this study, *P. mendocina* NSYSU and soils collected from the OCDF-contaminated site (OCDF concentration = 10.8 mg/kg) were used as the inocula. Glucose, which was used as the primary substrate, was supplied in the microcosms. Approximately 500 mg of glucose was added in the batch bottle to serve as the primary substrate for microorganisms and *P. mendocina* NSYSU. Each batch bottle contained 5 mL of glucose solution (100 g/L) (or 5 mL of mineral medium solution), 15 g of site soils, 5 mL of *P. mendocina* NSYSU solution as inocula (or 5 mL of mineral solution), and 35 mL of mineral medium (autoclaved before use) in a 70-mL serum bottle, which was sealed with Teflon-lined rubber septa.

Table 1 lists the constituents of different microcosms. Batch A was kill control batch containing 500 mg/L NaN₃ and 250 mg/L HgCl₂, and the soils were autoclaved before use. Batch B was live control batch containing OCDF-contaminated soils and *P. mendocina* NSYSU, but no glucose addition. Batch C was also live control batch containing OCDF-contaminated soils and glucose, but no *P. mendocina* NSYSU addition. Dead (Batch A) and live controls (Batches B and C) were prepared to assess the effects of substrate (glucose) and inocula addition on OCDF removal.

Batch D bottles contained sterilized soils, glucose, and *P. mendocina* NSYSU, and Batch E bottles contained unsterilized soils, glucose, and *P. mendocina* NSYSU. *P. mendocina* NSYSU was incubated aerobically in nutrient and glucose medium solution and the microcosms were operated at room temperature (20°C). Duplicate samples were analyzed for OCDF concentrations for each sampling event. The degradation efficiency of OCDF was calculated as a percentage of the concentration on day 0. The procedures for *P. mendocina* NSYSU incubation, soil extraction procedures, and OCDF analytical methods were described in Tu et al. (2014).

Table 1. Components of five batches of biodegradation experiments.

Microcosm	Inocula	Components
A (Kill control)	Sterilized soils	Sterilized OCDF-contaminated soils + nutrient medium solution + glucose + 250 mg/L HgCl ₂ + 500 mg/L NaN ₃
B (Control-no glucose)	Soils + <i>P. mendocina</i> NSYSU	OCDF-contaminated soils + nutrient medium solution + <i>P. mendocina</i> NSYSU
C (Control-no strain)	Soils	OCDF-contaminated soils + nutrient medium solution + glucose
D	Sterilized soils + <i>P. mendocina</i> NSYSU	Sterilized OCDF-contaminated soils + nutrient medium solution + <i>P. mendocina</i> NSYSU + glucose
E	Soils + <i>P. mendocina</i> NSYSU	OCDF-contaminated soils + nutrient medium solution + <i>P. mendocina</i> NSYSU + glucose

3 RESULTS AND DISCUSSION

Figure 1 presents the remained OCDF in A to E batches during the 50 days of operation. Slight OCDF removal [approximately 3% (Batch A) to 8% (Batch C) removal] was observed in kill-control batch (Batch A), control-no glucose batch (Batch B), and control-no NSYSU strain (Batch C). Results demonstrate that soil bacteria could not biodegrade OCDF effectively under aerobic conditions. This might be due to the fact that the furan-degrading bacteria were not the dominant bacteria in site soils. Results also reveal that supplement of primary substrate is a necessity to enhance the anaerobic dechlorination. Results demonstrate that OCDF could not be used as the carbon source by *P. mendocina* NSYSU or soil bacteria. Slight decrease in OCDF concentration in Batch B (control-no glucose) bottles was because natural organic carbon was consumed by *P. mendocina* NSYSU for primary substrate.

In Batch D bottles (sterilized soils with *P. mendocina* NSYSU addition), significant drop of OCDF was observed and about 62% of OCDF was degraded after 50 days. Results demonstrate that efficient OCDF biodegradation could be obtained aerobically by *P. mendocina* NSYSU with the supplement of glucose. The glucose could be used as the carbon sources by *P. mendocina* NSYSU. Thus, OCDF could be degraded through aerobic cometabolic mechanisms using glucose as the carbon sources. In Batch E bottles (non-sterilized soils with *P. mendocina* NSYSU addition), relatively lower efficiency OCDF degradation (27%) was detected. Results might be due to the fact that indigenous bacteria competed the supplied carbon sources with *P. mendocina* NSYSU resulting in the decreased efficiency of OCDF removal.

Figure 1. The remained OCDF in microcosms during the 50-day incubation period.

4 CONCLUSIONS

This study was conducted to evaluate the capability of *P. mendocina* NSYSU on the aerobic biodegradation of OCDF. Under aerobic cometabolic conditions, *P. mendocina* NSYSU had the capability to biodegrade OCDF. Glucose could be used as the primary substrate resulting in increased aerobic biodegradation of OCDF. The removal efficiencies for OCDF reached 65% in microcosms with the supplement of glucose under anaerobic conditions, respectively. Results demonstrate that OCDF could not be used as the carbon source for *P. mendocina* NSYSU and indigenous soil bacteria under aerobic conditions. Therefore, addition of an appropriate substrate was required to enhance the OCDF biodegradation. Results reveal that an on-site bioreactor or in situ bioremediation using *P. mendocina* NSYSU as the inocula would be a cost-effective and acceptable remedial system to remediate furan-polluted soils.

Experimental study on water-soil interaction influence for environmental change of marine soft soil

Han-min Liu, Dong Zhou, Heng Wu, Wen-can Jiao & Ye-tian Wang

College of Civil Engineering and Architecture, Guangxi University, Nanning, China

Key Laboratory of Disaster Prevention and Structural Safety of the Ministry of Education, Guangxi University, Nanning, China

ABSTRACT: In this paper, the research object is marine soft soil in Linhai Park of Qinzhou Port and Qisha Park of Fangchenggang Port. The marine soft soil environment factors, additional load stress of coastal reclamation layer and calcium ions of pore water chemical composition, were simulated by using a soil soaking-load linkage. The soil soaking-load linkage is mechanism simulation device. Impact on water-soil interactions of marine soft soil was analyzed for additional load stress of coastal reclamation layer and calcium ions of pore water chemical composition. The conclusion is as follows. Firstly, from the point of geotechnical engineering, there are mainly hydraulic connection, water chemical field and additional load stress of coastal reclamation layer for the soil and water environmental change of marine soft soil in coastal reclamation district. Secondly, the soil and water environmental change of marine soft soil in coastal reclamation district is simulated by using a soil soaking-load linkage. Thirdly, under the same circumstances of the calcium ions concentration of soak solution, the consolidation deformation of artificial soil samples come up under the action of additional load stress, consequently, artificial soil samples' porosity decreases. Artificial soil samples' porosity and osmotic coefficient decreases along with the increase of additional load stress of coastal reclamation layer. Artificial soil samples' calcium ions content decreases along with the increase of additional load stress of coastal reclamation layer. Fourthly, under the same circumstances of the additional load stress of coastal reclamation layer, artificial soil samples' calcium ions content increases along with the increase of calcium ions concentration of soak solution. Fifthly, artificial soil samples' porosity and osmotic coefficient decrease slightly along with the increase of the calcium ions concentration of soak solution under the same circumstances of the additional load stress of coastal reclamation layer with the exception of 180 kPa in Linhai Park of Qinzhou Port.

1 INTRODUCTION

Since the 21st century, large-scale coastal reclamation engineering was created in our country (Ge et al. 2014, Sun et al. 2012, Dong et al. 2014). Much of the coastal reclamation engineering is industry and urban construction land such as Linhai Park of Qinzhou Port and Qisha Park of Fangchenggang Port. There is a mass of soft soil in coastal reclamation district (Liu et al. 2014, Yi et al. 2015, Ou et al. 2015). The kind of project such as the coastal reclamation engineering has the following characteristics. First, the area of coastal reclamation land is large, according to the overall planning of Qinzhou City during 2008 to 2025, the total coastal reclamation area will reach about 79 km². Second, the schedule of coastal reclamation land is fast, the time is shorter than the coastal reclamation land use for industrial and urban construction land from construction to use. The coastal reclamation engineering of Linhai Park of Qinzhou Port and

Qisha Park of Fangchenggang Port completed by hydraulic filled sand, and applied directly to the engineering facilities construction after foundation treatment was fulfilled (Liu et al. 2012, Hu 2009). Third, the load of coastal reclamation layer to underlying layer strata is great. Coastal reclamation district extends gradually from tidal flats to shallow sea, along with the construction technology of Coastal reclamation become mature and demand for land use area increase. Thickness of coastal reclamation layer increase sharply, therefore the load of coastal reclamation layer to underlying layer strata also increase sharply. The depth of railway feeder hydraulic filled sand project from Dalanping to Qinzhou Free Trade Area is as deep as decade meters. Disturbance of environment of marine soft soil is extremely severe because of coastal reclamation compare with the formation of the natural evolution process of marine soft soil. Marine soft soil and its formation of the natural geological environment are a relatively stable state of dynamic

balance before coastal reclamation. The state of marine soft soil deposition would change rapidly after a violent disturbance of coastal reclamation, and its environment would achieve a new dynamic equilibrium.

2 BASIC PHYSICAL PROPERTIES OF SOIL SAMPLES IN COASTAL RECLAMATION DISTRICT

Test results of basic physical properties of soil samples in coastal reclamation district are shown in Table 1.

Particle size distribution of marine soft soil was measured by sieving method and densimeter method in Linhai Park of Qinzhou Port and Qisha Park of Fangchenggang Port. Test samples of marine soft soil mixed sodium hexametaphosphate that its concentration is 4%. Test analysis results of particle size distribution are as follows.

Content of fine grained soil which the particle size is less than 0.075 mm reach 80.55%, content of fine grained soil which the particle size is less than 0.005 mm reach 43.69% in Linhai Park of Qinzhou Port.

Content of fine grained soil which the particle size is less than 0.075 mm reach 82.2%, content of fine grained soil which the particle size is less than 0.005 mm reach 33.3% in Qisha Park of Fangchenggang Port.

3 ANALYSIS OF THE SOIL AND WATER ENVIRONMENTAL CHANGE OF MARINE SOFT SOIL FOR COASTAL RECLAMATION

That coastal reclamation impact on environment of marine soft soil is multifaceted. From the point of geotechnical engineering, in order to coastal reclamation engineering of Linhai Park of Qinzhou Port and Qisha Park of Fangchenggang Port as the research object, water-soil environmental change of marine soft soil was analyzed as follows.

First, environmental change of the hydraulic connection was analyzed. Hydraulic connection environment of marine soft soil will be significant changes before and after coastal reclamation engineering. Marine soft soil contact with seawater

directly before coastal reclamation engineering, hydraulic connection is strong, marine soft soil was separated by coastal reclamation layer of hydraulic filled sand, hydraulic connection is weaken. Marine soft soil contact with seawater by means of pore water seepage of coastal reclamation layer of hydraulic filled sand. The surface of coastal reclamation layer of hydraulic filled sand is ground surface which is exposed to air layer, the bottom contact with marine soft soil, one side of coastal reclamation layer of hydraulic filled sand contact with seawater, the other side contact with land directly. The nature of the changes of the original boundary conditions have taken place. Pore water source of coastal reclamation layer will be controlled by its boundary conditions.

Second, environmental change of water chemical field was analyzed. With marine soft soil environmental change of the hydraulic connection, discharge and supply conditions of marine soft soil's pore water will change, water chemical field and its chemical components of marine soft soil's pore water will change before and after coastal reclamation engineering. Material sources of coastal reclamation layer's pore water chemical composition divided into three parts. Section one of pore water chemical composition is derived from seawater lied in the side of the sea, section two of pore water chemical composition is derived from the groundwater seepage lied in the side of the land, section three of pore water chemical composition is derived from the surface seepage. Soil-water interactions of marine soft soil will be new changes, because the material composition of water field change.

Figure 1. The cumulative curve of grain size in Qinzhou and Fangchenggang.

Table 1. The physical properties of marine soft soil.

	Natural moisture content (%)	The proportion of soil particles	Plastic limit (%)	Liquid limit (%)	Plasticity index	Liquidity index
Qinzhou	52.57	2.70	20	42.5	22.5	1.45
Fangchenggang	65.07	2.69	25.3	49.2	23.9	1.67

Third, additional load stress of marine soft soil layer was analyzed due to coastal reclamation layer. Coastal reclamation layer consists of hydraulic filled sand. Coastal reclamation layer of hydraulic filled sand exert new additional load stress to marine soft soil layer. Additional load stress will produce corresponding geotechnical engineering geology effect to marine soft soil.

4 MECHANISM ANALYSIS OF SOIL-WATER INTERACTIONS

Water—soil—electrolyte system consists of marine soft soil, pore water and pore water chemistry composition. Ion composition exchange will happen between pore water of soft soil and soak liquid in the process of soaking, pore water ionic concentration and its components will change. The original dynamic equilibrium of Soil-water interactions is broken between soft soil clay mineral particles and pore water, until a new dynamic equilibrium is reached.

First, ion exchange adsorption occur between soft soil clay mineral particle and pore water solution when the pore water ionic concentration and its components change. The surface state of soft soil clay mineral particles will change because of ion exchange adsorption, and mechanical properties and engineering properties of soft soil will change. The characteristics of ion exchange adsorption is that dissociation ions of surface of soft soil clay mineral particles substitute for disappearing ions in the pore water solution. Ion exchange adsorption is the result of the interaction between clay mineral particles and pore water solution, the strength of the ion exchange adsorption depends on two aspects that are clay mineral particles and pore water solution.

Second, settling—dissolution chemical action of ion chemical compositions of pore water solution come up when the ion composition concentration of the pore water solution change. Calcium ions concentration was increased in in the process of the test, calcium ions precipitated, the generated solid cement filled in the pores of the soil particles, so that the pores of the soil particles would decrease.

5 EXPERIMENTAL STUDY ON WATER-SOIL INTERACTION INFLUENCE FOR ENVIRONMENTAL CHANGE OF MARINE SOFT SOIL

Water-soil environment of marine soft soil was simulated by using a soil soaking-load linkage (Wu et al. 2013) when calcium ions concentration of

soft soil pore water changes. Water-soil interaction taken place between soak liquid calcium ions and soft soil. And then meso-structures of soft soil changed, consequently, physical and mechanical properties of soft soil transformed.

Environmental change of marine soft soil was simulated under the action of additional load stress of coastal reclamation layer and soak liquid of calcium ions in Linhai Park of Qinzhou Port. Combination plans of working condition are a total of nine combinations are shown in Table 2.

Environmental change of marine soft soil was simulated under the action of additional load stress of coastal reclamation layer and soak liquid of calcium ions in Qisha Park of Fangchenggang Port. Combination plans of working condition are a total of nine combinations are shown in Table 3.

5.1 Calcium ions of soft soil

Ion components of soft soil are measured by using the instruments that is model number 5300DV

calcium ions concentration is 4.4%	1615.1	1494.3	1403.0	

Inductively Coupled Plasma Atomic Emission Spectrometer made in Optima Company.

Calcium ions content of disturbed soft soil samples is initial value before disturbed soft soil samples were soaked in Linhai Park of Qinzhou Port and Qisha Park of Fangchenggang Port. Calcium ions content of the center of the artificial soil samples were measured after the completion of the soft soil samples soaked. Test method is that extractive content of soft soil samples' calcium ions in deionized water is evaluation standard.

The determination results of soft soil samples' calcium ions content are shown in Table 4 and Table 5. The unit, mg/kg, shows calcium ions content in per kilogram soil samples.

Change laws of calcium ions content are shown in Figure 2 and Figure 3 along with the additional load stress of coastal reclamation layer.

Figure 2 and Figure 3 show that calcium ions content of artificial soil samples decreases along with the increase of the additional load stress of coastal reclamation layer under the same circumstances of calcium ions concentration of soak solution. With the combination of Figure 6, Figure 7, Figure 10 and Figure 11, we can infer that calcium ions inlet will decrease from soak solution to artificial soil samples along with the decrease of porosity and osmotic coefficient in the process of soaking.

Change laws of calcium ions content are shown in Figure 4 and Figure 5 along with the calcium ions concentration of soak solution.

Figure 4 and Figure 5 show that calcium ions content of artificial soil samples increases along with the increase of the calcium ions concentration of soak solution under the same circumstances of the additional load stress of coastal reclamation layer. The reason is that calcium ions inlet will increase from soak solution to artificial soil samples along with the increase of the calcium ions concentration of soak solution.

Figure 5. The change chart of calcium ions content along with the calcium ions concentration of soak solution in Qisha Park of Fangchenggang Port.

5.2 Porosity

Porosity of artificial soil samples are shown in Table 6 and Table 7 under different conditions in Linhai Park of Qinzhou Port and Qisha Park of Fangchenggang Port.

Change laws of artificial soil samples' porosity are shown in Figure 6 and Figure 7 along with additional load stress of coastal reclamation layer.

Figure 6 and Figure 7 show that artificial soil samples' porosity decreases along with the increase of additional load stress of coastal reclamation layer under the same circumstances of the calcium ions concentration of soak solution. The reason is that the consolidation deformation of soil samples come up under the action of additional load stress, consequently, soil samples' porosity decreases.

Change laws of artificial soil samples' porosity are shown in Figure 8 and Figure 9 along with calcium ions concentration of soak solution.

Figure 8 and Figure 9 show that artificial soil samples' porosity decreases slightly along with

Seawater in Fangchenggang (calcium ions concentration is 0.044%)	15.8	12.5	8.62
calcium ions concentration is 0.44%	14.1	10.6	8.02
calcium ions concentration is 4.4%	11.0	9.35	7.49

soak solution because part of the pores was filled by cementing material precipitation of calcium ions. The reason of the exception of 180 kPa in Linhai Park of Qinzhou Port may be that impact on artificial soil samples' porosity is little for the increase of soak solution's calcium ions concentration. Variable quantity of artificial soil samples' porosity was concealed by error in the process of experiment.

5.3 Osmotic coefficient

Osmotic coefficient of artificial soil samples are shown in Table 8 and Table 9 under different conditions in Linhai Park of Qinzhou Port and Qisha Park of Fangchenggang Port.

Change laws of artificial soil samples' osmotic coefficient are shown in Figure 10 and Figure 11 along with additional load stress of coastal reclamation layer.

Figure 10. The change chart of artificial soil samples' osmotic coefficient along with additional load stress of coastal reclamation layer in Linhai Park of Qinzhou Port.

Figure 11. The change chart of artificial soil samples' osmotic coefficient along with additional load stress of coastal reclamation layer in Qisha Park of Fangchenggang Port.

Figure 10 and Figure 11 show that artificial soil samples' osmotic coefficient decreases along with the increase of the additional load stress of coastal reclamation layer under the same circumstances of calcium ions concentration of soak solution. The change law of artificial soil samples' osmotic coefficient is consistent with change law of artificial soil samples' porosity.

Change laws of artificial soil samples' osmotic coefficient are shown in Figure 12 and Figure 13 along with calcium ions concentration of soak solution.

Figure 12 and Figure 13 show that artificial soil samples' osmotic coefficient decreases slightly along with the increase of the calcium ions concentration of soak solution under the same circumstances of the additional load stress of coastal reclamation layer with the exception of 180 kPa in Linhai Park of Qinzhou Port. The change law of artificial soil samples' osmotic coefficient is consistent with change law of artificial soil samples' porosity.

Figure 12. The change chart of artificial soil samples' osmotic coefficient along with calcium ions concentration of soak solution in Linhai Park of Qinzhou Port.

Figure 13. The change chart of artificial soil samples' osmotic coefficient along with calcium ions concentration of soak solution in Qisha Park of Fangchenggang Port.

6 CONCLUSION

In this paper, the research object is marine soft soil in Linhai Park of Qinzhou Port and Qisha Park of Fangchenggang Port. The marine soft soil environment factors, additional load stress of coastal reclamation layer and calcium ions of pore water chemical composition, were simulated by using a soil soaking-load linkage. The soil soaking-load linkage is mechanism simulation device. Impact on water-soil interactions of marine soft soil was analyzed for additional load stress of coastal reclamation layer and calcium ions of pore water chemical composition. The conclusion is as follows.

1. From the point of geotechnical engineering, there are mainly hydraulic connection, water chemical field and additional load stress of coastal reclamation layer for the soil and water environmental change of marine soft soil in coastal reclamation district.

2. The soil and water environmental change of marine soft soil in coastal reclamation district is simulated by using a soil soaking-load linkage.
3. Under the same circumstances of the calcium ions concentration of soak solution, the consolidation deformation of artificial soil samples come up under the action of additional load stress, consequently, artificial soil samples' porosity decreases. Artificial soil samples' porosity and osmotic coefficient decreases along with the increase of additional load stress of coastal reclamation layer. Artificial soil samples' calcium ions content decreases along with the increase of additional load stress of coastal reclamation layer.
4. Under the same circumstances of the additional load stress of coastal reclamation layer, artificial soil samples' calcium ions content increases along with the increase of calcium ions concentration of soak solution.
5. Artificial soil samples' porosity and osmotic coefficient decrease slightly along with the increase of the calcium ions concentration of soak solution under the same circumstances of the additional load stress of coastal reclamation layer with the exception of 180 kPa in Linhai Park of Qinzhou Port. The reason of the exception of 180 kPa in Linhai Park of Qinzhou Port may be that impact on artificial soil samples' porosity is little for the increase of soak solution's calcium ions concentration. Variable quantity of artificial soil samples' porosity was concealed by error in the process of experiment.

ABSTRACT: This study is to assess greenhouse gases and energy use of China's PPI using an accounting framework that makes up the entire supply chain. A cradle-to-grave tracking is applied in the calculation. We consider three groups of raw materials—wood, waste paper, and non-wood fiber—yet focus on wood and waste paper, which are further divided into two subclasses according to the sources: domestic and imported. The different impacts in the major exporting countries to China's PPI are analyzed by considering the land use change. In addition, sensitivities to changes in major factors in the supply chain are examined. The results of this study are useful in framework designing and decision making of regional strategy department of PPI.

1 INTRODUCTION

Greenhouse Gas (GHG) emissions have become a focus of international attention as the impacts of global climate change increase. Burning of fossil fuels is a major source of GHG emissions, and industries are major users of fossil energy. The Pulp and Paper Industry (PPI) is the fourth largest industrial energy user in the world; electricity and heat are needed for chemical pulping, paper making, black liquor evaporation, and other operations (Chen et al., 2012). Consequently, the PPI is one of the biggest emitters among all the industrial sectors (Nilsson et al., 1995; Gasbarro et al., 2012).

Since 2008, China has overtaken the US as No.1 emitter of GHGs in the world, accounting for 23.33% of global emissions in that year. Furthermore, carbon leakage may exist between Organization for Economic Co-operation and Development (OECD) countries and the newly emerging economies like China as polices in the OECD countries aim at the reduction of domestically produced GHGs, which may result in the relocation of emission-intensive industries to countries with less stringent emission standards. China is also ranked as the largest carbon exporter (Homma et al., 2012; Bruckner et al., 2010).

According to China Paper Manufacturers Association (2010), there were more than 3700 mills in China's PPI, annually producing 73.18 million tonnes of pulp and 92.70 million

tons of paper and paper board, respectively. The gross output value of China's PPI was about USD 95 billion (585 billion Yuan), which accounts for 3.64% of the total GDP (gross domestic product) in China's manufacturing sector. The total consumption of paper and paper board in 2010 was 91.73 million tons, a 7.05% increase from the previous year; per capita consumption of paper and paper board in China was 68 kg, about 23% of the average per capita consumption in developed countries (300 kg). Obviously, there is a great growth space for China's PPI. Thus, energy consumption and GHG emissions in China's PPI will increase inevitably in conjunction with the growing market.

In addition, China's PPI is facing great shortage of domestic raw material supply (Manda et al., 2012). In 2010, China imported 35.43 million m³ of industrial roundwood, an increase of 26.6% from the previous year, which accounts for 34.6% of its total domestic roundwood production (FAO, 2012). China is also a net importer of pulp; 35% of total pulp consumption during 2006–2010 was imported. Moreover, China is the world's biggest buyer of recovered paper (BIR, 2011). Over 62% of China's pulping materials in 2010 was recycled paper, of which 24.35 million tonnes was imported (CTAPI, 2011).

The huge market size of China's PPI highlights the need to investigate the energy use and GHG emissions. Although it has been proved that the

composition structure of raw materials has a great relationship with the energy use and GHG emissions of PPI (Hammett et al., 2001; Wang et al., 2012), imported materials along the supply chain also have a great impact on that because of different forest types and management practices across exporting countries (James, 2012). The perspective of whole supply chain is essential to assess the energy use and GHG emissions of PPI properly.

This paper will look into the energy use and GHG emissions of China's PPI using the supply chain approach and life cycle assessment. We will measure and compare energy use and GHG emissions of paper products made from different raw materials originating from domestic and foreign sources.

2 METHODOLOGY AND DATA

2.1 Assumptions

To achieve study goal, necessary assumptions are made as follows:

1. For raw materials, we included wood fiber, recovered fiber and non-wood fiber. All types of fiber are further divided into domestic and imported fiber except for non-wood fiber that is predominantly domestic grain stoves.
2. Imported wood fiber refers to chips exclusively under the consideration of transportation convenience and industry and employment opportunities protection.
3. Wood pulp is roughly divided into two categories: chemical pulp and mechanical pulp, to achieve a balance between calculation simplicity and obvious differences of energy consumption that exist in different types of wood pulp.
4. This study focuses on fiber only; therefore, other substances (such as fillers, chemicals) are excluded.
5. Carbon sink resulting from domestic forest cultivation to supply wood fiber to PPI is included in the total CO₂ emissions, while the carbon stock in the wooden product used as a raw material in the supply chain is considered as carbon emission.
6. Activities occurring in the final product utilization phase are not incorporated.
7. All used paper is assumed to be incinerated to generate electricity if not recovered, and energy contained in recovered paper is considered to be equivalent to the same amount contained in wood fiber.
8. Being a territorial accounting, transportation activities that occur outside of the study area are excluded consequently.

9. All measurements in this study are based on the production and consumption of 1 ton of paper, and energy is expressed on the Lower Heating Value (LHV) basis.

2.2 System boundary

The system considered in this study consists of wood harvesting, transportation, pulping, paper making, and waste paper disposing as well as importing of raw materials, intermediate products and final products. The system boundary is shown in Figure 1.

First, carbon sequestration in forest cultivation is calculated as emissions mitigation while those associated with wood and waste paper incineration, are ignored since sustainable forestry is assumed. Second, wood cutting and chipping operations are supposed to be carried out in-field before transportation, which is widely accepted as a rational option (Emer et al., 2011; Kallio et al., 2011; Acuna et al., 2012). Third, details of non-wood fiber production are not considered. Finally, energy contained in biomass or/and recycled paper is calculated as energy input, while waste paper discarded is assumed to be incinerated with municipal solid waste, which is considered as energy generation.

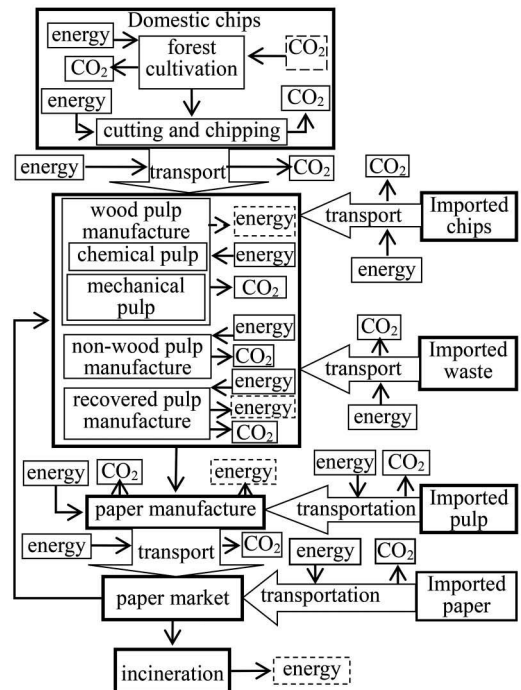

Figure 1. Details of the system boundary.

2.3 Calculation method

2.3.1 Energy consumption calculation

Energy consumption along the supply chain is calculated by subtracting the amount of total energy generation from the amount of total energy input (energy use).

Energy use in wood cutting and chipping operations are included in energy input with cultivation activities. Besides wood, imported pulp and waste paper put into the supply chain are converted into the wood equivalent to calculate biomass energy use. Energy use of non-wood pulp making is assumed to be 28.7 GJ/Adt, including raw material (mainly wheat straw) production, harvesting, chipping, transportation and pulping (Kissinger et al., 2007). The average transportation distance (one way) of domestic goods is assumed to be 150 km and 500 km is assumed for imported goods (Manda et al., 2012).

By-products in pulping processes can be used for energy generation. Generally, there are two sources of energy generation extracted from by-products: black liquor and rejects.

End-products also contain energy. Two end processes are assumed for waste paper: recycled and incineration. The recycle rate of waste paper in China in 2010 is 0.4 (Chen Q.W., 2010).

2.3.2 CO₂ emissions calculation

CO₂ emissions are calculated by multiplying total consumption of each type of energy with the carbon content of the energy source, as follows:

$$CO_2 \text{ emission} = \left(\sum_i E_{el_i} - \sum_j E_{eig_j} \right) * \alpha + \left(\sum_i E_{he_i} - \sum_j E_{heg_j} \right) * \beta + (Energy_{input \text{ cultivation}} + Energy_{input \text{ nonwood}}) * \gamma + Energy_{input \text{ transport}} * \theta - D_w * \tau \quad (1)$$

where α (kg CO₂/kwh) is the emission factor of electricity; β (kg CO₂/GJ) is the emission factor of steam, relying on main fuel used and convert efficiency in objective region; γ is the emission factor of energy used in wood cultivation and non-wood pulp acquisition; θ is the emission factor of energy used in transportation; and τ (kg CO₂/m³) is unit CO₂ emissions mitigation of forest cultivation.

The emissions factors used are the CO₂ emissions factors for fuel combustion as recommended by the IPCC (1996). Emission factors of national primary energy are used for the calculation of carbon emissions in the cultivation and non-wood pulp acquisition, which is accurate enough because the amount of energy use in these activities is minimal.

Table 1. Data of energy consumption and generation.

	Steam (GJ/Adt)	Electricity (kwh/Adt)
(Energy consumption/generation)		
Chemical pulp	22.2/22.2 ^b	700 ^a /2463 ^c
Mechanical pulp	-/5.4 ^d	2200 ^b /-
Recovered pulp	0.4 ^e /0.42 ^e	390 ^e /-
Paper making	5.6 ^e /-	608 ^e /-
paper incineration		-/1200 ^e
Wood incineration		-/1750 ^f

a. Nilsson et al. (1995); b. Gullichsen & Fogelholm (2000); c. Farahani et al. (2004); d. Holmberg & Gustavsson (2007); e. Laurijssen et al. (2010); f. Dornburg et al. (2006).

2.4 Input data

Current state-of-the-art technologies are supposed in estimating the parameters used in this study.

Table 1 presents the amount of energy use and/or generation in different processes. Emissions with energy used in forest cultivation are assumed to be equivalent to coal combustion in this study, because the primary energy used in China is coal (IEA, 2012). Energy used in transportation is assumed to be diesel. The average energy conversion efficiency set in this study is 35% for electricity and 90% for heat (Graus et al., 2007).

3 COMPUTATION RESULTS

3.1 Energy input

The total amount of six parts of energy input are 2914E6 GJ, 955.57E6 GJ, 537.2E6 GJ, 455.44E6 GJ, 372.24E6 GJ, 1.1E6 GJ for biomass, paper making, transportation, pulping, non-wood pulp production and cultivation, respectively, and the total energy input is 5235.55E6 GJ (Figure 2).

Energy use in cultivation is so minimal that it cannot be seen in the diagram. Energy use in pulping is not as much as it used in paper making in China's PPI that corresponds to the large amount of imported pulp as well as large amount of energy use in transportation. Energy contained in all materials put into the supply chain is accounted for, which can explain for the largest energy use among all parts.

3.2 Energy generation

Energy generation in pulping activities is 347.56E6 GJ. Energy generated from waste paper incineration is 679.34E6 GJ, and 1221.88E6 GJ is the energy contained in the recovered paper.

In 2010, there is a small amount of net exported paper and paper board whose energy contained is calculated as energy generation with conversion factor between paper and wood equivalent. In all, the total energy generation in China's PPI in 2010 is 2281.08E6 GJ.

3.3 Energy consumption

Based on energy use and energy generation, the total energy consumption in China's PPI can be calculated and the result is 2954.47E6 GJ. The average unit energy use per pulp consumption is 32.21 GJ/t paper. This figure is of the same magnitude with unit energy use in Dutch PPI (Laurijssen et al., 2010), which also verifies the accounting framework used in this study. Even though the value is higher than that in Netherland due to higher recycling rate in Netherland and differences in those two accounting frameworks.

3.4 CO₂ emissions

Total CO₂ emission from China's PPI in 2010 is 147.69E6 t CO₂ and average carbon emission per tonne of paper is 1610 kg CO₂. Energy use and CO₂ emission in some countries are listed in Table 2.

Figure 2. Energy input composition in China's PPI.

Table 2. Energy use and CO₂ emission of producing every 1 t paper in different countries.

Country	Energy use (GJ/t)	CO ₂ emission (kg/t)
China	32.2	1610
Canada	18.2 ^a	260 ^a
USA	32.5 ^b	787 ^c
Netherland	14 ^d	200 ^d
Sweden	29.3 ^b	204 ^b

a Adès J. et al. (2012), Only natural gas and oil products emit CO₂; electricity is not considered to emit CO₂; b Farahani S. et al. (2004); c Heath L. S. et al. (2010); d Laurijssen J. et al. (2010).

Energy use and carbon emissions depend strongly on energy efficiency, primary energy used and accounting framework. The high value of carbon emissions in this study is partly due to the energy contained in imported materials that is included, but the corresponding carbon sink in forest cultivation activities is excluded. In fact, a net importer of wood product should be responsible for carbon storage in imported wood materials (Heath, 2010).

3.5 Comparison with production-based accounting

Within production-based or territorial accounting calculation method (Bruckner et al., 2010), the total energy consumption in China's PPI in 2010 is 1974.0E6 GJ (21.3 GJ/t paper) and the total carbon emission is 118.26E6 t CO₂ (1275.7 kg CO₂/t paper). These two figures both smaller than the ones within incorporating impacts of imported goods, which may indicate that China is a carbon importer in terms of PPI.

3.6 Sensitivity Analysis

3.6.1 Importing

1. Change in quantity of imports

We investigate the sensitivity to the change in quantities of imported raw materials and final product of the supply chain (see Figure 3). To keep comparativeness, when the amount of imported chips changes, the amount of domestic chips changes accordingly and all other parameters are assumed to be unchanged in order to satisfy the paper market's demand. As the amount of imported chips increasing, unit energy use and CO₂ emission both increase (see Figure 3a).

Imported chips consume more energy in transportation and less energy in cultivation when compared to domestic chips; however, the energy use saved in cultivation activities cannot offset the extra energy used in transportation due to longer distance transportation of imported chip. With decreasing demand of domestic chips, carbon sink accompanied with cultivation activities decreases as well, which contributes to the increasing in carbon emissions. The marginal unit energy use is 0.03 GJ/t paper and the marginal unit carbon emission is 15.03 kg CO₂/t paper.

Figure 3b shows the sensitivity of unit energy use and unit carbon dioxide emission to quantity of imported pulp, which can give us insight of the influence of the amount of imported pulp. The quantity of domestic pulp changes with quantity of imported pulp changes to keep total paper production and consumption unchanged and the proportion of all kinds of raw materials to produce

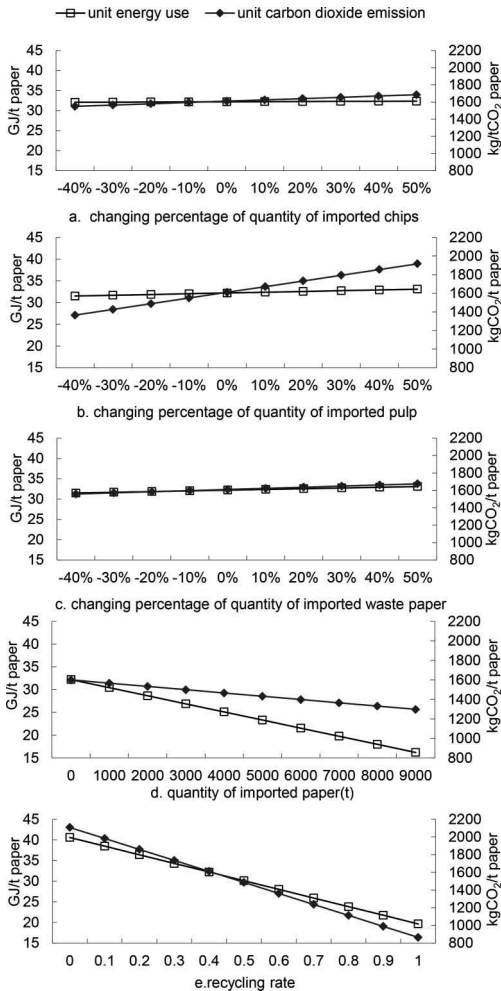

Figure 3. Sensitivity to the change in quantities of imported raw materials and final product of China's PPI.

domestic pulp is fixed invariably. With the amount of imported pulp increasing, unit energy use and unit carbon emissions go up. If the amount of imported pulp increases by 10%, unit energy use and unit carbon emission will have an increment of 0.18 GJ/t paper and a jump of 61.35 kg CO₂/t paper respectively. With conjunction of energy use and generation, the net energy use in pulping process is negative as well as carbon emissions.

A similar phenomenon is also found in sensitivity analysis for imported waste paper (see Figure 3c). The marginal unit energy use is 0.18 GJ/t paper and the marginal unit carbon emissions are 12.95 kg CO₂/t paper.

Figure 3d illustrates unit energy use and carbon emissions from one ton of paper products

consumed in China at different quantity of imported paper. With more paper imported, less energy consumption is required and less carbon is released. If all paper consumption in China is satisfied by import, the unit energy use is 15.89 GJ/t paper and the unit carbon emissions are 1291.97 kg CO₂/t paper.

Although importing paper can result in less energy use and carbon emissions, replacement of domestic paper production by imported paper may cause a decline of PPI in the country and severe issues of unemployment.

2. Different import sources

In our accounting framework, carbon emissions are calculated from the perspective of a country, however, impacts on carbon emissions associated with export countries should be taken into account.

Based on FAO data, China imports chips mainly from Vietnam, Thailand, Australia, Indonesia, New Zealand, Russian Federation, Cambodia, USA, and Malaysia, while imports pulp mainly from Canada, Brazil, USA, Indonesia, Chile, Russian Federation, Uruguay, Finland, Japan, New Zealand, Sweden, South Africa and, paper and paper board mainly from USA, Indonesia, Japan, Republic of Korea, Sweden, Russian Federation, Canada, Finland, Australia, Brazil, Germany, New Zealand, Thailand and Belgium. We convert the different products into Wood Raw Material Equivalent (WRME) underbark based on the research of James K. (2012).

Although carbon contained in wood fiber display slightly differences in different countries, the gap in carbon emissions among countries by considering land use change is significant as conditions of land use in different countries vary greatly. Don et al. (2011) identified absolute losses of 10.2–15 t C ha⁻¹ where primary forest is converted to secondary forest (including plantation), while Munoz et al. (2007) found that soil carbon under 50% lower than primary forest. The main exporters to China's PPI are divided into several groups, according to their changes of primary forest and planted forest, see Figure 4.

Based on the facts described above, countries in the top right corner in the diagram with increasing cover both in primary forest and plantation are perfect exporters within PPI in terms of carbon emissions. Then are the countries in the middle part from top to bottom, and countries in the top left corner should decrease their exports. This analysis illustrates that importing forest woody materials from Indonesia may cause worst carbon impacts among the countries under scrutiny.

Using the quantifying method proposed in James (2012), change in carbon stores associated with removing 1 m³ of WRME underbark of each

country can be measured based on FAO data, which is listed in Table 3. With the first group concerned, forest extends with carbon sink increasing. So the change in carbon stock with removing 1 of WRME can be considered as carbon mitigation in forestation. The calculation results illustrate that Russia is the best exporter in group 1. However, in group 2, with data available, it can be judged that as forest product exporter South Africa is better than Canada, and Thailand is better than Malaysia. Also, New Zealand is better than Cambodia in group 4, and in group 5, Australia may be the worst exporter since decreasing carbon stock and increasing forest area, which indicates the degradation of forest.

3.6.2 China's domestic recycle rate

Figure 3e shows trends of unit energy use and unit carbon dioxide emissions as the paper recycling rate in China increases from zero to one with anything else unchanged. The greater the domestic recycling rate is, the less the carbon emissions and energy use become. When no waste paper is recycled (recycling rate = 0), the unit energy use is 40.59 GJ/t paper and the unit carbon emissions are 2107.15 kg CO₂/t paper. The value of unit energy use will decrease by 2.1 GJ/t paper and the value of unit carbon emissions will increase by 124.29 kg CO₂/t paper with a 10% increase of recycling rate. A higher recycling rate indicates a reduction in waste paper incineration. Because paper incineration causes more GHG emissions than recycling, carbon emissions decline.

If ignore different uses of recycled waste paper, that is to say, all recycled waste paper is reused

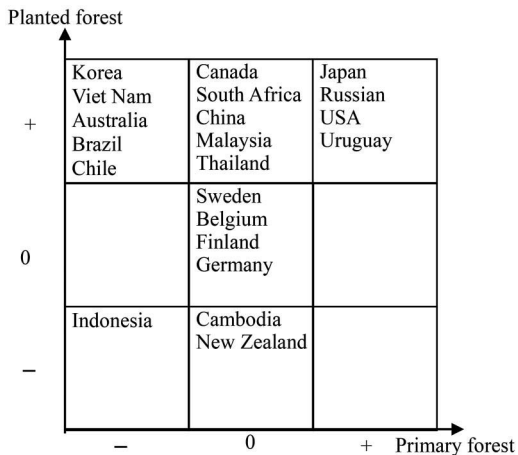

Figure 4. Dividing export countries into different groups according to change of primary forest and planted forest.

Table 3. Changes in carbon stock associated with the removal of 1 m³ WRME underbark, 2005–2010.

Group	Country	CO ₂ eq (t/m ³)	Group	Country	CO ₂ eq (t/m ³)
1	Japan	58.04	3	Sweden	N/A
	Russian	80.24		Belgium	6.47
	USA	20.72		Finland	N/A
	Uruguay	N/A		Germany	N/A
2	Canada	N/A	5	Korea	-60.34
	South Africa	N/A		Viet Nam	4.52
	Malaysia	7.87		Australia	N/A
	Thailand	7.42		Brazil	3.50
	China	1.83		Chile	1.94
4	Cambodia	2.30	6	Indonesia	14.59
	New Zealand	-7.10			

Figure 5. Comparison of two kinds of assumption of recycled paper on energy use and carbon emission.

in PPI, the amount of imported waste paper will decrease. Figure 5 shows the comparison of results between the two kinds of assumption on recycled paper. It is noted that when recycling rate reaches 0.7, domestic recycled waste paper can match the total amount of waste paper used in China's PPI supply chain and 0.7 is just the recycling rate in developed countries.

As depicted in Figure 5, the slope of the two curves with the assumption that Imported Waste Paper Change Corresponding to Recycling Rate (IWPCRR) are both steeper than the corresponding curve without IWPCRR, which strengthens the argument that recycling is beneficial with regard to emission and energy use.

4 CONCLUSION

In response to climate change, balancing energy use, GHG emissions, and resource scarcity in China's PPI is an important task in forest resource

planning and allocation and national sustainability development policy making. This study investigates the environmental impacts of PPI in China using energy use and CO₂ emissions as indicators and presents a new accounting framework from the viewpoint of supply chains, which can compensate for the deficiency of LCA widely used in research. With the proposed accounting framework, total energy use and total CO₂ emissions in China's PPI in 2010 are 2954.47 E6 GJ and 147.69 E6 t CO₂, respectively.

The results of this study are useful for decision making of the strategy departments of PPI. GHG emissions accounting framework designed from the viewpoint of supply chain can provide a new account sight to assess energy use and GHG emission of certain industry in a country or a region and an insight into the strategy such as resource allocation and sourcing decisions.

Issues that need further research are (i) combination of economic indicators and environment indicators in assessing different industries of a country or a region; (ii) environment impacts of allocation of limited raw materials among different industries.

ABSTRACT: In order to discover the effect of floor and rib failure on the whole entry stability in the three-soft coal seam, through site measurement and numerical simulation, the failure circle around the entry is obtained, and its mechanism is explored. Based on Protodyakonov's arch theory, the limit equilibrium arch function of entry roof is set up by considering the effect of floor and rib failure. It is found that the height of roof equilibrium arch is proportional to the equivalent width of the entry, and is inversely proportional to the friction coefficient of the rib and the roof. When the rib fail, the equivalent width of entry increases, and the increment of roof equilibrium arch height is proportional to the depth of rib failure zone. When floor fails, it causes the equivalent height of entry to increase, and results in the equivalent width of entry increasing and the height of roof equilibrium arch increasing. The increment of roof equilibrium arch height is proportional to the floor failure depth. Thus, the theory of equilibrium circle of entry is established based, and it is pointed that strengthening the ribs and floor is important to improve the stability of the whole entry.

1 INTRODUCTION

Usually, the roof is paid more attention than the ribs, and the floor is always ignored in the entry support. The main reason is unclear in the interactions of "floor-ribs-roof". There are a lot of research on soft rock entry support theory, but less study on the influence of the floor and ribs on the roof. Practice shows the soft floor has a direct effect on the rib deformation and influences the stability of the roof. Currently, the main theories on the entry and roadway support including Protodyakonov's arch theory (Li 1986), broken rock zone theory (Deng et al. 1994), key circle theory of entry (Kang 1997), self-stable arch theory (Huang 2014), and roof stability (Gou et al. 2006, Tan 2003, Xu et al. 2013).

There is some research dealing with the shape of the roof arch by considering the initial horizontal stress (Zhao 1978), and the surrounding rock stability of the roadway (Miao 1997). Some researches found that strengthening the floor and the two ribs had important impact on the whole stability of entry (Bai et al. 2011, Guo et al. 2013). But there is less study on the interaction mechanism of "floor-ribs-roof".

This research analysis involves the interaction mechanism of "floor-ribs-roof", and provides a new theory of entry support in the soft coal seam

with soft roof and floor, which is so called the three-soft coal seam.

2 LIMIT EQUILIBRIUM CIRCLE OF ENTRY

2.1 Failure circle measured around entry

The study entry is in the Gaocheng coal mine in Henan Province of China. The thickness of the No. 21 coal seam is 4.8 m and the average depth is about 450 m, the dip angle of coal seam is 8°–13°. The roof is in sliding structural zone, which is extremely broken, and the floor is soft sandy mudstone. It belongs to typical three-soft coal seam. The entry size is width 6.0 m and height 3.4 m. The mechanical parameters of coal and rock are shown in Table 1. The compressive strengths are 0.92–17.0 MPa, water softening coefficients are 0.24–0.36, and the elastic modulus are 33.0–413.8 MPa. It is clear that the surrounding rock is typical soft rock.

The original support of the entry is U section steel in arch-shaped yielding supports (Fig. 1).

The convergence between roof and floor is 1.5 ~ 2.0 m, and between ribs is 1.5 m. It belongs to large deformation soft entry. According to the radar scan and borehole observation in the No. 21051 roadway, the failure zone around the

Table 1. The physical and mechanical parameters of roof and floor in the No. 21 coal seam.

Stratum	Lithology	Uniaxial compressive strength (MPa)	Thickness (m)	Water softening coefficient	Tensile strength (MPa)	Shear strength		Elastic modulus (MPa)	Poisson's ratio	Unit weight (t/m ³)
						C(MPa)	$\Phi(^{\circ})$			
Coal seam	No.21 coal	0.92	4.86	0.32	0.10	0.70	20	33.0	0.28	1.35
Roof	Sandstone	16.35	8.00	0.24	2.97	5.12	35	351.2	0.20	2.65
Floor	Mudstone	15.44	15.00	0.36	3.32	0.86	25	413.8	0.20	2.44

Figure 1. Deformation of entry section.

entry is circle shape (Fig. 2). The height of roof arch is 3.8 ~ 4.1 m, and the thickness of failure zone in ribs is 2.6 ~ 3.1 m, and the deepness in floor is 1.0 ~ 1.5 m.

In general, the surrounding rock self-stable equilibrium circle refers to the circular boundary of the surrounding rock in the limit state of self-stability. In the entry roof, it is approximate to tensile stress boundary. And in ribs and floor, it is approximate to plastic zone and tensile failure zone boundary. Generally, the failure circle zone around entry refers the limit equilibrium self-stable circle.

2.2 Numerical simulation of failure circle

In order to explore the interaction and influence of “floor-rib-roof”, simulation models are set up by Flac3D and the result is shown in Fig. 3.

When the roof is weak ($c = 0.6$ MPa, $\sigma_t = 0.4$ MPa) and the floor is stronger ($c = 1.8$ MPa, $\sigma_t = 1.6$ MPa), the strength of ribs reduce from $c = 1.4$ MPa to 0.5 MPa, and $\sigma_t = 1.2$ MPa to 0.3 MPa, the height of roof arch increases 15%. Based on that, when the strength of floor is reduced from $c = 1.8$ MPa to 0.4 MPa and $\sigma_t = 1.4$ MPa to 0.2 MPa, the thickness of rib failure zone increases by 20%, and the height of roof arch increases by 25%. The total increment of roof arch height due to the influence of soft and soft floor is 43%. So, it is obvious that the soft floor and soft ribs have a significant impact on the development of roof failure arch of the three-soft entry.

Figure 2. Entry failure circle by site measurement.

2.3 Natural limit equilibrium arch of entry roof

If only the influence of soft roof is considered, the natural equilibrium arch in the entry roof can be determined by Protodyakonov's arch theory (Wang 1996). Actually, the arch is in limited equilibrium state, and the arch calculation model is shown in Fig. 4.

Assume that there is only axial compression force, and no shear force and bending moment on any cross-section of the limited equilibrium arch. Choose any point $M(x,y)$ in the arch curve, the bending moment of all the external force to the point $M(x,y)$ is

$$\Sigma M = Ty - qx^2/2 = 0 \quad (1)$$

where q is vertical uniformly distributed load on the arch, MPa; T is horizontal force at arch section, MN.

According to static equilibrium equation, $T = T'$

Based on Protodyakonov's arch theory, the horizontal force T' at the arch feet must meet the condition:

$$T' \leq qaf \quad (2)$$

where T' is the horizontal force at arch feet, MN; f is internal friction coefficient of roof. Put $T = qaf$ into Eqs. (1), and there is

$$y = x^2/2af \quad (3)$$

Figure 3. The failure circle development in three-soft entry.

Figure 4. Calculation model of the limit equilibrium arch.

The height of the nature equilibrium arch is:

$$b = a/2f \quad (4)$$

where b is the height of the arch with stable ribs, m; a is the half width of entry, m; f is the internal friction coefficient of the roof.

2.4 Height of the limit equilibrium arch with rib failure

When there is a failure in ribs, the maximum failure depth in rib can be calculated as:

$$r_1 = h/2f_b \quad (5)$$

where r_1 is the maximum depth of rib failure, m; h is the entry height, m; f_b is the internal friction coefficient of rib.

Rib failure is equivalent to the entry width increase, and leads to the development of roof equilibrium arch (Fig. 5). The equivalent half-width increment is given by $r_1^* = kr_1$, where r_1^* is equivalent width increment of rib, m; k is equivalent coefficient.

According to fracture mechanics, the equivalent increment of crack length is equal to half-width of the plastic zone. So, the equivalent width coefficient $k = 0.5$, and the equivalent half width of entry is

$$a_1 = a + r_1^* = a + 0.5r_1 \quad (6)$$

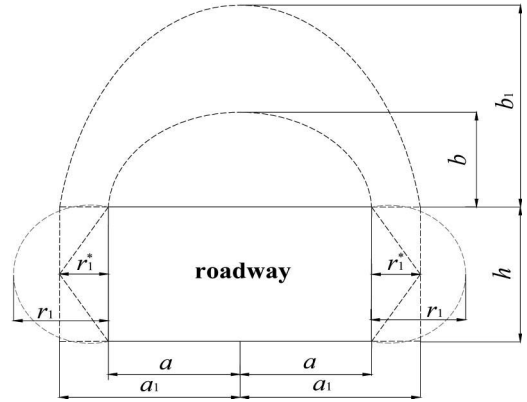

Figure 5. Limit equilibrium arch of entry with rib failure.

where a_1 is the equivalent half entry width with ribs failure, m.

Put $x = a_1, y = b_1$ into the Eqs. (3), the height of the limit equilibrium arch is:

$$b_1 = a_1/2f = (a + 0.5r_1)/2f = b + h/8ff_b \quad (7)$$

where b_1 is the height of equilibrium arch with ribs failure, m.

3 LIMIT EQUILIBRIUM CIRCLE THEORY

3.1 Limit equilibrium circle theory of entry support

In the three-soft entry, floor heave will cause ribs damage and result in the roof arch increment (Fig. 6).

Assume equivalent floor failure depth h_d is half floor failure depth, there is:

$$h^* = h + h_d \quad (8)$$

where h^* is equivalent height with floor failure, m; h_d is equivalent depth of floor failure, m.

Figure 6. Equilibrium circle of entry with floor and rib failure.

If the internal friction angles of ribs and floor are same, the width of floor influence by Eqs. (5) is:

$$r_2 = r_1 + h_d / 2f_b \quad (9)$$

where r_2 is the maximum depth of the rib failure zone influencing floor failure, m.

In the same way, the equivalent width of entry is:

$$a_2 = a + 0.5r_2 = a_1 + h_d / 4f_b \quad (10)$$

where a_2 is equivalent half width of floor failure.

So, the height of the limit equilibrium arch by considering the effects of floor and ribs failure is:

$$b_2 = a_2 / 2f = b + (h + h_d) / 8ff_b \quad (11)$$

where b_2 is the height of the limit equilibrium arch with floor and rib failure, m;

The increment of arch height by floor failure is:

$$\Delta b_2 = b_2 - b_1 = h_d / 8ff_b \quad (12)$$

3.2 Principles of entry support

Assume, $a = 2.5$ m, $h = 4.0$ m, $h_d = 1.0$ m, and $f = f_b = f_d = \tan 35^\circ = 0.7$, the roof arch height increment Δb with the width increment Δa is in Fig. 7.

Based on above analysis, the entry support principle is put forward:

1. Entry support design must put “roof-ribs-floor” as an integral whole. Rib strengthening is

Figure 7. Increment of arch height vs. half width.

Figure 8. Entry equilibrium circle evolution.

- important to maintain the stability of the roof. Floor strengthening is helpful to rib stability.
2. Integration of “rib-floor” and “roof-rib” (shadow zone in Fig. 8) are key areas in the entry.
3. When the height of roof equilibrium arch is less than the general bolt length, bolt length needs to be higher than the arch height.
4. For larger equilibrium arch, cables should be used and cable length should be longer than the equilibrium arch height.

4 CONCLUSIONS

In the three-soft coal seam, the failure zone in the surrounding rock of entry is observed as a circle type. The failure circle can be simply expressed in the limit equilibrium state. The size

of the circle is influenced by “floor–ribs–roof” interaction.

The height of the roof equilibrium arch is proportional to the width of the entry. Entry rib failure equals to increase the equivalent width of the entry. Strengthening ribs is helpful to decrease the development of the limit equilibrium arch, and improve the stability of the roof.

Entry floor failure will cause the rib failure and equivalent to increase the entry width. The equivalent width of the entry is proportional to the floor failure depth.

The purpose of entry support is to control the stability of rock mass in the limit equilibrium circle. The length of cable bolt can be determined by the height of the limit equilibrium arch of roof. Entry support should pay attention to the floor and rib control. The entry support design must take roof-rib-roof as a whole support system.

Evolution characteristics of rainfall erosivity area based on the frequency analysis method in Zhejiang Province

Jinjuan Zhang, Gang Li & Fangchun Lu

Zhejiang Institute of Hydraulics and Estuary, Hangzhou, Zhejiang, China

ABSTRACT: Based on the daily rainfall data of 84 meteorological stations from 1980 to 2009 in Zhejiang Province, the power function model was used to calculate rainfall erosivity. The frequency analysis method, the Mann–Kendall test method and the cumulative deviation method were used to mine data changes. And the spatial variation characteristic was analyzed by the radial basis function interpolation method. The results showed that the relationship of distribution area in different periods was R_l (low rainfall erosivity) $> R_e$ (extreme rainfall erosivity) $> R_m$ (medium rainfall erosivity) $> R_h$ (high rainfall erosivity). The area mutation of the R_l and R_m were detected in the early 21st century. And in 1980s, the area under R_h and R_e also mutated. The variation process of rainfall erosivity in the 30 years can be divided into three successive stages. In spatial distribution, central lower grade rainfall erosivity gradually spread into marginal higher grade rainfall erosivity.

1 INTRODUCTION

The potential ability of rainfall to infuse soil erosion is called rainfall erosivity. It is an objective evaluation index for soil separation and transport caused by rainfall. But it is not the concept of “force” in physics, and the rainfall erosivity R factor is calculated by the measured rainfall and rainfall intensity. The R factor is a statistical index to characterize the impact of rainfall on soil erosion and it can be used to evaluate the potential impact of regional climate on soil erosion (Fan et al. 2003). Thus, it becomes an important factor in soil erosion prediction model (Wischmeier and Smith 1978). At present, in the study on the large scale, the daily rainfall data are obtained from conventional meteorological stations are usually used to estimate the rainfall erosivity (Richardson et al. 1983; Zhang et al. 2002). Domestic scholars have made a lot of studies on the temporal and spatial evolution characteristics of rainfall erosivity in different regions of China. For instance, Wang (2013) studied the distribution law of rainfall erosion in the upper Yangtze River. Wu (2011) analyzed the change characteristics of rainfall erosivity in Three Gorges Reservoir area. Mu (2010) discussed the spatial-temporal characteristics of rainfall erosivity on the Loess plateau. Liu (2012) explored the rainfall erosivity in the southwest mountain area. However, many studies were aimed at measuring rainfall erosivity on a certain scale. How to grade the rainfall erosivity

and the temporal-spatial variation characteristics of different grades rainfall erosivity were less studied. Therefore, this study used the hydrological frequency method to grade rainfall erosivity. The coverage area changes of different rainfall erosivity were analyzed. It is aimed to provide the basis for comprehensive management of soil and water conservation and ecological environment construction.

2 DATA AND METHODS

Considering the integrity and unity of data sequence, it was ultimately determined to use the daily rainfall data of 84 meteorological stations from 1980 to 2009. The power function model widely used in China was selected to calculate the rainfall erosivity (Zhang et al. 2003). The average annual rainfall erosivity was graded by the hydrological frequency analysis method (Guo et al. 2010). At the same time, the mutation points of the time series of rainfall erosivity were determined by the non-parameter Mann–Kendall test method (Li et al. 2011). The different rainfall erosivity phased variation characteristics were explored by the accumulation of the measured data distance away from average (Wang et al. 2007), abbreviated as ADDA. In the spatial analysis, the spatial interpolation of rainfall erosion force is analyzed by using the radial basis function interpolation method in ARCGIS10.2 software.

3 RESULTS AND ANALYSIS

3.1 The gradation standard of rainfall erosivity

In the frequency analysis of hydrology in China, the Pearson III type curve has been used as the hydrology frequency curve. The parameters of hydrological frequency curve usually were obtained by curve-fitting method. In other words, based on the empirical frequency point and under certain curve-fitting conditions, parameters were solved. The best estimation method that can meet the requirement of hydrologic frequency analysis was determined. Figure 1 showed three types of Pearson III type curve with different parameters. The three curves had good fitness, but by comparison, the curve that features skewness coefficient equal to two times the variation coefficient has a higher adaptability. Therefore, this paper adopted this curve to evaluate the frequency distribution of rainfall erosivity. According to the calculation of the data series and the parameters, the values of rainfall erosivity under different frequency were 8361 ($p = 0.5$), 9572 ($p = 0.2$) and 10249 ($p = 0.1$). Based on the calculated results at different frequencies, the gradation standard of rainfall erosivity was established (in Table 1).

3.2 The area of different rainfall erosivity

The area of different grades rainfall erosivity had an obvious difference (Figure 2). The relationship of different grades of rainfall erosivity in different periods were $R_l > R_e > R_m > R_h$. In 1990s,

the area where the R_l and R_e occurred obviously change. In 1980s and the early 21st century, the area proportion of the R_l was 57.5% and 58.8%, respectively. But only 38.3% in 1990s. On the contrary, the area proportion of R_e in 1990s (33.5%) was obviously higher than that in 1980s (14.9%) and the early 21st century (20.9%). For medium rainfall erosivity, in 1980s and 1990s, the area accounted for nearly 17.8%, respectively. The proportion (13.9%) relatively slightly lower in the early 21st century. The area of the R_h was also relatively close in 1980s (9.9%) and 1990s (10.4%), and the proportion decreased to 6.4% in the early 21st century. Through rainfall erosivity gradation and area statistics, the area of the R_l was found to be the largest, and R_e next highest, which mutated in the 1990s and early 21st century. Their area proportion accounted for 76%. It followed that the distribution of different gradation rainfall erosivities appeared to be polarization. The area of R_l in each period broadly remained unchanged. The values of R_m and R_h decrease, but R_e increases.

3.3 Time variation trend of area

Figure 3 clearly shows the annual variation trend of areas with different rainfall erosivities. The average area of the R_l was $5.32 \times 10^4 \text{ km}^2$, and the inter-annual variation coefficient less than 0.5 (Table 2). The time series showed a weak downward trend ($Z < 0$). The mutation test showed obviously increased mutation occurring in 2003 ($5.74 \times 10^4 \text{ km}^2$) and 2006 ($1.13 \times 10^4 \text{ km}^2$),

Figure 1. Pearson-III frequency curve of rainfall erosivity.

Grades	Range	Code
Low	$R < 8361$	R_l
Medium	$8361 \leq R < 9572$	R_m
High	$9572 \leq R < 10249$	R_h
Extreme	$R \geq 10249$	R_e

Figure 2. Area with different rainfall erosivities.

Figure 3. Time series characteristics of area.

Table 2. Gradation standard of rainfall erosivity.

Code	Cv.	Z value	My.	Vr.
R_l	0.47	-0.357	2003	5.74↑
			2004	1.80↓
			2006	1.13↑
R_m	0.52	-0.500	2002	0.48↑
R_h	0.66	0.749	1986	0.34↓
			2005	0.18↓
R_e	0.68	0.785	1984	5.01↓
		0.785	1987	4.05↑

Note: Cv. stands for variation coefficient. Z value is the statistical eigenvalue of Mann–Kendall. My. stands for mutation year. Vr. stands for variation range (Unit is 10^4 km^2).

and a significantly decreased mutation in 2004 ($1.80 \times 10^4 \text{ km}^2$).

The average area of R_m was $1.79 \times 10^4 \text{ km}^2$ and the inter-annual variation coefficient 0.52. The annual variation of area also showed a downward trend. The mutation occurred in 2002 ($0.48 \times 10^4 \text{ km}^2$). The average area of R_h was $0.61 \times 10^4 \text{ km}^2$, the inter-annual variation was highly variable. The area variation trend was increasing, and a significantly decreased mutation appeared in 1986 ($0.38 \times 10^4 \text{ km}^2$) and 2005 ($0.18 \times 10^4 \text{ km}^2$). In terms of extreme rainfall erosivity (R_e), the area was an average of $2.47 \times 10^4 \text{ km}^2$. Inter-annual variation was highly variable. The time series increased, and the mutation occurred in 1984 ($5.01 \times 10^4 \text{ km}^2$) and 1987 ($4.05 \times 10^4 \text{ km}^2$).

The ADDA processes of different rainfall erosivity were different (Figure 4). The variation process of the R_l can be divided into three stages, which was in the continuing increasing stage (1980–1986), decreasing stage (1987–2002) and gradually increasing stage (2003–2009). The process of R_m was relatively complex, and its area was fluctuating between 1980 and 1992, which belonged to volatile stage. The ADDA curve showed a continuous increase trend (in 1993–2000). But in the nearly ten years, the area was decreasing. The distribution area of R_h also mainly presented three variation stages. The process showed a downward trend in 1980–1992, increasing continuously in 1993–2002, and decreasing in 2003–2009. There were also three great variation stages for the R_e . The area gradually shrank in 1980–1987. The continuous fluctuation in the increasing stage occurred in 1988–2002. But the process showed a slight downward trend in 2003–2009.

3.4 Spatial distribution characteristics

The distributions of rainfall erosivity in different periods were shown in Figure 5. It can be seen that

in 1980s the R_l widely distributed in the north and center region of Zhejiang. The R_m and R_h distributed along the boundary of R_l . The distribution of the R_e showed three zones. By comparison, in 1990s the distribution of different rainfall erosivities showed a drastic change. The distribution area shrunk from three sides to the middle. The distribution shape of the R_m and R_h did not change, but the area underwent a change. The area of the R_e expanded obviously, and was widely distributed in the west and the southeast coast of Zhejiang. By the beginning of 21st century, the distributions of different rainfall erosivities were further changed. The area of R_l expanded to the west of Zhejiang. The distribution belt of R_m in the west changed short and wide, and the area in the east changed narrow. The distribution belt of the R_h in the west disappeared, and the belt in the southeast changed narrow. The R_e was concentrated in the southeastern coast of Zhejiang.

In the distribution of average rainfall erosivity of thirty years, the whole north and center region

Figure 4. Time series of the ADDA.

Figure 5. Spatial distribution of rainfall erosivity.

belonged to low rainfall erosivity range. The medium rainfall erosivity mainly showed a long belt distribution in the edge of low rainfall erosivity. The high rainfall erosivity distributed along the edge of medium rainfall erosivity, but the belt was narrower. Extreme rainfall erosivity concentrated in the west and the southeastern coast of Zhejiang.

4 CONCLUSIONS

The study concluded that the relationship of different rainfall erosivities in different periods was $R_l > R_e > R_m > R_h$. It showed that the composition of rainfall erosivity presented polarization. The average area of the low rainfall erosivity accounted for 51%, the extreme take up 25%, and the medium and high were responsible for 24%.

Through time series analysis of the area of different rainfall erosivities, the low and medium rainfall erosivity showed a moderate variation. The time series showed a decreasing trend, and the mutation occurred in the early 21st century. The high and extreme rainfall erosivity showed the highest variation, and the time series had an increasing trend. The mutation mainly occurred in 1980s. The variation process of different rainfall erosivities can be divided into three stages. The process of low rainfall erosivity showed the trend of increase-decrease-increase. The medium rainfall erosivity showed the trend of fluctuation-increase-decrease. The high and extreme rainfall erosivity showed a trend of decrease-increase-decrease.

The low rainfall erosivity was mainly distributed in the north and the center region of Zhejiang. The medium and high rainfall erosivity showed a belt distribution in the west and southeast. The extreme rainfall erosivity showed a concentrated distribution in the west and southeast. During thirty years evolution, the distribution of different rainfall erosivities had changed obviously.

Research on the Norbulingka garden art characteristics under the background of Han-Tibetan cultural blending

Chang Liu & Min Wang

Huazhong Agricultural University, Wuhan, China

ABSTRACT: Norbulingka is one of the centers of politics, religion and culture in Tibet. Only in Norbulingka, a perfect combination of architectural art, religious art and garden art can be seen. Garden art is the detailed embodiment of people's life. This paper, through the analysis of garden art of Norbulingka, explores the world outlook, philosophy of life and values of the Tibetan. In the meanwhile, the research on the common features between Tibetan garden art and traditional Hans garden art reflects the two nationalities have many similarities when they are dealing with the relationship between man and nature.

1 INTRODUCTION

The Han and Tibetan people created a completely different living space in order to meet the needs of their own lives because of the different living environments. Especially the Tibetan people's living environment is more difficult than the Han people. But on the other hand, the Han and the Tibetan people living together formed a mutually dependent and harmonious ethnic relation. The culture of the two nationalities influenced each other.

Garden is a reflection of the higher level of people's spiritual and material life called "linka" in Tibet. "Linka" means a small forest, trees or gardens originally. And the same time, the meaning of garden is same with the Han Chinese garden. But there are great differences in the form and style of the garden between "linka" in Tibetan and garden in inland of China. In the Tibetan language, "linka" describes a beautiful place with lush flowers and trees and the environment is favorable. On the other hand, "linka" is a small piece of artificial forest surrounded by earth, stone or fences in order to serve the ruling class of the old Tibet to play and feast. This paper just focuses on the characteristics of garden art as a traditional garden now. "Linka" is an important form of China's classical gardens in Tibetan Gardens.

Norbulingka is the representative of Tibet Garden "linka". Its gardens, sculptures, murals and architecture have a very high artistic status. As far as the garden art of Norbulingka is concerned, some of its characteristics are related to the Han culture. Through studying the relationship between Han culture and Norbulingka, we can observe that the philosophy of life and values of Tibetan and Han are the same.

2 NORBULINGKA

2.1 Introduction

"Norbulingka" means the garden is precious as pearls in the Tibetan language. It covers an area of 36 hectares located in the southwest of Potala Palace spanning at least 2 kilometers. Norbulingka was listed as a world heritage site in 2001 by United Nations Educational, Scientific and Cultural Organization. It was founded in the middle of the eighteenth century to handle affairs, held ceremonies and religious activities, spend summer holiday for Darailama. The three main groups of palace are "gesang" palace, "gesang" palace and "dadanjiju" palace. Norbulingka is the most distinctive of the large-scale garden in Tibet, which sets gardens, palaces and buildings as one. It shows the unique history, culture, nature and other features of Tibet with high value in history, science and art.

2.2 Origin

This area was originally a shrub in which the trees were lush and the birds and animals often appeared. People called this scenic place "lawacai". According to the records of Tibetan documents, there was a fountain said to be able to cure people. So the VII Dalai Lama "gesangjiacuo" usually went there to have rest. At the time of the Ambans, a simple structure for rest called "wuxiao palace" which means "pavilion palace" was designed for the emperor Qian Long in the Qing dynasty. This is the initial state of the Norbulingka.

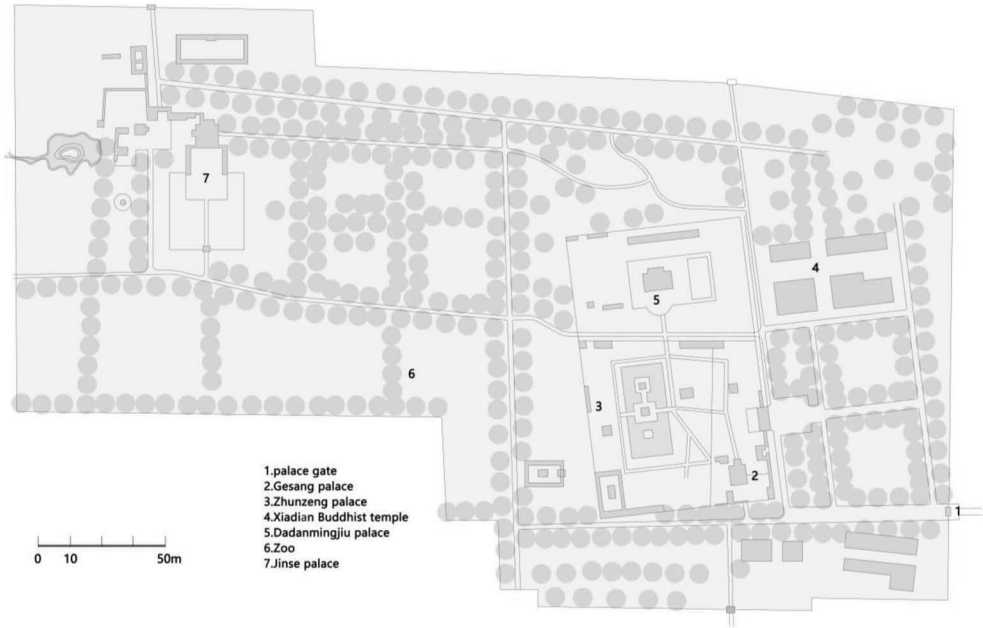

Figure 1. The plan of Norbulingka.

2.3 Layout

Norbulingka can be divided into two parts of East and West according to the distribution of buildings ordinarily. The western part is called “Jinselinka” and the eastern is called “Norbulingka” by the local people. But according to the overall landscape effect, Norbulingka can be divided into the palace area, before the palace area and forest area. Each area has its different landscape characteristics. The palace area had palaces built in different periods. The area before the palace was built was used to hold meetings. The forest area is the back garden for Dalai Lama. But the three areas connected perfectly. The overall layout of the space is very sparse with distinct levels, and the layout of the form is very diverse.

3 LANDSCAPE FEATURES

3.1 Terrain

Basically the terrain is flat without artificial construction rockery because Tibetan people are very devout to the mountains. So Tibetan people respect the original landform extraordinarily when they created the gardens. On the other hand, the vast ground is very rare in the plateau region. At the meanwhile, this type of site selection was done to simulate the “Elysian Fields” depicted

Figure 2. The color of the building is very bright.

in Buddhist scriptures because the ground of the “Elysian Fields” is flat like a palm.

3.2 Planting

The description for the Elysium in Buddhist scriptures is “Seven roads to form a road network, seven lines of trees by the roadside”. The cedar and poplar are planted by column and occasionally planting peach and willow to create a fresh literary scene. The way of planting mainly used cypress to memory Shakya Muni feed by cedar seed.

3.3 Decoration

The altitude is high and the air is thin in Tibet plateau. Because of the air with high transparency, the

various colors of objects are constantly changing under sunlight. So the bright colors are used to decorate buildings. The interior decoration of buildings is affected by the Hans techniques such as wood windows and screens.

4 SIMILARITIES

The Han and the Tibetan people have formed special national characteristics because of different ways of life. But on the other hand, the two nationalities never stop blending. The traditional culture of Han and Tibetan people communicates from past to present. So there are many similarities in their way of daily life. In garden art aspect, the characteristics of Norbulingka have many resemblances with classical garden for Hans.

4.1 *A lake with three hills*

There is a pool in the west of the Gesang palace. Three islands are arranged in a straight line. One of the islands is called “Huxingong”, and another one is “Longwangdian”. A lot of trees planted on the last island at the south. “A Lake With Three Hills” is a classical model of terrain design of Chinese classical gardens first appeared in “Shanglin yuan” in the Qin Dynasty. This composition simulated the three mountains called “Penglai” “Fangzhang” “Yingzhou,” which is a paradise living many gods in Chinese fairy tales.

4.2 *The combination of palace and garden*

The palace and the garden for imperial families, which is in organic combination, is an important template of the later imperial gardens planning represented by the “Jianzhanggong” from Han dynasty. The palace is in the north and the garden is in the south in Jinse palace. This pattern is very similar to the Imperial Palace and Jingshan in Beijing.

Figure 3. Huxingong is the middle one of the three islands in water.

4.3 *The function for animal farm*

The early Chinese gardens have the function of animal farm as early as in the Shang Dynasty. This function is handed down in the Norbulingka. There is a zoo in Norbulingka covering an area of 4000 square meters and breeding a variety of rare animals.

The palace and the garden for imperial families, which is in organic combination, is an important template of the later imperial gardens planning represented by the “Jianzhanggong” from the Han dynasty. The palace is in the north and the garden is in the south in Jinse palace. This pattern is very similar to the Imperial Palace and Jingshan in Beijing.

4.4 *Planting*

The planting way in Norbulingka mostly is similar to the Temple of Heaven in Beijing. It is called determinant planting, which is the form of an extension of the building to set the great and solemn mood for the building. On the other hand, this way forms a sense of sequence of space creating a holy and sacred tour experience.

4.5 *Garden in the garden*

Garden in the Garden is one of the structural layouts of the Royal classical gardens. The small garden is the basic units for the whole garden such as the “Xiequyuan” in the Summer Palace. We can see this pattern in Norbulingka that the boundaries between each atom are distinct. But this layout in the Norbulingka is formed because each dominator builds a park. So there is no organic link between the respective small gardens. At this point, the Tibetans and Hans are still very different.

4.6 *Scenery-borrowing*

The scenery-borrowing is an important artistic technique in the Constitution. Its core is the universe view of “harmony between man and nature”.

Figure 4. Trees are planted in rows.

Figure 5. The garden is divided into different small parts by the plants.

Figure 6. At the end of the road before the palace, we can see the other palace and the mountains in the distance.

The layout in Norbulingka particularly emphasizes the placement technique to create a discrete echo around the landscape, which sets off each other.

5 CONCLUSIONS

As part of a culture, classical garden is not only closely related to literature, painting and other art forms, but also to the detailed embodiment

of the people's way of life. Though the Han and the Tibetan people created a completely different national culture due to different living environments, they had influenced each other over the past two thousand years. Classical garden is typical of the blending of the two cultures.

Classical garden is the combination of traditional culture, both of Han and Tibetan people. They are the embodiment of pursuit of the material and spiritual life. In terms of the development degree, linka has not reached the level of garden art. But classical garden is typical. Linka not only has been affected by the culture of Han in many ways but also absorbed it. The styles and methods of gardening and some ideas and life styles spread to Tibet. People build gardens and feel the beauty. People can experience both the culture of Han and Tibet in one garden, which shows the combination of different culture.

Releasing flux and characteristic of nitrous oxide from wastewater land treatment systems

X.X. Zhang, Y.H. Li, Y. Wang & H.Y. Weng

School of Resources and Civil Engineering, Northeastern University, Shenyang, Liaoning, China

ABSTRACT: Wastewater land treatment system can remove pollutants deeply through a combination process of physical, chemical and biological functions. During the complex process of biological metabolism, greenhouse gases, such as nitrous oxide (N_2O), are released from the substrate bed, causing the block of land treatment system and the destruction of atmospheric environment. This paper reviews the production mechanism of N_2O released from wastewater land treatment system. Furthermore, the influence of impact factors (types of system, plant and temperature) on N_2O release characteristic was summarized in constructed wetland system, slow rate land treatment system, rapid infiltration system, overland flow system and subsurface wastewater infiltration system. The method of accounting N_2O releasing flux was introduced. Finally, the viewpoint was pointed out that temperature, matrix composition and operation conditions affect N_2O releasing flux considerably.

1 INTRODUCTION

Wastewater land treatment system utilizes self-regulation mechanism and comprehensive purification function of soil–microorganism–plant to make sewage reclamation harmless, including rapid infiltration system, slow rate land treatment system, overland flow system, wetland system, and subsurface wastewater infiltration system (Li et al. 2015). Compared with traditional processing for wastewater such as activated sludge process, wastewater land treatment system gains the advantages of high decontamination efficiency, low operating costs and ecological services function (Yang et al. 2007, Zachrit & Fuller 1993, Zheng et al. 2012). However, wastewater land treatment system still has some shortcomings in the design and practical application. The greenhouse gas releasing from this kind of system is mainly nitrous oxide (N_2O). Besides, the decomposition product of N_2O is the main source of NO, which is the key substance in the chemical chain reaction of ozone layer destruction (Lin et al. 2008). Wastewater land treatment system is a useful and necessary complementary form of centralized sewage treatment methods. It has been applied widely in rural, suburban, and other areas without uniform sewage networks. So the releasing flux and characteristics of N_2O has aroused worldwide concern.

2 MECHANISM OF N_2O EMISSIONS

At present, domestic and foreign scholars have basically reached a consensus on the release

mechanism of N_2O in land treatment systems. According to literature, N_2O is generated by the following three kinds of biochemistry processes (Capra et al. 2007, Lin et al. 2008, Liao et al. 2010): ① Nitrification process: In the process of N converted into NO_2^- and NO_3^- as electronic receptor, N_2O releases as side-product (Fig. 1) (Qu et al. 2008). This process is controlled by aerobic nitrifier and Nitrosobacteria; ② Denitrification process: in the process of $NO_3^- - N$ converted into N_2 , N_2O is produced as an intermediate product (Fig. 2) (Qu et al. 2008). This process is controlled by anaerobic denitrifying bacteria; ③ Non-biological nitrogen (N) converting processes: NO_3^- and NO_2^- react with organic or inorganic matter to N_2O or N_2 . Most of the reports indicate that processes of nitrification and denitrification are the main process of N_2O produced.

According to the release mechanism, the factors affecting process of nitrification and denitrification in the substrate layer is also the main factor influencing N_2O emissions. The influencing factors are as follows.

Figure 1. N_2O release from the nitrification process.

Figure 2. N_2O release from the denitrification process.

3 INFLUENCING FACTORS OF N₂O EMISSION

3.1 *Effect of system types*

Due to the differences in building forms, process, and operation parameters between the different types of land treatment systems, there are big differences in the process of N₂O release. Research (Wu et al. 2009) shows that both Subsurface Flow (SF) and Free Water Surface (FWS) constructed wetland system to be emission source of N₂O, and the SF process promotes N₂O emissions. The mean N₂O fluxes are 0.2965 mg·m⁻²·h⁻¹ and 0.0282 mg·m⁻²·h⁻¹ respectively in SF and FWS constructed wetland systems. This is mostly because of the wetland types and substrate water content. In FWS constructed wetland, sewage on soil layer reduces the permeability of the soil. The anaerobic conditions promote denitrification process, and hinder N₂O diffusing to the atmosphere, thus increasing the rate of N₂O converted to N₂. So FWS process can reduce N₂O emissions.

3.2 *Effect of plant types*

Plants are important part of the soil–microorganism–plant system. Its type and coverage can impact soil nitrogen load, Dissolved Oxygen (DO) etc. and then affect N₂O release. Reeds, cattail and sedge are common aquatic plants in wetland. Wetland plants work in two aspects: ① they can absorb some of the nutrients; ② their roots provide places for the metabolism of microbes and the degradation of nutrients (Li et al. 2007). Plants remove nitrogen through absorption. More plant biomass can absorb more N, which means fewer N₂O emissions. Plant types, environment, nutrition and plant adaptation can affect the ability of N₂O removal (Wang et al. 2013). Research (Li et al. 2010) indicates that N₂O fluxes are quite different in vegetation cover and vegetation-free sediment systems. Compared with vegetation-free sediment systems, reeds in vegetation sediment systems show improvement on N₂O emissions, and during the growing season, the effect is more pronounced, increasing the emissions from 0.71 μg·m⁻²·h⁻¹ to 566.28 μg·m⁻²·h⁻¹. Under the typical dry-wet alternate condition of the high tidal flat, plant physiological activities NO₃⁻–N, NO₄⁻–N, temperature and water content affect the nitrification–denitrification process.

3.3 *Effect of substrate types*

Substrate is the living place of microbes. Its composition, structure, and physico-chemical properties greatly affect N₂O emissions by affecting

microbiological activity. For example, higher porosity substrate means higher DO level. High DO concentration hinders N₂O release. Microbiological denitrification is a strictly anaerobic process. When DO concentration is above 0.2 mg/L, denitrification is difficult to happen (Lim et al. 2001). High soil pH is not conducive to N₂O release. Generally, the optimum pH for nitrification is 7.5–8.6, while 7–8 for denitrification (Al-Omari et al. 2003). When pH is lower than 6.0, denitrification is rapid as pH decreases. Sun et al. (2007) show that humus marsh soil and meadow marsh soil have similar change ranges of N₂O emission rate. But the latter has a much higher N₂O emission rate; the change ranges of their denitrification rate are not similar. Meadow marsh soil has a higher denitrification rate. Nitrification plays an important part in N₂O release and nitrogen removal in meadow marsh soil, while denitrification is important in humus marsh soil.

3.4 *Effect of temperature*

Nitrogen cycle in the soil mainly depends on catabolic metabolism of microbes and absorption of plants. Temperature greatly impacts the growth and metabolism of plants and microbes. Microorganisms will be inactive in low temperature, so the influence of biochemical process can be ignored. Above a certain temperature, the rate of biochemical reaction increases rapidly following Arrhenius formula (Rodríguez-Aragón et al. 2005). The optimal temperature of nitrification is 25°C–35°C. The nitrification will be restricted if the temperature is over 40°C or under 4°C. Temperature for denitrification is wide with a range of –4°C to 70°C, and the optimal temperature is 10°C–25°C (Lang et al. 2012). Researches show that N₂O fluxes and water temperature have a significant positive correlation ($p < 0.05$) in constructed wetland (Wu et al. 2009).

Grunfeld (1999) believes that solar radiation can accelerate gas exchange of plants. Radiation increases the temperature. On the one hand, molecular diffusion is faster in high temperature, conducive to the spread of N₂O. On the other hand, high temperature increases microorganism activities, conducive to N₂O generation. N₂O is the intermediate product of nitrogen transformation. Under stable environmental conditions, soil nitrogen remains relatively stable forms. Environment changes cause the changes in nitrogen forms. Therefore, N₂O emissions not only depend on the environmental conditions, but also the intensity and frequency of environment changes. Wang et al. (2007) analyzed N₂O emission characteristics in freezing–thawing cycles. The result shows that freezing–thawing cycles impact the process and strength of nitrogen transformation, increasing

N₂O emissions. On the one hand, freezing–thawing cycles change the aqueous phase in soil, breaking the stability of the soil aggregates. Thus, N₂O is released. On the other hand, the decomposing of microbial residues releases many nutrients. Nitrification and denitrification use these nutrients to produce N₂O.

3.5 *Effect of hydrography*

Soil water content affects wetlands N₂O generation primarily through impacting microbial activity and DO content (Wang et al. 2013). Low soil moisture and long sustained flooding are not conducive to the growth of nitrifying and denitrifying bacteria. Pore water saturation of soil has been an important controlling factor of N₂O release for a long time. It affects the degradation of organic matter, ammonification rate, denitrification rate and the path of N₂O emissions. So pore water saturation reflects the humidity conditions of sediment better (Lang et al. 2012, Zheng et al. 2014). Studies (Arriaga et al. 2010) show that when the soil pore water saturation is 30%–60%, N₂O emissions are mainly from nitrification, and when 60%–90%, mainly from denitrification. Soil pore water saturation too high or too low are detrimental to N₂O emissions. Research (Wolf et al. 2000) indicates that nitrification and denitrification take place concurrently. Water content determines the main reaction. When soil moisture is unsaturated, nitrification is the main reaction, and NO production was significantly higher than that of N₂O production. When soil moisture is saturated, denitrification plays a leading role, but nitrification cannot be ignored, and N₂O production is higher in unsaturated moisture conditions.

3.6 *Effect of Oxidation–Reduction Potential (ORP)*

Oxidation–Reduction Potential (ORP) is an important indicator of soil permeability and oxygen condition. It can affect the production and emission of greenhouse gases. Kong et al. (2002) found that there is a significant positive correlation between ORP and N₂O emission. When ORP remains above +200 mV with good ventilation, N₂O production is half of that in no ventilation. To ensure the efficiency of the system, Subsurface Wastewater Infiltration System (SWIS) will continuously run from aerobic to anaerobic environments. This provides different ORP conditions, so nitrification and denitrification can go on at the same time. In denitrification process, oxygen will inhibit N₂O from transforming to N₂, making N₂O final metabolite of denitrification. So, high ORP conditions can increase N₂O emission.

4 ACCOUNTING FOR N₂O RELEASING FLUX

At present, there is no accurate and unified quantitative method for N₂O emissions accounting in wastewater land treatment system. Scholars mostly reference the estimating methods and models of agro-ecological system to calculate. Intergovernmental Panel on Climate Change (IPCC) guideline recommends a method (Liu et al. 2013). It introduces the calculation process of N₂O emission in detail. Coefficients in the emission process are important. Calculation of N₂O emission can be divided into two parts: ① N₂O releases after sewage or treated sewage is discharged into receiving waters, and the emission factor is 5 g N₂O–N/kg N; ② N₂O releases from the process of nitrification and denitrification in the sewage treatment plant, and the emission factor is 3.2 g N₂O–N/(person·a) (Wang et al. 2010). However, it is just a rough calculation based on per capita emissions, and it is based on amount of nitrogen input and emission factors. Therefore, estimation results are uncertain. Based on the IPCC methods, Zheng (2008) and others have developed a regional nitrogen cycle model, IAP-N. IAP-N model fully considers every process of nitrogen cycle in ecosystems, so the results are more scientific than the IPCC method. Li et al. (2014) used IAP-N model to estimate N₂O emissions in a system similar to constructed wetland ecosystem. IAP-N models have been used for estimating N₂O emissions in large-scale ecosystems. In addition, to simulate the complex process of organic nitrogen cycle in ecosystems, some models such as DNDC, CASA, CENTURY and EXPERT-N are expected to be used for N₂O emissions accounting in sewage land treatment system.

5 SUMMARY AND PROSPECTS

Wastewater land treatment system has been widely used, especially in underdeveloped towns and scattered scenic spots lacking uniform drainage systems. Emission mechanism of N₂O was generally accepted. Among the dominant factors, temperature, matrix composition and operation conditions (such as influent loading, hydraulic retention time and distribution depth) affect N₂O releasing flux considerably. However, the research on the releasing characteristic of N₂O is inadequate. Biological-physical-chemical interactions and the migration and transformation of nitrogen need further research.

A study of development planning for conservation areas in Taiwan

Tung-Ming Lee

China Institute of Technology, Taipei, Taiwan

ABSTRACT: The conservation of ancient monuments has special meaning in its times. As time goes by, the area preserves the original style of the area. More and more conservation areas are formed step by step in the procedure of the changes and development. And they are still the units in the construction of a developing city. Nowadays, we are still paying much attention to the hardware in the case of which the conservation areas of ancient monument and conservation areas are delimited in few cases. The great majority of ancient monuments are still persevered without integrity conservation concepts.

1 INTRODUCTION

The protection of cultural heritage assets by the United Nations Educational, Scientific, and Cultural Organization (UNESCO) focuses mostly on the authenticity and integrity of such assets. In addition to buildings being adequately preserved, proximal environments should be protected to the same level, and attention should be paid to the historical and cultural pathways and spaces to maintain the integrity and authenticity of monuments or historical buildings. In the twenty-first century, the concept of cultural heritage protection focuses on an integrity conservation approach, in which the authenticity and integrity of a conservation area should be examined. The famous Irish poet Oscar Wilde said: “The one charm of the past is that it is the past.” In light of this statement, protecting conservation areas is the most onerous and arduous task among initiatives for protecting historical and cultural heritage. A monument and its conservation area are a historical and cultural phenomenon marking the history of a specific era. Preserving the memory of each period, protecting the continuity of history, and retaining the context of human civilization are essential for the future development of human civilization. The development and context of initiatives for protecting the historical and cultural heritage internationally involve (1) protecting not only architectural and artistic treasures (e.g., palaces, churches, official residences, and temples) but also historic buildings that reflect the lifestyles of regular people (e.g., houses and shops) and (2) protecting all the relevant historical structures, whether an individual building, an environment, or a district.

The current development in cultural asset conservation area is not very effective; the problems are the major issues. It lacks in integrity conservation concept. Legal regulations are rudimentary.

Administrative coordination is difficult. Data integration was not employed.

Although Articles 33–36 of the Cultural Heritage Conservation Act stipulate the definition of a conservation area and regulate its development, the topic of conservation areas is complicated, and thus current legal regulations continue not to satisfy the demands of developing conservation areas. Therefore, relevant examples of conservation areas in Taiwan are scant, and no concrete achievements serve as a reference for communities in the Taiwanese society. Neither are there legal regulations that can be followed in developing a conservation area, thereby creating a predicament where the management of conservation areas focuses on tangible but not intangible assets. Future development of conservation areas should first focus on preserving intangible assets and on elevating the Quality Of Life (QOL) of local residents. In addition to preserving tangible and intangible cultural assets, the following should be incorporated into future development projects: (1) integration of the techniques required for meeting demands of daily living and (2) safety and disaster prevention projects that are critical to residents’ lives and property safety. Establishing the parameters of cultural tourism for providing local cultural tourism resources can further the application of cultural resources and the development of cultural tourism, thus enabling culture to serve as a basis for elevating the cultural and economic value and local economic competitiveness of the conservation areas.

2 CURRENT SITUATION AND PROBLEMS OF CONSERVATION AREAS IN TAIWAN

Currently, most research reports and survey results on monuments in Taiwan have discussed how conservation areas should be designated, but

such designations have not progressed beyond the reporting stage. However, the required management methods and measures remain at the recommendation stage. Although a few monument conservation areas have been officially designated “conservation areas for urban planning” by urban planning departments, the integrity of designated conservation areas and the conservation of monuments remains a problem; hence, Taiwan’s Directions for the Operation of Urban Design Review or Regulations for Urban Land Use and Control cannot be effectively implemented in conservation areas, and designated conservation areas for urban planning cannot be adequately managed and controlled. Accordingly, conservation areas for urban planning exist for just name sake; this problem extends to matters related to coordinating relevant organizations and preserving intangible assets.

The aforementioned problems can be divided into five major issues:

- A. Unclear Concept of Integrity Conservation.
- B. Legal Regulations on Tangible Asset Conservation.
- C. Ambiguity in Future Benefits and Relevant Measures.
- D. Difficulty of Administrative Coordination between Urban Planning and Cultural Authorities.
- E. Difficulty of Data Integration.

3 THEORY OF CONSERVATION AREA DEVELOPMENT IN THE TWENTY-FIRST CENTURY

3.1 *Household, neighborhood, and community units in designated conservation areas*

In earlier times, a characteristic of historical spaces was that they generally included areas that were within a walking distance. Household and neighborhood relationships were established through interpersonal and social organization, blood lineage, and geopolitical relations. Such relationships enabled establishing friendly, harmonious, and stable living domains with specific characteristics, including temples, churches, plazas, public spaces, and units that were within walking distance of other units. The current significance attached to areas designated for preserving monuments involves the shared consciousness of the residents living near the areas; in other words, the significance of monument conservation areas is associated with the household, neighborhood, and community units within the areas.

3.2 *Design and maintenance of urban public spaces in designated conservation areas*

From traditional cities in Europe to Taiwan, public buildings (e.g., churches, temples, and private residential buildings) are often surrounded by plazas,

temple courtyards, roads, or parks and green spaces, thus forming systems of public spaces in urban cities. Accordingly, the maintenance of public spaces must be considered in maintaining and preserving monuments and their surrounding areas with the aim of enhancing the quality of environments designated for monument conservation.

3.3 *Fair resource redistribution and rational benefit distribution in designated conservation areas*

Because designating conservation areas for monuments inevitably increases or decreases the rights and interests of certain section of people, most countries offer government subsidization (e.g., subsidies, tax reductions, reward systems, or transfers of development rights) to compensate these people. Therefore, fairness in redistributing resources must be considered when designating conservation areas for monuments, and the rationality of benefit compensation must be maintained after the redistribution of resources.

3.4 *Integrated coordination in designated conservation areas*

Designating conservation areas for monuments entails managing and coordinating landscapes and public facilities (e.g., ornamental plants, landmarks, architectural styles, and water and electricity infrastructure) through urban planning and urban design measures. For example, expanding the designation of a conservation area through urban renewal measures must be coordinated with the regulations on the transfer of development rights. Accordingly, conservation areas should be designated according to a set of integrated methods.

3.5 *Expansion of designated conservation areas*

Designating conservation areas for monuments should include improving undesirable surrounding environments, using resources effectively, and maintaining and enhancing the area’s socioeconomic activities. The designation should expand in coordination with overall development projects for cities and towns to ensure that the designated conservation areas are embedded with specific significance.

3.6 *Revitalization of designated conservation areas*

A lack of management and maintenance at monuments and their surrounding environments can cause these valuable assets to be lost someday. Accordingly, after conservation areas are designated, governments should provide subsidies for

the purpose of preserving and maintaining the environments of these areas, thereby improving and revitalizing the QOL of local residents.

4 NEW ORIENTATIONS FOR CONSERVATION AREA DEVELOPMENT IN THE TWENTY-FIRST CENTURY

Humans experienced two world wars in the twentieth century that led to major social, economic, and cultural problems such as ecological damage, social disintegration, and environmental pollution. In the twenty-first century, humans have reflected on the various catastrophes and conflicts caused previously and started to construct new values, cultures, and lifestyles. Developing conservation areas provides an opportunity for people to preserve and examine the various cultural heritage sites left by their predecessors over the last century as well as to learn about universal values and formulate personal goals. Recently, theories regarding the subsequent development of heritage assets have facilitated cultivating potential developmental orientations and goals.

4.1 *Conservation of the outstanding universal value of monuments: a central initiative and goal of conservation area development*

Previously, monuments were mostly preserved or protected because of personal affection and historical remembrance. Since the emergence of the “world heritage” concept, the conservation and protection of monuments has focused on sustaining and furthering the authenticity and integrity of monuments with universal value. Accordingly, the surrounding environments related to the monuments must be incorporated into the areas designated for conservation and protection. Therefore, the concept of conservation area development does not merely focus on monuments but involves the historical fabric and context, aiming to fully and prominently reveal the universal value of such monuments. Therefore, the central goal of developing conservation areas in the future should focus on promoting the universal value of monuments.

4.2 *Both prominent monuments and common ancient buildings must be preserved to realize the practical significance of conservation area development*

Previously, efforts aimed at preserving monuments have focused primarily on prominent monuments while neglecting the ancient buildings belonging to ordinary people, which are mostly located on the periphery of prominent monuments but are essential for establishing the overall universal value of

monuments. However, the lack of an appropriate concept of conservation area development has frequently caused common ancient buildings (e.g. those of ordinary people) to be demolished and razed in protecting the prominent monuments, thus destroying the integrity of the monument areas, an element essential for establishing their universal value. Accordingly, an appropriate concept of conservation area development should not involve designating conservation areas according to the social status of historical buildings. Instead, designating conservation areas according to whether the historical buildings are essential to the integrity and universal value of the preserved monuments is more adequate.

4.3 *Monument conservation is no longer limited to preserving monumental cultural heritage sites: industrial heritage is extensively emphasized in recent years and is critical to conservation area development*

The scale of the conservation areas for industrial heritage is large; thus, independently preserving each monument located within an industrial heritage area diminishes the authenticity and integrity of the universal value of the overall heritage area. Hence, the concept of conservation area development must be similarly applied to industrial heritage conservation, in which all the relevant historical buildings located within an industrial heritage area should be incorporated to highlight its unique historical value and industrial characteristics. An appropriate concept for developing a conservation area in the future will involve extensively incorporating various types of historical buildings and reasonably expanding the scope of the conservation area to ensure that initiatives for preserving a variety of heritage assets can be successfully implemented.

4.4 *Reducing the impact of contemporary construction in monument complexes: crucial to concretizing and expanding conservation areas, protecting the urban fabric, and structuring urban development programs*

The emergence of contemporary buildings within monument complexes frequently degenerates or destroys the integrity and universal value of such a complex; nevertheless, contemporary construction is inevitable in urban cities and thus may lead to a dilemma. Applying the concept of conservation area development can combine the measures and goals of urban development programs and conservation area development schemes to minimize the impact caused by newly constructed buildings within monument complexes, to create functional spaces benefiting the complexes, and to generate

development benefits by equally emphasizing the fair use and conservation of relevant areas and sites (e.g., urban disaster prevention and favorable urban life functions). An appropriate concept of conservation area development in the future can be formulated from the perspective of the existing urban fabric, thus enabling the urban fabric to become a part of the overall urban development program and ensuring the successful implementation of development initiatives for conservation areas.

4.5 *Conservation of a cultural landscape that emphasizes and reflects human life and culture and land use: a new direction of and the key to successful conservation area development*

In recent years, much attention has been focused on cultural landscape, which is a cultural asset that can reflect the relationships between and the universal value of human life, culture, and land use. A cultural landscape generally does not entail a building or a construction complex; nevertheless, it is associated with universal value and thus is a critical cultural asset to preserve. Because the scope of a cultural landscape is generally large, the concept of conservation area development must be applied to preserving cultural landscapes. The conservation of cultural landscapes is a new domain that is key to developing conservation areas and critical to formulating new directions and topics for conservation area development, which are critical to implementing initiatives for preserving cultural landscapes and successfully developing conservation areas.

5 CONCLUSION

In the 20 years since the Council for Cultural Affairs was established in Taiwan, the concept and consciousness of conservation has become deeply rooted in the Council, which has developed relevant conservation techniques and accumulated considerable achievements. In the twenty-first century, preserving a comprehensive heritage area that simultaneously expresses cultural significance and historical value will be the focus of future conservation schemes.

Previously, the conservation and maintenance of monuments neglected the surrounding environments and areas. However, subtle changes in the conservation and maintenance schemes of international cultural heritage areas have occurred in recent decades. The focus of monument conservation and maintenance has expanded to include relevant building complexes (not merely individual historical buildings), the essence or pathways of historical developments in cities and towns, and

even the associated intangible values, operations management, and education projects in preserved areas. In recent years, attention has been focused on maintaining and protecting heritage areas; hence, more appropriate concepts have been developed to comprehensively preserve the internal and external environments of a heritage. This approach should be the key to developing theories on conservation area development in the twenty-first century.

Because of differences in the social, economic, and educational conditions of countries committed to preserving cultural heritage areas, the time devoted to and the intensity, methods, and goals of developing conservation areas may differ. Nevertheless, fundamental requirements for environmental landscapes, transportation, conservation, health, and safety should be consistent. The changes in residential areas and environments around preserved area result in interrelated issues of economic benefits, convenience, and safety.

Consequently, how to adequately formulate the purposes, goals, legal regulations, strategies, and instruments for developing designated areas of cultural heritage conservation is not only an essential topic for enhancing the conservation of cultural heritage assets but also a major task for preserving, maintaining, and developing Taiwan's monuments. Theory on developing conservation areas for cultural heritage must be constructed from the perspectives of social equality and justice, environmental ecology, and economic activity to achieve sustainable development.

The study on the control optimization and strategy of indoor visual comfortable environment system

Dan Wang, Hongwei Yin, Pu Dong & Yifei Chen
China Agricultural University, Beijing, China

ABSTRACT: The primary goal of the daylighting and shading system is to reduce the consumption of light and meet occupants' visual comfort. Thinking for many related control systems, they were designed that based on different algorithms, architectural models, simulation software and evaluation systems to meet the requirement. For these considerations, there is a need to propose optimization programs and develop suitable control algorithms based on the control constraints, the control strategies and experimental models. This paper summarizes several control systems of the indoor visual comfortable environment and finally gives some recommendations for the future research. Presented current indoor visual environment control methods and the characteristics were analyzed in this paper, and it can be found that the automatic control strategy has great improved space for optimization by studying on an intelligent control method as well as its simulation.

1 INTRODUCTION

The issued Directive 2010/31/EU of the European Parliament and Council of 19 May 2010 on the energy performance of buildings requires all new buildings to be “Nearly Zero Energy Buildings” (NZEB) by 2020 (EPBD, 2010), thus the energy efficiency of building environment has been the top priority (Nielsen 2011). According to recent studies, lighting energy consumption represents between 40% and 70% of total energy consumption within the tertiary sector, and moreover, it is expected that this consumption will increase in the future (Alcalde 2012). At this regard, energy efficiency in lighting is one of the key elements of nearly zero-energy buildings.

With the continuous improvement of the life quality, creating a comfortable visual environment with low energy consumption has been the most basic requirements of the occupants. In order to achieve both energy-efficient lighting and visual comfort, people have made great efforts in the relevant field of study. Advanced lighting control is the most effective way to improve energy efficiency, and it can meet the requirements of the occupants by way of regulation based on human perception. The settings of lighting and shading devices for example lighting blocking louver blinds are the key factors in regulating the indoor visual environment. One of the methods is to exploit the daylight coming into the indoor areas more effectively. If the lighting can be automatically turned off according to the level of daylight flowing

indoors, the amount of electrical energy consumed for artificial lighting can be thereby reduced. The application of the dynamic operation of daylighting and shading systems can make the available resources, such as solar radiation and natural light, to get a better exploitation, so that the lighting energy saving 30%–77% (Yang 2010, Tzempelikos 2007), the energy efficiency and visual comfort can be improved at the same time (Lee 1998). According to the paper findings, the dynamic operation of daylighting and shading systems has many advantages in comparison to traditional control, for example, it can use the natural light efficiently, maximize energy efficiency and improve the quality of indoor lighting. However, there are some limits on the dynamic operation of daylighting and shading systems, such as the stability and versatility of the system, and the optimization of visual comfort control systems in energy-efficient buildings will be the focus of the future researches.

2 CONTROLLING ELEMENTS

2.1 *Visual comfort*

There are many factors influencing in the control of indoor visual comfortable environment, generally including architectural factors and non-construction factors, such as illumination intensity, solar radiation, climate, lamps as well as their power, windows' orientation and size, area ratio between the window and wall, indoor reflectance,

sun-shading measures and so on (Chen 2004). In accordance with international standard UNE EN-12665 (E. 2011) visual comfort can be defined as a subjective condition of visual well-being induced by the visual environment. Rodriguez et al. (2015) took visual comfort as a function of appropriate levels of both illuminance and glare. Some indexes for these parameters are defined, and some methodologies are applied to calculate the indexes. For instance, Table 1 can be observed the appropriate levels of indoor illuminance, glare rating and color rendering for common tasks which are developed inside offices.

More specifically, visual comfortable condition can be defined as function of the luminance distribution, illuminance and its distribution, glare, color of light, color rendering, flicker rate and amount of daylight (Castilla 2014).

2.2 Peripheral equipment

In fact, solar energy can be used in daylight and solar heating gain, benefiting both energy performance and psychophysical comfort, providing the use of that dynamic facade elements and integrated multi-criteria decision methods. It is very helpful for the optical data exchange technology (Castilla 2008) to have a wide range of lighting and light control techniques in the construction of the external envelope.

Shading devices mainly includes shutter, discount blinds, vertical blinds and venetian blinds which are classified by the static or dynamic shading device, manual or automatic control. The structure and material of shading devices largely affect the quality of indoor light and the indoor temperature. Decker M. (2013) found that the shape of movement triggered with the application of electric charge blocks which directly gains solar heat or allows daylight into the building. According to the literature reviewed on Phase Change Materials (PCM) by Silva et al. (2016) PCMs increase thermal comfort conditions in buildings and therefore occupants' satisfaction. Besides the conventional

components, there are dynamic technologies under development, which are based on new, "smart" materials. Lelieveld C. (2007) and Thompson R. (2014) put forward that new smart materials are being developed. Martirano et al. (2016) noted that the lighting energy demand is sensitive to lighting type and control technique—in particular, two types of lighting (fluorescent versus LED) and two lighting control techniques (dimming versus switching)—its sensitivity affects the overall energy demand.

2.3 Occupants' behavior

Occupants' satisfaction and comfort are invaluable and relate to their well-being and working-performance (Heschong 2002, Veitch 1996). Occupants' satisfaction is influenced by their visual and thermal comfort as well as their ability to control the conditions of their working environment. Their response might be the cause for discrepancies between calculated and measured data due to the fact that the occupants' behavior is not often well represented in simulation models (Roetzel 2010). Occupants' response to dynamic daylighting and shading systems relates to their comfort and also affects buildings energy performance. Some advanced controls add more control variables, for example, user preferences may be integrated into the controller by automatically learning user preferences (Guillemin 2002).

3 CONTROL SYSTEM

3.1 Control strategy

In the existing literatures, the most common control objects are venetian blinds and roller shades. From the traditional control strategies (Colaco & Kurian 2008) to more advanced control systems, which have demonstrated their positive impact on energy performance and comfort. Rodriguez et al. (2015) focused on the development of a preliminary fuzzy logic control system which allows maintaining visual comfortable conditions and its validation inside a meeting-room. More specifically, the control system has been tested through real tests inside a meeting-room of a bioclimatic building. These preliminary results have shown that the proposed control architecture has been able to maintain the specified visual comfortable conditions with the available means while decreasing the use of artificial light. Another example of advanced control uses an adaptable hierarchical fuzzy blind controller optimized by genetic algorithms that consider various state variables (Daum 2010). Similarly, there are many control algorithms

Table 1. Recommendation for indoor lighting of offices.

Activity	Maintained Illuminance[lux]	Limiting glare rating
Filing, copying, etc.	300	19
Writing, typing, reading, et.	500	19
Technical drawing	750	16
CAD work stations	500	19
Conference and meeting-rooms	500	19
Archives	200	25

have been developed in the control systems. Li (2008) focus on the perspective of intelligent control way, based on the physical model of indoor shading system and aluminum blinds with electric shade, to control the blind turning angle by fuzzy neural network to adjust the light in the room and make ensure that the indoor illumination meets the visual comfortable requirements. Lang (2008) proposed a computer indoor lighting control system based on two-dimensional pure fuzzy control algorithm. Referring to the fuzzy rules, applying the hardware interface can control the angle of blinds and the fill light angle effectively. Chen (2010) proposed an adaptive fuzzy control method to control the rotation angle of blinds adaptively based on the relationship analysis between the illumination and interior shading blinds rotation angle.

3.2 Energy assessment

In order to evaluate the energy-saving and visual comfort of control system, Shen et al. (2014) compared the energy and visual comfort performance of seven independent and integrated lighting and daylight control strategies. For independent closed-loop control and closed-loop dimming control window, blinds are always fully deployed and controlled by the solar position and incident light angle. During daytime, the blind slat angle rotates to the cut-off angle to block solar incident light. Lighting is controlled to maintain a set point illuminance of 500 lx on the work plane surface. It can be also controlled by occupancy-based switching. For the fully integrated lighting and daylight controlling with blind tilt angle, the goal is to maintain task illuminance close to the required lighting levels and minimize energy consumption for electric lighting. Blinds are always fully deployed and operated in the energy-saving and the comfort mode. Blinds operate as described previously in the energy-saving mode. In the comfort mode, when there is insufficient light, the integrated controller opens the blind slats to admit daylight to ensure no glare. In case of the target illuminance is not reached, the electric lights are dimmed on for insufficient daylight. Respectively, when the lighting levels are above the set-point, the electric lights are slowly dimmed.

The article focused on the quantitative analysis of performance of the seven lighting and daylight control strategies. The co-simulation platform includes EnergyPlus, BCVTB and Matlab, which is developed to estimate the energy and visual comfort performance in a typical medium office building. The results showed that the fully integrated lighting and daylight control with blind tilt angle (Figure 1) performed well in most cases and reached the lowest level of power consumption.

Figure 1. Integrated lighting and daylighting control.

Similarly, Shen and Hong (2009) developed an integrated daylight and lighting control, evaluated the energy savings in an office model using Energy-Plus simulations, and found lighting energy savings of 64–84%, and heating, mechanical ventilation and airconditioning (HVAC) savings from 3% to 43% depending on location, compared to a base case with clear windows and all lighting fully on.

In general, lighting control plays a key role in NZEB project. The strategies used concern: (1) reducing wasted hours of lighting unoccupied spaces; (2) automatically adjusting electric light levels in synchrony with available daylight via the dynamic façade (Cziker 2007, Cziker 2008). According to the actual situation and the review of the literatures, the current situation of the dynamic operation of daylighting and shading systems can be summarized as follows conclusions:

1. Daylighting varies according to climatic conditions, building orientation and area ratio of the window and wall. But the systematic studies of literatures are in a particular environment, which is based on the set conditions for commissioning.
2. There is a limit to system energy estimation.
3. The acceptance level by users in the control system used to be a great impact on the effective implementation of the control system. The current developed control strategies developed are too complex or too simple for users, which cause difficulties of operation or their unwarness to the problem.

4 AN INTELLIGENT CONTROL METHOD

This article presents RBF neural network control approach that efficiently ensures visual comfort and energy saving. This paper analyzes the impact factors and the control rules of the indoor visual environment, introduces the learning algorithm of RBF neural network and builds control system of indoor visual comfortable environment based on the RBF neural network control (Figure 2). And finally the simulating experiments are carried

out under the environment of MATLAB. By comparing the differences of the control performance between the BP neural network and the RBF neural network as shown in Table 2, the indoor visual environment control system based on RBF neural network has higher control accuracy in rotation angle of venetian blinds and lighting system. Experimental results (Figure 3) show that this control method not only achieves the purpose of saving energy, but also improves the

control quality of the indoor visual comfortable environment.

The innovation of this project is the use of artificial neural network control algorithm, which can fully approximate to any complex nonlinear relationship. And the self-learning function of controller increases the precision of the control system. On the other hand, this paper constructs a multi-input multi-output system which is suitable for different weather conditions and thus matches practical condition for the control system.

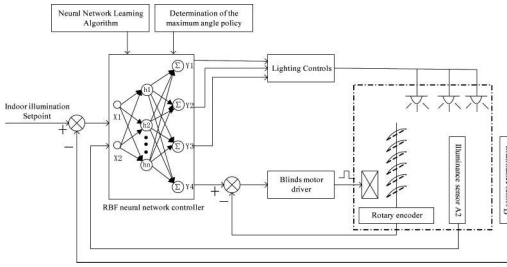

Figure 2. The system structure of indoor visual environment based on neural network control. *Illuminance sensor B is used to measure the outdoor illumination, Illuminance sensor A2 is used to measure the indoor illumination.

Table 2. Error comparison.

Output	RBF average error	BP average error	RBF error variance	BP error variance
Blinds angle of rotation	0.3428	0.6629	0.7077	40.7511
Light A2	0.0094	0.2029	0.0010	0.0638

Figure 3. The fit of the RBF neural network output curve.

5 CONCLUSIONS

According to the previous discussion, the following recommendations are meant to guide future researches in the optimization of the systems:

1. It is efficient for the control system to improve the control performance by using more advanced control algorithms special in sun shading control.
2. In future studies, the control system optimization criteria may include personal preferences in order to realize more advanced intelligent control, and embedded into Smart Home System.
3. Future research will be considered using Radiance for daylight imulation and EnergyPlus for energy simulation to realize more accurate simulation results, and using more realistic and advanced simulation strategies.
4. At present, few researches deal with global optimization of energy demand and users' comfort, see e.g. (Ippolito 2014, Tagliabue 2012). Future Studies should be committed to the application of advanced smart materials, which are the key to reach energy saving and visual comfort.
5. With aim to obtain significant results, solar radiation, electric lighting, HVAC and shading systems cannot be considered separately but have to be handled as a whole, because solar radiation affects both lighting and HVAC and it impacts both energy performance and comfort, introducing sunlight and overheating possibly uncomfortable for occupants. Therefore, reasoning one controlled integrated goal is worth to be researched.
6. This system is one of special mixed system, and studying one valid control method to this mixed system is also next work.

A study of a low-carbon and intelligent city index system

Yu-Sheng Shen

Academia Sinica, Taipei City, Taiwan

Hsiao-Lan Liu

Department of Land Economics, National Chengchi University, Taipei City, Taiwan

ABSTRACT: The low-carbon and intelligent city is the city combines the technology, digital information, low-carbon, and sustainable development together. In order to evaluate the status of low-carbon and intelligent city effectively, city governments need to develop an index system. However, most city governments lack the suitable index system of low-carbon and intelligent city. Therefore, this paper seeks to establish the appropriate index system of low-carbon and intelligent city by correlation analysis and factor analysis rating method, and evaluate the status of low-carbon and intelligent cities within the Taiwanese domain. According to the empirical results, there are five evaluative aspects of the low-carbon and intelligent city: (1) economic and intelligent technology, (2) consumption of energy and resource, (3) health and environmental conservation, (4) local development, and (5) social status. Based on the comprehensive performance of the low-carbon and intelligent city index system, Taipei City shows the best performance.

1 INTRODUCTION

The low-carbon and intelligent city is the city combines the technology, digital information, low-carbon, and sustainable development together. The development of low-carbon and intelligent city not only can integrate the digital information and apply advanced technology, but also can solve the environmental problems and carbon emissions of urbanization. Effective evaluation of low-carbon and intelligent degree are the most important tasks to develop low-carbon and intelligent cities. The evaluation can reveal the current conditions of urban developments, and the gaps between those conditions and the prospective goal. Moreover, the evaluation can guide the cities to become low-carbon and intelligent cities, and examine the efficiency of cities setting policies in motions. The evaluation can also help to monitor the status of developing low-carbon and intelligent cities, and implement corrective action as needed.

In order to evaluate the status of low-carbon and intelligent cities effectively, city governments need to develop the index system. However, most city governments lack the index system of low-carbon and intelligent cities, while they strive towards the goal of becoming low-carbon and intelligent cities. Besides, most of the evaluation indicators tend to lean toward particular area and lacked comprehensive consideration, thus influencing the final results. Therefore, this paper seeks to establish

the appropriate evaluation index system, based on virtues, ideas, and goals of low-carbon and intelligent cities. Furthermore, the paper utilizes the opportunity to evaluate the status of low-carbon and intelligent developments of cities within the Taiwanese domain, in order to provide reference for urban development in the future.

2 RESEARCH DESIGN

2.1 Analytical framework

Because the past studies lack operational framework, this study proposes the analytical framework, which includes seven steps (Figure 1). In addition to an analytical framework for this paper, it also can apply to other cities in different regions and countries due to its general rule.

2.2 Method

In order to avoid the subjectivity of selecting and determining index system, correlation analysis and factor analysis rating method are used to construct the index system in this paper. The factor analysis rating method decides the index system by factor analysis, factor analysis is a multivariate analysis that simplifies a lot of complicated indicators to the few meaningful aspects/component using the correlation matrix. Therefore, factor analysis is not

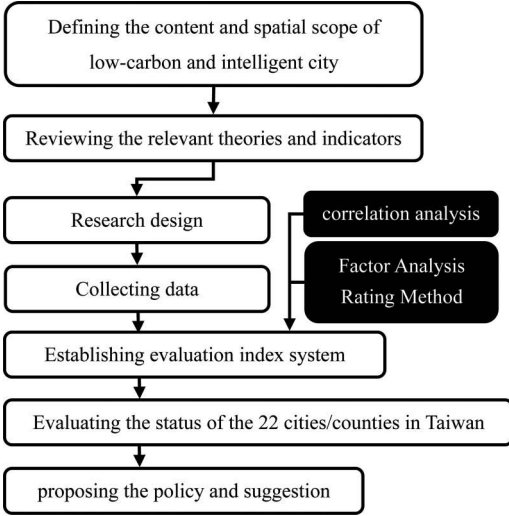

Figure 1. Analytical framework.

only used to simplify the numbers of indicators and select the meaningful indicators in this paper, but also determine the relative weight of each aspect and indicators. In the empirical analysis of factor analysis, principal-axis factoring analysis (PFA) is used as the way of factor extraction, and varimax is used as the way of rotation.

The weight of low-carbon and intelligent city evaluation index system established in this paper includes aspects weight and indicators weight. The former comes from the total variance of certain aspect divided by the total variance of selected aspects, as in Formula (1); the latter is obtained by multiplying the ratio of factor loadings in each aspect with aspects weight, as in Formula (2).

$$A_i = a_i / \sum_{i=1}^n a_i \quad (1)$$

$$B_{ij} = A_i \times (|b_{ij}| / \sum_{j=1}^m |b_{ij}|) \quad (2)$$

A_i : weight of aspects

a_i : total variance of aspects

B_{ij} : weight of indicators in certain aspects

b_{ij} : factor loading of indicators

i : aspects

j : indicators of certain aspects

2.3 Defining indicators

Low-carbon and intelligent city is the combined concept of low-carbon and intelligent systems, therefore, this paper reviews and organizes the indicators of low-carbon development

and intelligent systems respectively, in defining indicators. Moreover, quantifiable indicators are preferred in this paper to maintain the objectivity, verifiability and comparability of the indicator system and evaluation results. According to the research on low-carbon (Chen and Zhu 2013; Su et al. 2012; Price et al. 2013) and intelligent system (Deakin 2012; Deakin 2013; Deakin 2014), this paper generalizes the 48 quantifiable indicators for the evaluation of low-carbon and intelligent cities.

Due to the difference in data, type, unit and range of the indicators, formula (3) and (4) are used to convert the original data. If the indicator is maximizing form (the bigger the value, the better the performance), formula (3) is used; If the index is minimizing form (the smaller the value, the better the performance), formula (4) is chosen.

$$x_i^c = (x_i - x_{min}) / (x_{max} - x_{min}) \quad (3)$$

$$x_k^c = (x_{max} - x_k) / (x_{max} - x_{min}) \quad (4)$$

x_i^c : indicator value after maximizing conversion

x_k^c : indicator value after minimizing conversion

x_i : original value of indicator i

x_k : original value of indicator k

x_{max} : maximum value in all (selected) indicators

x_{min} : minimum value in all (selected) indicators

3 DATA

Based on considering consistency in data and accuracy and coherence in the analysis, 22 cities in Taiwan were chosen for applying spatial scope of empirical analysis. As for data type, all indicators are quantitative, quoted from Urban and Regional Development Statistics, and statistical database of Directorate-General of Budget, Accounting and Statistics in Taiwan. Considering the limitations of the governmental data content, samples for factor analysis come from the data of the 22 cities between 2006 to 2010. Data of the Taiwan's 22 cities in 2010 is used for evaluating low-carbon and intelligent status of cities.

4 EMPIRICAL ANALYSIS AND DISCUSSION

4.1 Establishing the evaluation indicator system for low-carbon and intelligent city

4.1.1 Model verification

In the verifying suitability of factor analysis for data, the results passed the Bartlett's test of sphericity, and the Kaiser–Meyer–Olkin measure of sampling adequacy (KMO) is 0.817. Therefore, the data was suitable for factor analysis. In verifying the number of components by extracting,

Table 1. Results of eigenvalue and variance by factor analysis.

Aspect	I	II	III	IV	V
Eigenvalue	38.64	11.36	5.43	3.73	2.62
Total variance (%)	49.54	14.56	6.96	4.78	3.35
Cumulative variance (%)	49.54	64.11	71.08	75.87	79.23

the results achieved the three standards (such as Kaiser criterion, Cattell criterion, cumulative variance criterion). The six aspects were the best number of factor extraction as the cumulative variance reaches 81.76%, and all eigenvalue of each component was above 1 (Table 1).

4.1.2 Results analysis and discussion

After factor extraction and rotation through factor analysis, the result of evaluation indicator

Table 2. Evaluation index system for low-carbon and intelligent cities.

Evaluation indicator system	Content of indicator	Aspect weight	Indicated weight
F1: economy and intelligent technology		0.6	
Low-carbon and low pollution industries market value ratio	Ratio of market value in tertiary industries to total market value		0.162
Low-carbon and low pollution industries employment ratio	Ratio of employed population in tertiary industries to total employed population		0.156
Number of network users	Number of network users		0.144
Construction of network hardware	Number of construction of network hardware		0.138
F2: consumption of energy and resource		0.18	
Fossil energy consumption	Fossil energy consumed by living and production activities		0.0324
Electric power consumption	Electric power resource consumed by living and production activities		0.0306
Renewable energy consumption	Renewable energy consumed by living and production activities		0.0288
Water consumption	Water resource consumed by living and production activities		0.0306
F3: health and environmental conservation		0.09	
PSI exceeding 100 ratio	Ratio of days with PSI exceeding 100 to total days investigated		0.0189
Sewage emissions	Sewage emissions generated by living and production activities		0.0180
Waste generated	Waste generated by living and production activities		0.0180
Hospital beds	Number of hospital beds in medical institutions		0.0162
Medical employees	Number of medical employees in medical institutions		0.0189
F4: local development		0.06	
Green building	Number of green building		0.0096
Public facilities land area	Area of public facilities land		0.0070
Forest coverage area	Coverage area of forest		0.0091
Urban land density	Ratio of urban planning area to total land area in city		0.0078
F5: social status		0.04	
Unemployed population	Number of unemployed population		0.0064
Gini coefficient	Ratio of the area between Lorenz curve and line of equality to area below line of equality		0.0068
Resource recycling	Number of resource recycling in all organization and communities		0.0068
Car and motorcycle ownership	Number of automobiles and motorcycles ownership with license		0.0064

Note: PSI is Pollutant Standard Index that reports the concentration of five air pollutants, particulate matter, sulfur dioxide, carbon monoxide, ozone, nitrogen dioxide.

Figure 2. Results of evaluation of low-carbon and intelligent.

system, which were established for low-carbon and intelligent city included economic and intelligent technology, consumption of energy and resource, health and environmental conservation, local development, and social status (Table 2). The weight of aspects and indicators could be obtained through the formula (1) and (2). Based on Table 2, the aspect of economic and intelligent technology was the most important component for its variance reporting 49.54, and the indicators (such as low-carbon and low pollution industries market value ratio, low-carbon and low pollution industries employment ratio, number of network users, and construction of network hardware) were also the most important indicators. Therefore, the aspect of economic and intelligent technology served as a foundation for low-carbon and intelligent city. While consumption of energy and resource occupied the position as the secondary aspect, and various indicators included by this aspect for the development of low-carbon and intelligent city. The rest of indicators still were importance and effectiveness for low-carbon and intelligent city.

4.2 Evaluation and strategy for low-carbon and intelligent development of Taiwan's cities

The results of evaluating the low-carbon and intelligent status of Taiwan's 22 cities in 2010 were shown in Figure 2. Taipei city scored 0.806 in total score, showing the best performance among the 22 cities in Taiwan. Taipei city also does particularly well in aspects of economic and intelligent technology, consumption of energy and resource, and local development. Moreover, the future improvement of Taipei city (on low-carbon and intelligent status) should be centered on two aspects, including health and environmental conservation and social status. On the contrary, the worst performance was Changhua county, with the total score of 0.261. Therefore, in order to ameliorate the degree

of low-carbon and intelligent system, Changhua county should not only improve its economic and intelligent technology primarily, but also elevate its performance in local development and social status.

5 CONCLUSION AND SUGGESTION

Environmental issues regarding global warming and human habitability have received much emphasis recently, as a result of which low-carbon and intelligent systems gradually assumed prominence as the goal of urban development. Despite the fact that numerous cities in the world have set low-carbon and intelligent systems as developmental goal, a corresponding evaluation system is missing. This paper has attempted to construct an objective and quantifiable evaluation indicator system by factor analysis, and to evaluate the status of the 22 cities in Taiwan. The results of the above can be regarded as references for the urban development and policy in the future. The results of empirical analysis show that the index system should encompass five aspects and 32 indicators in total. The low-carbon and intelligent status of all cities in Taiwan, Taipei city shows the best performance, whereas Changhua county shows the worst performance. Application of evaluation indicator system for low-carbon and intelligent city depends greatly on the local features. The indicator system may call for specific adjustments to adapt to various cultures when applied to different regions. Moreover, the indicator system must be updated according to the latest changes and developments of indicators. If the database is sufficient, it is strongly recommended to include analysis and comparison of various regions at different times in the future researches.

ABSTRACT: In recent years, Energy Service Companies (hereinafter called ESCO) emerged from concerns of the entire world on enterprises' energy saving and environmental protection issues. The success of financing from banks to ESCO would be no doubt the key factor influencing ESCO's development. In this study, we have interviewed some financing experts to realize what key factors will be evaluated when banks are facing this new business financing cases, and we tried to analyze with nonlinear quantified model, Fuzzy Dematel, to find out key principles and factors to ESCO's development when they are under limited resources, which could be their lean strategies in the future.

1 INTRODUCTION

In 1980s, increasing scientific evidence indicated the correlation between rising greenhouse gas emissions and global climate change. According to International Energy Agency (IEA, IEA Energy Technology Perspective 2010), 38% of global carbon emissions will be reduced from better energy efficiency (IEA Energy Technology Perspective 2010). It is inevitable for governments and private enterprises to develop energy conservation equipment and high-efficiency equipment, however, their high set-up costs for new energy-saving equipment could not meet the market requirement. From the 21st century, most governments have been promoting ESCO to speed up energy conservation and reduction of carbon emission.

Most studies of ESCO concentrated on operational models, development strategies and energy-saving efficiencies. In recent years, some scholars have studied and discussed on financing operation (Huang, 2007; Chen, 2011; Chen, 2014). Earlier studies mainly discussed ESCO's financing methods and models. According to Chen (2014), investigations indicated only 34% enterprises in Taiwan applied financing to banks and only 12.5% of

them succeeded. It is because of the market size of ESCO's that could not successfully get banks' attention. Bank crediting personnel did not get clear of ESCO's operational models, ESCO's were most small or medium enterprises, and most of them were newly established. Therefore, the purpose of the study is to explore the key factor to influence bank financing of ESCOs, when banks are under limited resources, and then analyze the causation and degree of influence between these factors to find out key strategy factors of bank financing. At last, the key strategy factors can be used by ESCO to adjustment of management and strategy.

2 LITERATURE REVIEWS

2.1 *What is ESCO*

The WTO has broadly defined "Energy Services Company (ESCO)" as the enterprises running for oil/electricity trade service, electricity generation/transportation/supply/distribution, water resources, energy-saving, and management of coal/electricity/gas/nuclear/power/oil/renewable energy. Ministry of Economic Affairs in Taiwan then defined it as the enterprises running for new clean

energy, energy-saving, energy efficiency promotion or peak demand transfer equipment/system/engineering/planning, feasibility study/design/installation/construction/maintenance/detection/thirdgeneration/hardware and software construction/ related technical service.

2.2 Management models of ESCO

World Bank has classified ESCO’s business model into eight types (World Bank GEF Energy Efficiency Portfolio Review and Practitioners’ Handbook, 2004), which provided initial direction of business model planning. In practice, however, some extended and change models have produced due to individual differences between energy users, ESCO and financial institutions. Chen (2011) found that almost all models have been tried in Taiwan and two types were mostly accepted by the market: “Energy Efficiency Guarantee Type” and “Energy Efficiency Share Type”. Energy Efficiency Guarantee Type means energy users sign contracts with ESCO to install equipment to lower energy use and improve energy efficiency, which results in the capital demand of energy users. To energy users, though the guarantee contracts allow them to fulfill payment after energy-saving effects have been achieved, they still have to be responsible for the financing. (Energy Charter Secretariat, 2003)

To strengthen energy users to execute energy-saving projects, ESCO promoters have developed “Energy Efficiency Share Type”. Energy Council (2008) has explained that ESCO should be the sponsor of bank financing and energy users could use the amount saved by energy efficiency guarantee project to pay ESCO. In that way, ESCO has to run the risk of project achievement and the repayment pressure after financing. Financial institutions still run the risk of repayment ability of debtors, while energy users only provide energy efficiency to ESCO in a certain period of time. (Energy Council, 2008)

In recent years, several scholars have studied ESCO financing issues. For example, Huang (2007) has probed ESCO’s financial mechanism models in Taiwan through in-depth interviews and put forward three models, ESCO credit guarantee model, local ESCO development fund or concessional loan project model, and local ESCO firefly fund project model. They all fit the developing model of ESCO financial in Taiwan. Chen (2011) also put forward three ESCO financing models, direct financing plus credit guarantee fund, contract financing plus accounts receivable, and lease. After experts’ confirmation, Chen then proceeded with in-depth interviews with bank institutions and ESCO to discuss local ESCO development and verify the feasibility of the three models.

3 RESEARCH METHODS

3.1 Research variables and factors

From document study and expert interviews, we have concluded five principles and 18 key factors in Table 1 as key for ESCO financing strategies of banks. Five principles are People, Purpose, Payment, Protection, and Perspective. People principle includes three factors of ESCO’s situation: business performance, and equipment and technical skill. Purpose principle includes three factors of use of funds: energy-saving financial plan, and concentrated purpose of funds. Payment principle includes four factors of attainability of energy efficiency, quality of accounts receivable, project business finance ratio, and business dispute. Protection principle includes four factors of guaranteed capability of the ESCO’s capital, responsible persons, collaterals, and external security. Perspective principle includes four factors of ESCO’s patents, capacity of resource integration, and government policies.

3.2 Fuzzy Dematel

Fuzzy Dematel is usually used for social science and the study of disorganized phenomena (Tamura, Nagata & Akazawa, 2002). It is a research tool to explain complicated relationships (Yang & Tzeng, 2011). It is a systematic structure designed by using professional knowledge (Liou, Yen, & Tzeng, 2008), and through the specific characteristics of each factor we can construct mutually interacting relationship between factors and transform this causation into a systematic structure model, which is the “Causal Diagram”. The main purpose of Causal Diagrams is to solve many problems in strategic decisions (Hu, 2003). Through combination and conclusion of questionnaires, we can use analyzing steps of Fuzzy Dematel to get a Total Relation Matrix (T), calculating prominence (D+R) and relation (D–R).

According to the Causal Diagram divided by average value of D+R and D–R, if D+R is bigger and D–R is above the average value, the

Table 1. Five principles and 18 factors of bank lending evaluation to ESCO.

Principles	Factors
People	Situation, Performance, Skills
Purpose	Funds, Plans, Concentrated
Payment	Attainability, Quality, Ratio, Dispute
Protection	Guaranteed, Responsibility, Collaterals, Security
Perspective	Others, Patents, Integration, Policies

coordinate locates in the first quadrant, which means the factor is closer to the core determining factors to problem resolution and should be taken into first priority. When $D+R$ is smaller and $D-R$ is above the average value, the coordinate locates in the second quadrant, which means this factor is highly independent and only has influence on certain characteristics. When $D+R$ is small and $D-R$ is below the average value, the coordinate locates in the third quadrant, which means this factor is highly independent and will be influenced by some certain characteristics. When $D+R$ is bigger and $D-R$ is below the average value, the coordinate locates in the fourth quadrant, which means this factor is a very significant core determining factors.

4 ANALYSIS AND RESULTS

4.1 Background analysis

Interviewees/respondents of the study are mainly ESCO financing personnel, who are mostly chiefs responsible for small/medium enterprise financing business, including Land Bank (8 persons), Taiwan Business Bank (14 persons) and Far Eastern International Bank (7 persons). There are totally 29 persons interviewed. Twenty-five of them have more than 6 years of experience in financing and 21 of them have 4 years' experience. Twenty-eight of them are bank chiefs. They are all appropriate interviewed objects.

4.2 Data analysis

The result of 29 questionnaires taken back and analyzed by FUZZY DEMATEL indicates the conclusion given in Table 2. And we transform these values into a Causal Diagram by Microsoft Excel in Figure 1.

From the causal diagram of Figure 1, the highest prominence principle (People; F1) indicates in general when banks deal with ESCO financing, key factors are ESCO's situation, business performance and equipment and technical skills. However, the

Table 2. The values of prominence and relation for five principles by Fuzzy Dematel analysis.

Principles	D	R	D+R	D-R
People (F1)	1.61	1.63	3.24	-0.02
Purpose (F2)	1.46	1.54	3.00	-0.08
Payment (F3)	1.37	1.37	2.74	0.01
Protection (F4)	1.38	1.35	2.73	0.04
Perspective (F5)	1.47	1.42	2.89	0.05

principle "People" is still influenced by principles "Perspective (F5)" and "Protection (F4)".

As a whole, on analysis of Figures 2 and 3, the most significant factors in the principle "Perspective" is "Government policies", because it can have great influence on ESCO's "Patents & Skills" and "Capacity of Resource Integration". The second significant factor in the principle "Protection" is "External Security".

	Policies (E4)	4.36	4.06	8.42	0.30

5 CONCLUSIONS AND SUGGESTIONS

Financial support has been playing an important role in the development of emerging industries. When global warming and climate change come into fact, energy conservation and reduction of carbon emission have become an obligation. This study used Fuzzy Dematel analysis to discuss what evaluation principles banks should take to face new type of business model, such as ESCO, to make sure that creditor's rights as well as actively assisting in ESCO's development needs are fulfilled. Meanwhile, we can use results of the analysis as for lean strategy and management key point of industrial development, so that to achieve the goal of energy-saving and reduce energy cost.

After discussions between experts from industries, government authorities and academics, this study has concluded banks' five evaluation principles and 18 specific factors to ESCO financing business, and has defined various kinds of factors. From the study, we know the highest principle of the prominence is "People", which indicates when banks deal with ESCO financing, key factors are ESCO's situation, business performance and equipment and technical skills. However, the principle "People" is still influenced by principles "Perspective", "Protection", and "Payment". Therefore, when banks are faced with ESCO financing, they should put emphasis on the principles "Perspective", "Protection", and "Payment". From the aspect of "Perspective", the most

important factor is "Government policies", which reflects actual support and industrial policy of the government is still the key factor to decide if the bank will accept financing application.

To ESCO, execution of energy efficiency projects is the way they gain profits. When banks do not understand relevant engineering and equipment techniques in the process of evaluation while ESCO owns only limited managing resources, ESCO should try to strengthen their "Patents & Skills" and "Capacity of Resource Integration" in principle "Prospective" as well as the "Guaranteed capability of the ESCO's capital" and "External Security" in principle "Protection". Thus financial personnel can improve their professional knowledge in energy-saving and then ESCO can get their capital successfully.

In-plane lateral load resistance of cast in-situ mortar panels

R. Iskandar, S. Suhendi & C. Lesmana

Department of Civil Engineering, Universitas Kristen Maranatha, Bandung, Indonesia

ABSTRACT: Cast in-situ mortar panel was a model of mortar wall that was designed to achieve effectiveness in terms of time, worker, and construction waste by using the unused sand from sand-filter as a construction material for building the wall. Although the wall panel is a non-structural element, the performance in residential buildings under wind and seismic loading is a major concern. The research aims to conduct an experiment of the mortar panels under lateral loading. Two panel specimens of mortar wall using a moving formwork were tested. The mortar panels demonstrated that the wall systems are advantageous in construction of residential or industrial buildings. The moving formwork was used for cast in-situ mortar panels to obtain solution of saving time and workers. The performances were acceptable, which was shown in the obtained results that pointed to higher strength with acceptable displacement for non-structural elements. It should be pointed out that the connection between the wall panels and the footing should be designed carefully to obtain an efficient load transfer mechanism in the structure. The inter-connection that attained from the moving formwork should be further studied since the presence of minimum dowel bars can significantly improve the lateral behavior by providing more ductility and higher strength. The cast in-situ mortar panels as alternative solution for non-structural construction material are recommended for the applications in the residential or industrial buildings.

Keywords: cast in-situ, lateral load, wall, mortar, moving formwork

1 INTRODUCTION

A more sustainable construction practice is encouraged in the population expansion. The construction of infrastructure facilities produces an amount of waste and consumes natural resources. A wall material such as masonry is commonly practiced for construction. Many researchers are eager to find the new building materials to find innovative solutions for environmental concern, such as composite masonry constructed with recycled building demolition waste and cement stabilized rammed earth (Jayasinghe et al., 2016), fine recycled aggregates from ceramic waste in masonry mortar manufacturing (Jiménez et al., 2013), recycled glass-fly ash geopolymers as low-carbon masonry units (Arulrajah et al., 2016), and so on. The technology of wall and mortar building materials has been developed to seek a viable alternative to reduce demolition waste and sustainable development (Jiménez et al., 2013). However, the more visible solutions remain unsolved since it depends on time, place, and availability materials.

A mortar is a workable paste from a mixture of sand and cements that often used to bind building blocks. The important characteristics of hardened mortar are mechanical strength, modulus of elasticity, water permeability, adhesive strength and resistance to weathering, and those of fresh

mortar are workability (NenoI et al., 2013, ASTM C270, 2014). The mortar usually uses a common construction material for bond the bricks or blocks but lack of research can be found in a wall panel by mortar, especially mortar that makes use of unused sand from sand-filter from the construction waste.

As a non-structural element, wall system must be easy to build, durable, strong enough to support self-weight and cost effective. Some of the evidence shows that many masonry walls crack due to wind or lateral loads (Cumhur et al., 2016, Triantafyllou, 1998, Taghdi et al., 2000). Those evidences demonstrate the need to have minimum lateral response although the wall is a non-structural element.

The construction techniques and the eliminating of intermediate processes in selecting and processing materials can effectively reduce material and transportation cost. A moving formwork has high degree automation and short construction period. It is suitable in the case of the remote area, fixed dimension and flat form of structure (Yang et al., 2015). A mortar panel using moving formwork can become a solution in wall material for the remote area.

In this paper, the utilization of construction waste such as unused sand from sand-filter for mortar panels can help to demolish the waste in order to create more sustainable construction practices is discussed. The experimental work was conducted

to observe the effectiveness of moving formwork for mortar panels. Besides, the mortar panels were tested in compressive and lateral strength to ascertain the possibility of the material as an alternative solution of sustainable materials for residential or industrial buildings in remote area.

2 EXPERIMENTAL INVESTIGATION OF MORTAR PANELS

As part of the investigation, two full-scale cast in-situ mortar panels were prepared using unused sand from sand-filter from the construction waste. The variable considered in this investigation were the compressive strength and performance of the lateral resistance of the mortar panels due to in-plane loading.

2.1 Materials

The mortar consisted of cement (pc), fine aggregate (fa), and water. The fine aggregate was using unused sand from sand-filter from the construction waste. The proportion of the material was mixed based on volume ratio of cement and fine aggregate as 1 pc: 7 fa with water/cement ratio 0.7. The weight volume of fine aggregates was 2.63 (SSD) with the absorption 6.07%. The water content was 8.46%.

2.2 Test specimens

The experimental program for mechanical characterization of mortar panel included tests in compressive strength. The cube specimens, 150 × 150 × 150 cm, were used to obtain the compressive strength in 7, 14, and 28 days. The total number of specimens was 9 as three specimens were prepared for each conservative day.

Two cast in-situ mortar panels are prepared using unused sand from sand-filter from the construction waste. The wall is constructed using a moving frame-work. The benefit of this type of wall are the surface of the wall is flat and relatively smooth, hence, the construction time is faster than traditional brick wall. The mortar is first made with the right proportion to obtain acceptable workability. The mortar is filled into moving formwork up to 80%, a direct compaction should be done and the formwork can move to upper section. The mortar needs to fill until the wall reaches the expected height. The dimension of the specimen was 1700 × 1460 × 100 mm that can be seen in Figure 1.

The in-plane lateral load was applied the tested specimens to obtain the resistance of the wall. The tests are performed at the Structural Testing Laboratory of Civil Engineering Department of Universitas Kristen Maranatha, Indonesia.

Figure 1. Plan elevation of the mortar panel.

Figure 2. Horizontal strengthened rebar in the middle of the wall for Specimen W2.

2.3 Experimental test program

The walls were subjected to in-plane monotonic load. The horizontal loading was applied until failure occurred. The walls were fixed to the floor and left free at the top. The horizontal displacement was measured at the top transfer beam shown in Fig. 1.

Two types of walls were prepared: W1 was the ordinary mortar wall and W2 was the mortar wall with the horizontal strengthened rebar for the connection joint.

3 DISCUSSION OF TEST RESULTS

3.1 Compressive strength

Table 1 shows the average compressive strength for the cube mortar specimens. The average compressive strength of the mortar (12,62 MPa) was higher than that of the brick material (5–7 MPa). The re-used material from unused sand for replacing fine aggregate in mortar wall was recommended to use. The result showed acceptable compressive strength for non-structural element.

Table 1. Compression test results.

Type	Day [hari]	Area [mm ²]	Weight [N]	Load [N]	Compressive strength [MPa]	Average compressive strength [MPa]
A-1	7	22837.50	58.96	139000	6.09	
A-2	7	21780.00	60.53	205000	9.41	
A-3	7	23179.06	64.65	151000	6.51	
B-1	14	22303.13	57.39	198000	8.88	
B-2	14	22425.00	61.51	242000	10.79	12.62
B-3	14	22459.00	61.80	205000	9.13	
C-1	28	22535.63	57.39	215000	9.54	
C-2	28	23293.13	64.45	345000	14.81	
C-3	28	22948.25	63.08	310000	13.51	

Figure 3. Crack pattern of Specimen W1.

3.2 Cracking

In the mortar wall specimen W1, the first major crack was observed at approximately in 4 mm of lateral displacement, which occurred in the middle of the wall. The horizontal crack widely spread from the middle and became wider and spread to create the vertical in the edge connection between mortar panel and frame as shown in Figure 3.

Different from specimen W1 that has relatively wider thickness crack about 30 mm, the specimen W2 has a crack of only about 5 mm thick. The horizontal strengthened rebar has shown good performance in strengthening the interconnection edge of the mortar wall due to the construction practice from moving formwork. The crack pattern in Figure 4 shows the mortar panel only has vertical crack.

Figure 4. Crack pattern of Specimen W2.

3.3 Strength

The strength of the mortar specimen W1 was lower than specimen W2. This result indicated that the horizontal perpendicular rebar can strengthen the panels. Good lateral resistance can be observed from

Figure 5. Load displacement of mortar wall.

Figure 5. The ultimate strength of specimen W1 was 11.40 kN in 15.95 mm horizontal displacement. Figure 5 illustrated that after the strength reached a maximum, the stiffness of the wall was decreased. The specimen W2 showed higher strength (20.2 kN) but the slip can be indicted in 15.60 kN.

4 CONCLUSIONS

The contribution of two different specimens to the in-plane lateral resistance of the mortar wall was experimentally investigated. The conclusions are summarized as follows:

1. The walls showed vertical cracks, with small thickness for the wall with strengthened and larger thickness for the wall without strengthening. The anchorage in the frame should be installed to have better load distribution.
2. High lateral resistance in the mortar wall of the specimen W2 is produced by the perpendicular strengthened horizontal rebar placed in the middle of the wall.
3. It is necessary to perform more tests to improve the models so the strength can be predicted.

4. The mortar wall that made from unused sand for replacing fine aggregate is recommended to use since it has acceptable compressive strength for non-structural elements and good lateral resistance.

A discussion on how people perceive co-housing that facilitates intergenerational communication

Shu-Ying Tsai & Cheng-Huang Ou

Department of Architecture, National Taipei University of Technology, Taipei, Taiwan

ABSTRACT: Diverse co-living has been a priority in the agenda of most nations in the world. This study attempts to investigate how people perceive co-housing from the perspective of intergenerational communication. To this end, a questionnaire survey was conducted for people living in the Taipei Metro Area. Totally, 192 valid copies of a specially designed questionnaire were collected, and the survey results indicated that the two most significant factors are the respondents' age and housing type, and that in co-housing, the public facilities most demanded by the respondents are public vegetable gardens/flower gardens, group dining space, and parking lots.

1 INTRODUCTION

In Taiwan, rapid population growth and over-expansion of cities have led to problems related to aging and high population density in cities, which in turn has degraded the quality of life. According to the demographic analysis of 2015 conducted by the Department of Statistics, the Ministry of the Interior of Taiwan, R.O.C., by the end of 2015, there were 2.95 million people aged 65 or above in Taiwan, i.e., 12.51% of the total population. This percentage is close to the 14% threshold of aging society as defined by the WHO. In addition, the birthrate of people at 0–14 has seen a decrease from 19.34% to 13.57% in the last ten years. These facts suggest that Taiwan might face the impact of both aging society and sub-replacement fertility, making diverse co-living one of the most important issue during the transformation of social structure in Taiwan.

As an approach to improve intergenerational relationship and the quality of life, co-housing helps different age groups that are alien to each other to live together and get along with each other and provides various social facilities that facilitate the elders' interaction with other age groups and thereby support good quality of life. The study particularly aims at two objectives:

1. To discuss how residents from both the elderly and other age groups perceive intergenerational communication and co-housing; and
2. To suggest public function that co-housing is expected to have for facilitating intergenerational communication to consider future planning of communities.

2 LITERATURE REVIEW

Aging population are present worldwide, and there is a transformation of population profile and limited contact between school-age children and the elderly. Hence, for reducing this intergenerational distance, interaction and relationship between generations should be rebuilt through their living in some common facilities that make possible their living together, supporting each other and so on, but not through mere one-time activities. Lin (2006) studies how the elderly use rooms in senior citizens' housing and finds that most elderly are capable of taking care of themselves and housework and that they value interpersonal relationship. There are various forms of senior citizens' housing around the world for meeting the needs of the elderly with different lifestyles. It is proper to plan for senior citizens' welfare starting from housing because senior citizens' housing of good quality can function as a great platform for them to enjoy independence in the latter part of their lives where they are respected and are not in despair (Lo, 2015). In terms of the outdoor environment, public facilities are essential to quality life for the elderly to interact with their neighbors and the society. It is necessary to think on the basis of the experience of elderly in living and interacting with the environment about how living space facilitates interactivity and provides support to the elderly, and thereby helps the elderly adapt themselves to interpersonal relationship, increase self-worth, and maintain their physiological health. Moreover, intergenerational relationship, living arrangement, and aging society are major concerns for future social development. This study probes into issues related to communication between generations and co-housing.

2.1 *Contents of intergenerational communication*

With changes seen in the areas of society, economy, life expectancy, population, and family structure, people may have more time to share with the seniors from not only their own families but also other families, and this presents opportunities for both the youngsters and the elders to understand each other's demands for development (Liu, 2006). The trend of intergenerational integration is an aspect of an ideal model of community development that suits the aging society (Masato & Huang, 2011). Kaplan (2007) asserts that different generations realize the levels of close intergenerational interaction in accordance with how deeply they participate. The levels of intergenerational interaction are intergenerational relationship, learning, support, and solidarity.

2.1.1 *Intergenerational relationship*

The parties of intergenerational relationship are not limited to people kind to each other, but what is important is to foster good relationship between different generations (Chen, 2009). Given the changing social structure in Taiwan as well as demographical increase in the elderly and decrease in children, it is essential to strengthen the connection between generations by redefining intergenerational relationship, so as to build social cohesion in the future where different groups live together and help each other irrespective of whether they share blood relation.

2.1.2 *Intergenerational support*

Intergenerational support is important for the health of the elderly and has been proven as an effective way to improve elders' physical and cognitive abilities and to educate children (Bangertter et al., 2015). Xu (2007) suggests two types of intergenerational support: (1) emotional support: providing suggestion, listening, or soothing through conversation with others; and (2) instrumental support: helping the elders or people in need by performing housework or sharing things with them.

2.1.3 *Intergenerational learning*

By sharing experience with and gaining knowledge and skills from each other, people of different generations may change their perception of each other, as they become equal in terms of learning (Chen, 2014). Intergenerational learning refers to a process where different generations learn from and interact with each other through sharing and exchanging their experiences so that both the elderly and younger groups can grow and gain knowledge with such interaction (Huang, 2007; Li & Tang, 2008).

2.1.4 *Intergenerational solidarity*

With regards to the issue of aging, the United Nations has addressed the following tasks for

promoting intergenerational equality and reciprocity and intergenerational solidarity (UN, 2002): (1) provide civic education to people to create awareness about population aging and its great importance in our society; (2) ensure that policies support intergenerational solidarity and advocate social integration; (3) implement systems that facilitate intergenerational communication and make the elderly irreplaceable valuable social resources; (4) encourage the elderly to get together with the other age groups, thereby closing the gap between generations; (5) strengthen intergenerational link and mutual support so as to achieve successful social development; and (6) diversify the elderly lifestyle with consideration to family co-living in different cultures and backgrounds.

2.2 *Development of co-housing*

Co-housing originated in North Europe when a large number of housing units sprang up. The core thinking is that housing should be built and used with consideration of people living there and that it should support multi-generation community and friendly neighborhood that exhibit diverse cooperation (Wen et al., 2015; Sanguinetti, 2014). Following this trend, some autonomous organizations have been established to build housing that meets residents' needs, and their efforts have also been seen in planning indoor and outdoor facilities for public use. These facilities are designed to have various functions that cater to different user groups, with the common goal to improve the residents' mental and physical health and welfare. To the residents, such housing facilities are community resources that provide for their needs and change their life (Scharlach, 2012).

As to the benefits of co-housing, Chatterton (2013) states that by concentrating residences and enriching the surroundings with public facilities that facilitate lifestyle with high interactivity, critical mass can be created. The following are some of the effects of co-housing: (1) opportunities of engagement, (2) meeting of user needs through negotiation among residents, (3) a website as a platform for community interaction, (4) social welfare, (5) feeling of safety, (6) residents' care and support for the elders, (7) sharing private courtyard with other residents, (8) residents having the authority to manage all the information in the website, (9) reduced living costs thanks to agglomeration, (10) reduced number of vehicles as well as separation between pedestrian and vehicles, so as to create a zero-car environment that is safe and has less carbon emission, and (11) significant engagement and ownership.

The combination of intergenerational communication and co-housing satisfies people's internal feeling and external needs not only by reducing

alienation among people in the urban scenario but also by meeting residents' needs in a better manner. These two inseparable aspects jointly form an optimal solution to urban coldness. During the implementation of co-housing, we face various problems that need to be addressed. This study primarily focuses on how to overcome these problems before accomplishing the vision of popularizing co-housing around the world.

3 SUBJECTS AND METHODS

3.1 Scope and subjects

The Taipei Metro Area is the most urbanized city in Taiwan and has a high population density that leads to urban coldness. This study thus focuses on the people living in the Taipei Metro Area.

3.2 Methods

This study investigates into how people perceive intergenerational communication and co-housing by reviewing relevant theories and articles, conducting a questionnaire survey, and analyzing in terms of people's perception, acceptance, and expectation of future promotion.

3.2.1 Questionnaire survey

A questionnaire was created on the basis of the understanding gained through literature review about how people perceive intergenerational communication and co-housing. A total of 215 copies of the questionnaire were issued; 192 collected copies were valid, while 23 were invalid.

3.2.2 Data analysis

The responses to the questionnaire were input to SPSS (Statistical Package for the Social Sciences), Chinese version 22.0, for data analysis.

4 ANALYSIS AND DISCUSSION

4.1 Analysis of individual subjects

This study summarizes the respondents' profiles as shown in Table 1. The results indicate that most respondents are female (69.3% of the total subjects); the majority occupation is housekeeping (24%); most respondents are in the education level of colleges and universities (63%); most respondents are satisfied with the status quo of their housing (81.8%); and most respondents are satisfied with the status quo of their neighborhood/communities (79.2%).

After the questionnaire analysis, the average of Cronbach's alpha is 0.706 for a total

Table 1. Respondents' profiles.

Item			Item		
Age	Count	Percentage	Housing type	Count	Percentage
15-24	31	16.1%	House	58	30.2%
25-44	34	17.7%	Townhouse	11	5.7%
45-64	62	32.3%	Apartments without elevators	80	41.7%
65+	65	33.9%	Mansions with elevators	39	20.3%
			Other	4	2.1%
Are you satisfied with your house?			Are you satisfied with your community?		
Yes	100	52.1%	Yes	157	81.8%
No	92	47.9%	No	35	18.2%

number of items of 55. Generally, Cronbach's alpha > 0.70 means the questionnaire used has good reliability.

4.1.1 People's perception of intergenerational communication

As many as 52.1% of the respondents are aware of co-housing and see intergenerational communication as helpful for better understanding groups outside their families (80.2%), gaining knowledge through interaction with each other (76%), reducing intergenerational distance (75%), improving belongingness and reciprocal relationship (72.9%), maintaining good relationship (72.4%), frequent communication (46.4%), concern and care for other groups (59.4%), and participation in activities held in the neighborhood/community (41.1%).

For identifying the factors that affect how people perceive intergenerational communication, this study considers the following assumptions:

Assumption I: respondents of different ages have different views on intergenerational communication; and

Assumption II: respondents who are satisfied and not satisfied with the status quo of their communities have different views on participation in activities held in the neighborhood/community.

4.1.2 Significance of questionnaire and cross analysis

Table 2 shows that the variable "age" displays the greatest significant difference, which is followed by occupation and housing type. Therefore, this study performs a cross analysis of significant items and summarizes the descriptive analysis according to the cross table, thereby clarifying the relationship between the items.

4.2 Discussion

4.2.1 Respondents' perceptual difference on intergenerational communication

According to the significant difference for the perceptions listed in Table 2, it is confirmed that “age” and “housing type” mostly affect the respondents’ perception of communicate with people outside their families, as stated below:

1. Perceptual difference about communicate with people by age

The respondents aged 65 and above reported that they often communicate with people outside their families (55.4%). Far few respondents aged 15–24 often communicate with people outside their families (51.6%). Their responses to this question indicate that age is a major factor affecting one’s perception of communicate with people outside their families.

2. Perceptual difference about communicate with people by housing type

The respondents living in houses show a higher frequency of communicate with people outside their families (55.2%). Here, 35.9% of the respondents living in mansions with elevators do not often communicate with people outside their families, showing that the housing type is a major factor

affecting how often the respondents communicate with people outside their families.

4.2.2 Demands for public facilities of co-housing by age

Some demands common to the respondents of different age groups seen in Table 3 are public gardens, group dining space, and parking lots. This means provision of these facilities can be an effective way to encourage intergenerational communication, making them the priorities of co-housing.

Due to urbanization, mansions with elevators form the dominant housing type. However, the resulting community/neighborhood environment is unfavorable to the residents’ social communication and in turn leads to different levels of alienation from people of not one’s family among different age groups. This problem is highly related to the global population aging and sub-replacement fertility. Thus, we should contemplate how to improve communicate between groups by building residences as co-housing that provides more diverse public facilities that facilitate communicate between generations and encourage residents to share time with people outside their families.

Table 2. Significant difference among people’s perception of intergenerational communication.

Item	Question	Gender	Age	Occupation	Education	Housing type	
People’s perception of intergenerational communication	Do you know what is co-housing for?	0.023*	0.335	0.693	0.209	0.165	
	Relationship	Maintaining good relationship	0.220	0.779	0.585	0.998	0.462
		Better understanding	0.158	0.502	0.224	0.970	0.354
	Learning	Learning knowledge from getting along with each other	0.240	0.736	0.750	0.303	0.272
		Idea communicate with other groups	0.981	0.031*	0.252	0.676	0.044*
	Support	Improved belongingness and reciprocal relationship	0.384	0.359	0.598	0.768	0.872
		Concern and care for other groups	0.654	0.035*	0.089	0.860	0.541
	Solidarity	Reduced intergenerational distance	0.280	0.390	0.952	0.266	0.250
		Participation in activities held in the neighborhood/ community	0.891	0.000***	0.024*	0.626	0.984

Significance Levels: *P < 0.05 = Significant, **P < 0.01 = Very Significant, ***P < 0.001 = Extremely Significant.

Table 3. People's demands for public facilities of co-housing.

	Age group	Public facility					
		Public kitchen	Public reception room	Public garden	Playground	Group dining space	Parking lot
	15–24	38.7%	38.7%	64.5%	54.8%	58.1%	54.8%
	25–44	32.4%	44.1%	76.5%	50.0%	55.9%	64.7%
	45–64	31.1%	36.1%	91.8%	49.2%	57.4%	60.7%
	65+	16.9%	30.5%	79.7%	40.7%	39.0%	37.3%

5 CONCLUSION AND RECOMMENDATION

5.1 Conclusion

Many cases are seen around the world in which co-housing successfully improves psychic isolation by transforming the urban high-density environment into a place where people can have commensalism, co-living, and sharing. This study finds that the respondents aged 15–24 and living in mansions with elevators form the group lacking communication with other people the most. To improve this, addition of public facilities such as public flower gardens/vegetable gardens, group dining space, and parking lots to their housing is a solution to encourage the residents to communicate with and support each other. In addition, some space currently occupied by buildings may be reconstructed into public facilities for public interest, so that in addition to parks and green lands, people can enjoy indoor and outdoor public facilities in their street blocks for community events, group dining, leisure, and so on. This idea may receive objections from residents at the initial stage, but it is believed that through environmental education and participatory design, people will see the benefits and turn to support co-housing.

5.2 Recommendation

1. Intergenerational communication is all about communicating with and supporting people outside one's own family and with no blood relationship in diverse ways.
2. It is recommended that events are held within and between communities and neighborhoods with common interests for residents to dine together and share things with each other, thereby fostering extensive interpersonal networks.
3. As a norm for co-housing design, subject to minimal requirements of private space, public facilities that serve the public interest should take the larger proportion.

4. Co-housing should be promoted as an important remedy for intergenerational barrier and as an effective approach to better quality of life and creation of an environment friendly atmosphere for the elderly. This is an issue we have to address in future.

A note on the ABAQUS Concrete Damaged Plasticity (CDP) model

W.S. Li

Electric Power Research Institute of Guangdong Power Grid Co. Ltd., Guangzhou, China

J.Y. Wu

State Key Laboratory of Subtropical Building Science, South China University of Technology, Guangzhou, China

ABSTRACT: In this work, the ABAQUS Concrete Damaged Plasticity (CDP) model is investigated both theoretically and numerically. The interrelations between this model and its two precursors, i.e., Barcelona model (Lubliner et al. 1988) and Lee & Fenves (1998) model, are clarified. In particular, they are analyzed with respect to the issue of mesh size dependence. On the one hand, as damage evolution is not accounted for in the definition of fracture energy, Barcelona model (Lubliner et al. 1988) and Lee & Fenves (1998) model cannot suppress the issue of mesh-size dependence. On the other hand, an incorrect definition of the cracking displacement is used in the ABAQUS CDP, resulting in not only the issue of mesh size dependence, but also unit system sensitivity. Accordingly, the input data of stress and damage variable necessary for the ABAQUS CDP model can only be given in terms of the cracking strain, whereas the ones defined in terms of crack displacement should be used with great care unless this issue is removed in the future release.

1 INTRODUCTION

Being the most widely used building material in engineering structures and infrastructure, concrete exhibits complex behavior. With plenty of well-documented experimental tests (Kupfer et al. 1969) and research efforts, it is now generally accepted that the exhibited nonlinearities in concrete behavior are mainly attributed to two types of micro-structural mechanisms: (i) evolution of microcracks and microvoids, and (ii) plastic flows along some preferred crack lips. The aforesaid physical mechanisms have to be addressed appropriately in a constitutive model for concrete.

Among the different alternatives that are available, the plastic-damage model, combining the plasticity theory and Continuum Damage Mechanics (CDM), has been widely adopted in the constitutive modeling of concrete and applied to the nonlinear analysis of structures (see Krajcinovic (2003)). Owing to its great success in reproducing the nonlinear behavior of concrete, several commercial finite element packages, e.g., ABAQUS, LS-Dyna, etc., developed their own plastic-damage models or incorporated those proposed in the literature. Particularly, a Concrete Damaged Plasticity (CDP) model for concrete was developed in ABAQUS version 6.3 based on the well-known Barcelona model. This model is able to capture the typical nonlinear behavior of concrete rather well, greatly extending the capability of ABAQUS and pushing forward its application in civil engineering.

For concrete like quasi-brittle materials exhibiting strain softening, it is important to guarantee the objectivity of the numerical results when using a material constitutive model to evaluate the stresses at quadrature points. That is, the numerical results have to be independent of the size and alignment of the finite element mesh, such that the load capacity and deformations of structures can be evaluated correctly.

However, as will be shown later, the aforementioned mesh size independence cannot always be guaranteed for the ABAQUS CDP model. Even worse, the numerical results obtained using different SI units do not always coincide. Consequently, the numerical results may be misleading and sometimes erroneous. We address in this work the relevant issues and stress that the ABAQUS CDP model should be used with great care until the exhibited problems are eliminated in future releases.

This paper is organized as follows. After this introduction, the ABAQUS CDP model is discussed in Section 2. Particularly, the similarities and differences between the CDP model and its two precursors, i.e., Barcelona model and Lee & Fenves (1998) model, are clarified. Section 3 is devoted to the theoretical analysis of the CDP model regarding the issue of mesh size dependence. Numerical examples are presented in Section 4 to support the theoretical results. The most relevant conclusions are drawn in Section 5 to conclude this paper.

2 THE ABAQUS CDP MODEL AND ITS PRECURSORS

In all the models to be discussed, the simplest stress *versus* strain relation is expressed as

$$\sigma = (1-d)\bar{\sigma}, \quad \bar{\sigma} = \mathbb{E}_0 : (\varepsilon - \varepsilon^p) \quad (1)$$

where ε and ε^p denote the second-order strain tensor and its plastic component, both being infinitesimal; σ and $\bar{\sigma}$ signify the nominal and effective stress tensors, respectively; \mathbb{E}_0 represents the fourth-order elasticity tensor of the material.

Before we discuss the ABAQUS CDP model, let us first introduce its two precursors, i.e., Barcelona model and Lee & Fenves (1998) model.

2.1 Barcelona model

In the Barcelona model (Lubliner et al., 1988), the plastic strain tensor ε^p is determined by the classical plasticity theory, i.e.,

$$\begin{cases} \varepsilon^p = \lambda \frac{\partial F_p(\sigma)}{\partial \sigma} \\ F(\sigma, q) \leq 0, \quad \dot{\lambda} \geq 0, \quad \dot{\lambda} F(\sigma, q) = 0 \end{cases} \quad (2)$$

where $F(\sigma, q)$ and $F_p(\sigma)$ represent the plastic yield and potential functions, respectively; $\dot{\lambda} \geq 0$ is the Lagrangian multiplier, with the non-vanishing value $\dot{\lambda} > 0$ upon plastic loading determined in terms of the consistency condition $\dot{F}(\sigma, q) = 0$.

One important contribution of the Barcelona model is that a simple plastic yield function $F(\sigma, q)$ is postulated for concrete under biaxial stress states

$$F(\sigma, q) = \frac{\alpha I_1 + \sqrt{3J_2} + \beta \langle \sigma_1 \rangle}{1 - \alpha} - q \leq 0 \quad (3)$$

where $I_1 = \text{tr} \sigma$ and σ_1 represent the first invariant and the major principal value of the stress tensor σ , respectively; $J_2 = \frac{1}{2} \mathbf{s} : \mathbf{s}$ denotes the second invariant of the deviatoric stress tensor $\mathbf{s} := \sigma - (I_1/3)\mathbf{I}$; the Macaulay brackets $\langle \cdot \rangle$ are defined as $\langle x \rangle = \max(x, 0)$. The stress-like internal variable q signifies the cohesion; material parameters α and β are given by

$$\alpha = \frac{f_{bc}/f_c - 1}{2f_{bc}/f_c - 1}, \quad \beta = (1 - \alpha) \frac{f_c}{f_t} - (1 + \alpha) \quad (4)$$

in terms of the equi-biaxial compressive strength f_{bc} , the uniaxial compressive one f_c and the uniaxial tensile one f_t , respectively.

In order to postulate the plastic and damage evolution laws, an internal variable κ is introduced as

$$\dot{\kappa} = w \dot{\kappa}^+ + (1-w) \dot{\kappa}^- \quad (5)$$

where the weight function $w(\sigma) := \sum_i \langle \sigma_i \rangle / \sum_i |\sigma_i|$ discriminates the dominant tension and compression; κ^\pm represent the normalized plastic work done in the uniaxial tension and compression, i.e.,

$$\kappa^\pm := \frac{1}{g_{t^\pm}} \int_0^{\varepsilon^{p\pm}} \sigma^\pm d\varepsilon^{p\pm}, \quad g_{t^\pm} = \int_0^\infty \sigma^\pm d\varepsilon^{p\pm} \quad (6)$$

with

$$\dot{\varepsilon}^{p+} = w \dot{\varepsilon}_{\max}^p, \quad \dot{\varepsilon}^{p-} = -(1-w) \dot{\varepsilon}_{\min}^p \quad (7)$$

where $\dot{\varepsilon}_{\max}^p$ and $\dot{\varepsilon}_{\min}^p$ represent the maximum and minimal principal values of the plastic strain rate tensor $\dot{\varepsilon}^p$, respectively. Once the uniaxial tensile and compressive stresses, $\sigma^\pm(\varepsilon^{p\pm})$, or, equivalently, $\sigma^\pm(\kappa^\pm)$, are calibrated, the evolution law for κ can be determined.

Both evolution laws for the cohesive q and the damage d are expressed as the following rate forms:

$$\dot{q} = \dot{\sigma}^- = h_p \cdot \dot{\kappa}, \quad \dot{d} = h_d \cdot \dot{\kappa} \quad (8)$$

in terms of the strain-like internal variable κ , where h_p and h_d denote the plastic and damage hardening/softening moduli, both determined from experimental test data.

The Barcelona model can capture the nonlinear behavior of concrete under monotonic loading, but the predictions under cyclic one are not so satisfactory. More specifically, as only one single damage variable d is adopted, the stiffness recovery due to the Microcracks Closure-Reopening (MCR) effects cannot be described. Similarly, the yield function (3) with a single plastic internal variable q is incapable of modeling distinct strength softening under dominant tension and compression.

2.2 Lee & Fenves model

In order to extend the Barcelona model to cyclic loading, Lee & Fenves (1998) proposed an improved plastic-damage model. The stress *versus* strain relation is still given by Eq. (1). However, the damage variable d is related to another two independent scalar ones through

$$1 - d = (1 - w d^+) [1 - (1 - w) d^-] \quad (9)$$

where d^+ and d^- represents the damage variables under dominant tension and compression, respectively, with distinct evolution laws.

When compared to the classical plastic evolution laws (2), the so-called effective stress plasticity (Ju, 1989) is considered, leading to

$$\begin{cases} \dot{\varepsilon}^p = \dot{\lambda} \frac{\partial \bar{F}_p(\bar{\sigma})}{\partial \bar{\sigma}} \\ \bar{F}(\bar{\sigma}, \bar{q}) \leq 0, \quad \dot{\lambda} \geq 0, \quad \dot{\lambda} \bar{F}(\bar{\sigma}, \bar{q}) \equiv 0 \end{cases} \quad (10)$$

where the yield function $\bar{F}(\bar{\sigma}, \bar{q})$ and potential one $\bar{F}_p(\bar{\sigma})$ are both expressed in terms of the effective stress $\bar{\sigma}$, with \bar{q} being the effective cohesion; $\dot{\lambda} \geq 0$ is the effective Lagrangian multiplier, with its non-vanishing value $\dot{\lambda} > 0$ upon plastic loading determined through the consistency condition $\dot{\lambda} \bar{F}(\bar{\sigma}, \bar{q}) = 0$.

In particular, the effective stress-based yield function $\bar{F}(\bar{\sigma}, \bar{q})$ is given by the similar form as Eq. (3)

$$\bar{F}(\bar{\sigma}, \bar{q}) = \frac{\alpha \bar{I}_1 + \sqrt{3 \bar{J}_2} + \bar{\beta} \langle \bar{\sigma}_1 \rangle}{1 - \alpha} - \bar{q} \leq 0 \quad (11)$$

where $\bar{I}_1 = \text{tr} \bar{\sigma}$ and $\bar{\sigma}_1$ represent the first invariant and the major principal value of the effective stress tensor $\bar{\sigma}$, respectively; $\bar{J}_2 = \frac{1}{2} \bar{s} : \bar{s}$ denotes the second invariant of the effective deviatoric stress tensor $\bar{s} := \bar{\sigma} - (\bar{I}_1/3)I$. The parameter α is coincident with Eq. (4), but $\bar{\beta}$ and \bar{q} are both variables, expressed as

$$\begin{aligned} \bar{\beta}(\kappa) &= (1 - \alpha) \frac{\bar{\sigma}^-(\kappa^-)}{\bar{\sigma}^+(\kappa^+)} - (1 + \alpha) \\ \bar{q}(\kappa) &= \bar{\sigma}^-(\kappa^-) \end{aligned} \quad (12)$$

in terms of the strain-like plastic internal variables $\kappa := \{\kappa^+, \kappa^-\}$ defined in Eq. (6). The effective stresses $\bar{\sigma}^\pm$ under uniaxial tension and compression are determined by

$$\bar{\sigma}^\pm(\kappa^\pm) = \frac{\sigma^\pm(\kappa^\pm)}{1 - d^\pm(\kappa^\pm)} \quad (13)$$

with the stresses $\sigma^\pm(\kappa^\pm)$ and damage variables $d^\pm(\kappa^\pm)$ calibrated from test data.

In both the Barcelona and Lee & Fenves models, the internal variables κ^\pm are defined as the normalized plastic work with respect to the total ones g_f^\pm during the whole deformation process. Furthermore, it is assumed that they are the specific fracture energies $g_f^\pm := G_f^\pm / l_{ch}$, for the fracture energies G_f^\pm under uniaxial tension and compression, respectively, and the characteristic length l_{ch} .

However, on the one hand, the monotonically increasing condition $\dot{\kappa}^\pm \geq 0$ cannot be guaranteed in the softening regimes. On the other hand, energy dissipation due to damage evolution is not accounted for. Consequently, it is not appropriate to assume the normalized plastic work as the specific fracture energy, nor select it as the internal variable.

2.3 ABAQUS CDP model

Perhaps noticing the aforesaid issues, the ABAQUS CDP model suggested adopting the cumulative (equivalent) plastic strains as the internal variables, i.e.,

$$\begin{cases} \kappa^{\pm} = \varepsilon^{p\pm} := \int \dot{\varepsilon}^{p\pm} dt \\ \dot{\kappa}^+ = w \dot{\varepsilon}_{\max}^p, \quad \dot{\kappa}^- = -(1-w) \dot{\varepsilon}_{\min}^p \end{cases} \quad (14)$$

With the above re-definitions, the non-negative property $\dot{\kappa}^\pm \geq 0$ can always be guaranteed.

When using the ABAQUS CDP model, the stresses σ^\pm and damage variables d^\pm under uniaxial tension and compression can be given in terms of the cracking (or inelastic) strains $\varepsilon^{cr\pm}$ defined as

$$\varepsilon^{cr\pm} = \varepsilon^{p\pm} + \frac{d^\pm}{1 - d^\pm} \cdot \frac{\sigma^\pm}{E_0} \quad (15)$$

Accordingly, the input data $\sigma^+(\varepsilon^{cr+})$ and $d^+(\varepsilon^{cr+})$ are then transformed into the required curves $\sigma^\pm(\varepsilon^{p\pm})$ and $d^\pm(\varepsilon^{p\pm})$ such that the effective uniaxial stresses $\bar{\sigma}^\pm$ and other quantities $(\bar{\beta}, \bar{q})$ in the yield function (11) can be determined. It is very important that the plastic strains $\varepsilon^{p\pm}$, transformed from Eq. (15), be positive. Otherwise, the analysis would be terminated.

Alternatively, for plain concrete structures in tension, ABAQUS suggests using the stress σ^+ and damage variables d^+ in terms of the following cracking displacement u^{cr+} :

$$u^{cr+} = u^{p+} + \frac{d^+}{1 - d^+} \cdot \frac{\sigma^+}{E_0} \cdot l_0 \quad (16)$$

where the length scale l_0 is assumed as $l_0 = 1$, independent of the actual mesh size or adopted unit system. Similarly, the non-negative plastic strains $\varepsilon^{p+} := u^p / l_{ch}$, with l_{ch} being a characteristic length, are determined from the given data $\sigma^+(u^{cr+})$ and $d^+(u^{cr+})$.

As will be shown, the definition (16) of cracking displacement is problematic. Consequently, the mesh-size dependence cannot be suppressed, and even worse, the numerical results are not objective regarding the adopted unit system.

3 DISCUSSION OF THE ABAQUS CDP MODEL

When using the ABAQUS CDP model, the key issue is to estimate the evolution of uniaxial stresses and damage variables in terms of either the cracking strain or cracking displacement. In this section, the above issues are analyzed theoretically.

3.1 Input data

In order to suppress the issue of mesh size dependence accompanying strain softening materials, Hillerborg et al. (1976) proposed the fictitious crack model based on the concept of cohesive crack (zone). Specifically, the softening traction t (equal to the uniaxial tensile stress σ ; in this section we omit the superscript ‘+’ for uniaxial tension) *versus* separation relation u^{cr} is suggested, with the area surrounded by the $\sigma(u^{cr})$ curve being a constant as

$$G_f = \int_0^\infty \sigma \, du^{cr} \quad (17)$$

for the mode-I fracture energy G_f usually regarded as material property.

It is not convenient to use the above fictitious crack model in finite element analyses. To this end, the so-called characteristic length l_{ch} is introduced, leading to the following cracking strain ε^{cr}

$$\varepsilon^{cr} = \frac{1}{l_{ch}} u^{cr} = \varepsilon - \frac{\sigma}{E_0} = \varepsilon^p + \frac{d}{1-d} \frac{\sigma}{E_0}$$

or, equivalently,

$$u^{cr} = l_{ch} \varepsilon^{cr} = l_{ch} \cdot \varepsilon^p + \frac{d}{1-d} \frac{\sigma}{E_0} \cdot l_{ch} \quad (18)$$

Accordingly, the condition (17) becomes

$$\frac{G_f}{l_{ch}} = \int_0^\infty \sigma \, d\varepsilon^{cr} = \int_0^\infty \sigma \, d\varepsilon \quad (19)$$

This is the crack band theory proposed by Bazant & Oh (1983). It implies that, for a uniaxial tensile stress *versus* strain curve $\sigma(\varepsilon)$, the surrounding area is not a constant, but is inversely proportional to the characteristic length l_{ch} . With the above regularization of a softening material model, the mesh size dependence of numerical results can be largely suppressed.

Generally, the permanent displacement u^p is assumed to be a fraction of the crack one, i.e., $u^p = \delta u^{cr}$ and $\varepsilon^p = \delta \varepsilon^{cr}$. Accordingly, it follows from Eq. (18) that

$$d = \frac{(1-\delta)\varepsilon^{cr}}{(1-\delta)\varepsilon^{cr} + \sigma/E_0} = \frac{(1-\delta)u^{cr}}{(1-\delta)u^{cr} + \sigma l_{ch}/E_0} \quad (20)$$

For the particular case $\delta=0$, no permanent displacement is present upon unloading and an elastic damage model is recovered. Eq. (20) can be used to produce the data of damage variable d necessary for the ABAQUS CDP model.

As can be seen, the cracking strain (15) in the ABAQUS CDP model coincides with the definition of (18a) suggested in the crack band theory. However, the cracking displacement (16) is different from Eq. (18b), unless the element characteristic length $l_{ch} = l_0 = 1$. That is, the two types of input data are inconsistent with each other. Consequently, numerical results independent of the mesh size cannot be guaranteed provided the stress σ and damage variable d are given in terms of the crack displacement (16). Even worse, the unit of length scale also affects the numerical results, violating the objectivity requirement.

3.2 Element tests

Let us consider a square plate of unit thickness, with edge length $L = 200$ mm. The plate is stretched by increasing displacements u^* with opposing directions at the left and right edges. At the initial stage, the material behaves linear elastic with Young’s modulus $E_0 = 3.0 \times 10^4$ MPa. After the stress σ arrives at the tensile strength $f_t = 3.0$ MPa, the material enters softening regimes, with the fracture energy $G_f = 0.12$ N/mm.

A single irreducible quadrilateral element Q1 is used to discretize the plate, resulting in a characteristic length $l_{ch} = L/200$ mm. For the sake of simplicity, a linear softening curve is considered, i.e.,

$$\sigma = \max(0, f_t + H \cdot u^{cr}) = \max(0, f_t + h \cdot \varepsilon^{cr}) \quad (21)$$

for the softening moduli $H = -37.5$ MPa/mm of the $\sigma - u^{cr}$ curve and $h = -7.5 \times 10^3$ MPa for the $\sigma - \varepsilon^{cr}$ one. The analytical solution of the reaction force F^* versus the imposed displacement u^* is depicted in Figure 1. Note that the result does not depend on the damage variable d since only the monotonic responses are concerned in this case.

For the given softening curve (21), the damage variable d can be generated with an assumed plastic fraction parameter $\delta \in [0, 1]$. As expected, provided that the stress and damage are given in terms of the cracking strain, the numerical predictions, independent of the parameter δ , are coincident with the analytical result; see Figure 1.

However, if the stress and damage are given in terms of the cracking displacement, the numerical predictions are totally different. As shown in

Figure 1. Numerical results using $\sigma - u^{cr}$ data.

Figure 2. Numerical results using $\sigma - \epsilon^{cr}$ data.

Figure 2, the numerical results not only are dependent on the parameter δ , but also are not identical to the analytical one except for the plastic model ($\delta = 1.0$) in which the value l_0 is irrelevant.

4 APPLICATION TO CONCRETE MODELING

In this section, a notched concrete beam under three-point bending (Petersson 1981) is considered. Figure 3 depicts the geometry of the specimen: a plain concrete beam of dimensions $2000 \times 200 \times 50 \text{ mm}^3$ with a notch of sizes $20 \times 100 \times 50 \text{ mm}^3$ at its bottom center. The beam is simply supported and an increasing displacement is enforced downward at its top center. The material properties are taken from Rots (1985), i.e., Young's modulus $E_0 = 3.0 \times 10^4 \text{ MPa}$, Poisson's ratio $\nu_0 = 0.2$, tensile strength $f_t = 3.33 \text{ MPa}$ and fracture energy $G_f = 0.124 \text{ N/mm}$. A linear softening curve (21) with the damage Eq. (20) is assumed, with two finite element meshes, the coarse and fine ones shown in Figure 4, are used in the numerical

simulations. Furthermore, two unit systems, i.e., SI-mm and SI-m, are considered.

The input data of stress and damage are first given in terms of the cracking strain. As can be seen from Figure 5(a), owing to the crack band theory, the numerical results are almost mesh size independent. Furthermore, the unit systems adopted in the simulations have no effects as expected.

Figure 3. Geometry, boundary and load conditions.

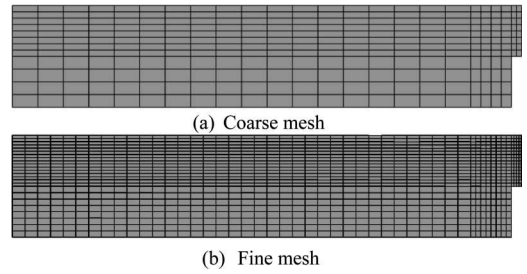

Figure 4. Finite element meshes.

(a) Coarse and fine meshes

(b) SI-mm and SI-m unit systems

Figure 5. Numerical results using the cracking strain.

Figure 6. Different units using cracking displacement.

The input data of stress and damage are then given in terms of the cracking displacement. As can be seen from Figure 6, the numerical results are heavily dependent on the unit systems adopted in the simulations. This unphysical problem, caused by the incorrect cracking displacement (16), is completely unacceptable.

5 CONCLUSIONS

In this work, the Concrete Damaged Plasticity (CDP) model in ABAQUS is investigated both theoretically and numerically. The interrelations between this model and its two precursors, i.e., Barcelona model (Lubliner et al. 1988) and Lee & Fenves (1998) model, are clarified. In particular, they are analyzed with respect to the issue of mesh size dependence. Owing to the inappropriate strategies adopted, mesh size-independent numerical results cannot be guaranteed in the aforesaid models. On the one hand, the issue exhibited in the Barcelona model (Lubliner et al. 1988) and Lee & Fenves (1998) model is attributed to the fact that damage evolution is not accounted for in the definition of fracture energy. On the other hand, and incorrect cracking displacement is used in the ABAQUS CDP model, resulting in not only the issue of mesh size dependence, but also the loss of unit system objectivity. Therefore, the input data of stress and damage variable necessary for the ABAQUS CDP model can only be given in terms

of the cracking strain, and the ones in terms of crack displacement should not be used unless the relevant issues are removed in the future release.

The cutting parameter model of energy consumption and its characteristics analysis

Shaohua Hu & Shilin Li

Chongqing Vocational Institute of Engineering, Chongqing, China

Jun Xie

Chongqing University of Technology, Chongqing, China

ABSTRACT: With the soar of the energy price and the increasingly serious environmental problems, the energy efficiency of manufacturing is becoming the focus of academia and industry gradually. It is able to provide theoretical basis and decision support for process planning and the energy-saving optimization of cutting parameters to master energy consumption characteristics. While the relationship between the energy consumption and the material removal rate has been conducted, the research on the influence characteristics of the cutting parameters on the energy consumption of machining process is still lacking. Therefore, this paper proposes a cutting parameter model of the energy consumption of the machine tools, and then discusses the influence characteristics of the cutting parameters on the energy consumption under a specific machining process based on the proposed model, and at last the influence characteristics were verified by experiments.

1 INTRODUCTION

With the soar of the energy price and the increasingly serious environmental problems, the energy efficiency of manufacturing is becoming the focus of academia and industry gradually (Jia, 2013). The machining systems that mainly consist of machine tools are numerous and widely used in industries. In China, for example, machining involves over 7 million machine tools, whose total power is greater than 70 million kilowatts. However, Many researches indicated that the energy efficiency of machining process is very low. For instance, the energy efficiency of a case described by Gutowski is only 14.8% (Gutowski, 2009). As a result, it has great potential for energy savings in machining processes.

In recent years, many famous universities, enterprises and international organizations have done a lot of work about the energy consumption of machine tools and machining system. Consortium on Green Design and Manufacturing (CGDM) of University of California Berkeley researched the impact of environment and the consumption of resource from mechanical design, processes planning, manufacture system modeling and environmentally conscious manufacturing (Munoz, 1995). Liu et al. established a multi-period energy model of electro-mechanical main driving system during the service process of machine tools that can

provide a theoretical basis for the follow-up study about the energy consumption of machining process (Liu, 2012; Wang, 2012).

In conclusion, some significant research on the energy consumption of machine tools has been performed. However, the research on the influence characteristics of the cutting parameters on the energy consumption of machining process is still lacking. This paper established the cutting parameter model of the energy consumption of the machine tools, which took the influence of the cutting parameters on the energy consumption of machining processes into consideration; then discussed the influence characteristics of the cutting parameters on the energy consumption based on the application of the model under a specific machining process; and the conclusions about influence characteristics were verified by experiments.

2 THE PARAMETER MODEL OF ENERGY CONSUMPTION OF THE MAIN DRIVING SYSTEM

2.1 *The power model of the main driving system*

The main driving system of machine tool consists of the motor driving system and the transmission system. Liu established a power equation of the main driving system in previous studies (Liu, 2012).

$$P_{in} = P_{Fe} + P_{Cu} + P_{ad} + P_{mco} + \frac{dE_{mm}}{dt} + \frac{dE_{ke}}{dt} + \sum_{j=1}^r P_{mcj} + \frac{d \sum_{j=1}^r E_{kj}}{dt} + P_c \quad (1)$$

P_{in} is the input power of the machine tool. P_{Fe} is the core loss of the motor. P_{Cu} is the winding loss of the motor. P_{ad} is the additional load loss of the machine tool. P_{mco} is the mechanical power loss of the rotor. E_{mm} is the magnetic field energy of the motor. E_{ke} is the kinetic energy of the motor rotor. P_{mcj} is the mechanical power loss of the mechanical transmission system. E_{kj} is the kinetic energy of the mechanical transmission system. P_c is the cutting power.

Some of the parameters in equation (1) are difficult to obtain, so we usually treat the power as the fixed power and named it as idle power P_u . When the machine tool operates in a stable state at a given speed, $\frac{dE_{mm}}{dt} = 0$. Therefore, when the machine tool runs steadily, the power equation of the machining process can be written briefly as follows:

$$P_{in} = P_u + P_{ad} + P_c \quad (2)$$

The idle power is the essential power which ensures the machine tool operation normally. The main driving system is of high inertia, when the machine tool runs at a specific spindle speed, the value of the idle power is a constant. For traditional machine tools, we can measure the idle power at every speed beforehand, and establish the idle power database as follows.

$$P_u(n) = \{P_u(1), P_u(2), \dots, P_u(j)\} (n=1, 2, \dots, j) \quad (3)$$

For CNC machine tools whose main driving system have While for the step-less speed, we can measure the idle power at several selected speed and construct the idle power fitting function.

$$P_u(n) = g(n) \quad (4)$$

Due to the additional load loss power is difficult to be obtained by measuring, the additional load loss power P_{ad} can be fitted by a quadratic function of the cutting power (Hu, 2010).

$$P_{ad} = a_2 P_c^2 + a_1 P_c \quad (5)$$

The parameters a_1 and a_2 in the formula are the additional load loss coefficients of the main driving system which can be obtained by experimental method (Hu, 2010).

2.2 The cutting power model of the main driving system

The cutting power is the power required by the tool tip to remove the material of the workpiece, which is the output power of the main driving system. The cutting power is given by the following.

$$P_c = F_c \times \frac{v_c}{60} \quad (6)$$

The cutting force has strongly related to the cutting parameters, and the relationship between the cutting force and its impact factors is so complicated that there is still lack of an authoritative method to calculate the cutting force. As a result the empirical method is usually used to calculate the cutting force in practical application, the model is as follows.

$$F_c = C_{F_c} a_p^{x_{F_c}} f^{y_{F_c}} v_c^{n_{F_c}} K_{F_c} \quad (7)$$

In equation (7), a_p denotes the depth of cut (mm), f denotes the feed rate (mm/r), $v_c = \frac{\pi D_0 n}{1000}$ denotes the cutting speed (m/min), C_{F_c} , x_{F_c} , y_{F_c} , n_{F_c} and K_{F_c} are the coefficients related to the machining process, the coefficients can be obtained from the look-up tables in the manual.

According to the equation (6) and (7), the cutting power is given by the following.

$$P_c = \frac{C_{F_c}}{60} a_p^{x_{F_c}} f^{y_{F_c}} v_c^{(n_{F_c}+1)} K_{F_c} \quad (8)$$

2.3 The model of energy consumption of the main driving system

According to the analysis described above, the parameter model of the input power can be obtained as follows.

$$P_{in} = \alpha_2 \left(\frac{C_{F_c}}{60} a_p^{x_{F_c}} f^{y_{F_c}} v_c^{(n_{F_c}+1)} K_{F_c} \right)^2 + (\alpha_1 + 1) \frac{C_{F_c}}{60} a_p^{x_{F_c}} f^{y_{F_c}} v_c^{(n_{F_c}+1)} K_{F_c} + P_u \quad (9)$$

Furthermore, the energy consumption of the main driving system can be calculated by the integral of input power over the time of the machining process.

$$E_{in} = \int_{t_1}^{t_2} \left[\alpha_2 \left(\frac{C_{F_c}}{60} a_p^{x_{F_c}} f^{y_{F_c}} v_c^{(n_{F_c}+1)} K_{F_c} \right)^2 + (\alpha_1 + 1) \frac{C_{F_c}}{60} a_p^{x_{F_c}} f^{y_{F_c}} v_c^{(n_{F_c}+1)} K_{F_c} + P_u \right] dt \quad (10)$$

In most cases, the load of machining process is continuous and stable, when the cutting parameters keep constant, the input power can be treated as a constant. For the variable load cutting process, each tiny period can be regarded as a constant load cutting process. Hence, this paper analyzes the influence characteristics of the parameters on the energy consumption under the constant load conditions, equation (10) can be changed into equation (11)

$$E_{in} = \frac{60V \left[\alpha_2 \left(\frac{C_{F_c}}{60} a_p^{x_{F_c}} f^{y_{F_c}} v_c^{(n_{F_c}+1)} K_{F_c} \right)^2 + (\alpha_1 + 1) \frac{C_{F_c}}{60} a_p^{x_{F_c}} f^{y_{F_c}} v_c^{(n_{F_c}+1)} K_{F_c} + P_u \right]}{a_p f v_c} \quad (11)$$

3 THE INFLUENCE CHARACTERISTICS OF THE CUTTING PARAMETERS ON ENERGY CONSUMPTION

3.1 Introduction of the machining process

The parameter model of the energy consumption mentioned above is a comprehensive model which can be used in different machining processes. For ease of understanding, taking a turning machining as an example, the influence characteristics of the cutting parameters on the energy consumption is discussed. The work-piece is shown as the Fig. 1. The machining process of CNC lathe (C2-6136HK/1) is chosen as a machining case. The specification of machine tool is shown in Table 1, the information of the cutter and blank material is listed in Table 2, and the cutting parameters are listed as Table 3, respectively.

According to the parameters listed in Table 1 and Table 2, the empirical parameters obtained from the look-up tables in the manual are listed in Table 4. According to the Fig. 3, we can draw the conclusion that with the increase of the cutting parameters, the input power increase too, and the input power of machine tool and the cutting parameters have positive correlation. On the other hand, the spindle speed has the strongest influence on the input power, and then is the depth of cut and the feed rate.

Figure 1. The blank drawing of the work-piece.

Table 1. Specification of machine tool.

Type: C2-6136HK/1
Rated power of the main motor (<i>kW</i>): 5.5

S45C Carbon steel	2795	1	0.75	–0.15	0.92

3.2 The influence characteristics of cutting parameters on energy consumption

3.2.1 Univariate influence characteristics on the energy consumption

The input power can only represent the transient state of the energy consumption of machine tools, and cannot reflect the characteristics of the energy consumption of the entire machining process. So the influence characteristics on the energy consumption will be studied following.

Figure 2. The univariate influence characteristics on the energy consumption.

Figure 3. The multivariate influence characteristics on the energy consumption.

Substituting the parameters listed in Table 3 and Table 4 into the equation (11), and the univariate influence characteristics is shown in Fig. 2. According to the Fig. 2 we can see that the energy consumption of machining process is inversely proportional to the machining rate. As a result, in the actual process of rough machining, to reduce the energy consumption, we should choose large machining rate for processing.

3.2.2 Multivariate influence characteristics analysis on the energy consumption

The analyses mentioned above are all about the univariate influence characteristics of the input power and the energy consumption, and can not reflect the influence characteristics of the cutting parameters. In the actual machining process, the processing is usually conducted at the request of a specific processing rate. So this paper will analyze the multivariate influence characteristics at a specific processing rate.

Machining at the request of a specific processing rate means the material removal rate of the process is a constant. To simplify the analysis below, the material removal rate is set as $0.5 \text{ cm}^3/\text{s}$.

$$MRR = \frac{a_p \cdot f \cdot v_c}{60} = \frac{a_p \cdot f \cdot n \pi D}{60000} = 0.5 \quad (12)$$

Substituting the parameters listed in Table 3 and Table 4 into the equation (11), the multivariate influence model of the energy consumption is as follows.

The Fig. 3 demonstrates that under the condition of a specific processing rate, the effect of the three parameters on the energy consumption is different. According to the Fig. 3, in the actual process of rough machining with the specific processing efficiency, to reduce the energy consumption, we should choose a large feed rate, a lower spindle speed and then choose a proper depth of cut according to the request machining efficiency.

4 EXPERIMENTAL VALIDATION

The equipment applied to measure the energy consumption is HIOKI 3390 power analyzer which can continuously record the input power of a machine tool at a 0.05 s sampling interval. The cutting parameters and the experimental results are listed in Table 5. According to the results of the experimental validation, we can draw the conclusions as follows: 1) we can see that when the cutting parameters (n, f, a_p) increase, the value of input power

Table 5. Parameters of process and experimental results.

Parameters						
No.	n (rpm)	f (mm/r)	a_p (mm)	Power (W)	Time (s)	Energy (J)
1	100	0.2	1.5	1044	600	551250
2	250	0.2	1.5	1753	240	370860
3	400	0.2	1.5	2329	150	312637.5
4	550	0.2	1.5	3017	109.08	299725.57
5	700	0.2	1.5	3410	85.72	262731.8
6	400	0.05	1.5	1570	600	879000
7	400	0.1	1.5	1653	300	456675
8	400	0.2	1.5	2329	150	312637.5
9	400	0.3	1.5	2853	100	250225
10	400	0.4	1.5	3427	75	222956.25
11	400	0.2	0.5	1314	375	492750
12	400	0.2	1.0	1810	187.5	339375
13	400	0.2	1.5	2329	150	312637.5
14	400	0.2	2.0	2730	112.5	270375
15	400	0.2	2.5	3085	75	231375

increases too. The power consumption is positively associated with the cutting parameters; 2) we can see that the increment of the power consumption of spindle speed is the largest, then is the depth of cut, and feed rate is the smallest; 3) the energy consumption decreases with the increase of each cutting parameters, and the energy consumption is inversely proportional to the cutting parameters; 4) it can be concluded that to reduce the energy consumption, we should choose a large feed rate, a lower spindle speed and a proper depth of cut. The experimental result is consistent with the conclusions from the analysis of the model.

5 CONCLUSIONS

This paper established the parameter model of and the energy consumption of machining processes based on the previous studies, which take the influence of the cutting parameters on the energy consumption of machining processes into consideration respectively; then discussed the influence characteristics of the cutting parameters on the energy consumption based on the application of the model under a specific machining process.

1. With the increase of the cutting parameters (n, f, a_p), the power consumption increases. Furthermore, the spindle speed (n) has the strongest influence on the input power while the feed rate (f) is the smallest.
2. The energy consumption of machining process was inversely proportional to the machining rate. As a result, in the actual process of rough machining, we should choose large machining rate for processing, which can not only reduce the energy consumption, but also improve processing efficiency.

Tibetan question parsing integrated with phrase structure and event feature

Ning Ma, Hongzhi Yu, Fucheng Wan & Xiangzhen He

Key Laboratory of National Language Intelligent Processing, Gansu Province (Northwest University for Nationalities), Lanzhou, Gansu, China

ABSTRACT: We use syntactic parsing technology based on phrase structure and event feature for analyzing Tibetan question sentences in the public information service. The core approaches include Tibetan question sentence pretreatment, syntactic parsing, and question semantic representation. Through an experiment, we obtained very successful results on accuracy rate and recall rate, which proves that the introduction of the event feature in Tibetan question sentence analysis is very useful.

1 INTRODUCTION

Big data appears with the rapid development of computer networks and the information on the Internet becomes large and semi-structured. Now we find it more and more difficult to search information we are interested in as the researching results on the Internet can no longer satisfy us. Thus, we need some new ways to find useful information.

The automatic question answering system depends on it but is quite different from the retrieving technology. It can be questioned by sentences which are denoted in the natural language, and the returning answers will never be collections of only related web pages. Recently, we have not found any mature Tibetan automatic question answering system in literature. This paper researches the Tibetan automatic question answering system for public information service and focuses on the strategy of Tibetan question parsing.

2 RELATED RESEARCH

The question answering system is a typical application example of natural language processing and also the focus and difficulties for academic research. In foreign countries, the automatic question answering system of English, Japanese, and German languages has been applied in a restricted domain (Kayes, 2015). In China, there are some successful automatic question answering systems, for example, the campus navigation system of Tsinghua University, the frequently asked question answering system of Harbin Institute of Technology, and the bank question answering system of Beijing Institute of Technology, and so on.

At present, with further research on natural language processing technology, the lexical, syntactic, semantic, and pragmatic research achievements are beginning to be applied in the automatic question answering system. Wei Chuyuan et al. used the valid information in event modeling to enhance the accuracy of questions in semantic representation annotation in the Chinese question answering system (Nguyen, 2015). Kang Haiyan et al. set up a Web intelligent question answering system based on the questions in semantic representations. Tang Suqin et al. introduced dependency grammar in Chinese sentence parsing and extracted the semantics of questions and the limitation relationship among each component of the question so as to obtain the question understanding results aiming towards the domain ontology knowledge base.

Research of Tibetan information processing develops slowly, and the research on automatic question answering system still stays in the lexical analysis domain. The syntactical research is still in the initial stages and focuses on dependency grammar.

3 TIBETAN QUESTION PARSING FOR PUBLIC INFORMATION SERVICE

3.1 *Strategy of technology*

As shown in Figure 1, we divide the Tibetan automatic question answering system into four steps: Tibetan question input, Tibetan question parsing, the solution of Tibetan FAQ, and Tibetan difficult questions, and the last Tibetan answer output. This paper mainly focuses on the research of Tibetan question parsing as shown in the dashed box.

Figure 1. Technology strategy of the Tibetan automatic question answering system.

3.2 Tibetan question pretreatment

In the Tibetan automatic question answering system, there are many redundant components like stopping words, for example, “འདྲི་ལྟོགས་ཅིག་ལེན་པོ་ (hello)”, “ལྟོགས་ཅིག་ལེན་པོ་ལྟོགས་ཅིག་ལེན་པོ་ (would you please tell me)”, “ལྟོགས་ཅིག་ལེན་པོ་ལེན་པོ་ (excuse me)”, and “ལྟོགས་ཅིག་ལེན་པོ་ལེན་པོ་ (is there anybody who can tell me)”. In order to analyze the Tibetan question parsing, at first we need to get rid of these redundant components and then continue to parse them effectively. We set up a Tibetan redundant words table to solve this problem.

After removing these redundant components, we use the Tibetan word segmentation system developed in our laboratory to segment the Tibetan words and get some line sequences of Tibetan words to prepare for the next steps.

3.3 Tibetan phrase syntactic parsing integrated with functional semantic information

We construct a small amount of Tibetan phrase syntactic treebank in early research and the treebank is mainly used for Tibetan event information. This paper is based on Tibetan phrase syntactic treebank and integrates with Tibetan functional semantic information, as shown in Table 1. The main argument roles are agent labeled as NP-SUB(ARG0) and patient labeled as NP-OBJ(AGR1), and the secondary argument roles are time labeled as ARGM-TEMP, location labeled as ARGM-LOC, manner labeled as ARGM-MNR, etc. so that Tibetan functional semantic information can be integrated into the Tibetan phrase syntactic tree.

Through the above labeling strategy, we successfully integrate Tibetan phrase syntactic tree with functional semantic information. Take the sentence “འདྲི་ལྟོགས་ཅིག་ལེན་པོ་ལེན་པོ་ (Beijing is the capital of China)” for example. Its syntactic tree is as shown in Figure 2.

3.4 Tibetan question semantic representation

Question semantic representation is a special representation method for question semantic parsing, which represents Tibetan questions as the most

Table 1. Tibetan functional semantic information labeling table.

Agent	ARG0-SUB	Patient	AGR1-OBJ	Time	ARGM-TMP
Location	ARGM-LOC		Manner	ARGM-MNR	

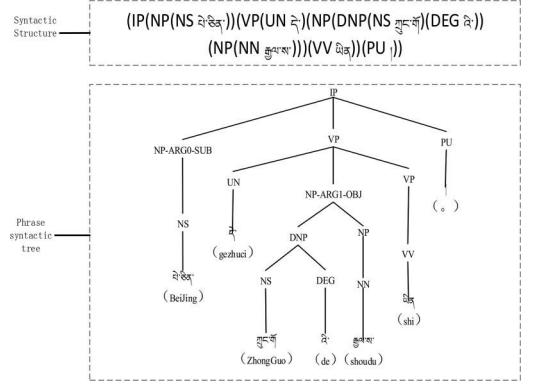

Figure 2. Structure of the Tibetan phrase syntactic tree.

intuitive questions in focus, with the main part and event information presented in an abstract labeling manner, so as to conduct semantic parsing for Tibetan questions. The Tibetan question semantic parsing representation labels Tibetan question semantic structure by a triple form as shown in the equation (1) below,

$$TQS(TQ) = \{TQf, TQt, TQe\} \quad (1)$$

In equation (1), TQS (Tibetan Question Semantic) is the Tibetan question semantic representation structure, TQf is Tibetan question focus blocks, TQt is Tibetan question topic blocks, and TQe is Tibetan question event blocks.

$$TQe = \langle TA, TL, TT, TD \rangle \\ = \langle TQe_a, TQe_l, TQe_t, TQe_d \rangle \quad (2)$$

Formula 2 represents the semantic structure of Tibetan question event blocks, TQe_a represents event trigger element of Tibetan question event blocks, TQe_l represents space element of Tibetan question event, TQe_t represents time element of Tibetan question event, and TQe_d represents the extent and effects element of Tibetan question time blocks, while the main semantic element is denoted with a vector. For example, TQ: ལྟོགས་ཅིག་ལེན་པོ་ལེན་པོ་ (would you please tell me), ལྟོགས་ཅིག་ལེན་པོ་ལེན་པོ་ (excuse me), ལྟོགས་ཅིག་ལེན་པོ་ལེན་པོ་ (is there anybody who can tell me)

can I take best from Wuquanshan in Lanzhou to west station in Lanzhou?).

3.4.1 Recognition of Tibetan question focus blocks

Question focus blocks are the most related elements with question information, including the combinations of question words and phrases, for example, the combinations of question words with noun phrases, verb phrases, prepositional phrases, and so on. “ཕྱོད་རྒྱུ་ལཱ་འཛོམ་ ཨང་དུ་བ་ (which bus)” is the combination of question words and noun phrases.

3.4.2 Recognition of Tibetan question topic blocks

Question topic blocks are the type and background of Tibetan questions. This paper researches the Tibetan automatic question answering system for public information service, which divides question types into traffic, education, science and technology, culture, health, and sports. Obviously, the topic type of the example sentence is འགྲིམ་འགྲུག་ (traffic).

3.4.3 Recognition of Tibetan question event blocks

Question event represents the event information or some actions that take place at certain times and places. Tibetan question event blocks are composed of a tetrad including action, time, space, and effect. The above-mentioned example sentence involves the element of action “བསྐྱད་(take)”, the element of time “ད་ལྟུ་(now)”, the element of space “ལན་ལྷ་ཚུ་མིག་ལྷ་ཅན་རི་ནས་ ལན་ལྷ་རྒྱ་རྒྱུ་ཕྱོགས་ས་ཚུགས་ ལྷ་འགྲོ་ན་(from Wuquanshan in Lanzhou to west station in Lanzhou)”, the element of effect “འགྲིག་(best)”. The final Tibetan question semantic representation is shown as below (3) and (4),

$$TQS(TQ) = \{TQf (\text{ཕྱོད་རྒྱུ་ལཱ་འཛོམ་ ཨང་དུ་བ་ (which bus)}, TQt (\text{འགྲིམ་འགྲུག་ (traffic)}), TQe\} \quad (3)$$

$$TQe = \langle TA, TL, TT, TD \rangle = \langle TQeA (\text{བསྐྱད་(take)}), TQeI (\text{ལན་ལྷ་ཚུ་མིག་ལྷ་ཅན་རི་ནས་ ལན་ལྷ་རྒྱ་རྒྱུ་ཕྱོགས་ས་ཚུགས་ ལྷ་འགྲོ་ན་ (from Wuquanshan in Lanzhou to west station in Lanzhou)}, TQeT (\text{ད་ལྟུ་(now)}), TQeD (\text{འགྲིག་(best)}) \rangle \quad (4)$$

The element of action is directly related to the trigger word of the Tibetan question. In general, the verb is the most important element of a Tibetan sentence, and the Tibetan verb is the trigger word of the event. If you can recognize Tibetan trigger words, you will be able to recognize the core verb in a Tibetan sentence. However, a lot of verbs are not included in the training corpus. For example, “དགེ་རྒན་ལ་བརྗེ་བཀུར་བྱས།(respect the teachers)”. Assuming that, “བརྗེ་བཀུར་(respect)” is not

included in the training corpus as an event trigger word, we cannot recognize this event. But the meanings of “བརྗེ་བཀུར་(respect)” and “བྱས་བཀུར་(esteem)” are similar. In view of this, we carry out Tibetan word semantic similarity computation on the basis of the Tibetan verb lexicon and lexicon trigger words in order to automatically expand the trigger words and cover various types of event trigger words as much as possible. Then the acquired seed trigger word and its information type will form a tuple combination (trigger, type), for example, (chairman, Person/Respect). Regarding one trigger word corresponding to multiple categories in special circumstances, due to its small probability, we mostly choose the category with the largest probability of occurrence in the training corpus. Through this method, we construct a table of “Tibetan seed trigger words and event information category”, in which the first column is event trigger words and the second column is information category.

In Table 2, the first column corresponds to seed trigger words, and the second column corresponds to the event information category of each trigger word. Each trigger word corresponds to only one event information category and the trigger words in the table cover all categories of event information.

“Time” is the time information element of the event in Tibetan question, “space” is the space information element of the event in Tibetan question, including location. To recognize the time and space, syntactic analysis features are used. The time element is labeled as NT, and the spatial element is labeled as NL. In syntactic parsing model, more features are introduced to train, in order to decode the test data, and finally identify the time and space elements.

“Effect” is the extent and effects element of the Tibetan question events. They are generally adverbs, which often exist in a Prepositional Phrase (PP) or adverb phrase (ADVP) in the whole sentence. We usually identify the effect element by combining block recognition with corresponding rules.

Table 2. “Tibetan seed trigger words and event information category”.

Seed trigger words	Event information category
རིབ་ལ། (bankrupt)	Business/ Declare-Bankruptcy
འགོག་རྒྱུ་ (contend)	Conflict/Attack
སྐྱོད་ལྷོ་ལ། (flee)	Movement/Transport
རྩམ་སྟོན། (demonstration)	Conflict/Demonstrate
...	...

4 EXPERIMENTS AND EVALUATION

4.1 Set up of experiment

For corpus selection, currently, there is no special corpus and standard evaluation criteria for the Tibetan language question answering system. In order to show our work effectively, we annotate 300 sentences for the corpus of Tibetan question answering system and include 70 sentences in the test data. The precision rate and recall rate are used for evaluation.

4.2 Experimental results

The results are shown in Table 4. The evaluation indexes are precision rate and recall rate. Since the Tibetan question-answering system research is still in its infancy stage, we do not compare the experiment results with a baseline system, but horizontally compare the triggering word recognition, syntactic parsing, and question parsing.

4.3 Result analysis

Table 4 shows that the accuracy of the Tibetan question parsing method in this paper is relatively high. The reasons are mainly as given below: (1) Early research has covered the removal of redundant words as well as word segmentation so that the accuracy rate of this part is high, but we have not considered the effect of functional words in Tibetan sentences. Take the example sentences in section 2.4. There are one position prepositions གྲུབ་པའི་ and two-state prepositions འདྲིལ་བའི་ and འདྲིལ་བའི་ in this sentence. In the next step, we will further research functional words in the Tibetan sentence; (2) In early laboratory research, we have built a number of Tibetan phrase syntactic treebanks, in which the accurate rate of syntax analysis for a sentence

composed of less than 15 words is relatively good. While in questions for public information service, the sentences are mostly composed of less than 15 words, and as such the accurate rate is also good in syntax analysis; (3) In Tibetan sentences with expression, the core verb is always located in the end of a predicative sentence, so it is easy to identify the triggered words; (4) The recognition of an event block is directly related with syntax parsing. Meanwhile, the labeling of linguistic features like time and space elements are conducive to event element recognition. This also proves that in the analysis of questions, the introduction of event features can help improve accuracy.

5 CONCLUSIONS AND FUTURE WORK

Tibetan question parsing model is based on phrase structure and ontology features, and on the basis of Tibetan syntactic parsing, it integrates with functional semantic information, time, and space information in the training step so as to provide support for Tibetan information extraction.

This paper provides a lexical, syntactic, and shallow semantic solution for the Tibetan question analysis, including Tibetan semantic information classification, Tibetan semantic information labeling, and Tibetan syntactic parsing.

The contribution for our work is to provide a question analysis scheme for other languages including Mongolia language, Uyghur language, and other minority languages.

Our work lies in the syntax and shallow semantic level. In the next step, we will enhance our research work at the lexical-syntactical level and research the Tibetan lexical syntax integration model, thus enabling the Tibetan information extraction model without word segmentation, i.e., a Tibetan parsing model based on syllable sequence so as to support the Tibetan question parsing.

Table 3. Set up of experimental corpus (sentence).

Corpus category	Training corpus	Test corpus
Corpus quantity		
Total	300	70

Table 4. Analysis of Tibetan information extraction results.

Evaluation	P	R
Phrase syntactic parsing	83.96%	81.47%
Trigger word recognition	93.20%	89.16%
Tibetan question parsing	91.76%	87.28%

ABSTRACT: The strategic alliances can respond rapidly to market changes and makes resource sharing more efficient among manufacturing partners. The partner selection problems in strategic alliances management extensively appear in social and management fields such as the selection of dynamic alliance strategies, assigning task problems, portfolio selection, agile production and supply chain management, etc. In this paper, a mathematical model, 0-1 programming model, is proposed on partner selection problems in strategic alliances management of new energy industry. The model is concerned with the former-latter relationship of the items and the dynamic receiving and paying of the capital flow. The established model is in conformity with the reality. It lays basis for further analyzing and solving the partner selection problem of new energy industry.

1 INTRODUCTION

Nowadays, more and more companies have established business strategic alliances to compete in a global changing environment and benefited greatly. The alliances meet the country's proposal of "building the technology innovation system with enterprises as mainstay, the market as guide, and the integration of production, education and research" (Heidl, 2014). Establishment of the alliances is based on enterprise requests of internal development and general common interests. Features of the alliances include joint development, complementary advantages, profit and risk sharing (Constantinos, 2016). Goals of the alliances are to enhance innovation abilities of industry and technology, to promote the optimization and upgrade of industrial architecture, and to advance the transformation of economic growth mode from extensive type to intensive type. The alliances will make efforts to realize economy sustainable development, improving comprehensive strength and core competition of the country (Donald, 1982).

However, according to management literature, about half of the alliances established turned out to be failures. One of the key factors for this failure is the choice of a wrong partner. The strategic alliances is a management or operation unit, which has the intention of profiting but without the concrete organization (specially, it doesn't organize

the concrete production activities and operation processes) (Ellram, 1990). The mode of the operation and management of such strategic alliances is that they contrive to gain projects or production tasks, decompose them, select the coordinate partners by call for tenders, and distribute the decomposed projects or production tasks to the selected coordinate partners to benefit from the process. It is evident that the amount of benefit relies on the selection of the coordinate partners. Under the condition of accomplishing the project or task, choosing the best coordinate partners to make enterprise benefit maximally is called the Partner Selection Problems (PSPs) in the strategic alliances management, which extensively appears in such social and management fields as the selection of dynamic alliance strategies, assigning task problems and the investment combination, etc.

The importance and meaning of the partner selection problems is clear, because it is not only the main parts of any strategic alliances management, but also the chief factor which affects upon the profits of any enterprise (Stevan, 2009). One of the focuses about strategic alliances management is to manage and coordinate the cooperation relationship between enterprises (Brouthers, 1995; Wu, 2010). However, the prerequisite of establishing good cooperative relationship needs to select the cooperative partner (Jin, 2008). At present, the correlative theories are mainly based on sharing total

information and complete cooperation between the core enterprise and the supplier (Mehralian, 2012). However, enterprises separate from each other to a certain extent, and have business secrets of their own. In addition, the trust mechanism of our country has a big risk, and the application of information technology in enterprises is not perfect (Holjevac, 2008). Then it is impossible that the complete cooperation and sharing all information can take place between enterprises (Kokangul, 2009). So it is a competitive-cooperative relationship of different degrees between enterprises because of these characteristics. And basing on cooperation of various degrees, the supplier's selecting standards vary greatly (Lee, 2009). So the enterprise should classify the partners at first, and then choose different kinds of cooperative partners. Taking the above factors into consideration, we propose the process of partner selection. The first stage is to define the type of the enterprises offering the different values, and the second stage is to select the cooperative partners of strategic alliances offering the same value on the basis of the first stage.

For recent years, more and more researchers have been interested in the PSPs, which are publicly considered as the hot problems in the agile production and strategic alliances management. This article puts forward a strategic alliance partner selection and evaluation model of new energy industry based on the operational research theory hoping to provide some useful references for the enterprise managers and relevant researchers. This paper establishes a mathematical model, 0-1 programming model, of the partner selection problems. The established model involves the former-latter relationship of the items and the dynamic receiving and paying of the capital flow. Therefore it is more conformable to reality and suitable for optimal algorithms. It is the theoretical basis of solving partner problem of new energy industry.

2 THE MATHEMATICAL MODEL OF PARTNER SELECTION PROBLEMS BASED ON OPERATIONAL RESEARCH

Many previous studies on partner selection and evaluation defined numerous evaluation criteria and selection frameworks for supplier selection. For example, Dickson surveyed buyers to identify factors they considered in awarding contracts. Out of the 23 factors considered, Dickson concluded that quality, delivery, and performance history are the three most important criteria. Another study by Weber et al. derived key factors thought to influence partner selection decisions. These factors were taken from 74 related articles that have

appeared since Dickson's well-known study. Based on a comprehensive review of vendor evaluation methods, they surmised that price was the highest-ranked factor, followed by delivery and quality. These empirical researches revealed that the relative importance of various selection criteria such as price, quality, and delivery performance is similar.

However, the establishment of a partner evaluation model from the above studies mostly did not focus on the needs of end consumers from the perspectives of the strategic alliances or the strategy of the enterprise itself. Their key factors were mostly obtained by questionnaires or professional interviews. Therefore, this study thus proposes a structured methodology for partner selection and evaluation of new energy industry based on the integration architecture, to help leading enterprises establish a systematic approach to selecting and evaluating potential partners of new energy industry. The continued importance of fast paced innovation, market pre-emption, and risk management has led firms to stretch their organizational boundaries, accessing resources from an increasingly diverse set of partners. A range of studies have established that during the past decades, firms of new energy industry were no longer able to 'go it alone' in their creation of innovative products, processes, and services within a reasonable time to market and hence entered dyadic alliances. The literature also reveals that under specific conditions, dyadic alliances might not suffice and the inputs of multiple partners will be required.

Suppose that an enterprise of new energy industry gets a project with many branch items, but does not have the enough capability and resources to accomplish the entire project, so it has to invite public bidding for each of the branch items, or the enterprise itself is virtual and the main means of its gaining profit is to earn the difference benefit by winning a tenders and distributing it to contractor. Assume a project is composed of n items, indicated respectively by $1, 2, \dots, n$, which have a fixed sequence being done, so form an activity networks (Jin, 2008). If item k can not begin until item i is completed, namely, item i is previous to item k (we call item i is a closely former operation of item k), we denote it by binomial relationship $(i, k) \in H$, where H is a set of all join-ship. For simplicity, suppose that $i < k$ holds for any $(i, k) \in H$, and the last term is denoted by n .

We have the following notations:

- n : the number of the items of the project.
- D : the project span-time stipulated by bidding contract.
- $e(t)$: the investment flow of the project, namely the investment extra at the moment t , $t = 1, 2, \dots, D$.

- r(t): the interest rate of borrowing and loaning at the moment t.
- $\beta(t)$: the rate of penalties, because of tardiness of t unit time than the project span-time stipulated by bidding contract and it is usually a piecewise increase-successively function.
- mi: the number of the candidates of item i, $i = 1, 2, \dots, n$.
- xij: the project span-time of item i promised by candidate j (span-time of item i done by candidate j), $j = 1, 2, \dots, mi, i = 1, 2, \dots, n$.
- fi(xij): the bidding of candidate j to the item i (or the expenses of item i done by candidate j), $j = 1, 2, \dots, mi$.
- C: the actual project span-time.

This paper only considers selecting partners in terms of the item expense and completing time of the project.

In addition, we suppose that the enterprise pays $afi(xij)$ at the beginning (for the candidate j of item i) and pay the rest, $(1-a)fi(xij)$, of the item expenses at the end of the item. In production practice the total predetermined fund of a large scale project is not appropriated once. It is usually paid by stages. When the appropriated fund is not enough to pay to the contractor, the enterprise has to loan from bank and pays interest to bank. If the project is not completed on time, the enterprise will be fined and suffers from some economical loss in a certain degree. Consequently, the total costs, Z, of the project are composed of the item expense, the interest of the bank and tardiness penalties, denoted by Z_1, Z_2, Z_3 respectively, therefore $Z = Z_1 + Z_2 + Z_3$.

For any $i = 1, 2, \dots, n, j = 1; 2, \dots, mi$, we introduce variable

$$w_{ij}(t) \begin{cases} 1, & \text{if item } i \text{ is contracted to candidate } j \\ & \text{and starts at the moment } t \\ 0, & \text{else} \end{cases}$$

Then Z_1 is represented as

$$Z_1 = Z_1(w_{ij}(t)) = \sum_{i=1}^n \sum_{j=1}^{m_i} f_i(x_{ij}) \sum_{t=1}^C w_{ij}(t). \quad (1)$$

The item expense having been paid by enterprise by the moment t is the sum of the expense of items being done and the expense of the items have been done, so the sum is

$$A = A(w_{ij}(t)) = \alpha \sum_{i=1}^n \sum_{j=1}^{m_i} \sum_{k=1}^t f_i(x_{ij}) w_{ij}(k) + (1-\alpha) \sum_{i=1}^n \sum_{j=1}^{m_i} \sum_{k=1}^t f_i(x_{ij}) w_{ij}(k-x_{ij}).$$

Since the amount of the investment received by enterprise at the moment t is $B = B(t) = \sum_{k=1}^t e(k)$. We introduce the notation

$$[A - B]^+ = \begin{cases} A - B, & A > B, \\ 0, & A \leq B. \end{cases}$$

Then $[A - B]^+$ is the amount of the money loaned from bank by the moment t. The amount of interest paid to bank is

$$\begin{aligned} Z_2 &= Z_2(w_{ij}(t)) = \sum_{t=1}^C r(t)[A - B]^+ \\ &= \sum_{t=1}^C r(t) \left[\alpha \sum_{i=1}^n \sum_{j=1}^{m_i} \sum_{k=1}^t f_i(x_{ij}) w_{ij}(k) \right. \\ &\quad \left. + (1-\alpha) \sum_{i=1}^n \sum_{j=1}^{m_i} \sum_{k=1}^t f_i(x_{ij}) w_{ij}(k-x_{ij}) \right. \\ &\quad \left. - \sum_{k=1}^t e(k) \right]^+. \end{aligned} \quad (2)$$

It is evident that the expression of the tardiness penalties is denoted as

$$Z_3 = \beta([C - D]^+) [C - D]^+.$$

Thus, the total expenses of the project, paid by the enterprise, can be represented as

$$\begin{aligned} Z(w_{ij}(t)) &= Z_1(w_{ij}(t)) + Z_2(w_{ij}(t)) + Z_3(w_{ij}(t)) \\ &+ \sum_{i=1}^n \sum_{j=1}^{m_i} f_i(x_{ij}) \sum_{t=1}^C w_{ij}(t) \sum_{t=1}^C r(t) \left[\alpha \sum_{i=1}^n \sum_{j=1}^{m_i} \sum_{k=1}^t f_i(x_{ij}) w_{ij}(k) \right. \\ &\quad \left. + (1-\alpha) \sum_{i=1}^n \sum_{j=1}^{m_i} \sum_{k=1}^t f_i(x_{ij}) w_{ij}(k-x_{ij}) - \sum_{k=1}^t e(k) \right]^+ \\ &+ \beta([C - D]^+) [C - D]^+. \end{aligned} \quad (3)$$

The intention of selecting partners and determining the starting time of every items (in other words, $w_{ij}(t), i = 1, 2, \dots, n, j = 1, 2, \dots, mi, t = 1, 2, \dots, C$) is to minimize the above total expenses $Z(w_{ij}(t))$, which is obviously the final purpose of PSP, namely the comprehensive object of PSP is

$$\min \{ Z(w_{ij}(t)) \mid w_{ij}(t) \in \{0, 1\} \}. \quad (4)$$

However, the above minimization must satisfy such constraints as

1. The 0-1 constraints

$$w_{ij}(t) \in \{0, 1\}, \quad \forall i, j, t.$$

2. The non-conflict constraints

$$\sum_{j=1}^{m_i} \sum_{t=1}^C w_{ij}(t) = 1, \quad i = 1, 2, \dots, n.$$

Namely, each of the items must have and only have one contractor, and must start at the moment t .

3. The former-later relationship constraints of items

$$\sum_{j=1}^{m_i} \sum_{t=1}^C (t + x_{ij}) w_{ij}(t) \leq \sum_{j=1}^{m_k} \sum_{t=1}^C t w_{kj}(t), \quad \forall (i, k) \in H,$$

i.e., if item i is a former operation of item k ($\forall (i, k) \in H$), then item i must have been completed when k begins.

4. The complete constraint

$$\sum_{j=1}^{m_n} \sum_{t=1}^C (t + x_{nj}) w_{ij}(t) = C,$$

i.e., the completing time of the n -th item is the finishing time of the entire project.

In summary, we can derive the following 0-1 programming model of PSPs

$$\min Z(w_{ij}(t)) \quad (5)$$

s.t.

$$w_{ij}(t) \in \{0, 1\}, \quad i = 1, 2, \dots, n \quad j = 1, 2, \dots, m_i, \\ t = 1, 2, \dots, C, \quad (6)$$

$$\sum_{j=1}^{m_i} \sum_{t=1}^C w_{ij}(t) = 1, \quad i = 1, 2, \dots, n, \quad (7)$$

$$\sum_{j=1}^{m_i} \sum_{t=1}^C (t + x_{ij}) w_{ij}(t) \leq \sum_{j=1}^{m_k} \sum_{t=1}^C t w_{kj}(t), \quad \forall (i, k) \in H, \quad (8)$$

$$\sum_{j=1}^{m_n} \sum_{t=1}^C (t + x_{nj}) w_{ij}(t) = C, \quad (9)$$

where $Z(w_{ij}(t))$ is determined by (3).

The number of variables in the above 0-1 programming model is $L = C \times \sum_{i=1}^n m_i$, but the scale of the searching space is $L = C \times \prod_{i=1}^n m_i$. It is obvious that even for a small scale problem, the searching space of this model is very big. However, the biggest advantage of the model is that, except such non-linear terms as $[A-B]^+$, all terms of the objective function are linear, so we can use the revised linear programming method to solve the model.

3 CONCLUSIONS

Enterprise strategy is a plan that develops through the process of an enterprise analyzing internal organizational strengths and weaknesses, as well as external environmental threats and opportunities. Enterprises use such plans to establish competitive models for promoting their competitiveness. In a dynamic competitive environment, if an enterprise wishes to maintain its competitive strengths, it must develop partner relationships at a strategic level rather than just focusing on products and prices. From the viewpoint of strategic alliances, an enterprise must also consider the purpose of establishing competitive strengths and developing long-term relationship while planning enterprise strategy. Consequently, enterprise competitive strategy and relationship strategy are both crucial influences on supplier selection and evaluation for strategic alliances. To straighten internal relationship of the alliance, to propel substantive and high level cooperation. The alliance should pay highly attention to R&D of key technologies based on national strategy, so as to improve its ability of original innovation, apply long-term and high level strategic cooperation. The partner selection is also an essential prerequisite for the alliance development.

In this paper, the 0-1 programming model is established on partner selection problem of new energy industry in strategic alliances management. The model is concerned with the former-latter relationship of the items and the dynamic receiving and paying of the capital flow. It is in conformity with the reality. The established model is the theoretical basis for further analyze and solve the partner selection problem of new energy industry. Solving the model has significant guidance for selecting a group of coordinate partners to collaboratively accomplish a project and to gain the best profit. Therefore this paper tries to analyze the principles in the selecting course of strategic alliances partner selection of new energy industry at first, provide a 0-1 programming model of partner selection and its realization methods next. Selecting different type of partners on the basis of defining the types of cooperative partner needs different evaluating models, so that it can make the course of partner selection of new energy industry more rational.

A fractal study on the surface topography of shearing marks

B.C. Wang

Shenzhen University, Shenzhen, China

C. Jing & L.T. Li

Guangdong Hengzheng Forensic Clinical Medicine Institute, Guangzhou, China

ABSTRACT: The surface topography of shearing marks is studied by using the fractal theory. The irregularity and random distribution of the surface topography shows the fractal characteristics. The data of the surface topography of shearing marks are collected digitally by using surface topography tools, and the fractal dimensions are calculated. The result shows that surface topography of shearing marks and fractal dimensions are different when metallic materials are sheared by different tools. Therefore, the fractal dimensions can be used as a characteristic index to describe the surface topography of shearing marks. It can help analyze the characteristics of surface topography of shearing marks effectively. It can also provide a reference for the judgment of shearing tools. It is a new method of quantitative inspection of shearing marks.

1 INTRODUCTION

On crime locations, various traces will be left behind by criminals using tools to destroy objects, the mark of a striation tool is one of them. It is usually composed of pliers and scissors and other tools. These tools will form a continuous striation seen visually or microscopically visible on every section in the process of cutting the objects. Traditionally, the tool marks are mostly inspected by visual comparison. It is to compare the striation tool marks collected from the crime scene with the test marks formed by suspected tools. The tool marks are determined based on striation comparison. This process is called “form inspection”. Practically, the surface topography of the striation tool marks is very complex and irregular, and also random and disorderly. Therefore, the surface topography of the striation tool marks cannot be described by digital description tools for a long time. The inspection of digital analysis cannot be used.

Fractal geometry theory can be used to describe irregular and disorderly graphics. The fractal dimension is an important parameter which is used to quantitatively characterize the “singularity” degree of chaotic attractor. It is widely used to describe the digital characteristics of a non-linear system of behavior. The surface topography of a material has been studied by using the fractal theory. The research data shows that fractal theory

gets certain achievements of surface topography in characterizing. (Brown & Savary 1991, Gagnepain & Roques-Carnes 1990, Ganti & Bhushan 1995). In this paper, the characteristics of the surface topography of shear marks are studied by applying the fractal geometry theory and the literature on the application of fractal research (Mou & Yang 2010, Su et al. 2014, Li et al. 2014). The purpose of this study is to apply the fractal theory to the inspection of shearing marks. The modern theory and the application technology can be combined to deepen the theory of mark inspection. It introduces new inspection technologies into the inspection of shearing marks during the investigation process which involves shearing tools.

In order to improve the automation and reliability of inspection, it is necessary to use a certain number to express the complex striation tool marks to achieve digital inspection and identification. To achieve this purpose, this study adopts scissors, steel pliers, and wire-breaking pliers as shearing tools to make samples of shearing marks. The sample surface was marked by the software to get the profile curve which is perpendicular to the surface of marks. The fractal dimensions of the profile curve are calculated by applying general fractal dimension methods. The characteristic parameters of the dimension's energy spectrum are calculated according to the fractal dimension spectrum. The energy spectrum of different

shearing marks is found according to the characteristic parameters of the dimension spectrum and then extracted and characteristics of different shearing marks recognized. It greatly improves the reliability of inspection and recognition by introducing the characteristics of the dimension energy spectrum.

2 EXPERIMENTAL CONDITIONS AND DATA ACQUISITION

Scissors and wire cutters are used as shearing tools to shear the lead wires. Several samples of shear marks are made. The samples are observed under the stereomicroscope and those samples which can reflect the stability characteristics of the shear marks are chosen to be collected digitally.

In this experiment, we used the Austria infinite focus auto-zoom three-dimensional surface topography measurement device with its objective magnification 10 times and the sampling resolution 1.1 μm . The surface of shearing marks is digitally collected and a three-dimension of shearing marks is stored in the computer. The stable part of the marks character is marked by the application software. The profile curve which is perpendicular to the marks surface is obtained. The profile curve which is perpendicular to the marks surface formed by scissors is as shown in Figure 1(a). The profile curve which is perpendicular to the marks surface formed by wire cutters is as shown in Figure 1(b). The profile curve which is perpendicular to the marks surface formed by wire breaking pliers is as shown in Figure 1(c).

Figure 1. Three profile curves.

3 GENERAL FRACTAL THEORY AND THE GENERAL FRACTAL DIMENSION SPECTRUM OF THE PROFILE CURVE

The fractal theory provides the theoretical basis for the description of a nonlinear behavior system. It is used to quantitatively characterize the singularity of chaotic attractor. The fractal dimension makes up for the deficiency of the traditional analysis model to a certain extent. In order to describe the nonlinear system behavior characteristics by fractal dimension, the various definitions and calculations methods are provided such as the box dimension method, the power spectrum method, the information dimension method, the correlation dimension method, and the multi-scaling dimension method, and so on (Wang et al. 2015). In this paper, the fractal dimension of the profile curves which are perpendicular to the marks surface formed by scissors, pliers, and wire pliers are calculated by the general dimension method.

The general fractal is used to describe the non-uniform random probability distribution of the fractal geometry on different layers; the general fractal dimension is an important parameter to describe the general fractal. This is the general definition of the fractal dimension. The expression is:

$$D_q = -\lim_{\varepsilon \rightarrow 0} \frac{I_q(\varepsilon)}{\ln \varepsilon} \quad (1)$$

$I_q(\varepsilon)$ is the formation entropy of the Renyi definition for which the expression is:

$$I_q(\varepsilon) = \begin{cases} \frac{1}{1-q} \ln \left[\sum_{i=1}^N P_i(\varepsilon)^q \right] & q \neq 1 \\ \sum_{i=1}^N P_i(\varepsilon) \ln P_i(\varepsilon) & q = 1 \end{cases} \quad (2)$$

$$q = -\infty, \dots, -1, 0, \dots, +$$

$P_i(\varepsilon)$ is the cover rate, D_q depends on parameter q . It is: When the locket with a side length of ε is used to cover fractal collect, $P_i(\varepsilon)$ is the rate of a dot in fractal collect falling into the locket. When q is different, it means the difference of the fractal dimension. For example, if $q = 0, 1, 2$, D_q is respectively equal to the box dimension, the information dimension, correlation dimension, and so on.

The most important problem in practical applications is how to calculate the general fractal dimension according to experimental results and observation data, and how to seek and find the multi-scaling characteristics according to the general fractal dimension spectrum $q-D_q$. Calculation measures of D_q spectral include: covering method, fixed radius method, fixed quality method, and so on.

Covering method can be used for all kinds of simple or complex fractal objects. It is one of the most common methods of the fractal study. For a multi-scaling fractal set, the object of study is covered by the box of scales ε , a probability distribution function of cover collection $P_i(\varepsilon)$ shall be first defined. The expression is:

$$P_i(\varepsilon) = \frac{A_i}{\sum_{i=1}^N A_i} \quad (3)$$

This formula is actually to be replaced with the approximate probability with frequency. Where A_i is covering "points" of the i box, $\sum_{i=1}^N A_i$ is the total "points" of the entire box covering. N is the total box quantity. So $P_i(\varepsilon)$ is the probability of points of fractal sets falling in the i box. The information entropy of the Renyi definition can be calculated according to the probability function $P_i(\varepsilon)$, scale ε and weighting factor q sequence.

The algorithm is as follows:

First, the analog signal or the continuous fractal contour curve $Z(x)$ is A/D converted conversion. It is called discretization. If the sampling length is L , the sampling interval is $\Delta\varepsilon$, then the number of sampling points is $N = L/\Delta\varepsilon$. The length of the signal or the curve is discretized into a one-dimensional array $Z = \{Z_1, Z_2, Z_3 \dots Z_N\}$.

Second, the meshing size division is ε , $\varepsilon_i = 2i\Delta\varepsilon$ is the grid width, the number of rows and columns of the grid is $m = L/\varepsilon_i$. If the k row and the t columns of the grid are called kt grid, i is the mesh type, then kt grid coordinates are $\{(k\varepsilon_i, (t-1)\varepsilon_i), (k\varepsilon_i, t\varepsilon_i), (k-1)\varepsilon_i, (t-1)\varepsilon_i), ((k-1)\varepsilon_i, t\varepsilon_i)\}$. The discerning data points of the grid is $B = \{Z/\varepsilon_i + 1\}$, while the kt grid covering the discrete data points is recorded as $A_{k,t}$, then kt grid covers the collection probability and can be as follows according to the equation (3):

$$P_{k,t}(\varepsilon_i) = A_{k,t} / \sum_{k=1}^m \sum_{t=1}^m A_{k,t} = A_{k,t} / N \quad (4)$$

A series of information entropy $I_q(\varepsilon)$ can be calculated according to this formula. A scale-free region is found in $\ln \varepsilon \sim \ln[I_q(\varepsilon)]$ figure fitting the slope of the segment by using the least squares method, the absolute value of this slope is D_q , a given value q .

The spectral values of the general fractal dimension are obtained with three kinds of profile curves according to the formula of the general fractal dimension. The dimension spectrum curve is shown in Figure 2.

From the general fractal dimension spectrum value, characteristic values are extracted such

Figure 2. Three kinds of dimension curve.

Table 1. Characteristic values of the multi-fractal dimension spectrum.

Dq	Sample a	Sample b	Sample c
D_0	1.6932	1.5364	1.8251
$D_{0.95}$	1.6251	1.4746	1.7445
D_1	1.6270	1.4772	1.7462
$D_{1.05}$	1.6321	1.4826	1.7513
D_2	1.5713	1.4354	1.6925

as $D_0, D_{0.95}, D_1, D_{1.05}, D_2$, and they are as shown in Table 1.

To take the iteration order of $q = 0.05$ in the calculation of the general fractal dimension, a series of fractal dimensions are obtained as shown in Figure 2. From the fractal dimensions shown in Figure 2, it can be found that the dimensional numerical showed monotonicity and was decreasing with the continuous increase in the value of q , that is, the dimensional numerical was decreasing with the q value increasing, but the fractal dimension value in the $q = 0.95$ and $q = 1.05$ generates mutations. From the general dimension spectrum value of three kinds of profile curves shown, the dimension values at $q = 0.95$ and $q = 1.05$, it respectively obtains high mutation and low mutation. So the dimension at the two points and fractal dimension of D_0, D_1 and D_2 combine together to describe the profile curve feature, and then the fractal dimension group of identification rules is established. Even if the fractal dimension ($D_0, D_{0.95}, D_1, D_{1.05}$ and D_2) at $q = 0, 0.95, 1, 1.05, 2$ and five special points are taken as a group to distinguish the different profile curve, it can be found from the

Table 2. The value of general dimension energy spectrum of three kinds of profile curves.

Profile curve	Sample a	Sample b	Sample c
Energy spectrum	13.28774	10.97557	15.35509

results, that three kinds of profile curves are different, and dimension spectra are also different.

4 THE ANALYSIS OF THE PROFILE CURVE CHARACTERISTIC BASED ON ENERGY SPECTRUM OF GENERAL FRACTAL DIMENSION

The energy used and spatial distribution is different when using three different tools to cut the object according to the energy theory. The dimension values are different when the fractal dimension is used to describe the different profile curves. The energy of the shearing process can be expressed as follows:

$$E = \sum_{i=1}^n |x_i|^2 \quad (5)$$

From the form of the energy equation (5) for the introduction of the general fractal energy spectrum to describe different profile curve characteristics, its expression is:

$$E_{Dq} = \sum |D_q|^2 \quad (6)$$

$$q = 0, 0.95, 1, 1.05, 2$$

General fractal energy spectra of three kinds of profile curves can be calculated by the formula (6). The calculated results are shown in Table 2.

It can be found from the results that the dimension spectrum of three kinds of profile curves is significantly different and the distinction is big.

5 CONCLUSIONS

The general dimension spectrum of three kinds of profile curves are calculated respectively, and the profile curve and dimension spectrum are also different. The dimension value of the spectrum is analyzed in different q values. According to the characteristics of the spectrum, the profile curve characteristics are described by the characteristic

value of five dimensions ($D_0, D_{0.95}, D_1, D_{1.05}$ and D_2), that is to identify the profile curve by using the fractal dimension group, the recognition rate is more reliable than using a single dimension.

The dimension energy spectrum is obtained based on this calculation. As the dimension energy spectrum value is combining 5 characteristic values, the profile curve characteristics can be reflected more comprehensively and accurately. It greatly improves the reliability of recognition of the profile curves formed by different tools. The results show that the dimension energy spectrum of three kinds of profile curves is significantly different and the distinction is big. Therefore, the characteristic value of the dimension and dimension energy spectrum can be used as the characteristic parameters of different profile curves. It can be used as a criterion for identifying different tools. The study provides a basis for the inference of shearing tools. It also provides a new method for quantitative inspection of shearing marks.

Investigation of denoising methods of infrared imagery

Ming-kai Yue

Beijing Institute of Technology, Beijing, China
Shenyang Ligong University, Shenyang, Liaoning, China

Jia-hao Deng

Beijing Institute of Technology, Beijing, China

ABSTRACT: As for the infrared imaging system, the denoising effect of infrared imagery, a key to influencing the infrared imaging quality of the target, directly determines the precision of the target segmentation and identification. The noise characteristics of infrared imagery are discussed and an integrated filtering method was proposed based on the contrasting advantages and disadvantages of two classic methods, median filtering and mean filtering. The experimental results and quantitative analysis indicate that the proposed method has an excellent denoising effect for infrared imagery containing mixed noise.

1 INTRODUCTION

The infrared imaging system has been widely applied in various weapon equipment systems due to many advantages, such as good disguising, strong anti-interference, high angular resolution, the capability to work all day long, etc. Since there is interference in every step during the course of obtaining, transmitting, and displaying infrared imagery, the noise will pollute infrared imagery and reduce its quality. Consequently, the processing and usage of infrared imagery will inevitably involve the denoising problem. As for the infrared imaging system, the denoising effect of infrared imagery directly determines the precision of the target segmentation and identification, therefore influencing the performance of the infrared imaging system. Hence, directly or through denoising, obtaining the higher Signal to Noise Ratio (SNR) infrared imagery is the primary premise to increase the performance of the infrared imaging system.

2 NOISE CHARACTERISTICS OF INFRARED IMAGERY

As infrared imagery is the premise and basis of auto-identification of the infrared imaging system and its noise characteristics decide which method to process, it is necessary to firstly discuss the noise characteristics. The infrared imaging system has the function to convert infrared light into the visible one. The optical system converts the infrared emanation signal into the electrical one by the

Figure 1. Schematic diagram of the infrared imaging system.

infrared detector and displays the video signal reflecting the target infrared emanation distribution on the monitor by processing electronically, which realizes the reversion from electricity to light and obtains visible imagery reflecting the target thermal imagery. Figure 1 shows the schematic diagram of the infrared imaging system.

It can be seen from Figure 1 that infrared radiation of the target can convert into infrared imagery after a series of processing such as atmospheric transmission, optical imaging, infrared detector, etc. Hence, both the environment outside the infrared imaging system and the physical parameter inside it influence the infrared imagery. The infrared image reflects the space distribution of the infrared radiation between the target and the background and its radiance distribution is mainly decided by the temperature of the observed target and the emissivity of the infrared wave. Since noise is the biggest factor to influence the quality of infrared imagery, denoising is the key point in pre-processing of the infrared imagery.

The infrared detector is the main noise source of the infrared imaging system and the thermal and $1/f$ noise produced by it can be approximately presented by Gaussian distribution, i.e., Gaussian noise. At the same time, the uniformity of the

infrared detector can produce some blind pixels and pulse noise, which is recognized as salt and pepper noise in infrared imagery. Hence, the main noise in infrared imagery can be approximately considered as a Gaussian one with some salt and pepper one, so the filtering in the pre-processing of infrared imagery mainly aims at the Gaussian noise and the salt and pepper. The infrared imagery is a little dark and has low definition and resolution. Also, the target and background with blur edges have low contrast. Consequently, the denoising must aim at the characteristics of infrared imagery, i.e., the factors disadvantageous to the post-processing of the infrared target identification system, such as the blur edges produced during denoising must be reduced as far as possible.

3 FILTERING OF INFRARED IMAGERY

The imagery filtering methods mainly include frequency domain and space. The former has heavy computation and bad real-time. The noise of the infrared imagery mainly consists of Gaussian noise and salt and pepper. The better processing method for the former is mean filtering while that for the latter is median.

3.1 Median filtering

The median filtering, one of the space domain filters belongs to nonlinear filtering technology and has light computation and is easy to realize.

The salt and pepper noise is also named as pulse one and its probability density function is

$$p(z) = \begin{cases} p_a & z = a \\ p_b & z = b \\ 0 & \text{else} \end{cases} \quad (1)$$

The noise pulse can either be a positive one or a negative one. When $a = 0$, $b = 255$ for the common eight-digit image, the positive pulse will be displayed as white points whilst the negative one as black points.

The fundamental of median filtering can be described as follows: the window W of odd pixels is firstly set up and every pixel lines up according to the gray scale size, and then the center gray scale $g(x, y)$ takes the place of the original $f(x, y)$ one, i.e.,

$$g(x, y) = \text{median}\{f(x - k, y - l), (k, l \in W)\} \quad (2)$$

The median filtering not only preferably protects the image edge information, but also has a better effect for many random noises, especially for the pulse noise because the darker or brighter points

among the pixel domain are forcibly converted into the median brightness for the $n \times n$ median filter and simultaneously wipes out the isolated pixels set, whose domain is less than $n^2/2$.

3.2 Mean filtering

The mean filtering can also be named as linear mean filtering and its fundamental is to mask the gray scale of all pixels by filtering to take the place of the gray scale of the pixels, i.e., using the gray

(a) Containing Gaussian noise

(b) After median filtering

(c) After mean filtering

Figure 2. Experimental effects using different filtering algorithms.

scale mean of deleted neighborhood S to take the place of every pixel gray scale:

$$g(x, y) = \frac{1}{M} \sum_{(i,j) \in S} f(i, j) \quad (3)$$

where $f(i, j)$ is the original image, $g(x, y)$ is the smoothed image, M is the pixel number in the deleted neighborhood S .

Although the mean filtering has a noteworthy effect by processing Gaussian noise, it often weakens the gradient change of the image gray scale and causes the blurred edges, and even weakens the effective feature in identification. Therefore, the sharpening process must be conducted in order to deepen the image edges after the mean filtering.

The most transient noise of infrared imagery belongs to the Gaussian one. The probability density function of the Gaussian random variable is

$$p(z) = \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{(z-\mu)^2}{2\sigma^2}} \quad (4)$$

where z is the gray scale, μ is the expectation of z and σ is the standard deviation of z .

The infrared tank imagery containing Gaussian noise was processed by two noise linear algorithms and the experimental results were shown as in Figure 2. Here, the radius of the filtering window was and σ was 10.

It can be seen from Figure 2 that median filtering has a better effect than the mean one in the aspect of restraining the Gaussian noise, but meanwhile, both methods delete the part detail and cause image edge information deficiency to some degree.

4 INTEGRATED FILTERING

The infrared imagery often contains both Gaussian noise and salt and pepper. It can be known from the above that the median and mean filtering have different effects when processing different noises, but the two methods have certain limits, i.e., weakening the image edge information and covering up some feature deficiencies of the target. In order to overcome their deficiency, i.e., protecting useful information (such as edge information), an integrated filtering method will be proposed to apply different denoising methods according to different noises.

The noise testing, a primary task of the integrated filter is the first and also key step and it lays the foundation for correct classification of the pixel points in the image and creates conditions for further denoising. The main principle of noise testing classification can be described as follows: the

pixel points in the image can be classified into three types below according to the gray scale of salt and pepper noise staying in the extreme black (less than 10) or the extreme white (more than 245) scopes: the pixel value of more than 245 is extreme white point, that of less than 10 is extreme black point, and that between 10 and 245 is a common point.

The methods used to judge extreme black or white points is to pick up the masking template of 5×5 , and transverse the whole image and $X(x, y)$ is the center pixel point of this window. When $X(x, y) < 10$ or $X(x, y) > 245$, calculate the number of common pixels in the sliding window. If the number is larger than the threshold value, then this point will be the one of salt and pepper noise. The salt and pepper noise points of the image will be conducted with median filtering of the masking of 3×3 while the other points will be done with mean filtering in the same way. The main advantages of this method are to restrain the noise when using a 5×5 sliding window to classify the noise while assuring not to weaken the image edge information when using the masking of 3×3 as far as possible.

5 RESULTS AND DISCUSSION

The Gaussian noise with variance 0.005 and the salt and pepper with variance 0.05 were added up to the infrared image to better test the effect of the above denoising algorithm. The experimental results are shown in Figure 3.

It can be seen from Figure 3 that although the mean filtering weakens the noise, the target edges become blurred and the salt and pepper noise is still obvious; the effect of median filtering when processing the salt and pepper noise is obviously better than that of mean filtering; the proposed integrated filtering not only wipes out both the Gaussian and salt and pepper noise but also assures not weakening the image edge information.

6 QUANTITATIVE ANALYSIS OF THE FILTERING EFFECTS

The imagery filtering effect can be analyzed from visual and quantitative views. The quantitative analysis measured by Mean Square Error (MSE) and SNR can be employed if it is difficult to analyze the filtering effect for the visual view. For a specified image, less the MSE and bigger the SNR after filtering, the better the denoising effect.

MSE can be defined as

$$MSE = \sqrt{\frac{1}{N} \sum_{i=1}^N (x(i) - \hat{x}(i))^2} \quad (5)$$

(a) Adding up noise

(b) After median filtering

(c) After mean filtering

(d) After integrated filtering

Figure 3. Denoising effects contrasting the different filtering methods of infrared imagery.

SNR can be defined as

$$SNR = 10 \log \left[\frac{\sum_{i=1}^N (x(i))^2}{\sum_{i=1}^N (x(i) - \hat{x}(i))^2} \right] \quad (6)$$

where N is the point of data, $x(i)$ and $\hat{x}(i)$ are original data and processed ones.

Figure 4 shows the visual effects contrasting of different denoising infrared imagery under better meteorological conditions. The definition of

(a) Directly collecting using CCD

(b) Median filtering

(c) Mean filtering

(d) Integrated filtering

Figure 4. Visual effects contrasting different denoising of infrared imagery.

the four pictures has a unobvious difference from visual view.

However, the describing filtering effect by SNR and MSE has an obvious difference from quantitative analysis. The filtering data of the three methods are shown in Table 1.

It can be seen from Table 1 that the denoising effect of the proposed integrated filtering is best contrasting the median and mean filtering based on the calculated results of SNR and MSE from the quantitative view.

Table 1. Filtering data contrast of three methods shown in Figure 4.

Filtering methods	SNR/dB	MSE
Median filtering	37.788	12.55
Mean filtering	38.279	11.59
Integrated filtering	40.635	6.38

7 CONCLUSIONS

The infrared imagery noise can be approximately regarded as mainly consisting of Gaussian noise with the addition of some salt and pepper noise, so pre-processing filter mostly aims at these two noises. The noise characteristics of the infrared image were discussed, as well as the median and mean filtering, two classic methods. An integrated filtering method was proposed based on analyzing the advantages and disadvantages of the two methods to effectively filter the mixed noise of Gaussian and salt and pepper. The experimental results and quantitative analysis showed that the proposed method has an

excellent restraining effect for mixed noise and the SNR of the target image gets a remarkable enhancement and the background noise level is also effectively restrained after denoising, which creates a strong premise for infrared target testing.

Feature optimization approach to improve performance for big data

Hua Zhu

College of Engineering, University of Michigan, Ann Arbor, MI, USA

ABSTRACT: The rapid growth of data has become a serious challenge and valuable opportunity for many industries. So, feature optimization approaches are important for large-scale complex data processing to maintain the original characteristics of the feature space. Feature selection, as a field of feature optimization, contains filter, wrapper, and embedded models, which can eliminate outliers and reduce the dimensionality. After feature selection, the data analysis takes less time and uses less computing resources. In this paper, different kinds of feature optimization methods are introduced.

1 INTRODUCTION

In big data, a large amount of data needs to be analyzed, which costs much time and computation. So some methods are used to reduce data size, simplify machine learning models, and improve performance. In this motivation, feature optimization approaches are widely adopted to reduce data dimension, which makes the model more transparent and more comprehensible and provide a better explanation of the system model.

Feature optimization approaches are divided into many kinds based on different angles containing high-dimensional reduction and feature selection. High-dimensional reduction refers to a mapping method that maps data points in the original high dimensional space to the low dimensional space. High-dimensional reduction approaches include Principal Component Analysis, Linear Discriminant Analysis, Isomap, Local Linear Embedding, Laplacian Eigenmaps, Local Preserving Projection, and Maximum Variance Unfolding (Liu et al. 2010). Meanwhile, feature selection does not change the original feature space, it only selects a part of the important features from the original high-dimensional feature space to a new low-dimensional space. According to the working order between feature selection algorithms with machine learning classifications, feature selection methods can be divided into three categories such as filter, wrapper, and embedded methods (Guyon and Elisseeff 2003).

A lot of research have proven that feature optimization approaches can effectively eliminate irrelevant and redundant features. The result of feature optimization approaches also enhances the understanding of results of the study. On the other hand, research results show that the performance of feature selection methods is better than that of high-dimensional reduction methods (Yu and Liu 2003).

Therefore, in this paper, we emphasize feature selection methods which can improve the efficiency of mining tasks and the performance of prediction.

2 FEATURE OPTIMIZATION APPROACHES

Feature selection is often viewed as a search problem in a space of feature subsets, which is divided into three categories: filter, wrapper, and embedded models. Filter model analyzes the general characteristics of features and calculates its relevance without involving any machine learning algorithm, such as Information Gain (IG) and Chi-squared Test (CHI) (Yang 1997). The wrapper model combines a predetermined learning algorithm and identifies the best features in the optimization process to fit the performance, such as Particle Swarm Optimization (PSO) (Duch et al. 2004). The embedded model incorporates feature selection as a step in the learning process, such as Decision Tree (DT), which splits training recording into successively purer subsets based on IG (Lin et al. 2008).

2.1 Chi-squared test

The calculation process of Chi-squared Test (CHI) is based on the theory of hypothesis testing in Statistics. At first, assuming features and categories are not related directly, then the deviation of observed value and expected value are calculated. If the deviation is bigger, the original hypothesis is denied (Forman 2003).

In the sample set, N is the size of samples, and A is the number of samples with feature x existing and belonging to category y_k . B is the number of samples with feature x existing but not belonging

to category y_k . C is the number of samples with feature x existing but belonging to category y_k . D is the number of samples with feature x neither existing nor belonging to category y_k and $N = A + B + C + D$. A , B , C , and D are observed value, while E_A , E_B , E_C , and E_D are the corresponding expected value.

The function for CHI is:

$$E_A = \frac{(A+B)(A+C)}{n}, \quad E_B = \frac{(A+B)(B+D)}{n}$$

$$E_C = \frac{(C+D)(A+C)}{n}, \quad E_D = \frac{(C+D)(B+D)}{n}$$

$$\chi^2(x, y) = \sum \frac{(\text{observed} - \text{expected})^2}{\text{expected}}$$

$$= \frac{(A - E_A)^2}{E_A} + \frac{(B - E_B)^2}{E_B}$$

$$+ \frac{(C - E_C)^2}{E_C} + \frac{(D - E_D)^2}{E_D}$$

$$= \frac{N(A * D - C * B)}{(A+C)(B+D)(A+B)(C+D)}$$

According to the deviation between theoretical value and practical value sorted in descending order, we can get the best features which have a strong correlation with categories.

2.2 Particle Swarm Optimization

Particle Swarm Optimization (PSO) is a random optimization method based on population (called a swarm). These particles move around in space according to their own best position and the entire swarm's best-known position. When improved positions are being discovered, conversely, the optimization result can guide the movement of the swarm. The process is repeated until the recycling conditions are satisfied (Kennedy 2011, Wang et al. 2007). PSO is used to select the best features from all features by fitting high detection accuracy.

Let the number of particles be S , and each has a position $x_i \in X$ and a velocity v_i in the sample space. The search termination condition is set as iteration number. The process of the algorithm is as follows:

Initialization: The position of the particle is created with a uniform matrix. The value of every element is limited to the boundary of the feature space. The velocity of particles is defined by the likely position.

Building Fitness: Fitness is defined to value the current result of the particle. In this work, the detection accuracy of the training set is treated as fitness.

Finding optimal positions: Comparing fitness and optimal position history to find the optimal

position p_i of every particle and global optimal position p_{gi} of all particles.

Updating position and velocity: According to the following functions:

$$v_i = w \cdot v_i + c_1 \cdot \text{rand}() \cdot (p_i - x_i)$$

$$+ c_2 \cdot \text{rand}() \cdot (p_{gi} - x_{gi})$$

$$x_i = x_i + p_i$$

where w is the inertia weight coefficient which balances global search ability and local search ability c_1 and c_2 are learning factors which control particle movement to global optimal positions and local optimal positions, usually $w \in [0.9, 1.2]$ and $c_1 = c_2 = 2$.

Optimization termination condition: Looping number is usually defined as termination condition of the particle finding optimal positions. The value can be taken as less than 200.

2.3 Decision Tree

Decision Tree (DT) classifiers use a tree structure for making predictions. The internal nodes of the tree represent a feature and the leaf nodes represent the ultimate decision result of the algorithm (Tan et al. 2006). In the decision tree, each internal node is labeled with an input feature. DT is considered based on a set of if-then decision rules. The deeper the tree, the more complex are the decision rules and fitter is the model.

A decision tree is constructed in a recursive partitioning by splitting the training records into successively purer subsets based on Information Gain (IG) to select the best features. When the nodes are assigned to the same value of the target variable or values are no longer added to the prediction, then the recursion is completed. Let D_t be the set of training features that are associated with note t and $y = \{y_1, y_2, \dots, y_n\}$ be the class labels. The process of DT is as following:

Step 1: if all instances in the dataset D_t belong to the same class y_t , then t is a leaf node which is labeled as y_t .

Step 2: if D_t contains records belonging to less than one class, an attribute test condition is selected to partition the records into smaller subsets. Then the records in D_t are distributed to children based on outcomes. The method is then recursively used to each child node.

DT tends to over-fit on data with a large number of features. However, pruning algorithms are effective to solve this problem, which takes global optimum into consideration. Anyhow, DT is simple to understand and interpret. The result tree can be visualized.

3 EXPERIMENT AND DISCUSSION

Almost in all previous papers, Confusion Matrix and related evaluation metrics, such as accuracy and Area Under the Curve (AUC) are utilized to evaluate and guide the performance of machine learning classifiers. The larger the AUC score or accuracy, the better the classifier performs.

The testing environment is set as Intel(R) Xeon(R) CPU E5-2620v3@2.40GHz with 32.0 GB RAM and 64-bit Windows 7 operating system.

3.1 Sample dataset and features

The dataset is used to make Android malicious application detection, which contains 1260 benign applications and 1210 malicious applications. Benign applications are downloaded from Google Play Store, and malicious applications are collected from the authoritative malicious application Web sites.

After decompiling, the features are extracted from source code files concluding .smali files and AndroidManifest.xml files (Aafer et al. 2013). Totally, we combine 429 permissions and 27,650 APIs as the feature universal set and the number is 28,079. In the next part, we just take the total 28,079 combined permissions and APIs as input data of feature selection models. Then the machine learning models are used to continue analyzing the result data to prove the validity of the feature selection (Peiravian and Zhu 2013).

3.2 Comparison with feature selected methods

IG represents the filter methods' select best features from high-dimension features dataset according to the relevance between features, while PSO representing wrapper methods get the global optimum value to identify the best features according to fitness of the training accuracy of predetermined machine learning algorithm. The selected feature is a subset of all features and in order to enhance the comparability of methods, DT is used as the malware classifier.

Figure 1 shows the accuracy of DT classifier with 100 to 600 features by feature selection methods. The performance of PSO is better than others for classification results. According to the trend of curves, we find that if the number of selected features is big, the accuracy becomes high. Moreover, the the performance of 300 selected features increases faster than all other features. We think 300 features selected by feature selection methods are optimal for machine learning classifiers.

According to the rules of data operation, we know that less number of features will take less time and use less computing resources, and some-

Figure 1. Comparison with filter and wrapper methods.

times we have to lose accuracy to exchange high performance. Just from the accuracy point, PSO is a good choice, but from the efficiency point, CHI outperforms. Therefore, in real-world applications efficiency is an issue. We should measure effectiveness and efficiency to choose feature selection methods.

3.3 Machine learning classification model comparison with feature selection

After feature selection, we can find 300 features selected just thought to be best features. Then we input these features to several machine learning classification models to explore how they affect performance.

Table 1 shows the performance for comparing seven machine learning methods based on feature selection. The difference between the comparing results originates from different processes of machine learning algorithm for data processing. kNN classifier relays on instances with the nearest neighbors which have no solution to outliers, so the performance is not good. While the final result of NB depends on the product of posterior probability from per features, the larger the sample dataset, the smaller is the detection rate. DT constructs the best tree based on the IG index to split the sample space and uses pruning algorithms to avoid the over-fitting problem. LR applies a logistic function to guarantee classification correctly in a training set while regularization is used to avoid over-fitting to ensure high accuracy in the testing set. SVM not only uses a kernel function to map low-dimension space to high-dimension space to improve accuracy but also uses slack variables and penalty factor to deal with noise data. So SVM has high accuracy but takes more time to process data. In order to detect correctly, Adaboost is adapted

Table 1. Machine learning classification model comparison with feature selection.

	kNN	NB	DT	LR	SVM	Adaboost	k-Means
Accuracy	0.9130	0.792	0.9356	0.9574	0.9434	0.9607	0.5104
AUC	0.9342	0.8436	0.9562	0.9698	0.9602	0.9815	0.5218
TPR	0.9429	0.8941	0.9715	0.9783	0.9773	0.9885	0.6510

to learn a series of weak classifiers to generate a boosted one. This process is so complex and loops many times and takes more time. In sum, DT, LR, SVM, and Adaboost all adopt appropriate strategies to solve the over-fitting problem so that test detection accuracies are higher while kNN and NB do nothing.

On the other hand, the performance of supervised learning methods is better than unsupervised learning methods like k-Means. It is mainly because class label used in supervised learning methods is helpful to classification while unsupervised learning methods do not pay attention to the class label. In fact, class label is a valuable information for classification. Therefore, supervised learning methods are recommended to use in the real world.

4 CONCLUSION

Feature selection methods containing filter, wrapper, and embedded models are used to eliminate outliers and reduce the amount of input data of machine learning models. Experiment results indicate that feature selection methods can improve efficiency and performance of machine learning classifiers. On the other hand, according to the rules of data operation, we know that less number of features will take less time and use less computing resources, but sometimes we have to lose accuracy to exchange high performance. Just from the accuracy point, PSO is a good choice, but from the efficiency point, CHI outperforms them. Therefore, in real-world applications efficiency is an issue. We should measure effectiveness and efficiency to choose feature selection methods.

Influence research on file of software defective testing configuration

Yangxin Yu & Liuyang Wang

Faculty of Computer and Software Engineering, Huaiyin Institute of Technology, Huai'an, China

ABSTRACT: Software defect testing technology is important means to find and remove software defects. Software defect detection is a part of software inspection process. Software reading techniques could be used by software inspectors in detecting defect from object-oriented design documents. Around the software defect detection, this paper deeply analyzes the strengths and weaknesses of current popular software defect testing technology and the key problems. Traceability-based reading technique was one of the scenario-based reading techniques which had been empirically validated to help software inspectors detect defects more effectively than the widely used checklist based reading technique due to its readability. This study was to discover whether software inspectors with different background can perform defect detection differently using Traceability-based reading technique. The result showed that software inspectors with different undergraduate degrees, undergraduate object oriented courses taken, and object-oriented work experience do not perform defect detection significantly differently.

1 INTRODUCTION

A majority of software inspection research has been on the technical view of software inspection. Software reading technique for defect detection was one of the main issues (Cataldo, 2009). These software reading techniques can be used on software artifact including software requirement, software design, and code.

Among the proposed reading techniques for object-oriented design documents, Ad hoc and Checklist-Based Reading (CBR) have been adopted in industrial practices, while the others, known as Scenario-based reading techniques including Defect-based reading (Andre B.de Carvalho, 2010), Perspective-Based Reading (PBR) (Chang Tiantian, 2009), Usage-based reading (Abel GarciaNajera, 2010), and Traceability-based reading (Chun Shan, 2014), have been validated empirically and experimentally.

A number of empirical researches comparing scenario-based reading techniques to Checklist-Based Reading (CBR) techniques or Ad hoc technique provided promising results (Elaine J, 2010). However, the results are not completely consistent. Most scenario-based reading techniques were claimed to provide more effectiveness of defect detection than Checklist-Based Reading (CBR) technique.

As defect detection in early stage in software development lifecycle is less cost to repair in later stages (Joel Lehman, 2011), software reading techniques can be applied to object oriented design and requirement for defect detection. Most of scenario-based reading techniques for

object-oriented design require some training on how to use the reading for the inspectors. Some experiments include a whole day subject training in the experimental protocol.

Object-oriented design specifications usually contain UML diagrams and descriptions, as well as descriptive requirement. Thus, object oriented software inspectors should understand the UML diagrams well enough. Traceability-based reading technique (Marco D'Ambros, 2012) allows inspectors to check whether the design corresponds to the requirements using vertical and horizontal reading. This reading technique provides software inspectors with steps on where and how to find defects in object oriented design documents.

Most students with software-related undergraduate degrees have taken at least one object-oriented course during their undergraduate study. These students should be ready to become software inspectors after graduation. With the software reading containing clear instructions, there should be a small amount of training on defect detection. With a readable reading technique such as Traceability-based reading technique, prior training and experience may not be necessary for a software inspector in defect detection on object-oriented design documents.

2 TRACEABILITY-BASED READING TECHNIQUE

This technique was specifically developed for object-oriented design document inspection (Nathalia Cristina Torres Mariani, 2014).

The main purpose of this technique is to ensure consistency and completeness of the work product. This reading technique covers horizontal readings, for checking the different design artifacts against each other, and vertical readings, checking whether the design corresponds to the requirements.

There are seven readings in a set of Traceability-based reading technique. Each reading asked inspectors to read specific design documents together, the steps to read them, and where and how to find defects in each step. The seven readings are:

Horizontal Review

- Class Diagrams with respect to Class Descriptions
- Class Diagrams with respect to State Machine Diagrams
- Interaction (Sequence) Diagrams with respect to State Diagrams
- Interaction (Sequence) Diagrams with respect to Class

Vertical Review

- Class Descriptions with respect to Requirements Description
- Interaction (Sequence) Diagrams with respect to Use cases
- State Diagrams with respect to Requirements Description and Use cases Diagrams

It was claimed that Traceability-based reading technique can help user without experience in software inspection through defect detection process in software reading.

3 EXPERIMENTAL PLANNING

3.1 Goals of the study

This study aims at discovering how inspectors of the different object oriented background perform defect detection using Traceability-based reading technique, namely OORT (Object-Oriented Reading Technique) (Chang Tiantian, 2009). The software inspector's object oriented backgrounds include undergraduate degree earned, undergraduate object-oriented courses taken, undergraduate degree performance, and object-oriented work experience.

3.2 Subjects

The subjects were 29 undergraduate students in Information Technology in Business Program at Huaiyin Institute of Technology. The students holding any Bachelor degree with at least 12 credits in information technology or statistics or

mathematics were qualified for admission to this program. The students in this program have common interest in pursuing a career in Information technology with different background in their undergraduate degrees ranging from social science to sciences.

An object-oriented analysis and design course is one of the core courses in the first year in the program. Prior to this course, students either have some undergraduate courses in object-oriented programming, object-oriented analysis and design, or software engineering, or none. Some students might have been working prior to admission to the program or just graduated.

3.3 Object-oriented design documents

The design document in this study was a car rental application consisting of requirement specification, use case diagram and description, class diagram and class description, sequence diagram, and state diagram modified from the prior study (Nagalakshmi, 2012). There were 23 seed defects put in the design document.

As defect detection in software designs had identified a defect classification scheme for object-oriented design in 5 classifications (Song Qinbao, 2011).

Omission: One or more design diagrams that should contain some concepts from the general requirements or from the requirement document do not contain a representation for that concept.

Incorrect Fact: A design diagram contains a misrepresentation of a concept described in the general requirements or requirement document.

Inconsistency: A representation of a concept in one design diagram disagrees with a representation of the same concept in either the same or another design diagram.

Ambiguity: A representation of a concept in the design is unclear, and could cause a user of the document (developer, low-level designer, etc.) to misinterpret or misunderstand the meaning of the concept.

Extraneous Information: The design includes information that, while perhaps true, does not apply to this domain and should not be included in the design.

To determine appropriate seed defects in the design document for this study, twelve object oriented student group project design documents were inspected to analyze the highest frequently defect subtype occurrence in each defect classification. Incorrect fact and extraneous information were the defect classification found least from the twelve object oriented student group project design documents inspected. A variety of seed defects were placed into the design document in

Table 1. Number of seed defects in design document.

Defect classification	Number of seed defect
Omission	5
Incorrect Fact	1
Inconsistency	5
Ambiguity	5
Extraneous Information	1
Total	17

this study according to the subtype of each defect classification.

However, there were defects that can be detected due to the main defect. For example, when a class was missing from a class diagram, attributes, methods, and associations of the missing class were also missing from the design and thus detected as Omission and Inconsistency type of defect classification, respectively. In this study, a missing class defect leads to additional 4 Omission defects and 2 Inconsistency defects.

3.4 Instructions to defect detection

This study adopted the OORT (Object-Oriented Reading Technique) (Chang Tiantian, 2009) that was translated into Chinese language in prior study (Nathalia Cristina Torres Mariani, 2014). A comparison on the effectiveness of the subjects using a full set of readings and subject using only four readings of the reading technique, Sequence Diagrams with respect to class, Sequence Diagrams with respect to State Diagrams, class descriptions with respect to requirements description, and Sequence Diagrams with respect to use cases was conducted to offer a way to reduce inspection time (Joel Lehman, 2011). It was found that the number of defect detected using the full set of readings and the reduced set were not significantly different. It was also found that the efficiency rate per defect detected of subjects using the reduced set was higher (Song Qinbao, 2011). Therefore, the reduced set of the readings was used in this study.

The experiment was conducted at the beginning of first object-oriented course at the graduate level. At the beginning of the experiment, subjects were asked to answer demographic data questionnaire, such as their undergraduate degree title, the number of undergraduate object oriented courses taken, and years of work experience after graduation.

Each subject was given four sets of documents to work on: a set of design document, a set of reading instruction, a worksheet to record the defects detected, and a description of UML notation. The subjects were given to complete the task in their own time.

3.5 Hypothesis

This study was intended to discover the effect of the software inspector profiles on their performance in defect detection in object oriented design documents. The software inspector profile included undergraduate degree, undergraduate object oriented courses taken, undergraduate performance, and object oriented working experience.

The software inspector's performance in defect detection in object oriented design documents included the number of defect detected in object oriented design documents using Traceability-based reading technique.

Hypothesis 1: The software inspectors with software-related undergraduate degree perform differently in defect detection to the software inspectors with other undergraduate degrees.

Hypothesis 2: The software inspectors taken at least one object-oriented undergraduate course perform differently in defect detection to the software inspectors with no object-oriented undergraduate course.

Hypothesis 3: The software inspectors with higher undergraduate Grade Point Average (GPA) perform differently in defect detection to the software inspectors with lower undergraduate grades.

Hypothesis 4: The software inspectors with object-oriented work experience can detect different number of defects to the software inspectors with no object-oriented work experience.

3.6 Procedure

The subjects were given a questionnaire asking for their profiles on work experience, undergraduate degree, and courses taken. These questionnaires were filled out before any of the inspection tasks began. The subjects were given no time limitation to inspect the design documents. Once they detected a defect, they filled out the defect detection report indicating where (which design document) that defects were detected and description of the defects. The task were given out the subjects in the first class of object oriented analysis and design course offering in the first semester of the program. In this first class, only object-oriented concept was given to the subjects.

4 EXPERIMENTAL RESULT

The summary report of defect detection behavior from this study was shown in Table 2.

When looking at the number of defect detected by individual subjects by their degree earned (software-related and non software-related), the result

Table 2. Defect detection behavior of subjects in the study.

Defect classification	No of defects NOT detected by any subjects	Average percentage of subjects that were able to detect defects
1. Omission	2 out of 9	27.72
2. Incorrect Fact	0 out of 1	6.90
3. Inconsistency	2 out of 7	40.89
4. Ambiguity	0 out of 5	24.83
5. Extraneous Information	1 out of 1	0.00

Table 3. T-test analysis comparing the number of defect detected by the subjects undergraduate degree.

	N	Mean	Std. Dev	Sig (2-tail)
Software-related undergraduate degree holders	20	7.7	2.96	0.08
Non software-related undergraduate degree holders	9	5.44	3.36	

is shown in Table 3. It can be concluded that the undergraduate degree does not differ the subject performances in the number of defect detected in object-oriented design document inspection.

The number of defect detected for each individual subject was counted regardless of defect classification. The average number of defect detected by 29 subjects was 7.0 with the highest number of defect detected of 14 defects and the lowest number of defect detected of one defect.

The result in Table 3 also indicated that the defect detection performance of the subjects with software-related undergraduate degree might be different from the performance of the subjects with other undergraduate degree at the level of significance of 90%. Therefore, looking into whether the subjects had taken any object-oriented undergraduate course might be a better analysis to prove the hypothesis 1.

When comparing the number of defect detected by individual of the subject's taking undergraduate object-oriented courses (such as object-oriented programming, object-oriented analysis and design, object-oriented technology), it can be seen in Table 4 that there is no significant difference in defect detection performance between subjects with at least one undergraduate object-oriented courses to subject with no undergraduate object-oriented course. Further analysis confirmed that no matter how many undergraduate object-oriented courses the subjects took does not differ in the subjects' performance in defect detection.

Table 4. The T-test analysis on the number of defect detected by the subjects with and without undergraduate object-oriented course taken.

	N	Mean	Std. Dev	Sig (2-tail)
At least 1 undergraduate OO course taken	18	7.61	3.35	.194
No undergraduate OO course taken	11	6.00	2.83	

Table 5. The t-test analysis on the number of defect detected by the subjects with different undergraduate degree performance.

	N	Mean	Std. Dev	Sig (2-tail)
Undergraduate GPA higher than or equal to 3.0	10	8.7	2.91	0.036*
Undergraduate GPA under 3.0	19	6.11	3.05	

Table 6. T-test analysis on the number of defect detected by the subjects with and without undergraduate object-oriented experience.

	N	Mean	Std. Dev	Sig (2-tail)
Undergraduate GPA higher than or equal to 3.0	11	8.27	2.83	0.150
Undergraduate GPA under 3.0	18	6.59	2.93	

The subjects participating in this study had an average undergraduate grade point average of 2.85. When comparing the number of defect detected by individual of the subject's undergraduate degree performance using grade point average, it can be seen in Table 5 that subjects with higher undergraduate degree performance (Grade Point Average or GPA of higher than or equal to 3.00) can detect defects in design document at a higher rate.

The subjects participating in this study had at least 3 years of experience with an average of 5.2 years. When counting the number of defect detected by subjects with the difference work experience (with object-oriented work experience and with no object-oriented work experience), it can be seen that the object-oriented work experience does not differ the subjects' performance in defect detection at the significant level of 95% as seen in Table 6.

Although only undergraduate GPA significantly indicates the difference in defect detection

performance, work experience, undergraduate object oriented courses taken and software-related degree encourage higher average number of defect detected. It is yet to be further analyzed that how much of the object oriented work experience, undergraduate object oriented courses taken significantly improve defect detection performance.

5 CONCLUSION

It can be concluded that the software inspectors with software-related undergraduate degrees, undergraduate object oriented courses taken, and object-oriented work experience do not perform defect detection significantly differently. However, the software inspectors with higher undergraduate performance perform significantly better in defect detection on object oriented design documents.

Traceability-based reading technique can be used for the newly recruited software inspectors with or without prior object-oriented profiles during training. However, the average defect detection performance of these subjects in this study was not high, especially on extraneous information and incorrect fact classification of defects.

Webpage automatic summary extraction based on term frequency

Yangxin Yu & Liuyang Wang

Faculty of Computer and Software Engineering, Huaiyin Institute of Technology, Huai'an, China

ABSTRACT: Document automatic summary is an important research in the field of natural language understanding. Search engines are used nowadays by all Internet users. Keyword selection is a fast-growing industry in which different tools are used by companies to suggest their webpage's keywords. The research goal of the web automatic summarization technology is to solve this problem directly to provide a concise and comprehensive information page content summary to the user, in order to improve the efficiency of user access to information. It is important to understand how different search engines would choose a webpage in search results based on a user's query. The paper's aim is to propose a method that suggests the keywords of a webpage based on frequent terms. The method used in this paper is the term frequency for defining frequent terms. An experiment is executed to validate the method results, and the result of the new method is compared with the Google AdWord tool. The accuracy of the proposed method is 82.4%, which is considered to be a promising result. The experimental results show that the judgment and readability of web page content in this system were superior to the general web page design of automatic summarization.

1 INTRODUCTION

With the rapid development of the Internet, a variety of data on the Web has increased dramatically. The network has become a potential source of data warehouse and knowledge. Keyword selection is used in many applications as an example of preprocessing, text classification, web mining, semantic web, and sponsored search. Semantically, keyword extension would allow improving the quality of selected keywords.

The technology will automatically document content in a simple way, when the information retrieval technology is developed to a certain degree of natural extension. Online advertising depends mainly on text advertising since advertisers should aim to increase the volume of bid phrases and also choose the most relevant phrases for their products, otherwise online users would not click on the ad that transfers them to the purchase page of the product or the service being promoted.

The proposed approach is divided into four steps. First, loading and parsing the webpage into tokenizes (small pieces). Second, removing the stop words from the list of terms extracted from the parser, and then the third step is stemming the terms to return to the word's stem. Finally, the list of terms and their frequency is extracted from the proposed system.

The rest of the paper is organized as follows. First, the author describes the problem. Then, previous work related to keyword selection is listed.

After that, the proposed method is presented; the next part will describe the system snapshots. Finally, the proposed method's performance is evaluated on the available dataset and results discussed. The paper conclusion includes benefits of the proposed approach and directions for future work.

2 RELATED WORK

2.1 *Keyword suggestion concept*

The process of keyword suggestion is so important for different fields, e.g., semantic web, data mining, natural language process, and advertising. Advertising companies use different tools that suggest the keyword. This step is very important since the most appropriate keywords could maximize their profit using the click-through rates (A. Joshi, 2006).

Keyword suggestion can be classified into proximity search, query log mining, and meta-tag spidering. Proximity search methods extract terms from the search engine's result pages that already exist in the search term.

The second type is the query log mining method. This method suggests past queries containing the search term. The Google AdWords tool and the Yahoo Search Marketing tool are known examples of this method (Dongqing Zhu, 2010).

The last method which is the meta-tag spidering method uses the engine with the seed and extracts meta-tags from the best suggestion ranking.

This method is considered to be of a lower quality than other methods (G. Chen, 2008). Using the semantic meaning of different words and extending keywords by semantically related phrases could be used by the advertiser’s website.

2.2 Keyword suggestion applications

Advertising companies use research studies to reach more profitable levels. Research studies investigate the suggestion keyword tools. Semantically related phrases can be extracted from any webpage and used to define the most important keyword to represent this webpage. It is very important to extract the keyword list that is less common but also most representative of a webpage. This can be achieved by defining the most similar words semantically by using the statistical occurrence methods.

The structure of the website can be improved by rearranging links between pages (H. Zahera, 2010). The text content can also be improved by identifying the most relevant keywords. These relevant keywords are extracted using Term Frequency-Inverse Document Frequency (TF-IDF).

The list of keywords that represent a specific webpage/document could be extracted not only by statistical methods but also using the conceptual similarity knowledge (Dongqing Zhu, 2010). In (J. Alpa, 2010) a novel approach proposed, called TermNet, the semantic relationships can be designed as a directed graph for defining the relevant terms extracted from a webpage.

Search engine results depend on a query or keyword; sometimes users do not use the right or specific keyword to reach the search goal (Jaime Arguello, 2011). Query recommendation systems are used to help the user reach his goal by suggesting some keywords that were used previously by the user or others (user log). Another way is to use the help of an information source or a thesaurus (J. Velasquez, 2004).

One of the well-known previous researchers who worked in online advertising proposed a method for phrase extraction for advertising purposes using HTML tags, TF-IDF, and query logs (L. Mostafa, 2009). Open Information Extraction (OIE) focuses on domain independent and scalable extraction of terms without requiring human input. S. Ravi, 2010 proposes a model of OIE over search query logs where clusters generated from the query logs can be very effective in web search.

2.3 Keyword suggestion tools

For the purpose of online advertising, different keyword suggestion tools also known as Bidterm suggestion tools (V. Abhishek, 2007) are used (Yuelin Li, 2010). Online advertisers bid on key-

words through auctions. The winner of the auction can put his ad and links on the search result page of the search company when querying the Bidterm (L. Mostafa, 2009). However, these tools are commercial tools and sometimes their result is not related to the required target (Yuelin Li, 2010).

Also, keyword selection tools are used by different search engines to provide relevant search results as a response to a user query.

The Google AdWords tool can be used for keyword selection purposes (A. Joshi, 2006). However, the drawback of this tool is the proximity based searches in which the keyword extracted must be listed as a search term.

Some systems solve the problem by adopting a strategy similar to proximity search, but using the result pages to build a bag of word vectors for the seed, and then suggest keywords that have a similar vector (H. Zahera, 2010).

3 PROPOSED APPROACH

This study aims at discovering how inspectors of the different object-oriented background perform defect detection using traceability-based reading technique namely Object-Oriented Reading Technique (OORT) (L. Li, 2008). The software inspector’s object-oriented backgrounds include undergraduate degree earned, undergraduate object-oriented courses taken, undergraduate degree performance, and object-oriented work experience.

The steps of the proposed method pass through three main modules, which are loader, parser, stopword remover, and stemmer, as shown in Figure 1. The input of the proposed approach is the webpage and the output is the list of words and their frequencies. The following figure shows the proposed approach framework.

3.1 Proposed approach phases

The parser module is the first step in which a parser is a program that breaks large units of data

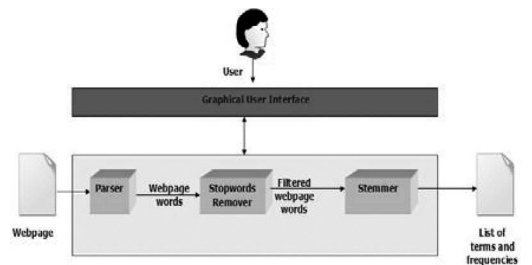

Figure 1. Proposed approach—three phases which include a parser, stopword remover, and stemmer.

into smaller pieces called tokens. After the webpage is fed to the system, the parser divides it into tokens. The output of the parser phase is the list of words in the webpage. The second phase is the stopword remover.

Stopwords are common words that carry less important meaning than the keywords. Usually, search engineers remove stopwords from a keyword phrase to return the most relevant result. Examples of stopwords are: the, an, a, are.

Different stopword removers can be used as PorterStemAnalyzer (L. Mostafa, 2009). The proposed approach uses Lucene English Stopwords removal (Lucene, 2011a) as it includes most of the existing stopwords list.

After removing the stopwords from the list of keywords, the relevant words can be discovered. The stemmer can then start working on these words.

Stemming is the process of reducing inflected or sometimes derived words to their stem, base or root form, e.g., education to educate. The process of stemming is important for search engines, query expansion or indexing, and natural language processing problems.

Different stemming algorithms can be used such as Porter stemming (2011b), Lovins stemming algorithm (2011c) and Krovetz stemming algorithm (2011d). One of the most used stemmers is the Snowball Stemmer (2011e). This stemmer is used in the proposed framework.

The output of the stemmer phase is terms with their frequencies. It is important to count the frequency of the terms so that terms with the highest frequency are considered as being one of the keywords of the webpage.

3.2 Approach tools

For preprocessing and extraction of keywords, an application was developed using the Java language environment that includes Java Integrated Development Environment (IDE), which is NetBeans and the Java virtual machine.

The stemming algorithm is a process for removing the commoner morphological and inflexional endings from words in English. Its main use is as part of a term normalization process that is usually done when setting up information retrieval systems. The stemmer used is Snowball Stemmer. The stopwords remover used is Lucene English stopwords removal (Lucien, 2011a).

4 PROPOSED APPROACH SYSTEM

The proposed framework is implemented using Java, a well-known object-oriented language.

Different modules were added, e.g., Snowball Stemmer. This section will describe the created system snapshots. The following figures will show the system's sequence.

The first step is feeding the webpage URL to the system, as described in the following Figure 2.

The second step as explained in the proposed approach section is parsing, stopword removal, and stemming. This step is shown in Figure 3.

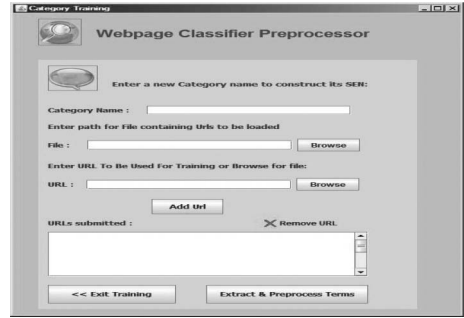

Figure 2. The system screen in which the user can insert the webpage URL.

Figure 3. The loading screen that represents steps of Parsing, Removal, and Stemming.

Figure 4. The last step of the proposed system that shows the output represented in a list of terms and their frequencies.

Figure 4 shows the last step which contains the list of terms and their frequencies.

5 EVALUATION AND TEST RESULTS

5.1 Experiment design

The goal of the experiment is to validate the result of the proposed approach by measuring the F-measure and accuracy level. The proposed method compares its keywords suggestion to Google AdWords keywords. The method suggests three keywords that can be used for webpage search query.

The experiment design was mainly divided into two parts. The first part examines F-measure (precision and recall); the second defines the accuracy of the proposed approach.

The F-measure is a combination of precision (the percentage of positive predictions that are correct) and the recall (the percentage of positively labeled instances that were predicted as positive).

To calculate the F-measure, it is required to compute the precision and recall values. The following equations (1) are used for this purpose.

$$\text{recall} = \frac{\text{number of relevant items retrieved}}{\text{number of relevant items in collection}} \quad (1)$$

$$\text{precision} = \frac{\text{number of relevant items retrieved}}{\text{total number of items retrieved}} \quad (2)$$

$$F_1(r, p) = \frac{2rp}{r + p} \quad (3)$$

To accomplish the experiment design, a dataset for webpages should be used. The DMOZ2 dataset (Open Directory) is used for this purpose. DMOZ or The Open Directory Project is the largest, most comprehensive human-edited directory of the Web. It is constructed and maintained by a global community of volunteer editors. The Open Directory was founded in the spirit of the Open Source movement and is the only major directory that is 100% free. The dataset used consists of 50 webpages of shopping domain extracted from the DMOZ dataset.

5.2 Experimental results

For the purpose of defining the proposed approach, validation F-measure is used. Based on the 50 web pages in the dataset, the value of F-measure is 0.7 compared to the Google AdWords keywords as shown in Table 1.

Table 1. F-measure and accuracy values.

Precision	0.5467
Recall	0.8913
F-Measure	0.6777
Accuracy	82.467

The experiment compares each keyword suggested by the proposed approach with the Google AdWord tool. Each correct suggestion will affect the value of precision and recall. After calculating the F-measure, the accuracy level is calculated for the proposed approach validation.

6 CONCLUSION

The paper provides a framework for webpage keyword suggestion; the framework is ready for adding other modules in future work since it is implemented using one of the object-oriented languages, which is Java. The input of the approach is the webpage and the output is a list of keywords suggested.

The process of suggestion in the proposed model depends on the combination of the parser, stop-word removal, and stemmer. After finishing this preprocessing step, the words and their frequency are calculated. The experiment depends on the comparison between each suggested word by the proposed approach and the Google AdWord tool. The accuracy of the proposed approach is measured along with the precision and recall values.

Research and optimization of the layout of F company truck interior workshop based on GA

Wei Jiang, Yanhua Ma & Yuanchao Pan

Institute of Mechanical Science and Engineering, Jilin University, Changchun, China

ABSTRACT: Nowadays, the competition in the manufacturing industry is more and more fierce and a good workshop layout will have a significant impact on enterprise production in all aspects, especially in reducing the logistics intensity and logistics cost, and improving the production efficiency. Based on this background, this paper aimed at studying the improvement of the truck interior workshop layout in F company. During the study, a series of scientific research methods were adopted like F-D, SLP, GA, and AHP. When compared to the initial layout, the results obtained from the optimal layout indicate that the new layout scheme will bring about improvement in efficiency and reduction of resource waste. The process and results of this study have an important practical value for similar research objects.

1 SITUATION ANALYSIS OF F COMPANY TRUCK INTERIOR WORKSHOP

The main content of F company truck interior workshop is conducted truck cab assembly. The interior workshop is mainly composed of A, B, two parallel assembly lines and assembly tasks. The dimensions of the shop interior are 320 m × 50 m, the assembly line length is 236 m and width 4 m. The workshop uses towline car to be assembled and has the characteristics of flexibility. Now, the existing plant layout work units are divided into a total of 16 operating units. The truck interior workshop units are divided and the drawn interior shop layout diagram is as shown in Figure 1.

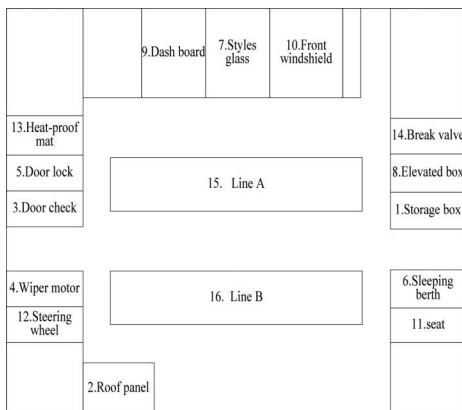

Figure 1. Truck interior existing plant layout.

The truck interior workshop with each work unit size and truck interior part list requirement is presented in Table 1. By the analysis of F Company workshop existing truck interior planar layout, we found out the following problems:

1. The amount of logistics and distance between operating units 1 and the assembly line was relatively large.
2. The amount of logistics produced in the assembly line between operating unit 7 and operating unit 13 was not satisfactory, but far away.

Table 1. Truck interior workshop with each work unit size and truck interior part list requirement.

No.	Name of work unit	Size (m)	Area (m ²)	Number/vehicle
1	Glove box	20 × 4	80	1
2	Top cover	10 × 8	80	1
3	Door stopper	10 × 4	40	1
4	Wiper motor	10 × 4	40	1
5	Door lock	10 × 4	40	2
6	Sleeper	20 × 4	80	2
7	Door glass	10 × 3	30	2
8	Elevated box	20 × 4	80	2
9	Dashboard	10 × 9	90	2
10	Front windshield	10 × 9	90	1
11	Seats	20 × 4	80	2
12	Steering wheel	10 × 4	40	1
13	Insulation pads	10 × 4	40	1
14	Brake valve	20 × 4	80	1
15	A line	236 × 4	944	
16	B line	236 × 4	944	

2 RESEARCH EXISTING LAYOUT USING LAYOUT DESIGN

2.1 The interior of the truck assembly plant in the existing layout analysis using the SLP method

Since A, B, two assembly lines are arranged in two parallels, so the A and B line intensity of superposition analysis of logistics were collected and the logistic capacity is as shown in Table 2.

From the operating units integrated correlation diagram, a truck interior workshop unit position correlation diagram is obtained, as shown in Figure 2.

The combined operating units location map and associated operating units in a conventional layout in the actual area can be arranged in a number of reasonable layout programs. Several programs can be selected to evaluate the optimal solution, but the process of obtaining the candidate program approximately has great subjectivity and limitations and cannot guarantee the optimal layout of the global scope of the program, so this will be the only program as part of the initial population of the genetic algorithm. Based on this conclusion, this paper searched globally to get a real sense of the optimal solution.

Table 2. From the total amount of logistics to the table.

Level B \ Level C	B1	B2	B3	B4	Level C Ordered by the total weight
C1	0.0608	0.0695	0.0974	0.1111	0.0942
C2	0.3531	0.3484	0.5695	0.4444	0.4184
C3	0.5861	0.5821	0.3331	0.4444	0.4873

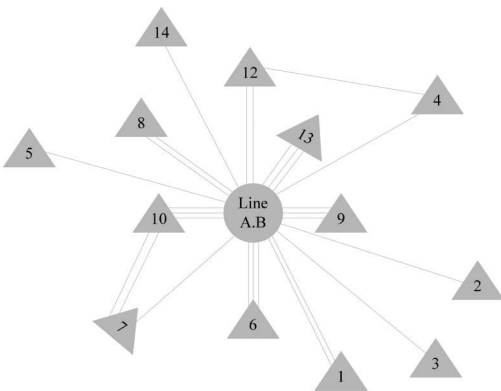

Figure 2. Truck interior workshop unit position correlation diagram.

2.2 The main steps of the truck interior workshop layout optimization procedure using genetic algorithms

1. The establishment of the fitness function
2. Design function constraints
3. The initial population design
4. Determining the coding method
5. Genetic operator design
6. Algorithm termination condition

2.3 The use of MATLAB to achieve genetic algorithm

By the MATLAB operation, this paper got two layout schemes in addition to the original layout, a total of three layout schemes. Next, it selected the best solution by conducting the comparative evaluation, where the original layout was named layout scheme 1, two programs by genetic algorithm are referred to as layout scheme 2 and scheme 3. Scheme 2 is as shown in Figure 3 and scheme 3 is as shown in Figure 4, with the original layout plan shown in Figure 5.

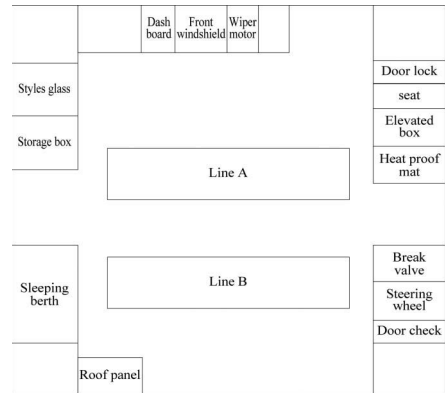

Figure 3. Layout scheme 2.

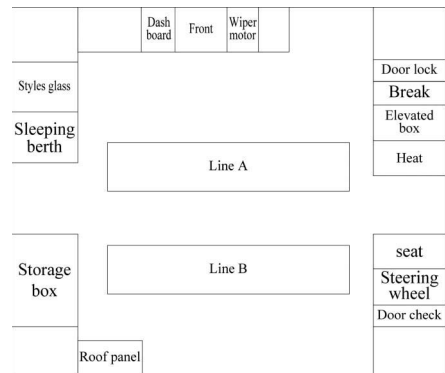

Figure 4. Layout scheme 3.

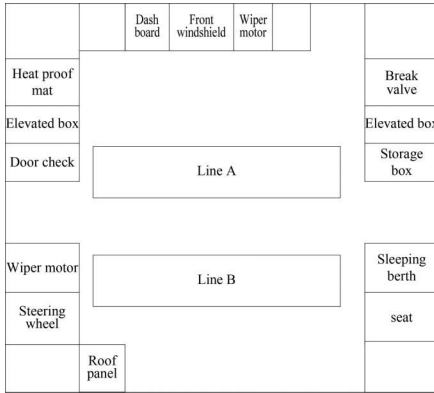

Figure 5. Layout scheme 1.

3 EVALUATION AND SELECTION OF THE BEST TRUCK INTERIOR WORKSHOP PLANAR LAYOUT PLAN

3.1 Evaluation and selection of the best truck interior workshop planar layout plan using the analytic hierarchy process

The paper selected the expert's questionnaires to build the judgment matrix and standards related target of judgment matrix as follows:

$$A = \begin{bmatrix} B_1 & B_2 & B_3 & B_4 \\ 1 & 1/3 & 2 & 1/5 \\ 3 & 1 & 4 & 1/3 \\ 1/2 & 1/4 & 1 & 1/7 \\ 5 & 3 & 7 & 1 \end{bmatrix} \quad (1)$$

AHP total sort results shown in Table 3.

Calculated overall consistency ratio $CR = 0.0117 < 0.1$ satisfies consistency. Total weight of the program to sort the results by the calculated layer can be seen. Total weight of the program C3> Total weight of the program C2> Total weight of the program C1.

It can be concluded that F company truck interior workshop layout scheme 3 is the optimal solution, but also an ideal layout is scheme 2. The two optimization programs are more excellent than the initial layout.

3.2 Comparative analysis results

By evaluating the safety factors, flexible layout, overall environment, the efficiency of logistics, and other aspects, the selected option 3 is the optimal layout, and integrated logistics cost from the following aspects before and after comparison with

Table 3. Total level sorting results.

Level C	Level B				Level C Ordered by the total weight
	B1	B2	B3	B4	
C1	0.1082	0.2532	0.0655	0.5731	0.0942
C2	0.0608	0.0695	0.0974	0.1111	0.4184
C3	0.3531	0.3484	0.5695	0.4444	0.4873

more intuitive results were demonstrated before and after optimization.

First, this paper calculated the cost of the initial layout of logistics.

Then it used the following formula to solve the collected amount of logistics and logistics costs:

$$Z = c \sum_{i=1}^n \sum_{j=1}^n (f_{ij} \times d_{ij}) \quad (2)$$

where c is the unit cost of transport from the logistics, taking $c = 1$.

We solved for the initial layout logistics costs $Z1 = 3.3 \times 10^7$. Based on genetic algorithms, using MATLAB, we can get the optimal layout of the logistics cost $Z3 = 1.5 \times 10^7$. Optimal layout reduces logistics costs by 1.8×10^7 than the initial layout, a reduction of 55% of logistics cost.

So we can see that the selected planar layout scheme 3 through genetic algorithms and assessment method compared with the initial planar layout 1, greatly reduced the cost of logistics.

4 CONCLUSION

Firstly, this paper started collecting related data of the present layout. Accordingly, it adopted the F-D analytical method to get data to find out the deficiency of the present layout. Secondly, aiming to optimize the layout, SLP and genetic algorithm method were selected to get two approximate optimal solutions. In the end, the evaluating method AHP was used to choose the most excellent layout. As a result, the evaluation method got a consistent result. Thus the layout chosen is the best for F trucks interior workshop.

The study and implementation of VoIP voice terminal system based on android platform

Gongjian Zhou

Xiamen University Tan Kah Kee College, Zhangzhou, Fujian, China

ABSTRACT: VoIP is a system which can realize real-time voice communication in IP network. Based on the research of VoIP related technology and protocol and Android platform, this paper designs and realizes the Android terminal VoIP voice communication system based on SIP protocol by applying Android NDK development framework and Java language integrated with SIPDroid. The test results show that the system is with multiple functions and in good performance, which can meet the practical application and marketing demand.

1 INTRODUCTION

In recent years, with the continuous development of Internet technology, IP-based real-time voice transmission technology has gradually become mature and VoIP (Voice Over Internet Protocol) telephone has been more and more widely used (Runsheng & Xiaorui 2004). The expansion of mobile communication services and the popularity of smart phones provide a strong market thrust for the application and promotion of soft-switching system which belongs to VoIP and achieves voice communication function through software. Given the fact that the Android system plays an absolute leading role in the mobile terminal market, this article uses Android NDK (Native Development Kit) integrated with SIPDroid (SIP open source protocol stack) as development environment after an in-depth study of the VoIP-related technology and Android platform, designs and realizes the VoIP communication system based on SIP protocol of Android terminal. The main achievements are as follows:

1. The paper analyses and studies VoIP technology, SIP protocol and Android technology, focusing on Android NDK development framework and SIPDroid architecture. We comprehensively understand and master the technological theories used by the system, which lays a solid theoretical foundation for the design and implementation of the system.
2. The paper uses MVC design pattern and Android NDK hierarchical structure, and divides the terminal system into four sub-modules, namely user interface, SIP message processing, voice processing, real-time transmission. Besides, the paper also uses Java language to develop and implement the four sub-modules.

3. The paper packages the developed programs to form apk, then downloads it in the cellphones. The paper also provides the corresponding experimental environment to test its functions, and uses Wireshark to analyze the package of voice packets and verify the completeness of the system's functions. The final results are correct, which achieves the design expectations.

2 SYSTEM-RELATED TECHNOLOGY AND PROTOCOL RESEARCH

2.1 VoIP technology

VOIP is a set of instant messaging technologies which transmit voice over IP network. It is not a specific agreement or standard, but a complex set of technologies (Runsheng & Xiaorui 2004). Its working principle can be showed in Figure 1.

The voice communication services can be realized as follows: convert voice signals to digital signals, compress coding and package the signals in groups, then turn the analog signals into IP telegrams with Internet as transmitting medium

Figure 1. VoIP data processing flow chart.

which can be transmitted and exchanged on the Internet. Finally, turn IP telegrams back to analog voice signals through a series of reverse operations (Rosenbery 2002, Jiantao & Kaiyan 2007).

The key technologies related with VoIP include: signaling technology, coding technology, real-time transmission technology, Quality of Service (QoS) guarantee technology, network transmission technology, etc (Duanfeng & Xinhui 2005). After comprehensively considering various conditions, the system adopts the SIP (Session Initiation Protocol) as the signaling control protocol, Speex coding algorithm as the voice coding technology, RTP (Real time Transport Protocol) as the voice real-time transmission; RSVP (Resource Reservation Protocol) and RTCP (Real Time Transport Control Protocol) as the quality of service QoS guarantee. In terms of network transport layer protocol, the system selects UDP, supplemented by gateway interconnect, routing, network management and security certification and billing, mute detection, echo cancellation and other related network communication technologies.

2.2 SIP protocol

The SIP protocol is a text-based, application-layer signaling control protocol proposed by the Internet Engineering Task Force (IETF) in 1999. It is mainly used to create, modify and release one or more participants of the session. These sessions are a collection of signaling data and media data. Participants can communicate via multicast, unicast or even multicast (Rosenbery 2002, Jiantao & Kaiyan 2007).

2.2.1 Network entities of SIP

The SIP protocol adopts the Client/Server (C/S) model to complete the call establishment through the request and response between the client and the server. A typical SIP network usually contains two kinds of network entities (User Agent) and Network Server (Network Server). The network framework is shown in Figure 2.

User Agent (UA) is divided into UAC (User Agent Client) and UAS (User Agent Server). UAC's main task is to initiate SIP call request and UAS's main task is to respond to the call request. In many cases, the user agent undertakes the dual role of the user agent client and the user agent server.

Figure 2. Network framework of SIP system.

The network server is composed of a proxy server, a register server, a redirect server, and other servers. Proxy server is mainly responsible for message routing. Registration server is mainly responsible for processing user registration information. Redirect server is mainly responsible for positioning. They can be distributed in different physical entities, and can also coexist in a device. According to actual needs, we will integrate the three servers into one through softwares.

2.2.2 SIP message mechanism

The messages in SIP are coded in text mode. They are composed of the start line, several message headers, blank lines and message bodies, and are divided into two types, namely request message and response message (Rosenbery 2002).

```
Generic-message = start-line
                  *message-header
                  CRLF
                  [message-body]
```

1. Start-Line gives the SIP version, the calling operation method, the current address of the invited user, the response type, and so on. The start line in the request message is the Request-Line, and the start line in the response message is the Status-Line.
2. Message header (Message-Header) is divided into four categories: general head, request head, response head and entity head. The symbol "*" indicates that the field can have more than one message head (Rosenbery 2002).
3. A blank line (CRLF) indicates the end of a message header field.
4. Message-Body generally uses the Session Description Protocol (SDP). It mainly includes the session description, and the cause and progress indication text may also be included in the response message.

The request message is used to activate SIP messages sent to the server, including INVITE, ACK, OPTIONS, BYE, CANCEL, and REGISTER, depending on particular operations.

The response message is used to respond to a request message indicating the success or failure status of the call. It contains a 3-bit integer status code to indicate the response of the called party to the request. The first bit indicates the response type, the last two bits indicate the specific response in the class. According to the different value, it is divided into the following types, 1xx, 2xx, 3xx, 4xx, 5xx, 6xx, and so on.

2.3 Android technology

Android is an open source operating system based on the Linux platform developed by Google and

the Open Handset Alliance, and it is primarily used in mobile devices. Its essence is to add a Java virtual machine Dalvik in the standard Linux system, and build a JAVA application framework in Dalvik virtual machine. All applications are built on the JAVA application framework (Batyuk et al. 2009). Android system uses a layered architecture. From the top to the bottom, it is divided into four layers, namely, Linux kernel, system libraries and Android runtime, application program layer and application framework layer, which can be shown in Figure 3.

1. Linux kernel: Android core system services rely on Linux2.6 kernel, such as memory management, process management, network protocol stack and driver model. The Linux kernel also serves as an abstraction layer for the hardware and software stacks.
2. System library and Android runtime: The system library includes nine subsystems, namely, layer management, media library, SQLite, OpenGL, FreeType, WebKit, SGL, SSL and Libc. Android runtime includes the core library and Dalvik virtual machine, and the core library is compatible with most of the Java language functions. Dalvik virtual machine is a register-based java virtual machine, and its main functions include the life cycle management, stack management, thread management, security and exception management and garbage collection and other important functions (Batyuk et al. 2009).
3. Application framework layer: application framework layer includes the following ten parts, telephone manager, resource manager, location manager, notification manager, and other six parts. It is the basis for Android application development. In most cases, developers are dealing with the layer. On the Android platform, the developer has full access to the APIs used by the core application, and any application can publish its own functional modules, or use other functional modules that have been published by other applications to perform component replacement.
4. Application layer: This layer provides some core application packages, such as e-mail, SMS,

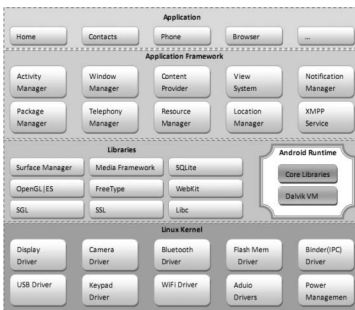

Figure 3. Android system architecture diagram.

calendar, maps, browser and contact management. At the same time, developers can use the Java language to design and compile their own applications.

3 THE OVERALL DESIGN OF THE SYSTEM

3.1 System layer module design

According to the functional requirements of the system, the system uses a hierarchical modular design ideas, as shown in Figure 4.

1. Access layer: It mainly uses the existing PSTN, 3G, 4G and IP networks to achieve system access services, and analyzes the SIP message and SDP message transmitted from the Internet through the SIP signaling protocol stack.
2. Ability layer: It mainly provides the function module to deal with SIP signaling and RTP voice, which is the core part of the system. The SIP soft switch platform achieves the User Agent (UA). When it calls, it is regarded as UAC. When it is called, it is regarded as UAS. We also set other modules, such as coding, recording, RTP media, conference management, IVR, data engine and so on. Above those modules, we set a service engine in order to dock with business layer.
3. Business layer: It is a system function provided for end-users. In addition to achieving the basic point-to-point voice calls, it can also achieve switch board IVR voice processes, conference calls, voice mail and other value-added functions.
4. Display layer: It is a carrier to use system provided for end-users. At the mobile end, specialized APP is used and on the PC end SIP soft terminal softwares are used (eg X-Lite, Eyebeam, etc.).

3.2 The protocol stack structure of the system

The system is based on IP network voice communication and the protocol stack structure can be shown in Figure 5.

Figure 4. System hierarchical module diagram.

Figure 5. System protocol stack structure.

At the application layer, SIP is used for voice signaling control, and RTSP is used to control “one-to-many” multimedia data flow. RSVP and RTPC are used to guarantee higher quality of service QoS. The former specifies the resource protection policy of the IP network and the latter is used to detect and potentially resolve transmission problems, thus monitoring the session quality and detecting the network. RTP is used to complete the end-to-end voice data real-time transmission services.

At the transport layer, we use the UDP protocol. On the one hand because the UDP does not require three handshake. The establishment process of SIP signaling has completed the functions which is equivalent to TCP three-way handshake. On the other hand, UDP can meet the real-time requirements of RTP while satisfying the requirement of SIP commonality (Stefano 2007).

3.3 Function modules' design of the system

Through the deep research of VoIP technology, SIP protocol and Android technology, we use NDK (Native Development Kit) framework which integrates open source SIPDroid under the Android platform as the development environment. The hierarchical functions planned by the system corresponds to the hierarchical modules in the NDK framework, which can be shown in Figure 6.

1. User Interface (UI) module: This module corresponds to the Java Application Layer of the NDK framework. It mainly uses the Java language to design and write the user interface, which is the part of the whole software system and user interaction. It implements the concrete SIP function by calling the interface of JNI layer (Java Native Interface Layer): for example, the initiation, establishment and termination of the session. Besides, it also includes many other subordinate function interfaces such as address book display, call parameter settings, dial-up and real-time calls.
2. SIP message processing module: This module corresponds to the NDK framework of the JNI layer and the native code layer (Native Code Layer), which is the core of the entire system. Android kernel itself does not provide SIP protocol stack, so in this module we use open-source SIP protocol stack SIPDroid SIP to process mes-

Figure 6. Terminal system function module.

sages. Its source code has included specific methods to process the SIP messages, so we only need to design the appropriate JNI Interface function and directly use it in the UI module^[3].

3. Voice processing module: This module corresponds to the NDK framework of the native code layer. The design of the layer are generally written in C language, which is mainly used to complete a series of functions such as the collection of voice data, compression, encoding and playback.
4. Real-time transmission module: This module corresponds to the NDK framework of the JNI layer and the native code layer. It is mainly used to transmit various messages of SIP, and RTP encapsulation and packing of voice data after voice processing, decapsulation of received voice data and so on (Batyuk et al. 2009). In SIPDroid framework, we design and implement the RTP transmission source code function, and use JNI to encapsulate and package calls.

4 THE SPECIFIC DESIGN AND IMPLEMENTATION OF THE SYSTEM

4.1 The design and implementation of User interface (UI interface)

UI interface is not only the interface of human-computer interaction, but also affects the user's overall experience of the application. In the framework of Android UI design, this system designs five UI interfaces, such as user login interface, parameter setting interface, dial interface, address book interface and real-time communication interface. The design mode of MVC (Model-View-Controller) can be shown in Figure 7.

The entire UI is built by View and View Group. Each visual interface uses Activity to achieve this component. Activity also carries a variety of different control elements. The use of XML file layout mechanism helps to define the user interface structurally and to ensure that the user interface is separated from the code definition. After completing the UI layout, the Android framework uses the event listener interface to listen to user interaction.

4.2 The design and implementation of SIP message processing module

SIP message processing module is the core module of the system, which can be realized by using open

Figure 7. UI interface design under MVC mode.

source VoIP protocol stack SIPDroid on Android platform. SIPDroid completely encapsulates the SIP message model, implements the RFC3261 protocol content, and employs high cohesive, low coupling software design architecture, which is easy for developers to customize their own new functions (Singhand & Schulzrinne 2006). The framework of SIPDroid protocol stack is shown in Figure 8.

1. UI layer: It is mainly responsible for the interface display and it provides users with the system interaction interface.
2. Core Engine Layers: This layer starts various services through SIPDroid Engine, initializes the software parameters, provides customized UI interfaces, and calls down the encapsulated SIP message processing interface, which is the core processing layer of the system. This layer contains several important files and classes: User Profile (User Profile) which is used to maintain the system configuration information and global variables; User Agent (user agent) which is used to handle a variety of user events and complete the SIP protocol stack call and session; Register Agent which is used to handle the registration event of the SIP message to complete the registration process of the client to the SIP server.
3. It mainly realizes the content of RTP and RTCP protocol, using UDP protocol to complete the data transmission and control. In addition, the layer also provides JSTN NAT penetration technology based on STUN protocol.

4.3 The design of voice processing module

We consider the design of voice processing module mainly from three aspects: the acquisition and playback of voice streams, compression and encoding and packaging and transmission the main process can be shown in Figure 9.

We use Audio development framework provided by Android media library to acquire and play voice

Figure 8. SIPDroid program framework diagram.

Figure 9. Voice processing module flow chart.

signals. Audio Record provided by Audio framework is used to record the voice and Audio Track is used to play the voice^[4]. We also employ Speex Algorithm to compress and encode voice signals. RTP and UDP protocols are used to pack and transmit voice signals.

4.4 The design and implementation of real-time transmission module

The data transmitted in VoIP system can be broadly divided into two types: SIP signaling data and session audio data. Based on the architecture of SIPDroid, we design the above two kinds of data streams into two different transmission channels, which can be shown in Figure 10.

1. SIP signaling data transmission: The operations of the user at the UI layer operation (such as dial-up, answer, etc.) will be broadcast to the SIPDroid core engine. According to the types of operations, SIPDroid core engine will deliver them to the User Agent or Register Agent and they will produce different requests. SIPDroid Provider will analyze those requests and form corresponding SIP packages. The packages will be delivered to Udp Transport. After being handled, the packages will be delivered to Udp Provider. We can call Udp Socket and bind it with the target address and finally transmit the date through Datagram Socket of Java. When receiving SIP packets from the network, the data transfer order is reversed.
2. Session audio data transmission: the terminal compresses and codes the sampled and then delivers them to the SIPDroid core engine. Meanwhile, the backstage system will start two thread classes. One is used to send RTP packet virtual class RtpStreamSender, and the other is used to receive RTP packets of virtual Class RtpStreamReceiver. These two classes are Java thread classes, both of which have achieved Runnable interface and are in the audio session after the establishment of continuous operation. RtpStreamSender data will be delivered to the RtpSocket. Then RtpSocket will package the data packet into Rtp

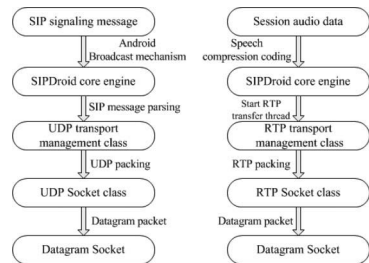

Figure 10. Two different real-time transmission data channels.

package, read the target IP address and the agreement of a good RTP port number, and bind those information with SIPDroid Socket. SIPDroid Socket can transmit the data by calling Java Datagram Socket. When receiving Rtp packets from the network, the data transfer order is reversed.

4.5 Database design

From the business logic point of view, the system selects open source, and operating system-independent SQLite as a database background, in which multiple tables are set up, including two most important tables, namely user information and contacts tables. The User Information Table includes SIP account, log-in password, permission level and other fields. The Contacts Table includes the contact name, SIP account number, E-mail address, and other fields.

5 OPERATION AND TESTING OF THE TERMINAL SYSTEM

After the development of all functional modules, we use ADT in Eclipse to package the program to generate the appropriate apk file and install it to the Android phone.

In the test, we choose the client application software developed in this paper as a caller, running on the HTC G23. Free VoIP soft phone X-Lite is chosen as the called party, running in the pc-side windows environment. The server uses the SIP server built by Asterisk and integrates the functions of the registration server and the proxy server. Wireshark uses the open-source network packet analysis software Wireshark to capture and analyze network packets during a call, which can be shown in Figure 11.

After comparing the data of Wireshark capturing packet with standard SIP call flow (see Figure 12), it is confirmed that the system is in good working condition and the basic function of voice terminal is complete. The main function modules can be used normally and the expected results are achieved.

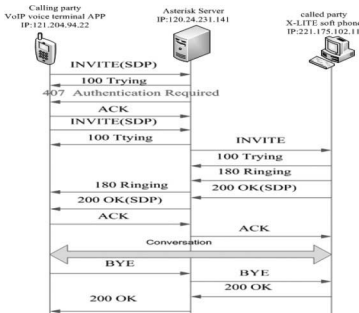

Figure 11. VoIP basic call process.

Figure 12. Wireshark capture graph.

6 SUMMARY

In this paper, we use open source development platform and tools to design and implement the VoIP voice terminal system based on the Android platform. Modularization method is also applied in this paper, so the system has the advantages of low development costs, complete voice communication functions, being convenient, practical, reliable, safe and good. The system can also be extended into the network interactive multimedia application with texts and video conferences to meet different application needs of the market, which has a good value for market application and promotion.

Research on a malicious code behavior acquisition method based on the Bochs virtual machine

H.Y. Liu & Y.J. Cui

Department of Information Engineering, Academy of Armored Forces Engineering, Beijing, China

ABSTRACT: Bochs is an open source IA-32 (x86) emulator written in C++ that simulates the entire PC platform, including CPU, I/O devices, memory, and BIOS. This paper presents a method to acquire the behavior of a malicious code based on the Bochs virtual machine. It intercepts the instruction stream and data stream information conditionally when a malicious code is running in Bochs by redesigning the Bochs system, and then it records and parses the intercepted information. It also gets the system call information by linear address analysis so as to provide the executed system calls of a malicious code for the following behavior analysis. Experiments show that this method can effectively acquire the behavior characteristics of malicious codes.

1 INTRODUCTION

With the development of the Internet, the network has brought great convenience to people. However, the security problem ensues and has become more and more serious. Malicious code is one of the most widely used network attack methods. At present, there are millions of different types of malicious codes that have been discovered. Since network security has been upgraded to be an important factor of national security, which is related to a country's information infrastructure, the speeding up of detection technology of malicious code has become far more significant to social and national security.

Malicious code detection methods are generally divided into two types, i.e., static detection, and dynamic detection.

1. Static detection. The static detection is based on the signature of malicious code previously found, which searches the signature in the target file, the IP package, the mail attachment, etc. This method does not actually execute the code but analyzes malicious code by disassembling, decompiling, analyses file structure and other methods to get the required information. Due to various advanced self-protection technologies used in a malicious code, such as shell processing and obfuscation technology, it becomes more and more difficult for static detection method to discover malicious codes.
2. Dynamic detection. In this kind of method, the detection system discovers a malicious code when it is running by analyzing its behavior characteristics.

Behavior refers to the operation of the operating system such as process, memory, files, registry,

and API functions. The basic idea behind malicious code detection is based on the behavioral analysis in that there is a clear distinction between the behavior that a malicious code exhibits when it is running on the system and the behavior that a normal program behaves when it runs so that it can be determined whether the code is malicious. Since there is no need for a predefined signature, malicious code detection based on behavioral analysis technology can discover unknown malicious code, which overcomes some of the limitations of static detection. With the high detection rate of this method, it has gradually become the focus of research in the field of malicious code detection. As such the research of behavior acquisition method has gradually become more and more important.

In this paper, the Bochs virtual machine is used in the acquisition of the behavior of a code, which provides the basis for modeling the behavior of a malicious code.

2 ANALYSIS OF THE PROGRAM BEHAVIOR ACQUISITION METHOD

At present, the main method to monitor the behavior of a running malicious code can be divided into three types, i.e., the environmental comparison method, debug method, and system call monitoring method.

Environmental comparison method, which is also called the black box observation method, acquires the behaviors of the malicious code by comparing different system views before and after the malicious code execution. However, this method cannot find specific reasons for the change of system views and cannot reflect the whole

dynamic process of execution, which may result in the loss of some malicious code behavior.

The debug method executes the code step-by-step and tracks system changes by setting breakpoints through the debugger. This method can monitor code execution step-by-step and also execute a program fragment at a time. Although this method can fully monitor the execution process of the code, it is useless for those malicious codes using some anti-debugging techniques.

System call monitoring method intercepts the system calls during the execution of the code. The method can acquire the operation of code execution in real time, which can be used for the analysis of behavior characteristics as well as the detection of malicious code. To avoid being infected by the malicious code, the sandbox technology is generally used to execute the malicious code samples, and the virtual machine is a typical kind of sandbox.

The virtual machine simulates a physical host by the software. A virtual environment can protect the real host from being infected by malicious codes. The actual execution of the malicious code in the virtual machine will not cause infection and attack to the host. The virtual machine has the following advantages when used in the analysis of a malicious code. First, multiple operating systems can coexist on a single physical machine and are isolated from each other. Second, a virtual machine can provide an instruction set architecture which is different from the host computer. In other words, the operating system of the client can be different from its host. Third, virtual machines are usually highly available to maintain and provides some disaster recovery capabilities.

In this paper, the Bochs virtual machine is used to intercept the system call information when a malicious code is running.

3 BOCHS VIRTUAL MACHINE

At present, virtual machines can be divided into three categories according to their degree of virtualization, i.e., fully virtualization, semi virtualization, and simulator.

1. Fully virtualization. The most typical product of full virtualization is VMware. VMware fully virtualizes the underlying hardware by using a common method of PC hardware virtualization, while the guest OS of the virtual machine often has lower performance than the original host.
2. Semi virtualization. Semi virtualization makes some modifications to the kernel of the operating system so that some of the original need to directly implement the CPU protection tasks can be directly implemented in the modified

kernel which improves the efficiency of the virtual machine.

3. Simulator. The simulator reads the CPU instruction of the program, explains the instruction, and simulates the execution. It also simulates the state of various registers and state machines of the hardware.

Bochs is essentially a simulator by reading the CPU instructions and simulating the execution to achieve the virtualization effect of various hosts. It can effectively record and intercept the instruction stream information when a malicious code is running. Since any action that occurs while a program is running is implemented by a sequence of instructions, the instruction stream information can not only reflect the path of the static binary code execution but also reflect the various behaviors of the binary code.

Bochs is a GPL-licensed INTEL IA-32 virtual machine which provides the simulation of the entire computer hardware platform. It is a full system simulator including functional simulation of one or more processors and commonly used external devices. It fully explains and executes the operation of virtual machine instructions and memory access. Bochs provides a complete simulation of CPU behavior, including extraction, decoding, execution, and other CPU internal behaviors. Bochs can simulate a variety of operating systems, including Linux, DOS, Windows 95/98/NT/2000/XP, etc. Bochs project is an open source project, which is developed mostly by C++ programming language. Since its CPU simulation module is relatively independent and well designed, it is suitable for users to further design based on its source codes. This article will realize a virtual machine which can conditionally intercept the instruction stream by revising the source code of Bochs.

4 BEHAVIOR ACQUISITION AND ANALYSIS BASED ON BOCHS

4.1 *Interception of instruction stream and data stream*

4.1.1 *Redesign of Bochs*

Bochs program is mainly composed of a CPU module, memory module, interrupt module, and the peripheral module. The CPU module is the core of Bochs, which is responsible for simulation execution of instructions. After Bochs starts, it initializes the hardware modules and then enters the CPU module. The CPU module consists of a loop composed of interrupt processing, fetching instructions, decoding instructions, and executing instructions. The basic execution process of the CPU is realized by the `cpu_loop()` function.

Based on the original code, we add the instruction stream intercepting module. The architecture

of Bochs after adding the runtime interception module is shown in Figure 1.

It is no doubt that the efficiency of the virtual machine will be greatly reduced if each instruction is intercepted. So instructions can be intercepted conditionally. These interception conditions can be time, instruction linear address, instruction type, or operand. Conditional interception module can reduce the impact on the efficiency of the virtual machine brought by interception. This article sets conditions to be the linear address range of instructions, thus it only intercepts instructions in a specific memory address space. The linear address of the instruction is very important for instruction analysis. Taking the system call as an example, the import address table

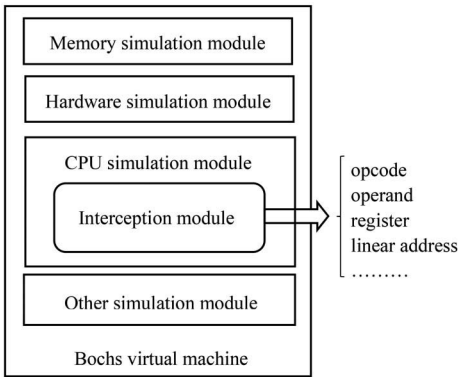

Figure 1. Bochs architecture with intercepting module.

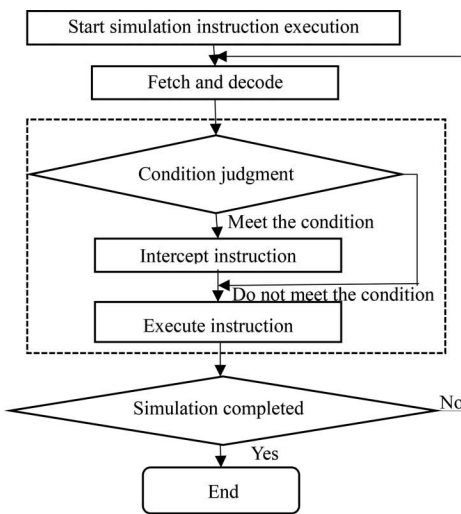

Figure 2. The process of conditional interception module.

of the system calls is known when the system is running, so which system call is now being executed can be known by checking the linear address in the import address table. The process of conditional interception module is shown in Figure 2.

4.2 Analysis of system call based on linear address

In Windows systems, the behavior of a malicious code is different from that of a normal program which can be described as a system call sequence. No matter how the malicious code evolves, the realization of its function must rely on system calls to be completed. So it can determine whether the code is malicious by combining the system call sequence with their parameters. Therefore, to get the executed system call sequence is the basis for identifying a malicious code.

To get the instruction stream and data stream in some readable form for further analysis, the intercepted instruction which is in binary format must be resolved to string format. The instruction stream after the analysis is shown in Table 1.

Table 1. The instruction stream after the analysis.

Linear address	Instruction	Register and memory value
[0 × 00542225]	MOV ECX, EDX	ECX[005421C1] EDX[00006BA4]
[0 × 00542225]	INC ESI	ESI[00527324]
[0 × 00542225]	SUB EAX, EBX	EAX[A16B9784] EBX[C60DFB26]
.....
[0 × 00542225]	PUSH ECX	ECX[005421C1]
[0 × 00542225]	CALL 004CD4 AB	MW[0000000000: 0023FF2C] [005421C1]

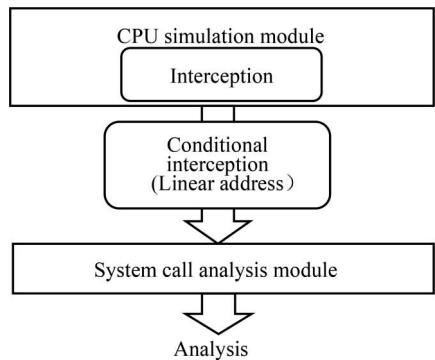

Figure 3. The overall structure of the system after redesigning.

The principle of system call resolving based on the linear address is as follows:

It determines the instruction function belongs to which system call according to the linear address of the instruction. For a particular operating system, the import linear address of a particular system call is usually invariant. Therefore, the analysis of a system call module can judge whether the function belongs to a system call according to the operating system information and the import linear address of the code block. For example, in the Windows PE 1.5 operating system, the import linear address of system call `Kernel32.GetProcAddress` is $0 \times 7C80AC28$. If an import linear address of the code block is $0 \times 7C80AC28$, the code block is determined as the system call `Kernel32.GetProcAddress`. The analysis of specific system call is conducive to rapidly analyze the behavior characteristics of the function. The overall structure of the system after adding the interception function as well as the system call analysis function based on the linear address is shown in Figure 3.

5 EXPERIMENT AND RESULTS

In order to test whether the Bochs virtual machine after our redesigning can acquire the system call of a running code, we do the following experiment.

1. To install Windows XP operating system in a redesigned Bochs virtual machine. Bochs starts is shown in Figure 4.
2. To make the malicious code sample `Win32.Kryptik.NX` run in Windows XP.
3. To intercept and analyze the system calls of a sample. The analytical results acquired by the system are shown in Table 2.

Figure 4. Bochs starts.

Table 2. The analytical results acquired by the system.

Linear address	System call
$0 \times 7C80B529$	<code>Kernel32.GetmoduleHandleA</code>
$0 \times 7C80AC28$	<code>Kernel32.GetProcAddress</code>

$0 \times 7C80AC28$	<code>Kernel32.GetProcAddress</code>
$0 \times 7C80AC28$	<code>Kernel32.GetProcAddress</code>
$0 \times 7C859B5C$	<code>Kernel32.OutputDebugStringA</code>
$0 \times 7C859B5C$	<code>Kernel32.CallWindowProcA</code>

6 CONCLUSION

Bochs virtual machine can be used to execute malicious code in research to protect a system from being infected or attacked. Since it is an open source project, it can also be used to acquire runtime instruction information by redesigning the program, which is the basis for behavior analysis of malicious code. In this paper, an instruction interception module is added to the CPU simulation module to acquire the instruction executed when a malicious code is running. The work of this paper provides a basis for modeling the behavior of a malicious code.

Research on the network security equipment allocation problem based on Monte Carlo tree search and machine learning

Cheng Chen, Hengjun Wang & Nianwen Si

Zhengzhou Institute of Information Science and Technology, Zhengzhou, China

Yingying Liu

Henan University of Animal Husbandry and Economy, Zhengzhou, China

ABSTRACT: In this paper, research on the allocation of network security equipment is carried out thoroughly. We model the network security equipment with structured language. Based on this, in order to solve the equipment allocation problem, we combine Monte Carlo tree search with machine learning algorithm to design specific solutions for the problem. Furthermore, in the process of the model of this problem, we also implement the representation for specific knowledge, establishing the state space for the problem and designing for knowledge solving algorithm. The results indicate that the proposed scheme significantly improves the speed and accuracy of equipment allocation.

1 INTRODUCTION

In today's world, the Internet revolution is changing with each passing day, which has a profound impact on the development of international politics, economy, culture, society, military, and other fields. With the continuous development of network expansion, the problem of network security is also increasing. The current network security protection system has established a relatively mature and complete model and designed the scheme of network security solution for diversification under various conditions. The security equipment performance has become more and more perfect. However, the problem of how to allocate the network system security equipment and the corresponding mature solution is still very limited. At present, most of the allocations for communication network security equipment still rely on manual methods. How to improve the accuracy and timeliness of the manual allocation is still a complex problem which needs to be solved.

The traditional manual allocation has many defects in accuracy and timeliness, and these two points are also the key problems for the allocation of the security equipment problem. If the machine learning method is introduced to this problem, the system can realize the automatic allocation through self-learning and this will improve the safety and accuracy of the network from the urgent task to have a more positive significance. In this paper, we propose an effective scheme which combines the Monte Carlo tree search with reinforcement learning to solve the allocation of the network security problem.

2 MONTE CARLO TREE SEARCH FOR EQUIPMENT ALLOCATION

2.1 *Preparing the new file with the correct template*

Using search to solve the problem is to find a solution in a possible space. This space is the object of the search and each of the elements in the space represents a possible state. The state is a mathematical description of the progress at a certain time when the problem is solving. The path of description must be to keep the relevant information as far as possible to ensure the accuracy of the state representation and all the states of the data structure is called the state space. The search process is based on these states and the corresponding search algorithm aims to solve the problem. So the object of the search is to find the state in the formatted state space. In order to solve the problem by using the search algorithm, the model must be established. The state and the state space must be determined.

In the form of the structure, the state which is a set of ordered minimal variables $(q_0, q_1, q_2, \dots, q_n)$ can be introduced to describe the difference between some things under different conditions. The form is defined as follows:

$$Q = \{q_0, q_1, \dots, q_n\} \quad (1)$$

Each of these elements is called a state variable. A specific state can be obtained by determining a set of values of the component.

The state space is an ordered set of all possible states Q_1, Q_2, \dots, Q_n as well as their relations. The form is defined as follows:

$$S = \{Q_1, Q_2, \dots, Q_n\} \tag{2}$$

Each of these elements is represented as a state of the problem. State space is in the form of a figure. The nodes correspond to the graph state and the edges between nodes correspond to the feasibility of state transition. The weight of the edge corresponds to the cost of transfer. The solution of the problem may be a state in the figure, or a path from the start state to the same states, or the cost of the target.

In problem solving using the search algorithm, we need to abstract various aspects of the problem for the computer, thus it can make way for it to be understood and also saved. The actual problem is ensured with the state of one correspondence, which is a model of the process for building. So this search problem can be established as follows.

Based on the known network **A**, the configuration of network security equipment, for example, required to configure each network node with the existing equipment, so as to ensure the dissemination of information in the safe range. If all the networks containing **N** nodes needs to configure the **M** warehouse equipment, these equipment are available for distribution and allocation, and these things can be set as follows:

P: The node to be allocated. The number of nodes is **N**. It can be expressed as a matrix $P = \{P_1, P_2, \dots, P_n\}$, each element represents a network node.

E: The type of equipment available for allocation. The number of types of equipment is **M**. It can be expressed as a matrix $E = \{E_1, E_2, \dots, E_m\}$. Each element represents a kind of type.

Number(Ex): The number of the class **X** equipment.

(S, Ex): In the state **S**, the next node to select the equipment **Ex**.

P(S, Ex): The probability choice function. The possibility of being selected in the **S** state of the equipment **Ex**.

T: The maximum simulation duration.

2.2 Target of problem search

According to the description of the problem, the solving process can be simplified in a **M*N** matrix (the number of equipment type is **M** and the number of the node is **N**). The problem is to find out the best path from the first node to the last node as shown in Figure 1.

Figure 1. The process of solving.

Table 1. Frame representation.

<Device name>	
<Attribute 1>	<Attribute value><Range>
<Attribute 2>	<Attribute value><Range>
.....
<Attribute n>	<Attribute value><Range>

First, the simulation method used in the scheme is the Monte-Carlo tree search so that the machine can be the reinforcement learning and get the choice probability **P(S, E)** of the corresponding equipment in the node. Then through continuously repeated simulation, the equipment selection probability **P(S, E)** of each state can be more precisely found. In the probability selection, the function **P(S, E)** can be obtained after optimization which begins from an initial state. According to the **P(S, E)**, each state will choose a large number to compare with and reach the final state of **Sn**. Therefore, the key to the problem is to find the ideal choice probability **P(S, E)** value (the more numbers in the simulation experiments used, the greater the **T** value will be, and more accurate the results will be).

2.3 Formal description of equipment and network node

There are many kinds of network security devices and nodes, which can be used to frame representation

Table 2. Knowledge representation for device based on framework.

Device attribute	Representative	Range of values
Tag	Name and type	Text
Type	Type of security device	
Layer	Which layer is located on the network	“datalink”, “network”, “transport”, “session”, “presentation”, “application”
Port	The type of port with device	“RJ45”, “fiber”, “RJ11”, “AUI”, “BNC”
Work_ with	what types of equipment can be interoperable with	Enumeration of devices that can communicate
Sum	Total number of devices	

Table 3. Knowledge representation for node based on framework.

Node attribute	Representative	Range of values
Number	Node ID	
Layer	Which layer is located on the network	“datalink”, “network”, “transport”, “session”, “presentation”, “application”
Port	The type of port	“RJ45”, “fiber”, “RJ11”, “AUI”, “BNC”
Connect_with	Which nodes need to communicate with	Enumeration of nodes that must communicate with

to describe the characteristics of equipment and nodes. The first is to extract the feature and then summarize it as a number of attributes and determine the attribute name and value range of each attribute. The representation is as follows:

To build the framework which is required to extract the properties of the device, the extracted attributes should meet the following criteria: 1. Strong expression ability, which means it is able to express the required knowledge; 2. Easy to understand, which means it is easy to build data structure; 3. Easy to solve and reasoning, which means the knowledge of the symbolic structure and reasoning mechanism can support the knowledge base on the advanced search. This could quickly introduce the conclusion from the existing knowledge.

From the perspective of solving the target, the extraction of device properties can refer to the following features: the name and type of equipment, the work environment, the environmental adaptability, the technology performance, the adapter group, the quantity, and so on. Through the comparison of the above characteristics, the network security equipment can be extracted from the following aspects:

Similarly, the node can be extracted from the following aspects:

3 OPTIMIZED SEARCH ALGORITHM

The Monte Carlo algorithm is selected for the equipment allocation, which is ready to be configured by directly abandoning the low coincidence rate of equipment library selection and giving up the calculation of the exhaustive method which consumes a large amount of computing resources and specifying the main direction of calculation so that it has a high rate of choice for a more accurate calculation and analysis, especially in the selection strategy which aims to add more equipment-related professional knowledge. This makes the Monte Carlo search based equipment configuration algorithm to be a higher level of selection compared with the random search.

Since the Monte Carlo search is based on a large amount of reinforcement learning, the learning process is the focus of algorithm design and the variables are set as follows:

C_{ij} : The matching of the node and the equipment. It can be expressed by matrix $CAP=(C_{ij})m*n$, where C indicates that the i node is matched with the j equipment. If the equipment can be operated at that node, it is 1, else it is 0.

$V(S, E_x)$: The average accumulation rate. It represents the number of times $E_x(x \in m)$ has been selected and winning in the previous simulation of the state S .

$X(S, E_x)$: The prior knowledge function. In the current state S , according to configuration rules between equipment or between the node and equipment, the probability of the next step is to choose the equipment $E_x(x \in m)$.

$u(S, E_x)$: Knowledge selection probability function. The choice function is determined by known knowledge. It represents the probability of selecting $E_x(x \in m)$ in the state S .

$N(S, E_x)$: Recording the number of all the winning simulations in the state S to select $E_x(x \in m)$

$L(S, E_x, t)$: Recording that the (S, E_x) is to be accessed in the time of t simulation. It can be accessed to be 1, otherwise 0.

$R_t(S, E_x)$: Reward function. Recording the outcome of the game in the t simulation of the selected action (S, E_x) . If it wins it is 1, otherwise 0.

The process of machine learning is to obtain a return function $R_i(\mathbf{S}, \mathbf{E}_x)$, which is combined with *a priori* knowledge. Constantly, it is also revised to the probability function $P(\mathbf{S}, \mathbf{E}_x)$. Finally, the optimal state transition path is found by $P(\mathbf{S}, \mathbf{E}_x)$.

In the beginning of the simulation process, due to the lack of experimental data, *a priori* knowledge is needed to remove some of the unreasonable combinations of the matching relationship between the equipment and the node (which can avoid such errors between the network layer equipment configuration and the physical layer). This not only reduces the state space but also improves the search speed. We can make the reasonable configuration that was earlier revealed, even if the data is not enough. Let $X(\mathbf{S}, \mathbf{E}_x)$ denote that the system is in the state \mathbf{S} according to the *a priori* knowledge, then it computes the probability of the next step to select \mathbf{E} .

$$X(S_i, E_x) = \frac{C_{i, E_x}}{\sum_{j=1}^m C_{ij}} \quad (3)$$

With the increasing number of simulations, the experimental data is gradually increasing and the reduction of the *a priori* knowledge is required to reduce the proportion of the *a priori* knowledge in the selection function. This will reduce the useless search and improve the convergence of the function, thus the choice of probability and *a priori* knowledge is proportional to the analog frequency which is inversely proportional. Let $u(\mathbf{S}, \mathbf{E}_x)$ denote that after the N round of simulations, the probability of the system is in the state \mathbf{S} in the first step to choose \mathbf{E}_x .

$$u(S, E) = \mu \frac{X(S, E)}{1 + N(S, E)} \quad (4)$$

At the end of each simulation process, the system will return a reward function based on the results of the simulation configuration. If such a configuration network is in accordance successfully, it returns back to $\mathbf{1}$, otherwise $\mathbf{0}$.

$$R_i(S, E_x) \begin{cases} 1 \\ 0 \end{cases} \quad (5)$$

Through constant repetition of the experiment, the reward function for $\mathbf{1}$ of the configuration is a steady stream of feedback. These "excellent" configurations were collected and used to determine the configuration of the next step with *a priori* knowledge. Let $N(\mathbf{S}, \mathbf{E})$ denote the previous time step $t-1$ in the simulation process in the state \mathbf{S}

case, the number of times we will select the equipment \mathbf{E} and the final equipment successfully.

$$N(S, E) = \sum_{i=1}^{t-1} L(S, E, i) R_i(S, E) \quad (6)$$

The use of reinforcement learning is to get feedback results as well as avoid information which is too much to be submerged into inspired information. Let $V(\mathbf{S}, \mathbf{E}_x)$ denote the probability of selecting equipment \mathbf{E}_x under the state \mathbf{S} , it is conducted according to the feedback of machine learning.

$$V_i(S, E) = \frac{1}{1 + N_i(S, E)} \sum_{i=1}^{t-1} L(S, E, i) R_i(S, E) \quad (7)$$

At the beginning of the simulation, the influence of *a priori* knowledge is relatively large and it can improve the convergence speed. With increasing number of simulations, the influence of the *a priori* knowledge is gradually reduced and influence of the feedback result of machine learning is increased so that the offset decreasing will make higher winning percentage allocation which is gradually displayed. Both of them are combined to get the probability choice function.

$$P(S, E) = (1 - \lambda)V(S, E) + \lambda u(S, E) \quad (8)$$

The methodology of Monte Carlo tree search with reinforcement learning can be described as follows:

Table 4. The steps of search.

Step 1	Set the number of simulations as \mathbf{T} , the initial value is $\mathbf{1}$
Step 2	Starting from the node \mathbf{P}_1 , through the probability choice function $P(\mathbf{S}, \mathbf{E}_x)$ optimal configuration
Step 3	If \mathbf{P}_1 is not the end node, then create the next node \mathbf{P}_2 , and select one of the configurations \mathbf{E}_x according to $P(\mathbf{S}, \mathbf{E}_x)$
Step 4	Continuous simulation until the completion of all the node configurations, if the results of the configuration is in line with the requirements of the topic selected by the action of the reward function $R_t(\mathbf{S}, \mathbf{E}_x)$ for $\mathbf{1}$, else $\mathbf{0}$
Step 5	According to the results of the last simulation update to the probability choice function $P(\mathbf{S}, \mathbf{E}_x)$, observe the simulation times \mathbf{T} whether it reaches the upper limit, if not $\mathbf{T}++$ and return to Step 1 , else the simulation is terminated

4 EXPERIMENTAL RESULTS

The network topology of information system is shown in Figure 2. The network is made up of four subnetworks, each of which has two terminals. Each subnet was formatted as the backbone network.

Configuration target: The whole network is divided into two secure subnets: the implementation of the subnet **A** and subnet **C**, which is the terminal security communication. Among the subnet **B** and **D** and the subnet **A** and **C**, the subnet **B** and **D** is the terminal which is not connected.

Available security equipment: The security equipment **EL1** and **EL2** are in data link layer, each of which can communicate with others. There are **6** sets of **EL1** and **2** sets of **EL2**. Network layer security equipment is **EW1**, **EW2**, and **EW3**. The equipment **EW1** and **EW2** can communicate with each other, but the equipment **EW3** cannot communicate with others. There are **2** sets of **EW1**, **2** sets of **EW2**, and **6** sets of **EW3**.

The name of the network node is shown in Figure 3.

Through the algorithm presented in the previous paper, it is concluded that there are 336 feasible solutions, that is, there are 336 states in the solution space and some results are shown in Table 1.

5 CONCLUSION

In this paper, the Monte Carlo search and reinforcement learning is applied to the selection of equipment configuration, which can give full play to intelligence, positive feedback, and cooperative characteristics of the algorithm. The experimental results show that the algorithm has better evolution ability and can obtain optimal allocation. In further research, the combination of two algorithms will be used to carry out the dynamic configuration of the equipment. In this way, we will make full use of the advantages of Monte Carlo search to find the solution in a wide range and this kind of algorithm will be more difficult to be strapped in the local optimum.

Robust automatic speech recognition based on neural network in reverberant environments

L. Bai, H.L. Li & Y.Y. He

National Computer Network Emergency Response Technical Team/Coordination Center of China, Beijing, China

ABSTRACT: The reverberant environment is still a big challenge to speech recognition. This paper presents a method of reverberant Automatic Speech Recognition (ASR) using front-end based methods and enhanced Voice Activity Detection (VAD). A 2-channel dereverberation method is adopted to achieve robust dereverberation under different reverberant conditions. Also a 2-channel spectral enhancement method is used where the gain of each frequency bin is controlled by acoustic scene, which is detected based on the analysis of full-band coherent property. We also use Deep Neural Network (DNN) as a feature extractor, and a DNN based VAD is also used to improve the ASR performance. The DNN based front-end allows a very flexible integration of meta-information. Bottle neck features are extracted in place of MFCC features used in the HMM-GMM system. Finally, we evaluate our methods on the data provided by REVERB challenge. On simulated data, the performance yields more than 33% relative reduction in Word Error Rate (WER).

1 INTRODUCTIONS

Improving the ASR performance in reverberant speech has been an important research topic for a long time. Lots of researches have proved that audio processing is helpful in improving the quality of the reverberant speech. Among the front-end signal processing technologies, three categories of dereverberation methods are generally applied: 1) beamforming using microphone arrays, 2) spectral enhancement, 3) blind system identification and inversion (Naylor & Gaubitch 2010). Spectral enhancement based dereverberation shows superiority due to its robustness in both reverberant and noisy environment (Yoshioka, Nakatani & Miyoshi 2009). Fractional time delay alignment filter is applied to the reverberant signal, and the acoustic scene is classified by analyzing the coherent component. Based on the acoustic scene, an appropriate spectral enhancing scheme is selected to eliminate the interference as much as possible while keeping the speech distortion always in a low level.

Recently, acoustic model based on the Deep Neural Networks (DNNs) has gained popularity with the consistent improvement in recognition performance over earlier Neural Network based front-ends, e.g. (Grézl *et al.* 2007). DNNs are either deployed as the front-end for standard Hidden Markov Model based on Gaussian Mixture Models (HMM-GMMs), or in a hybrid form to directly estimate state level posteriors. As noted in several publications (Larochelle *et al.* 2009, Seide

et al. 2011, Liu *et al.* 2014), DNNs show general WER improvements on the order of 10–30% relative across a variety of small and large vocabulary tasks when compared with HMM-GMMs built on classic features (e.g. MFCC, PLP). Neural network based features have long been used successfully in speech recognition (Stolcke *et al.* 2005, Grézl *et al.* 2009, Hain *et al.* 2012). While the early research did not involve deep layers (Larochelle *et al.* 2009), the path towards deep learning was laid in the stacking of bottleneck networks (Grézl *et al.* 2009). A DNN is a conventional Multi-Layer Perceptron (MLP) with many internal or hidden layers. The BottleNeck (BN) features extracted from the internal layer with a relatively small amount of neurons have been shown to effectively improve the performance of ASR systems. It is possibly due to the limited number of units which creates a constriction in the network and further forces the information pertinent to classification into a low dimensional representation (Seide *et al.* 2011, Tüske *et al.* 2013). In many ASR systems, the neural network based features performs better than the cepstrum or spectrum based features (e.g. MFCC, PLP).

According to the REVERB challenge, the reverberant data is simulated or recorded in various rooms with different distances between source and microphones (Paul & Baker 1992, Robinson *et al.* 1995, Lincoln *et al.* 2005), and three kinds of utterance are provided: 1-channel, 2-channel and 8-channel. We choose the 2-channel

dereverberation method for both Speech Enhancement (SE) task and ASR task. The work in this paper aims to extend and enhance the preliminary work in (Wang *et al.* 2015) with advanced DNN based feature extraction. We follow the standard strategies where the DNN includes one input layer, three hidden layers, another bottleneck layer and one output layer. The BN features are extracted from the bottleneck layer of DNN trained to predict the context-dependent clustered triphone states.

The rest of this paper is organized as follows. Section 2 introduces the algorithms of 2-channel dereverberation, VAD and DNN based feature extractor. Section 3 presents the experiment results. Finally, Section 4 concludes the paper and discusses the future work.

2 RECOGNITION OF REVERB SPEECH

2.1 System overview

Figure 1 shows the overall system proposed for REVERB challenge. It contains two basic modules, front-end module and back-end evaluation module. In the front-end module, different from our previous system, we adopt a DNN based feature extractor. For consistent comparison, we use the same recognizer provided by REVERB challenge organizer.

2.2 Dereverberation and Noise Reduction

Spectral enhancement methods show their priority on the robustness in the condition of both noise and reverberation. In this section, an acoustic scene aware dereverberation method is utilized for the purpose of achieving environmental adaptation (Wang *et al.* 2015). Two sensors are utilized since it is the basic topology of all microphone arrays and can be generalized to any other microphone arrays conveniently.

2.2.1 Signal model

Let $s(n)$ represent the target clean signal, and $x_m(n)$ is the time-aligned signal at sensor $m(m = 1, 2)$ $n_m(n)$ is the noise of environment. $h_m(t)$ can be seen as the time-delayed Room Impulse Response (RIR) which is the convolution of real RIR from target signal to sensor $m(m = 1, 2)$ and alignment filter where the alignment filter is designed to steer the

direction of target speech signal. Then the observed signal each channel can be expressed as follows.

$$x_m(n) = h_m(t) * s(n) + n_m(n) \quad (1)$$

Applying STFT to the 16 kHz time-aligned signal, we have signal expression at l th frame and k th frequency bin in time-frequency domain.

$$x_m(l, k) = H_m(l, k)S(l, k) + N_m(l, k) \quad (2)$$

2.2.2 Spectral enhancement

Spectral Enhancement method has a generalized form. The estimate of the amplitude spectrum of the target signal can be expressed as follows.

$$|\hat{S}(l, k)| = G(l, k) |\hat{X}(l, k)| \quad (3)$$

$G(l, k)$ is the gain estimated on each frequency bin and $|\hat{X}(l, k)|$ is the amplitude spectrum of signal to be enhanced. Before overlap-and-add scheme, regardless of leakage between frequency bins caused by STFT, both $G(l, k)$ and $|\hat{X}(l, k)|$ should be chosen cautiously versus distortion to achieve robustness.

2.2.3 Environmental adaptation based processing

Reverberation, especially late reverberation, shows isotropic property as well as the environmental diffuse noise, while the direct sound shows strong coherent property (Kuttruff 2009). There are two main acoustic scenes of the room. One is the reflection condition which can be interpreted by reverberation time (T60) and the other one is the speaker-mic distance. By estimating the proportion of coherent component, the effects of the two are synthesized. All the diffuse part can be seen as noise to be filtered. We follow the Coherent-to-Diffuse energy Ratio (CDR) estimation in (Jeub *et al.* 2011), which is expressed as follows.

$$\mathcal{E}(e^{j\Omega}) = \frac{|\sin c(\Omega f_s d_{mic} / c)|^2 - |\Gamma_{x_1 x_2}(e^{j\Omega})|^2}{|\Gamma_{x_1 x_2}(e^{j\Omega})|^2 - 1} \quad (4)$$

$\mathcal{E}(e^{j\Omega})$ is CDR estimator of each frequency bin and $\Gamma_{x_1 x_2}$ is the expression of complex coherence function (McCowan & Boulard 2003). And a Wiener filter can be formed based on the estimation of CDR which can filter the non-coherent part. According to (Jeub *et al.* 2011), it's more accurate when CDR is relatively large. Furthermore, We use global CDR, denoted by $\hat{\mathcal{E}}$, as a full-band acoustic scene aware controller indicating the level affected by reverberation and diffuse noise which can be interpreted as a direct sound activity detector to achieve environmental adaptation.

Figure 1. System structure.

Up to now, lots of 1-channel and 2-channel dereverberation methods have proved the efficiency under the framework of spectral enhancement and achieved the robustness to noise compared with the methods using inverse filtering. Fixed beamforming, such as Delay-and-Sum Beamformer (DSB), helps to suppress the reverberation based on priori DOA information though its suppression ability is limited. Late reverberation suppressing method using generalized statistic model of reverberation (Habets *et al.* 2009) shows outstanding performance especially when reverberation is strong. Based on the controller mentioned above, we compare $\hat{\epsilon}$ with three constants $\sigma_1, \sigma_2, \sigma_3$, (from large to small, chosen 15 dB, 10 dB, 5 dB).

Spectral enhancement strategy suggested above separates the acoustic scene into four cases. In the first case, the acoustic scene is ideal so that the speech signal recorded is very close to clean speech. In the second and third cases, a moderate trade-off between dereverberation and signal distortion is achieved. In the last case, more reverberation reduction means better performance when reverberation is strong enough.

To avoid music noise, both time recursive and adjacent frequency gain smoothing are conducted. The recovered signal is obtained by inverse STFT and overlap-and-add scheme. The phase of recovered speech signal equals the noisy phase of beamformer output. All the processing is with windows of 512 points and step-size of 256 points which means the result of a DFT with length 512 (32 ms) at a shift of 16 ms.

2.3 DNN based VAD

Voice Activity Detection (VAD) is important in speech processing. In the applications, the systems usually need to separate speech/non-speech parts, so that only the speech part can be dealt with. DNN, which proves its efficiency in speech recognition, has been widely used in recent years. We use simulated data to train a DNN based VAD. The input layer is the features of speech/non-speech parts, and the output layer is the posterior of speech/non-speech parts. We use Error Back Propagation (EBP) algorithm to train the model.

2.4 DNN based features

Figure 2 shows the architecture. It is similar to those in (Grézl *et al.* 2007, Grézl & Fousek 2008, Veselý *et al.* 2011). All DNNs are trained feed-forward with the TNET¹ on GPUs. In a default

Figure 2. DNN module structure.

TNET setup, 31 adjacent frame MFCC features are decorrelated and compressed with DCT into a dimension of $624(31 \times 39 \rightarrow 16 \times 39)$. Global mean and variance normalization are performed on each dimension before feeding as the DNN input. The 6 layered DNN structure is shown in Figure 2. On average 10% data in training set is reserved for cross validation in DNN training. The training stops automatically when the improvement of frame-based target classification accuracy on the cross validation set drops below 0.1%.

The bottleneck layer is placed just before the output layer, as in our initial experiments this topology gives the best performance. We set to 26 dimensions according to our experiments. DNNs are trained on classification targets of 3143 triphone states. In the bottleneck layer, linear BN features are extracted before the sigmoid activation.

3 EXPERIMENT

3.1 Data and system set

In the REVERB challenge, both simulated and real recorded data are provided. The simulated data (SimData) is convolved by clean utterance from WSJCAM0 corpus (Robinson *et al.*, 1995) with the recorded RIR in different rooms. The reverberation time of the rooms are 250 ms, 500 ms and 700 ms respectively. Recorded background noise is added to the reverberant data at a fixed Signal-to-Noise Ratio (SNR) of 20dB. The real recorded data (RealData), utterances from the MC-WSJ-AV corpus (Lincoln *et al.* 2005), consists of utterances recorded in a noisy and reverberant room with reverberation time of 700 ms. Both SimData and RealData include two types of distances between the speaker and microphone array (near = 50 cm and far = 200 cm). The test data are from the SimData and RealData databases under the following important assumptions. First, there is no drastic change in RIR within an utterance. Second, relative speaker-microphone position changes from utterance to utterance, which means the Direction of Arrival (DOA) of the target speech signal

¹<http://speech.fit.vutbr.cz/software/neural-network-trainer-tnet>

is uncertain, and this is essential to our dereverberation method. The recording 8-channel circular array has diameter of 20 cm and the 2-channel microphone distance, denoted by d_{mic} , which can be calculated.

Under the framework of HTK based recognizer, we retrain the acoustic model of “multi-condition” using HMMs structure and DNN respectively. The proper starting point is that the artificially distorted training signals are mismatch with the enhanced ones. Then the five possible cases are:

Clean+noEnh: “clean-condition” HMMs without dereverberation;

Multi+noEnh: “multi-condition” HMMs without dereverberation;

Clean+Enh: “clean-condition” HMMs with dereverberation;

Multi+Enh: “multi-condition” HMMs with dereverberation;

DNN+Multi+Enh: “multi-condition” HMMs with features from DNN.

3.2 Baseline experiments

For the ASR task, WER of test data is reported in Section 3.1. Baseline models of ASR task as well as retrained model are provided in this section. The “clean-condition” baseline system uses 39D Mel-Frequency Cepstral Coefficients (MFCCs) including Delta and Delta-Delta coefficients as features. As to acoustic models, it employs tied-state HMMs with 10 Gaussian components per state trained according to the maximum-likelihood criterion (Kinoshita *et al.*, 2013). All the training data for “clean-condition” HMMs is from WSJ-CAM0 corpus (Robinson *et al.*, 1995). Further, the model is retrained using the features of artificially distorted 7861 utterances to form the “multi-condition” HMMs. The utterances are in mixture with 24 kinds of RIRs and 6 kinds of noises. We test the enhanced signals on the two baseline systems both using and not using the unsupervised CMLLR model adaptation. We also retrain the

DNN based VAD to separate speech/non-speech parts.

Table 1 shows the WER results on SimData and RealData datasets respectively. It includes the ASR results of “clean-condition” model, “multi-condition” model. WER of near, far data and their average are reported separately. As we can see, “multi-condition” model performs better than “clean-condition” model. It achieves decrease on WER from 51.68% to 29.51% on average of SimData and from 88.53% to 56.94% on average of RealData. Consistent improvement across all recording conditions is achieved by using CMLLR which results in WER 25.25% on SimData and 48.85% on RealData.

3.3 2-channel dereverberation

Performance of dereverberation is examined using both “clean-condition” and “multi-condition” acoustic models. According to Table 2, recognizing the test set with “clean-condition” model without CMLLR adaptation, the dereverberation method achieves decrease on WER from 51.68% to 37.06% on average of SimData and from 88.53% to 72.62% on average of RealData. Consistent improvement across all recording conditions is achieved by using CMLLR which results in WER 27.93% on SimData and 62.12% on RealData. However, recognizing with “multi-condition” model without CMLLR adaptation, the performance (SimData: 34.22%, RealData: 59.72%) is worse than the “multi-condition” baseline (SimData: 29.51%, RealData: 56.94%) because the recognizing enhanced data is mismatched with the reverberant data used to train the “multi-condition” acoustic model, though using CMLLR gives a little improvement.

3.4 Bottleneck features from DNN

Table 3 shows the results for BN features based decoding. All the DNNs are trained with the

Table 1. Word error rate of baseline.

	CMLLR	14.72	19.23	19.95	25.07	25.42	34.02	23.07	54.52	54.62	54.57

triphone state targets force-aligned using training set. The decoding is performed on the test set. We achieve different performance without CMLLR and with CMLLR. On “Multi+Enh” case, we get 33.43% relative decrease on SimData using BN features without CMLLR. But we only get 2.49% relative decrease with CMLLR. That is because we only use DNN as a front-end. During decoding process, we use the HMM-GMM structure of baseline system. CMLLR may not be so work for the DNN features. Another reason lies the feature dimensions, we use 39-dimension MFCC features for our baseline system, but only 26-dimension BN features adopted in this paper.

4 CONCLUSION

We have presented out a dereverberation approach to the REVERB challenge based on spectral enhancement. An acoustic scene aware technique is proposed to make dereverberation robust to different conditions. For ASR task, when it is combined with back-end ASR with matched training, it produces a significant decrease on WER.

The DNN based front-end was tested in the context of reverberant speech recognition. Experiments showed that on SimData, BN features gave an average 33.43% relative WER reduction over using MFCC features without CMLLR. Retrain-

ing did not give as much gain as we got on MFCC features. We also need to do further experiments on RealData about the performance difference between MFCC features and BN features.

Yecheng Pu

School of Business Administration, Dongbei University of Finance and Economics, Dalian, China

ABSTRACT: This paper proposed a new view of the application of data mining analysis in electricity commerce, and examined how to use k-means cluster and association rule mining as an entity to accurately explore the association rules between varieties of indexes, with whatever quantitative data or qualitative data. The online shops' indexes like product ratings, percentages of delivery speed, ranges among the whole industry, and regional distribution were first classified and clustered, and then applied or mined by Apriori algorithm, a method of association rule mining. The results with a comprehensive analysis will be helpful not only in instructing the merchants who run an online shop, but also in offering valuable information to the investigators related to electricity commerce.

1 MODELS AND BASIC ALGORITHMS

1.1 Cluster analysis

A cluster is dividing the dataset into multiple classes or clusters. The data points set are as similar as possible in the same cluster and as far as possible in a different cluster. Cluster analysis, as an important part of statistics and the related research, has a long history and is an important part of data mining and pattern recognition.

The cluster is applied in business most typically for it can help market analysts find different kinds of customers from the database and depict characteristics of different customer base by buying patterns. There are some other applications of the cluster including speech recognition and character recognition in pattern recognition, the data compression in image segmentation, image processing and information retrieval, genetic classification of biology, etc. The commonly used algorithms like K-means algorithm, DBSCAN algorithm, CURE algorithm, and COBWEB algorithm are applied for discriminative situations and conditions, especially on data. Due to a large amount of data in this paper, the accuracy of the cluster is not high, so K-means cluster was chosen here.

1.2 K-means cluster

The basic idea of K-means algorithm is to classify the objects nearest to them by clustering the k points in space. The iteration method is used to update the value of each cluster center until the best clustering result is obtained.

Assuming that the sample is divided into c categories, the algorithm is described as follows:

1. The initial center of c classes is chosen appropriately.
2. In the "k" th iteration for any sample find its distance, which is usually the Markov Distance to the c centers and classify the sample into the class where the center with the shortest distance to the sample locates.
3. The center value of the class is updated by the rest samples' average and the like.
4. For all c cluster centers if the value is not changing, then the iteration ends. Otherwise, the iteration is continued.

1.3 Association rule analysis

Association rule analysis was invented initially for the retail industry, shopping basket, in particular, to find the relationship between the merchandise of consumers and discover the association rules. This kind of analysis benefits the retail industry to appoint a marketing strategy. As a result of the relevance analysis having a wide range of applicability, many researchers have done in-depth research on association analysis including optimizing the algorithm and improving the efficiency of the algorithm. The improved algorithm for association rules has been proposed ever since.

Association analysis aims to find association rules between data. For example, the customers in a supermarket who purchase A often buy B at the same time. That is $A \Rightarrow B$, which is treated as an association rule. In 1993, Agrawal *et al.* firstly

proposed mining association rules among items in the customer transaction database. The formal description is as follows.

Let I be a set of m different data items where the elements are called terms, the collection of items is called an item set, an item set containing k items is called a k -item set. Given a transaction D , that is the transaction database where each transaction T is a subset of data items, that is, $T \subseteq I$, there is a unique identifier TID. The transaction T includes the set X if and only if $X \subseteq T$. Then the association rule is an implication of " $X \Rightarrow Y$ ". As for $X \subseteq I, Y \subseteq I, X \cap Y = \emptyset$, the records that satisfy the condition in X must also satisfy the Y as per association rule $X \Rightarrow Y$ in the transaction database, with support S and confidence C .

The transaction dataset D has a support degree S , that is, D , at least $S\%$ of the transaction contains $(X \cup Y)$, described as support $(X \Rightarrow Y) = P(X \cup Y)$. It appears that support $(X \Rightarrow Y)$ equals that of the number of simultaneous purchases of goods X and Y plus the total number of transactions at the same time in transaction dataset D with confidence C , that is, the items included in the transaction D contains at least $C\%$ of Y at the same time, which is described as confidence $(X \Rightarrow Y) = P(Y|X)$. It is like when someone purchases the goods X and the possibilities for purchasing goods Y , and confidence $(X \Rightarrow Y)$ equals the number of transactions in which the goods X and Y are purchased at the same time, plus the number of transactions in which the goods X is purchased.

Association rule mining is to mine the transaction database on the basis of the given "minimum support" and "minimum confidence" in order to find the strongest association rules which satisfy minimum support and minimum confidence. The mining of association rules includes one-dimensional Boolean association rule analysis, multi-level association rule mining, and constraint-based association rule mining. The typical algorithm of one-dimensional Boolean association rule analysis is Apriori algorithm. The core idea of this algorithm is to find the frequent item set firstly and the association rules can be generated by satisfying the minimum support and minimum confidence condition. The generation of frequent item sets is an iterative process. In the process of finding k frequent item sets every time a large item set is selected from a candidate set, the database will be scanned once, which greatly reduces the efficiency of the algorithm. If the database is a large database, each candidate set is very large and the deficiency of the algorithm is more obvious. Thus, how to improve the validity of Apriori algorithm is a key problem. There are a lot of revised versions of Apriori algorithms designed mainly to improve the efficiency of the original algorithm. The improved methods

include compressing transaction sampling and the like to minimize the number of scans and number of scanning transactions.

1.4 Apriori algorithm

The property of Apriori (Combined by "a" and "priori") algorithm is called the priori principle that if an item set is frequent, then all of its non-empty subsets must also be frequent. Conversely, if an item set is infrequent, then all its supersets must be infrequent. If A does not satisfy the minimum support threshold s , then A is infrequent. If $P(A)$ adds b to A , then the support of the resulting item set $\{A, b\}$ will be less than A 's support, $\{A, b\}$ is not frequent.

The principle of the connection step: Suppose the element in the items and the items in the item set are sorted by the dictionary, if the first $k-2$ elements of I_1 and I_2 in the $k-1$ frequent item set are the same, then I_1 and I_2 can be connected to generate the new item set C_k .

Pruning principle: C_k is a superset of I_k , and scans the count of each item in the C_k in the total database to calculate the support. If it is greater than the support for the threshold, then it is the superset. If not, then it is discarded. If the number of item sets generated is too excessive to compute then we can use the Apriori property in this step: If the subset $k-1$ of the k item set is not included in the frequent $k-1$ item set, the candidate will not be frequent and will be deleted directly.

Algorithm steps:

Input: transaction database D , minimum support threshold.

Run the steps as:

1. Scan the database and generate C_1 in a set of items.
2. Count prune C_1 item set and then get frequent I_1 item set.
3. According to the frequent I_1 item set, the candidate item set C_2 is generated.
4. Scan the database and discard the undercounted part from C_2 to generate I_2 .
5. Use the Apriori property to generate and simultaneously prune (cut off the infrequent) getting C_3 .
6. Scan the database and discard the undercounted portion of C_3 to generate I_3 ; (n) Output: the final frequent item set according to the threshold.

2 EMPIRICAL ANALYSIS

2.1 About the data

The dataset includes 491 Taobao (a Chinese electronic commerce company like Amazon) electricity

business shop information, mainly in the mobile phone industry. Shop information or indexes include shop name, the industry, the company, the punishment ratings, product rating, bad ratings, delivery speed scores, praises, dispute rates, credit rankings, and so on. The data coverage time is from June 18, 2008, to September 26, 2014. A part of the source data is in Table 1.

2.2 Data preprocessing

First of all, we removed some of the indexes that are not so significant such as shop creation time, store-owned platform, store name, etc., and then pre-processed the data. The data preprocessing includes judgment of the missing value and process of discretizing the various numerical indexes. For the shop data with a huge number of missing values, we discarded it directly. For shop data with a small number of missing values, we treated the missing value as 0 or the global average. The continuous data discretization is also divided into two categories:

1. For more evenly distributed data, we selected the quartile for the boundaries and the data divided into high, fair, acceptable, and low as four levels.
2. For data with different distributions and different levels, we used K-means clustering method to select the appropriate cluster number by several attempts and divide them into suitable n clusters (n is mainly 3, 4, 5). As shown in the following Table 2, it is part of the data preprocessing results.

2.3 Empirical analysis and visualization

There were 46,653 effective rules generated after initial mining. Some representative association rules are shown in Table 3. For the 46,653 valid rules, they revealed some negative correlation characteristics between the distribution of support and confidence shown in Figure 1.

Table 1. A small part of the source data.

create_date	dsr_zl_grade_percent_5 stars	seller_title	shop_id
2014/5/20	0.9474	GZ Telecom flagship store	110999741
2011/10/17	0.9382	HLJ Telecom flagship store	69265553
2011/11/14	0.931	SX Telecom flagship store	69643988
2013/9/10	0.8944	EP Official flagship store	106319694

Table 2. A small part of the preprocessed data.

dispute_rate	refund_rate	seller_dsr_fw	avgRefund

Fair	hard	high	fast
mild	hard	high	fast
mild	easy	fair	fast
mild	hard	fair	fast
mild	very hard	fair	fast
mild	very hard	high	fair

Figure 1. Distribution of initial mining support and confidence.

From Table 2 we can see some strong association rules:

1. For merchants with a low or even general delivery speed rating and low description rating, their shipments are ranked lower in the same industry. What's more, most of this part of the merchants are from the Taobao platform (type = b). These problems even appear in the sellers with few industry disputes.
2. For some of the sellers with a relatively low score in the index “conformity in products and description” and a less than general score in delivery rating in the same industry ranked lower or even the general ranking of the seller, they often have problems like low delivery speed scores and a part of the merchants with a low success rate of refund.

Then, 46,653 rules were selected for support and confidence, and 152 association rules with the highest degree of support and confidence were selected. As can be seen, the strong association rules of this 152 gather into a number of shops with lower quality scores, slower shipments, and lower rankings in the industry, as shown in Figure 2.

As can be seen from Figure 2, the shop with a relatively strong correlation is the industry-level ranking. One with the poor speed of delivery in the industry ranks and poor product ratings in the industry ranks often comes with the high industry

Table 3. A representative part of the association rule analysis results.

Lhs	rhs	support	confidence	lift
{dsr_fw_com=lower}	=> {seller_dsr_fh_com=lower}	0.60	1.00	1.36
{seller_dsr_fw=fair}	=> {seller_dsr_fh_com=lower}	0.54	1.00	1.36
{seller_dsr_fw=fair}	=> {dsr_fw_com=lower}	0.54	0.99	1.58

{seller_dsr_fh_com=lower, seller_dsr_fw=fair}	=> {dsr_fw_com=lower}	0.54	0.99	1.58
{seller_dsr_fw=fair, dsr_zl_com=lower}	=> {seller_dsr_fh_com=lower}	0.54	1.00	1.35
{seller_dsr_fw=fair, dsr_zl_com=lower}	=> {dsr_fw_com=lower}	0.53	0.99	1.58
{seller_dsr_fw=fair, dsr_zl_com=lower, {dsr_fw_com=lower}	=> {seller_dsr_fh_com=lower}	0.53	1.00	1.35
{seller_dsr_fh_com=lower, seller_dsr_fw=fair, dsr_zl_com=lower}	=> {dsr_fw_com=lower}	0.53	0.99	1.58
{seller_user_type=b, seller_dsr_fw=fair}	=> {seller_dsr_fh_com=lower}	0.53	1.00	1.35
{dsr_fw_com=lower}	=> {seller_dsr_fh_com=lower}	0.43	1.00	1.35
{seller_dsr_zl_grade=bad}	=> {seller_dsr_fh_com=lower}	0.42	1.00	1.35
{seller_dsr_zl_grade=bad, dsr_zl_com=lower}	=> {seller_dsr_fh_com=lower}	0.42	1.00	1.36
{seller_dsr_zl_grade=bad, seller_dsr_fh_com=lower}	=> {dsr_zl_com=lower}	0.42	1.00	1.38
{dsr_zl_com=lower}	=> {dsr_fw_com=lower}	0.52	0.99	1.58

Figure 2. The rule distribution after screening.

dispute rate and a slow refund rate. At the same time, we can also know, for sellers with “general” speed of delivery, the refund rate is often slow. Sometimes there are low scores towards their goods.

Figure 3. Regular distribution after secondary screening.

For those association rules of stores with good or at least general performance in product ratings, delivery speed, and industry ranking, by reducing the support we can obtain a certain degree of association with little weaker association rules and some more information about this type of store as shown in Figure 3.

What can be found from Figure 3 is that a number of sellers with fast delivery and delivery of

Figure 4. Strong association rules.

high ratings often get a high score in the “product and description consistent”. At the same time, for some merchants with low rates of industry disputes, there is often a “shipping issue is controversial” issue occurred. Such merchants also make up a part of merchants located in Shenzhen, Guangdong Province, which can seem as a characteristic of the region. While in Shenzhen, Guangdong Province, the merchants also have a low delivery score, lower shipments in the industry rankings, which is just a conformity with the former conclusion.

3 CONCLUSIONS

3.1 Text and indenting

With the previous analysis, we conclude that:

1. Based on the characteristics of the source data, for most of the linear data, there is often an uneven distribution of the situation, especially because of the prevalent “Brush” phenomenon (merchants paid for increasing illusory high ratings and obliterating relatively lower ratings) in the industry, leading data distribution to be like the one with heavy head but light feet. For such data, if one wants to explore the correlation strength of indexes, the traditional contingency analysis or regression methods may cause something prone to the characteristics of the poor degree of fit, error, and poor predictive. The “cluster-association rule analysis” method used in this paper can enlarge the difference between data and make the distribution of processed data more even. The result is convincing and the error is controllable.
2. The relatively stronger association rules exist in the merchants or shops whose overall strength is considerably poor (shown in Figure 4). Thus, the problems of these merchants are much exhaustive like low product scores, slow delivery speed,

low dispute rate, behindhand industry rankings, and poor refund performance, the competitiveness of which is the overall backwardness of the merchants. If they want to improve the business situation, they need to start with the whole system from product to shipment to solve all kinds of problems after the sale.

3. For those merchants with a high index such as those with high product ratings or fast delivery or good refunds, the association rules for each of these metrics are weaker indicating that for merchants of the industry when an index with outstanding performance occurs, the performance of other indexes are often not satisfactory. For these shops, the improvement needed is to avoid weaknesses and at the same time, without ignoring the “bucket effect” of the existence. Their inherent impressive performance needs to be maintained. Relatively poor areas need to be further strengthened in order to search for diversified development.
4. As for the association rules for regional distribution, the most prominent one is the seller in Shenzhen, Guangdong, whose overall market performance is not high. It may be related to the development of the region itself, and merchants and governments in the region need to reflect on this.

As for the mining of association rules in this paper, the following problems exist:

1. Although there are 46,653 effective association rules in this paper, most of them have little-referenced value. For example, “some of the merchants with low score of delivery often come with low-ranking shipments in the industry”, this kind of association rules that can consider as “nonsense with obvious truth” often takes a large part, and a great part of them are in the strong association rules, which makes the selection of the result very difficult.
2. The Apriori algorithm used in this paper is the most basic one. It has some shortcomings such as “needs to scan the database for many times which may waste too much time unnecessarily”, “generates a large number of candidate sets” and “too much computation”. There is a certain amount of space for further optimization.

Research on a non-guided link discovery technology to obtain an early warning of financial risk

Chunyan Xue

Tan Kah Kee College, Xiamen University, Fujian Sheng, China

ABSTRACT: Early warning of financial risk is an important research direction in financial data mining. Financial risk warning is difficult because financial data are various, complex, and dynamic. Using data mining technology can discover the hidden abnormal transaction information from massive financial data, and then the technology can monitor and deal with it a timely manner. Early warning of financial risk can reduce the operational risk of financial institutions effectively. This paper introduces a method of discovering suspicious transaction information at risk with early warning. The method is based on the non-instructional link discovery technology in data mining. It can realize the hidden information found in massive data. The method first constructs the financial transaction network. Second, it finds the target node and path of the transaction, and then filters them. Then it calculates the transaction frequency of the selected path. Finally, it finds the outlier based on the distance-based outlier detection algorithm. These outliers are the suspicious transaction information. By processing these information, financial institutions can avoid financial risks.

1 INTRODUCTION

One of the main economic functions of the financial sector is to reduce and control the risks to investors and financiers in the process of social financing at an appropriate level. Early warning of financial risk refers to the supervision of the financial operation process and the warning on test results.

The system analyzes customer data including customer financial data, the credit contract information, the capital account transaction, the external judicial information, the financial information, and so on. Through the analysis, the system can detect suspicious transaction information and predict which customers in the future may be transformed into a bad customer.

Discovery of the suspicious transaction information is the most important part of the whole risk early warning system because bad customers' information is often more "alternative" than the normal customers. So it can infer the bad financial customers by discovering these "alternative" transaction information.

There are three main methods of detecting suspicious transaction information in the risk early warning system:

1. It uses manual calculation and manual monitoring to find the suspicious transaction information;
2. According to expert experience to solidify the knowledge into the model and then use

the model to find the suspicious transaction information;

3. Using machine learning techniques to identify suspicious transaction information intelligently.

However, these three methods have their own shortcomings.

This paper presents a method for discovering suspicious transaction information in the financial risk early warning system. The idea is to discover non-coherent link discovery technology in data mining. The purpose of this method is to discover hidden information of abnormal data from massive data.

2 THE COMPOSITION AND STRUCTURE OF THE SYSTEM

The system has six modules:

1. Establishment of the transaction network module: the transaction data in the database are recorded separately in order to reflect the relationship between various transaction nodes and records. The transaction data in this module include account, transaction amount, an organization of account, transaction time, trading location, trading network model, and the link between them. The module will use this data graph theory to build a trading network map.
2. Discovery of the target node and transaction path module: This module is based on the transaction network module. The source node is the

- given suspicious account. Then the module will find all the target nodes which have a direct relationship or indirect relationship with the source node and the transaction path between them;
3. Filter the target node and transaction path module: This module will provide five types of rules to filter the mass target node prior;
 4. Extraction of the transaction path type module: The module's main function is to extract the path type from the filtered transaction path. It prepares for the frequency calculation module;
 5. Frequency calculation modules: the module's main purpose is to quantify effect value between the goal node and each type of path. The value is the "frequency".
 6. Discovery of suspicious transaction information module: Calculate the frequency between all target nodes and the transaction path and then construct all the frequencies as eigenvectors. The outlier detection algorithm is then used based on the distance to find outliers. The outliers are the suspicious transaction information that the users are interested in.

3 THE APPLICATION OF NON-GUIDED LINK DISCOVERY TECHNOLOGY IN THE PROCESS OF GAINING EARLY WARNING OF FINANCIAL RISK

3.1 Non-guidance link discovery technology

Non-guidance link discovery method is the expansion of link analysis method in data mining. The method builds some disconnected objects into a network. It finds useful patterns and trends in the network. The whole process is divided into the following three stages: to set up a model stage, abnormal trading path discovery, and abnormal trading node discovery. The key to the study is to determine the object type in the transaction model and the relationship between them.

3.2 Financial risk early-warning process

3.2.1 Setting up the network module

The graph $G(V, E)$ represents the trading network. V is the nodes set. There are five type of nodes in the nodes set, including accounts, transaction amount, accounts organization, trading time, and trading locations. E is the edges set. The edges are the relationship among these six types of nodes shown in Figure 1.

Node type in the trading network:

- P_i account.
- D_i transaction time.
- T_i virtual node represents one transaction.
- S_i transaction amount.

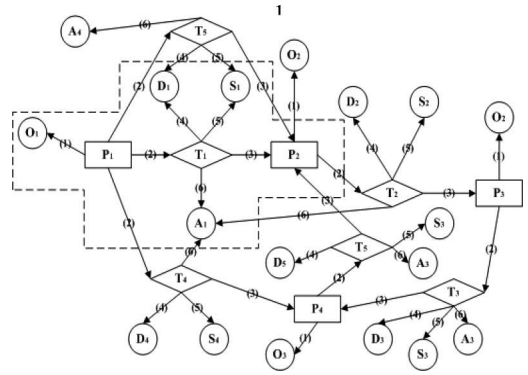

Figure 1. Trading network diagram.

- O_i account organization.
- A_i transaction locations.

3.2.2 Target node and transaction path discovery module

The main function of this module is to select the account from the bad customer account database as the source node in the transaction network diagram and then use the directed graph traversal algorithm to discover the target nodes connected to the source node and all the transaction paths between them.

For example, account P_1 is the source node, the target node which connected with P_1 and all transactions path are shown in Table 1.

3.2.3 Target node and transaction path filter module

Since the number of object nodes involved in the transaction network graph is huge, when the source node is given, the amount of target node and transaction path data obtained from the above module will be huge too. It will affect the computational efficiency of subsequent modules. According to business domain knowledge and expert experience, some information out of range can be filtered in advance, so this module defines five filtering rules to filter the target nodes:

- The amount filter rules M : When the amount node M_i ($0 \leq i \leq n$) is the destination node, it will reserve the nodes whose amount is greater than or equal to M , and the others will be filtered.
- Time filtering rules (T_m, T_n): When time node T_i ($0 \leq i \leq n$) is the target node, it will reserve the nodes in the period in (T_m, T_n).
- Place filter rules $\{A_m\}$: When the location node A_i ($0 \leq i \leq n$) is the destination node, the nodes that are in the set $\{A_m\}$ will be filtered.
- Filter rules to account organization $\{O_m\}$: When the account organization node O_i ($0 \leq i \leq n$) is

the destination node, the nodes who are in the set $\{O_m\}$ will be filtered.

- Account filtering rules $\{P_m\}$: When the account node P_i ($0 \leq i \leq n$) is the destination node, the nodes who are in the set $\{P_m\}$ will be filtered.

3.2.4 Trading path type extraction module

The main function of the module is to extract the transaction path according to the types. Since every node in the transaction model has a type, the transaction path composed of the nodes will also form different transaction path types. All paths in Table 1 can be merged into four types, as given in Table 2.

3.2.5 Frequency calculation module

Frequency is actually a relative measurement. It is established on the basis of different path types. It indicates that for the exchange path type tp , if S is the source node, count the probability of T which is the destination node". Frequency formula:

$$\text{Frequency} = N1/N2 \quad (1)$$

$N1$ represents the total number of transaction paths between the given source node S and the target node T , which satisfies the path type tp ;

Table 1. The path table as the source node is $P1$.

Source node-> Target node	Serial number	Trading path
P1->P2	Path 1	P1->T1->P2
	Path 2	P1->T5->P2
	Path 3	P1->T4->P4->T5->P2
	Path 4	P1->T1->P2->T2->P3->T3->P4->T5->P2
P1->P3	Path 6	P1->T1->P2->T2->P3
P1->P4	Path 7	P1->T4->P4
	Path 8	P1->T1->P2->T2->P3->T3->P4

Table 2. Path type whose source node is $P1$.

Path	Corresponding transaction path type	Merge paths
Path 1	Account->Virtual node->Account	1. Account->Virtual node->Account number 2. Account->Virtual node->Account->Virtual node->Account number 3. Account->Virtual node->Account->Virtual node->Account->Virtual node->Account number 4. Account->Virtual node->Accounts->Virtual node->Account->Virtual node->Account->Virtual node->Account number
Path 2	Account->Virtual node->Account	
Path 3	Account->Virtual node->Account->Virtual node->Account	
Path 4	Account->Virtual node->Account->Virtual node->Account	
Path 6	Account->Virtual node->Account->Virtual node->Account;	
Path 7	Account->Virtual node->Account	
Path 8	Account->Virtual node->Account->Virtual node->Account	

$N2$ represents the total number of transaction paths between the source node S and any destination nodes, which all match the path type tp .

According to the above description of the significance of frequency $N1/N2$, we can get a conclusion: when a source node terminates at a target node with a high probability, it means there are frequent trading path types between the source nodes and target nodes. So we think there is a close relationship between the source node and target node.

According to Figure 1, Table 1, and Table 2, $N1$, $N2$, and frequency values are calculated and given in Table 3.

3.2.6 Obtaining suspicious trading information

Quantification of the target nodes is the inputting condition. Outlier set $\{N\}$ are obtained by using the outlier mining algorithm based on distance. The final result is suspicious transaction information that the users are interested in.

Outlier mining algorithm based on distance: If the data set $\{D\}$ object has at least pct parts that the distance to the objects O is bigger than

Table 3. Frequency value table.

Node	Path type	N1	N2	Frequency
P1->P2	Type 1	2	3	2/3
	Type 2	1	2	1/2
	Type 3	0	1	0
	Type 4	1	1	1
P1->P3	Type 1	0	3	0
	Type 2	1	2	1/2
	Type 3	0	1	0
	Type 4	0	1	0
P1->P2	Type 1	1	3	1/3
	Type 2	0	2	0
	Type 3	1	1	1
	Type 4	0	1	0

Figure 2. Outlier point based on distance.

the d_{min} . So object O has outlier points based on parameters pct and d_{min} . In Figure 2, point A is the relative outlier to the other points. The data in Figure 2 is based on data in Table 3.

4 CONCLUSION

Non-guiding link discovery technology is efficient, time-saving, and labor-saving. The application of

this technology can handle large amounts of data and improves the processing efficiency of risk information. The method can ensure finding suspicious transaction information results in a timely manner. The method reduces business manual calculation and time of manual monitoring. The technology is not based on expert experience entirely and ensures objectivity. It can find the unknown mode of suspicious transaction information.

ABSTRACT: The concept of nanofluid was forward and the innovative PhotoVoltaic-Thermal (PVT) systems design using nanofluid as the heat transfer medium was carried out. The overall efficiencies achieved were over 5% higher than the conventional media, water and air, due to the higher heat capacity of nanofluid. The phase change material was used to store latent heat, which was different from sensible heat. The thermal efficiency of the PVT system was further improved. This article gives a review of the efficiencies of the PVT systems with different media, including air, water, nanofluids, phase change materials, and other hybrid media. The performance of the PVT system was evaluated.

1 INTRODUCTION

Renewable energy is widely advocated by many countries in order to deal with the energy crisis. Solar energy is one of the most important resources because it is abundant, clean, non-toxic, etc. Photovoltaic modules (PV) are composed of series-parallel multiples of solar cells, which can convert solar energy directly into electricity and storage, but the major concern for developers and users is the temperature effect, that is, the output decline of PV with their temperature increasing during operation. Skoplaki et al. (Skoplaki E, 2009) had reviewed a large amount of literature and summarized the relationship value of $\sim 0.5\%$ between temperature and electrical output of silicon PV cells. Silicon PV panels are the protagonists in practical applications. Therefore, cooling the PV is necessary. The passive cooling method is commonly used through the setting fluid channel on the back of the PV to take away the heat and reduce its temperature. A hybrid PhotoVoltaic/Thermal (PVT) integration system (Chow T. T, 2010) arises at the historic moment, which can not only improve the efficiency of power generation but also make full use of heat. Because of the different heating methods, the PVT systems can be a flat plate or concentrated. They are also classified according to the type of working fluid used for PV cooling, including air (Tonui J. K, 2007), water (He W, 2006 & Tyagi V. V, 2012), nanofluid

(Chandrasekar M, 2010), phase change material (Tian Y, 2013), and so on. This paper focuses on the performances of the flat-plate PVT systems with different media and evaluates the advantages and disadvantages of them.

2 PERFORMANCE ANALYSIS OF A FLAT-PLATE PVT SYSTEM

The general structure of a flat-plate PVT system is shown in Figure 1. It mainly contains six parts: front cover, encapsulated PV, absorber plate, flow channel, thermal insulation, and aluminum alloy frame. In the flat-plate PVT system, the core components are PV and thermal collector. The silicon PV panels are commonly selected due to their low

Figure 1. Cross-sections of a general PVT collector: (1) front cover; (2) encapsulated PV; (3) absorber plate; (4) flow channel; (5) thermal insulation; (6) aluminum alloy frame.

cost. Most of the thermal collectors are made up of copper and aluminum for their high thermal conductivity. The collector can work under different working media with different fluid flow in the channel.

2.1 Air

The design of the air-type flat-plate PVT system can be simplified in its structure, thereby reducing the cost of PV cooling with forced or natural flow as shown in Figure 2. Hegazy et al, (2000) compared four types of flat-plate PVT air collectors: air flowing over the absorber (Model I), air flowing under the absorber (Model II), air flowing on both sides of the absorber in a single pass (Model III), and air flowing on both sides of the absorber in a double-pass fashion (Model IV). It was found that the overall performance was dependent on the pass type of the model, the flow rate of the fluid, and the flow channel ratio under similar operational conditions. He also found the optimum ratio value is 2.5×10^{-3} , which effectively maximized the thermoelectric gains for such types of PVT air collectors. (Chandrasekar et al, 2015) verified experimentally that the cooling performance of flat PV modules could be enhanced by heat spreaders in conjunction with cotton wick structures. The electrical power of the PV module was increased by 14% with the developed air cooling methods. (Agrawal et al, 2013) comparatively analyzed different types of PVT air collectors. The overall annual thermal energy gain of hybrid PVT air collector is below 30% and nearly 60% without and with glass cover, respectively. (Raman et al, 2008) had not only evaluated annual thermal and exergy efficiency of a hybrid photovoltaic thermal air collector for different Indian climatic conditions but also analyzed the life cycle in terms of cost/kWh. It is observed that the exergy efficiency is 40% to 45% and the energy payback time and life cycle period were about 2 years and above 50 years, respectively.

2.2 Water

Due to the higher heat capacity of water, the water-type flat-plate PVT systems (Aste, N. del P. C, 2014), are used because they achieve higher overall efficiencies than air systems. (Zondag et al, 2003) also classified the water flat-plate PVT system into four types: sheet and tube, channel, free-flow,

Figure 2. Cross-sections of an air PVT collector.

Figure 3. Cross sections of a water PVT collector.

and two-absorber types. The channel-below-transparent-PV design and the PV-on-sheet-and-tube design were considered to be good alternatives because of their nearly annual efficiency, but the channel-below-transparent-PV design showed superior performance when compared with all types of collectors. (Saitoh et al, 2003) studied experimentally the performance of a single-glazed sheet-and-tube PVT collector under constant coolant supply temperature and flow rate and found that conversion efficiency of PV ranged from 10% to 13%, and thermal efficiencies were from 40% to 50%, respectively. (Shyam et al, 2016) evaluated the overall thermal energy gain and exergy gain performance of series connected PVT water collector. The pay-back time of overall thermal energy and exergy basis was found to be 1.50 and 14.19 years, which is shorter than the air PVT system.

2.3 Nanofluids

Considering the low thermal conductivity of air and water, (Choi, 1995) thermal conductivity was enhanced by adding nanoparticles in liquids called nanofluid. It is defined as a mixture of normal fluid with a very small amount of solid metallic or metallic oxide nanoparticles or nanotubes. As shown in Figure 4, a layer of nanofluid was inserted into the basic structure of the conventional PVT system. (Hussein et al, 2016) had given a comprehensive overview of the recent 10~15 years' advances related to the application of nanotechnology in different types of solar collectors. The thermal energy efficiency and overall energy efficiency were both enhanced about 5%~7%. (Otanicar et al, 2009) compared environmental and economic impacts of using nanofluids to enhance solar collector efficiency as compared to conventional solar collectors. The payback period of the nanofluid collector is slightly longer than the conventional collector. (Kasaieian et al, 2015) reviewed the applications of nanofluids in PVT systems. The

advantages and disadvantages of nanofluids were summarized. Nanofluids had unique mechanical, optical, electrical, magnetic, and thermal properties, but increasing costs, heavy toxicity, instability, and environmental damage.

2.4 Phase change materials

Thermal energy storage is practiced in two ways: sensible heat and latent heat. The sensible heat storage is the quantity of heat of material changes caused by temperature gradient and latent heat storage is the quantity of heat of material changes caused by phase change. Phase Change Materials (PCM) (Tiwari G. N, 1998) have considerably higher thermal energy storage densities. The structure of a PVT system is shown in Figure 5. The layer of phase change material had settled between the back plate of the thermal collector and insulation layer. Koca et al. (Tiwari G. N, 2008) analyzed the energy and exergy of a solar collector with phase change material. It was observed that the average system energy and exergy efficiencies are 45% and 2.2% in October, respectively. (Shukla

Figure 4. Cross sections of a nanofluid PVT collector.

Figure 5. Cross sections of the PVT system with phase change material.

et al, 2009) summarized the investigation and analysis of thermal energy storage incorporating with and without phase change material for use in solar water collectors. It was demonstrated that a large surface area for heat transfer could help enhance the thermal performance of solar water collectors by a phase change material. (Ma Tao et al, 2015) studied that electrical efficiency and thermal efficiency were both improved by using the phase change material. However, the PVT system with phase change material research is still in the laboratory. It will face attendant challenges for practical applications in the future.

2.5 The others

Tripanagnostopoulos introduced three alternative modes of PVT/bi-fluid collectors with improvement in thermal and electrical output features. The results showed that the integrative design is able to cut down payback time from 25 years to 15 years using a cheap diffuse reflector with lower concentration. Assoa et al. developed a PVT/bi-fluid collector that were able to reach thermal efficiencies approximately 80% for the specific collector length and mass flow rate. Jarimi et al. verified experimentally the model of a bi-fluid PVT solar collector. The primary energy saving efficiency of the collector was around 60% with air and water at the optimum flow rate. However, the design of this hybrid fluid PVT system is innovative but not practical owing to its high manufacturing difficulty.

3 RESULTS AND DISCUSSION

The performance comparisons of different PVT systems with different media were shown in Table 1, including cost, construction, toxicity, corrosivity, heat loss, operational temperature, and the environment. The nanofluids, PCMs, and other hybrid PVT systems were both of high cost and structurally complex, although they could work under high temperature for a long while or reduce the heat loss. In addition, the nanofluids PVT systems were not environment-friendly. Therefore, the air and water PVT systems would become the main force

Table 1. Performance comparisons of different PVT systems with different media.

Medium	Cost	Construction	Toxicity	Corrosivity	Heat loss	Operational temperature	Environment
Air	Low	Simple	No	No	Yes	Low	Friend
Water	Low	Simple	No	No	Yes	Low	Friend
Nanofluids	High	Complex	Yes	Yes	No	High	Bad
PCMs	High	Complex	No	Portion	No	High	Friend
Others	High	Complex	Yes	Portion	No	High	Portion

of integrated photovoltaic buildings due to their low costs, simple structures, easy installation, and convenient use. In view of the thermal efficiency, the water PVT system would be highly promoted. The hot water would also be produced for residents and convenient for nomadic living.

4 CONCLUSION

The above review shows that great efforts have been demonstrated by several types of research. This paper presents a comprehensive analysis of the research carried out on flat-plate PVT systems operating with different media. The overall thermal energy gain and exergy gain performance had been evaluated and a comparative analysis of the cost input and payback time had been done on different flat-plate PVT systems. This review will help in designing a suitable PVT system for energy storage and building-integrated photovoltaics.

A practical method for improving the coherence degree between SAR images

Wen Yu, Zhanqiang Chang, Xiaomeng Liu, Wei Wang & Jie Zhu

College of Resource, Environment and Tourism, Capital Normal University, Beijing, China

Key Laboratory of 3D Information Acquisition of Education Ministry of China, Beijing, China

ABSTRACT: The interferometric coherence is a key indicator of the quality of phase values in Interferometric Synthetic Aperture Radar (InSAR) processing. Accordingly, improving the coherence degree between SAR images will contribute to ensuring unwrapping smoothly and generating reliable interferograms. In this paper, we proposed a practical registration method for improving the coherence degree between SAR images on the basis of systematically analyzing various decorrelation sources. A large number of experimental results indicate that the proposed method can obtain better quality interferograms.

1 INTRODUCTION

In the field of Microwave Remote Sensing, Interferometric Synthetic Aperture Radar (InSAR) is an earth observation technique and one of the more popular research tools. It has been widely applied in the field of topographic mapping, geodynamics, glacier excursion, forest investigation, and oceanic surveys. The interferometric coherence and the changes of coherence degree have also been used in several applications such as InSAR processing, forestry stock volume estimation, and so on. In the InSAR processing, the interferometric coherence is a very important indicator of the quality of the phase values in the interferograms. Generally, high-quality interferograms from which we extract reliable deformation information in the study area is based on fine interferometric coherence degree. The relevant research achievements have shown that it will only be possible for unwrapping the interferometric phase in conventional SAR interferometry if the ensemble average of the coherence between SAR images is equal to or greater than 0.3 or 0.4 (Rott H, 2006; Chang Z, 2007). Whereas, it is rather difficult to improve the coherence degree between SAR images in the InSAR application. Accordingly, we will try to find a feasible method to improve the coherence degree between SAR images.

2 ANALYSIS OF VARIOUS DECORRELATION SOURCES

The total decorrelation formula can be expressed as follows (Zebker H. A. & Villasenor J., 1992; Wang, C. Zhang, H., Liu Z., 2002)

$$\rho = \rho_{thermal} \rho_{spatial} \rho_{DC} \rho_{coreg} \rho_{temporal} \quad (1)$$

where $\rho_{thermal}$ is the radar thermal noise decorrelation; $\rho_{spatial}$ denotes the decorrelation induced by spatial perpendicular baseline; ρ_{DC} is the decorrelation due to the difference of Doppler centroids between SAR images; ρ_{coreg} represents the decorrelation induced by co-registration error; and $\rho_{temporal}$ represents the decorrelation caused by physical changes on the ground surface over the time period between acquisitions.

Following this, we will analyze each influencing element respectively.

The correlation $\rho_{thermal}$ can be calculated according to the following formula (Zebker H. A. & Villasenor J., 1992):

$$\rho_{thermal} = \frac{1}{1 + SNR^{-1}} \quad (2)$$

where SNR is the ratio of signal to noise of the SAR system.

The spatial decorrelation is induced by the perpendicular baseline B_{\perp} , Zebker and Villasenor gave the following formula (Zebker H. A. & Villasenor J., 1992)

$$\rho_{spatial} = 1 - \frac{2 |B_{\perp}| \cos^2 \theta}{r \lambda} \quad (3)$$

The decorrelation induced by the frequency difference of Doppler centroid between SAR images can be calculated by the following formula (Wang, C. Zhang, H., Liu Z., 2002):

$$\rho_{DC} = 1 - \frac{\Delta f_{DC}}{B_A} |\Delta f_{DC} \leq B_A| \quad (4)$$

where B_A is the bandwidth of the signal; Δf_{DC} is the frequency difference of the Doppler centroids between SAR images.

The temporal decorrelation is very complicated and induced by many factors involving the motion of scatters, the changes of soil humidity and temperature, the vegetation growth, and so on. Given the probability distribution of the random scatters that obey Gaussian, it can be expressed (Zebker H. A. & Villasenor J., 1992) as

$$\rho_{temporal} = \exp\left\{-\frac{1}{2}\left(\frac{4\pi}{\lambda}\right)^2(\sigma_y^2 \sin^2 \theta + \sigma_z^2 \cos^2 \theta)\right\} \quad (5)$$

We note that this formula only takes the motion of scatters into consideration.

The decorrelation induced by co-registration error in the range or azimuth direction is calculated using the following formulae (Just, D., Bamler, R., 1994)

$$\rho_{coreg,r} = \sin c(\mu_r) = \frac{\sin(\pi\mu_r)}{\pi\mu_r} \quad (6)$$

$$\rho_{coreg,a} = \sin c(\mu_a) = \frac{\sin(\pi\mu_a)}{\pi\mu_a} \quad (7)$$

where μ_r and μ_a , respectively, denote the co-registration errors in the range and azimuth directions.

Analyzing the various decorrelation sources above, we get to know that it is very tough to control most decorrelation sources in InSAR processing since they are previously determined or fixed by SAR sensor performances, satellite orbit, or the properties of ground scatters. However, the only decorrelation which can be handled is the decorrelation induced by co-registration errors. We discovered that the search window size can influence the co-registration accuracy to some extent.

According to equations (6) and (7), the decorrelation due to co-registration error can be calculated by

$$\rho_{coregistration} = \rho_{coreg,r} \cdot \rho_{coreg,a} \quad (8)$$

where $\rho_{coreg,r}$ represents the co-registration errors in range, $\rho_{coreg,a}$ represents the co-registration errors in azimuth.

In the past years, there has been some relevant research about the search window size. Ming Sheng Liao proposed a Multi-Stage Matching Method combined with least square matching, which has solved the issues of efficiency, precision, and reliability well. In his paper, he did some experiments about the least square matching by changing different search window sizes ($N = 17 \sim N = 71$).

Jingfa Zhang also did relevant work and said that 64×64 and 128×128 were the best-suited search window sizes in registration processing. In this paper, we improve the research results by adjusting the search window size based on summing up the results of previous research. As a result, we find a better search window size after doing a lot of experiments.

3 EXPERIMENTAL PROCEDURE

Based on the above theoretical analysis, we selected more than 10 ASAR images on Track 218 for experiment analysis, which are outlined in Table 1.

The registration was processed by using Gamma software, which was developed by Gamma Company. In practice, the experiments were carried out according to the following steps:

First, the ten images were clipped into the same sizes of 3200×14842 ; Second, we picked out the 20 pairs of images by baseline matching of SARscape. Third, the different fit standard deviations in range and azimuth were obtained by adjusting the search window sizes in the registration module of Gamma. Finally, the suitable search window size was selected according to the fit standard deviations that came from the co-registration errors and improved coherent images were obtained.

4 EXPERIMENTAL RESULTS

Figure 1 and Figure 2 illustrate respectively the fit standard deviations in range and azimuth directions for different search window sizes when generating the 20 pairs of interferograms. Generally speaking, with the increase in search window sizes, the fit standard deviations in range and azimuth directions will be getting smaller.

Table 1. The experience dataset and corresponding parameters.

Figure 1. Comparison between fit standard deviations in range for different search windows sizes when generating interferograms.

Figure 3. The real lapsed time for different search windows sizes about the 20 pairs of images.

Figure 2. Comparison between fit standard deviations in azimuth for different search windows sizes when generating interferograms.

However, the 1024×1024 window size generates different results, which shows the instability of change. So the 1024×1024 is not the suitable search window size. Figure 3 shows that the real consumptive time has gotten longer with the increase of the search window. As a matter of fact, considering the fit standard deviations and the real consumptive time, we adopted 256×256 as the suitable search window size for co-registration and then implemented SAR interferometry to obtain

the reliable deformation field in the study area. The search window 512×512 can be a candidate choice if we need higher co-registration precision.

5 DISCUSSION AND CONCLUSION

By statistically analyzing the experimental results, we found that reasonably increasing the search window size can significantly reduce the co-registration error, which is a feasible method to improve the coherence degree between SAR images.

As a result, higher quality interferograms can be generated, which set the stage for obtaining consequently high-quality interferometric products, such as Digital Elevation Model data, ground surface deformation information, and canopy height, etc.

More concretely, the experimental results indicate that the search window 256×256 is the optimal size for co-registration in view of both the fit standard deviations and the real consuming time.

Apart from that, the search window 512×512 can be a candidate if we need higher co-registration precision. Furthermore, the fit standard deviations in range and azimuth directions should be a comprehensive consideration due to their unique patterns.

In the future, we will be focusing on the mechanism of this method.

Smart management and control of household appliances

Qiuyan Lu, Shizhe Chen & Tianran Li

School of Electrical and Automation Engineering, Nanjing Normal University, Jiangsu, China

ABSTRACT: In recent years, many traditional household appliances, like coal, oil, gas, and steam equipment, are gradually replaced by the electric power appliances. Subjective intention and objective requirement of residential users to participate in the demand side response are more and more strong. Through the simulation and analysis of the residential user's electricity behavior, the study is based on the principle of residential demand response of smart home appliances. In this study, the Smart Household Management (SHM) control strategy is proposed. The strategy provides feasible solutions for the residential customers to participate in the demand response plan, which in order to improve household electric economy, energy efficiency, and promote stability of distribution network, and to achieve mutual benefits for both supply and demand sides.

1 INTRODUCTION

At present, there are many researches on the load of residential housing. In the literature (Tsui, 2012; Du, 2011; Chen, 2012; Yi, 2013), the intelligent control strategy for the load of multiple resident houses is proposed, such as the peak filling valley of the same distribution network feeder, renewable energy involved in home user scheduling and so on. The control scheme is based on the actual situation of regional load. But the characteristics of the electric load of the residents in our country are obviously different, that is, there are obvious differences in the choice of equipment, use of time and frequency. For the reasonable participation in demand response of residential users, based on two-way friendship for electricity, the promotion of the experience of the intelligent residential power use, this paper proposes an intelligent residential load control strategy Smart Household Management (SHM).

Implementation of intelligent residential demand response needs the support of communication technology and control technology. The hardware foundation of SHM is the Home Area Network (HAN). HAN system realizes the wireless interconnection of the residential building internal power equipment and the direct control of the load and the intelligent socket. At the same time, the system can also be used to realize the information interconnection between the system, the community and the distribution network, so as to provide the electricity price and load information for the users to participate in the DR.

2 SHM LOAD INTEGRATED MODEL

2.1 SHM temperature model

1. Air conditioning load model

The control model of air conditioning and refrigeration operation state is as follows:

$$S_{C,t} = \begin{cases} 1 & T_{C,t} \geq T_{C,h} \\ 0 & T_{C,t} \leq T_{C,h} - \Delta T_C \\ S_{C,t-1} T_{C,h} - \Delta T_C < T_{C,t} < T_{C,h} \end{cases} \quad (1)$$

$$I_C = \begin{cases} \frac{T_{C,h} - T_{C,t} - \Delta T_C}{\Delta T_C} & S_{C,t} = 1 \\ \frac{T_{C,h} - T_{C,t}}{\Delta T_C} & S_{C,t} = 0 \end{cases} \quad (2)$$

In the formula, $S_{C,t}$ represents the running state of the air conditioner (1 run, 0 stop, the same below); $T_{C,t}$ represents the internal temperature of the house; $T_{C,h}$ represents the highest temperature of the summer residence set; ΔT_C represents the range of residential temperature changes in summer; I_C is introduced as a residential temperature comfort criterion.

2. Heating load model

Floor heating operation state control model are as follows:

$$S_{F,t} = \begin{cases} 1 & T_{F,t} \geq T_{F,l} \\ 0 & T_{F,t} \leq T_{F,l} + \Delta T_F \\ S_{F,t-1} T_{F,l} < T_{F,t} < T_{F,l} + \Delta T_F \end{cases} \quad (3)$$

$$I_F = \begin{cases} \frac{T_{F,i} - T_{F,l} - \Delta T_F}{\Delta T_F} & S_{F,i} = 1 \\ \frac{T_{F,i} - T_{F,l}}{\Delta T_F} & S_{F,i} = 0 \end{cases} \quad (4)$$

In the formula, $S_{F,i}$ represents the running state of the heating; $T_{F,i}$ represents the internal temperature of the house; $T_{F,l}$ represents the lowest temperature of the winter residence set; ΔT_F represents the range of residential temperature changes in winter; I_F is introduced as a residential temperature comfort criterion.

2.2 SHM uninterruptible load model

The running state control model of the uninterruptible load is as follows:

$$S_L = S_{PC} = S_{TV} = S_R = \begin{cases} 1 & I = -\infty \\ 0 & I = \infty \end{cases} \quad (5)$$

$$I_L = I_{PC} = I_{TV} = I_R = \begin{cases} \infty & R = 0 \\ -\infty & R = 1 \end{cases} \quad (6)$$

In the formula, S_L, S_{PC}, S_{TV}, S_R represents the running state of lamps, desktop computers, TV, refrigerator respectively. The formula introduces random parameter R (1 use, 0 nonuse, the same below). I_L, I_{PC}, I_{TV}, I_R represents the comfort criterion of lamps, desktop computers, TV, refrigerator respectively. The higher the value is, the higher the priority of the corresponding equipment will be.

2.3 SHM transferable load model

The control model of the load running state of the washing machine is as follows:

$$S_W = \begin{cases} 1 & I_W = -\infty \\ 0 & (T-1)_{W,s} + \Delta T_d > T_W > T_{W,s} + \Delta T_s \end{cases} \quad (7)$$

$$I_W = \begin{cases} \infty & R_W = 0 \\ -\infty & R_W = 1 \\ -(I_F + I_C) & R_W \neq 0,1 \end{cases} \quad (8)$$

In the formula, S_W indicates the running state of the washing machine; R_W is the introduction of random variables, which means that users need to use the device immediately for special reasons; T_W is the current time of washing machines; $T_{W,s}$ indicates the latest start running time of washing machine; ΔT_s indicates the single washing time; $(T-1)_{W,s}$ means the start running time of washing machine last time; ΔT_d indicates the operating

interval frequency of washing machine in plan; I_W is priority criterion.

3 SHM LOAD CONTROL STRATEGY

Take the control of four types of load as an example, and the corresponding four order control functions are as follows:

$$N = I \cdot N_B + N_A = \begin{bmatrix} I_1 & I_2 & I_3 & I_4 \end{bmatrix} \times \begin{bmatrix} N_{B1} & 0 & 0 & 0 \\ 0 & N_{B2} & 0 & 0 \\ 0 & 0 & N_{B3} & 0 \\ 0 & 0 & 0 & N_{B4} \end{bmatrix} + \begin{bmatrix} N_A & N_{A2} & N_{A3} & N_{A4} \end{bmatrix} \quad (9)$$

$$N_{Bi}(t) = \sum (m_i S_i, n_i P_i) \quad (10)$$

In the formula, N represents the priority control function; I represents device priority criteria for control; N_B is the basic control function; N_A is a modified control function based on price response or incentive response; S_i, P_i indicate the running state, running power of the equipment based on time; m_i, n_i indicate the model parameters based on different residents of residential users.

4 SIMULATION

Equipment detail and load type which participate in the simulation of demand response are as shown in Table 1.

4.1 Simulation 1

Simulation demand response data sampling period is set to 10 min. Residential load simulation global online load and all equipment priority changes are as shown in Figure 1.

Residential temperature, EV simulation results are shown in Figure 2.

Table 1. Load participating in simulation.

Device	Power/kW	Load type
Air conditioner	4.5	temperature control
Radiant floor heating	4.0	temperature control
Refrigerator	0.1	uninterruptible
Computer	0.5	uninterruptible
TV	0.3	uninterruptible
Lamps	0.2	uninterruptible
Washing machine	0.8	transferable
Electric vehicle	5.0	EV

Figure 1. Simulation results of total power and priority.

Figure 2. Floor heating and EV simulation results.

The results in Table 2 show that in the current power system price environment, the demand response of SHM control system has been able to realize the economic dispatch of the residential user load.

4.2 Simulation 2

Price incentive factors use Real-Time Pricing (RTP) system. The change degree of real time electricity price is drawn referring to the RTP curves in literature (Sheng, 2014; Zhang, 2004), as shown in Figure 3.

In this simulation, we increase the simulation sampling period to 3 mins. Residential load simulation of the global online load and all the device priority changes are as shown in Figure 4.

Residential temperature, EV control status are as shown in Figure 5.

Table 2. Comparison of the cost of electricity.

Without SHM	40.96 yuan
SHM control	30.98 yuan

Figure 3. Real Time electricity Price (RTP) curve.

Figure 4. Simulation results of total power and priority.

Figure 5. Simulation results of temperature control equipment (air conditioning).

Table 3. Comparison of the cost of electricity.

Without SHM	37.59 yuan
SHM control	32.73 yuan

The results in Table 3 show that the demand response level of SHM control system can be realized in the long-term electricity market RTP price environment, which can also realize cutting peak and filling valley and economic dispatch to the residential load.

5 CONCLUSION

This paper constructs a residential load control model based on demand side response, optimizes electrical characteristics of residential users and makes residents use electricity economically. The simulation results show that SHM economic dispatch strategy of cutting peak filling valley has been realized. Adding a new load EV significantly increases the residential housing demand response scheduling regulation capacity. And in the current and long-term power market environment, SHM control strategy is reliable and compatible. SHM control strategy on the one hand improves the use efficiency of electric energy of consumers, reduces the cost of electricity and improves the comfort of the use of electricity; on the other

hand, it optimizes resident load, transfers the load smoothly, smooths the load curve and promotes the stability of power supply and distribution network.

ABSTRACT: This paper discusses the configuration and main functions of “Online Monitoring and Positioning Systems for Partial Discharge of High-Voltage Cables (OMPSPDHVC)”, the design of high-frequency current sensors, the schematic design of collector hardware, software design and detection test. Field operation proves that the method disclosed herein is correct and effective.

1 INTRODUCTION

The author studied the signal characteristics and online monitoring of Partial Discharge (PD) of XLPE cables, developed an OMPSPDHVC, designed a wideband current sensor that has a wider working frequency band and better amplitude-frequency characteristics, determined the optimal parameters through analytic comparison, and verified the performance of the wideband current sensor designed.

An OMPSPDHVC based on the two-end detection technology was developed, whose hardware equipment includes high-frequency current sensors, PD signal collectors and PD signal monitoring servers. To realize real-time monitoring and remote diagnosis of PD signal of XLPE cables, the software system designed herein is divided into a front-end control system and a remote diagnosis system. The paper mainly introduces the realization of collection control, data processing and reliability related with the front-end control system, as well as the realization of remote data transmission, database and diagnostic analysis mainly related with the remote diagnosis system. The correctness and practicability of the OMPSPDHVC has been

verified through XLPE cable PD signal detection tests.

The OMPSPDHVC based on the two-end detection technology can monitor, at any time, the safety status of field equipment and the insulation condition of live HV cables to avoid accidents or further deterioration of insulation. Therefore, promptly detecting and positioning PD signal of XLPE cables are an important means to timely find hidden troubles and ensure safe and reliable operation of power cables. By minimizing periodic artificial inspection, labor cost, workload and outage time and avoiding safety risks caused by repair operations or old working procedures, the OMPSPDHVC significantly improves work efficiency, power safety and economic benefit.

2 SYSTEM CONFIGURATION (Wang Zhenhao, 2015 & Pang Dan, 2014)

The OMPSPDHVC is divided into three tiers: sensor HFCT; PD signal collection terminal; PD signal monitoring concentrator. The system architecture is shown in Figure 1.

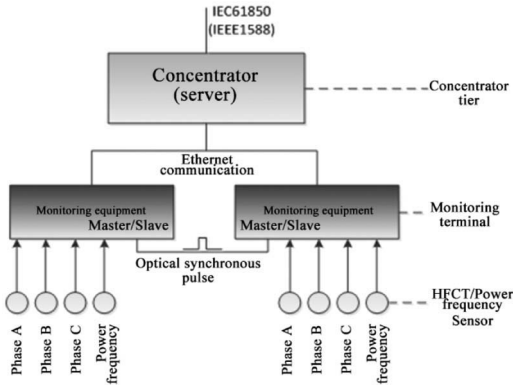

Figure 1. System architecture.

3 MAIN FUNCTIONS (Wang Zhenhao, 2015 & Pang Dan, 2014)

- 3.1. The synchronous multi-channel PD signal detection technology can realize synchronous detection of multiple phases of the same circuit and collect sufficient correlation information so as to increase the accuracy of detection.
- 3.2. By reconstructing the basic information of PD signal, it is possible to evaluate the amount of discharge and locate the source of discharge. By means of fuzzy classification algorithm and BP neural network algorithm, it is possible to identify the type of PD signal.

4 DESIGN OF HIGH-FREQUENCY CURRENT SENSORS

Soft magnetic materials are roughly divided into two types: metallic soft magnetic materials and ferrite soft magnetic materials. PD signals are micro current signals which cannot be detected by ordinary Rogowski coils. The purpose of using magnetic materials is to increase the coil's self-inductance coefficient "L", reduce the coil's size, number of turns, and stray capacitance "C", and thus improves its performance. The saturated magnetic induction strength, Curie temperature, basic magnetic permeability, and high-frequency eddy current loss of metallic soft magnetic materials are relatively high but their coercive force and bulk resistivity are relatively low, so such materials are suitable for low-frequency applications in most cases. Although the magnetic performance of ferrite soft magnetic materials is generally lower than that of metallic soft magnetic materials, their bulk resistivity is several orders of magnitude higher than that of the latter, and their high-frequency loss is small, so such materials are more suitable

for high-frequency applications. Furthermore, since ferrite soft magnetic materials are inexpensive, with high magnetic permeability, low loss, high saturated magnetic induction strength, high cutoff frequency, and high stability, they are widely used in the production of high-frequency inductor coil core so as to improve the coil's self-induction and reduce its volume.

Through comparative experiments and based on the existing conditions, the sensor parameters finalized herein are as follows: the magnetic core material is nickel zinc; the number of turns of the coil is about 15; the integral resistance is 100–150Ω.

5 HARDWARE SCHEMATIC DESIGN OF COLLECTOR (Wang Zhenhao, 2015; Pang Dan, 2014 & Wang Zhenhao, Pang, 2014)

Functionally, the PD signal collector can be divided into four parts: power management module, control processing module, data collection module, and signal conditioning module, as shown in Figure 2.

6 SOFTWARE DESIGN (Wang Zhenhao, 2015; Pang Dan, 2014; Wang Zhenhao Pang, 2014 & Zhang XiliN, 2014)

The upper computer software is installed in the tablet PC provided and communication with the collector is realized via the WiFi of the tablet PC. Test results are given after the wave forms captured by the collector are filtered and analyzed.

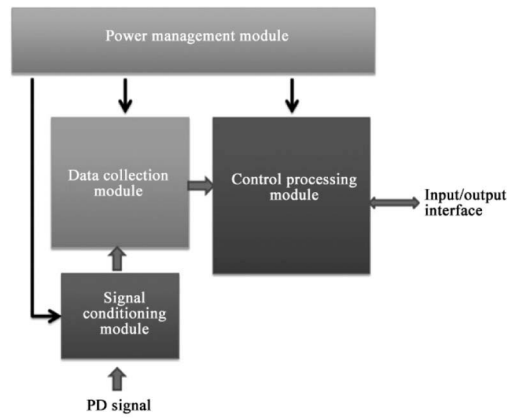

Figure 2. Hardware principle of collector.

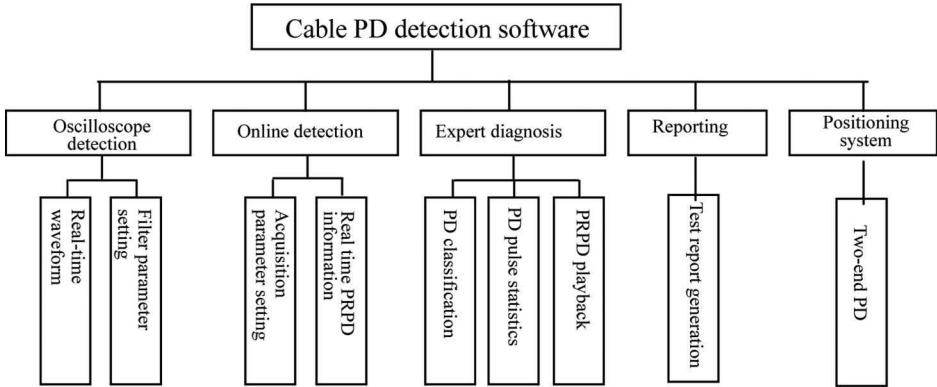

Figure 3. Functional block diagram of software system.

The software system is developed using QT development tools and adopts a modular design, the functional block diagram of which is shown in Figure 3.

7 DETECTION TEST

7.1 *In-situ investigation of cable tunnels and determination of electric power supply solutions*

The purpose is to understand the actual distribution of cable tunnels, determine the test plan and procedures, and solve the problem of power supply. Since the tunnel is not very long, power supply is led to the middle of the tunnel at the air vent. Where PD signal collectors work in the stand-alone operation mode, they are powered by batteries so as to facilitate on-site inspection.

7.2 *Propagation relationship test of PD signal in three-phase crossover interconnected cables*

Simulated PD signals are injected from different parts of the insulation joint, and an HFCT is respectively installed on the coaxial cable and the inner and outer shielding lines of the insulated cable connector to observe, via an oscilloscope, the propagation relationship of PD signal in three-phase crossover interconnected grounding wire. It is proved that installing HFCT on the cross connection box's grounding wire is feasible.

7.3 *In-situ PD signal detection test*

First, PD signal collectors are set in the stand-alone mode to perform signal sampling for all the 220kV cable insulation joints, with 50 sets of data collected for each joint. The upper computer software

analyzes the collected signals and the background noise (intensity and type of interference) of the site to find out the cable joints where suspected PD signals exist. Then, according to the result of stand-alone inspection, "hand in hand" network detection is performed for the cables on both sides of the cable joint where there are obvious "PD signals". In-situ network is built, power supply system & communication optical fiber is laid, and PD signal collectors are set in the network operation mode. The next step is to further determine the location the PD source and the amount of PD.

7.4 *Analysis of the collected data and conclusion of the detection test*

Conclusion of the detection test is given based on the results of the above test and analysis so as to find out hidden troubles in time and provide a basis for ensuring the safe and reliable operation of power cables.

8 SUMMARY

Since put into use, the OMPSPDHVC has produced satisfactory results and proved the correctness and effectiveness of the said system constitution, main functions, high-frequency current sensor design, collector hardware schematic design, software design, and test method.

The numerical analysis of rainfall erosivity irregularity in Zhejiang province

Fangchun Lu, Gang Li & Jinjuan Zhang

Zhejiang Institute of Hydraulics and Estuary, Hangzhou, Zhejiang, China

ABSTRACT: In this paper, new indexes are used to evaluate the temporal and spatial variation irregularity of rainfall erosivity, including the cumulative relative deviation rate (C_r), long-term variation rate (L_r), general deviation index (I_d) and special deviation index (D_i). The results showed that, since 1980s, the change process of rainfall erosivity in Zhejiang province was decrease-increase-decrease. But the change of rainfall erosivity was more complex in the early 21st Century. The I_d and D_i obviously showed the typical low value areas and high-value areas. In the spatial difference, the I_d and D_i of the eastern coastal area of Zhejiang were significantly larger than those of other regions ($p < 0.01$).

1 INTRODUCTION

Rainfall erosivity is the potential ability of soil erosion caused by rainfall, and it is also the most important external driving force. The rainfall erosivity R factor is an index to evaluate this kind of ability (Zhang et al. 2003). At present, the global temperature showed a significant increase. And this change has been profoundly effecting the global water distribution pattern by accelerating the water cycle process (Feng et al. 2006). The fluctuation of rainfall irregularity has already produced a significant impact on rivers, wetlands and natural vegetation (García-Barrón et al. 2011). And these have led to the change of the spatial distribution pattern of soil erosion, which is worth people's attention. The fourth assessment report of the UN Intergovernmental Panel on Climate Change (IPCC) noted that with the increase of heavy rainfall events frequency, if not in time to take measures to deal with global climate change, soil erosion in most areas will be further aggravated (IPCC 2007). Under the background of global climate change, the change of rainfall erosivity, caused by rainfall change (such as rainfall intensity, rainfall frequency and seasonal rainfall pattern changes), have a profound effect on soil erosion process (Zhang et al. 2005; D'Asaro et al. 2007). Therefore, the study on the spatial and temporal distribution of regional rainfall erosivity can accurately reveal the impact of climate change on regional soil erosion (Diodato and Bellocchi 2009).

2 DATA AND METHODS

According to the geomorphological features of Zhejiang province, the province was divided into

five regions. These were the north of Zhejiang (plain area), northwest of Zhejiang (mountainous area), the central region of Zhejiang (hilly area), the southwest of Zhejiang (mountainous area) and eastern coast of Zhejiang (coastal area). The daily rainfall data of 84 meteorological stations in Zhejiang province during 1980–2009 were collected, and the power function model was used to calculate the rainfall erosivity (Zhang et al. 2002). And the long-term evolution characteristics of annual rainfall erosivity were analyzed by using the cumulative relative deviation rate (C_r), long-term variation rate (L_r), the general deviation index (I_d) and the special deviation index (D_i).

The calculation formula of the cumulative relative deviation rate is as follows (Qing et al. 2010):

$$C_{ri} = \sum_{j=1}^i (P_j/\mu - 1)$$

Where P_j is the rainfall erosivity of j th year. The μ is the average rainfall erosivity.

Long-term variation rate is defined as follows:

$$L_{ri} = \sigma_{(i,i-4)}/\mu_{(i,i-4)}$$

Where the $\sigma_{(i,i-4)}$ is the standard deviation of five consecutive year rainfall erosivity. The $\mu_{(i,i-4)}$ is the average of five consecutive year rainfall erosivity.

The general deviation index formula (Lana et al. 2000) is

$$I_d = \sum((P_{i+1} - P_i)^2/(n-1))^{0.5}/\mu$$

Where P_i is the rainfall erosivity of i th year. The μ is the average rainfall erosivity.

The specific deviation index proposed by García-Barrón is

$$D_i = ((P_i - P_{i-1})^2/2 + (P_{i+1} - P_i)^2/2)^{0.5}/\mu_{(i-1, i, i+1)}$$

Where P_i is the rainfall erosivity of i th year. And the $\mu_{(i-1, i, i+1)}$ is average rainfall erosivity of three consecutive years.

3 RESULTS AND ANALYSIS

3.1 The cumulative relative deviation rate

Figure 1 showed the variation of the C_r in different geomorphologic divisions. On the whole, the C_r reflected the processes of 4 significant change stages of rainfall erosivity, which was decrease-increase with fluctuations-sharply decrease-slow increase. The C_r was negative downward trend from 1980 to 1986 with the annual average decrease 0.12. However, from 1987 to 2002, the C_r was upward trend, the variation of 15 years increased by 0.94. In 2003 and 2004, the C_r showed a sharply decline, as well as in 2005 it began to rise year by year. From the analysis of the overall changes in different geomorphologic divisions.

In 1980s, the C_r in the northwest, the central region, the southwest and the eastern coast, showed decreased trends, as well as a fluctuant increased trend in the north. However. In 1990s, the C_r in the north, the northwest, the central region, and the southwest, showed increased trends, as well as a slightly fluctuant decreased trend in the eastern coast. To the beginning of 21th Century. The C_r in the north, the southwest and the eastern coast was decrease in the first five year and increase in the last five year. And it showed complete decline trends in the northwest and the central region. Thus, in early 21th Century, the Province affected by the global climate change and other factors, the change of rainfall erosivity was more complex.

3.2 The long-term variation rate

There were differences in the L_r of rainfall erosivity in different regions of Zhejiang province in

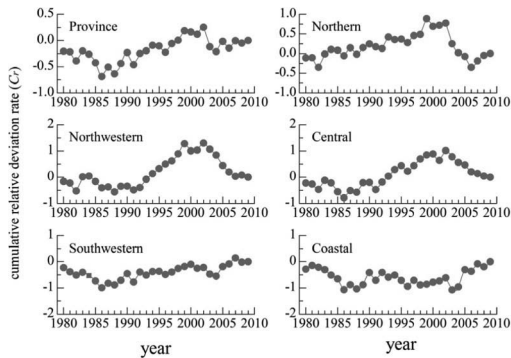

Figure 1. The cumulative relative deviation rate.

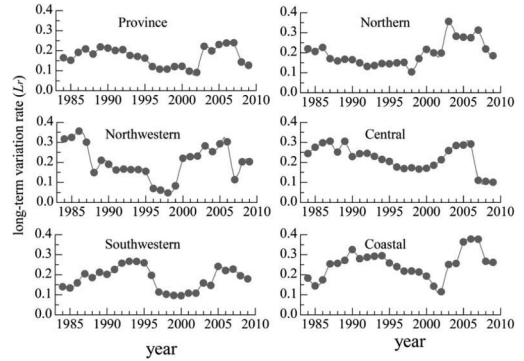

Figure 2. The long-term variation rate.

recent 30 years (Figure 2). For the whole provincial annual average rainfall erosivity, in 1980s and 1990s, the L_r was shown to slight decreased trend. In early 21th Century, the L_r increased rapidly within a few years, followed by five of the balance period, but from 2007, the L_r again decreased significantly. The change process of the L_r in the north and the central region was similar with that of the province. By comparatively, the L_r in the northwest was decrease more obviously in 1980s and 1990s, nevertheless obvious increased in the first five years of 21th Century. But the change of the L_r in the southwest and the eastern coast were on the contrary.

3.3 The general deviation index

The statistical analysis indicated that the change range of the I_d was from 0.157 to 0.441, average 0.254 and variation coefficient 0.209. In the spatial pattern, the I_d had obvious regional characteristics (Figure 3). The I_d presented two typical low value regions and three typical high value regions. The two typical low value regions were located in the north and the south of Zhejiang, respectively. In which the I_d was less than 0.20. The northern low value region included Xiaoshan district (in Hangzhou city), the northwest of Keqiao district and the north of Zhuji County (in Shaoxing city). The three high value regions were located in the most north, the west and the eastern coast in which the I_d could reach more than 0.3. The northern high value region included the north of Changxing County (in Huzhou city) and the northeast of Jiaying city. The western high value region involved the middle parts of Qujiang district and Kaihua County (in Quzhou city). The eastern coastal high value region related to three regional centers, which were Fenghua-Xiangshan center (in Ningbo city), Sanmen-Linhai center (in Taizhou city) and Leqing-Yuhuan center (in Wenzhou city).

Figure 3. The distribution of general deviation index.

Figure 5. The distribution of special deviation index.

Figure 4. The area composition in general deviation index intervals.

Figure 4 indicated the area distribution of the I_d was positive skewness. In the range of 0.22–0.24, the largest area proportion was 31.70%. Secondly, the area proportion was 21.25% in the range of 0.24–0.26. Thus, I_d in 0.22–0.26 range, the area proportion accounted for 52.95%. The variance analysis of the I_d in different geomorphologic regions indicated that the I_d in the eastern coast (0.305) was significantly higher than in other regions ($p < 0.01$). The I_d in the northwest (0.234), the central region (0.237) and the southwest (0.228), was significantly lower than that in province (0.254). The I_d was no significant difference between in the north (0.252) and in the province.

3.4 The special deviation index

The min-value of the special deviation index (D_i) was 0.227 and max-value 0.537, average 0.372 and variation coefficient 0.18. The spatial distribution characteristic of the D_i was similar to that of the

I_d (Figure 5). The D_i also presented two low value regions and three high value regions in the spatial distribution. The two low value regions were located in the north and the south. The northern low value region touched upon Xiaoshan district (in Hangzhou city), the west of Keqiao district and the north of Zhuji County (in Shaoxing city). The southern low value region covered the most region of Wuyi County, northeast of Suichang County (in Jinhua city), the northeast of Liandu district and the north of Songyang County (in Lishui city). Where the D_i was in the range of 0.22–0.30. The three high value regions were situated in the most north, the west and the eastern coast. The northern high value region included the north of Changxing County (in Huzhou city) and the whole northeast of Jiaxing city. The western high value region contained the central region of the kaihua County and Qujiang district (in Quzhou city). The eastern coastal high value region was a wide and contiguous range.

It contained Ningbo city (Ninghai County, Xiangshan County), Taizhou city (municipal districts, Sanmen County, linhai County and Wenling County), and Wenzhou city (municipal districts, Yueqing County, Yongjia County, Ou Hai District, Ruian County). The D_i in these regions was above 0.4.

According to the statistics (Figure 6), the D_i was mainly distributed in the 0.32–0.38 range. And the area proportion accounted for 58.69%. The area proportion in the range of 0.32–0.34 and 0.34–0.36 was close to 20%. In addition, the area proportion of D_i greater than 0.40 accounted for 18.21%. through analysis of variance found that the D_i in

Figure 6. The area composition in special deviation index intervals.

the eastern coast (0.436) was significantly higher than in other regions ($p < 0.01$), and the D_i in the southwest (0.335) was significantly less than that in the province (0.372), but there was no significant difference between the north (0.378), the northwest (0.344), the central region (0.349) and the province.

4 CONCLUSIONS

In the study of the rainfall erosivity variation, most scholars used the standard statistics, such as anomaly value, standard deviation and variation coefficient to measure the variation of rainfall erosivity. In the study of the rainfall erosivity variation, most scholars used the standard statistics, such as anomaly value, standard deviation and variation coefficient, to measure the variation characteristic of rainfall erosivity. However, these standard statistics cannot describe the irregularity of rainfall erosivity. In this paper, the new indexes were used to analyze the irregularity of rainfall erosivity in Zhejiang province. The results of the study were as follows:

The cumulative relative deviation rate (C_i) of rainfall erosivity in the whole province showed a significant time variation feature. Since 1980s, the rainfall erosivity had experienced the process of decrease-increase-decrease. By the beginning of 21st Century, due to the impact of global climate change and other factors, the change of rainfall erosivity was more complicated. The change of long-term variation rate (L_i) had regional characteristics. The L_i in the north, the northwest and the central region of Zhejiang, had experienced a slow decrease process in 1980s and 1990s. Sharply increase occurred during the 2000–2005. In recent years, there was a significant decline.

The general deviation index (I_i) and the special deviation index (D_i) have obvious spatial distribution characteristics, which were two low value regions and three high value regions. In the 52.95% region of the province, the I_d of rainfall erosivity

was in the 0.22–0.26. And In the 58.69% region, the D_i of rainfall erosivity was in the 0.32–0.28. In the regional differences, the I_d and D_i in the eastern coast of Zhejiang were significantly higher than that in other regions ($p < 0.01$). The I_d in the north, in the center region and in the southwest, was significantly smaller than that in the province. The D_i in the southwest of Zhejiang was significantly less than that of the province.

Module design of container architecture

Ruitong Zhu

College of Civil Engineering, Tongji University, Shanghai, China

ABSTRACT: Container architecture, derived from freight containers, has an increasingly important position in the field of temporary buildings. With its modular and detachable structure, this newly emerging type of architecture shows a great development potential. However, container architecture has been confined to the absence of corresponding codes and technical modifications. In this article, a hockey rink in Huijia High School was taken as an example to illustrate a modification technology of container architecture, in which standard containers were displaced by redesigned modular units. Simplified models for engineering application were built through 3D3S in order to analyze the bearing capacity under vertical loads.

1 INTRODUCTION

1.1 *Origin of container architecture*

Container architecture is combined by modular units with full architectural functions. These units would be prefabricated in factories and then assembled at the final location.

Container architecture originated from a large number of empty containers piled up in ports around the world. The rapid development of the logistics industry has brought about a huge demand for containers and it is estimated that about 300 million of them are circulating around the world every year (Gong & Zhang 2010). Due to the lopsided pattern of international trade, a great number of containers are transported from the eastern to western countries loaded with raw materials. Yet despite the good condition of these containers, most of them would end up rusting at destination ports with no prospect of being transported back to Asia, which is much more expensive than purchasing new containers and therefore unacceptable to merchants. As a result, about 1 million Twenty-foot Equivalent Unit (TEU) were decommissioned worldwide (Xu 2008).

Container architecture came into being under such circumstances serving as temporary installations in ports initially. With the green concept rising in the mainstream of architecture, container architecture has received a lot of attention. For decades, the number of containers used in a building has been increasing, as well as the diversity of the combination.

1.2 *Modular tendency*

The domain of container architecture is also expanding. The basic unit of buildings, which used to be a standard container has turned into specially designed modular blocks. This new type of modular frames shares similar superiorities with the original container architecture. With all the modular blocks prefabricated in factories, little work needs to be done on site, which improves the construction efficiency a lot. Also, those highly industrialized blocks make it possible to retain the mobility and provisionality of the architecture.

Barring the similarities, this new type of modular architecture presents with many improvements. The stress pattern of the container, of which the corrugated plates with higher stiffness bear much of the load (Lu 2014), is quite different from that of the framework. Therefore, orthodox container architecture has to keep those corrugated plates with restricted room in it. Yet after modification, the basic unit of the modular architecture is more of a frame. It means that the loads are to be carried by the columns at the corners leaving enough space to meet the requirements of a large bay. Due to the similarity of the modular blocks and boxes, this type of architecture is also known as box building (Li & Zhang 1992).

On June 1st, 2013, China issued *CECS 334:2013 Technical specification for modular freight container building* (CSCS 2013), the first national standard for reformation of modular containers. While traditional container architecture has been applied all over the world, however, the research over box

building is still fumbling. Thus, whether to choose modular container as units, or design the modular block afresh, is indeed a question worth considering, and circumstances alter these cases. When it comes to a certain project, checking calculation and modeling analysis are necessary.

2 PROJECT AND BACKGROUND

The auxiliary building of the hockey rink in Huijia High School is a three-story office building which is 49.32 meters in length, 13.2 meters in width, and a total building area of 1953square meters. The owner is strict with the construction time and makes a request for the movability of the buildings, expecting it to be reassembled easily somewhere else. Meanwhile, as an office building for conference and reception, it has to be equipped with a large bay.

As is shown in Figure 1, the large bay of the typical floor makes it impossible to maintain the corrugated plates of modular freight containers, which means that all loads are to be imposed on the skeleton of those containers. Generally speaking, such frames can offer little support. So in order to demonstrate the viewpoint, a calculating model for the solitary modular container was built.

3 MODEL

3.1 Model of universal container

Two types of modular freight containers are needed in order to correspond with the architectural design and those two types of containers, according to the drawings in the collection, share the same width and height, 12192 mm × 2438 mm × 2591 mm for IAA and 9125 mm × 2438 mm × 2591 mm for IBB.

Construction drawings in Appendix A of the code, *GB/T 1413-2008 Series 1 freight containers-Classification, dimensions and ratings* (2008), provide a scientific basis for structural simplification, as is shown in Figure 2.

The model was built in 3D3S, a software for steel structure modeling. The aim of the modeling

Figure 1. Typical floor plan.

Figure 2. Structure diagram of universal containers IAA.

is to disprove the reliability of the frame for freight containers, so container IBB was chosen as the model. With a shorter span in length, the container IBB ought to be more capable than container IAA. This means if IBB was unable to satisfy the requirements of bearing capacity, then IAA would be automatically proven unsafe.

For the convenience of modeling, the distance between the secondary beams at the bottom of the container was unified to be 300 mm, and the minimum cross section of these beams was adopted to be on the safe side. Additionally, all sections of profiled steel sheets were approximated as fundamental or thin-walled sections to fit the function of the software. The detailed approximation is listed in Table 1, and their corresponding positions are marked in Figure 3.

A bracing system would be set up to enhance the horizontal strength and stiffness of the structure resisting lateral wind and seismic loads. Therefore, only vertical loads need to be considered in this model. As an office building, the dead load of its bottom was evaluated as 0.5 kN/m², and the live load of 2.0 kN/m². The load transferring pattern at the bottom resembles that of a one-way slab, which means being equally divided onto the secondary beams on both sides. The transferring pattern at the top of the frame, on the other hand, was like a two-way slab, considering the great distance it spans. Suspended ceilings were estimated to apply 0.5 kN/m² to the top as dead load.

Loads of the upper layers were passed through the columns at the four corners equally because of the monolithic bottom board. To simulate the limit state of the frame, the model was based on the ground floor, bearing the loads passed from the two floors above. Detailed information of loads was elaborated in Table 2. With the consideration of load combination, all the dead loads would be multiplied by 1.2 and live loads by 1.4 before calculating. Force transmission between layers was completed through corner fittings where there

Table 2. Load distribution of a universal container.

Position	Force transferring mode	Dead load	Live load
Bottom	One-way slab	0.5 kN/m ²	2.0 kN/m ²
Top	Two-way slab	0.5 kN/m ²	/
Columns	Joint load	11.12 kN	22.25 kN

were hinge supports. Apart from the support, all the other joints were fixed.

The check of the model was based on *GB 50017-2003 Code for Design of Steel Structures*. Both strength and stability did not pass the examination and its strength-stress ratio was distinguished with different colors as shown in Figure 4.

Results show that over 5 of the components buckled and the maximum stress ratio of strength is up to 2.660. Moreover, slenderness ratio of some rods has gone beyond the limits. So far, it has been proven impracticable to take freight containers without corrugated wallboards as architectural units. In other words, the modular unit requires redesigning.

Figure 4. Distribution of stress ratio in the model of a universal container.

3.2 Model of a redesigned unit

The main principles of the design are to keep the feature of easy manufacturing and strengthen the frame of the module.

Still, two different types of modular units with identical width and height are necessary in order to match the architectural design. The difference lies in the phase of the conceptual design. The unit with greater length would be divided into the main body, which is exactly the same as the shorter one and the cantilevered part. For the sake of modular coordination, the units were designed to be 9020 mm × 3000 mm × 3100 mm and 12000 mm × 3000 mm × 3100 mm. The main body of the longer unit was 9.02 meters long while the rest of the part overhangs. Thus all the columns were in the same plane as is shown in Figure 5.

The longer unit would be taken as an example to illustrate how the frame was strengthened. In contrast with standard freight containers, universal beams and cold formed rectangles were chosen to form the frame, the cross sections of which are much larger. Also, secondary beams were added to the top, enhancing the stability as well as installing the ceiling.

The cantilevered part of the longer unit plays a negative role when calculating the structure, compared with the shorter unit. Therefore modeling longer unit is enough to ensure the safety of the units.

The second model is as shown in Figure 6, and detailed information is listed in Table 3.

On top and bottom of the unit, loading condition of this model in 3D3S was the same with the previous one, but the patterns of force transferring were both in the way of the two-way slab. Hinge supports were on the four corners of the main body. Based on what is mentioned above, the software can return the reaction force of the supports, which would be doubled and then added to the columns as the loads from the upper layers. Similarly, considering load combination, all the dead loads would time 1.2 and live loads would time 1.4. Detailed information was presented in Table 4.

Figure 5. Structural floor plan.

Figure 6. Frame of a redesigned unit.

Table 3. Components cross-references of the redesigned unit.

Mark	Type of section	Size of section
GL1	Cold formed rectangle	250 × 150 × 8
GL2	Universal beam	250 × 150 × 6 × 8
GL3	Cold formed rectangle	200 × 150 × 5
GL4	Universal beam	250 × 150 × 4.5 × 6
CL1	Cold formed rectangle	250 × 150 × 6
CL2	Cold formed rectangle	150 × 50 × 3
GZ1	Cold formed square	89 × 3

* All in mm.

Table 4. Load distribution of the redesigned unit.

Position	Force transferring mode	Dead load	Live load
Bottom	One-way slab	0.5 kN/m ²	2.0 kN/m ²
Top	Two-way slab	0.5 kN/m ²	/
Newels	Joint load	23.63 kN	24.13 kN
Front posts	Joint load	52.69 kN	47.87 kN

Judging from the outcome, the structure gets a sufficient safety margin with the maximum stress ratio of strength being 0.638 and stress ratio of stability being 0.608. As a consequence, the design of the modular unit is secure and feasible.

4 CONSTRUCTION MEASURES

Apart from the module design of the major structure, there are also some construction measures aimed at enhancing structural capacity.

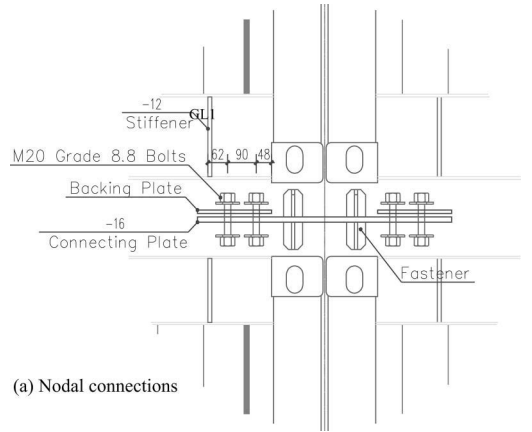

Straight braces were arranged longitudinally along the center line at the top of the unit with 2 mm-thick steel plates as roof and side beams on top were welded together, on which a coat of sealant was applied.

All the ceiling joists should not be put on the top plates. Instead, these joists should be welded to the secondary beams or angle steel attached to them.

The bottom was covered with 28 mm thick wooden floor specifically for containers with some space reserved for the installation of doors and windows.

Figure 7. Distribution of stress ratio in the model of the redesigned unit.

(a) Nodal connections

(b) The connection between beams.

Figure 8. The detailed structure of the junction.

There was a fitting on each corner of the unit through which the units were linked together. As is shown in Figure 8, the beams were aligned with corner fittings by backing plates. Two M20 grade 8.8 bolts were installed around each fitting along with the stiffener to avoid buckling.

Beams were connected through a steel lathing, welded with two contiguous beams. The interspaces were filled with Polyurethane Foam sealing agent (PU Foam) thicker than 100 mm.

Fittings on the top had a bolt hole on each of them for hoisting on the site, which would be filled with bolts upon completion.

The assembly had at most four members at the position of one beam or one column increasing the cross section of the beam or column tremendously. In this way, the frame would be strengthened and deflection decreased, influencing the usage and safety of the structure positively.

5 CONCLUSIONS

Modular buildings represented by the design in the article not only inherit the advantages like movability and prefabrication from the orthodox container

architecture but also remove all the restraints for space. The diversity of modular units makes the style of the building more flexible. Such modular buildings are bound to set off a revolution in the field of temporary buildings.

Design of a reflective pulse oximetry sensing system based on the semi-active RFID tag

Liyang Chen, Yang Wang & Hongwei Liu

School of Electronic and Information Engineering, Tianjin Polytechnic University, Tianjin, China

ABSTRACT: This paper describes the design of a reflective pulse oximetry sensing system based on the semi-active RFID tag. It can monitor human physiological signals continuously through the wireless sensor network. The system is composed of four modules: reflective pulse oximetry detection module, data processing module, RFID transceiver module, and PC interface. These modules can achieve the function of monitoring non-invasive, real-time, and long-distance wireless pulse oximetry. The reflectance probe is designed to collaborate with LEDs with wavelengths of 660 nm and 940 nm. The data processing module is designed to manage almost all of the internal processing. The RFID transceiver module is based on the EPC C1 GEN2/ISO 18000-6c protocol for communication. The RFID reader communicates with the RFID tag through the electromagnetic wave. The pulse and blood oxygen information measured by the sensor will be displayed in the upper computer interface. The experimental results show that the system has high accuracy and low power consumption, and will have a good application prospect in the direction of wearable medical wisdom research.

1 INTRODUCTION

The traditional health care philosophy is based on professional medical diagnosis and treatment institutions using professional diagnostic equipment to achieve unscheduled health care (Occhiuzzi, 2010; Peris-Lopez, 2011). This approach not only takes up excessive medical resources but also cannot grasp the body's health in real-time, even miss the best time to treat the disease, resulting in irreparable damage (Redondi, 2013). With the constant improvement of science and technology, networking technology, optical sensing technology, radio frequency identification technology, and smart micro-processing technology there has been rapid development. The portable intelligent medical monitoring devices begin to enter people's vision and towards the direction of the development of wireless communication and monolithic integrated chip (Catarinucci, 2013; Toh, 2009).

The real-time monitoring of vital signs of patients is a very important part in the new wisdom of the medical system (Ley, 2013). The medical point of human vital signs, such as oxygen saturation and pulse rate, are important indicators characterizing the degree of human health. So monitoring pulse oximetry safely and effectively plays an active role in the diagnosis of disease and health care aspects (Mendelson, 1988). As a kind of medical instrument, which can continuously and non-invasively collect the data of blood

oxygen saturation, the pulse blood oxygen measuring instrument can be divided into two types: transmission type and reflection type. Because of the limitation of the transmission type instrument to the human body collection position, the reflection type sensor has been paid more and more attention by people. At present, there are few reports about the reflectance pulse oximeter clinical monitoring data (Kirk, 2003). For the reflection type sensors, the design of hardware, software, and measurement methods are worthy of further exploration.

In this paper, the measurement of pulse oximetry employs a reflective optical measurement method according to the principle of infrared spectrum measurement. The pulse and blood oxygen saturation detection system based on DCM03 reflective sensor and a microprocessor with RFID technology is introduced in detail. The system uses advanced digital signal processing technology to effectively restrain the influence of human movement and weak perfusion measurement and provides a fast and accurate method for measuring blood oxygen saturation and pulse rate.

2 RELATED WORKS

Pulse is the number of times the heart beats in a minute. Blood oxygen saturation is the percentage of total content of hemoglobin (HbO₂) in the

blood, which can be combined with oxygen. Blood oxygen saturation is defined by the formula:

$$SpO_2 = \frac{HbO_2}{HbO_2 + Hb} \times 100\% \quad (1)$$

SpO₂ represents oxygen saturation, HbO₂ and Hb represent the content of hemoglobin and oxygenated hemoglobin in the blood, respectively. Measurement of oxygen saturation is based on the Lambert-beer law as the theoretical basis, using the principle of the spectrum effect combined with digital signal processing algorithms to achieve it. Blood in the veins of humans will be regarded as a liquid medium in the analysis process due to the absorption rate of different wavelengths of light for different components in the blood. So we can calculate the content of different components in blood by measuring the attenuation degree of light through blood.

Measurement of pulse oximetry is based on the principle that light absorption of ripple component in arterial blood will change with the contraction or expansion of the artery, while the light absorption of other organizations is almost constant. For the arterial blood vessel pulse, the light absorption of the arterial blood will change, which is known as the AC component. The light absorption of skin, muscle, bone, blood and non-pulsatile blood will be constant, known as the straight flow. Cardiac contraction or expansion will affect the volume of the artery. Change in the optical path will affect the absorbance according to the Lambert-Beer law and the ripple component of the artery is known as photoplethysmography (PPG). Based on the photon diffusion equation and time-resolved spectroscopy technique, reflective light intensity can be obtained by the formula shown below.

$$R(\rho, t) = (4\pi Dc)^{-3/2} z_0 t^{-5/2} \exp(-\mu_a ct) \exp\left(-\frac{\rho^2 + z_0^2}{4Dct}\right) \quad (2)$$

The relationship between the variation of the reflected light intensity and the absorption coefficient is derived as given below.

$$W = -\mu_a c \quad (3)$$

Connecting the absorption coefficient and absorption material concentration c, so that we can obtain the measurement method of dual wavelength blood oxygen saturation.

The following formula is obtained by the double beam method.

$$\frac{W_{\lambda_1}}{W_{\lambda_2}} = \frac{\epsilon_{Hb}^{\lambda_1} C_{Hb} + \epsilon_{HbO_2}^{\lambda_2} C_{HbO_2}}{\epsilon_{Hb}^{\lambda_2} C_{Hb} + \epsilon_{HbO_2}^{\lambda_1} C_{HbO_2}} \quad (4)$$

The formula of saturation of blood oxygen is obtained by selecting the wavelength of λ_2 as an equal absorption point.

$$SpO_2 = \frac{\epsilon_{Hb}^{\lambda_1}}{\epsilon_{Hb}^{\lambda_1} - \epsilon_{HbO_2}^{\lambda_1}} - \frac{\epsilon_{Hb}^{\lambda_2}}{\epsilon_{Hb}^{\lambda_1} - \epsilon_{HbO_2}^{\lambda_1}} \cdot \frac{W_{\lambda_1}}{W_{\lambda_2}} \quad (5)$$

The absorption of two kinds of hemoglobin in the red spectral region varies dramatically, but the difference of absorption in the near-infrared region of the spectrum is subtle, so the light absorption degree of different oxygen saturation depends on the content of two kinds of hemoglobin in the blood. According to the Lambert-Beer law, the analysis of light detector to the red and infrared volume pulse wave, hemoglobin concentration, and oxygen saturation can be calculated by analyzing the PPG of the red and infrared light.

3 SYSTEM DESIGN

The reflective pulse oximetry sensing system based on semi-active RFID tags is composed of four modules: the reflective pulse oximetry detection module, data processing module, RFID transceiver module, and the PC interface.

3.1 Pulse oximetry sensing system

The pulse oximetry detection module, data processing module, and RFID tag are respectively responsible for the collection, processing, and transmission of pulse oximetry information. The RFID reader is connected to the host computer through the USB interface. They are jointly responsible for coordinating the management of the pulse oximetry sensing system, obtaining real-time sensing information of all nodes, planning and coordinating the behavior of each module. The RFID reader communicates with the RFID tag through the electromagnetic wave. On the basis of power and precision, making the normal work of each module and establishing a stable communication are key to the design of the system. The overall design of the reflective pulse oximetry sensing system is shown in Figure 1.

In order to verify the feasibility of the system, we firstly select the appropriate hardware to build the system. Among them, the pulse oximeter sensor uses the APM's latest evaluation kit for the reflective SDPPG sensor, including DCM03

Figure 1. Structural block diagram of the reflective pulse oximetry sensing system.

reflection-type probe and a built-in 32-bit Cortex-M3 processor. The DCM03 reflective sensor used in this design is composed of a red light emitting diode, infrared light emitting diode, and a high-performance photodiode. It uses 660 nm red light and 940 nm near-infrared light as the incident light source. The light source and detector are located on the same side of the body tissue. A part of light emitted from the source is absorbed through human tissue, another part of the reflected light is absorbed by the detector. It can not only measure the PPG signal but also measure the SDPPG signal. Data processing module uses the STC-12C5A60S2 of STC MCU Limited. The reader adopts the RLM300 UHF RFID introduced by RAY-LINKS. RLM300 works within the range of 840–960 MHz based on the EPC C1 GEN2/ISO 18000-6C communication protocol. The design is based on advanced RFID analog circuit combined with the digital signal processing technology. The tag selects the IDS-SL900A used in the same EPC UHF G2 tag based on 18000-6C. The platform of the pulse oximetry sensing system is built as shown in Figure 2.

The four modules of the system are:

1. The pulse oximetry detection processing module comprising a reflection type sensor and a microprocessor. The light source device emits red light and infrared light of two different wavelengths under the control of a microprocessor. The light is received by an optical detector after reflection from human tissues, and carry the oxygen pulse information in the optical signal. The light signal is converted into an electrical signal by a light sensitive element and fed into a microprocessor. The electrical signal will be processed with amplification, filtering, and A/D conversion, and then separated into DC component and AC signal.
2. Data processing module includes high-speed A/D conversion module, six digital tube, central processing unit, and data memory EEPROM. Its input and output support UART and SPI, two kinds of interface mode. The pulse oximetry

Figure 2. The platform of the pulse oximetry sensing system.

detection processing module connects data processing module through the UART serial port, so pulse and blood oxygen information can be displayed on the digital tube. Communication between data processing module and the tag through the SPI protocol achieves the configuration of running parameters of the tag so that the analog signal will be written into the tag's EEPROM in the form of a digital signal after processing.

3. The RFID transceiver module includes two parts: RFID tag and RFID reader. RFID tags are generally composed of a tag chip and RF antenna. Each tag chip has a different identity code called EPC code. It is stored in a specific storage area of the tag memory, and can also operate and identify multiple tags through the EPC code at the same time. The RFID reader communicates with RFID tags through the transmission and reception of radio frequency signals. The microprocessor in the reader controls the work of the whole reader. It is responsible for decoding and encoding the received signal and communication with the host computer.
4. The PC interface includes a host computer and the interface written by VC++ MFC programming. The reader connects directly to the host computer through the USB interface and data obtained through wireless communication will be displayed on the interface. They can obtain real-time physiological information such as pulse and blood oxygen saturation. The pulse and blood oxygen saturation monitoring system are connected as shown in Figure 3.

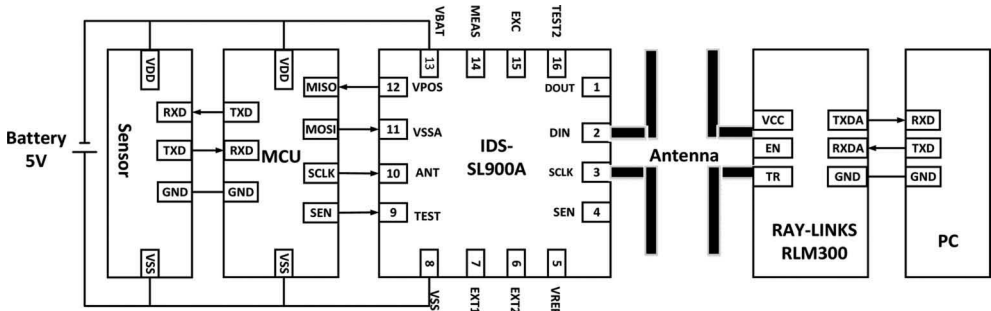

Figure 3. Diagram of the reflective pulse oximetry sensing system.

3.2 Data processing module

After running the entire system program, the hardware and software environment will firstly be initialized and then the host computer sends the sensor information to the reader. The reader will wait for query instructions of the sensor information sent by the host computer. If the reader does not receive any query from the host computer, the system remains in the initial state. Once the query instruction is received from the host computer, the reader will send selection, inventory, and access instructions to the tag through the non-modulated RF carrier, so that it will establish a connection with the label and complete the configuration of the parameters of the tag. When the tag receives the reader inquiry instruction, the data processing module transmits the enabling signal to the blood oxygen pulse sensor. The sensor begins to work after receiving the signal. Information will be sent to the data processing module after completion of the corresponding data acquisition. The data processing module communicates with the tag through the SPI interface, the received data will be written into the internal register of the tag after being extracted and analyzed. After the reader identifies the tag, the data will be transmitted to the internal register of the reader and the tag through wireless communication. Finally, the real-time data received by the reader will be displayed in the PC interface. The system flow diagram is shown in Figure 4.

3.3 Transceiver communications

Communications between the interrogator and tag are based on EPC C1 GEN2/ISO 18000-6c protocol. The parameter of the interface signals for RF communications, such as prescribed frequency and modulation, data coding, RF envelope, and data rate will be set up under the protocol. Tags shall receive power from and communicate with interrogators within the frequency range from 860 MHz to 960 MHz.

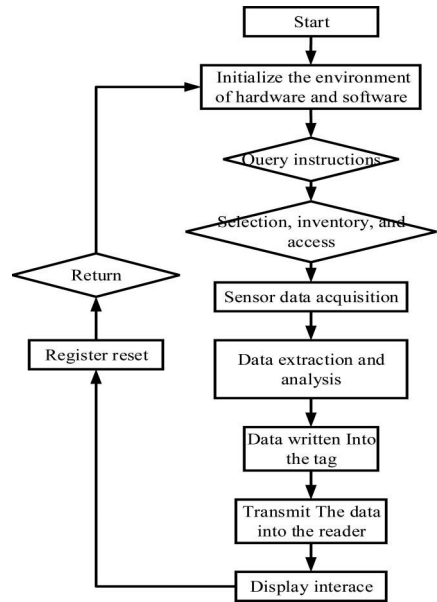

Figure 4. System flow diagram.

An interrogator manages tag populations using three basic operations: Select, Inventory, and Access. Tags shall implement a reply state. Upon entering a reply, a tag shall backscatter an RN16. If the tag receives a valid acknowledgment (ACK), it shall transition to the acknowledged state, backscattering the reply of its PC, EPC, and CRC-16. If the tag fails to receive an ACK or receives an invalid ACK or an ACK with an erroneous RN16, it shall return to arbitrate.

3.4 PC display interface

This design involves two kinds of PC display interface. One kind of interface can display the waveform of the measured data, which is obtained from the host computer connected directly with the pulse

Figure 5. Information obtained directly from the pulse blood oxygen sensor.

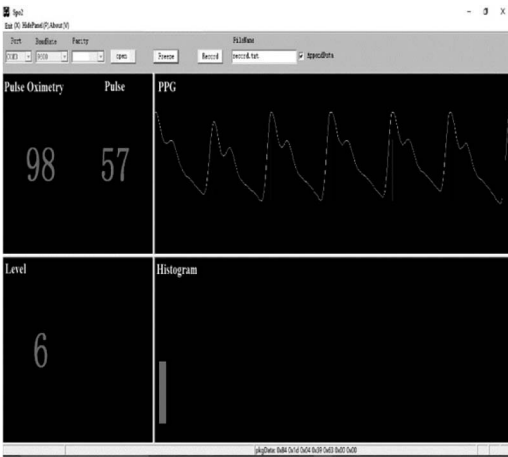

Figure 6. Data collected through the sensing system.

blood oxygen sensor module through the USB interface. The other can display data measured by the pulse blood oxygen sensor after processing by the data processing module and RFID transceiver module. The two pulse blood oxygen display interfaces are as follows:

1. The display interface of the pulse blood oxygen module can not only display the red and infrared PPG signals directly but can also display the red and infrared SDPPG signals in the interface as shown in Figure 5.
2. The real-time pulse blood oxygen information collected through the sensing system can be displayed by the waveform diagram, histogram,

and numerical method with the interface as shown in Figure 6.

4 EXPERIMENTAL VALIDATION

After debugging the software and hardware of the system, the clip type for adult probe BSJ09001C is selected from Shanghai Berry for contrast. Data measured by the oximeter will be compared with the data measured by the sensing system in order to verify further feasibility and accuracy of the system. Twenty individuals of the same age are selected for testing. Each person must have no strenuous exercise before the test and all subjects must have rest for at least 5 minutes before the signal was extracted. During the measurement, the room should be quiet and the result will be recorded when the measured data is stable.

The data measured by the pulse oximetry sensing system was analyzed and compared to the data obtained from the pulse oximeter. The results of blood oxygen saturation and pulse rate are shown in Figure 7 (a), and 7 (b). Series 1 represents the data measured by the blood oxygen sensor, and series 2 represents the data measured by the system.

The results of error analysis of blood oxygen saturation and pulse measurement are shown in Figure 8. The series 1 and 2 respectively represent the percentage error of the pulse rate and oxygen

(a) Blood oxygen saturation

(b) Pulse rate

Figure 7. Results of blood oxygen saturation and pulse rate.

Figure 8. The results of error analysis of the system.

saturation. After calculation, the average error of blood oxygen saturation is 0.35% and the maximum error is 1%. The average error of pulse rate is 1% and the maximum error is less than 2%. Overall, the system has good stability. It shows that this method can be applied to real-time monitoring of pulse and blood oxygen saturation basically to meet the design requirements.

5 CONCLUSION

In this paper, a reflective pulse oximetry sensing system is proposed based on active RFID tags. A sensor combined with a microprocessor and wireless communication technology can realize the function of real-time monitoring of pulse blood oxygen information in the middle and long distance. The experimental results prove the feasibility of the research project and the system has the characteristics of a stable operation, high accuracy, and low power consumption, and so on. Along with the development of science and technology, the improvement of medical treatment level, the characteristics of the miniaturization, and wireless real-time monitoring have good application prospects in the direction of the wearable medical wisdom.

ABSTRACT: The purpose of the greenhouse environment monitoring is to provide a good growing environment for plants, increase crop production, cut down the growth cycle and reduce the unconscious influence on the greenhouse. Combine the smart city, plant factories, large data, other hot evaluation, and design a system of long-range greenhouse environment monitoring based on the cloud technology combine the smart city. The system is mainly made up of cloud technology platform, STM32 microprocessor, sensor module, wireless module and monitoring terminal (mobile phones and personal computers), which realizes the long-range wireless environment monitoring and controlling. The System of STM32 microprocessor connects the sensor module and wireless module to collect the data of greenhouse environment (such as temperature, humidity, light, etc.), and transmits them to the cloud platform. Monitoring terminal visits the cloud platform to get and display the greenhouse environment data through TCP/IP. This system adopts the connection of cloud platform technology and Wi-Fi technology, which is more convenient than the traditional network and Bluetooth technology. The results show that the data collected by the system is stable, more real-time and has lower packet loss rate.

1 INTRODUCTION

The greenhouse environment monitoring and control obtains the optimal growth conditions for crops through changing the greenhouse environment factors (such as temperature, humidity, light intensity, etc.) (Zhang, 2013; Guo, 2010; Chen, 2011; Mittal, 2012), so as to prevent crop disease, improve crop quality and increase economic benefits. Our country is a large agricultural country with vast area, and every year serious losses are often caused by natural disasters to crops (Robert, 2008; Zhang, 2013; Zhao, 2012). Deploying the sensor nodes within the farm, access to climate conditions in real time and make corresponding measures are helpful for improving the yield of plants. Many scholars have conducted the research

in this field: the greenhouse environment monitoring system based on GSM message designed by Zhao Liyan et al. (Zhao, 2009) realized the real-time monitoring of environmental temperature, humidity and light intensity. The greenhouse environment monitoring system based on Bluetooth technology designed by Li Li et al. (Li, 2006) realized the wireless greenhouse environmental information collection through the Bluetooth. The greenhouse environmental data and control system based on ARM designed by Miao Fengyun, et al. (Miao, 2015) realized the greenhouse environment control in view of the damage of dew condensation on crop surface.

Greenhouse is a kind of advanced facility agriculture (Li, 2005), and the farmers can control environmental conditions to increase crop yield

and avoid the influence of climatic conditions on crops (Liu, 2015; Li, 2009). Greenhouse also plays an important role in anti-season vegetables and flowers. Traditional greenhouse monitoring system is mostly implemented by the wired multipoint system with complex wiring, difficult installation and poor anti-interference ability. The wireless transmission can solve the shortage of the traditional greenhouse monitoring, but Bluetooth and Wi-Fi can only achieve the short transmission control. GSM and GPRS can realize the wireless transmission control, but the SMS cost and traffic cost are high.

The research aims to design and implement a kind of remote wireless real-time greenhouse environment monitoring system based on Wi-Fi technology and cloud platform technology, so as to solve the above-mentioned problems existing in the greenhouse monitoring. STM32 is the main control chip, combined with the sensor module, realizes the collection of greenhouse environment, and uses ESP8266 Wi-Fi module to implement the wireless transmission of environment factor data; the cloud platform realizes the data storage, monitoring terminal realizes the data display and control, as well as the mass data processing in greenhouse, and reduces the influence of staff on the greenhouse environment. Also, the management personnel can timely understand the change of the greenhouse environment, control the greenhouse environment and increase the crop yield and quality.

2 SYSTEM HARDWARE PLATFORM DESIGN

This system mainly consists of the power module, sensor module, wireless module, mobile phone APP and cloud platform, etc. The development board and LED of power module provides the voltage for operation; sensor module is used for real-time acquisition of greenhouse environment parameters; wireless module is used for the acquisition of terminal access networks and wireless data transmission to the cloud platform; mobile phone APP is used for the remote access to environmental parameters and issuing control instructions; cloud platform is mainly used for data processing and storage. The schematic diagram is as shown in Figure 1.

The system main control chip uses the Cortex-M3 microprocessor chip of ST Company with the working frequency up to 72 MHz, cache of 512 bytes, SRAM of 64 K bytes and rich I/O interface, and the interrupt processing can satisfy the requirement of high real-time performance. The chip has rich resources and perfect software

Figure 1. General schematic diagram of the system.

library, can simplify the system hardware, greatly shorten the development cycle and reduce development cost; therefore, it is widely used in various kinds of electronic products, such as the electronic measuring instrument, environmental monitoring, hand held measuring tools, etc.

2.1 Wireless module design

The system uses the wireless access networks and adopts the wireless module highly integrated by ESP8266 chip with the built-in TCP/IP protocol, 32-bit microprocessor and a set of complete and self-contained Wi-Fi solution, which can carry the software application, and uninstall all network functions through another processor. The module has powerful processing and storage capabilities through GPIO port integrated sensor and other application specific equipment, so in the process of development, it occupies less system resources. Due to the low power consumption of system, it is widely used in mobile devices and wearable products. The module in this system is used to connect cloud server platform, realize the environment factor data transmission of collection terminal, and the connection with the MCU is as shown in Figure 2.

2.2 Sensor module design

The system environment temperature and humidity is collected using DHT11 sensor containing a resistor type moisture component, a NTC thermometer component and high-performance single chip microcomputer for processing data with the standard calibration function. The standard calibration coefficient is stored in the OTP memory, therefore, the sensor has high reliability and stability. It has widely measuring range, high precision, so it can satisfy the measurement task of this system. Its internal structure is as shown in Figure 3.

Light intensity of the system is collected using the TSL2560 chip sensor module of TAOS Company, and the module can convert light intensity analog signal into digital signal, which is a kind of high conversion rate, low power consumption,

Figure 2. Wi-Fi module connection schematic diagram.

Figure 4. Internal structure diagram of TSL2560.

Figure 3. Internal structure diagram of DHT11.

Figure 5. Relay connection schematic diagram.

wide range digital conversion chip. There are two channels inside the module, containing two photosensitive diodes, and the channel 0 is sensitive to visible light and infrared ray, and only channel 1 is sensitive to infrared light. The current through the photosensitive diode accumulates via A/D converter, and is translated into digital quantity stored in the chip. The chip has the programmable light intensity threshold, when the actual light exceeds the threshold, the interrupt signal will be sent, advantageous for the constant illumination function and satisfy the light acquisition task. Its internal structure is as shown in Figure 4.

2.3 Relay control circuit

The system environment control module has the relay module and single chip. The single chip receives the control commands from the upper machine, and executes the command to control the relay, so as to realize the control of heating system, ventilation system and the environment inside the greenhouse. Relay control circuit diagram is as shown in Figure 5 below.

2.4 PWM dimming modules

According to the special voltage and current characteristics of LED, it adopts the constant current drive mode, and the LED driver uses the PT4115 chip design. The chip is a step-down constant current source of continuous inductor current conduction mode, used to drive the one or more series

Figure 6. The connection schematic diagram of PWM dimming module and MCU.

LED. It has independent PWM control interface, and the connection with MCU is as shown in Figure 6.

PWM wave produced by STM32 is used to adjust the light intensity, the GPIO interface outputting the PWM wave is connected to the LED driver module, the output of LED driver is connected to the LED module, and MCU controls the brightness of LED lights by controlling the output of PWM wave.

3 SYSTEM SOFTWARE DESIGN

System software design includes the design of collection software, cloud platform building and monitoring terminal software design. The software and corresponding hardware platform work together, so as to realize the system function.

3.1 Collection software design

STM32 is the main control chip of collection end as the core of intelligent environmental factors acquisition and control. On the one hand, controlling the ESP8266 module access network realizes the connection with the cloud platform; on the other hand, the sensor module realizes the real-time acquisition and processing of greenhouse environmental parameters; it should complete the data transmission and execute commands from the PC, and start the actuators.

After the system is powered on, initialize the serial port and Wi-Fi module, guarantee that the equipment is connected to the network; after joining the network, the equipment will automatically send the IP address to cloud platform. Then initialize the sensor module to collect the environment temperature and humidity, light intensity, environmental parameters, and send to cloud storage platform, and then wait for the outside wireless packet. When receiving the wireless packet, detect the data packet, determine whether it is the device's IP address; if that, parse the packet; if not, discard the packet. When the accepted packet is the control command (such as the control of pump and humidifier, etc.), start the executing agency, execute the corresponding action, and complete the corresponding function.

3.2 Cloud platform building

Cloud platform technology is a new kind of data processing technology with a large volume of data, various data types, low value density, high commercial value and processing speed (Lu, 2016; Liu, 2016). Greenhouse environmental information collection and control contains huge amount of information. The cloud platform technology can help realize the greenhouse environment information acquisition and processing in different regions, providing accurate and timely data for the crop growth research.

The cloud platform of this system has perception layer, transport layer, cloud service layer and access layer. Perception layer is at the front end of the cloud platform, responsible for remote acquisition and control of greenhouse environment parameters; the transport layer is responsible for the transmission of greenhouse environmental data, user preferences and related commands. The cloud services layer is the core of the greenhouse environment monitoring system, used to provide the cloud infrastructure; the cloud application is based on the cloud platform infrastructure, the core of the cloud layer, which allows the user to view environmental parameters and control it anytime and anywhere, share logs, experience farming

fun; the access layer is used for the mobile terminal of platform, and provide the APP way into the cloud through the cloud computing center.

3.3 Mobile terminal software design

Mobile terminal system is the equipment of obtaining the environmental information and sending control command with the mobile phone as the mobile terminal equipment, making it convenience for users to access to information. Android is the open source mobile operating system developed by Google, including the interface development, application development, etc. This system uses the cloud platform as the intermediate connecting device, and the client development uses the Java language of Android, combined with socket for network communication and data interaction, and produces the APK installation file. It can be installed directly on the Android mobile phone; compared to the traditional wireless environment monitoring system, this system is not subject to the region, time, distance and other environmental factors. The software design of mobile terminal is as shown in Figure 7.

After the system client software starts, first of all, initialize the interface, enter the interface button and click the QR code scanning to scan the acquisition terminal equipment, the equipment system will automatically generate identifiable ID (only IP and port number), and

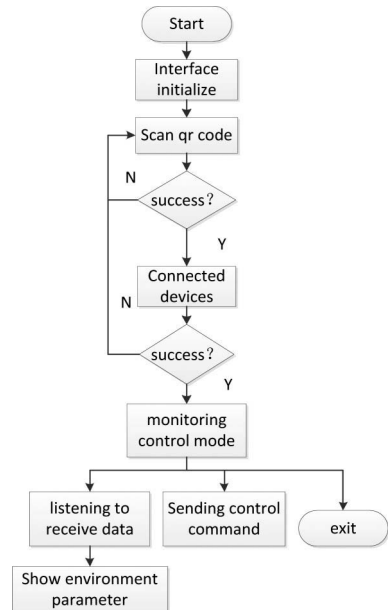

Figure 7. The software design of mobile terminal.

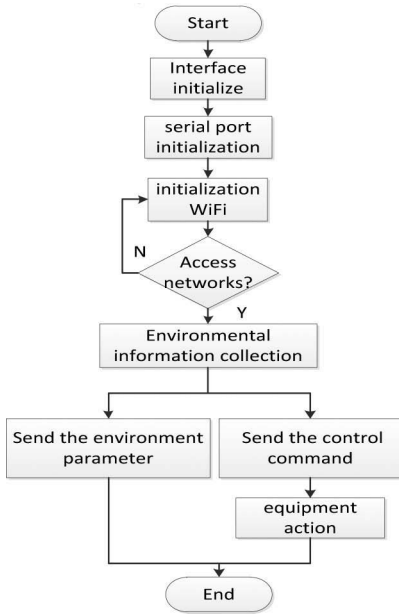

Figure 8. The software design of acquisition side.

the device ID is stored in the cloud platform; connect the devices into environmental monitoring control mode, send packets to the cloud platform and start listening mode, receive the environmental parameters from the cloud platform, and send the corresponding control command to the device through the control button. The software design of acquisition side is as shown in Figure 8.

4 SYSTEM FUNCTIONAL TEST AND ANALYSIS

In order to verify the feasibility of the designed monitoring system application and other performances, the whole system should be operated and tested.

4.1 System functional test

The test environment of this system is the smart plant growth chamber produced by Haiyu Company of Tianjin Polytechnic University; the monitoring system is installed in intelligent plant growth box with serial number in each growth chamber. Monitoring terminal uses the GALAXY Grand 7106 mobile phone produced by Samsung; inside the mobile phone is the designed APP; open the APP and scan QR code on the growth chamber, and make do a specific identification for

each growth chamber for convenient control and management of growth chamber.

Supply the power to the system, the system accesses to the network and begins to collect environment parameter, open the phone App, enter the environment parameters monitoring page, and you can see the current plant growth parameters, such as temperature, humidity and light intensity. The pages are as shown in Figure 9 above. Enter the settings page, set time, plant growth and other information as shown in the Figure below. Different buttons can be used to realize the control of collection relay, and the control of environmental parameters. The interface is as shown in Figure 10 below.

4.2 Analysis of system performance

To test and verify the packet loss rate of system, send the temperature parameters request command to different growth chambers on the PC

Figure 9. Environmental monitoring page.

Figure 10. Environmental control page.

Table 1. Unicast request packet loss rate.

Number	Number of sending data	Back packets	Packet loss rate (%)
1	2000	1995	0.25
2	2000	1996	0.20
3	2000	1996	0.20
4	2000	1993	0.35
5	2000	1995	0.25
6	2000	1994	0.30
7	2000	1991	0.45
8	2000	1992	0.40

side in the form of unicast, so as to test the system packet loss rate. The unicast packet loss rate is as shown in Table 1.

The system adopts cloud platform technology and Wi-Fi technology with no distance limit. No matter when and where it is, there is network in the phone, it can realize the real-time monitoring of greenhouse environment. In the case of 2G network, it can also refresh the page quickly.

5 CONCLUSION

This paper designs and implements a kind of remote wireless greenhouse monitoring system combined with cloud platform technology and Wi-Fi technology, so it effectively overcomes the traditional problems of greenhouse environment monitoring and management. It combines the cloud platform and Internet technology that the users are allowed to obtain and control the greenhouse environment parameters through App, so it effectively avoids the crop losses due to the improper environment parameters in greenhouse. Also, it realizes the unified management of the greenhouse environment monitoring, gets rid of the traditional individual greenhouse environment monitoring system, effectively realizes the multiple remote monitoring and management of greenhouse. It eliminates the defects of traditional greenhouse management, thus exploring the development of greenhouse environment monitoring and providing strong theoretical basis.

Negative emotion speech classification for a six-leg rescue robot

Xiaolei Han

College of Information and Computer Science, Shanghai Business School, Shanghai, China

ABSTRACT: This paper aims at providing an approach for a user-dependent emotion recognition system of affective speech based on multiple features using prosodic information and Higher Order Spectra (HOS) analyses. Prosodic features including speech rate, short-term energy, and pitch-related features are extracted to indicate the effect of linear aspects, and HOS analyses are utilized to indicate the impact of nonlinear aspects of affective speech signal. Some significant representatives are taken to form the reduced feature set and build the classifiers for emotion recognition. The proposed algorithm is implemented on our six-leg robot, which is designed for search and rescue tasks in real disaster sites using the predictive accuracy of dynamic time warping. The effectiveness of this algorithm in both emotional speech signal recognition and feature dimensionality reduction is illustrated with some experimental results. An important finding is that the proposed algorithm is shown to be effective for identifying negative-type emotion with excellent predictive capability.

1 INTRODUCTION

A huge earthquake with the magnitude 9.0 hit Fukushima, Japan on March 11th, 2011 and has raised the alarm of emergency measure problems both in information and robotics technology for the case of large-scale disasters. The advantage of utilizing rescue robots in such dangerous situations is that they are able to carry out high-risk tasks without exposing rescue crews to danger (Valero, 2010). This means that the rescuers' lives are less at risk and that survivors can be more easily and quickly located. If the robot cannot bring the survivors out on its own, it should be able to detect and transmit survivors' vital signs and emotional states to rescuers and doctors and keep the surviving life a friendly company while rescuers try to reach them.

Under such emergency conditions, the trapped survivors easily plunge into desperation and their audio signals normally have aspects of negative emotion (e.g., fear, sadness, panic, stress, hopelessness, and despair). With the ability of cognitive and affective reaction, once the rescue robot perceives a negative emotion through survivors' speech, it could try to ease and encourage them as rescuers or psychologists do. Recent developments in speech-based emotion recognition enable us to use them for this case (Koolagudi, 2012). In fact, negative emotion classification can not only be used to improve the naturalness and effectiveness of interaction between robots and humans, other applications can also benefit such as life-support systems,

in-car driver interfaces, call-center management, educational software, games, etc. (Koolagudi, 2012; Sravros, 2012; Ververidis, 2006; Chen, 2007).

Our motivation is to develop an emotional speech detection system for survivors and rescue robots in the context of disasters (earthquake, fire, building collapse, etc.). With emotional speech recognition ability, a teleoperated rescue robot could detect, analyze, and feed a survivor's vital signs and emotional states back to the control base outside the disaster area, and it could also be a friend to accompany trapped people while rescuers are trying to reach them. The main novelty is that we adopt Higher Order Spectra (HOS) to analyze nonlinear aspects of affective speech signals, and try to search for embedding dimension and associated features that best show the emotional class structure of our data.

2 PREPARATIONS

2.1 *Six-leg rescue robot*

The first version of our six-leg teleoperated rescue robot (Figure 1) is developed for executing rescue missions at disaster areas. With the help of rubber suction cups, it is capable of surmounting obstacles, operating valves, etc. in disaster areas. The sensory equipment includes auditory, tactile, ultrasonic, and vision sensors, which allow the rescue robot to behave autonomously and interact with rescuers. For protection consideration, all processing and control systems are located in the robot's body.

Figure 1. The six-leg rescue robot and a simulated scene of operating the valve.

After locating the survivors, the rescue robot can recreate and model its surroundings, and feed this information to rescuers waiting outside. Meanwhile, the rescue robot friend accompanies the survivors until rescuers arrive.

2.2 Difficulties of emotional speech recognition in disaster areas

The current ability of the six-leg rescue robot’s emotional speech recognition is not satisfied due to noise from the disaster environment. Rescuers can communicate with survivors even under quite noisy conditions. However, such noise is critical for the rescue robot. Meanwhile, the lack of corpus and studies dealing with emotions in the disaster environment encouraged us to build the SJTU corpus, which is a multi-language emotional database including seven emotion states.

Meanwhile, survivors’ emotional expressions occurring in the disaster area may have some particularities. Though much remains to be discovered, survivors’ emotions seem to be more intense and biased toward certain types of emotion states, such as inner strain and destructiveness of sadness, and fear controlled by the intensity of roiling emotions that block recovery. Some of these particularities are beneficial for emotion recognition because the recognition model can be built to interact specifically with survivors.

2.3 SJTU emotional database

Adapting any general emotion recognition system for a particular individual requires speech samples and prior knowledge about their emotional content. However, in real disaster scenarios, annotated emotional speech data is unavailable to train or adapt the models. To address this problem, this paper introduces an ongoing recorded SJTU corpus which is a syllable-based multi-language

Table 1. Number of utterances available per emotion type.

Emotion	Ch_M		En_M		Ch_F		En_F	
	Tr	Te	Tr	Te	Tr	Te	Tr	Te
Happiness	90	60	191	130	297	100	180	120
Sadness	180	120	401	270	147	200	450	300
Fear	135	90	296	200	222	150	315	210
Neutral	45	30	87	60	72	50	90	60
Total	450	300	975	660	738	500	1035	690

emotional database (English, Chinese, German, and Italian) including seven emotions: neutral, surprise, sadness, disgust, fear, happiness, and anger. The corpus was recorded in a sound-proof room (lower than 35 dB) where it can block any outside noise. So far, a total of 10 college students (5 males $25.6 \text{ years} \pm 3.65$ and 5 females 25.8 ± 2.49) without any history of voice disorders or larynx diseases participated in this research. Emotional stimuli used in this study are audio-visual film clips, which were examined for their appropriateness and effectiveness through a preliminary experiment.

Considering the factors such as lower computational power needed for speech processing, the 16-bit recordings were taken with a sampling frequency of 16 kHz. Emotional audio data are saved in .wav format. For our emotion detection system, we selected 5348 utterances through subjective evaluation tests by 20 listeners (students from Shanghai Jiao Tong University in China) including four emotions: happiness, sadness, fear, and neutral (Table 1). For this research, we assume sadness and fear as negative-type emotions. The meanings of the abbreviations in Table 1 and the rest of this paper are shown as follows:

- Ch_M, Ch_F: Chinese utterances by male speakers and female speakers.
- En_M, En_F: English utterances by male speakers and female speakers.
- Tr, Te: The number of utterances for training and testing.

3 ACOUSTIC FEATURES

It is well known that the performance of emotional speech recognition algorithms is greatly influenced by some fundamental issues in which parameters are selected as emotional features. Some researchers combined tens or even thousands of parameters to enhance performance in recognition of emotional states through speech. The most common features are prosodic features, qualitative features, vocal tract features, and features based

Table 2. List of extracted parameters.

Type	Abbr.	Description	No.
Prosodic parameters	Duration	Ratio of voicing against unvoiced segments	1
	Pause	Ratio of pauses against speech duration	1
	MeanF0	Mean pitch	1
	VarF0	Pitch variance	1
	StdF0	Standard deviation of pitch	1
	MedianF0	Median pitch	1
	MaxF0	99% value of pitch	1
	MeanEn	Mean of short time energy	1
	VarEn	Short time energy variance	1
	StdEn	Standard deviation of short time energy	1
	Median En	Median short time energy	1
	Max En	99% value of short time energy	1
	Min En	1% value of short time energy	1
	Nonlinear Parameters	HOS	Proposed HOS parameters

on the Teager energy operator (Sravros, 2012; Ververidis, 2006).

Teager suggested that the true source of sound production is actually the vortex-flow interactions, which are nonlinear. Therefore, nonlinear speech features are necessary to classify negative emotion speech from neutral. HOS offers a novel set of techniques, algorithms, and methodologies for the study and analysis of signals, especially it can detect and characterize nonlinearities in time series and can suppress additive Gaussian noise of unknown spectral characteristics. Emotional speech has significant nonlinearity, thereby making HOS a potential candidate in detection, parameter estimation, and classification problems. The objective of this study is to investigate whether or not bispectral analysis, a particular form of HOS, may be utilized for analyzing the emotion states through speech. As long as there is no common agreement on the best features to use, we chose to combine the most widely investigated prosodic parameters and the proposed HOS parameters as emotional feature sets which are listed in Table 2.

After pre-emphasis, we use the Teager Energy Operator (TEO)-based Voice Activity Detection (VAD) method to segment the utterances into syllabic units (Chen, 2007). To verify the performance of TEO based VAD method, we vary the testing condition. Noise is added to the clean speech corpus

Figure 2. The TEO-based VAD result of the noisy speech signal with neutral emotion at SNR of 20, 10, and 5 dB.

to create noisy signals at specific SNR 20, 10, and 5 dB (Figure 2). Then, each incoming speech signal is divided into 30 msec. long with 10 msec. overlapping duration. The features of all frames in one emotion syllabic unit are clustered to form a feature vector. All features are then standardized with zero mean and standard deviation of one.

3.1 Prosodic features

As prosody is believed to be the primary indicator of a speaker’s emotional state (Lee, 2005; Ingale, 2012), most of the works adopt prosodic features (Koolagudi, 2012). In this work, we extracted 14 prosodic parameters as listed in Table 2. Duration means the ratio of voicing against unvoiced segments. Pause here means the ratio of pauses against speech. Pitch (F0) contains information about emotion because it depends on the tension of the vocal folds and the subglottal air pressure, measured in Hz (Ververidis, 2006; Chen, 2007; Lee, 2005; Ingale, 2012). Short-term energy is based on the speech signal’s amplitude, which is related to the arousal level of emotions (Ververidis, 2006).

For emotion classification, not all parameters contribute. Some of the parameters may be highly correlated with redundant information and hence may not be optimal. We use the absolute value of Pearson’s correlation coefficient to calculate the linear correlation between different parameters, p_i and p_j :

$$\rho_{i,j} = \left| \frac{\text{cov}(p_i, p_j)}{\sigma_i \sigma_j} \right| \quad (1)$$

From Cauchy-Schwarz inequality, we know $\rho_{i,j}$ is less than or equal to 1. We find $\rho_{4,5}$, $\rho_{4,5}$, $\rho_{8,11}$, and $\rho_{9,10}$ presents significant linear correlation with minimum value varying from 0.91 to 0.96. It is crucial to discard irrelevant and redundant features for efficient computation and accurate

classification. According to the average value of $\{\rho_4, \rho_5, \rho_8, \rho_9, \rho_{10}, \rho_{11}\}$ it is equal to $\{0.48, 0.46, 0.57, 0.45, 0.47, 0.52\}$. We eliminate the pitch variance, mean and standard deviation of short time energy (index 4, 8, and 10) to reduce the higher correlation.

3.2 HOS features

Let $X(n)$ represents a syllabic unit of digital discrete-time emotional speech. Assuming the emotion expression of $X(n)$ is stable within a word and its moment up to order k exists, the n -th moment function of $X(n)$ is defined by

$$m_k(\tau_1, \tau_2, \dots, \tau_{k-1}) = E\{x(n)x(n+\tau_1)\dots x(n+\tau_{k-1})\} \quad (2)$$

where $E\{\cdot\}$ stands for the expected-value operator. m_k only depends on the time differences $\tau_1, \tau_2, \dots, \tau_{k-1}$. Bispectral analysis is related to the third moment (skewness) of $X(n)$. The relationship between the 3rd-order cumulant and the moment $m_3(\tau_1, \tau_2)$ is given by

$$c_3(\tau_1, \tau_2) = m_3(\tau_1, \tau_2) \quad (3)$$

Let $\tau_1 = \tau_2 = 0$ in equation(2) and (3). The skewness γ_3 is obtained by

$$\gamma_3 = c_3(\tau_1, \tau_2) = E\{x^3(n)\} \quad (4)$$

The bispectrum is the Fourier transform of the third order correlation of $X(n)$, which can be estimated by

$$B(f_1, f_2) = E\{X(f_1)X(f_2)X^*(f_1 + f_2)\} \quad (5)$$

where $*$ denotes the complex conjugate. $X(f)$ is the Fourier transform of $X(n)$. For more details of HOS please refer to (David, 1991; Mendel, 1991).

In order to observe the bispectrum of emotional speech, we do 128 samples of FFT for each syllabic unit. The contours plots of the magnitude of the indirectly estimated bispectrum for the ‘‘Sh-owl’’ (this order in Chinese will let the horse step back) by the same speaker in different emotions are shown in Figure 3. We notice that the bispectral analysis is capable of distinguishing different emotions. Each bispectrum is a 128×128 array, which is too large to be used in emotional speech recognition algorithm. To this end, the eigenvector and eigenvalue of the bispectrum are extracted. Through experiments, we found that each bispectrum matrix only has one eigenvalue. We only take the first column of the eigenvector,

Figure 3. The bispectra of neutral, surprise, sadness, disgust, fear, happiness, and anger on bifrequency plane for ‘‘Sh-owl’’.

V , into consideration, which is a 128×1 vector. V is further normalized as follows:

$$\hat{V} = |V| / \sqrt{\Sigma V^2} \quad (6)$$

where \hat{V} is the emotional feature of HOS analysis.

Compared to the dimension of \hat{V} , the size of training data is small, which will direct influence of the accurate rate of recognition. Therefore, we introduce Nonlinear Iterative Partial Least Squares (NIPALS) algorithm to handle this problem. Moreover, from Pearson’s correlation coefficient, we find the significant correlation period of \hat{V} is 5, and values of $\{\rho_{i,i+5}\}$ ($i = 1, 2, \dots, 123$) are higher than 0.9. This means \hat{V} contains a high correlation. The Nonlinear Iterative Partial Least Squares (NIPALS) algorithm has been developed by H. Wold, first for PCA and later on for Partial Least Squares (PLS). It can handle data matrices with a high degree of collinearity and perform well when the size of training data is small. NIPALS has been successfully applied in speech and visual related works. Thus, in this work, we apply the PLS method which is based on the NIPALS algorithm to training HOS feature vectors. More details about NIPALS can be seen in (Bowden, 2010; Alin, 2009).

4 EMOTION CLASSIFICATION AND RESULTS AND DISCUSSION

As an emotion classifier, we utilize the NIPALS method for HOS parameters and use a Dynamic Time Warping (DTW) method for prosodic features, since DTW is well proven although it has some imperfections. The results from emotion detection are classified into three categories: positive-type emotion (denoted as Pt), Negative-type emotion (Nt), and Neutral emotion (Ne). If a happiness emotion is detected from the speech, the system classifies it as a positive-type emotion.

If we detect fear or sadness, the system classifies it as a negative-type emotion. Otherwise, the system assumes a neutral emotion. As a result, if a negative-type emotion is detected, the rescue robots should take appropriate countermeasures to console and encourage survivors.

4.1 Results of emotion recognition performance

We compare the emotion recognition output from the system with labeled emotions. The results of the comparison are shown in Table 3. The ‘‘Average’’ means the average accuracy rate for emotion states. As a result, the average accuracy of happiness, sadness, fear, and neutral emotion detection from the speech is 73.03%, 82.43%, 67.59%, and 87.58%, respectively.

4.2 Results of recognition performance by using different features

Furthermore, we observe the effects of emotion category recognition and compare the performance of proposed features with some of the most commonly investigated emotional features:

- F_1 : HOS parameters.
- F_2 : *Set 1*, *Set 2*, and *Set 3*.
- F_3 : F_1 and F_2 .

F_1 is the proposed HOS feature, which presents the nonlinear aspect of the emotional speech signal. F_3 is the proposed feature vector which can also be used in Table 3, and the final emotion category for F_3 is generated by the ballot. In order to prove the effectiveness of this new emotional feature, the most investigated features of F_2 is: 1) preprocessed by grouping *Set 1*, *Set 2*, and *Set 3* together as one feature vector; 2) the final emotion category is generated by the ballot of sets of features with more than half of votes cast. Table 4 to Table 6 show the results of emotion category recognition (Pt : positive-type emotion, Nt : negative-type emotion, and Ne : neutral emotion). The ‘‘average’’ represents the rate that the system output correctly matched the labeled emotion states for all emotion states. As a result, the average accuracy by F_1 , F_2 , F_2 -vote,

and F_3 is 85.97%, 79.57%, 90.66%, and 92.72%, respectively.

4.3 Discussion

The performance of proposed features with votes cast (Table 6) is better than the one of prosodic features with votes cast (Table 5), increasing from 0% to 6.58%. The results illustrate that combining the existing emotion features with the proposed HOS feature can enhance the performance to classify emotion states and the ability of emotion category detection.

Although the average accuracy of using the proposed emotion detection algorithm for happiness,

sadness, fear, and neutral from speech is unsatisfied (77.66%), the one for emotion category recognition significantly increases the precision of the system (15.06%), that is to say the nonlinear aspect affects emotion expression and the HOS feature has a good ability to distinguish differences among positive-type emotion, negative-type emotion, and neutral emotion.

Since the prosodic features with votes cast perform better than the one without votes cast, increasing from 5.64% to 14.17%, the voting system is one of the important steps in emotion recognition. Meanwhile, some individual accuracy rates of Table 6 are lower than that of Table 5 and Table 3 because prosodic features, 3/4 of votes are the major factor that affects the final result of emotion category detection. On the other hand, the SJTU corpus was recorded by Chinese speakers, which will lower the naturalness of emotion expression in English. This may also be the reason why the accuracy rate of English is lower than Chinese.

The average accuracy of the negative-type emotion recognition is higher than the positive-type (2.75% in Table 6) and neutral emotion (3.21% in Table 6). The negative-type emotion recognition works well for this particular experiment because the proposed emotion recognition system is trained and evaluated under low noise conditions. The noise from a realistic disaster environment and the rescue robot itself will probably decrease the performance. Thus, for practical and effective use, we should improve the anti-noise ability of negative-type emotion detection performance in a real disaster situation. Our next step is to post-process the utterances by adding the noise of the rescue robot and disaster environment. The disaster environment noise can be acquired from the real disaster environments and disaster films, which are realistic and near to the situations defined by our application field.

5 CONCLUSION

This paper presented an approach to improve the interaction between rescue robots and survivors based on emotion recognition, particularly,

negative-type emotion. The experiment results revealed that HOS parameters are essential for this approach. Experiments were carried out with the SJTU database. Finally, this method was implemented in our six-leg rescue robot. However, the present research is being done in laboratory circumstances and does not consider the influence by disaster environmental noise. In the next step, we would like to achieve higher recognition accuracy and enhance the capability of anti-noise to make rescue robots work in the real world.

ABSTRACT: In this work, nonlinear vibration of a happiness model with commensurate fractional-order derivative is studied analytically and ascertained by numerical ones. The influences of the impact factor of memory on the curves of external frequency, excitation amplitude, and nonlinear damping coefficient versus maximal amplitude of one's response to external events are presented and compared by introducing the polynomial homotopy continuation technique. The result shows that when one's experiences have more and more influences on his/her present and future life, the vibration amplitude of one's response to external events becomes bigger and bigger under the same external events, and some strong nonlinear phenomena such as multiple solutions, bifurcation and peak amplitude with the increasing impact factor of memory are illustrated. In addition, we can find that all the stable solution branches obtained match well with the numerical ones.

1 INTRODUCTION

An interesting dynamic model of happiness composed of a 3-order differential equation has recently been reported by Sprott (Sprott, 2005). This model describes the time variation of happiness (or sadness) displayed by individuals under certain external circumstances, and the governing equation is given as

$$\frac{d^3 R}{dt^3} + \alpha \frac{d^2 R}{dt^2} + \beta(1 - R^2) \frac{dR}{dt} + R = f(t) \quad (1)$$

where α and β are the parameters of the model and β denotes the nonlinear damping coefficient. $f(t)$ is a time-dependent forcing function representing one's external circumstance. R represents that what others presume one's happiness to be based on one's circumstances.

Fractional-order derivative (Oldham, 1974), a generalization of the traditional integer order, has a history of over 300 years. It is an adequate tool for the study of the so-called "anomalous" social and physical behaviors, in reflecting the non-local, frequency and history-dependent properties of these phenomena (Monje, 2010). The integral-order derivative of a function is only related to its nearby points, while the fractional derivative has a relationship with all of the function history

information. As a result, a model described by fractional-order equations possesses memory. In fact, real world processes generally or most likely are fractional-order systems, namely dynamical systems governed by the fractional order derivative equations. As we all know, the emotion of happiness has a relationship with all of the past factors, that is, it is influenced by memory. Thus, the characteristics of fractional-order models and the practical emotion of happiness coincide with each other well. So it is more proper to describe the happiness model with fractional-order equations rather than with integer-order equations. For instance, Song et al. (Song, 2010) demonstrated and exhibited various behaviors of a dynamical model of happiness described through fractional-order differential equations via numerical simulations. Ahmad and Khazali (Ahmad, 2007) examined the fractional-order dynamical model of love and obtained the strange chaotic attractors under different fractional orders by using numerical simulations. Sun et al. (Sun, 2012) used the predictor-corrector scheme to demonstrate the dynamical analysis of a driven nonlinear happiness model.

This study aims to introduce methods of harmonic balance (Leung, 2016; Guo, 2016; Ju, 2015) and polynomial homotopy continuation (Sommese, 2005) to study the periodic vibration and effect of Impact Factor of Memory (IFM)

of an individual (fractional-order) on steady-state response of a happiness model with commensurate fractional-order derivative.

2 FRACTIONAL-ORDER MODEL OF HAPPINESS

The fractional-order derivative features the memory effect of past states. In equation (1), replacing the integer-order derivative with a fractional-order $0 < \lambda \leq 1$ in the sense of Caputo definition, a commensurate fractional-order happiness system is given as below.

$$D_t^{\lambda} R + \alpha D_t^{2\lambda} R + \beta(1 - R^2) D_t^{\lambda} R + R = f(t) \quad (2)$$

In state space, equation (9) can be rewritten as

$$\begin{cases} D_t^{\lambda} R = E \\ D_t^{\lambda} E = H \\ D_t^{\lambda} H = -R - \beta(1 - R^2)E - \alpha H + f(t) \end{cases} \quad (3)$$

where α and β are model parameters, $f(t)$ denotes a time-dependent forcing function and D_t^{λ} is the fractional derivative in the Caputo sense.

From Ref (Song, 2010), R represents one's responses to external events, namely, what others presume one's happiness depending on one's circumstance. E means one's true feelings. The parameter pair (α, β) is to categorize people with different personality, i.e., different (α, β) represents a different kind of individuals, and the order λ represents the impact factor of the memory of an individual, that is, as the value of λ increases from 0 to 1, the impact factor of the memory of individual increases correspondingly. It is noteworthy that the conception of the impact factor of memory is proposed here to denote a measurement of how the influence of an individual is by his/her past experiences. When one's IFM is low, his/her past experiences may have little influence on his/her present and future life; when the IFM is high, it might be difficult for him/her to escape from past experiences despite nightmares or sweet memories.

In fact, one's mood will change due to different external circumstances. We assume the external periodic event $f(t) = q \cos(\omega t)$ and then equation (3) becomes

$$\begin{cases} \frac{d^{\lambda} R}{dt^{\lambda}} = E \\ \frac{d^{\lambda} E}{dt^{\lambda}} = H \\ \frac{d^{\lambda} H}{dt^{\lambda}} = -R - \beta(1 - R^2)E - \alpha H + q \cos(\omega t) \end{cases} \quad (4)$$

3 STEADY-STATE RESPONSE ANALYSIS

Since the periodic solutions are of interest, the steady-state response of equation (4) can be expanded in the Fourier series

$$R(t) = \sum_{k=0}^n a_k \cos(k \omega t) + \sum_{k=1}^n b_k \sin(k \omega t) \quad (5)$$

where a_i, b_i are the unknown Fourier coefficients. n is an integer representing the maximum order which retained harmonics.

Substituting equation (5) into equation (4) and using the Galerkin procedure, it results in the following harmonic balance equations

$$\begin{aligned} R_k^c(a_0, a_1, \dots, a_n, b_1, \dots, b_n) \\ = \frac{2}{\pi} \int_0^{\pi} \Phi(D_{\tau}^{3\lambda} R, D_{\tau}^{2\lambda} R, D_{\tau}^{\lambda} R, R) \\ \times \cos(i \tau) d \tau, i = 1, 2, \dots, n \end{aligned} \quad (6)$$

$$\begin{aligned} R_k^s(a_0, a_1, \dots, a_n, b_1, \dots, b_n) \\ = \frac{2}{\pi} \int_0^{\pi} \Phi(D_{\tau}^{3\lambda} R, D_{\tau}^{2\lambda} R, D_{\tau}^{\lambda} R, R) \\ \times \sin(i \tau) d \tau, i = 1, \dots, n \end{aligned} \quad (7)$$

Where

$$\begin{aligned} \Phi(D_{\tau}^{3\lambda} R \omega^{3\lambda}, D_{\tau}^{2\lambda} R, D_{\tau}^{\lambda} R, R) = D_{\tau}^{3\lambda} R + \alpha \omega^{2\lambda} D_{\tau}^{2\lambda} R \\ + \beta \omega^{\lambda} (1 - R^2) D_{\tau}^{\lambda} R - q \cos(\tau). \end{aligned}$$

After carrying out the integration, it yields

$$[K(f, \mu)]\{f\} - \{F\} = \{R_1\} = 0 \quad (8)$$

where $[K(f, \mu)]$ is the total stiffness matrix, $\{R_1\} = [R_0^c, R_1^c, \dots, R_n^c, R_1^s, \dots, R_n^s]^T$, $\{f\} = [a_0, a_1, \dots, a_n, b_1, \dots, b_n]^T$. Given the parameter values of μ , equation (8) is solved using the method of harmonic balance in combination with homotopy continuation algorithm. Further, all the steady-state analytical solutions are obtained.

4 RESONANCE RESPONSE AND DISCUSSION

Considering the third-order harmonic case, all the steady-state solutions are obtained by the method of residue harmonic balance in combination with polynomial homotopy continuation in this section. The influence of the impact factor of memory is examined by external frequency, excitation amplitude, and nonlinear damping coefficient versus maximal amplitude of one's response to external events. The dynamics and some simple nonlinear phenomena are shown. In the following

figures, stable and unstable branches are indicated, respectively, by solid and broken lines. The circles correspond to the results of numerical simulation.

4.1 External frequency versus maximal amplitude

In this subsection, we focus on the effect of IFM on the relation of steady-state frequency versus maximal amplitude of one's response and true feeling. From Figure 1, we can find that (i) When the IFM $\lambda = 0.6$, the maximal amplitudes of response and true feeling slightly increase first and then decrease. The solutions are always stable, that is when one's past experiences have little influence on his/her present and future life, his/her response and true feelings to external events in a steady state only appear with some slight vibration. (ii) When one's experiences have more and more influence on his/her present and future life, the vibration amplitude

of response to external events becomes bigger and bigger and the model system sequentially presents quasiperiodic motion with increasing external frequency. When IFM $\lambda = 0.7, 0.8, 0.9$ respectively, the change of stable maximal amplitudes of vibration motion to one's response and feelings becomes more and more evident as increases in external frequency to $N_{0.7}(\omega \approx 1.155)$, $N_{0.8}(\omega \approx 1.251345)$, and $N_{0.9}(\omega \approx 1.296356)$ sequentially. In addition, the model system presents strong nonlinear phenomena such as multiple solutions, quasiperiodic motion, etc. When the IFM $\lambda = 0.7$, one's response and feeling to external events present three coexisting periodic solutions in the region of $[S_{0.7}, N_{0.7}] \approx [1.147962, 1.155]$, and as further increases in external frequency from point $N_{0.7}$, the vibration presents in quasiperiodic motion. Similarly, some key points for IFM $\lambda = 0.8$ and 0.9 are $S_{0.8} = 1.05191$, $N_{0.8} = 1.251345$, $S_{0.9} = 0.896894$, $N_{0.9} = 1.296356$. As a result, it is evident that, with the increase in IFM, the region of existing periodic motions gradually become broad and frequency of quasiperiodic motion occurring sequentially becomes big. (iii) All the stable branch solutions are in excellent agreement with numerical simulation ones.

4.2 Excitation amplitude versus maximal amplitude

In this subsection, the relation of excitation amplitude versus maximal amplitude of one's response and the effect of IFM are illustrated and shown. From Figure 2, we can find that: (i) As the excitation amplitude increases, the stable vibration amplitude of one's response slightly increases but change is not evident. (ii) When one's experiences have more and more influence on his/her present and future life, the vibration amplitude becomes bigger and bigger under the same external events. (iii) When IFM $\lambda = 0.7$, the model system first presents

Figure 1(a). Effect of IFM on external frequency versus maximal amplitude of steady response.

Figure 1(b). Effect of IFM on external frequency versus maximal amplitude of one's true feeling.

Figure 2. Effect of IFM on excitation amplitude versus maximal amplitude of one's response.

quasiperiodic motion, multiple solutions, and then develops into a stable response branch with increasing excitation amplitude. That is, when one's past experiences have a moderate influence on his/her present and future life and the excitation amplitude is smaller, one's response to external events will present a swing. The corresponding saddle-node points are $N_1(q \approx 0.5919)$ and $N_2(0.6856)$. (iv) All the present analytically stable solutions match well with the numerical ones.

4.3 Nonlinear damping coefficient versus maximal amplitude

This subsection illustrates the effect of IFM on the relation between nonlinear damping coefficient and maximal amplitude of response in the steady state. From Figure 3, it is evident that (i) When one's past experiences have little influence on his/her present and future life such as IFM $\lambda = 0.6, 0.7$, the maximal amplitude of one's response to external events in the steady state keeps decreasing as the nonlinear damping coefficient from -2 to 0 . (ii) As the IFM increases, for instance when $\lambda = 0.8$, the response to external events first increases and then decreases and presents a peak amplitude of nonlinear damping coefficient varying from -2 to 0 . (iii) When one's experiences have much influence on his/her present and future life, we can see

Figure 3. Nonlinear damping coefficient versus maximal amplitude curve and effect of IFM with $\omega = 1$.

Figure 4. Nonlinear damping coefficient versus maximal amplitude curve and effect of IFM with $\omega = 0.5$.

that the maximal amplitude of one's response to external events abruptly become very big when the nonlinear damping coefficient tends to zero as in Figure 3(b). (iv) When one's experiences have more and more influence on his/her present and future life, the vibration amplitude becomes bigger and bigger under the same nonlinear damping coefficient. In addition, all the present analytical solutions match well with numerical ones. In Figure 4, we expand the nonlinear damping coefficient from -2 to 2 and take external frequency $\omega = 0.5$ and IFM $\lambda = 0.25, 0.4, 0.5, 0.6$, and 0.7 , respectively. Similar responses are shown in Figure 4. However, from Figure 4, we can see that (i) when the IFM $\lambda = 0.6$, the peak amplitude of the curve of nonlinear damping coefficient versus maximal amplitude of response has emerged for nonlinear damping coefficient varying from -2 to 2 . (ii) When IFM $\lambda = 0.7$, the system presents some strong nonlinear phenomena such as multiple solutions, saddle-node bifurcation.

5 CONCLUSION

A model of happiness with commensurate fractional-order derivative has been explored in detail by using the method of harmonic balance

in combination with homotopy continuation. The influence of the impact factor of memory on curves of external frequency, excitation amplitude, and nonlinear damping coefficient versus maximal amplitude of one's response to external events is examined. The results show that when one's experiences have more and more influence on his/her present and future life, the vibration amplitude of the response to external events becomes bigger and bigger under the same external events. The model system sequentially presents quasiperiodic motion with the increasing of external frequency and the peak amplitude of curve of nonlinear damping coefficient versus maximal amplitude of one's response to external events will emerge as the IFM increases for the same parameters. In addition, all the stable solution branches have been verified and are in agreement with numerical ones.

Simulation analysis of airdrop cargo extraction posture

Hong Wang, Xu-hui Chen, Ya-hong Zhou & Xiang Li

Air Force Airborne Academy, Guilin, China

ABSTRACT: Based on the ANSYS/LS-DYNA software platform and taking certain types of heavy equipment airdrop systems for example, the method of numerical analysis was used to study the micro-cosmic changing process of cargo extraction posture in different situations. The change in the overturn angle and speed as time changes was analyzed. The best binding cargo barycenter position was determined, which provided guidance to the design of the airdrop system and the actual airdrop operation.

1 INTRODUCTION

In the airdropping process of heavy equipment, the binding cargo barycenter position has a great influence on cargo extraction posture. At present, cargo binding and moorage solutions are basically relying on experiences. It not only wastes a lot of manpower and material resources but also may cause damages to cargo. Therefore, it is necessary to study this problem. Based on ANSYS/LS-DYNA numerical simulation and analysis system (Li, 2012; Qi, 2014), aiming at certain types of heavy equipment airdrop systems, simulation analysis is made on the changing process of cargo extraction posture in this paper. Taking the cargo overturning speed and angle as a reference standard (Li, 2013), the best binding cargo barycenter position is determined at an extraction speed of 3 m/s, which provides guidance to the design of airdrop system and actual binding and moorage operation in airdropping.

2 SETTING UP A SIMULATION MODEL

2.1 *Simulation object*

Aiming at certain types of heavy equipment airdrop systems in this paper, a simulation study is done on airdropping heavy equipment, the time when the cargo leaving the cabin and the parachute cord of the main chute are completely straightened, the cargo at an extraction speed of 3 m/s and the relationship between barycenter position and the biggest overturn angle and speed (Zhang, 2014; Cheng, 2013). Heavy equipment airdrop system is generally composed of a cargo platform and parachute. Cargo platform is the cargo carrier. Here we take cargo and cargo platform as a rectangle overall, where the length, width, and height are 3.65 m,

2.4 m, and 2 m; respectively, and the cabin floor is 4 m × 2.4 m × 0.2 m cuboid.

Considering the characteristics of the airdrop process and the main purpose of numerical analysis, in order to reduce simulation difficulties and calculating time, the airdrop simulations are simplified as follows:

1. Choose the cargo extraction time from when the cargo platform geometric center reaching the cabin edge to the parachute cord of the main chute are straightened. This period of time is less than 3 s, so the simulation time is identified as 3 s.
2. When airdropping, keep the aircraft in a level flight and the aircraft cabin at floor level.
3. Take the cargo and cargo platform as a whole, use cuboid to substitute the actual model. Do not consider the moorage problem.
4. Take the aircraft as motionless, the cargo platform and cargo at an extraction speed of 3 m/s relative to the aircraft.

Based on the assumptions mentioned above, the changing process of the cargo extraction posture is simulated to find out the relationship between the barycenter position and the overturn angle and speed. According to actual airdrop experiences, 3 kinds of barycenter positions are chosen, simulation calculations in 3 kinds of working conditions (see Table 1) are made to seek the best binding cargo barycenter position. Coordinates of barycenter y and z are the model geometric centers in the directions, and the positions of x-direction are shown in Table 1.

2.2 *Structure model*

According to the cabin structure, the composition of heavy equipment airdrop system, geometric size of each part, assumption of simulation conditions, and actual process of airdropping cargo extraction

Table 1. Simulation calculation of the working condition.

Working conditions	Extraction speed (m/s)	Barycenter x coordinates (m)
Working condition 1	3	2.1132
Working condition 2	3	2.0172
Working condition 3	3	1.9211

Figure 1. Structure model of simulation analysis of the changing process of airdropping cargo extraction posture (side elevation).

(Chen, 2009), the structure model of simulation analysis of the changing process of airdropping cargo extraction posture is determined as shown in Figure 1.

Based on that, grid division on the finite element is done. Finite element models of cargo platform, cargo and cabin floor are set up as shown in Figure 2 and Figure 3.

2.3 Definition of physical conditions

In order to describe the whole extraction process of the cargo platform and cargo completely, physical conditions are defined as follows, such as material parameters, interface, boundary, and so on.

1. Definition of material parameters

Cabin floor, cargo platform, and cargo are all defined as linear elastic material. The elasticity modulus is 210 GPa, Poisson ratio is 0.3, the density of cabin floor is 7800 Kg/m³, density of cargo got from cargo quality and volume is 475 Kg/m³.

2. Definition of interface

The contact-impact problem is one of the most difficult nonlinear problems, because of which the response in the contact-impact problem is not smooth. When the impact occurs, the speed perpendicular to the interface is transient and discontinuous. As for Coulomb friction model, when there is a viscous glide action, tangential speed along the interface is also discontinuous. These characteristics of contact-impact problem bring obvious difficulties at the time integral of discrete

Figure 2. Finite element models of cargo platform and cargo.

Figure 3. Finite element model of cabin floor.

equations. Therefore, the selection of suitable methods and algorithm are vital to the success of numerical analysis. In this paper, there is a problem of contact pairs of cargo platform and cabin floor in the simulation analysis. According to the characteristics of the cargo platform gliding in the cabin, the contact is defined as a separable automatic surface contact model.

3. Definition of original and boundary condition
 Load: The gravity to cargo platform and cargo is 81340N, which is added to the barycenter position.

Speed: The extraction speed of cargo platform and cargo is given as 3 m/s.

Boundary condition: Displacement and turning degree of freedom on the cabin floor are all constrained in X, Y, and Z directions.

3 RESULTS AND ANALYSIS

By numerically calculating the simulation, motion pictures are used to visualize the extraction process of the cargo platform and cargo in different working conditions. Various parameters in the process are gained. By comparing the changing curve of displacement, a difference of nodes 807 and 808 in the Z direction in 3 s as time changes, we know the cargo overturning conditions. Since the distance of node 807 to 808 is 3.65 m, if the displacement difference of the two points reaches the peak value of 3.65 m, it shows that the cargo overturns to the vertical direction; if the peak value does not reach 3.65 m in 3 s, it shows that the cargo overturning angle in 3 s is less than 90 degrees. In 3 s, the less the peak value, the smaller the overturning angle is.

Figure 4. Diagram of nodes 807 and 808.

Figure 5. Displacement curve in the Z direction of nodes 807 and 808 in working condition 1.

3.1 Analysis of cargo posture changing process in working condition 1

Figure 5 shows the barycenter position $x = 2.1132$ m, that is the displacement curve in the Z direction of nodes 807 and 808 in working condition 1.

Figure 6 shows the barycenter position $x = 2.1132$ m, that is the displacement difference curve in the Z direction of nodes 807 and 808 in working condition 1.

Figure 5 and Figure 6 show that the cargo platform and cargo are mainly in a steady state before 0.2 s; it begins to overturn right after 0.2 s, the overturn angle is not big; it begins to overturn left after 1 s, it reaches the vertical direction at about 2.5 s and then overturns right again.

3.2 Analysis of cargo posture changing process in working condition 2

Figure 7 shows the barycenter position $x = 2.0172$ m, that is the displacement curve in the Z direction of nodes 807 and 808 in working condition 2.

Figure 8 shows the barycenter position $x = 2.0172$ m, that is the displacement difference curve in the Z direction of nodes 807 and 808 in working condition 2.

Figure 7 and Figure 8 show that the cargo platform and cargo are mainly in a steady state before 0.2 s and it begins to overturn right after 0.2 s, the overturn angle reaches the biggest at about 1.5 s, but does not reach the vertical direction and then it begins to overturn left until near about 2.5 s.

Figure 6. Displacement difference curve in the Z direction of nodes 807 and 808 in working condition 1.

Figure 7. Displacement curve in the Z direction of nodes 807 and 808 in working condition 2.

Figure 8. Displacement difference curve in the Z direction of nodes 807 and 808 in working condition 2.

3.3 Analysis of cargo posture changing process in working condition 3

Figure 9 shows the barycenter position $x = 1.9211$ m, that is the displacement curve in the Z direction of nodes 807 and 808 in working condition 2.

Figure 10 shows the barycenter position $x = 1.9211$ m, that is the displacement difference curve in the Z direction of nodes 807 and 808 in working condition 3.

Figure 9 and Figure 10 show that the cargo platform and cargo are mainly in a steady state before 0.2 s; it begins to overturn right after 0.2 s, then the overturn angle becomes bigger and bigger with the overturning left and right angles reaching the biggest and in the vertical direction at about 2.4 s, then it begins to overturn left till it is in a steady state.

Figure 9. Displacement curve in the Z direction of nodes 807 and 808 in working condition 3.

Figure 10. Displacement difference curve in the Z direction of nodes 807 and 808 in working condition 2.

Analysis results in 3 kinds of working conditions show that: at the beginning, cargoes in 3 kinds of working conditions are all overturning right, cargo overturns to vertical direction in working condition 1 at 2.5 s; the same as in working condition 3 at 2.4 s; only in working condition 2, it overturns to vertical direction at 3.5 s and the overall overturning speed is comparatively gentle and slow, and the overturning angle is not big. Therefore, all-in-all, at an extraction speed of 3 m/s, the choice of the barycenter position as in working condition 2 is better.

4 CONCLUSIONS

By numerical simulation analysis carried out in this paper, we obtained the changing curve of

cargo at an extraction speed of 3 m/s in different barycenter positions with overturning conditions as time passes. The result indicated that the binding barycenter position of cargo had an obvious influence on the overturning speed and angle after the cargo extraction, which determined the steady state of cargo extraction. As for certain types of heavy equipment airdrop systems in the paper, the best cargo barycenter position was $x = 2.0172$ m. This was mainly coherent with the monitoring result of cargo overturning in actual airdropping. This leads to the identification of using numerical simulation calculation methods that can provide a certain theoretical guidance to the study of how to control the cargo barycenter when airdropping heavy equipment, and at the same time this verifies the application probability of the numerical simulation method in this field.

ABSTRACT: In the existing mining algorithm based on uncertain data, we change the rules of building the UF-tree as follows: we merge the data item to the branch once the data item in transaction matched the tree node in a branch; otherwise, we create a new branch which is composed of the current item and subsequent items from the unmatched tree node. Then, the compressed UF-tree algorithm is proposed, while the UF-Eclat algorithm is proposed by transplanting the classic vertical mining algorithm-Eclat and applying it to uncertain data. It builds the probability vector of a single data item and calculates the degree of support for candidate data items to mine the frequent items. The results indicate that the compressed UF-tree algorithm is more efficient.

1 INTRODUCTION

With the continuous progress of technology, uncertain data research has gradually received wide attention, and mining frequent items has become one of the key research questions (Zhou, 2009). According to uncertain data mining of a frequent item, Chui et al. proposed U-Apriori algorithm (Chui, 2007) transplanted on Apriori. It got a large number of candidate items which led to large execution time and system consumption. Leung et al. proposed the UF-growth algorithm based on an FP-growth algorithm (Aggarwal, 2009), which used a tree structure to mine the frequent items. Chaoquan Chen et al. compressed the UF-tree and proposed the compressed UF-tree algorithm (Chen, 2014). To a certain extent, it could reduce the memory consumption and improve the feasibility and efficiency of the algorithm. In 2000, J. Zaki proposed a depth-first algorithm: Eclat (Liu, 2012), can efficiently mine frequent items in a vertical dataset. So the Eclat algorithm is transplanted and is used for uncertain data, then the UF-Eclat algorithm is proposed.

2 RELATED DESCRIPTION AND DEFINITION

In uncertain datasets, the data items of a transaction appear in a certain probability, then we use T_i

to represent a transaction, x represents a data item, then $p(x \in T_i)$ indicates the existence probability of T_i in x , if it does not exist x in T_i , then $p(x \in T_i) = 0$.

Definition 1. The degree of support for uncertain data items in the dataset is $\text{sup}(x) = \sum_{i=1}^k p(x \in T_i)$,

where k is the number of transactions in a dataset.

Definition 2. If the support for any data item x in the dataset satisfies the minimum support threshold value min Support , x is a frequent term, that is, $\text{sup}(x) > \text{min Support} * k$.

Definition 3. We define the vector of $1 \times k$, the existence probability of a single data item x in transaction T_i is p , then $V_{(1,i)} = p$ in V_x , the vector V_x obtained by this rule is the probability vector of x .

Definition 4. We filter out the useless candidate items from the search tree of the item set, define a decimal B as the pruning rate, which is between 0 and 1, and clip the extension of the tree structure to restrain the meaningless growth of the tree structure.

Definition 5. Define a decimal A as a matching rate which is between 0 and 1 and used to outline the probability of the shared node or branch when a transaction is added to the tree structure.

According to the possibility of the world model, there are two possibilities for the data item x and

transaction T_i : (1) when x exists in transaction T_i , we call it W1, $p(W_1) = p(x \in T_i)$ represents the possibility. (2) If x does not exist in transaction T_i , we call it W2, $p(W_2) = 1 - p(x \in T_i)$. For a multiple data item xy , its probability in T_i can be represented as $p(x \in T_i) * p(y \in T_i)$ (HAN, 2007). According to the Definition 2, $\text{sup}(xy) = \sum p(x \in T_i) * p(y \in T_i)$ is the degree of support for data item xy .

3 INTRODUCTION OF THE ALGORITHM

The UF-tree compression algorithm works in the form of a level dataset and its main research object is the transaction in the dataset, while the UF-Eclat algorithm works in the vertical form of datasets, the main research goal is the data item. The level of uncertain dataset is composed of TID: (Item: probability), as shown in Table 1.

We assume that the support threshold value is 0.08. According to the Definition 3, the minimum support value is $0.08 * 6 = 0.48$. Next, we count the degree of support for a single data item and sort the data items according to the size of the degree of support and update the dataset. 1. We sort each transaction of dataset according to the order of data items; 2. We delete the data item which does not meet the minimum support for the dataset (Chen, 2014). The dataset is shown in Table 2.

The form of vertical datasets is Item: (TID: probability). In order to objectively compare the two algorithms, the vertical dataset is produced by the level dataset, as shown in Table 3.

From Table 3 we can see that the form of vertical datasets is closer to the calculation process of the degree of support for a single data item.

Table 1. The uncertain dataset.

TID (transaction ID)	Item: probability
1	A:0.8 B:0.7 C:0.7 D:0.2
2	A:0.7 B:0.2 D:0.7
3	A:0.4 B:0.7 C:0.1 D:0.6
4	A:0.5
5	B:0.3 C:0.8 D:0.3
6	D:0.7 F:0.1 G:0.5

Table 2. The updated level dataset.

D	1:0.2 2:0.7 3:0.6 6:0.7
G	6:0.5

3.1 The UF-Eclat algorithm

The UF-Eclat algorithm is proposed by combining the Apriori algorithm and Eclat algorithm. It uses the depth first search process and takes an effective pruning strategy. The UF-Eclat algorithm uses a structure called the search tree of the item set to generate a candidate item. We extend the search tree and use the probability vector dot product operation to obtain the degree of support for the extension node. As the node of the search tree does not contain any data and the degree of support is calculated by the probability vector dot product, so the node of the search tree is a frequent item. An intuitive description of the UF-Eclat algorithm of construct for the item set search tree is as follows: (1) It scans the uncertain vertical database Ud, calculates the degree of support for the data item and uses the minimum support threshold to filter out the non-frequent items and sorts the dataset according to the degree of support in descending order. (2) It creates a root node, the single frequent item nodes are like the child nodes of the root node. The first child node of the root node is used as the current node. (3) If the number of sibling nodes of the current node is 1, then the only sibling node is a suffix node, do(4). If the parent node of the current is the root, that is the end. Otherwise, the next sibling node of the parent node is the current node, do(3). If the sibling number is greater than 1, the followed sibling nodes are the suffix node one by one, do(4). If the child node number of the current node is greater than 1, the first child node of the current node is used as the current node, otherwise, the next sibling node of the current is used as the current node, do(3). (4) Finally, it reduces prefix connection to the data items of the parent node and suffix node and gets the candidate item and calculates its degree of support. We compare it with the minimum degree of support, if the former is bigger than the latter, the frequent item is added to the search tree of the item set as the child node of the parent node. Return (3).

We take the depth-first strategy to build the search tree of the item set and prune the data from Table 3 without taking the *a priori* knowledge of the Apriori algorithm. The size of the set search tree is enlarged and a lot of lower layer nodes are useless, as shown in Figure 1.

In Figure 1, four nodes of the A node is useless. The UF-Eclat algorithm builds a complete search tree of the item set for data from Table 3, as shown in Figure 2.

3.2 The compressed UF-tree algorithm

When dealing with a large database, the UF-growth algorithm will take up a lot of memory to build the UF-tree and spend a lot of time. Therefore, the compressed UF-tree algorithm improves the structure of the tree based on UF-growth algorithm:1. It will match the current data item in a transaction with data items of the corresponding nodes of all tree branches. If they are matched with each other, the data item is merged into the branch and it shares the branch node; if not, a new branch is opened from the parent node of the matching node, and the new branch consists of the matching data item and its post data item.2. It saves the transaction's TID for the nodes of the last data item in each transaction. In addition, the tree node does not save the probability of the corresponding data item.

The compressed UF-tree constructed by the data from Table 2 is shown in Figure 3.

Figure 1. The subtree constructed by the depth first search from node A.

Figure 2. The search tree of the data item.

Figure 3. The compressed UF-tree.

The second step is the generation of candidate items and the process is as follows. (1) The leaf node is the start node to search tree nodes along the branch, the transaction number stored in the start node is transmitted to the search node. The candidate data items are composed of the initial node and the nodes from the start node to the node on the path of the search node. (2) The transaction number set saved by the initial node is passed to the generated candidate data items. It merges the transaction number sets for the same candidate data items. (3) The degree of support for candidate data items is calculated based on the probability vector of the single data item and the transaction number set of the candidate data.

4 EXPERIMENTAL ANALYSIS AND RESULTS

The experimental environment is Intel(R) 2.3 GHz CPU, 2 GB memory, 32 bit Windows 7 system PC, MyEclipse 8.5, Java language. The thirteen simulated datasets used in the experiment are generated by the modified IBM data generator. They meet the conditions: the name form of dataset is "sj+ transactions". In the transaction, the number of individual data items is randomly generated and controlled within 14, and the number of attributes is 14. The attribute name is simplified to the letter from a to n, and the probability value is controlled from 0 to 1. Algorithm 1 is the compressed UF-tree algorithm, algorithm 2 is the UF-Eclat algorithm.

The first experiment: the support threshold is fixed to 0.08, the dataset, in turn, takes sj10, sj30, sj50, sj80, sj100, sj300, sj500..... sj5000, sj10000. Run UF-Eclat algorithm and compression UF-tree algorithm, the number of frequent items of the two algorithms is the same as shown in Table 4.

Table 4. The number of frequent items (support threshold 0.08).

Dataset (transaction number)	Frequent item number
10	60
30	35
50	44
80	37
100	30
300	39
500	41
800	43
1000	45
3000	45
5000	45
8000	45
10000	45

The performance difference between the two algorithms is as shown in Figure 4.

The execution time of the algorithm increases with increase in the number of datasets, while the UF-Eclat algorithm increases slowly. The reason is that the compressed UF-tree algorithm scans the database two times while the other only scans one time; the compressed UF-tree algorithm generates the candidate item by traversing the tree structure. It screens the frequent items. While in the UF-Eclat algorithm, the node generated by expanding the search tree is a frequent item. The UF-Eclat algorithm is better for the mining of frequent items.

The second experiment: dataset is fixed to sj1000 and the support threshold value respectively is 0.01, 0.02, 0.03,..... 0.09. Run the two algorithms and the operation results are the same as we can see from Table 5. We compare the performance of the two algorithms, as shown in Figure 5.

Figure 5 shows the comparison of performance between the two algorithms in the same dataset. The gradually increasing support threshold has little effect on the execution time of the compressed UF-tree algorithm. The UF-Eclat algorithm shows a gradually decreasing trend. The support threshold affects the number of frequent items and then determines the execution time of the UF-Eclat

Figure 4. The performance difference between the two algorithms (support threshold 0.08).

Table 5. The number of frequent items (support threshold 0.08).

Support threshold value	Frequent item number
0.01	375
0.02	165
0.03	165
0.04	47
0.05	45
0.06	45
0.07	45
0.08	45
0.09	37

algorithm. The results of the above two experiments have verified that the mining results of the two algorithms are the same.

The third experiment: with the same experimental environment of the first experiment, the performance of the two algorithms is as shown in Figure 6.

In Figure 6 and Figure 7, the performance of the compressed UF-tree algorithm is better in most

Figure 5. The performance difference between the two algorithms (dataset sj1000).

Figure 6. The performance of the two algorithms (support degree 0.08).

Figure 7. The performance of the two algorithms (dataset sj1000).

cases. The conclusion is just the opposite of the first two experiments, that is, the effect of different properties of different datasets on the performance of the two algorithms is different and the specific analysis is as follows:

The number of transactions affects the performance of the compressed UF-tree algorithm, while it has no effect on the UF-Eclat algorithm; when the number of attributes is large, the performance of the UF-Eclat algorithm is greatly affected. In addition, the pruning rate and matching rate, to some extent, affect the performance of the algorithm. The high matching rate can reduce the consuming time of the compressed UF-tree algorithm and the low pruning rate can increase the running time of the UF-Eclat algorithm.

5 CONCLUSION

This paper studied the comparison between the compressed UF-tree algorithm and the UF-Eclat algorithm for uncertain data. Through experiments, we know that when we deal with a large database, the performance of the UF-tree algorithm is better; but there are still some limitations, for example, in the UF-tree compression algorithm. It takes a long time to generate the candidate items by traversing the tree structure and the process is more complicated. While the transaction number of datasets or attribute numbers is too much, it is a huge challenge for the memory to build the UF-tree or the item set search tree. Therefore, how to balance between memory and performance is also worth studying in the future.

Research on the sync technology of the ARINC659 bus redundancy fault-tolerant system

Yu Li & Xin Li

AVIC The First Aircraft Institute, Xi'an, China

Gang An

Xi'an Jiaotong University, Xi'an, China

ABSTRACT: The ARINC659 bus is suitable for high security and high reliability requirements of the integrated and modular aircraft airborne computer communication system design. This paper analyzes the structure of the ARINC659 bus, window activity and sync mode, introduces the system architecture, the bus bridge mode, and the working principle of four redundancy computers which is composed of the ARINC659 bus as the core. Sync is the basis and core function of redundant fault-tolerant computer system data transmission and redundancy management. This paper analyzes the cause for clock drift and asynchronous degree in the process of initialization sync and resynchronization, designs task sync algorithm of system application level, and message sync algorithm of bus communication level.

1 INTRODUCTION

Under the premise of the basic reliability index of components, in order to improve the reliability of the airborne system, the key components such as sensors, controllers, actuators, computers, and so on are usually designed with the technology of redundancy. Different units perform the same tasks in a system. The advantage of this design is that the fault unit can be effectively isolated and the task switched to the normal unit to continue execution. However, to ensure the reliability of the system, it has brought the management question of the redundant fault-tolerance system: the system will face how to ensure the coordination between various computing units.

Sync is the basis and key technology, which directly affects the function and operation of the system. It ensures that redundant modules keep step with work, an action to accomplish the same task at the same time. It can shield a few failures in accordance with the principle of the majority of the same to accurately switch to the normal module. The realization of the structure of the reconfiguration is such that the fault tolerant system can be sustained, correct and a reliable operation was done. In this way, the voting process of the fault tolerant system is significant.

ARINC659 bus from Honeywell's SAFEBus: In 1993, the SAFEBus was adopted by the Airlines Electronic Engineering Committee and became the standard and promulgated for the ARINC659

bus specification. The ARINC659 bus is a dual redundancy system based on time-triggered architecture, which supports robust time and space partitioning. It is a key technology of integrated and modular avionics system. The bus technology has been applied to the Airplane information management system of the Boeing's B777. The Chinese latest and most advanced, the largest military transport aircraft also used the bus, as the communication bus between high security and high-reliability redundancy fault-tolerant computer internal function modules of communication backplane bus and the computer.

2 REDUNDANT FAULT-TOLERANT COMPUTER SYSTEM

2.1 BUS structure

Each BIU (Bus Interface Unit) is connected to two buses. Each LRM (On Line Replaceable Module) has two bus interface units, BIU_x and BIU_y, transmission through the X and Y bus. Each bus is driven by an independent transceiver in the LRM to prevent a single failure from adversely affecting one or more buses.

Through cross validation between BIU_x and BIU_y and with the four buses cross-checked, LRM has a dual self-test capability. The use of serial transmission line reduces the hardware, simplifies the whole concurrency control, and improves the basic reliability of the bus. The cross-validation

Figure 1. ARINC659 bus architecture.

between the four buses improves the reliability and availability of data. Bus architecture, interface, and transmission line structure and connection relations are shown in Figure 1.

2.2 Bus activity

ARINC659 bus activity is composed of alternating message and gap, each window occupying the relevant LRM command table specified fixed time period.

The window can contain a data message, sync information, or free message. Each window can have a unique transmitter or a limited set of backup transmitters, which are programmed in a table memory. The source and destination addresses of each message are included in the table memory, not by bus. System designers can organize several types of intermodule message structures it supports: module to module (point to point) communication, a module to a set of modules (broadcast) communication. There are 2 types of messages: the basic message and the master/backup message. Basic messages for a single source and single purpose or a number of purposes. The master/backup message is used for a plurality of backup sources and for a single purpose or multiple purposes, and the system arbitration mechanism only allows one of the primary or backup sources to access the bus. A backup source is only the main and other priority than its high backup transmitter in a predetermined time period to remain silent on the bus to send.

2.3 Computer system

The greatest advantages of the ARINC659 bus are the time deterministic in the transmission process, dual self-test capability, fault detection, and isolation. So it is very suitable for the design of a redundant fault-tolerant computer system. In this paper, the computer system with the maximum redundancy level of aircraft is designed as the goal. This paper introduces the structure of a redundant computer system based on ARINC659 bus technology, as shown in Figure 2.

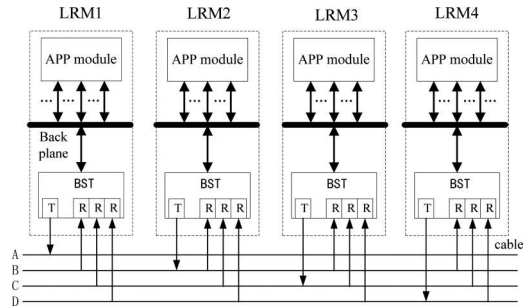

Figure 2. Four redundancy computer system.

Each LRM is a separate control channel. The channel is composed of application module, ARINC659 backplane, and Bus Bridge Transfer (BST) module. ARINC659 backboard bus is the core of the channel. Each function module is an intelligent node, which contains a processor or microcontroller. The signal on the function board is regulated and monitored by the processor or the microcontroller. Each function module can carry out information exchange, resource sharing, and resource reconstruction. Finally, the system can achieve the resource dynamic reconfiguration and fault-tolerance of the four redundant system.

BST board exchanges and shares the ARINC659 bus data between the computers. BST converts the backplane mode to cable mode for forwarding to other LRM. BST is a continuation of the bus signal and also is the backplane signal at the computer level conversion and transmission, and can realize the redundant channels between CCDL (Cross Communication Data Link).

ARINC659 bus specifies the physical layer and data link layer, and the data communication sync of ARINC659 bus mainly works on the data link layer. After the computer power is switched on, the BST is responsible for the initialization of the CCDL sync to achieve the data sync between channels. Then, each BST initiates the sync request to the ARINC659 bus in the channel and realizes the data sync between the internal function modules. In the task period, the BST is responsible for maintaining the bus sync and channel sync.

3 RESEARCH ON THE SYNC METHOD

3.1 Sync mode

For the system c, if the ideal clock time is T, and the node's clock time set as $c_c(T)$, for the other two systems p, q, if satisfied $|c_p(T) - c_q(T)| \leq \delta \max$ ($\delta \max$ which is the maximum degree of the asynchronous clock), the system p and q sync. According to different sync periods, sync technology can be

divided into clock sync, loose sync, and task level sync.

Clock sync is a distributed system which uses the same clock source to drive the nodes. Each node is synchronized to the clock cycle, so each node in the system is running at the same time, as shown in Figure 3. Clock sync is mainly based on hardware, the advantages of sync are strict, no extra time overhead, but the requirements of the clock is very high, which often requires the use of a fault-tolerant clock.

Loose sync is a time sync method based on time slice, as shown in Figure 4. Every time slice is composed of a plurality of clock cycles. In each time slice, it allows each node in the system to have an asynchronous degree. As long as the asynchronous degree is in the allowable range, each node in the system synchronization will be resynchronized in the next time slice. In this way, it is usually implemented with a logic clock sync software. The main purpose of loose synchronization is to periodically align the clocks of each node. This can reduce or eliminate the asynchronous degree between nodes and reduce the error accumulation of the clock. Loose sync can establish the same conditions for each node to complete the same task so that the suppression of the fault caused by the asynchronous module spread can be restrained. There is a certain deviation in the sync of loose sync, which can eliminate the influence of some instantaneous faults, but the time cost is large.

Task sync, which is a kind of loose sync, is the basic unit of time for the task period, and each task period includes task execution time and task

idle time. The resynchronization cycle is composed of multiple task cycles. Every node performs tasks repeatedly in each task cycle. One of the nodes of the clock or all the nodes of the clock is set to a reference clock. If there is a node of the clock in asynchronous degree greater than the maximum asynchronous, the standard clock corrects the standard for all nodes of the logical clock so that each node in the system returns to the status of sync, as shown in Figure 5. The clock of each node can be operated independently and the realization is simple and easy to implement.

3.2 Application level task sync design

Application level task sync refers to the task sync process which is based on the specific application requirements of the service system including initialization sync and resynchronization.

Figure 6 shows the initialization sync. LRM1, LRM2, LRM3, LRM4 began the duty cycle of the moment, respectively to t_a, t_b, t_c, t_d . The $t_a > t_b > t_c > t_d$, for several moments are not overlapping. In the first period, LRM1 did not receive the time information of the other three LRM, operating according to a predetermined time delay T_d and other LRM, although it can receive time information, but the time offset calculation is not yet complete. Therefore, it is according to the same predetermined delay time T_d of operation. In the second period, the time of LRM1 is taken as the baseline time of the whole network, and it is still in the time of the delay time T_d , and the other three LRM in accordance with the calculation of the time delay, respectively T_{db}, T_{dc}, T_{dd} .

If LRM1 and LRM2 in the $M + 1$ period achieved sync, then the formula (1) was established:

$$T_s + T_d + T_c + M*(T_s + T_c + T_{da}) + (t_a - t_b) = T_s + T_d + T_c + M*(T_s + T_c + T_{db}) \quad (1)$$

Figure 3. Clock sync.

Figure 4. Loose sync.

Figure 5. Task sync.

Figure 6. Task period initialization.

If LRM1 and LRM3 in the $N + 1$ period achieved sync, then the formula (2) was established:

$$\begin{aligned} T_s + T_d + T_c + M*(T_s + T_c + T_{da}) + (t_a - t_c) \\ = T_s + T_d + T_c + M*(T_s + T_c + T_{ab}) \end{aligned} \quad (2)$$

If LRM1 and LRM4 in the $P + 1$ period achieved sync, then the formula (3) was established:

$$\begin{aligned} T_s + T_d + T_c + M*(T_s + T_c + T_{da}) + (t_a - t_d) \\ = T_s + T_d + T_c + M*(T_s + T_c + T_{ad}) \end{aligned} \quad (3)$$

Therefore, LRM2, LRM3, and LRM4 were synchronized with LRM1 after three task periods. The delay times of the four LRM are $(t_a - t_b)/(T_{ab} - T_d)$, $(t_a - t_c)/(T_{dc} - T_d)$, $(t_a - t_d)/(T_{dd} - T_d)$, and finally the initialization sync is realized.

Resynchronization: Initialize sync is complete because each LRM hardware clock source, clock drift problem, and periodic task also exist with subtle differences. With the passage of time, clock drift differences continue to accumulate and showed larger asynchronicity. If the asynchronous degree exceeds the maximum allowed, it is considered that the four LRM is not in the sync state, as shown in Figure 7. After a period of time, compared to the LRM2, LRM3, LRM4, and LRM1, respectively, appeared the δ_{ab} , δ_{ac} , δ_{ad} synchronous, and $|\delta_{ad}|$ being the greatest, with the passage of time, δ_{ad} must first achieve the allowed maximum asynchronous degree δ_{max} . At this point, you need to reduce central processing unit D delay, delay T_{dd} operation in accordance with the newly calculated, making A and D achieve resynchronization, B and C resynchronization process with the process being similar.

Figure 2 shows the four LRM in the redundant fault-tolerant computer system, which is expressed as W, X, Y, Z. In the system dynamic operation process, each one of the ID of LRM is W, and the rest of the ID is X, Y, Z. So the corresponding relationship between the four LRM and W, X, Y, Z is as follows:

LRM1: W - LRM1, X - LRM2, Y - LRM3, Z - LRM4

LRM2: W - LRM2, X - LRM4, Y - LRM3, Z - LRM1

Figure 7. Task period resynchronization.

LRM3: W - LRM3, X - LRM1, Y - LRM2, Z - LRM4

LRM4: W - LRM4, X - LRM1, Y - LRM2, Z - LRM3

The sync process can be designed as shown in Figure 8.

3.3 Bus communication level sync design

Before the execution of the frame period, the user can define the window on the bus. The frame is composed of the sync, the data and the free window of the cycle period, and the frame period is equal to the sum of the length of each window of the frame.

Table memory can store the frame command sequences with different lengths. Frame switching is implemented by the frame switching command. There are two different types of frames: the version and non-version. In a version of the frame, all BIU on the bus should have the same table version number. The frame switching mechanism of the version ensures that all the sync of the BIU verifies its own version number according to the received frame switch messages in the version of the data. If the version number of the table is not consistent, it will lose sync with the bus.

In a non-version frame, the version of the table is ignored. As long as a BIU in the LRM can be synchronized with the bus, it is able to participate in the non-version of the frame. In addition, all messages in the non-version frame should be divided by the maximum time gap (9-bit time). For master/slave messages, the maximum step time gap (10-bit time) must be used.

When BIU is in an asynchronous state, it will attempt to recover sync with the active BIU.

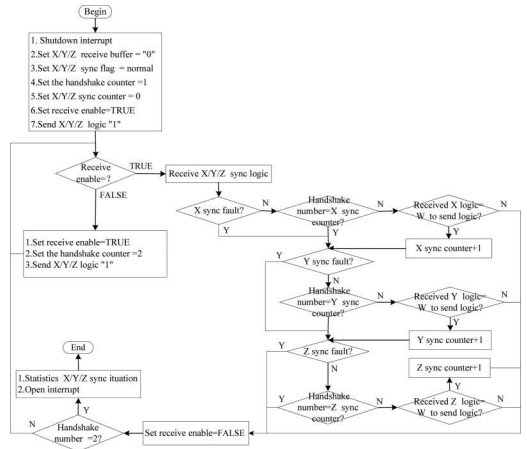

Figure 8. Sync process.

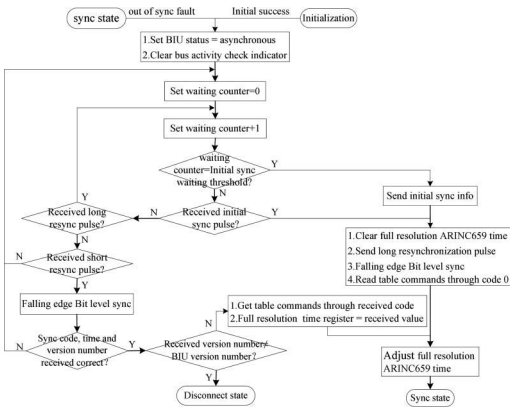

Figure 9. Flow chart of the frame level sync process.

Initialization sync limit wait time refers to the length of time that the BIU searches for sync messages (such as short message, long synchronization message, or initialization synchronization message) before the BIU decides to send the initialization sync pulse. If the BIU has not yet searched a sync pulse when the BIU exceeds the initialization sync limit wait time, the BIU will transmit an initialization sync pulse. If the BIU receives an initialization synchronization message (sent by another module or by itself), it will execute an inherent command immediately to receive a non-version into the sync message. Message synchronization code is “0” and the full resolution time value is “0”.

4 CONCLUSION

The ARINC659 bus has the advantages of large data throughput, high coding efficiency, transmission time determination, strict fault isolation, fault tolerance and so on. Communication system design for aircraft airborne computer, controller and so on are suitable for high security, high reliability, and high comprehensive degree. It can be designed to become the backplane data bus in a computer, but also to meet the communication needs of multiple computers. The four redundancy fault-tolerant computer system based on

ARINC659 bus is the basis of data transmission and redundancy management of the computer internal function module. In this paper, the characteristics of the bus, the characteristics of four redundancy fault-tolerant computer architecture, sync transmission mode, clock drift, and asynchronous degree are analyzed. The application task and bus communication two-level sync algorithm are designed to ensure that the data from the application level to the data link level are transmitted synchronously.

Identity recognition approach based on the improved phase congruency of the gait energy image

Ling-yao Jia, Chao Liang & Dong-cheng Shi

School of Computer Science and Engineering, Changchun University of Technology, Changchun, China

ABSTRACT: The use of phase congruency for marking features has significant advantages over gradient-based methods. It is a dimensionless quantity that is invariant to changes in image brightness or contrast, hence it provides an absolute measure of the significance of feature points. In this paper, identity recognition based on improved Log-Gabor phase congruency is proposed. The improved phase congruency algorithm is based on the improved local energy calculation method, frequency spread, and noise compensation tactics. The feature of improved phase congruency is of good location and recognition, and then the LDA method is used to project features into a low-dimensional space. The nearest neighbor classifier based on Euclidean distance is tested in the CASIA gait database. The experimental results show that our approach outperforms other state of the art automatic algorithms in terms of recognition accuracy.

1 INTRODUCTION

Gait recognition (Chai, 2011; Nixon, 2004) is the process of identifying an individual by the way they walk. This is a less unobtrusive biometric, which offers the possibility to identify people at a distance. Moreover, gait recognition offers great potential for recognition of low-resolution videos where other biometric technologies may be invalid because of insufficient pixels to identify human subjects.

2 RELATED WORK

Approaches for human recognition by gait can be divided into two categories: model-based approaches and model-free approaches. The former's main focus is the human body and uses parameters of the model for recognition, which results in a complex model. The computational time, data storage, and cost are extremely high due to its complex searching and matching procedures. The latter generally differentiates the whole motion pattern of the human body by a concise representation such as a silhouette without considering the underlying structure. Due to that reason, a large number of model-free approaches are proposed in recent years.

CR Li et al. (Li, 2012) presents an effective gait recognition method using the magnitude and the phase of Quaternion Wavelet Transformation (QWT). I Rida et al. (Rida, 2014) describe a supervised feature selection method to select relevant features for human recognition, which can mitigate

the impact of covariates (such as clothing, carrying conditions). HP Mohan Kumar et al. (Mohan, 2014) provides a new representation technique, which is able to capture variations in gait due to changes in cloth, carrying a bag, and different instances of normal walking conditions more effectively. YY Zhang et al. (Zhang, 2013) use three different local textural features of the Gait Energy Image (GEI) to represent the local space distribution of pixel brightness. In this paper, the identity recognition based on the improved Log-Gabor phase congruency of the GEI is proposed.

3 THE GAIT RECOGNITION SYSTEM BASED ON THE GEI

The structure of the gait recognition system based on GEI is shown in Figure 1. First, gait frames are extracted from gait videos and then the frames undergo silhouette pre-processing, morphological filtering, and binarization, which estimates the gait cycle and computes GEI.

Figure 1. The flow chart of gait recognition system based on the gait energy image.

Given a size-normalized and horizontal-aligned human walking binary silhouette sequence $B(x, y, t)$, the grey-level GEI $A(x, y)$ is defined (Han, 2006) as follows.

$$A(x, y) = \frac{1}{N} \sum_{t=1}^N B(x, y, t) \quad (1)$$

where N is the number of frames in complete cycles of the sequence, t is the frame number of the sequence, and x and y are values in the 2D image coordinate. The examples of normalized and aligned silhouette frames in walking sequences and GEI (the rightmost image) are shown in Figure 2.

3.1 Feature extraction of phase congruency

The process of feature extraction of improved phase congruency is as described previously (Kovesi, 1999). In this paper, the Log-Gabor is used for the calculation of phase congruency. On the linear frequency scale, the Log-Gabor function has a transfer function of the form

$$g(w) = e^{\frac{-(\log(w/w_0))^2}{2(\log(k/w_0))^2}} \quad (2)$$

where w_0 is the filter's center frequency. To obtain constant-shape ratio filters, the term k/w_0 must also be held constant for varying w_0 . Let I denote the signal and M_n^e and M_n^o denote the even-symmetric and odd-symmetric wavelets at a scale n , and then the responses of each quadrature pair of filters as forming a response vector,

$$[e_n(x), o_n(x)] = [I(x) * M_n^e, I(x) * M_n^o] \quad (3)$$

The amplitude of the transformation at a given wavelet scale is given by

$$A_n(x) = \sqrt{e_n(x)^2 + o_n(x)^2} \quad (4)$$

and the phase is given by

$$\phi_n(x) = a \tan 2(e_n(x), o_n(x)) \quad (5)$$

Each point in the signal will have a series of response vectors, each of which has a response vector of the filter response. One of the difficulties in the extraction of phase congruency is the processing of the noise response of the filter. According

Figure 2. Gait sequences and gait energy image.

to related description, the improved expression for energy can be got by

$$E = \sqrt{(\sum_n e_n)^2 + (\sum_n o_n)^2} \quad (6)$$

where e_n and o_n are the outputs of even and odd symmetric filters on scale n .

According to relevant theory, it can be concluded that amplitude distribution of energy vector obeys the Rayleigh distribution of the form

$$R(x) = \frac{x}{\sigma_G^2} e^{\frac{-x^2}{2\sigma_G^2}} \quad (7)$$

The mean and variance of the Rayleigh distribution are as follows.

$$\mu_R = \sigma_G \sqrt{\frac{\pi}{2}} \quad (8)$$

$$\sigma_R^2 = \frac{4 - \pi}{2} \sigma_G^2 \quad (9)$$

where σ_G^2 is the variance of the Gaussian distribution describing the position of the total energy vector.

The noise radius can be obtained by

$$T = \mu_R + k \sigma_R \quad k \in [2, 3] \quad (10)$$

If the estimated noise effect is subtracted from the local energy before normalizing it by the sum of the wavelet response amplitudes, spurious responses to noise can be eliminated. So the expression for phase congruency can be got by

$$PC(x) = \frac{\lfloor E(x) - T \rfloor}{\sum_n A_n(x) + \epsilon} \quad (11)$$

where $\lfloor \cdot \rfloor$ denotes that the enclosed quantity is equal to itself when its value is positive, and zero otherwise.

Phase congruency of feature points has important significance to identify only over a wide frequency range. Frequency expansion expression is as follows.

$$s(x) = \frac{1}{N} \left(\frac{\sum_n A_n(x)}{\epsilon + A_{\max}(x)} \right) \quad (12)$$

where N represents the total number of wavelet scales, $A_{\max}(x)$ is the amplitude of the filter pair having a maximum response at x , ϵ is also in order to prevent the denominator from being zero. A phase congruency weighting function can then

be constructed by applying a sigmoid function to the filter response spread value, namely

$$W(x) = \frac{1}{1 + e^{\gamma(c-s(x))}} \quad (13)$$

where c is the cut-off value of filter response spread below which phase congruency values become penalized, and γ is a gain factor that controls the sharpness of the cutoff. Thus, the calculation of phase congruency can be modified as follows.

$$PC(x) = \frac{W(x) \lfloor E(x) - T \rfloor}{\sum_n A_n(x) + \varepsilon} \quad (14)$$

For the fuzzy image, the positioning performance of phase congruency is relatively weak. For this reason, the calculation for $E(x)$ is modified by

$$\Delta\Phi(x) = \cos(\phi_n(x) - \bar{\phi}(x)) - |\sin(\phi_n(x) - \bar{\phi}(x))| \quad (15)$$

$$E(x) = A_n(x) \Delta\Phi(x) \quad (16)$$

Using this new measure of phase deviation, $\Delta\Phi(x)$, a new measure of phase congruency can be defined as

$$PC(x) = \frac{\sum_n W(x) \lfloor A_n(x) \Delta\Phi_n(x) - T \rfloor}{\sum_n A_n(x) + \varepsilon} \quad (17)$$

In order to be able to make the direction and possible connection of wavelet filter features, which are of equal importance, the extraction of phase congruency of one image can be defined as

$$PC2(x) = \frac{\sum_o \sum_n W_o(x) \lfloor A_{no}(x) \Delta\Phi_{no}(x) - T_o \rfloor}{\sum_o \sum_n A_{no}(x) + \varepsilon} \quad (18)$$

where o denotes the index over orientations. In order to achieve the effect of uniform coverage of the spectrum in all filtering orientations, the interval between the angle direction of the filter can be calculated by the following formula:

$$G(\theta) = e^{-\frac{(\theta-\theta_0)^2}{2\sigma_\theta^2}} \quad (19)$$

where θ_0 represents the filter orientation and σ_θ is the standard deviation of Gauss distribution function.

3.2 Individual recognition

In this paper, the features extracted from the gait energy image are subjected to the problem

of excessive dimensionality. To reduce their dimensionality, the multi-class linear discriminant analysis (Theodoridis, 2009) is used to project the features into a low-dimensional space. The GEIs used in this paper are normalized and aligned so that they can be clustered by the distance measure. The classic Euclidean distance and nearest neighbor classifier are adopted to discriminate different gait patterns.

4 EXPERIMENTAL RESULTS AND ANALYSIS

Our approach has been applied to the CASIA Dataset B database consisting of 124 different subjects with variations in walking status (normal, in a coat, or with a bag) at the lateral view. Each person has 10 GEIs with a resolution of 240 * 240 and they are divided into training and test set with the ratio 1:1. The related parameters are set as follows: number of scales, 5; number of orientations 8; scaling factor between successive filters 2.1; ratio of the standard deviation of Gaussian 0.55; number of standard deviations of noise energy beyond the mean at which we set the noise threshold point 2.0; the fractional measure of frequency spread below which phase congruency values get penalized 0.5; and the sharpness control of transition in sigmoid function used in weight phase congruency for frequency spread 10. One gait energy image and phase congruency using the jet colormap is shown in Figures 3 and 4, respectively, and the filter response of one scale in eight orientations is shown in Figure 5.

The cumulative matching characteristic and receiver operating characteristic are used to assess

Figure 3. Gait energy image.

the performance of the proposed approach. The related experimental data is shown in Tables 1 and 2.

It can be seen from Tables 1 and 2 that the proposed approach, as well as comparison with other approaches to individual recognition by gait, has the highest recognition rate of CMC in Rank 1 and verification rate of ROC in FAR = 1% practically. It can be concluded that the proposed approach renders the best recognition effect of the five approaches. In order to assess the overall performance of the five approaches, the equal error rate is computed and is shown in Figure 6.

The smaller the equal error rate, the better the overall performance of one algorithm. It can be seen from Figure 6 that the equal error rate of the proposed approach is the least.

The CMC and ROC curves of CASIA gait database at 0, 54, and 90 angles are shown in Figures 7–12, respectively.

In the CMC and ROC curves, the best performance of one approach should be close to the upper left corner as far as possible. It can be seen from Figures 7–12 that our approach (GEI-PC) is closest to the upper left corner. Usually, the area under the CMC and ROC curves can reflect the feature identification performance and algorithm verification performance, respectively. It can be seen from Figures 7–12 that the area under the curve of the proposed approach is the largest. The experimental results on CASIA gait database exhibit the effectiveness of the proposed approach.

5 CONCLUSIONS AND FUTURE WORK

In this paper, a new way of calculating phase congruency through the use of wavelets is adapted to extract features of the gait energy image. It shows that the extracted gait features are good localization and recognition. Experimental results on CASIA gait database show that the proposed approach has the characteristic of a high correct recognition rate. Further research will focus on the following aspects: a) explore a more effective method to extract gait features; b) seek a more effective feature dimension reduction method; c) seek a more effective method of similarity measurement; d) seek a more effective classifier; e) build more large-scale, more status of walking gait database to test the performance of the algorithm. In addition, it is important to find strategies to overcome some gait status under the interference of unexpected factors such as stopover and occlusion in the real scene.

ACKNOWLEDGMENT

This work was in part supported by the Education Department of Jilin Province Science and Technology Research Project in the 13th Five-Year in 2016 under contract No. 349. The CASIA gait database used in this paper was from the Institute of Automation of the Chinese Academy of Sciences. The authors would like to express their gratitude for their support.

Fractional-order generalized augmented Lü system and its application in image encryption

Hong-yan Jia & Yong-jun Wu

Department of Automation, Tianjin University of Science and Technology, Tianjin, China

ABSTRACT: Based on the fractional-order generalized augmented Lü system, a kind of double encryption algorithm method is designed to realize image encryption. The method mainly refers to the scramble of the pixel position and the transformation of the pixel value. The effectiveness of the double encryption method is verified by encrypting and decrypting the image. The experimental results indicate that this method not only has a better effect of image encryption and decryption, but also ensures the security of the encrypted image. The results from the histogram analysis and correlation analysis also verify the security and effectiveness of the proposed encryption method.

1 INTRODUCTION

Since Lorenz first proposed the famous Lorenz chaotic system in 1963, many scholars have put forward some new chaotic systems such as the Chen system (Lorenz, 1963), Qi system (Chen, 1999), Lü system (Hu, 2002). Subsequently, based on the Lü system, Qiao et al. proposed a new 3D autonomous chaotic system called the generalized augmented Lü system (Xiao, 2009), which is obtained by adding a linear state inverse controller in the third equation of the augmented Lü system. Although there are only three system parameters in the system, it has 5 balance points so that it can generate fan-shaped four-wing chaotic attractors without any need for external excitation.

Since the idea of chaotic encryption was firstly proposed by Matthews, the research of chaotic cryptography and chaotic secure communication has become a hot research topic (Zai, 2014; Li, 2016; Akram, 2016; Yi, 2016). At first, the chaotic encryption technology is mostly implemented by the low dimensional chaotic system, which has the advantages of a simple model and fast calculation. At the same time, the disadvantages that the key space is too small and the chaotic sequence is too simple are very distinct, which may lead to the low security of the encryption technology. Therefore, high dimensional chaotic systems, such as three-dimensional Lü system, some hyperchaotic systems are always used for image encryption because of the advantages of large enough key space of the encryption and high security of the encryption system.

Based on the fractional-order generalized augmented Lü system (Wei, 2014), this paper firstly

analyzes the chaotic characteristics of the system and gives Lyapunov exponent spectrum and bifurcation diagram of the 2.7 dimensional generalized augmented Lü system. In the second section, a simple but secure and efficient image encryption algorithm is designed based on the fractional generalized augmented Lü system. The results from the numerical analysis, histogram analysis, and correlation analysis verify the security and effectiveness of the proposed encryption algorithm.

2 FRACTIONAL GENERALIZED AUGMENTED LÜ SYSTEM

The fractional-order generalized augmented Lü system is described as (Wei, 2014)

$$\begin{cases} \frac{d^q x}{dt^q} = -[ab/(a+b)]x - yz \\ \frac{d^q y}{dt^q} = ay + xz \\ \frac{d^q z}{dt^q} = bz + xy + cx \end{cases} \quad (1)$$

where $0 < q < 1$, a , b , and c are constants, $a < 0$ and $b < 0$. By utilizing the time-frequency domain method, we obtain the attractors of the system (1) when $q = 0.9$, $a = -10$, $b = -6$, $c = 0.5$. The phase portraits are depicted in Figure 1.

From the phase portraits shown in Figure 1, we can see that chaotic attractors exist in the system (1) with $q = 0.9$, $a = -10$, $b = -6$, and $c = 0.5$. In addition, for the 2.7-order generalized augmented Lü system, the bifurcation diagrams and Lyapunov

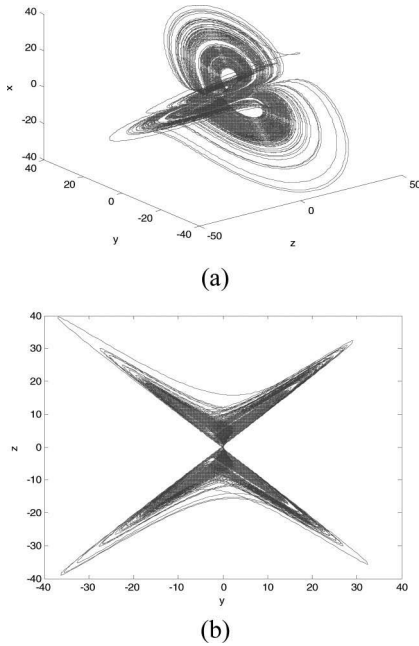

Figure 1. Phase portraits of the system (1) with $q = 0.9$, $a = -10$, $b = -6$, and $c = 0.5$: (a) x-y-z plane; (b) y-z plane.

Figure 2. Bifurcation diagrams of system (1).

exponents are also shown in Figure 2 and Figure 3, respectively. In the range from -30 to 0 of parameter a , bifurcation diagrams in Figure 2 show that there exist abundant and complex dynamical characteristics in the 2.7-order system. Moreover, the Lyapunov exponents represent the characteristics of the system movement. Two of the Lyapunov exponents in Figure 3 are always negative indicating that the adjacent orbits in the attractor of the system are average convergent in direction. The biggest Lyapunov exponent in Figure 3 is positive when $a \in (-25, -8)$ explaining that the adjacent orbits in the attractor of the system are average

Figure 3. Lyapunov exponent diagrams of system (1).

divergent. The above numerical analysis results from bifurcation diagrams and the Lyapunov exponents further verify that chaotic attractors exist in the system (1).

3 FRACTIONAL GENERALIZED AUGMENTED LÜ SYSTEM

3.1 Image encryption algorithm

During the process of image encryption, the color image is firstly decomposed into three tricolor components (R, G, B) that are red, green, and blue monochrome images. The selected image is regarded as an $m \times n$ matrix and each dot of the matrix presents a pixel value of the image. Before encrypting the image, we firstly transform the $m \times n$ matrix into a one-dimensional vector with the length of $m \times n$. The sequence x of chaotic sequences is sorted in ascending order and one can use it to scramble pixels of the image of R, G, and B components to obtain the scrambled image. Next, we implement the XOR operation on three components of the numerical matrices by using the 3D chaotic sequences respectively to complete the image encryption. Image decryption process is the inverse process of encryption. The three-color separations are firstly decomposed from the encrypted image, and the XOR operation is operated on three components of the numerical matrices by using chaotic sequences. Then the reduction of image pixel value scramble is realized by using the sequence x . Thus, decryption of the image is implemented finally.

3.2 Image encryption and decryption results

We select the image *Einstein.jpg* as the research object and its size is 512×512 . The experiment was implemented in MATLAB 2010, with the initial values of state variables being 0.1 , 0.2 , and 0.3 . In this manner, we obtained the encrypted images by

using the fractional-order generalized augmented Lü system shown in Figure 4. The decrypted images of *Einstein.jpg* are shown in Figure 5. A comparison of the encrypted image and decrypted image shows that the encrypted image is completely different from the original image, while the decrypted image and original image are identical. It illustrates that the image encryption algorithm is practical and effective and has good encryption effectiveness.

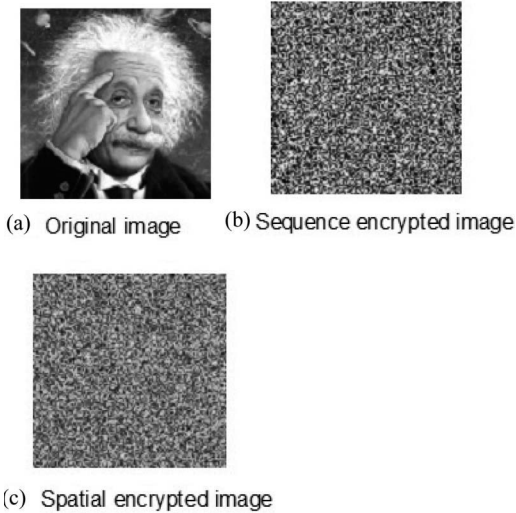

Figure 4. Encrypted images: (a) original image; (b) sequence encrypted image; (c) spatial encrypted image.

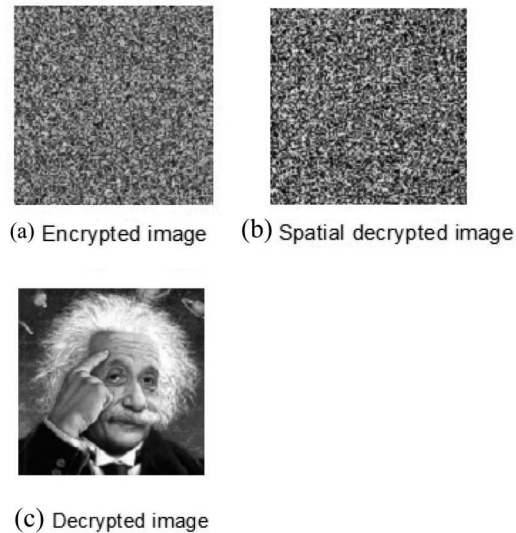

Figure 5. Decrypted images: (a) encrypted image; (b) spatial decrypted image; (c) decrypted image.

4 FRACTIONAL GENERALIZED AUGMENTED LÜ SYSTEM

4.1 Initial value sensitivity analysis

Selecting the system parameters as $q = 0.9$, $a = -10$, $b = -6$, $c = 0.5$, and the initial state value of the system $(x_0, y_0, z_0) = (0.1, 0.2, 0.3)$ as the encryption key, after the encryption, if you enter the correct key, you can get a successful decryption image as shown in Figure 5. When the initial value is increased by 0.000000001 , we get the wrong decrypted image as shown in Figure 6. One can also change the parameters a , b , or c by a small numerical value, such as 0.000000001 , obtaining the error decrypted image just as the image shown in Figure 6. It can be concluded that even a very small change in the key can also lead to the failure of decryption, which shows that the encryption system has high sensitivity to the encryption key.

4.2 Histogram analysis

Histogram of images can clearly reflect the distribution of characteristics of the images (Nooshin, 2012), so it is a practical and effective method for people to correctly evaluate the overall quality condition of the image. The histograms of *Einstein.jpg* are shown in Figure 7. We can find that most differences between histograms of the encrypted image and the original image are that the former is better than the latter in histogram distribution. That is to say, the encrypted image effectively masks the basic information of the original image, which indicates that it is able to resist the attack of statistical analysis very well.

4.3 Correlation analysis

The correlation coefficient among adjacent pixels of the encrypted image and original image are shown in Table 1. As can be seen from Table 1, the correlation coefficient of adjacent pixels in the original image is close to 1, which indicates

Figure 6. Error decrypted image.

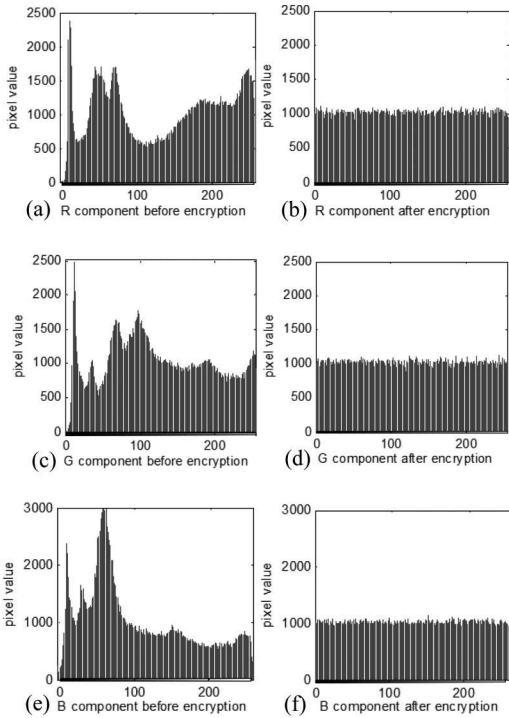

Figure 7. Histograms of original image and encrypted image: (a) R component for original image; (b) R component for encrypted image; (c) G component for original image; (d) G component for encrypted image; (e) B component for original image; (f) B component for encrypted image.

Table 1. Correlation coefficient.

Image	Correlation coefficient			
	Horizontal direction		Vertical direction	
R	0.99468	0.0020953	0.99547	0.0040664
G	0.99334	0.00094717	0.99433	0.0023295
B	0.99320	0.0023591	0.99419	0.0022439

that the adjacent pixels are highly correlated, while the correlation coefficient of adjacent pixels in the encrypted image is close to 0, which shows that the effect of the image encryption is better. The results verify that the encryption algorithm can well resist malicious attacks.

5 CONCLUSIONS

This paper adopts an effective and secure method to implement the image encryption operation. The method is based on the chaotic sequences generated by the fractional-order generalized augmented Lü system and combines the double encrypted technique including the pixel position scrambling of image and pixel value transform of the image. The experimental results and performance analysis show that this method not only has good encryption results, but also ensures high security of the encrypted image.

Highway School, Chang'an University, Xi'an, China

ABSTRACT: Airfield ground operation efficiency is an important basis to judge whether an airport's planning and design is reasonable. Using Simmod simulation software, taking the Beijing New Airport as an example, in this study, the airfield simulation models were established. The airport ground operation efficiency, arrival/departure flight delay time, and peak hour movements in southward and northward operation directions of the airport were explored in this study. The simulation results indicate that under the current construction scheme, the Beijing New Airport is able to meet the needs of the target year. In the main and secondary operation directions, the average ground delay time of departure flight is 2.73 minutes and 2.63 minutes, respectively, and that of arrival flight is less than 1 minute. The peak hour movements are about 90 flights.

1 INTRODUCTION

The continuous growth of social economy has driven China air transport on a fast-growing track, because of which China civil aviation has become the second largest air transport system in the world. Needless to say, the soaring aviation market leaves the airport systems with not many choices but to enlarge the airport system scale in order to tackle the booming demand of capacity. Under such a context, as an alternative to relieve the operation pressure of the Beijing Capital International Airport and to better the experience of air travelers in Beijing-Tianjin-Hebei region, construction of Beijing New Airport (hereinafter referred to as BNA) is imperative. With the current plan of four runways (three vertical and one horizontal), BNA is the first airport to have a non-parallel runway configuration in China. Given the complicated runway configuration and characteristic design of terminal building in BNA, and to better direct the planning, design, and operation of the new airport, it is necessary to conduct an in-depth exploration of ground operation efficiency of BNA's airfield using computer simulation.

In general, there are three approaches to evaluate airport capacity and operation efficiency:

(1) data statistics, (2) mathematical theory, and (3) computer simulation. (1) Method of data statistics is used to estimate the airport capacity by drawing a capacity envelope graph based on the existing statistical information of the airport flow. As a frequently used approach for capacity analysis in early stage, it involves certain disadvantages; it only evaluates the established operation pattern of the existing runway system in busy airport, which lacks prospectiveness (Gilbo, 1993). (2) The approach of mathematical theory can be harnessed to calculate the runway capacity by proposing a proper assumption and establishing mathematical equations of airport ground operation parameters. It is mainly used for macroscopic capacity evaluation, which lacks a consideration of operation details and commonality (Neufville, 2002; Yu, 2002; Chen, 2005; Chen, 2007). (3) Approach of computer simulation is at present the most popular solution for evaluation of airport capacity and efficiency. By establishing the operating environment and control rule models using the simulation software, the airport's operation status can be reflected with reality, and can be reached to the airport capacity based on the analysis of the simulated operation data (Wang, 2008; Gao, 2010; Huang, 2010; Yu, 2009). Simmod and TAAM are

the mainstream simulation modeling software for airport capacity evaluation (Huang, 2004).

Employing BNA as the research object and applying Simmod for computer simulation and modeling, in this paper, a comprehensive analysis has been performed on airport ground operation efficiency under different conditions, and the recommended schemes have been put forward. Conclusions in this paper can be used as a reference and instructions for planning, construction, and operation pattern selecting of multi-runway systems in China's large airports.

2 AIRFIELD LAYOUT AND OPERATION RULES OF BNA

In the current phase, the BNA construction project is to build four runways for a yearly passenger throughput of 72 million. The layout of its airfield is shown in Fig. 1. The planned terminal building, targeting a yearly passenger throughput of 45 million, applies a centralized combinational configuration, with the five concourses distributed in a “centrally radial” shape. Taking the main landing direction as an example, the runway operation pattern employed is West 1 Runway (W1) and North 1 Runway (N1) only used for take-off; West 2 Runway (W2) and East 1 Runway (E1) mainly used for landing; and E1 used for assisted take-off in the morning departure peak. The runways will operate independently.

Taxiing routes should be reasonably and appropriately setup, based on the airport operation, by the principle that main taxiways such as parallel taxiways, western and eastern contact taxiways, etc. should be operated in a monodirectional fashion. Taxiway system of airfield could be divided into four areas based on the average taxiing speed

Figure 1. Airfield layout and runway operation pattern of BNA.

Figure 2. Apron distribution.

(from 5 km/h to 46 km/h): push-out taxiway, apron taxiway, main taxiway, and high-speed taxiway.

As shown in Fig. 2, there are 322 gates in airfield, among which 197 are for passenger plane, 40 for cargo aircraft, and 85 for corporate aircrafts. Based on the differences among plane types, the corresponding boarding and alighting times are set accordingly in the scope from 30 to 80 minutes.

3 AIRPORT SIMULATION MODELING

Employing the simulation software Simmod Plus 7.6, the ground operation efficiency of BNA was simulated and evaluated. Simmod, launched in 1978 by the U.S. Federal Aviation Administration (FAA), is a microscopic, dynamic, and comprehensive airport simulation software. After constant upgrading and perfecting, it is now one of the most popular airport and airspace simulation software^[9,10]. Based on apron operation pattern (a), the simulation modeling mainly takes two operation directions (southward and northward) into consideration. Then, on that basis, and taking the southward operation as an example, further simulation and comparison on patterns (b) and (c) is conducted.

Landing interval is controlled mainly based on the wake vortex separation, as shown in Table 1. In addition, extra safe redundancy is taken into account. According to the differences between the aircrafts, departure separation of each runway is arranged at 80–140 seconds. Moreover, given the influence of the Beijing Capital International Airport on BNA in terminal airspace, departure interval of 3 minutes is considered for western runways in the morning time of 7:30–8:30, and a same departure interval is considered for eastern runways in the morning time of 8:30–9:30. When a single runway is in alternate operation, and the distance from the landing flight to the runway is less than 8 km, departure flights are forbidden to taxi out from the waiting point.

Based on the predicted flight volume of BNA and requirement of targeted yearly transportation volume of the terminal building, three typical daily flight schedules are planned in simulation, as shown in Table 2. The simulated operation demonstration is shown in Fig. 3.

Table 1. Wake vortex separation of landing flights.

Latter aircraft	Former aircraft		
	A380	Heavy	Medium
A380	8 km	6 km	6 km
Heavy	12 km	8 km	6 km
Medium	13 km	10 km	6 km

Table 2. Typical daily take-off and landing flights.

Yearly passenger throughput (person-time)	Typical daily aircraft movements	Aircraft movements in peak hour
30 million	808	80
45 million	1210	95
60 million	1600	115

Figure 3. Simulated operation demonstration.

4 OPERATION RESULTS AND ANALYSIS

Table 3 gives out the average ground delay times under different daily flight volumes when the airport is running in northward and southward directions. In the calculation of the comprehensive delay time, the proportion of operation in northern and southern directions is temporarily considered as 9:1. When the passenger throughput is 45 million person-times, average ground delay time of departure and arrival flights is 2.72 minutes and 58 seconds, respectively, which stands for a high operation efficiency. When the passenger throughput reaches 60 million person-times, the average ground delay time of departure flights is 4.41 minutes, which is still a sound efficiency of ground operation.

For departure flights using boarding gates, the total delay time consists of three parts: (1) take-off waiting, including waiting for take-off at runway entrance and delay of push-out; (2) delay in angle area of main terminal buildings, including waiting in apron taxiway and waiting caused by interference due to push-out of other flights; and (3) taxiing delay occurring in other areas. Table 4 presents the details and proportion of each part. With an increase of flight volume, the take-off waiting and taxiing delay in other areas grows evidently, whereas delay in angle areas grows slowly, with a slight change of delay time. When passenger throughput exceeds 45 million person-times, proportion of delay time in angle area is relatively low, accounting for 1/5 or 1/6 of total delay time; this indicates that it is not the bottleneck of airport ground operation.

Fig. 4 gives the aircraft movement in daily time frames under a passenger throughput of 45 million person-times. The total movement is 1210 flights, with 90 flights in each peak hour.

5 CONCLUSIONS

In this paper, a systematic analysis on the ground operation efficiency of the airfield of BNA was conducted. Utilizing the simulation software Simmod, a simulation study on ground operation efficiency, delay time, and peak hour movements

Table 3. Average ground delay time.

Yearly passenger throughput (person-time)	Departure flight average ground delay		Arrival flight average ground delay	
	Northward	Southward	Northward	Southward
30 million	1.32'	1.33'	0.57'	0.49'
45 million	2.73'	2.63'	0.97'	0.83'
60 million	4.43'	4.21'	1.42'	1.15'

Table 4. Constitution of ground delay of departure flights using boarding gates.

Yearly passenger throughput (person-time)	Airport operation direction	Total ground delay of departure flight	Take-off waiting	Delay in angle area	Taxiing delay in other areas
30 million	Northward	1.61	0.83	0.68	0.1
	Southward	1.51	0.82	0.6	0.09
	Mean value	1.6	0.83	0.67	0.1
	Proportion		51.8%	42.0%	6.2%
45 million	Northward	3.41	1.83	0.75	0.83
	Southward	3.36	1.88	0.72	0.76
	Mean value	3.41	1.84	0.75	0.82
	Proportion		53.9%	21.9%	24.2%
60 million	Northward	5.47	3.05	0.85	1.57
	Southward	5.25	3.02	0.91	1.32
	Mean value	5.45	3.05	0.86	1.55
	Proportion		55.9%	15.7%	28.4%

Figure 4. Distribution of aircraft movements in daily time frames.

was performed. Results of all the above-mentioned endeavors are as follows:

1. When the yearly passenger throughput is 45 million person-times, as for the construction scheme in current stage of BNA, the average ground delay time of departure flights is about 2.72 minutes, and that of arrival flights is about 58 seconds. This indicates that the airport is running in high efficiency, and that the target yearly transportation volume can be reached.
2. As for flights using boarding gates, over half of ground delay of departure flights is caused by take-off waiting and only 1/5 occurs in angle area between main buildings. Furthermore, this part accounts for a smaller proportion when the flight volume grows, proving that it is not the bottleneck of airport operation.
3. In BNA, the extreme value of take-off flight is in the morning. The peak hour movements are 90 flights, appearing at noon.

However, it should be noted that the simulation study in this paper only works for the capacity and delay time of the airport under normal operation. Furthermore, flight delay in simulation is normally less than that in actual cases, since influencing factors such as air traffic flow control, bad weather, airlines, military actions, and aviation events have been excluded in the study.

Matrix search algorithm of robust common quadratic Lyapunov function for uncertain switched systems

Xiaoyu Zhang, Ping Li & Bin Shen

School of Electronics and Information Engineering, North China Institute of Science and Technology, Beijing, China

ABSTRACT: Considering the stability problem of uncertain linear switched systems, this article puts forward a searching algorithm of Common Robust Quadratic Lyapunov Function (CRQLF). The sufficient conditions of CRQLF are given when the stable matrix set is not involuntary. The recurrence formula of CRQLF and the search algorithm in terms of Linear Matrix Inequality (LMI) are given. The simulation results verify the existence of the CRQLF for the stability of uncertain linear switched system under arbitrary switching signal.

1 INTRODUCTION

The stability of Switched Systems (SS) is a significant problem for practice. Many research works about it have been done since the early years. For example, the basic control analysis was carried out (Beldiman & Bushnell 1999). A Lie algebraic condition was proposed about the stability of SS (Liberzon & Morse 1999). The Lie-algebraic stability conditions for nonlinear switched systems subsequently were considered in (Margaliot & Liberzon 2006). Branicky showed solicitude for stability of SS in early years (Branicky 1994, Branicky 1997, Branicky 1998) and made excellent contribution to the field.

It is known that the subsystems stability does not guarantee the stability of the whole SS. An important stability analysis method is related to the existence of Common Lyapunov Functions (CLF). If there is a Lyapunov function whose time derivative is negative all the time along with every subsystem, the stability of the whole SS is reached. In (Narendra & Balakrishnan 1994), two subsystems who comprise SS are studied. It is well-known that the commutativity of the two system matrices is a sufficient condition for a Common Quadratic Lyapunov Function (CQLF). Therein an algorithm of NB Algorithm was born, that is for finding such a CQLF. Ooba and Funahashi present triangle conditions for the existence of a CQLF concerning a pair of linear systems (Ooba & Funahashi 1997). Furthermore, a sufficient condition for the global asymptotic stability of a switched nonlinear system is proposed by the analysis of the Lie bracket of any pair of each sub system. The pairwise

commutation of the vector fields is sufficient for the existence of a CLF (Mancilla-Aguilar 2000). Fierro et al. tried to find different way to validate a hybrid system that is composed of continuous subsystem, and certified that the method of CLF is conservative by contrast of cases (Fierro et al. 1996). How to find the CQLF? Cheng et al. expanded the NB-Algorithm and present a necessary and sufficient condition for the existence of a CQLF of a finite set of stable matrices. They also proved that a set of block upper triangular matrices share a CQLF, if each set of diagonal blocks share a CQLF (Cheng et al. 2003, Cheng et al. 2006). More particularly, the introduction about CLF refers to (Margaliot 2006, Liberzon 2003, Lin & Antsaklis 2009).

Recently, the CLF method continues to be concerned by many researchers. A switched linear copositive Lyapunov function method for switched positive systems is presented in (Liu 2009), and the existence problem of a Common Copositive Lyapunov Function (CCLF) for switched positive linear systems with stable and pairwise commutable subsystems is investigated in (Tong et al. 2013). The present results demonstrated that a CCLF can be constructed for the underlying system whenever its subsystems are continuous time, discrete-time or the mixed type. Further, For the finite-time stability problem of switched positive linear systems, Chen and Yang present a sufficient condition for finite-time stability using the CCLF and multiple copositive Lyapunov functions (Chen & Yang 2014). Meanwhile a computational method for vector functions used to construct the CLF is proposed. A Common Diagonal Lyapunov Function (CDLF) is constructed for a special

linear SS (Bykkoroglu 2012). Contradistinctively, a method of computing a CQLF for a stable linear time-invariant system, whose system matrix is tridiagonal (Yu & Gao 2009). Many CLF research work is carried out for nonlinear switched systems. A CLF is based on generalized Kullback-Leibler divergence or Csizsar's divergence between the state and equilibrium is presented in (Abou Al-Ola et al. 2011). Aleksandrov addressed the stability analysis of a class of switched nonlinear systems with uncertain nonlinear functions constrained in a sector set, which are called admissible sector nonlinearities (Aleksandrov et al. 2011). The existence condition in terms of linear inequalities of a CLF and a constructive algorithm based on the modified Gaussian elimination procedure are given. And for a family of nonlinear mechanical systems with one degree of freedom, He proposed the existence condition of a CLF once again (Aleksandrov & Murzinov 2012). In (Wang et al. 2014), sufficient conditions for the existence of a CQLF are given for two classes of switched linear systems which possess negative row strictly diagonally dominant and diagonalizable stable state matrices, respectively. Some kinds of different switched systems are concerned about their CQLFs or stability problems via CQLF. For example, planar linear switched system (Ben Salah et al. 2015), descriptor system (Gu et al. 2009, Zhai 2009) and switched Persidskii-type system (Chen et al. 2011). The non-existence of a CQLF for SS is also a interesting problem. A sufficient condition for the non-existence of a CQLF for N systems is presented and the determining algorithm is designed based on particle swarm optimisation (Duarte-Mermoud et al. 2012). The research work about CQLF is also extended to discrete switched system (Sun et al. 2011, Liu & Zhao 2015).

Finding a CLF is still a challenging problem for SS study. Although many results of CLF have been proposed during several past decades, the conditions of its existence and the finding algorithm are difficult yet. Furthermore, it is closely related with the control analysis and design. Majority of results about finding CLF are always based on the assumption that every subsystem matrix A_i is stable, i.e. $\mathbb{A} = \{A_1, A_2, \dots, A_N\}$ is a stable matrix set. When the matrices of the subsystems are not commutative, the NB Algorithm is not applicable. Under the situation Zhu et al. presented the method of constructing CQLF (Zhu et al. 2007). However, there is no specific applicable algorithm to find a CQLF in their method. And the conditions are difficult to be testified.

The purpose of the present paper is to provide a recurrence searching algorithm of a CQLF for uncertain switched system. It will discuss the CQLF problem, i.e. determination for uncertain

switched linear system stability. If considered individually the stability of linear switched systems with uncertainty, namely, the problem of robust stability and constructing a CQLF will be more difficult. In order to overcome this difficulty, this paper presents Robust Stable Matrix Set (RSMS) concept, and further releases the determinant and constructing theorems of a CQLF for a RSMS. The results make sense for robust control problem of uncertain switched linear systems under arbitrary switching rule.

2 PROBLEM FORMULATION

Consider the following uncertain switched system:

$$\dot{x}(t) = (A_\sigma + \Delta A_\sigma)x(t) \quad (1)$$

where $x(t) \in \mathbb{R}^n$ denotes the system state variable, ΔA_σ reflects the uncertainties of the parameters, $\sigma(t): \mathbb{R} \rightarrow \mathbb{N} \equiv \{1, 2, \dots, N\}$ is a piecewise constant function of the time t , also referred to as the switching signal (rule). Then we define a switching sequence:

$$\mathcal{Q} \triangleq x_0; (i_0, t_0), (i_1, t_1), \dots, (i_k, t_k), \dots, \\ \forall i_k \in \mathbb{N}, k \in \mathbb{Z}^+$$

i.e., the i_k -th subsystem operates when $t \in [t_k, t_{k+1})$.

For the switching signal $\sigma(t) = i, i \in \mathbb{N}$, the i -th subsystem parameters can be denoted as: $A_\sigma \triangleq A_i, \Delta A_\sigma \triangleq \Delta A_i$. Accordingly, for the k -th switching, when $t_k \leq t < t_{k+1}$. We can set $\sigma(t) = i$, i.e., $i_k = i \in \mathbb{N}$. According to (1), the system can be described as:

$$\dot{x}(t) = (A_i + \Delta A_i)x(t) \quad (2)$$

The switching system as described in (1) can satisfy the following assumptions.

Assumption 1 The uncertainty parameters, ΔA_i satisfy the following relationships:

$$\Delta A_i = H_{a,i} F_{a,i} (t) E_{a,i} \quad (3)$$

where $H_{a,i} \in \mathbb{R}^{n \times r_a}$ and $E_{a,i} \in \mathbb{R}^{r_a \times n}$ are all the known constant matrices, and the unknown time-varying matrices $F_{a,i}(t)$ satisfy: $F_{a,i}^T(t) F_{a,i}(t) \leq I$.

Generally, the stability problem of (1) is significant for control. The problem of this paper is: if $A_i, i \in \mathbb{N}$ comprise a stable matrix set, i.e., $\mathbb{A} = \{A_1, A_2, \dots, A_N\}$, then finding a CQLF guarantees the stability of uncertain switched system (1). Firstly two lemmas and a definition that are used in the present study will be introduced.

Lemma 1 (Schur Complement) Given a symmetric matrix $S = \begin{bmatrix} S_{11} & S_{12} \\ S_{21} & S_{22} \end{bmatrix}$, the following three conditions are equivalent.

- i. $S < 0$;
- ii. $S_{11} < 0, S_{22} - S_{21}S_{11}^{-1}S_{12} < 0$;
- iii. $S_{22} < 0, S_{11} - S_{12}S_{22}^{-1}S_{21} < 0$.

Lemma 2 Assuming that H and E are the matrices consisting of real constants with approximate dimension, $F(t)$ satisfies $F^T(t)F(t) \leq I$, the following relation is true for any constant $\varepsilon > 0$,

$$HF(t)E + E^T F^T(t)H^T \leq \varepsilon^{-1}HH^T + \varepsilon E^T E. \quad (4)$$

Lemma 3 If $\forall \varepsilon_i > 0$, the Linear Matrix Inequality (LMI)

$$\begin{bmatrix} P_i A_i + A_i^T P_i + L_i & P_i H_{a,i} \\ * & -\varepsilon_i I \end{bmatrix} < 0, \forall i \in \mathbb{N} \quad (5)$$

has a positive definite symmetric solution matrix P_p , every subsystem (2) is quadratically robust stable.

Proof: Select a Lyapunov function of every subsystem (2)

$$V_i(x(t)) = x^T(t)P_i x(t).$$

And find the time derivative along (2),

$$\dot{V}_i(x(t)) = x^T(t)[P_i A_i + A_i^T P_i + P_i \Delta A_i + \Delta A_i^T P_i]x(t)$$

According to Assumption 1 and Lemma 2, $\forall \varepsilon_i > 0$, the inequality

$$P_i \Delta A_i + \Delta A_i^T P_i \leq \varepsilon_i^{-1} P_i G_i P_i + L_i$$

holds with

$$G_i = \varepsilon_i^{-1} H_{a,i} H_{a,i}^T, L_i = \varepsilon_i E_{a,i}^T E_{a,i} \quad (6)$$

are matrix items produced by the system uncertainty. Substitute it into $\dot{V}_i(x(t))$, we have

$$\dot{V}_i(x(t)) \leq x^T(t)[P_i A_i + A_i^T P_i + P_i G_i P_i + L_i]x(t)$$

According to Lemma 1, if (5) is satisfied,

$$\dot{V}_i(x(t)) \leq -x^T(t)Q_i x(t)$$

hold, where Q_i is some positive definite matrix. Then every subsystem (2) is quadratically robust stable.

Suppose that every subsystem matrix A_i satisfies the following Assumption.

Assumption 2 Every matrix A_i in stable matrix set $\mathbb{A} = \{A_1, A_2, \dots, A_N\}$ is quadratically robust stable, i.e. satisfies Lemma 3.

To underlie the following analysis, define

$$P_{ij} = A_i^T P_j + P_j A_i, U_{i,j} = P_j G_i P_j + L_i, \forall i, j \in \mathbb{N}. \quad (7)$$

3 PRELIMINARIES OF CQLF

3.1 Known results

A great deal of research was conducted on the construction of a CQLF of a stable matrix set. The sufficient condition as well as important conditions for constructing a CQLF of a matrix set was elaborated in detail in Section 1. As described in (Zhu et al. 2007), the researchers probed into the methods for searching the CLF and concluded several conditions for the existences of CQLF. Based on the research results in (Zhu et al. 2007), when any two matrices in a stable matrix set \mathbb{A} are not interchangeable but satisfy the involution conditions, the CQLF can be constructed according to the following lemmas.

Assuming a stable matrix set $\mathbb{A} = \{A_1, A_2, \dots, A_N\}$ with their corresponding Lyapunov matrix P_p , and defining $[A_N, A_i] = \sum_{k=1}^N \gamma_i^k A_k, \forall i \in \mathbb{N}$, in which $\gamma_i^k > 0$ is a scaling coefficient parameter. Given a randomly selected $P_{N-1} > 0$, we set

$$P_{N,N} = P_N A_N + A_N^T P_N = -P_{N-1}.$$

Lemma 4 Given a stable matrix set $\mathbb{A} = \{A_1, A_2, \dots, A_N\}$, if $\forall i = 1, \dots, N-1$ the following conditions can be satisfied:

$$\begin{cases} \max(\gamma_i^l) < 2 \min[\operatorname{Re} \lambda(A_N)], \\ -P_{i,N-1} + \gamma_i^N P_{N-1} - \sum_{k=1, k \neq i}^{N-1} \gamma_i^k P_{k,N} > 0, \end{cases} \quad (8)$$

where $P_{i,j} = A_i^T P_j + P_j A_i, \forall i, j \in \mathbb{N} = \{1, 2, \dots, N\}$, P_N is a CQLF of \mathbb{A} .

Still, we should randomly select $P_{N-1} > 0$ and set $P_N A_N + A_N^T P_N = -P_{N-1}$, and moreover,

$$C_{N,j} = [A_N, A_j], \forall j \in \mathbb{N} \quad (9)$$

According to the results in [32], the following Lemma can be deduced.

Lemma 5 Given a stable matrix set \mathbb{A} , defining $C_{N,j}, \forall j \in \mathbb{N}$ as similar to (9), if the following inequality can be satisfied:

$$P_{i,N-1} + P_N C_{N,i} + C_{N,i}^T P_N < 0, i = 1, \dots, N-1 \quad (10)$$

P_N is a CQLF of \mathbb{A} .

3.2 Robust stable matrix set

Defining a robust stable matrix set

$$\mathbb{A} = \{A_1, A_2, \dots, A_N\},$$

in which each stable matrix is of robust stability, each matrix can satisfy Lyapunov Equation:

$$P_i A_i + A_i^T P_i + P_i G_i P_i + L_i = -Q_i, \quad \forall i = 1, 2, \dots, N \quad (11)$$

where G_i and L_i are the matrices of Lyapunov Equation induced by the system uncertainty; i.e. defined by (6).

If the matrix set \mathbb{A} is involutory, we still assume that

$$[A_N, A_i] = \sum_{k=1}^N \gamma_i^k A_k, \quad \forall i = \mathbb{N},$$

where $\gamma_i^k > 0$ is the scalar coefficient parameter. To random select $P_{N-1} > 0$ and set the fowling equation:

$$P_N A_N + A_N^T P_N + U_{N,N} = -P_{N-1}. \quad (12)$$

4 MAIN RESULTS

The following corollaries can be deduced based on Lemma 4 and Lemma 5.

4.1 Common robust quadratic Lyapunov function

Corollary 1 Given a robust stable matrix set $\mathbb{A} = \{A_1, A_2, \dots, A_N\}$, which can satisfy (11), if $\forall i = 1, \dots, N-1$ the following conditions can be satisfied:

$$\begin{cases} \max(\gamma_i^j) < 2 \min |\operatorname{Re} \lambda(A_N)|, \\ -P_{i,N-1} + \gamma_i^N P_{N-1} - \sum_{k=1, k \neq i}^{N-1} \gamma_i^k P_{k,N} + \gamma_i^i U_{i,N} \\ + \gamma_i^N U_{N,N} + U_{i,N} A_N + A_N^T U_{i,N} - U_{N,N} A_i \\ - A_i^T U_{N,N} > 0, \end{cases} \quad (13)$$

P_N is a common robust quadratic Lyapunov function of \mathbb{A} , i.e. they can satisfy the Riccati Inequality:

$$P_N A_i + A_i^T P_N + P_N G_i P_N + L_i < 0, \quad \forall i = 1, 2, \dots, N. \quad (14)$$

Proof:

$$\begin{aligned} & (P_{i,N} + U_{i,N}) \left(A_N + \frac{\gamma_i^i}{2} I \right) + \left(A_N + \frac{\gamma_i^i}{2} I \right)^T (P_{i,N} + U_{i,N}) \\ &= (P_N A_i + A_i^T P_N + U_{i,N}) A_N + A_N^T (P_N A_i + A_i^T P_N + U_{i,N}) \\ & \quad + \gamma_i^i (P_N A_i + A_i^T P_N + U_{i,N}) \\ &= P_N \left(A_N A_i - \sum_{k=1}^N \gamma_i^k A_k \right) + A_i^T P_N A_N + A_N^T P_N A_i \\ & \quad + \left(A_i^T A_N^T - \sum_{k=1}^N \gamma_i^k A_k^T \right) P_N + \gamma_i^i (P_N A_i + A_i^T P_N + U_{i,N}) \\ & \quad + U_{i,N} A_N + A_N^T U_{i,N} \\ &= (P_N A_N + A_N^T P_N) A_i + A_i^T (P_N A_N + A_N^T P_N) \\ & \quad - \gamma_i^N (P_N A_N + A_N^T P_N) - \sum_{k=1, k \neq i}^{N-1} \gamma_i^k (P_N A_k + A_k^T P_N) \\ & \quad + U_{i,N} (A_N + \gamma_i^i) + A_N^T U_{i,N} \\ &= -P_{i,N-1} + \gamma_i^N P_{N-1} - \sum_{k=1, k \neq i}^{N-1} \gamma_i^k P_{k,N} + U_{i,N} (A_N + \gamma_i^i) \\ & \quad + A_N^T U_{i,N} - U_{N,N} (A_i - \gamma_i^N) - A_i^T U_{N,N}. \end{aligned}$$

According to the second condition in (13), if the inequality

$$-P_{i,N-1} + \gamma_i^N P_{N-1} - \sum_{k=1, k \neq i}^{N-1} \gamma_i^k P_{k,N} + U_{i,N} (A_N + \gamma_i^i) + A_N^T U_{i,N} - U_{N,N} (A_i - \gamma_i^N) - A_i^T U_{N,N} > 0,$$

Is valid $\forall i = 1, 2, \dots, N-1$, the product of $P_{i,N} + U_{i,N}$ and the transposed matrix of $A_N + \gamma_i^i/2 I$ is positive definite. According to the first inequality in (13), it can be inferred that $A_N + \gamma_i^i/2 I$ is stable, and the following inequality is true:

$$P_N A_i + A_i^T P_N + P_N G_i P_N + L_i < 0, \quad \forall i \in \mathbb{N}. \quad (15)$$

It means that P_N is a common quadratic Lyapunov function of \mathbb{A} ; moreover, for each matrix A_i in \mathbb{A} , P_N satisfies the Riccati Inequality that contains the uncertain item $U_{i,N}$ (as described in (15)). Therefore, P_N is a CRQLF of \mathbb{A} .

Assuming a robust stable matrix set $\mathbb{A} = \{A_1, A_2, \dots, A_N\}$, in which each stable matrix A_i is of robust stability and thus satisfies Lyapunov equation as described in (11). We still define (6) and (12), but the matrix \mathbb{A} is not involutory. Based on the Lemma 5 on the search of the CQLF, the following Corollary 2 can be deduced.

Corollary 2 Given a robust stable matrix set $\mathbb{A} = \{A_1, A_2, \dots, A_N\}$, which satisfies (11), we define $C_{N,j}$ as described in (9). If $\forall i = 1, 2, \dots, N-1$, P_N satisfies

$$P_{i,N-1} + P_N C_{N,i} + C_{N,i}^T P_N + U_{N,N} A_i + A_i^T U_{N,N} - U_{i,N} A_N - A_N^T U_{i,N} < 0, \quad (16)$$

P_N is a CRQLF of \mathbb{A} , i.e. they can satisfy the Riccati inequality:

$$P_N A_i + A_i^T P_N + P_N G_i P_N + L_i < 0, \quad \forall i = 1, 2, \dots, N \quad (17)$$

Proof:

$$\begin{aligned}
& (P_{i,N} + U_{i,N})A_N + A_N^T(P_{i,N} + U_{i,N}) \\
&= (P_N A_i + A_i^T P_N + U_{i,N})A_N + A_N^T(P_N A_i + A_i^T P_N + U_{i,N}) \\
&= P_N(A_N A_i - C_{N,i}) + A_i^T P_N A_N + A_N^T P_N A_i \\
&\quad + (A_i^T A_N^T - C_{N,i}^T)P_N + U_{i,N}A_N + A_N^T U_{i,N} \\
&= (P_N A_N + A_N^T P_N)A_i + A_i^T(P_N A_N + A_N^T P_N) \\
&\quad - P_N C_{N,i} - C_{N,i}^T P_N + U_{i,N}A_N + A_N^T U_{i,N} \\
&= -(P_{i,N-1} + P_N C_{N,i} + C_{N,i}^T P_N + U_{N,N}A_i \\
&\quad + A_i^T U_{N,N} - U_{i,N}A_N - A_N^T U_{i,N}).
\end{aligned}$$

If the inequality as described in (16) is satisfied, $(P_{i,N} + U_{i,N})A_N + A_N^T(P_{i,N} + U_{i,N}) > 0$ is true for $\forall i = 1, 2, \dots, N-1$, suggesting that the product of $P_{i,N} + U_{i,N}$ and the transposed matrix of A_N is positive definite. As stated above, A_N is stable, and therefore, $P_{i,N} + U_{i,N} < 0$, $i = 1, \dots, N-1$ is true, *i.e.* the following inequality is true:

$$P_N A_i + A_i^T P_N + P_N G_i P_N + L_i < 0, \forall i \in \mathbb{N}. \quad (18)$$

Accordingly, P_N is a CQLF of \mathbb{A} , and moreover, for each matrix A_i in \mathbb{A} , P_N satisfies the Riccati Inequality that contains the uncertain item $U_{i,N}$ (as described in (18)). Therefore, P_N is a CRQLF of \mathbb{A} .

4.2 Recursive algorithm of CRQLF

Based on Lemma 5, the recursive algorithm for searching a CQLF of the stable matrix set can be constructed.

Theorem 1 Given a stable matrix set $\mathbb{A} = \{A_1, A_2, \dots, A_N\}$, if \mathbb{A} has a CLF, the matrix P_k ($\forall k \in \mathbb{N}$) that can satisfy the following conditions:

$$\begin{cases} P_{k,k} < 0, \\ A_i^T P_{k,k} + P_{k,k} A_i - P_k C_{k,i} - C_{k,i}^T P_k > 0 \end{cases} \quad (19)$$

can be regarded as the CQLF matrix of the matrix set $A_k = \{A_1, A_2, \dots, A_k\}$, in which

$$C_{i,j} = A_i A_j - A_j A_i.$$

Proof:

$$\begin{aligned}
& P_{i,k} A_k + A_k^T P_{i,k} \\
&= (P_k A_i + A_i^T P_k) A_k + A_k^T (P_k A_i + A_i^T P_k) \\
&= P_k (A_k A_i - C_{k,i}) + A_i^T P_k A_k + A_k^T P_k A_i \\
&\quad + (A_k A_i - C_{k,i})^T P_k \\
&= (P_k A_k + A_k^T P_k) A_i + A_i^T (P_k A_k + A_k^T P_k) \\
&\quad - P_k C_{k,i} - C_{k,i}^T P_k \\
&= A_i^T P_{k,k} + P_{k,k} A_i - P_k C_{k,i} - C_{k,i}^T P_k.
\end{aligned}$$

If the inequality in (19) can be satisfied, obviously, $P_{i,k} A_k + A_k^T P_{i,k} > 0$. Since A_k is a stable matrix,

$$P_{i,k} = A_i^T P_k + P_k A_i < 0, \forall i = 1, \dots, k$$

is true. Therefore, P_k is a CQLF of

$$\mathbb{A}_k = \{A_1, A_2, \dots, A_k\}.$$

We assume a robust stable matrix set \mathbb{A} in which each stable matrix is of robust stability and can satisfy Lyapunov equation as described in (11). Still, we define (7) but don't define (12), and the matrix set \mathbb{A} is not involutory. Based to the above-described Theorem 1 on the common quadratic Lyapunov function, the following algorithm for recursively constructing the CLF can be deduced.

Theorem 2 There is a CLF in robust stable matrix set $\mathbb{A} = \{A_1, A_2, \dots, A_N\}$. For arbitrary positive integer $\varepsilon_1, \varepsilon_2, \dots, \varepsilon_k$ and $\forall i = 1, \dots, k-1, k \in \mathbb{N}$ the positive definite symmetric matrix P_k ($\forall k \in \mathbb{N}$) that satisfies the following conditions:

$$\begin{cases} P_{k,k} + U_{k,k} < 0, \\ A_i^T P_{k,k} + P_{k,k} A_i - P_k C_{k,i} - C_{k,i}^T P_k \\ \quad + U_{i,k} A_k + A_k^T U_{i,k} > 0 \end{cases} \quad (20)$$

can be regarded as the CRQLF matrix of the matrix set $A_k = \{A_1, A_2, \dots, A_k\}$ And P_k satisfy the Riccati inequality:

$$P_k A_i + A_i^T P_k + U_{i,k} < 0, \forall i = 1, 2, \dots, k \quad (21)$$

where $C_{i,j} = A_i A_j - A_j A_i$.

Proof:

$$\begin{aligned}
& (P_{i,k} + U_{i,k}) A_k + A_k^T (P_{i,k} + U_{i,k}) \\
&= (P_k A_i + A_i^T P_k + U_{i,k}) A_k \\
&\quad + A_k^T (P_k A_i + A_i^T P_k + U_{i,k}) \\
&= P_k (A_k A_i - C_{k,i}) + A_i^T P_k A_k + A_k^T P_k A_i \\
&\quad + (A_k A_i - C_{k,i})^T P_k + U_{i,k} A_k + A_k^T U_{i,k} \\
&= (P_k A_k + A_k^T P_k) A_i + A_i^T (P_k A_k + A_k^T P_k) \\
&\quad - P_k C_{k,i} - C_{k,i}^T P_k + U_{i,k} A_k + A_k^T U_{i,k} \\
&= A_i^T P_{k,k} + P_{k,k} A_i - P_k C_{k,i} - C_{k,i}^T P_k \\
&\quad + U_{i,k} A_k + A_k^T U_{i,k}.
\end{aligned}$$

If the inequality in (20) can be satisfied, obviously, $(P_{i,k} + U_{i,k}) A_k + A_k^T (P_{i,k} + U_{i,k}) > 0$. Since A_k is a stable matrix,

$$P_{i,k} + U_{i,k} = A_i^T P_k + P_k A_i + U_{i,k} < 0, \forall i = 1, \dots, k-1$$

is true. Therefore, P_k is a CRQLF of

$$A_k = \{A_1, A_2, \dots, A_k\}.$$

5 NUMERICAL SIMULATION

A switched system (1) consisting of three subsystems ($N \triangleq \{1,2,3\}$) were simulated when the system state is measurable. The parameters of each subsystem are listed below.

Subsystem 1:

$$A_1 = \begin{bmatrix} -1 & 1 \\ 2.25 & -2.75 \end{bmatrix}, \Delta A_1 = \begin{bmatrix} 0.38 \sin 4\pi t & 0 \\ 0 & 1.1e^{-t} \end{bmatrix},$$

Subsystem 2:

$$A_2 = \begin{bmatrix} -5.6 & 0.4 \\ 3.4 & -2.6 \end{bmatrix}, \Delta A_2 = \begin{bmatrix} 0.65 \cos 7\pi t & 0.2 \cos 7\pi t \\ 0 & 0.56e^{-2.2t} \end{bmatrix},$$

Subsystem 3:

$$A_3 = \begin{bmatrix} -0.8 & -7.6 \\ 2.2 & -0.6 \end{bmatrix}, \Delta A_3 = \begin{bmatrix} 0 & 0 \\ 1.7 \sin 2\pi t & 0.76e^{-t^2} \end{bmatrix}.$$

According to Assumption 1, the uncertainty of every subsystem can be decomposed as the following.

$$\begin{aligned} H_{a,1} &= \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, F_{a,1} = \begin{bmatrix} \sin 4\pi t & 0 \\ 0 & e^{-t} \end{bmatrix}, E_{a,1} = \begin{bmatrix} 0.38 & 0 \\ 0 & 1.1 \end{bmatrix}, \\ H_{a,2} &= \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, F_{a,2} = \begin{bmatrix} \cos 7\pi t & 0 \\ 0 & e^{-2.2t} \end{bmatrix}, \\ E_{a,2} &= \begin{bmatrix} 0.65 & 0.2 \\ 0 & 0.56 \end{bmatrix}, \\ H_{a,3} &= \begin{bmatrix} 0 & 0 \\ 1 & 1 \end{bmatrix}, F_{a,3} = \begin{bmatrix} \sin 2\pi t & 0 \\ 0 & e^{-t^2} \end{bmatrix}, \\ E_{a,3} &= \begin{bmatrix} 1.7 & 0 \\ 0 & 0.76 \end{bmatrix}. \end{aligned}$$

We can testify that $A_i, i \in \mathbb{N}$ comprise a RSMS using Lemma 3. Namely Assumption 2 is satisfied. LMIs (21) was solved by Theorem 2 recursively. Let $k = 2, 3$ and the resolving results are following respectively.

A CRQLF of subsystem 1, 2 is

$$P_2 = \begin{bmatrix} 744.1 & 713.5 \\ 713.5 & 1162.7 \end{bmatrix}.$$

A CRQLF of subsystem 1, 2, 3 is

$$P_3 = \begin{bmatrix} 146220 & 21680 \\ 21680 & 474580 \end{bmatrix}.$$

Thus, we find a CRQLF of the system (1). It is showed that the system (1) is robust stable under arbitrary switching rule. The initial state value is

Figure 1. The system state signal $x(t)$.

Figure 2. The system switching signal $\sigma(t)$.

selected as $x(t_0) = [0.40.1]^T$. The system state running curves are simulated under arbitrary rule, which is in Fig. 1. The switching signal is in Fig. 2. They are showed that the switched system with uncertainty is robust stable under arbitrary switching rule.

6 CONCLUSIONS

The CQLF finding problem for uncertain switched linear systems is discussed. If the subsystem matrices constitute robust stability matrix set, the CQLF is called Common Robust Quadratic Lyapunov Function (CRQLF). A CRQLF determination method and its recursive constructing algorithm are proposed. Construction algorithm is in terms of recursive Linear Matrix Inequality (LMI) form,

which brings convenience to facilitate the solution and strong practicability. The numerical example and simulation verify the feasibility of the presented results.

ABSTRACT: RCS (Radar Cross Section) of an object is an important parameter in military action. The accuracy and stability of typical single radar can not be applied to many huge targets. With the development of MIMO (Multiple-Input and Multiple-Output) technology, a new way of RCS simulation based on MIMO system is formulated in this paper. It introduces the simulation theory of RCS which can be simulated by HFSS. After synthesizing the multiple radar effect, it's verified that MIMO system has a better property comparing with single radar.

1 INTRODUCTION

Nowadays, it's expected to alleviate the impact for targets RCS with the variation of the observation angle (Mark, 2014). Comparing with the traditional radar, MIMO radar has the advantage of parallel multi-channel access to information, so it has broad application prospect. MIMO radar uses the transmitted and received signals simultaneously. As a result, many signals can be separated among the time domain, spatial domain and polarization domain. It has the advantages of higher processing dimension, making full use of scattered and received apertures, and higher angular resolution. MIMO radar uses irrelevance of echo signal raised by spatial diversity of target scattering, keeps average energy received of echo wave approximate to constant and the air target RCS smoothly, improves the target RCS fluctuation, and increases the detection performance and spatial resolution.

Nowadays, it becomes convenient for us to estimate the RCS by means of electromagnetic simulator. With the development of high speed calculation methods, other types of software such as HFSS employing FEM algorithm have been used on electromagnetic simulation (Yoshihide, 2014).

2 FUNDAMENTAL THEORY

Based on array antenna structure, MIMO radar with M emitters and N receivers can radiate orthogonal signals at the same time, these

waveform signals can be scattered by the target and received by N array (Ghotbi, 2014). The model of statistical MIMO radar is shown in figure 1.

RCS is a key subject that reflects the observability of a target (Levent, 2013). It can be defined and calculated from the target-scattered field caused by an incident plane wave hitting on the object:

$$\sigma = \lim_{R \rightarrow \infty} 4\pi R^2 \frac{|E_s|^2}{|E_i|^2} \tag{1}$$

where R is the distance between the radar transmitter and the target, and E_s and E_i are the scattered and incident electric fields. The unit of RCS is square meter (m²) or dBsm (Doren, 2008).

Figure 1. Statistical MIMO radar target model.

HFSS is a high-performance full-wave electromagnetic (EM) field simulator for arbitrary 3-dimension passive device modeling which takes advantage of the familiar Microsoft Windows graphical user interface. Ansoft HFSS employs the Finite Element Method (FEM), adaptive meshing, and brilliant graphics to solve Maxwell's equations.

HFSS-IE uses MOM (method of moments) solution type to solve large, open, radiating or scattering analyses. It is a new Integral Equation solver technology in the HFSS desktop. So it's used to simulate the RCS of dihedral angle structure below.

In this paper, the length and width of dihedral angle (perfect electrical conduct) are all 5.6088λ , the rotated angle θ is 90° . The frequency of incident wave is 9.4 GHz with vertical polarization. In HFSS operation, the excitation is set to be 1V/m and the boundary is set to be perfect electricity boundary (Sheng, 2013). Fig. 3 shows the model of dihedral angle.

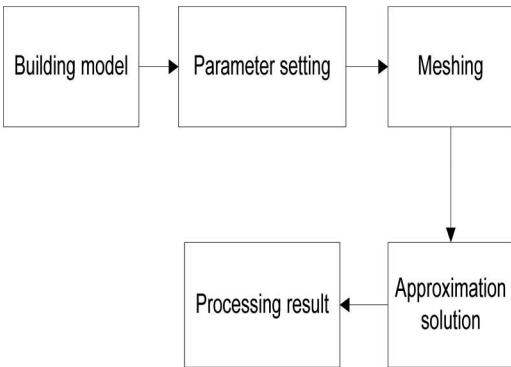

Figure 2. HFSS simulation process.

Figure 3. HFSS simulation model of dihedral angle.

Figure 4. Mono-static simulation model with incident wave phi ($-45^\circ \sim 135^\circ$).

Figure 5. Mono-static RCS simulation result.

3 MONO-STATIC SIMULATION

In the simulation of mono-static situation, the direction of incident wave is the same as that radiation wave. The rotated angle θ is 90° and azimuth angle φ sweeps from -45° to 135° , the scan interval is 1° . Fig. 4 shows the simulation model. The simulation result of RCS is revealed in Fig. 5 in which primary sweep is incident wave Phi and vertical axis unit is dB (RCS Total). For comparison, we also use the theoretical calculation values from reference article (Timothy, 1987).

Comparing the simulation result with correlative literature datum, it's obvious that simulation and calculation results of mono-static RCS match well with the change of azimuth angle.

4 MIMO BI-STATIC SIMULATION

In the MIMO system, four special angles are used to simulate RCS. The simulation model of bi-static is as same as mono-static. The bi-static RCS simulations of a target are obtained from

Figure 6. Calculated result compared with measured values of reference.

Figure 7. Simulation results of total RCS.

the amplitudes of received signal strength for each of the transmitting—receiving paths (Ebrahimi, 2007). Through four angles' data processing, MIMO radar's result can be revealed clearly.

4.1 Case 1

The electric field direction is set to be $\mathbf{E} = (0,0,1)$ and electromagnetic vector is $\mathbf{k} = (-1,-1,0)$. The incident angle is $\varphi = 45^\circ$ $\theta = 90^\circ$ while XOY plane as radiating direction. There is no change in the size of model. Fig. 7 reveals the simulation results and primary sweep is φ .

4.2 Case 2

The electric field direction is set to be $\mathbf{E} = (0,0,1)$ and electromagnetic vector is $\mathbf{k} = (1,-1,0)$. The incident angle is $\varphi = 135^\circ$ $\theta = 90^\circ$ while XOY plane as radiating direction. Fig. 8 reveals the bi-static simulation results.

4.3 Case 3

When the electric field direction is $\mathbf{E} = (0,0,1)$ and electromagnetic vector is set to be $\mathbf{k} = (1,1,0)$. The incident angle is $\varphi = 225^\circ$ $\theta = 90^\circ$ and XOY plane as radiating direction. Through the simulation and Fig. 9 reveals the results.

Figure 8. Bi-static RCS simulation results with $\varphi = 135^\circ$, $\theta = 90^\circ$.

Figure 9. Total RCS simulation results with $\varphi = 225^\circ$, $\theta = 90^\circ$.

Figure 10. RCS simulation results with $\varphi = 135^\circ$, $\theta = 90^\circ$.

4.4 Case 4

The electric field direction is set to be $\mathbf{E} = (0,0,1)$ and electromagnetic vector is $\mathbf{k} = (-1,1,0)$. The incident angle is set to be $\varphi = 315^\circ$ and $\theta = 90^\circ$ while XOY plane as radiating direction. Fig. 10 reveals the simulation result.

Figure 11. Average RCS results of last four cases.

5 RESULT ANALYSIS

Through extracting the data of four kinds of cases above, Some data listed in the following table 1. After average processing, the total result shown in Fig. 11.

From the above result, it can be found that the direction of the incident wave RCS is bigger than that of the others. Comparing MIMO radar with typical method, the fluctuation of RCS was improved efficiently by MIMO radar. This method can be used to forecast electromagnetic scattering characteristics of large complex targets with higher frequency (like airplane and ship) faster and more accurate.

6 CONCLUSION

RCS is one of the important features of radar target signal. Although the electromagnetic theory

has its integrity which can analyze the scattering mechanism of some objects, it's difficult for complex targets to calculate the RCS value using existed methods. Now RCS can be simulated by the electromagnetic simulation software. Traditional single radar can not be applied in some complex objects, so we will apply the MIMO radar to RCS simulation.

From dihedral angle RCS simulation in HFSS, it's verified that the result of HFSS simulation agrees well with the theoretical result. By RCS numerical treatment of four kinds of angles, we obtain the RCS curve under the MIMO system. It can be concluded that the value of the target RCS is related to the angle of incident wave. This study has successfully demonstrated the application of MIMO theory in radar signal receiving and target detection, especially laid the foundation of MIMO radar in the electromagnetic stealth technology of military equipment.

ABSTRACT: Tongue diagnosis is one of the most important diagnosis methods in Traditional Chinese Medicine (TCM). Tongue image segmentation is a crucial step in developing automatic tongue diagnosis system. Rough localization of tongue body is a useful preprocessing step in tongue image segmentation, which can eliminate the adverse effect of strong edges from neighboring tissues such as face and lip when extracting tongue body contour. After exploring the existing tongue rough localization method based on gray projection, we propose a modified method combining clustering with gray projecting in this paper. The proposed method first conducts clustering on image pixels' hue components in HSI (Hue, Saturation and Intensity) space to seek multiple thresholds. Then, image thresholding and morphological operations are conducted to generate a binary image, and the largest object region is taken as the initial localization result. Finally, the localization result is refined by gray projection on pixels' red components. Experiment results on a variety of tongue images show that the proposed method significantly improves the accuracy of tongue rough localization in comparison with the existing gray projection method.

1 INTRODUCTION

Tongue diagnosis (Kirschbaum, 2000) is one of widely used diagnostic methods in Traditional Chinese Medicine (TCM) due to its virtues such as effectiveness, painlessness, simplicity and immediacy. Tongue diagnosis has a history of at least 3000 years, and its practitioners have accumulated very rich clinical experiences on drawing physiological and pathological information according to the features of tongue body, such as color, texture, shape and coating. Eight principles of tongue diagnosis reveal that different sub-regions of tongue body can reflect health statuses of different human organs such as heart, lung, spleen and stomach. For example, tongue's appearance is the most useful gauge for monitoring the improvement or deterioration of a patient's health status. The color and texture features of tongue coating, which are called TCM syndromes, often reflect many diseases and human health conditions such as inflammation and infection (Hsu, 2003).

In modern Western Medicine, tongue has increasingly been taken as an extension of the upper gastrointestinal tract that can provide important clues to human health status. Some researchers in Western Medicine have also taken

tongue diagnosis as a helpful method for clinical decision making (Anastasi, 2009). For example, tongue coating is a risk indicator for aspiration pneumonia in edentate patients, as it is associated with a number of viable salivary bacteria (Abe, 2008). It has also been reported that the amyloidosis of tongue may be a diagnostic manifestation of plasmacytoma (Hoefert, 1999). These researches exhibit the potential for inferring systemic disorders from the tongue in clinical diagnosis.

The conventional tongue diagnosis lacks quantitative and robust diagnosis accuracy due to its high dependence on practitioners' experience. Now, powerful computer processors have made it possible to develop automatic computer-aided tongue diagnosis system (Pang, 2004) via image processing and pattern recognition techniques. This automatic tongue diagnosis system usually first extracts tongue body in a tongue image by image segmentation technique, then calculates the features of the tongue body by feature extraction technique, and finally uses a classifier to obtain the final diagnosis result. Hence, tongue image segmentation (i.e., extracting tongue body) is a crucial step. Some researchers have presented some algorithms (Ning, 2012; Shi, 2013) to resolve this problem. However, to date, tongue image segmentation is still a

challenging task due to large personal variation of tongue body on shape, color, coating, texture, and weak edges caused by similar color between tongue body and its neighboring tissues.

To improve accuracy of tongue image segmentation, Zhang and Qin (Zhang, 2010) proposed an image preprocessing method for tongue image segmentation, which uses gray projection technique to achieve rough localization of the object (i.e., tongue body) in a tongue image. The goal of tongue rough localization is to find the rectangle region located by the tongue body. Tongue rough localization is helpful for subsequent tongue segmentation since it can avoid strong image edges out of tongue body to be erroneously regarded as a part of tongue contour. After exploring the limitation of the existing tongue rough localization method based on gray projection (Zhang, 2010), we propose a modified rough localization method combining clustering and the gray projection. Experimental results on a series of tongue images with large variation on tongue size, shape, color, coating and texture demonstrate the effectiveness of the proposed method.

2 TONGUE ROUGH LOCALIZATION BASED ON GRAY PROJECTION

The tongue rough localization method based on gray projection is presented according to two prior knowledge. The first knowledge is that tongue root region is usually darker than other regions on human face when generating tongue images. The second knowledge is that there may exist dark regions near tongue contour due to the blocked light by stretched tongue body when generating tongue images. These dark regions cause those involved image rows and image columns have lower average gray values than other rows and columns, respectively.

For a given tongue image I with the size of $M \times N$, let $I(i, j)$ denote the gray level of pixel $p_{i,j}$ at the i -th row and j -th column. The detailed process of the gray projection based tongue rough localization is as follows:

1. Calculate average gray value of each image row, where the average gray value of i -th row is defined as

$$R(i) = \sum_{j=1}^N I(i, j). \quad (1)$$

Similarly, the average gray value of j -th column is defined as

$$C(j) = \sum_{i=1}^M I(i, j). \quad (2)$$

2. Find the row with the lowest R value among the front half of image rows, which can be formulated as

$$r_{up} = \min_{1 \leq i \leq M/2} R(i). \quad (3)$$

Similarly, the row with the lowest R value among the latter half of image rows can be determined as

$$r_{down} = \min_{M/2 < i \leq M} R(i). \quad (4)$$

3. Find the column with the lowest C value among the front half of image columns, which can be formulated as

$$c_{left} = \min_{1 \leq j \leq N/2} C(j). \quad (5)$$

Similarly, the column with the lowest C value among the latter half of image columns can be determined as

$$c_{right} = \min_{N/2 < j \leq N} C(j). \quad (6)$$

4. Use r_{up} , r_{down} , c_{left} and c_{right} to confine a rectangle region as the rough localization result of tongue body.

To intuitively show tongue rough localization results, we exhibit them as blue rectangles in original tongue images as shown in Figures 1 (b) and (d). After exploring the gray projection method, we found that it usually fails to obtain satisfactory result on those acquired original tongue images, but can obtain satisfactory result on those clipped tongue images. Figure 1 gives an example to explain the above conclusion, where Figures 1 (b) and (d) exhibit the rough localization results obtained by applying the gray projection method to an acquired original tongue image in Figure 1 (a) and its clipped version in Figure 1 (c), respectively. From Figure 1, one can observe that the gray projection method obtains satisfactory rough localization result on the clipped tongue image, but obtains unsatisfactory result on the original tongue

Figure 1. Rough localization results obtained by the gray projection method (Zhang, 2010): (a) original tongue image, (b) result of (a), (c) the clipped image of (a), (d) result of (c).

image. This demonstrates the limitation of the gray projection method on tongue rough localization.

3 THE PROPOSED METHOD

After exploring the gray projection method (Zhang, 2010), we found that it is invalid for acquired original tongue image as illustrated in Figure 1. To obtain satisfactory rough localization result, the method need clip original tongue image, which is time-consuming and inconvenient. To resolve this issue, we propose a modified rough localization method based on clustering and gray projection. The detailed rough localization process is as follows:

1. Color space transformation: this step maps an image in RGB color space into HSI color space, and the mapping is formulated as

$$H = \begin{cases} \theta, & G \geq B \\ \theta - 2\pi, & G < B \end{cases} \quad (7)$$

$$S = 1 - \frac{3}{R+G+B} \min\{R, G, B\}, \quad (8)$$

$$I = \frac{1}{3}(R+G+B), \quad (9)$$

where

$$\theta = \arccos\left\{ \frac{[(R-G)+(R-B)]/2}{[(R-G)^2+(R-B)(G-B)]^{1/2}} \right\}. \quad (10)$$

In Eqs. (7)–(10), R, G and B indicate the red, green and blue components of an image, respectively.

2. Thresholds determination based on clustering: this step uses a clustering scheme to seek three thresholds for subsequent image thresholding. Here, the H component of an image in HSI color space is used for clustering. Figure 2 (b) exhibits the H component of the used example in Figure 1 (a). In addition, the class number is empirically set to 3, and the three initial class centers are set to the minimum value, the median value and the maximum value of all image pixels' H values. The centers of three classes are updated iteratively until they are unchanged. At each iteration, we first classify each pixel's H value into one class according to the minimum absolute difference of H values, and then update each class center with the average H value of the class. After the clustering process on pixels' H values, we gather three final class centers into a set called T_{set} with ascending order.

3. Image thresholding and morphological operations: this step first uses the elements in T_{set} to conduct image thresholding, where the image thresholding result B_{img} is defined as

$$B_{img}(i, j) = \begin{cases} 1, & \text{if } Tset(1) < I(i, j) \text{ or } I(i, j) > Tset(3) \\ 0, & \text{otherwise} \end{cases} \quad (11)$$

where $T_{set}(i)$ denotes the i -th element in T_{set} . To further refine the thresholding result B_{img} as RB_{img} , we sequentially apply morphological operations (i.e., open operation and image filling operation) to B_{img} , where the structure element of the open operation is shown in Figure 2. Take the original tongue image used in Figure 1 (a) as an example, Figures 3 (c) and (d) exhibit initial image thresholding result B_{img} and the refined image thresholding result RB_{img} after the morphological operations, respectively.

0	0	1	1	1	1	1	0	0
0	1	1	1	1	1	1	1	0
1	1	1	1	1	1	1	1	1
1	1	1	1	1	1	1	1	1
1	1	1	1	1	1	1	1	1
1	1	1	1	1	1	1	1	1
1	1	1	1	1	1	1	1	1
0	1	1	1	1	1	1	1	0
0	0	1	1	1	1	1	0	0

Figure 2. Structure element of morphological open operation.

Figure 3. Tongue rough localization based on the proposed method: (a) original tongue image, (b) the H component in HSI color space, (c) image thresholding result of (b), (d) the refined image thresholding result after morphological operations, (e) the largest object region, (f) the remained object region after clipping operation according to row localization result, (g) the largest object region of (f), (h) final rough localization result.

4. Selection of object region: this step selects the largest object region (white region) in the refined image thresholding result RB_{img} as possible tongue body region, and records the largest object region in a binary image called O_{img} , where 1 and 0 denote object pixel and background pixel, respectively. Figure 2 (e) shows the image O_{img} , which is generated from Figure 2 (d).
5. Gray projection based row localization: this step first conducts row clipping by gray projection on those rows containing object (white) pixels in the binary image O_{img} , where we take the red component of an image in RGB color space for gray projection. In detail, we first calculate the average gray value of object pixels on those rows containing object pixels, and then find the row with the lowest average gray value among those image rows containing object pixels as the upper bound (r_{up}) of the rectangle located by the tongue body. In addition, we take the maximum row number of the object region in O_{img} as the down bound (r_{down}) of the rectangle located by the tongue body. Because we think that the tongue body should be located between the r_{up} -th row and the r_{down} -th row, we remove the object pixels on those rows out of the row range $[r_{up} r_{down}]$, i.e., setting corresponding object pixels' values in O_{img} as 0 s. Figure 3 (f) exhibits the remained object region after removing the object pixels on those rows out of $[r_{up} r_{down}]$.
6. Column localization based on the largest object region: this step first finds the largest object region in Fig. 3 (f), and then the left and the right bounds of the object region are determined as the left bound (c_{left}) and the right bound (c_{right}) of the rectangle located by tongue body.
7. Finish the tongue rough localization by using the row bounds (i.e., r_{up} and r_{down}) and the column bounds (i.e., c_{left} and c_{right}). To intuitively exhibit the rough localization result obtained by the proposed method, we use green rectangle to represent it in an original tongue image as shown in Figure 3 (h).

4 EXPERIMENTAL RESULTS

To evaluate the performance of the proposed method on tongue rough localization, we have applied it to a variety of tongue images with sizes of 640×480 . The rough localization results yielded by the proposed method were compared with those results obtained by the gray projection method (Zhang, 2010). To quantitatively measure the accuracy of tongue rough localization, we take the rectangle region obtained by each method as the object region in a binary segmentation result. In

this case, accuracy of rough localization can be quantitatively evaluated via Misclassification Error (ME) (Yasnoff, 1977) of the corresponding binary segmentation result. ME regards image segmentation as a pixel classification process. It reflects the percentage of background pixels incorrectly classified into foreground, and conversely, foreground pixels erroneously assigned to background. For a two-class segmentation, ME can be simply formulated as

$$ME = 1 - \frac{|B_o \cap B_T| + |F_o \cap F_T|}{|B_o| + |F_o|}, \quad (12)$$

where B_o and F_o are the background and foreground of the manual ideal segmentation result, B_T and F_T the background and foreground of the binary rough localization result, and $|\cdot|$ cardinality of a set. The value of ME varies between 0 for a perfectly classified image to 1 for a totally erroneously classified one. A lower value of ME means better accuracy of rough localization. All experiments were performed on a notebook PC with 1.7G Intel Core i5-3317U CPU and 4G RAM.

Our experiments are divided into four groups. Testing samples in the first group of experiments contain eight tongue images with large difference of tongue body size. The eight testing samples are shown in the first row of Figure 4, where the front four images have small tongue bodies, meanwhile the latter four images have large tongue bodies. The second row in Figure 4 exhibits manual segmentation results of tongue images, where tongue body contours are indicated by cyan curves. The third row in Figure 4 shows the rough localization results obtained by the gray projection method (Zhang, 2010), where the localization results are indicated by blue rectangles. The last row in Figure 4 exhibits the rough localization results obtained by the proposed method, where the localization results are indicated by green rectangles. From Figure 4, one can observe that the gray projection method can effectively find locations of tongue roots, but cannot correctly find locations of tongue tips and tongue bodies' left and right boundaries. Adversely, the proposed method successfully finds four boundaries of tongue bodies and obtains satisfactory rough localization results.

To further explore the performance of the proposed method on object rough localization of tongue images with large difference on tongue body's shape, color, coating and texture. Figure 5 exhibits visual rough localization results on eight tongue images with large tongue shape difference, where the front three images have square

Figure 4. Visual rough localization results of tongue images with large difference of tongue size from up to down: original images, manual segmentation results, localization results of the gray projection method (Zhang, 2010), localization results of the proposed method.

Figure 5. Visual rough localization results of tongue images with large difference of tongue shape from up to down: original images, manual segmentation results, localization results of the gray projection method (Zhang, 2010), localization results of the proposed method.

tongue bodies, the middle three images have flat tongue bodies, and the last two images have vertical tongue bodies. Figure 6 exhibits visual rough localization results on eight tongue images with large tongue color difference, where the front four images have tongue bodies with slight white color, and the latter four images have tongue bodies with deep red color. Figure 7 exhibits visual rough localization results on eight tongue images with strong tongue coating and texture, where the front four images have strong tongue coating, and the latter four images have strong texture. From Figures 5–7, one can observe that the proposed method successfully achieves object rough localization on the above tongue images with large difference on tongue shape, color, coating and texture of tongue body. However, the gray projection

method usually only finds the locations of tongue roots, and fails to successfully achieve tongue rough localization.

After performing the above qualitative comparison on tongue rough localization results, we further conduct quantitative comparison on four groups of tongue images. We used Misclassification Error (ME) to quantitatively evaluate those rough localization results. The average ME values corresponding to four groups of tongue images are listed in Table 1. From the table, one can conclude that the average ME value of the proposed method on each group is obviously lower than that of the gray projection method. This further demonstrates the advantage of the proposed method over the gray projection method.

1	0.482	0.067
2	0.442	0.063
3	0.419	0.067
4	0.414	0.070

5 CONCLUSIONS

Tongue image segmentation is a crucial step in developing automatic tongue diagnosis system. Rough localization of tongue body is a useful preprocessing step in tongue image segmentation. The existing rough localization method based on

gray projection fails to obtain satisfactory results on original tongue images. To resolve this issue, we presented a new method based on clustering in HSI color space and gray projection. Experimental results on a variety of tongue images with large difference on tongue size, shape, color, coating and texture shows the superiority of the proposed method over the existing gray projection method.

ABSTRACT: In order to satisfy the urgent needs of low-cost, high-performance measurement system for the attitude angle of the carrier, this paper presents a multi-sensor data fusion algorithm based on Direction Cosine Matrix (DCM). Aiming at the problem of inaccurate measurement of the attitude incurred by low-cost MEMS gyroscope drifting, the study constructs a multi-axis complementary filter, proposes reference vectors to detect gyroscope bias error in each axis and uses PI controller as feedback to compensate the drift error of gyros. Static experiment on a three-axis turntable shows that the static accuracy of the attitude angle is better than 0.2° , and dynamic vehicle experiment shows that the dynamic accuracy is better than 4° , meeting the application requirements of low-cost attitude determination system.

1 INTRODUCTION

As the first step to realize attitude control of the carrier, attitude measurement results play a crucial role in many navigation and control systems. The current trend towards miniaturization and real-time control has been fuelling research in the field of attitude measurement (Dong, 2016). The development of microelectronics gave birth to MEMS sensors, which possess the advantages of small size, low power consumption, and low cost (Robert, 2013). This made the realization of strap-down attitude angle determination system based on MEMS sensors feasible.

A variety of methods are adopted to get the three-dimensional attitude information for the strap-down attitude angle determination system. Some scholars use GPS carrier phase signals to determine the body's attitude (Park, 2004). This

kind of method does not accumulate errors over time; however, the installation of the antenna increases the complexity of the system (Gaygysyz, 2010). Some scholars have used images from the airborne camera to identify the horizon or sea-sky line. The roll angle and pitch angle of the aircraft can be measured quickly according to the obtained linear information (Mosavi, 2013; Hu, 2016; Ji, 2016). However, this method is limited in the complex terrain.

The mainstream method is an INS-aided system, and the key to this method lies in how to carry out data fusion. Typical data fusion algorithms can be roughly divided into two categories. One is from the frequency domain that distinguishes and eliminates noise, such as complementary filter (Vaibhav, 2014). The other is to use the state space method to design the filter in the time domain, such as Kalman Filter (KF), Extended Kalman

Filter (EKF), Unscented Kalman Filter (UKF), and so on (Stefano, 2010; Chingiz, 2016). As we know, Kalman filter is the optimal filter to estimate a linear system. However, many real-world systems are nonlinear in nature. EKF is developed to help account for these nonlinearities. The method is convenient to implement, and it can also meet the requirements of the application of nonlinear system in many cases. Using UKF, estimated accuracy and rate of convergence are apparently enhanced in comparison to EKF, but the problem of computational burden cannot be solved effectively with this method.

Research is currently being carried out in many laboratories for simple and effective filtering techniques that result in both linear and non-linear systems. A new method of multi-axis complementary filter based on Direction Cosine Matrix (DCM) is proposed in this paper. Experimental results show that the static accuracy of the attitude angle is better than 0.2° , and that the dynamic accuracy is better than 4° .

2 COORDINATE SYSTEM AND DCM-BASED ATTITUDE ALGORITHM

2.1 Definition of coordinate system

Geographical coordinate system is fixed to the inertial coordinate system and is linked to the Earth referential. The orthogonal axis of geographical coordinate frame is called North, East, Down (NED) frame, and the axes of x_n , y_n and z_n represent the axes of north, east and down, respectively, which satisfy the right-hand rule.

Body coordinate system is fixed to the airplane and represents a coordinate system that is attached to the carrier. The origin is the gravity centre of carrier; the x_b -axis points in the forward direction, and it is aligned with the roll axis; the z_b -axis (yaw) points to the bottom of the MIMU; and the y_b -axis (pitch) represents the direction of aircraft starboard. And rounds up the right-handed orthogonal coordinate system.

Figure 1 shows the relationship between the geographical coordinate system and the body coordinate system.

2.2 The direction cosine matrix

There are many ways to describe the orientation relation of the moving coordinate system with respect to the reference coordinate system, such as by using the Euler angle, the quaternion approaches and the DCM. Using the DCM to solve the attitude angle is more intuitive than the quaternion approaches, which provides the ability to work in the entire range of attitude angles (Chiemela, 2014).

Figure 1. Definition of a coordinate system.

The transformation from the body coordinate system to the geographical coordinate system can be realized by three times rotation. The relationship between the navigation coordinate system and the body coordinate system can be expressed by a matrix, that is, the DCM. As a result of the multiplication of three rotation matrices, each column of the DCM represents a coordinate system in another coordinate system. Therefore, DCM has two characteristics: orthogonal and unit.

2.3 Updating of DCM and extraction of attitude angle

Neglecting the influence of the earth self-rotation rate, the change of heading, pitch and roll angle tend to be zero when the time interval t tends to be infinity. The expression of DCM updating with time is as follows:

$$C_b^n(t+dt) = C_b^n(t) \begin{pmatrix} 1 & -d\psi & d\theta \\ d\psi & 1 & -d\phi \\ -d\theta & d\phi & 1 \end{pmatrix} \quad (1)$$

$$= C_b^n(t) \begin{pmatrix} 1 & -\omega_z dt & \omega_y dt \\ \omega_z dt & 1 & -\omega_x dt \\ -\omega_y dt & \omega_x dt & 1 \end{pmatrix} \quad (2)$$

The derivative of DCM is obtained as follows:

$$\dot{C}_b^n = C_b^n \Omega_b^b \quad (3)$$

$$\Omega_b^b = \begin{pmatrix} 0 & -\omega_z & \omega_y \\ \omega_z & 0 & -\omega_x \\ -\omega_y & \omega_x & 0 \end{pmatrix} \quad (4)$$

Ω_b^b represents the projection of the angular velocity of the body coordinate system with respect to the inertial coordinate system. ω_x , ω_y and ω_z represent the angular velocity of X, Y and Z axis in the body coordinate system, respectively.

ω_x , ω_y , and ω_z are measured by three gyro mounted on the carrier. The structured flowchart of DCM updating is shown in Figure 2.

By using the measured data of the gyroscope, the system realizes the real-time updating of DCM and also the real-time updating of attitude angle calculation. After getting the DCM, it is easy to deduce the expression of pitch angle, heading angle and roll angle:

$$\begin{aligned} \theta &= \arcsin(-C_{b31}^n) \\ \psi &= \arctan\left(\frac{C_{b21}^n}{C_{b11}^n}\right) \\ \phi &= \arctan\left(\frac{C_{b32}^n}{C_{b33}^n}\right) \end{aligned} \quad (5)$$

Yaw and roll angle have multiple values, and we need to judge the quadrant after working out the results. Due to space limitations, we have not provided a detailed description here.

3 COMPLEMENTARY FILTERING AND MULTI-SENSOR DATA FUSION

The attitude angles are obtained by integrating the angular rate of the gyro's output, which is accurate and reliable in short time. Due to the drift error of the MEMS gyroscope itself and the influence of various external noises, gyros and other sensors are often used in combination. The method of data fusion enables the system to provide accurate attitude information for a long time (Liu, 2014; Hu, 2016).

Figure 2. The flowchart of DCM updating.

Due to orthogonality and unit constraints, any pairs of rows or columns in the matrix are orthogonal to each other. However, owing to the accumulation of numerical rounding error, gyro drift and other reasons, the lengths of the matrix are not equal to each other in the process of constant updating of the DCM; therefore, the original orthogonal matrix is tilted, as shown in Figure 3.

Non-orthogonal change of the DCM is bound to affect the calculation accuracy of the attitude angle. The modification of the DCM is an urgent problem that needs to be solved in the process of obtaining the accurate attitude angle. It is known to us all that for the same set of vectors, with different coordinate systems, the mode and direction of the vectors must be the same. As mentioned earlier, there is a bias in the DCM. In this paper, we have modified the rotation matrix by calculating the deviation, and have further achieved the purpose of correcting the attitude angle.

In this study, we have selected two direction reference vectors. One is the vector of gravity field, measured by the accelerometer, and the other is the course vector, which is measured by the electronic magnetic compass. The gravity field vector is used to detect the deviation of pitch angle and roll angle, and the direction vector is used to detect the deviation of the heading angle. The direction reference vectors and the vectors obtained by the DCM are vectors of the same direction in theory. Their outer product is defined as the error vector we are seeking. The model value of the external product is directly proportional to the angle of the two vectors.

3.1 Calculation of pitch angle and roll angle error vector based on gravitational field

Set $[v_x, v_y, v_z]^T$ as the projection of gravity field $[0, 0, 1]^T$ under the body coordinate system. The following formula can be derived from the DCM:

Figure 3. Schematic diagram of DCM non-orthogonal change.

$$\begin{bmatrix} v_x \\ v_y \\ v_z \end{bmatrix} = \begin{bmatrix} \cos \theta \cos \psi & \cos \theta \sin \psi & -\sin \theta \\ \sin \phi \sin \theta \cos \psi - \cos \phi \sin \psi & \sin \phi \sin \theta \sin \psi + \cos \phi \cos \psi & \sin \phi \cos \theta \\ \cos \phi \sin \theta \cos \psi + \sin \phi \sin \psi & \cos \phi \sin \theta \sin \psi - \sin \phi \cos \psi & \cos \phi \cos \theta \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix} \quad (6)$$

$$\begin{bmatrix} v_x \\ v_y \\ v_z \end{bmatrix} = \begin{bmatrix} -\sin \theta \\ \sin \phi \cos \theta \\ \cos \phi \cos \theta \end{bmatrix} \quad (7) \quad a_{centrifugal} = \begin{pmatrix} 0 \\ \omega_z v_x \\ -\omega_y v_x \end{pmatrix} \quad (10)$$

$[v_x, v_y, v_z]^T$ obtained here is the projection of the gravity field in the body coordinate system, which are the direction reference vectors that we mentioned before. $[a_x^b, a_y^b, a_z^b]^T$ is the three axes force information measured by accelerometers under the body coordinate system. The main component is the projection of gravity in the three axes, which we set as $[g_x^b, g_y^b, g_z^b]^T$. However, due to the motion of the vehicle, the three axes force information also includes the motion acceleration and the centrifugal acceleration of the vehicle, which we set as $[v_x^b, v_y^b, v_z^b]^T$ and $a_{centrifugal}$, respectively.

Therefore, the projection of gravity in the three axes can be described by the following formula:

$$\begin{bmatrix} g_x^b \\ g_y^b \\ g_z^b \end{bmatrix} = \begin{bmatrix} a_x^b \\ a_y^b \\ a_z^b \end{bmatrix} - \begin{bmatrix} \dot{v}_x^b \\ \dot{v}_y^b \\ \dot{v}_z^b \end{bmatrix} - a_{centrifugal} \quad (8)$$

Among them, the calculation formula of the centrifugal acceleration is as follows:

$$a_{centrifugal} = \omega_{gyro} \times v = \begin{pmatrix} \omega_y v_z - \omega_z v_y \\ \omega_z v_x - \omega_x v_z \\ \omega_x v_y - \omega_y v_x \end{pmatrix} \quad (9)$$

$V = [v_x, v_y, v_z]^T$ is the velocity of the vehicle in the body coordinate system, which can be measured by the GPS receiver. V_x represents the forward direction speed of the carrier, which is much faster than the other two axes. Therefore, we think V_y, V_z approach zero. The expression of the centrifugal acceleration is as follows:

$$\begin{bmatrix} h_x \\ h_y \\ h_z \end{bmatrix} = \begin{bmatrix} \cos \theta \cos \psi & \sin \phi \sin \theta \cos \psi - \cos \phi \sin \psi & \cos \phi \sin \theta \cos \psi + \sin \phi \sin \psi \\ \cos \theta \sin \psi & \sin \phi \sin \theta \sin \psi + \cos \phi \cos \psi & \cos \phi \sin \theta \sin \psi - \sin \phi \cos \psi \\ -\sin \theta & \sin \phi \cos \theta & \cos \phi \cos \theta \end{bmatrix} \begin{bmatrix} m_x \\ m_y \\ m_z \end{bmatrix} \quad (13)$$

$[g_x^b, g_y^b, g_z^b]^T$ can be simplified as

$$\begin{bmatrix} g_x^b \\ g_y^b \\ g_z^b \end{bmatrix} = \begin{bmatrix} a_x^b \\ a_y^b \\ a_z^b \end{bmatrix} - \begin{bmatrix} \dot{v}_x^b \\ \omega_z v_x \\ -\omega_y v_x \end{bmatrix} \quad (11)$$

Therefore, the error vector used to modify the pitch angle and the roll angle can be calculated by the outer product of $[v_x, v_y, v_z]^T$ and $[g_x^b, g_y^b, g_z^b]^T$. We set this error vector as $error_{pitch,roll}$. The expression of $error_{pitch,roll}$ is as follows:

$$error_{pitch,roll} = \begin{bmatrix} v_x \\ v_y \\ v_z \end{bmatrix} \times \begin{bmatrix} g_x^b \\ g_y^b \\ g_z^b \end{bmatrix} \quad (12)$$

3.2 Calculation of heading angle error vector based on geomagnetic field

Magnetoresistive sensor is used for heading angle measurement. By measuring the horizontal component of the geomagnetic field, we can calculate the angle between the carrier and the magnetic north pole. When the magnetic resistance sensor is installed, the three sensitive axes of the magnetoresistive sensor become coincident with the body coordinate system.

The magnetic field of the x axis is b_x , and the magnetic field of the z axis is b_z . Similar to the method of using the gravity field as the reference vector to compensate the accelerometer, we select the theoretical value of the magnetoresistive sensor as the reference vector, which can be described as $[b_x \ 0 \ b_z]^T$. Now, we calculate the error vector to correct the heading angle.

Through the DCM, the output of the magnetoresistive sensor in the body coordinate system can be converted to the horizontal coordinate system. The conversion process is as follows:

In the formula, $[m_x, m_y, m_z]^T$ represents the output of the magnetoresistive sensor in the body coordinate system. The value of the vector modulus measured by the magnetoresistive sensor must be the same in the XOZ plane in the body coordinate system. Therefore, the following formula can be deduced:

$$b_x = \sqrt{(h_x^2 + h_y^2)} \quad (14)$$

The two methods get the same size of the vector in the Z-axis, so we get an equation: $b_z = h_z$. Now, we obtain the theoretical value of the magnetoresistive sensor in the navigation coordinate system, that is $[b_x \ 0 \ b_z]^T$. We use this vector to deduce backward to obtain the output of the magnetoresistive sensor in the navigation coordinate system, and we get the following vector $[m_{bx}, m_{by}, m_{bz}]^T$. The deduction process is as follows:

$$\begin{bmatrix} m_{bx} \\ m_{by} \\ m_{bz} \end{bmatrix} = C_n^b \begin{bmatrix} b_x \\ 0 \\ b_z \end{bmatrix} \quad (15)$$

At this point, the error vector used to correct heading angle can be obtained from the outer product of $[m_x, m_y, m_z]^T$ and $[m_{bx}, m_{by}, m_{bz}]^T$. We name this error vector as $error_{yaw}$, and its expression is as follows:

$$error_{yaw} = \begin{bmatrix} m_x \\ m_y \\ m_z \end{bmatrix} \times \begin{bmatrix} m_{bx} \\ m_{by} \\ m_{bz} \end{bmatrix} \quad (16)$$

In summary, we set the total error vector as $e = [e_x, e_y, e_z]^T$, which can be obtained by the following formula:

$$e = error_{pitch,roll} + error_{yaw} \quad (17)$$

3.3 Fusion strategy based on explicit complementary filter

Gyroscopes have an outstanding performance in dynamic response characteristics, but accumulate errors with time. Accelerometer and magnetoresistive sensors have no accumulated errors, but have disadvantages of poor dynamic response (Sousa, 2009). Therefore, they complement each other in the frequency domain. Due to the slow drift of the gyro, the noise has mainly low frequency, and the accelerometer noise mainly exists in the high-frequency band. The complementary filter can effectively filter out the interference of low-frequency and high-

frequency noise, and get close to the true value of the reconstructed signal (Roberto, 2016).

We constructed a multi-axis complementary filter, proposed a reference vector to detect gyroscope bias error in each axis and used PI controller as feedback to compensate the drift error. Our test system uses four kinds of sensors, including gyroscope, accelerometer, magnetic sensor and GPS receiver. As the accelerometer cannot interpret the difference between motion acceleration and acceleration of gravity, we had to use GPS to get the speed and then the acceleration of motion. The acceleration of motion is subtracted from the acceleration measured by the accelerometer, and the induction of the gravity field is obtained. The error vector is used as the input of the filter, and the corrected value of the gyroscope is the output of the filter. The structure of the multi-axis complementary filter fusion algorithm is shown in Figure 4.

The input error vector is $e = [e_x, e_y, e_z]^T$. The output of the system after PI adjustment can be expressed as follows:

$$u(k) = K_p e(k) + K_i \sum_{j=0}^k e(j) \quad (18)$$

The expression of the gyro angular rate ω after the correction is

$$\omega = \omega_g + Ku(k) \quad (19)$$

where ω_g is the angular rate measured by the gyroscope; K_p is the proportional coefficient; K_i is the integral coefficient; K is the new coefficient of the system after data fusion. In $K = 2\pi f t_s$, f is the cut-off frequency of the system, and t_s is the sampling period. The appropriate choice of filter parameters is equivalent to determining the cut-off frequency of the filter. Low cut-off frequency setting leads to relying on the gyro slightly more. High cut-off frequency setting leads to depending on the accelerometer and the magnetoresistive

Figure 4. The structure of the multi-axis complementary filter fusion algorithm.

sensor slightly more. Due to the influence of vibration and other factors, the high frequency noise interference is more in the practical application. Complementary filter cut-off frequency should select a smaller value in a reasonable range. Specific parameters need to be determined according to the level of noise in the actual application.

4 EXPERIMENTS AND RESULTS

In order to verify the effectiveness of the proposed method, this paper set up static and dynamic experiments.

4.1 Static experiment on a three-axis turntable

In order to obtain the attitude angle calculation accuracy of the attitude determine system at different positions, we set up the static experiment and compared the results between ECF algorithm and turntable feedback data.

The static experiment on a three-axis turntable was to verify the attitude angle calculation accuracy under the static condition. In order to increase the number of experiment samples and make the experiment more convincing, we used the high precision three-axis turntable as a static experiment platform. By setting the program, we controlled the rotation of the turntable and made it stable at different locations. The experimental system collected the data from the sensor at different angles under the static condition. The real-time feedback angle of three-axis turntable was used as the reference value. The accuracy and reliability of the algorithm were verified by comparing the attitude angle obtained by the proposed algorithm with the reference value.

The hardware system used in the experiment is an invention of our research group. Each axis is equipped with a gyroscope, an accelerometer and a geomagnetic sensor, and all the three are MEMS devices. A single antenna GPS receiver module is also integrated in the system. In order to facilitate the outdoor experiment record data, the system integrates the 8 GB chip data storage. The physical diagram of the static experiment is shown below.

The experimental steps of the static experiment are as follows:

1. Turn on the turntable, power on the experiment system and make its pitch angle at the following position:
0°, 30°, 45°, 60°, 75°, 0°, -30°, -60°, 0°
2. Make the three-axis of the turntable return to zero position, subsequently;
3. Make its roll angle at the following position:
0°, 30°, 45°, 60°, 75°, 0°, -30°, -60°, 0°

Figure 5. Static experiment on a three-axis turntable.

4. Get the feedback data of turntable and calculation results of the experiment system.

The magnetoresistive sensor could be largely affected owing to the iron material of the turntable; therefore, no heading angle test was carried out. Comparing the feedback angle of the turntable with the result from the attitude algorithm based on the ECF algorithm, we could obtain the following experiment result.

According to the military standard GJB 729-1989, attitude angle accuracy assessment standards of the static experiment are as follows:

$$RMS = \sqrt{\frac{1}{n} \sum_{i=1}^n \frac{1}{m_i} \sum_{j=1}^{m_i} \Delta E_{i,j}^2} \quad (20)$$

$\Delta E_{i,j}$ stands for the attitude angle error of number j sampling time during number i experiment. m_i stands for data sampling points of the number i experiment. n is the number of the effective experiments. From the above formula, attitude angle calculation accuracy under the static condition can be calculated such that RMS_{pitch} is 0.1648° and RMS_{roll} is 0.1059°. From the experimental results, it can be seen that when the carrier is placed in a stable position, the attitude angle calculation accuracy is high, and the attitude angle error is less than 0.2°.

4.2 Dynamic vehicle experiment

In order to verify the calculation accuracy of attitude angle under dynamic conditions and the heading angle accuracy, which is not verified in the static experiment, we proposed a dynamic vehicle experiment. Our test system and the high-precision inertial navigation system (considered as reference) were installed side by side on the test

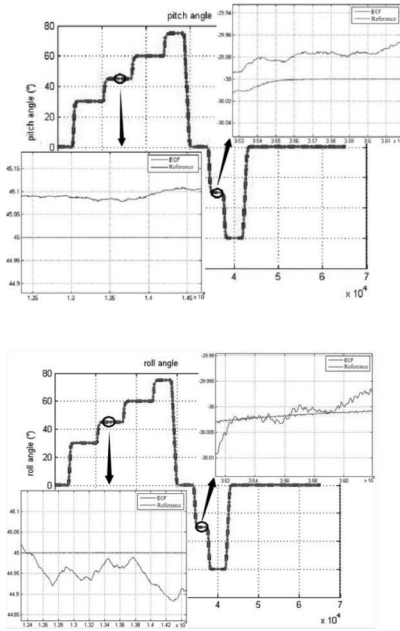

Figure 6. Experimental result of the static experiment.

Figure 7. Test platform of the dynamic vehicle experiment.

platform, which was connected with the car body. The motion information of the vehicle body was collected by the two systems at the same time, and the test time was about 180 seconds. The test platform of the dynamic vehicle experiment is shown in Figure 7.

The output of attitude angle from our test system was compared with that from the high-precision inertial navigation system, and the results are shown in Figure 8.

It can be seen from Figure 8 that the attitude angle deviation due to the gyro drift is evidently reduced. Under the dynamic environment of vehicle experiment, the attitude angle obtained by the proposed ECF algorithm is highly consist-

(a) Heading angle

(b) Roll angle

(c) Pitch angle

(a) Heading angle error

(b) Roll angle error

(c) Pitch angle error

Figure 9. Attitude angle error curve.

ent with the attitude information provided by the high-precision inertial navigation system. The new algorithm has the performance of real-time tracking of dynamic changes.

From Figure 9, it can be seen that the heading angle error is the largest in the three-axis attitude angle error, reaching 4° . This is because the determination of heading angle requires geomagnetic sensor, and the sensor itself is vulnerable to interference. Fortunately, after using the proposed ECF algorithm, the heading angle error divergence is suppressed, and the error value becomes stable.

Roll angle error and pitch angle error are relatively small. Roll angle error is less than 2.3° , and the pitch angle error is less than 3.1° . The error curve has no tendency to diffuse. From the above experimental data, the RMSE of heading angle, roll angle and pitch angle can be calculated, and the values are 3.2682° , 1.3257° , and 1.5954° , respectively.

5 CONCLUSION

In this paper, a new complementary filter algorithm for the attitude angle based on DCM is proposed. In this method, we constructed a multi-axis complementary filter, proposed reference vectors to detect gyroscope bias error in each axis and used PI controller as feedback to compensate the drift error of gyros. The proposed algorithm was tested through three-axis turntable and actual vehicle experiment. The experiment result showed that the static accuracy of the attitude angle is better than 0.2° , and the dynamic accuracy is better than 4° , satisfying the application requirements of low-cost attitude determination system.

ABSTRACT: Personalized information service has become an inevitable trend with the development of the current information technology. Aiming at the defects of today's personalized information service as well as the growing requirement of personalized information, a personalized information push service model based on context awareness has been put forward in this paper. In this model, Internet of things and context awareness have been used to build a context information acquisition environment and to gather the context information of users. Furthermore, a user-personalized interest model has been constructed and combined with the spatio-temporal correlation to catch the relationship among the user groups, so that an information push mechanism based on spatio-temporal correlation can be achieved. Our method provides a more efficient and precise information push service.

1 INTRODUCTION

With the user at the core, the personalized information service is devoted to push more effective and pointed personalized information service to the user by studying some context information such as the user's behavior, environment, and emotions. This makes it possible to obtain the user's demand information automatically and decrease the user's search decision. Personalized information service needs to provide for real time and individual demands of the users and fulfill their personalized needs, which means that the service should possess the characteristic of self-adaptability. With the conventional information push technology, the user demands are maintained stably, but lack individuation, real time, and renewability; therefore, the traditional methods of catching user message are no longer in use. With the boom of the Internet Of Things (IOT), any information that is linked to the user's conduct, target, or the surrounding environment is all considered as an item that has some interactive relation with the user and the pervasive computing environment; thus, combining the context data with the user's behavior would be a great way to figure out the user's interest preference. Using the IOT technology to gain relative context information and considering a user's behavior on

the Internet, we can learn about the interests of the user more comprehensively, and then be able to offer personalized information service to the user independently.

The context awareness technology is derived from the context calculation; therefore, the "context" also inherits the advantage of "who, when, where, what" of pervasive computing. Recently, context information has been deemed as the foremost part of the Recommendation and push System (RS) (Feng, 2014). The traditional information push mined user information through the Internet and pushed the information after completing its analysis and processing. With the dramatic development of the IOT, letting the context information join the conventional two-dimensional push system "user-item" and building a three-dimensional push system based on the form of "user-item-context" has already become a mainstream trend of information push service. JinHai Feng proposed using indoor positioning technology to track user activity in the market, in line with the historical information that is recorded, which contains information about where the user came from and what commodities the user browsed to estimate the user's hobbies and favorites, and then accurately recommending goods to the user that they might be interested in (Wang, 2012). LiCai Wang

has been trying to judge whether the requirements of mobile users would suffer from the context by computing the volatility of mobile users' behavior that is under constraint of the context, and to make sure of the extent of the influence by making use of the volatility (Gong, 2011). Combining mobile Internet and QRCode, XinWen Gong designed a mobile learning platform based on context awareness, in which the known context information of the users can be used as an important reference to provide the corresponding learning content (Li, 2012). Based on context awareness technology, XiaoYan Li established three application scenarios to provide shopping reminders for users automatically by combining user opinion with the context to mine users' shopping decisions and underlying demands and accordingly sending shopping reminders to the users automatically (Adomavicius, 2005). Champiri and his coworkers hold the view that there are three conditions of context information: user context, file context, and environment background. They also emphasized combining the concept of context with user opinion to make academic recommendations in the academic field; therefore, a digital library recommendation system based on context awareness has been designed and implemented effectively (Baltrunas, 2011). Gavalas and Kenteris used context information such as the current location, time, and condition to extend collaborative filtering technology and provide corresponding mobile travel guidance according to the user's mobile device (Gavalas, 2011).

Based on the influence and function of context awareness in the process of personalized information push, with the IOT as a basic technology to collect and handle the context information, a personalized information push service model based on the context awareness has been proposed in this paper. In addition, the spatio-temporal correlation semantics technology has been added to the procedure of information push in order to push more delicate information. The rest of the paper is composed of the following: the personalized information push model framework has been constructed in section 2; the user personalized interest has been described and presented in section 3; in section 4, the information push mechanism based on spatio-temporal correlation has been proposed; and finally, the conclusions have been drawn.

2 THE CONSTRUCTION OF PERSONALIZED INFORMATION PUSH MODEL

Personalized information push uses context awareness as the main way to capture user behavior. According to the user interest and preference, a

user model can be constructed. By matching the context information and user interest, the information that users want can be pushed to the users, by which we can provide adaptive adjustment according to user feedback, thus achieving a personalized information push. Hence, a personalized information push system mainly includes the capturing and handling of context information, the user interest modeling and information push. The framework of the personalized information push model based on context awareness is as shown in Figure 1.

The sensing layer of the whole framework of information push mainly captures information, including explicit and implicit information. The data layer organizes and manages the captured data information and builds user interest model with the data information stored orderly. The transport layer conducts information match of the newly captured information and user model. Lastly, the application layer combines time and space relation with similar user interest to push correlated information to the users. The work process of information push system is as following: firstly, get context information (environment information, user message) through the wireless sensor; use context-aware computing and mining technology to catch user interest and similar users; build database to store user information and data information (real-time information and history information); then build the context model to mine different users or the preference attributes of different conditions for the same users, by building the match rules, proposing the favor of users, extracting the information that matched with the users, and sending it to them; and finally, get user feedback across the context and make some adjustments and optimizations.

3 THE DESCRIPTION AND REPRESENTATION OF PERSONALIZED USER INTEREST

3.1 *User interest modeling based on context awareness*

With the foundation of research groups' prior results, a user interest model based on context awareness has been constructed in the paper, as shown in Figure 2. The construction of this model mainly includes four parts: information retrieval, information processing, model building, and model matching. Data flow is captured by context awareness and mining of network data. Here, the information is divided into explicit information and implicit information. By adaptive adjustment of the weight of the two kinds of information, interest tags that match with the information through

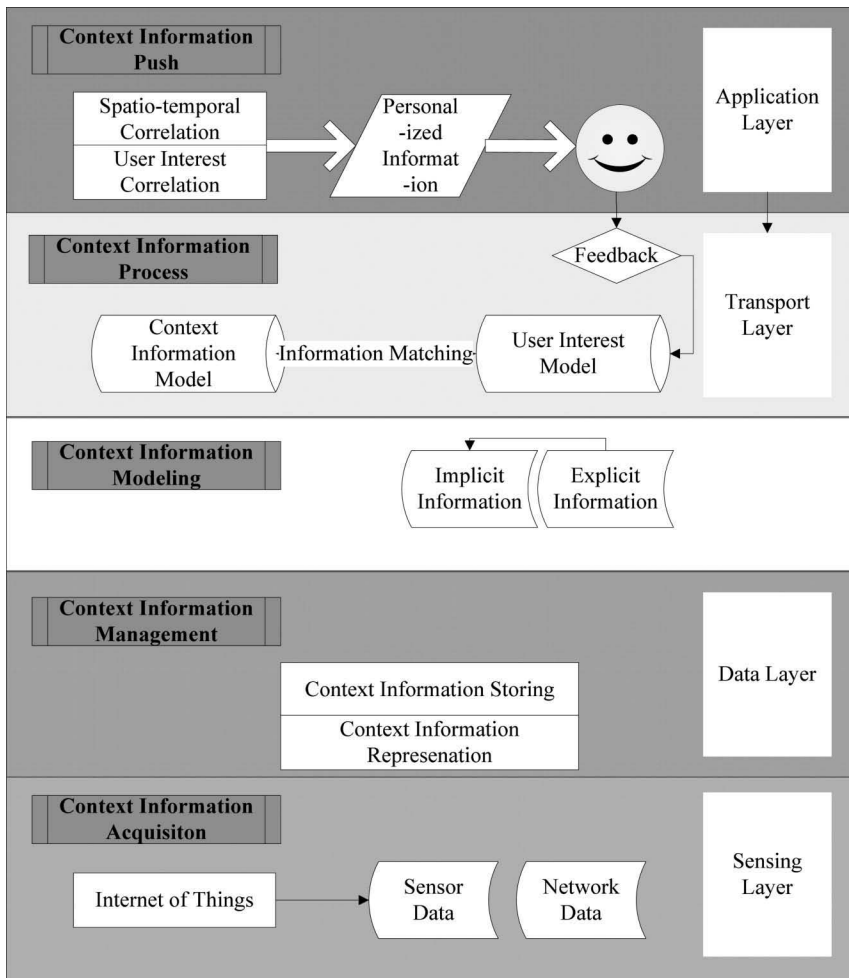

Figure 1. The personalized information push framework based on context awareness.

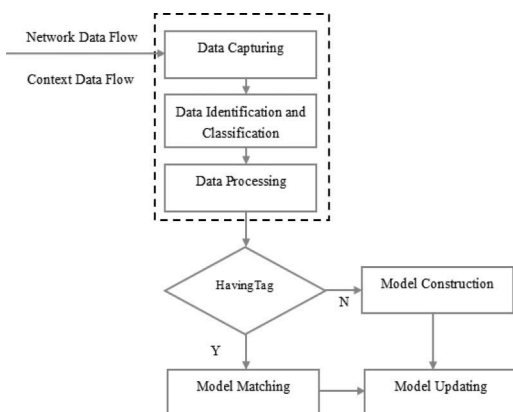

Figure 2. M-C-W user interest model based on context.

similar algorithms are found, and the users are judged with or without the model according to the user tags. If the model fails in case of interest information while finding out the matched interest tags, it will build the user interest model directly; otherwise, it will update the original user model when successful. The process of constructing user context interest model is shown in Figure 2 (Ge, 2016).

3.2 The representation of the user interest model

The context information captured by the sensor is modeled in an angle of “user-item-context”, which contains the user’s context, behavior, and item, and is expressed in the form of recorded data. The expression form can be summarized as: *context*

(*user, condition, location*). In this formula, context means the perceptive context information in the system; user means the user object; condition means the current situation of the user; and location means the current location of the user.

The user interest can be expressed as follows (1):

$$M_i = f(U_i, C_i, W_i) \tag{1}$$

where M_i is the user interest model; U_i is the object of the user; C_i is the context information of the user; and W_i is the degree of user interest.

4 THE INFORMATION PUSH MECHANISM BASED ON SPATIO-TEMPORAL CORRELATION

The IOT environment comprises certain kind of temporal and spatial correlation among things and humans. As time goes by, the number and the relation of things changes as well. For instance, effectiveness of space is a necessary characteristic of IOT data, and it is also a valuable property when considering the relation among people; people and things; and things. In order to understand the user interest better, we can carry out comprehensive calculation in the user model about the information of adjacent users and similar items; collect the users that have the same behavior; put them in one set based on the temporal and spatial similarity; and then push the spatio-temporal correlation information.

4.1 User context information acquisition based on spatio-temporal correlation

The context properties are divided into three classes: time, location, and relation. The acquisition of mobile user information is mainly done via tracking and learning about the user preference information and conducting the correlation calculation of user information by considering different properties. In terms of the angle of “user-item-context”, it needs to get the context of users, task, and environment and combine them to get the information push, as shown in Figure 3.

For example, a smart library and museum has a vital significance for acquiring the relation among the users according to the same location and reading time. Time and place is the temporal and spatial definition about the affairs the user’s joined or implemented item; therefore, we mainly use the spatio-temporal correlation of context environment to catch user environment context and to combine, link, and match the user context, task, and environment, in order to obtain the similar

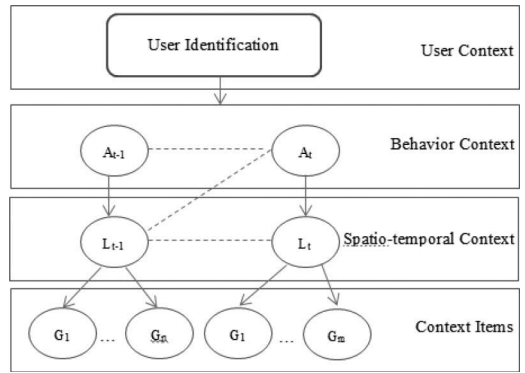

Figure 3. User context information acquisition based on spatio-temporal correlation.

user groups by the combination of time and space situations and to push the collaborative information at the end. The collaborative push based on spatio-temporal correlation mainly fulfills the similarity between time and space and promotes the adaptive matching of situation between the needs of users and the push services of system.

4.2 User interest similarity criterion based on spatio-temporal correlation

4.2.1 Spatio-temporal similarity calculation

User interest change should be described from the perspective of change of space, time, and property, in which the change of state, space, and interest property of users within different periods are included. In the semantic net, spatio-temporal semantics is deemed as the common repression of time semantics, space semantics, and property semantics. We use a relationship like “user-item-context” to display the interest of spatio-temporal correlation. Among the user objects that have similar interests exists certain special space and time links. In the link of spatio-temporal correlation, users have a special space and time correlation emphasizing the relation of time at which the affairs occurred; the qualitative relation is shown in Figure 4.

It is assumed that the data range of temporal and spatial similarity is between 0 and 1, where 0 means totally unrelated in time-space, and 1 means related perfectly. Therefore, the spatio-temporal similarity criterion under the influence of the space and time is equal. Except the time relation, the spatio-temporal correlation also emphasizes space relation and spatial timeliness. For example, when the space similarity is in the state of 0, and even the time similarity is 1, the state of space similarity would also be 0, which means that they are still dissimilar in terms of time-space character.

Figure 4. The space and time relationship of user interest.

Some corresponding relations exist among time, place, and property. The occurrence of a behavior property must occur in a special period of time and space. In spatio-temporal correlation, user A 's state of interest in time T and space P would be similar to user B 's interest at a similar time T or a similar space location P .

Let's suppose that M is a collection of property, where $M = \{m_1, m_2, \dots, m_n\}$; T is a collection of time, where $T = \{t_1, t_2, \dots, t_n\}$. t is regarded as a point in time or a period of time; m_n and t_n can't be empty, and t is the only number, which means that the occurrence of property must be in a mere period of time, but a point in time or a period of time has many properties. The relation between property and time, and property and place is both $n:1$, and $1:1$ is the relation between time and space. Therefore, we can make sure of one user's property with time and place.

The similarity measure of time-space series should contain spatial similarity measurement and time series similarity measurement. The object distance of spatial point can be measured in many ways. In this paper, we use the Euclidean Distance of two-dimensional space computing, for two points $P_i (X_{i1}, X_{i2}, \dots, X_{in})$ and $P_j (X_{j1}, X_{j2}, \dots, X_{jn})$ in R^n . The general form of generalized distance is as follows (2):

$$d_n(p_i, p_j) = \left[\sum_{k=1}^n (x_{ik} - x_{jk})^n \right]^{1/n} \quad (2)$$

The space object is usually expressed in the two-dimensional or three-dimensional geographic spaces; therefore, n is always 1, 2, 3. We mainly think about the two-dimensional space, using Euclidean Distance to carry out the spatial similarity calculation.

When $n = 2$, it is shown as follows (3):

$$d_{ij} = \left[\sum_{k=1}^n (x_{ik} - x_{jk})^2 \right]^{1/2} \quad (3)$$

To express the close relationship between the distances more directly, we use similarity factor to measure the level of similarity of variables, to get the degree of correlation between the spaces, in which the distance variable needs to be transformed as shown below:

$$sim(p_i, p_j) = \frac{1}{1 + d(p_i, p_j)} \quad (4)$$

The time correlation measurement is based on the linear correlation coefficient of time series; it is carried out by calculating within the same period of time and conducting similarity computation of two equal length time series. Assuming that u and v are two time series of the same length; the correlation coefficient between u and v can be described as follows (5):

$$\rho(u, v) = \frac{\sum_{i=1}^n (u_i - \bar{u})(v_i - \bar{v})}{\sqrt{\sum_{i=1}^n (u_i - \bar{u})^2} \sqrt{\sum_{i=1}^n (v_i - \bar{v})^2}} \quad (5)$$

In this formula, n represents the length of time-space series. The values of $\rho(u, v)$ range from $[-1, 1]$, in which $\rho(u, v) > 0$ means positive correlation, while $\rho(u, v) < 0$ means a negative correlation, and the absolute value of $\rho(u, v)$ refers to the level of the degree of correlation. When $\rho(u, v) = 1$, it means a completely positive correlation, which shows that there is an evident relation between the two series, whereas $\rho(u, v) = 0$ means a totally negative correlation, which means that there is no relation between the two series.

To measure the degree of temporal and spatial similarity, we need to calculate time similarity and space similarity separately. If the time-space possesses similarity, then we judge the relation between users through temporal and spatial similarity, and then judge the interest relation between users by capturing the users' time-space interest through the user group.

4.2.2 Spatio-temporal correlation calculation

Due to the advantage of probabilistic method in memory requirements that can judge the interest relation between users, we used the Bayesian method for the calculation. On getting the conclusions, Bayesian computation should consider not only the current observed sample information, but also the past experience and knowledge reasoned. Provided that every temporal and spatial characteristic property is conditionally independent, the deduction based on Bayesian computation is as follows (6):

$$P(y_i | x) = \frac{P(x | y_i)P(y_i)}{P(x)} \quad (6)$$

The denominator is constant for all categories; therefore, it is only necessary to maximize the molecular. Meanwhile, the attributes are independent of the conditions, and thus the computing is according to the following formula (7):

$$P(y_i | x) = \frac{P(y_i) \prod_{j=1}^m P(x | y_j)}{P(x)} \quad (7)$$

In formula (7), $P(y_i | x)/p(x)$ is called “probability function”. As an adjustment factor, it makes the estimated probability closer to the real probability. First, it estimates a prior probability, and then it combines the experimental results to observe if the experiment enhances the prior probability, so that we can get the posterior probability that is close to reality. Here, when $P(y_i | x)/p(x) > 1$, it means that the prior probability is enhanced, the possibility of occurrence of event y becomes bigger, and user has more interest in y . When the probability function is 1, the occurrence of affair x does not judge the possibility of A . If the probability function is less than 1, it means that the prior probability is weakened, and the probability of event A becomes small (Shang, 2012).

To judge the spatio-temporal correlation, we need to judge the influence relation between the time property and space property. Here, we set event properties to be $Ei(l, t_i)$. It can be expressed by spatio-temporal correlation as follows (8):

$$P(t_i | l) = \frac{P(l) \prod_{i=1}^m P(l | t_i)}{P(t_i)} \quad (8)$$

In the model of personal interest, there is an important relationship among the interest, behavior, and score of users. In the environment of context, user interest always has vital relation with time and space, because the time-space relation between the user and himself is always 1:1, whereas the relation between time and space is $n:m$; therefore, when judging the user interest in a certain time and space, we need to judge the time-space relation of ourselves. If the relationship between time and space is related to a certain time and space, we need to judge the possibility of $P(t_i | l)$, if the time or time period that occurs when an event occurs in the L space does exist.

4.3 The information push mechanism based on spatio-temporal correlation

Starting with the angle of “user-item-context”, we can conduct information push by combining the background of time-space, the users, and

the project. The information push mechanism is shown in Figure 5. Known from the relation of time-space, if user A and B have a similar relation in time and space, it can be inferred that user A and user B have similar spatio-temporal relationships; therefore, they might have similar interests, and then we can consider pushing the interest of user A to user B .

When judging the spatio-temporal correlation of user groups, if similarity relation in time and space exists, then it is thought that this user has a similar relation with others, and a similar interest push can be made, combined with the spatio-temporal relationship in order to determine the user’s personal interest model. If the level of spatio-temporal correlation is high, we can get user interest tags from the user interest model to push the information. Its approximate process is shown in Figure 6.

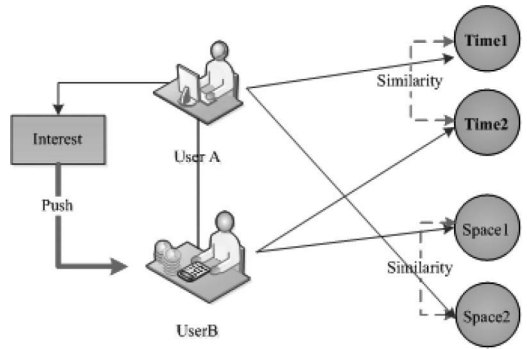

Figure 5. User interest criterion based on spatio-temporal correlation.

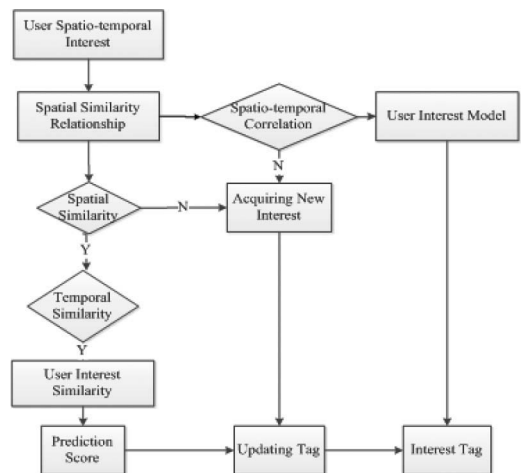

Figure 6. User information push mechanism based on spatio-temporal correlation.

5 CONCLUSIONS

The context awareness technology has the ability to percept user needs in an intelligent and invisible manner. It can reduce the interaction and participation of users and capture their personalized interest smartly. Traditional information push can no longer satisfy user commands consistently, in real-time, and with personalization. Combining the technology of context awareness and information push, a personalized information push model based on context awareness and spatio-temporal correlation was proposed in this paper, in which spatio-temporal correlation was considered to build a new information push method, in order to realize the combination of intelligent input and output, and then to provide a true meaning of personalized information push service. In the future work, we will apply the model to a digital ethnography museum to validate the efficiency further.

Design of a new in-flight entertainment terminal

Hairong Xu, Hong Zhou & Hui Yang

College of Air Transportation, Shanghai University of Engineering Science, Shanghai, China

ABSTRACT: A new design of In-Flight Entertainment terminal is presented in this paper. Qualcomm's quad-core processor APQ8016 is used as an application processor to process multimedia, games, and applications. This design integrates advanced OLED display technology and intelligent detection technology. The new terminal will provide passengers with more intelligent and personalized service through the Android operating system and big data analysis technology. It will be more intelligent and greatly reduce power consumption.

1 INTRODUCTION

In-Flight Entertainment (IFE) system is an important component of civil aircraft cabin systems and an important way to improve the quality of service. It connects to cabin communication system through wired or wireless connection. It can achieve cabin announcements and entertainment services. The basic idea behind the IFE system is to provide passengers with comfort during long flights; therefore, these services were initially based on delivering food and beverages to passengers. As passengers' demand for services increased, accompanied with an increase in airlines competition and technology advancement, more services were introduced, and modern electronic devices began playing a remarkable role in the same. This caused a change in the basic concept behind the IFE system. It became more than just delivering physical comfort and providing food. It has been extended to provide interactive services that allow passengers to participate as a part of the entertainment process as well as providing business-oriented services through connectivity tools. Moreover, it can provide means of health monitoring and physiological comfort.

Flight entertainment began before the First World War by the Graf Zeppelin. Starting from 1960, IFE system began to attract attention; it was basically a pre-selected audio track that could be accompanied with a film projector. The IFE system was gradually developed into a powerful system. Cabin telephones allowed passengers to make phone calls during the flight. The system became interactive and allowed passengers to select their own services, while in the past, passengers had to follow fixed services. Web-based internet services allow passengers to use some services such as

emails and SMS messaging. IFE's data transmission system has been gradually upgraded from the analogue mode to the digital mode (Kang, 2012). The IFE system consists of a server, the passenger terminal, and the network. Passenger terminal includes a multimedia processing circuit board, display panel, and passenger control unit. It is connected to the server by wired or wireless connection, and the server provides audios, videos, games, and advertisements to the passengers.

A new design of passenger terminal system is presented in this paper. In this design, powerful hardware will meet all kinds of requirements of the passengers. The software system will provide various services and applications to facilitate passengers' travel experience through advanced operating system. With big data analytics, airline companies can analyze a mix of complex datasets from various sources in order to gain important insights into customer behavior and use such feedback to provide better customer service. This design can push personalized media, games, and advertisements to the terminal from an on-board server according to various passengers' demands.

In the new design, passenger terminal system will integrate cutting edge technology of electronics, communications, computers, and big data analysis. These advanced technologies will provide more personalized service and increase the economic benefits of the airline companies. Passenger terminal system will place more emphasis on the comfort of the seats because the passengers spend most of their travel time in their seats. Audios and videos will be saved in local storage instead of the server, which will reduce the dependence on the server and the network (Akl, 2011).

2 HARDWARE DESIGN OF THE SYSTEM

Terminal system of the IFE system has a monitor, a circuit board, buttons, a touch panel, and accessories such as a headset. A typical terminal uses LCD or CRT as the display device, which has a big size and high power consumption. The central processor in the traditional terminal is not powerful enough to run certain games. Buttons and touch panel are used as the input, which are installed behind the backrest or installed on the roof of the cabin.

In the new design, each terminal is an independent information carrier and multimedia processing unit. Large-capacity data storage in the terminal can store various games, movies, and applications. The central processor can handle various applications and games. The terminal can retrieve content from the server and update passenger's data to the server through wired or wireless connection (Alamdari, 1999).

The new design uses a powerful multimedia processing chip APQ8016 (Qualcomm's processor) to handle audios, videos, and games. High-resolution Organic Light-Emitting Diode (OLED) display panel is used as the display device, and a capacitive touch screen is used as an input device. Passengers can play games with joystick connected to the USB host connector. The terminal has data acquisition interface to connect to the seat belt sensor system and passengers' health sensor system (Z, 2016). It can automatically acquire real-time data and send it to the server. This kind of data can also be saved in local massive storage. The new terminal is more intelligent and powerful compared to the traditional device. The hardware design block diagram is shown in Figure 1.

2.1 CPU subsystem design

The CPU subsystem is the core of the entire hardware system. It is made up of application processor, power management chip, and memory chip. Qualcomm Snapdragon 410 processor APQ8016

is used as the multimedia processor. APQ8016 has quad 64-bit ARM Cortex-A53 MPcore Harward Superscalar core, LP-DDR2 / LP-DDR3 SDRAM interface, Hexagon QDSP6, 13.5 MP camera support, 400 MHz Adreno 306 GPU, 1080p video encode/decode, gpsOneGen 8 A with GLONASS, Bluetooth 4.0, OpenGL ES 3.0, DirectX, OpenCL, Renderscript Compute, and FlexRender support. APQ8016 can support a variety of multimedia applications and game applications.

The PM8916 mixed-signal HV-CMOS device is used as a power management chip. It has 20 low dropout linear regulators, which can power external devices. System power on and off can be controlled by APQ8016 through SPMI interface. There is an audio codec inside APQ8016, and one stereo head phone driver is supported.

The memory chip (MCP) includes 1GB LPDDR3 and 8GB solid state storage, which is used for the operating system and different applications. It is connected to the main processor through high-speed data bus. Extended SD card can be used to save audios, videos, and games. The CPU subsystem design diagram is shown in Figure 2.

2.2 Man-machine interaction subsystem

Man-machine interaction subsystem is the main part of the design. This subsystem has an input section and an output section. The input section will receive the passenger's command, and the output section will display the passenger's favorite content on the screen.

Traditional display device uses Liquid Crystal Display (LCD) panel as the output. A backlight system is used for display module, as LCD does not produce light by itself. LCD needs illumination (ambient light or a special light source) to produce a visible image.

In this design, 720p OLED display panel is used. OLED is a kind of new display technology with better power efficiency and thickness, and it has

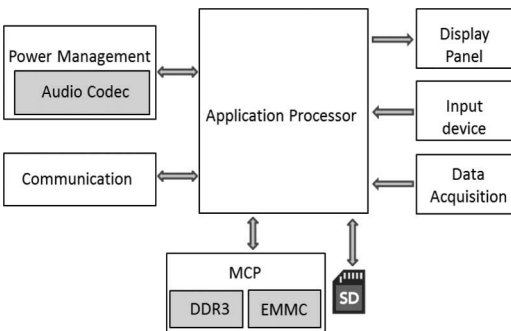

Figure 1. Hardware design.

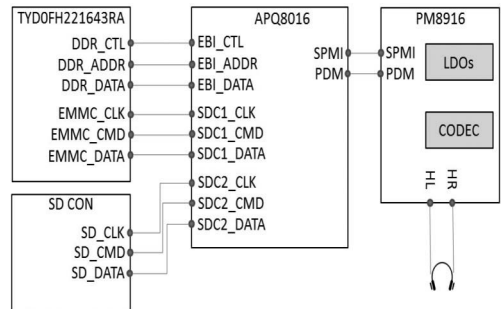

Figure 2. CPU subsystem design.

much faster response time than the LCD. OLED display panel is connected to the core processor via MIPI interface. Since OLED display works without a backlight system, power consumption is very low, and heating phenomenon does not exist in the display module; thus, it can improve the economic efficiency and improve the airline safety.

Normal design of the terminal uses resistive touch screen as the input that does not support multi-touch with fingers. Capacitive touch screen is used in this design, which can recognize two or more points of contact on the surface concurrently. It is extremely good for object manipulations—touch, drag, and zoom in and out, which greatly facilitate the interaction between the passengers and the device; it is also good for certain games.

Flight conditions may cause the cabin environment to be tough, especially for people who can face ill conditions. Flight duration, dehydration, pressure, engine noise, and other factors can be the reasons of physical and/or psychological problems. New intelligent seat with the seat belt monitoring system, health monitoring system, and other sensors can help get passengers’ status during their flights (Z, 2016). All these monitoring systems in the seat can be connected to device via I2C interface. Passenger’s status data can be saved in the terminal and be sent to on-board server. Cabin crew can monitor the status of all passengers on the server side; thus, it will reduce the workload of the cabin service and greatly improve the efficiency of passengers’ services. When the aircraft would experience some turbulence, cabin crew won’t need to walk through the cabin and do a seatbelt check one by one for the passengers. A sensory system integrated in the IFE system can provide a way to sense bad health conditions for passengers with health problems and can either inform the crew members or perform an action to reduce the effect. The server will save all the data that is acquired from the passengers, and this data will be analyzed by big data processing technology on the local server after landing.

Capacitive touch screen and the heartbeat, seat belt monitoring system can be connected to the device via I2C interface.

The terminal works as a media center and game station. The joystick must be supported, as it is a principal control device for games; it can be connected to the device via a USB host connector.

Man-machine interaction subsystem design diagram is shown in Figure 3.

Figure 3. Man-machine interaction subsystem design.

Figure 4. Communication subsystem design.

wireless connection can reduce the costs of network inside the cabin. Wired and wireless connections interface are both implemented in the device. Peer-to-peer network can be set up to distribute video content over the network instead of traditional client-server architecture. The peer-to-peer approach will allow IFE units to monitor, store, and serve media content with each other.

In this new design, wired and wireless connections are supported. The device uses RF transceiver WCN3620 to support WIFI and Bluetooth. WCN3620 integrates two different radio technologies: WLAN, compatible with IEEE 802.11b/g/n specification; and Bluetooth, compatible with BT version 4.1 specification. DM9620 A is USB to 10/100Mbps fast Ethernet controller that is used to implement wired connection between the on-board server and the terminal.

The terminal can communicate with the on-board server via wireless or wired connection. The server can push flight information, shopping information, and news to the passengers according to their specific requirements and preferences. A Bluetooth headset can be connected to the device to listen to music. Gaming systems can be networked to allow interactive playing by multiple passengers and enable high-quality gaming in an aircraft cabin environment. The communication system design is shown in Figure 4.

2.3 Communication system design

Nowadays, wired networks are the principal technology of implementing IFE systems. Ethernet is currently the standard for wired communication in different fields. Compared with wired connection,

3 SOFTWARE DESIGN OF THE SYSTEM

In order to support various applications and games on the terminal, Android is used as the

operating system. It is a mobile operating system developed by Google, based on the Linux kernel, designed primarily for touchscreen device such as smartphones and tablets. Android's source code is released by Google under open source licenses.

Applications that extend the functionality of devices are written using the Android Software Development Kit (SDK). One customized Android system is required because there is a big difference between tablets and terminals. Applications used in the terminals are not same as the applications used in the mobile devices and tablets. These applications must be based on cabin services and entertainment.

The software system consists of login applications, cabin information applications, flight information applications, online shopping applications, settings, and various games. It also has certain background services that get data from the seat and communicate with the on-board server. Basic diagram of the whole software architecture is shown in Figure 5.

There are four main software layers in the whole system as shown in the architecture diagram.

1. Linux kernel

At the bottom of the layers is Linux kernel. It provides a level of abstraction between the device hardware and contains all the essential hardware drivers such as OLED display, capacitive touch panel, I2C, Joystick, WIFI, Bluetooth, and Ethernet. The kernel works as the abstract layer between software and hardware. It hides all the detailed information of the hardware and provides a uniform interface for upper layers.

2. Libraries and Android runtime

It encompasses those libraries that are specific to audio and video playback, game graphics, drawing, and database access.

Android runtime provides a key component called Dalvik Virtual Machine (VM), which is a kind of Java Virtual Machine specially designed and optimized for Android. The Dalvik VM enables every Android application to run in its own process, with its own instance of the Dalvik VM.

3. Application Framework

The application framework layer provides many higher level services to applications in the form of Java classes.

Server manager is the interface for the data transmission between terminal and server. Applications and services use this manager to get data from the server and push data to the server.

Notification manager is the interface that is used to send the cabin information message to the terminal.

4. Applications

You will find all the Android applications at the top layer. Examples of such applications are media player, cabin information, flight information, online shopping, settings, and games. Media and commodities may be different according to different passengers, since they may have various differing requirements. All the data pushed to the passengers is highly customized according to the analysis result of big data processing.

4 BIG DATA PROCESSING

There are two ways to collect data from passengers: one way is from the internet, and another way is from the terminal. Passengers' hobbies will be gathered if they use the internet. Passenger's heart beat data, seat belt status data, and tracking data in each application will be sent to on-board server and then to the local server after landing. All the related data can be analyzed by big data processing technology to create a profile for each passenger. This profile is a snapshot of the passenger. The content of the profile includes the personal information of the passengers, their favorite food and beverages, and so on. This profile is used to configure applications and games in the terminal and provide customized content to the passengers. Each passenger will be able to access different applications, videos, and game; therefore, the passenger would not need to waste time in selecting items during the flight, and the profile of the passenger would be used for future travels. For health services, automatic pop-up reminders can be used to stop passengers from being stuck to the entertainment content.

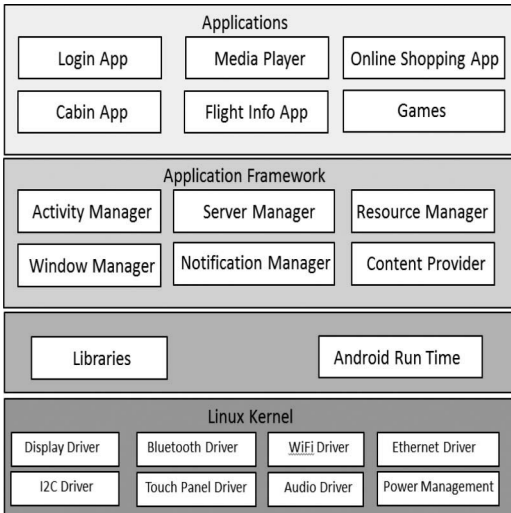

Figure 5. Basic diagram of the whole software architecture.

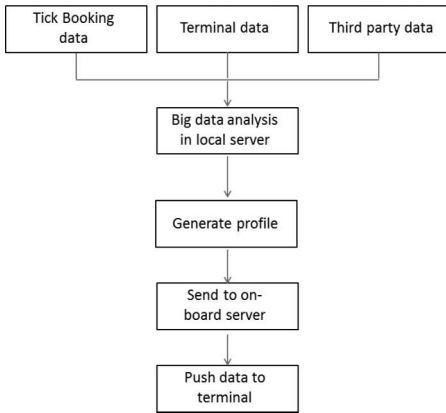

Figure 6. Working flow of big data processing.

Profile data and media data will be updated and pushed to the passenger terminal before the plane takes off.

The working flow is shown in Figure 6.

5 CONCLUSION

At the beginning, the IFE system was targeting just the comfort of the passengers. With time, the system began to reveal another dimension of services to support crew members and airline companies in order to facilitate crew tasks and increase airline revenue. Compared with the traditional terminal design, the new design can greatly reduce the weight of the terminal system and improve the

economic efficiency of airline companies. This design makes the passenger the prime focus, and as a digital intelligent system, provides personalized services to end users. The new design integrates big data analysis technology, latest display technology, and electronic technology. Multi-touch panel and joystick are supported, which greatly improve the interaction and operability of the terminal.

IFE system is still in the development phase and under research. Although the development of the IFE system made a great leap in the past years, there are still various issues that need further research. These developments range from enhancing current systems to adding new components and services. As the technology improves, more advanced devices can be used to enhance current components such as increasing network bandwidth, using more accurate contactless sensors, wireless devices, and lighter components. There is no limit for new services that can be added to IFE systems. Using 3D displaying devices can introduce a new sensation to IFE entertainment. Furthermore, hologram images can be used to present safety instructions instead of crew members doing the same.

The countdown traffic light error detection method based on union color spaces and fuzzy PCA

Shaoqing Mo, Rui Zhang & Yuexiang Wen

School of Automotion and Transportation, Tianjin University of Technology and Education, Tianjin, China

ABSTRACT: Traffic lights are very important for traffic management and control. If there are errors in traffic lights, managing the traffic becomes difficult. Therefore, it is highly essential to recognize the state of traffic lights on line. This paper proposes a detection method of errors in countdown traffic lights based on color union spaces and fuzzy Principal Component Analysis (PCA). In this method, first, pixels are classified into color pixels and achromatic pixels in RGB color space. Then, the principal color of the color pixels is extracted by histograms in HVS space, and the color feature is recognized based on the H component of the principal color. The color countdown characters are converted into gray according to the principal color, and then the training samples of the countdown characters are divided into subsets in terms of fuzzy degree; then, their corresponding PCA subspaces are constructed. Lastly, the character is recognized in the specific subspaces, which are chosen by the character's fuzzy degree. The experiment results show that our method has a more favorable comprehensive performance than other algorithms, and that it can better meet the demands of precision and real-time processing simultaneously.

1 INTRODUCTION

Traffic lights are highly significant for traffic control and management, and they are indispensable for city roads, which are increasingly becoming congested. Traffic lights not only help vehicles and people pass through intersections from different directions in an orderly fashion, but also ensure higher traffic flow and traffic safety (Jensen, 2016). The countdown on traffic lights displays the residual time of the current phase. Drivers can make decision in advance according to the residual time, which can improve the traffic capacity of a given road and ensure greater traffic safety. Therefore, the countdown traffic lights are becoming increasingly popular in city traffic systems. As traffic lights operate in the exterior environment, they break down easily, and their state is difficult to maintain regularly manually, as they are scattered across the city. When the traffic lights are faulty, the traffic management department is unable to channel the traffic flow timely due to less information, which causes traffic jams and even causes traffic accidents. Therefore, it is necessary to recognize state of the traffic lights automatically.

The main errors in the traffic lights are the following: a) inaccurate color of traffic lights; b) phase color conflict; c) countdown character errors such as incomplete characters display or messy code; d) countdown time conflict. Based on the above-mentioned errors, the core issues of error detection

in countdown traffic lights are the color features and countdown character recognition.

The existing traffic lights error detection methods can be classified into two classes: methods based on hardware detection (Kong, 2015; Zou, 2012), and methods based on video recognition (Diaz, 2015; Omachi, 2009; Gomez, 2014; Jie, 2015). The former is based on the measurement of internal current and voltage of traffic lights. Due to difference in internal structures of traffic lights, curves and amplitudes of current and voltage are not similar; therefore, methods based on hardware are not universal. Moreover, the countdown characters cannot be recognized by the amplitudes of the current and voltage. The methods based on video recognition always use the color, shape, and texture. However, these features are difficult to extract due to the change of lighting condition.

This paper proposes a new countdown traffic light error detection method based on union color space and fuzzy Principal Component Analysis (PCA). First, we classify pixels into color pixels and achromatic pixels according to the maximum difference of R, G, and B components in RGB color space. Then, the principal color of color pixels is extracted by histograms in HVS space, and the color feature of traffic light is recognized based on the H component of the principal color. The color countdown characters are converted to gray images according to the principal color, and the fuzzy degree of the gray image is computed

by using triangular norm and non-fuzziness cardinality. Then, training samples of the count-down characters are divided into subsets in terms of fuzzy degree, and their corresponding PCA subspaces are constructed. Lastly, the character is recognized in the specific subspaces, which are chosen by the character's fuzzy degree. The experiment's results show that our method has a more favorable comprehensive performance than other algorithms; it can better meet the demands of precision and real-time processing simultaneously.

2 COLOR FEATURE RECOGNITION

The color of traffic lights has a large dynamic range due to reflection and backlight, as shown in Fig. 1. In Fig. 1, a) shows two images for traffic lights on black; b) shows two images for traffic lights on red; c) shows two images for traffic lights on green; and d) shows two images for traffic lights on yellow. The color of left image in each group is distorted heavily and has a halo, and the color of the right image is also different than the standard color. The color feature of red is always represented by $2R - G - B$, the green is represented by $2G - R - B$, and the yellow is represented by $R + G - 2B$, in RGB color space. In HSV color space, the color feature is always represented by the H component. Fig. 2 shows histograms of images in Fig. 1; a) shows histograms of $2R - G - B$, rep-

resenting the red component; b) shows histograms of $2G - R - B$, representing the green component; c) shows histograms of $R - G - 2B$, representing the yellow component; and d) shows histograms of the H component. In each figure, black, red, green, and yellow curves depict histograms for a), b), c), and d) in Fig. 1 respectively; solid lines are for the left images and the dotted lines are for the right images of a) to d). As shown in Fig. 2, black, red, green, and yellow for traffic lights can't be discriminated in RGB space and HVS space, which results in difficulty of color feature recognition.

By statistical analysis, the reason for no obvious division of colors is interference of achromatic pixels in HVS color space. Therefore, we classify pixels into color pixels and achromatic pixels according to the maximum difference of R, G, and B components in RGB color space, and then recognize the color feature in HVS space for color pixels.

For image I in RGB color space, the maximum difference of R, G, and B, denoted by $md(i, j)$ is computed by equation (1):

$$md(i, j) = \max(|R - B|, |R - G|, |G - B|) \quad (1)$$

where R, G, and B are the red, green, and blue values of pixel (i, j) , respectively.

According to $md(i, j)$, pixels are classified into color and achromatic, as is described in equation (2):

$$C(i, j) = \begin{cases} 1, & md(i, j) > T_1 \\ 0, & md(i, j) \leq T_1 \end{cases} \quad (2)$$

$C(i, j) = 1$ denotes that pixel (i, j) is color; otherwise, pixel (i, j) is achromatic, and T_1 is a given threshold.

Then, image I is transformed from RGB space to HVS space. The H component histogram of color pixels is defined as equation (3):

$$hist(x_i) = \frac{S(x_i)}{\sum C(i, j)}, s.t. H(i, j) = x_i \ \& \ C(i, j) = 1 \quad (3)$$

We denote the peak value of histogram as MH . The principal color, (Pcolor), is defined as the weighted mean of H histograms, whose deviation from MH is less than the given threshold T_3 :

$$PColor = \frac{\sum_{d=-T_3}^{T_3} (MH + d) * hist(MH + d)}{\sum_{d=-T_3}^{T_3} hist(MH + d)} \quad (4)$$

Figure 1. Traffic lights under different conditions.

Figure 2. Histograms for images of Fig. 1 respectively.

Then, the distances between the principal color and the standard red ($H = 0$), standard yellow ($H = 1$), and standard green ($H = 2.1$) respectively, are computed by equations (5).

$$\begin{aligned} distR &= Pcolor \\ distY &= |Pcolor - 1| \\ distG &= |Pcolor - 2.1| \end{aligned} \quad (5)$$

If $minDist = \min\{distR, distY, distG\} < T_4$, then the color of traffic light is the color whose distance is minimum. If $minDist \geq T_4$, then the traffic light is not red, green, and yellow, which is in error.

Fig. 3 shows histograms of color pixels for images in Fig. 1, respectively. When the traffic light is black, there are no color pixels, as shown in Figure 3(a). H component of red centers around 0 or 2π ; that of green centers 2.8; and that of yellow is about 1, as shown in Figure 3(b), (c), and (d), respectively. The principal color of same color traffic lights is nearer, and the distance of principal colors for red, green, and yellow is longer. That is to say, the distance of same colors reduces; otherwise, the distance of different colors gets enhanced, which is good for the color feature recognition of traffic lights.

3 COUNTDOWN CHARACTER RECOGNITION

3.1 Fuzzy degree

In order to highlight the characters and reduce the background and noise, the character images are translated into gray image according to equation (6):

$$GI(i, j) = \begin{cases} 255 - \frac{255 * |H(i, j) - Pcolor|}{\max\{|H(i, j) - Pcolor|\}'} & C(i, j) = 1 \\ 0 & C(i, j) = 0 \end{cases} \quad (6)$$

Figure 3. The H histogram of color pixels.

To the gray image GI with K pixels, V_{ij} denotes the $k*k$ neighborhood of pixel (i, j) , and its gray feature is defined by equation (7).

$$\mu_G(i, j) = \frac{[0V(M(i, j) + m(i, j) - 2GI(i, j))]^2}{[M(i, j) - m(i, j)]^2} \quad (7)$$

where $M(i, j)$ and $m(i, j)$ are the maximum and minimum gray values, respectively. If $M(i, j) = m(i, j)$, $\mu_G(i, j) = 0$.

The variance feature of V_{ij} is described as

$$\mu_D(i, j) = 1 \wedge [01(D(i, j) - D_1)] / (D_2 - D_1) \quad (8)$$

where D_2 and D_1 are the given thresholds, and $D_2 > D_1 > 0$; $D(i, j)$ is gray variance, such as

$$D(i, j) = \sum_{(s,t) \in V_{ij}} (GI(s,t) - \overline{GI(i,j)})^2 \quad (9)$$

where $\overline{GI(i,j)} = \sum_{(s,t) \in V_{ij}} GI(s,t) / k^2$

The local contrast feature $\mu_L(i, j)$ is acquired based on the triangular module operation of $\mu_G(i, j)$ and $\mu_D(i, j)$.

$$\mu_L(i, j) = T(\mu_G(i, j), \mu_D(i, j)) \quad (10)$$

where T is triangular module.

Then, the fuzzy degree of image I is

$$FuzzyD = 1 \wedge [lgK - lg \sum Count(L)] / F_0 \quad (11)$$

where $\sum Count(L) = \sum_{i,j} \mu_L(i, j)$, and F_0 is fuzzy threshold, ranging from 4 to 8.

The fuzzy degree, $FuzzyD$, ranges from 0 to 1; the bigger the value, the more blurred the image.

3.2 PCA classification method

PCA is a statistical method that reduces multiple indicators into a few composite indicators (Abdelmalek, 2007; Oja, 1983; Purnima, 2012). PCA method simplifies data by projecting high dimensional data into low dimensional space with less information loss. According to PCA method, PCA subspace classifier extracts salient features of each class and represents it by a template set. The core of PCA subspace classifier is that each class has its own feature set, and the feature set changes according to the class.

Suppose there is a sample space set containing K subclasses, the number of samples for each subclass is N_p , and the test sample is x . The PCA classification method can be described as follows.

1. Arranging original images into feature vector by rows or columns, and denoting the j th sample vector of the i th class as x_j^i ; then computing the covariance matrix of subclass.

$$R_i = \frac{1}{N_i} \sum_{j=1}^{N_i} (x_j^i - M_i)(x_j^i - M_i)^T \quad (12)$$

where M_i is the mean value of the i th class samples. N_i is the number of samples.

2. Computing eigenvectors $\mu_j^{(i)}$ ($j = 1, 2, \dots, p$) and eigenvalue $\lambda_j^{(i)}$ according to SVD;
 3. Arranging eigenvalues in descending order ($\lambda_1^{(i)} \geq \lambda_2^{(i)} \geq \dots \geq \lambda_p^{(i)}$), and determining dimension m of subspaces.

$$\sum_{j=1}^m \lambda_j^{(i)} / \sum_{j=1}^p \lambda_j^{(i)} \geq r \quad (13)$$

where $0 < r < 1$, and m is the smallest integer of equation (13).

The characteristic matrix $U^{(i)}$ is

$$U^{(i)} = (u_1^{(i)}, u_2^{(i)}, \dots, u_m^{(i)}) \quad (14)$$

and the subspace L^i is

$$L^i = (u_1^{(i)}, u_2^{(i)}, \dots, u_m^{(i)}) \quad (15)$$

4. Constructing the project matrix for each subspace;
 5. Computing the project residual error distance:

$$g_s(x, L^i) = \|x - M_i\|^2 - \|P_i(x - M_i)\|^2 \quad (16)$$

The minimum residual error distance $\min D = \min(g_s(x, L^i))$ the class which has $\min D$ is $i = \min\{g_s(x, L^i)\}$. If $\min D < T_s$, then the character is the i th class; otherwise, the character is error.

3.3 PCA based on fuzzy degree

PCA classifier demands samples of each subclass to have similar features. If samples of each subclass differ from each other, in other words, if the subclass has bigger intra-subclass distances, the feature of the subclass is no longer salient. Then the character matrix derived from PCA method can't describe the subclass sufficiently, which will result in missorting. Due to the change of light and vibration, countdown characters of traffic lights are blurred to some extent, which augments the intra-subclass distance and reduces the inter-subclass distance; as a result, there is high error rate for using PCA classifier directly. In order

to get higher recognition rate, the intra-subclass distance must be reduced and the inter-subclass distance must be enhanced. Therefore, we group samples into subsets according to their fuzzy degree. Samples of each subset are more similar to each other, and the intra-subset distance becomes smaller. Then, we build the subspace of each subset and recognize characters in the corresponding subspace according to the character's fuzzy degree. The complete procedure can be stated as follows:

a. Classifying total training samples into three subsets S_1 , S_2 , and S_3 . Ensuring that the testing sample locates to the appropriate subset, the three subsets overlap each other: the fuzzy degree of S_1 is $[0, 0.35]$, that of S_2 is $[0.3, 0.65]$, and that of S_3 is $[0.6, 1]$;
 b. Constructing projection matrix $\{P_i\}^s$ for every character of each subset, where $i = 1, 2, \dots, K$, denoting the indices of characters, $s = 1, 2, 3$, denoting the indices of subsets;
 c. Selecting appropriate $\{P_i\}^s$ for recognition according to the *FuzzyD* of the testing sample. The selection rule is

If *FuzzyD* < 0.325, select $\{P_i\}^1$;
 If $0.325 \leq \text{FuzzyD} < 0.625$, select $\{P_i\}^2$;
 If $0.625 \leq \text{FuzzyD}$, select $\{P_i\}^3$

4 EXPERIMENTS

To evaluate the performance of our method, we tested on six video sequences acquired under different conditions. Video 1 was acquired in the morning with strong reflection; video 2 was acquired at noon with normal light; video 3 was acquired at afternoon with backlight; video 4 was acquired at night; video 5 was acquired in rain; and video 6 was acquired in fog day. Total 54000 countdown characters ranged from 99 to 0, half of the characters were training samples, and the remaining were testing samples. The color recognition result is shown in Table 1, and the countdown character recognition result is shown in Table 2.

Table 1. Experiment results of color recognition.

Video	Recognition rate		
	Our method	HVS method	RGB method
Video 1	0.92	0.85	0.83
Video 2	0.94	0.93	0.92
Video 3	0.93	0.87	0.87
Video 4	0.93	0.89	0.88
Video 5	0.92	0.90	0.89
Video 6	0.93	0.89	0.90

Table 2. Experiment results of countdown character recognition.

Method	Recognition rate	Recognition time (ms)
Our method	0.94	4.2
Traditional PCA method	0.87	3.8

According to Table 1, our method outperforms the HVS method and RGB method in general. Under normal lighting condition, our method has recognition rate similar to the HVS method and the RGB method; however, when the illumination condition is not ideal, such as reflection, backlight, rainy, and foggy, and so on, the color of traffic lights distorts to some degree, and our method has higher recognition rate than the other methods.

According to Table 2, our method outperforms the traditional PCA method as well. The reason is that the intra-subclass distance decreases and the inter-subclass distance gets enhanced after classifying the samples into subsets according to fuzzy degree.

5 RESULTS

This paper presented a robust detection method for countdown traffic light errors based on union color spaces and fuzzy PCA classification. Based on the union color spaces of RGB and HSV, our method eliminates the effect of color tone shifting and halo disturbances and exhibits excellent performance in color recognition. Classifying countdown characters into different subsets according to the image quality enhances the intra-similarity and increases the inter-difference, and the character recognition rate is improved. The experiment results of six video sequences with different time and conditions show that our method has a favor-

able comprehensive performance, which can better meet the demands of precision and real-time processing simultaneously.

Study of the optimization evaluation algorithm of improved genetic-BP neural network in the monitoring and diagnosis of shortwave transmitting system

Yong Luo & Jun Gao

Naval University of Engineering, Wuhan, China

ABSTRACT: In the process of monitoring the running state of shortwave transmitting system, it is necessary to realize the intelligent discrimination and analysis of the monitoring data and enable users to obtain the real-time health status of the system quickly and accurately. Considering the large amount of information in monitoring data and the highly difficult analysis, the initial structure of BP neural network is optimized with genetic algorithm based on the calculation evaluation with traditional BP neural network algorithm, and then the optimal initial weight value is obtained by the optimizations such as improvement of chromosome coding, selection of fitness function and design of related operators. Based on the simulation training of a large number of monitoring data, the improvement effect of the algorithm is experimentally verified and analyzed. After this improvement, the algorithm optimization evaluation in the monitoring and diagnosis of shortwave transmitting system gets strong convergence ability and high diagnostic accuracy, which greatly increases the use efficiency of the monitoring system and lays a good practical foundation.

1 INTRODUCTION

Today, with the deepening of artificial intelligence research, various intelligent algorithms have been widely used in various fields, leading to a series of revolutionary technological and scientific research innovations. It has no exception in the intelligent monitoring research of shortwave transmitter. Compared with the traditional manual monitoring disposal, the automatic monitoring control and intelligent state discrimination and disposal also need to be introduced. Artificial intelligence is a very broad field, involving a lot of technical concepts and research directions. One important aspect is the artificial neural network. Artificial neural network can well solve the problem of pattern recognition which is difficult to be distinguished by traditional means because of its own features such as parallelism, self-learning, self-organization and associative memory. Among the monitoring technologies based on neural network, BP neural network is a widely used model. In the intelligent monitoring of the state of shortwave transmitter, due to many types of equipment state, unapparent information difference and so on, relying solely on BP algorithm may cause problems, such as slow convergence rate of discrimination model, easy to fall into local extremum. Therefore, it is necessary to optimize and adjust BP neural network to a certain degree. In this paper,

the genetic algorithm with excellent global search ability is used to optimize and improve the BP neural network model, and it can realize the quick discrimination and accurate diagnosis of the transmitter state better.

2 TRADITIONAL BP CALCULATION EVALUATION METHOD

As shown in Figure 1, the classic BP neural network consists of three parts, namely input layer, hidden layer and output layer. The number of hidden layers is adjusted according to the need of

Figure 1. Typical structure diagram of BP neural network.

actual calculation. The number of nodes in each layer of the network structure is set according to the types of input and output data as well as related requirements of network construction, and the number of nodes on the network is the number of neurons. Data enters into the network in the input layer and moves forward along with the arrow direction, then moves forward after calculated at each node, and finally the result is output on the output layer.

In general, BP neural network on the third layer is common. Assuming the number of neurons on each layer is respectively M , N and Q , x_j ($1 \leq j \leq M$) is the input of the j -th node on the input layer, o_k ($1 \leq k \leq Q$) is the output of the k -th node on the output layer, and y_k is the desired output of the k -th node on the output layer. The threshold value of the i -th node on the hidden layer is θ_i ($1 \leq i \leq N$), the threshold value of the k -th node on the output layer is a_k ; w_{ij} is the weight from the j -th node on the input layer to i -th node on the hidden layer; v_{ki} is the weight from i -th node on the hidden layer to the k -th node on the output layer; $g(x)$ and $f(x)$ are respectively the transfer functions of the hidden layer and output layer.

The input and output of the i -th node on the hidden layer are:

$$s_i = \sum_{j=1}^M w_{ij}x_j + \theta_i \quad (1)$$

$$b_i = g(s_i) = g\left(\sum_{j=1}^M w_{ij}x_j + \theta_i\right) \quad (2)$$

Similarly, the input and output of the k -th node on the output layer are:

$$t_k = \sum_{i=1}^N v_{ki}b_i + a_k \quad (3)$$

$$= \sum_{i=1}^N v_{ki}g\left(\sum_{j=1}^M w_{ij}x_j + \theta_i\right) + a_k$$

$$o_k = f(t_k) = f\left[\sum_{i=1}^N v_{ki}g\left(\sum_{j=1}^M w_{ij}x_j + \theta_i\right) + a_k\right] \quad (4)$$

Then for each sample p , the error function between the actual output value o_k and the ideal expected value y_k of the neural network is:

$$E_p = \frac{1}{2} \sum_{k=1}^Q (y_k - o_k)^2 \quad (5)$$

The total error function for P training samples is:

$$E = \frac{1}{2} \sum_{p=1}^P \sum_{k=1}^Q (y_k^p - o_k^p)^2 \quad (6)$$

The essence of the BP neural network algorithm is taking the total error function as the objective function. By adjusting the weights and thresholds of each layer with the gradient descent method, the final modified network output can approach the expected value, so as to find the minimum error. In the initial stage of training neural network, the actual output value is largely deviated from the expected value, and the relative value of the error function is large, with a larger space to adjust down. Thus, a substantial adjustment of the error function will increase the convergence rate of the network; as the number of training samples and the number of training times increase gradually, the output value gradually approaches the expected value, the relative value of the error function continues to decrease and the decline space will continue to decrease. At this time, the micro-adjustment of the error function will slow down the convergence rate of the network. Therefore, in the practical application, the convergence rate of traditional BP algorithm in the later period of training will be slow. As the optimization is gradually carried out in the process of gradual decline of the error function, when the surface space of the error function is multi-dimensional, it is possible to make the minimum error found in training a local minimum rather than the global optimum.

3 FIGURES AND TABLES OPTIMIZATION AND IMPROVEMENT OF BP NEURAL NETWORK BASED ON GENETIC ALGORITHM

As the genetic algorithm is based on group optimization, the global search from multiple samples can effectively avoid the search being trapped into the local optimal solution, thus better finding the global minimum error or the good sub-optimal solution. Therefore, in order to improve the accuracy of BP network algorithm and the accuracy of state recognition and to overcome the drawback of easily falling into local minimum, the genetic algorithm is used to optimize the structure parameters of neural network. For the BP neural network, the essence of the algorithm is an optimization problem of the complex function. Its weight distribution and size contain the network's all ideas. Therefore, the genetic algorithm can be used to optimize the weight of neural network, so as to better improve the overall performance of the system. Its basic structure thought is to divide the optimization of neural network structure into two steps:

1. Using genetic algorithm to achieve fast global optimization, namely building the structure parameters of the neural network as the chromosome of genetic algorithm, using genetic and mutation recombination for global optimization of weights and thresholds of the network, and quickly converging the network structure to the global optimal solution or its vicinity through fitness screening;
2. Taking the optimal network structure found by the genetic algorithm as the starting point of BP algorithm studying, using BP algorithm for further local search, and again optimizing the network weights and thresholds. In this way, the network structure can be quickly adjusted to the optimal solution or satisfactory solution.

Here we mainly deal with the following three problems: chromosome coding improvement, fitness function selection and related operator design. The genetic algorithm is used to improve the structure of BP neural network and improve the convergence effect of the algorithm.

3.1 Chromosome coding design

The key step of genetic algorithm optimization is to reconstruct the chromosomes in the group by genetic variation, and gradually search the individuals with good fitness in the group, so as to achieve the goal of finding the optimal solution by gradually increasing the number through mutation. In order to achieve reasonable genetic variation, it is necessary to encode the parameters in the problem space and convert the solutions in the space that can be processed by the genetic algorithm for optimization. At present, the typical encoding method is binary coding. However, in dealing with the problem of large data volume, binary coding will increase the length of the chromosome and increase the search space, resulting in lower search efficiency. As the overall performance of BP network is closely related to the weights and thresholds in network structure, the method of floating-point coding is used in this paper. BP neural network adopts three-layer structure. The parameters to be optimized are all weights and thresholds, and the number is $(L + 1)M + (M + 1)N$. All the parameters constitute a chromosome, and the sorting order of genes in the chromosome is from input layer to hidden layer weight, hidden layer to output layer weight, hidden layer threshold, output layer threshold. The mapping relationship of code is:

$$X = \{w_{11}, w_{12}, \dots, w_{NM}, v_{11}, v_{12}, \dots, v_{QN}, \theta_1, \theta_2, \dots, \theta_N, a_1, a_2, \dots, a_Q\} \quad (7)$$

Thus, each individual constituted corresponds to the parameter on the network structure. It can be considered that the characteristics of the individual represent the structural characteristics of the neural network.

3.2 Construction of fitness function

The fitness function is also called as the evaluation function, which is often used in the genetic algorithm to measure the degree of excellence that the individual can reach or approach the optimal solution in the optimization calculation. The value generated by the fitness function can also be considered as the “scoring” or “judgment” of the individual and it is a criterion to distinguish between good and bad individuals in a group. The convergence rate of genetic algorithm and the choice of optimal solution depend largely on the selection of fitness function. The design principles are non-negativity, continuity, uniqueness, rationality and simplicity. The key is rationality and simplicity, which requires that the fitness function should really reflect the advantages and disadvantages of the corresponding solution, and the calculation process should be as simple as possible to reduce the time and complexity of calculation as well as the cost of calculation. It is often difficult to reach these conditions. In this paper, the fitness function is chosen as the reciprocal of the mean square error function. When the individual error is larger, the corresponding fitness is smaller. When the error is smaller, the corresponding fitness is larger.

$$f(x_p) = \frac{1}{1 + E_p} = \frac{1}{1 + \frac{1}{2} \sum_{k=1}^Q (y_k - o_k)^2} \quad (8)$$

3.3 Selection Algorithm

According to the basic genetic concept, it is necessary to select the superior and eliminate the inferior individuals. This process is achieved by selection algorithm in calculation. The fitness of the individual is taken as a genetic standard. If the fitness is high, the probability of being inherited to the next generation of group is large. In this way, the individuals with higher fitness will be retained as far as possible, so that the fitness of individuals in the group constantly approaches the optimal solution. A typical selection algorithm is the roulette selection algorithm. In order to better avoid the loss of useful genetic information, improve the global convergence and computational efficiency, the best reservation selection algorithm is used as a supplement of the typical roulette selection algorithm.

In the typical roulette selection algorithm, the probability p_c of the individual being passed on to the next generation can be calculated by the Equation (9):

$$p_c = f(x_p) / \sum_{p=1}^P f(x_p) \quad (9)$$

All the individuals in the group are placed on a disc, and the circular area is divided into the corresponding fan-shaped areas according to the number of individuals. Each area represents an individual. The size of the area is proportional to the individual fitness. When the disk is rotated at random, it is clear that the larger the fan-shaped area is, the larger the probability of the pointer stopping in this area is, namely, the larger the probability of individual selected corresponding to the fan-shaped area is. However, due to limited size of the group and the randomness of operation, there may be some discrepancies between the actual number of individuals selected and the expectation. Therefore, the selection error of this original roulette algorithm is relatively large, or even some optimal solutions may be lost. In order to avoid this omission, the best reservation method is adopted, that is, executing the selection operation of genetic algorithm with the roulette selection method, and then retaining the individuals with the highest fitness in the current group to the next generation, thus ensuring that the iterative termination results are the individuals with the highest fitness in the past generations.

3.4 Cross Algorithm

The inheritance and evolution of natural organisms are mainly achieved through mating and reconstructing. The genetic algorithm uses cross for imitation. Two individuals are selected from the group based on a certain probability, and new genetic individuals are generated by exchanging part of genes. This exchange method is called as cross algorithm. In general, there is single point, multiple points, order, cycle cross and so on. When encoding chromosomes, the sort order of genes is from input layer to hidden layer weight, from hidden layer to output layer weight, hidden layer threshold, output layer threshold. Different kinds of neural network structure parameters play different roles in calculation. Therefore, when considering crossing genes, it is necessary to distinguish them. In this paper, for parameters of neural network, the multi-point cross method is used, as shown in Figure 2:

Figure 2. Structure diagram of multi-point cross method.

3.5 Mutation Algorithm

Mutation is also a way to generate new individuals. In genetic algorithm, the method of replacing some gene values in the individual chromosome coding by other values is used to achieve mutation simulation. In the process of inheritance, the mutation is usually randomly generated. Compared with selection and crossover operation, the individual's local mutation, as the supplement of the new individual method, can avoid the loss of some information and ensure the effectiveness of the genetic process. Genetic algorithm achieves a global search by the crossover operation and improves local random search ability by mutation operation. In this paper, the method of uniform mutation is used, namely setting the gene locus in the chromosome coding as the mutation point, and randomly selecting a numerical value to replace the original gene value in the value range of the gene corresponding to the mutation probability p_m , thus generating new individuals at a lower probability.

4 MONITORING DATA SIMULATION AND COMPARISON

For shortwave transmitter, the power status data is a very important technical indicator, directly affecting the distance and reliability of communication. At present, the data that can be directly monitored and analyzed in the working process of transmitter are the transmitter's input power, output RF power, antenna transmission forward power and reverse power. In the working process of the transmitter, the transmitter mainly experiences four states, namely waiting for transmission, transmission beginning, transmission and transmission ending. Transmission beginning and transmission ending are two dynamic processes, and the change of monitored power data is big. The role of the neural network is to classify and identify the monitoring data, and to correctly identify the specific working status of the transmitter.

Table 1. Typical input and output samples.

Number	Sample output after normalization processing										Sample output
	T1	T2	T3	T4	T5	T6	T7	T8	T9	T10	
1	0			0.158		0.667		0.932		0.988	1
	0.935			0.961		0.935		0.961		0.935	
2	0.854			0.854		0.879		0.854		0.888	2
	0.854			0.879		0.859		0.879		0.854	
3	0.967			0.967		0.948		0.967		0.963	3
	0.965			0.969		0.666		0.145		0	
4	0			0.146		0.677		0.879		0.683	7
	0.686			0.705		0.686		0.705		0.683	
5	0.447			0.591		0.879		0.889		0.695	8
	0.641			0.553		0.472		0.563		0.528	
6	0.699			0.688		0.686		0.688		0.670	9
	0.591			0.594		0.578		0.145		0	

The main faults of transmitter include abnormal input power, abnormal out RF power, and abnormal antenna transmission forward power and reverse power. To verify the recognition performance and convergence of BP neural network improved by genetic algorithm, two models of conventional BP network and improved BP network are established. For the different states of the transmitter in the working process, 5000sets of monitoring data are sampled to constitute the training sample. The typical training sample is shown as follows:

The correspondence between the sample output of the neural network and the fault state of the transmitter is shown in the following table.

The convergence curves of two BP algorithms are shown in Figures 3, 4.

10 sets of test data are randomly selected as the test samples, as shown in Table 3. The results obtained from the simulation of two kinds of neural are shown in Table 4.

From the simulation results it can be seen that:

1. The convergence rates of traditional BP network and genetic BP network are relatively fast in the early stage of training and learning, with the same effects. However, the difference is obvious in later period. The traditional BP network converges very slowly in the later period of training, difficult to meet the requirements after long time of training; while the genetic BP network converges still relatively fast in the later period of training, able to meet the training requirements faster.
2. After early optimization of improved BP neural network by genetic algorithm, the initial network structure finds the optimal solution. After later training, the recognition and analysis of

Figure 3. Convergence process curve of traditional BP network.

Figure 4. Convergence process curve of improved BP network.

monitoring data can be accurately and comprehensively realized. Therefore, the agreement of recognition and analysis of test samples by genetic BP network with the real result is obviously higher than by traditional BP network, and the recognition accuracy is greatly improved.

Table 2. Correspondence between the sample output and the fault state of the transmitter.

Sample output	State description	Fault analysis
1, 4	When transmission starts, the RF power output is normal, the power input is normal, and the transmission system is working properly	Null
2, 5	During the transmission, the RF power output is normal, the power input is normal, and the transmission system is working properly	Null
3, 6	When transmission ends, the RF power output is normal, the power input is normal, and the transmission system is working properly	Null

	0.594		0.578		0.145		0				

5 CONCLUSION

For the difficulties such as large amount and difficult analysis of monitoring data of shortwave transmitting system, the initial structure of the BP neural network is optimized with genetic algorithm based on the calculation evaluation with tradi-

tional BP neural network algorithm, and the simulation experiment is applied to verify the results. By genetic algorithm, we can realize the global optimization in the solution space, quickly find a more optimized network structure, quickly converge to the vicinity of the global optimal solution, and then we use BP algorithm for local calculation,

Table 4. Summary of simulation results.

Number	Output of traditional BP network	Output of genetic BP network	Actual state	State description
1	1.0210	1.0107	1	It works normally when transmission starts
2	2.0045	2.0042	2	It works normally during the transmission
3	3.0401	2.9989	3	It works normally when transmission ends
4	6.9875	7.0035	7	It works abnormally when transmission starts
5	7.9986	8.0010	8	It works abnormally during the transmission
6	8.9797	8.9968	9	It works abnormally when transmission ends

effectively avoiding traditional BP network from being easily trapped in the problem of local optimum, and effectively improving the training effect and accuracy of neural network. After the BP network model improved by genetic algorithm is

effectively used in the monitoring of shortwave transmitter, the accuracy of optimized evaluation algorithm becomes higher and the effect of intelligent evaluation and judgment becomes more ideal.

Loyalty model in the networked environment based on catastrophe

Qiaoge Liu

Agricultural Bank of China, Beijing, P.R. China

Chenguang Yang

Chinese Electronic Equipment System Corporation Institute, Beijing, P.R. China

ABSTRACT: Loyalty is an important index to evaluate a customer. Understanding the dynamic process of loyalty and its impact factors is very useful for service system. On the basis of the catastrophe theory, a loyalty model influenced by satisfaction and switching cost is studied. In particular, we analyzed the loyalty model with word-of-mouth.

1 INTRODUCTION

A service system is very complex as it includes many different roles, relations, and interactions. Customers and service providers are two vital parts in a service system. A service provider always wants to hold a large amount of loyal customers and then bring the maximal profit to them. In this paper, we will focus on modeling the relationship of customers and service providers from the viewpoint of customer loyalty.

Customer loyalty and his repeated purchase intention are closely related (Wang, 2005). A loyal customer does not likely change his choice because of once dissatisfaction with the service. A satisfied customer does not mean he will choose the service again. Therefore, loyalty is regarded as an important goal in the service system, and it has attracted numerous studies on the principle of loyalty (Yang, 2004). Although the phenomenon of positive influence of service satisfaction to loyalty is well known and many conceptual models have been proposed, how satisfaction affects loyalty is not clear, especially in the modern society with popular networks.

Oliva (1992) used the catastrophe model to describe the loyalty model. This model showed how satisfaction degree and switching cost could influence loyalty.

On the basis of the basic model in Oliva (1992), we will combine the analysis of economics, psychology, sociology, catastrophe, complex network, and control theory to evaluate loyalty. By modeling the satisfaction degree, we will show how satisfaction and thus loyalty is affected in the networked environment. Because of the interaction between customers, loyalty will not change in a large range. Judging a person's loyalty is not limited in his own behavior, but largely affected by his surroundings.

This paper is organized as follows. Loyalty model based on the catastrophe theory is presented in Section 2. Analysis of loyalty in the networked environment by modeling satisfaction is presented in Section 3. Section 4 presents some simulations results showing the influence of network on loyalty. Conclusion is given in Section 5.

2 LOYALTY MODEL BASED ON THE CATASTROPHE THEORY

2.1 Overview of the catastrophe theory

Issues surrounding nonlinearities, discontinuities, and multivaluedness have presented difficult problems for researchers. The catastrophe theory is such a technique for estimating a class of nonlinear dynamic systems.

The catastrophe theory was proposed by Thom 4 in 1975 and developed by Zeeman 5. It describes how small and continuous changes in independent variables can have a sudden, discontinuous effect on a dependent variable. The elementary catastrophe theory focuses on seven models and the cusp catastrophe model is widely used. The cusp catastrophe model is (1) given by:

$$z^3 + yz - x = 0 \quad (1)$$

where z represents the dependent variable, and the independent variables x and y are control variables. The surface defined by (1) is shown in Figure 1.

Variable x exhibits a right and left movement, y shows a back and front movement, and z exhibits a vertical movement. Changing the control variables x and y can affect the dynamic of z . If y is large, smooth change of z occurs and is proportional to

Figure 1. Cusp catastrophe model.

that of x . If y is small, change of x will produce only a relatively small change of z until x reached a threshold value. Then, z will have a sudden discontinuous shift. When x is increasing and z is at the bottom of the surface, z will not increase quickly and will keep moving in the bottom but not in the upper part until x is large enough. When x is decreasing and z is at the top, z will stay at the top with only a slight decrease. Until x drops low enough, z will fall suddenly to the bottom and reduce as x does. Thus, the dynamics of z is controlled by x and y . z cannot change fluently, and there are some values that it cannot approach when y is large.

The catastrophe theory has been applied in many studies, such as physics, biology, and finance, social sciences, work, and organization behavior. For example, the cusp catastrophe model has been applied to explain not only job turnover of employees but also loyalty in services 3.

2.2 Loyalty model of catastrophe

The loyalty model based on the cusp catastrophe model was defined as (1). z , x , and $-y$ represent customer loyalty, customer satisfaction degree, and switching cost, respectively.

Customer satisfaction has always been treated as a determinant component in many customer retention programs. However, recent studies have found that although satisfaction is a necessary component of loyal or secure customers, the mere quality of being satisfied does not necessarily make customers loyal 1. Sudden and discontinuous shifts are very familiar phenomena in the reality. For example, a customer's emotional response may change from one side to the opposite side without any intermediate process. When a sudden shift occurs, it is difficult to return to the former side. The relationship between customer satisfaction and customer loyalty is stronger for customers

with high switching costs than for those with low switching cost.

3 LOYALTY IN THE NETWORKED ENVIRONMENT

There are always many customers focusing on or buying one service from one service provider. The customers will communicate information with each other by many ways, such as face to face, website, or news. Especially with the popularization of the Internet, it is much easier for a customer to collect information widely. Any evaluation about one service or some service provider is easily searched or spread. Thus, opinion of a customer is not only that of him, but also influenced by others. Then, to manage the satisfaction and loyalty of customers is difficult than before.

This section will model satisfaction degree and analyze how the interaction influences a customer's loyalty.

3.1 Word-of-mouth

The interactions between customers in a networked environment have been studied a lot from different aspects. 67

Word-of-Mouth (WOM) is a pervasive and intriguing phenomenon. Both satisfied and dissatisfied consumers tend to spread positive and negative WOM, respectively, regarding the services they use. WOM spreads through the customer network. Nowadays, massive quantities of data on large social networks are available from blogs, social networking sites, newsgroups, chat rooms, and so on. Therefore, the size of the customer network is enlarged dramatically. Most of the customers can easily know others' opinion.

WOM has been studied using complex theory widely 8. In this paper, we choose a simple decision function for each node in the customer network:

$$y_i(k+1) = w_i \cdot \left(\sum_{j=1}^{N_i} y_j(k) \right) / N_i + (1-w_i) \cdot y_i(k) \quad (2)$$

where $y_i(k)$ represents the satisfaction degree of i th node at time k , N_i is the number of nodes connecting with node i , $\left(\sum_{j=1}^{N_i} y_j(k) \right) / N_i$ denotes the influence of conjoint nodes, and w_i shows the characteristic of each node. Some customers may only rely on others' opinions ($w_i = 1$), some customers may not be influenced by others ($w_i = 0$), some customer may consider others' opinions ($0 < w_i < 1$), and so on.

3.2 Satisfaction degree

As defined in 9, customer satisfaction degree can be explained as the difference between the level of service performance expected and perceived by the customer. The perceived service performance is positive relative to the service quality provided by the service provider. The expected service is influenced by word-of-mouth, personal needs, and past experience, as proposed by 10 and popularly recognized by most of the researchers. Therefore, on the basis of the definition in 9, its quantitative description is given by:

$$Sd = S_p - S_e \quad (3)$$

where S_e is the expected service, S_p is the perceived service, and Sd is the satisfaction degree.

Expected Service (S_e) is influenced by past experience (P_e), word-of-mouth (W_{OM}), and personal need (P_N). Suppose the function is (4):

$$S_e = f_{es}(P_e, P_N, W_{OM}) \quad (4)$$

Both expected service and perceived service are the psychological results of the customer. Considering that service degree is the difference between them, we propose a quantitative method to calculate satisfaction degree, on the basis of the thought of control system framework. That is, the satisfaction degree can be thought as the degree of personal need being satisfied, which is influenced by past experience and word-of-mouth. Satisfaction degree is an accumulation variable 9, so the influence of past experience can be viewed as an integral part. The integration result is averaged and influenced by WOM.

According to the satisfaction degree, the service provider will make improvement and provide service to satisfy the customer's need. Then, a service cycle is presented in such control framework.

The control framework of service providing is shown in Figure 2. The service provider makes improvement according to the satisfaction degree and provides service to satisfy the customer's need.

Figure 2. Control framework of service providing.

3.3 Switching cost

Switching cost is the cost involved in changing from one service to another. It is a key factor in service systems, which always plays an important role when customers want to change from one service provider to another. As a lock-in method, switching cost can help prevent customers from switching. Therefore, it is very important for service providers to manage switching cost, especially in the competitive environment.

How to evaluate switching cost is difficult which has been shown in many articles. First, switching cost is the collective result of economic, psychological, and physical analyses. Second, different types of service have different features. We have done some research on modeling switching cost mathematically in other papers. Here, for simplicity, switching cost is supposed not to change a lot.

4 SIMULATION RESULTS

We choose a random network as the customer network and three types of nodes mentioned above. The data are randomly generated and scaled to zero mean-centered value. Figures 3–10 respectively show the dynamic influenced from WOM or not.

Figures 3–6 show curves that are not influenced from WOM.

Figure 3 shows the dynamic curves of average satisfaction degree and average loyalty. Figure 4 is the 3D dot plot of the catastrophe model and the relationship curves of loyalty, satisfaction degree, and switching cost. Because of limited line or dot types, we use only one type of lines or dots to represent the traces of all the customers.

Figure 3. Average of loyalty and satisfaction degree without influence from WOM.

Figure 4. Relation of loyalty, satisfaction degree, and switching cost without influence from WOM.

Figure 6. Relation of loyalty, satisfaction degree, and switching cost without influence from WOM—three types of customers.

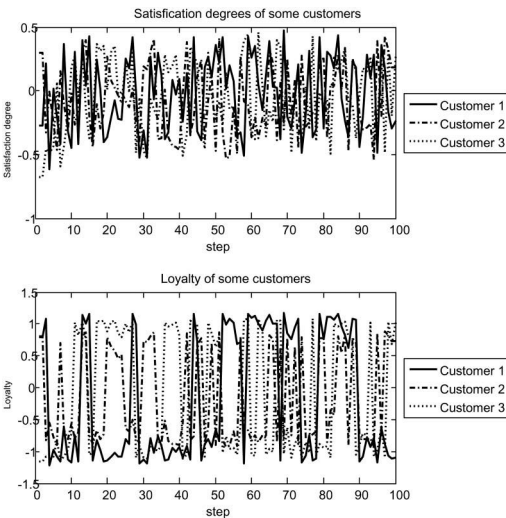

Figure 5. Dynamic of loyalty and satisfaction degree without influence from WOM—three types of customers.

Figure 5 shows the loyalty and satisfaction degree of three customers. Each of them represent a different type of node, and are marked with three types of lines. The solid line represents “Customer 1” who will consider others’ opinions ($0 < w_i < 1$). The dash-dot line denotes “Customer 2” who relies only on others’ opinions ($w_i = 1$). The dotted line denotes “Customer 3” who is not influenced by others ($w_i = 0$).

Figure 6 shows the relationship curves of loyalty, satisfaction degree, and switching cost of these three types of customers. Different dots

Figure 7. Average of loyalty and satisfaction degree with influence from WOM.

represent a different type of customer. The dots marked with “.” are “Customer 1” who are not influenced by others. The dots marked with “+” are “Customer 2” who will consider others’ opinions. The dots marked with “o” are “Customer 3” who relies only on others’ opinions.

Figures 7–10 are curves influenced from WOM. Figure 7 is the dynamic curves of average satisfaction degree and average loyalty. Figure 8 is the

3D dot plot of catastrophe model and the relationship curves of loyalty, satisfaction degree, and switching cost. Because of limited line or dot types, we use only one type of lines or dots to represent the traces of all the customers.

Figure 9 shows loyalty and satisfaction degree of three customers. Each of them represent a type of node, respectively, and are marked with three types

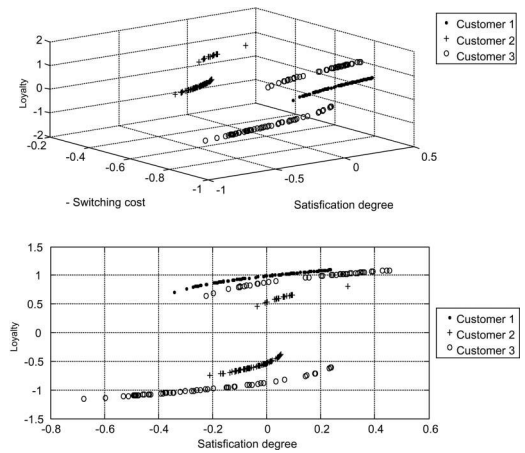

Figure 10. Relationship between loyalty, satisfaction degree, and switching cost with influence from WOM—three types of customers.

of lines. The solid line represents “Customer 1” who will consider others’ opinions ($0 < w_i < 1$). The dash–dot line denotes “Customer 2” who only relies on others’ opinions ($w_i = 1$). The dotted line denotes “Customer 3” who is not influenced by others ($w_i = 0$).

Figure 10 is the relationship curves of loyalty, satisfaction degree, and switching cost of these three types of customers. Different dots represent a different type of customer. The dots marked with “.” are “Customer 1” who are not influenced by others. The dots marked with “+” are “Customer 2” who will consider others’ opinions. The dots marked with “o” are “Customer 3” who only relies on others’ opinions.

Simulation results show that the interaction between customers has a great effect on satisfaction degree and loyalty. It makes the satisfaction degree and loyalty around the middle status. Compared with no interaction, satisfaction degree and loyalty will float smaller and without much diversity. Average curves in Figure 7 change with a smaller range than those in Figure 3. Customers satisfaction and loyalty shown in Figure 5 seem to change more steadily with the effect of the customer network than in Figure 9.

For different types of customers, those who are not influenced by other’s opinions are more smooth than others. Therefore, these types of customers can easily become loyal with several satisfied service. However, once a customer becomes disloyal, service providers must pay more attention to improve his/her satisfaction. Because employing word-of-mouth effect cannot make sense, for the customers who can listen to others’ opinions, utilizing customer interaction is a good method

to increase his/her satisfaction and loyalty. While for those who are prone to make decision relying on others, introducing a group of some loyal customers to him is an easy way.

Therefore, service providers may consider pushing the process to increase the network effect. Especially, when the customers have a low level of loyalty, try to increase the word-of-mouth to find loyal customers easily. Also clearly grouping the customers types can help service providers make detailed plans aiming at different customers.

5 CONCLUSION

Loyalty is so important for service providers that it will influence the retention of customers to repurchase. In this paper, the loyalty model was studied. By modeling satisfaction and analyzing word-of-mouth and switching cost, we showed how the loyalty is influenced in the networked environment. Besides improving the service quality to attract more customers, well utilizing the network interaction is very useful to gain loyalty. Understanding such complex model of customers will help service providers to predict the response of the delivered service among customers.

Research on obstacle avoidance of a mobile robot based on visual information

Jin Jiang

Department of Information Engineering, Jiangsu Polytechnic College of Agriculture and Forestry, Jurong, Jiangsu, China

ABSTRACT: Active obstacle detection and avoidance behavior control has been the key research topic in the field of robot control. In this paper, we propose a visual information acquisition scheme on the basis of visual information and then analyze the visual information into path information source. According to the established route, when encountering obstacles, an algorithm is used to adjust the moving track in real time to meet the goal of intelligent control of mobile robots. The simulation results show that the integration of the visual sensing information can not only obtain the obstacle information, but also guarantee the real-time accuracy of the robot movement control.

1 INTRODUCTION

In recent years, with the rapid development of science and technology, robots have been widely used in various fields. At the same time, the user requires higher degree of robot intelligence. How to select and adjust the real-time route as well as how to take the initiative to avoid obstacles in an unknown environment for the process of robot movement will be undoubtedly one of the key issues to be solved (Khansari, 2012).

At present, the use of ultrasonic, infrared, stereo vision, and other sensor technologies is an important means to detect obstacles. Avoiding strategy after an obstacle is found as one of the key issues of the current robotic exploration. A large number of studies have been carried out in the academic circles. For example, Kim (2015) adopted a neural network-based method to find the optimal path, Huang (2015) adopted a method based on the comprehensive analysis of the grid method means to find the shortest movement trajectory, and Montiel (2015) adopted the artificial field potential method to dynamically adjust the movement trajectory of the robot. Therefore, in this paper, we choose the mode to detect obstacles based on visual information and focus on the strategy and path adaptive control of obstacle avoidance in the process of robot moving.

2 VISUAL INFORMATION CONVERSION

In order to avoid obstacles, the robot needs to follow the collected visual information to carry out

the following process. To effectively reduce the volume and weight of the robot, this paper uses a pinhole camera to collect the information of the surrounding environment.

As shown in Figure 3, according to the imaging principle of the pinhole camera, the pixel coordinates in the image plane can be collected by the camera, and the 3D coordinates of the robot coordinate system can be transformed into the coordinate system (Cherubini, 2014). Assuming that the camera is fixed on the robot's height H , the origin of parameters O_L for the robot coordinate system is (X_L, Y_L, Z_L) , the lens optical center O_c in the robot coordinate system parameter is (O_{cx}, O_{cy}, O_{cz}) , the origin of parameters of image center O_I in camera coordinate system is on the Z_c axis, (I_x, I_y) is one of the feature points in the image and (x_r, y_r) is the point coordinate on the ground in the robot coordinate system.

According to the principle of imaging and the internal and external parameters of the camera, the coordinates of the points on the ground can be determined by using the coordinates of points extracted from the image (X_L, Y_L) . The space position relation between the object and the object in the robot coordinate system is obtained.

The camera captures image information, and an ideal image should be a digital image without no distortion, small noise, and clear image. The general optical imaging system is far away from the optical axis, the image will have a larger distortion, including barrel distortion and the distortion of the shape of the pillow.

Considering the radial and tangential distortion in the imaging optical system to model distortion

Figure 1. Camera imaging model.

and distortion parameters through the appropriate existing system, it can be better to correct the distortion caused by the error.

Image distortion model coefficients are usually defined as the normalized image coordinates of the ideal linear pinhole model. No image distortion is normalized to (x_n, y_n) , $r = \sqrt{x_n^2 + y_n^2}$ denotes an image point from the optical axis of the camera, and the amount of distortion is represented by δ . The tangential distortion is generally expressed as:

$$\begin{bmatrix} \delta x^{(t)} \\ \delta y^{(t)} \end{bmatrix} = \begin{bmatrix} 2p_1 x_n y_n + p_2 (r^2 + 2x_n^2) \\ p_1 (r^2 + 2y_n^2 + 2p_2 x_n y_n) \end{bmatrix} \quad (1)$$

The radial distortion generally uses the following formula:

$$\begin{bmatrix} \delta x^{(t)} \\ \delta y^{(t)} \end{bmatrix} = \begin{bmatrix} x_n (k_1 r^2 + k_2 r^4 + k_3 r^6 + \dots) \\ y_n (k_1 r^2 + k_2 r^4 + k_3 r^6 + \dots) \end{bmatrix} \quad (2)$$

where k_i represents the order coefficient. Because of the different calculation model, the calculated mean number of parameters and parameter values are very different, and different calculation models may lead to different errors.

3 FRAME OF ROBOT OBSTACLE AVOIDANCE BASED ON VISION

Vision-based robot obstacle avoidance framework involves two kinds of systems: visual information collection and mobile control. The design principles and ideas of the framework can be described as follows.

First, by installing the camera on the robot to detect environmental information, the information is transmitted to the robot behavior control system

in order to carry out the analysis of environmental information. Meanwhile, according to the camera used to capture the image data, the operation range is determined.

Then, the behavior control system to receive the video data, after the image processing, traffic information will be collected, obstacle information and target position data are used to construct the corresponding two-dimensional map. Then, using the path planning module, we generate a path from the initial point to the target point and then the obstacle avoidance algorithm is used to control the behavior of obstacles.

In the process of moving the control system, robot will be used to obtain the coordinate values, speed, steering angle, and other parameters, in order to guide the movement of the robot. The robot obstacle avoidance framework is shown in Figure 2.

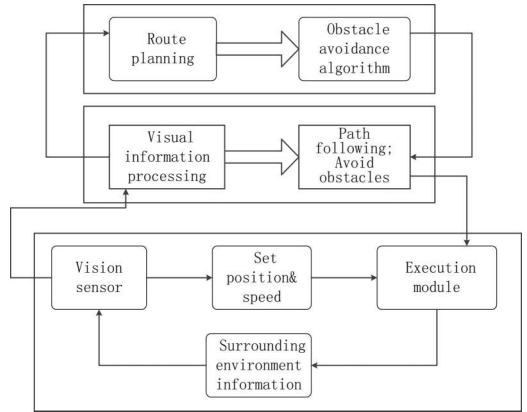

Figure 2. Frame of robot obstacle avoidance based on vision information.

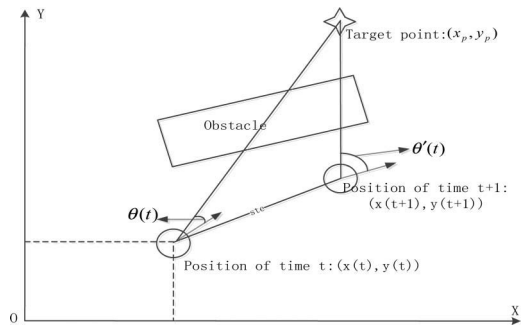

Figure 3. Representation of parameters in a coordinate system.

4 DESIGN OF ROBOT OBSTACLE AVOIDANCE ALGORITHM

Figure 3 shows the establishment of a two-dimensional reference coordinate system for the controlled object and robot movement. For the convenience of calculation, it is assumed that there is no sliding between the wheel and the ground (Yang, 2016). The initial coordinate system is XOY ; the target point coordinates are (x_p, y_p) ; at any moment t , the robot's line speed is $v(t)$, and the robot's current position state is $(x(t), y(t), v(t))$.

Assuming that current heading angle of the robot and the connection point between the centroid target is $\theta(t)$ and the steering angle is $\theta'(t)$, the following relationship exists between the various parameters:

$$v(t) = \arctan \frac{|\Delta y|}{|\Delta x|} = \frac{|y(t+1) - y(t)|}{|x(t+1) - x(t)|} \quad (3)$$

$$D = \sqrt{(x_p - x(t))^2 + (y_p - y(t))^2} \quad (4)$$

$$\theta(t) = \arctan \frac{|y_p|}{|x_p|} - v(t) \quad (5)$$

When the robot departs from the starting point, it will move to the target point in accordance with established routes. In the process of moving, if the camera sensor does not detect the obstacle information or detects obstacle distance, according to the detected robot vision-based orientation sensor and the target heading to the robot connection to the steering by angle $\theta(t)$, it moves to the target point with the speed of $v(t)$. In the course of motion, if the vision sensor detects the obstacles, which have a relatively close distance, the steering control is carried out according to the direction of the obstacle relative to the robot and the direction of the target, by avoiding obstacles at the speed of $v(t)$. The lower the distance of the obstacle, the greater the value of $\theta(t)$, so as to avoid collision. After the obstacle is avoided, the robot will move to the target point based on the angle $\theta(t+1)$ measured by the azimuth detector.

The steps involved in moving the robot according to the obstacle avoidance algorithm are as follows:

- Step 1: Determine whether the current position is the target point; if it is stopped, enter the next step.
- Step 2: To determine whether the current collision is possible, if any, then go to the next step, or jump to step 4.
- Step 3: According to the algorithm to control the robot dynamic obstacle avoidance, avoid obstacles.

Step 4: Toward the target point movement and after a decision cycle, jump to step 1.

5 SIMULATION OF OBSTACLE AVOIDANCE MODEL

In order to facilitate the simulation, four types of parameters need to be set. The first is to set the starting position of the robot. The second is to set the target position of the robot. Once again, set up multiple obstacles. Finally, set up obstructions distance (when the distance between the obstacle and the car is greater than the distance, it is not affected by the obstacles). In order to facilitate the representation, assuming that the starting position and the ending position are parallel to the coordinate axes, the upper and the lower edges of the two connecting lines are respectively provided with two obstacles, and the middle of the connecting line is provided with an obstacle.

According to the above design ideas and algorithms, this experiment uses MATLAB to simulate. There from, the robot obstacle avoidance trajectory model can be simulated as shown in Figure 4.

Similarly, in accordance with the above design ideas, set four types of parameter information.

Different from the first simulation model, the starting position and the target position are set on the two axes of the segmentation line, and the two coordinate axes are distributed with 45° . Meanwhile, the mobile robot designed in this paper adopts two wheel drives, which are divided into linear motion and circular motion. If the line speed on both sides of the wheel is consistent, the robot moves along a straight line. If the line speed of the two wheels is not consistent, the robot will make a certain radius of circular motion. According to the previous algorithm, the robot obstacle avoidance trajectory model is simulated as shown in Figure 5.

Using the simulation model of the robot by controlling the speed and direction of movement of the line angle, we can achieve the purpose of controlling a mobile robot. Because different parameter settings will produce different results, we cannot achieve the desired goal, which may be related to the obstacles in the distance setting, and the initial coefficient is not suitable for the relevant.

Figure 4. Trajectory model of robot obstacle avoidance.

Figure 5. Trajectory model of robot obstacle avoidance.

As can be seen from the above model, the robot uses the information collected by the vision sensor to be sent to the control center for processing and meets the requirements of real-time obstacle avoidance. Simulation results prove that the algorithm is feasible and obstacle avoidance control process has certain stability.

6 CONCLUSIONS

The dynamic environment information sensed by the mobile robot is the key to avoid obstacles. Meanwhile, the vision sensor not only needs to be large enough to detect the scope, but also needs a higher acquisition real-time performance. Therefore, it is an urgent problem to be solved in the process of robot control to avoid obstacles in the dynamic environment with static and moving objects.

In this paper, we discussed the algorithm of obstacle avoidance of a mobile robot in the pro-

cess of acquiring, using visual environment obstacle information, then according to the direction of movement and obstacle area dynamic obstacle avoidance processing, effectively avoiding obstacles and moving to goal. However, there are still problems such as real-time system problems, diversification of the target characteristics, and uncertainty of the road surface in the process of robot control, which need to be studied in the future.

Multifocus image fusion based on defocus map estimation and NSCT

Ruixia Shi, Fanjie Meng, Dalong Shan, Pingping Zeng & Yanlong Wang
Institute of Intelligent Control and Image Engineering, Xidian University, Xi'an, China

ABSTRACT: A novel method based on the defocus map estimation and the Non-Subsampled Contourlet Transform (NSCT) is proposed in this paper. First, the degree of defocus of source images is estimated. Second, source images are divided into the left focused area, right focused area, and uncertain area, according to the defocus map estimation of source images. At the same time, high-frequency coefficients and low-frequency coefficients of source images are obtained after the NSCT is employed for source images. For uncertain area, Sum of Modified Laplace (SML) and Spatial Frequency (SF) are employed to fuse low-frequency coefficients and high-frequency coefficients, respectively. For the left focused area and the right focused area, the corresponding focused areas of source image are selected directly. Finally, through the combination of the fused uncertain area, the left focused area and the right focused area of the fused image are achieved. Compared with the traditional methods, experiment results show that the fusion effect is improved obviously in vision and parameters.

1 INTRODUCTION

Because of the limitation of focused range of optical lens, getting an image in which all targets are clear in one scene is difficult. Usually there are parts of focused and defocused targets in an image. Therefore, in order to achieve an image that all targets are clear, multifocus images must be fused.

Usually, multifocus image fusion methods are based on the pixel-level fusion and region-level fusion. Traditional pixel-level fusion (Li, 2004) is mainly based on multiscale transform, which includes pyramid transform (Liu, 2001), wavelet transform (Amolins, 2010), contourlet transform (Nencini, 2007), and NSCT transform (Cunha, 2006). These methods only concerned multiscale images, but not analyzed region characteristics of the source images. Because of the limitation of rules of pixel-level fusion, it cannot select all coefficients from the focused area, which will decline the quality of the fused image. Region-level fusion methods are mainly based on region segmentation and regional block segmentation.

The traditional segmentation methods are K-means clustering segmentation (Pena, 1999), entropy rate superpixel segmentation (Li, 2013), 3D doctor (Bindu, 2014), and regional block segmentation. However, the traditional segmentation method makes some blocks containing both focused and unfocused regions, thereby declining the quality of the fused image. However, region block fusion is very likely to cause the blocking artifacts in the fused image.

In order to solve the above problems, this paper proposes a fusion algorithm on the basis of region-level fusion and pixel-level fusion. The focused region is fused based on region level, and the uncertain region is fused based on pixel-level. This method can make focused area more accurate and the utilization of useful information of the source image maximum.

2 REGIONAL DIVISION BASED ON DEFOCUS MAP ESTIMATION

In recent years, the focused region is detected by calculating the Root Mean Square Error (RMSE) (Yang, 2015) between initial fused image and source images, or Symantec Security Information Manager (SSIM) between initial fused images and source images (Ning, 2015). Then, a mathematical morphological filter is employed to filter the initial region detection map. Finally, the final regional detection map is achieved. However, the methods of region detection based on RMSE and SSIM rely on initial fusion rules, different initial fused images can be obtained with different fusion rules, and different region detection maps are obtained. Therefore, these algorithms have higher requirement for the quality of the initial fused image; otherwise, we cannot obtain the accurate region detection map, leading to choosing the wrong region of the source image as the region of fused image.

Currently, the detection of fuzzy region has made some achievements. Zhuo (2011) used a

Gaussian kernel to re-blur input source image and calculate the ratio of the gradients of input to re-blurred images. By propagating the blur amount at edge location to the entire image, a full defocus map can be obtained. The robustness of the method is higher and not susceptible to noise. The higher the luminance value of the region in defocus depth estimation map, the more blur the corresponding region is. The lower the luminance value of the region in defocus depth estimation map, the clearer the corresponding region is, as shown in Fig. 1.

For multifocus images, by estimating the degree of defocusing of source images, the defocus estimated map of source images is obtained, as shown in Figure 2(c) and (d). By comparing the defocus estimated map of image A and image B, a binary map C is achieved:

$$C(i, j) = \begin{cases} 1 & A1(i, j) - B1(i, j) \geq T \\ 0 & A1(i, j) - B1(i, j) < T \end{cases} \quad (1)$$

where A1 represents the defocus estimated map of the right focused image, B1 represents the defocus estimated map of the left focused image, C represents the initial region detection map, and T is a threshold; generally T is 0 or (-0.5 to 0.5).

Then, a mathematical morphological filter is employed to the initial detection map to remove isolated dots and small-area regions. However, the dividing line between the focused region and defocused region is not very accurate, if the fuse

Figure 1. (a) Source image and (b) defocus map of (a).

Figure 2. (a) Left focus image, (b) right focus image, (c) defocus map of (a), (d) the defocus map of (b), (e) the consequence of Ref. (Wang, 2012), (f) the consequence of ref. (Sun, 2013), and (g) and (h) consequences of our method.

source image is obtained directly from the initial detection map. It will result in a wrong choice of local border region, which reduces the quality of the fused image. Therefore, volatile operation is employed for white areas and black areas of C, and then the gray region, namely the uncertain region, is achieved, as shown in Figure 2(g). The region detection map, which is divided into left focused area, right focused region, and uncertain region, is shown in Fig. 2(h).

3 THE NSCT AND FUSION ALGORITHM

3.1 Introduction of the NSCT

The NSCT is based on Non-Downsampling Pyramid (NSP) and no-subsampled directional filter banks to implement multiscale and multidirectional decomposition, respectively. It is proposed based on improved contour transform. The structure of NSCT is similar to that of contour transform, but comparable to that of contour transform. It not only has the advantages of retaining multiresolution, localization, and multidirection, but also has the advantage of translation invariance, which can eliminate the Gibbs phenomenon. It overcomes the limitation of direction in traditional wavelet transform and variation of translation in contour transform, and can better express the detailed features of the image.

3.2 Fusion algorithm based on the NSCT

1. Estimate the degree of defocusing of the source image A and B, and then defocus the estimated map of A and B to achieve A1 and B1.
2. By comparing A1 and B1, a binary map C is achieved. Then, the morphological filter is employed to filter map C; finally, we can obtain the zoning map C1, which is divided into left focused area, right focused area, and uncertain area.
3. The NSCT is employed for source images, selecting fusion rules of the uncertain area.
4. According to the zoning map C1, select the corresponding area of left focus image A as the left focused area of fused image and select the corresponding area of right focus image B as the right focused area of fused image.
5. Combining the fused uncertain area, the left focused area, and the right focused area, the final fused image F is achieved.

The fusion flowchart is as follows:

The coefficient in the low-frequency sub-band represents the approximate information of source images and contains the highest energy of the source images. However, traditional average fusion

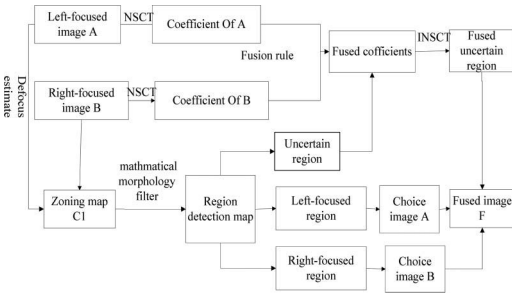

Figure 3. Schematic diagram of the proposed image fusion algorithm.

methods not only decrease the overall brightness of image, but also make the fused image fuzzy.

Therefore, considering that the visual characteristics of the human eye and SML can evaluate degree of focus better, the fusion rule of low-frequency coefficients presented in this paper employs the principle of SML on the basis of local visual contrast. Local features of an image are not determined by a single pixel, but are characterized by a plurality of pixels in a common region. Thus, we calculate the region's LV of each low-frequency coefficient in equation (2). The size of window is $n \times n$, where $n = 3$.

It is defined as follows:

$$LV^x(i, j) = \begin{cases} \frac{SML^x(i, j)}{\overline{L^x(i, j)}^{1+a}} & \text{if } \overline{L^x(i, j)} \neq 0 \\ SML^A(i, j) & \text{otherwise} \end{cases} \quad (2)$$

$$LV1^x(x, y) = \sum_{p=-(n-1)/2}^{p=(n+1)/2} \sum_{q=-(n-1)/2}^{q=(n+1)/2} LV^x(i+p, j+q) \quad (3)$$

where $a = 0.6$, $\overline{L^x(i, j)}$ is the mean value region of the pixel (i, j) , and x is the source image A or B. The final fused rule is defined as follows:

$$L^F(i, j) = \begin{cases} L^A(i, j) & LV1^A(i, j) \geq LV1^B(i, j) \\ L^B(i, j) & LV1^A(i, j) < LV1^B(i, j) \end{cases} \quad (4)$$

where $L^A(i, j)$ and $L^B(i, j)$ represent the low-frequency coefficients of image A and B, respectively, and $L^F(i, j)$ is the fused low-frequency coefficient.

After the NSCT transformation of source image, the high-frequency coefficient can fully reflect the rich details information of source image, such as edge profile. Spatial Frequency (SF) reflects fundamental features used by the human visual system, so for image fusion, salient information and more detailed information can be extracted from source

images effectively via SF. Our fusion method is defined as follows:

The Row Frequency (RF) and the Column Frequency (CF) of an image are expressed as:

$$CF^2 = \sum_{i=1}^m \sum_{j=0}^n (f(i, j) - f(i-1, j))^2 \quad (5)$$

$$RF^2 = \sum_{i=0}^m \sum_{j=1}^n (f(i, j) - f(i, j-1))^2$$

where $f(i, j)$ represents the images of size $M \times N$. The total spatial frequency is calculated by Equation (6):

$$SF = \sqrt{\frac{1}{M \times N} (RF^2 + CF^2)} \quad (6)$$

Therefore, regional spatial high frequency is computed by equation (7), with the size of window $n = 3$:

$$S^x(i, j) = \sum_{p=-(n-1)/2}^{p=(n+1)/2} \sum_{q=-(n-1)/2}^{q=(n+1)/2} SF_i(i+p, j+q) \quad (7)$$

$S^x(i, j)$ is regional spatial frequency of pixel (i, j) and x represents the left focused image A or the right focused image B. The fused rule is defined as follows:

$$H^F(i, j) = \begin{cases} H^A(i, j) & S^A(i, j) \geq S^B(i, j) \\ H^B(i, j) & S^A(i, j) < S^B(i, j) \end{cases} \quad (8)$$

where $H^A(i, j)$, $H^B(i, j)$, and $H^F(i, j)$ represent the high-frequency coefficients of images A, B, and fused image F, respectively.

Finally, according to image C1, the corresponding area of left focus image A is selected as the left focused area of the fused image, and the corresponding area of right focus image B is selected as the right focused area of fused image. Combining the fused uncertain area, the left focused area, and the right focused area, the final fused image F is achieved.

4 EXPERIMENTS

Because there are no reference images, the noise or false information may be introduced in the process of fusion, and the parameters of entropy, spatial resolution, and gradient evaluation cannot evaluate the quality of fused image correctly. Therefore, the Mutual Information (MI) and the edge-dependent (Q_{abf}) are used to measure how much information of the original images the fused image F contains.

Figure 4. Fusion results of images. A) Left focus image, B) right focus image, C) region detection map, and D) fusion results of our method: D1)–D4) fusion results of Wang (2012), Sun (2013), Maruturi (2014), and Liu (2015), respectively.

The larger the value of MI and Q_{abf} , the better the fusion result is. Compared with the fusion methods proposed recently (Maruturi, 2014; Liu, 2015; Luigi, 2009; Lillo, 2008), the superiority of the method proposed in this paper is verified.

Figure 4 shows that the DCT algorithm has the block effect and cannot describe the information correctly. Pixel-level fusion algorithms based on NSCT cannot obtain focus area accurately. The proposed method can not only extract the focus

Table 1. Objective evaluation of different fusion methods for different multifocus images.

Image	Evalu- ation index	Multifocus image fusion methods				Ours
		Ref (Maruturi, 2014)	Ref (Liu, 2015)	Ref (Luigi, 2009)	Ref (Lillo, 2008)	
Images 1	MI	6.9547	7.0390	7.1023	8.2346	8.8162
	Q_{abf}	0.7517	0.7183	0.5854	0.7755	0.7827
Images 2	MI	7.2076	7.0077	7.4177	8.7226	8.8343
	Q_{abf}	0.6984	0.6428	0.5154	0.7430	0.7457

	Q_{abf}	0.7134	0.6209	0.4952	0.7432	0.7447

area better, but also fully utilize the useful information of source image.

Table 1 shows the objective evaluation index of four group images. It can be seen from the table that the indexes of the method proposed in this paper are higher than those of other methods; the fused image in this paper can not only extract useful information fully from the source image but also make the spectrum information of fused image loss minimum.

A new and effective image retrieval method based on representative regions

Dalong Shan, Fanjie Meng, Ruixia Shi, Yanlong Wang & Pingping Zeng
Institute of Intelligent Control and Image Engineering, Xidian University, Xi'an, China

ABSTRACT: In this paper, we propose a new image retrieval system based on representative regions. First, image is segmented to several categories using K-means and Affinity Propagation (AP) clustering methods, and the largest region of every category is found as the representative region. Then, color and texture features of the representative regions are obtained through the HSV color histogram and Local Binary Pattern (LBP). Representative Region Matching (RRM) algorithm is used for calculating the distance between the query image and database images combining color, texture features with location, and area weight. Experimental results show that the proposed method is more prominent than retrieval using some of the existing methods.

1 INTRODUCTION

With the development of computer technology and network, information disseminating through digital images is becoming more and more general. To find the target images from the big date, the Content-Based Image Retrieval (CBIR) (Flickner, 1995; Stricker, 1995) technology attracts extensive attention. However, it is also faced with some problems, especially “the semantic gap” (Chen, 2005), which refers to the gap between the low-level visual feature and human semantic interpretation of an image. Region-Based Image Retrieval (RBIR) technology is the most common method, which can solve this problem by segmenting image into regions and choosing one or multiple regions to participate in the matching; the way of matching mainly includes individual region matching and integrate region matching. Li et al. (2001) from Stanford University proposed the SIMPLiCity system, which extracts color, texture, shape, and location characteristics of all regions in the image. The Integrated Region Matching (IRM) algorithm is used to allow one region matching with many regions belonging to another image, so the influence on the retrieving result due to image segmentation error is reduced; in other words, the robustness of the system is improved. Yuber et al. (Li, 2001) proposed an RBIR system, in which a binary coding method is used to accelerate the running of system by coding regions of images in the database, and to reduce the influence of irrelevant regions, the user can select regions from the query image that represent their interest. In the integrate region matching system such as SIMPLiCity, regions are assigned different weights. However,

the similarity of regions is ignored and the similar regions are matched repeatedly, which result in the interference to the weights of other regions. In individual region matching system, there are mainly two methods to obtain regions: artificial selection and salience method. The former causes the neglect of background and low-level salient regions in the image, whereas the latter can bring huge workload for the user.

To solve these problems, this paper proposes an image retrieval method based on representative regions. Image is segmented into independent regions by using K-means and Affinity Propagation (AP) clustering segmentation methods. The largest region of every object is recorded as the representative region participating

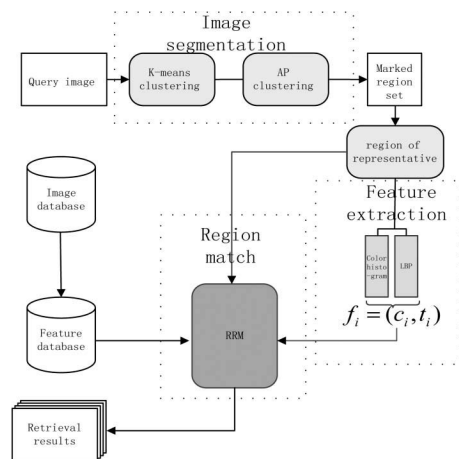

Figure 1. Algorithm of the proposed method.

in matching to ensure the integrity and avoid repetition of matching. Then, the color and texture features of the representative regions are obtained through the HSV color histogram and Local Binary Pattern (LBP), respectively. Representative Region Matching (RRM) algorithm is used for calculating the image distance between query image and database images combined with color, texture features, location, and area weight. Experimental results show that the proposed method provides better retrieving result than retrieval using some of the existing methods. The outline of the proposed framework is illustrated in Fig. 1.

2 PROPOSED METHOD

A formal description of the proposed retrieval framework based on representative regions is given in this section.

2.1 Extraction of representative regions

In order to find blocks representing different substance in an image precisely, K-means and AP clustering segmentation methods are used. In K-means algorithm, n objects are divided into K clusters and classified depending on the similarity of data. The number of clusters (K) need to be set in advance in K-means; however, the number of objects in different image are not equal, so setting a confirmed value K is inaccurate. K-means is combined with AP algorithm in our method to identify the number of clusters automatically. The strategy we adopt is over clustering and clustering again; categories of objects are usually less than 10 in an image, and accordingly, images are operated by the K-means clustering, where K is set to 10, and then, the results are operated by AP clustering in order to merge the similarity regions to the same category. The reason for not adapting AP along is that the algorithm is complex and time-consuming facing a big database.

The largest region of every category is found as the representative region used for matching with assigned different weights. Our method can describe image feature more accurately than the methods focusing on salient region detection and those based on fixed block.

2.2 Feature extraction

We calculate the color features represented regions using HSV histogram statistics, and H, S, and V color channels are divided into 18, 3, and 3 sections, respectively. The LBP method is used to calculate the texture features of regions and then distribute the LBP results into 24 sections and normalized:

$$c(h,s,v) = \frac{N(h,s,v)}{N_{total}} \quad (1)$$

$$t(lbp) = \frac{N(lbp)}{N_{total}} \quad (2)$$

$$lbp = \sum_{r=0}^7 l(g_r - g_c)2^r \quad (3)$$

$$l(x) = \begin{cases} 1, & x \geq 0 \\ 0, & x < 0 \end{cases} \quad (4)$$

where c , t are color and textual features, respectively; $N(h, s, v)$ represents the number of pixels whose value is h, s, v in H, S, V channel, respectively; N_{total} means the number of pixels in the area; $N(lbp)$ indicates the pixels number when the LBP value is lbp in regions; g_c is the average pixel value of 3×3 block, and g_r is the value of pixel r .

2.3 Representative region matching

IRM algorithm is used to allow one region matching with many regions of another image, so the influence to the retrieving results due to image segmentation error is reduced. However, the similarities of regions are ignored, and similar regions were matched repeatedly, which result in the interference of weight

Figure 2. (a) Original image, (b1–b3) regions participated in matching in Krishnamurthy (2015), (c1–c5) regions participated in matching in Rashno (2015), (d1–d3) regions participated in matching in the proposed method.

Figure 3. Five images and their segmentation results of K-means combined with AP clustering method.

of other regions; At the same time, regions weight is assigned just by its area in IRM algorithm, which cannot represent the interest of regions precisely. Therefore, RRM algorithm with combined area and location weight is proposed to calculate the distance between images precisely.

For computing the color and texture features and the distance between representative regions in I_1 and I_2 , we choose the region b_j in I_2 with the minimum distance between a_i in I_1 as the matched region of a_i . The distance between a_i and b_j is defined as:

$$D_{ij} = d(c_i, c_j) + d(t_i, t_j) \quad (5)$$

where i and j are the ordinals of representative regions in I_1 and I_2 ; $c_i, c_j, t_i,$ and t_j are, respectively, the color and texture feature vectors of region a_i and b_j . The distance between I_1 and I_2 is defined as:

$$D = \sum_{i=1}^m \min_{j=1}^n (D_{ij}) * W(i) \quad (6)$$

where W is the weight vector of representative regions in query image:

$$W(i) = 1 / (\sum_{i \in r} \|f(n) - (0.5, 0.5)\| / N_i) + \text{sqrt}(N_i / N_{total}) \quad (7)$$

$$f(n) = [n_x / row, n_y / col] \quad (8)$$

where m and n are the numbers of representative regions in images I_1 and I_2 ; N_i, N_{total} respectively, are the number of pixels in representative region i and the total image; n_x, n_y represent the coordinates of pixel n in i ; row and col denote the length and breadth of image. The weight of representative regions vary directly as the area of regions and inversely as the average distance between pixels in regions and the center of the image, that is, the region closer to the center of image and with a larger area will have a high weight.

3 EXPERIMENTAL RESULTS

The algorithm has been implemented using MATLAB-2014a in Windows 7 and run on CPU 3.20GHz PC. The database used in our experiments is Wang database, which has 1000 images and categorized into 10 categories (African, beach, building, buses, dinosaurs, elephants, roses, horses, mountains, and food). In order to indicate the validity of our method, precision rate is used to evaluate the result, and is defined as:

$$P = n_k / K \quad (9)$$

where K is the number of retrieved images and n_k is the number of relevant images in the retrieved

images. The average precision of the images belonging to the category q is given by:

$$\bar{P} = \sum_{q=1}^{10} P_q / 10 \quad (10)$$

In the proposed algorithm, multiple regions with different weights participating in matching not only ensure the integrity of image features, but also avoid repeated matching. As shown in Fig. 4, no matter images with complex scenes like beach and building which do not have an obvious salient region or the images have clear objects, such as flowers and horses, both show excellent retrieval performance. Table 1 shows a comparison of our method and others, from which we can find that our method is better with six types of images: bus, dinosaur, elephant, flower horse, and food. However, our method does not have prominent performance when dealing with images that have complex background

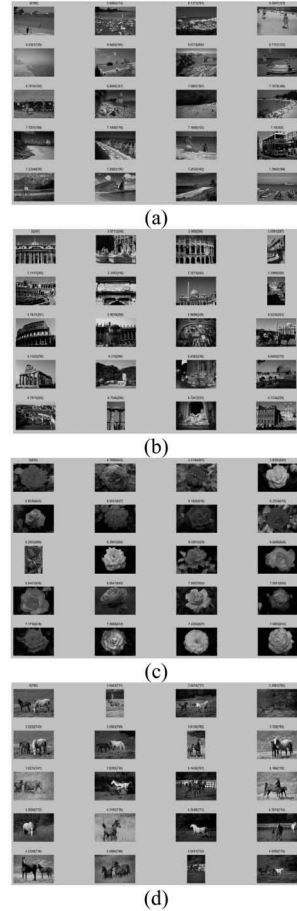

Figure 4. Some image retrieving results.

Table 1. Precision of the retrieval by different methods when K = 20.

Category	CTD				
	CIRS (2011)	Vimina (2013)	Rashno (2015)	Lin (2009)	Proposed method
African	56.20	71.52	44.80	68.30	62.00
Beach	53.60	43.60	47.20	54.00	52.50
Building	61.00	53.55	53.40	56.20	60.00
Buses	89.30	85.30	73.40	88.80	90.50
Dinosaurs	98.40	99.55	99.80	99.30	99.80
Elephants	57.80	59.10	56.80	65.80	75.00
Roses	89.90	90.95	87.50	89.10	94.50
Horses	78.00	92.40	70.70	80.30	94.50
Mountains	51.20	38.35	39.30	52.20	47.50
Food	69.40	72.40	61.00	73.30	75.00
Average precision	53.24	70.67	63.39	72.70	75.13

Figure 5. Average precision of different methods.

such as Africa, beach, and mountain; this indicates that our method is suitable for the images that have obvious salient regions. Generally speaking, the average retrieval precision of 75.13% is more prominent than the other method mentioned.

The comparison of average precision obtained by the proposed system with other retrieval systems when K is 20, 40, 60, 80, and 100 is shown in Fig. 5. We can observe that the average precision of our method is not highest when K = 100. These results clearly show that the performance of the proposed method is better than that of the other methods.

4 CONCLUSIONS

We propose a new image retrieval system based on representative regions. First, the image is segmented into several categories using K-means and AP clustering methods. The largest region of every category is found as the representative region. RRM algorithm is used for calculating the distance between query and database images combining color, texture features with location, and area weight. Experimental results show that

the proposed method is more prominent than the existing methods. The aim of our next work is to further improve the accuracy of segmentation and make the method to have better applicability in the images with complex background.

Semantic similarity research on case retrieval based on ontology

Yiling Liu, Hong Duan & Lei Luo

College of Information System and Management, National University of Defence Technology, Changsha, Hunan, China

ABSTRACT: Case retrieval is an important link in Case-Based Reasoning (CBR). In this paper, we choose ontology as a tool to describe cases and construct case library. On this basis, we analyze the features and retrieval requirements to choose appropriate similarity measurement and design the case retrieval algorithm. We proposed a new similarity measurement called Matched Genealogy Measure (MGM), considering not only elements separately but also cases as a whole. Then, we took combat simulation as an example to illustrate the ontology-based algorithm and designed experiments to evaluate it by comparing with some existing measurements. Furthermore, we performed user studies to obtain the ideal retrieval results and compared the retrieval results of different algorithms using Window Distance with the ideal results. The results suggest that MGM could perform better in matching human intuition and obtain reasonable retrieval results. Finally, we adjusted the two coefficients in MGM and demonstrated that MGM could meet different preferences of users.

1 INTRODUCTION

Case-Based Reasoning (CBR) is one of the three reasoning methods, together with Rule-Based Reasoning and Model-Based Reasoning. The main idea of CBR is to take advantage of historical experiences to solve new problems. Thus, we could know the importance of case retrieval by determining which cases are similar to the new one and could help to solve the problem. Most of the cases are recorded in natural text, and the traditional retrieval algorithms would match them by keywords. However, the keyword-based matching could result in more outlying information. Thus, more and more studies focus on knowledge expressing and semantic retrieval.

Ontology (Gruber, 1993; Asuncion, 1999; Xie, 2009) is a specification of a conceptualization, and it is very important for knowledge expressing and organizing, which facilitates essential semantic knowledge describing and understanding in computers. The recently studied ontology modeling makes use of these features to organize knowledge and takes some effects; for example, Gruninger (Gruninger, 1995) put forward a method to design and describe ontology and constructed a frame to evaluating the completeness of ontology.

In this paper, we proposed a new similarity measurement called Matched Genealogy Measure (MGM), which is based on the chosen Genealogy Measure and affected by matching ratio. The GM method described semantic similarity between concepts, but it is short of presenting cases or

collections as a whole. In fact, when we consider two similar cases, they are apparently not only similar in concepts, but also their construct or scale will have something in common. The MGM will present these features and try to perform better on meeting human intuition.

Taking combat simulation as an example to illustrate the ontology-based algorithm, we describe some combat simulation cases based on ontology and design experiments on the case library. We conducted user studies to get an ideal list of cases ordered by their similarity compared with a given case. Different algorithms will get different orders of these cases and compare these lists to know how well these algorithms meet human intuition.

The remainder of this paper is organized as follows: Section 2 introduces some related work on similarity measurements. Section 3 describes the case retrieval algorithm based on ontology. Sections 4 and 5 present the experiments on combat simulation cases and results. Section 6 provides some conclusion and proposes some further research issues.

2 RELATED WORK

In particular, case retrieval refers to calculating similarity between cases on which to base the choice of some similar cases to the current one from library, according to a certain similarity measurement. There are several studies on concept or case similarity.

Bernstein A proposed “ontology distance” (Bernstein, 2005) to describe the shortest path with a common ancestor node of two objects or the shortest common path linking two objects with a common descendant node. It can be predicted that the similarity will be higher at a smaller distance. The ontology distance considered both the distance between two concepts in the tree and the information described by the depth of concepts in the tree. It fits more to measure semantic similarity of concepts in the same ontology, but is difficult to measure similarity between objects or collections.

Al-Mubaid and Nguyen (Al-Mubaid, 2006) combined path length and common trait to get concept similarity, where path length is the length of the shortest path between two concepts, and common trait depends on the depth of the Least Common Subsumer of two concepts.

Traditionally, objects are considered as collections of concepts when calculating similarity, for example, Dice’s similarity formula (Ganesan, 2003):

$$sim_{Dice}(X, Y) = \frac{2 \times |X \cap Y|}{|X| + |Y|}$$

Some other methods also abstract concepts or elements into dimension in vector space, while objects as vectors, which is the most widely used model for information retrieval (Salton, 1983). An apparent benefit of this model is that the weight of different elements could be adjusted. In vector space model, similarity between two objects is normally measured by the cosine value of the two corresponding vectors. Another method measures the similarity by Pearson’s correlation coefficient, which is commonly used in consensus filter, such as GroupLens’ research (Resnick, 1994).

Ganesan P (Xie, 2009) improved the vector space model by redefining dot product of leaves with the depth of the Least Common Ancestor, calling it as Generalized Co-sine-Similarity Measure (GCSM). However, considering that objects could be quite different from each other, the vectors could be so sparse that the data redundancy is serious. Another algorithm proposed by Ganesan P is Genealogy Measure, which introduced hierarchical domain structure and measured similarity with the depth of the Least Common Ancestor. The authors also put forward some improvements for multiple occurrences. The four algorithms in Ganesan’s thesis fit different situations: GCSM does well in long query, especially when containing some similar key words; OGM focuses more on similarity of objects while ignore differences; choice between BGM and RGM depends on whether the user focuses on coverage or distribution of elements. Besides, RGM could balance the coverage and distribution of elements by adjusting parameters.

3 CASE RETRIEVAL ALGORITHM BASED ON ONTOLOGY

3.1 Genealogy measure for similarity

Ontology is actually a specification of conceptualization, which could be shown by many methods. Assume that ontology O could be depicted by a concept tree U , which has a prior weighting function W for its leaves. Then, the cases could be expressed as a collection of leaves of the concept tree. For given leaves l_1 and l_2 , we can define the Lowest Common Ancestor (LCA) as the deepest ancestor node of l_1 and l_2 , notated as $LCA(l_1, l_2)$. In general, the Genealogy Measure is based on the depth of LCA.

Consider two objects C_1 and C_2 , defining introduced trees as T_1 and T_2 . Define $LCA_{T_1, T_2}(l_i)$ for every leaf l_i in T_1 , expressing the deepest ancestor of l_i appeared in T_2 . Then, we determine the similarity of the two objects following Balanced Genealogy Measure (BGM):

1. Find a matching in T_2 for every leaf l_i in T_1 , denoted as l_{2i} ; enlarge the *match_count* value for l_{2i} , which records how many times l_{2i} matched leaves in T_1 .
2. Define:

$$optleafsim_{T_1, T_2}(l_i) = \frac{depth(LCA_{T_1, T_2}(l_i))}{depth(l_i)}$$

then we have:

$$leafsim_{T_1, T_2}(l_i) = optleafsim_{T_1, T_2}(l_i) \times \beta^{match_count(l_{2i})-1}$$

3. Similarity between C_1 and C_2 is defined as the weighted average for *leafsim* values of all the leaves in T_1 :

$$sim(C_1, C_2) = \frac{\sum_{l_i \in C_1} leafsim_{T_1, T_2}(l_i) \times W(l_i)}{\sum_{l_i \in C_1} W(l_i)}$$

3.3 Matched genealogy measure

Intuitively, two main factors affect similarity among objects:

1. How many elements could be matched in another object, called overlap ratio;
2. To what extent are the elements matched to each other, called element similarity.

BGM focused more on element similarity, but ignored the overlap ratio. Define a match collection:

$$match_{T_1, T_2}(l_1) = \{l_2 \in C_2 \mid LCA(l_1, l_2) = LCA_{T_1, T_2}(l_1)\}$$

which includes all the elements in C_2 that could be matched with the elements in C_1 following the rule $LCA(l_1, l_2) = LCA_{T_1, T_2}(l_1)$. To understand intuitively, $match_{T_1, T_2}(l_1)$ is a collection of all the similar elements of l_1 in C_2 . By denoting $|match_{T_1, T_2}(l_1)|$ as the number of elements in $match_{T_1, T_2}(l_1)$, we define matching ratio for l_1 as:

$$\xi_1 = \frac{|match_{T_1, T_2}(l_1)|}{|C_2|}$$

Then, ξ_1 is the element's percentage in C_2 that could match l_1 . As for a whole introduced tree, we define collection $match_{T_1}(T_2)$ similarly to include all the elements in C_2 that could match any elements in C_1 , and the matching ratio for T_1 and T_2 is given by:

$$\xi_{T_1, T_2} = \frac{|match_{T_1}(T_2)|}{|C_2|}$$

In a weighted model, we have:

$$\xi_{A, B} = \frac{\sum_{l_i \in match_{T_1}(T_2)} W_{l_i}}{\sum_{l_j \in C_2} W_{l_j}}$$

where W_{l_i} is the weight value of the corresponding leaf.

Apparently, matching ratio is a real number less than 1, which presents overlap ratio of two collections or cases.

The matching ratio and similarity calculated by BGM present the two aspects of similarity between cases. Thus, we define a new similarity measurement called Matched Genealogy Measure (MGM), which integrates both the factors:

$$sim_{MGM}(A, B) = a \times sim_{BGM}(A, B) + b \times \xi_{A, B}$$

where a and b present the importance of BGM similarity and the matching ratio when considering the similarity between two cases. In other words, the coefficients describe which of the two factors do the case library or user emphasize, element similarity or overlap ratio. They are prior knowledge of the retrieved library or field, and could be assigned by experts or users.

4 EXPERIMENTS

4.1 Describe combat simulation cases

A combat simulation case mainly contains three parts: combat entities, combat scenarios, and simulation resources. Thus, the ontology is also

constituted by three parts: entity ontology, mission ontology, and simulation ontology. The logistic structure of combat simulation case ontology is shown in Figure 1.

These concepts include more specific aspects, and are finally developed into a concept tree of ontology. Case retrieval based mainly on scenario tables (Kolonder, 1993), which describe entities, missions, and other elements related to the tasks in a combat simulation, regulated mainly by entity ontology and mission ontology. Figure 2 gives part of scenario table, including some specific attributes of a combat simulation case, hinting the relationships between the attributes and the three ontologies. Contents regulated by simulation ontology, however, are usually stored in resource tables as solutions and results of cases, such as data tables of simulation experiments and experiment scheme tables. For example, we have a case described as (A_obj, battle, F117A,...), where all the elements are actually leaves of the concept tree, referring to a simulation of a battle aimed at A_obj with F117A being the main platform.

4.2 Evaluation algorithm

The most direct way to evaluate a retrieval algorithm is testing to what extent the algorithm meets user's requirements. It is not reasonable to expect users to come up with absolute similarity scores between cases. Instead, we conducted user studies, asking them to rank cases according to their similarity to a given case.

Figure 1. Logistic structure of case ontology.

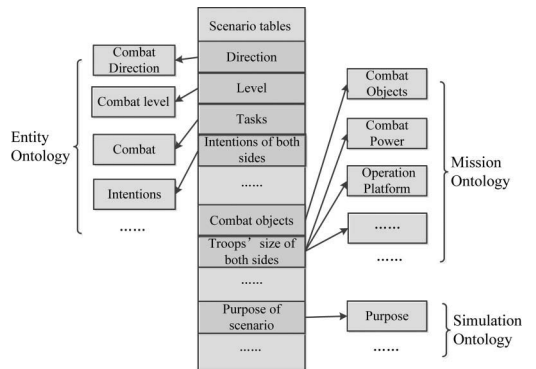

Figure 2. Part of scenario tables.

We described 16 cases based on some typical battles or combat simulations in history as the case library. We asked some “users” to sort the cases by similarity with a given case (case X), and get an “ideal order” (L) of the 16 cases on the basis of statistic results.

Assume that we can rank a list of all cases in the designed library with a given retrieval algorithm M , denoting the rank as $L(M)$. If $rank_M(A)$ is the ranking value of case A in rank $L(M)$, then we express the Window Distance (Ganesan, 2003) between $rank_M(A)$ and the ideal list (L) as:

$$WindowDist_{L,M,I,K}(X) = \frac{\sum_{i=1}^{I+K-1} |rank_M(L[i]) - i|}{K}$$

where L is the ideal list of the given cases, I is the start position, and K is the size of the window.

Intuitively, the Window Distance gives a quantitative description of differences between the list to be evaluated and the ideal list. For example, case A is listed at the third position in the testing list while at the first position in the ideal one; then, it will contribute 2 to the Window Distance of the testing list.

5 RESULTS

5.1 Results of user study

We choose 100 people to participate in our user study and get “ideal list” from the statistic results. For example, the statistic results of the first place in the list are given in Table 1; we regard Case 2 as the most similar one to X.

5.2 Evaluation results

We compared our modified algorithm (MGM) with the original algorithms: OGM, BGM, and RGM. Considering the volume of library, we set the size of window as $K = 5$.

As we claimed before, the two coefficients of MGM could be adjusted to meet different preferences of users. First, we set $a = b = 0.5$. Figure 3 shows the Window Distance of different algorithms as a function of window position. We can conclude that the Window Distance of MGM is generally smaller than others', which suggests that it matched human intuition better, especially in the first few ones. In other words, the retrieval

Table 1. Example of user studies results.

Case number	1	2	5	7	8	10
Proportion (%)	12	76	3	6	2	1

Figure 3. Window distance of different algorithms.

Table 2. First seven cases of result list.

Ideal list	OGM list	BGM list	RGM list	MGM list
2	2	1	2	2
1	1	2	1	1
12	16	16	12	12
15	15	15	16	16
9	12	12	15	15
16	13	13	3	9
13	5	6	13	13

results of MGM match users' intuition better, especially for the most similar ones.

It also shows that the first three or five distances of all the algorithms are acceptable but will get larger as the position moves on. That means, these measurements could describe similarity well when the cases actually share something in common under the given conditions, but the original algorithms have no idea to differ the “not-that-similar” aspects. Thus, the performance gets worse as the window position moves to the end. Table 4 shows that cases in the first seven collections are substantially the same in the list of MGM, but the GMs have some disagreements about case 13, which also proved that results of MGM match human intuition better.

5.3 Adjusting for different users' preference

When $a = b = 0.5$ in MGM, we get a relatively good result, as we showed before. It is important to note that a certain group of coefficients could not fit all case libraries or users. The users could also adjust the coefficients to meet different requirements. For instance, some users might focus only on the first few cases of the list, while others might concern on the whole list.

If the users focus more on the first few cases of the list, we expect that the first three window distances could be as smaller as possible. We find that when $a = 0.61$ and $b = 0.39$, we could meet the expectation, and the results are shown in Figure 4 and Table 3.

If users want the algorithm to exhibit a better performance over the whole library, which means that we expect the average distance of the whole

Figure 4. Window distances when $a = 0.61$, $b = 0.39$.

Table 3. Average distance of the first three windows.

	OGM	BGM	RGM	MGM
Average distance	1.7333	2.0667	1.1333	0.8

Figure 5. Window distances when $a = 0.61$, $b = 0.39$.

Table 4. Average distance when $a = 0.61$, $b = 0.39$.

	OGM	BGM	RGM	MGM
Average distance	3.1667	2.8500	3	2.2500

list, we have $a = 0.65$ and $b = 0.35$ to meet the requirement, and the results are given in Figure 5 and Table 4.

Briefly, different users could determine different values and get different results. However, we suggest $a = b = 0.5$ as a balance if users have no idea about them.

6 CONCLUSIONS AND FUTURE WORKS

Case retrieval is an important link for Case-Based Reasoning, and semantic retrieval is popular in recent researches for case retrieval.

The main contribution of this paper is proposal of a new semantic similarity measurement between cases based on ontology, called the Matched Genealogy Measurement (MGM), which is proved to perform well in matching human intuition. We took combat simulation as an example to illustrate ontology-based algorithm and described some typical combat simulation cases with the method as case library. The conclusion is supported by a user study and analysis of Window Distance. MGM could also meet different users' requirements by adjusting coefficients. It is actually a general measurement

of semantic similarity, and could be used widely in information retrieval and recommendation systems.

Further research will focus on the semantic information presented by relations of different level of the ontology. A possible direction may be constructing a concept tree with weighted edges. The depth of LCA could develop to the distance from the root.

We also need to pay some attention to the influence of the volume of cases. Considering that the Genealogy Measures are essentially average value of leaves' similarity, the similar or different features might be submerged by a large number of elements. It may be solved by assigning significant elements. However, it is difficult to say which elements are more important than others, and it might change with different user of application.

Vibration energy acquisition and storage management system based on MSMA

Qingxin Zhang, Kai Lin & Jikun Yang
Automation Institute, Shenyang Aerospace University, China

ABSTRACT: Load identification is a major concept in the field of smart homes and smart grids. Nonintrusive Load Monitoring (NILM) method is applied to solve this problem, which is performed by analyzing the total current and voltage signal of the main distribution board to estimate the energy consumption of individual appliance and turning on/off or other operation. In this paper, we used the theory of NILM to identify household electric load. By analyzing the total current signal, extracting related features, and using Genetic Algorithm (GA) and Support Vector Machine (SVM), we identify different electric loads. We also use the BLUED data set (Anderson et al. 2012) as the experimental data set. Finally, rationality and effectiveness of the proposed method was verified by MATLAB simulation.

1 INTRODUCTION

MSMA is a new kind of intelligent material. Studies have shown that the Martensitic transformation appears when exogenous magnetic field and stress was applied to the MSMA. In theory, it can produce 10% linear deformation rate and 18% bent deformation rate (Aljanaideh, 2013). Magnetic control shape memory characteristics can be reused. On the one hand, under the action of external magnetic field deformation, it can produce the output force. On the other hand, its vibration under the excitation of the magnetic properties changes and then produces larger electromagnetic signal changes. Studies have also shown that the excellent performance of MSMA is particularly applicable to the collection of micro energy. Thus, MASA has a broad prospect for development (Zhang, 2013; Zhang, 2015).

The author analyzes the MSMA principle of vibration energy harvesting and establishes the equivalent circuit model of vibration energy harvesting of MSMA. In order to collect and store the weak AC voltage, the author designed the MSMA vibration energy acquisition power management circuit.

2 MSMA ENERGY HARVESTING DEVICE

2.1 Principle of MSMA energy harvesting device

MSMA is a new kind of intelligent material, which is used in the field of vibration energy acquisition. In this paper, we use the MSMA material of frame size $5 \times 5 \times 20$ mm purchased from the AdaptaMat

company of Finland (Zhang, 2015; John, 2000). The principle of vibration energy acquisition in a device is shown in Figure 1.

When MSMA is subjected to external stress, its magnetization will change such that the magnetic flux of the induction coil changes. According to Faraday's law of electromagnetic induction, the magnetic induction intensity will change too. The experiment indicates that the instantaneous value of induction voltage can reach 46 V (Wen, 2012; Zhang, 2016).

As shown in Figure 1, when a mechanical vibration force is applied to the stretching rod, the material would be deformed by the force. According to the Villari effect (when MSMA is affected by an external force, such as vibration), the coefficient of magnetic conductivity will be proportional to the deformation of material. Under a bias magnetic field, magnetization will also be changed with the stretch and compression of the MSMA material, and the maximum change range could be up to 0.7T. If the magnetic flux through the internal material

Figure 1. MSMA energy harvesting device working principle diagram.

permeability changes, the constant magnetic field forces around the MSMA will change. Meanwhile, the magnetic flux through the coil will change too. The induction voltages could be obtained as follows:

$$V = -\frac{\partial B}{\partial t} NS \quad (1)$$

where V is the induction voltage in the coil (V); B denotes the magnetic induction intensity caused by the change of the magnetic intensity in the material (T); $B = \mu_0(H + M)$, where H is the imposed magnetic field (A/m); M is the magnetization of the material (A/m); μ_0 is the permeability of vacuum (H/m); N is coil turns (turns); and S is the cross-sectional area of the coil (m^2).

2.2 Circuit model of MSMA vibration energy collector equivalent

In this section, we establish an equivalent model to calculate the corresponding induced voltage. The equivalent circuit and magnetic circuit of the vibration energy acquisition system are shown in Figure 2 while ignoring the eddy effects, saturation effect, and hysteresis effect.

$$\Phi_c = \frac{R_{mPM} \Phi_{PM}}{R_{mPM} + R_{mc} + \frac{(R_{mG} + R_{MSMA}) R_{mS}}{R_{mG} + R_{MSMA} + R_{mS}}} \quad (2)$$

where Φ_{PM} is produced by a constant permanent magnet flux; R_{mPM} represents bias air gap reluctance; R_{mc} is the core reluctance; R_{ms} is the magnetic reluctance through the material leakage; R_{mG} is the air gap reluctance between the MSMA material and iron core; and R_{MSMA} is the reluctance of MSMA material. The shape of the MSMA material changes with the air gap and material width. Therefore, R_{mG} and R_{MSMA} depend on the deformation state of the MSMA material. In addition, R_{MSMA} also depends on the internal magnetic field (H_{MSMA} , B_{MSMA}) of the MSMA material. By calculating following equality, we can get the magnetic flux of the coil:

Figure 2. MSMA collector–magnetic equivalent circuit diagram.

When the external vibration causes the deformation of the MSMA, the magnetic flux of the coil is changed, and the corresponding induction voltage can be obtained as:

$$u_e = N \frac{d\Phi_c}{dt} = \frac{N}{l_{MSMA}} \frac{d\Phi_c}{d\varepsilon} V \quad (3)$$

where l_{MSMA} is the length of the material and V is the speed of change of the shape of MSMA materials. From (3), we know that the induced voltage is influenced by the geometry of drives and material parameters as well as the speed of MSMA material.

3 POWER MANAGEMENT SYSTEM BASED ON MSMA

The author proposes a case of MSMA vibration energy-based power management system to collect and store the MSMA vibration energy output voltage AC. It is composed of six parts: AC/DC rectifier circuit, the voltage-control circuit, super-capacitor circuits, DC/DC converters based on LTC3526L boost regulator circuit, a temporary storage circuit, and lithium-ion battery charging circuit based on MAX1811. The schematic is shown in Figure 3.

When the force disappears, the charge generated by the MSMA vibration energy collector disappears immediately. Therefore, we need an external capacitor to storage the charges. As shown in Figure 3, the collective electric from MSMA vibration energy collection device is stored in the super-capacitor after passing the rectifier circuit. When the control module to monitor the voltage of the supercapacitor meets the set value, turn on the DC/DC chip LTC boost voltage regulator circuit. Then, the stable supplying DC voltage will be stored in a supercapacitor. When the voltage of the capacitor reaches the requirement of the input voltage of the

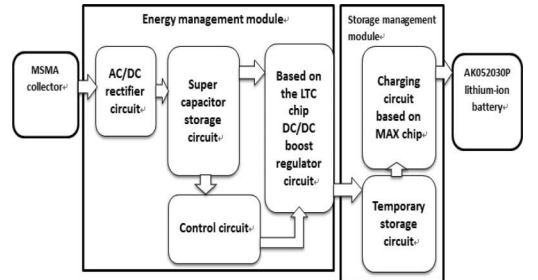

Figure 3. MSMA vibration energy harvesting power management.

MAX1811 charging control terminal, the charging circuit begins to work for the lithium battery, and the power management of the energy is realized.

3.1 Supercapacitor storage

In micro-vibration energy harvesting systems, supercapacitor is regarded as energy storage components. The output of the system would be instantaneous pulse DC. The supercapacitor will discharge rapidly when the capacitor voltage reaches the discharge level; however, the discharge process is difficult to control. Therefore, it is difficult to adopt supercapacitor direct power to supply the electrical equipment directly. In this paper, the supercapacitor is used as a temporary energy storage element. 0.01f supercapacitor is generally used as a temporary storage element, and the circuit is shown in Figure 4.

3.2 LTC3526L chip introduction

LTC3526L is a kind of DC/DC converter with synchronous output disconnection function and fixed frequency. The chip uses a startup voltage of 0.68V, and once it starts, it will operate at voltages as low as 0.5V. In the intermittent operation mode, LTC3526L implements burst mode operation under light load conditions so as to exhibit high efficiency under a wide load range. Antiringing control circuit can reduce EMI (Electro Magnetic Interference) by damping the sensor of the intermittent mode of operation. Figure 5 is the peripheral circuit.

3.3 Simulation analysis based on MSMA energy management circuit

The author used LTspice IV software for simulation analysis to verify the stability of the circuit module design. The circuit schematic diagram is shown in Figure 6.

Figure 4. Supercapacitor storage emulation.

Figure 5. LTC3526L peripheral circuit diagram.

Figure 6. MSMA energy management circuit schematic diagram.

Figure 7. Circuit output simulation diagram under different input stress amplitudes.

We could obtain different input voltages in different vibration conditions. In order to analyze the stability of the simulating circuit, we observe the effects of different amplitude and frequency on the output response. In this paper, we adopt the method of inputting analog value, observing the output state of the simulating circuit by inputting different sine waves. First, keeping frequency of the stress constant $f = 12.5$ Hz and changing the size of the amplitude, the results change with output-induced voltage in Figure 7. The greater the external force, the shorter time required for the output voltage to reach a stable state. Simulation results show that the circuit can output stable output DC voltage in different stress amplitudes.

Second, we tried to control the amplitude of stress always being 4.5N. By changing the frequency of stress, we observed the effects of different frequency to output response. With the increase of the frequency of the external force, the output voltage gradually reaches steady state at shorter times. Simulation results show that the

circuit can output stable output DC voltage in different stress frequencies.

Different vibration conditions produce different voltages. Regardless of the amplitude or frequency of change, the results show that the design management circuit can output a stable 3.3V DC voltage.

3.4 Energy storage management module

MAX1811 is a high-performance charging management chip produced in the United States. The input voltage is 4.35–6.5V; the maximum charging voltage is 4.1 or 4.2V; the maximum voltage of error range is 0.5%; and the charging current can be controlled with 100 or 500 mA. It has a built-in temperature control circuit and a battery voltage detector. There is no necessity to be controlled by a microprocessor with low power consumption. MAX1811 pin diagram is shown in Figure 9.

The operating voltage of the designed management charging chip is 4.35–6.5V. However, when the 3.3V circuit acquisition and management is lower than 4.35V, the chip cannot work. In order to save energy and improve the charging efficiency, the acquisition power is stored in supercapacitors C1 temporarily. The power management chip cannot work until the input voltage reaches more than

Figure 8. Circuit output simulation diagram under different input stress frequencies.

Figure 9. MAX1811 pin map.

Figure 10. MSMA energy storage management module.

4.35V. Meanwhile, the temporary electric energy storage in supercapacitors can also supply energy to MAX1811. The light-emitted diode VD1 is lit. Once the voltage on the super capacitor is less than the threshold value of the chip, in order to reduce the dissipated energy, MAX1811 will automatically turn off. The output voltage of MAX1811 will be kept on a constant value as long as the voltage exceeds 4.35V, regardless of the fluctuation of the voltage of the supercapacitor.

In the test, the storage circuit input voltage is a stable DC voltage of 3.3V, and the SELV pin of the MAX1811 and SELI pin are set high and low, respectively, to make the lithium-ion charging current 100 mA and the final charge voltage 4.2V. In the charging experiment, a capacity of 250 mAh lithium battery-AK052030P is selected. Results show that the AK052030P lithium battery is fully charged in 2.8 h at a charging current and voltage are 100 mA and 4.2V, respectively.

4 CONCLUSION

In this paper, we designed a power management system based on MSMA. By utilizing the MSMA power management system, the mechanical energy in the environment can be transferred into electrical energy. The feasibility and superiority of the system are proved by experiment results. The advantages of the proposed method are small, green, and pollution-free. With the improvement of material properties and the progress of microelectronics and MEMS techniques, there is every reason to believe that integrated energy storage device will appear in the future.

Architecture of the on-chip debug module for a multiprocessor system

Kexin Zhang & Jian Yu

Changzhou College of Information Technology, Changzhou, Jiangsu Province, China

ABSTRACT: This paper proposes an architecture description of the on-chip debug module aiming at a multiprocessor system. Some special function registers were used for setting the debugging mode and debugging flow control. Through the internal priority register setting, different processors can be set with or without different priority level, by which the different debugging structure can be realized. Internal arbitration mechanism handles the competition between different processors and decides the access order for different processors. Finally, all these techniques are integrated to make the on-chip debugging operation more efficient and flexible.

1 INTRODUCTION

With the development of integration technology, more and more electrical systems consist more than one highly integrated processor (Benini, 2005; Tan, 2012; S, 2014). With such a development, the complexity of the whole system and the increasing levels of integration result in novel challenges in the development of debugging methods.

For system with a single processor, some dedicated circuits would be used to gain access to some of the processor internal state, and the information will be communicated via serial interface such as JTAG (Maier, 2003; Portelagarcía, 2011); then, the on-chip debug function is realized.

Currently, on-chip debug method is mainly applied for single-processor systems, which cannot respond to the development of multiprocessor system. This paper proposes a high-performance on-chip debug architecture, which not only includes on-chip debug functions (such as internal or external breakpoint and single-stepping) for single processor, but also presents some specific features for multiprocessor systems. Such architecture has been developed to support on-chip debug for multiprocessor system, and the essential advantage is based on such architecture. The multiprocessor debug system with a high performance and flexibility would be built and used easily.

2 ON-CHIP DEBUG SUPPORT REALIZATION

2.1 Structure of on-chip debug module for single-processor system

The typical debugging device uses some dedicated facilities to gain access to some of the processor's

internal state, and these devices generally use a serial debug interface (like JTAG) to communicate between the processor and the host computer (Zhang, 2013; Wang, 2011).

By contrast, as Figure 1 shows, this paper first presents the basic structure of on-chip debug module for single-processor systems, which is composed of three function units. First, the submodule of communication is used as an intermediate for data transmission between host PC and on-chip debug module. Second, the module configuration register submodule controls the operation modes of the entire on-chip debug module. Third, the control unit is responsible for controlling the entire debugging flow. The last unit of data register is used for temporary data storage.

Through this method, only some SFR (Special Function Register) and some control logic realize the main debugging functions. The definition of such SFRs determines the debugging mode, which decides under which conditions the debugging function will be triggered.

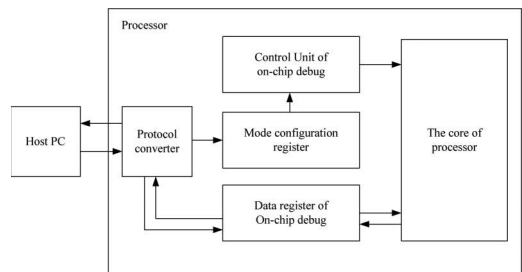

Figure1. On-chip debug module for single-processor system.

2.2 Structure of on-chip debug module for multiprocessor system

Moving from single-processor to multiprocessor system, one critical problem needed to be solved is how to handle the competition of more than one processors sending debugging request to the same target processor. In this paper, the master-slave structure was adopted from the ARM protocol (Seys, 2009)

The on-chip arbitration is designed to be used as a central multiplexer. On the basis of the internal arbitration mechanism, all the master processors (e.g., microprocessors) drive out the debugging, requesting singles, and debugging commands, indicating that the debugging transfer they wish to perform and the on-chip arbiter of slave processor determine which request is granted. Figure 2 illustrates the structure required to implement the on-chip debugging aiming at multiprocessor system with three master processors and one slave processor.

Once the presetting conditions are satisfied, the operation of processor is paused and the system is moved into debugging mode, and the control of the system will be transferred to the on-chip debug module. During the debugging mode, the information required would be recorded and sent out. After the debugging work finished, some external stimulus is sent to microprocessors to make it work continually from the paused point. The additional pins would remain hidden otherwise and be controlled by the software developer.

2.3 Definition of debugging special function register

The on-chip debug system constructs the integrated entity that comprises hardware and software

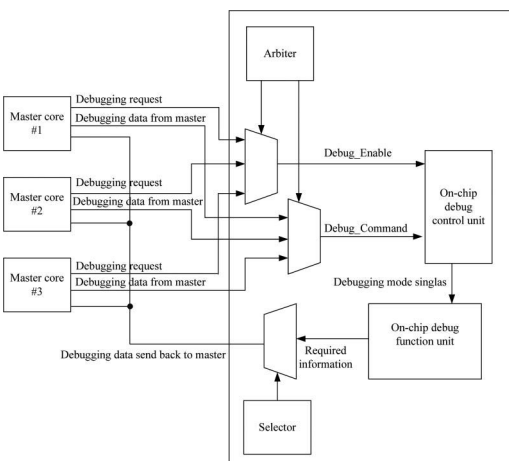

Figure 2. Structure of on-chip debug for multiprocessor.

together. The on-chip debug capability provides functions as breakpoint, single stepping, and external breaking. Either internal or external breaking is treated as a special form of interruption.

When implemented, the on-chip debug logic is part of the actual microprocessor silicon, the on-chip debug system provides the means to set the internal or external breakpoints, checking the internal states of the processors, and single step through coding the special function registers.

The definition of special function register for on-chip debug includes the following three main parts:

- Enabling/disabling on-chip debug system;
- On-chip debug mode setting;
- Debugging priority setting.

The format of the command, including all the above information that is sent from master processors, is depicted in Figure 3.

The debugging mode decides which debugging function is selected among the internal breakpoint, external breakpoint, single stepping, and other debugging functions. If internal breakpoint mode is selected, the source between special SFR or particular address comparing with target value set in breakpoint register can be further selected. Finally yet importantly, flag of priority level gives a clear sign of priority level, and the principle is the priority level decreases as the number increases, which means all zero get the highest priority.

2.4 Archiving of on-chip debug

When coming into debugging mode, the processor compares the corresponding signals with certain conditions, which were set beforehand. If the value matches one of the targeted values, the processor will come into breakpoint debugging mode. This is called the function of breakpoint.

The advantage is the breakpoint conditions could be set either external or internal. External breakpoint is the PC breakpoint, namely it comes into debugging mode when PC index reaches the given value. In the same way, on-chip debug module can also choose internal SFR comparing with target value.

Figure 3. Format of debugging command.

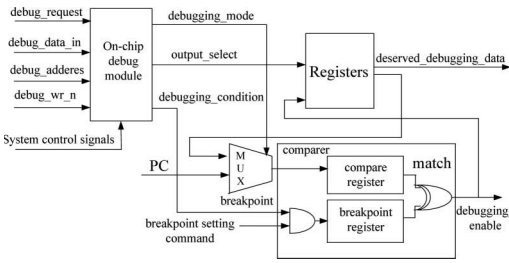

Figure 4. Hardware description of on-chip debug module.

As shown in Figure 4, as the debugging condition is satisfied, the matched signal will be sent out as debug-enabled signals, which indicates the clock module to pause the running of the clock, and then the entire processor will consequently stay in the pause state.

3 PRIORITY SETTING AND ARBITRATION

3.1 Arbitration mechanism

The arbitration mechanism is critical for multiprocessor system because the processors may run independently. There are inevitably some cases that more than one processor send debugging request to the same target microprocessor.

In our design, the internal on-chip arbitration mechanism is proposed to ensure that only one master has access to the target processor at any one time.

The main principles of the judgment are as follows:

- The internal on-chip arbiter performs the function of observing the debugging request from different master microprocessors and deciding which one is the highest priority master.
- Requests with different priorities: the request with a higher priority wins the control of the target microprocessor, the request with a lower priority should wait until the higher priority finished.
- On the contrary, if the request with the same priority, that is, internal Round-Robin mechanism, is applied, then the request would get the equal opportunity to get control of the target microprocessor. If one request wins, the others should wait until the debugging is finished.

The Round-Robin switch selects the request from different microprocessors having equal priority one by one. After the judgment, if a higher priority exists, the other debugging request should

be forced to keep in the waiting state; if any request having higher priority exists, the cycle repeats.

3.2 Priority setting

Select the system topology as the first step in designing a multiprocessor system because the performance of multiprocessor system depends heavily on the strategy of selecting the structure of the multiprocessor system.

Different applications based on the multiprocessor system leads to different structure requirements; thus, the primary target of our design provides a flexible on-chip debug module, which would be adjusted according to the multiprocessor system architecture. In our design, one agile method—different priority setting—was used.

The overview of processing of different priority settings is as follows:

- First, all the processors are regarded as equal before the priority setting; therefore, from the perspective of debugging, now the whole system is flat, no master processors or slave processors;
- Then, through the internal priority register setting, the processors under debugging can be divided into different groups with different debugging priorities. Apparently, for processors with lower priority, the higher one acts as master, which control the debugging processing;
- After priority setting, from the perspective of debugging, the whole system becomes a hierarchy now. One issue arises when more than one processors with the same priority sending debugging requests to the same slave processor. In such cases, some arbitration mechanisms are needed, as described in the “arbitration” section;
- The number of bits predefined in debugging special function register decides how many possible combinations on priority levels we have in our multiprocessor system debugging process. For instance, if three bits were used, then we would have eight possible priority levels, that is, from 3'b000 to 3'b111.
- With debugging priorities setting, different processors can get different or the same priority level; therefore, the debugging structure can be freely adjusted according to the practical applications.

4 DEBUGGING OPERATION

4.1 Overview of the debugging operation process

From the perspective of debugging, microprocessors in a multiprocessor system can be categorized into two types—debugging processor or target processor. The debugging processor act as master

and the target processor acts as slave in the system. The protocol is designed to be used with a central multiplexor interconnection scheme. Using this scheme, all the debugging processors (masters) drive out the control information, indicating the debugging work they wish to perform to the central arbiter; then, through the internal mechanism, the arbiter determines which master gets the control of the debugging of the slaves.

As Figure 5 shows the detailed operation process of debugging, the complete debugging process has five steps:

- Step 1: If the required debugging conditions are triggered, the normal operation of the debugging processor (as master in the whole debugging process) is paused, and the system gets into debugging mode;
- Step 2: Through the setting of debugging mode, the debugging control information becomes available, which includes the address of target processors (slave), and is drove out to the arbiter;
- Step 3: Before the debugging work commence, the debugging processor must be granted. This process is carried out by the debugging processor by asserting a debugging request to the central arbiter, whose role is to control which master accesses to the target processor (slave). For a detailed description of arbitration scheme, the reader is referred to section “Arbitration mechanism design”.
- Step 4: A granted debugging processor starts the debugging work by driving the debugging control information to the target processor. The control information leads the target processor into debugging mode such as single-stepping, breakpoint of SFR, and breakpoint of address;

- Step 5: The significant advantage of on-chip debug is that it provides an efficient way to know the real-time state of processor under debugging. After the target processor is forced into debugging mode, the operation of processor is paused, and the specific area, such as some SFRs and memory, is recorded. These information are sent back to the debugging processor, which decides the next step.

5 SIMULATION RESULT

The experimental multiprocessor system platform was implemented containing four processors.

The simulation result in Fig. 6 shows that if debugging request is sent with a different priority level to the same slave, then the microprocessor with a higher priority level will win the competition; and if priority levels are the same, then the debugging request followed the round-robin order one by one.

We can conclude from Fig. 7 that when the pre-defined condition is satisfied (in this case, it means when the value of ACC matches the value of the breakpoint), the on-chip debug function is triggered, and the debugging process begins.

6 CONCLUSIONS

Debugging is a critical issue in the multiprocessor system, requiring a high-quality, efficient way to investigate the internal running state of the system. Current on-chip debug module is focused on the single-processor system. How to upgrade

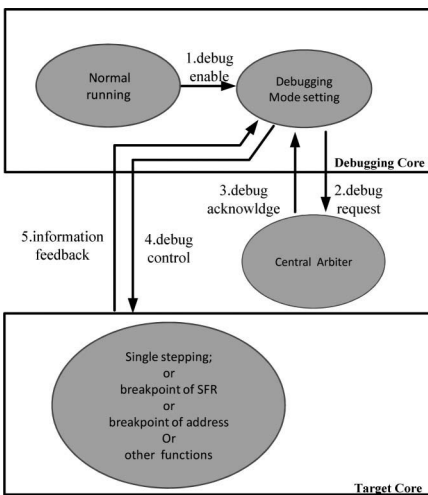

Figure 5. Debugging operation process.

Figure 6. Arbitration test.

Figure 7. On-chip debug function test.

such module to adjusting the ever increasing multiprocessor system and overcome the limitation of the debugging management and communication between multiprocessor systems is the main problem that needs to be addressed. From the available results, it is possible to conclude that the proposed on-chip debug module is an efficient and flexible solution for verifying and validating a multiprocessor system.

Load balancing algorithm for computing cluster using improved cultural particle swarm optimization

Weihua Huang, Zhong Ma, Xinfu Dai, Yi Gao & Mingdi Xu

Wuhan Digital Engineering Institute, Wuhan, China

ABSTRACT: Aiming at defect of premature convergence in particle swarm optimization algorithm, an improved cultural particle swarm optimization algorithm is put forward for load balancing of computing cluster. Firstly, main population space of particle swarm optimization algorithm and knowledge space of cultural algorithm are combined to form the mechanism of “double evolution and double promotion”, which can improve global searching capacity of algorithm and operational efficiency. Then evolution mechanism of genetic algorithm is adopted to enhance evolution operation of knowledge space. Finally, the algorithm is applied to load balancing problem of computing cluster to find solution. Experimental results show that the proposed algorithm increases resource utilization rate of computing cluster and makes load more balanced, proving to be an effective and reliable load balancing algorithm.

1 INTRODUCTION

Load balancing for computing cluster is to achieve equitable distribution of loads under certain constraint of real computation environment. Its purpose is to minimize response time of tasks for application programs, and it is proved to be a typical NP-hard problem (Z, 2016). Scholars have done extensive research in this field. Load balancing algorithm is mainly divided into static and dynamic way (Li, 2015). As static load balancing algorithm cannot correctly reflect current load on any node, its application is restricted (Jiang, 2016). Dynamic load balancing algorithm, which takes into consideration the current state of node load, becomes the main balancing algorithm employed to handle load balancing issues for computing cluster. Existing balancing algorithms optimize connection numbers and response time. Though they have good performances for small cluster system, they cause low efficiency and load imbalance for large cluster system (Wang, 2008; Sun, 2011).

Aiming at NP-hard feature of load balancing, some scholars put forward many inspirational algorithms, such as genetic algorithm (Wang, 2016), simulated annealing algorithm (Su, 2016), ant colony algorithm (Ghumman, 2015) and particle swarm optimization algorithm (Zhao, 2015). Due to the advantages of strong swarm intelligence and search capability, those algorithms can effectively optimize load balancing and improve resource utilization rate of CPU (Zhao, 2016; Jain, 2016; Kanimozhi, 2015). Among these algorithms, particle swarm optimization algorithm is a

swarm intelligence algorithm successfully applied to load balancing problem for computing cluster (Wu, 2010). However, particle swarm optimization algorithm can easily fall into local optimization and premature, causing certain inconsistency between optimization results and ideal results (Huang, 2012).

Cultural Particle Swarm Optimization (CPSO) (Deng, 2016; Wu, 2010) algorithm is an intelligent algorithm that integrates cultural algorithm into particle swarm optimization algorithm. During the evolution of CPSO, the particles can be updated by tracking two goals, namely global extreme value and individual extreme value (Yan, 2012). The continuous iteration of present global optimal solution up to now form a trajectory, which will be stored and considered as global knowledge space for global iterative search. Thus, acquired knowledge is transmitted to the next generation, guiding the individuals towards perceived global optimal solution and providing a systematic method for self-evolution. At the same time, greater global searching capacity of algorithm is achieved through double evolution and mutual effect of PSO space and knowledge space (Qin, 2016). However, due to the local optimum deficiency of knowledge space in cultural algorithm, knowledge space cluster cannot achieve desirable effect during self-evolution, reducing influence on lower-layer main cluster space.

To avoid above phenomenon, an Improved Cultural Particle Swarm Optimization algorithm (ICPSO) is put forward in this paper. Experimental results demonstrate that the proposed algorithm is

an effective optimization algorithm for balancing computing cluster.

The rest of paper is organized as follows: Section II describes the load balancing problem. In Section III, the improved algorithm is introduced. Section IV explains in detail the working process of the algorithm. Section V gives the experimental settings and the result discussions. Finally, conclusions and further research directions are given in Section VI.

2 LOAD BALANCING PROBLEM

Load balancing for computing cluster performs reasonable load distribution so as to improve resource utilization rate of cluster system and accelerate response time of user requests.

Suppose cluster system consists of n computing nodes, $\{N_1, N_2, \dots, N_n\}$, and within a period of time, there are m concurrent requests, then load index definition of the i -th node is as follows:

$$Load(N_i) = \omega_1 * Lcpu(N_i) + \omega_2 * Lmemory(N_i) + \omega_3 * Lio(N_i) + \omega_4 * Lqtime(N_i) \quad (1)$$

where weighted value is $\sum \omega_i = 1$.

Suppose that T_i is the time needed when computing node N_i processes user requests, then the optimum balancing scheme for computing cluster is to find out the minimum value of $\sum T_i$, which can be denoted by:

$$\min \sum \tilde{T}_i \quad (2)$$

3 IMPROVED CULTURAL PARTICLE SWARM OPTIMIZATION ALGORITHM

Cultural algorithm obtains useful knowledge and information through the evolution space of micro-level, main population space, and reserves it in the evolution space of macro-level, belief space. By incorporating population evolution mechanism of genetic algorithm into self-evolution process of knowledge space, the proposed algorithm can evolve and update knowledge space cluster through selection, crossover and mutation, so as to improve global searching capacity and operational efficiency of its evolutionary operations. The framework of ICPSO algorithm is as shown in Fig. 1.

Based on population evolution mechanism of genetic algorithm, the evolution and update of knowledge space is improved to evolve through three operations: selection, crossover and mutation.

Figure 1. Framework of ICPSO algorithm.

3.1 Selection operation

Step 1. Calculate fitness value of each individual: $f(i)$, $i = 1, 2, \dots, n$.

Step 2. Confirm individual selection probability $P(C_i)$. Individual sorted from small to large according to adaptability is marked as: $\{C_1, C_2, \dots, C_n\}$, and then individual selection probability is:

$$P(C_i) = \frac{1}{n} \left\{ \sigma^s - \frac{\sigma^a - \sigma^b}{n-1} (i-1) \right\} \quad (3)$$

In the above equation, i is ordinal number of individual; σ^s is expected value of optimal individual C_1 after selection operation and $\sigma^s = n \times P(C_1)$; σ^b is expected value of the worst individual C_n after selection operation and $\sigma^b = n \times P(C_n)$. Generally, we require $1 \leq \sigma^s \leq 2$ and $\sigma^b = 2 - \sigma^s$. When $\sigma^s = 2$ and $\sigma^b = 0$, the expected number for the worst individual surviving in next generation is 0 and selection probability of optimal individual is obviously greater than that of other individuals, which will lead the algorithm to converge too early. When $\sigma^s = \sigma^b = 1$, selection pattern (Liu, 2016) becomes distributed random selection. In real practice, $\sigma^s = 1.1$.

Then individual probability is calculated according to equation (3), namely, recording relatively superior individual in accordance with rules of roulette wheel selection method.

3.2 Crossover operation

This paper adopts single-point crossover method to perform operation. A single crossover point is randomly selected for both father generations. Then all priority value beyond that point is

		Crossover Point							
		↓							
Father		0.53	0.38	0.43	0.24	0.11	0.33	0.012	0.08
Generation 1									
Father		0.71	0.42	0.09	0.2	0.52	0.018	0.11	0.29
Generation 2									
		▽							
Child		0.53	0.38	0.43	0.24	0.11	0.018	0.11	0.29
Generation 1									
Child		0.71	0.42	0.09	0.2	0.52	0.33	0.012	0.08
Generation 2									

Figure 2. Crossover operation.

swapped between two parent organisms, as shown in Fig. 2, to form two new child generations.

3.3 Mutation operation

Mutation operator performs operations based on mutation probability P_m . The priority value (Bonyadi, 2016) of some individual is selected according to P_m , and then their original values are replaced by values generated randomly between interval (0,1) according to uniform distribution.

4 PROCEDURE OF LOAD BALANCING BASED ON ICPSO

The load balancing algorithm for computing cluster using improved cultural particle swarm optimization works as follows:

- Step 1.** Initialize parameters, such as the maximum iterations of main population space and knowledge space respectively, G_1 and G_2 , inertia weight ω , population size N and so on;
- Step 2.** Calculate particle fitness value of each cluster, and record the present optimal position and present optimal fitness value;
- Step 3.** Calculate new speed and position for particles in knowledge space according to equation (4) and (5), and meanwhile, limit the range for new position and speed of each particle respectively,

$$v_{id}^{t+1} = \omega v_{id}^t + c_1 r_1 (p_{id}^t - x_{id}^t) + c_2 r_2 (p_{gd}^t - x_{id}^t) \quad (4)$$

$$x_{id}^{t+1} = x_{id}^t + v_{id}^{t+1} \quad (5)$$

In the above equations, ω represents inertia weight; c_1 and c_2 are learning factors; r_1 and r_2 are random numbers distributed uniformly within range of (0,1); vector x_i^t and v_i^t respectively represent the position coordinate and velocity of the i -th particle in t -th generation; p_i^t represents

present optimal location of individual; p_g^t represents global optimal location of population;

Step 4. Perform the evolution and update of knowledge space using improved cultural particle swarm optimization. Replace the present optimal location of the particle with new fitness value if fitness value is greater than the optimal location of the particle; Update present global optimal location to the new fitness value if fitness value is greater than the global optimal location. Thus, the evaluation index of the premature convergence for the particle swarm is computed;

Step 5. Compare fitness value of each particle with extreme value of cluster, and if it is more superior to extreme value of cluster, then replace extreme value of cluster with fitness value of the particle, and replace optimal location of cluster with location of the particle;

Step 6. Judge whether acceptance function is true. If it is true, it means the output value of function is larger than theoretical sum. This output value describes the adaptive degree of global optimal particle for both population space and knowledge space. Then replace the particle with the worst fitness in knowledge space with particle that has the best fitness value in the population space;

Step 7. When maximum allowable number of iteration is exceeded or the searched optimal location satisfies the minimum threshold value, the search should stop and optimal location and optimal fitness value will be output. Otherwise, return to step 3 to continue the search;

Step 8. Decode optimal location node for task allocation and obtain optimal scheme of load balancing for computing cluster.

5 EXPERIMENTS

5.1 Experimental environment

In order to verify the performance of the proposed algorithm, experiments are carried out. The framework of computing cluster is as shown in Fig. 3.

Figure 3. Framework of computing cluster.

The overall cluster environment is configured with CentOS 6.6 operating system, one test terminal, one management node and 30 computing nodes.

The performance of the algorithm will be evaluated by the following three indexes: average utilization rate of CPU, average response time to user requests, and average throughput capacity of cluster. Meanwhile, Generic Algorithm (GA) and standard Cultural Particle Swarm Optimization algorithm (CPSO) will also be tested for contrast analysis. Parameters for GA are specified as: population size is 20; crossover rate is 0.8; mutation rate is 0.02. Parameters of ICPSO is specified as: population size is 50; inertia factor ω is 1.2; c_1 and c_2 are 2; all algorithms are iterated 200 times.

5.2 Results and analysis

Regarding experiments on GA, CPSO and ICPSO, CPU utilization rate is sampled every minute. CPU utilization rate of five groups of experiments is shown in Fig. 4; average response time for user requests is shown in Fig. 5; throughput capacity of computing cluster is shown in Fig. 6.

Figure 4. Comparison of CPU utilization rate.

Figure 5. Comparison of average response time.

Figure 6. Comparison of throughput capacity of computing cluster.

From Fig. 4, CPU utilization rate of GA algorithm is the lowest, and it is mainly because of local optimum and premature defect in GA algorithm. CPU utilization rate of CPSO algorithm is higher than that of GA algorithm, and it is mainly because cultural algorithm and particle swarm optimization algorithm complement each other to form a more superior computing load dispatch scheme. CPU utilization rate of ICPSO is the highest. Comparison results show that the “double evolution and double promotion” mechanism of the main population space and knowledge space can improve global searching capacity and operational efficiency. The evolution mechanism of GA is adopted to avoid the problem that knowledge space of cultural algorithm is likely to be trapped into local optimization. Thus, global optimization solution can be obtained and overall utilization rate of computing cluster is improved.

Fig. 5 shows that as the number of user requests increases, average response time of GA, CPSO and ICPSO increases correspondingly. The time increasing degree for GA is the greatest, followed by CPSO and ICPSO has the smallest increasing range. Compared with GA and CPSO algorithm, ICPSO algorithm accelerates average response for user requests. Computing cluster using ICPSO has good performance of load balancing so as to take respond to user request more quickly. This feature is favorable especially for large scale computing cluster with massive user requests.

It can be observed from Fig. 6 that throughput capacity of ICPSO algorithm is obviously greater than that of GA and CPSO algorithm because of the capability of global optimization. This means load scheduling for computing cluster through ICPSO algorithm is more applicable and effective to large scale computing cluster.

From the above analysis, the conclusion can be reached that ICPSO outperforms GA and CPSO.

6 CONCLUSION

Aiming at deficiency existing in standard particle swarm optimization algorithm, an improved cultural particle swarm optimization algorithm for load balancing is put forward. Experimental results show that the proposed algorithm is an effective and reliable load balancing algorithm that can improve resource utilization rate and make load more balanced for computing cluster. However, further work should be dedicated to establishing the theory model of parameter setting and figuring out how it influences the final solution.

ABSTRACT: Open Source Software (OSS) is the software which grants access to its source code. A better understanding of how OSS functions may help developers take a more effective means for the system development. Studying software systems by the complex network theory can potentially provide useful insights into the diversity and success of OSS. However, research efforts on OSS concentrates on relationships among software systems. Little attention has been paid to operating systems themselves. In this paper, a data collection framework is proposed, and the distribution network of Linux operating systems is constructed. The network models distributions as nodes and dependencies among them as edges according to data crawled from DistroWatch. It is found that the distribution network is a scale-free and small world network similar to those identified in other fields. The inconsistency in share of distributions and targeted users is revealed and discussed. It is expected the constructed model can be a guide for distribution development in the future.

1 INTRODUCTION

In recent years, the dramatic growth to identify and classify network has been witnessed in a wide variety of fields. Rather different from those found in regular networks or simple random networks, it has been discovered that the underlying structures of these networks—including scientific collaboration networks (Wang, 2013), movie actor collaboration in sociology, and Power Grids (Pagani, 2013) and engineering informatics (Zhao, 2008) in engineering—share many scale-free and small-world qualities. The small-world characteristic of complex networks reflects “six degrees of separation” phenomenon in a real social network, while its scale-free feature bears the Matthew effect in the field of economy.

Software systems have become the core of the information-based world and take an important part in modern society. The rapid development in the Open Source Software (OSS) domain gives researchers opportunity to access kinds of software systems and collect data easily. Studying

open source software systems from a perspective of complex networks theory contributes to manage its functional complexity and high evolvability (Zheng, 2008). While research results of modeling software system as complex networks in turn conduce to a better understanding of other forms of complex networks.

Studies of software systems based on complex networks theory nowadays are mainly focusing on dependency of software modules and packages. Christopher Zachor (2013) examined the structure, function, and evolvability of software collaboration networks. All of them reveal scale-free and/or heavy-tailed degree distributions, which implies software systems represent another important field which complex networks theory can contribute to the quantifiable measures. One disadvantage of Christopher’s work is that only a few hundred software packages are analyzed. Xiaolong Zheng et al.(2008) modeled the whole package network of a Linux distribution Gentoo. They developed two new network growth models which take into consideration

aging effect of old nodes to better explain empirical results.

Social network theory provides another powerful tool to model individuals as nodes and relationships among them as edges. Orcun Temizkan et al. (2015) modeled open source projects from SourceForge as self-organizing and collaborate social networks. They argued open source movement is preferentially connected networks. Through the social networks analysis of virtual communities for OSS projects, S.L. Toral et al. (2010) discern the major contributors in OSS projects. The results suggested a small brokers network plays an important role in projects. All of works is to analyze relationships among packages and individuals. However, little of them have focused on the relationship among operating systems underneath OSS.

In this paper, the Linux distributions dependency is analyzed by modeling it as a complex network based on the data crawled from the DistroWatch website. It is hypothesized that Linux distributions display preferential attachment in its structure. The empirical analysis suggests this is the case. The rest of this paper is structured as follows. In Section 2, a framework of data collection is presented. The distribution network is constructed by modeling distributions as nodes and dependencies among them as edges. In Section 3, an empirical analysis of the Linux distribution network is taken on. Results show that the Linux distribution network complies with a small-world and scale-free network similar to those identified in other fields. The research provides another example of complex networks in the real world. At last, the conclusions are summarized and possible future research is discussed.

2 METHODOLOGY

The Linux kernel was first proposed by Linus Torvalds in 1991. Prior to that, Richard Stallman found the Free Software Foundation (FSF) and the GNU project to contribute to various GNU programs. After continuous outstanding developers joining the GNU project, they created the Linux, also known as GNU/Linux system. Different Linux distributions are used for different purposes ranging from embedded devices and personal computers to powerful supercomputers. The distributions come in all shapes and sizes. They can be divided into two categories, one is a commercial company maintenance release with Red Hat as the representative, and the other is entirely community-driven distributions. Debian is representative of the latter.

A network which has parts or all of the features of self-organization, self-similar, attractor, small-world and scale-free is called a complex network (Ren, 2016). The complex network theory aims to reveal the principles of network systems forming, and remaining robust and adaptable when evolving. The rise of the open source software movement gives researchers sufficient data and chances to apply complex networks theory to. For this study, data was gathered from the DistroWatch, a web-based Linux distributions popularity ranking project. It provides information for over 200 distributions. It is noted that not all distributions are listed at DistroWatch. However, given the popularity of the site, it is rational to suppose distributions at DistroWatch could be representative of Linux distributions.

The data collection architecture is shown in Figure 1. Scrapy, a python-based crawler module, drives the data flow. Scrapy can be adopted to extract information from a site like DistroWatch which does not provide an API or other programmable access mechanism. Spiders schedule the first URL to crawl based on *CrawlerRules*. Scheduler sorts URL requests into a queue, and then sends them to the Downloader. Once the webpage is downloaded completely, Downloader sends the response content to Spiders, and then Spiders transfers the response to a HTML Filter for further process. Spiders returns new requests to the Scheduler at the same time. HTML Filter is the key of the architecture. It extracts the distribution dependency from a webpage. Due to the asynchronous network, the dependency is first saved in an intermediate file for each distribution webpage. After all of dependencies are collected, they are converted into a GraphML file which models distributions as nodes and dependencies among them as edges for the next complex network analysis. The process repeats until there are no more requests from the Scheduler.

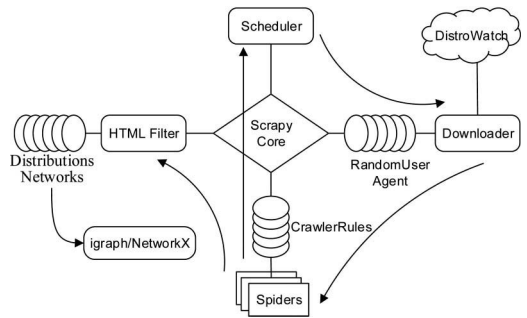

Figure 1. Data collection architecture of DistroWatch.

It can be noted that there are two middlewares `CrawlerRules` and `RandomUserAgent` in the architecture. The `RandomUserAgent` is customized to prevent the crawler being identified or blocked by servers because of the generic user agent being frequently used. In order to improve the efficiency of the crawler, `CrawlerRules` defines a set of rules to only crawl pages containing distribution-specific information rather than all of them. Considering small size of the network, either `igraph` or `NetworkX` (Akhtar, 2014) module can be used to analyze characteristics of distribution networks.

3 RESULTS AND DISCUSSION

At last, after removing a self-loop edge, a complex network with 286 nodes and 318 edges was constructed as of the last 12 months. The average degree is about 1.12. The number of edges is 40755 in a complete graph with the same number of nodes, which is more than 128 times bigger. That is, the distribution network is sparse, which is similar to the Gentoo network.

In this section, properties of the distribution network are analyzed. The degree distribution and clustering coefficient are mainly focused.

Power-law Distribution: The real-world networks tend to show deviation from randomly constructed graphs with two non-trivial properties: power-law distribution and small-world effect. That is, the probability of a vertex having m edges decays with respect to the constant a . If the node degree of a network follows the power-law distribution, it can be said the network is a scale-free network, while random networks follow Poisson distribution basically.

Let $p(x)$ be the probability distribution function. If its histogram is a straight line on log-log, that is, $p(x) = -a \ln x + c$ where a and c are constants. With the maximum likelihood method, the exponent a of the degree distribution could be calculated as follows:

$$a = 1 + n \left[\sum_{i=1}^n \ln \frac{x_i}{x_{\min}} \right] \quad (1)$$

where x_{\min} is the minimum value above which power-law only follows at real-world networks. So the exponent of a network could be got from a set of n values x_i .

The degree distribution of the network can be seen in Figure 2. The plot shows that the degree of the distribution network follows power-law distribution. That is, the network is a scale-free network. It declines rapidly with the dashed line with

Figure 2. Probability density function of the distribution network.

a slope a , sharing same properties with other real networks.

Clustering Coefficient: Let $\lambda_G(V_i)$ be the number of all closed triplets (3 edges and 3 vertices) including v_i in graph G . Let $\tau_G(v_i)$ be the number of all open triplets (2 edges and 3 vertices) including v_i in G . The clustering coefficient \bar{C} is defined below:

$$\bar{C} = \frac{1}{n} \sum_i C(i) = \frac{1}{n} \sum_{i=1}^n \frac{\lambda_G(v_i)}{\tau_G(v_i) + \lambda_G(v_i)} \quad (2)$$

In a random network, there is $\bar{C} \sim 1/n$. However, it has been shown that nodes have a strong tendency to form groups, which means real networks has a bigger clustering coefficient compared to random networks. Especially, a network with highly clustering coefficient like regular networks and small average path length like random network is called small world networks.

The clustering coefficient for the distribution network is about 0.34, while the clustering coefficient of a corresponding random graph is $\bar{C} = M / N(N - 1) = 0.0039$. So the clustering coefficient of the distribution network is 87 times higher than the random network. For the corresponding Barabási-Albert model with same number of nodes and $m = 2$, a network with 569 edges is obtained, where m is the number of new edges in each step. The clustering coefficient of the network is 0.12, which is in the same order of magnitude as that of the distribution network. Considering its average path length is 2.36, it could be said that the distribution network is a small world network, which provides further evidence that complex networks is widespread in the real world.

Different with other social or biological networks like the actor-movie network, where over 90% of actors belong to a giant cluster, the largest

cluster with Ubuntu and Debian as its core comprises of 52% of distributions, which indicates that the distribution network is not as connected as other complex networks. One of the reasons may be the diversity of distributions. There are 36 distributions which do not belong to any clusters. Two quintessential examples that should be cited are Smoothwall which is a family to Internet security products and SliTaz which is designed to run speedily on limited hardware. These distributions are not as universal as other desktop distributions, so they have to be developed independently.

The second largest cluster is a Red Hat focused network. The two clusters are representative of Linux distributions in desktop and server operating systems. As Diomidis et al. (2012) proposed that the function to fix or modify operating systems based on users' particular needs makes OSS a choice of competitive advantage for companies. Although there is only about 1.6% desktop computers using Linux, distributions oriented toward desktop use occupy the majority. It can be explained by the diverse needs of users for desktop environment. Anyone may create a distribution according to his flavor. While Linux is a leading operating system on servers, distributions oriented toward server use are relatively less. The reason may be that Linux servers have to run for years without failure. The downtime could have disastrous consequences for users. So only well-known server distributions survive.

4 CONCLUSION

With the rapid development of big data and cloud computing technology, open source operating systems are playing an increasingly important and irreplaceable role. In this paper, a distribution network with data crawled from DistroWatch was constructed. Different from previous random networks, the work has for the first time discovered that the distribution network is a scale-free and small world network. A giant cluster comprising of 52% distributions exists in the network. The results also reveal marked inconsistencies in share of distributions and targeted users. Desktop users who contribute most of the distributions have a priority need of customized systems, while server users focus on the stability of the system. This may help explain the success of OSS movement. That is, do one thing well and provide users with alternatives.

The study mainly concentrates on degree distribution and clustering coefficient of a complex

network. Further studies could involve other features of a complex network, such as closeness centrality, betweenness centrality, degree growth rate, etc., which will provide useful insights into open source operating systems in the future.

ABSTRACT: In this paper, we propose a fitness information recording and network monitoring system prototype based on BDS/GPS and Arduino Yun. UM220-III NL as a BDS/GPS of China independent intellectual property rights affords accurate coordinate position. Arduino Yun, integrating Atmega 32U4 and Linino AR9331, is used as the controller and Wi-Fi connecting to Yeelink, which offers powerful cloud service. The experimental results show that our proposed system prototype has not only realized fitness information recording and network monitoring, but also provided accurate and reasonable description by utilizing its low-cost, convenient, and controllable characteristics.

1 INTRODUCTION

People vigorously carry out the national fitness program and promote the balanced development of recreational sports and competitive sports. The Rio Olympic Games showed a big grand feast to people all over the world. Athletes and fitness enthusiasts have been always deeply concerned about their fitness training (Noh, 2010). Besides professionals, people of different ages have got into fitness activities (Wen, 2013). Other than traditional styles, GPS, ECG, body area sensor network, walking route navigation system, and many other methods (Choi, 2013; Varatharajah, 2013) have been used to assist fitness activities, such as walking, hiking, and outdoor fitness equipment and medical monitoring (Pitman, 2012; Komninos, 2015). Even some merchants develop several fitness applications for smartphones (Buttussi, 2010; Altini, 2014). The construction of urban and rural public sports and exercise facilities are accelerated, and the national fitness program has taken root.

With the motivation of the above literature review, a prototype of fitness information recording and network monitoring system based on BDS/GPS and Arduino Yun is proposed in this paper. The main goal of this work is to design and implement a low-cost, commonly used, convenient, and controllable prototype.

In Section II, we review related works about BDS/GPS, Arduino Yun, and Yeelink. Section III presents our proposed system. Experimental results of the proposed system are shown in Section IV. Finally, conclusions are summarized in Section V.

2 RELATED WORKS

2.1 BDS/GPS

Global Navigation Satellite Systems (GNSS) provides significant benefit to improve satellite geometry, accuracy, integrity, continuity, and availability. There are four operational GNSS: Global Positioning System (GPS), GALILEO, GLONASS, and BeiDou System (BDS). The BDS navigation satellite system is an important part of GNSS, which is independently built by China. According to its overall planning schedule, the BD system is planned to be established completely and provide global service by 2020. Then, it will consist of five Geostationary Earth Orbit (GEO) satellites and 30 Non-Geostationary satellites (Ren, 2015). Moreover, the interoperability between BDS and other navigation satellite systems is expected to further enhance the accuracy of district positioning contribution based on BDS/GPS navigation satellite system (Basiri, 2014). Positioning technology for

fitness purpose has been widely studied by many scholars (Peng, 2016).

Navigation is becoming more and more important from national strategy to civilian facilities. Smart wearable devices with BDS/GPS chip are emerging. At present, there are mainly four BDS/GPS companies in China: Icofchina in Hangzhou, Unicorecomm in Beijing, CEC Huada Electronic Design Co., Ltd. in Beijing, and MenXin Technology in Wuhan.

UM220-III NL of Unicorecomm is a BDS/GPS dual-system module designed for auto aftermarket, such as vehicle monitoring and navigation. It is also a good choice for hand-held devices. Here, we choose UM220-III NL as our BDS/GPS navigation. As shown in Figure 1, UM220-III NL is the third generation of UM220 series module based on Unicore Low power GNSS SoC (HumbirdTM)1, and is by far the smallest domestic BDS/GPS module in the market. UM220-III NL is small and lightweight, requires ultralow power (120mW), less expensive, has high precision of 0.1m/s (RMS), data update rate of 1Hz, and independent intellectual-property rights.

Table 1 shows the RMC protocol description of NMEA message for UM220-III NL, the format of which is \$-RMC, time, status, Lat, N, Lon, E, spd, cog, date, mv, mvE, mode*cs, such as \$GPRMC, 123400.000,A,4002.217821, N, 11618.105743,E,0.026,181.631,180411,,E,A*2C.

2.2 Arduino

In this paper, the Wi-Fi, which has built-in Arduino Yun Board, allows only the authorized user to interact with the Internet.

By using wireless communication, the data packets and signal are transferred in a dynamic environment between the user and system device. Arduino is an open-source simple tool that can sense, monitor, store, and control more applications than desktop computers.

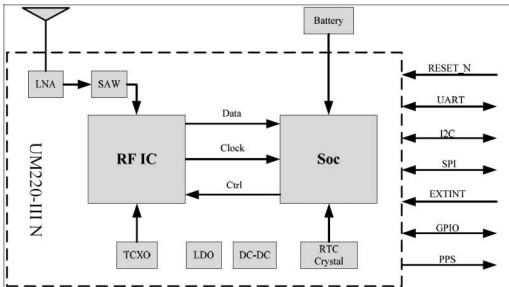

Figure 1. Structure diagram of UM220-III NL.

As shown in Figures 2 and 3, Arduino Yun is a microcontroller board based on the ATmega32u4 and the Atheros AR9331, which supports a Linux distribution based on OpenWrt named OpenWrt-Yun. The board has built-in Ethernet and Wi-Fi support, a USB-A port, micro-SD card slot, 20 digital input/output pins, a 16 MHz crystal oscillator, a micro-USB connection, and an ICSP header.

Table 1. RMC protocol description of NMEA message.

Parameter name	Type	Description
-	STR	GP(GPS); BD(BDS); GN(GPS and BDS)
time	STR	hhmmss.sss
status	STR	V: invalidity; A: validity
Lat	STR	ddmm.mmmmm
N	STR	N: north latitude; S: south latitude
Lon	STR	ddmm.mmmmm
E	STR	E: east longitude; W: west longitude
spd	Double	Land speed
cog	Double	Land direction (clockwise from north)
date	STR	Ddmyy
mv	Double	magnetic declination (always vacant)
mvE	STR	magnetic declination direction (E)
mode	STR	Location: N(not); A(single); D(double)
cs	STR	Checksum (from '\$' to '*')

Figure 2. Arduino Yun PCB board.

Figure 3. Structure diagram of Arduino Yun.

The Bridge library facilitates communication between the two processors, giving Arduino sketches the ability to run shell scripts, communicate with network interfaces, and receive information from the AR9331 processor. The USB host, network interfaces and SD card are not connected to the 32U4, but the AR9331 and the Bridge library also enable the Arduino to interface with those peripherals.

2.3 Yeelink

Yeelink is an open-source hardware and intelligent equipment service company, which provides the sensor cloud services. Through real-time data processing, Yeelink platform provides users with safe and reliable condition monitoring. The developer can use it by following: Step1, Registering users; Step2, Adding device; Step3, Adding sensors; Step4, Uploading data; Step5, Retrieving data, and then repeating Step4 and Step5. The Yeelink API key is coded by JSON (JavaScript Object Notation), of which ① POST(upload), ② PUT(edit), ③ GET, and ④ DELETE are the four formats.

- ①: `curl --request POST --data-binary @datafile.txt --header "U-ApiKey: YOUR_API_KEY_HERE" http://api.yeelink.net/v1.0/device/12/sensor/3/datapoints`
- ②: `curl --request PUT --data-binary @datafile.txt --header "U-ApiKey: YOUR_API_KEY_HERE" http://api.yeelink.net/v1.0/device/12/sensor/3/datapoint/2016-10-15T17:53:16`
- ③: `curl --request GET --header "U-ApiKey: YOUR_API_KEY_HERE" http://api.yeelink.net/v1.0/device/12/sensor/3/datapoint/2016-10-15T17:53:16`
- ④: `curl --request DELETE --header "U-ApiKey: YOUR_API_KEY_HERE" --http://api.yeelink.net/v1.0/device/12/sensor/3/datapoint/2016-10-15T17:53:16`

3 SYSTEM DESCRIPTION

3.1 Hardware system

As shown in Figures 4 and 5, the proposed prototype of fitness information recording and network monitoring system mainly consists of BDS/GPS, Arduino Yun, and ASR (Auto Speech Recognize) voice module. Fitness information including coordinate position, moving speed, and distance can be recorded and monitored by using smartphone Yeelink APP or Website in computer network (Hu, 2015; Yang, 2015).

ASR voice module, which can translate voice to data as well as translate information to speaking, is the interaction between person and system prototype. BDS/GPS gains coordinate position of itself and offers longitude, latitude, and speed by its self-calibrating algorithm. Data information from ASR and BDS/GPS input Arduino Yun by its SoftwareSerial function. The Bridge library of Arduino Yun facilitates communication between its own processors Atmega 32U4 and AR9331. By using Wi-Fi, the encoded fitness information data are transmitted to Yeelink, which could provide cloud service. One can analyze the real-time fitness information using a smartphone or PC as well as acquire them in SD card.

3.2 Software description

Figure 6 shows a brief flowchart for system software. Arduino Yun, including Atmega 32U4 and AR9331, ASR voice module, and BDS/GPS reset first. ASR interaction module translates voice speaking to data. BDS/GPS transmits coordinate position of itself, including longitude and latitude, and speed by its self-calibrating algorithm to Arduino Yun by system reset configuration. Here,

we choose a frequency of 1Hz. Atmega 32U4 decodes the RMC protocol of NMEA message for UM220-III NL according to Table 1. The Bridge library of Arduino Yun transmits encoded data to AR9331 according to Yeelink API key, whose time interval should be greater than 10s. Figure 7 is the bridge process function based on Yeelink API key. The fitness information can be provided on Yeelink terminal, including smartphone APP and website online, and can also be gained in SD card offline.

4 EXPERIMENTAL RESULTS

UM220-III NL as a BDS/GPS of China independent intellectual property rights affords accurate coordinate position. Arduino Yun, integrating Atmega 32U4 and Linino AR9331, is used as the

controller and Wi-Fi connecting to Yeelink, which offers powerful cloud service.

Figure 8 shows smartphone APP interface and a three-circle normal walking playground test coordinate position. Figures 9 and 10 are the speed and distance curves for the test. Figure 11 shows the SD card recording data description including coordinate position and speed.

The experimental results of our proposed system prototype show that the BDS/GPS coordinate position accuracy, at a reasonable speed of 4.7 km/h and the three-circle playground distance more or less based on BDS/GPS 1Hz data sample frequency and Yeelink 10 s time interval.

5 CONCLUSION

Our proposed fitness information recoding and network monitoring system prototype based on BDS/GPS, Arduino Yun, and Yeelink has not only realized fitness information recoding and network monitoring, but also provided accurate and reasonable description, with a utilization of low-cost, convenient, and controllable character. Furthermore, an in-depth study should be conducted based on the proposed system prototype.

A knowledge integration method for innovation teams based on social tagging in an open environment

Xinmiao Li & Xuefeng Zhang

School of Information Management and Engineering, Shanghai University of Finance and Economics, Shanghai, China

ABSTRACT: In today's global economic integration, the direction of global innovation is moving toward open innovation, and in the open innovation environment, cross-organizational, cross-regional open innovation teams have become the main carrier of knowledge innovation. In the open team knowledge innovation process, it is one of the most important factors in improving the knowledge innovation capability and innovation efficiency of the team that distributed knowledge is acquired accurately and integrated rapidly. In this paper, a knowledge integration method for innovation teams based on social tagging in an open environment was proposed. Further, a corresponding model describing this technique was constructed. This method is classified into tacit knowledge integration method and explicit knowledge integration method. Based on the knowledge integration method for innovation teams based on social tagging in an open environment, the high level of match between the knowledge and the knowledge requirement can be selected for the team member.

1 INTRODUCTION

In an era of knowledge-driven economy, innovation is regarded to have replaced efficiency and quality as the core competitiveness for companies (Schumaker, 2013). In the open innovation environment, cross-organizational, cross-regional open innovation teams have become the main carrier of knowledge innovation (Wei, 2014). Knowledge is one of the most important factors for innovation. In an open innovation environment, explicit knowledge and experts with tacit knowledge are distributed in different geographical locations and different organizations. In the open innovation environment, it is the key factor to acquire required knowledge quickly (including explicit knowledge and tacit knowledge possessed by experts) and integrate distinctive knowledge effectively in order to complete the innovation task collectively.

Since an innovation task is creative, the knowledge required by the task usually cannot be clearly addressed and described by some words. In addition, the knowledge required by the innovation team members is changing constantly as the task is progressing. Because knowledge requirements of innovative tasks have the characteristics of vagueness and dynamics, the existing knowledge search and knowledge organization methods can hardly support the acquirement and integration of knowledge in an open environment for the innovation team.

Knowledge search based on key words is the most common approach (Li, 2009). This approach

is both convenient and inexpensive. However, this approach does not build a close connection between key words. In addition, various people may have different cognitions on key words and a person may generate distinctive understandings at different time. Thus, the key word used by a person can't be necessarily recognized by the others. Therefore, the method of knowledge search based on key words is low accuracy and efficiency (Ning, 2008).

Some scholars have studied methods like knowledge maps (Hao, 2010). However, methods of knowledge map need the knowledge demander to classify and search knowledge based on the categories they are not familiar with (Lin, 2009). Some knowledge demanders have difficulty in recognizing classification and some even do not agree with such classification standards. In that case, innovation team members are not willing to use such methods for knowledge coordination and management. What's more, the standards of knowledge classification are so fixed that they are not suitable for the characteristics of dynamics and vagueness of innovative task's knowledge requirements. In that case, the method of knowledge classification could hardly support knowledge acquirement and integration for innovation team members in an open environment.

Social tagging is one of the most widely used method in Web 2.0 (Gabriel, 2014). This paper has come to a conclusion that social tagging has the following characteristics (Esteban-Gil, 2012): (1) social tagging allows knowledge users to label knowledge

based on their own cognitions. Since social tagging is open for sharing, knowledge sharing and interaction in social tagging system is more convenient. (2) One piece of knowledge can be labelled with different tags, which reflect the knowledge's different characteristics. In that case, knowledge users can search knowledge according to their own knowledge requirements from different perspectives instead of based on defined and fixed classification and key words. Therefore, the method of social tagging enhances the efficiency of knowledge searching. (3) There is correlation between tags in social tagging system, which is beneficial for integrating collective wisdom and creating new knowledge. (4) Tags will change dynamically as knowledge and persons' cognitions change, which is suitable for the characteristics of dynamics of innovative task's knowledge requirements and knowledge integration. (5) Tags have the characteristics of vagueness in describing knowledge, which meets the demand of knowledge innovation.

Based on the above characteristics of social tagging, the method of social tagging is suitable for knowledge integration for open innovation teams. Even though social tagging has the above advantages, there is a lack of research on Tag's application in supporting open team knowledge

innovation. R. Arakji, R. Benbunan-Fich and M. Koufaris (2009) studied the motivation for users in using tags in social network. E. Tsui, W. M. Wang, C. F. Cheung and A. S. M. Lau (2010) established a hierarchical structure for a social tagging system. W-T. Hsieh, J. Stu, Y-L. Chen and S-C. T. Chou (2009) built a tag system of team coordination in order to manage group knowledge.

Based on our review, this paper proposed a knowledge integration method for innovation teams based on social tagging in an open environment and constructed the corresponding model. This model focuses on the recognition and integration of experts (tacit knowledge) and explicit knowledge in an open environment, which can support for open team knowledge innovation.

2 KNOWLEDGE INTEGRATION METHOD FOR INNOVATION TEAMS BASED ON SOCIAL TAGGING IN AN OPEN ENVIRONMENT

In this paper, we proposed a knowledge integration method for innovation teams based on social tagging in an open environment, as shown in Figure 1.

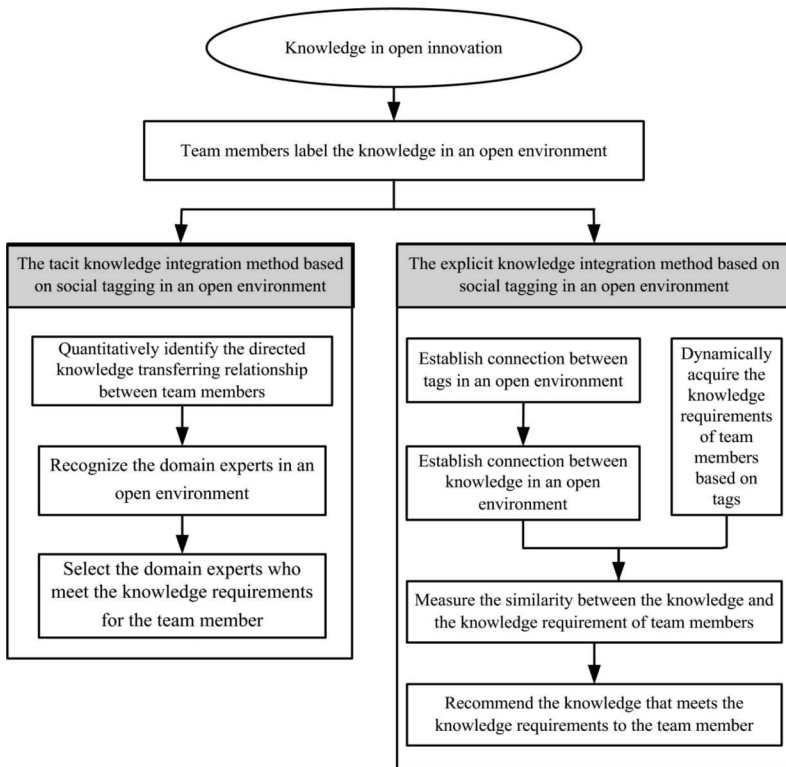

Figure 1. A knowledge integration method for innovation teams based on social tagging in an open environment.

In Figure 1, first, team members label the knowledge in an open innovation environment. Second, the knowledge integration method for innovation teams based on social tagging in an open environment can be classified into two parts: tacit knowledge integration method and explicit knowledge integration method based on social tagging in an open innovation environment. In the tacit knowledge integration method, first, domain experts are identified by directed knowledge transfer relationship between team members. After the domain experts are recognized in an open environment, the domain experts who meet the knowledge requirements of the team member can be selected for the team member. In the explicit knowledge integration method, first, relationship between tags is established based on tags' co-occurrence. Second, the knowledge requirement of the team member is acquired dynamically based on tags labeled by him. Third, the similarity between the knowledge and the team member's knowledge requirement is measured. Finally, the knowledge that meets the knowledge requirements of the team member can be selected for the team member.

3 TACIT KNOWLEDGE INTEGRATION METHOD BASED ON SOCIAL TAGGING IN AN OPEN ENVIRONMENT

Based on team member's labeling behavior in an open environment, according to the direct knowledge transfer relationship between team members, the domain experts can be recognized and selected. The Tacit knowledge integration method based on social tagging in an open environment is based on the following assumption:

Assumption 1: In an open environment, a team member will label the knowledge if the member considers the knowledge is valuable to complete the innovation task. On the contrary, the member will not label the knowledge.

Based on the above assumption, we suppose that $TEAMMATE_i$ is the i th member, $KNOWLEDGE_k$ is the k th term of knowledge, and TAG_i is the i th tag. We suppose that the team member $TEAMMATE_j$ released the term of knowledge $KNOWLEDGE_{kj}$. If the team member $TEAMMATE_i$ read and labeled the term of knowledge $KNOWLEDGE_{kj}$, then $f_{TEAMMATE_i \rightarrow KNOWLEDGE_{kj}} = 1$, which represents the team member $TEAMMATE_i$ label the term of knowledge $KNOWLEDGE_{kj}$ once. On the contrary, $f_{TEAMMATE_i \rightarrow KNOWLEDGE_{kj}} = 0$.

The tacit knowledge integration method based on social tagging is based on the following rule of team members' knowledge labeling behavior to identify domain experts with tacit knowledge in an open environment.

Rule 1: In the process of open team knowledge innovation, if the member $TEAMMATE_i$ always reads and labels the knowledge of other people released, furthermore the other members never label the knowledge released by $TEAMMATE_i$, $TEAMMATE_i$ can be considered as a junior knowledge learners in the open team. With more and more people label the knowledge released by $TEAMMATE_i$, $TEAMMATE_i$ gradually becomes a knowledge transmitter from a knowledge acquirer, even a knowledge creator from a junior knowledge learner. When $TEAMMATE_i$ becomes a domain expert, he will seldom label the knowledge released by the other team members. In the meantime, more team members will label the knowledge released by him.

Based on Rule 1, the knowledge transfer relationship between $TEAMMATE_i$ and $TEAMMATE_j$ is established as follows:

$$R(TEAMMATE_i, TEAMMATE_j) = \frac{\sum_{k=1}^n \frac{f_{TEAMMATE_i \rightarrow KNOWLEDGE_{kj}}}{\lg(\text{Month}(\text{CurrentDate} - \text{LabeledDate}_{kj}) + 1)}}{\sum_{p=1}^m \frac{f_{TEAMMATE_j \rightarrow KNOWLEDGE_{pi}}}{\lg(\text{Month}(\text{CurrentDate} - \text{LabeledDate}_{pi}) + 1)}} + b_1 \quad (1)$$

Where $R(TEAMMATE_i, TEAMMATE_j)$ represents the knowledge transfer relationship between $TEAMMATE_i$ and $TEAMMATE_j$. $KNOWLEDGE_{kj}$ is the k th term of knowledge released by $TEAMMATE_j$. $TEAMMATE_j$ released n terms of knowledge. $KNOWLEDGE_{pi}$ is the p th term of knowledge released by $TEAMMATE_i$. $TEAMMATE_i$ released m terms of knowledge. LabeledDate_{kj} is the labeled date of $KNOWLEDGE_{kj}$. CurrentDate is the current date. $\text{Month}()$ is the number of months converted from the difference between the current date and the labeled date. b_1 is a constant used to adjust $R(TEAMMATE_i, TEAMMATE_j)$.

The labeled date of knowledge influences on current team knowledge innovation in an open environment. The influence rule is as follows:

Rule 2: The smaller the difference between LabeledDate and CurrentDate of the term of knowledge is, the greater influence the term of knowledge has on current team knowledge innovation. On the contrary, if LabeledDate of the term of knowledge is far away from CurrentDate , the term of the knowledge has a minor influence on the current team knowledge innovation, which should be given a smaller weight to the term of knowledge.

Based on Rule 2, the function of $\frac{1}{\lg(x+1)}$ is a monotone decreasing function. $\frac{1}{\lg(x+1)} \geq 1$, the

Figure 2. The knowledge transfer relationship between team members in an open innovation team.

first derivative $\frac{1}{\lg(x+1)} < 0$ and the second derivative $\frac{1}{\lg(x+1)} > 0$, which show that $\frac{1}{\lg(x+1)}$ decreases with the independent variable x increases, and the decreasing rate gradually slows down. Therefore, the function of $\frac{1}{\lg(x+1)}$ can be used to fit the influence of labeled time of knowledge on current team knowledge innovation. In (1), we use $\frac{1}{\lg(\text{Month}(\text{CurrentDate} - \text{LabeledDate}) + 1)}$ to represent the influence of labeled time of knowledge on current team knowledge innovation.

The knowledge transfer relationship between team members is shown in Figure 2. In Figure 2, the arrow points to those members who acquire knowledge. The more upside located a team member, the more senior he is in the domain. In Figure 2, *TEAMMATE₁* and *TEAMMATE₅* are both on the top. Moreover, there is no arrow between them. This means that *TEAMMATE₁* and *TEAMMATE₅* are likely to be in different knowledge domains. *TEAMMATE₂* acquires knowledge from *TEAMMATE₁* and *TEAMMATE₅*, which indicates *TEAMMATE₂* is likely to create new knowledge by combining the knowledge in two domains. *TEAMMATE₄* is a junior knowledge acquirer. Therefore, based on (1), we can recognize the domain experts according to the knowledge transfer relationships between team members in an open environment. After the domain experts are recognized in an open environment, the domain experts who meet the knowledge requirements of the team member can be selected for the team member.

4 EXPLICIT KNOWLEDGE INTEGRATION METHOD BASED ON SOCIAL TAGGING

4.1 Establishing the relationship between tags

Knowledge in an open innovation environment is distributed in different geographical locations and

different organizations. It is difficult to quickly acquire the demanded knowledge and effectively integrate knowledge. In this paper, we integrate knowledge by establishing the relationship between tags.

We establish the relationship between tags through calculating the correlation degree based on co-occurrence between tags. The algorithms of the correlation degree between tags can be mainly divided into the symmetric algorithm and the asymmetric algorithm. The symmetric algorithm for the correlation degree between TAG_a and TAG_b is as (2):

$$R(TAG_a, TAG_b) = \frac{\sum f(TAG_a, TAG_b)}{\sum f(TAG_a) + \sum f(TAG_b)} \quad (2)$$

Where TAG_a and TAG_b are two different tags in an open innovation environment. $\sum f(TAG_a, TAG_b)$ is the co-occurrence frequency of TAG_a and TAG_b . $\sum f(TAG_a)$ is the occurrence frequency of TAG_a . $\sum f(TAG_b)$ is the occurrence frequency of TAG_b .

In (2), if one of the dividers is extremely large or small, a big deviation will be produced in the symmetric algorithm. Therefore, we use the asymmetric algorithm to calculate the correlation degree between TAG_a and TAG_b . The asymmetric algorithm for the correlation degree between TAG_a and TAG_b is as (3):

$$R(TAG_a, TAG_b) = \frac{\sum f(TAG_a, TAG_b)}{\sum f(TAG_a)} \quad (3)$$

In accordance to the correlation degree, the relationship between tags can be established. Based on the relationship between tags, the relationship between knowledge is established in an open innovation environment.

4.2 Measuring the similarity between the knowledge and the knowledge requirements

Team members' knowledge requirements are multidisciplinary and integrated. And team members' knowledge requirements are changing with the progress of the innovation task dynamically, which brings difficulties to the knowledge integration for an open innovation team. The explicit knowledge integration method based on social tagging in an open environment is based on the following assumption:

Assumption 2: In an open innovation environment, team members' labeling behavior for knowledge really reflects the process of members' acquiring, sharing and creating knowledge.

Based on Assumption 2, we use the tags labeled by $TEAMMATE_i$ to represent for the knowledge requirements of $TEAMMATE_i$. Therefore, the similarity between the tags labeled by $TEAMMATE_i$ and other knowledge' tags can be used to represent for the similarity between the knowledge requirements of members and other knowledge. Based on the similarity, the knowledge meets the requirements of the team member can be identified and selected for the team member.

We suppose $TEAMMATE_i$ is the target team member. All tags that $TEAMMATE_i$ labeled are extracted from an open environment. The repetitive tags are removed. $Tag_{TEAMMATE_i}$ is the set of tags labeled by $TEAMMATE_i$. $Tag_{TEAMMATE_i}$ is used to express the knowledge requirements of the target member $TEAMMATE_i$.

All tags of the k th term of knowledge $KNOWLEDGE_k$ are extracted. The repetitive tags are removed. $Tag_{KNOWLEDGE_k}$ is the tags set of $KNOWLEDGE_k$. $Tag_{KNOWLEDGE_k}$ is used to express the features set of $KNOWLEDGE_k$.

$Sim(Tag_{TEAMMATE_i}, Tag_{KNOWLEDGE_k})$ is the similarity between $Tag_{TEAMMATE_i}$ and $Tag_{KNOWLEDGE_k}$. The larger the similarity, the higher level of match between $KNOWLEDGE_k$ and the knowledge requirement of $TEAMMATE_i$.

$Tag_{TEAMMATE_i} = \{TAG_{i1}, TAG_{i2}, \dots, TAG_{im}\}$ is the set of knowledge requirements of the team member $TEAMMATE_i$. $Tag_{KNOWLEDGE_k} = \{TAG_{k1}, TAG_{k2}, \dots, TAG_{kn}\}$ is the features set of $KNOWLEDGE_k$. The similarity between $Tag_{TEAMMATE_i}$ and $Tag_{KNOWLEDGE_k}$ is as (4):

$$Sim(Tag_{TEAMMATE_i}, Tag_{KNOWLEDGE_k}) = \frac{1}{m \times n} \sum_{x=1}^m \sum_{y=1}^n Sim(TAG_{ix}, TAG_{ky}) \quad (4)$$

$$Sim(TAG_{ix}, TAG_{ky}) = \left(\frac{\sum f(TAG_{ix}, TAG_{ky})}{\sum f(TAG_{ix})} + \frac{\sum f(TAG_{ix}, TAG_{ky})}{\sum f(TAG_{ky})} \right) \div 2 \quad (5)$$

Where TAG_{ix} is the x th tag labeled by $TEAMMATE_i$. TAG_{ky} is the y th tag of $KNOWLEDGE_k$.

The created date of knowledge influences on current team knowledge innovation in an open environment. The influence rule is as follows:

Rule 3: The newer the knowledge is, the greater the knowledge influences on current team innovation. The influence of knowledge's created time shows that new knowledge is usually more valuable than old one. Therefore, new knowledge should be given greater weight. On the contrary, the knowledge created earlier has minor influence on team knowledge innovation and should be given smaller

weight. That is to say, the smaller the difference between $CreatedDate$ and $CurrentDate$ of the term of knowledge is, the greater influence the term of knowledge has on current team knowledge innovation. On the contrary, if $CreatedDate$ of the term of knowledge is far away from $CurrentDate$, the term of the knowledge has a minor influence on the current team knowledge innovation, which should be given a smaller weight to the term of knowledge.

Based on Rule 3, the function of $\frac{1}{\lg(x+1)}$ is a monotone decreasing function. $\frac{1}{\lg(x+1)} \geq 1$,

the first derivative $\frac{1}{\lg(x+1)}' < 0$ and the second derivative $\frac{1}{\lg(x+1)}'' > 0$, which show that

$\frac{1}{\lg(x+1)}$ decreases with the independent variable x increases, and the decreasing rate gradually slows

down. Therefore, the function of $\frac{1}{\lg(x+1)}$ can be used to fit the influence of the created time of knowledge on current team knowledge innovation.

In this paper, we use $\frac{1}{\lg(Month(CurrentDate - CreatedDate) + 1)}$ to represent the influence of the created time of knowledge on current team knowledge innovation.

$\frac{1}{\lg(Month(CurrentDate - CreatedDate) + 1)}$ is used as the time influence factor to modify the similarity between the tags labeled by $TEAMMATE_i$ and other knowledge' tags. Therefore, (4) is changed to (6) as follows:

$$score = \frac{Sim(Tag_{TEAMMATE_i}, Tag_{KNOWLEDGE_k}) * b_2}{\lg(Month(CurrentDate - CreatedDate) + 1)} \quad (6)$$

Where $CreatedDate$ is the date that the knowledge is created. b_2 is a constant used to adjust $score$.

Based on (6), the bigger $score$, the higher level of match between $KNOWLEDGE_k$ and the knowledge requirement of $TEAMMATE_i$. Therefore, the knowledge with the bigger $score$ should be recommended to $TEAMMATE_i$.

5 CONCLUSIONS

Social tagging is one of the most widely used concepts of the Web2.0 era. In this paper, a knowledge

integration method for innovation teams based on social tagging in an open environment was proposed. This method is classified into tacit knowledge integration method and explicit knowledge integration method. Based on the tacit knowledge integration method for innovation teams based on social tagging in an open environment, the high level of match between the domain experts and the knowledge requirement can be selected for the team member. Based on the explicit knowledge integration method for innovation teams based on social tagging in an open environment, the high level of match between the knowledge and the knowledge requirement can be recommended to the team member.

A study on the classification of Yunnan folk songs based on ensemble learning

Dong Wang

School of Art, Southwest Forestry University, Yunnan Province, China

Key Laboratory of Educational Informatization for Nationalities Ministry of Education, Yunnan Province, China

Yan Zhang & Dan-Ju Lv

School of Computer and Information, Southwest Forestry University, Yunnan Province, China

ABSTRACT: Nowadays, music classification has become an important application field for classification algorithms. There is only little research about folk songs classification. This paper used the original folk songs in Yunnan Province as research objects, extracting their CELP audio characters on a 11-dimensional scale, comparing and analyzing the classified experimental data from different proportions of marked training samples, which are processed by a single classifier and an ensemble classifier (such as Bagging, AdaBoost, and MCS). Among them, AdaBoost is the most efficient one with an accuracy rate of higher than 85%. The result showed that the ensemble classifiers could mean the effectiveness of the study methodology.

1 INTRODUCTION

As an important auxiliary measure to searching music information and audio processing, music classification plays a potential critical role in musical research theory and practicing. At present, music classification studies mainly focused on fields such as musical emotion, musical genres, instruments, and traditional dramas, whereas it is seldom applied in ethnical music style research (Sun, 2014).

Ethnic music has very high cultural and artistic value (Hong, 2014). The various folk music, which spread by oral teaching of different ethnic groups in Yunnan Province, show obviously different music styles in performance form, singing ways, melody, scale, mode, and rhythm, being originated from different geographical environment, ethnic origin, languages, religious faith, life style, and customs (Zhang, 2006). This paper classified and summarized the characters of different folk songs in Yunnan Province by modern digital audio processing techniques and built a database of those musical characters. This study provided a new way for digital processing of music, which could also be a reference and methodology for music producers.

2 ENSEMBLE LEARNING

In contrast to ordinary learning approaches, which try to construct on one type of learner from

training data, ensemble methods try to construct a set of learners and combine them. Ensemble learning is also called committee-based learning, or learning multiple classifier systems (Zhou, 2012). To build an effective ensemble system, three strategies need to be considered, including data sampling or selection; training member classifiers; and combining classifiers. In ensemble learning, the key issue is how to design the base classifiers with stronger generalization and diversity (Zhang, 2012). The success of ensemble learning lies in achieving a good trade-off between the individual performance and diversity. Therefore, it is desired that the individual learners should be accurate and diverse. How to measuring diversity in classifier ensembles are diversity for building the ensemble are presented in detail in literature (Kuncheva, 2004). The Bagging and Boosting algorithms are popular ensemble strategies in the application.

2.1 Bagging

Bagging (Breiman, 1996) was proposed by Breiman. It uses bootstrap sampling to obtain the data subsets for training learners and adopts the most popular voting strategy for aggregating the outputs of each individual learner. Therefore, it should be used with unstable learners such as neural network and decision trees. That is, the more unstable, the larger the performance improvement. If the base classifiers are stable, the improved performance of the bagging is not

obvious. The bagging algorithm (Zhang, 2006) is summarized as follows.

Input: Training data set L, learning method H, number of base classifiers N

Output: H_{final}

For $i = 1$ to N

$L_i = \text{bootstrap sample from } L;$

$H_i = H(L_i); // \text{train a classifier } H_i \text{ on } L_i \text{ with } H;$

End For

$$H_{final} = \arg \max_{y \in Y} \sum_{i=1}^N I(H_i(x) - y)$$

2.2 Boosting

Boosting is a general method for improving the performance of a weak learner. It works by training a set of learners sequentially and combining them for prediction, where the later learners focus more on the mistakes of the earlier learners.

AdaBoost (Adaptive Boosting) is a popular ensemble algorithm that improves the simple boosting algorithm via an iterative process. The amount of focus is quantified by a weight that is assigned to every pattern in the training set. Initially, the same weight is assigned to all the patterns. In each iteration, the weights of all misclassified instances are increased, whereas the weights of correctly classified instances are decreased. As a consequence, the weak learner is forced to focus on the difficult instances of the training set by performing additional iterations and creating more classifiers. Furthermore, a weight is assigned to every individual classifier. This weight measures the overall accuracy of the classifier and is a function of the total weight of the correctly classified patterns. Thus, weights are used for the classification of new patterns (L. Rokach, 2010).

2.3 Ensemble with different-type base classifiers

Different types of classifiers are trained by the same training data and combined with some strategies. The final classifier classifies new data and gives their label by predictions. The multi-classifier system is built by m classifiers with m learning algorithms, and the model is shown in Fig 1.

Figure 1. Model of the multi-classifier ensemble.

To measure ensemble diversity, a classical approach is to measure the pairwise dissimilarity between two learners and then average all the pairwise measurements for the overall diversity (Kuncheva, 2003). Given a data set $D = \{(x_1, y_1), \dots, (x_m, y_m)\}$, for two classifiers h_i and h_j , some characters are denoted:

$$a = \sum_{k=1}^m I(h_i(x_k) = y_k \cap h_j(x_k) = y_k) \quad (1)$$

$$b = \sum_{k=1}^m I(h_i(x_k) = y_k \cap h_j(x_k) \neq y_k) \quad (2)$$

$$c = \sum_{k=1}^m I(h_i(x_k) \neq y_k \cap h_j(x_k) = y_k) \quad (3)$$

$$d = \sum_{k=1}^m I(h_i(x_k) \neq y_k \cap h_j(x_k) \neq y_k) \quad (4)$$

Two approaches need to be adopted: correlation coefficient and kappa-statistic.

1. Correlation coefficient:

$$\rho_{ij} = \frac{ad - bc}{\sqrt{(a+b)(a+c)(c+d)(b+d)}} \quad (5)$$

This is a classic statistic for measuring the correlation between two binary vectors. The value indicates that the smaller the measurement, the larger the diversity.

2. Kappa-statistic

It is defined as:

$$K_p = \frac{\theta_1 - \theta_2}{1 - \theta_2} \quad (6)$$

where θ_1 and θ_2 are the probabilities that the two classifiers agree and agree by chance, respectively. The probabilities for h_i and h_j can be estimated on the data set D .

$$\theta_1 = \frac{a + d}{m} \quad (7)$$

$$\theta_2 = \frac{(a+b)(a+c) + (c+d)(b+d)}{m^2} \quad (8)$$

The value indicates that the smaller the measurement, the larger the diversity.

2.4 Random forest

Random Forest (RF) (Breiman, 2001) is an extension of bagging, which consists of a combination of tree classifiers, where each classifier is generated

using random vector sampled independently from the original training examples. Given a training set size N with M attributes, the bagging method generates a number of new training sets each of size n ($n < N$) by randomly drawing samples with replacement from the original training set. For each node of the tree, m ($m < M$) attributes are randomly chosen to provide the base for calculating the best split at that node. Once the random forest is formed, each sample is classified to the class taking the most popular votes from all the tree predictors in the forest.

3 EXPERIMENTAL DATA AND METHOD

The experimental data are acquired from live recording in villages of Yunnan Minority, with 44.1 sampling rate, 16 bits, and stereo-track. The folk song data include five types of minority, such as Daizu, Hanizu, Nuzu, Wazu, and Yizu. The song's audio length amounts to almost 7 min. The denoising is executed in the preprocessing stage.

3.1 Feature extraction

The feature extraction is executed based on the bit-stream through the G.723.1 data encoding on the Matlab 7.1 platform. The receiving terminal unpacks the bit-stream as frame-stream. LPC features are extracted at each bit-frame 10 order coefficients from 0~23bit (LPC0~LPC2), which consists of 10 dimensions of LPC features (Zhang, 2014). The process of exacting feature is shown in Fig 2.

3.2 The method of experiment

The experiment is carried out on the platform of development Weka. At first, the feature data are converted to an ARFF format file. Then, the ARFF format file can be obtained, and the

module is classified in Java development based on the Weka. The experiments compared the performances of the single classifier and ensemble classifiers.

The single classifier includes traditional classifying methods such as decision tree J48 and neural network, while Bagging, AdaBoost, and random forest are involved in the ensemble strategies.

4 ANALYSIS OF THE EXPERIMENTAL RESULTS

In the experiment, the data are selected from the total according to a third of the total amount of data in each category. It is 10 times sampling randomly with 67% as the training examples and 33% as test samples. Five classes of music samples are shown in Table 1.

4.1 Single-classifier experiment

The single-classifier algorithm adopts the decision tree (J48), Neural Network (NN), Naïve Bayes (NB), Radial Basic Function (RBF), and Random Forest (RF). The results of classification are listed in Table 2. According to the table, the random forest outperforms others, whereas the Naïve Bayes and RBF show worse performance. BP is secondly to RF, but better than J48. Accuracy of each class and Overall Accuracy (OA) in three better single classifiers are shown in Table 3.

4.2 Ensemble with multiple classifiers

4.2.1 Select diverse base classifiers

There are five base classifiers above the experiment. In order to select the larger diversity classifiers involved in the ensemble, two methods are

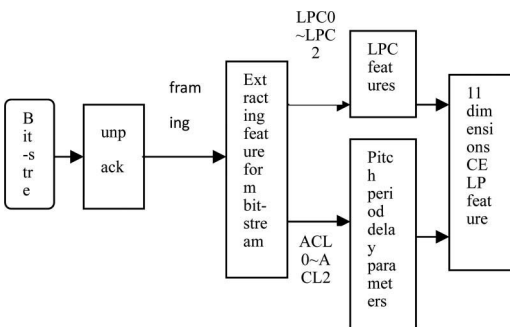

Figure 2. Extracting of CELP features from folk songs audio.

adopted to measure the diversity candidate classifiers. The process is as follows.

- Step 1: To calculate the index of difference of each pairwise classifier;
- Step 2: To construct the difference matrix;
- Step 3: To calculate the value of difference of each classifier and sort the results in ascend order;
- Step 4: To select the top ones for the ensemble classifiers.

In the experiment, the difference value of each classifier is calculated as illustrated in Table 4. According to the smaller difference value and larger diversity, three out of five classifiers are selected including, decision tree, neural network, and random forest (bold font in Table 4), which are involved in the ensemble multiple classification.

4.2.2 Ensemble classifiers

In the experiment of Bagging and AdaBoost, decision tree, neural network, and random forest are used as the base classifier, and the performances are summarized in Table 5.

It is obvious that the performances of Bagging, AdaBoost, and MCS are superior to the base classifier for the music classification in terms of overall

accuracy. Especially, that of AdaBoost is better than others. In addition, the classifiers have shown the different performance on specific classes, indicating that the classifier performing well for one class may be poor for other classes. Class “hani” and “yizu” obtained better performance with most classification methods, while classes “nuzu” and “wazu” had relatively low accuracy. In this case, the MCS is only better than Bagging with J48, but inferior to the other base classifiers in Bagging and AdaBoost. In the three base classifiers, RF has the highest accuracy, whereas BP has a lower accuracy and J48 has the lowest accuracy. In both Bagging and AdaBoost, the accuracy of the base classifiers ranked in the pattern as using the base classifiers. Furthermore, J48, BP, and RF showed better accuracies in AdaBoost than in Bagging.

5 CONCLUSIONS

Yunnan folk music is a treasure of ethnic culture and art and hence its classification is significantly valuable. Ensemble learning, constructing a set of classifiers, and then classifying new data via taking a vote of their predictions is a good way to achieve high accuracy in classifying. This research

is about classifying five types of Yunnan folk music through extracting their main features. This research contains experiments of using single classifier, and ensemble methods including Bagging, AdaBoost, MCS, and random forest to analyze music data and classify them. From the results, better performance is found in ensemble methods. An effective way of classification can be provided by ensemble methods. Among these methods, the AdaBoost performs the best. More studies about combining ensemble learning with semi-supervised learning to build learning model with high accuracy are on underway.

RFID-based elevator positioning algorithm by the virtual reference label

Sheng Zhang & Xiu-Shan Zhang

Department of Computer Science, Naval University of Engineering, Wu Han, China

ABSTRACT: In this paper, a localization algorithm based on RFID is proposed to solve the problem of elevator positioning in the centralized monitoring system. The algorithm follows Euclidean distance by the received signal strength value (RSSI) between the reference tag and unknown node, adopts the dichotomy to rapidly approximate to determine the corresponding positioning interval, inserts the virtual label according to the required positioning precision dynamically, and estimates the unknown node positioning using the least-squares method. Performance analysis results indicate that the RFID-based system has an error of less than 0.1 m and improves the accuracy approximately 50% comparing with the common centroid algorithm. The results indicate that the algorithm can effectively locate the elevator and have a good positioning accuracy.

1 INTRODUCTION

The elevator safety problem is widely concerned nowadays. Therefore, it is necessary to monitor the elevator effectively to guarantee the safe operation of the elevator. The single-vendor solution cannot meet the actual demand because of the different hardware interface of different brand elevators (Jiang, 2015). To solve the unified supervision of different brand elevators, much research has been done by scholars from all fields, and several achievements have been made, such as network monitoring equipment, video overlay, and complete sets of elevator monitoring sensor system. In the above-mentioned solution, real-time acquisition of the elevator position information is a key problem. Therefore, it can be divided into two types according to the way of elevator position information acquisition. One is through the elevator own level sensor to achieve location information collection. The implementation method is mainly to install optical or magnetic induction sensor, which can provide a switching value when the elevator moves through a flat baffle. Then, we can know the position information about the elevator. The biggest shortcoming in this way is that the positioning accuracy is in floors, so that the system cannot detect the potential problems in the elevator motion process. The other is to collect the absolute position information of the elevator directly by laser, infrared, and other methods. It has higher positioning accuracy, which can be in the scale of centimeters. However, because of the mobility of car and the more dust and shelter in the environment of elevator shaft, the robustness

of the system is low and the implementation cost is rather high (Hui, 2013).

In order to solve the shortcomings of the above two schemes, this paper proposes an elevator positioning algorithm based on RFID technology, which combines the characteristics of elevator movement on the basis of RFID indoor positioning technology. It can realize low-cost positioning of the elevator and have a better positioning accuracy.

2 BACKGROUND KNOWLEDGE

In this section, we introduce the RFID-based location technology using RSSI and the weighted centroid algorithm, which are the foundations of our study.

2.1 RFID-based location technology using RSSI

RFID is a technology to achieve information in noncontact ways through wireless transmission of signals. Thus, according to the theory of wireless communication, the signal in the process of transmission will attenuate with the increase of distance. The path loss has the following empirical formula in indoor environment (De Angelis, 2010):

$$PL(d) = PL(d_0) + 20N \lg \frac{d}{d_0} + X_\sigma \quad (1)$$

where $PL(d)$ represents the path loss of the unknown node, which is at a distance of d from the reader, $PL(d_0)$ is the path loss at reference distance

d_0 , N is the pass loss factor of the links, which depends on the signal transmission environment, and X_σ is an environment variable, which is a normal distribution random variable with mean 0.

Assuming that the power of the signal after the antenna gain of the reader is P_0 , the signal RSSI value can be expressed as:

$$RSSI(d) = P_0 - PL(d) = RSSI(d_0) - 20N \lg \frac{d}{d_0} - X_\sigma \quad (2)$$

Therefore, we can get the value of the path loss factor N by collecting a large number of sample points and estimate X_σ according to the Gaussian distribution method proposed by Zhi-feng Lin in (2011).

2.2 Weighted centroid algorithm

Considering the actual situation of the elevator movement, we set the vertical axis of the reference tag as the reference axis and the vertical axis of the elevator movement as the track axis. Under the ideal circumstances, we can determine the location of the current node A when distances r_1 and r_2 are the distances between the conference nodes and the unknown point A is given (Tao, 2014). However, in practice, the calculated distance between node A and the reference axis may be greater than r_0 , as shown in Figure 1.

To solve the problem of calculation of point A in the real environment, the following processing is performed. First, the two-dimensional coordinate system is constructed, and the reference axis is the y-axis; therefore, the coordinates of the two reference nodes are $(0, h_1)$ and $(0, h_2)$. Then, set

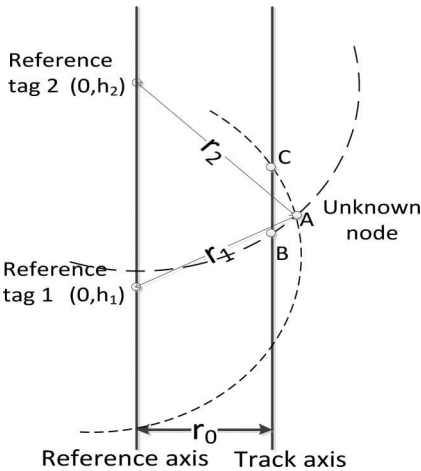

Figure 1. Principle of weighted centroid algorithm.

the two reference nodes for the center points and construct two circles R_1 and R_2 with radii of r_1 and r_2 , respectively. A is the intersection point in the limited quadrant (here is the first quadrant). By substituting r_0 into the equation of R_1 and R_2 , we can get the intersection part of the line $x = r_0$ and two circles. Let the points B and C be the intersection points given by the line $x = r_0$ and two circles which are the two closest points to A . Now, A is on line BC . The traditional centroid algorithm takes the BC midpoint as the actual coordinate of point A . However, in the weighted centroid algorithm, the RSSI value is used to determine the size of the center of mass decision, that is, the larger the node RSSI value, the greater the impact on the position of the center of mass. Let $B(r_0, y_b)$ and $C(r_0, y_c)$, respectively, take the value of point A in the weighted centroid algorithm as:

$$\begin{cases} x = r_0 \\ y = \frac{\frac{y_c + y_b}{r_1 + r_2}}{\frac{1}{r_1} + \frac{1}{r_2}} \end{cases} \quad (3)$$

3 ALGORITHM IMPROVEMENT

Because the RSSI value is greatly affected by the environment, and when the entity label measurement error is larger, the estimation result will have a bigger error, so we need to improve the algorithm.

3.1 Use dichotomy to estimate elevator node position

Throughout the elevator positioning algorithm, the reader may receive the reflected signals from more than two tags. According to formula (2), we always select two reference nodes that are the closest to the unknown nodes to reduce the influence of environmental factors. That is to say, the greater the density of the reference labels, the smaller the distance of the positioning interval. Therefore, the distances between the given nodes and unknown node are lower and the positioning accuracy is higher. However, in the actual deployment process, we found that the density of the reference label can not only increase the hardware cost of the system but more importantly lower the positioning accuracy because of the signal interferences between the tags while the density is too large. In this regard, we take the method of inserting virtual tags to improvement.

There is always a point D_{max} on the reference axis, which is r_0 away from the elevator in the case of the

special trajectory of the elevator. The RSSI value of D_{max} should be maximum, and we think D_{max} is the projection of the elevator node on the reference axis whose y-coordinate is the same as the elevator node. If we ignore the influence of environmental factors, the RSSI values at two points are the same when the distances of two points to D_{max} on the reference axis are equal. On the basis of this feature, the dichotomy process of calculating the elevator position is as follows:

1. Assuming the reader selects the physical reference labels B and C as the two ends of the positioning interval, we read the RSSI values of two points.
2. We take the midpoint D of the line BC as the D_{max} and ΔRSSI as the difference between the RSSI values of the two points B and C . If $\Delta\text{RSSI} \in [-\delta, +\delta]$, we think that the signal strength values of B and C are equal. The midpoint of the line BC is the actual position of D_{max} , where δ is the error tolerance setting in consideration of the influence of environmental factors.
3. When $\Delta\text{RSSI} \notin [-\delta, +\delta]$, according to formula (2) we can select one with a larger RSSI value (we take B here). Then, make D replace C as new C .
4. Repeat Step 2, let d_1 be the current distance of CD . Here, d the distance between C and the imaginary elevator node is $\sqrt{d_i^2 + r_0^2}$, and then through formula (2) to calculate the current C-point RSSI value.

In this way, we can acquire the estimating coordinates (r_ρ, y) , where y is the height information of lift by a certain number of recursive processes.

3.2 Estimate the elevator node using the least-squares method

In Section 3.1, the idea of recursion of limit by dichotomy was used to estimate the position of elevator nodes. However, the uncertainty of recursion may lead to a longer computational time, which leads to the real-time degradation of the positioning system. In order to solve the above problems, the dichotomy method is adopted to obtain the appropriate positioning interval quickly, and then the least-square method is used to determine the elevator node position.

When we acquire the positioning interval, the RSSI value of the end point may be in two cases. If the end point is an entity tag, then the value is read by the reader actually. Otherwise, when the reference node is a virtual node and the location interval is $[a, b]$, the elevator node currently projecting on the y-axis. Take a random point $D_i(0, d_i)$ ($d_i \in [a, b]$) as the D_{max} and calculate the virtual node signal power RSSI_i . Then, use the weighted

centroid algorithm to obtain the lift nodes (r_ρ, y_i) . According to the principle of least squares, assume $Y = a+bx$, $\Delta = Y_i - Y_i$:

$$\varphi(a, b) = \sum_{i=1}^n \Delta^2, \quad (n \geq 20) \quad (4)$$

When $\varphi(a, b)$ is minimum, we can get the linear fitting relationship between the horizontal and vertical coordinates of the elevator node in the interval. Because the horizontal coordinate of the elevator node is r_0 in this case, the fitting relationship is a straight line parallel to the X-axis, that is, the equation of the line must be $Y = C$. Equation (4) can be simplified as:

$$\varphi(C) = \sum_{i=1}^n (y_i - C)^2 \quad (5)$$

When the above formula is used to obtain the minimum, that is, $C = C_{min}$, the location of the elevator is (r_0, C_{min}) .

3.3 Estimate the error tolerance δ and the location interval L

In the previous two sections, we establish an algorithm model to calculate the position of the elevator node by inserting virtual labels between the two entity tags. In this section, we estimate the error tolerance (δ) and the interval distance (L) involved in the preceding model.

According to equation (2), when the distances from two reference nodes to lift are equal, the main cause of $\Delta\text{RSSI} \neq 0$ is X_σ . In accordance with 3σ distribution law of normal distribution, the probability that $X_\sigma \in [-\sigma, \sigma]$ is about 68%, and the value of σ can be calculated in the method provided by Cui-Cui Yu (Yu, 2015). Then, according to the size of the value of σ set δ , usually take $\sigma/3$.

Positioning distance (L) depends on the positioning accuracy requirements. As Figure 1 shows that the calculation error $\varepsilon < L$, the value of L must be taken less than positioning accuracy requirements.

4 EXPERIMENT AND SIMULATION

4.1 Establish experimental system

Establish a simulation system to simulate the movement of the elevator process in the laboratory environment. The RFID system hardware devices are shown in Table 1, and the entire system hardware deployment is shown in Figure 2.

RFID readers and laptops are placed on the top of the stroller bracket, the reader mode of work is

set to active mode, the query interval is 100 ms, the transmission power is set to 30dBm, and the baud rate is 57600dps. The computer and the reader communicate through the RS232 serial port. The reader is connected to an external antenna through a TNC antenna interface. The antenna is suspended under the crosspiece of the trolley. The vertical distance to the ground is 0.5 m. The antenna plane is parallel to the ground. Passive tags are evenly spaced on the ground with a distance of 0.5 m between adjacent tags.

4.2 Results and analysis

4.2.1 Static measurement experiment

In the experiment, the displacement of equipment is fixed, and the center of the antenna is located as the lift node. Distances between lift node and two entity tags are 0.53 and 0.58 m. Then, 20 groups of RSSI data are collected and the position of lift is determined (setting $\delta = 4\text{dBm}$, $L = 0.1\text{ m}$). The error result is shown in Figure 3.

As shown in Figure 3, the improved positioning algorithm has obvious advantages compared with the weighted centroid algorithm, the error is reduced by nearly 50%, and the error is less than 0.1 m.

Figure 3. Errors of two algorithms.

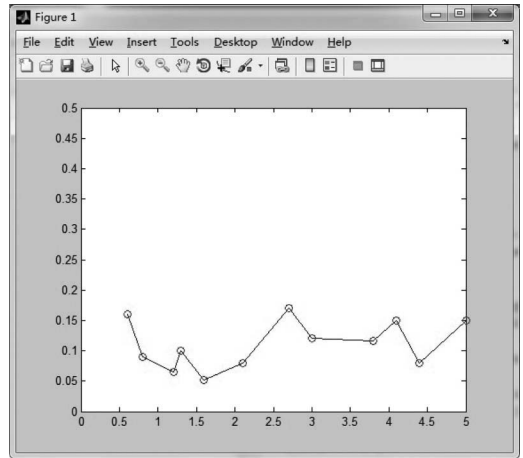

Figure 4. Errors of dynamic measurement experiment.

	Transmission power	30dBm
Tags	Brand model number	ZK-RFID606
	Mode standard	EPC C1G2
	Antenna	Polarization mode

Figure 2. Simulation experiment system.

4.2.2 Dynamic measurement experiment

As the elevator is often in dynamic motion, it is necessary to verify the algorithm through dynamic experiments. The whole movement process of elevator is divided into three stages: constant speed, acceleration, and deceleration. Therefore, in the experiment process, we imitate the states of the movement, record the actual lift position, and the entity tags RSSI value, which constitutes the positioning interval. After the above processing, we process the data using MATLAB2010b, and the results are shown in Figure 4.

Figure 4 shows that when a car is in dynamic motion, its positioning error is higher than that in the static state, but the average error is about 0.1 m, which still has a high positioning accuracy.

5 CONCLUSION

In this paper, an improved algorithm is proposed on the basis of the weighted centroid algorithm. This is the first algorithm to use dichotomy reduced positioning interval and obtain position information of the lift range nodes, and finally through a linear least squares regression to estimate the node position of elevator. The feasibility of the experiment is verified. The experimental results show that the algorithm has a better positioning accuracy, meets the basic needs of elevator positioning system, and has a certain practical value.

Design of the omnidirectional mobile robot control system based on dSPACE

Huan-huan Liu, Chang-sheng Ai, Hong-hua Zhao & Xuan Sun

School of Mechanical Engineering, University of Jinan, Jinan, China

ABSTRACT: In recent years, the use of omnidirectional mobile robot has become a bright spot in the logistics scheme of equipment manufacturing industry. It has played a certain role in improving production efficiency, reducing costs, and improving product quality and management level. However, its application is limited due to its low flexibility, low efficiency, and difficulty of operation in complex environment. In order to realize the flexibility and maneuverability of this type of movement, the mobile structure and motion control system are designed. The structure design used mecanum wheel as its moving wheel. Its control system design used dSPACE real-time simulation and control platform, dSPACE simulation, and MATLAB/Simulink perfect combination. Through the establishment of the simulation model, the motor speed characteristics of the motor were tested. Therefore, it can realize the design and debugging of control system. The experiment shows that the control effect of dSPACE real-time simulation platform is good. The control system model can be built conveniently and quickly, and the development period of the control system can be shortened simultaneously.

1 INTRODUCTION

The omnidirectional mobile robot has the advantages of high self-planning, fast self-organization, self-adjustment, and so on (Wang, 2015). It is suitable for complex working environment, such as for indoor warehouse handling, space exploration, and security checking for automobile chassis, pipelines, and containers. Thus, the omnidirectional mobile robot will be widely used in factory automation, construction, mining, military, agricultural services, and so on. Therefore, more and more high requirements for its mobility and flexibility are required, especially for the performance requirements of the control system. There are many ways to design a control system for an omnidirectional mobile robot. For example, few scholars from the Islamic Azad University used PI-fuzzy control strategy to design the control system of four-wheeled omnidirectional mobile robot (Feng, 2010). Several researchers from Taiwan used the fuzzy logic controller and visualization to design the control system of the omnidirectional mobile robot (Ehsan, 2011). Although these methods can realize the control system design of the mobile platform, the design and development of the test cycle is long. Not only the development time is long, but also the cost is very high. To this end, the dSPACE real-time simulation software and hardware platform was used for the design of its control system. dSPACE is based on the development of

MATLAB/Simulink real-time simulation system software and hardware platform, which achieved a seamless combination with MATLAB/Simulink (Lang, 2013). ControlDesk interface can be used to provide various parameters of the window to adjust the parameters of the controller or real-time editing program so as to achieve rapid control prototype verification.

2 BASED ON THE PRINCIPLE OF DSPACE MOBILE ROBOT MOTION CONTROL SYSTEM DESIGN

The schematic diagram of control system of omnidirectional mobile robot based on dSPACE is shown in Figure 1. The figure shows the speed control system based on dSPACE, including the PC, dSPACE hardware, servo motor, servo motor driver, serial ISP download bus, and omnidirectional wheel. The PC computer is the bottom tool, which has the software of dSPACE of MATLAB/Simulink, RTW, RTI and ControlDesk installed in it. The PC has a serial port ISP download bus and dSPACE controller MicroAutoBox for signal transmission. When the block diagram is set up, the digital output channel and the port of the controller are set up. The MicroAutoBox slot of the controller is connected with the output port line corresponding to the controller, and is connected with the corresponding port of the servo driver to

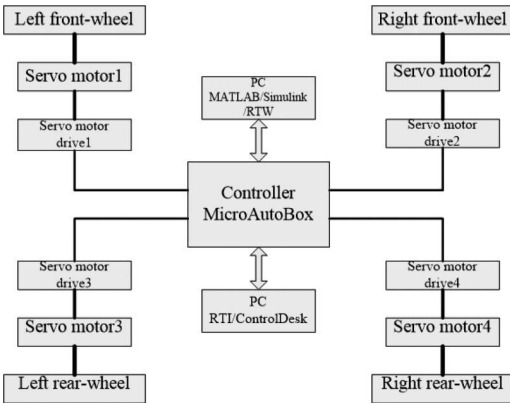

Figure 1. Schematic diagram of control system of omnidirectional mobile robot.

ensure the normal transmission of the signal. For the needs of different users, dSPACE provides a variety of alternative hardware systems, such as the single-board system and the standard-component system.

3 ANALYSIS OF THE FORCE APPLIED TO MECANUM WHEEL OF THE OMNIDIRECTIONAL MOBILE ROBOT

The Structure Design of Omnidirectional Moving Mechanism used Mecanum wheel (Gferrer, 2008). The shape of Mecanum wheel is like a helical gear. The tooth is a rotatable drum-shaped roller, and the roller axis and the wheel axis formed α angle. The roller has 3 degrees of freedom. It can rotate about itself and around the axle simultaneously and can rotate around a roller in contact with the ground point. The wheel itself also has 3 degrees of freedom: rotation around the axle and translation along the perpendicular direction of the roller axis and rotation around the contact point of the roller and ground. In this way, the driving wheel has the active driving capability in one direction, and the other direction has the movement characteristics of free movement. The wheel circumference is not composed of ordinary tires, but the distribution of many small rollers. The theory circle of these rolls contour line is coincident with the wheels, and the roller can rotate freely. During the motor rotation of the drive wheel, the wheel rotates normally forward along the direction perpendicular to the drive shaft, and the roller wheel rotates around the axis of rotation along their respective freedom. Accordingly, the deviation of the small roller is divided into left and right Mecanum wheels. Compared with the universal wheel, Mecanum wheel has the characteristics of flexibility, accuracy,

and efficiency, which is a kind of universal wheel control. Its mobile states are: forward, backward, left and right lateral and transverse shift left anterior oblique, right anterior oblique shift, left posterior oblique shift, right posterior oblique shift, rotation center with $0-360^\circ$, and the right after the origin of rotating omnidirectional mobile mode.

Among them, the omnidirectional mobile platform going forward, right lateral, right oblique shift, right rear wheel rotation, as the origin of omnidirectional mobile platform to center for the analysis of motion diagram of Figure 2 in the origin of 360° rotation and after rotation of the wheel center (a), (b), (c), (d), (e), and (f) shown. In Figure 2 (a), the torques of the four-wheeled mobile robot are T_1 , T_2 , T_3 , and T_4 . The X-direction decompositions of their moment are offset each other, and the Y-direction decompositions of the moment are pointing to the front; the synthesis of the moment is also pointing to the front so the omnidirectional mobile robot is moving forward. In Figure 2 (b), analysis of the omnidirectional mobile robot transverse direction, Y-decomposition torque offset each other, only the direction decomposition of X torque. Because the X-direction decomposition of the moment, the moments after the synthesis are pointing to the right and the omnidirectional mobile robot to traverse. In Figure 2 (c), the right front wheel and left rear wheel of the omnidirectional mobile robot have no input torque, and the left front wheel and the right rear wheel have torques T_1 and T_2 , respectively. When T_1 and T_2 face the right front, the Y-direction decompositions of the moment are forward, X-direction decomposition of the moment fall to the right, when the omnidirectional mobile robot moves to the right front. In Figure 2 (d), the right front wheel and the right rear wheel of the omnidirectional mobile robot have no input torque, whereas the left front and left

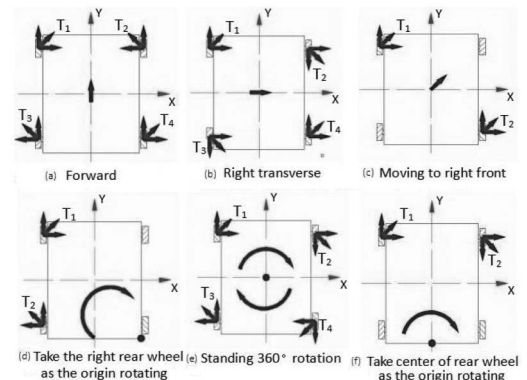

Figure 2. Graph of the analysis of the force applied to Mecanum wheel of the omnidirectional mobile robot.

rear wheel have torques T_1 and T_2 , respectively. The left front wheel is subjected to the right front direction of the torque, the left rear wheel is left forward to the torque, when the omnidirectional mobile robot to the right rear wheel as the origin of rotation. In Figure 2 (e), the four wheels of an omnidirectional mobile robot are subject to torque. When the left front wheel torque is toward the right direction, the right front wheel toward right to the left rear wheel torque, torque is to the left front, right rear wheel is left to the torque, the clockwise rotation of an omnidirectional mobile robot. In Figure 2 (f), the left rear wheel and right rear wheel of the omnidirectional mobile robot have no input torque, and the left front wheel and the right front wheel have torques T_1 and T_2 , respectively. When the left front wheel is subjected to the right front direction, the right front wheel is subjected to the right rear torque.

4 DESIGN OF FOUR-WHEEL DRIVE

Four-wheel drive (Xin, 2015), also called all wheel drive, refers to the front wheel and the rear wheel have driving force, and the engine output torque is distributed in all the wheels according to the different road conditions. Its main function is to effectively control the vehicle's lateral movement characteristics and improve the ability of the vehicle. Four-wheel drive relies on the four-wheel independent steering. All wheels can be turned around the same instantaneous center of rotation to achieve different steering radius and even zero turning radius so that it has a high degree of flexibility in the steering wheel. The narrow working space brings great challenge to the mobile robot. Therefore, the control system of the omnidirectional mobile robot adopted the four-wheel drive. The four-wheel drive system is mainly composed of a motor and its driver, driving power supply, and deceleration device. Among them, the servo motor is controlled by pulse and direction.

5 STRUCTURE OF DSPACE SYSTEM

DSPACE real-time simulation system was developed by German dSPACE company. It is a software and hardware platform for control system development, testing and hardware in-the-loop simulation based on MATLAB/Simulink. Its greatest feature achieved completely seamless connection with MATLAB/Simulink (Zhang, 2012). DSPACE real-time system mainly consists of two parts: software system and hardware system.

V-Cycle development process is a parallel development model, whose process is shown in Figure 3.

It is the software and hardware development for joint debugging. Automatically generated from the C Simulink code and downloaded to the controller (such as MicroAutoBox). The virtual instrument NG ControlDesk debugging is used to accelerate the design of the iteration loop process and greatly decelerate the control design process (Liu, 2014). In addition, the simulation can be carried out online or offline.

5.1 dSPACE software structures

The software system of dSPACE mainly consists of three parts. First, according to the needs, we can use MATLAB/Simulink to quickly and easily establish the simulation model. For the preparation of C and other procedures, the building block diagram is simple and easy to understand and accelerate the process of system development. Second, RTI (Real-Time Interface) is a bridge connecting the dSPACE real-time system and MATLAB/Simulink simulation (SHAO, 2012). According to the requirement of user selection model and the MATLAB/Simulink library RTI library to build the control model, we compile and generate C code and download the program to the controller. Finally, the ControlDesk interface provides users with a variety of parameters of the window, which can change the parameters of the controller in real time.

5.2 dSPACE hardware structure

DSPACE hardware provides a variety of components and a single-board system. DS1401/1512/1513 single-board system has two modules: 1512 modules and 1513 modules with 156 pins. Therefore, the function is very powerful. However, the 1512 module is much more complex than the 1513 module. Because it has two IP modules more than

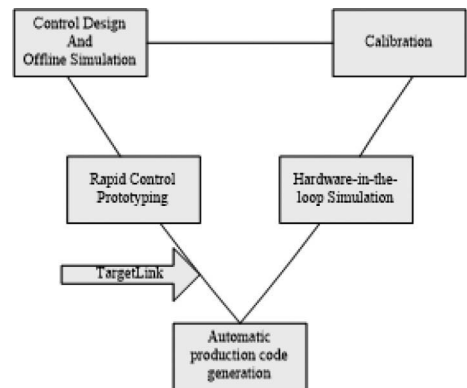

Figure 3. Flowchart of dSPACE V-cycle.

1513 modules, it is more complex to use. According to the motion control system design of mobile robot, the relative difficulty is not high, and considering the cost and other factors, the choice of 1513 can meet the design requirements. 1513 module I/O port resources are rich, including digital output, digital input, analog input, and analog output.

5.3 Establishment of the simulation platform of control system based on dSPACE

The motion control system of omnidirectional mobile robot adopted PWM pulse modulation (XU, 2012). Combined the MATLAB and the RTI module libraries provided by PC, we selected the 4 TP4 PWM DIO module. In the dSPACE real-time interface, we established the simulation model as shown in Figure 4. The model can output 4 PWM pulse signal. The signal output port are CH1, CH2, CH3, and CH4. The four-pulse signals can carry on the duty cycle and the start and stop of control system in real time. The PWM debugging of the servo motor is to change the pulse frequency and direction of the servo motor. The PWM module of the four corresponding output ports of CH1, CH2, CH3, and CH4 connected with the input port PUL1, PUL2, PUL3, and PUL4 of the four servo motor drives. The specific operation is to set the duty cycle T1, T2, T3, and T4 and the period cycle a, b, c, and d of the four PWM modules. Changing the cycle is to change the pulse frequency. Then, the corresponding four motors m1, m2, m3, and m4 will get the corresponding speeds n1, n2, n3, and n4. The omnidirectional mobile robot can achieve forward, right traverse, standing 360° rotation so as to realize the mobile control ability of the omnidirectional mobile robot.

After the model is built in MATLAB/Simulink, a key to compile and generate C code and save in the Sdf file is proposed. The project is set up and saved in ControlDesk. The hardware circuit and communication equipment are connected through the registration of the hardware platform to download the program to the Micro-AutoBoxII controller. In the ControlDesk interface, we establish a virtual instrument and the relevant parameters of the changes. As long as the program is downloaded to the controller, it also carried out off-line operation. In the ControlDesk interface, according to the variables in the column of relevant variables, such as Gain, Wave Sine, Sum, and constant, to establish the required virtual instruments, such as Plotter, Knob, and Bar, for the entire control system debugging. One of the great advantages of dSPACE is that the real time is very strong. We can change the program at the same time observe the running state of the actuator.

Figure 4. Model of PWM debugging and simulation.

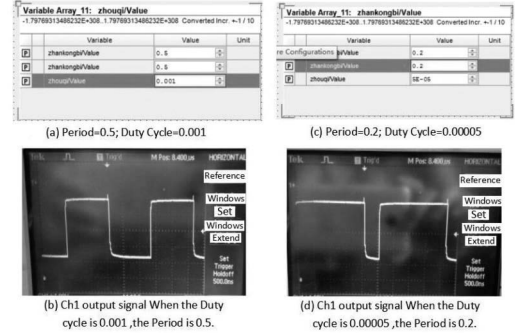

Figure 5. PWM CH1 output pulse waveform.

In the motor PWM debugging, we establish an array of variables table. By changing the value of the array variable duty cycle and the cycle of two and so on simultaneously, the corresponding motor speed, the oscilloscope to detect the pulse signal waveform cycle, and pulse width are changed. Figure 5 shows the PWM port CH1 to the array of variable cycle and duty cycle to change and the corresponding pulse waveform changes. In Figure (a), the set period is 0.001 and duty cycle is 0.5. Figure (b) shows an oscilloscope to detect the corresponding output waveform. In Figure (c), the set period is 0.00005 and the duty cycle is 0.2. Figure (d) is an oscilloscope to detect the corresponding output waveform.

6 CONCLUSIONS

The motion control system of mobile robot is designed on the basis of dSPACE real-time simulation platform. The motion control model was built by using the RTI and MATLAB module library. A key to generate C code through the host computer will be downloaded to the controller. We use the ControlDesk user interface of the host computer to set the parameters. By rapid construction of motion control system simulation platform, mobile robot can realize the omnidirectional mobile and shorten the development period of the control

system. DSPACE simulation platform is effective for the development of control system and the pre-experiment verification.

ABSTRACT: The optimization design of oil circuits in a Hydraulic Manifold Block (HMB) is a typical Multiobjective Optimization Problem (MOP), and typical optimization objectives include the number of cross-drills, the depth of working holes and cross-drills, and the length of oil circuits. MOP for HMB design is usually converted to a Single-objective Optimization Problem (SOP) by weighting method; however, the validity is not guaranteed. In this paper, maze algorithm—NSGA-II optimization method (MA-NSGA-II) is presented as improve NSGA-II. In this approach, a coordinate bunch format is proposed to encode the oil circuit parameters and the oil circuit connection; then, the maze algorithm is used to generate the initial population; further new operators of crossover and mutation are introduced and applied to adapt classical NSGA-II to suit the proposed encoding format. On the basis of this approach, an optimization design system for HMB is developed by using SolidWorks Application Programming Interface (API), VB.NET, and Microsoft Access. The system effectively realizes the automatic generation and optimization of oil circuits. A case study is conducted to verify the validity of the approach and the system.

1 INTRODUCTION

HMB is one of the key components in integrated hydraulic systems. However, the manual design of HMB is a complex and time-consuming process; and hence, it is highly desirable to generate oil circuits automatically. There are two types of holes in an HMB: working holes and cross-drills. Working holes are holes connected with hydraulic component ports while cross-drills are auxiliary holes. While designing an HMB, we have to consider the layout of hydraulic components, the connectivity of ports, and many other design constraints. For ports that cannot be connected directly, cross-drills are necessary.

In recent years, much research has been carried out to solve spatial pipe routing design and oil circuit design for HMB, for example, the design of pipeline layouts of aeroengines or ships. For the problem of pipe routing and oil circuit, a system utilizing AI and CAD techniques was described by Chambon (1991) to solve combined 3D component-placing and routing-design problems of HMB. Wong (1997) proposed an object-oriented

approach to represent the behavior and the design knowledge of hydraulic circuit and component and presented a 3D circuit connection algorithm of HMB. A method was proposed by Feldmann (2006) for the generation and manipulation of bore chains of HMB, in which BOHRZUG objects are created between ports to be connected. When a new point is included in the chain, an existing bore is replaced by two new ones. Using the pattern match method, Park (2002) presented an automatic pipe-routing algorithm. For the problem of optimal design, Ito (1999) presented a genetic algorithm approach to support interactive planning of a piping route circuit. Fan (2007) presented a variable-length encoding format and corresponding genetic operators to ensure the association of genes chromosome. Guirardello (2005) presented an optimization approach for the design of a chemical plant geometric layout, and the task is decomposed into a sequence of subproblems, which are then solved by using Mixed Integer Linear Programming models (MILP). Ferreira (2010) presented a framework using a multidisciplinary design optimization methodology, which tackles the design of

an injection mold. Liu (2008) studied the optimal method of oil circuit using genetic algorithm and simulated annealing algorithm. Although an MOP is converted to an SOP by using objective weight method above, the diversity of solutions cannot be reflected by the obtained results. Appropriate weights factors, which the objective weight method heavily relies on, are difficult to choose; meanwhile it is also time-consuming and inefficient to obtain an optimal solution. Hence, it is essential to investigate the application of multiobjective optimization methods, for example, NSGA-II proposed by Deb (2002), for HMB oil circuit.

On the contrary, the maze algorithm has been successfully applied to HMB design, but only little attention has been paid to enhance it with optimization methods. Lee (1961) proposed the maze algorithm to search the circuit of two points in a plane. Maze algorithm in HMB design is used by P.K. Wong (1997) to realize the oil circuit connection, but the strong connectivity of the algorithm leads to too many cross-drills.

In this paper, a novel approach termed as MA-NSGA-II is proposed by combining the maze algorithm and NSGA-II. The remainder of this paper is organized as follows. Section 2 introduces a multiobjective optimization model of HMB, explaining the design variables, objective functions, and design constraints. Section 3 presents the approach of MA-NSGA-II, and some new operators for genetic algorithm. Section 4 presents the implementation and case study of the approach. Finally, in Section 5, conclusion is drawn and future work is defined.

2 MULTI-OBJECTIVE OPTIMIZED MODEL OF HMB

The oil circuit is utilized to realize the connective relation between ports of hydraulic components in HMB, and the relation is specified in the hydraulic scheme diagram. An oil circuit is composed of various oil holes. Because of the diversity of hydraulic components and oil circuit structure, the oil hole types and features are complex, and the related concepts are shown in Table 1.

Figure 1 shows an exemplary oil circuit connecting two hydraulic components, c_1 and c_2 , and there are two working holes, h_1 and h_3 , and one cross-drill, h_2 , in which h_1 is a bottom hole and h_3 is a bottom center hole. The coordinate system of HMB is also shown in Figure 1.

An HMB is designed on the basis of its hydraulic scheme diagram. The design of HMB is to layout hydraulic components and to connect oil circuits, subject to some design objectives and design constraints. Parameters of hydraulic components,

Table 1. Oil hole types and features.

Oil hole type	Oil hole feature
Bottom hole	Connected with port of the plate valve
Bottom center hole	Connected with bottom center port of cartridge valve
Side hole	Connected with side port of cartridge valve
Cross-drill	Not connected with hydraulic components, but connected with holes that cannot be connected directly

Figure 1. Coordinate system of HMB and flowpath model.

ports, and oil holes are involved in the design progress.

2.1 Design variables

To simplify the expression, the following matrices are used to represent related design variables.

2.1.1 Hydraulic components parameters matrix C

The basic information of hydraulic components is included in matrix C , and the i th row represents the parameters of the i th component, which is noted as $[c_i c_{vx_i} c_{vy_i} c_{vz_i} c_{x_i} c_{y_i} c_{z_i} c_{o_i}]$, where c_i is the ID of the hydraulic component HC_i , $c_{vx_i} / c_{vy_i} / c_{vz_i}$ is its installation surface vector, and the vectors of the surfaces of up, down, front, back, left, and right are listed in Figure 1, where $c_{x_i} / c_{y_i} / c_{z_i}$ is the benchmark point coordinate and c_{o_i} is the installation angle. If there are m hydraulic components, then the dimension of C is $m \times 8$.

2.1.2 Port parameters

The interface information of hydraulic components and oil circuits is described in matrix P , and the i th row $[p_i p_{x_i} p_{y_i} p_{z_i} p_{d_i} p_{s_i} c_j f_k]$ represents the parameters of the i th port, where p_i is the ID of port $port_i$, $p_{x_i} / p_{y_i} / p_{z_i}$ is its associate point coordinate, p_{d_i} is its diameter, p_{s_i} is its structure type, and

f_k is the ID of the owned oil circuit. If there are s ports, then the dimension of P is $s \times 8$.

2.1.3 Oil hole parameters matrix H

The information of all the holes is described in matrix H , where the i th row $[h_i, h_{x_i}, h_{y_i}, h_{z_i}, h_{vx_i}, h_{vy_i}, h_{vz_i}, h_{d_i}, h_{s_i}, h_{f_i}]$ represents the parameters of the i th working hole or cross-drill, where h_i is the ID of oil hole OH_i , $h_{x_i}/h_{y_i}/h_{z_i}$ is its starting point coordinate, $h_{vx_i}/h_{vy_i}/h_{vz_i}$ is its starting point vector, h_{d_i} is the hole diameter, h_{s_i} is the hole depth, h_{f_i} is the hole structure type (0/1/2/3: cross-drill/bottom hole/bottom center hole/side hole), and f_i is the ID of the oil circuit, to which the hole belongs. If there are p working holes and q cross-drills, then the dimension of H is $n \times 11$, where $n = p + q$.

2.2 Objective function

2.2.1 Shortest oil circuit length

There are three objective functions as shown in Equations (1)–(3) with respect to single oil circuit length, the length sum of all oil circuits, and the length of the longest hole, respectively:

$$\min L_{p_i}(C, P, H) = \sum_{j=1}^{M_i} h_{l_j} \quad i = 1, 2, \dots, S \quad (1)$$

$$\min L_p(C, P, H) = \sum_{i=1}^S L_{p_i} \quad (2)$$

$$\min \left(\max \left(h_{l_1}, h_{l_2}, \dots, h_{l_{M_1}}, \dots, h_{l_1}, h_{l_2}, \dots, h_{l_{M_S}} \right) \right) = L_{\min(\max)} \quad (3)$$

where L_{p_i} is the length of oil circuit p_i , h_{l_j} is the depth of oil hole l_j of the oil circuit, M_i is the number of oil holes of p_i , L_p is the length sum of all oil circuits, and S is the number of oil circuits.

2.2.2 Minimize the number of cross-drills

There are three objective functions as shown in Equations (4)–(6) with respect to cross-drills number of single oil circuit, the sum of all cross-drills, and the most cross-drills number of one oil circuit, respectively.

$$\min N_{p_i}(C, P, H) \quad i = 1, 2, \dots, S \quad (4)$$

$$\min N_p(C, P, H) = \sum_{i=1}^S N_{p_i} \quad (5)$$

$$\min \left(\max \left(N_{p_1}, N_{p_2}, \dots, N_{p_S} \right) \right) = N_{\min(\max)} \quad (6)$$

where N_{p_i} is the number of cross-drills in the oil circuit p_i and N_p is the number of cross-drills in all oil circuits.

2.3 Constraints

The oil holes and cross-drills must meet the following constraints:

1. The flow cross-sectional area (A_i) of holes intersection parts must be larger than the minimum flow cross-sectional area (A_{\min}), that is, $A_i \geq A_{\min}$.
2. The wall thickness of nonconnected flowpaths must be higher than the security wall thickness (W_{\min}), that is, $W_{ij} \geq W_{\min}$ and $W_{if} \geq W_{\min}$, where W_{ij} is the wall thickness between holes and W_{if} is the wall thickness between hole and surface of HMB.
3. A single oil hole can be processed within the depth scope, that is, $D_i/L_i \geq C_k$, where D_i is the hole diameter, L_i is the hole depth, and C_k is the hole machining depth index.

3 DESCRIPTION OF THE PROPOSED APPROACH (MA-NSGA-II)

NSGA-II is a fast algorithm to obtain a Pareto optimal solution set consisted of non-nominated solutions. NSGA-II uses a non-nominated sort algorithm to obtain Pareto front solutions. Moreover, a crowding distance is defined to preserve the diversity of solutions. The individuals are sorted according to the priority order defined by Equation (7):

$$i \prec_n j, \text{ if } (i_{rank} < j_{rank}) \vee (i_{rank} = j_{rank}) \wedge (i_{distance} > j_{distance}) \quad (7)$$

where \prec_n is the crowding comparison operator, $rank$ is the rank of non-nominated sort, and $distance$ is crowding distance.

NSGA-II has been widely applied in various fields because of its high efficiency and robustness. However, it has not been applied for the design of HMB because the encoding formats and operators in NSGA-II are not suitable for the complex oil circuit structure of HMB. Here, a coordinate bunch encoding format is proposed on the basis of grid concepts, and the maze algorithm is used to realize the oil circuit connection and to generate initial population. Furthermore, new crossover and mutation operators, which are suitable for the encoding format, are introduced. The flowchart of the approach is shown in Figure 2. Major concepts and steps of the flowchart are explained in the followed subsections.

3.1 Encoding method and initial population

When the maze algorithm is used to generate circuit and initial population, the quality of starting solutions can be improved.

3.1.1 Grids division and obstacles set

The layout space of HMB is divided into three-dimensional grids with a dimension of $M \times N \times L$, and each grid has a coordinate (x, y, z) based on the row, column, and floor in the space. The outer surface of the HMB, except places where ports lies, are denoted as obstacles, and the grids on existing oil circuit are denoted as obstacles, and their values are set to "#". All other grid's values are set to 0.

3.1.2 Circuit encoding

The encoding of circuit is described by using a chain table composed of linked nodes, such as [5 1 3;5 2 3;5 3 3;6 3 3;7 3 3;8 3 3;9 3 3;9 4 3;9 5 3;9 6 3;9 6 4;9 6 5;9 6 6;9 6 7;9 6 8;10 6 8], and a circuit also represents an individual of NSGA-II. In the chain table, the first and last coordinates represent

ports. A circuit is a 3D polyline composed of a number of line segments from the start position to end position. In any two adjacent grids, the latter one must be an adjacent grid of the former one in six directions to ensure that the path is straight or orthogonal but not diagonal.

3.1.3 Circuit connection and population initialization

In the expansion process from one grid to the adjacent grid, a limit direction search strategy and the following rules are used: the node is specified by its tag value and direction, the value of the six neighbors of one grid is its value plus 1, and if one of the adjacent grid is the target port, then the extension stops.

By retracing from the target port to the source port, some circuits can be generated randomly, and these circuits are the initial population of NSGA-II.

3.2 Adapted NSGA-II

The existing encoding methods and genetic operators of NSGA-II are not suitable for the circuit encoding the format described above. Therefore, the crossover operator and mutation operator are redesigned as explained here.

3.2.1 Crossover operator

Crossover is the main way to generate new individuals in NSGA-II. The chromosomes generated after crossover or mutation must ensure the connective relationship of nodes to prevent producing illegal individuals. Here, a random point-cross strategy is described.

In a random point crossover, two different nodes are selected from two individuals of the parent generation, and then a sub-circuit is generated to connect the two nodes. The subcircuit will be inserted into the two individuals of the parent generation with correctness or reverse, and the latter parts of crossover node are exchanged to generate two new individuals in the children's generation. Figure 3 shows an example of random point crossover. The path starts from point (5,1,3) and ends

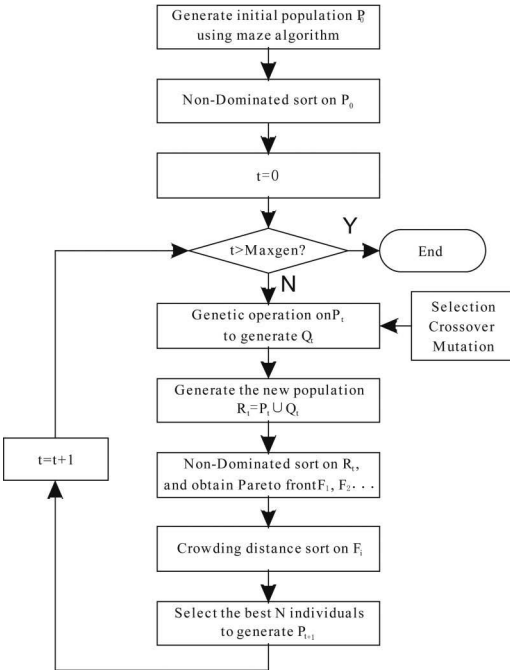

Figure 2. Flowchart of MA-NSGA-II.

Figure 3. Random point crossover.

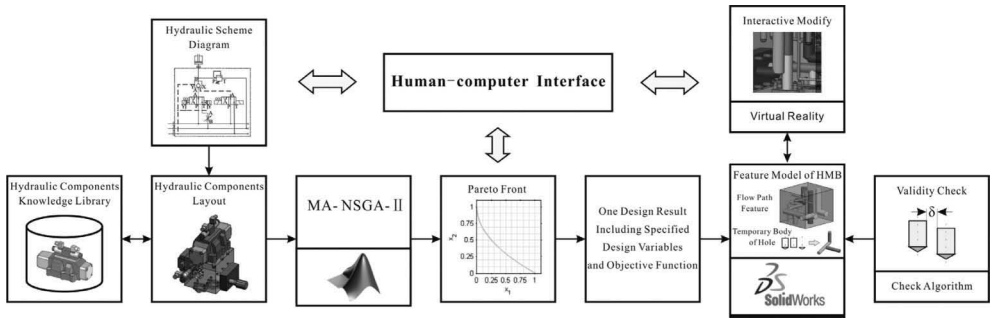

Figure 4. Flowchart of optimal design system for HMB.

at point (10,6,8), and the random crossover points are (6,1,5) and (9,5,5).

3.2.2 Mutation operator

Mutation can maintain the diversity of population to prevent premature convergence. The mutation method is to delete one part of the chromosomes randomly and then add another part, which is a subcircuit. This heuristic mutation operation increases the chances to reduce turnings or bend around obstacles.

4 IMPLEMENTATION AND CASE STUDY

An optimal design system for HMB has been developed, and Figure 4 shows the flowchart. The basic design information is obtained from the hydraulic scheme diagram and knowledge library of hydraulic components. After the initial layout of hydraulic components by human-computer cooperation, the design parameters of hydraulic components and ports can be obtained. Then, the MA-NSGA-II approach will be operated to generate and optimize circuits by using MATLAB. The calculation result is a Pareto front set composed of population size solutions. The detailed results are the objective function valves, rank of non-nominated sort, and crowding distance of every solution. The optimal parameters of design variables will drive the system to generate 3D solid model of HMB with validity check in SolidWorks circumstance. The design results can be interactively modified until it is satisfying.

In the feature-modeling progress, the oil circuit feature is described by using temporary body model and B-Rep model. The temporary body model is created by solid modeling technology and used for representing feature semantics and showing the flowpath. The B-Rep model is used for saving the final results.

Figure 5 illustrates a hydraulic scheme diagram including nine hydraulic components and seven

Figure 5. Schematic diagram of one hydraulic system.

oil circuits. The hydraulic components, oil circuits, and connective relations of ports are listed in Table 2. These hydraulic components are the products of Bosch Rexroth company. The dimensions of HMB are determined according to the maximum edge length of hydraulic components, and the hydraulic components must have enough room for adjustment. In this case, the length, width, and height are 230, 212, and 250 mm, respectively, and the grids are divided into $23 \times 21 \times 25$.

In practical applications, the performances of MA-NSGA-II are dependent on some parameters of algorithms, but how to select these optimal parameters is not completely solved yet. In this paper, practical design experience of HMB and the orthogonal experiment method are combined to explore the optimal parameters. The running parameters are as follows: population size is 20, generation is 200, crossover probability is 0.8, mutation probability is 0.05, crossover distribution index is 20, and mutation distribution index is 20. In the optimization and validity check process, the constraints are as follows: the least-flow cross-sectional area (A_{\min}) is 28 mm^2 , the least security

wall thickness (W_{min}) is 5 mm, and the oil hole machining depth index (C_k) is 0.045.

The Pareto set is constructed where each design has the best combination of objective values, so that improving one objective is impossible without sacrificing one or more of the other objectives. After the calculation, the system obtains 20 non-nominated sorted optimal solutions. An optimal design solution whose rank is 1 can be seen in Tables 3 and 4, where the values in Table 3 are the optimized design variables valves, and Table 4 shows the objective function values.

Figure 6. Optimal design plan model.

The choice of final HMB design should be made from the set of Pareto optimal designs, which may not be explicitly represented in the model by using additional customer preferences and criteria.

Figure 6 shows the optimal design plan model, and Table 3 lists its structure parameters. The layout of hydraulic components is compact and reasonable, the oil circuits can be connected with less cross-drills, and the flow cross-sectional area, wall thickness, and oil hole depth are all in the range of constrains. The results show the feasibility and validity of the approach and system.

5 CONCLUSIONS

In this paper, we presented a novel hybrid algorithm, MA-NSGA-II, aiming at the multiobjective design optimization of the oil circuits in HMB. This approach proposes a coordinate bunch encoding format for the oil circuit design of HMB. On the basis of the encoding format, the maze algorithm is proposed to set up the oil circuit connection and generate initial population, and new crossover and mutation operators are proposed to adapt NSGA-II to the encoding format. An HMB

optimization design system is developed by using SolidWorks API and VB.NET, which can effectively realize the automatic generation and optimization of oil circuits of HMB.

To develop a more realistic model for HMB in future, it will be necessary to refine the optimization model by including all important variables. It is also important to integrate MATLAB with SolidWorks to generate some high-quality models, as well as CAD tools to visualize that the design solutions are also fundamental in a fully integrated HMB optimization system.

ABSTRACT: In this paper, we present the computation of single-event transients for calculating the charge collection in dual-well structure. A well gradient collapse drain injection for SRAM cell is demonstrated through TCAD modeling. Simulation presents that the deposited charge will induce parasitic bipolar amplification to broaden the transient widths for PMOS device under the effects of N-well region. The efficiency of charge collection is correlated to the distribution of SET pulse widths. Aiming at improving the reliability of devices, well potential contacts are expected to be established.

1 INTRODUCTION

Critical charge to represent a logic state in Integrated Circuits (ICs) is steadily decreasing with the shrinking device technology feature sizes. Single-Event Effects (SEEs) induced by heavy-ion irradiation has become a primary reliability issue for deep submicron processes because of the reduced nodal charge and space between devices (P.E. Dodd, 2010 & D. Munteanu, 2008). Traditionally, the close proximity of transistors means that the deposited charge cloud from an ion strike is expected to encompass multiple transistors on ICs, resulting in multiple-node charge collection (termed charge sharing) in devices (O.A. Amusan, 2006). Thus, it is imperative to characterize the single-event transient response to different design and layout practices. Dual-well bulk CMOS technology has been the subject of extensive studies on improving the reliability of manufacturing space and military electronic devices. The effects of dual-well structure were mainly analyzed and results showed that Single-Event Transients (SETs) using the dual-well technology were shorter than those in the triple-well technology (T. Roy, 2008). Perturbations in n-well and p-well potentials also have been shown to affect strongly the

charge collection, charge sharing, and parasitic bipolar transistor characteristics (N.J. Gaspard, 2011 & O.A. Amusan, 2006). A comparative analysis of heavy ion-induced upsets in dual-well bulk SRAMs shows that dual-well process is vulnerable to low-LET particles, whereas triple-well technology is more vulnerable to high-LET particles (I. Chatterjee, 2011). Despite these previous studies, response reported for dual-well and triple-well processes have been proposed to mitigate SEEs, single-event transients caused by heavy ions with high Linear Energy Transfer (LET) values are still inevitable to affect the stability and performance of the devices, resulting from the fact that much remains to be understood about the complex physics of carrier transport and enhancement in devices fabricated with well structures. Therefore, full three-dimensional physical models are conducive to the incorporation of device analyses into the behavioral abstractions of carrier motions and potential field perturbations in the wells.

This paper describes primarily the physical insights for accurately modeling single-event transient currents and charge collection using full three-dimensional Technology Computer-Aided Design (TCAD) simulations and explores the spatial extent and temporal characteristics of SEEs,

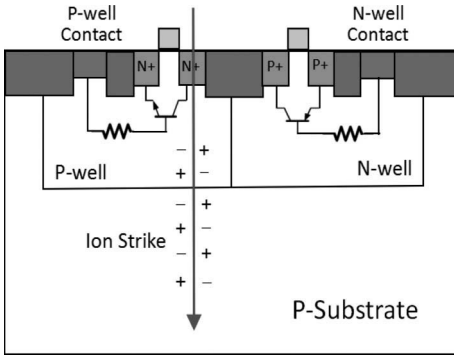

Figure 1. Schematic cross section view of NMOS and PMOS implemented with dual-well technology, showing parasitic elements.

which are affected by dual-well structure. First, the schematic cross view of dual-well CMOS technology is illustrated in Figure 1. A particle strikes a sensitive region of a circuit module and deposits a dense track of electron-hole pairs, where the deposited charges will cause a potential gradient in the bulk from the strike location to the substrate, which could possibly activate the parasitic bipolar transistor of MOSFETs in the P-well and N-well, as well as affects the potential modulation process of multiple junctions.

2 TEST STRUCTURE AND EXPERIMENTAL SETUP

The modeling and simulation of the charge generation, transport, and collection processes are crucial issues in the computation subjected to ionizing radiation. In this work, Sentaurus H-2013 TCAD from Synopsys Corporation was adopted to perform structures and device simulations. For the dual-well structure, the typical 6-T SRAM cell as the storage unit was carried out by using 65 nm bulk CMOS technology. Figure 2 describes the conceptual schematic of a typical 6-Transistors SRAM cell. Two cross-coupled inverter modules, inverter #1 and inverter #2, are connect with each other and additional two access pass-gate transistors, and the output nodes VT1 and VT2 store opposite values. In the circuit, supply voltage is set to be 1.2 V.

For three-dimensional SRAM model calibration, the dual-well model was preliminarily referenced to the layout of target SRAM device cell with detailed designs, as illustrated in Figure 3. The ratio of width to length (W/L) in the NMOS is $W_n/L_n = 0.30/0.06 \mu\text{m}$, whereas the W/L of the PMOS is $W_p/L_p = 0.45/0.06 \mu\text{m}$, and they were generated with a 65 nm standard cell library in accordance with the Semiconductor Manufacturing International

Figure 2. Conceptual schematic of a typical 6-T SRAM cell formed by two cross-coupled CMOS inverters. The blue dashed outline shows inverter #1, and the light red region represents inverter #2.

Figure 3. Layout of the target SRAM cell calibrated with 65 nm process design kit.

Corporation (SMIC) layout design rules. The I-V electrical characteristics (I_d-V_d and I_d-V_g curves) of NMOS and PMOS transistors, which are built into the dual-well CMOS structure, have obtained good agreements with the HSPICE models. Thus, the junction capacitance between drain/source and bulk agrees with reality.

As shown in Figure 4, a full 3-D SRAM cell structure is implemented on dual-well CMOS technology, N-channel transistors are placed in the P-type substrate, and all the P-channel transistors (TP1 and TP2) are generated in the implanted N-well inside the P-type substrate. An N-well contact band is placed near the two transistors with a distance of $0.3 \mu\text{m}$, the source and drain junctions of NMOS is 25 nm, and Light Doped Drain-source (LDD) are inserted between the channel and the source/drain, respectively. The thickness of the gate oxides are generated according to the spice model so that the gate capacitance agrees with actual process. Furthermore, the Shallow Trench Isolations (STI) are used to separate transistors for maintaining good electrical characteristics.

In the following 3-D TCAD simulations, the special-purpose supercomputer facilities are used

Figure 4. Full 3-D SRAM model implemented on 65 nm CMOS process.

to shorten the work of extended numerical calculations at the MPIT laboratory in Shenzhen. Taking design parameters into account, Finite-Element Method (FEM) numerical simulations are performed to solve the Poisson and drift-diffusion current continuity equations, and the following physical models are incorporated during the whole simulations: 1) Fermi-dirac statistics; 2) bandgap narrowing effects; 3) doping-dependent Shockley-Read-Hall (SRH) recombination and Auger recombination; 4) mobility models, electric field, interface scattering effects, and carrier-carrier scattering impact on mobility; 5) density gradient quantization model; 6) a hydrodynamic model is used for carrier transport; and 7) heavy ions are modeled using a Gaussian distribution profile with a characteristic $1/e$ radius of 50 nm, and a Gaussian temporal profile with a 2 ps characteristic time.

To investigate the process of charge collection, heavy ions were used to strike the TCAD models, considering that the particle struck the drain region of TN2 transistor in inverter #2. Broad-beam heavy-ion experiments were performed with Linear Energy Transfers (LETs) ranging from 10 to 50 MeV-cm²/mg, and the LET suppression method was set as a stable step-up 10 MeV-cm²/mg iteration. Normally, the LET values were kept constant along the heavy-ion track, and every ion irradiation was performed at an angle of 90°; thus, the angular effects were ignored.

3 MATHEMATICAL FORMULATION

The physical mechanisms related to the production SETs in microelectronic devices consist in three

main successive steps: (1) the charge deposition by the energetic particle striking the sensitive region, (2) the transport of the released charge into the device, and (3) the charge collection in the sensitive region of the device. The mathematical formulations that affect the charge collection of SET in dual-well structure are explained in this section. When a heavy ion penetrated the SRAM cell, it loses energy and creates a trail of electron-hole pairs; the ion-striking deposited charge was collected by the drain and the transient currents are generated to turn on the output logic state of inverter #2. The device is assumed to consist of a collection of reverse-biased depletion regions and electrodes, and the device simulation considers the popular drift-diffusion transport equation by considering the methods of moments, and the electron (J_n) and hole (J_p) current densities are expressed as follows:

$$J_n = qn\mu_n E + qD_n \text{grad}(n)$$

$$J_p = qn\mu_p E - qD_p \text{grad}(p) \quad (2)$$

where (1) and (2), n and p are the electron and hole densities, μ_n and μ_p are the electron and hole mobility, respectively, and E is the built-in electric field. The first term corresponds to the drift component, which is driven by the electric field and the second term to the diffusion component caused by the gradient of carrier concentrations. D_n and D_p are the diffusion coefficients corresponding to the carrier mobility via the Einstein equation (A. Grove, 1967):

$$D_{n,p} = \frac{k_B T}{q} \mu_{n,p} \quad (3)$$

where k_B is the Boltzman constant and T is the carrier temperature equal to the lattice temperature as the carrier gas in the drift-diffusion approximation is assumed to be in thermal equilibrium. In the formulations, finite-element numerical simulations are performed to solve the Poisson and drift-diffusion current continuity equations. The transients due to particles striking the dual-well are computed by a double current pulse as follows:

$$I_d = \frac{Q}{\tau_\alpha - \tau_\beta} (e^{-t/\tau_\alpha} - e^{-t/\tau_\beta}) \quad (4)$$

where I_d is the drain total current, whose unit is A, Q is the collected charge due to the LET values, τ_α and τ_β are the falling time and rising time constants of the current pulses to determine the amplitudes and widths respectively, and τ_α and τ_β can be defined as:

$$\tau_{\alpha} = \frac{4ds^2}{\pi^2 D_{n,p}} \quad \tau_{\beta} = \frac{4ds^2}{9\pi^2 D_{n,p}} \quad (5)$$

4 RESULTS AND DISCUSSIONS

When a charge column has been created in the dual-well SRAM structure by an ionizing particle, the physical phenomena in drift-diffusion, hydrodynamic, and thermodynamic transport models are considered for characterizing the charges transported. Figure 5 shows the current pulses of the drain electrode of TN2 transistor, the amplitudes of parasitic transient currents have been decreased by varying time and sensitive duration to charge collection for maintaining the electrostatic potential gradients. The transients indicated that the drain total currents consist of a fast drift and a slower contribution from charge diffusion in the shallow P-well and N-well. This causes the electrons to drift into the n-well, leaving the holes behind in the p-well. When the P-well and its contact are held constant, NMOS TN2 transistor single-event transient currents are governed by the depressed drain contact voltage. After a short duration, current peaks corresponding to the channel conduction supported of drain voltage as well as most of deposited charges flow out of the struck transistor absorbed in P-substrate. Thus, the drain voltage recovers to its original value, and these current pulses decrease toward zero.

For quantifying the charge collection effects on dual-well SET performances, the cross-sectional view and simplified equivalent circuit models for TN2 and TP2 devices fabricated in the 6-T SRAM cell have been characterized as presented in Figure 6. These small signal models account for the series impedance (Z_{in}) between the source

Figure 5. Current pulses of the drain electrode of TN2 transistor in dual-well structure.

(S_n, S_p) and drain (D_n, D_p) nodes of TN2 and TP2. The dual-well impedances (Z_{DW}) for TN2 and TP2 consist of back to back diodes for each transistor, which take into account the series impedance R3 in TN2 of the transition region between P-well and P-substrate. The channel impedance (R_{ch}) varies according to gate voltage biases (G_n and G_p). When a negative V_{Pwell} and a positive V_{Nwell} are applied to the shallow-well regions, and a negative voltage (V_{sub}) is applied to the P-substrate contact, the diode D2, D2', D4, and D4' junctions are reverse-biased, and only the electric yields of P-well to light P-doping region follow asymmetry conduction. SRAM soft-error rates depend on the critical charge of the circuit and the amount of charge collected by sensitive circuit nodes.

Because of the complex interaction between the heavy-ion charge track and the collection areas as well regions and resulting funnels, nearly simultaneous multiple nodes at the output voltage VT2 charge collection influenced by the SEE charge sharing effect were observed, as illustrated in Figure 7. Results present that the transient voltages are substantial steady with time, and after approximately 0.6 ns, both amplitude and width start to change the logic state. At the moment, PMOS devices are affected by the parasitic bipolar amplification effects, where the deposited charges are relative to the sensitive node and the resultant final collected charge. With the LETs increasing, a large amount of electronic charge within the well lead to the P-well and shallow N-well potential collapse, which results in parasitic bipolar conduction and the wider transients. Simulations verification of the effect of P-well contact together with the shallow N-well in reducing the charge collection lead

Figure 7. Transient voltages of VT2 node induced by the heavy-ion transient current duration.

Figure 8. Charge collection with varying LETs for NMOS and PMOS devices. The significant increase of the charge collected with increasing LETs for PMOS device due to the parasitic bipolar amplification.

to the lower transient amplitudes than those of the TN2 transistor. Figure 8 shows the charge collection of NMOS and PMOS devices with varying LETs in the bulk CMOS technology, and PMOS transistors have significant increase of the charge collected with increasing LETs than NMOS transistors due to the parasitic bipolar amplification effects in the N-well region.

5 CONCLUSIONS

In this paper, the characterization of SET pulses among SRAM logic nodes was performed in 65 nm dual-well CMOS technology. Furthermore, we expatiated the pulse widths and amplitudes of NMOS and PMOS devices, simulation dates indicate that charge collection in N-well will activate the parasitic bipolar amplification for PMOS, and well contacts help maintain the well potential collapse, thereby reducing the charge collection and SET pulse width. This paper further provides referential analytical mechanisms for SETs fabricated in dual-well CMOS devices for ensuring good electrical reliability.

Research on missing value processing methods based on advanced community detection

Fuqiang Zhao, Guijun Yang & Xue Xu

Tianjin University of Finance and Economics, Tianjin, China

ABSTRACT: In complex network graph, connectivity of graph depends on the second smallest eigenvalue of the Laplacian matrix. Correlation coefficients are introduced to this cut model to resolve overlapping community detection by minimizing the algebraic connectivity of complex networks. In this paper, we define edge centrality for each edge by spectral analysis and propose an advanced algorithm of community detection on the basis of centrality measure and correlation coefficients. By the analysis of the algorithm and missing value processing, three methods of missing value processing are put forward. The study subject is classified into several groups by the algorithm of community detection on the basis of centrality measure. Then, it calculates the centrality of the study subject with missing value in the group and deletes the record with a low centrality; on the contrary, the traditional methods of missing value processing are adapted to process missing data in same group. This method is applied to evaluate a fast-food company with missing data. The results show that the missing value processing method based on community detected outperforms the traditional mean imputation method, multiple imputation method, and K-means algorithm. It offers a practical approach for missing value processing.

1 INTRODUCTION

With the rapid development of many social networks (Twitter, Google+, Facebook) in the last decade, the social network has a huge amount of data. The number of network nodes can reach millions or billions (Charu, 2011). The processing of huge data also promotes the development of complex network models and methods. Although some community detection algorithms can effectively identify communities in complex networks, the algorithm complexity is still high. The time complexity of Zhou & Lipowsky (2004) and Donetti & Muñoz (2005) is $O(n^3)$, and Clauset et al. (2004) time complexity is $O(n \log^2 n)$. The time complexity of GN (Girvan, 2002) algorithm is $O(m^2 n)$. The time complexity of sparse networks is $O(n^3)$. Duch & Arenas (2005) time complexity is $O(n^2 \log n)$. Fortunato et al. (2004) time complexity of is $O(nm^3)$. Eckmann & Moses (2002) time complexity is $O(m < k^2 >)$. Capocci et al. (2005) time complexity is $O(n^2)$. A cutting edge model based on the edge centrality measure is proposed in the Edge Centrality Cut Model (ECCM, Zhang, 2012). Although the model reduces the time complexity, it did not consider the overlapping community nodes. Its time complexity is $O(n + m)$.

There is a large amount of data in social network, but the experimental study or survey will

inevitably cause missing data. The main reasons for this are:

1. The subjects are unwilling to provide the required survey information;
2. The uncontrollable factors cause the missing data;
3. The researcher or survey system does not collect complete information;
4. The error of information reporting summary cause the missing data.

The traditional methods of missing value processing mainly include deletion, imputation, and likelihood maximum (Ye, 2014). Imputation of missing values include imputation mean, random imputation method, and Multiple Imputation (MI) (Zhao, 2013; Yozgatligil, 2013). Multiple imputation method is widely applied in psychology, medicine, finance, climatology, pharmaceuticals (Ji, 2013; Twisk, 2013; Donneau, 2015). Loss mechanism of missing data includes Missing Completely At Random (MCAR), Missing At Random (MAR), and Missing Not At Random (NMAR). Ye (2014) provides an inspection and identification method. Yang (2012) analyzed the effect of the full Bayesian and partial Bayesian methods on parameter estimation with different missing ratios. However, these studies do not deal with missing data based on the classification of data.

In summary, this paper presents an advanced community detecting algorithm, which effectively reduces time complexity. The missing data are processed in the same community. The centrality of survey subject decides whether missing data are deleted or not.

2 EDGE CENTRALITY MEASURE OF THE COMMUNITY DIVISION ALGORITHM WITH THE CORRELATION COEFFICIENT

Community detection algorithm can be divided into the following classic algorithms: Graph Partitioning (Kernighan, 1970), Agglomerative Clustering (Girvan, 2002), Divisive Algorithm (2004), Modularity Methods (J. Mei, 2009), Spectral Algorithm (Luxburg, 2007), and Markov Clustering (Dongen, 2000). The algorithms of community detection detect communities by optimizing an objective function. Among them, Graph Partitioning, Modularity Methods, and Spectral Algorithm optimize a specific objective function. The Advanced Edge Centrality Cut Algorithm (AECCA) with the correlation coefficient is introduced. The algorithm cuts graph edges and divides community into two graphs. The missing data are processed in the same community.

The Laplacian matrix, $L(G) = AA^T$, is independent of the orientation. In fact, $L(G) = D(G) - A(G)$, where $D(G)$ is the diagonal matrix of vertex degrees and $A(G)$ is the $(0, 1)$ adjacency matrix. The diagonal entry L_{ii} is the degree of node i , if $(i, j) \in E$ then $L_{ij} = -1$, otherwise $L_{ij} = 0$. $L(G)$ is a symmetric, positive semidefinite matrix (Merris, 1994).

The second smallest eigenvalue $\lambda_2(L)$ is called the algebraic connectivity of the graph G , and the corresponding normalized eigenvector is called the Fiedler vector. The algebraic connectivity is considered a measure how well-connected a graph is. That is, the more connected graph has the greater algebraic connectivity on the same vertex set. The magnitude of this value reflects how well connected the overall graph is. $\lambda_2(L) > 0$ if and only if G is connected. $\lambda_2(L)$ is monotone increasing in the edge set. The algebraic connectivity function of complex networks is a monotone convex function. If $G_1 = (V, E_1)$ and $G_2 = (V, E_2)$, $E_1 \subset E_2$, then $\lambda_2(L_1) \leq \lambda_2(L_2)$. The Courant-Fischer Minimax Principle implies (Mohar, 1991):

$$\lambda_2(L) = \min_{v \in \mathbb{R}^n} \left\{ \frac{v^T L v}{v^T v} \right\} \quad (1)$$

That is, we want to solve the problem that the following convex function is minimal:

$$\begin{aligned} & \text{minimize} \quad \lambda_2 \left(L - \sum_{i=1}^m x_i a_i a_i^T \right) \\ & \text{subject to} \quad 1^T x \leq k, \\ & \quad \quad \quad x \in [0, 1]^m, \end{aligned} \quad (2)$$

Where $x_l = 1$ if edge l belongs to the edge subset, otherwise, $x_l = 0$. l_{ij} is an edge connecting nodes i and j , $l \sim (i, j)$. Assign weight w_l to the every edges according to its importance, $0 \leq w_l \leq 1$. The weight is inversely proportional to the corresponding values in the Fiedler vector. The convex relaxation can be formulated as follows:

$$\begin{aligned} & \text{minimize} \quad \lambda_2 \left(L - \sum_{i=1}^m x_i w_i a_i a_i^T \right) \\ & \text{subject to} \quad 1^T x \leq k, \\ & \quad \quad \quad x \in [0, 1]^m, \end{aligned} \quad (3)$$

We choose k edges from candidate edges that lead to the greatest decrease in algebraic connectivity when these edges are cut from G . The gradient of the objective function is $w_i(v_i - v_j)^2$. The proof procedure is shown below. The objective function $\lambda_2 \left(L - \sum_{i=1}^m x_i w_i a_i a_i^T \right)$ is a monotone function. Let matrix $Y = \sum_{i=1}^m x_i w_i a_i a_i^T$ is the Laplacian matrix, which can be written as $\tilde{L} = L - Y$, such that

$$\lambda_2(\tilde{L}) \leq \frac{v^T(\tilde{L})v}{v^T v} \Rightarrow \lambda_2(\tilde{L})v v^T \leq v^T(\tilde{L})v \quad (4)$$

According to (4), we obtain:

$$\lambda_2(\tilde{L}) \leq \lambda_2(L) + \left\langle v^T v, (\tilde{L} - L) \right\rangle \quad (5)$$

where $\lambda_2(L)$ is an analytic function of L , and therefore of x . In this case, the supergradient is the gradient, that is,

$$\frac{\partial \lambda_2(L - w_i x_i a_i a_i^T)}{\partial x_i} = w_i v^T a_i a_i^T v \quad (6)$$

Definition 1. The edge that leads to the greatest decrease in the algebraic connectivity is defined as the center edge. The nature of this edge is called Edge Centrality.

Definition 2. The center node is the node in the core position of each community in the social network.

The cutting edge model based on edge centrality measures is different from the traditional community detection algorithm in social network. It is proposed to deal with the large-scale community

structure based on the edge centrality measure. Nodes i and j correlation coefficients are calculated as:

$$r_{ij} = \frac{\langle x_i x_j \rangle - \langle x_i \rangle \langle x_j \rangle}{\left[\left(\langle x_i^2 \rangle - \langle x_i \rangle^2 \right) \left(\langle x_j^2 \rangle - \langle x_j \rangle^2 \right) \right]^{\frac{1}{2}}} \quad (7)$$

where the average $\langle \cdot \rangle$ is over the first few nontrivial eigenvectors. The quantity r_{ij} measures the community closeness between nodes i and j .

ECCM with correlation coefficient is as follows:

1. Calculate the spectral centrality for each edge of graph G on the basis of the edge centrality function and sort them.
2. Find one edges with the highest spectral centrality, and then, delete them; renew the complex network to G^{new} . The choice of k is based on the edge sparse degree of complex networks. When G is a sparse graph, k is equal to one. Otherwise, k is more than one.
3. Calculate algebraic connectivity of a graph. If $\lambda_2 = 0$, the algorithm goes to step (4), otherwise it goes to step (1).
4. When the corresponding component value of the Fiedler vector of a node is less than the threshold α , we should analyze the necessity of computing the correlation coefficient. Moreover, we should calculate the correlation coefficient of the node if the difference in the number of edges that it connects to the two communities is less than 2.
5. Use formula (3) to calculate the correlation. By comparing the two correlation coefficients of the nodes in the two communities, we can determine to which community the node belongs to.
6. Update the complex network new graph G_1^{new} and G_2^{new} . The graph G is divided into two communities.

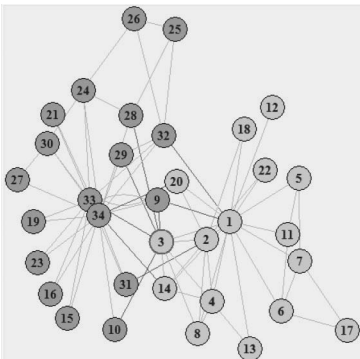

Figure 1. Karate network correct bisect result diagram.

The above six steps that described G are divided into two communities, G_1^{new} and G_2^{new} . If G_1^{new} and G_2^{new} need further partition, we need to repeat step (1) to step (6). Node 3 should have the same community with node 1 and 2. The result of community detection by AECCA is shown in Fig. 1.

3 MISSING VALUE PROCESSING METHOD BASED ON ADVANCED COMMUNITY DETECTION

Imputation mean is that missing data are replaced by the mean value of all the variables without missing values. Multiple imputation is to construct m estimates for each missing value ($m > 1$) and produce m a complete data set. K-means is the missing value that is replaced by clustering center value.

The missing value processing method with improved community partition algorithm is based on using the above cut edges algorithm. The steps are described in detail as follows:

1. Processing the survey data and constructing social network graph G based on the relationship between the subjects of social networks.
2. Cutting the graph G edges, calculating the spectral centrality for each edge of graph G based on the edge centrality function, and sorting them. Moreover, we should calculate the correlation coefficient of the node if the difference in the number of edges that it connects to the two communities is less than 2. The graph G is divided into two communities G_1^{new} and G_2^{new} .
3. Judging the centrality of the node in its community by $w_i(v_i - v_j)^2$.
4. If the centrality of node with missing data is less than a , its recording is deleted. Otherwise, the missing data are replaced by imputation mean (or K-means) in the same community.
5. Repeat step (3), traversing a community of all nodes and other communities.

The processing methods of missing value based on social network community detection include imputation mean, random imputation method, and multiple imputation with the community partition algorithm. Nodes (subjects) in the same community have the same preference and behavior; therefore, the missing value processing method is more accurate and effective.

4 EMPIRICAL ANALYSIS

Taking a fast-food company as the research object, the experiment collects the data of customer expectations, overall customer satisfaction, and corporate image by online surveys. The subject

is RenRen user. A questionnaire link is sent to subjects. The subjects fill in and submit the questionnaire. The feedback results are stored in the database and complete the data collection. Every ID corresponds to specific questionnaire data. With the basic theory research of complex networks, R environment, Curl packages, and other related technologies, we crawl all the data on the RenRen and construct the actual network. According to the relationship between the subjects, using the community partition algorithm, the respondents can be divided into two groups.

Compared with K-means, the imputation mean with community detection is an improved one. Its deviation is smaller and closer to the original value. The number of iterations of multiple imputation with community detection is nine. Every community applies this method. The result is better than the traditional multiple imputation.

The overall expectation value density distribution is shown in Fig.2 with the missing value ratio of 30%. Fig.3 shows the overall expected missing rate and value distribution. The highest value of customer satisfaction is 10. Sample size is 112, blue indicates the observed value, red indicates the imputation value, and the number of iterations is nine. The imputation result is satisfactory.

Figure 4 indicates a comparison of missing data ratio and RMSE with different missing ratios (Zhao, 2013). Fig.4(a) shows respectively Mean Imputation, Classification Mean Imputation (C Mean Imputation), and Community Detection Mean Imputation (CD Mean Imputation). Fig.4(b) shows respectively K-means, Classification K-means, and Community Detection K-means ($k = 5$ or 10). Fig.4(c) shows respectively Multiple Imputation, Classification Multiple Imputation, and Multiple Imputation with Community Detection.

The results show that three kinds of missing data processing method exceed traditional

Figure 2. Overall expectation value density distribution.

Figure 3. Overall expected missing rate and value distribution.

(a) (b)

(c)

Figure 4. Missing data ratio and RMSE.

method. K-means method based on the community detection has the minimum RMSE. Multiple Imputation with Community Detection is the most important RMSE. Because there is a link between the subjects and larger correlation between datum in the social network, Imputation missing data in sub-community is closer to the original value than that in the whole community. The missing value processing method based on community detection is effective.

Although several EB (exabytes) of data are generated daily, missing data are relatively common in practical applications because of the problems of the existing software and hardware resources, data collection, processing, and storage. Accordingly, with the improvement of missing value processing precision and high speed, the missing value processing method has a partial use of space under certain conditions.

5 CONCLUSION

Through analysis of community detection and missing value processing method, in this paper, we proposed the edge centrality measure of the community division algorithm with the correlation coefficient and three kinds of missing value processing method on the basis of advanced community detection (imputation mean, multiple imputation, and K-means with community partition algorithm). It takes a fast-food company as the research object and tests the three methods. The results show that our missing data processing method is superior to the traditional imputation methods. With the development of network, there are more and more nodes in a community. Therefore, future research should aim at decreasing the computational complexity of community detecting algorithms and applying faster cut edges method to process missing data.

Research on the knowledge discovery system in intelligent manufacturing based on the big data

Jian Li, Xiangyang Liu, Shuming Jiang, Zhiqiang Wei & Shuai Wang
Information Research Institute, Shandong Academy of Sciences, Jinan, China

Jianfeng Zhang
Electrical Engineering and Automation of Tianjin University, Tianjin, China

ABSTRACT: Intelligent manufacturing has increasingly become the major trend of the future development of manufacturing and core content. It is an important performance measure of the comprehensive national strength. It is an important force to promote scientific and technological innovation, economic growth, and social stability, and become the opportunities of the various countries' development and transformation as well as form a new competitive battlefield. It is also an inevitable choice to build a new international competitive advantage under the new normal. However, in the development stage of the new things rapidly, accurately, and effectively in the first place to obtain new knowledge in the field of intelligent manufacturing new dynamic is the best way to lead enterprises an inevitable step in the market. Therefore, it is very important for the research of knowledge discovery system in the intelligent manufacturing under the Big Data. On the basis of the background of Big Data, this paper combines the knowledge discovery system and intelligent manufacturing field and designs the knowledge discovery system.

1 BIG DATA

In recent years, Big Data has attracted considerable attention. As early as the 1980s, an American social thinker Alvin Toffler praised the "Big Data" as "the third wave of the color movement" in the book *The Third Wave*.

Big Data is a combination of several old and new technologies. It can help companies to obtain meaningful data content, make in-depth analysis of users' needs, and even determine potential knowledge needs of users, revealing the relationship between information resources, to provide more accurate knowledge discovery services. Therefore, Big Data can be thought as the ability of management of vast amount irrelevant data at the right time and applying it to real-time analysis and response. Big Data has three typical features: volume (large amount of data), variety (variety), and velocity (fast and efficient) (Zhang, 2016).

In the era of Big Data, we can analyze more data, even sometimes deal with all the data associated with a particular phenomenon, rather than relying on random sampling. A well-known scholar at Harvard University suggested that the massive data sources had begun to quantify processes in all areas, whether academics, business, or government (Liu, 2014). With the rapid expansion of the amount of information, it has become the top

priority of information services how to effectively use a large number of structured, semi-structured, and unstructured complex data gradually.

2 INTELLIGENT MANUFACTURING AND BIG DATA

2.1 *Key status of big data*

The data have a huge value of innovation. We should not only pay attention to the actual amount of data, but also to the large data processing methods. With the increasing complexity of the data, the ability of transforming data into intelligence will be increasingly demanded.

How to achieve intelligent manufacturing from big data? A large number of entrepreneurs that come from excellent manufacturing have a general consensus. They realize intelligent manufacturing from digital transformation. Digital transformation not only means simply digital companies, but also the core driving force of intelligent manufacturing which needed to be used to integrate the industrial chain and value chain (Wang, 2008).

In the field of manufacturing, one type of data is derived from the human trajectory generated data, and the other is the machine automatically generated data. These two types of data constitute today's large multistructured data sources. In

the field of industrial data, we have to pay more attention to the integration of machine data and industrial data with human behavior data in addition to continuing to care about human data or people-related data (Wang, 2010).

2.2 Relationship between big data and intelligent manufacturing

Enterprises can keep abreast of the processes, problems, and solutions in the production process and find new ways to create additional value on the basis of large data tools, data analysis, and mining.

Manufacturing industry can achieve business model changes, transform and enhance customer experience, improve the internal operational processes, and keep abreast of industry trends in order to market decision-making step ahead by using big data tools and thinking.

3 KNOWLEDGE DISCOVERY SYSTEM ARCHITECTURE

The data itself are worthless. The data will not let our manufacturing industry more advanced. It must be converted into information. The information will be valuable for industry (Wu, 2010). With the advent of the era of Big Data, users urgently need a simple and fast ideal platform that gains access to all the knowledge. Big Data is the basis of intelligent manufacturing; its core is the custom platform. If we do not invest in Big Data and data analysis, intelligent manufacturing pursuit of excellence operation will fall short. It is the Big Data analysis technology instead of Big Data itself that promotes intelligent manufacturing, namely the knowledge discovery system.

Knowledge discovery is a nontrivial process of identifying valid, novel, potentially useful, and eventually understandable patterns from the data set. The process of knowledge discovery translates information into knowledge, finds the data gold from the data mine, and contributes to knowledge innovation and economic development.

In the field of intelligent manufacturing, through cooperation with enterprises, we build knowledge discovery service platform. In the industrial technology information, talent discovery, knowledge recommendation, and other aspects of service enterprises in the benefit analysis, customer relations, and so on enhance the competitiveness of enterprises in all directions. The purpose of knowledge discovery is to break the limitations of the previous books directory, make full use of citation index and part of the literature, and provide users with comprehensive

and efficient knowledge mining and data analysis capabilities of the knowledge discovery system, in order to achieve the discovery from the resource to knowledge change.

Information organization supported by the technology of data mining carries out the knowledge association and the data analysis processing of books, further discovers large amount of hidden data, and then establishes a powerful new generation of academic resource discovery platform to help the information users to obtain the required knowledge or node more quickly.

3.1 Data mining

Data mining is a process that extracts implicit, unknown, and potential useful information from large amount of data that are incomplete, noisy, fuzzy, and random (Ouyang, 2001).

Data mining is also known as knowledge discovery in database. It creates model and finds out relationships, and then makes a decision and prediction among data from huge amounts of data by various methods and analysis tools.

As shown in Figure 1, the data mining process includes the following steps:

Understanding and defining the problem.

Data mining professionals work with domain experts to make an in-depth analysis of the problem in order to determine possible solutions and to evaluate the results of the study.

Related data collection and extraction.

Collect relevant data according to the definition of the problem. In the process of data extraction, database query function can be used to accelerate the data extraction.

Data exploration and cleaning.

Understand the meaning of the field in the database and its relationship with other fields. Check and clean out the data that are contained in the data extracted from the data.

Data engineering: reprocesses the data.

It mainly includes selecting related subsets of attributes to eliminate redundant attributes, and according to the knowledge discovery task to

Figure 1. Data mining step in the process of knowledge discovery.

reduce the amount of learning, and transforming the way of expressing data to adapt the learning algorithm, in order to make the data and tasks achieve the best match. This step may be repeated several times.

Algorithm selection.

According to the data and the problem to be solved, select the appropriate data mining algorithm and decide how to use the algorithm on these data.

Run the data mining algorithm.

Using the selected data mining algorithm to extract the processed data pattern.

Evaluation of results.

The evaluation of learning results depends on the issues that need to be resolved. The novelty and effectiveness of the patterns will be evaluated by domain experts. Data mining is a basic step in the knowledge discovery process. It includes a specific mining algorithm that discovers patterns from the database. The knowledge discovery process uses data mining algorithms to extract or identify knowledge from a database on the basis of specific metrics and thresholds. This process includes pre-processing of the database, sample partitioning, and data transformation.

The task of data mining is finding models from data. It extracts useful and interesting knowledge and models from a large number of data by means of theory, methods, and tools related to the development. The enormous data in a database often contain high-level information or knowledge such as rules, laws, and assertion. We cannot acquire this information only through the query process. On the basis of the data provided by the database, data mining looks for some inner relationship between data to find potential and important roles for forecasting and decision-making behavior patterns through data analysis and reasoning and finally establishes a new business model to achieve the goal of helping decision makers to make the right decisions.

3.2 Data analysis

On the basis of the knowledge organization and presentation of existing structured and unstructured data by utilizing data mining and learning technology, reasoning knowledge discovery system could obtain a change direction and trend of literature resources. Automatic and intelligent analysis can help users to get dynamic, informative, and advanced knowledge of the literature. The primary role of data analysis is to help people to sample, extract, analyze operation process, and check the analysis results by setting the human-computer interaction interface and utilizing software environment. The potential regularity in huge amounts of information resources and its development

trend will be shown dynamically and intuitively by means of visualization technology. The data analysis flowchart is shown in Figure 2.

In the knowledge discovery system, data mining and data analysis make deeper development and application with information under cloud computing and Big Data environment. Data mining is the basis of data analysis; data analysis is the deepening of data mining. The content of data mining is the premise and guarantee for data analysis, data analysis systems reasoning, and the development trend and direction of knowledge based on the results of data mining. It thus puts forward ground-breaking and prospective prediction, verifies the depth and breadth of knowledge mining, and feeds back to the knowledge mining system for improvement. Therefore, data mining and data analysis, as two modules of knowledge discovery system, supplement and interact with each other.

3.3 System design principles

The design of knowledge discovery system should follow the basic principles of system development:

- **Structural integrity**

The knowledge discovery system gathers a large number of structured, semi-structured, and

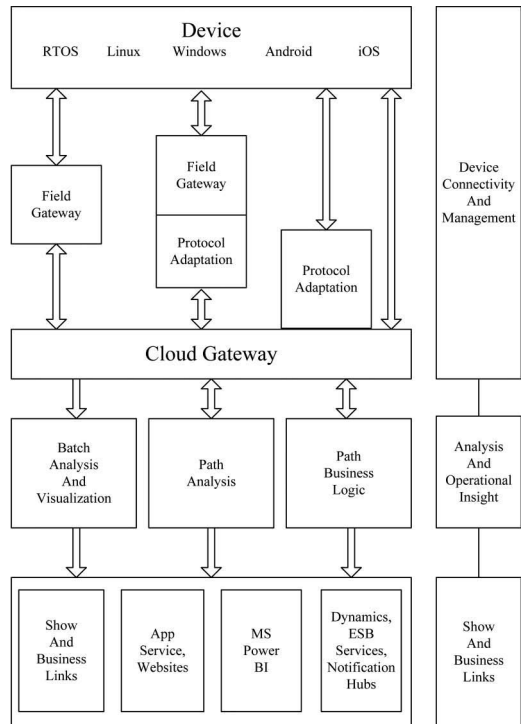

Figure 2. Data analysis flowchart.

unstructured complex data. It matches, analyzes, and mines the information agency and user needs and search behavior. Thus, it establishes a complete system architecture. And it widely and accurately reveals the multiple, three-dimensional relationship of the various types of data and the knowledge network link (Wang, 2010).

- Advanced technology

The knowledge discovery system innovates in the technical route. This system can not only dock with information service institution's original full-text information system, but also provide users with optimal results sorting and knowledge push through the advanced warehouse management technology, indexing technology, data mining technology, and so on.

- Platform security

Knowledge discovery system establishes a complete and effective system security, platform backup, and fault-handling mechanisms to ensure the stable operation of the platform. Job and synchronization system ensure safe and stable data operations. The design of hardware redundancy fully protects the daily data's security backup. Real-time monitoring module realizes the use of the database storage space and data access observation and monitoring, and it will alarm in case of emergency.

- System development

The knowledge discovery system adopts extensible development language and database type, such as distributed storage and distributed indexes. The performance of the system and its scalability have been greatly improved. The knowledge discovery system also provides OAI-DP services and standard interfaces. It allows seamless interfacing with other full-text access systems of information organizations. It can facilitate the docking of other platform on the system and the secondary use so that the utilization of information is improved and the system's life cycle is extended. The old and new systems of succession and development have been achieved.

- Interface friendliness

The knowledge discovery system obeys the basic principles of interaction design. It is user-centric interface designed. Its purpose is to plan and describe the mode that the users access knowledge, and then describe and communicate the knowledge information to the users efficiently. It provides users a friendly operating platform, and visualization results display and export services and gives a good user experience.

For the user, knowledge discovery system is a simple, easy-to-operate, and user-friendly platform.

3.4 Knowledge discovery system model

The knowledge discovery system extracts implicit, unknown, and potentially useful information from

a large amount of data that are incomplete, noisy, fuzzy, and random (Studer, 1998). Its purpose is to shield details for users, extract significant and succinct knowledge from original data, and directly report to users so that it can provide knowledge discovery service for business manager and information organization. In general, resource integration, knowledge discovery, and achievement exhibition are functional goals of knowledge discovery system.

The frame diagram of knowledge discovery system in the field of intelligent manufacturing is shown in Figure 3. It consists of four parts: data collection, data mining and analysis, data visualization, and knowledge service. Data collection module collects and receives original data, transports them to data mining and analysis module, in which important and interesting data are extracted, and the data are reduced for conversion to appropriate format. Finally, the generated knowledge model is evaluated, and valuable knowledge is integrated into corporate intelligent system.

This system combines data and knowledge discovery system and discovers the unknown correlation between them. It also makes it more possible to break information island Big Data used in operation and new data sources, such as social media, Internet of things, and so on, to analyze the solution capacity of Big Data. All these data are integrated, and knowledge discovery system can provide decision and prediction for management.

The firm boundary is becoming more and more vague in manufacturing industry. Subversive innovation is the most unpredictable external factor.

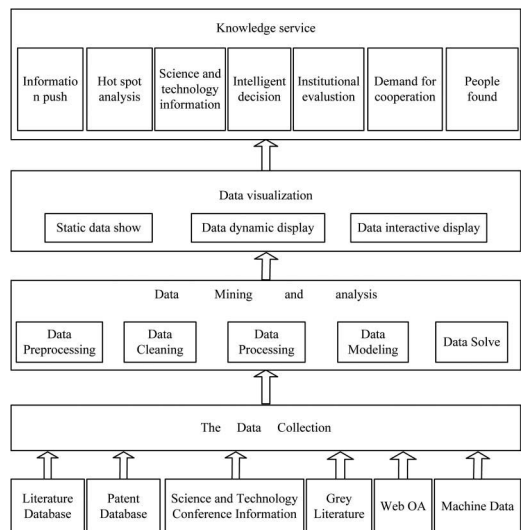

Figure 3. Knowledge discovery system framework diagram of intelligent manufacturing domain.

Interconnection entirely changed rules of the business and business managers need to realize cutting-edge technology and its correlations, make use of modern enterprise architecture to refine enterprise, and obtain more efficient, intelligent, and high-interest serving product through digital supply chain.

4 SUMMARY

The matching of knowledge discovery system and enterprise management is the key to the enterprise performance. In the era of knowledge economy, the competition between enterprises is the competition of knowledge, information acquisition, and their application ability. Knowledge discovery can discover useful knowledge from the mass data of the enterprise. On the basis of the mature information technology, this paper establishes an efficient search, discovery, accumulation, communication, sharing, and reuse of knowledge platform. It also makes the enterprise to realize the true meaning of the knowledge sharing and reuse in a wider range, promotes enterprises to achieve effective knowledge management so as to enhance the core competitiveness of enterprises.

The system architecture proposed in this paper provides a useful way for the development of

knowledge discovery system. However, in the next step, we need to pay attention to the specific technical implementation details of the system architecture and its application effect.

Study on the positioning system in China's Advanced Broadcasting System-Satellite

Ming Yan & Jing-yi Yang

GxSOC Research Institute, Communication University of China, Beijing, China

Xin-gang Wang

Administrative Center for the DTH Service in China, Beijing, China

ABSTRACT: The Advanced Broadcasting System-Satellite (ABS-S) technical specification is an independent research and development satellite radio and television signal transmission technology in China. In this paper, we first introduce the development situation of satellite broadcasting technologies and then analyze the physical layer interface specifications of ABS-S. A positioning system in ABS-S is mainly studied because the system needs to know the user's position to insure they are in the rural area. Using the position management system, the security and stability of the total system have been improved to satisfy the demands in China.

1 INTRODUCTION

In the early 21st century, the State Administration of Radio Film and Television (SARFT) of China has begun to carry out the research on satellite system for radio and television (TV) broadcasting of Ku and Ka frequency band (Wang, 2015; Shi, 2008; Lin, 2007). For building a safer and more reliable satellite live broadcasting operating system, further standardizing the market of live satellite radio in China, and improving the safety of the satellite live broadcasting system, in July 2009, the SARFT approved the technical specification of radio, film, and television industry for the satellite live broadcasting: Advanced Broadcasting System-Satellite transmission system's frame structure, channel coding, and modulation: security mode (GD/JN 01-2009). On the basis of this specification, for building satellite live broadcasting system, in October 2009, the SARFT officially approved the technical specification for satellite live broadcasting security mode modulator: the technical requirements and measuring method for live broadcasting satellite safe mode modulator (GD/JN 02-2009).

As a supplementary technology of cable TV, the satellite live broadcasting system is forbidden to be used in the area with coverage of cable TV, such as metropolis, in China. Therefore, the positioning system is a key technology in ABS-S, which is used to locate the terminal receiver and judge the legality of the user. If the positioning system finds the terminal receiver located in illegal area, it will tell

the management system to lock the receiver (Cui, 2015; Liu, 2015).

The rest of this paper is organized as follows. In Section 2, we investigate the development situation of satellite live broadcasting technologies worldwide. In Section 3, we present the physical layer technologies and transmission parameters of ABS-S. In Section 4, we study the requirements of positioning system in ABS-S and design a positioning system, which can provide location service for ABS-S. Finally, the paper is concluded in Section 5.

2 DEVELOPMENT SITUATION OF SATELLITE LIVE BROADCASTING

The main feature of satellite live broadcasting system is that the TV program can directly transmit to the user with satellite, so the users can receive TV or radio programs by simply using a small satellite receiving antenna. Since the early 1990s, satellite live broadcasting television service, satellite mobile communication, and satellite digital audio broadcasting business had been undergoing a technical breakthrough firstly in the United States and stepping into industrialization and commercialization, and forming a new industry to promote the growth of the economy. At present, these three satellite communication and broadcasting businesses are rapidly expanding globally. Especially, the satellite live broadcasting radio and television industry is developed rapidly

and achieved great success in operating (Wang, 2015; Shi, 2008; Zhao, 2015).

In 1993, US Hughes Corporation first developed and built a commercial television satellite system with digital video compression technologies and founded the DirecTV Company by a variety of financing channels in charge of the operation of the satellite system. After few years, the company dominated the market of satellite TV live broadcast in the United States and Canada and entered into the markets in Mexico, Latin America, and Japan. After the Hughes Corporation achieved success in developing satellite television broadcast, many large companies in the United States, Japan, and Europe also successively entered into the satellite digital TV market. Some traditional for-profit and non-profit satellite communications companies also began to enter into this market, trying to find their places in the world live satellite radio and television market.

The Europe SES Corporation owns about 10 communication broadcasting satellites, and the radio and TV programs has more than 1000 sets, which are transmitted by these satellites, with tens of millions of users. In the United States, there are many direct broadcast satellites in three satellite orbits, transmitting more than 600 programs. The EchoStar Corporation owns nine direct broadcast satellites, with more than 1000 programs and 10 million users, and earned more than 8 billion dollars in 2004.

In China, the ABS-S technical specification is an independent research and development satellite radio and television signal transmission technology. The ABS-S has independent core technology and international advanced level in satellite broadcasting transmission technologies. It provides the interface specification of signal transmission in the physical layer, which is channel coding and modulation specification (Liu, 2008).

Compared with the Digital Video Broadcasting-Satellite (DVB-S2) technology, which is widely adopted worldwide currently, the ABS-S has obvious advantages. In the same transmission conditions, the ABS-S can provide greater signal transmission capacity; in other words, it can compete more poor transport conditions at the same transmitting efficiency. At the same time, the ABS-S also provides more transmission configuration choices. In addition, the ABS-S adopts different implementation methods in logical frame structure, physical frame structure, channel coding scheme, modulation system, pilots insertion, interleaving, scrambling, and signaling in band compared with DVB-S2 (Lan, 2015; Zhang, 2014).

3 PHYSICAL LAYER TRANSMISSION SYSTEM IN ABS-S

In the technology design, the various losses of satellite channel and their effects on signal receiving performance are considered adequately in the ABS-S system, such as the nonlinearity of satellite power amplifier, group delay characteristics, phase noise and frequency drift in the front-end of receiver, and thermal noise in uplink and downlink. At the same time, the ABS-S system takes advantage of the latest research findings of the satellite signal transmission technologies in the world and is improved and developed on the basis of the requirements of direct broadcast satellite in China. The ABS-S system adopts Low Density Parity Check (LDPC) code in channel coding, which leads to a completely different implementation model compared with the DVB-S2, in accordance with the current latest technology standards worldwide. The encoded frame length of the ABS-S is less than a quarter of the DVB-S2, and the ABS-S does not use the combination mode with LDPC and BCH. Therefore, the complexity degree of implementation of the ABS-S reduces significantly but has the same performance with the DVB-S2 (Zhou, 2006; Cheng, 2008).

3.1 *Frame structure of physical layer*

A more concise and more reasonable physical frame structure compared to the DVB-S2 is designed in the ABS-S system, and the ABS-S adopts a special inserting scheme of pilot training symbols, so it has better synchronization performance and shorter synchronization time than that of the DVB-S2. Meanwhile, it can merge Constant Coding and Modulation (CCM) and Adaptive Coding Modulation (ACM) together. Fig.1 shows the main functional block of the transmission system in ABS-S. The input data stream is formatted in baseband and then processed with Forward Error Correction (FEC). After bit mapping, the stream generates frame data in physical layer and then scrambles these symbols. The data go through a filter and are transformed from baseband to Radio Frequency (RF) data, which are Ku data transmitted to the receivers (Jiang, 2013; Yi, 2005).

The ABS-S is designed especially for broadcasting business application, considering the technological change and influence of the power capacity and repeater configuration in China's direct broadcast satellite adequately. In ABS-S system, two carrier modulation schemes, QPSK and 8 PSK, are adopted in satellite broadcast services. Combining with different channel coding rates, it can provide more transmission scheme solutions for the platform operation and take full advantage

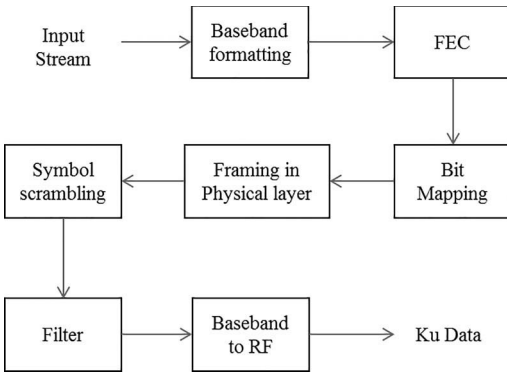

Figure 1. Functional block of the transmission system in ABS-S.

of the transmitting ability of the satellite platform. Meanwhile, it can resist the nonlinear impact of Travelling Wave Tube Amplifier (TWTA) power amplifier. In addition, the ABS-S can be extended to use higher-order modulation schemes, such as 16 APSK and 32 APSK, to satisfy the requirements of transmitting capacity enhancement and interactive business application in the satellite platform.

3.2 Video coding and parameters of transmission coverage

At present, the vast majority of digital television broadcast systems adopt Motion Picture Experts Group 2 (MPEG-2) as their video coding. In the application process of MPEG-2 standard, the technologies also develop continually, especially the application of noise-reducing filter, dynamic statistical multiplexing of multiple programs, so the compression efficiency increases greatly. Both the central and provincial satellite TV systems in China mainly adopt the compression bit rate from 4.2 to 6.9 Mbps. The China Central Television has tested the coding bit rate with the fixed rate of the encoding systems and found that the encoding rate with 3.2 Mbps can guarantee the video quality, which can completely meet the needs of radio and television broadcast system.

The key parameters applied in the ABS-S direct broadcast satellite platform are listed below:

- Input signal: MPEG-TS bit stream with 188 bytes.
- Coding scheme of FEC: LDPC coding, frame size is 15360 bits.
- FEC code rate: 1/4–9/10, 14 combination modes with QPSK and 8 PSK.
- Carrier modulation scheme: QPSK and 8 PSK.
- Roll down factor of pulse shaping filter: 0.35, 0.25, 0.2.

Table 1. Parameters of transmission coverage for ABS-S.

Parameters	Values
Repeater bandwidth	36 MHz
Repeater code rate	43.2 Mbps
MPEG-2 standard definition video bit rate (statistical multiplexing)	2.677 Mbps * 12 = 32.124 Mbps
TV audio bit rate	128 Kbps * 12 = 1.536 Mbps
SI bit rate	2 Mbps
Entitlement management message data rate	2 Mbps
System overhead data rate	2 Mbps

- Pilot frequency: optional, QPSK symbol.
- Supporting variable code modulation and adaptive coded modulation.

Table 1 gives the parameters of transmission coverage for ABS-S.

4 POSITIONING SYSTEM IN ABS-S

4.1 Requirements of positioning system in ABS-S

In terms of positioning mechanism, although the mobile base stations can effectively control the moving range of the comprehensive decoding terminal, the base station cannot estimate whether the terminal locates in the legal installation area for the first installation, which results in illegal installation of decoding terminal. On the contrary, the built-in position lock module in the comprehensive decoding terminal of direct broadcast satellite is independent of the main module, so the positional information of the terminal can be modified through the replacement method of the built-in information in module, which also results in illegal moving of the terminal.

Aiming at the above technical questions, we improve and optimize the position management prototype system on the basis of the preliminary development, adding the function of collecting the geographical position information, and avoiding the illegal installation of direct broadcast satellite terminals in the area with cable TV coverage by using this geographical position information to confirm the installation location. A digital signature mechanism is used in the process of positioning information transmission between the position management module and the main module in the direct broadcast satellite terminals to prevent illegal module forging positioning information. Through the above improvement, the security and stability of the total system have been improved to satisfy the demands of the large-scale application

4.2 Design of position management system

The position management system takes advantage of the character that the geographic position of mobile communication base station is relative fixed, and the base station can provide effective return channel to lock the comprehensive decoding terminal with the base stations nearby the installing position when installing the terminal. The system uses the General Packet Radio Service (GPRS) uplink channel to return the base station information back to the position server, judging whether the current position is legal installation location by comparing with the information in the position server. When the decoder is working, the system can determine whether the position is moving by scanning the change of the surrounding base station (Kim, 2016).

The position management system is composed of position lock server, Short Messaging Service (SMS), Entitlement Management Message Generator (EMMG), signature validation server, decoding terminal with locating function, and geographical position information, which are shown in Fig. 2.

The position lock server is located in the direct broadcast satellite user management center. Its major functions are listed below:

- Integrate the uploading data of the receiver and create the database of service stations.
- Receive the base station information uploaded by the receiver and the user registration information from boss system simultaneously. Combining with the base stations list from the geographical position information block, complete the comparison of base station and return the comparing results to the boss system to determine whether to authorize the user's account.
- Store all the location management information and status information of the receiver.
- Output the combination statements.

The signature validation server verifies the signature validity of the location management information uploaded by the receiver and returns the verification result to the position management server.

The decoding terminal with locating function and geographical position information contains location management module, which can communicate with the server, supporting the two working modes of locking and unlocking. The key functions are listed below:

- Collect the information of all retrievable base stations.
- Transmit the base station information together with the encryption key of the receiver, smart

Figure 2. Position management system of ABS-S.

- card serial number, and Interning Mobile Equipment Identity (IMEI) number to the direct broadcast satellite user management center.
- Store the location management information in the smart card.
- Obtain the new location management information when the terminal starts up every time and compare with the location management information stored in the smart card.
- Realize location management function on the basis of the comparing result.

5 CONCLUSIONS

The ABS-S system is designed especially for broadcasting business application, considering the technological change and influence of the power capacity and repeater configuration in China's direct broadcast satellite adequately. In this paper, we studied a position management system, which takes advantage of the character that the geographic position of mobile communication base station is relatively fixed and the base station can provide effective return channel. This mechanism can lock the comprehensive decoding terminal with the base stations nearby the installing position when installing the terminal. Therefore, this system can judge whether the current position is legal installation location by comparing with the information in the position server.

ABSTRACT: A numerical study was undertaken to investigate the mechanical properties of metal-ceramic nanolayered composites. We utilized Aluminum (Al)/Silicon Carbide (SiC) alternating layers with same thickness as a model system. Finite element modeling was employed to analyze the microcompression behavior on pillars which consist 41 Al/SiC multilayers. It deformed in a non-uniform way under compression, especially when a tapered side wall included in the numerical model. Then elastic modulus was obtained from stress-strain curve and compared with previously calculated modulus value of the composite. It was found that the base material connected to the pillar plays a significant role in the measured mechanical response. The simulation result were also used to rationalize some of the experimental observations.

1 INTRODUCTION

Nanomaterials are called “the future of materials”. Nanotechnology is an emerging and rapidly growing field. Many of the devices and systems used in modern industry are already in the nano-scale domain. Nanomaterials may possess advantages of extremely high strength, fatigue resistance, thermal resistance, wear resistance and bio-compatibility, compared with traditional material. Nanomaterials are finding applications in area spanning from structural coatings to microelectronics. Synthetic and natural composite laminates have been shown to exhibit a combination of excellent strength and toughness (D.R. Lesuer, 1996). Composite laminates on the nano-scale with unique properties have been developed. These composites have been investigated in many different layered combinations: Metal-metal composites, metal-ceramic composites, and ceramic-ceramic composites. Metal-ceramic nanolaminate systems can exhibit a combination of high strength, high toughness, damage tolerance, as well as their potential applications in functional devices (T.C. Chou, 1992 & C.H. Liu, 1996).

Indentation technique has become the most popular approach to characterize the mechanical properties of nanomaterial. While in the past years, a new technique of microcompression on

free standing pillar-shaped materials was developed to investigate the mechanical behavior at the micro- and nano-scale (K.S. Ng, 2008; S.X. Song, 2009 & D. Kiener, 2008). The pillar samples with the size of a few hundred nanometers to several micrometers are prepared by Focused Ion Beam (FIB) milling. The compression tests are conducted using a modified nanoindentation device with a flat-punch indenter tip. The flat-punch indenter is usually produced by truncating the tip of a Berkovich indenter. The pillar is always attached to a base material (the original substrate). In order to avoid the buckling which usually happens when compressing on a thin and long pillar, a technique of tensile tests rather than compression on the pillar sample has also been developed. In most of the cases, the samples are cylindrical, although other type of pillar like a square cross section, does exist.

In this paper, a numerical model was constructed to simulate compression tests on the multilayered composite pillars. The experimental part of work has been performed by scientists at Arizona State University and the detail has been published in *Acta Materialia* (D.R.P. Singh, 2010). Nano-indentation simulations on the same structure (Al₁₅₀/SiC₅₀ nanolaminates) have been investigated in the past by our authors (G. Tang, 2009; 2008 & 2010). The effective elastic modulus along perpendicular direction to the multilayer is found

to be 117 GPa, which will be used as a guidance in this article.

2 MODEL

Microcompression can be treated as a special form of “indentation” test, where a flat-bottom indenter is used to press onto a rod-like specimen prepared by FIB-milling, shown schematically in Figure 1 (a). Two dimensional axisymmetric models were constructed for the analysis of the compression tests. Figure 1 (b) shows the schematics of a pillar consists 41-layer Al/SiC (same thickness) on

(a)

(b)

Figure 1. (a) Schematic showing microcompression on a pillar with base (b) Numerical model of the Al/SiC multilayer pillar on a Si base.

Si base; the compression axis is perpendicular to the layer directions. The geometry of the model is defined by the pillar height h , pillar cross section radius r (or cross section diameter d), base height H and base width W . The aspect ratio of the pillar is defined as the ratio of pillar height over pillar cross section diameter (h/d).

3 RESULTS AND DISCUSSION

3.1 Elastic modulus of the multilayer composite pillar

The stress-strain curve and apparent Young’s modulus can be directly obtained from the finite element analysis. Table 1 lists the simulated Young’s modulus for the model. The apparent modulus is 77 GPa, much below the true modulus value for the Al/SiC multilayers of 117 (GPa G. Tang, 2009). This is attributed to the compliance of the Si base and diamond indenter. The corrected pillar modulus can be obtained by subtracting the axial strains of the indenter and/or base from the total axial strain. Simulation shows that the contribution of the Si base is very significant and that of the indenter is moderate. When the compliances of both are accounted for, the true Al/SiC composite modulus of 117 GPa can be recovered. This finding suggests the importance of correcting the raw data by accounting for the base and “machine” deformation when conducting experimental studies.

We now focus on the stress-strain curves when the deformation is sufficiently large to cause significant plastic yielding. During deformation, the cross section area changes in a non-uniform manner. Here we use the cross section area in the middle of the pillar for calculating the stress. The stress-strain curve of the pillar structure, together with the stress-strain curve of the true composite, are plotted in Figure 2. The stress-strain curve of the true composite is plotted using the data from previous work (G. Tang, 2009; 2008 & 2010). The stress-strain curve of multilayer pillar is significantly below the curve of the true composite. One reason could be the compliance of the indenter and the base. At the nominal strain, the actual strain of

Table 1. Young’s modulus of multilayered pillar.

Setting	Modulus (GPa)
FEM-with no correction	77.2
FEM-diamond compliance correction	80.7
FEM-Si compliance correction	110.0
FEM-diamond & Si compliance correction	117.3
True E_{22} of Al50SiC50 composite	117

the pillar itself is smaller than the nominal strain, so the stress is much lower than the stress of the true composite. Another reason could be the extrusion of the Al layer under compression which will be discussed in section 3.3.

3.2 Elastic modulus of the multilayer composite pillar with taper

In experiments, the pillar is produced by FIB milling. It is difficult to achieve a true vertical side wall from the process, so there is always an angle. To examine how this imperfect geometry may influence the test result, we constructed one set of models of the 41-layer pillar on a Si base with different taper angles of 1°, 2° and 4°. For comparison purposes, we also constructed another set of models of pure Al pillar on an Al base, with the same taper angles of 1°, 2° and 4°. For each model, we have conducted the compression simulation with a displacement up to 0.3 μm. The stress-strain curves of each model, together with the one with no taper, are plotted in Figure 3. When the strain is relatively

Figure 2. Stress strain curves of multilayer pillar model and true composite.

Figure 3. Stress strain curves of multilayer pillar with taper angle of 1°, 2° and 4°.

small, all the curves are very close to one another. When the strain is large enough, the curves with taper are all below the curve of the non-tapered model. The difference increases with an increasing taper angle. For practical purpose, the effect may be ignored if taper angle is within 1–2°.

The Young’s modulus of all the multilayer pillar models with different taper angles are calculated and listed in Table 2. The values in the left column are those obtained directly from finite element analysis, while the ones in the right column are the ones with the compliance correction of diamond and Si following the same approach as in the previous section. One can see that the taper does not have any significant effect on the modulus values.

3.3 Stress and deformation evolutions

Before examining the stress evolution of the multilayer pillar model, we first present the simulation results on the pure Al pillar with an Al base. Figure 4 (a) and (b) shows the equivalent plastic strain contours of the pure Al pillar with no taper, at the compression displacement of 100 nm and 325 nm respectively. Figure 4 (c) and (d) shows the equivalent plastic strain contours of the pure Al pillar with a 2° taper angle at 100 nm and 325 nm compression depths, respectively. The deformations for the tapered and non-tapered model are quite similar, with the deformation of the tapered model being a little stronger.

Figure 5 (a) and (b) show the Von Mises stress contours of the multilayer pillar, with no taper, at compression depths of 100 nm and 325 nm, respectively. It is evident that the Al layers deformed much more than the SiC layers. At greater depths, a significant portion of the soft Al layers was extruded out from the side. This extrusion of Al layer could be the reason that the stress-strain curve of the multilayer pillar is below the curve of true composite. When Al extruded out the overall stress will become smaller than the theoretical stress. Figure 5 (c) and (d) show the Von Mises stress contours of the multilayer pillar model with 2° taper angle at compression depths of 100 nm and 325 nm, respectively. The Al layer deformed much more than SiC layers. It is interesting to observe that, with only a small taper angle,

Table 2. Young’s modulus of multilayered pillar with taper.

Setting	FEM (GPa)	FEM-diamond & Si compliance correction (GPa)
No taper	77.2	117.0
1°	77.0	115.6
2°	76.8	115.4
4°	76.1	114.7

Figure 4. Equivalent plastic strain of the pure Al pillar (a) no taper at compression depth of 100 nm (b) no taper at 325 nm (c) taper angle of 2° at compression depth of 100 nm (d) taper angle of 2° at 325 nm.

the several Al layers near the top have undergone severe squeezing and were extruded much further out compared to the lower Al layers. It is worth pointing out that, in the case of a pure Al pillar, such type of deformation was not observed even with taper. The uneven extrusion of Al is caused by the multilayer arrangement.

3.4 Comparison with experiments

We now focus on the deformed configuration of the Al/SiC multilayer pillar. Figure 6 (a) and (b) show the experimental SEM pictures of the pillar before and after, respectively, the compression tests. The 2° taper can be seen in the as-processed specimen. Figure 6 (b) shows a dramatic view that the upper half of the pillar has been crushed, while the lower half remains relatively intact. Although the experimental picture at smaller displacement is not available, the severe localization of deformation in the upper portion can still be correlated with the simulated result in Figure 5 (d). This comparison, along with the other geometric features studied in the previous sections, serves to illustrate the versatility of applying finite element

Figure 5. Von Mises stress contours of the Al/SiC multilayer pillar on a Si base (a) no taper at compression depth of 100 nm (b) no taper at 325 nm (c) taper angle of 2° at compression depth of 100 nm (d) taper angle of 2° at 325 nm.

modeling in studying the mechanical behavior of nano- and micro-scale materials.

4 CONCLUSIONS

A numerical study has been carried out on micro-compression of metal/ceramic multilayered pillars. The modulus obtained from simulation is compared with the true value of elastic modulus of the layered structure. Results from the compression tests on the micro-pillar structure showed a strong dependence on the specimen geometry. It is essential to correct the raw data by taking into account the compliance of the pillar base and the machine. In the case of Al/SiC multilayered pillar, a small

degree of taper gives rise to severe extrusion of the Al layers out of the side boundary in the top portion of the pillar, leading to a highly non-uniform deformation configuration not seen in pillars made out of a homogeneous material. The simulated deformed contour plots serve well to rationalized deformation observed during experiments. Also the modulus value obtained from current work is found to be consistent with that of previous nano-indentation simulation. Thus microcompression, as another approach to characterize mechanical properties of nanomaterial, can be as important as nano-indentation.

A neighborhood search algorithm for the unrelated parallel machine scheduling problem

Y. Zhan & Y.G. Zhong

School of Mechanical and Electrical Engineering, Harbin Engineering University, China

ABSTRACT: In this paper, the unrelated parallel machine scheduling problem with machine eligibility restrictions is studied with the objective of minimizing the maximum makespan. A new neighborhood search algorithm is proposed to find a near optimal solution, which is based on insertion and swap moves. An efficient method is developed to find a feasible swap move. We present computational results for a set of randomly generated instances. The results show that the proposed algorithm outperforms simple heuristics with respect to solution quality.

1 INTRODUCTION

Neighborhood Search is an important local search method that defines and explores neighborhoods to find a near-optimal solution. It can find high-quality solutions in the practical computation time in the cases where exact algorithms fail to return a solution. Therefore, it has been applied to a wide variety of NP-hard problems.

Parallel machines scheduling problem with machine eligibility restrictions is a well-known NP-hard optimization problem. Therefore, most algorithms are developed only for restricted versions of this problem. Ebenlendr et al. (2008) develop a 1.75-approximation algorithm for the problem where each job can be assigned to at most two machines. Lin and Liao (2008) proposed an exact algorithm for the situation, where machines and jobs can be classified into two levels: high and low levels. Some useful properties inherent in the problem are used in their algorithm, such as the impact of the number of high-level machines on solutions.

For general problems with machine eligibility restrictions, some two-phase algorithms are developed. Salem and Armacost (2002) presented a two-phase algorithm for the unrelated parallel machines scheduling problem. In phase 1, constructive heuristics are used to build an initial solution, followed by an improvement heuristic to improve the initial solution in phase 2. Eliyi et al. (2009) dealt with the problem with time windows and eligibility constraints. They developed a constraint-graph-based construction algorithm for generating near-optimal solutions and then used a genetic algorithm to enhance the near-optimal solutions. For more detailed information about parallel machines scheduling problem with machine eligibility restrictions,

the reader is referred to the survey papers Leung and Li (2008) and Liao and Sheen (2008).

The purpose of this paper is to develop a new neighborhood search algorithm for the studied problem. The remainder of this paper is organized as follows. In Section 2, we give the formal introduction of the studied problem. The proposed neighborhood search algorithm is presented in Section 3. In Sections 4 and 5, we present the computational results and conclusion, respectively.

2 PROBLEM DEFINITION

The problem considered in this paper can be formally described as follows: a set $J = \{J_1, J_2, \dots, J_n\}$ of n independent jobs are scheduled on m identical parallel machines $M = \{M_1, M_2, \dots, M_m\}$. Each job has to be processed by exactly one machine. The processing time of job J_i is denoted by T_i . In identical parallel machine scheduling problem, each job has the same processing time regardless of the machine to which it is assigned. Machine eligibility restrictions are considered in this paper. That is, not all of the m parallel machines are capable of processing each job. For each job, it is eligible to be processed on certain machines only.

We select the minimization of the maximum completion time or makespan (C_{max}) as the optimization criterion. The makespan is determined by the maximum workload among parallel machines, where the workload of a machine is the sum of processing times of all jobs assigned to it. The goal of schedule is to distribute workload among parallel machines as equally as possible so as to minimize the makespan. According to the three-field classification scheme, the scheduling problem studied in this paper can be denoted by $P_m/M/C_{max}$.

There are many real problems that can be modeled as the $P_m/M_j/C_{max}$ problems, especially the production systems where one or more stages have several machines in parallel. Our research is motivated by some real-world scheduling problems arising in the shipbuilding company, where a fixed-position layout is used. The product is too large to move and requires machines and staff to bring it.

The following notations and definitions are used to define the studied problem.

Adjacency matrix $A_{n \times m}$: the machine eligibility restrictions can be represented by an adjacency matrix $A_{n \times m}$, where entry A_{ij} in row i and column j is:

$$A_{ij} = \begin{cases} 1 & \text{if job } J_i \text{ can be processed by machine } M_j \\ 0 & \text{otherwise} \end{cases}$$

C_j : the makespan of machine M_j .

C_{max} : the makespan of a feasible schedule.

x_{ij} : a binary variable which takes value 1 if J_i is assigned to M_j and 0 otherwise.

A straightforward Mixed Integer Linear Programming (MILP) formulation for the studied problem is as follows:

$$\min C_{max} \quad (1)$$

such that

$$C_{max} \geq C_j \quad \forall_j \quad (2)$$

$$C_j = \sum_{i=1}^n x_{ij} T_i A_{ij} \quad \forall_j \quad (3)$$

$$\sum_{j=1}^m x_{ij} A_{ij} = 1 \quad \forall_i \quad (4)$$

$$x_{ij} \in \{0,1\} \quad \forall_{i,j} \quad (5)$$

In the formulation described above, Equation (1) is the objective function. It concerns the minimization of the maximum completion time on the parallel machines. Equation (2) defines the maximum completion time, which is obviously as large as all completion times on each machine. Equation (3) is used to compute the completion time on each machine for a given schedule. Equation (4) indicates that each job is scheduled only once on an eligible machine. Finally, equation (5) indicates that x_{ij} is a binary variable.

3 NEIGHBORHOOD SEARCH ALGORITHM FOR $P_m/M_j/C_{MAX}$ PROBLEM

In this section, we will describe four neighborhood structures: (Insert(i, j), Swap(i, j), Insert(num), and

Swap(num)). And we proposed the neighborhood search algorithm for the $P_m/M_j/C_{max}$ problem.

3.1 Solution representation and initial solution

The studied problem includes one decision of assignment of jobs to machines. To represent a solution, we use the job-based encoding scheme. In the case of n different jobs, the schedule S is encoded into a string of digits. The length of the string is equal to the total number of jobs. The index of each digit represents the index of each job. The value of each digit represents the index of a machine used to process the job. Consider a problem with four jobs and three machines. Let $S = \{1, 3, 2, 2\}$ be a feasible solution. The decoding of S results in the following assignment: J_1 will be processed on M_1 , J_2 on M_3 , and the remaining two jobs on M_2 .

The initial solution construction problem includes two decisions of job sequencing and machine selection. Job sequencing determines the arrangement of the jobs that is to be assigned. Machine selection finds which machine is used to process a given job.

In the process of building an initial solution, the order of jobs for assignment is determined by job sequencing at first; then, jobs are assigned in this order to machines determined by machine selection. Job sequencing is the major module of the initial solution construction algorithm. The heuristic is used in job sequencing, which is described below.

Shortest processing time first: select the currently available job with the shortest processing time to be processed first.

For machine selection, a greedy heuristic is used in this paper. For a given job, the eligible machine with the minimum workload is selected.

The initial solution construction algorithm is described as follows:

Input: J, M, T, A .

Output: initial solution S_i

Step 1: unfinished job set $J_w \leftarrow J, (S)_n \times m \leftarrow 0$.

Step 2: if $J_w = \Phi$, output F_j ; otherwise, select a job J_x from J_w based on Shortest Processing First rule.

Step 3: select a machine M_y in U_x with the minimum workload.

Step 4: $(S)_{x,y} \leftarrow 1$.

Step 5: delete J_x from J_w , go to Step 2.

3.2 Neighborhood structure

The initial solution may be highly unbalanced. The following four neighborhood structures are used for searching a more balanced solution.

1. Insert(i, j): Select a job J_j randomly and then select a machine M_j on which J_i is not scheduled.

From the definition of $\text{Insert}(i, j)$, we know that given a schedule S , its insertion neighborhood consists of all schedules that can be obtained by removing a job from the current machine in S and re-assigning it to another eligible machine.

2. $\text{Swap}(i, j)$: Select two jobs, J_i and J_j , and then interchange the machine assignments of J_i and J_j .

From the definition of $\text{Swap}(i, j)$, we know that given a schedule S , its swap neighborhood consists of all schedules that can be obtained by interchanging the assigned machines of J_i and J_j in S .

To avoid generating duplicates, J_i and J_j should be scheduled on different machines. Whether or not two jobs belong to two different machines, this can be represented by a undirected graph $G(V, E)$, where:

$V = \{V_1, V_2, \dots, V_n\}$ is a set of vertices, which corresponds to the set of jobs. For example, V_i corresponds to job J_i .

E is the set of edges, which indicates that two jobs connected by an edge belong to two different machines.

On the basis of $G(V, E)$, we just need to select an edge in G randomly to generate a swap neighbor.

3. $\text{Insert}(\text{num})$: Perform independent $\text{Insert}(i, j)$ num times simultaneously.

4. $\text{Swap}(\text{num})$: Perform independent $\text{Swap}(i, j)$ num times simultaneously.

We now present a neighborhood search algorithm for the studied problem.

Input: initial solution S_i

Output: near optimal solution S_o

Step 1. $S_c \leftarrow S_i$, counter $\leftarrow 0$, input the value of maxIter and the value of maxCounter .

Step 2. While(counter < maxCounter) do

 Nei: Select a neighborhood structure randomly and generate a neighbor S_n of S_i .

 If S_n is better than S_o , then $S_o \leftarrow S_n$, counter $\leftarrow 0$. Otherwise, counter \leftarrow counter+1.

Step 3. Iter \leftarrow Iter+1. If (Iter > maxIter), output S_o . Otherwise, counter $\leftarrow 0$, $S_i \leftarrow S_o$, goto Step 2.

4 COMPUTATIONAL RESULTS

The neighborhood search algorithm presented in this paper is coded in Visual Studio 2010 C# and implemented on an i7@2.60GHz personal computer with 4G memory. The Central Processing Unit (CPU) time limit is set to 10 min.

The factors considered in this experiment are the number of jobs, the number of machines, the eligible machine set for each job, the processing time of each job, and the initial solution construction heuristics used in phase 1. The details of the above factors are as follows:

Table 1. Results of computational experiments.

m	n	T_s	S_i	S_o
2	10	10.18	268	253
2	20	98.39	652	608
4	10	100.04	188	154
4	20	489.63	224	217
6	10	326.34	126	99
6	20	517.11	227	192
8	10	458.31	121	91
8	20	598.74	184	156

1. Number of jobs (n): 10, 20.

2. Number of machines (m): 2, 4, 6, 8.

3. The machine eligibility restrictions are important factors in the studied problem, which have a strong impact on CPU time required to search the optimal solution. Obviously, CPU time will increase as the size of the eligible machine set increases, as the size of alternating search tree is much larger in this case. In order to evaluate the efficiency of the improvement algorithm in the worst cases, we consider the most difficult situation that every machine is eligible for every job.

4. The processing time of each job is uniformly distributed in the interval [50, 100].

Table 1 reports the average results of the computational experiments on 10 runs for each instance. T_s is the CPU time used by the proposed neighborhood search algorithm, which is in seconds.

As can be seen from Table 1, in each instance, the quality of S_o is better than that of S_i . Meanwhile, the solution times increase considerably with an increase in the number of jobs and the number of machines. In the worst case, the proposed algorithm can handle 8×20 size problem in reasonable time, which is less than 10 min.

5 CONCLUSIONS

In this study, the scheduling problem of minimizing the makespan on parallel machines with eligibility restrictions is studied. We developed a neighborhood search algorithm to find a near-optimal solution. A computational experiment is designed for evaluating the performance of the proposed algorithm. The results reveal that it can handle 8×20 size problem in reasonable time, which is less than 10 min.

A novel medical image enhancement algorithm based on ridgelet transform

Yunfeng Yang & Yuewen Yang

School of Mathematics and Statistics, Northeast Petroleum University, Daqing, China

ABSTRACT: A new medical image enhancement method based on ridgelet transform was proposed in this paper. Medical images enhancement is important in the clinical medicine. And the key work of enhancement methods based on ridgelet transform is how to enhance coefficients of ridgelet transform. The multiwavelet transform is used after the Radon transform in the process of ridgelet transform, and these multiwavelet coefficients are enhanced with weight factors. In order to reduce the effects of noise, the soft threshold method was selected to de-noise the coefficients of ridgelet transform. The piece wise histogram transform was used to stretch the range of gray level of the enhanced image for getting abundant gray levels. Experiments have shown that the method can not only enhance an image's details, but also hold the image's edge features effectively.

1 INTRODUCTION

With the development of information technology, medical images have been applied in the clinical medicine successfully. Medical images can provide more visual information about the disease in the clinical medicine. However, the quality of medical images are not high enough to use directly due to many reasons, such as low contrast and noise. Therefore, medical image enhancement technology is very important for clinical medicine. In addition, enhanced images can also be effective for the registration and segmentation of medical images and so on.

Wavelet transform has been widely used in image processing fields for that it is an effective time-frequency analysis tool developed in the 1980s. There are many medical image enhancement methods based on wavelet transform (Y. Yang et al. 2010, Bhutada 2011). After the wavelet transform, the ridgelet transform is another important tool for multiscale analysis (Candes et al. 1998, Candes et al. 1999). It mainly includes two procedures: Radon transform and Wavelet Transform (WT). The ridgelet transform has been widely used in the field of image processing (Jiang Yuan et al. 2016, Deng Chengzhi et al. 2009). It is also widely used to enhance image quality (Li Hongbing et al. 2011, Qiu Ju et al. 2009).

Ridgelet transform is an effective processing method for an image. However there is also some high-frequency information hidden in high-frequency sub-images after wavelet transform of the image. Better enhancement results can be

obtained if the information of high frequency is used effectively. On the basis of this thought, an improved enhancement method of a medical image based on ridgelet transform was proposed in this paper, in which multiwavelet transform is selected to replace wavelet transform after Radon transform.

2 MEDICAL IMAGE ENHANCEMENT BASED ON NEW RIDGELET TRANSFORM (NRT)

Ridgelet transform is a new representation method of an image, which mainly includes two procedures: Radon transform and Wavelet Transform (WT), as shown in Formulas (1) and (2). In this paper, the improvement of ridgelet transform is proposed for image enhancement:

$$R_f(\theta, t) = \int_{R^2} f(x) \delta(x_1 \cos(\theta) + x_2 \sin(\theta) - t) dx, \quad (1)$$

where $\theta \in [0, 2\pi]$, $t \in R$ and δ is the Dirac function.

$$CRT_f(a, b, \theta) = \int_R \psi_{a,b}(t) R_f(\theta, t) dt, \quad (2)$$

where $\psi(x)$ is the wavelet function.

The proposed enhancement method based on ridgelet transform is described in Fig. 1. It mainly includes Radon transform, multiwavelet transform, enhancement of coefficients of ridgelet transform, inverse multiwavelet transform, inverse Radon transform, and histogram transform.

2.1 Improved ridgelet transform

The ridgelet transform proposed by Donoho is shown in Formulas (1) and (2). In this part, according to formula (2), the multiwavelet transform is provided to replace the wavelet after Radon transform. More high-frequency information can be obtained through multiwavelet transform. These more detail information can be used to enhance the features of an image. In order to watch clearly, the procedure of multiwavelet transform of an image is shown in Figures 2 and 3.

2.2 Copying old text onto a new file and enhancement of ridgelet coefficients

In this part, the coefficients of ridgelet transform are de-noised by soft threshold method initially. After this, the coefficients are enhanced by enhancement factor shown in Formula (3):

$$CRT_f(a,b,\theta) = \omega_i CRT_f(a,b,\theta), \tag{3}$$

where ω_i , ($i = 1,2$) denotes enhancement factor action on the coefficients of multiwavelet transform.

$$T_f(x,y) = \begin{cases} f(x,y)M/N, & f(x,y) \in [0, N] \\ \frac{(f(x,y) - N)(255 - 2M)}{(f_{\max} - 2N)} + M, & f(x,y) \in [N, f_{\max} - N] \\ \frac{(f(x,y) - f_{\max} + N)M}{N} + 255 - M, & f(x,y) \in [f_{\max} - N, f_{\max}] \end{cases}, \tag{4}$$

where $f(x,y)$ denotes the pixel of reconstructed image at position (x,y) , f_{\max} is the max value of the pixels, $M \in [0,255]$, and $N \in [0, f_{\max}]$.

2.3 Histogram transform

The inverse multiwavelet transform and inverse Radon transform are executed on the basis of the

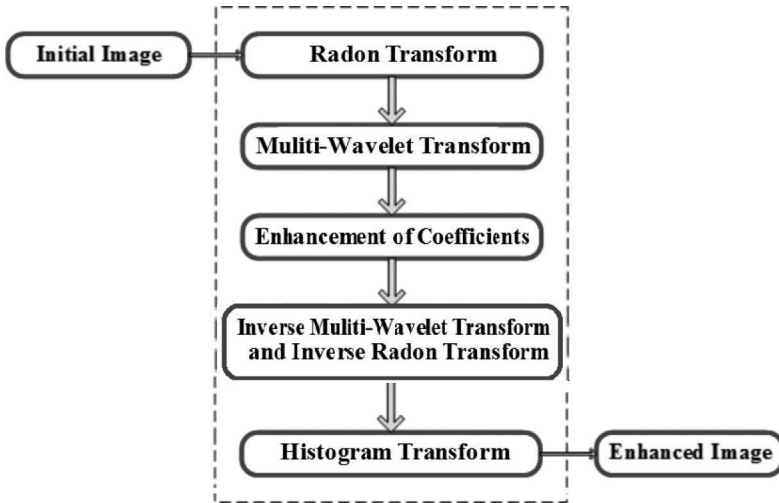

Figure 1. Enhancement procedure based on ridgelet transform.

Figure 2. Multiwavelet transform of 2-D signal.

enhanced coefficients of ridgelet transform. So far, the reconstruction of the image is accomplished. However, gray level of the reconstructed image may be lower, which could result in a darker image. In order to change the problem, the piecewise histogram transform shown in Formula (4) is taken to obtain the more abundant information of an image's gray level.

3 EXPERIMENTS

In the experiments, we selected $M = \frac{255}{3}$, $N = \frac{f_{\max}}{4}$, $\omega_1 = 1.5$, and $\omega_2 = 1.8$. The results of experiments based on the proposed enhancement method are shown in Figures 4 and 5, where panels (a) show the initial image, (b) show the

Fig. 5(c)	Enhancement by NRT	52.31

enhancement result by wavelet transform, and (c) show the enhancement result by ridgelet transform proposed in the paper. The PSNR is shown in Table 1.

4 CONCLUSIONS

An important problem of medical image enhancement is how to use the coefficient of ridgelet transform effectively. In this paper, the two key steps are selected in the procedure of medical image enhancement. First, the multiwavelet transform is selected to replace wavelet transform after Radon transform. Second, different weights act on the ridgelet coefficients, that is, the weight factor ω_1 of enhancement is used to enhance the coefficients of multiwavelet transform, and the weight factor ω_2 is used to enhance the coefficients of obtained by inverse multiwavelet transform. Those techniques help acquire better enhancement results. Experiment results showed that better enhanced images could be obtained using the proposed method.

Significance of deep learning on big data analytics

Jilei Mao

Wuhan University of Technology, Hubei Province, China

Zijun Mao

Capital University of Economics and Business, China

ABSTRACT: Deep learning and big data analytics are two high foci of data science. With the huge volumes of data available today, big data brings us more opportunities and transformative potential; it also brings unprecedented challenges to address data and information. The data are too large to be analyzed using the traditional technology. Therefore, deep learning algorithm is becoming an important department in providing big data analytics a new way to get predictive analytics solutions. Deep learning gives us an important opportunity for completing neural network algorithms and models to deal with analytics problems related to big data compared with the traditional technology used to deal with data analytics problems.

1 INTRODUCTION

In the rapidly growing digital world, there are two hottest study trends: deep learning and big data. The concept, application, and relationship between big data and deep learning will be mainly introduced in this paper.

Big data refers to the digital data with the sheer growth and wide availability and is difficult or even impossible to be addressed and analyzed by traditional data analytics tools and technologies. The shapes and the size of data are growing at an astonishing rate.

While big data offers a great potential for revolutionizing all aspects of our society, getting useful information from big data is challenging. It requires the development of advanced technologies, and the work form virtuous tends experts working in close cooperation to get the large and rapidly growing size of information hidden in the astonishing volume of digital data.

As the size of data is becoming larger, deep learning is becoming an important department in providing big data predictive analytics solutions, particularly with the increased processing power and advances in graphics processors. Deep learning algorithm makes a better job of potentially providing a solution to solve the data analytics and learning problem found in massive volume of input data compared with another machine learning and feature engineering algorithms. More specifically, it aids in automatically extracting complex data representations from large volumes of unsupervised data. These features make deep learning a useful

tool for the big data analytics of the data that are considered generally unsupervised and uncategorized. The multi-tier learning model and extraction of different complex levels and data abstractions in deep learning provide a certain degree of simplification for big data analytics tasks, especially for analyzing large volumes of data, semantic indexing, data tagging, and discriminative tasks such classification and prediction.

2 DEEP LEARNING ALGORITHM

The field of machine learning has made great progress especially in the algorithm. And we call it deep learning algorithm. In this part, a brief introduction about deep learning algorithm is given.

The deep learning algorithms are mostly influenced by the study about artificial intelligence, with the aim of emulating the human brain's ability to learn, analyze, observe, and make decisions, especially for complex problems related to large volumes of data. Work related to these complex challenges has been a key motivation behind deep learning algorithms, which strive to emulate the hierarchical learning approach of the human brain.

Deep learning algorithm is a learning model composed of multilayer neural networks, as shown in Figure 1. Neural network is a learning model consists of many logical units, which is organized in different levels. And the output of the first layer is the input variable of the next layer. The first layer is called the input layer, the last layer is called

Figure 1. Three layers of neural network.

the output layer, and the middle layer is the hidden layer.

We can make a simple summary: Deep architecture of consecutive layers is the main idea of deep learning algorithm. A nonlinear transformation is set in the input of each layer, which provides processed data in its output.

The target of the algorithm is to learn a complex and abstract representation of the data in a hierarchical manner by passing the data through multiple transformation layers. The sensory data (such as an image) is fed to the first layer. The input layer transforms the features into another field, and the output features are the input of the next layer. The features of the data are transformed and passed by layers to learn and set the model of the data. Therefore, the concept of deep learning can be defined combined with data processing.

Deep learning is an algorithm that can learn a model from data and use the model to predict the new data. According to this feature, we cannot separate deep learning from data. The essence of learning is to build a machine learning model with several hidden layers and use large volumes of training data to learn more meaningful features so as to enhance the accuracy of classification or prediction. Therefore, “deep model” is a path and “feature learning” is the purpose of the algorithm.

Deep learning algorithm has two features: 1) it emphasizes the depth of the model structure, usually with one or two, or more hidden layers (as shown in Figure 2); 2) it highlights the importance of feature learning and transforms the features layer by layer. It transforms the samples features from the original space to a new feature space, thus making it easier to classify or predict.

Compared with the traditional way, deep learning algorithm is more accurate to portray the information inside the data.

3 TYPICAL APPLICATIONS OF DEEP LEARNING

Some basic concepts and principles of deep learning algorithm have been introduced. Examples of application are given in this part.

3.1 *Neural network machine translation system*

Google has released the Neural Machine Translation System (GNMT) recently. The improvement in speed and accuracy brings a better service to the users. The translation quality of English, France, and Spanish has reached about 90%. And the translation quality between Chinese and English can also reach 80%.

Figure 3 shows the scores of human translation, Neural Machine Translation System, and Phrase-based Machine Translation System, where 0 represents “totally meaningless translation” and 6 represents “perfect translation”. Neural network Machine Translation System has a higher score than Phrase-based Machine Translation clearly.

3.2 *Mechanical arm*

Deep learning can teach robots how to use the robot arm to complete a task. Traditional mechanical arm, which is programmed by a programmer, cannot be seriously disturbed; otherwise, it cannot grasp the target accurately. Deep learning algorithm can perform much better than the traditional algorithm. Deep learning algorithm can train the mechanical arm to pick the object up. If failed in the first time, then re-learn and try again until the task is finished. Deep learning increases the ability of the robots to learn how to finish the task.

Figure 2. Neural network with two hidden layers.

Figure 3. Translation model.

3.3 AlphaGo

In March 2016, AlphaGo won the world championship. Deep learning algorithm played a key role in this game.

In go game, each move has more than 300 types, and every chess has 200 steps on average. This question cannot be resolved in the traditional way. Deep learning algorithm can make machines have human intuition and predict the next step that the opponent will analyze, making the best decision. The deep learning algorithm is the reason for the success of AlphaGo.

3.4 Face recognition

By using deep learning algorithm in face recognition, more information can be obtained, such as the location of the face in the picture, name, gender, age, and facial expression of the person. The algorithm can even analyze the movement of the lips to know what people say. The speed and accuracy have been greatly improved compared with the technology before, such as support vector machines.

4 BIG DATA

Big data refers to the data with size beyond the traditional database system processing power. It requires high transfer speed. Its structure is not suitable for the original database system. This definition is intentionally subjective and incorporates a moving definition of how big a data set needs to be in order to be considered big data—the big data cannot be defined in terms of being larger than a certain number of terabytes (thousands of gigabytes). As technology advances over time, the data

Figure 4. Global information created and storage.

sets that qualify as big data will also increase (as shown in Figure 4). The size of data in our world has been exploding. As an all-encompassing term, big data has a very vague definition. The input list of the big data is long, including the social network, satellite images, broadcast audio streams, bank transactions, rock music MP3, Web page content, government file scanning, GPS route, and financial market data. These data are not the same thing, and data sources are abundant.

5 CONCLUSIONS

Deep learning algorithm is mostly influenced by the study of artificial intelligence, which is aimed to emulate the human brain's ability by science analytics. It is a learning model composed of multilayer neural networks. Big data refers to the data whose size is beyond the traditional database system processing power.

As the data keep getting bigger, deep learning is coming to play a key role in providing big data predictive analytics solutions, particularly with the increased processing power and the advances in graphics processors. Compared with the traditional way, the deep learning algorithm is more accurate to portray the information inside the data and provide a solution to solve the data analysis and learning problems found in massive volumes of input data. The study about deep learning and big data is very important and significant and requires more attention from all fields. More efforts are necessarily taken to further apply deep learning to the problems associated with big data.

Branch pipe routing method based on a 3D network and improved genetic algorithm

Yaxiao Niu, Wentie Niu & Weiguo Gao

Key Laboratory of Mechanism Theory and Equipment Design of the State Education Ministry, Tianjin University, Tianjin, China

ABSTRACT: Pipe routing plays an important role in many industries, especially for the ship building design. In this paper, a rectilinear branch pipe routing method for automatic generation of the optimal branch pipe routes based on a 3D network and improved Genetic Algorithm (GA) for ships is proposed. By extending the 2D escape graph, a 3D network graph is constructed first. It can model the 3D constrained layout space and reduce the storage space effectively. Then, an improved genetic algorithm is employed to solve the rectilinear branch pipe routing optimization problem on the basis of the network graph. Fixed-length coding method, one-point crossover, and location mutation are adopted to improve the computational efficiency. Finally, a case study of pipe routing for a ship engine room is conducted to validate the performance of the proposed method.

1 INTRODUCTION

Pipe routing plays an important role in many industries, especially for the ship building design. Because of the large space of ship layout and various design constraints, it takes more than 50% of the man-hours in the detailed design phase by using the traditional pipeline design method. Therefore, an automatic pipeline layout approach might offer an attractive way to improve the design efficiency, leading to saving of time and money.

In the past decades, the two-terminal pipe routing problem has been widely studied. However, in practice, more than 70% of pipelines contain at least one branch pipe (Asmara & Nienhuis 2006). To solve the branch pipe routing problem, a series of research (Wu et al. 2008, Jiang et al. 2015, Sui & Niu 2016) has been conducted using a cell-generation method. According to computational geometry, the Steiner Minimal Tree with Obstacles (SMTO) problem can be formulated by constructing a shortest collision-free network interconnecting some given terminals while allowing for addition of auxiliary points called Steiner points (Liu & Wang 2012). By combining the Steiner tree theory with Particle Swarm Optimization (PSO) algorithm, rectilinear branch pipe routing method (Liu & Wang 2011) and nonrectilinear branch pipe routing approach (Liu & Wang 2012) were proposed to automatically generate the branch pipe routes of aero-engines.

In this paper, branch pipe routing method based on 3D network and improved genetic algorithm is

proposed for the rectilinear branch pipe routing problem. First, a 3D network graph is constructed by extending the 2D escape graph. Then, an improved genetic algorithm is employed to solve the rectilinear branch pipe routing optimization problem in the 3D network graph. Finally, a case study of pipe routing for ship engine room is conducted to validate the proposed method.

2 PROBLEM DESCRIPTION

Branch pipe routing problem can be formulated as finding the Rectilinear Steiner Minimal Trees with Obstacles (RSMTO) (Liu & Wang 2012). For the RSMTO problem, one of the important tasks is to construct a reasonable layout space model.

By extending the horizontal and vertical lines from the terminals and the obstacle vertices to any boundary of the design space and obstacles, 2D escape graph can be constructed. For the escape graph, if an instance of the RSMTO problem is solvable, there is an optimal solution composed only of escape segment in the escape graph (Ganley & Cohoon, 1994). The escape graph method is applied to construct the network graph model in the 3D layout space. By extending the 2D escape graph, 3D layout space can be constructed. The detailed steps are as follows:

Step 1. Extend lines from obstacle vertex in X, Y, and Z directions to any boundaries of the design space and obstacles and record the intersection points as vertexes.

Figure 1. Example of 3D network graph.

Step 2. Extend lines from terminal in X, Y, and Z directions to any boundaries of the design space and obstacles and record the intersection points as vertices.

Step 3. Combine all the lines and vertexes into the 3D network graph.

Figure 1 shows an example of 3D network graph with four obstacles and three terminals, in which black points denote the obstacle vertexes, white points denote the intersection points, and gray points denote the pipe terminals.

3 IMPROVED GENETIC ALGORITHM

Genetic algorithm is adopted to deal with the optimization problem for its global characteristic, robustness, and easy implementation. In this paper, the improved genetic algorithm is adopted to determine the number and position of the Steiner points on the 3D network graph. The flow-chart of the improved genetic algorithm is shown in Figure 2.

3.1 Fixed-length encoding

The key problem of solving the Steiner minimal tree for a given graph $G = (V, E)$ with N connection points is to determine the number and positions of the Steiner points. The chromosome coding method of the improved genetic algorithm is presented referring to the PSO coding in the literature (Liu & Wang 2012). Assuming that V is a collection of all the points in the graph G , so $r = (V - N)$ is the collection of all the middle points. A chromosome is randomly generated by the fixed-length encoding method:

$$(Node(1), 0), (Node(2), 1), \dots, (Node(i), 1) \dots (Node(r), 0) \quad (1)$$

where $(Node(2), 1)$ denotes that node 2 is the Steiner point and $(Node(1), 0)$ denotes that node 1 is the potential Steiner point, which may become Steiner point as the system iterates. For N -point connection problem, the number of Steiner points should be less than $(N - 2)$. Hence, the chromosomes that do not meet this requirement should be deleted during the iteration. Figure 3 shows an example of a chromosome code and a Steiner tree on a network graph. As depicted in Figure 3, black points denote the pipe connection points, bold solid lines represent the Steiner tree, and points 4 and 10 denote the Steiner points.

3.2 Genetic operator

3.2.1 One-point crossover

The one-point crossover method is used in the improved genetic algorithm to generate the child chromosome. Take the network graph in Figure 3 as an example. First, randomly select two parent chromosomes P1 and P2 from the population. Then, a random number k ($0 < k < 1$) is generated.

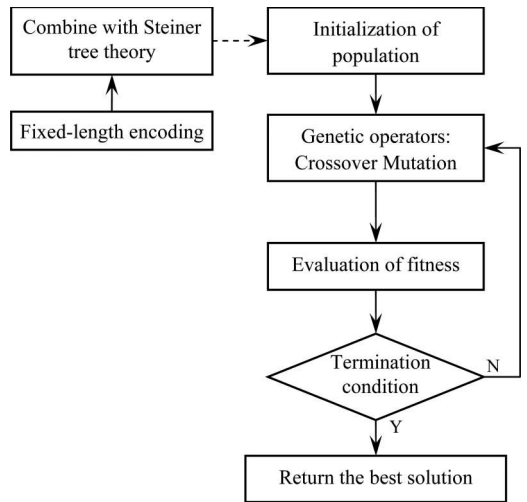

Figure 2. Improved genetic algorithm.

Figure 3. Example of chromosome code and a Steiner tree on a network graph.

Here, if $k \leq p_c$ (p_c denotes the crossover probability), the two parent chromosomes are recombined to produce two new children, as shown in Figure 4. There are four pipe connection points on the network graph, so the number of Steiner points must be less than two. The children with more than two Steiner points would be deleted.

3.2.2 Location mutation

Mutation operation can increase the population diversity and the search space. Location mutation is utilized in the genetic operation. The location mutation method is shown in Figure 5. In location mutation, a chromosome is randomly selected from the population first. Then, a random number k ($0 < k < 1$) is generated. If $k \leq p_m$ (p_m denotes the mutation probability), a random quantity of potential Steiner points are selected and transformed into Steiner points; accordingly, the corresponding quantity of Steiner points are turned

into potential Steiner points. Figure 5 shows the change of Steiner tree after the Steiner point 4 is substituted by point 5. Because the location mutation operation does not change the number of Steiner points, the filtering operation is not needed in the mutation operation.

3.3 Evaluating an individual

Considering practical engineering rules, the pipeline should be away from dangerous equipment, such as the electrical regions or the high temperature-areas, and close to some equipment that are easy to install the supports. To cope with the problems, the concept of potential energy is proposed by Ito (1999). By allocating different potential energy values to the cells around the equipment, different engineering constraints can be satisfied. On the basis of the concept of potential energy, a different value of potential energy

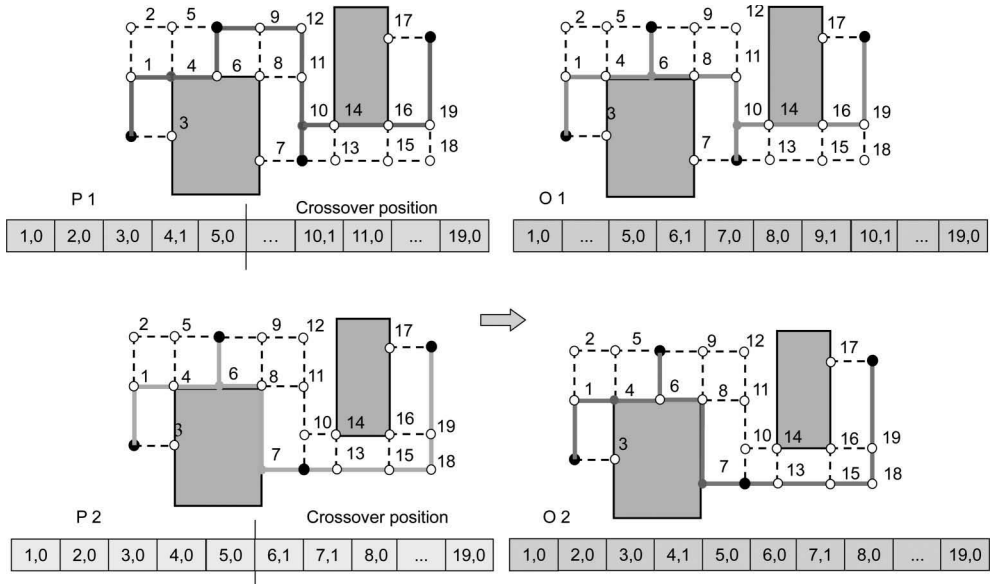

Figure 4. One-point crossover method.

Figure 5. Location mutation method.

(E_p) is assigned to each vertex in the 3D network graph for satisfying three engineering constraints.

A lower potential energy value means that the pipe route is close to equipment that are easy to install the supports, while a higher energy value means that the pipe route is close to the electric regions or high-temperature areas.

For example, as shown in Figure 3, assume that obstacle O1 is the equipment that may generate heat. Then, a potential energy value E_p is appended on the vertexes, which are on the boundary of the obstacle O1, such as vertexes 3, 4, 6, 7, and 8. The generalized length of pipeline segment between two vertexes can be calculated as follows:

$$L'_{seg} = L_{seg} + E_{p1} + E_{p2} \quad (2)$$

where L_{seg} represents the length of the pipeline segment and E_{p1} and E_{p2} denote the potential energies of the two vertexes, respectively.

Another problem that needs to be considered is the number of pipe bends. The pipe routing cost increases with the increase of the number of bends. Considering the potential energy and the number of bends, the fitness function of a chromosome can be formulated as:

$$F = c_1 \times L_g + c_2 \times N_B \times B_{bend} \quad (3)$$

where L_g represents the generalized length of the chromosome, B_{bend} denotes the equivalent length of a bend, N_B denotes the total number of bends

of the chromosome, and c_1 and c_2 denote the weighting factors associated with the objectives, respectively.

According to the aforementioned chromosome coding method and genetic operation, the fast algorithm for Steiner trees (Kou et al. 1989) is used to construct a minimal Steiner tree. The fitness value of a chromosome can be calculated as follows:

Step 1. Construct the point set of the chromosome, including the Steiner points and the connection points. There should be totally $(N + q)$ points in the set, where N is the number of connection points and q is the number of the Steiner points.

Step 2. The fast algorithm for Steiner trees is employed to solve the minimum Steiner tree problem on the network graph for connection of the $(N + q)$ points.

Step 3. According to Eqs. 2 and 3, calculate the Minimum Steiner Tree (MST) length, which is viewed as the fitness of the chromosome.

4 CASE STUDY

An equipment layout of a ship cabin is shown in Figure 6. The main equipment includes two fuel oil storage tanks, two marine main engines, two diesel generators, one steam boiler, one water boiler, and two oil pumps. Two fuel pipes are chosen as examples to validate the proposed method. The design information of these pipes is presented in Table 1.

Figure 6. Equipment and branch pipe layout in a ship cabin.

For pipe 1, the 3D network graph contains 220 points and 800 edges. For pipe 2, the 3D network graph contains 260 points and 1060 edges, in which the routed pipe 1 is regarded as an obstacle. The parameters of the genetic algorithm run were the population size, 60; the number of generation, 100; the crossover ratio, 0.8, and the mutation ratio, 0.1; and the weighting factors $c_1 = 0.5$, $c_2 = 0.5$. As for electrical regions, potential energy value $E_p = 100$ is assigned to diesel generators 1 and 2.

The optimal results of the two pipes are shown in Figure 6. The total length of pipe 1 is 9526 cm, and it contains six bends and three T-joints. The total length of pipe 2 is 8722 cm, and it contains eight bends and three T-joints. In the optimization process of pipe 2, the parallel part of the pipe 1 is set as a shorter generalized pipe length, for the parallel part can share the supports. The convergence curves of two optimal branch pipelines are shown in Figure 7. The convergence generations of two optimal branch pipelines are about 22 and 44, respectively.

Table 1. Information of piping route path and connecting points.

Route path name	Included cabins and equipment with corresponding coordinates of connecting points
Path 1	Fuel oil storage tank 1: (100, 305, 318) Fuel oil storage tank 2: (100, 305, 823) Marine main engine 1: (695, 200, 335) Marine main engine 2: (695, 200, 744) Diesel generator 2: (905, 165, 940)
Path 2	Fuel oil storage tank 1: (100, 305, 280) Fuel oil storage tank 2: (100, 305, 793) Hot water boiler: (795, 115, 70) Steam boiler: (505, 65, 867) Diesel generator 1: (905, 165, 940)

Figure 7. Convergence curves of two optimal branch pipelines.

CONCLUSIONS

In this paper, we presented an improved GA and 3D network-graph-based branch pipe routing approach, which mainly includes layout space construction, coding, fitness function, and specific genetic operation strategy.

A 3D network graph is first constructed by extending the 2D escape graph. Branch pipe routing problem can be formulated as finding the Rectilinear Steiner Minimal Trees with Obstacles. Branch pipes in the layout space are represented by the Steiner points and the connection points included in the chromosome. The fast algorithm for Steiner trees is employed to solve the minimum Steiner tree problem on the network graph for the connection of these points. On the basis of the 3D network graph and potential energy value, design goal and some engineering constraints are modeled. The genetic operator is then devised, in which one-point crossover and location mutation strategy are presented to improve the quality of chromosomes. A case study of a fuel piping system in a ship engine room demonstrates the feasibility and effectiveness of the proposed method.

Future research should focus on more engineering constraints, such as pipe grading, to avoid vibration and ensure the usage security of the pipeline.
