-filled lesions
- Secondary lesions:
 - Scales:
 - Thin plates of dried cornified epithelium partially separated from the epidermis
 - Lichenification:
 - Dried plaques resulting in skin furrowing
 - Erosion:
 - Moist surface uncovered by rupture of vesicles or bullae
 - Excoriation:
 - Linear loss of the skin due to trauma

- Ulcer:
 - Deep loss of the skin involving the epidermis and a variable amount of the dermis and SC tissue
- Configuration:
 - Circles or arcs
 - Serpiginous (creeping or worm like)
 - Iris grouping (bull's eye appearance)
 - Irregular grouping
 - Zosteriform grouping
 - Linear grouping
 - Retiform grouping
- The color of a lesion or the entire skin may be due to a number of substances:
 - Red or red-brown lesions result from oxyhemoglobin found in RBCs.
 - The macular erythematous lesions seen in viral exanthema usually represent dilated superficial cutaneous vessels.
 - Purpura and petechiae result from leakage of RBCs out of the vascular space.
 - Hypopigmentation or hyperpigmentation represent postinflammatory change from either increases or decreases in melanin production.
 - Depigmentation refers to the total loss of pigment secondary to autoimmune effect (vitiligo) or congenital disorders (albinism).
- Scales represent a proliferative disorder of epidermal cell turnover.

ETIOLOGY

- Papulosquamous:
 - Infections:
 - Viral or bacterial
 - Rickettsial or fungal
 - Allergic reactions
 - Autoimmune disorders
- Purpura and petechiae:
 - Clotting or platelet disorder
 - Vascular fragility disease
 - Vasculitis
 - Overwhelming infection
- Vesicobullous:
 - Infection
 - Drug reaction
 - Autoimmune disorder
- Ulcer:
 - Infection
 - Vascular insufficiency

DIAGNOSIS

SIGNS AND SYMPTOMS

- Fever (consider infectious exanthemas)
- Pruritus
- Joint pain
- Abdominal pain
- Heart murmur

History

Obtain a detailed history:

- Age group: Conditions, distribution, and appearance may vary with age
- Development, progression, pattern, and duration of the rash
- Lesions synchronous or asynchronous
- Associated symptoms
- Prodromes—cough, rhinorrhea, pharyngitis, fever, meningismal symptoms, pruritus
- Family history, exposures, immunizations
- Recent travel; insect or arthropod bites
- Medications especially new medications
- Generic dermatoses
- Atopic dermatitis; psoriasis

Physical-Exam

- Cardiac:
 - Murmurs/rubs
- Pulmonary:
 - Crackles/wheezing
- Abdominal:
 - Tenderness
 - Hepatosplenomegaly
- Skin: See Essential Workup.

ESSENTIAL WORKUP

Classify the rash based on the primary lesions:

- Papulosquamous
- Vesicobullous
- Purpuric

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Indicated if the rash is purpuric:
 - CBC with platelet count
 - Bleeding screen (prothrombin test, partial thromboplastin time, bleeding time, disseminated intravascular coagulation [DIC] screen)
- Indicated if fever present:
 - CBC
 - Electrolytes, BUN, creatinine to evaluate dehydration and scarlatiniform rash (exclude glomerulonephritis)
 - Viral culture and titers for suspected exanthems
 - Lactate and blood cultures for suspected sepsis/bacteremia
- Lumbar puncture if *meningococcus* or other meningitides or encephalitis suspected

Imaging

Chest radiograph for suspected pulmonary involvement

Diagnostic Procedures/Surgery

- Potassium hydroxide (KOH) preparations:
 - Indicated with scaling lesions to differentiate dermatophytosis from nummular eczema and pityriasis rosea
 - Superficial scale sample from active border of lesion removed from the skin with a scalpel or the edge of a glass slide
 - Place on a slide and add 1 drop of 10% KOH.
 - Place a coverslip and heat slowly without boiling. Allow to set for a few minutes and scan for hyphae.
- Wood lamp:
 - Useful in dermatophytosis and erythrasma
- Scabies preparations:
 - Most of the mite population resides on the hands and feet.
 - Place a drop of mineral oil on the lesion. Scrape with a no. 15 blade to produce speck of blood.
 - Examine under low power for the mite, ova, larva, or fecal matter.

DIFFERENTIAL DIAGNOSIS

Maculopapular Rash

- Solid, skin colored, or yellow:
 - Keratotic
 - Wart
 - Corn or callus
 - Nonkeratotic
 - *Molluscum contagiosum*
 - Sebaceous cyst

- Basal and squamous cell carcinoma
- Nevi
- Solid, brown:
 - Café au lait patch
 - Nevi
 - Freckle
 - Melanoma
 - Photoallergic/phototoxic drug eruption
 - Tinea nigra palmaris hypopigmentation
- Solid, red, nonscaling:
 - Nonpurpuric
 - Exanthems
 - Rubeola, rubella, or roseola
 - Scarlet fever
 - Toxin-producing staphylococcal or streptococcal disease
 - Erythema infectiosum (“fifth disease”)
 - Rubella-like rash (echoviruses, Coxsackie A viruses)
 - Varicella (early manifestations)
 - Variola (smallpox: Early manifestations)
 - Epstein–Barr virus
 - Enterovirus or adenovirus
 - *Mycoplasma*
 - Kawasaki disease
 - Erythema multiforme
 - Localized, pruriginous
 - Insect bites, scabies
 - Allergic or irritant contact dermatitis
 - Purpuric
 - Bacteremia sepsis
 - Meningococemia, pneumococemia, gonococemia, *Haemophilus influenzae*
 - Endocarditis
 - Plague
 - DIC
 - Rocky Mountain spotted fever (RMSF)
 - Henoch–Schönlein purpura
 - Idiopathic thrombocytopenic purpura
 - Leukemia
 - Underlying bleeding disorder
 - Ecthyma gangrenosum
 - Rarely, pityriasis rosea
- Solid, red, scaling:
 - Without epithelial disruption:
 - Tinea corporis, capitis, pedis, or cruris

- Pityriasis rosea
- Secondary syphilis
- Lupus erythematosus
- With epithelial disruption:
 - Papular urticaria
 - Eczema
 - Seborrheic, diaper, contact, or stasis dermatitis
 - Impetigo
 - Candidiasis
 - Tinea corporis, capitis, pedis, or cruris
 - Vesiculobullous rash
 - Herpes virus: Varicella, *variola* (smallpox)
 - Herpes simplex/zoster
 - Hand-foot-and-mouth syndrome
 - Scabies
 - Drug hypersensitivity, toxic epidermal necrolysis
 - Staphylococcal scalded skin syndrome
 - Impetigo, bullous impetigo
 - Cat scratch disease
 - Dermatitis herpetiformis
 - Eczema
 - Erythema multiforme
 - Lichen planus

Pustular

- Acne
- Folliculitis
- Candidiasis
- Gonococemia
- Meningococemia
- Fever present, consider:
 - Infection
 - Drug reaction
 - Systemic inflammatory disease (juvenile rheumatoid arthritis, systemic lupus erythematosus, etc.)

TREATMENT

PRE HOSPITAL

Field management is indicated when there are signs of systemic instability:

- Airway management using precautions to avoid exposure to respiratory secretions; IV access

- Identify rashes with a potentially life-threatening illness or need for special isolation.

INITIAL STABILIZATION/THERAPY

- Aggressive, empiric management of children with a purpuric rash associated with fever or unstable vital signs:
 - Airway support, IV access, fluid resuscitation, pressors if cardiovascular collapse
 - IV antibiotics should be administered for suspected etiologies

ED TREATMENT/PROCEDURES

- Specific ED treatment should be directed to the underlying etiology.
- Diphenhydramine should be used when an allergic reaction is suspected.

MEDICATION

- Acetaminophen: 10–15 mg/kg PO/PR q4–6h; do not exceed 5 doses/24 h
- Cefotaxime: 50 mg/kg IV q6h; max. dose, 12 g/24 h
- Ceftriaxone: 50 mg/kg IV q12h; max. dose, 4 g/24 h
- Diphenhydramine: 1.25 mg/kg PO/IM/IV q6h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Hospital admission is determined by the underlying disorder.
- Other illnesses associated with systemic illness or potential deterioration, SSS, rubeola, and varicella, as well as others, may require inpatient care.

Discharge Criteria

Discharge instructions should be based on the underlying disorder.

Issues for Referral

- Exanthems associated with self-limited entities in stable children.
- Follow-up with primary care physician or dermatologist should be arranged.

FOLLOW-UP RECOMMENDATIONS

Patient should return for re-evaluation for any rapidly spreading rash, changes in rash morphology, petechiae or hemorrhage, new onset fever or neck stiffness.

PEARLS AND PITFALLS

- Note where rash 1st appeared and how it is spreading.

- Note associated signs and symptoms. They are often key for critical illness.
- Keep meningococemia in mind in any rash with fever.

ICD10

- L22 Diaper dermatitis
- R21 Rash and other nonspecific skin eruption
- R23.3 Spontaneous ecchymoses

REACTIVE ARTHRITIS

Christopher M. Fischer

BASICS

DESCRIPTION

- Syndrome classically includes triad of conjunctivitis, urethritis, arthritis
- Also known as “Reiter’s syndrome,” although the eponym has fallen out of favor:
 - Typically taught as the syndrome of “can’t see, can’t pee, can’t climb a tree”

ETIOLOGY

- Exact incidence difficult to determine because of lack of standardized diagnostic criteria
- 2 main types:
 - Postdysentery:
 - Salmonella, Shigella, Campylobacter, Yersinia, *Clostridium difficile*
 - Venereal:
 - *Chlamydia trachomatis*, *Neisseria gonorrhoeae*
- Also described after upper respiratory infections, UTIs, BCG treatment for bladder carcinoma
- M > F (~5:1)
- Peak onset during 3rd decade

DIAGNOSIS

SIGNS AND SYMPTOMS

- Urogenital: Occur in >90% of cases, seen in both forms of disease
- Arthritis, tendonitis:
 - Typically polyarticular, asymmetric
 - Knees and ankles most commonly affected
 - May also affect fingers, back, sacroiliac joints
 - Achilles tendonitis present in 40% of cases
- Ophthalmologic: Occur in 30–60% of cases:
 - Conjunctivitis is most common:
 - Usually bilateral
 - Uveitis, keratitis is less common:
 - Usually unilateral
 - Usually preceded by 1–2 days of eye discomfort
- Mucocutaneous:
 - More common in patients with HLA-B27 positivity

History

- Symptoms generally within 4 wk of infection, although may be delayed up to 1 yr
- Diagnosis made by history and physical exam findings
- Only 1/3 have the complete triad of conjunctivitis, urethritis, arthritis
- Postdysentery: Usually preceded by symptomatic GI infection, especially in children
- Venereal: Often follows asymptomatic infection

Physical-Exam

- General:
 - May include fever, fatigue, weight loss, malaise
- Urogenital:
 - Urethritis
 - Cervicitis
 - Prostatitis
- Extremities:
 - Swelling, painful range of motion, erythema may all be present.
 - Sausage digit (diffuse swelling of an entire digit) present in ~15% of cases
- Ophthalmologic:
 - Conjunctivitis:
 - Often with mucopurulent discharge
 - Symptoms range from mild irritation to severe inflammation.
 - Uveitis:
 - Eye pain, redness, photophobia, miosis, blepharospasm
- Skin/mucosa:
 - Keratoderma blennorrhagicum:
 - Begins as erythematous macules and vesicles on palms and soles, progresses to pustules and dark plaques
 - Similar in appearance to pustular psoriasis
 - Circinate balanitis: Present in >50% of males:
 - Plaques, vesicles or papules on glans penis
 - Ulcerative vulvitis may be associated with vaginal discharge
 - Nail changes, including nail dystrophy, periungual pustules
 - Oral lesions, include ulcerations, geographic tongue, palatal erosions, usually painless

ESSENTIAL WORKUP

- Clinical diagnosis is based on characteristic physical exam findings and a history of GI illness, sexually transmitted infection or upper respiratory infection.
- Must exclude other serious time-sensitive diagnoses that require prompt treatment

DIAGNOSIS TESTS & INTERPRETATION

Lab

No lab tests can confirm the diagnosis:

- CBC may show leukocytosis and mild anemia
- ESR and CRP are usually elevated
- Urinalysis may show sterile pyuria

Imaging

- No radiology exams can confirm the diagnosis
- Plain x-ray can be considered of affected extremities to exclude other diagnoses:
 - _ May show swelling around affected joint, indicating joint effusion

Diagnostic Procedures/Surgery

Arthrocentesis:

- Should be performed if septic arthritis is considered
- Synovial fluid analysis may show leukocytosis, PMN predominance:
 - _ Crystals not present, and indicate other pathologies (gout, pseudogout)

DIFFERENTIAL DIAGNOSIS

- Gonococcal urethritis
- Chlamydial urethritis
- Syphilis
- Gout
- Gonococcal arthritis
- Septic arthritis
- Rheumatoid arthritis
- Pustular psoriasis
- Behçet disease
- Contact dermatitis
- Psoriasis
- Kawasaki disease (in children)

TREATMENT

PRE HOSPITAL

No specific pre-hospital considerations

ED TREATMENT/PROCEDURES

- Once other serious infections have been excluded, treatment is symptomatic
- No consensus about the role of antibiotics
- Rationale for antibiotic treatment is that reactive arthritis is caused by bacterial infection, which may have long-term viability in synovium (especially Chlamydia):
 - _ Studies have demonstrated no long-term benefit with doxycycline,

ciprofloxacin, azithromycin

- Short course of systemic corticosteroids may be helpful in severe or prolonged disease
- Arthritis:
 - Rest, ice, elevation
 - NSAIDs
- Conjunctivitis:
 - Topical antibiotics may provide symptomatic relief
- Urethritis:
 - Should be treated if initial infection not recognized or treated

MEDICATION

No definite role for medication

FOLLOW-UP

DISPOSITION

Admission Criteria

Treatment is generally outpatient, once syndrome is recognized and other diagnoses have been excluded.

Discharge Criteria

Most patients with reactive arthritis can be discharged with follow-up with their primary care provider.

Issues for Referral

Severe uveitis should be referred to ophthalmology for close follow-up.

FOLLOW-UP RECOMMENDATIONS

With primary care provider. Most cases have a prolonged course (3–12 mo), and ~25% may have recurrent episodes.

PEARLS AND PITFALLS

Failing to diagnose serious life- or limb-threatening diseases is a pitfall:

- Septic arthritis
- Gonococcal arthritis
- Kawasaki disease

- 711.10 Arthropathy associated with Reiter's disease and nonspecific urethritis, site unspecified

ICD10

M02.30 Reiter's disease, unspecified site

RECTAL PROLAPSE

Marilyn M. Hallock

BASICS

DESCRIPTION

- Full-thickness evagination of the rectal wall outside the anal opening
- 3 types of rectal prolapse:
 - _ Full-thickness prolapse:
 - Protrusion of the rectal wall through the anal canal; the most common
 - _ Partial thickness or mucosal prolapse:
 - Only mucosal layer protrudes through anus
 - _ Occult (internal) prolapse or rectal intussusception:
 - Rectal wall prolapse without protrusion through the anus
 - May be difficult to diagnose

ETIOLOGY

- Cause unclear and multifactorial:
 - _ Chronic constipation/excessive straining
 - _ Laxity of sphincter:
 - Pelvic floor trauma/weakness; childbearing
 - Neurologic disease
- More common in women, peak in 7th decade

Pediatric Considerations

- Very rare after age 4 yr
- True rectal prolapse unusual in children; more likely partial or intussusception
- Consider chronic diarrhea, parasites, cystic fibrosis (CF), malnutrition as contributing causes

DIAGNOSIS

SIGNS AND SYMPTOMS

- Dark red mass protrudes from the rectum
- Possible mucous or bloody discharge
- Sensation of rectal mass
- Tenesmus
- Constipation or incontinence

History

- History with emphasis on bowel obstruction and duration of prolapse

- Often progressive symptoms over time with self-reducing prolapse initially

Physical-Exam

- Rectal exam must differentiate prolapse from polyps, hemorrhoids, and intussusception.
- True prolapse shows dark red mass at the anal verge with or without mucus; circumferential circular folds in beefy mucosa of protruding rectum.
- Mucosal prolapse rarely greater than a few centimeters of protrusion; will not contain circular folds of muscular layer
- Internal hemorrhoids identified by folds of mucosa radiating out like spokes in wheel
- Prolapsed polyps and hemorrhoids do not involve the entire rectal mucosa and do not have a hole in the center.
- Intussusception identified by complaints of intermittent, severe abdominal pain; may appear more ill:
 - Examiner's finger can be passed between the apex of the prolapsed bowel and the anal sphincter; whereas, in rectal prolapse the protruding mucosa is continuous with the perianal skin

ESSENTIAL WORKUP

Careful physical exam

DIAGNOSIS TESTS & INTERPRETATION

Lab

- No lab test necessary for uncomplicated prolapse
- Preoperative testing for incarcerated rectal prolapse, going to OR

Imaging

No imaging is necessary for uncomplicated prolapse

DIFFERENTIAL DIAGNOSIS

- Prolapsed internal hemorrhoids
- Prolapsed rectal polyp
- Intussusception
- Other rectal mass

TREATMENT

PRE HOSPITAL

- Position of comfort
- Prevent mucosal desiccation with moist gauze

- Avoid trauma to mucosa

INITIAL STABILIZATION/THERAPY

- Stabilization generally not needed in simple prolapse
- Incarcerated or ischemic prolapse:
 - _ NPO
 - _ IV fluids
 - _ Prepare for surgery

ED TREATMENT/PROCEDURES

Manual reduction of rectal prolapse:

- Place in knee-chest position
- Apply gentle steady pressure for 5–15 min
- Invert mucosa through lumen from distal
- Sedation as needed to relax sphincter
- Finger may be placed in rectum to guide reversal of prolapse
- Prolapse very large or difficult to reduce:
 - _ Apply 1/2–1 cup sugar to reduce swelling and assist manual reduction
- Prolapse recurs immediately after reduction:
 - _ Apply pressure dressing with lubricant, gauze, tape; buttock may be taped together for several hours
- If prolapse incarcerated or ischemic, or if manual reduction fails or prolapse frequently recurs:
 - _ Admission for emergent surgical correction

ALERT

- Constriction of blood flow to rectum by anal sphincter can lead to ischemia, venous obstruction and thrombosis, full-thickness necrosis, possible loss of gut
- Timely reduction decreases risk
- Surgical intervention required for ischemic mucosa
- Most common complication of spontaneous or manual reduction:
 - _ Localized pain
 - _ Self-limited mucosal bleeding

MEDICATION

Sedation and pain medication only as needed

FOLLOW-UP

DISPOSITION

Admission Criteria

- Necrotic or ischemic mucosa

- Inability to reduce acute prolapse or frequently recurs

Discharge Criteria

- Reduced rectal prolapse
- Stable and tolerating PO
- Instructions to treat the presumed underlying cause:
 - _ Correct constipation:
 - Stool softeners
 - Increase fluid intake
 - Increase dietary fiber
- Avoid prolonged sitting or straining

Discharge Criteria

Refer for workup including:

- Search for leading lesion
- Refer for definitive surgical repair of recurrent prolapse
- Testing for CF in children

FOLLOW-UP RECOMMENDATIONS

Colorectal follow-up

PEARLS AND PITFALLS

- Perform careful physical exam to differential rectal prolapse from polyps, hemorrhoids, and intussuscepted bowel
- For large or difficult to reduce rectal prolapse, apply sugar to reduce swelling and assist in manual reduction

RECTAL TRAUMA

Stephen R. Hayden

BASICS

DESCRIPTION

- Injury to rectal mucosa
- Simple contusion to full-thickness laceration with extension into peritoneum or perineum
- 2/3 of rectum is extraperitoneal.

ETIOLOGY

- Penetrating trauma:
 - Gunshot wounds: 80% penetrating rectal trauma
 - Knife wounds
 - Impalement injuries
- Blunt trauma:
 - Motor vehicle accidents
 - Waterskiing and watercraft accidents:
 - Hydrostatic pressure injury
 - Pelvic fractures:
 - Bony fragments penetrate rectum
- Foreign body:
 - Autoeroticism
 - Anal intercourse
 - Assault
 - Ingestion of sharp objects
- Iatrogenic trauma: Most common cause of rectal injury:
 - Barium enema:
 - Perforation occurs in 0.04% patients
 - 50% mortality
 - Colonoscopy:
 - 0.2% perforation rate
 - Increased risk with polypectomy
 - Hemorrhoidectomy
 - Urologic and Ob-Gyn procedures:
 - Episiotomy

Pediatric Considerations

- Rectal injury may result from thermometer insertion.
- Any rectal trauma in young children should raise the suspicion of nonaccidental

trauma.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Perineal, anal, or lower abdominal pain
- Signs of perforation or peritonitis:
 - Guarding
 - Rebound tenderness
 - Fever
- Rectal bleeding
- Obstipation
- Presence of pelvic fracture
- History of anal manipulation, foreign-body insertion, sexual abuse

History

- Time and mechanism of injury
- Suspect rectal injury in all patients with gunshot wound, stab wound, or impalement injury to trunk, buttocks, perineum, or upper thigh.
- Consider in any patient with history of anal manipulation complaining of lower abdominal or pelvic pain.

Physical-Exam

- Inspect and palpate thoroughly buttocks, anus, and perineum.
- Identify entrance and exit wounds if penetrating trauma.
- Perform digital rectal exam:
 - Assess for gross blood or guaiac-positive stool
 - Note position of prostate
- Assess perineal integrity:
 - Speculum and bimanual exam in all female patients
 - Thorough genitourinary exam in all male patients, including prostate exam

ESSENTIAL WORKUP

- Labs: CBC, urinalysis
- Acute abdominal series
- CT abdomen and pelvis if blunt trauma
- Sigmoidoscopy: Following extraction of foreign body
- Evidentiary exam: Required in cases of sexual assault

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - Blood loss
 - Leukocytosis/bandemia suggesting peritonitis
- Type and screen:
 - If evidence of hemorrhage
- Urinalysis:
 - Evaluate for fecal matter

Imaging

- Supine/upright abdominal films, pelvic radiographs:
 - Evaluate for pneumoperitoneum or extraperitoneal and extrarectal densities suggesting perforation.
 - Identify location, size, and shape of foreign body.
 - Identify pelvic fracture or diastasis of symphysis pubis, which may accompany rectal injury.
- CT abdomen and pelvis
 - IV, PO, or PR contrast (gastrografin) per the clinical situation

Diagnostic Procedures/Surgery

- Retrograde urethrogram if high-riding prostate noted on rectal exam
- Contrast enema helpful only in situations where perforation is unclear:
 - Water-soluble contrast (e.g., gastrografin)

DIFFERENTIAL DIAGNOSIS

- Colon injuries
- Genitourinary injuries

TREATMENT

PRE HOSPITAL

- Airway, breathing, and circulation
- Spinal precautions if blunt trauma
- Fluid resuscitation if blood loss, hypotension
- Do not attempt removal of rectal foreign body
- Control bleeding

INITIAL STABILIZATION/THERAPY

Penetrating or blunt abdominal trauma, follow trauma protocols:

- Primary survey
- Resuscitation
- Secondary survey
- Treatment

ED TREATMENT/PROCEDURES

- Tetanus prophylaxis if needed
- Broad-spectrum antibiotics if significant mucosal disruption or signs of peritonitis are present
- Foley catheter (after excluding urethral injury)
- Rectal foreign body removal in ED:
 - _ Determine location and type of foreign object
 - _ Sedation:
 - Avoid sedation if possible; ideally, patient can aid extraction by bearing down during procedure
 - _ With patient in lithotomy position:
 - Local anesthesia to maximize anal sphincter dilation
 - Gentle digital sphincter dilation
 - Obstetric, ring, or biopsy forceps, tenaculum, or suctioning device to aid extraction
 - Suprapubic pressure
 - Patient Valsalva
 - _ Foley catheter:
 - Pass above foreign body, inflate balloon, and apply gentle traction to release suction and permit extraction
 - Using 3 catheters, pass each alongside of foreign body, inflate, and gently pull (helpful for smooth objects or if unable to pass Foley above object)
 - _ Sigmoidoscopy to evaluate mucosal injury following extraction
- Surgical consultation:
 - _ Peritonitis
 - _ All traumatic rectal mucosal lacerations
 - _ Objects > 10 cm from anal verge
 - _ Sharp objects whose removal may provoke mucosal injury
 - _ Inability to extract foreign body in ED

MEDICATION

- Antibiotics with coverage against gram-negative and anaerobic organisms:
 - _ Ampicillin/sulbactam:
 - Adults: 3 g q6h IV (peds: 50 mg/kg IV)
 - _ Cefotetan:
 - Adults: 2 g q12h IV (peds: 40 mg/kg IV)
 - _ Cefoxitin:
 - Adults: 2 g q6h IV (peds: 80 mg/kg q6h IV)
 - _ Piperacillin/tazobactam:
 - Adults: 3.375 g IV (peds: 75 mg/kg IV)
 - _ Ticarcillin/clavulanate:
 - Adults: 3.1 g IV (peds: 75 mg/kg IV)

- Additional anaerobic coverage:
 - Clindamycin:
 - Adults: 600–900 mg IV (peds: 10 mg/kg IV)
 - Metronidazole:
 - Adults: 1 g IV (peds: 15 mg/kg IV)
- Combination therapy:
 - Adults: Ampicillin 500 mg IV q6h, gentamicin 1–1.7 mg/kg IV, and metronidazole 1 g IV
 - Peds: Ampicillin 50 mg/kg IV q6h, gentamicin 1–1.7 mg/kg IV, and metronidazole 15 mg/kg IV
- Sedation and analgesia:
 - Fentanyl: 2–3 µg/kg IV (peds and adults)
 - Midazolam: 0.01–0.2 mg/kg IV (peds and adults)
 - Lidocaine: Topical or injectable

SURGERY/OTHER PROCEDURES

- Perforation
- Torn sphincter
- Foreign body:
 - General anesthesia required to remove high-riding or sharp object
 - Laparotomy is last resort

FOLLOW-UP

DISPOSITION

Admission Criteria

- Perforation
- Significant bleeding
- Unstable vital signs
- Abdominal pain
- Torn anal sphincter
- Foreign body that requires extraction in operating room

Discharge Criteria

- Stable vital signs
- No abdominal pain
- Normal sigmoidoscopy/anoscopy exam

FOLLOW-UP RECOMMENDATIONS

- Repeat abdominal exam 12–24 hr
- Return to ED:

- Abdominal pain
- Vomiting
- Fever

PEARLS AND PITFALLS

- Consider rectal injury in all patients presenting with abdominal pain following lower GI or genitourinary procedure.
- 60% of foreign bodies can be removed in ED.
- Failure to recognize perforation following extraction of foreign body
- Creativity and imagination can aid successful extraction of foreign body in ED.

CODES

ICD9

- 664.30 Fourth-degree perineal laceration, unspecified as to episode of care or not applicable
- 863.45 Injury to rectum, without mention of open wound into cavity
- 863.55 Injury to rectum, with open wound into cavity

ICD10

- O70.3 Fourth degree perineal laceration during delivery
- S36.60XA Unspecified injury of rectum, initial encounter
- S36.63XA Laceration of rectum, initial encounter

RED EYE

Franklin D. Friedman

BASICS

DESCRIPTION

- May be caused by almost any eye disorder
- Often benign; but may represent systemic disease
- Due to vascular engorgement of conjunctiva
- Main causes include inflammatory, allergic, infection, or trauma
- Conjunctivitis is the most common etiology

ETIOLOGY

- Inflammatory:
 - Uveitis:
 - Anterior and posterior
 - Iritis (perilimbal injection)
 - Episcleritis (70% are idiopathic)
 - Scleritis (50% associated with systemic disease)
 - Systemic inflammatory reactions
- Allergic:
 - Due to histamine release and increased vascular permeability, resulting in swelling of conjunctiva (chemosis), watery discharge, and pruritus; usually bilateral
- Infectious:
 - Bacterial (purulent mucous discharge), viral (watery or no discharge), or fungal
 - Orbital cellulitis
 - Dacryocystitis
 - Canaliculitis
 - Endophthalmitis
- Traumatic:
 - Corneal abrasion
 - Subconjunctival hemorrhage (SCH)
 - Foreign body
 - Occult perforation
- Other:
 - Pingueculitis and pterygium, hemorrhage, blepharitis, dry eye syndrome, acute angle-closure glaucoma, ophthalmia neonatorum, conjunctival tumor

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Age (especially neonatal and age > 50 yr)
- Time of onset, duration of symptoms
- Exposures (i.e., chemicals, allergens)
- Patient's occupation (i.e., metal worker)
- Associated signs and symptoms (headache, systemic symptoms, other infections)
- Ocular symptoms:
 - Pain
 - Foreign-body sensation
 - Change in vision
 - Discharge
 - Pruritus
- Contact lens use
- Other comorbidities

Physical-Exam

- Thorough physical exam:
 - Preauricular or submandibular adenopathy
 - Rosacea (may cause blepharitis)
 - Facial or skin lesions (herpes)
- Ophthalmologic:
 - Visual acuity
 - General appearance:
 - Universal eye redness or locally
 - Conjunctival injection
 - Lid involvement
 - Purulent or clear discharge
 - Obvious foreign body
 - Proptosis
 - Photophobia
 - Eyelash against globe (trichiasis)
 - Pupil exam
 - Confrontational visual field exam
 - Extraocular muscle function
 - Slit-lamp exam with fluorescein:
 - Anterior chamber cell or flare
 - Pinpoint or dendritic lesions in HSV
 - Corneal abrasion
 - Foreign body
 - Lid eversion

- Fundoscopy and tonometry

ESSENTIAL WORKUP

- Consider systemic causes of red eye
- Physical exam as described above

DIAGNOSIS TESTS & INTERPRETATION

Tests should be directed toward the suspected etiology of red eye:

- Dacryocystitis: Culture discharge
- Corneal ulcers: Scrape cornea for culture (often is performed by ophthalmologist)
- Bacterial conjunctivitis:
 - Moderate discharge: Obtain conjunctival swab for routine culture and sensitivity (usually *Staphylococcus aureus*, *Streptococcus*, and *Haemophilus influenzae* in unvaccinated children); however, not always needed, as conjunctivitis is often treated presumptively
 - Severe discharge: *Neisseria gonorrhoeae*
 - Note special culture media and procedures depending on suspected etiology (i.e., Thayer–Martin plate for GC)

Pediatric Considerations

- *Chlamydia trachomatis* is the most common neonatal infectious cause of conjunctivitis (monocular or bilateral, purulent or mucopurulent discharge)
- *N. gonorrhoeae* is the other neonatal infectious etiology; typically presents within 2–4 days after birth; marked purulent discharge, chemosis, and lid edema
- Complications may be severe

Lab

- Often not indicated
- Useful if etiology is thought to be systemic disease
- If bilateral, recurrent, granulomatous uveitis is suspected, send CBC, ESR, antinuclear antibody, VDRL, fluorescent treponemal antibody–absorption, purified protein derivative, ACE level, chest x-ray (sarcoidosis and tuberculosis), Lyme titer, and HLA-B27, *Toxoplasma*, and cytomegalovirus (CMV) titers

Imaging

Obtain plain films and/or CT scan of the orbits if suspect foreign body, orbital disease, or trauma

Diagnostic Procedures/Surgery

- Tonometry if glaucoma considered
- Slit-lamp exam with cobalt blue light and fluorescein:
 - Wood lamp exam with fluorescein in young children
- Removal of simple corneal foreign bodies

DIFFERENTIAL DIAGNOSIS

- Local: Infection, allergy, trauma (also see Etiology)
- Acute angle-closure glaucoma
- Systemic (generally an inflammatory reaction):
 - Arthritic disease
 - Ankylosing spondylosis
 - Ulcerative colitis
 - Reiter syndrome
 - TB
 - Herpes
 - Syphilis
 - Sarcoidosis
 - Toxoplasma
 - CMV

TREATMENT

PRE HOSPITAL

- Analgesic and comfort measures
- Initiate irrigation for a chemical exposure

INITIAL STABILIZATION/THERAPY

- Removal of contact lenses if applicable
- Irrigation for chemical insult
- Treat systemic illness if applicable

ED TREATMENT/PROCEDURES

- Direct therapy toward specific etiology
- Medication as indicated
- Special reminders:
 - Differentiate between a corneal abrasion and a corneal ulcer
 - Eye patching is no longer recommended and often contraindicated for abrasions
 - Update tetanus immunization for injury
 - Refrain from contact lens use
 - Do not spread infection to the unaffected eye or to unaffected individuals
 - Diagnosis of conjunctivitis caused by *N. gonorrhoeae* or *C. trachomatis* requires treatment of systemic infection for the individual and the source individual(s)
 - Always include workup and treatment of systemic disease if this is suspected

Special Topics

Corneal Abrasion

- Noncontact lens wearer:
 - Ointment or drops:
 - Erythromycin ointment every 4 hr
 - Polytrim drops 4 times/d
- Contact lens wearers need pseudomonal coverage:
 - Tobramycin, ofloxacin, or ciprofloxacin drops 4 times/d
- Dilate eyes with cyclopentolate 1–2%, 2–4 gtt daily to prevent pain from iritis
- Abrasions will heal without patching
- Systemic analgesics, opiate, or nonopiate
- Re-evaluation if symptomatic at 48 hr

Corneal Ulcer

- Noncontact lens wearer:
 - Polytrim ointment 4 times/d
 - Ofloxacin, ciprofloxacin drops q2–4h
- Contact lens wearers need pseudomonal coverage (see above)

Severe or Vision-threatening Corneal Ulcers

- Central > 1.5 mm or with significant anterior chamber reaction
- Treat as aforementioned and add increased frequency of antibiotic drops such as 1–2 gtt every 15 min for 6 hr, then every 30 min around the clock
- Ophthalmology consult for further recommendations, which may include ciprofloxacin 500 mg PO BID or fortified antibiotic drops made by pharmacist
- Hospitalization is often recommended in consultation with ophthalmologist

Acute Angle-closure Glaucoma

- Symptoms typically include rapid onset, severe eye pain, redness, decreased vision, and pupil in mid-dilation and unreactive
- Other symptoms may include:
 - Nausea and vomiting
 - Headache
 - Blurred vision and/or seeing halos around light
 - Increased tearing
- Diagnosis is further suspected when tonometry detects elevated eye pressure (> 21 mm Hg)

Subconjunctival Hemorrhage

- If large and in the setting of trauma exclude penetrating injury to the globe
- For minor SCH reassure, comfort measures and lubricating drops may speed recovery

Herpes Simplex or Zoster

- Add trifluridine (viroptic) 1%, 2 gtt 9 times/d or vidarabine 3% ointment 5 times/d (ointment preferred for children)
- Ophthalmology consultation

Pediatric Considerations

Herpes infections:

- Usually associated with HSV2 infections
- May be associated with encephalitis or as an isolated lesion
- Neonate onset occurs 1–2 wk after birth
- Presentation: Generally monocular, serous discharge, moderate conjunctival injection

ALERT

Ocular HSV infection carries significant risk of vision loss

Trauma or Uveitis

Rule out foreign body

MEDICATION

- Antibiotic drops:
 - Ciprofloxacin 0.3%: 1–2 gtt q1–6h
 - Gentamicin 0.3%: 1–2 gtt q4h
 - Ofloxacin 0.3%: 1–2 gtt q1–6h
 - Polytrim: 1 gtt q3–6h
 - Sulfacetamide 10%: 0.3% 1–2 gtt q2–6h
 - Tobramycin 0.3%: 1–2 gtt q1–4h
 - Trifluridine 1%: 1 gtt q2–4h
- Antibiotic ointments (ophthalmic):
 - Bacitracin: 500 U/g ½ in ribbon q3–6h
 - Ciprofloxacin 0.3%: ½ in ribbon q6–8h
 - Erythromycin 0.5%: ½ in ribbon q3–6h
 - Gentamicin 0.3%: ½ in ribbon q3–4h
 - Neosporin: ½ in ribbon of ointment q3–4h
 - Polysporin: ½ in ribbon of ointment q3–4h
 - Sulfacetamide 10%: ½ in ribbon of q3–8h
 - Tobramycin 0.3%: ½ in ribbon q3–4h
 - Vidarabine: ½ in ribbon 5 times/d
- Mydriatics and cycloplegics:
 - Atropine 1%, 2%: 1–2 gtt/d to QID
 - Cyclopentolate 0.5%, 1%, 2%: 1–2 gtt PRN
 - Homatropine 2%: 1–2 gtt
 - Phenylephrine 0.12%, 2.5%, 10%: 1–2 gtt BID–TID

- Tropicamide 0.5%, 1%: 1–2 gtt PRN
- Corticosteroid antibiotic combination drops (use only with ophthalmology consultation):
 - Blephamide: 1–2 gtt q1–8h
 - Cortisporin: 1–2 gtt q3–4h
 - Maxitrol: 1–2 gtt q1–8h
 - Pred G: 1–2 gtt q1–8h
 - Tobradex: 1–2 gtt q2–6h
- Glaucoma agents (always use with ophthalmology consultation):
 - Acetazolamide: 250–500 mg PO QD–QID
 - Betaxolol 0.25%, 0.5%: 1–2 gtt BID
 - Carteolol 1%: 1 gtt BID
 - Levobunolol 0.25%, 0.5%: 1 gtt QD–BID
 - Dipivefrin 1%: 1 gtt BID
 - Mannitol: 1–2 g/kg IV over 45 min
 - Pilocarpine 0.25%, 0.5%, 1%, 2%, 3%, 4%, 6%, 8%, 10%: 1–2 gtt TID–QID (use only if mechanical closure is ruled out)
 - Timolol 0.25%, 0.5%: 1 gtt BID

FOLLOW-UP

DISPOSITION

Admission Criteria

- Endophthalmitis
- Perforated corneal ulcers
- Orbital cellulitis
- Concurrent injuries (e.g., trauma)
- If indicated for systemic disease

Pediatric Considerations

Neonates with conjunctivitis suspected to be due to *N. gonorrhoeae* should be hospitalized for IV antibiotics (cefotaxime), and consideration should be given to septic workup

Discharge Criteria

Ability to follow outpatient instructions

Issues for Urgent Referral

- Dacryocystitis
- Corneal ulcer
- Scleritis
- Angle-closure glaucoma

- Uveitis
- Proptosis
- Orbital cellulitis
- Vision loss
- Uncertain diagnosis
- Gonorrheal or chlamydial conjunctivitis

FOLLOW-UP RECOMMENDATIONS

- Prompt re-evaluation if symptoms not resolving over expected time course
- Avoid use of contact lenses until approved by ocular specialist.

PEARLS AND PITFALLS

- Failure to recognize and treat ulcers, herpetic infections, neonatal bacterial infections, angle-closure glaucoma, and penetrating trauma
- Steroids should only be used with ophthalmology consultation

RENAL CALCULUS

Matthew A. Wheatley • Ryan A. Stroder

BASICS

DESCRIPTION

- Urinary tract obstruction
- Intermittent distention of the renal pelvis of proximal ureter produces pain
- Kidney stones:
 - Most common cause of renal colic
 - Stone composition:
 - 80%: Calcium stones (calcium oxalate > calcium phosphate)
 - 5% uric acid
 - Others: Magnesium ammonium phosphate (struvite), cystine
 - Associated with infections caused by urea-splitting organisms (e.g., *Pseudomonas*, *Proteus*, *Klebsiella*) along with an alkalotic urine
 - 90% of urinary calculi are radiopaque

ETIOLOGY

- 6–12% lifetime risk in the general population
- Twice as common in men as women
- Peak incidence between 40 and 60 yr old
- Theories on stone formation:
 - Urinary supersaturation of solute followed by crystal precipitation
 - Decrease in the normal urinary proteins inhibiting crystal growth
 - Urinary stasis from a physical anomaly, catheter placement, neurogenic bladder, or the presence of a foreign body
- Recurrence rate of 40% at 5 yr and 75% at 20 yr
- Associated with chronic kidney disease, hypertension, type 2 diabetes mellitus, metabolic syndrome, and an increased risk of coronary artery disease

Pediatric Considerations

- Rare in children
- When present, often is an indication of a metabolic or genetic disorder
- 60% present with flank or abdominal pain though up to 30% only present with hematuria
- Pediatric patients < 16 yr comprise ~7% of all cases of renal stones.
- 1:1 sex distribution
- Causes of stone formation:
 - Metabolic abnormalities (50%)
 - Urologic abnormalities (20%)

- Infection (15%)
- Immobilization syndrome (5%)

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Sudden onset of severe pain in the costovertebral angle, flank, and/or lateral abdomen
- Colicky or constant pain:
 - Patient cannot find a comfortable position
- Hematuria:
 - Gross hematuria in 1/3 of patients
- Nausea/vomiting
- Diaphoresis
- History of prior stone formation

Physical-Exam

- Vital signs:
 - Fever suggests an occult infection.
 - Hypotension with an altered mental status suggests urosepsis
- Abdominal exam:
 - Tenderness to palpation, rebound tenderness, or guarding suggests a more serious intra-abdominal process
 - Palpate the abdominal aorta for tenderness or pulsatile enlargement suggestive of an aneurysm
- Genitourinary exam:
 - Examine the genitalia for evidence of hernia, epididymitis, torsion, or testicular masses

ESSENTIAL WORKUP

- Urinalysis
 - Microscopic hematuria present in > 80%
 - Gross hematuria
 - Absent urinary blood in 10–30%
 - WBC/bacteria suggests infection
 - No correlation between the amount of hematuria and the degree of urinary obstruction

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - WBC > 15,000 suggests concomitant infection
- Urine culture
- Electrolytes, glucose, BUN, creatinine
- Pregnancy test when suggestive

Imaging

- CT:
 - Helical CT has replaced IV pyelogram (IVP) as test of choice
 - Detects calculi as small as 1 mm in diameter
 - Directly visualizes complications, such as hydroureter, hydronephrosis, and ureteral edema
 - Advantages over IVP:
 - Performed rapidly
 - Does not require IV contrast media
 - Detects other nonurologic causes of symptoms, such as abdominal aortic aneurysms (AAAs)
 - Disadvantages:
 - Does not evaluate flow or renal function
 - Nonenhanced helical CT in the evaluation of renal colic:
 - Sensitivity 95%
 - Specificity 98%
 - Accuracy 97%
 - Indications:
 - 1st-time diagnosis
 - Persistent pain
 - Clinical confusion with pyelonephritis
- IVP:
 - Establishes diagnosis in 95%
 - Demonstrates the severity of obstruction
 - Scout film prior may localize stones that would otherwise be obscured by the dye.
 - Postvoiding film
 - Useful to identify stones at the ureteral vesicular junction or distal ureter that are obscured by a full bladder
- Kidney, ureter, and bladder (KUB) radiograph:
 - Indicated when allergy to IVP dye and when renal scanning and US not available
 - Distinguishes calcium-bearing stones (radiopaque) from noncalcium stones
 - Assists in locating radiopaque stones and the exclusion of other pathologies in nonpregnant patients
 - Difficult to distinguish radiopaque body:

- Phlebolith
- Bowel contents
- Obstruction within the urinary tract on the KUB
- Oblique films assist in localizing suspicious calcifications.
- US:
 - _ Useful in the detection of larger stones and hydronephrosis
 - _ Provides anatomic information only
 - _ Helpful in diagnosing obstruction and localizing stones in the proximal and distal portions of the ureter
 - _ Ability to detect hydronephrosis:
 - Sensitivity 85–94%
 - Specificity 100%
 - _ Limitations:
 - May miss stones <5 mm in size
 - May miss an obstruction in the early phase of renal colic
 - Time delay until the onset of pyelocaliectasis even after total obstruction

Pregnancy Considerations

- Every effort should be made to minimize ionizing radiation exposure to the fetus
- US is the imaging modality of choice

Diagnostic Procedures/Surgery

Ureteroscopy, shock-wave lithotripsy, percutaneous nephrolithotomy

DIFFERENTIAL DIAGNOSIS

- Dissecting or rupturing AAA
- Pyelonephritis
- Papillary necrosis (sickle cell disease, NSAID analgesic abuse, diabetes, or infection)
- Renal infarction (vascular dissection or arterial embolus)
- Ectopic pregnancy
- Ovarian cyst/torsion
- Appendicitis
- Intestinal obstruction
- Biliary tract disease
- Musculoskeletal strain
- Lower lobe pneumonia
- Malingering or narcotic dependence (diagnosis of exclusion)

TREATMENT

PRE HOSPITAL

Parenteral opiates may be required for pain control with long transport times

INITIAL STABILIZATION/THERAPY

- Rapid dipstick urine test for blood:
 - Positive test in conjunction with clinical findings sufficient to begin analgesic therapy
- Provide adequate analgesia when diagnosis suspected on clinical and lab findings

ED TREATMENT/PROCEDURES

- Hydration:
 - Initiate IV crystalloid infusion with 1 L of normal saline infused over 30–60 min followed by 200–500 mL/h
 - Bolus volume compromised patients with 500 mL increments until urine output adequate
- Analgesics (morphine, ketorolac):
 - Combination of IV NSAIDs and opioids decrease ED stay and provide better pain control than either alone
- Antiemetics (prochlorperazine, ondansetron, droperidol, hydroxyzine)
- α -Blockers (tamsulosin) or calcium-channel blockers (nifedipine) have been shown to decrease time to spontaneous stone passage:
 - Most efficacious for stones < 5 mm in diameter
 - Tamsulosin and nifedipine equally effective
 - Prescribe on discharge

Pregnancy Considerations

Avoid NSAIDs in pregnancy, particularly in 3rd trimester

MEDICATION

- Hydromorphone (Dilaudid): 1–4 mg (peds: 0.015 mg/kg/dose) IM/IV/SC q4–6h PRN. Reduce dose in opiate-naive patients.
- Hydroxyzine hydrochloride (Vistaril): 25–50 mg (peds: 0.5–1 mg/kg/dose) IM (not IV) q4–6h
- Ketorolac (Toradol): 30–60 mg IM or 30 mg (peds: 0.5 mg/kg/dose up to 1 mg/kg/24–48 h) IV (alone or with opiates); reduce dose to 30 mg IM or 15 mg IV if > 65 yr or < 50 kg.
- Morphine sulfate: 2–10 mg (peds: 0.1–0.2 mg/kg/dose q2–4h) IM/IV/SC q2–6h PRN; may redose more frequently if needed
- Nifedipine 30 mg PO daily.
- Ondansetron (Zofran): 4 mg (peds: 0.1 mg/kg \times 1) IM/IV, not to exceed 8 mg/dose IV.
- Prochlorperazine (Compazine): 5–10 mg IM/IV q4–6h; 25 mg suppository PR
- Promethazine (Phenergan): 12.5–25 mg (peds: 0.25–1 mg/kg not to exceed 25 mg)

IM/IV/PR q4–6h

- Tamsulosin (Flomax) 0.4 mg PO daily for 4 wk

FOLLOW-UP

DISPOSITION

Admission Criteria

- Obstruction in the presence of infection mandates immediate urologic intervention.
- Intractable pain with refractory nausea and vomiting
- Severe volume depletion
- Urinary extravasation
- Hypercalcemic crisis
- Solitary kidney and complete obstruction
- Relative admission indications (discuss with urologist):
 - High-grade obstruction
 - Renal insufficiency
 - Intrinsic renal disease
 - Stones of size <5 mm usually pass spontaneously; those >8 mm rarely do.

Discharge Criteria

- Normal vital signs
- No evidence of concomitant urinary tract infection
- Adequate analgesia
- Able to tolerate PO fluids to maintain hydration status
- Reliable patient with an adequate home situation
- Appropriate outpatient follow-up arranged
- Normal renal function
- Provide a urine strainer to collect the stone for possible future stone analysis
- Arrange urologic follow-up

Issues for Referral

Imaging if pain persists and diagnosis not established in ED

FOLLOW-UP RECOMMENDATIONS

All patients should have urology follow-up, especially:

- 1st episode of renal stone
- Large stone >5 mm
- Patients who fail to pass a stone after 4 wk of conservative therapy

PEARLS AND PITFALLS

- Do not miss a vascular catastrophe mimicking as renal colic
- Aggressive pain management and hydration promote passage of stones
- The absence of hematuria does not exclude the diagnosis of acute renal colic

CODES

ICD9

- 592.0 Calculus of kidney
- 592.1 Calculus of ureter
- 788.0 Renal colic

ICD10

- N20.0 Calculus of kidney
- N20.2 Calculus of kidney with calculus of ureter
- N23 Unspecified renal colic

RENAL FAILURE (ACUTE KIDNEY INJURY)

Michael D. Burg • Matthew N. Graber

BASICS

DESCRIPTION

- The disorder is now known as acute kidney injury (AKI); the term renal failure is outdated.
- Changes in glomerular filtration rate (GFR) and urine output (UO) encompassing a spectrum ranging from normal physiologic response to end-stage renal disease (ESRD) and measured by accumulation of nitrogenous by-products.
- Defined by the RIFLE criteria:
 - 3 stages of renal injury:
 - **Risk**: Increased creatinine (Cr) $\times 1.5$ or GFR decrease $> 25\%$, UO < 0.5 mL/kg/h $\times > 6$ h
 - **Injury**: Increased Cr $\times 2$ or GFR decrease $> 50\%$, UO < 0.5 mL/kg/h $\times > 12$ h
 - **Failure**: Increased Cr $\times 3$ or GFR decrease $> 75\%$ or Cr ≥ 4 mg/dL (acute rise of ≥ 0.5 mg/dL), UO < 0.3 mL/kg/h $\times 24$ h or anuria $\times 12$ h
 - 2 stages of outcome:
 - **Loss**: Loss of renal function > 4 wk
 - **ESRD**: Loss of renal function > 3 mo
- The most severe marker defines stage.
- AKI based upon changes within last 48h; however, must often base on most recent data.
- Higher RIFLE stages correlate with higher 1 and 6 mo mortality rates for hospitalized patients.

ETIOLOGY

- Prerenal AKI:
 - Caused by renal hypoperfusion
 - Renal tissue remains normal unless severe/prolonged hypoperfusion.
- Intrarenal AKI:
 - Caused by diseases of the renal parenchyma
- Iatrogenic AKI causes include:
 - Aminoglycoside antibiotics
 - Radiocontrast material administration
 - NSAIDs
 - ACE inhibitors
 - Angiotensin receptor blockers

- Postrenal AKI:
 - Due to urinary tract obstruction (e.g., prostatic hypertrophy, prostatitis)

DIAGNOSIS

SIGNS AND SYMPTOMS

Acute Kidney Injury

- Often asymptomatic and commonly diagnosed with incidental lab findings
- Oliguria (< 400 mL/d urine production)
- Fluid overload:
 - Dyspnea
 - Hypertension
 - Jugular venous distention
 - Pulmonary and peripheral edema
 - Ascites
 - Pericardial and pleural effusion
- Nausea/vomiting
- Pruritus/skin changes
- Confusion/mental status changes

Prerenal AKI

- Absolute or relative volume deficit
- Dry mucous membranes
- Hypotension
- Tachycardia
- Low cardiac output
- Congestive heart failure
- Systemic vasodilation (e.g., sepsis, anaphylaxis)

Intrinsic AKI

- Allergic Interstitial Nephritis:
 - Fever
 - Rash
 - Recent myocardial infarction
- Renal vein thrombosis:
 - Nephrotic syndrome
 - Can be associated with pulmonary embolus
 - Flank or abdominal pain
- Glomerulonephritis, vasculitis
- Hemolytic uremic syndrome (HUS)
- Thrombotic thrombocytopenic purpura (TTP):

- Mild elevation of BUN/Cr
- Fever
- Altered mental status
- Anemia & thrombocytopenia
- Neurologic: Coma, seizure, headache, altered mental status
- Allergic interstitial nephritis fever:
 - Rash
 - Arthralgias

Postrenal AKI

- Abdominal or flank pain
- Distended bladder
- Oliguria or anuria

Complications of AKI

- Uremic syndrome:
 - Altered mental status
 - Asterixis
 - Reflex abnormalities
 - Focal neurologic abnormality
 - Seizures
 - Restless leg syndrome
 - Pericarditis
 - Pericardial effusion/cardiac tamponade
 - Ileus
 - Platelet dysfunction
 - Pruritus
- Hematologic disorders:
 - Anemia
 - Increased bleeding time & platelet dysfunction
 - Leukocytosis

History

- Prior history of AKI
- Medication history including nephrotoxins
- Weight change

Physical-Exam

- Mental status changes/confusion
- Eyes: Fundoscopy
- CV exam: Jugular venous distention, S3
- Lungs: Rales, crackles

- Abdomen: Flank tenderness, palpable kidneys
- Edema
- Skin changes

Geriatric Considerations

- Prone to prerenal AKI
- Cr will vary by body mass index, so a “normal” range in elderly may represent an elevation.
- Increased risk of contrast- and medication-induced AKI

Pediatric Considerations

- Prerenal AKI a concern in neonates
- Anatomic abnormalities

Pregnancy Considerations

- Intrinsic renal azotemia
- Pre-eclampsia/eclampsia
- Ischemia: Postpartum hemorrhage, abruptio placentae, amniotic fluid embolus
- Direct toxicity of illegal abortifacients
- Postpartum TTP, HUS

ESSENTIAL WORKUP

- Electrolytes including Ca, Mg, PO₄
- BUN/Cr
- Urinalysis (UA):
 - Centrifuged specimen helps to distinguish different etiologies of AKI.
 - Exam for casts, blood, WBCs, and crystals
- Fractional excretion (FE) of Na and/or urea
- CBC: Anemia common with chronic disease
- Postvoid residual volume (> 100 mL suggests obstruction) OR
- Ultrasound to rule out obstruction—especially in older men (e.g., prostatic hypertrophy, prostatitis)
- ECG

DIAGNOSIS TESTS & INTERPRETATION

Lab

Prerenal

UA:

- Specific gravity > 1.018
- Osmolality > 500 mmol/kg
- Sodium < 10 mmol/L

- Hyaline casts
- BUN/Cr ratio > 20
- $FE_{NA} < 1\%$
- Rapid recovery of renal function when renal perfusion normalized

Intrarenal

- BUN/Cr ratio < 10–15
- $FE_{NA} > 2\%$
- Glomerulonephritis, vasculitis:
 - _ UA with red cell or granular casts
 - _ Complement and autoimmune antibodies
- HUS or TTP:
 - _ UA normal
 - _ Anemia
 - _ Thrombocytopenia
 - _ Schistocytes on blood smear
- Nephrotoxic acute tubular necrosis (ATN):
 - _ UA:
 - Brown granular or epithelial cell casts
 - Specific gravity = 1.010
 - Urine osmolality < 350 mmol/kg
 - Urine Na > 20 mmol/L
- Ethylene glycol ingestion:
 - _ UA: Calcium oxalate crystals
 - _ Anion gap metabolic acidosis
 - _ Osmolar gap
- Rhabdomyolysis:
 - _ Elevated serum K^+ , PO_4 , myoglobin, creatine phosphokinase, uric acid
 - _ Decreased serum Ca^{2+}
- Tubulointerstitial disease
- Allergic interstitial nephritis:
 - _ UA with WBC casts, WBCs, RBCs, and proteinuria
 - _ Peripheral eosinophilia

Postrenal

UA:

- Usually normal
- May have some hematuria but no casts or protein
- FE_{NA} often > 4%
- Urine osmolality usually < 350 mmol/kg

Imaging

- US:

- 98% sensitive for excluding obstruction
- Helical CT scan:
 - Without contrast sensitive for obstruction
 - May detect intrarenal changes
- Duplex scan for:
 - Renal artery or vein thrombosis
- Renal arteriogram:
 - Definitive diagnosis of renal artery thrombosis
- Inferior vena cava and renal vessel venogram for renal vein thrombosis
- IV pyelogram

Diagnostic Procedures/Surgery

ECG:

- Hypertension secondary to volume overload may cause ischemia.
- Sensitive for significant, acute electrolyte changes

TREATMENT

PRE HOSPITAL

- Airway, breathing, and circulation (ABCs):
 - Supplemental oxygen for hypoxia
- IV NS for volume depletion

INITIAL STABILIZATION/THERAPY

- ABCs:
- Supplemental oxygen for hypoxia
- IV NS for volume depletion
- Correct electrolyte disturbances
- Indications for emergent dialysis:
 - Intractable hypertension
 - Intractable volume overload
 - Uremic encephalopathy, bleeding, or pericarditis
 - BUN > 100 mg/dL
 - Intractable metabolic acidosis (pH < 7.2)
- Avoid nephrotoxic drugs.
- Monitor UO.

ED TREATMENT/PROCEDURES

Prerenal AKI

- Treat hypoperfusion with IV NS
- Packed RBC for blood loss or anemia after lack of response after 2 boluses

- Invasive cardiac monitoring if unable to assess cardiac failure vs. hypovolemia
- Response to NS good indicator of the degree to which hypovolemia is a factor

ALERT

Administer NS fluid challenge cautiously to avoid fluid overload in liver failure with ascites.

Intrarenal AKI

- Glomerulonephritis:
 - Glucocorticoids or plasma exchange
- ATN:
 - Volume replacement
- Hyponatremia: Free water restriction
- Hyperkalemia:
 - Sodium polystyrene sulfonate (SPS) or calcium polystyrene sulfonate (CPS) for asymptomatic patient with $K^+ > 5.5$ mEq/L
 - For $K^+ > 6.5$ mEq/L or ECG abnormalities consistent with hyperkalemia:
 - Albuterol via nebulizer
 - Dextrose and insulin
 - Furosemide if patient not anuric
 - Calcium stabilizes myocardium in severe hyperkalemia
 - Calcium gluconate for awake patient
 - Calcium chloride for patient without pulse
 - Dialysis for intractable hyperkalemia
- Metabolic acidosis:
 - Consider sodium bicarbonate for $pH < 7.2$ or $HCO_3^- < 15$ mEq/L in *chronic disease*
 - Hyperphosphatemia:
 - Calcium carbonate
 - Aluminum hydroxide
 - Myoglobinuria—aggressive fluid resuscitation with NS

ALERT

- Calcium is only indicated by ECG for widened PR, QT, or QRS intervals. Peaked T waves alone are *not* an indication.
- Sodium bicarbonate is a considerable sodium load; use caution in anuric/oliguric patients.

MEDICATION

- Albuterol: 10–20 mg via nebulizer
- Aluminum hydroxide (amphojel): 0.5–1.5 g PO
- Calcium carbonate (Os-Cal): 0.250–3 g PO

- Calcium gluconate: 10 mL of 10% solution over 5 min IV (may repeat q5min)
- Calcium chloride: 10 mL of 10% solution
- Dextrose: D₅₀W 1 amp (50 mL or 25 g) (peds: D₂₅W 2 mL/kg) IV
- Furosemide: 20–400 mg IV push
- Insulin: 0.1 U/kg regular IV with dextrose (decrease dose by 50% for severe renal and/or liver disease)
- Sodium bicarbonate: 1–2 mEq/kg IV
- SPS (Kayexalate) or CPS: 1 g/kg up to 15–60 g PO or 30–50 g retention enema in sorbitol q6h

ALERT

Diuretics (in the absence of volume overload) and dopamine are not recommended in AKI.

FOLLOW-UP

DISPOSITION

Admission Criteria

- New-onset AKI
- Hyperkalemia/significant electrolyte abnormalities
- Fluid overload with hypoxia/congestive heart failure
- Uremia
- Altered mental status

Discharge Criteria

- Stable
- Normal electrolytes

Issues for Referral

Refer to primary physician for progressive AKI in an otherwise stable patient.

PEARLS AND PITFALLS

- Insulin dose for hyperkalemia should be reduced for significant liver or renal disease so as to avoid hypoglycemia.
- NSAIDs to be avoided with any degree of AKI
- SPS has a considerable sodium load; CPS is preferred when volume overload is a concern.
- Avoid contrast if possible in AKI, as it may worsen renal function.

- N99.0 Postprocedural (acute) (chronic) kidney failure

RENAL INJURY

Albert S. Jin

BASICS

DESCRIPTION

- Kidneys are located in the retroperitoneal space and are surrounded by adipose tissue and loose areolar connective tissue.
- Kidneys lie along the lower 2 thoracic vertebrae and 1st 4 lumbar vertebrae.
- Left kidney is positioned slightly higher than the right.
- Kidneys are not fixed:
 - Shift with the diaphragm and are supported by the renal arteries, veins, and adipose tissue to the renal (Gerota) fascia

ETIOLOGY

- Most common of all urologic injuries
- Occurs in ~8–10% of all abdominal trauma
- Blunt renal trauma accounts for 80–85% of all renal injuries and is 5 times more common than penetrating injury:
 - Mechanisms include motor vehicle accidents, falls, domestic violence, and contact sports.
 - Pathophysiology includes rapid deceleration and displacement mechanisms.
 - ~20% of cases are associated with intraperitoneal injury.
- Mechanisms responsible for significant renal injury almost never affect the kidney alone:
 - Most often disrupt and injure other vital organs that can be responsible for patient mortality
- Renal injuries are graded by type and severity of injury (Association for the Surgery of Trauma [AAST] criteria)
 - Grade I
 - Contusion: Microscopic or gross hematuria, urologic studies normal
 - Hematoma: Subcapsular, nonexpanding without parenchymal laceration
 - Grade II:
 - Hematoma: Nonexpanding, perirenal hematoma confined to retroperitoneum
 - Laceration: <1 cm parenchymal depth of renal cortex without urinary extravasation
 - Grade III
 - Laceration: >1 cm parenchymal depth of renal cortex without collecting system rupture or urinary extravasation

- Grade IV:
 - Laceration: Parenchymal laceration extending through renal cortex, medulla, and collecting system
 - Vascular: Main renal artery or vein injury with contained hemorrhage
- Grade V:
 - Laceration: Completely shattered kidney
 - Vascular: Avulsion of renal hilum, devascularizing the kidney

Pediatric Considerations

- The kidney is the organ most commonly damaged by blunt abdominal trauma.
- Contributing factors:
 - Relatively larger size of kidneys compared with adults
 - 10th and 11th ribs are not completely ossified until the 3rd decade of life.
- Significant abdominal injury occurs in about 5% of nonaccidental trauma cases but is the 2nd most common cause of death after head injury.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Mechanism of injury and kinematics are important factors.
- Majority of renal injuries are associated with injury of other abdominal organs.
- In blunt trauma, note the type and direction (horizontal or vertical) of any deceleration or compressive forces.
- In penetrating trauma, note the characteristic of the weapon (type and caliber), distance from the weapon, or the type and length of knife or impaling object:
 - Injuries result from a combination of kinetic energy and shear forces of penetrating object.

Physical-Exam

- Hematuria is the best indicator of traumatic urinary system injury:
 - Severity of renal trauma does not correlate with the degree of hematuria.
 - Absence of hematuria does not exclude renal injury
- Microscopic hematuria with a systolic BP < 90 mm Hg
- Flank mass or ecchymosis
- Tenderness in the flank, abdomen, or back
- Fracture of the inferior ribs or spinal transverse processes
- Nausea and vomiting

ESSENTIAL WORKUP

- In 1989, Mee et al. published the hallmark article (10-yr prospective study) that

established guidelines for the evaluation and treatment of blunt renal trauma:

- Major renal lacerations represent significant reparable renal injuries.
- Adult patients at risk for having sustained major lacerations:
 - Gross hematuria, *or*
 - Microhematuria ($\geq 3\text{--}5$ RBCs/HPF) with shock (systolic BP ≤ 90 mm Hg) in the field or on arrival in the ED, *or*
 - History of sudden deceleration without hematuria or shock
- IV contrast-enhanced CT scan is the procedure of choice in identifying urologic injury.
- Guidelines are not applicable in cases of penetrating renal trauma or in children.
- Adults with blunt renal trauma and gross hematuria, or microhematuria in the presence of shock, require renal imaging for further evaluation of renal injury.
- In adults with penetrating renal trauma, significant injuries to the kidney and ureter can occur without hematuria:
 - Location of penetrating wound in relation to urinary tract is the most important factor in deciding need for radiographic imaging.
 - Penetrating injuries with any degree of hematuria should be imaged.
- Important to rule out coexisting injuries

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Urinalysis: Gross hematuria or > 50 RBCs/HPF in adults and > 20 RBC/HPF in children is suggestive of renal injury.
- Baseline lab values including hematocrit and BUN/creatinine should be obtained.

Imaging

- Plain abdominal films:
 - May show fractured inferior ribs or transverse processes, a unilateral enlarged kidney shadow, or obscuring of the psoas margin
- IV pyelogram (IVP):
 - Bolus infusion IVP with nephrotomography study of choice in institutions without 24-hr availability of CT
 - Rapid injection of 1.5–2 mL of contrast material per kilogram of body weight to a maximum of 150 mL after obtaining a preliminary kidney, ureter, and bladder image
 - Postinfusion supine film is obtained followed by 1-, 2-, and 3-min supine films.
 - Allows evaluation for renal viability and function
 - Extravasation reflects injury to the collecting system.
 - Nonvisualization of a kidney may indicate renal pedicle injury or parenchymal shattering.
 - Abnormal findings are often nonspecific and require more definitive

studies.

- **Ultrasound:**
 - Role in evaluation of renal injury is controversial
 - Routinely performed at bedside in trauma patients as part of focused assessment with sonography in trauma (FAST)
 - May show size of perirenal hematoma and whether it is expanding or resolving
 - Low sensitivity for identification of retroperitoneal free fluid
 - Otherwise, exam is nonspecific and does not provide enough information
- **CT scan:**
 - An IV contrast-enhanced helical CT scan is the diagnostic procedure of choice.
 - Superior anatomic detail and diagnostic accuracy of 98% for renal injury
 - Sensitive indicator of minor extravasation, parenchymal laceration, vascular injury, and nonrenal injuries

Pediatric Considerations

- Major blunt renal trauma can occur in the absence of gross hematuria or shock (as children have a high catecholamine output after trauma, which maintains BP until ~ 50% of blood volume has been lost).
- Meta-analysis has defined 50 RBC/HPF as the microscopic quantity below which imaging can be omitted and no significant injuries missed.
- CT scan is the imaging modality of choice.

Diagnostic Procedures/Surgery

- Renal parenchymal injury
- Renal vascular injury
- Ureteral injury
- Bladder or urethral injury

TREATMENT

PRE HOSPITAL

- Obtain details of injury from pre-hospital providers.
- IV access
- Penetrating wounds or evisceration should be covered with sterile dressings.

INITIAL STABILIZATION/THERAPY

- Airway management (including C-spine immobilization)
- Standard Advanced Trauma Life Support (ATLS) resuscitation measures:
 - Adequate IV access, including central lines and cutdowns, as dictated by the patient's hemodynamic status

- Fluid resuscitation, initially with 2 L of crystalloid (NS or lactated Ringer solution), followed by blood products as needed
- Rule out potential life-threatening injuries 1st.

ED TREATMENT/PROCEDURES

- Immediate laparotomy in the acutely injured patient who is hemodynamically unstable with presumed hemoperitoneum and renal injury
- Significant injuries (grades II–V) are found in only 5.4% of renal trauma cases.
- 98% of blunt renal injuries can be managed nonoperatively.
- ~80–90% of renal injuries have major associated organ injury that can affect the choice of renal injury management.
- Angiography and selective renal embolization has an increasing role and is an alternative treatment to laparotomy in patients not requiring immediate surgery.
- Penetrating renal trauma:
 - Previously exploratory laparotomy was recommended for all patients with penetrating renal injuries.
 - Nonoperative management has become more accepted for grades I–III with penetrating renal injuries in the absence of associated intra-abdominal injury or hemodynamic instability
- Blunt renal trauma:
 - Isolated renal injury without significant associated injuries occurs more commonly from blunt trauma, and in most circumstances, can be managed nonoperatively.
 - Classes I and II: Contusions and minor lacerations with stable vital signs and urographically normal renal function can be managed nonoperatively.
 - Class III: Renal lacerations with urinary extravasation:
 - Controversy between operative vs. nonoperative management
 - Management should be based on degree of injury using CT scanning.
 - Classes IV and V: Shattered kidney or renal pedicle injuries and hemodynamically unstable patients require emergent laparotomy.
 - All ureteral injuries require operative repair.

FOLLOW-UP

DISPOSITION

Admission Criteria

Patients with significant renal injury require hospitalization for definitive laparotomy or observation.

Discharge Criteria

- Adult trauma patients without hematuria, shock, or no renal injury confirmed

radiographically

- Adult blunt trauma patient with microhematuria ($\geq 3\text{--}5$ RBCs/HPF) but no shock (systolic BP ≤ 90 mm Hg)
- Pediatric blunt trauma patient with ≤ 50 RBC/HPF and no other coexisting major organ injuries

Issues for Referral

- Outpatient referral to urologist should be made for microhematuria to ensure that it does not represent a more serious underlying condition.
- Urinoma formation is the most common complication (1–7%) of patients with renal trauma:
 - Urinary extravasation resolves spontaneously in 76–87% of cases

- S37.019A Minor contusion of unspecified kidney, initial encounter
- S37.049A Minor laceration of unspecified kidney, initial encounter

REPERFUSION THERAPY, CARDIAC

Shamai A. Grossman • Joshua J. Solano

BASICS

DESCRIPTION

- Cardiac reperfusion therapy is required on patients that present with ST-segment elevation myocardial infarction (STEMI)
- Early percutaneous coronary intervention (PCI), but not fibrinolytics may be considered in those with unstable angina (UA)/non-ST-segment elevation MI (NSTEMI)
- Fibrinolytic therapy:
 - Reduces morbidity and mortality in STEMI in cases that PCI is not available in < 120 min
 - The earlier fibrinolytics are started, the more myocardium is salvaged
 - Goal of fibrinolytic therapy is a door-to-needle time of 30 min if PCI is not planned or delayed > 120 min
- PCI:
 - Balloon inflation, stent placement, and thrombus removal are possible options in the cath lab and result in overstretching of vessel wall and partial disruption of intima, media, and adventitia, resulting in enlargement of lumen and outer diameter of diseased vessel and restoration of epicardial coronary arterial flow
 - Goal of primary PCI is a door-to-balloon time of 90 min from 1st medical contact for STEMI or < 120 min if at a non-PCI center
 - Stent placement decreases early and late loss in luminal diameter seen with percutaneous transluminal coronary angioplasty (PTCA).
 - PCI provides greater coronary patency and thrombolysis in MI flow than do fibrinolytics and decreased mortality and morbidity
 - Lower risk of bleeding than with fibrinolytics
 - Immediate knowledge of extent of disease
 - PCI should be strongly considered within 1st 48 hr after NSTEMI in discussion with a cardiologist
- Glycoprotein IIb/IIIa inhibitors:
 - Antiplatelet agents that bind to platelet receptor glycoprotein IIb/IIIa and inhibit platelet aggregation
 - Reduce mortality and reinfarction rate in patients in whom PCI is planned; reasonable to administer at time of primary PCI
 - Not indicated for patients with STEMI, unless also undergoing PCI
- Unfractionated heparin (UFH) and low-molecular-weight heparin (LMWH):
 - Adjuncts in treatment with aspirin, clopidogrel, fibrinolytics, glycoprotein

Iib/IIIa inhibitors, and PCI

- Anticoagulant therapy with either UFH or LMWH is indicated in patients with either STEMI (with PCI or fibrinolytics) or UA/NSTEMI
- Clopidogrel or Prasugrel should be added to standard therapy regardless of whether PCI or reperfusion therapy is planned.
- Statin therapy reduces clinical events in patients with stable coronary artery disease. This may also extend to patients experiencing an acute ischemic coronary event
- Post arrest patients may have therapeutic hypothermia initiated in the ED prior to PCI or during PCI

ETIOLOGY

- STEMI is caused by occlusion of an epicardial coronary artery, usually as a result of a thrombotic event
- UA/NSTEMI is caused by a partial occlusion of coronary artery, also due to thrombus.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Chest pain, heaviness, or pressure feeling
- Shortness of breath
- Arm, neck, or back pain
- Weakness or fatigue
- Nausea, vomiting
- Diaphoresis
- Palpitations
- Dizziness or syncope
- STEMI ECG

ESSENTIAL WORKUP

- History is critical in assessing window for use of both fibrinolytics and PCI.
- ECG:
 - Will be normal ~ 50% of time
 - Must be compared with prior tracings if available and may evolve in short period of time, consider repeat ECGs
 - ST elevation in the absence of left ventricular hypertrophy or left bundle branch block (LBBB) with new ST elevation at the J point in at least 2 contiguous leads of ≥ 2 mm in men or ≥ 1.5 mm in women in leads V_2 – V_3 and/or of ≥ 1 mm (0.1 mV) in other contiguous chest leads or the limb leads (7)
 - New or presumably new LBBB has been considered a STEMI equivalent.

Most cases of LBBB at time of presentation; however, are “not known to be old” because prior ECG is not available for comparison.

- New or presumably new LBBB at presentation occurs infrequently, may interfere with ST-elevation analysis, and should not be considered diagnostic of acute myocardial infarction (MI) isolation without symptoms of ACS; use of Sgarbossa criteria is recommended for definitive diagnosis
- Baseline ECG abnormalities other than LBBB (e.g., paced rhythm, LV hypertrophy, Brugada syndrome) may obscure interpretation
- New ST-segment changes or T-wave inversions are suspicious for UA or non-Q-wave infarct
- 1-mm depression of the ST segment below the baseline, 80 ms from the J point, is characteristic of UA or non-Q-wave infarct
- Chest radiograph: May be helpful if aortic dissection is being considered
- Heme stool test: Helpful in establishing baseline, especially in setting of anticipated anticoagulation

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Cardiac enzymes, troponin preferred
- Baseline creatinine, hematocrit, and coagulation profile are all appropriate in initial workup.

DIFFERENTIAL DIAGNOSIS

- Aortic dissection
- Anxiety
- Biliary colic
- Coronary aneurysm
- Costochondritis
- Esophageal spasm
- Esophageal reflux
- Herpes zoster
- Hiatal hernia
- Hyperkalemia
- Mitral valve prolapse
- Peptic ulcer disease
- Psychogenic symptoms
- Panic disorder
- Pericarditis
- Pneumonia
- Pulmonary embolus
- Ventricular aneurysm

TREATMENT

PRE HOSPITAL

- IV access
- Oxygen
- Cardiac monitoring
- Sublingual nitroglycerin for symptom relief, unless use of phosphodiesterase inhibitor in the last 24 hr
- Aspirin 162 or 325 nonenteric coated
- Local EMS system and hospital system should preferentially transport STEMI to PCI-capable hospital
- Controversies:
 - _ Whether to allow EMS activation of cardiac catheterization labs and administration of fibrinolytics.

ALERT

- All chest pain should be treated and transported as a possible life-threatening emergency.
- Therapy with fibrinolytics and glycoprotein IIb/IIIa inhibitors in the field is not currently standard of care.

INITIAL STABILIZATION/THERAPY

- IV access
- Oxygen
- Cardiac monitoring
- Oxygen saturation
- Continuous BP monitoring and pulse oximetry
- Nitrates
- Therapeutic hypothermia if indicated post arrest

ED TREATMENT/PROCEDURES

- Aspirin
- Clopidogrel
- Fibrinolytics for STEMI
 - _ Unless contraindicated
 - _ If PCI is not readily available within 120 min
- PCI is preferred for both diagnostic and therapeutic options for STEMI and UA/NSTEMI
- PCI and fibrinolytics therapy must be used with either UFH or an LMWH, such as enoxaparin or bivalirudin
- LMWH:
 - _ Kinetics more predictable
 - _ Requires no monitoring

- Less potential for platelet activation
- Lower bleeding rate
- Is at least as effective as UFH in treatment of acute coronary syndromes
- Glycoprotein IIb/IIIa inhibitors
- Direct thrombin inhibitors—bivalirudin if history of heparin-induced thrombocytopenia

MEDICATION

- Aspirin: 162–325 mg PO nonenteric coated
- Enoxaparin (Lovenox): 1 mg/kg SC q12h
- Clopidogrel (Plavix): 300–600 mg PO load, 75 mg PO per day
- Prasugrel 60 mg PO load, 10 mg PO per day
- Not to be used in patients with history of stroke
- Ticagrelor 180 mg PO load, 90 mg PO BID
- Glycoprotein IIb/IIIa inhibitor:
 - Abciximab (ReoPro): For use before PCI only; 0.25 mg/kg IV bolus; 0.125 µg/kg/min to a max. of 10 µg/kg/min for 12 hr
 - Eptifibatide (Integrilin): 180 µg/kg IV over 1–2 min, followed by continuous IV infusion of 2 µg/kg/min up to 72 hr
 - Tirofiban (Aggrastat): 0.4 µg/kg/min for 30 min, then 0.1 µg/kg/min for 48–108 hr
- Heparin 60 U/kg IV bolus (max. 4,000 U), then 12 U/kg/h (max. 1,000 U/h)
- Bivalirudin 0.1 mg/kg bolus, followed by 0.25 mg/kg/h for UA/NSTEMI and 0.75 mg/kg bolus, followed by 1.75 mg/kg/h in STEMI
- Metoprolol: 5 mg IV q2min for 3 doses followed by 25–50 mg PO starting dose as tolerated (note: β-blockers contraindicated in cocaine chest pain)
- Fibrinolytics:
 - Recombinant tissue plasminogen activator (Retepase): 10 U IV bolus, repeat dose after 30 min; patients should also receive heparin 5,000 IU IV bolus, then infuse 1,000 IU/h for 48 hr, keeping activated partial thromboplastin time (aPTT) 1.5–2.5.
 - Streptokinase: 1.5 million U over 60 min; patients should also receive methylprednisolone 250 mg IV.
 - Tissue plasminogen activator: 15 mg IV bolus, then 0.75 mg/kg (max. 50 mg) over 30 min, then 0.5 mg/kg (max. 35 mg) over 60 min; patients should also receive heparin 5,000 IU IV bolus, then infuse 1,000 IU/h for 48 hr keeping a PTT 1.5–2.5
 - Tenecteplase: Weight-based dosing with max. single dose of 30–50 mg given over 5 sec; IV bolus over 5 sec
 - Contraindications:
 - Active internal bleeding
 - History of cerebrovascular accident in last 6 mo
 - History of a hemorrhagic cerebrovascular accident

- Recent (within 2 mo) intracranial or intraspinal surgery or trauma
- Intracranial neoplasm, arteriovenous malformation, or aneurysm
- Known bleeding diathesis
- Severe, uncontrolled hypertension
- Pregnancy
- Head trauma within last month
- Trauma or surgery within last 2 wk that may result in closed-space bleed

FOLLOW-UP

DISPOSITION

Admission Criteria

All patients being considered for reperfusion therapy should be admitted to a cath lab or transferred to a PCI center or admitted to tele bed or an ICU setting

Discharge Criteria

No patient being considered for reperfusion therapy should be discharged home from ED

PEARLS AND PITFALLS

- Goal of reperfusion therapy is primary PCI within 90 min of 1st medical contact. Transfer to a PCI-capable facility when this window can be accomplished or assess for fibrinolytics if > 120 min for transfer
- Goal of fibrinolytics therapy is a 30 min door-to-needle time if PCI not possible or will be delayed
- Goal of reperfusion in STEMI patients by either fibrinolytics or PCI is the major goal
- PCI should be considered in all post arrest patients along with hypothermia

REPERFUSION THERAPY, CEREBRAL

Kama Guluma

BASICS

DESCRIPTION

- An ischemic cerebrovascular accident (CVA), or stroke, is an acute, sudden or gradual, interruption of regional cerebral blood supply
- Cerebral reperfusion therapy involves:
 - Administration of an IV thrombolytic agent to rapidly dissolve a thromboembolic occlusion
 - Site-specific endovascular intra-arterial thrombolysis
 - Mechanical clot removal

ETIOLOGY

- Thrombotic CVA is from an in situ thrombosis:
 - At an ulcerated atherosclerotic plaque or other prothrombotic endothelial abnormality
 - From hypercoagulable states:
 - Antithrombin III, protein C or S deficiency
 - From sludging:
 - Sickle cell disease
 - Polycythemia vera
- Embolic CVA is caused by acute obstruction by an embolus from:
 - Cardiac mural thrombus formed in:
 - Atrial fibrillation
 - Hypokinetic ventricle (MI, cardiomyopathy)
 - Ventricular aneurysm
 - An abnormal or prosthetic cardiac valve
 - Aortic, carotid, or cerebrovascular atherosclerotic plaques
- Other occlusive events include:
 - Vascular dissection in aorta, cerebral, vertebral, carotid, or innominate arteries
 - Cerebral vasospasm induced by:
 - Subarachnoid hemorrhage (SAH)
 - Vasoconstrictive agents (e.g., cocaine)

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Acute focal neurologic symptoms presenting within 4–5 hr of onset
- Time of symptom onset is critical:
 - If time of onset cannot be firmly established, the time the patient was last known normal should be used as a surrogate
- Historical elements that may suggest an etiology other than routine thromboembolic stroke:
 - Neck injury in carotid or vertebral dissection
 - Tearing back pain in aortic dissection
 - Drug abuse in vasospastic occlusions

Physical-Exam

- Consider reperfusion therapy for symptoms and signs consistent with a distinct vascular supply territory
- Middle cerebral artery:
 - Contralateral hemiplegia and hemisensory deficits (upper > lower)
 - Contralateral homonymous hemianopsia
 - Expressive or receptive aphasia (if in dominant hemisphere)
 - Contralateral neglect
- Posterior cerebral artery:
 - Cortical blindness in half the visual field
 - Visual agnosia (inability to recognize and identify persons and objects)
 - Thalamic syndromes:
 - Abnormal movements (chorea or hemiballismus)
 - Hemisensory deficit
- Vertebrobasilar system:
 - Impaired vision, visual field defects
 - Nystagmus, vertigo, dizziness
 - Facial paresthesia, dysarthria
 - Cranial nerve palsies
 - Contralateral sensory deficits (pain and temperature)
 - Limb ataxia, abnormal gait
- Anterior cerebral artery:
 - Contralateral hemiplegia and hemisensory deficits (lower > upper)
 - Apraxia
 - Confusion, impaired judgment
- Lacunar (deep subcortical):
 - Pure motor hemiplegia (most common), or pure sensory hemiplegia
 - Dysarthria with hand ataxia (clumsy hand), or dysarthria with facial weakness
 - Ataxic hemiparesis
- The National Institutes of Health Stroke Scale (NIHSS) can be used to delineate severity of a CVA as follows (total of subcategory scores):

- 1a. Level of consciousness (LOC): Alert = 0; drowsy = 1; stuporous = 2; coma = 3
- 1b. LOC questions: Answers both correctly = 0; 1 correctly = 1; none correct = 2
- 1c. LOC commands: Obeys both correctly = 0; 1 correctly = 1; none correctly = 2
- 2. Best gaze: Normal = 0; partial gaze palsy = 1; forced deviation = 2
- 3. Visual: No visual loss = 0; partial hemianopia = 1; complete hemianopia = 2; bilateral hemianopia = 3
- 4. Facial palsy: Normal, symmetric = 0; minor paralysis = 1; partial paralysis = 2; complete paralysis = 3
- 5 to 8. Best motor (computed for each arm and leg): No drift = 0; drift = 1; some effort against gravity = 2; no effort against gravity = 3; no movement = 4
- 9. Limb ataxia: Absent = 0; present in 1 limb = 1; present in 2 or more limbs = 2
- 10. Sensory (pinprick): Normal = 0; partial loss = 1; dense loss = 2
- 11. Best language: No aphasia = 0; mild to moderate aphasia = 1; severe aphasia = 2; mute = 3
- 12. Dysarthria: Normal articulation = 0; mild to moderate dysarthria = 1; unintelligible = 2
- 13. Neglect/inattention: No neglect = 0; partial neglect = 1; complete neglect = 2

ESSENTIAL WORKUP

Essential Labs

- Stat bedside blood glucose testing
- CBC, prothrombin time (PT)/partial thromboplastin time (PTT)
 - To assess thrombolytic therapy risk in patients at risk of coagulopathy

Essential Imaging

- Immediate noncontrast head CT scan:
 - Can be part of a multimodal imaging protocol
 - Can reveal other etiologies of symptoms (such as hemorrhage, tumor)
 - Very likely normal in the hours after symptom onset:
 - Early signs of ischemia (e.g., edema) should prompt a re-evaluation of time of onset

DIAGNOSIS TESTS & INTERPRETATION

EKG to assess for dysrhythmia, pericarditis, MI

Additional Labs

- Serum electrolytes, BUN, creatinine
- Urine pregnancy test
- Urine toxicology screen
- Liver function tests in patients prone to liver dysfunction

Additional Imaging

- Multimodal MRI (with perfusion- and diffusion-weighted protocols):
 - Can detect ischemic CVA almost immediately after onset
- Perfusion brain CT can reveal a perfusion deficit immediately after onset
- MR angiography or CT angiography can provide anatomical information
- Carotid US
- CXR

DIFFERENTIAL DIAGNOSIS

- Intracranial hemorrhage (ICH) or SAH
- Seizure
- Complex migraine
- Bell palsy or other focal neuropathies
- Hypoglycemia and other metabolic abnormalities
- Cerebral venous sinus thrombosis
- Intracranial neoplasm
- Intracranial trauma
- Meningitis, encephalitis, or brain abscess
- Vasculitis
- Air embolism or decompression illness
- Spinal cord lesion
- Psychogenic

TREATMENT

PRE HOSPITAL

- Assess for deficits:
 - Dysarthria, facial weakness
 - Arm or leg weakness
- Notify and mobilize ED and hospital resources
- Test blood glucose:
 - Hypoglycemia can mimic a CVA
 - Treat hypoglycemia with dextrose

INITIAL STABILIZATION/THERAPY

- Supplemental oxygen to correct hypoxia (pulse ox < 94%)
- RSI for airway protection or ventilatory insufficiency if needed

- IV access and NS bolus to correct hypotension
- Cardiac monitoring and pulse oximetry

ED TREATMENT/PROCEDURES

- Exclude other diagnoses in the differential
- Thrombolytic therapy should be reserved for thromboembolic ischemic strokes
- Inclusion criteria for IV thrombolytic therapy:
 - _ Age \geq 18 yr of age
 - _ Defined onset of symptoms within 4.5 hr
 - _ No hemorrhage on noncontrast head CT
- Absolute contraindications to IV thrombolytic therapy:
 - _ CVA, serious brain injury, or intracranial surgery within previous 3 mo
 - _ Prior ICH
 - _ Clinical presentation consistent with SAH
 - _ Arterial puncture at noncompressible site in previous 7 days
 - _ Active bleeding on exam
 - _ Uncontrollable HTN $>$ 185/110 mm Hg
 - _ Known bleeding diathesis such as:
 - Platelet count $<$ 100,000/mm³ (if no history of thrombocytopenia, tissue plasminogen activator [tPA] can be initiated before platelet count, but should be discontinued if it is low)
 - Heparin within 48 hr, with elevated aPTT
 - Current anticoagulant use with an INR $>$ 1.7, or PT $>$ 15 sec
 - _ Blood glucose $<$ 50 mg/dL
 - _ Hypodensity in $>$ 1/3 cerebral hemisphere on CT
- Relative contraindications to IV thrombolytics (weigh risk against benefit):
 - _ Major surgery or trauma within previous 14 days
 - _ Mild or resolving neurologic symptoms
 - _ GI or GU bleeding within 21 days
 - _ Seizure at the time stroke was observed
 - _ Acute MI within previous 3 mo
- Treat BP $>$ 185/110 mm Hg with 1–2 doses of labetalol, nicardipine, or other appropriate agent:
 - _ Do not aggressively normalize BP
 - _ Stroke patient may be dependent on an elevated mean arterial pressure for cerebral perfusion
 - _ Avoid thrombolytic therapy if BP cannot be reduced to \leq 180/110 mm Hg with minimal intervention
- Administer IV tPA; alteplase
- Avoid antiplatelet agents and anticoagulants for 24 hr
- Monitor arterial BP during the 1st 24 hr after treatment with tPA and aggressively treat an SBP $>$ 180 mm Hg or a DBP $>$ 105 mm Hg:
 - _ Check BP every 15 min for 2 hr, then every 30 min for 6 hr, then every hour

- for 24 hr
- Keep BP < 180/105 mm Hg using medication such as labetalol or nicardipine
- Consider nitroprusside for HTN unresponsive to labetalol or nicardipine, or for a DBP > 140 mm Hg
- Monitor for signs of ICH:
 - Decreased LOC
 - Increased weakness
 - Headache
 - Acute HTN or tachycardia
 - Nausea or vomiting
- If ICH suspected, obtain an emergent head CT to confirm diagnosis:
 - If present, treat as follows:
 - Discontinue tPA
 - Obtain blood samples for PT, PTT, platelet count, fibrinogen level
 - Prepare cryoprecipitate, fibrinogen, and platelets, and infuse as needed
 - Obtain neurosurgical consultation
- Intra-arterial or mechanical recanalization may be considered for selected patients
 - Though not as well studied as IV tPA, they may be administered out to 6 hr from onset

ALERT

- For patients presenting between 3 and 4.5 hr of onset; there are additional exclusion criteria for IV tPA:
 - Age > 80 yr
 - Oral anticoagulant use (regardless of INR)
 - NIHSS > 25 or > 1/3 MCA territory involved
 - History of previous stroke and diabetes
- There is up to a 6% risk of ICH with tPA that goes up significantly in patients with NIHSS > 20

MEDICATION

First Line

- Alteplase (tPA): 0.9 mg/kg IV, max. 90 mg, over 1 hr:
 - Give 10% of dose as a bolus over 1 min.
 - Immediately follow with the remainder, infused over the subsequent 59 min
- Labetalol: 10 mg IV over 1–2 min; then, if needed:
 - Repeat or double dose q10–20min up to a max. of 300 mg, or
 - Start a drip at 2–8 mg/min
- Nicardipine: 5 mg/h as a drip; titrate upward in 2.5 mg/h increments every 5 min, up to a max. of 15 mg/h

Second Line

- Nitroprusside: 0.5–1 µg/kg/min, continuous IV drip, titrated to BP parameters
- Cryoprecipitate and fibrinogen: 6–8 U IV
- Platelets: 6–8 U IV

FOLLOW-UP

DISPOSITION

Admission Criteria

All patients given reperfusion therapy for a CVA should be admitted to an intensive care setting for frequent neurologic checks and vital sign assessments.

Issues for Referral

Not applicable

PEARLS AND PITFALLS

- Be specific in eliciting time of onset; patient or family may note “time of onset” as the time the stroke was 1st recognized (e.g., upon awakening from sleep)
- tPA has a plasma half-life of <5 min; a delay between bolus and infusion, or pause in the infusion, may result in a decrease in plasma levels and effectiveness
- “Time is brain” (and hemorrhage); initiate treatment as quickly as possible, even if the patient presents early

RESPIRATORY DISTRESS

Erik D. Barton • Joy English

BASICS

DESCRIPTION

Respiratory distress, shortness of breath, or dyspnea is a common complaint for patients presenting to the ED.

ETIOLOGY

- Upper airway obstruction:
 - Epiglottitis
 - Croup syndromes
 - Laryngotracheobronchitis
 - Foreign body
 - Angioedema
 - Retropharyngeal abscess
- Cardiovascular:
 - Pulmonary edema/CHF
 - Dysrhythmias
 - Cardiac ischemia
 - Pulmonary embolus
 - Pericarditis
 - Tamponade
 - Air embolism
- Pulmonary:
 - Asthma
 - Chronic obstructive pulmonary disease (COPD)/emphysema
 - Pneumonia
 - Influenza
 - Bronchiolitis
 - Aspiration
 - Adult respiratory distress syndrome (ARDS)
 - Pulmonary edema
 - Pleural effusion
 - Toxic inhalation injury
- Trauma:
 - Pneumothorax
 - Tension pneumothorax
 - Rib fractures
 - Pulmonary contusion

- Fat embolism with long-bone fractures
- Neuromuscular:
 - Guillain–Barré syndrome
 - Myasthenia gravis
- Metabolic/systemic/toxic:
 - Anaphylaxis
 - Anemia
 - Acidosis
 - Hyperthyroidism
 - Sepsis
 - Septic emboli from IV drug use or infected indwelling lines
 - Salicylate intoxication
 - Drug overdose
 - Amphetamines
 - Cocaine
 - Sympathomimetic
 - Obesity
- Psychogenic:
 - Anxiety disorder
 - Hyperventilation syndrome
- Bioterrorist threats:
 - Anthrax
 - Pneumonic plague
 - Tularemia
 - Viral hemorrhagic fevers

Pediatric Considerations

- Respiratory failure is the most common cause of cardiac arrest in infants.
- Croup syndromes include:
 - Viral
 - Spasmodic
 - Bacterial
 - Congenital defects
 - Noninflammatory causes (foreign body, gastroesophageal reflux, trauma, tumors)
- Most common cause of upper airway obstruction:
 - <6 mo: Congenital laryngomalacia
 - >6 mo: Viral croup
- Epiglottitis:
 - Highest incidence at ages 2–4 yr
 - Abrupt onset
 - Fever
 - Respiratory distress and stridor

- Difficulty swallowing oral secretions
- Restlessness and anxiety

Pediatric Considerations

- Amniotic fluid embolism during or after delivery
- Septic embolism from septic abortion or postpartum uterine infection

DIAGNOSIS

SIGNS AND SYMPTOMS

- Tachypnea
- Dyspnea
- Tachycardia
- Anxiety
- Diaphoresis
- Cough (“barking,” productive)
- Stridor
- Hoarse voice
- Difficulty swallowing or handling oral secretions
- Upper airway rhonchi (wheezes)
- Lower airway crackles (rales)
- Increased work of breathing
- Accessory and intercostal muscle use
- Hypoxemia
- Hypocapnia or hypercapnia if severe
- Respiratory acidosis
- Cyanosis
- Lethargy, then obtundation

History

- Previous history of asthma, COPD, cardiac disease, or dysrhythmia, CHF, foreign-body aspiration, or toxic exposure
- Recent fever or upper respiratory tract infection, cough, sputum production, sore throat, systemic disease, anxiety disorder
- Recent chest or long-bone trauma
- IV drug use or indwelling catheters
- Recurrent fevers, night sweats, weight loss

Physical-Exam

- Observe: Mental status, level of distress, work of breathing, jugular venous pressure, skin color
- Feel/palpate: Distal pulses, heart perioperative MI, chest wall, peripheral edema

- Percuss: Lungs for dullness or resonance, abdominal distention, or hepatomegaly
- Auscultate: Heart sounds, murmurs, lung wheezes or crackles, neck for upper airway stridor, abdomen bowel sounds

Pediatric Considerations

- Evaluate retractions, behavior, respiratory rate, breath sounds, and skin color.
- Weak cry, expiratory grunting, nasal flaring, tachypnea and tachycardia, retractions, and cyanosis in neonates

ESSENTIAL WORKUP

- Pulse oximetry
- Cardiac and BP monitoring
- EKG if suspected cardiac etiology

DIAGNOSIS TESTS & INTERPRETATION

Lab

- ABG for severity and acid–base determination
- CBC
- Electrolytes, BUN/creatinine, glucose
- Sputum cultures, smears, and Gram stain
- Blood cultures for fever or sepsis
- B-type natriuretic peptide (BNP) for undifferentiated shortness of breath or CHF severity
- Venous thromboembolus test (VTE) for low-risk PE
- HIV
- Seasonal and “novel” flu testing
- Urinary output monitoring for CHF
- Toxicology screen or salicylate level if suspected

Imaging

- CXR for:
 - Pneumonia
 - Pneumothorax
 - Hyperinflation
 - Atelectasis
 - CHF/pulmonary edema
 - Abscess/cavitary lesions/other infiltrates
 - Tuberculosis
- Ultrasound for:
 - Lung and rib evaluation using *linear transducer*
 - Pneumothorax
 - Hemothorax/pleural effusion

- CHF
- Rib fractures
- Echocardiography using *phased array transducer*:
 - Cardiac effusion/tamponade
 - CHF/cardiac dilatation
 - RV dilatation for PE
- Spirometry (peak expiratory flow rates) for asthma, COPD
- Neck CT or radiographs to assess epiglottis and soft-tissue spaces, foreign body
- CT angiography or ventilation/perfusion scan for pulmonary embolus

Pediatric Considerations

- Chest/neck radiograph may show foreign body or “steeple sign” in croup syndromes.
- Chest fluoroscopy may be used to assess inspiratory and expiratory excursions if foreign body is suspected.

Diagnostic Procedures/Surgery

- Fiberoptic laryngoscopy to assess epiglottis, vocal cords, and pharyngeal space
- Bronchoscopy for foreign body in trachea or bronchus
- Pulmonary artery (Swan-Ganz) catheter for severe CHF, ARDS, pulmonary edema

DIFFERENTIAL DIAGNOSIS

See Etiology.

TREATMENT

PRE HOSPITAL

- Assume a position of comfort for patient.
- 100% oxygen:
 - Assisted bag-valve mask (BMV) ventilation if obtunded
- Airway adjunct devices (oral or nasal) to maintain patency if tolerated
- Intubation for severe respiratory distress
- Needle aspiration of suspected tension pneumothorax

INITIAL STABILIZATION/THERAPY

- ABCs
- Ensure patent airway; BVM assist or intubate for severe distress or arrest
- IV fluids if hypotensive
- 100% oxygen by face mask:
 - Use cautiously in patients with severe COPD or chronic CO₂ retention.
- Monitor BP, heart rate, respirations, pulse oximetry
- Advanced cardiac life support for dysrhythmias or arrest

ED TREATMENT/PROCEDURES

- Treat underlying etiology as appropriate.
- CHF or pulmonary edema:
 - Diuretics
 - Nitroglycerin
 - Nitroprusside if hypertensive
 - Pulmonary artery catheter if severe
 - Noninvasive positive-pressure ventilation (NPPV/BiPAP) or intubation if severe
- Asthma, bronchiolitis, COPD:
 - Bronchodilators
 - Steroids
 - Antibiotics for infection
 - Antivirals for influenza
 - NPPV or intubation if severe
- ARDS, aspiration, toxic lung injury:
 - Mechanical ventilation as needed
 - Steroids controversial
- Pneumonia:
 - Antibiotics
 - Respiratory isolation for TB
- Pneumothorax:
 - Immediate decompression if suspected tension pneumothorax
 - Aspiration or tube thoracostomy (see Pneumothorax)
- Pleural effusion:
 - Determine etiology
 - Diagnostic and symptomatic thoracentesis
- Croup:
 - Cool, misted air or oxygen
 - Steroids
 - Racemic epinephrine
 - Antibiotics for bacterial infection
- Epiglottitis:
 - Immediate airway stabilization with intubation or tracheostomy in OR if possible
 - Antibiotics for *Haemophilus influenzae*
- Anaphylaxis, angioedema:
 - IV steroids
 - H₁/H₂-blockers
 - SQ or IV epinephrine
 - Early intubation
- Retropharyngeal abscess:

- Drainage
- IV antibiotics
- ENT consult
- Cardiac:
 - Treat dysrhythmias or ischemia
 - Anticoagulation or thrombolysis for PE
 - Pericardiocentesis for tamponade
 - NSAIDs or aspirin for pericarditis
- Neuromuscular:
 - Support ventilation
 - Pyridostigmine bromide or neostigmine for myasthenia gravis
- Metabolic/toxic:
 - Treat underlying cause
- Psychogenic:
 - Anxiolytics

Pediatric Considerations

- Transtracheal jet ventilation if unable to intubate (cricothyrotomy not recommended in children < 10 yr)
- Bronchiolitis:
 - Bronchodilators
 - Antivirals for respiratory syncytial virus
 - Antibiotics for infection
- Spasmodic croup:
 - Very sensitive to misted air
- Bacterial croup (membranous laryngotracheobronchitis):
 - Treat *Staphylococcus aureus*.

Pregnancy Considerations

- Supportive oxygen therapy and heparin for PE or amniotic fluid embolism
- IV antibiotics for septic embolism

MEDICATION

Refer to specific etiologies

FOLLOW-UP

DISPOSITION

Admission Criteria

- Continued supplemental oxygen requirement
- Cardiac or hemodynamic instability:

- Requiring IV therapy or hydration
- Requiring close airway observation or repeated treatments
- Respiratory isolation
- As required by underlying cause or significant comorbid disease

Discharge Criteria

- Correction of underlying disease
- Stable airway
- Acute supplemental oxygen not required

Issues for Referral

Refer to specific etiologies

PEARLS AND PITFALLS

- Consider immune-compromised state.
- Consider “novel” flu strains (H1N1).
- Start antibiotic treatment within 6 hr of ED arrival (JCAHO Quality Measure).

- R06.09 Other forms of dyspnea

RESUSCITATION, NEONATE

Roger M. Barkin

BASICS

DESCRIPTION

- Annually, almost 1 million deaths worldwide are related to birth asphyxia.
- 10% of newborns require some assistance at birth.
- 1% of newborns require extensive resuscitation.
- Consider NOT initiating resuscitation if:
 - Newborns confirmed to be <23-wk gestation or 400 g
 - Anencephaly
 - Babies with confirmed trisomy 13 or 18
 - Ideally, discuss with family and health care team prior to delivery.
- Activity, pulse, grimace, appearance, respiration (APGAR) scores do not guide resuscitation:
 - Do not wait to assign APGAR scores before starting resuscitation.
 - APGAR scores should NOT guide resuscitative efforts. It is a measure of an infant's status and response to resuscitation.
 - APGAR score: 5 categories with score of 0, 1, or 2 in each at 1 and 5 min
- Heart rate (HR): 0 = absent; 1 = <100 bpm; 2 = >100 bpm
- Respirations: 0 = absent; 1 = slow, irregular; 2 = good, crying
- Muscle tone: 0 = limp; 1 = some flexion; 2 = active motion
- Reflex irritability: 0 = no response; 1 = grimace; 2 = cough, sneeze, cry
- Color: 0 = blue or pale; 1 = pink body and blue extremities; 2 = all pink

ETIOLOGY

- Newborn's transition from dependence on the placenta to dependence on the lungs for oxygen.
- Hypoxia initially causes tachypnea followed by primary apnea.
- Stimulation may cause resumption of breathing during primary apnea.
- Continued hypoxia leads to secondary apnea.
- Secondary apnea requires assisted ventilation.
- Antepartum risk factors associated with need for resuscitation include:
 - Maternal diabetes
 - Pregnancy-induced hypertension
 - Chronic hypertension
 - Anemia
 - Previous fetal or neonatal death
 - Bleeding in 2nd or 3rd trimester
 - Maternal infection

- Maternal cardiac, renal pulmonary, thyroid or neurologic disease
- Polyhydramnios
- Oligohydramnios
- Premature rupture of membranes
- Post-term gestation
- Multiple gestation
- Size–dates discrepancy
- Drug therapy
- Maternal substance abuse
- Fetal malformation
- Diminished fetal activity
- No prenatal care
- Maternal age <16 yr or >35 yr
- Intrapartum risk factors associated with need for resuscitation include:
 - Emergency C-section
 - Forceps or vacuum assist
 - Breech or other abnormal presentation
 - Premature labor
 - Precipitous labor
 - Chorioamnionitis
 - Prolonged rupture of membranes
 - Prolonged 2nd stage of labor
 - Fetal bradycardia
 - Nonreassuring fetal heart tracing
 - General anesthesia
 - Uterine tetany
- Narcotics administered to mother within 4 hr:
 - Meconium-stained amniotic fluid
 - Prolapsed cord
 - Abruption placenta
 - Placenta previa

DIAGNOSIS

SIGNS AND SYMPTOMS

Compromised infants requiring resuscitation may exhibit 1 or more of:

- Decreased muscle tone
- Depressed respiratory drive
- Bradycardia
- Hypotension
- Tachypnea
- Cyanosis

History

Risk factors as above predict the need for resuscitation

Physical-Exam

- Respirations—rate and effectiveness
- HR—by auscultation or palpation of umbilical cord
- Color

ESSENTIAL WORKUP

ABCs:

- Airway
- Breathing
- Circulation
- Drying and warming child

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Bedside blood glucose measurement
- Blood gas

Imaging

Chest radiograph

Diagnostic Procedures/Surgery

- Endotracheal intubation:
 - Straight blades Miller 1 for full term, Miller 0 for preterm
 - Endotracheal tubes (ETTs):
 - 2.5 for <1,000 g or <28 wk
 - 3 for 1,000–2,000 g or 28–34 wk
 - 3.5 for 2,000–3,000 g or 34–38 wk
 - 4 for >3,000 g or >38 wk
 - Have stylet, end-tidal CO₂ detector, suction, tape, meconium aspirator available.
- Umbilical vein catheterization:
 - Tie umbilical tape around base of cord.
 - Prefill syringe attached to umbilical catheter (3.5 or 5F).
 - Cut cord on clean edge below clamp.
 - Identify umbilical vein (large, thin walled, and single).
 - Insert catheter into umbilical vein directed cephalad.
 - Advance 2–4 cm until blood flows freely into syringe.
 - Check position with plain film.

- Inject drugs/fluids as appropriate.

TREATMENT

PRE HOSPITAL

- Resuscitation should be started by pre-hospital personnel.
- Neonatal resuscitation equipment should be available. Anticipation and preparation required.
- Pay particular attention to heat retention and warming.

INITIAL STABILIZATION/THERAPY

- ABCs
- Provide warmth, clear airway, stimulate
- If meconium, poor respiratory effort, poor muscle tone, cyanosis, or prematurity are present, proceed with resuscitation.
- Initial steps include:
 - Warm the baby.
 - Position (neck slightly extended, sniffing position) and clear the airway (meconium may necessitate intubation—see below).
 - Dry thoroughly; stimulate (flick feet, rub trunk or extremities).
 - Provide oxygen:
 - In term infant, room air resuscitation may be advantageous to avoid hyperoxia.
 - In premature infants, blended oxygen with close monitoring of oximetry is appropriate.
- Meconium:
 - Meconium present and baby is NOT vigorous:
 - Insert ETT.
 - Suction with ETT meconium aspiration device.
 - Slowly withdraw tube.
 - Repeat as necessary until little meconium is recovered or HR is maintained.
 - Meconium present and baby is vigorous:
 - Suction mouth then nose with bulb or suction catheter.
- If re-evaluation within 30 sec reveals apnea or HR < 100 bpm, proceed with:
 - Positive-pressure ventilation with 100% oxygen
 - Self-inflating or flow-inflating (anesthesia type) bag
 - Proper-fitting mask
 - 1st breath may require high pressure, necessitating occlusion of “pop-off” valve.
 - Rate of 40–60 breaths/min
 - Pressure of 30–40 cm H₂O

- If prolonged, place nasogastric (NG) tube.
- If re-evaluation after 30 sec of positive-pressure ventilation with 100% oxygen reveals HR < 60 bpm, proceed with:
 - Continued positive-pressure ventilation and chest compressions
 - 2-thumb technique: Hands encircle torso
 - 2-finger technique:
 - Compress ~ 1/3 of the anterior–posterior diameter of chest and release.
- 3 compressions followed by 1 ventilation
- 120 events/min (90 compressions and 30 breaths)
- If after 30 sec HR is > 60 bpm, stop compressions.
- If after 30 sec HR is > 100 bpm, stop positive-pressure ventilator.
- If after 30 sec HR still < 60 bpm, administer epinephrine (IV or via ET tube).

ED TREATMENT/PROCEDURES

- If evidence of blood loss or poor response to resuscitation, administer volume expander.
- NS, lactated Ringer, O-negative blood (cross-matched if time permitting)
- If severe metabolic acidosis is suspected or proven:
 - Ensure adequate ventilation.
 - Administer sodium bicarbonate.
- If hypoglycemia is proven or suspected, treat with IV dextrose.
- If HR and color improve but respiratory effort and tone are poor and mother received narcotics within 4 hr, treat with naloxone hydrochloride:
 - Contraindicated in mothers addicted to narcotics or receiving methadone: Can precipitate seizures.
- Persistent distress may indicate pneumothorax.
- Known or suspected diaphragmatic hernias should be treated with immediate endotracheal intubation and placement of NG tube.
- Consider discontinuation of resuscitation if 10 min of asystole.

MEDICATION

- Dextrose: 2–4 mL/kg of D₁₀W given IV (umbilical vein)
- Epinephrine: 0.1–0.3 mL/kg of 1:10,000 solution, may be given IV or via ETT (0.3–1 mL/kg if giving via ETT)
- Naloxone hydrochloride: 0.1 mg/kg. Administer IV or via ETT; can administer IM or SC, but onset of action is delayed.
- Sodium bicarbonate: 2 mEq/kg (4 mL/kg of 4.2% solution) (0.5 mEq/mL). Administer slowly via IV route (umbilical vein).
- Volume expanders: NS, lactated Ringer, blood. Initial dose 10 mL/kg, may be repeated, all given IV (umbilical vein).
- Other agents as specifically indicated by newborn's underlying condition

FOLLOW-UP

DISPOSITION

Admission Criteria

- All newborns require admission.
- If significant resuscitation is necessary, admit to NCIU.

PEARLS AND PITFALLS

- Resuscitation and care of low-birth-weight infants may lead to the following complications:
 - Difficulty with thermoregulation
 - Intraventricular hemorrhage
 - Chronic lung disease
 - Retinopathy of prematurity
- Oxygen and the very low-birth-weight (VLBW) infant:
 - VLBW infant defined as birth weight < 1,500 g
 - VLBW infants are at increased risk of oxidative stress and damage including retinopathy of prematurity.
 - Some studies suggest resuscitating with < 100% oxygen in this group, possibly even 21% (room air), to avoid oxidative stress and damage.

RESUSCITATION, PEDIATRIC

Brian Clyne • Seth Gemme

BASICS

DESCRIPTION

Emergent treatment of pediatric patients with imminent or ongoing respiratory or circulatory failure

ETIOLOGY

- Respiratory failure
- Early shock (compensated)
- Late shock (uncompensated)
- Cardiopulmonary arrest
- Respiratory and/or circulatory failure leads to tissue hypoxia, acidosis, and cell death.
- Multisystem organ failure subsequently develops.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- History from caregivers/parents of onset, progression, inciting, contributing, or predisposing trauma/exposure/conditions, associated findings, past medical history, family history, medications, ingestions
- History of preceding events from pre-hospital personnel
- Respiratory failure:
 - Tachypnea
 - Slow, irregular breathing pattern prearrest
 - Decreased or absent breath sounds; inadequate ventilation
 - Retractions, accessory muscle use, expiratory grunting, nasal flaring
 - Mottled skin, cyanosis
 - Altered level of consciousness: Irritability, agitation, lethargy, weak or absent cry, decreased response to pain
 - Weak or absent cough or gag reflex
 - Most common presenting condition
- Early shock (compensated):
 - Vital signs initially compensated
 - Orthostatic changes or isolated tachycardia
 - Slightly delayed cap refill (> 2 sec)

- Warm, dry skin in early septic shock
- Late shock (uncompensated):
 - Tachycardia, tachypnea, prearrest bradycardia
 - Hypotension, weak peripheral pulses
 - Mottled, pale, cool extremities with markedly decreased capillary refill
 - Poor muscle tone
 - Decreased urine output progressing to anuria
 - Decreased LOC, seizures, coma
 - Fever or hypothermia in septic shock
- Cardiopulmonary arrest:
 - Final common pathway of progressive deterioration of respiratory and circulatory function

Physical-Exam

- Airway assessment:
 - Look, listen, feel for air movement, breath sounds, and chest movement. Observe for stridor or signs of obstruction.
- Breathing assessment:
 - Respiratory rate: Tachypnea or slow/irregular pattern (more ominous)
 - Respiratory effort: Note grunting, nasal flaring, head bobbing, retractions, stridor.
 - Pulse oximetry reflects hemoglobin oxygen saturation, not necessarily oxygen delivery.
 - Auscultation: Assess for wheezing, rales, diminished breath sounds.
- Circulatory assessment:
 - Pulse: Tachycardia or bradycardia (more ominous); orthostatic changes noted easily.
 - BP: Typical SBP in children is 90mm Hg plus twice the age (yrs). Hypotension is a late finding; widened pulse pressure in early septic shock.
 - Peripheral pulse presence and strength (correlates better than BP)
 - Capillary refill: Delayed > 2 sec with poor perfusion
 - Skin: Mottled, pale, or cyanotic
- Mental status assessment:
 - Decreased responsiveness, irritability, confusion, agitation, poor muscle tone, sluggish pupillary response, posturing.
- Complete set of vital signs including rectal temperature, oximetry, and orthostatics when appropriate

ESSENTIAL WORKUP

- ABCDE evaluation:
 - Airway: Assess ability to speak/cry; assess for air movement. Assess for stridor or trauma.
 - Breathing: Observe for nasal flaring, grunting, head bobbing, retractions,

- tracheal deviation, chest injury or pneumothorax; auscultate, apply oxygen.
- Circulation: Evaluate for pulses, capillary refill, mottling, cyanosis.
- Disability: Determine mental status with alert/verbal/painful/unresponsive (AVPU) scale or Glasgow Coma Scale. Assess for neurologic deficits; check stat glucose.
- Exposure/environment: Fully expose for skeletal survey. Prevent hypothermia.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Workup directed by history, assessment of (ABCs), and differential diagnosis
- Arterial blood gas with oximetry to assess oxygenation, ventilation, acid–base status
- Glucose, electrolytes
- Other metabolic/toxicology tests as indicated
- Sepsis evaluation including lumbar puncture, urine and blood cultures as indicated

Imaging

- CXR to evaluate pulmonary or cardiac sources
- Lateral decubitus, inspiratory/expiratory film, or laryngoscopy/bronchoscopy if foreign body (FB) suspected
- ECG
- Echocardiogram
- Cervical spine, other trauma films as indicated
- CT brain for trauma or abnormal neuro exam
- US as indicated

DIFFERENTIAL DIAGNOSIS

- Respiratory:
 - Upper airway obstruction: Croup, epiglottitis, peritonsillar or retropharyngeal abscess, FB, tracheitis, congenital abnormalities
 - Lower airway obstruction: Asthma, pneumonia, bronchiolitis, FB, cystic fibrosis
 - Thoracic trauma, near drowning
- Hypovolemia: Trauma/hemorrhage, diarrhea/vomiting, burns
- Cardiovascular: Congenital/acquired heart disease, myocarditis, pericarditis, CHF, dysrhythmias
- Infectious: Sepsis, meningitis, gastroenteritis, peritonitis, pyelonephritis
- CNS: Status epilepticus, epidural/subdural hematoma
- Metabolic: DKA, hypoglycemia, hyponatremia, hypo/hyperkalemia, acidosis
- Toxicologic: CO poisoning, cardiotoxic agents
- Near sudden infant death syndrome/apparent life-threatening event

- Consider child abuse when history is inconsistent with the illness or pattern of injury.

TREATMENT

PRE HOSPITAL

- Stabilize ABCs; monitor.
- Avoid prolonged on-scene times
- Gather pertinent history from family/bystanders
- Recognize respiratory or circulatory failure; intervene early.
- Recognize impending arrest; support ABCs
- Automated external defibrillator for ventricular fibrillation (VF) and pulseless ventricular tachycardia (VT) in children ≥ 1 yr.
- Early ED notification to allow preparation

INITIAL STABILIZATION/THERAPY

- Early recognition and stabilization of shock
- Glucose, IV, oxygen, cardiac monitoring
- Diagnose and treat immediate life-threats
- Employ Broselow Pediatric Emergency Tape for appropriate drug doses and equipment.

ED TREATMENT/PROCEDURES

- Airway:
 - Secure 1st in every resuscitation.
 - Employ head tilt/chin lift or modified jaw thrust (if trauma suspected).
 - Clear secretions and blood with suction.
 - Temporary stabilization with oral or nasal airway, bag-valve mask assistance
 - Intubation as necessary using appropriate tube size ($[16 + \text{age in years}]/4$) or size similar to patient's little finger or nares
- Rapid-sequence intubation:
 - Preoxygenate
 - Pretreatment: Atropine to prevent bradycardia, lidocaine if head injury
 - Induction agents: Midazolam, thiopental, etomidate (avoid in septic shock), ketamine
 - Paralytics: Rocuronium, vecuronium, pancuronium, succinylcholine
 - Position of endotracheal tube (ETT) at lips (cm) = 3 times diameter of tube (mm)
 - Postintubation: Confirm placement with continuous end-tidal CO₂ monitoring
- Breathing:

- Oxygenate with supplemental O₂, nonrebreather mask; assist ventilation with bag-valve mask or control ventilation if intubation performed.
- Treat conditions that limit ability to oxygenate/ventilate: Pneumothorax, hemothorax, cardiac tamponade, circumferential burns.
- Circulation:
 - Obtain IV, intraosseous (IO), or central access
 - Resuscitate with 0.9% NS or LR bolus at 20 mL/kg; repeat if necessary
 - Control obvious bleeding sources: Apply direct pressure; elevate.
 - Consider transfusion of packed RBCs after crystalloid replacement in trauma.
 - Use pressors early; peripheral use OK
 - Dopamine preferred 1st line; if refractory, norepinephrine (warm shock) or epinephrine (cold shock)
- Cardiopulmonary resuscitation:
 - Provide blood flow to vital organs while restoring spontaneous circulation
 - Infant < 1 yr: Check brachial/femoral pulse
 - Child 1–8 yr: Check carotid pulse
- Cardiac dysrhythmias:
 - Often due to respiratory/metabolic process
 - Treat dysrhythmias per PALS algorithms.
 - Unstable tachydysrhythmias may require adenosine, amiodarone, procainamide, cardioversion, or defibrillation.
 - Unstable bradydysrhythmias may require atropine, epinephrine, or pacing.
 - Pulseless rhythms: VF, pulseless VT, pulseless electrical activity, asystole may require defibrillation, epinephrine, amiodarone, lidocaine.

MEDICATION

- 1st or loading dose unless otherwise noted
- All IV doses may be given IO if necessary
- LEAN (lidocaine, epinephrine, atropine, naloxone) may be given by endotracheal route
- Epinephrine: Multiple uses:
 - Pulseless arrest/symptomatic bradycardia: 0.01 mg/kg 1:10,000 IV q3–5min (max. 1 mg) or 0.1 mg/kg 1:1,000 ETT q3–5min
 - Asthma: 0.01 mg/kg 1:1,000 SC q15min
 - Anaphylaxis: 0.01 mg/kg 1:1,000 IM in thigh q15min (max. 0.3 mg); if hypotensive, 0.01 mg/kg 1:10,000 IV q3–5min (max. 1 mg)
 - Shock/hypotension: 0.1–1 mcg/kg/min IV
 - Toxins/overdose: 0.01 mg/kg 1:10,000 IV; may repeat to max. 0.1 mg/kg 1:1,000 IV.
- Rapid-sequence intubation
 - Pretreatment:
 - Atropine: 0.02 mg/kg IV (min. 0.1 mg)

- Lidocaine: 1–2 mg/kg IV
- Induction:
 - Etomidate: 0.3 mg/kg IV
 - Ketamine: 1–1.5 mg/kg IV; 4–5 mg/kg IM
 - Midazolam: 0.1–0.2 mg/kg IV
 - Thiopental: 3–5 mg/kg IV
- Paralytics:
 - Succinylcholine: 1–2 mg/kg IV
 - Rocuronium: 0.6–1.2 mg/kg IV
 - Vecuronium: 0.1–0.2 mg/kg IV
 - Pancuronium: 0.1 mg/kg IV
- Antiarrhythmic agents:
 - Adenosine: 0.1 mg/kg (max. 6 mg) IV rapid push; 2nd dose 0.2 mg/kg (max. 12 mg).
 - Amiodarone: 5 mg/kg IV, max. dose 300 mg. Give as bolus for pulseless VF/VT, load over 20–60 min for SVT/VT.
 - Lidocaine: For VF or pulseless VT: 1 mg/kg IV bolus, 20–50 ug/kg/min IV infusion
 - Magnesium sulfate: 25–50 mg/kg (max. 2 g) for pulseless VT with torsades de pointes
 - Procainamide: 15 mg/kg IV over 30–60 min
- Inotropes and pressors:
 - Dobutamine: 2–20 ug/kg/min IV
 - Dopamine: 2–20 ug/kg/min IV
 - Inamrinone: Load 0.75–1 mg/kg IV over 5 min; maintenance 5–10 mcg/kg/min
 - Milrinone: Load 50 ug/kg IV over 10–60 min; maintenance 0.25–0.75 ug/kg/min
 - Norepinephrine: 0.1–2 ug/kg/min IV
- Other agents:
 - Albuterol: For asthma or anaphylaxis, multidose inhaler 4–8 puffs q20min or nebulizer 2.5 mg/dose (5 mg/dose if >20 kg) q20min; severe symptoms: 0.5 mg/kg/h by nebulizer (max. 20 mg/h)
 - Alprostadil: 0.05–0.1 ug/kg/min IV for ductal-dependent congenital heart disease
 - Calcium chloride: 20 mg/kg slow IV push in hypocalcemia, hyperkalemia, Ca channel blocker overdose
 - Dexamethasone: 0.6 mg/kg IV (max. 16 mg) for severe croup or asthma
 - Dextrose: 0.5–1 g/kg IV. D₂₅W 2–4 mL/kg or D₁₀W 5–10 mL/kg.
 - Diphenhydramine: 1–2 mg/kg IV q4–6 hr
 - Ipratropium: 250–500 mcg q20min × 3
 - Naloxone: 0.1 mg/kg IV q2min (max. 2 mg)

- Sodium bicarbonate: 1 mEq/kg IV
- Terbutaline: 10 mcg/kg SC q10–15min or 0.1–10 mg/kg/min IV for status asthmaticus
- Cardioversion: 0.5–1 J/kg, increase to 2 J/kg
- Defibrillation: 2 J/kg, increase to 4 J/kg

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with impending or ongoing respiratory or cardiovascular compromise
- Survivors of cardiopulmonary arrest require continuous monitoring for decompensation postresuscitation in an ICU setting.
- Consider transfer to pediatric critical care center.

Discharge Criteria

Patients with mild dehydration who respond to fluid resuscitation without signs of hemodynamic instability may be considered for discharge.

Discharge Criteria

- Consultation as appropriate depending on specific etiology
- Involve authorities if abuse is suspected.

FOLLOW-UP RECOMMENDATIONS

- Educate patients, parents, and caregivers regarding household products and toxins
- Educate patients about self-administration of epinephrine in anaphylaxis (if age appropriate).

PEARLS AND PITFALLS

- Empiric treatment is often necessary.
- Be vigilant for signs of early sepsis in children.
- Consider abuse if history contradicts exam
- Early recognition and stabilization

- J96.00 Acute respiratory failure, unsp w hypoxia or hypercapnia
- R57.9 Shock, unspecified

RETINAL DETACHMENT

Carl G. Skinner

BASICS

DESCRIPTION

- 3 types of retinal detachments with common final pathway:
 - Rhegmatogenous retinal detachments (RRD)
 - Tractional retinal detachments (TRD)
 - Exudative retinal detachments (ERD)
- RRD:
 - Most common
 - Break or tear of sensory retina allows vitreous fluid to separate the sensory and pigmented parts of retina from each other.
 - Acute event, flashes secondary to tearing of nerve fibers, floaters secondary to bleeding
- TRD:
 - Contraction of fibrous vitreous bands, as a result of previous insult, pulls the sensory retina off the pigmented retina.
 - Chronic and progressive
 - Asymptomatic unless hemorrhage or retinal tear occurs
- ERD:
 - Subretinal fluid accumulates and separate retinal layers without violating either layer.
 - Do not usually require surgery
 - Usually secondary systemic disease such as severe acute hypertension, sarcoid, cancer

ETIOLOGY

- RRD:
 - Myopia
 - Cataract surgery
 - Marfan syndrome
 - Structural degeneration of underlying anatomy of vitreous body, sensory or pigmented retina
 - Trauma
- TRD:
 - Proliferative diabetic retinopathy
 - Vasculopathy
 - Perforating injury
 - Chorioretinitis:

- Retinopathy of prematurity, sickle cell disease, or toxocariasis
- Trauma
- ERD:
 - Malignant hypertension, preeclampsia
 - Tumors of the choroid or retina (melanoma, retinoblastoma)
 - Inflammatory disorders (Coats or Harada disease, posterior scleritis)

DIAGNOSIS

SIGNS AND SYMPTOMS

- Flashes of light
- Floaters
- Curtain-like vision loss
- Peripheral/central vision loss or other visual field defects
- Asymptomatic

History

- Symptoms onset, course, description:
 - May progress over hours or weeks
 - Dark curtain or veil
 - Usually begins peripherally
- Associated symptoms: Flashing lights, floaters, painless
- Ophthalmologic history:
 - Baseline eyesight, myopia, surgery, eye disease, trauma
- Systemic disease

Physical-Exam

- Visual acuity, visual fields by confrontation—prior to dilation:
 - May have normal visual acuity if macula spared
 - Detachment is on opposite side of field defect
- May have afferent pupillary defect
- May have loss of red reflex
- Fundoscopy:
 - Pale, opaque, wrinkled retina
 - Cannot rule out detachment on fundoscopy alone
- Slit-lamp exam: Anterior vitreous pigment granules (“tobacco dust”) suggest retinal tear.

ESSENTIAL WORKUP

- Complete ophthalmologic exam
- Thorough neurologic exam to exclude cerebrovascular accident/transient ischemic attack

DIAGNOSIS TESTS & INTERPRETATION

Lab

As needed to work up underlying diseases

Imaging

Ocular US: ~97% sensitive by trained EM physicians

Diagnostic Procedures/Surgery

- Intraocular pressure (IOP) measurement: IOP usually lower in the affected eye
- Dilating pupil with short-acting mydriatic carries very low risk of acute angle-closure glaucoma.

DIFFERENTIAL DIAGNOSIS

- Central retinal artery or vein occlusion
- Vitreous hemorrhage
- Migraine with or without aura
- Choroidal detachment
- Methanol poisoning
- Other retinal or CNS disease

TREATMENT

PRE HOSPITAL

- Bed rest
- Consider transport to hospital with neurology and ophthalmology availability.

INITIAL STABILIZATION/THERAPY

If suspected ERD, treat systemic disease.

ED TREATMENT/PROCEDURES

- Bed rest:
 - Rest head on pillow with side of detachment down, side opposite of field defect
- Emergent ophthalmologic consultation

FOLLOW-UP

DISPOSITION

Admission Criteria

Need for surgical repair

Discharge Criteria

- Any patient with retinal detachment seen by an ophthalmologist and deemed safe to go home
- Chronic retinal detachments are repaired over the same time course as it took to create them.
- ERD resolves with treatment of the underlying problem.

Issues for Referral

Detachments with macula involvement require repair within 1 day.

FOLLOW-UP RECOMMENDATIONS

Per ophthalmologist

PEARLS AND PITFALLS

- Fundoscopy alone does not provide sufficient visualization to rule out detachment.
- Early recognition of retinal tears allows possible prophylactic:
 - 90% risk of retinal tear with “tobacco dust”
- Do not fail to recognize central retinal artery occlusion (CRAO):
 - Increased risk of stroke for patient with CRAO in setting of carotid disease or cardioembolic disease

RETRO-ORBITAL HEMATOMA

Chao Annie Yuan • Michael J. Holman

BASICS

DESCRIPTION

- Also known as retrobulbar hematoma
- Rare complication of orbital trauma and facial surgery
- Collection of blood behind the globe causing increased retro-orbital pressure leading to tissue ischemia
- Vision loss can occur within 90 min if not diagnosed and treated with irreversible damage at 120 min
- A sight-saving procedure called lateral canthotomy is often needed to be performed in the emergency department
- A thorough exam is needed as many patients with ROH may be unconscious
- Frequent repeat exams are mandatory due to hematoma progression

EPIDEMIOLOGY

- Incidence is difficult to estimate because ROH can be from multiple causes, both traumatic and iatrogenic.
 - _ 0.45–3% of blunt or penetrating trauma
 - _ 0.45–0.6% coexist with orbital wall fractures
 - _ 0.0052% of blepharoplasty
 - _ 0.3% of surgical facial fracture repair
 - _ 0.006% of endoscopic sinus surgery
- True incidence has been debated as only slightly more than half of diagnosed retro-orbital hemorrhage has been confirmed either with a preceding CT scan or with the presence of an evacuated hematoma.

ETIOLOGY

- Trauma to the globe or orbital walls and the orbital plexus
- Rapid increasing pressure behind the orbit secondary to hematoma formation impedes venous outflow and arterial inflow to the retina and the optic nerve to cause orbital compartment syndrome
- There may also be a stretching to the optic nerve as the patient develops proptosis which contributes to the decrease in visual acuity

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Penetrating or blunt trauma to the orbit
- Recent facial/orbital surgery
- Eye pain
- Vision loss

Physical-Exam

- Decreased visual acuity
- Increased IOP
- Proptosis
- Diplopia
- Pain
- Decreased EOM
- Relative afferent papillary defect, preserved consensual reflex

ESSENTIAL WORKUP

- Obtain history of injury
- High degree of suspicion
- Thorough physical exam
- Evaluate for immediate surgical decompression
- STAT ophthalmology consult
- Imaging

DIAGNOSIS TESTS & INTERPRETATION

Lab

None diagnostic or suggestive of this diagnosis

Imaging

- CT scan is gold standard but do not delay sight-saving intervention pending imaging
- Ultrasound (bedside if available): Sensitivity/specificity not studied. “Guitar-pick” sign.

DIFFERENTIAL DIAGNOSIS

The patient may present after trauma to the face with any of the following:

- Decreased vision
- Blurry vision
- Eye pain
- Eye discharge
- Photophobia
- Eye pressure
- Nausea and vomiting

The patient may present after having the following procedures:

- Reduction of facial fracture
- Eyelid surgery
- Endoscopic sinus surgery
- Regional anesthesia via retrobulbar injection
- Dacryocystectomy

One must consider as their differential:

- Orbital fracture
- Retro-orbital edema
- Retro-orbital emphysema
- Blow-in fractures
- Orbital roof fractures with brain herniation
- Intracranial bleeds
- Other major trauma associated with injury

TREATMENT

PRE HOSPITAL

- ABCs
- Pre-hospital lateral canthotomy very controversial

INITIAL STABILIZATION/THERAPY

- ABCs
- Immediate transfer to Level 1 Trauma Center
- If past window of 90–120 min, lateral canthotomy & inferior cantholysis may be attempted by competent physician provider

ED TREATMENT/PROCEDURES

Surgical therapy:

- Indication: IOP > 40, proptosis in unconscious patient
- Contraindication: Ruptured globe.
- The only definitive treatment

Lateral canthotomy and inferior cantholysis:

- Prep site with 5% Betadine
- Local anesthesia of cutaneous and deep tissues lateral to angle of the eye. Take caution to avoid the globe and orbit
- Clamp across the lateral canthus with hemostats for ~ 1 min
- With blunt scissors cut in lateral fashion along clamp marks from lateral angle of eyelid to the orbital rim
- Expose the inferior and superior crus of the lateral canthal tendon by pulling down the lateral aspect of the lower lid
- Ligate the inferior crus at its insertion into the lower lid with blunt scissors. The

lower lid should relax downward

MEDICATION

- Methylprednisolone
 - 30 mg/kg loading dose
 - 15 mg/kg q6h
- Mannitol
 - 1.5–2 g/kg over 30 min, with the 1st 12.5 g over 3 min
- Acetazolamide: 500 mg intravenously (do not use if allergic to sulfa or sickle cell pts)
- Hyperbaric oxygen

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with suspected ROH should be admitted for definitive treatment in the OR and observation
- All patients need to be followed by an ophthalmologist
- All patients need to be worked up for other significant trauma

Discharge Criteria

Patients should not be discharged

Issues for Referral

- STAT ophthalmology consultation in the ED
- Do not delay decompression procedure due to consultation delay
- Emergency lateral canthotomy is within the scope of practice for emergency physicians

PEARLS AND PITFALLS

- Delayed diagnosis of retro-orbital hematoma due to:
 - Poor physical exam
- Lack of suspicion
- Lack of equipment such as a Tono-Pen:
 - Unconscious patient
- Waiting for CT/imaging thereby delays sight saving procedure
- Delayed consultation arrival

- S05.11XA Contusion of eyeball and orbital tissues, right eye, init

RETROPHARYNGEAL ABSCESS

Jasmeet S. Dhaliwal • Maria E. Moreira

BASICS

DESCRIPTION

- Deep tissue infection of the retropharyngeal space:
 - Potential space bound anteriorly by buccopharyngeal fascia, posteriorly by alar fascia, superiorly by skull base, inferiorly by fusion of fascial layers at T2
 - Space fused by raphe at midline with chains of lymph nodes extending down each side
 - Alar fascia is poor barrier and allows retropharyngeal infections to spread into “danger” space and posterior mediastinum
- Primarily a disease of children, but increasing frequency in adults:
 - Peak incidence at 3–5 yr when retropharyngeal nodes most prominent
- Prognosis is good when promptly diagnosed and aggressively managed with IV antibiotics and/or surgical drainage
- Complications due to mass effect, rupture, or spread are the major source of morbidity and include:
 - Airway compromise (most common)
 - Aspiration pneumonia due to rupture
 - Sepsis
 - Spontaneous perforation
 - Necrotizing fasciitis
 - Mediastinitis
 - Thrombosis of the internal jugular vein
 - Jugular vein suppurative thrombophlebitis (Lemierre syndrome)
 - Erosion into carotid artery (primarily adults)
 - Atlantoaxial dislocation from erosion of ligaments
 - Cranial nerve palsies (typically IX–XII)
 - Epidural abscess
 - Recurrent abscess formation (1–5%)

ETIOLOGY

- Causes:
 - Most often arises from infection of nasopharynx, paranasal sinuses, or middle ear
 - Infection then spreads to lymph nodes between posterior pharyngeal wall and alar fascia
 - Trauma, foreign bodies, and iatrogenic introduction of infection from

instrumentation also common cause, especially in adults

- Diabetes and other immunosuppressed states may predispose to this infection
- Bacteriology: Predominately polymicrobial with anaerobes and aerobes
- Most common organisms are:
 - *Streptococcus pyogenes* and *Streptococcus viridans*
 - *Staphylococcus aureus* (including MRSA)
 - Respiratory anaerobes (including *Prevotella*, *Fusobacterium*, and *Veillonella*)
- Less common organisms are:
 - *Haemophilus* species
 - Acid-fast bacilli
 - *Klebsiella pneumoniae*
 - *Escherichia coli*
 - *Mycobacterium tuberculosis*
 - *Aspergillus* and *Candida* species

DIAGNOSIS

SIGNS AND SYMPTOMS

May differ between adults and children

History

- Most common:
 - Sore throat
 - Neck pain/stiffness
 - Odynophagia
 - Dysphagia
 - Fever
- Additional presenting symptoms:
 - Stridor, dyspnea
 - Muffled voice
 - Trismus

Pediatric Considerations

Young children may present with only:

- Poor oral intake
- Lethargy or irritability
- Cough

Physical-Exam

- Adults:
 - Posterior pharyngeal edema

- Nuchal rigidity
- Cervical adenopathy
- Fever (67%)
- Drooling
- Stridor
- Dysphonia (cri du canard)
- Tracheal “rock” sign: Tenderness on moving the larynx and trachea side to side
- Children and infants:
 - Cervical adenopathy
 - Fever
 - Neck stiffness with extension most frequently limited
 - Retropharyngeal bulge
 - Trismus
 - Torticollis
 - Drooling
 - Agitation
 - Respiratory distress

ESSENTIAL WORKUP

Rapid assessment of airway and respiratory status:

- Normal exam does not rule out diagnosis
- No lab tests make the diagnosis
- When suspicious, obtain lateral neck x-ray or CT of neck with IV contrast

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC (WBC >12,000 in 91% of children):
 - Nonspecific
- Blood cultures (both aerobic and anaerobic)
- Throat cultures

Imaging

- Portable films appropriate if concern for airway compromise
- Lateral neck radiographs:
 - Film taken in inspiration with neck slightly extended
 - May not get good exposure of soft tissue if cannot adequately extend neck due to pain or difficulty cooperating in young age
 - Increased suspicion if:
 - Retropharyngeal space anterior to C2 >7 mm or 2× the diameter of the vertebral body (sensitivity 90%)
 - Space anterior to C6 >14 mm in preschool children or 22 mm in

adults

- Loss of normal cervical lordosis

- Chest radiograph:
 - Indicated if abscess identified to assess for inferior spread of infection and/or aspiration of ruptured abscess contents
 - Mediastinal widening is suggestive of mediastinitis and possible rupture
- US of neck:
 - Low sensitivity
 - Not recommended
- CT of neck with IV contrast:
 - Now preferred imaging modality
 - Obtain when x-rays nondiagnostic or to determine exact size and location of abscess noted on x-ray
 - Abscess appears as hypodense lesion with peripheral ring enhancement in retropharyngeal space
 - Sensitivity: 64–100%
 - Specificity: 45–88%
 - Can aid in operative planning, revealing extent of invasion into retro/parapharyngeal spaces
 - Unclear if it reliably can distinguish abscess from cellulitis and lymphadenitis
 - Due to radiation exposure and need for sedation, CT should only be obtained in young children if x-rays are nondiagnostic
- MRI:
 - More sensitive than CT
 - Also useful for imaging vascular lesions such as jugular thrombophlebitis

Diagnostic Procedures/Surgery

- Surgical drainage/needle aspiration should be performed in OR:
 - Presence of pus is gold standard for making diagnosis
 - Abscess should be completely evacuated
 - Pus should be sent for Gram stain and culture
- No role for nasopharyngolaryngoscopy

DIFFERENTIAL DIAGNOSIS

- Tonsillopharyngitis
- Epiglottitis
- Peritonsillar abscess
- Croup
- Foreign body
- Tracheitis
- Meningitis
- Retropharyngeal hemorrhage

- Dystonic reactions
- Cervical osteomyelitis
- Dental infections
- Mononucleosis
- Epidural abscess
- Other deep space infection of the neck

TREATMENT

PRE HOSPITAL

- Keep child in position of comfort:
 - _ Forcing child to sit up or flex neck may occlude airway
- Pulse oximetry, cardiac monitor
- Supplemental oxygen
- Adequate hydration
- Suction, endotracheal tube, tracheostomy equipment ready for potential emergent intubation
- Airway control will be required for:
 - _ Airway compromise
 - _ Prior to long transport

INITIAL STABILIZATION/THERAPY

- Assess and control airway
- Provide supplemental oxygen
- IV access:
 - _ Avoid if signs of airway compromise

ED TREATMENT/PROCEDURES

- Early endotracheal intubation or tracheostomy for patients with respiratory distress or impending obstruction:
 - _ Caution must be used with induction, as sedation medications may lead to relaxation of airway muscles causing complete obstruction
 - _ Rescue airway equipment such as a laryngeal mask airway available, as pharyngeal swelling may make intubation difficult
 - _ Cricothyrotomy may be required if upper airway is obstructed
- Surgical consultation (ear/nose/throat if available)
- Early administration of IV antibiotics

MEDICATION

Empiric IV antibiotic therapy to cover group A streptococci, *S. aureus* (including MRSA), and respiratory anaerobes:

- Antibiotic tailored to local preferences and susceptibilities
- Coverage is narrowed when culture results and sensitivities return

- Use of corticosteroids is controversial and recommended only after consultation with ear/nose/throat
- Immunocompromised, diabetics, IV drug users, institutionalized patients, and young children (<1 yr) at high risk for MRSA

First Line

Several antibiotic regimens are available:

- Clindamycin: 600–900 mg (peds: 25–40 mg/kg/24 h) IV q8h (max. 4.8 g/d)
- Clindamycin + Metronidazole (loading dose 15 mg/kg IV not to exceed 4 g/d followed by 7.5 mg/kg PO/IV)
- Penicillin G + Metronidazole
- Cefoxitin 1 g IV q6–8h/3–4 g/d max.
- Ticarcillin/Clavulanate 3.1 g IV q4–6h
- Piperacillin/Tazobactam 3.375 g IV q6h

Second Line

If patients do not respond or there is concern for MRSA:

- Vancomycin: 15–20 mg/kg (peds: 40–60 mg/kg/24 h IV q6–8h) IV q12h
- Linezolid: 600 mg (peds: 0–11 yr: 30 mg/kg/24 h q8h; >12 yr: Adult dose) IV/PO q12h

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with retropharyngeal abscess should be admitted to the hospital for IV antibiotics and possible surgical drainage
- Criteria for surgical drainage:
 - Airway compromise or other life-threatening complications
 - Large (>2 cm hypodense area on CT)
 - Failure to respond to parenteral antibiotic therapy
- ICU admission for patients with:
 - Airway compromise
 - Sepsis
 - Altered mental status
 - Hemodynamic instability
 - Infants and toxic-appearing children
 - Major comorbidities

Discharge Criteria

Patients with retropharyngeal abscesses should not be discharged

Issues for Referral

Transfer should be considered if facility does not have the ability to drain infection:

- Airway should be stabilized prior to transfer

PEARLS AND PITFALLS

- Diagnosis should be considered in all children who present with fever, stiff neck, or dysphagia:
 - High clinical suspicion is required in children, as they present with nonspecific signs and symptoms
- Adult cases most often present in the setting of underlying illness, recent intraoral procedures, neck trauma, or head and neck infections
- When imaging is nondiagnostic and clinical suspicion remains high, surgery should be consulted
- Early surgical consultation and administration of IV antibiotics is essential to prevent complications such as airway compromise and extension into mediastinal structures

REYE SYNDROME

Brian D. Euerle

BASICS

DESCRIPTION

- Reversible clinicopathologic syndrome of unknown etiology
- Primary mitochondrial injury
- Decreased enzyme activity:
 - Krebs cycle
 - Gluconeogenesis
 - Urea biosynthesis
- Fatty infiltration:
 - Liver:
 - Hyperammonemia due to decreased conversion from ammonia to urea
 - Hepatorenal syndrome may be the end result.
 - Rapid recovery of liver function in survivors
 - Brain:
 - Encephalopathy of unclear etiology
 - Cytotoxic edema
 - Deteriorating level of consciousness reflects increasing intracranial pressure (ICP).
 - Herniation is the most common cause of death.
 - Normal recovery of neurologic function in survivors
 - Skeletal and myocardial muscle
 - Fatty infiltration and distorted mitochondria
- <10% of cases occur before the age of 1 yr:
 - Average age is 7 yr
 - Peak age is 4–11 yr
 - Extremely rare in age >18 yr.
- Regional differences:
 - Highest incidence in the Midwestern states
 - Lower incidence in the states of the Southeast and far West
- More common in whites than in blacks
- Peak incidence in winter and early spring
- Reye-like syndrome:
 - Describes conditions resulting in defects in urea and fatty acid metabolism, toxicologic injury, and impaired gluconeogenesis

ETIOLOGY

- Not known with certainty
- Multifactorial causes have been epidemiologically implicated:
 - Antecedent viral syndrome
 - Influenza A or B
 - Varicella
 - Diarrhea illness
 - Genetic predisposition
 - Exposure to salicylates
 - Other undefined factors

DIAGNOSIS

SIGNS AND SYMPTOMS

- Usually the patient is afebrile.
- Tachycardia
- Hyperventilation

History

- Biphasic history marked by an infectious phase (viral illness or prodrome) followed by an encephalopathic stage
- Profuse and repeated vomiting:
 - Typically 4–5 days after the start of the viral illness
- Marked behavioral changes, including delirium and combativeness, disorientation, and hallucination

Physical-Exam

- No focal neurologic signs
- Hepatomegaly in 40% of cases
- Pancreatitis
- Clinical staging of Reye syndrome with Lovejoy classification:
 - Stage 0:
 - Wakeful
 - Stage I:
 - Vomiting
 - Lethargy
 - Sleepiness
 - Stage II:
 - Disorientation
 - Delirium
 - Combative/stuporous
 - Hyperventilation
 - Hyperreflexia

- Appropriate response to noxious stimuli
- Stage III:
 - Obtunded
 - Coma
 - Hyperventilation
 - Inappropriate response to noxious stimuli
 - Decorticate posturing
 - Preservation of pupillary light reflexes
 - Preservation of oculovestibular light reflexes
- Stage IV:
 - Deeper coma
 - Decerebrate rigidity
 - Loss of oculovestibular reflexes
 - Dilated, fixed pupils
 - Disconjugate eye movements in response to caloric stimulation
- Stage V:
 - Seizures
 - Absent deep tendon reflexes
 - Respiratory arrest
 - Flaccid paralysis
 - No pupillary response
- Infants: Atypical presentation:
 - Tachypnea
 - Apnea
 - Irritability
 - Seizures
 - Hypoglycemia

ESSENTIAL WORKUP

- Establish the presence of encephalopathy and liver abnormalities.
- Lab testing to assess for characteristic biochemical abnormalities
- Liver biopsy confirms the diagnosis.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Liver function tests:
 - $\geq 3 \times$ rise in aspartate aminotransferase, alanine aminotransferase
 - Serum ammonia level $> 1.5\text{--}3 \times$ normal:
 - Transient 24–48 hr after mental status changes
 - Level $> 300 \mu\text{g/dL}$ is associated with poor prognosis.
 - Serum bilirubin should be normal or slightly elevated.
- Hypoglycemia may be present, especially in infants.

- Elevated BUN
- Ketonuria
- The prothrombin time may be prolonged due to decreased liver-dependent clotting factors (II, VII, IX, X).
- Normal platelet count and blood smear
- Negative toxicology screen

Imaging

Head CT scan:

- May show diffuse cerebral edema
- Edema is diffuse, and lumbar puncture is not contraindicated.

Diagnostic Procedures/Surgery

- Lumbar puncture:
 - Perform after head CT
 - Measure opening pressure
 - < 8 leukocytes/mm³
- Percutaneous liver biopsy:
 - Useful in patients with atypical presentation (1 yr old, recurrent, familial)

DIFFERENTIAL DIAGNOSIS

- Inborn errors of metabolism:
 - Disorders of the urea cycle
 - Disorders of fatty acid oxidation
 - Systemic carnitine deficiency
 - Organic acidemias
 - Disorders of the electron transport chain
- Hypoglycemia
- Toxin exposure:
 - Toxic encephalopathy without liver dysfunction (Gall syndrome)
 - Lead
 - Hydrocarbons
- Drug intoxication:
 - Acetaminophen
 - Salicylates
 - Ethanol
- Infection:
 - Sepsis
 - Meningitis
 - Encephalitis
 - Varicella hepatitis
- Trauma, head

TREATMENT

PRE HOSPITAL

- Decreased mental status:
 - Glucose
 - Narcan
- Coma:
 - Assist respirations with bag-valve mask.

INITIAL STABILIZATION/THERAPY

- Place on a cardiorespiratory monitor.
- Supplemental oxygen
- Rapid-sequence intubation if airway management required
- Glucose if mental status is altered:
 - 10% glucose solution IV
 - Rate of 2/3 maintenance requirement after dehydration is corrected
 - Follow serum glucose hourly; maintain glucose 125–175 mg/dL.
- Avoid early overhydration.

ED TREATMENT/PROCEDURES

- Institute treatment before the liver biopsy.
- Vitamin K:
 - Indicated if prothrombin time is elevated.
- Fresh-frozen plasma:
 - To control bleeding
 - To correct a severe coagulopathy
- Interventions aimed at lowering ICP:
 - Stage III or greater
 - Stage II with serum ammonia $> 300 \mu\text{g/L}$:
 - Intubation using rapid-sequence protocol
 - Hyperventilation
 - Fluid restriction
 - Barbiturate coma
- Osmotically active agents:
 - Mannitol
 - Furosemide
- Monitor ICP:
 - Subarachnoid bolt
 - Intraventricular cannula

MEDICATION

- D₅₀W: 1–2 mL/kg/dose (0.5–1 g/kg) IV for age > 3 yr

- D₂₅W: 2–4 mL/kg/dose (0.5–1 mg/kg) IV for age of < 3 yr; maintenance infusion 10% dextrose solution at a rate of 2/3 maintenance
- Fresh-frozen plasma: 10 mL/kg/dose q12–24h IV or PRN
- Lasix: 1 mg/kg IV
- Mannitol: 0.25–1 g/kg IV q4–6h
- Pentobarbital: 3–5 mg/kg IV slowly while monitoring BP; maintenance infusion 1–2 mg/kg/h; maintain level at 2–5 mg/L
- Vitamin K: 1–2 mg/dose IV slowly (infants and children); 2–10 mg/dose IV (adolescents)

FOLLOW-UP

DISPOSITION

Admission Criteria

- All children with suspected Reye syndrome should be admitted to the ICU.
- Hospital capable of ICP monitoring

Discharge Criteria

Hospital discharge criteria are individualized for each case:

- Mental status and lab values have improved and stabilized.

Issues for Referral

Close follow-up with specialists in gastroenterology (hepatology) and neurology

FOLLOW-UP RECOMMENDATIONS

Long-term psychological and neuropsychological testing

PEARLS AND PITFALLS

- Aspirin and salicylates are found in many medications and combination products.
- All efforts must be directed at identifying other possible causes of illness in the patient with suspected Reye syndrome.
- Monitoring and control of intracranial pressure is a key component of treatment.

BASICS

DESCRIPTION

Abnormal systemic release of muscle contents—creatinine phosphokinase (CPK), myoglobin, potassium, phosphate, urate—caused by trauma, poisoning, infection, primary muscle disorders, and many other disease states. Complications include:

- Myoglobin-induced renal failure in 15–50% adults, only 5% in children
- Hyperkalemia may lead to sudden death
- Hypocalcemia and acidosis
- Volume loss—fluid sequestration in injured muscle or result of underlying illness
- Compartment syndrome of muscles in crush, worsened by IV fluid sequestration in damaged tissue
- Hepatic dysfunction in 25%
- DIC (Disseminated intravascular coagulation)

EPIDEMIOLOGY

Incidence

- 26,000 per year in US
- Disaster situations lead to 100s of cases of renal failure.

RISK FACTORS

- Inherited myopathy
- Alcohol or drug use
- Medications as listed below
- Overexertion with or without risk factors

PATHOPHYSIOLOGY

- Sarcolemma keeps intracellular calcium low.
- Etiologies disrupt cell membrane and lead to following cascade.
- Breakdown of sarcolemma Na–Ca pumps allows calcium to enter cell.
- Calcium-dependent proteases cause destruction.
- Ischemia and neutrophils cause damage.
- Escape of cell contents: Myoglobin, potassium, phosphate, CPK, lactate, etc.
- Myoglobin causes renal damage by direct toxicity in acidic urine.
- Myoglobin precipitates with other proteins to obstruct renal tubular flow.
- Volume depletion also leads to renal vasoconstriction and failure.
- Hyperkalemia can lead to arrhythmias.
- Calcium precipitates with phosphate, leading to systemic hypocalcemia.

ETIOLOGY

Cause usually obvious, but not always.

Adults: Trauma, toxicity, infection

Children: Viral myositis, trauma

- Muscle injury—due to trauma/crush, burn, electrical shock—most common cause overall.
- Muscle exertion: Strenuous exercise; marathon running; exercise in hot, humid conditions; exercise in individuals with an inherited myopathy or with poor physical training; status epilepticus; delirium tremens; tetanus; psychotic agitation
- Muscle ischemia: Extensive thrombosis, multiple embolism, generalized shock, sickle cell crisis
- Surgery: Immobilization, hypotension, ischemia due to vessel clamping
- Massive blood transfusion
- Hypothermia, hyperthermia
- Prolonged immobile state without trauma
- Drugs/toxins: Alcohols, cocaine, amphetamines, and analogs (methamphetamine and ecstasy), toluene, opiates, LSD, phencyclidine (PCP), caffeine, carbon monoxide, snake venom, bee/hornet venom, hemlock, buffalo fish, tetanus toxin, mushroom poisoning (*Tricholoma equestre*)
- Medications: Most common—haloperidol, phenothiazines, HMG-CoA reductase inhibitors (statins) and other cholesterol-lowering agents, antihistamines, selective serotonin receptor inhibitors (SSRIs).
- Sports supplements including ephedra, caffeine, androgenic steroids, creatine, diuretics
- Neuroleptic malignant syndrome (idiosyncratic and not dose-related)
- Metabolic disorders: Hypokalemia, hypophosphatemia, hypocalcemia, hyper- and hyponatremia, diabetic ketoacidosis, hyperosmolar state, hypoxia, hyperthyroid state (rare), pheochromocytoma (rare)
- Infections:
 - Viral: Coxsackievirus, herpesviruses, HIV, influenza B, cytomegalovirus, Epstein–Barr virus, adeno/echovirus
 - Bacterial: Legionnaires' disease, pyomyositis, salmonellosis, shigellosis, *Staphylococcus*, *Streptococcus*, *Listeria*, tetanus, toxic shock syndrome, tularemia, gas gangrene, *Bacillus cereus*
 - Parasitic (*Plasmodium falciparum*), protozoan (leptospirosis), rickettsial
 - Inherited myopathic disorders: McArdle disease, Tarui disease, CPT deficiency.
- Immunologic disorders: Dermatomyositis, polymyositis
- Idiopathic

COMMONLY ASSOCIATED CONDITIONS

- Crush syndrome
- Compartment syndrome

- Alcohol and drug abuse
- Elderly and acutely immobile (found on floor)

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Can vary dramatically, reflecting underlying disease process.
- Trauma or crush usually obvious.
- Consider nonaccidental trauma with unclear details of history.
- If no trauma, consider in drug toxicity, heat illness, immobilization, or overexertion states.
- Ask about reddish brown urine and decreased urine output
- Most nontraumatic cases in children <9 yr old are due to viral illness with myositis

Physical-Exam

- Hypothermia/hyperthermia
- Alert/obtunded
- Muscle pain (only 40–50%)
- Neurovascular status of involved muscle groups if compartment syndrome is suspected.
- Hypovolemic state, dry mucous membranes, poor skin turgor, tachycardia, hypotension
- Decreased urine output
- Urine color (tea-colored) is early sign
- Children more often have absent physical findings

DIAGNOSIS TESTS & INTERPRETATION

Lab

Initial lab tests

- History and physical exam are insensitive in making the diagnosis
- Serum and urine myoglobin levels often normal due to rapid metabolism and excretion.
- Serum CPK level > 1,000 (standard) considered positive
- CPK level not always predictive of renal failure but most often associated with level > 15,000
- Urine dipstick test positive for heme but absent for RBCs suggests rhabdomyolysis
- Microscopic urinalysis to look for pigmented tubular casts
- Because of rapid urinary excretion of myoglobin, some patients with

rhabdomyolysis have negative urine dipstick test.

- In children, heme <2+ on urine dip correlates with reduced risk of acute renal failure (ARF)
- Serum electrolytes (potassium, calcium, magnesium, phosphorus, BUN, creatinine, uric acid, bicarbonate)
- In addition to above consider:
 - Arterial and venous blood gases (ABG/VBG) (baseline pH if considering bicarbonate therapy).
 - Urine/serum myoglobin, but may be too transient to be useful
 - Serum glucose
 - LFTs including GGTP, LDH, albumin
 - Toxicology screen in absence of physical injury
 - PT/PTT, platelet count, fibrinogen, fibrin split products if DIC is suspected

Imaging

- Renal US to rule out long-standing renal failure (small, shrunken kidneys) or renal obstruction (hydronephrosis)
- MRI is 90–95% sensitive in visualizing muscle injury but does not change initial ED treatment.
- Other imaging as indicated

Diagnostic Procedures/Surgery

- Early ECG: Hyperkalemia or hypocalcemia before serum levels available
- Measure compartment pressure if compartment syndrome is suspected.

DIFFERENTIAL DIAGNOSIS

Conditions that may present with elevated serum CPK but are not rhabdomyolysis:

- Nontraumatic myopathies including muscular dystrophies and inherited myopathies
- Chronic renal failure
- IM injections
- Myocardial injury
- Stroke

TREATMENT

PRE HOSPITAL

- Rapid extrication in case of crush injury
- Early IV saline before extrication to prevent complications of restored blood flow to injured limb (hypovolemia, hyperkalemia, etc.)
- “Crush injury cocktail” during extrication is 1.5 L 0.9% NS per hour; consider adding 1 amp (50 mEq) bicarbonate and 10 g of mannitol to each liter

(controversial)

- Pediatric recommendation: 10–15 mL/kg/h saline initially, then switch to hypotonic (0.45%) saline upon arrival to hospital. Add 50 mEq bicarbonate to each 2nd or 3rd liter to alkalinize urine

INITIAL STABILIZATION/THERAPY

- Manage ABCs
- Immobilization of trauma/crush injuries
- Adult crush injury treatment literature extrapolated to children
- IV saline for hypovolemia at rate of 1–1.5 L/h (10–20 mL/kg/h). Volume restored within 6 hr helps prevent renal failure

ED TREATMENT/PROCEDURES

- May need 12 L/d, 4–6 of which should include bicarbonate. Use CVP, urine output
- Diuretics only after patient's volume restored to keep urine output 200–300 mL/h (3–5 mL/kg/h)
- Mannitol: Diuretic, free radical scavenger. May help compartment syndrome
- Furosemide and other loop diuretics if indicated in management of oliguric (<500 mL/d) renal failure; controversial
- Bicarbonate: Alkalinize urine (pH >6.5) most studied in crush/trauma. Most authorities recommend its use as long as urine pH and calcium are monitored.
- Monitor for hyperkalemia frequently with serum levels and ECG. Higher potassium correlates with more severe injury
- Treat hyperkalemia as usual but do not use calcium unless it is severe
- Hypocalcemia: Treat only if symptomatic (tetany or seizures) or arrhythmias present. Calcium infusion can lead to hypercalcemia later as precipitated calcium mobilizes
- Bicarbonate can trigger symptoms by increasing free calcium binding to albumin

FOLLOW-UP

DISPOSITION

Admission Criteria

All but the most trivial elevations in CPK (<1,000) should be admitted, since complications can occur at any level and are difficult to predict. Children seem to be less susceptible to renal complications:

- Critical care admission criteria:
 - Hyperkalemia or CPK levels > 15,000–30,000 due to worse prognosis
 - Underlying severe illness

Discharge Criteria

Levels decreased to <1,000 after therapy

MEDICATION

First Line

- Bicarbonate; add 50 mEq bicarbonate to each 2nd or 3rd liter to keep urine pH >6.5. Discontinue if urine pH fails to rise after 6 hr or if symptomatic hypocalcemia develops
- Albuterol, insulin/dextrose, polystyrene resin (kayexalate), for hyperkalemia treatment. Avoid calcium if possible.

Second Line

- Mannitol 20%: 50 mL (10 g added to each liter up to 120–200 g/d (1–2 g/kg/d)
- Discontinue if fail to achieve diuresis and osmolal gap >55

SURGERY/OTHER PROCEDURES

- Hemodialysis for refractory hyperkalemia, fluid overload, anuria, acidosis
- Consider central venous monitoring of volume
- Fasciotomy for compartment syndrome

PROGNOSIS

- No renal failure—almost no mortality
- Renal failure—3.4–30% mortality
- ICU—59% if renal failure, 22% without

COMPLICATIONS

- ARF
- Hyperkalemia
- Compartment syndrome
- Hypocalcemia
- Acidosis

PEARLS AND PITFALLS

Suspect in unexplained renal failure.

RHEUMATIC FEVER

Jon D. Mason

BASICS

DESCRIPTION

- Constellation of symptoms and signs (Jones criteria)
- Follows group A streptococcal infection (GAS) also known as *Streptococcus pyogenes*; usually pharyngitis
- Uncommon in US; most cases are in developing nations
- Remains a major cause of cardiac morbidity and mortality worldwide with over 230,000 deaths per year
- Most common in 5- to 15-yr-olds

ETIOLOGY

- GAS infection
- Inflammatory, autoimmune response following GAS infection

DIAGNOSIS

2 major or 1 major and 2 minor elements of the **Jones criteria** plus evidence of a recent GAS infection

SIGNS AND SYMPTOMS

Jones Criteria

- Major manifestations:
 - *Migratory polyarthriti*s in 60–75% of initial attacks:
 - Involves larger joints: Knees, hips, ankles, elbows, and wrists
 - Lower extremity joints more commonly involved
 - Rheumatic arthritis generally responds to salicylates
 - *Carditis* occurs in 1/3 to 1/2 of new cases:
 - Pericardium, myocardium, and endocardium may be affected (pancarditis)
 - Myocarditis may lead to heart failure but is frequently asymptomatic
 - Valvular disease and endocarditis are most serious sequelae of acute rheumatic fever (ARF)
 - Carditis heralded by a new murmur, tachycardia, gallop rhythm, pericardial friction rub, or CHF
 - Echocardiogram aids in diagnosis
 - *Chorea* occurs in 10% of cases:
 - Sydenham chorea predominantly affects teenage girls
 - Purposeless, uncoordinated movements of the extremities sometimes

- called St. Vitas dance
- Movements are more apparent during periods of anxiety and disappear with sleep
- Chorea may be the sole manifestation of ARF
- Other neuropsychiatric symptoms of emotional lability or obsessive compulsive disorder may also occur
- *Erythema marginatum* occurs in <5% of cases:
 - Nonpruritic pink eruptions with central clearing and well-demarcated irregular borders
 - Usually seen on the trunk and the extremities
- SC nodules in small percentage of patients:
 - Crops of small SC, painless nodules located most commonly on extensor surfaces
- Minor manifestations:
 - Clinical:
 - Fever (>38°C)
 - Arthralgia
 - Lab:
 - Elevated acute phase reactants
 - Prolonged P-R interval
- Supporting evidence of recent GAS throat infection:
 - Positive throat culture or rapid antigen test
 - Elevated or increasing antibody test: Antistreptolysin O (ASO) titer

History

- Fever
- Sore throat (often 2–4 wk prior)
- Rash
- Joint pains
- Unusual movements of extremities
- Dyspnea
- Lower extremity edema

Physical-Exam

- Pharyngeal erythema
- Rash consistent with erythema marginatum
- SC nodules
- New heart murmur consistent with mitral or aortic disease
- Evidence of fluid overload/CHF

ESSENTIAL WORKUP

- Careful exam to look for skin lesions/joint swelling
- Careful heart and lung exam

- Throat swab for rapid strep test or culture
- ECG
- Chest x-ray
- Echocardiogram
- See other labs below

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Rapid antigen strep test
- Throat culture
- ASO titer
- CBC
- ESR or C-reactive protein
- Other serology tests to rule out other rheumatologic diseases

Imaging

- Chest radiograph
- Echocardiogram

Diagnostic Procedures/Surgery

- ECG
- Diagnosis is based on clinical picture and meeting Jones criteria

DIFFERENTIAL DIAGNOSIS

- Juvenile idiopathic arthritis
- Infective endocarditis
- Reiter syndrome
- Systemic lupus erythematosus
- Postgonococcal arthritis
- Other infectious causes of arthritis and carditis:
 - _ Coxsackie B virus and parvovirus

Pediatric Considerations

Rheumatic fever is primarily a pediatric disease but can occur in young adults. Testing for strep throat is not recommended under 3 yr of age in US due to low incidence of strep throat and rare ARF

Pregnancy Considerations

Prenatal counseling recommended if woman has a history of rheumatic fever due to increased cardiac risks

TREATMENT

PRE HOSPITAL

- Oxygen as needed
- Monitors if in distress
- IV access may be prudent

INITIAL STABILIZATION/THERAPY

Some patients in CHF will need airway management

ED TREATMENT/PROCEDURES

- Pericardial effusions may need drainage
- In severe carditis, start prednisone
- In case of severe chorea, start haloperidol
- Penicillin IM, IV, or PO
- Aspirin for arthritis/arthralgia

MEDICATION

- Aspirin: 4–8 g/d (peds: 100 mg/kg/d) PO q4–6h; do not exceed 4 g/24h
- Azithromycin 500 mg day 1, then 250 mg PO for 4 more days. (peds: 10 mg/kg day 1 then 5 mg/kg daily PO for 4 more days)
- Digoxin: 0.25–0.5 mg (peds: 0.04 mg/kg) IV
- Erythromycin: 250 mg (peds: 30–50 mg/kg/d) q6h PO for 10 days
- Furosemide: 20–80 mg (peds: 1 mg/kg/dose) IV
- Haloperidol: 2–10 mg (peds: 0.01–0.03 mg/kg/d; use only > 2 yr and > 15 kg) q6h IM or PO
- Penicillin (benzathine benzylpenicillin): 1.2 million U (peds: 600,000 U for < 27 kg) IM acutely and monthly thereafter (prophylaxis)
- Penicillin VK: 500 mg (peds: 250 mg) PO q8h for 10 days (acute treatment)
- Prednisone: 1–2 mg/kg/d for 14 days with taper for the next 2 wk

First Line

- Aspirin (carditis patients)
- Penicillin
- Haloperidol (for chorea)

Second Line

Corticosteroids

FOLLOW-UP

DISPOSITION

Most patients with a new diagnosis should be admitted for stabilization and further evaluation of the severity of the heart disease.

Admission Criteria

- CHF
- New diagnosis
- Uncontrolled chorea
- Uncontrolled pain
- Pericardial effusion

Discharge Criteria

- Pain is controlled
- Stable cardiovascular status
- Education regarding prolonged treatment and endocarditis prophylaxis
- Patient has reliable follow-up option

Issues for Referral

- All patients need close follow-up with their primary physician and cardiologist
- Consider referral to infectious disease specialist and rheumatologist

FOLLOW-UP RECOMMENDATIONS

- Cardiology for echocardiogram and advice on subacute bacterial endocarditis prophylaxis
- Infectious disease specialist to advise on prolonged use of penicillin to prevent recurrence
- Rheumatology if needed for chronic joint problems (uncommon)

PEARLS AND PITFALLS

- Rheumatic fever is uncommon in US, but must be vigilant to treat strep infections to prevent resurgence of disease
- More common in patients living in poor and crowded conditions
- No need to do throat cultures in children under age 3

RIB FRACTURE

Charles W. O'Connell

BASICS

DESCRIPTION

- Result of major or minor thoracic trauma
- Can be classified as traumatic or pathologic

ETIOLOGY

- Blunt thoracic trauma:
 - Simple fall, fall from height
 - Motor vehicle crash
 - Assault
 - Missile
 - CPR-related
- Penetrating trauma is a less likely cause.
 - Ribs usually break at the point of impact or the posterior angle, the structurally weakest region
- Stress fractures in upper and middle ribs can occur with recurrent, high force movements:
 - Athletic activities: Golf, rowing, throwing
 - Severe cough
- Pathologic fractures associated with minor trauma or significant underlying disease:
 - Advanced age
 - Osteoporosis
 - Neoplasm

Pediatric Considerations

- Relatively elastic chest wall makes rib fractures less common in children.
- Consider nonaccidental trauma for infants and toddlers without appropriate mechanism.
- Obtain a skeletal survey to assess for other fractures in infants suspected of being abused

Geriatric Considerations

- Elderly are more prone to rib fractures as well as atelectasis, pneumonia, respiratory failure, and other associated complications.
- Morbidity and mortality are twice that found in younger populations.

SIGNS AND SYMPTOMS***History***

- Blunt thoracic trauma by any mechanism
- Mechanism as described by patient, parent, or pre-hospital personnel:
 - Seat belt usage
 - Steering wheel damage
 - Air bag deployment
- Localized chest wall pain that increases with deep inspiration, coughing, movement
- Pleuritic chest pain
- Dyspnea, shortness of breath

Physical-Exam

- Point tenderness
- Pain referred to fracture site with palpation of the involved rib elsewhere
- Bony step-off
- Crepitus
- Localized edema
- Erythema
- Ecchymosis:
 - Impact from seat belt, aka “seat belt sign” or steering wheel associated with motor vehicle accidents
- Intercostal muscle spasm
- Splinting respirations
- Hypoxia, tachypnea, respiratory distress
- Auscultation shows normal or diminished breath sounds, occasionally an audible click over fracture site.
- Segmental paradoxical movement of chest suggests flail chest indicating multiple, unattached fractured ribs.

ESSENTIAL WORKUP

- Diagnosis is initially made on clinical grounds and confirmed on imaging studies.
- Evaluate for injury to underlying structures

ALERT

- The 1st 3 ribs are relatively protected and require significant impact to fracture, may indicate intrathoracic injury.
- Ribs 9–12 are relatively mobile; their fracture suggests possible intra-abdominal injury.

- Multiple rib fractures may be associated with flail chest and pulmonary contusion.
- Morbidity correlates with degree of injury to underlying structures, number of ribs fractured, and age.

DIAGNOSIS TESTS & INTERPRETATION

Lab

ABGs may reveal hypoxemia or elevated alveolar–arterial gradient:

- Not indicated for simple, uncomplicated rib fractures
- May consider in patients with multiple rib fractures or pre-existing pulmonary disease

Imaging

- Anteroposterior (AP) and lateral chest films are used routinely to diagnose rib fractures
- Chest radiography is indicated to rule out associated intrathoracic injury but can miss up to 50% of rib fractures:
 - _ May reveal associated intrathoracic pathology:
 - Pneumothorax
 - Hemothorax
 - Pneumomediastinum
 - Pulmonary contusion
 - Atelectasis
 - Widened mediastinal silhouette
 - _ Pulmonary contusion appears within 6–12 hr after injury:
 - Ranges from patchy alveolar infiltrates to frank consolidation
- Rib radiograph series offer higher sensitivity but are controversial and are often low yield
- CT is more sensitive for detecting rib fractures and internal injuries.
- CT of the chest may be required to rule out intrathoracic injuries.
- CT or US of the abdomen may be required to rule out associated intra-abdominal injuries.
- Angiography can be used for the detection of vascular injury if signs and symptoms of neurovascular compromise are present:
 - _ Injury to the 1st and 2nd ribs can be associated with vascular injury, particularly with posterior displacement.
- Ultrasound is a promising diagnostic tool for evaluating rib fractures, even for cartilaginous injury

DIFFERENTIAL DIAGNOSIS

- Rib contusion or intercostal muscle strain
- Pneumothorax
- Costochondral separation

- Sternal fracture and dislocation
- Nontraumatic causes of chest pain:
 - Cardiovascular:
 - Myocardial ischemia or infarction
 - Pericarditis
 - Aortic dissection
 - Pulmonary embolism
 - Pulmonary:
 - Embolism
 - Infections
 - Inflammation
 - Barotrauma
 - Musculoskeletal:
 - Costochondritis
 - Cervical or thoracic spine disease
 - GI:
 - Esophageal reflux or spasm
 - Mallory–Weiss tear
 - Biliary or renal colic
 - Peptic ulcer disease
 - Gastritis, pancreatitis, hepatitis
 - Dermatologic:
 - Herpes zoster
 - Chest wall tumor

TREATMENT

PRE HOSPITAL

Focus on airway maintenance, analgesia, and supplemental oxygen

INITIAL STABILIZATION/THERAPY

- For simple fractures, generally no significant stabilization is required.
- Multiple fractures, elderly patients, or significant underlying lung disease:
 - Manage airway and resuscitate as indicated.
 - Endotracheal intubation indicated for patients with severe hypoxemia ($\text{PaO}_2 < 60$ mm Hg on room air, < 80 mm Hg on 100% O_2) or impending respiratory failure

ED TREATMENT/PROCEDURES

- Simple fractures:
 - Pain control:
 - Key to maintaining adequate pulmonary function, avoiding

atelectasis and subsequent pneumonia

- Intercostal nerve blocks with 0.5% bupivacaine are safe and effective:
 - Provides 6–12 hr of pain relief
 - Intercostal nerve block should be performed posteriorly, 2–3 fingerbreadths from the vertebral midline.
 - Inject 0.5–1 mL just under the inferior surface of the rib where the neurovascular bundle is located.
 - Aspirate 1st to be certain the intercostal vessels have not been punctured.
- Deep breathing or incentive spirometry should be encouraged with adequate pain control.
- Avoid binders or banding of the chest wall because these restrict ventilation and promote atelectasis.
- Multiple fractures, elderly patients, or significant underlying lung disease:
 - Pain control and pulmonary toilet
 - Search for associated injuries; treat exacerbation of underlying lung disease.
 - Intercostal nerve blocks for multiple fractures are safe and effective providing 6–12 hr of pain relief.
 - For the admitted patient, thoracic epidural analgesia or patient-controlled analgesia (PCA) is effective, with minimal inhibition of respiratory drive.

MEDICATION

- 1st Line: NSAIDs with or without opioids
 - Ibuprofen: 600 mg PO q6h (peds: 5–10 mg/kg PO q6–8h)
 - Naproxen: 250–500 mg PO q12h (peds: 10–20 mg/kg/d PO div. q12h)
- Opioid analgesics
- Multiple acetaminophen/opioid analgesic combinations are available; see “Alert” below.
 - Acetaminophen: 300 mg/codeine 30 mg (peds: 0.5–1 mg/kg codeine) PO q4–6h
 - Acetaminophen: 325 mg/hydrocodone 2.5–10 mg PO q4–6h
 - Acetaminophen: 325 mg/oxycodone 2.5–10 mg PO q4–6h
- 2nd line: For PO intolerance or more severe pain
 - Hydromorphone: 2–8 mg PO q3–4h (peds: 0.03–0.08 mg/kg PO q4–6h)
 - Hydromorphone: 0.5–4 mg IV/IM/SC q4–6h (peds: 0.03–0.08 mg/kg)
 - Morphine sulfate: 2.5–10 mg IV/IM/SC q2–6h (peds: 0.1–0.2 mg/kg)
 - PCA using hydromorphone or morphine sulfate is effective.
 - Bupivacaine 0.5%: 0.5–1 mL per injection for intercostal nerve blocks

ALERT

- Consider thoracic epidural analgesia:
 - Patients with intractable pain
 - Oversedation

- Hypoventilation from narcotic analgesics
- Avoid NSAIDs when contraindicated due to renal insufficiency or GI bleed
- The dose of acetaminophen/narcotic analgesic combinations is limited by acetaminophen's potential for causing hepatic toxicity.
 - Do not exceed 4 g/24h acetaminophen in adults, 5 doses of 10–15 mg/kg/24 h acetaminophen in children.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Intractable pain
- Inability to cough and clear secretions
- Compromised pulmonary function
- Multiple fractures, fractures of the 1st 3 ribs
- Displaced rib fractures
- Associated pneumothorax, pneumomediastinum, pulmonary contusion, intra-abdominal or intrathoracic pathology
- Elderly patients and patients with significant underlying lung disease:
 - Chronic COPD, CHF, pulmonary fibrosis, asthma
- Inadequate pain control on oral analgesics
- ICU care for elderly patients with 6 or more rib fractures

Discharge Criteria

- Patients with normal pulmonary function, no underlying pulmonary injury, and adequate pain control on oral analgesics
- Strict return criteria should be discussed with the patient prior to discharge:
 - Shortness of breath
 - Increased pain
 - Inadequate pain control
 - Fever
 - Cough

FOLLOW-UP RECOMMENDATIONS

- Most rib fractures heal within 6 wk, but patients should be able to return to regular daily activities much sooner.
- Routine follow-up chest x-ray are not recommended

PEARLS AND PITFALLS

- Be vigilant for the underlying intrathoracic and intra-abdominal pathology that

can be associated with rib fractures.

- Ensuring adequate pain control and ventilation are paramount in the treatment
- Each successive rib fracture carries added morbidity and mortality
- Pediatric rib fractures imply significant force and should raise suspicion for nonaccidental trauma

RING/CONSTRICTING BAND REMOVAL

Carl K. Hsu • Bradley Peckler

BASICS

DESCRIPTION

- *Primary constricting band*: A band tightened around an appendage causes swelling and pain (e.g., a hair knotted around a toddler's toe).
- *Secondary constricting band*: Injury or disease process that causes swelling and edema as a result of tightness against the band (e.g., impacted ring with an underlying fracture of the finger)
- Untreated, the constricting band may become *embedded* and interrupt skin integrity.
- Tourniquet syndrome occurs when anything causes a constriction and there is distal tissue effect.

Pediatric Considerations

In the preverbal child, a constricting band may be a manifestation of child abuse or neglect. It should also be considered as a cause of inconsolable crying.

Geriatric Considerations

The cognitively impaired nursing home resident or Alzheimer patient may be unable to give an indication of injury or pain.

ETIOLOGY

Tourniquet syndrome may result from allergic, dermatologic, iatrogenic, endocrinologic, infectious, malignant, metabolic, physiologic, or traumatic conditions, or it may be related to pregnancy.

DIAGNOSIS

SIGNS AND SYMPTOMS

- A constricting band with swollen tissue and skin of an appendage, most commonly involving a finger
- Other locations include wrist, ankle, toe, umbilicus, earlobe, nipple, septum or nares of nose, penis, scrotum, vagina, labia, uvula, or tongue.
- Pain on manipulation of the appendage or constricting band

History

Usually straightforward but in nonverbal populations it can be a cause of unidentified pain. An inconsolable crying infant may be having pain due to a hair tourniquet.

Physical-Exam

- Evaluate area of concern.
- If evaluating an inconsolable infant or agitated nonverbal adult, assess fingers, toes, and genitalia.

ESSENTIAL WORKUP

- Primary constricting band: Diagnosis made by history and physical exam with special attention to neurovascular status.
- Secondary constricting band: Diagnosis of underlying pathology may depend on results of imaging and lab test results.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Usually not indicated for acute treatment
- Measurement of electrolytes, BUN, and creatinine; thyroid function tests; and Tzanck smear of vesicular lesions may be useful in identifying the underlying diagnosis.

Imaging

Plain films for evaluation of underlying fracture or residual foreign body *after* band removal

DIFFERENTIAL DIAGNOSIS

Any condition causing marked swelling and edema predisposing to the tourniquet syndrome

TREATMENT

PRE HOSPITAL

Remove rings and other potential constricting bands before development of tourniquet syndrome:

- Particularly in regions of extremity trauma

INITIAL STABILIZATION/THERAPY

Pain management or procedural sedation as needed

ED TREATMENT/PROCEDURES

- Removal of the constricting band either by advancing the band distally or by division
- These adjuvant methods may be used alone or in combination:
 - Elevation of the affected extremity may decrease vascular congestion.
 - *Cooling* the extremity with ice or cold water may reduce edema and

erythema.

- *Lubrication* with soap or mineral oil may allow slippage over an inflamed or edematous area.
- *Digital block* with 1–2% lidocaine *without epinephrine* decreases the discomfort of removal and manipulation of an underlying injury.
- A digital block may; however, increase local swelling. Consider regional blocks.
- *Gauze* or a *needle holder* may be used to manipulate the band.
- The distal swollen finger, especially the proximal interphalangeal joint, is an important obstacle in constricting band removal.
- Distal to proximal edema reduction by sequential compression:
 - *Self-adherent tape* is wrapped from distal to proximal to form a smooth and decompressed area over which the band is advanced.
 - A *Penrose surgical drain* or a finger cut from a small glove is stretched to fit over the distal swelling before attempted removal.
 - With lubrication, the proximal end of the drain is pulled under the ring to form a cuff around the ring; the cuff with distal traction applied advances the band over the decompressed area.
 - *Suture material* (no. 0 silk, dental floss, or umbilical tape) is wrapped under tension in a tight layer advancing over the edema in a distal-to-proximal direction; the proximal tail of the suture material or floss is tucked under the ring; with lubrication, the tail under tension is pulled distally and unwound, forcing the ring over the layered suture material and decompressed area.
- Constricting band removal by division:
 - *Scissors* may be used to 1st lift and then cut the offending fibrous band constricting a toddler's toe or penis.
 - A *no. 11 scalpel* blade with cutting edge up may be sufficient to cut constricting bands formed by hair, fibers, or plastic ties.
 - A topical commercially available depilatory agent may be used to divide a tourniquet formed by a suspected hair obscured by local edema.
 - A *handheld wire cutter/stripper* may divide small-girth metallic rings with minimal discomfort to the underlying injury; this type of removal may; however, impart a crush defect to the ring, making repair difficult.
 - A *long-handled bolt cutter*, available in most operating rooms or hospital engineering departments, may be used to divide large-girth or broad-sized rings:
 - Long handles provide the significant mechanical advantage needed to cut large rings.
 - The reinforced cutting blades may not easily fit through a constricting band with adjacent swollen tissue and skin.
 - A *standard hand-powered, medically approved ring cutter* (Steinmann pin cutter with a MacDonald elevator) may be used to divide small-girth metallic constricting bands made of soft metals (gold/silver)

- This method has the advantage of a cleaner cut for subsequent repair of the ring.
- The disadvantage is that the handheld ring cutter is labor-intensive and may aggravate the pain of an underlying injury.
- A *motorized high-RPM cutting device* may be used to rapidly divide constricting bands irrespective of girth and size of the ring; it may be DC- or AC-powered or pneumatically driven in the operating suite.
- Cutting procedure:
 - The initial cut is made on the band on the volar aspect of the extremity.
 - A tenaculum may be used to spread the band in softer metals.
 - For a 2nd cut, the band should be rotated 180° on the extremity, allowing the 2nd cut on the band over the volar aspect of the extremity.
- Motorized cutting:
 - Remove *flammable solvents* from the work area.
 - *Protective eyewear* should be worn by everyone present, including the patient.
 - Place a thin *aluminum splint* (shaped to the curvature of the ring) between the patient's skin and the ring as a shield to protect underlying tissue.
 - Cool splint and cutting surface with ice water irrigations before and during the cutting procedure.
 - Limit cutting with motorized device to 5 sec with max. intervals of 60–90 sec between ice water irrigations to avoid producing local excessive heat.
- Depilatory cream:
 - Can be used if suspected constriction is caused by hair in place of “unwinding or excising” the hair.
 - Swelling of tissues heaped up around the hair may obscure the hair tourniquet leaving only a visible crease with the underlying hair buried below.
 - Depilatory cream applied to the crease may release the hair tourniquet within 10 min.
- Postdivision care:
 - Underlying injuries should be irrigated thoroughly to remove metallic dust and avoid foreign-body reaction and granuloma formation.
 - Tetanus prophylaxis should be provided if indicated.

MEDICATION

- Tetanus prophylaxis: Tetanus toxoid 0.5 mL IM
- No medications are typically required unless evidence of or at risk for infection

First Line

- Cefazolin: 1 g IV/IM (peds: 20–40 mg/kg IV/IM single dose in ED) and
- Cephalexin: 500 mg PO (peds: 25–50 mg/kg/d) QID for 7 days.
- Amoxicillin/clavulanate: 875/125 mg PO (peds: 25 mg/kg/d) BID for 7 days

- Erythromycin: 333 mg PO TID (peds: 40 mg/kg/d q6h for 7 days)

Second Line

- If patient is penicillin allergic:
- EES: 800 mg PO, then 400 mg PO q6h for 7 days *or*
- Clindamycin: 300 mg PO q6h for 7 days

FOLLOW-UP

DISPOSITION

Admission Criteria

- Neurovascular compromise or injury requiring surgical repair
- Concomitant infection or necrosis
- Investigation of abuse and or neglect

Discharge Criteria

Successful band removal with restoration of circulation.

Issues for Referral

Wounds at high risk for infection should have close follow-up in 1–2 days.

FOLLOW-UP RECOMMENDATIONS

Return to the ED for increasing pain, numbness, tingling, redness, swelling drainage, fevers, or other changes in clinical presentation.

PEARLS AND PITFALLS

- Failure to completely examine the fingers, toes, and genitalia of the irritable infant
- The hair causing a hair tourniquet may be obscured by edema and heaped up tissue and skin.
- Rings must be removed early after trauma to the distal extremity.

- S90.446A External constriction, unspecified lesser toe(s), initial encounter

ROCKY MOUNTAIN SPOTTED FEVER

Roger M. Barkin

BASICS

DESCRIPTION

Rickettsial invasion of small blood vessels:

- Causes direct vascular damage
- Superimposed additional vascular damage/vasculitis due to immunologic phenomena

ETIOLOGY

- Acute infection by *Rickettsia rickettsii* via tick vector:
 - _ *Dermacentor andersoni* (wood tick) in the western states
 - _ *Dermacentor variabilis* (dog tick) in the eastern states
- Reported in all states; 1/2 of cases occur in 5 states (NC, SC, TN, OK, AR), as well as parts of Central America and South America
- More common April–September, but can occur any month
- More common in males and in individuals 40–64 yr of age

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Tick bite reported within 14 days of rash in 60% of patients
- Incubation varies 2–14 days with median 7 days
- Exposure to ticks, often in rural environment

Physical-Exam

- Rash:
 - _ Initial rash (3–5 days)
 - Macular, red, and flat
 - Blanches under pressure
 - 1–4 mm diameter
 - _ In hours to days:
 - Becomes darker, papular, dusky, and palpable
 - _ In 2–3 days:
 - Petechial or purpuric
 - Positive Rumpel–Leede test
 - May coalesce or ulcerate

- In severe disease, necrosis of dependent peripheral parts may occur.
- Location:
 - Begins in flexor surfaces of wrist and ankles, rapidly spreading to palms and soles
 - Spreads centripetally involving extremities; may involve trunk and face
 - 15% with centrifugal spread to palms and soles
 - 10% of patients do not have rash
 - Often not identified when patient initially presents for care
- Pulmonary:
 - Nonproductive cough
 - Chest pain
 - Dyspnea
 - Rales
- GI:
 - Often associated with fatal Rocky Mountain spotted fever
 - Secondary to vasculitis
 - Nausea/vomiting
 - Abdominal pain/distention
 - Ileus
 - Hepatosplenomegaly
- Neurologic:
 - Focal or generalized neurologic manifestation in 2/3
 - Meningismus
 - Severe, unremitting headache
 - Encephalitis
- Other:
 - Generalized edema
 - Dehydration
 - Malaise
 - Myalgia
 - Retinal hemorrhage and conjunctivitis
- Complications:
 - Disseminated intravascular coagulation (DIC)
 - Noncardiogenic pulmonary edema
 - Acute renal failure
 - Severe or fatal in advanced age, male sex, African American, chronic alcohol abuse, glucose-6-phosphate dehydrogenase deficiency

ESSENTIAL WORKUP

Clinical diagnosis supplemented by confirmatory lab findings such as hyponatremia, anemia, and thrombocytopenia

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Serology:
 - Diagnose by single titer $> 1:64$ or 4-fold increase. Antibody may not be detected in the 1st few days of symptoms
 - Methods:
 - Immunofluorescent antibody (sensitivity of 95%)
 - Complement fixation
 - Indirect hemagglutination test
 - Indirect immunofluorescence assay is reference standard.
- CBC:
 - Normal WBC count
 - Thrombocytopenia
 - Anemia
- Electrolytes, BUN/creatinine, glucose:
 - Hyponatremia < 130 mEq/L
- Liver profile:
 - Elevated aspartate aminotransferase
 - Lactate dehydrogenase
- Arterial blood gas for:
 - Hypoxia
 - Respiratory alkalosis
- Coagulation profile if DIC suspected
- Microbiology:
 - Immunohistologic antibody stain of skin biopsy
 - Isolation of *R. rickettsii* (time-consuming/ expensive)
 - Polymerase chain reaction assay
- CSF:
 - Pleocytosis and increased protein

Imaging

- Chest radiograph for pulmonary edema, pneumonia
- Echocardiography:
 - Decreased left ventricular contractility

Diagnostic Procedures/Surgery

Skin biopsy may be confirmatory if immunohistologic antibody studies available.

DIFFERENTIAL DIAGNOSIS

- Other tick-borne diseases:
 - Ehrlichiosis: Older adults

- Relapsing fever
- Lyme disease: Erythema chronicum migrans
- Tularemia
- Babesiosis
- Colorado tick fever
- Infectious diseases:
 - Meningococemia—late winter, early spring; maculopapular or petechial rash
 - Measles—late winter, early spring; severe prodrome
 - Rubella—palms and soles spared
 - Varicella—does not have rash in extremities
 - Viral exanthem
 - Infectious mononucleosis—palms and soles spared
 - Disseminated gonococcal infection—pustular lesions
 - Typhus—rash starts at trunk with centrifugal spread
 - Secondary syphilis
 - Scarlet fever
 - Kawasaki disease—red, cracked lips
 - Toxic shock syndrome
 - Gastroenteritis
 - Staphylococcal sepsis
- Inflammatory causes:
 - Allergic vasculitis
 - Thrombotic thrombocytopenic purpura
 - Collagen vascular disease
 - Juvenile rheumatoid arthritis
- Heat illness

TREATMENT

PRE HOSPITAL

Stabilize as appropriate

INITIAL STABILIZATION/THERAPY

- ABC management
- 0.9% NS IV fluid bolus for dehydration
- Oxygen for hypoxia

ED TREATMENT/PROCEDURES

- Correct fluid and electrolyte deficits.
- Initiate antibiotic therapy immediately based on clinical and epidemiologic findings. Should not be delayed until lab confirmation is obtained:

- Doxycycline—drug of choice
- Chloramphenicol in pregnant and allergic patients
- Sulfonamides make infection worse.
- Administer acetaminophen for fever.
- Consider high-dose steroids for severe cases complicated by extensive vasculitis, encephalitis, or cerebral edema (controversial).
- Better outcome in children if treatment begins before day 5 of illness
- Treat complications:
 - DIC
 - Adult respiratory distress syndrome
 - CHF
- Medication

Pediatric Considerations

- Highest incidence in 5–9 yr olds
- 2/3 of cases occur in children < 15 yr.
- Doxycycline is used in children due to potential for fatal cases, the relatively low risk of significant dental discoloration with a short course, and adverse effects of chloramphenicol

Pregnancy Considerations

Use chloramphenicol in pregnant patients.

MEDICATION

First Line

Doxycycline: 100 mg (peds: 2 mg/kg for <45 kg) PO or IV BID for 5–7 days. Patient should generally be treated 2–3 days beyond becoming afebrile.

Second Line

- Acetaminophen: 500 mg (peds: 10–15 mg/kg/dose) PO q4h; do not exceed 5 doses/24 h or 4 g/24 h
- Chloramphenicol: 75 mg/kg/24 h PO or IV q6h for 5–7 days and 48 hr after defervescence
- Solu-Medrol: 125 mg (peds: 1–2 mg/kg) IV

FOLLOW-UP

DISPOSITION

Admission Criteria

Moderate to severe symptoms

Discharge Criteria

- Mild, early disease with early treatment
- Notify family because of clustering and potential exposures.

Issues for Referral

Reflective of defined complications

FOLLOW-UP RECOMMENDATIONS

Reflective of ongoing complications

PEARLS AND PITFALLS

Early treatment based on the clinical presentation and epidemiology is indicated.

ICD10

A77.0 Spotted fever due to *Rickettsia rickettsii*

ROSEOLA

Moses S. Lee

BASICS

DESCRIPTION

- Exanthem subitum
- Incubation period of 5–15 days
- Mode of acquisition unknown:
 - Horizontal spread by oral shedding suggested
 - It is spread person to person but is not very contagious.
 - Human is the only host.
- Pathophysiology:
 - Complex immune response (cytokines, antibody responses, T-cell reactivity)

ETIOLOGY

- Human herpesvirus 6 (HHV-6):
 - Large, double-stranded DNA
 - Closely related to human cytomegalovirus
- Peak incidence at 6–12 mo; 90% occurrence within 1st 2 yr
- Highest incidence in late spring and early summer

DIAGNOSIS

SIGNS AND SYMPTOMS

- Usually self-limited
- Diarrhea
- Irritability
- Rarely causes severe or fatal disseminating diseases:
 - Infectious mononucleosis syndrome of hepatitis
- Complications
 - Febrile seizures in 5–35%
 - Aseptic meningitis/encephalopathy
 - Thrombocytopenic purpura
- Reactivation in immunocompromised individuals. Manifestations are fever, rash, hepatitis, bone marrow suppression, pneumonia, and encephalitis

Pediatric Considerations

- Most newborns are seropositive for HHV-6 due to transplacental antibodies.
- By age 1–2 yr, >90% of infants are seropositive.

History

- Classic history is the onset of sudden, high fever 39.4–41.2°C (103–106°F) commonly followed by defervescence and the appearance of rash
- Absence of physical findings:
 - Child looks well
 - Temperature normalizes in 3–4 days
 - Irritability and anorexia may be present
 - Bulging fontanelle may be noted

Physical-Exam

- Enlarged lymph nodes
- Maculopapular eruption from trunk to arms and neck after temperature normalizes
- Rash fades within 3 days.
- Erythematous papules in pharynx (Nagayama spots)
- Otitis media is common
- Cervical and postoccipital lymphadenopathy

ESSENTIAL WORKUP

Clinical diagnosis:

- High fever in well-appearing child

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - Initial increase in WBC, then normalization with lymphocytosis; WBC may decrease 3–5 days after onset of illness
 - Platelets may be decreased
- HHV-6 DNA:
 - Detected by polymerase chain reaction
 - Available at research level
 - IgM appears early and declines as IgG is produced
 - May be done on blood and CSF
- CSF if concern about meningitis

DIFFERENTIAL DIAGNOSIS

- Fever of unknown origin
- Scarlet fever:
 - “Sandpaper” rash, Pastia lines, and strawberry tongue
- Measles (rubeola):
 - Koplik spots, cough, coryza, conjunctivitis, and fever
- Rocky Mountain spotted fever:

- Rash begins at ankles and wrists.
- Rubella:
 - Fever after rash
- “Fifth disease” (erythema infectiosum)
- Dengue fever
- Pneumococcal bacteremia
- Meningitis, especially with bulging fontanelle

TREATMENT

PRE HOSPITAL

None

INITIAL STABILIZATION/THERAPY

ABC management

ED TREATMENT/PROCEDURES

- Supportive
- Antipyretics:
 - Acetaminophen
 - Ibuprofen

MEDICATION

- Acetaminophen: 500 mg (peds: 15 mg/kg/dose) PO q4h; do not exceed 5 doses/24 h or 4 g/24 h
- Ibuprofen: 200–600 mg (peds: 5–10 mg/kg PO q6–8h); suspension 100 mg/5 mL; oral drops 40 mg/mL

FOLLOW-UP

DISPOSITION

Admission Criteria

Fever in child who is toxic and does not respond to initial supportive care

Discharge Criteria

Usually, all patients may be discharged. Usually may not return to daycare until rash has resolved

FOLLOW-UP RECOMMENDATIONS

Re-evaluate if persistent fever after 3–4 days

PEARLS AND PITFALLS

- Child looks well
- Antivirals are not recommended in the immunocompetent child.
- Febrile seizures need appropriate evaluation.

RUBELLA

Moses S. Lee

BASICS

DESCRIPTION

- Also known as German measles or 3-day measles
- Transmission via droplets from respiratory secretions
- Moderately contagious:
 - Especially during rash eruption and infants with congenital rubella syndrome (CRS)
- Up to 50% may be subclinical.
- Infants with congenital rubella shed large quantities of virus for several months.
- Infectious period 7 days before to 5 days after appearance of rash
- Incubation period: 14–21 days

ETIOLOGY

- Rubella virus (family: *Togaviridae*, genus: *Rubivirus*)
- Live, attenuated virus vaccine indications:
 - All children > 12 mo and entering school
 - All women of childbearing age

DIAGNOSIS

SIGNS AND SYMPTOMS

- Acute viral disease
- Complications:
 - Uncommon, tend to occur more in adults
 - CRS: Infected women in 1st trimester (hearing loss, mental retardation, cardiovascular defect, ocular defect)
 - Arthritis:
 - More common in women (up to 79%)
 - Chronic arthritis is rare.
 - Begins after 2–3 days of illness
 - Knees, wrists, fingers affected
 - Hemorrhagic manifestations:
 - Secondary to thrombocytopenia
 - More common in children
 - Neurologic sequelae:
 - Encephalitis most common in adults; prognosis usually good
 - No causal relationship to autism

History

- Low-grade fever
- Malaise
- Headache
- Upper respiratory tract symptoms

Physical-Exam

- Rash:
 - Rash is fainter than measles rash and does not coalesce.
 - Red macular rash evolving to pink-red maculopapules with occasional pruritus
 - Begins in face with rapid caudal spread
 - Completed in 1st day and disappears in 3 days
 - May have hemorrhagic manifestations
- Lymphadenopathy:
 - Postauricular
 - Occipital
 - Posterior cervical

ESSENTIAL WORKUP

Generally clinical diagnosis

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - Decreased WBC, platelets (more common in children)
- Urinalysis:
 - Hematuria
- Reverse transcriptase–polymerase chain reaction
- ELISA to detect rubella IgM
- Rubella antibody titer:
 - Acute and convalescent serum specimens
 - Hemagglutination-inhibition test most common
 - Rubella specific IgM antibodies using enzyme immunoassay (EIA) commercially available. Detectable 4 days after onset of rash
 - Definitive diagnosis in acute infection
 - Compare infant with maternal sera for CRS.
 - False positives in parvovirus, infectious mononucleosis, rheumatoid factor
 - May be useful to check for immunity of pregnant patients with potential exposure.
- Pharynx:
 - Virus may be isolated from pharynx 1 wk before and until 2 wk after rash

onset (valuable epidemiologic tool).

- CSF:
 - Few WBCs (monocytes) in encephalitis

Diagnostic Procedures/Surgery

- Lumbar puncture if suspected encephalitis
- Arthrocentesis in unexplained arthritis.

DIFFERENTIAL DIAGNOSIS

- Scarlet fever:
 - “Sandpaper” rash, Pastia lines, and strawberry tongue
- Measles (rubeola):
 - Koplik spots, cough, coryza, conjunctivitis, and fever
- Roseola infantum:
 - Spring and fall
- Rocky Mountain spotted fever:
 - Rash begins at ankles and wrists.
- Rheumatoid arthritis

TREATMENT

PRE HOSPITAL

Use N95 filter mask for potential respiratory transmission.

INITIAL STABILIZATION/THERAPY

ABC management

ED TREATMENT/PROCEDURES

- Symptomatic therapy
- Antipyretics and anti-inflammatory agents:
 - Acetaminophen
 - Ibuprofen
- Isolate rubella patients from susceptible persons (e.g., pregnancy).
- Vaccine:
 - Measles, mumps, and rubella vaccine
 - Rubella vaccine is live attenuated virus.
 - Indications:
 - > 12 mo and entry to school
 - Susceptible postpubertal females
 - High-risk groups (colleges, military, places of employment)
 - Unimmunized contacts
 - Healthcare workers and women of childbearing age born after 1957

- Nonpregnant women may have arthralgia in up to 25%
- Contraindicated in pregnant women
- Avoid pregnancy for 3 mo after vaccination.
- 1 dose confers probable lifelong protection.
- Common complaints are fever, lymphadenopathy, and arthralgia.
- Immunoglobulin:
 - Will not prevent viremia but may modify symptoms

MEDICATION

- Acetaminophen: 500 mg (peds: 15 mg/kg/dose) PO q4h; do not exceed 5 doses/24 h or 4 g/24 h
- Ibuprofen: 200–600 mg (peds: 5–10 mg/kg PO q6–8h); suspension 100 mg/5 mL; oral drops 40 mg/mL
- Immunoglobulin: 0.5 mL reconstituted vial SC (0.25–0.50 mL/kg)

FOLLOW-UP

DISPOSITION

Admission Criteria

- CRS
- Encephalitis

Discharge Criteria

- Most patients may go home.
- Inquire regarding vaccination status of family members.

Issues for Referral

- Potential exposure or disease in pregnant women
- Complications
- CRS-suspected child will need comprehensive evaluation.

FOLLOW-UP RECOMMENDATIONS

Pregnant women with suspected rubella or exposure must be followed with titers and counseling should have obstetric consult.

PEARLS AND PITFALLS

- Current literature does not support a causal relationship between childhood vaccination with thimerosal-containing vaccines and development of autism-spectrum disorders.
- Infected individual should be isolated from susceptible (pregnancy,

immunocompromised) individual for 7 days.

CODES

ICD9

- 056.9 Rubella without mention of complication
- 647.50 Rubella in the mother, unspecified as to episode of care or not applicable
- 771.0 Congenital rubella

ICD10

- B06.9 Rubella without complication
- O35.3XX0 Maternal care for (suspected) damage to fetus from viral disease in mother, not applicable or unspecified
- P35.0 Congenital rubella syndrome

SACRAL FRACTURE

Allan V. Hansen • Jaime B. Rivas

BASICS

DESCRIPTION

- They occur in 45% of all pelvic fractures and are rarely isolated
- They are defined by the orientation of the fracture line.
- Mechanism:
 - Axial compression
 - Direct posterior trauma
 - Massive crush injury
 - Insufficiency fractures in elderly and osteoporotic patients

Fracture Classification

Transverse

- Above S4:
 - Neurologic injury common
 - Can see cauda equina syndrome (CES)
- Below S4:
 - Associated rectal tears
 - Neurologic injury is rare

Vertical

- *Lateral to sacral foramina:*
 - Sciatica
 - L5 root injury
 - Neurologic deficit infrequent
- *Foraminal (zone 2):*
 - Bowel/bladder dysfunction
 - L5, S1, S2 root injury
 - Neurologic deficit frequent
- *Canal (zone 3):*
 - Bowel/bladder dysfunction
 - Sexual dysfunction
 - L5, S1 root injury
 - Neurologic deficit often present (> 50%)

ETIOLOGY

- Transverse: Fall from height, flexion injuries, direct blow
- Vertical: Usually high-energy mechanism

Geriatric Considerations

Sacral insufficiency fractures should be considered in elderly patients with severe back pain

DIAGNOSIS

SIGNS AND SYMPTOMS

- Pain in buttocks, perirectal area, and posterior thigh
- Swelling and ecchymosis over the sacral prominence
- Possible sacral nerve dysfunction:
 - Absent or diminished anal sphincter tone is an important finding.
 - Bowel or bladder incontinence

ESSENTIAL WORKUP

- History and physical exam with attention to loss of anal sphincter tone, sensation in the perineum, and bowel and bladder sphincter control.
- Sacral fractures rarely occur in isolation; look for associated injuries.
- Rectal exam will elicit pain in the sacrum; blood in the rectum suggests an open fracture.

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- Only 30% of sacral fractures are detected on plain radiograph.
- CT provides optimal imaging to identify sacral fractures.
- MRI is indicated when neurologic dysfunction is present.

DIFFERENTIAL DIAGNOSIS

- Contusion
- Lumbar spine fracture
- Pelvic fractures

TREATMENT

PRE HOSPITAL

- Sacral fractures are frequently associated with other spinal and intra-abdominal injuries.
- Immobilize with backboard and C-spine collar.

INITIAL STABILIZATION/THERAPY

- Manage ABCs as needed.
- Early immobilization in unstable pelvis or spine fractures

- Pain control with NSAIDs or narcotic analgesics

ED TREATMENT/PROCEDURES

- Vertical unstable fractures require a rapid and thorough assessment for life-threatening injuries as well as orthopedic consultation (see “Pelvic Fracture”).
- Nondisplaced isolated transverse sacral fractures are treated symptomatically with touch-down weight bearing on affected side and early orthopedic referral.
- Surgery is often required for fractures associated with neurologic injury.

MEDICATION

First Line

Analgesia as indicated

FOLLOW-UP

DISPOSITION

Admission Criteria

- Critically injured trauma patient with unstable pelvic fracture
- Neurologic impairment requires orthopedic consultation.

Discharge Criteria

- Isolated nondisplaced sacral fractures
- Consider intermediate or assisted-care setting for elderly patients.

FOLLOW-UP RECOMMENDATIONS

- Only nondisplaced, transverse fractures are appropriate for outpatient follow-up
- Prompt surgical evaluation is indicated for displaced fractures.

PEARLS AND PITFALLS

- Sacral fractures are rarely isolated; consider associated pelvic fractures.
- Detailed neurologic exam, including rectal sphincter tone and perianal sensation, is indicated to assess for associated sacral nerve root injury.
- Foley catheter in a trauma patient may mask voiding problems from sacral nerve root injury.

- S32.14XA Type 1 fracture of sacrum, init encntr for closed fracture

SALICYLATE POISONING

Michele Zell-Kanter

BASICS

DESCRIPTION

- Respiratory alkalosis and metabolic acidosis:
 - Secondary to inhibition of Krebs cycle and uncoupling of oxidative phosphorylation
- Dehydration, hyponatremia or hypernatremia, hypokalemia, hypocalcemia:
 - Owing to increased sweating, vomiting, tachypnea
- Noncardiogenic pulmonary edema:
 - Because of toxic effect of salicylate on pulmonary endothelium resulting in extravasation of fluids
- Salicylate pharmacokinetics change from first order to zero order in overdose setting; i.e., a small dosage increment results in a large increase in salicylate concentration.

Geriatric Considerations

- Greater morbidity
- Respiratory distress/altered mental status indicative of severe toxicity
- Diagnosis of salicylate intoxication delayed because underlying disease states mask signs and symptoms; e.g., CHF

Pediatric Considerations

- Children exhibit faster onset and more severe signs and symptoms than adults:
 - Results from salicylate being distributed more quickly into target organs such as brain, kidney, and liver
- Respiratory alkalosis (hallmark of salicylate poisoning in adults) may not occur in children.
- Metabolic acidosis occurs more quickly in children than in adults.
- Hypoglycemia more common than hyperglycemia
- Ingestion of more than “a taste” of oil of wintergreen (98% methyl salicylate) by children < 6 yr or > 4 mL of oil of wintergreen by patients > 6 yr warrants ED assessment.

ETIOLOGY

Sources of salicylate:

- Aspirin:
 - Ingestion of > 150 mg/kg can cause serious toxicity
- Oil of wintergreen:

- Any exposure should be considered dangerous.
- Bismuth subsalicylate
- Salicylsalicylic acid (salsalate)

DIAGNOSIS

SIGNS AND SYMPTOMS

- GI:
 - Nausea
 - Vomiting
 - Epigastric pain
 - Hematemesis
- Pulmonary:
 - Tachypnea
 - Noncardiogenic pulmonary edema
- CNS:
 - Tinnitus
 - Deafness
 - Delirium
 - Seizures
 - Coma

History

- Ask if taking aspirin or aspirin products:
 - Many patients do not list aspirin among their regular medications, may not consider aspirin a medication.
- Patients may not know the difference between aspirin, acetaminophen, and the OTC NSAIDs

ESSENTIAL WORKUP

- Salicylate level:
 - At presentation and then q2h until level begins to decline
 - Verify that units are correct, generally mg/dL.
- Watch for recurrence of signs of salicylate toxicity and increasing levels even after levels have declined due to intestinal absorption of enteric-coated products and salsalate

Guidelines for Assessing Severity of Salicylate Poisoning

- Acute ingestion of:
 - < 150 mg/kg or < 6.5 g of aspirin equivalent—considered nontoxic
 - 150–300 mg/kg—mild to moderately toxic
 - > 300 mg/kg—potentially lethal
- In the chronic overdose setting:

- Manage patient on clinical findings and not solely on levels
- Clinical findings are better indication of severity than plasma salicylate levels
- No valid nomogram exists for salicylate level interpretation
- Salicylate levels needed to achieve anti-inflammatory effect (20–25 mg/dL) approach toxic levels
- Enteric-coated aspirin absorbed in intestine; peak level delayed

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Arterial blood gas (ABG):
 - Respiratory alkalosis
 - Metabolic acidosis
- CBC
- Electrolytes, BUN/creatinine, glucose:
 - Anion-gap metabolic acidosis
 - Hypokalemia
 - Baseline renal function
- Urinalysis:
 - Urine pH
- PT/PTT with significant ingestions
- Ferric chloride test:
 - Purple if salicylate present
 - Positive 30 min postingestion
- In the presence of salicylate, Phenistix turn brown-purple; may detect concentrations as low as 20 mg/dL

Imaging

- Abdominal flat-plate radiograph for concretions
- Chest radiograph for pulmonary edema

DIFFERENTIAL DIAGNOSIS

- Acute salicylate poisoning:
 - Consider with change in mental status, unexplained noncardiogenic pulmonary edema, mixed acid–base disorder.
 - Methanol
 - Ethylene glycol
 - Conditions causing noncardiogenic pulmonary edema
- Chronic salicylate poisoning:
 - Impending myocardial infarction
 - Alcohol withdrawal
 - Organic psychoses

- Sepsis
- Dementia

TREATMENT

PRE HOSPITAL

In suspected overdose settings, medication bottles must be brought in for review

INITIAL STABILIZATION/THERAPY

- Management of airway, breathing, and circulation (ABCs)
- Naloxone, thiamine, glucose (or Accu-Chek) for altered mental status
- IV rehydration with 0.9% normal saline (NS) for hypotension

ED TREATMENT/PROCEDURES

- Morbidity from chronic salicylate poisoning may be greater than from acute poisoning.
- Aggressively manage all salicylate intoxication.

Gastric Decontamination

- Administer activated charcoal in alert patients.
- Whole-bowel irrigation of theoretical benefit:
 - For concretions visible on abdominal radiograph
 - For ingestion of sustained-release preparation
 - If salicylate levels continue to increase despite appropriate management
 - Do not use in patients who may develop altered mental status

Enhanced Elimination

- Alkalinization:
 - Enhances elimination of ionized salicylate
 - Indications:
 - Acidosis
 - Presence of symptoms
 - Elevated salicylate levels
 - 1 or 2 ampules of sodium bicarbonate followed by IV D₅W 1L with 3 ampules of sodium bicarbonate:
 - Goal: Urine pH of 7.5–8 at the rate of 3–6 mL/kg/h
 - Add 20–40 mEq KCl per liter to avoid hypokalemia
 - Avoid fluid overload with CHF or CAD
 - Closely monitor serum potassium
- Indications for hemodialysis include:
 - CHF
 - Noncardiogenic pulmonary edema

- CNS depression
- Seizures
- Unstable vital signs
- Severe acid–base disorder
- Hepatic compromise
- Coagulopathy
- Underlying disease state compromising elimination of salicylate
- Absolute salicylate level should not be used as sole criterion for deciding to dialyze without considering patient’s clinical status unless level is $> 80\text{--}100$ mg/dL in acute ingestion.
- Threshold to dialyze is lower in patients with chronic overdose.

MEDICATION

- Activated charcoal slurry: 1–2 g/kg up to 90 g PO
- Dextrose: D₅₀W 1 amp (50 mL or 25 g) (peds: D₂₅W 2–4 mL/kg) IV
- Naloxone (Narcan): 2 mg (peds: 0.1 mg/kg) IV or IM initial dose
- Thiamine (vitamin B₁): 100 mg (peds: 50 mg) IV or IM

FOLLOW-UP

DISPOSITION

Admission Criteria

- Monitor patients with salicylate levels > 25 mg/dL until level drops < 25 mg/dL and symptoms abate.
- Salicylate levels increasing after having trended downward to nontoxic levels:
 - In patients who ingest sustained-release aspirin, enteric-coated aspirin, and any aspirin product with delayed absorption
- ICU admission for altered mental status, metabolic acidosis, pulmonary edema

Discharge Criteria

Repetitive salicylate levels < 25 mg/dL and resolution of symptoms

FOLLOW-UP RECOMMENDATIONS

- Psychiatric referral for intentional ingestions
- Close primary care follow-up for chronic ingestions

PEARLS AND PITFALLS

- Patients need to maintain their respiratory drive to reverse acidemia, respiratory acidosis:
 - Do not intubate prematurely.

- It is extremely difficult to achieve and maintain mechanical hyperventilation in these patients.
- Salicylate poisoning may result from topical exposure to salicylate-containing lotions or creams, rectal suppositories, oral antidiarrheal preparations.
- Salicylate levels may trend downward only to begin increasing again due to absorption of product from the intestine or from a salicylate bezoar in the gut.

SARCOIDOSIS

Maureen L. Joyner • Jesse B. Cannon

BASICS

DESCRIPTION

- Chronic, multisystem disorder characterized by local accumulation of T lymphocytes and mononuclearphagocytes forming noncaseating epithelioid granulomas
- Symptoms mainly due to organ dysfunction due to disruption of local tissue architecture:
 - Predominance of lung symptoms
- ACE and Vitamin D levels may be increased due to secretion from granulomatous tissue
- Prevalence 10–20/100,000 in US and Europe
- Affects almost all races and geographic locations
- Symptoms typically begin in patients 10–40 yr of age
- 2.4% lifetime risk to blacks in US, relative to whites at 0.85%

ETIOLOGY

Unclear, but appears to be an overly robust cell-mediated immune response to unidentified self- or nonself antigen(s)

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Constitutional:
 - Fatigue, general weakness
 - Fever
- Skin (25% patients):
 - Rash, lesions
- Cardiac/respiratory (most patients):
 - Dyspnea
 - Chest pain
 - Palpitations
 - Cough
 - Hemoptysis
- Neurologic:
 - Nerve palsy (usually CN VII)

- Seizure
- Altered mental status
- Ocular (20% patients):
 - Eye pain
 - Blurred vision
- Renal:
 - Flank pain
- Musculoskeletal:
 - Arthralgias

Physical-Exam

- Constitutional:
 - Fever
 - Lethargy
- Skin:
 - Erythema nodosum
 - Subcutaneous nodules
 - Maculopapules
 - Plaques
 - Infiltrative scars
 - Lupus pernio
- EENT:
 - Uveitis
 - Keratoconjunctivitis
 - Parotid gland enlargement
- Neurologic:
 - Nerve palsy (usually CN VII)
- Respiratory:
 - Rales
 - Rarely wheezing
- Cardiac (~ 5% patients):
 - Dysrhythmias, conduction abnormalities, AV block
 - CHF (due to restrictive cardiomyopathy)
 - Murmurs (due to papillary muscle dysfunction)
- Renal:
 - Nephrolithiasis
- Musculoskeletal:
 - Polyarthralgias
- Löfgren syndrome:
 - Bilateral hilar adenopathy
 - Erythema nodosum
 - ± Polyarthralgias
- Heerfordt–Waldenström syndrome:

- Fever
- Uveitis
- Parotid gland enlargement
- ± CN VII palsy

Pediatric Considerations

- Children < 4 yr old classically present with triad of rash, uveitis, and arthritis.
- Children ≥ 4 yr old present similarly to adults.

ESSENTIAL WORKUP

- Physical exam with emphasis on lung, skin, eye, heart, and musculoskeletal
- Pulse oximetry/ABG
- ECG (dysrhythmias, conduction delays)
- Slit-lamp eye exam

DIAGNOSIS TESTS & NTERPRETATION

Lab

- Serum ACE elevated in 75% cases
- Basic chemistry panel
- LFTs: Mild, usually asymptomatic, mainly elevated alk phos but possible mild elevation transaminases
- Serum calcium: Hypercalcemia due to excessive vitamin D
- UA: Hypercalciuria
- Hypergammaglobulinemia
- CSF analysis: Lymphocyte predominance, elevated ACE level

Imaging

Chest radiograph (abnormal in 90% sarcoid patients)—reason for frequent incidental diagnosis:

- Type 1: Bilateral hilar lymphadenopathy
- Type 2: Lymphadenopathy and parenchymal lung changes (reticular opacities)
- Type 3: Parenchymal lung changes without hilar lymphadenopathy
- Type 4: Reticular opacities, pulmonary fibrosis; particularly in upper lobes
- Radiotracer scans may identify granulomatous disease but is nonspecific

Diagnostic Procedures/Surgery

- Biopsy:
 - Bronchoscopy and bronchoalveolar lavage
 - Skin lesions if feasible
- Kveim–Siltzbach test:
 - Subcutaneous injection of antigen with subsequent spleen biopsy
 - Rarely used

DIFFERENTIAL DIAGNOSIS

- HIV
- Interstitial lung disease
- Lymphoma
- Mycobacterial infection
- Parathyroid disease

TREATMENT

PRE HOSPITAL

Provide supplemental oxygen.

INITIAL STABILIZATION/THERAPY

- Provide supplemental oxygen.
- Monitor for dysrhythmias.

ED TREATMENT/PROCEDURES

- Patients should be observed without therapy, if possible, since disease resolves spontaneously in 50% patients.
- Initiate steroids in patients demonstrating 1 of the following:
 - Symptomatic or progressive stage II pulmonary disease
 - Stage III pulmonary disease
 - Malignant hypercalcemia
 - Severe ocular disease
 - Neurologic sequelae
 - Nasopharyngeal/laryngeal involvement
- Consider topical corticosteroids and cycloplegic agents for anterior uveitis or dermatologic manifestations.

MEDICATION

- Prednisone: 10–80 mg (peds: 0.5–2 mg/kg) PO QD
- Lower doses for hypercalcemic nephropathy and mild to moderate disease
- Higher doses for neurosarcoïdosis

FOLLOW-UP

DISPOSITION

Admission Criteria

- Hypoxia
- Patients with moderate to severe respiratory symptoms
- Significant cardiac conduction delays

- Severe thrombocytopenia

Discharge Criteria

Follow-up is established.

Issues for Referral

- Cardiology:
 - For any conduction disturbances or CHF
- Rheumatology:
 - For routine care and follow-up:
 - ~q2mo for patients with active disease on steroids, q3–4mo for asymptomatic patients
- Pulmonary:
 - For formal pulmonary function testing (to monitor for progression of restrictive lung disease) with spirometry and DLCO
- Ophthalmology:
 - Within 48 hr for acute uveitis

FOLLOW-UP RECOMMENDATIONS

- Restrict excess calcium from the diet.
- Monitor for complications related to chronic steroid therapy

PEARLS AND PITFALLS

- Evaluate patients with chest radiographs to determine stage and progression of disease.
- Prednisone is treatment of choice for exacerbations of disease.
- Monitor for signs of hypercalcemia and related complications.
- Be aware of acute neurologic and ocular sequelae.

ICD10

- D86.0 Sarcoidosis of lung
- D86.3 Sarcoidosis of skin
- D86.9 Sarcoidosis, unspecified

SCABIES

James Q. Hwang

BASICS

DESCRIPTION

- Mites mate on skin surface and gravid female burrows into stratum corneum to lay eggs:
 - Animal scabies can burrow but cannot reproduce on human hosts
- Symptoms result from delayed type IV hypersensitivity reaction to mite, eggs, saliva, and feces:
 - Inflammatory reaction leads to intense pruritus, which is the hallmark of the disease
 - Crusted Norwegian scabies is characterized by large numbers of mites and is seen in the immunocompromised, disabled, and institutionalized:
 - More infectious than ordinary scabies due to high mite count
- Despite > 2,500-yr existence, an effective way to prevent scabies is still not known
- Secondary infection is common and, as such, the morbidity associated with scabies may be underestimated
- Scabies is a major global health problem in many crowded, resource-poor communities
- Infestations become secondarily infected and epidemic acute poststreptococcal glomerulonephritis and rheumatic heart disease are often associated with endemic scabies

Pediatric Considerations

- Scabies manifests itself in various forms in children and differs from that in adults:
 - More inflammatory (vesicular or bullous)
 - Involvement of face, scalp, palms, or soles
- Highest prevalence is in children < 2 yr old

ETIOLOGY

- Epidemiology:
 - Over the past 2 decades, the number of patients with scabies is increasing
 - Up to 300 million cases yearly
 - Burden of disease is highest in tropical countries
- Produced by the human scabies mite, *Sarcoptes scabiei* var. *hominis*, or from animal mites
- Transmitted by prolonged (15–20 min) direct skin-to-skin contact or, less commonly, by infested bedding or clothing:
 - It is a disease of overcrowding and poverty, rather than a reflection of poor

hygiene

- Probability of being infected is related to number of mites on infected person and length of contact
- Family members, sexual contacts, and institutional settings are at high risk for transmission
- Schools do not ordinarily provide the level of contact necessary for transmission
- Mites subsist on a diet of dissolved human tissue (do not feed on blood) and can live up to 3 days off a host's body
- On average, the number of mites on a host at any time is ~5–15:
 - Main difference between crusted Norwegian scabies and ordinary scabies is the number of mites present on the host
 - Patients with crusted Norwegian scabies are infected with thousands or up to a million mites

DIAGNOSIS

SIGNS AND SYMPTOMS

Generalized and intense itching that is worse at night and usually spares the head and face

History

- Site, severity, duration, and timing of itch
- History should include family members and close contacts
- Generalized, intensely pruritic eruption:
 - Pruritus is intensified at night
- Onset 10–30 days after exposure and infestation; reinfestation provokes immediate (within 1–3 days) pruritus:
 - Patients with crusted Norwegian scabies are usually immunocompromised, have a decreased inflammatory response, and have less pruritus

Physical-Exam

- Often minimal cutaneous findings
- Primary lesion: Linear, elevated, white-gray burrow (up to 1 cm long, width of a human hair) with small vesicle containing black dot at the end (mites barely visible to naked eye):
 - Found symmetrically in web spaces of fingers, flexor surfaces of wrists and elbows, waistline, periumbilical skin, axillary folds, buttocks, penis, scrotum, vulva, and areola
 - Head and neck rarely affected in adults but more commonly in infants and children
- Secondary lesions: Inflammatory papules, nodules, excoriations, or secondary

impetigo or folliculitis seen on back, shoulders, axilla, waist, buttocks, and flexor aspects of elbows:

- Secondary lesions are usually more numerous and prominent than burrows but also may be few if topical steroids used
- Longstanding infestation results in chronic excoriation, eczematization, and hyperpigmented and lichenified skin
- Crusted Norwegian scabies produces gross scaling with hyperkeratotic plaques on hands, feet, scalp, and pressure-bearing areas:
 - Scales can become warty
 - Fissures may appear
 - Nail involvement is common
- Genitalia should be examined in all instances of suspected scabies

Pediatric Considerations

- Eruption may be seen from head to toe
- Vesicles are often found in infants due to their predisposition for vesicle formation
- Neonatal scabies is associated with poor feeding, poor weight gain, and super infection

ESSENTIAL WORKUP

- Careful history and skin exam for characteristic lesions
- The diagnosis is easily missed and should be considered in any patient with persistent generalized pruritus
- Factors related to missed diagnosis in patients admitted through the ED:
 - Overcrowding, time constraints, and lower patient illness severity scores

DIAGNOSIS TESTS & INTERPRETATION

Lab

- May be indicated in immunocompromised patients or in patients with systemic infection:
 - Elevated IgE and IgG and peripheral eosinophilia can be seen in crusted scabies
- New diagnostic lab studies are being developed (circulating IgE levels, PCR, ELISA, and DNA finger printing)
- When endemic, empiric treatment may be more cost effective than lab testing
- Consider screening for other STDs

Imaging

Epiluminescence microscopy and noncomputed dermoscopy are noninvasive, simple, accurate, and rapid imaging techniques

Diagnostic Procedures/Surgery

- Scrape skin at burrows or under fingernails with no. 15 blade and mineral oil (adheres scraped material to blade) and observe under low-power microscope for mites, eggs, or fecal material; may be operator dependent
- A negative scraping does not exclude infestation due to low number of mites in classic scabies:
 - Sensitivity < 50% and is affected by number of sites sampled and sampler's experience
- Skin biopsy may confirm diagnosis but findings may also be absent and reveal only a delayed hypersensitivity reaction

DIFFERENTIAL DIAGNOSIS

- Atopic dermatitis
- Eczema
- Dermatitis herpetiformis
- Papular urticaria
- Folliculitis
- Lichen planus
- Pruritic urticarial papules and plaques of pregnancy
- Adult linear IgA bullous dermatosis
- Syphilis
- Pediculosis
- Pityriasis rosea
- Impetigo
- Seborrheic dermatitis
- Flea bites and bedbugs

TREATMENT

PRE HOSPITAL

Maintain universal precautions.

INITIAL STABILIZATION/THERAPY

- No specific stabilization necessary
- ED is an important route for admission to the hospital and detecting infested patients early can be achieved by screening for high risk patients

ED TREATMENT/PROCEDURES

- Treatment should not be empiric for patients with generalized itching but reserved for patients with a history of exposure, a typical eruption in a characteristic distribution, or both
- Treat patient and all persons in immediate contact with topical scabicide:
 - Treat all contacts at the same time, regardless of the presence of symptoms
- Permethrin 5% is 89–92% effective, and is well tolerated (category B pregnancy):

- < 2% of permethrin is absorbed into the skin, making its potential toxicity low:
 - For children ≥ 2 mo older
 - Massage from head to toe (avoid eyes and mouth) and remove in shower 8–14 hr later
 - Repeat 2nd application in 1–2 wk time
- Crotamiton 10% is 50–60% effective and used when other scabicides are not tolerated
- Ivermectin administered orally for 2 doses 7–14 days apart has shown similar efficacy as permethrin (but not used in pregnant or lactating women or children < 15 kg):
 - Effective in patients unable to tolerate topical scabietics or in patients with resistant or crusted Norwegian scabies
 - May not be effective against all stages of life cycle (may not sterilize scabies eggs)
- Lindane 1% may be slightly less effective and is potentially toxic to the CNS:
 - Lindane absorption (through skin, lung or intestinal mucosa, or mucous membranes) is about 10%
 - Side effects include nausea, headache, vertigo, amblyopia, irritability, and seizure
 - Do not use in pediatric patients or patients with extensive excoriations or dermatitis
- Sulfur is the oldest known treatment of scabies, and is the drug of choice for infants < 2 mo and for pregnant or lactating women
- Crusted Norwegian scabies 1st requires removal of hyperkeratotic scale with keratolytic to facilitate entry of the scabicide
- Treatment failures:
 - Treatment failures are frequent in crusted Norwegian scabies, and use of multiple agents including oral medications is often necessary
 - Machine wash and dry in hot cycles (60°C) or dry clean all clothes and bedding worn within 2 days of treatment or place items in plastic bags for 3 days
 - Vacuum household floors, carpets, mattresses, and furniture
 - Autoclaving, bleaching, or fumigation are not indicated
 - Emphasize that itching may continue for 1–4 wk after mites are killed due to skin inflammatory reaction
 - Topical steroids and oral antihistamines can reduce pruritic symptoms
 - Relapses can occur from untreated areas such as the scalp and subungual regions
 - Treatment failures tend to arise from poor patient understanding and inadequate patient education

MEDICATION

- Scabicides:
 - Crotamiton 10% lotion or cream: Apply topically from neck down in adults and entire skin surface in children QHS for 2 nights, then rinse off 48 hr after last application
 - Ivermectin 3 mg tablets: 1st PO dose of 200 µg/kg should be followed by 2nd PO dose of 200 µg/kg 7–14 days later (pregnancy category C). Take with food
 - Lindane 1% lotion or cream: Apply topically from neck down and rinse off after 8–12 hr; contraindicated in infants, pregnancy, lactation, excessive excoriations, or seizure disorder
 - Permethrin 5% cream (Elimite): Apply topically from neck down in adults and entire skin in children QHS; rinse off after 8–14 hr (pregnancy class B, unknown safety in breast-feeding)
 - Sulfur 5–10% precipitated in petrolatum: Apply topically nightly for 3 consecutive nights and then wash off 24 hr later
- Antipruritics:
 - Low sedating/selective antihistamines:
 - Cetirizine (Zyrtec): Adults and peds >6 yr: 5–10 mg/d PO; 6–12 mo: 2.5 mg/d PO; 12–24 mo: 2.5 mg/d PO to BID; 2–6 yr: 2.5–5 mg/d PO
 - Fexofenadine (Allegra): Adult and peds >12 yr: 180 mg/d PO or 60 mg PO BID; 6 mo–5 yr: 15–30 mg PO BID; 6–11 yr: 30 mg PO BID
 - Loratadine (Claritin): Adults and peds >6 yr: 10 mg/d PO; 2–5 yr: 5 mg/d PO
 - Sedating/nonselective antihistamines:
 - Diphenhydramine (Benadryl): Adults and peds >12 yr: 25–50 mg PO q4–6h; 2–6 yr: 6.25 mg PO q4–6h; 6–12 yr: 12.5–25 mg PO q4–6h
 - Doxepin: 25–50 mg PO BID, peds: Dosing currently unavailable
 - Hydroxyzine HCl (Atarax): Adults and peds >12 yr: 25–100 mg PO q6–8h; <6 yr: 2 mg/kg/d PO div. q6–8h; 6–12 yr: 12.5–25 mg PO q6–8h

First Line

Permethrin 5% cream

Second Line

PO Ivermectin or Crotamiton 10% lotion or cream

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with severe topical or systemic super infection
- Refractory or relapsing cases

Discharge Criteria

Nontoxic appearing patients with routine symptoms

FOLLOW-UP RECOMMENDATIONS

Re-evaluate after 1–4 wk for recurrence:

- Itching may persist for up to 4 wk after correctly applied therapy
- Treatment failure is often due to incorrect application of topical agents or due to failure to treat all contacts
- Retreat if live mites are found

PEARLS AND PITFALLS

- Scabies is a common parasitic infection that is transmitted by prolonged direct skin-to-skin contact
- Scabies in children can differ from that in adults
- Crusted Norwegian scabies is characterized by a large number of mites, and is seen in immunocompromised or institutionalized patients
- Treatment failure is common:
 - Proper patient education can decrease treatment failures.

SCAPHOID FRACTURE

Davut J. Savaser • Robyn Heister Girard

BASICS

DESCRIPTION

- The scaphoid is the most commonly fractured carpal bone.
- This bone is the stabilizer between the distal and proximal carpal rows.
- Injury may result in arthritis, avascular necrosis, or malunion.
- Classified as:
 - Proximal 3rd (10–20%)
 - Middle 3rd (the waist, 70–80%)
 - Distal 3rd (the tuberosity)
 - Tubercle fractures
- Fractures are missed on initial radiographs 10–15% of the time, and delayed diagnosis greatly increases risk of complications.
- The blood supply to the scaphoid enters distally
- The more proximal the fracture, the higher the likelihood for avascular necrosis
- As the wrist is forcibly hyperextended, the volar aspect of the scaphoid fails in tension and the dorsal aspect fails in compression resulting in a fracture.

ETIOLOGY

Generally results from a fall on an outstretched (dorsiflexed) hand (FOOSH injury).

DIAGNOSIS

SIGNS AND SYMPTOMS

History

FOOSH injury

Physical-Exam

- Maximal pain and tenderness in the anatomic snuffbox (may be elicited with direct palpation or axial loading of the thumb); 90% sensitive, 40% specificity.
- Dorsal wrist pain distal to the radial styloid and decreased range of motion of the wrist and thumb
- Rarely, incidental damage to the superficial branches of the radial nerve results in sensory changes.
- Palpate the scaphoid tubercle for tenderness by radially deviating the wrist and palpating over the palmar aspect of the scaphoid; 87% sensitivity, 57% specificity.

Pediatric Considerations

- Carpal fractures are rare in children (and the elderly), as the distal radius usually fails 1st.
- If present, carefully evaluate mechanism.

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- Radiographic imaging should include 3 views of the wrist: PA, lateral, oblique, and scaphoid views (wrist prone and in ulnar deviation).
- Pay special attention to the middle 3rd, or waist, of the bone: 70% of injuries occur here.
- Fracture may be identified by subtle findings such as a displaced fat pad.
- 10–15% of all fractures are not visible on radiographs at the time of injury.
- Bone scintigraphy or MRI as early as 3 days postinjury can rule out fracture and allow for earlier rehabilitation:
 - CT is not as reliable.

Diagnostic Procedures/Surgery

- If fracture is open or associated injuries are identified, urgent surgical intervention may be indicated.
- Associated injuries with scaphoid fracture:
 - Scapholunate dissociation
 - Distal radial fracture
 - Lunate fracture/dislocation
 - Bennett fracture of thumb
 - Radiocarpal joint dislocation
 - Proximal and distal carpal bone joint dislocations

DIFFERENTIAL DIAGNOSIS

- Bennett fracture
- Rolando fracture
- Extra-articular fracture at the base of the thumb metacarpal
- Gamekeeper thumb
- De Quervain tenosynovitis
- Perilunate dislocation
- Scapholunate dissociation
- Lunate fracture or dislocation

TREATMENT

PRE HOSPITAL

Splint or immobilize as appropriate.

INITIAL STABILIZATION/THERAPY

- Evaluate patient for other injuries.
- Dress open wounds.
- Immobilize with thumb in neutral position, ice, and elevate.

ED TREATMENT/PROCEDURES

- Assess mechanism of injury and point of maximal tenderness.
- Exam with special attention to skin integrity and neurovascular status.
- If snuffbox tenderness is present, place in thumb spica splint.
- Counsel patient regarding risk of malunion (10%) and avascular necrosis.
- Clinically suspected scaphoid fractures without radiographic evidence:
 - Should be treated as a nondisplaced scaphoid fracture
 - Spica splint thumb in a position as if the patient was embracing a wine glass.
 - Repeat physical/radiographic exam in 7–10 days.
- Nondisplaced scaphoid fractures:
 - Thumb spica splint
- Displaced scaphoid fractures:
 - Nonunion rate of 50%
 - Often an indication for internal fixation

MEDICATION

Pain control with NSAIDs or narcotics as needed

FOLLOW-UP

DISPOSITION

Admission Criteria

Open fracture or presence of other more serious injuries

Discharge Criteria

- Closed injuries, with 72-hr orthopedic follow-up
- Patients with splints for nondisplaced fractures may be allowed to return to full work or activity of work/sport if the cast does not interfere with the exercises of work or specific sport activities.

Issues for Referral

- If fracture is angulated or displaced > 1 mm, immediate orthopedic referral is indicated.

- All scaphoid or suspected scaphoid injuries must be referred to orthopedics.
- If no radiographic abnormalities found on initial radiograph, after placing in thumb spica splint, refer to orthopedics or primary care in 7–10 days with repeat radiographs at that time.

PEARLS AND PITFALLS

- Perfusion enters scaphoid bone distally.
- Avascular necrosis (especially with proximal 3rd fractures), occurs with inadequately reduced or immobilized fractures.
- Patients presenting with symptoms of a sprained wrist must have the diagnosis of acute scaphoid fracture ruled out.

SCHIZOPHRENIA

Celeste N. Nadal • Melissa P. Bui

BASICS

DESCRIPTION

- A chronic psychotic disorder characterized by delusions, hallucinations, disorganization, negative symptoms, and cognitive deficits:
 - Premorbid phase:
 - Development of negative symptoms with deterioration of personal, social, and intellectual functioning
 - Active phase:
 - Development of active delusions, hallucinations, and bizarre behavior
 - May be precipitated by a stressful event
 - Residual phase:
 - Patients are left with impaired social and cognitive abilities
 - Psychotic symptoms may persist
 - Subtypes: Catatonic, disorganized, paranoid, residual, undifferentiated
- Onset typically early in adulthood (age < 30)
- Comorbid substance abuse (alcohol, cannabis, tobacco, and stimulants) is common
- Violence may result from impaired judgment, paranoia, and command hallucinations
- Life expectancy 12–25 yr less than general population likely because:
 - 41% of patients have metabolic syndrome with increased risk of death due to cardiovascular events
 - 5–10% of patients commit suicide
 - Patients have decreased access to medical care
- Disorganized thinking, abnormal behavior, and delusions may obscure the detection of medical illness
- Medication noncompliance is a key reason for psychiatric decompensation and presentation to the ED

ETIOLOGY

- Pathophysiology unclear but dopamine pathway strongly implicated
- Genetic component (concordance rate of 50% in monozygotic twins)
- Specific genes uncertain:
 - Higher risk in patients with DiGeorge syndrome (22q11.2 deletion)
- Perinatal risk factors:
 - Influenza during 2nd trimester
 - Maternal and postnatal infections
 - Advanced paternal age

- Use of cannabis may unmask psychosis in predisposed individuals

DIAGNOSIS

SIGNS AND SYMPTOMS

Criteria of the *Diagnostic and Statistical Manual of Mental Disorders IV (DSM-IV)* require the presence of at least 2 of the following symptoms for more than 6 mo:

- Delusions (fixed, false beliefs):
 - Bizarre, paranoid, or grandiose
 - Often persecutory, religious, or somatic content
- Hallucinations:
 - Commonly auditory or visual but may involve any sensory modality
- Thought disorder:
 - Disorganized speech ranging from odd, idiosyncratic logic to incoherence
- Grossly disorganized or catatonic behavior
- Negative symptoms:
 - Apathy and amotivation
 - Flat affect
 - Social isolation
 - Anhedonia

ESSENTIAL WORKUP

- Complete general and neurologic exam including vital signs and mental status exam
- Screen for psychosis:
 - Delusions:
 - “Do you feel anyone is trying to harm you or that you are being followed?”
 - “Is anyone trying to send you messages, steal, control, or block your thinking?”
 - Hallucinations:
 - “Do you ever see or hear things that other people cannot see or hear?”
 - “Do you ever hear voices telling you to do things such as to harm yourself or others?”
- Evaluate potential dangerousness to self or others:
 - Screen for past violence or self-injury
 - Content of psychotic symptoms should be explored to assess safety
- Patient history and medication compliance may be unreliable. Obtain collateral history from additional sources:
 - Friends and family
 - Treaters (PCP, therapist, psychiatrist)
 - Pharmacy

- Evaluate for affective psychosis (bipolar, major depression, or schizoaffective disorder)
- Evaluate for delirium or dementia
 - Schizophrenia does not affect orientation.
- Assess for drug-induced psychosis (see “Psychosis, Acute”)
- Psychosis due to medical etiology should be ruled out

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Toxicology screen
- Electrolytes, BUN, creatinine, glucose, calcium
- CBC with differential
- TSH
- Urinalysis

Imaging

Consider head imaging for new onset psychosis of undetermined etiology or new onset neurologic symptoms

Diagnostic Procedures/Surgery

EKG to monitor QT

DIFFERENTIAL DIAGNOSIS

- Delirium
- Drug-induced psychosis
- Psychosis secondary to general medical conditions such as TLE, MS, LBD
- Bipolar disorder
- Major depression with psychotic features
- Schizoaffective disorder:
 - Schizophrenia with prominent depressive and/or manic symptoms during psychosis
- Delusional disorder
- Schizotypal personality
- Brief psychotic episode:
 - Similar symptoms, duration of < 1 mo
- Schizophreniform disorder:
 - Similar symptoms, duration between 1 and 6 mo

TREATMENT

PRE HOSPITAL

- Patients can display unpredictable and violent behavior toward themselves and others
- Patients may require police presence and/or restraints to maintain safety
- Local laws vary as they apply to involuntary restraint

INITIAL STABILIZATION/THERAPY

- Safety of healthcare workers and patient is paramount; security presence may be required
- Behavioral interventions should be 1st line:
 - _ Provide a calm, containing environment
 - _ Potentially dangerous items should be removed from the patient's room
 - _ Use a reassuring voice and calm demeanor to set boundaries and verbally redirect the patient
- If safety is a concern, patient needs to be under constant observation and physical or chemical restraints may be necessary
- Acute agitation may be treated with haloperidol PO/IV/IM which can be augmented with lorazepam PO/IV/IM:
 - _ Encourage voluntary PO meds prior to IM administration
 - _ Other IM antipsychotics include olanzapine, chlorpromazine (monitor orthostatics), ziprasidone (monitor QT), and aripiprazole
 - _ IM olanzapine should not be combined with IV benzodiazepines as this increases risk of cardiopulmonary collapse

ED TREATMENT/PROCEDURES

- Psychiatric consultation in cases of decompensated schizophrenia
- Antipsychotic medications are the mainstay of treatment
- High-potency typical antipsychotic agents:
 - _ Associated with less QT prolongation
 - _ Higher propensity for extrapyramidal symptoms:
 - Dystonia
 - Parkinsonism
 - Akathisia
 - Tardive dyskinesia
 - _ IV haloperidol associated with fewer extrapyramidal symptoms than PO/IM
- Low-potency typical antipsychotics:
 - _ Higher risk of QT prolongation
 - _ Fewer extrapyramidal symptoms
 - _ More sedating
 - _ Orthostatic hypotension (must monitor)
 - _ Anticholinergic side effects
 - _ Lower seizure threshold
- Atypical antipsychotic agents:
 - _ Better tolerated with less EPS

- Associated with metabolic syndrome and weight gain
- Can cause orthostatic hypotension
- Nearly all antipsychotics increase QT:
 - More likely (ziprasidone)
 - Less likely (aripiprazole)
- Clozapine is the only antipsychotic that is clearly more effective for reducing psychotic symptoms and suicide risk:
 - Requires close monitoring of WBCs due to agranulocytosis
 - Highly sedating, hypotensive, lowers seizure threshold
 - Can cause QT prolongation
- Long-acting antipsychotic preparations (given q2–6wk) include:
 - Fluphenazine decanoate
 - Haloperidol decanoate
 - Olanzapine depot (Relprevv)
 - Paliperidone palmitate (Sustenna)
 - Risperidone microspheres (Consta)
- If a high-potency conventional antipsychotic agent is initiated, patients younger than age 40 can be started on benztropine (Cogentin) 2 mg BID for 10 days to reduce the risk of dystonic reactions

MEDICATION

- Typical antipsychotics (1st generation):
 - High potency:
 - Haloperidol 0.5–100 mg/d. Acute agitation 2.5–10 mg PO/IV/IM. Repeat q20–60min as needed
 - Fluphenazine 10 mg/d
 - Thiothixene 1–30 mg/d
 - Medium potency:
 - Perphenazine 2–24 mg/d
 - Trifluoperazine 1–20 mg/d
 - Low potency:
 - Chlorpromazine 0–200 mg/d in 3 div. doses
 - Loxapine 5–100 mg/d
 - Thioridazine 50–800 mg/d in 2–3 div. doses
- Atypical antipsychotics (2nd generation):
 - Aripiprazole 5–30 mg/d
 - Asenapine 5–20 mg/d (SL)
 - Clozapine 12.5–900 mg/d
 - Iloperidone 1–24 mg/d
 - Lurasidone 20–160 mg/d
 - Olanzapine 5–20 mg/d
 - Paliperidone 6–12 mg/d
 - Quetiapine 25–800 mg/d

- Risperidone 1–16 mg/d
- Ziprasidone 20–160 mg/d
- Benzodiazepines:
 - Lorazepam (Ativan) 0.5–2 mg per dose augments antipsychotic for acute agitation

Geriatric Considerations

Black box warning: Elderly patients with dementia-related psychoses treated with antipsychotic drugs are at increased risk of death.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Admit to inpatient psychiatric hospital, if patient is medically stable and:
 - Is a danger to self or others
 - Is gravely disabled and unable to care for himself due to psychosis
 - Has new-onset psychosis and medical etiology has been ruled out
- Prior to transfer to psychiatric facility, patient must have acute medical and surgical issues addressed
- Criteria for involuntary psychiatric hospitalization vary by state

Discharge Criteria

- Patient is not a danger to self or others and is able to perform activities of daily living
- Psychiatric follow-up is arranged
- Psychotic symptoms may persist at time of discharge

FOLLOW-UP RECOMMENDATIONS

- Outpatient psychopharmacologic follow-up should occur within 1 wk of discharge
- Patients taking antipsychotics (especially atypicals) should be monitored for QT prolongation and for obesity and related metabolic syndromes
- Adjunctive cognitive behavioral therapy and other psychosocial treatments can help patients manage psychotic symptoms and improve medication compliance
- Discuss smoking cessation and referral:
 - 50–80% of patients with schizophrenia smoke tobacco

PEARLS AND PITFALLS

- Visual, olfactory, gustatory, or tactile hallucinations should prompt medical workup for secondary causes of psychosis, as should atypical age of onset (> 30 yr)

old)

- Early treatment with antipsychotic medications and social interventions have consistently been associated with better outcomes in schizophrenia
- Avoid using IM olanzapine with IV benzodiazepines as this increases risk for cardiopulmonary collapse
- Patients who recently started antipsychotics who present with fever, rigidity, autonomic instability, and mental status changes should be assessed for neuroleptic malignant syndrome

SCIATICA/HERNIATED DISC

Nas N. Rafi

BASICS

DESCRIPTION

- Pain that radiates from the back into buttocks and lower extremity distal to knee, with or without sensory or motor deficits:
 - 95% sensitive, 88% specific for herniated disc (HD)
 - 3–5% lifetime prevalence
 - Peaks 4th to 5th decade
 - 2–10% of low back pain
 - 95% L5 or S1 nerve root
 - 90% improve with conservative management
 - Radicular symptoms usually resolve within 6 wk
 - 5–10% require surgery

ETIOLOGY

- Protrusion of colloidal gel (*nucleus pulposus*) through weakened surrounding fibrous capsule (*annulus fibrosis*)
- Risk factors:
 - Smoking
 - Repetitive lifting/twisting
 - Vehicular/machinery vibration
 - Obesity
 - Sedentary lifestyle

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Low back pain precedes onset of leg pain
- Leg pain predominates with time
- Sharp, well localized, radiates distal to knee
- Exacerbated by activities that increase intradiscal pressure:
 - Valsalva maneuver
 - Cough
 - Nerve-root tension (sitting, straight leg raise)
- Relieved by decreasing pressure/tension:
 - Lying supine

- Walking
- Paresthesia is the most common sensory symptom

Physical-Exam

- Neurologic exam (motor, sensory, deep tendon reflexes)
- L4 root/L3–L4 disc:
 - Knee extension/hip adduction
 - Anteromedial leg/knee/medial malleolus
 - Patellar reflex
- L5 root/L4–L5 disc:
 - Great toe and foot dorsiflexion
 - Dorsomedial foot/1st web space
 - No reflex
- S1 root/L5–S1 disc:
 - Foot plantarflexion
 - Posterior leg/lateral malleolus/dorsolateral foot
 - Achilles reflex
 - Rectal exam (tone, sensation)
- Straight leg raise:
 - Elevate ipsilateral leg by heel 30–60° with or without dorsiflexing foot
 - Reproduces radicular pain past knee
 - 80% sensitive for HD
- Crossed straight leg raise test (pathognomonic):
 - Elevate contralateral leg
 - Pain in involved leg
 - Less sensitive but very specific for HD

ESSENTIAL WORKUP

- Complete history and physical exam
- See below for test indications

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Indicated if clinical suspicion for differential diagnoses (DDX), not limited to:
 - CBC
 - ESR/CRP
 - UA

Imaging

PA/Lateral of LS spine

- Helps to rule out some DDX
- Indications:

- Extremes of age (< 20, > 55 yr)
- Unresolved back pain (> 4–6 wk) despite conservative treatment
- Red flags on history and physical exam:
 - Trauma
 - Constitutional symptoms (fever, unexplained weight loss, malaise)
 - History of cancer
 - Immunocompromised
 - IV drug abuse
 - Recent bacterial infection
 - Worse at night/wakes patient from sleep
 - Fever
 - Midline point tenderness
 - Neurologic deficits

MRI (Criterion Standard)

- Indications:
 - Acute, severe neurologic deficits (order from ED)
 - Suspicion of infectious etiology of back pain:
 - Epidural abscess
 - Osteomyelitis
 - Discitis
 - 6 wk failed conservative therapy (order on outpatient basis)
 - Disc disease (> 25%):
 - Incidental finding on MRI in asymptomatic patients
 - No relationship between extent of protrusion and degree of symptoms

CT Myelogram

- Rarely used alternative for MRI
- CT better at bone details

Diagnostic Procedures/Surgery

- Postvoid residual (PVR):
 - Overflow incontinence = PVR > 100 mL, suspect cauda equina syndrome

DIFFERENTIAL DIAGNOSIS

- Lumbosacral strain
- Degenerative joint disease
- Spondylolisthesis
- Hip/sacroiliac joint (infection, fracture, bursitis)
- Pneumonia, pulmonary embolus
- Pyelonephritis, renal calculi
- Ectopic pregnancy, pelvic inflammatory disease
- Abdominal aortic aneurysm (AAA)
- Peripheral vascular disease (claudication)
- Herpes zoster

- Psychological: Functional or secondary gain (drug seeking, disability)
- Irritating lesion affecting a lumbosacral nerve anywhere along its route:
 - Brain:
 - Thalamic or spinothalamic tumor, hemorrhage
 - Spinal cord (*myelopathy*):
 - Spinal stenosis, tumor, hematoma, infection (epidural abscess, discitis, osteomyelitis)
 - Root (*radiculopathy*):
 - Intradural: Tumor, infection
 - Extradural: HD, lumbar spine/foraminal stenosis (pseudoclaudication), spondylolisthesis, cyst, tumor, infection
 - Plexus (*plexopathy*):
 - Tumor, AAA, infection (iliopsoas abscess), hematoma (retroperitoneal)
 - Peripheral nerve (*neuropathy*):
 - Toxic/metabolic/nutritional, infection, trauma, ischemia, infiltration, compression, entrapment

Pediatric Considerations

- Usually secondary to trauma or serious underlying medical disease (e.g., leukemia); consider complete workup
- < 10 yr:
 - Infection
 - Tumor
 - Arteriovenous malformation
- ≥ 10 yr:
 - Traumatic HD
 - Spondylolisthesis
 - Scheuermann disease
 - Tumor

Pregnancy Considerations

- Ectopic pregnancy
- Labor
- Pyelonephritis
- Musculoskeletal

TREATMENT

PRE HOSPITAL

Full spine precautions for trauma victims

INITIAL STABILIZATION/THERAPY

Evaluate for neurosurgical emergency

ED TREATMENT/PROCEDURES

Pain relief:

- NSAIDs 1st line
- Muscle relaxants, opioids as needed in acute phase

MEDICATION

- NSAIDs:
 - Ibuprofen (Motrin, Advil): 600–800 mg (peds: 5–10 mg/kg/dose) PO TID--QID
 - Naproxen (Naprosyn, Aleve): 500 mg PO BID
- Muscle relaxants (short term):
 - Cyclobenzaprine (Flexeril): 5--10 mg TID
 - Diazepam (Valium): 2–10 mg (peds: 0.1 mg/kg/dose) PO TID--QID
 - Methocarbamol (Robaxin): 1,000–1,500 mg PO QID
- Opioids (short term):
 - Hydromorphone (Dilaudid): 2–4 mg PO/0.5–2 mg IM/IV q4–6h PRN
 - Morphine sulfate: 2–10 mg (peds: 0.1 mg/kg/dose) IM/IV q2–4h PRN
 - Codeine 30 mg + acetaminophen 300 mg; do not exceed acetaminophen 4 g/24 h
 - Hydrocodone 5 mg + acetaminophen 300 mg; do not exceed acetaminophen 4 g/24 h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Severe neurologic deficit (cauda equina syndrome, inability to walk)
- Progressive neurologic deficit
- Multiple root involvement
- Unstable fracture, infection, neoplasm
- Inability to manage as outpatient (social situation/pain)

Discharge Criteria

Patient able to ambulate, follow instructions, has reliable home situation and planned follow-up

Issues for Referral

Abnormal workup that does not warrant immediate admission. Where and when depend

on results (large DDX)

FOLLOW-UP RECOMMENDATIONS

- Consultant (orthopedic spine surgeon or neurosurgeon) or PCP within 1 wk
- Conservative treatment (4–6 wk):
 - Medication as noted
 - Avoid complete bed rest, 2 days at most
 - Limited activity in acute phase but gradually increase activity/exercise as tolerated
 - Avoid movements that load lower back or exacerbate pain:
 - Heavy lifting, twisting, bending, stooping, bodily vibration
- Therapies of unproven benefit:
 - Chiropractic care
 - Transcutaneous electrical nerve stimulation
 - Traction
 - Back brace/corset
 - Ultrasound
 - Diathermy
 - Acupuncture, acupressure
 - Massage
 - Systemic glucocorticoids

SEBORRHEIC DERMATITIS

Ian Glen Ferguson • Eric Norman Chow

BASICS

DESCRIPTION

- A common and chronic papulosquamous inflammatory skin disorder
- Affects all age groups and varies from mild dandruff to extensive adherent scale
- Found in areas with high concentrations of sebaceous follicles and glands
- Sharply demarcated yellow to red to brown, greasy, scaling, crusting patches/plaques
- Periods of remission and exacerbation frequent in adults

ETIOLOGY

- Exact pathogenesis not fully understood
- Multifactorial with environmental, genetic, hormonal, immunologic, microbial, and nutritional influences
- Strong association with *Malassezia* yeasts
- Complex physiologic response:
 - Immunologic
 - Inflammatory
 - Hyperproliferation
- Disease flares are common with physical and emotional stresses or illness
- Factors predisposing patients to develop seborrheic dermatitis and more severe or refractory disease:
 - Parkinson disease
 - Paralysis
 - HIV/AIDS
 - Mood disorders including depression
 - Congestive heart failure
 - Immunosuppression in premature infants
- Medications known to induce or aggravate seborrheic dermatitis include:

Arsenic Interferon- α

Auranofin Lithium

Aurothioglucose Methoxsalen

Buspirone Methyl dopa

Carbamazepine Phenothiazines

Chlorpromazine Phenytoin

Cimetidine	Primidone
Ethionamide	Psoralen
Gold	Stanozolol
Griseofulvin	Thiothixene
Haloperidol	Trioxsalen

DIAGNOSIS

SIGNS AND SYMPTOMS

Infants

- Onset during 1st few weeks of life, is usually self-limited and resolves by 12 mo of age
- May present concurrently with atopic dermatitis
- Flexural fold involvement may appear as diaper dermatitis:
 - Frequently develops a bacterial or fungal superinfection
- Cradle cap:
 - Thick greasy, adherent scale concentrated on the vertex of the scalp
 - Affects up to 70% of newborns during the 1st 3 mo of life
 - May be accompanied by inflammation or secondary infection

Young Children

- Blepharitis:
 - White scale adherent to eyelashes and eyelid margins with erythema
 - Resistant to treatment and persistent
 - May result in blepharoconjunctivitis

Adolescents and Adults

- Classic seborrheic dermatitis:
 - Minor itching with greasy, fine, dry, white scaling overlying red, inflamed skin
- Exacerbated by avoidance of washing
- Usually bilateral, symmetrical, and favoring the following areas:
 - Scalp, forehead, eyebrows, eyelids
 - Areas of facial hair
 - External ear canals
 - Nasolabial and posterior auricular folds
 - Posterior neck
 - Presternal, navel, and body folds:
 - Axillary and inframammary regions

- Groin and anogenital regions
- May cause areas of hypopigmentation in dark-skinned individuals

ESSENTIAL WORKUP

Diagnosis is based on clinical history and physical exam

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Potassium hydroxide preparations of skin scrapings may suggest yeast involvement
- Fungal culture may help to exclude dermatophytosis as an alternate diagnosis

Imaging

None required

Diagnostic Procedures/Surgery

Skin biopsy (rarely required):

- May help to exclude other diagnoses
- Consider, if the diagnosis remains unclear or the condition fails to respond to treatment

DIFFERENTIAL DIAGNOSIS

- Atopic dermatitis:
 - Later onset in infants (usually > 3 mo)
 - Characteristically affects antecubital and popliteal fossa in adults
 - Pruritus, oozing, and weeping support the diagnosis of atopic dermatitis
 - Family history of atopy (asthma and allergic rhinitis) favors atopic dermatitis
 - Axillary involvement favors the diagnosis of seborrheic dermatitis
- Contact dermatitis:
 - Polymorphous with erythema, edema, and vesicles
 - Tends to spare skin folds
 - May complicate seborrheic dermatitis as an unwanted reaction to treatment agents
- Cutaneous candidiasis:
 - Primary or secondary infection of the skin by *Candida* fungus
 - May affect any body area
 - Pruritus, erythema, mild scaling, and occasional blistering
 - Often associated with diabetes, obesity, or other illness
 - Common in infants
 - Presence of pseudohyphae on cytologic exam with potassium hydroxide does not exclude seborrheic dermatitis

- Dermatophytosis:
 - Generally distributed asymmetrically
 - Tinea capitis (scalp), corporis (body), cruris (groin), barbae (facial hair), faciei (face)
 - Can be very difficult to distinguish from seborrheic dermatitis
 - Hyphae on cytologic exam with potassium hydroxide is suggestive of tinea
- Langerhans cell histiocytosis:
 - Systemic signs (e.g., fever and adenopathy)
 - Infants affected may display scaling
 - Reddish-brown papules or vesicles
 - Associated splenomegaly
 - Purpuric lesions
- Leiner disease:
 - Prevalent in infant females
 - Rapid onset in 2nd to 4th month of life
 - Deficiencies of complement C3, C5
 - Severe generalized, exfoliative, erythrodermic form of seborrheic dermatitis
 - Fever, anemia, diarrhea, vomiting, weight loss, and failure to thrive
- Lupus erythematosus:
 - Erythematous malar rash of the nose and malar eminences
 - Chronic or discoid lupus:
 - Discrete erythematous papules/plaques
 - Thick adherent scale
 - “Carpet tack” appearance if removed
- Psoriasis:
 - Thicker plaques with silvery white scales
 - Less likely confined to scalp
- Rosacea:
 - Usually with central facial erythema or forehead involvement
- Tinea versicolor (pityriasis versicolor):
 - Chronic superficial fungal disease usually located on the neck, upper arms, and trunk
 - Characterized by fine, scaly, coalescing, hypopigmented or hyperpigmented macules
 - Patient usually asymptomatic
 - Also associated with *Malassezia* yeast
 - Not a dermatophyte
 - Short, thick hyphae with spores (spaghetti-and-meatball pattern) seen on cytology with potassium hydroxide

Pediatric Considerations

Infants with seborrheic dermatitis and cradle cap may present with concurrent atopic dermatitis

ALERT

- Seborrheic dermatitis is 1 of many conditions that may cause erythroderma (generalized exfoliative dermatitis):
 - _ Severe scaling erythematous dermatitis involving 90% or more of the body

TREATMENT

PRE HOSPITAL

None required

INITIAL STABILIZATION/THERAPY

None required

ED TREATMENT/PROCEDURES

- Seborrheic dermatitis is a chronic condition:
 - _ Emergent treatment is not required unless secondary infection or erythroderma is present

MEDICATION

- Pharmacologic options are often utilized in a multifaceted approach
- Therapy is directed at decreasing the reservoir of lipophilic yeast and the sebum that supports its growth, thus reducing inflammation and improving hygiene
- Severe cases may require removing scales and cornified nonviable epithelium to facilitate further treatment
- Scales may be softened by applying mineral oil (overnight if necessary) prior to washing
- Gentle brushing with a soft brush (toothbrush) or fine-tooth comb after washing may help remove stubborn scales
- Patient education:
 - _ Early treatment when condition flares
 - _ Emphasize hygiene and demonstrate proper cleansing of scaly lesions
 - _ Moderate UV-A/UV-B sunlight exposure may be beneficial as it inhibits growth of *Malassezia* yeasts
 - _ Refrain from hair sprays and hair pomades
- Infantile seborrheic dermatitis:
 - _ Responds readily to shampoos, emollients, and mild topical steroids
 - _ Aggressive keratolytic or mechanical removal may cause further inflammation
- Adult seborrheic dermatitis:
 - _ Treatment aimed at controlling symptoms, rather than curing the condition
- Blepharitis:
 - _ Warm to hot compresses to affected areas
 - _ Gentle cleansing with baby shampoo and cotton tip debridement of thick

scale

- Cradle cap in infants:
 - Topical olive oil (as emollient)
 - Topical imidazoles
 - Low-potency topical corticosteroids
- Scalp findings in children & adults:
 - Topical shampoos:
 - Pyrithione zinc
 - Coal tar
 - Salicylic acid
 - Selenium sulfide
 - Ciclopirox
 - Ketoconazole
- Nonscalp findings in children & adults:
 - Topical antifungals ± corticosteroids
 - Topical calcineurin inhibitors

First Line

- Imidazoles:
 - Inhibits ergosterol synthesis of fungal cell membrane
 - Target *Malassezia* species:
 - Ketoconazole 2% topical
 - Nizoral, Extina, Xolegel
- Topical corticosteroids:
 - Skin atrophy, striae, hypopigmentation, and telangiectasia may occur with extended use
 - Higher-potency agents indicated only for refractory conditions to less-potent agents
 - Use only briefly, as frequent use may foster recurrence and rebound effect
 - Use low-potency agents on areas with thinner skin (e.g., skin folds, neck, face):
 - Hydrocortisone 0.5%, 1%, 2.5%
 - Consider high- to mid-potency agents only on areas of thicker skin (e.g., trunk, scalp):
 - Fluocinolone acetonide
 - Triamcinolone acetonide
 - Betamethasone dipropionate
 - Clobetasol propionate
- Pyrithione zinc*:
 - Reduces epidermal cell turnover
 - Antifungal & antibacterial properties
- Salicylic acid*:
 - Keratolytic properties

- Useful in areas where scaling and hyperkeratosis are prominent
- Selenium sulfide*:
 - Reduces epidermal and follicular corneocyte production
 - Antifungal properties
- Coal tar/liquor carbonis detergens (LCD)*:
 - Inhibits mitotic cell division
 - Antipruritic, antiseptic properties
 - Reduces epidermal thickness
 - Avoid on face, skin flexures, or genitalia
- Sulfur/sulfonamide combinations:
 - Prevents PABA to folic acid conversion via dihydropteroate synthase inhibition:
 - Carmol scalp treatment
 - Ovace

*These agents are contained alone or in combination in formulations of the following:

- Denorex
- Head & Shoulders
- Neutrogena T/Gel or T/Sal
- Selsun Blue

Second Line

- Ciclopirox:
 - Anti-fungal, -bacterial, -inflammatory effects
- Topical calcineurin inhibitors:
 - Anti-inflammatory & antifungal properties
 - Lack long-term effects of corticosteroids
 - Black box warning concerning malignancy:
 - Pimecrolimus 1%
 - Tacrolimus 0.1%

FOLLOW-UP

DISPOSITION

Admission Criteria

Admission unlikely to be required unless severe secondary infection or erythroderma is present

Discharge Criteria

Patients may be discharged with recommended medications and follow-up

Issues for Referral

- Refer patients to primary care physician when considering underlying illness or comorbidities
- Consider referral to a qualified dermatologist when the diagnosis remains elusive or the condition fails to respond to therapy

FOLLOW-UP RECOMMENDATIONS

- Symptoms should improve within 7–10 days, but may take months to resolve completely and may recur
- Adolescent and adult forms may persist as a chronic dermatitis
- Provide return precautions for signs of secondary bacterial or fungal infections:
 - Fever, erythema, tenderness, or ulcerations

PEARLS AND PITFALLS

- Severe and sudden attacks of seborrheic dermatitis may be the initial presentation of an immunocompromised patient (e.g., HIV/AIDS)
- Admission may be warranted for further evaluation of the underlying disease process

ICD10

- L21.0 Seborrhea capitis
- L21.1 Seborrheic infantile dermatitis
- L21.9 Seborrheic dermatitis, unspecified

SEIZURE, ADULT

Atul Gupta • Rebecca Smith-Coggins

BASICS

DESCRIPTION

- Generalized seizures:
 - Classically tonic–clonic (grand mal)
 - Begin as myoclonic jerks followed by loss of consciousness
 - Sustained generalized skeletal muscle contractions
 - Nonconvulsive generalized seizures:
 - Absence seizures (petit mal); alteration in mental status without significant convulsions or motor activity
- Partial seizures:
 - Simple:
 - Brief sensory or motor symptoms without loss of consciousness (i.e., Jacksonian)
 - Complex:
 - Mental and psychological symptoms
 - Affect changes
 - Confusion
 - Automatism
 - Hallucinations
 - Associated with impaired consciousness
- Status epilepticus:
 - Variable definitions:
 - Seizure lasting longer than 5–10 min
 - Recurrent seizures without return to baseline mental status between events
 - Life-threatening emergency with mortality rate of 10–12%
 - Highest incidence in those <1 yr and >60 yr of age
- At least one-half of patients presenting to the ED in status do not have a history of seizures.
- Alcohol withdrawal seizures (“rum fits”):
 - Peak within 24 hr of last drink
 - Rarely progress to status epilepticus
- Patients with a single seizure have a 35% risk of recurrent seizure within 5 yr

Pediatric Considerations

Febrile seizures are generalized seizures occurring between 3 mo and 5 yr of age:

- Typically lasts <15 min

- Associated with a rapid rise in temperature
- Without evidence of CNS infection or other definitive cause

ETIOLOGY

- Hypoxia
- Hypertensive encephalopathy
- Eclampsia
- Infection:
 - Meningitis
 - Abscess
 - Encephalitis
- Vascular:
 - Ischemic stroke
 - Hemorrhagic stroke
 - Subdural hematoma
 - Epidural hematoma
 - Subarachnoid hemorrhage
 - Arteriovenous malformation
- Structural:
 - Primary or metastatic neoplasm
 - Degenerative disease (i.e., multiple sclerosis)
 - Scar from previous trauma
- Metabolic:
 - Electrolytes
 - Hyponatremia
 - Hyponatremia
 - Hypocalcemia
 - Hypo/hyperglycemia
 - Uremia
- Toxins/drugs:
 - Lidocaine
 - Tricyclic antidepressants
 - Salicylates
 - Isoniazid
 - Cocaine
 - Alcohol withdrawal
 - Benzodiazepine withdrawal
- Congenital abnormalities
- Idiopathic
- Trauma

DIAGNOSIS

SIGNS AND SYMPTOMS

- Altered level of consciousness
- Involuntary repetitive muscle movements:
 - Tonic posturing or clonic jerking
- Seizures of abrupt onset:
 - Aura may precede a focal seizure
- Duration usually 90–120 sec:
 - Impaired memory of the event
 - Postictal state is a brief period of confusion and somnolence following a seizure
- Evidence of recent seizure activity:
 - Confusion or somnolence
 - Acute intraoral injury
 - Urinary incontinence
 - Posterior shoulder dislocation
 - Temporary paralysis (Todd paralysis)
- Other findings may suggest etiology of seizure:
 - Fever and nuchal rigidity (CNS infection)
 - Needle tracks; stigmata of liver disease (drugs and alcohol)
 - Head trauma:
 - Papilledema (increased intracranial pressure)
 - Lateralized weakness, sensory loss, or asymmetric reflexes

History

- History of seizures:
 - Medication compliance
- Recent illness
- Head trauma
- Headaches
- Anticoagulation therapy
- Fever
- Neck stiffness

Physical-Exam

- Complete neurologic exam:
 - Todd paralysis
- Complete secondary and tertiary survey to evaluate for any trauma secondary to seizure or potential cause for seizure

ESSENTIAL WORKUP

- A thorough history is the most valuable part of the workup:
 - Witness accounts
 - History of prior seizures

- Presence of acute illness
- Past medical problems
- History of substance use
- Patients with chronic seizure disorder and typical seizure pattern may need to have only serum glucose and anticonvulsant levels checked
- New-onset seizure mandates workup:
 - Electrolytes including calcium, phosphorus
 - Head CT
 - Toxicology screen
 - Pregnancy test if woman is of childbearing age
 - Lumbar puncture indicated if:
 - New-onset seizure with fever
 - Severe headache
 - Immunocompromised state
- Persistently altered mental state:
 - Search for specific underlying cause
 - Patient's condition and resources for follow-up determine whether all these tests must be done in the ED

Pediatric Considerations

- A child with a 1st febrile seizure should receive fever workup as dictated by clinical condition
- Inquire about family history of febrile seizures
- Labs and radiographs as needed to determine source of fever
- Lumbar puncture for 1st febrile seizure:
 - Consider if age < 1 yr
 - Ill appearing
 - Lethargy or poor feeding
 - Exam difficult
 - Unreliable follow-up

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Serum anticonvulsant levels
- Blood–alcohol level
- Toxicology screen
- CBC:
 - WBC often elevated
- Chemistry panel:
 - Bicarbonate often low
- Lactate may be elevated
- CSF:

- May have transient increase in WBC to 20/ μ L

Imaging

- Noncontrast head CT:
 - Persistent or progressive alteration of mental status
 - Focal neurologic deficits
 - Seizure associated with trauma
- CT scan with contrast should be obtained in HIV-positive patients to rule out toxoplasmosis
- MRI is sensitive for low-grade tumors, small vascular lesions, early inflammation, and early cerebral infarcts:
 - Consider electively in new-onset seizures

Diagnostic Procedures/Surgery

- EEG may be arranged with neurology on an outpatient basis
- Bedside EEG may be performed in ED if there is suspicion of nonconvulsive status epilepticus or psychogenic seizures

DIFFERENTIAL DIAGNOSIS

- Syncope (may also have incontinence, twitching, and jerking)
- Hyperventilation syndrome
- Psychogenic seizures
- Transient ischemic attacks
- Sleep disorders
- Delirium tremens
- Hypoglycemia

TREATMENT

PRE HOSPITAL

Anticonvulsant as per local protocol

INITIAL STABILIZATION/THERAPY

- Airway management as indicated
- Pulse oximetry, oxygen with suction available:
 - C-spine precautions
 - Rapid-sequence intubation if patient cannot protect airway or with hypoxia or major head trauma
 - IV access, rapid determination of serum glucose:
 - If hypoglycemic, give IV dextrose 25 g
 - Lorazepam or diazepam for active seizures
 - Naloxone if concern for narcotic overdose

ED TREATMENT/PROCEDURES

- 1st-time seizure:
 - Normal head CT if performed
 - Return to baseline with normal neuro exam:
 - Discharge with close follow-up with PCP and/or neurologist
- 1st-time seizure:
 - Structural lesion on CT or MRI:
 - Start antiepileptic drug (AED) in consultation with PCP and/or neurologist
- Recurrent seizure not on AED:
 - Start AED in consultation with PCP and/or neurologist
- Recurrent seizure with subtherapeutic AED level:
 - IV and/or PO load current AED
- Recurrent seizure with therapeutic AED level:
 - Need careful evaluation for cause of seizures, new lesions, etc.:
 - Adjust and/or add AED in consultation with neurologist
- Seizure in a pregnant patient:
 - Evaluate as other seizure patients
 - Strongly consider eclampsia if >20-wk gestation
 - OB consultation, arrange for C-section
 - Magnesium
- Seizures related to alcohol:
 - Determine if seizure is caused by withdrawal (typically 6–48 hr after cessation of drinking) or another cause
 - Management of withdrawal seizures is benzodiazepines

Pediatric Considerations

- Fever control with acetaminophen and ibuprofen
- Anticonvulsants not needed for febrile seizures
- Anticonvulsants should be prescribed in conjunction with neurologist.

MEDICATION

- Acetaminophen: 500 mg PO/PR q4–6h; do not exceed 4 g/24 h
- Diazepam: 0.2 mg/kg IV per dose; 0.5 mg/kg PR
- Fosphenytoin: 15–20 mg/kg phenytoin equivalents (PE) at rate of 100–150 mg/min IV/IM
- Ibuprofen: 5–10 mg/kg PO
- Levetiracetam: Start 500 mg PO/IV q12h (peds: Start 20 mg/kg/d PO div. BID; age 4–15 yr)
- Lorazepam: 2–4 mg IV/IM (peds: 0.05–0.1 mg/kg IV per dose)
- Naloxone: 0.4–2 mg IV/IM/SQ (peds: 0.1 mg/kg IV/IM/SQ)
- Phenobarbital: 15–20 mg/kg IV at rate of 1 mg/kg/min (plan to protect airway)
- Phenytoin: 15–20 mg/kg IV at rate of 40–50 mg/min (peds: Use rate of 0.5–1

mg/kg/min)

- Propofol: 5–50 µg/kg/min IV, titrate to effect (plan to protect airway)
- Valproate sodium: 10–20 mg/kg/d

First Line

Benzodiazepines

Second Line

- Fosphenytoin
- Levetiracetam
- Phenobarbital
- Phenytoin
- Propofol
- Valproate sodium:
 - works as well as second line agent in status epilepticus and can be given faster

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with status epilepticus should be admitted to the ICU
- Patients with seizures secondary to underlying disease (e.g., meningitis, intracranial lesion) must be admitted for appropriate treatment and monitoring
- Patients with poorly controlled repetitive seizures should be admitted for monitoring
- Delirium tremens

Discharge Criteria

- Patient with normal workup and appropriate neurology follow-up
- Uncomplicated seizure in patient with chronic seizure disorder
- Seizure secondary to reversible cause:
 - Hypoglycemia if blood sugar has stabilized
 - Alcohol withdrawal if baseline mental status and no further seizures
- Simple febrile seizure

Issues for Referral

- Consider early neurology follow-up
- Anticonvulsant drug level monitoring

FOLLOW-UP RECOMMENDATIONS

No driving until seizures are under control

PEARLS AND PITFALLS

- Most common cause of recurrent seizure is subtherapeutic anticonvulsant drug level
- Benzodiazepines are the 1st-line treatment to stop seizure activity
- Treat the underlying cause if identifiable
- Seizures lasting longer than 5–10 min should be treated as status epilepticus
- Valproate likely works as well as phenytoin/fosphenytoin as a second line agent in treating status epilepticus and can be administered more quickly with less chance of an adverse effect

SEIZURE, FEBRILE

John P. Santamaria

BASICS

DESCRIPTION

- Occurs between 6 mo and 5 yr of age associated with fever:
 - No evidence of intracranial infection or other defined CNS primary cause
 - Average age of onset is 18–22 mo
 - Children with previous nonfebrile seizures excluded
- Most common pediatric convulsive disorder:
 - Affects 2–4% of young children in US
- Occurs in normal children with a systemic viral illness
- High-risk children:
 - History of febrile seizure in immediate family members
 - Delayed neurologic development
 - Males
- Subgroups:
 - Simple febrile seizures:
 - Brief, self-limited lasting < 10–15 min, resolve spontaneously
 - Generalized without any focal features
 - Complex febrile seizures:
 - Duration > 15 min
 - Focal features
 - More than 1 seizure within a 24-hr period
- Risk of recurrence:
 - One-third of cases
 - Early age of onset, history of febrile or afebrile seizures in 1st-degree relatives, and temperature < 40°C during initial seizure increase the likelihood of recurrence
- Risk of subsequent epilepsy:
 - Greatest for those with prior abnormal neurologic development, a complex (> 15 min) 1st febrile seizure, a focal seizure, or a family history of afebrile seizures
 - Only slightly greater than the general population if 1st febrile seizure is simple and neurologic development normal
 - Not affected by the use of prophylactic medications

ALERT

Because this is usually self-limited, intervention must be individualized in relation to airway, breathing, and seizure management

ETIOLOGY

Common childhood infections:

- Upper respiratory illnesses
- Otitis media
- Roseola
- GI infections
- *Shigella* gastroenteritis

DIAGNOSIS

SIGNS AND SYMPTOMS

- Fever
- Seizure may occur concurrent with recognition of the febrile illness
- Seizure
- Generalized tonic-clonic seizure most common:
 - _ Tonic phase:
 - Muscular rigidity
 - Apnea and incontinence
 - Self-limited and last only a few minutes
 - _ Other seizure types:
 - Staring with stiffness
 - Limpness
 - Jerking movements without prior stiffening

History

- Careful history and physical exam help confirm diagnosis and rule out other etiologies
- Symptoms/evidence of infectious illness
- Duration and pattern of fever
- Medication exposure/toxin
- Recent immunizations
- Trauma/occult trauma
- Growth pattern and developmental level
- Family history of seizures
- Complete description of seizure

Physical-Exam

- Reducing temperature may be useful in evaluation; give antipyretics early
- Evidence of infectious illness-rash, ear infection, respiratory infection, diarrhea, etc.
- Careful neurologic exam including mental status
- Presence of meningismus, bulging fontanelle, nuchal rigidity, etc.

- Evidence of focal deficit or increased ICP

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Routine lab studies not indicated
- Evaluate for a source of fever if serious bacterial infection is suspected:
 - WBC
 - UA
 - Blood and urine cultures
- Lumbar puncture:
 - Not routinely indicated
 - Indications 12–18 mo of age:
 - History or irritability, decreased feeding, lethargy
 - Consider if deficient in *Haemophilus influenzae* type b or *Streptococcus pneumoniae* immunizations
 - Physical signs of meningitis and/or history consistent with meningitis
 - Complex seizure
 - Prolonged postictal state
 - Prior antibiotics altering presentation
 - Abnormal mentation after postictal state
 - Indications >18 mo old:
 - Signs/symptoms of CNS infection present
 - Electrolytes and bedside glucose in infants and children with vomiting or diarrhea
- EEG:
 - Not helpful in the initial evaluation of febrile seizures
 - May be indicated if developmental delay, underlying neurologic abnormality, or focal seizure
 - Does not help predict recurrences or risk for later epilepsy
- Anticonvulsant levels
- Toxicology studies of blood and urine if history and physical exam suggestive

Imaging

- Chest radiograph only in patients with significant respiratory symptoms or pertinent findings on physical exam
- Head CT:
 - Indicated with traumatic injuries, focal neurologic findings, or inability to exclude elevated intracranial pressure

DIFFERENTIAL DIAGNOSIS

- Febrile delirium
- Febrile shivering with pallor and perioral cyanosis

- Breath-holding spell during febrile event
- Acute life-threatening event
- Other causes of seizure:
 - Afebrile seizure occurring during febrile event
 - Sudden discontinuance of anticonvulsants
 - Infection:
 - Meningitis/encephalitis
 - Acute gastroenteritis, often with dehydration
 - Head trauma
 - Toxicologic:
 - Anticholinergics
 - Sympathomimetics
 - Other
 - Hypoxia
 - Metabolic disease
 - Intracranial masses
 - CNS vascular lesions

TREATMENT

PRE HOSPITAL

- Protect the airway
- Oxygen
- Support breathing as needed
- Cautions:
 - Keep child from incurring injury while actively convulsing
 - Respiratory insufficiency and apnea occur secondary to overaggressive treatment with benzodiazepines
 - Simple febrile seizures are self-limited and generally require no anticonvulsant therapy or ventilatory support

INITIAL STABILIZATION/THERAPY

- Support the airway and breathing
- Benzodiazepines rarely needed:
 - Prolonged seizures or compromised patients
 - Lorazepam, diazepam, or midazolam
 - Rectal diazepam or nasal midazolam may be easily administered with good efficacy

ED TREATMENT/PROCEDURES

- Rarely is pharmacologic intervention required; usually self-limited
- Seizures refractory to benzodiazepines:

- Phenytoin or fosphenytoin
- Phenobarbital
- Workup to exclude other etiologies
- Administer antipyretics acutely and routinely for at least the next 24 hr:
 - Acetaminophen and/or ibuprofen (may use both)
- Appropriate antibiotic treatment for specific bacterial disease if identified
- Reassure and education of parents is essential

MEDICATION

- Acetaminophen: 10–15 mg/kg/dose PO, PR; do not exceed 5 doses/24 h
- Diazepam: 0.2 mg/kg IV (max. 10 mg); 0.2–0.5 mg/kg PR (max. 20 mg)
- Fosphenytoin: 20 mg/kg IV over 20 min
- Ibuprofen: 10 mg/kg PO
- Lorazepam: 0.1 mg/kg IV (max. 5 mg)
- Midazolam: 0.05–0.1 mg/kg IV; 0.2 mg/kg buccal/IN/IM (max. 7.5 mg)
- Phenobarbital: 15–20 mg/kg IV over 20 min or IM; monitor for respiratory depression
- Phenytoin: 15–20 mg/kg IV over 30–45 min

FOLLOW-UP

DISPOSITION

Admission Criteria

- Recurrent or prolonged seizures
- Fever with source not appropriately treated as outpatient

Discharge Criteria

- Simple febrile seizures:
 - Normal neurologic exam
 - Source of fever is appropriately treated as outpatient
- Reassurance to parents

FOLLOW-UP RECOMMENDATIONS

Schedule follow-up with primary care physician

PEARLS AND PITFALLS

- Although aggressive treatment of fever with antipyretics is often recommended, there is no evidence that this reduces seizure recurrence
- Oral diazepam during febrile illness may reduce risk of recurrence; prophylactic anticonvulsants with other anticonvulsants rarely indicated—such treatment is controversial and to be considered only after extensive discussion

ICD10

- R56.0 Febrile convulsions
- R56.00 Simple febrile convulsions
- R56.01 Complex febrile convulsions

SEIZURE, PEDIATRIC

John P. Santamaria

BASICS

DESCRIPTION

Sudden, abnormal discharges of neurons resulting in a change in behavior or function

ETIOLOGY

- Febrile seizures
- Infection
- Idiopathic
- Trauma
- Toxicologic:
 - Ingestion
 - Drug action
 - Drug withdrawal
- Metabolic:
 - Hypoglycemia
 - Hypocalcemia
 - Hypo/hyponatremia
 - Inborn errors of metabolism
- Perinatal hypoxia
- Intracranial hemorrhage
- CNS structural anomaly or malformation
- Degenerative disease
- Psychogenic

DIAGNOSIS

SIGNS AND SYMPTOMS

Neonates

- Subtle abnormal repetitive motor activity:
 - Facial movements
 - Eye deviations
 - Eyelid fluttering
 - Lip smacking/sucking
- Respiratory alterations
- Apnea
- Seizure activity:

- Focal or generalized tonic seizures
- Focal or multifocal clonic seizures
- Myoclonic movements
- Generalized problems (metabolic, infection, etc.) may present with focal seizures

Older Infants and Children

- Generalized seizures:
 - Tonic-clonic
 - Tonic
 - Clonic
 - Myoclonic
 - Atonic (“drop”)
 - Absence
- Partial or focal seizures:
 - Simple:
 - Consciousness maintained
 - Simple partial seizures:
 - Motor, sensory, and/or cognitive symptoms
 - Motor activity focal: 1 part or side
 - Paresthesias, metallic tastes, and visual or auditory hallucinations
 - Complex:
 - Consciousness impaired
 - Complex partial seizure
 - Simple partial seizure progresses with impaired consciousness:
 - Aura precedes altered consciousness; auditory, olfactory, or visual hallucination
 - May generalize
- Status epilepticus:
 - Generalized is most common
 - Sustained partial seizures
 - Absence seizures
 - Persistent confusion; postictal period

History

- Determine whether seizures are febrile or afebrile
- Determine type of seizure:
 - Partial vs. generalized
 - Presence of eye findings, aura, movements, cyanosis
 - Duration
 - State of consciousness, postictal state
 - Predisposing conditions/history/family history (syndromes with a genetic component)

Physical-Exam

- Vital signs, including temperature
- Careful neurologic exam, including state of consciousness
- Eye, including fundoscopic exam
- Skin exam to identify neurocutaneous diseases such as tuberous sclerosis

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Bedside glucose test
- Performed in young infants and those in status epilepticus
- Select studies in other children reflecting history and physical exam:
 - Electrolytes
 - BUN
 - Creatinine
 - Glucose
 - Calcium
 - Magnesium
 - CBC
 - Toxicology screen
- Patients on anticonvulsant therapy:
 - Drug levels
- Febrile seizure:
 - Lab studies to evaluate for a serious underlying bacterial infection if suspected

Imaging

- Head CT:
 - Focal seizure
 - New focal neurologic abnormality
 - Suspected intracranial hemorrhage or mass lesion
 - New-onset status epilepticus without identifiable cause
 - Not routinely indicated for 1st afebrile seizure
- Lumbar puncture:
 - Suspicion of meningitis or encephalitis
 - CT 1st if suspect increased intracranial pressure
- MRI:
 - Rarely urgently indicated for seizures
- EEG:
 - Generally indicated in children with an afebrile seizure as a predictor of risk of recurrence and to classify the seizure type/epilepsy syndrome
 - Postictal slowing seen within 24–48 hr of a seizure and may be transient; delay EEG if possible

- Rarely helpful in the acute setting

DIFFERENTIAL DIAGNOSIS

- Neonates:
 - Apnea due to other causes
 - Jitters or tremors
 - Gastroesophageal reflux
- Infants and toddlers:
 - Breath-holding spells
 - Night terrors
- Children and adolescents:
 - Migraine headache
 - Syncope
 - Tics
 - Pseudoseizures
 - Hysteria

TREATMENT

PRE HOSPITAL

Cautions:

- Many conditions may be mistaken for seizures (see “Differential Diagnosis,” below)
- Immobilize cervical spine if trauma suspected
- Check fingerstick glucose or administer dextrose as appropriate

INITIAL STABILIZATION/THERAPY

- ABC support if actively seizing
- Airway:
 - Oxygen/monitor pulse oximetry
 - Nasopharyngeal airway preferred over oral airway
 - Bag valve–mask support if hypoventilating or persistently hypoxic
 - Intubation if seizures are refractory and bag valve–mask support is unsuccessful
- IV access:
 - If hypoglycemic, give dextrose
- Maintain spine precautions if trauma suspected

ALERT

Airway and breathing must be stabilized concurrent with management of ongoing seizures if present

ALERT

Early treatment of long-lasting seizure is critical in reducing potential morbidity, including brain damage

ED TREATMENT/PROCEDURES

Status Epilepticus

- Benzodiazepine:
 - When treating IV lorazepam is preferred due to its longer duration of action
 - Valium is acceptable
 - If IV access is not available:
 - Buccal midazolam (most convenient)
 - Intranasal lorazepam
 - Per rectum diazepam
- Phenytoin:
 - If benzodiazepines fail
 - For longer-term control
 - Fosphenytoin easier to administer
- Phenobarbital:
 - Use if benzodiazepines and phenytoin fail to break the seizure
 - Risk of respiratory depression greatly increases if a benzodiazepine has also been given
- Alternative therapies in the event of refractory status epilepticus
- Consultation appropriate:
 - Paraldehyde (per rectum)
 - Barbiturate coma:
 - Barbiturate (pentobarbital) coma requires intubation and EEG monitoring to be sure the seizure is suppressed
 - Associated hypotension
 - General anesthesia:
 - A final resort
 - Continuous EEG is needed to be sure the seizure is abolished
- Neonates:
 - Phenobarbital is an acceptable 1st-line therapy
 - Preferred maintenance drug

ALERT

Note: Aggregate response to 2nd- and 3rd-line agents is <10%

MEDICATION

- D₁₀: 5 mL/kg IV for neonates
- D₂₅: 2 mL/kg IV for children
- Diazepam: 0.2 mg/kg IV (max. 10 mg); 0.2–0.5 mg/kg PR (max. 20 mg)

- Fosphenytoin: 20 mg/kg IV over 20 min
- Lorazepam: 0.1 mg/kg IV, IN (max. 5 mg)
- Midazolam: 0.05–0.1 mg/kg IV; 0.2 mg/kg buccal/IN/IM (max. 7.5 mg)
- Pentobarbital: 3–5 mg/kg IV over 1–2 hr; maintenance: 1–3 mg/kg/h IV; monitor for respiratory depression
- Phenobarbital: 15–20 mg/kg IV over 20 min; monitor for respiratory depression
- Phenytoin: 15–20 mg/kg IV slowly over 30–45 min

FOLLOW-UP

DISPOSITION

Admission Criteria

- ICU:
 - Active status epilepticus, intubated, or persistent mental status changes
 - Repetitive seizures in narrow time frame
- Inpatient unit:
 - Status epilepticus resolved in the ED
 - Underlying cause of seizure unresolved, uncontrolled, or poorly understood
 - Intracranial hemorrhage
 - Mass lesion
 - Meningitis/encephalitis
 - Drug
 - Toxin ingestions

Discharge Criteria

- The child is alert with normal mental status and neurologic exam
- No evidence of an underlying cause requiring hospitalization
- Reliable parent or caregiver
- Home telephone

Issues for Referral

Unresponsive or repetitive seizures

FOLLOW-UP RECOMMENDATIONS

- Provide seizure precautions and aftercare instructions
- Follow-up with PCP or pediatric neurologist

PEARLS AND PITFALLS

- Phenobarbital is the preferred treatment for theophylline-induced seizures, poor response to benzodiazepines and phenytoin

- Consider buccal or intranasal benzodiazepine if no IV access

ICD10

- R56.00 Simple febrile convulsions
- R56.1 Post traumatic seizures
- R56.9 Unspecified convulsions

SEPSIS

Daniel J. Henning • Nathan Shapiro

BASICS

DESCRIPTION

- Presence of an infection with an associated systemic inflammatory response
- The systemic inflammatory response syndrome (SIRS) is composed of 4 criteria:
 - _ Temperature $> 38^{\circ}\text{C}$ or $< 36^{\circ}\text{C}$
 - _ Heart rate > 90 bpm
 - _ Respiratory rate $> 20/\text{min}$ or $\text{PaCO}_2 < 32$ mm Hg
 - _ WBC $> 12,000/\text{mm}^3$, $< 4,000/\text{mm}^3$, or $> 10\%$ band forms
- Sepsis = infection with ≥ 2 SIRS criteria:
 - _ Release of chemical messengers by the inflammatory response
 - _ Macrocirculatory failure through decreased cardiac output or decreased perfusion pressure
 - _ Microcirculatory failure through impaired vascular autoregulatory mechanisms and functional shunting of oxygen
 - _ Cytopathic hypoxia and mitochondrial dysfunction
- Hemodynamic changes result from the inflammatory response:
 - _ Elevated cardiac output in response to vasodilatation
 - _ Later myocardial depression:
- Multiple organ dysfunction syndrome (MODS):
 - _ Adult respiratory distress syndrome (ARDS)
 - _ Acute tubular necrosis and kidney failure
 - _ Hepatic injury and failure
 - _ Disseminated intravascular coagulation
- Sepsis should be viewed as a continuum of severity from a proinflammatory response to organ dysfunction and tissue hypoperfusion:
 - _ Severe sepsis: Sepsis with at least 1 of the following organ dysfunctions:
 - Acidosis
 - Renal dysfunction
 - Acute change in mental status
 - Pulmonary dysfunction
 - Hypotension
 - Thrombocytopenia or coagulopathy
 - Liver dysfunction
 - _ Septic shock: Sepsis-induced hypotension despite fluid resuscitation:
 - Systolic BP < 90 mm Hg or reduction of > 40 mm Hg from baseline
- Sepsis is the 10th leading cause of death in US:
 - _ In-hospital mortality for septic shock is $\sim 30\%$

ETIOLOGY

- Gram-negative bacteria most common:
 - *Escherichia coli*
 - *Pseudomonas aeruginosa*
 - Rickettsiae
 - *Legionella* spp.
- Gram-positive bacteria:
 - *Enterococcus* spp.
 - *Staphylococcus aureus*
 - *Streptococcus pneumoniae*
- Fungi (*Candida* species)
- Viruses

Pediatric Considerations

- Children with a minor infection may have many of the findings of SIRS.
- Major causes of pediatric bacterial sepsis:
 - *Neisseria meningitidis*
 - *Streptococcal pneumonia*
 - *Haemophilus influenzae*

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Question for signs of infection and a systemic inflammatory response:
 - Fever
 - Dyspnea
 - Altered mental status:
 - Change in mental status
 - Confusion
 - Delirium
 - Nausea and vomiting
- Look for a source of the infection:
 - Cough, shortness of breath
 - Abdominal pain
 - Diarrhea
 - Dysuria/frequency
- Past history should highlight risk factors and immunosuppressive states:
 - Underlying terminal illness
 - Recent chemotherapy
 - Malignancy

- History of a splenectomy
- HIV
- Diabetes
- Nursing home resident

Physical-Exam

- An elevated respiratory rate is an early warning sign of sepsis and occurs without underlying pulmonary pathology or acidosis.
- BP is often normal early in sepsis.
- Hypotension when septic shock occurs
- Extremities are often warmed and flushed despite hypotension.
- Look for a source of the infection:
 - Abdominal exam
 - Rectal exam to assess for an abscess
 - Chest exam for signs of pneumonia
 - Any rash is important:
 - Localized erythema with lymphangitis (streptococcal or staphylococcal cellulitis)
 - Rash involving palms of hands and soles of feet (rickettsial infection)
 - Petechiae scattered on the torso and extremities (meningococemia)
 - Ecthyma gangrenosum (pseudomonas septicemia)
 - Round, indurated, painless lesion with surrounding erythema and central necrotic black eschar
 - Decubitus ulcers
 - Indwelling catheter:
- CNS infections:
 - Coma
 - Neck stiffness (meningitis)

ESSENTIAL WORKUP

- Serum lactate should be done early in the course to assess severity and need for goal-directed therapy
- Blood cultures prior to antibiotics:
 - Broad spectrum of lab tests and imaging studies to locate the source of the infection and assess for MOF.
 - Placement of a central line with an ScvO₂ catheter may be used to adjust therapy.

DIAGNOSIS TESTS & NTERPRETATION

Lab

- Serum lactate:

- > 4 mmol/L defines severe sepsis
- Normal lactate does not rule out septic shock
- CBC with differential:
 - Leukocytosis is insensitive and nonspecific
 - Neutrophil count < 500 cells/mm³ should prompt isolation and empiric IV antibiotics in chemotherapy patients.
 - > 5% bands on a peripheral smear is an imperfect indicator of infection.
 - Hematocrit:
 - Patients should be maintained with a hematocrit > 30% and hemoglobin > 10 g/dL.
 - Platelets:
 - May be elevated in the presence of infection or sepsis-induced volume depletion
 - Low platelet count is a significant predictor of bacteremia and death.
- Electrolytes, BUN, creatinine, glucose:
- Ca, Mg, pH
- C-reactive protein
- Cortisol level
- INR/prothrombin time/partial thromboplastin time
- Liver function tests
- ABG or VBG:
 - Mixed acid–base abnormalities: Respiratory alkalosis with metabolic acidosis
 - VBG correlates very closely with ABG, except for SaO₂
- Blood cultures:
 - From 2 different sites
 - 1 may be drawn through an indwelling central line (i.e., Broviac).
- Urine analysis and culture

Imaging

- CXR:
 - Determine whether pneumonia is the infectious source.
 - Fluffy, bilateral infiltrates may indicate that ARDS is already present.
 - Free air under the diaphragm indicates the source of the infection is intraperitoneal and a surgical intervention is mandatory.
- Soft tissue plain films:
 - Indicated if extremity erythema or severe pain
 - Air in the soft tissues associated with necrotizing or gas-forming infection
- Imaging studies to locate the source of the infection based on the presentation:
 - CT scan of the abdomen and pelvis
 - Abdominal US for gallbladder disease
 - Transthoracic or transesophageal echocardiogram

Diagnostic Procedures/Surgery

- Lumbar puncture:
 - For meningeal signs or altered mental status
- Central venous access:
 - Central venous pressure (CVP) and ongoing measurement of central venous oximetry.

DIFFERENTIAL DIAGNOSIS

- Pancreatitis
- Trauma
- Hemorrhage
- Cardiogenic shock
- Toxic shock syndrome
- Anaphylaxis
- Adrenal insufficiency
- Drug or toxin reactions
- Heavy metal poisoning
- Hepatic insufficiency
- Neurogenic shock

TREATMENT

PRE HOSPITAL

Aggressive fluid resuscitation for hypotension

INITIAL STABILIZATION/THERAPY

- ABCs
- Supplemental oxygen to maintain $\text{PaO}_2 > 60$ mm Hg
- Intubation and mechanical ventilation if shock or hypoxia are present
- Administer 0.9% NS IV.

ED TREATMENT/PROCEDURES

- Early goal-directed therapy:
 - 500 cc boluses of 0.9% saline up to 1–2 L empirically
 - Place central line.
 - Continue 500 cc saline boluses until $\text{CVP} > 8$ cm H_2O .
 - If the mean arterial pressure < 65 mm Hg and $\text{CVP} > 8$, then initiate pressors:
 - Norepinephrine or dopamine to raise BP
 - Norepinephrine is preferred if tachycardia or dysrhythmias are present.
 - Epinephrine for cases where shock is refractory to other pressors

- If the ScvO₂ < 70 and HCT < 30, transfuse 2 U PRBCs.
- If ScvO₂ > 70 and HCT > 30 and MAP > 60, then add dobutamine.
- Administer antibiotics early, based on the most likely organisms or site of infection.
- If source identified, or highly suspected, treat the most likely organisms:
 - _ Cover for MRSA, VRE, and *Pseudomonas* if there are risk factors
 - _ Pulmonary source:
 - 2nd- or 3rd-generation cephalosporin and gentamicin
 - _ Intra-abdominal source:
 - Ampicillin and metronidazole and gentamicin
 - Cefoxitin and gentamicin
 - _ Urinary tract source:
 - Ampicillin or piperacillin and gentamicin or levofloxacin
- Consider stress-dose hydrocortisone if recent steroid use or possible adrenal insufficiency

Pediatric Considerations

- Antibiotic therapy based on age:
 - _ < 3 mo (2 drugs): Ampicillin and gentamicin or cefotaxime (50–180 mg/kg/d div. q4–6h)
 - _ ≥ 3 mo: Cefotaxime or ceftriaxone (50–100 mg/kg/d div. q12–24 h)
- Initiate vasopressors after no response to 60 mL/kg IV fluid.
- Avoid hyponatremia and hypoglycemia.
- Dexamethasone for children with bacterial meningitis:
 - _ 0.15 mg/kg q6h for 4 days

MEDICATION

- Ampicillin: 1–2 g (peds: 50–200 mg/kg/24 h) IV q4–6h
- Cefoxitin: 1–2 g (peds: 100–160 mg/kg/24 h) IV q6–8h
- Ceftazidime: 1–2 g (peds: 100–150 mg/kg/24 h) IV q8–12h
- Dopamine: 1–5 µg/kg/min (renal dose); 5–10 µg/kg/min (pressor dose)
- Gentamicin: 1–1.5 mg/kg (peds: 2–2.5 mg/kg q8h) IV q8h
- Hydrocortisone: 100 mg IV q6–8h
- Metronidazole: Load with 1 g (peds: 15 mg/kg) IV, then 500 mg (peds: 7.5 mg/kg q6h)
- Nafcillin: 1–2 g IV q4h (peds: 50 mg/kg/24 h div. q4–6h)
- Norepinephrine: 2–8 µg/min
- Piperacillin: 3–4 g IV q4–6h
- Vancomycin: 500 mg (peds: 10 mg/kg) IV q6h

First Line

- Normal immune function without an identifiable source:

- 2nd- or 3rd-generation cephalosporin and gentamicin
- Nafcillin and gentamicin
- Add vancomycin if there is a history of methicillin-resistant *S. aureus*, or the patient resides in a nursing facility, or there is a history of recent hospitalizations.

Second Line

Immunocompromised host without an identifiable source:

- Piperacillin and gentamicin
- Ceftazidime and either nafcillin or vancomycin and gentamicin

FOLLOW-UP

DISPOSITION

Admission Criteria

Sepsis almost always requires inpatient care.

Discharge Criteria

Patients with less severe infections (e.g., streptococcal pharyngitis) meeting the criteria for sepsis with stabilized vital signs

Issues for Referral

Sepsis with toxicity, septicemia, or septic shock requires admission, generally to an ICU.

PEARLS AND PITFALLS

- Start antibiotics as soon as sepsis is suspected.
- Failure to recognize multiorgan failure and initiate aggressive fluid resuscitation in the initial presentation of sepsis is a pitfall.

- A41.51 Sepsis due to Escherichia coli [E. coli]
- A41.52 Sepsis due to Pseudomonas

SEROTONIN SYNDROME (DRUG-INDUCED)

Andrew C. Kendall • Jenny J. Lu

BASICS

DESCRIPTION

- Constellation of signs and symptoms from excessive stimulation of central and peripheral serotonergic receptors
- Spectrum of symptoms may range from mild and subtle findings to severe and sometimes fatal toxicity
- Results from use of serotonergic agents, alone or in combination with other serotonergic agents (may be therapeutic, intentional overdose, recreational, drug interactions)
- Classic triad:
 - Autonomic dysfunction: Hyperthermia, diaphoresis, tachycardia, and hypertension
 - Cognitive changes: Confusion, agitation, hallucinations, decreased responsiveness
 - Neuromuscular excitability: Hyperreflexia, myoclonus, tremors

EPIDEMIOLOGY

Incidence and Prevalence Estimates

- SSRIs implicated most often, alone or in combination with other drugs
- Incidence higher in females but fatalities greater in males
- Highest incidence in ages 19–39
- Most fatalities from drug/drug interactions or recreational abuse

ETIOLOGY

- Serotonin produced by metabolism of L-tryptophan
- Exerts action on 5-hydroxytryptophan (5-HT) receptors of which there are 7 types located in central and peripheral nervous systems:
 - Influences sleep and temperature regulation, affective behavior, food intake, migraines, emesis, sexual behavior, nociception, motor tone, GI motility, and vascular tone
- Extensive list of serotonergic agents, with psychiatric meds most common (SSRIs, SNRIs):
 - Examples: Citalopram, desvenlafaxine, duloxetine, escitalopram, fluoxetine, fluvoxamine, paroxetine, sertraline, trazodone, venlafaxine
- Other serotonergic agents include (not exhaustive):
 - Buspirone, cocaine, dextromethorphan, fentanyl, lithium, MAOIs, MDMA

(ecstasy), meperidine, methadone, metoclopramide, ondansetron, selegiline, St. John's wort, TCAs, tramadol, triptans (controversial)

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- May be difficult to obtain:
 - Family, friends, EMS personnel, may provide additional information
- Patient medication list: Prescribed medications, over-the-counter medications, herbal supplements
- Medical history:
 - Seizures, migraines, attention deficit/hyperactivity disorder, Parkinson, recent illnesses
- Psychiatric history
- Illicit drug abuse history
- Onset of symptoms:
 - Mental status/behavioral changes, development of hyperthermia, muscular rigidity/clonus

Physical-Exam

- Vital signs:
 - Hyperthermia
 - Tachycardia
 - Hypertension or hypotension (may evolve into frank shock and cardiovascular collapse)
- Dermatologic:
 - Diaphoresis, normal color
- GI:
 - Hyperactive bowel sounds
 - Diarrhea
- Mental status/neurologic:
 - Agitation
 - Altered mental status
 - Ocular clonus
 - Hallucinations
 - Waxing/waning delirium
- Musculoskeletal:
 - Clonus: Most helpful finding in diagnosis, greater in lower extremities
 - Hypertonicity and rigidity, greater in lower extremities
 - Hyperreflexia, greater in lower extremities

ESSENTIAL WORKUP

- Careful history and physical exam as it is a clinical diagnosis
- Hunter criteria – most sensitive (84%) and specific (97%) criteria for diagnosis. Requires having taken/been on a serotonergic agent and 1 of the following:
 - Spontaneous clonus
 - Inducible clonus plus agitation or diaphoresis
 - Ocular clonus plus agitation or diaphoresis
 - Tremors plus hyperreflexia
 - Hypertonia plus temperature $> 38^{\circ}\text{C}$ plus ocular clonus or inducible clonus
- Consider other etiologies (sepsis, CVA, etc.)

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Blood chemistry/electrolytes, renal function
- Urine and serum tox screens may detect coingestants
- Lactate, pH
- Total CK
- Cell count, blood/urine cultures if infectious process suspected

Imaging

- Consider CT head if appropriate (trauma, infectious)
- EKG:
 - Evaluate QRS/QT intervals, dysrhythmias

DIFFERENTIAL DIAGNOSIS

- Other intoxications (cocaine, amphetamines, anticholinergic agents, ecstasy, PCP):
 - Neuroleptic malignant syndrome
 - Sympathomimetic toxicity
 - Malignant hyperthermia
 - Anticholinergic toxicity
 - Infectious process (meningitis, encephalitis)

TREATMENT

PRE HOSPITAL

- Stabilize airway
- Vital signs
- IV access
- Fingerstick glucose
- Oxygen administration if needed

INITIAL STABILIZATION/THERAPY

- Stabilize airway, establish IV access, continuous cardiac and temperature monitoring
- Conscientious avoidance of additional serotonergic agents while in-hospital (e.g., caution with ondansetron, fentanyl, linezolid, meperidine, dextromethorphan)
- Supportive care is cornerstone of treatment
 - Aggressive cooling measures particularly important if hyperthermia present
 - Fluid resuscitation

ED TREATMENT/PROCEDURES

- Benzodiazepines are 1st-line medications:
 - Lorazepam, diazepam
- Aggressive cooling measures for hyperthermia:
 - Ice packs, cooling blanket, cool mists/fans
 - Hyperthermia derives from muscular rigidity and is not usually responsive to antipyretic medications
- Severe symptoms (e.g., uncontrollable hyperthermia) may necessitate intubation:
 - Paralytics may be required to control muscular rigidity and hyperthermia
- Cyproheptadine:
 - Nonspecific antihistamine with 5-HT_{2A} antagonist activity may be considered for severe cases, but benefit has not been definitively established
 - Only PO available (must be crushed and given through oro- or nasogastric tube)
- Poison Control Center/Toxicology guidance (1-800-222-1222)

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients suspected to have serotonin toxicity, even mild-appearing cases, should be admitted for monitoring and treatment
- Severe symptoms including uncontrollable hypertension, altered mental status, cardiovascular instability, hyperthermia require ICU monitoring

Discharge Criteria

- Discharge may be considered when all symptoms have resolved
- Careful evaluation of discharge medications and patient education is essential
- Poison Control Center guidance is recommended

FOLLOW-UP RECOMMENDATIONS

Follow up with primary care after discharge

PEARLS AND PITFALLS

- Serotonin syndrome may be mild to severe in presentation; diagnosis in mild cases often elusive/missed
- Mental status changes, hyperthermia, muscular clonus in lower extremities are important findings
- Hyperthermia is due to muscular rigidity, should be aggressively controlled, and is not responsive to antipyretics
- Cyproheptadine has not been shown definitively to be beneficial but may be considered in severe cases
- Attentive supportive care and avoidance of serotonergic agents is the mainstay of care

CODES

ICD9

333.99 Other extrapyramidal diseases and abnormal movement disorders

ICD10

G25.89 Other specified extrapyramidal and movement disorders

SERUM SICKNESS

Anika Backster • Murtaza Akhter

BASICS

DESCRIPTION

- Type III hypersensitivity reaction
- When a foreign protein or drug (the antigen) is injected, the body's immune system responds by forming antibodies to the foreign material and subsequently forms complexes composed of the antigen, antibody, and complement.
- These complexes then deposit in tissue, inciting an inflammatory response:
 - C3a and C5a act as anaphylatoxins.
 - C5a is strongly chemotactic for neutrophils.
 - The neutrophils then infiltrate the vessel wall at the site of the immune complex deposition and release enzymes, such as collagenase and elastase, which damage vessel walls.
- Typically, symptoms arise 6–21 days after the primary exposure to the antigen.
- Symptoms can start 1–4 days after exposure if there has been an initial immunizing exposure.
- Symptoms typically last 1–2 wk before spontaneously resolving.

ETIOLOGY

- Serum sickness:
 - Vaccines containing foreign protein or serum such as pneumococcal vaccine or rabies.
 - Antivenom and tetanus inoculations made with horse or sheep protein
 - Monoclonal antibodies
- Serum sickness–like reaction:
 - Caused by nonprotein drugs, mostly antibiotics:
 - Penicillins, amoxicillin
 - Cephalosporins (i.e., Cefaclor)
 - Sulfonamides (i.e., Bactrim)
 - Thiazides
 - Gold
 - Thiouracils
 - Hydantoins
 - Phenylbutazone
 - Aspirin
 - Streptomycin

DIAGNOSIS

SIGNS AND SYMPTOMS

Classic presentation is fever, rash, arthralgias, and lymphadenopathy.

History

- Fever
- Rash (urticarial, morbilliform, scarlatiniform)
- Arthralgias
- Myalgias
- Lymphadenopathy
- Facial and neck edema
- Chest pain
- Shortness of breath

Physical-Exam

- Fever
- Rash
- Lymphadenopathy
- Arthritis
- Edema
- Splenomegaly
- Peripheral neuritis
- Myocarditis/pericarditis
- Anaphylaxis

ESSENTIAL WORKUP

- History of a possible offending agent and time course of 6–21 days before onset of symptoms
- Physical exam revealing rash as well as joint, muscular, cardiac, neurologic, or renal insult from vasculitic type process

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Decreased complement levels
- CBC, possible eosinophilia
- Elevated ESR
- Hypergammaglobulinemia
- Urine with proteinuria or hematuria

Imaging

Consider CXR.

Diagnostic Procedures/Surgery

Biopsy is the only means of definitive diagnosis.

DIFFERENTIAL DIAGNOSIS

- Vasculitides (e.g., polyarteritis nodosa, Goodpasture, Wegener)
- Rashes (e.g., erythema multiforme, toxic epidermal necrolysis)
- Immunologic (e.g., systematic lupus erythematosus, polymyositis, anaphylaxis)
- Infectious (e.g., tick-borne disease, Rocky Mountain spotted fever, mononucleosis)

TREATMENT

PRE HOSPITAL

- ABC stabilization
- Anaphylaxis treatment as indicated.

INITIAL STABILIZATION/THERAPY

ABCs if a severe systemic reaction is present

ED TREATMENT/PROCEDURES

- Symptomatic relief until the disease spontaneously resolves in 1–13 wk
- Antihistamines
- Antipyretics
- NSAIDs
- Prednisone is controversial

MEDICATION

- Acetaminophen: 325–650 mg PO/PR (peds: 10–15 mg/kg) q4–6h
- Diphenhydramine: 50–100 mg (peds: 5 mg/kg/d, div., max. dose 50 mg/dose or 300 mg/24h) q6–8h
- Hydroxyzine: 25–50 mg (peds: 0.5 mg/kg/dose) q6–8h
- Ibuprofen: 200–800 mg PO (peds > 6 mo: 5–10 mg/kg) q6–8h
- Prednisone: 5–60 mg/d PO (peds: 0.5–2 mg/kg/d), 2-wk taper

FOLLOW-UP

DISPOSITION

Admission Criteria

- Involvement of the airway
- Relapse of symptoms and signs after initial steroids
- Immunosuppression
- Concomitant serious disease

- Sociologic considerations

Discharge Criteria

Stable; most cases are self-limiting.

Issues for Referral

Skin testing with heterologous antisera is performed routinely to avoid anaphylaxis to future administration of heterologous serum.

FOLLOW-UP RECOMMENDATIONS

Primary care follow-up

PEARLS AND PITFALLS

- Identification and cessation of the offending antigen is crucial in the treatment of serum sickness.
- Significant morbidity comes from a failure to diagnose when the serum sickness is not considered on the differential.

SEXUAL ASSAULT

Lauren M. Smith

BASICS

DESCRIPTION

Specific legal definition varies from state to state:

- Nonconsensual completed or attempted penetration between the penis and vulva or penis and anus
- Nonconsensual contact between the mouth and the penis, vulva, or anus
- Nonconsensual penetration of the anal or genital opening with a finger, hand, or object
- Nonconsensual intentional touching, directly or through clothing, of the genitalia, vagina, anus, groin, inner thigh, or buttocks

ETIOLOGY

- Lifetime prevalence of sexual assault in US is 18% in women, 5% in men
- 72% of female rape victims are raped by someone they know; however, men are primarily raped and physically assaulted by strangers and acquaintances, not intimate partners.
- Women who are disabled, pregnant, or attempting to leave their abusers are at increased risk of intimate partner rape.
- Prevalence of sexual assault in men is higher in those who are gay, bisexual, veterans, prison inmates or seeking mental health services
- Nearly 25% of women and 7% of men have been raped or sexually assaulted by a current or former partner.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Victims might not disclose assault:
 - Most will reveal the history only in response to direct questions.
- Tachycardia or pounding heart beat
- Headaches
- Nausea
- Back pain
- Skin problems
- Menstrual symptoms
- Sudden weight change
- Sleeping disorders
- Abdominal pain

- Trouble breathing
- Associated injuries:
 - Of those with injuries, 70% report no injury at presentation.
 - Lacerations of perineum
 - Vulvar trauma
 - Laceration of vaginal wall (more common in younger patients, near introitus)
 - Multiple contusions
 - Abrasions
 - Human bite
 - Lacerations or puncture wound to extremity
 - Burns
 - Depressed skull fracture

Pediatric Considerations

- ~ 54% of rapes of women occur before the age of 18.
- Must follow state laws regarding child abuse
- Most of the physical exams in child sexual abuse cases are normal
- In prepubertal children, an exam will most likely not require a speculum exam. If a speculum exam is warranted, it should be done under sedation; consider involving a sexual assault examiner.
- In interviewing the child, ask open-ended questions.
- Use toys and dolls to have the child explain what happened.
- Early psychiatric intervention is necessary.

Pregnancy Considerations

Women who are pregnant have higher rates of abuse/assault

History

- Obtain complete history even if patient does not wish to file charges, including:
 - Date, time, and place of assault
 - Physical description of assailants
 - Number of assailants
 - Types of penetration: Vaginal, oral, rectal
 - Assailant ejaculation: Ask if assailant used condom
 - Any bodily fluid exchange
 - Use of force, weapons, restraints, drugs, or alcohol
 - Ask if victim has memory loss or loss of consciousness
 - Victim's activity since assault:
 - Changed clothes
 - Douched
 - Bathed

- Urinated
- Defecated
- Eaten
- Tampon use
- Full gynecologic history
- Last voluntary intercourse
- Sperm may be mobile up to 5 days in cervix and 12 hr in vagina
- Address all physical complaints.

Physical-Exam

- Use local evidence kit even if victim is unsure of reporting to police.
- Female chaperone required if male physician
- If clothes soiled, photograph prior to undressing, with patient's consent.
- Note emotional state of victim.
- Note general appearance of clothes:
 - Staining
 - Tears
 - Mud
 - Leaves
 - Wood lamp for seminal stains
 - Have patient disrobe while standing on sheet and place all clothes in paper bag.
- Plastic causes mold and increases bacterial counts.
- Only the patient should handle the clothing.
- Arrange for change of clothes.
- Complete physical exam should be done with emphasis on:
 - Abrasions
 - Lacerations
 - Bites
 - Scratches
 - Foreign bodies
 - Ecchymosis
 - Dried semen on skin
- Forensic collection:
 - Fingernail scrapings
 - Scalp or pubic hair samples
 - If oral penetration, swab between teeth for acid phosphatase (assay for semen) and sperm.
 - Throat culture for *Gonococcus* and *Chlamydia* if oral sex
- Gynecologic exam:
 - Explain all steps and allow patient to pace exam.
 - Comb and collect pubic hair per local protocol.
 - Lubricate speculum with water (not lubricant).

- Look for genital trauma even in asymptomatic patients.
- May use toluidine blue to identify small pelvic lacerations from traumatic intercourse:
 - Best applied to vaginal mucosa at introitus
- Special attention to hymen as 1 of the most common places for trauma
- Lacerations to vaginal wall near introitus more common in younger patients
- Aspirate secretions pooled in posterior fornix and place in sterile container to be examined for sperm and acid phosphates:
 - If no secretions in posterior fornix, wipe with cotton tip.
 - Swab and microscopically examine for sperm and acid phosphates.
- Swab for *Gonococcus* and *Chlamydia*:
 - Controversial; evidence can be used by defense to show promiscuity.
- Colposcope allows visualization of small lesions and enables photography of findings (performed by many sexual assault nurse examiner [SANE] programs)
- Rectal exam and cultures for *Gonococcus* and *Chlamydia* if there was penetration or attempted penetration

ESSENTIAL WORKUP

- Obtain written consent prior to any exam, test, or treatment.
- Allow patient to pause and proceed at comfortable pace.
- Allow advocate to stay with patient during exam with patient's consent.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Syphilis serology
- Hepatitis B and C panel
- HIV testing and counseling
- Drug testing (if suspect victim was drugged, can be used against victim if other agents detected)
- Blood type
- Pregnancy test
- *Gonococcus* culture
- *Chlamydia* culture
- Other labs as needed based on injuries

Imaging

As indicated by injuries

Diagnostic Procedures/Surgery

As indicated by injuries

TREATMENT

PRE HOSPITAL

- Treat patient in a kind, nonjudgmental manner.
- C-spine immobilization for patients with head/neck trauma

INITIAL STABILIZATION/THERAPY

Treat life-threatening injuries.

ED TREATMENT/PROCEDURES

- Place patient in quiet, private room.
- Assure patient of confidentiality regarding name and reason for visit.
- Regularly assure patient of safety.
- Enforce nonjudgmental behavior by staff.
- Designate nursing and medical provider for entire stay who is familiar with evidence collection kit.
- Have SANE perform exam if available.
- Contact community or in-hospital advocate to stay with patient while in ED.
- Alert hospital security to possibility of assailant presenting to ED.
- Contact police if patient consents or local law requires.
- Collect evidence as outlined above and according to local law.
- Offer pregnancy prophylaxis if not currently pregnant
- Administer prophylactic therapy for *Gonococcus*, *Chlamydia*, *Trichomonas*
- Consider prophylactic HIV treatment
- Consider prophylactic therapy or vaccine for hepatitis B

MEDICATION

ALERT

Risk of pregnancy after rape is ~ 5%

Pregnancy Prophylaxis

Hormonal therapy if within 72 hr:

- Levonorgestrel 0.75 mg PO 1st dose stat and repeat in 12 hr (preferred) or Levonorgestrel 1.5 mg PO, single dose
- Ethinyl estradiol 100 µg PO and levonorgestrel 0.5 mg PO 1st dose stat, repeat in 12 hr (less side effects but less effective)

ALERT

All patients should be offered prophylaxis for STIs

STI Prophylaxis

- Ceftriaxone 250 mg IM once or Cefixime 400 mg PO single dose (*Gonococcus*)

- Doxycycline 100 mg PO BID for 7 days *or* azithromycin 1 g PO, single dose (*Chlamydia*)
- Metronidazole (Flagyl) 2 g PO, 1 dose (*Trichomonas*)

ALERT

If PCN allergic, treat with Azithromycin 2 gm po single dose for *Gonococcus* and *Chlamydia*

Hepatitis B

If not already immunized, start hepatitis B vaccination in the ED, HBIG is not required unless assailant is known hepatitis B positive

HIV Prophylaxis

IF WITHIN 72 HR

- **High-risk exposures** (source known to be HIV+ or is an intravenous drug user [IVDU], or history of men having sex with men) – Lopinavir/ritonavir (Kaletra) 200 mg/50 mg 2 tablets twice daily plus emtricitabine/tenofovir (Truvada) 200 mg/300 mg once daily for 28 days
- Emtricitabine/tenofovir (Truvada) 200 mg/300 mg once daily for exposures from persons other than those noted above, or lamivudine plus zidovudine (Combivir) 1 tab po twice a day for 28 days
- If HIV prophylaxis medications are started, baseline CBC, BMP, and LFTs should be obtained.

FOLLOW-UP

DISPOSITION

Admission Criteria

Serious traumatic injury

Discharge Criteria

- Medical follow-up for culture and HIV test results and monitoring of HIV prophylactic medication side effects (if applicable)
- Psychological follow-up
- Safe place for patient to go to

Issues for Referral

- Mental health services and counseling
- For all pediatric cases, the Department of Children and Family Services should be contacted.

FOLLOW-UP RECOMMENDATIONS

Follow-up should be provided for repeat HIV testing at 6 wk, 3 mo, and 6 mo

PEARLS AND PITFALLS

- ~70% of rape victims do not tell their doctors or seeking mental health services
- Most victims will not disclose assault, unless in response to direct questions.
- Most of the pediatric exams in alleged sexual assault cases will be normal (80–96%)
- Extragenital trauma may be more common than genital
- Over 600 SANE/SART(specially trained forensic examiners) programs exist in US; use of a SANE, if available, may improve medical, legal, and psychological care of sexual assault victims

ADDITIONAL READING

SHOCK

Nathan Shapiro • Christopher M. Fischer

BASICS

DESCRIPTION

- Inadequate supply of blood flow to tissues to meet the demands of the tissues
- Tissue oxygen requirements are not fulfilled.
- Toxic metabolites are not removed.
- If untreated, inevitable progression from inadequate perfusion to organ dysfunction and ultimately to death.
- Major categories of shock:
 - Hypovolemic shock:
 - Decreased blood volume
 - Suspect hemorrhage if acute onset
 - Severe dehydration if progressive onset and elevated hematocrit, BUN, and creatinine
 - Obstructive (cardiogenic) shock:
 - Decreased cardiac output and tissue hypoxia with adequate intravascular volume and myocardial dysfunction
 - Venous congestion with increase in central venous pressure
 - Compensatory increase in SVR
 - May be caused by cardiac dysfunction, obstruction to inflow of blood to the heart, or obstruction to outflow of blood from the heart
 - Septic shock:
 - An initial infectious insult overwhelms the immune system.
 - Biochemical messengers (cytokines, leukotrienes, histamines, prostaglandins) cause vessel dilatation.
 - Capillary endothelium becomes disrupted and the vessels leak.
 - Drop in SVR leads to inadequate tissue perfusion.
 - Secondarily, decreased cardiac output from “cardiac stun” resulting in cold septic shock
 - Neurogenic shock:
 - Spinal cord insults disrupt sympathetic stimulation to vessels.
 - Loss of sympathetic tone causes arteriodilating and vasodilatation.
 - Lesions proximal to T4 disrupt sympathetic, spares vagal innervation causing bradycardia.
 - Anaphylactic shock:
 - An antigen stimulates the allergic reaction.
 - Mast cells degranulate.
 - Histamine releases, along with autocooids, stimulate an anaphylaxis

- cascade.
- Vascular smooth muscle relaxes.
- Capillary endothelium leaks.
- Drop in SVR leads to inadequate tissue perfusion.
- Pharmacologic agents may cause shock through smooth muscle dilation or myocardial depression.

ETIOLOGY

- Hypovolemic shock:
 - Abdominal trauma, blunt or penetrating
 - Abortion—complete, partial, or inevitable
 - Anemia—chronic or acute
 - Aneurysms—abdominal, thoracic, dissecting
 - Aortogastric fistula
 - Arteriovenous malformations
 - Blunt trauma
 - Burns
 - Diabetes
 - Diarrhea
 - Diuretics
 - Ruptured ectopic pregnancy
 - Epistaxis
 - Fractures (especially long bones)
 - Hemoptysis
 - GI bleed
 - Mallory–Weiss tear
 - Penetrating trauma
 - Placenta previa
 - Postpartum hemorrhage
 - Retroperitoneal bleed
 - Severe ascites
 - Splenic rupture
- Toxic epidermal necrolysis:
 - Vascular injuries
 - Vomiting
- Cardiogenic shock:
 - Cardiomyopathy
 - Conduction abnormalities and arrhythmias
 - MI
 - Myocardial contusion
 - Myocarditis
 - Pericardial tamponade
 - Pulmonary embolus

- Tension pneumothorax
- Valvular insufficiency
- Ventricular septal defect
- Vasogenic shock:
 - Acute respiratory distress syndrome
 - Bacterial infection
 - Bowel perforation
 - Cellulitis
 - Cholangitis
 - Cholecystitis
 - Endocarditis
 - Endometritis
 - Fungemia
 - Infected indwelling prosthetic device
 - Intra-abdominal infection or abscess
 - Mediastinitis
 - Meningitis
 - Myometritis
 - Pelvic inflammatory disease
 - Peritonitis
 - Pyelonephritis
 - Pharyngitis
 - Pneumonia
 - Septic arthritis
 - Thrombophlebitis
 - Tubo-ovarian abscess
 - Urosepsis
- Anaphylactic:
 - Drug reaction (most commonly to aspirin, β -lactam antibiotics)
 - Exercise (rare)
 - Food allergy (peanuts, tree nuts, shellfish, fish, milk, eggs, soy, and wheat account for 90% of food-related anaphylaxis)
 - Insect sting
 - Latex
 - Radiographic contrast materials
 - Synthetic products
- Pharmacologic:
 - Antihypertensives
 - Antidepressants
 - Benzodiazepines
 - Cholinergics
 - Digoxin
 - Narcotics

- Nitrates
- Neurogenic:
 - Spinal cord injury

DIAGNOSIS

SIGNS AND SYMPTOMS

Generalized shock:

- Hypotension
- Decreased peripheral pulses
- Tachycardia
- Tachypnea
- Decreased urine output
- Diaphoresis
- Obtundation
- Lethargy

History

Standard medical history with a goal of deducing the etiology of the shock and important precipitating factors

Physical-Exam

- Standard physical exam to assist in determining the etiology (e.g., wounds, cardiac exam signs of cellulitis and urticarial rash, etc.)
- Targeted physical exam to focus on the type of shock state:
 - Hypovolemic (classic symptoms):
 - Neck veins are flat.
 - Mucous membranes are dry.
 - Extremities are cold.
 - Cardiogenic shock (classic symptoms):
 - Jugular venous distension is present.
 - Mucous membranes are moist.
 - Extremities are cold.
 - Early septic shock (classic symptoms):
 - Neck veins are flat.
 - Mucous membranes are dry.
 - Extremities are warm.
 - During late shock, extremities may become cold and mottled.

ESSENTIAL WORKUP

- Identify type or types of shock present.
- Identify underlying cause of shock.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Hemoglobin/hematocrit
- WBC:
 - High: Nonspecific marker of infection
 - Low: Neutropenic infections
- Electrolytes
- Blood glucose:
 - High: Diabetic ketoacidosis or septic shock
 - Low: Pediatric sepsis
- Prothrombin time/partial thromboplastin time
- Cardiac enzymes
- Urinalysis
- β -human chorionic gonadotropin
- Lactic acid level:
 - Good surrogate marker of shock state

Imaging

- CXR
- ECG
- Abdominal US
- CT abdomen:
 - Requires that the patient 1st be stabilized
 - In the setting of abdominal trauma and in search for suspicion of abdominal infection

Diagnostic Procedures/Surgery

EKG:

- Assess for ischemia and other disorders of cardiac muscle:
- Electrical alternans or low voltage with cardiac tamponade
- Right-heart strain with pulmonary embolism

TREATMENT

PRE HOSPITAL

- ABCs per standard protocol
- Fluid resuscitation as warranted

INITIAL STABILIZATION/THERAPY

- Large-bore IV access:
 - When possible, central venous access and monitoring

- Fluid resuscitation in noncardiogenic shock patients
- Control bleeding with direct pressure measures.
- Stabilization of a fractured pelvis with sheet or commercial device or external fixation

ED TREATMENT/PROCEDURES

- Hypovolemic shock:
 - _ Identify source of volume depletion
 - _ Aggressive fluid resuscitation keeping systolic blood pressure (SBP) > 100 mm Hg until definitive treatment
 - _ 2–3 L crystalloid initially
 - _ Packed RBCs if 2–3 L crystalloids do not improve SBP
 - _ Identify source of bleeding and rapidly move toward definitive treatment.
 - _ Thoracotomy and aortic cross-clamping in refractory shock with penetrating torso trauma
- Cardiogenic shock:
 - _ Ease work of breathing with intubation
 - _ Insult-specific therapy (e.g., thrombolytics for MI, pericardiocentesis for pericardial tamponade)
 - _ Treat dysrhythmias.
 - _ Vasopressors (norepinephrine or dopamine) as needed
- Septic shock:
 - _ Aggressive crystalloid fluid resuscitation
 - _ Titrate fluid to urine output > 30 cc/hr
 - _ Blood product transfusion to maintain HCT 30–35%
 - _ Early antimicrobial therapy
 - _ Inotropic support as needed
 - _ Norepinephrine as preferred 1st-line infusion
- Anaphylactic shock:
 - _ Intubation for airway compromise
 - _ Epinephrine
 - _ Subcutaneous in noncritical settings
 - _ IV drip for immediate life threats or refractory hypotension
 - _ H1 blockers (diphenhydramine)
 - _ H2 blockers (cimetidine)
 - _ Corticosteroids (hydrocortisone or methylprednisolone)
 - _ Nebulized β 2-antagonists for bronchospasm
 - _ Patients taking β -blockers may be more likely to experience severe symptoms of anaphylaxis
- Pharmacologic shock:
 - _ Decontamination of overdoses with charcoal
 - _ Inotropic agents as needed
 - _ Drug-specific antidotes

- Neurogenic shock:
 - Supportive therapy
 - Traction and fracture stabilization
 - Corticosteroids

MEDICATION

- Albuterol: 2.5 mg/2.5 cc nebulizer PRN
- Calcium gluconate: 100–1,000 mg IV at 0.5–2 mL/min
- Cimetidine: 300 mg IV
- Diphenhydramine: 50–100 mg IV over 3 min
- Dobutamine: 5–40 µg/kg/min IV:
 - Dopaminergic: 1–3 µg/kg/min IV
 - β-effects: 3–10 µg/kg/min IV
 - α/β-effects: 10–20 µg/kg/min IV
 - α-effects: 20 µg/kg/min IV
- Epinephrine:
 - 1–4 µg/min IV infusion
 - Endotracheal 1 mg (10 mL of 1:10,000) once followed by 5 quick insufflations
 - Place 1 mg in 250 mL D₅W = 4 µg/mL
- Glucagon: 1–5 mg IV bolus initial, then 1–20 mg/h infusion
- Hydrocortisone: 5–10 mg/kg IV
- Methylprednisolone: 1–2 mg/kg IV
- Naloxone: 0.01 mg/kg IV initial, titrate to effect
- Norepinephrine: Start 2–4 µg/min IV, titrate up to 1–2 µg/kg/min IV
- Phenylephrine: 40–180 µg/min IV

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients in shock need to be admitted.
- ICU criteria:
 - All patients with persistent shock need ICU monitoring.
- Patients with shock definitively reversed may be admitted to non-ICU setting (e.g., tension pneumothorax that has been decompressed and chest tube placed).

Discharge Criteria

Patients who are in shock should not be discharged home from the ED.

Issues for Referral

- Traumatic hypovolemic shock (hemorrhagic shock) patients may require a trauma center.
- Patients with cardiogenic shock due to MI may require cardiac catheterization or additional cardiac surgery support.
- Septic shock due to necrotizing fasciitis may require advanced surgical support.
- Neurogenic shock with spinal cord injury will require neurosurgical care.

PEARLS AND PITFALLS

- Identify the etiology of shock.
- Aggressively resuscitate the patient, 1st with IV fluids and next with vasopressor support to minimize hypoxic exposure.

ADDITIONAL READING

- 785.51 Cardiogenic shock
- 785.59 Other shock without mention of trauma

ICD10

- R57.0 Cardiogenic shock
- R57.1 Hypovolemic shock
- R57.9 Shock, unspecified

SHOULDER DISLOCATION

Doodnauth Hiranman • Wallace A. Carter

BASICS

DESCRIPTION

- Shoulder is a very dynamic joint, prone to injury.
- Anterior dislocation (90–96%):
 - Injury is from direct or indirect forces on the abducted and externally rotated arm.
 - Injury may also result from a direct blow to posterolateral aspect of shoulder.
- Posterior dislocation:
 - Often missed
 - Forces on the adducted and internally rotated arm result in posterior dislocation of humeral head in relation to glenoid fossa.
 - Most common mechanism is seizure and sudden contraction of all the posterior muscle groups.
 - Other mechanisms include electrocution and direct blow to anterior shoulder.
- Inferior dislocation (rare):
 - Luxatio erecta
 - Hyperabduction of arm, tear of rotator cuff, and rotation of arm 180° above head
 - Commonly seen after a fall from a height:
 - Arm has struck object on descent and is thrust above the head.
 - Often accompanied by neurovascular injury and fracture

Pediatric Considerations

Dislocation is rare in children: Epiphyseal fractures must be suspected.

Geriatric Considerations

Dislocation is often accompanied by fracture.

ETIOLOGY

- Falls from height
- Impact injuries
- Distraction injuries of upper arm
- Seizures
- Electrocution

SIGNS AND SYMPTOMS

- Severe pain in the affected shoulder
- Anterior dislocation:
 - Shoulder is squared off.
 - Prominent acromion process and palpable anterior fullness
 - Arm is held in slight abduction and external rotation.
- Posterior dislocation:
 - Coracoid process is prominent, with a palpable posterior bulge.
 - Arm is held in slight adduction and internal rotation.
- Inferior dislocation (luxatio erecta):
 - Rare but easy to identify
 - Arm is shortened and fixed above head as if raised to ask a question.
- Head of humerus may be palpable on the lateral chest wall.

ESSENTIAL WORKUP

- Evaluate neurovascular status of distal arm.
- Retest neurovascular status after any manipulation.
- Dislocation requires prompt treatment:
 - Incidence of post-traumatic arthritis increases with time dislocation is untreated.
 - Plain films of the shoulder should be obtained immediately.
 - Even in clinically obvious cases, films should be obtained before manipulation, unless a significant delay will result.
 - An impacted humeral head fracture may be converted to a displaced humeral head fracture if manipulated.

DIAGNOSIS TESTS & INTERPRETATION***Imaging***

- At least 2 views should be obtained:
 - Anteroposterior (AP):
 - To visualize dislocation or fracture
 - Trans-scapular Y or axillary view:
 - To visualize if anterior or posterior
- Anterior dislocation:
 - Posterolateral compression fracture of the humeral head (Hill–Sachs deformity)
 - Corresponding lesion on anterior glenoid rim is the Bankart lesion:
 - These do not require treatment.
 - Fractures of the greater tuberosity of the humeral head are seen in 15–35%:
 - If there is > 1 cm displacement after reduction, surgical intervention

may be necessary.

- Posterior dislocation:
 - Often missed on AP film
- Degree of overlap on radiographic film is smaller and displaced superiorly, producing the meniscus sign.
- Rotated humerus yields “light bulb on a stick” finding on AP view:
 - Reverse Hill-Sachs deformity from compression fracture of the anterior medial humeral head may also be seen.

DIFFERENTIAL DIAGNOSIS

- Fracture of the humeral head
- Fracture of the humeral shaft
- Acromioclavicular injury
- Septic shoulder joint
- Hemarthrosis in shoulder joint
- Scapular fracture
- Cervical spine injury

TREATMENT

PRE HOSPITAL

Neurovascular injury should be identified and the arm splinted in the position of most comfort.

INITIAL STABILIZATION/THERAPY

- Airway management and resuscitate as indicated.
- Exclude more serious injuries, especially in multitrauma patient.
- Ensure no injury to axillary nerve or vessels.

ED TREATMENT/PROCEDURES

- Adequate analgesia and muscle relaxation are essential for successful reduction:
 - Procedural sedation with a short-acting opioid and a benzodiazepine *OR*
 - Methohexital or etomidate alone
 - In the cooperative patient, intra-articular block only (20 cc of lidocaine 1% or bupivacaine 0.5%) into shoulder joint
- Anterior dislocation reduction techniques:
 - Scapular manipulation:
 - Patient seated, traction to arm in horizontal plane, countertraction with other hand on clavicle
 - 2nd person adducts tip of scapula medially, moving glenoid fossa
 - Stimson:
 - Patient in prone position with arm dangling over side, hang 10–15 lb around wrist; muscle fatigued over 20–30 min

- Can concurrently use scapular manipulation
- Only 1 person required
- Traction/countertraction:
 - Patient in supine position with continuous longitudinal traction to affected arm
 - Countertraction from sheet wrapped around chest
 - Arm internally or externally rotated if unsuccessful after several minutes
- External rotation:
 - Patient supine; elbow at 90°; gentle, slow external rotation of arm
 - Should be done slowly and with cooperative patient
- Posterior dislocation reduction techniques:
 - May use Stimson or traction/countertraction techniques with manipulation of humeral head anteriorly
- Inferior dislocation (luxatio erecta) reduction techniques:
 - Patient in supine position; gentle longitudinal traction to distract humeral head
 - Gentle countertraction with sheet draped over trapezius and chest
 - Arm slowly rotated from 180–0°
- Postreduction care:
 - Postreduction films
 - Place in sling and swath or shoulder immobilizer immediately after reduction.
 - Shoulder should remain immobilized for 2–3 wk in young patients.
 - Immobilization time should be less in older patients to avoid frozen shoulder.

MEDICATION

- Bupivacaine 0.5%: 20 cc intra-articular to shoulder
- Diazepam: 5–10 mg IV (peds: 0.2 mg/kg)
- Etomidate: 0.2 mg/kg IV (adult and peds)
- Fentanyl: 50–100 µg IV (peds: 2–4 µg/kg)
- Lidocaine 1%: 20 cc intra-articular to shoulder
- Methohexital: 1–1.5 mg/kg IV (peds: Not routinely used)
- Midazolam: 2–5 mg IV (peds: 0.035–0.1 mg/kg)
- Morphine: 2–8 mg IV (peds: 0.1 mg/kg); use preservative-free formulation.
- Propofol: 1–2 mg/kg IV

FOLLOW-UP

DISPOSITION

Admission Criteria

- Failure to reduce shoulder may require admission for reduction under general anesthesia or open reduction.
- Patients with neurovascular compromise

Discharge Criteria

- Patients with successful reductions, confirmed by plain films, may be discharged with shoulder in appropriate immobilizer and with orthopedic follow-up.
- Recurrent dislocation may require elective surgery.
- Patients with residual neurapraxia from injury or manipulation may be safely discharged with instructions that most symptoms will resolve, but should have neurology follow-up.

Issues for Referral

- Patients with residual neurapraxia should be advised to see a neurologist.
- Routine orthopedic consultation should be advised with all successful reductions.

PEARLS AND PITFALLS

Make sure to document sensory exam of axillary nerve prior to reduction.

SICK SINUS SYNDROME

David F. M. Brown • Nirma D. Bustamante

BASICS

DESCRIPTION

- Collective term used to describe dysfunction in the sinus node's automaticity and impulse generation
- Mechanism:
 - Caused by progressive degeneration of the intrinsic functions of the sinoatrial (SA) node
 - Characterized by periods of unexplained sinus node dysfunction leading to bradyarrhythmias, often without appropriate atrial or junctional escape rhythms
- Syndrome includes:
 - Chronic SA nodal dysfunction
 - Frequently depressed pacemakers
 - Arteriovenous nodal conduction disturbances
 - Sluggish return of SA nodal activity after DC cardioversion
- Presents in all age groups (mean age >65 yr)
- Male/female ratio is 1:1

ETIOLOGY

- Intrinsic causes:
 - Most common cause: Idiopathic degenerative fibrosis of sinus node
 - Coronary artery or SA nodal artery disease
 - Cardiomyopathy
 - Ion channel mutations/familial SSS
 - Leukemia and metastatic disease
 - Infiltrative cardiac or collagen vascular disease, including amyloidosis
 - Surgical trauma
- Inflammatory diseases:
 - Rheumatic heart disease
 - Chagas disease
 - Pericarditis and myocarditis
- Extrinsic causes (not true SSS but similar presentation):
 - Drugs:
 - β -blockers, calcium channel blockers, clonidine
 - Digoxin, amiodarone
 - Lithium, phenytoin
 - Autonomically mediated syndromes (cholinesterase deficiency)

- Hyperkalemia/hypokalemia
- Hypothyroidism
- Hypothermia
- Hypoglycemia
- Sepsis/infection

Pediatric Considerations

Associated with congenital abnormalities and subsequent surgical repair, as well as with congenital SA nodal artery deficiency

DIAGNOSIS

SIGNS AND SYMPTOMS

Symptoms represent CNS hypoperfusion from bradydysrhythmia or traditional cardiovascular presentations

History

- Asymptomatic
- Palpitations/fatigue
- Syncope/presyncope/dizziness
- Anginal equivalents (chest pain/SOB)
- Activity intolerance
- Sudden death

Physical-Exam

- Bradycardia
- Alternating bradycardia and atrial tachycardia
- Altered mental status
- Cyanosis
- Transient ischemic attack/stroke

ESSENTIAL WORKUP

- Ascertaining etiology
- 12-lead EKG
- CXR

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Serum electrolytes (including magnesium and calcium)
- Cardiac markers
- Digoxin level, if appropriate

- Thyroid function testing

Imaging

EKG:

- Most common finding: Chronic, inappropriate sinus bradycardia
- Sinus pauses or SA block
- Atrial fibrillation with slow ventricular response
- Prolonged pauses after cardioversion or carotid massage
- Bradyarrhythmias may alternate with supraventricular tachydysrhythmia.
- Tachy-brady syndrome: Bursts of atrial tachycardia interspersed with bradycardia

Diagnostic Procedures/Surgery

Most electrophysiologic studies are no longer recommended due to poor sensitivity and specificity.

DIFFERENTIAL DIAGNOSIS

- Other bradydysrhythmias
- Other tachyarrhythmias: In particular, be careful to distinguish SSS from atrial fibrillation, because DC cardioversion or the use of nodal agents in presumed Afib can be harmful if SA node dysfunction coexists.
- Electrolyte derangements
- Medication toxicity: β -blockers, calcium channel blockers, clonidine, digoxin
- Excessive vagal tone

TREATMENT

PRE HOSPITAL

- Advanced life support transport
- Oxygen supplementation
- Cardiac monitoring
- Atropine if bradycardic and hemodynamically unstable
- Transcutaneous pacing for unstable patients

INITIAL STABILIZATION/THERAPY

- Atropine if a bradydysrhythmia is causing unstable signs/symptoms: Angina, mental confusion, or hypotension
- Transcutaneous pacing if atropine unsuccessful
- If this fails, emergent transvenous pacing

ED TREATMENT/PROCEDURES

Supraventricular tachydysrhythmia alternating with bradycardia:

- Unstable:

- Cardiovert
- Anticipate subsequent profound bradycardia
- Stable patients:
 - Cardiac monitoring
- Digoxin, diltiazem, verapamil, or magnesium can be used for tachydysrhythmia
- Any medication may cause profound bradycardia
- Bradycardia:
 - Discontinuation of medications that alter sinus node function
 - Correct reversible causes of SA nodal depression: O₂, warming, glucose

ALERT

Rewarming is critical in hypothermia as atropine may cause myocardial instability:

- Anticoagulate patients with atrial fibrillation and tachy-brady syndrome.

MEDICATION

- Atropine: 0.5–1 mg IV/ET:
 - Repeat q5min as necessary, max. dose of 0.04 mg/kg (peds: 0.02 mg/kg, min., 0.1 mg)
- Diltiazem: 0.25 mg/kg IV over 2 min followed in 15 min by 0.35 mg/kg IV over 2 min
- Verapamil: 2.5–5 mg IV bolus over 2 min:
 - May repeat with 5–10 mg q15–30min max. 20 mg
 - Peds < 1 yr: 0.1–0.2 mg/kg over 2 min; repeat q30min 1–15 yr: 0.1–0.3 mg/kg over 2 min, max. dose 5 mg/dose, can repeat once.
- Digoxin: 0.5 mg IV initially then 0.25 mg IV q4h until desired effect (max. 1 mg IV)
- Isoproterenol: 2–3 µg/min IV, titrate to goal heart rate/BP, max. 10 µg/min (peds: 0.1 µg/kg/min)—do *not* coadminister with epinephrine and *only* use in unstable patient
- Epinephrine: 1 mg IV (peds: 0.01 mg/kg IV): For cardiac arrest
- Glucagon: 0.05–0.15 mg/kg IV (peds: 0.05–0.10 mg/kg)
- Heparin: Load 80 U/kg IV; infusion at 18 U/kg/h
- Magnesium: 1–2 g IV

First Line

1st-line definitive therapy is a permanent demand pacemaker to provide a “floor” to bradydysrhythmia:

- Patients with additional tachydysrhythmias will require additional nodal agents.

Second Line

No clear evidence to distinguish between 1st- and 2nd-line treatment.

FOLLOW-UP

DISPOSITION

Admission Criteria

- New onset
- Symptomatic: CHF, syncope, chest pain, dizziness
- Persistent bradyarrhythmia or tachydysrhythmia
- Advanced age; > 60 yr
- Patients should be admitted to a telemetry floor with cardiology consultation.
- Most will require permanent pacing.

Discharge Criteria

- Asymptomatic, otherwise healthy patients can be evaluated as outpatients.
- Holter monitoring

Issues for Referral

- Need for formal cardiac electrophysiology evaluation
- Need for permanent pacemaker placement

FOLLOW-UP RECOMMENDATIONS

Geriatric Considerations

- High incidence of CAD is present in patients with sick sinus syndrome, so a complete cardiovascular risk-factor evaluation and prevention is needed.
- Patient with atrial fibrillation and tachy-brady syndrome need long-term anticoagulation.
- All patients require evaluation by a cardiologist or EP specialist for permanent pacemaker.

PEARLS AND PITFALLS

- Patients who are asymptomatic on ED arrival may have normal EKGs. Consider obtaining a rhythm strip or Holter monitor if clinical suspicion remains high.
- Use of any nodal agents (BB, CCB, or digoxin) in patients with SSS-related tachydysrhythmia risks SA block or SA arrest and should only be administered when prepared for transcutaneous pacing.

ICD10

I49.5 Sick sinus syndrome

SICKLE CELL DISEASE

Steven H. Bowman • Marcus E. Emebo • Mary E. Johnson

BASICS

DESCRIPTION

- Sickle cell disease (SCD) is an autosomal recessive hemoglobinopathy characterized by abnormal hemoglobin (HbS) which polymerizes under stress and deforms RBCs, resulting in hemolysis, vaso-occlusion, and subsequent tissue ischemia/infarction
- HbS production secondary to a single amino acid substitution in hemoglobin gene
- Occurs in people of African, Mediterranean, Middle Eastern, and Asian descent; areas where malaria is endemic
- Severity variable even among the same phenotype
- Genotypes and severity in African Americans:
 - HbSS, severe
 - HbSC, mild to moderate severity
 - HbS β -thalassemia, mild to moderate severity
 - HbAS, sickle cell trait:
 - No manifestation of disease
 - At risk for sudden death with extreme physical exertion, severe hypoxia, severe dehydration, or maternal labor
- Chronic hemolytic anemia associated with progressive vasculopathy manifested by systemic and pulmonary hypertension, cholelithiasis, cutaneous leg ulcers, and priapism
- Acute vaso-occlusive crisis (VOC) can occur in essentially any organ systems:
 - Bone/joint crises:
 - Vaso-occlusion of bone microvasculature causes infarction
 - Long bones, ribs, sternum, spine, and pelvis affected
 - Dactylitis, or “hand–foot syndrome,” occurs at ages 6–24 mo
 - Acute chest syndrome:
 - Vaso-occlusion of pulmonary vasculature
 - Fat embolism from infarcted bone marrow and/or infections (viral or bacterial) may contribute
 - Associated *Chlamydia pneumoniae* and *Mycoplasma pneumoniae* isolated in sputum and *Streptococcus pneumoniae* bacteremia
 - High mortality (2–14%)
 - 50% of sickle cell patients will experience at least 1 episode
 - Radiographic pulmonary infiltrate with fever and respiratory symptoms makes it difficult to distinguish from pneumonia
 - More common in children
 - Splenic sequestration:

- Splenic sinusoids become congested with sickled RBCs, obstructing outflow
- Estimated 6–17% of SCD deaths
- Circulatory collapse may be rapidly fatal
- More common in children <5 yr old
- Aplastic crisis:
 - Bone marrow suppression usually occurs secondary to viral infection, most commonly Parvovirus B19
 - Hallmark acute anemia with low reticulocyte count
 - Acute bone marrow suppression significantly worsens chronic anemia
 - Generally self-limited
 - More common in children
- Cerebrovascular accident/transient ischemic attack (CVA/TIA):
 - Secondary to vaso-occlusion by sickled cells and thromboembolism in children and older patients, respectively
 - Children with SCD have a 300-fold increased risk of CVA/TIA
 - Most events occur before the age of 10 and after the age of 29 yr
- Bacterial infection:
 - Sepsis is the leading cause of death in patients with SCD
 - Increased risk of bacteremia, meningitis, and osteomyelitis
 - Impaired splenic function impairs ability to fight encapsulated organisms
 - *S. pneumoniae*, *Haemophilus influenzae*, *Staphylococcus aureus*, *Escherichia coli*, and *Salmonella* are leading organisms
 - Children <5 yr of age have 400-fold increase in pneumococcal infections.
- Priapism:
 - Painful, sustained, unwanted erection > 3 hr
 - More commonly low-flow (ischemic) priapism than high-flow (nonischemic)

Pediatric Considerations

- Acute sickle cell complications in children carry high morbidity and should be screened for aggressively
- Infections commonly precipitate crisis
- Confirm immunization history (pneumococcal and *H. influenzae* type b)
- Determine if child is receiving prophylactic penicillin, normally indicated in children ≤5 yr old
- Overwhelming infection highest in children <3 yr of age

Pregnancy Considerations

- Variable frequency of crisis episodes, not uncommon for increased frequency

- Anemia is more profound
- Increased rates of hypertensive disorders of pregnancy, asymptomatic bacterial infections, UTI, and pyelonephritis leading to septicemia
- Increased risk of spontaneous abortions, antepartum bleeding, and premature rupture of membranes
- Increased risk of preterm labor, intrauterine growth restriction, and low birth weight

ETIOLOGY

Common crisis precipitants:

- Infection (bacterial and viral)
- Dehydration
- Hypoxemia
- Acidosis
- Emotional stress
- Surgery/trauma
- Weather changes
- Pregnancy
- Toxins

DIAGNOSIS

SIGNS AND SYMPTOMS

- May present with either:
 - Pain crisis
 - Complications of the disease
 - Combination of above
- May not demonstrate usually autonomic signs of acute pain
- Sickle cell pain crisis:
 - Bone/joint crisis:
 - Pain in extremities, back, sternum, or joints
 - Variable extremity and joint swelling/warmth
 - Hand–foot syndrome in infants; swelling in hands and feet and a reluctance to walk or use hands
 - Abdominal crisis:
 - Abdominal pain without peritonitis
 - Variable nausea, vomiting, diarrhea
 - Priapism: Prolonged painful erection
- Complications/progression of disease:
 - Acute chest syndrome:
 - Chest pain
 - Fever
 - New pulmonary infiltrates on chest radiographs

- Respiratory symptoms
- Hypoxemia
- Splenic sequestration crisis:
 - Abdominal pain, splenomegaly
 - Fatigue, lethargy, pallor
 - Hypotension, tachycardia, syncope, shock
- Aplastic crisis:
 - Variable fever, headache, nausea, vomiting
 - Fatigue, pallor, tachycardia
- CVA/TIA:
 - Focal neurologic deficit
 - Mental status changes
 - Seizure

History

- Genotype
- Onset of current symptoms
- Previous crises
- Immunizations
- Surgical history
- Determine typical vs. atypical crisis

Physical-Exam

Conduct a thorough physical exam:

- Vital signs: BP, HR, temperature, O₂ saturation
- General appearance: Jaundice, pallor
- Cardiopulmonary exam:
 - Rales, wheezing, tachypnea
 - Peripheral edema, elevated JVD
 - Gallops, murmurs
- Abdominal exam:
 - Organomegaly, tenderness, peritonitis
- Musculoskeletal exam
 - Erythema on extremities
 - Warm, swollen hands and feet in children
- Neurologic exam:
 - Focal neurologic impairment
 - Cranial nerve palsy

ESSENTIAL WORKUP

Conduct a thorough physical exam, with focus on signs of infection or ischemia.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - Compare Hb with prior values if available
 - Leukocytosis is common and does not necessarily indicate infection
- Reticulocyte count is generally elevated in SCD individuals, and decreased with aplastic crisis
- Complete metabolic panel (CMP):
 - Be aware that creatinine may appear normal despite baseline chronic renal dysfunction
 - Elevated total bilirubin levels may indicate intravascular hemolysis
- Markers of hemolysis (total bilirubin, haptoglobin, and LDH) may be present at variable degrees
- Serial arterial blood gases and A-a gradients helpful in acute chest syndrome
- Cultures: Blood, urine, throat, and CSF (if indicated)
- Type and screen (or cross)
- Urine pregnancy test in women

Imaging

- Radiographs should be directed to confirm diagnosis:
 - Chest radiograph if pneumonia or acute chest syndrome suspected
 - Extremity radiographs if osteomyelitis suspected
- IV contrast may exacerbate or precipitate a crisis
- Head CT/MRI to evaluate stroke

Diagnostic Procedures/Surgery

- Lumbar puncture if CNS infection or subarachnoid hemorrhage is suspected
- Arthrocentesis for acute arthritis

DIFFERENTIAL DIAGNOSIS

- Sick cell crises may mimic or obscure more serious underlying pathology (e.g., acute abdomen, MI, PE, nephrolithiasis)
- Suspect other diagnoses if pain is more severe or atypical

TREATMENT

INITIAL STABILIZATION/THERAPY

- Identify and treat high morbidity complications
- Establish venous access
- Assess pain and initiate therapy

ED TREATMENT/PROCEDURES

- Choice of analgesics dependent on patient, severity of presentation, and prior agents:
 - Reassess pain frequently (e.g., every 15–30 min) and titrate until improvement
 - IV opiates (e.g., morphine, hydromorphone, fentanyl) 1st line, consider adjunct agents
 - Adjuncts: Acetaminophen, NSAIDs (use with caution given impaired renal function)
 - Caution with meperidine as metabolites may accumulate and pose seizure risk
 - If no venous access, PO and subcutaneous analgesics preferred over IM
- Hydration:
 - Oral hydration if patient tolerating po
 - Parenteral IV solution 0.45% NS for adults and children or 0.2% NS for infants
 - Avoid over-hydration, at risk for:
 - Hyperchloremic metabolic acidosis which promotes RBC sickling
 - Atelectasis which precipitates acute chest syndrome
- Complication-specific therapy:
 - Acute chest syndrome:
 - Oxygen, bronchodilators, incentive spirometer
 - Consider exchange transfusion for worsening respiratory symptoms, hypoxemia, and increasing A–a gradient
 - Splenic sequestration:
 - Simple transfusion, promotes remobilization of RBCs
 - Be aware risk of precipitating VOC after raising Hb levels
 - Ideal treatment is prevention: Chronic transfusions, splenectomy
 - Aplastic crisis:
 - Simple transfusion
 - Isolation from pregnant healthcare workers
 - Priapism:
 - 1st line: Intracavernosal aspiration with α -adrenergic agonist (e.g., epinephrine, terbutaline) irrigation
 - 2nd line: Exchange transfusion if failed aspiration
 - Empiric antibiotics: Sepsis, pneumonia, and osteomyelitis
 - Exchange transfusion may be required for complications such as CVA and priapism
- Consultations:
 - Hematology especially if exchange transfusion required
 - Neurology/neurosurgery for acute CNS events
 - Urology for priapism

FOLLOW-UP

DISPOSITION

Admission Criteria

- Refractory pain
- Complications: Acute chest syndrome, sequestration crisis, aplastic crisis, CVA/TIA, refractory priapism
- Signs of bacterial infection or fever of undetermined etiology
- Symptomatic anemia
- ICU admission for hemodynamic instability, worsening hypoxemia in acute chest syndrome, and severe acute CNS events.

Discharge Criteria

- Resolution of pain crisis
- No indications for admission
- Follow-up arranged with hematologist

Issues for Referral

Meticulous primary care can limit the frequency and severity of pain crises.

FOLLOW-UP RECOMMENDATIONS

If discharged, patient should see PCP or hematologist in 1–2 days.

PEARLS AND PITFALLS

- Distinguish typical sickle cell crisis from acute life-threatening complications
- Treat pain aggressively with appropriately selected and administered analgesic agents
- Patients with acute pain may not demonstrate typical signs, such as tachycardia or diaphoresis

- D57.40 Sickle-cell thalassemia without crisis

SINUSITIS (RHINOSINUSITIS)

Cory A. Siebe • Maria E. Moreira

BASICS

DESCRIPTION

- Inflammation of mucous membranes lining the paranasal sinuses and nasal passages with or without fluid collection in the sinus cavities
- Classifications:
 - Acute: Signs and symptoms for < 4 wk
 - Subacute: Signs and symptoms for 4–8 wk
 - Chronic: Signs and symptoms for > 8 wk in spite of antibiotic treatment
 - Recurrent: 3 or more episodes per year

ETIOLOGY

- Acute rhinosinusitis pathophysiology:
 - Viral upper respiratory infection or allergies causes mucous membrane inflammation
 - Inflammation causes obstruction of sinus ostia, decreased mucociliary clearance, and thickening of secretions
 - Viruses are the primary cause, but 0.5–2.2% develop into bacterial infection after bacteria become trapped and multiply, resulting in suppuration
 - Nosocomial rhinosinusitis associated with nasogastric and nasotracheal tubes
 - Immunocompromised patients at higher risk for rhinosinusitis
- Subacute and chronic rhinosinusitis pathophysiology:
 - Multifactorial, role of bacteria remains elusive
 - Allergic inflammation causing narrowed ostia and blocked drainage
 - Immune dysfunction leading to increased infectious risk
 - Impaired ciliary function leading to decreased mucous clearance
 - Odontogenic infection causing maxillary sinusitis
 - Fungus ball
 - Anatomical obstruction or polyps obstructing sinus ostia
- Microbiology:
 - Acute rhinosinusitis:
 - Nontypable *Haemophilus influenzae*
 - *Streptococcus pneumoniae*
 - *Moraxella catarrhalis*
 - *Staphylococcus aureus*
 - Anaerobes
 - Viruses: Parainfluenza, adenovirus, rhinovirus, influenza

- Chronic rhinosinusitis:
 - Same as acute, often polymicrobial, with increasing anaerobes and gram negatives
- Nosocomial rhinosinusitis:
 - *S. aureus*
 - Streptococcal species
 - *Pseudomonas*
 - *Klebsiella*
- Immunocompromised patients with rhinosinusitis:
 - Bacteria as above
 - Fungal pathogens (*Aspergillus*)

Pediatric Considerations

- Nontypable *H. influenzae* more common than *S. pneumoniae* as cause of acute bacterial rhinosinusitis in children
- Ethmoid and maxillary sinuses present at birth
- Frontal and sphenoid sinuses do not emerge until age 6–7 yr
- Rhinosinusitis more common in children
- Periorbital/orbital cellulitis is a common complication of ethmoid rhinosinusitis in children:
 - Periorbital swelling, fever, ptosis, proptosis, and painful or decreased extraocular movements

DIAGNOSIS

SIGNS AND SYMPTOMS

- Facial–dental pain, headache, halitosis, hyposmia, cough
- Purulent nasal discharge and postnasal drainage
- Fever
- Frontal sinusitis:
 - Pain of the lower forehead
 - Pain worsened when lying on the back; improves when upright
- Maxillary sinusitis:
 - Malar facial pain
 - Maxillary dental pain
 - Referred ear pain
 - Pain worsens with head upright or bending forward and improves with reclining
- Ethmoid sinusitis:
 - Retro-orbital pain
 - Periorbital edema
- Sphenoid sinusitis (very uncommon):

- Pain over the occiput or mastoid
- Pain worse when lying on back or bending forward

History

- Acute viral rhinosinusitis:
 - Symptoms typically resolve in 7–10 days
- Acute bacterial rhinosinusitis needing antibiotic treatment can present in 3 different patterns:
 - Pattern 1: Persistent symptoms lasting > 10 days without improvement
 - Pattern 2: Severe symptoms or:
 - Temperature $\geq 39^{\circ}\text{C}$ and purulent nasal discharge for 3–4 days at the beginning of illness
 - Pattern 3: Worsening symptoms:
 - Return of symptoms after a 5–6- day duration of upper respiratory infection that was improving
- Other important history:
 - Symptom history and time course
 - Allergy history
 - Recent NG or NT tube placement
 - Immunocompromised state

Physical-Exam

- Vital signs, toxic/nontoxic appearance
- Edema of the nasal mucous membranes and turbinates
- Purulence in the nares or posterior pharynx
- Warmth, tenderness, or cellulitis over sinus
- Sinus tenderness on palpation
- Periorbital edema
- Failure of transillumination of maxillary sinuses:
 - Observed through the palate
- Dental exam revealing abscess or tenderness of maxillary teeth

ESSENTIAL WORKUP

- Clinical diagnosis based on history and physical exam
- Determine if patient fits pattern of acute bacterial rhinosinusitis that should be treated with antibiotics (see “History”)

DIAGNOSIS TESTS & INTERPRETATION

Lab

Lab studies not helpful for diagnosis or management

Imaging

- Imaging unnecessary in uncomplicated cases
- Plain-film radiography:
 - Normal films do not exclude bacterial cause
 - Waters view can be ordered, but has moderate sensitivity in diagnosing maxillary sinus abnormality and poor sensitivity in diagnosing lesions in other sinuses
 - Odontogenic maxillary sinusitis may be missed by dental exam and panorex films, but is apparent as periapical lucency on cone beam CT or sinus CT
- CT:
 - Preferred if imaging is necessary
 - Warranted in patients with complicated rhinosinusitis, severe headache, seizures, focal neurologic deficits, periorbital edema, or abnormal intraocular muscle function
 - IV contrast if concern for osteomyelitis or abscess

Diagnostic Procedures/Surgery

- Sinus aspirate culture:
 - Gold standard for making a microbial diagnosis but not routinely performed
- Culture of discharge may have benefit but remains unstudied and is not typically performed
- Functional endoscopic sinus surgery (FESS):
 - Restores physiologic sinus drainage

Pediatric Considerations

FESS is a safe and effective treatment in children

DIFFERENTIAL DIAGNOSIS

- Uncomplicated viral or allergic rhinitis
- Otitis media
- Dacryocystitis
- Migraine and cluster headache
- Dental pain
- Trigeminal neuralgia
- Temporomandibular joint disorders
- Giant cell arteritis/temporal arteritis
- Rhinitis medicamentosa (decongestants, β -blockers, antihypertensives, birth control pills)
- Nasal polyp, tumor, or foreign body
- CNS infection
- Granulomatous or ciliary disease
- Aspergillosis
- Rhinocerebral mucormycosis:
 - Rare rapidly progressive fungal infection

- Occurs in diabetics and the immunocompromised
- Orbital/facial pain out of proportion to exam
- Lethargy, headache in a systemically ill-appearing patient
- Black eschar or pale area on the palate or nasal mucosa

Pregnancy Considerations

- Rhinitis of pregnancy:
 - Estrogen has cholinergic effect on mucosa
 - Worse during 3rd trimester
 - Resolves within 2 wk postpartum

TREATMENT

PRE HOSPITAL

No special considerations

INITIAL STABILIZATION/THERAPY

Toxic-appearing patients may require airway management and fluid resuscitation.

ED TREATMENT/PROCEDURES

- Identifying rhinosinusitis needing antibiotics
- Counseling and reassurance to patients requesting antibiotics for mild symptoms <10 days duration

MEDICATION

- Nonantibiotic therapies:
 - Pain control
 - Saline nasal irrigation may be beneficial
 - Oral corticosteroids as adjunctive to oral antibiotics are effective, but data limited
 - Intranasal steroids recommended as adjunct to antibiotics primarily in those with allergies:
 - Beclomethasone dipropionate: 1 spray per nostril QD/TID/BID
 - Dexamethasone sodium phosphate: 2 sprays per nostril BID/TID
 - Antihistamines recommended for patients with underlying allergy
 - Nasal or oral decongestants not recommended (phenylephrine, pseudoephedrine, oxymetazoline)
 - Expectorants may be helpful:
 - Guaifenesin:
 - Adult: 200–400 mg PO; not > 2.4 g/24 h
 - Peds 2–5 yr: 50–100 mg PO; not > 600 mg/24 h;
 - Peds 6–11 yr: 100–200 mg PO; not > 1.2 g/24 h

- **Antibiotics:**
 - Amoxicillin–clavulanate: 250–500 mg PO TID or 875 mg PO BID (peds: 40 mg/kg/d, based on the amoxicillin component)
 - If high risk (systemic toxicity w/fever $\geq 39^{\circ}\text{C}$, attendance at daycare, age < 2 or > 65 yr, recent hospitalization, abx use in last month, or immunocompromised) use amoxicillin–clavulanate: 2 g PO BID (peds: 90 mg/kg/d, based on amoxicillin component)
 - Doxycycline: 100 mg PO BID (alternative for initial empiric therapy in adults)
- 2nd- and 3rd-generation oral cephalosporins no longer recommended for empiric monotherapy due to resistance among *S. pneumoniae*. Can use following combination:
 - Cefpodoxime: 200–400 mg PO BID (peds: 10 mg/kg/d PO BID) or
 - Cefuroxime: 250–500 mg PO BID (peds: 15 mg/kg/d PO BID) +
 - Clindamycin: 150–300 mg PO q6h (peds: 8–16 mg/kg/d PO split q6–8h, MRSA-suspected use 40 mg/kg/d PO split q6–8h)
- Macrolides (clarithromycin and azithromycin) not recommended due to high rates of resistance amongst *S. pneumoniae* (30%)
- Trimethoprim–sulfamethoxazole (TMP/SMX) not recommended due to high rates of resistance among *S. pneumoniae* and *H. influenzae* (30–40%)
- Type 1 penicillin allergy:
 - Levofloxacin: 500 mg PO per day (peds: 8 mg/kg) children under 50 kg max. dose 250 mg/d. Children over 50 kg max. dose 500 mg/d.
 - Moxifloxacin: 400 mg PO per day (adult)
- If symptoms not improved after 3–5 days of 1 antibiotic, switch to another antibiotic
- Recommended duration of therapy:
 - Acute: 10–14 days in children; 5–7 days in adults
 - Chronic: 3–6-wk course of antibiotics (controversial), douche, and nasal steroids

First Line

Supportive care

Second Line

Antibiotics

FOLLOW-UP

DISPOSITION

Admission Criteria

- Evidence of spread of infection beyond the sinus cavity or toxic-appearing patients
- Immunocompromised/diabetic patients with extensive infection
- Multiple sinus or frontal sinus involvement
- Extremes of age
- Severe comorbidity
- ENT evaluation and aspiration if patient is severely ill, immunocompromised, or has pansinusitis and is ill-appearing

Discharge Criteria

Most cases of uncomplicated rhinosinusitis may be managed on an outpatient basis.

Issues for Referral

- Complications of acute infection
- Immunocompromised patients
- Chronic rhinosinusitis or nasal polyps
- Concerns for osteomyelitis, CNS infection, or abscess
- Acute rhinosinusitis–aspergillosis

FOLLOW-UP RECOMMENDATIONS

If patient has no relief with initial treatment and nonantibiotic therapies, follow up with PCP or ENT.

PEARLS AND PITFALLS

- Patients presenting with < 10 days of mild symptoms should be treated with supportive care
- Patients presenting with ≥ 10 days of symptoms, severe symptoms at 4–5 days with fever, or worsening after initial improvement can be diagnosed with acute bacterial rhinosinusitis and should be treated with antibiotics
- Term rhinosinusitis preferred, since inflammation of sinuses rarely occurs without inflammation of the nasal mucosa

CODES

ICD9

- 461.9 Acute sinusitis, unspecified
- 473.0 Chronic maxillary sinusitis
- 473.9 Unspecified sinusitis (chronic)

ICD10

- J01.90 Acute sinusitis, unspecified
- J32.0 Chronic maxillary sinusitis
- J32.9 Chronic sinusitis, unspecified

SKIN CANCER

John J. D'Angelo

BASICS

DESCRIPTION

- Most common cancer in US
- Increasing incidence
- 1 in 6 will have skin cancer during their lifetime
- Actinic keratosis:
 - Premalignant lesion
 - Thickened scaly growth caused by sunlight or other artificial light source
 - Found on areas of body with high sun exposure
 - 0.1–10% may transform into squamous cell carcinoma (SCC)
- Nonmelanoma skin cancer:
 - Less commonly fatal
 - Fast growing
 - May be destructive if left untreated
 - Basal cell carcinoma (BCC):
 - Cells arise from epidermis
 - Most common skin cancer
 - Account for 75% of all nonmelanoma skin cancers
 - Male > female, 3:2.
 - Locally invasive without risk of distant metastasis
 - Most important risk factor is sun exposure
 - More common in fair-skinned patients
 - Most lesions are on the head and neck
 - SCC:
 - 2nd most common skin cancer
 - 20% of cases of skin cancer
 - Most arise from precancerous actinic keratosis lesions
 - Male > female
 - Most important risk factor is sun exposure, especially sunburn
 - 70% occur on head and neck
 - More common in older, fair-skinned patients
 - Risk of regional lymph node and distant metastasis
 - SCC lesions of mucosal surfaces are more aggressive
- Melanoma:
 - 5% of all diagnosed skin cancer in US
 - 62,000 new cases in 2008
 - 15% are fatal

- 75% of skin cancer cause deaths
- Arises from melanin-producing cells
- Most important risk factor is sun exposure, especially sunburn
- Additional risk factors:
 - Fair skin; blond/red hair
 - Multiple common melanocytic nevi
 - Atypical nevi
 - Immunosuppression
 - Positive family history
 - History of nonmelanoma skin cancer (BCC or SCC)
 - ≥ 5 sunburns in early life doubles the risk for malignant melanoma
- Risk of regional lymph node and distant metastasis

ETIOLOGY

- UV irradiation:
 - Both UVA and UVB rays
 - Sun exposure
 - Tanning beds
- SCC often associated with human papilloma virus (HPV)
- Immunosuppression may predispose to SCC
- Vitamin D metabolism may play a role

DIAGNOSIS

SIGNS AND SYMPTOMS

- Actinic keratosis:
 - Rough, pink, circumscribed lesions < 1 cm in diameter
 - A lesion may have both actinic keratosis and SCC
- BCC:
 - May be single or multiple
 - Usually painless
 - Usually appears in sun-exposed areas of skin
 - Erosion or bleeding with mild trauma may be 1st symptoms
 - Nodular BCC:
 - Most common
 - Waxy or pearly papule, possibly with telangiectasia
 - Well-demarcated borders
 - May have central ulceration
 - Pigmented BCC:
 - Similar to nodular BCC with brown, blue, or black coloration
 - Often mistaken for superficial spreading or nodular melanoma
 - Cystic BCC:
 - Bluish/gray cystic nodules

- May be mistaken for benign cysts
- Superficial BCC:
 - Scaly patch-like or papule surrounded by small, clear micropapules
 - Pink, red, or brown
- Micronodular BCC:
 - Well-defined border
 - Aggressive
 - Rarely with ulceration
- Morpheaform BCC:
 - Poorly defined borders
 - May appear “scar like”
 - Aggressive
 - Ulceration and bleeding are rare
- SCC:
 - Characteristic lesion is raised, firm, keratotic papule or plaque
 - Often enlarging
 - Usually asymptomatic but may be ulcerated and painful as invasion occurs
 - Ulcers often crust and ooze
 - Cranial nerve involvement may indicate an aggressive tumor with perineural invasion:
 - Facial numbness, asymmetry, weakness, or pain
- Melanoma:
 - Pigmented skin lesion:
 - 2% will be amelanotic
 - Features suggestive of melanoma (the *ABCDEs* of melanoma):
 - Asymmetry (not regularly round or oval)
 - Border irregularity (notched or poorly defined)
 - Bleeding (spontaneous)
 - Color variegation (shades or combinations of brown, tan, red, white, or blue-black)
 - Diameter > 6 mm
 - Elevation/Enlargement
 - Lesions rarely symptomatic unless ulcerated
 - Superficial spreading melanoma:
 - 70% of all malignant melanomas
 - May have a wide variety of colors
 - Often arise from dysplastic nevus
 - Usually < 3 cm
 - Slight elevation and induration is common
 - Often have satellite lesions
 - Nodular melanoma:
 - 10–15% of melanomas
 - The most symmetric of the different melanomas

- Dark brown or black
- Often exophytic
- Lentigo maligna melanomas (LMM):
 - Always starts as *lentigo maligna*, a macular insitu malignancy which is an evolving lesion of melanoma
 - *LMM* occurs after the lesion begins vertical growth into the dermis – typically indicated by papular or nodular areas
 - Irregular shape and multiple colors
- Acral lentiginous melanoma:
 - Equal among black and white patients
 - Most common form of melanoma found in Asians and African Americans
 - Occur on palms, soles, and subungual region with predilection for soles of feet
 - May be mistaken for subungual hematoma
 - Involvement of the proximal nail fold (Hutchinson sign) is an indicator of melanoma
- Mucosal lentiginous melanoma:
 - Develops from mucosal epithelium in respiratory, GI, and GU tracts
 - Often diagnosed at a later stage of disease
 - Very rare
- Metastatic melanoma:
 - Presentation related to affected organ system
 - Lymphangitic spread with local to regional lymphadenopathy
 - Typical visceral sites of hematogenous spread include liver, lung, bone, brain, and intestines

ESSENTIAL WORKUP

All suspicious lesions require biopsy, a procedure rarely done in ED

DIAGNOSIS TESTS & INTERPRETATION

Lab

No specific testing is required

Imaging

- CXR may show pulmonary involvement by metastatic melanoma
- Head or body CT scan may show visceral involvement by metastatic SCC or melanoma
- Cross-sectional imaging does not rule out metastasis

Diagnostic Procedures/Surgery

Biopsy usually performed by consultant

DIFFERENTIAL DIAGNOSIS

- For BCC:
 - SCC
 - Bowen disease
 - Actinic keratosis
 - Paget disease
 - Benign nevus
 - Melanoma
- For SCC:
 - Actinic keratosis
 - BCC
 - Keratoacanthoma
 - Melanoma
 - Wart
- For melanoma:
 - Atypical nevus
 - Common nevus
 - Actinic keratosis
 - Pigmented BCC
 - SCC

TREATMENT

PRE HOSPITAL

No specific pre-hospital care is required

INITIAL STABILIZATION/THERAPY

- No specific stabilization is usually required beyond basic wound care
- Stabilization may be required for invasion into vascular structures or edema from intracranial metastasis

ED TREATMENT/PROCEDURES

- Skin lesions themselves require no specific ED treatment
- Treat complications of visceral involvement by metastatic melanoma, SCC or locally invasive BCC.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Admission typically only occurs due to complications associated with visceral

involvement or invasive spread

- Admission is rarely required because of the dermatologic lesions themselves

Discharge Criteria

Patients are generally discharged with instructions on obtaining biopsy and/or further evaluation

Issues for Referral

Discharged patients should be advised to consult a dermatologist or primary care physician experienced with skin biopsy.

FOLLOW-UP RECOMMENDATIONS

- Biopsy is required for diagnosis of skin cancer
- Urgent follow-up with dermatologist or primary care physician is advised
- Ensure adequate documentation of conversation with patient regarding urgency of follow-up
- Patients with nonmelanoma skin cancer have a 30–50% chance of developing additional skin cancer within 5 yr

PEARLS AND PITFALLS

- Advise patient to obtain urgent follow-up for any suspicious lesion
- 1 in 6 people will have skin cancer during their lifetime
- Protection from UVA and UVB rays is key to preventing skin cancer

SLEEP APNEA

Ajay Bhatt

BASICS

DESCRIPTION

- Disorder characterized by cessation of breathing during sleep:
 - Defined as apneic episodes > 10 sec with brief EEG arousals or > 3% oxygenation desaturation
- Risk factors:
 - Obesity
 - Male
 - > 40 yr of age
 - Upper airway anomalies
 - Myxedema (hypothyroidism)
 - Alcohol/sedative abuse
 - Smoking
- Associated illness:
 - Various dysrhythmias, particularly atrial fibrillation and bradyarrhythmia
 - Right and left heart failure
 - MI
 - Stroke
 - Motor vehicle accidents
 - Hypertension poorly controlled by medical therapies

EPIDEMIOLOGY

- Affects about 9% of middle-aged men and 4% of middle-aged women
- 80% of moderate or severe cases undiagnosed in middle-aged adults

ETIOLOGY

3 classifications of sleep apnea:

- Obstructive (84%) is due to upper airway closure despite intact respiratory drive:
 - Also known as Pickwickian syndrome
 - Pharyngeal airway is narrowed
- Central (0.4%) is due to lack of respiratory effort despite patent upper airway.
- Complex (15%) is due to a combination of obstructive and central sleep apnea.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Excessive daytime sleepiness

- Snoring
- Irritability

History

- Significant other apnea report
- Difficulty sleeping
- Decreased attention/concentration
- Depression
- Decreased libido/impotence

Physical-Exam

- Hypertension, hypoxemia
- Obesity
- Craniofacial anomalies
- Macroglossia
- Enlarged tonsils
- Elevated jugular veins (secondary to pulmonary hypertension)
- Large neck circumference

ESSENTIAL WORKUP

- Pulse oximetry
- ECG
- Chest radiograph

DIAGNOSIS TESTS & INTERPRETATION

Lab

ABG is the best test to demonstrate hypercarbia and hypoxemia.

Imaging

- Consider lateral neck soft tissue radiograph to rule out other etiologies of upper airway obstruction.
- Chest radiograph to assess other etiologies of hypoxemia
- Chest CT rarely indicated

Diagnostic Procedures/Surgery

Polysomnogram (PSG) is required for diagnosis:

- > 5 apneic episodes per hour
- Not a consideration for ED management

DIFFERENTIAL DIAGNOSIS

- Asthma
- Cheyne–Stokes breathing

- COPD
- Diaphragmatic paralysis
- High altitude–induced periodic breathing
- Hypothyroidism
- Left heart failure
- Narcolepsy
- Obesity hyperventilation syndrome
- Primary pulmonary hypertension

TREATMENT

PRE HOSPITAL

Caution not to overventilate patient with chronic CO retention

INITIAL STABILIZATION/THERAPY

Chin lift/jaw thrust maneuver, oxygen as needed, oral or nasal airway devices

ED TREATMENT/PROCEDURES

- Proper technique is required for airway management:
 - Supplemental oxygen as needed
 - Bag-valve-mask ventilation may be difficult:
 - Consider the use of nasal and oral airways
 - 2-person technique to ensure a good seal
- Continuous positive airway pressure (CPAP) is the standard of treatment:
 - Acts as a pneumatic splint by maintaining upper airway patency
 - BiPAP is an alternative for patients requiring high pressures or with comorbid breathing disorders.
 - Long-term CPAP therapy decreases BP, insulin resistance, metabolic syndrome, and risk of cardiovascular disease.

ALERT

Endotracheal intubation

- Higher prevalence of difficult intubation:
 - Patients frequently have higher Mallampati scores.
 - Excess pharyngeal tissue in lateral walls often obstructs airway visualization.
 - Patients have overall lower arterial oxygen saturation.
- Plan and consider several methods of definitive airway control:
 - Have alternative devices (laryngeal mask airway, bougie) available.
 - Be prepared to perform cricothyroidotomy if necessary.
- Use neuromuscular blockade only if successful oral intubation is reasonably likely

and bag-mask ventilation is easy.

- Positive end-expiratory pressure for ventilated patients

MEDICATION

- Insufficient evidence to recommend any medication for treatment
- See Airway Management for details on induction agents and neuromuscular blockade.
- Wakefulness-promoting agents (modafinil and armodafinil) are approved as an adjunct to CPAP patients with excessive sleepiness.

ALERT

Avoid sedative use:

- Relaxes the upper airway and worsens airway obstruction and snoring

Long-term Management

- Gold Standard
 - CPAP compliance and weight loss strongly recommended by the American College of Physicians
- Surgical considerations:
 - Most intend to reduce or bypass the excessive pharyngeal/airway resistance that occurs during sleep.
 - Efficacy is unpredictable; no good randomized trials
 - Not a consideration for ED management
- Dental devices:
 - Currently recommended by the American Academy of Sleep Medicine (AASM)
 - Available appliances include tongue repositioning and mandibular devices or soft-palate lifters.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Ventilatory failure, especially if intubation is necessary
- Hemodynamic instability

Discharge Criteria

- Maintenance of O₂ saturation > 85% for several hours using oxygenation or ventilation equipment available to the patient at home
- Very low likelihood of decompensation overnight
- Patients with sleep apnea who present after motor vehicle crashes:

- Manage initially like other blunt trauma patients.
- Later, consider the increased risk with sleep apnea and intervene to prevent future accidents.

FOLLOW-UP RECOMMENDATIONS

- PCP referral for sleep apnea and associated comorbidities
- Encourage compliance, use of CPAP
- Referral of patients with suspected sleep apnea to a pulmonologist
- Encourage weight loss and diet control
- Cardiology referral is appropriate when sleep apnea is complicated by heart failure or dysrhythmias.

PEARLS AND PITFALLS

- Sleep apnea increases risk of cardiovascular disease, stroke, and diabetes mellitus.
- CPAP is the standard of treatment.
- Avoid the use of sedatives.
- Preparation is essential, as sleep apnea increases intubation complications.
- Primary care referral and CPAP compliance education improve therapy.

SLIPPED CAPITAL FEMORAL EPIPHYSIS

Virag Shah

BASICS

DESCRIPTION

- Femoral epiphysis translates (slips) posteriorly and inferiorly relative to the femoral head/neck
- Classification systems:
 - Degree of femoral head “slip” as a percentage of femoral neck diameter:
 - (Mild, grade 1) < 33.3%
 - (Moderate, grade 2) 33.3–50%
 - (Severe, grade 3) > 50%
 - Temporal:
 - Acute: < 3 wk of symptoms
 - Chronic: > 3 wk of symptoms
 - Acute on chronic: > 3 wk of symptoms, now with acute pain
 - Stability:
 - Stable: Bears weight w/or w/o crutches
 - Unstable: Unable to bear weight
- Epidemiology:
 - Peak age: 12–14 yr (boys), 11–12 yr (girls)
 - Male > female (1.6:1)
 - Bilateral slips: 20% at presentation; additional 20–40% progress to bilateral
 - Atypical SCFE: Endocrinopathy associated:
 - Patient may be < 10 yr age, > 16 yr age, or weight < 50th percentile
 - High risk of bilateral SCFE (up to 100%)

ETIOLOGY

- Proximal physis position changes in adolescence from horizontal to oblique; hence hip forces shift from “compression” to “shear”
- Shear force > strength of femoral physis
- Weakest point of physis = zone of hypertrophy
- Risk factors:
 - Obesity: May contribute to shear forces
 - Down syndrome
 - Endocrinopathy such as hypothyroidism, growth hormone deficiency, renal osteodystrophy (2° hyperparathyroidism): May contribute to growth plate weakening

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Determine chronicity of symptoms and whether or not the patient can bear weight
- Pain in the knee, thigh, groin, or hip (referred pain from the obturator nerve):
 - Vague and dull for weeks in chronic SCFE
 - Severe and sudden onset in acute SCFE, often in the setting of trauma

Physical-Exam

- If stable, presents with limp or exertional limp
- If unstable (patient cannot ambulate), avoid further ambulation attempts
- Commonly presents with leg externally rotated
- Restricted internal rotation, abduction, and flexion (cannot touch thigh to abdomen)
- Anterior hip joint tenderness
- Test: Apply gentle passive hip flexion → if hip externally rotates + abducts → highly suggestive of SCFE
- Gait:
 - Antalgic (patient takes short steps on affected side to minimize weight-bearing during “stance” phase of gait)
 - Trendelenburg (shift of torso over affected hip; sign of moderate/severe slip)
 - Waddling (sign of bilateral SCFE)

ESSENTIAL WORKUP

- Plain radiographs:
 - Further imaging with aid from consultant
- Orthopedic consultation

DIAGNOSIS TESTS & INTERPRETATION

Lab

- If no diagnostic radiographic abnormality, the practitioner may consider the following to help risk stratify possible alternative diagnoses:
 - CBC with differential, sedimentation rate, C-reactive protein
- If endocrinopathy suspected, consider thyroid function testing

Imaging

- Both hips should be imaged for comparison
- Some clinicians prefer cross-table lateral view in acute SCFE instead of frog-leg view (theoretical risk of worsening displacement)
- Anteroposterior radiograph:
 - Widened or irregular physis

- Bird’s beak appearance of the epiphysis “slipping” off of the femoral head
- Klein line: Parallel line drawn from superior border of the femoral neck; line intersects the epiphysis in normal patient
- Lateral radiograph (frog-leg or cross-table)

Diagnostic Procedures/Surgery

If septic hip is suspected, aspiration and fluid analysis may be needed to exclude.

DIFFERENTIAL DIAGNOSIS

- Legg–Calvé–Perthes:
 - Typically seen in 4–9-yr-old age range
- Septic arthritis of hip
- Osteomyelitis
- Toxic synovitis
- Femur or pelvic fractures
- Inguinal or femoral hernia

TREATMENT

PRE HOSPITAL

Patient should be immobilized for transport, as with suspected hip fracture or dislocation.

INITIAL STABILIZATION/THERAPY

- Immobilize hip; keep nonweight bearing
- Do not attempt reduction.

ED TREATMENT/PROCEDURES

- SCFE is an urgent orthopedic condition; delay in diagnosis may lead to chronic irreversible hip joint disability.
- Consult orthopedics immediately for definitive immobilization or operative intervention.

MEDICATION

Pain management as indicated; avoid oral medications if operative intervention is planned

FOLLOW-UP

DISPOSITION

Admission Criteria

- Acute, acute on chronic and bilateral SCFE requires orthopedic admission for urgent operative fixation (usually insitu single cannulated screw fixation)
- Chronic SCFE may be managed with delayed operative fixation

Discharge Criteria

None (no role for observation or attempts at closed reduction due to risk of complications, including osteonecrosis and/or chondrolysis)

FOLLOW-UP RECOMMENDATIONS

Should be arranged by orthopedic specialist

PEARLS AND PITFALLS

- Klein line can be a helpful tool in picking up the abnormality on plain radiograph
- Remember to examine the hip when a child presents with knee or thigh pain

CODES

ICD9

- 732.2 Nontraumatic slipped upper femoral epiphysis
- 732.9 Unspecified osteochondropathy

ICD10

- M93.003 Unspecified slipped upper femoral epiphysis (nontraumatic), unspecified hip
- M93.013 Acute slipped upper femoral epiphysis (nontraumatic), unspecified hip

- M93.023 Chronic slipped upper femoral epiphysis (nontraumatic), unspecified hip

SMALL-BOWEL INJURY

Barry J. Knapp

BASICS

DESCRIPTION

2 general causes:

- Blunt visceral trauma
- Penetrating: Visceral injury (96% of gunshot wounds, 50% of stabbings)—serosal tear, bowel wall hematoma, perforation, bowel transection, mesenteric hematoma/vascular injury

ETIOLOGY

- Blunt:
 - 3rd most commonly injured organ (5–10% of all blunt trauma victims)
 - Motor vehicle accidents
 - Nonvehicular trauma: Abuse/assault, bicycle handlebars, large-animal kick
 - Blast victims
- Mortality rate from small-bowel injury is 33%.
- Mesenteric tears may initially be asymptomatic:
 - Deceleration injury at fixed points (e.g., ligament of Treitz)
 - Shearing mechanisms near fixed points (e.g., ileocecal junction, adhesions)
 - Compressive force against anterior spine
 - Bursting or “blowout” at antimesenteric margin from sudden closed-loop intraluminal pressure rise
- Associated injuries:
 - Liver and splenic lacerations; thoracic and pelvic fractures
 - Seatbelt syndrome: Abdominal wall ecchymosis, small-bowel injury; Chance fracture of L1, L3
- Penetrating:
 - Small bowel is the 2nd most commonly injured organ (32%) in anterior abdominal stabbing.
 - Small-bowel injury is most common in gunshot wounds (49%).

Pediatric Considerations

- Blunt:
 - Less common in children (1–8% of all blunt pediatric trauma)
 - Lower chance of intestinal injury in vehicular accidents when both shoulder and lap belts are worn.
 - Be cautious of nonpenetrating trauma: Airgun accidents at close range (< 10 ft)

- Consider the possibility of nonaccidental trauma.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Physical signs and symptoms are unreliable
- Delays in diagnosis are common
- Presence of a “seatbelt sign” doubles the risk for small-bowel injury.
- Initial presentation may be mild:
 - Uniformly, patients will progress to serious signs/symptoms.
- Delays in diagnosis add to morbidity and mortality:
 - Mortality is 2% when diagnosis is made within 8 hr; 31% when made after 24 hr.

History

- History of blunt or penetrating abdominal trauma
- Must consider in ill children without a definite history of trauma (child abuse)

Physical-Exam

- In awake, alert patients look for:
 - Abdominal tenderness (87–98%)
 - Abdominal pain (85%)
 - Peritoneal signs (67%)
- Many patients will have:
 - Abdominal wall bruising (54%)
 - Hypotension (38%)
 - Guaiac-positive rectal exam (5%)
- Small-bowel injury may initially be obscured by abnormal mental status, severe associated injuries.
- Small-bowel injury not initially apparent may be indicated by:
 - Progressive abdominal pain
 - Intestinal obstruction
 - Decreased urine output
 - Tachycardia

ESSENTIAL WORKUP

- Initial physical exam should note all wounds and areas of tenderness.
- CT for all medically stable patients
- For patients with a negative CT scan in which there is high suspicion of bowel injury, further evaluation or serial exams are indicated.
- For medically unstable patients, diagnostic peritoneal lavage (DPL) is superior to US in determining presence of a hollow viscus injury.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- No diagnostic test has proven highly sensitive in the prediction of small-bowel injury.
- Serum amylase, lipase, and liver function tests have poor sensitivity for acute injury.

Imaging

- Plain radiography of chest/abdomen:
 - _ Not useful for small-bowel injury
 - _ Incidence of pneumoperitoneum visible on plain radiograph is only 8%.
- CT:
 - _ Diagnostic standard for solid-organ injury and head trauma but is less sensitive for hollow viscus injuries
 - _ Newest-generation helical CT scanners have a sensitivity of 88% and a specificity of 99%.
 - _ The benefits of oral contrast are controversial; it is acceptable to use IV contrast only
 - _ Blunt trauma:
 - Used in stable patients
 - Indications for CT in blunt trauma include abdominal tenderness, hypotension, altered mental status (GCS < 14), costal margin tenderness, abnormal CXR, HCT < 30% and hematuria
 - Specific signs for small-bowel injury on CT are pneumoperitoneum (sensitivity 50–75%) and extravasation of contrast (sensitivity 12%).
 - Signs on CT suggestive of small-bowel injury include unexplained free intraperitoneal fluid (most sensitive 93%), thickened bowel wall > 3 mm (61% sensitive), intramural hematomas (75–88% sensitive), interloop fluid, mesenteric streaking.
 - _ Penetrating: CT is not recommended because sensitivity is only 14%; false-negative result rate is 18%.
- US: Not sensitive in hollow viscus injury because air in bowel makes visualization difficult

Diagnostic Procedures/Surgery

- DPL:
 - _ Invasive but may be helpful in unstable patients or in patients with clinically suspicious but nondiagnostic abdominal CT
 - _ Sensitive for hemoperitoneum but not source of bleeding
 - _ Positive if RBC count of > 100,000/mm³
 - _ Lavage amylase > 20 IU/L and leukocyte count > 500/mm³ (late markers of

- small-bowel injury)
- Lavage microscopy for succus/vegetable matter/feces is specific for small-bowel injury but not sensitive.
- Lavage alkaline phosphatase (> 3 IU/L) is reported to be a useful immediate marker of small-bowel injury.
- Laparoscopy: Plays a key role in diagnosing small-bowel injury in stable patients with progressive signs or symptoms

DIFFERENTIAL DIAGNOSIS

- Hemoperitoneum owing to vascular insult
- Solid visceral organ injury or gastric/colon/rectum perforation
- Vertebral injury and associated ileus

Pediatric Considerations

Delay in diagnosis of 1–2 days is common and increases morbidity.

TREATMENT

PRE HOSPITAL

ALERT

- Patients should be transported to the nearest trauma center.
- Do not attempt to replace eviscerated abdominal contents; cover with moist gauze, blanket, and transport.
- Do not remove impaled objects in the abdomen; stabilize the object with gauze and tape and transport.

INITIAL STABILIZATION/THERAPY

- Standard advanced trauma life support protocols, including airway, breathing, and circulation management
- Aggressive fluid resuscitation, central line suggested with pressure infusion of warmed IV fluid (lactated Ringer solution or normal saline)
- Cover eviscerated small bowel with moist gauze; do not remove impaled foreign body in ED.

ED TREATMENT/PROCEDURES

- Immediate transfer to OR is required for patients with an indication for laparotomy:
 - Evisceration
 - Abdominal pain with hypotension
 - Positive DPL or abdominal CT
 - Thoracic abdominal herniation visualized on chest radiograph
 - Impaled foreign body

- Penetrating gunshot wound to the abdomen
- Tetanus and antibiotic prophylaxis should be given for penetrating abdominal wounds and blunt injury requiring surgical exploration.
- Local wound exploration is safe for abdominal stab wounds.
- Serial abdominal exams and observation for otherwise stable patients
- Judicious analgesia as BP permits after diagnosis is established

MEDICATION

- Cefotetan (Cefotan): 1–2 g (peds: 20 mg/kg) IV q12h *or*
- Cefoxitin (Mefoxin): 1–2 g (peds: 40 mg/kg) IV q6h *or*
- Ceftizoxime (Cefizox): 1–2 g (peds: 50 mg/kg) IV q8–12h +
- Metronidazole: 500 mg (peds: 7.5 mg/kg) IV q6h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Indication for laparotomy
- Abnormal mental status/intoxication with abdominal injury
- Presence of abdominal pain, tenderness (even with a negative workup) mandates admission for observation and serial exams.
- Stab and gunshot wounds that violate the abdominal fascia, positive DPL, or worsening findings on clinical exam

Discharge Criteria

- Minimal mechanism blunt trauma in a sober patient with normal exam result who has no abdominal pain and will receive adequate follow-up
- Explicit discharge instructions to return for worsening signs/symptoms are important to identify those with unsuspected injury.
- Penetrating wounds that do not violate abdominal fascia

FOLLOW-UP RECOMMENDATIONS

Discharged patients who develop abdominal complaints should return promptly to the ED.

PEARLS AND PITFALLS

- Small-bowel injury should be considered in any blunt/penetrating abdominal trauma victim.
- Initial presentation of patients with small-bowel injuries may be unimpressive.
- Presence of a “seat belt sign” doubles the risk for small-bowel injury.
- CT scanning may miss a significant percentage of small-bowel injuries.

- Observation and serial exams are an important aspect of detecting occult injuries.

SMOKE INHALATION

Trevonne M. Thompson

BASICS

DESCRIPTION

- Suspect smoke inhalation in anyone involved in a fire within a closed space or with a history of loss of consciousness.
- May cause direct injury to the upper (supraglottic) airway structures
- May cause chemical/irritant effect to lower airway structures
- May cause systemic toxicity from inhaled substances

ETIOLOGY

- Direct heat injury from heated gases/smoke:
 - Limited to supraglottic structures because of the heat-dissipating properties of the upper airway
- Irritant effect from smoke components
- Systemic toxicity from inhaled cellular toxins:
 - Carbon monoxide
 - Hydrogen cyanide

ALERT

Inhalation of steam can be rapidly fatal:

- Steam has ~4,000 times the heat-carrying capacity of hot air.
- Can rapidly cause obstructive glottic edema, thermally induced tracheitis, and hemorrhagic edema of the bronchial mucosa

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Exposure to a fire or heavy smoke
- Typically in a confined space
- Maintain high index of suspicion with history of loss of consciousness

Physical-Exam

- May have a normal physical exam with symptoms developing during the 24-hr interval following exposure
- Upper airway (supraglottic):
 - Nasopharyngeal irritation

- Hoarseness
- Stridor
- Cough
- Lower airway:
 - Chest discomfort
 - Hemoptysis
 - Bronchospasm
 - Bronchorrhea
- May have symptoms and signs of carbon monoxide and/or cyanide toxicity

ALERT

The following signs are suggestive of significant inhalation injury:

- Facial and upper cervical burns
- Carbonaceous sputum
- Singed eyebrows and nasal vibrissae

ESSENTIAL WORKUP

- Pulse oximetry:
 - May be falsely elevated in cases of carbon monoxide exposure
- ABG measurement:
 - Hypoxia
 - Metabolic acidosis in cases of carbon monoxide or hydrogen cyanide
- Chest radiography:
 - Initial radiograph typically normal
 - May show signs of pulmonary injury over the next 24 hr

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Electrolytes, BUN, creatinine, glucose
- CBC
- Coagulation profile
- Creatine phosphokinase when indicated in burn patients
- Carboxyhemoglobin to evaluate for potential carbon monoxide exposure
- Cyanide level:
 - In suspected cases of cyanide exposure, do not wait for the level before initiating therapy.
 - May send lactate level as a marker of cyanide toxicity
- Pregnancy test

Diagnostic Procedures/Surgery

- Peak expiratory flow rate:
 - Low peak flow associated with more severe injury

- PaO₂/FiO₂ ratio:
 - A ratio of < 300 after initial resuscitation is associated with the development of respiratory failure.

DIFFERENTIAL DIAGNOSIS

- Irritant gas exposure
- Asphyxiant gas exposure
- Cardiogenic pulmonary edema
- COPD exacerbation
- Asthma exacerbation
- Pneumonia

TREATMENT

PRE HOSPITAL

- 100% oxygen by face mask
- Intubation for patients with agonal breathing
- Rapid transport to ED for those with stridor:
 - May need advanced airway management
- Albuterol nebulizer therapy for bronchospasm

INITIAL STABILIZATION/THERAPY

- 100% oxygen via face mask
- Intubation:
 - Respiratory distress
- Drooling
- Stridor:
 - Refractory hypoxia
 - CNS depression
 - Significant facial/upper airway burns
- Establish IV access.

ED TREATMENT/PROCEDURES

- Inhaled or nebulized albuterol as needed for bronchospasm
- Corticosteroids as needed for patients with history of asthma or COPD
- Intubated patients:
 - Low endotracheal tube cuff pressure
 - Frequent suctioning
 - Positive end-expiratory pressure
- If indicated, treat for carbon monoxide toxicity:
 - 100% oxygen
 - Hyperbaric oxygen in appropriate cases when available

- If indicated, treat for cyanide toxicity:
 - 100% oxygen
 - Hydroxocobalamin (preferred)
 - If only older nitrite-containing cyanide antidote kit is available
 - Sodium nitrite should be used with caution in cases of significant carbon monoxide exposure
 - Sodium thiosulfate can be used safely with CO exposures

MEDICATION

- Albuterol nebulization: 2.5–5 mg in 2.5 mL of normal saline q20min:
 - Alternatively, 15 mg nebulizer treatment continuous over 1 hr
- Methylprednisolone 40 mg IV (peds: 1–2 mg/kg)
- Prednisone: 40–60 mg PO (peds: 1–2 mg/kg)
- Sodium thiosulfate 12.5 g (50 mL of 25% solution) slow IV infusion (peds: 412.5 mg/kg or 1.65 mL/kg of 25% solution)
- Hydroxocobalamin 5 g IV infused over 15 min (peds: 70 mg/kg)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Intubated
- Significant associated burns
- Persistent dyspnea, hoarseness, odynophagia, carbonaceous sputum
- Persistent cough
- Asthma/COPD with bronchospasm
- Significant carbon monoxide or cyanide exposure
- Comorbid medical illnesses

Discharge Criteria

- Minimal exposure history
- Asymptomatic
- Significant exposure history, asymptomatic after 4–6 hr observation

Issues for Referral

- In cases of significant associated burn injuries, transfer to burn facility as appropriate.
- In cases of significant carbon monoxide toxicity, transfer to hyperbaric oxygen facility as appropriate.

FOLLOW-UP RECOMMENDATIONS

Burn follow-up for patients with associated burns.

PEARLS AND PITFALLS

- In suspected cases of cyanide exposure, do not wait for the level before initiating therapy.
- Order carboxyhemoglobin to evaluate for potential carbon monoxide exposure.

SNAKE ENVENOMATION

Patrick M. Lank • Timothy B. Erickson

BASICS

DESCRIPTION

- Pit viper venom:
 - Mixture of proteolytic enzymes and thrombin-like esterases:
 - Enzymes cause local muscle and subcutaneous tissue necrosis.
 - Esterases have defibrinating anticoagulant effect, leading to venom-induced consumption coagulopathy (VICC) in severe envenomations.
- Bite location:
 - Extremity bites most common
 - Head, neck, or trunk bites more severe than bite on extremities
- Severe envenomation:
 - Direct bite into artery or vein
 - Neurotoxic envenomations
- Bite mark significance:
 - Pit viper bite: Classically includes 1 or 2 puncture marks
 - Nonvenomous snakes and elapids: Horseshoe-shaped row of multiple teeth marks
- 25% of all pit viper bites are dry and do not result in envenomation.

ETIOLOGY

Venomous Snakes Indigenous to US

- Pit vipers (Crotalinae):
 - Account for 95% of all envenomations
 - Rattlesnakes, cottonmouths, and copperheads
- Coral snakes (Elapidae):
 - Neurotoxic
 - Western coral snakes, found in Arizona and New Mexico
 - More venomous eastern coral snakes, found in Carolinas and Gulf states

International Exotic Venomous Snakes

Occur in zoos or in owners of exotic snakes

Pediatric Considerations

- 30% of all snakebites involve patients younger than 20 yr. 12% of all snakebites are 9 yr or younger.
- Because of their low body weight, smaller children and infants are more

vulnerable to severe envenomation with systemic symptoms.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Local (Crotaline):
 - Classic skin changes:
 - 1 or 2 puncture wounds
 - Pain and swelling at site
 - Swelling and edema of involved extremity:
 - Within 1 hr in severe envenomations
 - Tender proximal lymph nodes
 - Ecchymosis, petechiae, and hemorrhagic vesicles develop within several hours.
- Systemic (Crotaline):
 - Weakness, dizziness
 - Diaphoresis
 - Nausea
 - Scalp paresthesias
 - Periorbital fasciculations
 - Metallic taste
 - Severe bites can lead to:
 - Coagulopathy (VICC)
 - Hypotension
 - Pulmonary edema
 - Hematuria
 - Rhabdomyolysis
 - Renal failure
 - Cardiac dysfunction
 - Potential elevated compartment pressure in involved extremity
- Symptoms (Crotaline):
 - Primarily neurotoxic, leading to weakness, diplopia, confusion, delayed respiratory depression:
 - Local effects may be deceptively minimal.

History

- Description of snake
- Geographic location of bite

Physical-Exam

Search for manifestations of bites as described above.

ESSENTIAL WORKUP

- Careful exam of wound site and involved extremity:
 - Essential in judging severity of envenomation
 - Mark wound margins to follow progression
- Assess for anaphylactic reactions

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Coags
- Fibrinogen, d-dimer
- Electrolytes, BUN/creatinine, glucose
- Creatine phosphokinase (CPK)
- UA
- Type and cross-match with moderate to severe envenomation.

Imaging

Plain radiographs if foreign body suspected

DIFFERENTIAL DIAGNOSIS

- Nonvenomous snakes (in the US):
 - Narrow head
 - Round pupils
 - No rattles
- Pit vipers:
 - Triangular- or arrow-shaped head
 - Vertical or elliptical pupils
 - Heat-sensing pits just behind the nostrils and in front of eyes
 - ± Rattles
- Coral snakes (applies only in US, not internationally):
 - “Red on yellow—kill a fellow”
 - “Red on black—venom lack”

TREATMENT

PRE HOSPITAL

- Retreat well beyond striking range of snake.
- Immobilize extremity in functional position at the level of heart.
- Keep physical activity minimal.
- Remove rings, watches, and all constrictive clothing.
- It is ill-advised to transport a snake to a health care facility for identification

purposes:

- If you are close enough to get a good picture with a camera/phone, you are too close to a potentially venomous snake.
- Even severed head can envenomate.
- Controversies:
 - Pre-hospital local wound maneuvers are NOT recommended because they cause worse local tissue damage and increase the risk of infection. These include:
 - Incision and drainage
 - Mechanical suction devices
 - Oral suction
 - Tourniquets
 - Cryotherapy
 - Electrocutation
 - Pressure immobilization
 - Incision attempts by inexperienced can lead to severe tendon, nerve, and vascular damage.

Pediatric Considerations

- Envenomation more likely to be severe.
- Severity due to relatively low body weight of small child with same volume of venom.

INITIAL STABILIZATION/THERAPY

- Airway, breathing, and circulation management (ABCs)
- Maintain euvolemia with 0.9% normal saline (NS) to maintain renal blood flow
- Wound monitoring
- Immobilize bitten extremity

ED TREATMENT/PROCEDURES

- Supportive care
- Monitor for compartment syndrome:
 - Repeated measurements of extremity circumference every 15–20 min until local progression/swelling subsides.
 - A true compartment syndrome is unlikely following rattlesnake envenomation.
 - Elevated compartment pressures are treated with more antivenom, as surgical intervention with fasciotomy causes more damage to the area.
 - Surgical therapy considered only in incredibly rare cases and should only be considered in consultation with a regional poison center and medical toxicologist
- Analgesia with IV opioids
- Tetanus prophylaxis if needed

- Broad-spectrum antibiotics not routinely indicated
- Steroids not indicated except for reactions to antivenom (see below)
- Routine use of blood products not indicated
- Wound severity:
 - Minimal:
 - Local swelling and tenderness
 - Moderate:
 - Extremity swelling
 - Evidence of systemic toxicity
 - Severe:
 - Obvious toxicity
 - Unstable vital signs
 - Coagulopathy
 - Elapid envenomation
 - Lab abnormalities

Antivenom

- Indications for Crotalid antivenom therapy:
 - More than minimal extremity swelling
 - Extremity swelling that is progressing
 - Clinical signs of systemic toxicity
 - Unstable vital signs
 - Coagulopathy (low platelets or fibrinogen, elevated PT)
- CroFab:
 - Fundamental treatment for North American pit viper envenomation
 - High-affinity purified ovine Fab antibody fragment antivenom
 - CroFab causes less frequent hypersensitivity reactions than older polyvalent antivenom
 - Pediatric antivenom dose = adult antivenom dose
 - Dosing: 4–6 vials initially
 - Reconstitute each CroFab vial with 25 mL sterile water. Dilute in 250 mL 0.9% NaCl and infuse over 1 hr.
 - If hypotensive or with serious active bleeding, initial dose is 8–12 vials
 - Evaluate for envenomation control 1 hr after antivenom bolus infusion. Control is defined by stable wound appearance, improving coagulation studies, and hemodynamic stability.
 - If envenomation control achieved after 1st bolus of antivenom, may need maintenance antivenom therapy at 2 vials q6h × 3 doses.
 - If envenomation control not achieved after 1st bolus of antivenom, repeat initial bolus and reassess. Discuss with regional poison center or medical toxicologist.
- Victims of envenomation who develop an allergic reaction to antivenom:
 - Stop infusion of antivenom

- Administer antihistamines, corticosteroids, and fluids. Consider epinephrine for severe reactions.
- Discussion of risks/benefits of restarting antivenom should take place with regional poison center or medical toxicologist
- Coral snake antivenom:
 - No longer being manufactured, but stockpile exists in geographically appropriate locales.
 - Effective against more toxic eastern coral snake but not against western coral snakes
 - After proper skin testing, 3–5 vials of antivenin recommended.
 - Treatment complications include anaphylaxis and serum sickness.
 - Coral snake venom is neurotoxic; watch for respiratory depression, control airway
- International exotic venomous snakes:
 - Specific antivenoms may be available at local zoos or through the Antivenom Index.

Pediatric Considerations

- Proportionally more antivenin per body weight
- Standard adult doses required

Pregnancy Considerations

- If mother has systemic signs of envenomation toxicity, fetus is also at risk; timely antivenom therapy is still indicated.
- Consult obstetrician

Treatment Assistance

- Contact local poison center 800-222-1222, medical toxicologist, local zoo, or regional herpetologist.
- Call Antivenom Index at 602-626-6016 in Tucson, Arizona, for assistance in treatment of exotic snakes not indigenous to US

FOLLOW-UP

DISPOSITION

Admission Criteria

- 24-hr observation after control of envenomation progression for patients requiring antivenom administration after pit viper bites.
- 24-hr observation for asymptomatic patients with elapid bites.
- ICU admission for:
 - Patients receiving antivenom

- Evidence of moderate to severe envenomation, especially in children
- All victims of elapid bites and for symptomatic exotic snake envenomations

Discharge Criteria

Suspicious bite that shows no signs or symptoms of envenomation for 6–8 hr and has normal lab panel:

- Dry bites may be observed for 8 hr and discharged if there is no development in local toxicity and if lab studies normal.
- Minor envenomations should be observed for 12–24 hr and have labs repeated 6 hr after presentation, then again before discharge.
- Discharge with follow-up in 24 hr.

FOLLOW-UP RECOMMENDATIONS

PCP or toxicology follow-up 1 wk after antivenom therapy to assess for possible serum sickness or envenomation wound infection.

PEARLS AND PITFALLS

- Avoid overly aggressive pre-hospital care interventions. It is best to rapidly transport to closest medical center.
- Be sure to administer proper dose of antivenom in a timely fashion when clinically indicated.

SPIDER BITE, BLACK WIDOW

Tarlan Hedayati • Christopher S. Lim

BASICS

DESCRIPTION

- Syndromes caused by envenomation by black widow spider bite
- Mechanism of toxicity:
 - Females are responsible for human envenomations
 - Venom contains potent neurotoxin, α -latrotoxin:
 - Causes cation-channel opening presynaptically, resulting in increased neurotransmitter release into synapses and neuromuscular junctions
 - Increased neurotransmitter release causes increased neurologic, motor, and autonomic effects
- Morbidity and mortality are dose dependent
- Severity of envenomation depends on:
 - Premorbid health of victim:
 - HTN or cardiovascular disease increase risk
 - Size and age of victim:
 - Children (i.e., smaller size for a given dose of venom) are at greater risk of morbidity and mortality.
 - Number of bites
 - Location of bite wounds
 - Size and condition of spider
- Rarely fatal

ETIOLOGY

Black widow spider features:

- Appearance:
 - Glossy black with red markings shaped like an hourglass or a pair of spots on the ventral aspect of the globular abdomen
 - Females have 25–50 mm leg spans and 15 mm long bodies
- Found throughout North America, except the far north and Alaska
- Prefer dark sheltered hideaways such as garages, barns, outhouses, woodpiles, and low-lying foliage
- Most bites occur during the warmer months when spiders are defending their webs and egg clutches

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- History of spider bite very unreliable and species usually not identified
- Bite:
 - Described as a pinprick or pinch, if felt at all
- Local complaints (within minutes of bite):
 - Pain:
 - Sharp, burning at the bite site
 - Usually resolves spontaneously within minutes or hours
 - May become worse and spread proximally from the bite
- Systemic complaints (within 15–60 min):
 - Cardiac:
 - Palpitations
 - Chest pain or tightness
 - Pulmonary:
 - Shortness of breath
 - Cough
 - Neuromuscular:
 - Headache
 - Dizziness
 - Painful regional muscle cramps and spasms
 - Cramping may progress to larger muscle groups
 - Arm bites may lead to arm and chest muscle tightness and dyspnea
 - Leg bites may lead to abdominal pain and leg spasms
 - Cutaneous dysesthesias and hyperesthesias
 - Localized or diffuse diaphoresis
 - GI:
 - Nausea, vomiting
 - Abdominal pain
 - Genitourinary:
 - Painful persistent erection
 - Gynecologic:
 - Pregnant patients may develop uterine contractions and preterm labor
 - Skin:
 - Pruritus
 - Psychiatric:
 - Anxiety
 - Sense of impending doom

Physical-Exam

- Vital signs may be abnormal:
 - HTN or hypotension
 - Tachycardia or bradycardia

- Fever
- Tachypnea
- Cardiac:
 - Dysrhythmias
 - Myocarditis
- Pulmonary:
 - Bronchorrhea
 - Pulmonary edema
 - Respiratory failure:
 - Usually due to respiratory muscle weakness
- Abdomen:
 - Rigidity
- Genitourinary:
 - Priapism
- Neurologic findings:
 - Tetanic contractions, fasciculations or tremors of extremities
 - Spasm and rigidity in large muscle groups
 - Autonomic instability
 - Seizure
- Skin:
 - Local:
 - 2 pinpricks from the spider’s fangs
 - Tender and blanched skin with surrounding erythema (“target lesion”)
 - Swelling
 - Localized sweating
 - Diffuse:
 - Urticaria
 - Piloerection
 - Generalized diaphoresis
- Psychiatric:
 - Acute toxic psychosis
 - Agitation or restlessness

ESSENTIAL WORKUP

Diagnosis is based on:

- Clinical presentation
- Careful inquiry to elicit spider bite history
- Identification of spider (if possible)

DIAGNOSIS TESTS & NTERPRETATION

Lab

- No specific blood tests for black widow spider venom
- CBC:
 - WBC may be mildly elevated
- Electrolytes, calcium
- BUN, creatinine
- Lipase, LFTs
- Creatine kinase:
 - Elevated in patients with significant muscle spasm
- Cardiac enzymes
- Pregnancy test
- Urinalysis:
 - May demonstrate albuminuria
- ABGs in rare cases with pulmonary edema
- ECG and cardiac monitoring for:
 - Patients with known cardiac disease
 - Patients with chest pain, unstable vital signs or dysrhythmias
 - May show digitalis effect transiently

Imaging

- CXR for respiratory complaints
- Abdominal imaging to rule out other causes of pain

DIFFERENTIAL DIAGNOSIS

- Acute surgical abdomen (e.g., appendicitis, cholecystitis, pancreatitis, AAA)
- Ureterolithiasis/nephrolithiasis
- Sympathomimetics (e.g., cocaine, amphetamines)
- Hypocalcemia
- Tetanus
- Muscular injury or strain
- Hypertensive emergency
- MI/acute coronary syndrome
- Anxiety disorder
- Allergic reaction

TREATMENT

PRE HOSPITAL

- ABCs/ACLS
- Immobilize the wound site and apply cool compresses or ice for comfort during transport to hospital
- Supportive measures (analgesics, anxiolytics) may be required for patients with systemic symptoms

- Negative-pressure venom extraction devices have not been recommended for widow spider bites
- Every effort should be made by caregivers at the scene to find and bring in the responsible spider for identification

INITIAL STABILIZATION/THERAPY

- ABCs
- ACLS as needed
- Fetal monitoring for pregnant patients

ED TREATMENT/PROCEDURES

- Clean the bite site thoroughly
- Tetanus prophylaxis
- Antiemetics for nausea and vomiting
- Analgesics
- Antihistamines
- Benzodiazepines for agitation and restlessness
- Muscle cramps/spasm therapy:
 - Benzodiazepines
 - Narcotics
- Antihypertensive agents for symptomatic HTN
- Antivenin:
 - Elicit history of allergy to horse or horse serum
 - Indications:
 - Moderate to severe symptoms that do not respond to symptomatic measures
 - Significant HTN
 - Respiratory distress
 - Symptomatic and pregnant
 - Priapism
 - Severe rhabdomyolysis
 - Compartment syndrome
 - Seizures
- Perform a skin test for sensitivity to horse serum prior to antivenin administration (test kit included in the antivenin package)
- Watch for type I immediate hypersensitivity reaction in the 1st 20 min:
 - Occurs in up to 25% of recipients
 - Consider pretreatment with antihistamines or SC epinephrine 1:1,000
 - Treat anaphylactic reactions with steroids, antihistamines, epinephrine, and cardiopulmonary support
 - Due to the small quantity of antivenin used, if serum sickness reactions occur, they are usually mild
 - Effectiveness is usually apparent within 2 hr of the 1st treatment and

- repeated doses are rarely necessary
- Antivenin may help prevent persistent neuropathic symptoms

MEDICATION

- Antivenin: 1 ampule (2.5 mL) diluted into 50–100 mL of D₅W or NS (peds: Same dose) IV over 1 hr
- Diphenhydramine: 10–50 mg IV or IM q6–8h (peds: 5 mg/kg/d div. QID)
- Lorazepam: 1–2 mg IV or IM (peds 0.01 mg/kg IV or IM)
- Morphine sulfate: 2–10 mg (peds: 0.1 mg/kg) IV or IM PRN (titrate to patient response)
- Sodium nitroprusside: 0.5–10 mcg/kg/min if diastolic > 120 mm Hg
- Tetanus prophylaxis

FOLLOW-UP

DISPOSITION

Admission Criteria

- Pediatric, elderly, pregnant, or symptomatic patients
- Significant cardiovascular symptoms and signs, or severe HTN, particularly in presence of premorbid cardiac disease or chronic HTN
- Respiratory distress or pulmonary edema
- Persistent symptoms not responding to aggressive management and specific antivenin

Discharge Criteria

- Asymptomatic patients with no positive identification of a black widow spider can be released after observation for 1–2 hr
- Asymptomatic patients with no comorbid illness with a positive identification of the black widow spider should be observed for a minimum of 4–6 hr and discharged if their condition does not change
- All discharged patients must be instructed to watch for the following symptoms and to seek appropriate follow-up:
 - Hematuria
 - Rash
 - Joint pain
 - Lymphadenopathy
 - Shortness of breath
 - Signs of infection
- Discharged patients who received antivenin should be instructed to watch for signs of serum sickness:
 - Type III delayed hypersensitivity

- Uncommon
- Occurs 5 days–3 wk post treatment
- Treat with antihistamines and steroids

Issues for Referral

Toxicology consult for patients requiring admission or antivenin administration

FOLLOW-UP RECOMMENDATIONS

- In most untreated patients, symptoms peak after 2–3 hr and then begin to resolve, occasionally recurring episodically over the following few days
- In otherwise healthy adults, complete resolution of symptoms occurs within 2–3 days
- Neurology follow-up if persistent neurologic symptoms last weeks to months including:
 - Fatigue
 - Generalized weakness or myalgias
 - Paresthesias
 - Headache
 - Insomnia
 - Impotence
 - Polyneuritis

PEARLS AND PITFALLS

- Widow bites in infants may present as intractable crying
- A high fever and WBC count should prompt consideration of alternatives to spider bites (e.g., infection)

ICD10

T63.311A Toxic effect of venom of black widow spider, acc, init

SPIDER BITE, BROWN RECLUSE

Tarlan Hedayati • Christopher S. Lim

BASICS

DESCRIPTION

Local or systemic illness caused by brown recluse spider bite envenomation

ETIOLOGY

- Brown recluse spider (also known as the fiddleback spider) features:
 - Appearance:
 - Delicate body and legs spanning 10–25 mm
 - Tan- to dark-brown with darker violin-shaped marking visible on the upper aspect of the head
 - 3 pairs of eyes
 - Found widely throughout the south-central part of US
 - Habitat: Typically warm and dry locations, indoors or outdoors such as wood piles, bundles of rags, cellars, under rocks, or in attics
 - Bites are typically defensive
- Mechanism of toxicity:
 - Venom is a complex cocktail of enzymes and peptides that:
 - Binds to RBC and causes hemolysis
 - Causes prostaglandin release and activates complement cascade
 - Causes lipolysis and tissue necrosis
 - Triggers platelet aggregation and thrombosis
 - Triggers allergic response to venom antigenic properties
 - May lead to shock and DIC in rare cases
 - Toxicity proportional to:
 - The amount of venom relative to the size of patient
 - Location of envenomation on the body

Pediatric Considerations

- Children are more vulnerable to a given amount of venom than healthy adults
- Fatality more common in children due to severe intravascular hemolysis

DIAGNOSIS

SIGNS AND SYMPTOMS

Diagnosis is based not only on the clinical presentation but also on a reliable history of a spider bite.

History

- An isolated cutaneous lesion is the most common presentation
- Bite sites are usually located in areas under clothing where spider gets trapped between clothing and skin
- Local wound symptom onset:
 - Bite onset is usually asymptomatic, but some may report burning or stinging sensation
 - 1–24 hr later, patients may report aching or pruritis locally
- Systemic features:
 - Rare complication
 - More common in children than adults
 - Develop during the 1st 1–3 days postenvenomation.
 - Patient may report:
 - Fever, chills
 - Weakness, malaise
 - Nausea, vomiting, diarrhea
 - Dyspnea
 - Myalgias, muscle cramps, arthralgias
 - Jaundice
 - Petechial or urticarial rash
 - Generalized pruritic rash
 - Hematuria or dark urine

Physical-Exam

- Bite wound:
 - Usually no visible injury if examined within the 1st 1–3 days
 - There may be a pinprick lesion, local blanching and induration, or erythema.
 - Tissue injury may develop at bite site:
 - Initially, bite mark may be surrounded by edema
 - Next, an erythematous border will develop around a purple center with a thin ring of ischemia between the 2
 - Serous or hemorrhagic bullae may form in the center after 24–72 hr
 - Blister may gradually enlarge and darken with the development of and eschar of skin and subcutaneous fat necrosis over 3–4 days
 - Eschar sloughs off 2–5 wk later leaving an ulcer in its place
 - Necrosis develops most extensively where subcutaneous fat is greatest
 - Lower-extremity blisters may spread distally under the influence of gravity
 - Local response is not dependent on the extent of envenomation and cannot be used to predict the likelihood or severity of subsequent systemic illness
- Skin:

- Jaundice
- Petechia
- Urticaria
- Generalized maculopapular rash

ESSENTIAL WORKUP

- Careful inquiry required to elicit the spider bite history
- Routine lab testing not necessary unless systemic toxicity present.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Spider venom can be detected in skin lesions, but widespread clinical testing is not available yet
- CBC:
 - Hemolytic anemia
 - Thrombocytopenia, particularly with DIC
 - Leukocytosis
- Electrolytes:
 - Hyperkalemia or acidosis in renal failure
- BUN, creatinine
- Creatine kinase may be elevated in rhabdomyolysis
- Prothrombin time/partial thromboplastin test may be prolonged in DIC
- α -dimer and fibrin degradation products may be elevated in DIC
- Fibrinogen may be decreased in DIC
- Urinalysis:
 - Hemoglobinuria
 - Proteinuria

Imaging

- CXR in systemic toxicity
- Soft tissue radiograph of bite site

DIFFERENTIAL DIAGNOSIS

- Angioedema
- Bacterial soft tissue infection; MRSA
- Burn
- Cutaneous anthrax
- Diabetic ulcer
- Decubitus ulcer
- Erythema nodosum
- Fungal infection
- Gonococcal hemorrhagic lesion

- Herpes simplex
- IV drug use or “skin popping”
- Vascular insufficiency with secondary ulcer
- Lyme disease
- Neoplastic lesion
- Other arachnid envenomation
- Poison ivy or oak
- Pyoderma gangrenosum
- Sporotrichosis
- Stevens–Johnson syndrome
- Thrombosis
- Vasculitis
- Warfarin use

TREATMENT

PRE HOSPITAL

- Loosely immobilize wound site
- Elevate the affected extremity
- Cover bite with cool compresses
- Transport to hospital when patient experiences immediate onset of symptoms
- Supportive measures for patients with systemic symptoms

ALERT

Every effort should be made by caregivers at the scene to find and bring in the responsible spider for identification.

INITIAL STABILIZATION/THERAPY

IV fluids, oxygen, cardiac monitoring if the patient is experiencing signs of systemic collapse

ED TREATMENT/PROCEDURES

- Cleanse the bite site thoroughly
- Tetanus prophylaxis
- Analgesics
- Antibiotics:
 - Appropriate if wound appears infected
 - Not indicated prophylactically
 - Antistaphylococcal
- Dapsone:
 - Controversial: Consider for severe toxicity.
 - Screen for G6PD deficiency before initiating
 - Monitor for methemoglobinemia, hemolysis, and leukopenia during therapy

- Excision of necrotic wound:
 - Not indicated in the 1st 8 wk because may cause more severe ulcer formation
- Hemoglobinuria:
 - Treated with IV fluids and alkalinization
 - Monitor renal, fluid, and electrolyte status
- Dialysis for renal failure
- Pressors for shock state
- Blood products in severe hemolysis, DIC
- Specific antivenin:
 - Not commercially available
 - Not FDA approved for use in US
- Therapies requiring further investigation:
 - Topical or systemic steroids
 - Hyperbaric therapy (has been shown to decrease wound size in animal model)
 - Topical nitroglycerin
 - Negative pressure wound therapy, or vacuum-assisted closure

MEDICATION

- Antibiotics:
 - Clindamycin: 150–300 mg PO q6h (peds: 8–16 mg/kg/d PO div. QID)
 - Severe skin infections:
 - Vancomycin: 1 g IVPB q12h (peds: 10 mg/kg q6h)
- Dapsone: Progressive dosage of 50–200 mg/d (peds: 2 mg/kg/24 h PO)
- Methylprednisolone: 125 mg IV bolus followed by prednisone 30–50 mg/d for 5 days (peds: methylprednisolone 1–2 mg/kg IV, prednisone 1–2 mg/kg PO)
- Morphine sulfate: 2–10 mg (peds: 0.1 mg/kg) IV or IM PRN

Pediatric Considerations

- Use dapsone only in severe cases because of increased potential for side effects such as:
 - Hepatitis
 - Methemoglobinemia
 - Hemolytic anemia
 - Leukopenia

FOLLOW-UP

DISPOSITION

Admission Criteria

- Significant local reaction or signs of systemic toxicity
- Lower threshold for children, patients with significant comorbidities

Discharge Criteria

- No evidence of systemic toxicity or severe progression of local wound necrosis after envenomation
- Daily reassessment by primary physician, including blood work, until 3–4 days after envenomation to evaluate for systemic toxicity
- Patients should be advised about prolonged course for skin healing with consideration for surgical excision after 8 wk
- Patients should be advised about potential for extensive scarring, infection, and recurrent ulceration

Pediatric Considerations

Longer observation period or admission because of the higher mortality in this population

Issues for Referral

Consider consultation with:

- General surgery or plastic surgery for wound management
- Hyperbaric specialist for wound management
- Toxicologist
- Nephrologist for cases of renal failure
- Intensivist in cases of shock or DIC

FOLLOW-UP RECOMMENDATIONS

- Primary care physician for continued evaluation of wound
- General surgery or plastic surgery for management of complicated wounds
- Hyperbaric specialist for wound management

PEARLS AND PITFALLS

- Remember the limited range of brown recluse spiders and the rarity of arachnidism as a cause of necrotic skin wounds
- In the absence of a reliable spider bite by history, other diagnoses must be carefully sought and excluded
- Be sure to screen for G6PD deficiency as it causes methemoglobinemia and hemolysis in patients receiving dapsone
- Have a low threshold for admitting pediatric patients, adults with systemic symptoms, or anyone with a large, painful, or infected wound

SPINAL CORD SYNDROMES

Stephen R. Hayden

BASICS

DESCRIPTION

- Anterior cord syndrome:
 - Results from flexion or axial loading mechanism or direct cord compression from vertebral fractures, dislocations, disc herniation, tumor, or abscess
 - Rarely, can be caused by laceration or thrombosis to the anterior spinal artery
- Brown-Séquard syndrome:
 - Hemisection of the spinal cord, classically as a result of a penetrating wound
 - Rarely unilateral cord compression
- Central cord syndrome:
 - Most commonly occurs in elderly patients who have pre-existing cervical spondylosis and stenosis
 - Forced hyperextension causes buckling of the ligamentum flavum, creating a shearing injury to the central portion of the spinal cord.
- Dorsal cord syndrome:
 - Associated with hyperextension injuries
- Complete cord syndrome:
 - Blunt or penetrating trauma that results in complete disruption of spinal cord
 - Symptoms that remain > 24 hr generally are permanent.

ETIOLOGY

- Spinal cord syndromes result from localized disruption of neurotransmission and exhibit mixed motor and sensory deficits. The most common mechanism is trauma.
- Patients with arthritis, osteoporosis, metastatic disease, or other chronic spinal disorders are at risk of developing spinal injuries as the result of minor trauma.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

Acute loss of motor and/or sensory function usually following a traumatic event

Physical-Exam

- Anterior cord syndrome:
 - Bilateral spastic paralysis and loss of pain and temperature sensation below the level of the lesion
 - Preservation of dorsal column function (proprioception and position sense)
- Brown-Séquard syndrome (lateral cord syndrome):
 - Ipsilateral spastic paresis and loss of dorsal column function (proprioception and position sense)
 - Contralateral loss of pain and temperature sensation
 - Deficits usually begin 2 levels below the injury.
- Central cord syndrome:
 - Loss of motor function affects upper extremities more severely than lower extremities.
 - Most profound deficits occur in the distal upper extremities.
 - Sensory loss is more variable.
- Dorsal cord syndrome:
 - Loss of proprioception, position sensation, and coordination below the level of the lesion
- Complete cord syndrome:
 - Flaccid paresis below the level of the injury
 - Low BP and heart rate, flushed skin, priapism may be present (loss of sympathetic tone).
- Sensory deficit levels:
 - C2: Occiput
 - C4: Clavicular region
 - C6: Thumb
 - C8: Little finger
 - T4: Nipple line
 - T10: Umbilicus
 - L1: Inguinal region
 - L5: Dorsum of the foot
 - S5: Perianal area
- Motor deficit levels:
 - C5: Elbow flexion
 - C7: Elbow extension
 - C8: Finger flexion
 - T1: Finger abduction
 - L2: Hip flexion
 - L3: Knee extension
 - L4: Ankle dorsiflexion
 - S1: Ankle plantar flexion

ESSENTIAL WORKUP

- Detailed neurologic exam, focused on determining if any deficit exists and

- attempting to define the level of injury
- A neurosurgical consultation if deficit exists is recommended in most cases

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Basic preoperative lab studies are indicated.
- Consider sedimentation rate and C-reactive protein to risk-stratify other potential diagnoses.

Imaging

All areas of clinical suspicion should be imaged with plain radiographs.

Geriatric Considerations

Cases in which plain radiographs may be difficult to interpret due to severe DJD, the use of CT may be more appropriate.

- CT of the spine when plain films are normal or ambiguous:
 - _ CT allows assessment of the spinal canal and any impingement by bone fragments.
- MRI is the imaging modality of choice for detection of spinal cord damage; in the acute setting, the indications for MRI are:
 - _ Neurologic deficits not explained by plain films or CT
 - _ Clinical progression of a spinal cord lesion
 - _ Determination of acute surgical candidacy
 - _ Disadvantages of MRI include:
 - The inability to adequately monitor the patient while undergoing the study
 - The incompatibility with certain metal devices
 - The time to complete the exam

Diagnostic Procedures/Surgery

- Myelography is used with CT when MRI is not available or cannot be performed.
- A lumbar puncture may be required if considering Guillain–Barré, multiple sclerosis, or transverse myelitis.

DIFFERENTIAL DIAGNOSIS

- Dorsal root injury
- Peripheral nerve injury
- Guillain–Barré syndrome
- Multiple sclerosis
- Transverse myelitis
- Epidural abscess
- Cerebral vascular accident

TREATMENT

PRE HOSPITAL

- Full spinal immobilization
- IV access should be established for fluid resuscitation in the setting of neurogenic shock.
- Patients should be transported to the nearest trauma center:
 - Prompt evaluation and neurosurgical intervention may lead to a better outcome.

Pediatric Considerations

Cervical collars must be the appropriate size for the child; splinting the head and body with towels and tape is a reasonable alternative.

INITIAL STABILIZATION/THERAPY

- Spinal immobilization must be maintained at all times.
- Intubation must proceed with in-line spinal immobilization.
- IV fluids should be administered at maintenance levels unless shock is present:
 - Spinal trauma may cause hypotension due to loss of sympathetic tone; fluid administration is 1st-line treatment.
 - Other causes of hypotension (e.g., hemorrhage) should be sought before being attributed to spinal cord injury (SCI).
 - Generally, hypovolemic shock causes tachycardia, whereas neurogenic shock results in bradycardia.
 - If BP does not improve after a fluid challenge and no other cause for hypotension can be found, vasopressor use may be necessary; α -agonist is preferred.

ED TREATMENT/PROCEDURES

- Other injuries must be treated as indicated.
- Level of SCI should be determined as a baseline to follow for improvement or deterioration.
- A neurosurgeon must be consulted once an SCI is suspected, even when plain films are normal; early surgical decompression or immobilization may reduce morbidity.
- The patient with an SCI should be managed at an appropriate regional trauma or spinal center:
 - If necessary, transfer should occur as soon as management of other injuries allow.
- IV antibiotics and tetanus prophylaxis are given to patients with a penetrating injury.
- IV vasopressor support may be required to treat neurogenic shock.

MEDICATION

- Phenylephrine: 0.5–2 µg/kg bolus then 50–100 µg/min drip
- Ancef: 1,000 mg q8h

ALERT

In the early 1990s, the use of high-dose methylprednisolone infusion was widely adopted as standard of care following the reports of the 2nd and 3rd National Acute Spinal Cord Injury Study (NASCIS II, NASCIS III); however, extensive systematic review of this therapy and the evidence to support it has demonstrated that this therapy is not recommended for routine use in SCI.

FOLLOW-UP

DISPOSITION

Admission Criteria

All patients with spinal cord syndrome must be admitted to an ICU setting.

Discharge Criteria

No patient with symptoms suggestive of SCI should be discharged.

PEARLS AND PITFALLS

- A detailed neurologic exam and attempt to document the spinal level of neurologic symptoms is critical.
- Involve neurosurgical consultants early, as outcome is time-dependent in many cases.
- EM physicians should not start methylprednisolone treatment for acute SCI.

ADDITIONAL READING

SPINE INJURY: CERVICAL, ADULT

Gary M. Vilke

BASICS

DESCRIPTION

- Injury to the neck that results in injury to the spinal cord, cervical spine, or ligaments supporting the cervical spine
- May have more than 1 mechanism concurrently
- Flexion injuries:
 - Simple wedge fracture: Usually a stable fracture
 - Anterior subluxation: Disruption of the posterior ligament complex without bony injury; potentially unstable injury
 - Clay shoveler's fracture: Avulsion fracture of the spinous process of C7, C6, or T1; stable fracture
 - Flexion teardrop fracture: Extremely unstable fracture; may be associated with acute anterior cervical cord syndrome
 - Atlanto-occipital dislocation: Unstable injury
 - Bilateral facet dislocation: Can occur from C2–C7; unstable injury
- Flexion/rotation injuries:
 - Unilateral facet dislocation “locked” vertebra: Stable injury
 - Rotary atlantoaxial dislocation: Unstable injury
- Extension injuries:
 - Extension teardrop fracture: An avulsion fracture of the anteroinferior corner of the involved vertebral body; unstable in extension and stable in flexion
 - Posterior arch of C1 fracture: Arch is compressed between the occiput and the spinous process of the axis during hyperextension; unstable fracture
 - Avulsion fracture of the anterior arch of the atlas: Horizontal fracture of C1 and prevertebral soft tissue swelling on the lateral C-spine
 - Hangman fracture: Traumatic spondylolisthesis of the axis involving the pedicles of C2; unstable fracture
 - Hyperextension dislocation: Described as the syndrome of the paralyzed patient with a radiographically normal-appearing C-spine
- Extension–rotation injury:
 - Pillar fracture: Generally stable fracture
- Vertical compression (axial loading) injuries:
 - Jefferson fracture: Burst fracture of both the anterior and posterior arches of C1; extremely unstable fracture
 - Burst fracture: A comminuted fracture of the vertebral body with variable retropulsion of the posterior body fragments into the spinal canal

ETIOLOGY

- Blunt trauma is the major cause of neck injuries:
 - Automobile accidents account for >50%.
 - Falls account for ~20%.
 - Sporting accidents account for 15%.
 - Minor trauma in patients with severe arthritis may result in cervical injuries.
- Penetrating trauma

DIAGNOSIS

SIGNS AND SYMPTOMS

- Neck pain, tenderness on palpation
- Numbness, weakness, paresthesias of upper or lower extremities
- Always assume a C-spine injury in any patient with:
 - Altered mental status (unconscious, intoxicated, on drugs, or hypoxic) following trauma or if events are unknown but trauma is likely
 - Inability to communicate (mentally retarded, language barrier, or intubated) following trauma or if events are unknown but trauma is likely
 - Distracting injury
 - Blunt trauma involving head or neck
- Incomplete cervical cord syndromes (see separate chapter):
 - Brown-Séquard syndrome: Hemisection of cord from penetrating injury (ipsilateral motor paralysis/contralateral sensory hypesthesia)
 - Anterior cord syndrome: Cervical flexion injury causing cord contusion (paralysis/hypesthesia with sparing of position/touch/vibratory sensations)
 - Central cord syndrome: Patients with cervical degenerative arthritis with forced hyperflexion (deficits greater in upper extremities relative to lower extremities)

History

- Obtain history of head or neck trauma.
- Identify history of ankylosing spondylitis or other brittle bone diseases.
- Specific symptoms:
 - Neck pain
 - Weakness
 - Numbness or tingling
 - Stinger

Physical-Exam

- Direct visualization of neck for bruising or deformity
- Palpation over the spinous processes

- Motor, sensory, and reflex exam of upper and lower extremities

ESSENTIAL WORKUP

Complete physical exam and radiographic imaging if clinically indicated

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- Standard radiographs include 3 separate views: Lateral, anteroposterior, and open-mouth views of the odontoid while still immobilized.
- Lateral radiograph must include C1–T1; a swimmer's view may be necessary to view lower levels.
- Supine oblique views may help in identifying subtle rotational injuries.
- CT should be obtained when C-spine fractures, dislocations, or soft tissue swelling is seen on plain films or for unexplained neck pain/neurologic deficit with normal radiograph.
- CT (helical) is considered a good alternative to plain films and is favored in certain patients, including intubated victims of blunt trauma.
- Flexion–extension views may be needed to evaluate for dynamic ligamentous injuries if static radiographs are negative and the alert, cooperative patient still complains of pain.
- MRI has become a valuable tool in evaluating patients with neurologic deficits, including spinal cord injury without radiographic abnormality.

DIFFERENTIAL DIAGNOSIS

- Cervical muscle strain injury (whiplash)
- C-spine dislocation
- Cervical fracture dislocation
- Complex or simple cervical fractures

TREATMENT

PRE HOSPITAL

- If C-spine injury suspected, immobilize with a hard collar, neck pads, and backboard.
- Immobilized patients require constant observation in case of vomiting.
- Immobilize C-spine in patients with penetrating neck wounds only if a neurologic deficit is present.
- If the weapon is still embedded, immobilize the neck to avoid further injury and do not remove the impaling object unless it directly impedes breathing.

INITIAL STABILIZATION/THERAPY

- Immobilize the spine using a rigid collar and backboard plus tape/towels or

lightweight foam pads along the side of the neck.

- Stabilize the airway, establish IV access, and support circulation:
 - Preferred method is careful orotracheal rapid sequence intubation with inline spinal immobilization.
 - Fiberoptic intubation set should be at the bedside and considered if available.

ED TREATMENT/PROCEDURES

- Assess patient for other injuries; remember that the abdominal exam in a C-spine-injured patient is unreliable and further objective testing is indicated.
- Patients with ankylosing spondylitis or other brittle bone diseases are at risk for fracture and cord injury with even trivial mechanisms.
- Patients may be clinically cleared and do not require C-spine radiograph (based on NEXUS) if they:
 - Have no altered level of alertness
 - Are not intoxicated
 - Have no tenderness in the posterior midline cervical spine
 - Have no distracting painful injury
 - Have no focal neurologic deficit
- If a neurologic deficit is present, consult neurosurgery.
- If the radiographs or CT is abnormal, consult neurosurgery or the orthopedic spine service.
- If the radiographs are normal but the alert and cooperative patient is having severe neck pain, consider flexion–extension films, CT, or MRI; if abnormal, consult neurosurgery.

MEDICATION

High-dose steroid protocol for patients with neurologic deficits due to fractures or dislocations.

First Line

Methylprednisolone: 30 mg/kg IV bolus then 5.4 mg/kg/h over the next 23 hr; begin within 8 hr of injury

FOLLOW-UP

DISPOSITION

Admission Criteria

- C-spine fractures or dislocations associated with a neurologic deficit or any unstable fracture or dislocation should be admitted to the ICU or a monitored setting.

- Stable C-spine fractures or dislocations should be admitted.
- Isolated spinous process fractures that are not associated with any neurologic deficit or instability on plain films.
- Simple cervical wedge fractures with no neurologic deficit.

Discharge Criteria

- Patients with acute cervical strain “whiplash”
- Musculoskeletal injuries that are associated with mild to moderate pain, no neurologic deficit, and normal radiographs

Issues for Referral

- The patient with a radiographically normal C-spine but continuous pain may be discharged with a hard collar and appropriate orthopedic follow-up.
- Patients with persistent symptoms from stinger should be followed up in 3–4 wk for EMG.

FOLLOW-UP RECOMMENDATIONS

Return to ED for evaluation if pain increases or numbness, weakness, stingers, or other clinical changes develop.

PEARLS AND PITFALLS

- Trivial neck injuries in patient with ankylosing spondylitis or other brittle bone diseases may result in significant injuries.
- All the NEXUS criteria need to be applied to safely rule out a clinically significant spinal fracture without imaging.

SPINE INJURY: CERVICAL, PEDIATRIC

Roxanna A. Sadri

BASICS

DESCRIPTION

- Relatively rare, present in 1–2% of patients with severe blunt trauma
- Children <8 yr of age are more likely to have upper cervical spine injuries (C1–C3) and are at risk of growth plate injuries:
 - Spinal fulcrum is higher (C2–C3 at birth)
 - Relatively larger head to body
 - Weaker cervical musculature
 - Ligamentous laxity
 - Immature vertebral joints
- Children >8 yr of age:
 - Increased incidence of pancervical injuries
 - Vertebral body and arch fractures
 - Lower cervical spine injuries more common
- Special considerations:
 - Down syndrome
 - Klippel–Feil syndrome
 - Morquio syndrome
 - Larsen syndrome
- Spinal cord injury without radiographic abnormality (SCIWORA):
 - Based on study population, incidence from 4.5–35% of children with spinal injuries
 - More common in children <8 yr of age
 - May present as definite spinal cord injury:
 - Spinal shock
 - Neurologic deficits
 - Symptoms may be transient and have resolved by time of evaluation:
 - Paresthesias
 - Burning sensation of hands
 - Weakness
 - Symptoms often occur immediately after injury but may have delayed onset (i.e., minutes to days).

ETIOLOGY

- Birth – breech vaginal delivery
- <8 yr – MVC and falls
- >8 yr – MVC and sports injuries

SIGNS AND SYMPTOMS

- Local cervical spine pain
- Limited range of motion
- Neurologic deficit (may be transient)
- May be masked by altered mental status or distracting injury
- Abnormal vital signs:
 - Hypotension
 - Bradycardia
 - Hypoventilation or apnea
- Neck signs:
 - Tender to palpation over cervical spine
 - Limited range of motion
 - Muscle spasm
- Neurologic signs:
 - Paresthesias or sensory deficit
 - Flaccid tone
 - Loss of rectal tone
 - Paralysis
- Paralysis:
 - Anterior cord syndrome:
 - Hyperflexion injury
 - Paralysis
 - Loss of pain sensation, preservation of light touch, and proprioception
 - Central cord syndrome:
 - Hyperextension injury
 - Weakness upper greater than lower extremities
 - Burning sensation in hands and fingers
 - Brown-Séquard syndrome:
 - Cord hemisection
 - Ipsilateral paralysis
 - Contralateral loss of pain
 - Horner's syndrome:
 - Disruption of sympathetic chain
 - Ipsilateral ptosis, miosis, anhidrosis
 - Also consider carotid dissection
 - Quadriplegia
 - Absent reflexes
- Preverbal child may be unable to express symptoms and may not cooperate during exam.

ESSENTIAL WORKUP

- Obtain cervical spine radiographs for:
 - Cervical spine tenderness
 - Altered mental status
 - Neurologic deficit (even if transient)
 - Distracting injury
 - Mechanism of injury
- Additional imaging studies (CT, MRI) may be indicated if plain radiographs are inconclusive OR clinical exam suggests injury
- Nexus criteria can be applied safely to children > 8 yr of age, but not younger

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- Cervical spine radiographs:
 - Standard initial views: Anteroposterior, cross-table lateral, and open-mouth odontoid
 - Cross-table lateral identifies ~80% of fractures, dislocations, and subluxations
 - Addition of AP and odontoid increases sensitivity
 - Need to visualize all 7 cervical vertebrae and C7–T1 junction
 - Space between anterior arch of C1 and anterior aspect of odontoid process:
 - 5 mm or smaller in children and 3 mm in adults
 - Thickening of prevertebral soft tissue:
 - Suggests underlying fracture or ligamentous injury
 - Also occurs with neck flexion, expiration, swallowing
 - Too much variability exists for measurements to be highly sensitive.
 - Soft tissue below the glottis should be approximately twice as thick as above the glottis.
 - Pseudosubluxation of C2:
 - Normal variant
 - A result of ligamentous laxity and often resolves by the age of 8 yr
 - C2 anteriorly displaced on C3
 - Posterior cervical line retains normal relationships.
 - Line drawn between anterior aspect of spinous processes of C1 and C3 should pass within 2 mm of anterior aspect of spinous process of C2.
 - Larger than 2-mm space suggests underlying hangman fracture.
 - Can be applied only at C1–C3
 - Anterior vertebral wedging of C3 and C4:
 - May be mistaken for compression fracture
 - Epiphyseal growth plates may resemble fractures:
 - Posterior arch of C1 fuses by 4 yr of age.

- Anterior arch of C1 fuses by age 6 yr of age.
- Base of odontoid fuses with body of C2 by 7 yr of age.
- Flexion and extension views:
 - Limited use
 - May be useful if suspected occult ligamentous injury
 - Negative cervical spine films
 - No neurologic abnormalities
- CT scan:
 - If fracture suspected despite negative plain radiographs
 - For further definition of fracture identified on plain radiographs
 - Suspicion of a fracture seen on plain radiographs
 - Inadequate radiographs
- MRI:
 - Suspected spinal cord injury with or without abnormalities found on plain radiographs or CT

DIFFERENTIAL DIAGNOSIS

- Cervical muscle strain
- Torticollis
- Cervical adenitis
- Retropharyngeal abscess
- Meningitis

TREATMENT

PRE HOSPITAL

- Immobilize all infants and children with potential cervical spine injuries
- Appropriate size cervical collar
- Tape, towels, padding in combination with car seat or spine board if formal collar not available
- Place padding under neck, shoulders, and back, as relatively larger cranium can cause flexion
- In setting of sports injuries, helmets should be left on

INITIAL STABILIZATION/THERAPY

- Maintain cervical spine immobilization.
- Logroll patient.
- Maintenance of inline cervical spine immobilization if intubation is required.

ED TREATMENT/PROCEDURES

- Any trauma patient with neurologic deficit consistent with spinal cord injury should have methylprednisolone considered.
- Neurosurgical consultation:

- True subluxation
- Fracture
- Transient or persistent neurologic deficit

MEDICATION

CONTROVERSIAL

- Methylprednisolone: Loading dose 30 mg/kg IV over 1 hr; maintenance infusion 5.4 mg/kg/hr over next 23 hr; initiate within 8 hr of injury
- Can cause immunosuppression and increase risk of infection
- Recommend discussion with neurosurgery prior to initiation

FOLLOW-UP

DISPOSITION

Admission Criteria

- Altered mental status
- Signs/symptoms of spinal cord injury
- Fracture
- Obtain appropriate consultation:
 - Neurosurgery
 - Orthopedic spine

Discharge Criteria

- Completely normal mental status
- No radiographic abnormalities
- No transient or persistent neurologic deficit
- Educate parents:
 - SCIWORA can present with delayed onset of symptoms.
 - Patient should return to hospital if paresthesias, weakness, or paralysis is present.

FOLLOW-UP RECOMMENDATIONS

- Follow up with orthopedic surgeon or neurosurgeon as directed
- If concussion suspected, follow-up suggested
- Children with significant trauma should have psychological follow-up.

PEARLS AND PITFALLS

- Maintain appropriate immobilization during evaluation.
- In most cases, plain radiographs can be used as initial screening tool.

- Be aware of unique features of pediatric cervical spine.
- Symptoms of SCIWORA can be transient or delayed.

SPINE INJURY: COCCYX

Gary Schwartz

BASICS

DESCRIPTION

- Usually results from a fall that ends with the victim in sitting position
- Fall usually occurs from standing height
- Can occur during childbirth
- More common in women

ETIOLOGY

See “Description.”

DIAGNOSIS

SIGNS AND SYMPTOMS

- Tenderness localized over the coccyx
- Ecchymosis over the gluteal fold
- Pain with sitting, especially when leaning forward, and with defecation

History

Patient or witness to provide full history of accident including any earlier events that might influence mechanism of fall or insult

Physical-Exam

A full physical exam:

- Including rectal exam to assess tenderness or mobility of coccyx
- No evidence of neurologic deficit should be found in isolated coccygeal fractures.

ESSENTIAL WORKUP

Most often isolated injury, but if other spinal injury of concern, spinal immobilization should be instituted.

DIAGNOSIS TESTS & NTERPRETATION

Imaging

Routine radiographic imaging unnecessary:

- Concern about unnecessary radiation to gonads when diagnosis can be made clinically
- Imaging is indicated if concern for other spine injuries.

- Radiographs can be hard to interpret because coccyx has normal variant positions that can be confused with fracture.
- Lateral radiograph is a best view for fracture and dislocation.

DIFFERENTIAL DIAGNOSIS

- Coccygodynia
- Levator ani syndrome
- Pilonidal cyst
- Perirectal abscess

TREATMENT

PRE HOSPITAL

- Pain management
- Assess for other injuries

INITIAL STABILIZATION/THERAPY

- Usually none required; if patient unstable, consider other diagnoses.
- Medicate for pain.

ED TREATMENT/PROCEDURES

- Pain medication
- Reduction of displaced coccygeal fracture, but rarely necessary.

TREATMENT GENERAL MEASURES

Recommend donut-shaped seat cushion for comfort.

MEDICATION

- Medication for pain if and as needed
- Stool softener

SURGERY/OTHER PROCEDURES

Reduction may be attempted if displaced coccygeal fracture evident, but rarely needed or successful.

FOLLOW-UP

DISPOSITION

Admission Criteria

Admission is generally not required.

Discharge Criteria

Coccygeal fracture can be managed on an outpatient basis unless other intercurrent injury makes admission necessary.

- S39.92XA Unspecified injury of lower back, initial encounter

SPINE INJURY: LUMBAR

Stephen R. Hayden

BASICS

DESCRIPTION

- Flexion compression fracture:
 - Wedge compression:
 - If < 50% anterior compression of the vertebral body, injury considered stable
 - No ligamentous injury
 - No neurologic deficit
 - Burst fracture:
 - Vertebral body fracture with retropulsion of bone into the neural canal
 - Kyphosis evident on lateral radiograph
 - Posterior ligamentous injury
 - Anterior compression, lower extremities, calcaneal fractures
 - Possible neurologic deficit
- Flexion distraction (lap belt injury):
 - Abdominal injuries likely
 - Chance fracture:
 - Purely bony injury; fracture line through spinous process, pedicles, and vertebral body
 - No kyphosis evident on lateral radiograph
 - Often no neurologic deficit
 - Facet dislocation:
 - Mostly soft tissue injury; no fracture
 - Complete disruption of posterior ligaments and intervertebral disc
 - Neurologic deficit may be present.
- Flexion rotation:
 - Unstable injury
 - Neurologic deficit often present
- Extension:
 - Unstable, uncommon
 - Disruption of anterior longitudinal ligament and intervertebral disc
 - Neurologic sequelae rare but possible
- Shear injuries (translational injuries):
 - Anterior, posterior, or lateral translation of superior vertebral segment over the inferior segment
 - Complete ligamentous disruption

- Neurologic deficit present
- Simple fractures:
 - Isolated spinous process fracture:
 - Ligamentous disruption
 - No neurologic deficit
 - Isolated transverse process fracture:
 - Ligamentous disruption
 - Neurologic deficit possible; rare isolated root injury

ETIOLOGY

- Blunt trauma with axial distraction, axial compression, or translational forces applied to lumbar region
- Fall from height landing on the feet (associated calcaneal fractures) or on the buttocks
- Motor vehicle accidents (MVA)

Pediatric Considerations

- Rare reports of child abuse presenting as lower extremity flaccid paralysis owing to lumbar spine fracture.
- Spinal cord terminates at L3 in newborn and recedes to T12 by adulthood; direct cord damage possible in children with high lumbar fractures.
- End plate avulsion fractures: Adolescent injury usually at L4–L5 or L5–S1 level; ligament pulls off vertebral body end plate; associated neurologic findings.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Pain or localized tenderness to palpation in lumbar midline
- Ecchymosis or deformity overlying lumbar region; palpable deformity; paraspinal muscle spasm
- Increased interspinous distance by palpation
- Step-off (anterior or posterior displacement of spinous process) by palpation
- Neurologic deficits referable to lumbar spinal nerves:
 - Loss of bladder control
 - Motor: Hip flexion (L1–L4), leg extension (L3, L4), ankle dorsiflexion (L4, L5), toe extension (L5)
 - Sensory: Inguinal crease (L1), medial thigh (L2–L3), knee (L4), lateral calf (L5)
 - Reflexes: Knee jerk (L2–L4)
- Pain may be masked by associated distracting injuries (e.g., pelvis, calcaneal fractures).
- Patients with multiple injuries and altered mental status have an unreliable

clinical exam and require imaging.

History

Mechanism to suggest forces applied to lumbar region:

- MVA
- Fall
- Direct impact to lumbar region

Physical-Exam

- Midline lumbar tenderness or deformity
- Neurologic findings involving lumbar spinal nerves

Geriatric Considerations

- Consider abuse in cases of uncertain mechanism.
- Increase suspicion of bleeding consequences, such as spinal hematomas, in patients taking Coumadin or other anticoagulants.

ESSENTIAL WORKUP

Following criteria associated with higher risk of thoracolumbar (TL) spine injuries and should be imaged:

- TL pain or tenderness to palpation
- Decreased level of consciousness (Glasgow Coma Scale <14)
- Drug intoxication, altered pain perception
- Neurologic deficits (described above)
- Painful, distracting injuries
- Severe injury mechanism (e.g., rollover MVA, auto vs. pedestrian, fall > 10 ft)
- Lumbar radiographs (described under Imaging)
- Careful neurologic exam including:
 - _ Assessment of rectal tone
 - _ Bulbocavernosus and cremasteric reflexes
 - _ Perineal sensation

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Standard multitrauma labs if indicated:
- CBC
- Chemistry panel
- Coagulation studies
- Urinalysis

Imaging

- Lumbar radiography with minimum of anteroposterior and lateral views. Characteristics of *unstable* fractures include:
 - Widening of interspinous, interlaminar, or interpedicular distance
 - Kyphosis $> 20^\circ$
 - Translation > 2 mm
 - Vertebral body height loss $> 50\%$
 - Articular process fracture
- Radiographs may not identify burst fractures in 25% of cases.
- If a fracture is identified, entire spine should be imaged to evaluate for associated injuries.
- Spinous process fracture, transverse process fracture, or simple transverse sacral fracture require lumbar flexion–extension films if patient is neurologically intact and there is no evidence of unstable injury.
- CT or MRI should be performed for further evaluation of suspected fractures or fractures identified on plain films to assess spinal cord integrity.

Diagnostic Procedures/Surgery

Consider postvoid residual urinary catheterization or ultrasound to identify urinary retention.

DIFFERENTIAL DIAGNOSIS

- Contusion
- Pathologic fracture (metastatic cancer)
- Osteoporosis
- Pelvic fracture
- Traumatic herniated disc
- Low posterior rib fracture
- Tuberculous spondylitis (Pott disease)
- Ankylosing spondylitis
- Osteogenesis imperfecta (pediatric)
- Congenital scoliosis with hemivertebra (mistaken for lateral wedge fracture)
- Child abuse
- Spinal hematoma
- Epidural abscess

TREATMENT

PRE HOSPITAL

It is difficult to determine whether an injury is stable in the field; any patients with suspected spinal injuries should be immobilized to prevent further injury.

INITIAL STABILIZATION/THERAPY

- Immobilization while tending to immediate life-threatening conditions
- Airway, breathing, and circulation management

ED TREATMENT/PROCEDURES

- Maintain spinal immobilization.
- High-dose methylprednisolone protocol for any neurologic deficit (best in concert with specialist consultation)
- Consultation with orthopedic spine or neurosurgery service
- Appropriate analgesia
- The following stable injuries may be treated conservatively if CT confirms stability of injury and patient is neurologically intact:
 - _ Isolated spinous process, transverse process fracture
 - _ Chance fracture
 - _ Anterior wedge compression (<50%) fracture
 - _ Stable burst fracture
- Total contact orthotic devices may be useful; limited activities; sleep prone; avoid pillows and soft mattresses, which may worsen deformity.

MEDICATION

- Narcotic pain medication in absence of contraindications
- High-dose steroid protocol: Methylprednisolone: 30 mg/kg IV load over 1 hr, then 5.4 mg/kg/h for the next 23 hr; initiate in ED within 8 hr of injury.

First Line

- Tylenol: 1 g (peds: 15 mg/kg) PO q4h PRN
- Motrin: 400–800 mg (peds: 10 mg/kg) PO q6h PRN
- Dilaudid: 1–2 mg (peds: 0.015 mg/kg) IV/IM q3h PRN
- Morphine: 2–10 mg (peds: 0.1–0.2 mg/kg) IV/IM q3h PRN
- Toradol: 30 mg IV or 60 mg IM (peds: 0.5 mg/kg IV or 1 mg/kg IM) q6h PRN:
 - _ Use half Toradol dose for patients >65 y

Second Line

- Flexeril: 5–10 mg PO q8h PRN
- Soma: 350 mg PO q8h PRN
- Zofran: 4–8 mg IV/PO (peds: >4 y, 4 mg IV/PO) q8h PRN
- Compazine: 5–10 mg IV/IM/PO (peds: 2.5 mg PR/PO) q8h PRN
- Phenergan: 12.5–25 mg IM/PO/IV (peds: 0.5–1 mg/kg IM/PR) q8h PRN:
 - _ IV Phenergan NOT recommended due to reports of tissue necrosis

FOLLOW-UP

DISPOSITION

Admission Criteria

Patients with traumatic lumbar fractures should be admitted for stabilization procedures, parenteral pain control, management of possible ileus, and evaluation for associated injuries.

Discharge Criteria

- Neurologically intact patients with stable injuries evaluated in conjunction with a spine surgeon
- Patients with simple compression (wedge) fractures with no neurologic deficit may be considered for outpatient management if adequate pain control and appropriate follow-up can be arranged.
- Simple transverse sacral fracture, isolated spinous process fracture, and isolated transverse process fracture may also be considered for outpatient management.
- The patient must be neurologically intact with a stable living situation; CT scan and flexion–extension films must confirm fracture stability.

Issues for Referral

Patients discharged with stable injuries should have primary care or orthopedic appointment in 1 wk to monitor for recovery and evaluate for potential complications.

FOLLOW-UP RECOMMENDATIONS

Return to ED for new neurologic symptoms or pain not controlled by discharge medications. Otherwise, follow-up as described above.

PEARLS AND PITFALLS

- Lumbar fractures are rare in pediatrics. Aggressively pursue causative factor if mechanism is not evident.
- Older individuals may have underlying medical cause of lumbar pathology. Pursue alternative causes of pain, such as hematomas and infections. Be vigilant in patients taking anticoagulants.
- CT should follow compression fractures seen on plain films to assess for stability and potential canal involvement.
- Otherwise healthy, ambulatory patients with simple post MVA low back pain may be safely discharged without imaging if the exam is otherwise reassuring.

SPINE INJURY: THORACIC

Lauren N. Elliott

BASICS

DESCRIPTION

- The following forces account for most thoracic fractures and dislocations:
 - Axial compression
 - Flexion–rotation
 - Shear
 - Flexion–distraction
 - Extension
- 3 anatomically distinct columns; if 2 of the 3 columns are disrupted, the spinal column is unstable:
 - Posterior column: Posterior bony arch and interconnecting ligamentous structures
 - Middle column: Posterior aspects of the vertebral bodies, posterior annulus fibrosis, and posterior longitudinal ligament
 - Anterior column: Anterior longitudinal ligament, anterior annulus fibrosis, and anterior vertebral body
- Major vs. minor fractures:
 - Minor:
 - Isolated articular fracture
 - Transverse process fracture
 - Spinous process fracture
 - Pars interarticularis fracture
 - Major:
 - Compression fracture
 - Burst fracture
 - Seat belt injury
 - Fracture–dislocation
- Compression fracture (anterior or lateral flexion):
 - Fracture of anterior portion of vertebral body with intact middle column
 - May be posterior column disruption
 - Type A: Fracture through both end plates
 - Type B: Fracture through superior end plate
 - Type C: Fracture through inferior end plate
 - Type D: Both end plates intact
- Burst fracture (axial loading):
 - Fracture through middle column of spine
 - May have spreading of posterior elements and laminar fractures with

possible retropulsion into the spinal canal and potential neurologic compromise

- Type A: Fracture through both end plates
- Type B: Fracture through superior end plate
- Type C: Fracture through inferior end plate
- Type D: Burst in middle column with rotational injury leading to subluxation
- Type E: Burst in middle column with asymmetric compression of anterior column
- Seat belt injury (flexion–distraction):
 - Distraction of posterior and middle columns with anterior column intact
 - Typically caused by lap belts used without shoulder harness
 - Type A: Through bone
 - Type B: Primarily ligamentous
 - Type C: Disruption of bone through middle column
 - Type D: Through ligaments and disc with no middle column fracture
- Fracture dislocations:
 - Failure of all 3 columns following compression, tension, rotation, or shear forces
 - Type A: Flexion–rotation; fall from height
 - Type B: Shear-violent force across long axis of trunk
 - Type C: Flexion–distraction; bilateral facet dislocation

ETIOLOGY

- Thoracic spine is rigid owing to the support of the rib cage and the costovertebral articulations:
 - The spinal canal is narrowest in the thoracic spine
- Traumatic thoracic spine fractures require enormous forces. Motor vehicle and motorcycle collisions, pedestrian's struck, and falls (particularly from height > 10 ft) account for most fractures:
 - A small percentage are caused by penetrating injuries (see “Spinal Cord Syndromes”)
 - 50% of all spinal fractures and 40% of all spinal cord injuries occur at the thoracolumbar junction (T11–L2)

Pediatric Considerations

- Suspect child abuse if thoracic spine injury without clear history of motor vehicle trauma.
- Posterior rib fractures raise index of suspicion for abuse and require closer survey of thoracic spine and entire body for occult injury.

Geriatric Considerations

Increased brittleness of bones in elderly (>65 yr) predispose to fractures with less

severe mechanism, falls from lesser height.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Significant force is required to produce thoracic vertebral fractures.
- Pain at the fracture site or impingement of nearby structures by bone fragments.
- Because of the stabilizing influence of the rib cage, a tremendous amount of force is needed to cause thoracic spine dislocations:
 - Concomitant internal injury should be suspected
 - Thoracic spine fracture–dislocation is less common than thoracolumbar fracture–dislocation but has higher incidence of neurologic impairment
 - Spinal injury at another anatomic level should heighten suspicion for thoracic injury and vice versa
- Common signs and symptoms:
 - Localized soft tissue defect
 - Ecchymosis or hematoma:
 - Scapular contusions
 - Step-offs, deformity, or widening of disc space (more specific)
 - Pain or tenderness (more sensitive):
 - Localized—pain and tenderness over spinous process
 - Referred—paraspinal, anterior chest, or abdomen
 - Paraspinal muscle spasm
 - Paresthesia or dysesthesia
 - Weakness (focal or global)
 - Distal areflexia, flaccid plegia
 - Bowel or bladder incontinence
 - Priapism
 - Loss of temperature control
 - Spinal shock—hypotension with bradycardia

History

- Mechanism of injury
- Comorbidities

ESSENTIAL WORKUP

- Rapid evaluation of ABCs.
- Primary and secondary trauma survey.
- Detailed neurologic exam, including rectal tone and perianal sensation.
- Thorough spine exam for deformity or tenderness.
- Any midline tenderness elicited on exam, distracting injury, altered mental status or intoxication with concerning mechanism mandates plain film spine

radiography.

- If fracture present, determine whether it is stable or unstable.
- Assess for bulbocavernosus reflex in spinal shock.

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- Midline pain or tenderness, significant motor vehicle accident, or falls from height are indications for screening with anteroposterior and lateral plain film views of the spine.
- Thin-cut CT scanning is indicated in any patient with evidence of spinal fracture on plain films and patients with normal plain films and significant pain or tenderness and mechanism for severe injury. Patients with mediastinal widening on plain film should also have evaluation for thoracic spine injury or aortic injury.
- Any finding of a fracture anywhere in the thoracic spine mandate imaging of the entire spine with plain radiographs at a minimum as 10% patients will have an additional fracture.
- Data from the CT of the chest/abdomen/pelvis are increasingly being reformatted to clear the thoracolumbar spine in trauma patients:
 - _ More sensitive than plain radiographs without additional cost or radiation
- MRI for further evaluation of suspected spinal cord injury, compression, or ligamentous tear.

DIFFERENTIAL DIAGNOSIS

- Arthritis (degenerative and rheumatoid)
- Ankylosing spondylitis
- Spina bifida
- Congenital malformation
- Degenerative disc disease
- Neoplasm
- Pathologic fracture:
 - _ Osteoporosis
 - _ Benign or malignant bone tumors

TREATMENT

PRE HOSPITAL

- If the patient's positioning initially prevents placement of a long spinal board, a short board should be placed until the patient is fully extricated.
- Patients with neurologic deficit should be transported directly to a trauma center.

INITIAL STABILIZATION/THERAPY

- Manage airway and resuscitate as indicated:
 - Airway intervention should be done with inline cervical immobilization
 - Identify hypotension that may be secondary to hemorrhage vs. neurogenic
 - Patients with hypotension in setting of trauma should be treated as hypovolemic from hemorrhage until proven otherwise
 - Consider fluid resuscitation with crystalloid followed by blood products if indicated
- Preserve residual spinal cord function and prevent further injury by stabilizing the spine.

ED TREATMENT/PROCEDURES

- Perform all needed resuscitation and diagnostic tests with the patient in full spinal immobilization. This does not require the use of the spinal board which should be removed promptly on arrival during the initial exam.
- If spinal cord injury is suspected, consider the administration of high-dose steroids and consult a spine surgeon.
- If spinal fracture or ligamentous injury is suspected without neurologic impairment, arrange CT or MRI scanning while consulting neurosurgery or orthopedic surgery.
- Pain control should be administered as soon as possible; NSAIDs, opiates, and benzodiazepines are the mainstays of treatment.
- Neurogenic hypotension presents with bradycardia or normal heart rate and patient will be warm from peripheral vasodilation. This is in contrast to the tachycardia and cool extremities seen with hypovolemic shock:
 - Neurogenic hypotension should be treated with crystalloid bolus but may require vasopressors

MEDICATION

- High-dose steroid administration is rapidly falling out of favor due to lack of evidence supporting use and risk of untoward effects of steroids.
- If given, must be within 8 hr of injury as indicated by regional/hospital protocol.
- Methylprednisolone: 30 mg/kg IV bolus over 15 min followed 45 min later by a maintenance infusion of 5.4 mg/kg/h for the next 23 hr if started within 3 hr of injury; consider continuing for 48 hr if started 3–8 hr after injury.
- High-dose steroid treatment not recommended > 8 hr after injury.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with significant spinal cord or column injury should be treated at a

regional trauma center.

- Unstable spinal column injury
- Spinal cord or root injury
- Ileus
- Pain control
- Concomitant traumatic injury
- ICU-level care based on severity of injuries

Discharge Criteria

Stable minor fractures after orthopedic or neurosurgical evaluation.

FOLLOW-UP RECOMMENDATIONS

Outpatient neurosurgical or orthopedic follow-up as indicated after appropriate ED or inpatient evaluation and treatment.

PEARLS AND PITFALLS

- Suspect and evaluate for thoracic spine injury in any trauma patient.
- CT evaluation is indicated for any patient with significant mechanism, pain, or tenderness; distracting injury or injury at another spinal level; intoxication or altered mental status.
- Maintain spinal immobilization until cleared by radiologic and clinical exam.
- Early consultation with spine surgeon if presence of fracture, neurologic deficit, or instability.
- Treatment with high-dose steroids is currently an area of controversy. Begin treatment within 8 hr of injury if initiating high-dose steroid protocol.

SPLENIC INJURY

Albert S. Jin

BASICS

DESCRIPTION

- The spleen is formed by reticular and lymphatic tissue and is the largest lymph organ.
- The spleen lies posterolaterally in the left upper quadrant (LUQ) between the fundus of the stomach and the diaphragm.

ETIOLOGY

- The spleen is the most commonly injured intra-abdominal organ:
 - _ In nearly 2/3 of cases, it is the only damaged intraperitoneal structure
 - _ Blunt mechanisms are more common
- Motor vehicle accidents (auto–auto, pedestrian–auto) are the major cause (50–75%), followed by blows to the abdomen (15%) and falls (6–9%)
- Mechanism of injury and kinematics are important factors in evaluating patients for possible splenic injury.
- Splenic injuries are graded by type and severity of injury [American Association for the Surgery of Trauma (AAST) criteria]:
 - _ Grade I:
 - Hematoma: Subcapsular, <10% surface area
 - Laceration: Capsular tear, <1 cm in parenchymal depth
 - _ Grade II:
 - Hematoma: Subcapsular, 10–50% surface area; intraparenchymal, <5 cm in diameter
 - Laceration: Capsular tear, 1–3 cm in parenchymal depth and not involving a trabecular vessel
 - _ Grade III:
 - Hematoma: Subcapsular, >50% surface area or expanding, ruptured subcapsular or parenchymal hematoma; intraparenchymal hematoma, ≥5 cm or expanding
 - Laceration: >3 cm in parenchymal depth or involving the trabecular vessels
 - _ Grade IV:
 - Laceration: Involving the segmental or hilar vessels and producing major devascularization (>25% of spleen)
 - _ Grade V:
 - Laceration: Completely shattered spleen
 - Vascular: Hilar vascular injury that devascularizes the spleen

Pediatric Considerations

- Poorly developed musculature and relatively smaller anteroposterior diameter increase the vulnerability of abdominal contents to compressive forces.
- Rib cage is extremely compliant and less prone to fracture in children but provides only partial protection against splenic injury.
- Splenic capsule in children is relatively thicker than that of an adult; parenchyma of spleen seems to contain more smooth muscle than in adults.
- Significant abdominal injury occurs in only about 5% of child abuse cases but is the 2nd most common cause of death after head injury.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- In blunt trauma, note the type and direction (horizontal or vertical) of any deceleration or compressive forces:
 - Injuries are caused by compression of the spleen between the anterior abdominal wall and the posterior thoracic cage or vertebra (e.g., lap-belt restraints).
- In penetrating trauma, note the characteristic of the weapon (type and caliber), distance from the weapon, or the type and length of knife or impaling object:
 - Injuries result from a combination of the kinetic energy and shear forces of penetration.

Physical-Exam

- Systemic signs from acute blood loss:
 - Syncope, dizziness, weakness, confusion
 - Hypotension or shock
- Local signs:
 - LUQ abdominal tenderness
 - Palpable tender mass in LUQ (Balance sign)
 - Referred pain to the left shoulder (Kehr sign)
 - Abdominal distention, rigidity, rebound tenderness, involuntary guarding
- Contusions, abrasions, or penetrating wounds to the chest, flank, or abdomen may indicate underlying splenic injury.
- Fractures of lower left ribs are commonly seen in association with splenic injuries.

Pediatric Considerations

Age-related difficulties in communication, fear-induced uncooperative behavior, or a concomitant head injury make clinical exam less reliable.

ESSENTIAL WORKUP

- History and physical exam are neither specific nor sensitive for splenic injury.
- Adjunctive imaging studies are required.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- No hematologic lab studies are specific for diagnosis of injury to the spleen.
- Obtain baseline hemoglobin, type and cross-match, and chemistries.

Imaging

- Plain abdominal radiographs:
 - Too nonspecific to be of value
 - CXR findings suggestive for splenic injury:
 - Left lower rib fracture(s)
 - Elevation of left hemidiaphragm
 - Medial displacement of gastric bubble (Balance sign)
 - Left pleural effusion
- Ultrasound:
 - Routinely performed at bedside in trauma patients as part of focused assessment with sonography (FAST)
 - Primary role is detecting free intraperitoneal blood, which may suggest splenic injury
 - Does not image solid parenchymal damage well
 - Technically compromised by uncooperative patient, obesity, substantial bowel gas, and subcutaneous air
- CT scan:
 - Noncontrast CT is procedure of choice in stable patient due to speed and accessibility
 - Depicts the presence and extent of splenic injury and adjacent organs, including the retroperitoneum
 - Provides the most specific information in patients stable enough to go to the CT scanner
- MRI:
 - May be applicable to subset of hemodynamically stable patients who cannot undergo CT scan (e.g., allergic to IV contrast)
- Angiography:
 - Has been added to the diagnostic and treatment options for selected cases

Diagnostic Procedures/Surgery

- Diagnostic peritoneal lavage (DPL):
 - Extremely sensitive for the presence of hemoperitoneum although

- nonspecific for source of bleeding and does not evaluate retroperitoneum
- Largely replaced by the FAST exam in most major trauma centers.

DIFFERENTIAL DIAGNOSIS

- Intraabdominal organ injury, especially liver
- Injury to retroperitoneal structures
- Thoracic injury

TREATMENT

PRE HOSPITAL

- Obtain details of injury from pre-hospital providers.
- IV access
- Penetrating wounds or evisceration should be covered with sterile dressings.

INITIAL STABILIZATION/THERAPY

- Airway management (including C-spine immobilization)
- Standard Advanced Trauma Life Support (ATLS) resuscitation measures:
 - Adequate IV access, including central lines and cutdowns, as dictated by the patient's hemodynamic status
 - Fluid resuscitation, initially with 2 L of crystalloid (NS or lactated Ringer solution), followed by blood products as needed

ED TREATMENT/PROCEDURES

- Immediate laparotomy may be appropriate in the acutely injured and hemodynamically unstable patient with presumed hemoperitoneum and splenic injury.
- Most patients with acute splenic injury either are hemodynamically stable or stabilize rapidly with relatively small amounts of fluid resuscitation.
- Adjunctive diagnostic procedures supplementing the physical exam should be performed early in the evaluation, followed by laparotomy when indicated by positive diagnostic findings.
- Gunshot wounds to the anterior abdomen are routinely explored in the OR.
- Stab wounds can be managed by local wound exploration, followed by US or DPL when intraabdominal penetration is suspected.
- Operative vs. nonoperative management:
 - Patients with signs and symptoms of intraabdominal hemorrhage, those with operative indications based on imaging//diagnostic procedures, and those who fail nonoperative management should undergo laparotomy.
 - Angiographic embolization is an option in hemodynamically stable patient
 - Splenectomy vs. splenic salvage depends on the grade of splenic injury.
 - >70% of all stable patients are currently being treated via nonoperative management:

- Hemodynamic stability
- Negative abdominal exam
- Absence of contrast extravasation on CT
- Absence of other clear indications for exploratory laparotomy
- Absence of associated health conditions that carry an increased risk for bleeding (e.g., coagulopathy, hepatic failure, anticoagulant use, coagulation factor deficiency)
- Injury grades I–III

Geriatric Considerations

- Patients > 55 yr should be considered for operative management due to decreased physical tolerance to traumatic insult (splenic capsule thins with age) and reduced physiologic reserve.
- Embolization is relatively contraindicated in patients > 55 yr due to higher failure rates in these patients.

Pediatric Considerations

- Nonoperative management of splenic injuries is considered safe:
 - _ Concerns for overwhelming postsplenectomy infection/sepsis

FOLLOW-UP

DISPOSITION

Admission Criteria

All patients with splenic injury require hospitalization for definitive laparotomy or observation with serial abdominal exams, serial hematocrit determinations, and bed rest.

Discharge Criteria

Only asymptomatic patients objectively demonstrated not to have splenic or other traumatic injury may be discharged.

- S36.039A Unspecified laceration of spleen, initial encounter

SPONDYLOLYSIS/SPONDYLOLISTHESIS

Lisa G. Lowe Hiller

BASICS

DESCRIPTION

- Spondylolysis:
 - Bony defect at the pars interarticularis (the isthmus of bone between the superior and inferior facets)
 - Can be unilateral or bilateral
 - Bilateral form has a much higher likelihood of slippage or spondylolisthesis than the unilateral form.
- Spondylolisthesis:
 - The slipping forward of 1 vertebra upon another
 - Spondylolysis can contribute to spondylolisthesis, which is noted in ~5% of the population. It is 2–4 times more common in males.
 - Of those with spondylolysis, 50% will have some degree of spondylolisthesis develop during their lifetime, and 50% of those will be symptomatic:
 - Literature does not associate athletic activity with increased slippage.
 - Spondylolisthesis predisposes to nerve root impingement and frequently sciatica.
- Classification:
 - Type 1—dysplastic: Congenital defect of the neural arch or intra-articular facets is often associated with spina bifida occulta
 - Type 2—isthmic: Stress fracture from repetitive microtrauma through the neural arch
 - Type 3—degenerative: Long-standing segmental instability
 - Type 4—traumatic
 - Type 5—pathologic: Generalized or focal bone disease
 - Spondylolisthesis is divided into 4 grades based on degree of slippage (Meyerding grading system):
 - Grade I: Up to 25% of the vertebral body width
 - Grade II: 26–50% of vertebral body width
 - Grade III: 51–75% of vertebral body width
 - Grade IV: 76–100% of vertebral body width
 - The most common location for spondylolisthesis is L5 displaced on the sacrum (85–95%), followed by L4 on L5.

Pediatric Considerations

- Spondylolysis is one of the most common causes of serious low back pain in children, although it is most often asymptomatic.

- Symptoms most often present during adolescent growth spurt from age 10–15 yr.
- Seen commonly in athletic teens; particularly in sports involving back hyperextension (e.g., gymnastics, diving, football).
- Acute symptoms are related to trauma.

ETIOLOGY

Unknown; theories include congenital pars anomalies, alterations in bone density, and recurrent subclinical stress injury.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Onset often gradual, unless traumatic
- Often associated with feeling of stiffness or spasm in paravertebral muscles
- Pain in the back and proximal legs aggravated by standing and walking
- Sitting or forward bending relieves pain.
- Pain occurs after varying amounts of exercise, with standing, or with coughing:
 - Aggravating factors can include repetitive hyperextending movements.
 - Alleviating factors can include rest, although the course is variable and slow and usually requires sitting or stooping positions.
- Systemic/neurologic symptoms: Minimal, unless there is significant trauma or “slip.”

Physical-Exam

- Hyperlordotic posture:
 - Trunk may appear shortened.
 - Rib cage approaches iliac crests.
- Hamstring tightness:
 - Knees flexed to allow patient to stand upright
- Only “typical” finding is 1-legged hyperextension:
 - Standing on 1 leg and leaning backward reproduces pain on ipsilateral side.
- Palpation may reveal step-off with a prominent spinous process of L5 in significant spondylolisthesis.
- Neurologic exam is usually normal:
 - If abnormal, pain and sensorimotor loss is in a dermatomal distribution.
 - Consider herniation or spondylolisthesis.

Pediatric Considerations

- Spondylolysis in a child <10 yr is rare; these patients should be watched for the following:

- Constant pain lasting several weeks
- Pain occurring spontaneously at night
- Pain that interferes repeatedly with school, play, or sports
- Pain associated with marked stiffness, limitation of motion, fever, or neurologic signs
- Pain at the lumbosacral junction

DIAGNOSIS TESTS & INTERPRETATION

Lab

There are no required lab studies.

Imaging

- Lumbosacral spine radiographs:
 - Lateral and oblique radiographs of spine most helpful.
 - Spondylolysis will manifest as a radiolucent defect in the pars interarticularis, visible as a “collar” or “broken neck” on the oblique view “Scottie dog”
 - Secondary radiographic signs may include sclerosis of the contralateral pedicle and spina bifida occulta at the level of the spondylolysis.
 - Majority (80–95%) found at L5–S1 level, 15% at L4–L5.
 - Spondylolisthesis will manifest as forward slipping of one vertebral body on another (seen on lateral view).
- Single photon emission computed tomography (SPECT)—better specificity for linking back pain to spondylolysis.
- CT scan:
 - Pathology more clearly demonstrated than on plain films
 - Can identify other spinal pathology
 - Plays an important role for orthopedics in management decisions through identification of new stress fractures and healing of old stress fractures.
 - If a CT scan is obtained in the ED, sagittal reconstructions should be performed and the CT scanner should be at minimum a 16-slice scanner.
 - Outpatient evaluation unless history of recent trauma.
- MRI—exact role not yet clarified in literature:
 - Useful for defining nerve root impingement and central canal and neuroforaminal narrowing.
 - May be useful in the assessment of acuity of abnormality.
 - Can identify alternate pathologic diagnoses.

Pediatric Considerations

- Lower threshold for ordering imaging studies.
- Progressive slipping more likely to occur than in adults.

DIFFERENTIAL DIAGNOSIS

- Tuberculosis (Pott disease)
- Discitis
- Bone or spinal cord tumor
- Pyelonephritis
- Retroperitoneal infection
- Injury to muscles or joints of back
- Congenital hip dislocation
- Rickets
- Ruptured intervertebral disc
- Vascular claudication
- Osteomyelitis
- Osteoid osteoma
- Aortic aneurysm

TREATMENT

PRE HOSPITAL

Spinal precautions are not needed unless there is a history of recent trauma.

INITIAL STABILIZATION/THERAPY

Vigorous attempts at traction should not be pursued.

ED TREATMENT/PROCEDURES

- Pain control and muscle relaxants as clinically needed
- Supportive therapy if symptoms are mild
- Restrict activities if repetitive trauma is likely aggravating cause (e.g., sports) for 3–6 wk, followed by reintroduction of activity when asymptomatic.
- Consider antilordotic braces (controversial) or physical therapy.
- Orthopedic consult or referral if symptoms are moderate to severe or unresponsive to supportive care
- Surgical intervention typically consists of spinal fusion in the flexed position:
 - 50% of symptomatic patients with spondylolisthesis may require surgery.
- All symptomatic patients with grade III or IV spondylolisthesis should probably undergo surgery.
- Exercises are not of proven benefit.

Pediatric Considerations

- Activity restriction is not necessary if minimal or no symptoms.
- Literature suggests good outcome for young athletes with conservative treatment.

MEDICATION

- Muscle relaxants:
 - E.g.—methocarbamol: 1,000–1,500 mg PO QID (peds: Safety and effectiveness for children < 12 yr of age not established)
 - Diazepam: 2–10 mg PO TID–QID
 - Cyclobenzaprine: 5–10 mg PO TID (peds: Safe for ages > 15 yr old)
- NSAIDs:
 - E.g.—ibuprofen: 200–800 mg PO TID–QID (peds: 5–10 mg/kg PO q6h)
- Opioids (doses can vary on oral medications):
 - Example—morphine sulfate: 0.1 mg/kg up to 2–4 mg increments IV.
 - Acetaminophen/hydrocodone: 5/500 mg 1–2 tabs PO QID; do not exceed acetaminophen 4 g/24 h (peds: Do not exceed 5 doses of 10–15 mg/kg acetaminophen in 24 hr)
 - Acetaminophen/oxycodone: 5/325 mg 1–2 tabs PO QID; do not exceed acetaminophen 4 g/24 h (peds: Do not exceed 5 doses of 10–15 mg/kg acetaminophen in 24 hr)
 - Acetaminophen/codeine: 300/30 mg 1–2 tabs PO QID (peds: 0.5–1 mg/kg codeine PO q4–6h; max. 60 mg/dose codeine; 1 g/dose, 75 mg/kg/d up to 4 g/d > 3 yr old); do not exceed acetaminophen 4 g/24 h (peds: Do not exceed 5 doses of 10–15 mg/kg acetaminophen in 24 hr)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Inability to walk
- Inability to cope at home due to pain or social situation
- New or progressive neurologic deficit

Discharge Criteria

- Orthopedic follow-up arranged
- Social support system in place
- Pain control
- Patient education

Pediatric Considerations

Close follow-up is mandatory.

SPONTANEOUS BACTERIAL PERITONITIS

Alison Foster-Goldman • Christopher T. Richards

BASICS

DESCRIPTION

- Infection of ascites fluid without an evident intra-abdominal surgically treatable source:
 - Ascites fluid polymorphonuclear leukocyte count (PMN) $> 250/\text{mL}$ with a positive bacterial peritoneal fluid culture
- Must be distinguished from secondary bacterial peritonitis:
 - Nonsurgical management of secondary bacterial peritonitis carries 100% mortality.
 - Surgical management of spontaneous bacterial peritonitis (SBP) carries 80% mortality
- Up to 30% yearly incidence of SBP in patients with ascites

ETIOLOGY

- Mechanism:
 - Portal hypertension causes translocation of intestinal bacteria through edematous gut mucosa to the peritoneal cavity
 - Variceal bleeding increases the risk of SBP due to a compromised barrier between the GI tract and blood stream
 - Transient bacteremia with low serum complement
 - Decreased host defense mechanisms
 - Impaired activity of reticuloendothelial system phagocytosis and opsonization
 - Can also seed ascitic fluid via bacteremia from infections outside of the gut
- Usually seen in the setting of cirrhosis:
 - Rare in other conditions causing ascites (nephrotic syndrome or CHF)
- Predominant organisms:
 - 63% aerobic gram-negative (*Escherichia coli*, *Klebsiella*, others)
 - 15% gram-positive (Streptococci)
 - 6–10% enterococci
 - $< 1\%$ anaerobic
- Gram-positives account for 50% of cases in patients who are on prophylactic therapy with fluoroquinolones.

DIAGNOSIS

SIGNS AND SYMPTOMS

Up to 30% of patients with SBP have no signs or symptoms of infection.

History

- Abdominal pain: Diffuse, constant, often very mild
- Fever, chills
- Diarrhea from bacterial overgrowth
- Worsening ascites
- Altered mental status
- Fatigue, myalgias

Physical-Exam

- Fever is the most common sign:
 - _ A lower threshold for fever ($> 37.8^{\circ}\text{C}$ or $> 100^{\circ}\text{F}$) is maintained for cirrhotic patients owing to baseline hypothermia
 - _ 80% of patients with SBP have fevers and chills
- Altered mental status
- Ascites
- Abdominal tenderness:
 - _ Development of a rigid abdomen may not occur because of the separation of visceral and parietal pleura due to ascites

ESSENTIAL WORKUP

- Paracentesis is the mainstay of diagnosis unless patient has peritoneal dialysis
- Coagulopathy does not have to be corrected before the procedure (except for platelets $< 20,000$)
- Procedure:
 - _ Use ultrasound guidance when available
 - _ Location (with patient supine):
 - 3–5 cm cephalad and medial to anterosuperior iliac spine, lateral to the rectus sheath OR
 - 2 cm caudad to the umbilicus (ensure bladder emptying beforehand)
 - _ 40–50 mL should be aspirated, then change needles to avoid contamination:
 - 10 mL for each culture bottle
 - 10 mL for cell count, chemistries, Gram stain (lithium–heparin tube, EDTA tube, and sterile container)
 - _ Inoculate culture bottles with peritoneal fluid immediately at the bedside

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Routine ascitic fluid assays:
 - _ Cell count and differential:
 - Count bands as PMNs

- Total protein
- Albumin
- Culture
- Gram stain
- Optional fluid assays:
 - o Glucose
 - o LDH (from lysed PMNs)
 - o Amylase
- Characteristics of ascitic fluid consistent with SBP:
 - PMNs $> 250/\text{mm}^3$
 - Diagnosis suggested when:
 - o WBC $> 1,000/\text{mm}^3$
 - o WBC $> 250/\text{mm}^3$ with $> 50\%$ PMNs
 - Total protein $< 1 \text{ g/dL}$
 - pH < 7.34
 - Normal amylase
 - Positive culture:
 - o Only 30–50% of cultures become positive; this rate increases with high volume bedside inoculation of culture bottles
 - Positive Gram stain
 - Glucose $< 50 \text{ mg/dL}$
 - Ascites LDH $>$ serum LDH
 - Lactoferrin > 242 shows promise as marker for SBP
 - Serum–ascites albumin gradient $> 1.1 \text{ g/dL}$ consistent with portal hypertension
 - If hemorrhagic ascites ($> 10,000 \text{ RBC}/\text{mm}^3$), subtract $1 \text{ PMN}/\text{mm}^3$ for every $250 \text{ RBC}/\text{mm}^3$ in ascites fluid interpretation
- Blood tests (usually reflect underlying disease):
 - CBC with differential
 - Basic metabolic panel
 - PT/PTT
 - LFTs (including albumin)
 - Blood cultures
 - UA and culture

Imaging

- Abdominal ultrasound:
 - Confirms presence of ascites
 - Helps guide paracentesis
- Chest radiograph
- Abdominal radiographs: Flat-plate and upright to evaluate for perforation or

obstruction

- Water-soluble contrast CT if suspect secondary bacterial peritonitis

Diagnostic Procedures/Surgery

Surgery consultation to consider exploratory laparotomy if free air on x-ray or extravasation of contrast on CT

DIFFERENTIAL DIAGNOSIS

- Secondary bacterial peritonitis:
 - _ Due to perforation or abscess
 - _ Polymicrobial Gram stain or 2 of the following:
 - Ascites total protein > 1 g/dL
 - Ascites glucose < 50 mg/dL
 - Ascites LDH > 1/2 upper limit of normal serum LDH or LDH > 225
 - _ Orange ascites with bilirubin > 6 mg/dL suggests ruptured gallbladder
- Acute hepatitis:
 - _ Fever, leukocytosis, abdominal pain \pm ascites
 - _ Ascites PMNs < 250/mm³
- Culture-negative neutrocytic ascites:
 - _ Ascites PMNs > 250/mL, culture negative
- Monomicrobial non-neutrocytic bacterascites:
 - _ Due to colonization phase of SBP
 - _ Ascites PMNs < 250/mm³, monomicrobial culture
 - _ Treated like SBP if symptomatic
- Polymicrobial bacterascites:
 - _ Due to accidental gut perforation (1 in 1,000 paracenteses)
 - _ Ascites PMNs < 250/mm³, polymicrobial culture
- Pancreatitis:
 - _ Elevated ascites amylase
- Peritoneal carcinomatosis or tuberculous peritonitis:
 - _ Secondary bacterial peritonitis criteria with non-PMN predominance and lack of fever

TREATMENT

PRE HOSPITAL

- IV fluids for hypotension
- Blood glucose for altered mental status
- Supplemental oxygen for respiratory complaints

INITIAL STABILIZATION/THERAPY

- ABCs

- Prompt antibiotic treatment and IV fluids for septic shock

ED TREATMENT/PROCEDURES

- Administer platelets before paracentesis only if platelet count is $< 20,000/\text{mm}^3$
- Give empiric antibiotics immediately after paracentesis for:
 - Ascites PMNs $> 250/\text{mm}^3$ or
 - Temperature $> 37.8^\circ\text{C}$ or
 - Altered mental status or
 - Abdominal pain/tenderness or
 - Clinical features most consistent with SBP
- Antibiotic options:
 - Ceftriaxone or cefotaxime
 - Ampicillin–sulbactam, piperacillin–tazobactam or aztreonam
 - Avoid aminoglycosides, fluoroquinolones
 - Add metronidazole for secondary bacterial peritonitis
- IV albumin is helpful in preventing renal impairment and reducing mortality in diagnosed SBP

Prognosis

- In-hospital noninfection–related mortality is 20%
- Can be precursor to hepatorenal syndrome
- 1- and 6-mo mortality rates after an episode of SBP are 32% and 69%, respectively

MEDICATION

First Line

- Cefotaxime: 2 g IV q8h
- Albumin for high-risk patients: 1.5 g/kg IV on day 1 and 1 g/kg IV on day 3

Second Line

- Ceftriaxone: 2 g IV q8h
- Piperacillin–tazobactam: 3.375 g IV q6h
- Ampicillin–sulbactam: 1.5–3 g IM/IV q6h
- Aztreonam: 0.5–2 g IM/IV q6–12h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Admit all patients for IV antibiotics and gastroenterology consultation
- ICU admission for septic shock or severe hepatic encephalopathy

Discharge Criteria

- All patients with suspected or known SBP should be admitted.
- If patient refuses admission and has no signs of shock, encephalopathy, azotemia, or GI bleeding, a dose of IV ceftriaxone and a course of oral fluoroquinolones followed by close follow-up may be considered

Issues for Referral

- Hepatology and gastroenterology referral may be indicated
- Prophylaxis with norfloxacin or trimethoprim/sulfamethoxazole

ALERT

Infections related to continuous abdominal peritoneal dialysis:

- Symptoms: Cloudy peritoneal fluid (90%), abdominal pain (80%), and fever (50%)
- Signs: Abdominal tenderness 70%
- Diagnosis: Peritoneal WBCs > 100/mL with > 50% PMNs and positive Gram stain or culture:
 - _ Fluid should be accessed by trained personnel
- Microbiology:
 - _ > 50% of cases are due to gram-positives, most commonly staphylococci
 - _ *E. coli* is an *uncommon* cause of peritonitis in patients with chronic ambulant peritoneal dialysis
- Treatment:
 - _ Antibiotics are given through the intraperitoneal (IP) route
 - _ 1st choice: Cefazolin (1 g IP per day) + ceftazidime (1 g IP per day)
 - _ Vancomycin (2 g IP every week) is an alternative to cefazolin
 - _ Amikacin 2 mg/kg/day IP

FOLLOW-UP RECOMMENDATIONS

Gastroenterology or PCP follow-up for patients with SBP

PEARLS AND PITFALLS

- Rule out secondary bacterial peritonitis first
- Bedside inoculation of blood culture bottles with ascitic fluid increases culture yield
- Maintain high suspicion for SBP, since many patients are asymptomatic

ICD10

K65.2 Spontaneous bacterial peritonitis

SPOROTRICHOSIS

Matthew Hinderaker • Adam Kellogg

BASICS

DESCRIPTION

- Lymphocutaneous:
 - Most common form
 - Inoculation of fungus (*Sporothrix schenckii*) into skin/soft tissue
 - Disease with or without hematogenous spread after traumatic inoculation with soil or plant material
 - Secondary to animal bites/scratches, especially from cats, trauma
 - Increased risk: Farmers, gardeners, landscapers, forestry workers
- Pulmonary:
 - Inhalation of conidia aerosolized from soil/plant decay
 - Increased risk: Alcoholics, diabetics, COPD, steroid users
- Multifocal extracutaneous:
 - Cutaneous inoculation and hematologic spread
 - Increased risk: HIV/immunosuppressed patients

ETIOLOGY

- Fungal infection caused by *S. schenckii*:
- Dimorphic fungus
- Occurs as mold on decaying vegetation, moss, and soil in temperate and tropical environments
- Animal vectors, notably cats and armadillos

DIAGNOSIS

SIGNS AND SYMPTOMS

- Several clinical manifestations/syndromes
- Determined by mode of inoculation and host factors
- Lymphocutaneous:
 - Initial lesions appear days to weeks after inoculation
 - Begin as papules, become nodular, often ulcerate:
 - Distal extremities more commonly involved
 - Size: Millimeters to 4 cm
 - Pain absent or mild
 - Drainage is nonpurulent
 - Systemic symptoms usually absent
 - Secondary nodular lesions develop along lymphatics draining the original

- site.
- May wax and wane over years if untreated
- Fixed cutaneous:
 - Plaque-like or verrucous lesion at the site of inoculation (typically face and extremities)
 - Ulceration uncommon
 - Do not manifest lymphangitic progression
 - Common in endemic regions of South America
- Extracutaneous:
 - Osteoarticular:
 - Secondary to local or hematologic inoculation
 - Septic arthritis more common than osteomyelitis
 - Joint inflammation, effusion, and pain
 - Single or multiple joint involvement of extremities: Knee, elbow, wrist, ankle
 - Indolent onset, few systemic symptoms
 - Tenosynovitis, septic arthritis, bursitis, nerve entrapment syndrome
 - Usually poor outcome due to delayed diagnosis
- Pulmonary:
 - Syndrome resembles mycobacterial infection (TB)
 - Fever, weight loss, fatigue, night sweats
 - Productive cough, hemoptysis, dyspnea
 - Uniformly fatal if untreated
- Multifocal extracutaneous (disseminated):
 - Low-grade fever, weight loss
 - Diffuse cutaneous lesions
 - Arthritis/osteolytic lesions/parenchymal involvement
 - Chronic lymphocytic meningitis
 - Ocular adnexa, endophthalmitis
 - Genitourinary, sinuses
 - Can be fatal if untreated
 - Often occurs in immunocompromised host

History

- Activity with exposure to soil, moss, organic material, or to cats in endemic areas
- Fixed cutaneous or lymphocutaneous: Healthy host
- Disseminated/extracutaneous: Diabetics, COPD, HIV/AIDS

Physical-Exam

- Fixed cutaneous/lymphocutaneous: Lesions found on exam
- Disseminated: Nonspecific findings

ESSENTIAL WORKUP

Diagnosis dependent on isolation *S. schenckii* from site of infection:

- Culture from aspirated material, tissue biopsy, or sputum

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Blood tests not indicated with cutaneous disease
- Cultures of sputum, synovial fluid, CSF, blood as indicated by extracutaneous manifestations
- No reliable serologic assays available

Imaging

- Pulmonary:
 - Chest radiograph reveals cavitary lesions
- Extracutaneous/disseminated:
 - Consider bone scan in immunocompromised host.

Diagnostic Procedures/Surgery

- Lymphocutaneous/fixed cutaneous:
 - Biopsy reveals pyogranulomatous inflammation, 3–5 mm cigar-shaped yeast
- Pulmonary:
 - Gram stain of sputum may yield yeast; sputum cultures often positive
- Extracutaneous/disseminated:
 - CSF reveals lymphocytic meningitis, increased protein/decreased glucose

DIFFERENTIAL DIAGNOSIS

- Lymphocutaneous:
 - Leishmaniasis
 - Nocardiosis
 - *Mycobacterium marinum*
 - Tularemia
- Fixed cutaneous:
 - Bacterial pyoderma
 - Foreign-body granuloma
 - Inflammatory dermatophyte infections
 - Blastomycosis
 - Mycobacteria
- Osteoarticular:
 - Rheumatoid arthritis
 - Gout
 - Tuberculosis
 - Bacterial arthritis
 - Pigmented villonodular synovitis

- Pulmonary and meningitis:
 - Mycobacterial infections
 - Histoplasmosis
 - Coccidioidomycosis
 - Cryptococcal disease

TREATMENT

INITIAL STABILIZATION/THERAPY

Airway/hemodynamic stabilization for severely ill patients with extracutaneous manifestations

ED TREATMENT/PROCEDURES

- Lymphocutaneous/fixed cutaneous:
 - Itraconazole (drug of choice): Efficacious, but expensive and potential for hepatotoxicity, has numerous drug–drug interactions, black box in heart failure
 - Terbinafine: Less expensive alternative if failure of itraconazole, only in cutaneous disease
 - Saturated solution of potassium iodide (SSKI): Inexpensive but bitter taste and side effects (anorexia, nausea, diarrhea, fever, salivary gland swelling) lead to limited acceptability
 - Local heat therapy for cutaneous disease ($> 35^{\circ}\text{C}$) inhibits fungal growth, use in pregnant patients or others who cannot tolerate medication, therapy may take 3–6 mo
- Pulmonary:
 - Itraconazole or amphotericin B in early disease, effective in $\sim 30\%$ of cases
 - More advanced disease often requires resection plus amphotericin B
- Osteoarticular:
 - Itraconazole: 1st-line therapy for more than 1 yr, amphotericin B if refractory
- Disseminated:
 - Amphotericin initially
 - Itraconazole in stable, immunocompetent patients
 - HIV and sporotrichosis: Suppressive therapy with itraconazole is recommended after initial infection

MEDICATION

- Amphotericin B: Lipid form 3–5 mg/kg daily (preferred, especially in pregnancy and peds); if using deoxycholate form (pt with no risk of renal dysfunction) 0.7–1 mg/kg daily and infuse over 2 hr
- Itraconazole: Lymphocutaneous: 100–200 mg (peds: 6–10 mg/kg/d, max. 400 mg)

- PO TID for 3 days, then 100–200 mg per day for 2–4 wk after lesions resolve, pulmonary/osteoarticular: 200 mg PO TID for 3 days, then BID for 12 mo
- SSKI: 5 drop (peds: 1 drop) in water or juice TID; increase by 5 drops per dose each week up to a max. 40–50 drops TID (peds: max. of 1 drop/kg) as tolerated, for 6–12 wk or until lesions resolve
 - Terbinafine: Lymphocutaneous only: 250–500 mg PO per day for 2–4 wk after lesions healed

FOLLOW-UP

DISPOSITION

Admission Criteria

- Systemic signs/symptoms
- Pulmonary, CNS, multifocal disease
- Immunosuppressed host with disseminated disease

Discharge Criteria

Lymphocutaneous/fixed cutaneous form, nontoxic

Issues for Referral

Infectious disease consultant as appropriate

FOLLOW-UP RECOMMENDATIONS

Infectious disease specialist, dermatology, appropriate specialist given disease involvement (orthopedics, neurology)

PEARLS AND PITFALLS

Fixed cutaneous, lymphocutaneous, pulmonary, extracutaneous/disseminated disease secondary to *S. schenckii*:

- Inoculation with soil, moss, or organic material (skin break or inhalation)
- Contact with cats
- Healthy hosts develop fixed cutaneous/lymphocutaneous disease, immunocompromised hosts develop extracutaneous/disseminated disease
- Disseminated disease presents with nonspecific symptoms that often result in delayed diagnosis and poor outcome.
- Oral itraconazole is 1st-line therapy except for disseminated disease, where amphotericin is used initially

STAPHYLOCOCCAL SCALDED SKIN SYNDROME

Roger M. Barkin

BASICS

DESCRIPTION

- Results from the actions of a soluble epidermolytic exotoxin produced by *Staphylococcus aureus*:
 - _ Produced at a distant site of infection or colonization
 - _ Disseminates hematogenously
 - _ Lyses desmosomes of granular cells in the superficial epidermis
 - _ Results in generalized intradermal exfoliation
- Typically affects infants and children <6 yr of age:
 - _ Adults have specific staph antibodies allowing them to localize, metabolize, and excrete the staph toxins.
 - _ Infants and children are unable to metabolize and excrete toxin efficiently.
 - _ Immunocompromised adults and those with severe renal dysfunction are also susceptible
- Presentation determined by age and extent of rash:
 - _ Classic staphylococcal scalded skin syndrome
 - _ Pemphigus neonatorum
 - _ Bullous impetigo
 - _ Generalized in the newborn: Ritter disease
- Typically, coagulase-positive phage group II *Staphylococcus*:
 - _ Phage groups I and III also implicated

ETIOLOGY

- Colonization often without overt infection
- Concurrent infection or break of skin barrier:
 - _ Nasopharynx
 - _ Urinary tract
 - _ Minor skin abrasions
 - _ Circumcision site
 - _ Conjunctivitis
 - _ Umbilicus/omphalitis
 - _ Impetigo
 - _ Endocarditis and septicemia
- Often no focus identified

DIAGNOSIS

SIGNS AND SYMPTOMS

- Constitutional symptoms:
 - Malaise
 - Fever
 - Irritability
 - Child may appear well, ill, or overtly toxic
 - Abrupt onset
- Scarlatiniform erythematous rash (sandpaper like) resembling a “sunburn”—erythroderma
- Exquisitely tender skin
- Areas of prominence:
 - Around the flexor areas of the neck
 - Intertriginous areas, especially axilla and groin
 - Near the eyes and mouth
 - Increased erythema in skin creases
- Facial edema with radial crusting fissures around the eyes, nose, and mouth
- Flaccid bullae:
 - Within 1–3 days after onset of rash
 - Initially over flexures (axillae, groin, body orifices)
 - Bullae migrate through epidermis with light lateral pressure; epidermis separates with minor pressure (Nikolsky sign).
 - Rupture within hours
 - Epidermis separates with minor trauma.
 - Epidermis is shed in sheets.
 - Denuded areas are moist, sensitive, and painful.
 - Complete healing within 2 wk, no scarring
- Purulent conjunctivitis
- Mucous membranes not affected
- Complications rare:
 - Hypothermia
 - Fluid and electrolyte imbalance
 - Secondary infection
 - Pneumonia
 - Septicemia
 - Cellulitis
 - Osteomyelitis

ESSENTIAL WORKUP

- Clinical presentation is diagnostic.
- Determine location/source of toxin producing *Staphylococcus*.
- Assess systemic nature of infection.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC and urinalysis:
 - _ Assess for sepsis if source not obvious.
- Electrolytes:
 - _ Indicated if signs of dehydration or extensive rash
- Blood cultures (rarely positive)

Imaging

Indicated as need to determine location/source of infection

Diagnostic Procedures/Surgery

- Fluid aspirated from bullae:
 - _ Sterile in staphylococcal scalded skin syndrome
 - _ Consistent with hematogenous dissemination of the toxin
- Isolation of staphylococci from a site other than the blisters:
 - _ Commonly conjunctivae, nasopharynx, or blood
- Skin biopsy or frozen histologic section:
 - _ Determine level of epidermal/dermal separation (cleavage is in granular layer of dermis).
 - _ Indicated for children on medications, those > 6 yr, and in cases of mixed presentation

DIFFERENTIAL DIAGNOSIS

- Infection:
 - _ Scarlet fever:
 - Involves the mucous membranes
 - Strawberry tongue
 - Painful desquamation does not occur
- Bullous impetigo:
 - _ Turbid or cloudy bullous fluid
- Bullous varicella:
 - _ Tzanck prep or viral base reveals giant cells.
 - _ 5 days after the onset of varicella
- Toxic shock syndrome:
 - _ Rapid development of clinical signs and symptoms
 - _ Mucous membrane and multiorgan involvement
- Toxic epidermal necrolysis or drug eruption:
 - _ Much more common in adults
 - _ Severely afflicted mucous membranes
 - _ Full-thickness epidermal necrosis
- Dermatologic:
 - _ Erythema multiforme
 - _ Epidermolysis hyperkeratosis

- Epidermolysis bullosa
- Pemphigus vulgaris
- Scald injury
- Secondary rash of an underlying disorder:
 - Lymphoma
 - Aspergillosis
 - Irradiation
 - Graft-versus-host reaction
 - Kawasaki disease

TREATMENT

PRE HOSPITAL

- 9% NS fluid bolus if dehydration present
- Initial burn treatment

INITIAL STABILIZATION/THERAPY

- Management is similar to an extensive 2nd-degree burn:
 - Involvement of large body surface area will require IV fluids.
- Provide adequate analgesia.
- Undress and place child on sterile linen.
- Limit handling of child.
- Apply moist sterile dressings.
- Avoid excess heat loss.

ED TREATMENT/PROCEDURES

- Topical burn creams are of no proven benefit.
- Steroids are contraindicated.
- IV antibiotics effective against penicillinase-resistant *S. aureus*:
 - Cefazolin
 - Nafcillin
 - Vancomycin if methicillin-resistant *S. aureus* (MRSA) suspected
- Oral antibiotics for mild involvement:
 - Dicloxacillin
 - Erythromycin
 - Cephalexin

MEDICATION

- Cefazolin: 50–100 mg/kg/24 h IV div. QID
- Cephalexin: 25–100 mg/kg/24 h PO div. QID
- Dicloxacillin: 12–25 mg/kg/24 h PO div. QID
- Erythromycin: 30–50 mg/kg/24 h PO div. QID
- Nafcillin: 1–2 g IV q6h (peds: Newborns, 50–100 mg/kg/24 h IV div. q6h; children,

100–200 mg/kg/24 h IV div. q6h)

- Vancomycin: 40 mg/kg/24h IV q 6 hrs

FOLLOW-UP

DISPOSITION

Admission Criteria

- Children < 1 yr
- All toxic-appearing children
- Widespread skin involvement
- Dehydration and/or electrolyte derangement

Discharge Criteria

- Older, well-appearing children with mild involvement
- Oral antibiotics for 7 days
- Follow-up within 48 hr

Issues for Referral

- Infectious disease consultant
- Surgeon if source needs excision/drainage

ICD10

L00 Staphylococcal scalded skin syndrome

STERNOCLAVICULAR JOINT INJURY

Christopher M. Tedeschi • Wallace A. Carter

BASICS

DESCRIPTION

- Sternoclavicular joint (SCJ) is the only joint that connects the upper limb to the trunk.
- Among the least frequently injured joints in the body
- Most commonly due to athletic or vehicular injuries
- Congenital or spontaneous dislocation and subluxation are rarely seen
- SCJ stability depends on ligamentous attachments, primarily anterior and posterior sternoclavicular ligaments, interclavicular ligament, and costoclavicular ligament

ETIOLOGY

- Injury to the SCJ can be from sprains, subluxations, or dislocations of the ligamentous structure
- In sprains, ligamentous capsule remains intact
- Subluxation occurs when sternoclavicular ligament ruptures while costoclavicular ligament remains intact
- Complete ligamentous disruption leads to dislocation
- The SCJ can dislocate anteriorly or posteriorly. A large force is required. A greater force is required to displace the clavicle posteriorly.
- Direction of dislocation depends on the shoulder position:
 - Anterior dislocation more likely when the acromion is posterior to the manubrium.
 - Posterior dislocation more likely when the acromion is anterior to the manubrium.
- Anterior dislocation is more common (more than 90% of dislocations):
 - Caused by a posteriorly directed force to the anterolateral aspect of the shoulder
 - Reciprocal anterior displacement of the medial clavicle
 - May be associated with pneumothorax, hemothorax, pulmonary contusion, and rib fractures
 - Subluxation and dislocation may occur spontaneously.
- Posterior SCJ dislocation results from:
 - Anterior-to-posterior blow to the medial clavicle
 - Anteriorly directed force to the lateral aspect of the ipsilateral shoulder
 - A blow to the contralateral shoulder when the injured side is braced against an immobile object

- Posterior dislocation is a surgical emergency:
 - Indications for immediate reduction:
 - Compression or tear of trachea, esophagus, or great vessels
 - Recurrent laryngeal nerve injury

Pediatric Considerations

- The medial epiphyseal growth plates of the clavicles are last to ossify, and fuse between ages 22 and 25:
 - Until fusion, growth plate is the weakest part of the joint
- Fractures through the medial epiphysis mimic SCJ dislocations:
 - Most commonly Salter–Harris type I or II fractures
 - True dislocations of the SCJ are extremely rare in children because of strong ligamentous attachments.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Pain and swelling localized to the medial clavicle and SCJ with appropriate mechanism
- Affected arm supported across the chest by the contralateral arm
- Inability to abduct or externally rotate arm
- If subluxed or sprained, the SCJ is tender on direct palpation and with shoulder movement:
 - No deformity or significant AP mobility
- If the SCJ is dislocated, shoulder appears shortened:
 - Head tilts toward injured side due to sternocleidomastoid muscle spasm
- In anterior dislocation, medial end of the clavicle is visibly prominent and palpable.
- In posterior dislocation, there may be a sulcus of the SCJ area through which the lateral border of the manubrium may be palpated:
 - Dislocation may be masked by significant swelling over the SCJ region, and may mimic anterior dislocation.
- Posterior dislocation may be accompanied by signs of vascular compromise or damage to mediastinal structures:
 - Signs of shock
 - Difficulty breathing or speaking
 - Upper extremity pain or neurologic symptoms

History

- High-energy direct blow, most often from athletic injuries or motor vehicle collisions
- Sprains and subluxations may be associated with other injuries of the shoulder

girdle.

Physical-Exam

- Tenderness and swelling in sprains and subluxations
- In anterior dislocation, prominence of medial clavicle
- For any concern of posterior dislocation, assess for signs of airway or neurovascular compromise:
 - Dysphagia or respiratory distress may signify compression or disruption of trachea or esophagus.
 - Assess pulses in upper extremities
 - Hoarseness may signify injury to the recurrent laryngeal nerve.
 - Motor or sensory deficits suggest brachial plexus injury
 - Assess venous return in upper extremities:
 - Venous compression may lead to engorged upper extremity veins or venous thrombosis

ESSENTIAL WORKUP

- Comprehensive trauma evaluation and resuscitation for other life-threatening injuries
- Special attention to respiratory, neurologic, and vascular status
- A posterior dislocation implies substantial mechanism of injury; other life-threatening injuries must be ruled out.
- Appropriate analgesia for patient comfort

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- Difficult to assess SCJ injury with routine radiographs:
 - May demonstrate asymmetry of the SCJ compared with contralateral side
 - More useful to assess coexisting bony, pulmonary, and mediastinal injury
 - Chest x-rays may be read as normal and further imaging is warranted if index of suspicion is high
- US can reliably demonstrate SCJ dislocations:
 - May be useful in the initial ED evaluation of unstable patients with chest trauma
 - Use high-frequency linear probe
 - In anterior dislocation, medial clavicle seen anterior relative to manubrium compared to contralateral side
- CT scan is best to evaluate the SCJ:
 - Useful when plain films are inconclusive
 - Accurately differentiates fractures from dislocations
 - Demonstrates the position of the medial clavicle
 - Shows detailed anatomy of the thoracic outlet and mediastinum

- Contrast CT can show related vascular injuries and is the imaging modality of choice.
- MRI can be useful in demonstrating ligamentous and soft tissue SCJ injuries:
 - The articular disc is the most vulnerable soft tissue structure in SCJ injury.
 - Can demonstrate specific ligamentous injuries in the setting of joint subluxation
 - Better suited after the initial period of diagnosis and treatment
 - Can help distinguish true dislocation from physeal injury in pediatric patients

DIFFERENTIAL DIAGNOSIS

- Sternoclavicular sprain, subluxation, or dislocation
- Medial clavicle fracture
- Septic arthritis
- Osteomyelitis of medial clavicle

TREATMENT

PRE HOSPITAL

- Attention to airway and vital signs, and neurovascular status of affected extremity
- Affected arm should be splinted in the position of comfort before transport to the ED.

INITIAL STABILIZATION/THERAPY

- Endotracheal intubation for signs of airway compromise or as needed in the trauma patient
- Emergent SCJ reduction for:
 - Unstable or compromised airway
 - Signs of shock
 - Diminished pulses
 - Hoarseness
 - Dysphagia
 - Neurovascular compromise:
 - Upper extremity weakness
 - Paresthesia

ED TREATMENT/PROCEDURES

- *Sprains and subluxations* may be treated symptomatically with ice, NSAIDs, sling immobilization, and orthopedic follow-up.
- *Anterior dislocations* may be reduced in the ED:
 - Procedural sedation for adequate pain control and muscle relaxation
 - Rolled towel placed between the shoulder blades in the supine position:
 - Longitudinal traction applied to the extended arm with shoulder

- abducted 90°
- Assistant applies gentle pressure over the displaced end of the clavicle.
- After reduction, immobilize with a well-padded figure-of-8 dressing.
- Many anterior dislocations remain unstable after reduction.
- Surgery rarely indicated, as deformity is mainly cosmetic
- *Posterior dislocations* require urgent reduction best achieved in the OR under general anesthesia:
 - Orthopedic and thoracic surgery consults
 - Closed reduction is preferred (and often successful) but may not be possible in injuries >48 hr.
 - If surgeon not immediately available, emergent reduction in the ED may be necessary:
 - Relieve serious airway, neurologic, or vascular compromise
 - Adequate sedation and analgesia are essential
 - Patient placed supine with a roll between shoulder blades
 - Affected arm is abducted and extended
 - Increased traction as arm is brought into extension
 - If unsuccessful, a sterile towel clamp is used to grasp medial clavicular head and apply gentle anterior traction

MEDICATION

Procedural sedation:

- Etomidate: 0.1 mg/kg IV
- Fentanyl: 1–2 µg/kg IV
- Ketamine: Peds: 1 mg/kg IV – up to 2 additional doses of 0.5 mg/kg IV PRN
- Midazolam: 0.01 mg/kg (peds: 0.05–0.1 mg/kg) IV q2–3min
- Propofol: Initial bolus 1 mg/kg IV, then 0.5 mg/kg q3min as needed (adults and peds)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Posterior dislocations of the SCJ require admission for possible reduction in the OR and evaluation for potential intrathoracic complications.
- Coexisting injury significant enough to warrant hospitalization

Discharge Criteria

- SCJ sprains
- Anterior dislocations of the SCJ without neurovascular compromise or other

significant injury

- Appropriate outpatient orthopedic follow-up arranged

Issues for Referral

Outpatient referral to an orthopedist should be recommended for patients with any significant SCJ injuries.

FOLLOW-UP RECOMMENDATIONS

- It is difficult to achieve long-term stability after closed reduction of dislocations, so close orthopedic follow-up is advisable.
- Simple sling sufficient for sprains
- Figure-of-8 dressing for more severe injuries
- Repeat MRI or CT imaging may be beneficial.
- Even for mild sprains and subluxations, high-risk activity should be avoided for up to 3 mo.

PEARLS AND PITFALLS

- Since SCJ injuries are rare, this potentially life-threatening injury may be missed during ED evaluation and resuscitation.
- Posterior dislocations mandate early thoracic and cardiothoracic surgery consultation.
- Posterior dislocation may be mistaken for anterior due to marked swelling over the joint.
- In the pediatric population, a Salter–Harris fracture may mimic a dislocation.

STEVENS–JOHNSON SYNDROME

Herbert G. Bivins • James Comes

BASICS

DESCRIPTION

- Stevens–Johnson syndrome (SJS) is an idiosyncratic, severe mucocutaneous disease:
 - Blistering of < 10% of the body surface area (BSA)
 - 95% of patients have mucous membrane lesions:
 - Usually at 2 or more sites
 - 85% have conjunctival lesions
 - Lesions often involving face, neck, and central trunk regions become confluent over hours to days
- On a continuum with toxic epidermal necrolysis (TEN); but thought to be a distinct disease entity from erythema multiforme (EM):
 - SJS: < 10% of BSA
 - SJS–TEN overlap syndrome: 10–30% of BSA
 - TEN: > 30% of BSA, can affect up to 100% BSA

ETIOLOGY

- The most common causes include medications and infections:
 - Damage to the skin is thought to be mediated by cytotoxic T lymphocytes and mononuclear cells aimed at keratinocytes expressing (drug-related) antigens
 - Cytokines from activated mononuclear cells probably contribute to cell destruction and systemic manifestations
- Causative medications:
 - Antibiotics (e.g., penicillin, sulfonamide)
 - Anticonvulsants
 - Oxicams
 - NSAIDs
 - Allopurinol
- Infections:
 - *Mycoplasma pneumoniae*
 - Herpes simplex

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- *Prodrome:*
 - Usually 1–3 days prior to development of skin lesions
 - Fever
 - Headache
 - General malaise
 - Upper respiratory infection (URI) symptoms
 - Arthritis, arthralgias, and myalgias prior to mucocutaneous lesions
- **Skin:** Mild to moderate skin tenderness followed by skin pain, burning sensation, and paresthesias
- **Eye:** Conjunctival burning or itching
- **Mucous membranes:** Painful micturition, painful swallowing
- **Drug exposure precedes symptoms usually by 2 wk:**
 - Re-exposure may result in onset of symptoms within 48 hr
- **Risk factors include HIV, genetic factors, viral infections, and underlying immunologic diseases**

Physical-Exam

- **Rash:** Target lesions, erythematous or purpuric macules with or without confluence, and raised flaccid blisters or bullae with skin detachment that spread with lateral pressure (Nikolsky sign) on erythematous areas
- **Mucous membrane:** Erythematous tender erosions of the mouth, pharynx, trachea, genitalia, or anus; possibly pseudomembrane formation
- **Eye:** Mild to severe conjunctivitis with possible formation of pseudomembranes and corneal ulcers

ESSENTIAL WORKUP

A complete history and physical exam with careful attention to mucous membranes, percentage of blistering, and identification of likely etiology

DIAGNOSIS TESTS & NTERPRETATION

Lab

- **Electrolytes**
- **Liver enzymes may be mildly elevated**
- **CBC:**
 - **Anemia and lymphopenia are common**
- **UA**

Imaging

Chest radiography if pneumonia is a consideration

Diagnostic Procedures/Surgery

Skin biopsy of lesions and mucous membranes demonstrates necrosis of the entire epidermal layer with formation of subepidermal split above basement membrane

DIFFERENTIAL DIAGNOSIS

- SJS if < 10% of BSA
- Overlapping SJS and TEN (skin detachment between 10% and 30% of BSA plus widespread macules or flat atypical target lesions)
- TEN (skin detachment > 30% of the BSA plus widespread macules or flat atypical targets)
- EM
- Thermal burns
- Phototoxic reactions
- Exfoliative dermatitis
- Pustular drug eruptions
- Bullous fixed drug eruptions
- Paraneoplastic pemphigus
- Graft-versus-host disease in bone marrow transplant patients
- Toxic shock syndrome
- Staphylococcal scalded skin syndrome

Pediatric Considerations

Staphylococcal scalded skin syndrome is in the pediatric differential diagnosis of severe blistering mucocutaneous diseases

TREATMENT

PRE HOSPITAL

- ABCs
- Observe universal precautions
- IV access if indicated
- Transport to burn center if > 30% of body surface involved

INITIAL STABILIZATION/THERAPY

- Endotracheal intubation and ventilatory support may be required for impending respiratory failure (more commonly associated with TEN)
- IV fluids

ED TREATMENT/PROCEDURES

- Fluid replacement:
 - Fluid losses may be significant
- Recognize and treat underlying infections:
 - Sepsis is the primary cause of death, frequently from gram-negative

pneumonia

- Secondarily infected cutaneous lesions can be treated with débridement of blisters, compresses, and systemic antibiotics

- Corticosteroids are controversial
- Prophylactic antibiotics may be indicated if systemic steroids are given
- Intravenous immunoglobulin (IVIG) may be beneficial
- Mild systemic symptoms may be treated with acetaminophen or NSAIDs provided they are not the cause of the mucocutaneous reaction
- Mucous membrane lesions are extremely painful and may require parenteral analgesics
- Large extensive bullae should be débrided, ideally in a burn unit

MEDICATION

- Acetaminophen: 500 mg PO/PR q4–6h (peds: 10–15 mg/kg/dose; do not exceed 5 doses/24 h); do not exceed 4 g/24 h
- Acyclovir: 5–10 mg/kg IV q8h (for herpes simplex virus infections)
- Ibuprofen: 300–800 mg PO (peds: 5–10 mg/kg/dose)
- Morphine sulfate: 0.1 mg/kg/dose IV

First Line

- Fluid replacement
- Treat underlying etiology
- Treat secondary infections
- Analgesia

Second Line

- IVIG
- Corticosteroids

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with SJS should be admitted to the hospital
- Patients with extensive epidermal detachment should be admitted to a burn center or a specialized intensive care unit

Discharge Criteria

Patients with EM minor may be discharged with appropriate and timely follow-up

Issues for Referral

Patients must be made aware of the likely offending drug (and its class) and that it must never be administered to them again

FOLLOW-UP RECOMMENDATIONS

Follow-up with PCP and/or dermatologist

PEARLS AND PITFALLS

- SJS may begin like an influenza illness. Lesions appear 1–3 days after the prodrome
- The diagnosis is clinical and biopsy is supportive
- *M. pneumoniae* and herpes simplex are more common triggers in children than in adults

STING, BEE

Daniel T. Wu

BASICS

DESCRIPTION

- Injection of hymenoptera venom causes:
 - Release of biologic amines
 - Local or systemic allergic reactions
- Reactions are:
 - Usually IgE-mediated type I hypersensitivity reactions
 - Rarely type III (Arthus) hypersensitivity reactions

ETIOLOGY

- Hymenoptera—order of the phylum Arthropoda
- Includes bees (Apidae family), wasps and hornets (Vespidae family), fire ants (Formicidae family)

DIAGNOSIS

SIGNS AND SYMPTOMS

History

History and physical exam—keys to diagnosis

Physical-Exam

5 types of reactions to stings:

- Local reaction:
 - Most common type of reaction
 - Local pain, erythema, and edema at sting site
 - Symptoms occur immediately and resolve within 1–2 hr
- Large local reaction:
 - Similar to local reaction but affects larger area or entire limbs
 - Peaks at 48 hr and can last several days
 - Mild to moderate fever
- Systemic reaction:
 - Includes anaphylaxis
 - Can be fatal (usually owing to respiratory failure)
 - Respiratory:
 - Wheezing
 - Coughing

- Stridor
- Shortness of breath
- Hoarseness
- Angioedema
- GI:
 - Nausea
 - Vomiting
 - Diarrhea
 - Abdominal pain
- Cardiovascular:
 - Hypotension
 - Chest pain
 - Tachycardia
 - Shock
- Other:
 - Urticaria
 - Pruritus
 - Flushing
- Symptoms occur within 15–20 min and last ≤ 72 hr
- Toxic reaction:
 - Result of multiple stings and large doses of venom
 - Symptoms similar to anaphylaxis
- Unusual reactions:
 - Owing to unusual immune response
 - Vasculitis
 - Nephrosis
 - Serum sickness
 - Neuritis
 - Encephalitis
 - Reaction delayed (days to weeks after sting)

ESSENTIAL WORKUP

- History and physical exam key to diagnosis
- No radiologic or lab test will confirm hymenoptera envenomation or anaphylaxis

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC, electrolytes, BUN, creatinine, glucose, arterial blood gases (ABGs):
 - Not routine
 - Consider when significant systemic effects present

Diagnostic Procedures/Surgery

ECG:

- When significant systemic effects present in patients at risk for cardiovascular disease

DIFFERENTIAL DIAGNOSIS

- Insect bites sometimes cause pain; stings always cause pain.
- Cellulitis:
 - _ Difficult to distinguish between large local reactions and cellulitis
 - _ Infections of hymenoptera envenomations are rare and usually caused by wasp envenomations.
 - _ Local reaction can resemble periorbital cellulitis.
- Gout
- Soft tissue trauma
- Systemic/toxic reactions:
 - _ Pulmonary embolus
 - _ Anaphylaxis from different agent
 - _ Hyperventilatory syndrome/anxiety
 - _ Acute coronary syndrome

TREATMENT

PRE HOSPITAL

Most deaths occur within 1st hour owing to either respiratory obstruction or anaphylaxis causing cardiovascular and respiratory collapse.

INITIAL STABILIZATION/THERAPY

Acute Severe Systemic Reaction/ Anaphylaxis

- ABCs:
 - _ Intubation/ventilation with rapidly increasing signs of laryngeal compromise
 - _ Oxygen
 - _ 0.9% normal saline (NS) IV access
- Epinephrine SC/IV
- Antihistamines IV
- Corticosteroids
- When signs of systemic reactions:
 - _ Assess for patent airway
 - _ Establish IV access

ED TREATMENT/PROCEDURES

- Systemic reactions:

- Epinephrine for respiratory symptoms/hypotension
- Antihistamines—H₁ (diphenhydramine) and H₂ (cimetidine, ranitidine, or famotidine) blockers
- Steroids (prednisone, methylprednisolone, or dexamethasone)
- Inhaled β -agonist for wheezing/shortness of breath
- For persistent hypotension:
 - o 0.9% NS IV fluid resuscitation
 - o Vasopressor (epinephrine/ α -adrenergic) for hypotension resistant to IV fluids
- Removal of remnants of stinger at site of envenomation (bees may leave stingers with venom sacs) by scraping, not squeezing
- Local reactions:
 - Cool compress
 - Elevation
 - Remove constrictive clothing or jewelry
 - Topical antihistamine/topical steroidal cream as needed
 - Oral antihistamine or steroids as needed

MEDICATION

- Albuterol, β -agonist (inhaled): 3 mg in 5 mL NS (peds: 0.1 mg/kg of 5 mg/mL concentration) via nebulization
- Cimetidine: 300 mg (peds: 5 mg/kg) IV/IM/PO
- Diphenhydramine:
 - 50–100 mg (peds: 1 mg/kg) IV for severe reactions
 - 25–50 mg (peds: 1 mg/kg) PO QID for severe local reactions
- Epinephrine:
 - 0.1 mg: 1 mL of 1:10,000 dilution (peds: 0.01 mg/kg 0.1 mL/kg of 1:10,000 dilution up to 1 mL) IV over 5 min for shock
 - 0.3 mg (0.3 mL of 1:1,000 dilution); (peds: 0.01 mg/kg up to 0.5 mg) SC for severe reactions but not in shock
- Famotidine: 40 mg IV (peds: 1 mg/kg/d div. BID IV)
- Methylprednisolone: 125 mg (peds: 1–2 mg/kg) IV
- Norepinephrine: 2–4 μ g/kg/min (peds: 0.1 μ g/kg/min) titrated continuous infusion
- Prednisone: 60 mg (peds: 1–2 mg/kg) PO
- Ranitidine: 50 mg IV/IM (peds: 2–4 mg/kg/d div. q6–8h IV/IM)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Worsening symptoms, airway compromise
- Persistent unstable vital signs require ICU admission.
- Life-threatening reaction requires 24-hr observation.
- Systemic reaction requires minimum of 6 hr of observation.

Discharge Criteria

- Minimal isolated local reaction
- Systemic reactions that resolve and do not recur during 6-hr observation period

Issues for Referral

Follow-up:

- Provide patients with life-threatening reactions, emergency anaphylaxis kits (EpiPen; peds: EpiPen Jr if < 15 kg), and medical identification bracelets (Medi-Alert).
- Systemic reaction requires follow-up for possible immunotherapy.

FOLLOW-UP RECOMMENDATIONS

Allergist follow-up for patients with systemic reactions.

PEARLS AND PITFALLS

- Treat patients who present with systemic reactions to bee stings aggressively.
- Provide prescriptions for EpiPen to patients discharged after presenting with life-threatening reactions to bee stings.

ICD10

T63.441A Toxic effect of venom of bees, accidental, init

STING, SCORPION

Frank LoVecchio

BASICS

DESCRIPTION

- Scorpion venom is neurotoxic:
 - Sodium channels opening
 - Prolonged firing of neurons
- Autonomic, somatic, and cranial nerve excitation occurs.
- Symptoms begin within minutes of bite.
- Symptoms persist 1–72 hr.

ETIOLOGY

- *Centruroides* species found in Southern US, Mexico, Central America, and Caribbean
- Many other species in Asia, Africa, Israel, South America, and Middle East

Pediatric Considerations

- Can be misdiagnosed as seizures, amphetamine poisoning, or meningitis
- Higher mortality and severity of illness

DIAGNOSIS

SIGNS AND SYMPTOMS

- Onset within minutes, progressing to maximum severity in ~1–2 hr but may persist \leq 48–72 hr.
- Scorpion species determines symptomatology (*Centruroides sculpturatus*, aka *Centruroides exilicauda* or bark scorpion, is the only species in US causing symptoms).
- Local tissue effects:
 - No erythema
 - Pain
 - Hyperesthesia
- Autonomic effects:
 - Sympathetic symptoms:
 - Tachycardia
 - Hypertension
 - Hyperthermia
 - Pulmonary edema
 - Agitation

- Perspiration
- Parasympathetic effects:
 - Hypotension
 - Bradycardia
 - Hypersalivation
- Somatic effects:
 - Involuntary muscle contractions
 - Restlessness
- Cranial nerve effects:
 - Roving eye movements
 - Blurred vision
 - Nystagmus
 - Tongue fasciculations
 - Loss of pharyngeal muscle control

ESSENTIAL WORKUP

- Identification of scorpion species not needed if scorpion is native to US (see above).
- Maintain high clinical suspicion in endemic areas
- Assess envenomation grade severity:
 - Grade I: Local pain and/or paresthesias at site
 - Grade II: Local pain and/or paresthesias at a remote site
 - Grade III: Either cranial/autonomic *or* somatic skeletal neuromuscular dysfunction
 - Grade IV: Both cranial/autonomic *and* somatic skeletal muscle dysfunction

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Grades I and II envenomations:
 - None
- Grades III and IV envenomations:
 - BUN, creatinine
 - Electrolytes
 - UA
 - CBC
- Severely agitated patients:
 - Creatine kinase
 - Urine myoglobin
- Severe respiratory distress:
- ABGs

Imaging

- Chest radiograph for respiratory symptoms
- ECG for tachycardia

DIFFERENTIAL DIAGNOSIS

- Snake, spider, insect envenomation
- Tetanus
- Diphtheria
- Botulism
- Overdose/dystonic reaction
- Seizures
- Infections

TREATMENT

PRE HOSPITAL

- Evaluate ABCs
- IV access

INITIAL STABILIZATION/THERAPY

- ABCs
- Endotracheal intubation if necessary
- IV
- O₂
- Monitor

ED TREATMENT/PROCEDURES

- Mild envenomations—grades I and II:
 - Oral analgesics
 - Tetanus prophylaxis
- Severe envenomations—grades III and IV:
 - Antivenom (Anascorp), expensive therapy
 - Tetanus prophylaxis
 - Hypertensive urgencies/emergencies (rare):
 - Standard therapy such as labetalol
 - Hypotension:
 - IV fluid resuscitation and pressor therapy with dopamine
 - Severe agitation:
 - Midazolam
 - Treatment for rhabdomyolysis if present

MEDICATION

- Antivenom: Centruroides (scorpion) (Rx: Anascorp infuse 3 vials IV over 10 min);

monitor for up to 60 min after completing infusion to determine if symptoms are resolved. Additional doses may be used if needed; infuse 1 vial at a time at 30–60 min intervals.

- Dopamine: 2–5 µg/kg/min IV; increase in 5–10 µg/kg/min as needed
- Midazolam: 1–2 mg (peds: 0.01–0.05 mg/kg) IV
- Labetalol: 20 mg (peds: 0.3–1 mg/kg/dose) q10min
- Fentanyl: 50–150 µg (peds: 1–3 µg/kg) IV
- Tetanus toxoid: 0.5 mL IM (peds: Same dose)

Pediatric Considerations

Antivenom doses are the same in children because dosage is based on venom burden.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Grades III and IV envenomations require admission to ICU.
- If antivenom is given with resolution of symptoms, observe for 1–2 hr if asymptomatic.

Discharge Criteria

- Grades I and II envenomations after a short observation period (3–4 hr after sting occurred) for progression of symptoms
- Grades III and IV envenomations given antivenom with resolution of symptoms can be discharged.
- If patient received antivenom, discuss signs and symptoms of delayed serum sickness.
- Discuss possibility of persistence of pain and paresthesias at site.
- Encourage patient to return for progression of symptoms.

Pediatric Considerations

Toddlers are more likely to have early airway involvement.

FOLLOW-UP RECOMMENDATIONS

Primary care follow-up if antivenin given.

PEARLS AND PITFALLS

- Maintain high index of suspicion for scorpion stings in endemic areas when patients present with typical symptoms.

STREPTOCOCCAL DISEASE

Scott C. Sherman

BASICS

DESCRIPTION

- Increase in frequency of aggressive streptococcal necrotizing skin infection noted in 1980s and dubbed “flesh-eating bacteria.”
- Affects otherwise healthy patients aged 20–50 yr who did not have underlying predisposing diseases.
- Rapid progression of shock and multiorgan dysfunction, with death occurring within 1–2 days.
- Incidence is 3–4 per 100,000 in industrialized countries
- Invasive infections caused by group A *Streptococcus* (GAS) include:
 - Necrotizing fasciitis (NF):
 - Progressive, rapidly spreading soft tissue infection located within the deep fascia and subcutaneous fat
 - Streptococcal toxic shock syndrome (STSS):
 - May occur in patients with GAS associated NF.
 - Portals of entry for streptococci include vagina, pharynx, mucosa, and skin.
 - Unknown cause in 50% of cases.
 - “Other” invasive disease defined as isolation of GAS from a normally sterile body site (i.e., sepsis, bacteremic pneumonia, septic arthritis, etc.)
- Occurs sporadically, with occasional outbreaks in long-term care facilities and hospitals.
- Rate of invasive GAS disease 6 times the annual incidence of meningococcal disease.

STSS Case Definition

- Isolation of GAS from sterile or nonsterile body site
- Hypotension
- 2 or more of the following:
 - Renal impairment
 - Coagulopathy
 - Liver abnormalities
 - Acute respiratory distress
 - Extensive tissue necrosis (NF)
 - Erythematous rash

ETIOLOGY

- NF:
 - GAS is causative in 10% of cases. Blunt trauma is risk factor.
 - Mixed anaerobic and aerobic organisms are found in 70% of cases.
 - *Staphylococcus aureus*, *Clostridium* species, and other enteric organisms
- Streptococcal toxic shock syndrome:
 - Occurs when susceptible host is infected with virulent strain
 - M protein types 1, 3, and 28 are most common.
 - Pyrogenic exotoxins (e.g., A, B, and C) produce fever and shock via activation of tumor necrosis factor and interleukins.
 - Nonsteroidal anti-inflammatory drugs appear to mask or predispose patients.
 - Risk factors:
 - Age < 10 or > 60 yr
 - Cancer
 - Renal failure
 - Leukemia
 - Severe burns
 - Corticosteroids

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- *Pain*:
 - Most common initial symptom of NF:
 - Occurs in 85% of cases
 - Out of proportion to physical findings
 - Often abrupt in onset and severe
 - Often requires palliative IV narcotics
 - Usually involves an extremity
 - May mimic peritonitis, pelvic inflammatory disease, pneumonia, acute MI, or pericarditis

Physical-Exam

- *Fever* most common sign:
 - Can present with hypothermia, especially if patient is in shock
- *Altered mental status* present in 55% of cases
- *Soft tissue infection* (erythema and swelling) present in 80%:
 - Indistinct borders, blisters, bullae
 - No lymphangitis or lymphadenopathy
- *Influenza-like syndrome* in 20%:

- Fever
- Chills
- Myalgias
- Nausea, vomiting
- Diarrhea
- Shock:
 - Present at admission or within 4–8 hr in *all* patients
 - Frequently persists despite fluids, antibiotics, and vasopressors
- Renal failure:
 - Precedes onset of shock in many cases
 - Dialysis often necessary
 - Kidney function returns to normal within 4–6 wk in survivors.
- ARDS:
 - Occurs in 55% of patients

ESSENTIAL WORKUP

- Suspect NF when pain is out of proportion to exam.
- Obtain plain films to search for presence of air in soft tissues.
- Blood cultures should be obtained.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC with differential:
 - Mild leukocytosis with left shift initially
- Electrolytes, BUN, and creatinine
- Calcium level:
 - Hypocalcemia in association with fat necrosis from NF
- Urinalysis:
 - Hemoglobinuria if renal involvement
- Serum creatine phosphokinase:
 - An elevated or rising level correlates with NF or myositis.
- Aerobic and anaerobic blood cultures
- Wound cultures
- PT/PTT/INR/DIC panel

Imaging

- Plain films:
 - Gas in soft tissues in 25–75% of cases of NF, but not as frequently associated with group A β -hemolytic streptococcal infection
 - More common in mixed anaerobic infections
- CT scan:
 - Asymmetric thickening of deep fascia

- Gas
- MRI:
 - High signal intensity of the fascia in T2-weighted images associated with NF

Diagnostic Procedures/Surgery

Aspiration of involved areas with Gram stain and culture may be useful

DIFFERENTIAL DIAGNOSIS

- Sepsis
- Cellulitis
- Erysipelas
- NF/myositis secondary to infection by another pathogen

TREATMENT

PRE HOSPITAL

Stabilize as appropriate

INITIAL STABILIZATION/THERAPY

- Maintain ABCs.
- Treat shock with fluids and vasopressors as needed:
 - Hypotension is often intractable, and up to 10–20 L/day may be required.
- Intubation and mechanical ventilation for:
 - ARDS
 - Severe shock
 - Ventilatory failure

ED TREATMENT/PROCEDURES

- Broad-spectrum antibiotics immediately after cultures until the presence of GAS has been confirmed:
 - Clindamycin is a potent suppressor of GAS bacterial toxin synthesis and inhibits M protein synthesis
- Early surgical consultation. Most patients will require an operative procedure (e.g., fasciotomy, surgical débridement, exploratory laparotomy, intraocular aspiration, amputation, or hysterectomy):
 - Immediate surgery is indicated if there is:
 - Extensive necrosis or gas
 - Compartment syndrome
 - Profound systemic toxicity
- Droplet precautions for the 1st 24 hr of antibiotic therapy
- Reports of successful use of IV immunoglobulin
- Hyperbaric oxygen therapy still controversial

MEDICATION

- NF due to invasive streptococcal disease (NOTE: In the ED, empiric treatment should be initiated until monomicrobial NF caused by GAS has been confirmed):
 - Clindamycin: 900 mg IV (peds: 40 mg/kg/d), *and*
 - Penicillin G: 4 million U IV (peds: 250,000 U/d), *or*
 - Vancomycin: 15 mg/kg IV (peds: 10 mg/kg q6h) if patient has penicillin allergy
- Empiric treatment of NF from all causes (*Clostridium perfringens*, GAS, methicillin-resistant *S. aureus* [MRSA], mixed anaerobes/aerobes):
 - Piperacillin/tazobactam 3.5 g IV *and*
 - Clindamycin 900 mg IV *and*
 - Vancomycin 1 g IV
 - For patients with a penicillin allergy treat with aztreonam 2 g IV, clindamycin 900 mg IV, vancomycin 1 g IV, and metronidazole 500 mg IV

FOLLOW-UP

DISPOSITION

Admission Criteria

ICU admission required for all patients with suspected invasive streptococcal infection. Mortality from GAS NF ~ 20%, but with both NF and STSS, mortality rate increases to 70%.

Discharge Criteria

None

PEARLS AND PITFALLS

- Hypotension and shock may require large volumes of IV fluids and vasopressors.
- Broad-spectrum antibiotics should be administered until the presence of GAS can be confirmed.
- Surgical consultation should be obtained for débridement.

ICD10

- [A48.3 Toxic shock syndrome](#)
- [B95.0 Streptococcus, group A, causing diseases classd elswhr](#)
- [M72.6 Necrotizing fasciitis](#)

BASICS

DESCRIPTION

- High-pitched audible wheezing and vibratory harsh sounds mainly on inspiration.
- Impedance of air movement through the upper airway.
- It implies a laryngotracheal airway obstruction.

ETIOLOGY

- Congenital:
 - Laryngomalacia
 - Laryngeal webs/rings
- Vocal cord dysfunction:
 - Congenital
 - Surgical injury
 - Postintubation trauma
 - Thyroid malignancy
 - Mediastinal mass
 - Neural abnormalities (e.g., meningomyelocele, Arnold–Chiari malformation)
- Subglottic stenosis:
 - Postoperative scarring
 - After radiation therapy
 - After prolonged endotracheal intubation
- Subglottic hemangioma
- Infection:
 - Bacterial tracheitis
 - Epiglottitis
 - Viral croup
 - Peritonsillar abscess
 - Retropharyngeal abscess
 - Supraglottitis
 - Uvulitis (e.g., Quincke disease)
 - Ludwig angina
 - Diphtheria
 - Tetanus
- Extrinsic compression:
 - Trauma
 - Hematoma

- Vascular anomalies (e.g., rings)
- Intraluminal obstruction of the trachea:
 - Foreign body
 - Tracheomalacia
 - Cyst
 - Invasive tumors
 - Squamous cell
 - Lymphomas
 - Thyroid masses/carcinomas
 - Laryngeal or tracheal papilloma
- Angioedema

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Breathing difficulties
- Audible stridor (worsens with feeds, crying, and on lying supine)
- Muffled hoarseness “Hot potato” voice in adults
- Feeding difficulties in infants (amount of feeds and regurgitation with GERD)
- Apneas and cyanotic attacks
- Antenatal, perinatal, and birth events (e.g., resuscitation at birth with intubation)
- Anxiety
- Cough
- Drooling
- Sore throat

Physical-Exam

- Tachypnea
- Dyspnea
- Dysphagia
- Fever
- Respiratory distress, worse with agitation
- Nasal flaring, intercostal retractions, subcostal indrawing
- Paradoxical diaphragmatic movement (late finding)
- Audible stridor (inspiratory/biphasic stridor)
- Cyanosis
- Trismus:
 - Peritonsillar abscess, retropharyngeal abscess, Ludwig angina

ESSENTIAL CONSIDERATIONS

- Visualization of the upper airway:
 - Radiographic if symptoms very mild; be careful!
- Direct visualization in OR with a surgeon prepared to perform a cricothyrotomy or tracheostomy is the safest approach.

DIAGNOSIS TESTS & INTERPRETATION

Lab

These tests are not helpful and thus avoidable; may upset a child even more.

Imaging

Radiograph of lateral and posteroanterior neck and chest:

- Not essential
- Only done in extremely mild cases or when there is suspicion of foreign body aspiration

Diagnostic Procedures/Surgery

- Fiberoptic laryngoscopy:
 - Should be performed with an intubating fiberoptic laryngoscope in a setting where a rapid surgical airway can be obtained
- Direct laryngoscopy:
 - Diagnostic study of choice
 - Should be performed in a setting where a rapid surgical airway can be obtained

DIFFERENTIAL DIAGNOSIS

- Stertor:
 - Pharyngeal obstruction while wheezing
- Bronchospasm
- Malingering (patient breathing against a closed glottis)

TREATMENT

PRE HOSPITAL

- Keep child calm, with mother if possible.
- Supply blow-by oxygen.
- Maintain adequate airway.
- Use bag-valve-mask (BVM) if respiratory status deteriorates.
- Intubate if BVM ineffective.
- Provide rapid transport with ED notification.

INITIAL STABILIZATION/THERAPY

- In children: Avoid agitation. Supply blow-by oxygen.
- Use 100% nonrebreathing-type face mask
- Pulse oximetry to check oxygen saturation and monitoring of vitals.

Pediatric Considerations

- Avoid agitating child.
- Watch for rapid deterioration of respiratory status.

ED TREATMENT/PROCEDURES

- Airway management:
 - Stridor comprises a difficult airway passage:
 - Be prepared to create an airway surgically before intubation.
 - If time permits, perform intubation in OR with surgeon and pediatric anesthesiologist present.
 - Intubate with tube 1 or 2 sizes smaller than would be normally used.
- Oral awake intubation:
 - Ketamine induction
 - Patient is sedated but continues to ventilate during procedure.
- Avoid blind nasotracheal intubation.
- Oral intubation is preferred initially. After oral intubation the oral tube is replaced by a nasal tube of the same size.
- Provide surgical airway if intubation fails or sudden deterioration in respiratory status occurs.
- Postintubation ceftriaxone in cases of infectious cause
- Sedation/paralysis for duration of intubated status after airway is secured.
- Extubation could be attempted when an air leak develops around the tracheal tube, which can take around 2–10 days.
- Controversies:
 - Heliox therapy
 - Racemic epinephrine therapy
 - Early intubation

MEDICATION

- Atropine: 0.02 mg/kg IV
- Ceftriaxone: 1–2 g IV
- Diazepam: 2–10 mg IV (peds: 0.2–0.3 mg/kg)
- Etomidate: 0.3 mg/kg IV
- Fentanyl: 3 µg/kg IV
- Ketamine: 1–2 mg/kg IV or 4–7 mg/kg IM
- Lidocaine: 1.5 mg/kg IV
- Midazolam: 1–5 mg IV (0.07–0.3 mg/kg for induction)
- Vecuronium: 0.1 mg/kg IV
- Nebulized epinephrine: 1 mL of 1:1,000 diluted to 5 mL with normal saline

- Dexamethasone: 0.15 mg/kg oral/IV

FOLLOW-UP

DISPOSITION

Admission Criteria

All cases of stridor that are not completely resolved during the ED course mandate admission of patient to hospital.

Discharge Criteria

Stridor fully resolved or identified as a nonstridorous abnormal breathing sound.

Issues for Referral

Consultation with an otolaryngologist or a pediatric surgeon prior to airway visualization

PEARLS AND PITFALLS

- Attempting visualization of the airway without the backup needed for an emergency tracheostomy is a pitfall.
- Laryngoscopy findings determine the indications for other complementary exams such as barium swallow, polysomnography, echocardiography, CT, or magnetic resonance scans of neck and thorax.
- Patients, especially children with stridor, often have associated abnormalities involving respiratory tract which mandates not only endoscopic exam of the larynx, but also the tracheobronchial system.

- R06.1 Stridor

SUBARACHNOID HEMORRHAGE

Alfred A. Joshua

BASICS

DESCRIPTION

- Bleeding into the subarachnoid space and CSF:
 - Spontaneous:
 - Most often results from cerebral aneurysm rupture
 - Aneurysms that occur are more likely to rupture (> 25 mm).
 - Traumatic:
 - Represents severe head injury

EPIDEMIOLOGY

- Incidence is 6–16 per 100,000 individuals.
- Affects 21,000 in US annually
- Associated mortality in 30–50% of patients
- Uncommon prior to 3rd decade; incidence peaks in 6th decade

RISK FACTORS

- Previous ruptured aneurysm who have other aneurysms
- Family history
- Hypertension
- Smoking
- Alcohol abuse
- Sympathomimetic drugs:
 - Cocaine, methamphetamine, and ecstasy (MDMA) use
- Gender (female:male 1.6:1)

Genetics

- 3–7-fold increased risk with 1st-degree relatives with subarachnoid hemorrhage (SAH)
- Strongest genetic association represents only 2% of SAH patients:
 - Autosomal dominant polycystic kidney disease, Ehlers–Danlos type IV, familial intracranial aneurysms

Pediatric Considerations

- Most often due to arteriovenous malformation in children
- Although rare in children, SAH is a leading cause of pediatric stroke.

ETIOLOGY

- “Congenital,” saccular, or berry aneurysm rupture (80–90%):

- Occur at bifurcations of major arteries
- Incidence increases with age.
- Aneurysms may be multiple in 20–30%.
- Nonaneurysmal perimesencephalic hemorrhage (10%)
- Remaining 5% of causes include:
 - Mycotic (septic) aneurysm due to syphilis or endocarditis
 - Arteriovenous malformations
 - Vertebral or carotid artery dissection
 - Intracranial neoplasm
 - Pituitary apoplexy
- Severe closed head injury

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Classically a severe, sudden headache:
 - Often described as “thunderclap” or “worst headache of life”
 - Headache is often occipital or nuchal, but may be unilateral.
 - Usually develops within seconds and peaks within minutes
 - Distinct from prior headaches
 - Headache often maximal at onset
- Sentinel headaches and minor bleeding occur in 20–50%:
 - May occur days to weeks prior to presentation and diagnosis
- Seizures, transient loss of consciousness, or altered level of consciousness occur in more than 50% of patients.
- Vomiting occurs in 70%.
- Syncope, diplopia, and seizure are particularly high-risk features for SAH.

Physical-Exam

- Focal neurologic deficits occur at the same time as the headache in 33% of patients:
 - 3rd cranial nerve (CN III) palsy (the “down and out” eye) occurs in 10–15%.
 - Isolated CN VI palsy or papillary dilation may also occur.
- Nuchal rigidity develops in 25–70%.
- Retinal hemorrhage may be the only clue in comatose patient.

ESSENTIAL WORKUP

- Complete neurologic exam and fundoscopic exam
- Emergent noncontrast head CT scan:
 - Diagnoses 93–98% of SAH if performed within 12 hr

- Thin cuts (3 mm) through base of brain improve diagnostic yield.
- CT is less sensitive after 24 hr or if hemoglobin < 10 g/L.
- Lumbar puncture (LP) and CSF analysis must be performed if CT negative and history suggests possibility of SAH.

Pregnancy Considerations

- Incidence slightly increased in pregnancy
- Workup should include CT and LP

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Baseline CBC and differential
- Electrolytes, renal function tests
- Coagulation studies
- Cardiac markers:
 - Troponin I elevated in 10–40%
- CSF analysis (see below)

Imaging

- Chest radiograph for pulmonary edema:
 - Occurs in up to 40% with severe neurologic deficit
- Traditional gold standard: 4-vessel digital subtraction cerebral angiography
- Spiral CT angiography:
 - Useful for operative planning
 - Quite sensitive for detection of aneurysms > 4 mm, less with smaller aneurysms
- MR angiography:
 - MRI is less sensitive for hemorrhage
 - Quite sensitive for detection of aneurysms > 4 mm, less with smaller aneurysms
- Transcranial Doppler ultrasound:
 - May be useful in detecting vasospasm.

Diagnostic Procedures/Surgery

- LP:
 - Presence of erythrocytes in CSF indicates SAH or traumatic tap:
 - If traumatic tap suspected, LP should be performed 1 interspace higher.
 - Diminishing erythrocyte count in successive tubes suggests but does not firmly establish a traumatic tap.
 - Xanthochromia is diagnostic of SAH if performed 12 hr after onset.

- An elevated opening pressure may indicate SAH, cerebral venous sinus thrombosis, or pseudotumor cerebri.
- ECG:
 - ST-segment elevation or depression
 - QT prolongation
 - T-wave abnormalities
 - Often mimics ischemia or infarction
 - Symptomatic bradycardia, ventricular tachycardia, and ventricular fibrillation

DIFFERENTIAL DIAGNOSIS

- Neoplasm
- Arterial dissection
- Aneurysm (unruptured)
- Arteriovenous malformation
- Migraine
- Pseudotumor cerebri
- Meningitis
- Encephalitis
- Hypertensive encephalopathy
- Hyperglycemia or hypoglycemia
- Temporal arteritis
- Acute glaucoma
- Subdural hematoma
- Epidural hematoma
- Intracerebral hemorrhage
- Thromboembolic stroke
- Sinusitis
- Seizure disorder
- Cerebral venous sinus thrombosis
- Cavernous sinus thrombosis

TREATMENT

PRE HOSPITAL

- Initial assessment and history:
 - Level of consciousness
 - Glasgow Coma Scale score
 - Gross motor deficits
 - Other focal deficits
- Patients with SAH may need emergent intubation for rapidly deteriorating level of consciousness.

- IV access should be established.
- Provide supplemental oxygen.
- Monitor cardiac rhythm.
- Patients should be transported to a hospital with emergent CT and ICU capability.

INITIAL STABILIZATION/THERAPY

- Manage airway, resuscitate as indicated:
 - _ Rapid-sequence intubation
 - _ Pretreat with lidocaine and defasciculating dose of nondepolarizing paralytic to blunt increase in intracranial pressure (ICP) during intubation.
 - _ Cardiac monitoring and pulse oximetry
 - _ Establish adequate IV access
- Obtain urgent neurosurgical consultation

ED TREATMENT/PROCEDURES

- Prevent rebleeding:
 - _ Risk of rebleeding highest in the 1st few hours after aneurysmal rupture
- Manage ICP:
 - _ Elevate head of bed to 30°.
 - _ Prevent increases in ICP from vomiting and defecation with antiemetics and stool softeners.
 - _ Treat increased ICP with controlled ventilation and mannitol.
 - _ Maintain central venous pressure > 8 mm Hg and urine output > 50 mL/hr
- BP control:
 - _ Balance HTN-induced rebleeding vs. cerebral hypoperfusion
 - _ Goal mean arterial pressure 100–120 mm Hg, systolic BP < 160:
 - Labetalol, hydralazine, nitroprusside, or nicardipine for hypertension
 - _ Correct hypovolemia:
 - Should start within 96 hr of SAH
 - Treat hypotension with volume expansion.
- Cerebral vasospasm:
 - _ May cause secondary ischemia and infarction after SAH:
 - _ Oral nimodipine improves functional outcome:
 - Discuss with neurosurgeon prior to administration
 - _ Monitor with transcranial Doppler.
- Adequately treat pain.
- Seizures:
 - _ Manage with IV benzodiazepine
 - _ Consider prophylactic anticonvulsants in immediate posthemorrhagic period
- Correct temperature, electrolyte, glucose, or pH abnormalities.
- Treat coagulopathy, thrombocytopenia, and severe anemia.
- Monitor for and correct pulmonary edema and cardiac arrhythmias.
- Antifibrinolytic therapies:

- Discuss with neurosurgeon prior to initiation
- Consider administration immediately after aneurysmal rupture in patients at high risk of rebleeding when this is combined with treatment of aneurysm and monitoring for hypotension.
- When patient is stable, expedited transfer to hospital with neurosurgical capabilities is mandatory.

MEDICATION

- Diazepam: 5–10 mg (peds: 0.2–0.3 mg/kg) IV/IM q10–1min PRN; max. 30 mg (peds: 10 mg)
- Fentanyl: 1–3 µg/kg (adults and peds) IV q1–4h PRN
- Fosphenytoin: 15–20 phenytoin equivalents (PE) per kg (adults and peds) IV × 1; maintenance 4–6 mg/kg/d IV
- Hydralazine: 10–20 mg (peds: 0.1–0.5 mg/kg IV) q30min–4h PRN
- Labetalol: 20 mg IV bolus, then 40–80 mg q10min; max. 300 mg; follow with IV continuous infusion 0.5–2 mg/min (peds: 0.4–1 mg/kg/h IV continuous infusion; max. 3 mg/kg/h)
- Lidocaine: 1–1.5 mg/kg IV × 1 (adults and peds)
- Lorazepam: 2–4 mg (peds: 0.03–0.05 mg/kg/dose; max. 4 mg/dose) IV q15min PRN
- Midazolam: 1–2 mg (peds: 0.15 mg/kg IV × 1) IV q10min PRN
- Morphine: 2–10 mg (peds: 0.05–0.2 mg/kg IV) q2–4h PRN
- Nicardipine: 5–15 mg/h IV continuous infusion (peds: Safety not established)
- Nimodipine: 60 mg PO/NGT q4h; (peds: Safety not established)
- Nitroprusside: 0.25–10 µg/kg/min IV continuous infusion (adults and peds)
- Ondansetron: 4–8 mg (peds: 0.1–0.15 mg/kg max. 4 mg) PO/IM/IV TID PRN
- Phenytoin: 15–20 mg/kg IV load at max. 50 mg/min; max. 1.5 g; maintenance 4–6 mg/kg/d IV; (adult and pediatric)
- Promethazine: 12.5–25 mg (peds > 2 yr old: 0.25–1 mg/kg; max. 25 mg/dose) PO/IM/IV q4–6h PRN

SURGERY/OTHER PROCEDURES

- Per neurosurgical consultant
- Early operative or endovascular intervention may prevent vasospasm and improve outcome.

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with SAH should be admitted to an ICU.

- Patients with negative CT findings and equivocal LP findings should be admitted for observation.

Discharge Criteria

- Patients with negative CT and LP findings and onset of symptoms < 2 wk
- Outpatient follow-up for headache treatment and further evaluation

Issues for Referral

Early referral to center with access to neurosurgeons and endovascular specialists (if none at practicing institution)

PROGNOSIS

- Mortality is 12% before arrival to hospital.
- Ultimately fatal in more than 50%.
- In cases of “sentinel bleed” or early detection of aneurysmal rupture, outcomes are improved with early surgical or interventional approaches.

PEARLS AND PITFALLS

- Failure to consider SAH in differential diagnosis for new, acute headache
- Failure to assess previous headache workup as complete (CT and LP)

SUBDURAL HEMATOMA

Stephen R. Hayden

BASICS

DESCRIPTION

- Classification of subdural hematoma (SDH):
 - Acute: Diagnosis within the 1st 3 days
 - Subacute: Diagnosis 3 days–3 wk
 - Chronic: Diagnosis after 3 wk
- CT description:
 - Rarely crosses midline
 - Does cross suture lines
 - Inner margins are often seen to be irregular.
- Acute:
 - Most commonly due to acceleration–deceleration forces and less commonly from direct trauma
 - Sagittal movement of the head causes stretch of parasagittal bridging veins.
 - Other bleeding sites include:
 - Laceration of dura
 - Venous sinus injury
 - Cortical arteries
 - Nontraumatic injuries: Intracerebral aneurysm rupture, arteriovenous malformation, coagulation disorder, arterial HTN, drug or alcohol abuse
- Chronic:
 - Encapsulated hematoma most likely caused by repeated small hemorrhages of bridging veins.

ETIOLOGY

- Acute:
 - Most common type of intracranial hematoma (66–70%)
 - Occurs most commonly at cerebral complexities > falx cerebri > tentorium cerebelli
 - Peak incidence 15–24 yr, 2nd peak >75 yr
 - Represents 26–63% of blunt head injury
 - Motor vehicle crash (MVC) is most common cause overall.
 - Falls and assault more commonly result in isolated SDH (72%) than do MVCs (24%).
 - Elderly patients and those with seizure disorders are at increased risk.
 - Mortality is related to presenting signs and symptoms as well as

comorbidities:

- Mortality is 50% for age >70
- Less than 1/2 present as *simple extra-axial collection* (22% mortality rate)
- ~40% of patients will have *complicated SDH*: Parenchymal laceration or intracerebral hematoma (mortality rate >50%)
- 3rd group *associated with contusion* (30% mortality rate with functional recovery of 20%)
- Coagulopathy: INR >2 increases risk of bleed ×2, INR >3 is associated with larger initial volume and increased expansion
- Chronic:
 - _ Most common in babies or elderly with atrophy:
 - Associated with infarction in underlying brain
- 75% of patients are >50
- <50% have history of trauma
- 50% are alcoholic
- Epilepsy and shunting procedures

Pediatric Considerations

- May occur secondary to trauma at birth
- Nonaccidental trauma more common

DIAGNOSIS

SIGNS AND SYMPTOMS

- Acute:
 - _ 1/5 have diagnosis discovered at autopsy.
 - _ Most commonly misdiagnosed as intoxication or cerebrovascular accident (CVA)
 - _ Headache and altered mental status:
 - 50% unconscious at discovery
- Subacute/chronic:
 - _ Headaches, nausea, vomiting, and seizures are frequent symptoms.
 - _ Presentation varied:
 - Fluctuating mental status
 - Unsteady gait
 - Slow progression of deficits

Pediatric Considerations

Imaging is necessary in infants with persistent vomiting, new seizures, lethargy, irritability, bulging, or tense fontanelles.

Physical-Exam

- Acute:
 - Headache and altered mental status
 - Most common clinical signs are hemiparesis or hemiplegia:
 - Seen in 40–65%
 - SDH opposite motor deficit in 60–85%
 - Pupillary abnormality seen in 28–79%:
 - SDH will be on same side of pupillary abnormality in 70–90%.
 - Seizures may be seen in ~10% initially.
 - Papilledema in <1/3
- Chronic:
 - Presentation is varied and mimics other diseases.

ESSENTIAL WORKUP

Obtain directed history:

- Mechanism of injury kinetics
- Neurologic status: Baseline and at-scene
- Complicating factors:
 - Past medical history, medications
 - Allergies, drug use
 - Rapid neurologic assessment:
- Glasgow Coma scale ([GCS] after fluid resuscitation most important)
- Brainstem reflexes:
 - Anisocoria
 - Pupillary light reflex
 - Corneal, gag, oculocephalic/oculovestibular
 - Head imaging

DIAGNOSIS TESTS & INTERPRETATION

Lab

- ABG, CBC, electrolytes with glucose, prothrombin time (PT), partial thromboplastin time (PTT)
- Blood ethyl alcohol, drug screen

Imaging

- Head CT in coordination with other necessary trauma workup
- Acute:
 - Characteristic CT finding is crescent-shaped clot overlying hemispheric convexity.
 - May have irregular medial border of hematoma
 - Mixed density of clot may represent active bleeding
 - Most (60%) associated with other intracranial lesions

- Intracranial volume of hematoma >2% predicts poor prognosis
- Chronic:
 - MRI is a better choice, as lesion may be isodense on CT from 2–3 wk.
 - MRI volume in diffusion-weighted images correlates with Rankin disability score.
 - CT may show hypodense lesion after 3 wk.
 - Spinal radiographs

Pediatric Considerations

US can be used to visualize cerebral structures if fontanelles are patent.

DIFFERENTIAL DIAGNOSIS

- Acute:
 - Diffuse axonal injury
 - Cerebral contusion
 - Intracerebral bleed
 - Subdural hygroma
 - Epidural hematoma
 - Shaken baby/battered child syndrome
- Chronic:
 - Pseudotumor cerebri
 - Brain tumor
 - Dementia
 - Meningitis
 - CVA/transient ischemic attack
 - Cerebral atherosclerosis
 - Toxic, metabolic, respiratory, or circulatory causes

TREATMENT

INITIAL STABILIZATION/THERAPY

- Manage airway and resuscitate as indicated:
 - Hypoxia is a strong predictor of outcome.
 - Maintain SaO₂ >95%.
 - Rapid-sequence intubation (RSI) is indicated for GCS <9 or for evidence of increased intracranial pressure (ICP).
 - RSI for PaCO₂ >45, anisocoria, drop of GCS by 3, loss of gag reflex, C-spine injury
- Routine hyperventilation is no longer recommended due to resultant diminished cerebral perfusion pressure.
- Controlled ventilation to maintain PCO₂ 35–40 mm Hg:

- NS to maintain mean arterial pressure (MAP) 100–110 is necessary:
 - A single episode of systolic BP < 90 is associated with poor outcome.
- Spine precautions
- Elevate head of bed 20–30° (only after adequate fluid resuscitation to avoid resultant decrease in cerebral blood flow [CBF]).
- Not considered helpful:
 - Steroids
 - Antibiotic prophylaxis
 - Hyperventilation (unless herniation is imminent)
 - Fluid restriction
 - Calcium channel blockers
 - Hypothermia not proven
 - NaCl 3% not yet proven helpful

ED TREATMENT/PROCEDURES

- Acute
- Early neurosurgical intervention (< 4 hr) in comatose patients shows reduced mortality:
 - Burr holes may be used as temporizing measure in deteriorating patients.
 - ICP monitoring is indicated for patients with abnormal CT who are intubated.
 - Subdural evacuating port system has been shown to be equivalent to Burr hole for acute treatment of SDH
- Nonoperative treatment may be indicated for small SDH:
 - < 20 mL of blood, < 1 cm, midline shift < 5 mm, no mass effect, no neurologic deficit
 - This requires frequent neurologic reassessment.
 - 10% go on to require operative intervention.
- Maintain euvolemic state with isotonic fluids:
 - Arterial line placement to monitor MAP, PO₂, and PCO₂
 - Foley catheter to monitor I/O status
- Control ICP:
 - Prevent pain, posturing, and increased respiratory effort:
 - Sedation with benzodiazepines
 - Neuromuscular blockade with vecuronium or rocuronium in intubated patients
 - Etomidate is a good induction agent.
 - Mannitol may be used once euvolemic:
 - Shown to increase MAP > cerebral perfusion pressure and CBF as well as decrease ICP
 - Keep osmolality between 295 and 310.
 - Use furosemide (Lasix) as an adjunct only if normovolemic.
 - Treat HTN:

- Labetalol, nicardipine, or hydralazine
- Treat coagulopathy
- Use fresh frozen plasma 4+ units
- Use prothrombin complex concentrate
- Treat hyperglycemia if present:
 - Associated with increased mortality in traumatic brain injury
- Treat and prevent seizures:
 - Diazepam and phenytoin (Dilantin), levetiracetam: Prophylactic anticonvulsants not indicated

MEDICATION

- Diazepam: 5–10 mg (peds: 0.2–0.3 mg/kg) IV/IM q10–15min PRN; max. 30 mg (peds: 10 mg)
- Dilantin: Adults and peds: Load 18 mg/kg at 25–50 mg/min
- Etomidate: 0.3 mg/kg IV for induction of RSI
- Fentanyl: 2–4 µg/kg
- Hydralazine: 10–20 mg (peds: 0.1–0.5 mg/kg IV) q2–4h PRN
- Labetalol: 20 mg IV bolus, then 40–80 mg q10min; max. 300 mg; follow with IV continuous infusion 0.5–2 mg/min; (peds: 0.4–1 mg/kg/h IV continuous infusion; max. 3 mg/kg/h)
- Lasix: Adults and peds: 0.5 mg/kg IV
- Levetiracetam: 1,500 mg PO/IV q12h
- Lidocaine: As preinduction agent, 1.5 mg/kg IV
- Mannitol: Adults and peds: 0.25–0.5 g/kg IV q4h
- Midazolam: 1–2 mg (peds: 0.15 mg/kg IV × 1) IV q10min PRN
- Nicardipine: 5–15 mg/h IV continuous infusion (peds: Safety not established)
- Pentobarbital: 1–5 mg IV q6h
- Prothrombin complex concentrate: 50 U/kg IV
- Rocuronium: 1 mg/kg for induction
- Thiopental: As induction agent, 20 mg/kg IV

FOLLOW-UP

DISPOSITION

Admission Criteria

- Acute SDH patients should be admitted to the operating room or ICU by the neurosurgical service.
- Subacute subdurals should be admitted to a monitored setting.

Discharge Criteria

Patients with chronic SDH often can be managed as outpatients in conjunction with

neurosurgery, adequate home resources, and appropriate follow-up.

Issues for Referral

All patients need neurosurgical evaluation immediately.

PEARLS AND PITFALLS

The following factors predict prognosis:

- GCS on admission
- Time to treatment
- Pupil abnormalities
- CT volume of hematoma and presence of midline shift
- Midline shift > hematoma volume

SUDDEN INFANT DEATH SYNDROME (SIDS)

Genie E. Roosevelt

BASICS

DESCRIPTION

- Sudden, unexpected death of an infant <1 yr old who was typically well before being placed down to sleep
- Death remains unexplained after being thoroughly investigated by autopsy, exam of the death scene, investigation of the circumstances, and review of the family and infant medical histories.
- Leading cause of death in infants 1 mo–1 yr of age; the incidence has declined markedly since the initiation of the “Back to Sleep” program in 1994:
 - 1992: 120 deaths/100,000 live births (US)
 - 2001: 56 death/100,000 live births (US)
 - No change from 2001–2006
- Peak occurrence of SIDS at 1–4 mo of age:
 - 90% occur <6 mo of age
 - 2% occur >10 mo of age
- Ethnic differences: 2006 rates per 100,000 live births: All populations, 54.5; non-Hispanic white, 55.6; non-Hispanic black, 103.8; American Indian/Alaska Natives, 119.4; Asian American or Pacific Islander, 22.8; Hispanic, 27.
- Sleeping on back (supine) reduces incidence significantly (“Back to Sleep”). Practice of infants sleeping on their backs began initially in Europe and then in US

ETIOLOGY

- Most likely multifactorial
- SIDS infants likely have predisposing conditions that make them more vulnerable to both internal and external stressors.
- Potential stressors include anemia, congenital diseases, dysrhythmias, electrolyte abnormalities, genetic defects, infection, metabolic disorders, neurologic events, suffocation, trauma, upper airway obstruction.
- Maternal and antenatal risk factors:
 - Alcohol and illicit drug use
 - Intrauterine growth restriction
 - Lower socioeconomic status
 - Poor prenatal care
 - Prior sibling death secondary to SIDS
 - Shorter interval between pregnancies
 - Smoking
 - Younger age

- Infant risk factors:
 - Bed sharing
 - Exposure to environmental smoking
 - Gastroesophageal reflux (GER)
 - Hyperthermia
 - Low birth weight, prematurity
 - Male gender
 - Soft bedding, soft sleeping surface
 - Recent febrile illness
- Supine sleeping position, breast-feeding, and pacifier use are protective.
- Home monitoring has not been shown to prevent SIDS.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- No significant pre-existing signs or symptoms to alert caretakers
- Unpredictable
- Most infants appear normal when put to bed.
- Death occurs while the infant is sleeping.
- Typically the event is silent with no signs of struggling.
- No clinical or pathologic explanation for death.
- Apparent life-threatening event (ALTE) is an acute event that is frightening to the caretaker:
 - Characterized by apnea (either central or obstructive) causing changes in skin color—cyanosis, pallor, or erythema with limpness, choking, and/or gagging.
 - Infant should be transported to hospital for evaluation and monitoring.
 - Appears well when evaluated by clinicians after recovery from ALTE.
 - Associated with an increased risk of SIDS.

Physical-Exam

- Prior to the event, the infant is seemingly healthy and well appearing, well developed, and well nourished.
- If event was brief and self-limited, may appear well when evaluated after the episode.
- Potential complications for surviving infants include pulmonary edema, aspiration pneumonia, and neurologic sequelae secondary to hypoxia including seizures.

ESSENTIAL WORKUP

- SIDS is a diagnosis of exclusion, so requires an evaluation to identify primary

and/or contributing conditions.

- Thorough investigation of the death scene:
 - Conditions surrounding sleeping space (temperature, surface, bedding, bed sharing)
 - Position in which infant was sleeping
 - Interview of parents, family members, and caregivers
 - Exam of potentially relevant items from the death scene
 - Maintain sensitivity toward family as investigation may be difficult for them.
- Review infant and family histories:
 - Prenatal, perinatal, and postnatal infant medical history
 - Family medical and social histories, particularly mother
- Impact of investigation on family:
 - Family is very vulnerable during the investigation
 - May help them through the grieving process.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Selective studies reflecting nature of episode and patient condition
- Arterial/venous blood gas
- Blood culture and other sepsis workup as indicated
- CBC
- ECG
- Include family member to evaluate for familial dysrhythmias such as prolonged QT syndrome
- EEG
- Electrolytes including calcium, magnesium and phosphorous. Liver function tests
- Toxicology screen
- UA and culture

Imaging

- Chest radiograph to assess cardiopulmonary status
- Skeletal survey to evaluate for child abuse (may be performed by pathologist)
- Head CT if child survives to assess intracranial pathology
- Consider upper GI to evaluate for GER

Diagnostic Procedures/Surgery

- Autopsy:
 - Most states require an autopsy for potential SIDS cases
 - Important that postmortem exam be performed as SIDS is a diagnosis of exclusion

- Involves microscopic exam of vital organs through tissue samples as well as gross exam
- Some postmortem findings in SIDS cases that might establish alternative cause of death:
 - o Congenital cardiomyopathies
 - o Cardiac rhabdomyomas
 - o Tuberous sclerosis
 - o Rare genetic/metabolic diseases
 - o Viral myocarditis
 - o Intracranial arteriovenous malformations

DIFFERENTIAL DIAGNOSIS

- Cardiovascular:
 - Anomalous coronary artery
 - Aortic stenosis
 - Cardiomyopathy
 - Dysrhythmia
 - Myocarditis
- Respiratory:
 - Aspiration
 - Suffocation
- Infection:
 - Botulism
 - Bronchiolitis/respiratory syncytial virus
 - Encephalitis
 - Meningitis
 - Pertussis
 - Sepsis
- CNS:
 - Arteriovenous malformation
 - Central hypoventilation
 - Neuromuscular disorders
 - Seizures
 - Tuberous sclerosis
- GI:
 - GER
 - Diarrhea
 - Pancreatitis
 - Volvulus
- Endocrine/metabolic:
 - Carnitine deficiency
 - Congenital adrenal hyperplasia
 - Glycogen storage disease

- Long- or medium-chain acyl-coenzyme A deficiency
- Urea cycle defect
- Systemic:
 - Child abuse
 - Dehydration
 - Intentional poisoning
 - Hyperthermia

TREATMENT

- Initiate resuscitation at the scene; transport infant to ED and continue protocols en route.
- On very rare occasion and under medical direction, resuscitations have been aborted and the infant is pronounced at the scene; consideration must be given to the emotional, social, and clinical circumstances.

PRE HOSPITAL

- Resuscitation procedures supplemented by support for the family
- Evaluate setting; determine if suspicion of abuse

INITIAL STABILIZATION/THERAPY

- Assess and support ABCs (bedside).
- Administer appropriate medications per protocols by endotracheal tube if IV access unobtainable (atropine, epinephrine, lidocaine, and naloxone).
- Monitor vital signs: BP, heart rate, respirations, and oxygen saturation continuously.
- Conduct a thorough physical exam; look for unintentional as well as intentional traumas.
- Assess the scene, family members, and other caretakers.

ED TREATMENT/PROCEDURES

- Resuscitate patient per established protocols continuing efforts initiated by pre-hospital personnel:
 - Health care providers are encouraged to offer family members the opportunity to be present during resuscitation.
- If resuscitation unsuccessful and no obvious diagnosis found, parents should not be told that SIDS is the cause of death:
 - In speaking with the parents, SIDS may be included among the possible causes of death.
 - A diagnosis cannot be made until completion of an autopsy, investigation of circumstances and death scene, and exploration of the medical histories of the infant and family.
- Family support:

- If resuscitation unsuccessful, attention should then focus on the family; if resuscitation ongoing, communication and support of family is essential.
- All family members and caregivers are affected; they experience grief, guilt, failure, and inadequacy.
- Some parents want to spend quiet time holding their infants after an unsuccessful resuscitation.
- Family is defined variably among different cultures; ED personnel should attempt to be sensitive to cultural needs and expectations of the family.
- Family should be offered support in the ED and supplied with resources of support for beyond the day of the infant's death; local, state, and national SIDS Foundation resources should be made available.
- Support may be obtained from Sudden Infant Death Syndrome Alliance/First Candle, 1314 Bedford Avenue, Suite 210, Baltimore, MD 21208 (800-221-7437) or local SIDS support organization.
- The child's PCP should be involved in the follow-up and support of the family.
- Emergency personnel support:
 - ED debriefing should be conducted for all staff who were involved in the infant's care, including EMS personnel; it is important to allow people to express their feelings and freely process the event in a supportive environment.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Observe all infants who have ALTE for evaluation and monitoring after initial resuscitation and stabilization.
- Most high-risk infants have 1 of the following variables: Obvious need for admission, significant medical history, and > 1 ALTE in 24 hr.

Discharge Criteria

Patients are generally admitted for observation and monitoring for documented episodes and support of family.

Issues for Referral

- All surviving infants should have a pediatric consultation.
- Families will need support.

PEARLS AND PITFALLS

Infants with SIDS or ALTE should be resuscitated appropriately. Autopsies are essential for diagnosis and should be considered mandatory. Use available resources including social workers and chaplains as support for the family is crucial.

SUICIDE, RISK EVALUATION

Helen M. Farrell • Vithya Balasubramaniam

BASICS

DESCRIPTION

- The intentional taking of one's own life
- Suicidal ideation:
 - Passive: A conscious desire not to live
 - Active: Intention to die with or without a plan
- Parasuicidal behavior: Self-injury not intended to cause death (e.g., superficial cutting, cigarette burns, head banging)
- Reckless behavior: Not taking prescribed medications, taking too much of prescribed medications, running into traffic
- Risk-to-rescue ratio—lethality of plan compared with likelihood of rescue:
 - High risk-to-rescue ratio indicates increased severity of attempt.
- Occult presentation:
 - Many individuals at risk for suicidal behavior seek care in the ED for nonbehavioral complaints
 - Improved suicide screening practices may be needed to capture this population.

ETIOLOGY

- 36,891 suicides in US (CDC 2009)
- 12–25 attempts per every completed suicide
- 25.4 per 100,000 males (CDC 2009)
- 7.4 per 100,000 females
- 11.1 per 100,000 general population
- 2 peaks in age group most at risk for suicide:
 - Age 15–24 yr (3rd leading cause of death in this age group)
 - Age > 60 yr (highest rates of any age group, increasing incidence with age)

Risk Factors for Suicidal Behavior

- Depression (bipolar or unipolar)
- Alcohol or drug abuse
- History of physical or sexual abuse
- Unemployment
- Incarceration
- History of head injury or neurologic disorder
- Firearms in the home
- Cigarette smoking

- Positive family history of suicide attempt
- Psychiatric or medical comorbidities
- Gender:
 - Women 3 times more likely to attempt suicide.
 - Men 3 times more likely to complete suicide.
- Psychological:
 - Impulsivity/aggression
 - Depression
 - Anxiety
 - Hopelessness
 - Self-consciousness/social disengagement
 - Poor problem-solving abilities
 - Lack of social supports
 - Widowed
 - Divorced
 - Separated
 - Lack of social supports
 - Recent loss of relationship
 - Anniversary of loss
- Environmental
- Rural areas:
 - Access to firearms
 - Poverty
 - Unemployment

Risk Factors for Completed Suicide

- Male
- Age > 60 yr
- White or Native American
- Widowed/divorced
- Living alone
- Unemployment/poverty
- Past suicide attempt

Methods of Suicide (CDC 2009)

- Firearms (most common among men and 2nd most common in women)
- Overdose (Most common among women); most common means of suicide attempt (70% of failed attempts are by overdose)
- Hanging
- Suffocation

Populations at Highest Risk for Completing Suicide

- > 90% of patients who commit suicide have a psychiatric diagnosis.
- Depression—especially psychotic depression
- Anxiety and panic disorder
- Alcohol or drug intoxication
- Schizophrenia
- Adolescents

Others at Risk for Completing Suicide

- Recent discharge from psychiatric facility
- History of suicidal ideation or suicide attempt
- Serious physical illness present in up to 70% of all suicides, particularly in elderly patients.
- History of incarceration
- Physicians
- Victims of violence/abuse

Interventions that Lower Risk

- Patients with mood disorders (major depression and bipolar disorder) treated with lithium
- Patient with major depression treated with electroconvulsive therapy
- Patients with schizophrenia treated with clozapine
- **NOT** shown to decrease suicide rates: Treatment with selective serotonin reuptake inhibitors (SSRIs) for major depression

Protective factors

- Strong social supports
- Family cohesion
- Peer group affiliation
- Good coping and problem-solving skills
- Positive values and beliefs
- Ability to seek and access help

DIAGNOSIS

SIGNS AND SYMPTOMS

- Depressed mood
- Verbalization of suicidal ideation with or without plan
- Hopelessness
- Helplessness
- Anger/aggression
- Impulsivity
- Psychotic symptoms (i.e., paranoia, command auditory hallucinations)

History

- Obtain history to assess risk:
 - Asking about suicide does not increase risk for attempt
- Degree of suicidal ideation
- Plan immediate risk of self-injury?
 - Means available to complete plan
 - Activity toward initiating plan
 - Patient's expectations of lethality of plan
- Intent: Reasons, goal
- Risk-to-rescue ratio
- Plan or intent to harm others?
- Presence of acute precipitants:
 - Recent losses, lack of social supports
- Risk factors:
 - History of past suicide attempts
 - Psychiatric review of symptoms: Depression, psychosis, panic/anxiety
 - Chronic medical illness
 - Alcohol or drug abuse
- Serial assessment of mental status, consistency of responses
- Factors preventing suicide

Physical-Exam

- As needed to address acute medical issues
- Look for evidence of injuries and signs of self-neglect.

Scoring Systems

- Modified SAD PERSONS Score:
 - Sex: Male 1 point
 - Age <19 or >45 yr 1 point
 - Depression or hopelessness 2 points
 - Previous attempts or psychiatric care 1 point
 - Excessive alcohol or drug use 1 point
 - Rational thinking loss 2 points
 - Separated/divorced/widowed 1 point
 - Organized or serious attempt 2 points
 - No social supports 1 point
 - Stated future intent 2 points
 - Data suggests that patients with a score of <5 can safely be managed as an outpatient

ESSENTIAL WORKUP

- Collateral information from outpatient care givers, family, friends
- Safety plan:

- Would the patient immediately seek help if suicidal ideation recurred?
- Elimination of means of suicide
- Access to other means of suicide
- Support and supervision in the outpatient setting
- Prompt outpatient follow-up with psychiatric therapy
- Patient investment in not attempting suicide
- Identifying reasons for living
- Safety contracts are no guarantee that individuals will not attempt suicide.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Blood–alcohol level
- Serum toxicology screen: Aspirin, acetaminophen, and other medications
- Urine drug screen:
 - Many psychiatric facilities require toxicology screen before placement.
- Carbon monoxide (as indicated)

Imaging

Not routinely indicated

Diagnostic Procedures/Surgery

ECG – as indicated

DIFFERENTIAL DIAGNOSIS

- Normal despondency
- Bereavement
- Adjustment disorder with depressed mood
- Major depressive disorder
- Bipolar disorder
- Organic mental disorder (head injury, dementia, delirium)
- Schizophrenia
- Panic and anxiety disorders
- Alcohol or drug abuse
- Borderline personality disorder
- Antisocial personality disorder
- Accidental death
- Attempted homicide

Pediatric Considerations

- Suicide is a leading cause of death among young people 15–24 yr of age.
- More than 4,000 adolescents commit suicide every year (CDC 2009)
- Rapidly increasing in young black males ages 10–14 yr

- Less evidence available to link suicide in youth to overt psychiatric illness
- Stresses:
 - Prior attempts
 - Family disruption
 - History of psychiatric disorder
 - Depression
 - Disciplinary crisis
 - Broken romance
 - School difficulties
 - Bereavement
 - Rejection
 - History of physical or sexual abuse
- Early warning signs:
 - Progressive declining schoolwork
 - Multiple physical complaints
 - Substance abuse
 - Disrupted family relations
 - Social withdrawal
 - Anhedonia

Geriatric Considerations

- Suicide rates highest in age > 65 yr
- Completed suicide: 83% men
- Risk factors: Divorced, widowed, male, social isolation
- Tend to use more lethal methods
- Lower ratio of attempts to completions

TREATMENT

PRE HOSPITAL

- For potentially dangerous patient who refuses transport to treatment facility; involve police and impose restraint.
- Risk to medics on the scene in cases of firearms or other weapons
- Know state and local laws, availability of mobile crisis units, and when to involve the police.

INITIAL STABILIZATION/THERAPY

- Prevent ability to elope
- Ensure patient safety:
 - Remove sharp objects, belts, shoelaces, and other articles that could be used for self-injury
- Provide safe environment

- Appropriate supervision

ED TREATMENT/PROCEDURES

- Confer with patient's outpatient therapist or physician if possible
- Voluntary admission to psychiatric facility
- Involuntary admission if patient refuses voluntary
- For involuntary psychiatric admission, patient must have psychiatric disorder and 1 of the following:
 - _ Risk for danger to self
 - _ Risk for danger to others
 - _ Inability to care for self

MEDICATION

Treat underlying psychiatric disorder.

FOLLOW-UP

DISPOSITION

Admission Criteria

- If patient endorses suicidal ideation with plan and intent, admission may be needed for safety.
- If impulsivity, anger, or aggression hinder ability to control behavior

Discharge Criteria

- Patient has no suicidal ideation.
- Patient agrees to return to ED immediately or seek psychiatric help if suicidal ideation recurs.
- Patient has passive suicidal ideation without plan or intent.
- Patient has good support network or placement in appropriate crisis housing
- Appropriate outpatient psychiatric follow-up is ensured.
- In some cases, patients who express suicidal ideation while intoxicated may be discharged if no longer suicidal once they are sober.
- Some patients with borderline personality disorder and chronic suicidal ideation are discharged after careful psychiatric evaluation in consultation with long-term outpatient caregivers.

FOLLOW-UP RECOMMENDATIONS

Close psychiatric follow-up for those with acute illness who do not require admission

PEARLS AND PITFALLS

- A careful history will identify risk factors for suicide.

- Access collateral sources of information about patient's recent thoughts and behavior.
- Maintain patient safety during evaluation
- Hospital admission may be required if patient endorses suicidal ideation and plan.

- R45.851 Suicidal ideations
- Z81.8 Family history of other mental and behavioral disorders
- Z91.5 Personal history of self-harm

SUPRAVENTRICULAR TACHYCARDIA

James G. Adams • Matthew S. Patton

BASICS

DESCRIPTION

- Rhythm that originates ectopically above the His bundle
- Heart rate of 100 bpm or greater
- Irregular narrow complex supraventricular tachycardia (SVT):
 - Atrial fibrillation (AF):
 - Most common form of pathologic SVT seen in the ED
 - 10% of people >75 yr of age have AF.
 - Atrial flutter with variable block
 - Multifocal atrial tachycardia
- Regular narrow complex SVT:
 - Atrial flutter
 - Atrioventricular nodal re-entry tachycardia (AVNRT):
 - 60% of SVT in adults, 70% are female
 - Typically present age 30–40 yr
 - Atrioventricular reciprocating tachycardia (AVRT) involving an accessory pathway
- Wide complex SVT:
 - Conduction is outside of the normal His-Purkinje system.
 - Accessory pathway or a bundle branch block is present.
 - More common in younger patients without structural disease
 - Always suspect a ventricular rhythm with a wide complex rhythm
 - Treat as ventricular tachycardia (VT) unless absolutely certain of SVT

ETIOLOGY

- Atrial tachycardia:
 - Precipitated by a premature atrial or ventricular contraction
 - Electrolyte disturbances
 - Drug toxicity (i.e., theophylline)
 - Hypoxia
 - Increased atrial pressure
- Junctional tachycardia:
 - AV nodal re-entry
 - Myocardial ischemia
 - Structural heart disease
 - Pre-excitation syndromes
- Wolff–Parkinson–White (WPW) syndrome:

- Intrinsic accessory pathway
- Drug and alcohol toxicity
- AF:
 - HTN
 - Coronary artery disease
 - Hypo-/hyperthyroidism
 - Heavy alcohol intake
 - Mitral valve disease
 - Chronic pulmonary disease
 - Pulmonary embolus
 - WPW syndrome
 - Hypoxia
 - Digoxin toxicity
 - Chronic pericarditis
 - Sepsis
- Atrial flutter:
 - Ischemic heart disease
 - Valvular heart diseases
 - CHF
 - Myocarditis
 - Cardiomyopathies
 - Pulmonary embolus
 - Other pulmonary disease

DIAGNOSIS

SIGNS AND SYMPTOMS

- Palpitations (most common)
- Lightheadedness, pressure in the head
- Dyspnea
- Diaphoresis
- Dizziness
- Weakness
- Chest discomfort
- Syncope
- Prominent neck veins “frog sign”
- Signs of instability:
 - Mental status changes
 - Chest pain/ischemia
 - Acute pulmonary edema
 - Hypotension

History

- Abrupt onset of palpitations, lightheadedness, weakness, chest pain:
 - Current symptoms
 - Previous episodes
- Insidious onset of generalized weakness, exercise intolerance, and malaise
- Prior cardiac history
- Medications:
 - Over-the-counter, decongestants
- Illicit drug use

Physical-Exam

- Vital signs:
 - Tachycardia
 - BP normal or hypotensive
 - Respiratory rate normal or tachypneic
- Cardiac:
 - Regular or irregularly irregular rhythm
 - JVD may be present in setting of heart failure
- Pulmonary:
 - Rales may be present in setting of heart failure.

ESSENTIAL WORKUP

- ABCs, assess stable vs. unstable
- History
- EKG

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Electrolytes
- Cardiac enzymes, BNP
- Thyroid function (usually low yield)

Imaging

- CXR:
 - Assess cardiac size
 - Evaluate for pulmonary process
 - More useful in AF/flutter

Diagnostic Procedures/Surgery

- EKG:
 - AF:

- Atrial fibrillatory waves without discernable P-waves
- Irregularly irregular ventricular rate of 100–220
- Atrial flutter:
 - Regular atrial rate usually > 300
 - Beat-to-beat uniformity of cycle length, polarity, and amplitude
 - Sawtooth flutter waves directed superiorly and most visible in leads II, III, aVF
 - AV block, usually 2:1, but occasionally greater or irregular
- Multifocal atrial tachycardia:
 - 3 distinctly different P-waves with varying pulse rate intervals
- Atrial tachycardia:
 - Rate of 100–200 bpm
 - P-wave precedes QRS and is morphologically different from the sinus P-wave.
- Junctional tachycardia:
 - Usually 1:1 conduction, with ventricular rates equaling the atrial rate.
 - May be either paroxysmal or sustained
 - Ventricular rates > 200 bpm in an adult suggest an accessory pathway syndrome such as WPW syndrome.
 - Absence of preceding P-waves
 - Often retrograde P-waves buried in the QRS

DIFFERENTIAL DIAGNOSIS

- Sinus tachycardia:
 - Sepsis
 - Hypovolemia
 - Pericardial tamponade
 - Acute MI
 - Drug intoxication
- Wide complex tachycardias:
 - Distinguish between supraventricular with aberrancy or ventricular origins.

TREATMENT

PRE HOSPITAL

- Supplemental oxygen
- IV access
- Monitor

INITIAL STABILIZATION/THERAPY

- IV access
- Oxygen

- Monitor

ED TREATMENT/PROCEDURES

- AF/atrial flutter:
 - AF is most likely diagnosed when the rhythm is irregular
 - When unstable, then immediate synchronized cardioversion
 - When stable, rate control is a priority:
 - β -blockers or calcium channel blockers, amiodarone, and digoxin
 - Cardioversion in stable patients should not be attempted unless the dysrhythmia is known to be acute (< 48 hr in duration) due to risk of embolism
- WPW syndrome:
 - Consider direct current cardioversion or amiodarone, flecainide, or procainamide.
 - Avoid AV node blocking agents such as adenosine, β -blockers, calcium channel blockers, and digoxin.
- In regular narrow complex SVTs:
 - Vagal maneuvers will occasionally terminate the dysrhythmia:
 - Carotid massage (although beware of carotid disease, especially in elderly)
 - Ice to face in children (mammalian diving reflex)
 - Valsalva maneuver
 - If this is unsuccessful, adenosine is the drug of choice.
 - Adenosine 6 mg will convert 60–80% of SVT
- Wide complex SVT:
 - Try to determine whether VT or SVT with aberrancy
 - If in doubt must be treated as VT
 - Brugada criteria may help identify VT (See “Ventricular Tachycardia”).
 - Verapamil is absolutely contraindicated.
 - Adenosine should be reserved for SVT with aberrancy and is rarely indicated.
 - Electrical cardioversion:
 - Fewer potential complications than antiarrhythmic drugs when mechanism unknown
 - Antidysrhythmic drugs:
 - IV procainamide and IV amiodarone
 - Lidocaine is less effective, although sometimes more readily available.
 - Bretylium lacks any evidence of efficacy.

Pediatric Considerations

- Synchronized cardioversion for unstable patient 0.5–1 J/kg
- SVT is the most common dysrhythmia seen in young adults and children without underlying heart disease:

- Initial vagal maneuvers:
 - Infants: Ice/water bag to forehead × 15 sec
 - Children: Valsalva: “Blow into straw”
- Aberrant conduction:
 - WPW syndrome and AVNRT are the 2 most common forms of SVT seen in children.
- Use verapamil only > 1 yr of age.

Pregnancy Considerations

- Adenosine considered safe
- 2nd-line agents IV propranolol or metoprolol
- Avoid verapamil (maternal hypotension)
- Cardioversion is safe.

MEDICATION

- Adenosine: 6 mg (peds: 0.1 mg/kg up to 6 mg) rapid IVP; if no response after 1–2 min, then 12 mg (peds: 0.2 mg/kg up to 12 mg), may repeat 12 mg (0.2 mg/kg)
- Amiodarone: Load with 15 mg/min IV over 10 min (peds: 5 mg/kg over 20–60 min), then 1 mg/min IV for 6 hr, then 0.5 mg/min IV for 18 hr
- Digoxin: 0.5 mg IV initially, then 0.25 mg IV q4h
- Diltiazem: 0.25 mg/kg IV (usually 10–20 mg) over 2 min, followed in 15 min by 0.35 mg/kg IV over 2 min
- Esmolol: 0.5 mg/kg IV over 1 min; maintenance infusion, 0.05 mg/kg/min IV over 4 min, then 0.1–0.2 mg/kg/min IV continuously
- Lidocaine: 100 mg IV
- Metoprolol: 5–15 mg slow IV push at 5-min intervals to total of 15 mg
- Procainamide: 20–30 mg/min IV up to 17 mg/kg, may increase to 50 mg/min for more urgent situations
- Propranolol: 0.1 mg/kg div. into equal doses at 2–3-min intervals
- Sotalol: Load 10 mg/min IV up to 1–1.5 mg/kg body weight
- Verapamil: 2.5–5 mg IV bolus over 2 min; may repeat with 5–10 mg q15–30min to max. of 20 mg

FOLLOW-UP

DISPOSITION

Admission Criteria

- Possible cardiac ischemic event
- Persistent SVT
- Possible pre-excitation syndrome

- Other underlying metabolic abnormalities

Discharge Criteria

Terminated rhythm without organ hypoperfusion

Issues for Referral

If there are no concerns for underlying cardiac disease or metabolic derangement, a patient with uncomplicated SVT that is successfully treated may be discharged to follow-up with a primary doctor or cardiologist.

FOLLOW-UP RECOMMENDATIONS

The patient should return to the ED if feeling faint, dizzy, numbness or weakness of the face or limbs, or trouble seeing or speaking. Avoid high-risk activities (swimming, piloting, diving, etc.) until further evaluation.

PEARLS AND PITFALLS

- Valsalva maneuvers should, ideally, be attempted with the patient lying flat. Despite the modest likelihood of success, the maneuver is simple and efficient.
- AF is the most worrisome rhythm in patients with an accessory pathway such as WPW. At high ventricular rates, AF can appear deceptively regular, but should not be mistaken for benign SVT.
- When adenosine has no apparent effect, an escalating dose beyond 12–18 mg, is sometimes used. However, if any lower adenosine dose transiently slows the heart rhythm, but the fast rate quickly resumes, then an increased dose is not warranted and an alternative medication should be used.
- A wide complex tachycardia of uncertain etiology should be treated as VT, typically with amiodarone and potentially with procainamide if an accessory pathway is possible.
- Since procainamide can be administered at a maximum rate of 50 mg/min, it takes a minimum of 20 min to administer 1 g, or 30 min to administer 1.5 g. Therefore, request the medicine promptly to optimize timing of administration. If QRS widening or hypotension occur, slow the rate of administration or discontinue the medication.

CODES

ICD9

- 427.0 Paroxysmal supraventricular tachycardia
- 427.89 Other specified cardiac dysrhythmias

ICD10

I47.1 Supraventricular tachycardia

SYMPATHOMIMETIC POISONING

Sean Patrick Nordt

BASICS

DESCRIPTION

- Direct or indirect stimulation of adrenergic receptors in sympathetic and central nervous systems
- Often no correlation between dosage and degree of toxicity
- Cocaine may also block sodium channels of cardiac myocytes, leading to “tricyclic” or class 1a–type dysrhythmias.

Pediatric Considerations

- Sympathomimetic poisoning in children may present similarly to meningitis or other systemic illness.
- Urinary toxicology screening may be only way to discover sympathomimetic poisoning in children presenting with altered mental status.
- Methylphenidate (Ritalin, Concerta) and other sympathomimetics used for ADHD may cross-react with altered mental status.

ETIOLOGY

- Sympathomimetic toxicity can result from use of any sympathetically active drug, including:
 - All amphetamines, methamphetamines, and derivatives (ecstasy, MDMA)
 - Cocaine
 - Synthetic cathinones “Bath Salts”
 - Phencyclidine (PCP)
 - Lysergic acid diethylamide (LSD)
 - Decongestants (rare)
- Drug delivery routes: Inhalation, injection, snorting, or ingestion

DIAGNOSIS

SIGNS AND SYMPTOMS

- Vital signs:
 - Tachycardia:
 - Bradycardia possible for cocaine and some other decongestants
 - Increased BP:
 - Severely intoxicated patients may be hypotensive.
 - Tachypnea
 - Hyperthermia:

○ Often present, may be severe, and is often overlooked

- CNS:
 - Anxiety
 - Headache
 - Agitation
 - Altered mentation
 - Diaphoresis
 - Seizures
 - Stroke
 - Dystonia (rare)
- Cardiovascular:
 - Palpitations
 - Chest pain
 - Myocardial ischemia or infarction
 - Tachydysrhythmias
 - Cardiovascular collapse
 - Murmur (e.g., endocarditis)
- Other:
 - Dilated pupils
 - Dry mucous membranes
 - Urinary retention may cause enlarged bladder.
 - Needle track marks or abscesses on extremities should be sought.
 - Increased or decreased bowel sounds
 - The presence of diaphoresis and bowel sounds may help to differentiate sympathomimetic toxicity from anticholinergic poisoning.

History

- Assess history for possible sympathomimetic agents:
 - Cold preparations
 - Prescription amphetamines
 - Recreational drug use
- Assess for possible coingestions
- Evaluate for symptoms of end organ injury:
 - Chest pain
 - Shortness of breath
 - Headache, confusion, and vomiting

Physical-Exam

- Common findings include:
 - Agitation
 - Tachycardia
 - Diaphoresis

- Mydriasis
- Severe intoxication characterized by:
 - Tachycardia
 - Hypertension
 - Hyperthermia
 - Agitated delirium
 - Seizures
 - Diaphoresis
- Hypotension and respiratory distress may precede cardiovascular collapse
- Evaluate for associated conditions:
 - Cellulitis and soft tissue infections
 - Diastolic cardiac murmurs or unequal pulses
 - Examine carefully for trauma
 - Pneumothorax from inhalation injury
 - Focal neurologic deficits

ESSENTIAL WORKUP

- Monitor vital signs:
 - Increased temperature (>40°C possible):
 - Core temperature recording essential
 - Peripheral temperature may be cool
 - Indication for urgent cooling
 - Ominous prognostic sign
 - BP:
 - Severe hypertension can lead to cardiac and neurologic abnormalities.
 - Late in course, hypotension may supervene.
- ECG:
 - Signs of cardiac ischemia
 - Ventricular tachydysrhythmias
 - Reflex bradycardia

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Urinalysis for:
 - Blood
 - Myoglobin
- Electrolytes, BUN/creatinine, glucose:
 - Hypoglycemia may contribute to altered mental status.
 - Acidosis may accompany severe toxicity.
 - Rhabdomyolysis may cause renal failure.
 - Hyperkalemia—life-threatening consequence of acute renal failure
- Coagulation profile to monitor for potential disseminated intravascular

- coagulation (DIC):
 - _ INR, PT, PTT, platelets
- Creatine phosphokinase (CPK):
 - _ Markedly elevated in rhabdomyolysis
- Urine toxicology screen:
 - _ For other toxins with similar effects (e.g., cocaine)
 - _ Some amphetamine-like substances (e.g., synthetic cathinones, MDMA) may not be detected.
- Salicylate and acetaminophen levels if suicide attempt a possibility or if OTC medications ingested (e.g., cough, cold)
- Venous blood gas, ABG

Imaging

- CXR:
 - _ Adult respiratory distress syndrome
 - _ Noncardiogenic pulmonary edema
- Head CT for:
 - _ Significant headache
 - _ Altered mental status
 - _ Focal neurologic signs
 - _ Subarachnoid hemorrhage, intracerebral bleed

Diagnostic Procedures/Surgery

Lumbar puncture for:

- Suspected meningitis (headache, altered mental status, hyperpyrexia)
- Suspected subarachnoid hemorrhage and CT normal

DIFFERENTIAL DIAGNOSIS

- Sepsis
- Thyroid storm
- Serotonin syndrome
- Neuroleptic malignant syndrome
- Pheochromocytoma
- Subarachnoid hemorrhage
- Drugs that cause delirium:
 - _ Anticholinergics
 - _ Tricyclic antidepressants
 - _ Sympathomimetics
 - _ Ethanol withdrawal
 - _ Sedative/hypnotic withdrawal
 - _ Hallucinogens
 - _ PCP
- Drugs that cause hypertension and tachycardia:

- Sympathomimetics
- Anticholinergics
- Ethanol withdrawal
- PCP
- Caffeine
- Monoamine oxidase inhibitors
- Theophylline
- Nicotine
- Drugs that cause seizures:
 - Camphor
 - Carbamazepine
 - Carbon monoxide
 - Chlorinated hydrocarbons
 - Cholinergics
 - Cyanide
 - Ethanol withdrawal
 - Hypoglycemics
 - Isoniazid
 - Lead
 - Lithium
 - Local anesthetics
 - Phenothiazines
 - Propoxyphene
 - Salicylates
 - Sedative/hypnotic withdrawal
 - Strychnine
 - Sympathomimetics
 - Theophylline
 - Tricyclic antidepressants

TREATMENT

PRE HOSPITAL

- Patient may be uncooperative or violent.
- Secure IV access.
- Protect from self-induced trauma.

INITIAL STABILIZATION/THERAPY

- ABCs
- Establish IV 0.9% NS access
- Cardiac monitor
- Naloxone, dextrose (or Accu-Chek), and thiamine if altered mental status

ED TREATMENT/PROCEDURES

- Decontamination:
 - Gastric lavage not routinely recommended:
 - May consider if recent (within 1 hr) of life-threatening ingestion.
 - Activated charcoal not routinely recommended.
 - Consider activated charcoal with sorbitol in 1st dose if administered.
 - Consider activated charcoal with body stuffer or body packer ingestions.
 - Whole-bowel irrigation with polyethylene glycol solution – electrolyte solution for body packers
- Hypertensive crisis:
 - Initially administer benzodiazepines if agitated.
 - α -blocker (phentolamine) as 2nd-line agent
 - Nicardipine or nitroglycerin IV for severe HTN unresponsive to benzodiazepines
 - Nitroprusside can also be used for severe, unresponsive HTN
 - Avoid β -blockers, which may exacerbate HTN due to unopposed α activity
- Agitation, acute psychosis:
 - Administer benzodiazepines.
 - Use butyrophenones (e.g., haloperidol) *with caution* to manage agitation:
 - May lower seizure thresholds and may prolong QT duration
- Dysrhythmias:
 - Sodium bicarbonate IV push is treatment of choice for ventricular dysrhythmias indicative of sodium channel blocking (i.e., widened QRS complex).
 - Lidocaine for ventricular dysrhythmias refractory to alkalinization, benzodiazepines, and supportive care
- Hyperthermia:
 - Benzodiazepines if agitated
 - Active cooling if temperature $> 40^{\circ}\text{C}$:
 - Tepid water mist
 - Evaporate with fan
- Paralysis:
 - Indicated if muscle rigidity and hyperactivity contributing to persistent hyperthermia
 - Nondepolarizing paralytic preferred
- Rhabdomyolysis:
 - Administer benzodiazepines.
 - Hydrate with 0.9% NS.
 - Maintain urine output at 1–2 mL/min
 - Hemodialysis (if acute renal failure and hyperkalemia occur)
- Seizures:
 - Maintain airway

- Administer benzodiazepines
- Phenobarbital if unresponsive to benzodiazepines

MEDICATION

- Activated charcoal: 1–2 g/kg up to 100 g PO
- Dextrose: D₅₀W 1 amp: 50 mL or 25 g (peds: 1 to 2 mL/kg of D₂₅W; infants: 2.5 to 5.0 mL/kg of D10%) IV
- Diazepam (benzodiazepine): 5–10 mg (peds: 0.2–0.5 mg/kg) IV. Not recommended <6 months of age
- Lorazepam (benzodiazepine): 2–6 mg (peds: 0.03–0.05 mg/kg) IV
- Nicardipine IV infusion at 5 mg/h titrate by 2.5 mg/h q5min to max. 15 mg/h
- Nitroprusside: 0.5–10 µg/kg/min IV (titrated to BP)
- Phenobarbital: 15–20 mg/kg at 25–50 mg/min until cessation of seizure activity; monitor for respiratory depression. Safety not established <6 years of age
- Phentolamine: 1–5 mg IV over 5 min (titrated to BP)
- Sodium bicarbonate: 1 or 2 amps (50 mEq/amp) (peds: 1–2 mEq/kg) IV push

FOLLOW-UP

DISPOSITION

Admission Criteria

- Admit all body packers or stuffers to hospital.
- Severe manifestations of toxicity to monitored bed:
 - Seizures
 - Dysrhythmias
 - Hyperthermia
 - Rhabdomyolysis
 - Severe hypertension
 - Altered mental status
- Ischemic chest pain

Discharge Criteria

Mildly intoxicated patients can be observed and treated in ED until resolution of clinical manifestations.

FOLLOW-UP RECOMMENDATIONS

Patients may need referral for chemical dependency rehab and detoxification

PEARLS AND PITFALLS

- Admit patients with severe or persistent symptoms

- Hyperthermia above 40°C may be life threatening:
 - Treat with aggressive sedation and active cooling
- Recognize rhabdomyolysis and hyperkalemia
- Avoid physical restraints in agitated patients if possible
- Consider associated emergency conditions:
 - Chest pain – acute coronary syndrome
 - Infection in altered patients with fevers and history of IV drug use
 - Traumatic injury with methamphetamine abuse
- Benzodiazepines are 1st-line therapy in symptomatic sympathomimetic intoxication

SYNCOPE

Jarrold Mosier • Samuel M. Keim

BASICS

DESCRIPTION

- Transient loss of consciousness associated with loss of postural tone
- Ultimately, it is the lack of oxygen to the brainstem reticular-activating system, which results in a loss of consciousness and postural tone.
- Most commonly, an inciting event causes a drop in cardiac output.
- Cerebral perfusion is re-established by autonomic regulation as well as the reclined posture, which results from the event.
- Accounts for 3% of ED visits

Pregnancy Considerations

- Pregnant patients frequently experience presyncope or syncope from various causes. 5% of patients experience syncope, 28% experience presyncope throughout their pregnancy.
- Placenta acts as an AV malformation, causing decreased SVR that potentiates orthostatic symptoms.
- Fetus lying on IVC can lead to neurogenic and hypovolemic syncope.
- Pregnant patients at higher risk of DVT/pulmonary embolism (PE), UTI, seizures (preeclampsia), valvular incompetencies. Must exclude these diagnoses in ED evaluation.

Geriatric Considerations

- Elderly with highest incidence as well as increased morbidity
- >1/3 will have numerous potential causes.

ETIOLOGY

- Neurally mediated syncope:
 - Reflex response causing vasodilatation and bradycardia with resulting cerebral hypoperfusion
 - Vasovagal (common faint):
 - Often incited by pain or fear
 - Prodromal findings are usually present.
 - Typically lasts <20 sec
 - Tilt-table testing is the gold standard to diagnose.
 - Carotid sinus syncope:
 - Cough, sneeze
 - GI stimulation (e.g., defecation)

- Micturition
- Orthostatic:
 - Positional changes cause abrupt drop in venous return to heart.
 - Volume depletion:
 - Severe dehydration (e.g., vomiting, diarrhea, diuretics)
 - Hemorrhage (see “Hemorrhagic Shock”)
- Autonomic failure:
 - Diabetic or amyloid neuropathy
 - Parkinson disease
 - Drugs (e.g., β -blockers) and alcohol
- Cardiac arrhythmias:
 - Typically sudden and without prodromal symptoms
 - Tachydysrhythmia or bradydysrhythmia
 - Inherited syndromes (e.g., long QT syndrome, Brugada syndrome)
 - Pacemaker/implantable cardioverter defibrillator malfunction
- Structural cardiac or cardiopulmonary disease:
 - Valvular disease (especially aortic stenosis)
 - Hypertrophic cardiomyopathy
 - Acute myocardial infarction
 - Aortic dissection
 - Pericardial tamponade
- Pulmonary embolus
- Neurologic:
 - Transient spike in intracranial pressure that exceeds cerebral perfusion pressure
 - Postsyncopal headache is almost universal
 - May be presentation of a subarachnoid hemorrhage
- Cerebrovascular steal syndromes

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Prodromal symptoms:
 - Lightheadedness
 - Diaphoresis
 - Dimming vision
 - Nausea
 - Weakness
- The following findings suggest an underlying life threat:
 - Sudden event without warning

- Chest pain or palpitations
- 6 Ps of a syncope history:
 - 1. Prodrome activities
 - 2. Prodrome symptoms—visual symptoms, nausea
 - 3. Predisposing factors—age, chronic disease, family history of sudden death
 - 4. Precipitating factors—stress, postural symptoms
 - 5. Passerby witness—what did they see?
 - 6. Postictal phase, if any—suggests seizure

Physical-Exam

- Evaluate for trauma
- Orthostatic vital signs
- Check for difference in BP in both arms suggesting aortic dissection or subclavian steal syndrome.
- Careful cardiovascular exam, including murmurs, bruits, and dysrhythmias
- Rectal exam to check for GI bleeding
- Urine pregnancy test in reproductive-age female
- Careful neurologic exam

Pediatric Considerations

- Warning signs of a potential serious underlying disease:
 - Syncope during exertion
 - Syncope to loud noise, fright, extreme stress
 - Syncope while supine
 - Family history of sudden death at young age (<30 yr)

ESSENTIAL WORKUP

- ECG immediately upon arrival to check for:
 - Ischemia
 - Dysrhythmias
 - Block
 - Long QT interval
 - Brugada syndrome
 - Wolff–Parkinson–White syndrome
- Detailed history and physical exam will determine diagnosis in 85% of those who eventually obtain a diagnosis.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Driven by history and physical exam
- CBC in suspected occult hemorrhage
- Serum bicarbonate:

- Normal with most syncopal events
- Marked decreased bicarbonate obtained <1 hr after the event:
 - Suggestive of a grand mal seizure rather than syncope
 - If due to seizure, should normalize 1 hr after the event
- Cardiac enzymes in suspected ischemia
- Pregnancy test in reproductive-age female
- Electrolytes in patients with profound dehydration or diuretic use

Imaging

- ECG and monitoring until cardiac etiology ruled out
- Chest radiograph ± CT angiography if congestive heart failure (CHF), dissection, or massive PE suspected
- Head CT if abnormal neurologic exam or transient ischemic attack suspected
- Echocardiogram if concern for structural defects

DIFFERENTIAL DIAGNOSIS

- Seizure is most commonly mistaken for syncope:
 - Key differentiating factor is postictal confusion.
 - Brief tonic movements and urinary incontinence may be seen with syncope.
- Metabolic disorders (e.g., hypoxemia, hyperventilation, hypoglycemia)
- Toxicologic
- Stroke
- Psychogenic syncope
- Malingering
- Breath-holding spells in children

TREATMENT

PRE HOSPITAL

- Oxygen
- Cardiac monitoring
- IV access

INITIAL STABILIZATION/THERAPY

- Advanced cardiac life support (ACLS) interventions for unstable patients
- Oxygen
- Cardiac monitoring
- IV access with normal saline fluid bolus in suspected hypovolemia
- Consider coma cocktail—dextrose, thiamine, and naloxone for persistent altered mental status

ED TREATMENT/PROCEDURES

- ACLS interventions for dysrhythmias
- Standard regimens for acute myocardial infarction
- Control BP for subarachnoid hemorrhage and aortic dissection
- Consider thrombolytics for submassive PE.

MEDICATION

- Dextrose: D₅₀W 1 amp (50 mL or 25 g) IV (peds: D₂₅W 2–4 mL/kg IV)
- Naloxone: 2 mg IV or IM (peds: 0.1 mg/kg)
- Thiamine: 100 mg IV or IM (peds: 50 mg)

FOLLOW-UP

DISPOSITION

Admission Criteria

- San Francisco Syncope Rule identifies patients at high risk for serious short-term outcomes (“CHESS”):
 - History of CHF
 - Hematocrit < 30%
 - Abnormal ECG
 - Patient complaint of shortness of breath
 - Systolic BP < 90
- Other recommendations:
 - Suspected cardiac syncope must be admitted to monitored bed
 - GI bleeds consider intensive care unit bed
 - Admit elderly patients with syncope.

Discharge Criteria

- Neurally mediated syncope or orthostatic syncope from volume depletion may be evaluated on outpatient basis with close follow-up, if patient is reliable and has a good social structure.
- Driving restrictions until cleared

PEARLS AND PITFALLS

- Use of criteria such as the San Francisco Syncope Rule prevents unnecessary admissions.
- Do not assume vasovagal cause in syncope associated with headache or chest pain.

ADDITIONAL READING

- R55 Syncope and collapse

SYNDROME OF INAPPROPRIATE ANTIDIURETIC HORMONE SECRETION (SIADH)

Matthew D. Bitner

BASICS

DESCRIPTION

- Most common cause of hyponatremia in hospitalized patients (and doubles inpatient mortality in some studies)
- A *water balance problem* more than 1 of sodium (Na) balance
- Normal regulation of water balance:
 - _ Antidiuretic hormone (ADH):
 - Integral controller of water balance
 - Increases water permeability of the collecting tubules, resulting in free water reabsorption
 - Synthesized by hypothalamus but secreted by posterior pituitary
 - _ Water deprivation (increased plasma osmolality) stimulates secretion as sensed by:
 - Osmoreceptors/atrial stretch receptors
 - Carotid baroreceptors
 - Aortic arch/pulmonary veins
- Hyponatremia:
 - _ *Mild*: Serum sodium < 135 mEq/L
 - _ *Moderate*: Serum sodium < 130 mEq/L
 - _ *Severe*: Serum sodium < 125 mEq/L
 - _ Excess extracellular water *relative* to Na
 - _ Depletional hyponatremia:
 - Sodium depletion can be caused by diet, GI losses, diuretic use, and renal or adrenal disease.
 - Often accompanied by extracellular fluid volume depletion
 - Hyponatremia associated with clinical signs of hypovolemia
 - Increased Hct, BUN, Cr
 - Urinary sodium excretion < 20 mEq/L
 - _ Dilutional hyponatremia:
 - Increased extracellular water in presence of normal or increased total body sodium
 - Can be caused by increased fluid intake (oral, IV), drugs, or medical conditions
 - Euvolemia with edema
 - Normal or decreased Hct, BUN, Cr
 - Urinary sodium excretion > 20 mEq/L

- Inappropriate ADH secretion is a form of dilutional hyponatremia.
- Definition of SIADH:
 - ADH secretion in absence of hyperosmolality or hypovolemia
- Criteria for definition:
 - Essential features:
 - *Hyponatremia*—despite correction for hyperglycemia, hyperproteinemia, or hyperlipidemia
 - *Euvolemia*—no clinical signs of volume depletion (orthostasis, tachycardia) or volume overload (edema, ascites)
 - *Hyposmolality* of the plasma— < 275 mOsm/kg of water
 - Normal renal, adrenal, and thyroid function
 - No recent diuretic use
 - Urine Osm > 100 mOsm/kg of water
 - Supplemental features:
 - Plasma uric acid < 4 mg/dL
 - BUN < 10 mg/dL
 - FENa $> 1\%$
 - Failure to correct hyponatremia after an infusion of normal saline (NS) 0.9%
 - Abnormal water load test (inability to excrete $\geq 90\%$ of a 20 mL/kg water load in 4 hr)

ETIOLOGY

- **Malignant disorders:**
 - ADH-producing tumors
 - Cancer (Small-cell lung, pancreatic, prostate)
 - Pituitary tumors
 - Thymoma
 - Lymphoma
- **Pulmonary disorders:**
 - Pneumonia
 - TB
 - Lung abscess
 - COPD
- **CNS disorders:**
 - Meningitis/encephalitis
 - CVA
 - Head injury
- **Medications:**
 - Thiazides
 - Chlorpropamide
 - Vincristine
 - Anticonvulsants (carbamazepine)

- Antidepressants (tricyclics, SSRIs)
- Antipsychotics
- NSAIDs
- Ecstasy (MDMA)
- Vasopressin analogs (DDAVP, oxytocin, vasopressin)
- **Transient:**
 - Endurance exercise
 - General anesthesia
 - Pain
 - Stress
- **Other:**
 - Hereditary
 - Positive-pressure ventilation
 - HIV/AIDS
 - Idiopathic

ALERT

Cerebral salt-wasting syndrome (CSWS) can mimic SIADH.

- Seen in patients with cerebral tumors or subarachnoid hemorrhage and in neurosurgical patients
- Etiology unclear
- Represents appropriate water resorption in the face of salt wasting (urine Na > 30–40 mmol/L)
- Fluid restriction can help differentiate the 2:
 - In SIADH: Hypouricemia will correct
 - In CSWS: Hypouricemia will persist
- Treatment of CSWS may differ from that of SIADH:
 - Infusion of NS
 - May benefit from fludrocortisone therapy

DIAGNOSIS

SIGNS AND SYMPTOMS

- Serum sodium < 135 mEq/L:
 - May be asymptomatic
- Serum sodium < 130 mEq/L:
 - Weakness/lethargy
 - Weight gain
 - Headache
 - Anorexia
- Sodium serum < 120 mEq/L:
 - Altered mental status
 - Seizure/coma

- Chronic hyponatremia: 50% asymptomatic
- High mortality in acute hyponatremia

History

- Thorough medication history
- Course of illness (acute, subacute, or chronic)

Physical-Exam

- Volume status
- Mental status
- Stigmata of malignancy

ESSENTIAL WORKUP

- Diagnosis is 1 of exclusion, need to evaluate for other causes of:
 - Depletional or dilutional hyponatremia
- Electrolytes, BUN, Cr, glucose, protein, lipids:
 - Hyponatremia (serum Na < 135 mmol/L)
 - Serum hyposmolality (serum Osm < 275 mOsm/kg)
- Urine osmolality:
 - Inability to excrete dilute urine
 - Urine osmolality > 100 mOsm/kg
- Urine sodium:
 - Continued urinary excretion of sodium
 - Urinary sodium > 20 mEq/L

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Serum protein levels
- Lipid levels
- Glucose levels
- Serum osmolality
- LFT and thyroid function test
- Morning cortisol level

Imaging

Consider imaging (CXR, CT head) to screen for pathology causing SIADH (tumors/masses)

DIFFERENTIAL DIAGNOSIS

Causes of Hyponatremia

- See etiologies above

- Increased extracellular fluid (dilutional hyponatremia):
 - _ Renal failure/insufficiency
 - _ CHF
 - _ End-stage liver disease
- Normal extracellular fluid (dilutional hyponatremia):
 - _ SIADH
 - _ Myxedema
 - _ Sheehan syndrome (postpartum hypopituitarism)
 - _ Reset osmostat syndromes (dilute urine at lower than normal sodium levels)
- Decreased extracellular fluid (depletional hyponatremia):
 - _ Increased losses:
 - Excessive sweating (endurance sports)
 - GI losses (vomiting, diarrhea)
 - _ 3rd-space sequestration
 - _ Diuretic use
 - _ Aldosterone deficiency:
 - Addison disease
 - _ Salt-losing nephropathies:
 - Renal tubular acidosis
- Pseudohyponatremia (seen in hyperglycemia, hyperproteinemia, hyperlipidemia)

TREATMENT

PRE HOSPITAL

- In patients with altered mental status, maintenance and protection of the airway are paramount.
- When hypovolemia is suspected, appropriate fluid resuscitation should be initiated.
- Rapid patient evaluation and transport are essential.

INITIAL STABILIZATION/THERAPY

- Severe symptomatic hyponatremia with CNS manifestations
- Endotracheal intubation for patients in need of airway protection
- Identify/treat other causes of altered mental status
- Treat seizures with benzodiazepines
- Proceed to hyponatremia treatment

ED TREATMENT/PROCEDURES

- Most effective treatment of SIADH is successful *eradication of the underlying cause*.
- Initial treatment of hyponatremia caused by SIADH is the same for all causes of euvolemic/hypervolemic hyponatremia.

Mildly Symptomatic Hyponatremia, Chronic Hyponatremia with Minimal Symptoms,

Asymptomatic Hyponatremia

- Serum sodium usually > 125 mEq/L
- Fluid restriction 800–1,000 mL/day alone or in conjunction with:
 - 0.9% NS infusion and/or IV furosemide
- Correct serum sodium by no more than 0.5 mEq/L/hr (5–6 mEq/day):
 - Too rapid correction of serum sodium levels can induce *central pontine myelinolysis*, associated with development of bulbar palsy, quadriplegia, seizures, coma, and death.

Severe Hyponatremia

- Symptomatic patient, serum sodium < 125 mEq/L
- Increase serum sodium by no more than 12 mEq/L in 1st 24 hr at a rate of 1 mEq/L/hr (8–12 mEq/day when serum sodium below 125 mEq/L and slow to 5–6 mEq/day when serum sodium rises to 125 mEq/L).
- Target level: 125 mEq/L
- Treat patients with significant neurologic symptoms with 3% saline solution.
- Serum sodium lab testing every 1–2 hr

Acute Life-threatening Hyponatremia

- Serum sodium usually < 120 mEq/L
- Associated with seizures or coma
- Clinical goal: Stop seizure and improve neurologic status
- Therapeutic goal: Same as for severe hyponatremia
- Administer hypertonic saline solution (3%)
- Stop hypertonic saline when symptoms (i.e., seizures) resolve and transition to NS.
- IV furosemide to promote diuresis and induce a negative fluid balance.
- Once serum sodium = 125 mEq/L, further IV fluid should be in the form of 0.9% saline solution.
- Restoration of serum sodium to normal levels should take place over ≥ 48 hr.
- Drugs that inhibit the secretion/effects of ADH:
 - Indicated when SIADH not self-limited and cause cannot be removed
 - Demeclocycline (blocks effect of ADH)

MEDICATION

- Conivaptan 20 mg IV over 30 min (for severe hyponatremia in concert with admitting physician)
- Demeclocycline: 300 mg PO BID–QID
- Hypertonic saline solution (3% NaCl): 250–500 mL (max. initial dose 5 mL/kg):
 - 25–100 mL/hr
 - Limit rate in rise of serum sodium to 0.5–1 mEq/L/h.
 - Discontinue when seizure resolves or serum sodium of 125 mEq/L is reached.
 - Rise in serum sodium by 4–6 mEq/L is usually sufficient to stop seizures.

- 0.9% NS: Maintenance rates
- Lasix: 1 mg/kg up to 20–40 mg IV

FOLLOW-UP

DISPOSITION

Admission Criteria

- Severe life-threatening hyponatremia
- Symptomatic hyponatremia
- Serum sodium < 125 mEq/L regardless of symptoms
- New-onset SIADH in which underlying cause or complications must be diagnosed and treated
- Patient's compliance an issue

Discharge Criteria

- Asymptomatic chronic hyponatremia
- Serum sodium > 125 mEq/L
- No unstable comorbid factors
- Known diagnosis of SIADH

FOLLOW-UP RECOMMENDATIONS

All patients with hyponatremia that meet discharge criteria still require follow-up to check for resolution, monitoring, and/or diagnosis of the underlying cause of the SIADH/hyponatremia.

PEARLS AND PITFALLS

- SIADH is a diagnosis of exclusion.
- Must evaluate for other causes as well as renal, thyroid, adrenal, cardiac, and hepatic dysfunction.
- Take a thorough medication history.

ICD10

- E22.2 Syndrome of inappropriate secretion of antidiuretic hormone
- E87.1 Hypo-osmolality and hyponatremia

SYNOVITIS, TOXIC

Daniel A. Popa • Ian R. Grover

BASICS

DESCRIPTION

- Nonspecific inflammation and hypertrophy of the synovium with an effusion of the hip joint in children
- It can affect any joint but most commonly affects the hip.
- Disease process is self-limiting.
- Most common cause of acute hip pain and a limp in children aged 3–10.
- Also referred to as acute transient synovitis and irritable hip syndrome.
- Age group most affected is 3–6 yr.
- Male > female (2:1)
- Right hip > left

ETIOLOGY

- Cause of toxic synovitis is unknown.
- Infectious etiology is suspected, because an upper respiratory infection precedes the symptoms of transient synovitis in ~50% of cases.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Unilateral hip pain
- Pain in the anteromedial thigh and knee
- Pain with weight bearing
- Limp
- Low-grade fever
- Decreased range of motion (ROM) of the affected hip
- Pain with ROM of the affected hip

History

- Acute onset of unilateral hip pain
- No history of trauma
- Pain with ambulation
- Recent upper respiratory infection

Physical-Exam

- Low-grade fever, usually <38.5°C (101.3°F)
- High-grade fevers are more concerning for septic arthritis

- Nontoxic appearing
- Limited hip ROM due to pain
- Hip is usually held in the flexed and externally rotated position for maximal comfort.

ESSENTIAL WORKUP

- Hip x-rays
- AP pelvis
- CBC, C-reactive protein (CRP), ESR if concerned for septic arthritis

DIAGNOSIS TESTS & INTERPRETATION

Lab

CBC, CRP, ESR:

- May be normal or elevated
- An elevated white blood cell (WBC) count, CRP, or ESR alone does not differentiate toxic synovitis from septic arthritis or osteomyelitis.
- If WBC count, CRP, and ESR are normal, more serious causes of hip pain are less likely.
- If CRP < 2 mg/dL and able to bear weight, more likely to be toxic synovitis

Imaging

- Plain hip films (anteroposterior and frog-leg view):
 - Usually normal
 - May detect an effusion or other causes of hip pain
- US to rule out joint effusion and to guide hip joint aspiration if required
- MRI (rarely indicated):
 - Very useful in diagnosing Legg–Calvé–Perthes (LCP) disease
- Bone scan:
 - Used to differentiate LCP disease from toxic synovitis
 - Can detect osteomyelitis
 - The increased radiation is usually reserved for recurrent cases or cases in which the diagnosis is still in question.

Diagnostic Procedures/Surgery

Joint aspiration:

- Not necessary if the patient is afebrile with a normal WBC count, CRP, and ESR
- Abnormal joint fluid analysis indicates SA (see “Arthritis, Septic”)

DIFFERENTIAL DIAGNOSIS

- SA
- Osteomyelitis
- Soft tissue infection

- LCP disease
- Slipped capital femoral epiphysis
- Juvenile rheumatoid arthritis
- Rheumatic fever
- Chondrolysis
- Gaucher disease
- Osteosarcoma
- Ewing sarcoma
- Osteoid osteoma
- Leukemia
- Tuberculosis of the hip
- Fracture
- Lyme disease
- Psoas abscess
- Sickle cell crisis

Pediatric Considerations

- 4–17% of children have a recurrent episode.
- 10% of recurrent cases may be the presenting feature of a chronic inflammatory condition.
- 2–10% of patients with toxic synovitis later develop LCP disease:
 - Suggested that toxic synovitis may represent an early stage of LCP disease.

TREATMENT

PRE HOSPITAL

- Keep leg in position of comfort.
- Treat with NSAIDs.

ED TREATMENT/PROCEDURES

- Conservative treatment
- Bed rest in position of comfort: Flexion and external rotation
- Initiate NSAIDs
- Apply heat to the area
- Antibiotics and steroids are not indicated
- Some authors recommend no weight bearing for 7–10 days following improvement and return of normal hip function, citing increased risk for recurrence.
- Close follow-up is essential, with repeat radiographs due to association with LCP.

MEDICATION

First Line

- Ibuprofen: 200–600 mg (peds > 6 mo old: 5–10 mg/kg/dose) PO q6h PRN
- Naproxen: 250–500 mg (peds > 6 mo old: 5–10 mg/kg/dose) PO BID PRN

Second Line

Acetaminophen: 500 mg (peds: 10–15 mg/kg, do not exceed 5 doses/24 h) PO/PR q4–6h, do not exceed 4 g/24 h

FOLLOW-UP

DISPOSITION

Admission Criteria

Patients with severe joint pain or a large effusion may require hospitalization for bed rest and analgesics.

Discharge Criteria

All patients who have had more serious causes of hip pain excluded and have been diagnosed with toxic synovitis can be discharged from the hospital with good follow-up.

Issues for Referral

Follow-up with an orthopedic surgeon in 1–2 wk for repeat evaluation.

FOLLOW-UP RECOMMENDATIONS

- Return to the ED immediately for worsening pain in the hip or increasing fever.
- Follow-up with pediatric orthopedic surgeon in 1–2 wk for repeat evaluation.
- Patients should have repeat x-rays done in 6 mo to exclude LCP disease.

PEARLS AND PITFALLS

- Most cases are diagnosed by history and physical exam alone with fever and weight bearing as key elements.
- ~ 50% of children have a history of a preceding viral illness.
- NSAIDs help treat the pain and shorten the course of the illness.
- Nearly all children recover from toxic synovitis within 2 wk and without sequelae.
- ~ 2–10% of children with toxic synovitis develop LCP disease.

SYPHILIS

Jessica Freedman

BASICS

DESCRIPTION

- Sexually transmitted disease
- 12 million new cases diagnosed annually worldwide
- Acquired via mucous membranes/disrupted skin
- Divided into 3 stages:
 - Primary syphilis:
 - Painless chancre or ulcer
 - Secondary syphilis:
 - Replication and hematogenous spread
 - Begins 3–6 wk after primary lesion
 - Late latent secondary phase
 - Tertiary or late syphilis:
 - Very uncommon
 - Cardiovascular and neurologic symptoms

ETIOLOGY

Treponema pallidum:

- Spirochete bacteria

DIAGNOSIS

SIGNS AND SYMPTOMS

Primary (Early) Syphilis

- 21-day incubation period
- No constitutional symptoms
- Chancre:
 - Painless papule at site of inoculation
 - Clean-based, circular, sharply defined borders:
 - Solitary lesions
 - Commonly on penis, vulva, and rectum
 - Bilateral regional lymphadenopathy
 - Heals spontaneously in 3–6 wk
- Rectal chancre:
 - Painful or painless
 - Rectal irritation/discharge

- Painless enlargement of lymph nodes

Secondary (Early) Syphilis

- Occurs 3–6 wk after primary lesion
- Disseminated stage
- Rash (most common):
 - Symmetric, diffuse, polymorphous, papular, or maculopapular rash
 - Rash may be diverse and not fit a pattern
 - Starts on trunk and flexor extremities
 - Spreads to involve palms and soles:
 - Discrete, red/reddish-brown
 - 0.5–2 cm in diameter
- Condyloma lata:
 - Large raised gray/white lesions, painless, moist
 - Mucous membranes:
 - Oral cavity and perineum
 - Very contagious
 - Intertriginous areas
 - Flat rectal warts
- Systemic symptoms:
 - Fever, headache, malaise, anorexia, sore throat, myalgias, and weight loss
- Diffuse lymphadenopathy:
 - Palpable nodes at inguinal, axillary, posterior cervical, femoral, and/or epitrochlear regions
 - Painless, firm, and rubbery
- Less common:
 - “Moth-eaten” alopecia
 - Syphilitic meningitis
 - Scleritis
- Loss of lateral 3rd of eyebrows
- Painless mucosal lesions (mucous patches)
- Secondary stage resolves spontaneously in 1–2 mo

Latent Secondary Syphilis

- Begins after primary and secondary symptoms resolve.
- Period of no symptoms but positive serology:
 - CSF normal
- Late latent stage not infectious except for fetal transmission in pregnant women
- Persists for lifetime or develops into tertiary syphilis

Tertiary (Late) Syphilis

- Occurs in about 15% of patients with untreated latent secondary syphilis

- Can appear 10–20 yr after initial infection
- Neurologic and cardiovascular involvement:
 - Destructive stages of disease
- Neurosyphilis (most common):
 - Asymptomatic:
 - Positive CSF – Venereal Disease Research Laboratories (VDRL)
 - CSF pleocytosis (10–100 lymphocytes)
 - Elevated CSF protein at 50–100 mg/dL
 - Meningitis:
 - Aseptic; CSF with positive VDRL, higher protein, and lower glucose (compared with above)
 - Cranial nerve palsy, including isolated 8th nerve palsy
 - General paresis:
 - Loss of cortical function
 - Argyll Robertson pupils (small fixed pupils that do not react to strong light, but do react to accommodative convergence)
 - Tabes dorsalis (peripheral neuropathy)
- Degeneration of posterior columns/posterior or dorsal roots of spinal cord
- Dementia
- Paresthesias, abnormal gait, and lightning (sudden, severe) pain of extremities/trunk
- Progressive loss of reflexes, vibratory/position sensation
- Positive Romberg sign
- Vision: Optic atrophy
- Pupils: Argyll Robertson pupils
- Urinary incontinence
- Gummas:
 - Late benign syphilis of cutaneous skin/viscera:
 - Bone, brain, abdominal viscera, etc.
- Granulomatous, cellular hypersensitivity reaction:
 - Round, irregular, or serpiginous shape
 - “Great pox”
- Cardiovascular:
 - Thoracic aortic aneurysm (ascending most common):
 - Dilated aorta and aortic valve regurgitation
 - Aortic valve insufficiency
 - Coronary thrombosis
 - Destructive lesions of skeletal structures or skin
- HIV-infected:
 - Strong association with syphilis
- Increased incidence of neurosyphilis

Congenital Syphilis

- In utero infection:
 - Age <2 yr:
 - Hepatosplenomegaly, rash, condyloma lata, rhinitis (snuffles), jaundice (nonviral hepatitis), osteochondritis
- Older children (syphilis stigmata):
 - Interstitial keratitis, nerve deafness, anterior bowing of shins, frontal bossing, mulberry molars, Hutchinson teeth, saddle nose, etc.

ESSENTIAL WORKUP

Rapid plasma reagin (RPR)

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Serology:
 - Nontreponemal test:
 - RPR
 - VDRL
 - Positive 14 days after chancre appears
 - Early false negatives, especially ≤ 7 days after primary chancre
 - Repeat negative test in 2 wk and correlate with disease activity
 - False positives in 1–2% of general population
 - 4-fold change in titer clinically significant
 - 100% sensitivity in secondary syphilis
 - Nonreactive after successful treatment
 - Treponemal antibody test:
 - Fluorescent treponemal antibody absorption (FTA–ABS)
 - Hemagglutination assay for antibody to *T. pallidum* (MHA–TP)
 - More sensitive and specific
 - 1% false-positive rate
 - Confirmatory test
 - Reactive for patient's lifetime
 - More costly and harder to perform
 - Dark-field microscopy:
 - Identifies treponemes from primary and secondary lesions
 - Suspicious early lesions with negative serology (early primary syphilis)
 - False negatives with ointments, creams
 - Oral specimen unsuitable
 - CSF analysis for tertiary neurosyphilis:
 - Tertiary syphilis
 - Positive VDRL/RPR
 - Lymphocytes > 5/mL

- Protein > 45 mg/dL
- Decreased glucose

DIFFERENTIAL DIAGNOSIS

- Genital ulcer:
 - Chancroid (painful)
 - Genital herpes:
 - Vesicular, multiple lesions
 - Lymphogranuloma venereum
 - Granuloma inguinale
 - Superficial fungal infection
 - Carcinoma
- Secondary and tertiary syphilis:
 - Pityriasis rosea
 - Drug-induced rash
 - Acute febrile exanthems
 - Psoriasis
 - Lichen planus
 - Scabies
 - Infectious mononucleosis
 - Viral illness
 - Bacteremia
 - Tertiary syphilis:
 - Psychosis
 - Dementia
 - Multiple sclerosis
 - Meningitis
 - Encephalitis
 - Delirium
 - Unknown overdose

TREATMENT

INITIAL STABILIZATION/THERAPY

Lower BP and establish IV access for aortic dissection.

ED TREATMENT/PROCEDURES

- Treatment other than penicillin with increased relapse rate:
 - Desensitize those allergic to penicillin.
- Pregnancy:
 - Treat with penicillin even in latent syphilis.
 - If patient allergic to penicillin, admit for desensitization.

- Jarisch–Herxheimer reaction:
 - Transient febrile reaction to therapy
 - May be owing to antigen liberation from spirochetes or activation of complement cascade
 - Peaks at 8 hr, resolves in 24 hr
 - Symptoms:
 - Fever, headache, malaise, worsening rash
 - Treat with antipyretics
 - No serious sequelae
- Recommended testing:
 - Sexual partners
 - Concomitant sexually transmitted diseases including HIV
 - Repeat serology test in 6 and 12 mo.

MEDICATION

- Early primary, secondary, early latent (<1 yr):
 - Benzathine penicillin G: 2.4 million U IM
 - Doxycycline: 100 mg PO BID for 14 days
 - Tetracycline: 500 mg PO QID for 14 days
- Late latent (>1 yr) except neurosyphilis:
 - Benzathine penicillin G: 2.4 million U IM 3 times over 2 wk on days 0, 7, and 14
 - Doxycycline: 100 mg PO BID for 4 wk
 - Tetracycline: 500 mg PO QID for 4 wk
- Neurosyphilis:
 - Penicillin G: 3–4 million U IV q4h for 10–14 days
 - Procaine penicillin: 2.4 million U IM daily +
 - Probenecid: 500 mg PO QID for 10–14 days
- Congenital syphilis:
 - Penicillin G: 50,000 U/kg IM q8–12h for 10–14 days; or
 - Procaine penicillin: 50,000 U/kg IM daily for 10–14 days

FOLLOW-UP

DISPOSITION

Admission Criteria

- Neurosyphilis requires IV antibiotics
- Pregnant women allergic to penicillin requiring desensitization

Discharge Criteria

Follow-up care:

- Measure for falling titers in 6 mo and 1 yr after treatment.
- Tertiary/latent (>1 yr):
 - Measure for falling titers in 3, 6, 12, and 24 mo after treatment.

Issues for Referral

Infectious disease consultation for secondary and tertiary syphilis as well as congenital and neurosyphilis

FOLLOW-UP RECOMMENDATIONS

Titers must be monitored.

PEARLS AND PITFALLS

- Syphilis is known as the “great imitator.”
- In patients presenting with unknown rash, think of syphilis and ask about history of genital lesions.
- Be sure to examine mucous membranes of all patients presenting with rash.
- Think of tertiary syphilis with neurologic symptoms of unknown etiology.

CODES

ICD9

- 091.2 Other primary syphilis

- 091.9 Unspecified secondary syphilis
- 097.9 Syphilis, unspecified

ICD10

- A51.0 Primary genital syphilis
- A51.49 Other secondary syphilitic conditions
- A53.9 Syphilis, unspecified

SYSTEMIC LUPUS ERYTHEMATOSUS

Susanne M. Hardy • John P. Lemos

BASICS

DESCRIPTION

- Chronic autoimmune disease; peak onset between ages 15 and 40 yr; characterized by flares and remissions
- Multisystem disease with diverse clinical manifestations:
 - _ Mucocutaneous:
 - Most commonly involved system
 - 4 specific skin rashes
 - _ Arthritis
 - _ Cardiac:
 - Endocarditis
 - Myocarditis
 - CHF
 - Conduction abnormalities
 - Atherosclerosis
 - MI
 - _ Renal:
 - Glomerulonephritis
 - Renal failure
 - _ Pulmonary:
 - Pleural effusion (usually exudative)
 - Pneumonitis/pleuritis
 - Pulmonary hemorrhage
 - Pulmonary embolism
 - Pneumonia
 - Pulmonary edema
 - Pulmonary hypertension
 - _ Neurologic:
 - Lupus cerebritis
 - _ Vascular:
 - Vasculitis
 - Thrombosis
 - Atherosclerosis
 - _ GI:
 - Peritonitis
 - Mesenteric vasculitis and ischemia
 - Pancreatitis

Pediatric Considerations

- Neonatal lupus may occur when maternal autoantibodies cross the placenta:
 - Associated with transient anemia and thrombocytopenia
- Congenital heart block is the most serious complication

Geriatric Considerations

- 10 times greater risk of MI due to atherosclerosis
- High incidence of osteoporosis related to chronic steroid use

RISK FACTORS

Genetics

- More common in females than males (9:1 ratio)
- More common in women of childbearing age
- More common in African Americans
- Higher frequency of systemic lupus erythematosus (SLE) and other autoimmune diseases among 1st-degree relatives

ETIOLOGY

- Autoantibody production against cell nucleus and cytoplasmic structures, leading to inflammatory changes, vasculitis, and immune complex deposition in multiple organ systems
- A significant percentage of patients have an associated antiphospholipid syndrome:
 - Characterized by antibodies against cellular phospholipid components
 - Tendency toward recurrent vascular thrombosis
- Lupus is a chronic disease with several exacerbating factors:
 - Infection
 - Sun exposure
 - Fatigue
 - Trauma
 - Medications (sulfonamides)
 - Stress
 - Diet
- Drug-induced lupus is a milder disease that eventually resolves once the drug is discontinued. Usually presents with skin and joint manifestations while renal and neurologic involvement is rare.
- Common medications include:
 - Chlorpromazine, methyldopa, procainamide, hydralazine, isoniazid, quinidine, minocycline

- 4 of the 11 criteria in the following list are needed to make the diagnosis:
 - Malar rash
 - Discoid rash
 - Photosensitivity rash
 - Oral ulcers
 - Arthritis
 - Serositis
 - Neurologic disorders
 - Hematologic disorders
 - Immunologic disorders
 - Renal disorders
 - Antinuclear antibodies

SIGNS AND SYMPTOMS

- Systemic:
 - Fatigue
 - Fever
 - Weight loss
 - Dyspnea
- Skin:
 - Malar rash (butterfly maculopapular facial)
 - Discoid rash (raised red patches)
 - Photosensitivity rash (subacute cutaneous lupus)
 - Bullous rash (large blisters)
- Musculoskeletal:
 - Myalgias
 - Joint pain
 - Arthritis:
 - Defined as 2 or more peripheral joints
 - Polyarthritis, symmetric, or migratory
- Heart:
 - Chest pain
 - Pericardial rub
 - Murmur
- Vascular:
 - Vasculitis
 - Thrombosis
 - Atherosclerosis
 - Peripheral vascular disease
- Lungs:
 - Dyspnea
 - Tachypnea
 - Pleural rub

- Rales
- Nervous system:
 - Psychosis/depression
 - Headache
 - Seizures
 - Peripheral neuropathies
 - Stroke/cranial nerve deficits
 - Cerebritis
- GI:
 - Painless oral ulcers
 - Abdominal pain
 - Positive stool guaiac suggests mesenteric ischemia

History

- Symptoms commonly accumulate and exacerbate over years, with flares and remissions. A history of fatigue, rashes, and joint pain may point to the diagnosis.
- Patients describe arthralgias out of proportion to physical findings

Physical-Exam

- Check for fever
- Carefully evaluate skin for rashes and vasculitis

ESSENTIAL WORKUP

- Thorough history and physical exam needed to distinguish between major and minor flare-ups
- Major flare-ups:
 - CBC
 - Electrolytes, BUN, creatinine, glucose
 - UA
 - ESR
 - Chest radiograph, ECG, and pulse oximetry for cardiorespiratory symptoms

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - Leukopenia, thrombocytopenia, normochromic normocytic anemia
 - Degree of hematologic disorders suggests degree of disease activity
- ESR:
 - May be elevated during acute exacerbations
 - Not a good indicator of active disease
- CRP may also be elevated; marked elevation may be a sign of infection
- PTT:

- May be elevated in patients with lupus anticoagulant
- UA:
 - Protein (persistent proteinuria > 0.5 g/day or 3+ persistently)
 - Casts (red blood cell)
 - Hematuria
 - WBCs
- Amylase is elevated in mesenteric ischemia and pancreatitis
- Send antinuclear antibody, rheumatoid factor (RF), antistreptolysin O (ASO) titer if diagnosis unclear
- Anti-Sm and anti-dsDNA are diagnostic
- A false-positive Venereal Disease Research Laboratory (VDRL) test is supportive of the diagnosis
- Joint aspirate typically shows fluid with fewer than 3,000 WBCs
- LP if suspicion for meningitis or encephalitis

Imaging

- CXR:
 - Pneumonitis
 - Pneumonias
 - Pleural effusion
 - Cardiomegaly
- ECG/echocardiogram
- CT chest:
 - Pulmonary embolus
 - Pulmonary hemorrhage
 - Diffuse alveolar hemorrhage
- CT head for change in mental status or neurologic findings (lupus cerebritis is a diagnosis of exclusion)

Pregnancy Considerations

- Pregnancy is not recommended during active disease owing to the high risk of spontaneous abortion
- The effect of pregnancy on disease activity is variable

DIFFERENTIAL DIAGNOSIS

- Hypotension in the known lupus patient may be due to shock from a major flare-up, secondary to acute steroid withdrawal, or the result of sepsis
- Other autoimmune diseases:
 - Rheumatic fever
 - Rheumatoid arthritis
 - Dermatomyositis
 - Overlap syndromes
- Skin changes:

- Urticaria
- Erythema multiforme
- Idiopathic thrombocytopenic purpura
- Multiple sclerosis
- Epilepsy

TREATMENT

INITIAL STABILIZATION/THERAPY

ABCs

ED TREATMENT/PROCEDURES

- Mainstays include NSAIDs, corticosteroids, antimalarials, and immunosuppressive drugs
- Special attention must be given to CNS and renal involvement as well as infections; these are the main determinants of morbidity
- Mild flare-ups—arthralgias, myalgias, fatigue, and rash:
 - NSAIDs (careful with lupus nephritis), acetyl salicylic acid (ASA), topical steroids for rash, sunscreen
 - Topical steroids for most cutaneous manifestations
 - If not sufficient, begin low-dose prednisone
- Major flare-ups—life- or organ-threatening:
 - Methylprednisolone
 - Anticoagulation for thrombosis; give blood products early if needed
 - Psychotropics for neuropsychiatric symptoms
 - Anticonvulsants for seizures
 - If poor response, consult rheumatology before starting cytotoxic medications
- Chronically:
 - Prednisone taper
 - NSAIDs
 - Rheumatologist initiated:
 - Antimalarials: Quinacrine, chloroquine:
 - Side effect is irreversible retinopathy
 - Cyclophosphamide
 - Azathioprine
 - Methotrexate
 - Belimumab (FDA approved for active, autoantibody positive disease in patients under active treatment)
 - Hormonal therapy, mycophenolate mofetil, rituximab, and autologous marrow stem cell transplant are under investigation

MEDICATION

- Methylprednisolone: 15 mg/kg/d IV up to 1 g; consult rheumatologist for peds dosing
- Prednisone: 5–30 mg (peds: < 0.5 mg/kg) PO daily for minor flare
- Prednisone: 1–2 mg/kg/d PO for major flares in adults
- Ibuprofen: 800 mg (peds: 5–10 mg/kg) PO TID

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients who have end-organ disease such as renal, cardiac, or CNS involvement
- Thrombocytopenia with hemorrhage, arterial or venous thrombosis
- Consider admission with pericarditis, myocarditis, pleural effusion or infiltrates, and evidence of vasculitis
- Those with severe end-organ or life-threatening manifestations should be admitted to the ICU
- Patients with lupus should be treated as immunocompromised and suspected or diagnosed infections should be treated aggressively

Discharge Criteria

- Patients may be discharged home with mild flare-ups if afebrile, well hydrated, and not ill appearing
- ESR should not be used as disposition criterion as it may be elevated long after a flare-up has subsided

Issues for Referral

Because lupus is a chronic disease, a rheumatologist or knowledgeable primary care physician (PCP) must follow the patient adequately

FOLLOW-UP RECOMMENDATIONS

PCPs must educate patients regarding sun protection, immunizations, and lowering risks of atherosclerosis

PEARLS AND PITFALLS

- The diagnosis of SLE is complicated and requires a thorough history and physical exam supported by appropriate lab testing
- Chronic steroid therapy leads to immunosuppression
- Renal involvement confers a poor prognosis
- Serum creatinine may be elevated, but is a poor indicator of the disease (urinalysis

- is more sensitive with proteinuria and/or red blood cell casts)
- All patients with SLE should be offered annual, seasonal influenza vaccinations and be sure that pneumococcal vaccination is up to date
- VDRL may be falsely positive

- M32.12 Pericarditis in systemic lupus erythematosus
- M32.14 Glomerular disease in systemic lupus erythematosus

TACHYDYSRHYTHMIAS

James G. Adams • Matthew S. Patton

BASICS

DESCRIPTION

- Any disturbance of the heart's rhythm resulting in a rate > 100 bpm
- Sinus tachycardia:
 - _ Narrow complex regular rhythm at a rate of 100–150 bpm
 - _ Max. rate typically 220 minus age
 - _ Functional response to physiologic stress caused by increased catecholamine tone or decreased vagal stimulation
- Supraventricular tachycardia (SVT):
 - _ A narrow complex tachycardia that originates above the His bundle
- Regular SVT:
 - Atrial tachycardia
 - Junctional tachycardia:
 - Regular tachycardia without preceding depolarization waves
- Irregular SVT:
 - Atrial fibrillation (AF)
 - Atrial flutter
 - Multifocal atrial tachycardia
- Ventricular tachycardia (VT):
 - _ ≥ 3 consecutive ventricular ectopic beats at a rate of 100 bpm
 - _ Most common initiating rhythm in sudden death in patients with previous MI
- Torsades de pointes:
 - _ Paroxysmal form of VT with undulating axis and prolonged baseline QT interval
 - _ Secondary to either congenital or acquired abnormalities of ventricular repolarization
 - _ Often the result of drug therapy or electrolyte disturbances
- VF:
 - _ Oscillations without evidence of discrete QRST morphology
 - _ Accounts for 80–85% of sudden cardiac deaths
 - _ Frequently results from degeneration of sustained VT

ETIOLOGY

- Sinus tachycardia:
 - _ Acute MI
 - _ Anemia

- Anxiety
- CHF
- Drug intoxication
- Hyperthyroidism
- Hypovolemia
- Hypoxia
- Infection
- Pain
- Pericardial tamponade
- Pulmonary embolus
- Atrial tachycardia:
 - Precipitated by a premature atrial or ventricular contraction
 - Electrolyte disturbances
 - Drug toxicity
 - Hypoxia
- Junctional tachycardia:
 - AV nodal re-entry
 - Myocardial ischemia
 - Structural heart disease
 - Pre-excitation syndromes
 - Drug and alcohol toxicity
- AF:
 - HTN
 - Coronary artery disease
 - Hyper-/Hypothyroidism
 - Alcohol intake
 - Mitral valve disease
 - Chronic obstructive pulmonary disease
 - Pulmonary embolus
 - Wolf–Parkinson–White (WPW) syndrome
 - Hypoxia
 - Digoxin toxicity
 - Chronic pericarditis
 - Idiopathic AF
- Atrial flutter:
 - Ischemic heart disease
 - Valvular heart disease
 - CHF
 - Myocarditis
 - Cardiomyopathies
 - Pulmonary embolus
 - Electrolyte abnormalities
 - Recent cardiac surgery

- Multifocal atrial tachycardia:
 - Hypoxic effects of chronic lung disease
 - Theophylline toxicity
- VT:
 - Dilated cardiomyopathy
 - Cardiac ischemia
 - Hypoxia
 - Cardiac scarring/fibrosis
 - After cardiac surgery or congenital anomaly repair
 - Digoxin toxicity
 - Long QT syndrome
 - Electrolyte abnormalities
- Torsades de pointes:
 - Drug toxicity (antiarrhythmic class IA and III agents, antipsychotics, antibiotics, etc.)
 - Hypokalemia
 - Hypomagnesemia
 - Congenital QT prolongation
- VF:
 - Acute MI (most common)
 - Chronic ischemic heart disease
 - Hypoxia
 - Acidosis
 - Anaphylaxis
 - Electrocutation
 - Shock
 - Hypokalemia
 - Initiation of quinidine therapy
 - Massive hemorrhage

DIAGNOSIS

SIGNS AND SYMPTOMS

- Asymptomatic
- Palpitations
- Lightheadedness
- Dyspnea
- Diaphoresis
- Dizziness
- Weakness
- Chest discomfort
- Angina

- Syncope
- Prominent neck veins
- Signs of instability:
 - Hypotension
 - Pulmonary edema
 - Chest pain
 - Mental status changes

History

- Acute onset of palpitations, lightheadedness, generalized weakness, or shortness of breath
- Sudden collapse, often preceded for minutes–hours by chest pain
- Prior history of cardiac disease common (ischemia, CHF)

Physical-Exam

Determine if the patient is hemodynamically stable:

- Assess mental status.
- Assess heart rate.
- Assess BP: Normal or hypotensive
- Cardiac exam

ESSENTIAL WORKUP

- ABCs
- Determination of unstable vs. stable patient
- Detailed history
- 12-lead EKG and rhythm strip to categorize the tachycardia

DIAGNOSIS TESTS & INTERPRETATION

Lab

Studies should be ordered based on the presentation to evaluate underlying metabolic abnormalities or ischemia.

Diagnostic Procedures/Surgery

EKG:

- SVT:
 - Narrow complex, rate usually 130–160
 - Uniformity of polarity and amplitude
 - No P-waves visible
- AF:
 - Irregular, narrow QRS complex, rate < 150--170 bpm
- Atrial flutter:
 - Regular atrial rate, usually > 300

- Beat-to-beat uniformity of cycle length, polarity, and amplitude
- Sawtooth flutter waves directed superiorly and most visible in leads II, III, aVF
- AV block usually 2:1, but occasionally greater or irregular
- Multifocal atrial tachycardia:
 - 3 distinctly different conducted P waves with varying pulse rate intervals
- VT:
 - QRS > 0.12 sec and often > 0.14 sec.
- Torsades de pointes:
 - Wide complex, ventricular rate > 200 bpm
 - QRS structure displays an undulating axis, with the polarity of the complexes appearing to shift around the baseline.
 - Occurrence is often in short episodes of < 90 sec.
- VF:
 - EKG shows oscillations without evidence of discrete QRST morphology.
 - Oscillations are usually irregular and occur at a rate of 150–300 bpm.
 - When the amplitude of most oscillations is 1 mm, the term “coarse” is used.
 - “Fine” VF is used for oscillations < 1 mm.

TREATMENT

PRE HOSPITAL

Cardiopulmonary resuscitation if pulseless

INITIAL STABILIZATION/THERAPY

- IV access
- Oxygen
- Cardiac monitor
- Determine rhythm

ED TREATMENT/PROCEDURES

- Irregular narrow complex (A fib):
 - Rate control
 - β -Blockers or calcium channel blockers
 - Anticoagulation if onset is > 24 hr
 - Cardioversion for *severe* hemodynamic compromise
- Regular narrow-complex tachydysrhythmia:
 - Vagal maneuvers occasionally terminate the dysrhythmia:
 - Beware of carotid disease in elderly.
 - Adenosine:
 - May be diagnostic, revealing underlying AF/atrial flutter
- Stable wide-complex tachycardia:

- Determine whether VT or SVT with aberrancy
- Administration of AV nodal-blocking agents (verapamil, adenosine) may result in VF:
 - With WPW, use amiodarone, flecainide, procainamide, or DC cardioversion.
- Electrical cardioversion should be utilized when mechanism unknown.
- Antidysrhythmic drugs include procainamide and amiodarone.
- Torsades de pointes:
 - Magnesium, overdrive pacing, amiodarone
 - Correct underlying abnormal electrolytes.
 - Consider repletion of serum K to 4.5.
- Polymorphic VT (variable QRS morphology):
 - Ejection fraction (EF) normal:
 - β -Blockers, lidocaine, amiodarone, or procainamide
 - EF abnormal:
 - Amiodarone or lidocaine; then synchronized cardioversion
 - Treat ischemia and correct electrolytes.
- Monomorphic VT:
 - EF normal:
 - Procainamide preferred to amiodarone, sotalol, lidocaine; synchronized cardioversion
 - EF abnormal:
 - Amiodarone or lidocaine
 - Procainamide with caution as may cause hypotension; synchronized cardioversion
- VF or pulseless VT:
 - Treatment per ACLS protocol

MEDICATION

- Adenosine: 6 mg (peds: 0.1 mg/kg up to 6 mg) rapid IV push; if no response after 1–2 min, then 12 mg (peds: 0.2 mg/kg up to 12 mg), may repeat 12 mg (0.2 mg/kg)
- Amiodarone:
 - *VT/SVT with pulse*: 150 mg IV over 10 min (peds: 5 mg/kg IV over 20--60 min, redose up to 15 mg/kg, 300 mg max), then 1 mg/min for 6 hr and 0.5 mg/min for next 18 hr.
 - *VF/pulseless VT*: 300 mg IV push (peds: 5 mg/kg IV), may give 150 mg IV push 3--5 min after if no response (peds: redose up to 15 mg/kg or 300 mg max), followed by infusion as above.
- Diltiazem: 0.25 mg/kg IV (usually 10–20 mg) over 2 min, followed in 15 min by 0.35 mg/kg IV over 2 min
- Epinephrine: 1 mg (peds: 0.01 mg/kg) IV push q3–5min; 2.5 mg (peds: 0.1 mg/kg) endotracheally q3–5min

- Lidocaine: 1–1.5 mg/kg (100 mg) (peds: 1 mg/kg) IV push, may repeat q5–10min, max. dose 3 mg/kg
- Magnesium sulfate: 2 g diluted in 100 mL D₅W IV over 2 min (peds: 25–50 mg/kg, max. 2 g, IV over 10–20 min)
- Metoprolol: 5–15 mg slow IV push at 5-min intervals to total of 15 mg
- Procainamide:
 - *VF/pulseless VT*: 30 mg/min (peds: Not recommended) IV load until rhythm resolves, hypotension, QRS widens > 50% or max. 17 mg/kg, then 1–4 mg/min IV
 - *Perfusing VT*: 20 mg/min (peds: 15 mg/kg IV over 30–60 min) IV load until rhythm resolves, hypotension, QRS widens > 50% or max. 17 mg/kg, then 1–4 mg/min IV
 - *SVT*: 15–17 mg/kg IV at 20–30 mg/min *or* 100 mg IV q5min slow IV push until rhythm resolves or max. dose 1,000 mg (peds: 3–6 mg/kg IV over 5 min, max. 100 mg/dose, may repeat q5–10min as needed to total dose 15 mg/kg)
- Vasopressin: 40 U (peds: Not recommended) IV push once

FOLLOW-UP

DISPOSITION

Admission Criteria

- VT or VF
- Possible cardiac ischemic event
- Persistent SVT
- Underlying metabolic abnormalities

Discharge Criteria

Terminated supraventricular rhythm without organ hypoperfusion

Issues for Referral

Electrophysiologic testing:

- Diagnostic but not required emergently
- Determines therapy for accessory pathways

PEARLS AND PITFALLS

- Always suspect a ventricular rhythm with a wide complex rhythm, especially in the older patient.
- Antidysrhythmic administration may increase success rate of cardioversion.
- Rapid, uninterrupted chest compressions may increase the success rate of

defibrillation for a patient with a pulseless rhythm.

TASER INJURIES

Christian M. Sloane

BASICS

DESCRIPTION

- Tasers are part of a class of less lethal weapons referred to as conducted energy weapons (CEWs).
- Most common in US are those made by Taser International; these include the M-26, X-26, and X2 although others exist.
- These devices use a high-voltage low-amperage current to override the subject's ability to control the peripheral nervous system; they cause pain so as to induce subject compliance.
- Handheld devices such as stun guns require the application of 2 exposed probes to the skin (or close to the skin) to cause a localized response (usually pain).
- Other devices, such as the Taser International devices, have barbed probes attached to thin wires that can be shot up to 35 ft to deliver current from a distance.
- Needle lengths of CEW barbs are of varied lengths but generally less than or around 0.5 in.
- The effects of CEWs vary depending on the type of device being used, location, placement, and distance between the probes on the subject's body. If probe spread on the body is <5 cm, effectiveness is less.
- Skin effects
 - May leave marks at site of probe contact, called “signature marks”
 - Small puncture wound from barbs
- Skeletal effects
 - Fractures may result from falls.
 - Vertebral compression fractures have been reported as a result of a Taser discharge.
 - Barbs may penetrate bone.
- Muscle effects
 - Strains possible
 - Rhabdomyolysis possible with repeated prolonged use, though more likely could result from the underlying cause leading to use of the Taser (e.g., excited delirium syndrome [ExDS])
- Cardiovascular effects
 - Theoretically could cause ventricular fibrillation if a charge was delivered over the heart during a vulnerable part of the cardiac cycle. This risk is not easily quantifiable but estimated to be very low.
 - A case of atrial fibrillation has been reported following Taser use.

- No significant effects in otherwise healthy subjects. Does not cause changes in ECG or troponin I.
- Unclear how device would affect pacemakers/automatic internal cardiac defibrillators (AICDs). Energy is low; theoretically should not cause damage. Could cause an AICD to deliver a shock if electrical activity of the CEW is misinterpreted as a dysrhythmia.
- Nervous system effects
 - There have been case reports of skull penetration and seizure.
- Respiratory effects
 - Initial concerns that the CEWs would disrupt ventilation proved unfounded. Research has shown that subjects actually increase ventilation during an application.

ETIOLOGY

The devices are commonly used in law enforcement but may also be used in the military, self-defense, by those wishing to commit a crime, or an accidental discharge of a weapon on to law enforcement personnel.

DIAGNOSIS

SIGNS AND SYMPTOMS

ALERT

Subjects on whom a device has been used may be in a state of ExDS.

History

A history of the use of a device is usually obtained. Important factors are:

- The type of device
- The mode used (probe or drive stun)
- The number of cycles discharged
- The duration of cycles applied
- Location of contact on the body

Physical-Exam

- Pay particular attention to the location of barb strike. Barbs in the skin, though unlikely, may cause injury to underlying structures:
 - Eye
 - Face
 - Neck
 - Groin
 - Genitals
 - Secondary injuries do occur
 - From fall

- From aspiration if device is deployed in the water
- From tetanic muscle contraction
- From barb penetration

ESSENTIAL WORKUP

- All persons who have been exposed to CEW activation should receive a medical evaluation. The scope of that evaluation should depend on the type of use and state of the subject.
- For a subject who subsequently becomes compliant, is alert, and is acting appropriately and/or had CEW darts hit areas that are not medically sensitive, the darts may be removed and an evaluation done at intake to a detention facility.
- Given the risk to a subject who is in a state of ExDS regardless of CEW use, such a person requires an ED evaluation.

Geriatric Considerations

The above groups warrant a medical evaluation, given that there are so few data to guide any definitive statements about their use.

DIAGNOSIS TESTS & INTERPRETATION

Labs should be directed at the underlying reason the person was “tasered.” No labs are required simply because the person was tasered.

Lab

If ExDS is present:

- CBC
- Chemistry panel
- Creatine kinase
- UTOX
- VBG to check for acidosis
- Lactate

Imaging

- Not routine
- If altered level of consciousness with no clear cause, then head CT
- X-ray if Taser barb penetrated bone; this is most likely if it hit a digit or where bone is close to skin (e.g., tibia, nose).
- US if individual is pregnant
- Other imaging guided by suspicion of traumatic/secondary injury

Diagnostic Procedures/Surgery

- Pacemaker interrogation if patient has pacemaker or AICD, since the device may have been damaged or have delivered a shock.
- ECG if there is underlying significant heart disease

- Women who are pregnant > 20 wk should have fetal monitoring.

DIFFERENTIAL DIAGNOSIS

Usually not unclear if device used.

TREATMENT

PRE HOSPITAL

- If patient is acting normally, has normal vital signs, and AO \times 4, appropriate, no special intervention is needed. Depending on jurisdiction, barb may be removed if not in sensitive area (face, eye, groin, neck, genitals). Otherwise, stabilize barb and transport patient to hospital for removal.
- If patient is agitated, treatment as per agitation/ExDS.
- If cardiac dysrhythmia is present, initiate cardiac monitoring, IV access, oxygen, treat if in protocol and scope or practice.
- Treat any secondary traumatic injuries.

INITIAL STABILIZATION/THERAPY

If ExDS, then treat per guidelines, including medications.

ED TREATMENT/PROCEDURES

Initial treatment is steered toward underlying injuries.

- If patient acting normally, normal vital signs, AO \times 4 appropriate, and no complaints of secondary injury, no special intervention needed.
- Update tetanus status as needed.
- Taser barb removal: Using 2 fingers of nondominant hand, stabilize skin around the barb by holding it down. Use dominant hand to grasp barb shaft and pull barb out.
- Treat the puncture wound like any other.
- Approach secondary traumatic injuries per trauma protocols.
- Treat dysrhythmias per protocol.
- Consider and treat ExDS if patient unstable.

MEDICATION

- Tetanus vaccination, dT or dTaP: 0.5 mL IM
- Midazolam (Versed) 5 mg IM/IV for agitation
- Haloperidol (Haldol) 5 mg IM/IV for agitation

FOLLOW-UP

DISPOSITION

Admission Criteria

- Admit for signs of:
 - Cardiac instability
 - Excited delirium syndrome
 - Serious secondary injury

Pregnancy Considerations

Any female who is pregnant should undergo a medical evaluation of the pregnancy; if viable, she should undergo fetal monitoring at an appropriate facility.

Discharge Criteria

Patient acting normally, normal vital signs, AO × 4 appropriate, and no complaints of secondary injury, or secondary injuries treated and stable for discharge

Issues for Referral

Wound care, injury follow-up

PEARLS AND PITFALLS

- These patients may be suffering from ExDS, hence law enforcement became involved or Taser was used. Failure to aggressively treat this life-threatening condition will result in untoward outcome.
- Always screen for possible secondary injury.
- Stable, alert, appropriate subjects do not need much more than simple barb removal (if necessary), a tetanus vaccination update, and wound care.

CODES

ICD9

- 919.8 Other and unspecified superficial injury of other, multiple, and unspecified sites, without mention of infection
- 994.8 Electrocution and nonfatal effects of electric current

ICD10

- T14.8 Other injury of unspecified body region
- T75.4XXA Electrocution, initial encounter

TEMPORAL–MANDIBULAR JOINT INJURY/SYNDROME

Ben Osborne • Jennifer Dohrman

BASICS

DESCRIPTION

- Myofascial pain causing temporomandibular joint (TMJ) dysfunction
- Prevalence of 40–75% of 1 sign of TMJ disorder
- Most common in 20–50-yr-olds
- Females seek treatment more frequently
- 40% have symptoms that resolve spontaneously
- TMJ is a synovial joint:
 - Allows for hinge and sliding movements
- Articular disorders:
 - Congenital or developmental
 - Degenerative joint disorders:
 - Inflammatory (rheumatoid arthritis)
 - Noninflammatory (osteoarthritis)
 - Trauma
 - TMJ hypermobility:
 - Laxity
 - Dislocation
 - Subluxation
 - TMJ hypomobility:
 - Trismus
 - Fibrosis
 - Infection
 - Neoplasm
- Masticatory muscle disorders:
 - Local myalgias
 - Myositis
 - Muscle spasm
 - Contracture
 - Myofascial pain disorder
- TMJ clicking:
 - May be normal finding; present as a transient finding in 40–60% of the population
- TMJ motion:
 - Typical range is 35–55 mm (maxillary to mandible incisors)
 - Limited by adhesions within the joint or disk displacement or trismus from muscle spasm

- Intra-articular disk disorder:
 - Anterior displacement with reduction:
 - Displacement in closed mouth position
 - Often with a click and variable pain with opening mouth
 - May worsen over time
 - Anterior disk displacement without reduction:
 - Disk is a mechanical obstruction to opening mouth
 - Maximal opening may be 20–25 mm
 - Often difficult to correct

ETIOLOGY

TMJ dysfunction is poorly understood:

- Multifactorial:
 - Bruxism (teeth grinding)
 - Trauma
 - Malocclusion
- Onset may be related to stress

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Preauricular pain:
 - Constant but with fluctuating intensity
 - Dull and aching
 - May be referred to the ipsilateral ear, head, neck, or periorbital region
 - Exacerbated by mandibular movement (pathognomonic)
 - More conspicuous at night and may cause insomnia
 - Often worsens through the day
- Tongue, lip, or cheek biting
- Ear pain
- Ear fullness
- Tinnitus
- Dizziness
- Neck pain
- Headache
- Eye pain

Physical-Exam

- Joint sounds:
 - Popping or clicking sensation with TMJ articulation

- A palpable or audible click with opening and closing
- Not sufficient for diagnosis if not accompanied by pain or other dysfunction
- Misalignment and limited range of motion:
 - Dentoskeletal malocclusion or lateral deviation
 - Open or closed locking of the jaw
- Tenderness over the muscles of mastication and TMJ:
 - Masseter muscle most commonly painful
- Pain with dynamic loading (bite on gauze)

ESSENTIAL WORKUP

- Diagnosis based on history and physical exam
- Exclude other causes of headache and facial pain

DIAGNOSIS TESTS & INTERPRETATION

Lab

No specific lab tests are indicated unless there is concern for other disease process, i.e., ESR may help distinguish temporal arteritis from TMJ dysfunction.

Imaging

- Panorex is the screening radiograph of choice:
 - May demonstrate fracture or intra-articular pathology (i.e., tumor or degenerative joint disease) but usually unremarkable
- CT: Best for evaluating bony structures for fractures, dislocations, etc.
- MRI: Best imaging for nonreducing displaced disks:
 - Allows for better visualization of joints simultaneously

DIFFERENTIAL DIAGNOSIS

- Acute coronary syndrome
- Carotid artery dissection
- Intracranial hemorrhage (subarachnoid hemorrhage)
- Inflammatory diseases:
 - Giant cell (temporal) arteritis
 - Rheumatoid arthritis
- Trigeminal or glossopharyngeal neuralgia
- Vascular headache
- Intraoral and dental pathology
- Herpes zoster
- Salivary gland disorder
- Otitis media, otitis externa
- Sinusitis
- Elongated styloid process pain
- Jaw trauma (fracture or dislocation)

TREATMENT

PRE HOSPITAL

Provide comfort and reassurance

INITIAL STABILIZATION/THERAPY

Make sure airway is patent

ED TREATMENT/PROCEDURES

- Acute therapeutic options:
 - _ Patient reassurance and education—”usually mild and self-limited”
 - _ Rest
 - _ Heat
 - _ Analgesics and anxiolytics
 - _ Urgent reduction of open or closed locking TMJ
 - _ Reduction of TMJ dislocation:
 - Dislocation usually bilateral
 - IV muscle relaxant may be helpful
 - Often requires procedural sedation
 - Monitor airway
 - May face the patient or perform from behind the patient
 - Protect thumbs with gauze and/or tongue depressors
 - Thumbs rest on intraoral surface of mandible
 - Fingers wrap around jaw
 - Firm, progressive downward pressure as jaw is guided 1st in a caudal direction and then posteriorly
 - _ Physical therapy—moist heat or ice packs
 - _ Pain site injections with mixture of steroids/lidocaine
- Outpatient management:
 - _ Combination pharmacotherapy:
 - NSAIDs
 - Muscle relaxants
 - Antidepressants
 - Sedative hypnotics
 - _ Home physical therapy—moist heat or ice packs and mechanically soft diet
 - _ Caution not to open mouth > 2 cm for 2 wk
 - _ Avoid triggers such as gum chewing
 - _ Occlusal appliance worn during sleep
 - _ Referral to dentist or oral–maxillofacial surgeon

MEDICATION

First Line

- Naproxen: 250–500 mg PO BID (peds: 10 mg/kg/d PO div. q12h)
- Cyclobenzaprine: 5–10 mg PO TID (peds: 5–10 mg PO TID if > 15 yr old); caution with hepatic impairment
- Diazepam: 2–10 mg PO BID–TID (peds: < 12 yr old 0.12–0.8 mg/kg/d PO div. q6–8h); poor efficacy when used alone
- Ibuprofen: 600 mg (peds: 10 mg/kg) PO q8h; less effective than naproxen

Second Line

- Nortriptyline: 10–50 mg PO qhs
- Narcotic analgesic
- Sedative hypnotics

FOLLOW-UP

DISPOSITION

Admission Criteria

TMJ syndrome can be managed on an outpatient basis unless a locked or dislocated joint cannot be reduced

Discharge Criteria

Treat as outpatient with pain medication, muscle relaxants, and warm compresses

FOLLOW-UP RECOMMENDATIONS

Patients with TMJ syndrome may need referral to ENT, oral surgeon, or dentist for further care

PEARLS AND PITFALLS

- TMJ locking must be addressed urgently
- If ear pain with no ear findings, evaluate for TMJ
- NSAIDs, rest, and heat are 1st-line therapy

TENDON LACERATION

Nicholle D. Bromley

BASICS

ALERT

Tendons near lacerations must be explored through *complete range of motion* to rule out injury.

DESCRIPTION

- Based on mechanism
- External trauma:
 - Penetrating trauma:
 - Gunshot wounds
 - Glass
 - Knives
 - Foreign bodies
 - Blunt trauma:
 - Crushing force or avulsion from hyperextension of a joint
- Internal trauma:
 - Entrapment/laceration from bony fracture (rare)

ETIOLOGY

Tendon injuries grossly categorized into those affecting upper vs. lower extremities:

- Upper-extremity injuries frequently related to the workplace, home, an assault, or attempted suicide
- Lower-extremity injuries most often associated with work or motor vehicle accident

DIAGNOSIS

SIGNS AND SYMPTOMS

- Pain is the cardinal symptom.
- Functional deficit
- Soft tissue damage:
 - Swelling
 - Ecchymosis
 - Lacerations
 - Hemorrhage
- Abnormal resting position of the extremity or large joint instability increases suspicion for tendon injury.

ESSENTIAL WORKUP

- A careful history:
 - Mechanism, time of injury
 - Hand position during injury
 - Hand dominance
 - Drug allergies
 - Medications
 - Past medical history
 - Tetanus vaccination status
- Physical exam:
 - Examine resting position of hand. (At rest there is natural flexion of fingers increasing from radial to ulnar side.)
 - Examine the wound in position of initial injury.
 - Perform neurovascular exam before local anesthesia is instilled.
 - Examine each digit separately.
 - Test strength against resistance.
 - Examine tendon with direct visualization through full range of motion.
- Flexor digitorum profundus injuries:
 - Present with inability to flex the distal interphalangeal (IP) joint
 - Exam involves stabilizing the proximal IP joint in full extension while the patient attempts to flex distal IP joint.
- Flexor digitorum superficialis injuries:
 - Present with inability to flex the proximal IP joint of a digit
 - Usually established by means of standard superficialis tendon test:
 - While holding the uninjured digits in full extension, the patient attempts to flex the affected finger at the proximal IP joint.
 - False negative if profundus is functional.
 - The distal IP joint extension test:
 - May make this diagnosis more apparent
 - Patient is asked to make a precision pinch between thumb and the injured finger.
 - Then asked to flex the proximal IP joint so that the distal IP joint is hyperextended
 - Confirms the integrity of the flexor digitorum superficialis
- Forearm and wrist flexor injuries:
 - Present with inability to flex ulnar or radial side of wrist or to flex the wrist while opposing the thumb to the little finger
- Extensor tendon injuries:
 - Found by weakness or lack of extension of the distal phalanx against resistant
 - Indicates partial or complete disruption
 - Best determined with patient placing palm on flat surface and asking the patient to attempt to extend the fingers individually

- Palpate each tendon.
- Loss of normal tension indicates injury.
- Further explore tendons and wounds after local anesthesia (1% lidocaine or 0.5% bupivacaine) in a bloodless, well-lit surgical field:
 - Tendons near lacerations must be explored through complete range of motion.
 - Best elucidates tendon injuries distal or proximal to a skin wound

Pediatric Considerations

- More difficult to get an adequate exam
- The healing process is usually quicker and more often associated with complete return to preinjury function.

DIAGNOSIS TESTS & INTERPRETATION

Lab

Wounds 1st examined >12 hr after injury or wounds with evident infection should be cultured.

Imaging

- Radiographs are frequently needed to identify radiopaque foreign bodies or fractures.
- High-frequency US can be used to identify complete tendon lacerations:
 - Partial tendon lacerations difficult to image
 - A water bath may help when attempting to image a painful extremity.
- US guidance may help to guide removal of foreign bodies.
- MRI

DIFFERENTIAL DIAGNOSIS

- Always rule out an associated foreign body or fracture.
- Lacerations over the proximal IP joint may involve the lateral bands or the central slip of the extensor mechanism:
 - Boutonnière deformity from improper repair
- Disruption of the extensor tendon distal to the central slip results in a mallet finger deformity.
- “Jersey finger” is a closed traumatic injury with avulsion of the flexor digitorum profundus, seen when a football player grabs the jersey of another player and his finger gets stuck.
- Avulsion of the flexor digitorum superficialis distally may be present with or without an associated avulsion fracture:
 - Suspect when a grasping finger is hit by a fast-moving object (jammed finger).

TREATMENT

PRE HOSPITAL

- Do not remove foreign matter from the patient in the field.
- Immobilize and transport patient.
- Apply direct pressure to control hemorrhage.
- Assess distal neurovascular status for signs of compromise.
- Contact medical control before any attempted reduction.

INITIAL STABILIZATION/THERAPY

- Evaluate extremity and control hemorrhage with direct pressure.
- Remove all jewelry or constricting bands.

ED TREATMENT/PROCEDURES

- Pain control as required
- Administer tetanus toxoid as needed.
- Copious irrigation with 1 L NS
- Broad-spectrum antibiotic, such as a 1st-generation cephalosporin (Cefazolin)
- Tendon lacerations associated with human bites:
 - _ Must be copiously irrigated
 - _ Place on IV antibiotics with coverage of oral anaerobes (ampicillin/sulbactam).
 - _ Immobilize and elevate the hand.
- Remove all foreign bodies and provide débridement of avascular tissue.
- Partial tendon lacerations that involve >20% of the cross-sectional area of the tendon must be repaired.
- Simple extensor tendon lacerations may be repaired in the ED:
 - _ Use a 4-0 or 5-0 nonabsorbable suture in a figure-of-8 or a modified Kessler stitch.
- All suspected flexor tendon, wrist, and distal forearm tendon lacerations require consultation by a hand surgeon, ideally within 12 hr.
- Tendon lacerations over the proximal IP joint may result in a boutonnière deformity:
 - _ Refer to a hand surgeon.
- The superficial nature of multiple tendons, nerves, and vessels on the volar aspect of the wrist renders them easily vulnerable to penetrating trauma:
- “Spaghetti wrist” or “full house”:
 - _ Volar wrist laceration with at least 10 structures involved
 - _ Requires prompt consultation with a hand surgeon
- Tendon lacerations associated with fractures require referral for operative repair.
- If a surgeon is not promptly available:
 - _ Irrigate copiously.

- Close skin without repair of tendon.
- Immobilize injured hand with a bulky volar dressing and splint.
- Wrist in 20–30° of flexion
- Metacarpal joint in 60–70° of flexion
- IP joints in 10–15° of flexion

MEDICATION

- Ampicillin/sulbactam: 3 g IV q6 (peds: 200 mg/kg/d IM or IV div. q6h)
- Cefazolin: 1 g IV piggyback (peds: 100 mg/kg/d IM or IV div. q6h, followed by 40 mg/kg/d PO QID for 5–7 days)
- Tetanus toxoid: 0.5 mL IM (peds: <7 yr–diphtheria–pertussis–tetanus vaccine preferred; in those >7 yr, adult dose tetanus toxoid if immunization series not completed), tetanus immune globulin, as required, 250 IU administered IM

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with infected tendon lacerations must be admitted for operative débridement.
- Any patients with tendon injury secondary to human bite must be admitted for operative débridement and IV antibiotics.
- Any patients with significant flexor tendon laceration may be admitted for timely operative repair or transferred to the nearest hand surgeon.

Discharge Criteria

- Patients with an extensor tendon laceration that is not infected, nor associated with other significant injury or underlying fracture, which was repaired by the ED physician and is now properly splinted, may be discharged with timely surgical follow-up.
- Patients with an extensor tendon laceration requiring surgeon referral for repair (wrist, forearm, proximal IP joint), which has been properly treated and splinted, with the patient placed on antibiotics, may be discharged for timely surgical follow-up.

PEARLS AND PITFALLS

- Partial lacerations are common but more difficult to diagnosis than complete disruptions because they may demonstrate intact function:
 - Alterations of the normal resting hand position may indicate partial laceration.

- Lacerations over the metacarpophalangeal joint should be considered the result of a human bite until proven otherwise:
 - Look for associated extensor tendon injury while metacarpophalangeal joint flexed.
- It is very important to test strength because tendon injuries with up to a 90% full-thickness laceration can have normal range of motion. Therefore, test strength against resistance.
- Tendon laceration with > 20% cross-sectional area of involvement need repair

- S56.429A Laceration of extensor muscle, fascia and tendon of unspecified finger at forearm level, initial encounter
- S86.909A Unspecified injury of unspecified muscle(s) and tendon(s) at lower leg level, unspecified leg, initial encounter

TENDONITIS

James Killeen

BASICS

DESCRIPTION

- The term “tendinitis” has been used to describe chronic painful tendon injuries before the underlying pathology was understood. This term has led to confusion about the cause, chronicity, and treatment of the underlying disorder. The terms “tendinosis” or “tendinopathy” should be used to describe chronic tendon disorders.
- Overuse syndrome:
 - Clinical syndrome of chronic pain and tendon thickening
 - Synovial cells increase in thickness
 - Excess synovial fluid collection
 - Constant irritation
- If no further injury occurs, the acute process may last from 48 hr–2 wk.
- Tendinopathy is described as fibrosis being present without inflammatory cells and symptoms persist longer than 3 mo.

ETIOLOGY

- Mechanical overload or repetitive microtrauma to the musculotendinous unit:
 - Intrinsic factors:
 - Inflexibility
 - Muscle weakness or imbalance
 - Extrinsic factors:
 - Excessive deviation, frequency, or activity
 - In tendinopathies, the collagen is in a state of disrepair, with proliferation and chronic irritation of neurovascular repair tissue in the tendon and its linings.
- Chemotactic and vasoactive chemical mediators are released:
 - Vasodilatation and cellular edema increasing the number and activity of PMNs

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- The patient’s history should explain what movement led to the injury.
- Repetitive stress and mechanical overload
- The classic inflammatory signs include pain, warmth, erythema, and swelling.

- Pain will resolve quickly after initial movement, only to become a throbbing pain after exercise.

Physical-Exam

- Defined as inflammation of the tendon only
- There is a poor distinction between tendonitis and tenosynovitis (degree of inflammation). These are now termed as tendinopathies.
- Clinical findings:
 - Warmth
 - Presence of an effusion
 - Decreased range of motion
 - Instability
 - Pain on motion
 - Tenderness over tendon site

Specific Conditions Supraspinatus Tendinopathy

Supraspinatus and other rotator cuff tendons:

- Compressed between humerus and acromion
- Overuse of the extremity may lead to microtrauma of the tendons and fibers.
- Neer classification:
 - Stage 1:
 - Age < 25
 - Involved in sports requiring repetitive overhead motion (e.g., swimmers or pitchers)
 - Edema and hemorrhage of the tendon
 - Flexion–abduction motion will elicit pain.
 - “Dull aches”
 - Stage 2:
 - Age 25–40
 - Pain is constant and worsens at night.
 - Active motion is limited by pain.
 - Passive range of motion is preserved.
 - Diffuse, intense pain
 - Fibrosis and thickening of the tendon
 - Stage 3:
 - Partial or complete tendon tears
 - Raising the humerus in a forced forward flexion while preserving scapular rotation causes impingement.

Calcific Tendonitis

- Age older than 40 yr with unknown etiology.
- Any tendon of the rotator cuff can be affected, but there is a predisposition for the supraspinatus.
- Most cases are asymptomatic and are found on routine radiographs.
- Calcium is deposited within the tendon over time, undergoes spontaneous

resorption, causing pain.

- Acute attacks may develop from crystal release.

Bicipital Tendinopathy

- Pain to the anterior shoulder, which radiates down the radius
- Discomfort when rolling on the shoulder or trying to reach a hip pocket or back zipper
- Focal tenderness is between the greater and lesser tuberosities of the humerus.
- Yergason test:
 - _ Elbow at 90° and arm against the body
 - _ Pain increases with resisted supination of the wrist.
- Speed test:
 - _ Pain along the bicipital groove with resisted forward flexion and forearm supination

Lateral Epicondylitis (Tennis Elbow)

- Rotational repetitive motion causes pain.
- Dull ache on the outside of the elbow that increases with grasping and twisting
- Inflammation at the insertion of the common extensor tendon at lateral epicondyle of humerus
- Resisted active dorsiflexion of the wrist on extension of the middle finger against resistance can reproduce pain with the elbow extended.
- Inflammation at site of insertion of the flexor carpi radialis on the medial epicondyle:
 - _ Bowlers, golfers, pitchers
 - _ Active flexing of the wrist against resistance causes pain.

Wrist/Hand

- Inflammatory changes of the synovial lining between tendons and the retinaculum
- De Quervain tenosynovitis:
 - _ Inflammation of the abductor pollicis longus and extensor pollicis brevis
 - _ Finkelstein test:
 - Patient makes fist with thumb curled in palm.
 - Wrist is deviated in the direction of the ulna.
 - Pain occurs in 1st extensor compartment.
 - _ Osteoarthritis of the carpal metacarpal joints or GC tenosynovitis causes the same pain.

Trigger Finger

- Proximal portion of the palmar flexor tendon sheath becomes stenosed and catches as the finger is moved.
- Symptoms vary from pain to locking in flexion.

Ankle

- Achilles tendinopathy:
 - _ Overuse injury commonly seen in males
 - _ Trauma or systemic disease causing inflammation
 - _ With repeated stress, scar tissue formation and degeneration of the tendon

will occur.

- Patient will have pain, reduced range of motion, or morning stiffness
- Achilles tendon rupture
 - Seen more commonly in 30–40-yr-old recreational athletes
 - “Popping sensation”
 - Acute weakness, inability to continue activity
 - Feels like being kicked or hit in back of leg
 - May initially have a gap by palpation, followed by ecchymosis and a boggy sensation
 - Inability to plantar flex the foot with complete rupture
 - Thompson test:
 - Patient lies prone with the feet hanging over the edge of the bed.
 - Physician squeezes the calf muscles and looks for plantar flexion
 - 20–30% of Achilles tendon ruptures are missed at the initial visit because the clinician was falsely reassured by the patient’s ability to plantar flex or walk.
 - The Matles Test: the patient lies prone with knees flexed to 90°. Observe whether the affected foot is dorsiflexed or neutral (both are abnormal) compared to the uninjured side, where the foot should appear plantarflexed.

Pediatric Considerations

- Apophysitis occurs in children at an ossification center subject to traction:
 - Little League elbow at the medial epicondyle
 - Osgood–Schlatter syndrome at tibial tubercle
- Avascular necrosis (AVN):
 - Presents with pain and swelling around a joint
 - Can occur at various locations
 - Well-recognized sites:
 - Capitellum of the humerus
 - Head of the femur
 - Tarsal navicular
 - Metatarsal head
 - Diagnosis is made by plain radiographs.
 - Radiographs are often required to rule out fracture, AVN, osteochondritis dissecans, or bony tumor.

ESSENTIAL WORKUP

Physical exam

DIAGNOSIS TESTS & INTERPRETATION

Lab

CBC, C-reactive protein (CRP), ESR only if more serious infection suspected

Imaging

- Radiographs:
 - Extra-articular from articular etiologies
 - “SECONDS”:
 - Soft tissue swelling
 - Erosions
 - Calcifications
 - Osteoporosis
 - Narrowing
 - Deformity
 - Separation
- Ultrasound
 - Evaluate joint effusions
 - More sensitive than MRI
 - Used more frequently in the emergency setting
 - Focal tendon thickening
 - Focal hypoechoic areas
 - Irregular and ill-defined borders
 - Peritendinous edema
- MRI:
 - Internal morphology of the tendon and the surrounding structures
 - Helps diagnose retrocalcaneal bursitis and insertional tendonitis
 - Reveals tendon thickening and increased signal with chronic tendon abnormalities
- Scintigraphy:
 - ⁹⁹Techetium pertechnetate phosphate (binds with plasma protein) and concentrates in joint space (bursitis)

DIFFERENTIAL DIAGNOSIS

- Septic arthritis
- Fracture
- Osteoarthritis

TREATMENT

PRE HOSPITAL

Immobilize injured extremity as indicated.

INITIAL STABILIZATION/THERAPY

Ice, immobilization pending work-up

ED TREATMENT/PROCEDURES

- General:
 - Rest
 - NSAIDs
 - Ice (10–20 min intervals)
 - Range of motion exercises
 - Eccentric exercise is the application of a load (i.e., muscular exertion) to a lengthening muscle.
 - Local injection for pain control
 - Outpatient management
 - Admit only for surgery or severe disability
 - Allow 6–12 wk to heal
 - Recent studies have described successful investigational therapies
 - Prolotherapy, an ultrasound-guided injection of dextrose and lidocaine to stimulate repair.
 - Sclerotherapy injections of Polidocanol, a sclerosing substance to reduce neovascularity
 - **Aprotinin** is a broad-spectrum protease and matrix metalloproteinase (MMP) inhibitor, injected peritendinously
- Calcific tendonitis
 - Low-energy radio shock-wave therapy has recently shown significant pain relief:
 - Thought to increase the resorption of calcium
 - Cimetidine has been used to decrease pain and calcium deposits.
- Trigger finger:
 - Conservative treatments such as rest, splinting (thumb spica) and NSAIDs for most
 - Some physicians suggest cortisone injections, (84–91% cure rate).
 - Surgical release of A-1 Pulley may be required.
- De Quervain tenosynovitis
 - Rest, ice, NSAIDs
 - Thumb spica splint for 3–5 days often helps
- Achilles tendonitis:
 - Rest, ice, NSAIDs
 - Orthotics or heel wedges
 - Cryotherapy has shown to be useful in controlling inflammation.
 - Achilles rupture should be splinted posteriorly in slight plantar flexion:
 - Refer to orthopedics, as patients often need surgery

MEDICATION

- Ibuprofen: 400–800 mg PO q6–8h (max. 2,400 mg per day); peds: 5–10 mg/kg/dose PO q4–6h (max. 50 mg/kg/d)
- Acetaminophen: 10–15 mg/kg/dose every 4–6 hr as needed; do not exceed

acetaminophen 4 g/24 h (peds: Do not exceed 5 doses of 10–15 mg/kg acetaminophen in 24 hr)

FOLLOW-UP

DISPOSITION

Admission Criteria

Admit patients if require surgery or other more serious illness/injury

Discharge Criteria

Most patients may be managed as outpatients with appropriate referral.

Issues for Referral

- All complete tendon ruptures merit referral for surgical consultation.
- Partial tendon tears and chronic tendinopathy that fail to improve with 3–6 mo of conservative treatment may benefit from consultation with a specialized runners' clinic, physical medicine and rehabilitation specialist, physical therapist, or orthopedic surgeon

FOLLOW-UP RECOMMENDATIONS

Prevention of reinjury is central to follow-up care.

PEARLS AND PITFALLS

- Fluoroquinolones
- Tendinopathy and tendon rupture have been reported uncommonly in adults given fluoroquinolones but have been reported with most fluoroquinolones.

ADDITIONAL READING

Tenosynovitis

CODES

ICD9

- 726.0 Adhesive capsulitis of shoulder
- 726.10 Disorders of bursae and tendons in shoulder region, unspecified
- 726.90 Enthesopathy of unspecified site

ICD10

- M65.819 Other synovitis and tenosynovitis, unspecified shoulder
- M75.30 Calcific tendinitis of unspecified shoulder
- M77.9 Enthesopathy, unspecified

TENOSYNOVITIS

James Killeen

BASICS

DESCRIPTION

- Definition
 - Inflammation of the tendon and tendon sheath
- Caused by inflammation, overuse, or infection
- Synovial sheaths cover tendons as they pass through osseofibrous tunnels:
 - Visceral and parietal layers of the synovium lubricate and nourish the tendons.
 - Infection can be introduced into tendon sheath.
- Skin wound
- Hematogenous spread
- Flexor tenosynovitis (FTS) of hand:
 - Typically infectious etiology
 - Penetrating injury especially at flexion creases of the finger is the most common mechanism.
 - High-pressure “injection” injury to fingers
- Air tools
- Paint sprayers
- Hydraulic equipment
- May appear minor on the surface but are associated with high incidence of FTS

ETIOLOGY

- De Quervain tenosynovitis:
 - Caused by overuse
 - Inflammatory in nature
 - 2 thumb tendons: The abductor pollicis longus (APL) and extensor pollicis brevis (EPB).
 - On their way to the thumb, the APL and EPB traverse side-by-side through a thick fibrous sheath that forms a tunnel at the radial styloid process
- GC tenosynovitis:
 - *Neisseria gonorrhoea*
- Nongonococcal infectious tenosynovitis:
 - *Staphylococcus aureus* and Streptococci are most common in penetrating injuries.
 - *Pasteurella multocida* is common with cat bites.
 - *Eikenella corrodens* is common in human bites.
 - *Pseudomonas* is seen in patients with diabetes or marine-associated injuries.

- *Mycobacterium* species may occur in immunocompromised patients.
- Fungal tenosynovitis may occur from puncture wounds due to thorns or woody plants

DIAGNOSIS

SIGNS AND SYMPTOMS

- Cardinal signs of Kanavel for FTS include:
 - Tenderness and symmetric swelling along flexor tendon sheath (sausage digit)
- Flexed position of the digit
- Pain with passive extension of the finger
- Pain with palpation along the tendon sheath

Hand

- De Quervain tenosynovitis:
 - Repetitive pinching motion of thumb and fingers
- Assembly-line workers
- Carpenters
- Landscaping or weeding
 - Pain in the radial aspect of the wrist becomes worse with activity and better with rest.
 - Pain occurs on palpation along the radial aspect of the wrist.
 - Pain occurs with passive range of motion of the thumb.
 - Finkelstein test:
 - Pain occurs with ulnar deviation of the wrist with the thumb cupped in a closed fist.
- GC tenosynovitis:
 - Most commonly affects teenagers, young adults
 - Seen in the ankle, hand, or wrist
 - More commonly seen in women
 - Vaginal or penile discharge usually absent
 - Fever, chills, polyarthralgia are common.
 - Erythema, tenderness to palpation, and painful range of motion of the involved tendon
 - Dermatitis may be present.
 - Hemorrhagic macules or papules on the distal extremities or trunk

Forearm

Traumatic tenosynovitis is seen after a direct blow to the lower portion of the forearm.

Ankle

- Stenosing tenosynovitis:
 - Commonly seen at the inferior retinaculum of the peroneus tendon
 - Patients are usually >40 yr old and have some predisposing trauma.
 - Motion increases the pain.
- Rheumatoid tenosynovitis:
 - Medially, the posterior tibial and flexor hallucis longus tendons are commonly involved.
 - Laterally, the peronei are involved.
 - Anteriorly, the anterior tibial tendon is involved.
 - Motion increases the pain.
 - Spontaneous rupture may occur.

History

- Assess for infectious etiology:
 - History of sexually transmitted disease exposure, penile or vaginal discharge
- Obtain history of mechanism:
 - High-pressure injections
 - Puncture wounds, bites
 - Environmental exposures
- Assess tetanus status and comorbid factors (e.g., diabetes and immunocompromised).

Physical-Exam

- Assess Kanavel signs.
- Document neurovascular status.
- Tubular swelling of the tendon sheath if acute tenosynovitis is present.
- Identify signs and symptoms of systemic illness as well as other potential sites of infection.

ESSENTIAL WORKUP

Thorough history and physical exam will often lead to appropriate diagnosis.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC, ESR:
 - May be of assistance in infectious etiology
- GC cultures (urethra, cervix, rectum, or pharynx) may be useful.
- Liver function tests may be elevated with disseminated *N. gonorrhoea* infection.

Imaging

- Radiographs are low yield, unless a retained radiopaque soft tissue foreign body is suspected.

- MRI has proven accurate in assisting the diagnosis of tenosynovitis:
 - Generally unnecessary in ED

Diagnosis Procedure/Surgery

NA

DIFFERENTIAL DIAGNOSIS

- Ankle, soft tissue injuries
- Bursitis
- Carpal tunnel syndrome
- Cellulitis
- Compartment syndrome
- Endocarditis
- Felon
- *Gonorrhea*
- Gout and pseudogout
- Hand infections
- High-pressure hand injuries
- Soft tissue hand injuries
- Soft tissue knee injuries
- Reiter syndrome
- Rheumatic fever
- Rheumatoid arthritis

TREATMENT

PRE HOSPITAL

- Delay to definitive treatment leads to significant increased morbidity and loss of function.
- Elevation and immobilization of the affected extremity should be performed.

INITIAL STABILIZATION/THERAPY

- Manage airway and resuscitate as indicated:
 - Septic shock
- Elevation, immobilization of affected extremity
- IV access
- Tetanus status
- Procedure
 - Diagnostic arthrocentesis is indicated if joint effusion is present with tenosynovitis:
 - Most patients with disseminated GC infection have coexisting septic arthritis.

- Cultures are negative in 50% of patients.
- 25% GC arthritis is polyarticular.
- Joint fluid glucose is normal.
- WBCs usually are <50,000 and a Gram stain is positive in 25% of the patients.

ED TREATMENT/PROCEDURES

Hand

- High-pressure injection injuries to hand:
 - Surgical emergency
 - Immediate hand surgery consultation
 - Pain management
- Infectious FTS of hand:
 - Immediate hand surgery consultation
 - Broad-spectrum antibiotic coverage
- De Quervain tenosynovitis:
 - Rest, NSAID agents, and thumb spica splint
 - Consider lidocaine/corticosteroid injection if condition is unresponsive.
 - Phonophoresis (application of hydrocortisone gel to the radial styloid area daily) helps relieve pain in minor cases.
- GC tenosynovitis:
 - Admit for IV antibiotic therapy.
 - Penicillin or 1st-generation cephalosporins for initial therapy
 - 2nd-generation cephalosporins as an alternative
 - Surgical drainage may be indicated if antibiotics do not improve the condition.
 - Pain management
- Nongonococcal infectious tenosynovitis:
 - If diagnosis is equivocal, the patient should receive IV antibiotic therapy and consultation with a hand surgeon.
 - Cover for *Staphylococcus*, *Streptococcus*, as well as anaerobic bacterial infection.
 - Consider coverage for *Pseudomonas* for the diabetic or immunocompromised patient.
 - Aminoglycosides may be added for double coverage.
 - Pain management

Forearm

- Traumatic tenosynovitis:
 - Rest, ice, elevation, immobilization
 - NSAIDs

Ankle

- Stenosing tenosynovitis:
 - Rest, ice, elevation, immobilization
 - NSAIDs
- Rheumatoid tenosynovitis:
 - Rest, ice, elevation, immobilization
 - NSAIDs

MEDICATION

- Cefazolin: 1–2 g IV q8h (peds: 50–100 mg/kg/d IV div. q8h)
- Cefotetan: 1–2 g IV q12h (peds: 50–100 mg/kg/d IV div. q12h)
- Cefoxitin: 1–2 g IV q8h (peds: 80–160 mg/kg/d IV div. q6–8h)
- Ceftriaxone: 1–2 g IV q12h (peds: 50–100 mg/kg/d IV div. q12h)
- Clindamycin: 600–900 mg IV q8h (peds: 20–40 mg/kg/d div. q8h)
- Penicillin G: 12–24 mIU IV div. q4–6h (peds: 100,000–400,000 IU/kg/d IV div. q4–6h)
- Timentin: 3.1 g IV q6h (peds: 200–300 mg/kg/d IV div. q4–6h)
- Tobramycin: 1 mg/kg IV q8h or 5 mg/kg IV q24h (peds: 2–2.5 mg/kg IV q8h)
- Zosyn: 3.375 g IV q6h (peds: 200–400 mg/kg/d IV div. q6–8h)

FOLLOW-UP

DISPOSITION

- Patients with FTS require immediate consultation with a hand specialist and admission.
- Patients presenting 24–48 hr may have more conservative therapy to include immobilization, elevation IV antibiotics, and close observation.
- Surgical débridement indicated if patient is not improved within the 1st 24 hr, or physical findings are not resolved within 48 hr.
- Patients presenting longer than 48 hr require surgical débridement in the operating room.
- The hand surgeon may attempt continuous catheter irrigation of the tendon sheath.

Admission Criteria

Infectious or high-pressure etiologies for tenosynovitis should be admitted.

Discharge Criteria

Inflammatory etiologies can be managed as outpatients with appropriate referral.

Issues for Referral

Stenosing and rheumatoid tenosynovitis

FOLLOW-UP RECOMMENDATIONS

Patients whose etiology is inflammatory should be referred for follow-up within 1–2 wk

PEARLS AND PITFALLS

- High-pressure injection injuries may have subtle clinical findings, small puncture wounds
- Early hand surgeon consultation for suspected infectious etiology or high-pressure injection injuries is paramount
- De Quervain tenosynovitis may require thumb spica immobilization in order to improve

- M65.9 Synovitis and tenosynovitis, unspecified

TESTICULAR TORSION

Edward Newton

BASICS

DESCRIPTION

- Rotation of the testicle around the spermatic cord and vascular pedicle
- Rotation often occurs medially (two-thirds of cases):
 - _ Ranges from incomplete (90–180°) to complete (360–1,080°) torsion
 - _ Depending on the degree of torsion:
 - Vascular occlusion occurs
 - Infarction of the testicle after more than 6 hr of warm ischemia
- Testicular salvage:
 - _ 73–100% with <6 hr of ischemia
 - _ 50–70% at 6–12 hr
 - _ <20% after 12 hr
 - _ It is still worthwhile to attempt to salvage the testicle up to 24 hr after the onset.
- Testicular infarction leads to atrophy and may ultimately decrease fertility.

EPIDEMIOLOGY

Bimodal distribution of torsion:

- Peak incidences in infancy and adolescence
- 85% of cases occur between ages 12 and 18 yr, with a mean of 13 yr.
- Torsion is rare after age 30 but still possible.

ETIOLOGY

- Congenital abnormality of the genitalia:
 - _ High insertion of the tunica vaginalis on the spermatic cord
 - _ Redundant mesorchium
 - _ Permits increased mobility and twisting of the testicle on its vascular pedicle
- The anatomic abnormality is bilateral in 12%, so both testicles are susceptible to torsion.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Sudden onset of unilateral testicular pain
- Scrotal swelling and erythema

- Less commonly, torsion may present with pain in the inguinal or lower abdominal area.
- Up to 40% of patients may describe previous similar episodes that remitted spontaneously:
 - Represents spontaneous torsion and detorsion
- Nausea and vomiting occur in 50% of cases.
- Low-grade fever occurs in 25%.
- There is often a history of minor trauma to the testicle preceding the onset of pain.
- Symptoms of urinary infection (dysuria, frequency, and urgency) are absent.

Physical-Exam

- In distinguishing torsion from epididymitis, localized tenderness is helpful early; however, once significant scrotal swelling occurs, the anatomy becomes indistinct.
- Torsion of the appendix testis is less painful and does not threaten the viability of the testicle
- Characterized by the “blue dot” sign
- The affected torsed testicle may lie transversely as opposed to the normal vertical lie.
- Cremasteric reflex is frequently absent on the affected side with testicular torsion.
- Sensitivity 96%; specificity 66%
- Prehn sign:
 - Relief of pain on elevation of the testicle in epididymitis
 - Worsening or no change in the pain with torsion
 - Considered unreliable

ESSENTIAL WORKUP

- The presentation of an “acute scrotum” in a child or adolescent requires rapid assessment and immediate consultation with a urologist.
- These patients require noninvasive flow studies or surgical exploration to confirm torsion.
- 3.3 (ED)–30% (Urology service) of these patients ultimately prove to have testicular torsion.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Elevated WBC count with a left shift is present in 50% of cases.
- Urinalysis is usually normal, but up to 20% of cases of torsion include pyuria.
- There are no lab tests specific for testicular torsion.

Imaging

ALERT

- There are limitations of all flow studies:
 - _ Reflect only the current state of perfusion
 - _ Spontaneously detorsed testicle may show normal or even increased flow.
 - _ Still at high risk for recurrent torsion
- Traditional criterion standard has been technetium-99m radionuclide scans:
 - _ Decreased flow in the torsed testicle compared with the unaffected side
 - _ Frequent time delays in obtaining scans
- Doppler ultrasound:
 - _ Assess testicular blood flow and visualize the torsed spermatic cord directly.
 - _ Has replaced nuclear scanning:
 - Less invasive
 - More readily available test
 - Comparable results
 - _ Overall sensitivity and specificity of 98% and 100%, respectively for torsion but lower in distinguishing between testicular torsion and torsion of the appendix testis.
 - _ Epididymitis will reveal increased flow due to inflammation.
 - _ Torsion will reveal decreased or no blood flow.
 - _ Color-flow Doppler is most commonly available.
 - _ Use of Doppler contrast material may enhance the accuracy.
 - _ High definition ultrasound (HDUS) is emerging as an accurate means of directly imaging the torsed spermatic cord

Pediatric Considerations

- All imaging techniques have technical limitations in infants:
 - _ Testicular vessels are very small.
 - _ Amount of blood flow to the testicle under normal conditions is minimal.
- Scrotal exploration may be required.

Diagnostic Procedures/Surgery

- Scrotal exploration can be done rapidly under local anesthesia to diagnose and treat torsion.
- The “bell-clapper” deformity of both testicles should be corrected by orchiopexy.

DIFFERENTIAL DIAGNOSIS

- Acute hydrocele
- Epididymitis/orchitis
- Henoch–Schönlein purpura
- Incarcerated inguinal hernia
- Testicular neoplasm
- Testicular trauma or rupture of the testicle
- Torsion of the appendix testis (31–70% of acute scrotum cases)
- Other intra-abdominal conditions:

- Appendicitis
- Pancreatitis
- Renal colic

TREATMENT

PRE HOSPITAL

- There is no definitive treatment that can be rendered in the field.
- Pre-hospital personnel must recognize the urgency of acute testicular pain in young patients.
- These patients should be transported to the ED immediately.

INITIAL STABILIZATION/THERAPY

IV fluid, analgesics as appropriate

ED TREATMENT/PROCEDURES

- Rapid triage and assessment
- Exam of testicle to exclude primary neoplasm
- Establish the diagnosis and mobilize appropriate urologic care.
- Applying an ice pack to the scrotum relieves pain:
 - May prolong the viability of the ischemic testicle
- If definitive care is likely to be delayed beyond 4–5 hr from the onset of torsion, manual detorsion may be attempted (26.5–80% successful).
 - Externally rotate the affected testicle opposite the usual medial direction of torsion.
 - Continue until pain is relieved, normal anatomy is restored, or Doppler US shows return of flow.
 - All patients who undergo manual detorsion must be surgically explored.

MEDICATION

Analgesia

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with confirmed torsion must be admitted for scrotal exploration and bilateral orchiopexy.
- Flow studies that are inconclusive and technical failures mandate further investigation by surgical exploration of the scrotum.
- Admission for urgent surgical exploration of an acute scrotum is mandatory if

there is any potential delay in obtaining a flow study:

- Patients in whom apparent spontaneous detorsion has occurred should undergo elective exploration for bilateral orchiopexy.

Discharge Criteria

- Patients with negative scrotal exploration and those with normal flow studies can be discharged with appropriate urologic follow-up.
- Parameters for return to ED must be discussed because of the possibility of recurrent torsion.
- Patients with an obvious diagnosis other than testicular torsion can be referred for care.

PEARLS AND PITFALLS

- Testicular torsion can mimic acute appendicitis in children.
- Remember that “time is testicle”; emergent workup and consultation are required.
- Maintain a high index of suspicion for testicular torsion in all age groups even though peak incidence is in adolescents and neonates.
- If testicular torsion is diagnosed early, a near 100% salvage rate for the testicle is possible. Orchiopexy is not a guarantee against future torsion, although it does reduce the odds.

- N44.02 Intravaginal torsion of spermatic cord

TETANUS

Daniel T. Wu

BASICS

DESCRIPTION

- Rare disease in US but still prevalent in 3rd-world countries
- About 30 cases per year in US
- One-half of the cases involve people >50 yr of age
- Majority of cases in US occur in the unvaccinated, >10 yr since last booster or IVDUs
- 500,000–1,000,000 cases worldwide
- High mortality rates even with treatment
- Incubation period:
 - Inoculation to the appearance of the 1st symptoms:
 - 48 hr to 3 wk or more
 - Period of onset:
 - <7 days—poor prognosis
 - Very poor prognosis if <48 hr from 1st symptom to initial reflex spasm
- Neonatal tetanus:
 - Due to infected umbilical stump
 - Symptom onset in 2nd week of life when maternal antibodies decrease
 - Rare in US but common in 3rd-world countries
 - Worldwide, accounts for over one-half of all tetanus infections

ETIOLOGY

- Clostridium tetani:
 - Slender, motile, heat-sensitive, anaerobic gram-positive rod with a terminal spherical spore
 - Spore characteristics
 - Resistant to oxygen, moisture, temperature extremes
 - Can survive indefinitely until it germinates
 - Ubiquitous in soil and feces
- When inoculated into a wound or devitalized tissue or injected IV as a contaminant of street drugs, the spores germinate under anaerobic conditions and produce 2 toxins.
- Toxins:
 - Tetanolysin:
 - Damages tissue
 - Does not cause clinical manifestations of tetanus infection

- Tetanospasmin:
 - Powerful neurotoxin
 - Disrupts the release of neurotransmitters such as γ -aminobutyric acid (GABA)
 - Responsible for the clinical manifestations
- Muscle spasms
- Autonomic instability
- Uncontrolled motor activity

DIAGNOSIS

SIGNS AND SYMPTOMS

Generalized

- Most common type accounting for about 80% of all cases
- Initial presentation:
 - Muscle stiffness and pain
 - Trismus (initial)
 - Risus sardonicus (characteristic facial appearance)
- Systemic symptoms:
 - Irritability
 - Restlessness
 - Diaphoresis
- Later manifestations:
 - Muscle group rigidity
 - Sudden burst of tonic contractions of muscle groups causing:
 - Opisthotonos
 - Flexion and adduction of the arms
 - Clenching of fists
 - Extension of the lower extremities
 - Diaphragmatic spasm or paralysis:
 - May compromise respiration
- Hypersympathetic state (most common cause of death):
 - Begins in the 2nd week
 - Dysrhythmias
 - BP changes
 - Diaphoresis
 - Hyperthermia

Local

- Less common form of disease, accounting for about 17% of all cases
- Typical localized spasms around area of initial infection may:

- Be mild
- Persist for months before resolving
- Evolve to generalized form (13%)

Cephalic

- Rare variant of disease
- Follows head injury or otitis media
- Spasm of lower cranial and facial muscles:
 - Cranial nerve (CN) palsies, CN VII most common
- May progress to generalized tetanus

Neonatal

- Generalized form of tetanus occurring during the 1st weeks of life
- Often caused by infection of umbilical stump
- Clinical manifestations:
 - Irritability
 - Poor suck
 - Facial grimacing
 - Muscle spasms with touch
- Very high mortality rate (50–100%)
- Incubation period 1–2 wk

History

- Investigate source of infection.
- Acute skin wound not necessary to contract infection
- > 25% of infections occurred in the absence of known acute trauma.
- Infections can occur from abscesses, ulcers, and gangrene.
- Elicit tetanus immunization status.

ESSENTIAL WORKUP

- Perform complete physical exam focusing on cardiovascular and respiratory status, neurologic and CN exam.
- Diagnosis of tetanus is clinical:
 - Suspect in all cases of trismus
 - No wound recalled in one-fifth of cases
 - Full tetanus immunization almost eliminates diagnosis.

DIAGNOSIS TESTS & INTERPRETATION

Often of limited or no benefit for diagnosis but useful for ruling out other etiologies or assessing complications of disease

Lab

- CBC

- Electrolytes, BUN, creatinine, glucose, calcium:
 - For hypocalcemia
- Strychnine level
- ABG, pulse oximetry:
 - For oxygenation status
- Wound culture for *C. tetani*:
 - Positive only about 30% of time
- *C. tetani* titers:
 - Will be useful only after the fact
- CSF analysis:
 - Normal in tetanus
 - Exclude meningitis/encephalitis

Imaging

CT brain for altered mental status:

- Normal in tetanus

DIFFERENTIAL DIAGNOSIS

- Strychnine poisoning
- Jaw muscles usually spared or not involved early in strychnine poisonings
- Dystonic reaction to dopamine blockade
- Infection:
 - Meningitis
 - Rabies
 - Encephalitis
 - Peritonitis
 - Alveolar abscess
- Black widow spider envenomation
- Botulism
- Serotonin syndrome
- Hypocalcemic tetany
- Bell palsy (cephalic form, before trismus)

TREATMENT

PRE HOSPITAL

- Evaluate airway carefully:
 - Endotracheal intubation complicated by trismus, vocal cord paralysis, and facial/neck rigidity
- Avoid excessive stimulation because it may provoke tetany of musculature.

INITIAL STABILIZATION/THERAPY

- ABCs:
 - Prophylactic intubation
 - Require neuromuscular blockade due to trismus
 - Establish IV 0.9% NS
 - Monitor BP and cardiac rhythm (autonomic instability).
- Administer benztropine or diphenhydramine to exclude dystonic reaction.

ED TREATMENT/PROCEDURES

- Focuses on 3 goals:
 - Stabilizing the patient and supportive care
 - Neutralizing the toxin
 - Removing any remaining organism
- Stabilization and supportive care:
 - Secure airway:
 - Prophylactic intubation may be necessary.
 - Paralytic agent may be needed in the setting of trismus:
 - Succinylcholine should be used with caution due to the risk of hyperkalemia from upregulation of acetylcholine receptors.
 - Treat muscle spasms with benzodiazepines; if large doses fail, can administer dantrolene.
- Autonomic instability therapy:
 - Occurs days to weeks after the onset of symptoms
 - Tachydysrhythmia and hypertension:
 - No treatment universally effective
 - α - and β -blockers can be tried but may cause worsening of symptoms (labetalol has been used for its α - and β -blocking effects).
 - Clonidine, magnesium, morphine, fentanyl, and epidural anesthesia may be tried.
 - Hypotension:
 - Rule out septicemia and hypovolemia.
 - Initiate dopamine or dobutamine when low cardiac output.
 - Neutralization of the toxin
- Human tetanus immune globulin (TIG):
 - 3,000–6,000 U IM for both adults and children
 - Administer *before* débridement of wound.
 - Neutralizes unbound toxins
 - No effect on toxin already bound in CNS
- Removal of remaining organism:
 - Limits the severity of the infection
 - Débridement removes any necrotic tissue.
 - Antibiotics are effective in eliminating *C. tetani* when used in conjunction with débridement
 - Metronidazole is the antibiotic of choice.

- Penicillin is a viable alternative.
- Prevention:
 - Primary vaccination series should be completed by age 18 mo; children receive the booster at ages 4, 11, and then every 10 yr after.
 - Diphtheria, pertussis, and tetanus vaccine for children <7 yr
 - Tetanus diphtheria (Td) can be used for children >7 yr and adults.
 - 1 dose of Tdap should be administered to everyone >11 yr of age if not received previously to address increase in pertussis.
 - Clinical tetanus does not confer immunity.
 - For clean, minor wounds:
 - Td should be given if unknown prior vaccination history or >10 yr since last booster.
 - For tetanus-prone wounds:
 - Td should be given if unknown vaccination history or >5 yr since last booster.
 - TIG should be given if unknown vaccination or patient has never received the primary series.

MEDICATION

- Benztropine: 1–2 mg IV
- Chlorpromazine: 10–50 mg IM
- Diazepam (benzodiazepine): 5–10 mg (peds: 0.2–0.4 mg/kg) IV
- Diphenhydramine: 50 mg IV
- Dobutamine: 2.5–15 µg/kg/min IV
- Dopamine: 2–20 µg/kg/min IV
- Doxycycline: 100 mg IV q12h
- Erythromycin: 500 mg IV q6h
- Labetalol: 20 mg (peds: 0.3–1 mg/kg/dose) IV q10min up to 300 mg PRN—start infusion 2 mg/min (peds: 0.4–1 mg/kg/h max. 3 mg/kg/h as needed)
- Metronidazole: 1 g (peds: 15 mg/kg) load, followed by 500 mg (7.5 mg/kg) IV q6h
- Penicillin G: 1.2 mU on 2 separate entries (peds: 100,000 IU/kg/24 h) IV q6h for 10 days
- Propranolol: 0.5–1 mg (peds: 0.01–0.1 mg/kg) IV
- TIG:
 - 250 IU IM
 - Administer in separate site from Td toxoid
 - For unimmunized or incompletely immunized in presence of tetanus prone wound
- Td 0.5 mL IM

FOLLOW-UP

DISPOSITION

Admission Criteria

All patients should be admitted to an ICU.

Discharge Criteria

None for suspected generalized tetanus

PEARLS AND PITFALLS

Aggressive management is indicated for tetanus-prone wounds.

THEOPHYLLINE POISONING

Navneet Cheema

BASICS

DESCRIPTION

- Theophylline causes:
 - Release of endogenous catecholamines resulting in stimulation of β_1 - and β_2 -receptors
 - Adenosine antagonism
 - Inhibition of phosphodiesterase (at supratherapeutic levels)
- Available in immediate- and sustained-release formulations
- Peak absorption is 60–90 min with immediate-release and 6–10 hr with sustained-release formulations
- *Acute overdose*:
 - Ingestion within an 8-hr interval in a patient with no prior theophylline use
- *Acute-on-chronic overdose*:
 - Single excessive dose in a patient previously receiving usual therapeutic doses for ≥ 24 hr
- *Chronic intoxication*:
 - Accumulation of theophylline > 20 $\mu\text{g}/\text{mL}$ associated with prior therapeutic use for ≥ 24 hr secondary to:
 - Drug–drug, drug–diet, or drug–disease interactions
 - Use of serial excessive doses

ETIOLOGY

- Acute ingestions require larger concentrations to achieve specific toxic effects compared with acute-on-chronic or chronic overdoses.
- Drug–drug interactions:
 - Inhibiting theophylline metabolism (leads to toxicity when started):
 - H_2 -receptor antagonists
 - Macrolide antibiotics
 - Fluoroquinolones
 - Allopurinol
 - Influenza vaccine
 - Interferons
 - Enhances theophylline metabolism (leads to toxicity when discontinued):
 - Carbamazepine
 - Barbiturates
 - Smoking
 - Rifampin

- Chronic theophylline accumulation:
 - Uncontrolled CHF
 - Liver disease (cirrhosis or severe hepatitis)
 - Acute viral infections

DIAGNOSIS

SIGNS AND SYMPTOMS

- Cardiovascular:
 - Sinus, atrial, and ventricular tachycardias:
 - Multifocal atrial tachycardia
 - Atrial fibrillation
 - Premature ventricular contractions
 - Ventricular tachycardia
 - Due to β_1 -receptor stimulation and adenosine antagonism
 - Hypotension:
 - Associated with theophylline $> 100 \mu\text{g/mL}$ (acute ingestion)
 - Due to vasodilatation induced by β_2 -receptor stimulation
 - May be refractory to fluids, positioning, and conventional vasopressors
- CNS:
 - Tremor
 - Mental status changes
 - Seizures:
 - 14% of chronic intoxications
 - 5% of acute intoxications
- GI:
 - Nausea, vomiting:
 - Protracted and may be refractory to antiemetics at usual doses
 - 75% of acute intoxications
 - 30% of chronic intoxications
 - Abdominal pain
 - Pharmacobezoars:
 - From sustained-release preparations in acute ingestions
 - Delays peak concentrations
- Metabolic:
 - Hypokalemia:
 - Typically decreases approximately to 3 mEq/L
 - Due to β -receptor stimulation
 - Hyperglycemia
 - Leukocytosis
 - Hypophosphatemia and hypomagnesemia

- Metabolic acidosis with increased serum lactate levels

ESSENTIAL WORKUP

- Serum theophylline concentration:
 - Finding of ≥ 20 $\mu\text{g}/\text{mL}$ confirms diagnosis.
- ECG and cardiac monitoring
- Detailed history to differentiate acute from acute-on-chronic from chronic intoxication

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Serum theophylline level:
 - Repeat every 2 hr until decreasing to confirm immediate absorption is complete and peak value has occurred.
 - Serious morbidity in acute overdose if ≥ 100 $\mu\text{g}/\text{mL}$
- CBC
- Electrolytes

Imaging

- KUB (kidneys, ureters, bladder):
 - Undissolved sustained-release tablets or pharmacobezoars may appear as radiopacities.
 - Bead-filled capsules may appear as radiolucencies.
- US of stomach may detect intact sustained-release dosage forms.

DIFFERENTIAL DIAGNOSIS

- Caffeine/ β -agonist bronchodilator overdose
- Amphetamines
- Sympathomimetics
- Anticholinergic agents
- Drug withdrawal syndromes
- Pheochromocytoma
- Thyrotoxicosis

TREATMENT

PRE HOSPITAL

Bring pill bottles/pill samples in suspected overdose.

INITIAL STABILIZATION/THERAPY

- ABCs:
 - Cardiac monitor

- Isotonic crystalloids as needed for hypotension
- Naloxone, thiamine, and dextrose (D₅₀W) as indicated for altered mental status
- Cardiovascular:
 - Initiate β -blockers or calcium channel blockers for rate control with supraventricular tachyarrhythmias (SVT).
 - Adenosine is antagonized by theophylline and may not be effective to treat SVT.
 - Administer isotonic crystalloid IV fluid resuscitation for hypotension:
 - With treatment failure, consider β -blocker to reverse theophylline-induced β_2 -receptor-stimulated vasodilation.
 - If vasopressors are needed, choose vasopressor that is not a β -agonist, such as phenylephrine.
 - Treat ventricular dysrhythmias conventionally.
- Seizures:
 - Administer benzodiazepines.
 - Phenytoin is contraindicated; it is usually ineffective and may paradoxically worsen seizures in theophylline intoxications.

ED TREATMENT/PROCEDURES

Decontamination

- Administer activated charcoal
- Multidose activated charcoal:
 - Especially with sustained-release products
 - Binds theophylline, which back-diffuses in to the small intestine
 - For mild to moderate toxicity
 - 25 g q2h until theophylline level ≤ 20 $\mu\text{g}/\text{mL}$
- Initiate whole-bowel irrigation with sustained-release products:
 - Administer 1–2 L/hr of polyethylene glycol until a clear, colorless rectal effluent or theophylline level ≤ 20 $\mu\text{g}/\text{mL}$
- Treat protracted vomiting with metoclopramide or 5-HT₃-receptor antagonists.
- Avoid syrup of ipecac.

Electrolyte Disturbances

- Treat hypokalemia in acute ingestions cautiously:
 - Relative hypokalemia owing to β -receptor-mediated intracellular shift of extracellular potassium.
 - Aggressive correction leads to potentially serious hyperkalemia as theophylline concentrations decrease.
- Most electrolyte imbalances respond to β -blocker therapy:
 - Generally not indicated; however, because of absence of associated morbidity and potential for β -blocker-induced bronchospasm in pulmonary

patients

Extracorporeal Elimination

Initiate hemodialysis or hemoperfusion if theophylline level:

- ≥ 90 $\mu\text{g/mL}$ and symptomatic in acute ingestions
- ≥ 40 $\mu\text{g/mL}$ and:
 - Seizures or
 - HTN unresponsive to IV fluid or
 - Ventricular dysrhythmias

MEDICATION

- Activated charcoal: 1 g/kg PO, if dose ingested is known, 10 g/1 g theophylline ingested, max. dose 100 g
 - Multidose-activated charcoal 25 g q2h until theophylline level ≤ 20 $\mu\text{g/mL}$
- Diazepam: 0.1 mg/kg IV q5–10min until seizures controlled, up to 30 mg
- Diltiazem: 0.25 mg/kg IV bolus; may repeat after 15 min, then 5–15 mg/h infusion for control of heart rate in patients with contraindication to β -blockade
- Esmolol: 500 $\mu\text{g/kg}$ IV bolus, followed by 50 $\mu\text{g/kg/min}$ infusion; increase by 50 $\mu\text{g/kg/min}$ increments to max. of 200 $\mu\text{g/kg/min}$
- Metoclopramide: 10 mg IV bolus; may repeat to max. of 1 mg/kg
- Ondansetron: 0.15 mg/kg IV bolus up to max. of 16 mg total
- Polyethylene glycol (high molecular weight): 1–2 L/h via nasogastric tube

FOLLOW-UP

DISPOSITION

Admission Criteria

ICU:

- Acute overdoses with serum theophylline concentrations ≥ 100 $\mu\text{g/mL}$
- Acute-on-chronic or chronic theophylline with either serum concentration ≥ 60 $\mu\text{g/mL}$ or patient > 60 yr old
- Seizures or hypotension refractory to fluids and vasopressors in a patient with serum theophylline concentration ≥ 40 $\mu\text{g/mL}$

Discharge Criteria

- 2 consecutive (≥ 2 hr apart) decreasing serum theophylline concentrations with most recent concentration < 30 $\mu\text{g/mL}$
- Mildly symptomatic or asymptomatic patient meeting above criterion and no evidence of suicidal intention

FOLLOW-UP RECOMMENDATIONS

- Follow up with medical toxicologist or primary care doctor
- If patient is on chronic theophylline, dosing regimen may have to be adjusted.

PEARLS AND PITFALLS

- Seizures are a major complication.
- Tachydysrhythmias are common in overdose.
- Multi-dose activated charcoal is beneficial in theophylline overdose.

A special thanks to Dr. Harry Karydes who contributed to the previous edition.

THORACIC OUTLET SYNDROME

Adam J. Heringhaus • Daniel C. McGillicuddy

BASICS

DESCRIPTION

- The symptoms of thoracic outlet syndrome (TOS) are produced by compression of the brachial plexus, subclavian vein, or subclavian artery during their passage from the cervical area toward the axilla and proximal arm.
- Subdivided into 3 categories depending on the predominant symptoms:
 - Neurogenic thoracic outlet syndrome (NTOS):
 - Comprises 90–98% of adult patients
 - Female > male
 - True (1–3%): Those with objective findings
 - Disputed (90%): Those with no or limited objective findings
 - Venous thoracic outlet syndrome (VTOS):
 - 2–4% of patients
 - Arterial thoracic outlet syndrome (ATOS):
 - Least common, <1%
 - Male = female
- Vascular manifestations are more common in adolescents, seen in >50% of teens with TOS.
- Right extremity is more commonly affected.

ETIOLOGY

- Anatomic anomalies:
 - Bony anomalies include cervical rib, 1st thoracic rib, or clavicular abnormalities:
 - Cervical ribs occur in <1% of the population, ~70% in women, and most are asymptomatic.
 - Less commonly, fracture of the clavicle and trauma to the sternoclavicular and costoclavicular joints
 - Congenital bands or anomalous muscles
 - May play a role in neurologic and venous types but is almost always implicated in arterial type
- Neurogenic:
 - Often have a history of neck trauma, such as whiplash (hyperextension injuries) or with repetitive motion patterns
- Venous:
 - May be preceded by excessive activity, especially in adolescent athletes
 - Caused by acute thrombosis of the subclavian vein (also called Paget–

Schrötter disease) or by venous impingement

- Arterial:
 - Often develop spontaneously
 - Unrelated to trauma or work
 - May experience true claudication with overhead exercises
 - Almost always have a complete cervical rib or an anomalous 1st rib
 - Caused by subclavian artery aneurysm or subclavian/axillary artery impingement:
 - Arterial emboli that arise from either mural thrombus in the subclavian artery aneurysm or from thrombus forming distal to subclavian artery stenosis
- Descent of the shoulder girdle and sagging musculature can also predispose to TOS:
 - Aging
 - Obesity
 - Heavy breasts

DIAGNOSIS

SIGNS AND SYMPTOMS

- Neurogenic:
 - Classically, pain, paresthesia, and weakness of the hand, arm, and shoulder
 - May see wasting of the thenar eminence, also known as Gilliatt–Sumner hand
 - Analogous but not as severe as Erb–Duchenne syndrome
 - May also see Raynaud phenomenon, hand coldness, color change:
 - Not caused by ischemia, rather due to overactive sympathetic fibers that run on the circumference of the lower trunks of the brachial plexus
 - Similar symptoms can be seen in arterial TOS, so the 2 must be differentiated by evaluating for other signs and symptoms.
- Venous:
 - Swelling of the arm and cyanosis:
 - NTOS and ATOS do not exhibit arm swelling.
 - May see pain, aching of the arm
 - Hand paresthesia:
 - May be due to swelling as opposed to nerve compression
- Arterial:
 - Digital ischemia, claudication, pallor, coldness, paresthesia, and pain of the hand
 - Usually spares the shoulder and neck
 - Pallor and coldness are due to ischemia and not Raynaud

- Aneurysmal:
 - o Painless pulsating mass

History

- May be positional or exacerbated by repetitive use (i.e., working overhead)
- Usually insidious in onset and progressive
- Can occur or worsen suddenly after trauma or with acute clot

Physical-Exam

Provocative maneuvers can reveal NTOS (VTOS and ATOS often diagnosed with history and symptoms only):

- Roos, aka elevated arm stress test (EAST):
 - Arms abducted 90° from the thorax and elbows flexed at 90°
 - Shoulders braced slightly back of the frontal plane
 - Fists are open and closed for 3 min.
 - Early heaviness and fatigue of the arm
 - Gradual onset of hand numbness
 - Progressive aching through the arm and top of shoulder
 - Negative test is having only fatigue in forearms
- Adson test:
 - Arm down, patient rotates head toward extremity, looks up, and inhales.
 - Positive result is the alteration or obliteration of the radial pulse or change in the BP.
 - Not a reliable test, as many patients with NTOS have a negative test and many control patients have a positive test.
- Wright test:
 - Progressive hyperabduction and external rotation of affected arm while palpating pulse on ipsilateral side
 - Positive result if paresthesias or diminishing pulses
- None of the above is very sensitive nor specific.
- Difference of >20 mm Hg in BP is suggestive of compromise of subclavian artery in right clinical context

ESSENTIAL WORKUP

- Careful history and physical exam
- EKG to rule out cardiac ischemia

DIAGNOSIS TESTS & INTERPRETATION

Lab

Consider a coagulation workup for either venous or arterial TOS.

Imaging

- Perform as outpatient except in case of limb-threatening ischemia and/or suspicion of venous thrombus
- CXR:
 - Assess for anatomic abnormalities: 1st rib, cervical rib, clavicle deformity:
 - Without an abnormality, ATOS is very unlikely.
 - Pulmonary disease
- Cervical spine series:
 - Fracture
 - Scoliosis
- US can diagnose venous thrombosis
- Duplex scanning is the best way to screen for subclavian artery aneurysm or stenosis, which, if present, can lead to arteriography
- Arteriogram:
 - Usually used to help a surgeon plan reconstruction
 - Indications include:
 - Decreased radial pulse
 - BP is 20 mm Hg less than the opposite limb.
 - Suspected subclavian stenosis
 - Bruit or abnormal supraclavicular pulsations or pulsating mass
 - Peripheral emboli in the upper extremity
- Venography:
 - Indicated if edema, peripheral unilateral cyanosis, or distended thoracic and extremity veins
- NTOS:
 - No gold standard test: Diagnosis remains mostly clinical.
 - Electromyography and nerve conduction velocity tests are often normal.
- MRI may be required to assess for spinal cord disease, herniated cervical disk, or assessing for pancoast tumor.

DIFFERENTIAL DIAGNOSIS

- Cardiac ischemia
- Cervical spondylosis or disk disease
- Carpal tunnel syndrome or nerve entrapments
- Pancoast tumor; other neck/mediastinum malignancies
- Neuritis
- Myositis
- Raynaud disease
- Multiple sclerosis or degenerative spinal cord disease
- Shoulder inflammatory diseases: Arthritis, rotator cuff injury, bicipital tendonitis
- Atherosclerotic or thromboembolic disease

TREATMENT

ED TREATMENT/PROCEDURES

- Heparinization if signs of arterial or venous thrombosis
- Vascular surgery consult for signs of ischemia and for catheter-directed thrombolysis if needed:
 - Anticoagulation and thrombolysis followed by surgical decompression is required for thrombosis
- Initial management:
 - The majority improve with conservative treatment consisting of physical therapy and medications for symptomatic relief.
- Surgery reserved for failure of medical therapy:
 - Often required for vascular forms
 - People with NTOS often undergo more extensive evaluation and medical management prior to surgical intervention
 - 70–90% of patients experience some to complete relief postoperatively.

MEDICATION

- Cyclobenzaprine: 10 mg PO TID
- Diazepam: 5 mg PO TID
- Ibuprofen: 800 mg PO TID
- Methocarbamol: 1,000–1,500 mg PO TID
- Soothing liniments or ointments

FOLLOW-UP

DISPOSITION

Admission Criteria

- Ischemia
- Venous thrombosis
- Arterial thrombosis
- Arterial aneurysm or stenosis
- Intractable pain

Discharge Criteria

- Nonlimb-threatening neurologic findings
- Absence of arterial or venous thrombosis

FOLLOW-UP RECOMMENDATIONS

Vascular, neurologic, or orthopedic consultation is indicated according to the pathologic condition.

PEARLS AND PITFALLS

- 3 types of TOS: Neurogenic, arterial, and venous:
 - Neurogenic is most common in adults.
 - ATOS and VTOS are the more common types in children and adolescents.
- VTOS is the only type that has arm swelling and edema.
- Both NTOS and ATOS have hand coldness and pallor, but for different reasons.
- May have a history of repetitive use or trauma
- Exam or imaging may reveal a congenital abnormality such as a cervical rib.

THROMBOTIC THROMBOCYTOPENIC PURPURA

Hany Y. Atallah

BASICS

DESCRIPTION

- Thrombotic thrombocytopenic purpura (TTP) is a severe disorder of abnormal clotting affecting multiple organ systems.
- Classically characterized by pentad of:
 - Thrombocytopenia
 - Hemolytic anemia
 - Mild renal dysfunction
 - Neurologic signs
 - Fever
- Uncommon to see all 5 features in 1 patient; if present, severe end-organ damage or ischemia has likely taken place.
- Thrombocytopenia and hemolytic anemia are the most common features.
- Associated with acquired or congenital deficiency of plasma von Willebrand factor–cleaving protease (VWFcp)
- Patients who present with severe neurologic abnormalities with acute renal failure are best described by the comprehensive term TTP-HUS

Classic Course

- Acute onset
- Fulminant course lasting days to a few months
- Nearly always fatal without treatment:
 - >90% mortality without treatment
 - Reverses to >90% survival with modern treatment
- Clinical presentations include:
 - Idiopathic
 - Familial, chronic, or relapsing
 - Drug induced:
 - Allergic or immune mediated (quinine, ticlopidine, clopidogrel)
 - Dose-related toxicity (mitomycin C, cyclosporine)
 - Pregnancy, postpartum associated:
 - 10–25% of cases
 - Bone marrow transplantation associated
 - Infection
- More common in the 3rd–6th decades of life
- Uncommon in pediatric or geriatric populations
- Women affected about twice as frequently as men

ETIOLOGY

- Unknown primary stimulant; possibly systemic endothelial cell damage results in inactivation of coagulation pathway
- Platelet aggregation and fibrin deposition occurring in arterioles and capillaries leading to microthrombi and obstruction to blood flow
- Platelet aggregation leads to:
 - Consumption of platelets
 - Widespread microvascular hyaline thrombotic lesions
- Microvasculature obstruction with platelet aggregates leads to:
 - Red cell hemolysis
 - Accumulation of heme breakdown products
 - Anemia
- End-organ ischemia results from diffuse thrombosis in small vessels:
 - Most common in heart, brain, kidney, pancreas, and adrenal glands
- Deficiency of vWFcp causes failure of control of coagulation pathway.

RISK FACTORS

Genetics

- Some cases are genetic/familial.
- vWFcp was recently identified as new member of ADAMTS family and designated ADAMTS13.
- Mutations in ADAMTS13 gene cause autosomal recessive form of chronic relapsing TTP.

DIAGNOSIS

SIGNS AND SYMPTOMS

5 major clinical features: Classic pentad

- Thrombocytopenia:
 - Platelet count $< 20,000/\text{mm}^3$
- Microangiopathic and hemolytic anemia:
 - Hb $< 10 \text{ g/dL}$ ($< 6 \text{ g/dL}$ in 40%)
- Neurologic symptoms:
 - Presenting complaint in 60%, occur in 90%
 - Typically fluctuating
 - Headache
 - Altered mentation (confusion, stupor, coma)
 - Behavioral or personality changes
 - Focal sensory or motor deficits or aphasia
 - Seizures
 - Spontaneous intracranial hemorrhage

- Renal insufficiency:
 - Usually mild
 - Creatinine < 3 mg/dL
- Fever:
 - Occurs in acute episodes and prodromal syndromes
 - Fever is the least common feature
- Rare for all components of pentad to be present in the same individual

History

- General:
 - Weakness
 - Fatigue
 - Fever
 - Malaise
- Hemorrhage:
 - Easy bruising
 - Epistaxis
 - Menorrhagia
 - GI bleeding
 - Loss or change in vision
- GI complaints:
 - Anorexia
 - Diarrhea
 - Abdominal pain
- Neurologic:
 - Headache
 - Confusion
 - Seizure
 - Behavioral or personality changes
 - Focal sensory or motor deficits or aphasia

Physical-Exam

- Purpura
- GI hemorrhage
- Epistaxis
- Jaundice
- Shock
- Altered mental status
- Focal sensory or motor deficits
- Pulmonary infiltrates and edema
- Alteration of vision, retinal hemorrhage/detachment.
- Abnormalities of cardiac conduction

ESSENTIAL WORKUP

Clinical Diagnosis

- Because of success of treatment, base diagnosis on:
 - Identification of 2 major findings:
 - Thrombocytopenia
 - Microangiopathic hemolytic anemia
 - Exclude other major differential diagnoses.
- Comprehensive history and physical exam with directed lab testing
- Identify possible drug-associated disease and avoid re-exposure.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC/platelet count/reticulocyte count:
 - Anemia: Hemoglobin < 10 g/dL
 - Thrombocytopenia < 20,000/mm³
 - Increased reticulocyte count
- Coagulation studies:
 - Normal
- Peripheral blood smear:
 - Macroangiopathic changes
 - Schistocytes
 - Helmet cells
 - Nucleated RBCs
- Coombs test:
 - Negative direct Coombs test
- Electrolytes, BUN, creatinine, glucose:
 - Mild elevation of BUN, creatinine
 - Hyperkalemia owing to RBC lysis
- Lactate dehydrogenase (LDH):
 - Elevated 5–10 times due to hemolysis and tissue ischemia
- Bilirubin:
 - Increased unconjugated bilirubin
- Urinalysis:
 - Hematuria (microscopic to gross)
- ADAMTS13 assay may be used to distinguish chronic recurring TTP, TTP secondary to presence of ADAMTS13 inhibitor, and hemolytic-uremic syndrome (HUS):
 - ADAMTS13 deficiency does not detect all patients who may respond to plasma exchange transfusions.

Imaging

- CT head:
 - To rule out intracranial hemorrhage

Diagnostic Procedures/Surgery

- Biopsy:
 - Confirms diagnosis
 - Reveals hyaline lesions in small vessels
 - Contraindicated during fulminant presentation (hemorrhage risk)
- EEG:
 - To predict need for anticonvulsant therapy

DIFFERENTIAL DIAGNOSIS

- HUS:
 - Triad of thrombocytopenia, schistocytosis, and renal dysfunction
 - Neurologic symptoms unusual
 - Often preceded by infectious prodrome and diarrhea
- Disseminated intravascular coagulation (DIC):
 - Causes deposition of fibrin in microvasculature and not hyaline
 - Coagulation studies abnormal
- Idiopathic thrombocytopenic purpura (ITP):
 - No evidence of hemolysis
 - LDH and bilirubin normal
- Pregnancy-related thrombocytopenia:
 - Preeclampsia, eclampsia
 - Pregnancy-associated hemolysis
 - HELLP (hemolysis, elevated liver enzymes, and low platelets)
- Evans syndrome:
 - Autoimmune hemolytic anemia
 - Prominence of microspherocytes rather than schistocytes
 - Positive direct Coombs test
- Malignant hypertension
- Bacterial sepsis
- Subacute bacterial endocarditis
- Autoimmune disorders (e.g., systemic lupus erythematosus [SLE])
- Disseminated malignancy
- Heparin-associated thrombocytopenia
- Prosthetic valves or severely calcified aortic stenosis

TREATMENT

PRE HOSPITAL

- ABCs

- Evaluate for other possible causes of altered mental status (hypoglycemia, overdose)

INITIAL STABILIZATION/THERAPY

- ABCs
- 0.9% normal saline (NS) IV fluid resuscitation for shock or GI hemorrhage
- RBC transfusions:
 - _ For significant anemia or bleeding complications
- Platelet transfusions:
 - _ Reserve for life-threatening hemorrhage (e.g., CNS bleeds) or required invasive procedures
 - _ May aggravate the thrombotic, microvascular obstructive process and worsen the end-organ ischemia and shock

ED TREATMENT/PROCEDURES

- *Fresh frozen plasma* (FFP) or fresh unfrozen plasma:
 - _ Initiated as bridge to exchange transfusions on diagnosis of TTP
 - _ Success rate approaching 64%
 - _ Provides a platelet-antiaggregating factor absent or diminished in patient's own serum
 - _ Used prophylactically to prevent recurrence in chronic relapsing variant
- Plasma exchange transfusions:
 - _ Most important component of treatment
 - _ Combination of plasmapheresis and FFP infusion
 - _ Plasmapheresis removes:
 - Immune complexes responsible for endothelial damage and initiation of TTP
 - Circulating proaggregation factors promoting platelet aggregation
 - _ Perform daily until:
 - Platelet count normalizes
 - Neurologic symptoms improve
 - LDH normalizes
 - _ Improvement of renal function may lag behind other findings.
 - _ Taper frequency based on empiric judgment of response; may need to resume if relapse occurs.
 - _ Complications include:
 - Allergy or serum sickness
 - Secondary infection
 - Hypotension
- Corticosteroids:
 - _ Unproven therapeutic benefit
 - _ May limit immunologically mediated endothelial damage and decrease splenic sequestration of platelets and damaged RBCs

- Supportive benefit if adrenal glands damaged through hemorrhage or ischemia
- Antiplatelet or immunosuppressive drugs:
 - Aspirin and dipyridamole most commonly used
 - Use of sulfapyrazine, dextran, and vincristine has been reported.
 - Used with variable effectiveness
 - Can worsen bleeding complications
- Splenectomy:
 - Historically recommended
 - Of uncertain efficacy
- Dialysis:
 - For renal failure

MEDICATION

- Aspirin: 325–650 mg PO q4–6h
- Dipyridamole: 75–100 mg PO QID
- FFP:
 - Plasma infusion: 30 mL/kg/d (75–100 mL/h)
 - Plasma exchange transfusion: 3–4 L/d
- Methylprednisolone: 0.75 mg/kg q12h
- Prednisone: 1–2 mg/kg/d (high dose up to 200 mg/d)
- Rituximab: 375 mg/m² IV once per week for 4–8 doses
- Vincristine: 1.4 mg/m² once per week IV

FOLLOW-UP

DISPOSITION

Admission Criteria

- Newly diagnosed serious platelet disorder, especially with bleeding complications or altered mental status or renal dysfunction
- ICU admission for TTP with active bleeding or neurologic findings:
 - Transport to tertiary care center with appropriate specialty care facilities.

FOLLOW-UP RECOMMENDATIONS

Patients with known disease and found to be stable may follow up with a hematologist.

PEARLS AND PITFALLS

- TTP can be confused with HELLP syndrome in pregnant females.
- Because of the high mortality of untreated TTP, recognition of the disease and initiation of treatment is key.

THUMB FRACTURE

Daniel R. Lasoff • Leslie C. Oyama

BASICS

DESCRIPTION

- Distal phalangeal fractures:
 - Blunt trauma, hyperextension of the thumb, axial loading of the thumb, and crush injuries.
 - *Tuft fracture* is a similar fracture in other digits, in which the distal phalanx is crushed and/or fragmented.
 - It may be open or closed and associated with nail bed injury.
 - Severe nail bed injury, intra-articular, displaced/angulated fractures, or tendon injuries warrant orthopedics' consultation.
 - Noncomplex tuft fractures can be splinted and treated as soft tissue injuries.
- Proximal phalangeal fractures and thumb metacarpal fractures:
 - Blunt trauma to the thumb:
 - Axial loading of the thumb with the metacarpophalangeal (MP) joint partially flexed, the hand closed or the thumb MP joint otherwise stabilized
 - Bennett fracture (type I):
 - Intra-articular fracture/dislocation at the base of the metacarpal where the ulnar aspect of the metacarpal maintains its attachment.
 - Rolando fracture (type II):
 - Comminuted Y- or T-shaped intra-articular fracture of the base of the 1st metacarpal.
 - Similar to a comminuted Bennett, these can be much more complex with multiple comminuted fractures.
 - Type III fractures
 - Extra-articular metacarpal fractures. Tend to be transverse or less commonly oblique.

ETIOLOGY

- Falls, hyperflexion, hyperextension
- Motor vehicle accidents
- Sports, especially downhill or alpine skiing
- Basketball
- Baseball
- Football
- Rugby

 **DIAGNOSIS****SIGNS AND SYMPTOMS**

- Pain, swelling, and deformity of the thumb
- Exam should include the thenar eminence for pain or deformity.
- The thumb may be rotated distal to the fracture site.
- The base of the thumb may appear radially deviated relative to the rest of the hand in the resting position.
- Occasionally, there may be damage to the thumb digital nerves.

Pediatric Considerations

- Fractures to the thumb sometimes occur in children.
- Consider nonaccidental trauma.
- Do not neglect appropriate pain management in children.

Physical-Exam

- Immobilize the thumb pending definitive evaluation.
- Neurovascular exam with 2-point discrimination.

ESSENTIAL WORKUP

Radiography as noted below

DIAGNOSIS TESTS & NTERPRETATION***Imaging***

- Plain radiography of affected areas
- Avoid testing stress of thumb MP joint, as in testing for gamekeeper thumb, until all plain radiography is complete.

DIFFERENTIAL DIAGNOSIS

- Extra-articular fracture of the base of the thumb metacarpal
- Scaphoid fracture
- Gamekeeper thumb: Ulnar collateral ligamentous injury

 **TREATMENT****PRE HOSPITAL**

- Dress open wounds.
- Immobilize hand and wrist with thumb in neutral position.
- Elevate and apply cold to reduce swelling.
- Age-appropriate social management

INITIAL STABILIZATION/THERAPY

Immobilize thumb pending definitive evaluation.

ED TREATMENT/PROCEDURES

- Thumb spica splint with the thumb in neutral position, as if holding a beverage can
- Splint instructions should be provided to patient.
- Angulated extra-articular fractures of the 1st metacarpal require reduction. Can tolerate up to 30° of angulation. Angulation > 30° requires another attempt at reduction or orthopedics' consultation.
- Distal phalangeal fractures require DIP splint in extension for 3–4 wk.

MEDICATION

Pain control with oral analgesic preparations

FOLLOW-UP

DISPOSITION

Admission Criteria

Open fracture, presence of multiple trauma, or other more serious injuries

Discharge Criteria

- Counsel the patient that there is a strong likelihood of the need for operative repair for 1st metacarpal injuries.
- Closed injuries: Referral, splinting, and explain frequent need for operative fixation

Issues for Referral

72-hr orthopedic referral

PEARLS AND PITFALLS

Due to tendon insertions, fractures at the base of thumb are often unstable and frequently require operative fixation

TIBIAL PLATEAU FRACTURE

Sarah V. Espinoza • Leslie C. Oyama

BASICS

DESCRIPTION

- Synonym: Tibial condylar fracture
- Fracture or depression of the proximal tibial articulating surface
- Valgus or varus force applied in combination with axial loading onto tibial plateau

Schatzker Classification of Plateau Fractures

- Type 1:
 - Split fracture of the *lateral* tibial plateau *without* depression of the plateau
- Type 2:
 - Split fracture *and* depression of *lateral* tibial plateau
 - Associated with lateral meniscus injury
- Type 3:
 - Central depression of the *lateral* plateau
 - Injuries may be unstable
- Type 4:
 - Split of the *medial* tibial plateau
 - Can cause damage to other structures:
 - Popliteal vessels
 - Peroneal nerve
 - MCL
 - Lateral meniscus
 - Lateral collateral ligament
 - Cruciate ligaments
 - Tibial spines
 - Compartment syndrome
- Type 5:
 - Bicondylar tibial plateau fracture
 - Same associated injuries as type 4
- Type 6:
 - *Bicondylar*, grossly comminuted fracture of the plateau
 - Diaphyseal–metaphyseal dissociation
 - Same associated injuries as types 4 and 5

ETIOLOGY

- Mechanism of injury:
 - Types 1 & 2 from a valgus force with axial loading, generally a low-energy

injury

- Associated with contact sports, twisting motions (e.g., skiing) or classically, pedestrians struck by a vehicle bumper
- Type 3 are low-energy injuries in osteopenic bone
- Types 4–6 are high-energy injuries usually from motor vehicle/cycle collisions and falls from height causing medial plateau fractures
 - Associated with neurovascular injuries
- Age associated
 - Type 1: Younger patients with cancellous bone of the plateau resists depression.
 - Types 2 & 3: Depression fractures seen in osteopenic older bones

Pediatric Considerations

Tibial plateau fractures are rare in children because of the dense cancellous bone of the tibial plateau

DIAGNOSIS

SIGNS AND SYMPTOMS

- Painful swollen knee
- Inability to bear weight
- Knee effusion (hemarthrosis)
- Active and passive range of motion limited
- Tender along the proximal tibia and joint line
- Possible varus or valgus deformity of the knee
- Possible joint instability due to associated ligamentous injury

History

- Hit to lateral knee
- Fall from a height with axial load
- Twisting injury

Physical-Exam

- Decision tools for the use of radiography:
 - Ottawa knee rules (highly sensitive): Knee radiographs are indicated if *any* of the following are present:
 - Age > 55 yr
 - Tenderness of the fibular head
 - Inability to flex to 90°
 - Isolated patellar tenderness
 - Inability to transfer weight for 4 steps both immediately after the injury and in the ED

- Limping is allowed.
- Pittsburgh knee rule (highly sensitive and specific): Knee radiographs are indicated in fall or blunt trauma when the following are present:
 - Age <12 or >55 yr
 - Inability to bear full weight for 4 steps in the ED
 - Limping is *not* allowed
 - Pittsburgh knee rule should be applied with caution to patients <18 yr old
- Neurovascular exam:
 - High-energy mechanism carries risk for neurovascular injury and compartment syndrome
 - Watch for unrelenting pain, muscle weakness, tense muscle swelling, hypesthesia or anesthesia, pain with passive stretch of muscles
 - Check popliteal, posterior tibial, and dorsalis pedis pulses
 - Check integrity of peroneal nerve:
 - Ankle and great toe dorsiflexion
 - Sensation in dorsal web space between great and 2nd toes

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- Plain radiography:
 - Tibial plateau view:
 - Anteroposterior (AP) view angled at 10–15° of flexion to evaluate the tibial spines, fracture lines extending into the joint, and depressions
 - Sunrise view of the patella:
 - Useful in identifying fractures of the patella not visualized on AP or lateral views
 - Cross-table lateral view:
 - To evaluate the medial plateau and reveal lipohemarthrosis (fat–fluid level)
 - Oblique view:
 - To identify fractures not apparent on other films and provide more information on fracture patterns
 - Pay attention to areas of ligamentous attachment where avulsion fractures may take place:
 - Medial and lateral femoral condyles
 - Tibial spine (intercondylar eminence)
 - Fibular head
- CT used to reveal occult fracture(s) not seen on plain film & further characterize known fracture
- MRI used for identifying soft tissue injuries (ligamentous and meniscal injuries)
- Arteriography helpful in localizing the injured area but should not delay

revascularization and is indicated if:

- High-energy mechanism
- Schatzker type 4, 5, or 6 fracture
- Alteration in distal pulses
- Expanding hematoma
- Bruit
- Injury to anatomically related nerves

Diagnostic Procedures/Surgery

- Arthrocentesis to look for fat globules and bone marrow elements indicative of intra-articular fracture:
 - Indication to do procedure: Effusion present without fracture on plain radiographs
- Compartment pressure measurements are indicated if:
 - Pain not over fracture site
 - Pain on passive stretch
 - Paresthesias
 - Decreased distal pulses
 - Intracompartmental pressures > 30 mm Hg are an indication for emergent orthopedic consultation

DIFFERENTIAL DIAGNOSIS

- Knee dislocation
- Proximal fibular fracture
- Femoral condyle fracture
- Patellar fracture
- Tibial subcondylar fracture
- Tibial tuberosity fracture
- Tibial spine fracture
- Cruciate ligament tears
- Collateral ligament tears
- Meniscal tears

Pediatric Considerations

Include oblique views as part of routine radiography

TREATMENT

PRE HOSPITAL

Cautions:

- In high-energy mechanisms, associated major injuries take precedence
- Immobilize to prevent further neurologic or vascular injury

INITIAL STABILIZATION/THERAPY

- Stabilization of the multiple-injury trauma patient
- Long leg splint in full extension
- Ice
- Elevation
- Frank dislocations with vascular compromise may need immediate reduction in ED

ED TREATMENT/PROCEDURES

- Nonweight bearing
- Pain control
- Nondisplaced fractures or minimally displaced (< 8 mm) *lateral* plateau fractures without ligamentous injury:
 - Aspiration of hemarthrosis and injection of local anesthetic
 - Exam for ligamentous instability
 - If knee is *stable*:
 - Compressive dressing
 - Ice and elevation for 48 hr
 - No weight bearing/crutches
 - Knee is *unstable* if fracture is causing vascular injury or compartment syndrome
 - Urgent orthopedic consultation is warranted in the unstable knee
- Open fractures:
 - Remove contaminants
 - Apply moist sterile dressing
 - Assess tetanus immunity
 - Antibiotics
 - Early administration of antibiotic, within 2–3 hr
 - Orthopedics consult for early surgical débridement

MEDICATION

Open fractures: Aminoglycoside + Cephalosporin

- Cefazolin: 2 g IV (peds: 50 mg/kg)
- Gentamicin: 2–5 mg/kg IV (peds: 2.5 mg/kg)
- Tetanus toxoid if indicated
- Vancomycin: 1 g IV loading dose (peds: 10 mg/kg) if penicillin allergic

FOLLOW-UP

DISPOSITION

Admission Criteria

- Open fractures for débridement, irrigation, and IV antibiotics

- Comminuted, bicondylar fractures for traction
- High-energy mechanisms for observation of neurovascular status and development of compartment syndrome; may occur 24 or more after injury
- Pain control

Discharge Criteria

Nondisplaced or minimally displaced, stable fractures of the lateral plateau

FOLLOW-UP RECOMMENDATIONS

Orthopedic follow-up:

- Long leg splint with ice, elevation, and nonweight-bearing status of affected joint

PEARLS AND PITFALLS

- Consider popliteal artery injury with high-energy mechanisms of injury
- Lipoarthrosis (blood and fat globules) on arthrocentesis, is pathognomonic for intra-articular knee fracture
- Tibial plateau fractures, Segond fractures, and Salter–Harris 1 fractures are easily missed on plain knee radiographs

TIBIAL/FIBULAR SHAFT FRACTURE

Stephen R. Hayden

BASICS

DESCRIPTION

Fracture Description

Tibia

- 80% have associated fibular fractures
- Open (24% are open) vs. closed
- Extent of soft tissue damage
- Gustilo–Anderson classification of open fractures:
 - Type I:
 - Wound < 1 cm
 - Little soft tissue damage
 - No crush injury
 - Type II:
 - Wound > 1 cm
 - Moderate soft tissue damage
 - Little or no devitalized soft tissue
 - Type III—severe soft tissue injury:
 - A—adequate soft tissue coverage of bone
 - B—tissue loss/periosteal stripping
 - C—neurovascular injury requiring surgery
- Anatomic location:
 - Proximal, middle, or distal 3rd
 - Articular extension
- Displacement
- Degree of shortening
- Angulation
- Configuration:
 - Spiral, transverse, or oblique
 - Comminuted, with butterfly fragment or multiple fragments

Fibula

- Proximal:
 - Associated with peroneal nerve injury
 - Disruption of ankle syndesmosis (Maisonneuve fracture)
- Middle
- Distal

Pediatric Considerations

- 3rd most common long bone fracture in children
- 2nd most common long bone fracture in nonaccidental trauma (usually apophyseal or metaphyseal corner)
- Nonphyseal fracture patterns:
 - Compression (torus): Distal metaphysis
 - Incomplete tension–compression (greenstick)
 - Plastic/bowing deformity of fibula may occur.
 - Complete fractures
- Physeal fracture patterns:
 - Tibial shaft fractures may extend to the physis in Salter–Harris II pattern.

ETIOLOGY

- High- vs. low-energy injury
- Amount of soft tissue injury is prognostic and determined by the degree of energy involved.
- Indirect force—frequently low-energy trauma:
 - Rotary and compressive forces often result in oblique and spiral fractures.
- Skiing, fall, child abuse
- Direct force—high-energy trauma:
 - Direct blow to leg often results in transverse and comminuted fractures.
- Pedestrian vs. auto, motor vehicle crash (MVC):
 - Bending force over a fulcrum often produces comminution with a wedge-shaped butterfly fragment.
- Skier's boot top, football tackle, MVC

Pediatric Considerations

- Bicycle spoke injury:
 - Foot and lower leg get caught between frame and wheel spoke
 - Crush injury is the primary problem.
 - Initial benign appearance of the soft tissues is often deceiving:
 - Full-thickness skin loss can occur in days.
 - Orthopedic surgery consultation should be obtained for all spoke-injury patients with associated fractures.
- Toddler fracture:
 - Spiral fracture involving the distal 3rd of the tibia with intact fibula secondary to rotational force (turning on planted foot)
 - Age range is 9 mo–6 yr, most often when learning to walk.
 - Fractures in midshaft or more transverse are suggestive of nonaccidental trauma.

SIGNS AND SYMPTOMS

History

- History of trauma
- Pain is usually immediate, severe, and well localized to the fracture site.

Physical-Exam

- Visible or palpable deformity at the fracture site
- Significant soft tissue damage with high-energy trauma
- Inability to bear weight if tibia involved:
 - _ May be able to walk if isolated fibular fracture
- Foot drop on affected leg from injury to the peroneal nerve as it wraps around the fibular head
- Compartment syndrome

Pediatric Considerations

- Rely on parents for historical information.
- Child may present limping with no obvious deformity.

ESSENTIAL WORKUP

- Careful assessment of soft tissues
- Careful neurovascular exam (compare with contralateral side)
- Examine for associated injuries.
- Completely expose patient and put into gown.
- Assessment for compartment syndrome

ALERT

- Compartment syndrome
- Occurs in 8% of diaphyseal fractures, more common in younger patients
- Relatively common complication of tibial fractures and may not appear until 24 hr after injury
- Pain disproportionate to that expected
- Patient may have swollen, tight compartment, but does not always have pain on palpation of compartment.
- Pain on passive stretch of foot, toes
- Sensory deficit
- Motor weakness is a late finding.
- Pulselessness is not a sign of compartment syndrome:
 - _ Palpable pulses are almost always present in compartment syndrome unless there is underlying arterial injury.
- 4 leg compartments: Anterior, lateral, deep posterior, and superficial posterior
- Anterior compartment:
 - _ Deep peroneal nerve

- Sensation of 1st web space
- Ankle and toe dorsiflexion
- Anterior tibial artery feeds dorsalis pedis artery
- Lateral compartment:
 - Superficial peroneal nerve
 - Sensation of dorsum of foot
 - Foot eversion
- Deep posterior compartment:
 - Tibial nerve
 - Sensation to sole of foot
 - Ankle and toe plantar flexion
 - Posterior tibial and peroneal arteries
- Superficial posterior compartment:
 - Branch of sural cutaneous nerve
 - Sensation to lateral foot

DIAGNOSIS TESTS & INTERPRETATION

Lab

Include creatine phosphokinase levels if concerned about compartment syndrome

Imaging

- Anteroposterior and lateral views of the leg, knee, and ankle
- Bone scan at 1–4 days for toddler fracture and stress fractures if radiographs unrevealing
- CT scan for complex fracture pattern to evaluate for rotational malalignment
- CT or MRI for pathologic fracture
- MRI for stress fractures may be necessary.

Diagnostic Procedures/Surgery

Compartment pressures:

- Pressures > 30 mm Hg are an indication for orthopedic consultation and fasciotomy.
- Delta P or difference between diastolic BP and compartment pressure < 20 is indicative of compartment syndrome
- Repeated pressure measurements over time, taken within 5 cm of fracture site, are necessary.

Pediatric Considerations

Oblique radiograph to detect nondisplaced fractures

DIFFERENTIAL DIAGNOSIS

- Stress fracture

- Pathologic fracture
- Osteomyelitis

Pediatric Considerations

- Sarcoma
- Pathologic fracture
- Osteomyelitis
- Nonaccidental trauma

TREATMENT

PRE HOSPITAL

- Look for associated injuries in high-energy mechanisms.
- Assess for neurologic or vascular compromise.
- Adequate immobilization is essential to prevent further injury.

INITIAL STABILIZATION/THERAPY

- Manage airway and resuscitate as indicated.
- Life-threatening injuries take precedence.
- Immobilize extremity.
- Apply ice
- Strict NPO
- Pain control

ED TREATMENT/PROCEDURES

- Closed fractures:
 - Gentle attempt at reduction if fracture is displaced (do not attempt multiple reductions; may increase risk for compartment syndrome).
 - Immobilization:
 - Well-padded long leg posterior splint
 - Knee in 10–20° of flexion
 - Avoid circumferential cast.
 - If pain persists after immobilization, suspect:
 - Compartment syndrome
 - Avoid elevation of leg in suspected compartment syndrome; it lowers perfusion to the extremity.
 - Nerve compression
 - Crutches
- Open fractures:
 - Remove contaminants and cover wound with moist, sterile dressing.
 - Antibiotics
 - Tetanus prophylaxis

- Immobilization with well-padded long leg posterior splint
- Immediate orthopedic surgery consultation for débridement and fracture fixation
- Isolated fibular fracture:
 - Usually treated symptomatically:
 - Padded splint
 - Elevation
 - Ice
 - No weight bearing until swelling resolves
 - Crutches if not bearing weight

MEDICATION

- Gram-positive cocci coverage for open fractures: Cefazolin 2 g loading dose then 1 g (peds: 50 mg/kg/d) IV/IM q8h
- Gustilo–Anderson type III, add gram-negative rod coverage: Gentamicin 3–5 mg/kg (peds: 2.5 mg/kg) IV q8h
- Farming accident, add *Clostridium* spp coverage: Penicillin G 10 million IU (peds: 250,000–400,000 IU/kg/d) IV q6h
- Tetanus 0.5 mL IM and tetanus immune globulin 250 U IM as indicated by the type of wound and the number of primary immunizations
- If penicillin allergic: Vancomycin 1 g (peds: 10 mg/kg) IV q12h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Multiple trauma
- High-energy mechanism
- Soft tissue involvement
- Risk for compartment syndrome
- All open fractures
- Displaced, angulated, transverse, shortened, comminuted, and otherwise unstable fractures
- Intra-articular involvement
- Neurovascular compromise
- Inadequate pain control
- Pathologic fracture
- Nonaccidental trauma in children

Discharge Criteria

- Minimally displaced fracture with low-energy injury mechanism

- Close orthopedic follow-up
- Return parameters for compartment syndrome in a reliable patient
- If fracture is >48 hr old, compartment syndrome is unlikely to develop; if it has not occurred, discharge criteria may be more liberal.

FOLLOW-UP RECOMMENDATIONS

- Most pediatric fractures are treated with long leg cast for 4–6 wk.
- Nondisplaced and minimally displaced fractures in adults may be treated with long leg cast and closed reduction.
- Open contaminated fractures may be treated with external fixation and débridements.
- Treatment with intramedullary nail allows for early mobilization and weight bearing as tolerated.
- Kirschner wires are sometimes used in the treatment.

PEARLS AND PITFALLS

- High incidence of associated injuries in high-energy trauma:
 - Associated injuries commonly include:
 - Femoral fractures (“floating knee injury”)
 - Head trauma
 - Spine fractures
 - Deep venous thrombosis occurs in 10–25% of patients following tibial fracture.

ADDITIONAL READING

TICK BITE

Jonathan A. Edlow

BASICS

DESCRIPTION

Even in high endemic areas for tick-borne diseases, the risk of infection with a tick-borne pathogen is very low. After a tick bite, patient concerns include:

- Tick removal
- Local effect of the bite
- Possibility of acquiring a tick-borne illness:
 - Fear of contracting Lyme disease
 - Desire to be tested or treated for Lyme

ETIOLOGY

- Specific tick-borne infections are discussed in other chapters.
- Tick bite can be from different species of ticks of 2 major types:
 - Soft ticks (*Ornithodoros*):
 - Cause tick-borne relapsing fever
 - Only feed for minutes and therefore almost never provoke a visit to the ED
 - Hard ticks—especially *Ixodes* and *Dermacentor*:
 - Feed for several days to a week and therefore, more likely to be noticed by patient and lead to an ED visit
- Lyme disease transmission:
 - Species of tick, stage of development, duration of attachment, and geography may all play a role in the possibility of developing Lyme disease.
 - Most cases of Lyme are associated with bites from nymphal *Ixodes scapularis* ticks.
 - Most cases of Lyme are transmitted only after the tick has been attached for 24–48 hr:
 - Degree of engorgement is a marker for duration of attachment.

DIAGNOSIS

SIGNS AND SYMPTOMS

Tick is attached to skin.

History

- The patient usually has made the diagnosis themselves, although sometimes they mistake the tick for skin tags or other skin lesions.

- Ask regarding duration of tick attachment, as this may influence the decision to prescribe antibiotic prophylaxis.

Physical-Exam

Directly examine the skin and the tick:

- Try to identify the tick species.
- Estimate degree of engorgement.

ALERT

- Some tick-borne infections are potentially fatal. Because there are no confirmatory diagnostic tests that are available in real time, they must be diagnosed based on history, physical, and epidemiologic context.
- Because the drug of choice for some of these infections—doxycycline—is not usually prescribed for empiric therapy for acutely ill febrile patients, ask about the potential for tick bites in the history of febrile patients and consider using this drug in the appropriate settings.

ESSENTIAL WORKUP

Accurate history and physical exam searching for presence of tick

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Testing for Lyme disease is *not* indicated:
 - Such antibody testing would only reflect prior exposure to *Borrelia burgdorferi*
 - No treatment implications whatsoever for the current bite

Diagnostic Procedures/Surgery

- Testing of the tick itself is not recommended.
- See treatment for tick removal.

DIFFERENTIAL DIAGNOSIS

- Tick-borne diseases in North America:
 - Lyme disease
 - Other Lyme-like diseases such as Southern tick-associated rash illness (STARI) and *Borrelia miyamotoi* infection
 - Babesiosis
 - Anaplasmosis (formerly ehrlichiosis)
 - Rocky Mountain spotted fever (RMSF)
 - Relapsing fever
 - Tularemia
 - Colorado tick fever

- Q-fever
- Tick-borne encephalitis (Powassan fever)
- Tick paralysis
- Additional tick-borne diseases found in Europe:
 - Tick-borne encephalitis
 - Boutonneuse fever (*Rickettsia conorii*)
 - Other spotted fever rickettsiae

TREATMENT

INITIAL STABILIZATION/THERAPY

Remove tick:

- Early removal reduces the likelihood of transmission of tick-borne infections.

ED TREATMENT/PROCEDURES

- Tick removal method:
 - Grasp the tick with very fine forceps, as close to the skin as possible, and gently lift up over 30–120 sec.
 - Most ticks will come out.
 - Do not to squeeze the tick, which could inject infectious materials into the patient's skin.
 - If mouthparts are left in the skin, although this could lead to local infection or foreign body reaction, it has no implications for transmission of tick-borne diseases.
- Another described method:
 - Inject an intradermal wheal of lidocaine with epinephrine beneath the tick.
 - Tick may crawl out of its own accord.
- Methods *not* to use include:
 - Burning the tick with a match
 - Covering it with petroleum jelly or other noxious agents
- Lyme disease prophylaxis:
 - Indicated if the tick is an engorged *I. scapularis* nymph is found within 72 hr of the bite, or if the physician decides to prophylax
 - Doxycycline 200 mg for 1 dose
 - For children, there is no studied single-dose regimen:
 - Prescribe amoxicillin (25–50 mg/kg) for 10 days in divided doses.
 - No data support prophylactic antibiotics for other tick-borne diseases.

Pediatric Considerations

- Several studies used 10 days of amoxicillin in children for prevention of Lyme disease.
- No patients in the treated groups developed Lyme or seroconverted.

- Tick paralysis is a rare disease but usually occurs in children, especially in girls with long hair; never diagnose Guillain–Barré syndrome without doing a thorough inspection of the entire body, especially the scalp, for ticks.

Pregnancy Considerations

Although there are no high quality data on antibiotic prophylaxis for Lyme disease in pregnant women, some authors recommend having a very low threshold for treating pregnant women with tick bites (using amoxicillin).

MEDICATION

- Amoxicillin: 25–50 mg/kg in div. doses TID for 14–21 days
- Doxycycline: 200 mg PO for 1 dose

FOLLOW-UP

DISPOSITION

Admission Criteria

- Tick bite with symptoms or signs of tick paralysis or in patients who have an established tick-borne disease which is severe (e.g., hypotension or sepsis)
- Tick bite leading to systemic infection sufficiently severe to require admission (e.g., RMSF, anaplasmosis, babesiosis [especially in a splenectomized patient]).

Discharge Criteria

All other patients, the vast majority, are safely discharged.

FOLLOW-UP RECOMMENDATIONS

- Follow-up with primary care physicians if there are issues regarding local bacterial infection from the bite (cellulites) or subsequent symptoms and signs of 1 of the tick-borne infections listed above.
- Seek medical attention in the event of a febrile illness and to report the history of the tick bite to that physician.
- Patients who have been bitten by ticks should be counseled about future tick bite prevention, including potential use of DEET to the skin and permethrin-treated clothing.

PEARLS AND PITFALLS

- Early tick removal reduces the likelihood of transmission of tick-borne infections.
- Lyme disease prophylaxis is indicated if the tick is an engorged *I. scapularis* nymph.
- Consider babesiosis in splenectomized patients presenting with fever.

TINEA INFECTIONS, CUTANEOUS

Aaron J. Monseau

BASICS

DESCRIPTION

- Superficial fungal infections of the hair, skin, or nails:
 - Usually confined to the stratum corneum layer
 - Among the most common diseases worldwide
- Requires keratin for growth, so does not involve mucosa
- Named for location of infection

ETIOLOGY

- Dermatophytes:
 - *Microsporum*
 - *Trichophyton*
 - *Epidermophyton*
 - *Malassezia furfur*, a yeast, is the etiologic agent of tinea versicolor (not a true tinea)
- Trauma or maceration of the skin may allow fungal entry into skin
- Transmission may be person to person, animal to person, or soil to person

Pediatric Considerations

- Fungi can be spread from toys and brushes
- Tinea unguium is rare in children and is associated with:
 - Down syndrome
 - Immunosuppression
 - Tinea pedis or capitis

DIAGNOSIS

SIGNS AND SYMPTOMS

- Tinea capitis:
 - Children are predominately affected
 - Most contagious dermatophytosis
 - Alopecia, dandruff-like scaling
 - Kerion:
 - Boggy, inflammatory mass that exudes pus and causes cervical lymphadenopathy
 - “Black dots” from infected hairs broken off at the scalp
- Tinea corporis (“ringworm”):

- Arms, legs, and trunk
- Sharply margined, annular lesion with raised margins and central clearing
- Hair follicle involvement may produce indurated papules and pustules
- Lesions may be single, multiple, or concentric
- Pets are often a vector
- Tinea cruris (“jock itch”):
 - Erythematous, scaly, margined patches involving the perineum, thighs, and buttocks
 - Associated with heat, humidity, and tight-fitting undergarments
 - Unlike the case in candidiasis, the scrotum and penis are spared
- Tinea pedis (“athlete’s foot”):
 - Scaling, maceration, fissuring between the toes
 - Risk factors:
 - Advanced age
 - Immunocompromised status
 - Hot, humid climates
 - Infrequent changing of socks
 - More common in adults than children
 - Most common tinea infection in US
 - “Trichophytid” reaction:
 - Vesicular eruption remote from infection
 - Involving hands, mimics dyshidrotic eczema
- Tinea unguium:
 - 1 type of onychomycosis
 - Yellow or brown discoloration with thickening and debris under the nails
 - Onycholysis: Loosening of the nail from bed
 - May involve the plantar surface of the foot
- Tinea versicolor (not true tinea):
 - Most common in warm months
 - Round or oval superficial brown, yellow, or hypopigmented macules that may coalesce
 - Upper trunk, arms, and neck
 - Facial involvement is common in children

History

- Time of onset from inoculation to visible skin changes is about 2 wk
- Main symptom is itching:
 - Hair loss with tinea capitis
- Participation in contact sports or contacts with similar skin disease

Physical-Exam

- Tinea capitis: Alopecia, broken hairs at scalp surface
- Tinea corporis: Areas of exposed skin typically involved with annular scaly plaques, raised edges, may have pustules and vesicles
- Tinea cruris: Erythematous lesions on groin and pubic region with central clearing and raised edges
- Tinea pedis: Scaling, maceration, and fissuring of toe webs, often only 1 foot affected
- Tinea unguium: Separation of nail plate from nail bed with thickened, discolored, broken nails

ESSENTIAL WORKUP

- Diagnose by clinical exam
- If diagnosis is in doubt, confirm with microscopy before starting oral antifungals because of possible side effects

DIAGNOSIS TESTS & INTERPRETATION

Lab

Fungal cultures are slow growing and should not be routinely done

Imaging

Generally not indicated

Diagnostic Procedures/Surgery

- Wood lamp is insensitive:
 - *Trichophyton*, the most common cause of tinea infections, does NOT fluoresce
 - *Microsporum* fluoresces bright green
 - *Malassezia* (tinea versicolor) fluoresces yellow to yellow-green
 - Erythrasma (nontinea corynebacterial infection) will fluoresce coral red
- Microscopy:
 - Cleanse area with 70% ethanol
 - Scrape active margin of lesion with no. 10 or no. 15 scalpel blades
 - Place scrapings on a glass slide, add a drop of 10–20% potassium hydroxide solution, and cover with a coverslip
 - The presence of septate hyphae confirms dermatophyte infection
 - Budding yeasts and short hyphae (“spaghetti and meatballs”) confirms *Malassezia*

Pediatric Considerations

- Methods to obtain fungal elements for culture or microscopy:
 - Brushing the hair with a toothbrush
 - Rolling a moistened cotton swab
 - Collecting skin cells with transparent tape

DIFFERENTIAL DIAGNOSIS

- Tinea capitis: Impetigo, pediculosis, alopecia areata, seborrheic dermatitis, atopic dermatitis, and psoriasis
- Tinea corporis: Impetigo, herpes simplex, Lyme disease, verruca vulgaris, psoriasis, nummular eczema, granuloma annulare, herald patch of pityriasis rosea, erythema multiforme, urticaria, seborrheic dermatitis, and secondary syphilis
- Tinea cruris: Impetigo, seborrheic dermatitis, psoriasis, candidal infection, irritant and allergic contact dermatitis, and erythrasma
- Tinea pedis: Scabies, erythrasma, *Candida*, allergic and contact dermatitis, and psoriasis
- Tinea unguium: Psoriasis, dermatitis, lichen planus, and congenital nail dystrophy
- Tinea versicolor: Vitiligo, secondary syphilis

TREATMENT

PRE HOSPITAL

Maintain universal precautions.

INITIAL STABILIZATION/THERAPY

Only in immunocompromised or septic patients

ED TREATMENT/PROCEDURES

- Improvement usually occurs within 1–2 wk of treatment; hair and nail tinea require longer treatment of 3–6 mo
- Topical antifungals do not penetrate hair/nails:
 - Use in conjunction with systemic agent for tinea capitis or unguium.
- Tinea capitis:
 - Terbinafine is now considered the drug of choice by most:
 - Pill form may be crushed in food
 - Newer oral antifungals, including terbinafine, itraconazole, and fluconazole, are preferred:
 - Retained in tissues longer
 - Allows for shorter treatment courses without a decrease in efficacy
 - Improved compliance
 - Selenium sulfide or ketoconazole shampoo reduces transmissibility
 - Kerion may respond more rapidly with addition of prednisone (peds: 1 mg/kg PO QD for 2 wk)

ALERT

Terbinafine may be less effective than griseofulvin against *Microsporum* species causing tinea capitis; however, *Trichophyton* species are the predominant causative organism in children:

- Tinea corporis, cruris, and pedis:

- Topical terbinafine or imidazoles (ketoconazole, miconazole, and clotrimazole) are 1st-line agents:
 - Topical terbinafine has been shown to be as effective as or more effective than the imidazoles, with a shorter course
- Oral therapy may be necessary for cases resistant to topical treatment or for immunocompromised patients
- Keep the area dry (talc powders) and frequently change socks and underclothes
- Tinea unguium:
 - Requires oral therapy and longer course than other tinea infections
 - Terbinafine had a slightly higher cure rate than imidazoles (ketoconazole, miconazole, and clotrimazole) or griseofulvin in a meta-analysis
 - Ciclopirox 8% nail lacquer approved for treatment but has low cure rates:
 - May enhance oral therapy
- Tinea versicolor:
 - Topicals are 1st-line therapy:
 - Selenium sulfide 2.5% shampoo was as effective as topical ketoconazole
 - Oral ketoconazole, itraconazole, or fluconazole have been used with cure rates up to 97% but are not as safe as topicals

MEDICATION

- Ciclopirox 8% nail lacquer: Apply to the affected nails daily, max. 48 wk; remove with alcohol every 7 days (peds: Same).
- Clotrimazole: Apply 1% cream to affected area BID for 4–6 wk (peds: Same).
- Fluconazole: Tinea unguium—150–300 mg/wk pulse therapy for 3–6 mo for fingernails, 6–12 mo for toenails; tinea corporis, cruris, and pedis: 150 mg PO weekly for 4–6 wk; tinea versicolor: 400 mg PO single dose (peds: 6 mg/kg/d for 3–6 wk for tinea capitis)
- Griseofulvin: Tinea capitis, corporis, cruris—500 mg PO QD for 4–6 wk (peds: 10–20 mg/kg up to 500 mg PO QD until the hair regrows, usually 6–8 wk)
- Itraconazole: Tinea capitis: Adults and peds: 3–5 mg/kg PO QD for 2–4 wk; tinea unguium: 200 mg PO QD for 3 mo; tinea versicolor: 400 mg PO QD for 3–7 days; contraindicated in CHF
- Ketoconazole: 2% topical cream QD for 4–6 wk; tinea capitis, corporis, cruris, pedis—200 mg PO QD for 4 wk (peds: 3.3–6.6 mg/kg PO QD for 4 wk); tinea versicolor—400 mg PO × 1 or 200 mg QD for 7 days (contraindicated with terfenadine and astemizole); soda increases absorption 65%
- Miconazole: Apply cream to affected area BID for 4–6 wk (peds: Same)
- Selenium sulfide: 2.5% shampoo to affected area for 10 min for 1–2 wk (peds: Same)
- Terbinafine: 1% topical cream BID for 4–6 wk for tinea pedis QD for tinea corporis and tinea cruris; tinea unguium—250 mg PO QD for 6 wk for fingernails, 12 wk

for toenails (peds: < 20 kg, 67.5 mg/d; 20–40 kg, 125 mg/d; > 40 kg, 250 mg/d at same interval as adult); tinea pedis: 250 mg PO per day for 2 wk; tinea capitis: 250 mg/d for 4 wk (dose by weight as for tinea unguium for 4 wk)

- Tolnaftate: Apply 1% cream/powder/solution to the affected area BID for 4–6 wk (peds: Same)

ALERT

- The oral antifungals may rarely cause hepatotoxicity; consider checking liver transaminases prior to initiating therapy

Pediatric Considerations

Topical preparations are preferred when possible

Pregnancy Considerations

- Few studies addressing the use of antifungal medications during pregnancy in humans
- Some of the imidazoles have shown adverse effects in animals – class C (fluconazole, itraconazole, ketoconazole)
- Clotrimazole, miconazole, and terbinafine are class B drugs
- Weigh risk: Benefit as elective antifungal therapy generally not recommended.

First Line

- Tinea capitis: Terbinafine
- Tinea corporis, cruris, pedis: Topical terbinafine or imidazoles (ketoconazole, miconazole, and clotrimazole)
- Tinea versicolor: Selenium sulfide shampoo and topical ketoconazole

FOLLOW-UP

DISPOSITION

Admission Criteria

- Invasive disease in immunocompromised host
- Kerion with secondary bacterial infection

Discharge Criteria

- Most patients may be managed as outpatients
- Children may return to school once appropriate treatment has been initiated

Issues for Referral

Patients started on oral antifungals should be referred for follow-up to monitor therapy and advised regarding symptoms of hepatitis

FOLLOW-UP RECOMMENDATIONS

- Monitor for bacterial superinfection, cellulitis, generalized invasive infection:
 - Especially in immunocompromised (diabetics, HIV patients)

PEARLS AND PITFALLS

- Tinea capitis is the most common pediatric dermatophyte infection
- Itching is the main symptom in most forms of tinea, with associated hair loss in tinea capitis
- Cellulitis frequently complicates of tinea pedis
- Relapse of tinea pedis/cruris is common
 - Patients should wash or replace contaminated socks/towels/footwear

- B35.1 Tinea unguium
- B35.4 Tinea corporis

TOLUENE POISONING

Michael E. Nelson

BASICS

DESCRIPTION

- Prototypical volatile hydrocarbon
- Clear, colorless liquid with sweet odor

ETIOLOGY

- Abused for its euphoric effect
- Occupational exposures
- Used as organic solvent found in:
 - Oil paints and stains
 - Paint thinners
 - Glues, inks, dyes, correction fluid
 - Coolants
 - Petroleum products
 - Aerosolized household products
 - Degreasers
- Production and use of gasoline is largest source of exposure

Pediatric Considerations

- Prevalent in adolescent age group:
 - Inexpensive “high” with readily available sources
 - Many psychosocial problems
- May develop chronic neurologic dysfunction
- Mechanism:
 - Rapidly absorbed by inhalation
 - Readily crosses blood–brain barrier, reaching high concentrations in brain
 - May sensitize myocardium to dysrhythmogenic effect of catecholamines
 - Inhibits myocardial voltage-gated sodium channels and inward rectifying potassium channels
 - Alveolar excretion and liver metabolism
- Methods of intoxication:
 - Sniffing: Simple inhalation of substance directly from container
 - Huffing: Vapors inhaled through cloth saturated with substance
 - Bagging: Vapors inhaled from bag containing substance
- Toxic range:
 - 100 ppm: Impairment of psychomotor and perceptual performance
 - 500–800 ppm: Headache, drowsiness, nausea, weakness, and confusion,

potential lethal ranges

- >800 ppm: Convulsions, ataxia, staggering gait
- 10,000–30,000 ppm: Anesthesia within 1 min

DIAGNOSIS

SIGNS AND SYMPTOMS

- Acute:
 - Neurologic:
 - Depression
 - Euphoria
 - Ataxia
 - Dizziness
 - Seizures
 - Cardiac:
 - Fatal dysrhythmias
 - Pulmonary:
 - Chemical pneumonitis
 - Pulmonary edema
 - Electrolytes:
 - Hypokalemia
 - Hypocalcemia
 - Hyperchloremic metabolic acidosis, likely from hippuric acid metabolite
 - GI:
 - Abdominal pain
 - Nausea, vomiting
 - Hematemesis
 - Renal:
 - Distal renal tubular acidosis
 - Hematuria
 - Proteinuria
 - Musculoskeletal:
 - Diffuse weakness
- Chronic:
 - Neurologic:
 - Peripheral neuropathy (diffuse demyelination)
 - Leukoencephalopathy
 - Cerebral/cerebellar atrophy
 - Optic atrophy
 - Dementia
 - Cognitive/neurobehavioral abnormalities

- Cardiac:
 - Dysrhythmias
 - Dilated cardiomyopathy
- Renal:
 - Distal renal tubular acidosis
 - Renal failure
 - Fanconi syndrome
- Musculoskeletal:
 - Rhabdomyolysis
- Psychiatric:
 - Addiction/withdrawal

Pregnancy Considerations

- Fetal solvent syndrome reported from mothers who chronically abused toluene while pregnant, resembles fetal alcohol syndrome
- Infant more likely premature, low birth weight, microcephaly, and developmental delay

History

- Detailed history of sniffing, huffing, bagging, or other abuse of paints/solvents
- Occupational exposures

Physical-Exam

- Presence of agent on lips, nose, or clothes (metallic paint has highest concentration)
- Perioral eczematous dermatitis from chronic huffing or bagging
- Odor of agents

ESSENTIAL WORKUP

- Detailed physical exam
- CXR for suspected pneumonitis

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Electrolytes, BUN, creatinine, glucose:
 - Hypokalemia
 - Normal or high anion gap metabolic acidosis
 - Hyperchloremia
 - Impaired renal function
 - Severe hypocalcemia/hypophosphatemia
- Urinalysis:
 - Check for myoglobin (rhabdomyolysis)

- Hematuria and protein often present
- Creatinine kinase if suspect rhabdomyolysis
- Alcohol level—often coingestant
- Liver enzymes, prothrombin time (PT), partial thromboplastin time (PTT), INR, as may cause hepatotoxicity
- Urine for hippuric acid (metabolite of toluene):
 - Confirms exposure but does not correlate with systemic effects
- Serum levels only detectable for short time after exposure

Imaging

- EKG:
 - For atrial and ventricular dysrhythmias
- CXR:
 - Indicated if dyspnea or low oxygen saturation
 - Chemical pneumonitis
- CT head:
 - For altered mental status/chronic exposure
 - Cerebral/cerebellar atrophy, white matter hypodensity

Diagnostic Procedures/Surgery

CSF often unremarkable but may be indicated for altered mental status to rule out other etiologies

DIFFERENTIAL DIAGNOSIS

- Alcohol intoxication
- Other hydrocarbon abuse
- Other inhalants (nitrous oxide, difluoroethane, butane, etc.)
- Methanol
- Ethylene glycol
- Salicylate
- Heavy metal exposure
- Guillain–Barré syndrome
- Metabolic abnormalities

TREATMENT

PRE HOSPITAL

- Rapid onset of toxicity
- Death possible with sudden cardiac dysrhythmias (sudden sniffing death), often from catecholamine surge (e.g., eluding police)
- Topical decontamination as needed
- Forced emesis is not indicated:

- Decreased level of consciousness may lead to aspiration.

INITIAL STABILIZATION/THERAPY

- ABCs
- Supplemental oxygen
- Cardiac monitor
- 0.9% NS IV access
- Naloxone, thiamine, and check glucose if altered mental status

ED TREATMENT/PROCEDURES

- Treat cardiac dysrhythmias in standard fashion:
 - Consider β -blocker for tachydysrhythmias.
- Monitor respiratory status with pulse oximetry, CXR, and ABG if significant inhalation.
- Steroids not recommended for pneumonitis.
- Correct metabolic abnormalities:
 - Potassium
 - Calcium
 - Phosphate
- Acidosis resolves with IV fluids.
- If rhabdomyolysis, maintain high urine output.
- Gastric decontamination for oral ingestion rarely useful and may cause harm:
 - Charcoal does not bind hydrocarbons well and stomach distention may predispose to vomiting and aspiration.

MEDICATION

- Dextrose: D₅₀W, 1 amp: 50 mL or 25 g (peds: D₂₅W, 2–4 mL/kg) IV
- Naloxone (Narcan): 2 mg (peds: 0.1 mg/kg) IV or IM initial dose
- Thiamine (vitamin B₁): 100 mg (peds: 50 mg) IV or IM

FOLLOW-UP

DISPOSITION

Admission Criteria

- Altered mental status
- Dysrhythmias
- Hepatic dysfunction
- Renal failure
- Rhabdomyolysis
- Severe metabolic derangements
- Refractory hypokalemia

Discharge Criteria

After 4–6 hr of observation:

- Mental status at baseline
- No evidence of cardiac, metabolic, or neurologic derangement

FOLLOW-UP RECOMMENDATIONS

- Psychiatry referral for intentional/repeated ingestions and addiction counseling
- Cessation of use is most important intervention

PEARLS AND PITFALLS

- Myocardial sensitization to catecholamines:
 - Possibility of sudden dysrhythmia/death
 - Cardiac dysrhythmias have poor prognosis
- Monitor and replete electrolyte abnormalities.

- F18.120 Inhalant abuse with intoxication, uncomplicated

- T52.2X1A Toxic effect of homologues of benzene, accidental (unintentional), initial encounter

TOOTHACHE

Franklin D. Friedman

BASICS

DESCRIPTION

- Tooth pain is caused by irritation of the root nerves located in pulpal tissue:
 - The pulp is the tooth's center and its neurovascular supply
- Other etiologies, both inside the mouth and referred to the oral cavity, may cause oral pain

ETIOLOGY

- Dental:
 - Dental caries (hard structures demineralized by bacteria)
 - Pulpitis (inflamed pulp secondary to infection)
 - Reversible pulpitis is mild inflammation of the tooth pulp caused by caries encroaching on the pulp
 - Irreversible pulpitis is the result of an untreated carious lesion causing severe inflammation of the pulp and severe, persistent, poorly localized discomfort
 - Periapical abscess (necrotic pulp and subsequent abscess)
 - Postextraction pain (dry socket, infection)
 - Cracked-tooth syndrome (pain, cold sensitivity, crack difficult to visualize)
- Periodontal disease:
 - Gingivitis and periodontitis (gingivitis with loss of periodontal ligament attachment)
 - Periodontal abscess (gum boil)
 - Pericoronitis (gingival inflammation from malerupted tooth)
 - Acute necrotizing ulcerative gingivitis (gingival pain, ulcers with/without pseudomembranes)
 - Denture stomatitis
 - Herpetic gingivostomatitis
 - Aphthous ulcers (canker sores)
 - Traumatic ulcers

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Tooth pain:

- May be referred to jaw, ear, face, eye, and neck (sensory distribution of 5th cranial nerve)
- Pain often associated with chewing, changes in temperature, and recumbency
- Malodorous breath
- Fever and chills
- Foul taste in mouth
- Associated symptoms
- Duration of symptoms
- Treatments that have already been tried

Physical-Exam

- Dental decay
- Facial swelling or erythema
- Trismus:
 - Decreased maximal interincisal opening (normal opening, 35–50 mm)
- Inspect and palpate lips, salivary glands, floor of the mouth, lymph nodes of the neck
- Assess voice changes
- Identify periodontal abscess
- Evaluate for deep-space infection
- Examine face for swelling, redness, tenderness, and increased warmth
- Examine neck for adenopathy and stiffness
- Teeth should be percussed for tenderness and mobility
- Teeth should be examined for fracture and missing teeth
- Dental numeric system used in adults:
 - Maxillary: Right to left 1–16; mandibular: Left to right 17–32 (peds: A–J and K–T)
 - Alternatively identification of teeth by their location is also appropriate (i.e., left rearmost, upper molar)

ESSENTIAL WORKUP

- Obtain appropriate medical and dental history
- Ask about drug allergies, especially antibiotics and analgesics, and current medications
- Assess need for pre-dental procedure antibiotic prophylaxis:
 - Rheumatic fever
 - Cardiac valve replacements
 - Orthopedic joint replacements
 - Mitral valve prolapse or valvular heart disease
- If physical exam conflicts with patient's history and intraoral source of pain is not apparent consider other sources of pain:
 - Nonodontogenic etiologies of pain

- Factitious pain/drug-seeking behavior

DIAGNOSIS TESTS & INTERPRETATION

Lab

- No lab tests needed except in patients with signs of systemic toxicity and those patients with perceptible deep-space infection
- As with any other infection with symptoms of systemic toxicity, consider CBC, blood cultures, markers of inflammation like ESR or CRP

Imaging

- Panoramic and periapical radiograph views if suspicion exists about dental infection or fracture
- CT or MRI to evaluate deeper infections

Diagnostic Procedures/Surgery

A local or regional dental nerve block may sometimes offer both therapeutic and diagnostic benefit

DIFFERENTIAL DIAGNOSIS

- Sinusitis
- Otitis media
- Pharyngitis
- Peritonsillar abscess
- Temporomandibular joint syndrome:
 - Usually presents with pain around the ear
- Trigeminal neuralgia
- Vascular headache
- Herpes zoster
- Cardiac ischemia

Pediatric Considerations

- Tooth eruption in a child or infant may cause oral pain, irritability, low-grade fever, diarrhea, and decreased food intake
- Facial swelling with fever and leukocytes $> 15,000/\text{mm}^3$ suggests a nonodontogenic source
- Children have a maximum of 20 deciduous teeth, 10 upper and 10 lower

TREATMENT

PRE HOSPITAL

- Maintain patent airway in patients with severe facial swelling or trismus

- The patient should be kept in a sitting position if possible

INITIAL STABILIZATION/THERAPY

- Airway management for deep-space infection and airway compromise
- Early pain management as indicated

ED TREATMENT/PROCEDURES

- Appropriate analgesia
- NSAIDs are *1st-line* therapy for uncomplicated dental pain
- Opiate analgesics are an alternative therapy
- Dental anesthetic field block:
 - Injected along the buccal surface of the affected tooth
 - Specific nerve block for multiple teeth
 - Long-acting anesthetic (e.g., bupivacaine)
- Antibiotics if dental infection is present:
 - *Penicillin is the antibiotic of choice* if patient is not allergic
 - Clindamycin for patients with penicillin allergy or for predominance of anaerobes
- Localized periapical and periodontal abscesses should be incised, drained, and irrigated:
 - Drain may be placed for 24 hr
- Saline rinses at home 4 times a day and dental referral in 24 hr

MEDICATION

- Antibiotics:
 - Ampicillin/sulbactam 1.5–3 g IM/IV q6h (peds: 300–600 mg/kg/d [max. 3 g] IV div. q6h)
 - Clindamycin: 150–450 mg PO q6h (peds: 15–30 mg/kg/24 h [max. 2 g] q6h):
 - IV dose 300–900 mg (peds: 25–40 mg/kg/24 h div. q8h)
 - Penicillin VK: 500 mg PO q6h (peds: 25–50 mg/kg/24 h [max. 3 g] q6h)
 - Penicillin G potassium aqueous: 4 mU IM/IV q4h (peds: 250,000–400,000 U/kg/d IM/IV div. q4–6h, max. 24 mU/d)
- Analgesics:
 - Acetaminophen: 500 mg PO/PR q4–6h (peds: 10–15 mg/kg/dose; do not exceed 5 doses/24 h); do not exceed 4 g/24 h
 - Acetaminophen and codeine no. 3: 1–2 tablets PO q4–6h (peds: elixir–codeine 12 mg/5 mL)
 - Oxycodone 5 mg ± with acetaminophen 325 mg: 1 or 2 tablets PO q6h (peds: 0.05–0.15 mg/kg (oxycodone) per dose [max. 5 mg]); not available in liquid preparation
 - Ibuprofen: 400–800 mg PO q8h (peds: 10 mg/kg PO q6h)
 - Ketorolac: 30 mg IV, 30–60 mg IM q6h (peds: 1 mg/kg/dose IM/IV)

- Morphine sulfate: 2–8 mg SC or IM/IV q2h (peds: 0.1 mg/kg/dose SC or IM/V q2h)

Pediatric Considerations

Teething infants may be helped by over-the-counter topical anesthetics and oral analgesics

FOLLOW-UP

DISPOSITION

Admission Criteria

- Suspicion of deep-space infections (e.g., Ludwig angina, retropharyngeal abscess)
- Facial cellulitis proximal to the eye
- Extensive trismus
- Inability to maintain nutrition and hydration
- Evidence of systemic toxicity

Discharge Criteria

Patients with toothache and localized dental infections can be discharged from the ED

Issues for Referral

Patients treated in the ED should be referred to a dentist or dental surgeon promptly

FOLLOW-UP RECOMMENDATIONS

Regular and routine dental evaluations

PEARLS AND PITFALLS

- Mistaking a deep infection for local infection
- Failing to identify source of referred pain to the mouth

TORTICOLLIS

Andrew K. Chang • Robert Meyer

BASICS

DESCRIPTION

- Torticollis is a symptom, not a disease
- “Twisted neck” (L. *tortus*, twisted + *collum*, neck)
- A fixed or dynamic posturing of the head and neck
- Synonym(s): Cervical dystonia, wry neck

ETIOLOGY

Local

- Acute wry neck:
 - Develops overnight without provocation
 - Most prevalent
 - Self-limited, symptoms resolve in 1 to 2 wk
 - Cervical spine disease
 - Fracture
 - Dislocation, subluxation
 - Infections
 - Spondylosis
 - Tumor
 - Scar tissue–producing injuries
 - Ligamentous laxity in atlantoaxial region
- Inflammatory disease causing muscular damage:
 - Myositis
 - Lymphadenitis
 - Tuberculosis
 - Myasthenia gravis
 - Neuritis of the auriculotemporal branch of the trigeminal nerve
- Infections of surrounding soft tissues:
 - Nasopharyngeal abscess
 - Retropharyngeal abscess
 - Cervical adenitis
 - Tonsillitis
 - Meningitis
 - Mastoiditis
 - Sinusitis

Compensatory

- Tilt with essential head tremor (patient tilts head to suppress tremor)

- Ocular muscle palsy

Central

- Idiopathic spasmodic torticollis:
 - Female > male
 - Onset 31–60 yr old
- Dystonias:
 - Torsion dystonia
 - Generalized tardive dystonia
 - Wilson disease
 - λ-Dopa therapy
 - Acute (neuroleptic drugs)
 - Strychnine poisoning

Pediatric Considerations

Local

- Congenital:
 - Odontoid hypoplasia
 - Hemivertebrae
 - Spina bifida
 - Arnold–Chiari syndrome
 - Pseudotumor of infancy
 - Hypertrophy or absence of cervical musculature
- Otolaryngologic:
 - Vestibular dysfunction
 - Otitis media
 - Cervical adenitis
 - Retropharyngeal abscess
 - Pharyngitis
 - Mastoiditis
 - Esophageal reflux
 - Syrinx with spinal cord tumor
- Trauma:
 - Cervical fracture/dislocation
 - Clavicular fractures
 - Pneumomediastinum
- Juvenile rheumatoid arthritis

Compensatory

- Strabismus (4th cranial nerve paresis)
- Congenital nystagmus
- Posterior fossa tumor

Central

Dystonias:

- Torsion dystonia

- Drug induced
- Cerebral palsy

DIAGNOSIS

SIGNS AND SYMPTOMS

- Intermittent painful spasms of sternocleidomastoid (SCM), trapezius, and other neck muscles
- Head is rotated and twisted to 1 direction
- Pure flexion (anterocollis) or extension (retrocollis) is *rare*:
 - Represents symmetric involvement of muscles
- Symptoms usually aggravated by standing, walking, or stressful situations
- Usually does not occur with sleep

History

- Obtain a complete medication history
- The majority of antipsychotic medication–induced dystonic reactions occur between 12 and 23 hr
- Obtain a complete trauma history

Physical-Exam

- Head is rotated and twisted to 1 direction
- Neck movements vary from jerking to smooth
- The presence of fever supports an infectious or inflammatory etiology
- If the neurologic exam is focal, consider spinal cord or CNS disease
- Congenital form:
 - A firm, nontender enlargement of the SCM muscle visible at birth

ESSENTIAL WORKUP

- Geared toward diagnosing life-threatening etiologies above
- Distinguish torticollis from other causes of neck stiffness (meningismus)
- Cervical spine films to evaluate for fracture except patients with chronic paroxysmal episodes

DIAGNOSIS TESTS & NTERPRETATION

Lab

No specific tests helpful

Imaging

- CT or MRI of cervical spine if retropharyngeal abscess or tumor suspected
- High-frequency and color Doppler ultrasonography is the test of choice for

congenital muscular torticollis

- Plain films, lateral and AP view for acquired torticollis resulting from trauma
- CT scan of the neck or cervical spine in nontraumatic acquired torticollis

Diagnostic Procedures/Surgery

- Consider administering an anticholinergic medication if drug-induced etiology is suspected
- Consider performing the Tensilon test if myasthenia gravis is a consideration

DIFFERENTIAL DIAGNOSIS

- CNS infections
- Tumors of soft tissue or bone
- Basal ganglia disease
- Abscess of cervical glands
- Myositis of cervical muscles
- Cervical disk lesions
- Myasthenia gravis

TREATMENT

PRE HOSPITAL

- Ensure patent airway
- Cervical spine precautions for any history of trauma
- Support head

INITIAL STABILIZATION/THERAPY

Cervical spine immobilization if fracture is suspected

ED TREATMENT/PROCEDURES

- Drug (e.g., phenothiazine) induced:
 - Diphenhydramine or benztropine
- Acquired:
 - Soft collar and rest
 - Physical therapy
 - Massage
 - Local heat
 - Analgesics

MEDICATION

- Benztropine (for drug-related dystonia): 1–2 mg IM or slow IV, followed by 3–5 days PO
- Clonazepam (2nd-line drug): 0.5 mg PO TID
- Diphenhydramine (for drug-related dystonia): 25–50 mg IV or IM followed by 3–5

days PO q6–8h; (peds: 5 mg/kg/24 h div. q6h IV, IM, or PO)

- Trihexyphenidyl (a 1st-line drug): 2–5 mg/d PO, advance to 30 mg/d
- Valium: 2–5 mg IV, 2–10 mg PO TID (peds: 0.1–0.2 mg/kg/dose IV or PO q6h)
- Botulinum toxin is the 1st-line agent for treating nondrug-induced torticollis, though this is not typically administered in the ED setting

FOLLOW-UP

DISPOSITION

Admission Criteria

- Cervical spine fracture
- Diagnosis in doubt
- Infectious causes
- Toxic appearance
- Inability to maintain adequate fluid intake
- Lack of support system

Issues for Referral

Some patients who fail medical treatment may benefit from surgical treatment, such as accessory nerve ablation or deep brain stimulation

FOLLOW-UP RECOMMENDATIONS

- Outpatient referral to an orthopedist, neurologist, or neurosurgeon who uses botulinum toxin in his or her practice
- Physical therapy and consider chiropractic care
- Return to ED for weakness or worsening symptoms

PEARLS AND PITFALLS

Exclude infectious, inflammatory, traumatic, spinal cord and CNS causes of torticollis.

- M43.6 Torticollis
- Q68.0 Congenital deformity of sternocleidomastoid muscle

TOXIC EPIDERMAL NECROLYSIS

Andrew K. Chang • Andrew E. Chertoff

BASICS

DESCRIPTION

- One of the most fulminant and potentially fatal of all dermatologic disorders
- Skin sloughing at the dermal–epidermal interface results in the equivalent of a 2nd-degree burn
- Can affect up to 100% of total body surface area (BSA)
- May extend to involve:
 - GI mucosa
 - Respiratory mucosa
 - Genitourinary/renal epithelium
- Mechanism unclear, research indicates immunologic, cytotoxic, and delayed hypersensitivity may be involved as well as genetic susceptibility
- Current classification system proposes 3 categories within the spectrum of Stevens–Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN), distinct from erythema multiforme major and based on percentage of total BSA:
 - SJS: <10% of BSA
 - SJS–TEN overlap syndrome: 10–30% of BSA
 - TEN: >30% of BSA, can affect up to 100% BSA
- More common in older patients and immunocompromised patients
- Mortality rate is about 30%, usually due to secondary sepsis from *Staphylococcus aureus* and *Pseudomonas aeruginosa*
- Synonym(s):
 - Lyell syndrome
 - Fixed drug necrolysis
 - Epidermolysis necroticans combustiformis
 - Epidermolysis bullosa

ETIOLOGY

- Dose-independent drug reactions are the usual cause of TEN:
 - Drugs introduced within previous 1–3 wk are most likely candidates
 - Frequently implicated drugs include:
 - Sulfonamide and PCN antibiotics
 - Anticonvulsants (carbamazepine, phenytoin, phenobarbital, lamotrigine)
 - NSAIDs (oxicams, pyrazoles, sulindac),
 - Allopurinol
 - Corticosteroids

- Antiretroviral drugs
- Other rare causes: Infections, graft-versus-host disease, vaccinations, idiopathic cases (combined < 4%)

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Prodrome: Influenza like, one to several days of fever, malaise, pruritus, cutaneous tenderness, erythema, anorexia, myalgias, arthralgias
- Mucous membranes are commonly affected 1–3 days before skin lesions appear (oropharynx, eyes, genitalia, anus, esophageal and intestinal mucosae, respiratory epithelium) leading to conjunctivitis, esophagitis, pharyngitis, GI bleeding, vomiting, diarrhea, dysuria, cough, dyspnea

Physical-Exam

- Skin:
 - Rash usually begins on face (scalp usually spared) and trunk as erythematous macules, irregular target-like bullae, or diffuse, ill-defined erythema; initially may have pain at sites out of proportion to exam
 - Widespread epidermolysis, denuding of skin surfaces, flaccid bullae, and sheet-like sloughing of epidermis generally progress over 3–4 days but can progress rapidly over hours
 - Nikolsky sign: With lateral pressure, the skin denudes and sloughs from separation of epidermis from dermis
- Mucous membranes involved in > 90% of cases, initial swelling and erythema followed by blistering and ulceration
- Ocular lesions (pseudomembranes, synechiae or adhesions, keratitis, corneal erosions)

ESSENTIAL WORKUP

- Diagnosis is made clinically:
 - Based on history and characteristic skin and mucous membrane lesions

DIAGNOSIS TESTS & INTERPRETATION

Lab

- No confirmatory lab tests exist
- CBC: Normocytic anemia, leukocytosis, lymphopenia/neutropenia, and thrombocytopenia may be present
- ESR may be elevated as a result of systemic inflammation

- Serum chemistry: Electrolyte derangements if extensive fluid losses:
 - Prerenal azotemia
 - Serum bicarbonate < 20 associated with $40 \times$ higher mortality
- LFTs: Elevated transaminases, low total protein and albumin
- UA may show hematuria (urethral–mucosal erosion, glomerulonephritis) or casts (acute tubular necrosis)
- Wound/skin cultures and blood cultures
- Serum granulysin (an implicated cytotoxin)

Imaging

Chest radiograph should be obtained

Diagnostic Procedures/Surgery

- Severity of illness score for TEN (SCORTEN): Each risk factor earns 1 point, a higher score means a poorer prognosis:
 - Age > 40 yr
 - Malignancy
 - Tachycardia $> 120/\text{min}$
 - Initial percentage of epidermal detachment $> 10\%$
 - BUN > 27 mg/dL
 - Serum glucose level > 252 mg/dL
 - Serum bicarbonate level < 20 mEq/L
- Biopsy may be performed by consulting dermatologist to rule out autoimmune bullous diseases, staphylococcal scalded skin syndrome, and other diagnoses:
 - Results not immediately available to ED physician

DIFFERENTIAL DIAGNOSIS

- Stevens-Johnson syndrome (SJS)
- Erythema multiforme major (EMM):
 - Differentiation of SJS/TEN from EMM:
 - Immunopathologically distinct
 - *Etiology*: SJS/TEN is mainly drug-induced, mechanism uncertain; EMM both infection and drug-induced, mechanism type IV hypersensitivity
 - *Lesions*:
 - TEN: Widely distributed, mainly on the trunk and face, nonspecific, target-like lesions that often are confluent and too numerous to count, then desquamation
 - EMM: Limited in number, symmetric and acral distribution, typical target type (at least 3 concentric rings) with or without blisters
 - *Prognosis*: EMM is usually benign; recurrence of disease is common (30%)
- Staphylococcal scalded skin syndrome (SSSS):
 - Differentiation of TEN from SSSS:
 - *Age*: TEN: Primarily adults (but may occur in children); SSSS: Primarily

affects children

– *Etiology:*

- TEN most often represents an idiosyncratic, drug-induced, dose-independent reaction and hence does not require treatment with antibiotics
- SSSS results from infection and requires antibiotics

– *Pain:* TEN, painful; SSSS, painless

– *Mucous membranes:* Involved with TEN; spared with SSSS

– *Skin cleavage:* Dermal–epidermal junction in TEN; intraepidermally in SSSS (both can produce a positive Nikolsky sign)

- Autoimmune bullous diseases (pemphigus vulgaris, bullous pemphigoid)
- Scarlet fever
- Toxic shock syndrome
- Chemical or thermal scalds
- Hypersensitivity vasculitis
- Kawasaki syndrome

TREATMENT

PRE HOSPITAL

- Transport to facility with burn center
- Care during transport should be gentle to avoid skin trauma
- IV catheter should be avoided for short transport if hemodynamically stable (more sterile conditions in ED)
- Avoid using adhesive materials

INITIAL STABILIZATION/THERAPY

- If intubation or nasogastric tube is required, gentle technique must be used to minimize mucosal damage
- Meticulous sterile technique
- Peripheral IV line is preferred over central line to decrease risk of sepsis
- Cardiac monitor, pulse oximeter, nasogastric tube, Foley catheter

ED TREATMENT/PROCEDURES

- Identify and stop any causative medication
- Aggressive fluid resuscitation and electrolyte management as in burn care (Parkland formula):
 - Urine output should target a rate of 0.5–1 mL/kg/hr.
- Warming measures and frequent core temperature evaluation are important
- If available, cover with biologic dressings (e.g., Biobrane):
 - Reduces pain, decreases caloric and evaporative losses, and facilitates healing

- Antibiotic drops for eyes
- Petroleum jelly application to lips
- Prevention of peptic stress ulcers
- Topical antibiotics, including silver nitrate, are unproven but may be applied with the exception of silver sulfadiazine (sulfonamide derivative).
- Timely admission to burn unit/ICU
- Ophthalmology consultation is required for eye involvement (evaluation and removal of pseudomembranes and adhesions)

MEDICATION

There are no established treatment regimens; however, there are several suggested guidelines:

- Pain should be controlled with IV opiates
- Antibiotics should be used when documented signs of sepsis are present or for sudden deterioration in the clinical setting; coverage should include gram-positive, gram-negative (including *P. aeruginosa*), and aerobic organisms
- Antihistamines can be used for pruritus
- Anticoagulation should be considered while patients are nonambulatory for prevention of thromboembolic events
- Systemic corticosteroids continue to be controversial:
 - Retrospective studies show no benefit and suggest greater risk of death from infection
- IVIG should be started 48–72 hr after bulla formation but can be helpful after 72 hr
- The following experimental therapies are under investigation:
 - Plasmapheresis
 - Cyclosporine
 - Cyclophosphamide
 - N-acetylcysteine
 - Anti-TNF- α antibodies (i.e., Infliximab) but Thalidomide contraindicated (harm shown)

FOLLOW-UP

DISPOSITION

Admission Criteria

All patients with suspected TEN should be admitted to a burn unit (if burn unit is unavailable and transfer is not possible, then admit to ICU)

Issues for Referral

- Transfer to facility with burn unit has been shown to improve patient outcome
- Dermatology should be called to help confirm the diagnosis

- Ophthalmology should be called to evaluate and prevent corneal ulcerations and adhesions
- Surgery or plastic surgery should evaluate the need for wound débridement.
- Respiratory therapy should initiate pulmonary toilet in the setting of pulmonary mucosal sloughing.

PEARLS AND PITFALLS

- Burn units and ICUs offer the best management settings
- Remember to educate patients on medications (including combinations, medications, and structurally similar medications)
- Aggressive fluid hydration is essential

Burns

CODES

ICD9

- 695.14 Stevens-Johnson syndrome-toxic epidermal necrolysis overlap syndrome
- 695.15 Toxic epidermal necrolysis

ICD10

- L51.2 Toxic epidermal necrolysis [Lyell]
- L51.3 Stevens-Johnson synd-tox epdrml necrolysis overlap syndrome

TOXIC SHOCK SYNDROME

Michelle J. Sergel • Kristopher Wnek

BASICS

DESCRIPTION

- Toxic shock syndrome (TSS) is a severe, acute life-threatening illness
- Etiologic organisms:
 - *Staphylococcus aureus*, more common (TSS)
 - Group A streptococcus or GAS, less common (Streptococcal TSS or STSS)
- *S. aureus* produce structurally similar toxins:
 - Toxic shock syndrome toxin (TSST-1)
 - Enterotoxin B (SEB)
 - Enterotoxin C (SEC)
- GAS pyrogenic exotoxins:
 - Exotoxin A (SPEA)
 - Exotoxin B (SPEB)
- Exotoxins act as superantigens causing overwhelming immune response:
 - Massive cytokine production
 - Induce fever directly at the hypothalamus or indirectly via interleukin-1 (IL-1) and tumor necrosis factor (TNF) production
 - Enhance delayed hypersensitivity
 - Suppress neutrophil migration and immunoglobulin
 - Enhance host susceptibility to endotoxins
- Massive vasodilation occurs
 - Serum protein and fluid shifts leading to hypotension

ETIOLOGY

- Initial cases described in young healthy menstruating females due to highly absorbent tampons
 - Changes made in tampon composition to decrease incidence
- Approximately one-half of reported TSS cases are nonmenstrual:
 - Surgical wounds
 - Postpartum wound infections
 - Mastitis
 - Septorhinoplasty
 - Sinusitis
 - Osteomyelitis
 - Arthritis
 - Burns
 - Nasal packing (nasal tampons)

- Cutaneous and subcutaneous lesions
- Nonmenstrual cases predominantly due to SEB and SEC producing *S. aureus*
- 30–50% of healthy adults and children carry *S. aureus* in the nasal vestibule, vagina, rectum and/or on the skin
- GAS infections often begin within 24–72 hr at the site of minor trauma, often without a visible in skin
- Despite increased incidence of Methicillin-resistant *S. aureus* (MRSA) infections, a recent study reported MRSA only accounting for 7% of cases

DIAGNOSIS

SIGNS AND SYMPTOMS

TSS Criteria for Diagnosis

- CDC case definition:
 - Fever $> 38.9^{\circ}\text{C}$ (102°F)
 - Hypotension (systolic BP < 90 mm Hg) or shock
 - Diffuse, blanching nonpruritic macular erythroderma rash
 - Subsequent desquamation 1–2 wk after the onset of illness (particularly involving palms and soles)
 - Multisystem involvement—*at least 3* of the following should be present:
 - GI: Profuse diarrhea or vomiting at onset of illness
 - Musculoskeletal: Severe myalgias or greater than a 2-fold increase in creatine phosphokinase (CPK)
 - Mucosal inflammation: Conjunctival, vaginal, or pharyngeal hyperemia
 - Renal: Increase in BUN or creatinine > 2 times normal upper limit or sterile pyuria without evidence of infection
 - Hepatic: Total bilirubin or transaminases > 2 times normal upper limit
 - Hematologic: Thrombocytopenia $< 100,000/\text{mm}^3$
 - CNS: Disorientation, confusion, or hallucinations
 - Negative results on the following tests, if obtained: Throat, or CSF cultures, rise in titer to Rocky Mountain spotted fever (RMSF), leptospirosis, or rubeola

Streptococcal TSS (STSS) Criteria for Diagnosis

- CDC case definition:
 - Isolation of GAS from a normally sterile site
 - Hypotension
 - Plus 2 or more of the following:
 - Renal impairment (creatinine > 2)

- Coagulopathy
- Liver involvement (> 2 times the upper limit of normal for transaminases or bilirubin)
- ARDS
- Erythematous macular rash, may desquamate
- Soft tissue necrosis

Other

- Tachycardia frequently present
- Can rapidly progress to multisystem dysfunction (ARDS or DIC)
- STSS often presents with diffuse or localized pain—abrupt in onset and severe
- Pain precedes physical findings
- Nearly 80% of patients with STSS have clinical signs of soft tissue infection

ESSENTIAL WORKUP

- Clinical diagnosis using diagnostic criteria in the absence of other attributable illness
- Thorough history and physical exam

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - Leukocytosis or leukopenia, marked bandemia common
- Electrolytes, BUN, creatinine, glucose:
 - Elevated BUN and creatinine common
- Calcium, magnesium:
 - Hypocalcemia/hypomagnesemia often present
- Urinalysis:
 - Normal or sterile pyuria without evidence of infection
- CPK:
 - 2-fold increase
- Hepatic function:
 - Elevated total bilirubin, AST, ALT
- Prothrombin time (PT), partial thromboplastin time (PTT), platelets:
 - Thrombocytopenia < 100,000 platelets/mm³
- Culture the site of injury/infection if possible
- Blood, urine, throat, and CSF cultures as indicated:
 - The case definition does not require a positive blood culture for *S. aureus*, but does for *Streptococcus* organisms.
- Serology for RMSF, rubeola, and leptospirosis
- Hepatitis B surface antigen

Imaging

- Chest x-ray – to rule out other sources of systemic illness
- Consider x-ray or CT scan if localized pain is concerning for abscess or necrotizing infection

DIFFERENTIAL DIAGNOSIS

- Staphylococcal scalded skin syndrome:
 - In children <5 yr of age
 - Initial macular rash followed by the formation of ill-defined bullae that can be rubbed off revealing a shiny, moist epidermis (positive Nikolsky sign)
- Scarlet fever:
 - Preceding streptococcal pharyngitis
 - Rash begins on the upper chest, neck, and back spreading to the remainder of the trunk, sparing the palms and soles
 - Hypotension absent
- Kawasaki disease:
 - Fever, conjunctival hyperemia, and erythema of the mucous membranes
 - Not associated with renal failure, hypotension, or thrombocytopenia
- Stevens–Johnson syndrome:
 - Severe multisystem involvement
 - Mucosal involvement of the mouth, conjunctivae, vagina, anus, and urethral meatus
- Leptospirosis:
 - Transmitted through contact with infected animals
 - Fever, headache, severe myalgias, and conjunctival suffusion
 - Truncal rash that only desquamates in children
- RMSF:
 - Rash is pink and macular, beginning on the wrists, palms, ankles, and soles spreading to the trunk and face
 - Petechiae appear after 4 days
- Meningococemia:
 - Meningismus present
 - Rash is petechial

TREATMENT

PRE HOSPITAL

- ABCs
- IV access
- IV fluids for hypotension

INITIAL STABILIZATION

- Again, ABCs
- Aggressive management of circulatory shock
 - IV fluids
 - Pressors

ED TREATMENT/PROCEDURES

Hypotension

- Aggressive fluid replacement
 - The 1st 24 hr may require 4–20 L of crystalloid and/or fresh frozen plasma (colloid)
 - *Caution:* Large amounts of IV fluids and pressors used to treat refractory hypotension can result in rapid onset pulmonary edema
 - Pressors (dopamine/norepinephrine) if fluid correction fails to restore normal arterial pressure

Infection Management

- Search for and treat the focus of infection
- Remove the source of infection (e.g., tampon, nasal or wound packing)
- Early surgical/gynecologic consultation if drainage or débridement of infectious sites necessary
- Antibiotics
 - Recommended to reduce recurrence, but have not been shown to alter the course of the initial infection
 - Clindamycin and linezolid are potent suppressers of bacterial toxin synthesis
 - Clindamycin or linezolid + vancomycin for TSS
 - Linezolid + vancomycin for TSS with extensive infection
 - If TSS due to known methicillin-susceptible *S. aureus* then clindamycin + oxacillin or nafcillin
 - Clindamycin + imipenem or meropenem or ticarcillin–clavulanate or piperacillin–tazobactam for STSS
- IV immunoglobulin (IVIG) treatment:
 - May be efficacious in streptococcal toxic shock, but no controlled trials have proven efficacy in staphylococcal TSS.
 - May initiate if no response to fluids, pressors, and antibiotics in patients with pulmonary edema and hypotension

MEDICATION

- Clindamycin: 600–900 mg (peds: 20–40 mg/kg/24 h) IV q6–8h
- Dopamine: 2–20 µg/kg/min IV, titrate to BP
- Linezolid: 600 mg (peds: 10 mg/kg/12 h) IV q12h
- Meropenem: 1 g IV q8h

- Nafcillin: 1.5 g (peds: 100 mg/kg/24 h) IV q4h
- Norepinephrine: 0.01–3 mcg/kg/min IV, titrate to BP
- Oxacillin: 1–2 g (peds: 50–100 mg/kg/24 h) IV q4h
- Piperacillin–tazobactam: 4.5 g q6h
- Ticarcillin–clavulanate: 3.1 g q4h
- Vancomycin: 30 mg/kg QD IV div. in 2 doses (peds: 40 mg/kg QD IV div. in 4 doses)
- Staphylococcal TSS: IVIG, 400 mg/kg over several hours
- Streptococcal TSS: IVIG 1 g/kg on day 1 then 0.5 g/kg on days 2 and 3

FOLLOW-UP

DISPOSITION

Admission Criteria

- Cases necessitate admission
- ICU admission for critically ill or those in shock

Discharge Criteria

None

Issues for Referral

Early surgical/gynecologic consultation if drainage or débridement is needed

FOLLOW-UP RECOMMENDATIONS

- Patients who are bacteremic are treated for a minimum of 14 days:
 - Depending on the clinical course
 - Continue treatment for 14 days from the last positive culture.
- Screening for *S. aureus* nasal carriage in patient with *S. aureus* TSS and eradication of the carrier state with mupirocin

PEARLS AND PITFALLS

- Consider the diagnoses of staphylococcal TSS and GAS TSS
- Ensure adequate supportive care for hypotension in TSS
- Prompt and aggressive exploration and débridement of suspected deep-seated infection
- Empiric broad-spectrum antibiotics including clindamycin or linezolid is recommended

TOXOPLASMOSIS

Roger M. Barkin

BASICS

DESCRIPTION

- *Toxoplasma gondii*—intracellular protozoan parasite:
 - 3 forms:
 - Tachyzoite: Asexual invasive form
 - Tissue cyst: Persists in tissues of infected hosts during chronic phase
 - Oocyst: Contains sporozoites and produced during sexual cycle in cat intestine
- Transmission:
 - Ingesting tissue cysts or oocysts:
 - Ingesting undercooked meat
 - Vegetables contaminated with oocysts
 - Contact with cat feces, through cat or soil
 - Transplacental
 - Blood product
 - Organ transplantation

ETIOLOGY

- 70% of adults seropositive
- Asymptomatic in most immunocompetent patients
- Worldwide; cats are the common host
- Incubation is 7 days with a range of 4–21 days

DIAGNOSIS

SIGNS AND SYMPTOMS

4 types of infection

Immunocompromised Host

- CNS:
 - Subacute presentation (90%)
 - Encephalitis
 - Headache
 - Altered mental status
 - Fever
 - Seizures
 - Cranial nerve palsies
 - Spinal cord lesions

- Cerebellar signs
- Meningitis-like symptoms
- Movement disorders
- Neuropsychological symptoms:
 - Psychosis
 - Paranoia
 - Dementia
 - Anxiety
 - Agitation
- Pulmonary:
 - Pneumonitis
 - Prolonged febrile illness
 - Nonproductive cough
 - Dyspnea

Immunocompetent Host

- 90% are asymptomatic
- Lymphadenopathy, usually cervical
- Fever
- Malaise
- Mononucleosis-like syndrome with macular rash and hepatosplenomegaly
- Headache
- Sore throat
- Night sweats
- Maculopapular rash
- Urticaria
- Usually, self-limited process; resolves in 2–12 mo
- Rarely presents with pneumonitis or encephalitis

Ocular Toxoplasmosis

- Blurred vision
- Scotoma
- Pain
- Photophobia
- Retina:
 - Small clusters of yellow-white cotton-like patches
 - Chorioretinitis; affects 85% of young adults with untreated congenital infection

Congenital Toxoplasmosis

- Results from an asymptomatic acute infection during pregnancy
- 1st trimester:
 - Spontaneous abortion
 - Stillbirth
 - Severe disease up to 25% of the time
- 2nd or 3rd trimester:

- 50–60% chance of acquiring congenital toxoplasmosis
- 2% fatal
- Most asymptomatic at birth
- Delayed onset. 70–90% asymptomatic at birth:
 - CNS disease
 - Ocular disease (blindness months to years later)
 - Lymphadenopathy
 - Hepatosplenomegaly
 - At birth, may have maculopapular rash, lymphadenopathy, hepatomegaly, splenomegaly, jaundice, thrombocytopenia

ESSENTIAL WORKUP

- Diagnose via:
 - Isolation of organism:
 - Blood
 - CSF for encephalitis
 - Bronchoalveolar lavage for pneumonitis
 - Amniotic fluid
 - Aqueous humor
 - Detection of tachyzoites in tissues or body fluids
 - Demonstrating characteristic lymph node pathology
- Thorough ocular exam:
 - Retinal exam
 - Visual acuity

DIAGNOSIS TESTS & INTERPRETATION

Lab

- LDH > 600/UL associated with toxoplasmosis
- CBC:
 - Atypical lymphocytes
- ABG/pulse oximetry for pulmonary symptoms
- IgG antibodies:
 - High number of false-positive and false-negative results
 - Common tests:
 - Sabin–Feldman dye test
 - Indirect fluorescent antibody
 - Agglutination
 - Enzyme-linked immunosorbent assay test
- Immunoglobulin M (IgM) antibodies:
 - Absence excludes diagnosis in immunocompetent host
 - Reference labs may be helpful, such as Remington (650-853-4828 Toxoplasma Serology Laboratory) (www.pamf.org/serology)

- Diagnoses acute infection
- Appear in 5 days
- Disappear in weeks to months
- Neonatal testing differentiates from maternal infection

Imaging

- Chest radiograph for pulmonary symptoms:
 - Pneumonitis associated with reticulonodular pattern
- CT head with contrast:
 - Multiple bilateral hypodense ring-enhancing lesions
- MRI brain:
 - High signal abnormalities on T2-weighted images
- Serial fetal ultrasonography can be useful in exploring congenital infection of the CNS or other signs.

Diagnostic Procedures/Surgery

Brain biopsy for encephalitis—definitive diagnosis

DIFFERENTIAL DIAGNOSIS

- Cryptococcal meningitis
- CNS lymphoma
- *Pneumocystis carinii* pneumonia
- Cytomegalovirus retinitis
- Mycobacterial infection

TREATMENT

INITIAL STABILIZATION/THERAPY

- Treat seizures in standard fashion with diazepam and phenytoin.
- Initiate oxygen if hypoxia due to pneumonitis.

ED TREATMENT/PROCEDURES

Immunocompetent

Toxoplasmic lymphadenitis:

- No antibiotics unless symptoms severe and persistent
- Treat symptomatic patients with pyrimethamine and folinic acid plus sulfadiazine or clindamycin for 3–4 wk
- Clindamycin may be a useful alternative to sulfadiazine because of the side effects of the latter and in those who are hypersensitive to sulfa
- Pyrimethamine and sulfadiazine (Eon Labs 800-526-0225) is available as a combination drug.

- Corticosteroids may be useful for ocular complications and CNS disease.
- Reassess to determine if longer therapy needed.

Immunocompromised

- Confirmed acute infection by serology/symptoms:
 - Treat with pyrimethamine and folinic acid + sulfadiazine or clindamycin for 4–6 wk after resolution of symptoms.
 - Alternative medications:
 - Trimethoprim–sulfamethoxazole
 - Pyrimethamine and folinic acid + dapsone
- CNS symptoms + a lesion on CT or MRI:
 - Treat empirically with pyrimethamine and folinic acid + sulfadiazine or clindamycin.
 - Brain biopsy or CSF to confirm diagnosis
 - Administer anticonvulsants only if confirmed prior seizures:
 - Poorer outcome for patients on anticonvulsants
- Chronic asymptomatic infection:
 - No therapy required
 - Prophylaxis options for toxoplasmosis in AIDS and immunosuppressed patients:
 - Trimethoprim–sulfamethoxazole; lifelong prophylaxis should be considered in HIV patients after consultation.
 - Pyrimethamine (75 mg/wk) and dapsone (200 mg/wk) and leucovorin 10–25 mg with each dose pyrimethamine

Ocular

- Treat with pyrimethamine and sulfadiazine for 1 mo.
- May add clindamycin
- Administer systemic steroids with macular or optic nerve involvement.

Acute Acquired Infection in Pregnancy

- Initially treat with spiramycin pending confirmatory tests and consultation (FDA, Division of Special Pathogens and Transplant Drug Products 301-796-1600 or CDC at 404-718-4745).
- After the infection is documented, initiate treatment after consultation:
 - Spiramycin in the 1st 17 wk
 - Pyrimethamine and sulfadiazine after 17 wk
- Spiramycin may reduce congenital transmission but does not treat fetus if infection is in placenta; maternal therapy may decrease severity of congenital disease.
- Treat congenital infection with sulfadiazine, pyrimethamine, and folinic acid for 12 mo.
- Prevention of exposure in seronegative pregnant women is important when

contacting cats or their excrement.

MEDICATION

- Clindamycin:
 - 600 mg (peds: 20–40 mg/kg/24 h) IV q6h
 - 300 mg (peds: 8–20 mg/kg/24 h) PO q6h
 - Useful if patient hypersensitive to sulfa
- Dapsone: 50 mg PO per day or 200 mg PO per week (child > 1 mo: 2 mg/kg PO per day)
- Folinic acid: 5–25 mg PO daily in conjunction with pyrimethamine therapy
- Pyrimethamine: 100 mg BID on 1st day loading dose, then 25–50 mg PO per day
- Spiramycin: FDA authorization required
- Sulfadiazine: 500 mg–2 g (peds: 100–200 mg/kg/24 h div. BID) PO q6h
- Trimethoprim–sulfamethoxazole: 5 mg/kg of trimethoprim component IV or PO q12h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Acute infection with severe systemic symptoms
- Immunocompromised patients with:
 - Toxoplasmosis encephalitis
 - Pneumonitis
 - Sepsis

Discharge Criteria

- Immunocompetent patients with:
 - Mild symptoms
 - Ocular
- Maternal/congenital infection with mild symptoms

Issues for Referral

Infectious disease consultant

TRANSFUSION COMPLICATIONS

Philip Shayne

BASICS

EPIDEMIOLOGY

- Of 39 million hospital discharges in US, 5.8% (2.3 million) were associated with blood transfusions (2004).
- In 2011 there were 30 deaths in US fully attributable to transfusion complications.
- Some type of transfusion reaction occurs in 2% of units transfused within 24 hr of use.
- Noninfectious complications:
 - Febrile nonhemolytic reaction: RBCs 1 in 500 transfusions, platelets 1 in 900
 - Allergic reaction (nonanaphylactic): 1 in 3 to 1 in 300
 - Anaphylaxis: 1 in 20,000 to 1 in 50,000
 - Acute hemolytic reaction: 1 in 38,000 to 1 in 70,000
 - Delayed hemolytic reaction: 1 in 4,000 to 1 in 11,000
 - Transfusion-associated circulatory overload (TACO): 1 in 100, but as high as 10% in susceptible populations
 - Alloimmunization: 1 in 10 to 1 in 100
 - Graft-versus-host disease: 1 in 400,000; rare but has >90% mortality.
 - Transfusion-related lung injury (TRALI): 1 in 5,000 to 1 in 190,000; represents 13% of reported transfusion-related deaths
 - Iron overload: Unknown incidence, depends on volume of blood, often occurs after >100 RBC units
 - Hypocalcemia: Unknown incidence
 - Hyperkalemia: Unknown incidence
- Infectious complications:
 - Bacterial contamination: RBCs 1 in 65,000 to 1 in 500,000; platelets 1 in 1,000 to 1 in 10,000:
 - Most common bacterial agents: *Yersinia enterocolitica*, *Pseudomonas spp*, *Serratia spp*.
 - Leading cause of mortality among infectious complications; 17–22% of all cases
 - Hepatitis C: 1 in 1.6 million
 - Hepatitis B: 1 in 100,000 to 1 in 400,000
 - HTLV I and II: 1 in 500,000 to 1 in 3 million
 - HIV: 1 in 1.4 million to 1 in 4.7 million
 - HAV: 1 in 1,000,000
 - B19 parvovirus: 1 in 40,000; post-transfusion anemia rare with scattered case reports

- Parasites: *Babesia* and malaria: <1 in 1 million
- Parasites: *Trypanosoma cruzi*: 1 in 42,000
- Case reports of Epstein–Barr virus, Lyme disease, brucellosis, human herpesvirus, Creutzfeldt–Jakob disease

Acute Intravascular Hemolytic Transfusion Reaction

- Mortality and morbidity correlate with amount of incompatible blood transfused (symptoms can occur with exposure to as little as 5–20 mL)
- Occurs immediately from:
 - ABO incompatibility
 - Blood type identification error
 - Incompatible transfused cells immediately destroyed by antibodies
- Intravascular hemolysis causing activation of coagulation system, leading to inflammation, shock, and DIC
- Mediators (cytokines) released during inflammatory response
- Renal failure:
 - Cytokines cause local release of endothelin in kidney, causing vasoconstriction.
 - Leads to parenchymal ischemia and acute renal failure
- Respiratory failure owing to pulmonary edema/adult ARDS:
 - Free hemoglobin (Hb) causes vasoconstriction in pulmonary vasculature.

Other Transfusion-related Complications

- Hemolysis because of Rh incompatibility:
 - Mild, self-limiting
 - 1:200 U transfused
- Febrile nonhemolytic transfusion reaction:
 - Most common transfusion reaction, diagnosis of exclusion.
 - Temperature increases at least 1°C with chills within 6 hr
 - Antigen–antibody reaction to transfused blood components (WBCs, platelets, plasma)
 - Usually mild
 - Occurs more often with multiparous women or multiple transfusions
 - Recurs in 15% of patients
 - Acetaminophen may be used prophylactically; its use as premedication is controversial, though not harmful.
- Allergic transfusion reaction:
 - Occurs in 1% of transfusions
 - Usually seen with immunoglobulin A (IgA)–deficient patients
 - Urticaria alone is not a reason to stop transfusion.
 - Antihistamine may be used as therapy or prophylactically.
- Premedicating with acetaminophen and diphenhydramine found to have no effect

on incidence of transfusion reaction compared with placebo in some trials.

Delayed Reactions

- Infection:
 - HIV, hepatitis B, hepatitis C
 - Blood screened for viruses
 - Blood treated to inactivate viruses
 - Blood donors with recent history of travel or poor health are deferred from donating.
- Delayed extravascular hemolytic reaction:
 - Occurs 7–10 days after transfusion
 - Antigen–antibody reaction that develops after transfusion
 - Coombs test positive
 - Usually asymptomatic
 - Blood bank analysis detects antibody
- Electrolyte imbalance:
 - Hypocalcemia: Calcium binds to citrate
 - Hyper/hypokalemia: Citrate metabolized to bicarbonate, which drives potassium intracellularly; prolonged storage of blood may cause hemolysis and hyperkalemia
- Graft-versus-host disease:
 - Fatal in > 90%
 - Immunologically competent lymphocytes transfused into immunocompetent host
 - Host unable to destroy new WBCs
 - Donor WBCs recognize host as foreign and attack host's tissues.
- Anaphylactic reaction:
 - Can occur with < 10 mL of exposure
 - Generalized flushing, urticaria, laryngeal edema, bronchospasm, profound hypotension, shock, or cardiac arrest.
 - Treat with subcutaneous epinephrine, supportive hemodynamic and respiratory care.
- TRALI:
 - Symptoms typically begin with 6 hr of transfusion.
 - Acute onset of respiratory distress, bilateral pulmonary edema, fever, tachycardia, hypotension, with normal cardiac function
 - 3rd most common cause of fatal transfusion
 - Difficult to distinguish from ARDS and TACO; often misdiagnosed and underreported
 - Provide supportive care.
 - Disease is typically self-limited within 96 hr.
 - Mortality is 5–10%.
 - Diuretics contraindicated

Pediatric Considerations

Blood can be transfused through 22G peripheral catheter under pressure (but < 300 mm Hg) with minimal hemolysis.

DIAGNOSIS

SIGNS AND SYMPTOMS

- **General:**
 - Fevers
 - Chills
 - Burning at infusion site
 - Urticaria/pruritus/skin erythema
- **Pulmonary:**
 - Dyspnea
 - Bronchospasm
 - Respiratory distress/failure
- **Cardiovascular:**
 - Tachycardia
 - Hypotension
 - Substernal chest pain/tightness
- **GI:**
 - Nausea
 - Vomiting
 - Diarrhea
- **Hematologic:**
 - Bleeding
 - Hemoglobinuria
 - Oozing from surgical wounds
 - Jaundice
 - DIC
- **Miscellaneous:**
 - Low back pain
 - Renal failure (oliguria/anuria)
 - Classic triad of fever, flank pain, and red-brown urine of acute hemolytic reactions is rarely seen.

ESSENTIAL WORKUP

- Recognize clinical findings of transfusion reaction.
- Recheck identifying information of blood and patient compatibility.
- Recognize evidence of hypotension/shock, severe respiratory distress, sepsis, fever, and urticaria; intervene appropriately.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Electrolytes, BUN, creatinine, glucose:
 - For electrolyte abnormalities
- PT, PTT
- Serum calcium
- Fibrinogen, fibrin degradation products
- Bilirubin (direct/indirect)
- Coombs test
- Hemoglobinemia:
 - Pink or red supernatant of plasma or serum indicates hemolysis.
- Urinalysis:
 - Hemoglobinuria: Dipstick-positive blood without RBCs on micro
- Lab findings indicating hemolysis:
 - Thrombocytopenia ($< 100,000$)
 - Fibrinogenopenia (< 150 mg/L)
 - Fibrin degradation products
 - Prolonged activated PTT (aPTT)
 - Spherocytosis
- Lab findings indicating hemolysis due to Rh incompatibility:
 - Positive Coombs test
 - Elevated indirect bilirubin
 - Post-transfusion Hb/hematocrit not showing expected rise

Imaging

Chest radiograph: Diffuse patchy infiltrates without cardiomegaly if TRALI.

Diagnostic Procedures/Surgery

ECG for dysrhythmia, sign of electrolyte abnormality

DIFFERENTIAL DIAGNOSIS

- Sepsis
- Anaphylaxis/allergic reaction to medication

TREATMENT

PRE HOSPITAL

Routine stabilization

INITIAL STABILIZATION/THERAPY

- Immediately stop infusion:
 - Severity of reaction proportional to amount of blood transfused

- ABCs
- Supplemental oxygen—intubation and mechanical ventilation if needed
- Recheck blood-identifying information—patient’s bracelet, blood labels, call blood bank

ED TREATMENT/PROCEDURES

- Hypotension:
 - 0.9% normal saline (NS) hydration with 2 large-bore IVs
 - Avoid Ringer lactate or solutions containing dextrose.
 - Trendelenburg position
 - Dopamine
- Prevention of renal failure:
 - Maintain urine output of 1 mL/kg/h
 - Adequate hydration
 - Furosemide or mannitol if oliguric
 - Dopamine infusion at 2 µg/kg/min
- Febrile reactions:
 - Antipyretics (acetaminophen/nonsteroidal anti-inflammatory drugs [NSAIDs])
 - Antihistamine (diphenhydramine + ranitidine) IV
 - Steroids (methylprednisolone)
- Allergic reactions:
 - Antihistamine (diphenhydramine + ranitidine) IV
 - Epinephrine for respiratory symptoms
 - Steroids (methylprednisolone)
- Redraw blood sample for repeat ABO/Rh typing, direct antiglobulin testing.
- Foley catheter to monitor urine output
- Replenish calcium if hypocalcemia develops.
- Treat DIC

MEDICATION

- Calcium gluconate: 10 mL of 10% (peds: 100 mg/kg/dose) solution slow IV push
- Dopamine: 2–20 µg/kg/min IV
- Diphenhydramine: 25–50 mg (peds: 1.25 mg/kg) IV or PO
- Ranitidine: 50 mg IV (peds: 1–2 mg/kg/dose max. 50 mg)
- Epinephrine (1 in 1,000): 0.3–0.5 mL (peds: 0.01 mL/kg) SC
- Methylprednisolone: 125 mg (peds: 2 mg/kg) IV

FOLLOW-UP

DISPOSITION

Admission Criteria

- Acute hemolytic transfusion reaction, pulmonary complications, anaphylaxis, sepsis:
 - Require ICU monitoring
- Delayed hemolytic transfusion reactions for evaluation/treatment
- Electrolyte abnormalities requiring cardiac monitoring

Discharge Criteria

Uncomplicated febrile or allergic reaction

PEARLS AND PITFALLS

- Blood transfusion is substantially over utilized and has significant associated risk, such as transfusion reactions, transmission of pathogens, and immune suppression.
- Maintaining body temperature during massive transfusion is crucial to correcting coagulopathy.
- Failure to properly compare patient identification to labeling on blood or failure to wait for fully cross-matched blood carries significant risks.
- Suspect acute intravascular hemolysis if patient develops hypotension, dark urine, or oozing from IV or other puncture sites.

TRANSIENT GLOBAL AMNESIA

Kama Guluma

BASICS

DESCRIPTION

- Transient global amnesia (TGA) has the following features:
 - Episode of amnesia with abrupt onset
 - No focal neurologic signs or symptoms
 - Temporary, severe, anterograde amnesia:
 - Acute inability to form new memories
 - Permanent memory gap after the episode
 - Temporary short-range retrograde amnesia:
 - More recent memories at more risk
 - Previously encoded memories unavailable only temporarily
 - Gradually improves until only remaining memory deficit is the gap induced by the anterograde amnesia
- Incidence between 3 and 8 per 100,000 people:
 - 75% occur in people of 50–70 yr old
 - TGA rare < 40 yr
- Most attacks last between 1 and 8 hr (range 15 min–7 days)

ETIOLOGY

- Multimodal MRI, SPECT, and PET have shown some abnormalities of regional blood flow in selectively vulnerable hippocampal structures
- The exact etiology of TGA is unknown; speculation is controversial
- Speculated causes:
 - Vasoconstriction due to hyperventilation:
 - Psychogenic hyperventilation in setting of age-related cerebrovascular autoregulatory dysfunction
 - Hippocampal venous congestion with Valsalva:
 - Ultrasonography has suggested internal jugular vein incompetence
 - Migraine (in younger patients)
- No correlation between TGA and thromboembolic cerebrovascular disease has been found

DIAGNOSIS

SIGNS AND SYMPTOMS

Diagnostic criteria:

- Attack must be witnessed

- Acute onset of anterograde amnesia
- No alteration in consciousness
- No cognitive impairment except amnesia
- No loss of personal information (e.g., name, birth date, address, etc.)
- No focal neurologic symptoms
- No epileptic features
- No recent history of head trauma or seizures
- Attack must resolve within 24 hr
- Other causes of amnesia excluded

History

- Often precipitated by stressful condition:
 - Cough, Valsalva
 - Physical exertion
 - Sexual intercourse
 - Extreme fright or shock
 - Intense heat or cold
- Patient will likely feel something is wrong:
 - May ask “how did I get here?”
 - May be repetitive in questions
 - Will be generally aware of attack
- May have other subtle transient symptoms at onset, such as headache, dizziness, nausea
- Historical features helpful in excluding other diagnoses are:
 - Onset of attack witnessed, with no seizure activity or epileptiform features noted
 - No history of seizures in prior 2 mo
 - No history of recent traumatic brain injury
 - Acute anterograde amnesia with relatively preserved remote memory

Physical-Exam

- Marked anterograde amnesia
- Most cases ($\geq 90\%$ in case series) will demonstrate repetitive questioning
- Neurologic and general exam normal
- TGA patient *WILL NOT* be:
 - Somnolent
 - Inattentive
 - Globally confused
 - Confabulate
- TGA patient *WILL* be:
 - Oriented to name, birth date, address, phone number, date
 - Able to perform complex tasks and following complex commands

- Aphasia, apraxia, and agnosia are NOT findings consistent with TGA

ESSENTIAL WORKUP

- True TGA can be diagnosed with a careful history and physical exam alone
- If clinical diagnosis is certain, no other workup is essential

DIAGNOSIS TESTS & INTERPRETATION

Testing indicated only when the diagnosis is uncertain

Lab

- CBC, comprehensive chemistries including glucose, LFTs, NH₃, thyroid studies, and UA for organic–metabolic etiologies were implicated
- Tox screen, alcohol level for toxic etiologies were suspected

Imaging

- Consider MRI if indicated.
 - In true TGA, MRI may show a focal hippocampal DWI or T2 lesion that resolves over time
- Head CT for intracranial mass if indicated

Diagnostic Procedures/Surgery

- EEG for seizure or nonconvulsive status if suspected
- Lumbar puncture and CSF analysis for encephalitis if suspected

DIFFERENTIAL DIAGNOSIS

- Other entities may present somewhat similarly but will likely have historical or physical exam features that readily distinguish them from TGA:
 - Anterior choroidal artery or posterior cerebral artery or TIA:
 - Additional related neurologic signs such as hemianopia
 - Acute confusional state/Korsakoff syndrome/metabolic disorder:
 - Alcohol, medication, or toxin ingestion
 - Decreased attention or other findings of an encephalopathy
 - Impairment with serial 7s or spelling “world” backward
 - Able to lay down new memory if allowed time to encode
 - Complex partial seizures/epileptic amnesic attacks:
 - Witnessed epileptiform activity or features (e.g., blank stares, automatisms, lip-smacking, olfactory hallucinations)
 - Short duration (typically < 30 min; TGA lasts hours)
 - No repetitive questioning
 - Frequent and rapid recurrences
 - Psychogenic amnesia:
 - Younger patient with a known psychiatric stressor
 - Prominent retrograde amnesia

- Psychogenic memory loss for personal identification, name, birth date, etc.
- Temporal lobe brain lesion or encephalitis affecting the temporal lobe:
 - Has other associated neurologic symptoms (e.g., visual field cut, confusion)
 - Progressive and permanent amnesia
- Previously unrecognized Alzheimer dementia:
 - Memory loss for personal information such as date, phone number, address
 - Signs of additional global cognitive impairment

TREATMENT

PRE HOSPITAL

There are no considerations in true TGA that are specific to the pre-hospital environment

INITIAL STABILIZATION/THERAPY

There is no known effective therapy for TGA

ED TREATMENT/PROCEDURES

- TGA is a self-limited, relatively benign entity
- Observe the patient for improvement
- Assuming a true diagnosis of TGA, no acute treatment beyond reassurance of patient and family is indicated

MEDICATION

First Line

Not applicable

Second Line

Not applicable

FOLLOW-UP

DISPOSITION

Admission Criteria

- Admission for further observation for patients without significant improvement at the time of disposition
- Patients with uncertain diagnosis

- Patients showing a trend toward resolution but who have suboptimal social support at home

Discharge Criteria

- A clear diagnosis of TGA
- Resolving or resolved amnesia
- Good social support

Issues for Referral

- Recurrence rate of TGA is 8%
- Refer patients with recurrent episodes of TGA to a neurologist:
 - May benefit from ambulatory EEG to workup epilepsy

FOLLOW-UP RECOMMENDATIONS

Given median age of TGA patients (60 yr), follow-up with primary care provider for general cardiovascular risk factor modification may be beneficial:

- No follow-up specific to TGA is indicated
- See “Issues for Referral” for patient with recurrent episode of TGA

PEARLS AND PITFALLS

- TGA is a distinct and relatively benign entity:
 - Acute onset of isolated anterograde amnesia
 - Resolves spontaneously
- Be aware of subtle features that may suggest a more pathologic alternative diagnosis:
 - Short, recurrent episodes or automatisms in epilepsy
 - Cognitive impairment with encephalopathy
 - Subtle neurologic signs in encephalitis or TIA
- If there is uncertainty regarding the diagnosis, the highest yield tests are multimodal MRI and EEG

- R41.2 Retrograde amnesia

TRANSIENT ISCHEMIC ATTACK (TIA)

Casey Grover • Rebecca Smith-Coggins

BASICS

DESCRIPTION

- TIA – an episode of reversible neurologic deficit caused by a temporary decrease in blood flow to an area of the central nervous system (CNS)
- Classically described as symptoms lasting < 24 hr, but most TIA symptoms resolve in < 1 hr
- A warning for stroke, as 12–30% of strokes will be preceded by TIA

ETIOLOGY

- Transient decrease in perfusion to an area of the CNS, which can be caused by:
 - Thrombosis in medium to large arteries with atherosclerosis (25%)
 - Intracranial small vessel disease (25%)
 - Embolic cause from the heart (20%)
 - Miscellaneous, including arterial dissection, vasculitis, and hypercoagulable states (5%)
 - No clear predisposing vascular cause found (25%)

DIAGNOSIS

SIGNS AND SYMPTOMS

- Symptoms are determined by the vascular territories which are affected
- Large vessel TIA syndromes:
 - Anterior cerebral artery (ACA) – unilateral motor/sensory loss to leg > arm, disinhibition
 - Middle cerebral artery (MCA) – unilateral motor/sensory loss to face/arm > leg, aphasia if dominant hemisphere, neglect if nondominant hemisphere, homonymous hemianopsia
 - Posterior cerebral artery (PCA) – homonymous hemianopsia, may have alexia, prosopagnosia (can't recognize faces)
 - Anterior inferior cerebellar artery (AICA) – unilateral deafness, vertigo, tinnitus, vomiting, ipsilateral facial weakness and limb ataxia, contralateral decrease in pain and temperature sensation
 - Posterior inferior cerebellar artery (PICA) – unilateral palatal weakness, unilateral limb ataxia, unilateral Horner's syndrome, decreased pain/temperature sensation on contralateral body:
 - Wallenberg syndrome
 - Vertebrobasilar artery – ataxia, oculomotor palsies, facial paresis, loss of

consciousness, quadriplegia

- Carotid artery – unilateral motor/sensory loss to face/leg/arm, aphasia if dominant hemisphere, neglect if nondominant hemisphere, homonymous hemianopsia
- Small vessel TIA syndromes:
 - Amaurosis fugax – transient monocular blindness from occlusion of ophthalmic branch of internal carotid
 - Lacunar infarcts – occlusion of a deep penetrating artery of the brain. Usually produce pure motor or pure sensory deficits
 - Internal capsule – hemiparesis or dysarthria with clumsy hand
 - Corona radiata – hemiparesis
 - Pons – dysarthria with clumsy hand
 - Thalamus – sensory loss to 1 side of the body

History

- Historical features suggestive of TIA:
 - Sudden onset
 - Short duration (as >60% of events last <1 hr)
 - Negative symptoms – CNS is underperfused and therefore, not functioning, so TIA syndromes generally produce loss of neurologic function – i.e., weakness or aphasia
 - Symptoms are focal, related to specific vascular territory
- Historical features not suggestive of TIA:
 - Gradual onset
 - Positive symptoms – increased neurologic function in a particular area, such as convulsion, tingling, or twitching, suggests increased CNS activity as with migraine or seizure

Physical-Exam

- Detailed neurologic exam: Strength, sensation, coordination, gait, naming/speech, and visual fields
- Persistent neurologic deficits suggest acute stroke rather than TIA
- The National Institute of Health Stroke Scale (NIHSS) is a reliable and easily repeatable neurologic exam
(http://www.ninds.nih.gov/doctors/NIH_Stroke_Scale.pdf)

ESSENTIAL WORKUP

- Rapid history and physical exam including detailed neurologic exam
- Fingerstick glucose – hypoglycemia can produce focal neurologic deficits
- Noncontrast CT head – rule out hemorrhage
- If patients present with persistent deficits, obtain STAT neurologic consultation with concern for acute stroke rather than TIA

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Glucose
- Chemistry panel – check Na, renal function
- CBC – exclude anemia, polycytosis
- Troponin – rule out concomitant ACS or demand ischemia
- Hemoglobin A1C and fasting lipid panel for patients being admitted/observed

Imaging

- CT:
 - Upon arrival to ED, STAT noncontrast head CT to rule out CNS hemorrhage
- MRI:
 - Up to 50% of patients that clinically have a TIA will have evidence of infarction on MRI:
 - Goal is to have MRI in < 24 hr
 - Diffusion-weighted imaging (DWI) is the most sensitive protocol for detection of tissue infarction
- Vascular imaging:
 - Either with initial imaging or inpatient workup, perform vascular imaging of the head and neck:
 - Almost 50% of patients with TIA have stenosis or occlusion of large arteries
 - Carotid duplex ultrasound can be used to detect internal carotid stenosis
 - CT angiography:
 - Can be performed at the time of initial noncontrast head CT
 - Can be used to detect stenosis in intracranial and extracranial vessels
 - Requires contrast
 - MR angiography:
 - Can be used to detect stenosis in intracranial and extracranial vessels
 - Time of flight (TOF) sequences can provide angiographic images without contrast

Diagnostic Procedures/Surgery

- ECG – evaluate for thrombogenic rhythms such as atrial fibrillation
- Echocardiography in patients with no other cause for TIA – exclude existing thrombus and abnormal wall motion or aneurysms that cause thrombus

DIFFERENTIAL DIAGNOSIS

- Hypoglycemia
- Seizure
- Paralysis after seizure (Todd's paralysis)

- Atypical migraine
- Psychiatric disease
- Stroke
- CNS tumors or metastases
- Subdural hemorrhage
- Subarachnoid hemorrhage
- Multiple sclerosis
- Intracerebral hemorrhage
- Air embolism
- Vasculitis
- Arterial dissection

Pediatric Considerations

- Congenital heart disease
- Vasculitis
- Arterial dissection
- Sickle cell disease
- Neurocutaneous syndromes
- Vascular malformations
- Meningitis

TREATMENT

PRE HOSPITAL

- Rapid assessment of neurologic deficits
- Consider transport to a stroke center, when available, if deficits persist

INITIAL STABILIZATION/THERAPY

- IV access
- Cardiac monitoring
- Supplemental oxygen if hypoxic

ED TREATMENT/PROCEDURES

- Main goals in the management of TIA:
 - Improve perfusion to ischemic tissue
 - Prevent a subsequent stroke
- BP management:
 - BP should not be lowered acutely unless over 220/120 mm Hg
 - Hypertensive patients with TIA should have their BP lowered if stable at 24 hr after TIA
 - Key in patients upon discharge
 - 1st line – HCTZ or ACE inhibitor

- **Antiplatelet therapy:**
 - All patients, in the absence of contraindications, need antiplatelet therapy for stroke prevention
 - 1st line – aspirin (ASA):
 - Safe, cheap, effective
 - ASA allergy – clopidogrel, ticlopidine
 - ASA/dipyridamole may be more effective than ASA alone
- **Anticoagulation:**
 - Indicated for new onset atrial fibrillation or existing atrial fibrillation not on anticoagulants
 - Options include heparin/low-molecular-weight heparin with a transition to warfarin or dabigatran
 - The decision to anticoagulate is not emergent; discuss with admitting physician
- **Carotid endarterectomy (CEA):**
 - CEA within 2 wk after TIA in patients with >70% carotid stenosis reduces stroke risk by 10–15%
- **Lipid therapy:**
 - AHA guidelines recommend statin therapy for patients with TIA with a goal LDL of under 70 mg/dL
 - Key in patients upon discharge

MEDICATION

- **Antiplatelet agents:**
 - Aspirin 160–325 mg daily
 - Aspirin/dipyridamole 25 mg/200 mg daily
 - Clopidogrel 300 mg initially then 75 mg daily
- **Anticoagulation:**
 - Heparin 5,000–7,500 U IV bolus, followed by 1,000 U/h infusion OR 80 U/kg IV bolus then 18 U/kg/h
 - Warfarin dose is dependent on age and weight, but goal INR for atrial fibrillation is 2–3
 - Dabigatran 150 mg daily (normal renal function)
- **Acute BP management:**
 - Labetalol 20 mg IV bolus, followed by 20–80 mg IV every 10 min; max. cumulative dose of 300 mg
 - Nicardipine 5 mg/h infusion, increase by 2.5 mg/h every 5–15 min; max. dose of 15 mg/h

FOLLOW-UP

DISPOSITION

Admission Criteria

- There are no clear indications for admission or discharge
- Patients with TIA have variable short-term risk of stroke
- Goal of admission is to prevent subsequent stroke in high-risk patients
- Scoring systems have been developed to predict short-term risk of stroke and therefore can guide disposition
- Most common = ABCD2 score:
 - _ Age >60 = 1 point
 - _ BP >140/90 = 1 point
 - _ Clinical features:
 - Unilateral weakness = 2 points
 - Speech difficulty alone = 1 point
 - _ Duration:
 - >60 min = 2 points
 - 10–59 min = 1 point
 - <10 min = 0 points
 - _ Diabetes = 1 point
- ABCD2 score 0–3 = low risk of stroke (~1% at 7 days)
- ABCD2 score 4–5 = moderate risk for stroke (~6% at 7 days)
- ABCD2 score 6–7 = high risk for stroke (~12% at 7 days)
- Patients with moderate to high risk for short-term stroke = admission
- Patients with low risk for short-term stroke, but poor follow-up = observation unit

Pediatric Considerations

All children with TIA should be admitted for close neurologic observation, with strong consideration of ICU level care

Discharge Criteria

- No clear discharge criteria exist:
 - _ Low risk for short-term stroke, with good follow-up

Issues for Referral

- The risk of stroke after TIA is highest within 2 days of symptoms
- Discharged patients need to see neurology/primary care within 24–48 hr

FOLLOW-UP RECOMMENDATIONS

- Primary Care/Neurology – management of risk factors for cerebrovascular disease (hypertension, diabetes, etc.)
- Vascular surgery – for carotid stenosis. Follow-up within 1 wk, plan for possible CEA within 2 wk
- Cardiology – for those patients with cardiac cause of stroke, such as atrial fibrillation or cardiomyopathy

PEARLS AND PITFALLS

- Pearls:
 - Risk stratification scores (such as ABCD2) can help guide disposition
 - Patients with carotid stenosis need rapid vascular surgery follow-up
- Pitfalls:
 - Failure to recognize the subtle lacunar TIA syndromes, such as sensory loss
 - Failure to rapidly check a glucose in a patient with a focal neurologic deficit
 - Discharging patients with TIA without close outpatient follow-up

TRANSPLANT REJECTION

Kyle R. Brown • Jeffrey N. Siegelman

BASICS

DESCRIPTION

Immune response to a graft's genetically dissimilar antigens resulting in rejection of the transplanted organ:

- **HLA incompatibility:**
 - _ Most common cause of rejection
 - _ Rejection of solid organ transplants
- **Blood group incompatibility:**
 - _ Much less of a risk to graft survival than HLA incompatibility
 - _ May result in hyperacute rejection of primarily vascularized grafts (kidney and heart)
- **3 phases of rejection:**
 - _ **Hyperacute:**
 - Immediate postoperative period
 - Antibody reaction to red cells or HLA antigens
 - Endothelial damage
 - Platelets accumulate, thrombi develop, and tissue necrosis occurs.
 - Rare with careful donor–recipient matching
 - _ **Acute:**
 - _ Within the 1st 3 mo postop
 - _ At any time if immunosuppressant (IS) medication is stopped
 - _ T-cell–dependent process. Inflammatory cells infiltrate allograft, release cellular and humoral factors, destroys graft
 - _ Presents with constitutional symptoms and signs of transplant organ insufficiency
 - _ **Chronic:**
 - _ Occurs over years
 - _ Results in gradual organ failure

EPIDEMIOLOGY

Incidence and Prevalence Estimates

- **Solid organ transplants:**
 - _ End of 2007: 183,222 living transplant patients
 - _ 27,281 organs transplanted in 2008
 - _ Most transplanted organs: Kidney (59%), liver (21%), heart (8%), lung (5%), pancreas (4%)
 - _ Most common diagnosis from visit to ED: Infection (36%), GI/GU pathology

(20%), dehydration (15%), electrolyte (10%), CV and pulmonary pathology (10%), injury (8%), rejection (6%). 60% required hospitalization

- Hematopoietic stem cell transplants:
 - 4,300 transplants in 2008
 - Acute graft-versus-host disease incidence: 20–80%.

ETIOLOGY

- Reduction or noncompliance with medication:
 - Medication interactions with cyclosporine, tacrolimus, or sirolimus:
 - Phenobarbital, phenytoin, carbamazepine, rifampin, isoniazid
- Kidney transplant rejection:
 - Early rejection caused by T and B lymphocytes, which attack microvasculature and impair graft perfusion; volume depletion, hypotension, infection
 - Chronic rejection caused by progressive nephrosclerosis of renal vessels, infection
- Liver transplant rejection:
 - Acute: 48% by 6 wk, 65% by 1 yr
 - Commonly follows reduction in the IS regimen
 - Chronic: <5%
 - 1 wk to 6 mo MC range to experience
- Cardiac transplant rejection:
 - Acute rejection:
 - 75–85% of patients within the 1st 3–6 mo due to T-cell-mediated response
 - Chronic rejection:
 - Accelerated atherosclerosis is the hallmark
 - Associated with change in IS therapy
- Lung transplant rejection:
 - Acute rejection develops early:
 - Can occur up to 6 times in the 1st year
 - Chronic rejection:
 - 25–40% of patients postop
 - MCC of death in 2nd postop year
 - Rejection caused by endothelial, vascular, and lymphocyte inflammation, recurrent acute rejection
- Bone marrow transplant rejection:
 - Acute graft-versus-host disease:
 - Immune attack of donor marrow on lung tissue
 - Chronic graft-versus-host disease:
 - 25–50% of patients
 - Marrow rejection:
 - MC in patients with plastic anemia who do not receive total body

radiotherapy or in patients receiving mismatched or unrelated transplants

DIAGNOSIS

SIGNS AND SYMPTOMS

- Renal transplant rejection:
 - Progressive systemic HTN
 - Decreased urine output
 - Swelling, fever, and tenderness:
 - Uncommon with IS therapy
- Liver transplant rejection:
 - Fever, RUQ pain, jaundice
- Heart transplant rejection:
 - Fever, dyspnea, chest pain, hypo- or hypertension, palpitations, nausea, vomiting, syncope, sudden death
 - Can be asymptomatic
- Lung transplant rejection:
 - Cough, dyspnea, fever, rales, and rhonchi
- Bone marrow transplant rejection:
 - Fever, wasting, mucositis, keratoconjunctivitis, dysphagia, cough, dyspnea, hypoxia, chest pain, abdominal pain, diarrhea, jaundice, rash, encephalopathy, seizures

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- IS medication levels:
 - Levels may not represent through if patient took medication prior to ED visit.
- Blood cultures
- Renal transplant rejection:
 - Electrolytes, BUN, creatinine, CRP
 - Urinalysis with micro:
 - Proteinuria may signal early rejection. Presence of leukocytes may be seen during rejection as well as with infection.
 - FENa helps differentiate rejection from iatrogenic causes
- Liver transplant rejection:
 - Coagulation panel, lipase, cultures (blood, urine, ascites), liver function tests
 - Late acute rejection presents with elevated bilirubin and transaminases.

- Heart transplant rejection:
 - Cardiac troponin
- Lung transplant rejection:
 - ABG, electrolytes, kidney function, CRP, liver function, bilirubin, LDH, CPK, EBV, CMV, cyclosporine levels
- Bone marrow transplant rejection:
 - ABG, liver function tests

Imaging

- CXR:
 - Acute lung rejection:
 - Diffuse infiltrates are seen early
 - Normal or unchanged > 1 mo after transplantation
 - Bone marrow transplant rejection:
 - Interstitial infiltrates, pleural effusion, pulmonary edema
- Renal US:
 - Indicated for suspicion of renal transplant rejection:
 - Hydronephrosis implies obstructive uropathy and may need urgent percutaneous nephrostomy.
- Liver transplant:
 - Hepatic US
 - CT abdomen
- Echocardiography:
 - Heart transplant
 - Assess for changes in cardiac output.
- MRI:
 - Renal transplant:
 - May be done with or without contrast
 - Consult transplant team before giving contrast

Diagnostic Procedures/Surgery

- Liver transplant rejection:
 - ERCP cholangiography
- Heart transplant rejection:
 - EKG:
 - Commonly demonstrates 2 P waves because the native sinus node is spared
- Lung transplant rejection:
 - Peak flow reduced FEV1
 - Early bronchoscopy and biopsy to differentiate infection from rejection

ESSENTIAL WORKUP

- Consider drug toxicity and infection as well as rejection.

- Ask about medication dose or compliance changes
- Low threshold for screening labs and imaging even with minimal signs and symptoms

DIFFERENTIAL DIAGNOSIS

- Infections:
 - Wide variety of bacterial, mycobacterial, fungal, viral, and parasitic pathogens can cause opportunistic infections in transplant patients.
- IS toxicity
- Drug interactions with IS medication
- Renal transplant rejection:
 - Any disorder that can affect the native kidneys can also occur in the transplant
 - Iatrogenic nephrotoxicity: Cyclosporine, tacrolimus, other medications
 - UTI/pyelonephritis:
 - Classic organisms as with native kidney infections
 - Tubulointerstitial nephritis caused by the BK-polyomavirus (incidence 3–5%)
 - Acute occlusion of the transplant renal artery or vein:
 - Acute occlusion usually occurs within the 1st post-transplant week (incidence 0.5–8%) and causes oliguria and acute renal failure.
 - Peritransplant hematoma
 - Urinary leak
 - Obstructive uropathy
 - Bleeding after renal graft biopsy
- Liver transplant rejection
 - Ascending cholangitis:
 - Possible from colonized postop biliary stent.
 - Cholestatic hepatitis from azathioprine
 - Methotrexate-induced hepatotoxicity
- Lung transplant rejection
 - MC bacterial infection in lung transplant is cytomegalovirus pneumonia.
 - MC fungal infection is Aspergillus.
 - Upper respiratory infection or bronchitis:
 - Mimic chronic lung rejection
 - Medication-induced pneumonitis

TREATMENT

PRE HOSPITAL

Avoid aggressive fluid resuscitation.

INITIAL STABILIZATION/THERAPY

- ABCs
- Shock state treated with IV fluids, and pressor agents.
- Treat hypertensive crisis like other hypertensive emergencies.

ED TREATMENT/PROCEDURES

ALERT

Always discuss with transplant service early unless unstable, especially when adding or changing medications.

ALERT

Caution with use of NSAIDs; there are many associated complications in these patients.

- Kidney, heart, lung, and liver rejection:
 - Administer high-dose steroids
 - Stress-dose corticosteroid coverage is also indicated in any ill-appearing transplant patient. Consult with transplant service early
 - Avoid blood transfusions because these need special screening to prevent transmission of disease.
- Heart transplant rejection:
 - Pressors and inotropics work as usual in the transplanted heart.
 - Atropine will have no effect on bradycardia because there is no vagal innervation.
 - Use dopamine, epinephrine drips, or external pacing to increase heart rate if bradycardia is symptomatic.
 - IV methylprednisolone: 1 gm/d for 3 days
- Lung transplant:
 - Treat for infection and rejection
 - IV methylprednisolone: 15 mg/kg daily × 3 days
- Graft-versus-host disease:
 - 1–2 mg/kg daily PO or IV steroids
 - For chronic, may need adjustments of IS therapy.
- Common IS regimens are cyclosporine, prednisone, and azathioprine or tacrolimus and prednisone.

MEDICATION

As directed by transplant team

FOLLOW-UP

DISPOSITION

Admission Criteria

- Admit transplant recipients with fever, shortness of breath, signs or symptoms of rejection, abdominal pain, or other signs of organ infection, pneumothorax, and respiratory failure.
- Admit to the ICU patients who are septic, in acute renal failure, or have cardiopulmonary compromise.

Discharge Criteria

Nontoxic patients in whom rejection or serious infection has been excluded may be discharged with close follow-up and in consultation with their transplant service.

Issues for Referral

Treatment decisions should be made in consultation with the patient's oncologist, transplant surgeon, or organ specialist.

FOLLOW-UP RECOMMENDATIONS

- The patient's transplant team should actively participate in the follow-up plan:
- All attempts at verbal communication with the covering transplant physician should be made while the patient is in the ED with any symptoms suggestive of rejection.

PEARLS AND PITFALLS

- Transplant patients presenting with minor complaints are at high risk for rejection and require an in-depth assessment in the ED, in conjunction with their transplant team.
- Patients with signs of possible transplant rejection should also be considered for infection and drug toxicity.
- A high percentage require admission

TRAUMA, MULTIPLE

Daniel Davis • Alexander L. Bromfield

BASICS

DESCRIPTION

- Standardized approach for rapid assessment of the trauma patient
- Although presented as a sequential method for gathering information, many of these steps can be performed simultaneously.
- In general, injuries must be prioritized in order of severity to increase survival. Life-threatening injuries, particularly when abnormal vital signs are present, must be immediately addressed and treated before going on to the next level of care.
- With any change in the patient's status, the primary survey should be repeated.

ETIOLOGY

Variety of causes such as:

- Motor vehicle/motorcycle crashes
- Falls from heights
- Assault
- Airplane crashes
- Train derailments
- Results of mass-casualty weapons
- Terrorism

DIAGNOSIS

- Triage to a major trauma center is determined by local protocols.
- Injured patients with a need for surgical, neurosurgical, or orthopedic intervention should be transported to a major trauma center.
- Recent recommendations from the American College of Surgeons suggest that trauma victims with unstable vital signs should be taken to a Level I trauma center, where a larger volume of critically injured patients are seen.
- Primary survey should be performed at the scene and en route.

SIGNS AND SYMPTOMS

- Primary survey (ABCDE):
 - Airway, cervical spine:
 - Look, listen, and palpate from nose/mouth to trachea/bronchial tree.
 - Assess airway patency.
 - Evaluate gag reflex.
 - Cervical spine must be immobilized with significant mechanism of injury and either altered mental status or distracting injuries or with

signs and symptoms suggestive of neck injury.

- Ability to speak or effective movement of air with respiration indicates patency.
- Gurgling, stridor, wheezing, snoring, choking, or absence of air movement requires immediate intervention.
- Manage airway compromise before next step in primary survey.

– Breathing:

- Awake, alert patient with normal speech and good air movement suggests effective breathing.
- Symmetric chest wall rise/fall, equal breath sounds, normal respiratory rate, and oxygen saturation at 95% or more suggest effective breathing.
- Asymmetric chest movement, unequal breath sounds, abnormal respiratory rate, decreased oxygen saturation, inadequate air movement, or an obtunded patient suggests ineffective breathing.
- Decreased unilateral breath sounds, tracheal shift, hyperexpansion, hyperresonance to percussion, subcutaneous air, hypoxia, or hemodynamic compromise raises concerns about tension pneumothorax.
- Decreased breath sounds with dullness to percussion suggest hemothorax.
- Manage patients immediately with needle thoracostomy followed by tube thoracostomy.

– Circulation:

- Adequate circulating blood volume must be maintained.
- Primary assessment includes BP, heart rate, pulse quality, and end-organ function (e.g., mentation, urine output, capillary refill).
- Tachycardia and oliguria indicate early shock; hypotension is a late finding and necessitates a search for hemorrhage

– Disability:

- Assess level of consciousness, gross motor function, and pupillary size/reactivity.
- Glasgow Coma Scale is most commonly used; score of ≤ 8 indicates severe head injury/coma.
- Spinal cord injuries are grossly assessed by observing movement of all extremities.
- Pupillary size and reactivity to light measure brainstem function.

– Exposure:

- Patient should be undressed completely.

● Secondary survey:

- After the primary survey has been completed
- Patient stabilized at each level
- Complete physical exam from head to toe is performed.

- “Tubes and fingers in every body cavity”

History

The mechanism of injury, initial clinical presentation, suspected injuries, and treatment rendered should be elicited from EMS personnel.

Physical-Exam

Initial stabilization should begin simultaneously with essential workup.

ESSENTIAL WORKUP

- Primary and secondary surveys
- Cervical spine and chest radiographs are mandatory for victims of major trauma.
- Pelvic radiographs should be performed with clinical suspicion of pelvic trauma or with hemodynamic instability.
- Hemoglobin/hematocrit, ABG, blood type; a toxicology screen may also be considered.
- Urine dip for blood
- UA if dip shows positive result
- Urine-based pregnancy test for any female patient of childbearing age

DIAGNOSIS TESTS & INTERPRETATION

Lab

Baseline coagulation and chemistry studies with massive injury or hemorrhage

Imaging

- Loss of consciousness, post-traumatic amnesia (anterograde or retrograde), or persistent altered level of consciousness is indication for head CT.
- Significant blunt and penetrating chest trauma requires objective evaluation of the heart and great vessels with echocardiography, CT scan, angiography, or direct visualization.
- Blunt abdominal trauma requires objective evaluation using US, abdominal CT, or diagnostic peritoneal lavage, depending on patient's condition:
 - Hemodynamically stable patients should have an abdominal CT with IV contrast.
 - Unstable patients should have an abdominal ultrasound (FAST exam) or diagnostic peritoneal lavage.
 - Many centers now doing “Pan CT scan,” including head, neck, chest, abdomen/pelvis in a single pass with IV contrast
 - Pan CT lowers missed injury rate but involves significant radiation exposure
- Extremity injury:
 - Radiographs
 - Suspected vascular damage requires angiography or duplex ultrasound.

DIFFERENTIAL DIAGNOSIS

Some level of clinical suspicion should be maintained for other medical conditions leading to trauma (e.g., seizures, dysrhythmias).

TREATMENT

INITIAL STABILIZATION/THERAPY

- The initial treatment should parallel the primary survey with injuries treated before addressing the next assessment level.
- Airway with cervical spine control:
 - Jaw thrust, suctioning, and oropharyngeal or nasopharyngeal airways provide initial airway support.
- Rapid sequence intubation is the airway management option of choice for multiple trauma patients:
 - Insertion of an extraglottic airway (e.g., Combitube, laryngeal tube, or laryngeal mask airway) or cricothyroidotomy may be necessary.
 - Use of video laryngoscopy may allow endotracheal intubation with minimal impact on potential traumatic brain injury or an unstable cervical spine
- Breathing:
 - 100% oxygen and respiratory monitoring
 - Tension pneumothorax should be diagnosed clinically and decompressed on an emergency basis with a needle thoracostomy below the axilla or above the 2nd rib in the midclavicular line.
 - Tube thoracostomy should follow.
 - Open chest wounds should be covered with an adherent dressing and a tube thoracostomy performed.
 - Respiratory distress from flail segment or pulmonary contusion should prompt early intubation with mechanical ventilation and positive end expiratory pressure.
 - Hyperventilation should be avoided except with impending herniation or intracranial HTN resistant to other therapies; end-tidal carbon dioxide monitoring should be used.
- Circulation:
 - 2 large-bore IV lines with constant hemodynamic and cardiac monitoring should be placed.
 - A thoracotomy may be considered in a previously stable patient with penetrating chest trauma and an acute deterioration in status
 - A Foley catheter can be placed to help monitor urine output but should be withheld if blood is present at the urethral open until additional imaging can be performed
- Alternatives include central lines, venous cut-downs (e.g., saphenous or femoral), or intraosseous lines:

- Aggressive fluid replacement with 3 parts fluid for every 1 part circulatory volume loss remains most widely recommended care; adjust fluids based on ongoing assessment:
 - 2 L initial bolus in adults, 20 mL/kg in children
 - Whole blood or autotransfused blood for hemorrhagic shock or uncontrolled bleeding
- Pericardial tamponade requires emergent pericardiocentesis/pericardial window.
- External bleeding should be managed with direct pressure.
- Unstable pelvic fractures should be treated with pelvic binding
- Disability:
 - Head injury with Glasgow Coma Scale score of ≤ 8 should initiate treatment for elevated intracranial pressure with mannitol or hypertonic saline, rapid-sequence intubation, oxygenation, and controlled ventilation to a PCO_2 of 35 mm Hg.
 - Elevate head 20–30°, maintaining spine immobilization.

ED TREATMENT/PROCEDURES

- Definitive treatment is often surgical.
- Prompt stabilization, early recognition of the need for operative intervention, and appropriate trauma surgical consultation are paramount.

MEDICATION

Dictated by need for specific interventions

Pediatric Considerations

Intraosseous lines are an alternative to IV lines for fluids and medications. Lack of rib cervical spine fractures does not exclude spinal cord injury

FOLLOW-UP

DISPOSITION

Admission Criteria

- Most major trauma patients should be admitted for observation, monitoring, and further evaluation.
- Patients with significant injuries or hemodynamic instability should be admitted to an ICU.
- Patients requiring frequent assessments should be admitted to a monitored setting.

Discharge Criteria

Patients with minor trauma and negative objective workup/imaging may be observed in

the ED for several hours and then discharged.

Issues for Referral

The main indications for referral concern the availability of subspecialists, such as neurosurgeons, orthopedists/hand surgeons, otolaryngologists, plastic surgeons, or intensivists.

FOLLOW-UP RECOMMENDATIONS

Follow-up should be driven by the types of injuries and subspecialty care required.

PEARLS AND PITFALLS

- The ABCs of trauma remain the standard approach to guide the initial assessment and treatment of trauma patients.
- A high level of suspicion for occult injuries should be maintained, with a low threshold for obtaining objective imaging.
- Trauma systems are defined by an organized approach to accessing quality trauma and subspecialty care.

TRICHOMONAS

Herbert Neil Wigder • Erin Nasrallah

BASICS

DESCRIPTION

- Sexually transmitted disease (STD)
- Associated with high prevalence of other STDs
- Causes urogenital infections
- Sequelae:
 - May cause premature rupture of membranes or preterm labor in pregnancy
 - May cause low-birth-weight newborns
 - May facilitate transmission of HIV
- Prevalence:
 - 3–5 million cases per year in US
 - 35% of women treated in STD clinics
 - Overall prevalence 3.1%:
 - Prevalence in black women 13.3%
- Incubation 4–28 days
- May be asymptomatic

ETIOLOGY

Trichomonas vaginalis:

- Flagellated protozoan:
 - Commonly found in urethra, bladder, and Skene gland

DIAGNOSIS

SIGNS AND SYMPTOMS

OTHER

- Vaginitis:
 - Vaginal discharge is seen in < 30% of patients
 - Frothy yellow/green to gray/white
 - Vulvar itching and irritation
 - Vaginal odor
 - Symptoms same as with bacterial vaginosis (caused by Gardnerella vaginalis) and vulvovaginal candidiasis (caused by Candida albicans)
 - Dysuria and urinary urgency
 - Painful sexual intercourse
 - Often asymptomatic (50%)

- Cervix:
 - Diffuse erythema (10–33%)
 - Punctate hemorrhage—colpitis macularis or strawberry cervix (2%)
- Abdominal pain uncommon

Male

- Often asymptomatic (75%) or self-limited
- Male to male transmission is uncommon
- Nongonococcal urethritis:
 - 20% of nonspecific urethritis
 - Scant discharge
 - Dysuria and urinary urgency
- Complications:
 - Prostatitis
 - Epididymitis
 - Reversible sterility

Physical Exam

- Female:
 - Vaginal discharge:
 - Frothy yellow/green to gray/white
 - Odor
 - Red ulcerations—vaginal wall and cervix
- Male:
 - Scant discharge

ESSENTIAL WORKUP

- Treat empirically if high enough clinical suspicion
- Females: Wet mount (“Hanging-drop”):
 - 60–70% sensitive in symptomatic patients
 - Saline wet mount from cervical/vaginal vault smear:
 - Requires immediate evaluation of slide
 - Many polymorphonuclear leukocytes (PMNs)
 - Motile, pear-shaped, flagellated trichomonads (slightly larger than leukocytes; seen in 60%)
 - Specimen from spun urine less sensitive
 - Absence of trichomonads does not rule out *T. vaginalis* infection (only present in 60–70%)
 - Many EDs not equipped to perform wet mount
- Elevated vaginal pH (> 4.5) common:
 - Not specific
- Males: Wet mount insensitive
 - PCR reliable but not widely available

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Culture:
 - 95% sensitivity:
 - Prostate massage before collection increases sensitivity in males.
 - Do culture when trichomonads suspected but not confirmed by wet-mount microscopy
- Point-of-care tests:
 - High specificity (>97%) but variable sensitivities
- Polymerase chain reaction (PCR):
 - Expensive

DIFFERENTIAL DIAGNOSIS

- UTI
- Gonorrhea
- Chlamydia
- Bacterial vaginosis
- Candidal vaginitis
- Nonspecific vaginitis

TREATMENT

ED TREATMENT/PROCEDURES

- Female:
 - Metronidazole 2 g PO once:
 - 90–95% cure rate
 - Metronidazole 250 mg PO TID for 7 days (urethritis)
 - Tinidazole 2 g PO once:
 - 86–100% cure rate
 - Metronidazole gel, less effective:
 - Not recommended
- Pregnant:
 - Symptomatic:
 - Metronidazole (FDA category B)
 - Asymptomatic:
 - Treatment is controversial as it does not reduce incidence of premature rupture of membranes or preterm delivery
 - Metronidazole
- Males (urethritis):
 - Metronidazole 2 g PO once
 - Tinidazole 2 g PO once

- Metronidazole 250 mg PO TID for 7 days
- HIV positive
 - Consider 7-day course of treatment because of evidence of increased single dose treatment failure
- Treat sex partners to prevent reinfection
 - No sexual intercourse until both partners are asymptomatic and until after at least 1 wk after treatment completed
- Advise using latex condoms
- Avoid concomitant alcohol use with metronidazole:
 - No alcohol for 24 hr after last metronidazole as it precipitates Antabuse reaction

FOLLOW-UP

DISPOSITION

Discharge Criteria

All patients

PEARLS AND PITFALLS

- Typical treatment for nongonococcal urethritis (e.g., azithromycin, doxycycline) does not treat *T. vaginalis*.
- Vaginitis in females not responding to treatment for bacterial vaginosis might be due to *Trichomonas* infection.
- Nongonococcal urethritis in males not responding to azithromycin or doxycycline might be due to *Trichomonas*.

TRICYCLIC ANTIDEPRESSANT, POISONING

Steven E. Aks

BASICS

DESCRIPTION

- Primary mechanism of tricyclic antidepressant (TCA) toxicity:
 - Sodium channel blocking effect (quinidine-like effect)
 - Inhibition of norepinephrine reuptake
 - α -blockade
 - Anticholinergic effect
- Selective serotonin reuptake inhibitors (SSRIs):
 - Wider margin of safety than TCA
 - Less CNS/cardiovascular toxicity
- Nonselective serotonin reuptake inhibitors:
 - Serotonin and norepinephrine reuptake inhibitors (SNRIs)
 - Can cause cardiac dysrhythmias or seizures
 - Venlafaxine (Effexor)
 - See “Antidepressants, Poisoning.”

ETIOLOGY

- TCAs:
 - Amitriptyline
 - Nortriptyline
 - Imipramine
 - Doxepin
- Newer-generation antidepressants (nontricyclic):
 - Have different toxic profile than TCAs
 - See “Antidepressants, Poisoning.”
- Rapid deterioration may occur.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Rapid deterioration may occur.
- Classic TCA compounds (imipramine, amitriptyline, nortriptyline)—greatest cardiovascular toxicity
- Newer agents (serotonergic agents)—less overall toxicity in overdose
- CNS:
 - Stimulation or depression
 - Stimulation:

- Tremulousness
- Agitation
- Fasciculation
- Seizures (resulting acidemia may lead to worsening cardiovascular toxicity)
- Depression:
 - Drowsiness
 - Lethargy
 - Coma
- Cardiovascular system:
 - Hypotension
 - Tachycardia:
 - Early; owing to blockade of norepinephrine reuptake and anticholinergic effects
 - Bradycardia:
 - Late; owing to catecholamine depletion state
 - ECG changes:
 - QRS widening ($> 100\text{--}120$ ms)
 - Rightward shift in terminal 40 ms in frontal plane axis (R wave > 3 mm in aVR)
 - Dysrhythmias:
 - Supraventricular tachycardia (SVT)
 - Ventricular arrhythmias
- Anticholinergic effects (less common):
 - Dilated pupils
 - Decreased bowel sounds
 - Urinary retention

History

Substance ingestion in patient with access to TCA

Physical-Exam

- CNS:
 - Stimulation or depression
- Cardiovascular:
 - Tachycardia
 - Mydriasis or midrange pupils
 - Decreased bowel sounds
 - Urinary retention (rare)

ESSENTIAL WORKUP

- ECG: Factors associated with TCA poisoning:
 - Sinus tachycardia (almost always present at some time after poisoning)

- QRS widening:
 - o >100 ms associated with seizure
 - o >160 ms associated with ventricular dysrhythmia
- QT prolongation
- PR prolongation
- Rightward shifting of terminal 40 ms QRS axis
- R-wave amplitude in aVR > 3 mm
- Continuous cardiac monitor

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Electrolytes, BUN, creatinine, glucose
- ABG
- Urine toxicology screen:
 - Rule out other toxins.
- TCA levels:
 - Not useful
 - Do not correlate well with degree of toxicity
 - Qualitative screen appropriate to confirm ingestion if necessary

Imaging

Chest radiograph for aspiration pneumonia/pulmonary edema

DIFFERENTIAL DIAGNOSIS

- Drugs that cause coma:
 - Alcohols
 - Alcohol withdrawal
 - Anticholinergics
 - Lithium
 - Phencyclidine (PCP)
 - Opioids
 - Phenothiazines
 - Sedative hypnotics
 - Salicylates
- Cardiotoxic drugs:
 - Antidysrhythmics (category IA)
 - Digoxin toxicity
 - Sympathomimetics
 - Anticholinergics
- Drugs that cause seizures:
 - Alcohol withdrawal

- Anticholinergics
- Camphor
- Isoniazid
- Lindane
- Lithium
- Phenothiazines
- Sympathomimetics
- Toxic alcohols

TREATMENT

PRE HOSPITAL

- Do not be lulled into false sense of security with well-appearing patient:
 - Rapid onset of altered mental status, seizures, and dysrhythmias occur.
- Perform endotracheal intubation if any evidence of compromise.
- Secure IV access.
- Administer sodium bicarbonate if any evidence of QRS widening ($> 100\text{--}120$ ms):
 - 1 ampule in adults
 - 1–2 mEq/kg in children
- Ipecac contraindicated (risk for aspiration with development of depressed mental status or seizure)

INITIAL STABILIZATION/THERAPY

- ABCs:
 - Low threshold to intubate patients with altered mental status
- IV 0.9% normal saline (NS)
- Oxygen
- Cardiac monitor:
 - For wide-complex rhythm (QRS $> 100\text{--}120$ ms) bolus sodium bicarbonate
- Naloxone, thiamine, glucose (Accu-Chek) for altered mental status
- Flumazenil contraindicated in combined TCA/benzodiazepine overdose

ED TREATMENT/PROCEDURES

Cardiac Toxicity

- Initiate therapy for cardiac toxicity aggressively to prevent deterioration.
- QRS widening ($> 100\text{--}120$ ms):
 - Bolus with 1 amp (peds: 1–2 mEq/kg) of sodium bicarbonate; repeat if sudden increase in QRS width
 - Maintain arterial pH of 7.45–7.5 with hyperventilation.
 - Initiate sodium bicarbonate infusion if hyperventilation alone does not reach target pH.

- **Dysrhythmia:**
 - Sinus tachycardia requires no treatment.
 - Bolus 1–2 amps of sodium bicarbonate (1–2 mEq/kg in children) for sudden change in rhythm
 - Follow advanced cardiac life support (ACLS) protocol with addition of sodium bicarbonate boluses:
 - Lidocaine is 2nd-line agent after sodium bicarbonate.
 - Use of class IA (procainamide) and IC agents and physostigmine contraindicated

Hypotension

- 0.9% NS fluid bolus
- Norepinephrine:
 - Preferred pressor (over dopamine)
 - Counters α -blockade better
 - Dopamine requires higher doses.

Decontamination

- Gastric lavage:
 - For recent ingestion (< 1 hr)
 - Performed when airway has been secured in lethargic patient
- Administer activated charcoal with sorbitol.
- Ipecac contraindicated

Seizure

- Diazepam 1st-line followed by phenobarbital
- Neuromuscular paralysis with short-acting agent (rocuronium/vecuronium) for refractory seizures (monitor EEG)
- Sodium bicarbonate bolus to prevent acidosis

MEDICATION

First Line

- Sodium bicarbonate: 1–2 amps (50–100 mEq) IV push (peds: 1–2 mEq/kg)
- Activated charcoal slurry: 1–2 g/kg up to 90 g PO

Second Line

- Dextrose: D₅₀W, 1 amp: 50 mL or 25 g (peds: D₂₅W, 2–4 mL/kg) IV
- Diazepam (benzodiazepine): 5–10 mg (peds: 0.2–0.5 mg/kg) IV
- Dopamine: 2–20 μ g/kg/min IV infusion titrated to desired effect
- Intralipid fat emulsion 20%: 1.5 mL/kg IV followed by 0.25 mL/kg/min (experimental for patients refractory to bicarbonate). Call Poison Control Center

for guidance.

- Lorazepam (benzodiazepine): 2–6 mg (peds: 0.03–0.05 mg/kg) IV
- Naloxone (Narcan): 2 mg (peds: 0.1 mg/kg) IV or IM initial dose
- Norepinephrine: 4–12 µg/min (peds: 0.05–0.1 µg/kg/min) IV infusion titrated to desired effect

FOLLOW-UP

DISPOSITION

Admission Criteria

- Symptomatic patients observed > 6 hr
- Altered mental status
- Dysrhythmia or conduction delay
- Seizure
- Heart rate > 100 beats/min 6 hr after ingestion
- Coingestion requiring prolonged observation

Discharge Criteria

- Asymptomatic after 6-hr observation
- No alteration in mental status
- Normal ECG with heart rate < 100 beats/min
- Active bowel sounds; tolerated, activated charcoal
- Psychiatry clearance if there has been suicide attempt or gesture

Issues for Referral

Toxicology or poison center consultation for significant ingestions

FOLLOW-UP RECOMMENDATIONS

Psychiatry for suicide attempts

PEARLS AND PITFALLS

- The hallmark of TCA poisoning is rapid clinical deterioration.
- Vigilant monitoring for QRS widening beyond 120 ms is essential.
- Achieve target pH with hyperventilation in the intubated TCA overdose patient.
- Treat acute widening of the QRS beyond 120 ms with bolus bicarbonate.

TRIGEMINAL NEURALGIA

Adam Z. Barkin

BASICS

DESCRIPTION

- The trigeminal nerve (cranial nerve [CN] V) innervates the face, oral mucosa, nasal mucosa, and cornea with its sensory fibers
- Trigeminal neuralgia is also known as tic douloureux:
 - _ Tic = spasmodic muscular contraction or movement
 - _ Douloureux = painful
- Usually occurs in patients >50 yr of age
- Facial pain syndrome recognizable by history alone
- Classical:
 - _ Paroxysmal attacks of unilateral (uncommonly bilateral) pain affecting 1 or more divisions of the trigeminal nerve
 - _ Has 1 of the following characteristics:
 - Superficial, sharp, or stabbing pain
 - Precipitated from trigger areas or factors
 - _ Lasts for <1 sec–2 min
 - _ Episodes are stereotyped in each individual
 - _ No clinically evident neurologic deficit
 - _ Not caused by another disorder
- Symptomatic:
 - _ Same as above but a causative lesion (not vascular compression) is identified
- Most common age group is 50–60 yr
- Females > males

ETIOLOGY

- Mechanism of pain production remains controversial; accepted theory suggests:
 - _ Demyelination of CN, leading to ectopic stimulation and pain:
 - Demyelination caused by tortuous or aberrant vascular compression of nerve root
 - 80–90% of classical trigeminal neuralgia have compression
 - Superior cerebellar artery is the most common (75%)
 - Anterior inferior cerebellar artery (10%)
- Secondary causes:
 - _ Herpes zoster
 - _ Multiple sclerosis
 - _ Space-occupying lesions:

- Cerebropontine angle tumor
- Aneurysm
- Arteriovenous malformation

DIAGNOSIS

SIGNS AND SYMPTOMS

- Brief, intense, recurrent sharp pain
- Often described as “electric like”
- Unilateral in the distribution of a branch of the trigeminal nerve:
 - Can occur in all 3 nerves: Maxillary > mandibular > ophthalmic
- More common on right side of face
- May occur without provocation, but triggers can be produced by talking, smiling, chewing, brushing teeth, shaving, or touching the face:
 - Touch and vibration are the most common stimulus
- Can occur infrequently or hundreds of times per day
- No pain between episodes, although chronic cases may complain of a continuous ache

History

- Rule out possible symptomatic causes with the following atypical features:
 - Abnormal neurologic exam
 - Abnormal oral/dental exam
 - Abnormal ear exam or hearing loss
 - Symptoms of dizziness, vertigo, visual changes, or numbness
 - Pain lasting > 2 min
 - Not in trigeminal nerve distribution

Physical-Exam

- Physical exam findings are normal; if abnormality found, consider other cause
- Carefully examine head and neck, with emphasis on CNs
- Patient’s report of pain following stimulation of a trigger point is pathognomonic

ESSENTIAL WORKUP

- Diagnosis is made clinically
- Clinical features to differentiate classical and symptomatic disease:
 - Age on onset < 50 yr
 - Sensory deficits
 - Bilateral involvement

DIAGNOSIS TESTS & INTERPRETATION

Lab

No specific lab tests apply

Imaging

- Patients with characteristic history and normal neurologic exam may be treated without further workup
- If dental problems are suggested, dental radiographs may be useful
- MRI brain/CT head may be useful if multiple sclerosis or tumor is suggested:
 - May be useful in initial presentation

DIFFERENTIAL DIAGNOSIS

- Multiple sclerosis
- Temporomandibular joint syndrome
- Glossopharyngeal neuralgia
- Compression of trigeminal root by tumors
- Dental problems/pain
- Cluster headache
- Postherpetic neuralgia
- Sinusitis
- Otitis media
- Temporal arteritis

TREATMENT

ED TREATMENT/PROCEDURES

- Appropriate pain relief
- Medical therapy:
 - Carbamazepine most commonly used
 - Other antiepileptics show some support as adjuvants for refractory pain.
- May need neurosurgical evaluation for treatment and/or exploration

MEDICATION

First Line

Carbamazepine: 200–800 mg/d PO BID

Second Line

- Gabapentin: Start 300 mg PO QD
- Lamictal: Start 25 mg PO QD
- Oxcarbazepine: 450–1,200 mg PO BID; start 300 mg PO BID
- Phenytoin: 300–400 mg/d div. QD–TID
- Valproic acid: Start 250 mg PO BID

FOLLOW-UP

DISPOSITION

Admission Criteria

- Trigeminal neuralgia with presence of other focal neurologic findings
- Positive CT or MRI studies may require emergent neurologic or neurosurgical consultation
- Refractory or recurrent trigeminal neuralgia not responding to outpatient pain management or anticonvulsant therapy:
 - May require admission for surgical intervention and ablation of the trigeminal nerve

Discharge Criteria

Patients without any focal neurologic findings and improved pain control in the ED may be managed as outpatients.

Issues for Referral

- Surgical therapy may be indicated for those who fail medical treatment
 - Pain relief in 85–90%
- Referral to a pain management center may be helpful in cases of refractory pain
- Anesthetic blocks of the trigeminal ganglion may be helpful

FOLLOW-UP RECOMMENDATIONS

- Follow up with PCP or neurologist for treatment
- Referral to a neurosurgeon may be indicated for refractory pain:
 - Percutaneous vs. open surgical treatment

PEARLS AND PITFALLS

- Unilateral, paroxysmal, and sharp/stabbing facial pain, following a portion of CN V distribution
- Trigger points are pathognomonic
- Do not miss an alternate (nonvascular) cause of nerve compression, such as CNS mass or aneurysm
- Carbamazepine is the most common treatment

TUBERCULOSIS

Vittorio J. Raho

BASICS

DESCRIPTION

- Tuberculosis (TB) is an infectious disease with protean manifestations, causing significant global morbidity and mortality.

Mechanism

- Infectious droplet nuclei are inhaled through the respiratory tract.
- Bacteria are dispersed through coughing, sneezing, speaking, singing.
- Primary TB/latent TB infection (LTBI):
 - _ Initial infection occurs when organisms enter the alveoli, become engulfed by macrophages, and spread via regional lymph nodes to the bloodstream.
 - _ Patients are usually asymptomatic.
 - _ May be progressive/fatal in immunocompromised hosts.
 - _ Positive reaction to purified protein derivative (PPD) indicates past exposure or infection.
 - _ Negative PPD does not rule out active TB.
 - _ May progress to active TB (5–10%).
- Reactivation TB:
 - _ LTBI becomes active TB.
 - _ Systemic (15%) and pulmonary (85%) symptoms.
- TB affects about one-third of the world's population (90 million new cases in the past decade worldwide, with about 30 million deaths).
- Centers for Disease Control and Prevention (CDC) statistics from 2011 show TB in US at an all-time low.
- TB rates in US have continued to decline since 1993.
- Increase in US foreign-born cases
- Still an estimated 10–15 million people are infected in US alone.

ETIOLOGY

- Infection with *Mycobacterium tuberculosis*, a slow-growing, aerobic, acid-fast bacillus resulting in disease.
- Humans are the only known reservoir.
- Recent TB epidemics:
 - _ HIV-infected patients
 - _ Multidrug-resistant TB (MDR-TB)
 - _ Extensively drug-resistant TB (XDR-TB):
 - High mortality, few effective drugs

SIGNS AND SYMPTOMS

- Depending upon site of infection; all human tissues have potential for infection.
- Pulmonary TB:
 - Cough
 - Fever, night sweats
 - Malaise, weight loss
 - Hemoptysis
 - Pleuritic chest pain
 - Shortness of breath
- Extrapulmonary TB:
 - CNS infections:
 - Meningismus
 - Cranial nerve defects, diplopia
 - Headache, fever, malaise
 - Confusion
 - Acute ischemic stroke
 - Pericarditis:
 - Pleuritic chest pain increased with recumbency
 - Renal infection:
 - Fever
 - Flank pain
 - Spinal TB (Potts disease):
 - Back pain/stiffness, point tenderness
 - Fever
 - Decreased range of motion
 - Cervical lymphadenitis (scrofula):
 - Unilateral, painless
 - May form draining sinus tracts
 - Miliary TB:
 - Multiorgan system involvement
 - Diffuse adenopathy
 - Hepatomegaly
 - Splenomegaly
 - Weight loss, fever

History

Predisposing factors and conditions for TB:

- HIV infection and other immunocompromised states (organ transplant, renal failure, diabetes)
- Drug and alcohol abuse

- Poverty, homelessness (living in shelters)
- Institutionalization (nursing homes, prisons)
- Immigration from an endemic area
- Positive PPD test/previous infection

Physical-Exam

- Fever
- Tachycardia
- Hypoxia
- Cachexia
- Abnormal breath sounds
- Cervical lymphadenopathy

ESSENTIAL WORKUP

- Diagnosis difficult due to the variety of clinical presentations.
- Chest radiography:
 - Most valuable test for active pulmonary TB
- Skin testing: PPD

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- Electrolytes, BUN, creatinine, glucose, LFTs
- Hyponatremia (due to syndrome of inappropriate antidiuretic hormone)
- ABGs for oxygenation/ventilation assessment
- Sputum staining for acid-fast bacilli (Ziehl–Neelsen stain):
 - Provides a quick presumptive diagnosis
- Sputum, CSF, blood, urine, or peritoneal fluid culture:
 - Gold standard for diagnosis of TB
 - Average time for positive culture is 3–6 wk.
 - DNA polymerase chain reaction (PCR) testing more rapid
- Lumbar puncture with CSF analysis:
 - For suspected TB meningitis
 - Elevated WBCs with lymphocyte predominance
 - Elevated protein
 - Low to normal glucose

Imaging

- Chest radiograph:
 - May be normal
 - In primary disease, parenchymal infiltrates with unilateral hilar adenopathy are the classic findings.

- Reactivation TB typically appears as cavitary lesions with or without calcification, usually in upper lung segments.
- Miliary TB shows bilateral disseminated 2-mm nodules throughout lungs.
- Chest radiograph may be nondefinitive in AIDS/immunocompromised patients.
- Unilateral pleural effusion in both primary and reactivation TB
- Tracheal deviation with scarring or atelectasis
- Ghon focus—calcified scar/healed primary focus of infection
- Ghon complex—primary infiltrate with associated unilateral hilar adenopathy
- Spine radiographs for Potts disease:
 - May be normal
 - Anterior wedging of 2 involved vertebral bodies and destruction of disk
- CT chest:
 - Better defines extent of disease

Diagnostic Procedures/Surgery

Skin testing:

- Inject 0.1 mL of PPD intradermally in the forearm.
- Positive test indicates prior or current infection with *M. tuberculosis*.
- Test results are read between 48 and 72 hr after administration.
- Interpretation of positive: > 5-mm induration:
 - Close contacts with TB patients
 - Positive chest radiographs for TB
 - HIV-positive
 - Organ transplant or other immunosuppression
- > 10-mm induration:
 - IV drug users
 - Immigrants from high-prevalence countries (within 5 yr)
 - Underlying disease (diabetes, renal failure, malignancies)
 - Healthcare workers
 - Prison inmates
 - Institutionalized (nursing home, homeless shelters)
- > 15-mm induration:
 - Low-risk individuals

DIFFERENTIAL DIAGNOSIS

- Bacterial pneumonia
- Bronchiectasis
- Coccidiomycosis
- Histoplasmosis
- Lung abscess
- Lung carcinoma

- Lymphoma
- *Pneumocystis carinii* pneumonia
- Pulmonary embolism
- Sarcoidosis

TREATMENT

PRE HOSPITAL

- Place patient in respiratory isolation (negative flow).
- Place a mask on the patient to prevent respiratory spread of the disease.
- Initiate treatment with an IV, oxygen, and pulse oximetry.
- Endotracheal intubation may be required in patients with severe hemoptysis or respiratory compromise.
- Providers should wear submicron particulate filter masks (N-95 designation).
- Inform close contacts.

INITIAL STABILIZATION/THERAPY

- ABCs:
 - Control airway as needed.
 - Administer oxygen as needed.
 - Place on patient cardiac monitor and pulse oximetry.
 - Establish IV access with 0.9% normal saline
- Isolate patients in negative pressure rooms with at least 6 air exchanges per hour.
- Protection for healthcare workers (N-95 masks)

ED TREATMENT/PROCEDURES

- *Isolation* and strict respiratory precautions
- Treatment is augmented due to increasing multidrug resistance.
- Any regimen must contain at least 2 drugs to which the TB bacillus is susceptible.
- CDC currently recommends initial therapy that includes 4 1st-line drugs.
- LTBI with normal chest x-ray given isoniazid (INH) for 9 mo or weekly combination of INH and rifapentine (RPT) for 12 wk.
- Consult infectious disease specialists when treating HIV patients on antiretroviral therapies.
- Add dexamethasone for TB meningitis.
- Surgical drainage for TB empyema may be necessary; consult thoracic surgeon.
- Directly observed therapy (DOT) may be necessary to ensure compliance in certain populations.
- Intermittent (biweekly) regimen may demonstrate higher patient compliance.

MEDICATION

First Line

- INH: 5 mg/kg, max. 300 mg (peds: 10–15 mg/kg, max. 300 mg) PO/IM per day:
 - Refractory seizures in overdose, treat with pyridoxine 5 g IV over 5 min or PO
 - Caution with alcohol coingestion, hepatitis
- Rifampin (RIF): 10 mg/kg, max. 600 mg (peds: 10–20 mg/kg, max. 600 mg) PO/IV per day
- Pyrazinamide (PZA): 20–25 mg/kg/d max. 2 g (peds: 15–30 mg/kg/d) or:
 - <55 kg: 1 g PO per day
 - 56–75 kg: 1.5 g PO per day
 - >75 kg: 2 g PO per day
 - Not recommended in pregnancy
- Ethambutol (ETB): 15–20 mg/kg, max. 1,600 mg (peds: 15–30 mg/kg, max. 1 g) PO per day or up to TID
 - Not recommended <13 yr old, requires visual testing
- RPT: 10 mg/kg, max. 900 mg (peds: Not recommended <12 yr old) PO once per week or 300 mg PO weekly for 10–14 kg, 450 mg PO weekly for 14.1–25 kg, 600 mg PO weekly for 25.1–32 kg, 750 mg PO weekly for 32.1–49.9 kg, 900 mg PO weekly for >50 kg
- Rifabutin: 5 mg/kg, max. 300 mg (peds: Unknown) PO per day

Second Line

(Less effective, more toxic)

- Streptomycin: 15 mg/kg/d, max. 1 g (peds: 20–40 mg/kg/d) IM/IV per day:
 - Teratogenic: Contraindicated in pregnancy
- Ethionamide: 0.5–1 g (peds: 10–20 mg/kg/d) PO div. QID
- Levaquin: 750 mg (peds: Contraindicated) PO/IV per day

FOLLOW-UP

DISPOSITION

Admission Criteria

- Respiratory compromise
- Suspicion of diagnosis
- Inability to comply with outpatient therapy
- Unavailable outpatient resources (no PCP)
- Involuntary admission for noncompliant outpatients occurs:
 - Be aware of respective state laws concerning involuntary admission (consult infectious disease specialist).

Discharge Criteria

- Without respiratory compromise
- Home isolation procedure compliance
- Ability and willingness to comply with long-term therapy
- Appropriate outpatient follow-up and treatment available
- Notification of the public health authorities is mandatory.

Issues for Referral

Referral to Department of Public Health for DOT

FOLLOW-UP RECOMMENDATIONS

- Sputum analysis periodically to document clearance
- Medication toxicity monitoring:
 - _ INH, RIF, PZA: Monitor liver function tests for hepatitis
 - _ PZA: Check uric acid levels
 - _ ETB: Eye testing for color blindness

PEARLS AND PITFALLS

- Early isolation and respiratory precautions
- Careful history to establish risk factors
- The chest x-ray and PPD are great diagnostic aids.
- Initial 4-drug regimen for active disease
- Nonadherent, active TB patients are considered a public health hazard:
 - _ Specific state laws are applicable in numerous areas.

TULAREMIA

Scott Bentz

BASICS

DESCRIPTION

- Tularemia is an acute febrile illness caused by the small aerobic gram-negative pleomorphic intracellular *coccobacillus Francisella tularensis*:
 - _ Organism is highly infectious.
 - _ Person-to-person transmission has not been reported.
- Humans become infected through different environmental exposures:
 - _ Bites from infected tick, deerfly, mosquito, or other infected insect
 - _ Direct contact with infectious animal tissue or fluid
 - _ Contact with or ingestion of contaminated food, water, or soil
 - _ Inhalation of infected aerosols (e.g., cutting grass with power mowers, which may aerosolize the organism)
- The 4 major strains of the bacterium have different virulence and geographic location:
 - _ 2 subspecies cause human infection in North America: *F. tularensis* subspecies tularensis (type A, more virulent) and *F. tularensis* subspecies holartica (type B, less virulent)
- Natural hosts:
 - _ Lagomorphs and other rodents
 - _ Found in species of wild animals (insects, rabbits, hares, ticks, flies, muskrats, beavers, mice), domestic animals (sheep, cattle, cats), ticks, and water and soil contaminated by infected animals
- Natural vectors:
 - _ Ticks
 - _ Biting flies
 - _ Mosquitoes
 - _ Wild rabbits
- Weaponization of tularemia was accomplished during the Cold War:
 - _ Because of its virulence and ability to be aerosolized, it remains a potential biologic agent for mass destruction.
- Lab technicians handling culture specimens are at high risk:
 - _ *F. tularensis* cultures should be manipulated only in a biosafety level 3 facility.
- Also known as “rabbit fever” or “deerfly fever”

ETIOLOGY

- Individuals who spend time outdoors in endemic areas are at higher risk:

- Farmers
- Hunters
- Forest workers
- Those who handle animal carcasses are at highest risk (taxidermists and butchers).
- Two-thirds of cases occur in males.
- Although tularemia can occur worldwide, it is endemic in the northern hemisphere:
 - Reported nationwide except in Hawaii
 - States with the highest incidence include Missouri, Arkansas, Kansas, South Dakota, and Oklahoma.
 - Few hundred cases annually in US, although probably underreported
 - Peak season is June–October.
- Mortality is 5–15%. Appropriately treated patients have mortality as low as 1%.

Pediatric Considerations

- 25% of cases occur in children 1–14 yr of age.
- Children who spend time outdoors in endemic rural areas are at highest risk.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Tularemia has different presentations based on route of entry:
 - Primary route of entry is through skin; most often a cutaneous ulcer develops.
- Incubation is 3–5 days, range 1–14 days. Lesion usually begins as papule, often with fever.
- 6 forms of illness:
 - Ulceroglandular:
 - Most common presentation (70–80% of cases)
 - Inoculated cutaneously (scratch, abrasion, insect bite) with as few as 50 organisms
 - Initially, a local cutaneous papule at point of entry
 - Followed by tender regional adenopathy and constitutional symptoms to include fever, chills, myalgias, and headaches
 - Associated with pneumonia in 30% of cases
 - Glandular:
 - Rare form
 - Gains access to lymphatic system or bloodstream through inapparent abrasion
 - Tender regional lymphadenopathy with no local lesions
 - Oculoglandular:
 - Rare form

- Organism enters through a splash of infected blood/fluid to the eye or is introduced by eye rubbing after handling infectious materials (e.g., rabbit carcass).
- Edema, conjunctivitis, injection, chemosis with periauricular, submandibular, or cervical lymphadenopathy
- Pharyngeal:
 - Rare form
 - From ingestion of contaminated food or water
 - Severe throat pain with exudative pharyngitis and regional lymphadenitis
- Pneumonic:
 - Secondary to inhalation
 - Seen in sheep shearers, farmers, landscapers, and lab technicians
 - Fever, dry cough, and pleuritic chest pain develop.
 - Pneumonia can occur in 30% of patients with ulceroglandular tularemia
- Typhoidal:
 - Historically, the typhoidal form defined as devoid of skin or mucous membrane lesion or remarkable lymph node enlargement.
 - No known point of entry (probably oral or respiratory).
 - Only when no route of infection can be established may the term still be acceptable.
 - In North America, where type A is prevalent, fulminant manifestations are reported, including severe sepsis, meningitis, endocarditis, hepatic failure, and renal failure.
 - Septicemia associated with type A tularemia is usually extremely severe and potentially fatal. High fever, abdominal pain, and diarrhea may occur early in the course of disease.

History

- Exposure and epidemiologic risk factors can be helpful.
- Sudden fever, chills, headaches
- Progression of components of signs and symptoms may be useful in defining form of illness.

Physical-Exam

- Fever
- Tender, well-demarcated cutaneous ulcer
- Tender regional lymphadenopathy; lymph nodes can develop fluctuance and spontaneously drain.
- Exudative pharyngitis (with pharyngeal tularemia)
- Ulcerations of the conjunctiva with pronounced chemosis (with oculoglandular

tularemia)

DIAGNOSIS TESTS & INTERPRETATION

Lab

- No rapid diagnostic test available
- Routine lab studies nonspecific:
 - CBC can be normal.
 - ESR might be slightly elevated.
 - CSF: May have increased protein or mild pleocytosis
 - LFTs are often abnormal.
- Gram stain, cultures, and tissue biopsies:
 - Often negative
- Blood cultures usually negative because of specific growth requirements
- Enzyme-linked immunosorbent assay and polymerase chain reaction are available through reference labs.
- Serum antibody titers:
 - Typically do not reach diagnostic levels until ≥ 10 days after the onset of illness
 - A single titer of at least 1:160 for tube agglutination is diagnostic for *F. tularensis* infection.
 - May not be elevated before day 11 of illness and generally are diagnostic after 16th day.

Imaging

- Chest radiograph for:
 - Consolidative process, pleural effusions, and hilar adenopathy
- CT scan of chest for:
 - Severe pulmonary symptoms
 - Other possible etiologies of atypical pneumonia

DIFFERENTIAL DIAGNOSIS

- Ulceroglandular tularemia mimics include:
 - Tuberculosis
 - Cat scratch disease
 - Syphilis
 - Chancroid
 - Lymphogranuloma venereum
 - Toxoplasmosis
 - Sporotrichosis
 - Rat-bite fever
 - Anthrax
- Oculoglandular tularemia mimics include:

- Adenoviral infection
- Pharyngeal tularemia mimics include:
 - Diphtheria
 - Bacterial pharyngitis
 - Infectious mononucleosis
 - Adenoviral infection
- Typhoidal tularemia mimics include:
 - Salmonellosis
 - Brucellosis
 - Legionnaire disease
 - Q fever
 - Malaria
 - Disseminated fungal or mycobacterial infections
- Pulmonary tularemia mimics include:
 - Mycoplasmal infection
 - Legionnaire disease
 - Chlamydial infection
 - Tuberculosis

TREATMENT

PRE HOSPITAL

- Universal precautions
- Management of ABCs
- Treat dehydration/hypotension with boluses of normal saline.

INITIAL STABILIZATION/THERAPY

- ABCs
- Supplemental oxygen for hypoxia
- Fluid resuscitation with normal saline for intravascular volume depletion or septic shock
- Central line access for unstable patients
- Vasopressors for persistent hypotension

ED TREATMENT/PROCEDURES

- Fever control with acetaminophen
- Early administration of antibiotic therapy after obtaining cultures
- Antibiotic options:
 - 1st-line agents: Streptomycin or gentamicin continued for 10 days
 - Ciprofloxacin if community-acquired pneumonia is in the differential diagnosis of patients ≥ 18 yr of age
 - Tetracycline or doxycycline in those > 8 yr of age; or chloramphenicol:

- Continue for 14 days, since these drugs are only bacteriostatic.
- Associated with a higher rate of treatment failures than the previously mentioned antibiotics
- 3rd tier of treatment, since they are static
- *F. tularensis* is resistant to β -lactam drugs and carbapenems

Pediatric Considerations

Streptomycin and gentamicin are recommended as 1st-line agents.

MEDICATION

First Line

- Gentamicin: 5 mg/kg IV or IM q24h (peds: 2.5 mg/kg IV or IM q8h) \times 10 days
- Streptomycin: 1 g IM (peds: 15 mg/kg, not to exceed 2 g/d) q12h \times 10 days

Second Line

- Ciprofloxacin: 400 mg IV q12h \times 10 days
- Doxycycline: 100 mg (peds: If weight \geq 45 kg and child $>$ 8 yr, 100 mg; if weight \leq 45 kg and child $>$ 8 yr, 2.2 mg/kg) IV q12h for at least 14 days (longer treatment needed since doxycycline is bacteriostatic); max. 200 mg/d
- Chloramphenicol is usually avoided due to the possibility of adverse reactions. However, chloramphenicol may be considered in cases of tularemic meningitis due to its ability to cross the blood–brain barrier and reach higher concentrations in the CSF.

FOLLOW-UP

DISPOSITION

Admission Criteria

- ICU admission for advanced age, neutropenia, severe hypoxemia, hemodynamic instability, or patients presenting with typhoidal tularemia
- Inpatient floor bed admission for mild to moderate illness:
 - Isolation bed required only for the purpose of ruling out other etiology (e.g., tuberculosis)

Discharge Criteria

Outpatient therapy: Oral or IM therapy for mild illness with close follow-up

Issues for Referral

Critical care and infectious disease consultation to assist in assessment of differential considerations and manage life-threatening complications

FOLLOW-UP RECOMMENDATIONS

Infectious disease consultation to manage ongoing treatment and reduce subsequent exposures

PEARLS AND PITFALLS

- Patients presenting with high fever and regional lymphadenopathy, especially if there is an ulcer or conjunctivitis, should have tularemia in the differential.
- Epidemiology may be useful in pointing to this diagnosis.
- Definitive diagnosis ultimately based upon serology, which usually isn't positive until > 10 days of infection.
- Vaccine currently under review by FDA; not currently available in US
- Currently listed as category A (critical agent of concern) bioterrorism agent because of pathogenicity. It can be disseminated via dispersal in food, water, or air.

TUMOR COMPRESSION SYNDROMES

Hany Y. Atallah

BASICS

DESCRIPTION

- Complications arising from the compression of neural or vascular structures by solid tumors or their direct infiltration of such structures
- Spinal cord compression:
 - Affects over 20,000 patients each year
 - Occurs in 5–14% of cancer patients
 - More than 50% of cases are metastases from lung, breast, or prostate cancer.
 - Vertebral metastases are far more common than epidural spinal cord compression (ESCC).
 - Approximately 20% of cases of ESCC represent the initial manifestation of malignancy.
- Other neurologic tumor compression:
 - Brachial plexus
 - Recurrent laryngeal nerve compression by mediastinal lymph nodes
- Superior vena cava (SVC) syndrome:
 - Obstruction of returning blood flow in the SVC by compression, infiltration, or thrombosis
 - Venous hypertension within the area ordinarily drained by the SVC
 - In severe cases, gradual elevation of the intracranial pressure (ICP), with altered mental status and coma
 - 60–85% caused by malignancy

ETIOLOGY

- Spinal cord compression:
 - Prostate cancer
 - Breast cancer
 - Lung cancer
 - Renal cell carcinoma
 - Multiple myeloma
 - Melanoma
 - Thyroid cancer
 - Lymphoma
 - Sarcoma
- Brachial plexus compression:
 - 0.4% of cancers

- 2–5% of those who receive radiation treatment
- Lung cancer
- Breast cancer
- SVC syndrome from tumor compression:
 - Lung cancer (most common):
 - Small cell lung cancer primarily
- Postirradiation fibrosis
- Lymphoma
- Breast cancer
- Testicular cancer
- See “Differential Diagnosis” for non malignant etiologies of the SVC syndrome.

Pediatric Considerations

In children with spinal cord compression, common causes are sarcoma, neuroblastoma, germ cell tumors, and lymphoma.

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Spinal cord compression:
 - History of malignancy
 - Back or neck pain:
 - Prolonged
 - Worse with rest
 - Most commonly affects the thoracic spine
 - Paresthesias
 - Difficulty ambulating
 - Constipation
 - Urinary retention
 - Urinary or fecal incontinence
 - Weight loss
- Brachial plexus compression:
 - Neuropathic pain involving the medial aspect of the upper extremity
- Intrathoracic vagal nerve compression:
 - Ipsilateral aching facial pain around the ear
- SVC syndrome:
 - Orthopnea
 - Dyspnea
 - Tightness of the shirt collar
 - Cough

- Chest pain
- Headache
- Facial swelling
- Head fullness
- Blurred vision
- Dizziness
- Syncope

Physical-Exam

- Spinal cord compression:
 - Loss of rectal tone
 - Loss of anal wink
 - Weakness in 60–85% of patients
 - Sensory findings less common
- Laryngeal nerve compression:
 - Hoarseness
 - Vocal cord paralysis
- Brachial plexus:
 - Ulnar paresthesias
 - Weakness and wasting of intrinsic hand muscles
 - Pan-plexopathy
 - Horner's syndrome
- SVC syndrome:
 - Periorbital edema
 - Conjunctival suffusion
 - Facial swelling
 - Facial plethora
 - Upper extremity edema
 - Findings exacerbated by recumbent or stooped-over position
 - Usually worse in the early morning hours
 - ICP may be elevated in severe cases:
 - Altered mental status
 - Coma
 - Papilledema

DIAGNOSIS TESTS & INTERPRETATION

Imaging

- Chest radiograph:
 - Spinal cord compression:
 - May identify a primary lung tumor
 - Helpful in excluding tuberculous spondylitis
 - SVC compression:

- Mass present in 10%
- Pleural effusion in 25%
- Plain spinal radiography
- Will show 85% of metastases causing compression
- A normal spine (or 1 showing just degenerative changes) on plain radiology does not exclude the diagnosis of possible cord compression.
- CT:
 - Contrast CT is more sensitive and specific than plain radiography and radionucleotide imaging in distinguishing benign from malignant disease in spinal compression syndrome
 - May identify mass and impingement in vena cava obstruction
- MRI:
 - Study of choice for spinal cord compression
 - Indicated in patients with back or neck pain and:
 - History of cancer
 - Bowel or bladder dysfunction
 - Lower extremity weakness
 - Sensory loss
 - Saddle anesthesia

Diagnostic Procedures/Surgery

- CT myelography:
 - Indicated for spinal cord compression when MRI is unavailable or contraindicated (pacemaker, metallic implants, severe claustrophobia)
- Minimally invasive techniques can often be used to establish a tissue diagnosis in cases of SVC syndrome.
- Occasionally an invasive procedure is required to obtain a tumor biopsy in patients with SVC syndrome:
 - Bronchoscopy
 - Mediastinoscopy
 - Scalene node biopsy
 - Limited thoracotomy
 - Video-assisted thoracic surgery (VATS)
- Radiation therapy (RT) can be done to shrink the tumor:
 - Should be done after tissue diagnosis is made, as RT can obscure tissue and make definitive diagnosis difficult.
- Endovascular stents can be used to achieve more rapid relief than can be achieved using RT.

DIFFERENTIAL DIAGNOSIS

Spinal Cord Compression

- Amyotrophic lateral sclerosis

- Arteriovenous malformations
- Epidural abscess
- Intervertebral disk disease
- Multiple sclerosis
- Neurologic diseases
- Osteoporotic vertebral fractures
- Primary bone tumors
- Spinal infarction
- Spondylitis
- Spondylosis
- Transverse myelitis

Superior Vena Cava Syndrome

- Pericardial tamponade
- Nephrotic syndrome
- Cor pulmonale
- Cirrhosis
- Nonmalignant etiologies of SVC syndrome:
 - Goiter
 - Pericardial constriction
 - Primary thrombosis
 - Idiopathic sclerosing aortitis
 - Tuberculous mediastinitis
 - Fibrosing mediastinitis
 - Histoplasmosis
 - Indwelling central venous catheters

TREATMENT

INITIAL STABILIZATION/THERAPY

- Early diagnosis and treatment are the keys to an improved outcome.
- Level of neurologic dysfunction on presentation is a key factor in the prognosis for spinal cord compression.
- Avoid IV line placement in upper extremities if severe SVC compression is present.

ED TREATMENT/PROCEDURES

Spinal Cord Compression

- Corticosteroids (dexamethasone):
 - Administer in ED.
 - Higher doses alleviate the pain more rapidly, but studies indicate no significant difference in outcome with regard to sphincter function or

ambulation between the dose schedules.

- Radiotherapy:
 - Definitive treatment modality
 - Pain medication with narcotics
 - Oncology, radiotherapy, and neurosurgical consultation for further management of tumor/malignancy
 - Consider empiric broad-spectrum antibiotics prior to the MRI if an epidural abscess is being considered.
- Urgent neurosurgical consultation

SVC Compression

- Manage the underlying malignancy with either radiotherapy or chemotherapy.
- Elevation of the head of the bed.
- Supplemental oxygen
- Administer steroids if there is respiratory compromise
- Judicious use of diuretics may transiently improve symptoms, but there is poor evidence to support efficacy.
- Urgent oncology referral
- Intravascular stents can relieve the obstruction more rapidly.

MEDICATION

- For ESCC there is limited evidence suggesting steroids are beneficial, but it is still generally considered to be part of the standard regimen of treatment
- For paresis or paraplegia high dose dexamethasone: 1 mg/kg loading dose, then halve the dose every 3 days
- For patients with minimal neurologic dysfunction dexamethasone 10 mg followed by 16 mg daily initially in divided doses with a gradual taper once definitive treatment is underway
- For SVC syndrome steroids can reverse symptoms from steroid responsive malignancies such as lymphoma or thymoma.
- In patients undergoing RT steroids are often prescribed to prevent swelling
- Furosemide (Lasix): No prior use—40 mg IVP; prior use—double 24 hr dose (80–180 mg IV)
- Hydrocodone/acetaminophen: 5/500 mg PO q4–6h
- Oxycodone/acetaminophen: 5/500 mg PO q4–6h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Admission is advisable for all patients presenting with a tumor compression

syndrome.

- Transfer to a center with neurosurgical capabilities may be needed for patients with spinal cord compression.

Discharge Criteria

None

Issues for Referral

- Radiation oncology should be consulted for patients presenting with tumor compression.
- Early neurosurgical consultation for patients with spinal cord compression

PEARLS AND PITFALLS

- Average life expectancy among patients who present with malignancy-associated SVC syndrome is ~6 mo.
- Presentations may be subtle and compression syndromes should always be considered in patients with known malignancy and unexplained complaints.

- G95.29 Other cord compression
- I87.1 Compression of vein

TYMPANIC MEMBRANE PERFORATION

Andrew K. Chang • Michelle M. Davitt

BASICS

DESCRIPTION

Perforations can be classified in several ways:

- **Duration:**
 - Acute (< 3 mo)
 - Chronic (> 3 mo)
- **Site:**
 - Pars tensa
 - Pars flaccida
- **Extent:**
 - Limited to 1 quadrant (< 25%)
 - 2 or more quadrants
 - Total perforation

ETIOLOGY

- **Infection (acute otitis media):**
 - Most common cause of an acute perforation
- **Blunt trauma (slap to the ear):**
 - Domestic violence, street fight
- **Penetrating trauma (Q-tip)**
- **Extrusion of tympanostomy tubes**
- **Rapid pressure change (diving, flying):**
 - Rupture usually occurs between 100 and 400 mm Hg (at a depth of 2.6 ft, there is a pressure differential of 60 mm Hg)
- **Extreme noise (blast)**
- **Lightning**
- **Acute necrotic myringitis (β -hemolytic streptococcus)**
- **Slag burns (welding or metalworking)**
- **Complications of surgical procedures:**
 - Myringotomy, tympanoplasty, tympanostomy tube insertion

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Ear pain (mild)

- Severe pain or complete hearing loss in the affected ear suggests additional injuries
- Tinnitus
- Vertigo (especially if perforation occurs in water)

Physical-Exam

- Loss of hearing (partial)
- Purulent or bloody discharge from ear canal
- Insufflation via pneumatic otoscope:
 - Small perforations may be evident only as an immobile tympanic membrane
 - Holding pressure for 15 sec (the fistula test) may cause nystagmus or vertigo if the pressure is transmitted through the middle ear and into a labyrinthine fistula
- Weber test (tuning fork on midline bone):
 - Sound should be equal or louder in the injured ear, consistent with decreased conduction
 - Sound localizing to the opposite side of injury indicates possible otic nerve injury
- Rinne test (tuning fork on mastoid process):
 - Usually normal (air conduction detected after bone conduction fades) or shows a small conductive loss

ESSENTIAL WORKUP

Clinical exam:

- Direct visualization of tympanic membrane with otoscope
- Test hearing in both ears
- Note any nystagmus with changes of position or pressure on the tragus occluding the canal (fistula sign)

DIAGNOSIS TESTS & INTERPRETATION

Lab

If an aural drainage is present, it may be desirable to culture the drainage

Imaging

Cranial CT:

- Obtain if clinically indicated to rule out temporal bone fracture

DIFFERENTIAL DIAGNOSIS

- Temporal bone fracture
- Serous otitis media
- Infectious otitis media

- Otitis externa
- Cerumen impaction
- Barotrauma
- Acoustic trauma
- Foreign body
- Child abuse

TREATMENT

INITIAL STABILIZATION/THERAPY

ABCs of trauma care:

- Immobilize cervical spine and investigate for intracranial injury when indicated

ED TREATMENT/PROCEDURES

- Remove debris from the ear canal:
 - Do not irrigate because this may force more debris into the middle ear
 - If the tympanic membrane is not visible because of impacted cerumen and suspicion for perforation is high, remove cerumen by manual disimpaction or suctioning
- If clinically indicated, obtain CT scan to rule out temporal bone fracture
- Prophylactic antibiotics are not indicated
- Prescribe antibiotics if there is evidence of infection or if water or contaminants may have entered the ear canal:
 - Amoxicillin
 - Augmentin
 - Cefixime, ceftriaxone
 - Azithromycin
 - Clindamycin
- Analgesics if needed for pain
- With the exception of fluoroquinolones, the use of ototopical medication is controversial because of the risk of ototoxicity:
 - Most advocate an antibiotic–cortisone otic medication whenever a discharge is present because this may treat or prevent an external canal infection and hasten the resolution of the middle-ear infection
 - Ototopical antibiotics provide a high concentration of antibiotic in the middle ear, potentially exceeding the MIC of organisms
 - Ototopical fluoroquinolones are the 1st-line therapy for chronic suppurative otitis media and in traumatic TM perforation with suspected entry of water into the middle ear (SCUBA, bathing, etc.)
- Urgent ENT consultation (indications):
 - Vertigo
 - Sensorineural hearing loss

- Severe tinnitus
- Active and significant bleeding
- Facial paralysis

MEDICATION

- Amoxicillin: 500 mg PO TID (peds: 80–90 mg/kg/24 h PO BID) for 7–10 days
- Augmentin: 875 mg (peds: 90 mg/kg/24 h) PO BID for 7–10 days
- Cefixime: 400 mg (peds: 8 mg/kg/24 h) PO QD for 7–10 days
- Ceftriaxone: 1–2 g IV/IM (peds: 50 mg/kg IM, max. 1 g) × 1 dose
- Azithromycin: 2 g (peds: 30 mg/kg, max. 1,500 mg) PO × 1 dose
- Clindamycin: 150–450 mg (peds: 30 mg/kg/24 h) PO QID for 7–10 days
- Ciprofloxacin/dexamethasone otic: 4 drops BID for 7–10 days
- Neomycin/polymyxin B/hydrocortisone otic suspension: 4 gtts in ear TID–QID (peds: 3 gtts TID–QID); max. 10 days; lie with affected ear upward for 5 min

First Line

- Amoxicillin and Augmentin are the primary antibiotic choices for acute otitis media with subsequent tympanic membrane perforation
 - Augmentin should be selected for patients with recurrent infections or those who have used antibiotics within 1 mo
 - Ciprofloxacin with dexamethasone otic drops are the medications of choice for chronic suppurative otitis media and traumatic tympanic membrane perforation with suspicion of water or contaminant entry into the middle ear (SCUBA, bathing, Q-tip)

Second Line

- Penicillin-allergic patients may be prescribed cephalosporins:
 - Ceftriaxone IM may be preferred in patients with vomiting or compliance issues
- Azithromycin or clindamycin may be used for patients with hypersensitivity type I allergic reaction to penicillin

FOLLOW-UP

DISPOSITION

Admission Criteria

- Associated injuries requiring admission
- Severe vertigo impairing ambulation

Discharge Criteria

Almost all patients will be discharged

Issues for Referral

- Arrange outpatient ENT follow-up within 1 wk:
 - After detailed exam and formal audiometric tests, most otolaryngologists practice “watchful waiting” because most tympanic membrane perforations heal spontaneously
 - Hearing loss increases with the size of the perforation and does vary appreciably with the location
 - Operative repair (patch or tympanoplasty) is reserved for the 10–20% that do not heal spontaneously

FOLLOW-UP RECOMMENDATIONS

- Provide detailed discharge instructions:
 - Occlude the ear canal with cotton coated in petroleum jelly or antibiotic ointment when showering to prevent entry of water into the middle ear, which can be painful and may cause further infection
 - Swim only with fitted earplugs
 - Avoid forceful blowing of the nose
- Expected outcome:
 - Most perforations heal spontaneously in a few days to several months; in 1 study of children, 70% closed within 1 wk and 94% closed within 1 mo
 - Spontaneous healing is associated with the perforation size, etiology, and whether it is dry or serosanguinous
 - Wet perforations tend to heal more quickly
 - Perforations caused by molten metal or electrical burns are less likely to heal spontaneously
 - Complications include:
 - Infection
 - Dislocation of ossicles
 - Perilymph leak
 - Cholesteatoma

PEARLS AND PITFALLS

- Acute otitis media is the most common cause of tympanic membrane perforation.
 - Small tympanic membrane perforations may be diagnosed only through insufflation by pneumatic otoscope
 - Debris, cerumen, or discharge should be suctioned or manually removed; irrigation is contraindicated in cases of suspected tympanic membrane perforation
 - Otological fluoroquinolones are the antibiotics of choice for chronic suppurative otitis media and traumatic tympanic membrane perforation with suspected penetration by foreign body, water, or contaminant
 - Most perforations heal spontaneously; however, care must be exercised to

prevent further introduction of infectious agents into the open middle ear

- Chronic otitis media is a recurrent infection of the middle ear and/or mastoid air cell tract in the presence of a tympanic membrane perforation
- Chronic suppurative otitis media is diagnosed when there is a persistent purulent drainage through a perforated tympanic membrane for > 6 wk
- Use neomycin/polymyxin B/hydrocortisone otic SUSPENSION (not solution) when treating otitis externa in the setting of TM perforation

CODES

ICD9

- 384.20 Perforation of tympanic membrane, unspecified
- 384.22 Attic perforation of tympanic membrane
- 872.61 Open wound of ear drum, without mention of complication

ICD10

- H72.10 Attic perforation of tympanic membrane, unspecified ear
- H72.90 Unsp perforation of tympanic membrane, unspecified ear
- S09.20XA Traumatic rupture of unspecified ear drum, initial encounter

ULTRAVIOLET KERATITIS

Yasuharu Okuda • Nicholas Genes

BASICS

DESCRIPTION

- Corneal epithelial damage caused by direct exposure to ultraviolet (UV) light.
- Also known as photokeratitis, UV conjunctivitis, snow blindness, and welder's flash.

ETIOLOGY

- Work-related exposures seen in welders, electricians, and mechanics
- Recreational exposures, including water sports, snow sports, and tanning booths
- Occurs with corneal absorption at 290 nm, the cutoff between UV-B and UV-C light
- UV light penetrates to epithelial nociceptor axons, destroying them and triggering pain from subendothelial nerve stimulation
- Related to intensity and duration of exposure

DIAGNOSIS

SIGNS AND SYMPTOMS

- Patients will present with bilateral eye pain, photophobia, redness, and tearing.
- No purulent discharge will be present.
- Associated facial edema, lid edema, erythema, and blepharospasm may be present.

History

- Elicit history of exposure to UV light 6–12 hr prior to complaint of pain.
- In addition to pain, complaints may include:
 - Photophobia
 - Tearing
 - Foreign-body sensation

Physical-Exam

- Visual acuity may be mildly diminished.
- Eye exam reveals chemosis, injection, tearing.
- Slit-lamp exam with topical ophthalmic anesthetics and fluorescein:
 - Multiple superficial punctate corneal lesions
 - Otherwise unremarkable

ESSENTIAL WORKUP

- Accurate history including:

- Type, timing, and duration of exposure
- Visual acuity
- Complete ocular exam including:
 - Extraocular movements
 - Exam of conjunctiva/sclera/cornea with fluorescein
 - Anterior chamber checking for cell and flare
 - Eversion of lids to check for foreign bodies

DIAGNOSIS TESTS & INTERPRETATION

Lab

Blood testing will not be necessary unless widespread severe sunburn is present.

Imaging

A careful history should obviate need for orbital US/CT/MRI for foreign body.

DIFFERENTIAL DIAGNOSIS

- Infection:
 - Bacterial or viral conjunctivitis
 - Corneal ulcers
- Allergic conjunctivitis
- Corneal abrasion
- Traumatic iritis
- Foreign bodies
- Acid, alkali, or thermal burns

TREATMENT

PRE HOSPITAL

When diagnosis is unambiguously established, pressure patching or applying mild pressure to eyes with closed lids may provide temporary relief.

ED TREATMENT/PROCEDURES

- Topical anesthetic to facilitate slit-lamp exam.
- Provide adequate oral analgesia as needed.
- Apply topical antibiotic ointment.
- Initiate short-acting cycloplegic agent.
- May apply eye patching for comfort (patching has not been shown to accelerate healing):
 - Soft double patching with mild pressure
 - If both eyes involved, either patch both eyes or patch the eye that is more severely affected.

MEDICATION

- Topical anesthetic agent (for ED only):
 - Tetracaine hydrochloride ophthalmic solution 0.5%: 1–2 drops into affected eye:
 - Do not prescribe for outpatient as this may impair healing and increase corneal ulcer formation.
- Oral analgesics:
 - Ibuprofen 10 mg/kg TID with meals
 - Acetaminophen with oxycodone 500 mg/5 mg, q4–6h PRN for breakthrough pain
- Topical antibiotic ointment:
 - Erythromycin ophthalmic ointment 0.5%, apply to affected eye QID
- Cycloplegic agent:
 - Scopolamine hydrobromide ophthalmic solution 0.25%: 1 or 2 drops into affected eye q6–8h
 - Cyclopentolate hydrochloride ophthalmic solution 0.5%: 1 or 2 drops into affected eye q6–8h

FOLLOW-UP

DISPOSITION

Admission Criteria

Consider admission in cases of severe decreased visual acuity, bilateral patching, or in situations when self-care and follow-up are difficult.

Discharge Criteria

Nearly all patients may be discharged from the ED following treatment with oral analgesics, topical antibiotics, cycloplegics, and/or patching:

- Lesions should heal completely in 24–72 hr.

FOLLOW-UP RECOMMENDATIONS

- Follow up with ophthalmologist within 24–48 hr to monitor healing and symptom resolution.
- Long-term UV damage to eye may result in pterygium and some forms of corneal degeneration, though association with UV keratitis episodes has not been demonstrated.

PEARLS AND PITFALLS

- Determining UV exposure 6–12 hr prior is the key to diagnosis and prevention:
 - The patient may not be aware of exposure

- Those at risk for occupational exposure must wear UV safety goggles, not glasses or lenses.
- Exquisitely painful but self-limited injury; risks from repeated exposures are not well defined.

URETHRAL TRAUMA

Amanda Jillian-Lamond Holden

BASICS

DESCRIPTION

- Blood at the urethral meatus, a palpable full bladder, inability to void, and/or gross hematuria are common findings with urethral trauma.
- Found in 14% of pelvic fractures
- High association with bilateral pubic rami fractures (aka, straddle fractures)
- Females: Urethral injuries are rare likely due to short, unexposed, and mobile urethras.
- Girls <17 yr old: Higher injury rate likely from a more flexible pelvic ring
- Bladder neck most commonly injured location.
- Males: The urethra is divided into 2 sections.
- Posterior urethra:
 - More commonly injured (~ 90%)
 - Prostatic portion
 - Membranous
- Anterior urethra:
 - Injuries are rare
 - Bulbar
 - Penile
- Posterior urethra injuries comprise up to 90% of trauma:
 - Type 1: Urethra stretched but not ruptured
 - Type 2: Prostatic/membranous portions disrupted (either partially or completely); urogenital diaphragm intact
 - Type 3: Urethral disruption both proximal and distal to the genitourinary diaphragm

ETIOLOGY

- Females:
 - Rare with pelvic fractures
 - Straddle injuries
 - Childbirth or vaginal surgery
 - Sexual trauma/abuse
- Males:
 - More common with pelvic fractures
 - More common with straddle injuries
 - Penetrating trauma, mutilation
 - Sexual activity/instrumentation

DIAGNOSIS

SIGNS AND SYMPTOMS

- Males:
 - Blood at the urethral meatus
 - Gross hematuria
- Females:
 - Blood in the vaginal vault
 - Gross hematuria

History

Trauma to pelvic area

Physical-Exam

- Exam of the torso and pelvis during the secondary survey may elicit pelvic pain.
- Triad of blood at the urethral meatus, inability to urinate, and a palpably full bladder
- Blood at the meatus found in 50% of cases.
- Urologic injury can be indicated by gross hematuria (any color to the urine other than clear or yellow)
- Digital rectal exam: “High-riding prostate” has a sensitivity of <50%. Do not rely on this finding to rule out urethral trauma if suspected.
- Bedside US: FAST exam, suprapubic views may reveal blood surrounding the bladder.

ESSENTIAL WORKUP

- Females:
 - Perform a detailed vaginal exam to exclude vaginal laceration or other etiologies of bleeding.
 - If injury is suspected, radiologic evaluation of urethra should be performed.
 - If not possible, suprapubic aspiration or cystostomy should be done.
- Male:
 - If injury is suspected, radiographic evaluation of urethral integrity should be performed before urinary catheter placement to prevent turning a partial urethral tear into a complete tear.
 - If not possible, suprapubic aspiration or cystostomy should be performed.

Pediatric Considerations

- If an exam of the male or female genitalia cannot easily be performed, exam under anesthesia should occur.
- An exam with procedural sedation or in the OR, in addition to being better tolerated by the patient, allows the physician to rule out sexual abuse and to

confirm that the injury is consistent with the history.

DIAGNOSIS TESTS & INTERPRETATION

Lab

Urinalysis, hematocrit, BUN, creatinine

Imaging

- Retrograde urethrography (RUG):
 - Water-soluble contrast is injected via a catheter-tipped syringe at the urethral meatus.
 - Extravasation of contrast and its relation to the prevesical space and urogenital diaphragm should be noted.
 - Proximity of the extravasation to the meatus and the bladder should be appreciated.
 - If the urethral tear is complete, there will be no contrast within the bladder and marked extravasation will occur.
 - A partial tear will demonstrate contrast material within the bladder with varying amounts of extravasation.
- Excretory urethrography should be performed to define proximal urethral tears.
- Cystography
- 40% of urethral injuries have concomitant bladder injuries.

Diagnostic Procedures/Surgery

Urethral trauma warrants urgent urologic consultation.

DIFFERENTIAL DIAGNOSIS

- Perineal and vaginal trauma
- Bladder injury
- Ureter or kidney trauma

TREATMENT

PRE HOSPITAL

Pre-hospital trauma protocols

INITIAL STABILIZATION/THERAPY

Stabilization of multiple traumas takes precedence.

ED TREATMENT/PROCEDURES

- Urethral contusions, lacerations, and avulsions are best managed by an experienced urologist.

- Bladder decompression is an important initial intervention. If urethral Foley catheter placement is not possible, suprapubic aspiration/cystostomy may need to be performed.

MEDICATION

Appropriate analgesia

First Line

Opioids:

- Morphine, dilaudid, or fentanyl, as needed per trauma protocols for pain

FOLLOW-UP

DISPOSITION

Admission Criteria

- Concurrent traumatic injuries
- Need for emergent operative management of urethral, penile, or bladder injuries
- Partial lacerations:
 - Managed with urethral or suprapubic drainage
- Complete lacerations:
 - Managed surgically or with suprapubic drainage alone:
 - Some are repaired with end-to-end anastomosis.

Discharge Criteria

Isolated urethral injuries frequently may be managed in the outpatient setting after appropriate urinary catheterization or suprapubic cystostomy with next-day urologic follow-up.

Issues for Referral

Urologic follow-up is necessary if patient is discharged from ED.

FOLLOW-UP RECOMMENDATIONS

Urologic follow-up is necessary for all patients with urethral injuries.

PEARLS AND PITFALLS

- Consult urology before attempting to insert a Foley in a trauma patient in whom urethral injury is highly suspected.
- Passing a Foley catheter against resistance could convert a partial tear to a complete tear.
- Failure to recognize a urethral injury can result in urinary incontinence and sexual

dysfunction.

Pelvic Trauma

CODES

ICD9

- 665.50 Other injury to pelvic organs, unspecified as to episode of care or not applicable
- 867.0 Injury to bladder and urethra, without mention of open wound into cavity
- 867.1 Injury to bladder and urethra, with open wound into cavity

ICD10

- N36.8 Other specified disorders of urethra
- O71.5 Other obstetric injury to pelvic organs
- S37.33XA Laceration of urethra, initial encounter

URETHRITIS

Hany Y. Atallah

BASICS

DESCRIPTION

- Urethritis is inflammation of the urethra from any cause (usually infection).
- Associated with urethral discharge and dysuria
- Urethritis may develop after exposure to a partner with an STD, bacterial vaginosis, or UTI.
- Urethritis may also develop after orogenital contact.

ETIOLOGY

- STD; the most common causes are:
 - *Neisseria gonorrhoeae* (35%)
 - *Chlamydia trachomatis* (25–50%)
 - *Mycoplasma genitalium* and *Ureaplasma urealyticum* (30%)
- Rarer causes:
 - *Trichomonas vaginalis*
 - Candidal species
 - Herpes simplex virus
 - Adenovirus
 - Genital warts
 - Enteric bacteria (in the setting of insertive anal sex)
 - Alcohol
 - Systemic illnesses
 - Urethral foreign bodies

DIAGNOSIS

- Symptoms usually develop 1–2 wk after exposure but can take up to 4–6 wk.
- Initially minimal or absent in many patients

SIGNS AND SYMPTOMS

- Urethral discharge, dysuria
- Cloudy 1st portion of urine
- Pyuria
- Inguinal adenopathy may be present.

History

- Color, consistency, and quantity of urethral discharge.
- Associated symptoms of dysuria, urgency, frequency, hematuria, and

hematospermia

- Risk factors for STDs:
 - Recent new partner or multiple sexual partners
 - Symptoms of partner
 - Anal/oral practices
 - Young age
 - Lower socioeconomic status

Physical-Exam

- Urethral discharge
- Staining on undergarments
- Meatal crusting
- Genital lesions
- Lymphadenopathy
- Palpate testes, epididymis, and spermatic cord:
 - Masses or tenderness

ESSENTIAL WORKUP

- Urethral swabs for *N. gonorrhoeae* and *Chlamydia* species will confirm the diagnosis.
- DNA amplification, DNA probe, and testing of urine specimens via polymerase chain reaction (PCR) have shown good sensitivity and are acceptable tests
- A rapid plasma regain (RPR) or Venereal Disease Research Laboratory (VDRL) should be drawn because STDs frequently occur together.
- An HIV test should also be offered to the patient.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Gram stain and cultures from urethral swabs should be reviewed when the patient is re-evaluated by his or her physician after treatment.
- DNA amplification (ligase chain reaction [LCR] or PCR) can be used on 1st-void urine or urethral swab:
 - Equal efficacy for diagnosing *N. gonorrhoeae* and *Chlamydia* species
- UA should be performed after urethral swabs to identify UTIs.

DIFFERENTIAL DIAGNOSIS

- Chemical irritation from soaps or spermicides
- Epididymitis
- Orchitis
- Pelvic inflammatory disease
- Prostatitis
- Reactive arthritis (formerly Reiter syndrome)

- Urethral chancre (from syphilis)
- UTI

Pediatric Considerations

- Urethritis in children should arouse suspicion of child abuse.
- Because *N. gonorrhoeae* infects the entire vaginal vault in prepubescents, a speculum exam is not required:
 - External exam and cultures are sufficient.
- Potential complications:
 - Recurrent infections
 - Ascending UTIs, including pelvic inflammatory disease and epididymo-orchitis
 - Fallopian tube damage and infertility
 - Arthritis
 - Conjunctivitis, uveitis, and blindness

TREATMENT

INITIAL STABILIZATION/THERAPY

Most patients will not require significant stabilization.

ED TREATMENT/PROCEDURES

- Treatment may be given empirically based on probable etiology.
- Patients should be treated for both *N. gonorrhoeae* and *C. trachomatis*.

MEDICATION

- Gonorrhea:
 - Azithromycin 2 g orally once
 - Cefixime 400 mg PO once
 - Cefotaxime 500 mg IM once (administered with probenecid 1 g orally once)
 - Cefoxitin 2 g IM once (administered with probenecid 1 g orally once)
 - Cefpodoxime 400 mg PO once
 - Ceftizoxime 500 mg IM once
 - Ceftriaxone 250 mg (peds: 25–50 mg/kg) IM/IV once
 - Cefuroxime 1 g orally once
 - Ciprofloxacin 500 mg PO once
 - Gatifloxacin 400 mg PO once
 - Levofloxacin 250 mg PO once
 - Ofloxacin 400 mg PO once
 - Spectinomycin 2 g IM once
- Chlamydia:
 - Azithromycin 1 g (peds: 10 mg/kg day 1, 5 mg/kg days 2–5) PO once

- Doxycycline 100 mg PO BID for 7 days
- Erythromycin base 500 mg (peds: 40 mg/kg/d div. QID) PO QID for 7 days
- Erythromycin ethyl succinate 800 mg (peds: 30–50 mg/kg/d div. QID) PO QID for 7 days
- Levofloxacin 500 mg PO QD for 7 days
- Ofloxacin: 300 mg PO BID for 7 days
- *M. genitalium*:
 - Azithromycin 1 g (peds: 10 mg/kg day 1, 5 mg/kg days 2–5) PO once

Pregnancy Considerations

- Fluoroquinolones and doxycycline are contraindicated in pregnancy
- Azithromycin is safe and effective
- Repeat testing 3 wk after treatment is recommended to ensure cure.

ALERT

Increasing incidence of quinolone-resistant *N. gonorrhoeae* nationwide.

FOLLOW-UP

DISPOSITION

Admission Criteria

Patients should not require admission for urethritis unless there are other complaints or infections.

Discharge Criteria

All patients should be discharged with follow-up arranged at an outside clinic or with PCP.

Issues for Referral

- If child abuse is suspected, child protective services must be involved; the child should be admitted if a safe home situation cannot be ensured.
- Sexual partners should be evaluated.
- In many states, STDs require reporting.

FOLLOW-UP RECOMMENDATIONS

- All patients should follow up with primary care to ensure adequate treatment of the infection.
- All patients with suspected or confirmed urethritis should be referred for HIV testing.
- Patients should be given information regarding safe sexual practices.

PEARLS AND PITFALLS

- Always treat for both *N. gonorrhoeae* and *C. trachomatis* in suspected urethritis.
- There is increasing evidence suggesting that patients with recurrent urethritis should be evaluated for infection with other atypical organisms (doxycycline-resistant *U. urealyticum* or *M. genitalium*; *T. vaginalis*)
- Always consider other STDs in patients with urethritis.
- Ensure that patients will inform their sexual partners so that they can be treated as well.

URINARY RETENTION

Denise S. Lawe

BASICS

DESCRIPTION

- Acute urinary retention (AUR):
 - _ Sudden inability to void spontaneously
 - _ Occurs most frequently in men >60 yr old
 - _ Most common cause of AUR in the ED is benign prostatic hyperplasia (BPH)

ETIOLOGY

- Multiple diagnostic considerations, following list is not exhaustive
- Anatomic:
 - _ Penis:
 - Phimosis
 - Paraphimosis
 - Meatal stenosis
 - Foreign-body constriction
 - _ Urethra:
 - Tumor
 - Pelvic masses
 - Prolapse of pelvic organs
 - Foreign body
 - Calculus
 - Urethritis
 - Stricture
 - Meatal stenosis (can also be seen in females)
 - Hematoma
 - Vulvar edema after vaginal delivery
 - _ Prostate gland:
 - Benign prostatic hypertrophy
 - Carcinoma
 - Prostatitis
 - Contracture of bladder neck
 - Prostatic infarction
- Neurologic causes:
 - _ Motor/paralytic:
 - Spinal shock
 - Spinal cord syndromes
 - _ Sensory/paralytic:

- Diabetes
- Multiple sclerosis
- Spinal cord syndromes
- Drugs:
 - Antihistamines
 - Anticholinergics
 - Antispasmodics
 - Tricyclic antidepressants
 - α -Adrenergic stimulators
 - Narcotics
 - NSAIDs

DIAGNOSIS

SIGNS AND SYMPTOMS

- Lower abdominal or suprapubic discomfort
- Patients may appear restless or in distress
- Chronic urinary retention usually painless

History

- Past medical history:
 - History of urinary retention?
 - History of BPH or prostate cancer?
 - History of other cancer?
 - History of radiation treatment?
 - History of pelvic trauma?
- Any signs or symptoms of infection including an abscess?
- Any signs or symptoms of calculus?
- Any neurologic symptoms?
- History of or current IV drug abuse?
- Back pain?
- Complete list of all medications

Physical-Exam

- Vitals (Any evidence of infection? Shock?)
- Abdominal exam
- Rectal exam
- Genitourinary exam; consider pelvic exam in all women
- Thorough neurologic exam if appropriate
- In the trauma patient, evaluate for evidence of urethral injury

ESSENTIAL WORKUP

Due to the multiple causes of AUR a thorough history and physical exam are imperative, and will determine further workup

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Basic chemistry to assess renal function only if concerned for acute renal insufficiency (this usually does not occur in AUR)
- No benefit to PSA test in ED; usually elevated in setting of AUR
- Urinalysis if indicated on history or exam

Imaging

- Abdominal or pelvic US or CT abdomen/pelvis if concerned for mass, malignancy, abscess, bladder calculi, or other anatomic etiologic agent
- Neuro or spinal imaging if there is concern for an acute neurologic process

Diagnostic Procedures/Surgery

Postvoid residual: More than 200 mL is usually considered abnormal.

DIFFERENTIAL DIAGNOSIS

Chronic urinary retention

TREATMENT

PRE HOSPITAL

Address any life-threatening presentation

INITIAL STABILIZATION/THERAPY

- Identify and treat any life-threatening presentation
- Prompt bladder decompression:
 - Try placement of 14–18F urinary catheter
 - If unable to pass a 14–18F catheter and there is a history of prior transurethral procedure or known stricture, downsize to a 10–12F
 - In men with no prior instrumentation and unable to pass catheter, consider a 20–22F catheter with a coude tip
 - If unable to pass a catheter, then either suprapubic aspiration as a temporizing measure or placement of suprapubic catheter is indicated
- Defer catheterization of the ureter in the trauma patient suspected of having a ureteral injury (gross hematuria, high-riding prostate on rectal exam, blood at the meatus) until a retrograde urethrogram has been done

ED TREATMENT/PROCEDURES

- Drain bladder and monitor urine output:
 - Rapid decompression following catheter placement may result in transient gross hematuria, rarely clinically significant
 - Postobstructive diuresis:
 - Can be a complication of AUR in the catheterized patient
 - No randomized trials comparing rapid and intermittent bladder decompression
 - It is generally now felt that rapid bladder decompression is safe provided that supportive care is available if hypotension develops
- Probably best to observe for 2–3 hr after bladder decompression to ensure that a postobstructive diuresis does not cause clinical deterioration
- Place leg catheter bag before discharge if catheter is to remain indwelling
- Educate patient and family on catheter care.
- Although commonly used, prophylactic antibiotics are not indicated for patients with an indwelling urinary catheter and no evidence of infection
- Start patients with BPH on an α -blocker
- Consider stopping any medication that may be contributing to AUR
- Treat constipation if appropriate

MEDICATION

- Prazosin HCl (Minipress) for treatment of BPH: Initially 1 mg PO BID to TID, slowly increase to 20 mg/d in div. doses
- Tamsulosin (Flomax) is an α -1 antagonist used to treat BPH: 0.4 mg PO QD after the same meal daily; may increase to 0.8 mg PO QD
- Alfuzosin (Uroxatral) is an α -blocker used to treat BPH: 10 mg PO daily after the same meal each day
- Terazosin (Hytrin) facilitates urinary flow in the presence of BPH: Start 1 mg PO QHS, max. 20 mg/d

FOLLOW-UP

DISPOSITION

Admission Criteria

- Significant postobstructive diuresis requiring IV fluids or pressors
- Sepsis
- Obstruction related to spinal cord compression
- Consider in patient with obstruction due to malignancy or mass
- Any process requiring acute urologic or surgical intervention

Discharge Criteria

Most patients can be discharged

FOLLOW-UP RECOMMENDATIONS

Most patients will need follow-up for ongoing evaluation and management of AUR as well as catheter management

PEARLS AND PITFALLS

- Carefully evaluate for evidence of a mass or malignancy as the cause of AUR.
- Carefully evaluate for evidence of spinal cord compression as the cause of AUR.
- Take a thorough drug history including over-the-counter medications, especially if no other clear reason for AUR.

- R33.9 Retention of urine, unspecified

URINARY TRACT FISTULA

Denise S. Lawe

BASICS

DESCRIPTION

Urinary tract fistulas can form between any part of the urinary tract and structures in the thoracic cavity, the abdominal cavity, the pelvis, and the skin.

ETIOLOGY

- Colovesical fistula:
 - Usually complication of primary GI disease such as diverticular disease (most common), Crohn's disease, or colon carcinoma
 - Iatrogenic (postsurgical or radiation treatment most common)
 - Urethral disruption from trauma
 - More common in males
- Vesicovaginal, urethrovaginal, and ureterovaginal fistulas:
 - Vesicovaginal fistula is the most common acquired fistula of the urinary tract
 - Etiology varies with geography (developed vs. developing countries):
 - In developed countries it is usually due to injury to the structures during surgery, pelvic pathology, radiation therapy, or injuries incurred in the healing process. Radiation-induced fistulas may not present for months to years after exposure.
 - In developing countries it is usually due to obstructed labor and obstetric trauma.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Colovesical fistula:
 - Chronic or recurrent UTIs
 - Suprapubic pain
 - Abnormal urine: Pneumaturia, fecaluria, hematuria, malodorous urine, debris in the urine (food particles)
- Vesicovaginal fistula:
 - If after surgical procedure, may present on removal of urinary catheter or 1–3 wk post procedure
 - Usually painless
 - Constant urine leakage from the vagina (may be confused with urinary incontinence)

- Perineal skin irritation due to urine leakage
- Urethrovaginal fistula:
 - Symptoms largely dependent on size and location of fistula
 - May be asymptomatic or with continuous vaginal urine drainage
- Ureterovaginal fistula:
 - Usually a history of recent surgery, particularly a complicated hysterectomy
 - Abdominal or flank pain, fever, and ileus. If these symptoms present, likely due to urinoma or renal obstruction
 - Intermittent urine leakage from vagina

History

- A thorough past medical, surgical, and obstetric history to determine risk factors
- Description and timing of presumed urinary discharge: Intermittent or positional usually due to ureterovesical fistula; continuous flow more likely to be from vesicovaginal fistula.
- Characteristics of presumed urinary discharge
- Associated symptoms

Physical-Exam

- Colovesical fistula:
 - There might be findings consistent with the primary GI disease; otherwise physical exam is frequently unremarkable
- Vesicovaginal, urethrovaginal, ureterovaginal fistulas:
 - Speculum exam may reveal a small reddened area of granulomatous tissue at site of the fistula opening. May also see pooling of the urine in the vaginal vault.

ESSENTIAL WORKUP

Must evaluate for associated urinary infection, renal obstruction, or acute emergencies related to primary disease processes (e.g., complications from a malignancy or Crohn's disease).

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Urinalysis:
 - Colovesical fistula:
 - WBCs, bacteria, and debris
 - Vesicovaginal, urethrovaginal, and ureterovaginal fistulas:
 - WBCs, bacteria
- BUN and creatinine:
 - If renal obstruction is present, might be abnormal.

Imaging

- Usually not an emergent need to image and would discuss with specialist
- Colovesical fistula:
 - CT of the abdomen and pelvis with contrast
- Vesicovaginal, urethrovaginal, and ureterovaginal fistulas:
 - Cystoscopy with retrograde pyelography or IVP

Diagnostic Procedures/Surgery

- Usually an outpatient workup
- Colovesical fistula:
 - Oral administration of activated charcoal will result in black particles in urine, which can be diagnostic.
- Vesicovaginal, urethrovaginal, ureterovaginal fistulas:
 - Double-dye test: (1) Tampon is placed in vagina, (2) oral phenazopyridine is administered, (3) methylene blue or indigo carmine is instilled into the bladder, (4). if, after an hour, tampon is yellow-orange at the top, ureterovaginal fistula is suggested. Midportion blue discoloration suggests vesicovaginal fistula. Distal blue discoloration suggests urethrovaginal fistula.

DIFFERENTIAL DIAGNOSIS

- Colovesical fistula:
 - Recurrent UTI
 - Other causes of pneumaturia:
 - UTI with gas-forming organism such as clostridia
 - Fermentation of diabetic urine
 - Recent urinary tract instrumentation
- Vesicovaginal, urethrovaginal, and ureterovaginal fistulas:
 - Urinary incontinence
 - Normal vaginal discharge
 - Vaginitis

TREATMENT

INITIAL STABILIZATION/THERAPY

Treat urosepsis (rare) with IV fluid bolus, pressors, and IV antibiotics as appropriate.

ED TREATMENT/PROCEDURES

- Colovesical fistula:
 - Evaluate for complications from patient's primary disease.
 - Obtain cultures if there are signs of UTI.
 - Initiate antibiotic if infection is found.

- Urgent urologic referral for further management and possible surgical treatment.
- Vesicovaginal, urethrovaginal, and ureterovaginal fistulas:
 - Consider placing urinary catheter
 - Initiate antibiotics if a UTI is present.
 - Urgent referral to urologist and gynecologist for further care

FOLLOW-UP

DISPOSITION

Admission Criteria

- Sepsis
- Inability to take oral antibiotics if needed
- Acute emergencies from primary GI disease or malignancies

Discharge Criteria

- No evidence of sepsis
- Able to tolerate oral antibiotics if UTI present

FOLLOW-UP RECOMMENDATIONS

Urogenital specialist (Urology or Gynecology) follow-up is required.

PEARLS AND PITFALLS

- Suspect a urinary tract fistula in the patient with the appropriate risk factors (usually a complicated recent pelvic surgery) and recurrent UTIs
- In the presence of urinary tract fistula, malignancy is always an important diagnostic consideration
- Urine leakage from the vagina may be confused with urinary incontinence

ICD10

- N32.1 Vesicointestinal fistula
- N36.0 Urethral fistula
- N82.0 Vesicovaginal fistula

URINARY TRACT INFECTIONS, ADULT

Paul A. Szucs • Barnet Eskin

BASICS

DESCRIPTION

- Colonization of urine with uropathogens and invasion of genitourinary (GU) tract
- Defined as urinary symptoms with $\geq 10^2$ to 10^5 CFU/mL of uropathogen and ≥ 10 WBC/mm³
- Lifetime risk of UTI in women is $> 50\%$
- Uncomplicated cystitis:
 - Females aged 13–50
 - Symptoms < 2 –3 days
 - Not pregnant
 - Afebrile (temperature $< 38^\circ\text{C}$)
 - No flank pain
 - No costovertebral angle tenderness (CVAT)
 - Fewer than 4 UTIs in past year
 - No recent instrumentation or previous GU surgery
 - No functional/structural GU abnormality
 - Not immunocompromised
 - Neurologically intact
- Complicated cystitis:
 - Do not meet above criteria
 - Male gender
 - Patients with anatomic, functional, or metabolic abnormalities of GU tract
 - Postvoid residual urine
 - Catheters
 - Resistant pathogens
 - Recent antimicrobial use
- Uncomplicated pyelonephritis:
 - Renal parenchymal infection
 - Dysuria, frequency, urgency
 - Fever, chills, myalgias, nausea, vomiting
 - Flank, back, or abdominal pain
 - CVA tenderness
 - Leukocytosis (common)
- Complicated pyelonephritis:
 - Renal parenchymal infection
 - Temperature $> 40^\circ\text{C}$
 - Urosepsis with septic shock

- Intractable nausea, vomiting
- Diabetes, other immunosuppression
- Pregnancy (especially latter half)
- Concomitant obstruction or stone
- Asymptomatic (occult)

ETIOLOGY

- Mechanism:
 - Organisms colonize periurethral area and subsequently infect the GU tract.
- Risk factors:
 - Population:
 - Newborn, prepubertal girls, young boys
 - Sexually active young woman
 - Postmenopausal woman, elderly males
 - Behavior:
 - Sexual intercourse, spermicides, diaphragms
- Elderly females/postmenopausal state
- Less efficient bladder emptying, bladder prolapse, alteration of bladder defenses
- Increased vaginal pH
- Contamination due to urinary or fecal incontinence (Enterobacteriaceae)
- Instrumentation:
 - Elderly males due to prostatic hypertrophy and instrumentation
- Organisms:
 - *Escherichia coli* (80–85%)
 - *Staphylococcus saprophyticus* (10%)
 - Other (10%): *Klebsiella*, *Proteus mirabilis*, *Enterobacter* spp., *Pseudomonas aeruginosa*, group D streptococci

DIAGNOSIS

SIGNS AND SYMPTOMS

- Lower tract infection: Cystitis:
 - Dysuria, frequency, urgency, hesitancy
 - Suprapubic pain
 - Hematuria
- Upper tract infection: Pyelonephritis:
 - Symptoms of cystitis:
 - Fever, chills
 - Flank pain and/or tenderness
 - Nausea, vomiting, anorexia
 - Leukocytosis
 - Up to 50% of patients with cystitis may actually have pyelonephritis:
 - Symptom duration > 5 days, homelessness, and recent UTI are risk

factors for upper tract infection

- Elderly or frail patients:
 - Altered mental status
 - Anorexia
 - Decreased social interaction
 - Abdominal pain
 - Nocturia, incontinence
 - Syncope or dizziness

ESSENTIAL WORKUP

- Urinalysis (dipstick test, microscopy)
- Females: Rule out pregnancy, urethritis, vaginitis, pelvic inflammatory disease (PID)
- Males: Rule out urethritis, epididymitis, prostatitis; inquire about anal intercourse/HIV.
- Urologic evaluation in young healthy males with 1st UTI is *not* routinely recommended.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Rapid Urine Screen:
 - Dipstick (leukocyte esterase + nitrite) most effective when urine contains 10^5 CFU/mL
 - Lab specimen unnecessary if pyuria and bacteriuria confirmed by dipstick
 - Leukocyte esterase: Positive likelihood ratio (LR+) ~5, negative likelihood ratio (LR-) ~0.3
 - Nitrite: LR+ ~30, LR- ~0.5
- Urinalysis/microscopy:
 - Obtain if rapid urine screen is unavailable or negative in patients with presumed UTI.
 - 10 WBC/mm³ in clean catch midstream urine indicates infection.
 - Bacteria detected in unspun urine indicates $>10^5$ CFU/mL. (LR+ ~20, LR- ~0.1)
- Indications for urine culture:
 - Complicated UTIs
 - Negative rapid urine screen or microscopy in patients with presumed UTI
 - Persistent signs and symptoms after 2–3 days of treatment
 - Recurrence (relapse vs. reinfection)
 - Recently hospitalized patients
 - Nosocomial infections
 - Pyelonephritis

Geriatric Considerations

- Asymptomatic bacteriuria (including positive cultures) occurs in 20% of women >65 yr, 50% of women >80 yr and generally should *not* be treated.
- Consider treating symptomatic geriatric patients for 5–10 days to decrease risk of recurrent or persistent bacteriuria.
- Fluoroquinolones may cause CNS side effects.

Imaging

- Indicated for complicated upper tract disease (see Pyelonephritis)
- Helical CT, renal ultrasound, or IV pyelogram if concomitant stone or obstruction suspected

Diagnostic Procedures/Surgery

Patients with significant hematuria, recurrent UTI with same uropathogen, or symptoms of obstruction *need* urologic evaluation to identify structural or functional abnormality.

DIFFERENTIAL DIAGNOSIS

- Appendicitis
- Diverticulitis
- Epididymitis
- Nephrolithiasis
- PID/cervicitis
- Prostatitis
- Pyelonephritis
- Urethritis
- Vulvovaginitis

TREATMENT

INITIAL STABILIZATION/THERAPY

Urosepsis/septic shock:

- Manage airway and resuscitate as indicated
- IV crystalloid and vasopressors as needed
- Early goal-directed therapy

ED TREATMENT/PROCEDURES

Stable Patients

- For uncomplicated UTIs in women for most antibiotics, 3 days of therapy:
 - More effective than single dose
 - Clinically as effective as 5–10-day course with fewer side effects
- Resistance varies by place and changes over time:

- In North America, 40–50% of *E. coli* are resistant to ampicillin; 3–17% to fluoroquinolones and is increasing.
- Resistance to trimethoprim–sulfamethoxazole (TMP/SMX) is increasing (up to 30%).
- Nitrofurantoin: In some studies, nitrofurantoin resistance is less than for other more widely used antibiotics.
- Culture resistance may not correlate with clinical effect because urine antibiotic concentrations are much higher than those used in laboratory testing. However, symptom resolution may be delayed a few days in patients with resistant bacteria.
- Antibiotics of choice:
 - Nitrofurantoin
 - TMP/SMX
 - Fluoroquinolones 2nd-line treatment in women:
 - Sulfonamide intolerance
 - All quinolones equally effective (~95% susceptibility rates) but side effects vary
 - High frequency of antimicrobial resistance related to recent treatment
 - Live in areas with unknown or >20% resistance to TMP/SMX
 - Oral cephalosporins may be reasonable alternatives in specific circumstances:
 - Require 7-day treatment regimens
 - Amoxicillin–clavulanate not as effective as ciprofloxacin, probably due to failure to eradicate vaginal *E. coli*
 - Diabetic women have increased risk of bacteriuria with *Klebsiella* spp.
 - Treat dysuria with phenazopyridine.
 - Treat pain with appropriate analgesics.
- Cranberry juice or tablets/products:
 - Prevents specific *E. coli* from adhering to uroepithelial cells but probably does not lower UTI recurrence rate in women with history of recurrent UTIs
 - Evidence suggests ineffective for treatment
- Treatment of upper tract disease—*rule of 2s*:
 - 2 L of IV crystalloid
 - 2 tablets of oxycodone/acetaminophen
 - 2 g of ceftriaxone or 2 mg/kg of gentamicin
 - If fever drops by 2°C and patient can retain 2 glasses of water
 - Discharge with fluoroquinolone for 2 wk.
 - Follow up in 2 days.

Pregnancy Considerations

- Treat asymptomatic bacteriuria in pregnancy with 4–7-day course of antibiotics:
 - Nitrofurantoin:
 - May cause birth defects if used in 1st trimester

- Contraindicated in G6PD-deficiency
- Amoxicillin (not 1st-line treatment due to high rate of resistance)
- Fosfomycin (safe and effective)
- TMP/SMX:
 - SMX should be avoided late in pregnancy as kernicterus can result.
 - TMP should be avoided in 1st trimester (folic acid antagonist; possible birth defects).
- Quinolones should be avoided:
 - CNS reactions
 - Blood dyscrasias
 - Effects on collagen formation

MEDICATION

- Amoxicillin: 500 or 875 mg PO q12h
- Cefixime: 400 mg PO q24h
- Cefpodoxime: 400 mg PO q12h
- Ceftazidime: 1–2 g IV q8–12h
- Ceftriaxone: 1–2 g IV/IM q24h
- Cefuroxime: 250–500 mg PO q12h
- Cephalexin: 250–500 mg PO q6h
- Ciprofloxacin: 100–500 mg PO q12h
- Doripenem: 500 mg IV q8h
- Fosfomycin: 3 g single dose
- Gentamicin: 2 mg/kg IV or IM q8h
- Levofloxacin: 250 mg PO q24h
- Nitrofurantoin macrocrystals 100 mg PO q12h
- Norfloxacin: 400 mg PO q12
- Ofloxacin: 200 mg PO q12h or 400 mg IV q12h
- Phenazopyridine: 200 mg PO TID for 2 days:
 - For symptomatic treatment of dysuria
 - May turn urine and contact lenses orange
- TMP/SMX: 160 mg/800 mg PO q12h or 10 mg/kg/d IV div. q6–8–12h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Inability to comply with oral therapy
- Toxic appearing, unstable vital signs
- Pyelonephritis:
 - Intractable symptoms

- Extremes of age
- Immunosuppression
- Urinary obstruction
- Consider if coexisting urolithiasis
- Significant comorbid disease
- Outpatient treatment failure
- Late in pregnancy

Discharge Criteria

- Well appearing, normal vital signs
- Can comply with oral therapy
- No significant comorbid disease
- Adequate follow-up (48–72 hr) as needed
- Healthy patients with uncomplicated pyelonephritis who respond to treatment in ED according to rule of 2s
- Pyelonephritis in early pregnancy with good follow-up may be treated as outpatients

Issues for Referral

Recurrent UTIs require workup for underlying pathology.

FOLLOW-UP RECOMMENDATIONS

Follow-up for UTIs should start with primary care physician.

PEARLS AND PITFALLS

- For women who have more than 2 episodes of acute cystitis in 6 mo or 3 episodes in 1 yr, consider long-term (6–12 mo) prophylactic antibiotics or postcoital prophylaxis
- Pregnant women should be screened and treated for asymptomatic bacteriuria (ASB) because 20–40% of women with ASB progress to pyelonephritis.
- ASB in pregnant women associated with increased risk of preterm birth, low birth weight, and perinatal mortality.
- Treat ASB in renal transplant recipients, patients who have recently undergone a urologic procedure, and neutropenic patients.
- Risk factors for acute cystitis in men: Increased age, uncircumcised, HIV infection (low CD4 counts), anatomic abnormalities (BPH or urethral strictures), and sexual activity (especially insertive anal intercourse).
- 25% of male GU complaints are attributable to prostatitis. TMP/SMX or fluoroquinolones are 1st-line treatment.
- In patients with indwelling catheters, pyuria is less strongly correlated with UTI than in patients without catheters.

- N30.90 Cystitis, unspecified without hematuria
- N39.0 Urinary tract infection, site not specified

URINARY TRACT INFECTIONS, PEDIATRIC

Suzanne Z. Barkin

BASICS

DESCRIPTION

- Bacteria colonize via retrograde contamination of rectal or perineal flora:
 - Infants—often hematogenous spread
 - Older children—vesicoureteral reflux (VUR) major risk
- UTI is defined by culture of a single organism of $> 10,000/\text{mL}$ on a catheterized or suprapubic specimen. Other collection techniques are not routinely used in young children for definitive diagnosis.
- In infants 0–3 mo old, UTI is associated with a 30% incidence of sepsis.
- Predisposing factors:
 - Poor perineal hygiene
 - Short urethra of female
 - Female $>$ male
 - Infrequent voiding
 - Constipation
 - Sexual activity
 - Male circumcision probably reduces risk

ETIOLOGY

- UTI found in 4–7% of febrile infants
- Bacterial agents:
 - *Escherichia coli* accounts for 80%
 - *Klebsiella pneumoniae*
 - *Staphylococcus aureus*
 - *Enterobacter* species
 - *Proteus* species
 - *Pseudomonas aeruginosa*
 - *Enterococcus* species

DIAGNOSIS

ALERT

UTIs in children may be difficult to diagnose without lab confirmation.

SIGNS AND SYMPTOMS

History

- Often nonspecific
- Neonates:
 - Manifestations of sepsis
 - Feeding difficulties
 - Irritability, listlessness
 - Fever, hypothermia
- 1 mo–3 yr of age:
 - Fever
 - Irritability
 - Vomiting, diarrhea
 - Abdominal pain
 - Poor feeding, failure to thrive
- Hematuria
- In girls <2 yr, an increased risk is associated with those having ≥ 3 factors (<12 mo old, white, temperature $\geq 39^\circ\text{C}$, absence of other source of fever, fever ≥ 2 days)
- Children >3 yr of age:
 - Dysuria
 - Frequency
 - Enuresis
 - New onset of urinary incontinence
 - Pain: Abdominal, suprapubic, back, costovertebral angle (CVA)
 - Fever
 - Hematuria
 - Malodorous cloudy urine
 - Systemic toxicity: High fever and chills with CVA tenderness
- Complications:
 - Recurrent UTI
 - Pyelonephritis
 - Chronic renal failure:
 - Scarring probably may be reduced by early detection and intervention
 - Perinephric abscess
 - Bacteremia/sepsis
 - Urolithiasis

Physical-Exam

- Vital signs, esp. temperature and blood pressure
- Toxicity
- Growth parameters
- Abdomen: Tenderness, esp. CVA pain
- GU: Genitalia

ESSENTIAL WORKUP

- UA with microscopic RBC and WBC counts and Gram stain for bacteria:
 - UA alone has low diagnostic sensitivity in infants.
 - Causes of pyuria besides UTI include chemical (bubble bath) or physical (masturbation) irritation, dehydration, renal tuberculosis, trauma, acute glomerulonephritis, respiratory infections, appendicitis, pelvic infection, and gastroenteritis.
 - Leukocyte esterase correlates with presence of pyuria.
 - Positive nitrite test indicates presence of bacteria capable of fixing nitrate. False-negative tests common
 - Gram stain of urinary sediment is more reliable than dipstick methods of diagnosis and superior to traditional UA.
 - Up to 80% of UAs in neonates with documented UTIs may be normal.
- Urine culture:
 - Specimen should be cultured within 30 min or refrigerated.
 - False-negative results may be caused by dilution, improper culture medium, recent antimicrobial therapy, fastidious organisms, bacteriostatic agent in urine, and complete obstruction of ureter.
- Clean-catch and bag specimens
 - Clean catch in cooperative male children
 - Plastic bag collection adequate for UA (70% contamination rate).
 - Clean the perineum (females) and glans (males) before application.
 - Can be used as a screening tool to rule out an infection if patient is not placed on antibiotics empirically and follow-up culture possible if the initial assessment is suggestive of infection.
- Catheterization is the preferred technique to obtain urine because contamination is common with bag collection and clean catch:
 - Bladder catheterization:
 - Acceptable in all infants
 - Higher success rate than suprapubic aspiration
 - Aseptic technique essential
 - Discarding the 1st 1–2 mL of urine before collecting specimen reduces contamination.
- Suprapubic aspiration is used on rare occasion and does provide a good specimen:
 - Most useful in infants
 - Full bladder optimal
 - Uncommonly used
 - Ultrasound may be useful adjunctive measure to improve yield.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC and blood culture for young children with fever or nonspecific symptoms and no source on exam. Consider additional evaluation as appropriate.

- Electrolytes, BUN, creatinine:
 - Check if there is dehydration, pyelonephritis, or recurrent infection.

Imaging

- Children requiring radiologic evaluation:
 - Infants < 3 mo of age
 - Males (increased association with anomaly) with 1st UTI
 - Clinical signs and symptoms consistent with pyelonephritis
 - Clinical evidence of renal disease
 - Some suggest that girls < 3 yr of age with a 1st UTI should be studied.
 - Females > 3 yr of age
 - 1st UTI in patients who have a family history of UTIs, abnormal voiding pattern, poor growth, HTN, urinary tract anomalies, or failure to respond promptly to therapy
 - 2nd UTI
- Voiding cystoureterogram (VCUG):
 - UTI is often associated with VUR and other genitourinary abnormalities and identified by VCUG. The importance of identifying VUR has been questioned.
- Renal/bladder ultrasound (US):
 - Ultrasonography is useful in excluding obstructive lesion and identifying children with solitary/ectopic kidney and some patients with moderate renal damage/scarring:
 - Renal/bladder US is indicated to identify anatomic abnormalities. Should be done in children < 2 yr with 1st febrile UTI, children with recurrent febrile UTIs, children with a UTI and family history of GU disease, poor growth, or hypertension as well as those children who do not respond as anticipated to antibiotics.
 - Nuclear cystogram (DMSA) may be substituted for VCUG in females. Its role is being clarified.
 - Further evaluation with nuclear medicine studies depends upon the grade of VUR and response to treatment

DIFFERENTIAL DIAGNOSIS

- Infection:
 - Vulvovaginitis
 - Viral cystitis
 - Urethritis (*Neisseria gonorrhoeae* or *Chlamydia trachomatis*)
 - Glomerulonephritis
 - Appendicitis
- Trauma:
 - Chemical irritation/cystitis
 - Perineal

- Sexual abuse
- Genitourinary
- Masturbation
- Foreign body
- Nephrolithiasis
- Diabetes

TREATMENT

INITIAL STABILIZATION/THERAPY

- Treat infants < 3 mo old presumptively for sepsis if febrile and/or toxic until blood and other appropriate cultures are final.
- Airway intervention for septic/acidotic infants with depressed respiratory drive
- Bolus of 20 mL/kg 0.9% NS for dehydration, hypovolemia, or sepsis; may repeat

ED TREATMENT/PROCEDURES

- Initiate IV antibiotics in all febrile infants < 3 mo with UTI:
 - Ampicillin and gentamicin in neonates
 - Cephalosporins after 4–8 wk of age
- Outpatient oral antibiotic for 10–14 days for children discharged. Should reflect local resistance patterns. Once sensitivity is known, antibiotic may need to be changed:
 - Amoxicillin
 - Amoxicillin/clavulanate
 - Cephalexin
 - Trimethoprim–sulfamethoxazole (TMP–SMX)
 - Many suggest 3rd-generation cephalosporin (cefixime, cefdinir) as 1st-line drug in treatment of children without GU anomaly because of changing resistance patterns. Oral therapy is generally adequate although close follow-up is essential to monitor clinical response and sensitivity of the etiologic organism.
 - Recent UTI may provide information related to sensitivities in children with recurrent UTIs
 - Length of treatment in children with afebrile UTI may be shortened to 5 days in children > 2 yr. The short course is still not generally recommended in children with febrile UTI.

MEDICATION

First Line

- Amoxicillin: 40 mg/kg/24 h PO q8h
- Amoxicillin/clavulanate: 40 mg/kg/24 h PO q8h

- Ampicillin: 100 mg/kg/24 h IV q6h
- Cefdinir 14 mg/kg/24 h PO QD
- Cefixime 16 mg/kg/24 h PO on 1st day followed by 8 mg/kg/24 h PO QD
- Ceftriaxone: 50–75 mg/kg/24 h q12–24h IV or IM
- Cephalexin: 50 mg/kg/24 h PO q6–12h
- Gentamicin: 2.5 mg/kg/dose IV q8h if full-term and age >7 days; 2.5 mg/kg/dose IV q12h if full-term and age 0–7 days (special dosing regimens in infants <36 wk postconceptual age)
- TMP–SMX (Bactrim or Septra suspension): 5 mL liquid (of 40/200 per 5 mL) per 10 kg per dose PO BID

FOLLOW-UP

DISPOSITION

Admission Criteria

- Infants <3 mo
- Dehydration
- Ill appearance/toxicity/sepsis
- Suspected pyelonephritis
- Urinary obstruction
- Vomiting, inability to retain medications
- Failure to respond to outpatient therapy
- Immunocompromised patient
- Renal insufficiency
- Foreign body (indwelling catheter)
- Pregnant patient

Discharge Criteria

- Sufficiently hydrated
- Low risk for sepsis or meningitis
- Nontoxic
- Able to take oral antibiotics; compliant

Issues for Referral

- Patients needing admission often require a pediatrician, urologist, or infectious disease consultant, esp. if there is VUR, renal anomaly, impaired renal function, recurrent infection, or hypertension.
- Good follow-up is mandatory.

FOLLOW-UP RECOMMENDATIONS

Monitoring of urine for sterility, further evaluation for underlying pathology, and

following growth pattern

PEARLS AND PITFALLS

- UTI may require lab confirmation of clinical suspicion. Signs and symptoms are often nonspecific.
- Febrile infants with UTI may be bacteremic.
- Neonates with UTI may have normal urinalysis.

- 041.49 Other and unspecified Escherichia coli [E. coli]
- 593.70 Vesicoureteral reflux unspecified or without reflux nephropathy
- 599.0 Urinary tract infection, site not specified

ICD10

- B96.20 Unsp Escherichia coli as the cause of diseases classd elswhr
- N13.70 Vesicoureteral-reflux, unspecified
- N39.0 Urinary tract infection, site not specified

URTICARIA

Fred A. Severyn

BASICS

DESCRIPTION

- Cutaneous mast and basophil cellular release of inflammatory mediators, primarily histamine:
 - Increased vascular permeability and pruritus
- Edema of the epidermis as well as the upper and middle dermis:
 - More common in children and young adults
 - More common in women
 - More common in the atopic patient
- 40% of patients with urticaria will have a component of angioedema:
 - Affects deeper subdermal and/or submucosal sites

Pediatric Considerations

- Urticaria is often the result of reactions to foods and infections
- Swelling of distal extremities and acrocyanosis may be prominent in infants
- Bullae may form in the center of the wheal, especially on legs and buttocks

ETIOLOGY

Acute:

Presumptive trigger may be found, but majority of cases are idiopathic

Course of < 6 wk

- Drugs:
 - Few have recurrent urticaria on later antigenic challenge
- Foods or additives
- Herbal medications, vaccines, opiates
- Insect bites and stings
- Connective tissue diseases
- Endocrine disorders, especially Hashimoto's thyroiditis
- Cancers, especially lymphoproliferative
- Hormonal imbalance, pregnancy, menstrual cycle, exogenous estrogens
- Infections:
 - Viral (including hepatitis, HIV)
 - Viral URI most common associated infection
 - Bacterial
 - Fungal
 - Parasitic
- Inhaled or contact allergen

- Emotional stress
- Physical urticaria—> 20 identified types, including:
 - Dermographism:
 - Most common physical form
 - Reaction to skin pressure
 - Linear wheals under tight clothing
 - Areas scratched with a firm object
 - Cholinergic:
 - Monomorphic wheals 2–3 mm
 - Bright red flare and intense pruritus
 - A response to elevated core temperature:
 - Hot bath
 - Fever
 - Exercise
 - Other rare forms:
 - Cold-induced (may be fatal in cold immersions)
 - Sun exposure
 - Aquagenic

Chronic:

Course of >6 wk

- 75% idiopathic in nature
- Autoimmune disease spectrum
- Immune complex–induced
- Often an unrecognized recurring physical urticaria
- May be due to occult or subclinical infection or systemic disease

 **DIAGNOSIS**

SIGNS AND SYMPTOMS

History

- Prior history
- Familial history
- Alleviating and/or aggravating factors
- Time course of current presentation:
 - Often helpful to circle lesions to document their duration
 - Fever and systemic symptoms
 - Arthralgias and myalgias
 - Weight loss and lymphadenopathy
 - Hypotension, flushing, headache
 - Swelling of mucosal sites
 - Respiratory distress or airway symptoms:

- May be part of an anaphylactic reaction

Physical-Exam

- Focus on signs of systemic allergic reaction or infection
- Airway—angioedema, airway compromise, inability to handle secretions, abnormal phonation, stridor
- Breathing—wheezing
- Circulation—systemic signs of anaphylaxis, such as hypotension
- Abdomen—hepatosplenomegaly, pregnancy
- Dermal—associated edema, associated petechiae, or purpura:
 - Generalized, transient, pruritic, well-circumscribed skin eruptions
 - May include palms or soles
 - May include bullae or purpuric lesions
 - Lesions are of various sizes and shapes, haphazard in distribution, and may become confluent
 - Wheals usually resolve in 3–4 hr
 - New lesions evolve as old ones resolve
- Lymphadenopathy
- Dermographism:
 - Scratch skin with a tongue blade; observe for linear wheal
- Cholinergic:
 - Exercise challenge to raise core temperature or induce sweating
- Expose to sunlight
- Cold-induced:
 - Place an ice cube on skin for 5 min
- Aquagenic:
 - Apply tap water at differing temperatures
- Significant mucosal edema:
 - Suspect angioedema
 - Severe reaction with hypotension
 - Suspect anaphylaxis
- Prolonged, painful, or nonblanching lesions:
 - Suspect urticarial vasculitis

ESSENTIAL WORKUP

- Complete history and physical exam
- Lesion appearance, location, timing, duration
- Identify as acute vs. chronic time-course
- Associated symptoms, triggers
- Coexisting diseases, allergies, medications
- Evaluate for sources of infection and signs of systemic diseases

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Acute urticaria: No labs needed
- Chronic urticaria:
 - Evaluate for infection or systemic disease:
 - CBC with differential, ESR, and/or CRP
 - Thyroid-stimulating hormone and thyroid functions
 - Urinalysis, liver function tests
- Skin biopsy if urticarial vasculitis suspected (not done in ED)

Imaging

- Acute cases: Not needed
- Chronic cases:
 - Directed at search for occult infection

Diagnostic Procedures/Surgery

Skin biopsy—for chronic urticaria or urticarial vasculitis

DIFFERENTIAL DIAGNOSIS

- Angioedema:
 - Can be life-threatening
 - May have component of abdominal symptoms
 - Hereditary or acquired
- Cutaneous vasculitis
- Serum sickness
- Erythema multiforme
- Bullous pemphigoid
- Juvenile rheumatoid arthritis
- Erythema marginatum
- Dermatitis herpetiformis
- Systemic mastocytosis
- Henoch–Schonlein purpura

TREATMENT

PRE HOSPITAL

- Cautions:
 - Systemic allergic reactions can rapidly progress if not treated with early epinephrine
- Severe reaction:
 - Manage airway, oxygen
 - IM epinephrine
 - Parenteral or inhaled β -agonist for bronchospasm

- IV crystalloid and vasopressors as needed

INITIAL STABILIZATION/THERAPY

Remove offending agent if possible

ED TREATMENT/PROCEDURES

- Largely symptomatic except in severe reactions
- Treatment aimed at stimulus, effector cells, inflammatory mediators, and target receptors
- β -Agonist (parenteral or inhaled):
 - Severe hives, angioedema, systemic features
- H_1 -receptor antagonist (1st or 2nd generation):
 - Mainstay of treatment
- H_2 -receptor antagonist:
 - May be beneficial as adjunct to H_1 blocker when no response to H_1 blocker alone
- Corticosteroid (oral):
 - Severe or refractory cases
- Avoid NSAIDs and opiates:
 - May exacerbate condition
- Concurrent use of ketoconazole or macrolides alters hepatic metabolism of antihistamine; use with caution

MEDICATION

- β -Agonists:
 - Epinephrine (1:1,000 solution): 0.1–0.5 mg IM q10–15min PRN (peds: 0.01 mg/kg, IM [max. single dose not to exceed 0.3 mg] q15min PRN)
 - IV epinephrine 0.1–0.25 mg (1:10,000 sol) IV over 5–10 min q5–15min then 1–4 μ g/min IV ONLY if anaphylactic shock
 - Albuterol (0.5% solution): 0.5 mL nebulized q20min PRN (peds: 0.01–0.05 mL/kg per dose [max. 0.5 mL/dose] nebulized q20min PRN bronchospasm)
 - Terbutaline: 0.25 mg SC q15–30min PRN (max. 0.5 mg q4h); (peds: <12 yr old; 0.005–0.01 mg/kg [max. 0.4 mg/dose] SC q15–20min \times 3 PRN bronchospasm)
- H_1 -receptor antagonist (1st generation—lipophilic and sedating)
 - Diphenhydramine: 25–50 mg PO, IV, or IM q6h (peds: 1 mg/kg q6h [max. 300 mg/24 h])
 - Hydroxyzine: 25–50 mg PO or IM q6h (peds: 2 mg/kg/24 h PO div. q8h or 0.5–1 mg/kg IM q4–6h PRN)
- H_1 -receptor antagonist (2nd generation—less sedating and preferred):
 - Cetirizine: Adult and peds \geq 6 yr old: 5–10 mg PO QD (peds 2–6 yr old: 2.5 mg QD to BID)

- Loratadine: 10 mg PO BID (peds 2–6 yr old: 5 mg PO QD)
- Fexofenadine: 60 mg PO BID or 180 mg PO QD (peds 6–12 yr old: 30 mg PO BID)
- H₂-receptor antagonist (suggested dosage):
 - Famotidine: 20 mg IV q12h or 20–40 mg PO QHS (peds: 1 mg/kg/d div. QID [max. 40 mg/24 h])
 - Ranitidine: 150 mg PO BID (peds: Neonate: 2–4 mg/kg/24 h PO div. q8–12h or 2 mg/kg/24 h IV div. q6–8h; infants and children: 4–5 mg/kg/24 h PO div. q8–12h or 2–4 mg/kg/24 h IV or IM div. q6–8h)
- Corticosteroid:
 - Methylprednisolone: 125 mg IV (peds: Start at 2 mg/kg × 1)
 - Prednisolone: 50 mg PO QD for 3 days (peds: 0.5–2 mg/kg/24 h [max. 80 mg/24 h] div. QD to BID for 3–5 days)
 - Prednisone: 40 mg PO QD or 20 mg PO BID for 3–5 days (peds: 1–2 mg/kg/24 h [max. 80 mg/24 h] div. QD to BID for 3–5 days)
- Antileukotrienes:
 - Montelukast: 10 mg PO QD
 - Zafirlukast: 20 mg PO BID

First Line

- H₁-receptor antagonist, 2nd generation
- Corticosteroids
- β-Agonists:
 - Albuterol if bronchospasm present
 - Epinephrine for severe or systemic signs

Second Line

- Antileukotrienes
- H₁-receptor antagonist, 1st generation
- H₂-receptor antagonist, data weak

FOLLOW-UP

DISPOSITION

Admission Criteria

- Systemic allergic reaction with:
 - Respiratory distress or failure
 - Refractory hypotension or shock
- Severe case with dysfunction of health-related quality of life
- Other comorbidities

Discharge Criteria

- Normal vitals
- Absence of other condition requiring admission
- Adequate ability of caregivers at home to monitor for further exacerbations

FOLLOW-UP RECOMMENDATIONS

Follow with PCP, especially if lasting >6 wk

PEARLS AND PITFALLS

- If severe presentation, there is often a biphasic course. Rebound may occur in 4–6 hr
- Chronic urticaria often has a systemic cause

UVULITIS

James P. Brewer

BASICS

DESCRIPTION

Uvulitis refers to any inflammatory condition involving the uvula. Uvulitis can be separated into 2 broad categories:

- Infectious:
 - Bacterial
 - Viral
 - Candidal
- Traumatic or noninfectious

EPIDEMIOLOGY

Incidence and Prevalence Estimates

- Exact incidence is unknown owing to limited reporting
- Once thought to be rare but may in fact be more common (e.g., viral etiologies)
- Children (age 5–15) more often affected than adults due to prevalence of group A streptococcal infections in this age group
- Noninfectious causes more common than infectious causes in adult population

ETIOLOGY

- Infectious:
 - Bacterial:
 - Group A streptococcal infection (GAS), most common
 - *Haemophilus influenzae* type b (Hib)
 - Other bacterial infections (*Fusobacterium nucleatum*, *Prevotella intermedia*, *Streptococcus pneumoniae*)
 - Viral:
 - Not well reported but suspected in mild/transient cases
 - Known to cause uvular lesions however rare in isolation
 - Coxsackie virus (other enteroviruses)
 - Herpes simplex virus
 - Varicella-zoster virus
 - Epstein–Barr virus
 - Candidal infections
- Noninfectious:
 - Trauma/procedure related
 - Inhalation/ingestion of chemical or thermal irritants

- Vasculitis
- Allergic
- Angioedema:
 - Hereditary
 - Medication induced (e.g., Angiotensin-converting enzyme inhibitor [ACEi], Angiotensin receptor blocker [ARB])

DIAGNOSIS

SIGNS AND SYMPTOMS

Dependent upon etiology and associated structural involvement (pharyngitis, epiglottitis, laryngitis, etc.)

History

- Generally rapid in onset (< 4–6 hr) depending on etiology
- All types:
 - Foreign-body sensation
 - Sore throat
 - Dysphagia
 - Odynophagia
 - Dyspnea
- Infectious:
 - Fever (reported)
- Noninfectious:
 - Trauma or recent procedure
 - New medication exposure (ACEi)
 - Caustic or thermal ingestion
- Prior event of tongue, lip, or mouth swelling
- Immunization history in pediatric population
- Medical comorbidity leading to immune compromise

Physical-Exam

- Ranging from limited and well appearing to severe and marked distress
- General:
 - “Toxic” appearance
 - Muffled or “hot-potato” voice
 - Drooling
 - Stridor
 - Gagging
 - Respiratory distress
- HEENT:
 - Erythematous or pale uvula

- Uvular edema
- Exudate (present on uvula or oral pharynx)
- Cervical lymphadenopathy
- Pharyngitis
- Associated findings:
 - Fever
 - Hypoxia
 - Urticaria
 - Wheezing

ESSENTIAL WORKUP

- Evaluation and stabilization of airway as needed
- Determine infectious vs. noninfectious etiology
- Initiate treatment based on suspected etiology (antibiotics, steroids, antihistamine, etc.)
- Consultation with otolaryngologist as warranted

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Rapid GAS antigen
- Surface mucosa bacterial culture
- CBC:
 - Leukocytosis suggesting bacterial infection
 - Eosinophilia suggesting allergic etiology
- Complement testing:
 - Elevated C4 level suggesting esterase deficiency
 - C1 esterase immunochemical assay

Imaging

- Used to rule out other conditions in the differential diagnosis when clinical suspicion exists or when physical exam is limited
- Lateral neck x-ray to visualize and evaluate the epiglottis or for foreign-body aspiration
- CT scan soft tissue neck with IV contrast to evaluate for space occupying fluid collection, cellulitis, deep tissue involvement

Diagnostic Procedures/Surgery

- As warranted and in consultation with otolaryngology when severity of disease warrants:
 - Fiberoptic nasopharyngeal endoscopy
 - Cricothyrotomy
 - Uvular aspiration/decompression

DIFFERENTIAL DIAGNOSIS

- Pharyngitis
- Peritonsillar abscess
- Retropharyngeal abscess
- Epiglottitis
- Angioedema
- Aspirated foreign body

TREATMENT

PRE HOSPITAL

- Rapid assessment of airway, definitive management as warranted
- Supplemental oxygen
- Peripheral IV access
- Assessment of patient surroundings, potential ingestions/inhalants
- Per pre-hospital protocol, IM epinephrine injection, nebulized β -agonist, or racemic epinephrine
- Rapid/emergent transport

INITIAL STABILIZATION/THERAPY

- Initial focus on managing ABCs
- Rapid assessment of airway and need for definitive management
- Peripheral IV access
- Cardiac and oxygen saturation monitoring
- Continued pre-hospital therapy or initiate respiratory therapy:
 - Supplemental oxygen
 - Nebulized β -agonists or racemic epinephrine
- Definitive airway:
 - Endotracheal intubation:
 - Rapid sequence
 - Delayed sequence/awake
 - Fiberoptic assist and indirect laryngoscopy
 - Cricothyrotomy in severe cases
- Early consultation with otolaryngology as warranted

ED TREATMENT/PROCEDURES

- Basic ED treatment is focused on rapid reversal of inflammatory conditions (allergic, angioedema)
- Oral therapy vs. parenteral dependent upon severity of condition

MEDICATION

- Severe conditions (airway compromise):
 - Epinephrine, 1:1,000: 0.3–0.5 mg (peds: 0.01 mg/kg) SQ or IM q30min × 3 doses
 - Diphenhydramine: 25–50 mg (peds: 1–2 mg/kg) IV
 - Methylprednisolone: 125 mg (peds: 0.5–1 mg/kg) IV q4h
- Suspected infectious etiology:
 - Empiric parenteral antibiotic to cover most common etiologies (GAS and Hib)
 - Several options based on patient profile/allergy:
 - Ceftriaxone: 1–2 g (peds: 50 mg/kg) IV (max. dose 2 g/d)
 - Clindamycin: 300 mg (peds: 25–40 mg/kg) IV q8h
 - Empiric oral antibiotic options:
 - Penicillin V: 500 mg (peds: <27 kg 250 mg, >27 kg 500 mg) PO BID–TID × 10 days
 - Amoxicillin: 875 mg (peds: 50 mg/kg/d PO div. q8h) PO q8h × 10 days
 - Clindamycin: 300 mg (peds: 25–40 mg/kg) PO QID × 10 days
- Suspected hereditary angioedema:
 - Anabolic steroid:
 - Danazol: 200 mg PO BID–TID
 - Purified C1 inhibitor concentrate:
 - Berinert: 20 U/kg IV × 1
 - Cinryze: 1,000 U IV
 - Selective bradykinin B₂-receptor antagonist:
 - Icatibant: 30 mg SC × 1
 - Reversible inhibitor of plasma kallikrein:
 - Ecallantide: 30 mg SQ × 1 (as 3–10 mg injections)
 - Fresh frozen plasma:
 - Generally not for acute attacks

FOLLOW-UP

DISPOSITION

Disposition dependent upon severity of condition and response to therapy

Admission Criteria

- Severe airway obstruction warranting definitive airway and ventilatory management
- Need for surgical intervention
- Indication of systemic bacterial infection and need for parenteral antibiotics
- Moderate to severe conditions not responsive to treatment:
 - Hypoxia or oxygen requirement

- Ongoing respiratory compromise
- Inability to tolerate oral intake
- Intractable pain
- Significant comorbid illness
- Poor social conditions limiting outpatient care

Discharge Criteria

- Rapid reversal of condition
- Observation in the ED for 4–6 hr without recurrent symptoms
- No respiratory compromise
- Able to tolerate oral medications and liquids
- Close follow-up available within 24–48 hr
- Access to prescription medications

Issues for Referral

History of recurrent angioedema warrants adjustment of medication, possible referral to Otolaryngology

FOLLOW-UP RECOMMENDATIONS

- Severe infectious etiologies warrant close follow-up with primary physician (24–48 hr) to ensure improvement
- For suspected angioedema, immediately discontinue use of ACEi and ARB

PEARLS AND PITFALLS

- Uvulitis can be caused by several etiologies ranging from infection to hereditary disorder
- Treatment should be directed toward the suspected etiology based on history and exam
- Uvulitis in isolation rarely causes respiratory compromise. If severe respiratory distress, look for additional causes (epiglottitis, anaphylaxis, retropharyngeal abscess, etc.)
- Emergent definitive airway management should be anticipated with tools, medications, and other resources kept near the patient at all times
- Early consultation with otolaryngology when anticipated

CODES

ICD9

528.3 Cellulitis and abscess of oral soft tissues

ICD10

K12.2 Cellulitis and abscess of mouth

VAGINAL BLEEDING

Carla C. Valentine

BASICS

DESCRIPTION

- Common presenting complaint to EDs
- Most cases have benign etiology
- Some patients may have potentially life-threatening conditions
- Key principles in evaluating women with vaginal bleeding:
 - Any woman capable of childbearing might be pregnant
 - Menstrual and sexual histories do not rule out pregnancy

ETIOLOGY

PREGNANCY RELATED

- Early pregnancy:
 - Ectopic pregnancy (occurs in 2% of pregnancies)
 - Abortion:
 - Threatened, incomplete, complete, missed, inevitable, septic
 - Molar pregnancy
 - Trauma
- Later pregnancy:
 - Placenta previa
 - Placental abruption
 - Molar pregnancy
 - Labor
 - Trauma
- Immediate postpartum period:
 - Postpartum hemorrhage
 - Uterine inversion
 - Retained placenta
 - Endometritis

NONPREGNANT PATIENTS

- Dysfunctional uterine bleeding (DUB)
- Structural abnormalities:
 - Uterine fibroids
 - Cervical/endometrial polyps
 - Pelvic tumors
- Atrophic endometrium:
 - Most common cause of postmenopausal bleeding
- Rare for systemic disorders to present solely with vaginal bleeding:

- Von Willebrand disease
- Idiopathic thrombocytopenic purpura
- Trauma
- Foreign bodies
- Infections

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Light headedness
- Fatigue
- Weakness
- Thirst
- Duration of bleeding
- Quantity:
 - Average tampon holds ~ 5 mL
 - Average pad holds ~ 5–15 mL
- Last menstrual period
- Home pregnancy tests
- Prior ectopic pregnancy
- Passage of clots or tissue
- Menstrual history
- Family history
- Trauma

Physical-Exam

- Vital signs
- Cardiopulmonary exam
- Abdominal exam (gravid uterus, masses)
- Pelvic exam:
 - Source of bleeding
 - Evidence of trauma
 - Cervical os open or closed
- Change in mental status may occur with significant blood loss and/or hypotension

ESSENTIAL WORKUP

- Qualitative pregnancy test:
 - Point-of-care urine-based pregnancy test preferred
- Pelvic exam:
 - Essential for all women with vaginal bleeding

- Assess whether cervical os open or closed
- Delay pelvic exam pending US result in late pregnancy:
 - Evaluate for placenta previa
- Defer exam if patient is near term with possible rupture of fetal membranes
- Pregnancy test mandatory for all patients with childbearing potential
- Early pregnancy:
 - Blood type and Rh
 - US to confirm intrauterine pregnancy (IUP)
 - Quantitative β -human chorionic gonadotropin (HCG)
 - Hematocrit
 - Type and cross-match:
 - Ectopic pregnancy
 - Low hematocrit levels
 - Hemodynamic instability
 - UA
- Later pregnancy:
 - Type and Rh
 - Fetal heart tones
 - US indications:
 - No fetal heart tones
 - No documented IUP
 - Unknown placental lie
 - Hematocrit if significant bleeding
 - Type and cross-match if placenta previa/abruption or low hematocrit levels
 - DIC panel if placental abruption:
 - Platelets, PT, PTT, Fibrinogen, fibrin split products
- Early postpartum:
 - US for retained products
 - Hematocrit
 - β -HCG if concern for retained tissue

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Qualitative and/or quantitative HCG
- Hematocrit for women with significant bleeding
- Type and Rh
- Platelet count for suspected thrombocytopenia
- PT/PTT for suspected coagulopathy
- Send any passed tissue or clot for pathology evaluation

Imaging

- Bedside US may be indicated based on presentation, pregnancy status, and other

considerations:

- US and discriminatory zone:
 - _ Transabdominal US:
 - Should detect gestational sac if HCG > 6,500 mIU/mL
 - _ Transvaginal US:
 - Should detect gestational sac if HCG > 1,000–1,500 mIU/mL

DIFFERENTIAL DIAGNOSIS

- DUB
- Ectopic pregnancy
- Menorrhagia
- Menometrorrhagia
- Threatened miscarriage
- Placental abruption
- Placenta previa
- Postpartum hemorrhage
- Leiomyoma
- Pelvic masses and tumors
- Postcoital bleeding
- Traumatic injury
- Thyroid dysfunction
- Bleeding disorders

TREATMENT

PRE HOSPITAL

- Establish IV 0.9% NS with 1–2 L fluid bolus for significant bleeding or hypotension
- Administer high-flow oxygen in pregnant or unstable patients
- In later pregnancy:
 - _ Place patient in left lateral recumbent position to prevent occlusion

INITIAL STABILIZATION/THERAPY

- Manage airway and resuscitate as indicated
- Place cardiac/pulse oximeter monitors
- Oxygen for significant bleeding or unstable patient
- Establish 2 large-bore IVlines and initiate fluid bolus (1–2 L) for hypotensive patients
- Type and cross-match:
 - _ Transfuse blood if continued hypotension from blood loss despite IV fluid resuscitation
 - _ Conjugated estrogens (Premarin) 25 mg IV slowly over 10–15 min q4–6h until bleeding stops for uncontrolled menorrhagia:

- Not to exceed 4 doses

ED TREATMENT/PROCEDURES

- If unstable with surgical condition, arrange for transfer of the patient to the OR as soon as possible
- RhoGAM for vaginal bleeding, pregnancy, and Rh-negative mother

EARLY PREGNANCY

- If US reveals an ectopic pregnancy:
 - Methotrexate according to standards at treating institution
 - Definitive treatment is surgery
- If US reveals an IUP without concerns of heterotopic pregnancy (1/2,600–1/30,000):
 - Discharge patient with arranged obstetric follow-up with precautions for a threatened miscarriage
- US indeterminate for IUP or ectopic with β -HCG greater than institutional discriminatory zone:
 - Cannot exclude ectopic pregnancy
 - If hemodynamically stable with little bleeding, repeat measurement of β -HCG and outpatient obstetric follow-up within 48 hr
 - Strict return parameters
- US indeterminate for IUP or ectopic with β -HCG level less than institutional discriminatory zone:
 - Patient stable with low risk for ectopic pregnancy may be discharged
 - Repeat measurement of β -HCG level and obstetric follow-up within 48 hr
 - Patient may still have an ectopic pregnancy
- Complete abortion:
 - Discharge patient if stable without significant ongoing bleeding
- Incomplete abortion:
 - Obstetric consultation is required
 - Dilation and curettage vs. expectant management
- Missed abortion:
 - Expectant management initially
- Septic abortion:
 - IV antibiotics and admission
- Molar pregnancy:
 - Chemotherapy
 - Very responsive in early stages of disease

LATER PREGNANCY

- Placenta previa:
 - Obstetric consultation for possible admission
- Placental abruption:
 - Induction of labor if large
 - Can lead to fetal/maternal death

- May require cesarean section

IMMEDIATE POSTPARTUM

- Uterine inversion:
 - Prevent by avoiding strong traction on umbilical cord after delivery
 - Replace uterus immediately
 - Occasionally requires operative management
- Postpartum hemorrhage:
 - Extraction of placenta if retained
 - Hysterectomy if uncontrolled life-threatening bleeding

EARLY POSTPARTUM

- Retained tissue:
 - Dilation and curettage
- Endometritis:
 - IV antibiotics

NONPREGNANT

- Menses:
 - NSAIDs and supportive care
- DUB:
 - <35–40 yr of age:
 - If known anovulatory DUB:
 - Medroxyprogesterone (Provera)—warn patient about withdrawal bleeding
 - Oral contraceptive pill daily for 7 days
 - Patients >35–40 yr of age:
 - US for any masses palpated during physical exam
 - Gynecologic referral
 - Uterine sampling necessary before initiation of hormonal treatment
 - Evaluate for endometrial cancer

STRUCTURAL ABNORMALITIES

- Pap smear/biopsy for cervical lesions
- US for workup of pelvic masses
- Fibroids or uterine tumors
- Conservative management or lumpectomy/hysterectomy

MEDICATION

- Conjugated estrogens 25 mg IV slowly over 10–15 min q6h until bleeding stops(not to exceed 4 doses)
 - If no response after 1–2 doses re-evaluation needed
- Known anovulatory DUB:
 - Medroxyprogesterone 10 mg PO per day for 1st 10 days of menstrual cycle (warn patient about withdrawal bleeding)
 - Norethindrone and ethinyl estradiol (Ortho-Novum) 1/35 BID for 7 days
- MICRhoGAM 50 µg IM if <12 wk pregnant

- RhoGAM 300 µg IM if > 12 wk pregnant

FOLLOW-UP

DISPOSITION

Admission Criteria

- Ectopic pregnancy not meeting methotrexate discharge criteria
- Uterine inversion
- Septic abortion
- Placental abruption
- Postpartum hemorrhage
- Endometritis
- Unstable DUB
- Newly diagnosed molar pregnancy

Discharge Criteria

- Stable vital signs
- Confirmed IUP
- Ectopic pregnancy meeting institutional methotrexate discharge criteria
- Pregnant patient with low risk for ectopic pregnancy:
 - No findings of IUP on US
 - Levels of β-HCG below discriminatory zone
- Nonpregnant patients with vaginal bleeding that are hemodynamically stable

Issues for Referral

Obstetric/gynecologic referral

FOLLOW-UP RECOMMENDATIONS

- Obstetric referral within 48 hr for 1st-trimester vaginal bleeding without identified IUP
- OB/GYN referral for patients with menorrhagia for continued evaluation, workup, and treatment

PATIENT EDUCATION

Ectopic precautions: Return immediately for increasing abdominal pain, vaginal bleeding more than 1 pad per hr for 3–4 hr, fever >100.4°F, syncope, or dizziness. Patients should not be left alone until the diagnosis of ectopic pregnancy can be safely ruled out. Family and friends should also be instructed on the warning signs and symptoms of ruptured/bleeding ectopic pregnancies.

PEARLS AND PITFALLS

- Pregnancy test for all women of reproductive age
- If there is 1st-trimester vaginal bleeding, evaluate for ectopic pregnancy

- N93.9 Abnormal uterine and vaginal bleeding, unspecified

VAGINAL BLEEDING IN PREGNANCY

Paul Ishimine

BASICS

DESCRIPTION

- Major cause of maternal/fetal morbidity and mortality
- Early pregnancy hemorrhage (≤ 20 wk):
 - Occurs in 30% of all pregnancies
 - 50% lead to spontaneous abortion
- Late pregnancy hemorrhage (> 20 wk):
 - Occurs in 3–5% of all pregnancies
- Risk factors:
 - Advanced maternal age
 - Substance abuse
 - Pelvic inflammatory disease (PID)
 - Previous cesarean section
 - Previous termination of pregnancy
 - Previous dilation and curettage (D&C)
 - Previous ectopic pregnancy
 - Increased parity
 - Multiple gestation
 - Preeclampsia
 - Hypertension
 - Trauma
 - Use of assisted reproductive technology
- Genetics:
 - 50–60% of miscarriages due to chromosomal abnormalities

ETIOLOGY

- Vaginal
- Cervical
- Uterine
- Uterine–placental interface
- Hematologic dysfunction

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Intensity and duration of bleeding:
 - Amount (clots, number of pads)
 - Color (dark or bright red)
 - Painful or painless
 - Watery, blood-tinged mucus
 - Life-threatening conditions may present with only minimal bleeding
- Last normal menstrual period
- Passage of tissue
- Estimated duration of gestation
- Gravidity/parity
- Fever
- Last intercourse
- Intrauterine device use
- Previous obstetric–gynecologic complications
- Syncope or near-syncope
- Previous obstetric–gynecologic complications
- Spontaneous abortion: Classically crampy, diffuse pelvic pain
- Ectopic pregnancy: Classically sharp pelvic pain with lateralization
- Placenta previa: Classically painless bright red hemorrhage
- Placental abruption: Classically painful dark red hemorrhage

Physical-Exam

- Vital signs:
 - Tachycardia
 - Hypotension
 - Orthostatic changes
 - Signs of hemodynamic instability may be absent due to pregnancy-related physiologic increase in blood volume
- Fetal heart tones:
 - Fetal cardiac activity seen on transvaginal US at 6.5 wk
 - Auscultated with hand-held Doppler past 10 wk gestation
 - Normal fetal heart rate: 120–160 beats/min
- Abdominal exam:
 - Uterine size:
 - 12 wk: Palpable in abdomen
 - 20 wk: Palpable at umbilicus
 - Peritoneal signs
 - Firm or tender uterus in late pregnancy suggests abruption
- Pelvic exam—only in early pregnancy:
 - Evaluate source and intensity of bleeding
 - Determine patency of cervical os (use finger and only in first trimester):
 - Threatened abortion: os closed
 - Inevitable abortion: os open

- Incomplete abortion: os open or closed
- Complete abortion: os closed
- Embryonic demise (missed abortion): os closed
- Products of conception (POC) may be noted in incomplete or completed abortion:
 - POC in the cervical os can result in profuse bleeding
- Evaluate uterine size, tenderness
- Evaluate for uterine fibroids or adnexal masses
- Late pregnancy: Do not perform pelvic exam unless in controlled OR setting:
 - Severe hemorrhage may ensue
 - Placenta previa or vasa previa must be ruled out by US prior to pelvic exam

ESSENTIAL WORKUP

- CBC
- Type and screen
- Quantitative HCG in early pregnancy
- Urinalysis
- US:
 - Transvaginal US provides more information than transabdominal US in early pregnancy

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - Dilutional “anemia” is a normal physiologic change in pregnancy:
 - Blood volume expands by 45%
- Qualitative beta-human chorionic gonadotropin (β -hCG)
- Quantitative β -hCG:
 - Imperfect correlation with US findings
 - Detectable 9–11 days following ovulation
- Blood typing and Rh typing:
 - Cross-match if significant bleeding
- Disseminated intravascular coagulation (DIC) panel in embryonic demise, placental abruption
- Blood cultures with septic abortion
- Suspected POC to lab for identification of chorionic villi

Imaging

- US:
 - Essential diagnostic modality:

- Confirms intrauterine pregnancy (IUP)
- Detects gestational sac at 5 wk (usually with β -hCG \geq 1,000–2,000 IU), yolk sac at 6 wk, and cardiac activity at 5–6 wk of gestation
- Essentially rules out ectopic pregnancy by showing IUP (except in women at high risk for heterotopic pregnancy)
- Proves ectopic pregnancy by showing fetal pole outside uterus
- Suggests ectopic pregnancy by detecting free fluid in cul-de-sac or adnexal mass
- Detects retained POC
- Demonstrates “snowstorm” appearance within uterus with gestational trophoblastic disease

Diagnostic Procedures/Surgery

- **Culdocentesis:**
 - Limited use
 - Identifies free fluid in cul-de-sac
- **D&C or vacuum aspiration:**
 - Indicated if suspected incomplete or septic abortion, embryonic demise, gestational trophoblastic disease, or anembryonic gestation to evacuate retained POC
- **Laparoscopy/laparotomy:**
 - Indicated for unstable patients
 - Definitive diagnosis and treatment of ectopic pregnancy

DIFFERENTIAL DIAGNOSIS

- **Early pregnancy (< 20 wk):**
 - Implantation bleeding
 - Threatened abortion
 - Complete, incomplete, inevitable, embryonic demise (missed abortion), and septic abortion
 - Ectopic pregnancy
 - Heterotopic pregnancy
 - Gestational trophoblastic disease (molar pregnancy)
 - Subchorionic hemorrhage
 - Anembryonic gestation (blighted ovum)
 - Infection (e.g., cervicitis)
 - Trauma
 - Cervical and vaginal lesions (e.g., polyps, ectropion, carcinoma)
 - Bleeding disorders
- **Late pregnancy (> 20 wk):**
 - Placental abruption (30%)
 - Placenta previa (20%)
 - Bloody show (associated with cervical insufficiency or labor)

- Vasa previa
- Cervical/vaginal trauma or pathology
- Uterine rupture (uncommon)
- Infection (e.g., cervicitis)
- Trauma
- Cervical and vaginal lesions (e.g., polyps, ectropion, carcinoma)
- Bleeding disorders

TREATMENT

PRE HOSPITAL

- Unstable vital signs warrant aggressive resuscitation
- In late pregnancy, position patient on left side to decrease uterine compression of inferior vena cava (IVC)
- Consider preferential transport of a woman with late pregnancy to a facility with obstetric capabilities

INITIAL STABILIZATION/THERAPY

- Airway management
- Oxygen
- Pulse oximetry
- Cardiac monitor
- 2 large-bore IV lines
- Blood transfusion as indicated
- Continuous fetal monitoring in later pregnancy

ED TREATMENT/PROCEDURES

- All women with early pregnancy vaginal bleeding must be evaluated for ectopic pregnancy (preferably by transvaginal US)
- Administer Anti-Rh₀ (D) immune globulin if patient is Rh-negative
- Suspected ectopic pregnancy:
 - Unstable: Consider bedside US with emergent OB/GYN consultation for laparoscopy/laparotomy
 - Stable: Perform US:
 - If confirmatory or suggestive of ectopic pregnancy, obtain OB/GYN consultation for surgery or methotrexate therapy
 - If inconclusive, obtain OB/GYN consultation and arrange for repeat β -hCG testing in 2 days
- Threatened abortion:
 - Emergent OB/GYN consultation for heavy/uncontrolled bleeding
 - Arrange OB/GYN follow-up for minimal bleeding
- Inevitable/incomplete/missed (embryonic demise) abortion:

- POC in the cervical os can result in profuse bleeding
- If POC cannot be removed with gentle traction, obtain emergent OB/GYN consultation
- Arrange OB/GYN follow-up if bleeding minimal
- Complete abortion:
 - Emergent OB/GYN consultation for heavy/uncontrolled bleeding
 - Arrange OB/GYN follow-up if bleeding minimal
- Septic abortion:
 - Initiate broad-spectrum antibiotic therapy
 - Emergent OB/GYN consultation for D&C
- Late pregnancy vaginal bleeding:
 - Hemodynamic stabilization:
 - Fluid resuscitation
 - Positioning of patient onto left side or displacement of uterus laterally to relieve compression by IVC
 - DIC:
 - Associated with late pregnancy bleeding
 - Especially with placental abruption
 - Treated with blood products
 - Immediate obstetric consultation and rapid transfer to obstetric unit

MEDICATION

First Line

- Anti-Rh₀ (D) immune globulin: < 12 wk–50 µg IM; > 12 wk–300 µg IM
- Methotrexate:
 - Variable dosing regimens
 - Only recommended for hemodynamically stable women with unruptured ectopic pregnancy with low β-hCG
- Antibiotics for septic abortion:
 - Multiple acceptable antibiotic regimens
 - Must provide polymicrobial coverage

Second Line

Misoprostol has been used in completed abortion to facilitate uterine evacuation in completed miscarriage

FOLLOW-UP

DISPOSITION

Admission Criteria

- Early pregnancy vaginal bleeding with:
 - Unstable vital signs or significant bleeding
 - Ruptured ectopic pregnancy
 - Incomplete abortion (open os)
 - Septic abortion
- All patients with late pregnancy vaginal bleeding need to be admitted to a labor and delivery unit

Discharge Criteria

- Stable patients with threatened abortion complete abortion, embryonic demise, or anembryonic gestation
- Asymptomatic, hemodynamically stable patient with small, unruptured ectopic (or suspected ectopic) pregnancy after OB/GYN consultation
- Controlled bleeding from vaginal/cervical source

Issues for Referral

- Patients with embryonic demise, anembryonic gestation, or gestational trophoblastic disease need to be referred for uterine evacuation if D&C not performed in ED
- Women with threatened, inevitable, complete, or missed (embryonic demise) abortion should have OB/GYN follow-up within 24–48 hr

FOLLOW-UP RECOMMENDATIONS

- Discharge instructions:
 - No strenuous activity, tampon use, douching, or intercourse
 - Seek medical advice for increased pain, bleeding, fever, or passage of tissue
- All pregnant women with vaginal bleeding during pregnancy who are discharged from the ED require follow-up care
- Women with threatened abortions, known or suspected ectopic pregnancy require repeat β -hCG testing and repeat exams in 2 days

PEARLS AND PITFALLS

- Failure to check Rh status in pregnant women with vaginal bleeding
- Failure to give Anti-Rh₀ (D) immune globulin in Rh-negative women with vaginal bleeding
- Placenta previa or vasa previa must be ruled out by US prior to pelvic exam in late pregnancy

VAGINAL DISCHARGE/VAGINITIS

Elizabeth M. Foley • Carrie Tibbles

BASICS

DESCRIPTION

- Vaginitis is vulvovaginal inflammation with or without abnormal vaginal discharge.
 - Common symptoms: Itching, burning, irritation, pain.
 - Abnormal discharge is defined as an increased amount or change in color.
- Some amount of vaginal discharge is normal.
 - Glands in the cervix produce clear mucus that may turn white or yellow when exposed to air.

ETIOLOGY

- Bacterial vaginosis (BV):
 - The most common cause
 - Loss of normal *Lactobacillus* sp. (e.g., antibiotics)
 - Inability to maintain normal vaginal pH
 - Overgrowth of normally present bacteria such as *Gardnerella vaginalis*, *Mycoplasma hominis*, *Mobiluncus* sp., *Prevotella* sp., and Peptostreptococcal
- Bacterial infections:
 - *Trichomonas vaginalis* (Trichomoniasis)
 - Group A strep
 - *Staphylococcus aureus*
- Fungal infections:
 - *Candida* sp. most common
 - Often underlying immune dysfunction:
 - Diabetes
 - HIV
- Chemical irritants
- Foreign body
- Atrophic vaginitis:
 - Caused by estrogen deficiency
- Hypersensitivity
- Collagen vascular disease
- Herpes simplex virus (HSV):
 - Vulvovaginitis
 - Cervicitis
- Lichen sclerosis (atrophic)
- Fistula

DIAGNOSIS

SIGNS AND SYMPTOMS

- Abnormal discharge
- Vaginal or vulvar irritation
- Localized pain
- Dyspareunia
- Erythema
- Edema
- Dysuria
- Pruritus
- Excoriations
- Abnormal odor
- Can be asymptomatic

History

- Description and duration of symptoms
- Description of discharge, if any
- Timing with regard to menses
- Sexual history of patient and partners
- Sexual practices
- Hygienic practices
- Use of oral contraceptives and/or antibiotics
- Likelihood of pregnancy
- Other symptoms (e.g., abdominal pain; must rule out pelvic inflammatory disease [PID])

Physical-Exam

- Abdominal exam to assess for tenderness
- Inspection of vulva, vaginal os, perineal area
- Speculum and bimanual exam

ESSENTIAL WORKUP

- Pelvic exam
- Saline and KOH wet prep of vaginal discharge

DIAGNOSIS TESTS & NTERPRETATION

Lab

- β -human chorionic gonadotropin (β -hCG)
- pH of discharge with Nitrazine paper:
 - Normal in premenopausal adults: < 4.5

- >4.5: BV, trichomoniasis
- pH normal in candidiasis
- Saline wet prep of discharge:
 - Clue cells: BV
 - Motile flagellated protozoa: Trichomoniasis
 - Presence of polymorphonuclear leukocytes
- Potassium hydroxide (KOH) wet prep of discharge:
 - Pseudohyphae, budding yeast: Candidiasis
- KOH prep “Whiff” test:
 - Amine or “fishy” odor suggests BV, trichomoniasis.
- Trichomonas Rapid Test:
 - Point-of-care test
 - Immunochromatographic dipstick
- PIP test card for BV:
 - Point-of-care test
 - Detects proline aminopeptidase
- Nucleic acid probe test for *Trichomonas*, *G. vaginalis*, and *Candida albicans*
- Gram stain:
 - Large, gram-positive rods: Lactobacilli (normal flora)
 - Small, gram-variable coccobacilli and curved rods: *Gardnerella*, *Prevotella*, *Mobiluncus* (BV)
- Vaginal culture:
 - *Gardnerella*: Not routinely recommended
 - *Candida*: Recommended for recurrently symptomatic patients
 - *Trichomoniasis*: Gold standard
- Endocervical swab for gonorrhea (culture—Thayer–Martin media; DNA probe; amplification techniques—PCR/LCR) and chlamydia (DNA probe or amplification techniques—PCR/LCR)
- Viral cultures for HSV, DFA, or Tzanck smear for multinucleated giant cells if ulcers or vesicles are present
- Urinalysis/urine culture if c/o dysuria
- Rule out sexually transmitted infections:
 - GC/Chlamydia testing
 - Consider RPR to rule out syphilis.
 - Discuss HIV testing.

Imaging

N/A unless fistula is suspected.

DIFFERENTIAL DIAGNOSIS

- UTI
- PID
- Dermatitis

- Discharge from cervicitis can be mistaken for vaginitis
- *Chlamydia trachomatis*
- *Neisseria gonorrhoeae*

TREATMENT

ED TREATMENT/PROCEDURES

- BV:
 - _ Metronidazole vaginal gel daily × 5 days *or*
 - _ Metronidazole 500 mg PO BID × 7 days *or*
 - _ Clindamycin vaginal cream × 7 days *or*
 - _ Clindamycin ovules PV daily × 3 days
 - _ Rx before certain gynecologic procedures
 - _ Advise against alcohol intake if taking metronidazole for 24 hrs after treatment.
 - _ Routine treatment of male sex partner: NO
 - _ *Lactobacillus* not found to be more effective than placebo
- Candidiasis:
 - _ Single-dose oral fluconazole *or*
 - _ Intravaginal imidazole drug × 7 days
 - _ Routine treatment of male sex partner: NO
- Chemical irritant:
 - _ Avoid irritant
 - _ Use sitz baths, cotton underwear.
- Foreign body:
 - _ Removal of foreign body
 - _ Sedation may be required for removal
 - _ Give appropriate antibiotics if infection present
- Chlamydia cervicitis:
 - _ Azithromycin 1 g PO in single dose (for cervicitis, not adequate for PID) *or*
 - _ 7 days of doxycycline, ofloxacin, levofloxacin, or erythromycin
 - _ Treat for presumed concurrent gonococcal infections.
 - _ Routine treatment of male sex partners: YES
- Gonococcal cervicitis:
 - _ Ceftriaxone 250 mg IM × 1 AND azithromycin 1 g PO × 1 *or* doxycycline 100 mg BID × 7 days.
 - _ Oral cephalosporins (cefixime) no longer recommended.
 - _ Treat for presumed concurrent chlamydial infection.
 - _ Routine treatment of male sex partners: YES
- HSV:
 - _ Acyclovir, famciclovir, or valacyclovir for 7–10 days for initial attack; 5 days for recurrences

- Lidocaine jelly for topical relief
- Rule out other causes of genital ulcers. Offer RPR, HIV testing, and counseling.
- Routine treatment of male sex partners: Only if symptomatic; however, patient and partner may shed virus asymptotically.
- Lichen sclerosis:
 - Referral to gynecologist for estrogen cream and further treatment
- Trichomoniasis:
 - Metronidazole 2 g PO once *or*
 - Tinidazole 2 g PO once *or*
 - Metronidazole 500 mg PO BID for 7 days (avoid ethanol)
 - Routine treatment of male sex partners: YES
- All sexually transmitted causes:
 - Advise patient to avoid sexual contact with partner until partner is evaluated and treated when appropriate.
 - Educate regarding STDs/safer sex/HIV/hepatitis vaccines

Pregnancy Considerations

- BV:
 - Treat symptomatic women with oral metronidazole or clindamycin
 - Insufficient evidence for screening or treatment of asymptomatic pregnant women
- Candidiasis:
 - Only topical azole drug recommended in pregnancy; no oral fluconazole.
- Chlamydia cervicitis:
 - Azithromycin is the 1st-line choice for treating chlamydia in pregnant patients
 - Do not treat with doxycycline, ofloxacin, or levofloxacin.
- Trichomoniasis:
 - Metronidazole given early in pregnancy shown to increase preterm birth.
 - Give 2 g single-dose metronidazole, preferably after 37 wk gestation.

Pediatric Considerations

- Ask about new irritants: Bubble bath, soap, and laundry detergent.
- Consider sexual assault/abuse.

MEDICATION

- Acyclovir: 200 mg PO 5 times per day × 10 days or 400 PO TID × 10 days (for initial attack); 200 mg PO 5 times per day × 5 days or 400 PO TID × 5 days (for recurrent attack)
- Azithromycin: 1 g PO × 1
- Butoconazole 2% cream: 5 g PV × 3 days
- Butoconazole SR 2% cream: 5 g PV × 1

- Ceftriaxone: 125 mg IM or 250 mg IM × 1
- Ciprofloxacin: 500 mg PO × 1
- Clindamycin 2% cream: 1 applicator PV QHS × 7 days
- Clindamycin: 300 mg PO BID × 7 days
- Clotrimazole 1% cream: 5 g PV × 7–14 days
- Clotrimazole: 100 mg vaginal tablet × 7 days
- Doxycycline: 100 mg PO BID × 7 days (class D)
- Erythromycin ethyl succinate: 800 mg PO QID × 7 days
- Erythromycin base: 500 mg PO QID × 7 days
- Famciclovir: 250 mg PO TID × 7–10 days (for initial attack); 125 mg PO BID × 5 days (for recurrent infection)
- Fluconazole: 150 mg PO × 1
- Levofloxacin: 500 mg PO per day × 7 days
- Metronidazole: 500 mg PO BID for 7 days
- Metronidazole 0.75% gel: PV daily × 5 days
- Miconazole: 1,200 mg PV × 1
- Miconazole: 200 mg PV QHS × 3 days
- Miconazole 2% cream: 5 g PV QHS × 7 days or 100 mg supp. PV QHS × 7 days
- Nystatin 100,000 unit vaginal tablet: Nightly × 14 days
- Terconazole: 80 mg supp QHS × 3 days
- Terconazole 0.8% cream: 5 g PV × 3 days
- Terconazole 0.4% cream: 5 g PV × 7 days
- Tinidazole: 2 g PO daily × 1 day
- Tioconazole 6.5% cream: 5 g PV × 1
- Valacyclovir: 1 g PO BID × 7–10 days (for initial attack); 500 mg PO BID × 3–5 days or 1 g PO per day × 5 days (for recurrent attack)

FOLLOW-UP

DISPOSITION

Admission Criteria

- Disseminated gonococcal infection
- Sepsis secondary to foreign body
- PID toxicity
- Pain control, consequent inability to urinate or pass stool (HSV)

Discharge Criteria

Most can be discharged. Follow-up in ~1 wk is suggested.

Issues for Referral

- Vaginal discharge and vaginitis can be safely managed as an outpatient by the

patient's primary physician or gynecologist:

- Suggested follow-up in 1 wk

FOLLOW-UP RECOMMENDATIONS

- Recommend good hygiene
- Advise patient to return to the ED or see her doctor if:
 - Symptoms do not resolve in 3–5 days
 - Abdominal pain or cramping
 - Fever or chills
 - Pain during sexual intercourse
 - Lower back or flank pain
 - Difficulty urinating or urinary frequency

PEARLS AND PITFALLS

- pH of BV is often > 4.5
- Candidiasis often presents right before menses and can be precipitated by antibiotic use, DM, and immunosuppression.
- Trichomoniasis often presents after menses and has similar risk factors as other sexually transmitted diseases, including number of sexual partners and sexual practices.
- Partner treatment required for gonococcal and chlamydial infection, trichomoniasis.

- N76.0 Acute vaginitis
- N95.2 Postmenopausal atrophic vaginitis

VALVULAR HEART DISEASE

Liudvikas Jagminas

BASICS

DESCRIPTION

- **Mitral stenosis:**
 - Obstruction of diastolic blood flow into the left ventricle (LV)
- **Mitral regurgitation:**
 - Inadequate closure of the leaflets allows retrograde blood flow into the left atrium (LA).
 - Acute: Pressure overload in LA and pulmonary veins causing acute pulmonary edema
 - Chronic: LV volume overload with dilatation and hypertrophy with LA enlargement
- **Aortic stenosis:**
 - Obstruction of LV outflow with increased systolic gradient
 - Progressive increase in LV systolic pressure and concentric hypertrophy
- **Aortic regurgitation:**
 - Acute LV pressure and volume overload leading to left-heart failure and pulmonary edema
 - Chronic volume overload with LV dilation and hypertrophy

Pregnancy Considerations

Pregnancy is associated with significant hemodynamic changes that can aggravate valvular heart disease and increase the risk of thromboembolic events.

Geriatric Considerations

- Degenerative valvular disease is most common (aortic stenosis and mitral regurgitation)
- Aortic valve replacement is the most common surgical procedure

ETIOLOGY

- **Mitral stenosis:**
 - Rheumatic fever
 - Cardiac tumors
 - Rheumatologic disorders (lupus, rheumatoid arthritis)
 - Myxoma
 - Congenital defects: Parachute valve
- **Mitral regurgitation (acute):**
 - Ruptured papillary muscle (infarction, trauma)

- Papillary muscle dysfunction (ischemia)
- Ruptured chordae tendineae (trauma, endocarditis, myxomatous)
- Valve perforation (endocarditis)
- Weight-loss medications (fenfluramine, dexfenfluramine)
- Aortic stenosis:
 - Congenital aortic stenosis: Male > female (4:1)
 - Congenital bicuspid valve (1–2%)
 - Rheumatic aortic stenosis
 - Calcific aortic stenosis
- Aortic regurgitation:
 - Infective endocarditis
 - Rupture of sinus of Valsalva
 - Acute aortic dissection
 - Chest trauma
 - Following valve surgery
 - Bicuspid aortic valve
 - Rheumatic fever
 - Weight-loss medications (fenfluramine, dexfenfluramine)
 - Collagen vascular or connective-tissue diseases
 - Systemic lupus erythematosus
 - Marfan syndrome
 - Pseudoxanthoma elasticum
 - Ankylosing spondylitis
 - Ehlers–Danlos syndrome
 - Polymyalgia rheumatica

DIAGNOSIS

SIGNS AND SYMPTOMS

- Mitral stenosis:
 - Malar flush (“mitral facies”)
 - Prominent jugular A-waves
 - Right ventricular lift
 - Loud S1
 - Opening snap
 - Low-pitched diastolic rumble
 - Exertional dyspnea
 - Fatigue
 - Palpitations
 - Paroxysmal nocturnal dyspnea
 - Orthopnea
 - Hemoptysis

- Systemic emboli
- Pulmonary edema
- Mitral regurgitation:
 - Acute pulmonary edema
 - Jugular venous pressure (JVP) exhibits cannon A-waves and giant V-waves.
 - Harsh blowing apical crescendo–decrescendo murmur radiating to the axilla
 - Palpable thrill at apex
 - S3 and S4
 - Palpitations
 - Atrial fibrillation
 - Dyspnea
 - Orthopnea
 - Nocturnal paroxysmal dyspnea
 - Peripheral edema
 - Systemic emboli
 - Normal JVP
 - Left ventricular hypertrophy (LVH)
 - Apical high-pitched pansystolic murmur
 - Decreased or obscured S1
 - Widely split S2
 - S3
- Aortic stenosis:
 - Exertional angina
 - Syncope (during exercise)
 - CHF (initially diastolic failure, then systolic)
 - Sudden death secondary to ventricular fibrillation
 - Harsh crescendo–decrescendo (diamond-shaped) systolic murmur at aortic focus radiating to carotids
 - Absent aortic component of S2
 - Delayed upstroke in peripheral pulse (pulsus parvus et tardus)
 - S4 gallop
 - Ejection click
- Aortic regurgitation:
 - Fatigue
 - Dyspnea on exertion
 - Paroxysmal nocturnal dyspnea
 - Orthopnea
 - Syncope
 - Acute pulmonary edema
 - High-pitched blowing decrescendo diastolic murmur at aortic area
 - Accentuated A2 heart sound
 - Wide pulse pressure
 - Corrigan pulse (collapsing pulse)

- Duroziez sign (to-and-fro murmur)
- De Musset sign (head bobbing with systole)
- Quincke pulse (nail bed pulsations)
- Austin Flint murmur (soft diastolic rumble)

ESSENTIAL WORKUP

- History and symptoms
- Thorough cardiopulmonary exam
- ECG

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Blood cultures
- Presumed endocarditis
- CBC:
 - Anemia

Imaging

- CXR:
 - Mitral stenosis:
 - Enlarged LA
 - Pulmonary vascular congestion (Kerley B lines)
 - Prominent pulmonary arteries
 - Mitral regurgitation:
 - LV and LA enlargement in chronic cases
 - Pulmonary edema and normal LV and LA dimensions in acute cases
 - Aortic stenosis:
 - LVH
 - Aortic calcification
 - Dilation of ascending aorta
 - Pulmonary congestion and cardiomegaly
 - Aortic regurgitation:
 - Acute = normal cardiac silhouette and pulmonary edema
 - Chronic = enlarged LV and dilated aorta
- ECG:
 - Quality assessment of valvular structures
 - Measurements of flow through valves
 - Identification of regurgitation
 - Ventricular dilatation or hypertrophy
- Spiral CT scan:
 - To exclude aortic dissection with acute aortic regurgitation

Diagnostic Procedures/Surgery

EKG:

- Mitral stenosis:
 - LA enlargement (broad notched P-waves)
 - RV hypertrophy
 - Right axis deviation
 - Atrial fibrillation
 - Acute mitral regurgitation:
 - Left atrial enlargement
 - LVH
 - Left axis deviation
- Aortic stenosis:
 - LVH most common
 - Atrial fibrillation
 - Interventricular conduction delay
 - Complete AV block
- Aortic regurgitation:
 - Acute = LV strain
 - Chronic = LVH and strain

DIFFERENTIAL DIAGNOSIS

See Etiology.

TREATMENT

PRE HOSPITAL

Avoid vasodilators in aortic stenosis.

INITIAL STABILIZATION/THERAPY

- ABCs
- Administer oxygen.
- Monitor and measure pulse oximetry.
- IV access

ED TREATMENT/PROCEDURES

- Mitral stenosis:
 - Treat symptoms of CHF.
 - Rate control if in atrial fibrillation
 - Digoxin
 - β -blockers
 - Heparin (if new-onset atrial fibrillation)
 - Diuretics
 - Endocarditis prophylaxis/education

- Mitral regurgitation:
 - Differentiate between acute and chronic MR:
 - Acute:
 - Afterload reduction (nitroglycerin, morphine, or sodium nitroprusside)
 - Diuresis
 - Intra-aortic balloon pump (temporizing for urgent surgery)
 - Chronic:
 - Diuresis
 - Nitrates
 - Hydralazine
 - ACE inhibitor
 - Digoxin
 - β -adrenergic blocker (ventricular rate control)
 - Calcium antagonist (ventricular rate control)
 - Heparin (if atrial fibrillation)
 - Endocarditis prophylaxis/education
- Aortic stenosis:
 - Gentle diuresis if CHF
 - Mild hydration if hypotensive and not in CHF
 - Avoid nitrates and afterload reduction.
 - Digoxin
 - Intra-aortic balloon pump (temporize for surgery)
 - Endocarditis prophylaxis/education
- Aortic regurgitation:
 - Chronic:
 - Preload and afterload reduction
 - Digoxin
 - Diuretics
 - Endocarditis prophylaxis/education
 - Acute:
 - Preload and afterload reduction
 - Intra-aortic balloon pump
 - Urgent surgery

MEDICATION

- Atenolol: 0.3–2 mg/kg/d PO, max. 2 mg/kg/d (peds: 1–2 mg/kg/dose PO daily suggested)
- Digoxin: 0.5 mg bolus IV, then 0.25 mg IV q2h up to 1 mg; 0.125–0.375 mg/d PO
- Diltiazem: 0.25 mg/kg IV over 2 min (repeat in 15 min PRN with 0.35 mg/kg) then 5–15 mg/h
- Enalapril: 1.25 mg IV q6h; PO 2.5–10 mg BID (peds: 0.1–0.5 mg/kg/d PO div. q12–24h, max.: 0.58 mg/kg/d or 40 mg/d)

- Esmolol: IV: 500 µg bolus, then 50–400 µg/kg/min
- Furosemide: 20–80 mg/d PO/IV/IM; titrate up to 600 mg/d for severe edematous states (peds: 1 mg/kg IV/IM slowly under close supervision; not to exceed 6 mg/kg)
- Heparin: 80 U/kg IV bolus, then 18 U/kg/h drip, adjust to maintain partial thromboplastin time 1.5–2 × control (INR 2–3)
- Hydralazine: 10–25 mg IV q2–4h (peds: 0.1–0.5 mg/kg IM/IV q4–6h; max. 20 mg/dose)
- Metoprolol: 5 mg IV q2min × 3 doses; then 50 mg PO q6h × 48 hr
- Nitroglycerin: Start at 20 µg/min IV and titrate to effect (up to 300 µg/min); SL 0.3–0.6 mg PRN; USE NON-PVC tubing. Start at 5 µg/min, titrate up by 5 µg/min every 3–5 min until desired effect. Topical 1/2–2 in of 2% q6h (peds: 0.25–0.5 µg/kg/min IV, increase by 0.5–1 mg/kg/min; max. 20 µg/kg/min)
- Phentolamine: 5 mg bolus IV, then 1–2 mg/min IV infusion
- Propranolol IV: 1–3 mg at 1 mg/min
- Sodium nitroprusside IV: 0.5 µg/kg/min; increase in increments of 0.5 to 1 µg/kg/min q5–10min up to 10 µg/kg/min
- Amoxicillin: 2 g PO 1 h before the procedure; alternatively, 3 g PO 1 h before the procedure, followed by 1.5 g PO 6 h after the initial dose:
 - Pediatric dose: 50 mg/kg PO 1 h before procedure
- Ampicillin: 2 g IV/IM 30 min before the procedure (peds: 50 mg/kg IV/IM 30 min before the procedure)
- Clindamycin: 600 mg PO 1 h before procedure (peds: 20 mg/kg PO 1 h before procedure; not to exceed 600 mg)

FOLLOW-UP

DISPOSITION

Admission Criteria

- New-onset atrial fibrillation
- CHF/pulmonary edema
- Hemodynamically unstable
- Acute mitral or aortic regurgitation
- Cardiac ischemia
- Angina
- Syncope
- Arrhythmias

Discharge Criteria

- Hemodynamic stability
- Unchanged ECG

- Resolution of CHF symptoms with diuresis
- Chronic mitral regurgitation

Issues for Referral

- For patients who are candidates for outpatient management, close follow-up with a cardiologist to assess severity of valvular disease and need for cardiac surgery
- Educate patient about risks of valvular heart disease and need for antibiotic prophylaxis with dental and medical procedures.

PEARLS AND PITFALLS

In patients with chest pain and aortic stenosis, nitrates are contraindicated.

CODES

ICD9

- 394.0 Mitral stenosis
- 424.0 Mitral valve disorders
- 424.90 Endocarditis, valve unspecified, unspecified cause

ICD10

- I05.0 Rheumatic mitral stenosis
- I34.0 Nonrheumatic mitral (valve) insufficiency
- I38 Endocarditis, valve unspecified

VARICELLA

Michael J. Bono

BASICS

DESCRIPTION

- Commonly known as chickenpox
- Most common in late winter and early spring
- Vaccine has reduced incidence by 85%
- Adults have a 15 times greater risk for death from varicella than children

ETIOLOGY

- DNA virus:
 - _ Latency in cranial nerve ganglia, dorsal root ganglia, and autonomic ganglia with periodic reactivation
 - _ Presents as herpes zoster or shingles decades after primary infection
 - _ Virus is transmitted by respiratory route and direct contact with skin lesions
 - _ Humans are only known reservoir

DIAGNOSIS

SIGNS AND SYMPTOMS

- Varicella causes a spectrum of disease
- Classic childhood illness:
 - _ Usually affects children ages 1–9
 - _ Low-grade fever (100–103°F), headache, malaise, usually precedes rash by 1–2 days
 - _ Pruritus, anorexia, and listlessness
 - _ 10–21 day incubation period
 - _ Infectious from 48 hr before vesicle formation until all vesicles are crusted, typically 3–7 days after onset of rash
 - _ Classic exanthem:
 - Lesions begin on the face, spreading to the trunk and extremities
 - Papules, vesicles, or pustules, on erythematous base
 - Lesions in varying stages of evolution, which is hallmark of Varicella
 - “Dewdrop on rose petal”
 - Vesicles 2–3 mm in diameter
 - Duration of vesicle formation 3–5 days
 - May involve conjunctival, oropharyngeal, or vaginal mucosa
 - Skin superinfection with group A streptococcus or staphylococcus in 1–4% of healthy children

- Adolescents and adults:
 - Similar presentation to children but greater risk of severe disease:
 - Extracutaneous manifestations in 5–50%, particularly pneumonia
- Immunocompromised patients:
 - HIV, transplant patients, leukemia patients at highest risk for disseminated form
 - Patients on chemotherapy, immunosuppressants, and long-term corticosteroid therapy at high risk
 - More numerous lesions that may have hemorrhagic base
 - Healing may take longer
 - Pneumonia common in these patients
- Pregnant patients:
 - Prevalent in young expectant women
 - More severe disease presentation:
 - Risk to fetus greatest in 1st half of pregnancy
 - Risk to mother greatest if infection in 2nd half of pregnancy
 - Perinatal disease can occur from 5 days predelivery to 48 hr postdelivery
- Congenital varicella syndrome
- Occasionally follows maternal zoster infection
- Limb hypoplasia or paresis
- Microcephaly
- Ophthalmic lesions
- Extracutaneous manifestations:
 - Pneumonitis:
 - 25 times more common in adults
 - Highest risk in adult smokers and immunocompromised children
 - Occurs 3–5 days after onset of rash
 - Signs: Continued eruption of new lesions, and new-onset cough
 - Tachypnea, dyspnea, cyanosis, pleuritic chest pain, and hemoptysis
 - Cerebellar ataxia:
 - May develop 5 days after rash
 - Ataxia, vomiting, slurred speech, fever, vertigo, tremor
 - Cerebritis:
 - Develops 3–8 days after start of rash
 - Duration about 2 wk
 - Progressive malaise
 - Headache, meningismus, vomiting, fever, delirium, seizures
 - Reye syndrome risk

Geriatric Considerations

- Increased risk of extracutaneous manifestations
- Lower immunity allows for reactivation as herpes zoster

Pediatric Considerations

- No aspirin for treatment of fever, possible association with Reye syndrome:
 - Acetaminophen—is recommended antipyretic treatment
- Parents need to be cautioned regarding risk for secondary bacterial infection and possible progression to sepsis

Pregnancy Considerations

- Pregnant women with no childhood history of varicella and no antibodies to varicella zoster virus (VZV) require varicella zoster immunoglobulin (VZIG)
- Varicella pneumonia in pregnancy is medical emergency, associated with life-threatening respiratory compromise and death (mortality can be 10–45%)
- Likely to occur in 3rd trimester

History

- Thorough history:
 - _ Fever, systemic symptoms
 - _ Immunization history
 - _ Immunocompetent vs. immunocompromised

Physical-Exam

- Thorough physical exam:
 - _ Characterize rash spread and extent
 - _ Evaluate for any extracutaneous manifestations

ESSENTIAL WORKUP

- History and physical exam are sufficient in uncomplicated cases
- Pneumonitis:
 - _ CXR shows 2–5 mm peripheral densities, may coalesce and persist for weeks
- Reye syndrome:
 - _ Ammonia level peaks early
 - _ LFTs will be elevated
 - _ PT, PTT
- Cerebritis:
 - _ Lumbar puncture demonstrates lymphocytic pleocytosis and elevated levels of protein

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Viral culture (results in 3–5 days), polymerase chain reaction (PCR), or direct fluorescent antibody using skin scrapings from crust or base of lesion
- Serologic tests for varicella antibodies
- PCR is diagnostic method of choice, but uncomplicated patients need no labs

Imaging

Not generally indicated unless there is concern for extracutaneous manifestations

Diagnostic Procedures/Surgery

Liver biopsy definitive test for Reye syndrome

DIFFERENTIAL DIAGNOSIS

- Impetigo
- Disseminated herpes
- Disseminated coxsackievirus
- Measles
- Rickettsial disease
- Insect bites
- Scabies
- Erythema multiforme
- Drug eruption (especially Stevens–Johnson syndrome)

TREATMENT

PRE HOSPITAL

- Nonimmune transport personnel must avoid respiratory or physical contact with patients
- Transport personnel who have varicella or herpes zoster should not come in contact with immunocompromised or pregnant patients

INITIAL STABILIZATION/THERAPY

- Airway management and resuscitate as indicated:
 - Protect airway if obtunded

ED TREATMENT/PROCEDURES

- Generally, acetaminophen and antipruritics are the keys to treating classic childhood illness
- Closely cropped nails and good hygiene help prevent secondary bacterial infection
- Infants/children ≤ 12 yr of age:
 - Acyclovir:
 - Recommended in children taking corticosteroids, long-term salicylate therapy, or chronic cutaneous or pulmonary diseases
 - Modest benefit, reduces lesions by 25% and fever by 1 day
 - Should be given within 24 hr of symptom onset
 - NOT recommended in uncomplicated Varicella in healthy children
 - Prophylaxis with VZIG in susceptible patients:
 - Immunocompromised children at high risk for complication with

- significant exposure
 - Susceptible children in the same household as person with active chickenpox or herpes zoster
 - In 2012 FDA extended period for VZIG administration to 10 days after exposure
 - VZIG in short supply, difficult to obtain
- Adolescents/adults:
 - Acyclovir now recommended in adults with uncomplicated varicella initiated within 24 hr to decrease progression to disseminated disease
 - Symptomatic treatment with antipyretics and antipruritics
- Pregnant women:
 - If exposed to Varicella, no childhood history of varicella, no antibodies to VZV, need VZIG
 - 80–90% immune from prior infection, need antibody testing prior to administration of VZIG
 - Acyclovir or Valacyclovir prophylaxis especially during 2nd or 3rd trimesters:
 - Safe during pregnancy (category B)
 - IV acyclovir for pneumonitis/other complications:
 - Respiratory, neurologic, hemorrhagic rash, or continued fever > 6 days
- Immunocompromised patients:
 - IV Acyclovir recommended, poor PO bioavailability
 - PO valacyclovir better bioavailability, approved in 2008 for lower risk immunocompromised patients
 - Should be started within 24 hr of onset to maximize efficacy
 - Foscarnet for acyclovir-resistant disease
 - Prophylaxis with VZIG for the susceptible immunocompromised patient
- Extracutaneous:
 - IV acyclovir or foscarnet if resistant
- Vaccine:
 - Children:
 - Routine vaccination for all susceptible children at 12 mo and older, 2 doses
 - Adolescents and adults:
 - Age 13 and older without history of varicella need vaccine
 - 2 doses separated by 4–8 wk
 - Recommended in high-risk groups: Health care workers, family member of immunocompromised person, susceptible women of childbearing age, teachers, military, international travelers
 - Post exposure prophylaxis:
 - Susceptible patients 12 mo or older, given with 72–120 hr, with 2nd dose at age appropriate interval

- Will produce immunity if not infected
- Immunocompromised persons:
 - Most immunocompromised persons should not be immunized

MEDICATION

- Acyclovir:
 - Uncomplicated: *Adults*: 800 mg PO QID for 5 days; *Adolescents* (13–18 yr old): 20 mg/kg per dose QID for 7 days; *Peds*: 20 mg/kg suspension PO QID for 5 days [max. 800 mg PO QID]
 - Immunocompromised: *Adults*: 10 mg/kg IV q8h infused over 1 hr, or 800 mg PO 5 times a day for 7 days. *Peds*: 10–12 mg/kg IV q8h infused over 1 hr, or 500 mg/m²/day IV q8h for 7–10 days
- Valacyclovir: 1 g PO TID for 5–7 days
- Famciclovir: 500 mg PO TID for 7 days
- Foscarnet: *Adults*: 90 mg/kg q12h IV over 90–120 min for 2–3 wk; *Peds*: 40–60 mg/kg q8h over 120 min for 7–10 days; Foscarnet is not FDA approved
- Hydroxyzine: *Adults*: 25–50 mg IM or PO q4–6h. *Peds*: 0.5 mg/kg q4–6h suspension (supplied as 10 and 25 mg/5 mL)
- Diphenhydramine: *Adults*: 25–50 mg IV, IM, or PO q4h. *Peds*: 5 mg/kg/d elixir
- VZIG: *Adults*: 625 IU IM. *Peds*: 1 vial per 10 kg IM to a max. of 5 vials [each vial contains 125 IU]

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with pneumonia require admission:
 - ICU for respiratory observation or support
- Immunocompromised patients: ICU vs. ward, depending on severity of illness
- All admitted patients must be kept in isolation

Discharge Criteria

- Immunocompetent children without evidence of Reye syndrome or secondary bacterial infection
- Adults with no evidence of extracutaneous disease

FOLLOW-UP RECOMMENDATIONS

Patients who are discharged need close follow-up with PCP to assure resolution without complications

PEARLS AND PITFALLS

- Patients with varicella are infectious from 48 hr before vesicle formation until all vesicles are crusted
- Immunocompromised patients with Varicella need careful consideration and admission in most cases
- Varicella pneumonia is medical emergency, particularly in pregnancy

ICD10

- B01.9 Varicella without complication
- B02.9 Zoster without complications
- B02.31 Zoster conjunctivitis

VARICES

Galeta C. Clayton

BASICS

DESCRIPTION

- Increased portal venous pressure results in portal–systemic shunts.
- Shunts at gastroesophageal junction result in fragile submucosal esophageal varices.

ETIOLOGY

- 10–30% of all cases of upper GI bleeding
- 90% of upper GI bleeding in patients with cirrhosis
- Variceal hemorrhage occurs in 30% of patients with cirrhosis:
 - 50% will stop bleeding spontaneously
 - 30% mortality per episode
 - 70% have recurrent bleeding
- In adults:
 - Cirrhosis due to alcoholism or chronic hepatitis
 - Storage disease: Wilson or hemochromatosis
 - Middle East: Schistosomiasis
- In children:
 - Intrahepatic obstruction from biliary cirrhosis
 - Biliary atresia
 - Cystic fibrosis
 - β -antitrypsin deficiency
 - Hepatitis

DIAGNOSIS

SIGNS AND SYMPTOMS

- General:
 - Weakness and fatigue
 - Tachycardia
 - Tachypnea
 - Hypotension
 - Cool, clammy skin; prolonged capillary refill
- Abdominal:
 - Significant active upper GI bleeding:
 - Hematemesis
 - Hematochezia

- Melena
 - 20–40% of total blood volume loss possible
- Abdominal pain
- Stigmata of severe hepatic dysfunction:
 - Jaundice
 - Spider angiomata
 - Palmar erythema
 - Pedal edema
 - Hepatosplenomegaly
 - Ascites
- History of portal hypertension:
 - Most commonly alcoholic cirrhosis
 - Others, including:
 - Primary biliary cirrhosis
 - Schistosomiasis
 - Budd–Chiari syndrome
 - Severe CHF
 - Sarcoidosis
- Cardiovascular:
 - Chest pain/shortness of breath
- CNS:
 - Syncope
 - Confusion and agitation initially
 - Lethargy and obtundation later

Pediatric Considerations

- Massive hematemesis: Typical initial presentation:
 - Hypotension may be a late finding.

History

- Gastroesophageal varices are present in 50% of patients with cirrhosis and correlate with severity of disease.
- The most important predictor of hemorrhage is size of the varices. Other factors include number of varices, severity of hepatic disease and endoscopic findings.
- Patients with PBC develop varices and variceal hemorrhage early in their course of disease, even prior to development of cirrhosis.

Physical-Exam

- Vitals signs may be normal or may show tachycardia (early) and hypotension (late).
- Altered mental status with encephalopathy or poor perfusion
- Active hematemesis

- Stigmata of alcoholic liver disease:
 - Ascites
 - General edema
 - Jaundice

ESSENTIAL WORKUP

- Gastric tube placement:
 - Determines whether patient is actively bleeding
 - Decompresses stomach that may aid in hemostasis. Possible role in reducing aspiration risk
 - Facilitates endoscopic exam
 - Will not increase or cause esophageal variceal bleeding
- Emergent endoscopy

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Type and cross-match 6–8 U:
 - Significant transfusion requirements
- ABG for:
 - Acidosis
 - Hypoxemia
- CBC:
 - Hematocrit is an unreliable indicator of early rapid blood loss.
 - Perform serial CBCs to follow blood loss.
- Electrolytes, BUN, creatinine, glucose:
 - Evaluate renal function.
 - BUN:creatinine ratio > 30 suggest significant blood in GI tract.
- PT/PTT/INR and platelets:
 - Coagulopathy
 - Prolonged bleeding times
 - Thrombocytopenia

Imaging

- Chest radiograph (portable) for aspiration/perforation
- ECG for myocardial ischemia

DIFFERENTIAL DIAGNOSIS

- Bleeding/perforated peptic ulcer
- Erosive gastritis
- Mallory–Weiss syndrome
- Boerhaave syndrome
- Aortoenteric fistula

- Gastric varices
- Gastric vascular ectasia

TREATMENT

PRE HOSPITAL

- Airway stabilization
- Treat hypotension 0.9% normal saline infusion bolus through 2 large-bore 16G or large IV lines.
- Cardiac and pulse oximetry monitoring

INITIAL STABILIZATION/THERAPY

- ABCs with early aggressive airway control/intubation:
 - _ Early intubation = easier intubation
 - _ For AMS or massive hemoptysis
 - _ Facilitates emergency endoscopy
- Establish central IV access with invasive intravascular monitoring for hypotension not responsive to initial fluid bolus.
- Replace lost blood as soon as possible:
 - _ Initiate with O-negative blood until type-specific blood available.
 - _ 10 mL/kg bolus in children
 - _ Fresh-frozen plasma and platelets may be required.
- Place gastric tube nasally (awake) or orally (intubated)
- Controversy:
 - _ Overly aggressive volume expansion may lead to rebound portal HTN, rebleeding, and pulmonary edema.
 - _ Transfusion goal is Hb = 8.
 - _ rFVIIa may decrease hemostasis failure rates in Child–Pugh class B/C patients

Pediatric Considerations

- Initiate intraosseous access if peripheral access unsuccessful in unstable patient.
- Most bleeding in children stops spontaneously.
- Vital sign changes may be a late finding in children:
 - _ Subtle changes in mental status, capillary refill, mild tachycardia, or orthostatic changes may indicate significant blood loss.
 - _ Overaggressive correction in infants can quickly lead to significant electrolyte abnormalities.

ED TREATMENT/PROCEDURES

- Emergent endoscopy required for active bleeding:
 - _ Use pharmacologic and tamponade devices as temporizing measures.

- **Endoscopy**
 - Emergent with active bleeding in nasogastric tube
 - Procedure of choice in acute esophageal bleeding
 - Esophageal band ligation equivalent to sclerotherapy with fewer complications:
 - May be difficult to visualize in cases of massive bleeding
 - Sclerotherapy with massive bleeding
 - Gastric varices are not amenable to endoscopic repair due to high rebleeding rate:
 - Treat pharmacologically.
 - Administer antibiotics at time of procedure to decrease risk for spontaneous bacterial peritonitis:
 - Fluoroquinolone or ceftriaxone
- **Pharmacological Therapy**
 - Somatostatin is 1st-line therapy where available (not widely available in US) due to greater efficacy and fewer side effects when compared to octreotide
 - Octreotide is 1st-line therapy where somatostatin not available:
 - Complications include hyperglycemia and abdominal cramping.
 - Vasopressin replaced by octreotide/somatostatin secondary to high incidence of vascular ischemia
- **Balloon Tamponade**
 - Initiate in massive uncontrollable bleed.
 - Sengstaken–Blakemore and Minnesota tubes
 - Applies direct pressure but risks esophageal perforation and ulceration
 - Temporary benefit only with massive uncontrolled bleeding in the hands of experienced clinician
- **Refractory Bleeding Therapy**
 - Interventional radiology:
 - Transjugular intrahepatic portosystemic shunt procedure.
Recommended for refractory gastric varices or for patients who are poor surgical candidates
 - Surgical options:
 - Portacaval shunt
 - Variceal transection
 - Stomach devascularization
 - Liver transplantation

MEDICATION

- Ceftriaxone: 2 g (peds: 50–75 mg/kg/24 h) IV q24h in Child–Pugh class B/C or in quinolone-resistant areas
- Cefotaxime: 2 g (peds: 50–180 mg/kg/24 h) IV q8h
- Erythromycin 250 mg IV:

- Shown to aid in gastric clearing for better visualization during endoscopy
- Norfloxacin 400 mg PO q12 or Ciprofloxacin 500 mg IV q12 if cannot tolerate PO (contraindicated in peds)
- Octreotide: 50 µg bolus, then 50 µg/h infusion for 5 days
- Somatostatin: 250 µg IV bolus followed by 250 µg/h IV infusion for 5 days

First Line

- Somatostatin or octreotide (if somatostatin not available)
- Norfloxacin PO or ciprofloxacin IV

Second Line

- Erythromycin
- Ceftriaxone

FOLLOW-UP

DISPOSITION

Admission Criteria

- ICU admission for actively bleeding varices
- Recent history of variceal bleeding
- High risk for early rebleeding:
 - Age >60 yr, renal failure, initial hemoglobin count <8

Discharge Criteria

Nonbleeding varices

Issues for Referral

- Continued hemorrhage requiring surgery or higher level of care
- Liver transplant

FOLLOW-UP RECOMMENDATIONS

- Timely outpatient GI follow-up:
 - Will need annual surveillance endoscopies
- Medication and lifestyle modifications

PEARLS AND PITFALLS

- Intubate early, especially in patients with hepatic encephalopathy or hemodynamic instability.
- Begin prophylactic antibiotics prior to endoscopy. Improves survival
- In US, octreotide has replaced vasopressin owing to better side-effect profile. If

vasopressin is required, use IV nitroglycerin infusion concomitantly to reduce end-organ ischemia.

- Control the airway prior to placement of balloon tamponade device, which provides only a temporizing measure prior to surgery or TIPS
- Hematochezia in a hemodynamically unstable patient is an upper GI bleed until proven otherwise.
- Consult your GI specialists early, since endoscopy is the 1st-line diagnostic and therapeutic procedure.

CODES

ICD9

- 456.0 Esophageal varices with bleeding
- 456.1 Esophageal varices without mention of bleeding
- 456.21 Esophageal varices in diseases classified elsewhere, without mention of bleeding

ICD10

- I85.00 Esophageal varices without bleeding
- I85.01 Esophageal varices with bleeding
- I85.10 Secondary esophageal varices without bleeding

VASCULITIS

Richard S. Klasco

BASICS

DESCRIPTION

- Injury to the walls of blood vessels from inflammation:
 - Ischemia and necrosis
 - Aneurysms and hemorrhage
 - Immunopathologic mechanisms:
 - Deposition of circulating antigen–antibody complex and complement fixation
 - Cell-mediated hypersensitivity
 - Granulomatous tissue reaction from persistent inflammation and formation of epithelioid giant cells
- The vasculitides represent a wide group of disorders:
 - Multisystem disease with constitutional symptoms and inflammatory lab indices
 - Secondary to another disorder or trigger, or primary if vasculitis is the principal feature and the cause is unknown
 - Multiple factors determine presentation:
 - The size of the affected blood vessels
 - The specific distribution, severity, and duration of the inflammation
 - Degree of permeability or occlusion of the affected vessels
- 1 out of 2,000 adults has some form of vasculitis

ETIOLOGY

- Classification is evolving and is increasingly based on presence or absence of antineutrophil cytoplasmic antibodies (ANCA).
- Traditional classification is based on vessel size.
- Large vessel vasculitides:
 - Temporal (giant cell) arteritis:
 - Granulomatous arteritis of the aorta and its major branches often involving the temporal artery
 - Patients > 50 yr
 - Takayasu arteritis:
 - Granulomatous inflammation of the aorta and its major branches
 - Usually occurs in patients < 50 yr
- Medium vessel vasculitides:
 - Polyarteritis nodosa (PAN):
 - Small- and medium-sized arteritis

- Common distribution includes vessels supplying the muscles, joints, intestines, nerves, kidneys, and skin
- Most common in middle age
- Kawasaki disease (mucocutaneous lymph node syndrome):
 - Coronary arteries are often involved and involves large-, medium-, and small-sized arteries
 - Usually occurs in children
- Isolated CNS vasculitis
- Small vessel vasculitides:
 - Granulomatosis with polyangiitis (Wegener granulomatosis):
 - Necrotizing vasculitis affecting small- to medium-sized vessels
 - Granulomatous inflammation of the upper and lower respiratory tract and glomerulonephritis
 - Microscopic polyangiitis:
 - Necrotizing affecting small vessels
 - Glomerulonephritis is very common.
 - Pulmonary capillaritis often occurs.
 - Churg–Strauss syndrome (allergic granulomatosis):
 - Small- and medium-sized arteries
 - Mainly lungs, GI, and nerves
 - Can also involve heart, skin, and kidney
 - Henoch–Schönlein purpura:
 - Most patients <20 yr
 - Buerger disease (thromboangiitis obliterans):
 - Hypersensitivity vasculitis:
 - Recurring inflammation and thrombosis of small and medium arteries and veins of the hands and feet
 - Typically between 20 and 40 yr and male
 - Secondary vasculitides:
 - Bacterial infections:
 - Streptococcal, tuberculous, staphylococcal, Lyme disease, leprosy
 - Viral infections:
 - Hepatitis B or C, CMV, HSV, HIV
 - Rickettsial infections
 - Drug related
 - Connective tissue disease:
 - Systemic lupus erythematosus
 - Rheumatoid arthritis
 - Behçet disease
 - Malignancy:
 - Hairy cell leukemia
 - Lymphoma

- Mixed cryoglobulinemia
- Goodpasture syndrome
- Serum sickness

DIAGNOSIS

SIGNS AND SYMPTOMS

- Systemic complaints are common early in the presentation of vasculitis, before vascular-related complications occur:
 - Fever, fatigue, weight loss, diffuse aches and pains
- Signs of arterial insufficiency:
 - Ischemic pain:
 - Angina, abdominal angina, claudication, jaw claudication
 - Neurologic ischemia:
 - Headache, TIA, stroke, visual and sensorineural hearing loss, hallucinations, neuropathy, vision loss
 - Renal ischemia:
 - Severe or resistant HTN
 - Dermatologic ischemia:
 - Classic skin findings include palpable purpura.
 - Nodular lesions, ulcers, livedo reticularis, and digital ischemia may also be seen
 - Oligoarthritis
 - Ocular ischemia:
 - Diplopia, retinal hemorrhages, scleritis, and episcleritis
 - Respiratory tract:
 - Sinusitis, epistaxis, nasal and oral ulcerations, strawberry tongue
 - GI ischemia:
 - Hematochezia, melena, hematemesis, peritonitis, hepatitis
 - Cardiac:
 - Coronary artery aneurysms, myocarditis, pericarditis, valvular disease, CHF

History

- Suspect vasculitis with general systems and signs of arterial insufficiency:
 - Claudication, angina, abdominal angina, or TIA, in a young patient
 - Prolonged systemic illness with multiorgan dysfunction
 - History of glomerulonephritis, peripheral neuropathy, or autoimmune disease
- Diagnostic clues to the etiology:
 - Age, gender, ethnicity, travel history
 - Specific complaints that suggest the size of the involved vessel and organs

- Recent infections
- Connective tissue disorders
- Medications that may cause vasculitis:
 - Levsamisole (as a cocaine adulterant), phenytoin, carbamazepine, isoniazid, methimazole, minocycline, penicillamine, propylthiouracil, sulfasalazine

Physical-Exam

Classify vasculitis:

- Large arteries:
 - Diminished pulses and bruits over several large arteries
 - BP discrepancy > 10 mm Hg between left and right limbs
 - Pulse discrepancy > 30 mm Hg between the left and right limbs
 - Cool extremities due to claudication and ulceration
- Medium and small arteries:
 - Palpable purpura (nodules, ulcers, livedo papules)
 - Skin ulcers
 - Digital ischemia

ESSENTIAL WORKUP

- History and physical exam
- CBC, ESR, CRP, urinalysis, BUN, creatinine

DIAGNOSIS TESTS & NTERPRETATION

Lab

- CBC:
 - Leukocytosis
 - Eosinophilia
 - Anemia
- Creatinine
- LFT
- CRP
- ESR
- ANA
- ANCA
- Complement
- CPK
- Urinalysis:
 - Proteinuria and hematuria

Imaging

- CXR:

- PAN usually has a nonspecific patchy alveolar infiltration.
- CT scan:
 - Sinus CT for suspected granulomatosis with polyangiitis (Wegener)
- CTA:
 - Coronary artery aneurysms in Kawasaki
- Echocardiography:
 - Coronary artery aneurysms in Kawasaki
- MRI and MRA:
 - Positron emission tomography (PET) scan for suspected Takayasu and Kawasaki
- ECG:
 - Indications:
 - Suspected Takayasu and Kawasaki
- US:
 - Temporal artery US for suspected giant cell arteritis
 - Use pretest probability in interpretation of results
- Arteriography

Diagnostic Procedures/Surgery

- EKG:
 - Pericarditis, conduction disturbances
- Endoscopy, sigmoidoscopy, and colonoscopy for GI tract involvement
- Tissue biopsy

DIFFERENTIAL DIAGNOSIS

- Endocarditis
- Adverse drug reaction
- Viral infections (e.g., enterovirus)
- Scarlet fever
- Staphylococcal scalded skin syndrome
- Toxic shock syndrome
- Stevens–Johnson syndrome
- Rocky Mountain spotted fever
- Leptospirosis
- Antiphospholipid antibody syndrome
- Disseminated intravascular coagulation
- Cholesterol emboli
- Calciphylaxis

TREATMENT

INITIAL STABILIZATION/THERAPY

Stabilization of cerebrovascular complications

ED TREATMENT/PROCEDURES

- Treatment for vasculitis is determined by the underlying cause or the specific disease and is best initiated by rheumatology.
- Kawasaki: Aspirin, IVIG
- Giant cell arteritis: Corticosteroids
- PAN: Steroids, cyclophosphamide
- Takayasu arteritis: Corticosteroids, methotrexate, azathioprine, cyclophosphamide
- Wegner granulomatosis: Corticosteroids:
 - Cyclophosphamide, azathioprine may be substituted
 - Plasma exchange may be helpful in severe disease.

MEDICATION

- Azathioprine: 2 mg/kg/d PO
- Cyclophosphamide:
 - IV: 0.5–1 mg/m² body surface area
 - PO: 2 mg/kg/d (up to 4 mg/kg) (peds: dose as per consultant)
- IVIG: 1–2 g/kg IV
- Methylprednisolone: 0.25–1 mg/d IV
- Methotrexate: 7.5–15 mg/wk PO
- Prednisolone: 1 mg/kg/d PO
- Prednisone: 40–60 mg/d (peds: 1–2 mg/kg/d) PO

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with evidence of severe disease and end-organ dysfunction should be admitted.
- Consult for procedures to revascularize ischemic organs.

Discharge Criteria

Less-symptomatic patients without evidence of end-organ involvement

Issues for Referral

- Any patient suspected of vasculitis and being managed as an outpatient should be referred as soon as possible to a rheumatologist for the definitive diagnosis and treatment.
- Consult appropriate specialties based on the severity of the end-organ damage.

FOLLOW-UP RECOMMENDATIONS

Stress the need for close follow-up with general symptoms to confirm the diagnosis and initiate therapy that will be life-saving on a long-term basis.

PEARLS AND PITFALLS

- Drug therapy may be toxic; do not prescribe without specialist consultation.
- Patients may be immunosuppressed and at risk for opportunistic pathogens.
- Do not miss subacute bacterial endocarditis as a mimic of vasculitis.
- Temporal (giant cell) arteritis does not occur before age 50 yr.
- Nodular lesions are the skin changes most likely to yield a diagnosis of vasculitis.

VENOUS INSUFFICIENCY

Cameron R. Wangsgard • Bo E. Madsen

BASICS

DESCRIPTION

- Inadequacy of the venous valves that causes impaired venous drainage leading to edema of the lower extremities.
- A chronic condition of lower extremity vascular incompetence.
- Normal blood flow in the venous system is unidirectional from the superficial veins to the deep veins.
- Unidirectional flow is maintained by contraction of leg muscles and by valves within the veins.
- Damage to the valves, e.g. following DVT, causes them to become rigid and they lose their ability to prevent retrograde blood flow properly.
- Decreased venous return from lower extremities causes increased pressure and distention of the veins, which in turn causes separation of the valve leaflets.
- Increased pressure transmitted into the dermal microcirculation results in extravasation of macromolecules and red blood cells causing inflammatory injury resulting in ulcer formation, skin changes, and poor ulcer healing.

ETIOLOGY

- Primary valve incompetence (most common)
- Deep vein thrombosis (DVT)
- Risk factors include advanced age, family history, smoking, sedentary lifestyle, obesity, lower extremity trauma, prior DVT, and pregnancy

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Asymptomatic phase:
 - Venous dilation ranging from venous flares to small varicosities
- Symptomatic phase:
 - Ankle and calf swelling
 - Varicose veins
 - Skin discoloration/hyperpigmentation
 - Ulcer formation
 - Lipodermatosclerosis
 - Dull ache/pain in the legs:

- Worsened by prolonged standing
- Resolves with leg elevation
- Burning sensation
- Pruritus
- Night cramps

Physical-Exam

- Varicose veins
- Ankle- and calf-dependent edema
- Ulcers, most often situated over the malleoli or medial portion of calf:
 - Must have preserved peripheral pulses to ensure ulcers are due to venous insufficiency and not arterial insufficiency
- Red, purple discoloration of skin
- Telangiectasias
- Reticular veins
- Stasis dermatitis
- Brownish hyperpigmentation
- Sclerosis, induration, and atrophy of skin
- Bacterial infection:
 - Surrounding cellulitis
 - Rapidly growing ulcer
 - Purulent drainage from ulcer
 - Increased pain
 - Fever
 - Lymphangitis
- Other etiologies than venous insufficiency, proximal to the lower extremity, should be suspected in the following settings:
 - History of heart failure
 - History of liver disease
 - Leg edema and ulcers in a patient with ascites
 - Periorbital edema
 - Orthopnea
 - Positive hepatojugular reflex
 - Jugular venous distention

ESSENTIAL WORKUP

The physical exam is essential to the diagnosis.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Lab tests add little to the physical exam unless other causes need to be excluded.
- Cardiac markers, brain natriuretic peptide, albumin, and tests of renal function

can be sent if considering other causes of leg edema.

Imaging

- Doppler auscultation (DopA):
 - Used to assess for arterial flow to the lower extremities in differentiating venous insufficiency from arterial insufficiency
 - Used to estimate blood flow, as well as the presence or absence of reflux in a given vein.
 - Indications are diameter > 3 mm, signs/symptoms of chronic venous insufficiency, the presence of a painful vessel, or concern for arterial insufficiency (no distal pulses, history of peripheral vascular disease, decreased ankle–brachial index)
- Duplex US (DUS):
 - Combines Doppler and gray-scale imaging and shows vascular anatomy, soft-tissue features, detection and quantification of reflux and the source of it
 - Can assess for DVT, valvular incompetence, and retrograde flow.
 - Can be used for diagnosis, as part of the treatment (duplex-guided sclerotherapy and endovenous ablation) and for postoperative evaluation.
- Photoplethysmography (PPG):
 - Assesses venous hemodynamics and venous refilling time with and without leg muscle contraction.
 - Used to measure vein outflow and inflow, as well as muscle pump adequacy.
- Venography:
 - Expensive and invasive
 - Despite still often being considered the gold standard, duplex ultrasonography has been found to be more sensitive and specific in predicting the clinical severity of venous insufficiency.

Diagnostic Procedures/Surgery

Ankle–brachial index:

- Should be measured if arterial insufficiency is suspected

DIFFERENTIAL DIAGNOSIS

- Venous valvular incompetence
- Deep venous thrombosis (DVT)
- Arterial insufficiency
- Lymphatic disorders or obstruction
- Soft-tissue infections (diabetic foot ulcers)
- Trauma (compartment syndrome, vascular or lymphatic disruption, inflammatory response)
- Ruptured Baker cyst

- Pyoderma gangrenosum
- Congestive heart failure
- Pulmonary hypertension
- Renal disease (nephrotic syndrome, renal failure resulting in hypervolemia)
- Liver disease (ascites)
- Vasculitis or autoimmune disorders (polyarteritis, hypothyroidism with myxedema, systemic lupus erythematosus)
- Pregnancy (both normal pregnancy and preeclampsia/eclampsia)
- Medications (NSAIDs, calcium channel blockers)

TREATMENT

INITIAL STABILIZATION/THERAPY

- Leg elevation to above the level of the heart
- Control bleeding with direct pressure.

ED TREATMENT/PROCEDURES

- Leg elevation above the level of the heart
- Compression stockings
- Barrier creams (white petroleum jelly or Zinc oxide) with wound dressings applied to ulcers
- Anticoagulants if confirmed DVT
- Antibiotics if signs of infection, specifically cellulitis or infected ulcer
- Aspirin (improves ulcer healing rate)
- Topical steroids for stasis dermatitis, pruritis, dry skin
- Antihistamines for pruritus

MEDICATION

- Aspirin: 325 mg once daily PO
- Augmentin: 875 mg BID PO
- Benadryl: 12.5–25 mg QID PO
- Cephalexin: 500 mg QID PO
- Dicloxacillin: 500 mg QID PO
- Coumadin: Dose per prothrombin time/INR
- Lovenox: 1 mg/kg SC BID

FOLLOW-UP

DISPOSITION

Admission Criteria

- Arterial insufficiency

- Evidence of cellulitis, lymphangitis, or osteomyelitis may require admission, specifically in a patient that is immunocompromised (on steroids, receiving chemotherapy or radiation therapy, history of diabetes)
- DVT in the following setting:
 - Thrombosis is extensive
 - There is concern for pulmonary embolism
 - The patient is at high risk for bleeding with anticoagulation
 - Outpatient management with low molecular weight heparin and/or close follow up is not appropriate or available
- Treatment of an underlying etiology of lower extremity swelling other than primary venous insufficiency or the patient's other comorbid conditions warrant admission

Discharge Criteria

- Lower extremity pulses are present
- No evidence of bleeding or compartment syndrome
- DVT has been ruled out with DUS or patient is low risk (See Well's Criteria for DVT)
- No evidence of bacterial infection requiring admission
- Appropriate follow-up/referral arranged
- Patient has been given instructions for wound care, dressing changes, and the use of compression stockings

Issues for Referral

The patients should be referred to their primary care physician. They should be referred to a vascular surgeon if there is concern for peripheral vascular disease.

FOLLOW-UP RECOMMENDATIONS

- Home health care or close follow-up with outpatient care provider for ulcer management
- Immediate surgical procedures are not required for varicose veins.
- Vein stripping, vein ligation, sclerotherapy and endovenous thermal ablation are options for cases refractory to medical management:
 - These do not improve healing of ulcers but reduces ulcer recurrence
 - All these methods cause irreversible changes to the venous system of the lower extremity which can result in recurrence of edema and can increase risk for DVT in the future.

PEARLS AND PITFALLS

- In patients with no palpable pulses, extremity pain, ulcerations, or risk factors for peripheral artery disease, ensure that arterial insufficiency is not the underlying cause before assuming venous insufficiency.

- Compression therapy is contraindicated in patients with peripheral vascular disease and venous insufficiency presenting with overlying cellulitis.

VENTILATOR MANAGEMENT

Ruth L. Lamm

BASICS

DESCRIPTION

- Mechanical ventilation is machine generated flow of gas into and out of the lungs that acts as a substitute for normal respiratory function

Basic Concepts: Physiology and Pulmonary Mechanics

- Mechanical ventilation is *positive pressure ventilation* indicating that forced gas delivery generates positive pressure during inspiration
- Negative pressure ventilation:
 - _ Natural respiratory pattern
 - _ At rest (functional residual capacity) surface tension of alveoli is balanced by elastic recoil of chest wall; alveoli pressure equals atmospheric pressure at this point
 - _ In inspiration, lungs expand causing alveolar pressure to become negative compared with atmospheric pressure and air travels down pressure gradient into lungs
 - _ Exhalation is normally passive, but can be made active with the use of accessory muscles in the setting of airway obstruction/increased airway resistance
- Minute ventilation (MV):
 - _ Total volume of breaths in 1 min
 - _ Breaths in 1 min is respiratory rate (RR)
 - _ Standard breath is called tidal volume (TV)
 - _ $MV = TV \times RR$: Each component can be adjusted to control ventilation
- Oxygenation is controlled with adjusting fraction of inspired oxygen (FiO_2) and positive end-expiratory pressure (PEEP)
- Compliance:
 - _ Describes lung distensibility
 - _ Defined as change in volume with given change in pressure
 - _ Decreased lung compliance can be caused by problems with the lung parenchyma (i.e., pneumonia, ARDS) or problems with the chest wall/pleura (i.e., abdominal distension)
 - _ Lung compliance determines *plateau pressure*:
 - Plateau pressure is the steady state pressure; represents the attenuated pressure that is distributed to the small airways and alveoli during positive pressure ventilation
 - Goal ≤ 30 mm Hg
- Resistance:

- Defined as change in pressure with given flow
- Main determinant is airway radius
- Increased resistance can be caused by problems with the airways (i.e., bronchospasm), problems with the endotracheal tube (i.e., secretions), or problems with ventilator tubing
- Resistance determines *peak pressure*:
 - Peak pressure is the pressure seen in the larger airways before delivered volume is distributed to smaller airways and alveoli
 - Also determined by TV delivered
 - Goal ≤ 40 mm Hg

DIAGNOSIS

SIGNS AND SYMPTOMS

- Indications for mechanical ventilation:
 - Failure to oxygenate:
 - Diffusion defect (i.e., pulmonary edema, pneumonitis, pneumonia)
 - Severe ventilation/perfusion mismatch (i.e., PE, severe hypoventilation)
 - Severe shock:
 - Shock = oxygen supply does not meet oxygen demand by tissues
 - Mechanical ventilation can help improve shock states in 2 ways:
 - Increased oxygen delivery
 - Reducing overall oxygen demand by replacing organ system with high oxygen requirement
- Failure to ventilate:
 - Obtundation/sedation
 - Loss of ability to control diaphragm or intercostals (i.e., high spinal cord injury)
 - Severe myopathy
 - Dysfunctional chest wall (i.e., flail chest, increased abdominal pressures leading to decreased chest wall excursion, obesity)
 - Increased dead space (large PE, airway obstruction)
 - Metabolic acidosis (creates need for higher MV to compensate)
- Other:
 - Patient safety/need for evaluation
 - Predicted deterioration in clinical course
- *Ventilation strategy should specifically address the indication for mechanical ventilation!*
 - Example: In the setting of severe acidosis a preferred mode would be one where you could control MV closely

- Example: In severe pulmonary edema controlling the MV is not as important as ensuring oxygen delivery

Incidence and Prevalence Estimates

HISTORY & PHYSICAL EXAM

- Focus on underlying etiology for respiratory failure
- Exam on mechanical ventilation should include assessing oxygen saturation, evaluating end-tidal CO₂ (ETCO₂) with capnometry and capnography (see below), auscultating lung sounds/air movement, observing chest wall rise, palpating for abdominal distension
- ETCO₂:
 - Capnometry is the quantitative partial pressure of ETCO₂.
 - Capnography is the graphic representation of the changes in ETCO₂ with respiratory cycle
 - Normal lungs have a small degree of ventilation/perfusion mismatch as well as anatomic dead space. As a result, ETCO₂ is usually around 2–5 mm Hg lower than PaCO₂
 - Capnometry will be affected by: Amount of dead space or ventilation/perfusion mismatch; changes in metabolic CO₂ production (although ratio between PaCO₂ and ETCO₂ will not change); venous return (also will not affect ratio)
 - Evaluation of the ETCO₂ waveform can be very useful:
 - Can help assess response to bronchodilator therapy as waveform in airway obstruction has a steeper upslope instead of a plateau given the prolonged expiratory phase
 - Can help assess adequacy of CPR (will see return of waveform with good compressions)
 - Can help assess cause of tachypnea or dyssynchrony
- Monitor hemodynamic status closely with mechanical ventilation

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Arterial blood gas (ABG):
 - Should be checked within 15–30 min of initiation of mechanical ventilation and repeated with any change in clinical status
 - pH and PaCO₂ will help assess ventilation
 - PaO₂ will assess oxygenation
 - With ability to assess continuous oxygen saturation and ETCO₂ need for frequent ABGs, even after change in ventilator settings, may be eliminated

or reduced

- Serum chemistries including basic electrolytes with bicarbonate, liver function, renal function may help assess acid/base status which will affect ventilation strategy
- Hemoglobin/hematocrit will help describe state of oxygen delivery

Imaging

Imaging may include bedside US, chest x-ray, and chest CT to assess for endotracheal tube placement and pathophysiology of the lung and chest wall

DIFFERENTIAL DIAGNOSIS

See indications for mechanical ventilation above

TREATMENT

PRE HOSPITAL

Respiratory support per local EMS protocol

INITIAL STABILIZATION/THERAPY

- Cardiac monitor
- BP monitoring
- Pulse oximetry
- End-tidal CO₂ monitoring when available

ED TREATMENT/PROCEDURES

Critical actions include: Choosing appropriate ventilatory mode; assessing and adjusting ventilator settings; standard postintubation care; treatment of the underlying process.

- Postintubation care is of utmost importance. Includes: Sedation and/or analgesia; confirmation of tube placement; adjustment of ventilator settings based on clinical condition and ABG; establishing ETCO₂ gradient if using capnometry; elevating head of bed; placement of NG or OG tube.
- Settings common to most modes include:
 - RR:
 - In all modes, but will be set by patient in more spontaneous modes
 - Normal starting rates can vary from 12–20
 - Consider underlying pathophysiology before arbitrarily setting rate (i.e., elevated ICP, severe asthma)
 - Fraction of inspired oxygen (FiO₂):
 - Oxygen concentration in gas mixture
 - Usually start out with FiO₂ of 1 (100%) but wean down quickly after confirmation of stable oxygenation with prompt ABG

- PEEP:
 - Pressure that is applied to end expiration to maintain alveolar recruitment
 - Significant increase in work of breathing is required to open up collapsed alveoli
 - Collapsed alveoli do not participate in gas exchange, creating ventilation/perfusion (V/Q) mismatch and difficulty oxygenating and ventilating
 - By stenting open more alveoli, increased PEEP can improve oxygenation, especially at lower TVs (although be careful of high PEEP and overdistension which can lead to significant alveolar injury)
 - With normal chest wall compliance, basic starting PEEP will be 5–10 mm Hg
 - In setting of low chest wall compliance (obesity, anasarca, abdominal distension) may need to start with higher PEEP, around 10–15 mm Hg
- Inspiratory:expiratory ratio (I:E): Will alter flow rates. Allows for optimal mechanics in disease specific situations: E.g., increase E fraction in obstructive airway disease to prevent “breath stacking.” Normal ratio ~ 1:2.

Basic modes of ventilation:

- Early, classic modes of ventilation allowed for only simple ventilator/patient interaction and limited control of small number of variables
- *Continuous mandatory ventilation (CMV):*
 - CMV is the classic mode where only 1 variable can be set
 - Allows for NO interaction between the patient and the ventilator—all breaths are fully controlled breaths
 - Breathes are delivered only at a set rate—time is the trigger for every breath
 - Breathes are defined only by the control:
 - Volume controlled (also known as volume cycled) CMV: Delivers set volume with each breath and guarantees certain MV
 - Pressure controlled (also known as pressure cycled) CMV: Delivers constant flow of gas until set inspiratory pressure reached which guarantees peak pressures will be reasonable
 - The variable that is not set cannot be controlled (i.e., may have very high peak inspiratory pressures in order to deliver a certain TV or may dangerously hypoventilate in order to keep safe airway pressures)
- *Assist-control (AC):*
 - Similar to CMV in that all breaths are the same controlled breaths based on machine determined variables
 - In AC, patient can trigger a breath, but the same machine controlled breath is delivered
 - Spontaneous breath trigger is either the reduction in airway pressure or the

increase in air flow as patient initiates breath

- *Intermittent mandatory ventilation (IMV)*:
 - Delivers controlled breath at set RR
 - Patient may breath spontaneously between these breaths; however:
 - Spontaneous breaths are not supported
 - Can lead to breath stacking as ventilator does not take patient's spontaneous breaths into consideration
 - In some IMV modes, spontaneous breaths can be pressure supported, but this is not the rule
- *Synchronous intermittent mandatory ventilation (SIMV)*:
 - Same as IMV, but ventilator tries to synchronize patient's spontaneous breaths with those set by RR
 - Lowers risk of breath stacking
- *Pressure support ventilation (PSV)*:
 - Ventilator augments patient's spontaneous breaths with set amount of pressure
 - If support is adequate to meet needed driving pressure and patient is able to initiate breaths, often most comfortable mode
- Most modern ventilators and newer modes allow for much more complex interaction between ventilator and patient as well as increased control of multiple variables:
 - Newer modes are quite variable and are dependent on patient specifics.
 - May be dynamic combination of more traditional types of breaths as described below
 - Can often tailor breath delivery to optimize mechanics in specific disease process
- Risks of mechanical ventilation:
 - Ventilator-induced lung injury (VILI): Overdistension caused by high pulmonary pressures leads to inflammation and alveolar injury
 - Derecruitment injury: Inflammation and injury caused by repetitive opening and collapse of alveoli; can be reduced with appropriate use of PEEP
 - Barotrauma outside lungs due to cyclical reinflation (i.e., pneumothorax, pneumoperitoneum, subcutaneous emphysema)
 - Oxygen toxicity
 - Decreased venous return and subsequent drop in cardiac output/BP due to elevated intrathoracic pressures
 - Increased V/Q mismatch due to altered pattern of gas delivery (alveoli that usually do not get significant gas delivery in natural breathing will be responsible for more gas exchange without any augmented blood supply AND overdistension of alveoli may cause compression of alveolar blood supply)
 - Loss of upper airway defenses against infection
 - Associated risks of sedation (delirium, increased immobility, prolonged

- illness, etc.)
- Associated risks of immobility (severe myopathy, thrombosis, prolonged illness, etc.)
- Stress ulcer formation
- Problems related to endotracheal tube or tracheostomy such as tracheomalacia or vocal cord paralysis

MEDICATION

- Sedation and analgesia strategies should prioritize pain control, target the lowest level of sedation possible, and utilize intermittent bolus therapy before resorting to infusion
- Oversedation and benzodiazepines are both associated with risk of critical illness delirium
- Propofol: 0.3–1 mg/kg IV loading dose, maintenance initiated at 5–50 µg/kg/min IV infusion. Causes vasodilation and associated hypotension. Especially with bolus loading dose. Risk of propofol infusion syndrome with prolonged infusions.
- Dexmedetomidine: 0.2–1.4 µg/kg/h. Can be used with loading bolus of 1 µg/kg. Does not cause respiratory depression. Can be associated with significant bradycardia.
- Ketamine: Load 1–3 mg/kg with maintenance 1–2 mg/kg/h. Potential benefit is avoiding hemodynamic instability seen with many other agents. Benzodiazepine dosing prior to emergence can help prevent emergence nightmares. There is controversy about using ketamine in patients with elevated intracranial pressures, but it may actually help maintain cerebral perfusion pressure in mechanically ventilated patients.
- Fentanyl: Bolus 0.5–1.5 µg/kg IM or slow IV. Infusion rates start at 1 µg/kg/h. Consider prior opiate exposure when dosing.
- Albuterol: 2.5–5 mg/5 mL saline q4h via in-line endotracheal delivery
- Ipratropium bromide: 0.5 mg/2.5 saline q4h vial in-line endotracheal delivery

FOLLOW-UP

DISPOSITION

Admission Criteria

ICU admission required for all intubated patients

PEARLS AND PITFALLS

- Physiology can help you troubleshoot the vent. Remember that you control ventilation by adjusting the TV and RR and that you control oxygenation by adjusting PEEP and FiO₂. Peak pressure is determined by airway resistance.

Elevated peak pressures can be caused by problems such as bronchospasm, secretions, or kinked tubes. Plateau pressure is determined by lung and chest wall compliance. Elevated plateau pressures can be caused by problems such as ARDS, pulmonary fibrosis, obesity, or edema.

- Knowing the indication for mechanical ventilation is key to choosing the most appropriate and least harmful mode of ventilation and ventilator settings
- It is important to understand whether a breath is controlled or assisted, what triggers a breath, and how the breath is given in order to understand modes of ventilation. Most modern modes of ventilation are a complex combination of different types of breaths based upon goals set by the clinician or interactions with the patient.
- ARDS requires low TV ventilation and open lung ventilatory strategies can be used for severe cases
- Remember to allow time for full expiration for patients with obstructive airway disease

Z99.11 Dependence on respirator [ventilator] status

VENTRICULAR FIBRILLATION

Marie-France Petchy • Richard E. Wolfe

BASICS

DESCRIPTION

- Ventricular fibrillation (VF) is completely disorganized depolarization and contraction of small areas of the ventricle without effective cardiac output.
- Cardiac monitor displays absence of QRS complexes and T-waves with the presence of high-frequency, irregular undulations that are variable in both amplitude and periodicity.

ETIOLOGY

- Damaged myocardium creates sites for re-entrant circuits:
 - Myocardial damage may be caused by multiple factors including ischemia, necrosis, reperfusion, healing, and scar formation
- Most often a result of severe myocardial ischemia:
 - 7% of patients with STEMI develop sustained VF, 80–85% occurring in the 1st 24 hr
- Complication of cardiomyopathy:
 - Up to 50% of patients with dilated cardiomyopathy suffer an episode of VF.
 - In hypertrophic cardiomyopathy, unexpected sudden death occurs with reported frequency of up to 3%/yr.
- Nonischemic causes of ventricular tachycardia may evolve into VF:
 - Drug toxicities (cyclic antidepressants, digitalis)
 - Electrolyte or acid–base abnormalities
 - Congenital and acquired prolonged QT syndromes.
 - Short QT syndrome
 - Brugada syndrome
- Premature ventricular complexes (PVCs) with R-on-T phenomenon
- Other less common causes of VF:
 - Electrocution
 - Hypoxia
 - Hypothermia
 - Blunt chest trauma
 - Iatrogenic myocardial irritation from pacemaker placement or pulmonary artery catheter
- Idiopathic VF (5–10%)

Pediatric Considerations

- Primary ventricular dysrhythmias are extremely rare in children.

- VF usually results from a respiratory arrest, hypothermia, or near drowning.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Loss of consciousness
- Seizure
- Transient gasping followed by apnea
- Absent pulse and heart sounds
- Death if the rhythm remains untreated:
 - VF is the initial rhythm in ~5–70% of patients sustaining sudden cardiac death in the pre-hospital setting

ESSENTIAL WORKUP

- AED or manual defibrillator to confirm and treat a shockable rhythm
- Cardiac monitor

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Lab tests are not useful during resuscitation
- After return of spontaneous circulation (ROSC): Electrolytes including calcium and magnesium, BUN, creatinine, troponin, ABG, lactic acid level, and toxicology screen

Imaging

- After ROSC
- To identify cause of VF:
 - EKG
 - Cardiac US
 - CXR, also to monitor placement of an endotracheal tube (ETT)

DIFFERENTIAL DIAGNOSIS

- Asystole:
 - Fine VF may mimic asystole in a single lead.
 - Check rhythm in another lead for fine fibrillations

TREATMENT

ALERT

- Early defibrillation of VF is the most important determinant of survival, and each minute without defibrillation reduces survival by 7–10%.

- Single shock defibrillation strategy is the current standard
- Supraventricular tachycardia or VT with a pulse may degenerate into VF if cardioverted without synchronization.
- In a hypothermic cardiac arrest with VF, follow standard defibrillation strategy while rewarming the patient
- Do not defibrillate any conscious patient.

Controversies

- Escalating biphasic energy levels have been shown to improve conversion of VF:
 - Almost all automated external defibrillators (AED) and manual defibrillators commercially available are biphasic
 - Biphasic defibrillators are recommended because less energy is required
- Some study raised questions on the benefit of epinephrine in cardiac arrest
- The benefit of amiodarone or lidocaine in post cardiac arrest after ROSC is uncertain
- The benefit of procainamide as a 2nd-line antiarrhythmic remains controversial and is no longer included in the AHA guidelines

PRE HOSPITAL

- Promptly recognize cardiac arrest
- Follow initial stabilization/therapy
- Ideally, transport to the closest facility delivering comprehensive post cardiac arrest treatment

INITIAL STABILIZATION/THERAPY

- Use AED or manual defibrillator as soon as available
- Perform early CPR starting with chest compressions until defibrillator is ready
- Defibrillator confirms shockable rhythm
- Initiate SCREAM acronym
- **Shock:**
 - Immediate defibrillation with 1 shock
 - Biphasic energy level:
 - Follow manufacturer's recommendations (e.g. 120–200 J) for 1st shock; if unknown, use maximum available
 - Same or higher energy for subsequent shocks
 - 360 J monophasic for 1st and subsequent shocks
 - May repeat q2min until rhythm changes
- **CPR:**
 - Immediately resume CPR after each shock for 2 min starting with chest compressions
 - 30:2 compression–ventilation ratio if no advanced airway in place
 - ≥ 100 compressions per minute
 - Minimize CPR interruptions

- **Rhythm** check after every 2 min of CPR
- Secondary ABCD survey to try and determine underlying cause while resuscitation in progress
- Establish IV/IO access
- **Epinephrine** if defibrillation is unsuccessful:
 - Start after 2nd shock
 - May repeat q3–5min
 - Vasopressin may replace 1st or 2nd dose of epinephrine
- **Antiarrhythmic medications** if refractory VF:
 - Start after 3rd shock
 - Amiodarone
 - Lidocaine if amiodarone is not available
 - Magnesium for torsade de pointes
 - May consider a continuous infusion of the antiarrhythmic agent associated with ROSC
- Advanced airway management:
 - Should not delay initial CPR and defibrillation
 - Resume CPR with continuous chest compressions ≥ 100 /min and 1 ventilation every 6–8 sec
 - Use capnography to monitor ETT position, optimize quality of CPR, and detect ROSC

Pediatric Considerations

- Defibrillation sequence: Monophasic 2 J/kg, 2–4 J/kg, 4 J/kg
- May consider 4–10 J/kg or adult maximum dose for subsequent shocks

ED TREATMENT/PROCEDURES

- Post cardiac arrest care
- Identify and treat the cause of the VF arrest recognizing that the most likely cause is acute myocardial infarction:
 - Provide percutaneous coronary intervention when indicated
- Maintain SpO₂ $\geq 94\%$ and PETCO₂ at 35–40 mm Hg
- Treat SBP < 90 mm Hg
- Maintain body temperature at 32–34°C
- Treat hyperglycemia > 180 mg/dL (> 10 mmol/L)

MEDICATION

- Epinephrine: 1 mg IV/IO bolus, may repeat dose q3–5min
- Vasopressin: 40 U IV/IO bolus single dose
- Amiodarone: 300 mg in IV/IO bolus, may repeat 150 mg IV/IO bolus once:
 - Amiodarone infusion after ROSC: 1 mg/min for 1st 6 hr then 0.5 mg/min for 18 hr. Max. cumulative dose 2.2 g/24 h
- Lidocaine: 1–1.5 mg/kg IV/IO bolus, may repeat 0.5–0.75 mg/kg IV bolus q5–

- 10min; 3 doses max. or max. cumulative dose 3 mg/kg:
 - Lidocaine infusion after ROSC: 1–4 mg/min (30–50 µg/kg/min)
- Magnesium sulfate: 1–2 g in 10 mL D₅W IV/IO bolus
- Follow each medication with a 20 mL NS flush.

Pediatric Considerations

- Epinephrine: 0.01 mg/kg IV/IO, may repeat q3–5min; max. cumulative dose 1mg
- Amiodarone: 5 mg/kg IV/IO, may repeat 5 mg/kg; max. cumulative dose 15 mg/kg/d
- Lidocaine: 1 mg/kg IV/IO:
 - Lidocaine infusion 20–50 µg/kg/min
- Magnesium sulfate: 25–50 mg/kg IV/IO up to 2 g
- Follow each medication with a 3–5 mL NS flush.

FOLLOW-UP

DISPOSITION

Admission Criteria

All patients who survive need admission to the ICU/CCU.

Discharge Criteria

No patient who suffers a VF arrest may be discharged from the ED.

Issues for Referral

Patients with episodes of VF occurring >48 hr post-MI may need referral to electrophysiology.

PEARLS AND PITFALLS

ACC/AHA guidelines recommend that patients with an acute myocardial infarction should have their serum potassium maintained above 4 mEq/L to prevent ventricular dysrhythmias

VENTRICULAR PERITONEAL SHUNTS

Richard S. Krause

BASICS

DESCRIPTION

- Ventricular peritoneal (VP) shunts are usually placed for hydrocephalus:
 - Conduit between CSF and peritoneal cavity (or right atrium)
- **Obstruction:** Shunt malfunction impairs drainage of CSF:
 - Increases intracranial pressure (ICP)
 - Rate of increase in ICP determines severity
 - 30–40% mechanical malfunction rate in 1st year
- **Overdrainage syndrome:**
 - Upright posture increases CSF outflow
 - Decreases ICP
 - Produces postural headache and nausea (as after lumbar puncture)
- **Infection:**
 - Shunt is a foreign body
 - *Staphylococcus epidermidis* and other *Staphylococcus* species in 75% of infections
 - Gram-negative organisms also implicated
 - Multidrug-resistant *Staphylococcus aureus* (MRSA) has been reported
 - Most occur soon after placement
 - Shunt removal usually required
- **Slit ventricle syndrome:**
 - Prolonged overdrainage causes decreased ventricular size
 - Intermittent increases in ICP occur owing to proximal obstruction

Pediatric Considerations

- Complications more common in children, especially neonates
- If cranial sutures are open, CSF may accumulate without much ICP increase
- Produces relatively nonspecific signs and symptoms:
 - Drowsy
 - Headache
 - Nausea and Vomiting

ETIOLOGY

- Shunt may be needed to treat increased ICP due to:
 - Congenital malformations
 - Idiopathic intracranial hypertension (pseudotumor cerebri)
 - Post CVA

- Tumor or other mass lesions
- Post head trauma
- Subarachnoid hemorrhage
- Scarring at base of brain after bacterial meningitis

DIAGNOSIS

SIGNS AND SYMPTOMS

- Shunt obstruction:
 - Headache, nausea
 - Malaise, general weakness, irritability
 - Decreased level of consciousness (LOC)
 - Increased head size or bulging fontanelle
 - Seizures: New-onset or increased frequency
 - Autonomic instability
 - Decreased upward gaze
 - Apnea
 - Papilledema—rare
- Overdrainage syndrome:
 - Headache, focal neurologic signs, malaise, seizures, coma
 - Signs and symptoms often postural
- Rapid overdrainage may cause upward shift of the brainstem, leading to signs and symptoms of herniation: Apnea, bradycardia, decreased LOC
- Shunt infections:
 - Fever (may be absent)
 - Meningeal signs
 - Local signs of infection (erythema, swelling, tenderness)
 - Peritonitis (can cause retrograde CSF infection)
 - Infections usually occur soon after shunt placement (about 80% \leq 6 mo)
- Slit ventricle syndrome:
 - Episodic headache
 - Alternating periods of normal behavior and lethargy
 - Headache, nausea, and vomiting

History

- Timing of shunt placement
- Reason for shunt
- Recent instrumentation/revision

Physical-Exam

- Altered mental status
- Focal neurologic deficit

- Fever
- Erythema or tender shunt

ESSENTIAL WORKUP

- Suspected shunt malfunction:
 - Manipulation of the pumping chamber:
 - Chamber should compress easily and refill within 3 sec
 - Failure to compress easily implies distal obstruction
 - Failure to fill implies proximal obstruction
 - *Up to 40% of malfunctioning shunts compress/fill normally*
 - Head CT
 - Shunt series:
 - Radiographs of skull, chest, abdomen
 - Aids in diagnosis of disconnection, malposition, or kinking of shunt components
- Suspected infection:
 - Aspiration of CSF from shunt reservoir (in consultation with neurosurgeon):
 - May be performed using sterile technique and 23G butterfly needle
 - Slowly aspirate 5–10 mL CSF for the studies noted in the next section

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Electrolytes, renal function, and glucose
- Anticonvulsant levels
- CBC
- Suspected infection:
 - Analysis of CSF from the shunt reservoir:
 - Send for culture, cell count, Gram stain, glucose, and protein levels
 - CSF analysis may have normal early result, especially with prior antibiotic treatment
 - Blood cultures

Imaging

- Head CT: To compare ventricular size and evaluate catheter position:
 - Enlarged ventricles: Shunt malfunction
 - Smaller ventricles: Overdrainage
 - Most useful when compared with previous scan
 - Diagnose subdural hematoma
- US: Used in children with open fontanelle to evaluate position of shunt tip and assess ventricular size

Diagnostic Procedures/Surgery

- If symptoms of shunt malfunction are present but CT scan is not diagnostic, shunt tap is the next test:
 - Shunt manometry: High pressure > 20 cm H₂O implies distal shunt obstruction
 - Also used to evaluate CNS infection

DIFFERENTIAL DIAGNOSIS

- Seizure disorder (idiopathic, toxic, metabolic)
- Infections:
 - CNS infection not related to the shunt
 - Systemic infections
- Metabolic abnormalities:
 - Hypoglycemia
 - Hyponatremia
 - Hypoxia
- Intoxication/poisoning
- Head trauma

TREATMENT

PRE HOSPITAL

- Patients with shunt malfunction are at risk for apnea and respiratory arrest
- Oxygen should be applied with close monitoring of respiratory status
- When increased ICP is suspected, transport patient with head elevated to 30°

INITIAL STABILIZATION/THERAPY

- Signs of impending herniation:
 - Rapid-sequence intubation and controlled ventilation to Pco₂ ~ 35 mm Hg
 - Consider pretreatment with lidocaine (pediatric: Plus atropine)
 - Thiopental or etomidate for induction
 - Succinylcholine may increase ICP a few mm Hg, although this may not be clinically significant
 - Use only pretreatment dose of nondepolarizing agent if depolarizing agent chosen
 - Nondepolarizing agent (rocuronium) may be preferable
- Forced pumping of shunt chamber:
 - Flush the device with 1 mL of saline solution to remove distal obstruction
 - Allow slow drainage of CSF from the reservoir to achieve pressure < 20 cm H₂O
- IV mannitol to lower ICP
- *Ventricular puncture* and CSF drainage is a procedure of last resort if less invasive procedures unsuccessful and neurosurgeon unavailable

- *Status epilepticus*: Treated with benzodiazepines (lorazepam)

ED TREATMENT/PROCEDURES

- Early neurosurgeon consultation
- Shunt malfunction:
 - Elevate head of bed to 30°
 - Medical management with diuretics (mannitol, furosemide) may be appropriate in certain mild cases
- Overdrainage syndrome:
 - Maintain patient's supine position
 - Correct volume depletion
- Shunt infection:
 - Systemic antibiotics:
 - Vancomycin *plus* cefotaxime or gentamicin if gram-negative suspected

MEDICATION

- Adult and pediatric doses:
 - Atropine: 0.02 mg/kg IV (min. 0.1 mg)
 - Cefotaxime: 1–2 g (peds: 50 mg/kg) IV/IM q8–12h
 - Furosemide: 1 mg/kg IV
 - Gentamicin: 2–5 mg/kg IV
 - Lidocaine: 1 mg/kg IV
 - Mannitol: 1 g/kg IV
 - Rocuronium: 1 mg/kg IV
 - Succinylcholine: 1.5 mg/kg IV
 - Vancomycin: 15 mg/kg loading dose IV
 - Vecuronium: 0.08-0.1 mg/kg IV

FOLLOW-UP

DISPOSITION

Admission Criteria

Patients with shunt complications usually require neurosurgical consultation and admission. An ICU or other monitored setting is often needed.

Discharge Criteria

When shunt malfunction is ruled out, disposition depends on alternate diagnosis and patient condition.

PEARLS AND PITFALLS

- Avoid “tunnel vision” in a patient with a shunt and consider other causes for the

presentation

- Severe constipation may cause increased intra-abdominal pressure and decrease drainage resulting in increased ICP:
 - Treatment of constipation may ameliorate the apparent “shunt malfunction”

VENTRICULAR TACHYCARDIA

Daniel C. McGillicuddy • Emily M. Mills

BASICS

DESCRIPTION

- A wide complex tachydysrhythmia with a quasirandom signal (QRS) > 120 and a rate > 100
- Rapid and regular depolarization of the ventricles independent of the atria and the normal conduction system
- Re-entry:
 - Structural heart disease most common
 - Seen in dilated cardiomyopathy, ischemia, and infiltrative heart disease, previous MI, scarring
 - May be pharmacologically induced
 - Usually produces a regular and monomorphic rhythm
- Triggered automaticity:
 - Minority of ventricular tachycardia (VT)
 - Caused by repetitive firing of a ventricular focus
- Torsades de pointes:
 - Polymorphic form of VT
 - Alternating electrical polarity and amplitude
 - Prolongation in repolarization necessary
 - Usually pharmacologically induced
- Regardless of the mechanism, all VT may degenerate to ventricular fibrillation (VF).

ETIOLOGY

- Wide complex tachycardia:
 - 80% likelihood of being VT
 - 20% supraventricular tachycardia (SVT) with a baseline left bundle branch block (LBBB) or aberrancy
- Wide complex tachycardia and a history of MI:
 - $> 98\%$ likelihood of being VT
 - Age > 35 : 80% risk of VT
 - Age < 35 : 75% risk of SVT
- Incidence of nonsustained VT:
 - 0–4% in the general population
 - Up to 60% of patients with dilated cardiomyopathy
- Associated with increased risk for sudden cardiac death (SCD)

SIGNS AND SYMPTOMS***History***

- Asymptomatic
- Syncope/near syncope
- Lightheadedness/dizziness
- Shortness of breath
- Palpitations
- Chest discomfort/pain
- Diaphoresis
- Cannon A-waves
- Hypotension
- CHF
- Beat-to-beat variability of systolic BP
- Variability in heart tones, especially S1

Physical-Exam

- Establish presence of pulses, mental status and vital sign abnormalities.
- Auscultation of heart will reveal tachycardia.

ESSENTIAL WORKUP

- EKG:
 - Most important initial test to differentiate VT from SVT with aberrancy or LBBB
- VT definition:
 - ≥ 3 consecutive QRS complexes with a ventricular rate over 100 bpm and a QRS duration > 120 msec
- Torsades de pointes:
 - Polymorphic VT that rotates its axis every 10–20 beats
- Criteria to determine VT:
 - Atrial ventricular (AV) dissociation (present in 60–75%)
 - Fusion beats (P-wave partially activates ventricle in advance of next VT cycle), capture beats (P-wave totally activates ventricle)
 - Uniform morphology (except in the case of torsades)
 - Extreme axis deviation (-90° to $+180^\circ$)
 - QRS > 140 msec, with right bundle branch block (RBBB) morphology; or QRS > 160 msec, with LBBB morphology, but > 160 suggests VT regardless of bunch branch morphology
 - QRS concordance in the precordial leads
 - RBBB pattern V1 with $R > R'$ is VT 50:1.

- LBBB pattern with Q or QS pattern in V 6 is VT 50:1.
- Brugada criteria defines VT in wide complex tachycardia:
 - 99% sensitivity, 97% specificity
 - Only need to meet 1 criterion
 - AV dissociation
 - R-S interval absent in all precordial leads
 - QRS onset to the nadir of S >100 msec in any precordial lead
 - V1 R-wave >30 msec; R-S interval >70 msec, slurred, notched S
 - Wide QRS with LBBB in precordium
- Indicators of SVT with aberrancy include:
 - Normal-axis QRS <140 msec
 - Absence of Q-waves
 - RBBB in V1 with rsR' triphasic pattern
 - AV nodal blockade: Slowing of impulse conduction velocity seen with antiarrhythmic drugs is more pronounced at faster rates, so may result in wide complex SVT (SVT with aberrancy)

DIAGNOSIS TESTS & NTERPRETATION

Lab

- Cardiac enzymes
- Electrolytes, BUN, creatinine, glucose
- Magnesium level
- Calcium level
- Digoxin level if toxicity suspected

Imaging

CXR:

- Cardiomegaly or other cardiac anomalies may be apparent.

ECHO:

- Structural disease may be identified.

Diagnostic Procedures/Surgery

Esophageal pacing catheters:

- May be able to detect atrial activity to establish AV dissociation and therefore diagnose VT
- Catheters can then be used to overdrive pace if refractory to cardioversion/antiarrhythmics.

DIFFERENTIAL DIAGNOSIS

- SVT with aberrancy or baseline LBBB
- Proarrhythmia secondary to antidysrhythmia medications; suspect if:
 - VT morphology is different than previous episodes of VT

- Medications have recently been started or changed
- QT interval is >440 msec.
- Torsades de pointes
- If VT continues to recur after cardioversion

TREATMENT

PRE HOSPITAL

- Cautions:
 - Transport stable patients suspected of being in VT without attempting to convert them.
 - *Synchronized* cardioversion for unstable patients with a pulse
 - Defibrillation for pulseless VT
- Controversies:
 - Lidocaine:
 - No benefit in the prevention of VT in patients with isolated premature ventricular contractions, regardless of the frequency

INITIAL STABILIZATION/THERAPY

Pulseless VT: Defibrillate immediately and follow the VF treatment plan.

ED TREATMENT/PROCEDURES

- Unstable patient:
 - Definition:
 - Chest pain
 - Hypotension
 - Evidence of worsening heart failure
 - Initiate immediate synchronized cardioversion with 100 J, quickly progressing to 200 J, 300 J, and 360 J if no response.
 - If the VT is polymorphic, begin cardioversion at 200 J.
 - Sedate the patient before cardioversion if at all possible.
 - If unable to terminate the VT, administer lidocaine and repeat the cardioversion.
 - Antitachycardia overdrive pacing if torsades
 - After successful return of sinus rhythm, begin amiodarone.
- Stable patient, monomorphic VT:
 - Normal cardiac function at baseline:
 - Procainamide *or* sotalol; may also consider amiodarone or lidocaine
 - Avoid sotalol if evidence of prolonged QT or known long QT syndrome.
 - Impaired cardiac function at baseline:
 - Amiodarone bolus, then infusion *or* lidocaine, then synchronized

cardioversion

- Stable patient, polymorphic VT:
 - Normal QT interval at baseline:
 - Correct electrolyte abnormalities.
 - Treat ischemia if present.
 - Then begin 1 of the following: b2-blockers, lidocaine, amiodarone, procainamide, or sotalol.
 - Prolonged QT Torsades de pointes:
 - Correct electrolytes.
 - Magnesium sulfate *or* overdrive pacing *or* 1 of the following: Isoproterenol, phenytoin, lidocaine
 - Isoproterenol is used to overdrive the tachycardia if the patient has no history of coronary artery disease or long QT syndrome.
 - Temporizing measure until external pacing available
 - Impaired cardiac function at baseline
 - Amiodarone bolus *or* lidocaine bolus then synchronized cardioversion

Pediatric Considerations

- Primary cardiac arrest and VT are rare in children.
- Usually secondary to hypoxia and acidosis
- VT is tolerated for longer periods in children than adults and is less likely to degenerate to VF.
- Infants in VT most commonly present with CHF.
- VT in children results from:
 - Cardiomyopathy
 - Congenital structural heart disease
 - Congenital prolonged QT syndromes
 - Coronary artery disease secondary to vasculitis
 - Toxins, poisons, drugs
 - Severe electrolyte imbalances, especially of potassium

MEDICATION

First Line

- Procainamide: 3–6 mg/kg over 5 min, may repeat every 5–10 min to max. total dose of 15 mg/kg. Do not exceed 100 mg/dose or 500 mg in 30 min (peds: 15 mg/kg IV/IO over 30–60 min).
- Amiodarone: 150 mg IV bolus over 10 min, may repeat; arrest dose is 300 mg IV/IO max. cumulative dose 2.2 g IV/24 h; followed by 1 mg/min for 6 hr, then 0.5 mg/min for 18 hr. (peds: 5 mg/kg IV or IO over 20–60 min, max. 15 mg/kg/d)
- MgSO₄: 2 g in D₅W over 5–10 min followed by infusion of 0.5–1 g/h IV, titrate to control torsades (peds: 25–50 mg/kg IV/IO over 10 min, max. dose 2 g)

Second Line

- Lidocaine: 1–1.5 mg/kg bolus IV push 1st dose, 0.5–0.75 mg/kg 2nd dose, and q5–10min for a max. of 3 mg/kg; tracheal administration 2–4 mg/kg; maintenance infusion 1–4 mg/min if converted. Not recommended for ACS induced VT (peds: 1 mg/kg bolus with infusion 20–50 µg/kg/min)
- Adenosine: 6 mg IV push followed by 12 mg IV push if needed in 1–2 min (peds: 1 mg/kg, max. 6 mg). Note: Does not convert VT, do not use if unstable or irregular WCT.
- Isoproterenol: 2–10 µg/min, titrate to heart rate (peds: 0.1 µg/kg/min). Note: Do not give with epinephrine, may precipitate VT/VF (no longer part of ACLS protocol), do not give if prolonged QT.
- Sotalol: 100 mg IV over 5 min. (peds: Use not recommended for initial management). Note: Do not give if prolonged QT.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Admit sustained VT to a critical care setting.
- Admit nonsustained VT and a history of MI or dilated cardiomyopathy for electrophysiologic studies.

Discharge Criteria

- Rare patients with nonsustained VT and a previous evaluation that revealed no structural heart disease can be discharged:
 - At low risk for SCD
- Patients with automatic internal cardiac defibrillators that are well functioning can also be discharged.

Issues for Referral

All patients discharged with VT should be followed by a cardiologist within 48 hr.

FOLLOW-UP RECOMMENDATIONS

Patients should follow-up with a cardiologist.

PEARLS AND PITFALLS

- Search for contributing factors such as toxins, metabolic abnormalities, trauma, hypothermia, thrombosis.
- Unstable VT requires early cardioversion.
- Administer postresuscitation maintenance medications to prevent recurrence.

- Watch for bradycardia and GI toxicity after amiodarone administration.
- Discontinue any proarrhythmic drugs
- Consider b2-blockade for ischemia-induced VT and polymorphic VT.

VERTEBROBASILAR INSUFFICIENCY

Andrew K. Chang

BASICS

DESCRIPTION

- Vertebrobasilar (VB) vascular system feeds the posterior region of the brain, which includes the brainstem, cerebellum, and inner ear
- 2 vertebral arteries (VA) derive from subclavian arteries and give rise to the anterior spinal artery and then join to form the basilar artery
- Arteries supplying the brainstem and cerebellum originate from the VB system before it branches into the 2 posterior cerebral arteries (PCA), such that a wide variety of focal neurological deficits arise from VB circulatory dysfunction
- Vertebrobasilar insufficiency (VBI) results in inadequate perfusion of VB arterial circulation from thrombotic, embolic, or low-flow states

ETIOLOGY

- Mechanism:
 - _ Thrombosis:
 - VB ischemia due to underlying VB atherosclerosis and clot formation
 - _ Embolus:
 - VB ischemia due to embolization of clot from proximal location
 - _ Low-flow states:
 - Hypoperfusion of VB system from systemic (e.g., cardiogenic shock) or localized (e.g., subclavian steal) reduction in blood flow
 - _ Less common etiologies:
 - Fibromuscular dysplasia
 - Hypercoagulable states
- Ischemic mechanisms causing VB insufficiency can herald and lead to VB territory infarcts
- Severe episodes of VB hypoperfusion or loss of circulation can lead to:
 - _ “Locked-in” syndrome:
 - Quadriplegia (eyelid or eye movement only) with intact consciousness
 - _ “Top-of-basilar” syndrome:
 - Pontine and cerebellar dysfunction with diminished level of consciousness

DIAGNOSIS

SIGNS AND SYMPTOMS

All history and physical exam items may present intermittently

History

- Dizziness/vertigo (“mild,” “nonviolent”; may be isolated finding)
- Onset usually abrupt and spontaneous rather than position induced
- May have a flurry of spells within a few weeks time
- “Drop attack”
- Headache
- Nausea/vomiting
- Paresis/paresthesia
- Seizure
- Syncope
- Neurologic symptoms localizing to the posterior circulation:
 - Visual changes (double vision, blurry vision, blindness)
 - Numbness of the face or extremities
 - Weakness in arms or legs
 - Clumsiness in arms or legs
 - Confusion or loss of consciousness
 - Difficulty with speech
 - Difficulty swallowing
 - Pain in neck or shoulder

Physical-Exam

- Brainstem:
 - “Crossed” findings (i.e., ipsilateral facial and contralateral body deficits)
 - Altered mental status or responsiveness
 - Decreased respiratory drive
 - Horner's syndrome (enophthalmos, ptosis, miosis, anhidrosis)
 - Internuclear ophthalmoplegia
 - Nystagmus (especially nonfatigable, vertical/rotatory)
 - Paresis/paresthesias
- Cranial nerves:
 - Extraocular muscle paresis (e.g., diplopia)
 - Pupillary abnormalities
 - Facial paresthesia
 - Facial muscle paresis
 - Hearing abnormalities
 - Dysphagia
 - Dysarthria
- Cerebral cortex (PCA circulation):
 - Visual disturbances (e.g., homonymous hemianopsia)
- Cerebellar:
 - Ataxia
 - Dysmetria
 - Gait abnormality

- Cardiovascular:
 - Carotid/VA bruit
 - Irregular/asymmetric/weak pulses

ESSENTIAL WORKUP

- Emergent head CT (noncontrast) to evaluate for hemorrhage (parenchymal, subarachnoid, traumatic), large acute infarcts, prior pathology
- Thorough neurologic and cardiac exam
- Neurology consultation
- 12-lead ECG for arrhythmias and myocardial ischemia
- CTA and/or MRA for imaging of the posterior circulation

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC:
 - Anemia, thrombocytopenia; polycythemia, thrombocytosis
- Coagulation studies (PT/PTT):
 - Hypo- and hypercoagulable states; baseline values for anticoagulant and fibrinolytic therapies
- Electrolytes, BUN/creatinine, glucose
- Cardiac markers for concurrent myocardial ischemia
- Urinalysis
- ESR for systemic vasculitides
- Rapid plasma reagin
- Thyroid stimulating hormone
- Lipid profile

Imaging

- Emergent head CT (noncontrast)
- Head and neck CT angiogram (CTA) for evaluation of posterior circulation and possible acute vascular intervention
- Chest radiograph; consider chest CTA for cardiopulmonary and great vessel pathology
- MRI/magnetic resonance angiography (MRA) for improved characterization of ischemic lesion and cerebrovascular circulation (e.g., congenital VB anomalies, exclusion of VA dissection)
- Echocardiography for intracardiac embolic source
- Cervical Doppler US
- Transcranial Doppler US

Diagnostic Procedures/Surgery

- Neuroangiography for diagnosis

- Directed intra-arterial thrombolytic therapy/angioplasty/stenting/embolectomy are still under investigation)

DIFFERENTIAL DIAGNOSIS

- CNS:
 - CVA (hemorrhagic or ischemic):
 - Cerebral
 - Cerebellar
 - Brainstem
 - Multiple sclerosis
 - Migraine syndromes
 - Seizure (focal)
 - Traumatic injury/postconcussive
 - Tumor
 - Vascular malformation hemorrhage (arteriovenous malformation, subarachnoid)
 - Brainstem herniation
- Peripheral nervous system:
 - Vestibular neuritis
- Ear, nose, throat:
 - Cerebellopontine angle tumor
 - Ear canal pathology (foreign body, tumor)
 - Labyrinthitis/otitis media
 - Ménière disease
 - Benign paroxysmal positional vertigo
- Cardiovascular:
 - Arrhythmia
 - Myocardial ischemia/infarct
 - Aneurysm/dissection (VA, basilar artery, subclavian artery, aorta)
 - Hypovolemia
 - Vasculitides
- Endocrine:
 - Adrenal insufficiency
 - Hypothyroidism
- Hematologic:
 - Anemia
 - Coagulopathy/hypercoagulable state
- Infectious:
 - Encephalitis/meningitis
 - Otitis media/mastoiditis
 - Septic shock
 - Syphilis
- Metabolic:

- Hypoglycemia; hyperglycemia
- Electrolyte imbalance
- Toxicologic:
 - Ataxia: Alcohols, lithium, phenytoin
 - Salicylism
 - Serotonin syndrome
 - Iatrogenic

TREATMENT

PRE HOSPITAL

- ABCs
- Fingertick glucose measurement
- Naloxone if indicated
- Notification:
 - Urgent contact with receiving facility if airway compromise or hemodynamic instability

INITIAL STABILIZATION/THERAPY

- ABCs
- Administer oxygen
- Place on cardiac monitor and pulse oximeter
- Establish IV access with 0.9% normal saline

ED TREATMENT/PROCEDURES

- Cerebrovascular perfusion management:
 - Supportive care
 - Supine position
 - Antiplatelet agent if no hemorrhagic source
 - Anticoagulation:
 - Consider in consultation with neurology if significant risk factors for embolic source, unstable or progressive ischemic symptoms
 - Ideal BP targets not well defined; maintain BPs within patient's expected range (i.e., account for chronic hypertension)
- If hypotensive: Fluid resuscitation; vasopressors or blood as indicated
- If hypertensive: Administer titratable antihypertensive medications for severe HTN (mean arterial pressure > 140 mm Hg, systolic BP > 220 mm Hg, diastolic BP > 130 mm Hg) or hemorrhage/aneurysm/dissection, myocardial or other end-organ dysfunction
- GI:
 - NPO (rehydrate with IV fluids; maintain normoglycemia)
 - Antiemetics

- Consultation:
 - Neurology
 - Vascular interventional radiology for neuroangiography

MEDICATION

- Aspirin: 325 mg PO
- Clopidogrel: 75 mg PO
- Warfarin (dose for atrial fibrillation): 2–5 mg PO loading dose
- Heparin (dose for atrial fibrillation): 50–60 U/kg IV bolus, then IV infusion at 12–18 U/kg for target PTT 50–70 sec
- Labetalol: 20–40 mg IV over 2 min, then 40–80 mg IV q10min (max. 300 mg IV)
- Meclizine: 25 mg PO q8–12h
- Naloxone: 0.4–2 mg IM/IV q2–3min PRN
- Nitroprusside: 0.25–10 µg/kg/min IV infusion (max. 10 µg/kg/min)
- Ondansetron: 4 mg IV
- Promethazine: 12.5–25 mg PO/PR/IV q6–8h
- Ticlopidine: 250 mg PO BID

FOLLOW-UP

DISPOSITION

Admission Criteria

- ICU admission for:
 - Altered mental status with airway issues
 - Concurrent hemodynamic instability
 - Malignant cardiac arrhythmias
- Admit to hospital to identify or exclude etiologies of VB ischemia and to prevent recurrence or progression to VB circulation cerebrovascular accident, especially in the following populations:
 - Elderly
 - Inability to ambulate
 - Inability to tolerate oral intake
 - Inability to arrange (expeditious) outpatient follow-up
 - New or changing neurologic deficit
 - Persistent dizziness
 - Syncope
 - Vascular risk factors

Discharge Criteria

- Consider discharge with outpatient follow-up in populations with the following:
 - None of above indications to consider admission

- Alternative explanation for symptomatology

Issues for Referral

- VB ischemia-related referrals as arranged/recommended by admitting team
- Arrange expeditious referrals with PCP or appropriate specialist (e.g., neurology, otorhinolaryngology, vascular surgery) as indicated for alternative explanation for symptomatology

FOLLOW-UP RECOMMENDATIONS

- VB ischemia-related follow-up as arranged/recommended by admitting team
- Urgency and nature of other follow-up as determined by alternative explanation of symptomatology

PEARLS AND PITFALLS

- Always consider VB insufficiency for dizziness, vertigo, mental status changes, syncope, and overlapping/atypical neurologic presentations
- VBI more likely to occur in patients with spontaneous vertigo lasting a few minutes with accompanying neurologic symptoms and who have cardiovascular risk factors
- Start antithrombotic/antiembolic treatments for VB insufficiency in the absence of contraindications

435.3 Vertebrobasilar artery syndrome

ICD10

G45.0 Vertebro-basilar artery syndrome

VERTIGO

William E. Baker

BASICS

DESCRIPTION

- Dizziness, 3–4% of ED visits, difficult symptom to diagnose, describes a variety of experiences, including:
 - Vertigo
 - Weakness, fainting
 - Lightheadedness
 - Unsteadiness
- Vertigo, a hallucination of movement:
 - Spinning or turning
 - Sensation of movement between the patient and the environment
 - Oscillopsia (illusion of an unstable visual world)
 - Most patients have an organic etiology.
- Maintenance of equilibrium depends on interaction of 3 systems:
 - Visual
 - Proprioceptive
 - Vestibular
- Any disease that interrupts the integrity of above systems may give rise to vertigo.
- Peripheral vertigo:
 - Often, severe symptoms
 - Intermittent episodes lasting seconds to minutes, occasionally hours
 - Horizontal or horizontal–torsional nystagmus (also positional, fatigues, and suppressed by fixation)
 - Normal neurologic exam
 - Sometimes associated hearing loss or tinnitus
- Central vertigo:
 - Usually mild continuous symptoms
 - All varieties of nystagmus (horizontal, vertical, rotatory)
 - No positional association
 - Presence of neurologic findings most of the time

ETIOLOGY

Peripheral

- Acute peripheral vestibulopathy (APV):
 - Vestibular neuritis (most common):
 - Single acute attack continuous rotational vertigo

- Constant for several days
- Present even when still
- No hearing deficits
- Highest incidence in 3rd–5th decade
- Acute labyrinthitis:
 - Similar to vestibular neuritis but:
 - Associated with hearing deficit
 - May be viral (common), serous, acute suppurative, toxic, or chronic
- Benign paroxysmal positional vertigo (BPPV):
 - Most common cause recurrent vertigo
 - Posterior canal, 85–95% of BPPV cases
 - Lateral semicircular less common
 - Probable cause is loose particles (otoliths) in semicircular canals
 - Can be secondary to other entities including trauma and APV
- Ototoxic drugs:
 - Aminoglycosides
 - Antimalarials
 - Erythromycin
 - Furosemide
- Ménière disease:
 - Episodic vertigo, hearing loss, and tinnitus
- Acoustic neuroma:
 - Tumor of Schwann cells enveloping the 8th cranial nerve (CN VIII)
 - Develops into central cause
 - Progressive unilateral hearing deficits and tinnitus
 - May also involve CN V, VII, or X
- Trauma:
 - Rupture of tympanic membrane, round window, labyrinthine concussion, or development of perilymphatic fistula can all have severe symptoms.
- Otitis media and serous otitis with effusion
- Foreign body in ear canal

Central

- Vertebrobasilar artery insufficiency:
 - Disturbances may be transient or exacerbated by movement of the neck.
- Cerebellar infarction
- Cerebellar hemorrhage:
 - Neurosurgical emergency
 - Sudden onset of headache, vertigo, vomiting, and ataxia
 - Visual paralysis to affected side
 - Ipsilateral CN VI paralysis
- Multiple sclerosis:

- Onset between 20–40 yr
- All forms of nystagmus
- May have abrupt onset of severe vertigo and vomiting
- History of other vague and varying neurologic signs or symptoms
- Brainstem hypertensive encephalopathy
- Trauma:
 - Vertiginous symptoms common after whiplash injury
 - Postconcussive syndrome or damage to labyrinth or CN VIII secondary to basilar skull fracture
 - Vertebral artery injury has been seen after chiropractic manipulation.
- Temporal lobe epilepsy:
 - Associated with hallucinations, aphasia, trancelike states, or convulsions
 - More common in younger patients
- Vertebrobasilar migraines:
 - Prodrome of vertigo, dysarthria, ataxia, visual disturbances, or paresthesias followed by headache
 - Often a family history of migraines or similar attacks
- Tumor
- Subclavian steal syndrome:
 - Exercise of an arm causing shunting of blood from vertebral and basilar arteries into the subclavian artery, resulting in vertigo or syncope
 - Secondary to a stenotic subclavian artery
 - Diminished unilateral radial pulse or differential systolic BP between arms
- Hypoglycemia

DIAGNOSIS

SIGNS AND SYMPTOMS

Sensation of motion, spinning, disorientation in space, or disequilibrium

History

- Does true vertigo exist?
- Timing of onset:
 - Gradual (hours–days): Probably neuritis
 - Sudden and fixed symptoms (seconds–minutes) consider stroke (but see BPPV below)
 - Multiple prodromal episodes in months, especially weeks prior (TIAs): Stroke more likely
 - Repeated intense episodes provoked/exacerbated by head movements: BPPV more likely but could be TIA
 - Episodic attacks with auditory symptoms: Consider Ménière
- Stroke risk factors including age > 50 and vascular risks

- Severity of symptoms: Imbalance out of proportion to vertigo, consider stroke
- Modifiers: Head movement, BPPV more likely
- Associated symptoms:
 - Hearing loss (new unilateral): Labyrinthitis, Ménière (with tinnitus), rarely, but possibly stroke
 - Neurologic symptoms (central cause):
 - Unilateral limb weakness
 - Dysarthria
 - Headache
 - Ataxia
 - Numbness of the face
 - Hemiparesis, headache
 - Diplopia/visual disturbances
 - Has there been head or neck trauma?
- Past medical history/ROS:
 - Stroke risk factors
- Medication history

Physical-Exam

- Extraocular movements:
 - Nystagmus (direction defined by fast component)
 - Unilateral, horizontal, some rotational component in (unilateral) APV, worse with gaze in the direction of nystagmus (fast away from lesion, linear slow phase)
 - Worse with occlusive ophthalmoscopy (cover 1 eye, examine optic disc with ophthalmoscope): APV more likely
 - Bilateral direction suggests central etiology, as does pure vertical or torsional nystagmus. If direction changes with gaze, central cause.
- Head impulse test (HIT) for unilateral vestibular loss (smartphone with slow motion video app promising aide for such testing):
 - Face patient, grasp head with both hands
 - Patient to look at your nose (or camera)
 - Rapidly rotate head 10–20° then back to midline:
 - Normal: Maintains gaze
 - Abnormal: Lag in maintaining gaze and corrective saccade back to nose/camera
 - Rotation to left, tests left vestibular apparatus
- Skew deviation testing (predicts central pathology):
 - Face patient
 - Patient to look at your nose
 - Alternately cover each eye
 - Normal: Eyes motionless
 - Abnormal: Refixation saccade after uncovered, (refixation upward,

ipsilateral medullary stroke, refixation downward, contralateral stroke)

- Dix–Hallpike test for posterior canal BPPV
- Supine Roll test for lateral canal BPPV
- Auscultation of the carotid and vertebral arteries for bruits
- Pulses and pressures in both arms
- Inspection of the ears:
 - Evaluation of hearing (Weber and Rinne tests)
 - Ocular assessment (pupils, fundi, visual acuity, nystagmus)
- Cardiac auscultation
- Full neurologic exam, common stroke findings:
 - Unilateral limb weakness
 - Gait ataxia
 - Unilateral limb ataxia and/or sensory deficit
 - Dysarthria

ESSENTIAL WORKUP

- Ask patient to describe the sensation without using the word “dizzy.”
- Determine whether the cause is a peripheral or a central process using patient’s clinical presentation (see above).

DIAGNOSIS TESTS & INTERPRETATION

Lab

Electrolytes, BUN, creatinine, glucose

Imaging

- EKG for any suspicion of cardiac etiology
- Head CT/MRI for evaluation of suspected tumor, or post-traumatic cause
- MRI/MRA for suspected vertebrobasilar insufficiency (CT poor sensitivity)

Diagnostic Procedures/Surgery

Audiology or electronystagmography often helpful in outpatient follow-up

DIFFERENTIAL DIAGNOSIS

More likely other cause when “dizziness” actually is lightheadedness or malaise:

- DM
- Hypothyroidism
- Drugs (e.g., alcohol, barbiturates, salicylates)
- Hyperventilation
- Cardiac (i.e., arrhythmia, MI, or other etiologies of syncope); peripheral vascular disease (i.e., HTN, orthostatic hypotension, vasovagal)
- Infection/sepsis

TREATMENT

PRE HOSPITAL

Treatment and medication per EMS protocol based on symptoms

INITIAL STABILIZATION/THERAPY

- IV access for dehydration/vomiting
- Monitor
- Trauma evaluations as indicated
- Finger-stick blood glucose

ED TREATMENT/PROCEDURES

- Based on accurate diagnosis:
 - Central etiologies require more aggressive workup than peripheral.
 - Neurosurgical intervention for cerebellar bleed
 - Symptomatic treatment for peripheral vertigo with appropriate follow-up
- Administer medication to control vertiginous symptoms and/or nausea:
 - Antihistamines
 - Benzodiazepines
 - Antiemetics
- Initiate IV antibiotics for acute bacterial labyrinthitis (rare).
- Repositioning maneuvers such as Epley and Semont for posterior BPPV. Roll or Lempert maneuver for lateral BPPV

MEDICATION

- Diazepam (Valium): 2.5–5 mg IV q8h or 2–10 mg PO q8h
- Dimenhydrinate (Dramamine): 25–50 mg IV, IM or PO q6h
- Diphenhydramine (Benadryl): 25–50 mg IV, IM, or PO q6h
- Lorazepam (Ativan): 1 mg IV, IM or 1–2 mg PO q4–6h
- Meclizine (Antivert): 25 mg PO q6h PRN
- Promethazine (Phenergan): 12.5 mg IV q6h or 25–50 mg IM, PO, or PR q6h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Cerebellar infarct/hemorrhage
- Vertebrobasilar insufficiency
- Acute suppurative labyrinthitis
- Intractable nausea/vomiting
- Inability to ambulate

Discharge Criteria

Patient with peripheral etiology and stable

Issues for Referral

Otolaryngology follow-up for suspected acoustic neuroma or perilymphatic fistula

FOLLOW-UP RECOMMENDATIONS

- Primary care, neurology, or otolaryngology follow-up for all
- Epley and Semont maneuvers are extremely effective in treating BPPV.

PEARLS AND PITFALLS

- Isolated vertigo can be the sole symptom of stroke or bleed
- Central cause clues: Imbalance and/or ataxia out of proportion to vertigo
- Learn the specialized exam and repositioning techniques

VIOLENCE, MANAGEMENT OF

Elizabeth R. Dunn • David S. Kroll

BASICS

DESCRIPTION

- EDs and waiting rooms are areas of high prevalence for violence
- Higher risk associated with busier EDs
- Patients with primary psychiatric complaints are likely to be boarding > 24 hr and may not be receiving psychiatric care
- Risk factors for violence in the ED:
 - Prior history of violence OR being a victim of violence
 - Patient arriving in police custody
 - Substance abuse history/intoxication
 - Poor impulse control
 - Male gender
 - Psychiatric illness (complex relationship to risk)
- No clear difference in risk associated with:
 - Ethnicity
 - Language
 - Education
 - Medical diagnosis

ETIOLOGY

- Primary psychiatric problem:
 - Most commonly psychosis or mania, but associated with many different diagnoses
- Acute primary medical problem:
 - Infection
 - Metabolic:
 - Hypoglycemia
 - Hypoxia
 - Hypothermia or hyperthermia
 - Toxicologic:
 - Alcohol intoxication or withdrawal
 - Illicit drug intoxication or withdrawal
 - Sedatives
 - Pain medications
 - Anticholinergics
 - Steroids
 - Neurologic:

- Seizure
- Stroke
- Head injury or bleed
- Brain lesion or mass
- Chronic primary medical problem:
 - Dementia
 - Intellectual disability
 - Traumatic brain injury
- Criminal behavior or psychopathy

DIAGNOSIS

SIGNS AND SYMPTOMS

- Early signs of impending violence risk (nonspecific):
 - Loud speech
 - Physical agitation or tension (pacing, clenching fists, darting eyes)
- Later signs of impending violence risk:
 - Abusive or provocative language
 - Behaving irrationally; unable to comply with reasonable limit setting
 - Invading personal space
 - Eliciting anger in staff

History

- Prior history:
 - Violent behavior
 - Self-injurious behavior
 - Medical and psychiatric histories
 - Substance use history
 - Legal or criminal history
- Current HPI:
 - Recent substance use
 - Potential head injury
 - Pain or discomfort from medical or psychiatric symptoms or environment
 - Plan or threat of violence
- Indicators of a higher likelihood of medical etiology:
 - Age >40 without a history of similar symptoms or behaviors
 - Concurrently emerging medical complaints
 - Comorbid medical conditions commonly associated with mental status changes:
 - Neurologic problems (including seizure disorders, CNS infections)
 - Chronic cognitive impairment
 - Vascular or cardiovascular disease

- Diabetes mellitus
- Chronic pain treated with opiates
- Inflammatory disorders treated with steroids
- Cancer
- HIV/AIDS
- Recent traumatic injury

Physical-Exam

- Exam signs suggesting a medical cause for the mental status change:
 - Abnormal vital signs
 - Focal neurologic findings
 - Seizure activity
 - Speech or gait deficits without evidence of alcohol or substance abuse

ESSENTIAL WORKUP

- Identify early warning signs
- Pay careful attention to findings during neurologic and mental status exams and note vital signs
- May be performed with the patient in restraints in an emergency

DIAGNOSIS TESTS & INTERPRETATION

- Follow clinical indicators for further testing, but if planning a psychiatric admission, labs and/or imaging may be required
- Basic labs and ECG may be useful in assessing and monitoring risks associated with chemical restraint use

Lab

- CBC, electrolytes, BUN, creatinine, and glucose if medical cause is suspected or if psychiatric admission or chemical restraint use is likely
- Consider LFTs, Ca, Mg, and Ph if chronically medically ill or pursuing delirium
- Drug screen if ingestion is likely

Imaging

CT head if bleed or stroke suspected

Diagnostic Procedures/Surgery

Obtain ECG if chemical restraint use is likely

TREATMENT

ALERT

- Medical workup is important, but in an emergency you may need to restrain

potentially violent patients 1st to reduce risk of harm to self or others

- Involve security or police as needed

PRE HOSPITAL

- Physically restrain violent patients and seek police assistance if necessary
- Keep weapons and other dangerous items (sharp objects, medications, cords, etc.) out of the patient's reach

INITIAL STABILIZATION/THERAPY

- Prevention:
 - _ Environmental:
 - Control access to ED: Secured doors, protected entrances, metal detectors, cameras
 - Visible security staff
 - Post visible rules stating clearly that weapons are not allowed
 - Exam room exits clear of obstruction
 - _ Procedural:
 - Identify high-risk patients at triage
 - Shorter ED wait times are helpful
 - Search/derobe patients after triage; if involuntary, ensure careful documentation of reasons in terms of risk to patient and providers
 - See to patients' comfort quickly
 - Alleviate pain
 - Online alerts for patients with past history of violence in ED
 - Clear ED protocols for managing violence and documenting interventions
 - Enlist family support when possible; if not, remove family to safe place
 - Train all clinical staff to recognize and manage potentially violent situations
- Approaching the potentially violent patient:
 - _ Do not go alone
 - _ Remove your own personal articles that could be used as weapons (neckties, jewelry, trauma shears, etc.)
 - _ Keep 2 arm's lengths between you and patient; open stance
 - _ Introduce yourself and try to address the patient's concerns as soon as possible
 - _ Maintain open exit for patient and staff
 - _ Leave immediately and initiate seclusion or restraint if there is an open threat of violence or imminent violence seems likely

ED TREATMENT/PROCEDURES

- Verbal de-escalation:

- Attempt to clarify and validate patient’s immediate concerns
- Calmly explain potential need for a restraint if de-escalation is not successful
- Offer patient choices when possible
- Seclusion:
 - If an appropriate room is available, this may obviate the need for restraint
- Physical restraint:
 - Follow your institutional protocol
 - Must document appropriate reason for restraint, attempts to verbally de-escalate, and plans for appropriate monitoring and reassessments
 - Whenever possible, treating physician should not be part of restraint team
 - Use leather restraints for combative patients; soft restraints for patients who are unlikely to be combative or try to elope
 - Supine position if patient needs to be examined; side position if aspiration risk is significant
 - If restraint in prone position is needed, ensure adequate airway is maintained
- Chemical restraint:
 - Offer voluntary PO or IM sedative medication prior to initiating involuntary restraint
 - Avoid PO medications for involuntary restraint due to bite risk
 - Choice of medication should depend on underlying cause; either a benzodiazepine or a neuroleptic or both may be appropriate:
 - If agitation results from delirium or other medical condition, 1st attempt to treat the underlying cause
 - Consider benzodiazepines for hyperadrenergic (including cocaine) state or if there is a contraindication to neuroleptics
 - Consider neuroleptics for most primary medical or psychiatric causes, sedative intoxication, or primary behavioral cause
 - Often used in combination
 - Contraindications to neuroleptics:
 - Knowledge of or suspicion for Parkinson disease, dementia with Lewy bodies or frontotemporal dementia
 - Neuroleptic malignant syndrome, dystonic reaction, or catatonia
 - Prolonged QT
 - Anticholinergic overdose
 - Potential adverse effects:
 - Dystonia: Treat with IM benztropine 1 mg or IM diphenhydramine 50 mg
 - QTc prolongation and/or torsades de pointes (rare)
 - Neuroleptic malignant syndrome (rare): Stop all antipsychotics; begin intensive monitoring and supportive care

MEDICATION

ALERT

- Patients who are elderly, have medical or neurologic illness, or have cognitive impairment are more vulnerable to adverse effects and may respond to lower doses (e.g., haloperidol 0.5 mg)
- If 1st dose of IM haloperidol is ineffective, may be repeated after 30–60 min.
- First line:
 - _ Haloperidol: 5–10 mg IV, IM, or PO
 - _ Lorazepam: 1–2 mg IV, IM, or PO
- Second line:
 - _ Droperidol: 2.5–5 mg IV or IM; watch QTc
 - _ Olanzapine: 5–10 mg IM or PO; if IM, do not give with IM/IV benzodiazepines due to risk of respiratory depression
 - _ Risperidone: 0.5–1 mg PO
 - _ Ziprasidone: 10 mg IM every 2 hr, not to exceed 40 mg IM per day

FOLLOW-UP

DISPOSITION

Admission Criteria

- Medical admission for medical conditions not temporary or reversible in the ED
- Medical admission if further medical workup needed for which ED setting is not optimal
- Psychiatric admission if patient has a treatable psychiatric illness appropriate for inpatient level of care
- Involuntary admission for safety may be necessary according to criteria defined by individual state laws

Discharge Criteria

- Underlying medical or psychiatric causes have been stabilized
- Appropriate follow-up is in place
- Access to weapons has been assessed
- If intoxication played a role in presentation, sober re-evaluation should occur prior to discharge
- Discharge to police custody may be appropriate if no psychiatric or medical issues remain
- If patient elopes, must consider imminent danger to self or others; notify police if risk is high or if safety evaluation not complete
- Duty to warn or protect 3rd parties from risk of harm: “Tarasoff” laws vary among states, so know yours

ADDITIONAL TREATMENT

Issues for Referral

- Psychiatric consultation in the ED can be helpful, especially if primary mental illness suspected
- Other consultation may be indicated based on the underlying etiology

FOLLOW-UP RECOMMENDATIONS

- Patients with psychiatric illness should follow-up with community mental health provider
- Patients who are using substances should be offered counseling and/or detox

PEARLS AND PITFALLS

- Do not assume that patients with violent behavior have only psychiatric problems
- Patients who have been restrained require appropriate monitoring, including regular nursing checks and VS, and labs/ECG if chemical restraints are used
- “Distracting staff” is annoying and may interfere with the care of other patients, but this is not an indication for restraints
- Document need for restraints and renewal of restraints per your hospital’s protocol

VISUAL LOSS

Jason Hoppe

BASICS

DESCRIPTION

- Decrease in visual function (i.e., visual acuity, visual fields, blurry vision)
- Visual loss has many etiologies and can be caused by multiple body systems

ETIOLOGY

- Ophthalmologic:
 - Eyelid or tear film abnormality
 - Anterior segment (cornea, anterior chamber, iris, lens)
 - Posterior segment (vitreous, retina, optic nerve)
 - Posterior to the eye (optic nerve, chiasm, radiations)
- Traumatic:
 - Corneal abrasion
 - Hyphema
 - Lens dislocation
 - Ruptured globe
 - Commotio retinae
 - Retinal detachment
 - Retinal/vitreous hemorrhage
 - Retrobulbar hemorrhage
 - Intraocular foreign body
- Neurologic:
 - Cerebral (cerebrovascular accident [CVA]) or intracranial pathology (mass lesion)
 - Multiple sclerosis
 - Optic neuritis
 - Migraine
- Cardiovascular system:
 - Embolic
 - Thrombotic
 - Ischemic
 - Hypertensive events
- Immunologic system:
 - Uveitis
 - Giant cell arteritis
- Infection:
 - Orbital cellulitis/abscess

- Cavernous sinus thrombosis
- HIV optic neuropathy or cytomegalovirus (CMV) retinitis
- Endocrine:
 - Diabetic retinopathy
 - Thyroid disease may cause diplopia (muscle hypertrophy) or corneal erosions
- Toxic:
 - Methanol (acute severe loss, subacute optic atrophy)
 - Licorice (transient loss, self-limited)
 - Digitalis (flashing lights, color changes)
 - Amiodarone (rare cause of optic neuropathy)

DIAGNOSIS

- Categorize visual loss by the properties associated with the decrease in visual function
- Transient (< 24 hr):
 - Minutes:
 - Transient ischemic attack = amaurosis fugax (unilateral)
 - Vertebrobasilar artery insufficiency (bilateral)
 - Minutes to hours:
 - Migraine
 - Sudden BP changes
- Persistent (> 24 hr):
 - Painless: Sudden:
 - Retinal artery or vein occlusion
 - Vitreous hemorrhage
 - Retinal detachment
 - Optic neuritis
 - Giant cell arteritis
 - Cerebral infarct
 - Painless: Gradual (weeks to years):
 - Cataract
 - Presbyopia
 - Refraction errors
 - Open-angle glaucoma
 - Chronic retinal disease
 - Macular degeneration
 - Diabetic retinopathy
 - CMV retinopathy
 - CNS tumor
 - Painful:
 - Corneal abrasion, ulcer, burn, or foreign body

- Angle-closure glaucoma
- Optic neuritis
- Iritis/uveitis/endophthalmitis
- Keratoconus with hydrops
- Orbital cellulitis/abscess
- Monocular: Pathology anterior to optic chiasm
- Binocular: Pathology posterior to optic chiasm
- Associated with systemic neurologic symptoms of visual field defects:
 - CVA (especially posterior or occipital circulation)
 - Mass lesion (pituitary adenomas, aneurysm, meningioma, other tumors)
- Malingering/hysteria

SIGNS AND SYMPTOMS

History

- Decreased vision:
 - Loss of vision
 - Blurry vision
 - Double vision:
 - Horizontal or vertical
- History of trauma
- Use of corrective lenses:
 - Contacts
 - Glasses
- Prior eye surgery or problems
- Eye pain
- Conjunctival redness or discharge
- New floaters
- Flashing lights
- Pain with eye movement
- Key elements to determine:
 - Acute or gradual onset
 - Length of symptoms
 - Transient vision loss or permanent
 - Binocular or monocular
 - Degree of vision loss
 - Painful or painless
 - Other comorbidities

Physical-Exam

- Ophthalmologic:
 - Visual acuity
 - Pupil exam

- Afferent papillary defect
- Confrontational visual field exam
- Extraocular muscle function
- Slit-lamp exam
- Intraocular pressure (Tonometry)
- Fundoscopy:
 - Optic nerve swelling
 - Pale retina with a cherry-red spot
- Cardiovascular:
 - Murmurs
 - Carotid bruits
 - Temporal artery tenderness
- Neurologic exam:
 - Complete exam for other deficits
 - Optic chiasm and intracerebral lesions
 - Occipital and posterior circulation lesions
- General:
 - Signs of immune, endocrine, or toxic disorders

ESSENTIAL WORKUP

Thorough history and physical exam

DIAGNOSIS TESTS & INTERPRETATION

Lab

- May be obtained to determine extent of other comorbidities in association with vision loss (i.e., diabetes, cardiovascular disease)
- Erythrocyte sedimentation rate if giant cell arteritis is suspected

Imaging

- Tests should be directed toward the suspected etiology of visual loss
- Dilated fundus exam may be performed to assess for posterior segment disease
- Temporal artery biopsy may be obtained if giant cell arteritis is suspected
- Brain CT, MRI, MRA, and transcranial Doppler may be used to evaluate neurologic symptoms and vertebrobasilar artery
- Urgent cardiac and carotid US if a retinal artery occlusion is diagnosed
- Facial CT may be used to evaluate extent of traumatic injuries

DIFFERENTIAL DIAGNOSIS

- Trauma
- Neurologic lesion
- Infectious
- Cardiovascular

- Toxic/metabolic
- Autoimmune

TREATMENT

PRE HOSPITAL

- Chemical burns:
 - Begin copious irrigation with water or saline

ED TREATMENT/PROCEDURES

- Direct therapy toward cause of visual loss
- Ophthalmology consultation for visual loss with an uncertain diagnosis
- 3 conditions for which identification and treatment must begin within minutes:
 - Central retinal artery occlusion
 - Chemical burn
 - Acute angle-closure glaucoma

Central Retinal Artery Occlusion

- Clinical criteria:
 - Unilateral, painless, dramatic vision loss
 - Afferent pupillary defect
 - Pale fundus with a cherry-red spot (macula)
 - Counting fingers to light perception in 94% of patients
- Therapy:
 - Immediate ophthalmology consultation
 - Maneuvers and medications to lower intraocular pressure, allowing the embolus to move to the periphery:
 - Ocular massage: Direct pressure to eye for 5–15 sec then sudden release, repeat for 15 min
 - Acetazolamide: 500 mg IV or PO
 - Topical β -blocker
 - Anterior chamber paracentesis by an ophthalmologist
 - Referral for cardiac and carotid artery workup
 - Rule out giant cell arteritis

Chemical Burn

- Clinical criteria:
 - Alkali worse than acids
 - White eye (vessels have already sloughed) worse than red eye (vessels are intact)
 - Examples: Mace, cements, plasters, solvents
- Therapy:

- Topical anesthetic
- Copious irrigation of the eyes with LR or NS (nonsterile water is acceptable if others not available); minimum of 30 min
- Goal: Neutral pH at 5–10 min after ending irrigation
- Do not try to neutralize acids with alkalis or vice versa
- Evert lids and use moist cotton-tipped applicator to sweep furnaces for residual chemical precipitants
- Dilate with cycloplegic (atropine, cyclopentolate, tropicamide)
- Do not use phenylephrine; vasoconstricts already ischemic conjunctival blood vessels
- Erythromycin ointment q1–2h
- Artificial tears q1h
- Check intraocular pressure

Acute Angle-closure Glaucoma

- Signs and symptoms:
 - Unilateral, painful vision loss
 - Nausea, vomiting, headache
 - Cornea injected, edematous
 - Mid-dilated, sluggish/nonreactive pupil
 - Swollen, “steamy” lens
 - Cell, flare in a shallow anterior chamber
 - Increased intraocular pressure (> 20 mm Hg)
- Therapy:
 - Topical β -blocker
 - Topical prostaglandin analog
 - Acetazolamide
 - Topical α -2 agonist
 - Pilocarpine
 - Mannitol: If no decrease in IOP after 1 hr

MEDICATION

- Antibiotic drops:
 - Ciprofloxacin 0.3%: 1–2 gtt q1–6h
 - Gentamicin 0.3%: 1–2 gtt q4h
 - Ofloxacin 0.3%: 1–2 gtt q1–6h
 - Levofloxacin 0.5%: 1–2 gtt q2h
 - Polymyxin (Polytrim) 1 gtt q3–6h
 - Sulfacetamide 10%, 0.3%: 1–2 gtt q2–6h
 - Tobramycin 0.3%: 1–2 gtt q1–4h
 - Trifluridine 1%: 1 gtt q2–4h
- Antibiotic ointments:
 - Bacitracin 500 U/g 1/2 in ribbon q3–6h

- Ciprofloxacin 0.3%: 1/2 in ribbon q6–q8h
- Erythromycin 0.5%: 1/2 in ribbon q3–6h
- Gentamicin 0.3%: 1/2 in ribbon q3–4h
- Neosporin 1/2 in ribbon q3–4h
- Polysporin 1/2 in ribbon q3–4h
- Sulfacetamide 10%: 1/2 in ribbon q3–8h
- Tobramycin 0.3%: 1/2 in ribbon q3–4h
- Vidarabine 1/2 in ribbon 5 times per day
- Mydriatics and cycloplegics:
 - Atropine 1%, 2%: 1–2 gtt/day to QID
 - Cyclopentolate 0.5%, 1%, 2%: 1–2 gtt PRN
 - Homatropine 2%: 1–2 gtt BID–TID
 - Phenylephrine 0.12%, 2.5%, 10%: 1–2 gtt TID–QID
 - Tropicamide 0.5%, 1%: 1–2 gtt PRN dilation
- Corticosteroid–antibiotic combination drops (with ophthalmology consultation):
 - Prednisolone (Blephamide) 1–2 gtt q1–8h
 - Hydrocortisone/neomycin/bacitracin/polymyxin B (Cortisporin) 1–2 gtt q3–4h
 - Dexamethasone/neomycin/polymyxin B (Maxitrol) 1–2 gtt q1–8h
 - Prednisolone/gentamicin (Pred-G) 1–2 gtt q1–8h
 - Dexamethasone/tobramycin/chlorobutanol (TobraDex) 1–2 gtt q2–26h
- Glaucoma agents (always with ophthalmology consultation):
 - α -2 agonists:
 - Brimonidine 1% 1 gtt TID
 - Apraclonidine 1% 1 gtt TID
 - β -blocker:
 - Betaxolol 0.25%, 0.5%: 1–2 gtt BID
 - Carteolol 1%: 1 gtt BID
 - Levobunolol 0.25%, 0.5%: 1 gtt QD–BID
 - Carbonic anhydrase inhibitor:
 - Acetazolamide 500 mg PO/IV QD–QID
 - Miotic (parasympathomimetic):
 - Pilocarpine 0.25%, 0.5%, 1%, 2%, 3%, 4%, 6%, 8%, 10%: 1–2 gtt TID–QID
 - Osmotic agent:
 - Mannitol 1–2 g/kg IV over 45 min
 - Prostaglandin analog:
 - Latanoprost 0.005%: 1 gtt QD
- Only if mechanical closure is ruled out:
 - Timolol 0.25%, 0.5%: 1 gtt BID

DISPOSITION

Admission Criteria

- Ruptured globe
- Hyphema (depending on severity)
- Orbital cellulitis/abscess
- Cavernous sinus thrombosis
- Significant cardiac, carotid, or neurologic disease
- Unexplained, progressive vision loss

Discharge Criteria

If the diagnosis is certain and visual loss will not progress

FOLLOW-UP RECOMMENDATIONS

- Follow-up should be discussed with ophthalmology for emergent or urgent issues
- Referral for cardiac and carotid workup in embolic disease

PEARLS AND PITFALLS

- Document visual acuity for all eye complaints
- Topical anesthesia will aid in diagnosis as well as facilitating a proper eye exam
- Consider ocular issues and a detailed eye exam with headache complaints

VITREOUS HEMORRHAGE

Kevin F. Maskell, Jr. • Carl G. Skinner

BASICS

DESCRIPTION

Vitreous hemorrhage is a secondary diagnosis; identification of a specific cause is necessary for successful treatment:

- Retinal vessel tear due to vitreous separation
- Sudden tearing of vessels due to trauma
- Spontaneous bleeding due to neovascularization (e.g., diabetics)

ETIOLOGY

- Blunt or penetrating trauma
- Retinal break/tear/detachment
- Any proliferative retinopathy
- Diabetes mellitus
- Sickle cell disease
- Retinal vein occlusion
- Eales disease
- Senile macular degeneration
- Retinal angiomas
- Retinal telangiectasia
- Peripheral uveitis
- Subarachnoid or subdural hemorrhage:
 - Terson Syndrome
- Intraocular tumor

Pediatric Considerations

- Prematurity
- Congenital retinoschisis
- Pars planitis
- Child abuse:
 - Shaken-baby syndrome

DIAGNOSIS

SIGNS AND SYMPTOMS

- Sudden, painless unilateral loss or decrease in vision
- Appearance of dark spots (floaters), cobwebs, or haze in visual axis:
 - Above findings sometimes accompanied by flashing lights; floaters move

with head movements

- Blurred vision, decreased visual acuity
- Loss of red reflex
- Inability to visualize fundus
- Mild afferent papillary defect

History

- Ocular or systemic diseases
- Trauma

Physical-Exam

Fundoscopic exam:

- Absent red reflex
- No view of the fundus
- Acute:
 - RBCs in anterior vitreous
- Chronic:
 - Yellow appearance from hemoglobin breakdown

ESSENTIAL WORKUP

- History with special attention to pre-existing systemic disease and trauma
- Complete ocular exam including:
 - Slit lamp
 - Tonometry
 - Dilated fundoscopic exam

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC
- PT/PTT/INR if indicated
- Electrolytes, BUN, creatinine, glucose

Imaging

- B-scan US when no direct retinal view is possible to rule out retinal detachment or intraocular tumor
- Fluorescein angiography to define the cause
- CT scan/anteroposterior/lateral orbital films to rule out intraocular foreign body

Diagnostic Procedures/Surgery

If nontraumatic, scleral depression

DIFFERENTIAL DIAGNOSIS

- Vitreitis (leukocytes in the vitreous):
 - May include anterior or posterior uveitis
- Retinal detachment without hemorrhage
- Central retinal venous occlusion (CRVO)
- Central retinal artery occlusion (CRVA)

TREATMENT

PRE HOSPITAL

Protect the eye from trauma or pressure:

- Monitor BP

INITIAL STABILIZATION/THERAPY

- Bed rest with head of bed elevated
- No activity resembling Valsalva maneuver (lifting, stooping, or heavy exertion)
- Avoid NSAIDs and other anticlotting agents.

ED TREATMENT/PROCEDURES

- Urgent ophthalmologic consultation within 24–48 hr is needed with treatment based on the cause of the hemorrhage; an exam is carried out by the consultant:
 - Laser photocoagulation or cryotherapy for proliferative retinal vascular diseases
 - Repair of retinal detachments
- Surgical vitrectomy is needed for:
 - Blood that does not clear with time
 - VH from retinal detachment
 - Associated neovascularization
 - Hemolytic or ghost-cell glaucoma

FOLLOW-UP

DISPOSITION

Admission Criteria

Retinal break or detachment

Discharge Criteria

Retinal break or retinal detachment must be excluded as cause of hemorrhage.

FOLLOW-UP RECOMMENDATIONS

Re-evaluation daily for 2–3 days; if etiology is still unknown, B-scan US every 1–3 wk.

PEARLS AND PITFALLS

- Be sure to consider alternate diagnoses of CRVO or CRAO.
- Consider retinal detachment.
- Get history of trauma and use of blood thinners.
- Even minor bleeds require urgent ophthalmology consultation.

VOLVULUS

Ronald E. Kim

BASICS

DESCRIPTION

- Axial twist of a portion of the GI tract around its mesentery causing partial or complete obstruction of the bowel
- Often associated with other GI abnormalities
- In pediatric setting, infants typically involved:
 - Abnormal embryonic development
- Can be precipitated by pathologic distention of the colon
- Blood supply may be compromised by venous congestion and eventual arterial inflow obstruction, leading to gangrene of the bowel and potential infarction

ETIOLOGY

- 3rd most common cause of colonic obstruction (10–15%) following tumor and diverticular disease
- Epidemiology:
 - 0–1 yo: 30%
 - 1–18 yo: 20%
 - Over 18 yo: 50%
- Often associated with other GI abnormalities
- Cecum (52%):
 - More common in young adults, < 50 yr old
 - Due to improper congenital fusion of the mesentery with the posterior parietal peritoneum, causing the cecum to be freely mobile in varying degrees
 - Associated with increased gas production (malabsorption and pseudo-obstruction)
 - Can be seen in pregnancy and after colonoscopy
- Sigmoid (43%):
 - More common in:
 - Elderly
 - Institutionalized
 - Chronic bowel motility disorders (Parkinson)
 - Psychiatric diseases (schizophrenia)
 - Due to redundant sigmoid colon with narrow mesenteric attachment
 - Associated with chronic constipation and concomitant laxative use
- Transverse colon and splenic flexure (5%)
- Gastric volvulus (rare) associated with diaphragmatic defects

Pediatric Considerations

- Midgut volvulus:
 - Due to congenital *malrotation* in which the midgut fails to rotate properly in utero as it enters the abdomen
 - Entire midgut from the descending duodenum to the transverse colon rotates around its mesenteric stalk, including the superior mesenteric artery
 - Common in neonates (80% < 1 mo old, often in 1st week; 6–20% > 1 yr old)
 - Males > females, 2:1
 - Sudden onset of bilious emesis (97%) with abdominal pain
 - May have previous episodes of feeding problems/bilious emesis
 - In children > 1 yr old, associated with failure to thrive, alleged intolerance to feedings, chronic intermittent vomiting, bloody diarrhea
 - Constipation
 - Mild distention, since obstruction higher in GI tract
 - May not appear toxic based on degree of ischemia

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Infants: Vomiting in 90%:
 - May be bilious
- Older children and adults: Variable and often insidious:
 - 80% with chronic symptoms; weeks to months to years
- Bowel obstruction secondary to volvulus:
 - Colicky, cramping abdominal pain (90%)
 - Abdominal distention (80%)
 - Obstipation (60%)
 - Nausea and vomiting (28%)
- Cecal volvulus:
 - Highly variable; intermittent episodes to sudden onset of pain and distention
- Sigmoid volvulus:
 - Vomiting uncommon
 - More insidious onset
 - Abdominal pain/distention, nausea, and constipation
- Gastric volvulus:
 - Triad of Borchardt: Severe epigastric distension, intractable retching, inability to pass nasogastric tube (30% of patients)

Physical-Exam

- Presence of gangrenous bowel:
 - Increased pain
 - Peritoneal signs: Guarding, rebound, and rigidity
 - Fever
 - Blood on digital rectal exam
 - Tachycardia and hypovolemia
- Cecal volvulus:
 - Distended abdomen
 - Often a palpable mass in the left upper quadrant/midabdomen

Pediatric Considerations

- Child will appear well with normal exam early in clinical course
- 70% present with chronic symptoms
- 40% of neonates with bilious vomiting will require a surgical intervention
- Hematochezia, abdominal distention or pain, and shock indicate ischemia/necrosis

ESSENTIAL WORKUP

- CBC, BMP, UA
- Plain abdominal radiograph
- Upper GI series (best initial exam for children)
- CT abdomen/pelvis with IV contrast (optimal for adults)
- Barium enema
- US

DIAGNOSIS TESTS & INTERPRETATION

Lab

- May give clues as to the presence of gangrenous bowel, but normal lab values do not exclude the diagnosis
- CBC:
 - Leukocytosis (WBC > 20,000) suggests strangulation with infection/peritonitis.
- Electrolytes, BUN, creatinine, glucose:
 - Anion gap acidosis due to lactic acidosis
 - Prerenal azotemia due to dehydration
- Urinalysis:
 - Elevated specific gravity and ketones

Imaging

- Plain abdominal radiograph:
 - Suggestive but often inconclusive
 - Diagnostic finding present in < 70% of cases

- Sigmoid volvulus: Inverted U-shaped loop of dilated colon arising from the pelvis
- Cecal volvulus—dilated and displaced:
 - Cecum in the left abdomen (kidney shaped), often with dilated loops of small bowel
- CT scan:
 - “Whirl” sign in cecal volvulus
 - May be useful in sigmoid volvulus to determine extent of obstruction
- Upper GI series (best for duodenum, but operator dependent):
 - Abrupt ending or corkscrew tapering of contrast seen (75%)
 - Subtle findings (25%)
- Barium enema:
 - “Bird’s beak” deformity at the site of torsion
 - Perform cautiously because of perforation risk
 - Beware of false positives with infants who normally have inadequately fixed cecums
- US (specific but not sensitive):
 - Abnormal position of the superior mesenteric vein (anterior or left of SMA)
 - “Whirlpool” sign of volvulus: Vessels twirled around the base of the mesentery
 - 3rd part of duodenum not in normal retromesenteric position (between mesenteric artery and aorta)

Pediatric Considerations

- Diagnosis of midgut volvulus:
 - Duodenum lies entirely to the right of the spine on plain films
 - “Double-bubble” sign on an upright film due to distended stomach and proximal duodenal loop
 - Established by upper GI swallow: Coiled spring/corkscrew appearance of jejunum in the right upper quadrant
 - Plain x-ray normal or equivocal in 20% of cases

ALERT

- Evaluate any child with signs/symptoms of obstruction (including bilious vomiting and abdominal pain) for malrotation, even if he or she appears nontoxic
- Delay in diagnosis > 1–2 hr results in gangrenous bowel, necessitating large resection and leading to permanent parenteral nutrition with its associated complications

Diagnostic Procedures/Surgery

- Laparoscopy:
 - Useful when diagnostic imaging equivocal
 - Can differentiate congenital malrotation from volvulus

DIFFERENTIAL DIAGNOSIS

- Obstruction due to colonic tumor or diverticulitis
- Small bowel obstruction
- Ileus
- Intussusception
- Appendicitis
- Pelvic inflammatory disease and salpingitis, especially for cecal volvuli
- Ovarian torsion
- Perforated viscus
- Cyclic vomiting syndrome

Pediatric Considerations

- Meconium ileus
- Hirschsprung disease
- Duodenal atresia
- Meckel diverticulum
- Necrotizing enterocolitis (especially premature infants)
- Intussusception
- Appendicitis
- Medical conditions:
 - Colic
 - Henoch–Schönlein purpura
 - Inborn errors of metabolism
 - Trauma
 - Gastroesophageal reflux
 - Pyelonephritis
 - Meningitis

TREATMENT

PRE HOSPITAL

- Establish IV assess
- NPO

INITIAL STABILIZATION/THERAPY

- ABCs
- Aggressive fluid resuscitation with 0.9% NS bolus of 20 mL/kg (peds) or 2 L bolus (adult)
- NGT

ED TREATMENT/PROCEDURES

- Obtain surgical and/or GI consultation

- NPO
- Correct hypovolemia and electrolyte abnormalities
- Preoperative broad-spectrum antibiotics if suspected sepsis or perforation

Definitive Therapy

Sigmoid Volvulus

- Nontoxic patient:
 - Reduce volvulus nonoperatively with sigmoidoscopy:
 - 80–95% successful
 - 60% recurrence (within hours to weeks)
 - Follow with elective sigmoid resection and primary anastomosis (< 3% recurrence)
- Toxic patient:
 - Emergent resection of sigmoid and any gangrenous bowel, with placement of end colostomy
- Endoscopic decompression with rectal tube placement:
 - Successful in 78% of patients with sigmoid volvulus; less effective for cecal volvulus
 - Recurrence is common
 - Elective surgical treatment after endoscopic detorsion

Cecal Volvulus

- Emergent operative reduction followed by colectomy and primary anastomosis (preferred), or cecopexy if the cecum is still viable (higher recurrence)

Pediatric Considerations

- Laparotomy within 1–2 hr to reduce risk for ischemia
- Surgical detorsion of bowel with resection of gangrenous bowel and a Ladd procedure is performed to prevent recurrent volvulus

MEDICATION

- Ampicillin sulbactam (Unasyn): 3 g (peds: 100–200 mg/kg/24 h) IV q6h
- Cefoxitin (Mefoxin): 2 g (peds: 80–160 mg/kg/24 h) IV q6h
- Ceftriaxone 1–2 g IV q12–24h (peds: 50–75 mg/kg/d q12–24h) AND metronidazole 500 mg IV q8h (peds: 30 mg/kg/24 h q6h)
- Piperacillin–tazobactam 3.375–4 g IV q4–6h (peds: 200–300 mg/kg/d of piperacillin component q6–8h)

FOLLOW-UP

DISPOSITION

Admission Criteria

Admit with a surgical consult all suspected of having a volvulus.

Discharge Criteria

None

Issues for Referral

- Surgical consultation necessary
- Atypical malrotation: Asymptomatic or symptoms of gastroesophageal reflux:
 - _ Close observation with repeat contrast study
 - _ Defer surgery

FOLLOW-UP RECOMMENDATIONS

Surgical follow-up postoperatively

PEARLS AND PITFALLS

- Consider volvulus in any child < 1 mo old presenting with vomiting:
 - _ Bilious vomiting is due to mechanical intestinal obstruction until proven otherwise
- Delayed diagnosis leads to increased morbidity, more often with adults than children:
 - _ 70% adults not diagnosed until > 6 mo from initial presentation; most present with chronic abdominal symptoms
 - _ If gangrene present, mortality = 25–80%
- Operative repair for all adult patients
- Upper GI contrast series is the best initial test for children
- CT abdomen/pelvis is preferable for adults

VOMITING, ADULT

Scott G. Weiner

BASICS

DESCRIPTION

- 3 phases:
 - Nausea: Unpleasant sensation prior to vomiting
 - Retching: Rhythmic contractions of diaphragm, abdominal muscles, intercostals that bring gastric contents up the esophagus
 - Vomiting: Forceful retrograde expulsion of gastric contents through the mouth
- Vomiting center in medulla coordinates vomiting through vagus, phrenic, spinal nerves
- Irritated by impulses from the GI tract, pharynx, vestibular system, heart, genitalia, or via stimulation of chemoreceptor trigger zone (CTZ) in the area postrema of the brain by medications, toxins, or hormones in circulation
- CTZ response mediated by dopamine D₂, serotonin (5-HT₃), cholinergic, and histamine receptors:
 - Medications providing symptomatic treatment of vomiting antagonize these receptors

ETIOLOGY

- GI:
 - Appendicitis
 - Boerhaave syndrome
 - Bowel obstruction or ischemia
 - Cholecystitis, biliary colic
 - Gastric outlet obstruction, gastroparesis
 - Gastritis
 - Gastroenteritis (e.g., infectious)
 - GI bleeding
 - Hepatitis
 - Inflammatory bowel disease
 - Pancreatitis
 - Peptic ulcer disease, dyspepsia
 - Perforated viscus
 - Peritonitis
- Neurologic:
 - Elevated intracranial pressure (ICP)
 - Intracranial blood

- Labyrinthitis, vertigo
- Meningitis
- Migraine
- Stroke
- Tumor
- Endocrine:
 - Adrenal insufficiency
 - Diabetic ketoacidosis (DKA)
 - Hypoparathyroid, hyperparathyroid
 - Hypothyroid, hyperthyroid
 - Uremia
- Pregnancy:
 - Hyperemesis gravidarum
 - Nausea/vomiting of pregnancy
- Drug toxicity:
 - Acetaminophen
 - Aspirin
 - Digoxin
 - Theophylline
- Therapeutic medication use:
 - Antibiotics
 - Aspirin
 - Chemotherapy
 - Ibuprofen
- Drugs of abuse:
 - Narcotics/narcotic withdrawal
 - Alcohols
- Genitourinary:
 - Gonadal torsion
 - Nephrolithiasis
 - UTI/pyelonephritis
- Miscellaneous:
 - Carbon monoxide or organophosphate poisoning
 - Electrolyte disorders
 - Glaucoma
 - Motion sickness
 - Myocardial infarction/ischemia (MI)
 - Pain
 - Post-procedural (after anesthesia)
 - Self-induced (eating disorders)
 - Sepsis/shock

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Symptom duration, frequency, severity:
 - Acute, recurrent, chronic, cyclic
- Characteristics of vomiting: Timing, description, content of vomitus
- Associated symptoms: Pain, fever, diarrhea, neurologic
- Past surgical or GI history
- Medication and drugs use
- Last menstrual period
- Complete past medical history

Physical-Exam

- Vital signs:
 - Fever: Appendicitis, gastroenteritis, cholecystitis, hepatitis, bowel perforation
 - Tachycardia: Dehydration
- Head, ears, eyes, nose, throat:
 - Abnormal anterior chamber: Glaucoma
 - Dry mucous membranes: Dehydration
 - Nystagmus: Labyrinthitis, stroke, tumor, intracranial hemorrhage
 - Papilledema: Elevated ICP
- Abdomen:
 - Blood in stool or emesis: Peptic ulcer, Mallory–Weiss tear
 - Decreased bowel sounds: Ileus
 - Distention, high-pitched bowel sounds, scars or hernias: Intestinal obstruction
 - Pain: Appendicitis, cholecystitis, pancreatitis, perforated viscus, ovarian torsion
 - Testicular pain: Torsion
- Neurologic:
 - Abnormal mental status, cerebellar test abnormalities, cranial nerve abnormalities: CNS pathology

ESSENTIAL WORKUP

The workup is aimed at determining the underlying cause of vomiting and excluding dangerous sequelae

DIAGNOSIS TESTS & NTERPRETATION

Lab

- **CBC:**
 - Elevated WBC: Infectious process (e.g., appendicitis, gastroenteritis)
 - Elevated hematocrit: Dehydration
 - Decreased hematocrit: GI bleed from ulcer
- **Electrolytes/renal function:**
 - Prolonged vomiting may cause hyponatremia, hypokalemia.
 - BUN/creatinine ratio > 20 may indicate dehydration.
 - Renal insult may occur from dehydration
- **Liver/pancreatic function tests:**
 - Amylase/lipase elevation: Pancreatitis
 - AST/ALT elevation: Hepatitis
 - Alkaline phosphatase elevation: Cholecystic etiology
- **Urine analysis:**
 - WBC, nitrites, leukocyte esterase, bacteria: UTI
 - Ketones: Dehydration, DKA
 - Pregnancy test in women of childbearing age
- **Toxicology screen/drug levels:**
 - For suspected drug toxicity or overdose

Imaging

- **Abdominal series (kidney, ureter, bladder/upright):**
 - Suspected bowel obstruction or perforated viscus
- **CT abdomen/pelvis:**
 - Suspected appendicitis, obstruction, nephrolithiasis
- **CT/MRI head:**
 - Suspected intracranial etiology
- **US:**
 - Suspected biliary disease, gonadal torsion, nephrolithiasis

Diagnostic Procedures/Surgery

- **EKG:**
 - Suspected MI
- **Endoscopy:**
 - Peptic ulcer disease leading to significant GI bleed

TREATMENT

PRE HOSPITAL

- Aimed at stabilizing patient until arrival in the ED, where the workup of underlying cause of vomiting can proceed
- Placement of IV, oxygen, cardiac monitor

- Begin administration of isotonic fluids in suspected dehydration
- Fingerstick glucose in mental status change
- Specific protocols may permit antiemetics for motion sickness or other etiologies of vomiting

INITIAL STABILIZATION/THERAPY

- Address ABCs
- Urgent fluid resuscitation if vomiting has led to hypovolemic shock
- Urgent antiemetic therapy for patient comfort
- Urgent analgesic therapy if indicated

ED TREATMENT/PROCEDURES

- 3 principles of ED treatment:
 - Correct fluid, electrolyte, and nutritional deficiencies as a result of vomiting
 - Identify and treat underlying cause
 - Suppress or eliminate symptoms.
- Antibiotics if indicated: UTI, appendicitis, bacterial gastroenteritis
- Medications:
 - Serotonin antagonists often 1st line treatment:
 - Ondansetron, dolasetron, granisetron
 - Useful in chemotherapy-induced nausea
 - Ondansetron available as an oral dissolving tablet for patients who cannot tolerate pills
 - Can cause QT prolongation
 - Dopamine D₂ antagonists also useful in most types of nausea:
 - Prochlorperazine, promethazine, metoclopramide, droperidol
 - Side effects (e.g., akathisia, dystonia) more common than in serotonin antagonists
 - Note black box warnings on use of droperidol (potential QT prolongation and/or torsades de pointes) and promethazine (tissue injury with IV administration)
 - Anticholinergic and antihistamine agents useful in labyrinthitis, positional vertigo, and motion sickness:
 - Meclizine, diphenhydramine, scopolamine
 - Benzodiazepines and glucocorticoids have mild antiemetic properties and can be used as adjuncts
- Consultation with other specialties (e.g., surgery, gynecology, gastroenterology) depending on underlying etiology

MEDICATION

- Diphenhydramine: 25–50 mg IM/IV/PO
- Dolasetron: 12.5 mg IV
- Droperidol: 0.625–1.25 mg IM/IV

- Granisetron: 1 mg IV or 2 mg PO
- Hydroxyzine: 25–100 mg IM
- Meclizine: 25–50 mg PO
- Metoclopramide: 10 mg IM/IV/PO
- Ondansetron: 4–8 mg IM/IV/PO
- Prochlorperazine: 5–10 mg IM/IV/PO or 25 mg PR
- Promethazine: 12.5–25 mg PO/PR/deep IM
- Scopolamine: 1.5 mg patch applied behind the ear 4 hr prior to travel

Geriatric Considerations

- Dopamine-antagonizing antiemetics have potential cardiac side effects:
 - The doses of these medications should be reduced in the elderly
- Serotonin antagonists are safer in this population:
 - Still consider using lower doses and obtaining an EKG to detect QT prolongation prior to administration

Pediatric Considerations

- Vomiting in children can result from a host of other diagnoses, e.g., structural/anatomical disorders, infections, and metabolic disorders:
 - Workup and treatment may therefore be different in children

Pregnancy Considerations

- Vomiting occurs in >25% of pregnancies
- Dopamine D₂ antagonists (e.g., promethazine, chlorpromazine, metoclopramide) or serotonin antagonists (e.g., ondansetron, granisetron) most commonly used

First Line

- Serotonin antagonists
- Dopamine D₂ antagonists

Second Line

- Anticholinergics
- Antihistamines
- Benzodiazepines
- Glucocorticoids

FOLLOW-UP

DISPOSITION

Admission Criteria

- Depends on underlying pathology
- Significant underlying disease or symptoms necessitating close observation or surgical procedure
- Uncontrolled emesis resulting in inability to tolerate food or liquids by mouth
- Severe dehydration requiring continued IV fluids
- Significant electrolyte disturbances
- Unknown etiology of vomiting with inadequate outpatient follow-up

Discharge Criteria

- Significant underlying pathology is excluded
- Patient is sufficiently hydrated
- Emesis is controlled
- Close follow-up is arranged (preferably within 24–36 hr)

FOLLOW-UP RECOMMENDATIONS

- All patients who are unable to tolerate fluids at home should return to the ED
- Patients in whom the etiology of vomiting is unknown or who had electrolyte disturbances should follow-up

PEARLS AND PITFALLS

- Vomiting is a symptom and not a diagnosis:
 - It is important to be familiar with the broad differential diagnoses and exclude dangerous etiologies
- Many antiemetics have notable side effects, ranging from dystonia to cardiac arrhythmias.
 - Know contraindications and treatment of adverse reactions before using these agents
- Oral dissolving tablets and suppositories useful to avoid IV and for home care

CODES

ICD9

- 643.00 Mild hyperemesis gravidarum, unspecified as to episode of care or not applicable
- 787.01 Nausea with vomiting
- 787.03 Vomiting alone

ICD10

- O21.0 Mild hyperemesis gravidarum
- R11.10 Vomiting, unspecified
- R11.2 Nausea with vomiting, unspecified

VOMITING, CYCLIC

Rosaura Fernández

BASICS

DESCRIPTION

- A chronic, idiopathic disorder characterized by recurrent, discrete episodes of disabling nausea and vomiting separated by symptom-free intervals lasting a few days to months
- Adult population – average age of diagnosis is 31:
 - Average age of onset is 21
- Pediatric population – average age of diagnosis is 5
- General characteristics:
 - Phase 1: Interepisodic phase:
 - Symptom free
 - Phase 2: Prodrome:
 - Varying intensity of nausea and diaphoresis
 - Phase 3: Emetic phase:
 - Intense nausea/vomiting/retching/dry heaving up to 7 days
 - Phase 4: Recovery phase:
 - Improvement of nausea and tolerance of PO intake

EPIDEMIOLOGY

Incidence and Prevalence Estimates

- True incidence and prevalence in adult general population unknown due to limited data and research, increasing recognition in syndrome
- In pediatric population, cyclic vomiting syndrome affects 0.04–2% of population with estimated new cases 3/100,000 annually

ETIOLOGY

- Etiology unknown
- Pathophysiology is also unknown and is under research:
 - Limited research suggests multifactorial factors such as autonomic, central, and environmental to be involved

DIAGNOSIS

SIGNS AND SYMPTOMS

Commonly present to ED with unexplained onset of nausea/vomiting and abdominal pain.

History

- History of similar prior episodes
- No preceding trigger identified at times but typically when asked specifically may identify
- Will complain of abdominal pain, usually epigastric

Physical-Exam

May have benign physical exam or various findings based on degree of dehydration:

- Normal vital signs or abnormal vital signs demonstrating:
 - Tachycardia
 - Hypotension (including orthostatic hypotension)
 - Tachypnea
- Cool extremities and/or delayed (> 2 s) capillary refill indicating shock
- Varying degrees of consciousness:
 - Alert, lethargic, or obtunded
- Dry mucous membranes:
 - Sunken eyes
 - Dry/sticky or cracked mouth
- Poor skin turgor
- Oliguria or anuria

Pediatric Considerations

May present with above in addition to refusal to eat/drink, reduced or lack of tear production, sunken fontanel, reduced or absent urine output (reduced wet diapers)

ESSENTIAL WORKUP

Must rule out other potentially serious conditions (see Differential Diagnosis)

DIAGNOSIS TESTS & INTERPRETATION

- Perform necessary exam and lab or radiographic tests necessary to rule out other conditions with similar presenting signs and symptoms
- Cyclic vomiting has no specific diagnostic feature nor specific biochemical marker
- Extensive list of other diagnostic possibilities
- Diagnosis of adult cyclic vomiting is based on Rome III criteria:
 - Stereotypical episodes of vomiting regarding onset (acute) and duration (< 1 wk)
 - At least 3 episodes in the past year
 - Absence of nausea/vomiting between episodes

Lab

- CBC
- Electrolytes, BUN/Cr, glucose
- Liver enzyme, liver profile

- Lipase
- Lactate
- Urinalysis
- Pregnancy test
- Toxicology screen/drug levels:
 - Acetaminophen
 - Salicylic acid
 - Alcohols:
 - Ethanol, isopropanol, methanol, ethylene glycol
 - Digoxin

Imaging

Atypical severity or atypical episodes should raise suspicion of underlying disorder not due to cyclic vomiting:

- Tailor imaging to individual patient presentation

Diagnostic Procedures/Surgery

Outpatient gastric emptying study should be done to r/o gastroparesis or other gut motility disorders as cause of frequent emesis.

DIFFERENTIAL DIAGNOSIS

- Infectious:
 - Appendicitis
 - Pyelonephritis
 - Pneumonia
 - Cholecystitis
- Metabolic/endocrine:
 - Renal failure/uremia
 - Electrolyte disorder
 - Diabetic ketoacidosis
 - Thyroid disorder
 - Adrenal insufficiency
 - Pheochromocytoma
 - Pregnancy or hyperemesis gravidarum
- Renal:
 - Nephroureterolithiasis
 - UVJ obstruction/hydronephrosis
- GI:
 - Gastroparesis
 - Bowel obstruction
 - Peptic ulcer disease
 - Cholelithiasis
 - Pancreatitis

- Malrotation with volvulus
- Inflammatory bowel disease
- CNS:
 - Intracranial hemorrhage
 - Brain tumor
 - Hydrocephalus
 - CVA
- Cardiovascular:
 - Anginal equivalent
 - STEMI/NSTEMI
- Toxicology (examples):
 - Cannabinoid hyperemesis
 - Mushroom toxicity:
 - >100 species
 - Acute alcohol/toxic alcohol ingestion:
 - Ethanol, isopropanol, methanol, ethylene glycol
 - Alcohol withdrawal
 - Heroin withdrawal
 - Any acute/subacute ingestion; consider:
 - Acetaminophen
 - Salicylic acid
 - Digoxin
- Psychiatric:
 - Self induced
 - Bulimia
 - Anorexia
 - Anxiety

Pediatric Considerations

Munchausen by proxy

TREATMENT

PRE HOSPITAL

- Address airway/breathing/circulation
- Initiate IV, oxygen (if indicated), place on cardiac monitor
- Start IV fluids if presenting with vomiting and/or abnormal vital signs

INITIAL STABILIZATION/THERAPY

- Address airway/breathing/circulation
- Continue IV/O₂ (as indicated), cardiac monitor
- Address abnormal vital signs specifically hypotension and tachycardia:

- Adults: 500 to 1000 mL bolus 0.9% NS
- Pediatric: 20 mL/kg bolus 0.9% NS

ED TREATMENT/PROCEDURES

- Supportive care in acute phase
- Abort emetic phase of nausea/vomiting with antiemetics
- IV 0.9 normal saline:
 - Add dextrose after initial boluses
- Correct electrolyte abnormalities
- Treat pain with analgesics
- Provide light sedation for very symptomatic patients
- Administer gastric acid suppressants:
 - H₂ receptor antagonist
 - Proton pump inhibitors
- Consider antimigraine triptans

MEDICATION

Antiemetics

- Ondansetron 4–8 mg IV/PO/ODT q4–8h prn
- Metoclopramide 10 mg IV/IM q2–3h prn 4–8 mg IV/PO/ODT q4–8h prn
- Prochlorperazine 5–10 mg IV/PO/IM (peds: 0.1 mg/kg/dose PO/IM/PR) q6–8h prn
- Promethazine 12.5/25 mg PO/IM/PR q4–6h (IV use common but not approved) (peds: 0.25–1 mg/kg PO/IM/PR q4–6h prn if > 2 yr)

Pain/Sedation

- Ketorolac 15–30 mg IV
- Lorazepam 0.5–1 mg IV/IM/PO
- Morphine 0.1 mg/kg IV
- Sumatriptan 4–6 mg SC-repeat in 1 hr prn

Gastric Acid Suppressants

- Cimetidine (H₂-blocker): 800 mg PO at bedtime nightly (peds: 20–40 mg/kg/24 h)
- Famotidine 20 mg IV q12h
- Pantoprazole 40 mg IV q24h
- Ranitidine 50 mg IV/IM q8h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Vital signs/lab or physical exam findings suggestive of moderate to severe dehydration
- Inability to tolerate PO fluids

Discharge Criteria

- Stable vital signs
- Cessation of vomiting and pain control
- Able to tolerate PO fluids and keep self hydrated

Issues for Referral

- GI consult for further outpatient workup when symptom free
- Consider additional referral to specialist managing this syndrome

FOLLOW-UP RECOMMENDATIONS

- Prophylaxis:
 - Identification and avoidance of triggers:
 - Emotional stress, poor sleep, fasting, illness, marijuana, specific foods (chocolate, cheeses, etc.)
 - Management of coexisting conditions:
 - Migraine headaches, psychiatric disorders, chronic narcotic, and marijuana use
 - Medications (outpatient-in active research):
 - Tricyclic antidepressants (amitriptyline)
 - Propranolol
 - Coenzyme Q-10
 - Antihistamines
 - Antianxiety medications

PEARLS AND PITFALLS

- Obtain good history about prior cyclic episodes and similarities to prior episodes
- Manage active coexisting conditions if applicable
- Exclude other disorders with similar presentations of nausea/vomiting/abdominal pain

CODES

ICD9

- 346.20 Variants of migraine, not elsewhere classified, without mention of intractable migraine without mention of status migrainosus
- 346.21 Variants of migraine, not elsewhere classified, with intractable migraine, so stated, without mention of status migrainosus
- 536.2 Persistent vomiting

ICD10

- G43.A Cyclical vomiting
- G43.A0 Cyclical vomiting, not intractable
- G43.A1 Cyclical vomiting, intractable

VOMITING, PEDIATRIC

Christina M. Conrad

BASICS

DESCRIPTION

- Forceful, coordinated act of expelling gastric contents through the mouth; characterized by nausea, retching, and emesis; no gastric contents are expelled during retching.
- Emesis results from sustained contraction of abdominal muscles and diaphragm; at the same time, the pylorus and antrum contract.

ETIOLOGY

Mechanism:

- GI/mechanical: Gastroesophageal reflux (GER), meconium ileus, necrotizing enterocolitis, hypertrophic pyloric stenosis, intussusception, malrotation with midgut volvulus, Hirschsprung disease, congenital obstructions (atresias, stenoses, and webs), hernia, foreign body/bezoar, pancreatitis, appendicitis, paralytic ileus
- Metabolic/endocrine: Inborn errors of metabolism (amino acidurias, fatty acid oxidation disorders, urea cycle defects), uremia, diabetic ketoacidosis, congenital adrenal hyperplasia, kernicterus
- Neurologic: CNS bleeding (often due to trauma), tumor, hydrocephalus
- Infectious: Otitis media, UTI, pneumonia, sepsis, gastroenteritis, meningitis/encephalitis
- Feeding problems: Chalasias, improper technique (overfeeding, improper position), milk allergy
- Other: Toxicologic, nonaccidental trauma, pregnancy

DIAGNOSIS

SIGNS AND SYMPTOMS

- General:
 - Appearance variable depending on the underlying cause
 - Signs of dehydration, including tachycardia, tachypnea, pallor, decreased perfusion, and shock
 - Altered mental status may occur secondary to shock, hypoglycemia, or extra-abdominal conditions (sepsis, inborn error of metabolism, increased intracranial pressure, toxicologic poisoning).
- Vomiting characteristics:
 - Assess color, composition, onset, progression, and relationship to intake and position.

- Nonbilious emesis is caused by a lesion proximal to the pylorus.
- Bilious (green) emesis indicates obstruction below the duodenal ampulla of Vater; in infants, bilious emesis is associated with a more serious underlying condition (malrotation, volvulus, intussusception, bowel obstruction); may also be due to adynamic ileus or sepsis.
- Bloody emesis (hematemesis) involves a lesion proximal to the ligament of Treitz; bright red bloody emesis has little or no contact with gastric juices due to an active bleeding site at or above cardia.
- “Coffee-grounds” emesis results from reduction of heme by gastric secretions.
- Feculent odor suggests lower obstruction or peritonitis.
- Undigested food in emesis suggests an esophageal lesion or one at or above the cardia.
- GER: Begins shortly after birth, remains relatively constant, usually with normal weight gain.
- Hypertrophic pyloric stenosis: Begins insidiously at 2–6 wk of age and progresses, becoming increasingly forceful (projectile) after feedings.
- Obstruction and/or ischemic bowel (malrotation with midgut volvulus, intussusception, necrotizing enterocolitis): Sudden onset associated with rapid progression to appearing ill out of proportion to the duration of illness; abdomen distended and tender.
- Abdominal:
 - Distention suggests obstruction.
 - Peritoneal signs suggest inflammation and possible perforation.
- Complications:
 - Aspiration
 - Mallory–Weiss tear
 - Boerhaave syndrome

History

- Constitutional:
 - Fever
- Vomiting characteristics:
 - Timing, duration
 - Bilious?
 - Bloody?
- Associated symptoms:
 - Diarrhea
 - Anorexia
 - Abdominal pain
 - Dysuria
 - Inguinal swelling
- PMHx:

- History of similar
- Past surgical history

Physical-Exam

- General:
 - General appearance, vital signs, hydration status
- Cardiovascular:
 - Quality heart tones
 - Pulses, perfusion
- Abdominal:
 - Tenderness, distention, mass
 - Bowel sounds
- Genitourinary:
 - Scrotal swelling, tenderness, mass
- Rectal:
 - Presence of blood, mass, tenderness

ESSENTIAL WORKUP

Exclude life-threatening causes of vomiting.

DIAGNOSIS TESTS & NTERPRETATION

Lab

- As indicated by history and physical exam and consideration of differential:
 - Metabolic assessment (glucose, electrolytes)
 - Infection assessment (CBC, culture—urine)
 - Pregnancy tests for females of childbearing age

Imaging

- As indicated by differential considerations
- Abdominal radiographs (flat plate, upright, and decubitus) helpful for evaluation of obstruction or perforation
- Pelvic and abdominal US for evaluation of hypertrophic pyloric stenosis, intussusception, appendicitis as well as pelvic or scrotal pathology
- Abdominal CT scan helpful for evaluation of appendicitis, mass/tumor often requiring contrast

Diagnostic Procedures/Surgery

Nasogastric tube:

- Location, character, and severity of gastric bleeding

DIFFERENTIAL DIAGNOSIS

- Neonate/infant:

- GI/mechanical: GER, meconium ileus, necrotizing enterocolitis, hypertrophic pyloric stenosis, intussusception, malrotation with midgut volvulus, Hirschsprung disease, congenital obstructions (atresias, duplications, imperforate anus. stenoses, and webs), hernia, foreign body/bezoar, paralytic ileus
- Metabolic/endocrine: Inborn errors of metabolism (amino acidurias, fatty acid oxidation disorders, urea cycle defects), uremia, congenital adrenal hyperplasia, kernicterus
- Neurologic: CNS bleeding (often due to trauma), tumor, hydrocephalus
- Infectious: Otitis media, UTI, pneumonia, sepsis, pertussis, meningitis/encephalitis
- Feeding problems: Chhalasia, improper technique (overfeeding, improper position), milk allergy
- Other: Toxicologic, nonaccidental trauma
- Child/adolescent:
 - GI: Gastroenteritis, obstruction (hernia, adhesions, intussusception, foreign body, bezoar), pancreatitis, appendicitis, peptic ulcer, peritonitis, paralytic ileus, trauma (duodenal hematoma)
 - Metabolic/endocrine: Diabetic ketoacidosis, uremia, adrenal insufficiency
 - Infectious: Gastroenteritis, UTI, sinusitis, upper respiratory infection, sepsis, meningitis, encephalitis, pneumonia, hepatitis
 - Neurologic: CNS mass/tumor, CNS bleeding (often due to trauma), cerebral edema, concussion, migraine
 - Other: Toxicologic, (nonaccidental) trauma, pregnancy, bulimia

TREATMENT

PRE HOSPITAL

Not applicable

INITIAL STABILIZATION/THERAPY

- Fluid resuscitation with 0.9% NS IV; caution if concern about increased intracranial pressure.
- Determine bedside fingerstick glucose.

ED TREATMENT/PROCEDURES

- Continue fluid resuscitation and correction of electrolyte imbalance if present.
- Decompress stomach with nasogastric or orogastric tube if abdomen distended or vomiting persistent.
- Continue evaluation for underlying cause.
- Consider antiemetic medications.
- Surgical consultation if acute abdomen; antibiotics if peritonitis or other systemic

infection present

MEDICATION

Antiemetics may be helpful once the underlying cause of vomiting has been determined.

First Line

Ondansetron: 4–8 mg (peds: 0.1 mg/kg per dose) IV or PO q6h

Second Line

- Metoclopramide: 10 mg (peds: 0.1 mg/kg per dose) PO q6h
- Prochlorperazine: 2.5–5 mg (peds: 0.1 mg/kg per dose) IV, IM, or PR q6h
- Promethazine: 12.5–25 mg (peds: 0.25 mg/kg per dose) PO, PR, or IM q6h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Unstable vital signs, including persistent tachycardia or other evidence of hypovolemia
- Serious etiologic condition or inability to exclude serious etiologic conditions
- Intractable vomiting or inability to take oral fluids
- Inadequate social situation or follow-up

Discharge Criteria

- Stable; able to tolerate oral fluids
- Benign etiology considered most likely and serious or potentially important etiologies excluded
- Parental understanding of instructions to advance clear liquids slowly and return for continued vomiting, abdominal distention, decreased urination, fever, lethargy, or unusual behavior

Issues for Referral

- Chronic or recurrent episodes of vomiting or abdominal pain:
 - Pediatric gastroenterology

FOLLOW-UP RECOMMENDATIONS

PCP in 1–2 days

PEARLS AND PITFALLS

- Determine presence or absence of bile or blood in emesis.

- Bilious vomiting in the neonate is an important anatomic abnormality such as malrotation until proven otherwise.
- Consider causes of vomiting other than just GI (see Differential Diagnosis).

- R11.14 Bilious vomiting

VON WILLEBRAND DISEASE

Matthew A. Wheatley • Ryan A. Stroder

BASICS

DESCRIPTION

- Coagulopathy caused by deficiency or dysfunction of von Willebrand factor (vWF)
- vWF functions:
 - Mediates platelet–endothelial cell adhesion
 - Carrier protein for factor VIII
- Prevalence as high as 1–2% in the general population
- Genetics:
 - Most cases inherited—multiple genetic defects identified
 - Type 1—quantitative defect of vWF:
 - 70% of cases
 - Autosomal dominant
 - vWF deficiency results from decreased synthesis and increased clearance of protein.
 - Manifestation ranges from asymptomatic to moderate bleeding.
 - Type 2—qualitative defect of vWF:
 - 10–15% of cases
 - Divided into types 2A, 2B, 2M, 2N—all are autosomal dominant except 2N which is autosomal recessive.
 - Decrease in intermediate and high molecular-weight multimer
 - 2N—decreased binding to factor VIII
 - Leads to decreased levels of VIII and thus more serious coagulopathy
 - Type 3—absent or severe deficiency in amount of vWF:
 - Rare disease—1 per million cases
 - Autosomal recessive
 - Severe coagulopathy
 - vWD genetically associated with sickle cell disease, hemophilia A, factor XII deficiency, hereditary hemorrhagic telangiectasia, and thrombocytopenia

ETIOLOGY

- In addition to genetic causes, acquired forms exist.
- Multiple mechanisms:
 - vWF antibody production
 - Decreased synthesis
 - Proteolysis
 - Increased clearance from binding to tumor cells
- Seen in association with the following:

- Malignancy:
 - Wilms tumor
 - Multiple myeloma
 - Chronic lymphocytic leukemia
 - Non-Hodgkin lymphoma
 - Chronic myelogenous leukemia
 - Waldenstrom macroglobulinemia
 - Monoclonal gammopathy of uncertain significance
- Immunologic:
 - Systemic lupus erythematosus
 - Rheumatoid arthritis
- Medication induced:
 - Valproic acid
 - Ciprofloxacin
 - Hetastarch
 - Griseofulvin
- Miscellaneous:
 - Hypothyroidism
 - Uremia
 - Hemoglobinopathies
 - Cirrhosis
 - Congenital heart disease
 - Disseminated intravascular coagulation

DIAGNOSIS

SIGNS AND SYMPTOMS

- Symptoms vary depending on type of disease.
- Many type 1 and some type 2 are asymptomatic, severe type 2 and type 3 are symptomatic:
 - Easy bruising
 - Menorrhagia
 - Recurrent epistaxis
 - Gum bleeding
 - GI bleeding
 - Soft-tissue bleeds and hemarthroses
 - Prolonged or excessive procedural bleeding
 - Postoperative hemorrhage

History

- Most often diagnosed in pediatric and adolescent populations
- Family history

- Minor/moderate recurrent mucosal bleeding most common historical clue
- Heavy menses

Physical-Exam

- Most will have normal exam
- Multiple large bruises
- Deep-tissue hematomas, hemarthroses

Pregnancy Considerations

- Pregnancy causes increased vWF levels in patients with types 1 and 2 disease
- Pregnancy, labor, and delivery are usually uncomplicated
- vWF levels fall quickly after delivery:
 - Patients may suffer postpartum bleeding 10–28 days after delivery

Pediatric Considerations

Always consider nonaccidental trauma in an infant or child presenting with bruising or bleeding of unknown cause

ESSENTIAL WORKUP

- Screen and refer for testing if historical concerns or consistent physical findings
- For type 1 diagnosis, patient must have significant mucocutaneous bleeding, lab confirmation, and family history of type 1 disease

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CBC: Normal platelet count and morphology
- PT: Normal
- PTT:
 - Mildly prolonged in 50%
 - Due to low factor VIII levels or coexistent factor deficiency
- Measurement of vWF level and activity:
 - vWF ristocetin cofactor activity (vWF:RCo):
 - Uses platelet agglutination to determine vWF function
 - vWF antigen—tests for vWF level in serum using rabbit antibodies
- Bleeding time:
 - May be normal in type 1 (50%); prolonged in types 2 and 3
 - Not specific and hard to reproduce; has fallen out of favor for diagnosis

DIFFERENTIAL DIAGNOSIS

- Hemophilia A, B
- Platelet defects
- Use of antiplatelet drugs—NSAIDs

- Platelet-type pseudo vWD
- Bernard–Soulier syndrome

TREATMENT

PRE HOSPITAL

Direct pressure for control of hemorrhage

INITIAL STABILIZATION/THERAPY

Resuscitation with crystalloid and packed RBCs as needed

ED TREATMENT/PROCEDURES

- As with all significant bleeding, apply direct pressure to site of bleeding
- 3 treatment strategies:
 - _ Increase endogenous vWF
 - _ Replacement of vWF
 - _ Agents that generally promote hemostasis but do not alter levels of vWF
- Desmopressin acetate (DDAVP):
 - _ Promotes release of vWF from endothelial cells, increases factor VIII levels
 - _ Maximal levels obtained at 30–60 min, with duration of 6–8 hr
 - _ Effective for type 1; variable effectiveness for type 2; not indicated for type 3
 - _ Patients may use intranasal spray at home before menses or minor procedures
- vWF replacement therapy:
 - _ Humate-P factor VIII concentrate with vWF:
 - Treated to reduce virus transmission risks
 - Indicated for type 3 vWD and severe bleeding in all types
 - Doses, length of treatment depend on severity of bleeding
 - Cryoprecipitate is no longer a treatment of choice as it carries risk of virus transmission. If no other treatments are available and patient having life-threatening hemorrhage, it can be used
- Antifibrinolytic therapy:
 - _ Aminocaproic acid (Amicar) and tranexamic acid (Cyklokapron)
 - _ Block plasmin formation to prevent clot degradation
- Topical agents—applied directly to bleeding site:
 - _ Gelfoam or Surgicel soaked in thrombin
 - _ Micronized collagen
 - _ Fibrin sealant
- Avoid antiplatelet agents

- Minor bleeding (epistaxis, oropharyngeal, soft tissue):
 - IV or intranasal desmopressin
- Major bleeding (intracranial, retroperitoneal):
 - Replace vWF and factor VIII so activity level is at least 100 IU/dL

Second Line

- Minor bleeding:
 - vWF concentrate:
 - Given if desmopressin is ineffective
 - Should be given in consultation with a hematologist
 - Aminocaproic acid or tranexamic acid:
 - For mild mucocutaneous bleeding

MEDICATION

- Aminocaproic acid: 50–60 mg/kg PO/IV q4–q6h
- Cryoprecipitate: 10–12 U initial dose or 2–4 bags/10 kg
- Desmopressin (DDAVP):
 - 0.3 µg/kg IV, max. 20 µg
 - 0.3 µg/kg SQ, max. 20 µg
 - 300 µg (1 spray each nostril) intranasal
 - Peds: < 50 kg—150 µg (1 spray in each nostril) intranasal
- Antihemophilic factor/vWF complex, human (Humate-P): 20–40 U/kg IV
- Tranexamic acid: 20–25 mg/kg PO, IV q8h
- Fresh frozen plasma (FFP)—10–20 mL/kg IV

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with significant bleeding requiring further IV medical management
- Observation after major trauma for types 2 and 3 vWD
- Consider transferring patients with major bleeding events to a center with round-the-clock lab capability, and a care team that includes a hematologist and a surgeon skilled in management of bleeding disorders

Discharge Criteria

- Control of hemorrhage
- Adequate follow-up and access to medical therapy

FOLLOW-UP RECOMMENDATIONS

Hematology:

- Severe, difficult-to-manage bleeding
- Prior to elective/semielective procedures
- Definitive workup of suspected cases

PEARLS AND PITFALLS

Patients may not know their type of hemophilia:

- Consider FFP for the patient with unknown type of hemophilia in the setting of trauma or bleeding

ICD10

D68.0 Von Willebrand's disease

WARFARIN COMPLICATIONS

Molly C. Boyd

BASICS

DESCRIPTION

- Most commonly prescribed oral anticoagulant
- Inhibits vitamin K metabolism required for activation of factors II, VII, IX, and X
- Blocks the coagulation cascade's extrinsic system and common pathway
- Commonly used for venous thromboembolism and prevention of embolism with prosthetic heart valves or atrial fibrillation
- Adjustments based on the international normalization ratio (INR)
 - Typical therapeutic range 2–3
 - 2.5–3.5 for mechanical valves and antiphospholipid syndromes
- Contraindications include any condition in which the risk of hemorrhage or adverse reaction outweighs clinical benefit
 - Prior hypersensitivity
 - Skin reactions
 - Recent surgeries
 - Active or potential GI, intracerebral, or genitourinary bleeding
 - Fall risk

ETIOLOGY

- Bleeding complications:
 - 15% of patients/yr
 - 4.9% major bleeding events
 - Up to 0.8% fatal, most commonly intracranial hemorrhage (ICH)
 - Bleeding risk is directly related to INR
 - Increases dramatically above 4
- Risk factors for nontherapeutic INR:
 - Age >75 yr
 - Hypertension, cerebrovascular disease, severe heart disease
 - Diabetes, renal insufficiency
 - Alcoholism or liver disease
 - Hypermetabolic states, fever
 - Hyperthyroidism
 - Cancer
 - Collagen vascular disease
 - Hereditary warfarin resistance
 - Cytochrome P450 polymorphism

Common Interactions

Increase INR	Decrease INR
Multiple antibiotics	Carbamazepine
NSAIDs	Barbituates
Amiodorone	Rifampin
Propranolol	Haloperidol
Prednisone	St. John wort
Cimetidine	High vitamin K foods
Grapefruit, garlic	
Ginko biloba	

Pregnancy Considerations

- Pregnancy class X
- Crosses the placenta causing spontaneous abortion and birth defects

DIAGNOSIS

SIGNS AND SYMPTOMS

- Presentation may be occult or dramatic:
 - High index of suspicion required to detect potentially life-threatening complications
- Subtherapeutic/low INR: Breakthrough thrombosis
- Therapeutic and suprathereapeutic: GI, CNS, retroperitoneal bleeding
- Skin necrosis and limb gangrene:
 - Classic lesions of warfarin skin necrosis and limb gangrene begin on the 3rd–8th day of therapy
 - Capillary thrombosis in subcutaneous fat (skin necrosis) and obstruction of venous circulation of the limb (limb gangrene)
 - Often associated with protein C deficiency
 - Eschar in center differentiates lesions from ecchymosis
- Intentional overdose
 - May be asymptomatic
 - Superwarfarin (rat poison) can result in prolonged bleeding risk (months)
 - Follow serial INR
 - Do not start vitamin K empirically, may mask late development of INR elevation
 - Consider activated charcoal

ESSENTIAL WORKUP

- Thorough history:
 - Many chief complaints are complicated by anticoagulation.
 - Reason for anticoagulation, recent dose changes, compliance, recent INR testing, other prescriptions, over the counter, and alternative medicines
 - Subtle changes in mental status, recent “minor falls,” or bleeding
- Check for vital sign abnormalities:
 - Early hemorrhagic shock
 - Hypertension and bradycardia may be secondary to Cushing response in ICH.
 - Cardiac meds often mask important changes in vital signs.
- Examine carefully for:
 - Pallor, contusions, abrasions, ecchymosis, palpable pulses in affected extremity and skin lesions
 - Check stool for blood.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- PT/PTT/INR:
 - Significant bleeding may occur even in INR therapeutic range.
 - PTT also elevated with toxicity
 - Elevations will be delayed in overdose
- CBC:
 - Initial HCT inaccurate measure of acute rapid bleeding
 - Platelets:
 - Aspirin and ADP inhibitors/Plavix result in normal platelet levels but qualitative deficits.
- Electrolytes, BUN, creatinine, LFTs, and glucose:
 - Elevated BUN may indicate blood in GI tract.
 - Coingestants if intentional ingestion
- Type and cross-match

Imaging

- Low threshold for CT imaging to detect occult but life-threatening bleeding:
- Head CT:
 - Minor mechanisms of blunt head trauma without loss of consciousness
 - Detect ICH prior to symptom onset
- Abdominal CT:
 - Blunt abdominal trauma without significant tenderness
 - Retroperitoneal hemorrhage
 - Solid organ or visceral injury

DIFFERENTIAL DIAGNOSIS

- All causes of bleeding:
 - GI, retroperitoneal, CNS, and traumatic
- Skin lesions—hemorrhagic skin disorders:
 - Hemostatic deficits such as platelet disorders
 - Vascular purpuras including glucocorticoid use, vitamin C deficiency, purpura fulminans, disseminated intravascular coagulation, Henoch–Schönlein purpura, protein C deficiency

TREATMENT

PRE HOSPITAL

- ABCs
- Treat hypotension with 2 large-bore IV lines and 0.9% NS infusion.
- Cardiac and pulse oximetry monitoring

INITIAL STABILIZATION/THERAPY

- Establish central IV access for hypotension not responsive to initial fluid bolus:
 - Compressible sites only
- Replace lost blood as soon as possible
 - Initiate with O-negative blood until type-specific blood available.
 - 10 mL/kg bolus in children

ED TREATMENT/PROCEDURES

- Specific management depends on the INR, presence of bleeding, reason for anticoagulation, and reliability of patient:
 - INR < 5 without bleeding:
 - Lower or omit next dose.
 - Recheck INR in 24 hr.
 - INR ≥ 5 –<9 without bleeding:
 - Omit next 1 or 2 doses or omit 1 dose and give 1–2.5 mg PO vitamin K.
 - If at increased risk for bleeding or pre-op, then administer vitamin K 1–5 mg PO, INR will be lowered in 24 hr.
 - Recheck INR in 24 hr.
 - INR ≥ 9 without significant bleeding:
 - Hold warfarin and give vitamin K 2.5–5 mg PO; INR will be substantially lowered in 24–48 hr
 - INR > 20 with minor bleeding or life-threatening bleeding regardless of INR:
 - Hold Warfarin
 - Vitamin K 10 mg by slow IV infusion
 - Fresh frozen plasma (FFP) or prothrombin complex concentrate (PCC)

- depending on volume status and availability
 - PCC shows faster INR reversal and hemostasis; however, no clear benefit has been shown in patient outcome
 - PCC preferred in cases of ICH, volume overload, or massive bleeding.
- In the setting of controlled bleeding, maintain the INR at the lower level of therapeutic efficacy:
 - 1.5–2 for atrial fibrillation
 - 2–2.5 with mechanical heart valves
- Starting reversal agents before transferring patient leads to better outcomes

MEDICATION

- Vitamin K1 phytonadione:
 - Side effects:
 - Anaphylaxis with IV >> IM or PO
 - SC absorption unpredictable
 - IM administration may result in hematoma formation.
 - Breakthrough thromboembolism with complete correction, prolonged risk if high dose vitamin K
 - 10 mg IV infusion over 10–30 min is recommended for life-threatening active bleeding with effects beginning in 1–2 hr
- FFP:
 - Traditionally 3–4 U of FFP (1 L) are given to control continued bleeding in the short term without excessive risk of thromboembolism.
 - Additional units may be necessary
 - Follow serial INR closely
 - Patient response is variable and may not correlate with correction of the INR.
 - Side effects:
 - Fluid overload
 - Virus transmission-rare
 - Transfusion-related acute lung injury (TRALI) – rare
- PCC:
 - Long shelf life and easy reconstitution into a highly concentrated volume (20 mL vs. 1 L of FFP per dose)
 - Rapid reversal without volume overload
 - Side effects:
 - Thrombosis
 - Less virus transmission than FFP
 - Multiple studies show more rapid reversal of INR, reduction bleeding compared to FFP
 - Relationship to patient outcome has not been demonstrated
 - **4-factor PCC** (Kcentra) is a fractionation product of FFP containing equal amounts of factors II, VII, IX, and X:

- FDA approved in 2013, not widely available
- For patients with an INR of 2–3.9, administer 25 U/kg, 4–5.9, 35 U/kg, and >6, 50 U/kg
- **3-factor PCC** (Bebulin-VH, Profilnide-SD) contains very little factor VIIa:
 - Some use in combination with VIIa or VIIa alone depending on availability
 - 50 U/kg PCC and 1–2 mg FVIIa has been suggested
 - Consider FFP supplementation of FVIIa unavailable
 - More widely available in US
 - Warfarin reversal is off label use

FOLLOW-UP

DISPOSITION

Admission Criteria

- Active GI, retroperitoneal, or CNS bleeding
- Anticoagulated trauma patient with evidence of active bleeding requires:
 - Reversal of anticoagulation and blood replacement
 - Early surgical consultation for operative intervention
 - Transport to a level 1–trauma center after initial stabilization for definitive care.
- Skin necrosis and limb gangrene requires admission for anticoagulation with alternative agents in consultation with a hematologist.
- Subtherapeutic patient may require adequate anticoagulation with inpatient heparin or low molecular weight heparin to prevent a breakthrough thromboembolism:
 - Outpatient Lovenox therapy followed by increased warfarin with close follow-up prevents unnecessary hospitalization

Discharge Criteria

- Asymptomatic reliable patient with a supratherapeutic INR after consideration of:
 - Indication for anticoagulation, reason for supratherapeutic level, underlying comorbidities, overall risk of bleeding, fall risk, social situation, reliability, and availability of follow-up
- Asymptomatic anticoagulated patient with minor trauma, therapeutic INR, stable hemoglobin, normal imaging studies, and reliable caretakers, can be discharged with close follow-up.

Issues for Referral

- Patient should follow up with primary care physician or specialist within 24–48 hr of discharge for INR check and further warfarin adjustments.

- Psychiatric referral for intentional overdose

FOLLOW-UP RECOMMENDATIONS

Educate patient on monitoring for signs and symptoms of excessive bleeding and/or new thrombotic event.

PEARLS AND PITFALLS

- Maintain a low threshold for imaging trauma patients on warfarin
- No vitamin K for an INR <5 without bleeding
- Vitamin K1 IV may result in fatal anaphylaxis:
 - Use only in patients with INR >20 with minor bleeding, or patients with life-threatening bleeding
 - Administer PO for everyone else.
- For rapid reversal, FFP is still considered a 1st-line agent
- 4-factor PCC, or 3-factor PCC/FVIIa should be used in patients with ICH, volume overload, or massive bleed

WARTS

Gary M. Vilke

BASICS

DESCRIPTION

- Warts are caused by the human papillomaviruses (HPV)
- Causes cellular proliferation and vascular growth
- Lesions are typically verrucous and hyperkeratotic
- Lesions resolve spontaneously in most cases:
 - 1/3 within 6 mo
 - 2/3 within 2 yr
 - 90% within 5 yr
 - Likely due to cell-mediated immune response
- Cutaneous warts:
 - Verrucae vulgaris (common warts):
 - Dorsum of hands
 - Sides of fingers
 - Adjacent to nails
 - Usually asymptomatic
 - Verrucae plantaris (plantar warts):
 - Weight-bearing parts of sole: Heels, metatarsal heads
 - Often symptomatic and painful
 - More common in adolescents and young adults
 - Flat (juvenile) warts:
 - Primarily on light-exposed areas
 - Head, face, neck, legs, dorsum of hands
 - Small in size
 - Range from a few to hundreds
- Anogenital warts:
 - Known as condyloma acuminata or venereal warts
 - Most are asymptomatic and may go unrecognized
 - HPV types 6 and 11 account for 90% of anogenital warts
- HPV types 16 and 18 account for 70% of cervical cancers

ETIOLOGY

- HPV is host-specific to humans
 - Cause infection of epithelial tissues and mucous membranes
 - Infects the basal layer of skin or mucosa
- There are > 100 types of HPV that variably infect different body sites
- HPV transmission is:

- Direct: Skin to skin
- Indirect: Contaminated surface to skin
- Autoinoculation: Scratching, sucking (especially in young children)
- Incubation period can range from weeks to >1 yr

Pediatric Considerations

- 10–20% of children will have warts
- Peak incidence between 12 and 16 yr
- May produce laryngeal papillomatosis in infants from viral exposure at birth
- Must consider sexual abuse in children with anogenital warts

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Complete sexual history
- Prior history of warts and treatment
- HIV status
- Cutaneous warts:
 - Common warts:
 - Usually asymptomatic unless on a pressure point
 - May present with bleeding secondary to minor trauma
 - Plantar warts:
 - Often painful with weight bearing
 - Flat (or juvenile) warts:
 - On light-exposed areas of skin
 - May spread with shaving face, neck, legs
- Anogenital warts:
 - In men, usually on glans penis, shaft, scrotum, or anus
 - In women, found on labia, vagina, cervix, or anus
 - May extend into urethra, bladder, or rectum:
 - Dysuria
 - Pain, itching, and/or bleeding with bowel movements
 - May have symptoms involving mouth or throat if oral sexual contact

Physical-Exam

- Cutaneous warts:
 - Common warts:
 - Hard, rough, raised, dome-shaped lesions
 - Obscure normal skin markings
 - Hypervascular and may bleed with minor trauma

- Plantar warts:
 - Soles of the feet
 - Obscure normal skin markings
 - Hypervascular and may bleed with gentle scraping
- Flat (or juvenile warts):
 - Flesh colored
 - Flat top and smooth
 - Small: Range from pinpoint to size of pencil eraser
- Anogenital warts:
 - Pedunculated growths often with cauliflower-like appearance
 - Lesions are soft and usually present in multiples
 - Flesh colored to slightly pigmented or red

ESSENTIAL WORKUP

Diagnosis made by characteristic appearance of lesions

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Pregnancy test for females
- Biopsy and viral typing not recommended for typical lesions
- If difficult to see, add acetic acid to suspected area, which will cause infected areas to whiten and become more visible
- Screen for other sexually transmitted diseases

Diagnostic Procedures/Surgery

Biopsy indicated if failing therapy, patient immunocompromised, or warts are pigmented, indurated, fixed, or ulcerated

DIFFERENTIAL DIAGNOSIS

- Cutaneous warts:
 - Common wart
 - Callus; will not bleed
 - Plantar wart:
 - Callus, corn, bunion
 - Flat (or juvenile) wart:
 - Moles, skin tag, lichen planus
- Anogenital wart:
 - Condyloma latum (secondary syphilis)
 - Herpes simplex
 - Prominent glands around head of penis
 - Benign or malignant neoplasm
 - Molluscum contagiosum

TREATMENT

INITIAL STABILIZATION/THERAPY

None required

ED TREATMENT/PROCEDURES

- Cutaneous warts:
 - Occlusion with duct tape:
 - Least invasive
 - Maintain on wart for 6 days
 - Gentle debridement with pumice stone or nail file on day 7
 - Good for young children
 - May also enhance other topical treatments
 - Salicylic acid:
 - Inexpensive, mild side effects
 - OTC is 17% salicylic acid
 - Prescription strength has up to 70% salicylic acid
 - Soak wart in warm water for 10–20 min
 - Apply salicylic acid overnight
 - Gently debride in morning
 - Patches are also available
 - Resolution may take weeks to months
 - May be more effective combining with cryotherapy
- Anogenital warts:
 - May use imiquimod, podofilox, podophyllin, trichloroacetic acid (TCA), bichloroacetic acid (BCA), or alternative therapies listed below
 - Nonintervention may be best course in children, as treatment has not been well studied
- Alternative treatments:
 - Cryotherapy with liquid nitrogen or dry ice
 - OTC cryotherapy kits
 - Electrocautery
 - Laser therapy
 - Surgical excision
 - Interferon for use by subspecialists
- Provide appropriate referral

MEDICATION

- Topical medications (patient applied):
 - Imiquimod 5% cream:
 - Apply 3 times/wk for up to 16 wk
 - Cream may weaken diaphragms and condoms

- Podofilox 0.5% gel or solution:
 - Apply BID for 3 days, then rest 4 days; may repeat for 4 cycles
 - Do not use on perianal, rectal, urethral, or vaginal lesions
- Salicylic acid:
 - Wash off 6–10 hr later
 - May be repeated weekly
- Topical medications (provider administered):
 - Podophyllin 10–25% in benzoin:
 - Weekly topical application:
 - Protect surrounding normal tissue with petroleum jelly
 - Wash off 1–4 hr later
 - Do not use in pregnancy: Highly toxic and teratogenic
 - Do not use on cervix, vagina, or anal canal as may cause dysplastic changes
 - TCA or BCA 80–90%
 - Apply weekly for 6–10 wk
 - Cryotherapy with liquid nitrogen or cyroprobe
 - May be repeated every 1–2 wk
- Vaccine:
 - Gardasil: Targets HPV types 6, 11, 16, 18:
 - Recommended for girls > 9 yr
 - 3-shot series over 6 mo
 - For the prevention of cervical cancer, vulvar and vaginal cancer, genital warts, and other low-grade cervical lesions
 - Cervarix: Targets HPV types 16, 18:
 - 3 shots over 6 mo
 - Universal vaccination may provide significant reduction of cervical cancer in developing countries without well-established screening
 - Both vaccines are 96% effective
 - There are still controversies surrounding routine use and acceptance

FOLLOW-UP

DISPOSITION

Admission Criteria

Disseminated cases in immunocompromised patients may require admission

Discharge Criteria

Most patients can be treated as outpatients

Issues for Referral

- All medication-based therapies require follow-up and subsequent dosing. Should not initiate treatment unless follow-up can be secured
- For treatment failures, referral to PMD or dermatology should be made for alternative treatment options
- Refer sexually active teenage girls to pediatrician or primary care for HPV vaccination

FOLLOW-UP RECOMMENDATIONS

- Pain, burning, redness, or other changes in symptoms require prompt re-evaluation
- Arrange follow-up with appropriate provider: Pediatrician, gynecologist, dermatologist, primary care physician

PEARLS AND PITFALLS

- Pregnancy test must be done before initiation of medical therapy
- HPV vaccine does not protect from all forms of HPV, just those most commonly associated with cervical cancer
- Consider sexual assault in children with anogenital warts

WEAKNESS

Kathryn A. Volz • Jason C. Imperato

BASICS

DESCRIPTION

- Defined as a decrease in physical strength or energy
- Often multifactorial
- Distinguish neuromuscular disorder vs. non-neuromuscular disorder
- Categories of neuromuscular disorders:
 - Upper motor neuron (UMN) lesions:
 - Deep tendon reflexes (DTR) increased
 - Plantar reflexes upgoing
 - Increased muscle tone
 - Muscle atrophy absent
 - Lower motor neuron (LMN) lesions:
 - DTRs decreased to absent
 - Plantar reflexes absent or normal
 - Decreased muscle tone
 - Muscle atrophy present
 - Fasciculations
 - Neuromuscular junction (NMJ) lesions:
 - DTRs normal
 - Plantar reflexes normal or absent
 - Decreased muscle tone
- Categories of non-neuromuscular disorders:
 - Infectious
 - Endocrine
 - Metabolic
 - Cardiac
 - Rheumatologic
 - Toxic
 - Psychiatric

ETIOLOGY

- Neuromuscular disorders:
 - UMN lesions:
 - Multiple sclerosis
 - Amyotrophic lateral sclerosis (mixed)
 - Transverse myelitis
 - Poliomyelitis

- LMN lesions:
 - Guillain–Barré syndrome
 - Toxic neuropathies
 - Impingement syndromes
 - Diphtheria
 - Porphyria
 - Seafood toxins
- NMJ lesions/others:
 - Myasthenia gravis
 - Lambert–Eaton syndrome
 - Botulism
 - Periodic paralysis
 - Tick paralysis
- Non-neuromuscular disorders:
 - Dehydration
 - Anemia
 - Electrolyte imbalances
 - Malignancy
 - Cerebrovascular accident
 - Head or neck trauma
 - Myocardial ischemia
 - Infection/sepsis:
 - UTI
 - Pneumonia
 - Meningitis
 - Mononucleosis
 - HIV
 - Arboviruses
 - Endocrine abnormalities:
 - Hypothyroidism
 - Adrenal crisis
 - Periodic paralyzes
 - Rheumatologic disorders:
 - Systemic lupus erythematosus
 - Polymyalgia rheumatica
 - Toxins:
 - Medications
 - Environmental
 - Carbon monoxide poisoning
 - Cocaine
 - Alcohol

SIGNS AND SYMPTOMS

- Altered physical strength:
 - Assessment of strength:
 - 1: No contraction
 - 2: Active movement with gravity eliminated
 - 3: Active movement against gravity
 - 4: Active movement against gravity and resistance
 - 5: Normal power
 - Change in muscle tone:
 - Flaccidity
 - Spasticity
 - Rigidity
 - Abnormal DTRs
 - Abnormal plantar reflexes
 - Muscle atrophy:
 - Difference of > 1 cm in the leg and thigh and > 0.5 cm in the forearm and arm
- Systemic findings:
 - Weakness
 - Fatigue
 - Dizziness
 - Paresis
 - Paresthesias
 - Hoarse voice
 - Dysphagia
 - Visual changes
 - Confusion
 - Associated symptoms:
 - Fever
 - Chest pain
 - Dyspnea
 - Cough
 - Weight loss
 - Rash
 - Dysuria
 - Upper respiratory infection symptoms

ESSENTIAL WORKUP

- Review of medications
- Clinical suspicion gathered through history and physical exam guides further testing:

- Generalized vs. focal
- Acute vs. chronic
- Proximal vs. distal
- Ascending vs. descending
- Symmetric vs. asymmetric
- Improved vs. worsened with activity

DIAGNOSIS TESTS & INTERPRETATION

Diagnostic testing should be broad unless history and physical exam identify the cause of weakness.

Lab

- Serum glucose
- CBC
- Electrolytes
- BUN/creatinine
- Toxin screen
- Urinalysis
- Thyroid function tests (rule out hypothyroidism)
- ESR (rule out rheumatologic cause)
- Carboxyhemoglobin (rule out CO poisoning)
- Troponin/CK-MB (rule out cardiac ischemia)
- Digoxin level (rule out digoxin toxicity)

Imaging

- EKG (rule out acute coronary syndrome [ACS]/arrhythmia)
- CXR (rule out pneumonia)
- CT/MRI head (rule out intracranial pathology)

Diagnostic Procedures/Surgery

- Bedside spirometry:
 - Forced vital capacity, negative inspiratory force, peak expiratory flow rate
 - May identify those with impending ventilatory failure
- Lumbar puncture:
 - In suspected Guillain-Barré syndrome:
 - Albumin-cytologic dissociation in CSF (protein > 400, WBC < 10) is virtually diagnostic.
- Tensilon test:
 - Distinguishes myasthenic crisis from cholinergic crisis in myasthenia gravis

DIFFERENTIAL DIAGNOSIS

- Physiologic causes of weakness:
 - Simple fatigue:

- Excessive physical activity
- Inadequate rest
- Excessive or inadequate diet
- Pregnancy
- Psychiatric causes of weakness:
 - Anxiety/depression
 - Dependent personality
 - Hypochondriasis
 - Chronic fatigue syndrome
 - Fibromyalgia
 - Malingering

TREATMENT

Treatment is geared to the underlying cause of weakness.

PRE HOSPITAL

- Supplemental oxygen
- IV access
- Finger-stick glucose determination
- Consider endotracheal intubation in patients with severe respiratory distress.

INITIAL STABILIZATION/THERAPY

- Supplemental oxygen
- IV access
- Endotracheal intubation for impending ventilatory failure

ED TREATMENT/PROCEDURES

- Neurology consult if needed
- When the diagnosis is determined, specific therapies can be applied:
 - TPA for CVAs meeting criteria
 - Plasma exchange and/or IV immunoglobulin (IVIG) for Guillain–Barré syndrome
 - Hydrocortisone for adrenal insufficiency
 - Potassium supplementation for hypokalemia
 - Dextrose for hypoglycemia
 - Antibiotics for infectious etiologies
 - Specific antidotes for botulism and diphtheria
 - Digibind for digoxin toxicity

FOLLOW-UP

DISPOSITION

Admission Criteria

- All patients with new-onset neuromuscular disorders should be admitted for definitive diagnosis.
- Any evidence of impending ventilatory or circulatory compromise warrants ICU admission.

Discharge Criteria

- Resolution of symptoms
- Stable vital signs
- Definitive diagnosis and correction of abnormality

FOLLOW-UP RECOMMENDATIONS

- Discharged patients with non-neurologic etiologies should have follow-up with their PCP.
- Discharged patients with neurologic etiologies should have urgent neurology follow-up.

PEARLS AND PITFALLS

- Identify early and aggressively treat patients at risk for respiratory compromise due to Guillain–Barré, botulism, myasthenia gravis.
- Identify elderly patients with ACS or infection presenting as weakness.
- Consider endocrine causes of weakness, including adrenal insufficiency and hypothyroidism.

CODES

ICD9

- 728.2 Muscular wasting and disuse atrophy, not elsewhere classified
- 728.87 Muscle weakness (generalized)
- 780.79 Other malaise and fatigue

ICD10

- M62.50 Muscle wasting and atrophy, NEC, unsp site
- M62.81 Muscle weakness (generalized)
- R53.1 Weakness

WEST NILE VIRUS

Roger M. Barkin

BASICS

DESCRIPTION

Infectious agent is an arbovirus, an RNA member of the *Flaviviridae* family.

ETIOLOGY

- Vector-borne virus
- Transmitted by infected mosquitoes in late summer/early fall
- Wild birds are primary reservoir hosts; humans are infected by cross-feeding mosquitoes.
- Introduced to Western Hemisphere in 1999; became more widespread owing to vector of *Culex* mosquito and is now endemic in North America
- Infection after blood transfusion and solid-organ transplant can occur.
- There are case reports of occupational exposure and infection of lab workers via percutaneous inoculation.
- Following recovery, immunity is considered lifelong. Reoccurrence is rare
- The 2011 outbreak had a mortality rate of 4–5%. Cases were reported in 48 states.

Pregnancy Considerations

Infection via transplacental transmission and breast-feeding has been reported.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Variable severity of illness:
 - 80% asymptomatic
 - 20% mild symptoms, flu-like illness
 - ~1/150 with CNS involvement (encephalitis, meningitis)
- Incubation period is usually 2–6 days but can be up to 14 days in average patient and up to 21 days in immunocompromised patient.
- Symptoms have a sudden onset and last < 1 wk with mild infection.
- Mortality rate in severe cases is estimated at 7%.
- Severity of illness is related to degree of CNS invasion by virus. Risk is enhanced with increased age and immunosuppression
- Immunocompromised patients have prolonged viremia, delayed development of antibody, and increased likelihood of severe disease.
- Persistent symptoms of fatigue, memory impairment, weakness, and headache have been reported to last for 1–2 mo

Geriatric Considerations

- Patients >60 yr, if infected, are at higher risk for developing more severe disease and neurologic consequences.
- Advanced age is the most important risk factor for death.

History

- General:
 - _ Fever
 - _ Malaise
 - _ Anorexia
 - _ Headache
 - _ Acute phase resolves within several days but fatigue and weakness may persist for weeks
- Neurologic:
 - _ Altered mental status (change in level of consciousness, confusion, agitation, irritability)
 - _ Severe, diffuse muscle weakness; may be asymmetric and involve the face
 - _ Flaccid paralysis, which may resemble poliomyelitis-like syndrome, associated with anterior horn cell injury. Cranial nerve and bulbar abnormalities have been reported
 - _ May resemble Guillain–Barré syndrome
 - _ Seizures
 - _ Encephalitis more commonly reported in adults and meningitis in children
- GI:
 - _ Nausea, vomiting, diarrhea, anorexia
 - _ Abdominal pain
- Musculoskeletal:
 - _ Myalgia
 - _ Arthralgia
 - _ Back pain
- Respiratory:
 - _ Cough
 - _ Sore throat
- Ophthalmologic:
 - _ Photophobia
 - _ Eye pain

Physical-Exam

- General:
 - _ Temperature >38°C (>100°F)
 - _ Transient maculopapular rash
 - _ Rhabdomyolysis

- Neurologic:
 - Altered mental status
 - Hyporeflexia, areflexia
 - Ataxia
 - Extrapyrarnidal signs
 - Cranial nerve palsies, paresis
 - Myoclonus
 - Profound motor weakness
 - Flaccid paralysis
- GI:
 - Hepatosplenomegaly, hepatitis, pancreatitis
- Musculoskeletal:
 - Nuchal rigidity
- Hematologic:
 - Lymphadenopathy
- Dermatologic:
 - Rash (maculopapular or morbilliform on neck, trunk, extremities) usually lasting < 1 wk
- Cardiovascular:
 - Myocarditis (rare)
- Ophthalmologic:
 - Optic neuritis
 - Vitritis
 - Chorioretinitis

ESSENTIAL WORKUP

- Most sensitive screening test is serologic testing of CSF and serum for IgM antibody-capture enzyme-linked immunosorbent assay (MAC-ELISA) and culture.
- Centers for Disease Control and Prevention (970-221-6400)
- Can be detected during 1st 4 days of illness, nearly all tests are positive by day 7–8; may remain positive up to 1 yr after infection
- Procedures for submitting samples vary by state.
- Refer to local public health department for guidelines.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- CSF:
 - Pleocytosis with lymphocyte predominance
 - Elevated protein
 - Normal glucose
- CBC:
 - WBCs may be mildly elevated (50%) or normal.

- Leukopenia may be present (15%).
- Anemia can occur.
- Chemistry:
 - Hyponatremia sometimes seen:
 - Cause uncertain, possibly syndrome of inappropriate antidiuretic hormone (SIADH) when CNS involvement exists
 - Pancreatitis (rare)
 - Fulminant hepatitis (rare)

Imaging

- CT head usually normal
- MRI can be useful to identify CNS inflammation:
 - 1/3 of patients show abnormality.
 - Imaging findings generally nonspecific but may include enhancement of leptomeninges and/or periventricular white matter or can mimic demyelinating process.

Diagnostic Procedures/Surgery

- Lumbar puncture
- MAC-ELISA may be used on serum and CSF samples

DIFFERENTIAL DIAGNOSIS

- Other causes of meningitis:
 - Bacterial
 - Viral
 - Tuberculous
 - Fungal
- Other causes of viral encephalitis:
 - Other arboviruses, especially St. Louis encephalitis virus
 - Enterovirus, particularly in patients ≤ 16 yr of age
 - Herpes simplex virus (HSV)
 - Cytomegalovirus (CMV)
 - Epstein–Barr virus (EBV)
 - Mumps virus
 - Varicella zoster virus
 - Rabies virus
- Intracranial abscess
- CNS vasculitis
- Nonspecific viral syndrome
- Gastroenteritis

TREATMENT

INITIAL STABILIZATION/THERAPY

- ABCs
- Seizure precautions

ED TREATMENT/PROCEDURES

- Supportive care
- IV fluids for signs of dehydration
- For signs of meningitis, administer antibiotics pending results of CSF.
- Consider acyclovir if index of suspicion for the only treatable cause of viral encephalitis, HSV, is high.
- Administer antipyretics and pain medications.
- No known effective antiviral therapy or vaccine
- No controlled studies proving effectiveness of interferon α -2b, ribavirin, corticosteroids, anticonvulsants, or osmotic agents

FOLLOW-UP

DISPOSITION

Admission Criteria

- Neurologic symptoms
- Dehydration
- Concerning risk factors (advanced age, immunocompromise)

Discharge Criteria

- No signs of CNS involvement (encephalitis, meningitis)
- Able to tolerate oral solutions

FOLLOW-UP RECOMMENDATIONS

Neurologist to monitor for potential ongoing residual.

PEARLS AND PITFALLS

Consider HSV in differential, since HSV is treatable.

- A92.32 West Nile virus infection with oth neurologic manifestation

WHEEZING

Stephen K. Epstein

BASICS

DESCRIPTION

- Result of turbulent airflow:
 - High-pitched sound with dominant frequency at 400 Hz:
 - Gas flowing through constricted airways analogous to a vibrating reed
 - Resonant vibration of the bronchial walls when airflow velocity reaches critical values
- Caused by airway narrowing between 2–5 mm:
 - Wheezing is very low pitched with airway diameters of 5 mm.
 - Airways of <2 mm are unable to transmit sound because the energy is lost as friction heat.
- Airway narrowing is caused by a combination of ≥ 1 of the following:
 - Constriction (as with reactive airway disease)
 - Peribronchial interstitial edema
 - Inflammation
 - Obstruction

ETIOLOGY

- Pulmonary (small airway):
 - Asthma
 - Acute respiratory distress syndrome
 - Anaphylaxis
 - Aspiration pneumonia:
 - Wheezing occurs early in the disease due to intense bronchospasm following the event.
 - Byssinosis:
 - Occupational lung disease of textile workers exposed to cotton dust
 - Drugs:
 - Can precipitate angioedema or allergic reaction
 - ACE inhibitors
 - β -blockers
 - Aspirin and NSAIDs
 - Forced exhalation in normal patients
 - Hyperventilation
 - Chronic obstructive pulmonary disease
 - Chronic cor pulmonale

- Chemical pneumonitis
- Carcinoid tumors
- Paroxysmal nocturnal dyspnea
- Pulmonary edema
- Pulmonary embolism:
 - Rarely associated with wheezing
 - Focal
- Pneumonia
- Sleep apnea
- Pulmonary (large airway):
 - Vocal cord dysfunction (paralysis, paradoxical movement)
 - Foreign body
 - Epiglottitis:
 - Wheezing associated with stridor in 10% of cases
 - Diphtheria
 - Smoke inhalation
 - Bronchial tumor
 - Tracheal tumor

Pediatric Considerations

- Viral bronchiolitis in patients < 3 yr of age
- Asthma
- Infection:
 - Croup
 - Rhinovirus
- Foreign-body aspiration
- Congenital abnormalities:
 - Tracheomalacia
 - Tracheal stenosis
- Cystic fibrosis
- CHF

DIAGNOSIS

SIGNS AND SYMPTOMS

- A whistling sound made while breathing:
 - Diffuse:
 - As with reactive airway disease or pulmonary edema
 - Focal:
 - As with pneumonia or pulmonary embolism
- Dyspnea
- Respiratory distress

- Chest pain
- Cough
- Sputum production:
 - Frothy (pulmonary edema)
- Stridor
- Fever
- Cyanosis
- Tachypnea
- Tachycardia

History

- Current URI:
 - Rhinoviruses implicated in reactive airways
- Recent exercise:
 - Exercise-induced asthma, vocal cord dysfunction

Physical-Exam

- Mental status:
 - Lethargy, confusion, and fatigue in the setting of respiratory distress are the primary reasons for airway management.
- Presence of muscle retractions
- Lung auscultation

ESSENTIAL WORKUP

- Pulse oximetry:
 - Useful for assessing severity, but not for predicting hospital admission
- Peak flow:
 - Useful in assessing need for hospitalization
- CXR

DIAGNOSIS TESTS & INTERPRETATION

Lab

- ABG:
 - Sometimes used to determine whether patient is fatiguing by noting falling oxygenation, rising CO₂, and acidosis
 - Clinical assessment is a more reliable indicator of the need for airway management.
- WBC:
 - Elevated WBC does not distinguish infection from other disorders, as stress causes demargination.
 - WBC is also elevated in noninfected patients taking steroids.

- A normal WBC does not rule out an underlying pneumonia.

Imaging

- Peak expiratory flow (PEF):
 - To assess function of small airways
 - Use to determine severity and track the progress of therapy in patients with reactive airway disease.
- CXR:
 - Assess for diagnosis of pulmonary conditions:
 - Pneumonia
 - Foreign-body aspiration
 - Assess for pulmonary edema.
- EKG:
 - Useful when patient is at risk for cardiac ischemia
 - Indicated in all cases in which wheezing is caused by pulmonary edema
- Soft-tissue neck:
 - Used to assess for foreign body or obstructing mass

Diagnostic Procedures/Surgery

Laryngoscopy/bronchoscopy:

- Indicated when obstruction is thought to be causal
- Used to retrieve an inhaled foreign body or diagnose an underlying tumor

DIFFERENTIAL DIAGNOSIS

See Etiologies.

TREATMENT

PRE HOSPITAL

- Supplemental oxygen
- Initiate pulse oximetry and cardiac monitoring.
- Initiate therapy for underlying condition when indicated:
 - Asthma
 - Pulmonary edema
- Intubate for respiratory failure or anticipated respiratory failure.

INITIAL STABILIZATION/THERAPY

- ABCs
- Intubation for impending airway failure:
 - Prepare for possible foreign body in airway.
 - Anticipate difficult airway.

ED TREATMENT/PROCEDURES

- Correct hypoxemia: Supplemental oxygen
- Initial assessment of severity:
 - PEF >40%: Mild–moderate
 - PEF <40%: Severe
- Treat the underlying condition.
- Rapid reversal of airflow obstruction:
 - Bronchodilators:
 - Reversibility following the use of short-acting β -agonists such as albuterol or terbutaline suggests reactive airway disease.
 - Anticholinergics: Ipratropium bromide:
 - Add to β -agonist therapy for severe disease
- Reduce likelihood of relapse:
 - Trial of steroids indicated if wheezing is caused by bronchospasm or noninfectious inflammation.
- Adjunctive agents:
 - Heliox:
 - Less dense than air or oxygen alone
 - Decreases work of breathing
 - More efficacious in large-airway disease
 - Not as effective for small-airway disease
 - Magnesium sulfate:
 - Evidence for benefit only in moderate to severe asthmatics
 - Ketamine:
 - For intubation of the asthmatic patient

MEDICATION

First Line

- Albuterol: 2.5–5 mg in 2.5 mL NS q20min inhaled \times 3 doses (peds: 0.15 mg/kg/dose q20min \times 3 doses; min. dose 2.5 mg)
- Levalbuterol: 0.63 mg q8h (peds: 6–12 yr 0.31 mg q8h; >12 yr 0.63 mg q8h) via nebulizer
- Prednisone: 40–80 mg PO (peds: 1 mg/kg/d in 2 div. doses; max. 60 mg/d)
- Prednisolone: Peds 1–2 mg/kg/d in 2 div. doses PO; ipratropium insert in peds dose (peds: >12 yr 0.25–0.5 mg)
- Racemic epinephrine: Peds 0.25–0.5 mL nebulized for croup

Second Line

- Ipratropium bromide: 0.5 mg q20min \times 3 doses (peds: 0.25–0.5 mg q20min \times 3 doses); may mix with albuterol
- Methylprednisolone: 40–80 mg IV (peds: 1–2 mg/kg/d IV or PO in 2 div. doses, max. 60 mg/d) for patients who cannot tolerate PO

- Terbutaline: 0.25 mg SC q0.5h for 2 doses (peds: 0.01 mg/kg up to 0.3 mg SC):
 - No proven advantage over aerosol therapy
- Magnesium sulfate: 0.1 mL/kg of 50% solution IV over 20 min, then 0.06 mg/kg/h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Hypoxia
- Persistent or worsening wheezing
- Underlying condition requires hospital admission

Discharge Criteria

- Improvement or resolution of wheezing
- PEF > 70% predicted
- Adequate oxygenation

Issues for Referral

Asthma:

- Referral should be made for a written asthma action plan.

FOLLOW-UP RECOMMENDATIONS

The patient should be instructed to return to the ED with shortness of breath, fever, hemoptysis, or chest pain.

PEARLS AND PITFALLS

Be prepared to manage the airway if administering an anxiolytic.

WITHDRAWAL, ALCOHOL

Trevonne M. Thompson

BASICS

DESCRIPTION

- Alcohol withdrawal is the most common withdrawal syndrome encountered in the emergency department
- Neuroexcitation is the hallmark of alcohol withdrawal
- Alcohol withdrawal may be life threatening.
- More severe symptoms and signs are seen in patients with prior episodes of withdrawal, a process called kindling
- Alcoholism is not uncommon among older adults.
- Age-related increase in alcohol sensitivity
- Alcohol-related problems may be misdiagnosed as normal consequences of aging.

ETIOLOGY

- Chronic alcohol use downregulates GABA (inhibitory) receptors, upregulates NMDA (excitatory) receptors.
- Abstinence or reduction in use leads to increased adrenergic activity because of these receptor adaptations
- 4 components to alcohol withdrawal:
 - _ Early withdrawal
 - _ Withdrawal seizures
 - _ Alcoholic hallucinosis
 - _ Delirium tremens (DTs)
- DTs occur in 5% of patients experiencing alcohol withdrawal
- DTs have a 5–15% mortality rate

DIAGNOSIS

SIGNS AND SYMPTOMS

- Early withdrawal:
 - _ Occurs: 6–8 hr after the last drink
 - _ Duration: 1–2 days
 - Tremulousness
 - Anxiety
 - Palpitations
 - Nausea
 - Anorexia
- Withdrawal seizures:

- Occurs: 6–48 hr after the last drink
- Duration: 2–3 days
 - Generalized seizures, generally brief
- Alcoholic hallucinosis:
 - Occurs: 12–48 hr after the last drink
 - Duration: 1–2 days
 - Visual hallucinations (most common)
 - Tactile hallucinations
 - Auditory hallucinations
 - Sensorium typically otherwise clear
- DTs:
 - Occurs 48–96 hr after the last drink
 - Can last up to 5 days
 - Not necessarily preceded by hallucinosis or seizures:
 - Tachycardia
 - HTN
 - Diaphoresis
 - Delirium
 - Agitation
 - Sensorium typically not clear

History

- Obtain substance abuse history:
 - Time of last substance use
 - History of previous withdrawal and how severe

Physical-Exam

A thorough physical exam is necessary

ESSENTIAL WORKUP

Thorough history and physical exam with attention to the vital signs

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Electrolytes, BUN, creatinine, glucose, magnesium
- CBC
- Alcohol level
- Urine drug screening rarely alters management
- Urinalysis
- Blood/urine culture:
 - For suspected infection

Imaging

- Not necessary if early withdrawal is clearly the presenting issue
- CT head:
 - _ For altered mental status or if the clinical situation is not straightforward
- CXR:
 - _ If secondary infection (e.g., aspiration pneumonia) is suspected.

Diagnostic Procedures/Surgery

ECG when clinically warranted

DIFFERENTIAL DIAGNOSIS

- Benzodiazepine withdrawal
- Barbiturate withdrawal
- Intracerebral hemorrhage
- CNS infection
- Epilepsy
- Hypoglycemia
- Hyperthyroidism
- Sepsis
- Drug intoxication
- Psychosis
- Electrolyte disorder

TREATMENT

PRE HOSPITAL

- Assess vital signs
- Assess capillary glucose

INITIAL STABILIZATION/THERAPY

- Attention to the ABCs
- Obtain IV access
- IV fluid administration
- Cardiopulmonary monitoring

ED TREATMENT/PROCEDURES

- Aggressive supportive care
- Benzodiazepines:
 - _ The standard therapy
 - _ No single benzodiazepine is more effective than another
 - _ High doses are often required to control symptoms and signs
- Barbiturates may be used as an alternate or adjunct to benzodiazepines.

- Propofol may also be used in severe cases.

MEDICATION

- Diazepam: 5–20 mg PO for mild symptoms and signs; 5–10 mg IV; repeat for severe symptoms and signs
- Lorazepam: 2 mg PO, repeat q2–4h as needed for mild symptoms and signs; 2 mg IV in repeated doses as necessary for severe symptoms and signs
- Phenobarbital: 30–60 mg PO for mild symptoms and signs; 15–20 mg/kg slow intravenous administration for severe symptoms or status epilepticus
- Propofol: Start with 25–75 µg/kg/min, then titrate as necessary

FOLLOW-UP

DISPOSITION

Admission Criteria

- Moderate-to-severe symptoms
- Persistent symptoms despite treatment
- DTs or impending DTs
- Comorbid medical illness

Discharge Criteria

Mild symptoms and signs responsive to therapy

FOLLOW-UP RECOMMENDATIONS

Referral to detox program or facility

PEARLS AND PITFALLS

- Misdiagnosis of medical disease as withdrawal syndrome
- Misunderstanding the relationship between withdrawal syndromes and comorbid medical illness
- Administer sufficient quantities of benzodiazepines to control symptoms.

ADDITIONAL READING

WITHDRAWAL, DRUG

Trevonne M. Thompson

BASICS

DESCRIPTION

- Neuroexcitation is the hallmark of benzodiazepine, barbiturate, and opiate withdrawal
- Benzodiazepine and barbiturate withdrawal can be life threatening
- Opiate withdrawal can be extremely uncomfortable but is not typically life threatening
- Cocaine and amphetamine withdrawal are similarly not life threatening

ETIOLOGY

- Chronic exposure to certain drugs cause adaptive changes in the CNS
- Withdrawal syndromes occur when the constant presence of drug is removed or reduced and the adaptive changes persist
- Tolerance occurs when increasing amounts of drug are required to achieve a given response
- Withdrawal and tolerance are distinct entities

DIAGNOSIS

SIGNS AND SYMPTOMS

- Benzodiazepines and barbiturates:
 - Anxiety
 - Agitation
 - Irritability
 - Tremor
 - Sleep disturbance
 - Tachycardia
 - Hypertension
 - Hyperthermia
 - Autonomic instability
 - Seizures
- Opiates:
 - Restlessness
 - Irritability
 - Drug craving
 - Yawning
 - Piloerection

- Mydriasis
- Nausea
- Vomiting
- Diarrhea
- Abdominal pain
- Tachycardia
- HTN
- Cocaine:
 - Depressed mood
 - Fatigue
 - Vivid dreams
 - Sleep disturbance
 - Psychomotor retardation or agitation
- Amphetamines:
 - Fatigue
 - Irritability
 - Sleep disturbance
 - Anxiety

History

- Obtain substance abuse history
 - Time of last substance use
 - History of previous withdrawal

Physical-Exam

A thorough physical exam is necessary

ESSENTIAL WORKUP

Thorough history and physical exam with attention to the vital signs

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Electrolytes, BUN, creatinine, glucose
- CBC
- Urine drug screening rarely alters management

Imaging

If the clinical situation is not straightforward for withdrawal, CNS or plain radiograph imaging may be indicated depending on the clinical presentation.

DIFFERENTIAL DIAGNOSIS

- Ethanol withdrawal

- Intracerebral hemorrhage
- CNS infection
- Encephalopathy
- Hypoglycemia
- Hyperthyroidism
- Sepsis
- Psychosis
- Electrolyte disorder
- Drug intoxication

TREATMENT

PRE HOSPITAL

- Assess vital signs
- Assess capillary glucose

INITIAL STABILIZATION/THERAPY

- Attention to ABCs
- Obtain IV access
- IV fluid administration
- Cardiopulmonary monitoring

ED TREATMENT/PROCEDURES

- Benzodiazepine and barbiturate withdrawal:
 - Aggressive supportive care
 - Begin long-acting agent of the same class causing the withdrawal
- Opiate withdrawal:
 - Supportive care
 - Antiemetics for nausea and vomiting
 - Clonidine to reduce severity of signs and symptoms
 - Opiate therapy if withdrawal is complicating other disease states
- Cocaine and amphetamine withdrawal:
 - Supportive care

MEDICATION

- Clonidine: 0.1–0.3 mg PO q4–6h
- Diazepam: 5–20 mg PO for mild signs and symptoms; 5–10 mg IV in repeated doses as necessary for severe symptoms and signs
- Lorazepam: 1–2 mg PO for mild symptoms and signs; 2 mg IV in repeated doses as necessary for severe symptoms and signs
- Phenobarbital: 30–60 mg PO for mild symptoms and signs; 15–20 mg/kg slow IV administration for severe symptoms or status epilepticus.
- Ondansetron: 4–8 mg PO/IV

FOLLOW-UP

DISPOSITION

Admission Criteria

- Moderate-to-severe withdrawal symptoms
- Persistent withdrawal symptoms
- Psychosis with withdrawal
- Autonomic instability
- Concomitant medical condition that may complicate withdrawal
- Suicidal ideation or otherwise psychiatrically unstable

Discharge Criteria

- Mild symptoms responsive to therapy
- Psychiatrically stable

FOLLOW-UP RECOMMENDATIONS

Referral to detox program or facility

PEARLS AND PITFALLS

- Misdiagnosis of medical disease as withdrawal syndrome
- Misunderstanding the relationship between withdrawal syndromes and comorbid medical illness
- Important to administer sufficient quantities of benzodiazepines for patient in benzodiazepine withdrawal states.

ADDITIONAL READING

WOLFF-PARKINSON-WHITE (WPW) SYNDROME

James J. Rifino

BASICS

DESCRIPTION

- Syndrome resulting from the presence of an abnormal (accessory) pathway that bypasses the AV node (Kent bundles) between the atria and ventricles
- Wolff-Parkinson-White (WPW) pattern on the ECG is defined by a short PR interval and a Δ -wave reflecting early conduction (pre-excitation):
 - Accessory pathways occur in 0.1–0.3% of the population.
- WPW syndrome requires ECG evidence of the accessory pathway and related tachycardia.
- Accessory pathways:
 - Small bands of tissue that failed to separate during development:
 - Left lateral (free wall) accessory pathway: Most common
 - The posteroseptal region of the AV groove: 2nd most common location
 - Right free wall
 - Anteroseptal
- Conduction in WPW may be antegrade, retrograde, or both.
- Orthodromic re-entrant tachycardia is the most common (70%):
 - Impulse travels antegrade from the atria down the AV node to the ventricle and then retrograde up the accessory pathway.
 - This re-entrant tachycardia is a narrow complex rhythm unless a bundle branch block or intraventricular conduction delay is present.
- Antidromic is less common (30%):
 - Impulse travels antegrade down the accessory pathway and retrograde through the AV node resulting in a wide quasi-random signal (QRS) complex.
- Sudden death occurs in 1 per 1,000 patient-years in persons with known ventricular pre-excitation.

ETIOLOGY

- Idiopathic:
 - Unknown mechanism in most cases, with familial predisposition
- Rarely inherited as an autosomal dominant trait
- Associated in rare cases with a familial hypertrophic cardiomyopathy

DIAGNOSIS

SIGNS AND SYMPTOMS

History

- Asymptomatic
- Palpitations:
 - Fast or irregular
- Chest pain
- Dyspnea
- Dizziness
- Diaphoresis
- Syncope
- Sudden death (rare)

Physical-Exam

- Tachycardia:
 - Rapid and regular:
 - Supraventricular tachycardia
 - Atrial flutter
 - Irregular:
 - Atrial fibrillation
- Signs of instability:
 - Chest pain
 - Hypotension
 - Change in mental status
 - Rales
 - Cyanosis

ESSENTIAL WORKUP

- WPW syndrome should be considered the underlying etiology in all cases of tachydysrhythmia.
- The diagnosis should be based on the characteristic ECG findings.

DIAGNOSIS TESTS & INTERPRETATION

Lab

- Cardiac enzymes only if signs of ischemia
- Consider electrolytes and thyroid disease

Diagnostic Procedures/Surgery

- EKG
- Pre-excitation:
 - Short PR interval, < 0.12 sec
 - Δ -wave: Small slurred upstroke at the beginning of the QRS

- Prolonged QRS, >0.10 sec with variable morphology linked to specific accessory pathway
- Left lateral pathway:
 - Positive Δ -waves
 - Q-waves with negative to isoelectric deflections in V1 and in the inferior leads:
 - May suggest a former high lateral MI and right axis deviation
- Posteroseptal accessory pathway:
 - Negative deflecting Δ -waves
 - QRS complexes in the inferior leads:
 - Often mistaken for prior inferior MI
- Tachydysrhythmias:
 - Orthodromic atrioventricular re-entrant tachycardia (OAVRT):
 - The pathway that conducts the impulse to the ventricle is the AV node/His–Purkinje system
 - Narrow QRS complex tachycardia
 - However, this may be associated with a wide QRS complex in the presence of a pre-existing or rate-related functional bundle branch block.
 - P-wave following the QRS
 - Rate between 150–250 bpm
 - The Δ -wave seen during sinus rhythm is lost since antegrade conduction is not via the accessory pathway
 - Antidromic AVRT:
 - Regular
 - Wide QRS complex
 - The antegrade limb is usually the accessory pathway.
 - Atrial fibrillation:
 - Irregular
 - Wide complex with variable QRS morphologies

DIFFERENTIAL DIAGNOSIS

- Pre-excitation:
 - Inferior MI
- Narrow complex supraventricular tachycardias without an accessory pathway:
 - AV nodal re-entry tachycardia (AVNRT)
- Wide complex tachycardia:
 - Atrial fibrillation with intraventricular conduction delay
 - Ventricular tachycardia

TREATMENT

PRE HOSPITAL

- Supplemental oxygen and monitor
- Vagal maneuvers (Valsalva), carotid massage, and ice water on the face
- Synchronized cardioversion for:
 - Signs of instability (hypotension, AMS, etc.)
 - Atrial fibrillation with WPW; wide complex tachycardia
- Pre-hospital use of adenosine:
 - Stable patients: No emergent conversion.
 - Unstable patients: Need cardioversion, not adenosine.

INITIAL STABILIZATION/THERAPY

- Unstable patients:
 - Synchronized cardioversion (start with 100 J)
 - Increase incrementally until sinus rhythm is restored (200 J then 360 J).
- Stable patients with wide complex tachycardia:
 - Amiodarone
 - Procainamide
 - **DO NOT USE:** Lidocaine, calcium channel blockers, β -blockers, and Digoxin in patients with wide complex tachycardia and suspected WPW.

ED TREATMENT/PROCEDURES

- Stable patients:
 - Vagal maneuvers: Valsalva and carotid massage:
 - Right carotid artery massage for no more than 10 sec
 - Auscultate the artery 1st for a bruit that would contraindicate this procedure.
 - Fluid replacement and Trendelenburg if the patient has mild hypotension
 - Pharmacologic conversion if carotid massage fails
- Orthodromic (usually narrow complex) AVRT:
 - Adenosine or verapamil
- Antidromic (usually wide complex) AVRT:
 - Procainamide is the drug of choice
 - Although verapamil and β -blockers can be used when the diagnosis is certain, their administration can be dangerous in ventricular tachycardia and WPW with atrial fibrillation, which can be hard to distinguish from this dysrhythmia.
- Irregular wide complex tachycardia:
 - WPW syndrome with atrial fibrillation
 - Amiodarone or procainamide.

Pediatric Considerations

- Children may develop ventricular rates up to 320 bpm that are poorly tolerated.
- Cardiovert unstable children with 0.5–2 J/kg.

- Vagal maneuvers and adenosine are safe in stable children.

MEDICATION

- Adenosine: 6 mg rapid IV bolus over 1–2 sec; if ineffective, repeat with 12 mg (peds: 0.1 mg/kg rapid IV push, repeat with 0.2 mg/kg)
- Amiodarone: 150 mg IV over 10 min, 360 mg over the next 6 hr
- Magnesium: 2 g IV bolus
- Procainamide: 6–13 mg/kg IV at 0.2–0.5 mg/kg/min until either arrhythmia controlled, QRS widens 50%, or hypotension, then 2–6 mg/min, max. of 1,000 mg

First Line

- Amiodarone for wide complex tachycardias
- Adenosine for narrow complex tachycardias

Second Line

- Procainamide for wide complex tachycardias
- IV Procainamide, IV Verapamil 5–10 mg, IV Diltiazem 10–20 mg, or Esmolol can be considered as 2nd-line agents for patients with WPW presenting with regular narrow complex tachycardias.

FOLLOW-UP

DISPOSITION

Admission Criteria

- Signs of instability and/or history of syncope
- Failure of outpatient therapy for continuous pharmacologic control or ablation

Discharge Criteria

- Most patients will be stable and can be discharged once converted to sinus rhythm
- Follow-up should be arranged with a cardiologist

Issues for Referral

Electrophysiology studies to assess for radiofrequency ablation or surgery may be performed on outpatient basis.

FOLLOW-UP RECOMMENDATIONS

The patient should be instructed to return to the ED with any symptoms suggestive of a tachydysrhythmia:

- Palpitations
- Dizziness
- Chest pain

- Feeling faint or actual syncope

PEARLS AND PITFALLS

Never use calcium channel blockers, β -blockers, or digoxin in patients with pre-excitation with atrial fibrillation or wide complex tachycardia:

- These medications prolong the refractory period of the AV node, increasing the rate of transmission through the accessory pathway, and may result in fatal ventricular dysrhythmias.
- If symptoms > 48 hr, anticoagulation must be addressed prior to cardioversion as 1–3% of patients will have embolic event. Transesophageal echo should be considered to rule out left atrial thrombus.

WOUND BALLISTICS

Brian K. Snyder

BASICS

DESCRIPTION

The physical forces that determine the wounding potential of gunshot and other penetrating wounds

ETIOLOGY

- Wounding potential of bullet is determined by mass and velocity.
- The type and severity of a wound is determined by:
 - Wounding potential
 - Construction and shape of the bullet
 - Orientation of the bullet upon striking body
 - Deformity or fragmentation
 - What tissues the bullet traverse
- Traditional distinction between low and high muzzle **velocity** does not differentiate kind and severity of wounding:
 - A civilian hunting rifle or a large-caliber handgun with a hollow-point bullet may produce a more severe wound than a bullet with a full metal jacket from a “high-velocity” military rifle.
- Bullets wound by 2 main mechanisms—**crush** and **stretch**:
 - Sonic pressure wave that precedes bullet has no role in wounding.
 - Bullet crushes the tissue it directly passes through, forming a *permanent cavity*.
 - *Stretch* is produced by radial energy transferred from bullet as it slows down in tissue, forming a *temporary cavity*.
 - A bullet is stabilized in flight by *spin* transmitted from rifling in the barrel.
 - Spin minimizes *yaw*, which is the angle between the long axis of the bullet and its flight vector.
 - Without spin, a bullet would yaw to its most stable flight configuration, which is base and center of mass forward:
 - Not aerodynamically efficient
- As bullet enters tissue, spin of bullet is reduced and bullet will yaw.
- When yaw is 90°, a bullet crushes maximal amount of tissue, slows down the most, and maximal stretch injury occurs.
- Bullets designed to deform in tissue (soft point, hollow point) will expand on impact:
 - Increases amount of crush injury
 - Moves bullet center of mass forward

- Jacketed bullets prevent lead stripping in the barrel, which occurs at high muzzle velocities:
 - Jacketed bullets do not deform but may fragment.
 - Fragmentation increases surface area and crush injury.
- Bullets striking bone often fragment and may cause bone fragments to become secondary projectiles.
- Severity of wound also depends upon *tissue composition and thickness*:
 - Minimally elastic tissues, near-water-density tissue (brain, liver), fluid-filled (heart, bowel) and dense organs (bone) may be injured by the temporary cavity.
 - More elastic tissue, such as lung and skeletal muscle, may absorb the energy from temporary cavity formation and sustain minimal damage.
 - Extremities are often not thick enough for the bullet to fully yaw:
 - Temporary cavity formation is minimal.
 - Most damage is caused by direct crush injury of the bullet, its fragments, or secondary projectiles.
- Short-range shotgun blasts can produce severe wounds with compromise of the blood supply:
 - In short-range shotgun injuries, pellets may be greatly scattered in tissue secondary to the pellets striking each other.
- Stab wounds with knives and other sharp instruments are low-energy wounds with tissue injury from direct weapon contact.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Severe underlying tissue damage and life-threatening injury may occur with even small entrance wounds.
- A knowledge of how different kinds of weapons and bullets wound, the trajectory of the bullet through the body, and the effect on different body tissues will allow the physician to carefully evaluate gunshot and stab wounds and their potential morbidity and mortality.

History

- Field personnel can provide information about weapon type and size, distance, and angle between the weapon and victim:
- This information may not be available or may be inaccurate.

Physical-Exam

- Evaluate for entrance and exit wounds:
- May estimate trajectory and potential for tissue damage
- Exit wounds are often stellate and larger than entranced wounds unless energy is

dissipated at skin surface by special bullet type (hollow point, etc.).

- With high-velocity projectiles, exit wound may be much more extensive than entrance wound.
- Because of the elasticity of the skin, bullet can often be palpated subcutaneously.
- It is not always possible to differentiate entrance from exit wounds; clinicians do this poorly, so wounds should be described fully and classification as entrance or exit wounds should be avoided.

ESSENTIAL WORKUP

- ABCs must be stabilized prior to any workup.
- Account for all injury tracts.
- Place markers at wound sites.
- Examine all areas of the body for wounds (remember the perineum, axillae, and scalp).

DIAGNOSIS TESTS & INTERPRETATION

Lab

Initial lab tests are not especially helpful in diagnosis but may be helpful in guiding resuscitation.

Imaging

- Anteroposterior and lateral radiographs help localize bullet:
 - With placement of markers at wound sites, wound trajectory can be estimated
 - Fragments, fractures, pneumothoraces, or hemothoraces can be identified.
- US:
 - A positive FAST scan is highly predictive of a therapeutic laparotomy. A negative FAST scan does not exclude significant intra-abdominal injury.
 - US for pericardial effusion in potential mediastinal injuries
- CT scanning:
 - Identify location of projectile.
 - Location and amount of tissue damage (especially to the head and brain)
 - Abdominal CT is increasingly used in the evaluation of stable patients with penetrating back/flank or abdominal trauma.
 - In penetrating trauma of the thorax, an initial negative CT scan of the thorax obviates the usual practice of repeated chest radiographs.
- Angiography may be necessary if patient has potential vascular injury and surgical exploration is not otherwise warranted.

Diagnostic Procedures/Surgery

- Local wound exploration with clear delineation of the base of the wound tract that does not penetrate deep structures may be sufficient to evaluate stab wounds.

- Abdominal wounds that encroach the posterior fascia require further evaluation, either diagnostic peritoneal lavage or surgical exploration.
- Extent of tissue injury often apparent only on surgical exploration.

DIFFERENTIAL DIAGNOSIS

Organs at risk of damage can be inferred from weapon type, distance, locations of entrance and exits wounds, or projectiles on imaging.

- Tissues surrounding the projectile tract are also at risk of injury (i.e., from temporary cavity).
- Projectiles may fragment and create multiple injury tracts.

TREATMENT

PRE HOSPITAL

- Gunshot and stab wounds to chest with unstable vital signs warrant a needle thoracostomy in the side of the chest with the entrance wound:
 - _ Relieves tension pneumothorax
 - _ If no improvement, a needle thoracostomy should be placed in the contralateral hemithorax.
- Impaled objects or projectiles should not be removed:
 - _ Immobilize with tape and gauze and transport.
- Clothing should be preserved if possible:
 - _ Clothing should be cut around holes made by the projectiles to preserve evidence.
- Patient should be transported to the closest trauma center.
- Hypotensive patient may be taken directly to the OR.

INITIAL STABILIZATION/THERAPY

Stabilize airway, breathing, and circulation. Secure adequate IV access.

ED TREATMENT/PROCEDURES

- Impaled objects should be removed only in the OR.
- In the ED, estimate tissue injury based on the above principles.
- Wound care includes appropriate exploration, irrigation, and debridement of devitalized tissue.
- All bullets are contaminated with bacteria and are **not** sterilized by being fired:
 - _ All nongrazing bullet wounds warrant empiric antibiotics.
- Early trauma, orthopedic, and vascular surgery consultation is necessary.

MEDICATION

Prophylactic antistaphylococcal antibiotics should be prescribed for several days:

- Cefazolin 1 g IV q6h
- Cephalexin 500 mg PO q6–8h

- For penicillin-allergic patients or patients at risk for methicillin-resistant *Staphylococcus aureus* then vancomycin 1 g IV q12h, clindamycin 300 mg IV/PO q6h, or sulfamethoxazole/trimethoprim DS 1 tablet BID can be prescribed
- Intra-abdominal wounds require broader coverage (many regimens available) such as cefotetan 1 g IV q12h, piperacillin/tazobactam 3.75 mg IV q6h, or the combination of ciprofloxacin 500 mg IV q12h with metronidazole 500 mg IV q8h

FOLLOW-UP

DISPOSITION

Admission Criteria

- Patients with neurovascular compromise and extensive tissue damage must be admitted for appropriate surgical intervention.
- Patients with nontrivial injury to the head, neck, torso, or abdomen should be admitted.
- Patients with injury from high-velocity projectiles or gunshot wounds should be admitted to a monitored setting for observation of neurovascular status.

Discharge Criteria

Patients with minor penetrating extremity trauma or stabbing victims found not to have significant injury may be discharged with appropriate follow-up.

Issues for Referral

Emergent consultation of appropriate surgical specialists should be obtained for patients with potential injuries to vascular or nervous structures.

FOLLOW-UP RECOMMENDATIONS

Patients not admitted to the hospital should have scheduled follow-up with a trauma surgeon or an appropriate surgical specialist (e.g., orthopedist for extremity trauma).

PEARLS AND PITFALLS

- Do not underestimate the extent of underlying tissue damage or injury to critical structures given the size or location of entrance or exit wounds.
- Account for all projectiles and all injury tracts.
- Gunshot and stab wounds are usually reportable to local law enforcement.

Streptococcal toxic shock syndrome (STSS), 1082–1083

Streptococcus bovis, endocarditis from, 366

Streptococcus pneumoniae, endocarditis from, 366
Streptococcus pyogenes, lymphadenitis from, 666
Streptococcus viridans, endocarditis from, 366
Stridor, 1084–1085
 diagnosis, 1084
 treatment, 1084–1085
STSS. *See* Streptococcal toxic shock syndrome (STSS)
Stupor, 248
Subarachnoid hemorrhage, 214–215, 486, 1086–1087
 diagnosis, 1086
 imaging, 1086
 risk factors, 1086
 treatment, 1087
Subclavian steal syndrome, 1220
Subdural hematoma (SDH), 1088–1089
 classification, 1088
 diagnosis, 1088
 imaging, 1088
 treatment, 1088–1089
Sudden infant death syndrome (SIDS), 1090–1091
 diagnosis, 1090–1091
 imaging, 1090
 risk factors, 1090
 treatment, 1091
Suicide, risk evaluation, 1092–1093
Superficial spreading melanoma, 1036
Superimposed preeclampsia, 904
Superior vena cava (SVC) syndrome, 1172–1173
Supracondylar fracture, 360–361
Supraspinatus tendonopathy, 1116–1117
Supraventricular tachycardia (SVT), 1094–1095, 1108–1109
 diagnosis, 1094
 imaging, 1094
 treatment, 1094–1095

SVT. *See* Supraventricular tachycardia (SVT)

Sympathomimetic poisoning, 1096–1097

diagnosis, 1096–1097

imaging, 1096

treatment, 1097

Sympathomimetic toxidrome, 244, 892

Syncope, 1098–1099

imaging, 1098

pregnancy and, 1098

treatment, 1099

Syndesmosis sprain, 70

Syndrome of inappropriate antidiuretic hormone (SIADH), 590

Synovitis, toxic, 1102–1103

diagnosis, 1102

imaging, 1102

treatment, 1103

Syphilis, 1104–1105

diagnosis, 1104–1105

stages of, 1104

treatment, 1105

Systemic inflammatory response syndrome (SIRS), 1018–1019

Systemic lupus erythematosus (SLE), 1106–1107

diagnosis, 1106–1107

genetics, 1106

risk factors, 1106

treatment, 1107

Systolic heart failure, 256

T

Tachycardia, 892

pacemaker-mediated, 182

Tachydysrhythmias, 1108–1109

diagnosis, 1108–1109

treatment, 1109

Tachypnea, 893

Takayasu arteritis, 1206

TAPVR. *See* Total anomalous pulmonary venous return (TAPVR)

Taser injuries, 1110–1111

diagnosis, 1110

imaging, 1110

treatment, 1111

Technetium^{99m} sestamibi, in cardiac testing, 185

Temporal arteritis. *See* Giant cell arteritis (GCA)

Temporal lobe epilepsy, 1220

Temporomandibular joint (TMJ) dysfunction, 1112–1113

diagnosis, 1112

treatment, 1113

TEN. *See* Toxic epidermal necrolysis (TEN)

Tendonitis, 1116–1117

definition, 1116

diagnosis, 1116–1117

imaging, 1117

treatment, 1117

Tendon laceration, 1114–1115

diagnosis, 1114

imaging, 1114

treatment, 1114–1115

Tennis elbow, 1116–1117

Tenosynovitis, 1118–1119

definition, 1118

diagnosis, 1118

treatment, 1119

Tension pneumothorax, 882–883

Testicular salvage, 1120–1121

Testicular torsion, 1120–1121

bimodal distribution of, 1120

diagnosis, 1120–1121

imaging, 1120

treatment, 1121

Tetanus, 1122–1123

diagnosis, 1122

incubation period, 1122

treatment, 1123

Tetralogy of Fallot (TOF), 254

“Tet spells,” 254

TGA. *See* Transient global amnesia (TGA)

Thalamic hemorrhage, 612

Theophylline poisoning, 1124–1125

Thermal burns, 168–169

corneal, 268

Third-degree atrioventricular block, 118–119

Thoracic aortic dissection, 78–79

Thoracic outlet syndrome (TOS), 1126–1127

diagnosis, 1126–1127

imaging, 1127

treatment, 1127

Thoracic pain, 224

Thoracic spine injury, 1062–1063

diagnosis, 1062–1063

treatment, 1063

Thought disorder, 1006

Threatened abortion, 12

treatment, 13

Thrombocytosis, 632

Thrombosis

cavernous sinus, 204–205

deep vein, 288–289

Thrombotic thrombocytopenic purpura (TTP), 960, 1128–1129

Thumb fracture, 1130–1131

Thyroiditis, 574

Thyroid stimulating hormone (TSH), 574

Thyrotropin-releasing hormone (TRH), 574

TIA. *See* Transient ischemic attack (TIA)

Tibial fractures, 1134–1135

Tibial plateau fracture, 1132–1133

- diagnosis, 1132–1133
- imaging, 1132
- Schatzker classification of, 1132
- treatment, 1133

Tic douloureux, 1166–1167

Tick bite, 1136–1137

Tillaux fracture, 68

Tinea capitis, 1138–1139

Tinea corporis, 1138

Tinea cruris, 1138

Tinea infections, cutaneous, 1138–1139

Tinea pedis, 1138

Tinea unguium, 1138

Tinea versicolor, 1010, 1138

TMJ clicking, 1112–1113

Toddler fracture, 1134

Toluene poisoning, 1140–1141

- diagnosis, 1140–1141
- pregnancy and, 1140
- treatment, 1141

Toothache, 1142–1143

Tooth fractures, 300

Torsades de pointes, 1108–1109

Torticollis, 1144–1145

Torticopelvic crisis, 348

Torus fracture, 424–425

TOS. *See* Thoracic outlet syndrome (TOS)

Total anomalous pulmonary venous return (TAPVR), 254

Toxalbumins, 870–871

Toxic cardiomyopathy, 190

Toxic epidermal necrolysis (TEN), 388, 1076–1077, 1146–1147

- Toxic shock syndrome (TSS), 1148–1149
- Toxidromes, 892–893
- Toxoplasma gondii*, 1150–1151
- Toxoplasmosis, 1150–1151
 - diagnosis, 1150
 - imaging, 1150
 - treatment, 1151
- Tracheitis, bacterial, 124–125
 - diagnosis, 124
 - treatment, 125
- Tractional retinal detachments (TRD), 974
- Transanal injury, 246
- Transfusion complications, 1152–1153
- Transient global amnesia (TGA), 1154–1155
- Transient ischemic attack (TIA), 1032, 1156–1157
 - diagnosis, 1156
 - imaging, 1156
 - treatment, 1157
- Transplant rejection, 1158–1159
 - diagnosis, 1158–1159
 - epidemiology, 1158
 - treatment, 1159
- Transposition of the great arteries (TGA), 254
- Transudative effusion, 872
- Trauma
 - abdominal
 - blunt, 6–7
 - imaging, 8–9
 - penetrating, 10–11
 - chest
 - blunt, 226–227
 - penetrating, 228–229
 - colon, 246–247
 - dental, 300–301

diaphragmatic, 316–317

duodenal, 340–341

esophageal, 392–393

extremity, 398–399

geriatric, 456–457

head

blunt, 486–487

penetrating, 488–489

lightning injuries and, 656

multiple, 1160–1161

otologic, 788–789

pancreatic, 796–797

pediatric, 812–813

in pregnancy, 906–907

rectal, 954–955

urethral, 1178–1179

Traumatic amputation, 56–57

diagnosis, 56

treatment, 56–57

Traumatic aortic rupture/injury (TAI), 80–81

Traumatic diplopia, 324–325

Traumatic iritis, 616–617

TRD. *See* Tractional retinal detachments (TRD)

Trichomonas, 1162–1163

Trichomonas vaginalis, 1162

Tricuspid atresia, 254

Tricyclic antidepressant poisoning, 1164–1165

Trigeminal neuralgia, 1166–1167

Trigger finger, 1116–1117

Triplane fracture, 68

Truncal ataxia, 112

Truncus arteriosus, 254

TSS. *See* Toxic shock syndrome (TSS)

TTP. *See* Thrombotic thrombocytopenic purpura (TTP)

Tuberculosis (TB), 1168–1169

diagnosis, 1168–1169

imaging, 1168

mechanism, 1168

reactivation, 1168

treatment, 1169

Tuft fracture, 1130

Tularemia, 1170–1171

diagnosis, 1170–1171

treatment, 1171

weaponization of, 1170

Tularemia, as biologic weapon, 140–141

Tumor compression syndromes, 1172–1173

diagnosis, 1172–1173

imaging, 1172

treatment, 1173

Twisted neck, 1144–1145

Tympanic membrane perforation, 1174–1175

U

UFH. *See* Unfractionated heparin (UFH)

Ulcerative colitis (UC), 608

Ultraviolet keratitis, 1176–1177

Uncomplicated pregnancy, 908–909

diagnosis, 908–909

imaging, 908–909

treatment, 909

Unconjugated (indirect) hyperbilirubinemia, 630

Unfractionated heparin (UFH), 964

Unresponsiveness, 248

Unstable angina, 26

Upper gastrointestinal bleeding, 454–455

Uremic syndrome, 960

Ureterovaginal fistula, 1184–1185

Urethral trauma, 1178–1179

diagnosis, 1178

imaging, 1178

treatment, 1179

Urethritis, 1180–1181

Urethrovaginal fistula, 1184–1185

Urinary retention, 1182–1183

Urinary tract fistula, 1184–1185

Urinary tract infections

adult, 1186–1187

pediatric, 1188–1189

Urticaria, 1190–1191

acute, 1190

chronic, 1190

diagnosis, 1190–1191

treatment, 1191

Uterine rupture, trauma in pregnancy, 906

Uvulitis, 1192–1193

diagnosis, 1192

epidemiology, 1192

treatment, 1192–1193

V

Vaginal bleeding, 1194–1195

in pregnancy, 1194, 1196–1197

in spontaneous abortion, 12

Vaginal discharge, 1198–1199

Vaginitis, 1198–1199

Valsalva maneuvers, and pneumomediastinum, 876

Valvular heart disease, 1200–1201

diagnosis, 1200–1201

imaging, 1200–1201

pregnancy and, 1200

treatment, 1201

VAP. *See* Ventilator associated pneumonia (VAP)

Variceal hemorrhage, 238, 1204–1205

Varicella, 1202–1203

Varices, 1204–1205

Vasculitis, 370, 1206–1207

Vasogenic shock, 1026–1027

VBI. *See* Vertebrobasilar insufficiency (VBI)

Venom-induced consumption coagulopathy (VICC), 1046–1047

Venous insufficiency, 1208–1209

- diagnosis, 1208
- imaging, 1208
- phases of, 1208
- treatment, 1209

Venous thoracic outlet syndrome (VTOS), 1126–1127

Ventilation

- airway management, 40–41
- percutaneous translaryngeal, 40

Ventilator associated pneumonia (VAP), 878

Ventilator management, 1210–1211

Ventricular fibrillation (VF), 1212–1213

Ventricular peritoneal (VP) shunts, 1214–1215

Ventricular tachycardia (VT), 1108–1109, 1216–1217

Vertebrobasilar insufficiency (VBI), 1218–1219

- diagnosis, 1218–1219
- imaging, 1218
- mechanism, 1218
- treatment, 1219

Vertebrobasilar migraines, 1220

Vertigo, 1220–1221

- central, 1220
- and labyrinthitis, 640–641
- peripheral, 1220

Vesicovaginal fistula, 1184–1185

Vesiculobullous lesions, 946

Vibrio parahaemolyticus

diarrhea from, 318

gastroenteritis from, 450–451

VICC. *See* Venom-induced consumption coagulopathy (VICC)

Violence

domestic, 336–337

management of, 1222–1223

Viral conjunctivitis, 258–259

Visual loss, 1224–1225

diagnosis, 1224

imaging, 1224

treatment, 1224–1225

Vitamin K toxicity, 889

Vitreous hemorrhage, 1226–1227

Vocal cord dysfunction, 1084–1085

Volvulus, 1228–1229

diagnosis, 1228–1229

imaging, 1228

malrotation with, 156

treatment, 1229

Vomiting

adult, 1230–1231

cyclic, 1232–1233

pediatric, 1234–1235

von Willebrand disease, 1236–1237

diagnosis, 1236

genetics, 1236

treatment, 1236–1237

von Willebrand factor (vWF), 1236–1237

VTOS. *See* Venous thoracic outlet syndrome (VTOS)

W

Warfarin complications, 1238–1239

Warts, 1240–1241

Weakness, 1242–1243

Weapons of mass destruction, biologic, 140–141

Wedge fracture, neck, 1054–1055

West Nile virus, 1244–1245

Wheezing, 1246–1247

Whole-bowel irrigation, 890–891

Wide complex tachycardia, 1216–1217

Wilson disease, 592

Withdrawal

- alcohol, 1248–1249

- drug, 1250–1251

Withdrawal toxidrome, 892

Wolff–Parkinson–White (WPW) syndrome, 1094–1095, 1252–1253

Wound ballistics, 1254–1255

Wound botulism, 154–155

Wrist tendinitis, 1116–1117

Wry neck, 1144–1145

Y

Yersinia

- diarrhea from, 318

- gastroenteritis from, 450–451

Z

Zygomatic arch fractures, 400
