3.3 Motion control function of particles

Particles obey the second Newton law. The motion function of a single DOF is,

$$m \frac{d^2 x(t)}{dt^2} = F(t), t \geq 0 \quad (19)$$

where, m is a constant, $x(t)$ and $F(t)$ are functions of time.

Central difference equation is adopted to solve the function and the acceleration can be described as,

$$\ddot{x} = \frac{d^2 x(t)}{dt^2} = \frac{1}{h^2}(x_{n+1} - 2x_n + x_{n-1}) \quad (20)$$

where, h is the time increment step and is a constant.

The difference equation at time t can be as follows.

$$x_{n+1} = \frac{F^n}{m} h^2 + 2x_n - x_{n-1} \quad (21)$$

Then,

$$\begin{cases} x_{-1} = x_0 - h\dot{x}_0 + \frac{h^2\ddot{x}_0}{2} \\ x_1 = x_0 + h\dot{x}_0 + \frac{h^2 F^0}{2m} \end{cases} \quad (22)$$

After obtaining the value when $n = 1$, the difference equation can be used to solve the function step by step forward and the corresponding displacement of each time step can be achieved.

Figure 3. Schematic view of the virtual particle model of the film.

3.4 Model calculation

The film model is created as shown in Figure 3 by the virtual particle method. The model is composed of nine particles and the lines connecting these points. The size and the thickness of the cell film are $12\text{ mm} \times 12\text{ mm}$ and 0.05 mm , respectively. Since the film is distributed symmetrically, 1/4 of upper right corner of the film is used to calculate the model. Given the film properties for middle density PE material, the elastic modulus $E = 172\text{ N/mm}^2$, poisson ratio $\nu = 0.439$, and the density $\rho = 0.00139\text{ g/mm}^3$. The film is bearing the wind force, windage, and gravity perpendicular to the film surface. The wind speed is given as 0.2 m/s and 0.35 m/s .

3.5 Solving results

The software Matlab is used to program and calculate the function based on virtual particle method. The force bearing vs. displacement variation is shown in Figure 4 for particle 1 while the wind speed is 0.2 m/s . With the increase of the force bearing, the displacement of particle 3 becomes larger and larger. The maximum value is $3.2969 \times 10^4\text{ mm}$.

4 SIMULATION AND EVALUATION

In order to evaluating the above calculated results, the FEM software Ansys Fluent is used to mode and calculate the two-way fluid solid coupling for films. The model is shown in Figure 5 with 2.62 million mesh cells and 2.07 million nodes.

Figure 6 shows the simulation results while the wind speed is 0.2 m/s , which coincides with the

Figure 4. The calculating result of particle 1.

Figure 5. FEM model.

Figure 6. Simulation results.

calculated one and the introduced mathematical modeling method has been evaluated.

5 CONCLUSIONS

1. A novel mathematical calculating method, virtual particle method, has been introduced for modeling the deformations of plastic films.
2. The two-way fluid solid coupling method is used to build the FEM model for plastic films by the software Ansys Fluent. The simulation results coincide with that from the mathematic model.
3. The deformation rules can be solved in the near future based on the proposed method. It will be applied to design optimizations of wind sorting equipments of waste plastic films for enhancing the sorting accuracy.

An experimental study of installing-holes distances parameter optimization for metallic inserts bonded into CFRP laminates

Jing Liu, Hui Zhang & Kun Hou
China Aero-Polytechnology Establishment, China

ABSTRACT: Metallic inserts are one kind of aerospace fasteners, which are usually installed in metallic components by using an interference fit. However, when metallic inserts are installed in the CFRP laminates by using the traditional installing method, delamination and low efficiencies are troublesome. Therefore, excellent quality and cost-effective installing of metallic inserts into the CFRP laminates remains a challenge. In this paper, a series of experiments were carried out to study the installing-holes distances parameter optimization for metallic inserts bonded into CFRP laminates.

1 INTRODUCTION

Being an advanced material, CFRP laminates are characterized by properties such as high specific strength, high specific stiffness, and good corrosion resistance, which have been widely used in manufacturing of aeronautics structure components. Meanwhile, high rigidity and brittleness of CFRP laminates bring about new technical problems and difficulties in assembling (Mccarthy, C. T., & Mccarthy, M. A. 2005). Especially for metallic inserts, the traditional interference fit is not adapted to these new types of materials, which would easily lead to stress concentration and delamination at the fastener hole of the CFRP laminates (Camanho, P. P., Fink, A., Obst, A., & Pimenta, S. 2009). This results in reduced strength against fatigue and compromised structure integrity (Hopkins, M. 2006). Therefore, it is important to develop new techniques to improve the quality and efficiency of mechanically fastened metallic inserts in CFRP laminates (Camanho, P. P., Tavares, C. M. L., Oliveira, R. D., Marques, A. T., & Ferreira, A. J. M. (2005.)) Over the years, some researchers have studied the bonding to fasten the metallic inserts in CFRP laminates, the method of which is considered as a good method to satisfy the joint strength and avoid the assembly defect (Camanho, P. P., & Matthews, F. L. 2000). In this paper, a series of experiments were performed to study the installing-holes distances parameter optimization for metallic inserts bonded in CFRP laminates.

2 EXPERIMENTAL SETUP AND PROCEDURE

2.1 Setup and conditions

The CFRP laminates bonded with metallic inserts are shown in Figure 1 and there are two metallic

inserts in each sample. The test parameters for the experiments are summarized in Table 1. Figure 2(a) shows a computer-controlled electronic universal testing machine, which is used to test the push-out values of metallic inserts installed in the CFRP laminates and mainly consists of a loading spindle, a samples fixture, a worktable, a power supply system, and a computer. The maximum loading and feed speed are 20 kN and 500 mm/min, respectively. Figure 3(a) shows a torsion testing machine, which is used to test the breakaway torque values of metallic inserts installed in the CFRP laminates and these mainly consist of a torsion spindle, a samples fixture, a feed direction worktable, a power supply system, and a computer. The maximum torque and spindle speed are 50 N.m and 500 rpm, respectively.

Table 1. Test parameters for the experiments.

Parameters	Sample
Outer diameter of the metallic insert	Ø3 mm
Material of the metallic insert	Steel
Thickness of the CFRP laminate	5 mm
Adhesives	Epoxy Resin Adhesive
Material of mandrel	A286
Installing-holes distances type	A<B<C<D
Injection pressure	(0/60/80/100)PSI

2.2 Experimental procedure

Four type installing-holes distances samples are prepared to test the push-out and breakaway torque values of metallic inserts bonded into CFRP laminates. Firstly, each sample is prepared to finishing injection pressure for 0/60/80/100PSI. Secondly, the push-out and breakaway torque tests are carried out. The test conditions are summarized in Table 2.

The push-out test process is illustrated in Figure 2. The computer-controlled electronic uni-

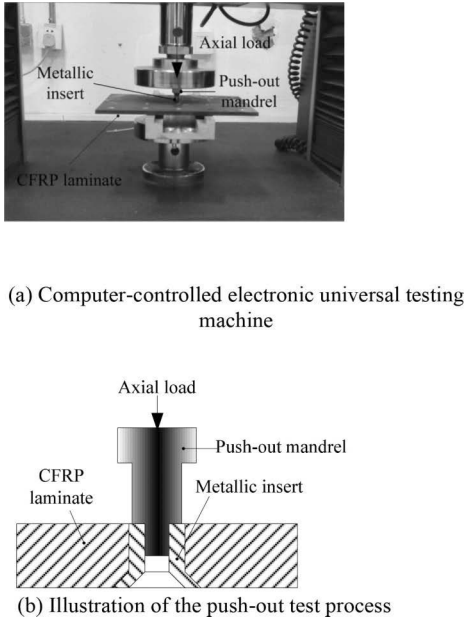

Figure 2. Picture and schematic of the push-out test.

Table 2 Test conditions

Samples	Injection pressure	Metallic inserts	Tests	Quantity
A	0 PSI	SD-A-1#-1~SD-A-1#-2	Push-out/breakaway torque	1/1
	60 PSI	SD-A-2#-1~SD-A-2#-2	Push-out/breakaway torque	1/1
	80 PSI	SD-A-3#-1~SD-A-3#-2	Push-out/breakaway torque	1/1
	1000 PSI	SD-A-4#-1~SD-A-4#-2	Push-out/breakaway torque	1/1
B	0 PSI	SD-B-1#-1~SD-B-1#-2	Push-out/breakaway torque	1/1
	60 PSI	SD-B-2#-1~SD-B-2#-2	Push-out/breakaway torque	1/1
	80 PSI	SD-B-3#-1~SD-B-3#-2	Push-out/breakaway torque	1/1
	1000 PSI	SD-B-4#-1~SD-B-4#-2	Push-out/breakaway torque	1/1
C	0 PSI	SD-C-1#-1~SD-C-1#-2	Push-out/breakaway torque	1/1
	60 PSI	SD-C-2#-1~SD-C-2#-2	Push-out/breakaway torque	1/1
	80 PSI	SD-C-3#-1~SD-C-3#-2	Push-out/breakaway torque	1/1
	1000 PSI	SD-C-4#-1~SD-C-4#-2	Push-out/breakaway torque	1/1
D	0 PSI	SD-D-1#-1~SD-D-1#-2	Push-out/breakaway torque	1/1
	60 PSI	SD-D-2#-1~SD-D-2#-2	Push-out/breakaway torque	1/1

3 EXPERIMENTAL RESULTS AND DISCUSSION

3.1 Push-out test results and discussions

The push-out test results are shown in Figure 4. The minimum push-out value of the A type sample is 835 N and the maximum fluctuation in amplitude of the push-out is 449 N under the four different types of injection pressure. The minimum push-out value of the B type sample is 280 N and the maximum fluctuation in amplitude of the push-out is 440 N under the four different types of injection pressure. The minimum push-out value of the C type sample is 360 N and the maximum fluctuation in amplitude of the push-out is 280 N under the four different types of injection pressure. The minimum push-out value of the D type sample is 360 N and the maximum fluctuation in amplitude of the push-out is 400 N under the four different types of injection pressure. Figure 4 shows that the fluctuation in amplitude of the push-out for four types samples is not according to the regulation. Therefore, it is mainly attributed to the different mixed ratios for the adhesive to cause different adhesive strengths. Moreover, the installing-holes distances of metallic inserts play a less important role in adhesive strength than that of the different mixed ratios for adhesives.

3.2 Breakaway torque test results and discussions

Under the four different types of injection pressure, the breakaway torque test results are shown in Figure 5. In the test, the threshold value of stopping the breakaway torque is set for 4 N.m. In these tests, all the inserts are not loosened. However, due to the fact that the strength of mandrels is not enough to lose the bonded metallic inserts, a less number of mandrels were broken when the torque value is less than 4.0 N.m. The minimum torque value of the A type sample is 3.55 N.m. The minimum torque value of the B type sample is 3.83 N.m. The minimum torque value of the C type sample is 2.23 N.m. The minimum torque value of the D type sample is 3.52 N.m. The torque curves during the test of four types of installing-holes distances are displayed in Figure 5(e). Because most of the breakaway torque values can reach the threshold value, it is considered that the performance of the bonded joint is stable.

4 CONCLUSIONS

In this paper, a series of experiments were carried out to study the installing-holes distances parameter optimization for metallic inserts bonded into CFRP laminates. By performing the push-out and breakaway torque test for the four types of installing-holes distances samples, the installing-holes distances parameter optimization experiments are studied and the following conclusions are drawn:

1. For different types of installing-holes distances, the push-out bearing capacity of metallic inserts bonded into CFRP laminates is not decreased obviously. The performance of the bonded joint is stable.
2. For different types of installing-holes distances, the breakaway torque bearing capacity of metallic inserts bonded into CFRP laminates is not decreased significantly. The performance of the bonded joint is stable.
3. The joint strength of metallic inserts bonded into the CFRP laminates is affected largely by the adhesive property than that of the installing-holes distances, and so the adhesive parameters and installation process should be strictly controlled.

ABSTRACT: Fiber reinforced thermoplastic composites have been widely applied in the civil aircraft design for their excellent advantages, which were produced under the conditions of high temperature and cooling rate. The thermo-residual stresses in the composites will be formed due to the mismatch in thermal expansion coefficients of the fiber and matrix, anisotropy of the adjacent fabric layers, and the temperature gradient distribution. The thermo-residual stresses have an important role to play in the mechanical properties of the thermoplastic parts and need to be considered in the design. It will be beneficial to study the mechanism and test methods of thermo-residual stresses to control the residual stress level of the thermoplastic composites, which are the main contents of this study and the formation reasons of the residual stresses were discussed from three levels. The test methods of the thermo-residual stresses were also studied by using the non-destructive and destructive methods, and their advantages and disadvantages are also discussed.

1 INTRODUCTION

Fiber reinforced thermoplastic composites have been widely used in aerospace for the high toughness and short molding cycle (J. Bernhardson, 2000 & G. Schinner, 1996). Thermo-residual stresses will be created when the parts are cooled to service temperature for the mismatch of the thermal expansion coefficient of the fiber and thermoplastic matrix (P.P. Parlevliet, 2006 & 2007). The factors such as temperature gradient, crystalline shrinkage, and interaction of the tool and composites will cause the thermo-residual stresses and affect the mechanical properties of the composites, which need to be considered to obtain qualified parts.

The formation of thermo-residual stresses is estimated from three levels in the present study to control and decrease the stress levels in the thermoplastic composites. In addition, test methods of the stresses were discussed based on the non-destructive and destructive methods as well.

2 FORMATION AND EFFECTS ON THERMO-RESIDUAL STRESSES

2.1 Formation mechanism

Nairn et al. tested the thermo-residual stresses of the carbon fiber reinforced polyether sulfone by using the photo-elastic method (J.A. Nairn, 1985).

The effect of the temperature on thermo-residual stresses of fiber composites was also studied by Favre (J.A. Barnes, 1994). The thermo-residual stresses can be discussed from three levels, i.e. constituent materials, laminate plates, and structure parts. The interaction between the fiber and matrix is shown in Figure 1 and the classification of thermo-residual stresses is presented in Table 1.

2.2 Constituents level thermo-residual stresses

2.2.1 Effect of the fiber on thermo-residual stresses

The carbon fiber has been widely used in the aerospace industry and the thermal expansion

Figure 1. Diagram of the interaction of the fiber and matrix for thermoplastic composites.

Table 1. Classification of the thermo-residual stresses.

Levels	Mechanism analysis
Constitute materials	Deformation inconsistency of the fiber and matrix in the cooling process for the difference of the thermal expansion coefficient
Laminate plates	Mismatch of the thermal expansion coefficient of the fabric layer along the radial and transverse direction of the composites, including that of the transverse crystalline layer
Structure parts	Temperature gradient in the cooling process for the thermoplastic composites having a certain thickness

interaction along the axial and vertical directions of the fiber causes the thermo-residual stresses in the cooling process and leads to fiber deformation; however, it is smaller than that of the polymer matrix in the whole process of thermoplastic composite materials. The effect of the thermo-residual stresses caused by the fiber can be neglected based on previous studies.

2.2.2 Effect of the matrix on thermo-residual stresses

The thermoplastic matrix exhibits visco-elastic properties when the process temperature is cooled to service temperature, in which the thermo-residual stresses will be released when to the molecular thermal motion has sufficient energy. The matrix has the thermal elasticity properties when the temperature decreases, and the thermo-residual stresses at this stage will exist in the final composites. The cooling rate plays an important role on the thermo-residual stresses, which degrades the thermo-residual stress relaxation at a higher cooling rate (K.S. Kim, 1989). These two mechanisms coexist and compete with each other. The thermo-residual stresses were also affected by the elastic modulus of the matrix and a decreasing trend with a decrease in the elasticity modulus.

2.3 Plate level thermo-residual stresses

All the influence factors of the constituent materials level will also act at this level; but the effect of the layup pattern on the thermo-residual stresses was mainly concerned, including the angle-ply information and fiber structure. The thermo-residual stresses increase with an increase in the difference of the stress-free temperature and the service temperature, which can be determined by using the heating method based on the thermoplastic composites until the deformation disappears (S.L. Gao, 2000). During the crystallization process,

the thermo-residual stresses of the obtained composites caused by the temperature gradient of the laminates will be accumulated.

2.4 Structural level thermo-residual stresses

The thermo-residual stresses will be formed when the composites attain a certain thickness, and it is affected by the cooling process. The thermo-residual stresses in the thermoplastic composites different from each other due to the different cooling processes, though with the same crystallinity degree. The annealing method can be used to release the thermo-residual stresses and decrease the residual stresses gradient. It improves the crystallinity level of the thermoplastic composites; but it will increase the process time and the energy consumption.

Mould materials used for molding the composites also have an important effect on the thermo-residual stresses, which play a role on the thermal and mechanical properties (E.M. Asloun, 1989). The thermal interaction will obviously affect the formation of the thermo-residual stresses, which is determined by the mould materials' properties and the cooling rate of the parts' surfaces. The mechanical interaction is caused due to the mismatch of the thermal expansion coefficient of the tool and composites. It will degrade the compressive residual stresses on the surface plies of the composites near the mould and has a transverse stress distribution in the laminates.

3 TEST METHODS OF THE THERMO-RESIDUAL STRESSES

The thermo-residual stresses of the thermoplastic composites formed during the molding process have the important effect on its mechanical properties, and it will be beneficial to obtain the residual stresses level in the designing process of the laminates. The commonly used test methods of non-destructive and destructive methods for obtaining the thermo-residual stresses are presented in Table 2.

Table 2. Test methods of the thermo-residual stresses.

Test patterns	Detailed methods		
Non-destructive testing methods	Constituent material	Embedding sensors	Warpage
Destructive testing methods	Removal layer	Blind-hole	Grooving

3.1 *Methods of the constituent material*

The properties of the constituent material will be changed as the composites exhibit change in their thermo-residual stresses, which can be measured by using the photo-elastic, Raman spectrum and conductivity methods. Photo-elasticity studies are conducted by using the static stress analysis, in which a transparent matrix is required to obtain the stress field (A. Pawlak, 2001). The molecular orientation distribution alters when there are thermo-residual stresses that can be calculated with the light intensity and phase difference. This method can be used to determine the thermo-residual stress distribution; however, it can be only used in the laminates of the low fiber volume fraction.

The Raman spectroscopy technique is widely used to obtain the thermo-residual stress of the composites by monitoring the change of the Raman spectrum peak position, which is highly dependent on the internal stress level (A.S. Nielsen, 2002). In the test, the plots of the spectrum peak and the thermo-residual stresses of the fiber in air and the matrix should be firstly constructed and studied to determine its intrinsic features. The glass fiber shows a tiny Raman response and the aramid fibers can be added into the thermoplastic matrix as the sensors due to the strong Raman responses. The results of this method exhibit high accuracy; however, it needs to take the matrix peaks' contribution into account to avoid errors in the test process.

The electrical conductivity of the composites will be affected by strain, damage, and temperature, which can be used as indicators without an additional sensor that will change the original thermo-residual stresses in the thermoplastic composites. Its resistivity will also be affected by the pressure in the molding (S.K. Wang, 2001). Moreover, poor adhesion of the adjacent layers will increase the electrical resistance as well, which means more efforts are needed to obtain the thermo-residual stresses in the test.

3.2 *Methods of embedding sensors*

The sensors embedded into the thermoplastic composites can be used to monitor the stress with the results of the sensors, which commonly include the resistance strain gauge, fiber optic sensors, and metallic particles with X-rays. The strain gauges have been used to obtain the residual stress change of the carbon fiber/PEEK laminates by placing into the surface layer in the heating and cooling processes (R.H. Fenn, 1993).

The fiber optical sensors have been widely used as the strain gauges to obtain the thermo-residual stresses of the composites for their high accuracy,

which includes the fiber Bragg grating and the Fabry–Perot interferometric sensors (B.P. Arjyal, 1998). However, the stresses concentration will be created when the fiber optical sensors are perpendicular to the fiber direction.

The X-ray diffraction method is achieved by placing the metallic particles into the matrix, by monitoring the deflection of the peak angle and crystal lattice caused by thermo-residual stresses. The particles can be silver, copper, and aluminum materials. It can be used to measure the intra-laminar and inter-laminar thermo-residual stresses; but it can only give the surface properties of the specimens with the thickness lying between 0.3 and 0.5 mm.

3.3 *Methods of the deformation measurement*

The light wave's interference principle can be used to obtain the thermo-residual stresses of the composites by measuring its deformations. It was caused by the Moiré effect as the light through the two gratings grids at a small angle. The residual stresses can be obtained with the in-plane and out-of-plane deformations. However, it can only show the macroscopic residual stress information.

The thermo-residual stresses can also be studied with the warpage of the unsymmetrical lay-up laminates. Nairn et al. studied the thermo-residual stresses in the composites by using the warpage method. The residual stresses increase with the positive proportional increase of the laminate warpage of a certain thickness. However, the results' accuracy may be degraded due to the errors of the test results.

Residual stress of the curved member plate can be obtained with the deflection chord length and curvature of the specimen. The deflection is obtained with the microscope and the chord size is obtained with the ruler. This method is easy to manipulate; but it cannot provide the residual stresses along the thickness direction. It also cannot be used to study the residual stress of the symmetric laminates.

3.4 *Methods of the destructive technology*

The thermo-residual stresses of the thermoplastic composites can also be determined with the destructive techniques, which are achieved by removing the part of the laminate to make the residual stresses release. These stresses can be obtained by using the methods of first-layer removal and blind-hole by testing the caused deformation.

The first-layer removal method is widely used in testing the thermo-residual stresses by removing the layer of the thermoplastic laminate and testing the released strain. It has a poor precision, and the

thermal and micro-cracks in the removal process will affect the residual stress (M. Eijpe, 1997). The process simulation method was used to reduce the effect of the removal process by placing a thin film into the adjacent layers. It separates the adjacent layers and reduces the interaction, the validity of which has been proved with the test results.

The blind-hole method is the stresses relaxation technique in drilling holes in the composites and monitored the strain changes to determine the thermo-residual stresses. However, the obtained strain might be released in the drilling-hole process (A. Makino, 1994). In addition, the crack buckling method and the notch technique are also used in testing of the thermo-residual stresses according to the previous studies, which can be used to obtain the strain, and then the residual stress is obtained with the change of the crack length before and after the damage process.

4 CONCLUSIONS

The thermo-residual stresses may be caused by the mismatch of the thermal expansion coefficient of the fiber and matrix and the interaction of the adjacent layers for the anisotropy properties, as well as the temperature gradient of the laminates. The formation of the thermo-residual stresses of the thermoplastic composites were discussed from three different levels in the present study. Moreover, the destructive and non-destructive methods of measuring the thermo-residual stresses were also studied. The advantages and disadvantages of each method were evaluated, which can be used to produce the thermoplastic composites with a suitable residual stress level.

ABSTRACT: The effects of lithium slag from lepidolite on the workability, mechanical properties, and parts of the durability of concrete were investigated. SEM was used to observe and analyze the interface structure of lithium slag concrete. The results show that adding a moderate amount of lithium slag can improve the workability and mechanical properties of concrete; and its anti-impact property will be enhanced significantly. Adding 20% lithium slag can improve the impact resistance of concrete by 45%. And the study of the interface structure shows that lithium slag can consume calcium hydroxide effectively, bring more amount of gels, inhibit the formation of ettringite, and enhance the density of concrete.

1 INTRODUCTION

The associated lepidolite content in the Tantalum–Niobium Ore resource in Jiangxi province is extremely abundant (Zeng Chuanlin 2012, Zeng Qingling 2014). However, extracting lithium from lepidolite will produce massive solid waste slag (hereinafter referred to as lithium slag) in industries. The main treatment methods of lithium slag are landfills, dam construction, and piling at present, which will cause serious pollution and land wastage. Strengthening the study of comprehensive utilization of extracting lithium from lepidolite has a great significance for economizing the resource and protecting the environment.

Using lithium slag as the cement concrete admixture is one of the important ways of using lithium slag. At present, there are many studies about using lithium slag from spodumene as a cement concrete admixture in China (Yang Hengyang 2012, Zhang Lanfang 2008, Zhang Lanfang 2012, Hu Zhiyuan 2008). However, very few studies concentrate on using lithium slag from lepidolite as a cement concrete admixture. By studying the effect of lithium slag from lepidolite on the workability, mechanical properties, anti-impact property, anti-chloride ion permeability, and interface meso-structure of concrete, we can provide theoretical reference for the application of lithium slag from Yichun lepidolite in the concrete field.

2 EXPERIMENTAL SECTION

2.1 Raw materials

Cement: P.O42.5R cement was produced by East Asia JiangXi Cement Co. Ltd. The apparent

density of the cement is 3.07 g/cm³. Lithium slag: lithium slag from lepidolite was produced by Jiangxi Ganfeng Lithium Co. Ltd. The specific surface area of lithium slag is equal to 550 m²/kg and its middle diameter is equal to 12 μm. The chemical constituents of lithium slag are given in Table 1. Fine aggregates: sand was obtained from Gan River with a fineness modulus of 2.5 and apparent density of 2.7 g/cm³. Coarse aggregate: continuous grading limestone artificial gravels were obtained with the maximum grain size of 20 mm. Water reducing agent: the polycarboxylate superplasticizer (powder) was obtained with a water reducing ratio of 26%.

2.2 Experimental method

The mixture proportion of lithium slag and cement concrete is given in Table 2; the water–binder ratio is 0.47 and the mixing value of the water reducer is 0.4% invariably. Workability of cement concrete: according to GB/T 50080-2002 Standards for test method of performance on ordinary fresh concrete. Mechanical properties of cement concrete: according to GB/T 50081-2002 Standards for test method of mechanical properties on ordinary concrete to test flexural and compressive strength of cement concrete. Anti-impact property of cement concrete: according to the falling weight test results. The impact hammer is a hemispherical cylinder (height is 150 mm and diameter is 150 mm). The weight of the impact hammer is 4.5 kg. The height of the impact hammer (the distance between the bottom of the impact hammer and specimen surface) is 1 m. When the first crack appears in the specimen, the

Table 1. The chemical constituents of lithium slag.

Materials types	SiO ₂	Al ₂ O ₃	CaO	Fe ₂ O ₃	MgO	SO ₃	Na ₂ O	K ₂ O	TiO ₂	Loss	Sum
Lithium slag	47.62	21.56	2.02	0.48	0.12	0.03	10.68	3.05	3.46	0.14	90.63

Table 2. The mixture proportion of lithium slag cement concrete (kg/m³).

Sample	Water	Cement	Lithium slag	Fine aggregate	Coarse aggregate
L0	234	500	0	640	1139
L1	234	450	50	640	1139
L2	234	400	100	640	1139
L3	234	350	150	640	1139

impact times (denoted by *n*) can be recorded as the maximum times of impact resistance. With an increase in *n*, the impact resistance of cement concrete becomes stronger. Interface structure: the interface structure of cement concrete was studied by using a QUANTA-200FEG Field Emission Environment Scanning Electron Microscope (FEI, America).

3 RESULTS AND DISCUSSION

3.1 Effect of lithium slag on the work performance of cement concrete

The test results of the slump of lithium slag concrete are shown in Fig. 1.

As test results are shown in Fig. 1, while mixing an increased quantity of lithium slag, the slump of ordinary concrete showed a decreasing trend. The experimental results also indicated that the normal concrete without lithium slag has poor cohesiveness and water retention, and there is bleeding at the bottom while testing the slump. After adding 10% lithium slag, the slump of cement concrete is slightly improved. Meanwhile, the cohesiveness and water retention of cement concrete are improved obviously. The aggregate is firmly wrapped by cement paste and no apparent water bled from cement concrete. When the mixing amount of lithium slag is more than 10%, the slump of cement concrete began to decrease. When it is increased to 30%, the slump of cement concrete collapsed to 132 mm. It indicates that mixing a little lithium slag can improve the workability of cement concrete to a certain amount. However, when adding more than 10% lithium slag, with an increment in the mixing amount, the water demand of cement concrete increased, and the flowability decreased. Therefore, the mixing amount of lithium slag should be controlled to 13% in practical applications to ensure that the slump of cement concrete is in accordance with the design requirements.

Figure 1. Effects of lithium slag on the work performance of cement concrete.

Figure 2. Graph showing the effect of lithium slag on the concrete compressive strength.

3.2 Effect of lithium slag on concrete compressive strength

Fig. 2 shows the relationship between compressive strength and the amount of lithium slag added. Adding within 20% lithium slag can increase the strength in 28 days dramatically. The

compressive strength ratio can reach 95% in 28 days while adding 30% lithium slag. But adding lithium slag has a negative effect on the strength in 7 days. With addition of lithium slag after the mixing amount reaches 10%, the compressive strength on 7 days decreases slowly. While adding 30% lithium slag, the strength ratio reaches 85%. The result shows that adding lithium slag can increase the compressive strength in the middle-later period and decrease the prophase strength in low amplitude.

3.3 Effect of lithium slag on concrete flexural strength

The test results of the flexural strength of lithium slag concrete are shown in Fig. 3. As depicted in Fig. 3, the effect of lithium slag on concrete's flexural strength and the effect on the compressive strength are approximately same. But the negative effect of the flexural strength reduced significantly in 7 days. When the mixing amount of lithium slag is less than 30%, the flexural strength is about 5.9 MPa in 7 days, and ranged from 5.7 MPa to 6.1 MPa. However, in this amount, the incorporation of lithium slag played a positive role in the flexural strength. Even if the mixing amount reached 30%, the flexural strength still exceeds that of the sample without lithium slag in 28 days. These may be due to the fact that after the cement hydration reached a certain extent, lithium slag can undergo a secondary hydration reaction with products from cement hydration, which will make the concrete more compact and improve the interface structure of concrete, thereby increasing the flexural strength of concrete. However, when the mixing amount of lithium slag is in excess, the hydration products will be reduced. As lithium slag cannot hydrate by itself, residual lithium slag can only fill in concrete, which decreases the strength of concrete gradually.

Figure 3. Graph showing the effect of lithium slag on concrete's flexural strength.

3.4 Effect of lithium slag on anti-impact property of concrete

Depending on the test results of impact resistance of lithium slag concrete (see Fig. 4), we can see that with the incorporation of lithium slag, the impact resistance of concrete can be improved significantly. When compared to the specimen without lithium slag (L0), the impact resistance of specimens with 10%, 20%, and 30% lithium slag improved at different degrees. Concrete with 20% lithium slag (L2) has the strongest impact ability that is 45%, which is higher than L0. This result has a strong relativity with the compressive strength and flexural strength of lithium slag concrete. It shows that the incorporation of lithium slag can improve the mechanical properties of concrete.

3.5 Effect of lithium slag on the interfacial micro-structure of cement concrete

Figs. 5 and 6 are SEM images of interfaces of cement concrete without lithium slag and with 10% lithium slag, respectively after 28 days. As shown in Fig. 5, without lithium slag, a lot flocculent C-S-H gels accompanied with many acicular ettringites appear in the interfaces of cement concrete. As depicted in Fig. 6, the interface structure of cement concrete with 10% lithium slag is more tight and the hydration product mainly is flat C-S-H gels. The amount of ettringite used was significantly increased when compared with the cement concrete without lithium slag. There were few ettringites in the sample in Fig. 6. It shows that, in the doped cement concrete of lithium slag, more $\text{Ca}(\text{OH})_2$ is consumed and the production of ettringite is reduced due to its pozzolanic effect (Wang Ling 1998). Meanwhile, as a result of adding lithium slag, the amount of C-S-H gels is increased and the density of cement concrete is improved, which is an important reason for strengthening of cement concrete.

Figure 4. Graph showing the effect of lithium slag on the anti-impact property of concrete.

Figure 5. SEM image of interfaces of L0 after 28 days.

Figure 6. SEM image of interfaces of L1 after 28 days.

4 CONCLUSIONS

As a concrete admixture, lithium slag from lepidolite has a higher activity index than traditional volcanic materials. While mixing 30% lithium slag, the compressive strength ratio after 7 days and 28 days reach 85% and 95%, respectively, which shows that lithium slag is a high quality material as a concrete admixture.

Impact resistance of concrete can be improved significantly when mixing lithium slag. Adding 20% lithium slag can improve the impact resistance of the concrete by 45%. And adding little lithium slag can also improve the working performance of concrete.

SEM observation shows that adding lithium slag can improve the interface structure, inhibit the formation of ettringites, and enhance the density of the concrete.

ABSTRACT: The aim of this paper was to investigate the adsorption behavior of iron ions in wastewater with a novel type of adsorbent, 2,2,6,6-tetramethylpiperidine-1-oxyl radical (TEMPO)-oxidized natural cellulose, which is synthesized in a special oxidation system with raw natural cellulose. The effects of adsorbent dosage, pH, temperature, initial concentration, and adsorption time on the adsorption efficiency were explored. The results demonstrated that the removal efficiency of iron ions with TEMPO-oxidized cellulose could be achieved as high as 99% under certain conditions. Adsorption isothermal studies also revealed that the adsorption process of iron ions was well-fitted with the Freundlich and Langmuir-type adsorption isotherms. Our results indicated that TEMPO-oxidized cellulose may have wide-ranging applications in the sequestration or removal of metal ions and many other wastewater treatment industries as a new adsorption material in future.

1 INTRODUCTION

Modern industries discharge a certain quantity of wastewater containing large amounts of heavy metals every day. Because of their toxicity, bioaccumulation, and their various forms, these metals do great harm to the ecological environment and survival of human beings after being discharged into the environment. A number of methods are available to remove heavy metals from water or wastewater, including chemical precipitation, ion exchange, adsorption, membrane process, reverse osmosis, and so on (H. Xu & Y. Liu. (2008), T. A. Kravchenko et al. (2009), Y. Y. Xiong et al. (2014), G. Ferraiolo et al. (1990), V.K. Gupta et al. (2004), V. K. Gupta et al. (2005)). Among these technologies, adsorption is considered to be the most effective and efficient approach for dealing with large volumes of wastewater in recent years (B. Volesky (2001), A. T. Paulino et al. (2008)). And the adsorption process has been applied as one of the most popular treatment processes due to various advantages, such as high efficiency, low cost, wide applicable scope, etc. Cellulose, which is a kind of inexpensive material and the main constituent of plants, is the most abundant biodegradable natural polymer biomass on the earth and has been utilized in many applications such as pulp, paper, filters, film, and the textile industries (D. Klemm et al. (2005)). To use

cellulose as a heavy metal ion adsorbent, however, chemical modifications such as esterification, etherification, and oxidation targeting the hydroxyl group present in cellulose are essential (V. A. G. Leandro et al. (2008), W. O. David et al. (2008), L. V. A. Gurgel et al. (2008)). Furthermore, up to now, few reports can be found on the adsorption and reduction mechanisms of iron ions onto TEMPO-oxidized natural cellulose except literature about sorption TEMPO-oxidized cellulose hydrogel to some heavy metal ions (N. Isobe et al. (2013)).

In this paper, a new adsorption material was prepared by using the chemical-modified natural cellulose, namely TEMPO-oxidized natural cellulose. And ferric ion-sorption experiments were also carried out in order to study the adsorption properties of the new materials. Natural cellulose has great superiority as the new experimental material, since cellulose is the most abundant and renewable biopolymer and is one of the promising raw materials available in terms of cost for preparing various functional materials. And so, it will provide strong support for the application of this new type of adsorbent. With the single variable controlling method, all kinds of factors affecting the adsorption efficiency were investigated, and the optimum conditions for the new removal of iron ions with TEMPO-oxidized natural cellulose were determined.

2 MATERIALS AND METHODOLOGY

2.1 Materials

Iron ions solution was prepared by using iron sulfate. TEMPO-oxidized natural cellulose was synthesized in our laboratory. Deionized water was used for all experiments. Other reagents used were of analytical grade in all experiments.

2.2 Synthesis of the new adsorbent

Natural cellulose was oxidized in an oxidation system constituted by 2,2,6,6-tetramethylpiperidine-1-oxyl radical (TEMPO)/NaBr/NaClO under certain conditions (A. Isogai & Y. Kato (1998), T. Saito et al. (2005)). The new adsorbent prepared is a long chain molecule with lots of hydroxyl groups and some carboxyl groups, and its chemical structure is illustrated in Fig. 1. The details of the synthesis of TEMPO-oxidized natural cellulose are as follows: designed weight Natural Cellulose (NC) was suspended in purified water which contained TEMPO (0.1 mmol/g NC) and sodium bromide (1.0 mmol/g NC). And then, a designed amount of the 10% NaClO solution (5.0~10.0 mmol/g NC) was added to the slurry dropwise, and the mixture was stirred by mechanical means at room temperature. And meanwhile, the pH of the mixture system was maintained between 10.5 and 11.0 by using a pH stat until no 0.5 M NaOH consumption was observed in the reaction process. Oxidation was quenched by adding ethanol (ca. 10 mL). Oxidized cellulose was washed thoroughly with purified water and then ethanol by filtration. The wet product was dried by lyophilization and then followed by vacuum-drying at 50°C for about 48 h. And then, the synthesis compounds were milled into powder after drying for the following adsorption experiments.

2.3 Adsorption experiments

Adsorption was carried out according to the following steps: (1) 20 mL of different concentra-

Figure 1. Structure of oxidized natural cellulose (R, H, or Na).

tions of wastewater was placed into small beakers; (2) a certain amount of adsorption materials was filled into the solution after its pH was adjusted with sodium hydroxide and hydrochloric acid; (3) all the suspended solutions were placed in a constant temperature oscillator for a designed duration of time; (4) the concentration of iron (III) ions was determined with adjacent dinitrogen spectrophotometry after stopping, oscillating, and standing for a period of time. Therefore, the optimum adsorption conditions were determined on the basis of setting the adsorption conditions by using the orthogonal principle.

2.4 Calculation method

The effect of adsorbing iron ions can be formulated by adsorbing capacity (q_e) and adsorption efficiency (R%).

Adsorbing capacity (q_e) refers to the quality of Fe^{3+} ions adsorbed into the adsorbent (1 g mass) when the adsorption system achieves adsorption equilibrium. And it was calculated according to Equation (1).

$$q_e = \frac{(C_0 - C_e) \times V}{m} \quad (1)$$

where q_e ($mg\ g^{-1}$) is the adsorbing capacity, C_0 ($mg\ l^{-1}$) is the initial concentration of Fe^{3+} , C_e ($mg\ l^{-1}$) is the equilibrium concentration of Fe^{3+} , V (l) is the total volume of wastewater, and m (g) is the mass of adsorbent.

The removal efficiency (R%) refers to the specific value between the quality of Fe^{3+} ions adsorbed into the adsorbent and the initial quality of Fe^{3+} ions when the adsorption system achieves adsorption equilibrium. It is defined as Equation (2).

$$R\% = \frac{(C_0 - C_e)}{C_0} \times 100\% \quad (2)$$

3 RESULTS AND DISCUSSION

3.1 SEM results

The morphologies of natural cellulose and NOCs were studied by SEM analysis in order to make a comparison more directly before and after synthesis of NC. Two typical images at two magnifications of NC and TEMPO-oxidized natural cellulose are shown in Fig. 2a and b. Evidently, both of them are characterized by a level of inhomogeneity owing to natural growth. And the dimension of TEMPO-oxidized natural cellulose is 4–8 nm in width. But there many many sags and crests on the surface of TEMPO-oxidized natural cellulose, which increases undoubtedly the surface area of the adsorbents.

Figure 2. SEM micrographs of natural cellulose (a) and TEMPO-oxidized natural cellulose (b).

3.2 Adsorption experiments results

3.2.1 The influence of adsorbent dosage on the removal efficiency

The influence of adsorbent dosage on the removal efficiency of iron ions is shown in Fig. 3. The removal efficiency of iron ions increased significantly with an increasing amount of adsorbent in the range of 0.1–0.15 g, and then it began to fall down slightly when the adsorbent dosage was larger than 0.15 g. It could be inferred that the removal efficiency of iron ions was the optimum and adsorption process was saturated when the adsorbent dosage was about 0.15 g.

The behavior of efficiency dependency on the adsorbent dosage could be explicated such that the removal efficiency of the heavy metal increased along with an increase in adsorbent quality, and that was to say with an increase in the number of active adsorption sites (Z. k. Luan & H. X. Tang (1993)). Moreover, due to an uneven distribution of oxidized cellulose surface positions, adsorption sites had strong and weak points naturally. The surface active points enabled competitive adsorption among the adsorption sites when the adsorbent dosage was in excess. In addition, owing to the hydrogen-bond interaction, cross-linking among the high molecules of the adsorbent would be formed in this case. And so, it would lead to the result that surface active points cannot be made full use of and were not conducive to the adsorption. Thereby, it would result in a decrease in the efficiency.

3.2.2 The influence of adsorption time on the removal efficiency

In our research, we found that adsorption time was one of the important influence factors. From Fig. 4, it can be observed that, in the beginning, the concentration gradient between the solution and the

Figure 3. The influence of adsorbent dosage on the removal efficiency of Fe^{3+} ions.

surface of TEMPO-oxidized natural cellulose was very high and hence the driving force was strong too; therefore, the resulting adsorption speed was very high. The removal efficiency of iron ions had reached more than 90% at the time of 40 min, and then the removal efficiency still increased despite the decrease in the concentration gradient and the adsorbent tending to saturation gradually. It is not difficult to find that the adsorption efficiency was reaching the maximum and the adsorbent was reaching saturation at 60 min from Fig. 4. As time goes on, desorption began to appear and resulted in the declining of the removal efficiency.

3.2.3 The influence of the initial concentration of metal ions on the removal efficiency

The initial concentration of metal ions had an effect on the occurrence of ion exchange and

Figure 4. The influence of adsorption time on removal efficiency of Fe^{3+} ions.

Figure 5. The influence of the initial concentration of metal ions on the removal efficiency of Fe^{3+} ions.

complexation in the suspended solution. The dependency of the removal efficiency of iron ions on the initial concentration of metal ions is shown in Fig. 5. Meanwhile, the graph presented a curve rising at first and declining in the studied range, while the best initial concentration of the oxidized cellulose adsorption of iron ions is $100 \text{ mg} \cdot \text{L}^{-1}$. This may be due to the fact that, when the initial concentration increased in the adsorption process, the concentration gradient increased between the solution and the surface of TEMPO-oxidized natural cellulose, thereby leading to an increase in the driving force. The adsorption capacity of TEMPO-oxidized natural cellulose increased rapidly at first and then went back into equilibrium. When it surpassed the equilibrium level, the high concentration solution reduced the chance of functional atoms combining with iron ions, due to the fact that the amount of iron ions

in the solution exceeded the maximum adsorbing capacity of the adsorbent at this time. Therefore, the adsorption quantity no longer increased. And so, the excessive increase of the initial concentration led to a reduction in the adsorption efficiency. It indicated that the initial concentration had a fitting range.

3.2.4 The influence of temperature on the removal efficiency

Temperature was one of the critical factors affecting adsorption. It was mainly due to the high sensitivity of the solubility of copper to temperature in a certain temperature range, which promoted adsorption. However when the temperature exceeded a certain limit, high temperatures would lead to excessive thermal motion of the molecules and ions, which was not conducive to form stable chemical bonds, and therefore led to a decrease in the adsorption efficiency ultimately.

The influence of temperature on the removal efficiency of Fe^{3+} ions is revealed in Fig. 6. The adsorption temperature experiments were performed in the range of $15\text{--}35^\circ\text{C}$. The adsorption efficiency of iron ions increased slowly with an increase in the temperature. When the temperature was about 25°C , the adsorption efficiency of oxidized cellulose was the highest (more than 99%). And then, it slightly reduced with an increase in temperature. In general, the impact of temperature on the adsorption efficiency of iron ions with TEMPO-oxidized natural cellulose as the adsorbent was not obvious, and the adsorption efficiency of iron ions was above 98% in a wide range ($15\text{--}30^\circ\text{C}$). Therefore, it was sufficient to indicate that there would be a wide range of available temperatures for the sorbent of oxidized cellulose in the wastewater treatment process.

Figure 6. The influence of temperature on the removal efficiency of Fe^{3+} ions.

3.2.5 The influence of pH on the removal efficiency

The pH of the solution was another important factor that affects the adsorption process. Considering that the pH value of wastewater is usually below 7, the simulated wastewater was treated with acid solution (pH ranged from 2 to 7) in our experiment. The influence of the pH value on the removal efficiency of iron ions is shown in Fig. 7.

The adsorption efficiency was low at low pH and improved obviously with an increase in the pH. The efficiency reached more than 90% when the pH ranged from 4 to 7. Especially, under the pH value of 4–5, the highest removal efficiency was achieved, close to 93%. The removal efficiency then began to decrease with an increase in pH. It can be expected that the removal efficiency would be lesser when $\text{pH} > 7$, because iron ions and OH^- groups can easily cause precipitation in the alkali solution.

When pH was low, both effects of pH were disadvantageous to the efficiency. On one hand, more hydronium ions were in the solution, which would compete with iron ions at the active site on the surface of the adsorbent; on the other hand, the adsorbent was in a cationic atmosphere, and this would decrease the number of the active sites at which adsorption may take place. When the pH was high, two competing factors determined the efficiency. Fe^{3+} and OH^- ions formed deposits more easily, and the metal ions were surrounded by anions and were not easily combined with adsorbent. At the same time, pH could also affect the acid–base properties of the adsorbent, which led to a change of its structure. Therefore, there was an optimal pH for the efficiency. The condition of partial acid was more desirable for copper removal especially when the pH is 4–5.

Figure 7. Graph showing the influence of the pH value on the removal efficiency of Fe^{3+} ions.

3.2.6 Adsorption isotherms

The capacity of the adsorbent can be estimated through adsorption equilibrium studies. It is usually described by adsorption isotherms. And the experimental data were applied to the Langmuir and the Freundlich isotherm equations, respectively. Two equations (Equation (3) and Equation (4)) were obtained as follows:

Langmuir equation:

$$\frac{1}{q_e} = \frac{0.0069}{C_e} + 0.0052 \quad (R^2 = 0.9991) \quad (3)$$

Freundlich equation:

$$\ln q_e = 0.9484 \ln C_e - 1.7755 \quad (R^2 = 0.9996) \quad (4)$$

where C_e ($\text{mg}\cdot\text{L}^{-1}$) is the equilibrium concentration of iron ions and q_e ($\text{mg}\cdot\text{g}^{-1}$) is the adsorption capacity of iron ions at equilibrium.

According to the above-mentioned two equations, the high correlation coefficients indicate that the adsorption process of iron ions by TEMPO-oxidized natural cellulose corresponded well with the Freundlich and Langmuir model. It also demonstrated that the adsorption process is a physical–chemical mixed model which needs further detailed study.

4 CONCLUSIONS

TEMPO-oxidized natural cellulose is a new type of adsorbent, which can be synthesized by natural cellulose under an oxidized condition. We found that the material had a great effect on the adsorption of iron ions from wastewater. The optimum conditions of adsorption from the experiments were obtained. The removal efficiency of iron ions could reach as high as 99% under the conditions where the temperature was 25°C , the iron ions concentration was $100\text{ mg}\cdot\text{L}^{-1}$ and the value of pH was 4–5 in the solution, dosing 0.15 g adsorbents and adsorption time of 60 min . Kinetic studies also showed that the adsorption isotherm of Fe^{3+} corresponded with the Freundlich and Langmuir models. Other adsorption mechanisms such as adsorption thermodynamics will be further studied subsequently. In conclusion, the present work predicts that the new adsorption material will have wide-ranging application in the sequestration or removal of metal ions and many other industrial processes in the future owing to the advantages such as raw materials easily available with many sources, large adsorption capacity, ease of operation, and low cost.

ABSTRACT: In order to obtain better grinding homogeneity and lower grinding cost, the optimization experiments of grinding were carried out in the fourth series of the Meishan iron ore concentrator. When compared with the results before application, the results of the test showed the following: the average size of the secondary overflow was similar, but the qualified fraction increased to 0.6 percentage point; the fraction of $-10\ \mu\text{m}$ decreased to 1.05 percentage point while decreased to 15.56 percentage points in magnetic separation tailings; the average size increased to 0.06 mm. Simultaneously, the power consumption reduced to 1.68 kw•h/t, the ball consumption dropped to 0.1 kg/t, the noise of grinding dropped to 2–6 dB, the temperature of pulp decreased to 0.5–2°C, the life of primary mill liners extended to 6 months and the life of secondary mill liners extended to 1 year. The grinding costs reduced to 1.70 RMB/t and the effect of energy conservation was very significant. Results of the fourth series could be applied in the same type grinding operations of other series.

1 INTRODUCTION

Mostly, the iron ore was the magnetite, martite, hematite, siderite, and pyrite and silicate minerals in Meishan. The structure of the ore mainly comprised of dense patches, disseminated, breccia and mottled structure. Currently, Meishan iron ore dressing concentrator adopted a two stage closed-circuit grinding process. The grinding operation power consumption accounted for 46% of the total power consumption. It exerted great pressure for the settlement, emissions, and comprehensive utilization of tailings (Liu, 2005). Shi Guiming (2013) studied the optimization of particle size obtained through grinding on the tungsten polymetallic ore grinding system and improved the metal distribution characteristics. Xiao Qingfei (2007) reviewed the development of the grinding medium and optimization research. Wang Peng (2010) studied the shape and size selection principle of the new type of grinding media. Li Jian (2010) discussed the quality of mill grinding, and thought it can improve the quality of grinding, save energy, and reduce consumption. In order to improve the uniformity of the grinding process and reduce costs, in this paper, the fourth series grinding system in Meishan is studied.

2 GRINDING SYSTEM STATUS BEFORE THE INDUSTRIAL TEST

The fourth series closed-circuit grinding system of the Meishan iron ore concentrator was made up of two sets of a $2.7 \times 3.6\ \text{m}$ ball mill and a 1.6 m double helix grading unit. The mill speed was 21.7 r/min, filling rate was 38%, and grinding concentration was above 88%.

The process investigation deciphered the following problems before the industrial test: (1) the primary stage spiral classifier has no underflow, with classifier efficiency approaching 0%, which did not have any screening effect; (2) the primary stage steel ball size was 120 mm and the secondary stage ball size was 80 mm, which led to the -10 microns productivity of the primary stage classification overflow being 11.75%, and the -10 microns productivity of the secondary stage classification overflow being 15.39%, thereby increasing the over-crushing. On the other hand, it would impact the mill cylinder liner and reduce the service life of the lining board. At the same time, the remaining amount of useless energy was too much and was transferred into heat; (3) the liberation degree of the Fe particle size range was 0.3 mm–38 microns and the liberation degree of the S particle size

range was 76–10 microns, the liberation scope of which was different and therefore, Fe was suitable for coarse grinding and S was suitable for fine grinding; (4) the –10 microns products of secondary classification overflow was in high grade that the Fe grade was 30.26%, S grade was 0.77%, and the metal mass loss was greater which leads to the recovery of Fe. S was only 80.28% and 86.59% in qualified products of 0.3 mm–10 microns fraction.

3 INDUSTRIAL TEST PLAN

According to the research results of the laboratory's high-precision grinding and practice experience, the major industrial test under the premise of without changing the existing mill capacity is shown as follows:

1. The grinding concentration was adjusted, the concentration and overflow fineness of the first stage grinding classification process were classified, the amount of sand return was increased, and the grinding process was improved. At the same time, a new ball was added in accordance with the method $\Phi 100: \Phi 80 = 60\%:40\%$.
2. The grinding concentration was adjusted, the concentration of the secondary grinding classification process was classified, and the classifier overflow fineness was stabilized. At the same time, a new ball was added in accordance with the method $\Phi 60 = 100\%$.

4 INDUSTRIAL TEST RESULTS

4.1 Particle size distribution in the grinding-classification circuit

When compared with the effect of the industrial test, the fourth series were in contrast with the

third series. The fourth series has implemented a new industrial test plan since October 1, 2013. It obtained sample and analysis data after stable operation from November. Particle size distributions of the third series production and the fourth series grinding-classification circuit are listed in Table 1.

It can be seen from Table 1 that after the high-precision grinding process, although the secondary classification overflow failed to meet –0.074 mm which accounted for 63%, the average particle size of secondary classification overflow products was the same, the content of the 0.3–10 microns qualified fraction was higher and the content of –10 microns over the crushed fraction was lighter. Moreover, the product quality of the secondary classification overflow of the fourth series was better than that of the third series overall.

4.2 Product quality of overflow in secondary classification

During the industrial experiment, the comparison results of the product quality of secondary classification overflow in the third and fourth series are shown in Table 2.

It can be seen from Table 2 that after the utilization of high-precision grinding technology, the better product quality of the secondary classification overflow was obtained under the same processing capacity of the mill.

4.3 Sorting effect of secondary classification overflow

To test the quality improvement of the secondary classification overflow in fourth series, the contrast experiments for the third or fourth series were carried out in a laboratory. The dressing process and parameters were the same with the actual process

Table 1. Particle size distribution of the product of the grinding-classification circuit/%.

Indicator		Primary grinding	Primary sand return	Primary overflow	Secondary grinding	Secondary sand return	Secondary overflow
$\gamma_{-76\mu\text{m}}$	3	35.45	0	36.55	30.50	13.38	64.15
	4	28.20	13.16	32.78	32.93	13.84	60.55
$\gamma_{-10\mu\text{m}}$	3	9.28	0	9.63	3.83	3.36	15.20
	4	7.63	3.93	8.60	7.43	3.38	14.15
$\gamma_{0.3-10\mu\text{m}}$	3	55.45	0	54.37	74.32	58.28	80.15
	4	43.72	19.5	48.73	75.05	53.14	80.75

Table 2. Comparison results of the product quality of the final overflow in different series/%.

Indicator	$\gamma_{-0.076\text{mm}}$	$\gamma_{0.3\text{mm}-10\text{mm}}$	D/mm	$\gamma_{-10\mu\text{m}}$
3#	64.15	80.15	0.10	15.20
4#	60.55	80.75	0.10	14.15
Increased/decreased amplitude	-5.61	+0.75	0	+6.91

of the Meishan iron ore concentrator. The dressing effects of the secondary classification overflow in 3# and 4# series are shown in Table 3.

It can be seen in Table 3 that after the utilization of high-precision grinding technology, the productivity and grade of the iron concentrate were the same, but the loss of Fe and S also reduced because of the improvement of the particle size characteristics. The recovery of iron reduced to 0.02 percentage point and the recovery of sulfur reduced to 0.23 percentage point.

In order to further investigate the separation influence of magnetic tailings, the separation indexes of magnetic separation tailings in the 3# and 4# series are listed in Table 4.

It can be seen from Table 4 that after the utilization of high-precision grinding technology, the -10 microns productivity of magnetic separation

tailings reduced to 15.56 percentage point, and the average particle size increased to 0.06 mm.

4.4 Saving energy and reducing consumption

After the utilization of high-precision grinding technology, the grinding efficiency and quality were greatly improved. Saving energy and reducing consumption of the grinding process were significant. The energy-saving and consumption-reducing indicators are listed in Table 5.

It can be seen from Table 5 that the mill power consumption reduced to 1.68 kW·h/t, steel consumption reduced to 0.1 kg/t, mill noise dropped to 2~6 dB, grinding pulp temperature reduced to 0.5~2°C, the service life of the first grinding mill lining board prolonged for 6 months, and the second stage grinding can be extended to more than

Table 3. The dressing effect of the secondary classification overflow in different series/%.

1 year. Saving energy and reducing consumption were very significant.

4.5 *Benefits of saving energy and reducing consumption*

In the 4# series, according to the price of the industry, the cost of electricity was 0.6 RMB/(kW·h), the cost of steel ball was 4000 RMB/t, the price of the manganese steel lining board was 160000 RMB/set, the price of the magnetic lining board was 210000 RMB/set, and the annual total cost of grinding reduced by 1.70 RMB/t.

5 CONCLUSIONS

1. The appropriate grinding condition is very important for the improvement of the grinding quality.
2. After the introduction of a high-precision grinding technological process, the quality of the secondary classification overflow and magnetic separation tailings was significantly improved. The qualified fraction increased to 0.6 percentage points and the -10 microns content reduced to 1.05 percentage points in the secondary classification overflow. The -10 microns content reduced to 15.56 percentage points, and the average particle size increased to 0.06 mm in the magnetic separation tailings.
3. After the introduction of the high-precision grinding technological process, the energy-saving effect was very significant. The mill

power consumption reduced to 1.68 kW·h/t, the steel consumption reduced to 0.1 kg/t, the mill noise reduced to 2~6 dB, the grinding pulp temperature reduced to 0.5~2°C, and the grinding cost reduced 1.70 RMB/t.

An experimental study on the dynamic characteristics of compact transmission lines bundles following ice shedding

Kunpeng Ji, Bin Liu, Xueping Zhan & Xiangze Fei

China Electric Power Research Institute, Xicheng District, Beijing, China

Chun Deng & Liang Liu

Jibe Electric Power Research Institute, Xicheng District, Beijing, China

ABSTRACT: Ice shedding is one of the main reasons threats the mechanical security of overhead electric transmission lines. This study attempts to gain the dynamic response of conductor bundles following sudden ice shedding, by conducting a series of ice shedding tests on a reduced scale single span conductor bundle physical model in a laboratory. The influence of ice load, lumped mass number, and location was systematically studied, and the time histories and maximum values of displacement at different key points were measured. With a total of 30 ice shedding scenarios in a reduced scale conductor bundle physical model, these indicate that the ice load, the number of lumped mass, location, and number of released lumped mass significantly affects the dynamic response of the conductor bundle. It is found that the maximum displacement of measured points increases with the ice deposit mass and the maximum displacement along the span in all the scenarios always occurs at the midpoint. Also, the conductor vibrates mainly following the first order mode and it is affected by the particular ice shedding arrangement. This study helps to understand the dynamic response of conductor bundles, which is significant to the design of overhead transmission lines in cold regions.

1 INTRODUCTION

Atmospheric icing is one of the main natural hazards that threaten the safety of overhead transmission lines. It is reported that atmospheric icing and ice shedding have caused serious loss to electric power networks in countries like America, Canada, China and Russia (Farzaneh, 2008). The accidents resulting from icing can be divided into two catalogues, one is electrical accidents, such as flashover and short circuit, and the other is mechanical accidents, such as strands or conductor breakage, insulator rupture, cross-arm deformation, or tower collapse (McClure, 2002).

Ice shedding is a phenomenon in which ice chunks are shed off the conductor or ground wires suddenly due to high temperature, strong winds, or mechanical de-icing (Morgan, 1964; Jamaledine, 1993). When ice shedding happens, the conductor will jump dramatically and the tension of the conductor will change largely; the gravitational and strain potential energy of ice and conductor were released and converted into kinetic energy following ice shedding.

The compact transmission lines have superior economic and social benefits to ordinary transmission lines, because these need less corridor space,

cause less environmental pollution, but increase the natural transmission power and reduce the wave impedance, by reducing the phase conductor distance and increasing the sub-conductor number and conductor diameter. However, it has higher risk to ice shedding accidents due to the closer phase distance.

A series of ice shedding tests were conducted by Morgan and Swift on a five-span 230 kv transmission line, from which the equation of the conductor jump height after ice shedding was deduced and the effects of different insulator assembly methods were studied (Morgan, 1964). Jamaledine *et al.* carried out several ice shedding tests on a two-span reduced scale line and was the first to use non-linear commercial finite element software to study the dynamic response of the conductor following ice shedding. It is proved that the numerical simulation results agree well with the model tests (Jamaledine, 1993). Roshan Fekr and McClure simulated 21 ice shedding scenarios, by changing conductor density, to study the influence of ice thickness, span length, and elevation difference on the ice shedding response (Fekr, 1998). Meng *et al.* conducted an ice shedding test on a real scale transmission line and studied the influence of conductor damping (Meng, 2012). Li *et al.* study the towers–lines coupled effect and the anti-vibration

measure for towers during the ice shedding process (Li, 2008). Yang studied the dynamic loads on Ultra-High Voltage (UHV) towers following ice shedding (Yang, 2014). Kollar *et al.* was the first who systematically studied the dynamic characteristics of bundled conductors in different ice shedding scenarios, such as whole span shedding, large chunks shedding and un-zipping shedding, and the FE modeling method was validated by using a reduced scale twin sub-conductor bundle (Kollar, 2008; László, 2013). In the study, the influence of ice shedding from certain sub-conductors, sub-conductor distance, and sub-conductor number were studied. Shen *et al.* studied the influence of different FE models, the equivalent single conductor model, and the bundle model (Shen, 2012). Ji *et al.* considered the induced ice shedding effects in dynamic analysis, and so the time-varying characteristics of the system can be considered in FE analysis, which is more realistic (Ji, 2015).

Although the ice shedding phenomenon has been studied in previous studies, there is a lack of ice shedding tests on bundle conductors, which are widely used in extra and UHV transmission lines. Thus, in this paper, a reduced scale physical transmission line model of the conductor bundle is designed to obtain its dynamic characteristics in different ice shedding scenarios. This study will offer more experimental data for transmission line designs in cold regions and is helpful for the mechanical safety of transmission lines and the operation of electric power networks.

2 EXPERIMENTAL SETUP

The reduced scale physical model is a single span bundle with eight sub-conductors and no spacer is installed for simplicity. A high strength buckle was used to connect the bundle to the dead end at the left end and the right end of the bundle is connected to a tension sensor first by using a buckle, and then the tension sensor is connected to a screw, which is used to adjust the conductor tension. Five laser sensors are set underneath the conductor bundle on the test platform. The lumped mass was hung on the bundle with a rope to model the ice load and the ice shedding phenomenon is modelled by suddenly cutting the rope. The experimental setup is shown in Fig. 1.

In the tests, laser sensors produced by Panasonic were used to detect the real time displacement of measured points and force sensors produced by Tecsis were used to measure the tension of sub-conductors.

A total of 30 scenarios of ice shedding tests were studied, by changing the total mass of the ice deposit, lumped mass number and ice shedding locations. The combinations of ice shedding scenarios are listed in Table 1 and shown in Fig. 2 (only the five lumped loads scenario is illustrated).

In Table 1, 5%, 10%, and 15% refer to the fact that the total ice load is 5%, 10%, and 15% of the conductor bundle mass, respectively. The total ice load was modeled by 1, 3, and 5 lumped masses in different scenarios.

(f) Maximum jump height of the five measured points (M2+M3+M4 were released)

Figure 4. Results of the test where the ice load is simulated by the five lumped mass.

3 DYNAMIC RESPONSE ANALYSIS OF BUNDLED CONDUCTORS IN THE EXPERIMENTS

In the tests, the displacement of the five measure points is recorded. Figures 3 and 4 show the displacements time history of the midpoint (point 3) and maximum displacements of every measured point in different test scenarios, where the total ice load is 15% of the cable mass. For the sake of paper length, only the scenarios with three (Figure 3) and five (Figure 4) lumped masses are listed in this article.

It indicates from the figures that the dynamic response of the conductor bundle is significantly influenced by the number of lumped mass, location, and number of released lumped mass. The maximum displacement along the span in different scenarios always occurs at the midpoint and the displacement time history decays due to the damping effect. Among all the tests, the maximum jump height of the midpoint appears in the scenario with only one lumped mass. In addition, the conductor vibrates mainly following the first order mode and is affected by the particular ice shedding arrangement, and the second order mode may be excited when uneven and non-synchronous ice shedding happens.

Besides, the comparison of 5%, 10%, and 15% ice load scenarios shows that the maximum displacement of measured points increases with the ice deposit mass, and the vibration modes with the same number and arrangement of lumped mass are similar when the ice load varies.

4 CONCLUSIONS

A reduced scale single span conductor bundle physical model was established to study the dynamic response of the bundle following sudden ice shedding. By changing the ice load, lumped mass number, and releasing the arrangement of the lumped mass, it obtained the displacement time history and maximum displacement of the measured points. The test results show that the maximum displacement always occurs in the mid-

point of the span and increases with total ice load. The main vibration mode was excited in the tests is the first order mode with one loop. The number and release location of the lumped mass have significant influence on the dynamic response of the conductor bundle. The study and findings in this paper are useful for the design of overhead transmission lines in cold regions.

A single-lens optimal imaging system based on a liquid crystal spatial light modulator and micro-scanning optical wedge

Ning Xu, Zhi-Ying Liu & Dong Pu

*School of Opto-Electronic Engineering, Changchun University of Science and Technology,
Changchun, Jilin, China*

ABSTRACT: A simple and high-resolution single-lens imaging system is generated by using a liquid crystal spatial light modulator to correct wavefront distortion and reconstructing a high resolution image with micro scanning by using an optical wedge. A zygo interferometer is used to measure of wavefront data of single-lens focusing infinite distance; ZEMAX is used to simulate to obtain wavefront data of finite distance and use Zernike Polynomials to describe it. Based on the relationship between the phase and grayscale of a liquid crystal spatial light modulator, a conjugate wavefront of distortion wavefront is obtained for completing static wavefront correction before assessing the correction effect by Imatest software. In order to improve the image resolution, an optical wedge is used to perform multiple 2×2 micro-scannings of a same scene for imaging. A high-resolution static scene image is reconstructed by using a fast high-resolution algorithm based on the Keren registration method and template convolution.

1 INTRODUCTION

With the development of science and technology, demands for optical systems with a small volume and high resolution imaging have become increasingly intense. In an optical system, single lens imaging can be employed to reduce its volume effectively. As a result, the structure and price of this system are substantially simplified and brought down respectively. However, single lens imaging is provided with certain wavefront distortions that are able to give rise to imaging blurring for such an optical system. Therefore, the solution to the wavefront distortion is the core of using single lens imaging.

In recent years, application of adaptive optics into wavefront distortion correction has become a hotspot due to the development of liquid crystal display technology and relevant techniques as well as abundant liquid crystal materials. As a wavefront corrector, the liquid crystal spatial light modulator is featured with high resolution, low energy consumption, small volume, ease of control, low price, etc. (Cai et al, 2008). In this paper, defocus and aberration are compensated by virtue of the liquid crystal spatial light modulator. A 1272×1024 pixels pure phase type liquid crystal spatial light modulator developed by the Hamamatsu Company in Japan is adopted in combination with Zemax simulation and Zygo interferometer test to carry out fitting for wave surfaces so as to achieve an effect of compensation. In addition, Imatest is utilized to grade it based on images that are processed by

using the liquid crystal spatial light modulator or otherwise. Thus, wavefront distortion correction effects of the modulator are evaluated.

Additionally, a method of employing a CMOS Sensor for integration on a focal plane is also used in this paper. CMOS staggers half of the pixel along the direction of the linear array to perform twice imaging. In other words, the method of sub-pixel imaging is adopted. Moreover, an approach of 2×2 micro-scanning is also applied to fill the infinitesimal displacement to improve the sampling frequency so that the original CMOS sampling frequency can be increased by times. In this way, the imaging quality is further improved.

2 DEFOCUS AND ABERRATION CORRECTION BY USING THE LIQUID CRYSTAL SPATIAL LIGHT MODULATOR

2.1 Construction of experimental optical path

A K9 single lens with a focal length of 35 mm and a diameter of 25.4 mm is selected for experiments in this work. The distance from a front-end test card to a lens is 500 mm, while it is 800 mm from a back-end test card to the lens. Figure 1 shows an overall structure block. Due to limitations of the field of view, ISO 12233 reflective test cards of 0.5X are chosen. They should be placed up and down without overlaying. In addition, a read monochromatic source of 633 nm is adopted. While the

Figure 1. The overall structure diagram.

Figure 2. Picture of the overall structure of appearance.

micro-scanning optical wedge is aimed at achieving high resolution imaging implementation, the polarizing film only plays a part in horizontal polarized light because of the adoption of a liquid crystal spatial light modulator. Furthermore, it is under the control of this modulator that controls it through the PC. The relevant overall structure is presented in Figure 2.

2.2 Simulation and calculation of defocus

Defocus usually takes place in an optical system that is constructed by using a single lens. Therefore, it is assumed that there are two ISO12233 test cards at the front and the back ends to evaluate this system. The corresponding focal length is adjusted to make the front-end test card just situated at the focal plane. At this time, a defocus phenomenon appears correspondingly as long as the test card at the back end is moved. Thus, defocus of the optical system can be simulated.

As given in Figure 3, the focal plane is located at a test card plane at 500 mm. Clearly, we almost cannot see a test card at 800 mm nearly, thereby signifying that a great distorted wavefront exists at 800 mm. In the case that half field of view with an object height of 500 mm are simulated by Zemax, a giant aberration exists in a single lens system and the edge field of view is also dramatically different from the central field of view, etc., under the circumstance that no additional elements are added, as shown in Figure 4.

Zemax can be utilized to obtain wavefront data under conditions of a finite element object distance. In order to acquire a clear image on a CMOS sensor, the front-end test card is adjusted in the first place. And then, the distance from the back-end test card to the lens can be figured out, so as to further simulate the corresponding coefficient of Zernike Polynomials by virtue of Zemax, as presented in Figure 5. In detail, item 4 of this

coefficient refers to spherical aberration and aberration items of the wavefront fitted.

2.3 Aberration measurement

As for the imaging at infinity, a digital wave phase-shifting interferometer is employed to precisely measure wave aberration of the single lens. Thus, wavefront matrix data are acquired.

The digital wave phase-shifting interferometer is used to precisely measure the wavefront of an optical system and provides data required by the subsequent corrections. The experimental optical path for measurement is shown in Figure 6. GPI-XPIV, a digital wave phase-shifting interferometer manufactured by Zygo, is adopted. To be specific, its principle is a Fizeau interferometer. Owing to the accuracy of this apparatus itself, we only need to place the polarizing film, optical system and reflector before such an interferometer (Wang & Yu, 2008). In addition, phase-shifting interference is employed by it. Concerning its major advantages, uncertainty can be up to 1/50 wave length in spite of a high measurement precision. Besides, data processing software mounted in the interferometer can export binary data files of the wavefront and also provides an exe program that can be utilized to convert such binary files into wavefront XYZ values stored in ASCII code. Based on a concrete wavefront data matrix, the wavefront can be accurately corrected and the relevant measurement process is shown in Figure 7. As for its experimental results, they are given in Figure 8.

Figure 8 shows that wavefront patterns can be displayed in the gray scale in the MetroPro after measurement by virtue of the Zygo interferometer.

Figure 6. Picture of the experimental optical path structure.

Figure 7. Measurement structure diagram.

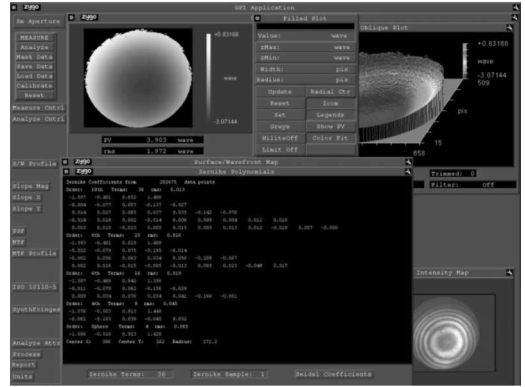

Figure 8. Zygo interferometer output interface.

In addition, 36 coefficients of the Fringe Zernike Polynomials are also given. The wavefront of an optical system or optical elements is always continuous and smooth. Considering this, the continuous function is used to represent wave aberration or the surface shape of an optical system. In normal cases, a series of orthogonal linear combinations of the Zernike Polynomials are adopted for this representation (Zhang et al, 2015). Although the Zernike Polynomials are provided with a considerably high accuracy, wavefront data exported by MetroPro directly are more accurate. Notably, the Zernike Polynomials will be employed to describe these uniformly for the convenience of the unification between defocus and aberration.

2.4 Wave aberration correction for liquid crystal spatial light modulator

The core component used for wave aberration correction is the liquid crystal spatial light modulator, a device performing spatial light modulator for spatial distribution of optical waves (Wyant et al, 1992). Generally, a spatial light modulator is constituted by multiple independent units that are arranged into one-dimensional or two-dimensional arrays spatially. Every unit can be controlled by optical or electric signals independently. Hence, its optical properties are altered according to such signals so as to modulate optical waves lighting on it (Love, 1997).

A distorted wavefront can be represented by using a series of linear combinations of orthogonal Zernike Polynomials, which is able to describe complex wavefront phase information and generate sufficient precision at the same time (Born & Wolf, 1978). The Zernike Polynomials in a circle is usually expressed in 2-dimensional polar coordinates as follows (Nam & Rubin, 2005):

$$Z_n^m(\rho, \theta) = \begin{cases} N_n^m R_n^{|m|}(\rho) \cos(m\theta) & m \geq 0, \\ -N_n^m R_n^{|m|}(\rho) \sin(m\theta) & m \leq 0, \end{cases} \quad (1)$$

$$N_n^m = \sqrt{\frac{2(n+1)}{1+\delta_{m0}}}, \quad \delta_{ij} = \begin{cases} 1 & i = j, \\ 0 & i \neq j, \end{cases} \quad (2)$$

$$R_n^m(\rho) = \sum_{s=0}^{n-|m|/2} \times \frac{(-1)^s (n-s)!}{s! \left(\frac{n+|m|-s}{2}\right)! \left(\frac{n-|m|-s}{2}\right)!} \rho^{n-2s}, \quad (3)$$

In the equations, angular and radial frequency numbers of the polynomials are provided respectively. They are important parameters reflecting the spatial frequency of the Zernike Polynomials (Cai et al, 2008).

The liquid crystal spatial light modulator should carry out phase modulation under a condition of polarized light. Therefore, the polarizing film is installed in the optical path. After this modulator is electrified, the liquid crystal correspondingly rotates according to a gray-scale map loaded so as to change the phase distribution on an incident wave surface. In the case that the coefficient of the Zernike Polynomials is obtained, control signals of the Zernike pixel should be determined. In other words, the compensated coefficient of the Zernike Polynomials is found. Popularly speaking, a conjugate coefficient of the original Zernike coefficient is taken. At that time, Matlab is utilized in conjunction with phase modulation characteristics of the liquid crystal spatial light modulator (Cai et al, 2007) to write the wave aberration fitting code and further generate gray-scale maps for compensated defocus and aberration. Subsequently, gray-scale signals are transferred to the drive circuit of the liquid crystal spatial light modulator through the PC. It is important to note that a monochromatic source of 633 nm is employed during the experiment. Under such a circumstance, the phase value $(0-2)\pi$ of the X10468 series liquid crystal spatial light modulator manufactured by Hamamatsu is linearly correlated to the gray level (0-255). It means that there is no need to recalibrate the relation between the phase and gray scale under such a waveband, as shown in Figure 9.

Figure 9. Phase modulation curve of the X10468 series modulator.

Figure 10. Modulator driver software to load the Fresnel grayscale image.

To expand the scope that can be adjusted by using the liquid crystal spatial light modulator, the gray-scale map portrayed is converted into a Fresnel gray-scale map. As a result, the modulation range of such a modulator can be enlarged. However, its modulation range cannot be extended infinitely. As far as the X10468 series is concerned, the maximum phase that it can modulate is at 25π . And then, the gray-scale map portrayed is loaded onto software of the liquid crystal spatial light modulator (Fig. 10).

2.5 Estimation on the correction effect of liquid crystal spatial light modulator

Imatest is digital image evaluation software developed by the Imatest LCC in America and it has been extensively applied. The overall system of this software is established based on Matlab, which consists of multiple function modules, such as SFR, Colorcheck, Stepchart, etc. In addition, Imatest takes advantage of the Spatial Frequency Response (SFR) which requires lower cost to measure the MTF curve. This is a very simple approach. The required MTF curves can be acquired only by analyzing black and white slanted edges with a certain angle of inclination (Chen et al, 2014).

3 HIGH RESOLUTION RECONSTRUCTION FOR MICRO-SCANNING

A CMOS sensor of 1.3 million pixels is adopted during the experiment. The pixel size of the CMOS is $5.2 \mu\text{m}$. Dependent on the scheme of liquid crystal spatial light modulator, the CMOS sensor becomes a factor restricting the improvement

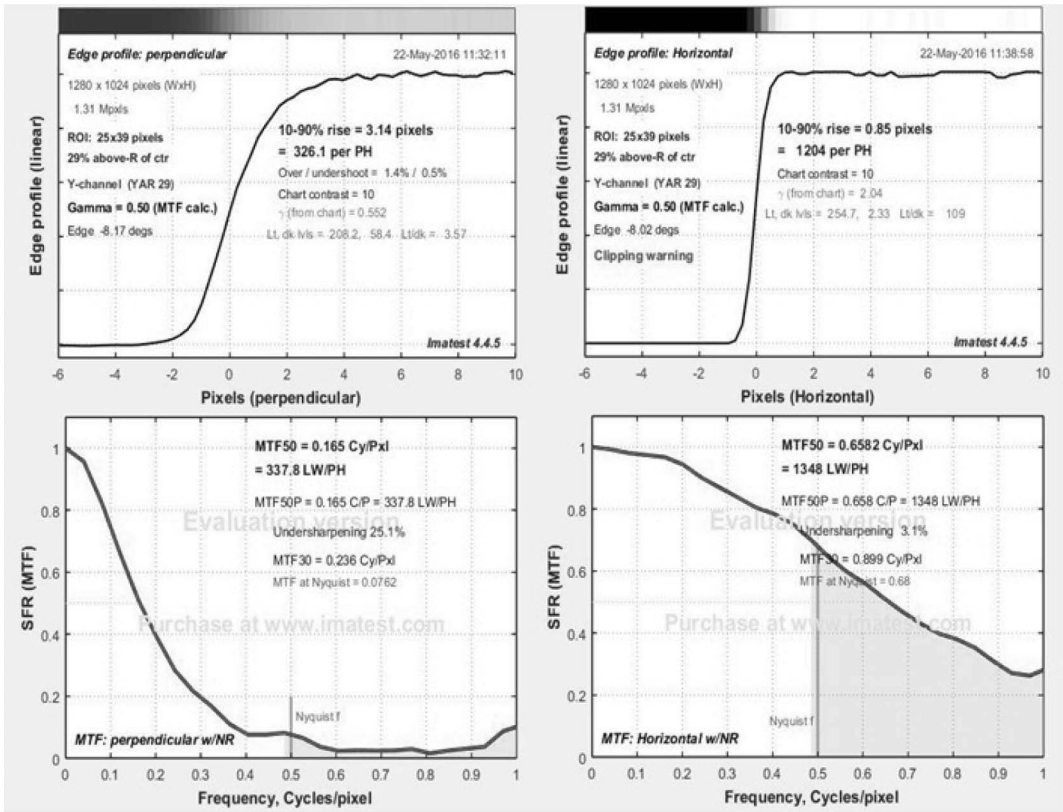

Figure 11. Graphs showing the comparison of results before and after loading.

of image quality. In order to perfect the resolution of the imaging on the premise of changing no CMOS sensor, high resolution imaging is realized by means of micro-scanning.

Micro-scanning is an over-sampling imaging process that takes place multiple times for an identical scene and each sampling is referred to as sub-sampling. According to the micro-scanning process, images achieved by sampling are noted down each time and then images obtained by each subsampling process are recombined in line with their sequences of micro-scanning. As a result, high resolution images are obtained through sub-pixel processing. What needs to be pointed out is that the relevant scenes and fields of view are required being static or moving slightly in the processes of sampling and imaging. In other words, micro-scanning can acquire a high spatial resolution by sacrificing the temporal resolution (Zhang et al, 1999).

Theoretically, the larger the number of scanning is, the better the reconstruction effect will be. But, a 2×2 micro scanning pattern is the most reasonable in terms of this experiment for the pur-

pose of efficiency improvement. To be specific, four pictures are captured by rotating the micro-scanning optical wedge and these are integrated into a high resolution image based on the corresponding algorithm. In a word, the 2×2 micro-scanning method is selected for use, according to the below-mentioned equations:

$$\delta = (n - 1)\alpha \quad (4)$$

$$\Delta = \delta f_0 \quad (5)$$

In line with equations for deviation angle δ and displacement Δ , the wedge angle of the optical wedge is 21° and the associated machining tolerance is $\pm 2^\circ$, as shown in Figure 12, which is a schematic diagram of the micro-scanning structure. If the optical wedge rotates around a ray axis to perform azimuthal rotation, the focus point of the converged light beams can form a circumference on the focal plane and this circumference uses the original image point as the center and Δ as the radius. In the case that the rotating optical plate respectively stays at four positions that are

90° away from each other, that is 45°, 135°, 225°, and 315°, for under sampling imaging (as the high resolution image reconstruction principle given in Figure 13), micro displacement of adjacent sampling points in a detector can be expressed as $P = L/2$ (Kim et al, 2000). In this equation, L is the pixel pitch and the value of micro-scanning displacement is $(\sqrt{2} L)/4$.

With an aim to improve the possibility of real-time application of the high resolution reconstruction technique for images and enhance its tolerance of the registration error, a fast robust high-resolution image reconstruction algorithm based on Keren registration and interpolation is used. According to this algorithm, low resolution images after registration are projected onto a high

resolution grid in conformity with transformation parameter. And then, template convolution is utilized to iteratively fill missing pixel values so as to reconstruct a high resolution image. Additionally, such an algorithm is compared with another four high resolution image reconstruction algorithms, including the non-uniform interpolation method, the convex set mapping method, the robust iterative backward mapping method and the structurally adaptive normalized convolution method. Experimental results indicate that this algorithm is insensitive to registration errors within a certain range of precision, although it is provided with some advantages in terms of speed and reconstruction effects. Totally speaking, it is an effective, robust and rapid high-resolution multi-frame image reconstruction algorithm. Hence, a fast high-resolution algorithm based on Keren registration and template convolution is implemented and used for the resolution reconstruction of static scene image sequences. In line with Table 1, this algorithm can be employed to estimate pixel points with a difference of 0.0001. In other words, superiorities of the registration based on the Keren algorithm possess characteristics such as high speed, high precision, etc. (Fortin et al, 1996). After completing registration based on the Keren algorithm, Structure-Adaptive Normalized Convolution (SANC) is used to integrate images together. Pictures with four frames ($m = 4$) and two amplification factors ($q = 2$) are selected for irregular interpolation by virtue of twice-normalized convolutions. In this manner, high resolution reconstruction can be implemented. Results after high resolution reconstruction of the above-mentioned two algorithms are shown in Figure 14.

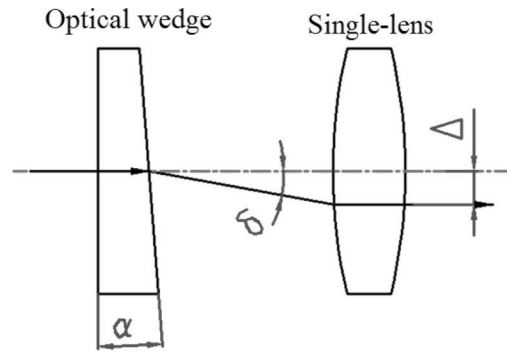

Figure 12. Schematic of the micro-scanning structure principle.

4 CONCLUSIONS

An optimal single lens imaging system is constructed with wave aberration correction by using the liquid crystal spatial light modulator and the high-resolution by using a micro-scanning optical wedge. Firstly, a high precision digital interferometer is utilized to measure the aberration of the single lens together with the acquisition of wavefront data of out-of-focus Zernike Polynomials by means of Zemax simulation. And then, Matlab software is adopted to accurately portray a conjugate gray-scale map that is loaded onto the liquid crystal spatial light modulator later. Thus, wave aberration of the optical system can be corrected depending on the linear phase modulation characteristics of the modulator. In addition, effect improvement generated by the employment of the liquid crystal spatial light modulator is tested by Imatest. Moreover, 2×2 micro-scanning imaging is made use of to perform an oversampling of multiple times and an identical scene. With respect to the micro-scanning imaging, images obtained through each sampling are recorded in the first place; and then, images achieved by each sub-sampling are recombined otherwise according to their sequences of micro-scanning. These are processed into high-resolution images by sub-pixels. This method is featured with high precision, good adaptability, etc. As the liquid crystal technology progresses, the cost of a modulator in the future can be further brought down and it will have a smaller volume. Therefore, a preferable solution will be provided for obtaining high-resolution images by simplifying the optical system.

A geometry-based path optimization approach for motion control of the NC grinding machine

Fan Zhang, Jie Gong, Yijun Liu, Wen Xia, Maofang Huang & Yunfei Fu

Agricultural Product Processing Research Institute at Chinese Academy of Tropical Agricultural Sciences, Chinese Agricultural Ministry Key Laboratory of Tropical Crop Products Processing, Zhanjiang, P.R. China

ABSTRACT: A Geometry-Based Path Optimization Approach (GBPOA) is proposed to solve the motion control of the NC grinding machine which contains four processing procedures. The GBPOA firstly analyzes the structure of the DXF graphical file and develops an Analyzing Algorithm to obtain the data from the DXF file based on Java; and then a Zooming Algorithm is proposed to solve the motion path of the tool of the NC grinding machine according to the value of grinding; next a Path Compensation Algorithm is proposed to solve the path offset problem caused by tool wear in the process of extract grinding and polishing; finally, the NC codes of four processing procedures are generated automatically. A CNC grinding system proves the feasibility and effectiveness of the above-mentioned method, which can improve the machining accuracy of parts and company production efficiency.

1 INTRODUCTION

A grinding machine, which is also called grinder, is used for processing components by using four procedures of kibbling, fining grinding, extract grinding and polishing. A grinder can be widely used in the areas of glass, stone, metal components, ceramic tile, and so on. It is suitable for grinding the inclined plane of the metal strip with different sizes and thicknesses, such as round edge, straight edge, and duck mouth-shaped edge type. DXF (Drawing Exchange Format) is developed by Autodesk for enabling data interoperability between AutoCAD and other programs. By reading and identifying the DXF file of the workpiece, the machine can generate the track of processing automatically.

It is a typical engineering problem that changes the data of DXF files to the NC code, which has appealed to many researchers. D Sreeramulu presented an automated feature recognition system, which was intended to extract the geometric information of rotational parts from the DXF file, and utilized this information to recognize the turning features (D Sreeramulu, 2011). Chen Shumin analyzed DXF files and extracted the coordinate data, and then generated NC codes for the cutting path of layout results (2012, Chen Shumin). Ying Bai studied a motion control system by obtaining the graphic data from the DXF file, and then generated the processing data and sent the data to the designed microcontroller to drive a stepper motor (Ying Bai, 2013). Huibin Yang proposed a graphic information extraction method to transform the graphic information identified from the DXF file

into the bottom motion controller's codes, which can drive the engraving machine (Huibin Yang, 2015). Gabriel Mansour proposed an expert CNC system, which analyzed the DXF file and optimized the machine path process by deciding the optimum path (Gabriel Mansour, 2013). Kovacic constructed an autonomous and intelligent CAD/CAM programming system for the cutting device controller based on an evolutionary genetic algorithm (Kovacic, 2005). In short, studying the DXF file is advantageous to the second development of drawing software. The above-mentioned studies have been used to automate the tool path of the CNC (Computerized Numerical Control) machine and to improve the processing efficiency. However, it is not easy and flexible for the grinding machine to change the processing path spontaneously when the feeding amount is adjusted. Furthermore, in the procedures such as extract grinding and polishing, the tool abrasion may lead to deformation of the part. And so, it is necessary to develop an open interface for the grinding machine, which can generate all the NC codes for four processing procedures.

A Geometry-Based Path Optimization Approach (GBPOA) is devised to solve the motion control of the NC grinding machine. The GBPOA firstly discusses the structure of the DXF and develop a graphical recognition interface based on Java, which can read the graphical information, and can translate the graphical data into coordinate or line information (Section 2); Nextly, a zooming algorithm is proposed to solve the motion path of the tool of the NC grinding machine according to the value of grinding, and presents a path compensation algorithm to solve the

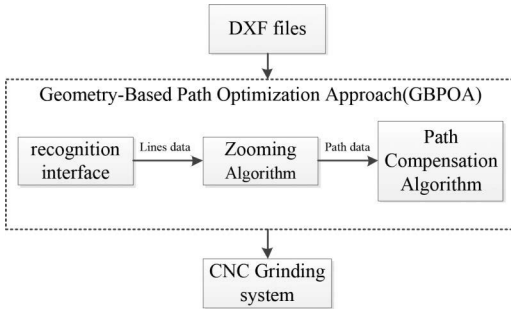

Figure 1. The framework of GBPOA.

path offset problem caused by tool wear in the process of fine grinding and polishing (Section 3). Last but not least, a CNC grinding system, which contains the NC code of four procedures, is totally developed to work directly with the DXF file (Section 4). The framework of the GBPOA is shown in Fig. 1.

2 ANALYZING ALGORITHM FOR THE DXF FILE

As a CAD data file format, DXF has the function of data interoperability between AutoCAD and other programs. The complete structure of DXF includes seven segments called SECTION, which contains HEADER, CLASSES, TABLES, BLOCKS, ENTITIES, OBJECTS, and EOF. Each section has its corresponding function, while the ENTITIES covers all the information of the drawing entities, including the name of each primitive layer, the name of each line, the basic geometry data of each line, and so on. And so, by analyzing the ENTITIES from DXF file, we could obtain the graphical information effectively.

The ENTITIES section is made up of group codes and associated values, which contains all the graphic element objects including LINE, LWPOLYLINE, CIRCLE, ARC, ELLIPSE, and SPLINE. The graphic element objects cover all the geometry data for drawing lines. For example, the LINE has the group code of 10, 20, and 30 corresponding to x , y , and z of the starting point, while the group code of 11, 21, and 31 corresponding to x , y , and z of the terminal point. The other ENTITIES have the same format as that of a group code corresponding to a value.

According to the characteristic of the DXF file, an analyzing algorithm is proposed to extract the graphic data based on Java. In order to store the necessary information, a parametric variable named *LineList*, whose object type is ArrayList, is used with all the information of each feature such as the name, the start and end point, the central point of the circle, the radius, and so on. When a graphic

element object is analyzed, the result will be added to the end of *LineList*. The implementation of the analyzing algorithm can be described as follows:

Analyzing(*fileList*, *lineString*)

Parameters:

fileList: all string information of DXF file

lineString: string of each row

- 1) **for** each *lineString* of item*List* **do**
- 2) **if** *lineString* = 'ENTITIES'
- 3) *lineString* = *fileList*.ReadLine()
- 4) obtain the data from *lineString*
- 5) add the data to *lineList*
- 6) **end for**
- 7) **return** *lineList*

After analyzing all the primitive data, we sort the data, so that these can be read and converted more efficiently. And in order to correspond with NC code, in this paper, a set of data storage rules is also developed, which can be described as follows: firstly, 'G01' is taken as the storage symbol of LINE, and then the starting point and end point follow alongwith. Secondly, 'G02' or 'G03' is taken as the storage symbol of CIRCLE or ARC, and among these 'G02' represents the clockwise arc, while the other represents the counterclockwise arc, and then the central point, the start angle, and the end angle follow alongwith. Particularly, it is difficult for the NC grinding machine to process the ELLIPSE and SPLINE line, and so in the range of acceptable accuracy of the project, the ELLIPSE and SPLINE line are discretized into a multi-segment line. And so, we use 'GPL' to represent the LWPOLYLINE and other multi-segment lines, which is integrated with lots of points. From then, the type of *lineList* contains two parts content, one of which is the code of the line whose index is 0, and the other is the data of line. Table 1 shows the storage rules of analyzed DXF graphical data.

Table 1. The storage rules of analyzed DXF graphical data.

Code	Type of ENTITIES	Data character	Index
G01	LINE	Start point (x , y) End point (x , y)	(1,2) (3,4)
G02 or G03	ARC and CIRCLE	Central point (x , y) radius start angle and end angle	(1,2) 3 4,5
GPL	LWPOLYLINE, ELLIPSE and SPLINE	The coordinate of the i -th point (x , y)	($2i-1, 2i$) ($i = 1, 2, \dots$)

3 ZOOMING ALGORITHM AND PATH COMPENSATION ALGORITHM

Traditionally, the final size and shape of a component are always given so that we can get the processing path easily. However, several questions are ignored such as the irregular shape of the blank workpiece, the orientation of the workpiece on the grinding machine, and the abrasion of the grinding wheel. As for this, during the practical manufacture process, the DXF file of the blank component and the grinding amount would be designated, where the workpiece is processed with a principle of using a small grinding amount one time but many times. It means that the processing path will be zoomed in or zoomed out several times. Therefore, after setting the grinding amount, a zooming algorithm is proposed to compute the processing path as follows:

```

Zooming(lineList, gAmount, inOrOut)
Parameters:
lineList=Analyzing(fileList,lineString,lineList)
gAmount: the grinding amount of single processing
inOrOut: specified external grinding or internal grinding
pathList: aggregation of each processing path
1) for each item line of lineList do
2) calculate the two parallel lines pLine of line according to the gAmount
3) isIn = whether pLine is interior or exterior of the figure
4) if isIn equals to inOrOut
5) pathList.add( pLine)
6) end for
7) for each item pLine of pathList do
8) nextPLine = the next item of pLine in the pathlist
9) node = compute the node of the pLine and the next-PLine
10) update the data of each pLine of pathList according to the node
11) end for
12) return pathList
    
```

After calculating the processing path according to the zooming algorithm, this result can be used to generate the NC code when grinding the workpiece in the procedures of kibbling and fining grinding. However, tool wear must be considered when grinding the component in the procedures of extract grinding and polishing because of the requirement of grinding accuracy. The orientation offset of the processing workpiece caused by tool wear is shown in Fig. 2. Therefore, in order to

Figure 2. Schematic of the orientation offset of the processing workpiece.

avoid the distortion of the processing workpiece, a path compensation algorithm is proposed to compute the compensated path. The implemented course of the algorithm can be revealed as follows:

```

PathCompensation(pathList, wearRate)
Parameters:
pathList = Zooming(lineList,gAmount,inOrOut)
wearRate: the wear rate of grinding tool for fixed-distance fd
fd
cPathList: the path after tool compensation
cPointList: all the point for Arc compensation, whose size is Arc' s circumference in fd
1) for each item path of pathList do
2) if path is Line or Lwpolyline
3) calculate the compensating line cPath according to wearRate
4) if path is Arc
5) get all cPointList of path
6) for each step i of cPointList' s size do
7) cpi = cPcPointList.get(i),
   cpi+1 = cPcPointList.get(i+1)
8) calculate the compensation point cpi' of cpi and cpi+1' of cpi+1 according to wearRate
9) calculate the compensation cPath whose start point is cpi', end point is cpi+1'
10) set radius that is the same of path
11) cPathList.add(cPath)
12) end for
13) return cPointList
    
```

Figure 3. Schematic of the case for the path compensation algorithm.

Line 3 calculates the offset slope of the processing line, so as to obtain the compensating line for the line segment. For the arc segment, a subsection compensation method is presented in line 4–line 10. Firstly, we define some parameters of the arc segment such as the radius r , the central point P_c , the start point P_0 , the end point P_{end} , and the wear rate wr . Secondly the compensation points P_i ($i = 1, 2, \dots, n$) of the arc segment according to the wear rate, thereupon the arc can be described as $(P_0, P_1, P_2, \dots, P_i, \dots, P_n, A_{end})$. When the tool goes to P_i , the wear of the tool became $i * wc$, and then P_i will be dealt with the point P_i that is the intersection between the circle, whose radius is $(r - i * wc)$ and central point is the P_c , and the line segment whose start point is P_i and end point is P_c .

Figure 5. Part of the NC code of the presented graph.

And then, the curve of $(P_{i,j}, P_i)$ will become the curve of $(P_{i,j}, P_j)$. In order to fit the rule of the grinder that only line and arc segments can be processed, the curve of $(P_{i,j}, P_j)$ will be dealt with the arc whose radius is r . Therefore, the compensating path of the arc segment is going to be (Arc (1), Arc (2), ..., Arc (end)). A case in point is shown in Fig. 3.

4 THE CNC GRINDING SYSTEM

Based on the Geometry-Based Path Optimization Approach (GBPOA), a CNC grinding system, which can generate the NC codes of the four procedures automatically, is totally developed to work directly with the DXF file. The CNC grinding system developed by Java is shown in Fig. 4.

From Fig. 4, it can be observed that the graph area displays the processing of the part. The black line presents the blank part, the red line shows the shape of the product and the blue line shows the tool path of the grinder. The cutline manger pane shows the operation mode. After setting all the parameters, the NC code will be generated in the NC code area.

Fig. 5 shows one part of the NC code of the presented graph for the grinding machine.

5 CONCLUSION

In this paper, a novel approach, such as the GBPOA, is presented to solve the motion control of the NC grinding machine. The three main steps of this approach are as follows: analyzing the DXF graphical file, performing tool path calculation, implementing path compensation; these are critical to the GBPOA. The CNC grinding system based on the GBPOA is developed to handle automatically the processing path of the parts for four procedures, and to generate the NC codes for the NC grinder. With more intelligence, the system can be quite practically used.

Future work will be focused on the path optimization for more parts and more constraints.

A study on carbon electrode-based photoelectrochemical-type self-powered high-performance UV detectors

Qi Meng, Xiao Fan, E'qin Wu & Liang Chu

Advanced Energy Technology Center and School of Science, Nanjing University of Posts and Telecommunications (NUPT), Nanjing, P.R. China

ABSTRACT: The carbon nanoparticle film was applied as the counter electrode for photoelectrochemical-type UV detectors for the first time, in which the ultraviolet light-response layer was the TiO₂ nanoparticle film. Under zero bias conditions, the UV detector was sensitivity under pulse UV light, and showed rectangular square-wave signals. The response time and recovery time were 0.06 s and 0.17 s, respectively. The carbon electrode-based self-powered UV detector has potential commercial application because of low cost and high sensitivity.

1 INTRODUCTION

The UltraViolet (UV) detection technology has attracted wide attention due to its applications in food disinfection, binary switch, flame detection, optical communications, switch of UV lights, *etc* (Z. H. Lin, 2014 & H. Zhou, 2015). Nowadays, different types of UV detectors have been achieved, such as Schottky contact (H. Chen, 2012), P–N junction (Y. Q. Bie, 2011), *etc*. However, most of those have complicated preparation processes and low sensitivity. Particularly, they need external power as a force field to separate the excited electrode–hole pairs, which waste energy.

Z. L. Wang has proposed the “self-powered” concept, which means the devices or systems are wireless devices to be self-powered without using battery (Z. L. Wang, 2006 & 2012). Photoelectrochemical-type UV detectors can work under zero bias, which are self-powered ones. After the devices absorb UV light, the electron–hole pairs are excited, and separated by the redox reaction to achieve detection function without external energy. For now, the counter electrodes of the photoelectrochemical-type UV detectors are mainly Pt and Au (S. M. Hatch, 2013 & T. Dixit, 2016 & S. Lu, 2014), which are noble metals and expensive (W.-J. Lee, 2011). It is well-known that carbon materials have numerous advantages, such as cheap, broad application prospects and high stability. In addition, some members in our group previously studied that carbon electrodes were used commendably for dye-sensitized solar cells (W. Ahmad, 2015).

In this work, we developed a photoelectrochemical-type self-powered UV detector, which was based on carbon electrodes for the first time.

The UV sensitive layer was the TiO₂ film (Z. Song, 2016 & Z. Liu, 2015 & X. Li, 2012). Under zero bias voltage conditions, the detector showed high sensitivity and stable signals. The response time and recovery time were 0.06 s and 0.17 s, respectively, and exhibited a rectangular square wave signal in pulsed UV irradiation. Due to the advantages of low cost, signal stability, high sensitivity, and self-powered character, the as-prepared UV detector has great potential in business applications.

2 EXPERIMENTAL DETAILS

2.1 Chemicals and reagents

Fluorine-doped Tin Oxide (FTO, $\sim 7 \Omega/2$) glasses were purchased from Nippin Sheet Glass Co., Ltd. P25 (TiO₂, 21 nm) and carbon nanoparticles (25 nm) were obtained from Degussa. Ethyl cellulose (200CPS), TiCl₄ (99.0%), terpineol, acetic acid (99.0%), pethanol (99.7%), and acetone (99.5%) were purchased from Sinopharm Chemical Reagent Co. Ltd. Guanidinium thiocyanate (GuSCN, 99.0%) was acquired from Amresco. Lithium iodide (LiI, 99.999%), iodine (I₂, 99.99%), 1-methyl-3-propylimidazolium iodide (PMII, 98%), 4-Tert-Butylpyridine (4-TBP, 96%) and tert-butyl alcohol (99.5%) were obtained from Aladdin. Acetonitrile (99.8%) and valeronitrile (99%) were purchased from Alfa Aesar.

2.2 Fabrication of TiO₂ and carbon electrodes

The cut FTO glasses were washed with detergent under running water, and sonicated in deionized water, acetone, and ethanol for 20 min,

respectively. After dried, the well-cleaned FTO glasses were soaked in 0.04 M TiCl_4 solution at 70°C for 30 min to form a compact TiO_2 layer (L. Chu, 2015 & J.S. Zhong, 2015). P25 powder (1 g) or carbon powder (1 g) was mixed with 0.2 g acetic acid, 0.5 g ethyl cellulose, 3 g terpineol and some ethanol under continuous stirring by using a magnetic stirrer. And then, the mixture was grinded for about 20 min, and finally ultrasonically treated for about 10 min to make the expected pastes. Subsequently, the TiO_2 paste and carbon paste were printed onto the TiCl_4 -treated and clean FTO glasses, respectively. And then, the TiO_2 layer was heated at 125°C for 15 min, at 325°C for 5 min, at 375°C for 5 min, and at 450°C for 30 min, and the carbon layer was heated at 125°C for 15 min and at 325°C for 30 min.

2.3 Fabrication of the UV detector

The electrolyte was comprised of 0.6 M PMII, 0.05 M LiI, 0.03 M I_2 , 0.1 M GuSCN, and 0.5 M 4-TBP in the solution of acetonitrile and valeronitrile (V: V = 85: 15). For UV detectors, the carbon electrode was buckled on the TiO_2 photoelectrode, separated, and sealed by using a $50\ \mu\text{m}$ plastic sheet, where the internal space was filled with above-mentioned liquid electrolyte.

2.4 Characterization

The surface morphologies of the TiO_2 and carbon electrodes were characterized by using Scanning Electron Microscopy (SEM, FEI NOVA NanoSEM 450). The phase identification was examined by using an X-Ray Diffractometer (XRD) (Bruker D8 Advance X-ray diffractometer). The ultra-high pressure mercury lamp (Model CHF-XM500, Beijing Changtuo Technology Co., Ltd.) provided 365 nm UV light ($7\ \text{mW}/\text{cm}^2$). An electrochemical workstation (AUT84315, Netherlands) was used to obtain the current–voltage curve and current response under pulsed UV irradiation.

3 RESULTS AND DISCUSSION

Fig. 1a and b show SEM images of TiO_2 and carbon film electrodes. The results show the typical mesoporous films with uniform space and without agglomeration of nanoparticles. The nanoparticles propose an enormous specific surface area for sufficient contact with the electrolyte and the uniform space is beneficial for the injecting of the electrolyte. Thus, the TiO_2 and carbon nanoparticle mesoporous film could be used as an efficient UV sensitive layer and counter electrode, respectively. The XRD patterns of TiO_2 and carbon electrodes

in Fig. 1c and d reveal that the solvents and thickening agent in the pastes disappeared completely during annealing. P25 was mixed phases of anatase and rutile, carbon was the amorphous phase, and the phase of FTO substrates has the peaks of S(110), (101), (200), and (211) in the patterns.

Fig. 2 is the curve of current versus voltage under dark and UV irradiation conditions. When the device was irradiated by using UV light, current was significantly enhanced. More importantly, at zero bias voltage, the device has a significant current with UV irradiation. The results indicate that the UV detector is a self-powered device, which can work without external energy.

In fact, this UV detector is a photoelectrochemical type, whose schematics and work principle are shown in Fig. 3a and b. Firstly, electron–hole pairs were generated after absorbing ultraviolet light of

Figure 1. SEM images of **a**: TiO_2 photoelectrodes and **b**: carbon electrodes. Representative XRD patterns of **c**: TiO_2 photoelectrodes and **d**: carbon electrodes.

Figure 2. Current–voltage curves of the detector with or without UV illumination.

Figure 3. (a) Schematic illustration of the self-powered UV detector; and (b) work principles of the self-powered UV detector.

Figure 4. (a) The response and recovery currents under pulse UV illustration and zero bias; (b) the response and recovery times.

TiO₂ nanoparticles; and then, the electrons flow to conductive substrate through the TiO₂ layer, and the holes flow to the electrolyte. Meanwhile, the carbon electrode exhibits catalytic activity for electrons. The electrodes and holes carry out oxidation and reduction reactions between redox couples to ensure the continued operation of the self-powered UV detector.

Fig. 4a shows the current response of the UV detector under pulse UV irradiation at zero bias voltage. The device has a rectangular square wave signal with or without UV irradiation. The result indicates the self-powered UV detector with high responsibility and stability. To reveal the response and recovery time more clearly, the enlarged response and recovery currents are shown in Fig. 4b. The response and recovery times are the times needed to reach $(1-1/e)$ and to drop to $1/e$ of the maximum photocurrent (J.J. Hassan, 2012), respectively, which are 0.06 and 0.17 s. The results indicate that the self-powered UV detector has high sensitivity and stability. As a consequence, the self-powered UV detector has a simple preparation process, low prices, high sensitivity, good stability, and high performance, which is a desired kind of the commercial UV detector.

4 CONCLUSION

In summary, the carbon electrode was first used in photoelectrochemical-type UV detectors, which

has advantages of simple preparation process, low cost, high performance, and stability. More importantly, the UV detector is self-powered. In light of the simple fabrication, zero energy consumption, and outstanding UV-sensitive performance, we look forward to great potential applications in various fields, such as flame detection, UV radiation surveillance, binary switch, optical communications, and switch of UV light.

A scheme study of CFB power generation by using pet coke

H.T. Liu, L. Xue & D.F. Xu

SEPCO Electric Power Construction Corporation, Jinan, Shandong Province, China

ABSTRACT: High sulfur pet coke power generation through circulating fluidized bed technology is discussed in this paper. When compared with coal, pet coke has the following characteristics such as high carbon content, high sulfur content, high heat value, low ash content, and low volatile matter. CFB power generation technology is considered to be a good method to use high sulfur pet coke. A six times 300 MW sub-critical unit (6 × 300 MW) is proposed in this project.

1 INTRODUCTION

Pet coke is a by-product produced during heavy/residual oil's delayed coking process. Its main component is the element C, accounting for more than 80 wt%. The rest of the elements are H, O, N, and metallic elements. It has characters such as high heat value, high carbon content, low ash content, low volatile matter, etc. With respect to the sulfur content existing in the pet coke, content more than 3% is called high sulfur pet coke (Zhu 2012). High sulfur pet coke is normally used as fuel, and therefore, it is also called fuel grade pet coke (Miao et al. 2014). However, due to the large amount of pollutant emission, such as SO_x and NO_x, the large-scale use of high sulfur pet coke is limited. The ideal way to use high sulfur pet coke should consider both efficiency and cleanliness. IGCC power generation technology and CFB power generation technology are both considered to be good options to use high sulfur pet coke (Ding 2014, Xu et al. 2011, Wang & Leng 2009). When compared with IGCC technology, CFB power generation technology has advantages such as high combustion efficiency, high availability, large load adjustment range, and less corrosion to equipment and nature. There are already some commercial pet coke-fired CFB plants operating in the world.

Saudi Arabia is the world's biggest oil producer in contrast to most of the world's oil reserves. Its pet coke production grows continuously along with the growth of crude oil production. However, since the quality of crude oil declines continuously, the rate of production of high sulfur pet coke grows rapidly. Commissioned by one Saudi Arabia oil company, our company is carrying out research on the CFB power generation scheme by using high sulfur pet coke produced in this oil company's refinery. The aim of this paper is to provide reference for related research.

2 DESIGN INPUT

Pet coke used in this project is adopted from two nearby refineries. Each refinery can produce 6000 tons pet coke per day. Elements analysis and other analyses are shown in Tables 1 and 2.

When compared with coal, pet coke studied in this project has the following characteristics such as high carbon content, high sulfur content, high heat value, low ash content, and low volatile matter.

According to local emission requirements, the plant emission shall satisfy World Bank Targets, which is given in Table 3.

Table 1. Elements' analysis of pet coke (count as per air received base) wt%.

3 PET COKE FIRED CFB POWER GENERATION

3.1 Process description

The process of CFB power generation by using pet coke is roughly as follows: pet coke and limestone are crushed and then fed by using a feeding device to a combustion chamber. Pet coke is heated by using cycled high temperature materials and is burned soon. Limestone is used as a desulfurizing agent and supplement as the bed material at the same time. In the combustion chamber, the bed material, with the fuel, is fluidized with primary air which turbulently transports the solids up to the entire height of the combustion chamber. Combustion of the fuel takes place as it rises and heat is transferred to the membrane water-wall tubing that forms the walls of the combustion chamber. The hot combustion gases with the entrained solids are released at the top of the combustion chamber into the cyclone separator. The separator separates the solids from the combustion gases and returns the solids, including any unburned solid fuel, through the non-mechanical loop seal to the combustion chamber where they mix with incoming fresh fuel. The long solids residence time at combustion temperature and the retention and continuous recirculation of the solids ensure high combustion efficiencies for a wide range of fuels and result in an ideal system for the mixture of fine limestone with the fuel for efficient SO₂ retention in solid ash form.

Limestone is allowed to react continuously and therefore, it is necessary to continuously feed limestone with the fuel. The sulfation reaction requires that there is always an excess amount of limestone present. The amount of excess limestone that is required is dependent on a number of factors, such as the amount of sulfur in the fuel, the temperature of the bed, and the physical and chemical characteristics of the limestone. The ideal desulfurization efficiency can reach more than 90%. According to the situation, flue gas desulfurization measures can also be considered to be added onto the tail flue channel to satisfy SO₂ emission requirements.

Provisions are made for primary and secondary air supply to the combustion chamber. The primary air is supplied through the wind box to the fluidizing grid and provides the main fluidization air flow. The secondary air provides a staged combustion effect to ensure high combustion efficiencies and to minimize NO_x production. In addition, the Selective Non-Catalytic Reduction (SNCR) denitration system can also be adopted to meet NO_x emission requirements.

Flue gas and some fine size particulate matter leave the separator and pass through the convection section, which contains superheat, reheat, and economizer banks, along with an air preheater. The flue gas then enters a particle collector, where particulate matter is removed in compliance with environmental regulations. Clean flue gas is discharged to the stack via an induced draft fan.

Feedwater is sent to the CFB and heated to produce steam. Steam with high temperature and pressure is then sent to a steam turbine and obtains the power from the steam turbine generator. Details of the process are shown in Figure 1. Pet coke-fired CFB power generation technology has the following characteristics such as large load adjustment range, high availability, less corrosion to equipment and nature. Power and steam can be released as output at the same time.

3.2 Research progress

CFB technology using pet coke as fuel has been developed rapidly since 1980s. Till now, there are already dozens of power plants that are being commercial operated. Usage of pet coke in CFB boilers can be mainly divided into two ways, one is pure burning of pet coke and another is mixed burning pet coke with coal (Dong et al. 2014). At present, the main problems of pure pet coke burning methods are as follows: high carbon content in fly ash, little amount of cycle material, instability of bed temperature, high temperatures of the dense-phase zone, limited boiler load, slag of the bed material in the return feeder and cyclone separator, high

temperature corrosion at the separator center pipe, ash deposited on the heating surface, etc. (Pei et al. 2013, Zheng & Chen 2004). The high carbon content in fly ash can be controlled through measures such as strict control of the material particle size, thereby choosing an appropriate material circulation ratio and adjusting the secondary air volume. Problems, such as little amount of cycle material, instability of bed temperature, high temperature of the dense-phase zone, and limited boiler load, can be dealt with through measures such as improving the separation efficiency of the cyclone separator, adding sand in the bed material, and adjusting the ratio of primary and secondary air. Currently, there are no effective measures to overcome other problems (Pei et al. 2004, Li et al. 2005, Tang & Li 2004, Xiang & Yuan 2004, Liu et al. 2002, Yuan & Liu 2002). Further studies are still needed to proceed with.

4 SCHEME OF THIS PROJECT

Based on the pet coke production of two refineries and the heat value of the pet coke, it is assumed that thermal efficiency of the whole power plant is about 40%; it can be preliminarily evaluated that the scale of this power plant is around 1980 MW. Considering the mature mode of commercial products (steam turbine and CFB boiler), a six times 300 MW unit (6×300 MW) is proposed in this project. Related parameters of the steam turbine and CFB boiler are described as follows:

4.1 Steam turbine

As provided by the supplier, the information of the steam turbine is as follows: sub-critical, once reheated, four cylinders with one single flow High Pressure turbine (HP), one single flow Intermediate Pressure turbine (IP) and one double flow Low Pressure turbines (LP), with single axial, single back pressure condensing, water cooling condensing mechanisms. Main parameters of the steam turbine are given in Table 4.

4.2 CFB Boiler

To match with the steam turbine's capacity, six sub-critical CFB boilers are selected. The Boiler Maximum Continuous Rating (BMCR) is set to be the same as that of the turbine Valve Wide Open (VWO) operating condition and is equal to 1.05 times that of the Turbine Maximum Continuous Rating (TMCR) operating condition. The information of the boiler provided by the supplier is as follows: sub-critical, single steam drum, natural circulation, balanced

draft, autoignition, and combustion-supporting. Relevant details are given in Table 5.

4.3 Other systems

Other auxiliary systems, such as the combustion system, steam and water system, pet coke handling system, limestone handling system, ash removal system, water supply system, chemical water treatment system, waste water treatment and drainage system, firefighting system, air conditioning and ventilation system, electrical system, instrumentation and control system, environmental protection, etc., are all designed according to related standards and design inputs to balance the plant.

Table 4. Main parameters of the steam turbine (TMCR operating conditions).

Item	Unit	Parameter
Mode		N300-16.67/565/565
Rated output (TMCR + 0%)	MW	300
Maximum output (VWO + 0%)	MW	315
Rated steam pressure (main steam)	MPa	16.67
Rated steam temperature (main steam)	°C	565°C
Rated steam pressure (reheat steam)	MPa	4.16
Rated steam temperature (reheat steam)	°C	565
Rated main steam flow	t/h	925
Maximum steam flow	t/h	975
Rated exhaust pressure	kPa	10
Feed water temperature	°C	273.2
Heat rate	kJ/kWh	8017.7
Rated speed	r/min	3600
Regenerative system		3 HP heaters, 4 LP heaters and 1 deaerator

Table 5. Main parameters of the boiler (BMCR operating condition).

Item	Unit	Parameter
Maximum steam flow	t/h	975
Superheat steam outlet pressure	MPa	16.67
Superheat steam outlet temperature	°C	565
Reheat steam flow	t/h	860.5
Reheat steam inlet pressure	MPa	4.75
Reheat steam outlet pressure	MPa	4.37
Reheat steam inlet temperature	°C	372.6

5 CONCLUSION

High sulfur pet coke is normally used as fuel. When compared with coal, pet coke studied in this project has the following characteristics: high carbon content, high sulfur content, high heat value, low ash content, and low volatile matter. CFB power generation technology is considered to be a good method to use high sulfur pet coke. It has advantages such as high combustion efficiency, high availability, large load adjustment range, and low corrosion to equipment and nature. The scale of this project is evaluated around 1980 MW. A six times 300 MW sub-critical unit (6×300 MW) is proposed. Mode of the steam turbine is N300-16.67/565/565. Six sub-critical CFB boilers, under BMCR operating conditions that are equal to 1.05 times that of TMCR operating conditions, are selected to match with the steam turbine.

Design of the pilot-scale double effect evaporator for high-concentration sodium hydroxide production

Le Gao

Department of Chemical Engineering, University of Minnesota Twin Cities, Minnesota, USA

ABSTRACT: The objective was to use the pilot plant double effect evaporator in order to concentrate 75,000 gallons of aqueous sodium hydroxide from 10 wt% to 40 wt%. The purpose of the experiment was to determine the steady-state operating temperatures and pressures in order to calculate the overall heat transfer coefficients, U , and determine steady-state cooling water rates to the condenser. In order to accomplish the experimental purpose of running the pilot plant at steady-state operation, the accumulation rates of mass and heat were calculated and plotted over time. The closest time step to steady state was at 4500 ± 6 seconds from the start of data collection. The mass accumulation for this data set and the energy accumulation were obtained from the experimental data. The heat transfer coefficient for the first effect, second effect and condenser were compared to each other, which were found to be within the expected literature values. The cooling water rate provided to the condenser was calculated. Using these results, a design was proposed with a feed rate of 0.8 kg/s of the 10 wt% NaOH into the first effect and a cooling water flow rate of 0.004 kg/s. This resulted in an output flow rate of 0.2 kg/s 40 wt% solution, with a steam consumption of 1.35 kg/s and a steam economy of 0.4 kg vapor/kg steam.

1 INTRODUCTION

Analysis of steady-state operation of double effect evaporator and prediction were made on the process of sodium hydroxide solution. 1. Double effect distillation and thermal integration applied to the ethanol production process. The ethanol production process was simulated using Aspen Plus® software. The process included double effect distillation technology which achieved the reduction in the steam consumption. The study assessed the double effect distillation in ethanol production process, and its impact on energy consumption and electricity surplus production in the cogeneration system. The economic assessment was also done based on equipment cost. As a result, the reduction in steam consumption was calculated. Figures: process flow diagrams of conventional and double effect processes steam consumption and cost. 2. Prediction of energetic and exergetic performance of double effect absorption system. The topic was about solar double effect absorption system. The performance of double effect absorption system was analyzed and optimized using a computer program which has been developed by Engineering Equation Solver software to describe the mathematical model of the used absorption system. Also, the study predicted the Coefficient of Performance (COP) and exergetic efficiency of the system, and formulated them in equations as

functions of the operating parameters of the cycle. Figures: thermodynamic performance based on temperature of high pressure generator. 3. Design and computer simulation on multi-effect evaporation seawater desalination system using hybrid renewable energy sources in Turkey. The multi-effect evaporation was simulated with Visual Basic programming language based on data obtained by 18 stations for ten years. The comparison of the result with the literature values showed the accordance. Also, it compared the solar and wind energy as the energy source of evaporator. Multiple effect units; energy figure: process flow diagrams of multi-effect; flowchart. 4. Thermodynamic analysis of a trigeneration system consisting of a micro gas turbine and a double effect absorption chiller. A mathematical model of double effect absorption chiller was built using a MATLAB programming language to estimate the thermodynamic performance. The trigeneration system was evaluated at different operating conditions: ambient temperatures, generation temperatures and microturbine fuel mass flow rate. More about microturbine than double effect. 5. Simulation and Control of a Commercial Double Effect Evaporator: Tomato Juice The commercial double effect tomato paste evaporation system was simulated. The open loop simulation showed that the sample evaporator provided stable process. Backward feeding. 6. Dynamic Simulation of a Nonlinear Model of

a Double Effect Evaporator. The commercial double effect tomato paste evaporator was simulated using ACSL. Feed flow rate and product solids concentration from the simulation were compared with the experimental measurements. 7. Dynamic Response of a Double Effect Evaporator. A simple mathematical model was built with unsteady state material and energy balances. Agreement achieved between experimental response of the evaporator and the predicted response.

The purpose of the experiments was to determine the steady-state operating temperatures and pressures, in order to calculate the overall heat transfer coefficient of each of the heaters used in the double effect evaporator system. Steady state was measured as having zero mass or energy accumulation. Radiative and convective heat losses were also calculated for use in the energy balance and the design problem.

2 EXPERIMENT AND MODEL

2.1 *Experimental procedure*

2.1.1 *Start up*

Before the experiment, all valves were closed. Blow-down valves of pressure gauges P1-P4 were opened to blow out gases initially. The filling of evaporator started from 1st effect unit. Before filling, LLC was activated by opening valve A-14 to supply compressed air to LLC. After LLC was connected to the 1st effect, the water was fed to 1st heater passing through rotameter R1. The 1st disengaging chamber was filled to steady state operating level. Before filling 2nd effect unit, the water supply to vacuum pump was opened and then the vacuum pump was started to create vacuum in condenser. The vent valve, valve of condensate receiver to drain were closed to ensure that condenser unit was not open to atmosphere. To fill 2nd effect unit, the valve connecting 1st and 2nd effect was opened to feed water from 1st effect to 2nd effect unit. The circulating pump was started when filling 2nd effect, which forced a circulation between heater and disengaging chamber in 2nd effect. Then the cooling water was fed to condenser. After the 2nd disengaging chamber was half filled, the steam was fed to the 1st heater. The gauge pressure of steam supply was controlled to be around 170 Kpa (Sharqawy, 2010). After the steam was supplied to the system, the cooling water started to be fed to the condenser. The flow rate of cooling water was controlled to obtain 20°C temperature rise in cooling water. Condensate collected in condensate receiver was drained before it reached the liquid level of 0.70 m. After the operation of DEE system, the valve of steam calorimeter was

opened to measure the condition of steam before and after adiabatic expansion. The measurement of calorimeter was taken until the temperature of T8 and T9 were almost equal, which meant the steam constantly passed through the calorimeter and got ready for data collection.

2.1.2 *Attainment of steady state*

To achieve steady state, two important independent variables, liquid level heights of 1st and 2nd disengaging chamber were controlled to reach constant. The liquid level of 1st disengaging chamber was controlled by the liquid level controller, since the sensor automatically closed the feed valve as the liquid level increased. The liquid level of 2nd disengaging chamber was controlled manually through turning the feed valve to 2nd effect. Through the calculation and analysis in section 3.2 and 4, the system took around 4400 s to achieve the steady state of mass and energy. The rate of cooling water was changed around 3:30 PM to obtain 20°C temperature rise of cooling water passing condenser.

2.1.3 *Data collection*

In week 1, the double effect evaporator was filled with proper operation and all procedures, valves, and dimensions of equipment were recorded. In week 2, the filling of the double effect evaporator started at 1:40 PM. Operations such as filling and feeding steam were finished before 3:20 PM. Data collection started at 3:25 PM, and measurements were taken around every 10 min.

Measurements of the experiment included temperature of different streams or positions (T1-T13, TD4, TD5), pressure of different streams or positions (P1-P5), flow rate of different streams (R1-3, steam trap 1-2), and liquid level height of two disengaging chambers. Systematic errors with the equipment were recorded as well.

2.1.4 *Shut-down [13]*

The shut-down followed the procedures in handout [13] to ensure safety. The inlet of steam and water to the whole system was first stopped. Valve (S-11) for steam supply was closed and the remaining steam was vent through calorimeter. Valves for water feed to 1st and 2nd effect units were closed. The vacuum to condenser was opened fully and the condensate rotameter (R3) was bypassed. The condensate in receiver was drained through the vacuum pump. The circulating pump was stopped. The condenser and 2nd effect was vented once the temperature of 1st effect decreased to 80°C (175°F). The vacuum pump was shut off, and the feed water from main and water supply to vacuum pump were stopped by closing valves WM1 and VP-2. All drains and interconnecting valves were opened to drain water remained in the evaporator. Air supply to LLC was

stopped by closing valve A-14. Blow-down valves of pressure gauges and drain valve of vacuum pump were opened to drain water.

2.1.5 Precaution

Water was used in the experiment instead of sodium hydroxide solution. Basic rules such as safety goggles, long pants, and close-toed shoes were required in the laboratory. Special precautions for Double Effect Evaporator experiment were avoiding contacting hot pipes and hot equipment. Also, to make a safe experiment when operating the equipment, the water supply for vacuum pump was opened. The liquid level of disengaging chamber and condensate receiver was monitored to avoid overfilling. The shutdown procedures in handout was followed carefully after experiment.

2.1.6 Observation and Improvement

Liquid levels of two disengaging chambers were observed to be in ± 0.06 m, which were roughly determined to be mass steady state in 1st and 2nd effect units. Cooling water flow rate was one of the important independent variables of the experiment. In the experiment, the flow rate of water feed to condenser was so fast at first that the temperature raise only 10°C in cooling water. The cooling water flow rate was decreased after 4000 s of operation (around 4:30 PM) to obtain a temperature rise over 20°C in cooling water, which caused difficulty to achieve steady state. All settings should be controlled before operating and data collecting. The change of conditions during the operating may break the trend and take longer time to reach steady state.

2.2 Modeling

2.2.1 Double effect evaporator

The function of the double effect evaporator is to concentrate a solution by evaporation of the solvent. In each effect, steam is used to heat the liquid stream, which is separated in a disengaging chamber into vapor and condensate. In a feed-forward system, the vapor from the first effect enters the second effect heater and is used to heat the condensate from the first effect. The second effect is kept at a lower pressure than the first effect by the vacuum pump so that it operates at a lower temperature. To characterize steady state, Equations 1 and 2 were used to describe the mass and heat balances, respectively.

$$\sum m_{in} - \sum m_{out} = acc \quad (1)$$

$$\sum Q_{in} - \sum Q_{out} = acc \quad (2)$$

min and Qin represent the mass and heat terms entering the system, m_{out} and Q_{out} represent the

mass and heat terms exiting the system, and acc is the accumulation term, which is defined to be zero at steady state. The system was solved with overall mass and heat balances, as well as individual mass and heat balances on each effect.

Using steady-state values for temperature and heat transferred in each effect, the overall heat transfer coefficient describing the effectiveness of the heater can be calculated from equation 3:

$$U_i = Q_i / \Delta T_{m,i} A_i \quad (3)$$

U_i is the overall heat transfer coefficient the heater, Q_i is the heat transferred from the steam in the heater, $\Delta T_{m,i}$ is the mean temperature difference between the steam and the boiling point of the disengaging chamber, and A_i is the total area of heat transfer. The subscript "i" is used to denote that the values are specific to the heater in the i th effect.

Heat in the liquid and vapor streams were calculated with the following equations:

$$Q_{liquid} = m_L * H_L \quad (4)$$

$$Q_{vapor} = m_v * \lambda_v \quad (5)$$

m_L and m_v represent the mass flow rate of the liquid or vapor streams, respectively, H_L represents the enthalpy of the liquid stream, and λ_v represents the latent heat of vaporization of the vapor stream. The enthalpy of a liquid stream containing a solute could be found as a function of concentration and temperature from enthalpy-concentration charts. The assumption for the vapor streams was that they remained at the boiling point of the liquid in the disengaging chamber and exchanged heat by converting between liquid and vapor state. Latent heats of vaporization were found from temperature from the following correlation:

$$\lambda_v = 2.501 * 10^6 - 2.369 * 10^3 * T + 2.678 * 10^{-1} * T^2 - 8.103 * 10^{-3} * T^3 - 2.079 * 10^{-5} * T^4 \quad (6)$$

This correlation was found to be valid for pure liquid water within 0.01% for a temperature range between $0-200^\circ\text{C}$ when fit to experimental data [14].

3 RESULTS AND DISCUSSION

3.1 The measurements of the double effect evaporator

The definition of steady state is a point at which the accumulation of mass and energy within the system approaches zero. It was important to determine at

which point the pilot system began to operate at steady state. The mass accumulation terms for the system are displayed in in Figure 2(a-c). The mass flow rate data from the system was significant to calculate the rate of accumulation of mass in the overall system, the first effect, and the second effect.

To calculate the rate of accumulation of energy in the system, it was necessary to find how much steam first entered the system. This was found through the use of the steam calorimeter. The steam calorimeter data and steam quality value were used to estimate the energy loss during the process. It was also necessary to calculate the amount of energy dissipated out of the system as shown in Figure 3. It was found that convective energy loss was negligible compared to that of radiative energy loss, while the radiative energy loss was significant, due to the significant sources of radiative energy loss determined by the comparisons in different curves of Figure 3.

The energy over time values for liquid and vapor streams associated with the pilot system were calculated using the methods were presented. The accumulation of energy in the system at various times of operation are further characterized in the following chapter.

Using the energy over time values in Figure 3, it was possible to calculate the overall heat transfer coefficients for the heat exchangers in the pilot system. The overall heat transfer coefficients were calculated at the time at which the system was thought to be closest to steady state operation. The values for the overall heat transfer coefficients (as well as the parameters important to calculate them) are: $8200 \pm 502 \text{ W (m}^2 \text{ K)}^{-1}$ for the first effect heater, $2950 \pm 57 \text{ W (m}^2 \text{ K)}^{-1}$ for second effect heater and $135 \pm 6 \text{ W (m}^2 \text{ K)}^{-1}$ for condenser as shown in Table 1.

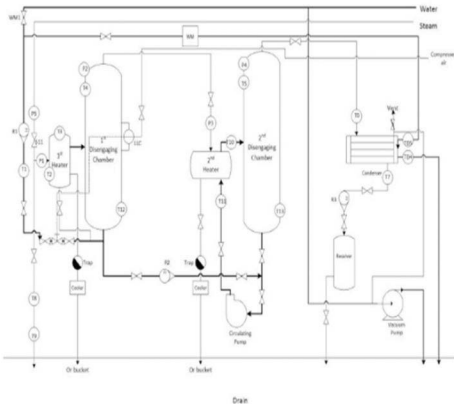

Figure 1. Process flow diagram of the pilot plant double effect evaporator.

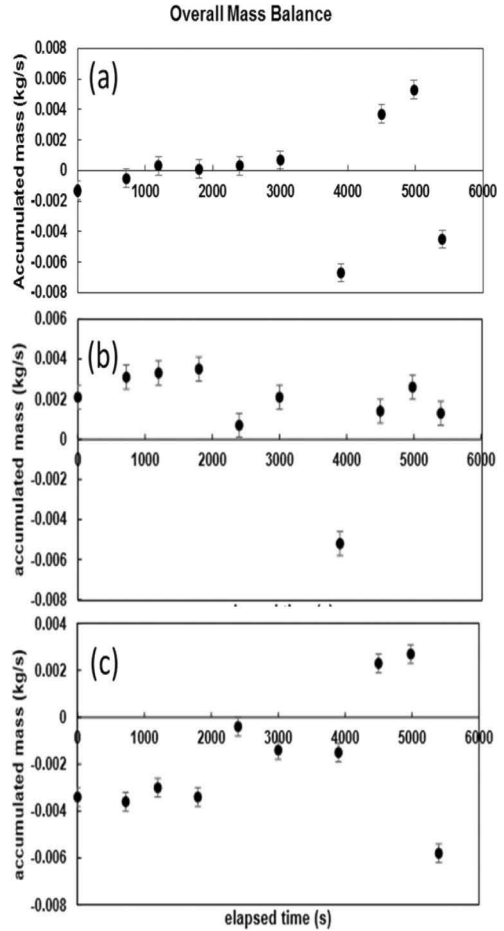

Figure 2. Mass accumulation of double effect evaporator: the accumulation of mass in the system over time for the (a) overall mass balance; (b) first effect accumulated mass and (c) second effect accumulated mass.

The general equation for each energy balance was Equation 4. The energy balance equations were used to monitor the rate of accumulation of energy in the system over time. It was approximated that the steam exiting each effect would be a completely saturated liquid. Because of this, the rate of energy input into the system by the steam. Knowing these values, the rate of accumulation of energy in the system was then calculated using the values rate of energy transferred to and from the system from Figure 3, Trial 8 and radiative energy loss values from Trial 6 because they were taken at similar times. The overall rate of accumulation of energy values and the values of the terms of which it was comprised of are featured in Figure 4 and Table 2.

Figure 3. Radiative energy loss data: Contains significant radiative energy loss values from equipment in the pilot system. The method for calculating these values and determining which values were significant is detailed in the model section.

3.2 Design of sodium hydroxide concentration procedure

The stated objective of the Figure 5 was to use the same pilot plant double effect evaporator system to concentrate 75,000 gallons of aqueous sodium hydroxide solution from 10 wt% to 40 wt%. This could be achieved with only two small modifications to the system (from Figure 1). First, the main water line was disconnected from the feed to the first effect heater and replaced with a feed line connecting to the supply of 10 wt% NaOH solution. The rotameter R1 would be used to set an upper limit on the feed mass flow rate, which is also controlled by the LLC to maintain steady-state in the 1st effect disengaging column. Additionally, a new pipe would need to be attached to the 2nd disengaging chamber to allow the concentrated solution to connect to other units for further processing. This flow rate would be controlled by the valve connected to rotameter R4. Start-up of the system could be done in a similar manner to the experimental procedure, described in experimental section. The first disengaging chamber would be allowed to fill to the steady-state level controlled by the level controller. Next, the second disengaging

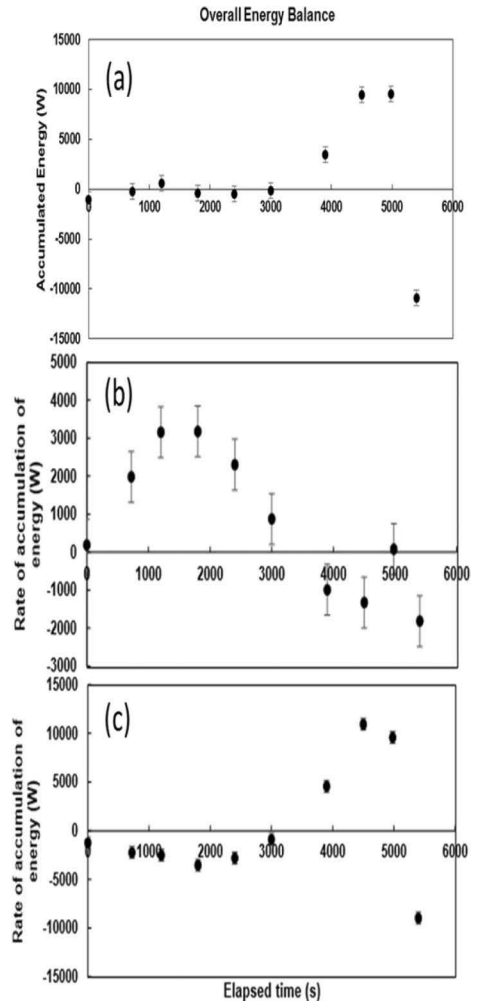

Figure 4. Energy balance of double effect evaporator: rate of accumulation of energy values vs. elapsed time for the (a) overall energy balance; (b) first effect energy balance and (c) second effect energy balance.

chamber would be filled from the first disengaging chamber by opening the valves through R2 and the circulating pump. The circulating pump would be powered on until the 2nd disengaging chamber was approximately half filled. The vacuum pump would be switched on, but the rotameter valve R4 would not be opened until the system had reached approximately steady state operation.

The derivations of Equations 4 were used to calculate the correct feed mass flow rate and cooling water flow rates from the mass balances, heat balances, and the capacity 30 equation for each effect. Assumptions were used to define the system and allow for a steady-state solution. The system

Figure 5. Modified process flow diagram of pilot plant double effect evaporator used in design problem.

was solve using a trial-and-error method in Excel. The feed was assumed to start at room temperature (20°C), with a mass flow rate of 0.8 kg/s. This mass flow rate was chosen with the assumption that slower mass flow rates would waste more energy through radiative heat losses. The flow rate through the circulating pump was chosen such that the linear velocity through the pump was at least 1 m/s in order to prevent fouling effects in the more concentrated second effect, as suggested by (Geankoplis, 2003) (page 299). The steam entering the first effect heater was assumed to start at 100°C (rounded up from the values reported in Table 2), and it was assumed to have the same quality value of 0.996 (from Table 2). The enthalpy of the steam entering was calculated from steam quality, and it was assumed to exit with the same enthalpy as the saturated liquid. Convective heat losses were assumed to be negligible compared to radiative heat losses. Radiative heat loss in piping was assumed to be negligible compared to losses in the heaters, columns, and condenser.

Cooling water flow rates were chosen to give a temperature drop as close to 20°C as possible. Cooling water was assumed to enter at 13°C, similar to what was measured in Table 4. The procedure for determining steady state from the spreadsheet was as follows: 1. Assume a mass flow rate. 2. Change boiling temperature for the first effect along with the enthalpy at the outlet (from Figure 8.4-3 in (Geankoplis, 2003)) until the concentration exiting the first effect is within the range of 0.1–0.4.3. Determine boiling point rise from Figure 8.4-2 (Geankoplis, 2003) and saturation pressure from steam Tables. 4. Change boiling temperature in 2nd effect along with the enthalpy at the outlet (Figure 4 (Geankoplis, 2003)) until

Table 3. Steam quality.

Enthalpy of saturated steam at system pressure (236972 Pa) ($\pm 0.66 \text{ kJ kg}^{-1} \text{ K}^{-1}$)	Enthalpy of saturated liquid at system pressure (236972 Pa) ($\pm 0.02 \text{ kJ kg}^{-1} \text{ K}^{-1}$)	Enthalpy of superheated steam at barometric pressure (97697 Pa) ($\pm 1.2 \text{ kJ kg}^{-1} \text{ K}^{-1}$)	Steam quality (± 0.001)

Steam/vapor temperature ($^{\circ}\text{C}$)	100	79.21		
Recycle stream flow rate (kg/s)	N.A.	2.7		

the concentration exiting the 2nd effect is 0.4. 5. Calculate mass flow rate of product produced, verify mass balances and calculate steam economy.

4 CONCLUSIONS

A double effect pilot system initially ran with a cooling water flow rate through the final condenser that caused a temperature increase in the cooling water which was below the operating criteria of 20°C . The system ran at this condition for approximately the first 4000 seconds of data collection. At approximately 4000 seconds, the cooling water flow rate to the condenser was lowered from 0.5783 kg s^{-1} to 0.0421 kg s^{-1} . This caused change in temperature of the cooling water through the condenser to increase from $10 \pm 0.6^{\circ}\text{C}$ to $30 \pm 0.6^{\circ}\text{C}$. Because of this, data from the pilot system that can be used to characterize steady state must be taken after this correction to the cooling water flow rate to the final condenser was made. Three data sets were taken after this correction. These were taken at elapsed times of 4500 ± 5 seconds, 4980 ± 5 seconds, and 5400 ± 5 seconds. Analysis of the accumulated mass and energy was performed to determine which of these data sets gives the best portrayal of the pilot system at steady state operation.

Using these results, a design was proposed with a feed rate of 0.8 kg/s of the $10 \text{ wt}\%$ NaOH into the first effect and a cooling water flow rate of 0.004 kg/s . This resulted in an output flow rate of 0.2 kg/s $40 \text{ wt}\%$ solution, with a steam consumption of 1.35 kg/s and a steam economy of $0.4 \text{ kg vapor/kg steam}$.

Early fault diagnosis of wind turbine gearboxes based on the DSMT

Zhouqun Liu & Guochu Chen

Electric Engineering School, Shanghai DianJi University, Shanghai, China

ABSTRACT: Aiming at the problem that early faults of the gear boxes are difficult to be identified effectively and the conventional DST-based fault diagnosis method requires no conflict between the evidence, a fault diagnosis system based on a DSMT wind turbine gearbox is proposed. The DSMT fusion method is used to fuse the conflicting evidences from each evidence source. An analysis of the gear box fault reliability value of numerical changes and determination of the fault type is carried out in this work. The results show that the DSMT is applied to the early fault diagnosis of the wind turbine gear box, which exhibits better fusion results than the DST method.

1 INTRODUCTION

A gearbox is the key equipment that connects the low speed shaft and the high speed shaft. Due to long-term bearing of noise, high temperature, vibration and other complex factors, it is prone to faults. Since wind farms are generally designed in mountainous areas that are far from residential areas or offshore far from the land, maintenance is extremely difficult when it fails. Therefore, to master the early fault characteristics of the wind turbine gear box, and according to the characteristics of early troubleshooting, one can effectively improve the maintenance efficiency and reduce the loss to a large extent.

2 DSMT THEORETICAL BASIS

DSMT (Dezert–Smarandache Theory) is an effective theory that is used to fuse the conflict evidence proposed by Dezert and Smarandache in 2002, which mainly deals with high uncertainty, high conflict, and imprecise information source evidence (Florentin Smarandache, 2011). DSMT can deal with the information fusion problem of any type of independent information sources represented by using the reliability function. In the subsequent development of DSMT, the combination rules of PCR1, PCR2, PCR3, PCR4, PCR5, and PCR6 are proposed. Among these, PCR6 (Florentin Smarandache, 2006) is a more accurate conflict allocation method. DSMT is able to handle complex, static or dynamic fusion problems without being restricted by the DST framework.

2.1 DSMT theoretical basis

Let $\Theta = \{\theta_1, \dots, \theta_n\}$, called the hyper-power set D^Θ [3] in the DSMT frame, which is defined as the set of all composite propositions built from elements of Θ with \cup and \cap operators is such that:

1. $\emptyset, \theta_1, \dots, \theta_n \in D^\Theta$.
2. if $A, B \in D^\Theta$, then $A \cap B \in D^\Theta$ and $A \cup B \in D^\Theta$.
3. No other elements belong to D^Θ , except those obtained by using rules 1 or 2.

When DSMT is applied to the wind turbine gearbox fault diagnosis, θ_i represents the failure mode of the fan gear box. The wind turbine gear box failure mode mainly wears away, gets pitting, gets scratches, and so on.

DSMT presents a new method for describing and analyzing problems. The hyper-power set in DSMT is based on the DST power set to relax the exclusive constraints. The proposition θ_i in frame Θ composes a set of finite propositions that expresses all the features of the fusion problem (Xusheng Zhai, 2012).

2.2 Gearbox of wind turbine conflict evidence fusion rules

The PCR6 rule is one of the more accurate fusion methods in DSMT, and it can obtain better fusion results than PCR5 when there are more than two sources of evidence. Under the generalized recognition frame Θ , there is a mapping of $m(\cdot): D^\Theta \rightarrow [0, 1]$, which satisfies the following three conditions:

1. $M(\theta) = 0$, θ is an empty set;
2. $\sum_{A \in D^\Theta} m(A) = 1$, where $A \in D^\Theta$;
3. $0 \leq m(A) \leq 1$, $A \in D^\Theta$.

And then, $m(A)$ is the generalized basic confidence distribution function of A (Florentin Smarandache, 2011).

Assuming that $m_1(\cdot)$ and $m_2(\cdot)$ denote the generalized basic confidence distribution functions provided by two independent and reliable sources, the classical combination rule (DSmC) and PCR6 rules for two information sources are as follows:

The classical combination rule (DSmC) is given as follows:

$$m_{DSmC}(Y) = \sum_{\substack{A, B \in D^\Theta \\ A \cap B = Y}} m_1(A) m_2(B) \vee / Y \in D^\Theta \quad (1)$$

Proportional Conflict allocation Rule (PCR6):

$$\begin{aligned} m_{PCR6}(\emptyset) &= 0 \\ m_{PCR6}(Y) &= m_{1,2,\dots,s}(A) + \\ &\sum_{i=1}^s m_i(A)^2 \sum_{\substack{\cap_{k=1}^{s-1} Y_{\sigma_i(k)} \cap A \neq \emptyset \\ (Y_{\sigma_i(1)}, \dots, Y_{\sigma_i(s-1)}) \in (G^\Theta)^{s-1}}} \\ &\left(\frac{\prod_{j=1}^{s-1} m_{\sigma_i(j)}(Y_{\sigma_i(j)})}{m_i(A) + \sum_{i=1}^{s-1} m_{\sigma_i(j)}(Y_{\sigma_i(j)})} \right) \end{aligned} \quad (2)$$

Among $m_i(A) + \sum_{j=1}^{s-1} m_{\sigma_i(j)}(Y_{\sigma_i(j)}) \neq 0$, and a detailed explanation of this equation can be found (Florentin Smarandache, 2006).

When comparing the classical combination rule with the proportional conflict allocation rule, we can see that the PCR6 method is more accurate. The conflict reliability between X and Y is composed of the conflict between X in information source 1 and Y in information source 2 and the conflict between Y in information source 1 and X in information source 2. With PCR6, one redistributes the partial conflicting mass to A and B proportionally with the masses $m_1(A)$ and $m_2(B)$ assigned to A and B , respectively and also the partial conflicting mass to A and B proportionally with the masses $m_2(A)$ and $m_1(B)$ assigned to A and B , respectively; thus, one gets now two weighting factors in the redistribution for each corresponding set A and B .

Since there are more than two information sources in this paper, PCR6 is used as the fusion rule in this paper.

3 EARLY FAULT DIAGNOSIS SYSTEM OF THE WIND TURBINE GEAR BOX

3.1 Wind turbine gear box's early fault diagnosis structure

The vibration sensor is arranged at several key positions of the fan gearbox. The data measured by

each sensor are firstly anti-aliased and then EMD is decomposed (Florentin Smarandache, 2004) and information entropy extraction is performed to obtain the corresponding eigenvector. The BP neural network is used to obtain the confidence distribution of each source of evidence, and finally PCR6 fusion is used to acquire the fault type.

3.2 Extraction of the feature vector

There are two steps to extract the eigenvector, which are EMD and IMF energy entropy extraction.

3.2.1 Empirical Mode Decomposition (EMD)

EMD decomposition can change a frequency irregular wave into a single frequency of a wave + residual wave form. For a given signal $y(t)$, the EMD decomposition process is as follows:

1. Find all the maximum points of the sequence $y(t)$ and fit the upper envelope of the original data with the cubic spline interpolation;
2. Find all the minimum points of the sequence $y(t)$ and fit the lower envelope of the original data with the cubic spline interpolation;
3. The mean value of the upper and lower envelopes is denoted by using m_l , the original sequence $y(t)$ is subtracted from the average envelope m_l to obtain a new data sequence h_l ;
4. If h_l satisfies the IMF (Lu Shen, 2010) criterion, it is denoted as the first IMF. If there are negative local maxima and positive local minima, this is not an Intrinsic Mode Function and needs to be continued. Filter until the first IMF component is obtained.
5. Calculate the residual signal $r_1(t) = y(t) - c_1(t)$ as a new signal, repeat the previous steps, until all the IMF components are found.
6. After the decomposition of each component, the original signal can be expressed as follows:

$$\text{Original wave} = \sum \text{IMF}_s + \text{Residual wave}$$

The main purpose of EMD is to smoothly process the signal and obtain a series of the IMF component from high-frequency to low frequency, in order to prepare for the extraction of information entropy.

3.2.2 Fault feature vector extraction based on EMD energy entropy

Information entropy is a subject which was formed and developed with the development of communication technology. In 1948, Claude Shannon first proposed the concept of information entropy. That is, the amount of information contained in a signal source is called information entropy. EMD energy entropy-based fault feature vector extraction steps are given as follows (Xusheng Zhai, 2012):

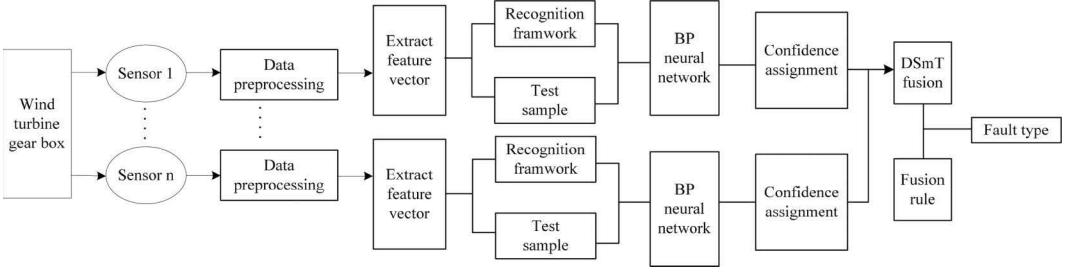

Figure 1. Schematic of the gearbox's early fault diagnosis structure.

1. For EMD decomposition of the vibration signal to be processed, select the main fault features including the first n IMF components.
2. Find the total energy of each IMF component E_i .

$$E_i = \int_{-\infty}^{+\infty} |C_i(t)|^2 dt \quad i=1,2,\dots,n \quad (4)$$

3. Construct an eigenvector T with energy as an element.

$$T = [E_1, E_2, \dots, E_n] \quad (5)$$

4. The vector is normalized

$$E = \left[\sum_{i=1}^n |E_i|^2 \right]^{1/2} \quad (6)$$

$$T' = \left[\frac{E_1}{E}, \frac{E_2}{E}, \dots, \frac{E_n}{E} \right] \quad (7)$$

And then, T' is the fault feature vector.

3.3 Wind turbine gear box early fault diagnosis data processing

1. Place the vibration sensor at an appropriate position on the test bed;
2. Filter the measurement data;
3. Obtain the eigenvector according to equation (2.2);
4. Through BP neural network training, we can obtain the output $\{p_i(1), p_i(2), \dots, p_i(q)\}$ of the i th sub BP neural network. If there are n fault patterns in the diagnosis system, then $q = n + 1$.
5. DSmT decision fusion is carried out, where the i th input m_i of DSmT is the confidence distribution of the output of the i th sub-BP neural network, which is calculated as follows:

$$m_i(j) = \frac{p_i(j)}{\sum_{j=1}^q p_i(j)} \quad (8)$$

$$m_i = \{m_i(1), m_i(2), \dots, m_i(q)\} \quad (9)$$

where $x = 1, 2, \dots, q$.

4 FAULT DIAGNOSIS OF THE WIND TURBINE GEARBOX

This test uses an experimental platform which includes a two horsepower motor, a torque sensor, a power meter, and electronic control equipment to simulate the fault of the wind turbine gear box. The tested bearing supports the motor shaft. A single point of failure was placed on the 6205-2RS JEM SKF bearing using EDM technology with a fault diameter of 0.007 inches. An experimental platform is shown in Figure 2.

In the experiment, the acceleration sensor was used to acquire the vibration signal, and the sensor was placed on the motor housing by using the magnetic base. The acceleration sensor is mounted near the support housing of the drive end spindle of the motor housing. The vibration signal is collected by using a 16-channel DAT recorder and processed later in the MATLAB environment. The digital signal sampling frequency is 12000S/s, and the sampling frequency of the drive side bearing fault data is 48000S/s. This study focuses on the motor drive end bearing fault research. The speed is 1797 rpm and the load is zero.

Figure 2. Picture of the test-bed physical graphics.

Table 1. Diagnosis case 1 of the wind turbine gearbox early fault.

The sensor number	BP network output	Basic confidence assignment	DST fusion	PCR5 fusion	PCR6 fusion
Number 1	[0.020 0.861 0.019 0]	$m(A_1) = 0$ $m(A_2) = 0.957$ $m(A_3) = 0.021$ $m(N) = 0.022$			
Number 2	[0.874 0 0.129 0]	$m(A_1) = 0.871$ $m(A_2) = 0$ $m(A_3) = 0$ $m(N) = 0.129$	$m(A_1) = 0$ $m(A_2) = 0$ $m(A_3) = 0$ $m(N) = 1$	$m(A_1) = 0.4172$ $m(A_2) = 0.5672$ $m(A_3) = 0.0003$ $m(N) = 0.0153$	$m(A_1) = 0.2770$ $m(A_2) = 0.7139$ $m(A_3) = 0.0003$ $m(N) = 0.0088$
Number 3	[0.011 0.889 0 0]	$m(A_1) = 0$ $m(A_2) = 0.988$ $m(A_3) = 0$ $m(N) = 0.012$			

Table 2. Diagnosis case 2 of the wind turbine gearbox early fault.

The sensor number	BP network output	Basic confidence assignment	DST fusion	PCR5fusion	PCR6 fusion
Number 1	[0 0.373 0 0.529]	$m(A_1) = 0$ $m(A_2) = 0.414$ $m(A_3) = 0$ $m(N) = 0.586$			
Number 2	[0.232 0 0.567 0]	$m(A_1) = 0.290$ $m(A_2) = 0$ $m(A_3) = 0.710$ $m(N) = 0$	Not applicable	$m(A1) = 0.0575$ $m(A2) = 0.1587$ $m(A3) = 0.5125$ $m(N) = 0.2713$	$m(A1) = 0.0735$ $m(A2) = 0.1022$ $m(A3) = 0.6397$ $m(N) = 0.1846$
Number 3	[0.114 0 0.679 0]	$m(A_1) = 0.144$ $m(A_2) = 0$ $m(A_3) = 0.856$ $m(N) = 0$			

Firstly, the sensor data from the nearest fault source are selected as the training samples, and 12000 samples are taken as a unit to measure the vibration samples of the vibration system of the bearings under the conditions of outer ring damage, inner ring damage, sphere damage, and normal state. And three sub-neural networks were trained on the basis of the samples. The vibration data of three sensors were taken as test samples to test the actual running state of the gearbox.

The recognition frame of DSMT is $\{A_1, A_2, A_3, N\}$, which is composed of the sphere fault, inner circle fault, and outer circle fault, where $A_1, A_2,$ and A_3 represent the three failure modes and N represents the normal state. The vibration signals collected by using the three sensors in different parts of the test bed are processed by EMD decomposition, and the first nine IMF components are taken. And the eigenvectors are calculated by using equations (4), (5), (6), and (7). And then, the eigenvectors are fed as input into the BP neural network, and the outputs of the BP network are transformed into confidence distributions by using equation (8) and (9), and then merged according to the DSMT decision rule or fusion rule.

As in the early weak stage, the wind turbine gearbox fault is not particularly evident. As can be seen from Tables 1 and 2, some sensors detect a failure mode, and some are not detected, and part of the

detected information between the sensors conflict with each other. In Diagnostic Case 1, the probability of the failure mode N measured by the three sensors is very small, but the DST fusion result shows that the failure mode is N , which is obviously illogical. However, the difference between the fault modes $A1$ and $A2$ is small, and it is obvious that the results of the PCR6 rule are more obvious than the PCR5 rule. In Diagnostic Case 2, the DST method cannot be applied, while PCR5 and PCR6 can diagnose the final failure mode as “outer-ring failure ($A3$)”. However, it is clear that the PCR6 diagnostic method is more accurate.

5 CONCLUSIONS

The characteristics of the early fault of a wind turbine gear box are weak, and it is difficult to identify these effectively. In this paper, an early fault diagnosis system based on DSMT for the wind turbine gearbox is designed. Based on the basic idea of information fusion, the sensor is arranged in several key parts of the wind turbine gear box, and the vibration information is obtained under the weak characteristics of the fault feature. And then, the EMD decomposition and IMF energy entropy extraction are used to obtain the eigenvector, combined with BP neural network and PCR6 fusion

rule in DSMT thereby making the final judgment about the fault condition.

1. The traditional DST and other methods cannot effectively identify the weak faults of the wind turbine gearbox early, and DSMT can be used to synthesize the conflict evidence effectively, which is suitable for the early fault diagnosis of the wind turbine gearbox.
2. Reasonable results can be obtained when the PCR5 fusion rule is used for fault decision, but the PCR6 fusion rule is more accurate.

A study of an improved method for horizontal alignment based on the line element

Y.H. Li, Y.J. Liu & Y.L. Li

Dalian University of Technology, Dalian, China

ABSTRACT: Based on the building-blocks method and taking line element as the foundation unit, an improved method for horizontal alignment is presented. It can solve the problem that the building-blocks end position cannot be controlled effectively. There are four independent parameters in this method, and the rest of the parameters can be calculated by themselves. Multiple types of horizontal alignment can be displayed by using the improved method, which can increase the selectivity.

1 INTRODUCTION

Methods of horizontal alignment are composed by using the straight-line and curve method. The straight-line method is the easiest method to use, because the calculation is relatively simple. However, it is difficult to make full use of the circular curve and transition curve. The straight-line method cannot deal with the complicated line effectively. The curve method improves the straight-line method, which is setting the wire before the curve. Considering the specifications and the actual requirements, taking the line element as the foundation unit can make the line more fluent. The curve method, according to the requirements of the different line layout, can be divided into the fitting method, building-blocks method, synthetic method, chord tangent method, etc. The idea that the complex horizontal alignment can be composed by several line elements dates back to the 1990s, when the famous studies on this subject were published (Li 1993, Wu 1965). This research field is still quite active (Xu 1997) and the controlled segmentary element design method has been investigated. More recently, Miao et al. (2001) proposed a method for the highway's horizontal alignment based on the segmentary element. In order to add the new line element, we need to carry out three steps by using the building-blocks method: first, we should determine the curve type and then determine the line element control parameters. According to the dynamic formulation of the end position, the rest of parameters can be calculated.

2 PROBLEMS IN LINE BUILDING-BLOCKS METHOD

2.1 *Difficulty in controlling the end point coordinates*

The building-blocks method is often difficult to accurately meet the requirements of controlled conditions. Generally, end point coordinates of the new design does not coincide with the reference coordinates.

2.2 *Single type of line element*

Building-blocks based on the line element can only display the preset line element type (circular curve, transition curve, and tangential straight line), thereby making the design lack selectivity.

3 IMPROVEMENT OF THE HORIZONTAL ALIGNMENT DESIGN

3.1 *Parameters*

In the traditional building-blocks method, the line element is used as the basic unit of the route design. In this article, the improvement is based on the traditional building-blocks method, and it emphasizes that the coordinate position has an effect on the linear position. There are eight basic parameters in common use, which are starting point coordinates B , end point coordinates E , starting tangential angle α_B , end tangential angle α_E , starting point radius R_B , end point radius R_E , line element deflection angle β ,

Table 1. List of the types of line element.

Type of line element	Abbreviation
Tangential straight line	TSL
Circular curve	CC
Forward holonomic transition curve	FHTC
Reverse holonomic transition curve	RHTC
Forward non-holonomic transition curve	FNHTC
Reverse non-holonomic transition curve	RNHTC

and the length of the line element L . There are four independent parameters at most, which are starting point coordinates B , end point coordinates E , starting point radius R_B , and end point radius R_E .

3.2 The type of line element

3.2.1 The design steps

Determine the starting point parameters of the line, including the starting point coordinates, starting tangential angle, as well as the starting point radius. For the first line element, it requires setting starting point parameters. In other cases, the end point of the previous line is the starting point of the next line, without additional settings.

Take the dynamic drawn position as an end point of line element. After determining the end point's position, we can calculate the basic parameters of six types, which can provide convenience for the designer to choose.

4 CALCULATION OF PARAMETERS

In this section, we briefly summarize the calculated steps of the line element, referring for a detailed description to the deflection angle.

The line element deflection angle and other parameters of a circular curve can be calculated by using the analytical method. As for all kinds of transition curves, an iterative method is the best choice. In this paper, we take the reverse holonomic transition curve as an example.

In order to obtain a reasonable horizontal alignment, the calculation of the reverse holonomic transition curve is divided into six steps.

Step one: establish a relative coordinate system $O'X'Y'$. Take the tangential direction of the end point E as $+X'$, and anticlockwise 90° as $+Y'$. Apparently, the end point E and the relative coordinate origin should be overlap.

Step two: calculate the direction angle of vector \mathbf{BE} in the relative coordinate system.

Starting tangential angle α_B is known, we can set α_B in equation (1) to calculate the direction angle of vector \mathbf{BE} in the relative coordinate system.

Figure 1. Graph showing the reverse holonomic transition curve.

$$\alpha_0 = \alpha_1 - \alpha_B, \alpha_0 \in (-\pi, +\pi), \alpha_0 \neq 0 \quad (1)$$

where α_1 is the vector direction angle in the cartesian coordinate system.

Step three: calculate the line element deflection angle. The reverse holonomic transition curve calculates the line element deflection angle by using an iterative method and the bisection method. Firstly, we should calculate the deflection angle by dichotomy:

$$\beta > \beta_{\min} = |\alpha_0|, \beta < \beta_{\max} = \pi \quad (2)$$

$$\beta_0 = (\beta_{\max} + \beta_{\min})/2 \quad (3)$$

Direction angle of the end point is given as follows:

$$\alpha_E = \alpha_B + \delta_0 \beta_0 \quad (4)$$

where δ_0 is the coefficient. If the line element is turned left, $\delta_0 = +1$, else $\delta_0 = -1$.

Substituting equation (4) into equation (5), the tangent direction angle can be drawn as follows:

$$\alpha'_E = \alpha_E + \pi \quad (5)$$

where α'_E is the tangent direction angle of the cyclotron line origin O' .

Since the tangent direction angle, coordinates of origin O' and starting point are provided, the line element deflection angle β can be worked out by using the following iterative equation:

$$dx' = 2R\beta f_x(\beta) \quad (6)$$

where dx' is the abscissa of the starting point B in the relative coordinates and $f_x(\beta)$ is a function about the line element deflection angle β .

$$dy' = 2R\beta^2 f_y(\beta) \quad (7)$$

where dy' is the co-ordinate of the starting point B in the relative coordinates, $f_y(\beta)$ is a function about the line element deflection angle β .

$$f_x(\beta) = \sum_{i=1}^{\infty} (-1)^{i-1} \frac{\beta^{2i-2}}{(2i-2)!(4i-3)} \quad (8)$$

$$f_y(\beta) = \sum_{i=1}^{\infty} (-1)^{i-1} \frac{\beta^{2i-2}}{(2i-1)!(4i-1)} \quad (9)$$

$$k' = \frac{dy'}{dx'} = \beta \frac{f_y(\beta)}{f_x(\beta)} \quad (10)$$

where k' is the ratio of the relative coordinates.

$$\beta = k' \frac{f_x(\beta)}{f_y(\beta)} = k' f(\beta) \quad (11)$$

Under the condition of the first trial, the line element deflection angle β , which is the tangent direction of the starting point B relative to the tangent direction of the origin O' , can be obtained. Set β in equation (12) to determine whether it is real.

$$\Delta\beta = \beta_0 - \beta \quad (12)$$

where β_0 is the result of the first trial calculation.

Apply the following rules:

$$|\Delta\beta| < \xi = 10e^{-6} \quad (13)$$

Line element deflection angle β is exact.

Else,

$$|\Delta\beta| > \xi = 10e^{-6}, \Delta\beta > 0, \beta_{\max} = \beta \quad (14)$$

$$\Delta\beta < 0, \beta_{\min} = \beta \quad (15)$$

Return to the equation (3) and enter the second trial calculation to obtain the second computation of deflection angle β . Set β in equation (12). Circulatory computation like this does not come to an end until the difference satisfies the inequality equation (13). The line element deflection angle β is exact. Step three is completed.

Step four: calculate relative coordinates of the starting point (X'_{BE}, Y'_{BE}) .

Based on the accurate solution of the deflection angle, we can calculate the tangent angle of transition curve origin.

Calculate the relative coordinates (X'_{BE}, Y'_{BE}) of the starting point in the relative coordinate system, according to equation (16).

$$\begin{Bmatrix} X'_{BE} \\ Y'_{BE} \end{Bmatrix} = \begin{bmatrix} \cos(\alpha'_{O'}) & \sin(\alpha'_{O'}) \\ -\sin(\alpha'_{O'}) & \cos(\alpha'_{O'}) \end{bmatrix} \begin{Bmatrix} X_B - X_E \\ Y_B - Y_E \end{Bmatrix} \quad (16)$$

Step five: calculate the tangent angle α_E of the end point E.

Calculate tangent angle α_E of the end point E by setting β in equation (17):

$$\alpha_E = \alpha_B + \delta_0\beta \quad (17)$$

Step six: calculate the rest of the parameters of the reverse transition curve.

$$R_B = \frac{X'_{BE}}{2\beta f_x(\beta)} \quad (18)$$

Substitute equation (18) in equation (19), and we will obtain the length:

$$L = 2R_B\beta \quad (19)$$

where L is the length of the line element.

5 CALCULATED EXAMPLE

As shown in Figure 2, in the cartesian coordinate system, the starting point coordinates are (200, 200), the starting tangential angle α_B is 40° , and the end point coordinates are (400, 300).

We can use the above-mentioned steps to calculate the rest parameters. The result is shown in Table 2, which presents the end tangential angle,

Figure 2. Schematic of the example of the improved method.

Table 2. Calculation of the basic line element.

No.	Types	α_E	R_B	R_E	β	L
1	TSL	40.00°	∞	∞	0	223.60
2	CC	-1.52°	344.86	344.86	-36.49°	219.07
3	FHTC	-15.04°	∞	116.84	-55.04°	224.47
4	RHTC	12.72°	228.57	∞	-27.28°	217.59
5	FNHTC	-4.98°	650.00	179.81	-44.98°	221.15
6	RNHTC	8.59°	270.00	756.54	-31.41°	218.16

starting and end point coordinates, line element deflection angle, and the length of the line element. Six basic line elements can also be drawn, which can facilitate the coordination of routes and increase selectivity.

6 CONCLUSIONS

1. When compared with the traditional building-blocks method, the coordinates of the end position can be effectively controlled.
2. There are three independent parameters in the tangential straight line and circular curve. The rest have four independent parameters. The typical independent parameters are the starting and end point coordinates and the starting and end radii.
3. For the continuous design, parameters related to starting point are known; we only need to determine the end point coordinates to obtain the rest parameters of the line element.
4. Line element deflection angle β is the key to the calculation of the untypical independent parameters. The circular curve uses the analytical method, while the other four types use an iterative method.
5. We can draw six basic line elements, which can increase the selectivity.

Theoretical analysis of mechanical properties and mechanical design for fabricated zero initial cable force friction dissipation

Q.X. Ye & A.L. Zhang

College of Architecture and Civil Engineering, Beijing University of Technology, Beijing, China

ABSTRACT: A type of Fabricated Zero initial cable force Friction Dissipation Re-centering Brace (FZFDRB) is proposed. The theoretical analysis of mechanical properties was carried out and mechanical design for FZFDRB was also constructed. The results show that, the brace has a simple structure. There is no stiffness degradation in the loading process, and the brace has a full hysteretic curve and shows stable energy dissipation law. When the brace stops re-centering at the residual displacement, releasing the high-strength bolts of the brass-slot steel friction plates can let the brace continue re-centering to zero point. This indicates that FZFDRB has an excellent re-centering function.

1 INTRODUCTION

As a component used to resist lateral force, brass can take on part of the lateral load in the structure, so as to reduce the damage degree of the structure. Due to its various forms and ease of processing, steel braces are widely researched and applied. From research at home and abroad, the steel brace mainly includes five types: ordinary steel brace, attached energy dissipator brace, buckling-restrained brace, prestressed cable brace, and re-centering function brace. Ordinary steel brace, attached energy dissipator brace, and buckling-restrained brace may produce irreversible residual deformation during major earthquakes, and the main structure could not be effectively protected, the structural seismic performance in the subsequent aftershocks will be severely affected (Wakabayashi, M. & Nakamura, T. 1973, Yoshino, T. & Kano, J. 1971, Christopoulos et al. 2003). Research shows that when the residual deformation angle is more than 5‰, the maintenance cost may even be greater than the cost of reconstruction after the quake (Erochko 2011). A pre-stressed cable brace is often the cross layout in the structure. It can improve the lateral stiffness of the framework, and make it have a certain ability of re-centering. But the pre-stressed cable brace has no energy dissipation capacity. Structures have to damage the main framework to dissipate energy (Zhang 2014). With the improvement of attached energy dissipator brace and buckling-restrained brace, the re-centering function brace takes the advantages of buckling-restrained in compression and energy dissipation. It can avoid the damage, and eliminate or reduce residual deformation of the structure. Zhu et al. (2006) proposed a kind of

Self-centering Friction Damping Brace (SFDB) and performed tests accordingly. Miller et al. (2011) connected stranded SMA wires to ordinary cables to provide the restoring force, utilized them in the mild steel energy-dissipative buckling-restrained brace with three-layer steel pipes to make a new type of the Self-Centering Buckling-Restrained Brace (SC-BRB), and conducted pseudo-static testing on a large-scaled specimen thereof. Liu et al (2012) placed an energy-dissipative mild steel into the above-mentioned specimen and below gaps between inner and outer steel pipes of equal length, allowed pre-stressed strands to pass through the inner and outer steel pipes and fixed them on both ends of the steel pipes to create a novel type of Self-Centering Buckling-Restrained Brace (SCBRB), and then tested its seismic performance via pseudo-static testing. Chen et al. (2014) proposed three kinds of large sizes of the self-centering brace based on SMA bars or plates, and gave the brief description to the construction. The author (2016) summarizes the advantages and disadvantages of currently research about the re-centering function brace, and points out the key problems needed to study in the future.

Previous studies showed that the re-centering braces still have the following shortcomings:

1. The re-centering material has to be pre-stressed, which makes the construction work more complicated. The pre-stressing force of pre-stressed cables inevitably loses after long-term placement. Tandem cables can improve the deformability, but reduce the cable stiffness by half. Due to the relatively high cost and difficulties in anchorage connection, the application of the

shape memory alloy as the re-centering material is not yet mature.

- At present, the re-centering braces normally adopt the structure of inner and outer dual pipes or even triple pipes and require the braces to be self-centered. According to this design concept, the overall brace structure is quite complicated. Moreover, the machining precision of the pipe length could also make a big difference to the load-bearing capacity of the brace.

To solve the inadequacies of the re-centering brace, a new type of the Fabricated Zero initial cable force Friction Dissipation Re-centering Brace (FZFDRB) is proposed; the structure and mechanical design are elaborated and the theoretical studies of mechanical properties are also made.

2 STRUCTURE, OPERATING PRINCIPLE AND THE RESTORING FORCE MODEL OF THE FZFDRB

2.1 Structure of the FZFDRB

The FZFDRB is comprised of the core part and outer holding pipes, of which, the outer holding pipes are two channel steels and the structure is as shown in Fig. 1. The main components are as follows: 1. loading end, 2. front anchoring part, 3. dowel bar, 4. small cover plate, 5. high-strength strain bolt (5a. bolt 1 and 5b. bolt 2), 6. fixed channel steel, 7. damper of the brass–slot steel friction plates (the part in the red circle in Fig. 1 consists of 7a. guard plate, 7b. brass friction plate, and 7c. slot steel friction plate), 8. pressure transducer and anchorage, 9. rear anchoring part, 10. 1st group of cables, 11. 2nd group of cables, and 12. fixed end.

The assembly process is as follows: the cross plate of the loading end is passed through the cross cut holes of the front anchoring part and then welded to the left connecting plat of the dowel bar. Let high-strength bolts pass through the corresponding preserved holes of the damper of the brass–slot steel friction plates, rear anchoring part, and the right connecting plate of the dowel bar to form the friction dissipation part of the FZFDRB. The 1st group of cables are passed through the preserved

hole on the left connecting plate of the dowel bar and then fixed to the front anchoring part and the right end of the dowel bar, respectively by using the anchorages. The 2nd group of cables are passed through the preserved hole on the right connecting plate of the dowel bar and then fixed to the rear anchoring part and left end of the dowel bar, respectively by using the anchorages to form the core part. The assembled core part is fastened by using the two fixed channel steels, high-strength bolts, and small cover plates.

2.2 Operating principle of the FZFDRB

Fig. 2 shows the simplified schematic diagram of the FZFDRB. One end of the cables is connected to the brass friction plate, and the other end is connected to fixed end. The slot steel friction plate is also fixed. And so, the moving of the brace is equal to sliding around of the brass friction plate on the slots steel friction plate. It is assumed that, when under pressure, the brace is equivalent to a brass friction plate with movement to the right, and when under tension, the brace is equivalent to the brass friction plate with movement to the left. When the loading end of the FZFDRB drives the dowel bar to move right, the damper of brass–slots steel plates has friction energy dissipation under compression. At this point, the brace is equivalent to as shown in Fig. 4 and brass friction plates have right distance to the slots steel friction plate. The first group of cables are tensioned, and the second group of cables with no internal force, it naturally

Figure 2. Simplified schematic diagram of the FZFDRB.

Figure 3. Schematic of the composition of the FZFDRB restoring force model.

Figure 4. Schematic of the positive pressure diagram of the FZFDRB.

Figure 5. Schematic of the negative tension diagram of the FZFDRB.

prolapse. When the loading end of the FZFDRB drives the dowel bar to move left, the damper of brass-slots steel plates has tensile friction energy dissipation that is equivalent as shown in Fig. 5. The brass friction plates have left distance to the slots steel friction plate. The second group of cables are tensioned, and the red cables naturally prolapse with no internal force.

2.3 Restoring force model of the FZFDRB

As shown in the operating principle of the FZFDRB, the restoring force model of the brace consists of two parts: 1) one is provided by the steel cables, i.e. elasticity, 2) the other is provided by the damper of brass-slot steel friction plates, as shown in Fig. 3. If only think about the force balance of the FZFDRB itself, a shows the residual displacement when the friction force is equal to the cable forces in Fig. 3, and the displacement of the brace can be calculated according to equation (1):

$$a = f/k \quad (1)$$

where, f is the sliding friction and k is the stiffness of the cables; Controlling the size of a can limit the brace deformation, control the residual deformation of the structure to less than 5% and guarantee the building process in a repairable area. After the brace has stopped re-centering and artificially relaxing the high strength bolts of the damper of brass-slot steel friction plates, the re-centering force of the brace is equal to the friction force,

and the re-centering function of the brace can be realized.

The restoring force model of the FZFDRB can be deduced by using the force mechanism of the brace. Taking the brass friction plate (shadow) center as the initial position to establish the equation and right is positive.

Positive, $X > 0$, as shown in Fig. 4: the 1st group of cables is tensioned, while the 2nd group of cables is slacked, and X extends from 0 to L_{\max}

$$F_1 = K_1 \cdot x + f \quad (2)$$

Negative, $x > 0$, as shown in Fig. 4: the 1st group of cables is tensioned, while the 2nd group of cables is slacked, and x extends from L_{\max} to 0

$$F_2 = K_1 \cdot x - f \quad (3)$$

Negative as shown in Fig. 5, $X < 0$: the 2nd group of cables is tensioned, while the 1st group of cables is slacked, and X extends from 0 to $-L_{\max}$

$$F_3 = K_2 \cdot x - f \quad (4)$$

Positive, $x < 0$, as shown in Fig. 5: the 2nd group of cables is tensioned, while the 1st group of cables is slacked, and x extends from $-L_{\max}$ to 0

$$F_4 = K_2 \cdot x + f \quad (5)$$

K_1 is the stiffness of the 1st group of cables,

$$K_1 = E \cdot A_1 / L_1$$

K_2 is stiffness of the 2nd group of cables,

$$K_2 = E \cdot A_2 / L_2 \quad (6)$$

A_1 is the effective area of the 1st group of cables;

A_2 is the effective area of the 2nd group of cables;

L_1 is the calculated length of the 1st group of cables;

L_2 is the calculated length of the 2nd group of cables; and

f is the sliding friction, calculated by using the equation: $f = n_1 \cdot \mu \cdot N$, wherein, n_1 is the number of friction surfaces, μ is the friction coefficient, measured from the test as shown in Fig. 7, for the brass-slot steel friction plates, $\mu = 0.26$, N is the pressure value of the friction surface, with bolt connection, $N = n \cdot P$, where, n is the number of bolts, and P is the pre-tightening force of high-strength bolts.

Figure 6. Picture showing the experiment of friction plates.

Figure 7. Graph showing the restoring force model of the FZFDRB.

The same cable length and cross section are taken, so that the two groups of cable stiffness are also the same. The restoring force model of the brace is shown in Fig. 7. The broken line shows the process that when the cable force is equal to the friction force, the residual displacement is a mm and the brace stops re-centering. Loosen the high strength bolts at this time and the friction to zero, the brace continues to re-center to zero with the re-centering force that is equal to the friction force.

3 DESIGN OF THE STRUCTURE SIZE OF THE FZFDRB

Currently, the connection of the frame and brace usually uses a large number of bolts or welding to achieve rigid connection or half rigid connection. In such cases, when the structure has a displacement,

the brace will be the bend member under an external load, and the end of the brace may be easily buckling or even rupturing failure. In view of the above reasons, the FZFDRB ends adopt the form of articulation, thereby making the brace always as the axial stress components under lateral load. And so, the design of the brace can only consider the axial load. When some components of the brace yield or are buckling under loading, that will need extra re-centering force; therefore, the design requirements of the brace components always stay flexible. Fig. 8 shows the internal structure of the FZFDRB.

Under tension, as shown in Fig. 9a, the loading end, dowel bar, guard plate, and the cables shown in Fig. 9a have the same axial displacement Δ to the left. The axial force of components is shown in Fig. 9b-e, the design formula can be received by using the force equilibrium equation. Known from the analysis of Fig. 9e, the force is entirely transmitted to the fixed end from the loading end. And so, the internal force between the front anchoring part, channel steels, and rear anchoring part is zero, and the design of the front anchoring part, channel steels, and rear anchoring part cannot be considered. From the force analysis of Fig. 9b-e, the axial force diagram is shown as Fig. 9f. The axial components should be designed according to strength, when the brace is under tension:

Figure 8. Schematic of the internal structure of the FZFDRB.

Figure 9. Schematic of the internal structure of the FZFDRB under tension.

$$1. \text{ Loading end: } \begin{cases} F_1 = F = F_s + f \\ A_1 > (F_s + f) / \sigma \end{cases} \quad (7)$$

$$3. \text{ Dowel bar } \begin{cases} F = F_3 + F_s = f + F_s \\ A_3 > f / \sigma \end{cases} \quad (8)$$

$$7a. \text{ Guard plate } \begin{cases} F = F_s + F_{7a} = F_s + f \\ A_{7a} > f / 2\sigma \end{cases} \quad (9)$$

$$12. \text{ Fixed end: } \begin{cases} F = F_{12} = F_s + f \\ A_{12} > (F_s + f) / \sigma \end{cases} \quad (10)$$

Under compression: as shown in Fig. 10a, the loading end, dowel bar, and guard plates have the same displacement Δ to the right. The axial forces of structural parts are shown in Fig. 10b–e. And so, the design equation can be obtained by using the force equilibrium equation. From the force analysis, the axial force diagram is shown as Fig. 9j. The axial compression of the brace should be designed according to the strength and stability control:

$$6. \text{ Fixed channel steel: } \begin{cases} F_6 = F_s \\ A_6 > F_s / 2\sigma \\ A_6 > F_s / 2\psi_6\sigma \end{cases} \quad (11)$$

$$1. \text{ Loading end: } \begin{cases} F_1 = F = f + F_s \\ A_1 > (f + F_s) / \sigma \\ A_1 > (f + F_s) / 2\sigma\psi_1 \end{cases} \quad (12)$$

$$3. \text{ Dowel bar: } \begin{cases} F = F_3 + F_s = f + F_s \\ A_3 > f / \sigma \\ A_3 > f / \sigma\psi_3 \end{cases} \quad (13)$$

$$7a. \text{ Guard plate: } \begin{cases} F = F_{7a} + F_s = f + F_s \\ A_{7a} > f / 2\sigma \\ A_{7a} > f / 2\sigma\psi_{7a} \end{cases} \quad (14)$$

$$12. \text{ Fixed end: } \begin{cases} F = f + F_s \\ A_{12} > (f + F_s) / \sigma \\ A_{12} > (f + F_s) / \sigma\psi_{12} \end{cases} \quad (15)$$

The connection between the channel steel and rear anchoring part can be designed according to the shear of friction type high strength bolts:

$$N_v^b > F_s / n \quad (16)$$

Because there is only contact pressure between the channel steel and front anchoring part, the high strength bolts can be used in the mechanical design.

F_1 denotes the internal forces of the loading end section;

F_3 denotes the internal forces of the dowel bar section;

F_6 denotes the internal forces of the one channel steel section;

F_{7a} denotes the internal forces of the one guard plate section;

F_{12} denotes the internal forces of the fix end section;

F_s denotes the internal forces of one group cable;

f denotes the friction force;

A_1 denotes the cross-sectional area of the loading end;

A_3 denotes the cross-sectional area of the dowel bar;

A_{12} denotes the cross-sectional area of one channel steel;

A_{7a} denotes the cross-sectional area of one group cable;

A_{12} denotes the cross-sectional area of the fixed end;

ψ_1 denotes the stability coefficient of loading end;

ψ_3 denotes the stability coefficient of dowel bar

ψ_{7a} denotes the stability coefficient of one channel steel;

ψ_{12} denotes the stability coefficient of the fix end;

N_v^b denotes the shear bearing capacity of one single high-strength bolt,

$$N_v^b = 0.9 \cdot n_f \cdot \mu \cdot P \quad (17)$$

n is the number of high-strength bolts;

n_f denotes the number of friction surfaces: single shear: 1 and double shear: 2;

μ denotes the slip resistance coefficient of the friction surface, according to the literature [11];

P denotes the pretension design value of high-strength bolts, according to the literature [11];

A_{it} denotes the cross-sectional area of each part of the brace in tension; and

A_{is} denotes the cross-sectional area of each part of the brace in compression.

In conclusion, the size of the cross-sectional area of each part in the FZFDRB should meet $\{A_{it}, A_{is}\}_{\max}$

Figure 10. Schematic of the internal forces of the FZFDRB during compression.

4 THEORETICAL ANALYSIS OF MECHANICAL PROPERTIES OF THE FZFDRB

The selection of specimen $\Phi 14$, $\Phi 20$ galvanized steel wire rope, S10.9, M16 and M20 high-strength bolts to test the theoretical analysis of seismic performance for the FZFDRB. The parameters of the galvanized steel wire rope and high-strength bolt are given in Table 1. According to the controlling target load method of taking the inter-laminar displacement angle of 0.00375, 0.005, 0.0075, 0.01, 0.015, and 0.02 rad in ANSI/AISC341 [12], the control target of the FZFDRB is the displacement. At each displacement amplitude (i.e., 10 mm, 15 mm, 20 mm, 25 mm, 30 mm, and 35 mm), two loading cycles are carried out. The theory of hysteresis curves and energy dissipation coefficient β_E under each amplitude are shown in Figure 11 and Table 2.

As shown in Figure 11, two hysteresis curves are all in the shape of quadrilateral. The stiffness remains the same in the loading process.

Table 1. List of energy dissipation coefficients at each displacement amplitude.

Test	Specimen	
	1	2
Diameter of the cable/mm	20	14
Area of the cable/mm ²	152	89.6
Length of the cable/mm	3000	3000
Elasticity modulus/10 ⁵ Mpa	110	110
Class of the bolt	10.9	10.9
Diameter of the bolt/mm	16	20
Theory friction/kN	104	161.2
<i>a</i> /mm	4.67	12.27

Figure 11. Theory hysteresis curve of the FZFDRB under amplitudes.

Table 2. List of energy dissipation coefficients at each displacement amplitude.

Displacement mm	β_E	
	$\Phi 20$ -M16	$\Phi 14$ -M20
10	1.77	2.20
15	1.38	1.80
20	1.13	1.52
25	0.96	1.32
30	0.84	1.16
35	0.74	1.04

In the process of re-centering, when the cable force is equal to the friction force (the residual displacement is *a*), the brace stops re-centering. Red and black dashed lines mean relaxing high strength bolts at this place, thereby eliminating the friction, and the brace continues re-centering to zero displacement under the re-centering force provided by the cables. By using M20 high strength bolt, the friction is bigger, the corresponding hysteresis loop back area is larger, the energy dissipation ability is stronger, and the re-centering force is greater than using M14 high strength bolts. By using the $\Phi 20$ steel wire rope, the load stiffness of the brace is bigger, and the bearing capacity is stronger. And so, the stiffness is proportional to the cable diameter, energy dissipation capacity is proportional to the high strength bolt's pre-tightening force. The residual displacement of brace $\Phi 14$ -M20 is 12.27 mm, which is more than the 4.67 mm of brace $\Phi 20$ -M16. Therefore, to make the structure have a better effect of energy dissipation and greater re-centering force, the reasonable collocation should be selected from cable force and high-strength bolts to meet the basic requirements of repairable structures after earthquakes.

As shown in Table 2, the energy dissipation coefficient β_E decreases with an increase in the displacement amplitude, and under each amplitude, β_E meets the requirements of more than 0.3 [13]. This shows that the brace has a good energy dissipation effect. Under the same displacement amplitude, the high-strength bolt model means the greater the friction, greater is the energy dissipation coefficient which shows the better energy dissipation effect.

Figures 12 and 13 show the force of $\Phi 14$ and $\Phi 20$ varies with the loading process of the brace. The load rule of the steel rope is always the same: one group of the cable force is under tension and the cable force of the other group is zero at the same time. Two groups of cable forces alternate in tension. The structure that uses two groups of cables alternating stress to avoid pre-stressed relaxation is feasible.

Figure 12. Graph showing the alternative variation of $\Phi 14$ cables force.

Figure 13. Alternative variation of $\Phi 20$ cables force.

5 CONCLUSION

In this paper, a fabricated zero initial cable force friction dissipation re-centering brace is proposed, its structure, working mechanism and design method of structure parts are expounded and theoretical analysis of the seismic performance is also performed to arrive at the following conclusion:

1. The FZFDRB has a simple structure. The initial cable force of two groups of the galvanized steel wire rope is zero. When the brace is under tension or compression, one group of the cables is always tensioned, the internal force of the other group of cables is zero, and natural relaxation occurs. This structure can simplify the complexity process that an existing re-centering brace needs to pre-stress in advance, and solve the question of pre-stressed relaxation.
2. The hysteresis curve of the FZFDRB is in the shape of a quadrilateral. The energy dissipation law is stability. In the process of loading, the stiffness remains the same; there is no stiffness degradation phenomenon. The energy dissipation coefficient β_E decreases with an increasing in the displacement amplitude, and under each

amplitude, β_E meets the requirements of more than 0.3.

3. The load stiffness is associated with the cables and energy consumption is associated with high-strength bolts. The ability of energy consumption is proportional to the friction, but by increasing the friction, the corresponding residual deformation will also increase at the same time. And so, with different design requirements, different cables and high-strength bolts should be selected, thereby making the brace with better energy dissipation effects and a higher re-centering force, under the basic precondition of repairable structures after earthquake.

ABSTRACT: The reasonable allocation of control rights of PPP is closely related to the efficiency of PPP. In this paper, an optimal allocation model of the residual control right of PPP is established from the perspective of the incentive constraint theory and incomplete contract theory, which is according to the ability difference and the goal difference between the public sector and the private sector and the uncertainty of the hydraulic PPP project. The relationship between the allocation proportion of residual control rights and many factors, such as the amount of investment of the private sector and public sector coordination, is analyzed based on the model, and a series of incentives and constraints are put forward based on optimization allocation of residual control rights. The research results of this paper not only provide theory and application basis for the optimal allocation of the residual control rights of PPP, but also perfect and supplement the contract design theory of the PPP model.

1 INTRODUCTION

As the innovation mode of the supply in the infrastructure, Public–Private Partnership (PPP) has been paid attention by the theory and industry widely, especially the co-operation efficiency between public and private sectors has attracted more and more attention. However, the efficiency of cooperation is closely related to the allocation of control rights (Hu 2012). The control rights between the public and private parties are assigned and transferred by using the concession agreement in PPP (Ye et al. 2011). The concession agreement drawn by the two parties is an incomplete contract on account of the limited rationality, the long-term cooperation, the incomplete information, and the uncertainty of the project (Rasmussen & Baird 2001). Who has the authority to make decisions when the contract is not expected to occur when there is a situation or decision-making problems? Although there is a principle for “who invests, who makes decisions, who gains, who bear the risk”, but the main investments of hydraulic PPP projects are numerous, and their interests are not consistent. At this point, who has the right to make a decision? What should be done to improve the efficiency of the supply of the hydraulic infrastructure? The key

to the problem lies in the allocation of control rights. The allocation of control rights can attract private sector participation and take advantage of the private sector’s management and technical advantages. On the other hand, the allocation of control rights should enable the public sector to obtain regulatory projects and ensure public interest. Based on the consideration of the above-mentioned two aspects, we can come to the conclusion that rational allocation of control rights should combine the characteristics of the hydraulic PPP project and the requirements of supply efficiency, thereby giving full play to the advantages of the public and private sectors, and coordinate the interest conflicts of both sides.

2 LITERATURE ON CONTROL RIGHTS ALLOCATION

A series of theoretical models about control rights have been constructed from the 1980s to the present in the abroad, which is shown in Table 1. Those theories have researched on control rights allocation gradually from privates’ cooperation to co-operation between public and private sectors, and from private goods to impure public goods.

Table 1. Theoretical model and influencing factors of control rights in foreign countries.

Influence factor	Theoretical model			
	GHM (Grossman & Hart 1986, Hart & Moore 1990)	HSV (Hart et al. 1997)	BG (Besley & Ghatak 2001)	FM (Francesconi & Muthoo 2006)
Partner type	Private and private	Private and public	Private and public	Private and public
Product degree of public	Private goods	Pure public goods	Pure public goods	Impure public goods
Level of product value evaluation	—	—	√	√
Investment type	—	√	—	—
Investment importance	√	—	—	√

The scope of research is constantly expanding and the applicability of the conclusion is rising too, which laid a solid theoretical foundation for the study of the rational allocation of control rights in China.

The research on control rights in foreign countries is systematic, but its research conclusion is not completely applicable to the current situation of China's hydraulic PPP project. The research on PPP control rights in our country has made some achievements, although it started relatively late. The domestic studies mainly focus on the theoretical model of the control rights allocation, which is derived from the incomplete contract theory or the principal agent theory. The control right is considered as that which is continuous from 0 to 1. The influencing factors of residual control rights are analyzed through the cooperation surplus maximization (Sun et al. 2011, Zhang et al. 2009). However, the existing research results not only simplify the private sector's output variables, but also ignore the differences of different enterprises' ability levels and different types of projects regardless of the mathematical model, game model, experimental research, case studies, and empirical research, and most of them dominated are by the static analysis (Chen 2010, Du & Wang 2013, Hu 2012, Sun et al. 2011, Zhang & Jia 2012). Although there are a few scholars who have discussed the influence of the ability to control the co-operation between the two sides (Cao et al. 2014), but they did not carry out a detailed and in-depth analysis of the differences in capacity. Some scholars have studied the control rights allocation of the public transportation service project, but the research on the control rights allocation of PPP is lacking practicality at this stage, whether it is applied in hydraulic facilities, municipal facilities, transportation facilities and environmental engineering, and especially lack of an in-depth study of control rights allocation of the hydraulic PPP project. At the same time, the research of control rights is not related to the

interests' demand of the public and the private sectors, and the research on how to ensure the goal of the private sector's economic efficiency and the realization of the social benefits of the public sector is still lacking, in particular.

An optimal allocation model of residual control rights of PPP was constructed from the perspective of an incentive constraint theory and incomplete contract theory, which is according to the ability difference and the goal difference between the public sector and the private sector and the uncertainty of the hydraulic PPP project. The relationship between the allocation proportion of residual control rights and many factors, such as the amount of investment of the private sector and public sector coordination is analyzed based on the model, and a series of incentives and constraints are put forward based on optimization allocation of residual control rights.

3 OPTIMIZING ALLOCATION MODEL

3.1 Model assumptions

- Assuming that the public sector (G) and the private sector (E) jointly work together in hydraulic PPP projects, both sides invested money in I . The public sector invested money in I_G , the private sector invested money in I_E , so that the initial stake of the public sector is $\pi_0 = I_G / (I_G + I_E) = I_G / I, 0 \leq \pi_0 \leq 1$, and the initial stake of the private sector is $1 - \pi_0 = I_E / (I_G + I_E) = I_E / I$.
- Existing research over-simplified the PPP projects' output or the influence variables of the project income (Zhang et al. 2009, Du & Wang 2013, Cao et al. 2014), instead of distinguishing the ability difference of the public sector and private sector. Based on classic Cobb–Douglas production function in Economics, in this paper, specific investment A_i of both the public and the private parties involved in

hydraulic PPP projects is assumed, in addition to the labor and capital, including inputs of special technology and management of the private sector and inputs of special information, coordination, and guarantee of the public sector. L_E^a and L_G^{b+c} are used to distinguish the level of human capital investment of the private sector, public sector, and social public. The output (R) of the hydraulic PPP project is given as follows: $R = A_i(L_E^a + L_G^{b+c})I^\beta$.

- Assuming that λ and ω are respectively the economic and social benefits of the output factor of hydraulic PPP projects, and then the economic and social benefits of expectation values are given as follows: $R_r = \lambda R$ and $R_s = \omega R$.
- Assuming the level of effort of the private sector is η . If $\eta > 0$, then the cost of efforts to $\frac{1}{2}\eta\alpha^2$; suppose the joint supervision cost factor in the public sector and the private sector is $\xi, \xi' > 0$, then both monitoring costs is given by the following relation: $\frac{1}{2}\xi(b^2 + 2kbc + c^2)$.
- Assuming the benefits of residual control rights include non-monetary benefits m and monetary benefits n , where $m > 0$ and $n > 0$, among which the non-monetary benefits m are only owned by the public sector and the general public; the private sector can get part-monetary benefits. Residual control rights for the private sector is supposed as $\pi, 0 < \pi < 1$; the private sector can obtain the monetary income of $\pi \cdot n$. The residual control right of the public sector is $1 - \pi$.

3.2 Model construction

In the hydraulic PPP mode, while in both the public and the private parties, uncertain events occur or the contract has not been agreed upon decisions and problems in the process of co-operation, the two sides will make the choice based on the maximization of their own interests, with the premise of ensuring the maximization of the project's total revenue. Therefore, according to the above-mentioned assumptions, the total income of the project can be obtained by using the following equation:

$$\max[A_i(L_E^a + L_G^{b+c})I^\beta + m + n - I - \frac{1}{2}\eta\alpha^2 - \frac{1}{2}\xi(b^2 + 2kbc + c^2)] \quad (1)$$

According to the efficiency theory, when combining the characteristics of hydraulic PPP projects, under the premise of satisfying the need of maximizing the total revenue, the private sector can attract social capital only in the case that the output is greater than the investment involved in hydraulic PPP projects; meanwhile, the public sector is also expected to obtain greater output than the expected social benefits. Hence, the following incentive constraints are observed:

$$(1 - \pi_0)[A_i(L_E^a + L_G^{b+c})I^\beta] + \pi \cdot n - \frac{1}{2}\eta\alpha^2 \geq I_E \quad (2)$$

$$(1 - \pi)\pi_0[A_i(L_E^a + L_G^{b+c})I^\beta] + m + (1 - \pi) \cdot n - \frac{1}{2}\xi(b^2 + 2kbc + c^2) \geq R_s \quad (3)$$

From the above-mentioned Equations (1)–(3), the Lagrange function is constructed as follows:

$$\begin{aligned} L = & \left[A_i(L_E^a + L_G^{b+c})I^\beta + m + n - I - \frac{1}{2}\eta\alpha^2 \right. \\ & \left. - \frac{1}{2}\xi(b^2 + 2kbc + c^2) \right] \\ & + \lambda_1 \left[(1 - \pi_0)[A_i(L_E^a + L_G^{b+c})I^\beta] \right. \\ & \left. + \pi \cdot n - \frac{1}{2}\eta\alpha^2 - I_E \right] \\ & + \lambda_2 \left[(1 - \pi)\pi_0[A_i(L_E^a + L_G^{b+c})I^\beta] \right. \\ & \left. + m + (1 - \pi) \cdot n - \frac{1}{2}\xi(b^2 + 2kbc + c^2) - R_s \right] \end{aligned} \quad (4)$$

Suppose $\frac{\partial L}{\partial \lambda_1} = 0$, then the optimal controls of the private sector are defined as follows:

$$\begin{aligned} \pi^* &= \frac{I_E - (1 - \pi_0)A_i(L_E^a + L_G^{b+c})I^\beta - \frac{1}{2}\eta\alpha^2}{n} \\ &= \frac{I_E - (1 - \pi_0)R - \frac{1}{2}\eta\alpha^2}{n} \end{aligned} \quad (5)$$

Or suppose $\frac{\partial L}{\partial \lambda_2} = 0$, then the optimal control rights of the private sector are defined as follows:

$$\pi^* = \frac{\pi_0 A_i(L_E^a + L_G^{b+c})I^\beta - \frac{1}{2}\xi(b^2 + 2kbc + c^2) + n + m - R_s}{\pi_0 [A_i(L_E^a + L_G^{b+c})I^\beta] + n} \quad (6)$$

3.3 Model analysis

By using the proposed analysis of the allocation of the residual control rights mechanism and model assumptions in hydraulic PPP projects, obtaining mathematical equations that enable allocation of residual control rights are defined as equation (5) or equation (6) in the private sector. Based on the equation (5) or equation (6), further analysis is put forward for both parties such that the factors, such as capacity and goal difference, have an impact on the residual control rights and incentive constraint mechanism designing.

a. From equation (5), we can obtain the following equation:

$$\frac{\partial \pi^*}{\partial I_E} = \frac{1}{n} > 0, \quad \frac{\partial \pi^*}{\partial \pi_0} = \frac{A_i(I_E^a + I_G^{b+c})I^\beta}{n} = \frac{R}{n} > 0,$$

Whereby the public sector should be based on the amount of investment and equity in the private sector to determine the allocation of residual control rights and incentive programs, the incentive program is given as follows: When the amount of financing is large in the private sector, it should be allocated with more residual control rights, to encourage private sector participation in hydraulic PPP projects and contribute to the implementation of the ultimate realization of the PPP project financing; the greater the initial stake possessed by the private sector is, the greater residual control rights is allocated, to encourage the private sector to create more economic benefits.

b. From equation (5) or equation (6), the following equation is obtained: $\frac{\partial \pi^*}{\partial A_i} = -\frac{(I_E^a + I_G^{b+c})I^\beta}{n} < 0$,

$$\frac{\partial \pi^*}{\partial u} = -\frac{A_i I^\beta I_E^a \ln L_E}{n} < 0$$

Whereby we receive the allocation of residual control rights and the incentive constraint program on the basis of capacity difference between the private sector and public sector, and the program is given as follows: when the private sector has advantages, such as the level of technical expertise, management ability, and the human capital investment is higher, the probability of hydraulic PPP projects succeeding and being controlled is greater. In this case, we can appropriately reduce the allocation of residual control over the private sector, to constrain the private sector, thereby keeping the level of good technical expertise and strong management and to achieve benefits; when the public sector has more advantages of the co-ordination and support ability, then the public sector should possess more residual control rights.

c. From equation (6), the following equation is obtained: $\frac{\partial \pi^*}{\partial R_S} = -\frac{1}{\pi_0(A_i(I_E^a + I_G^{b+c})I^{\beta+n})} < 0$

Whereby we can receive the allocation of residual control rights and the incentive constraint program in the public sector, and the program is given as follows: when the social efficiency exception is high, the public sector should enhance the proportion of residual control rights, which strengthen the monitor rights to hydraulic PPP projects, so as to ensure the interests of the public.

4 CONCLUSIONS

Residual control rights are continuous variables from 0 to 1, not simply by either the public

sector or the private sector owning alone. In order to attract social capital to participate in hydraulic PPP projects, to utilize the governance effect of control rights, and to stimulate specificity investment from the private sector, the public sector should share one part of the residual control rights with the private sector. In the whole life cycle of the hydraulic PPP projects, according to the type of uncertainty events, the degree and range of influence, the residual control should be dynamically adjusted between public and private sectors.

In the process of hydraulic PPP projects, investment amounts and equity ratios are positively correlated with the allocation of residual control rights in the private sector; the ability advantages of the private sector, such as technical level, management ability, and effort level are in negative correlation with its allocation of residual control rights; The ability advantages of coordination, supervision, as well as the expectations values of the social benefits of the PPP project are positively correlated with its allocation of residual control in the public sector.

Due to the incompleteness of the hydraulic PPP project contract and the uncertainty of public-private cooperation, allocation of control rights is a very complex system process. In this paper, influence factors that the proposed model has suggested is insufficient, such as we did not consider how the policy support and the trust degree of both public and private sectors affect the allocation of residual control rights. It will require further research to solve the problem.

A study on the optimized hydraulic circulation system of the artificial lake

Qiannan Jin, Aiju You & Haibo Xu

Zhejiang Institute of Hydraulics and Estuary, Hangzhou, Zhejiang, China

ABSTRACT: Constructing an optimized hydraulic circulation system is an effective means to improve the lake water's quality. The hydraulic circulation of the artificial lake in Shangyu was designed by including the external circulation system and the internal circulation system. The flow field of the lake was simulated and analyzed based on MIKE21 software, and the results showed that under the same water supplement and wind conditions, the internal circulation system combined with the morphological characteristics of the lake could eliminate the area of the dead water zone obviously.

1 INTRODUCTION

In recent years, the artificial landscape lakes come forth continuously in cities, for improving the living environment. However, artificial lakes face high risk of water pollution due to their poor flow-ability and low self-purification ability. And the lakes are always designed to be irregular in shape to meet the people's demand of landscape, and that is prone to create the "dead water zone". In the zone, the flow is slow, the water cannot be replaced, and a variety of pollutants are deposited, which leads to the deterioration of water quality, and spreading of pollutants to the entire lake.

The important measure to prevent dead water zone creation and to make water in the lake flow is constructing an optimized hydraulic circulation system. It means that, besides the strict control of pollution into the lake, good water should be supplied to the lake to update the lake water (Fu & Yu 2011, Kang et al. 2012), and the hydraulic circulation should be optimized and designed to prevent the adverse effects of irregular shape (You et al. 2014).

In this paper, as for the artificial lake in Shangyu, by combining with the morphological characteristics of lake, the hydraulic circulation system was proposed, based on the numerical simulation and comparative analysis of the flow field. We hope to provide references for similar projects.

2 PROJECT PREFACE

The planning artificial lake is located in the core area of the coastal town in Shangyu City. The area of the lake is about 80.54 hectares, the average water depth is 3.1 m and the normal water level is 3.1 m. The lake morphology is East–West, the distance from east to west is 2.8 km, and the widest point in the north–south direction is 850 m while the narrowest is 90 m. The original rivers on the south side of the lake were retained and formed with the lake in series and the width of the rivers is 30–70 m, and the total length is about 3 km. The layout of the artificial lake is shown in Figure 1. The rivers on the south side are winding prone to create a dead water zone.

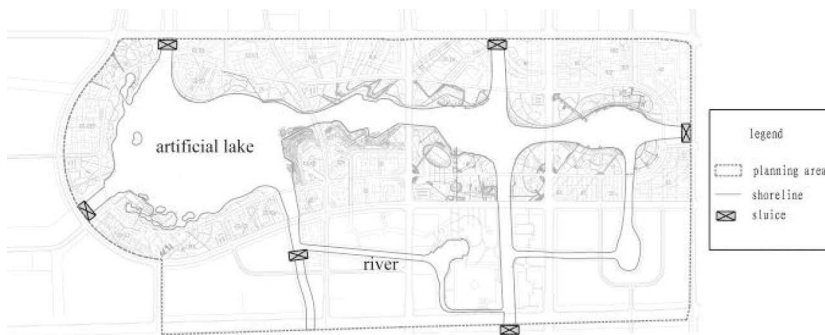

Figure 1. Layout of the artificial lake.

3 HYDRAULIC CIRCULATION SYSTEM DESIGN

Hydraulic circulation could promote the lake water flow, thereby having three benefits: (1) play the role of aeration, (2) prevent the dead water zone formation of the rivers on the south side, and (3) improve water quality combined with the ecological system in the rivers, where the pollutants could be better purified. The hydraulic circulation system was designed including two parts: the external circulation system and the internal circulation system, which is shown in Figure 2.

3.1 External circulation system

The external circulation system was constructed to supply good water to the lake to update the lake water. The supplement water requirement was mainly used for: (1) supplement for water losses due to evaporation and seepage to maintain the water level fluctuation in an acceptable range; (2) enhancing the water flow rate and reducing water retention time to prevent lake eutrophication. A variety of factors should be considered to determine the requirement, such as, the water quality condition of the supplement water source, the pollution source into the lake, and the lake target water quality. Through analysis, the water diversion scale was determined as 30,000 t/d ($0.35 \text{ m}^3/\text{s}$). The details of water requirement analysis could be found elsewhere (You et al. 2012). The supplement water source was supplied into the lake through three water inlets in the west side of the lake. The three inlets' flow rates were $0.09 \text{ m}^3/\text{s}$, $0.17 \text{ m}^3/\text{s}$, and $0.09 \text{ m}^3/\text{s}$.

3.2 Internal circulation system

The internal circulation system was constructed to accelerate the water flow to prevent the adverse

effects of irregular shape and the dead water zone of the rivers on the south side. The internal circulation system was composed of three weirs, a pump, an ecological system, and two adjustable outlets. Its working principle is as follows: $60,000 \text{ t/d}$ water was pumped from the eastern lake through weir 1 and filled into the ecological rivers; the water treated by using the plant purification system in the rivers were then filled into the lake through inner outlets 1 and 2 (weir 2 and 3).

4 NUMERICAL SIMULATION

4.1 Numerical model

MIKE21 software (DHI, Denmark) was used to simulate the hydraulic circulation of the artificial lake, and the flow field of the lake whether the internal circulation system and whether the constant wind (southeast, 3 m/s) effect were analyzed. A 2-D flow model of the lake region was built by using on MIKE21 software.

4.1.1 Computational grid generation

A 10-m ($x = y = 10 \text{ m}$) rectangular grid was used to divide the topography of the lake region. The grid-based terrain is shown in Figure 3.

Figure 3. Schematic diagram of grid-based terrain.

Figure 2. Schematic diagram of the hydraulic circulation system.

4.1.2 *Definite solution condition*

Initial conditions: the elevation of the lake was 3.1 m and the average water depth was about 3.0 m, according to the initial calculation of concentration.

Boundary conditions: the flow rate of the total amount of supplement water into the lake was 0.35 m³/s, thereby maintaining the balance of import and export.

4.1.3 *Other conditions and parameters*

The simulation time step was 0.5 s, the diffusion coefficient was 0.5 m²/s, and the continuous water exchange method was adopted.

4.2 *Result analysis*

The velocity variation of the lake based on different plans is listed in Table 1 and shown in Figure 4. The results show that wind played a leading role in the lake current (by comparison of plan 3 and plan 1 and plan 4 and plan 2). The wind-driven current played a dominant role while the inflow–outflow caused by water diversion made a relatively small impact on the lake current. However, the latter one still improved the area of relatively high flow velocity significantly, especially in the circulation path (by comparison of plan 3 and plan 5). The effect of the wind field on the lake was greater than that on the river, so that the velocity of the river was much slower than the lake, and was prone to create the dead water zone. Therefore, with the internal circulation system combining with the lake morphology, the dead water zone of the southern river could be eliminated (by comparison of plan 2 and plan 1 and plan 4 and plan 3). Moreover, the water

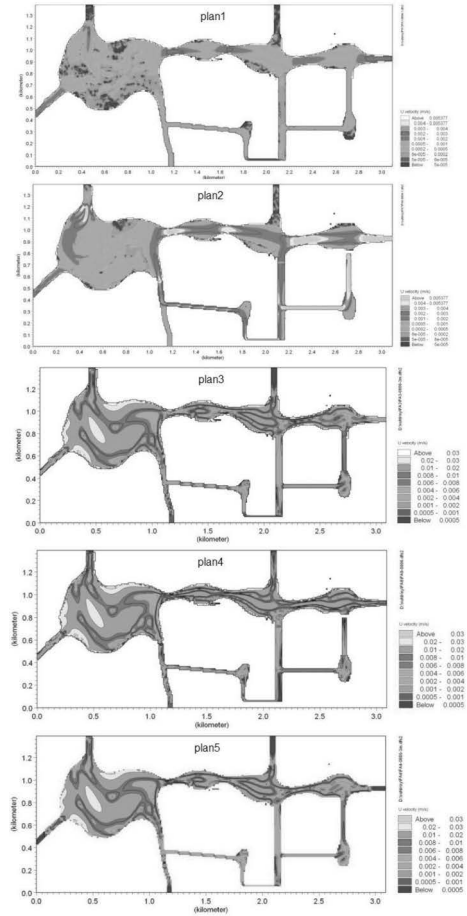

Figure 4. Velocity of the lake based on different plans.

of the lake could be further purified by using the river ecosystem.

5 CONCLUSION

The artificial lakes are conducive to improve the city landscape and ecological environment. The artificial lake in Shangyu was designed to be irregular in shape with winding rivers to meet the people's demand of the landscape that is prone to create the dead water zone, thereby leading to the deterioration of water quality. By combining with the morphological characteristics of the lake, the hydraulic circulation system was proposed including the external circulation system and the internal circulation system.

The hydraulic circulation of the artificial lake was simulated by MIKE21 software, and the flow field of the lake was analyzed. Under the same water supplement and wind conditions, the internal circulation system could achieve the following: the flow field distribution tends to be uniform, the state of the water flow is greatly improved, the area of

the dead water zone is eliminated obviously, and the fluidity of water in the southern river increased. In general, the optimized hydraulic circulation system could effectively maintain and improve the water quality, and MIKE 21 software is an effective tool to construct an eco-design of artificial lakes.

Development of new elastic constant estimation method using laser ultrasonic visualization testing

T. Saitoh & A. Mori

Department of Civil and Environmental Engineering, Gunma University, Japan

ABSTRACT: This paper presents a new elastic constant estimation method using the laser ultrasonic visualization testing for anisotropic elastic solids such as CFRP (Carbon Fiber Reinforced Plastics). In this paper, first, EFIT (Elastodynamic Finite Integration Technique) formulations for general anisotropic elastodynamics are described. Next, the procedure of our developed elastic constant estimation method is described with anisotropic elastodynamic theory. As numerical examples, elastic constants of a CFRP specimen are predicted by the proposed method. In addition, simulation of ultrasonic wave propagation in the CFRP with estimated elastic constants is implemented by using the EFIT and the results are compared with those obtained by the laser ultrasonic visualization testing to validate our proposed method.

1 INTRODUCTION

In recent years, anisotropic materials have been attracted lots of interest for various engineering fields. CFRP (Carbon Fiber Reinforced Plastics) is known as one of the anisotropic materials and has been used as a main material of aircraft and as a seismic strengthening member of civil and architectural structures. In general, the Ultrasonic non-destructive Testing (UT) is widely used for material inspection because the UT is portable for ready to use and transport compared to the Radiographic Testing (RT) which can be practiced by only suitably trained and qualified personnel. However, anisotropic materials sometimes make it difficult for inspectors to detect flaws because the phase and group velocities of elastic waves in anisotropic materials depend on their propagation directions. Therefore, a better knowledge of anisotropy is a great help for accurate the UT. In general, it is essential to determine the elastic constants of the anisotropic materials should be inspected in order to understand the anisotropic properties. Several researches about elastic constant estimation methods have been done since decades ago. A problem of conventional elastic constant estimation methods that need to be overcome is that we have to cut the test specimen to investigate the phase velocity of waves propagating in an oblique direction. This disadvantage is not efficient and economic, and should be resolved from the point of view of environmental aspect of waste generation.

Therefore, in this research, a new elastic constant estimation method for anisotropic materials

is developed. A laser ultrasonic visualization technique is incorporated to measure ultrasonic wave phase velocities which are required for elastic constant estimation.

As numerical examples, elastic constants of a CFRP specimen are predicted by the proposed method. In addition, simulation of ultrasonic wave propagation in the CFRP with estimated elastic constants is implemented by using the EFIT (Elastodynamic Finite Integration Technique) and the results are compared with those obtained by the laser ultrasonic visualization testing to validate our proposed method.

2 PROBLEMS

2.1 Fundamental equations

Let us consider a transversely anisotropic and homogeneous elastic material with density ρ as shown in Figure 1. The geometry of the elastic material is cuboid with width w , depth, d and height h . Elastodynamic field is excited by a laser ultrasonic non-contacting system with the central frequency f as shown in Figure 1. The displacement field $u_i(\mathbf{x}, t)$ on the field point \mathbf{x} at time t satisfies the equation of motion and the constitutive equation as follows:

$$\rho \frac{\partial \dot{u}_i(\mathbf{x}, t)}{\partial t} = C_{ijkl} u_{k,l}(\mathbf{x}, t) \quad (1)$$

$$\sigma_{ij}(\mathbf{x}, t) = C_{ijkl} u_{k,l}(\mathbf{x}, t) \quad (2)$$

Figure 1. A model for the laser ultrasonic visualization testing for an anisotropic specimen.

where $\sigma_{ij}(x, t)$ is the stress field and C_{ijkl} is the elastic constant. In addition, (\cdot) and $(\cdot)_{,i}$ denote the partial derivative with respect to time t and spatial variable x_i , respectively. For simplicity, 2-D formulation is considered hereafter. Taking time derivative of equation (2) and using engineering notation, which uses x, y, z for x_1, x_2, x_3 , for the resulting equation, the relation between stress and particle velocity can be obtained as follows:

$$\frac{\partial}{\partial t} \begin{pmatrix} T_1 \\ T_3 \\ T_5 \end{pmatrix} = \begin{pmatrix} C_{11} & C_{13} & 0 \\ C_{31} & C_{33} & 0 \\ 0 & 0 & C_{55} \end{pmatrix} \begin{pmatrix} \frac{\partial \dot{u}}{\partial x} \\ \frac{\partial \dot{w}}{\partial z} \\ \frac{\partial \dot{w}}{\partial x} + \frac{\partial \dot{u}}{\partial z} \end{pmatrix} \quad (3)$$

where T_1, T_3 and T_5 are defined by $T_1 = \sigma_{11}, T_3 = \sigma_{33}$ and $T_5 = \sigma_{31}$, respectively. In addition, $u_1 = u, u_3 = w$, and $C_{\alpha\beta} (\alpha, \beta = 1, \dots, 6)$ is the Voigt form of the elastic constant C_{ijkl} . Equation (1) can be rewritten using the engineering notation as follows:

$$\rho \frac{\partial \dot{u}}{\partial t} = \frac{\partial T_1}{\partial x} + \frac{\partial T_5}{\partial z} \quad (4)$$

$$\rho \frac{\partial \dot{w}}{\partial t} = \frac{\partial T_5}{\partial x} + \frac{\partial T_3}{\partial z} \quad (5)$$

Normally, Equations (3), (4) and (5) are solved by using appropriate numerical methods such as FEM (Finite Element Method), BEM (Boundary Element Method) or FDM (Finite Difference Method). In this research, EFIT (Elastodynamic Finite Integration Technique) (Nakahata et al., 2011, Fellingner et al., 1995) is used to obtain elastic wave fields in anisotropic materials.

2.2 EFIT formulation

A brief description of the EFIT formulation is given in this section. The starting point of the EFIT for elastodynamics is the integral form of equations (3), (4) and (5). The EFIT requires integrations over certain control surfaces S of the cells as defined in Figure 2. As seen in Figure 2, a square cell is used as an integral surface S . For each cell, the normal stresses T_1 and T_3 are located at the center of the cell. Considering a spatial staggered grid as shown in Figure 2, the particle velocities \dot{u} and \dot{w} , and the shear stress T_5 are naturally arranged at the midpoints of the edges and the corners of the cell. Therefore, the stresses T_1, T_3 and T_5 are calculated as follows:

$$T_1^{n+\frac{1}{2}}(i, k) = T_1^{n-\frac{1}{2}}(i, k) + \gamma C_{11} \left\{ \dot{u}^n \left(i + \frac{1}{2}, k \right) - \dot{u}^n \left(i - \frac{1}{2}, k \right) \right\} + \gamma C_{13} \left\{ \dot{w}^n \left(i, k + \frac{1}{2} \right) - \dot{w}^n \left(i, k - \frac{1}{2} \right) \right\} \quad (6)$$

$$T_3^{n+\frac{1}{2}}(i, k) = T_3^{n-\frac{1}{2}}(i, k) + \gamma C_{31} \left\{ \dot{u}^n \left(i + \frac{1}{2}, k \right) - \dot{u}^n \left(i - \frac{1}{2}, k \right) \right\} + \gamma C_{33} \left\{ \dot{w}^n \left(i, k + \frac{1}{2} \right) - \dot{w}^n \left(i, k - \frac{1}{2} \right) \right\} \quad (7)$$

$$T_5^{n+\frac{1}{2}} \left(i - \frac{1}{2}, k - \frac{1}{2} \right) = T_5^{n-\frac{1}{2}} \left(i - \frac{1}{2}, k - \frac{1}{2} \right) + \gamma C_{55} \left\{ \dot{w}^n \left(i, k - \frac{1}{2} \right) - \dot{w}^n \left(i - 1, k - \frac{1}{2} \right) \right\} + \gamma C_{55} \left\{ \dot{u}^n \left(i - \frac{1}{2}, k \right) - \dot{u}^n \left(i - \frac{1}{2}, k - 1 \right) \right\} \quad (8)$$

Figure 2. A spatial staggered grid of the 2D EFIT.

where $\gamma = (\Delta t / \Delta d)$, and Δt and Δd are time increment and the half length of the unit cell size, respectively. The particle velocities \dot{u} and \dot{w} are calculated as well as the stresses T_1 , T_3 and T_5 as follows:

$$\begin{aligned} \dot{u}^{n+1} \left(i - \frac{1}{2}, k \right) &= \dot{u}^n \left(i - \frac{1}{2}, k \right) \\ &+ \frac{\gamma}{\rho} \left\{ T_1^{n+\frac{1}{2}}(i, k) - T_1^{n+\frac{1}{2}}(i-1, k) \right\} \\ &+ \frac{\gamma}{\rho} \left\{ T_5^{n+\frac{1}{2}} \left(i - \frac{1}{2}, k + \frac{1}{2} \right) - T_5^{n+\frac{1}{2}} \left(i - \frac{1}{2}, k - \frac{1}{2} \right) \right\} \end{aligned} \quad (9)$$

$$\begin{aligned} \dot{w}^{n+1} \left(i, k - \frac{1}{2} \right) &= \dot{w}^n \left(i, k - \frac{1}{2} \right) \\ &+ \frac{\gamma}{\rho} \left\{ T_3^{n+\frac{1}{2}}(i, k) - T_3^{n+\frac{1}{2}}(i, k-1) \right\} \\ &+ \frac{\gamma}{\rho} \left\{ T_5^{n+\frac{1}{2}} \left(i + \frac{1}{2}, k - \frac{1}{2} \right) - T_5^{n+\frac{1}{2}} \left(i - \frac{1}{2}, k - \frac{1}{2} \right) \right\} \end{aligned} \quad (10)$$

For time-domain, the stresses T_1 , T_3 and T_5 are allocated at half time steps, while the particle velocities \dot{u} and \dot{w} are at full-time steps. The detail of the EFIT formulation is skipped due to the limitation of the spaces.

3 ELASTIC CONSTANT ESTIMATION

3.1 Laser ultrasonic visualization testing

Laser ultrasonic visualization testing is one of the non-contacting ultrasonic methods, which use lasers to generate ultrasonic waves and detect flaws in materials. The most important advantage of this method is that we can directly see the state of ultrasonic wave propagation in real time. The ultrasonic visualization testing is utilized to obtain the phase velocities of existing waves in anisotropic materials.

Figure 3 shows a system of the laser ultrasonic visualization testing. In this research, the system developed by Tsukuba Technology Co. Ltd. in Japan, which is called LUVI, is used. In this testing, only the ultrasonic waves propagating on the surfaces of test specimens can be visualized. No visualization data of wave propagation inside specimens can be obtained. Therefore, some numerical simulation techniques are used in conjunction with the laser ultrasonic visualization inspector to understand wave propagation phenomena inside specimens. Unfortunately, wave fronts seen in visualization data obtained by LUVI are not always

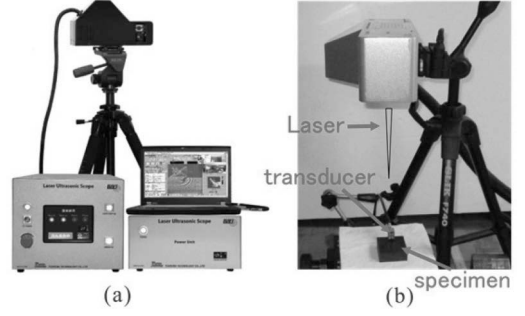

Figure 3. Laser ultrasonic visualization inspector (a) system of LUVI (b) excitation of laser ultrasonic waves.

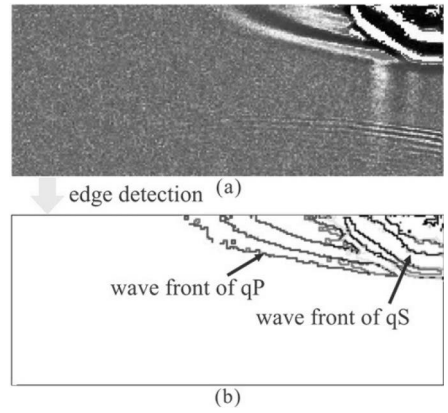

Figure 4. Laser ultrasonic visualization testing (a) a snapshot obtained by the Laser ultrasonic visualization testing (b) its edge detected-result.

clear. Consequently, the edge detection which is one of image processing methods is applied to the snapshots obtained by the laser ultrasonic visualization testing in order to enhance the wave fronts. Figures 4(a) and (b) show an example of snapshot obtained by the laser ultrasonic visualization testing and its edge detection result. As seen in Figure 4(b), we can clearly confirm the wave front of quasi P-wave (qP wave) and S-wave (qS wave) due to the image processing. The wave velocities of the qP and qS waves can be obtained by the time difference between some edge-detected pictures. It is possible to estimate elastic constants if qP and qS wave velocities are determined as explained in the following section.

3.2 Phase velocities and group velocities in anisotropic elastic materials

The phase velocity is equal to the group velocity for isotropic materials. However, the phase velocity

is not consistent with the group velocity for anisotropic materials. Therefore, this fact should be taken into account when elastic constants of an anisotropic materials are evaluated. If the phase velocity is known, elastic constants can be obtained using the following equations derived from Christoffel equation (Auld, 1990):

$$C_{11} = \rho V_{L-L}^2 \quad (11)$$

$$C_{33} = \rho V_{L-Z}^2 \quad (12)$$

$$C_{55} = \rho V_{T\perp ZC-Z}^2 = \rho V_{T\perp LC-L}^2 \quad (13)$$

$$C_{13} = -C_{55} + \frac{1}{2} \times \sqrt{(4\rho V_{L-ZL}^2 - C_{11} - C_{33} - 2C_{55})^2 - (C_{11} - C_{33})^2} \quad (14)$$

where V_{L-L} and V_{L-Z} are the phase velocities of qP waves traveling to the x_1 and x_3 direction, respectively. In addition, $V_{T\perp LC-L}$ and $V_{T\perp ZC-Z}$ are the phase velocities of qS waves polarized in the z direction propagating to the x direction, and in the x direction propagating to the z direction, respectively. V_{L-ZL} is the phase velocity of qP wave which propagates with an angle of 45° in the $x-z$ plane. V_{L-L} , V_{L-Z} , $V_{T\perp LC-L}$ and $V_{T\perp ZC-Z}$ can be deduced from the results of the laser ultrasonic visualization testing. However, the derivation of the phase velocity V_{L-ZL} is somewhat troublesome because the wave propagation seen in snapshots as shown in Figure 4(b) shows the group velocity. Therefore, in this research, the phase velocity V_{L-ZL} was derived from the fact that the wave vector must always be normal to the ray surface.

4 NUMERICAL EXAMPLES

4.1 Laser ultrasonic testing

Laser ultrasonic visualization testing was carried out for the CFRP specimen, Toray T800S-2592. The geometry parameters of the CFRP were set to be width $w = 5$ cm, depth $d = 5$ cm, and height $h = 2$ cm. The density ρ was given by $\rho = 160$ kg/m³. The 45° angle probe with the central frequency $f = 1$ MHz was used as ultrasonic wave receiver. Figure 5(a) shows a snapshot of the ultrasonic waves obtained by using the laser ultrasonic visualization testing at surface B as shown in Figure 1. As seen in Figure 5(a), the qP wave propagating parallel to the x -direction shows the fastest speed of all directions. The tendency of wave propagation in CFRP is similar to that in graphite epoxy (Furukawa et al., 2014). Estimated elastic constants obtained by using the proposed method are shown in Table 1. As predicted, the component of

Figure 5. Numerical results obtained by (a) laser ultrasonic visualization testing and (b) EFIT simulation with estimated elastic constants shown in Table 1.

Table 1. Estimated elastic constants.

C_{11}	C_{33}	C_{13}	C_{55}
161.4	13.4	9.036	7.109×10^9 GPa

the elastic constant C_{11} shows large value rather than other components.

4.2 EFIT simulation using the estimated elastic constants

Numerical examples using the 2-D EFIT were carried out for the ultrasonic wave propagation problem corresponding to the laser ultrasonic testing demonstrated in previous section. Estimated elastic constants as shown in Table 1 were used for the 2-D EFIT simulation in this section. In this analysis, the following time-domain incident wave with central period $T (= 2\pi/\omega)$ and angular frequency ω is considered:

$$\dot{w}(x, t) = \begin{cases} \sin\left(\frac{2\pi}{T}\right) & \text{for } 0 \leq t \leq T \\ 0 & \text{for otherwise} \end{cases}$$

The time-domain incident wave is given as the boundary condition at the point $(x, z) = (4.9, 2.0)$ cm. In addition, the stress free boundary condition is imposed over the surface of CFRP specimen except for the source point. Figure 5(b) shows the total particle velocity $\sqrt{\dot{u}^2 + \dot{w}^2}$ at the surface B of the CFRP specimen obtained by the EFIT simulation, which is corresponding to the result shown in Figure 5(a). As can be observed in Figure 5(b), the

ultrasonic waves propagate at different speeds for different directions due to the influence of anisotropic property. We can confirm qP wave traveling with the wave front of ellipsoidal form. Although some of the difference can be seen in the shape of qS wave front, the numerical result obtained by using estimated elastic constants is agree with that from the laser ultrasonic visualization testing.

5 CONCLUSIONS

Elastic constant estimation method using the laser ultrasonic visualization testing was presented. As a numerical example, elastic constants of a CFRP specimen were calculated by the proposed method. The results from EFIT simulation using estimated CFRP elastic constants were consistent with the corresponding those from laser ultrasonic visualization testing. In near future, the proposed method

will be extended to more complicated CFRPs with different type of laminations.

Selection for the frequency control point of the VAV air supply system in large underground spaces

Kedi Xue, Zhihua Zhou & Yufeng Zhang

School of Environmental Science and Engineering, Tianjin University, Tianjin, China

Yimiao Sun

School of Mathematics, South China University of Technology, Guangzhou, China

ABSTRACT: Ventilation is an important part of the mine and other underground spaces to ensure personal safety. Previous rough design and managements lead to larger system energy consumption. A control method is proposed in this paper for the current status of the ventilation system in large underground spaces not having been taken seriously and its operation being uneconomical, where the main duct airflow rate is variable, while the branch pipe airflow rate is constant. Based on this, an experimental system was built in a laboratory, taking practical engineering as the model. Through experiments, the system's total energy consumption, control effect, and actual airflow rate of each branch under different constant pressure points in constant static pressure control mode were studied, and were then compared with designed values. Results showed that the optimal constant pressure point location of the ventilation system in large underground spaces was where the static pressure was equaled to the average value of static pressures at the front and end of the main air duct, where it can be better controlled leading to increased energy-conservation.

1 INTRODUCTION

Several major incidents and accidents related to the presence of methane in underground coal mines with fatalities have been reported (Torano et al. 2009). Ventilation is a very important part of underground mines. Studies have shown that depending on the types of mines, the power consumption of the ventilation system is also different. Some mines reveal as high as 25%–40% of the total underground electricity consumption (Karcacan 2007, LI & WANG 2009). Currently, large-scale underground mines usually adopt steady ventilation. The mine ventilation system (Parra et al. 2006, Sahay et al. 2014) can be divided into many small regions, and meet the regional ventilation requirements by setting branch pipes. Since the thermal and moisture load in underground engineering undergo very little change over time, each region requires a certain air volume during operation, namely, but some regions may sometimes open and sometimes close, thereby resulting in the total airflow rate being mutative at any

time. In order to guarantee the airflow rate of each branch pipe while reducing total power consumption, an appropriate Variable Air Volume (VAV) system is clearly required.

The constant static pressure method was the commonly used fan control method. In most cases, a static pressure sensor is generally located two-thirds downstream in a main supply air duct (Shim et al. 2014, Zhang et al. 2010) although it is no longer recommended by ASHRAE. However, for mines and other large-scale underground areas, which have long distance pipe networks, more complex systems and changeable operation conditions, it is difficult to determine where and how many static pressure sensors should be placed, and the energy-saving effect is also difficult to guarantee (ASHRAE 2011).

In this paper, an experimental system was built in a laboratory by taking practical engineering as the model. And then, different constant pressure points were set. Finally, by the analyzing airflow rate and stability of each branch and also taking energy consumption into account, the best

location of the constant pressure point under constant static pressure control mode was determined.

2 METHODS

2.1 Experimental system

Based on an engineering model in practice, we designed a VAV air supply system, which comprised a main air duct and four branch pipes (I, II, III, and IV), as shown in Fig. 1. A main fan was installed on the main air duct, and three box-type centrifugal fans on II, III, and IV branches. In addition, there was also one fixed resistance valve, marked as 1, 2, 3, and 4, and one adjustable damping valve, marked as 5, 6, 7, and 8 on each branch system, respectively. Furthermore, a power meter was used to collect the electromotor input power. In order to test system pressure and control the main fan effectively, three measurement points were chosen, namely P1, P2, and P3 (see Fig. 1). The P1 constant pressure point was located at the main fan outlet, where air flow was stable. The distance from the P2 constant pressure point to the main fan was 2/3 length of the main air duct. The P3 constant pressure point was set at the end of the main air duct. In addition, a virtual static control parameter named as the P4 constant pressure point was set, which took the average value of P1 and P3 static pressure points.

2.2 Parameter test

2.2.1 Static pressure

A pressure sensor was installed at P1, P2, and P3 constant pressure points, respectively, and the static pressure value of the P4 constant pressure point was calculated by taking the average of P1 and P3 constant pressure point values.

2.2.2 Airflow rate

The method of testing the duct's airflow rate was as follows: measure the duct dynamic pressure at

some point and convert it into wind speed at this position by using equation (1), and then calculate the duct airflow rate by using equation (2). In addition, for the circular pipe, we should arrange measuring points based on the equal area method (Zhao et al. 2009).

$$v_a = \sqrt{\frac{2P_{da}}{\rho}} \quad (1)$$

$$Q = 3600 \times v_a \times S \quad (2)$$

In equation (1), P_{da} was calculated based on equation (3); ρ can be obtained by measuring the absolute static pressure, temperature, and humidity within 20 m from the wind pressure measurement position in the tunnel, as given in equation (4).

$$P_{da} = \left(\frac{\sqrt{P_{d1}} + \sqrt{P_{d2}} + \dots + \sqrt{P_{dm}}}{m} \right)^2 \quad (3)$$

$$\rho = 3.484 \times 10^{-3} \times \frac{P_0 - 0.3779 \phi P_{sat}}{273 + t} \quad (4)$$

2.3 Static pressure set point value

Set the PID controller and the frequency converter to the manual working state, and open the fixed resistance valve of each branch pipe fully. Turn on the main fan, and maintain the frequency converter at 50 Hz. Next, turn on the branch pipe fan sequentially, and adjust the adjustable damping valve of branch IV, III, II, and I sequentially till the airflow rate of each branch system reached its design value. Record the static pressures of each constant pressure point, which were taken as static pressure set point values.

3 RESULTS

3.1 Set point values

The set point values at each constant pressure point were measured, as given in Table 1.

3.2 Actual airflow rate

Maintain the static pressure at P1, P2, P3, and P4 points at its set point values sequentially, and the actual airflow rates are listed in Tables 2–5.

4 DISCUSSION

In this experiment, due to the different requirements for airflow rates among every region in the system, the rated airflow rate of branch I, II, III, and IV was 5400 m³/h, 4800 m³/h, 4800 m³/h, and 2800 m³/h, respectively. As can be seen from Section 3, the actual air supply volume of branch I fluctuated between 5000 m³/h and 5500 m³/h, only except for a few points; nevertheless, it gave about 7%–10% deviation when compared with the rated value of 5400 m³/h. Similarly, all deviations of the four branches were within ±15%, thereby meeting the standard requirements.

4.1 Operation stability

For each branch pipe, we calculated the standard deviation of ratios between the actual and rated air supply volumes under different operating conditions, and the results are summarized as Table 6.

When the constant pressure point was located at P4, the standard deviation of each branch reached to the minimum values, which illustrated their best air supply stability.

4.2 Energy consumption

Fig. 2 illustrates the inverter frequency and input power of different constant pressure point positions.

When the constant pressure point was located at P3, the inverter frequency reached to the minimum value of 39.05 Hz, which was significantly smaller than that of 50 Hz under full load operation conditions. What is more, the input power has also decreased from 12 kW to 4.8 kW. Likewise, when the constant pressure point was located at P1, P2, or P4, the input power has also decreased by 49.20%, 58.30%, and 57.50%, respectively.

Table 6. Standard deviation of ratios between actual and rated air supply volumes for each branch pipe (%).

Constant pressure point	P1	P2	P3	P4
Branch I	0.012	0.005	0.019	0.002
Branch II	0.017	0.005	0.007	0.002
Branch III	0.018	0.004	0.006	0.004
Branch IV	0.011	0.010	0.009	0.008

Figure 2. Comparison of fan frequency and input power for different constant pressure point positions.

Figure 3. Comparison of system stability and system energy consumption among different constant pressure point positions.

4.3 Determination of optimal constant pressure point location

Fig. 3 illustrates the comparison of system stability and system energy consumption among different constant pressure points positions.

As shown in Fig. 3, the P1 constant pressure point possessed the poor air supply stability and the largest energy consumption. P2 possessed a better air supply stability, but not the most energy-efficient point. P3 possessed the lowest energy consumption but the worst air supply stability. The biggest advantage of the P4 constant pressure point is that it possessed the best air supply stability on the basis of meeting the rated requirements of each branch system. What is more, its energy consumption was slightly higher than the P2 constant pressure point, but decreased by 16.39%

compared with P1 constant pressure point. Therefore, the P4 point was the optimal constant pressure point location in our experimental system.

5 CONCLUSIONS

In order to reduce the ventilation system energy consumption of the mines and other large underground spaces, on one hand, an appropriate ventilation system should be chosen; on the other hand, a suitable system operation control method should be adopted. In this paper, a frequency ventilation control program was proposed, taking an underground engineering for study. By the testing airflow rate, air pressure, fan input power, and other parameters under different operation conditions, different constant pressure points, and analyzing and comparison, the variable main duct air volume and constant branch pipe air volume control mode was adopted. Among the four constant pressure points, the point at where the static pressure is equaled to the average value of static pressures at the front and back of the main air duct showed the best results.

The innovations of the ship lock design for the Tugutang Hydropower Station in the Xiangjiang river

Huying Liu & Chongyu Wang

*Hunan Provincial Communications Planning, Survey and Design Institute, Changsha, China
Changsha University of Science and Technology, Changsha, China*

ABSTRACT: According to XJMWD and HNWTDP, the Tugutang Hydropower Station navigation-power hub was the last dam on the Xiangjiang River. And so, the construction and development of Hunan inland waterways is very important. Not only the general layout and engineering characteristics of its ship lock were analyzed, but also the innovations of the ship lock design are summarized. The innovations of the lock head, construction diversion program by structural optimizations, and considering the second ship lock in the general layout were adopted in this Hydropower Station. A design reference for similar hubs or ship locks was provided by using the above innovations.

1 BACKGROUND AND INTRODUCTION

According to “Xiangjiang River Mainstream Waterway Development Plan” (XJMWD, 2007), the channel from the stream outlet to Hengyang was planned for the level II, and the channel from Hengyang to Yongzhou was planned for the level III. With the implementation of Changsha hydro-junction and the first phase of Xiangjiang River waterway improvement, the channel from the stream outlet to Zhuzhou will be considered as level II. Xiaoxiang, Jinweizhou, WuXi, and XiangQi are four hydro-junctions that had been built on the Xiangjiang River. The water level between Jinweizhou and Dayuandu hydro-junction is not yet joined. Therefore, the level III waterway in Xiangjiang River can be extended to the Jinweizhou hydro-junction because of the construction of the Tugutang navigation-power junction, which will promote the economic development of the middle reaches and the upper reaches of the basin of Xiangjiang River.

In addition, a modernization of the water transport system will be built in Hunan according to “Hunan Water Transport Development Plan” (HNWTDP, 2011). The system relies on the Yangtze River in the region and Dongting Lake. Moreover, “One vertical and five horizontal” channel-net will be formed. The backbone is the “one vertical” channel i.e. Xiangjiang River. The construction of a 2000-tons ship-lock will soon start in the

Dayuandu hub and in the Zhuzhou hub located downstream of the Tugutang hub. The expansion of the 1,000-tons ship-lock of four hydro-junctions is planned upstream. The Xiang-Gui canal will be constructed, which can connect the Yangtze River basin and the Pearl River basin.

Therefore, the Tugutang hub is the last dam in Xiangjiang River. An important role will be played by this hub in the development of the Xiangjiang River channel and Hunan water transport system.

The Tugutang hub is located in the town of Yunji, Hengnan County, 39 km upstream of the city of Hengyang. The hub is a project for the ship, as well as taking into account hydropower generation, transportation, irrigation, water supply, aquaculture, and so on.

The navigation structure is a 1,000-tons ship-lock whose annual capacity is 15 million tons. The effective measure of the lock bay is $180 \times 23 \times 4.0$ m, and the position of the second-tier ship lock is reserved.

2 THE OVERALL SCHEME AND INNOVATIONS OF THE SHIP LOCK

2.1 *The general layout scheme of the ship lock*

According to the general layout scheme of the hub, the ship lock is arranged in the right-hand side bank of the river, and the axis of the ship lock is perpendicular to the axis of the dam. The main

Figure 1. The layout of the ship lock of the Tugutang hub.

buildings of the ship lock include the ship lock head, bay, navigation wall, boat pier, separating wall, and so on. Figure 1 shows the overall layout of the ship lock.

2.2 Innovations of the design

Three innovations were embedded in the design of the ship lock as follows, according to the overall layout of the hub, engineering features, construction plans, and long-term plans:

1. According to the construction diversion scheme of the hub, part of the ship lock shall be in construction area above the water level. In addition, during the construction process, a small cofferdam for the ship lock needs to be formed, and part of the main buildings near the river may be used to be the longitudinal cofferdam as well. In order to meet the above-mentioned demand, the structure of buildings must implement innovation and optimization.
2. According to PHWTD, the 1000-ton channel extension in the upper reaches of the Xiangjiang River and Xianggui canal construction will be constructed in the long term. It should be reserved for construction conditions of the Tugutang second-tier ship lock to meet with the plan of regional economic development. Therefore, not only positions are reserved for the construction of the second-tier ship lock in the design, but also buildings landside of one line lock gets structural innovations in order to accommodate the construction of the second-tier ship lock, which can avoid duplication and demolition of buildings.
3. The dam of this project is located in Hengnan city; after the completion of the hub, it will become a part of the scenery in the city. Taking into account the landscape requirements, we need to fully optimize structural arrangement and control the structure height in the design of the upper and lower lock head. The requirements of the scenery will be met in the ship lock area after completion of the hub.

3 CONSTRUCTION DIVERSION, DESIGN INNOVATION, AND STRUCTURAL OPTIMIZATION

3.1 Scheme of construction diversion

The project includes a ship lock, 17.5 sluice gates, turbine generators, and other units. It is divided in three phases. The first phase is around the ship lock and 7.5 sluice gates at the right-hand side of the bank. The second one is separately around the powerhouse at the left-hand side bank. A small cofferdam is constructed before removing the cofferdam at the first phase. Three phases closure is carried out after the ship lock, and the rest of the sluice gates are fenced. Figures 2 and 3 show layouts of construction diversion.

The innovations of the ship lock design are mainly reflected as follows:

1. Cofferdam in the first phase includes only lock heads, bay, and other primary and secondary navigation walls; the rest of the buildings of the ship lock shall be constructed above the water level.
2. After the formation of the cofferdam in the second phase, the transverse cofferdam in the first phase must be removed. And then, the ship lock is not completed and therefore, we shall continue to build the small cofferdam of ship locks. And the buildings by the river side shall be considered to be the longitudinal cofferdam as well.

3.2 The pile-pillar-slab separation wall

The main buildings out of the cofferdam include berthing piers, separation walls, diversion piers, which all need to be constructed above the water level. The general pile cap foundation is used in berthing piers and diversion piers. The separation wall must have the function of water diversion, which may be the structure with slab between the piers. The pier is designed innovatively in this

Figure 2. The layout of construction diversion in the first and second phases.

Figure 3. The layout of the small ship lock cofferdam and construction diversion in the third phase.

project as follows: “pile foundation + pillar structure”. Figure 4 shows the separation wall’s structure.

The pile–pillar–slab separation wall indicates the structure with pile foundation base, the pillar as the upper structure, and with slab between the pillars, whose pile is bored piles with a diameter of 2.5 m. In order to simplify the mechanical characteristics, the cylinders with the same diameter of 2.5 m are used as pillars, with 15 m as the column spacing. Mounting slots are reserved by the upstream and downstream ends of the cylinder. The precast slab with a thickness of 0.6 m is inserted. The riprap is used to closure it between the slab and the bed.

Advantages of the pile–pillar–slab separation wall are mainly given as follows: 1) deep foundations are facilitated through the construction above

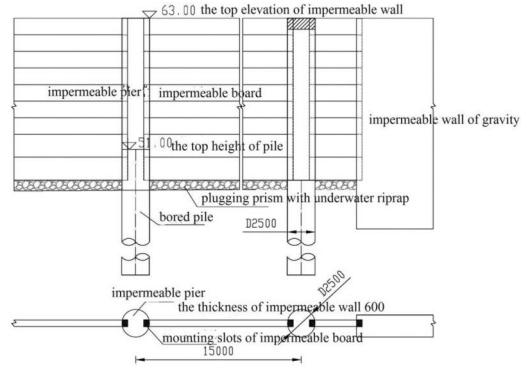

Figure 4. Schematic of an impermeable wall with piles plate inserted.

the water level; 2) the pile and pillar are designed with the same size for simple construction; 3) slabs are prefabricated firstly for a short time.

There are issues that need attention in this program: 1) the reserved position of the mounting groove must be precise in order to ensure a smooth installation of the slab; 2) when the force was calculated, the water level difference between both sides of the wall should be taken into account.

3.3 Chamber wall

According to the scheme of construction diversion, after the completion of the first phase of the sluice gate, the transverse cofferdam will be removed. The construction of the small cofferdam of the ship lock was proceeded, and the small cofferdam of the ship lock was used only to construct the lateral cofferdam. One part of the main structure of the ship lock caters the longitudinal cofferdam, including brake head, river-side chamber wall, and so on. The standard flow rate is 8000 m³/s and the water level is 58.10 m.

According to the arrangement and the construction needs, it can be observed that it is different for structural forms between the shore side and the river side of the chamber wall. Figure 5 shows a cross-sectional view of the chamber wall.

Approximately, an “L”-type gravity structure is constructed in the chamber wall at the river side. The weight of the trailing floor, upper backfill and water are fully used to improve the stability of the river-side wall against sliding. It also meets requirements during construction as a cofferdam.

The weight-balanced structure with an unloading-board is carried out in the shore-side chamber wall. The bottom width of the structure is 13 m. The unloading-board is added at the balancing platform location to lower the soil pressure of the backfill.

Figure 5. The cross-sectional view of the chamber wall.

With optimized design as mentioned above, both sides of the chamber wall can meet the overall stability requirements of the various conditions.

4 THE OPTIMIZATION OF THE DESIGN TAKING INTO ACCOUNT THE SECOND SHIP LOCK

According to the plan of the general layout, the second ship lock will be laid on the right-hand side of the ship lock. And so, buildings related to the second ship lock mainly include the navigation wall, boat pier, and so on.

4.1 Main navigation wall with holes

According to the layout of the first and the second ship locks (see Figure 1), the main navigation wall of the first and the second ship lock was played. The outer surface of the main navigation wall is constructed by using a boat segment. As an operational experience of multi-line locks, it will affect the approach channel's flow condition of the other ship lock when the water of the first ship lock flows in or out. Even great negative effects on the operation of the miter gate of the other by big water head are reversed.

To avoid the situation mentioned above, the main navigation wall with holes in the bottom was designed. It will improve the flow properties of approach channels. Figure 6 shows the structure drawing of the main navigation wall.

The broadened base is used in foundation of the main navigation wall. The counterfort wall was used as the upper structure, and the plate was used as the boat wall. There was a hole at the bottom of the plate. The hole size is determined by using the approach channel bottom elevation and the lowest navigable water level. The two lines of the ship lock water level are balanced by using holes. The reason for this structure in the first ship lock is that it can save the amount of concrete work at the present stage firstly, and also it is used to avoid

Figure 6. The chart of the main navigation wall.

Figure 7. Schematic of the bidirectional berthing pier.

concrete demolition projects in the second ship lock construction.

4.2 Two-way boat pier

A boat pier was constructed above the water level out of the cofferdam. It is concreted on the pile platform. According to the layout of the first and the second ship locks, boat piers of the first and the second ship lock are laid in the same location.

In order to avoid duplication and adverse effects on the first ship lock by the second ship lock's construction, the two-way berthing pier for the first tier ship lock was designed, taking into account the berthing capacity of the first and the second ship locks at the same time. But, the bollard installation slot was reserved by the side of the second ship lock. Figure 7 shows the structure drawing of a two-way berthing pier.

The plane size of the pier along the flow direction is 3.5 m, and vertical size is 5.5 m. The slab slots were reserved by the upstream and downstream surfaces of the pier for installation of the riser board when we constructed the second ship lock. To reduce the transverse flow velocity of the parking section, the boat pier can meet the requirements in two ways. It should be noted that the structure shall be calculated considering the combination of the impact force and the mooring force in both sides at the same time.

5 DESIGN OPTIMIZATION OF THE LOCK HEAD

5.1 Upper lock head

According to operation requirements of the ship lock, a hoist room needs to be arranged on both sides of the lock head. But the control center of the ship lock should only be arranged on one side, in order to facilitate the operators. Thus, the pipe line channels must be arranged over the ship lock for cables and water pipes. A road bridge or pedestrian bridge was practiced regularly over the lock.

However, taking into account the security of operation, the Xiangjiang River Bridge was arranged 500 m downstream of the river between the hub. And so, the pipe line channel cannot be laid by the bridge. If a footbridge over the lock was constructed, the investment will be added. In view of the factors mentioned above, the pipe line channel crossing the ship lock was arranged within the upper ship lock head.

Because the upper lock head was an entity concrete dock, the vertical shaft from the hoist room to the chamber's bottom and a horizontal tunnel across the chamber bottom were designed. A U-shaped pipeline corridor was formed, as shown in Figure 8.

5.2 Under lock head

Similarly with the upper lock head, the built-in hoist room is also used in the under lock head. Based on experience in similar projects, this elevation of the bottom of the hoist room may be determined by the flood control level of the hydraulic control device. It often leads to the elevation of the lock head much higher than the elevation of lock wall. It should be disharmony in visual. If we take measures to heighten the elevation of the lock wall, the cost of the lock wall would greatly increase.

To solve the problem mentioned above, the built-in hoist room of Tugutang is separately furnished. The room of the miter gate's hydraulic hoist and the room of the hydraulic control are separated. A concrete wall is set up between these, with waterproof casing as the communicating pipe

Figure 8. The cross-sectional view of the upper lock head. Not only was the cost of the pedestrian bridge over the lock saved, but also an open vision of the lock area was protected by this design.

Figure 9. The profile view of an under lock head.

to connect these rooms. Meanwhile, the bottom elevation of the hydraulic control room is reduced to 61.00 m (the highest navigable water level is 62.50 m). The sunken design scheme was carried out. Four concrete walls were arranged around the hydraulic control rooms. A drain pipe was set in the hydraulic room. A control valve was set at the end for drainage of the hydraulic room at a low water level. When the water level was above 61.00 m, the valve was shut off to form an enclosed room, and the water was pumped, as shown in Figure 9.

The top elevation of the under lock head had been reduced from 67.50 m to 65.00 m. Taking into account the overall coordination of elevation in the lock region, the elevation of the lock wall had been increased from 64.3 m to 65.00 m, which is consistent with the elevation of the chamber wall of the under lock head, thereby avoiding the lock area that is visually impaired and formed by projections of the under lock head.

6 CONCLUSION

1. The following innovations of the construction diversion program and structural optimizations were carried out: the pile–pillar–slab separation walls, the lock walls as the cofferdam, and so on. All these decreased the investment, and produced a significant reduction in construction time.
2. The innovations taken into account the second ship lock were carried out: the main navigation wall with holes, the two-way boat piers and so on. Taking into account all conditions of building the second ship lock, these will save the cost of the second ship lock, reduce construction difficulty and adverse effects.
3. The following innovations of the lock head were carried out: the U-shaped pipeline corridor, the built-in hoist room, the waterproof hydraulic control room, and so on. The elevation of the under lock head was reduced and the landscape area of the lock was improved by these innovations.

The above innovations were not only unique, but also versatile. These can provide a reference for similar hub or ship lock designs.

Knowledge management in construction—the framework of high value density knowledge discovery with graph database

Yong Jiang

School of Architecture, Tsinghua University, Beijing, China

Ying-chu Wang & Zuo Wang

UNIS Software Co. Ltd., Beijing, China

ABSTRACT: With the high speed development of information technology, the use of big data technology has been deepened into more and more areas. The outstanding problems of applying big data in construction industry are large scale, multi dimensions, strong supervision and serious information island phenomenon. How to obtain the useful business information (high value density knowledge) efficiently during the acquisition, storage and batch processing of large volume data is an important subject. Here we report a method of combining the graph algorithm and the traditional data warehouse concept to obtain high value density knowledge. This method uses the subjective judgment of human beings and the objective data analysis of the machines together to get more accurate results.

1 CONSTRUCTION INFORMATION CLASSIFICATION STANDARDS AND KNOWLEDGE TAG SYSTEM

The construction industry is the pillar industry of the national economy and the first major industry. It covers all aspects of the building life cycle, closely related to a variety of urban construction projects. It also relates to the construction of the second industry and design, management, financial services and other related contents of the third industry. How to use big data, Internet of things, cloud computing, mobile Internet and other modern information technology to improve efficiency is an important subject relating to the development of the construction industry, and it is also a prerequisite link in the future construction of smart cities.

The data processing during the whole life cycle of a construction project is a typical nonstructural and big data use case, fully embodies the big data's 4V (Volume, Velocity, Variety and Value) character. The future development and intelligence of the construction industry is relying on the accumulation and continuing the refinement of the construction project data, digging out the relationship between the various data. So as to eliminate the information island phenomenon and break information asymmetry. According to the characteristics and contents of the construction industry, building a unified data platform (see Figure 1) based on the classification of construction industry information and knowledge management is the most basic and important step for interconnecting

information and making full use of high value data. And the establishment of information classification method and keyword tag system is the key technology for this data platform.

The definition of information classification method and keyword tag system: A graph theoretic database structure based on IFC standard faceted classification. It stores all the information in the quality supervision platform of the construction project; uses data reduction and retrieves the relationship between different data on the subsequent development and evolution.

2 USING GRAPH DATABASE AS THE CORE INFRASTRUCTURE OF THE HIGH VALUE DENSITY KNOWLEDGE DISCOVERY SYSTEM IN CONSTRUCTION INDUSTRY

The main way to find high value density knowledge in the field of construction industry is analyzing, inquiring and exploring the relationship between different information classification tags attached on construction project data. Graph theory model is a priori advantage technology for handling this kind of “many to many to many” relation inquiries and the traverse computation as well as the quantitative analysis.

Graph theory is a branch of Mathematics, which is mainly about the study of graphs. The graph in graph theory is a shape which composes of a number of given points and lines (one line

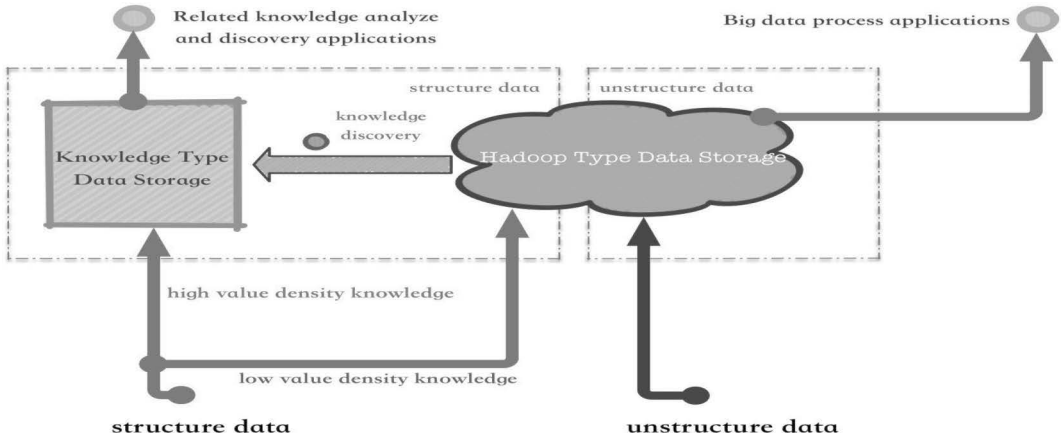

Figure 1. The data processing flow of the high value density knowledge discovery system.

joins two different points), it is usually used to describe certain relations of some things, with points representing things, by connecting the two points lines represent relationship between two things. In the most common sense of the term, a graph is an ordered pair $G = (V, E)$ comprising a set V of vertices or nodes or points together with a set E of edges or arcs or lines, which are 2-element subsets of V (i.e. an edge is associated with two vertices, and that association takes the form of the unordered pair comprising those two vertices). Usually, describing a graph is to draw points as a small circle, if the corresponding vertex has an edge, connect the two small circles with a line. How to draw these small circles and connections is not important, it is important to correctly reflect which vertices are connected by edges, which vertices are not connected by edges. Most areas in the real world can be modeled as graphs, such as social system, the recommended system and the association discovery system can be conveniently modeled as graphics. And the high value density knowledge discovery system discussed in this article is also a great scene for using graph theory model.

Graph databases are based on graph theory, they use graph theory to construct data access model, the whole data set in graph databases is modeled as a large and dense network structure, so that graph databases allow simple and rapid retrieval of complex hierarchical structures. Most graph databases based on NoSQL structures such as key-value or document-oriented store. These storage engines have the concept of tags(properties) for data elements, it naturally fits the technic requirement of information classification method and keyword tag system and allows data elements to be categorized for easy retrieval.

3 DESIGNING HIGH VALUE DENSITY KNOWLEDGE DISCOVERY SYSTEM BASED ON GRAPH DATA MODEL AND TRADITIONAL DATA WAREHOUSE STAR SCHEMA CONCEPT

The value density of knowledge data isn't an objective value. It depends on the subjective needs of different users. In order to obtain the required high value density knowledge data, users must input a number of constraints (classification keyword tag information) as the basic filter for the selection of knowledge data. The more flexible users can set the constraint conditions; the higher accurate knowledge data users can get from system. On the other hand, the knowledge data stored in the system are combination of some scalar value, which is an objective fact. Since the knowledge data in system are limited objective value, and shared by all users, so that the constraints (classification keyword tag information) used for filter information should also be a set of describable measures within a limited scope. In order to implement these characteristics in graphic data model logically and systematically, we can learn the concept of star schema from the traditional data warehouse (based on the principle of relational database storage technology). The following is a brief definition of several concepts related to the traditional data warehouse and star schema:

Fact: The fact is the data unit in the data warehouse, and is also a unit in the multi-dimensional space, which is restricted by the analysis unit. Each fact includes the basic information about the facts (such as income, value, satisfaction, etc.), and is related to the dimension.

Dimension: The dimension is the space axis of the coordinate system. The coordinate system in

the data warehouse defines the data unit, which contains the facts. In the data warehouse, the time is always one of the dimensions, other descriptive information with business implications are also main attributes used for defining dimension.

Star Schema: Star schema is a model that uses relational database to realize multidimensional analysis space (see Figure 2). It is a multidimensional data relationship, which is composed of a fact table (Fact Table) and a set of dimension table (Dimension Table). Each dimension table has a dimension as the primary key, all of these

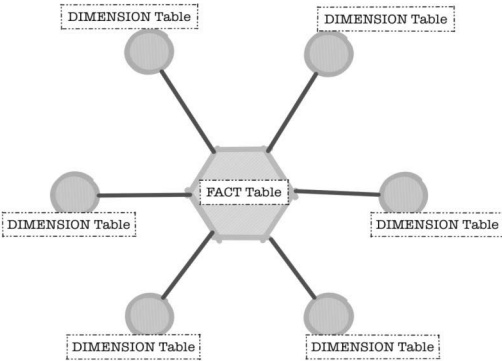

Figure 2. The internal database tables relationship of the star schema model.

dimensions' primary key composite the primary key of fact table. The non-primary key attribute of the fact table is called Fact, which are generally numeric or other data that can be calculated, and dimensions are mostly text, time or other data types. By organizing data in this way, fact can be clustered and computed according to the different dimensions (part or all of the primary key of the fact table). By using this method, users can analyze the situation of business topics from different points of view.

On the macro, the internal components of star schema of the traditional data warehouse are essentially characterized by a graph. It just uses relational model in the specific data query and access operation. Inspired by this, we can use the graph data model to design an "improved" version of the star schema based on the graph database (see Figure 3) to serve the needs of the high value density knowledge discovery system.

The following is the main technical features of this new star schema model:

1. On design logic level, the model uses Fact to represent the concept of knowledge data and Dimension to represent the concept of constraint conditions.
2. On system implementation level, the model uses the vertex in the graph theory model to create the fact. The fact vertex is used to identify the objective scalar value of the knowledge data.

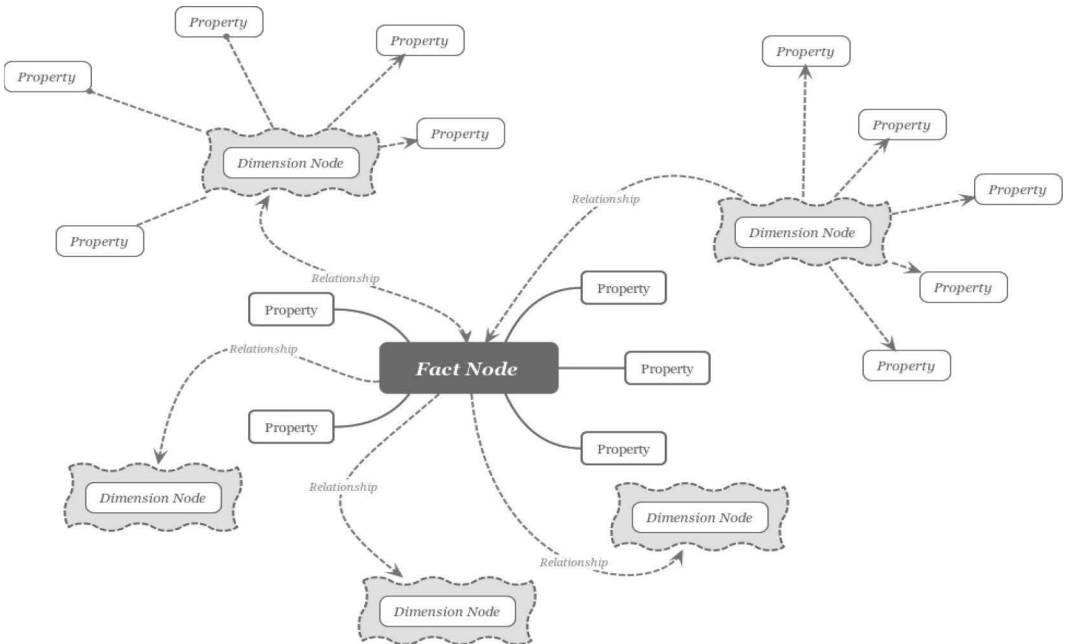

Figure 3. How to use graph data model to implement a "improved" star schema model.

These values are stored in the fact vertex as attributes.

3. On system implementation level, the model uses the vertex in the graph theory model to create the dimension. The dimension vertex is used to identify the constraint conditions users used to obtain high value density knowledge data. The dimension vertex only stores information associated with the constraint conditions. It does not store any data related to the knowledge data.
4. On system implementation level, the model uses the edge of graph theory to describe the relationship between Fact and Dimension. By setting the direction and different attributes of the edges, users can use the graph theory algorithm to screen the complex relationship between the fact vertices and the dimension vertices concisely.
5. Users can perform associated information discovery operations (multi node and multiple path correlation calculation algorithm in graph theory) on a particular dimension vertex to obtain the required high value density knowledge data (the fact vertices returned earlier by graph theoretic algorithms have higher value density).
6. Users can perform attributes query against fact vertices to select required knowledge data (similar to the traditional relational database data query).
7. When a specific fact vertex is obtained, according to their own subjective judgment, users can adjust and optimize the dimension vertices which are related to improve the accuracy of the value density of knowledge data under specific constraints.

4 CONCLUSIONS

The high value density knowledge discovery system which implemented on the framework we reported in this paper has the support of graph theory data model and algorithm. It can provide more powerful features and faster performance than the traditional relational model on discovering the association information under the multi dimension condition (the process of obtaining the high value density knowledge data). And by referencing the star schema concept in data warehouse field that has already been validated by IT industry, we can reduce the theoretical and practical risks of system design and implementation. At the same time, using the terminologies and operational methods that are familiar to the industry to obtain high density of knowledge data is conducive to the large-scale promotion and the use of the system.

Research of cold region green hospital design specification and practice

Yingzhi Gao & Hongyuan Mei

School of Architecture, Harbin Institute of Technology, Harbin, China

Jianfei Dong

School of Architecture, Hanyang Harbin Institute of Technology, Harbin, China

ABSTRACT: Presently, the green hospital design concept has attracted much attention, but the green hospital design work in cold regions involves more difficulties, so new technologies and methods for realizing “Green” hospital standards and effective design strategies for realizing the green hospital engineering in cold regions are also the research focus and difficulty in the medical design field. In this study, the design strategies for the green hospitals in cold regions that comply with the evaluation standards for green hospital buildings in cold regions are discussed, with the cold region hospitals that have been completed in recent years or are under research as the research objects, with the *Standard for Evaluation of Green Hospital Buildings* and *Heilongjiang’s Standard for Evaluation of Green Hospital Buildings* as the benchmark, through discussion about the cold adaptability and land-saving strategies involved in the green hospital planning and design, the energy conservation involved in green hospital construction measures and material selection, the sustainability of the green hospital water-saving measures and the humanization and environmental protection performance standard index in terms of indoor acoustic environment, light environment and thermal environment of green hospitals.

1 INTRODUCTION

In China’s building climate regionalization, the climate in cold regions is cool in summer and cold in winter. The energy consumption for heating in winter occupies the main part of annual energy consumption. Viewing the current building thermal insulation in China, compared with developed countries with similar climatic conditions, the unit building energy consumption in cold regions in China is 4–5 times that in developed countries, 2.5–3 times for roofing, 1.5–2.5 times for exterior windows, and 3–6 times in terms of air permeability of doors and windows. In terms of architectural design, blind pursuit of beauty is the main cause of increased building energy consumption. Besides, apparently, the division of building energy consumption types in cold regions is not thorough enough in many aspects in China. For example, in terms of space requirements for and habits of using medical buildings, the use of most office buildings peaks during the day, but the density of using such buildings involves uncertainty at night. Such use features can directly influence the energy consumption of buildings. Therefore, the issue concerning the ecological design of public buildings calls for detailed research and discussion.

The current architectural development trend is for green buildings, and architects in various countries are exploring ways to apply green technology to buildings. However, the question of how to create green buildings is an issue which is hard to solve in cold regions. Nowadays, most medical buildings involve large energy consumption, serious environmental pollution and lack of care for patients. With the cold regions in North China as the research object in this paper, based on the special climatic conditions in such regions and numerous green building theories at home and abroad, coupled with basic research on the medical environment within hospitals in cold regions, to further the practice of gradually meeting green hospital standards and characteristics of medical buildings, design strategies are presented which are suitable for green medical buildings in cold regions.

2 BASIC PRINCIPLES OF GREEN HOSPITAL BUILDINGS

Green hospital buildings refer to hospital buildings that provide people with healthy, useful and efficient spaces and which co-exist with nature harmoniously, featuring maximum resource

conservation, environmental protection and pollution reduction in the whole life cycle of each building. Green hospital buildings belong to a “Green Building” system and involve special requirements for hospital buildings. A green building is the result of the incorporation and introduction of “Ecological and Sustainable Development and Intelligent and Efficient Energy Conservation” into the hospital building field and is a new development trend for future hospital buildings.

According to GB/T50378-2014 Standard for Evaluation of Green Buildings, whose trial implementation commenced in July 2011, GB/T51153-2015 (Standard for Evaluation of Green Hospital Buildings), which was formally implemented as a global standard in August 2016, and relevant evaluation standards for green hospitals, the space treatment of green hospital buildings should be based on several important principles, including matching the site, land conservation, tree conservation, energy conservation, indoor and outdoor design efficiency, economy and environmental comfort. The matching site and land conservation issues can be solved through environmental optimization design involving underground space utilization, site ventilation, noise, sunlight and daylight, as well as site ecological environment creation (native plants, stratified greening, roof greening, permeable ground, etc.).

2.1 Site planning

The problem considered in this study was a hypothetical 10-m-diameter tunnelling situation. The Standard for Evaluation of Green Hospital Buildings provides that site environmental noise shall meet the National Standard GB3096 (Environmental Quality Standard for Noise) in terms of planning. Such buildings intended as ward buildings and dormitories shall not be adjacent to urban trunk roads, and additional sound insulation measures shall be taken. In order to realize human design factors, 5% of the land planned for construction shall be provided for patients, visitors and hospital staff as relaxation space directly linked to the natural environment. A wind speed of less than 5 m/s shall be guaranteed in the pedestrian areas around the above buildings, and in cold and severely cold and windy regions, consideration shall be given to providing windproof waiting facilities at the main hospital entrances and exits intended for patients. In the case of flat roofing, the area of greening or high-reflectivity material when used for roofing shall be at least 50% of the calculable roofing area. Room entry design for ambulances shall be provided at the entrances and exits of emergency departments of hospitals in cold and severely cold regions.

2.2 Architecture design

In terms of architecture, the thermal performance of building envelopes should meet building energy conservation design standards, while heating, ventilation and air conditioning system design should comply with the National Standard GB50189 chapter 5 *Standard for Energy Efficiency Design of Public Buildings*; and it is acceptable for such special areas as operating rooms and ICUs not to comply with Article 5.3.26. Hospital buildings should not have Line-Of-Sight (LOS) interference, especially between ward buildings and surrounding buildings, with spacing greater than or equal to 20 m. Full use of underground spaces of buildings should be made, and such spaces should occupy at least 20% of the floor area.

2.3 Indoor environment designing

In terms of indoor environment, the main functional rooms in a building should have good vision, and the day-lighting coefficient should meet the requirements in the existing National Standard GB50033 (Standard for Day-lighting Design of Buildings), i.e. at least 60%. The required illumination, unified glare value and general color rendering index of indoor lighting are three major factors that influence lighting quality and they need to meet the relevant provisions of GB50034 (Standard for Lighting Design of Buildings) and JGJ49 (Code for Design of General Hospital Buildings).

Adjustable sunshade and thermal insulation measures should be taken. For the transparent parts of exterior windows and curtain walls, the area of controlled sunshade and thermal insulation adjustment measures should be up to a proportion of 25%.

As for the rooms with no special requirements for air pollution control, it is preferable to adopt natural ventilation measures and suitable air filtration systems, while it is desirable to select purification and filtration equipment with rational filter resistance, dust filtering efficiency and germ filtering efficiency.

The indoor noise level in the main functional rooms should not exceed the standard average value in the existing National Standard GB50118 (Code for Sound Insulation Design of Civil Buildings).

3 DESIGN STRATEGIES FOR GREEN HOSPITALS IN COLD REGIONS

The design work for green hospitals in cold regions involves many difficulties, and I will summarize and analyze the green design strategies for many completed cold region hospitals involved in my participation or research.

3.1 *Attention to cold adaptation and land conservation-based green hospital planning and design*

The national land saving policies are adhered to and implemented in the design, and the functional relationships between buildings and the general layout of each building are rationally organized, culminating in layout relations between buildings which are mutually independent but closely linked. Based on land use, supporting engineering like landscape roads are rationally designed, and apart from the main buildings, land used for development is reserved, and at the same time, a large area of green space landscape is reserved as relaxation space, thereby realizing the dual purposes of land conservation and full utilization.

The square, buildings and green spaces in the entire courtyard, are subject to unified planning ideas, and under the premise of providing sufficient car parking spaces in the hospital, it is preferred to reserve as many sunny precincts as possible, with surrounding buildings and spatial gradients used as wind barriers and for wind induction, with more green vegetation for climate regulation. A south facing layout is adopted for buildings to ensure better sunshine. Underground parking arrangements, ambulance indoor entry design, etc. can help to shield hospital patients from the cold in winter. Attention is paid to the addition of indoor-outdoor transition areas, such as foyer arrangements at main entrances and exits, and hallways or antechamber transitions at secondary entrances and exits. Such areas as staircases, balconies, basements and roof terraces should match the thermal buffer area design

In terms of landscape, a green and ecological medical care environment is obtained by means of landscape gardens, much afforestation, and idyllic scenes with water body and micro-topography designs.

3.2 *Attention to the construction measures and material selection of green energy-saving hospitals*

Economical and practical thermal insulation materials are selected to ensure the thermal insulation of exterior walls of buildings. For example, thermal insulating rock wool boards with good thermal insulation and energy-saving and fire prevention performance can be selected. An extruded benzene board-based thermal insulation layer is adopted for roofing, while heat-insulating profile UPVC plastic steel windows are used as exterior windows, and single-frame three-layer double-hollow glass is adopted, having good air tightness and thermal insulation performance.

All stairwells are heated; for heating and non-heating rooms, relevant energy-saving structure

standard atlas are selected for such detailed structures as floor slabs, walls, parapets, plinths, canopies and deformation joints, and for thermal insulation between exterior doors & windows and walls, which can meet any restriction requirements. Energy-saving equipment is selected for supporting facilities involving power supply, heat supply and water supply, and green environmentally-friendly materials are used as pipe materials of ventilation systems, thermal insulating materials, bonders, etc.

3.3 *Attention to sustainable development-based energy-saving measures for green hospitals*

Recycled water is provided for greening, landscape water bodies, washing and underground water sources through establishment of a rainwater collection system, comprehensive utilization of rainwater resources, and water conservation. In addition, in the water supply mode adopted in the Panjin City Central Hospital Project, water is directly supplied to some water points from municipal facilities and frequency-convertible feed water booster pumps are used as booster pumps in the other parts; energy-saving sanitary ware and water distribution components are selected in this practice, and at the same time, each building monomer and water consumption departments in each building monomer uses water meters for charge collection, thereby limiting the waste of water. Also, water pond and water tank overflow level alarms are provided, which is a good water-saving strategy.

3.4 *Attention to humanistic care-based indoor environmental design of green hospitals*

In the hospital street and medical care port mode, consulting space design is integrated and optimized to improve the extent of streamline identification, and consulting and medical treatment efficiency. For example, Panjin City Central Hospital uses a hospital street-based consulting mode for its clinic and medical technical building, with the consulting rooms of each department distributed on both sides of the hospital street to reduce cross interference and facilitate identification. At the same time, the top day-lighting skylight design of the large-scale atrium, the hospital street and the consulting space design combined with natural landscape are also important design methods for improving the comfort of the consulting environment.

In terms of air conditioning, based on the room function zoning and the principle of separation of clean and dirty material, air conditioners, exhaust fans and induction units-based combination of a mechanical exhaust system and natural ventilation is adopted. This ensures meeting the required

degree of air purification in each functional space of the hospital, with the minimum per capita fresh air volume being 20 cubic meters/hour.

The table below shows the room ventilation plan we made while designing the “Jinzhou Central Hospital” Program.

In terms of the indoor acoustic environment, light environment and thermal environment, corresponding environmental protection measures are also taken to realize effective control, with basic indoor indicators basically meeting or exceeding the requirements of the *Standard for Evaluation of Green Hospital Buildings*. As for the acoustic environment, besides the use of sound-insulating materials for building envelopes, super low-noise water drainage plastic pipes are used for indoor water drainage systems, HDPE double-wall corrugated pipes are used for outdoor water drainage systems, and soundproofing plus anti-vibration measures are provided for fans. In the main tool room, the interior noise level meets the existing National Building Standard *GB50118* (Code for Sound Insulation Design of Civil Buildings), with all standard values met.

In terms of light environment adjustment, high-efficiency high-color rendering three-band straight tubular fluorescent lamps are used, with noise-free electronic ballasts used together with them, and anti-reflection lamps used in the special medical treatment rooms, creating a good light environment, with lower electricity consumption and reduced line loss.

Electric hot air screens are provided at the entrance for indoor heating of hospitals, and a ground radiation system (electric heating floor film) plus radiator-based heating mode is used in public spaces for winter heating featuring low energy consumption. In summer, an air conditioning

system is combined with refrigeration. The table below shows the indoor environment indicators of the Cancer Hospital Affiliated to Harbin Medical University, which exceeds the specific data requirements in the Standard for Evaluation of Green Hospital Buildings, indicating a comfortable hospital medical treatment environment.

4 CONCLUSIONS

In this paper, based on the writer’s practical experience, through in-depth thinking and research in three aspects, i.e. adaptation to cold in special climate environments; use of green structure technology and new materials to realize the energy conservation and material conservation of buildings; attention to medical patients’ psychological and physiological feelings and multi-aspect regulation of acoustic and photothermal effects to realize high-comfort indoor physical environment design, energy conservation, high efficiency and perfect function. A preliminary method for design of green medical buildings that fully adapts to the climatic conditions in cold regions has been constructed.

Research on improving the design of medical buildings in cold regions, a complex public building type, will be an important undertaking to improve the medical treatment environment in cold regions, and to achieve environmental protection and low energy consumption of medical buildings in cold regions.

ABSTRACT: In order to solve the problem of traditional residual current devices, a scheme of intelligent residual current devices was developed. In this paper, the basic principle of intelligent residual current devices is introduced, and then the hardware part of the PIC16F886 MCU system and the software architecture are described. The data showed that the intelligent residual current devices could monitor the real-time residual current and cut down the power supply quickly when there was a residual current caused by the fault, so that the devices could solve the residual current problem in the low-voltage distribution network.

1 INTRODUCTION

In low-voltage distribution networks, especially in the rural low voltage power grids, due to improper use of electrical appliances, electrical accidents, such as electric shock or short circuit, occur frequently. In order to protect people's lives and to ensure safety in low-voltage power supply networks, the installations of residual current devices are performed in the distribution network. But there are still some problems in traditional residual current devices which are installed in the system, such as the circuit breaks frequently, because of which the application of residual current devices in the distribution network is limited (Deng Xiaolin (2007), Gu Huimin (2006)). In order to solve the residual current problem in the low-voltage distribution network, it is important to develop an intelligent residual current device which can adapt to changes in low-voltage distribution networks.

2 PRINCIPLES OF RESIDUAL CURRENT DEVICES

In residual current circuit devices, the residual current is detected as well as the value of residual current is compared with a reference value. When the

residual current value exceeds the reference value, the main circuit will be cut down. Some residual current devices experience an overload or short circuit protection and over-voltage protection (Gu Qiaoli (2006), Wu Shaoqin (2010)).

Figure 1 shows the schematic of residual current devices. It is a three-phase, four-wire, and low-voltage distribution network; according to circuit theory, when the system is operating normally, the three-phase circuit is symmetrical. In this case, the output of the zero sequence current transformer TA is zero, that is,

$$I_a + I_b + I_c + I_o = 0 \tag{1}$$

Figure 1. Principles of residual current devices.

By the principle of electromagnetic induction, each phase current in the line and the neutral line current generated in the zero-sequence current transformer's magnetic flux phase is equal to zero, that is,

$$\varphi_a + \varphi_b + \varphi_c + \varphi_o = 0 \tag{2}$$

In this case, the output of the zero-sequence current transformer TA is zero, and current protection does not act. The normal power supply will not be cut down.

When short circuit or other electric shock occurs, the three-phase current will be no longer symmetrical. Residual current occurs, and the amount will no longer be equal to zero, that is,

$$I_a + I_b + I_c + I_o = I_r \tag{3}$$

The amount of each phase lines' current and neutral current and residual current is I_r . In this case, the zero-sequence current transformer magnetic field will have the potential existence. The magnetic flux of the magnetic field generated by the potential of each phase is actually the current in the line and the neutral line current in the zero-sequence current transformer's iron ring phase generator's flux core and that,

$$\varphi_a + \varphi_b + \varphi_c + \varphi_o = \varphi_r \tag{4}$$

Therefore, the output of the zero-sequence current transformer's secondary winding will not be zero. The voltage signal is proportional to the size of the residual current; when there is a more serious system failure, the larger the residual current is, the higher the zero-sequence current transformer's output voltages will be. The voltage is compared to a threshold voltage of the zero sequence current transformer's output; when the fault current reaches the setting value, the zero sequence current transformer output voltage exceeds the threshold voltage, the comparison circuit outputs a logic drive level start relay, and the relay circuit breaker will cut off the power supply quickly to achieve the residual current protection (Zhang lixu (2009)).

3 HARDWARE DESIGN OF INTELLIGENT RESIDUAL CURRENT DEVICES

3.1 Hardware design of the overall program

The hardware system of intelligent residual current devices includes the following: a micro-controller for signal conditioning parts, keyboard circuit, display circuit signal processing module, programming interface, operating circuit, and the power

supply section. The structure of this hardware is shown in Figure 2.

Zero sequence current transformer, Current Transformer (CT), voltage transformers (PT) respectively collect the residual current, load current and bus voltage signals, and then output the voltage with a linear relationship to the amplitude of the current signal.

The signal processing module with the filtering and amplification processing to the signal obtains a suitable subsequent stage in the signal processing circuit.

In order to achieve an intelligent residual current protection, the micro-controller with internal hardware and software resources is used to achieve a residual current automatic switching gear, which is to meet the requirements of the operating environment adaptation. Meanwhile, the single-chip analog signal-conditioning circuit's signal sent was sampled and digitally processed, thereby displaying real-time voltage and current, in order to achieve good interactive features.

An action execution unit receives the I/O port of the MCU, to achieve the operation of the relay driver circuit breaker and cut down the fault circuit.

A digital display and status indicator with LED digital display and light-emitting diodes are controlled by using the micro-controller.

The program is downloaded via ICD2 with a 5-pin port, which connects the MCU to the PC's USB port, and then it will be programmed into the micro-controller FLASH memory by using the MPLAB integrated development environment.

3.2 Design of the MCU module

As shown in Figure 3, PIC16F886 micro-controller's clock source modes can be classified as follows: the external or internal. The external clock modes rely on external circuitry for the clock source, an oscillator module (EC mode), quartz crystal resonators or ceramic resonators (LP, XT, and HS modes) and Resistor-Capacitor (RC) mode circuits. The

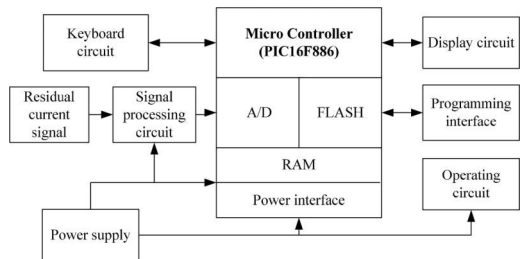

Figure 2. Hardware structure of the residual current devices.

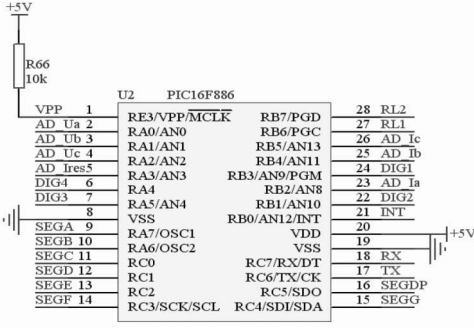

Figure 3. Schematic of the micro-controller system.

internal clock source module has two internal oscillators: 8 MHz High-Frequency Internal Oscillator (HFINTO-SC) and 31 kHz Low-Frequency Internal Oscillator (LFINTOSC); external or internal clock sources can be selected via the bit-select of the System Clock Select OSCCON register (SCS) (Microchip Technology (2005, 2002, 20-07)).

Since the external oscillator module requires a more complex I/O port and the peripheral circuit, the micro-controller internal oscillator is used as a clock source in this design; the clock frequency is selected to 8 MHz, and the corresponding bit is simply set in the OSCCON register.

3.3 ADC conversion

PIC16F886's ADC module can achieve an accuracy of 10-bit in digital-analog conversion. An analog input channel device uses a common sampling and holding circuit. The sampling and holding circuit is connected to the output of the converter input. A full approximation ADC generates a 10-bit binary result and saves the result in the ADC result registers (ADRESL and ADRESH). Software reference voltage conversion is connected to VDD or an external voltage reference pin is provided. The power supply voltage VDD is used as the ADC reference voltage in this design.

Conversion relation from the principle and the ADC reference voltage magnitude (+5V) can be drawn from the AD converter input voltage and by converting binary values i.e.,

$$NADC = 1023 \times (V_{in} - VR_{-}) / (VR_{+} - VR_{-}) \quad (5)$$

where V_{in} is the input voltage, VR_{+} is the reference voltage (+5V), and VR_{-} is a ground voltage, i.e. $VR_{-} = 0$. The conversion relationship is given as follows:

$$NADC = 204.6 \times V_{in} \quad (6)$$

3.4 Design of the residual current signal processing and amplifying circuit

Figure 4 shows the schematic of the signal rectifying and amplifying circuit. The amplifier circuit is divided into two parts, by using two integrated operational amplifiers, which are used in the design of an integrated four operational amplifier TL084. The operational amplifier with low signal distortion has a lot of advantages, such as the low input offset voltage, low offset current, low zero drift, and less noise (National Semi-conductor (2001)).

Since the voltage signal after the amplification stage after the AC signal is bipolar, while the micro-controller AD can be treated as a DC voltage signal 0~+5V; therefore, the AC signal should be rectified into a DC signal. In order to improve the measurement accuracy of small signals, the integrated operational amplifier amplification and depth of the negative characteristics of the feedback generated are used to overcome errors due to non-linear diode voltage and dead brought. The circuit diagram is shown in Figure 4.

In this circuit, the first part is composed of a high-precision half-wave rectifier, by using diodes D3 and D4 to achieve the half-wave rectifier, in which R3 and R4 should be equal, $R3 = R4$, otherwise the positive and negative half-wave will be asymmetrical, and thus the rectified waveform will be bad.

When $V_i > 0$ and $V_d < 0$, D4 works and D3 is turned off, so that,

$$V_{o1} = -V_i \quad (7)$$

When $V_i < 0$ and $V_d > 0$, D4 is turned off and D3 works, so that,

$$V_{o1} = 0 \quad (8)$$

The second part is the adder circuit made by using an operational amplifier, seen from the circuit parameters:

Figure 4. Schematic of the precision-rectifying and amplifying circuit for signal processing.

$$V_o = -(V_i + 2V_{oi}) \quad (9)$$

When $V_i > 0$,

$$V_{oi} = -(V_i - 2V_i) = V_i \quad (10)$$

When $V_i < 0$,

$$V_{oi} = -(V_i + 0) = -V_i \quad (11)$$

So that,

$$V_o = |V_i| \quad (12)$$

This circuit can achieve the full-wave rectification and transform AC residual current signals into DC signals.

4 SOFTWARE DESIGN OF INTELLIGENT RESIDUAL CURRENT DEVICES

The functional requirements of intelligent residual current protection are as follows: the devices can display the real-time value of residual current and other electrical parameters, when electric shock or short circuit occurs, and it can cut down the power supply quickly. The devices can be set automatically and the residual current and the load current can be operated manually through the key position, depending on the size of the over-current delay characteristics. The design based on the PIC16F886 micro-controller is used to control the internet module. The MCU control software is written by using C language and then it is developed by utilizing the microchip's MPLAB integrated development environment. Finally, the program is downloaded to the micro-controller FLASH through the compiler and the ICD2 machine code is also used to achieve intelligent protection.

According to the functional requirements of the system with a modular design idea, the software part is divided into the following modules: system initialization module, data acquisition module, data processing module, digital display and status display module, and movement gear switching module operation logic module. When the system works, it should make an initialization, and then it goes into the main loop, in which some tasks are operated, such as data acquisition and processing, current and voltage display, and the switch gear operation, in order to meet real-time requirements to ensure the normal operation and data processing of each module, by using a timer to interrupt and to control the execution of each module. Design and implementation of each module should be carried out with a lot of debugging.

5 TEST OF THE RESIDUAL CURRENT DEVICES

5.1 Residual current measurement experiment

The system hardware and software were debugged successfully, and then the IDB-1B residual current protection tester produced by Shanghai Siyuan equipment production company was used to generate a corresponding AC current source as a standard for residual current devices. The residual current RMS experiment was made to obtain a lot of experimental data in Table 1. According to the table, the test data show that the residual current devices could achieve an accuracy of at least 2.0% in measuring the residual current.

5.2 Protection action characteristic test

The residual current devices operation has inverse time operation characteristics, i.e. with an increase in the measured fault current, the delay acts more quickly, which can quickly cut off a serious fault. According to this requirement, it is necessary to protect the operating characteristics of the test, such as measurement data given in Table 2.

From Table 2, it can be observed that the residual current protection is achieved with inverse time characteristics in the action; the greater the fault

Table 1. Residual current measurement data.

Input residual current (mA)	Show value of the residual current devices (mA)	Absolute errors (mA)	Relative errors (%)
10	9.8	-0.2	-2.0
50	49.3	-0.7	-1.4

400	404.8	4.8	+1.2
500	504.4	4.4	+0.9
600	605.7	5.7	+0.9

Table 2. Protection action characteristic test data (Tset = 0.3S).

Times of overload residual current	The maximum value of cut-off time (ms)	Test value of the residual current devices (ms)
1	300	240
2	200	159
5	40	32

current was, the lesser the break time would be. The test results were given within the required time limit, so that the devices could solve the residual current problem in the low-voltage distribution network.

6 CONCLUSIONS

In this paper, the principle of the residual current devices is introduced; it described the development scheme of intelligent residual current devices based on the PIC16F886 micro-controller. And then, the circuit design of the hardware and software, which make parts of the program were also discussed. The hardware and software were debugged, the performance indicators of the system were also tested, and the experimental results showed that the device exhibited a good performance and high reliability to ensure electricity supply in the low-voltage distribution network.

Design of Control Moment Gyro equivalent sound source based on transfer function matrix inversion

Wei Cheng & Wei-Qing Sun

Beijing University of Aeronautics and Astronautics, Beijing, China

Guang-Yuan Wang

Beijing Institute of Spacecraft System Engineering, Beijing, China

Jiang-Pan Chen, Xiong-Fei Li & Jiao Jia

Beijing University of Aeronautics and Astronautics, Beijing, China

ABSTRACT: The micro-vibration induced by a CMG (Control Moment Gyro) is very important for spacecraft. Vibration validating testing before launch is always necessary. However the boundary conditions of the validation measurement on the ground are different from space. One of the main differences is the presence of an atmosphere versus vacuum in space. Therefore, one should consider the structural vibrations due to the CMG acoustic excitation on the ground, which doesn't exist in space because there is no acoustic medium in vacuum. To research the micro-vibration due to CMG acoustic excitation, an equivalent acoustic source was designed in this paper, which can reproduce the CMG acoustic performance and therefore can be used to evaluate the contribution of the CMG acoustic excitation to the total vibration in the future. FRF matrix inversion based on PCA was used to derive the drive voltage of the speakers on the equivalent sound source. A comparison of the acoustic energy level and directional characteristics was done between the CMG and the equivalent sound source. Moreover, a new assurance criterion based on the microphone auto power linear spectrum was used to simplify the accuracy validation. It was shown that the equivalent sound source can accurately represent the CMG acoustic excitation from 80 Hz to 800 Hz.

1 INTRODUCTION

Because of the large torque amplification capability and good momentum storage performance of a CMG (Control Moment Gyro) attitude control system, it has been widely used on satellites for moving target tracking or imaging capturing, which need rapid attitude manoeuvrability and high attitude precision and stability. (Bhat, 2009).

However, the micro-vibration caused by the CMG's broadband excitation can decrease pointing accuracy and the tracking control's stability for optical inter-orbit communication and astronomical telescope devices. (Kamesh, 2010; Luo, 2013) These disturbances are attracting more and more attention, because they are significant in the mid-high frequency range and excite flexible modes of the spacecraft, which cannot be controlled or reduced by the attitude and orbit control systems. (Steven, 1995) Therefore, spacecraft that use Control Moment Gyroscopes (CMG) for attitude control tend to have high sensitivity to pointing and jitter, creating a need for isolation. In recent years, some researchers have studied the methods to

evaluate CMG disturbance forces/torques by detecting the disturbance displacements or accelerations. Many other researchers have tried to build analytical CMG dynamic models, and then based on the model, many different kinds of passive or active isolators were designed to minimize the load of the CMG acting on structures. (Belvi, 1995; Keith, 1995; Zhang, 2014; Tomio, 2006).

Anyhow, satellite micro-vibration must be measured and evaluated thoroughly to implement appropriate designs for the pointing and tracking systems. The micro-vibrations on LANDSAT-4 (Sudey, 1985), OLYMPUS (Manfred, 1990), and ETS-VI (Morio, 2001) satellite in orbit were reported from 1984 to 2001. Moreover, micro-vibration comparisons between in orbit and on ground measurements were conducted on ARTEMIS (Munoz, 1997; Galeazzi, 1996) in 1997, on the SPOT-4 (Privat, 1999) satellite in 1999, and on OICETS (Morio, 2010) in 2010. During the data comparison between in orbit and on ground, it was found that the satellite micro-vibration performance in space is different from on the ground. Morio Toyoshima (Morio, 2010) found that the in-orbit micro-vibration is

greater, and thought it was caused by energy dissipation into air as heat or sound, which will not happen in space. It was also considered that the contribution of acoustical noise in the ground test might not be negligible. Acoustical noise does not exist in orbit but these effects might be included in the ground based measurement results.

In a ground based experiment, the vibration of a structure excited by a disturbance source can be separated into two parts. One part is structure borne vibration due to its structural force excitation. The other part is acoustic borne vibration due to its acoustic excitation. (Gajdatsy, 2010)

To evaluate the real vibration performance in space, the acoustic-borne vibration which will not exist in space needs to be subtracted from the ground testing result because there is no atmospheric medium and therefore no acoustic excitation in space. However, during operation of the CMG, the two kinds of excitation will act simultaneously. It's not possible to separate them directly. Therefore, if we could design an equivalent sound source, the acoustic energy of which is the same as the CMG, but which does not generate vibration, it could be put into the cabin structure to measure the vibration purely caused by acoustic excitation, then the difference of the micro-vibration performance in space and on the ground due to acoustic influence can be analysed.

In this paper, in order to design an equivalent sound source to simulate the CMG acoustic excitation, based on the acoustic signals from the microphones surrounding the CMG, a matrix inversion with PCA will be used to derive the drive voltages for the speakers on the equivalent sound source. The reproduction accuracy will be discussed for both energy level and directional characteristics aspects.

2 METHOD AND PRINCIPLE

2.1 Identify the acoustic characteristics of the original source

First of all, the acoustic characteristics of the original source need to be identified. Put the original acoustic source under a microphone array and get each microphone's sound pressure signal and then do Fast Fourier Transform (FFT) transform to get each microphone's spectrum, p_i ($i = 1, 2, \dots, m$, the number of microphones), from which its sound power and its directional characteristics can be obtained.

2.2 Frequency Response Function (FRF) testing from the speakers on equivalent source to microphones

According to the original source's directional characteristics, appropriate numbers of speakers will be

used to build up an equivalent sound source. Put the equivalent sound source under the same microphone array, the FRF from each speaker's drive voltage to each microphone, h_{ij} ($i = 1, 2, \dots, m$, the number of microphones; $j = 1, 2, \dots, n$, the number of speakers), will be measured.

2.3 Derive the drive voltage for the equivalent sound source

To simulate the acoustic excitation from the original source, the appropriate drive voltage of the speakers on equivalent sound source need to be determined. The derivation of the voltage for the equivalent sound source can be considered a dynamic load identification, which is a kind of inverse problem. There are many kinds of methods for dynamic load identification, but roughly they can be divided into two types, frequency domain methods and time domain methods. (Gursoy, 2009; Yan, 2009) Because time domain methods are theoretically complex and are very sensitive to boundary conditions, currently for engineering applications, frequency domain methods are still widely used for stationary load identification.

However, due to the frequency response matrix being ill-conditioned, the numerical precision and stability of the frequency domain approach are often not as good as expected. (Mao, 2010) In this paper, PCA technology was used to handle the matrix conditioning problem.

Given, p_j ($j = 1, 2, \dots, n$, the drive voltages for the equivalent sound source.

Therefore, the equation below can be obtained:

$$p_i = \sum_j h_{i,j} \cdot d_j \quad (1)$$

$$P = H \cdot D \quad (2)$$

where p_i , $h_{i,j}$ and d_j represent Fourier spectra for their respective frequencies. Calculations are conducted in the same way for all target frequencies.

If the number of microphones, m , is equal to the number of drive voltages, n , the transfer function matrix H becomes a square matrix. Then, both sides of Eq. (2) can be multiplied by the inverse matrix of H to enable the drive voltage D to be calculated, as shown in Eq. (3).

$$D = H^{-1} \cdot P \quad (3)$$

However, the accuracy of the calculation of the drive voltage D declines markedly in this method when noise is present in the measured transfer function matrix H , or when there is a high correlation among the transfer functions. Therefore principal component analysis was used here to provide a solution for these issues.

By means of principal component analysis, singular value decomposition is first applied to the transfer function matrix H measured between each microphone and drive voltage. The matrix will be decomposed into singular values, which will reveal the correlations between the principal components. The singular values in the matrix, S express the magnitude of the principal components in its diagonal elements.

$$H = U \cdot S \cdot V^{-1} \quad (4)$$

Before matrix pseudo-inversion, the principal components that are much smaller in comparison to the others are considered noise and should be discarded. If not, the small singular values will become big after matrix inversion, which will make phenomena with low importance become important and therefore the result will be unreliable.

After the small principal components have been discarded, the new regressed singular value matrix S_r , and unitary matrices U_r and V_r are formulated, and Eq. (5) is used to calculate the pseudo-inverse matrix of the transfer function matrix H , from which the noise components are removed.

$$H^{-1} = V_r^{-1} \cdot S_r^{-1} \cdot U_r \quad (5)$$

It is desirable to set the number of microphones, m , higher than the number of drive voltages, n , ($m \geq 3n$) to exclude the noise components included in the transfer functions and the microphone signals by means of principle component analysis.

$$D = V_r^{-1} \cdot S_r^{-1} \cdot U_r \cdot P \quad (6)$$

2.4 Validation of the equivalent sound source

We can put the equivalent sound source under the microphone array and drive the speakers by the voltages obtained from 2.3, measure the microphone signals to compare it to the original acoustic source to validate whether the equivalent sound source can replicate the acoustic emission of the original source.

3 EXPERIMENTAL TEST

Because of CMG's size not small enough compared to the cabin structure, and its directional acoustic properties, CMG cannot be considered a point acoustic source. By reason that CMG is always mounted on a plate, it can be approximated by 5 separated sources. Therefore, an equivalent sound source with five speakers was designed to simulate CMG acoustic radiation (see Fig. 1).

Figure 1. Sketch of the CMG (left) and equivalent sound source (right).

The size and mass distribution of the equivalent sound source is similar to the CMG. To validate whether the equivalent sound source can really represent the CMG's acoustic performance, a measurement based on ISO 3744 was done. If the signals of the 20 response microphones around the CMG and equivalent sound source are the same, we can conclude their sound power and directional characteristic are the same.

3.1 CMG noise measurement

The CMG was put under a microphone array (see Fig. 3). The signals of 20 microphones were measured to be used to calculate the five drive voltages of the equivalent sound source. Moreover, its sound power level and directional characteristics were also obtained to be compared with the equivalent sound source.

3.2 FRF measurement

For each of the five speakers, a broadband random signal with 800 Hz bandwidth was output separately to an independent amplifier, and then the FRFs between the output voltages from the signal generator and the 20 microphones surrounding the equivalent sound source were measured (see Fig. 2 and Fig. 3) while H_v estimator was used.

3.2.1 Signal/noise ratio check

To verify the speakers' frequency range, the coherence between speakers and microphones needs to be checked. For each speaker, the coherence curves of 20 microphones were averaged. The averaged coherence results of five speakers are shown in Fig. 4. It can be found that the signal/noise ratio is good from 80 Hz to 800 Hz. However, because of the speaker's limited size, the sound below 80 Hz can-

Figure 2. Principle of FRF measurement from drive voltage to microphones.

Figure 3. Noise identification and transfer function measurement in Anechoic room.

Figure 4. Averaged coherence results for the five speakers.

not be radiated. Therefore, the equivalent sound source can be used to simulate the CMG noise from 80 Hz to 800 Hz.

3.2.2 System linearity check

Because the sound pressure level of the microphones during FRF measurements could be different from the CMG, the linearity of the system needs to be checked. White noise signals with three different RMS levels (0.01 V, 0.05 V, 0.2 V) were output. As an example, the amplitude and also the phase of the FRF between the first microphone and drive voltage of one side speaker from 80 Hz to 800 Hz are compared in Fig. 5. We can see the

Figure 5. FRF amplitude and phase comparison for different of level acoustic excitation: (a) FRF Amplitude Spectrum; (b) FRF Phase Spectrum.

amplitude and phase are coincident, so the system is linear in the range 80–800 Hz.

3.2.3 FRF measurement

After system linearity and signal/coherence checks, FRFs between each of the 20 microphones and the 5 speakers were measured. Totally, there are 100 FRFs measured between each of the 5 source drive voltages and each of the 20 microphones as Eq. (7).

$$H_{20 \times 5} = \begin{bmatrix} h_{1,1} & h_{1,2} & h_{1,3} & h_{1,4} & h_{1,5} \\ h_{2,1} & h_{2,2} & h_{2,3} & h_{2,4} & h_{2,5} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ h_{20,1} & h_{20,2} & h_{20,3} & h_{20,4} & h_{20,5} \end{bmatrix} \quad (7)$$

3.3 Equivalent sound source noise measurement

As per 2.3, the five speakers drive voltage spectrums were derived through FRF matrix inversion,

Figure 6. Five speakers' drive voltage: (a) Frequency Spectrum; (b) time Signal.

as below. Subsequently, the output time signals were obtained by inverse FFT. (See Fig. 6) Finally, the equivalent sound source was put under the microphone array again while the derived voltage signal was applied on the five speakers. The equivalent sound source can be validated by comparing the microphone signals with the signals measured when the CMG was present.

4 VALIDATION

Based on the 20 microphone signals, a validation based on energy level and also directional characteristics is done below.

4.1 Sound power comparison

According to ISO 3744, the sound power of an acoustic source can be derived as Eq. (8),

$$L_w = \overline{L_p} + 10 \log \left(\frac{S}{S_0} \right) \quad (8)$$

where $\overline{L_p}$ is the sound pressure level averaged over the measurement surface; S is the area, in square meters, of the measurement surface; $S_0 = 1 \text{ m}^2$.

The sound power of the CMG and the equivalent sound source was calculated separately as shown in Fig. 7. It can be seen that the equivalent sound source can reproduce the energy level and spectrum characteristics of the CMG. On each peak frequency, the level difference was less than 1 dB. Moreover, the CMG's total sound power level is 58.1dB, compared to 57.4dB for the equivalent sound source, the difference still less than 1dB.

However, the equivalent sound source cannot reproduce the background signal of the CMG which is the reason of 1dB total sound power difference. The reason is that the background signal level is too low. Therefore, compared to the anechoic room background noise, the signal/noise ratio is not good enough.

4.2 Each microphone signal comparison

To validate whether the equivalent sound source can also reproduce the CMG's acoustic directional characteristics, each microphone's signal was compared.

Figure 7. Sound power comparison: equivalent sound source (a) and CMG (b).

The results of all 20 microphone spectra from the CMG and the equivalent sound source are shown in Fig. 8. It proves that the distribution of the acoustic energy not only over frequency but also spatially is substantially the same. Since the 20 microphones were positioned on every direction of the test objects, the equivalent sound source can be deemed to accurately reproduce the acoustic directional characteristics.

4.3 Auto Power Based Assurance Criterion (APAC)

To simplify the validation of the reproduction accuracy, a new metric, Auto Power Based Assurance Criterion (APAC) was designed as per Eq. (9), which will represent an overall correlation result for the entire frequency range for each microphone point.

$$APAC(j) = \frac{AP_{CMG}(\omega)_j \cdot AP_{EQS}^T(\omega)_j}{|AP_{CMG}(\omega)_j| \cdot |AP_{EQS}(\omega)_j|} \quad (9)$$

where $AP(\omega)_j$ is a row vector, which represent the auto power linear spectrum at microphone j for

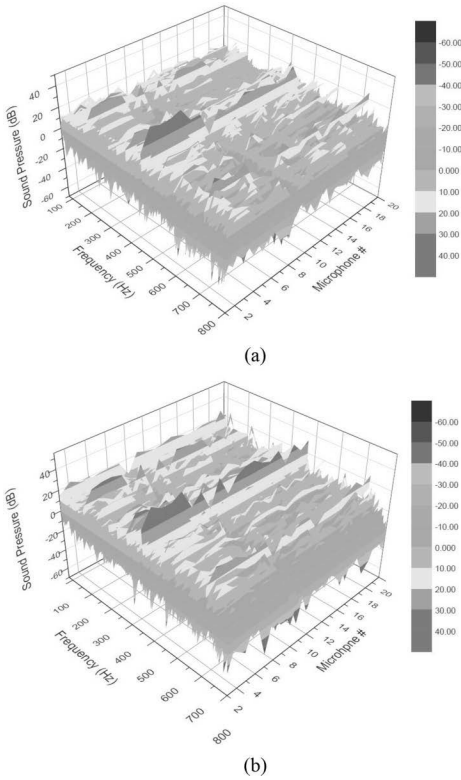

Figure 8. The microphone signals from the CMG and equivalent sound source: (a) CMG; (b) equivalent source.

Figure 9. Auto Power Based Assurance Criterion (APAC) and SPL of each microphone.

a range of frequency ω ; EQS means equivalent sound source; T means vector transverse; $|\cdot|$ means norm of vector.

An APAC close to 1 means good reproduction accuracy. The APAC for each microphone point is shown in Fig. 9. It can be seen that the APAC of all microphones are above 0.78, and the averaged APAC is 0.86, which means the reproduction accuracy should be acceptable.

Moreover, there is a trend: the higher the microphone number, the lower the APAC value, which is similar to the Sound Pressure Level (SPL) variation. The reason for that could be, because the higher number microphones were put closer to the top of the CMG, due to the CMG directivity characteristic, the signal/noise ratio was worse, therefore the reproduction accuracy was decreased.

5 CONCLUSIONS

In this paper, a method to design an acoustic source to each microphone simulate the CMG was proposed. Based on the acoustic signal from the microphones around the CMG, and the FRFs from the drive voltages of the speakers on the acoustic source to the microphones, an FRF matrix inversion by PCA was applied to calculate the required speaker drive voltages to simulate the CMG acoustic performance.

The accuracy of the reproduction was validated for both energy level and directivity aspects. We proved that the equivalent sound source can generally reproduce the acoustic excitation of the CMG.

Because of the frequency range of the speakers, the equivalent sound source in this paper cannot be used below 80 Hz. As a matter of fact, for sound below 80 Hz, the speaker size will be too large so that its geometry and weight cannot be similar to the CMG, which makes it not suitable for

measuring the CMG acoustic borne micro-vibration in the cabin. Therefore, this method is currently limited to the frequency range above 80 Hz.

ACKNOWLEDGEMENTS

The authors would like to express their appreciation to the members of the CMG team at Beijing Institute of Spacecraft System Engineering for their kind help.

A study of the magnetic field distribution with saddle-shaped coil of the electromagnetic flow meter

Hua Jia, Yueming Wang, Wentao Li & Yaoyao Zhang

School of Information Engineering, Inner Mongolia University of Science and Technology, Baotou, China

ABSTRACT: The saddle-shape excitation coil is available in the electromagnetic flow meter usually. To discuss the saddle-shaped excitation coil, firstly the magnetic fields in the space generated respectively by straight, elliptical, and circular excitations of the coil segment are analyzed by using the Biot–Savart law. On this basis, the magnetic field distribution inside the electromagnetic flow measurement sensor produced by the saddle-shaped excitation coil is investigated and discussed. Finally, a comparative analysis between magnetic field distributions excited by rectangular and saddle-shape coils inside the instrument is suggested.

1 INTRODUCTION

The electromagnetic flow meter is an important flow measurement instrument, and the excitation coil design is one of the key technologies used in an electromagnetic flow meter. Tingxiang Chen and Baosen Huang have calculated the magnetic field excited by several kinds of inhomogeneous type coils (Chen, 1982); Xutong Qiao and Lijun Xu gave the design of exciting Coils for multi-electrode electromagnetic flow meters (Qiao, 2002); Ningde Jin built simulations about magnetic field distributions of outward flow meters (Jin, 2009); Yueming Wang and Lingfu Kong carried out an optimization analysis for the excitation coil of concentrating flow meters (Wang, 2011; Kong, 2012; Li, 2012); and Chen Zhao and Bin Li suggested a line approximation algorithm to analyze the magnetic field distribution of saddle excitation coils in EM flow meter sensors (Zhao, 2008). Due to restrictions with installation space, the excitation coil of the saddle-shape structure is frequently used in the flow meter sensor, especially catering to a new sort of downhole flow meter. In this paper, the electromagnetic flow meter sensor's internal magnetic induction with saddle-shaped excitation coil is studied by using the Biot–Savart law, thereby providing a consulting reference to the magnetic field distribution inside the electromagnetic flow meter with saddle-shape excitation coil.

2 BIOT–SAVART LAW

From the Biot–Savart law, the magnetic induction generated by current element $I\vec{dl}$ at point P in space is decided by using the following equation:

$$dB = \frac{\mu_0}{4\pi} \frac{I\vec{dl} \times \vec{r}}{r^2} \quad (1)$$

where \vec{r} is the radius vector that the current element $I\vec{dl}$ directs to point P, r is the distance from point P to the current element $I\vec{dl}$, and μ_0 is the permeability of vacuum.

The magnetic induction at point P in the space which any current carrying conductor generates could be obtained by using the superposition principle.

$$\vec{B} = \oint dB = \frac{\mu_0}{4\pi} \oint \frac{I\vec{dl} \times \vec{r}}{r^2} \quad (2)$$

3 INTERNAL MAGNETIC FIELD INVESTIGATION ON THE SADDLE-SHAPED COIL

Different shapes of coil excite different magnetic fields; thus, the theoretical analysis of saddle-shaped coils is carried out to provide theoretical basis to the design of the electromagnetic flow meter.

3.1 Magnetic distribution calculation of saddle-shaped coils

Roughly speaking, a saddle-shaped coil is formed by two straight segments and two arc segments. And so, according to the magnetic induction superposition principle, the magnetic induction at point P in the space can be acquired by adding magnetic induction generated by using two straight segments and two arc segments at point P in the space.

Figure 1 shows the sketch map of the saddle-shaped coil. In Figure 1, the sub-graph (a) shows flow sensor schematic diagram with saddle-shaped excitation coil, and sub-graph (b) shows the cartesian coordinate system's schematic diagram with one of saddle-excitation coil. As shown in figure, L1 and L3 are the two straight segments and L2 and L4 are the two arc segments (L2 and L4 could be part of the ellipse or circle). Four pieces are connected each other into a form of coil circuit. To study the problem in universality, in this work, we define L2 and L4 ellipses (for circle is a special type of ellipse when the long and short radii are equal; we can study on elliptic coil and circle coil is also solved as which is pre-digested of the elliptic model). The x-axis and the y-axis are perpendicular to the z-axis; and so, x-axis, y-axis, and z-axis constitute a rectangular coordinate system. In electromagnetic flow meters, there are two identical coils that are symmetrically distributed. We can get the magnetic induction at one point by using the principle of superposition, and then the magnetic field distribution inside the instrument is described.

The Biot-Savart law is used to calculate the value of magnetic induction at point P in space. The function of L1 and L3 mentioned above are described as follows:

(a)

(b)

Figure 1. The schematic diagram of the saddle-shaped coil excitation.

$$\begin{cases} L1: x = a, y = b, z \in [-c, c]; \\ L3: x = -a, y = b, z \in [c, -c]; \end{cases} \quad (3)$$

In this work, for universality, the description of coordinates for both L1 and L3 consist of a, b, and c.

The measuring electrodes are completely covered by using the magnetic field of the excitation coil, and so the study focuses on the inside space of the coverage only. If a current element $I d\vec{l}$ in the coil whose coordinate position is (ζ, η, ζ) , and one arbitrary point P in the space whose coordinate position is (x_1, y_1, z_1) are defined, the distance from p to any current element $I d\vec{l}$ in coil could be defined as follows:

$$r = \sqrt{(x_1 - \zeta)^2 + (y_1 - \eta)^2 + (z_1 - \zeta)^2} \quad (4)$$

Substituting equation (3) in equation (4), we can calculate the distance from P to any point in the excitation coil.

According to the Biot-Savart law, the magnetic induction and its direction excited at point P in space by excitation coils of L1 and L3 are solved as follows:

Point P's magnetic induction and direction caused by excitation coils of L1 is given as follows:

$$\begin{cases} B1_x = \frac{\mu_0 I}{4\pi} \int_{L1} \frac{dl \times r1}{r1^2} = \frac{\mu_0 I (b - y_1)}{2\pi((a - x_1)^2 + (b - y_1)^2)} k1 \\ B1_y = \frac{\mu_0 I}{4\pi} \int_{L1} \frac{dl \times r1}{r1^2} = -\frac{\mu_0 I (a - x_1)}{2\pi((a - x_1)^2 + (b - y_1)^2)} k1 \\ B1_z = 0 \end{cases} \quad (5)$$

where

$$k1 = \frac{c + z_1}{\sqrt{(a - x_1)^2 + (b - y_1)^2 + (c + z_1)^2}} + \frac{c - z_1}{\sqrt{(a - x_1)^2 + (b - y_1)^2 + (c - z_1)^2}}$$

Point P's magnetic induction and direction caused by excitation coils of L3 is given as follows:

$$\begin{cases} B3_x = \frac{\mu_0 I}{4\pi} \int_{L3} \frac{dl \times r1}{r1^2} = -\frac{\mu_0 I (b - y_1)}{2\pi((-a - x_1)^2 + (b - y_1)^2)} k3 \\ B3_y = \frac{\mu_0 I}{4\pi} \int_{L3} \frac{dl \times r1}{r1^2} = -\frac{\mu_0 I (-a - x_1)}{2\pi((-a - x_1)^2 + (b - y_1)^2)} k3 \\ B3_z = 0 \end{cases} \quad (6)$$

where,

$$k3 = \frac{c - z_1}{\sqrt{(-a - x_1)^2 + (b - y_1)^2 + (c - z_1)^2}} + \frac{c + z_1}{\sqrt{(-a - x_1)^2 + (b - y_1)^2 + (-c - z_1)^2}}$$

We can also use the Biot–Savart law to solve the magnetic induction at point P in space excited by two arc segments (L2 and L4) and then acquire the final magnetic induction distribution by using the superposition principle.

The functions for L2 and L4 (parts of ellipse) are shown in equation (7). In the equation, the projection of L2 and L4's long and short radii along the x-axis is e and along the y-axis is f, and they have a projection respectively along the z-axis -c and c.

$$\begin{cases} \frac{x^2}{e^2} + \frac{y^2}{f^2} = 1 \\ z = \pm c \end{cases} \quad (7)$$

r stands for the distance from the center to the current element $I\vec{dl}$ (ζ , η , ζ) in the ellipse, according to elliptic equation in this work is given as follows:

$$\begin{cases} \zeta = e \cos \theta \\ \eta = f \sin \theta \\ r = \sqrt{e^2 \cos^2 \theta + f^2 \sin^2 \theta} \end{cases} \quad (8)$$

It should be noted that the θ in equation (8) is an eccentric angle.

Figure 2 shows the vector calculation diagram of an elliptic excitation coil. As shown in the figure, the point P(x_1, y_1, z_1) could be any point in the sensor space, the current element $I\vec{dl}$ belongs to the elliptic equation (L2 or L4), the center point of the elliptic

Figure 2. Vector diagram of the elliptic excitation coil.

equation is point O, \vec{r} is the vector that connects point P to the current element $I\vec{dl}$'s initial point, \vec{Pr} is the vector that connects the center point O of the elliptic equation (L2 or L4) to the point P, $r\vec{01}$ is the vector that connects point O to the current element $I\vec{dl}$'s initial point, and $r\vec{02}$ is the vector that connects point O to the current element $I\vec{dl}$'s terminal point, \vec{dl} is the vector that connects current element $I\vec{dl}$'s initial point to the current element $I\vec{dl}$'s terminal point, and $d\theta$ is the angle between $r\vec{01}$ and $r\vec{02}$. And so, we can obtain the following vector conjunction with Figure 2.

The equation (9) has expressed the vector \vec{Pr} as follows:

$$\vec{Pr} = x_1 i + y_1 j + (z_1 - c) k \quad (9)$$

where i, j, and k are the direction vectors; equation (10) expresses the vector $r\vec{01}$ and equation (11) expresses vector $r\vec{02}$ (because $d\theta$ is quite small, which means the approximate treatments such as $\cos d\theta \approx 1$ and $\sin d\theta \approx d\theta$ are possible).

$$r\vec{01} = e \cos \theta i + f \sin \theta j \quad (10)$$

$$r\vec{02} = e \cos(\theta + d\theta) i + f \sin(\theta + d\theta) j = e(\cos \theta - \sin \theta \cdot d\theta) i + f(\sin \theta + \cos \theta \cdot d\theta) j \quad (11)$$

And we can also obtain vector \vec{dl} , as given in equation (12), and the vector \vec{r} is given in equation (13)

$$\vec{dl} = r\vec{02} - r\vec{01} = -e \sin \theta d\theta i + f \cos \theta d\theta j \quad (12)$$

$$\vec{r} = \vec{Pr} - r\vec{01} = (x_1 - e \cos \theta) i + (y_1 - f \sin \theta) j + (z_1 - c) k \quad (13)$$

Equation (9)–(13) are substituted into equation (2); the magnetic induction and direction caused by the excitation of two arc segments coils (L2 and L4) at point P in space is expressed as equation (14).

$$\begin{cases} B_x = \frac{\mu_0 I}{4\pi} \int_{\theta_1}^{\theta_2} \left(\frac{1}{\sqrt{r1^3}} (z_1 - c) + \frac{1}{\sqrt{r2^3}} (z_1 + c) \right) f \cos \theta d\theta \\ B_y = \frac{\mu_0 I}{4\pi} \int_{\theta_1}^{\theta_2} \left(\frac{1}{\sqrt{r1^3}} (z_1 - c) + \frac{1}{\sqrt{r2^3}} (z_1 + c) \right) e \sin \theta d\theta \\ B_z = \frac{\mu_0 I}{4\pi} \int_{\theta_1}^{\theta_2} \left(\frac{1}{\sqrt{r1^3}} + \frac{1}{\sqrt{r2^3}} \right) (ef - x_1 f \cos \theta - y_1 e \sin \theta) d\theta \end{cases} \quad (14)$$

It should be noted that θ is the eccentric angle of the elliptic equation. In the equation, θ_1 and θ_2 in the integrator are the initial and terminal points of the eccentric angle.

For the case of the circular shape coil, we can make out magnetic induction and direction by just substituting $e = f$ in equation (14).

According to the superposition theorem, the gross magnetic induction and direction generated by each part of the excitation coil at the point P is given as follows:

$$\begin{cases} B_x = \sum_{i=1}^8 B_{ix} \\ B_y = \sum_{i=1}^8 B_{iy} \\ B_z = \sum_{i=1}^8 B_{iz} \end{cases} \quad (15)$$

where, i is defined as the identity number of each edge of the excitation coil; x , y , and z , respectively stand for the axial component of magnetic induction of point P on the x -axis, y -axis, and z -axis.

Similarly, the magnetic induction and direction of any point inside the sensor space can be calculated by using the above-mentioned method.

3.2 Magnetic induction distribution simulation for saddle and other shape coil

In the simulation experiment, substitute $a = 0.6R$, $b = 0.6 * \sqrt{3} R$ and $c = 5R$, where R is the radius of the sensor. Numerical simulation of the magnetic induction distribution of the saddle-shaped excitation coil is given as follows: Figure 3 shows the distribution of B_y (magnetic induction along direction of y -axis) inside the measuring tube where $z = 0$. The sub-map (a) is the distribution of B_y inside the measuring tube where $z = 0$ and the sub-map (b) is the potential diagram of B_y inside the measuring tube where $z = 0$.

Obviously, the magnetic induction distribution changes along with the variation of position and shape (different values of a , b , c , e , and f); however, under a new condition (set different values of a , b , c , e , and f), the magnetic induction distribution can also be acquired by using the above-mentioned method.

3.3 Comparison between the saddle and rectangular excitation coil

Table 1 shows the magnetic induction distribution performance comparative analysis between rectangle and saddle excitation coils.

In accordance with the method described above, more simulation of the magnetic induction distribution generated by different shapes and parameters (set different values of a , b , c , e , and f) has been established for comparison. In this section we built

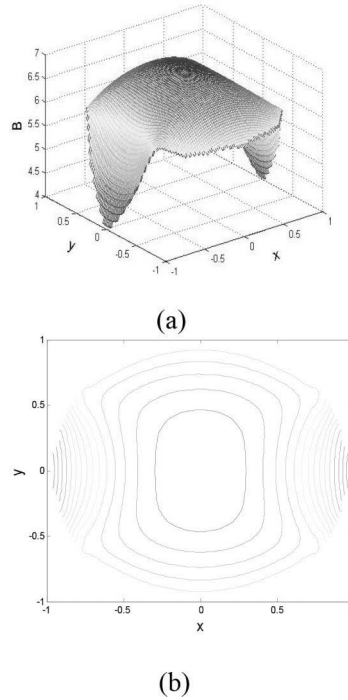

Figure 3. The distribution diagram of B_y (Y-direction of magnetic induction) with the saddle-shaped excitation coil in the measuring tube, where $z = 0$.

Table 1. The magnetic induction distribution performance comparative analysis.

Performance coil	Mean value	Standard deviation	Coefficient of variation	Uniformity of B_y
Rectangular	5.072	0.6345	0.1251	12.19%
Saddle-shaped	6.187	0.5888	0.0952	24.38%

a simulation for rectangular excitation coils which has the same size as saddle-shaped excitation coils mentioned in the previous section (a , b , and c are respectively $1.2R$, $1.2R$, and $5R$). Table 1 gives a comparative analysis of the magnetic induction distribution performance between rectangle and saddle excitation coils inside the measuring tube where $z = 0$.

The evaluation index given in the literature (WANG, 2011) is provided in Table 1. It is clearly seen that the saddle-shaped excitation coil has more advantages than the rectangular one under the same parameters by using the evaluation index from Table 1. In addition, the excitation coil of the saddle-shaped structure can save the sensor's installation space, which is suitable for installation in a relatively small position.

4 CONCLUSION

In this paper, the magnetic induction distribution in the space is analyzed by using the Biot–Savart law which produces straight line segments, oval arc and circular arc, and the magnetic induction distribution of saddle-shaped coil is investigated by calculation and simulation on this basis. Finally, the magnetic induction distribution performance is compared between rectangle and saddle-shape excitation coils inside the measuring tube in the same position.

In this paper, a study on the excitation coils of different shapes with different parameters is carried out, to provide a reference method of calculation of the magnetic field distribution inside the sensor, which provides technical support for the design of the sensor's excitation coil with different shapes, parameters, and positions. Meanwhile, through the analysis of the internal magnetic field of the sensor, the approach may help for the optimization in the design of coil parameters.

A study on a localizable CMOS temperature sensor based on wireless transmission

Liying Chen, Jiaqi Li & Yaoxian Li

School of Electronic and Information Engineering, Tianjin Polytechnic University, China

ABSTRACT: A CMOS temperature sensor is proposed, which is used in the wireless sensor and transmission network based on RFID technology. The current target's information can be tested timely and efficiently by using the intelligent electronic equipment in the Wireless Sensor Network. Meanwhile, the waste of human resources will be reduced. In this paper, the principle and hardware structure of the system are described. The results show that the CMOS temperature sensor's performance is good by being used in the RFID wireless sensor network. The accuracy of temperature is under 0.015°C in the range between -40 and 125°C . The error of the location system is within 0.4 meter in 5×5 meters range. Real-time transmission and data display can be achieved by using this sensor.

1 INTRODUCTION

With the rapid development of the Internet of Things (IOT), and with temperature sensors being widely used in many fields, such as the biological medical industry, vehicle-mounted system, the temperature measurement of industry, agriculture and fire-alarm systems, it becomes very increasingly important to trace the temperature of the target in real time. However, the current temperature tracking system lacks the characteristic of quick rhythm, which is convenience and veracity.

Radio Frequency Identification (RFID) technology has been considered as a way to increase the efficiency of the location in the temperature sensor field. There are many benefits in the RFID system, such as using small tools, real-time data transmission etc., which can allow data transmission for a long time (Amador, 2009). There are many location methods of the RFID, in which the most classic one is the LANDMARC algorithm. The LANDMARC algorithm is a very simple one with high accuracy of location and low complexity of hardware. And so, the LANDMARC algorithm is the foundation in most current location algorithms; in other words, the location algorithm originated from LANDMARC (Kung, 2015).

Two kinds of sensors are widely used in the area of temperature sensors. One is liquid-filled thermometer, the fluid material of which is hydrargyrum or kerosene. The liquid-filled thermometer with big volume is mainly used in hospitals and homes, which is only fit to measure

a target's temperature in a specific time; sometimes it may have a large error. The other is the electronic thermometer which receives the temperature signals through a thermistor. This kind of thermometer has the same disadvantages as that with liquid-filled thermometers. What is more, both thermometers cannot be integrated into other electronic equipment. Comparatively speaking, the CMOS temperature sensor has so many advantages, such as small volume, low cost, and low-power dissipation. The most important is that it can integrate into other electronic equipment. Because of that, CMOS temperature sensors are used worldwide and will gradually replace other thermometers.

In this paper, research on combining temperature sensors with RFID orientation technology has been carried out for many years worldwide. In 2009, Cecilia Amador, Jean-Pierre Emond, and Maria Cecilia do Nascimento Nunes published papers about RFID technology being used in receiving the data of Pineapple temperature change from temperature sensors. In 2016, Andrea Luvisia, Alessandra Panattonib, and Alberto Materazzib discovered the relationship between the temperature change and the change of microorganisms in soil by RFID technology (Luvisi, 2016; Feng, 2014).

A design is proposed in this paper to improve the insufficiency mentioned above. The design is a system which combines the RFID location technique and CMOS temperature sensor, and it realizes both location and temperature data received in real time. In addition, it also displays the information on the screen. The design could be used in

many occasions, such as hospitals, markets, factories, etc. To solve problems, first, the design can be used in fire prediction in factories and markers. Second, the design can track the temperature of every patient anywhere at hospital to determine its position timely, and then lead to finding and curing. Third, wireless sensing of biomedical equipment can become true by substituting the temperature sensor with any other physiology signs testing equipment.

2 SYSTEM STRUCTURE

The temperature sensor system includes mainly two blocks, which are the temperature sensing block and wireless communication system (Yue, 2012). The temperature sensing block includes reset circuit, CLK, PTAT voltage source, and digital transmission port. The wireless communication structure includes active frequency identification label, RF receiving block, location block, and PC data processing. The diagram of the whole system structure is shown in Figure 1.

The temperature sensing block collects the analog temperature data of the current environment; meanwhile, the digital transmission port can turn analog signals into digital signals. It sends the digital data to the active frequency identification label. And then, the label sends the digital data to the RF receiving block through the antenna of the label. Finally, the data will be processed and shown in the PC screen.

Simultaneously, the readers of the location block receive the RSSI of the active frequency identification label and then send the RSSI to the PC terminal. The RSSI data will be processed by using a specific location algorithm. In the end, the location information is received and also shown on the screen.

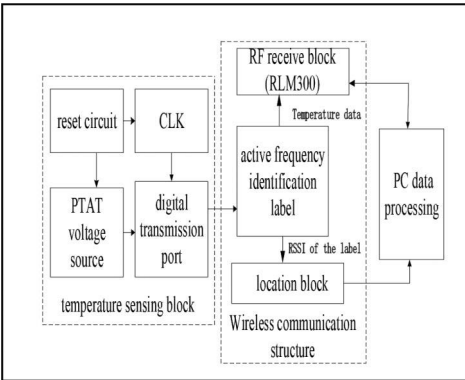

Figure 1. Diagram of the system structure.

3 TEMPERATURE SENSOR BLOCK

The temperature sensor is designed with 0.18 μm UMC CMOS technology. The circuit structure includes reset circuit, CLK, PTAT voltage source, and digital transmission port (Ohzone, 2007; Kim, 2013). After the circuit began to work, first, the circuit is reset. Second, the PTAT voltage source produces an analog voltage signal which is proportional to absolute temperature. Third, the digital transmission port outputs a series of parallel digital signals, when it turns the analog signal into digital one. Finally the digital signals will be sent to the RF label. In addition, the function of CLK is to provide a clock signal for the digital transmission port and RF label.

If that I_1 , I_2 , and I_3 are the electricity of pnp1, pnp2, and R2 (in the figure of this article, the letter P represents PMOS transistors and the letter N represents NMOS transistors). The differential operational Amplifier (AMP) works on deep negative feedback mode, which compels to its positive and negative ports' voltage equally. When the circuit is stable, the relationship of each parameter is shown as follows:

$$I_2 R_2 + V_{EB2} = V_{EB1} \quad (1)$$

$$V_{EB1} = V_T \ln(I_1/I_{S1}) \quad (2)$$

$$V_{EB2} = V_T \ln(I_2/I_{S2}) \quad (3)$$

$$V_T = kT/q \quad (4)$$

where I_{S1} and I_{S2} are the reverse saturation currents of pnp1 and pnp2. k is the Boltzmann's constant, T is the absolute temperature, and $q = 1.60 \times 10^{-19}$ Coulomb. When the voltages of P1 and P2's grids are equal, the expression for the output voltage is given as follows:

$$V_{out} = I_3 R_2 = \left(\frac{\beta_1}{\beta_2} \right) I_2 R_2 = \left(\frac{\beta_1}{\beta_2} \right) \left(\frac{R_2}{R_1} \right) \left(\frac{kT}{q} \right) \ln \left[\left(\frac{\beta_1}{\beta_2} \right) \left(\frac{A_2}{A_1} \right) \right] \quad (5)$$

Figure 2. Circuit diagram of the PTAT voltage source.

When the voltages of P1 and P2's grids are equal, the expression for the output voltage is shown as follows: $\beta_3/\beta_2 = I_3/I_2$, $\beta_1/\beta_2 = I_1/I_2$, where A1 and A2 are the emitter areas of the pnp transistor. Other parameters are all constant except T. And so, V_{out} is a voltage which is proportional to the parameter T.

The starting circuit is constituted by using P4, P5, P6, N1, and C1. During the time that VCC changes from 0V to supply voltage, N1 amounts to a certain capacitance. When the power starts to work, the grid of N1 is under low voltage conditions. Thus, P4, P5, and P6 start to work, and the electric current will help to enable P1 and P2. Finally, the circuit starts to work. However, with the grid of N1 being charged, the grid will remain under high voltage conditions. Meanwhile, P5 and P6 will be cut-off, and the starting circuit will end the job (Crepaldi, 2010).

The output voltage and error of CMOS temperature sensor are simulated by using the Spectre of Cadence software. The simulation curve of the error is shown in Figure 3. From Figure 3, 1650 points are tested. The error of output is within $\pm 0.015^\circ\text{C}$ when the change of temperature is between -40 and 125°C . The simulation curve of the output voltage is shown in Figure 4. From Figure 4, there are also 1650 points are tested. The relationship between temperature and the voltage shows that when the change of temperature

Figure 3. Simulation curve of errors.

Figure 4. Simulation curve of output voltages.

Figure 5. Layout of the CMOS temperature sensors.

is between -40 and 125°C , the output is between 350 mV and 570 mV. The voltage range of output can be processed easily. In addition, when the supply power is 1.8V, the power consumption is under 1.5 μW . Therefore, this design can be used to satisfy the demand of application. Finally, the layout is designed and displayed, as shown in Figure 5.

4 WIRELESS COMMUNICATION STRUCTURES

The function of the wireless communication system is to connect the user terminal and the sensor for increasing the transmission distance. In this paper, a wireless communication system is proposed which is set up with advanced equipment based on RFID. This system includes RF receiving block and location block. And an active tag in the system can be used to simplify the equipment.

4.1 RF receiving block

The RLM300 UHF RFID reader–writer is used in the RF receiving block, which has the advanced RFID analog circuits. It has the power processing chip with DSP technique. The protocol standard of this block is ISO 18000–6C and the working frequency is between 840 MHz and 960 MHz. RLM300 provides the API of Windows OS, the function of which is to receive the digital signals sent by using an active frequency identification label in this block and then the RLM300 sends it to the PC directly to process the data. From Figure 6, which shows the structure of RLM300, the data are the data-flow between PC and RLM300. And the antenna receives the temperature data sent by using the active frequency identification label (Guédon, 2015).

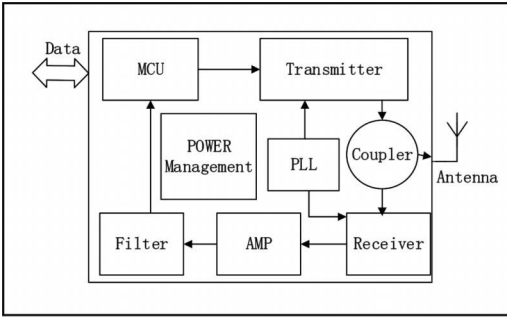

Figure 6. Schematic of the structure of RLM300.

Figure 7. Schematic of the block of the location block.

4.2 Location block

The basis of the location block in this article is RFID technology. The method is that the readers measure the RSSI of THE target tag, and locate the position of the tag by using the LANDMARC algorithm. The model founding includes 16 reference tags, a target tag, and four readers, which is shown in Figure 7. The data from readers will be transmitted to the processor and then sent to the PC. The reader equipment of this system is Intel R1000, which is produced by Intel. The RSSIs of 16 reference tags and a target tag are read with the LANDMARC location principle. And then, the RSSIs are sent to the PC. Finally, the localization is realized.

The LANDMARC algorithm is given as follows:

Assume that there are n readers, m reference tags, and one target tag. And the coordinates of target tag are (x, y) . We define the RSSI matrix of target tag as $S = [S_j]$ ($j=1 \dots n$) where S_j is the RSSI of the j th reader. The matrix $Q = [Q_{ij}]$ ($i=1 \dots m$) ($j=1 \dots n$) is the RSSI of the i th reference tag read by the j th reader. The matrix $E = E_i$ is the Euclidean distance between the target tag and the i th reference tag. Gett the minimum of E_i ($i=1 \dots k$), where k is

the number of nearest tags from the reference tag to the target tag. The coordinates of the reference tags are (x_i, y_i) ($i=1 \dots k$). The coordinates of the target tag are defined as $(x, y) = \sum_{r=1}^k w_r \times (x'_r, y'_r)$, where w_r is the weight of the k th reference tag. The expression of w_r is $w_r = 1/E_r^2 / \sum_{i=1}^k 1/E_{ir}^2$. In addition, the systematic error estimation is given by the following relation: $e_i = \sqrt{(x_i - x_0)^2 + (y_i - y_0)^2}$.

5 RESULTS AND ANALYSIS

Based on the principle mentioned above, we tested the performance of the system in the temperature sensor block. When comparing the CMOS temperature sensor and other electronic thermometers, we tested 50 groups of different temperature values. The consequence is that the maximum error between them is 0.25°C . And the average one is about 0.1°C . Figure 8 shows the chart of the errors.

In the side of the location, the 50 groups' data are tested in a $5\text{ m} \times 5\text{ m}$ indoor area. The environment of the area is complicated. The consequence is that the maximum error is 0.6 m and the errors of the regional center are about 0.3 m . The details are shown in Figure 9.

Figure 8. Chart of the errors.

Figure 9. Graph showing the errors of location.

6 CONCLUSION

The CMOS temperature sensor represents easy-to-use and cheap tools, which can solve the problems of current thermometers such as large volume, high loss of power, and the problem about the temperature data cannot be transmitted on time. A CMOS temperature sensor system is proposed, which is used in wireless sensor networks. The system can receive and transmit data immediately and timely. And it also can locate the temperature sensor. The consequence of the test is that the error of temperature measurement under 0.015°C and location is under 0.6 m. These can be shown on screen simultaneously. This successful design can be a basis of researching other human signal testing equipment.

Finite element analysis of the roller coaster wheel bridge based on virtual prototype technology

Yongming Wang, Jun Ye, Xuetan Xu & Song Song

School of Mechanical Engineering, Anhui University of Technology, Maanshan, China

ABSTRACT: The wheel bridge of the roller coaster is a key component, which connects the wheel frame and vehicle frame, and so its security is related to the entire roller coaster running safety. When the roller coaster is running in high speed, the forces of the wheel bridge are changeable instantaneously. The traditional static analysis method cannot meet the demand of the security assessment. Therefore, based on virtual prototype technology, a dynamics analysis was carried out on the roller coaster in this paper, and then the force curves of the wheel bridge were obtained. The finite element analysis model of the wheel bridge was established in ANSYS Workbench, and then the forces were applied. Finally, the displacement diagram and stress nephogram of the wheel bridge were obtained. The results indicate that the strength safety factor of the wheel bridge meets the amusement facilities safety specification stated in national standard GB8408-2008.

1 INTRODUCTION

The roller coaster is deeply loved by young people for its high speed and strong irritation. The roller coaster belongs to high-speed running equipment, and the wheel bridge is its key component. The wheel bridge connects the wheel frame and vehicle frame, and so its security is very important. However, the forces of the wheel bridge are very complicated, which are influenced by the orbital shape, the running condition of the carrying car, the weight of the carrying car, the gravity of the tourists, the running speed, and so on. Because the stresses of the wheel bridge are changeable instantaneously, an ideal analysis result cannot be obtained by using the traditional static method (Wang, 2010). The virtual prototype technology provides an effective way to solve this problem (Liang, 2008; Shen, 2007).

2 KINEMATICS AND DYNAMICS SIMULATION OF THE WHEEL BRIDGE

The structure of the roller coaster wheel bridge is shown in Figure 1.

According to design requirements, the total length of the roller coaster orbit is 567 m, the maximum height of the roller coaster orbit is 30 m, the distance of two orbits is 960 mm, and the maximum running speed is 80 km/h. As shown in Figure 2, two space curves were used to simulate the roller coaster orbit in the global coordinate system of ADAMS. The orbit is mainly composed of the platform, the lifting section, the transition section, the floating ring, the vertical ring, and the spiral

ring. The corresponding constraints of the components are listed in Table 1. The corresponding loads were applied on the components, such as the gravity, the friction between the wheel and orbit,

Figure 1. Schematic of the structure of the roller coaster wheel bridge.

Figure 2. The orbital space curve of the roller coaster.

Table 1. List of the corresponding constraints of the components.

No.	Component	Constraints
1	Orbit and ground	Fixed
2	Left wheel and orbit	PTCV
3	Right wheel and orbit	PTCV

5	Right wheel frame and wheel bridge	Fixed
6	Wheel bridge and frame	Rotation
7	Wheel bridge and tail connector	Rotation
8	Connecting rod and clevis	Rotation

the traction of the carrying car, and the wind loads (Li, 2009; Tian, 2006; He, 2006). In order to ensure the accuracy of the simulation data collection, the sampling frequency must be more than 20 Hz according to the sampling theory, i.e. the simulation step's length must be less than 0.05. Considering the computer performance and the simulation time, the simulation step length was set to 0.01.

Based on the ADAMS kinematics and dynamics simulation, the reference system of the former wheel bridge was selected as the measuring marker, and then the forces of the wheel bridge imposed by the wheel frame and frame body were measured. According to the simulation results, the force of the wheel bridge imposed by the right wheel frame in the Z-direction was almost zero, and so it was ignored. The force curves of the wheel bridge imposed by the left wheel frame in the X, Y, and Z directions are shown in Figure 3.

As shown in Figure 3, the force curves of the wheel bridge in X, Y, and Z directions are almost constant during the time of 0 s–26.33 s. It is because the roller coaster is running in the chain-lifted segment, and the carrying car is rising at a constant speed by the traction. When it reaches the highest point, the traction hook unhooks the carrying car, and the carrying car is going to run under the influence of gravitational potential energy. With the change of the radius, height, and the lateral angle of the orbit, the wheel bridge begins to bear the complex stress. During the time of 26.33 s–44.95 s, the changes of the radius, height, and the lateral angle of the orbit are very little, and so the forces of the wheel bridge change with a small fluctuation. As the carrying car goes ahead, the orbit shape is complex and changeable, and so the forces of the wheel bridge fluctuate greatly.

Figure 3(a) shows that the roller coaster is beginning to pass through the second spiral ring segment at the time of 55.93 s. Except for some individual cusps, the maximum force of the wheel bridge in the X direction is 18114.25 N at that time.

segment at the time of 56.74 s. Except for some individual cusps, the maximum force of the wheel bridge in the Y direction is 3983.52 N at that time.

Figure 3(c) shows that the roller coaster is also beginning to pass through the second spiral ring segment at the time of 58.14 s. Except for some individual cusps, the maximum force of the wheel bridge in the Z direction is 7936.31 N at that time.

The force curves of the wheel bridge imposed by the right wheel frame in X and Y directions are shown in Figure 4. Figure 4(a) shows that the roller coaster is beginning to pass through the second

spiral ring segment at the time of 57.13 s. Except for some individual cusps, the maximum force of the wheel bridge in the X direction is 16873.95 N at that time. Figure 4(b) shows that the roller coaster is also beginning to pass through the second spiral ring segment at the time of 57.13 s. Except for some individual cusps, the maximum force of the wheel bridge in the Y direction is 3109.28 N at that time.

The force curves of the wheel bridge imposed by the vehicle frame in X , Y , and Z directions are shown in Figure 5.

Figure 5(a) shows that the roller coaster is beginning to pass through the second spiral ring segment at the time of 59.26 s. Except for some individual cusps, the maximum force of the wheel bridge in the X direction is 5197.32 N at that time. Figure 5(b) shows that the roller coaster is beginning to pass through the vertical ring segment at the time of 46.98 s. Except for some individual cusps, the maximum force of the wheel bridge in the Y direction is 5866.7 N at that time. Figure 5(c) shows that the roller coaster is also beginning to pass through the vertical ring segment at the time of 46.98 s. Except for some individual cusps, the

(c) The force curve of the wheel bridge in the Z direction

Figure 5. The force curves of the wheel bridge imposed by the vehicle frame.

maximum force of the wheel bridge in the Z direction is -23151.53 N at that time. Based on the data obtained from the above-mentioned simulation, the strength analysis of the wheel bridge was carried out in the following.

3 STATIC ANALYSIS OF THE WHEEL BRIDGE

According to the structure of the wheel bridge shown in Figure 1, its simplified 3D model was established and imported into ANSYS

Workbench. The first step was to divide the mesh, and then exert the constraints and loads. The finite element mesh model of the wheel bridge is shown in Figure 6.

According to its location on the roller coaster, the wheel bridge mainly bears the loads exerted by the wheel frame and the vehicle frame. According to ADAMS simulation, the loads are given in Table 2. The constraints and loading positions of the wheel bridge are shown in Figure 7.

FEM results show that the maximum deformation of the wheel bridge is 0.0056–0.0063 mm, which mainly occurred near the contact area between the wheel shaft and wheel bridge. The wheel bridge mainly bears bending deformation, and its deformation nephogram is shown in Figure 8(a). The stress nephogram of the wheel bridge is shown in Figure 8(b). Figure 8 shows that there is stress concentration at the connection part of the wheel bridge. According to the Von Mises equivalent stress analysis, the maximum stress value is 24.31 MPa.

Figure 7. Constraints and loading position of the wheel bridge.

Figure 6. The finite element mesh model of the wheel bridge.

(b) Stress nephogram of the wheel bridge

Figure 8. Finite element analysis results of the wheel bridge.

Table 2. List of force parameters of the wheel bridge.

Direction	Time/s	Force/N
The left wheel frame in the X direction	55.93	18114.25
The left wheel frame in the Y direction	56.74	3983.52
The left wheel frame in the Z direction	58.14	7936.31
The right wheel frame in the X direction	57.13	16873.95
The right wheel frame in the Y direction	57.13	3109.28
The wheel frame in the X direction	59.26	5197.32
The wheel frame in the Y direction	46.98	5866.71
The wheel frame in the Z direction	46.98	-23151.53

The material of the wheel bridge is Q235-B, and its tensile strength $\sigma_b = 420 \text{ MPa}$ and yield strength is $\sigma_s = 235 \text{ MPa}$. According to GB8408-2008, the safety factor of the wheel bridge is selected as $[n] = 5$, and the impact coefficient $K = 2$. According to the design requirements, the safety factor of the wheel bridge n should be greater than the allowable safety factor $[n]$.

$$n = \frac{\sigma_b}{K \sigma_{\max}} = \frac{420}{2 \times 24.31} = 8.64 > [n] \quad (1)$$

According to equation (1) calculation results, the safety factor of the wheel bridge meets the requirements of the strength design.

4 CONCLUSIONS

Based on virtual prototype technology, kinematics and dynamic simulation analysis of the wheel bridge was carried out. On this basis, the static analysis of the wheel bridge was completed. According to the simulation results, the maximum stress of the wheel bridge is 24.31 MPa and the strength safety factor of the wheel bridge is 8.64. The strength safety factor of the wheel bridge meets the amusement facilities' safety specification given in national standard GB8408-2008. And so, the structure of the wheel bridge meets the requirements of safety evaluation.

Multi-axis coordination control based on siemens S7-CPU315T

Cunhai Pan, Yanlong Li & Mingwei Qin

College of Mechanical Engineering, Tianjin University of Science and Technology, Tianjin, China

ABSTRACT: Hot billets automatic marking equipment is an important part of the casting production lines, which is used to mark a group of particular characters on the billet side or its end surface according to the manufacturer, steel materials, production date and other information, and when quality problems arise, it can promptly trace back to the billet production information, in order to solve quality problems in the enterprise quickly and efficiently. In this paper, a multi-axis coordinated motion control system has been established by using Siemens CPU315T-2DP motion controller. The virtual cam technology of the Technology CPU is used to control two shaft (or multi-axis) coordinated motion, which can guarantee the trajectory curve coordinate movement between the two real axes. Experiments show that Siemens CPU315T-2DP with motion control functions can be designed a multi-axis coordinated control system flexibly, by means of polynomial fitting can easily design the trajectory curve or CAM. The Siemens PLC control system itself has the wealth of motion control information, such as the state of motion of each axis, the axis configuration parameters, limits setting information. etc., and the real axis motion control accuracy can be up to 1 μm .

1 INTRODUCTION

Any iron and steel enterprises all need to mark a group of particular characters on the billet side or its end surface according to the manufacturer, steel materials, production date and other information, and when quality problems arise, it can trace back to the billet production information timely, in order to solve quality problems in the enterprise quickly and efficiently (Pan, 2010; Chen, 2011). Billet production line is in a high temperature, large dust and moisture environment, using the automatic identification device instead of manual operation, the marking information can be more specific and clear, it is not only to improve the efficiency, but also to lighten the labor intensity of workers, which is an inevitable trend of development.

The Technology CPU integrates Motion Control functions in a SIMATIC CPU in order to combine the function of a SIMATIC CPU S7-300 with PLC open-compliant Motion Control functions. The control unit of the Technology CPU performs the tasks known from a standard CPU of the S7-300 family, and S7-Technology is an options package used to configure Motion Control functions. The Technology CPU operates the DP (DRIVE) PROFIBUS interface in synchronous mode. The integrated technology controls, evaluates and monitors all hardware components at DP (DRIVE) and the cam track is configured and activated by calling the technology function blocks. The switching state of the individual output cams can also be read and edited.

In this paper, using Siemens PLC as the core controller, it aims to research a set of billet automatic identification equipment, in order to control the virtual axis to lead two real axes synchronous forward according to pre-designed virtual cam.

2 SYNCHRONIZATION AXIS AND VIRTUAL CAM

A synchronization axis is a following axis which follows a leading axis. Synchronization axis technology object is to use the motion and position values of a leading axis as a master set-point. The synchronization axis contains all functions of the speed-controlled and positioning axes. The master set-points and slave values are coupled without physical conversion in the relevant programmed unit. For example, if the system operates with a linear leading axis (in mm units) and a slave rotary axis (in degree units), then one millimeter corresponds to one degree at a conversion ratio of 1:1.

A following axis can be interconnected with multiple master set-points using the synchronization object. However, only one master set-point can be evaluated actively at any time. The master set-point can be returned by positioning axes, or by a synchronization axes (real or virtual), or by external encoders.

Interpolation of a cam disk is a basic requirement for using it in synchronous operation. The continuity in the definition ranges of leading axis values and in the ranges of the following axis is

Figure 1. Cam control motion trajectory principle diagram.

checked. This check prevents redundant assignment of values to a definite value. These areas are padded according to the interpolation mode and cam disk type.

Virtual cam takes advantage of the flexible programming function of controller to modify the cam motion so as to adapt the needs of different occasions. This not only improves the adaptability of the organization, but also effectively avoids the problem in the process of cam manufacturing to prevent from movement distortion (Yu, 2000). As shown in Figure 1 is the principle diagram of using virtual cam to operate two axes to realize plane trajectory control. According to the rotation angle θ and φ of cam curves, which correspond to different plane positions, they can control indirectly motors to complete trajectory control.

In general, cam curve is often composed of straight line, sine curve and other lines. The function relation between the cam rotation angle and follower distance is:

$$y = F(\varphi) \quad (1)$$

The inverse function is:

$$\Phi = f(y) \quad (2)$$

In addition, using polynomial to express cam curve as follows:

$$y = C_0 + C_1\varphi + C_2\varphi^2 + C_3\varphi^3 + \dots + C_n\varphi^n \quad (3)$$

Therefore, according to equation 3, follower distance can be got by cam angle and reversed cam angle can also be obtained by the follower motion. The realization of virtual cam mainly includes three parts, which is to set the master and slave axis, the cam curve design and the cam path control implement.

3 BUILDING CONTROL SYSTEM

3.1 CPU315T configuration and control system

Using S7-CPU315T unique master and slave control mode, it needs to generate two real axes connected to S7-CPU315T by cam disk synchronization. Then,

the virtual main axis drives motor shaft corresponding virtual cam disk, so that the axis can coordinate motion according to the preset trajectory. System control scheme is shown in Figure 2.

The motor real axis and virtual control axis are configured by S7-Technology software. For virtual axis, since it has no end actuators, and reference of other axis' position, so should be configured as the virtual main axis. The second is to create two linear real axes X, Y to drive servo motor. At the same time, according to the requirements of the cooperative move, the two axes configure for synchronous linear axis, then proper communicate parameter and type of encoder are configured; and the corresponding technical system data is also generated. The control relationship between axes is as shown in Figure 3. System network configuration is as shown in Figure 4. The control system is also designed with the WinCC operator interface HMI.

Figure 2. The control system scheme of S7-CPU315T.

Figure 3. Relationship between servo controller, motor and S7-CPU315T control system.

Figure 4. Network configuration system.

3.2 Virtual cam based on polynomial fitting

S7-Tech can be used to plan cam curve by interpolation points and polynomial function. According equation 3, this system mainly uses the method of polynomial to define cam curve. Equation 4 is polynomial cam curve formula based on Siemens S7-CPU315:

$$y = a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + A\sin(\omega x + \varphi) \quad (4)$$

In order to avoid tedious coefficient calculation, cam curve can be planned for linear and circular arc form as far as possible. In this way, the equation 4 is simplified as:

$$y = a_0 + a_1x + A\sin(\omega x + \varphi) \quad (5)$$

After defining cam curve according to equation 5 in x,y cam disk, different position coordinates of X-Y plane can be got. Then, reversed rotation angle can be achieved by equation 3 to drive indirectly servo motor.

Cam configuration and parameter settings, coupling relation between master and slave axis through the cam plate are built by S7-Tech software and completed by configuration and axis synchronized window. Figure 5 defines cam plate polynomial curve of X axis.

S7-Tech provides the uniaxial, multiaxial and complex move control functions. For example, MC-CamIn function block can be called to control the virtual axis leading the real X-axis and Y-axis in accordance with the preset CAM curve synchronous movement. Furtherly it also need to set the master, slave and cam table of the modules according to DB block given by configuration. In addition, the parameters such as speed, acceleration, deceleration can be set according to the requirements of system.

3.3 Programming design

The program flow chart is as shown in Figure 6.

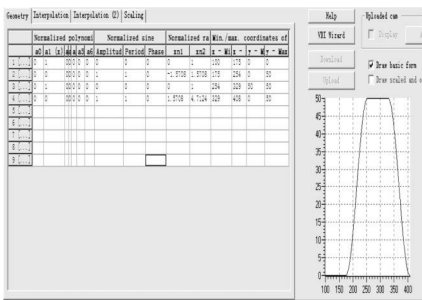

Figure 5. Configuration interface of X-axis cam curve.

Figure 6. Programming flow chart.

Table 1. Name and function of functions.

Name	Function
MC-Power	Start/Stop axis
MC-Home	Zero/Setting axis
MC-Moveabsolute	Absolute position
MC-Halt	Normal stop
MC-Stop	Emergency stop
MC-CamIn	Start cam
MC-CamOut	Stop cam

The system requirement of S7-CPU315 is to control servo motor to do coordinated motion in the two-dimensional plane, in which includes system initialization, zero point setting, motion parameters set and motion process control, etc. Initialization process mainly call the MC-Power function block to start axis and the MC-Home function block to make the axis back to zero. Motion process need to call MC-Moveabsolute, MC-CamIn and MC-CamOut function blocks to realize the main axis absolute location and slave axis coordinate move. Furthermore the MC-Halt and MC-Stop function blocks are called to halt or stop move process. Program flow chart is shown in Figure 6 and function modules used in the movement process are shown in Table 1.

4 THE EXPERIMENTAL RESULTS AND ANALYSIS

The S7T-Config Trace tool always uses to analysis the dynamic response of an axis and its positioning error. This tool not only records the actual position and the command position, and its error, but also records the actual speed and the command speed, and many other parameters which can be used to analyze the stability of a motion axis (Li, 2013).

Figure 7 is the virtual axis to lead the real servo X -axis synchronous trajectory curve; it clearly shows the synergistic effect between the virtual axis and the X -axis.

Siemens T—CPU can use PID control to realize the closed loop control of the system. Figure 8 can clearly see that PID rapidly adjustment the speed of a real X -axis, but when the speed and the acceleration parameter of a virtual main axis and a real axis are set, it must consider the facts such as synchronous demand and system stability. It's because the bigger acceleration, the greater the impact, and the more unfavourable to system stability.

Figure 9 is the set position curve and the actual position curve of the real X -axis, it's clearly that cam curve defined by mathematical polynomial

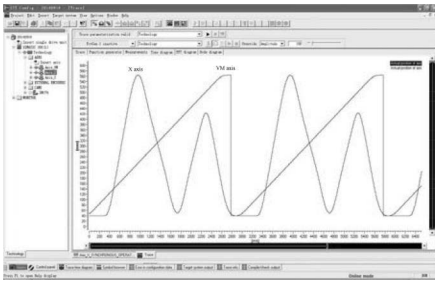

Figure 7. Synchronization of the virtual master axis and a real X -axis.

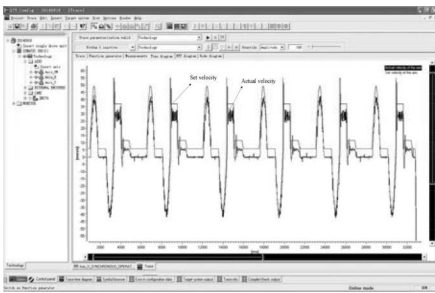

Figure 8. Relation between the set velocity and the actual velocity of a real X -axis.

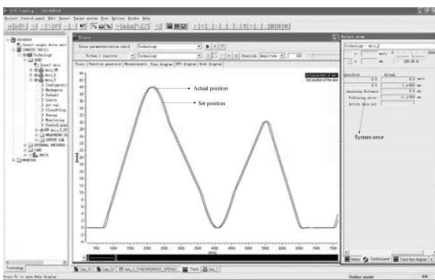

Figure 9. Relation between the set position and the actual position of a real X -axis.

method can meet the marking location needs rapidly and precisely, and the following error of the control system is up to 0.001 mm, this high accuracy no doubt can be achieved for accurate positioning requirements of the identification system. Of course, Y -axis also can be achieved.

According to the relationship between the command position and the actual position of an axis, it can analyze the response speed. And in accordance with the acceleration process of an axis, it can also determine that the system is subjected to impact severity, in other words, determine the dynamic stability of a system.

5 CONCLUSIONS

In this paper, a multi-axis coordinated motion control system has been established by using Siemens S7-CPU315 motion controller. The virtual cam technology of the Technology CPU is used to control two shaft (or multi-axis) coordinated motion, which can guarantee the trajectory curve coordinate movement. Experiments show that Siemens CPU315T-2DP with motion control functions can be flexibly designed a multi-axis coordinated control system, by means of a polynomial fitting can easily design the trajectory curve or CAM, and the real axis motion control accuracy can be up to 1 μ m.

The dynamic response of an axis and its positioning error can be analysed by the S7T-Config Trace tool. This tool not only records the actual position and the command position, but also records the actual speed and the command speed, and many other parameters which can be used to research the stability of a motion axis.

According to the relationship between the command position and the actual position of an axis, the response speed can be analyzed, and also in accordance with the acceleration process of an axis, the dynamic stability of a system can be determined.

ABSTRACT: Accurate PhotoVoltaic (PV) power forecasting can provide reliable guidelines for power dispatching and construction planning of PV power generation, which is also important to the sustainable development of solar utilization. According to the characteristics of PV power generation and the factors impacting PV output power, the human body amenity is proposed. The forecasting performance of the Least Squares Support Vector Machine (LSSVM) model largely depends on the parameters of the kernel function and penalty factor. In this paper, a hybrid PV power forecasting model combining Fruit fly Optimization Algorithm (FOA) with LSSVM is proposed to solve this problem, where the FOA is used to automatically select the appropriate parameter values for the LSSVM PV power forecasting model. The numerical results verify the effectiveness and accuracy of the proposed model and improved algorithm.

1 INTRODUCTION

Along with our country paying more attention to environment and energy sources, PhotoVoltaic (PV) power generation becomes more important in theory and actual use because of little pollution and high energy utilization. Accurate PV power forecasting can relieve the conflict between electricity supply and demand. Short-term forecasting will contribute to arrange the output of the conventional electric power supply by using the electric power dispatching system (Damousis, 2004; Ai-Hamadi, 2005; Almonacid, 2009). Lu and Qin (Lu, 2011) applied metrical information including temperature, pressure, humidity, and solar irradiance as inputs to predict the day type, and then calculated the power output of PV power generation under day types. However, the cycle of this forecasting model is very shorter, only in per hour.

Moreover, owing to the rising of intelligence techniques, many new intelligence forecasting algorithms were used for PV power generation forecasting. Keerthi and Lin (Keerthi, 2003) proposed a hybrid model combining support vector regression and differential evolution algorithm to

forecast the output power of PV, and this method was proved to outperform the SVR model with default parameters, regression forecasting model, and back propagation artificial neural network. Hsu and Chen (Hsu, 2003) implemented a knowledge-based expert system to support the choice of the most suitable forecasting model, and the usefulness of this method was demonstrated by using a practical application.

The human body amenity, which refers to take no effective measures under the premise of protection, can describe the degree of comfort by the person in the natural environment (Wu, 2003). This index can effectively use the various meteorological factors, reduce the input of the network, and improve the precision of forecasting. The Least Squares Support Vector Machine (LSSVM) extended by using the Support Vector Machine (SVM) is a powerful regression tool with a dynamic network structure (Cortes, 1995). The Fruit fly Optimization Algorithm (FOA) proposed by the scholar Pan (Pan, 2012) is a novel evolutionary computation and optimization technique. This new optimization algorithm has the advantages of being easy to understand and to be

written into program code, which is not too long when compared with other algorithms. Therefore, in this paper, an attempt is made to use the FOA to automatically select the parameters' value of the LSSVM for improving the LSSVM's forecasting accuracy in the short-term PV power forecasting.

2 HUMAN BODY AMENITY

As we all know, the output power of PV generation is in positive correlation with the solar irradiance. When compared with the solar irradiance, temperature, humidity, and wind speed are easier to obtain by the devices (Li, 2010; Qin, 2006). Therefore, the human body amenity is adopted to replace so many influenced factors, reduce the input of the network, and simplify the network model in this paper.

Generally speaking, the meteorological factors such as temperature, humidity, and wind speed have a great effect on the human body. Hence, the human body amenity is a non-linear equation based on these elements. Usually it is described as follows:

$$D = f(T) + g(U) + h(V) \tag{1}$$

where D is the human body amenity, T is the temperature ($^{\circ}\text{C}$), U is the average daily humidity (%rh), and V is the wind speed (m/s), which always assumes it as the average value of the maximum and minimum wind speed.

According to the empirical formula, the equation (1) can be represented as follows:

$$D = 1.8T + 0.55(1 - U) - 3.2\sqrt{V} + T_N \tag{2}$$

Where T_N is the reference temperature ($^{\circ}\text{C}$), which slightly varies with the region. In this paper, we take $T_N = 30$ ($^{\circ}\text{C}$) as the reference temperature of Jiangsu province in China.

3 LEAST SQUARES SUPPORT VECTOR MACHINE WITH FRUIT FLY OPTIMIZATION

3.1 Least Squares Support Vector Machine (LSSVM)

The Support Vector Machine (SVM) is a trainable and machine learning method, which is used to solve the problem of pattern recognition and has better generalization abilities (Gestel, 2001; Du, 2008).

Set $\{x_i, y_i\} (i = 1, 2 \dots l)$ as the training sample set; among these, $x_i \in R^n$ as the n-dimensional input vector, y_i as the output value of one-dimensional input vector, and l is the sample number.

The LSSVM model has two parameters, such as kernel function σ and penalty coefficient γ that need to be determined, which are very important in using the LSSVM model for forecasting. The parameters of σ and γ determine the squared bandwidth of the Gaussian RBF kernel and the trade-off between the training error minimization and smoothness, respectively. Many researchers selected the parameters by priori knowledge or individual experience, which may be un-efficient for forecasting. Therefore, we should develop an automatically efficiently method for selecting the appropriate parameters in the LSSVM model.

In order to achieve this goal, in this paper, the Fruit fly Optimization Algorithm (FOA) is used to automatically determine the parameter values of the LSSVM model.

3.2 Fruit fly Optimization Algorithm

Fruit fly Optimization Algorithm (FOA) is a new swarm intelligence method, which was proposed by Pan (Pan, 2012). The FOA is a new method for finding global optimization based on the food finding behavior of the fruit fly. The fruit fly is superior to other species in vision and osphresis. The food finding process of the fruit fly is as follows: firstly, it smells the food source by the osphresis organ, and flies towards that location; and then, after it gets close to the food location, the sensitive vision is also used for finding food and other fruit flies' flocking location, and it flies towards that direction. Figure 1 shows the food-finding iterative process of the fruit fly swarm.

The FOA belongs to a kind of interactive evolutionary computation, and also is a part of the artificial intelligence. Therefore, it has been widely applied to solve the problems in military, engineering, management, and financial affairs.

3.3 Fruit fly optimization algorithm for the parameters selection of the LSSVM model

Selecting appropriate values of the kernel function σ and penalty coefficient γ are particularly important.

Figure 1. Graph showing the food-finding iterative process of the fruit fly swarm.

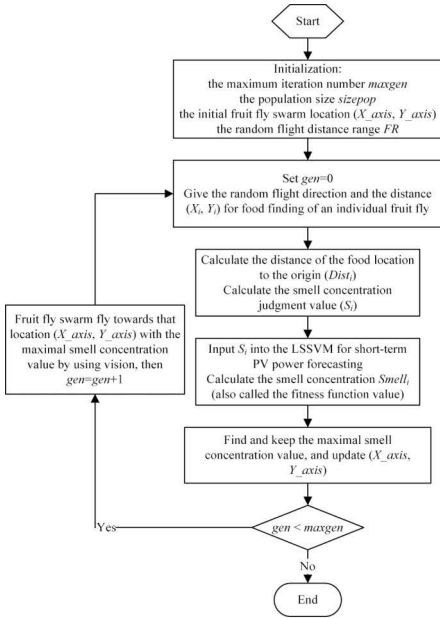

Figure 2. Flowchart of the FOALSSVM model.

In this paper, the FOA was used for selecting the suitable parameter values of the LSSVM model in order to effectively improve the short-term photovoltaic power forecasting accuracy.

The flowchart of the FOA for the parameters of the LSSVM model (abbreviated as FOALSSVM) is shown in Figure 2.

4 EXAMPLES COMPUTATION AND COMPARISON ANALYSIS

In this paper, the FOALSSVM algorithm was simulated by the MATLAB and one demonstration project of PV power generation in Jiangsu province was selected to prove the effectiveness of the proposed FOALSSVM algorithm.

The capacity of the PV power generation system is 380 kW. It was chosen as the local meteorological data and historical output power of PV generation as the training sample in July, and then forecasted the output power of the PV generation in step size of 15 minutes. As shown in Figure 3, it has provided the output power curves of PV power generation from July 13th to July 18th.

The operation curves of PV generation show that the effective working period of PV generation is from about 6 o'clock in the morning to 19 o'clock in the afternoon, while the output power of the PV generation is zero in the rest time of a day. Therefore, the output power forecasting of the PV generation can be only restricted in the working period.

The procedures for applying the proposed FOALSSVM algorithm to forecast the output power of the PV generation are described as follows:

Step 1: The process of sample data.

In this paper, the sample data were normalized to obtain data in the range from 0 to 1 by using the following formula:

$$X = \frac{x_i - x_{i\min}}{x_{i\max} - x_{i\min}}, i = 1, 2, \dots, l \quad (3)$$

where $x_{i\max}$ and $x_{i\min}$ are the maximal and minimal value of each input factor, respectively.

Step 2: Train the LSSVM model.

In the FOALSSVM model, the parameter values of the LSSVM are dynamically tuned by the FOA. The initial parameter values of the LSSVM were set up in the range of [0.01, 1]. After 100 times of iterative evolution, the optimal parameter values of the LSSVM model are obtained in Table 1.

Step 3: Forecast the output power of PV generation. According to the result of FOA tuning of the parameters of the LSSVM model, the parameters of kernel function σ and penalty coefficient γ are chosen as 0.18 and 5.48 to forecast the output power of PV generation, respectively. The final forecasted output power of PV generation is shown in Figure 4.

The historical output power data and the predictive meteorological data of the day are fed as input to forecast the output power of July 19th in 15 minutes, and compared with the actual output power of the PV generation station. The Absolute Percentage Error (APE) and Mean Absolute Percentage Error (MAPE) are adopted to analyze and measure the performance of the forecasting

Figure 3. Curves of PV power generation data.

Table 1. The parameter values of the three algorithms.

Parameter	SVM	LSSVM	FOALSSVM
σ	0.2	0.5	0.18
γ	1	10	5.48

Figure 4. Graph showing the PV power forecasting results.

Figure 5. Error curves based on different algorithms.

models in the PV power forecasting system, which can be calculated by using the following equation:

$$\mathcal{E}_{APE} = \frac{|Y_r - Y_e|}{Y_r} \times 100\% \quad (4)$$

$$\mathcal{E}_{MAPE} = \frac{1}{n} \sum_{i=1}^n \mathcal{E}_{APE} \quad (5)$$

Table 1 shows the forecasting results of PV generation by the SVM, LSSVM, and FOALSSVM algorithms in 15 minutes, respectively. Among these, the MAPE of short-term PV power forecasting based on FOALSSVM is 6.32%, while the values based on SVM and LSSVM are 8.93% and 7.67%, respectively. Figure 4 gives the forecasting results with the SVM, LSSVM, and FOALSSVM algorithms. Figure 5 describes the error analysis of the three forecasting algorithms.

From the forecasting results, we can arrive at the following conclusions:

1. It can be clearly seen that all the three forecasting algorithms capture the output trends of the PV generation, but the performance of the FOALSSVM algorithm is better than the others.
2. From 6 to 8 o'clock in the morning, the forecasting errors are relatively larger. Because

humidity has an effect on the PV power generation system, the curve of output power is unstable. However, there is an obvious correlation between the human body amenity and humidity, which causes the good forecasting performance by the FOALSSVM in this time quantum.

3. In the afternoon, the PV generation is covered by a part of cloud, which leads the output power of PV generation in high volatility. Therefore, there exist larger deviations between the forecasting results and the actual output.

Generally speaking, the proposed human body amenity and FOALSSVM algorithm can narrow the deviation between the forecasting results and the actual values, and it outperforms the SVM and LSSVM algorithms in the short-term PV power forecasting. When compared with the LSSVM algorithm, the FOALSSVM which uses the FOA to select the parameter values of the LSSVM can improve the forecasting accuracy effectively.

5 CONCLUSIONS

The LSSVM algorithm has been widely used in a variety of fields, but it is rarely found that the LSSVM has been applied to the PV power forecasting. In this paper, a hybrid model based on the human body amenity and LSSVM with FOA is proposed for the short-term PV power forecasting. The human body amenity can effectively use the various meteorological factors, reduce the input of the network, and improve the precision of forecasting. Meanwhile, the FOALSSVM model uses the FOA to automatically select the appropriate parameter values of the LSSVM in order to improve the forecasting accuracy. For comparison, another two models such as SVM and LSSVM are selected. The simulating results show that the FOA can select the appropriate parameter values of the LSSVM model, which could effectually improve the forecasting accuracy of PV output power. When compared with the SVM and LSSVM algorithm, the values of APE and MAPE are obviously smaller than that of other two algorithms.

ABSTRACT: Cloud manufacturing is a new manufacturing paradigm developed from existing advanced manufacturing models and enterprise information technologies under the support of Internet of Things (IoT) such as Radio Frequency Identification (RFID) technology. This paper presents an RFID-enabled Complex Event Processing (CEP) model for the Cloud manufacturing shopfloor by defining the basic and complex event to describe the typical operations and behaviors in the Cloud manufacturing environment. Firstly, RFID technology is used for creating the Cloud manufacturing shopfloors where typical events could be presented by CEP. Secondly, by defining different events, this paper categorizes various management such as workers, materials etc, so that the CEP model could be used for demonstrating various typical production logic. Two demonstrative cases are given in this paper for displaying the implementation of the proposed model in an RFID-enabled Cloud manufacturing shopfloor.

1 INTRODUCTION

Cloud manufacturing is a new manufacturing paradigm developed from existing advanced manufacturing models and enterprise information technologies under the support of cloud computing, Internet of Things (IoT), virtualization and service-oriented technologies, and advanced computing technologies so as to transform manufacturing resources and capabilities into various services, which can be managed and operated in an intelligent and unified way to enable the full sharing and circulating of them (Xu, 2012). Cloud manufacturing can provide safe and reliable, high quality, cheap and on-demand manufacturing ser-

vices for the whole lifecycle of manufacturing that refers to big manufacturing that includes the whole lifecycle of a product (e.g. design, simulation, production, test, and maintenance) (Tao, 2011).

The Cloud manufacturing shopfloors play a very important role in supporting the sharing of various resources and capacities (Zhong, 2013). Figure 1 shows a typical Cloud manufacturing shopfloor production. In this environment, traditional resources are converted into Smart Manufacturing Objects (SMOs) by using the Radio Frequency Identification (RFID) technology (Qu, 2012; Dai, 2012; Zhong, 2015). However, there are large number of complexities and varieties such as differences of workers' skill, large quantities of

Figure 1. An RFID-enabled cloud manufacturing shopfloor.

materials, machine deviations, technical challenges, and the control of various SMOs (Wang, 2012).

Within the RFID-enabled Cloud manufacturing shopfloors, great myriad of events will occur. An event is an interaction of two SMOs such as a reading operation. So that all the predefined events will be constructed by large number of SMOs' basic data. How to present the events is an practical question with great significance in Cloud manufacturing.

Complex Event Processing (CEP) is a method of tracking and analyzing streams of data about things that happen (events) and deriving a conclusion from them that combines data from multiple sources to infer events or patterns that suggest more complicated circumstances (Zhang, 2009). CEP is able to identify meaningful events and respond to them as quickly as possible (Zhong, 2008). Therefore, this paper introduces an RFID-enabled CEP model for the Cloud manufacturing shopfloor according to the production logic from real-life case. This model includes the RFID processing mechanism and models to deal with large number of events happened from SMOs. A logic CEP presentation is then proposed to reflect the requirements from different end-users.

The rest of this paper is organized as follows. Section 2 introduces the basic idea of CEP. Section 3 presents an RFID-enabled CEP model. Section 4 illustrates the implementation of this model. Section 5 concludes this paper by highlighting our contributions and future research directions.

2 COMPLEX EVENT PROCESSING (CEP)

The CEP has roots in discrete event simulation, the active database area and some programming languages (Zhong, 2015). The activity in the industry was preceded by a wave of research projects in the 1990s and the first project that paved the way to a generic CEP language and execution model was the Rapide project in Stanford University, which is

directed by David Luckham (Lan, 2015). In parallel there have been two other research projects: Infospheres in California Institute of Technology, directed by K. Mani Chandy, and Apama in University of Cambridge directed by John Bates (Huang, 2013). The commercial products were dependents of the concepts developed in these and some later research projects and community efforts started in a series of event processing symposiums organized by the Event Processing Technical Society, and later by the ACM DEBS conference series. One of the community efforts was to produce the event processing manifesto (Tao, 2014; Zhang, 2014; Zhong, 2014).

Based on the RFID-enabled Cloud manufacturing shopfloor production mode, the CEP in this paper is constructed as shown in Figure 2. From the bottom to the top, there are several layers such as hardware abstraction, event and data management, and application abstract. Each layer has different functionalities to enable the CEP in the Cloud manufacturing shopfloor work well. Hardware Abstraction Layer (HAL) is used for connecting the physical environment and abstract components. HAL manages the RFID readers, hardware connections and deletes the duplicated or error RFID data. Additionally, it provides the standard RFID data for the Event And Data Management Layer (EDML).

EDML is responsible for analyzing and processing the RFID data from HAL. It picks up the basic event from enormous data and interprets them so as to providing more rich information to

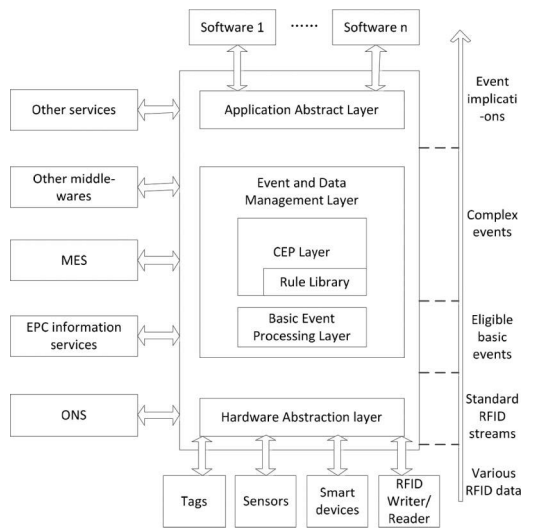

Figure 2. CEP mechanism for RFID-enabled Cloud manufacturing shopfloor.

period requirements	$X < \text{Min} \{ \text{time}1, \text{time}2, \dots, \text{time} n \} < \text{Max} \{ \text{time}1, \text{time} 2, \dots, \text{time} n \} < Y$	Basic events must occur within a certain period of time.	To complete a manufacturing order in a prescribed period of time.
time sorting constraint	$\text{time} 1 < \text{time} 2 < \dots < \text{time} n$	Basic events must occur in a particular order.	There is a time sequence relation in the process of a product.
enumeration	Count $\{ e1, e2, \dots, en \}$	Calculate the number of tags.	Statistics on the number of components of processing equipment.

the upper level like Application Abstract Layer (AAL). There are two sub-layers: basic event processing layer and CEP layer. The previous layer is responsible for sending the standard RFID data to Object Name System (ONS) so as to get the real-time status of the SMOs. The latter is for processing the obtained basic events according to the time and production logic.

AAL mainly focuses on various applications in distributed environments so as to providing reliable data communications. Moreover, the interpreted events could be issued to different parties so that they can be widely used.

3 AN RFID-ENABLED CEP MODEL

Basic event is the message presenter which carries the united information. It could be presented by a four tuple set $e = \langle \text{terminal Id, antenna Id, tag Id, time} \rangle$. Where, terminal Id is the reader ID which indicates the readers' type so as to differentiate each device, antenna Id is the label of each antenna. Each reader may have several antennas. Tag Id presents a tag which contains the bound objects' information so as to differentiate the SMOs. Time is the time stamp recording the event. Basic event includes the worker event, material event, and machine event.

Complex event is the meaningful messenger which is consisted by basic events. $E(e1, e2, e3, \dots, en) = \{ \text{operator} (\text{terminal Id}1, \text{terminal Id}2, \dots, \text{terminal Id} n), \text{operator} (\text{antenna Id}1, \text{antenna Id}2, \dots, \text{antenna Id}n), \text{operator} (\text{tag Id}1, \text{tag Id}2, \dots, \text{tag Id}n), \text{operator} (\text{time} 1, \text{time} 2, \dots, \text{time} n) \}$. Operator is

an event code. Thus, based on the definition, the CEP model for RFID-enabled Cloud manufacturing shopfloor will use the following logic (as show in Table 1) to present various events in the production environment.

4 IMPLEMENTATION

This model is used in a typical RFID-enabled Cloud manufacturing shopfloor which is equipped with some digital devices for creating an intelligent environment. Different users and departments are defined by the CEP following the Table 2.

Based on Table 2, various CEP could be used for guiding the operations. Figure. 3 demonstrates a typical implementation of this model using a demonstrative case. An operator will enter into the RFID-enabled Cloud manufacturing shopfloor. He/She will be sensed by the antenna 1-4. Assume the basic events are $e1 \sim e4$. Thus, we can get the entry and exit complex events:

$$E1 = (e1 | e4) \& (e2 | e3), \text{Max} \{ \text{time} 1, \text{time} 4 \} < \text{Min} \{ \text{time} 2, \text{time} 3 \}$$

$$E0 = (e1 | e4) \& (e2 | e3), \text{Min} \{ \text{time} 1, \text{time} 4 \} > \text{Max} \{ \text{time} 2, \text{time} 3 \}$$

Another implementation as shown in Figure 4 which demonstrates an inspector carries an RFID mobile PDA to do the quality check from three machine operators. Assume that the no. i product is sensed by the PDA which is an event ei . Then the complex event is:

$$E = e1 \& e2 \& \dots ei \& \dots \& en, \text{time} e1 < \text{Min} \{ \text{time} e2 \dots \text{time} en \}$$

Table 2. RFID CEP for different management.

Task	CEP class	Task description	Event model
Material management	Material receiving events	To monitor and control the use of material	$E = e^1 \& e^2 \dots \& e^i \dots \& e^n$, time $e^1 < \text{Min}\{\text{time } e^2, \dots, \text{time } e^i, \dots, \text{time } e^n\}$. $e^i = e1 ei2\dots eij\dots ein$. eij represents the basic event that tag i is identified by the j antenna of the same RFID reader.
	Material flowing events	To monitor the flow of material	$E = (e11 e14) \& (e12 e13)$, $\text{Max}\{\text{time } e11, \text{time } e14\} < \text{Min}\{\text{time } e12, \text{time } e13\}$. $e11$ and $e14$ represent that the same tag is identified by two different antennas, both at one end of the shop floor aisle, of the same RFID reader. On the contrary, the rest two basic events are both identified by different antennas at the other end
Production management	Production schedule control events	To monitor the processing status of all parts.	$E = e^1 \& e^2 \dots \& e^i \dots \& e^n$, time $e^1 < \text{time } e^2 \dots < \text{time } e^i \dots < \text{time } e^n$. $e^i = e1 ei2\dots eij\dots ein$. eij represents the basic event that tag i is identified by the j antenna of the same RFID reader.
	Assembly events	To monitor the assembly of products	$E = e^1 \& e^2 \dots \& e^i \dots \& e^n$, time $e^1 < \text{Min}\{\text{time } e^2, \dots, \text{time } e^i, \dots, \text{time } e^n\}$. $e^i = e1 ei2\dots eij\dots ein$. eij represents the basic event that tag i is identified by the j antenna of the same RFID reader.
	Production efficiency events	To monitor the production capacity and equipment processing capacity	$E = \text{Count}\{e^1, e^2, e^3, \dots, e^n\}$. $e^i = e1 ei2\dots eij\dots ein$. eij represents the basic event that tag i is identified by the j antenna of the same RFID reader.
	Product quality events	To monitor inspect work and completion acceptance	$E = e^1 \& e^2 \dots \& e^i \dots \& e^n$, time $e^1 < \text{Min}\{\text{time } e^2, \dots, \text{time } e^i, \dots, \text{time } e^n\}$. $e^i = e1 ei2\dots eij\dots ein$. eij represents the basic event that tag i is identified by the j antenna of the same RFID reader.
Staff management	Staff attendance events	To monitor staff attendance and staff access to production areas	$E = (e11 e14) \& (e12 e13)$, $\text{Max}\{\text{time } e11, \text{time } e14\} < \text{Min}\{\text{time } e12, \text{time } e13\}$. $e11$ and $e14$ represent that the same tag is identified by two different antennas, both at one end of the shop floor aisle, of the same RFID reader. On the contrary, the rest two basic events are both identified by the different antennas at the other end.
Device management	Device management events	Equipment working status and machining quantity	$E = e11 e12\dots e1j\dots e1n$, $X < \text{Min}\{\text{time } e11, \text{time } e12, \dots, \text{time } e1j, \dots, \text{time } e1n\} < \text{Max}\{\text{time } e11, \text{time } e12, \dots, \text{time } e1j, \dots, \text{time } e1n\} < Y$. $e1j$ represents the basic event that devices tag is identified by the j antenna of the same RFID reader.

5 CONCLUSIONS

This paper introduces an RFID-enabled CEP model for the Cloud manufacturing shopfloor. This model uses basic and complex event to present the typical operations and behaviors in the Cloud manufacturing environment. There are several contributions or innovations in this research. Firstly, RFID technology is used for creating the Cloud manufacturing shopfloors where typical events could be presented by CEP concept. Secondly, by defining different events, this paper categorizes various management such as workers, materials etc, so that the CEP model can be used for demonstrating various typical production logic.

Future research will be carried out as follows. First of all, this approach will be validated by using real-life data to present the real-life operations and logics in the Cloud manufacturing shopfloors. Secondly, more theoretical aspects will be focused in the near future to enhance the feasibility and practicality of the proposed CEP model. Finally, a

prototype system will be worked out by using the model to support different visibility or traceability of various materials or SMOs.

Optimization of extraction of polysaccharides from mulberries by using high-intensity Pulsed Electric Fields

Shenglang Jin

College of Tourism, Huangshan University, Huangshan, China

ABSTRACT: The high intensity Pulsed Electric Fields (PEFs) was used to extract polysaccharides from mulberries. The factors affecting the extraction yield, such as electrical field intensity, extracting temperature, pulse number, and the ratio of the material to liquid, were analyzed under specific conditions and the optimal extracting parameters were obtained as follows: the electrical field intensity is 40 kV/cm, the extracting temperature is 80°C, pulse number is 10, and the ratio of the material to liquid is 1:30. Under these conditions, the extraction yield of total polysaccharides was 82%. The PEF and conventional extraction method were compared. The extraction yield of polysaccharides by using the conventional method was 54%, and the microwave-assisted extraction yield of polysaccharides was 67%. The study demonstrates that the PEF is a reliable and great efficiency tool for the fast extraction of polysaccharides from mulberries. Extraction of these compounds from mulberries is a crucial step for use of these compounds in the food. The PEF-assisted extraction by pressing of polysaccharides from fresh mulberry stands as an economical and environmentally friendly alternative to conventional extraction methods, which require the product to be dried, use large amounts of organic solvents, and need long extraction times.

1 INTRODUCTION

The mulberry tree, a typical plant of genus *Morus*, has been widely cultivated for its leaves that serve as an indispensable food for silkworm. There are about 3,000 accessions of mulberry germplasm resources in China. Of which, over 60 accessions can be used as the mulberry fruit (Li, 2005). Some varieties introduced from mid-Asia have white fruit. Mulberry has been used as medicine from ancient times. The root bark and mulberry leaves have been used as herbal medicine (Machii, 1989). The mulberry fruit contains polysaccharides, organic acids, free amino acids, vitamins, micronutrients and other components (Elmaci, 2002).

Polysaccharides play a substantial role in the food industry, especially as the health ingredient in healthy food (Li, 2006). Polysaccharides have been proposed as the first biopolymers formed on Earth. These are classified on the basis of their main monosaccharide components and the sequences and linkages between them, as well as the anomeric configuration of linkages, the ring size (furanose or pyranose), the absolute configuration (D- or L-), and any other substituents present. Later work has shown that polysaccharides are involved in a number of important biochemical functions, such as cell-cell interaction and communication, the attachment for infectious bacteria,

viruses, toxins, and hormones. Some researchers now focus on the polysaccharides of mulberries. Generally, traditional extraction methods are very time-consuming and require large quantities of solvents (Chen, 2011). Consequently, the demand is increasing for extraction techniques that improve the yield, shorten the extraction time, and reduce the use of organic solvents. Pulsed Electric Field electro-technology (PEF) is an emerging technology in the field of food preservation. PEF can be widely used to analyze the functional components of natural products, with advantages of non-thermal, fast, efficient, low-power, and low-pollution. PEF-assisted extraction has shown promise as a technology for obtaining valuable compounds from soft vegetal materials.

Up to now, however, the extraction of polysaccharides from mulberries by PEF-assisted extraction technology has not been reported. In this study, the influence of the different factors on the extracting yield was investigated.

2 MATERIALS AND METHODS

2.1 *Materials*

The ripe mulberry fruits were sampled in Huangshan County, Anhui Province, China.

After sampling, the fruits were immediately carried to the laboratory, placed in plastic bags, and stored below 4°C in a refrigerator. Their size was about 1 cm long and their color was purple.

2.2 Reagents and chemicals

The reference standard of rutin was purchased from the National Institute for Control of Pharmaceutical and Biological Products (purity $\geq 98\%$). Ethanol, sodium nitrite, aluminum nitrate, sodium hydroxide, and other reagents were obtained from Tianjin Haiguang Chemical Co., Ltd., respectively. All solvents were distilled prior to use.

2.3 Instruments and equipments

An AEU-210 electronic analytical balance (Xiangyi Balance Instrument & Equipment Co., Ltd.), FW100 high-speed universal grinder (Tianjin City Taisite Instrument Co., Ltd.), SHZ-D (III) circulating water vacuum pump (Gongyi Yingyu Yuhua Instrument Factory), LD5-2A centrifuge (Beijing Medical Centrifuge Factory), and GZX-9140M E digital blast oven (Shanghai Xunda Industrial) were employed in this research.

2.4 Drawing standard curve

Suck the control solutions 0, 0.1, 0.2, 0.3, 0.4, and 0.5 mL precisely and place them in 10 mL-centrifuge tubes, respectively. The method of anthrone is adopted and the absorbance is detected ($K = 620 \text{ nm}$). Construct the standard curve by plotting the mean absorbance obtained from each standard against its concentration with absorbance value on the horizontal (y) and the vertical (x) axis. Calculate the regression equation of the standard curve:

$$y = 6.4609x - 0.0024, r = 0.9997 \quad (1)$$

2.5 Statistical analysis

Results reported in this paper are the average of at least two measurements found in two independent experiments. To determine the influence of the electric field strength, the results were analyzed by multiple regressions starting from a second-order polynomial model using the software Statgraphics Plus 5.1 (Statistical Graphics Corporation, USA). A backward regression procedure was used to determine the parameters of the models. This procedure systematically removed the effects that are not significantly associated ($P > 0.05$) with the response until a model with only a significant effect was obtained.

3 RESULT AND DISCUSSION

3.1 Characterization of PEF-induced damage in the cells of mulberries

Z_p was used to select the optimum PEF treatment conditions to permeabilize the mulberry cells. This index, which is based on the changes of the conductivity of intact and PEF-permeabilized tissue, has been used previously for this purpose in diverse vegetable tissues. Fig. 2 shows the influence of PEF treatment times on the Z_p of the mulberry tissue at different electric field strengths. The increase in the electric field strength and treatment time results in an increment of the Z_p to the highest value of 0.33 for the most intense treatment conditions tested. Independent of the applied electric field strength, the Z_p value increased significantly with an increase in the treatment time to approximately 60 μs . Above these values, the increment of the treatment time scarcely affected the Z_p value. The general trend of the influence of the electric field strength and treatment time on the Z_p value observed in this research is in good agreement with previously reported data for other vegetable tissues, such as potatoes, apples, and onions. However, in these tissues higher values (>0.8) for the Z_p were obtained even by using lower electric field strengths ($\leq 30 \text{ kV/cm}$). Therefore, the results obtained in this investigation seem to indicate that the permeabilization of mulberry tissue cells

Figure 1. Influence of the electric field strength and treatment time on the cell disintegration index (Z_p) of mulberries.

Figure 2. Relationship between the cell disintegration index (Z_p) of mulberries treated by PEF and liquid release by centrifugation.

requires applying more intense PEF treatments than those for other vegetable tissues.

Due to the low disintegration index determined for the mulberry tissue even at electric field strengths as high as 70 kV/cm, the other experimental method based on the release of the intracellular liquid from the PEF-treated tissue was used. The increment of the liquid leakage in the PEF-treated samples dependent on the treatment intensity can be interpreted as a consequence of the PEF-cell permeabilization. Quantification of the liquid released from a PEF-treated material subjected to a given centrifugation has been proven to be useful in the testing cell membrane's permeability. Fig. 2 shows that a solid correlation ($r = 0.97$) was obtained between the Z_p and the quantity of the liquid released by centrifugation when the same treatment conditions (electric field strength and treatment time) were applied. This good correlation indicates that the Z_p index measuring the degree of cell permeabilization over a short period of time is a suitable procedure to select the PEF treatment conditions that induce the highest permeabilization of mulberry cells.

3.2 Effect of electric field intensity on the extraction yield

The effect of different electric field intensities on the extraction yield was detected at a pulse number of 4, at the ratio of the material to liquid (ratio of mulberry to absolute alcohol) of 1:10, and at a temperature of 40°C. The extraction yield was the highest at an electric field intensity of 40 kV/cm and then decreased appreciably with an increase in the electric field intensity (Fig. 3). This is due to the fact that the phenomenon of cavities increases along with the enhancement of the electric field intensity, which accelerates the polysaccharides in mulberries. With an increase in the electric field intensity, from the micro-perspective, the potential difference between the inside and outside of the cell membrane became larger, and the electroporation of the cell membrane occurred. A higher electric field intensity could cause more solvent to enter the cell membrane and permeate the cell

Figure 3. Influence of the electric field intensity on the extraction yield of polysaccharides from mulberries.

membrane. Thus, increasing the electric field intensity could increase the extraction yield. However, when the electric field intensity increased from 20 to 40 kV/cm, the extraction yield of polysaccharides decreased. The reason might be that some of polysaccharides were decomposed in higher-intensity electric fields.

3.3 Effect of pulse number on the extraction yield

The effect of different pulse numbers on the extraction yield was detected at an electric field intensity of 30 kV/cm, at a ratio of the material to liquid of 1:10, and at a temperature of 40°C. The result showed that extraction yield increased with an increase of the pulse number, but after a certain time when osmotic-pressure of the cell reached a balance, the extraction yield maintained invariableness (Fig. 4). Therefore, pulse number of 8 was chosen in the following experiments.

3.4 Effect of the ratio of material to liquid on the extraction yield

The effect of different ratios of the material to liquid on the extraction yield was detected at an electric field intensity of 30 kV/cm, pulse number of 4, and temperature of 40°C. The extraction yield increased with an increase in the ratio of the material to liquid (Fig. 5). The extraction yield at the ratio of the material to liquid of 1:40 was 6.8% higher than that at a ratio of 1:30. The reasons might be that, at lower material to liquid ratios, the concentration of polysaccharides in the solution would be low, and the polysaccharides' exchange between the solid and solvent had reached equilibrium. Since a big ratio of the mulberry to absolute

Figure 5. Influence of the material liquid on the extraction yield of polysaccharides from mulberries.

alcohol might increase the difficulty in reclaiming alcohol, the ratio of the material to liquid at 1:40 is suggested, according to the experimental results.

3.5 Effect of temperature on the extraction yield

The effect of different temperatures on the extraction yield was investigated at an electric field intensity of 30 kV/cm, at a pulse number of 4, and at a ratio of material and liquid of 1:10. The extraction yield increased with an increase of temperature (Fig. 6). The yield of extraction at 80°C increased by 4.2% when compared with that at 70°C. The result showed that it is not necessary to maintain higher temperature conditions during the extraction process. Too high temperatures will be a disadvantage for the stability of polysaccharides from mulberry, and thus the extraction temperature should be maintained under 80°C.

3.6 Synthetic factors

On the basis of experiment and analysis of single factor, electric field intensity, temperature, pulse number, and the ratio of the material to liquid were selected separately to set up three levels of experiments (Table 1), and the influence of each factor on the extraction yield was observed. Design and results of orthogonal experiments are shown in Table 2.

Figure 6. Influence of temperature on the extraction yield of polysaccharides from mulberries.

Table 1. Factors and levels of orthogonal experiments.

Levels	Factors			
	Temperature (°C)	Pulse number	Ratio of the material to liquid (g:mL)	Electrical field intensity (kV/cm)
1	60	6	1:20	35
2	70	8	1:30	40
3	80	10	1:40	45

Table 2. The results of orthogonal experiments.

No. of test	Factors				Yield/%
	A	Br	C	D	
1	1	1	1	1	47
2	1	2	2	2	53
3	1	3	3	3	49
4	2	1	2	3	56
5	2	2	3	1	45
6	2	3	1	2	65
7	3	1	3	2	49
8	3	2	1	3	58
9	3	3	2	1	70
K ₁	49.667	50.667	56.667	54.000	
K ₂	55.333	52.000	59.667	55.667	
K ₃	59.000	61.333	47.667	54.333	
R	9.333	10.666	12.000	1.667	

Note: A—temperature; B—pulse number; C—the ratio of the material to liquid; D—electrical field intensity.

Table 3. ANOVA analysis results.

Source of variance	SS	F	F _a	Significance
A	132.667	28.427	28.427	*
B	202.667	43.426	43.426	*
C	234.000	50.139	50.139	*
D	4.667	1.000	1.000	
Error	4.67			

Note: A—temperature; B—pulse number; C—the ratio of the material to liquid; D—electrical field intensity. All freedom degrees are equal to 2, $\alpha = 0.05$. * represents significant difference.

From Table 2, we can draw a conclusion that the order of influence of different parameters on the extraction yield is as follows: the ratio of the material to liquid > pulse number > temperature > electric field intensity. The optimum condition is A₃B₃C₂D₂, which means that the extracting temperature is 80°C, pulse number is 10, the ratio of the material to liquid is 1:30, and the electric field intensity is 40 kV/cm. Variance analysis showed that extracting temperature, pulse number, and the ratio of the material to liquid also had remarkable influences on the extraction yield of polysaccharides from mulberries (Table 3). This was consistent with the results of the single factor test, indicating that the optimized extraction conditions were reliable. The verification experiment showed that under the optimal conditions, the extraction yield of polysaccharides from mulberries can reach up to 82%.

3.7 Comparison of PEF and the conventional extraction method

The yield of PEF-assisted extraction was higher than the conventional extraction method. Under the same experimental conditions (80°C, material-solvent ratio of 1:30) as well as the same filtering, concentration, and determination procedures, the extraction yield of flavonoids was 54%, and the microwave-assisted extraction yield of flavonoids was 67%.

4 DISCUSSIONS

PEF technology has been applied widely in the extraction of effective components of many materials. Some experiments have been carried out to develop the PEF extraction method. PEF extraction has been regarded as a fast, reliable, and inexpensive technique, and it is more applicable in the extraction of materials than the conventional techniques of extraction. Therefore, materials would produce huge energy by themselves and accelerate chemical reactions. Extracting the active materials from natural products by PEF-assisted extraction technology had the advantages of high extraction efficiency, strong selectivity, good repeatability, little time consumption, few solvents, low energy consumption, environmental benefits, and so on. Therefore, PEF-assisted extraction is expected to offer a new way for the production and analyses of the plant extractions and the modernization of pharmaceutical engineering.

Our study demonstrates that the PEF is a reliable and greatly efficient tool for the fast extraction of polysaccharides from mulberries, and the

optimized PEF-assisted extraction parameters are as follows: extracting temperature of 80°C, pulse number of 10, the ratio of the material to liquid of 1:30, and the electrical field intensity of 40 kV/cm. The highest extraction yield is about 82%.

Stress analysis of the interference fit in helical gear transmission

Tao Zhao

Zhonghuan Information College Tianjin University of Technology, Tianjin, China

ABSTRACT: The material mechanics method is important for structure analysis and for reducing the volume and weight of the driving parts in gear transmission. In this paper, a mathematical model is presented for the calculation and analysis of the interference fit joint. The formulation for the gear and shaft are provided in the paper. The calculation includes two aspects: first, calculating the contact stress in the matching surface and the minimum interference required under a known load; second, calculating the maximum allowable interference for the connecting parts in which no deformation or rupture occur. This method may also be applied to other interference fit joints.

1 INTRODUCTION

The interference fit joint, which is also known as the tight fit connector, uses the interference fit between the parts to achieve the connection result. Stress analysis is a commonly used research method for the preliminary design of the structure size. Because the assembly interference quantity between the gear and shaft directly affects the working performance of gear transmission, a precisely mathematical model is important.

Many analytical techniques have been proposed and successfully applied in the interference fit joint, for instance, the analysis of the preload and magnitude of the interference fit joint, the retting analysis for the relative sliding mode and stress distribution in the shaft and thick wall cylinder model.

The goal of this paper is to present a mathematical model that is aimed at achieving the computation of the amount of interference. The actual installation interference should be between the minimum interference and the maximum. The damage reason of the pinion is obtained by theoretical calculation, and the analysis validation is conducted by the finite element analysis software ANSYS.

2 THEORETICAL ANALYSIS OF INTERFERENCE FIT

2.1 The interference fit joint analysis

The interference fit is a way to realize the tight joint through the interference between enveloping parts (hole) and enveloped parts (shaft). It is mainly used for assembling hole and shaft parts

tightly to pass the axial force or torque. After being assembled, a surface pressure is created between the enveloping parts and enveloped parts due to the elastic deformation of the material. Work is dependent on the pressure produced by the friction to transmit torque, axial force, or both of the two complex loads. As a result, only if the contacted pressure on the surface of the interference fit joint is precisely calculated, the allowable load will be accurately determined. In this article, gear and shaft are used as interference fit joints. Figure 1 describes the geometric model of the interference fit of helical gears and shaft, and the theoretical model is simplified as a thick wall cylinder model.

The enveloped parts with an inside diameter of d_i is pushed into an enveloping part with an outside diameter of d_o . Nominal diameters of the hole and shaft are within their tolerance zone. The difference between the two parts is the magnitude of interference δ , and the coupled diameter value is d_f .

Figure 1. Schematic of the geometric model for the interference fit.

Figure 2. Schematic of the thick wall cylinder model.

Figure 3. Schematic of the enveloping parts and enveloped parts.

As is shown in Figure 3, the combination of compaction pressure will be produced in the interface that forms the interference fit fastening because of the magnitude of interference δ . When the connection sustains an axial force or torque, the frictional resistance and the frictional torque are generated for transmitting the external load. The pressure P_f of the joint surface is not only related to the extruding magnitude of interference δ and material property (elasticity modulus E and Poisson's ratio μ), but also with relation to the physical dimension (the coupled diameter d_f and copulate length L_f), structural dimension (inside diameter d_i of the enveloped parts and outside diameter d_a of enveloping parts).

2.2 Computation method of the interference fit

Calculate the former model with the theory of mechanics of materials. The elasticity modulus E_a and Poisson's ratio μ_a are calculated for the enveloping parts, the elasticity modulus E_i and Poisson's ratio μ_i are calculated for the enveloped parts.

The diameter variable quantity of the enveloping parts e_a is given as follows:

$$e_a = \frac{p_f d_f}{E_a} \left(\frac{d_a^2 + d_f^2}{d_a^2 - d_f^2} + \mu_a \right) \quad (1)$$

The diameter variable quantity of the enveloped parts e_i is given as follows:

$$e_i = \frac{p_f d_f}{E_i} \left(\frac{d_f^2 + d_i^2}{d_f^2 - d_i^2} - \mu_i \right) \quad (2)$$

The effective magnitude of interference δ is given as follows:

$$\delta = e_a + e_i \quad (3)$$

The minimum pressure of the enveloping parts for the transmitting load $p_{f \min}$, is given as follows:

$$p_{f \min} = \frac{\left[(2T / d_f)^2 + F^2 \right]^{1/2}}{\pi d_f L_f} \quad (4)$$

In the equation, the transmitting torque is T , the transmitting axial force is F , and the friction coefficient is f .

The minimum diameter variable quantity of the enveloping parts $e_{a \min}$ is given as follows:

$$e_{a \min} = \frac{p_{f \min} d_f}{E_a} \left(\frac{d_a^2 + d_f^2}{d_a^2 - d_f^2} + \mu_a \right) \quad (5)$$

The minimum diameter variable quantity of the enveloped parts $e_{i \min}$ is given as follows:

$$e_{i \min} = \frac{p_{f \min} d_f}{E_i} \left(\frac{d_f^2 + d_i^2}{d_f^2 - d_i^2} - \mu_i \right) \quad (6)$$

The minimum effective magnitude of the interference for transmitting load $\delta_{e \min}$ is given as follows:

$$\delta_{e \min} = e_{a \min} + e_{i \min} \quad (7)$$

According to the analysis of the thick wall cylinder model by using the mechanics of materials, Figure 4 describes the distribution of stress and the relationship between the magnitude of interference δ and the pressure of joint surface P_f .

The interference of p_f can be calculated from the following equation:

$$p_f = \frac{\delta}{d_f} / \left[\frac{1}{E_a} \left(\frac{d_a^2 + d_f^2}{d_a^2 - d_f^2} + \mu_a \right) + \frac{1}{E_i} \left(\frac{d_f^2 + d_i^2}{d_f^2 - d_i^2} - \mu_i \right) \right] \quad (8)$$

Figure 4. Schematic of the stress distribution of the interference fit joint.

Table 1. Geometrical parameters of helical gear transmission.

Name	Symbol	Pinion	Main gear
Number of teeth	z	21	101
Tooth width	b	169	167
Normal module	m_n	9	9
Normal pressure angle	α_n	20	20
Helical angle	β	8	8
Reference diameter	d	191	918
Contact ratio	ε	2.33	2.33

3 NUMERICAL EXAMPLE

The calculation of the numerical example is based on the above-mentioned mathematical model. Geometrical parameters of helical gear transmission are shown in Table 1. The basic parameters and machine settings of the example are adopted from the literature. The maximum stress of the gear hub is $\sigma_k = 551.85 \text{ Mpa}$, which exceeds the yield limit of the pinion that is $\sigma_s = 500 \text{ Mpa}$. And so, the gear wheel may undergo a fracture when it is working.

4 FINITE ELEMENT ANALYSIS

Authenticate the calculation of the model by using finite element analysis software ANSYS. Fig. 5 and 6 show the installation of the property of the

Figure 5. Stress direction of the pinion and shaft.

Figure 6. Stress direction of the mesh surface of the gear.

Figure 7. Graph showing the contact stress distribution.

contact surface such that normal penalty stiffness is 0.1; friction coefficient is 0.125; and the contact surface offset is 0.18. Fig. 7 imposed the boundary conditions and the load.

It can be seen from Fig. 8 that 2–3 teeth participate in the gear mesh of the transmission, coinciding with the operation circumstance. The stress

Figure 8. Results of finite element analysis.

of the root is 540 MPa. Exceeding the yield limit of the pinion may create the tooth root fracture failure.

5 OPTIMIZATION DESIGN OF THE DRIVE SHAFT BASED ON RELIABILITY

In order to avoid the fracture in the root of the helical gear tooth, the reliability design method is adopted in the structure optimization design. There are two ways to improve the structure: increase the root circle diameter of the helical gear tooth, or reduce the assembly interference. Because there is a corresponding function relationship between the root circle diameter and assembly limit interference quantity; any single change in variables affect the value of another, and so the use of the amount of interference δ and root circle diameter d_f of small gear tooth as design variables.

$$X = [x_1, x_2]^T = [\delta, d_f]^T \quad (9)$$

Failure modes of the interference fit including the relative slide in the mating surfaces of the shaft and pinion, plastic deformation of the pinion, or plastic deformation of the shaft. These are random events. As long as one occurs, it will lead to the abnormal working of the entire system. With series relationship of all, the reliability of the entire system is given as follows:

$$R(X) = R_1(X) \times R_2(X) \times R_3(X) \quad (10)$$

The goal is to make the reliability of the interference fit system maximum, and the objective function is given as follows:

$$\min f(x) = 1 - R_1(X) \times R_2(X) \times R_3(X) \quad (11)$$

If the three random events are assumed to be normally distributed, we can come to the conclusion that

$$R_1(X) = \Phi \left[\frac{(\bar{\delta} - \bar{\delta}_{\min}) / (C_{v\delta} \sqrt{\bar{\delta}^2 + \bar{\delta}_{\min}^2})}{\frac{x_1 - f_1(x_2)}{0.1\sqrt{x_1^2 + f_1^2(x_2)}}} \right] \quad (12)$$

$$R_2(X) = \Phi \left[\frac{(\bar{\delta}_{e\max} - \bar{\delta}) / (C_{v\delta} \sqrt{\bar{\delta}_{e\max}^2 + \bar{\delta}^2})}{\frac{f_2(x_2) - x_1}{0.08\sqrt{f_2^2(x_2) + x_1^2}}} \right] \quad (13)$$

$$R_3(X) = \Phi \left[\frac{(\bar{\delta}_{ei\max} - \bar{\delta}) / (C_{vi} \sqrt{\bar{\delta}_{ei\max}^2 + \bar{\delta}^2})}{\frac{f_3(x_2) - x_1}{0.08\sqrt{f_3^2(x_2) + x_1^2}}} \right] \quad (14)$$

Φ is the inverse function of the standard normal distribution function, $\bar{\delta}$, $\bar{\delta}_{\min}$ are the actual interference amount and the minimum quantity, $\bar{\delta}_{e\max}$, $\bar{\delta}_{ei\max}$ are the maximum effective interference amount of the small gear and the shaft which will not occur plastic deformation, $C_{v\delta}$, $C_{v\delta}$, C_{vi} are the variation coefficients of the yield strength gear and the shaft and the interference quantity. Given the system reliability requirements is $R = 0.9988$, according to the reliability allocation method of serial system, three random events of reliability is calculated respectively as $R_1 = 0.9997674$, $R_2 = 0.99998665$, and $R_3 = 0.9990324$. The resulting target constraint conditions are as follows:

$$G_1(X) = \bar{\delta} - \bar{\delta}_{\min} - C_{v\delta} \sqrt{\bar{\delta}^2 + \bar{\delta}_{\min}^2} \Phi^{-1}(R_1) \geq 0 \quad (15)$$

$$G_2(X) = \bar{\delta}_{e\max} - \bar{\delta} - C_{v\delta} \times \sqrt{\bar{\delta}_{e\max}^2 + \bar{\delta}^2} \times \Phi^{-1}(R_2) \geq 0 \quad (16)$$

$$G_3(X) = \bar{\delta}_{ei\max} - \bar{\delta} - C_{vi} \times \sqrt{\bar{\delta}_{ei\max}^2 + \bar{\delta}^2} \times \Phi^{-1}(R_3) \geq 0 \quad (17)$$

$$G_4(X) = d_{f\max} - d_f \geq 0 \quad (18)$$

$$G_5(X) = d_f - d_f^* \geq 0 \quad (19)$$

The objective function is given as follows:
function
 $f = \text{myfun}(x)$

$$f = 1 - \text{normcdf}((x(1) - 27.7 / (1 - x(2)^2) - 48.8) / (0.1 * (x(1)^2 + 27.7 / (1 - x(2)^2) + 48.8)^2)) \\ * \text{normcdf}((-x(1) + 575 / (3 + x(2)^4)^{0.5}) / (0.8 * (x(1)^2 + 575^2 / (3 + x(2)^4))^{0.5})) \\ * \text{normcdf}((-x(1) + 207 / (1 - x(2)^2)) / (0.08 * (x(1)^2 + (207 / (1 - x(2)^2))^2)^{0.5}))$$

The constraint conditions:

function[c,ceq] = mycon(x)

$$c = [-x(1) + 27.7 / (1 - x(2)^2) + 48.8 + 0.35 * (x(1)^2 + (27.7 / (1 - x(2)^2) + 48.8)^2)^{0.5}; \\ x(1) - 575 / (3 + x(2)^4)^{0.5} + 0.36 * (x(1)^2 + 575^2 / (3 + x(2)^4))^{0.5}; \\ x(1) - 207 / (1 - x(2)^2) + 0.248 * (x(1)^2 + (207 / (1 - x(2)^2))^2)^{0.5}; \\ 0.6865 - x(2); \\ x(2) - 0.7005];$$

ceq = [];

Call the objective function and constraint conditions

x0 = [220, 0.70];

lb = [103.24, 0.6865];

ub = [352.27, 0.7005];

options = [];

[x,fval,exitflag,output] = fmincon('myfun',x0,[],[],[],[],lb,'mycon',options)

The results:

x = 0.1875 186.7155

By using "MATLAB" software to calculate, the root circle diameter obtained is 178.8 mm. The optimization of the gear size and coupling interference quantity improves the defects of the initial design and achieve the expected purpose.

6 SUMMARY

In this paper, a mathematical model is presented for the calculation and analysis of the interference

fit joint. The theoretical analysis of the interference fit joint is captured by the formulation for the gear and shaft provided in the paper. The calculation is in accordance with the finite element analysis results. Through the optimization design, the interference fit system achieved the highest reliability. Finite element analysis was carried out on the optimization model validation, and the results show that the optimized structure can avoid the small gear tooth root fracture and meet the strength requirements. This method may also be applied to other interference fit joints.

A review of transformerless DC–DC boost converters for renewable energy sources

Jun Luo

School of Electrical and Electronic Engineering, Huazhong University of Science and Technology, Wuhan, China

ABSTRACT: The renewable energy sources and energy storage devices deliver output voltage at a range of around 12–125 VDC. Before being connected to the grid, such a low voltage level should be stepped up to a sufficient level according to different electrical network standards among countries. Boost DC–DC converters are used for the voltage adjustment, and have become the key parts in the energy system power chain as the overall performance of the system is affected by their efficiency. The major consideration in DC–DC conversion is often associated with high efficiency, reduction of stresses involving semiconductors, low cost, simplicity, and robustness of the involved topologies. In this review, we first analyze the conventional boost converter and then focus on the kinds of transformerless boost converters. Advantages and disadvantages of each boost converter topology are presented to help the designer with structure selection. A comparison and discussion of different DC–DC boost topologies are carried out across a number of parameters and presented in the end of this paper.

1 INTRODUCTION

In the last few decades, renewable energy sources like PhotoVoltaic (PV) modules, fuel cells and energy storage devices, such as super capacitors have been widely developed. However, the majority of these commonly used renewable energy sources deliver electric power at the output voltage range of 12V–125V, which cannot be directly connected to the grid for use. Typically, such low voltages are necessary to be stepped up to a voltage of around 300V–400V, varying with the different electrical network standards among countries (Abusara, 2013).

In the past, a centralized inverter was responsible for connecting several modules or other renewable energy sources into the grid. At the moment, centralized technology has been replaced. Boost DC–DC converters are now applied to adjust the voltage to a sufficient level, so that the attached cascade DC–AC inverter, which is coupled to the grid (1-or 3-phase), can be supplied (Kjaer, 2005). Therefore, the boost DC–DC converters have become the key part of a renewable energy system as the overall performance of the system is affected by their efficiency.

In applications where galvanic insulation is not a must, non-isolated DC–DC converters can be used to achieve voltage step-up or step-down, with consequent reduction of size, weight, and volume associated to the increase of efficiency because of the lack of a high-frequency transformer (Hu, 2014).

The classical or conventional DC–DC boost converter is widely employed in voltage step-up, and is also being studied in many books on power electronics (Mohan, 2007; Erickson, 2007). But for high-power applications, the boost converter is not a feasible solution because the load power is processed by using only two semiconductors, while appreciable current and/or voltage stresses exist. Particularly, in high-current applications, conduction losses lead to the significant reduction of efficiency because these increase with the square of the RMS current through the semiconductors. Although the parallelism of switches or even converters is possible, current sharing is compromised because of the intrinsic differences of the involved elements (Klimczak, 2008).

Considering the limitations of the classical boost converter, several studies have been carried out in the literature to improve key issues, such as the static gain, voltage stress across the semiconductors, efficiency, power capacity, and many other aspects of the original topology. The simultaneous search for the terms ‘DC–DC’ and ‘boost converter’ in IEEEEXPLORE® Digital Library demonstrates the relevance of this subject, revealing that more than 5000 papers have been published in conferences and journals over the last few decades.

In Session II, a topology of the conventional boost converter is presented and analyzed. And then, in Session III, some of the most popular improved transformerless DC–DC boost converters available in the literature are introduced and

classified. The classification of these differentiations is based on their topologies. Session IV gives a comparison and discussion of these different DC–DC boost converter topologies across numbers of parameters. Finally, a conclusion is drawn in Session V.

2 CONVENTIONAL DC–DC BOOST CONVERTERS

A conventional boost converter is shown in Fig. 1 (Kim, 2009), where the intrinsic series resistance of the inductor is represented by R_L . By using the volt-second balance principle and considering the operation in continuous-conduction mode, it is easy to demonstrate that the static gain G_v is given by equation (1).

$$G_v = \frac{V_o}{V_i} = \frac{1}{1-D} \cdot \frac{1}{\left(1 + \left(R_L / \left((1-D)^2 \cdot R_o\right)\right)\right)} = \frac{1}{1-D} \cdot \eta, \quad (1)$$

where V_o is the output voltage, V_i is the input voltage, R_o is the load resistance, D is the duty cycle, ranging from 0 to 1, and η is used to represent the theoretical efficiency of the boost converter.

As shown in equation (1), both static gain and efficiency depend on R_L , D , and R_o . Some interesting conclusions can be led with the analysis of equation (1). Firstly, the static voltage gain G_v theoretically is infinite when the duty cycle D reaches 1. But switch turn-on period becomes long as D increases thereby causing conduction losses to increase. The power-rating of the conventional single switch boost converter is limited to switch-rating. Secondly, if $R_L = 0$, the static gain is the same as that of an ideal boost converter and the converter is lossless as its efficiency is 100%. In practical terms, $R_L \neq 0$ and both static gain and efficiency decrease as R_L is increased. Finally, the conventional boost converter is a simple and adequate approach for applications with medium power requirements, as a significant reduction of efficiency may be caused by the equivalent series resistance of the output capacitor, reverse-recovery losses, and the rectifier diode.

Figure 1. Topology of the conventional boost converter. R_L is the equivalent resistance of the inductor.

3 IMPROVED TRANSFORMERLESS DC–DC BOOST CONVERTERS

Due to the effect of power switches, rectifier diodes, equivalent series resistance of inductors and capacitors and high voltage stresses on the power switches, conventional DC–DC boost converters are unable to provide high step-up voltage gain. In this part, some topologies of improved transformerless DC–DC boost converters are introduced.

3.1 Soft switching boost converters

In conventional designs, hard switching leads to switching losses, which, especially for high values of the switching frequency, cause a reduction in the energy conversion efficiency. Converters with soft switching technology have a slightly improved voltage gain in comparison to conventional boost converters. As shown in Fig. 2, the converter operates in ZVS (Zero Voltage Switching) mode (Park, 2010), while there is another kind of soft switching boost converter operating in ZCS (Zero Current Switching) mode. This topology dramatically reduces switching losses and thus achieves better efficiency. The disadvantage of that topology is the complexity of the circuit, as some resonant components are added including a switch and an extra inductor. Though the driving sequence is a bit more complex, both switches operate at the same ground potential, so that additional separation at the driver side is needless.

3.2 Interleaved boost converters

A four-phase interleaved boost converter is shown in Fig. 3 (Chen, 2009). As discussed in the literature (Crews, 2008), this topology has the advantages such as simplicity, smaller input and output current ripples, lower switching losses, higher efficiency, and smaller inductor size. The input current ripples are small because each interleaved cell shares the input current, and they help in increasing the life of PV modules.

Considering that a generic number of phases N can be used, N represents the number of cells. By

Figure 2. Topology of a soft switching boost converter.

Figure 3. Topology of an interleaved boost converter.

splitting the current into N power paths, conduction losses (I^2R) can be reduced, by increasing the overall efficiency when compared to a conventional converter. Moreover, the duty cycle of a single switch does not exceed $1/N$, and smaller inductors can be used along with the decrease in the power rating of switches and diodes. Switches are turned on and off one by one when driving sequentially, thereby enabling low output voltage ripples. When the ripples have already been small, further reductions may be unnecessary. And then, it is possible to make some different trade-offs, for instance, reducing the switching frequency by a factor N (to increase the conversion efficiency) and reducing the inductance per cell by the same factor N (reducing the converter size). As a result, the system will present a per-cell ripple that is N^2 times larger than that of a single-cell converter, but the net interleaved ripple will remain the same. Therefore, interleaving is recommended to increase the conversion efficiency and power density associated with the reduction of the ripple current (Garth, 1971).

The main disadvantage of this topology is relatively low voltage gain, usually not higher than two. To improve the voltage gain, interleaved structures can be mixed with transformers (Li, 2010) or the inductors can be coupled (Yu, 2009).

3.3 Boost converter with coupled inductors

In non-isolated DC/DC boost converters, coupled inductors can act as a transformer to avoid extreme duty cycles and to reduce the current ripple in high-gain boost conversion (Li, 2009). Fig. 4 shows a high-voltage gain boost converter by using coupled inductors, whose voltage gain is in proportion to the winding turns ratio and can be properly adjusted (Zhao, 2003). These converters can easily achieve high voltage gain by using low R_{DS-on} switches working at a relatively low level of voltage. However, the leakage inductance may lead to high-voltage spikes, which will increase the switch voltage stress resulting in serious EMI (Electro-Magnetic Interference) noise and reducing efficiency. The input current is also pulsating in this case.

Figure 4. Topology of a boost converter with coupled inductors.

Figure 5. Schematic of the topology of a boost converter with voltage multiplier cell.

Thanks to the active clamp circuit used, the leakage energy can be recycled. A clamping circuit is used to reduce the voltage stress across the main switch because of the leakage inductance of the coupled inductor. This is an approach recommended to low-input voltages and high-voltage step-up since efficiency is typically low because of the voltage ringing, while EMI levels are appreciable because of the pulsating input current (Silva, 2009).

At the kilowatt power level, the power dissipation within the components becomes an important issue especially in case of inductive components. Interleaved solutions can tackle that problem as the input current is shared between the cells. The coupled inductors can be integrated into a single magnetic core to reduce the passive component size.

3.4 Converter with voltage multiplier cell

A Voltage Multiplier Cell (VMC) is an electrical circuit that converts electrical power from a lower voltage to a higher voltage, typically by using a network of capacitors and diodes. In Fig. 5, an interleaved boost converter with VMC is presented (Li, 2010). A voltage multiplier cell is inserted in the conventional interleaved boost converter structure that is composed of two diodes, capacitor, and secondary windings of coupled inductors. In such a topology, a high voltage gain can be achieved by adjusting the turns ratio of the two same coupled inductors instead of extreme duty cycles (Li, 2010). It allows good trade-offs between the number of VMCs and the turns ratio of the coupled

inductor. By utilizing current-sharing technique by interleaving at the input, this topology allows the use of smaller inductors and lower power-rated switches. Low R_{DS-on} switches can be used to improve the converter performance. The presented circuit works in the turn-on ZCS mode, which can reduce switch losses and EMI noise as well.

3.5 Non-inductive boost converter

Without the inductive components, meaning no transformers are applied, there are remarkable benefits in circuit size, cost, weight reduction, and thus the reduction of overall complexity of the converter. What is more, the non-inductive boost converter is able to work at higher temperatures than inductor-based counterparts. In Fig. 6, a new converter without inductive components is presented (Qian, 2011), developed for the requirements of high efficiency and ability to work in high temperatures. The voltage gain is accomplished by VMCs that operate basing on the switching capacitor

principle. The disadvantage of this topology lies in the need of the relatively big number of switches, which is 12 in this case. Moreover, due to the capacitive load, the switches are exposed to high current stress. However, the possibility to use low-voltage rated switches and the lack of inductors make it possible to achieve the compact and cost effective solution in the DC–DC boost converter design.

4 COMPARISON AND DISCUSSION

A brief comparison of the transformerless DC-DC boost converters mentioned in Session III is presented in Table 1 with performance proven in hardware prototype. Those highlighted are the best efficiencies and voltage gains reported in this work. The solution chosen by the designer depends on particular design constraints. The demands should be confirmed first, and then it comes to determine the most robust and best performance topology.

As shown in Table 1, the output powers of these converters are no more than 2.50 kW, which is quite small. The reason may be concluded as that the output power is processed by only two semiconductors and losses become appreciable, especially those regarding the intrinsic resistance of the filter inductor. In this case, most transformerless DC–DC boost converters are not recommended for high-power or high-current applications. In practical projects, interleaving of several converters may be a solution to high-power requirement and reduce the size of filter elements.

For high voltage gain and high efficiency applications, topologies of converters with coupled inductors and VMC are what should be focused on. As given in Table 1, their voltage gains are nearly 10, which are even competitive among converters with transformers.

When compared to non-inductive converters, converters with coupled inductors show great advantages among the aspects listed in Table 1.

Figure 6. Schematic of the Topology of a non-inductive boost converter.

Table 1. Comparison of transformerless DC–DC boost converter hardware prototypes.

Topology	Figure	η [%]	P_{MAX} [kW]	Gain [V/V]	f_s [kHz]	V_I [VDC]	V_{BUS} [VDC]	Number of switches	Number of diodes
Soft-switching boost converter	2	96.2	0.60	3.0	30	130 to 170	400	2	3
Interleaved boost converter	3	97.3	2.50	1.3	25	250	320	4	4
Converter with coupled inductors	4	92.3	1.00	8.0	100	48 to 75	380	1	2
Converter with voltage multiplier cell	5	94.7	1.00	9.5	100	40 to 56	380	4	2
Non-inductive boost converter	6	94.0	0.45	5.6	100	12	68	12	0

Multiple inductors can be integrated into a single magnetic core in order to reduce the very dimensions of the power circuit. However, it does not mean that non-inductive converters are useless. There is an important parameter, called working temperature, which is not presented in this comparison. As non-inductive boost converters can work in high temperatures, it is worth thinking about for designers when it comes to high temperature applications.

5 CONCLUSION

Start from the basis of the conventional DC–DC boost converter, a series of improved transformerless DC–DC boost converters is introduced and discussed in this paper. These improved topologies are mostly proposed to solve some key issues, such as efficiency, voltage gain, and power handling capacity. Some of the most important techniques typically step the voltage up without the need of extreme duty cycles and may use interleaving of multiple cells to increase the output power levels.

High efficiency of boost DC–DC converters can be achieved by decreasing the duty cycle (lower conduction losses) and reducing voltage stress on switches (cheaper and lower R_{DS-on} switches) by applying the soft switching technique (minimizing switching losses) and utilizing active clamp circuits (recycling the energy stored in parasitic inductances).

Coupled inductor topology provides a compact design with the features rarely to be found in other topologies. First of all, the energy stored in parasitic leakage inductance of coupled inductors is recycled there. Avoiding the use of electrolytic capacitors improves the reliability of that solution. An active clamp circuit decreases the voltage stress on the switch. And finally, only one switch at a low-side is needed and so the driving scheme is simple.

Topology of using VMC technology is a compact and robust solution. The leakage energy is recycled by utilizing a passive clamp. Due to the voltage multiplier cell, the switch voltage stress is reduced and voltage gain extended. Input current ripples are low and input current sharing is obtained due to an interleaved input structure thereby allowing a lower duty cycle to be used.

The linear fatigue cumulative damage analysis of the welding seam

Yuyu Wang

Beijing Luoxin Technology Company, China

ABSTRACT: The welding seam's fatigue failure under random vibration is considered; therefore, based on the Miner's rule and rain flow counting method, in this paper, a random vibration analysis of the welding seam is performed by ANSYS Workbench with an analytical model of the vehicle exhaust pipe. Finally, the linear fatigue cumulative damage of the welding seam was concluded. And the analysis method in this paper provides guidance for the welding seam design.

1 INTRODUCTION

The reliability analysis of components under random vibration mainly includes two methods: time domain and frequency domain (Andrew, 1998). The analysis based on time domain features, such as uncertain amplitude, unrepeated vibration waveform, and large volume of data to be processed, namely, for a certain time t , the vibration amplitude and frequency are stochastic. However, because the amplitude and frequency have certain statistical laws, the frequency domain analysis method based on the power spectral density is simple in calculation and does not require cyclic counting. The frequency domain analysis method has been broadly applied to estimate the fatigue life of the dangerous location of components in automobile, aerospace, machine manufacturing industries, etc. (Li, 2005).

The welding structure is located where is most vulnerable to fatigue failure, which is stemmed from the defects, such as incomplete penetration, slag inclusion, undercut, cracks, etc. in the welding seam. This "innate" fatigue crack source can directly transverse the fatigue crack initiation stage, thereby dwindling the process of fatigue fracture. The severe concentrated stress and higher residual welding stress in the welding seam will make the welded structure more vulnerable to the fatigue fractures, thanks to the fatigue cracks (Qin, 2013).

The random vibration of the vehicle exhaust pipe during the movement was simulated by using the ANSYS Workbench random vibration analysis module based on the Miner's rule and rain flow counting method. The simulative analysis gave the inherent frequency of the vehicle exhaust pipe and the cumulative damage value of linear fatigue in the welding seam of the vehicle exhaust pipe to provide the ground for the weld design of the vehicle exhaust pipe.

2 MINER'S RULE

In 1945, M A Miner popularized a rule that had first been proposed by A. Palmgren in 1924. The rule, variously called as the Miner's rule or the Palmgren–Miner linear damage hypothesis states that, where there are k different stress magnitudes in a spectrum, S_i ($1 \leq i \leq k$), each contributing $n_i(S_i)$ cycles, then if $N_i(S_i)$ is the number of cycles to failure of a constant stress reversal S_i (determined by uni-axial fatigue tests), failure occurs when:

$$C = \sum_{i=1}^k n_i / N_i(l, t_i = 1, 2, \dots, k) \quad (1)$$

C is the fraction of life consumed by exposure to the cycles at a different stress level; in general, C is experimentally found to be between 0.7 and 2.2. Usually for design purposes, when the damage fraction reaches 1, failure occurs (Zhang, 2013). This can be thought of as the proportion of life is consumed by using a linear combination of stress reversals at varying magnitudes.

3 S–N CURVE

For fatigue analysis, a test-based S–N curve is needed. Most common equations for representing the S–N curve are power function (Zhao, 1993; Chen, 2005), as given below:

$$\sigma_a = \sigma'_f (2N_f)^b \quad (2)$$

$$\sigma_a = C + D \log N_f \quad (3)$$

The equation gives a straight line on log-linear coordinates. The commonly used S–N curves are described under GB50017; BS7608-1993 Code of Practice for Fatigue Design and Assessment of Steel Structural; Fatigue Design Recommendations

for Steel Structures; AWS D1.1/D1.1M-2006 Structural Welding Codes Steel; The NEW IIW Fatigue Design Recommendations Newly Revised and Expanded (Hobbacher, 2007); Manual of Standard and Recommended Practices Section C Part II: Specifications for Design, Fabrication, and Construction of Freight Cars.

4 RANDOM VIBRATION ANALYSES

4.1 Radom vibration load

The random vibration of the vehicle at driving is affected by various factors, including roughness of the road surface, characteristics of tires, characteristics of the suspension system, travel speed, engine operating conditions, the driver's operating level, etc. (Zhang, 2007). The vehicle exhaust pipe mounted on the frame is connected with the supercharger at one end, and connected with the post-processor of the engine at the other end. The exhaust pipe must withstand its own gravity as well as the random vibration load while driving the vehicle.

4.2 3D model

Before carrying out the finite element analysis of random vibration, 3D models of parts, such as the vehicle exhaust pipe, square flange, clamp, bracket, and bellows, were built by using Creo software, as illustrated in Fig. 2.

4.3 Finite element model

A 3D model of the vehicle exhaust pipe was exported into ANSYS Workbench to set up the fillet weld model as illustrated in Fig. 2.

The material properties of the vehicle exhaust pipe, square flange, clamp, and bracket are defined in Table 1. The bellows connected to the exhaust pipe is simulated by using the spring unit and its property is shown in Table 2.

Figure 1. 3D model of the vehicle exhaust pipe.

Figure 2. Schematic of the welding seam model of the vehicle exhaust pipe.

Table 1. Material properties.

Material	Young modulus	Poisson ratio	Density kg/m ³
304	200000	0.3	7700

Table 2. Bellow properties.

Axial stiffness	Radius stiffness
18 N/mm	5 N/mm

Figure 3. Schematic of the finite element model of the vehicle exhaust pipe.

The exhaust pipe of the vehicle, which is a kind of the thin-plate part, is grid-classified by shell units; The mesh is divided by using the shell unit. The square flange, clamp, and bracket are grid-classified by using the solid units; the number of elements is 35446 and the number of nodes is 42341. The finite element model of the vehicle exhaust pipe is shown in Fig. 3.

4.4 Modal analysis

The modal analysis, which is modern method to study the dynamic characteristics of structures,

is an important branch in the vibration theory. It is also a system identification method that is applied in the engineering vibration field (Zhang, 2011). The boundary condition of the actual loading condition is defined in the modal analysis for the vehicle exhaust pipe. The bracket of the vehicle exhaust pipe is connected with the frame, the square flange is connected with the supercharger, and the clamp is connected with the vehicle muffler. In the finite element analysis, the mounting holes of the mounting bracket, the bolt holes of the square flange, and the end face of the clamp are set as 0 in the offset value in all directions. The coordinate system is defined as follows: in the X direction that is the vehicle advancing direction corresponds with the braking condition; in the Y direction that is the vehicle's transverse direction corresponds with the camber condition; in the Z direction that is the vertical direction corresponds with the bumpy conditions. The appropriate frequency is given by modal analysis for modalities of all orders at 0–2000 Hz. The inherent frequency of the former six orders in the modal analysis is indicated in Table 3 for the exhaust pipe of vehicles. The vibration plot of the former six orders is shown in Fig. 4.

4.5 Random vibration analysis

The modal analysis results are input data for random vibration analysis. The bracket of the exhaust pipe is connected with the frame and its power spectral density function described under ISO16750-3 VII 4.1.3.2.3.2 is used as its load input condition, as shown in Table 4. The square flange of the exhaust pipe is connected to the supercharger and its power spectral density function described under ISO16750-3 VI 4.1.3.2.2.3 is used as its load condition.

The S–N curve at the G level under BS7608 is used as an input, as shown in Fig. 5.

According to the defined coordinate system, the power spectral density function is applied in X, Y, and Z axes at the vibration time of 94 h in each direction, the life at 500,000 km was simulated and

the cumulative damage value at X, Y, and Z directions was calculated. With the finite element analysis, the stress value σ_i of all the welding seams can be given. With comparison of S-N curves of the welding seam, the fatigue cyclic life N_i of the welding seam as appropriate to each stress value can be given. With the rain flow counting method, the times σ_i under the stress value n_i can be given during the random vibration analysis of the welding seam. With Miner's rule, the accumulative damage of linear fatigue can be given for the exhaust pipe, as shown in Table 6.

The cumulative damage values of linear fatigue of welding seam 1, 2, 3, and 4 are all less than one in the braking direction, camber, and bumpy

directions. The maximum cumulative damage value of the linear fatigue appears in the camber direction 0.414 at weld 4. The distribution plot of the equivalent stress of the weld 4 is shown in Fig. 6; the rain flow plot of weld 4 is shown in Fig. 7. The cumulative damage value meets the design requirements as it is less than what is described under the acceptance rule 1.

5 CONCLUSIONS

In this paper, a 3D model of the vehicle exhaust pipe is built by using Creo. The modal analysis and random vibration analysis are performed by using ANSYS workbench for the exhaust pipe and the accumulative damage of linear fatigue at the welding seam is given. In this paper, a method is provided for the welding seam design.

Application of wavelet analysis and resonance demodulation in mechanical fault diagnosis

Chenhui Shen & Wei Wang

Ordinance Engineering College, Shijiazhuang, Hebei, China

ABSTRACT: The vibration signal of the mechanical failure is always submerged in the noise signal of the whole system, and it is unable to accurately separate the fault characteristic frequency by frequency domain analysis. The traditional resonance demodulation method is widely accepted as a powerful tool in the fault diagnosis of rotating machinery. The method of wavelet decomposition combined with resonance demodulation is described in this paper, which is used to extract the fault feature. The test data of the fault bearing is collected, and the feasibility of the method is verified.

1 INTRODUCTION

In the technology of condition monitoring and fault diagnosis of mechanical equipment, the research on the theory and method of vibration signal processing is the basis of extracting fault feature and effectively developing fault diagnosis. However, in the running process of rolling bearings, signal acquisition is inevitably interfered by a large number of non-monitoring site vibration, thereby resulting in effective information of submerged bearings; this kind of phenomenon can be observed in the early stage of rolling bearing fault behavior (Su, 2012). Rolling bearing is one of the most widely used mechanical parts in all kinds of rotating machinery, and its running state often directly affects the performance of the whole machine (including precision, reliability, and life span). Rolling bearing is the wearing part; according to statistics, 30% of the rotating machinery fault is caused by the rolling bearing; fault monitoring and diagnosis have been the subject of domestic and foreign technical fields (Wang, 2012). When the bearing undergoes local damage or defect, in the operation process, the damaged parts and other parts collide. This impact will produce attenuation impulse, and the impact force pulse frequency range is relatively wide, so as to stimulate the high frequency vibration of bearings. This natural vibration of high frequency is the carrier of the bearing vibration, and its amplitude should be modulated by the pulse excitation force caused by these defects, so that the ultimate bearing vibration waveform performance is the complex amplitude modulation wave (Wang, 2011). Therefore, the fault characteristic signal can be obtained by using the resonance demodulation method.

2 THEORETICAL METHODS

2.1 Wavelet multi resolution analysis

Wavelet analysis is a time–frequency analysis method, in which the window size is fixed but the shape can be changed, namely time and frequency windows may change (Zhang, 2010). The spectrum of the fault signal is refined by multi-resolution analysis, which makes full use of the superior performance of time–frequency localization, which makes the fault feature information more obvious. The low frequency part of the discrete signal is further decomposed by multi-resolution analysis, and the high frequency part is not considered. A three-layer wavelet decomposition tree structure is shown in Figure 1.

2.2 Resonance demodulation technique

The collected signals are processed to obtain the fault characteristic frequency based on the principle that the impact force generated by the collision of the faulty parts cause the inherent vibration of the

Figure 1. Three-structured of the three-layer wavelet decomposition.

Figure 2. The basic principle of resonance demodulation.

system. The steps of the resonance demodulation technique of the signal are as follows: selecting a frequency band pass filter which is equal to the natural frequency of the selected component. The initial vibration signal collected by the vibration sensor is processed by the band-pass filter, and the natural vibration frequency component is extracted as the research object. Next, we detect the high frequency signal through the envelope detector, to eliminate the high frequency attenuation vibration frequency components, which contains only the rolling bearing fault feature of the low-frequency envelope signal. Finally, the envelope signal is obtained by using the traditional Fourier spectrum analysis, the location of the rolling bearing fault can be determined by using the observation of the spectrum (Wang, 2011; Wang, 2001). The basic principle of the resonance demodulation technique is shown in Figure 2.

2.3 The combination of wavelet analysis and resonance demodulation

The high frequency vibration signal is extracted by using a digital filter through the traditional resonance demodulation method. Due to the fact that the signal collected by the actual sensor is flooded with a lot of noise, the result is not satisfactory. The method of wavelet decomposition and reconstruction can replace the digital filter to extract high frequency signals to achieve better results. Wavelet multi-resolution analysis of the signal is decomposed into a number of frequency signals, through the requirements of the selection of a frequency achieved by the work of filtering.

3 BEARING FAILURE FREQUENCY

The frequency of the rolling element passing the outer ring is given as follows:

$$f_o = \frac{z}{2} f_s \left(1 - \frac{d}{D} \cos \alpha \right) \quad (1)$$

The frequency of the rolling element passing the inner ring is given as follows:

$$f_i = \frac{z}{2} f_s \left(1 + \frac{d}{D} \cos \alpha \right) \quad (2)$$

The frequency of the rolling element passing on the holder is given as follows:

$$f_b = \frac{D}{2d} f_s \left(1 - \frac{d^2}{D^2} \cos^2 \alpha \right) \quad (3)$$

d is the diameter of the ball, D is the diameter of the ball center's rotary track, f_s is the active shaft rotation frequency, and α is the contact angle.

4 BEARING FAULT EXPERIMENT

To conduct the single-stage gearbox vibration test, the driving gear Z_1 is set at 36, driven gear Z_2 is set at 28, and the meshing frequency is set at 688 Hz, Bearing parameters are as follows: number of rolling elements $Z = 6$, $d = 10$, $D = 37$, and $\alpha = 60^\circ$, and the active shaft rotation frequency f_s is 19.11 Hz. The outer ring on the active shaft bearing was damaged, as shown in Fig. 4. The acceleration sensor is attached to the bearing seat.

Figure 3. Picture of the single-stage gearbox vibration test.

Figure 4. Picture showing the damage of the outer ring.

Experimental procedure:

- acquisition of the vibration signal.
- the wavelet is used to decompose the collected signal, decompose the high frequency vibration component, and carry out the wavelet reconstruction.
- using the Hilbert transform to extract the signal envelope demodulation.
- spectral analysis of the obtained envelope signal to obtain the fault characteristic signal.

5 EXPERIMENTAL RESULTS AND ANALYSIS

Calculation result: the frequency of the rolling element passing the outer ring f_o is 49.5856 Hz, and the frequency of the rolling element passing the inner ring f_i is 65.0811 Hz; the frequency of the rolling element passing on the holder f_b is 34.7099 Hz.

The Fourier transform of the signal is collected by the frequency spectrum, as shown in Figure 5, from which the fault feature cannot be found directly. As can be seen from the chart, at a frequency of 688 Hz, there is an obvious peak, according to the experimental setup that is that the gear meshing frequency, the useful components required should be in the vicinity of the following two peaks. The useful signal should be in the second layer of the high-frequency frequency band, after the three-layer wavelet decomposition.

The collected signal is decomposed by using the db4 wavelet, and the wavelet is extracted and reconstructed. The reconstructed signal is shown in Fig. 6, and the 2-layer high frequency d2 is extracted as the useful frequency component.

By carrying out the envelope of high-frequency signal by Hilbert transform, the envelope spectrum analysis can be a significant fault characteristic frequency. As shown in Figure7, the fault characteristic frequency is 48 Hz, which is almost equal to calculation 49.5856 Hz, which verifies the feasibility of the method in this paper.

Figure 5. Graph showing the spectrum curve.

Figure 6. Each layer reconstruction signal after wavelet decomposition.

Figure 7. Fault feature spectrum curve of wavelet analysis and resonance demodulation.

Figure 8. Fault feature spectrum curve of resonance demodulation without wavelet decomposition.

If the signal does not carry out the wavelet decomposition, the direct use of the original signal is to carry on the back of the step; the signal obtained by the curve is shown in Fig. 8. This situation can provide accurate results, but the signal wave crest is smaller than the wavelet decomposition, which fail easily in a lot of interferences.

The different wavelet decomposition coefficients are chosen to carry out the following steps:

Fig. 9 shows the results obtained from the reconstructed signal of the selected d3 coefficients. Fig. 10 shows the results obtained from the reconstructed signal of the d1 coefficients. It can be seen that the choice of the frequency segment has a great influence on the correctness of the results of the resonance demodulation.

Figure 9. Fault feature spectrum curve obtained from the reconstructed signal of the selected frequency d3.

Figure 10. Fault feature spectrum curve obtained from the reconstructed signal of the selected frequency d1.

6 CONCLUSION

In this paper, the feasibility of the method is verified by the method of gear box experimental analysis. However, the selection of the wavelet frequency segment mainly depends on experience and observation, which cannot be accurately obtained. This will lead to inaccurate results. The method needs to be improved to find the frequency segment of the transient impact.

A study on the modeling of the slider-crank mechanism based on parameter identification

Xiangjiang Wang, Xiaohuan Tang & Jiang Shen

School of Mechanical Engineering, University of South China, Hengyang, Hunan, China

ABSTRACT: In order to solve the problem of the interval in the slider-crank mechanism and improve its position accuracy, this article will establish a simplified model of the slider-crank mechanism based on its simple mechanism, and make full use of the sensor to measure the movement parameters of each component of the slider-crank mechanism. And then, in this article, the system parameter of the slider-crank mechanism is identified via the parameter identification method, and finally the slider-crank mechanism with interval will be set up and analyzed through the simulation experiment. The comparison results show that the model building via the parameter identification possesses high accuracy and a simple modelling process. Meanwhile, this kind of modelling method can afford a new thinking for the modelling of the complex and non-linear electromechanical system.

1 INTRODUCTION

The slider-crank mechanism is an evolution form of the hinged four-bar linkage and is commonly used in the transformation of the rotary motion of the crank to the reciprocating linear motion of the slider. It has been widely used in engineering practice because of its simple structure, ease of manufacturing, and reliable operation (LIU, 2008). But in the process of design, manufacture, installation, and employment, it has clearance between kinematic pairs in the slider-crank mechanism (Bai, 2011). Meanwhile, because of the external factors, the clearance will produce friction among each component and eventually lead to a decrease in the position accuracy of the slider-crank mechanism and its reliability. Therefore, to improve the position accuracy of the slider-crank mechanism, it is necessary to study and solve the gap problem of the slider-crank mechanism. For now, the common method to solve this problem is to establish its mathematical model and then improve the position precision of the slider-crank mechanism through the relevant method of control theory, such as Ai Zhihao who used the matrix method to establish the dynamics equation of the slider-crank mechanism and its mathematical model is based on Lagrange equation and Hamilton principle (Ai, 2008). Luo Jiman and Sun Zhili established the mathematical model of the slider-crank mechanism from the perspective of kinematics based on the theory of reliability engineering and probability design of the mechanism (Luo, 2002). Zhang You took advantage of the Newton-Euler method to build the mathematical model of the slider-crank

mechanism and carry out a simulation analysis (Zhang, 2012). But all of these methods have a lot of disadvantages, such as the complex modeling process, heavy computation, involving many disciplines and so on. Meanwhile, it is difficult to set up their simulation model.

In this paper, the slider-crank mechanism is regarded as the research object, and the motion and connection relationship between its module component and other components are analyzed. At the same time, in this paper, the movement physical quantities of its each component will be measured by using the sensor and then analyze the measuring curve according to the parameter identification method and identify the system parameters, and eventually establish a model of the slider-crank mechanism with clearance.

2 SIMPLIFIED MODELING AND IDENTIFICATION PRINCIPLE

2.1 *Simplified model of the slider-crank mechanism*

Figure 1 shows the experiment equipment of this article, in which the crank length of the experimental device L_1 is 35.8 mm, quality m_1 is 0.32 kg, the center of mass moment of inertia $I_1 = 1185.4 \text{ kg} \cdot \text{mm}^2$, the length of the hole center on both ends of the link L_2 is 245.88 mm, quality m_2 is 0.175 kg, the center of the mass moment of inertia relative to the link I_2 is $4751.3 \text{ kg} \cdot \text{mm}^2$, slider quality m_3 is 0.895 kg, the difference semi-diameter of the hinge pin and shaft sleeve between the link and slide

block e is 0.5 mm, and the shaft pin radius R is 4 mm.

The whole slider–crank mechanism was driven by using a servo motor. Therefore, the rotation of the servo motor stimulated the whole mechanism. In order to further reveal the motion law of the mechanism under this stimulation, we have to accurately set up its mathematical model.

Figure 2 shows the diagram of the slider–crank mechanism with no clearance, and the crank angle is θ_1 , link angle is θ_2 ; the length of the crank and link are L_1 and L_2 respectively; the slider displacement is L_3 .

The closed vector loop equation of the slider–crank mechanism with no clearance is given as follows:

$$\vec{L}_1 + \vec{L}_2 = \vec{L}_3 \quad (1)$$

The vector equation is decomposed on the axis X and Y as following:

$$L_1 \cos \theta_1 + L_2 \cos \theta_2 = L_3 \quad (2)$$

$$L_1 \sin \theta_1 + L_2 \sin \theta_2 = 0 \quad (3)$$

Figure 1. Picture of the experiment equipment.

Figure 2. Diagram of the slider–crank mechanism with no clearance.

Figure 3 shows the diagram of the slider–crank mechanism with clearance. The clearance at the location C represents the clearance between the link and slider. Moreover, the clearance of the location C is the biggest in the experiment mechanism and has the greatest influence on the mechanism. While the location A and B also has clearance in the actual mechanism. If considering these clearances, the model of the mechanism, which is established by using the method of mechanism modeling, is too complicated for practical applications. And so, the parameter identification method is beneficial to establish a more precise mechanism model.

Because of the clearance on locations A, B, and C, we assume that the clearances in those three locations are disassembled to the link and the crank respectively in the process of movement, so that the length of the link and the crank not only is a real-time change value but also a function of time. If we can gain the law in which the length of the crank and link is changed with the time, we can receive the movement regulation of the slider through equation (2), and the laws we get must be consistent with the motion rule of the actual slide. Thus, this means that the accurate motion model of the mechanism has been built. This kind of modeling method has great significance for rapidly setting up a mathematic model of the mechanism and understanding its movement principle. Moreover, its modeling process is no longer as complex as the mechanism modeling, and it improves the efficiency and accuracy for the modeling of the complex electromechanical system.

From what we have mentioned above, we can know that the length of the crank L_1 and the link L_2 is the known quantity in the equations (2) and (3), so that the change rule of slider displacement L_3 can be deduced. If we regard L_1 and L_2 as variables and want to get their change rule, we have to rewrite the equations (2) and (3) to equations (4) and (5):

$$[\cos \theta_1 \quad \cos \theta_2] \begin{bmatrix} L_1 \\ L_2 \end{bmatrix} = L_3 \quad (4)$$

Figure 3. Diagram of the slider–crank mechanism with clearance.

$$[\sin \theta_1 \quad \sin \theta_2] \begin{bmatrix} L_1 \\ L_2 \end{bmatrix} = 0 \quad (5)$$

Comprehensive equations (4) and (5) to equation (6):

$$\begin{bmatrix} \cos \theta_1 & \cos \theta_2 \\ \sin \theta_1 & \sin \theta_2 \end{bmatrix} \begin{bmatrix} L_1 \\ L_2 \end{bmatrix} = \begin{bmatrix} L_3 \\ 0 \end{bmatrix} \quad (6)$$

2.2 The principle of parameter identification

Parameter identification is generally defined as that if the input and output of the system is the only thing we know, we can get the important parameters of the system by solving the unknown parameters in the system, so that the original unknown parameters of system can become clearer. From its identification, we can know that we need the specific data of the input and output of the system in order to identifying a system. And then, we can be aware of the types of the model according to the known conditions and also need to understand the identification algorithm; Figure 4 shows the principle of identification.

Figure 4 shows that the input signal of the system P is $u(k)$, the output signal is $y(k)$; $v(k)$ is the disturbance signal, $z(k)$ as the measuring error of the output signal of the actual system, P is the error, which is gained from a comparative study between the output of the identification model on the basis of the input and output of the actual system and the measured output of the actual system; $e(k)$ is the input of the identification method. The result is used to improve the model of the identification system.

The method of the least squares identification is commonly used in the identification algorithm; the principle of the least squares identification is shown as follows:

For a general linear system, if we set its variable as y, x_1, x_2, \dots, x_n , the parameters needed to be identified are listed as the $\theta_1, \theta_2, \dots, \theta_n$, and the

Figure 4. Schematic of the principle of the parameter identification.

following equation is arrived at (Ding, 2011; Xiao, 2002):

$$y = \theta_1 x_1 + \theta_2 x_2 + \dots + \theta_n x_n \quad (7)$$

If the variable y, x_1, x_2, \dots, x_n is a function of time, each sampling time is a fixed equation:

$$y(t) = \theta_1 x_1(t) + \theta_2 x_2(t) + \dots + \theta_n x_n(t) \quad (8)$$

3 ESTABLISHMENT AND VALIDATION OF THE PARAMETER IDENTIFICATION MODEL

3.1 Analysis of the measured results

To accurately get the law of the length of the crank and link, which change with time, the related sensor is particularly applied to measure the quantity of the corresponding components, as shown in Figure 5, and the data acquisition is shown in Figure 6.

Figure 6 shows the platform of experimental data acquisition, three analog input modules are analog input signals, which is used to collect the output data of sensor for the crank angle, link angle, and slider displacement. Before collecting, the interval time needs to be set, when the parameters of the

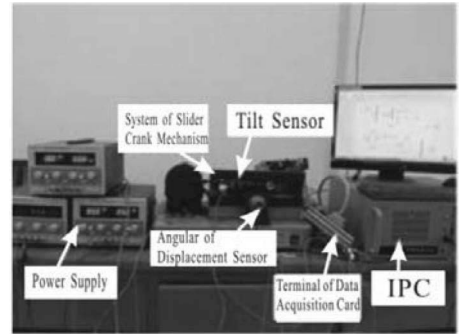

Figure 5. Picture of the object of the experiment device.

Figure 6. Schematic of the RTW platform of data acquisition.

module in each data point have been received. It is usually set as 0.005 s. Moreover, the voltage of the output analog signal has been set at 0.3V, the speed of the crank is 5 r/min; and acquisition time is 60 s. After successfully connecting the compile platform, the power of the experimental platform and sensor has been switched on. And then, the experiment was started. Finally, the experimental data were saved after the test.

The experimental data obtained from measurement are the voltage signals of the sensor. Therefore, it must be converted into the angle signal by using equation (9) and then fitted of the data by Originpro 8, as shown in Figures 7–9.

$$\theta_2 = \pi(0.25V - 0.625) \quad (9)$$

In this equation, θ_2 is the angle of the link and V is the output voltage of the angle sensor.

3.2 Modeling parameter identification and verification

The sine and cosine value of the crank angle and link angle are calculated separately through

Figure 7. Graph showing the angle curve of the link.

Figure 8. Graph showing the position curve of the slider.

measuring the crank angle, link angle, and the slider position. After that, the length of the crank and link can be worked out according to equation (8), and the identification results are shown in Figures 10 and 11.

After obtaining the change rule of the length of the link and crank, it can be put into the ideal

Figure 9. Graph showing the angle curve of the crank.

Figure 10. Graph showing the length curve of the crank after parameter identification.

Figure 11. Graph showing the length curve of the link after parameter identification.

model. And then, this kind of law has been integrated into the model calculation. However, before integrating, the initial speed of the servo motor should be set as 5 r/min, and the fixed step of the simulation should be 0.005 s. Moreover, the frequency of the input model in the Workspace also should be 0.005 s. and the simulation time has been set as 60 s. Thus, the simulation has been conducted after setting all the parameters. The simulation platform is shown in Figure 12.

The simulation results should be conformed to the slider displacement in the experiment according to the theory of parameter identification. Figure 13 shows the comparison results between the calculated results and the measured results of the slider displacement.

From Figure 13, we can know that the slider displacement, which is gained from the simulation model after joining the parameter identification, basically agrees with the change trend of the slider displacement in the actual measured graph. However, the error between the farthest position and the nearest position of the slider is big and even the mean square error arrives at 0.520067 mm,

which belongs to a reasonable range. The main reasons of this phenomenon are: firstly the too slow rotation speed that makes the shaft sleeve slower and need more time while the shaft sleeve reversely passes through the gap between the shaft pin and the shaft sleeve; secondly, due to the long process of the direction, the farthest position and the nearest position have been in an unstable transient state, so that the data which are collected in the slider displacement are not so accurate; thirdly, even though the calculable details collected from the link was fitted in order to facilitate the calculation, the fitting data still have differences with the original data, which leads to the result of calculation inaccuracy; fourthly, the types of error will be accumulated and even overlaid in the calculation, so that there will be errors between final simulation results and the actual measurement result.

To sum up, the slider–crank mechanism model building by using the parameter identification has more advantages than that of by the method of the mechanism model. Although the mechanism modeling method can be used in the establishment of the model on the basis of the laws and theories of the corresponding subjects, these also have some shortcomings, such as the process of the mechanism modeling is more complicated and the larger amount of calculation by comparing Figure 2 with Figure 14 (Shen, 2015) and the building simulation model is more complex by comparing Figure 12 with Figure 15 (Shen, 2015). This modeling method is not applicable for the complex system and not convenient for the computational simulation, and so the application of this method is limited. However, the method of the parameter identification all depends on the input and output of the system. Thus, the speed of the establishing model is quick and the modeling process is simpler, as shown in Figures 2 and 12. If we just know the simplified model of the mechanism in advance, we can carry on the parameter identification for the system, and get rid of the excessive consumption of the computational expense and time for the complex modeling. This method not only provides a new idea for the mathematical model of the complex electromechanical system, especially the mathematical model system with strong non-linear behavior, but also can be used more widely.

4 CONCLUSIONS

Through the analysis of the connection condition between the components status and the movement principle of the slider–crank mechanism, the clearance position in the slider–crank mechanism has been determined. Meanwhile, the simplified model of the system has been established. Moreo-

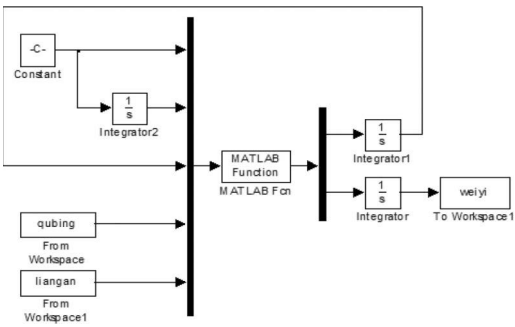

Figure 12. Schematic of the simulation platform of the model after identifying the parameters.

Figure 13. Graph showing the simulation results and measured results of the slider displacement.

ver, in this paper, the sensor is used to introduce the measurement of the corresponding physical quantities and obtain its characteristic curve, analyze the characteristic curve of the system by using the method of the parameter identification, so that the model of the slider-crank mechanism is established and the simulation experiment is carried out. This study shows that the results obtained by using the model, which is built by using the parameter identification method, is different from the results gained in the actual measurement. It has errors while the error is in a reasonable range. When compared with the mechanism modeling method, this modeling method is simpler and easier to realize industrialization and has certain engineering application value, thereby providing a new thought for the modeling of the complicated and non-linear mechanical and electrical system.

Angle measurement by comparing the amplitude technique of the sum-difference pattern radiometer

Hong Wang & Jing Xiao

School of Electronic and Optical Engineering, Nanjing University of Science and Technology, Nanjing, China

Bo Bi

Key Laboratory of Science and Technology on Millimeter-wave Remote Sensing, Beijing, China

ABSTRACT: The glint problem existing in amplitude comparison of the mono-pulse radar leads to angle-measuring errors. However, the radiometer detects the target only by using the radiation energy, which is not affected by such a problem. In this paper, the design principle of the sum-difference patterns of the three-channel millimeter wave radiometer on the W-band, and the angle measurement technique of the radiometer are mainly discussed. By carrying out the experiment of detecting airborne metal targets, the radiometer recognizes the target radiation and pinpoints it. The center of the target is identified from the sum channel signal, and the pitch and azimuth angle are measured by comparing the signals of two difference channels to that of the sum channel.

1 INTRODUCTION

One of the most widely used mono-pulse directional method is amplitude sum-difference patterns (Sherman, 1984). The biplane mono-pulse radar of the amplitude sum-difference patterns tracks the target effectively by using the three channel receiver's in a unique manner with high angle measuring accuracy and strong anti-interference performance (Zhou, 2014). But in the near field, the glint problem affects the angle measurement accuracy, which cannot be overcome for the tracking radar (Liu, 2013; Ma, 2009). The fast median filtering algorithm of the small window can make some suppression in the glint problem (Guo, 1996; Dunlop, 1981). In this paper, the use of the millimeter wave radiometer to measure the angle can completely compensate the glint problem in the near field. In this paper, the design and identification principle of the sum-difference patterns of the three-channel millimeter wave radiometer are introduced, and verifies it by carrying out an experiment of detecting airborne metal targets. Finally by carrying out digital signal processing to the received signal, we can identify the center of the target and get the pitch and azimuth angle of the target.

2 THE PRINCIPLE OF SUM-DIFFERENCE PATTERNS MILLIMETRE WAVE RADIOMETER

2.1 *The design principle of the millimetre wave radiometer*

The radiometer receives the radiation energy of the natural material (Sato, 2008). The detection system of the millimeter wave receives the millimeter wave thermal radiation energy of the electromagnetic spectrum object emitted by the radiometer of high sensitivity. And then, target recognition can be realized by the energy difference of the target and background (Li, 2009). In this paper, we design an AC all-power radiometer of sum-difference patterns at 3 mm.

The all-power radiometer can be divided into two major categories of DC coupling and the AC radiometer according to the structure characteristics. The DC coupling radiometer makes the DC level after detection as the signal of identify target directly. The AC radiometer makes the DC level through a blocking capacitor, what is used to determine the target is the exchange coupling signal. An alternating current radiometer is more

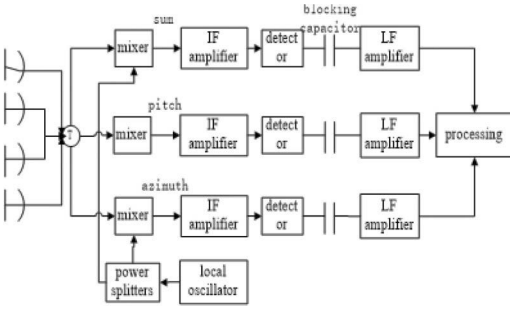

Figure 1. The schematic diagram of the AC all-power radiometer of sum-difference patterns.

likely to achieve as eliminating the calibration of the DC level when compared with direct current radiometer. The body of the sum-difference pattern radiometer is a three-channel radiometer, which is implemented by the antenna and the sum-difference network of the wave-guide. The schematic diagram of the AC all-power radiometer of sum-difference patterns is shown in Figure 1.

The AC radiometer of sum-difference patterns connects three radiometers by magic T, shares a local oscillator through the power splitters. The received electromagnetic wave of four antennas enters into the magic T. After sum-difference conversion, sum and differential signals can be obtained and then be put into three radiometers, respectively. In the radiometer of a single channel, the mixer converts the RF signal down to the IF signal. And then, by amplification and detection, the AC component can be extracted through the blocking capacitor, which is the required signal processing analysis.

The output voltage after low amplification of a single channel radiometer is given by the following equation:

$$U_d = C_d G k B \Delta T_a \quad (1)$$

where C_d is the detector sensitivity, G is the total gain, k is the Boltzmann constant, B is the bandwidth, and ΔT_a is the apparent temperature of the target and background temperature difference in the antenna. What we monitor and process is just the output voltage of the radiometer.

The antenna beams, respectively, scan the target and background back and forth. And then, the sum channel radiometer outputs the energy changes of four beams and the difference channel radiometers respectively output the energy changes in the pitch and azimuth plane. The recognition method of the sum channel of the sum-difference radiometer is the same as the ordinary radiometer. But it is different from the conical scan radiometer, which is

pinpoint target by the conical scanning. The sum-difference radiometer obtains the orientation of the target in a plane through two differential energies of the beam.

2.2 The principle of identification

The radiation energy of metal objects detected by using the millimeter wave detection system mainly comes from the environmental radiation energy reflected by the metal. The reflectivity (Kim, 2013) and the environmental radiation energy are related to the detection angle, and so the metal objects radiation energy is a function of the angle.

The objects emissivity ε is in a linear relationship with the reflectivity Γ and transmittance τ .

$$\varepsilon + \Gamma + \tau = 1 \quad (2)$$

Because the transmittance of most objects is small, it can be approximately regarded as zero, and then

$$\varepsilon + \Gamma = 1 \quad (3)$$

As shown in Fig. 2, assuming that the four antenna beams respectively are 1, 2, 3, and 4, the square represents the metal objects, the sky temperature is 50 k, and the ground temperature is 300 k (room temperature is 23°). The metal target can be seen as a non-emitter. And so, in the analysis, we can approximately think that the emissivity is $\varepsilon_T \approx 0$, and the reflectivity is $\rho_T \approx 1$.

When surface-to-air metal target identification occurs, assuming air without a cloud, when to detect a target, the temperature near the antenna is given by the following equation:

$$T_{BT} = \varepsilon_T \cdot T_T + \rho_T \cdot T_g = \rho_T \cdot T_g \quad (4)$$

Not to detect a target, the temperature near the antenna is given by the following equation:

$$T_{Bs} = T_s \quad (5)$$

The temperature contrast of the metal target and sky is given by the following equation:

$$\Delta T_T = T_s - T_g \quad (6)$$

Figure 2. Schematic of the process diagram of the antenna scanning the target.

Figure 3. The differential effect scheme of energy change.

Figure 2 is the process diagram of the antenna scanning the target. The sum channel energy is $\Sigma = 1+2+3+4$, azimuth difference energy is $\Delta_a = (1+3)-(2+4)$, and pitch difference energy is $\Delta_p = (1+2)-(3+4)$. When compared to the metal, the sky is cold. Hence, in the process of the antenna close to or far away from the goal, Σ is from low to high and high to low, the target center can be obtained from its peak. Δ_a is obtained from the negative energy gradually to the positive energy. Δ_p is always negative energy, but the size is changing. Therefore, azimuth and pitch angle can be obtained respectively by using the sum-difference amplitude ratio.

The energy change presented on the AC radiometer is a differential process, and so the result is a positive or negative pulse, as shown in Figure 3.

3 RADIATION SIGNAL MEASUREMENT AND ANALYSIS

The experiment with radiometer and metal plane mode is carried out to verify the identification ability of the sum-difference patterns millimeter wave radiometer. As shown in Figure 4.

First, by hanging the metal plane model in the air, the radiometer detects the target after aiming at the plane. Due to the antenna followed by magic T, the received sum and difference energy inputs into three receiver channels, respectively. After the frequency conversion and amplification, the signal waveform can be monitored by using an oscilloscope. The radiometer detects the energy difference between the metal plane and the sky. We can monitor the signal waveform of three channels by using an oscilloscope, which is shown in Figure 5. Figure 5(a) is the sum channel signal, (b) is the azimuth difference channel signal, and (c) is the pitch difference channel signal.

We can see from Fig. 5 that, once the radiometer detects the metal plane, it will output a signal. And the output voltages of three channels are different. The peak value of the sum channel signal is $V_\Sigma = 2.4V$, the peak value of the azimuth channel signal is $V_a = 500mV$, and the peak value of the pitch channel signal is $V_p = 700mV$. Therefore,

Figure 4. Picture of the experimental scheme.

(a)

(b)

(c)

Figure 5. Radiometer of the sum-difference patterns signal waveform.

the amplitude of the sum channel signal is greater than the difference, and the amplitude difference between two signals reflect the angle target deviation from the center of the antenna. To measure the angle, we make the peak time of the AC energy as a reference point. According to the principle of the sum-difference radiometer angle measurement, the target angle can be calculated and determined.

After the target radiation signal required, we perform digital signal processing, thereby choosing DSP F2812 (Han, 2009) chip as the core chip. The total signal processing board is composed of DSP F2812 and its peripheral circuit. First, signal sampling is carried out by the AD module of 2812 to transform the analog signal to the digital signal. In the AD sampling, the choice of the sampling rate is a key problem.

The calculated equation of the sampling rate is given as follows:

$$f_s = \frac{30M \times (DIV/2) \div (HISPCLK \times 2)}{(TIPR + 1) \times 2^{TPS}} \quad (7)$$

where, DIV is the setting of the PLLCR register to change the PLL double-frequency coefficients of the CPU. HISPCP is the setting of the SysCtrlRegs register to change the prescaler standard of the high speed clock. TIPR is the setting of the EvaRegs register to change the value of the cycle register TIPR. TPS is the setting of the T1CON register to change the clock frequency of the timer. The TIPR is often changed to alter the AD sampling frequency as it is simple and easy. And the sampling frequency is set according to the input analog signal frequency.

After AD sampling, the digital value corresponds to the analog voltage and it can be calculated as follows:

$$digital = 4095 * (analog - ADCLO) / 3 \quad (8)$$

For once experimental signals, the sampling results of sum, azimuth, and pitch channel are respectively displayed on CCS and are shown in Fig. 6(a)–(c). Also, the sum channel signal is greater, while the two difference signals is smaller and have some difference. We can see from Figure 5 that there is some noise in the signal.

After digital sampling, signal processing can be performed on the digital signal. First, for the sum channel signal, we find the first signal by the rising edge. And then, we continuously compared the signal value to find the maximum value until the fall edge. The fall edge is determined by the consecutive declining three signal values. Finally, if the maximum value reaches or exceeds the threshold value, the peak value can be required. Also, we can

Figure 6. Sum-difference channels' sampling signal.

output a pulse signal in each peak position, and then the corresponding recognition signal is generated, as shown in Figure 7. We know that, when the antenna aims at the center of the target, the received energy is the maximum. Therefore, the target center can be determined by the maximum energy of the sum channel.

And then, we need to determine the deviation angle of the antenna. We can get the peak value of two difference channels the same as the sum channel. And then, the sum channel signal as a reference signal, respectively contrasted with the signal amplitudes of two difference channels, we can obtain the amplitude ratio. And then, azimuth and pitch angle can be calculated according to the corresponding relationship between the amplitude ratio and angle. The angle measuring result is shown in Figure 8. The azimuth angle $\alpha = 5^\circ$

Figure 7. The recognition signal in the sum channel.

and the pitch angle $p = 9^\circ$. Figure 6 shows that the peak value of the azimuth channel is a little less than the pitch channel, and so the azimuth angle deviation is less than the pitch angle in the result.

4 CONCLUSION

The millimeter wave radiometer of sum–difference patterns eliminate the influence of the mono-pulse

glint problem and improve the angle measuring precision. The experiment of the radiometer detecting the air metal target verified the directional ability of the system.

ABSTRACT: Tension control is the key methodology for the lamination process of lithium batteries. However, the isolation film is easily broken when the tension is too great, and when the tension is too small it is prone to wrinkle retraction resulting in an irregular phenomenon. The paper describes the establishment of a model according to the structural characteristics of the lithium battery lamination machine, and the building of an experimental platform. The control strategy was designed by using active unwinding methodology, combined with the classic PID control method for experimental verification. The motion of the platform was used as the main axis, and the motor of the storage material axis and the other servo motors were used as the slaver axis. Compared with the existing passive unwinding methods, this novel active continuous unwinding and master-slave synchronization method realizes high speed continuous unwinding, and keeps the tension stability in the process of intermittent reciprocating lamination.

1 INTRODUCTION

Tension control methods are applied to various fields of industry, and over the years many advanced control algorithms have been proposed. The first such one to appear in the literature (Lee, 2012) proposed an advanced taper tension control method. This established the mathematical model of stress changes that the material belt section went through in the transmission process, and designed a pair of rollers to control strip force in the process of transmission by adjusting the single stick angle: the system of tension was controlled by a passive tension swing rod on the winding production line to enhance performance. Later studies (Chen, 2004) proposed an algorithm of tension control for the web feed machine based on the sliding mode control, and a further study (Park, 2014) used different fuzzy adaptive gain control methods to control the winding tension.

Synchronization motion control commonly used in master-slave synchronization technology for the design and study of chaotic systems can also be successfully applied. The literature (Wua, 2006) proposed two non-autonomous horizontal platform systems of master-slave synchronization control, by proving the criteria of a general coupling

matrix to derive the special coupling matrices by a linear state error feedback controller. Another study (Ding, 2011) proposed two horizontal master-slave synchronization platforms based on time delay feedback control, and in yet another study (Salarieh, 2009), the master slave synchronization technique was extended to the multiple synchronization problems, and the algorithm was designed by a feedback control strategy. Later studies (Yang, 2015) established the thrust equation of the linear motor. Other researchers (Albert, 2007) established the dynamic mathematical model of the traditional AC synchronous servomotor and linear motor dynamic mathematical model, and found that the linear motor has better positioning accuracy of the profile than a ball screw. The rationality of trajectory planning directly affects the vibration of the whole system. Studies (Liang, 2014; Li, 2009) have optimized the trajectory of the linear motor. The main function of the feed-forward control is to predict the development trend of the signal, and the master axis is often ahead of the slave axis in the master-slave synchronous motion because of the time lag. In the high-speed motion of the linear motor, it is called the tracking error. A study (Chen, 2007) introduced the feed-forward gains of speed and acceleration, which

can forcefully enhance the tracking ability of the repetitive controller and improve on the errors of the system. The feedforward control rate is introduced into the industrial system to improve the overall performance of the system (Kang, 2010; Zheng, 2016).

This paper studies the tension control method of the lithium battery lamination machine, in which there is a continuous active unwinding and an intermittent reciprocating motion of the laminated platform. Subsequent chapters are arranged as follows: second section analyzes the lamination machine structure characteristics, and establishes the kinematics model of the whole system. The third section focuses on the design and study of the control strategy, using the traditional PID control algorithm to achieve the variable speed unwinding. The fourth section describes the experimental platform for verifying the accuracy of control strategy and the mathematics model. The research results from this study have been applied in practice for production equipment.

2 SYSTEM MATHEMATICAL MODEL

Figure 1 shows the laminate machine experimental platform working principle diagram for this study. It mainly comprises the unwinding roller, the tension roller and its storage shaft, the laminate platform and its lifting part, and the pressure knife and an isolating membrane. The main goal of the research is to control the tension of the isolation membrane so that it is stable when the laminate platform is working at high speed. This section of the paper mainly analyzes the structural characteristics of the lamination machine and establishes its kinematics mathematical model as well as part of the dynamic mathematical model. Software is used to simulate the system's motion.

Figure 1. Working principle of the experiment platform.

2.1 Unwinding mathematical model

Changes in the unwinding diameter need to be analyzed because the changes occur in real time in the process of unwinding. The unwinding diameter and isolation membrane motion diagram is shown in Figure 2, while the flattened isolation membrane is shown in Figure 3.

The total length of the initial isolation membrane can be calculated according to the diameter of the coil and the thickness of the isolation film:

$$L_0 = (\pi[(D/2)^2 - (D_0/2)^2])/m \quad (1)$$

The relationship between the volume and the linear velocity of the film:

$$D = 2\sqrt{(L_0 - v_2 t)m/\pi + (D_0/2)^2} \quad (2)$$

Under the premise of ensuring uniform speed, the relationship between the volume change of the roll rate and the roll rate is further deduced:

$$\begin{aligned} n &= 60v_1/\pi \cdot D \\ &= 60v_1/\left(2\pi\sqrt{(L_0 - v_2 t)m/\pi + (D_0/2)^2}\right) \end{aligned} \quad (3)$$

2.2 The mathematical model of tension swing rod

The tension swing rod is mainly used to control the tension of the whole system at a constant tension with the help of PID adjustments and the initial unwinding diameter calculation. The force diagram is shown in Figure 4.

Figure 2. Roll dimension and membrane motion diagram.

Figure 3. Isolation film flattening size diagram.

Figure 4. Force diagram of tension swing rod.

The tension swing is driven by a rotary motor, O, as a rotation center, and f the isolation membrane tension. In order to ensure the isolation membrane tension is constant, it is necessary to apply a driving force in the rotary motor, which is mainly affected by the isolation membrane tension and tension pendulum inertia effect, for the establishment of the dynamic mathematical model. Tension swing rod total moment of inertia is:

$$J = m_1(x + 2R_1)^2 / 12 + 2[0.5m_1(R_1^2 - R_2^2) + m_2(0.5x + R_1)^2] \quad (4)$$

where m_1 is the tension swing rod quality and m_2 is the roll quality on the tension swing rod. In the constant tension control system, the driving force of the motor is balanced with the tension of the isolation membrane. The driving torque required by the tension swing drive motor is calculated as:

$$T = F(x + 2R_1) + 0.5J\beta^2 \quad (5)$$

where β is the angular acceleration of the current moment of tension swing rod; in the practical application it is possible to get feedback from the servo system. From the above formula, in the ideal case, the tension swing angular acceleration is 0, and the motor drive force is only related to the tension of the isolated film.

2.3 Mathematical model of laminated platform and mathematical model of linear motor

According to a recent study (Liang, 2014) the dynamic state space equation of linear motor can be expressed as:

$$\begin{bmatrix} \frac{di_{d1}}{dt} \\ \frac{di_{q1}}{dt} \end{bmatrix} = \begin{bmatrix} -\frac{R_1}{L_{d1}} & \frac{\pi}{\tau_1} \nu_{p1} \frac{L_{q1}}{L_{d1}} \\ -\frac{\pi}{\tau_1} \nu_{p1} \frac{L_{d1}}{L_{q1}} & -\frac{R_1}{L_{q1}} \end{bmatrix} \begin{bmatrix} i_{d1} \\ i_{q1} \end{bmatrix} + \begin{bmatrix} v_{d1} / L_{d1} \\ (v_{q1} - \pi \nu_{p1} c \lambda_1 / \tau_1) / L_{d1} \end{bmatrix} \quad (6)$$

where i_{d1} and i_{q1} indicate the armature currents, and v_{d1} and v_{q1} are the armature voltages for d-axis and q-axis, respectively. Similarly, L_{d1} and L_{q1} represent the armature inductance of each axis respectively. λ_1 , τ_1 , M , B represent maximum magnetic flux of PM, poles pitch of linear motor, mass of armature, and friction coefficient, respectively. Disturbance loading discussed here includes friction and propulsion ripple, in which for simplicity the ripple propulsion can be considered as a periodic sine wave.

There are some large impacts in the system when the laminated platform is in high speed reciprocating motion. In order to avoid the impacts and vibrations this study used a dissymmetrical S curve to plan a trajectory and added a dynamic model of the linear motor to simulate the system. The motor simulation curve is shown in Figure 5 and the tracking error curve in Figure 6.

2.4 Mathematical modeling of the storage shaft

The kinematic mathematical modeling of the storage shaft is mainly on the isolation membrane length change. The mathematical relationship of isolation membrane length change includes all three parts of the movement: the lamination platform, the pressure knife, and the unwinding shaft. The simulation trajectory of the linear motor combined

Figure 5. Running track of the lamination platform.

Figure 6. Simulation tracking error curve.

Figure 7. Running track of the storage shaft.

Figure 8. Simulation tracking error curve.

with the linear motor model is shown in Figure 7 and the tracking error curve in Figure 8.

3 CONTROL STRATEGY

Master-slave synchronization is defined as setting one as the master axis and the other as the slave axis in a multi axis control system; the velocity of the master axis changes the slave velocity. The storage shaft position is calculated according to the lamination platform and pressure knife position in this study, so the movement of laminated platform is set as the spindle.

Combined with the mathematical model established in the previous section, the control strategy diagram of master-slave synchronization is shown in Figure 9. The motion of the platform is used as the master axis, and the movement of the storage master is calculated according to the position of the master.

It is found that the increase of the current loop gain can improve the tracking performance of the linear motor. So we put feed forward on the current loop. A diagram of the feed forward control of the linear motor is shown in Figure 10.

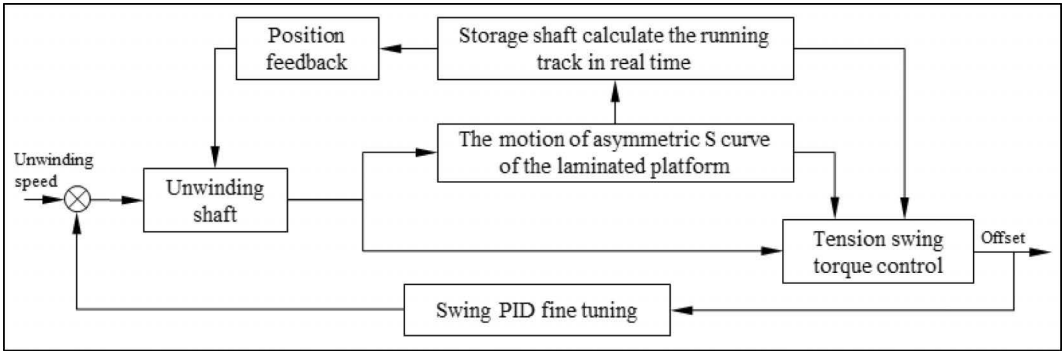

Figure 9. Lamination machine control strategy.

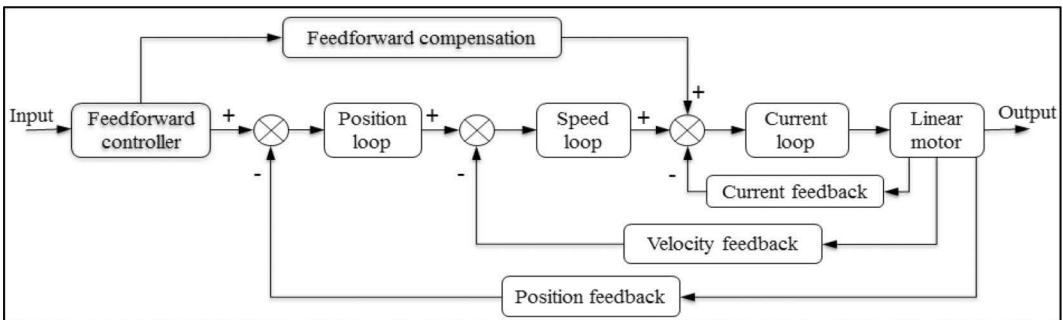

Figure 10. Diagram of feed forward control of the linear motor.

4 EXPERIMENT

The experimental platform is shown in Figure 11. The tension swing rod provides constant torque control, and so with the passive state of change of angular displacement it will move when the tension fluctuates. So the displacement of the tension swing rod reacts to the stability of tension fluctuations.

The actual curve of the displacement of the tension swing rod is shown in Figure 12. The tension swing angle range is only 0.15 degrees, which can be determined by the system tension being almost at a constant state throughout the whole process.

In the transmission process of the isolation membrane, the line velocity of the isolation membrane at a constant is based on the premise that tension must be stable. In the unwinding velocity curve is shown in Figure 13, the unwinding suddenly accelerates at the beginning followed by small-scale fluctuations. The fluctuations are impacted by PID rules, which dictate that the unwinding velocity is basically uniform.

The experiment of the overlapping separation membrane was carried out in the experimental platform with a set cycle time of 0.55 S. The effect of overlapping in the microscope observation chart is shown in Figure 14.

Figure 11. Experimental platform.

Figure 12. Displacement wave curve of tension swing rod.

Figure 13. Velocity curve of the unwinding.

Figure 14. Effect of overlapping isolation membrane.

Table 1. Regularity data table of isolation membrane.

Itemz	Left OH Max (um)	Right OH Max (um)	Alignment metric
Spec	1.25	1.25	0
USL	1.75	1.75	0.25
LSL	0.75	0.75	-0.25
Max	0.95	1.74	0.09
Min	0.79	1.60	-0.02
Mean	0.85	1.67	0.02
Range	0.17	0.14	0.11
Sigma	0.043	0.035	0.026
CP	3.876	4.762	3.252
CPK	0.800	0.761	2.936

According to the observed data used to calculate other indices, the positive and negative deviation and process capability index is a very important indicators. For computing these data, some important parameters are summarized in Table 1. In the production process of lithium batteries, it is required that the isolation membrane CPK > 1.3, so as this study's CPK = 2.936 the performance requirements is met.

5 CONCLUSION

This paper describes the model of the kinematics and dynamics of active continuous unwinding

and laminated platform intermittent reciprocating motion. It also explains the master-slave synchronization control method of a platform for experiment and analysis, with a lamination cycle of 0.55 S. The experiment has achieved very good results.

Design and kinematics analysis of a novel liquid-brewing steamer feeding robot

Jiashuang Zhang, Bin Li, Tongchen Zhang & Xinhua Zhao

*Tianjin Key Laboratory for Advanced Mechatronic System Design and Intelligent Control,
Tianjin University of Technology, Tianjin, China*

ABSTRACT: In this paper, a novel steamer feeding robot is designed and studied. When compared to the currently used steamer feeding robot, the feeding process of the proposed robot is continuous, and this way will greatly improve the efficiency and quality of the feeding process. Firstly, the mechanical structure and kinematics of the novel steamer feeding robot are introduced and analyzed. And then, the control system of the robot is introduced. Finally, experiment evidences are given to prove the efficiently of brewing by using this robot.

1 INTRODUCTION

Currently, robotics is one of the world's most popular fields of the study; many mature robot products have been widely applied in many aspects such as space flight, aviation, busywork in sea and land, underground exploitation, manufacturing, computer-aided medical instrument, biological engineering and micromechatronics system, and so on. More and more experts and producers have been concerned about the robotics studies and applications. On one hand, the studies on the robotics have become systematic and deep, in terms of the robot theory, the design, kinematics, dynamic, workspace, dimensional synthesis, etc., are the hot points of robotics studies. On the other hand, the applications of robotics have extended into more extensive domains, such as the Chinese traditional labor-intensive industry (Gu, 2006).

Liquor-making is a traditional labor-intensive industry in China. The whole process of liquor-making is mainly composed of cereals fermentation, feeding, steam distillation, filling, packaging, and transportation. Among these links in the production chain, the feeding operation is a very important link in the process of liquor-brewing. Its operation quality will directly determine the liquor yield and liquor quality. During the brewing process, we must spread the brewing raw materials as a uniform and loose layer in the wine barrel to ensure that brewing raw materials do not "run steam" and "pressure steam" in the process of distillation. Because of the high viscosity of brewing raw materials and because the barrel is large, round, and small, it is difficult to obtain the charging equipment with the operation

(Qian, 2013). The current brewing industry generally uses the traditional artificial steamer, through which the workers spread the materials layer by layer. And so, the operator labor intensity and the liquor stability is poor. The feeding link of most winery is still manually operated at present. Heavy manual labor is the characteristic of this process. Changing the traditional way of feeding to upgrade the liquor industry is imminent. And after years of research, we developed some feeding robots that can be practically applied. These kinds of robots use the existing joint type robot as the main operational body, and installed the feeding mechanism at the end of the manipulator. We complete the feeding operation by controlling the robot's anthropomorphic operation. But this kind of robot in the operation process is the interrupted type of carrying on the material and then spreading. If steam is released during this period, robots will not be able to feed in time, and this will greatly reduce the liquor out rate. In addition, due to the limited operation of the robot body, it is difficult for the part of the wine barrel edge to achieve uniform material. "Babel gap" will appear (Wang, 1992; Qian, 2013; Serdar, 2014; Liu, 2009).

This article is aimed at the feature of the feeding operation with "light, loose, uniform, thin, accurate, and flat"; and design an intelligent feeding robot combined with infrared vision technology and PLC control technology. In this paper, its mechanical structure and kinematics are introduced and analyzed firstly. And then, the introduction of its control system is carried out too. Finally, the actual test of liquor-brewing with this robot is taken to prove the possibility of brewing.

2 MECHANICAL DESIGN AND DESCRIPTIONS

As we know, the robot must keep moving to the designated position in the circular wine barrel when feeding. And so, it is necessary to ensure that the robot can rotate around the “Z” axis, with the accuracy and stability of motion at the same time. The rotation of the mechanical arm is realized by installing the servo motor to control the gear rotation; the arm needs to rise for a distance for the next round of feeding after finishing a layer of material, and so in order to ensure that the feeding mechanism and the material layer are not in contact with each other, we must provide a vertical direction for the robot’s translational degrees of freedom. And so, we use the servo motor to drive the rotation of the column and the ball–screw mechanism to realize the rise of the mechanical arm, and thinking of the global stability, we have designed four columns; one of them installed for the screw is for rising, and another is for support.

In the way of spreading, the feeding robot has been applied actually and is commonly used the hopper. When the material in the hopper is used up, the robot moves to the material to supplement, and then continues to feed. In the process of the supplement, the robot cannot give a remedy to the “leakage” phenomenon in the barrel. Therefore, in this paper, the robot manipulator is specially designed. Each of them is hollow inside and provided with a feed screw. It drives the continuous movement of the feeding screws to realize the transfer of the material in the mechanical arm through the auger motor. At the same time, the two mechanical arms are connected. The raw material can be passed through the two mechanical arms without leakage. There is a feed inlet that is directly connected with the feeding conveyor belt installed at the robot’s forearm to ensure the continuity of feeding.

The feed operation needs to be “light, loose, uniform, thin, accurate, and flat”. But the material out of the rear arm flows fast and spreads non-uniformly. And so, we design a spreader by using the leaf structure to make the material enter the barrel lightly, loosely, and uniformly. And it ensures the quality of the feeding process.

According to the above-mentioned structure requirements, the robot is built and assembled by Solidworks. Add the motor and other parts into the assembly; and we can get the three-dimensional model of the feeding robot, as shown in Figure 1. It is composed of a chassis, four upright posts, two mechanical arms three servo motors that control chassis and mechanical arm rotation and two auger motors that control feed screws rotate. The chassis not only plays the role of supporting the

Figure 1. Schematic of the steamer feeding robot system.

whole robot, but also can be driven by the servo motor 1 to achieve the rotation on the horizontal plane; the mechanical arm 1 is connected with the chassis through the upright post, it controls the mechanical arm to achieve the vertical up and down movement driven by using servo motor 2, the two mechanical arms are connected through a gear mesh, the mechanical arm 2 rotary is driven by using servo motor 3.

3 INVERSE AND FORWARD POSITION ANALYSES

3.1 Establishment of the direction matrix

When we are studying the feed movement of the robot, upward movement is not a decisive factor. And so, we ignore the upward mobility, and focus on the rotary motion of the spreader. And then, simplify the structure of the robot and we obtained the structure diagram, as shown in Figure 2.

It consists of a base S and two arms (PR and RS). Among these, the base and mechanical arm and the two mechanical arms are connected through a rotating pair (S and R), and the two axes of rotation are parallel to each other, respectively, thereby establishing the coordinate system with the base consolidation (x_0, y_0, z_0) and the end of arms (x_1, y_1, z_1) , (x_2, y_2, z_2) . The clockwise joint angle is negative, and the counter clockwise angle is positive, as shown in Figure 2. And it is expressed with D–H table in Table 1.

3.2 Analysis of positive kinematics

Assume that the Z axis is perpendicular to the direction of the paper. And according to Table 1,

Figure 2. Schematic of the structure.

Table 1. D-H parameters of the robot.

Connecting rot	α	A	D	θ
1	0	l_1	0	θ_1
2	0	l_2	0	θ_2

we obtain the homogeneous rotation transformation matrix from the coordinate system (x_0, y_0, z_0) to (x_2, y_2, z_2) as given in Equation (1).

$${}^0_2T = {}^0_1T \cdot {}^1_2T$$

$$= \begin{bmatrix} \cos \theta_1 & -\sin \theta_1 & 0 & 0 \\ \sin \theta_1 & \cos \theta_1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} \cos \theta_2 & -\sin \theta_2 & 0 & l_1 \\ \sin \theta_2 & \cos \theta_2 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

$$= \begin{bmatrix} \cos(\theta_1 + \theta_2) & -\sin(\theta_1 + \theta_2) & 0 & l_1 \cos \theta_1 \\ \sin(\theta_1 + \theta_2) & \cos(\theta_1 + \theta_2) & 0 & l_1 \sin \theta_1 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (1)$$

By dot multiplying the position vector $(p = (l_2, 0, 0, 1))$ and Eq. (1), we can obtain the position vector of the end of the connecting rod (P) in the base coordinate system (x_0, y_0, z_0) as follows:

$${}^0P = {}^0_2T \cdot {}^2P$$

$$= \begin{bmatrix} \cos(\theta_1 + \theta_2) & -\sin(\theta_1 + \theta_2) & 0 & l_1 \cos \theta_1 \\ \sin(\theta_1 + \theta_2) & \cos(\theta_1 + \theta_2) & 0 & l_1 \sin \theta_1 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} l_2 \\ 0 \\ 0 \\ 1 \end{bmatrix}$$

$$= \begin{bmatrix} l_1 \cos \theta_1 + l_2 \cos(\theta_1 + \theta_2) \\ l_1 \sin \theta_1 + l_2 \sin(\theta_1 + \theta_2) \\ 0 \\ 1 \end{bmatrix} = \begin{bmatrix} x_p \\ y_p \\ z_p \\ 1 \end{bmatrix} \quad (2)$$

And it can be rewritten as follows:

$$x_p = l_1 \cos \theta_1 + l_2 \cos(\theta_1 + \theta_2) \quad (3)$$

$$y_p = l_1 \sin \theta_1 + l_2 \sin(\theta_1 + \theta_2) \quad (4)$$

3.3 Analysis of inverse position

After establishing the kinematic equations mentioned above, if the end position of the manipulator is known, we can obtain the joint angle of the robot arm (θ_1 and θ_2) by using the kinematic equations. This is the inverse kinematics of the manipulator. Inverse kinematics can be used to control the joint angle and the end position of the robot arm. For this feeding robot, its inverse kinematics is the process of known x_p, y_p for θ_1, θ_2 .

Firstly, based on Equations (3) and (4), and performing the proper expansion and simplification yields the following equation:

$$x_p^2 + y_p^2 + l_1^2 - l_2^2 = 2l_1(x_p \cos \theta_1 + y_p \sin \theta_1) \quad (5)$$

In order to simplify the calculation, assume

$$\tan \theta_p = \frac{x_p}{y_p}, \theta_p = \arctan \frac{x_p}{y_p} \quad (6)$$

Substituting Equation (6) in Equation (3) yields the following equation:

$$x_p^2 + y_p^2 + l_1^2 - l_2^2 = \frac{2l_1 x_p}{\cos \theta_p} (\cos \theta_1 \cos \theta_p + \sin \theta_1 \sin \theta_p) \quad (7)$$

$$x_p^2 + y_p^2 + l_1^2 - l_2^2 = \frac{2l_1 x_p}{\cos \theta_p} \cos(\theta_1 - \theta_p) \quad (8)$$

According to Equation (8), we can obtain θ_1 which is as follows:

$$\theta_1 = \arccos \frac{\cos \theta_p (x_p^2 + y_p^2 + l_1^2 - l_2^2)}{2l_1 x_p} + \arctan \frac{x_p}{y_p} \quad (9)$$

In the same way as solving θ_1 , Equation (10) and (11) are obtained, and at last completed the calculation of θ_2 as Equation (12).

$$x_p^2 + y_p^2 + l_2^2 - l_1^2 = 2l_2 [\cos(\theta_1 + \theta_2) + \sin(\theta_1 + \theta_2)] \quad (10)$$

$$x_p^2 + y_p^2 + l_2^2 - l_1^2 = \frac{2l_2 x_p}{\cos \theta_p} \cos(\theta_1 + \theta_2 - \theta_p) \quad (11)$$

$$\theta_2 = \arccos \frac{\cos \theta_p (x_p^2 + y_p^2 + l_2^2 - l_1^2)}{2l_2 x_p} + \arctan \frac{x_p}{y_p} - \theta_1 \quad (12)$$

4 ANALYSIS OF THE WORKSPACE

The feed operation requires the robot to reach any point within the barrel. But according to the results of the positive and inverse position analysis mentioned above, we find that when the two arms are in the same line, the robot is in singular configuration. Except this, many other factors could influence the working space of the robot. And so, we respectively introduce these interferences and give the corresponding constraints.

1. Input angle: when the robot operates, the forearm may interfere with the conveyor or other equipment. And so, the swing angle of the forearm is often restricted to a certain angle. And so, the robot's working space is limited, so that the original part of the work space cannot be achieved. In this paper, the research on the robot forearm's swing angle sensor range is limited in the range of -60° – 80° by using a photoelectric limit sensor. When the swing angle of the current arm reaches the upper and lower limit positions, the trigger sensor stops the robot. When the robot works regularly, the robot will not trigger the limit sensor.
2. Singular configuration: when the singularity occurs, the robot is in a state of "sickness", and the working space will show some holes. According to above-mentioned equations, when the two arms are in the same line, the robot is in a singular position. But due to the spreader and the limitation of the chassis we set, the robot will not arrive at the singular position and will clear up the effect of the singular configuration.

5 REALIZATION AND TESTING OF THE ROBOT

According to the mechanical structure and structure parameters designed above, the factory processes the robot and connects the conveyor belt system to the upper end of the feed inlet. And on the basis of the mechanical system, in order to realize the function of feeding, we add the control system and the infrared vision system to the robot (Tian, 2013; Hu, 2001), as shown in Figure 3.

5.1 Working process of the robot

Before feeding, the control system resets the manipulator to the initial position. And then, when the robot begins to feed, the control system controls the mechanical arm's movement circle and the circle around the inside barrel to spread layer by layer; and after finishing two material layers, the infrared vision system starts to leak and displays an uneven position picture according to the actual

situation in the barrel, and then send the feeding information to the control system for controlling the robot's body to fill these positions. After the completion of the feeding of one layer, the control system controls the robot's rising by a layer distance, and then continues to carry on spreading the material layer by layer until the robot finishes feeding all of the entire barrel (Li, 2015; Zhang, 2015).

5.2 Experiment and summary

In order to detect the actual operation effect of the robot, the factory is powered on the spot to make the liquid. In the process of brewing, the robot can spread uniformly layer by layer; the vision system can detect the location of leakage accurately; and control the spreader to the accurate leak position. The leakage photos are taken by using the visual system, as shown in Figure 4.

According to the actual brewing results, this new feeding robot can simulate the artificial feeding process. During the operation, only one person will be required to shovel the material into the conveyor belt. It reduces the labor intensity of workers and saves labor cost. The yield and quality of the liquor brewed by using the robot is similar to traditional artificial feeding.

Figure 3. Picture of the steamer feeding robot.

Figure 4. Picture of the leakage.

6 CONCLUSIONS

In this paper, the urgent need of the feeding robot in the liquor-brewing industry is to design a new feeding robot, and carry out the related theoretical research work. Firstly, the mechanical structure design of the robot is carried out; and then, on this base, the forward and inverse solution analysis is carried out, and the working space is also analyzed. In the last part of this work, the control system of the robot is designed, and the field practice is carried out to verify the practicability of the robot. The experiment shows that the design of this robot is helpful for improving and perfecting the liquor production process, solving the poor working environment, recruitment difficulties, and other problems that the liquor industry faces. And there are also some guidelines for the further application of robot technology in the liquor-brewing industry.

Design and simulation analysis of a new type of multi-gear pump

Xuhui Zhang, Pingyi Liu, Wenjun Wei & Haitao Li

College of Engineering, China Agricultural University, Beijing, China

Guoping Tian

Beijing YIHE ZHONGWEI Precision Machine Co. Ltd., Beijing, China

ABSTRACT: Aiming at solving problems of great influence on hydraulic cylinders' flow rate caused by load pressure and poor synchronization at composite action, a new type of parallel multi-gear pump is put forward in this paper. According to the relationship between the number of center gear teeth and driven gears, the pump can be divided into three kinds. And then, the expressions for outlets' instantaneous flow rate of the three kinds of multi-gear pumps are derived. By using the dynamic mesh technique in Fluent software, transient simulation on flow characteristics of the multi-gear pump under various working conditions is carried out. The instantaneous and mean flow velocities of the three kinds of multi-pumps are analyzed. The results show that the mean flow rate is in a linear relationship with outlet pressure, and the flow rate of a sub-pump outlet is only related to its pressure but not that of the other sub-pumps. Sub-pumps have no influence on each other. The working states of every sub-pump of Class I are completely synchronous. The working states of sub-pumps of Class II are divided into groups, and the working form is packets that are synchronous and cooperative among groups.

1 INTRODUCTION

Hydraulic transmission is widely used in agricultural machinery because of its advantages such as large power, flexible installation, easy adjustment, low breakdown rate, convenient to realize continuously variable transmission, and so on (Li, 2012; Saleh, 2015). The actions of multiple actuators are simultaneous in most modern agricultural machinery (Zhao, 2014; Yang, 2005; Zhang, 2015; Liang, 2012; LV, 2014), which are controlled by using a multi hydraulic circuit system using one pump. The hydraulic system has problems that the flow rate is greatly influenced by load pressure and synchronization of the composite action is poor (Dong, 2010).

In this paper, a new type of parallel multi-gear pump is proposed, which can avoid the interference of pressure and flow among actuating cylinders. The design and classification of the multi-gear pump are carried out, and the expressions of each outlet are derived. By taking the Fluent software as a platform, the flow characteristics of the multi-gear pump under various working conditions are studied. The results provide theoretical basis for the multi-gear pump application in the multi-hydraulic circuit system.

2 DESIGN AND CLASSIFICATION OF THE NEW TYPE OF MULTI-GEAR PUMP

As shown in Figure 1, the new type of multi-gear pump is composed of one center gear and several

Figure 1. Schematic illustration of the new type of multi-gear pumps.

driven gears. Driven gears are uniformly distributed around the center gear and mesh with it. Being powered by using the center gear, driven gears rotate with high speed. And then, a series of sub-pumps are formed. Let z_1 be the number of center gear teeth and N be the number of driven gears. The multi-gear pump is composed of N sub-pumps. Every sub-pump has one outlet and one inlet. And then, the N inlets converge to one inlet. Therefore, the multi-gear pump has N outlets and one inlet.

Sub-pumps are clockwise named as NO. 1, NO. 2, ..., NO. N . Draw the line which connects

centers of the center gear and the NO. 1 driven gear in a horizontal manner, and also the symmetry line of the first tooth of the center gear. And then, the two lines coincide. When the line which connects centers of the center gear and NO. i driven gear coincides with the symmetry line of any tooth of the center gear, the instantaneous states of the NO. i and NO. 1 are completely synchronous. But if two lines do not coincide anywhere else, the instantaneous states of all sub-pumps contained in the multi-gear pump are not synchronous.

Let k be the greatest common divisor of z_1 and N . Based on the analysis mentioned above, the multi-gear pump is divided into three kinds.

1. $k = N$, that z_1 is divisible by N , and then the instantaneous states of N sub-pumps are fully synchronous. Define this kind of multi-gear pump as Class I.
2. $1 < k < N$, such that z_1 is not divisible by N , but z_1 and N is divisible by k simultaneously; and then, the working states of N sub-pumps are divided into groups. The working states of sub-pumps are packets that are synchronous, but cooperative among groups. The number of groups is N/k , and there are k sub-pumps in every group. The number of intervals among the k sub-pumps is $(N/k-1)$, that is the working states of NO. i , NO. $(N/k + i)$, NO. $(2N/k + i)$, ..., NO. $[(k-1)N/k + i]$ sub-pumps are synchronous. Define this kind of multi-gear pump as Class II.
3. $k = 1$, the instantaneous states of all the sub-pumps contained in the multi-gear pump are different. Define this kind of multi-gear pump as Class III.

According to the analysis mentioned above, the classification of the new type of multi-gear pump is related to the number of center gear teeth and driven gears, but not the number of driven gear teeth.

3 OUTLETS' INSTANTANEOUS FLOW RATE OF THE NEW TYPE OF MULTI-GEAR PUMPS

3.1 Position analysis of meshing points

The meshing of the center gear and a driven gear is shown in Figure 2. Point A is the beginning mesh point. Point B is the ending mesh point. Point C is the meshing pitch point which is fixed. Point D is the mesh point when the next pair of teeth begin to mesh at point A. Point M is the instantaneous mesh point of the two gears for oil expulsion. f_i is the distance between point M and point C.

Figure 2. Schematic showing meshing of the center gear and a driven gear.

1. The instantaneous mesh point positions relationship of sub-pumps contained in the Class I multi-gear pump can be determined as follows:

$$f_1 = f_2 = \dots = f_i = \dots = f_N \quad (1)$$

2. The instantaneous mesh point positions relationship of sub-pumps contained in the Class II multi-gear pump can be determined as follows:

$$f_i = f_{(N/k+i)} = f_{(2N/k+i)} = \dots = f_{[(k-1)N/k+i]} \quad (i = 1, 2, \dots, N/k) \quad (2)$$

$$f_i + \frac{[b_i \cdot N - (i-1)c]a}{k} = f_1 \quad (3)$$

wherein, define b_i as the distribution factor, and c as the tooth number difference factor.

$$\begin{cases} b_i = \text{ROUNDUP} \left[\frac{(i-1)c}{N} \right] \\ c = \text{MOD} \left(\frac{z_1}{N} \right) \end{cases} \quad (4)$$

wherein, define ROUNDUP() as the round up and integral function, and MOD() as the taking remainder function.

3. The instantaneous mesh point positions relationship of sub-pumps contained in the Class III multi-gear pump can be determined as follows:

$$f_i + [b_i \cdot N - (i-1)c]a = f_1 \quad (5)$$

wherein, b_i and c can be obtained from equation (4).

After collecting and analyzing equations (1), (2), (3), and (5) and their related parameter equations, the general formula of the instantaneous mesh point positions of sub-pumps for the N -link pump is obtained as follows:

$$\begin{cases} f_i = f_1 - \frac{[b_i \cdot N - (i-1)c]a}{k} \\ a = \frac{k\pi m \cos \alpha}{N} \\ b_i = \text{ROUNDUP} \left[\frac{(i-1)c}{N} \right] (i=1,2,\dots,N) \\ c = \text{MOD} \left(\frac{z_1}{N} \right) \end{cases} \quad (6)$$

where the value of f_1 is expressed as follows: with point C as the zero point, to the left of point C (AC direction) is negative and to the right (direction CD) is positive. And then, the value range of f_1 is given as follows:

$$f_1 \in \left[r_2 \cos \alpha \tan \alpha' - \sqrt{r_{a2}^2 - r_2^2 \cos^2 \alpha}, 0 \right] \cup \left[0, \pi m \cos \alpha + r_2 \cos \alpha \tan \alpha' - \sqrt{r_{a2}^2 - r_2^2 \cos^2 \alpha} \right] \quad (7)$$

The meshing point positions of the three kinds of multi-gear pumps show different characteristics along with different numbers of center gear teeth and driven gears.

3.2 Instantaneous flow rate equations of outlets

Based on the Finite Volume Method (FVM) (Huang, 2009), the instantaneous flow rate equations of N outlets can be obtained as follows:

$$\begin{cases} Q_{\text{ext}1} = \frac{B\omega_1}{2} \left[r_{a1}^2 + \frac{r_1}{r_2} r_{a2}^2 - r_1(r_1 + r_2) \frac{\cos^2 \alpha}{\cos^2 \alpha'} - \left(1 + \frac{r_1}{r_2} \right) f_1^2 \right] \\ \vdots \\ Q_{\text{ext}i} = \frac{B\omega_1}{2} \left[r_{a1}^2 + \frac{r_1}{r_2} r_{a2}^2 - r_1(r_1 + r_2) \frac{\cos^2 \alpha}{\cos^2 \alpha'} - \left(1 + \frac{r_1}{r_2} \right) f_i^2 \right] \\ \vdots \\ Q_{\text{ext}N} = \frac{B\omega_1}{2} \left[r_{a1}^2 + \frac{r_1}{r_2} r_{a2}^2 - r_1(r_1 + r_2) \frac{\cos^2 \alpha}{\cos^2 \alpha'} - \left(1 + \frac{r_1}{r_2} \right) f_N^2 \right] \end{cases} \quad (8)$$

where,

B is the width of the center gear and driven gears.

ω_1 is the angular velocity of the center gear.

r_1 is the graduated circle radius of the center gear.

r_2 is the graduated circle radius of the driven gear.

r_{a1} is the addendum circle radius of the center gear.

r_{a2} is the addendum circle radius of the driven gear.

α is the pressure angle of gears.

α' is the meshing angle of the gear pair.

According to above-mentioned equations, when geometric and motion parameters of the gear pair are all constant, the instantaneous flow rate equations of outlets have their only variable that is f_i . According to equation (6), the instantaneous flow rate equations share only one variable, that is f_1 . Just for Class II and Class III multi-pumps, the instantaneous flow rate phases of outlets are different.

4 SIMULATION AND ANALYSIS OF OUTLETS FLOW CHARACTERISTICS OF THREE KINDS OF MULTI-PUMPS

After building models for three kinds of multi-pumps, the simulation of flow characteristics is carried out by using CFD ICEM, Fluent and CFD-Post modules in ANSYS software.

4.1 Models building and data post-processing of three kinds of multi-pumps

The procedures of models building and data post-processing are as follows:

1. Building geometric models.

Building geometric models as three cases for three kinds of multi-pumps. Module m of center gears and driven gears is three. The teeth number of the driven gear z_2 is 10. The modification coefficient x_2 of the driven gear is 0.5. The number of driven gears N is 6. The teeth number of the three center gears are selected as 42, 43, and 44 for the three cases respectively, and the modification coefficients x_1 are all 0. Among these, the case of $z_1 = 42$ is considered as Class I, $z_1 = 44$ is considered as Class II, and $z_1 = 43$ is considered as Class III. The dimensions of the inlet and outlet are 14 mm and 12 mm, respectively. The radial gap between the housing and addendums of the center gear and driven gear is designed to be 0.1 mm.

2. Building calculation models.

After transferring the geometric models built as mentioned above to the CFD ICEM module, the mesh of flow domains (as shown in Figure 3) is divided properly by using triangular unstructured meshes globally. By using the dynamic mesh technique in Fluent, transient numerical simulation on the flow characteristics will be carried out. The calculation model is set for transient flow and $k-\varepsilon$ turbulence mode, and the pressure-velocity coupling method is called as PISO. The density of oil is 866 kg/m³. The viscosity is 0.0414 Pa·s. The gauge pressure values of six inlets are all set to 0 MPa. By using the UDF macro command, the rotating speed of the driven gear is 209.44 rad/s, and rotating speeds of the center gear of Class I, II, and

Figure 3. Schematic of the flow domain.

III are 49.867 rad/s, 47.6 rad/s, and 48.707 rad/s, respectively. The time step size is set as $1e-5$, and the data files are auto saved every 25 steps.

3. Computing data post-processing.

After transferring the data files generated by using the Fluent module to the CFD-Post module, data post-processing is carried out. Due to the fixed dimension of outlets, the instantaneous flow characteristics can be expressed by using flow velocity, and the displacement characteristics can be expressed by using the mean flow velocity. By setting up monitoring points at the center of six outlets, the variation law of flow velocity with time is obtained.

4.2 Simulation analysis of Class I multi-pumps

By setting different gauge pressure values of six outlets in the Fluent module, flow characteristics simulation under different conditions are carried out.

1. The pressure values of six outlets are diagonally the same and different with adjacent outlets. The condition 1 is as follows: gauge pressure values of NO. 1, NO. 3 and NO. 5 outlets are all 3.5 MPa, and NO. 2, NO. 4 and NO. 6 outlets are all 2 MPa. The instantaneous flow velocity curves of six outlets are shown in Figure 4. From Figure 4, we can learn that the three outlet instantaneous velocity curves of 3.5 MPa coincide, and also the three curves of 2 MPa. The six curves form two groups. The greater the pressure, the lower is the flow velocity. The phases of six outlet instantaneous flow velocity curves are the same.
2. The pressure distribution of six outlets present offset loads. The condition 2 is as follows: gauge pressure values of NO. 1, NO. 2 and NO. 3 outlets are all 3.5 MPa, and NO. 4, NO. 5 and NO. 6 outlet are all 2 MPa. The instantaneous flow velocity curves of six outlets are shown in Figure 5. From Figure 5, we can learn that the curves of condition 2 exhibit the same characteristics as condition 1.
3. The pressure values of six outlets are different. The condition 3 is given as follows: gauge pressure values of NO. 1, NO. 2, NO. 3, NO. 4,

Figure 4. The outlet instantaneous flow velocity curves of Class I multi-pump under condition 1.

Figure 5. The outlet instantaneous flow velocity curves of Class I multi-pumps under condition 2.

NO. 5 and NO. 6 outlet are 4.5 MPa, 4 MPa, 3.5 MPa, 3 MPa, 2.5 MPa, and 2 MPa respectively. The instantaneous flow velocity curves of six outlets are shown in Figure 6, and the mean flow velocity trend curve under different pressure values is shown in Figure 7.

From Figures 6 and 7, we can learn that, the six outlet instantaneous flow velocity values are degressive and the mean flow velocity decreases linearly along with an increasing in pressure.

4. Under different conditions, the instantaneous velocity values of the outlets whose pressure values are 2 MPa are compared. By collecting the outlets data of conditions 1, 2, and 3, the outlet instantaneous velocity curves are shown in Figure 8.

From Figure 8, we can observe that the instantaneous flow velocity curves of six outlets are coincident under different conditions. The result shows that the instantaneous flow velocity of an outlet is only related to its own pressure, but not the other sub-pumps.

4.3 Simulation analyses of Class II and Class III multi-pumps

Class II and III multi-gear pumps are simulated and analyzed under conditions which are the

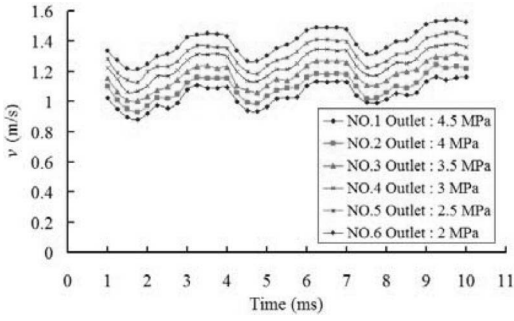

Figure 6. The outlet instantaneous flow velocity curves of Class I multi-pumps under condition 3.

Figure 7. The outlet mean flow velocity trend curve of Class I multi-pumps under condition 3.

Figure 8. The outlet instantaneous flow velocity curves of Class I multi-pumps under different conditions.

same as that of Class I. The rest characteristics of flow rate are the same as that of Class I, except the phases of the outlet's instantaneous velocity curves. Therefore, we list only the conditions such that the six outlet pressure values are the same for Class II and Class III multi-pumps.

1. The condition of Class II multi-pumps is as follows: gauge pressure values of outlets are all 2 MPa. The instantaneous flow velocity curves of six outlets are shown in Figure 9, and the mean flow velocity values are given in Table 1. From Figure 9 and Table 1, it can be observed that the six outlet instantaneous flow velocity curves form three groups as follows: NO. 1 and NO. 4 outlets as a set, NO. 2 and NO. 5 out-

lets as a set, and NO. 3 and NO. 6 outlets as a set. The wave amplitudes and periods of the three group curves are the same, but there is a 1 ms phase difference between each other. The six outlet mean velocity values are almost the same. The result shows that the states of six sub-pumps are divided into three groups, and each group has two sub-pumps.

2. The condition of Class III multi-pumps is as follows: gauge pressure values of outlets are all 2 MPa. The instantaneous flow velocity curves of six outlets are shown in Figure 10, and the mean flow velocity values are given in Table 2. From Figure 10 and Table 2, it can be observed that wave amplitudes and periods of the six instantaneous flow velocity curves are the same, but there is a 0.5 ms phase difference between each other. The six outlet mean velocity values are almost the same. The result shows that the six sub-pumps are in different states.

Figure 9. The outlet instantaneous flow velocity curves of Class II multi-pumps.

Outlet	NO. 1	NO. 2	NO. 3	NO. 4	NO. 5	NO. 6
Mean flow velocity (m/s)	1.396	1.405	1.396	1.395	1.403	1.394

Figure 10. The outlet instantaneous flow velocity curves of Class III multi-pumps.

Table 2. The outlet's mean flow velocities of Class III multi-pumps.

Outlet	NO. 1	NO. 2	NO. 3	NO. 4	NO. 5	NO. 6
Mean flow velocity (m/s)	1.388	1.382	1.396	1.397	1.383	1.384

5 CONCLUSION

In this study, a new type of multi-gear pumps is put forward. The design of the new type of multi-gear pump and transient numerical simulation on the flow characteristics are carried out. The results of the study are as follows:

1. According to the relationship between the number of center gear teeth and the driven gears, the pump can be divided into three kinds. The working states of six sub-pumps of Class I multi-pumps are completely synchronous. The working states of six sub-pumps of Class II multi-pumps are divided into groups, and the working form is packets that are synchronous and cooperative among groups. The working states of six sub-pumps of Class III multi-pumps are different from each other.
2. The outlet mean flow velocity decreases linearly with an increase in pressure. The mean flow velocity values are the same when the outlet pressure values are the same. It indicates that the flow velocity of an outlet is only related to its own pressure value but not the other sub-pumps. The sub-pumps contained in one multi-gear pump has no effect on each other.
3. The characteristics of the multi-pump indicate that the pressure and flow interference among actuating cylinders can be avoided by using the new type of multi-gear pump in a multi-loop hydraulic system, and finally construct cylinders according to their respective stroke and movement time.

A study on the torsional fatigue fracture location of steel wires

Wenjie Wei

University of Science and Technology Beijing, Beijing, China

ABSTRACT: In the torsional fatigue test, the fracture location of steel wires is a critical factor influencing the effectiveness of the test. Based on the actual force of steel wires, in this paper, an attempt is made to carry out the finite element analysis, thus obtaining the stress variation of the cylinder busbar of steel wires. The additional stress influencing area of the clamping force is labeled, and the fracture location of steel wires in the actual test is adopted for verification. Finally, the run-length testing method shows that the fracture location of steel wires in the test area is randomly distributed.

1 INTRODUCTION

In previous torsional tests of steel wires, the clamping area is usually designed to be thicker than the test area, so as to avoid the influence of additional stress in the clamping area. However, due to the surface stress state, the drawing degree and dimension of the spring material are generally different from other steel wires, and it is hard to be made into test samples that are thin in the middle for fatigue tests. In this paper, through the torsional fatigue test of spring steel wires, the high-stress spring fatigue performance can be obtained quickly. The steel wire is directly clamped to the test machine in the torsional fatigue test of steel wires. Since there is additional stress in the clamping area, the obtained fatigue data cannot reflect the real fatigue life of steel wires. But the authenticity of the fatigue data can be judged by using the fracture location of steel wires. (Shao, 2013; Zhang, 1997)

2 PRINCIPLE (SONG, 2012; XIE, 2006)

The stress of the object caused by the load distributed in a small area (or volume) of the elastomer has no effect on the area that is away from the loading area, and its stress only makes a difference to the resultant force and the moment. The load can only affect the stress distribution near the loading zone. In the torsional test of steel wires, the clamping force is even with the moment and resultant force is 0. Thus, the additional force only affects the stress distribution near the clamping area.

Through the finite element analysis of steel wires, the stress distribution that is affected near the clamping area can be obtained.

3 FINITE ELEMENT ANALYSIS

3.1 Geometric model

The solidworks is applied in this paper to establish the geometric model of steel wires, as shown Fig. 1.

For the convenience of applied torque and clamping force, a 10 mm-long area is left on the steel wire whose diameter is 4.0001 mm, which is slightly larger than elsewhere. However, it cannot affect the result of finite element simulation (the unit size divided below is far larger than 0.0001 mm).

3.2 Meshing and boundary conditions (Li, 2012; Xia, 2015; Lv, 2001)

Considering the precision and model, the torsional steel wire belongs to the long and thin model, but the stress variation of the round section is huge, and so the bar unit cannot be adopted. The spatial solid ele-

Figure 1. Schematic showing the geometric model of a steel wire.

ments of the four-nodes tetrahedron and eight-nodes hexahedron can be used together, and the automatic meshing can be used. In fact, the automatic switch between the tetrahedron mesh and hexahedron mesh can be conducted with this method. When the sweeping is available, the sweeping meshing will be executed; otherwise, the tetrahedron can be applied.

Since the diameter of the clamping area is slightly larger than that of other areas in this paper, the sweeping method cannot be applied for division in the whole model. In the arrows of Figure 1, a tetrahedron element is used. Its advantage is that its strong geometric adaptability and various irregular geometric models can be divided by it. And so, the four-node tetrahedron element unit becomes an indispensable unit type of the finite element analysis, and it can be used in the arrows of Figure 1. Because the tetrahedron element is a constant-strain element, many units are required to make up for the weaknesses of the function by itself in the big strain gradient area. Therefore, in the finite element analysis of the torsion shaft, the four-nodes tetrahedron element is used together with the eight-nodes hexahedron element, in order to ensure the precision of results. Furthermore, it can help to save the computing resources and reduce the calculation cost. In the local coordinate system, the standard unit of the eight-node hexahedral element is an eight-node cube. The coordinate origin is in the core of the cube with the edge length being 2 mm. The finite element model of the torsion shaft after meshing is shown in Figure 2.

3.3 Finite element calculation and results

Due to the constantly changing torque of the torsional steel wire in the test, the static analysis for the steel wire is meaningless. Instead, based on the actual situation, the transient dynamic analysis with the alternate torque is applied. According to the fact, a section of load and time process is

Figure 2. Schematic of the finite element model after meshing.

applied to the steel wire in this work. Seven load steps have been applied to the steel wire within 1/8 s, as shown in Table 1. Through the application of alternating loads, the transient dynamic analysis is carried out (Cai, 2012).

Because the left side of the steel wire is clamped on the static end in the actual test (as shown in Figure 1), six free degrees can be locked. The right-hand side cylinder diameter in Figure 1 is slightly larger than that of other areas. The alternating load can be applied as well as the 334 MPa additional force, so that the force of the steel wire will be completely consistent with that in the actual test.

According to the transient dynamic analysis of the finite element analysis for the torsional steel wire and the load–time process that is applied, the steel wire strain nephogram in a period is obtained, as shown in Figure 4. At the moment of the largest torsion angle, the maximum shear stress shows near the clamping area, but no dramatic change occurs due to the clamping force, and only 18 MPa is increased.

The stress diagram in the bus direction of the steel wire is extracted from the result. In the bus direction, one point of stress is taken every 1 mm to create the curve, as shown in Figure 5. It can be seen from the figure that, the additional stress influence is significant within 11 mm near the steel wire clamping area.

Figure 3. Schematic of the finite element model after amplification.

4 LABELING OF THE STEEL WIRE FRACTURE LOCATION IN THE TEST

4.1 Test materials and methods

The 55CrSi steel wire is adopted by this experiment as the test material. Its specific components are shown in Table 2, and others are Fe.

Since there's no specific test specification for the torsional fatigue test of steel wires, some labeling tests can be carried out in the early stage to determine the test specification of one diameter standard. The oil-quenching steel wire made by 55CrSi steel is used in this paper for the torsional fatigue test. Specific parameters are shown in Table 3.

Parameters confirmed in the test include the test frequency f (referring to ref. 1) shown in equation (1), and the clamping force F . The additional force needs to ensure that there is no slip of the steel wire affected by the alternating torque, which should not be too large to make the influence of the additional force significant.

According to the restrictive frequency f_n calculated in ref. 1, a safe value $\zeta = 0.8$ can be selected to obtain the following equation:

$$f_n = \frac{1}{4} \sqrt{\frac{T_n^2 - \frac{1}{384} (\tau_{\max} \pi d^3)^2}{(J_M + J_L) a}} \quad (1)$$

And so, $f < f_n$. The clamping force can be measured by using the work pressure of the hydraulic power pack and labeled by the test, as shown in Table 4.

In the experiment, it is found that the torque test can proceed smoothly within the clamping force scope, the obtained fatigue life is similar, and that the variance fluctuation is within 5%. The mid-value of the clamping force is selected in the test, because the work pressure in the hydraulic power pack is an adjustable mid-value with small error.

Table 2. Setting mass fraction of the chemical components of the 55CrSi steel wire.

C	0.46–0.54	Si	0.17–0.37
Mn	0.50–0.80	Cr	0.80–1.10
V	0.10–0.20	S	< 0.30
Cu	< 0.25	P	< 0.30
Ni	< 0.35

Table 4. Selection of the clamping force.

Length–diameter ratio	Clamping force	Clamping force for in the test
40	(4.0–5.0) MPa	4.5 MPa
50	(4.0–5.0) MPa	4.5 MPa
60	(5.0–6.0) MPa	5.5 MPa

Figure 6. Curve of steel wire fracture locations and cycling times.

4.2 Analysis of test results

The steel wire whose length–diameter ratio is 50 and it is selected by this test. With the method mentioned in Section 3.1, the test-restrictive frequency f_n is obtained, so as to test with the frequency as large as possible. The selected clamping force is 4.5 MPa, and the 1000 MPa stress level is selected by the test. The torque test with the cycling performance being 0 is conducted. The cycling times and fracture locations of the test are recorded to create the fitting curve, as shown in Figure 6. As seen from the fitting curve, it can be divided into two parts.

When the fracture location is close to the clamping area, the cycling times will be smaller than 1 million, and when it is far away from the clamping area, the cycling times will be around 1.7 million. Obviously, the influence of the clamping force on the former is more significant.

As can be seen clearly from the curve, when the fracture location is 11 mm away from the clamping area, there are sudden changes for the cycling times. It is also the boundary of the two cycling times levels, which can also be regarded as the demarcation line of whether it is affected by the additional force. The experiment is basically consistent with the result of finite element analysis.

5 THE RUN TEST (ZHANG, 2014; KONG, 2011; LI, 2010; ZENG, 2008)

When combined with the finite element analysis and the test verification, the demarcation point of determining whether the fracture location is effective is labeled. No matter the finite element analysis or the test verification, system errors or measurement errors do exist all the time. Thus, verification for the above conclusions is necessary.

Within the effective fracture location, the steel wire stress is only relevant to the diameter according to the torque theory, and its stress is the maximum at the steel surface. Therefore, the fracture

location of the steel wire should be a random variable. In this way, only the randomness of the fracture location shall be measured.

The runs test is a method specially used to check the data randomness. The test area is divided into several small areas, and the numbers are given in turn from the left to the right. In case there is steel wire fracture in the area, it is recorded as 1; otherwise, it is recorded as 0. As a result, the issue will turn to the check of the randomness of one 0–1 sequence. The test area is divided into 50 small areas evenly along with number provisions in turn. The obtained data are shown in the following table

It is assumed that H_0 denotes that the fracture in the table shows the random distribution, and H_1 denotes that the fracture in the table does not show the random distribution.

n_0 represents the number of 0 s, n_1 represents the number of 1 s, and R is the run length, and the statistics of the Runs test.

In cases when n_0 and n_1 are not larger than 20, the calculation test can be conducted by referring to the table, but n_0 and n_1 are both larger than 20 in this paper. Under the condition of H_0 , R conforms to the normal distribution and its expectation and variance are given as follows:

$$E(R) = \frac{2n_0n_1}{n_0 + n_1} + 1 \quad V(R) = \frac{2n_0n_1(2n_0n_1 - n_0 - n_1)}{(n_0 + n_1)^2(n_0 + n_1 - 1)}$$

Its form of standard normal distribution is given as follows:

$$Z = \frac{R - E(R)}{\sqrt{V(R)}} = \frac{R - \frac{2n_0n_1}{n_0 + n_1} - 1}{\sqrt{\frac{2n_0n_1(2n_0n_1 - n_0 - n_1)}{(n_0 + n_1)^2(n_0 + n_1 - 1)}}} \in N(0,1)$$

Therefore, the critical value of the rejection region can be obtained by referring to the table in the given confidence level α .

Table 5. List of fracture locations of the steel wire.

No.	Fracture	No.	Fracture	No.	Fracture	No.	Fracture	No.	Fracture
1	0	11	0	21	0	31	0	41	0
2	0	12	0	22	1	32	0	42	1
3	1	13	1	23	1	33	0	43	0
4	1	14	0	24	0	34	0	44	0
5	0	15	1	25	1	35	0	45	0
6	1	16	1	26	0	36	0	46	0
7	0	17	0	27	0	37	1	47	1
8	0	18	1	28	1	38	0	48	0
9	1	19	1	29	1	39	0	49	0
10	0	20	0	30	0	40	0	50	0

Thus, the random test issue of the original series can be solved by using the normal distribution. In the above test data table, it can be obtained that $n_0 = 33$, $n_1 = 17$, 23.44, and 21.72, and $Z = 0.00718$, because Z is in the range $(-1.96, 1.96)$ (1.96 is the critical value of the standard normal distribution when the significance is 0.95).

H_0 is accepted and the fracture in the table shows the normal distribution.

6 CONCLUSIONS

1. Based on the restriction of steel wires in the actual test, finite element analysis is carried out in this paper. The stress distribution curve of the cylinder bus of steel wires is elaborated and the demarcation point of the effective fracture location of steel wires is obtained. Based on the existing experimental data, the curve of fatigue life and fracture location are obtained, which is basically consistent with the theoretical demarcation point of the effective location.
2. The random test of the sample data of the steel wire fracture location is conducted, and the results show that the fracture location of steel wires in the test area is random, which further

verifies the rationality of the demarcation point division of the effective location.

The lightweight design of the support arm

Yaqin Tian

Taiyuan University of Science and Technology, Taiyuan, China

Dan Meng & Xiaoyi Lin

JMC Heavy Duty Vehicle Co., Ltd, Taiyuan, China

ABSTRACT: The model of the arm was established for supported kids' sickbeds under the bed board by using Creo software in this paper. The relationship of the arm width, plate thickness, stress, and the total weight was analyzed through topological optimization under the ANSYS Workbench, and a lightweight design is implemented. The weight of arm is reduced about 33% by topological optimization under the ANSYS Workbench and the production cost of beds is also reduced.

Keywords: topological optimization, light weight, structure optimization

1 INTRODUCTION

With the development of the medical industry, more and more medical bed series were designed. There were different structure designs for different age levels of sickbeds. A lightweight design is an important method to reduce the cost of the large quantity production. The materials' design of lightweight (Cho, 2009), shape and size optimization, structure optimization, and multi-objective optimization design (Leite, 2015) are the main directions of lightweight research. The weight can be reduced by 48% after applying the weight loss design for some structures (Raedt, 2014). The lightweight design of the sandwich structure can reduce weight 7.5 kg/m² for the trailer (Michael, 2013). The lightweight design of a continuous variable cross-section roll plate is used to design the hybrid column, which makes the weight of the car reduced by about 20% (Thomas, 2015). The lightweight design method based on the impact of the car body, and the body weight can be reduced by 5.2% from the sensitivity analysis and optimization calculation to the thickness of the main structure (Lan, 2010). Lightweight structures for interior and exterior as well as car bodies, which can be produced in a flexible manner, are in the center of discussion. In order to satisfy the performance requirement of high dynamic and static characteristics and light weight of the activity crossbeam, the mass of the activity crossbeam was decreased by 12.2% through a method of multi-objective optimization (Sun, 2015). It also can reduce the structure weight by 21.4% with the improved response surface method (Pan, 2010). An arm's model was established which supported kids' sickbeds under the bed board by using Creo

software in this paper. The lightweight design is implemented to the arm under the ANSYS Workbench, which contains the Modeler Design and three modules of the Mechanical and Xplorer Design.

2 TOPOLOGY OPTIMIZATION BASED ON THE VARIABLE DENSITY METHOD

The topology optimization method considers the material distribution as an object. The optimal distribution scheme can be found in the design space of uniformly distributed material, and then the final shape can be determined. Material utilization can greatly be improved (Kirsch, 1989). The main research methods of the continuum topology optimization are level set method, evolutionary structural optimization, (Kim, 2000), homogenization method (Nikos, 2015), variable density method etc. In addition, there is the discrete topology optimization (Cheng, 2014) and the method of topology optimization (Krister, 2009) based on the genetic algorithm (Kawamura, 2002) which is also being studied. ANSYS topology optimization simulation is the combination of the variable density method and finite element method. The variable density method includes SIMP (Solid Isotropic Microstructures with Penalization) and RAMP (Rational Approximation of Material Properties). These models are established by the penalty factor, which is a non-linear relationship between the elastic modulus of the material and the relative density of the element. Its effect is to punish the intermediate density value, so that the intermediate density value is gradually gathered to the 0/1 level. When the values of the design variables are in the range of (0, 1), in this way, the continuous variables can be well-approximated by

the model of 0–1 discrete variables. At this time, the intermediate density unit corresponds to a very small elastic modulus, and the influence of the structural stiffness matrix will become very small and can be ignored. For the RAMP density stiffness interpolation model, the intermediate density of the penalty is carried out by the following equation:

$$E_i = \frac{x_i}{1 + p(1 - x_i)} E_0$$

where, E_i is the elastic modulus of the No. i unit. E_0 is the elastic modulus of the material when the unit is filled, and p is the penalty factor.

Whether the intermediate density material can be effectively eliminated or not and obtain clear optimization results are affected by the penalty factor p . The general penalty factor p is in the range of 3–31.

In general, the optimization model of the variable density method is shown in Fig. 1. In the optimization model equation, x_i is the design variable and it is the relative density of materials; n is the number of finite elements in the design domain; $C(x)$ is the objective function, and it is the structural compliance; K is the total stiffness matrix of the structure; U is the general displacement vector of the structure; F is the load vector of the structure; V is the volume after the optimized structure; V_i is the unit volume; f is the volume fraction of a given material; V_0 is the volume of an initial structure; V^* is the volume cap; x_{min} is the minimum relative density. The optimization design process under the ANSYS Workbench is shown in Figure 1.

The Design Modeler is used to build a model module. It is the module to realize the interaction between CAD and CAE and it is the first step in product development and processing too. Simulation is the second step. The third is the Design Explorer. It can obtain clear optimization results by

choosing appropriate penalty factors and topology optimization.

3 THE MODELING PROCESS BY USING THE ANSYS FINITE ELEMENT

The specific steps of product optimization design by using the Ansys workbench is as follows: modeling, add dimension parameters, add material properties, meshing, add the loads and constraints, finite element analysis, topology optimization, shape optimization design, defined target parameters and status parameters, optimization, comparison, and validation. Parameter optimization is also solved directly for fixed shape.

The arm structure is the most important structure of the connection bed plate and hand screw pipe. In order to analyze the stress and deformation, the model must be simplified. The seamless steel pipe welded together with the arm is ignored. The model and the key parameters are imported to the Design Modeler Workbench platform through the Creo and Workbench ANSYS seamless connection and the parameters can be fully controlled by using the Workbench.

The material of the arm is ordinary carbon steel Q235. Its properties are as follows: the yield limit is 235 MPa, Poisson's ratio is 0.3, the elastic modulus is 2×10^5 MPa, and the density is 7.85×10^{-9} T/mm³. The original size of the arm is as follows: the length is 180 mm, width is 50 mm, and thickness is 2 mm. As the arm is stamping, the free divides of the function in meshing is selected. The grid size is 1 mm, the number of discrete nodes is 136431, and the unit number is 74359.

4 STATIC ANALYSIS

4.1 The boundary conditions and loading

The screw is connected with the support arm by using the pin. On the other end, the supporting arm is welded in a seamless steel tube of $\Phi 32 \times 2$. The arm has been in force when the bed is under working condition, and can be regarded as a two-force bar. The direction of the force is consistent with diameter connection of two different holes of the support arm. Children's weight is generally not more than 80 kg under 15 years of age, and the safety factor is 1.5. Thus, the putting weight is 120 kg. The maximum force is in the arm which lies on the left-hand side of the bed frame, and the bed component effects are neglected. And so, the applied force is 1200 N. The displacement constraint is 0 mm in the small hole in the X, Y, and Z directions. The solution result for the total mass is 0.27913 kg, the maximum stress is 34.517 MPa (Figure 2), and the maximum total deformation is 0.043639 mm (Figure 3).

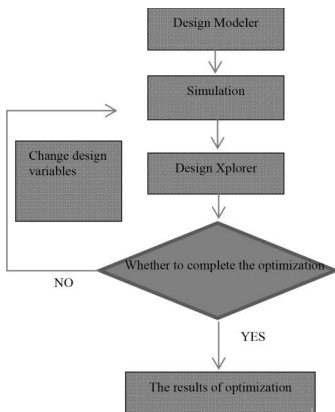

Figure 1. The process of optimization design on ANSYS Workbench.

Figure 2. Graph of arm stress.

Figure 3. Graph of arm deformation.

4.2 The size optimization of the arm

Before importing Workbench, the variable name must be modified in Creo. The width of the supporting arm of the variable name is changed to DS_d0, the thickness is modified to DS_d9, so that these two dimensions can be identified in Workbench Ansys. At the same time, the model type and the parameters of the model are selected. “P” will appear before the size (Figure 4), which indicates that the size is optimized at this time. Finally, the Modeler Design module is exited. In the same way, the quality, the maximum total deformation, and the maximum equivalent stress are parameterized. After the parameter setting is completed, the Experience Design module is entered. The width dimension (DS-d0) is between 40–50 mm and the plate thickness (DS-d9) is in the 1–2 mm range at the Input Parameters. Taking into account the extreme use of the situation, a certain degree of safety is set aside. The result requires that the maximum stress is less than the Q235 yield stress of 55 MPa, and the solution of the target is the minimum of the mass and the deformation.

4.3 Topology optimization design of the ANSYS Workbench

There are three ways to display the results in the Workbench ANSYS topology optimization module. First is to show that the topological iteration process through the list. The second is to display the topology of the iterative process with graphics. And the other topology optimization results are shown by using different colors on the entity. The penalty factor is set to reduce weight by 20%, and then the supporting arm shape topology

Figure 4. The setting process of parameter.

Figure 5. Schematic of the results of topology optimization.

Figure 6. Graph showing the effect of mass, deformation, and stress by size.

optimization is carried out. The most intuitive method of topology optimization is selected, and the results are shown in Figure 5.

The darker parts of the map can be removed in the region. The lighter part of the color indicates a less important part and can be removed or retained as needed. The gray-colored region is the retained region. After optimization, the effect of mass, deformation, and stress by size are shown Figure 6. The change of thickness has little influence on the quality of the arm while has a great influence on the total deformation and stress. The change of the width has little effect on the stress, as shown in Figure 6.

Ten groups of optimization design results (Figure 7) are compared. Stress over 55 MPa of the optimized groups 4, 6, 7, was excluded. The final optimization plan is the lightest of the quality of the group 2 in the remaining 7 groups. The arm width is 40 mm and thickness is 1.5 mm after optimization.

The arm size of the 2nd group was calculated by using the finite element method. The arm mass is

Figure 7. Graph showing the quality and stress of each scheme.

Figure 8. Graphs showing deformation–stress after optimization.

0.18709 kg after calculation. The maximum deformation is 0.09179 mm. The maximum stress is 48.287 MPa (Figure 8). It is less than the strength requirement of the material yield stress which is 55 MPa. After making a quality comparison before and after optimization, it can be observed that the weight reduced by 33% after optimization.

5 CONCLUSION

The arm’s optimization design was carried out for the initial width of 50 mm and thickness of 2 mm for supported kids’ sickbeds under the bed board by using ANSYS workbench in this paper. The width of the arm is 40 mm and the thickness is 1.5 mm after optimization. Based on the strength requirements, the optimized quality of the arm is reduced about 33%.

An analysis of the thermal elastohydrodynamic lubrication performance of the slope of the thrust bearing

YuLei Liu, YongHai Li, TianYu Niu, JueFei Huang & YuXin Wang

School of Mechanical and Engineering, Harbin University of Science and Technology, Harbin, China

ABSTRACT: A mathematical model of the thermal elastohydrodynamic lubrication of fixed and inclined thrust bearings is established according to the lubrication theory and the finite element numerical analysis method and the preparation of the calculation program and calculation are compared. The results show that the two calculation methods are in line with the general rules of the lubrication theory, and thermal elastohydrodynamic lubrication's calculation results tend to be safe. This conclusion can provide reference for the design and application of the thrust bearing.

1 INTRODUCTION

These are very important and the key problem in the design of the bearing is to improve the lubrication performance of the bearing, reduce the friction of the bearing, and reduce the failure of the thrust bearing. In order to improve the lubrication performance and reduce the thrust bearing's burning time to bring losses, many scholars studied variable viscosity and bearing deformations of the tilting pad's thrust bearing. The results showed that the bearing deformation had a larger effect on the lubrication performance of journal bearings (Wu, 2007; Zhu, 1990; An, 2011; Liu, 2010; Ge, 1983). But there were no studies on the fixed pad bearing, which is still under constant temperature and viscosity conditions of the simple calculation, to account for the variable viscosity and deformation of the shell of the fixed pad thrust-bearing's properties and lubrication properties' analysis. In this paper, the lubrication mechanism of the fixed and inclined thrust bearings is revealed by using the knowledge of fluid lubrication, included in the viscosity, temperature change, bearing deformation etc. These are factors identified on the basis of the above-mentioned research results. The results have theoretical significance and application value to the design of the thrust bearing.

2 MATHEMATICAL MODEL

2.1 Shape of the oil film

The fixed pad's thrust-bearing inclined plane is used in the structure of the horizontal axis. The bearing will form a dynamic pressure oil film, and the film shape is formed between the tile surface and thrust plate (mirror plate) gap's oil film, and set the tile

surface deformation as a parabolic and the thrust disc (mirror plate) as a rigid plane; the oil film shape is as shown in Figure 1. The governing equation of the oil film shape is given as follows (Ding, 1986; Chen, 1980; Pang, 1981; Wang, 2004; Han, 2004):

$$h_i = h_0 + \frac{c}{l} r_i \sin\left(\theta_i - \frac{\theta_0}{2}\right) + \frac{e^2}{e_A^2} \delta_{max} \quad (1)$$

where h_i is the oil film thickness of the surface; h_0 is the center of the surface of the oil film thickness; c is the elevation of the slope of the tile; l is the tile length; r_i is the tile surface at any point of the pole radius; θ_i is the tile surface at any point of the polar angle; θ_0 is tile angle; e is the distance to the tile surface at any point in the heart; e_A is the largest deformation point on the surface to the center distance; and δ_{max} is the largest deflection deformation of bearing.

Figure 1. Schematic of the oil film's shape.

$$e^2 = r_i^2 + r_0^2 - 2r_i r_0 \cos\left(\theta_i - \frac{\theta}{2}\right) \quad (2)$$

$$e_A^2 = r_A^2 + r_0^2 - 2r_A r_0 \cos\frac{\theta_0}{2} \quad (3)$$

where r_A is the outer radius of the tile and r_0 is the polar radius of the center point of the tile surface.

2.2 Oil film pressure equation

$$\frac{\partial}{\partial r}\left(\frac{r h^3}{\mu} \frac{\partial p}{\partial r}\right) + \frac{\partial}{\partial \theta}\left(\frac{h^3}{\mu} \frac{\partial p}{r \partial \theta}\right) = 6\omega r \frac{\partial h}{\partial \theta} \quad (4)$$

where P is the pressure of the fluid; μ is the lubricating oil's viscosity; h is the thickness of the oil film; ω is the angular velocity; and r and θ are respectively the radial and circumferential coordinates. The boundary condition can be written as zero pressure along the surface of the tile.

$$\bar{p}|_{\Sigma} = 0 \quad (5)$$

where Σ is the boundary.

2.3 Oil film temperature equation

The temperature field of the bearing can be solved by using the energy equation. The energy equation of the thrust bearing of the inclined surface tile is given as follows:

$$\begin{aligned} JC_{\rho} \rho g \left[\left(\frac{\omega r h}{2} - \frac{h^3}{12\mu} \frac{\partial p}{r \partial \theta} \right) \frac{1}{r} \frac{\partial T}{\partial \theta} - \frac{h^3}{12\mu} \left(\frac{\partial p}{\partial r} - \rho \omega^2 r \right) \frac{\partial T}{\partial r} \right] \\ - Jkh \left[\frac{\partial^2 T}{\partial r^2} + \frac{\partial^2 T}{r^2 \partial \theta^2} \right] + JK_B (T - T_0) = \frac{\mu \omega^2 r^2}{h} + \frac{h^3}{12\mu} \\ \times \left[\left(\frac{\partial p}{\partial r} \right)^2 + \left(\frac{\partial p}{r \partial \theta} \right)^2 \right] \end{aligned} \quad (6)$$

where J is the mechanical equivalent of heat; K and C_p are respectively the thermal conductivity of the oil film and specific heat capacity; T and ρ are respectively temperature and density; T_0 is the oil temperature; K_B is the heat conduction coefficient; and P is the solution of pressure values.

Boundary condition: $T=T_0$;

Temperature initial condition:

$$\varphi = 0, T = T_0, \frac{\partial T}{\partial R} = 0, r = R_2, \frac{\partial T}{\partial R} = 0.$$

2.4 Viscosity temperature equation

The viscosity temperature equation is obtained by using the Lagrange interpolation method.

$$\mu = \sum_{i=1}^n \left[\prod_{\substack{j=1 \\ j \neq i}}^n \frac{T - T_j}{T_i - T_j} \right] \mu_i \quad (7)$$

where T_i and U_i are the temperature and the viscosity value of the reference point; n is the number of the reference point; T is the interpolation temperature point; and μ_T is the response viscosity.

The oil temperature boundary conditions of the bearing can be carried through the heat equation to be determined.

$$T_{in} = \left(\frac{1-K}{1-K/2} \right) T_s + \left(\frac{K}{2-K} \right) T_{out} \quad (8)$$

where T_s is the oil supply temperature; T_{out} is the oil outlet temperature; and K is the hot oil carrying factor, whose value is 0.5–0.9; depending on the speed of the bearing surface of the selected bearing, $K=0$ is the carrying oil calculation.

$$T_{in} = T_{out}$$

2.5 Single tile oil film control equation

The general properties of the equations in a class of similar phenomena are taken into account, and marked as the dimensionless quantity:

$$\begin{cases} r = R\bar{r}, h_{\min} = \min\{h\}, h = h_{\min} \bar{h}, \mu = \mu_0 \bar{\mu}, p = p_0 \bar{p}, \\ T = T_0 \bar{T}, \theta = \bar{\theta}, \mu_0 = \left(\sum_{i=1}^N \mu_i \right) / N, p_0 = 6\mu_0 \omega R^2 / h_{\min}^2, \\ T_0 = p_0 / JC_{\rho} \rho g = 6\mu_0 \omega R^2 / JC_{\rho} g h_{\min}^2; D = 2\lambda / C_{\rho} \rho g h_{\min} \\ \omega d, M_R = m_r R / h_{\min}, M_{\theta} = m_{\theta} R / h_{\min}, A = \delta_{\max} / h_{\min}; e_A^2 = 1 \\ + R_0^{-2} - 2R_0 \cos(\bar{\theta}_r / 2), e = r + R - 2R_0 r \cos(\bar{\theta} - \bar{\theta}_r / 2) \end{cases} \quad (9)$$

The lubrication performance of the thrust bearing of the inclined surface tile can be solved by using the above equation. Because most of the mathematical models are composed of two partial differential equations, the finite element method is used to solve the problem.

3 EXAMPLE AND COMPARATIVE ANALYSIS

3.1 Calculation method of the lubrication performance

In the past, for the inclined plane thrust bearing's lubrication performance calculation with the traditional approximate calculation method, an approximate calculation equation was used, regardless of the lubricating oil viscosity changes and bearing deformation, through the look-up table and the

curve of rough calculation and there are many kinds of calculation methods. The thermal EHL numerical calculation method, finite element method, control equation of the simultaneous solution of the oil film shape equation, Reynolds equation, energy equation, viscosity temperature control equation, in the meantime, considering the change of oil viscosity and the bearing deformation (Zhang, 2014; Fan, 2013; Li, 2014; Yu, 2014; Fan, 2014; Ting, 1971; Sharma, 2002; Yoshimoto, 1993; Younes, 1993; Adam, 2003).

3.2 Calculation results and comparative analysis

The calculation of bearing parameters respectively is performed for the following parameters: the bearing's outer radius is 0.19 M, bearing's inner radius is 0.09 m, tile is 10 mm thick, number of tiles is 3, the lubricating oil brand is L-TEA46, lubrication is oil-immersed lubrication, and the oil temperature on the inside is 33°C.

3.2.1 Influence of speed on lubrication characteristics and comparative analysis

Figures 2–5 show the relationship between the velocity and the minimum oil film thickness, the maximum film temperature, the maximum film pressure, and the power consumption of the two

calculation methods. The sign of ▲ shows approximate calculation results. The sign of ■ shows thermal EHL calculation results.

It can be seen from the figures that, the relationship between two methods of calculating speed and minimum oil film thickness, maximal oil film temperature, maximum oil film pressure, and power consumption, in line with the general rules of the lubrication theory, oil film pressure and power consumption of the two calculation methods changed little, the minimum oil film thickness and maximum oil film temperature is slightly different, and the thermal EHL calculation tends to be more conservative. From the figures, the relationships between calculating speed and the minimum oil film thickness of two methods, the maximal oil film temperature, the maximum oil film pressure and power consumption can be obtained.

3.2.2 Effect of specific pressure on lubrication characteristics and comparative analysis

Figures 6–9 show the relationship between the two calculation methods, the specific pressure and the minimum film thickness, the maximum oil film temperature, the maximum oil film pressure, and power consumption. Because of the limited space, only the speed of the calculation is 18 m/s.

Figure 2. Variation curve of the minimum oil film thickness with speed.

Figure 4. Variation curve of the maximum film pressure with speed.

Figure 3. Variation curve of the maximum oil film temperature with speed.

Figure 5. Variation curve of the bearing's power consumption with specific pressure.

Figure 6. Variation curve of the minimum oil film thickness with specific pressure.

Figure 7. Variation curve of the maximum oil film temperature with specific pressure.

Figure 8. Variation curve of the maximum oil film pressure with specific pressure.

Figure 9. Variation curve of the power consumption with specific pressure.

From the graphs, we can see that the relationship between the ratio of the two calculation methods, the minimum oil film thickness, the maximum oil film temperature, the maximum oil film pressure and power consumption is similar to that mentioned in Section 3.2.1.

4 CONCLUSIONS

The maximum oil film temperature, the maximum oil film pressure and power consumption is computed by using the traditional method (regardless of the viscosity temperature change and the bearing deformation) and the thermal elastohydrodynamic lubrication method for computing (included in the viscosity temperature change and deformation of the shell), and the results show that calculation results of the two calculation methods are in line with the general rules of the lubrication theory, and thermal EHL calculation results tend to be more safe. These conclusions can provide reference for the design and application of the thrust bearing.

Chunlai Li & Yang Liu

Department of Weaponry Engineering, Naval University of Engineering, Wuhan, China

ABSTRACT: To study the motion performance of submarines carrying an external weapon module, in this paper, a method of approximation is used to calculate the hydrodynamic coefficients of submarines carrying the weapon module, the Matlab mathematical model of six-freedom-motion is built, and a comparative simulation analysis of five kinds of typical motions of submarines before and after carrying the external weapon module is performed. The result of the simulation indicates that carrying an external weapon module has an effect on a submarine's motion performance to some extent, thereby resulting in the reduction of its maneuverability and steering quality. The simulated model can reflect motion features of submarines with external weapon module, which provides the theoretical foundation for further feasibility analysis.

1 INTRODUCTION

Submarines carrying an external weapon module (the module can be divided into UUV, missile, torpedo, etc.) play an important role in promoting the underwater combating ability in current and future warfare. Referring to the literature, studies on motion modeling and simulation of submarines carrying external weapons are rather rare. Applications about submarines carrying external weapons are mainly about the mine layer box and UUV (Fan, 1995; Qian, 2003; Sirmalis, 2001); on the aspect of study of submarines' external carrying, the domestic research is mainly about conducting calculations of the hydrodynamic coefficient of the submarine-carrying pod (Yang, 2009). While on the aspect of submarine space operation simulation, foreign scientists have carried out much work in the theory of submerged maneuverability, security, attack elusion effect validity, onshore manipulation, simulation training, and comprehensive display centralized control (Fu, 1992; Xia, 1992; John, 1978); domestic research has also made many achievements (Hu, 2006). Based on the achievements mentioned above, in this paper, modeling simulation and initial analysis for the motion of the submarine carrying an external weapon module are conducted.

2 MODELING AND SIMULATION OF THE SUBMARINE MOTION

2.1 Modeling and solving

Establish the fixed coordinate system $E - \xi\eta\zeta$ and moving coordinate system $G - xyz$, as is shown in Figure 1. Assuming that the speed relative to the earth of the submarine barycenter is V , the projection of V on $G - xyz$ is u (longitudinal speed), v (horizontal speed), and w (vertical speed); the submarine rotates with an angular velocity of Ω , and the projection of Ω on $G - xyz$ is p (heel angular velocity), q (trim angular velocity), and r (yawing rate). And set that right-leaning of the heel angle as φ , right-turning of the heading angle as ψ , and stern-leaning of the pitch angle as θ ; the right rudder of the rudder angle δ_r is

Figure 1. Schematic of the fixed coordinate system and moving coordinate system.

positive, and the sign of the head rudder angle δ_h and stern rudder angle δ_s is determined with right-hand rule, and then the heading rudder angle δ_b is the positive rudder angle, and the stern rudder angle δ_s is the positive diving angle.

On an established coordinate system, according to the standard motion equation for the submarine simulation study carried out by Gertler (Martlon, 1967), the influence of the propeller burden can be ignored and the differentiation is moved to the left-hand side and the rest to the right-hand side of the equation, and the equation of the six-freedom-motion of submarines is obtained as follows:

Longitudinal force equation:

$$a_{11}\dot{u} + a_{15}\dot{q} + a_{16}\dot{r} = f_1 \quad (1)$$

Horizontal force equation:

$$a_{22}\dot{v} + a_{24}\dot{p} + a_{26}\dot{r} = f_2 \quad (2)$$

Vertical force equation:

$$a_{33}\dot{w} + a_{34}\dot{p} + a_{35}\dot{q} = f_3 \quad (3)$$

Heel torque equation:

$$a_{42}\dot{v} + a_{43}\dot{w} + a_{44}\dot{p} + a_{45}\dot{q} + a_{46}\dot{r} = f_4 \quad (4)$$

Trim torque equation:

$$a_{51}\dot{u} + a_{53}\dot{w} + a_{54}\dot{p} + a_{55}\dot{q} + a_{66}\dot{r} = f_5 \quad (5)$$

Yaw torque equation:

$$a_{61}\dot{u} + a_{62}\dot{v} + a_{64}\dot{p} + a_{65}\dot{q} + a_{66}\dot{r} = f_6 \quad (6)$$

In which,

$$a_{11} = m - \frac{1}{2}\rho L^3 X'_{\dot{u}}, a_{15} = \frac{1}{2}\rho L^3 m Z_G, a_{16} = -\frac{1}{2}\rho L^3 m y_G,$$

$$a_{22} = m - \frac{1}{2}\rho L^3 Y'_{\dot{v}}, a_{24} = -m Z_G - \frac{1}{2}\rho L^4 Y'_{\dot{p}},$$

$$a_{26} = m x_G - \frac{1}{2}\rho L^4 Y'_{\dot{r}},$$

$$a_{33} = m - \frac{1}{2}\rho L^3 Z'_{\dot{w}}, a_{34} = m y_G, a_{35} = -m x_G - \frac{1}{2}\rho L^3 Z'_{\dot{q}},$$

$$a_{42} = -m z_G - \frac{1}{2}\rho L^4 Z'_{\dot{v}}, a_{43} = m y_G, a_{44} = J_x - \frac{1}{2}\rho L^3 K'_{\dot{p}},$$

$$a_{45} = -J'_{xy},$$

$$a_{46} = -J_{zx}, a_{51} = -m z_G, a_{53} = m x_G - \frac{1}{2}\rho L^4 M'_{\dot{w}},$$

$$a_{54} = J_{xy}, a_{55} = J_y - \frac{1}{2}\rho L^5 M'_{\dot{q}}, a_{56} = -J_{yz}, a_{61} = -m y_G,$$

$$a_{62} = m x_G - \frac{1}{2}\rho L^4, a_{65} = J_{yz}, a_{64} = -J_{zx} - \frac{1}{2}\rho L^5 N'_{\dot{p}},$$

$$a_{66} = J_z - \frac{1}{2}\rho L^5 N'_{\dot{r}};$$

$$f_1 = \left[m x_G + \frac{1}{2}\rho L^4 X'_{\dot{q}} \right] q^2 + \left[m x_G + \frac{1}{2}\rho L^4 X'_{\dot{r}} \right] r^2 - m y_G p q + \left[\frac{1}{2}\rho L^4 X'_{\dot{q}} - m z_G \right] p r + \left[\frac{1}{2}\rho L^3 X'_{\dot{w}} + m \right] v r + \left[\frac{1}{2}\rho L^3 X'_{\dot{w}} - m \right] w q + \frac{1}{2}\rho L^2 \left[X'_{\dot{u}} u^2 + X'_{\dot{v}} v^2 + X'_{\dot{w}} w^2 \right] + \frac{1}{2}\rho L^2 u^2 \left[X'_{\dot{\delta}_h} \delta_r^2 + X'_{\dot{\delta}_b} \delta_b^2 + X'_{\dot{\delta}_s} \delta_s^2 \right] + \frac{1}{2}\rho L^2 \left[a_r u^2 + b_r u v + c_r u^2 \right] - (W - B) \sin \theta$$

$$f_2 = \left[\frac{1}{2}\rho L^4 Y'_{\dot{p}} - m x_G \right] p q + m y_G \left[p^2 + r^2 \right] - m z_G q r + \left[\frac{1}{2}\rho L^3 Y'_{\dot{r}} - m \right] u r + \frac{1}{2}\rho L^3 Y'_{\dot{p}} u p + \left[\frac{1}{2}\rho L^3 Y'_{\dot{w}} + m \right] w p + \frac{1}{2}\rho L^2 \left[Y'_{\dot{u}} u^2 + Y'_{\dot{v}} u v + Y'_{\dot{w}} v \left[(v^2 + w^2)^{1/2} \right] \right] + \frac{1}{2}\rho L^2 \left[Y'_{\dot{v}} v w + Y'_{\dot{\delta}_r} u^2 \delta_r \right] + (W - B) \cos \theta \sin^{-1} \varphi$$

$$f_3 = m z_G \left[p^2 + q^2 \right] - m x_G r p - m y_G r q + \frac{1}{2}\rho L^4 Z'_{\dot{r}} r^2 + \left[\frac{1}{2}\rho L^3 Z'_{\dot{q}} + m \right] u q - \left[m - \frac{1}{2}\rho L^3 Z'_{\dot{v}} \right] v p + \frac{1}{2}\rho L^3 Z'_{\dot{w}} v r + \frac{1}{2}\rho L^2 \left[Z'_{\dot{u}} u^2 + Z'_{\dot{w}} u w + Z'_{\dot{w}} |w| \left[(v^2 + w^2)^{1/2} \right] \right] + \frac{1}{2}\rho L^2 \left[Z'_{\dot{w}} |u| |w| + Z'_{\dot{w}} |w| \left[(v^2 + w^2)^{1/2} \right] \right] + \frac{1}{2}\rho L^2 \left[Z'_{\dot{v}} v^2 + Z'_{\dot{\delta}_b} u^2 \delta_b + Z'_{\dot{\delta}_s} u^2 \delta_s \right] + (W - B) \cos \theta \cos \varphi$$

$$f_4 = \frac{1}{2}\rho L^5 \left[K'_{\dot{q}} q r + K'_{\dot{p}} p q + K'_{\dot{p}} |p| |p| \right] + \frac{1}{2}\rho L^4 \left[K'_{\dot{p}} u p + K'_{\dot{r}} u r + K'_{\dot{w}} w p \right] + (J_y - J_z) q r - J_{xy} p r - J_{yz} \left(r^2 - q^2 \right) + J_{zx} p q + \frac{1}{2}\rho L^3 \left[K'_{\dot{u}} u^2 + K'_{\dot{v}} u v + K'_{\dot{w}} v \left[(v^2 + w^2)^{1/2} \right] \right] + \frac{1}{2}\rho L^3 \left[K'_{\dot{w}} v w + K'_{\dot{\delta}_r} u^2 \delta_r \right] + (y_G W - y_c B) \cos \theta \cos \varphi - (Z_G W - Z_c B) \cos \theta \sin \varphi - T_N$$

$$f_5 = (J_z - J_x) r p + J_{xy} q r + (r^2 - p^2) J_{zx} - J_{yz} p q + \frac{1}{2}\rho L^5 \left[M'_{\dot{r}} r^2 + M'_{\dot{r}} r p + M'_{\dot{q}} q |q| \right] + \frac{1}{2}\rho L^4 M'_{\dot{q}} u q + \frac{1}{2}\rho L^3 \left[M'_{\dot{u}} u^2 + M'_{\dot{w}} w + M'_{\dot{w}} |w| \left[(v^2 + w^2)^{1/2} \right] \right] + \frac{1}{2}\rho L^3 \left[M'_{\dot{w}} |u| |w| + M'_{\dot{w}} w \left[(v^2 + w^2)^{1/2} \right] \right] + \frac{1}{2}\rho L^3 \left[M'_{\dot{v}} v^2 + M'_{\dot{\delta}_b} u^2 \delta_b + M'_{\dot{\delta}_s} u^2 \delta_s \right] - (x_G W - x_c B) \cos \theta \cos \varphi - (z_G W - z_c B) \sin \theta$$

$$f_6 = (J_x - J_y) p q + (p^2 - q^2) J_{xy} + J_{yz} r p - J_{zx} r q + \frac{1}{2}\rho L^5 \left[N'_{\dot{p}} p q + N'_{\dot{r}} |r| |r| \right] + \frac{1}{2}\rho L^4 \left[N'_{\dot{p}} u p + N'_{\dot{r}} u r \right]$$

$$\begin{aligned}
& + \frac{1}{2} \rho L^3 \left[N'_0 u^2 + N'_v uv + N'_{|v|} v \left[(v^2 + w^2)^{1/2} \right] \right] \\
& + \frac{1}{2} \rho L^3 \left[N'_{vw} vw + N'_{\delta_r} u^2 \delta_r \right] + (x_G W - x_C B) \cos \theta \sin \varphi \\
& + (y_G W - y_C B) \sin \theta
\end{aligned}$$

The meaning of notes in the above-mentioned equation can be referred from the literature (Martlon, 1967).

By solving equation (1)–(6) simultaneously, the acceleration matrix can be obtained as follows:

$$\begin{bmatrix} \dot{u} \\ \dot{v} \\ \dot{w} \\ \dot{p} \\ \dot{q} \\ \dot{r} \end{bmatrix} = \begin{bmatrix} f_1 \\ f_2 \\ f_3 \\ f_4 \\ f_5 \\ f_6 \end{bmatrix} / \begin{bmatrix} a_{11} & \cdots & a_{16} \\ \vdots & \ddots & \vdots \\ a_{61} & \cdots & a_{66} \end{bmatrix} \quad (7)$$

In which the value of unvalued a_{ij} is 0.

Integrate the acceleration matrix in equation (7) and obtain speed and angular velocity, integrate again with the converted relation of the fixed and moving coordinate systems, and obtain the position and attitude angle of any time.

2.2 Verification of modeling

To testify the accuracy of the established model, verification is conducted according to the modeling simulation program in five typical motions of the submarine.

1. Horizontal steady rotation

Horizontal steady rotation is the rotation motion conducted when the submarine is on a direct route and the rudder is inclined at a fixed angle. Conduct a simulation study for the submarine on this motion with rudder angles of 15°, 25°, and 35° and the obtained barycentre locus curves are shown in Figure 2.

2. Horizontal Z-type steering motion

On practical voyage, the steering maneuver of the submarine is conducted on the basis of steady heading, the maneuverability of which can be studied with Z-type steering, and the focus is the response ability to the rudder. Conduct a simulation study for the submarine with the z-type steering motion with the obtained variation curves of the rudder angle and heading angle, as shown in Figure 3.

3. Vertical steady steep submerging and surfacing motion

The submarine will conduct the vertical steady steep submerging and surfacing motion when elevators are fixed on an angle in a fixed depth voyage. This motion reflects the depth maneuverability of the submarine. Conduct a simulation

study of this motion with elevators at the angles of 10° and 20° and the obtained barycenter locus curves are shown in Figure 4, and pitch angle variation curves are shown in Figure 5.

4. Vertical surpass maneuver motion

Adjust elevators regularly in the vertical plain and the submarine will conduct the vertical surpass maneuver motion. The response ability to elevators can be studied in this motion. Conduct a simulation study for the submarine with this motion with $\delta_s / \theta = 20^\circ / 10^\circ$, the obtained rudder angle and pitch angle variation curves are shown in Figure 6 and the depth variation curves are shown in Figure 7.

Figure 2. Locus curves of the motion in the horizontal plane.

Figure 3. Variation curves of the rudder angle and the heading angle of motion in the horizontal plane.

Figure 4. Locus curves of the motion in the vertical plane.

Figure 5. Variation curves of the pitch angle of the motion in the vertical plane.

Figure 6. Variation curves of the rudder angle and the pitch angle of the motion in the vertical plane.

Figure 7. Variation curves of the diving depth of the motion in the vertical plane.

Figure 8. Locus curves of the spatial helical motion.

5. Spatial steady helical motion

When the directions of the rudder angle and the elevator angle are fixed or only the direction of the rudder is fixed, the submarine will rotate around

axis $E\zeta$ and the barycenter's 3D motion path is a spiral line, and this motion is called spatial steady helical motion, which can be used to study the spatial maneuverability. Conduct a simulation study for the submarine with this motion with $\delta_r = 30^\circ$, $\delta_b = 10^\circ$, and $\delta_s = 0^\circ$, and the obtained barycentre locus curves are shown in Figure 8.

The simulation results of five typical motions shows that the character of the motion obtained by simulation results satisfies the common practice, and the established submarine six-freedom model is correct and can be used in predicting the motion of the submarine that carries an external weapon module.

3 APPROXIMATION OF THE SUMARINE CARRYING EXTERNAL WEAPON MODULE'S HYDRODYNAMIC COEFFICIENTS

The hydrodynamic coefficients will change when the external weapon module is loaded, and thus it must be confirmed. The method of obtaining coefficients includes experiment, theoretical calculation, approximation, etc. In this paper, the primary demonstration phase is presented and exhibits the estimating method. An approximation method (Li, 2008) is carried out by sorting masses of experimental results and estimation, which can obtain the approximate value rapids if certain deviations are allowed. This method assumes that the hydrodynamic coefficients of the submarine carrying an external weapon module are equal to the sum of that of the submarine and the external weapon module.

3.1 Approximation of weapon module acceleration

There can be a few external weapon modules in a single submarine. In this paper, the work is based on the condition of one single external weapon module (as shown in Figure 9). The length of the module is L , which is set to 10 m, width B and height H are set to 1.5 m, and the total underwater volume of the displacement ∇ is set to 8 m^3 .

Figure 9. Schematic diagram of submarines carrying the weapon module.

The weapon module of streamline shape can be replaced with an ellipsoid with three axes, take the main criterion L, B, H as three axes $2a, 2b, 2c$. Since in an ellipsoid, $\lambda_{ij} = 0 (i \neq j)$, the added weight that needs calculation is $\lambda_{ij} (i = j)$.

The added mass coefficients of the ellipsoid is obtained by Lamb through the potential-flow theory (Li, 2008). When the semi-major axis of the ellipsoid is a, b, c , the added weight of it can be obtained from Figure 10. K_{11}, K_{22}, K_{33} is the relative value of the added weight $\lambda_{11}, \lambda_{22}, \lambda_{33}$; K_{55}, K_{66} is the relative value of added rotational inertia $\lambda_{55}, \lambda_{66}$.

(a)

(b)

(c)

Figure 10. Graphs showing the added mass coefficient curves of the ellipsoid.

The added mass coefficient can be obtained by referring to Figure 10 with $L/B = 10.0, H/B = 1.0, K_{11} = 0.02, K_{22} = 0.96, K_{33} = 0.96, K_{55} = 0.87, K_{66} = 0.87$, through calculation, and the acceleration of the weapon module is given as follows:

$$(X'_{ii})_{wq} = -\frac{\pi B H}{3 L L} K_{11} = -2.09 \times 10^{-4}$$

$$(Y'_{v})_{wq} = -\frac{\pi B H}{3 L^2} K_{22} = -1.005 \times 10^{-2}$$

$$(Z'_{w})_{wq} = -\frac{\pi B H}{3 L^2} K_{33} = -1.005 \times 10^{-2}$$

$$(M'_{q})_{wq} = -\frac{\pi B H}{60 L^2} \left[1 + \left(\frac{H}{L} \right)^2 \right] K_{55} = -4.60 \times 10^{-4}$$

3.2 Approximation of the weapon module velocity coefficient

Refer to the attack angle derivation curves of ellipsoid (as is shown in Figure 11) with $L/\sqrt{\frac{1}{3}} = 5.0$ and $H/B = 1.0$,

$$\frac{\partial F'_L}{\partial \alpha} = 1.05 \times 10^{-2} \quad \frac{\partial M'}{\partial \alpha} = 1.03 \times 10^{-2}$$

The resistance coefficient of ellipsoid is given as follows:

$$F'_D = 0.05 \times \frac{\pi B^2}{4 L^2} = 0.39 \times 10^{-3}$$

And the velocity hydrodynamic coefficient of the weapon module can be calculated as follows:

$$(Y'_{v})_{wq} = (Z'_{w})_{wq} = -\left(\frac{\partial F'_L}{\partial \alpha} + F'_D \right) = -1.09 \times 10^{-2}$$

$$(N'_{v})_{wq} = (M'_{w})_{wq} = \frac{\partial M'}{\partial \alpha} = 1.03 \times 10^{-2}$$

Figure 11. Attack angle derivation curves of the ellipsoid.

Figure 12. Angular velocity derivation curves of the ellipsoid.

3.3 Approximation of the weapon module angular velocity

Refer to the angular velocity derivation curves of the ellipsoid with $L/\nabla^{\frac{1}{3}} = 5.0$ and $H/B = 1.0$,

$$\frac{\partial F'_L}{\partial \Omega} = 5.3 \times 10^{-3} \quad \frac{\partial M'}{\partial \Omega} = -1.66 \times 10^{-3}$$

Assuming that the barycenter of the weapon module is in the very center, that is the correction factor of buoyant centre position is 1, and then the angular velocity coefficient of the weapon module is given as follows:

$$(Y'_r)_{wq} = -(Z'_q)_{wq} = \frac{\partial F'_L}{\partial \Omega} = 5.3 \times 10^{-3}$$

$$(N'_r)_{wq} = (M'_q)_{wq} = \frac{\partial M'}{\partial \Omega} = -1.66 \times 10^{-3}$$

4 MOTION SIMULATION OF SUBMARINES CARRYING THE EXTERNAL WEAPON MODULE

According to the obtained hydrodynamic coefficient of the submarine carrying the weapon module, the simulation of five typical motions can be conducted with the established model.

4.1 Comparison of the horizontal steady rotation

Conduct the simulation to the submarine with the rudder at 15° , 25° , and 35° separately, and the barycentre locus curves of the submarine before and after loading the weapon module with the rudder at 15° is shown in Figure 13.

After calculation, the variation of maneuverability of the submarine is shown in Table 1.

From Table 1, the conclusion can be drawn that, after loading the weapon module, rotation

Figure 13. Comparison curves between motions in the horizontal plane.

Table 1. Contrast on performance indexes of maneuverability in the horizontal plane before and after carrying the weapon module.

		Rotation diameter/m	Steady time/s	Rotation period/s	Rotation angular velocity/rad·s ⁻¹
15°	Before	886.2	48.4	567.0	0.0111
	After	945.7	49.7	600.0	0.0105
25°	Before	596.2	127.3	454.4	0.0138
	After	624.8	129.3	473.4	0.0133
35°	Before	444.5	132.8	401.8	0.0156
	After	462.6	133.0	416.0	0.0151

diameter, steady time (the time needed to adjust the submarine to steady conditions), and rotation period, the rotation angular velocity and other maneuverability indexes are bigger than before, which means that the maneuverability has been reduced. Besides, through analysis of the absolute variation before and after carrying the weapon module, the conclusion can be drawn that the variation of maneuverability is bigger in a small rudder angle and smaller in a large angle.

4.2 Comparison of the horizontal z-type steering motion

The heading angle comparison curves obtained before and after carrying the weapon module obtained by using simulation is shown in Figure 14.

The calculation result shows that before carrying the weapon module, the primary rotation time is 31.0 s, the surpass heading angle is 11° ; after carrying the weapon, the rotation time changes to

33.7 s and the surpass heading angle changes to 12°. The absolute variation of the primary rotation time before and after carrying the weapon module is 8.71% and the surpass heading angle is 4.76%. The conclusion can be drawn that response ability to the rudder is reduced.

4.3 Comparison of vertical steady steep submerging and surfacing motion

Conduct a simulation study for the submarine (stern elevator at 20°) before and after carrying the external weapon module in the vertical steady steep submerging and surfacing motion, and the obtained barycentre locus comparison curves

Figure 14. Comparison curves between heading angles in the horizontal plane.

Figure 15. Comparison curves of the motion in the vertical plane.

Figure 16. Comparison curves between pitch angles of the motion in the vertical plane.

and pitch angles comparison curves are shown in Figures 15 and 16.

Through analysis we can know that the steady time and maximum pitch angle before carrying the weapon is 46.2 s and 59°, while that of the after carrying condition is 50.1 s and 52°; the carrying weapon module has a rather significant influence on maneuverability especially for the pitch angle.

4.4 Comparison of the vertical surpass maneuver motion

Conduct a simulation study for the submarine before and after carrying the weapon module with the surpass maneuver motion with $\delta_s / \theta = 20^\circ / 10^\circ$, and the depth and pitch angle comparison curves are shown in Figures 17 and 18.

The result shows that, before carrying the weapon module, the primary rotation time is 17.8 s, surpass depth is 0.4 m, and surpass pitch angle is 2.5°, and after that, the primary rotation time is 20.0 s, surpass depth is 0.5 m, and surpass pitch angle is 3.2°. Through calculation, the absolute variation of these factors are determined as 15.7%, 25.0%, and 28.0%. The conclusion can be drawn that the carrying weapon module has a bigger influence on the vertical maneuverability than that of the horizontal maneuverability. The loss of maneuverability in the vertical plain is greater.

Figure 17. Comparison curves of the diving depth of the motion in the vertical plane.

Figure 18. Comparison curves of pitch angles of the motion in the vertical plane.

Figure 19. Comparison locus curves of the spatial helical motion.

Table 2. Contrast on performance indexes of spatial maneuverability before and after carrying the weapon module.

	Rotation diameter/m	Rotation period/s	Lift distance/m	Relative lift velocity/ $m \cdot s^{-1}$
Before	460.1	402.8	226.6	0.5626
After	485.1	421.4	230.1	0.5462

4.5 Comparison of spatial, steady, and spiral helical motions

Conduct a simulation study for the submarine before and after carrying the weapon module with the spatial steady spiral helical motion with $\delta_r = 30^\circ$, $\delta_b = 10^\circ$, and $\delta_i = 0^\circ$, and the comparison locus curves are shown in Figure 19.

The rotation diameter, time, lift, relative lift velocity, and other main indexes obtained in simulation are shown in Table 2.

From Table 2, it can be observed that the submarine's spatial maneuverability before and after carrying the weapon module changes heavily, especially for the rotation diameter and time, which means that after carrying the weapon module, the submarine's spatial maneuverability is reduced.

5 CONCLUSION

By combining five typical motions, in this paper, a simulation study is conducted for the submarine carrying an external weapon module. The result

shows that the carrying weapon module reduces the maneuverability indexes. The result satisfies the real submarine motion characteristics, indicating that the model is reasonable. The simulation in this paper lays the theoretical foundation for the study of the validity of submarines carrying the external weapon module.

A multi-objective NC drilling parameter optimization model to achieve low energy consumption and costs

Wei Yan, Hua Zhang & Zhigang Jiang

School of Machinery and Automation, Wuhan University of Science and Technology, Hubei, China

ABSTRACT: Machining parameters are the important factors to energy conservation and emission reduction in the manufacturing industry. The drilling parameters' optimization problem for low energy consumption and costs is studied in this paper. Two objectives including energy consumption and costs are considered in this optimization model with two independent variables, namely drilling speed and feed rate per turn. Additionally, the constraints of the model are also considered. And then, the model is solved with the weighted method and the Adaptive Particle Swarm Optimization (APSO) algorithm. Finally, a case study is conducted for the verification of the proposed model and method.

1 INTRODUCTION

With the recent continuous increase in energy demand and constraints in carbon emissions, energy conservation and emission reduction have become priorities for the manufacturing industry (Li, 2015). In China, the manufacturing sectors consumed over 50% of the entire electricity produced, but the energy efficiency is low (Tang, 2006).

Drilling is a common processing method, which accounts for about 30% of the total machining methods. Energy consumption from drilling is huge. The drilling parameter plays a very important role in quality, efficiency, costs etc. (Dietmair, 2009). Some scholars have carried out much research on drilling parameter optimization. Zhang et al. (Zhang, 2006) proposed a minimum drilling time optimization method of cutting parameters based on fuzzy mathematics. Li et al. (Zhang, 2013) conducted an energy model for cutting processes of machine tools, and studied the energies of turning, drilling operations, etc. Zhao et al (Zhao, 2012) developed a parameter optimization system for costs and efficiency in the hole machining processes. Zhang (Zhang, 2011) studied a high-speed drilling parameter optimization method for small and deep-hole-processing of stainless steel. Zhang (Cui, 2007) proposed a drilling parameter fuzzy optimization method based on the machining reliability. Most of the above literature addressed the parameter optimization with the traditional single objective model such as quality, efficiency, or costs. Some are concerned with energy conservation and environmental emissions. However, there is hardly any reported research on the correlation between energy and costs of drilling.

Based on the above review, a multi-objective parameter optimization model of drilling for

achieving low energy and costs is presented in this paper. Energy consumption and cost are the optimization objectives and drilling speed and feed rate per turn are taken as independent variables. The APSO (Adaptive Particle Swarm Optimization algorithm) is applied as the solution method. Finally, a hole-processing example is given for the verification of the proposed model and methodology.

2 ESTABLISHMENT OF THE DRILLING MULTI-OBJECTIVE OPTIMIZATION MODEL

Drilling parameters include drilling speed, feed rate per turn, and cutting depth. However, the cutting depth can be calculated with diameters and allowances of the hole to be processed. Therefore, the drilling speed and feed rate per turn are selected as the independent variables and minimizing energy consumption and costs are considered as the two optimization objectives.

2.1 Multi-objective optimization functions

2.1.1 Costs function

The costs of drilling mainly include machining costs, tool change costs, other ancillary costs etc. Because the artificial costs are greatly influenced by the geographical and processing environment, it has not been considered in this paper. The function of drilling costs objective is shown as follows:

$$C_p = T_m X + T_c \frac{T_m}{T} X + \frac{T_m}{T} C_t + T_o X \quad (1)$$

where, C_p represents the cost of processing, X represents the production cost per unit time, T_m is the

drilling time, T_c is the tool change time, T_o is the other auxiliary time, C_t represents the tool change cost, T represents the tool durability, and the calculation methods for T and T_m are as follows:

$$T_m = \frac{60H}{nf} \quad (2)$$

$$n = \frac{1000v_c}{\pi D} \quad (3)$$

$$T = \left(\frac{60C_v D^{Z_v} K_v}{f^{Y_v} V_c} \right)^{\frac{1}{m}} \quad (4)$$

where, H is the drilling depth, f is the feed rate per turn, n represents the spindle speed, v_c is the drilling speed, D represents the drill diameter, C_v , Z_v , K_v , Y_v , and m represent the tool durability coefficients.

From Equation (1)–Equation (4), the cost function of drilling is shown in Equation (5).

$$C_p = 0.06 \times \frac{\pi DHX}{v_c f} + (T_c X + C_t) \frac{60 \left(\frac{1}{m} \right) \pi HD \left(\frac{1-Z_v}{m} \right) f \left(\frac{Y_v}{m} \right) v_c \left(\frac{1}{m} \right)}{1000 C_v^{\frac{1}{m}} K_v^{\frac{1}{m}}} + T_o X \quad (5)$$

2.1.2 Energy function

The energy consumption of drilling is mainly composed of five parts, namely drilling energy, no-load energy, feed system energy, additional load energy, and auxiliary system energy.

1. Drilling energy: it can be calculated with drilling force. The mathematical expression is shown in Equation (6).

$$E_m = P_m \times T_m = 2 \times 9.81 C_m D^{X_m} f^{Y_m} K_m T_m \quad (6)$$

where, P_m is the drilling power and C_m , X_m , Y_m , and K_m are the correlation coefficients, which can be obtained in the cutting quantity manual.

2. No-load energy: it continued along the whole drilling process, which is shown in Equation (7).

$$E_u = P_u \times T_m = (K_1 n^2 + K_2 n + K_3) T_m \quad (7)$$

where, P_u is the no-load power and K_1 , K_2 , and K_3 are the correlation coefficients with the spindle speed (Liu, 2012).

3. Additional load energy: it is related to the load and drilling force and the mechanism is very complicated. The energy consumption of additional load is commonly proportional to the energy consumption of the drilling process.

$$E_l = b E_m \quad (8)$$

where, b is the additional load factor of drilling; it is often 0.15–0.25 and depends on the experience.

4. Feed and auxiliary system energy: the energy consumption of the feed system is usually 1.5% of the main drive system, and the energy consumption of the auxiliary system has little impact on drilling parameters. Therefore, the energy consumption of the feed system and auxiliary can be regarded as a constant in Equation (9).

$$E_g + E_a = Q \quad (9)$$

Therefore, the energy consumption during the drilling operation is expressed as follows:

$$E_p = E_m + E_u + E_l + E_g + E_a = 1.177(1+b)(C_m D^{X_m} f^{Y_m} K_m) + \left[K_1 \left(\frac{1000V_c}{\pi D} \right)^2 + K_2 \frac{1000V_c}{\pi D} + K_3 \right] \frac{\pi DH}{1000V_c f} + Q \quad (10)$$

2.2 Constraints

The parameters of drilling are constrained by the machine tools, drilling process, quality etc. Therefore, all operating parameters shall be within the constraints in the optimized solution.

In this paper, the constraints of the spindle speed, feed rate, cutting force, drilling power, spindle torque, and tool life are considered.

The constraints of drilling parameters are shown in Equation (11).

$$s.t. \begin{cases} g_1(v_c, f) = n_{\min} - n \leq 0 \\ g_2(v_c, f) = n - n_{\max} \leq 0 \\ g_3(v_c, f) = f_{\min} - f \leq 0 \\ g_4(v_c, f) = f - f_{\max} \leq 0 \\ g_5(v_c, f) = C_f D^{X_f} f^{Y_f} K_f - F_{\max} \leq 0 \\ g_6(v_c, f) = P_m - P_{\max} \leq 0 \\ g_7(v_c, f) = M - M_{\max} \leq 0 \\ g_8(v_c, f) = T_m - T \leq 0 \end{cases} \quad (11)$$

Therefore, the energy consumption and costs parameter optimization of NC drilling is a typical constrained multi-objective optimization problem, which can be expressed as Equation (12).

$$\min F(v_c, f) = (\min C_p, \min E_p) \quad (12)$$

$$s.t. g_i(v_c, f) \leq 0 \quad i = 1, 2, \dots, 8$$

3 SOLVING THE MODEL

3.1 Transformation

For most multi-objective optimization problems, it is often difficult to achieve all the multiple

objectives at the same time. In order to facilitate the solution, the weighted sum method is introduced to construct in this paper.

$$F(v_c, f) = \lambda_C \frac{C_p - C_{\min}}{C_{\max} - C_{\min}} + \lambda_E \frac{E_p - E_{\min}}{E_{\max} - E_{\min}} \quad (13)$$

where, C_{\max} , C_{\min} , E_{\max} , and E_{\min} are the minimum and maximum values of costs and energy consumption respectively, and λ_C and λ_E are the weighted coefficients of costs and energy consumption, and $\lambda_C + \lambda_E = 1$.

3.2 Solution procedure of APSO

PSO (Particle Swarm Optimization) is an evolutionary algorithm, which searches for the optimal solutions through the iterative operation based on random solution, and evaluates the quality of the solution with fitness. Because of the ease of implementation and the fact that it does not need the gradient information of the objectives, PSO is widely used in solving constrained optimization problems.

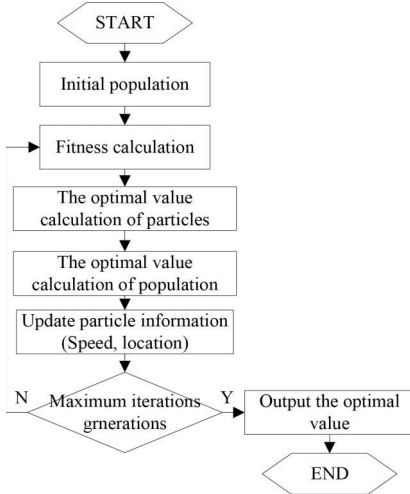

Figure 1. The flow chart of APSO.

Table 1. The information of the drilling case.

Minimum spindle speed (r/min)	Maximum spindle speed (r/min)	Minimum feed speed (mm/r)		Maximum feed speed (mm/r)				Maximum torque (Nm)		Maximum cutting force (N)		Maximum Power power (kw)		factor	
20	4000	0.1		3.4				28.5	5500	7.5	0.8				
Diameter (mm)	Hole depth (mm)	C_v	Z_v	K_v	Y_v	m	$T_b(s)$	C_f	X_f	Y_f	K_f	C_m	X_m	Y_m	K_m
20	35	11.1	0.4	0.87	0.5	0.2	1100	61.2	1.0	0.7	0.17	0.03	2	0.8	1.15
C_t	X	$T_c(s)$	$T_o(s)$	B	K_l							K_3		$Q(J)$	
4	0.05	16	60	0.2	0.00002			1.243				90.115		17115	

However, the flight time of particles are fixed in the traditional PSO, which may lead to oscillation and reduce the convergence speed (Xia, 2006).

Therefore, an improved algorithm called APSO (Adaptive Particle Swarm Optimization) was proposed in this paper. The global optimal value was added in the APSO to adjust the inertial weight and particle flight time adaptively. The equation of APSO is given as follows:

$$\begin{cases} v_{id}^{(t+1)} = w^t \cdot v_{id}^{(t)} + c_1 r_{1d} [p_{id}^{(t)} - x_{id}^{(t)}] + c_2 r_{2d} [p_{gd}^{(t)} - x_{id}^{(t)}] \\ x_{id}^{(t+1)} = x_{id}^{(t)} + v_{id}^{(t+1)} \times T_0 \times \left(1 - \frac{K_0 t}{I_{\max}}\right) \end{cases} \quad (14)$$

where, v_{id} is the particle speed, and $v_{id} \in [-v_{\max}, v_{\max}]$, c_1 and c_2 are the study factors, r_{1d} and r_{2d} are the random numbers, and $r_{1d}, r_{2d} \in [0, 1]$, x_{id} is the current location of the particles, $w^t = \exp\left(-\frac{F_b^t}{F_b^{t-1}}\right)$ is the inertial factor, and F_b^t, F_b^{t-1} is the global optimal value of the particles of t and $t-1$ generation, T_0 is the initial flight time, K_0 is the adjust parameter, and I_{\max} is the maximum evolution generation.

The flow chart of APSO is shown in Figure 1.

4 CASE STUDIES

In this paper, a hole-machining case is studied to verify the effectiveness of the optimization model. The equipment and machining information are shown in Table 1.

The program code of APSO was compiled with Matlab 2013b, and the algorithm parameters were set as follows: the initial population size was 30, the maximum generation was 150, the adjusting parameter was 0.9, and the initial flight time was 0.4. The APSO iteration process and optimization results are shown in Figure 2 and Table 2, respectively.

In this paper, the optimization results of cost ($\lambda_C = 1$), energy consumption ($\lambda_E = 1$) and cost and energy ($\lambda_C = \lambda_E = 0.5$) are also considered, and the results are listed in Table 2.

Figure 2. Graph showing the iterative convergence process of APSO.

Table 2. The optimization results of APSO.

Results	$\lambda_C = 1$	$\lambda_E = 1$	$\lambda_C = \lambda_E = 0.5$
Drilling speed (m/min)	24.05	27.09	26.18
Feed rate per turn (mm/r)	0.24	0.24	0.24
Time (s)	13.72	12.17	12.60
Cost (yuan)	0.881	0.918	0.901
Energy consumption (kJ)	207.80	207.63	207.66

When compared with the results of low costs or energy, the costs and energy consumption of drilling processes are changed with the drilling speed. When the goal is chosen as low cost and energy consumption, the results are between the above-mentioned values. It impacted in such a manner that the chosen parameters have important effects on energy consumption and costs, and the proposed model and method are effective for drilling processes optimization.

5 CONCLUSIONS

1. A multi-objective optimization model was established in this paper. The energy and cost are the optimization objectives, drilling speed, and feed rate per turn as independent variables,

and the constraints of spindle speed, feed rate, drilling torque, etc. are also considered.

2. An improved algorithm (APSO) of PSO is proposed in this paper, and the optimization model was solved with this algorithm.
3. The case of this paper is aimed at one drilling condition, but the energy of the drilling process is not only affected by machining parameters, but also by the processing environment. Therefore, the next research work may focus on the various factors of the energy consumption.

An experimental study of the dynamic equivalence leakage of rolling-piston compressors

Kuihua Geng, Wei Wei, Xiaobo Ma, Xiao Wang, Xiaogang Han, Taibai Zhao, Chongli Chen & Han Sun

School of Mechanical Engineering, Guangxi University, Nanning, Guangxi, China

ABSTRACT: Based on the rolling-piston compressor as the research object, in this work, a new type of dynamic equivalence testing device for the compressor is put forward, which simulates the working condition of the inside compressor cavity and accomplishes dynamic adjustable speed, controllable differential pressure, and variable clearance. More groups of experiments with dynamic changes of multi-factors are carried out and finally the quantity and regularity about the leakage change with speed, differential pressure, and clearance are obtained.

Keywords: Rolling-piston compressor; dynamic equivalence testing device; dynamic leakage; experimental study

1 INTRODUCTION

A rolling piston compressor owns a good property and has been widely applied in many domains (Ma, 2001). However, due to the clearance of kinetic fitting pieces inside, its leakage problem is also really prominent, which has a major negative influence on the volumetric efficiency of the compressor (Yue, 2011). In view of this, the leakage study on the rolling-piston compressor by far has become a research hotspot in the compressor's academic field and engineering field both within the country and abroad (Hao, 2004). When the compressor is running, each motion pair is under a dynamic condition, such as the position, temperature, clearance, pressure, and even the quantity and distribution of the lubrication medium is constantly changed. Thus, the leakage characteristics are essentially associated with multiple factors and changes with work process (Li, 2006). The leakage inside the compressor can be collected and processed under the condition that it can accomplish dynamic differential pressure, dynamic clearance, and dynamic components of working medium, which makes comprehending leakage regularities of the compressor at a higher level. It is not only meaningful but it is also necessary and important that the research model with dynamic variable parameters can be concentrated instead of the original limited one with static parameters. However, there are large numbers of leakage channels and most of them could be extremely small (Jin, 1986; Zhou, 2007; Shen, 2015); the working condi-

tions are complex and changing; it is really hard to complete the dynamic leakage tests inside the compressor. For the above-mentioned reason, in this work, a dynamic equivalence testing device is designed and fabricated for the rolling-piston compressor, by which there could be leakage data from the compressor under dynamic conditions.

2 EXPERIMENTAL TEST PLAN

The equivalent method is a kind of common scientific thinking method, which means, in a sense, unknown, complicated, and intractable issues could be converted into known, simple, and tractable ones on the premise that effects are same. It has been widely applied in mechanics, kinematics, electricity, optics, etc. which really means complicated practical problems are turned into simple familiar ones under the same effect. It will be easy to highlight the main factors, seize the essence and bring out laws if the team uses the simpler factors instead of the complicated ones. In this work, the testing about the leakage of the working medium was conducted inside compressors by using an equivalent device as the core. The selected dynamic equivalence leakage testing scheme in this work is shown in Fig. 1.

This experiment scheme consists of an air compressor, equivalent device, glass rotameter, precision pressure gauge, and so on. On one hand, the gas exhausted by using the air compressor enters the high pressure holder through the three-link con-

control valve, and then turns into the precision pressure gauge after passing the control valve, and finally enters the high pressure chamber of the equivalent device through the inlet control valve. On the other hand, the leakage gas from the low pressure chamber of the equivalent device threads the glass rotameter and then passes the vent control valve and the precision pressure gauge, and finally enters into the constant tin through the control valve, and between this and the high pressure holder there is a balance valve. During the experiment, the balance valve is kept closed; meanwhile, the vent control valve and the control valve comprise the constant tin maintaining stability of the pressure. In the experiment system, the precision pressure gauge is used to display the differential pressure between two chambers of the equivalent device; the DC-infinitely adjustable-speed motor is used to change the speed of the device; and the precision micrometer head is used to adjust and display the leakage gap.

Based on the experiment's schematic shown in Fig. 1, the built experimental platform about the dynamic equivalence leakage of rolling-piston compressors is shown in Fig. 2. The type of the

Figure 2. Picture of the dynamic equivalent leakage experiment's platform.

glass rotameter in the figure is LZB-10, in which the test medium is gas, and the test range is 250 L/h–2500 L/h.

The experiment proceeded under the condition that three sets of factors were kept different from each other. Based on the orthogonal experiment, there would be 3^3 results, thus the change of clearance was the first factor to be studied by experiments in different groups, which could show the change of leakage by other factors when the clearance was kept specific.

3 EXPERIMENTAL EQUIVALENT DEVICE

3.1 Basic structure and working principle

The equivalent device's internal structure is shown in Fig. 3 and its dynamic equivalent device assembly drawings are shown in Fig. 4. The device consists of an adjustable-speed motor, static cavity, dynamic cavity, rotor, precision micrometer head, deep groove ball bearing, transparent cavity, gasket, and so on. The rotor is driven by using the motor; the clearance is made by using the adjustable device on the right-hand side; the connection axis between the adjustable device and the bearing uses the interference fit. The viewing window is made of organic glass; the gasket is placed on each side to complete the clearance trimming.

Figure 3. Schematic of the equivalent device's internal structure.

Figure 4. Schematic showing the dynamic equivalent device assembly drawings.

1-Pedestal, 2-adjustable-speed motor, 3-lower cavity, 4-transparent cavity, 5-motor transmission axis, 6-rotor, 7-bearing, 8-upper cavity, 9-rotor connection axis, 10-probe connection axis, 11-precision micrometer head, and 12-holder.

The leakage clearance forms by assembly between the rotor and the contact area of the static cavity on the left-hand side, in which there is a high pressure chamber. The low pressure chamber is formed among the rotor's outer surface, the dynamic cavity on the right-hand side and the transparent cavity's inner wall. The high pressure gas enters into the high pressure chamber from outside, flows into the low pressure chamber through the leakage clearance and then vents, which realizes an equivalence leakage course of compressors.

In the equivalent device, the motion of the compressor is controlled by the DC-infinitely adjustable-speed motor, which is placed under the device. The motor's rated power is 210 W, its rated speed is 3000 rpm, it is driven by using a 24-V DC power drive and controlled by using DC sensor-less and brushless controllers (ZM-6615). The speed is adjusted by using the speed-control switch inside, and its number is present on digital display. The precision micrometer head on the top of the device controls and adjusts the leakage clearance, which is produced by a company named Mast Correct. Its measurement range is 0–25 mm and its measurement accuracy is 0.001 mm, which could enable micron-sized control. The gas enters into or out through the tube of the device, and its difference value is controlled by using the high pressure holder, constant tin, and the pressure gauge.

The following is the test principle of the dynamic equivalence device: there are two cavities in the device: the left-hand side one is placed in high pressure gas during the experiment to simulate the high pressure chamber of compressors, and the right-hand side one is connected with the atmosphere to simulate the low pressure chamber of compressors; there is an adjustable leakage clearance between the rotor and the static cavity, which is equivalent to the leakage channels of compressors. The differential pressure of the high pressure chamber and the low pressure chamber is controlled by using a precision pressure gauge; the motor speed is controlled by using the machine controller; the leakage clearance is adjusted by using the precision micrometer head; the leakage is measured by using the float flowmeter in the vent-pipe. When the differential pressure and the reading from the flowmeter become stable, the leakage can be directly read. During the experiment, the speed can be adjusted alone, and so do the clearance and the differential pressure, which can make adjustable single-factor tests come true. Finally, the quantity and regularity about the leakage change with speed, and the differential pressure and clearance were obtained.

3.2 Design and process

Based on the design thought mentioned above, parts of the equivalence device are designed.

Aluminium alloy and organic glass are chosen as work materials, which means that the upper and lower cavities, rotor, spindle, pedestal, and holder are made of aluminium alloy and the transparent cavity is made of organic glass. The SNS air hose is chosen as the gas tube. The finished parts are shown in Fig. 5.

3.3 Installing and debugging

Connect the assembled equivalence device, motor controller, tachometer, and the DC power supply. And then, connect the intake-tube and the gas supply system, and connect the vent-pipe, flowmeter, and the back pressure system. Check the pressure tightness of the sealing washer and working parts. As for the debugging process to increase the speed, turn the speed-control switch to the minimum, turn on the device, turn the switch upwards slowly to check the stationarity and check if it could reach the speed of the compressor working condition. The debugging experimental setup to increase the speed is shown Fig. 6, and it is found that the result is normal, which means the experiment could proceed.

As for the debugging to adjust clearance, adjust the micrometer head manually to make the bottom

Figure 5. Picture showing the dynamic equivalent device assembly and parts. 1-General assembly drawing, 2-rotor, 3-upper cavity, 4-transparent cavity and clearance, and 5-lower cavity.

Figure 6. Picture of the dynamic equivalent device that performs debugging to increase the speed.

of the rotor touch the superface of the lower cavity, and then lock the head and put in the pressure gas, check the pressure tightness and reset to the initial position. Turn on the self-locking switch, rotate the microdrum, and observe the reading from the micrometer head; turn off the self-locking switch when the reading reaches the default value. By this time, the clearance is well-adjusted, which could be lubricated to approximate the real compressor working conditions. The debugging experimental setup to adjust clearance is shown Fig. 7.

As for the debugging to maintain differential pressure, first blow up gasholders on both sides of the tube to reach the default value. Turn on the inlet control valve and observe the change of the pressure gauge, turn on the vent control valve when the reading is stable, and continue observing the pressure gauge. After debugging for a few times, the pressure could be maintained stable. The debugging experimental setup to maintain differential pressure is shown Fig. 8.

There are three major factors that affect the working medium leakage inside rolling-piston compressors: the clearance leakage (δ), the speed change (Δn) from the starting value to the default value and the differential pressure change (ΔP) between two chambers. The dynamic equivalence experiment of compressors below will proceed with these three factors.

Figure 7. Picture of the dynamic equivalent device's debugging experimental setup to adjust clearance.

Figure 8. Picture of the dynamic equivalent device's pressure difference debugging.

4 EXPERIMENTAL PROCEDURE

The dynamic equivalence experiment of compressors includes the following three steps:

Firstly, turn on the self-locking switch of the precision micrometer head, turn the clearance leakage to the default value, and then lock the micrometer head. Turn on the power supply of the equivalence device, controller and tachometer, turn on the adjustable-speed motor, and adjust the speed to the default value.

Secondly, turn on the vent control valve next to the glass rotameter, turn on the control valve, and turn off the balance valve and the inlet control valve. After that, turn on the air compressor, turn on the three-link control valve to inflate the high pressure holder; when the reading from the pressure gauge reaches the default value, turn on the control valve. After the reading from the precision pressure gauge is maintained as a stable value, turn on the inlet control valve and fill the gas in the equivalence device to check the pressure-tightness of the device.

Thirdly, based on the two steps mentioned above, after maintaining the differential pressure and speed as stable values, record readings of the clearance, differential pressure, and rotameter. If the floater waggles seriously during the experiment, adjust the lower rotary knob of the rotameter and record the reading when it is maintained stable again.

Adjust the clearance, differential pressure, and speed for a few times, repeat the three steps above mentioned until the experiment is finished.

5 RESULTS AND DISCUSSION

5.1 The effect of differential pressure

The clearance value (δ_1) of the equivalence device is set to 15 μm and the speed (n) is set to 1000 r/min, and then the test proceeded in the case that the differential pressure is maintained at 0.1, 0.2, and 0.3 MPa, respectively. The data are shown in Table 1 and the processing result is shown in Fig. 9.

Figure 9 shows that the corresponding leakage is about 0.41 g/s when the differential pressure is 0.1 MPa; it is about 0.50 g/s when the differential pressure is 0.2 MPa; it is about 0.59 g/s when the differential pressure is 0.3 MPa.

The clearance value (δ_1) of the equivalence device is set to 15 μm and the speed (n) is set to 3000 r/min, and then the test proceeds in the case that the differential pressure is maintained at 0.1, 0.2, and 0.3 MPa, respectively. The processing result is shown in Fig. 10.

Figure 10 shows that the corresponding leakage is about 0.44 g/s when the differential pressure is

0.1 MPa; it is about 0.56 g/s when the differential pressure is 0.2 MPa; it is about 0.65 g/s when the differential pressure is 0.3 MPa. It is clear that when the speed and the clearance is maintained as constant, the leakage is greatly affected by the differential pressure. The more the differential pressure, the more is the leakage, and every 0.1 MPa

Table 2. $\Delta \delta_i$ & ΔP_i experimental data.

Constant condition	Clearance ($\Delta \delta$)	Leakage ($\bar{m}_i \text{ (g/s)}$)
$n_1 = 1000 \text{ r/min}$ $\Delta P_1 = 0.1 \text{ MPa}$	$\Delta \delta_1 = 15 \mu\text{m}$	0.4127
	$\Delta \delta_2 = 25 \mu\text{m}$	0.4347
	$\Delta \delta_3 = 35 \mu\text{m}$	0.4443
$n_1 = 1000 \text{ r/min}$ $\Delta P_2 = 0.2 \text{ MPa}$	$\Delta \delta_1 = 15 \mu\text{m}$	0.5048
	$\Delta \delta_2 = 25 \mu\text{m}$	0.5598
	$\Delta \delta_3 = 35 \mu\text{m}$	0.5641
$n_1 = 1000 \text{ r/min}$ $\Delta P_3 = 0.3 \text{ MPa}$	$\Delta \delta_1 = 15 \mu\text{m}$	0.5925
	$\Delta \delta_2 = 25 \mu\text{m}$	0.6045
	$\Delta \delta_3 = 35 \mu\text{m}$	0.6400

differential pressure change could bring about 0.1 g/s leakage change.

5.2 The effect of clearance

The speed of the equivalence device is set to 1000 r/min and the differential pressure is set to 0.1, 0.2, and 0.3 MPa, respectively. And then, the test proceeds in the case that the clearance is maintained at 15, 25, and 35 μm , respectively. The processing results are shown in Table 2. As can be seen in Table 2, when the speed and the differential pressure is kept as constant, the more clearance makes more leakage, and every 10 μm clearance change could bring about a 0.02 g/s leakage change.

5.3 The effect of speed data

The clearance value of the equivalence device is set to 15 μm and the differential pressure is set to 0.1, 0.2, and 0.3 MPa, respectively. And then, the test proceeds in the case that the speed is maintained at 1000, 2000, and 3000 r/min, respectively. The processing results are shown in Table 3. As can be seen in Table 3, when the clearance and the differential

Table 3. The Δn_i and ΔP_i experimental data.

Constant condition	Speed (Δn)	Leakage (\dot{m}_1 (g/s))
$\delta_1 = 15 \mu\text{m}$ $\Delta P_1 = 0.1 \text{ MPa}$	$\Delta n_1 = 1000 \text{ r/min}$	0.4127
	$\Delta n_2 = 2000 \text{ r/min}$	0.4344
	$\Delta n_3 = 3000 \text{ r/min}$	0.4452
$\delta_1 = 15 \mu\text{m}$ $\Delta P_2 = 0.2 \text{ MPa}$	$\Delta n_1 = 1000 \text{ r/min}$	0.5048
	$\Delta n_2 = 2000 \text{ r/min}$	0.5576
	$\Delta n_3 = 3000 \text{ r/min}$	0.5644
$\delta_1 = 15 \mu\text{m}$ $\Delta P_3 = 0.3 \text{ MPa}$	$\Delta n_1 = 1000 \text{ r/min}$	0.5925
	$\Delta n_2 = 2000 \text{ r/min}$	0.6076
	$\Delta n_3 = 3000 \text{ r/min}$	0.6507

pressure are maintained as constant, the more speed leads to more leakage, and an every 1000 r/min speed change could bring about a 0.02 g/s leakage change.

6 CONCLUSION

This work utilizes the self-designed dynamic equivalence testing device for the compressor, which simulates the working condition inside the compressor chamber; and builds the experimental platform, which accomplishes dynamic adjustable speed, dynamic controllable differential pressure, and dynamic variable clearance. After testing, that the following conclusions can be drawn:

1. The leakage is affected by the differential pressure. The more differential pressure leads to more leakage, and every 0.1 MPa differential

pressure change could bring about a 0.1 g/s leakage change.

2. The leakage is affected by the clearance. The more clearance leads to more leakage, and every 10 μm clearance change could bring about a 0.02 g/s leakage change.
3. The leakage is affected by the speed. The more speed leads to more leakage, and every 1000 r/min speed change could bring about a 0.02 g/s leakage change.

The structure and transmission efficiency analysis research of a new pattern F2C-T pin–cycloid planetary transmission

Liang Xuan

School of Mechanical and Architectural Engineering, Jiangnan University, Wuhan, China

Heng Jiang & Tianmin Guan

School of Mechanical Engineering, Dalian Jiaotong University, DaLian, China

ABSTRACT: F2C-T transmission is a new K-H-V type of two-stage cycloid transmission device. It has high transmission efficiency advantages. In this paper, the structure and transmission efficiency of the new high precision type of F2C-T transmission are analyzed. The drive ratio calculation model of F2C-T transmission is deduced by using the solving method of the differential gear train transmission ratio. And the calculation method of the system's meshing transmission efficiency is deduced with the transmission ratio method. The transmission efficiency mathematical model of F2C-T transmission is established. And the transmission efficiency of the F2C-T455 model is calculated and analyzed.

1 INTRODUCTION

F2C-T transmission is a new pattern with a two-stage closed type cycloid transmission device. It exhibits properties, such as high transmission precision, small rotation error, high transmission efficiency, stable transmission, and so on. And so, it has an extremely widespread application prospect in the field of transmission. While studying the F2C-T drive, its structure requires analysis at first. The shape of the components and the transmission relationship between the parts can be grasped. And then, the power loss of the system in the transmission process can be found. The transmission efficiency of F2C-T transmission is calculated. Transmission efficiency is one of the important indexes to evaluate the performance of mechanical transmission devices, and its level also directly affects the research value and development prospects of the device. Therefore, it is of great significance to study the transmission efficiency of F2C-T transmission.

2 SYSTEM STRUCTURE AND TRANSMISSION PRINCIPLE OF F2C-T TRANSMISSION

2.1 Structure and characteristics of F2C-T transmission

The structure of F2C-T transmission is more complex, and it is composed with a stage of involute gear planetary transmission and a stage of cycloid-

pin planetary gear transmission as well as the bearing in the meshing transmission process. The structure diagram is shown as Figure 1.

According to the meshing transmission relationship between each part in the transmission process of the F2C-T transmission, the F2C-T transmission is divided into the following four parts:

1. The transmission part of the involute gear

The transmission part of the involute gear consists of the input shaft, the key gear, and three planetary gears. And the input shaft and the sun gear are fixedly connected together to form the input gear shaft. And three planetary gears are distributed at angles that are 120 degrees away according to the structure of the planet.

2. Eccentric transmission part

Each eccentric body is composed of a spline shaft, two eccentric shaft necks, and a rotary arm

Figure 1. Schematic of the F2C-T transmission structure.

bearing. Two eccentric shaft necks are 180 degrees away in distribution. In order to balance the inertia force, the two pieces of the cycloid gear should be also evenly arranged on the two eccentric axes at angles that are 180 degrees away from each other.

3. The part of the cycloid–pin gear transmission

It consists of a cycloid gear, a pin gear, and a pin gear housing. Different from the traditional two fulcrums and the three-fulcrums structure, the pin gear of F2C-T transmission chooses the horizontal pillow type installation method. It directly lies in the pin gear housing. In this way, the bending deformation of the pin gear can be greatly reduced, and the bending strength can be improved.

4. Output mechanism

It consists of output side flange, eccentric support bearing, spindle bearing, the supporting pin and the input side of the flange. The input and output side flanges are connected together with the supporting pin to form a simply-supported beam structure. It can greatly improve the carrying capacity of the mechanism body.

The structure of F2C-T transmission has the following characteristics:

1. The two stages of the transmission structure are used. Due to the transition of the first stage involute transmission part, the cycloid transmission part of the second stage is made more stable. It can greatly improve its life; (2) the cycloid gear adopts the two-tooth-difference structure and increases the carrying capacity; (3) the pin gear adopts the horizontal pillow type structure. In this way, when the pin gear and cycloid gear undergo meshing, the bending deformation and even bending damage can be avoided; (4) the output mechanism adopts the rigid flange output structure with bilateral support. When compared with the output mechanism of the traditional cycloid transmission

cantilever beam structure, it has greater stiffness and better impact resistance performance.

2.2 The working principle of F2C-T transmission

F2C-T transmission is a new pattern with two-stage closed type cycloid planetary transmission device. It is composed of the involute gear planetary transmission of the first stage and the cycloid–pin gear planetary transmission of the second stage. The transmission diagram is shown in Figure 2.

3 THE CALCULATION OF THE TRANSMISSION RATIO

According to Figure 2, the transmission diagram of the new pattern high precision F2C-T transmission, F2C-T transmission consists of two stages. The first stage transmission is composed of the input gear shaft 1 and the planet gear 2. The second stage transmission is composed of cycloid gear 4, the pin gear 5, and the pin gear housing 7. When the eccentric H(3) is fixed, the transformed transmission ratio can be obtained by using the following equation:

$$i_{12}^H = -\frac{Z_2}{Z_1}, i_{45}^H = \frac{Z_5}{Z_4} \quad (1)$$

In this type, Z_1 is the tooth number of the input gear shaft, Z_2 is the tooth number of the planet gear, Z_4 is the tooth number of the cycloid gear, Z_5 is the tooth number of the pin gear.

The pin gear is mounted on the pin gear housing during the installation. And so, the pin gear and the pin gear housing can be treated as a whole part in the calculation process. If the angular velocity of the pin gear 5 is ω_5 , the angular velocity of the eccentric body H is ω_H , the angular velocity of the cycloid gear 4 is ω_4 , the angular velocity of the output flange 6 is ω_6 , then $\omega_4 = \omega_6$ and the angular velocity of the eccentric H is 0, the relative angular velocity of each component is given as follows:

$$\begin{cases} \omega_5^H = \omega_5 - \omega_H \\ \omega_H^H = \omega_H - \omega_H = 0 \\ \omega_6^H = \omega_6 - \omega_H = \omega_4 - \omega_H \end{cases} \quad (2)$$

When the eccentric H is fixed, the transmission ratio of the mechanism can be obtained by using the following equation:

$$i_{65}^H = \frac{\omega_6 - \omega_H}{\omega_5 - \omega_H} = \frac{Z_5}{Z_4} \quad (3)$$

1) Input gear shaft, 2) planet gear, 3) eccentric body, 4) cycloid gear, 5) pin gear, 6) output shaft, and 7) pin gear housing

Figure 2. Transmission diagram of F2C-T transmission.

When the output shaft 6 is fixed, from the general equation $i_{ab}^c = \frac{1}{1-i_{bc}^a}$ of the transmission ratio calculation it can be obtained:

$$i_{H5}^6 = \frac{1}{1-i_{56}^H} = \frac{Z_5}{Z_5 - Z_4} \quad (4)$$

The output shaft is fixed, when the pin gear and the pin gear housing are obtained as the output, the transmission ratio is given as follows:

$$i_{15}^6 = i_{12}^H \cdot i_{H5}^6 = -\frac{Z_2 Z_5}{Z_1 (Z_5 - Z_4)} \quad (5)$$

And according to the general calculation equation of transmission ratio $i_{ab}^c = 1 - i_{ac}^b$, when the pin gear housing is fixed, the system transmission ratio can be obtained as follows:

$$i_{16} = i_{16}^5 = 1 - i_{15}^6 = 1 + \frac{Z_2 Z_5}{Z_1 (Z_5 - Z_4)} \quad (6)$$

The cycloid–pin gear transmission part of F2C-T transmission uses two-tooth-difference structure. And so, the result is $Z_5 - Z_4 = 2$; then,

$$i_{16} = 1 + \frac{Z_2 Z_5}{2Z_1} \quad (7)$$

4 TRANSMISSION EFFICIENCY ANALYSIS

The transmission efficiency of F2C-T transmission is mainly composed of two parts, which are meshing transmission efficiency and bearing efficiency. The meshing efficiency is the main part of the transmission efficiency. It is composed of two parts, which are involute gear meshing transmission efficiency and cycloid–pin gear transmission efficiency.

4.1 Meshing transmission efficiency analysis

The equation of meshing transmission efficiency is derived by using the method of transmission ratio. According to the transmission ratio equation of F2C-T transmission, it can be re-written in the following form:

$$i_{16} = \frac{-i_{12}^H i_{45}^H}{i_{45}^H - 1} + 1 \quad (8)$$

It turns out that the transmission ratio i_{16} of the differential gear transmission F2C-T transmission consists of the transmission ratio function of its

various transmissions. (When the eccentric body is fixed, the transmission ratio of the corresponding transmission can be obtained.) That is,

$$i_{16} = \frac{\omega_k}{\omega_6} = f(i_{12}^H, i_{45}^H) = \frac{-i_{12}^H i_{45}^H}{i_{45}^H - 1} + 1 \quad (9)$$

In this type, ω_1 is the angular velocity of the input shaft (rad/min) and ω_6 is the angular velocity of the output shaft (rad/min).

Similarly, the force transmission ratio \tilde{i}_{16} is also the function, which is composed of each corresponding force transmission ratio $\tilde{i}_{12}^H, \tilde{i}_{45}^H$. That is,

$$\tilde{i}_{16} = \frac{T_6}{T_1} = f(\tilde{i}_{12}^H, \tilde{i}_{45}^H) = \frac{-\tilde{i}_{12}^H \tilde{i}_{45}^H}{\tilde{i}_{45}^H - 1} + 1 \quad (10)$$

In this type, T_1 is the input torque ($N \cdot m$), T_6 is the output torque ($N \cdot m$), \tilde{i}_{16} is the ratio of the output to the input torque.

Therefore, the meshing transmission efficiency of F2C-T transmission is given as follows:

$$\eta_{16} = \frac{P_6}{P_1} = \frac{T_6 \omega_6}{T_1 \omega_1} = \frac{\tilde{i}_{16}}{i_{16}} = \frac{f(\tilde{i}_{12}^H, \tilde{i}_{45}^H)}{f(i_{12}^H, i_{45}^H)} \quad (11)$$

In this type, P_1 is the input power (kw), P_6 is the output power (kw). $\tilde{i}_{12}^H = i_{12}^H (\eta_{12}^H)^{x_1}$, $x_1 = \pm 1$; $\tilde{i}_{45}^H = i_{45}^H (\eta_{45}^H)^{x_2}$, $x_2 = \pm 1$;

η_{12}^H is the meshing transmission efficiency of the involute gear; η_{45}^H is the meshing transmission efficiency of the cycloid–pin gear.

The value representation of the index x_1, x_2 is $+1$, which indicates that the motion transmission ratio and the power flow are in the same direction; -1 indicates that the motion transmission ratio is opposite to the power flow. According to the literature (Yang, 1986),

$$x_1 = \text{sign} \frac{i_{12}^H}{i_{16}} \cdot \frac{\partial i_{16}}{\partial i_{12}^H} \quad (12)$$

While $\frac{i_{12}^H}{i_{16}} \cdot \frac{\partial i_{16}}{\partial i_{12}^H} < 0$, $x_1 = -1$. On the contrary, $x_1 = +1$.

According to equation (9), function i_{12}^H is derived as the partial derivative and multiply $\frac{i_{12}^H}{i_{16}}$ to obtain the following equation:

$$\frac{i_{12}^H}{i_{16}} \cdot \frac{\partial i_{16}}{\partial i_{12}^H} = \frac{i_{12}^H}{i_{16}} \cdot \frac{-i_{45}^H}{i_{45}^H - 1} = \frac{-i_{12}^H i_{45}^H}{i_{16} (i_{45}^H - 1)}$$

Since $i_{12}^H < 0, i_{45}^H > 0$. Substitute in the above equation to obtain the following equation:

$$\frac{i_{12}^H}{i_{16}} \cdot \frac{\partial i_{16}}{\partial i_{12}^H} > 0, \text{ that } x_1 = +1.$$

Similarly, according to equation (8), the function i_{45}^H is derived as the partial derivative and multiply $\frac{i_{45}^H}{i_{46}^H}$, to obtain the following equation: $\frac{i_{45}^H}{i_{46}^H} \frac{\partial i_{46}^H}{\partial i_{45}^H} < 0$, that $x_2 = -1$.

The above equations are substituted into equation (9), and the following equation can be obtained:

$$\tilde{i}_{16} = \frac{-i_{12}^H (\eta_{12}^H)^{i_1} i_{45}^H (\eta_{45}^H)^{-1}}{i_{45}^H (\eta_{45}^H)^{-1} - 1} + 1 = \frac{-i_{12}^H i_{45}^H \eta_{12}^H}{i_{45}^H - \eta_{45}^H} + 1 \quad (13)$$

Equation (12) is substituted into the transmission efficiency parameter of equation (10). The equation for calculating the meshing transmission efficiency of F2C-T transmission is given as follows:

$$\eta_{16} = \frac{\tilde{i}_{16}}{i_{16}^H} = \frac{(i_{45}^H - 1)(i_{45}^H - \eta_{45}^H - i_{12}^H i_{45}^H \eta_{12}^H)}{(i_{45}^H - \eta_{45}^H)(i_{45}^H - 1 - i_{12}^H i_{45}^H)} \quad (14)$$

4.2 Involute gear transmission efficiency calculation

The meshing transmission efficiency calculation equation of the involute gear transmission part (Zhu, 1983) is given as follows:

$$\eta_{12}^H = 1 - \pi \mu \left(\frac{1}{Z_1} + \frac{1}{Z_2} \right) (\varepsilon_1^2 + \varepsilon_2^2 + 1 - \varepsilon_1 - \varepsilon_2) \quad (15)$$

In this type, μ is the friction coefficient, $\mu = 0.05 \sim 0.1$; $\varepsilon_1 = \frac{Z_1}{2x} (tg \alpha_{a1} - tg \alpha)$; $\varepsilon_2 = \frac{Z_2}{2x} (tg \alpha_{a2} - tg \alpha)$;

α is the meshing angle of the involute gear, and $\alpha = 20^\circ$; α_{a1} is the addendum circle pressure angle of the key gear, $\alpha_{a1} = \arccos \frac{mZ_1 \cos \alpha}{2r_{a1}}$, ($^\circ$); r_{a1} is the addendum circle radius of the key gear, $r_{a1} = \frac{mZ_1}{2} + mh_a^*$, (mm); α_{a2} is the addendum circle pressure angle of the planetary gear, $\alpha_{a2} = \arccos \frac{mZ_2 \cos \alpha}{2r_{a2}}$, ($^\circ$); r_{a2} is the addendum circle radius of the planetary gear, $r_{a2} = \frac{mZ_2}{2} + mh_a^*$, (mm).

4.3 Efficiency calculation of cycloid–pin gear planetary transmission

The F2C-T pattern cycloid–pin gear planetary transmission is a type of K-H-V planetary transmission. The meshing transmission efficiency loss mainly comes from the loss of the cycloid gear and the pin gear meshing process. And so, the transmission efficiency calculation equation of the cycloid–pin gear transmission part can be derived according to the following equation:

$$\eta_{45}^H = 1 - \eta_K^H \quad (16)$$

In this type, η_K^H is the meshing efficiency loss of the cycloid gear and the pin gear.

4.4 Bearing total efficiency calculation

According to the F2C-T transmission structure, it can be known that the whole system is a total including three sets of bearings: spindle bearing, support bearing of the eccentric body, and rotary arm bearing. The former two are tapered roller bearings. The third one is a single row cylindrical roller bearing without outer ring. Therefore, the total efficiency η_B of bearing is given as follows:

$$\eta_B = \eta_{B1} \eta_{B2} \eta_{B3} \quad (17)$$

In this type, η_{B1} is the efficiency of the spindle bearing; η_{B2} is the efficiency of the eccentric body support bearing; and η_{B3} is the efficiency of the rotary arm bearing.

4.5 System transmission efficiency calculation

The F2C-T transmission efficiency is composed of two parts, which are the meshing transmission efficiency and the bearing total efficiency. Therefore, the transmission efficiency of F2C-T transmission is as follows:

$$\eta = \eta_{16} \cdot \eta_B \quad (18)$$

In this type, η_{16} is the meshing transmission efficiency and η_B is the bearing total efficiency.

5 CALCULATION EXAMPLE

Based on the above analysis and research as well as the transmission efficiency mathematical model of the F2C-T transmission, taking the F2C-T455 prototype as an example, the transmission efficiency is calculated. When the F2C-T455 prototype input shaft rated speed is $n = 1500$ r/min, the basic parameters are shown in Table 1.

The “transmission efficiency calculation” program is written by using the VB programming language, and the calculation program of F2C-T transmission efficiency can be obtained.

The transmission efficiency of the T455 prototype can reach 91.2%, thereby fully meeting the requirements that the transmission efficiency should be more than 90%.

Table 1. Basic parameters of the F2C-T455 prototype.

Parameter	Symbol	Numerical (mm)	Parameter	Symbol	Numerical (mm)
Eccentricity	α	2	Width of the cycloid gear	b	14
Tooth number of the cycloid gear	Z_c	27	Input gear's shaft teeth number	Z_1	12
Pin gear's teeth number	Z_p	28	Planet gear's teeth number	Z_2	36
Pin gear's center circle radius	r_p	90	Transmission ratio	i_{16}	81
Pin gear's radius	r_{rp}	3.5	Tooth difference	c	2
Module	m	2			

Figure 3. Basic parameter interface.

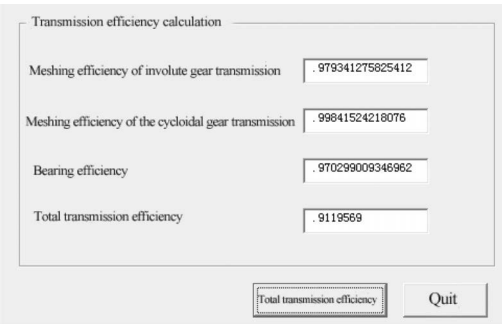

Figure 4. Transmission efficiency calculation interface.

6 CONCLUSIONS

In this paper, the structure and transmission efficiency of the new type of high precision F2C-T transmission are analyzed. The structure and characteristics of F2C-T transmission are mainly analyzed. And on those bases, according to the solving method of the differential gear train transmission ratio, the transmission ratio calculation equation

of F2C-T transmission is deduced. The calculation equation of the system's meshing transmission efficiency is derived by using the method of transmission ratio. The transmission efficiency mathematical model of the F2C-T transmission is established. And the transmission efficiency calculation for the F2C-T455 prototype models is carried out. The transmission ratio distribution model of the new pattern can be further optimized by using the calculation of transmission efficiency. It has a great significance.

ABSTRACT: In order to improve the comprehensive mechanical properties and zinc coating qualities of welding gears, the new zinc plating solution was used to electroplate after heat treatment of the welding gear. The results showed that after quenched–tempered heat treatment, the weld area organization of the welding gear was small and uniform tempered sorbite, which led to achieving excellency and stability of mechanical properties. The gears which were processed and manufactured by the way of pre-stack low carbon steel were tested and found to be qualified. The main composition of the coating was Zn, and the Fe content was less. The mass fraction of Zn was increasing along the base metal to coating, and Fe was just the opposite. The thickness of the plating layer was about 6–8 μm , and the zinc coating was closely attached to the gear. The minimum deformation heat treatment process was used to weld the gear, which ensured the dimensional accuracy, reduced the processing difficulty, and was conducive to the production of the workpieces. The mechanical performances of the weld area were improved significantly by using the process of bead welding of the transition layer. The national standard test showed that the electroplated coating had uniform thickness, reasonable distribution, good density, adhesion, and corrosion resistance.

1 INTRODUCTION

When the welding gear was working, it was affected by the large alternating impact load. The gear was required to have good comprehensive mechanical properties and corrosion resistance. In this paper, the gear ring material used was 34CrNiMo, and the shaft material was 42CrMo, which adopted the whole forging and the intermediate frequency quenching process (ZHENG, 2004). But in the practical application, it was found that the tooth part and the end face underwent cracking easily, which was not conducive to the production of many workpieces. The gear and the shaft of the transmission with ordinary galvanized steel plating method is used to prevent rust, and this caused serious hydrogen evolution, easy peeling and foaming of the coating, longer plating time, and loss of life (Barbosa, 2006; El, 2008; Kavitha, 2008). The coating was easy to burn. In order to improve the comprehensive mechanical properties and zinc coating qualities of the welding gear, the new zinc plating solution was used to electroplate after heat treatment of the welding gear.

2 THE TECHNOLOGICAL SCHEME AND PROCESS

2.1 Heat treatment

The welding structure of the gear should focus on solving the following problems in heat treatment:

1. Mechanical properties of the welded HAZ zone decreased.

The content of high carbon martensite in the HAZ area increased after welding. In the welding process, it was difficult to be heated evenly, and the high temperature tempering zone would appear in the near-crack zone, which decreases the whole structure strength, thereby resulting in the brittleness and hardening of the gear.

2. Crack and deformation of the weld zone

In the heating and cooling process of the welding structure of the gear, the thermal conductivity of different gear surfaces and internal temperatures changed to thermal expansion and contraction, and thermal stress could make the gear crack and lead to deformation.

Besides, the phase transition points of different materials were different, and the microstructure transformation was not the same, which increased the stress and the cracking and deformation tendency of the gear-welded zone.

In view of the above-mentioned problems, the following heat treatment process is developed:

1. The gear is set aside for heat treatment or heat treatment of gear teeth. Although the size precision was high, the hardness of heat treatment was high, and it was difficult to obtain the gear. Considering the processing properties, the gear tooth surface was set aside by 0.4 mm for heat treatment, and the deformation of gear teeth must be less than 0.4 mm after heat treatment.
2. Individual parts were pre-heat-treated, and the hardness of the quenched and tempered gear was adjusted to 230–270 HBW to achieve the grain refinement, uniform structure, and reduce the amount of deformation after welding.
3. After welding, heat stress was eliminated in the well-type furnace to reduce the cracking tendency and deformation of the weld zone.
4. In order to reduce the deformation caused by the weight of the parts, the welding gear was mounted in a vertical furnace in a well-type furnace, which was carried out by quenching and tempering. First, the high temperature of 900 degrees–860 degrees is set for the rapid heating furnace; quenching is carried out after which, the heating time is reduced, and oxidation and decarburization deformation are prevented. And then, oil quenching was carried out in the vertical parts of the gear, parts were cooled to MS and when the temperature fell below MS, stirring was stopped, slow cooling was carried out, and tissue stress was reduced. Finally, it was tempered to eliminate the internal stress generated during quenching.

2.2 Plating process plan

The pre-treatment of the gear with heat treatment before electroplating is as follows:

First degreased in 12% sodium hydroxide, 5% sodium carbonate, 7% sodium phosphate, 0.5% OP-10 emulsifier solution at 60–65°C for 20 min. After washing with water, it was pickled with 18% hydrochloric acid, 0.2% hexamethylenimine and 0.2% OP-10 emulsifier solution at 20–25°C for 15 min. And then into the 5% hydrochloric acid solution activation of about 8 s, activated washed.

The formulation of the zinc plating solution is as follows: 20 g/L of ammonium chloride, 3 g/L of malic acid, 1 g/L of OP-20 emulsifier, 0.1 g/L of cinnamic acid, 0.2 g/L of the main brightener, and 1 g/L of polyethylene glycol, pH 1.8 to 2.4.

In the experiment, vanadium aldehydes, o-nitrobenzaldehyde, and benzylidene acetone were used as the main brighteners for galvanizing the welding gear parts. The comparison test showed that benzylideneacetone was more suitable for zinc coating preparation of the heat-treated parts (Gao, 2001; Liang, 2007).

The electroplating process is as follows:

The gears were placed in the prepared hook on the galvanized gear, to maintain the current intensity of 0.5 A/dm², pre-plated for 5 min. And then, the current intensity is adjusted to 1 A/dm², by adding a mixture of the main brightener and cinnamic acid solution; adjust the current density; the pH value of zinc plating solution control is 1.8–2.4, and the plating time is 20–30 min for the gear surface to form a uniform zinc coating. After the galvanized gear parts are immersed in the mixture of 1 g/L sulfuric acid, 0.2 g/L nitric acid, and 60 g/L chromic anhydride, passivation is carried out for 8 s, hot water washing is carried out for 10 s, and finally, the gear is placed at 60°C for drying in the oven for 15 min.

In order to verify the effectiveness of the heat treatment process, comparison tests were carried out on the post-weld, quenched, and tempered gear and the original gear metal's performances.

An LDW200-4XB-type table-type optical microscope was used to observe the structures of the original gears and quenched and tempered gear, as given in Table 1. A wew-1000b hydraulic universal testing machine was used to measure the mechanical properties of the original gears and quenched and tempered gears, as given in Table 2.

From Tables 1 and 2, it could be seen that the residual stress was large because the heat treatment of the original gear structure had the upper bainite, so that the comprehensive mechanical properties decline. The mechanical properties of the weld zone were fine and homogeneous. The mechanical properties of the HAZ zone were softened, brittle, and hardened. The mechanical properties of the pre-heaped low carbon steel were the best after welding. According to the above-mentioned experimental results and analysis, in accordance

with the surfacing of the welding layer after the quenching and tempering process gear production, all the gears produced qualified the tests, as given in Table 3.

3 TEST AND ANALYSIS

3.1 Metal performance test

3.2 Electroplating layer quality test

1. Distribution of iron and zinc contents in coating

A JSM-6360 LV Scanning Electron Microscope (SEM) is used to test the metal content of the plating layer area, as shown in Figure 1. The composition of the electroplating layer in the scanning area was analyzed by using the Genesis 2000XM60S EDAX spectrometer, as shown in Figure 2. The coating chemical compositions of elements are given in Table 4.

From Figures 1 and 2 and Table 4, it could be seen that the main component of the electroplating layer was Zn, and a minor component was Fe. The mass fraction of Zn increased along the base metal due to the coating, while Fe decreased. This is because, in the initial stage of electroplating, Fe atoms on the based metal and Zn atoms formed an alloy, and with the continuous electroplating process, the main form of Zn coating formed polymer complexes, the substrate metal surface was covered by the Zn layer, so far away from the base metal outside the coating was mainly Zn, which could significantly enhance the corrosion resistance of the base metal.

2. Densification and thickness of the coating

The surface morphology of the plating layer magnified 5000 times is shown in Figure 3. The lower part of the base metal was galvanized for the middle layer and the upper part was galvanized for the

Figure 1. The coating area to be measured.

Figure 2. The energy spectrum of the coating components' analysis.

mosaic test SEM. The plating layer of good density was obtained to ensure adhesion and excellent corrosion resistance. By measuring the thickness

Table 4. List of coating components.

Element	Mass fraction/%	Atomic number fraction/%
Zn	95.17	94.61
Fe	4.83	5.39

Figure 3. SEM image of the coating.

of different parts of the galvanized layer, it could be seen that, the thickness of the layer was about 6–8 μm , thickness exhibited uniformity, reaching up to the national standard.

3. Coating adhesion

In accordance with GB/T5270-2005 adhesion strength test methods and standards, the adhesion strength of the galvanized layer was tested.

A 25 mm 3M fiber tape was applied to the cover of the test coupon with a 2 kg roller, and 10 seconds after the removal of the bubble, the tape was peeled off with a quasi-constant tensile force perpendicular to the surface of the overlay. No peeling phenomenon was found in the test, which indicated that the adhesion between the covering layer and the substrate was strong.

The standard sharp blade of the hard steel knife was used to draw six parallel lines, with a spacing of 2 mm, when the parallel line through the standard cuts through the cover to the substrate. No peeling of the cover layer was observed, indicating that the covering layer of the part was closely attached to the substrate.

4. Appearance and corrosion resistance

In accordance with GB/T 9799-1997 standards, the zinc plating layer on the standard appearance of the coating was detected. According to GB/T10125-1997 standards for the salt spray test and no corrosion point in 96 h indicated that the surface of the galvanized layer exhibited uniform thickness; it was compact with excellent corrosion resistance.

4 CONCLUSIONS

1. The welding gear tooth surface reserved for grinding and the use of the minimal deformation heat treatment process ensured the dimensional accuracy and reduced the difficulty of processing.
2. After welding and tempering, the mechanical properties of the weld zone could be improved, and the gears produced by processing could meet the testing results.
3. Scanning electron microscopy and Energy Dispersive Spectrometry (EDS) showed that the main component of the electroplated layer was Zn and the fractions of Fe and Zn were increasing along the base metal of the coating, while Fe was decreasing. The plating thickness was about 6–8 μm , which indicated that the thickness exhibited uniformity, reasonable distribution, and good density.
4. The results showed that the galvanized coating was close to the substrate and had excellent corrosion resistance. The coating had no roughness, blister, crack, porosity, or local coating. In this paper, the galvanized solution formulation and electroplating process worked well.

ABSTRACT: A hardware-in-the-loop simulation platform is developed to test the performance and function of a BMS. Hardware is constructed based on a PXI real time controller. Veristand software is adopted to manage the I/O channel configuration and user interface. The HIL test system can realize battery cell voltage simulation, current sensor simulation and CAN bus monitoring. It has been used for the static and dynamic test of the BMS product.

1 INTRODUCTION

In recent years, new energy source vehicles have become a hot area of research and development due to petroleum energy depletion and environment protection requirements. There are different technology options for new energy vehicles, such as electric vehicles, hybrid electric vehicles and fuel cell vehicles. A battery package is one of the key components of electric vehicles as the energy storage system, which can output energy to the electric motor during the vehicle driving state and recover energy from regenerative braking. The battery management system is responsible for state monitoring and safety management to realize suitable charging and discharging of the battery package. To reduce costs, shorten the development cycle. In the early development stage of the control system, Hardware in the Loop (HIL) simulation technology is often used (Ye, 2009). In the model-based development process, the test bed

system plays a key role, which can be developed to test different kinds of ECU (Electronic Control Unit) (Ouyang, 2008; Haupt, 2013; Jason, 2012). In this paper, design of a BMS HIL test system is introduced and then application of this test system in the BMS performance test is described in detail.

2 BATTERY MANAGEMENT SYSTEM

A distributed structure is often adopted for BMS and Figure 1 shows a star topology commonly used in product BMS.

A slave board is used for data acquisition of battery cell voltage and package temperature and equalization control. Data are sent to the master board through a CAN bus. The master board is responsible for SOC calculation, charging and discharging management and thermal management. One master can be connected with several slave boards according to the

Figure 1. BMS structure.

number of cells in the battery package. A BMS must rule and check the energetic car's behavior, reporting to the user all the relevant information about the battery. It must maximize the runtime per discharge and the number of life cycles. Usually a BMS is connected to the remaining electronic systems via a CAN bus (Buccolini, 2016).

Generally speaking, the function of BMS includes several aspects:

1. Battery state monitoring. Battery package operating parameters such as voltage, current, temperature, etc. are acquired. Based on these details, suitable algorithms are developed which includes cell equalization control, thermal management and safety management.
2. SOC and SOH calculation. SOC is an important parameter for the energy distribution algorithm of the vehicle control unit.
3. Bus communication. The BMS communicates with the vehicle control unit, information system and battery charger through the CAN bus.

3 DESIGN OF THE BMS TEST SYSTEM

3.1 Hardware structure

The design of the test system is shown in Figure 2. It consists of a host computer and a real time controller.

A notebook with Windows7 is adopted as host computer and Veristand software is used on it. The host computer has the function of operating panel design, I/O board configuration, model management and test sequence management. The host computer is connected with a real time controller through a LAN and TCP/IP protocol.

The real time controller is constructed with PXI hardware. PXI 1062Q is selected as the chassis which provides 4 PXI slots and 3 PXIe slots. PXIe4322 is adopted to simulate the cell voltage. It has 8 isolated analog output channels which can output maximum 20 mA current and 16 V voltage. PXIe6361 is selected to simulate the package voltage and current sensor. It has 16 analog input channels, 2 analog output channels and a 24-channel I/O signal. PXI 2722 is adopted to simulate the temperature sensor. It has a 5-channel programmable resistor output channel and the maximum resistor value is 16 kilohm. PXI 8512 provides a 2-channel CAN interface to connect with the BMS CAN bus.

3.2 Battery model

The Rint model is adopted for battery voltage calculation, which is shown in Eq. 1 to Eq. 3. V_{bat} and I_{bat} are the battery package voltage and current. R_{int} is the inner resistor of the battery, which can be obtained through a two-dimensional lookup table. V_{oc} is the open circuit in the model, which is the function of SOC.

$$V_{bat} = V_{oc} - I_{bat} R_{int} \tag{1}$$

$$R_{int} = f(I_{bat}, SOC) \tag{2}$$

$$V_{oc} = f(SOC) \tag{3}$$

3.3 HIL test process with Veristand

The hardware-in-the-loop test process with Veristand software is shown in Figure 3. A project in Veristand contains a system definition file and a

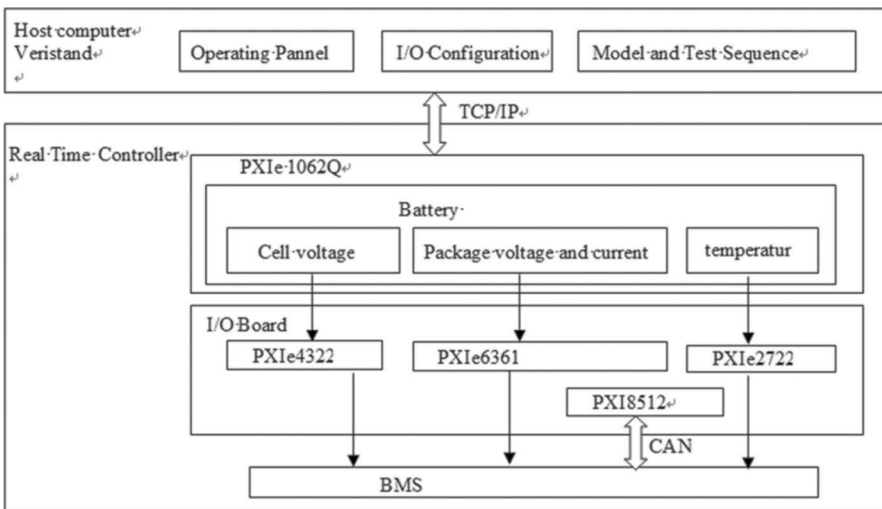

Figure 2. BMS test system structure.

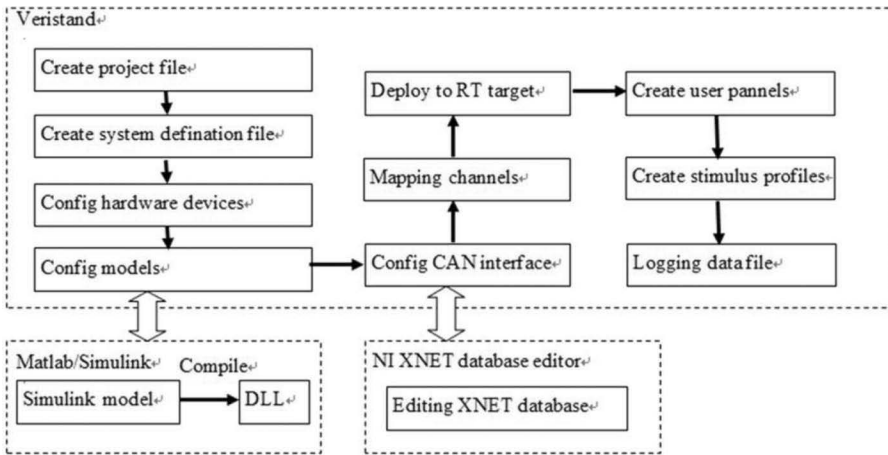

Figure 3. HIL test process with veristand.

workspace which consists of user panels to display data and curves. The system explore window is used to configure a system definition file which includes hardware configuration, model configuration, CAN communication information and mapping information. The battery model and power train model in Matlab/Simulink can be compiled into a DLL file and loaded into Veristand. The XNET database editor can create and edit the CAN frame definition file which can be loaded into Veristand to resolve CAN frame information. After the system definition file is defined, it can be deployed to the real time target, the PXI hardware. User panels contain display indicators and graphs can be designed on line to monitor test data. A stimulus profile can be created to realize test automation.

4 APPLICATION OF THE TEST SYSTEM

4.1 Testing of BMU cell voltage acquisition

The PXI NI 4322 board provides 8 cell voltage output channels, using a tandem structure, each cell voltage is set to 3.500 V, and the total voltage of the battery pack is 28 V. The PC can monitor the battery voltage through the CAN data using Veristand software. Its detection accuracy is less than 10 mv through resolving the CAN bus data. Figure 4 shows that the BMU can collect voltage with low error.

Figure 4. Cell voltage acquisition accuracy.

4.2 Testing of BCU total voltage acquisition function

The total voltage acquisition range of the BCU is 0–500 V. We can input a different analog voltage signal to the measurement port of the BCU using the HIL system. Figure 5 shows that the test accuracy will be increased by the increase of the total voltage.

Figure 5. Total voltage acquisition.

4.3 Testing of BCU pack current acquisition function

The BCU pack current acquisition range is 0–500 A. This study uses a NI PXI-6221 IO board card to simulate primary current by outputting different voltage whose range is 0–5 V to the BCU current acquisition port. Figure 6 shows that the pack current measured

Figure 6. Current pulse curve.

Figure 7. Photo of a BMS HIL test platform product.

by BMS delays for less than 1 second, compared with the target current, which is a current pulse up to 70 A, and we can obtain BMS measurement error less than 0.5 A from the acquisition data.

The real BMS HIL wiring diagram is shown in Figure 6. It includes a host computer, a real time controller and a BMS.

5 CONCLUSION

In this study, we developed a test bed for a BMS. It can assess the completeness and effectiveness of the BMS function, the accuracy of data acquisition, and the accuracy of the tested BCU and calculated SOC. This platform is a very powerful tool for testing and developing a BMS.

Experimental study on yarn friction slip in the yarn pull-out test

Weikang Li, Zhenkun Lei, Fuyong Qin, Ruixiang Ba & Qingchao Fang

State Key Laboratory of Structural Analysis for Industrial Equipment, Dalian University of Technology, Dalian, China

ABSTRACT: The single yarn pull-out test is a model experimental method to research the mechanical properties of fabric under impact. This paper aims to understand the yarn pull-out mechanism of Kevlar49 plain fabric by the single yarn pull-out test. The load–displacement curve contains the typical physical phenomena such as crimp extension, crimp swap, frictional slip of yarn, and fabric deformation behavior. During static friction, the pull-out load increased nonlinearly with the displacement and the crimp extension of the pulled warp yarn occurred gradually. Then, the kinetic friction started when the friction load reached its maximum, and the load–displacement curve decreased undulately until the warp was pulled out. During kinetic friction, the crimp swap and frictional slip were observed. Further analysis showed that in the pull-out test process, the friction force is not uniformly distributed along the pulled yarn and the friction dissipation is nonlinear.

1 INTRODUCTION

Kevlar fiber is a kind of aramid composite developed by DuPont in the 1960s, and it has high specific strength and modulus, good toughness, high temperature resistance, and high energy storage capacity and energy transfer efficiency. Kevlar fabric is weaved by Kevlar yarn, and each yarn consists of hundreds to thousands of Kevlar fibers. It is an ideal composite fiber for manufacturing bullet clothing (Carr, 1999).

In the impact process, there are three kinds of transfer of the kinetic energy of a bullet: the kinetic energy of yarn, the strain energy of yarn, and the friction dissipation caused by the frictional slip (Duan, 2005). The main role of friction force during impact is to strengthen the interaction of yarns, and the remote yarns can join into energy absorption.

Because of the high speed of the bullet impact, the fabric properties were studied by comparing the change of fabric state and bullet speed before and after the impact, which makes it difficult to monitor the deformation process of fabric during the impact and is impossible to understand deeply the friction mechanism during the impact. Some researchers developed the yarn pull-out test to simulate the process of yarn pulled out from fabric under impact (Bazhenov, 1997). This method gives a good look to the fabric deformation process under impact, and is helpful to understand the friction mechanism and energy absorbing mechanism.

Some studies show that yarn pull-out force is positive correlation with impact resistance, and a fabric with high yarn pull-out force behaves better

in the impact test (Bilisik, 2010; Dong, 2009). Zhu (2011) modeled the yarn pull-out process into the process of fiber pull out from the matrix, and established the analysis model of force-displacement. The model has important reference values because it takes crimp extension and contact area into consideration. Bilisik et al (Bilisik, 2010) studied the influence of fabric size and pull-out yarn mount as follows: the maximum of yarn pull-out load is proportional to the fabric longitudinal dimension, while the fabric transverse size has little effect on the maximum pull-out load. Bilisik et al (Bilisik, 2011) studied the effects of yarn mount and width/length ratio on the shear strength by the yarn pull-out test. Nilakantan's (2013) result shows that transverse preload is in positive correlation with the maximum pull-out force. Dolatabadi (2009) researched the deformation behavior of fabric under bias extension using the 2D-FFT method, and the result shows that there is a critical shear angle during bias extension which may correlate with the geometry parameter. However, the above studies are statistical research on the relationships between load and displacement, and load and fabric geometric size. There are few studies focusing on the distribution of friction force and the energy absorption mechanism at mesoscopic level.

In this paper, the process was measured by the DIC method, and the load–displacement curve was obtained by the yarn pull-out test. Combined with the mesoscopic geometry of the fabric structure, the pull-out load, frictional force distribution and energy absorption were investigated, and the yarn crimp extension, crimp swap, and frictional slip were discussed.

(a)

(b)

(c)

Figure 1. (a) Geometric dimension of plain woven fabric and (b) schematic diagram of warp trajectory with cross-fill yarns and a schematic diagram of fill trajectory with cross-warp yarns.

2 GEOMETRIC PROPERTIES OF FABRIC

The micrograph of Kevlar 49 plain fabric is shown in Figure 1(a), which is woven alternately by warp yarn in the vertical direction and fill (weft) yarn in the horizontal direction. There is a period cell structure consisted of 2×2 intersections of warp and fill yarns. Because of the interaction of warp and fill yarns formed during the process of weaving, the yarn wavy crimp exists in the fabric under relaxation conditions. The abridged view of warp yarn trajectory with cross-fill yarns and the fill yarn trajectory with cross-warp yarns is shown in Figure 1(b) and 1(c), respectively.

3 SINGLE YARN PULL-OUT TEST

3.1 Sample and experimental process

The test equipment used to conduct the experiment is shown in Figure 2(a). Two clamps are placed on a sliding rail to clip the two sides of the fabric. Each clamp is comprised of three parts: the front U-shaped groove, the back U-shaped groove, and the board between them. Before the test, the fabric was placed in the middle of the board and the back groove and fixed by the bolts installed in the front

groove. So, the fabric was clamped tightly between the board and the back groove. This design reduces the stress concentration of the boundary and improves the accuracy of the experiment.

Before the experiment, the direction of warp yarn is along the tension direction and the upper end of warp yarn is loaded. The width and length of the sample are both 15 cm. There are totally 65 cells (130 intersections) along the warp direction and same number of cells along the fill direction. There is no preload in the sample before the experiment. The middle warp yarn is pulled out using a universal testing machine (Instron 3345) and the pull-out speed is 100 mm/min.

3.2 Pull-out load and displacement curve

The load–displacement curve obtained during the yarn pull-out test is shown in Figure 2(b). There are two main distinct regions: the static friction region

(a)

(b)

Figure 2. (a) Experimental setup and (b) typical curve of load and displacement during the single yarn pull-out test.

and kinetic friction region. In the static friction region, the pulled yarn had crimp extension and produced the static friction force among the intersections, which led to fabric deformation. When the pull-out load reached the maximum, the pulled yarn began to slip in the kinetic friction region.

In the kinetic friction region, the load–displacement curve shows a classic “sine wave” feature corresponding to a yarn crimp swap, where the pull-out load first increased and then decreased.

The increase of pull-out load indicates that the bottom end of the pulled wrap yarn slips into the adjacent intersection, while the decrease of pull-out load indicates the bottom end slipping out of the current intersection. A sine wave corresponds to 2 intersections. When the pulled wrap yarn gets through 2 intersections, there is a “slip in-out” process corresponding to produce a sine wave in the load–displacement curve. Therefore, the load–displacement curve comprehends the fabric shear deformation at macroscopic scale and the yarn deformation at mesoscopic scale, which reflects a coupled physical phenomenon of yarn crimp extension, crimp swap, and friction slip.

4 RESULTS AND DISCUSSION

4.1 Friction distribution during kinetic friction

For simplicity, taking the first wave valley after the maximum static friction force as the starting point, the first wave number is 1, and so on, and the last wave number is 65. Extracting the load data of the wave peak and wave valley, the distribution of pull-out load during kinetic friction is shown in Figure 3(a).

In Figure 3(a), the horizontal axis represents the wave number, while the vertical axis represents the pull-out load. The pull-out load curves of the wave peak and wave valley have the same trend, and are exponentially decreased. The pull-out loads decreased sharply at beginning and then decreased slowly. At last, the curves coincided together.

4.2 Energy absorbing mechanism

In Figure 3(a), the area under the pull-out load and displacement curve is the total energy of the test machine. Each wave area of the curve during kinetic friction can be calculated by the sum of several sections, as shown in Figure 3(b), which shows that there is the relationship between the absorbed energy and the wave number. Every point on the curve represents the sum of energy absorption for all intersections. The absorbed energy decreases exponentially with the intersection number as the yarn is pulled out.

Figure 3. (a) Pull-out load curves and (b) absorbed energy curve.

5 CONCLUSIONS

The yarn pull-out test results indicate that the pull-out load and displacement curve well describe the macroscopic fabric shear deformation and mesoscopic yarn deformation, and reflects the yarn extension crimp, crimp swap, and friction slip. During static friction, the pulled yarn produced the crimp extension so that the overall shear deformation of fabric occurred under the pull-out load. During kinetic friction, when the pulled wrap yarn and the cross-fill yarns were a convex to convex contact, the pull-out load increased; when the pulled wrap yarn and the cross-fill yarns were a convex to concave contact, the pull-out load decreased. Further analysis showed that the friction force on the pulled wrap yarn was not uniformly distributed, which decreased exponentially with the pull-out intersections of fabric.

Analysis and research into the effect of dithering technology on ADC's SNR

KunKun Jin & Xiao Long Chen

School of Mechano-Electronic Engineering, Xidian University, Xi'an, China

ABSTRACT: The dithering technique that has been researched frequently in the current ADC application field is often used to improve the dynamic performance of ADC. However, adding a dither in the input signal will have a bad influence on ADC's SNR. In this paper, the characterization of the SNR and the factors that affect the ADC's SNR are analyzed theoretically. By establishing a simulation system on the Matlab platform, it is found that dithering technology increased the ADC's SFDR from 26.40 dB to 33.71 dB, but at the same time it reduced the ADC's SNR from 18.49 dB to 16.95 dB.

1 INTRODUCTION

With the development of modern science and technology, digital analogy conversion technology-ADC, as the most commonly used data acquisition technology, has played a more and more important role in military, medical, civil and other fields. However, ADC's dynamic range is greatly influenced by the existence of non-ideal characteristics of ADC. Dithering technology is an effective means to improve the non-ideal characteristics and increase the dynamic range of ADC. But, with the improvement of ADC's non-ideal characteristics, the dithering technique has bad influence on the ADC's SNR.

In this paper, firstly, we study the concept of ADC's SNR. Then we get the main factors that affect the ADC's SNR. Finally, the simulation is implemented to verify the theoretical result.

2 THE CHARACTERIZATION OF ADC'S SNR

The SNR refers to the ratio of the effective value of the fundamental component of the input signal and the effective value of the other noise except the harmonic component. We can express it by the mathematical expression given below:

$$SNR = 20 \lg \frac{V_m}{V_n} \quad (1)$$

Among the expression, V_m represents the effective value of the fundamental component of the input signal, and V_n indicates the effective value of the other noise except the harmonic component.

Considering the above formula (1), in order to calculate the signal-to-noise ratio, first, we need to

know the effective value of the fundamental component and the noise component. Assuming that the input signal is a sine wave, thus, the effective value of the fundamental signal is equal to the ADC's full-scale input signal divided by $\sqrt{2} - (2^{N-1} \times LSB) / \sqrt{2}$ where LSB means least significant bit. The quantization noise amplitude range of ADC is $\pm \frac{1}{2} LSB$, and the quantization error is caused by the analog input signal. According to the relationship between the effective value and the peak value of the triangle wave, we know that the effective value of the quantization noise is equal to its magnitude divided by $\sqrt{3} - (LSB / 2) / \sqrt{3} = LSB / \sqrt{12}$. Then, we reorganize the formula (1):

$$\begin{aligned} SNR &= 20 \lg \frac{V_m}{V_n} \\ &= 20 \lg \frac{(2^{N-1} \times LSB) / \sqrt{2}}{LSB / \sqrt{12}} \\ &= 20 \lg 2^N + 20 \lg \sqrt{6} - 20 \lg 2 \\ &\approx 6.02N + 1.76 \end{aligned} \quad (2)$$

In practical applications, the ADC's SNR can be roughly calculated by the following method: take the conversion accuracy of ADC and multiply by 6. For example, for a 10 bit analog to digital converter, the SNR should be greater than 60 dB, and for a 12 bit, the SNR should be greater than 72 dB.

3 INFLUENCE OF THE DITHERING TECHNIQUE ON ADC'S SNR

3.1 SNR under ideal conditions

According to the analysis above, under ideal conditions, the SNR of ADC refers to the ratio of the

effective value of the full range single frequency ideal sine wave input and the total effective value of the Nyquist bandwidth's all other frequency components' output of ADC (not including the DC component and harmonic components). In this condition, the ideal ADC's noise is only generated by its inherent quantization error, and we can know that the ADC's SNR is just about N through expression (2). Then, what is the relationship between N and quantization error? Since the conversion accuracy (N) of the ADC cannot be infinite in practical application, we can only use a limited conversion accuracy to represent an input signal. The limited conversion accuracy implies a finite quantization interval of q, and the finite quantization interval cannot accurately quantify each voltage value. Therefore, the voltage value of the input signal and the quantized voltage value usually have error which is called the quantization error. That is to say, N and ADC's quantization error has a direct relationship. The relation between the quantization error and the input signal can be described by the following picture:

3.2 SNR under non-ideal conditions

The ADC device we use in practice is non-ideal usually, there always is a deviation between the actual conversion curve and ideal transfer curve, and it appears as varieties of errors, such as zero error, full scale error, gain error, integral nonlinearity error-INL and differential nonlinearity error-DNL. Among them, the zero error, the full degree error and the gain error are constant errors, and they affect only the absolute accuracy of ADC but do not affect the SNR of ADC. INL refers to the maximum deviation between the actual conversion curve of ADC and the ideal conversion curve of ADC based on the calibration of the above constant error. While DNL refers to the maximum deviation between the actual quantization interval of ADC and the ideal quantization interval of ADC, we change the quantization error of ADC, which can directly calculate the influence of the deviation of the actual conversion curve of ADC and the ideal conversion curve of ADC on the ADC's SNR.

Non-ideal ADC, in addition to the above error, has all kinds of noise, such as thermal noise, aperture jitter and peripheral circuit noise. The thermal

Figure 1. The relation between quantization error and input signal.

noise is caused by the internal molecular thermal motion of the semiconductor device. The aperture jitter is caused by the uncertainty of the ADC's aperture delay. While the peripheral circuit of ADC will also bring noise, such as the thermal noise of the ADC's input circuit, the power/ground clutter, the space electromagnetic interference and the external clock's instability (leading to the ADC's sampling clock edge's uncertainty that brings the aperture jitter), it can be all equivalent to the above two kinds of internal noise of ADC.

In general, the non-ideal ADC's quantization noise, NDL, aperture jitter and thermal noise are independent of each other. Considering the influence of these four factors, the SNR calculation formula of ADC is as follows:

$$\begin{aligned}
 SNR &= \frac{P_s}{P_n} = 10 \lg \left(\frac{V_s^2}{V_n^2} \right) \\
 &= 10 \times \lg \left(\frac{V_s^2}{V_{DNL}^2 + V_{\Delta_{ij}}^2 + V_m^2} \right) \\
 &= -10 \lg \left[8 \times \left(\frac{1}{12} + \frac{\epsilon^2}{4} \right) + \left(2\pi f_{in} \sigma_{\Delta_{ij}} \times 2^N \right)^2 + 8\sigma_m^2 \right] \\
 &\quad + 6.02N \text{ (dB)}
 \end{aligned} \tag{3}$$

In formula (3), N represents the quantization bits of ADC. Δ_{ij} represents the aperture jitter. ϵ represents the effective value of the actual quantization interval and the ideal quantization interval error of ADC—the unit is LSB, f_{in} represents the frequency of the ADC's input signal—the unit is Hz. $\sigma_{\Delta_{ij}}$ represents the effective value of the ADC's aperture jitter—the unit is s. $\sigma_{\Delta_{in}}$ represents the input noise of the ADC—the valid value is LSB.

According to formula (3), in the case of the ADC's inherent quantization error, DNL and aperture jitter are fixed, due to the minus sign in front of the formula. If the input jitter noise increases, $\sigma_{\Delta_{in}}$ is large, and the SNR of ADC will be smaller. That is to say, the dithering technique will deteriorate the ADC's SNR.

4 SIMULATION AND VERIFICATION

Through the theoretical analysis, we can conclude that the dithering technique deteriorates the ADC's SNR while improving some of its non-ideal properties.

4.1 Simulation conditions

We construct a simulator through the Simulink module in MATLAB. The simulation condition is as follows: a sine wave generation module in Simulink is used to produce a sine wave whose

frequency is $f = 3 \text{ MHz}$, and amplitude is $V_{pp} = 7 \text{ V}$. We keep the sine wave signal through the sampling module and use a quantizer whose conversion precision is 3 bits and the maximum input voltage is 8 V to quantify the signal. We set the sampling holder's sampling frequency to $f_s = 100 \text{ MHz}$. For the dither signal, we use the noise module to generate the dither noise signal whose amplitude is 0.3 V less than 1 LSB (1 V). The block diagram of the simulation system is shown in Figure 2.

Figure 2 is the block diagram of the simulation system without dithering. Figure 3 shows the block diagram of the simulation system with dithering. We can see that the difference between the two pictures is just with or without dithering.

4.2 Simulation result

We observe the oscilloscope module's output in the Simulink and compare the quantized output results between without dithering and with dithering. The result is shown in Figure 4.

Figure 4 is the ADC's quantization output graph without dithering. We can see from the figure that the ADC's harmonic interference is serious, and the Spurious Free Dynamic Range (SFDR) is 26.40 dB and the SNR is 18.49 dB . Figure 5 shows the ADC's quantization output graph with dithering. We can see from the figure that the ADC's SFDR is improved, reaching 33.71 dB , but the substrate of the noise increases from the original 100 dB to 90 dB , and the Signal-to-Noise Ratio (SNR) is reduced to 16.95 dB .

Figure 2. The block diagram of the simulation system without dithering.

Figure 3. The block diagram of the simulation system with dithering.

Figure 4. The ADC quantization output graph without dithering.

Figure 5. The ADC quantization output graph with dithering.

5 CONCLUSION

From theoretical analysis and simulation, it can be concluded that dithering technology can indeed improve some non-ideal characteristics of ADC, but at the same time it will deteriorate the ADC's SNR. So, when using the dithering technology to improve the non-ideal characteristics of ADC, we should pay more attention to the requirement of the SNR.

ABSTRACT: The CANopen master stack is used for network management and communication with CANopen slave nodes. This paper presents the design and implementation of a specialized CANopen master stack for servomotor controllers in a 6-DoF manipulator. Based on the hardware and general CANopen master stack, additional profile configuration for the 6-DoF manipulator is defined. It is shown by the real-time performance that the specialized CANopen master stack satisfies the timing constraint of control.

1 INTRODUCTION

CANopen is an application-layer communication protocol that includes the layer above the data link layer in the OSI reference model (Farsi, 1999). The low layer under it can be implemented by Controller Area Network (CAN), Ethernet for Control Automation Technology (EtherCAT) and so on (CAN, 2016). By the application of various standardized device profiles (e.g. CiA 401, CiA 402) and a communication profile (i.e. CiA 301), devices with different specialization can be connected to one network, allowing interoperability with each other (Jeon, 2001; Portillo, 2006; Li, 2013; Duan, 2007; Zhe, 2010), as shown in Figure 1 (H, 2015).

The communication profile CiA 301 serves as the basis of various device profiles. It specifies the object dictionary as well as the CANopen communication objects. In addition, it specifies the CANopen network management services and protocols. Following the way of how CiA 301 specified, a CANopen master stack can be realized.

As for a high-level flexible communication protocol, CANopen is widely used in many different areas nowadays, showing good compatibility and performance (Jeon, 2001; Portillo, 2006; Li, 2013; Duan, 2007; Zhe, 2010). In this paper, according to the hardware of the 6-DoF manipulator, additional definition of CiA DSP-402 for servomotor controllers is provided on the basis of the master stack, together with the definition of the connection set and procedure for setting and using modes

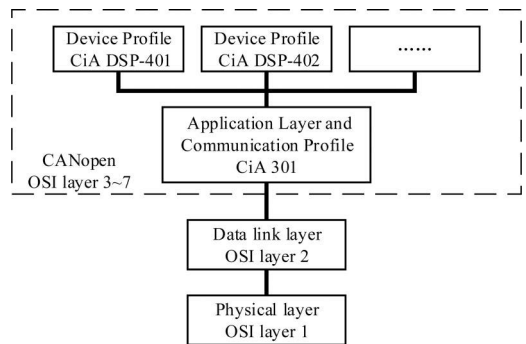

Figure 1. Schematic overview of CANopen and the low layer in the OSI reference model.

of operation. As a result, a specialized version of the CANopen master stack for a 6-DoF manipulator is implemented. The real-time performance testing result shows that the worst-case response time is less than 1.67 ms, which meets the demand of the controlling period of 50 ms for 6 servomotor controllers all in interpolated position mode.

2 HARDWARE CONFIGURATION

The hardware of the manipulator consists of several parts, of which some are highly concerned with CANopen, as illustrated in Figure 2.

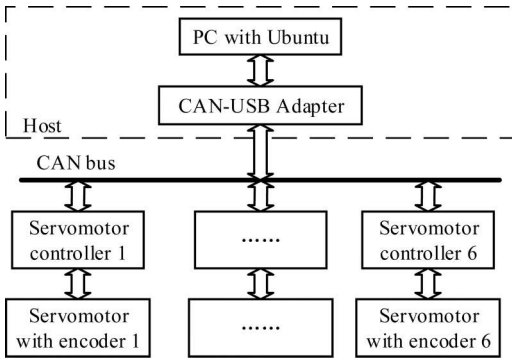

Figure 2. Network structure.

- PC with Ubuntu: the version of Ubuntu is 14.04 LTS; PC equipped with USB interface
- CAN-USB adapter: PCAN-USB adapter from PEAK system, of which the bit rates vary from 5 kbit/s up to 1 Mbit/s
- Servomotor controller: Gold Twitter from Elmo, with CAN and standard RS232 communication interface provided

3 SOFTWARE ARCHITECTURE OF THE GENERAL CANOPEN MASTER STACK

As mentioned before, the general CANopen master stack is instructed by CiA 301. According to the modularity, it can be roughly divided into several modules, as shown in Figure 3. All the programs mentioned are written in C++ 11.

Generally, there are two kinds of tasks that are generated by UI: one is to send messages to the devices and the other one is to get data from the object dictionary or additional defined objects. To meet the requirement of these two types of tasks, modules illustrated in Figure 3 are designed and implemented.

3.1 Message generation module

As its name prompts, this module generates different kinds of messages that are requested by the task from the host, including node guarding and node control from the NMT protocol, upload and download from the SDO protocol, RPDO from the PDO protocol, syncWrite from the SYNC protocol, etc. For the various protocols mentioned above, one same structure can be defined to describe the messages, consisting CAN-ID, message type (standard frame or extended frame), data length and data.

After the message to be sent is generated, there comes two ways of sending it. One is to send

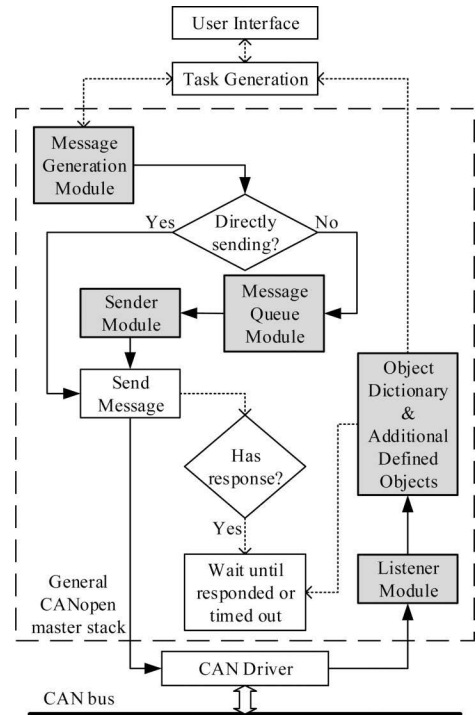

Figure 3. Framework of the CANopen master stack.

messages directly to the CAN bus in the thread that is the same as the one where the message is generated. This approach aims at the tasks that do not require real-time communication. The other one is to push the message into a circular queue, which is called the message queue. In contrast to the former way, this method aims at providing a mechanism that guarantees real-time communication as well as sequentiality and periodicity of sending messages.

3.2 Message queue module

The message queue is a FIFO circular buffer with a fixed maximum size. It deals perfectly with the producer-consumer problem. The basic idea is to use a front pointer and a rear pointer to make the queue perform as if it was connected from front to rear, in a ring form.

There are two functions that will change the number of element stored in the queue: push and pop. The diagram of the push function is presented in Figure 4. The pop function is almost the same except that it checks whether the queue is empty, gets the element from the front position and moves the front pointer to the next.

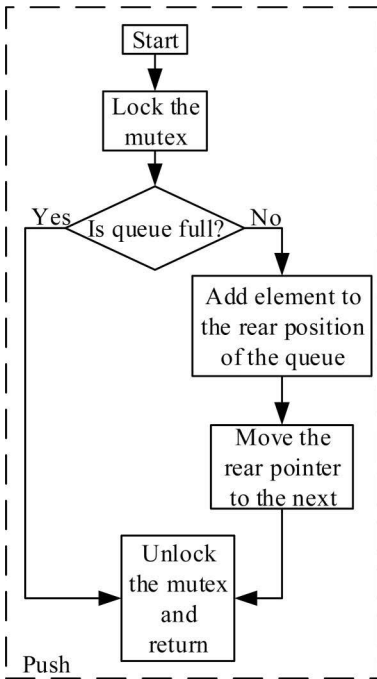

Figure 4. Push function of the message queue.

3.3 Sender module

The sender module gets the message from the queue using the pop function and then sends it to the CAN bus. This module lies in a separate thread that is different from the thread where messages are generated or stored.

The sending function in this module is illustrated in Figure 5. It is located in a loop that can be paused or exited until a corresponding command is delivered. The waiting operation after getting the message is the approach to keep the sending period of the “same message” according to the last sending time. Here, the last sending time only makes sense to the “same message”, and the “same message” has the same node ID and CAN ID.

3.4 Listener module

The listener module is responsible for getting the messages on the CAN bus from devices. Like the sender module, it is located in another thread. The function of the listener is in a loop that can be exited until the related command is delivered. Some of the code is listed in Figure 6, which shows that the process is switched by the function code of the coming CAN message. The processed result

will be stored in the object dictionary or additional defined objects.

4 CONNECTION SET AND PROCEDURE FOR SETTING MODES OF OPERATION

After the implementation of the CANopen master stack mentioned above, more work should be done to make it a specialized version for

controlling a 6-DoF manipulator with 6 servomotor controllers. The main work goes to the additional description of servomotor controllers profiled in CiA DSP-402 and the process of various tasks.

4.1 Connection set

For the sake of convenience and less effort to use devices supporting CANopen, a pre-defined connection set is provided in CiA 301. This pre-defined connection set supports 1 NMT, 1 SYNC, 1 TIME, 1 Emergency, 4 TPDOs, 4 RPDOs, 1 TSDO, 1 RSDO and 1 NMT error control, as shown in Table 1. Note that some of these items are needed for sending messages by the master stack, and the others should only be used for received messages.

4.2 Procedure for setting modes of operation

The 6-DoF manipulator uses several modes of operations, including the profile position mode, profile torque mode, interpolated position mode, etc. The main task of the specialized CANopen stack is to process the right procedure of setting these modes of operation.

An example of setting the interpolated position mode is given in Figure 7. Note that not all the modes of operation should be strictly set in this way. Modification is necessary in some situations. For example, when setting the profile torque mode, it is not allowed to set the motor state to OPERATION_ENABLE at the end because this operation may release the brake immediately and may lead to unwanted movement.

Table 1. Connection set.

COB	Function code	CAN-IDs
NMT	0000b	000h
SYNC	0001b	080h
TIME	0010b	100h
Emergency	0001b	081h~0FFh
TPDO1	0011b	181h~1FFh
RPDO1	0100b	201h~27Fh
TPDO2	0101b	281h~2FFh
RPDO2	0110b	301h~37Fh
TPDO3	0111b	381h~3FFh
RPDO3	1000b	401h~47Fh
TPDO4	1001b	481h~4FFh
RPDO4	1010b	501h~57Fh
TSDO1	1011b	581h~5FFh
RSDO1	1100b	601h~67Fh
NMT error control	1110b	701h~77Fh

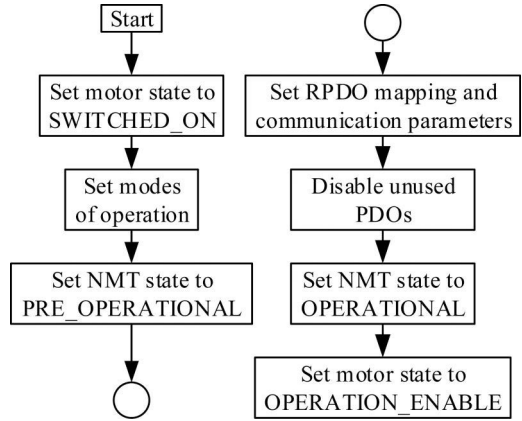

Figure 7. Procedure for setting the interpolated position mode.

Table 2. Worst-case response time experiment.

Platform	Clock frequency	Worst-case response time
Intel Core i5-480 M	2.66 GHz	1.361 ms
Intel Core i7-6700	3.40 GHz	1.025 ms

5 REAL-TIME PERFORMANCE

For the servomotor controllers working in the interpolated position mode, the response time is very important, because this mode of operation is highly time-sensitive. If the servomotor controller cannot receive the corresponding message within the required sending period, serious faults would happen immediately. For one servomotor controller in the interpolated position mode, 5 related messages are regarded as one sending unit. As a result, if all 6 servomotor controllers are in the interpolated position mode, considering that the sending period is limited to 50 ms, the response time of one message can only be within 1.67 ms.

The worst-case response time is tested using the SDO upload protocol, the result of which is listed in Table 2. For these two platforms, both of the worst-case response times are less than 1.67 ms, which meets the aforementioned requirement.

ACKNOWLEDGEMENT

Special thanks to Yongfeng Xia from HFUT for his help in guidance and participation in programming. Additional thanks to Qi Wang, Kun Wang and Xuanchen Zhang for their help in testing the program.

Design of a crane intelligent control system

Cancan Zhang, Shuguang Liu & Huawei Xie

School of Electronic and Information Engineering, Xi'an Polytechnic University, Xi'an, China

ABSTRACT: At present, the majority of cranes are still managed by manual control. The working efficiency is lower, so the method cannot meet the requirement of industrial production. Therefore, we design a crane intelligent control system, which is based on PLC and frequency converter. Particularly, we expound the design of hardware and software of the electric control system. The successful debugging proves that the system is feasible. Crane, as a transport machinery, is widely applied to the metallurgical industry, construction industry, etc. With the continuous expansion of modern industrial production, industrial production demands increasingly higher working efficiency of cranes. But currently, most of the cranes are still managed by manual control, to a certain extent, which restricts the working efficiency of the crane. We designed the intelligent control system, which is based on PLC and frequency converter. PLC serves as the kernel controller. It accomplishes the data acquisition of the field sensor and the output of the control signal. PLC connects the frequency converter with the CANOpen bus, whose aim is to realize the variable frequency control of motor speed of the system. The communication between industrial PC and PLC is transmitted by a wireless transmission module.

1 OVERALL STRUCTURE AND WORKING PRINCIPLE OF THE SYSTEM

The system of crane intelligent control is mainly composed of industrial PC, PLC, frequency converter, wireless transmission module and different kinds of sensors. The overall structure is shown in Figure 1.

The intelligent control system is PLC and frequency converter-based design (Sun, 2014). PLC serves as the kernel controller of the crane intel-

ligent control system, which accomplishes the data acquisition of the field sensor. After the logical operation, PLC will efferent the control signal to the frequency converter and then it will achieve the goal of managing the work of the crane. The communication between industrial PC and PLC is transmitted by the wireless transmission module. IPC can read the storage data of the PLC register and IPC can real-time display it at the software interface. At the same time, IPC can send the controlling signal to the PLC, and then PLC controls the frequency converter and the frequency converter controls the movement of the crane.

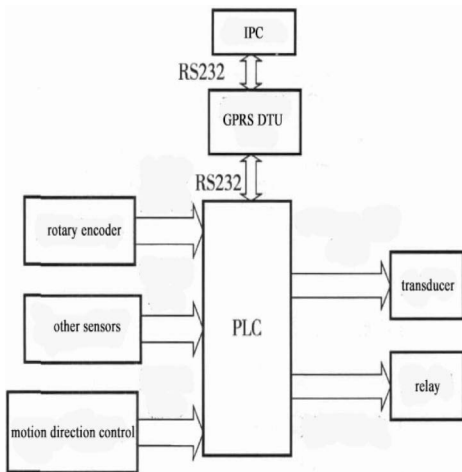

Figure 1. Overall structure block.

2 HARDWARE OF THE SYSTEM

The hardware of the intelligent control system is mainly composed of industrial PC, PLC, frequency converter, GPRS wireless module and some kinds of sensors. The structure diagram is shown in Figure 2.

2.1 Composition of PLC hardware

The signal, which the load module of PLC mainly receives, comes from 3 parts: the flashlight door signal (manual operation), data signals of the field sensor and the state of the system running. The signals of the flashlight door mainly include the signals of the system starting, stopping, the switching of the remote control/computer control and the quick signal. The quick signal controls the direc-

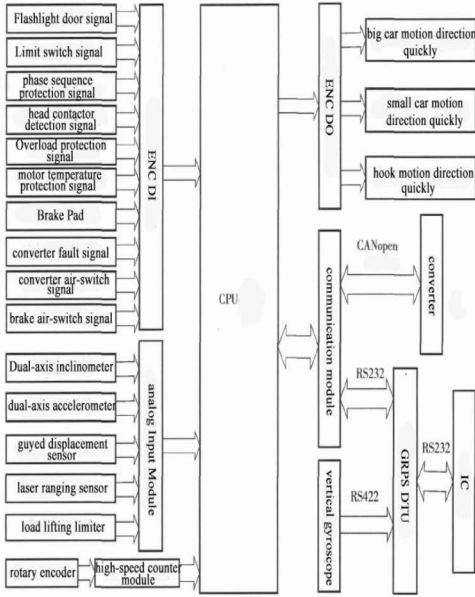

Figure 2. System hardware structure drawing.

tion of the big/small cars running institutions and lifting mechanism. It needs 12 input ports of digital quantity. Field sensors include three rotary encoders, which need to connect the high speed counting module (Jiang, 2011). The output of the other sensors is all analog. The state signals of the system include limit signals, deceleration limit signals, converter fault signals and guard signals. The limit signals come from the big car, small car and hook. The deceleration limit signals come from the hook. The converter fault signals come from the mechanism of the big car running and lifting. The guard signals mainly come from the phase order protection, the head contact detection, brake pad detection, overload protection, and motor temperature protection. All the above totally need 24 input terminals of digital quantity.

The output terminals of PLC mainly export the starting signal of the system and quick signal, which controls the direction of the big/small cars running institutions and lifting mechanism. It needs 20 output terminals of digital quantity.

2.2 Communication between PLC and frequency converter

The PLC, which the system adopts, comes from the series of Schneider M258 and the converters come from the series of ATV31 and ATV71. The PLC and converters are equipped with the CANopen communication protocols. So, they can be connected

with the networking through the CANopen bus to communicate, so as to realize E-control of the PLC to the converter. Through the CANopen bus, PLC can set the output frequency of the frequency converter and read the real-time output frequency value of the frequency converter (Xu, 2008).

The network is composed of PLC and frequency converter. In the network, PLC is set to the master station and the frequency converter is set to the slave station. The converter receives the controlling signal that is sent by PLC. In the software of So Machine, the ID of the master station node of PLC is set to 127 and the ID of the slave station node of the lifting mechanism converter is set to 1 (Song, 2008). The ID of the slave station node of the traveling mechanism converter of the big car is set to 2 and the ID of the slave station node of the traveling mechanism converter of the small car is set to 3.

Among the settings of the CANopen network, there will be a crucial parameter setting, the baud rate setting, to distinguish the different slave nodes, in addition to setting the address of slave nodes. Before the data exchange, the exchanging data comes from the master station and slave station in CANopen (Xu, 2009). The information of the baud rate needs checking. If the baud rate is different, they will not be able to do connection of communication, and hence the baud rate of the master station must be strictly consistent with that of the slave station. In the software of So Machine, the baud rate of PLC of the master station could be set and we set the baud rate to 125 kbit/s. Through the operation of the frequency converter, we could set the baud rate of the converter. Taking the lifting mechanism converter for example, in the communication menu, we could set the address of slave station 1, baud rate 125 kbit/s. The setting means that we set COM-/CnO-/AdCO = 1 (the address of the slave station) in the COM—of communication settings of the converter. The COM-/CnO-/bdCO is set to 125bit. The settings of two parameters must be strictly consistent with the settings of the lifting mechanism converter in the software of So Machine. The aim is to make sure that the communication between the PLC and the converter could go well.

2.3 Wireless transmission modules

There are two main functions of the wireless transmission module in the system: one of them is to realize the wireless communication of PLC and industrial control and the other is that industrial PC receives the data signal of vertical gyro.

2.3.1 Hardware connection

The ST-05 wireless transmission module, which the system chooses, can adopt the RS232 or RS485 bus

to connect and communicate with others. When the RS232 bus is connecting, the wireless transmission distance is up to 100 m. It can guarantee the normal work of the wireless transmission module.

The system needs two channels to do wireless transmission. One is for the wireless communication between PLC and industrial control, and the other is for the wireless data transmission from vertical gyro to industrial PC. Each channel needs two wireless modules, so we need two couples for four modules. One of them connects with the PLC, the other connects with the vertical gyro, and the remaining two connect with the industrial PC. The PLC, which the system chooses, contains communication port RJ45 that can be used to connect with RS232 or RS485 serial links. PLC can connect with the wireless transmission module through the RJ45 port then turning to the RS232 bus. The communication follows the Modbus—ASCII or the RTU protocol. The output signal of vertical gyro is a digital signal, and through the RS422 bus, the signal outputs. Then, the signal should be shifted from RS422 to RS232 to connect with the wireless transmission module. The wireless transmission module connects with the industrial PC by RS232. After the connection between each device and the wireless transmission module, we need to do some relative configuration of the module of each channel. The goal is that the communication from PLC to vertical gyro and industrial works normally (Zheng, 2004).

2.3.2 Software configuration

The system chooses the ST—05 wireless communication module and it installs a matching set of X-CTU software to configure the wireless transmission module. The main interface is shown in Figure 3.

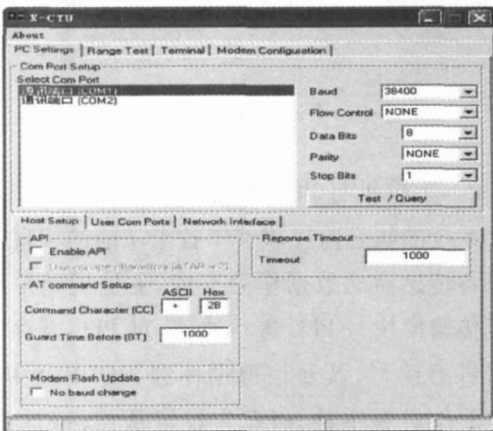

Figure 3. Wireless module configuration main interface.

In Figure 3, the Communication port 1 (COM1) is the communication port of PLC and industrial PC. The Communication port 2 (COM2) is the communication port of industrial PC. Industrial PC receives the data that comes from the vertical gyro (Wu, 2007). When it is configuring, firstly, we should select the communication port 1. Secondly, in the option of “PC Setting”, we should choose the communication channel which needs configuring. Then, we should set the “Baud” (Baud rate) 9600, and the rest of the options are the default settings. Clicking “Test/Query”, we test the module, because we do not know that the communication between module and software is normal. After the successful test, we should set the corresponding parameters to go on communicating.

3 SOFTWARE OF THE SYSTEM

The design of system software mainly includes 2 parts: the design of upper computer program and the design of PLC program. The program design of the upper computer mainly includes the system running state monitoring program and the communication with PLC program. PLC program is mainly the redact of the motion control program (Huang, 2009).

3.1 Communication between upper computer and PLC

The upper computer communicates with PLC through the wireless transmission module. It reads and writes the data of the PLC register, whose communication follows the standard MODBUS protocol. Among them, the upper computer is the master station, the PLC is the slave station, and the address is 01 (set in the PLC).

When the system is communicating, the upper computer, as the master station, sends instructions to PLC agreeing the standard MODBUS protocol (Xiong, 2008). PLC, as a slave station, responds the instructions of the upper computer.

3.2 PLC program

The PLC control program adopts modular programming, mainly including three parts: the sensor signal acquisition module, flashlight door control module and computer control module. By doing that, we can not only reduce the program statements, but also shorten the processing time and increase the responsiveness of the system so as to realize the rapid debugging of the program. The program flow chart of the PLC control system is shown in Figure 4.

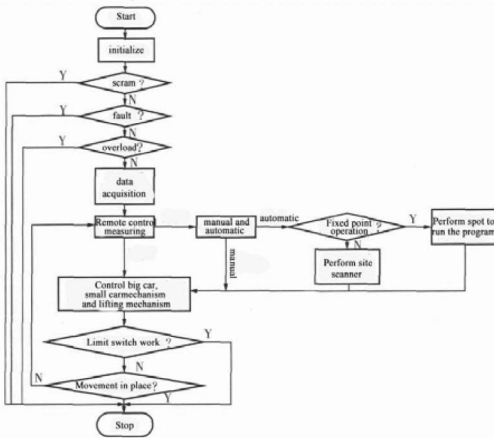

Figure 4. Flow chart of the PLC control system.

4 CONCLUSION

PLC is the core of the crane intelligent control system. The system communicates with industrial PC through the wireless module, which can realize the wireless remote monitoring to system status. PLC and frequency converter are managed by CANopen bus control, which not only saves the complex connection ports, but also improves the reliability of data transmission. For software design, we use the idea of modular to compile the program. Program 1 is acquisition data of PLC.

Program 2 is motion control of the system. After scene debugging and testing, the system runs in good condition. We achieved the design goal and have provided the basis for future related design.

Valve clearance fault diagnosis of an internal combustion engine based on wavelet packets and k-nearest neighbors

Rui Tan, Yu Zhang, Taixiong Zheng, Bin Yang & Yanjun Wang

School of Advanced Manufacturing Engineering, Chongqing University of Posts and Telecommunications, Chongqing, China

ABSTRACT: Considering the valve clearance fault that cannot be detected by a vehicle's on-board diagnostic system, the time-domain characteristics based on nearest-neighbor classifiers are proposed by using engine vibration acceleration signals. Especially, the diagnosis method consists of feature extraction using discrete wavelet packet decomposition and fault classification using the k-Nearest Neighbors (kNN) algorithm. Based on the feature extraction, the classifier is evaluated in terms of running time and identification rate compared with the Back Propagation Neural Network (BPNN), Support Vector Machine (SVM) and Least Square Support Vector Machine (LSSVM). The experimental results indicate that the proposed method has higher accuracy and the running time is shorter than that of the other methods.

1 INTRODUCTION

Internal Combustion Engine (ICE) is the power source of many machines in our daily life. It generates the necessary drive power to overcome the resistance loads by burning fuel and converting the energy content of the inlet mixture to mechanical motions. The valve-train is mainly a part of ICE, and it usually operates in high temperature, high pressure and gas shock environment, which can result in intermittent faults including valve head corrosion, broken spring and abnormal valve clearance. The abnormal valve clearance is difficult to be detected and it will bring serious damage to the engine, thereby increasing emission and fuel consumption. In this condition, the OBD systems as well as other monitoring and control systems may not detect the fault due to their adaptation to the technical condition change which has occurred (Mohammadpour, 2011; Dziurdz, 2010; Dąbrowski, 2011). Thus, it's very important to diagnose the fault of valve clearance when it occurs.

Several useful feature extraction techniques have been presented in abnormal valve clearance, such as Empirical Mode Decomposition (EMD) (Li, 2011; Wang, 2007; Si, 2012), short time Fourier transform (STFT) (Lei, 2011), Wigner-Ville Distribution (WVD) (Cai, 2012; Tang, 2010), and Wavelet Transform (WT) (Tang, 2010; Geng, 2010; Figlus, 2014; Pons-Llinares, 2011; Yang, 2014; Kankar, 2011). Although, WVD and STFT methods have a better performance in time-frequency analysis, the time window is fixed. WT is used to decompose the vibration signal, but the high-frequency resolution

of signals is not very accurate. For most random complicated signals, the high-frequency features are very important to analyze the signal. To this point, WT will lead to be inadequate feature extraction of signals. Wavelet packets can efficiently overcome this disadvantage and improve the high-frequency analytical ability of complicated signals. Furthermore, wavelet packets have a good solution simultaneously in both frequency and time domains, and they can also extract more information in the time domain at different frequency bands (Wu, 2012).

At present, in order to improve the diagnostic accuracy, many machinery diagnosis systems with intelligent classification have been developed, such as Support Vector Machine (SVM) (Yang, 2014; Kankar, 2011; Wu, 2012; Wu, 2012) and the Artificial Neural Network techniques (ANN). They, especially SVM, are powerful classification tools for small sampling and nonlinear data. However, SVM is sensitive to missing data and has no certain solution for nonlinear problems. ANN needs a large number of parameters and its learning process cannot be observed, which will affect the credibility and acceptable degree of the results.

In this paper, according to the engine vibration signal, a fault diagnosis method of valve clearance based on the discrete wavelet packet decomposition frequency band energy for feature extraction and classification using the kNN algorithm is proposed. Then, the simulation is conducted, compared with SVM (Yang, 2014), LSSVM (Wu, 2012) and BPNN, showing that the running time and classification accuracy of kNN are better.

2 PRINCIPLES OF FAULT DIAGNOSIS

In 1986, Stephane G. Mallat found the wavelet function in the field of harmonic analysis. Since then, some of the physical and mathematical earthquake researchers have begun to pay close attention to this issue. Recently, the wavelet theory, which mainly includes Wavelet Transform (WT) and Wavelet Packet Decomposition (WPD), has been applied in various fields, such as data compression, signal de-noising and feature extraction, etc.

The discrete wavelet packet decomposition is described as follows.

$$\begin{cases} d_{i,2j}(t) = \sqrt{2} \sum_k g(k) d_{i-1,j}(2t-k) \\ d_{i,2j-1}(t) = \sqrt{2} \sum_k h(k) d_{i-1,j}(2t-k) \\ d_{0,0}(t) = f(t) \end{cases} \quad (1)$$

where, $f(t)$ is the original signal, $h(k)$ is the high-pass filter, $g(k)$ is the low-pass filter, and $d_{i,j}(t)$ is the reconstruction signal of wavelet packet decomposition at the i th level for the j th node.

Based on the feature of the vibration signal, three times decomposition of the original signal is conducted. To this point, the energy $E_{i,j}$ of every frequency band is worked out, which can be defined as follows.

$$E_{i,j} = \int |d_{i,j}(t)|^2 dt = \sum_{k=1}^M |d_{i,j}(k)|^2 \quad (2)$$

where M is the number of discrete points of the reconstruct signal $d_{i,j}$.

It has great influence on the energy signal of each frequency band in the diagnosis system. Therefore, each frequency band energy based vector F is constructed in the third layer.

$$F = [E_{30}, E_{31}, E_{32}, E_{33}, E_{34}, E_{35}, E_{36}, E_{37}] \quad (3)$$

During the process of data analysis, the value of E_{3i} is so high that it is hard to compute. Thus, normalization processing of E_{3i} is necessary. And the feature vector F^* of the original signal is established.

$$F^* = F_i / \sum_{j=0}^7 E_{3j} \quad (4)$$

This paper measures four fault samples through the experiment and finds that the feature of each fault has a prominent performance in frequency band 5. Therefore, we define a feature vector F_{15}^* of sample X_i . Based on the previous theory, the

valve clearance faults can be classified using the kNN algorithm.

The kNN algorithm is one of the simplest and most commonly used machine learning methods. It is an important approach for nonparametric classification. The rules of kNN classification need to assign a category label for unknown samples by estimating their k-nearest neighbors based on known samples. A is the eigenvalues of known samples with respect to label B .

$$\begin{cases} A = (F_{1,5}^*, F_{2,5}^*, \dots, F_{m,5}^*) \\ B = (1, 1, \dots, 1, 2, 2, \dots, 2, 3, 3, \dots, 3, 4, 4, \dots, 4) \end{cases} \quad (5)$$

First, define a test F_0^* , and kNN can find the k training examples that are most similar to its k -nearest neighbors from $d_i(F_0^*, A_i)$ by measuring the similarity of the standard Euclidean distance between each training example A_i and the query point F_0^* :

$$d_i(F_0^*, A_i) = \|F_0^* - A_i\| \quad (6)$$

The label that appears the maximum times in k training examples is regarded as the prediction category label of the test point. For a discrete-valued target function, kNN returns the most common target function value among the neighbors of the test point. The kNN method gathers the k -nearest neighbors and lets them vote the class of most neighbors wins. k is the parameter of the kNN algorithm and its value should be selected between 1 and the total number of examples. The higher values of k provide smoothing that reduces vulnerability to noise in the training data. Note that if k is chosen as the total number of samples in the training set, then for any new instance, all the examples in the training set become the nearest neighbors. In this case the predicted response for each new or test case becomes just the frequent response variable in the training set.

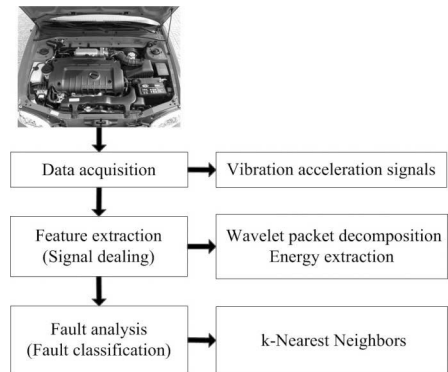

Figure 1. Block diagram of engine valve clearance fault diagnosis.

3 EXPERIMENTAL STUDIES

In the experiment, in order to achieve the proposed discrete wavelet packet decomposition using the kNN in the valve clearance fault diagnosis, an engine platform is used to measure the engine vibration signal of each valve clearance fault. Therefore, the engine vibration signal is regarded as the original data for the fault diagnosis process. And the process is divided into three parts: data acquisition, feature extraction, and fault analysis, which is shown in Figure 1.

The tests are conducted using two four-cylinder spark ignition engines of passenger cars. The vibration signal is extracted by an accelerometer, and the signal is recorded using a serial debugging assistant and the sampling frequency is chosen to be 20 kHz.

Additionally, the work condition of the engine valve-train can be divided into four parts: (i) ideal operation condition, (ii) exhaust valve clearance is 0.3 mm, (iii) exhaust valve clearance is 0.5 mm, and (iv) exhaust valve clearance is 0.7 mm. The ICE is operated under normal conditions and the speed is 3000 rpm. The accelerometer is mounted on the first cylinder head to collect the vibration signals generated during the operation of the engine.

4 RESULTS AND ANALYSIS

According to previous study, the exhaust valve clearance fault introduced to the engine is increased to 0.3 mm (positive), 0.5 mm (positive) and 0.7 mm (positive), respectively, which represents minor fault, moderate fault and serious fault. The vibration acceleration signal is collected from each fault condition, and the data of the time domain and frequency domain have been treated.

As the valve clearance is increased, the speed of the valve seat is increased. And the impact knock on the cylinder is also enhanced, which increases the signal energy in the fault frequency band. Therefore, this study decomposes sample signals three times and calculates the energy of each reconstructed signal in the third layer. Simultaneously, the frequency band energy normalized is regarded as the significant feature of the valve clearance fault. A sample of each band can be shown in Table 1 and the diagram is shown in Figure 2.

Figure 2 presents the changes of energy in each band which has been decomposed from different valve clearance vibration acceleration signals in an ICE. The data in Figure 2 show that the response value of frequency in band 5 increases from 0.1161 to 0.1577 with the exhausts valve clearance increasing from 0.2 mm to 0.7 mm. And the response value of frequency in band 6 is the same, but it is not obvious. As the condition of valve clearance changes, the normalized values of frequency energy in band 5 and band 6 have a regular variation from 5 Hz to 7.5 Hz. Therefore, the conclusion can be drawn that the feature frequency of the vibration acceleration signal ranges from 5 Hz ~ 7.5 Hz.

Furthermore, the energy ratio of frequency in band 5 is regarded as the fault feature that prepares for the latter fault classification. The paper randomly divide the total 40 samples of each condition into two parts, one of 30 for training to get a classifier and the other of 10 for testing the classifier to obtain the diagnostic yield. If the classifier has an ideal result, it can be used to predict the new or unknown data. In the course of experiment, 30 measured values of each fault are applied to the input of the k NN classifier and we define the number (1, 2, 3, and 4, respectively) as fault label. The selection of k is based on experimental tests, where k is selected from a small integral value to increase gradually.

Figure 2. Block diagram of engine valve clearance fault diagnosis.

Table 1. The energy of each frequency band.

Band/Hz Gap/mm	0.00~1.25	1.25~2.50	2.50~3.75	3.75~5.00	5.00~6.25	6.25~7.50	7.50~8.75	8.75~10.00
0.20	0.1673	0.1373	0.1327	0.1208	0.1161	0.1158	0.1108	0.0991
0.30	0.1591	0.2012	0.1044	0.1331	0.1191	0.0897	0.0994	0.0941
0.50	0.1587	0.2483	0.0771	0.0982	0.1365	0.1043	0.0825	0.0944
0.70	0.1377	0.1815	0.1213	0.1026	0.1577	0.1192	0.0786	0.1014

By comparing the accuracy of classification and the running time taken to build a classifier, we try to observe the efficiency and effectiveness of classifiers created by different values of k in the experiment. The optimal value of the nearest neighbors is acquired by comparing the results. Therefore, the value of k is selected from 2 to 17 and the results are shown in Table 2.

From Table 2, it can be seen that the accuracy of classification is 95.0% when k chooses 4, 5, 8, 9, 10, 17, respectively. However, the longer the running time, the larger the value of k . It shows that the accuracy of classification is always over 90.0% and the time response is about 2.3 seconds. The accuracy of classification do not increase with the increase of k in kNN classifiers, such as $k = 13$. Therefore, the optimal value of k in the experiment is selected as $k = 9$ and the accuracy of the classifier can reach to 95.0%.

The running time and accuracy are also recorded in the same simulation platform compared with BPNN, SVM and LSSVM. The data in Table 3 show that the identification accuracy of those algorithms is relatively high based on wavelet packet decomposition. The identification rate of kNN is better than BPNN and SVM. Under same conditions, the identification rate of kNN is 95.0% and the running time is 2.3108 s shorter than LSSVM.

Table 2. The comparison of accuracy and running time for different k .

k	Time (s)	Accuracy
2	2.2581	90.0%
3	2.2596	92.5%
4	2.2624	95.0%
5	2.2773	95.0%
6	2.2819	92.5%
7	2.2822	92.5%
8	2.2974	95.0%
9	2.3108	95.0%
10	2.3161	95.0%
13	2.3303	92.5%
17	2.4062	95.0%

Table 3. Comparison of diagnosis data for four algorithms.

Algorithm	Time (s)	Accuracy
BPNN	1.6356	90.0%
SVM	2.4973	92.5%
LSSVM	2.7926	95.0%
kNN	2.3108	95.0%

5 CONCLUSIONS

This paper presents a fault diagnostic method of valve clearance of ICE based on discrete wavelet packet decomposition and kNN that is applied to feature extraction and classification, respectively. Compared with BPNN, SVM and LSSVM, kNN achieves high accuracy. Moreover, the running time is rather short. The results indicate that the proposed method can also be used to detect the engine misfire fault. Furthermore, it has the following features:

1. Discrete wavelet packet decomposition overcomes the shortcoming of inadequate feature extraction of high-frequency signals.
2. For multiple classification problems, the effect of kNN is better than that of SVM.
3. kNN classification is easy to understand and the running time is short. In addition, the classification accuracy is high, and thus it is useful for other applications such as text classification, image-processing and predictive analysis.

ABSTRACT: The RV reducer performance test system based on an open power flow structure is proposed to test the dynamic and static performance of a RV reducer. The test system can be used for the measurement of the RV reducer's transmission efficiency, transmission angle error and hysteresis error. The system consists of three parts: mechanical structure, measurement and control unit, and data processing software. The magnetic powder brake is used to apply different load torques. The IPC combined with the data acquisition card is used for parameter and load control. The Labview platform is used for related software development, which can accurately measure the RV reducer relevant parameters such as motion characteristics and transmission performance.

1 INTRODUCTION

RV (Rotate Vector) reducers have been widely used in the modern industry as the main joints of industrial robot precision components, with their high load, large transmission range and high precision (L, 2011). To ensure the accuracy of RV reducers and transmission performance, it is particularly important to perform the RV reducer comprehensive performance test.

2 THE MEASURING PRINCIPLE AND METHOD

A RV reducer is a two stage high-precision reducer using a cycloid reducer mechanism. The structure uses a way of closed planetary transmission combined with a planetary gear drive and cycloid wheel drive (Gola C, 2008).

The main parameters affecting the transmission performance of the RV reducer include rated input speed, input power, output torque, transmission ratio, transmission efficiency, transmission error, torsion stiffness, backlash clearance, etc. Among them, the main indicators of dynamic efficiency include transmission accuracy, and static indicators mainly include hysteresis error, torsional stiffness and so on (Z, 2014). It is better to improve the transmission performance of the reducer for the purpose of these parameters

to detect the study. In this test system, the static test mainly carries on the hysteresis error test, and the dynamic test mainly carries on the transmission efficiency and the angle transmission error measurement (L, 2016).

2.1 Mechanical efficiency test

Mechanical efficiency, namely the ratio of the output of the mechanical work (amount of useful work) and the ratio of input power (power work quantity). For the RV reducer, the mechanical efficiency is the ratio between the output power and the input power. The reducer input power and output power are as follows:

$$P = \frac{T \cdot n}{9550} \quad (1)$$

The mechanical efficiency of reduction is as follows:

$$\eta = \frac{P_2}{P_1} \quad (2)$$

Among them, P is the output of the reducer or the input power, and the unit is Kw; T is the reducer input shaft and output shaft torque, and the unit is N·m; n is the reducer input shaft and output shaft speed, and the unit is r/min.

In the actual test, both ends of the reducer installed the torque sensor. Considering the coupling influence, in calculating the input and output power is to take into account the coupling mechanical efficiency η_1 (Predrag, 2007). The power formula becomes:

$$\eta = \frac{P_2}{P_1} = \frac{T_2 * n_2}{T_1 * n_1 * \eta_1} \quad (3)$$

Among them, n_1 is the input speed of the reducer, and the unit is r/min. n_2 is the output speed, and the unit is r/min.

The test method is as follows: the torque speed sensor installs in both ends of the measured RV reducer, real-time gathers the input end and the output end rotational speed and the torque signal of the measured RV decelerator. The signal is transmitted through the data acquisition card which connects with the IPC (Industrial Personal Computer) to the test program, and it is converted to the actual data through the program calculation. Then, the mechanical efficiency test result is obtained.

2.2 Transmission angle error test

Angle transmission error θ_{er} , namely reducer drive error. For the gear unit, the difference value between the theoretical output angle and the actual output angle θ_{out} at any input rotation angle θ_{in} of the gear unit can be calculated by formula (4):

$$\theta_{er} = \frac{\theta_{in}}{i} - \theta_{out} \quad (4)$$

The test method is as follows: during the test, the control motor to maintain low-speed rotation, the measured RV reducer input and output are installed around the grating encoder to capture the angular signal. The signal is transmitted through the data acquisition card which connects with IPC transfer to the test program, and converted to the specific test data for the program calculation. When the output shaft is rotated by 5° , a set of data is collected, and the output shaft is rotated by 360° for one cycle. 73 theoretical input angles $\theta_{in0}/i \sim \theta_{in72}/i$ and 73 actual output angles $\theta_{out0} \sim \theta_{out72}$, according to the formula (4) to calculate all of the actual test angle transmission error value $\theta_{er0} \sim \theta_{er72}$, and calculated according to the formula (5) of the gearbox angle transmission error θ_{er} .

$$\theta_{er} = \{ \theta_{ern} \}_{\max} - \{ \theta_{ern} \}_{\min} \quad (5)$$

2.3 Hysteresis error test

Hysteresis error in the gear transmission is abbreviated as hysteresis, which is defined as when the reducer input shaft steering angle changes, the amount of hysteresis on the output shaft also changes.

The hysteresis error measured in the hysteresis test of the reducer generally refers to the output shaft rotational angle caused by geometrical factors such as flank clearance in the drive chain, bearing clearance, etc., where the components are in good contact. Normally $\pm 3\%$ of rated torque is applied during the process to overcome internal friction and oil film resistance. Formula (6) is used for the calculation of hysteresis error:

$$j_T = [(\theta_{in})_{\max} - (\theta_{in})_{\min}] / i - [(\theta_{out})_{\max} - (\theta_{out})_{\min}] \quad (6)$$

The hysteresis error is mainly due to two reasons. First, it is the output shaft gear backlash hysteresis error caused by gear backlash. The second is the elastic deformation of hysteresis error caused by the geared rotor system and gear elastic deformation under the action of the external torque.

The test method is as follows: when measuring the hysteresis error, the output shaft of the measured RV reducer is locked by the magnetic powder brake. The motor applies the positive torque to the input shaft, gradually loads from 0 to the rated gear torque M , and then unloading to 0. The input rotary angle grating corresponding to each torque value is acquired at the same time during the loading and unloading processes. The data are transferred to the acquisition card and uploaded to the IPC. And then, the software analyzes the data and draws the hysteresis curve of the RV reducer.

3 DESIGN OF THE TEST BED STRUCTURE

3.1 The general system structure

The reducer static and dynamic performance test system test bed can be divided into two types such as open power flow and closed power flow, according to whether the energy is recycled in the experimental process of transmission.

The open power flow test stand structure is shown in Figure 1. In the entire measurement and control system, the drive unit for the measurement and control system to provide the power source is the general choice of synchronous motor and other devices. The load unit can be effectively loaded on the device under test to provide the RV reducer of different stress state and enhance system reliability

(Y, 2015). The measurement and control system with sensors is used to measure the performance of the reducer parameters. In the open power flow measurement and control system, the output power of the motor and other drive device flows through the measured reducer and the transmission to reach the loading unit. The load unit uses a variety of loading methods to consume energy, and to achieve effective loading.

Compared to the open power flow structure, closed power flow can realize energy cycles. For larger energy consumption and a longer run-time test, its operating costs are lower and more efficient. But for the system, the structure of the closed power flow test-bed is more complicated, and the open power flow is more mature and reliable. In this test, the test object is the small and medium RV reducer, the power requirements are low, and the dynamic transmission efficiency, transmission error and the static under the hysteresis error test does not require long-running time. Considering comprehensive test bench energy consumption and the general structure, an open power flow test system is designed. The functional block diagram is shown in Figure 2.

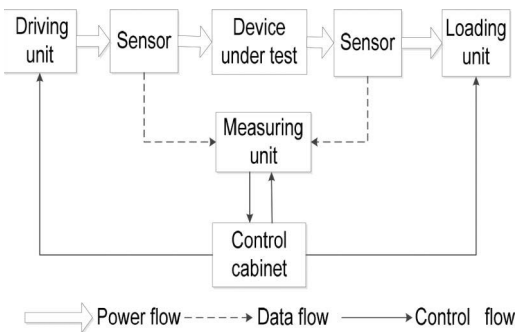

Figure 1. Schematic diagram of an open power flow test rig structure.

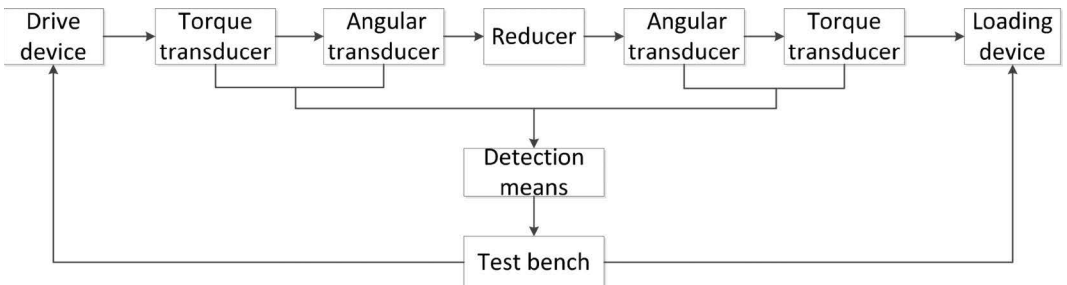

Figure 2. The principle diagram of the RV reducer test system.

3.2 Mechanical structure design of the test system

The test bench of the RV reducer static and dynamic performance test system mainly composed of the base, reducer bracket, measuring unit, mobile platform, etc. It mainly plays a role in the fixed supporting function of the components and the measuring elements in the system, and also has a key role in ensuring the measurement accuracy of the measurement and control system. The measuring unit consists of circle grating, torque speed sensor, magnetic powder brake and other components, which is used to complete the measurement and control in the test system.

The test bench adopts a horizontal structure, which is easy to ensure the coaxial degree. The mechanical institutions are as compact as possible, and they use coupling connection or key connection between devices. Input components can be moved in the horizontal direction, for different types of gear reducer, and it can be installed and tested normally. A three dimensional schematic diagram is shown in Figure 3.

Figure 3. The diagram of the RV reducer test bed structure. 1-magnetic powder brake 2-output shaft torque and speed sensor 3-output shaft circular grating 4-measured RV reducer 5-input shaft round grating 6-input shaft torque and speed sensor 7-drive motor.

4 MEASUREMENT AND CONTROL SYSTEM

4.1 Operating principle

The static and dynamic performance measurement and control system of the RV reducer is shown in Figure 4. When the RV reducer is tested for dynamic or static performance, the measured RV reducer is installed on the test platform. The input shaft and output shaft of the reducer are connected with the measuring spindle, the output shaft and torque sensor respectively. The two ends of the input and output of the reducer are equipped with high-precision circular gratings to measure the angle signals at both ends of the gearbox. The torque and speed sensors connected at both ends of the gearbox are used to output the speed and torque signals at both ends of the reducer.

The system uses motor to drive and magnetic brake to load. The IPC is equipped with a dedicated acquisition card for collecting the round grating signals of input and output as well as the torque and speed sensor signals of input and output.

When measuring, the operator sent control commands to the controller through the IPC. The driver receives the command and then drives the motor rotation to provide the power for the system. At the same time, the IPC connected with the program-controlled power, for the control loading of the magnetic particle brake. The measured RV reducer parameters are received by the sensor in the test, then collected by the acquisition card and uploaded to the IPC. The data are processed by the software for the output display to complete the measurement.

4.2 Drive control unit

A permanent magnet synchronous AC servo motor is selected, which is provided with a drive control unit, and it can realize the control and drive of the motor so as to provide energy sources for the system.

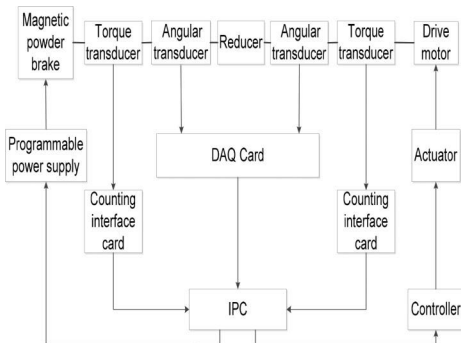

Figure 4. The diagram of the test system structure.

4.3 Signal acquisition unit

The signal acquisition system mainly includes torque sensors and circular gratings, which combines the acquisition card and other equipment to achieve the acquisition and collection of the signal. Then, the signal is uploaded to the IPC to achieve data processing.

4.4 Load unit

The magnetic particle brake acts as a load device in the system. The excitation current of the magnetic particle brake and transmission torque is basically a linear relationship, and as long as the value of the exciting current changes, the torque value can be controlled. So, the system can control the braking torque size according to the characteristics of the magnetic particle brake.

5 DATA PROCESSING SOFTWARE

The signal processing is carried out based on the hardware measurement. The software platform of the measurement and control system is set up in view of Labview. The measurement process and data processing method of the static and dynamic performance parameters (transmission efficiency, transmission error and hysteresis error) are analyzed, so as to realize the automatic detection of the RV reducer measurement and control system.

RV reducer dynamic and static performance test system software needs to achieve three parts of the target with motor control, data acquisition, data analysis and processing, so that the measurement and control system has become an organic whole.

1. Motor control: the return difference experiment in the static test needs to achieve the reverse load and unload for the reducer, and so it needs the measurement and control software to control the loading value of motor torque accurately. In the test of dynamic transmission error and transmission efficiency, it is necessary to make the reducer at different speeds, which requires measurement and control system software to accurately control the motor speed.
2. Data acquisition: the software needs to set up the data acquisition card. It can complete data acquisition with the input and output angle and torque of the RV reducer, and communicate normally with the controller and programmable power supply.
3. Data analysis and processing: the signal is collected for analysis and processing, according to the performance parameters of the system,

and the required output data and performance curves are obtained.

6 SUMMARY

On the basis of the dynamic and static performance parameters of the RV reducer, the principle and method of mechanical efficiency, angular drive error and return error of the RV reducer are deeply researched. With these methods, a RV reducer static and dynamic performance test system is designed. The system can quickly and accurately test the performance of different types of RV reducer. It is important to verify and improve the design theory and manufacturing method of the RV reducer, and its batch design and manufacture.

Analysis of automotive suspension compliance based on the main effects of rubber bushing

Bao Chen, Jiang-hua Fu & Zhe-ming Chen

College of Vehicle Engineering, Chongqing University of Technology, Chongqing, China

ABSTRACT: Taking the rubber bushing of a twist beam suspension as the research object, based on the bushing's static characteristic test results, the main effects of the six bushing's stiffness were determined by using the orthogonal experimental design method. The objective of this study is the case that the convergence of the suspension kinematics' evaluation index response is close to the target value range and the convergence of the suspension compliance' evaluation index response is smaller. The final values of the three axial bushing's stiffness were determined by using a full factorial experimental design method. The two sets of bushing stiffness data before and after optimization were substituted into the Motion-Solver for suspension compliance analysis. The results indicate that the optimization of the bushing parameters had almost zero effect on each evaluation index of compliance under the aligning torque, and the camber compliance loaded lateral and longitudinal force is also very small, but the compliance of the toe angle and wheel displacement was changed.

1 INTRODUCTION

Due to its simple structure, light weight and low cost, the twist beam suspension is widely used in the rear suspension of various economical cars. The main components connected with the sub-frame are the rubber bushings of a trailing arm. The lateral force, longitudinal force and aligning torque at the tire contact point are transmitted through the bushing to the vehicle body. It directly or indirectly influences the correct positioning of the suspension, vehicle ride comfort and NVH characteristics through its axial stiffness, torsional stiffness and its own viscoelastic properties (Liu, 2012). In addition, for the suspension with rubber bushings, its compliance and roll stiffness also impact on the vehicle handling stability (Chen, 2011). Therefore, it is important to study the Kinematics and Compliance (K&C) of a suspension with rubber bushings in order to improve the suspension and vehicle performances.

2 STATIC CHARACTERISTIC TEST OF A RUBBER BUSHING

The static characteristic test refers to the mechanical behaviour of a rubber bushing under static load. That is, the curve between the loading force and the displacement in the slower loading state, including three axial stiffness and three torsional stiffness (Wen, 1999).

Figure 1 a) shows the position of the rubber bushing of the trailing arm studied in the paper. Figure 1 b) shows a computer controlled universal electronic material test rig (RGM-4300).

The corresponding measurement principle is shown in Figure 2 a). The bushings installed in the fixture are fixed to the U-shaped fork by a screw to measure the radial stiffness (Y/Z direction). The corresponding measurement principle is shown in Figure 2 b).

The test loading method is unidirectional pressure. The force is increased linearly from zero to the set value. The setting range of loading force in the Z direction is 0–3000 N, and the setting range of loading force in X and Y direction is 0–5000 N

Figure 1. Twist beam suspension and a test rig.

and 0~9000 N, respectively. The Z-direction is designed with a radial shrinkage hole. The test procedure starts from zero time, and the running speed of the test rig is 1.0 mm/min. Its computer control system automatically records the load and the deformation of bushing at each moment. The exported data format is a .PSD file inputted to EXCEL. The three axial stiffness curves, as shown in Figure 3, are generated by using the insertion point pattern. Based on the three axial stiffness curves of bushing, the coefficients of its constitutive equation are optimized (Zhai, 2009), and finally the three torsional stiffness curves are shown in Figure 4.

3 MAIN EFFECT ANALYSIS OF THE BUSHING STIFFNESS

The six bushing's stiffness was used as the variable to optimize the evaluation index of suspension K&C, and the coordinate system of the optimization variables was consistent with the local coordinate system of the rubber bushing. In order to reduce the optimal parameters, shorten the development cycle, before the optimization of the bushing stiffness, the main effects of the bushing stiffness were analysed by using the experimental design of Hyper-study (Pei, 2014).

The range of bushing stiffness was set, that is, the upper and lower limits of design variables range of increase and decrease were 10% of the initial value, as the main effect of the bushing stiffness analysis of the upper and lower levels. Six design variables were just the six bushing's stiffness. It was designed as L8 (2⁷) orthogonal experimental table (Table 1), in which the number of experiments required is 8. The optimization targets are the out-of-ideal range of each index response in the suspension kinematic analysis, such as the toe angle, camber angle and longitudinal displacement. The constraint range was the interval value of each characteristic index in the suspension kinematic analysis, where “-1” indicates the lower level and “1” indicates the upper level.

Submitted to the orthogonal experimental table to calculate, listed 6 design variables impacted on the main effect of each index response shown in Figure 5. In this study, the toe angle is taken as an example. And after analysis, it is found that the three axial stiffness has a certain influence on the toe angle under the two-wheeled reverse excitation, in which the positive main effect of the radial stiffness K_x and axial stiffness K_z is larger, the positive main effect of the radial stiffness K_y is smaller, and it shows that when the stiffness increases in the upper and lower limits of the interval, the corresponding toe angle is also gradually increased.

The toe angle increases in the range of about 0.1321°~0.1366°, 0.1323°~0.1363°, and 0.1340°~0.1348° of K_x , K_y , and K_z , while the other three torsional stiffness has no effect of the toe angle. The six design variables on the evaluation index response of the suspension kinematics shows that the three axial bushing's stiffness has a great effect on the index response, and the three torsional stiffness effect on the index response is very small, and so the three axial bushing's stiffness was used as the object of further optimization research.

Figure 5. The diagram showing the main effects of the design variables.

4 THE IMPACT ANALYSIS OF BUSHING FOR SUSPENSION COMPLIANCE

Suspension kinematics is the relationship between the evaluation index and the wheel jump. Suspension elastic kinematics refers to the change of the evaluation index under the external forces such as lateral force, longitudinal force, aligning torque, etc. (Lin, 1992), which is also called suspension compliance (Sun, 2012).

4.1 Establishment of virtual test rig of a twist beam suspension with rubber bushings

Firstly, a subsystem model of the twist beam suspension was built. The main method was basing on the modal synthetic method and adopted motion/FLEX module to input the modal file for building a flexible body's twist beam. The rubber bush characterization data use the six bushing's stiffness at the zero level, as shown in Table 1.

Other components such as coil springs, shock absorbers, hubs, etc., were linked in Motion View/Solver modules according to the positioning and physical parameters of the actual suspension model. All hard points were created in a no-load state. The twist beam suspension simulation test rig is shown in Figure 6.

Figure 6. Test rig of a twist beam suspension simulation.

The main function of this simulation test rig is executing a simulation experiment of suspension K&C, wherein the outputs were set to toe angle, camber angle, and wheel displacement as evaluation index. In the simulation load process, the calculation was automatically carried out, and the relationship between output evaluation index and wheel jump and load was obtained by HyperView or HyperGraph.

4.2 Full factorial experimental design of the bushing

Among the six design variables, only the three axial stiffness of the rubber bushing had a significant effect on the indexes of suspension performances. So the three axial stiffness was chosen as the optimization variable. The upper and lower limits of the optimization variable were set in the range of 50% to 150% of the initial value.

The optimization objectives are determined as follows. The response convergence of the evaluation index of the suspension kinematics tends to be within the target value range, and the evaluation index's response of the suspension compliance is small.

Through the full factorial experimental design, the upper and lower limits of the three axial

bushing's stiffness were divided into five equal parts, the number of levels was set to 5, which was a 3-factor and 5-level full factorial experimental design. The number of calculations was 5 of the 3 power, a total of 125 times (Gao, 2014). The data of 125 sets of test combinations could be read from EXCEL, which analysed and selected the 46th group that accorded with the optimization objectives as the optimization result, which shows that the corresponding stiffness of the X direction is 937.5 N/mm, the stiffness of the Y direction is 4000 N/mm, and the stiffness of the Z direction is 250 N/mm.

4.3 Analysis on the main evaluation index's change rule of suspension compliance

Through various experiments and theoretical research, it is found that the rubber bushing has certain influence on the compliance of the twist beam suspension, but the contribution rate to the various sub-performance indexes are different.

After the optimization of bushing, the simulation was carried out again by using the simulation test rig shown in Figure 6. In the simulation of the lateral force loading, the vertical height of the wheel and the degrees of freedom of the axle were fixed, and only the results of one side of the tire were used; the load range was set to ± 4000 N. Then by using the Motion-Solver's calculation, the compliance results of the toe angle and lateral displacement are shown in Figures 7 and 8.

From the comparison of the dotted and solid line in Figure 7, it is found that the inclination of the right wheel's toe angle under the lateral force is smaller, which indicates that the optimization has greater influence on the toe angle under the lateral force, that is, when the vehicle turns left, it is possible to reduce the tendency of excessive steering. At the same time, as the lateral force changes, as shown in Figure 8, the comparison of the dotted and solid line shows that the slope of the lateral

Figure 7. Toe angle's compliance (lateral force).

displacement increases, which will lead to a larger wheel slip, increasing rolling resistance.

From the comparison of the dotted solid line in Figure 9, it is found that the inclination of the toe angle under the longitudinal force becomes large, which reduces the tendency of understeer. As can be seen from the comparison of the dotted and solid line in Figure 10, the longitudinal displacement under the longitudinal force increases,

Figure 8. Lateral displacement's compliance (lateral force).

Figure 9. Toe angle's compliance (longitudinal force).

Figure 10. Longitudinal displacement's compliance (longitudinal force).

Table 2. Compliance change of the suspension performance indexes.

Compliance with lateral force			Compliance with longitudinal force			Compliance with aligning torque		
Toe angle (°)/kN	Camber angle (°)/kN	Lateral displacement mm/kN	Toe angle (°)/kN	Camber angle (°)/kN	Lateral displacement mm / kN	Toe angle (°)/kN	Camber angle (°)/kN	Lateral displacement mm/kN
0.05875	0.03442	1.875	-0.0435	-0.03575	1.00	0.0002765	0.00000485	0.00101
0.03406	≈0.03442	2.958	-0.0480	≈-0.0358	1.37	—	—	—
-42.02%	≈0	57.73%	10.34%	≈0	37.00%	—	—	—

which is helpful to improve the vehicle ride comfort. In the longitudinal force loading test, the wheel vertical height and axle freedoms were also fixed, and only the test results of one-sided tires were studied. The load range was set between 0 and 4000 N. After the calculation in Motion-Solver, the compliance results of the toe angle and longitudinal displacement are shown in Figures 9 and 10.

In addition, the variation of each evaluation index's compliance under the lateral force and longitudinal force and the compliance index's change under the aligning torque was very small. So, the study ignores the corresponding change results. Table 2 shows the change value of the suspension performance index's compliance before and after optimization of the bushing stiffness.

From Table 2, it can be seen that by optimizing the bushing stiffness, the change of the toe angle and displacement compliance under the lateral force and longitudinal force is large. The absolute values of the change rate of the toe angle compliance are 42.02% and 10.34%, respectively, and the absolute values of the displacement compliance rate are 57.73% and 37.00%, respectively. But the camber compliance is significant under lateral force and longitudinal force basically unchanged. Under the aligning torque, it can be seen that the compliance indexes of the toe angle, camber angle and lateral displacement have been very small before optimization, that is, the aligning torque has little effect on the changes of compliance indexes.

5 CONCLUSIONS

Based on the test results of the static characteristics of rubber bushings, the coefficient of constitutive equation of rubber bushing can be optimized and the accurate bushing model can be constructed. Furthermore, the three torsional stiffness of bushing can be obtained by simulation, and the six bushing's stiffness are reconstructed.

Through the analysis of the main effect of the rubber bushing and the compliance analysis of the twist beam suspension, and compared with the main evaluation index, it can be found that the compliance of the toe angle, lateral and

longitudinal displacement is greatly affected by the change of the bushing stiffness under the lateral and longitudinal force, and the camber compliance is not affected by this. In particular, under the effect of the aligning torque, the change in each evaluation index's compliance is close to zero.

Experimental and simulation research on the friction and wear properties of surface textured friction pairs in CST

Shaoni Sun & Liyang Xie

School of Mechanical Engineering and Automation, Northeastern University, Liaoning, Shenyang, China

Risheng Long

College of Mechanical Engineering, Taiyuan University of Technology, Taiyuan, Shanxi, China

ABSTRACT: In order to realize the reliable soft starting and intelligent running of heavy duty scraper conveyors, the Controlled Start Transmission (CST) equipment is introduced to provide a feasible way to realize the soft starting, overload protection, and multi-driver power balance of scraper conveyors. The Hydro-viscous Drive Unit (HDU), which consists of multiple sets of friction pairs, is the core component of CST. The wear resistance and reliability of friction pairs are the decisive factors for the performance. The experimental models, with non-smooth surface as well as smooth surface having regular pit distribution, were established based on the typical sample size of the friction tester. The stress and wear resistant performance of the models with different non-smooth morphology parameters were studied through LS-DYNA analysis and wear tests. The results indicate that the wear resistant performance of biomimetic non-smooth samples is better than that of smooth ones; the pits can improve the contact stress distribution in the contact area of friction pairs, and the Von Mises stresses of biomimetic non-smooth samples are less than those of smooth samples; the wear resistant performance is the best when the pit distance equals 1 mm and the pit diameter equals 0.8 mm. This study would provide a basis for the future optimal design of the HDU of CST.

1 INTRODUCTION

As an effective method for soft starting, overload protection as well as multi-driver power balance, Controlled Start Transmission (CST) equipment has been increasingly applied to heavy duty scraper conveyors. The largest type of heavy duty scraper conveyor has reached to 3×1600 kW until now. The Hydro-viscous Drive unit (HDU) is the core component of CST. It consists of multiple sets of friction pairs, which are the decisive factors for the performance and reliability of the equipment.

The bionic non-smooth surface morphologies provide a feasible way to improve the wear resistant performance of the friction pair.

The surface characteristics, such as reducing adhesion and wear resistance, have a great relationship with their non-smooth surface morphologies. The typical non-smooth surface morphologies, including synapses, pits and scales etc., are mainly from natural creatures. Some typical bionic microscopic non-smooth surface morphologies are shown in Figure 1. These bionic surface misconstructions have been successfully applied to

Figure 1. Some SEM photos of the typical bionic non-smooth surface morphology.

Figure 2. Laser processed samples with regularly distributed pits.

the following fields: surface resistance enhancing of airplanes, stick reducing of the plough surface and wear performance improvement on the engine piston surface (Wang, 2001; Etsion, 2004; Etsion, 2004). At the same time, the wear-resisting performances of the biological surface morphology are becoming the research hotspot of tribology, and getting more and more attention (Wakuda M, 2003; Kligerman, 2001).

The recent studies show that the non-smooth technology can improve surface wear resistance significantly (Borgi, 2008; Song, 2006; Chen, 2008; Huang, 2008). L. Q. Ren et al. (2005) studied the wear resistances of different forms of bionic non-smooth surface morphology through micro-friction and wear tests. B. Y. Jia (2008) explored the freestyle abrasive wear performances of seven kinds of bionic non-smooth surface morphology by using a JMM wear-test machine. Yang (2005) studied the friction and wear behavior of W9Gr4V non-smooth samples with different pit-diameter and pit-distance concaves using a pin-on-disk wear tester.

In order to ensure the reliable starting and running performances of the heavy-duty scraper conveyor, it is necessary to further improve the wear resistance of friction pairs used in CST. The non-smooth surface morphologies are the future research direction of high performance friction pairs. Using laser cutting and drilling methods, nine kinds of samples are fabricated with different morphology parameters (see Figure 2). The wear

resistance tests of different samples are conducted on a universal pin-on-disk wear tester. Based on the Finite Element Analysis (FEA) theories and the LS-DYNA module of ANSYS (Jovicic, 2009; Rusinski, 2013), the stress behaviors of pin-on-disk models during the wear testing process were studied. The results would provide a basis for the future improvement and optimization of CST.

2 WEAR EXPERIMENTS OF SAMPLES WITH NON-SMOOTH AND SMOOTH SURFACES

According to the actual installation requirement of the pin-on-disk wear test machine, the samples were machined to a standard disk shape (see Figure 2). Through laser cutting and drilling methods, the upper surfaces of samples were processed with regularly distributed pits of different pit diameters and pit distances. A MMW-1 universal friction testing machine was used to test the friction and wear resistance of these samples, while an L-200 photoelectric analytical balance was used to measure their wear loss. The test conditions are listed here: load F , equals 0.98 MPa; testing time T , equals 5 min; rotating speed R , equals 480 r/min.

2.1 Wear loss analysis of non-smooth samples

The wear losses of non-smooth samples with different pit diameter and pit distance were analyzed.

Table 1. Wear loss and kinetic friction coefficient of non-smooth and smooth samples.

	Smooth	pad1	pad2	pad3	pad4	pad5	pad6	pad7	pad8	pad9
Pit distance/mm	0	1	1	1	1.25	1.25	1.25	1.5	1.5	1.5
Pit diameter/mm	0	0.4	0.6	0.8	0.4	0.6	0.8	0.4	0.6	0.8
Wear loss/mg	6.8	5.2	5.3	4.4	5.8	5.1	4.5	6.1	5.7	5.2
Kinetic friction coefficient	0.391	0.382	0.373	0.368	0.39	0.377	0.371	0.396	0.385	0.38

The results are listed in Table 1. From the wear loss data, it can be easily seen that the surface morphology parameters have great influence on the wear resistance of non-smooth samples. Theoretically, under the same test conditions, the wear resistance of the sample has a close relationship with its wear loss. If the mass loss of one sample is more than others, it means that its wear resistant performance is poorer than others.

Similarly, as shown in Table 1, it is evident that the wear loss of pad 3 is the minimum. So, under the experiment conditions, pad 3 possesses the best wear resistant performance. Its pit distance equals 1 mm and its pit diameter equals 0.8 mm. On the contrary, pad 7 possesses the worst wear resistant performance. Its pit distance equals 1.5 mm and its pit diameter equals 0.4 mm.

The influence of pit distance on wear loss is shown in Figure 3. When the pit diameter is fixed, it can be found that the wear loss of the sample increases gradually when the pit distance becomes larger. When the pit distance equals 1.5 mm, the wear losses of pad 7, pad 8 and pad 9 are all beyond 5 mg. Therefore, it can be concluded that the wear resistances of non-smooth samples take on opposite variation with the increase in pit distance.

The influence of pit diameter on wear loss is shown in Figure 4. From Table 1 and Figure 4, when the pit diameter equals 0.8 mm, it can be easily seen that the wear loss is significantly reduced. When the pit distance is constant, the larger the pit diameter is, the smaller the value of the wear loss is. Therefore, under the same experiment conditions, the wear resistant performance of the sample is enhanced when the pit diameter becomes larger. Instead, when the pit diameter gets smaller, the wear resistance of the sample will be accordingly reduced.

In addition, to compare the wear resistance of the non-smooth sample with that of the smooth sample, the wear test of smooth samples were performed under the same conditions. The average wear loss of smooth surface samples is 6.8 mg, as shown in Table 1.

It is assumed that the increment ratio of wear resistance is Q ,

$$Q = (K_2 - K_1) / K_2 \quad (1)$$

Figure 3. Wear loss versus pit distance.

Figure 4. Wear loss versus pit diameter.

Wherein, K_1 means the average wear loss of non-smooth samples; K_2 means the average wear loss of smooth samples. K_1 and K_2 are gained under the same test conditions mentioned before. It can be found that the average wear loss of smooth samples is evidently bigger than the average mass loss of non-smooth samples. That is, the wear resistance of the non-smooth sample with regular pit distribution is obviously higher than that of the smooth sample. Obtaining K_1 and K_2 from Table 1, the wear resistance increment ratio Q of pad3 equals 35.29%.

2.2 Kinetic friction coefficient analysis

The kinetic friction coefficient is an important parameter which cannot be ignored during the process of friction and wear test. The kinetic friction coefficients of the non-smooth sample with different surface morphology parameters and the average friction coefficient of smooth samples are both listed in Table 1.

As shown in Table 1, the average friction coefficient of the smooth samples equals 0.391. Almost all the kinetic friction coefficients of non-smooth samples are less than the average friction coefficient of the smooth samples. The decrease of the friction coefficient does not affect the HDU driving performance. Inversely, it is helpful to improve the wear resistance of the friction pair to some degree. The friction coefficient of pad 3 is the minimum, which equals 0.368. In general, the friction coefficients of samples with different surface morphology parameters have the same change tendencies with their wear losses.

3 FEA OF SAMPLES WITH BIONIC NON-SMOOTH MORPHOLOGY

The 3D pin-on-disk model was constructed in Pro/E, and the pit diameter and pit distance could be adjusted according to the actual morphology parameters of different samples. The model with a non-smooth surface is shown in Figure 5(a). The meshed Finite Element (FE) model is shown in Figure 5(b). The other parameters are the same with the test samples.

According to actual experimental conditions of the pin-on-disk friction and wear tester, the surface-surface contact type and automatic contact algorithm was used in the following simulations. During the FE analysis process, the upper surface of the disk sample was chosen as the target surface and the lower surface of the coupling pin was cho-

sen as the contact surface. The friction coefficient of the contact pair was set to 0.38 (Ren, 2005; Jia, 2008; Yang, 2005; Jovicic, 2009; Rusinski, 2013). All the constraints of the sample and pin are imposed according to actual work conditions. The upper non-smooth surface of the disk sample was applied with surface loads and a rotating speed.

The Von Mises stress curves of all non-smooth samples are shown in Figure 6. Wherein, Figure 6 (a)-(i) respectively corresponds to the Von Mises stress curves of nine kinds of non-smooth samples. In each sub-picture, the blue curve is the Von Mises stress of the current non-smooth sample, while the red curve is the Von Mises stress of the smooth sample. The average Von Mises stress of each non-smooth sample and the smooth sample are also embodied in every sub-picture.

As shown in Figure 6 (g), the Von Mises stress of pad 7 is slightly higher than the stress of the smooth sample, while the average Von Mises stress of the other non-smooth samples was less than the average of the smooth sample. Furthermore, the volatility of Von Mises stress of non-smooth samples is also significantly less than that of the smooth sample. From Figure 6(c), it is easy to find that the average Von Mises stress of pad 3 is significantly less than the average stress of the smooth sample. The volatility of Von Mises stress and its stress value was both significantly lower than other non-smooth samples too.

In addition, the Von Mises stresses of non-smooth samples have a certain relationship with the key parameters including pit diameter and pit distance. Overall, when the pit distance is fixed, the Von Mises stress of non-smooth samples will become small with the increase of pit diameter. For example, as shown in Figure 6 (a), (b), and (c), the pit distance equals 1 mm, the Von Mises stress of pads 1-3 decreased when the pit diameter varied from 0.4 mm to 0.8 mm. Similarly, Figure 6(d)-(f) and Figure 6 (g)-(i) show the same stress variation trends.

Figure 5. 3D model of a sample with non-smooth morphology (a) 3D model; (b) meshed FE model.

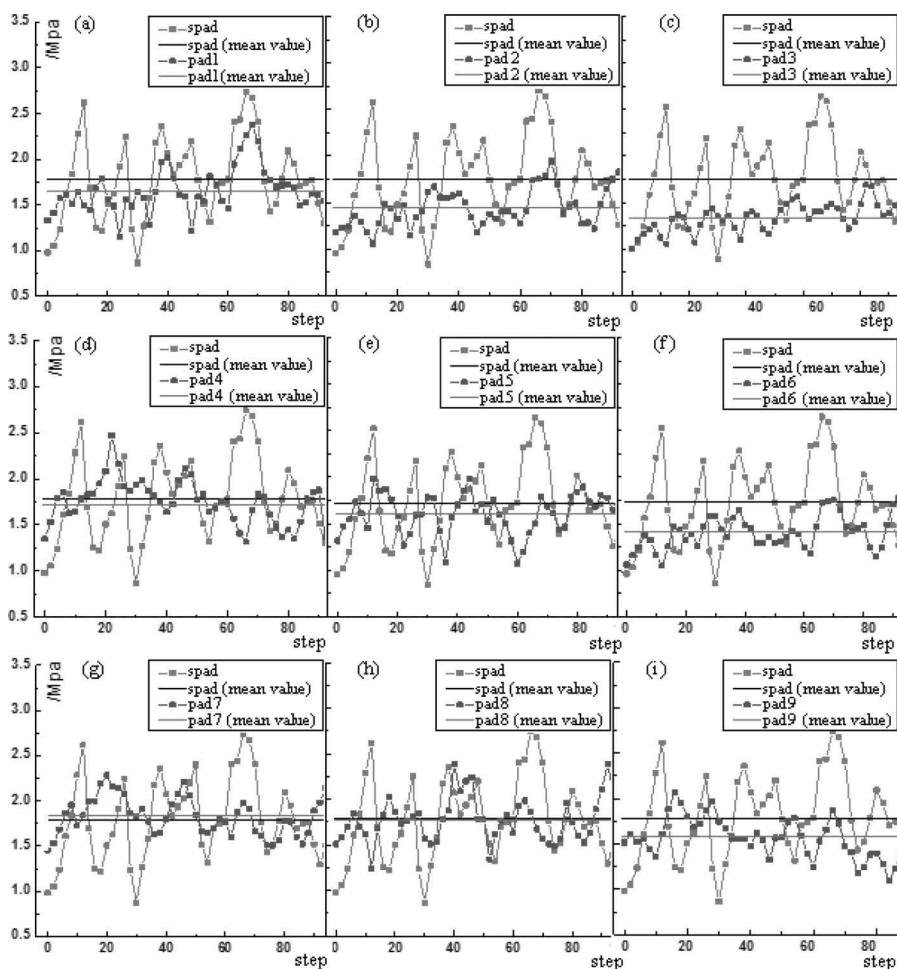

Figure 6. Von Mises stress contrast curve of all non-smooth disk samples (a) pad1; (b) pad2; (c) pad3; (d) pad4; (e) pad5; (f) pad6; (g) pad7; (h) pad8; (i) pad9.

4 CONCLUSIONS

The bionic non-smooth surface morphology is a feasible way to improve the wear resistant performance of friction pairs used in CST. Using laser cutting and drilling methods, nine kinds of samples are fabricated with different surface morphology parameters. The wear performance experiments of different samples are also conducted on a pin-on-disk wear tester. Based on the FEA theories and the LS-DYNA module of ANSYS, the stress behavior of the pin-on-disk model during wear test processing was also studied.

The experimental and FEA results are listed below:

1. The pit distance and pit diameter have a great influence on the wear loss of non-smooth samples.

The smaller the pit distance is, the smaller the value of wear loss is; the larger the pit diameter is, the smaller the value of wear loss is.

2. When the pit spacing equals 1 mm, and the diameter equals 0.8 mm, the non-smooth sample has the best wear resistant performance.
3. Through the comparison and analysis between the non-smooth and smooth samples, it can be concluded that the wear resistance of the non-smooth sample is obviously better than that of the smooth sample.
4. The Von Mises stresses of non-smooth samples are less than those of smooth samples. The non-smooth surfaces with regular pit distribution can reduce the stress concentration in the contact area, and the non-smooth samples have better wear resistant performance than smooth samples.

The above results will provide a basis for the future product improvement and optimization of the HDU of CST.

Simulation and analysis of MPPT used in photovoltaic grid-connected systems based on the improved disturb-and-observe method

Junfeng Wang & Hairu Zhao

School of Physics and Electronic Engineering of Yuxi Normal University, Yuxi, China

ABSTRACT: Based on the analysis of the output characteristics of photovoltaic cells and the theory of the disturb-and-observe method, a new improved disturb-and-observe method is proposed in this paper. This method first sets a time threshold, and then establishes the simulation model using MATLAB/Simulink. Simulation results indicate that the model has better dynamic performance and allows fast, accurate tracking of the maximum power point, which validates the proposed method to be feasible and reliable.

1 INTRODUCTION

In the solar photovoltaic power generation system, the output characteristics of photovoltaic power generation is nonlinear due to the effects of many conditions from outside world such as light intensity, temperature and load characteristic and their own factors (Lu, 2011). The main problem of photovoltaic power generation is that the output characteristics of photovoltaic cells are greatly affected by the external environment. The change of temperature and light intensity will lead to great changes to the output characteristics of photovoltaic power generation. Therefore, making full use of the energy produced by photovoltaic cells is the basic requirement of photovoltaic power generation systems (Zhao, 2004). In order to solve this problem, Maximum Power Point Tracking (MPPT) devices are required to be added between the photovoltaic power generation system and load, which makes photovoltaic cells' output maximum power so that the solar energy can be fully used (Min, 2006).

In order to obtain the maximum power output unceasingly under any conditions, maximum power point tracking control is needed for photovoltaic cells. MPPT is a self-optimizing process essentially. That is to say, photovoltaic cells can output maximum power in the environment of a variety of light intensities and temperatures by controlling terminal voltage or physical quantities (Jiang, 2013). The research of maximum power point tracking is a relatively mature technology. The common methods include the incremental conductance algorithm, three-point comparing algorithm, quadratic interpolation method, disturb-and-observe method and so on. An improved

disturb-and-observe method is proposed in this paper, which sets a time threshold.

2 EQUIVALENT CIRCUIT AND OUTPUT CHARACTERISTICS OF PHOTOVOLTAIC CELLS

2.1 Equivalent circuit of photovoltaic cells

The common ideal equivalent circuit of photovoltaic cells is shown in Fig. 1. VD represents an ideal diode, namely the semiconductor PN junction. One part of photo-electromotive force offsets the electric field within the PN junction and recharges the diode. The other part of photo-electromotive force connects to external circuit through the internal resistance in series and in parallel so that the terminal voltage of load R_L is U .

According to Kirchhoff's current theorem, the volt-ampere relation of photovoltaic cells can be expressed as Eq. 1.

Figure 1. Equivalent circuit of photovoltaic cells.

$$I = I_{ph} - I_s \left[e^{\frac{q(U+IR_s)}{AKT}} - 1 \right] - \frac{U + IR_s}{R_p} \quad (1)$$

In Eq. 1, I is the output current of photovoltaic cells and U is the output voltage. I_{ph} is the current of the photoproduction current source and I_s is the saturation current of the diode. q is the electronic charge and its unit is $1.6 \times 10^{-19} \text{C}$. K is Boltzmann's constant and its unit is $1.38 \times 10^{-23} \text{J/K}$. T is the absolute temperature and A is the ideal factor of the PN junction. R_p is the parallel resistance of photovoltaic cells and R_s is the series resistance.

2.2 Output characteristics of photovoltaic cells

According to Eq. 1, we know that the volt-ampere relation of photovoltaic cells is a transcendental exponential equation and it can't be expressed by linear equation. The output characteristics of photovoltaic cells are nonlinear functions and affected by the environmental temperature and light intensity. Based on short-circuit current I_{sc} , open-circuit voltage U_{oc} , the current of maximum power point I_m and the voltage of maximum power point U_m provided by solar battery manufacturers,

(a) U - I curves under different light intensities

(b) P - U curves under different light intensities

the output characteristic curves of photovoltaic cells under different light conditions are shown in Figure 2 (Chen, 2013).

As is shown in Figure 2, in the case of other conditions unchanged, the output power of photovoltaic cells will increase as light intensity enhances (Lu, 2011). There is a working point with maximum power output at any time under a certain light intensity, namely the maximum power point. The maximum power output of photovoltaic cells will change when the external environment changes. In order to obtain maximum power output of photovoltaic cells, the Maximum Power Point Tracking (MPPT) device is required to be added between photovoltaic cells and load (Liu, 2010).

3 IMPROVED DISTURB-AND-OBSERVE METHOD

3.1 Principle of the disturb-and-observe method

The disturb-and-observe method is also called the hill climbing method. Since its principle is easy and hardware implementation is economic, it has been the most common method. The principle of the disturb-and-observe method is shown in Figure 3. Its principle is described as follows. First, initiatively apply a small voltage disturbance to a certain photovoltaic operating voltage. Then, compare the output power after disturbance with the output power before disturbance. If the output power after disturbance increases, it states that the disturbance can enhance the output power and the disturbance in the same direction should be applied to the output voltage of photovoltaic cells next time. On the contrary, if the output power of the photovoltaic array decreases, the disturbance in the reverse direction should be applied (Liu, 2011). If $P/(dU) > 0$, then apply on the left side of the maximum power point. If $P/(dU) = 0$,

Figure 3. Curves of I - U , P - U and $|dP/dU|$ - U after calibrating the photovoltaic array.

Figure 2. Output characteristic curves of photovoltaic cells under different light conditions.

then apply at the maximum power point. If $P/(dU) < 0$, then apply on the right side of the maximum power point.

The voltage disturbs the output voltage of photovoltaic cells which can be expressed as Eq. 2.

$$U_{ref} = U_{ref} + \alpha \frac{dP}{dU} = U_{ref} + \alpha \frac{P(k) - P(k-1)}{U(k) - U(k-1)} \quad (2)$$

In Eq. 2, α is a positive number. It represents the variable step size speed factor and is used to adjust the tracking speed. When the operating point of the photovoltaic array is far away from the maximum power point, the tracking step size is big. Otherwise, the tracking step size is small. When the operating point of the photovoltaic array is close to the maximum power point, the tracking step size approaches zero (Huang, 2011). α can be determined by Eq. 3.

$$\alpha \leq \frac{U_{step-max}}{|dP/dU|_{max}} \quad (3)$$

In Eq. 3, $U_{step-max}$ is the maximum step size allowed by the disturb-and-observe method with fixed step size. $|dP/dU|_{max}$ can be calculated based on the photovoltaic array, and can also be estimated according to Eq. 4.

$$\left| \frac{dP}{dU} \right| \approx \left| \frac{P|_{U_{ref}=mU_{oc}} - P|_{U_{ref}=U_{oc}}}{mU_{oc} - U_{oc}} \right| = \left| \frac{mI|_{U_{ref}=mU_{oc}}}{m-1} \right| \quad (4)$$

In Eq. 4, m is a positive number approaching one and U_{oc} is the open-circuit voltage of the photovoltaic array. The range of variable step size speed factor α is first calculated by Eq. 3, and then the final value is determined by experiments (Wang, 2014).

3.2 Process of the improved disturb-and-observe method

The flow chart of improved MPPT is shown in Fig. 4. First, set a time threshold Δt , and the time threshold is about the time of the output power of the photovoltaic electrical source from zero to the maximum power point. Track the output power using normal disturbance within the time threshold so that the output power can be up to the maximum. Second, set a variation threshold of output power ϵ . When the output power reaches the maximum power point (namely $|P(k) - P(k-1)| \leq \epsilon$), stop the disturbance to make the output voltage remain the same. That is to say, the output voltage lies near the maximum power point.

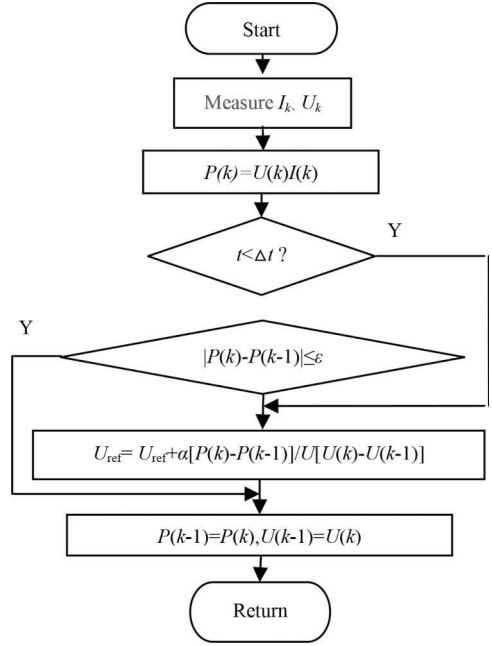

Figure 4. Flow chart of the improved disturb-and-observe method with variable step size.

If $U(k) - U(k-1) \neq 0$, automatically adjust the disturbance step size based on Eq. 4. Otherwise, end it and return.

4 MODEL AND SIMULATION OF THE PHOTOVOLTAIC GRID-CONNECTED SYSTEM

4.1 Simulation model

According to the above design, the simulation model of the overall system is set up in the simulation environment of Matlab/Simulink, and is shown in Figure 5. The model is composed of photovoltaic cells (PV modules), a controller module, a pulse-width modulation module and the Boost DC-DC circuit. In this model, the values of parameters are set as follows: load R is 30Ω ; inductance L is $6 \times 10^{-4}\text{H}$; CI is $1.3 \times 10^{-6}\text{F}$; $C2$ is $4.7 \times 10^{-6}\text{F}$. Two constant input modules are used as the parameter T of photovoltaic cells and the parameter S of light intensity.

4.2 Results and simulation analysis

According to the simulation results of Figure 6, it can be known that each parameter of the photovoltaic output is stable after 0.1 second since there is a disturbance. Analysis of the results under the

Figure 5. Simulation model of the overall system.

Table 1. Analysis of the results under the same light intensity and variable temperatures.

T(°C)	Output voltage (V)	Output current (A)	Output power (W)	Output voltage of boost circuit	Analysis of results
25	24~25.5	5.8~6.08	140~155	53~57	Change in temperature has a little influence on the output parameters
20	24~25.4	5.8~6.07	140~154	53~56.9	
30	24~25.6	5.8~6.09	140~156	53~57.1	

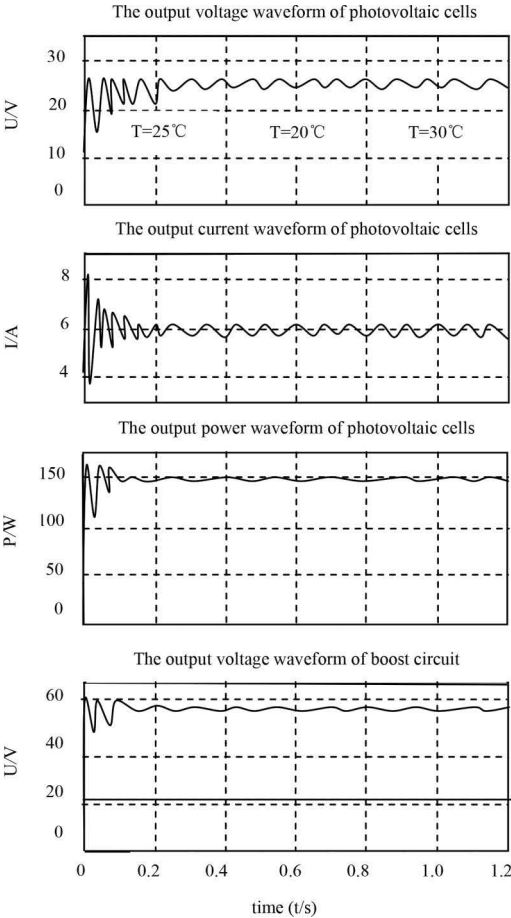

Figure 6. Simulation waveforms under the same light intensity and variable temperatures.

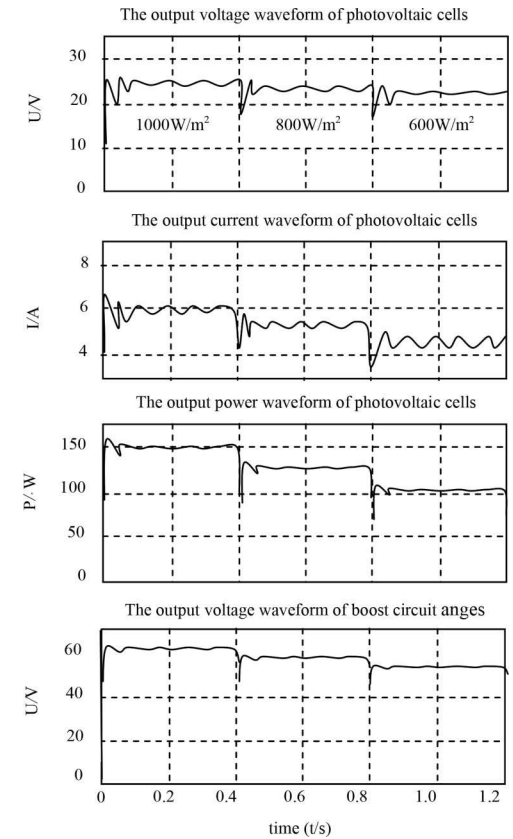

Figure 7. Simulation waveforms under the same temperature and variable light intensities.

same light intensity and variable temperatures is shown in Table 1.

It can be stated based on Table 1 that when the temperature changes, the output voltage, current, power of photovoltaic cells and the output voltage of boost circuit only have little fluctuation and always

keep the same value. That is to say, the change of temperature has little influence on the output parameters of photovoltaic cells. Photovoltaic cells can fast track the maximum power point when temperature changes, and the adjustment time is short.

It can be known based on the simulation results of Figure 7 that when the temperature changes,

Table 2. Analysis of the results under the same temperature and variable light intensities.

Light intensity (W/m ²)	Output voltage (V)	Output current (A)	Output power (W)	Output voltage of boost circuit	Analysis of results
1000	24~25.5	5.8~6.08	140~155	61~63	Each parameter of photovoltaic output will change when the light intensity changes
800	23.5~24	5.4~5.6	127~135	59~61	
600	23~23.5	5.0~5.2	115~122	57~59	

each parameter of the photovoltaic output can be stable after 0.05 second. Analysis of the results under the same temperature and variable light intensities is shown in Table 2.

It can be stated according to Table 2 that the output voltage, current, power of photovoltaic cells and the output voltage of boost circuit all reduce when the light intensity declines (Wu, 2014). Each parameter of the photovoltaic output will change when the light intensity changes. The photovoltaic cells can track the change of external environment quickly, and also can quickly realize the maximum power point tracking and the steady accuracy is high.

The above simulation results show that the temperature has little influence on the output characteristics of photovoltaic cells, while the light intensity has great influence on the output characteristics of photovoltaic cells. This is consistent with the characteristics analysis of photovoltaic cells. The improved disturb-and-observe method proposed in this paper can fast track the maximum power point of photovoltaic cells, and the tracking accuracy is high, which verifies that the proposed method is feasible.

5 CONCLUSION

An improved disturb-and-observe method was proposed in this paper, and the simulation model of the photovoltaic grid-connected system was built in Matlab/Simulink. Simulation results indicate that the model can fast track the maximum power point and has a higher tracking accuracy and a better dynamic performance than the incremental conductance algorithm, three-point comparing algorithm, quadratic interpolation method and traditional disturb-and-observe method, which proves that the proposed method is feasible and reliable.

Automatic control loop optimization method of thermal power plant based on internal model control

Song Gao, Xiangkun Pang & Jun Li

State Grid Shandong Electric Power Research Institute, Jinan, Shandong, China

Changwei Li & Huadong Li

Shandong Zhongshiyitong Co. Ltd., Jinan, Shandong, China

ABSTRACT: Automatic control loop is one of the important subsystems in the automatic control technology of thermal power plant. It is difficult to achieve satisfactory control effect when setting PID controller parameters in actual production process. This paper uses typical three impulse control of boiler water level as an example, introduces the closed-loop steady state time, gives the optimization strategy of PID controller parameters based on internal model control, and determines the design of feed-forward controller. Finally, the effectiveness and practicability of the control strategy are verified by the application on a typical 300MW unit.

1 INTRODUCTION

Automatic control loop is one of the important subsystems in the automatic control technology of thermal power plant. PID controller is used in more than 90% industrial process control loops, and therefore the PID controller parameter is one of the important factors that affect the quality of the control loop. PID regulator parameter optimization is generally determined by trial and error, and it is difficult to reach the satisfied result. This paper used the typical three impulse water control loop as an example, introduced an optimization method of PID controller parameters based on internal model control strategy and the concept of closed-loop steady state time.

The paper is organized as follows. In Section 2, the typical three impulse water control loop is introduced and some definitions are given. In Section 3, the control model based on internal model control is presented and Section 2 presents the automatic control strategy for three impulse water control loop. In Section 4, the application result is given to show the efficiency of the strategy. Finally, we conclude our paper in section 5.

2 THREE IMPULSE FEED-WATER CONTROL LOOP

Three impulse feed-water control loop is typical cascade control loop, and the control target is to maintain the constant value of drum water level

through adjusting the feed-water flow under different work conditions (Babykina, 2013; Rajkumar, 2013; Wu, 2012).

Three impulse water control loop is shown in Fig. 1, where, SP is the set-point value of drum water level; PV is the process value of drum water level; OP is the set-point value of feed-water flow; PVI is the process value of feed-water flow; OPI is the instruction of feed-water control valve.

The cascade control loop is divided into inner control loop and outer control loop. The inner water supply control loop is a single feedback control loop, and can be regarded as a fast follow-up system. The output value of the inner PID controller changes the water supply valve instruction, and then changes the feed water flow. The aim of the outer control loop is to maintain the drum water level as a constant value (always be considered as 0 mm), and the output value of the outer PID controller is the set-point value of the inner control loop (W, 2013; Huang, 2013; Chakraborty, 2014). Since the inner control loop is a fast follow-up system, the performance of the inner control loop

Figure 1. Three impulse feed-water control loop.

directly determines the performance of the outer control loop.

In the cascade loop, the closed-loop steady state time of the inner loop is about 1/4 of the steady state time of the outer loop. In this paper, the outer control loop are maintained unchanged, and the control structure and parameters of the inner loop are optimized only. The main purpose is to improve the performance of the inner control loop and reduce the steady-state time of the inner control loop.

3 AUTOMATIC CONTROL LOOP OPTIMIZATION METHOD

3.1 Internal model control

For the typical three impulse water supply control loop of thermal power plant, the first-order plus pure delay model is used to describe the characteristics of the transfer process of inner control loop. In fact, a large number of research results show that the first-order model is suitable for most industrial processes.

Internal Model Control (IMC) has advantages of high control accuracy, good robustness and anti-interference (Liu, 2013; Jahanshahi, 2014; Garrido, 2014; Jahanshahi, 2013). Therefore, it is widely used in the large-lag system in many industrial processes.

Consider a SISO feedback control loop depicted in Fig. 2. Here $P(s)$ and $C(s)$ are the process and the PID controller, respectively; $r(t)$, $u(t)$ and $y(t)$ are the set-point, the control signal, and the process output, respectively; $e(t)$ is the error between $r(t)$ and $y(t)$.

$P(s)$ is first-order plus delay time model,

$$P(s) = \frac{K}{T_1 s + 1} e^{-\theta s} \quad (1)$$

Here, K is the gain of transfer function, T_1 is first-order lag time constant, and θ is the pure delay time.

$C(s)$ is the PID controller,

$$C(s) = K_p \left(1 + \frac{1}{T_i s} + T_d s \right) \quad (2)$$

Figure 2. A SISO feedback control loop.

Here, K_p is the proportional gain of PID controller, T_i is the integration time of PID controller, and T_d is the derivative time of PID controller.

The PID controller setting for first-order plus pure delay time model as

$$K_p = \frac{T_1}{K(\tau_c = \theta)}, T_i = T_1, T_d = 0 \quad (3)$$

By taking the IMC tuning rule, the desired closed-loop response will be

$$G_{cl}(s) = \frac{1}{(\theta + \tau_c)s + e^{-\theta s}} e^{-\theta s} \approx \frac{1}{(\theta + \tau_c)s + 1 - \theta s} e^{-\theta s} \\ = \frac{1}{\tau_c s + 1} e^{-\theta s} \quad (4)$$

Here, the user-selected parameter τ_c stands for the desired close-loop time constant.

Based on the IMC tuning rule, the PID parameters can be determined by equation (3), with the desired closed-loop time constant τ_c is selected by users to adjust the performance of PID controller. The closed-loop time constant is shown in Fig. 3.

3.2 Object model and parameter optimization

In this section the method of optimization strategy is introduced based on a typical industrial case.

The corresponding relationship between the OP-PV (output value of PID controller to the process value of feed water flow) is established, which is the open-loop model of the control object. Data trends are shown in Figure 4, there, PV is process value of feed water flow, SP is set-point value of the feed water flow, and OP is the output value of

Figure 3. Closed-loop time constant τ_c .

Figure 4. Data trends of PV/SP/OP.

PID controller, which then gives the instructions of feed-water control valve.

The data of Fig. 4 can be identified based on the least-square method, and the process transfer function of the open-loop model is

$$\frac{3.143}{89.12s+1} e^{-1s}$$

Based on the above process transfer function, PV and OP value can be estimated. The matching degree between estimated value and the actual value is 84.9%, so the open-loop model can be considered reliable to describe the characteristics of the control object.

Based on the above IMC algorithm, the performance of the control loop can be evaluated. It is found that the performance is good, but the robustness is poor. That is, once the external disturbance occurs, the control performance will drop significantly. Hence, the original closed-loop steady time of 202 seconds is maintained, and parameters of PID controller is adjusted: K_p is updated from 0.12 to 0.55, T_i is updated from 100 seconds to 160 seconds.

3.3 Feed-forward controller design

After designing the parameters of the feedback controller, it is expected that the closed-loop steady state time can be further reduced, so the feed-forward controller is introduced. If the closed-loop steady state time reduced 50%, from 200 seconds

Figure 5. Matching degree between estimated value and the actual value.

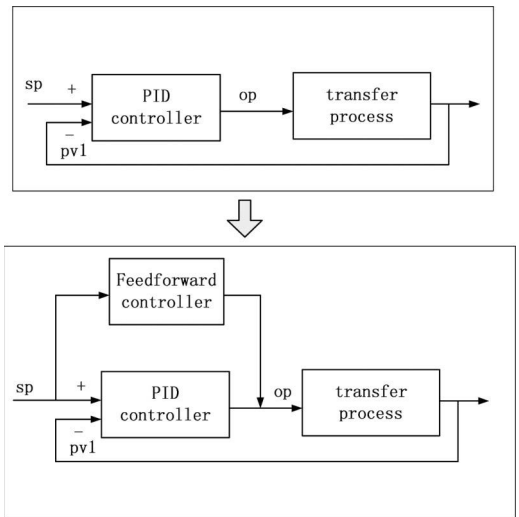

Figure 6. Feed-forward controller.

to 100 seconds, we can design a feed-forward controller based on the model, $K_f = 0.156$, $K_2 = 0.394$, $T_f = 25.25$. The feed-forward controller is shown in Fig. 6.

The feed-forward controller is

$$C_f(s) = K_1 + K_2 \left(1 - \frac{1}{T_f s + 1} \right)$$

4 APPLICATION

In this section, the automatic control loop optimization method is used in an example of 300 MW

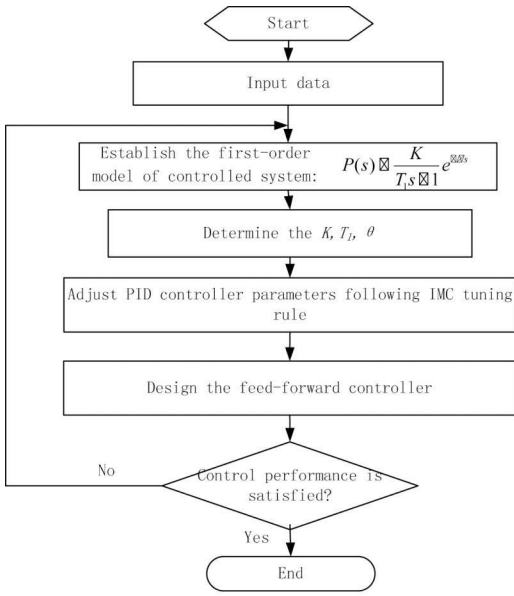

Figure 7. Control flow of optimization method.

Figure 8. Data trend of feed-water control loop after optimization.

thermal power plant. The implementation process is completed by the following steps in Fig. 7.

The actual test results of this control strategy which is used in a typical 300 MW thermal power plant are shown in Fig. 8, where SP is the set-point value of drum water level, and PV is the process value of drum water level.

Before optimization the standard deviation of the drum water level is 8.7628, and the standard deviation of the drum water level is 4.8612 after optimization, which is 55% times better than the original.

5 CONCLUSION

This paper introduces the typical three impulse feed-water control loop of thermal power plant, and establishes optimization strategy of PID controller based on internal model control. Finally, the effectiveness and practicability of the control strategy are verified by the application on a typical 300 MW thermal power unit.

Multidisciplinary optimization and parameter analysis of the in-wheel permanent magnet synchronous motor of a tram

X.C. Wang & Z.G. Lu

Institute of Rail Transit, Tongji University, Shanghai, China

ABSTRACT: Based on the theory of electromagnetic field and thermodynamics, this paper puts forward a multidisciplinary optimization model for In-wheel Magneto Synchronous Motors (I-PMSMs). On the condition of satisfying the limits for output torque and motor temperature, this model sets motor efficiency at rated condition and cogging torque ripple as the optimization objectives, designs the motor gap length, permanent magnet thickness, pole arc coefficient, pole-slot combination, and stator slot width as variables, and subjects to the constraints of flux density in the stator teeth, the stator yoke flux density, tank full rate and no-load back EMF. The results indicate that the optimized model not only meets the requirements of outline integrated parameter and temperature limits, but also reduces cogging torque and volatility of output torque, decreases the losses and improves the motor efficiency.

1 INTRODUCTION

Tram is a kind of light rail transport, driven by electric power and driving on tracks. Due to its features of construction with less upfront investment cost, energy saving, convenience and passenger comfort, many medium and small sized cities apply the tram widely. Wheel motor-driven trams have been running in foreign countries for many years, such as R3.1. Trams are wheel-motor driven low-floor trams produced jointly by Duewag and Siemens, which began running in Frankfurt, Germany in 1993. The domestic I-PMSM driven trams are also in rapid development. In 2014, 100% low-floor tram-like vehicles in CSR Qingdao Sifang Locomotive Co. rolled off the production line. That car was the first one to drive with a magneto synchronous motor, featured with high efficiency, low noise, environmental protection, good curving performances and so on. Low-floor bogies directly driven by permanent magnet motors don't have a traditional gear transmission system, which approves light truck weight, compact design and high transmission efficiency.

With further studies in energy saving and cost control of PMSM, lots of scholars focus on motor performance optimization. Kim et al. (1984) focus on energy consumption study of motors. Yue-jun et al. (2011) proposed the use of oblique pole rotors, a stator chute or changing the shape of permanent magnet (points segment or unequal thickness) and other methods to reduce motor output torque ripple and other issues. Haodong et al. (2011) proposed optimization of the pole arc coefficient and pole-slot combination to study vibration noise caused by

unbalanced magnetic force generated during operation of the motor and present optimization analysis method of the line size in the cooling system to solve the problem of the motor system temperature rise.

However, the optimized methods mentioned above can only concern several parameters or single discipline, which cannot analyze a set of parameters in different structures and multiple disciplines for optimization. In order to study the motor performance with different parameters in different disciplines, it is necessary to build a multi-parameter model with multidisciplinary factors when designing motors.

2 ANALYSIS OF THE I-PMSM MODEL

Considering the motor system consistency in the axial direction, the short axial length and limited axis end heat accumulation phenomenon, this paper simplifies the 3D electromagnetic field and thermodynamic models into two-dimensional plane models to simplify the model in multidisciplinary design optimization and improve computational efficiency. As shown in Figure 1,

Figure 1. Simplified cross-section model of I-PMSM.

the cross-section of the two-dimensional model presents isotropic in the circumferential direction when neglecting process structure impacts in the motor section.

2.1 Electromagnetic finite element analysis

The basic structure parameters of a permanent magnet motor can be determined according to the formula. But for many structure variables, including slot numbers, the stator slot shape, slot full rate, rotor poles, stator and rotor air gap, etc., the adjustments of which will considerably change the power density of the motor and further influence the output efficiency and output capability. So, it is essential to specifically analyze those variables and select a preferred structure to meet the needs of train traction power.

In Ansoft electromagnetic finite element software, the solve domain is generally divided into a discrete triangular network, which means the magnetic vector potential in an arbitrary unit will be divided into three node vectors by (1):

$$A = N_i A_i + N_j A_j + N_m A_m \quad (1)$$

Transient magnetic field analysis can solve the voltage, non-sinusoidal energizing current source, or there is motion in model. In the Ansoft transient magnetic field solver, magnetic vector potential A satisfies the following field (2):

$$\nabla \times \nu \nabla \times A = J_s - \sigma \frac{\partial A}{\partial t} - \sigma \nabla \nu - \nabla \times H_c + \sigma \nu \times \nabla \times A \quad (2)$$

where H_c = coercive force of the permanent magnet; ν = speed of moving objects; A = magnetic vector potential; J_s = source current density.

Maxwell 2D uses a reference frame when carrying on transient magnetic field analysis, fixed to a part of the model so that the speed is zero. Moving objects are fixed to their own coordinate system, and the partial time derivative turns into a full-time derivative. The motion equation is

$$\nabla \times \nu \nabla \times A = J_s - \sigma \frac{\partial A}{\partial t} - \sigma \nabla \nu - \nabla \times H_c \quad (3)$$

Thus, the magnetic vector potential can be calculated at every point of the finite element model in each time period. Based on the above principle, this paper establishes the electromagnetic finite element analysis model for I-PMSM by Ansoft software. The 2D transient electromagnetic analysis model produced by Ansoft is a 1/2 model, which

can speed up the analysis, shown in Figure 2; Figure 3 is the electromagnetic analysis process.

2.2 Thermodynamic analysis model

In order to enhance the optimization efficiency, the thermodynamic modeling of the I-PMSM system is based on the basic theory of heat transfer. The element internal energy equations on the 3D cylindrical coordinates are simplified and integrate to get the one-dimensional temperature distribution of the cylindrical wall with heat source inside as (4). According to (4), if the inside heat source power is constant, it is easy to deduce that the temperature distribution is parabolic.

$$T = -\frac{q_v}{4\lambda} r^2 + c_1 \ln r + c_2 \quad (4)$$

In the temperature curve, there is always a point of maximum temperature, and heat energy flows from this point to the sides, so this point is the starting heat point of the cylindrical wall. Similarly, according to the general expression of the thermodynamic equation, this point can be regarded as the heat insulating point. When the motor system is under normal operating conditions, the highest temperature part is located at the copper wire windings, so the heat insulating point, which also means the starting heat point, should be located

Figure 2. Motor 1/2 finite element model.

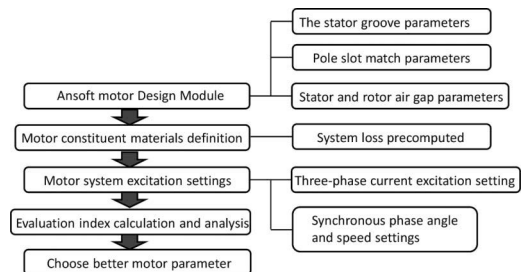

Figure 3. PMSM analysis process based on Ansoft.

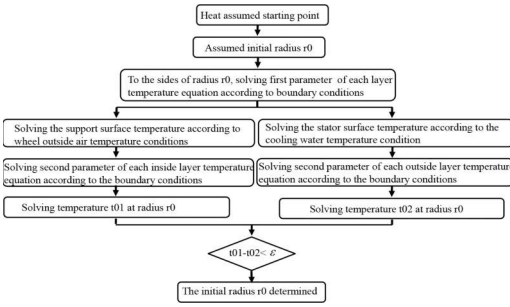

Figure 4. Algorithm of the thermodynamic analysis model.

Figure 5. Temperature distribution of the motor.

at some radial position on the copper windings. Two beams of heat transfer to the sides from the starting point. One inward transfers to the cooling water, and the other outward transfers to the air outside of the wheel support.

This paper sets up a thermodynamic mathematical model by MATLAB software. The algorithm flow is given in Figure 4. With the application of the above model and on the condition that the convection heat transfer coefficient of the stator inside cooling water is $800 \text{ W/K} \cdot \text{m}^2$, and the convection heat transfer coefficient of the external environment is $30 \text{ W/K} \cdot \text{m}^2$, Figure 5 shows the simulation result of motor internal temperature distribution along the radial direction at rated power output.

3 I-PMSM MULTIDISCIPLINARY OPTIMIZATION MODEL AND IMPLEMENTATION

3.1 Motor electromagnetic analysis and selection of evaluation parameters

Easy to know the efficiency of the motor rated conditions is an important parameter to evalu-

ate the performance of the motor, and hence this paper takes it as an optimization objective. Meanwhile, since the permanent magnet interacts with the slotted stator armature, it will produce cogging torque, which will not only fluctuate the motor output torque and generate additional vibration and noise, but also cause more difficulties to control the system. Therefore, cogging torque is another optimization objective of this paper.

From section 1.1, it is known that some parameters such as the gap length, the thickness of permanent magnets in the magnetization direction, the pole arc coefficient, the number of pole pairs and stator slot width have important effects on the motor operating performance. So, this paper selects these parameters as design variables. Meanwhile, the area of the stator slots, the width of stator teeth and stator slots, the air gap flux density, stator teeth magnetic density, the stator yoke magnetic density, motor slot full rate, the motor no-load back EMF and the rotor outer surface temperature must meet the I-PMSM constraints.

3.2 Design of I-PMSM multidisciplinary optimization model

The purpose of multidisciplinary optimization is to take advantage of synergies through the interaction of various disciplines (subsystem) to obtain the overall optimal solution. By enabling concurrent design, the design cycle is shortened, so that the developed products are more competitive. Multidisciplinary optimization can be simplified as a mathematical model and expressed as following:

$$\begin{aligned} &\text{find: } x \\ &\text{minimize: } f = f(x, y) \\ &\text{constrain: } h_i(x, y) = 0 \quad (i = 1, 2, \dots, m) \\ &\quad \quad \quad g_j(x, y) \leq 0 \quad (j = 1, 2, \dots, n) \end{aligned}$$

where f = objective function; x = design variables; y = state variable; $h_i(x, y)$ = equality constraints; $g_j(x, y)$ = inequality constraints. The calculation of state variables y , constraints h_i , g_j and objective function f involves multiple disciplines.

Through the above analysis, by meeting the traction torque and lower temperature limits, the I-PMSM multidisciplinary optimization model is designed as follows (Fenlian et al. 2012):

$$\begin{aligned} &\min_{z_1 \leq z_1 \leq z_m} \{f_1(z_1, z_2, \dots, z_n), f_2(z_1, z_2, \dots, z_n), \\ &\dots, f_i(z_1, z_2, \dots, z_n)\} (i = 1, 2, \dots, n) \text{ s.t. } \{c_1(z_1, z_2, \dots, z_n) \\ &\leq 0, c_2(z_1, z_2, \dots, z_n) \leq 0, \dots, c_j(z_1, z_2, \dots, z_n) \leq 0\} \end{aligned} \quad (5)$$

where $z_{il} = z_i$ upper limit value; $z_{in} = z_i$ lower limit value;

$f_1(z_1, z_2... z_n), f_2(z_1, z_2... z_n)...f_n(z_1, z_2... z_n)$, are objective functions;

$c_1(z_1, z_2... z_n) \leq 0, c_2(z_1, z_2... z_n) \leq 0...c_m(z_1, z_2... z_n) \leq 0$ are constraint functions;

$z_1, z_2... z_n$ are design variables.

This paper uses the OPTIMUS multidisciplinary design optimization platform to set up the I-PMSM optimization model. This software can integrate CAE, Matlab, ADAMS and other simulation tools. It can achieve the automation of the simulation process, including test design, single or multiple objective optimizations, robust and reliability of the design module.

Electromagnetic analysis of the optimization model is based on Ansoft electromagnetic finite element software, while the thermodynamic analysis of the model is based on MATLAB. The implementation process on computer is shown in Figure 6.

Corresponding to optimization model in Figure 6, Figure 7 shows the flow structure at OPTIMUS.

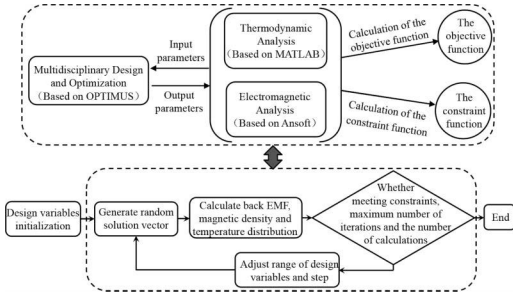

Figure 6. The design schematic of the motor multidisciplinary optimization model.

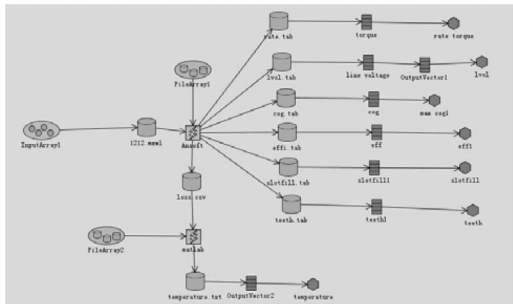

Figure 7. Workflow interface of PMSM performance optimization at OPTIMUS.

3.3 Multidisciplinary optimization algorithm

The multi-objective optimization algorithm has a variety of options, including the weight sum method, the weighted Chebyshev algorithm, and many other species. This paper uses the weighted Chebyshev aggregation algorithm, which is an improved method based on the weight sum method and Chebyshev method. Parameter ρ is added in that method. The weighted Chebyshev aggregation algorithm adjusts parameter ρ to control the ratio of two polymerizations, trying to combine the high speed of the weight sum method and reasonable distribution of the Chebyshev method. The mathematical description of the method is as follows:

$$\begin{aligned} \min g^{AT} \times \lambda, z^* \\ = \max_{i=1,...,n} \{ \lambda_i | f_i(x) - z_i^* | \} + \rho \sum_{j=1}^m | f_j(x) - z_j^* | \end{aligned} \quad (6)$$

where $\lambda = (\lambda_1, \dots, \lambda_m)$ is a set of weights vector, for all $i = 1, \dots, n, \sum_{i=1}^n \lambda_i = 1$ & $\lambda_i \geq 0$.

$z^* = (z_1^*, \dots, z_n^*)^T$ = the reference points, for all $i = 1, \dots, n, z_i^* = \min \{ f_i(x) | x \in \Omega \}$

4 OPTIMIZATION MODEL ANALYSIS AND RESULTS

4.1 The sensitivity (contribution) analysis of main parameters

Take I-PMSM shown in Figure 2 for an example. In Ansoft software, the motor speed is set to 253 rpm, and the energizing current is set to 97 A. Calculate the I-PMSM multidisciplinary optimization model by Ansoft solver. The optimization process and results are shown in Figures 8 to 10.

Figures 8 and 9 show the contribution analysis of design variables to optimization objectives

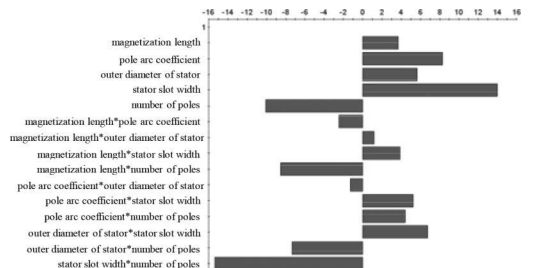

Figure 8. Contribution of design variables to cogging torque.

Figure 9. Contribution of design variables to motor efficiency.

Figure 10. Bubble chart of pole arc coefficient and permanent magnet thickness contribution to motor efficiency.

including cogging torque and motor efficiency. The abscissa shows the impact of each variable on the optimization objective, wherein the numerical size indicates the impact level, and sign indicates that the design variable is in positive or negative correlation with the optimization objective. As shown in Figure 8, increasing the number of pole pairs makes maximum contribution to reducing cogging torque, and increasing the outer diameter of the stator will decrease the gap length and then lead to torque fluctuation increase. At the same time, the change of stator slot width will cause the change of effective gap length between stator and rotor, and then affect the cogging torque. As shown in Figure 9, the decrease of gap length, caused by the increase of stator outer diameter, has a maximum effect on the decrease of motor efficiency. As is known, reducing the gap spacing will result in increased motor losses, thereby reducing its efficiency, which also verifies the validity of the model results.

Figure 10 is the Bubble chart for the workflow test. The size of the bubble represents the size of cogging torque, while the color of the bubble shows the change in efficiency. In practical application, it is hoped to get small cogging torque and

meanwhile ensure a certain degree of efficiency. So, in the bubble chart, it helps to find a set of parameters with smaller bubble and brighter color. As shown in Figure 9, the set of parameters (the magnet thickness ranges from 9.5–9.9 mm and pole-arc coefficients around 0.7–0.76) in the bottom right corner gets better results in the objective function.

4.2 The optimized results of motor performance parameters

Figure 11.a and 11.b illustrates the response surface in a 3D diagram for cogging torque and electric efficiency to pole-arc coefficients and the permanent magnet thickness in magnetization direction on the given slot-pole combination. It can be seen that the influence of improving motor efficiency by increasing the permanent magnet thickness is greater than that by increasing the pole-arc coefficients. Figure 11.c Figure 11.d shows the response surface for cogging torque and electric efficiency to stator slot width and outer diameter on the given slot-pole combination. The stator outer diameter has the same impact on cogging torque and efficiency, which can simultaneously decrease the torque and efficiency if it is too large or small. Similar to the stator slot width, when widening the slot, the electric efficiency and cogging torque both decline, but cogging torque shows a relatively more effective decline.

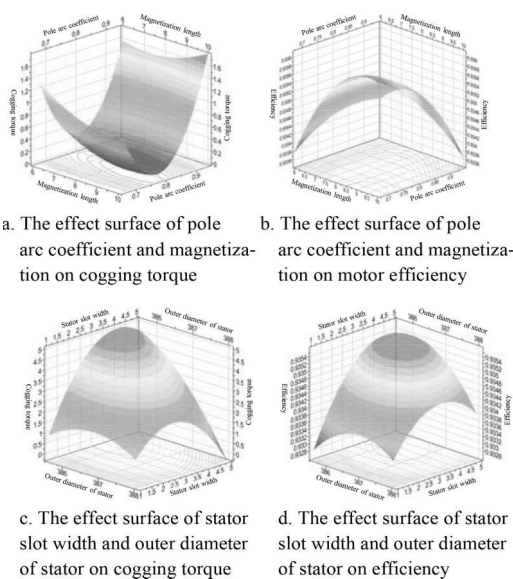

Figure 11. The effect surfaces of design variables on cogging torque and motor efficiency.

5 ANALYSIS OF MOTOR PERFORMANCE AFTER OPTIMIZATION

At rated conditions (speed: 253 rpm, power: 50 kW), the multidisciplinary optimized results of cogging torque and efficiency values on different weights are stated as Table 1.

Table 1. Comparisons of parameters before/after optimization.

Construction parameters	Before optimization	After optimization
Slot-pole combination	44/48	34/30
Number of conductors per slot	26	38
Gap length (mm)	1.5	1.5
Magnetization length (mm)	9	9.6
Stator slot width (mm)	3	4.6
Pole arc coefficient	0.85	0.75

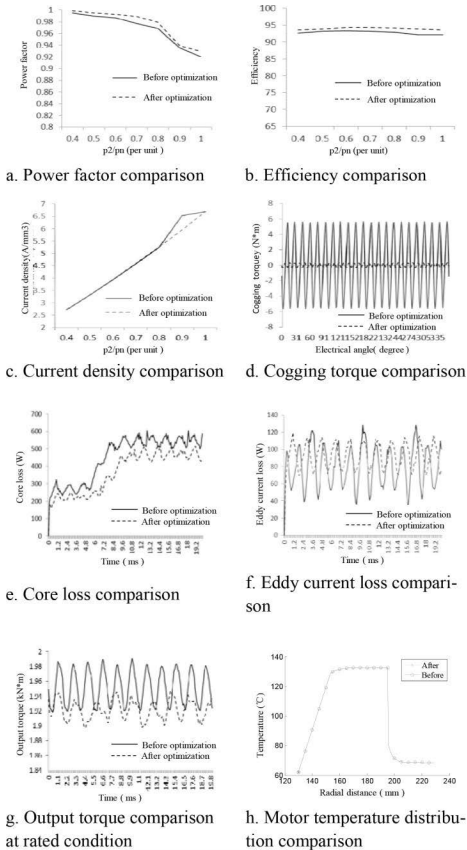

Figure 12. Comparison of motor characteristics before / after optimization.

Table 1 lists the comparisons of parameters before and after optimization. In order to testify and prove the optimized results, this paper uses the corresponding finite element model to analyze the difference between motor performance parameters (power factor, efficiency, stator current density) before and after optimization. The comparison is shown in Figure 12, which can manifest that the power factor and efficiency relatively get improved. In addition, the optimized parameters greatly decrease the cogging torque and consequently reduce the torque ripple during the motor running process.

From Figures 12 to 14, we can find that the copper loss and iron loss fade to some extent after optimization, both of which arise from the decrease of current density. From Figure 12, it is easy to understand that the optimized output torque can satisfy the demands on specific conditions and meanwhile decreases the frequency of torque ripple. For the outer surface temperature of the motor rotor, there is no big difference in optimization. However, the temperature around stator winding decreases a little due to the decrease of copper loss; the sine of air-gap flux density gets improved due to the possibility of the reduced slots in stator slotting, which further weakens the influence on effective air-gap fluctuations. Meanwhile, the decline of fundamental amplitude avoids the over saturation of air-gap flux density.

Figure 13. Analysis of air-gap flux density and harmonic number before optimization.

Figure 14. Analysis of air-gap flux density and harmonic number after optimization.

6 CONCLUSIONS

Based on the theory of electromagnetic fields and thermodynamics, this paper establishes a multidisciplinary optimization model for tram I-PMSM, which aims at optimizing the motor torque ripple and electrical efficiency based on the OPTIMUS platform. Emphasis is put on analyzing some design variables such as slot-pole combinations, pole-arc coefficient, gap length, the permanent magnet thickness in the magnetization direction, and stator slot width. The main conclusions are as follows:

1. Increasing the number of permanent magnet poles contributes the most to smoothing the cogging torque, while reducing the gap length and increasing the thickness of the permanent magnet will intensify the cogging torque ripple.
2. On the condition of equally adding the permanent magnets and the same output torque, compared with the method of increasing the pole-arc coefficient, increasing the permanent magnet thickness will produce smaller current density, which further means a less copper loss of stator windings and a higher efficiency.
3. Slot-pole combination affects the operating performance greatly. However, it is not a simple correlation due to the complexity of influence. The model proposed in this paper can set the range for pole pairs and slots of the permanent magnet, automatically achieve the slot-pole combinations and provide the results under specific conditions. Overall, it is a good solution for optimum simulation.

Dynamic simulation and muzzle vibration analysis of vehicle-mounted automatic mortar

Yu Fang, Jun-qi Qin & Chang-chun Di

Department of Guns Engineering, Ordnance Engineering College, Shijiazhuang, China

ABSTRACT: The vibration of gun muzzle is an important factor that affects the firing dispersion. In this paper, the dynamic model of vehicle-mounted automatic mortar considering suspension and tire parameters is established, and the vibration characteristics of the system are solved by the Lagrangian equation method of the Multi-Degree-of-Freedom (DOF) vibration system. Based on ADAMS software, the model of the tire-road system and the virtual prototyping model of vehicle-mounted automatic mortar are established. The dynamic characteristics of the mortar and the vibration of the muzzle are analyzed, which can provide reference for further research on vehicle-mounted weapon systems.

1 INTRODUCTION

The firing dispersion is one of the important indexes to evaluate the performance of artillery, and the gun muzzle vibration is an important factor that affects the firing dispersion. The position of the muzzle and the velocity of the muzzle are greatly changed when the gun fired, which leads to the change of the initial flight parameters of the projectile, and then affects the final bullet spread. As for vehicle-mounted weapons, there are more links between barrel and the ground. On the one hand, the barrel and the cradle of the weapon will be deformed, and on the other hand, the vibration of the vehicle will lead to muzzle vibration.

At present, there are some pieces of literature on the muzzle vibration of towed gun and vehicle-mounted weapons. CAI studied the impact of the mass of the muzzle brake, the position of the barrel support and other parameters on the muzzle vibration, while LIANG studied the effect of the arrangement of the recoil mechanism.

In this paper, vehicle-mounted automatic mortar is studied, which shoots without a rigid support. The body is connected to the ground through the suspension and the tire. At present, there are few research articles on this special case. The vehicle-mounted automatic mortar is used as the object of study, and the vibration characteristics of the system are solved by using the Lagrangian equation of the multi-degree-of-freedom vibration system. The dynamic model and the virtual prototyping model of the vehicle-mounted automatic mortar are established, and the dynamic characteristics of the vehicle are numerically simulated. The variation law of the muzzle is given, which will provide

reference for further research of vehicle-mounted weapon systems.

2 DYNAMIC MODEL OF VEHICLE-MOUNTED AUTOMATIC MORTAR

2.1 *Establishment of the dynamic model*

The vehicle-mounted automatic mortar mainly includes a driving system and a fire system. Among them, the driving system is the modified Dongfeng warrior EQ2050A chassis, composed of tires, suspension, body and other components, and the front and rear suspensions are double cross-arm independent suspension.

The fire system is the mortar system with an automatic mechanism. The fire system is mainly composed of the larger automaton, balancing machine, shelves, machine, car body, height direction machine and so on. The fire system is connected to the driving system through the trunk. The trunk can be rotated horizontally relative to the chassis, the barrel can rotate up and down relative to the trunk, in order to achieve a different direction angle and pitch angle of the mortar to fire.

In order to show the main movement and force of the mortar, according to the structural characteristics of the vehicle-mounted automatic mortar, the design of the mortar is simplified to the following components: the mass under suspension, body of car, cradle of mortar and recoil device.

The chassis of vehicle-mounted is a common two-axle vehicle, which can be simplified as a 1/2 dynamics model of vehicle-mounted automatic mortar with 6-DOF, which is shown in Figure 1.

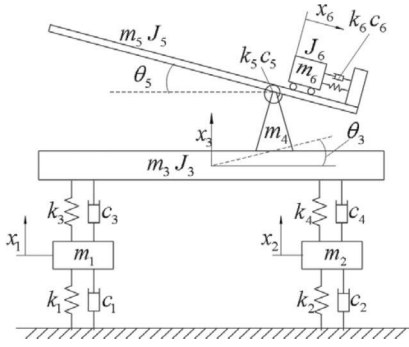

Figure 1. 1/2 Model of vehicle-mounted automatic mortar with 6-DOF.

In Figure 1, m_1 , k_1 , c_1 , and x_1 , respectively, represent the mass of the front wheel, the equivalent stiffness and damping coefficient of the front wheel, and the vertical displacement of the front tire; m_2 , k_2 , c_2 , and x_2 , respectively, represent the mass of the rear wheel, the equivalent stiffness and damping coefficient of the rear wheel, and the vertical displacement of the rear tire; k_3 , k_4 , c_3 , and c_4 , respectively, represent the front and rear suspension equivalent stiffness and front and rear suspension damping coefficient; M_3 , J_3 , x_3 , and θ_3 are the total mass and moment of inertia of the body and the vertical displacement and pitch angle of the body center of mass; M_5 , J_5 , m_6 , and J_6 , respectively, are the mass and moment of inertia of the barrel and mass and moment of inertia of the recoil part; m_4 and J_4 , respectively, are the mass and moment of inertia of the cradle; θ_5 and x_6 , respectively, are the elevation of the barrel and displacement of the recoil part. The stiffness coefficient and damping coefficient between barrel and cradle are denoted by k_5 and c_5 .

2.2 Assumptions and calculations of the model

The model assumes the following:

1. The body contacts with the ground through four double cross-arm independent suspension and four tires. Only vertical and pitching movement of the body and barrel are considered; there is no lateral force and movement.
2. The suspension system is equivalent to the spring damping system. The elastic connection between barrel and cradle forms into a coil spring damping system.
3. In this model, the barrel, the body of the car, the cradle and other parts are rigid; only consider the movement and stress, regardless of deformation factors.
4. The tire will not slip; the contact point between the tire and the ground is always fixed. The

contact with the ground is simplified as a vertical movement of the spring damping system, that the stiffness coefficient and damping coefficient are determined by the tire-surface coupling characteristics.

Based on the above assumptions, the Lagrangian equation of the multi degree-of-freedom system is used to construct the vibration equations of a 6-DOF model:

$$\frac{d}{dt} \left(\frac{\partial T}{\partial \dot{q}_i} \right) - \frac{\partial T}{\partial q_i} = Q_i - \frac{\partial V}{\partial q_i} \quad (1)$$

where T is the kinetic energy of the system:

$$T = \sum_{i=1}^n T_i \quad (2)$$

Q_i is the generalized force corresponding to non-dominated forces. In this model, the damping exists. It is necessary to determine the energy dissipation coefficient D of the system, that is, the energy dissipated by damping:

$$D = \frac{1}{2} c \dot{q}_i^2(t) = \frac{1}{2} \{ \dot{q}(t) \}^T [c] \{ \dot{q}(t) \} \quad (3)$$

The generalized damping force is:

$$R_i = - \frac{\partial D}{\partial \dot{q}_i} = - \sum_{j=1}^n c_{ji} \dot{q}_j \quad (4)$$

The resulting multi-degree-of-freedom system equations of motion are:

$$[M] \{ \ddot{q}(t) \} + [C] \{ \dot{q}(t) \} + [K] \{ q(t) \} = \{ Q(t) \} \quad (5)$$

In the formula,

$$\{ q(t) \} = [x_1, x_2, x_3, \theta_3, \theta_5, x_6]^T \quad (6)$$

The above formulas are vibration equations of the model.

3 ESTABLISHMENT OF THE VIRTUAL PROTOTYPE MODEL

3.1 Virtual prototype model of the tire-road system

According to the characteristics of the vehicle in an actual weapon system, the UA tire model is a commonly used model at present. Using the SAE coordinate system, considering the unsteady effect, side slip and longitudinal slip interaction, the model can only be used on flat roads.

MSC.ADAMS software was used to create the model of the vehicle. The model mainly includes a vehicle chassis model, double cross arm independent suspension model, tire model and road. The parameters of the UA tire model used in this paper are shown in Table 1.

3.2 Virtual prototype model of vehicle-mounted automatic mortar

Before the establishment of the model of vehicle-mounted automatic mortar, the mortar model was simplified and the cradle model was deleted, which has little influence on the simulation results. The mass of the cradle is equivalent to the car body and the sphere model is used to simulate the mortar projectile with the same mass as the real projectile. On stimulation at firing, the ADAMS software comes up with a STEP function to apply the force in bore, acting between the projectile and the breechblock, pointing along the barrel axis. During the firing process, the chassis is in the braking state, and the tire is not rotated. In order to reduce the computational cost, the component can be regarded as a rigid body with larger stiffness and smaller deformation, and the equivalent mass and moment of inertia can be processed for the components which have no influence on the motion and force.

In the modeling process of the paper, the vehicle is considered as a rigid body to be analyzed, the suspension damping system of the vehicle is standardized designed according to the spring damping system, and the virtual prototyping model of the vehicle-mounted automatic mortar, the model consists of 30 motion components, 22 revolute

joints, 9 fixed joints and 9 translation joints. The virtual prototype model is shown in Figure 2.

4 SIMULATION OF MUZZLE VIBRATION

Based on the virtual prototype model, the corresponding tire and road parameter files were imported, and physical parameters and structural parameters such as the fire line height and mass of body were imported. The linear and angular displacements of the muzzle point in the global coordinate system are calculated. The model is symmetrical, and only the forward firing condition is studied. The horizontal displacements in the muzzle parameters, the vertical displacement in the vertical direction, and the angular displacement in the pitch angle are the dependent variables. Table 2 shows the parameters of suspension.

The figures presented below show the muzzle dynamic simulation results in the single-shot condition. The angle of fire is 12 degrees, shooting straight ahead.

The curve in the figure can be divided into two parts: before firing and after firing. Since the model is not in the equilibrium position at the beginning of the simulation, from $t = 0$ s to $t = 3.99$ s, the vibration of the body and the gun body is small, and gradually stabilizes. When $t = 3.99$ s, the STEP function is triggered, resulting in force in the bore of mortar, making the projectile flow out of the barrel, while the breech recoils.

Starting from the moment of firing, the muzzle center point parameters began to change greatly. Muzzle has produced the front and back direction, the up and down direction vibration as well as pitching rotation. Among them, the amplitude of the pitch rotation angle is 1.6 degree, the displacement amplitude in the vertical direction is 71.08 mm, and the displacement amplitude in the front-back direction is 84.23 mm. From the firing time to the projectile flying out of the muzzle interval, the time taken is only 0.016 s. After 2 seconds, the muzzle center position tends to be stable, back to the initial launch position.

As can be seen from the figure, although there is muzzle vibration when shooting, the projectile from firing to the time between the muzzle time

Table 1. UA tire model parameters.

Parameter	Value	Parameter	Value
Tire unload radius (m)	0.48	Tire width (m)	0.28
Vertical stiffness (n/m)	1.9e5	Minimum friction coefficient	0.9
Vertical damping (n-s/m)	280	Maximum friction coefficient	1.1

Figure 2. Virtual prototype model of vehicle-mounted automatic mortar.

Table 2. Suspension parameters.

Parameters	Value
Front suspension stiffness (n/mm)	200
Front suspension damping (n-s/mm)	100
Rear suspension stiffness (n/mm)	380
Rear suspension damping (n-s/mm)	100

Figure 3. The muzzle dynamic simulation results in the single-shot condition. Every curve means:
 (a) Change of rotation angle of muzzle axis in the vertical plane.
 (b) Displacement of the muzzle center in the vertical direction.
 (c) Displacement of the muzzle center in the front-back direction.
 (d) The distance between projectile and the muzzle center.

interval is very short, only 0.016 s. When the projectile is out of the muzzle, the change in the muzzle parameters is still very small, almost no change; so, the intensity of a single-shot has little effect. Therefore, it can be concluded that for the vehicle-mounted automatic mortar in the single-shot condition, the muzzle vibration is harmless.

5 CONCLUSIONS

Based on the theory of the multi-degree-of-freedom vibration system, the dynamic characteristics of vehicle-mounted automatic mortar are modeled and analyzed, which are then simulated with MSC.ADAMS software. This modeling method is simple, efficient and accurate, which provides reference for further modeling research on vehicle-mounted weapons.

This type of vehicle-mounted automatic mortar, which shoots without a rigid support, indicates that the muzzle vibration is harmless when the mortar is fired in a single-shot condition.

Future research can be performed on the effects of muzzle vibration in continuous firing of the vehicle-mounted automatic mortar, to further

explore the characteristics of muzzle vibration of vehicle-mounted weapons.

Numerical simulation of aspheric glass lens during the non-isothermal molding process

Hongjie Duan & Zhiling Xiao

College of Mechanical and Electrical Engineering, Zhengzhou University of Light Industry, Zhengzhou, China

Junyi Tao

School of Management, Huazhong University of Science and Technology, Wuhan, China

ABSTRACT: Defects such as low productivity and short service life of the mold occur in the isothermal molding process of aspheric lens. On the basis of these problems, a new method of non-isothermal molding was introduced and the fundamental principle of non-isothermal molding was carefully analyzed. Non-isothermal molding is formed at different temperature conditions between glass blank and mold. The deformation flow of the glass is accompanied by heat transfer. Thus, non-isothermal molding of aspheric lens was simulated by the thermo-mechanical coupling 3D finite element method. The internal temperature and stress field of the glass and mold were analyzed. And then the simulation results of isothermal and non-isothermal molding were compared. The results indicated that the non-isothermal molding process was feasible and superior.

1 INTRODUCTION

Optical glass lenses are widely used in optical engineering, automotive engineering, biomedical, aerospace and other fields, which have huge market demand (Chen et al. 2010). The lens manufacturing not only requires ensuring the quality and use of optical performance, but also meets the high efficiency and low cost. At present, the isothermal molding method is widely used in the production of aspheric lens, which involves employing chunk glass into the mold at room temperature, and after a specified time, the mold is prepared when the temperature reaches molding temperature (Yan et al. 2009). The processing lenses have high surface precision using this method, but only after the end of the previous production cycle, we can start the next production cycle. Therefore, the production efficiency is quite low. In addition, the mold has a shorter service life because of repeated heating and cooling processes, and a large temperature range (Ma et al. 2009, Bai et al. 2015).

In this paper, a new method for manufacturing aspheric lens with non-isothermal molding is presented. The advantages and disadvantages of non-isothermal and isothermal molding methods were compared by means of a finite element simulation method, aiming at exploring the efficient non-isothermal molding process under the premise of ensuring the quality of lenses.

2 THE BASIC PRINCIPLES OF NON-ISOTHERMAL MOLDING

2.1 *Non-isothermal molding process*

The glass blank was usually heated to a temperature dozens of degrees above the conversion point in a preheat device at first. Then, it was put into the mold with temperature, maintained at a lower level by a mechanical transport device, molded and annealed in the mold. When the inner stress was reduced to a certain extent, the lens was removed from the molding chamber through a mechanical conveying device, and then further cooled to room temperature in a cooling device. The whole process must be performed in a vacuum environment to ensure that the high-temperature glass is not oxidized by air.

2.2 *Thermo-mechanical coupled finite element method*

The process involving non-isothermal molding of aspheric glass lenses included a flow-forming process for softened glass at high temperatures and a heat transfer process with a strong coupling effect. For the coupling problem covering temperature and displacement, the accurate analysis method was to follow the solution of the thermo-mechanical coupling field and process the two different field

equations containing heat conduction and force balance simultaneously. In this study, Marc software was used to conduct the coupling analysis of aspheric glass lens molding. Marc software has strong structure and contact analysis capability, which is suitable for large deformation analysis of viscoelastic materials under isothermal and non-isothermal conditions.

3 ESTABLISHMENT OF THE FINITE ELEMENT MODEL

3.1 Mesh model

Figure 1 shows the geometric model of aspheric lens during the simulation process.

The curve of the upper and lower aspheric surface satisfies the equation (Zhou, 2009):

$$y = \frac{x^2}{R \left(1 + \sqrt{1 - \frac{(1+k)x^2}{R^2}} \right)} + B_4 x^4 + B_6 x^6 + B_8 x^8 + B_{10} x^{10} \quad (1)$$

where R is the vertex radius of the curve, x is the horizontal coordinate, y is the vertical coordinate, k is the curve constant and B is the aspheric surface coefficient. Among the aspheric parameters:

$$R = -10.75431 \text{ mm} \quad (2)$$

$$K = 0 \quad (3)$$

$$B_4 = 8.621796 \times 10^{-3} \quad (4)$$

$$B_6 = -2.56179 \times 10^{-3} \quad (5)$$

$$B_8 = -3.037114 \times 10^{-4} \quad (6)$$

$$B_{10} = -1.82822 \times 10^{-5} \quad (7)$$

The parameters can be determined similarly.

Figure 1. Double aspheric lens geometry model.

Table 1. Glass characteristic parameters.

Performance parameter	Size
Young's modulus E/MPa	15800
Density ρ /(g/cm ³)	3.05
Poisson's ratio	0.247
CTE $\alpha \times 10^{-6}/^{\circ}\text{C}$	8.8 (100–300 $^{\circ}\text{C}$)
Thermal conductivity k/(W/(m. $^{\circ}\text{C}$))	10.28
Specific heat Cp/(J/(kg. $^{\circ}\text{C}$))	750

3.2 Material parameters

The prefabricated part of glass molding was glass ball blank which is L-BAL42. The material characteristic parameters are shown in Table 1. The three-dimensional model of glass ball blank was established by Solid Works software, and the solid model of upper and lower mold with an aspheric curve was established by Solid Works software too. Then the upper mold, lower mold and glass ball were fitted together according to the actual working position. The assembly was imported into the Marc software. The finite element meshing was divided by the auto mesh function. The assembly model was divided into tetrahedral elements.

4 ANALYSIS OF SIMULATION RESULTS

In the actual non-isothermal molding process of the aspheric surface of glass lens, the temperature was always not less than the molding temperature and not higher than its softening temperature Sp. When the temperature is higher than the softening point Sp, the viscosity of glass is very low, and its behavior is similar to the viscous fluid. It also can form bond to the mold (Zhao et al., 2009; Ni et al., 2015). The temperature of the mold should not be too low, and the surface and interior thermal contraction of glass will inconformity if there is a large gap between the temperature of glass and mold, so it comes into being a lot of internal stress and ever crack inside of lens. Therefore, aiming to the L-BAL42 optical glass, we defined the initial temperature of the glass as 590 $^{\circ}\text{C}$, the initial temperature of tungsten carbide WC mold and die holder was 560 $^{\circ}\text{C}$, and the temperature of molding was 580 $^{\circ}\text{C}$.

4.1 Analysis of the temperature field

The temperature field of aspheric lens in the molding process is shown in Figure 2. The spherical glass blank with 590 $^{\circ}\text{C}$ was put into the mold by mechanical devices. When the lower mold moved upward, the extrusion was produced between the upper surface of the glass blank and the upper mold, and the precise aspheric surface of the upper

(a) Internal temperature distribution of the glass with molding 98s

(b) Internal temperature distribution of the glass with molding 101s

(c) Internal temperature distribution of the mold with molding 101s

Figure 2. The temperature field of the aspheric lens glass molding process.

mold started to copy on the lens surface. The lowest temperature area inside the lens was contacted with the mold at this moment. With the mold pressing, the lowest temperature area on the upper surface of the glass lens moved towards the edge with the contact surface of the glass and mold enlargement. The temperature of the lower surface edge was relatively low, because it contacted with the die holder for a long time, and heat transfer was more fully performed.

After molding, glass was almost filled into the closed space formed by the mold and mold base. The upper and lower mold contacted with the glass, and the precision aspheric surface of the mold was copied on the lens surface. The internal temperature gradient of aspheric lens was clearly visible, and the highest temperature area occurred in the interior of the aspheric lens. The further the distance, the lower the temperature. The upper and lower surfaces were in direct contact with the

mold surface (Jain 2006), so the lowest temperature region appeared at the side edge of the mold holder. Its temperature was 560°C, which was close to the initial temperature of the mold. In the whole forming process, the internal heat of the high-temperature glass was transferred to the mold, mold holder and the environment filled with nitrogen gas through two ways, which are solid heat conduction and convection heat transfer.

4.2 Analysis of the stress field

Fig. 3 shows the stress field of the aspheric lens glass molding process. When molding runs at 78 seconds, the glass blank started to contact with the upper mold, and the equivalent stress of the glass ball surface center increased rapidly because the extrusion stress of the upper die and the stress of the edge of the mold began to increase. With the molding proceeding, two maximum stress points

(a) Internal stress distribution of the glass with molding 98s

(b) Internal stress distribution of the glass with molding 101s

(c) Internal stress distribution of the mold with molding 101s

Figure 3. Stress field of the spherical glass lens molding process.

Table 2. The stress field of the isothermal and non-isothermal molding.

Type of lens/MPa of mold/MPa	Maximum stress	Maximum stress
Isothermal molding	16.56	51.54
Non-isothermal molding	22.45	39.94

appeared inside the glass. One is in the center of the upper surface with the lowest temperature, which moved outward with the contact area with the upper surface and the mold enlarging. Another is the edges of the lower surface, namely the intersection of the aspheric surface and the plane of the glass edge. The glass blank bears a large shearing force, so a larger stress is produced. When molding proceeds to 98 seconds, the glass is close to the final shape, and the maximum stress area moves further to the edge. The stress of the upper and lower surfaces increases with deformation increasing. The stress distribution has no change but an increase in the value.

4.3 Contrastive analysis of non-isothermal and isothermal molding

Comparing with isothermal molding, non-isothermal molding has two main advantages such as high production efficiency and longer mold life. However, two factors involving strong heat transfer and internal temperature gradient can affect inner stress and surface accuracy of after-mold lens. In this paper, the simulation model of non-isothermal molding was used to compare non-isothermal molding (glass 590°C, mold 560°C) with isothermal (molding temperature 580°C). The comparison results are shown in Table 2.

It can be found that the lens have a small average stress when conducting the isothermal molding. The average stress within the mold is also small as the non-isothermal molding proceeds. A smaller mold stress will help to prolong the mold life, which confirms the advantage of the non-thermal molding method. Nevertheless, the non-isothermal molding method has a bigger stress of lens, which contributes to glass shrinkage during the process of deformation. The inner stress in the next step can be reduced by the annealing and cooling processes.

5 CONCLUSIONS

1. The reasons for the temperature gradient and the stress gradient inside the mold were explained.

The spherical lenses had a higher internal temperature during the non-isothermal molding process. Moreover, the average temperature and stress in the upper die were higher than those in the lower die, indicating that the upper die had a short service life.

2. The comparison between the non-isothermal molding and isothermal molding processes showed that the mold had good optical performance due to a small internal stress within the lens during isothermal molding, while it had a long service life because of a small internal stress within the mold during non-isothermal molding.

ABSTRACT: The pavement structure is usually under the impact of frequent changes in the temperature when it is completely exposed to the external environment. The solar and atmospheric radiation energy is part of the energy that can be reflected from the pavement surface. But the remaining energy will be stored in the form of heat in the pavement. This will lead to high road surface temperatures, and the pavement structure will be affected by the dynamic changing environmental conditions. It is known from the long highway maintenance experience that the road surface temperature can seriously damage the pavement structure strength and pavement performance. Therefore, it is very important to analyze the influence of the temperature field.

1 INTRODUCTION

The solar radiation and atmospheric radiation energy can be reflected from the pavement surface. As is known, the remaining energy will be stored in the form of heat that is stored in the pavement. It will cause high road surface temperature and will be affected by the dynamic changing environmental conditions (Elmer C. Hansen, 2013). It is known from the long highway maintenance experience that the road surface temperature can seriously damage the pavement structure strength and pavement performance, so it is significant to analyze the influence of the temperature field.

2 ESTABLISHMENT OF THE TEMPERATURE FIELD CALCULATION MODEL

2.1 Unit selection

In the process of analyzing the temperature field, the 3D solid model is used to simulate the

temperature field of the pavement structure (Bhutta m, Tsurutak, 2013). It usually analyses the temperature field of the pavement structure in the calculation by the finite element software ANSYS, and put the SOLID70 THERMAL unit of the three-dimensional solid thermal unit as the thermal unit (Bentz D P, 2007). In the experiment, put it to be equivalent to structural unit SOLID45 in the calculation of temperature stress (Huang Hui, 2010). The SOLID70 unit structure model is shown in Figure 1 and the SOLID45 structure model is shown in Figure 2.

SOLID70 is to be used as a three-dimensional solid element for the analysis of three-dimensional heat conduction. The element is defined by 8 nodes, as well as the characteristics of orthotropic materials (Tennis P D, 2004). This unit is applied to three-dimensional, steady-state or transient thermal analysis for analysis. In view of the characteristics of this unit, the temperature field model of PMC is established by using the element.

Figure 1. SOLID70.

Figure 2. SOLID45.

2.2 Computational model

According to the characteristics of porous modified concrete and regional characteristics, it can determine the modified porous cement concrete pavement structure in the cross-section that is shown in Figure 3. The road width is 12 meters and the top layer is the asphalt layer with a thickness of 4 cm. The top layer is regarded as a function of the asphalt layer that provides the structure of road roughness. The bottom layer is a porous modified cement concrete layer with a thickness of 30 cm. The sub-base is a cement stabilized macadam sub-base and its thickness is 18 cm. The gravel slope is 1:1.5. When the temperature reaches a certain depth, the temperature remains the same. Consulting from the literature, the depth of the foundation is 3m. The calculation of temperature field and temperature stress is based on the model.

In the calculation and analysis by ANSYS software, it usually employs the cross-section as the basis. Use the expansion foundation form to establish the finite element model of temperature field, then to divide the grid and the temperature field model of the grid. This is shown in Figure 4.

2.3 Boundary conditions and calculation parameters

In the pavement structure, the temperature change is relatively small. The pavement structure parameters can be regarded as constant. Thermal

Figure 3. Typical road cross-section.

Table 1. Thermal physical parameters of the road structure.

Material type	Temperature coefficient α (1/°C)	Thermal conductivity (W/m.°C)
Cement concrete	0.6×10^{-5}	1.1
Crushed stone	0.8×10^{-5}	1.2
Cement grave	1.4×10^{-5}	1.2
Subgrade	5×10^{-5}	1.3

Table 2. Thermal physical parameters of the road structure.

Temperature (°C)	-20°C	0°C	20°C	60°C
Thermal conductivity (W/m.°C)	1.84	1.22	1.56	2.36

parameters of the cement concrete layer are little affected by temperature, which can be seen as constant. According to the study on the pavement structure layer, the thermal parameters are shown in Table 1.

The thermal conductivity coefficient of different temperatures is shown in Table 2, and the temperature coefficient is 2×10^{-5} (1/°C). The heat exchange coefficient is selected by the different climate.

3 PMC TEMPERATURE FIELD ANALYSIS

3.1 Climatic condition analysis of different natural zoning

In the calculation of temperature stress, the changes of temperature field are mainly caused by the temperature change of climate and it is mainly affected by solar radiation. According to the specification and China atlas of climate division and other related materials, it is classified as the temperature characteristics of different natural regionalization that is shown in Table 3.

According to the different climatic conditions, it usually calculates the temperature field distribution under the different natural conditions; the climatic zoning is only considered from the first level division.

3.2 Analysis of temperature field distribution in different natural zoning

According to the model and calculation parameters, the temperature field distribution of different natural zones in different seasons can be obtained. The maximum temperature stress is mainly occurred in the hot summer season about the analysis in pavement temperature. It chooses the representative weather to analyze the temperature field that is the unfavorable situation. According to the model, it can get the distribution of temperature field in a moment of pavement structure and it is shown in Figure 5.

Table 3. Temperature characteristics of different natural regionalization.

Natural zoning	II, V	III	IV, VI	VII
Maximum temperature (°C)	34~37	30~35	36~40	27~31
Minimum temperature (°C)	-10~-5	-12~-8	3~7	-14~-19

Figure 5. Temperature distribution of the pavement structure in summer 14:00.

According to the different temperature schedules, it chooses 6:00, 14:00, and 22:00 in the summer. It calculates the distribution of road structure temperature in different times by ANSYS. From the metabolic diagram, it can be seen that the temperature changes with depth and time. The specific value is shown in Figures 6, 7, 8 and 9.

It can be seen from Figure 6 that the temperature difference in the pavement structure is the

Figure 6. PMCCP temperature changes with depth in area III.

Figure 7. Temperature changes of PMCCP in area V.

Figure 8. IV, VI PMCCP temperature changes with depth.

Figure 9. VII PMCCP temperature changes with depth.

largest at 14:00 in the natural division III district of summer. The porous cement concrete layer will reach the maximum positive temperature gradient with depth from the road extending to the bottom of the pavement. The temperature changes from 50 centigrade down to 20 centigrade and the temperature changes obviously. The pavement structure increases first, then show a decreased trend in the surface layer when the time is 6:00 and 22:00. The temperature reaches the maximum at the bottom layer, and then decreases with the depth change. When the depth is 1 m, the temperature variation is small and basically unchanged.

It can be seen from Figure 7 that the pavement structure temperature gradient reached the maximum temperature at 14:00. It reaches the highest temperature on the road surface. The temperature at the bottom of the road surface increases by 45% at 6:00 in the morning. The temperature in the concrete layer can reach the maximum. The temperature at the bottom of the road surface increases by 25% at 22:00 in the evening. When the depth increases, the temperature will not change with the depth.

We can see from Figure 8 that the summer temperature of the pavement structure has a sinusoidal variation in divisions IV and VI with the change of time. The concrete surface reached maximum at 14:00. In the hot season of summer, the pavement temperature can change from 25 to 60 centigrade. The change range can get to 55%. The middle and the bottom surface changes in the amplitude are not obvious for the relatively low temperature.

It can be seen from Figure 9 that the pavement structure temperature decreases with depth at 14:00. The road surface temperature can reach to 37 centigrade when the depth reaches to 70 cm. But the temperature will be reduced to 16 centigrade when the depth is 70 cm. When the temperature is 12 centigrade, the depth is 1 m. The temperature change is not very obvious.

Table 4. Maximum temperature gradients.

Natural zoning	II, V	III	IV, VI	VII
$T_{g,m}$ (°C/m)	63~68	71~76	67~73	75~81

3.3 Temperature gradient analysis of different natural zoning

The pavement temperature changes with the depth. The temperature gradient of the modified porous cement concrete slab is the ratio of the top temperature, fingerboard thickness and the bottom plate. The temperature gradient plays an important role in the temperature field analysis. The temperature gradient can reflect the temperature change of the pavement structure more intuitive.

According to the calculation result of the temperature field, the temperature gradient value is recommended, and the results are shown in Table 4.

It can be seen from Table 4 that the maximum temperature gradient of the porous cement concrete slab is 60~80°C/m, but the ordinary concrete maximum temperature gradient is up to 80~100°C/m. The temperature gradient of porous concrete is less than common concrete.

3.4 Influence of the asphalt layer thickness on the temperature field

Because of the temperature sensitivity of asphalt materials, the temperature of the porous cement concrete surface layer will change when the asphalt surface layer is added to the cement concrete surface layer. It is proposed to be the appropriate temperature gradient correction factor for analyzing the influence of the asphalt layer thickness on the temperature field.

3.4.1 Influence of the asphalt layer on the temperature field

Taking the temperature distribution of III area in summer as an example, the influence of the asphalt layer on the temperature field is analyzed in the table. The porous modified concrete layer temperature change condition is shown in Figure 10.

It can be seen from the Figure 10 that the asphalt road surface temperature is slightly small when the layer that does not pave asphalt compared to a thin layer. The reason is that the asphalt material absorbs a lot of heat in solar radiation and convection. If the PMC layer depth is deeper, the temperature change is smaller. When it reaches the bottom, the temperature basically remains unchanged. The reason is that the heat has certain loss with the heat delivering to the bottom layer. This will result in a little difference when heat reaches the bottom.

Figure 10. Temperature distribution of porous layer with different asphalt layers in summer.

Figure 11. Temperature distribution of the PMC layer in different asphalt layers during winter.

3.4.2 Influence of the asphalt layer thickness on the porous layer in winter and summer

The asphalt mixture is a kind of typical temperature sensitive material, in which its mechanical properties and road performance will be affected prominently with the change of temperature. It analyses the influence of asphalt layer thickness on the temperature field during the summer and winter. In winter, the temperature is 2.4 centigrade, the layer temperature is 0 centigrade, and the other parameters are consistent with the calculation method in the same summer. The data can be calculated by the finite element analysis, and the obtained data is shown in Figure 11.

It can be seen from Figure 11 that with the increase of asphalt layer thickness, the PMC layer temperature increased first and then decreased. The law is similar to summer. The temperature reaches the maximum when the PMC layer thickness is 2 cm. Then, when the asphalt layer thickness increases, the PMC layer temperature decreases. The PMC surface temperature change is obvious with the asphalt layer thickness increase. The middle and the bottom temperature changes are not big.

3.4.3 Temperature gradient correction coefficient of different asphalt layer thicknesses

The change of temperature gradient has great influence on the temperature stress. The temperature gradient is influenced by temperature, solar radiation and pavement material characteristics. Due to the thermal conductivity of different materials, the effects of heat transfer and diffusion are different. The asphalt layer gets the heat from the atmosphere by the action of radiation and convection. It transfers the heat to the pavement structure by conduction. So, the change of thickness affects the temperature gradient of the concrete slab.

Figure 12. Temperature gradient of PMC layer in different asphalt layers.

The temperature gradient of the PMC layer in different asphalt layers is shown in Figure 12.

It can be seen from Figure 12 that the PMC layer temperature gradient is the maximum in summer. The reason is that the maximum positive temperature gradient is generated at high temperature. At the beginning of the asphalt layer at 0~2 cm, the temperature gradient increases from 67°C/m to 73°C/m. With the increase of the thickness of the asphalt layer to greater than 2 cm, the temperature gradient decreases gradually.

4 CONCLUSION

The main conclusions by analyzing the formation of the temperature field, the selection of thermal parameters and the temperature field of the porous modified concrete pavement can be summarized as follows:

1. The distribution of temperature field of the road structure under different conditions by the temperature field model was calculated.

The distribution of the temperature field in different zoning conditions in summer was obtained by analyzing the temperature characteristics of different natural divisions. The temperature gradient in different regions was recommended by the calculation results.

2. The temperature gradient was found to be highest in summer and temperature stress was found to be in the most unfavorable conditions.
3. The appropriate temperature gradient values were recommended in different natural regions by analyzing the change in the temperature gradient of the PMC layer under different natural regionalization and analysis results.

A retrieval method based on a CBR finite element template

Qinyi Ma, Dapeng Xie, Lihua Song & Maojun Zhou

Department of Mechanical Engineering, Dalian Polytechnic University, Dalian, China

ABSTRACT: A framework of the finite element analysis template case database is systematically constructed based on Case-Based Reasoning (CBR). The analysis information, feature information, and attribute information are used as indices to achieve the reasoning. The information in the finite element analysis case is structurally described by means of ontology representation. The conceptual similarity computation method based on semantic information is used to compute the similarity between the case analysis information, the characteristic information and the attribute information in the process of using the basic information to retrieve the case. The priority of retrieval information is defined, and the different weights are assigned in the process of similarity calculation. On this basis, the global similarity is computed to obtain the comparison between the cases.

1 INTRODUCTION

Case-Based Reasoning (CBR) is a reasoning method adjusting the solution of previous problem to solve the current problem (Reisbeck C K, 1989). The basic process of CBR mainly includes four aspects: case retrieval, case reuse, case modification and case study. Among them, the main content of case retrieval is to retrieve the same or similar historical case set from the existing case base, and solve the current problems with the knowledge experience of historical cases. CBR is mainly based on the “similar problem with similar solution”, and it is one of the key technologies of case based reasoning to retrieve the target case which is similar to the source case.

The template case of finite element analysis includes the relevant knowledge and experience of analysis information, modeling characteristic information and attribute information. Because of the lack of analytical thinking, the new users will try to find some similar historical analysis cases and learn from them to find suitable method. It is the key for case retrieval to establish the finite element analysis template case library.

Finite element analysis template retrieval based on CBR can be divided into four steps: firstly, retrieving similar cases; then, solving the current problem with the case of information and knowledge; revising the solution; finally, learning experience knowledge in the process of case solving and coping with the needs of the case retrieval in the future. The case retrieval process is illustrated in Figure 1. The main standard of case retrieval is that the source case and the target case are labeled with the same semantic structure tree, so that the

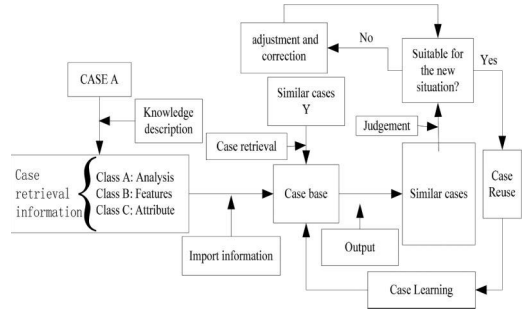

Figure 1. Framework of CBR.

structure and content are comparable in form. For example, source case A is indexed according to the basic information of the case. Case basic information includes analysis information, modeling characteristic information and attribute information. These details are respectively marked using the semantic annotation, and the corresponding semantic annotation file is the input for the case base. A higher matching target case Y will be found by the search algorithm and reach the solution of case A.

2 RESEARCH STATUS

CBR is an important technology in the field of artificial intelligence. As early as the end of 1970s, some scholars have studied CBR, and the early CBR thought comes from the Rog Schank (Sha Zhongyong, 2014). In 1983, Janet Kolodner adopted the idea of Rog Schank, and developed

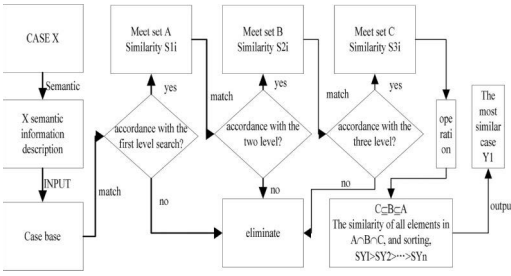

Figure 3. Three-level retrieval.

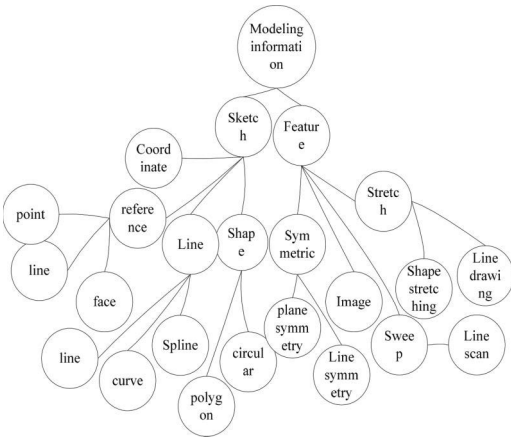

Figure 4. Feature semantic tree.

ontology semantic tree. The knowledge ontology is constructed according to the relevant field knowledge of FEA, case information is conceptualized and semantic, so that each case has the same semantic standard. So, there is a semantic hierarchy and semantic distance relationship between cases.

Taking the modeling feature information of the case as an example, the semantic relation of model feature information is constructed, as shown in Figure 4. Semantic similarity can be divided into two parts: direct similarity and indirect similarity. Direct similarity can be obtained according to the depth and distance between the semantic nodes; indirect similarity is a similar degree between the upper root nodes of the semantic node. This paper calculates the semantic similarity based on the inheritance relationship.

4.1 Calculation of direct similarity

Definition 1. The level of the semantic node in the semantic ontology tree is called the semantic depth,

and it is denoted as f . The maximum depth of the semantic tree is denoted as m . In the semantic tree, the number of line segments that are connected to the shortest path of the two semantic nodes is called the semantic distance, denoted as d .

The ontology semantic tree is constructed by model modeling information; its each node represents certain semantic information. The ontology semantic tree describes the relationship of the position and the information between semantic. In the model information semantic tree, the total depth of the tree is $m = 4$, and the direct similarity can be obtained from the depth and the semantic distance of the semantic node in the tree structure.

Definition 2. In the semantic tree, when the semantic distance is larger, the similarity is smaller; when the depth difference is smaller, the similarity is bigger. The direct similarity between C_1 and C_2 is defined as,

$$S_{c1, c2} = \frac{a}{d(c1, c2) + a * \max[|f(c1) - f(c2)|, 1]} \quad (1)$$

Among them, $f(c)$ represents the semantic depth of node c ; $d(c1, c2)$ represents the semantic distance of node $c1$ and $c2$; a represents the coordination coefficient, generally take $a = 2$.

Basically, formula (1) is used to calculate the similarity of the information in Figure 4. Comparison of the similarity between the linear correlation information and the spline information is S_{11} . Comparison of the similarity between the linear correlation information and the reference plane is S_{22} . Comparison of the similarity between the linear correlation information and the face is S_{13} . The calculation procedure is as follows:

1. The semantic depth of the linear correlation information and the spline is 4, that is $f(C_{11}) = f(C_{12}) = 4$; the semantic distance is $d(c_{11}, c_{12}) = 2$.
2. The semantic depth of linear correlation information and reference plane information is 4, that is, $f(C_{21}) = f(C_{22}) = 4$; the semantic distance is $d(c_{21}, c_{22}) = 4$.
3. The semantic depth of linear correlation information and the face of the information is 4, that is, $f(C_{31}) = f(C_{32}) = 4$; the semantic distance of $d(c_{31}, c_{32}) = 6$.
4. $a = 2$.

By formula (1), direct similarity is calculated.

$$\begin{aligned} S_{11} &= \frac{a}{d_{(c_{11}, c_{12})} + a * \max[|f(c_{11}) - f(c_{12})|]} \\ &= \frac{2}{2 + 2} = 0.5 \end{aligned}$$

$$S_{i2} = \frac{a}{d_{(c_{21}, c_{22})} + a \times \max[|f(c_{21}) - f(c_{22})|]}$$

$$= \frac{2}{4+2} \approx 0.33$$

$$S_{i3} = \frac{a}{d_{(c_{31}, c_{32})} + a \times \max[|f(c_{31}) - f(c_{32})|]}$$

$$= \frac{2}{6+2} = 0.25$$

4.2 Indirect similarity calculation

Definition 3. The upper node of the semantic node is called as the parent node. Indirect similarity is the similarity of upper nodes, recorded as S_f . The specific algorithm can be used to calculate S_f according to formula (1).

1. The semantic depth of the linear correlation information and the spline is 3, that is, $f(C_{11}) = f(C_{12}) = 3$; the semantic distance is $d(c_{11}, c_{12}) = 0$.
2. The semantic depth of linear correlation information and reference plane information is 3, that is, $f(C_{21}) = f(C_{22}) = 3$; the semantic distance is $d(c_{21}, c_{22}) = 2$.
3. The semantic depth of linear correlation information and the face of the information is 3, that is, $f(C_{31}) = f(C_{32}) = 3$; the semantic distance of $d(c_{31}, c_{32}) = 4$.

$$S_{f1} = \frac{a}{d_{f(c_{11}, c_{12})} + a \times \max[|f_f(c_{11}) - f_f(c_{12})|]}$$

$$= \frac{2}{0+2} = 1$$

$$S_{f2} = \frac{a}{d_{f(c_{21}, c_{22})} + a \times \max[|f_f(c_{21}) - f_f(c_{22})|]}$$

$$= \frac{2}{2+2} = 0.5$$

$$S_{f3} = \frac{a}{d_{f(c_{31}, c_{32})} + a \times \max[|f_f(c_{31}) - f_f(c_{32})|]}$$

$$= \frac{2}{4+2} \approx 0.33$$

4.3 Semantic similarity computation

Definition 4. The semantic similarity should not only satisfy the direct similarity, but also meet the indirect similarity. According to the probability principle, the probability that two conditions are met is equal to the product of both probability. So, the semantic similarity can be obtained by compre-

hensive direct similarity and indirect similarity, Sc representation. So, we define the semantic similarity between two semantic C_1 and C_2 as follows:

$$Sc(c_1, c_2) = S_i(c_1, c_2) * S_f(c_1, c_2) \quad (2)$$

From formula (2), the semantic similarity can be calculated:

$$S_{c1} = S_{i1} \times S_{f1} = 0.5 \times 1 = 0.5$$

$$S_{c2} = S_{i2} \times S_{f2} = 0.5 \times 0.33 = 0.165$$

$$S_{c3} = S_{i3} \times S_{f3} = 0.25 \times 0.33 = 0.0825$$

According to the above results, the position relation between a line and a spline in the semantic tree is that two nodes have the same parent node, so the similarity between the two is largest in line with the actual situation; linear relationship with the rest of the two are consistent in common sense. This method considers the semantic relation from the semantic level and structure, which makes the case matching more practical.

In the actual situation, the case similarity calculation includes the local similarity computation and the global similarity computation. The global similarity is obtained based on the local similarity according to the different weight influence [10]. There are two FEA cases X and Y; $X = \{P_x, Q_x, F_x\}$ and $Y = \{P_y, Q_y, F_y\}$; P is the case analysis information, Q is the model characteristics information, F is the case attribute information. P_x is the case of X analysis information, $P_x = \{P_{x1}, \dots, P_{xm}\}$; P_y is the case of Y analysis information, $P_y = \{P_{y1}, \dots, P_{yn}\}$. In the same way, model characteristic information and attribute information are expressed. The case X and Y global similarity is $S(X, Y)$, that is the case similarity.

$$S(X, Y) = \left[\sum_{i=1}^{\min(m,n)} w_i \max Sc(XPi, YPi) + \sum_{j=1}^{\min(r,z)} w_j \max Sc(XQi, YQi) + \sum_{k=1}^{\min(e,u)} w_k \max Sc(XFi, YFi) \right] / \left(\sum_{i=1}^{\min(m,n)} w_i + \sum_{j=1}^{\min(r,z)} w_j + \sum_{k=1}^{\min(e,u)} w_k \right) \quad (3)$$

1. In formula (3), w_i is the weight of the analysis information; w_j is the weight of the feature information; w_k is the weight of the attribute information. According to the priority of the case retrieval, provisions $w_i > w_j > w_k$.

2. $Sc(XP_i, YP_i)$ is the local similarity that is i class analysis information of X and Y .
3. $Sc(XQ_i, YQ_i)$ is the local similarity that is i class feature information of X and Y .
4. $Sc(XF_i, YF_i)$ is the local similarity that is i class attribute information of X and Y .

5 CONCLUSION

The ultimate goal of the CBR finite element template is to extract the solution of the matching case, and obtain a correct solution to achieve the case retrieval according to the related parameter information of the source case. This paper attempts to use semantic to express all analysis cases by integrating an ontology semantic tree in the case-based reasoning system, and establish the semantic structure and the relationship of case information. In this way, the similarity algorithm based on priority is proposed. The system is easy to determine the most matching case by comparing the similarity value, and the case retrieval is achieved.

Improved reduction of graphene oxide through femtosecond laser pulse trains

Ruyu Yan, Pei Zuo & Xiaojie Li

Laser Micro/Nano Fabrication Laboratory, School of Mechanical Engineering, Beijing Institute of Technology, Beijing, China

ABSTRACT: We report a novel and effective reduction method of graphene oxide films using femtosecond laser double-pulse trains. Femtosecond laser reduction of graphene oxide films under ambient air by using three laser processing approaches: (1) 1 KHz laser pulses, (2) 76 MHz laser pulses, and (3) 76 MHz double-pulse trains were investigated for comparison. As characterized by X-ray photoelectron spectroscopy, scanning electron microscopy and Raman techniques, femtosecond laser double-pulse trains with repetition rates of 76 MHz and a delay time of 3 picosecond could decrease the content of oxygen atoms in graphene oxide films from ~33.3% to ~15.1% and maintain the integrity of reduced graphene oxide sheets, which demonstrated the most effective reduction. This research adequately reveals the high-efficient reduction and patterning ability of fs laser double-pulse trains on graphene oxide for further large-area applications in various fields.

1 INTRODUCTION

Since the discovery of graphene in 2004, extensive studies regarding the synthesis of this promising material have been reported for widespread applications (Zhu et al. 2010). The production of graphene-based materials with various dimensions, quality and patterns is crucial for the market of graphene (Novoselov et al. 2012, Xiong et al. 2014). Significant advances in this field have been achieved, including growth by chemical vapor deposition, thermal or liquid phase exfoliation of graphite, and reduction of Graphene Oxide (GO) (Compton et al. 2010). GO is an electrical insulator which contains numerous Oxygen-Containing Groups (OCGs). Altering the OCGs of GO through chemical, thermal or photo reduction could restore its electrical properties and make it close to graphene (Chen et al. 2012). Among these reduction methods, photo-reduction, especially laser reduction, displays particular superiority because of its flexible, low-cost, eco-friendly and high-efficiency properties (Strong et al. 2012).

Femtosecond (fs) laser has been broadly adopted for high precision, high quality, flexible, and three-dimensional micro/nanoscale fabrication (Deng et al. 2015). Recently, femtosecond (fs) laser reduction and patterning of GO films has been reported. For instance, graphene microcircuits were created on GO films by direct fs laser reduction with 80 MHz repetition rates according to preprogrammed patterns (Zhang et al. 2010). In addition, fabrication of highly conductive graphene layers on flexible substrates were realized by

fs laser nonthermal reduction of GO films (Kymakis et al. 2013). However, the reduction degree and the integrity of the graphene lattice in reduced Graphene Oxide (rGO) films via fs laser were still restricted when compared with those reduced by continuous (El-Kady et al. 2012) or long pulse (Guo et al. 2012) lasers. Hence, further study on the improvement of reduction degree and integrity of rGO layers using fs laser is necessary.

Fs laser pulse trains technique which is based on electron dynamics control by using temporally shaped fs laser, has been reported to hold great advantages in the fabrication of ripples (Shi et al. 2013), high-quality concave microarrays (Zhao et al. 2015), and many other micro/nanostructures. In this work, we proposed an effective reduction method by using fs laser double-pulse trains with 76.08 MHz repetition rates (2M-fs laser), which has not been reported previously. Conventional fs laser with 1 kHz (K-fs laser) and 76.08 MHz (M-fs laser) repetition rates were studied for comparison. We investigated 2M-fs laser reduction of GO films by changing the delay time (Δt) between two subpulses. Experiment results demonstrated obvious improvement of reduction by 2M-fs laser with a Δt of 3 picosecond (ps).

2 MATERIALS AND METHODS

2.1 Preparation of graphene oxide films

In our experiments, the freestanding GO films with ~30 μm thickness were prepared by vacuum

Figure 1. Schematic diagram of the Michelson interferometer.

filtration of GO suspensions (XFNANO Advanced Materials Supplier, XF008). The dried GO films were peeled off from the filter membrane directly.

2.2 Experimental set-up

A regeneratively amplified Ti:Sapphire laser system (Spectra Physics, Inc.) was used to deliver 50 fs linearly polarized laser pulses with 800 nm central wavelength. Three kinds of laser sources: (1) K-fs laser, (2) M-fs laser and (3) temporally shaped 2M-fs laser were investigated. The reduced GO samples were respectively identified as K-rGO, M-rGO and 2M-rGO by the three types of laser sources we used. The fs laser double-pulse trains were generated via a Michelson interferometer which consisted of a beam splitter, a fixed reflector and a moveable reflector (Fig. 1). The delay time between the two subpulses had an accuracy of 66.7 fs. The splitting ratio for the double pulses was 50:50.

The GO samples were mounted on a computer-controlled, six-axis motion stage (M-840.5DG, PI, Inc.) with a maximum adjustable speed of 2 mm/s. The three kinds of laser beams were normally incident to the surfaces of GO samples under ambient air by a microscope objective lens ($5\times$, N.A. = 0.15). The energy of fs laser beam was measured before the objective lens by a power meter (Newport Corporation). Surface morphology was studied by Scanning Electron Microscopy (SEM). X-ray photoelectron Spectroscopy (XPS) and micro-Raman spectroscopy (632.8 nm light source) were performed to analyze surface chemical and physical properties.

3 RESULTS AND DISCUSSION

3.1 K-rGO

Differences between pristine GO and rGO could be observed clearly in the XPS spectra. As shown

Figure 2. XPS spectra of (a) pristine GO, (b) K-rGO under 1 overlapping K-fs pulses reduction, and (c) K-rGO under 100 overlapping K-fs pulses reduction.

Table 1. XPS components for different samples, normalized to the C-C peak intensity.

Sample	C-C	C-O	C = O
GO	53.0%	42.8%	4.2%
K-rGO (1)	55.2%	41.5%	3.3%
K-rGO (100)	59.7%	39.3%	1.0%
M-rGO	63.1%	34.7%	2.2%
2M-rGO (0 ps)	63.9%	34.1%	2.0%
2M-rGO (3 ps)	70.1%	29.3%	0.6%

in Figure 2, the C1s spectra of GO and rGO were decomposed into three peaks, which corresponding to C-C (284.6 eV), C-O (286.6 eV) and C = O (288.5 eV) peaks, respectively (Guo et al. 2012). For pristine GO, the content of oxygen atoms was as high as $\sim 33.3\%$ and the percentage of C-C bond was $\sim 53.0\%$ (Figure 2a). After 1 overlapping K-fs pulses reduction with laser energy of 0.5 μJ , the content of oxygen atoms slightly decreased to $\sim 28.9\%$. As shown in Figure 2b and Table 1, the contents of C-O and C = O bonds were partially reduced. After 100 overlapping K-fs pulses irradiation, the content of oxygen atoms could further decrease to $\sim 23.0\%$ (Fig. 2c), and the percentage of C-C bond was increased to $\sim 59.7\%$. The oxygen content of K-rGO could be reduced by increasing the overlapping number of pulses and tuning the laser energy. However, the effect of laser energy was weak. Hence, the reduction efficiency of K-fs laser was relatively low because multi-pulse overlap was necessary for a better reduction degree.

Additionally, K-fs laser reduction of OCGs in GO films was accompanied with the destruc-

Figure 3. SEM images of typical morphologies for K-rGO respectively under (a) 1, (b) 10 and (c) 100 pulses overlapping K-fs laser reduction.

Figure 4. SEM images of M-fs laser ablation of GO films. (a) M-rGO area with silver gray color; (b) comparison between M-rGO surface (left) and pristine GO surface (right); (c) enlarged image of M-rGO surface. The laser energy was ~ 0.13 nJ, corresponding to a measured laser power of ~ 10 mW.

tion of graphene sheets, which was a huge drawback for its electronics applications. Figures 3a-c showed the morphologies of K-rGO films respectively under 1, 10 and 100 pulses overlapping K-fs pulses reduction with laser energy of $0.5 \mu\text{J}$. SEM images indicated that the structural integrity of rGO sheets obtained by K-fs laser reduction was rather poor. The conductivity of K-rGO would be greatly restricted even though the OCGs could be removed partly. Lower laser energy could benefit the integrity of K-rGO layers, however, the reduction degree and reduction efficiency would become much lower.

3.2 M-rGO and 2M-rGO

To achieve effective reduction and maintain the integrity of rGO sheets, we studied the reduction of GO films by M-fs laser, which had ultrahigh repetition rates and ultralow pulse energy. The overlapping number of pulses was limited by the translational speed of the six-axis motion stage. High laser energy could arouse obvious ablation of GO films, which was not conducive to maintain its structural integrity. Meanwhile, low laser energy was insufficient for effective reduction. Therefore, after carefully studying the effect of laser energy and overlapping number of pulses on GO films, laser energy of ~ 0.13 nJ, scanning speed of $2000 \mu\text{m/s}$, and line interval of $5 \mu\text{m}$ ($\sim 1.1 \times 10^6$ overlapping number of pulses) were adopted for further study.

Figure 4b showed the comparison between M-rGO surfaces (silver gray area) and GO surfaces (dark area). Compared with K-rGO (Fig. 3), the reduction region in M-rGO could maintain intact. Furthermore, the reduction degree and efficiency by using M-fs laser were much higher than those by using K-fs laser. The content of oxygen atoms could decrease to $\sim 20.2\%$, and the content of C-C bond could increase to $\sim 63.1\%$. The accumulation of maxi-multiple pulses with ultralow single pulse energy by using M-fs laser induced effective reduction of GO films without surface damage to M-rGO layers.

Based on the good reduction effect of M-fs laser on GO films, we further investigated the reduction effect of 2M-fs laser, which has not been studied previously. The same laser energy (~ 0.13 nJ) was adopted for clearer comparison. As illustrated in Table 2, the content of oxygen atoms decreased gradually from $\sim 19.9\%$ when $\Delta t = 0$ ps to $\sim 15.1\%$ when $\Delta t = 3$ ps. Specifically, the proportion of C-C band increased from ~ 63.9 to $\sim 70.1\%$ (Fig. 5). Some residual OCGs were known to be advantages for numerous electrochemical redox reactions because OCGs could aid electron transfer (Griffiths et al. 2014). The morphologies of 2M-rGO with different delay times were almost the same as those of M-rGO with the same laser energy.

Raman spectra of GO and 2M-rGO with different delay times were analyzed to investigate the reduction effect of 2M-fs laser (Fig. 6). Raman spectra of GO films displayed obvious *D* and *G* peaks at ~ 1350 and $\sim 1591 \text{ cm}^{-1}$, respectively. The *D* peak was induced by structural disorder, and the *G* peak was the in-plane

Table 2. The content of oxygen atoms in 2M-rGO samples with increasing delay times.

Delay time	0 ps	0.5 ps	1 ps	3 ps
Oxygen atoms	19.9%	19.7%	18.2%	15.1%

Figure 5. XPS spectra of 2M-rGO reduced by 2M-fs laser with delay time of (a) 0 ps and (b) 3 ps.

Figure 6. Raman spectra of GO and 2M-rGO with different delay times.

vibration of the C atoms sp^2 network (Kymakis et al. 2013). GO displayed strong fluorescent background. The background fluorescence in the Raman spectra of 2M-rGO was significantly quenched (Senyuk et al. 2015), indicating effective reduction of GO. There was no significant shift of *D* and *G* bands or change of full width at half maximum of the *G* band among GO, 2M-rGO ($\Delta t = 0$ ps) and 2M-rGO ($\Delta t = 3$ ps). The ratio between *D* and *G* peak intensities (I_D/I_G) increased from 2.41 of pristine GO to 2.65 of 2M-rGO ($\Delta t = 0$ ps), which indicated a slight increase of defects after reduction. After 2M-fs ($\Delta t = 3$ ps) laser reduction, the I_D/I_G ratio of 2.52 was smaller than that of 2M-rGO ($\Delta t = 0$ ps). The more effective removal of OCGs by using 2M-fs ($\Delta t = 3$ ps) laser was responsible for this phenomenon, as we verified by using XPS.

4 CONCLUSIONS

In summary, we studied fs laser reduction of GO films by using three laser processing approaches: (1) 1 KHz fs pulses, (2) 76 MHz fs pulses, and (3) 76 MHz fs laser double-pulse trains. A direct and robust comparison for reduction effect of the three methods was performed. As characterized by XPS, SEM and Raman techniques, 76 MHz fs laser double-pulse trains with delay time of 3 ps was the most effective reduction condition in our experiments, which could decrease the content of oxygen atoms from ~33.3% to ~15.1% and maintain the integrity of rGO films. In addition, the reduction efficiency of 2M-fs laser was much higher than K-fs laser, demonstrating its high-efficient and large-area reduction as well as patterning ability. This study opens up alternative routes for fs laser reduction of GO with superior reduction effect and none surface damage, indicating predictable widespread applications of fs laser pulse trains for processing GO materials.

A nanoparticle-decorated silicon substrate for SERS via circularly polarized laser one-step irradiation

Ge Meng, Peng Ran & Yongda Xu

Laser Micro/Nano Fabrication Laboratory, School of Mechanical Engineering, Beijing Institute of Technology, Beijing, P.R. China

ABSTRACT: A simple and efficient approach to obtain nanostructured silicon substrates that are uniformly decorated with silver nanoparticles for surface enhanced Raman scattering by using circularly polarized femtosecond laser one-step irradiation in water is reported. The silver nanoparticles are produced by femtosecond laser photoreduction, with a diameter of 40–80 nm in the majority, thereby accounting for 75.6% and the mean diameter is around 66 nm. The irradiated surfaces exhibit excellent SERS performances with a maximum enhancement factor of up to 7.69×10^7 when Rhodamine 6G is used as the probe molecule, which presents a huge potential for trace detection. The nanostructured silicon surfaces decorated with silver nanoparticles can confine and enhance the Raman excitation laser through localized surface plasmon resonance, which played a determined role in such signal enhancement.

1 INTRODUCTION

In 1974, Fleischmann et al. (1974) acquired the Raman spectra of the monolayer pyridine for the first time by using a roughened silver electrode. Since then, Surface Enhanced Raman Scattering (SERS) has been widely researched for several decades (Jeanmaire et al. 1977, Ding et al. 2016, Wei H & Xu H 2013). The following two primary mechanisms are established to explain the enhanced Raman scattering: electromagnetic theory and chemical theory. In terms of electromagnetic theory, the localized surface plasmon resonance is regarded as the main reason for enhanced Raman scattering. In terms of chemical theory, the charge transfer between the chemisorbed species and the metal surface play a significant role in signal enhancement (Cialla et al. 2011). In this work, a roughened silicon surface covered with silver nanoparticles is investigated to enhance the Raman scattering primarily via the electromagnetic mechanism.

Nanostructures enhance the scattering signals via increasing the surface roughness and facilitating the generation of “hot spots”, which usually exist between the adjacent noble metal nanoparticles and could greatly enhance the electromagnetic field around them. Femtosecond (fs) laser direct writing has been proven to be an efficient approach to acquire such nanostructures for SERS (Yang et al. 2014, Jiang et al. 2012, Zhang et al. 2013, Diebold et al. 2009). In our previous study, the nanoripple-roughened surface and nanopillar-

roughened surface for SERS via linearly polarized fs laser have been fully studied, which exhibit a good SERS performance (Lin et al. 2009, Yang et al. 2015). However, to the best of our knowledge, the circularly polarized fs laser that is used to fabricate the SERS-active substrate has not been reported by far. And as we know, the morphologies and properties of the surface that is fabricated by using circularly polarized laser will be definitely different from that fabricated by using linearly polarized laser (Yasumaru et al. 2003, Varlamova et al. 2006, Huang et al. 2008, Zhu et al. 2006).

In this study, we present a one-step method for fabrication of silver nanoparticles decorated on the structured silicon surface by using circularly polarized fs laser irradiation in silver nitrate solution (AgNO_3) and demonstrate its ability for SERS for the first time. The silver nanoparticles are uniformly formed on the nanostructured silicon surface with a mean diameter of 66 nm, which is suitable for exciting localized surface plasmon at the visible light range for related applications. When compared to the multi-step approaches, the one-step approach we proposed to obtain the silver nanoparticle-covered SERS-active substrates is much more simple and efficient.

2 EXPERIMENTAL SETUP

The fs laser processing system consists of a Spectra Physics Spitfire regenerative amplifier (800 nm, 35 fs, 1 KHz), a computer-controlled six-axis motion

stage, and a Charge-Coupled Device (CCD) camera. The Gaussian profile laser focused by using a plano-convex lens ($f = 100$ mm) was incident normally to the sample surface with a focus diameter ($1/e^2$) of 31.6 μm . A quarter-wave plate was applied to obtain a circularly polarized laser. The morphologies were characterized by using a Scanning Electron Microscope (SEM) and the surface components were analyzed by using energy dispersive X-ray spectroscopy. The Raman spectra were recorded with a Renishaw Raman microscope by using a $50\times$ objective, and the maximum exciting power was 6 mW.

Silicon wafers (111) were cleaned in an ultrasonic bath with acetone for 15 min, rinsed with distilled water for 1 min, and then air-dried at room temperature. The cleaned silicon wafers were fixed in the bottom of a cuvette (25 mm \times 25 mm \times 30 mm) and submerged in a liquid. The height of the liquid layer was about 5 mm. Two silicon samples were raster-scanned in water and silver nitrate solution with circularly polarized laser, respectively. For comparison, two additional silicon samples were prepared. One was raster-scanned in air with circularly polarized laser and another was raster scanned in water with linearly polarized laser. The adjacent distance and the scan speed were 6 μm and 40 $\mu\text{m/s}$, respectively. The dimension of fabrication areas was 100 $\mu\text{m} \times 100$ μm .

3 RESULTS AND DISCUSSION

Figure 1 shows the morphologies of the silicon samples that were obtained under different processing conditions. With circularly polarized laser irradiating in water at a lower laser energy level ($E = 0.3$ μJ), nanoparticles are uniformly formed on the silicon surface (Fig. 1a), which is very different from the high spatial frequency LIPSS (HSFL) structures (mean period of 120 nm) that are obtained with linearly polarized laser (Fig. 1d). The nanoparticles are distributed on the silicon surface tightly and uniformly with a mean diameter below 100 nm, which reveals a potential for high sensitive SERS. However, when the laser energy increases to 0.6 μJ , nanoparticle-covered microholes appear (Fig. 1b). The mean diameter of these nanoparticles (covered on microholes) is around 150 nm and the nanoparticles are distributed unevenly. When the silicon is irradiated in air with circularly polarized fs laser at a laser energy of 0.6 μJ , distorted microstructures covered by floccules are obtained (Fig. 1c).

To demonstrate the ability of the nanoparticle morphology for SERS, we irradiated the silicon sample in 0.01 M AgNO_3 solution with circularly polarized fs laser. As shown in Figure 2a, the

Figure 1. SEM images of the irradiated silicon surfaces by fs laser: (a) circularly polarized, in water, $E = 0.3$ μJ ; (b) circularly polarized, in water, $E = 0.6$ μJ ; (c) circularly polarized, in air, $E = 0.6$ μJ ; and (d) linearly polarized, in water, $E = 0.3$ μJ . The scan speed is 40 $\mu\text{m/s}$. The insets are local enlarged pictures.

nanostructures are covered by using silver, which is acquired due to photoreduction. Besides, silver nanoparticles are also observed, which create “hot spots” and cause enhanced Raman scattering. In fact, fs-laser-ablation-induced chemical reduction dominates the synthesis of silver nanoparticles. When an fs laser source irradiates the silicon surface, silicon plasma plumes with high temperature and pressure are formed and cooled quickly to generate silicon nanoparticles. And then, the reactive silicon nanoparticles are easily oxidized, thereby contributing to the reduction of Ag(I) to Ag through the following process (Jiménez et al. 2010):

Figure 2b shows the components of the area 1 in Figure 2a. The weight ratio of Ag is 4.98% and the atom ratio of Ag is 1.35% , which demonstrates that silver is reduced definitely.

The size of the nanostructures has a significant effect on the SERS. And so, we analyzed the particle size distribution, as shown in Figure 3. The mean diameter of the silver nanoparticles is 66 nm. And the number of particles with sizes of around 40 – 80 nm is high, thereby accounting for 75.6% of the total number of particles, which is suitable for localized surface plasmon resonance at the visible light range (Kelly et al. 2003). The interparticle spacing is almost below 100 nm.

Figure 2. Silicon sample that is obtained by using circularly polarized fs laser irradiating in 0.01 M AgNO_3 solution: (a) SEM image of the silicon surface; (b) EDX spectrum of the area 1 in (a).

Figure 3. Size distribution of the silver nanoparticles fabricated by using circularly polarized fs laser.

All of these may contribute to the electromagnetic field enhancement.

Raman spectra of Rhodamine 6G molecules acquired from the SERS substrates, which covered silver nanoparticles, are shown in Figure 4. Four different spots of the substrates were detected. The samples were immersed in 10^{-6} M Rhodamine 6G solution for 90 minutes in order to ensure that more Rhodamine 6G molecules are adsorbed on the roughened surface. Raman spectra of the four different spots are represented by using a red curve (for spot 1), blue curve (for spot 2), magenta curve (for spot 3), and green curve (for spot 4), respectively. The lowest black curve represents the normal Raman spectra of 10^{-2} M Rhodamine 6G outside the processed region, and a weak Rhodamine 6G signal (almost a flat line) is seen. For SERS and normal Raman spectra, the exciting laser powers of the Raman spectrometer were 0.03 mW and 6 mW; and the accumulating times were 10 s and 20 s, respectively. The Enhancement Factor (EF) was evaluated by Baia et al. 2006:

$$EF = \frac{I_{surf}}{N_{surf}} \bigg/ \frac{I_{vol}}{N_{vol}} \quad (2)$$

where I_{vol} and I_{surf} are the normal Raman and SERS intensities in the unit of $\text{mW}^{-1} \text{s}^{-1}$; and N_{vol} and N_{surf} represent the number of molecules detected in the reference sample and on the SERS-active substrate, respectively. The accumulating N_{vol} and N_{surf} were estimated by using the solution concentration method. Table 1 presents the calculated EFs of the four different spots at the Raman peaks of Rhodamine 6G. The Raman scattering is magnified up to 10^7 and the highest EF is 7.69×10^7 , which occurs at the Raman peak 1360 cm^{-1} in the fourth spot.

Figure 4. SERS spectra of different spots on the silver nanoparticle-covered substrate.

Table 1. Enhancement factors at different spots.

Raman shift (cm ⁻¹)	Spot 1	Spot 2	Spot 3	Spot 4
1650	9.89E+06	1.46E+07	2.33E+07	5.96E+07
1510	1.09E+07	1.61E+07	2.56E+07	6.56E+07
1360	1.71E+07	2.10E+07	2.88E+07	7.69E+07
1310	1.30E+07	1.81E+07	2.57E+07	6.03E+07
610	8.09E+06	1.07E+07	1.49E+07	2.54E+07

Our experiments results demonstrate that the nanoparticle-decorated substrates that are fabricated by using circularly polarized fs laser have a great potential for high-sensitive SERS.

4 CONCLUSIONS

In summary, disparate surface nanostructures on the silicon surface have been obtained by using circularly polarized fs laser one-step irradiation in the water/AgNO₃ solution. For the first time, uniformly distributed Ag-coated nanoparticles are fabricated on the silicon surface, and the mean diameter of the nanoparticles is below 100 nm, which are quite different from the LIPSS structures that are obtained by using linearly polarized fs laser. Therein, fs-laser-ablation-induced chemical reduction of silver ions and structuring silicon synchronously play a determined role in such hybrid structures' formation. The unique structures exhibit excellent SERS performance such that the maximum enhancement factor is up to 7.69×10^7 when Rhodamine 6G is used as the probe molecule, which presents a great potential for trace detection and sensing applications.

An experimental study on rotation ultrasound-assisted drilling for high-strength engineering of mechanical connection components

S. Hong

Mechanical Engineering, Dalian Polytechnic University, China

ABSTRACT: To solve the serious wear problem of the drill tool in the drilling process of high-strength engineering of mechanical components with carbon fiber-reinforced composite material, in the conventional drilling and rotary ultrasound-assisted drilling tests have been conducted. The effects to the drilling tool's wear of both guide hole and rotary ultrasonic vibration-assisted drilling, and the axial force and drill torque of the work piece are studied. It is shown in the results that, with an increase in the drilling hole, the wear rate and axial force of the drill tool are increased. The guide hole can be added to effectively reduce the drilling axial force. Rotary ultrasonic vibration-assisted drilling effectively reduces the wear rate, the axial force, and torque of the drill tool. These tests can provide an important preference for researching the high-strength engineering mechanical connectors and carbon fiber-reinforced composite material drilling and drilling tool-processing characteristics.

1 INTRODUCTION

The carbon fiber-reinforced composite material has the advantages of light weight, high strength, high temperature resistance, corrosion resistance, good fatigue resistance, and good anti-vibration performance and mechanical properties. It has been widely used in military, aerospace, engineering machinery, automotive, and other fields (Xun Liu, 2016 & Liu Yang, 2015). With an increase in the high strength and good performance requirements on the connection components of engineering machinery, the new composite difficulty processing materials has been widely used in high-strength connection components of engineering machinery (Ren Shunan, 2013 & Jinyang Xu, 2016). Because the carbon fiber material has a unique high hardness and high strength, which make it more difficult to process, the carbon fiber material has the performance characteristics of long heating time, long processing time, strong axial force and big torque, and easy to cause tool wear (Julian M, 2015 & Shivraman Thapliyal, 2016). The wear of the drilling tool will lead to problems such as tearing, fluffing, roughness, and delamination in hole-drilling. At the same time, the drill tool will be scrapped too quickly, the efficiency will be low, and the economic cost will be high (Jun Cheng, 2015). In view of these problems, many scholars put forward the ultrasonic vibration-assisted method to process the material, and some scholars have carried out the corresponding experimental study. Jing Liu (2012) believes that the effect of RUEM can be beneficial to improve the cutting

force during processing and can increase the use life of cutting tools and improve the accuracy of drilling holes. Pei Z J (2005) studied the influence of rotary ultrasonic machining on the characteristics of brittle materials. Wang Jinming (2006) studied the three kinds of super-hard material on the different carbon fiber-milling tools to obtain a good performance in processing.

In this paper, the high-strength engineering of mechanical connection components of the carbon fiber-reinforced composite material has been studied in Dalian Shenglong Machinery Co., Ltd and our university. The experimental method has been used to analyze the effect of guide hole and rotary ultrasonic vibration on high-strength engineering of mechanical connection components. The experiment can show the axial force and torque of the work piece during the drilling process. The experiment can provide the theoretical guidance for processing of high-strength engineering of mechanical connection components and the carbon fiber-reinforced materials, and it also plays a positive promotion for the special processing of composite materials.

2 DRILLING TEST

2.1 Test equipment

The main test equipment for ultrasonic-assisted drilling is the Ultrasonic 65 device in the WMG high-tech equipment machining center. The other test equipment includes the YE5850 charge amplifier,

A/D converter, and computer. The measurement equipments of the drilling tool's wear include the stereomicroscope, the image scale software called Image Measure, and the JEOLJSM-6380 LV scanning electron microscope.

The ultrasonic driver is mounted on the drill tool holder and it generates a certain frequency of ultrasonic vibration through the piezoelectric effect (see Figure 1). The ultrasonic vibrator is installed in the tool feed direction. In this test, the vibration frequency and amplitude of the ultrasonic vibrator are determined by using the tool. Once the tool is fixed on the holder, the vibration frequency and amplitude of the tool system are fixed. In the application of ultrasonic vibration, the vibration frequency and amplitude will change correspondingly in different drilling processes, and different drilling processes will lead to different surface qualities finally.

2.2 Test materials and methods

The drilling test material is the isotropic, epoxy resin-based, carbon fiber-reinforced composite material; the volume fraction of the carbon fiber is 65%, and the material properties are given in Table 1. The work piece is a connection plate of the carbon fiber-reinforced composite material in the high-strength engineering machinery.

In order to obtain the variation of wear characteristics of the drill tool and the axial drilling force under different conditions, the 1.5 mm diameter guide hole is drilled uniformly on the carbon fiber-reinforced composite work piece, and the main purpose of the guide hole is to reduce the axial thrust in twist drilling. Similarly, in order to test the impact of the guide hole on the cutting edge, and ensure the integrity of the test, the same test has been conducted with no guide hole.

During the test, the cutting speed is set at 150 m/min and the feed rate is 0.06 mm/rev, and the

Peak-to-peak amplitude/ μm	5.4	4.8	5.3	4.4

conventional drilling and rotary ultrasonic-assisted drilling tests are carried out, respectively. The work piece numbers are 1#–10# in the drilling process; when all the hole-drilling processes are completed, a new drill is exchanged for conducting the same drilling processes. An average of five trials is taken for the test results to obtain the final calculated value. The parameters of the rotational ultrasonic-assisted drilling test are respectively given in Tables 2 and 3.

3 TEST RESULTS

3.1 Drilling tool wear

In order to compare the wear effect of the drill tool and wear region, the drill tool is captured by using a ZEISS Axiocam micro-camera. The abrasion area and the wear region are calculated with Matlab.

With an increase in the number of holes in the drilling process, the wear area of the drill tool's flank surface is increased (see Figure 2). For example, in the traditional without guide hole drilling process, the 1# hole wear area is 0.2 mm^2 ; when the all 10 holes are completed, the wear area of the 10# hole is increased to 1.6 mm^2 . However, the tool wear area is 1.19 mm^2 in the rotary ultrasonic-assisted drilling without guide holes process. In the traditional drilling process, the tool wear area is 1.61 mm^2 .

When compared to traditional drilling, the edge wear of the drilling tool has been greatly improved in the rotary ultrasonic-assisted drilling process. When all the 10 holes' drilling processes are completed, the wear of the drilling tool's cutting edge in rotary ultrasonic-assisted drilling is 0.031 mm^2 , while the same wear in traditional drilling is 0.058 mm^2 (see Figure 3).

Figure 2. Graph showing the tool flank wear.

Figure 3. Graph showing the tool's cutting edge wear.

Figure 4. SEM images showing the tool wear.

The conventional drilling and the rotary ultrasonic-assisted drilling are conducted under the without guide hole condition. After all the 10 holes' drilling processes are completed, the wear area of the drill tool is observed by using Scanning Electron Microscopy (SEM). The cutting edge wear of the drilling tool in the traditional drilling process is more severe, while under the same conditions of rotary ultrasonic-assisted drilling, the cutting edge wear of the drilling tool is less (see Figure 4).

3.2 Axial force

The axial force of the drill tool under different conditions are measured and stored by using the Kistler dynamometer with the test instrument. With an increase in the number of drilling holes, the drill tool's axial force increases. The drill tool's axial force in the traditional drilling process is different for different holes. For example, the axial force in hole 1# is 49 N, while the axial force in hole 10# is increased

to 721 N (see Figure 5). The axial forces are almost the same under the with guide hole condition in the conventional drilling and rotary ultrasonic-assisted drilling process. The magnitude of the axial force is obviously higher in the traditional drilling tool than that in the rotary ultrasonic auxiliary drilling under the no guide hole condition. The axial force in the traditional drilling process is 874 N, while the magnitude of the axial force in the rotary ultrasonic-assisted drilling process is only 550 N. Under the with guide hole condition, the ultrasonic vibration in the axial direction is useless; the vibration cannot effectively reduce the drill tool's axial force. Under the no guide hole condition, the ultrasonic vibration can lead to reduction in the magnitude of the drilling tool's axial force, the ultrasonic vibration can reduce drill tool wear and increase the drill tool's service life.

3.3 Torque

The drill torque can be greatly fluctuated in the drilling process, with an increase in the number of drilling holes. The torque has an increasing tendency (see Figure 6). The drill torque is less in the rotary ultrasonic vibration-assisted drilling process than that under the other conditions (the drill torque in the 1# hole is only 28.2 N.cm, while the drill torque in the conventional drilling process is 37 N.cm). The drill torque of the 10# hole in the ultrasonic drilling process is 36.5 N.cm, while the drill torque in the traditional drilling process is 41.4 N.cm.

Figure 5. Graph showing the drilling tool's axial force distribution in the drilling process.

Figure 6. Graph showing the torque changes in the drilling process.

4 CONCLUSIONS

In order to reduce the magnitude of the drilling axial force, the ultrasonic vibration-assisted drilling process combined with the pre-processed guide hole has been used to study the high-strength engineering of machinery connection components of the carbon fiber-reinforced composite material. It is shown in the results that the wear rate of the drilling tool increased with an increase in the number of drill holes; the ultrasonic vibration-assisted drilling process can effectively improve the drilling tool's wear. The magnitude of the drilling tool's axial force in the ultrasonic-assisted drilling process is less than that of the traditional drilling process.

Synthesis of PbO nanosheet-based thin films for all-solid-state supercapacitors

Jun Zhang & Haiyan Xie

Department of Physics, College of Science, Hohai University, Nanjing, P.R. China

Zhaojun Chen

College of Mechanics and Materials, Hohai University, Nanjing, P.R. China

ABSTRACT: In this work, the PbO nanosheet-based thin film was synthesized directly on the indium tin oxide-coated polyethylene terephthalate substrate through the electrodeposition method. The morphology and composition of the products were characterized systematically. The nanosheet-based film was used as a building block to fabricate flexible, All-Solid-State (ASS) SuperCapacitors (SCs) by using the PVA/H₃PO₄ gel as the solid electrolyte. Cyclic Voltammetry (CV), galvanostatic charge–discharge, and electrochemical impedance spectroscopy were carried out to study the electrochemical performance of PbO-based ASS thin film SCs. The results demonstrated that the device deposited at -0.7 V (vs. SCE) exhibited an areal capacitance of $173 \mu\text{F cm}^{-2}$ at $2.0 \mu\text{A cm}^{-2}$, which suggested its potential application as an electrode-active material for SCs.

1 INTRODUCTION

Lead oxide is one kind of semiconductor with a direct band gap energy of ~ 1.9 eV that has important applications in storage batteries, glass industry, and pigments (Shi et al. 2008, Li et al. 2012). PbO nanoparticles had been used as electrode materials for the valve-regulated lead acid battery and had shown improved electrochemical performances, such as excellent discharge capacity and prolonged cyclic life (Wang et al. 2001). The results implied that nanosized PbO would be advantageous as electrode materials in designing high performance SCs. So far, various PbO nanostructures, such as nanoplates, nanostars, nanorods (Ghasemi et al. 2008) and nanotubes (Behnoudnia et al. 2012) had been synthesized by using thermal deposition (Behnoudnia et al. 2012), laser-assisted deposition (Tuncheva & Baleva 1995), solvothermal route (Gao et al. 2013), sonochemical (Sadeghzadeh et al. 2009), and hydrothermal methods (Wang et al. 2013). However, most of these techniques are complex, expensive, and time-consuming, which are against its application in SCs.

In this paper, we report the synthesis of PbO nanostructures by using the simply electrodeposition method and its application as active materials to build ASS thin film SCs. The detailed synthetic procedure is shown in the Experimental section. The results show that the PbO nanosheets deposited at a potential of -0.7 V were almost vertical to the substrate and formed large open channels

between the nanosheets. The nanosheets-based film was used to fabricate ASS SCs by using the PVA/H₃PO₄ gel as the solid electrolyte. Since the configuration avoids the stocking of PbO nanosheets and fully utilizes the surfaces and edges for the Faradaic redox reaction, the PbO-based ASS thin film SCs exhibit an improved electrochemical performance with a high areal capacitance of $173 \mu\text{F cm}^{-2}$ at $2.0 \mu\text{A cm}^{-2}$.

2 EXPERIMENTAL SECTION

2.1 Synthesis of PbO-based thin film

Electrodeposition was performed by using an electrochemical workstation (Kest Wuhan CS300) in a conventional three-electrode mode with a platinum electrode as the counter electrode, a Saturated Calomel Electrode (SCE) as the reference electrode and a piece of ITO-coated PET film ($1.0 \times 2.0 \text{ cm}^2$) as the working electrode. For the deposition of PbO nanostructures, the electrolyte used was an aqueous solution of 5 mM Pb(CH₃COO)₂, 5 mM EDTANa (EthyleneDiamine TetraAcetic acid disodium salt), and 0.1 M KCl. The pH value was adjusted to 3 with 0.2 M HCl. Electrodeposition was carried out under potentiostatic conditions with the electrolyte temperature being kept at 60°C. After deposition, the working electrodes were rinsed in distilled water several times and dried naturally in the atmosphere.

2.2 Fabrication and electrochemical measurements of ASS thin film SCs

ASS thin film SCs were fabricated by stacking two identical PbO thin films adhered with PVA/H₃PO₄ gel electrolyte. Firstly, two pieces of electrodes were painted with PVA/H₃PO₄ gel electrolyte in order to form a thin layer of the electrolyte and were then dried for 24 h at room temperature to remove the redundant water. Secondly, the electrodes were painted with the gel again. After that, the two electrodes were sandwiched with a piece of cellulose membrane to form the ASS thin film SC device. Furthermore, the fabricated device was pressed under definite pressure for 5 min to enhance the interfacial contact of the gel electrolyte with PbO electrodes. The device was dried for another 24 h at room temperature to obtain the ASS thin film SC. The Cyclic Voltammetry (CV), galvanostatic charge–discharge and Electrochemical Impedance Spectroscopy (EIS) properties of prepared devices were evaluated by using a CHI 660D Electrochemical Workstation (Chenhua Co. Shanghai).

The PVA/H₃PO₄ gel electrolyte was prepared as follows (Ma et al. 2014): 6 g of H₃PO₄ was added to 60 mL of deionized water, and then 6 g of PVA powder was added. The whole mixture was heated to 85°C under stirring until the solution became clear.

3 RESULTS AND DISCUSSION

3.1 XRD results

The XRD patterns of the deposited thin film are shown in Figure 1. At -0.7 V (vs. SCE), the phase of the samples is very complicated, the weak peaks are located at 24.707° , 26.602° , and 35.352° corresponding to the tetragonal phase of α -PbO·H₂O (JCPDS No.77-1895), the strong reflections are located at 29.082° , 30.309° , and 35.948° thereby confirming the orthorhombic phase of β -PbO (JCPDS No.77-1971 and JCPDS No.78-1663), respectively. The main reason for multi-phase coexistences in one sample is that the lattice constant of different phase-structured PbO is little different. Small changes of the micro-environment (small changes of the electrolyte concentration near the surface of the deposits or the temperature of the electrolyte) would change the atomic distances and formed the second phase during electrodeposition. The phenomenon is very common during the electrodeposition process (Didier et al. 2014). At -0.8 V (vs. SCE), a new peak appeared at 31.305° , which corresponds to (111) of metallic Pb. While decreasing the deposition potential to -0.9 V (vs. SCE) or -1.0 V (vs. SCE), all diffraction peaks at 31.305° , 36.266° , 52.228° , 62.119° , and 65.236°

Figure 1. XRD patterns of the samples at different electrodeposition voltages: -0.7 V (vs. SCE); -0.8 V (vs. SCE); -0.9 V (vs. SCE); and -1.0 V (vs. SCE), respectively.

matched well with the cubic Pb (JCPDS card no. 04-0686). The results show that -0.7 V (vs. SCE) is the optimal deposition voltage for the formation of PbO nanostructures.

3.2 Surface morphology

Generally, the deposition potential is the most important parameter in the composition and morphology of electrodeposited nanostructures. In order to investigate the morphology evolution along with the electrodeposition potentials, SEM images of the samples are obtained. SEM images of the samples obtained at different voltages show drastic change in their morphologies, as shown in Figure 2. At -0.7 V (vs. SCE) (Figure 2a), the as-prepared products are nanosheets, and most of the nanosheets are perpendicular to the substrates with an edge length of about $10\ \mu\text{m}$. When decreasing the deposition potential to -0.8 V (vs. SCE) (Figure 2b), some nanowires with diameters of about several hundred nanometers are laid flatly on the substrate, and mixed with some Pb octahedron nanoparticles (proved by XRD results). While decreasing the deposition potential to -0.9 V (vs. SCE) or -1.0 V (vs. SCE) (Figure 2c and d), the products present sparsely distributed nanosheets; meanwhile, a layer of compact Pb nanoparticles appeared under the PbO nanosheets, which is consistent with XRD results. To optimize the ASS thin film SCs device properties, all PbO nanosheets thin films were synthesized under the deposition potential of -0.7 V (vs. SCE). Based on previous reported results, the vertically aligned PbO nanosheets film configuration is beneficial for fabricating the ASS SCs device for several reasons: 1) the vertically oriented nanosheet-based film formed large open channels between the nanosheets; the configura-

Figure 2. SEM images of the samples electrodeposited at various deposition potentials: (a) -0.7 V (vs. SCE); (b) -0.8 V (vs. SCE); (c) -0.9 V (vs. SCE); and (d) -1.0 V (vs. SCE).

tion avoids the stocking of PbO nanosheets and fully utilizes the surfaces and edges for the Faradaic redox reaction. 2) The solid electrolyte contacted with all the surfaces of the nanosheets, which is beneficial for the electronic transport during the charge-discharge process, thereby enabling these to be directly used as electrode materials without adding carbon black and binder.

3.3 TEM and EDS

TEM was used to study the morphologies and microstructures of the sample deposited at -0.7 V (vs. SCE). Although the sample displayed a uniform nanosheet-based structure in the SEM image, it is clearly observed that the sample presents two different morphologies (nanorods and nanosheets), as shown in Figure 3a and b. The reason for this is that the amount of nanorods is much smaller than that of nanosheets, and these were interleaved among the nanosheet-based film. High Resolution (HR)-TEM was also performed to study PbO microstructures. Figure 3c shows the HR-TEM image of the nanorods and clear lattice fringes indicated its good crystallinity. The measured d-spacings are 0.31 nm, 0.31 nm, and 0.28 nm as labeled on the image, which were corresponding to the (202), (103), and (220) planes of α -PbO \cdot H₂O. Figure 3d shows the HR-TEM images of the nanosheets, and the measured d-spacings are 0.29 nm and 0.49 nm, which matched well with the (111) and (001) planes of the orthorhombic phase of β -PbO (JCPDS No. 77-1971). The results illustrated that the nanosheets are β -PbO, while the nanorods are α -PbO. It is clear that the size of nanosheets is much bigger than that of nanorods

Figure 3. (a) and (b) TEM images of the sample deposited at -0.7 V (vs. SCE); (c) and (d) HR-TEM images of the nanorod and nanosheet, respectively; (e) and (f) EDS spectra of the nanorod and nanosheet, respectively.

from the SEM image in Figure 2a, and this may explain the diffraction intensity of β -PbO such that it is much stronger than that of α -PbO \cdot H₂O as shown in Figure 1. Furthermore, EDS was also performed to investigate PbO composition. The EDS spectra of the nanorod and nanosheet are shown in Figure 3e and f, respectively. All of these are composed of Pb and O elements (Cu and C signals are obtained from the supporting film). The quantitative EDS results show that the ratio of Pb:O is about 3:4 (Figure 3e) and 1:1 (Figure 3f), which are further evidence that the nanosheets are β -PbO while the nanorods are α -PbO, respectively.

3.4 Supercapacitive studies

ASS thin film SCs were fabricated by stacking two pieces of PbO nanosheet-based films adhered with PVA/H₃PO₄ gel electrolyte. The electrochemical properties of the devices were investigated systematically. Figure 4a shows CV curves of the ASS thin film SC device at scan rates of 5-200 mV s⁻¹ within a potential window of 0-0.5 V, which shows nearly rectangular shape without obvious redox

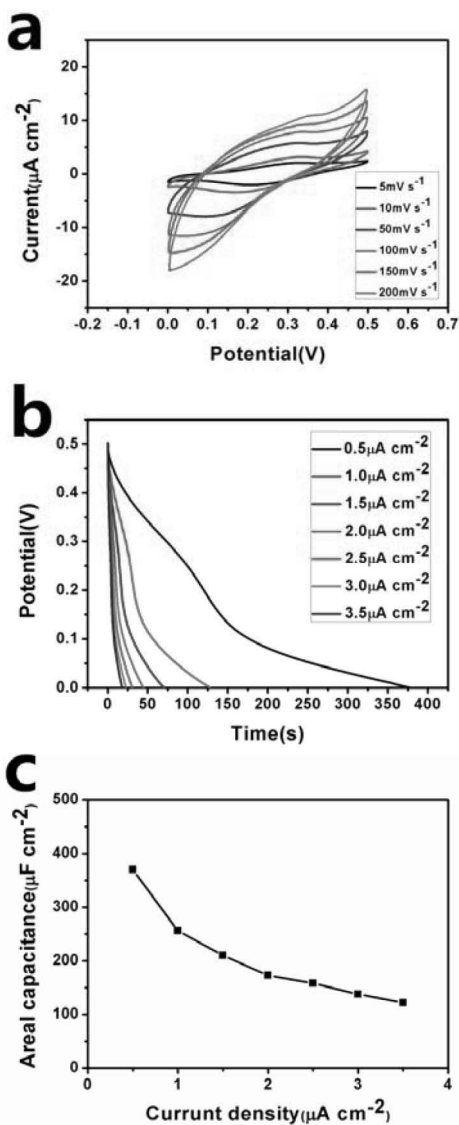

Figure 4. Electrochemical characterization of the PbO-based all-solid state device: (a) CV curves of PbO-SC in a potential range of 0–0.5 V at scan rates of 5–200 mV s^{-1} . (b) Galvanostatic discharge curves of PbO-SC at current densities of 0.5–3.5 $\mu\text{A cm}^{-2}$. (c) Areal capacitance at different current densities.

peaks. With an increase in the scan rate, the scan current is increased; the feature reveals the ideal capacitive and fast charge–discharge behavior of PbO SCs. The CV curves maintained their original shape and reversibility even at high scan rates, thereby suggesting excellent capacitive behavior of PbO SCs. Galvanostatic discharge curves of PbO nanosheet-based thin film ASS SC at various

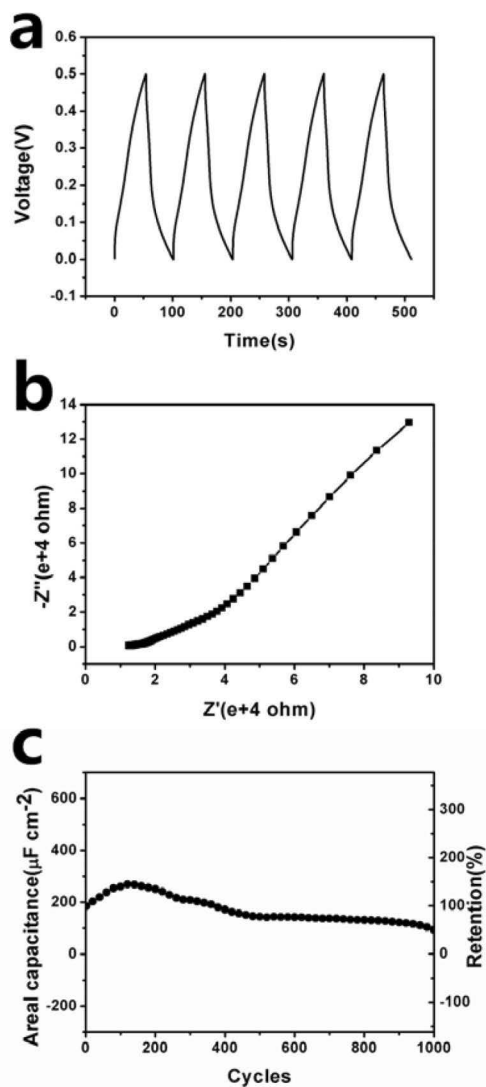

Figure 5. Electrochemical characterization of the PbO-based all-solid state device: (a) Five charge-discharge curves; (b) Nyquist plot of the PbO-SC; and (c) cycling performance at 2.0 $\mu\text{A cm}^{-2}$.

current densities are presented in Figure 4b; the barely IR drop during the discharge process indicates the good capacitive and fast charge–discharge behavior of PbO SCs. Figure 4c shows the corresponding areal capacitances; the calculated areal capacitances of the device are 370, 256, 210, 173, 158, 138, and 122 $\mu\text{F cm}^{-2}$ at 0.5, 1.0, 1.5, 2.0, 2.5, 3.0, and 3.5 $\mu\text{A cm}^{-2}$, respectively. Figure 5a shows five charge–discharge curves, the symmetry of the charge and discharge characteristics declare its excellent capacitive behavior, and the slope of the

curves changing at a high cell voltage reveals the occurrence of the redox process. Figure 5b shows the Nyquist plots of PbO nanosheets-based SC ranging from 100 kHz to 0.01 Hz. The Nyquist plot consists of a flat base in high frequency regions and a linear shape in low frequency regions. This plot features a high phase-angle (exceeding 45°) impedance plot, thereby indicating a fast ion transfer behavior in PbO nanosheets (Liu et al. 2010).

Excellent working stability under thousands of cycles is expected for SCs in practical applications. Further studies on the cycling stability of the PbO nanosheets-based SCs were performed by using the galvanostatic charge–discharge technique at a current density of 2.0 $\mu\text{A cm}^{-2}$. Figure 5c shows the areal capacitance as a function of the cycle number, the areal capacitance increased during the initial 150 cycles, which is attributed to the gradual increase of the electrochemically active surface area. After 150 cycles, the capacitance decreases gradually and tends to stabilization. The PbO SCs exhibit capacitance retention with 94 $\mu\text{F cm}^{-2}$ after 1000 cycles, which maintains only 50.8% of the initial value. The PbO SCs has an unsatisfactory cycling stability performance. The problem may be that the stability of the reversible electron transfer process between PVA/H₃PO₄ and PbO is not good enough.

4 CONCLUSIONS

In summary, we demonstrated a facile electrodeposition method for the synthesis of PbO nanosheet-based thin film directly on the ITO-coated PET substrate. Through a series of structural characterizations, it is confirmed that the sample deposited at -0.7 V (vs. SCE) mainly has the phase of β -PbO nanosheets. ASS thin film SCs were fabricated by using two identical PbO thin films as the working electrode materials and PVA/H₃PO₄ gel as the solid electrolyte. The PbO nanosheet-based thin film SC device exhibited an areal capacitance of 173 $\mu\text{F cm}^{-2}$ at 2.0 $\mu\text{A cm}^{-2}$. The good electrochemical properties of the PbO nanosheet-based thin film SC device are attributed to its vertically aligned configuration, which formed large open channels between the nanosheets and avoided the stocking of PbO nanosheets and fully utilized the surfaces and edges for the Faradaic redox reaction.

Although the long life stability of the device needs to be improved in the future, the vertically aligned design for electrode materials may provide a general route for high-performance ASS SCs.

A large-scale SERS substrate fabricated by using femtosecond laser with superhydrophobicity

Yongda Xu, Ge Meng & Peng Ran

Laser Micro/Nano Fabrication Laboratory, School of Mechanical Engineering, Beijing Institute of Technology, Beijing, P.R. China

ABSTRACT: In this study, a simple method is proposed to fabricate surface-enhanced Raman scattering substrates on Cu surfaces by using the crossed femtosecond laser direct-writing technique. As the scanning speed increases, the nanostructured surfaces exhibit superhydrophobic properties with the contact angle showing a generally rising tendency. With the speed of 2000 $\mu\text{m/s}$, we can acquire an area of $2500 \times 2500 \mu\text{m}^2$ in just 4 minutes at a static contact angle of 151° , which makes it a potential for large-area fabrication. After being modified with Au nanoparticles, the Cu substrates display high SERS sensitivity with an enhancement factor up to 3.60×10^9 . Possible reasons for the high sensitive SERS involve: 1) the Au nanoparticles with the size of 60 nm are uniformly distributed on the nanostructure-roughened Cu surfaces which induce strong localized surface plasmon resonance; and 2) due to the superhydrophobicity of the substrates, the detected molecules are confined into a small area, which makes the concentration increase equivalently.

1 INTRODUCTION

Superhydrophobic surfaces attract much attention, because of its practical applications such as self-cleaning (Ding et al. 2011, Sas et al. 2012), oil-water separation (Tai et al. 2014, Singh A.K. & Singh J.K. 2016), and anticorrosion (Leon et al. 2012, Shenton 2009). In the past few decades, many methods were successfully used to fabricate superhydrophobic surfaces, such as chemical etching (And & Shen 2005, Luo et al. 2011), spin coating (Xu et al. 2012), and laser fabrication (Baldacchini et al. 2006). The superhydrophobic Surface-Enhanced Raman Scattering (SERS) substrate is another important research field due to its ability of breaking through the detection limit by shrinking the aqueous solution to a small area. However, the fabrication of the superhydrophobic SERS substrate lacks controllability and consumes much time just as chemical etching would, which is not suitable for industrial applications. Femto-Second (fs) laser surface nanotexturing has been proved to be an efficient and controllable technology for fabricating various materials, which has a wide range of applications in modifying physico-chemical properties of the surfaces.

In this study, we have obtained high sensitive SERS Cu substrates with superhydrophobicity by using fs laser one-step irradiation. As the scanning speed increases, the contact angles of the roughened Cu surfaces show an increasing tendency, thereby reaching up to 151° at a scanning speed

of 2000 $\mu\text{m/s}$. Au nanoparticle colloids with the diameter of 60 nm are used to acquire “hot spots” on the roughened surfaces and strong Raman scattering signals are detected with an enhancement factor of 3.60×10^9 , due to the combination of strong localized plasmon resonance and superhydrophobicity.

2 EXPERIMENTAL SETUP

A copper sample with a size of 10 mm \times 10 mm \times 1 mm is cleaned in an ultrasonic bath with acetone for 30 minutes and then rinsed by using deionized water. The cleaned Cu wafer is fixed on the six-axis motion stage. The fs laser is incident normally to the Cu surface and this is achieved by using a plano-convex lens ($f = 100 \text{ mm}$) with a spot size of $\sim 30 \mu\text{m}$. The total power of the fs laser used to process is 100 mW. After processing, the morphologies of the processed Cu wafer are characterized by using Scanning Electron Microscopy (SEM) and its superhydrophobicity is measured by using an optical contact angle measuring device. And then, the nanostructured Cu sample is immersed in Au nanoparticle colloids for assembly. Rhodamine 6G (R6G) with the concentration of 10^{-7} M is employed for the Raman signal detection. Raman spectra are obtained by using a Ramanscope (inVia, Reflex, Reinshaw) with an exciting power of 6 mW, a wavelength of 632.8 nm, and a $50 \times$ objective.

3 RESULTS AND DISCUSSION

The Cu sample is scanned line-by-line by using the laser in the horizontal direction (x direction) and then in the vertical direction (y direction). Figure 1 shows the typical SEM micrograph of the nanostructures formed on the Cu surface with a laser power of 100 mW. Figure 1a–d present the surface morphologies of Cu substrates, which are processed at different scanning speeds of 500 $\mu\text{m/s}$, 900 $\mu\text{m/s}$, 1300 $\mu\text{m/s}$, and 2000 $\mu\text{m/s}$, respectively. After processing, tidy ravines appear on the Cu surface. In the case of low scanning speeds, large irregular microstructures are produced on the surface. With an increase in the scanning speed, the depths of the ravine become shallow intuitively and a large number of nanoscale spherical protrusions are present on the surface.

The wettability of the processed Cu surface is measured by using static water contact angle measurement, as exhibited in Figure 2. The Contact Angle (CA) for the roughened Cu shows a generally rising tendency with an increase in the scanning speed. When the scanning speeds are 1300 $\mu\text{m/s}$ and 2000 $\mu\text{m/s}$, the CAs of processed areas are beyond 150° , which reveals superhydrophobic properties. The apparent increasing of CAs can be ascribed to the increasing number of the nanoscale spherical protrusions, which prevents the water droplet from penetrating into the surfaces, as is shown in Figure 3. It is consistent with the Cassie model (Guo et al. 2007), which described that droplets are suspended across the large amount of protrusions and air is trapped between them, thereby resulting in a higher CAs.

Figure 1. Surface morphologies of the Cu substrates processed by using fs laser at different scanning speeds: (a) 500 $\mu\text{m/s}$, (b) 900 $\mu\text{m/s}$, (c) 1300 $\mu\text{m/s}$, and (d) 2000 $\mu\text{m/s}$.

Figure 2. CAs of the laser-processed areas on the Cu substrate at different scanning speeds.

Figure 3. Enlarged surface morphologies of the Cu substrate processed by using fs laser at different scanning speeds: (a) 500 $\mu\text{m/s}$ and (b) 2000 $\mu\text{m/s}$.

It was confirmed that noble metal nanoparticles, such as gold, silver, and copper, can exhibit localized Surface Plasmon Resonance (SPR), which produces strong extinction and scattering spectra for SERS enhancement (Haynes et al. 2005, Kneipp et al. 2006). And then, a simple method that requires no additional equipment is used to obtain the SERS substrate. We chose the substrate that was obtained at the scanning speed of $2000 \mu\text{m/s}$ as the sample, thereby looking forward to enhancing the Raman signal via superhydrophobic properties. The Cu substrate was decorated with Au nanoparticles by immersing the sample in Au nanoparticle colloids for 2 hours to enable the self-assembly of Au nanoparticles on the roughened Cu surface. The Au nanoparticles with the diameter of 60 nm adhere on the nanostructures, which cause “hot spots”, as shown in Figure 4. Some studies have indicated that the nanogaps

Figure 4. SEM pictures of the Cu substrate modified with Au nanoparticles. The local enlarged picture is shown in (b).

between nanoparticles play an important role in SERS enhancement (Tong & Käll 2014). As shown in Figure 4b, the nanogaps of Au nanoparticles are small enough to exhibit high localized plasmon resonance. Consequently, the proper diameter of the nanoparticles and the small nanogaps between the Au nanoparticles give rise to strong electromagnetic field enhancements, thereby leading to a high enhancement factor.

A droplet of R6G solution is added to the Au nanoparticles-decorated superhydrophobic Cu surface and natural evaporation is allowed to occur. The concentration of the R6G is 10^{-7} M . After solvent evaporation, the droplet is limited to a small area on the surface of the Cu substrate, which equivalently increases the concentration of R6G. Raman spectra of R6G molecules obtained from the Cu-nanotextured substrate decorated with Au nanoparticles are shown in Figure 5. Three spots were randomly selected in the area where R6G shrinks and evaporates. The purple curve of spot 1 shows the highest enhancement. The black curve represents the measured SERS spectra of 10^{-2} M R6G in the plain Cu surface. Obviously, the Cu substrates fabricated by fs laser and then modified by Au nanoparticles exhibit strong Raman signal intensity.

For obtaining Raman spectra in the fabricated regions and normal Raman spectra in the plain Cu surface, the Raman spectrometer laser powers were 0.6 mW and 6 mW ; and the accumulated time was 10 s . The SERS EFs can be evaluated by the following equation (Hamad et al. 2014):

$$EF = \frac{I_{\text{SERS}}}{N_{\text{SERS}}} \bigg/ \frac{I_{\text{Raman}}}{N_{\text{Raman}}} \quad (1)$$

where I_{SERS} is the Raman signal intensity of a Cu substrate at 10^{-7} M R6G, N_{SERS} is the number of

Figure 5. SERS spectra of Cu substrates with 10^{-7} M R6G.

molecules detected in the Cu SERS substrate at 10^{-7} M R6G, I_{Raman} is the normal Raman signal intensity of a plain Cu surface at 10^{-2} M R6G, and N_{Raman} is the number of molecules detected in the plain Cu surface at 10^{-2} M R6G. The highest EF, 3.60×10^9 , occurs at Raman peak 1510 cm^{-1} of the spot 1, which is very promising for detecting a single molecule (Lim et al. 2011, Zheng et al. 2015) and demonstrates high sensitivity.

4 CONCLUSIONS

In summary, superhydrophobic SERS substrates have been fabricated in one step by fs laser irradiation in open air. The maximum static Contact Angle (CA) of the processed Cu substrate can reach up to 151° , which demonstrates superhydrophobic properties. With Au nanoparticle decoration, the nanotextured Cu substrate presents a strong potential for SERS with an enhancement factor of 3.60×10^9 , when R6G is used as detection molecules. The superhydrophobic Cu surface confines the R6G droplet into a small area, which increases the concentration equivalently. And the uniformly distributed 60 nm Au nanoparticles with small nanogaps cause enough "hot spots", which can excite strong localized plasmon resonance, thereby resulting in electromagnetic enhancement. Both of these contribute to the high intensity of Raman scattering signals. In addition, the approach to fabricate the SERS substrate is simple and efficient (fabricate an area of $2500 \times 2500 \mu\text{m}^2$ in just 4 minutes), which shows its potential application in industrial production.

A study on the ship model resistance test and numerical simulation

H.C. Pan, S.N. Yu & Y.J. Yang

School of Mechanical Engineering, Hangzhou Dianzi University, Hangzhou, Zhejiang, China

ABSTRACT: The ship resistance is a very important parameter, which can directly affect the performance of the ship. In order to study the resistance of the ship, in this paper, a model S-175 is considered as a research object and combines theoretical analysis, numerical analysis, and test methods to study on it. A comprehensive test platform for the ship model has been built, and also carried out some related model tests. The resistance data of both CFD and experiments under different ship speeds have been obtained for comparison. The results show that the numerical calculated resistance data are closed to model experiment results, which can satisfy the engineering applications of ship resistance prediction. Simulating the flow field around the hull-based on CFD shows that, with an increase in the Froude number, the wave resistance increases, and the bow and stern wave height also increase. However, the height increase of the stern wave is not obvious when compared with the bow. Under low speed conditions, the wave-making was not obvious. As the speed increased to a certain range, the stern creates the stern wake. And its baseline will be stretched when the speed is increased.

1 INTRODUCTION

The main performance parameters of the ship include heavy resistance, buoyancy, stability, maneuverability and speed, etc. (Yu 2009). Among these, the ship's speed has a significant influence on the economy and utility, which also makes greater contribution to the maneuverability and operational capability of the warship. Basically, the speed is mainly affected by ship resistance. Hence, studies on the resistance of ship sailing are always the research hot spot in the ship design field.

At present, there are three ways to discover the ship resistance: theoretical research method, ship model test method, and numerical simulation method (Sheng & Liu 2014). The theoretical research method creates simple analysis, reasoning, and conclusion according to corresponding fluid mechanical knowledge and mathematical tool, and then the approximate ship's resistance can be evaluated. However, only depending on the approximate resistance evaluation method and the empirical equation to forecast the ship's resistance has no longer satisfied our request on accuracy. The ship model test method is the major and the most effective method in ship's resistance forecasting (Sun et al. 2003). However, it takes a lot of time to make the ship model and easily produce error, which also costs a large number of human and material resources. The numerical simulation method can reflect

the real condition of the flow field around the ship and make contribution to the research of speed, which decreases the human and material resources' costs in experiments. It also has great reference value in the aspect of optimization design and type selection (Deng et al. 2013). And so, studying on the ship's CFD method is essentially significant and meaningful (Xu 2012, Gao et al. 2014, Liu et al. 2001). At present, the numerical calculation method has been widely used in ship design and analytical calculation. There are three main numerical methods to simulate viscous flow: DNS (Piller et al. 2002, Wisink 2003, Versteeg & Malalaseker 1995), LES, and RANS (Michelassi et al. 2003, Stephane 2003). With the development and rapid progress of the modern computer technology, fluid researchers constantly create new and effective numerical methods to make it convenient for use. However, the ship structure is too complex to find out the real flow field around it; and so, the numerical simulation method can only solve the part of problems. As a result, the three typical research methods of ship resistance need to be combined to support each other.

Based on the theoretical research and aiming to achieve S-175 ship model resistance conditions, the vertical circulating tank experiment and numerical simulation research have been operated in this paper. The numerical simulation results were compared with the experimental results. In this paper, the gas and liquid distributions are also ana-

lyzed and the free surface condition with different Froude numbers (different speeds) are explored in detail.

2 SHIP MODEL RESISTANCE TEST

2.1 Model preparation

The S-175 model with length between perpendiculars of 2 m is made of fiber glass reinforced plastics, which has some advantages such as light unit weight and non-deformation after long-term use. The main particulars of the ship are given in Table 1.

2.2 Model water tank test

The model test is performed at the vertical circulating tank in Hangzhou Dianzi University. The length, width, and depth of the vertical circulating tank are respectively 4000 mm, 1500 mm and 1300 mm. The tank consists of a barrel, rectifier, honeycomb, porous plate, propelling plant, AC variable frequency motor, X-Y working platform, electronic speed control system, electronic control cabinet, control panel, IPC, etc. The arrows in Figure 1 show the flow direction of the tank.

The vertical circulating tank is adopted for resistance experiments with the velocity of flow in

the range of 0.2–2.0 m/s, and the ship model size is in the range of 1.5–2.5 m. Merchant ship and fishing boat are used as the experiment objects.

2.3 Resistance experiment and results

The ship model resistance experiment operation system is shown in Figure 2.

The experiment system can achieve following functions:

1. The generator's frequency and velocity of flow are adjusted by using an electronic control system.
2. The current meter monitors the real-time velocity of flow in the tank, which can be seen on the electronic control panel velocity of the flow measure system.
3. The ship model which is affected by flow can produce resistance that makes a tiny deformation on the steel wire. The S-type strain sensor on the ship model converts this deformation into an electrical signal. The data collector receives this signal and then converts it into resistance.

To perform the test, a ship model should be installed in the vertical circulating tank, according to Figure 3, and the ship model's plimsoll line should be located on the calm water surface by adjusting sand bags. After completion of the above preparations, the resistance meter and current meter are installed and the velocity of flow is adjusted by controlling the motor's frequency. Eight points were measured from low to high speed. The data were acquired and the experimental resistance values were obtained in Table 2.

Table 1. Main particulars of S-175.

S-175	Ship	Model
Lpp (m)	175	2

Figure 4. Picture of the ship model of S-175.

Figure 5a. Schematic of the computational domain and boundary conditions.

Figure 5b. Unstructured grids of the bow and stern.

3 MODEL CONSTRUCTION AND MESH GENERATION

In this paper, the calculation model and the experimental model are in the same measure. In view of the symmetrical structure, only half of the ship hull is used in the numerical simulation. Figure 4 shows the hull geometry of S-175.

The computational domain and boundary conditions are shown in Figure 5a. The length of the computational domain extends $6 L_{pp}$ in the y-direction, the width extends $10B$ in the x-direction, and the height extends $-3H \sim 3H$ from the free surface in the z-direction.

As shown in Figure 5b, the mesh near the bow and stern is an unstructured grid. Other computational domains are discretized by using a H-type structural mesh. The total numbers of meshes are 3771338. In order to well-reflect the complex flow around the hull and ship motion, the meshes near the bow, stern, plimsoll line, and around the hull surface are refined locally.

In the numerical simulation, the boundary conditions are set as follows:

1. Inlet boundary: the direction of flow is set to the Y-axis negative direction. The model test gives the flow velocity and the upstream is set to be the velocity entrance.
2. Outlet boundary: the downstream and top are prescribed to be an open outlet. And the relative static pressure and fluid direction are set in this work.
3. Wall boundary: hull, bottom, and right are set to be the non-slip wall.
4. Symmetry boundary: the symmetry is assumed to be under symmetrical boundary conditions.

4 ANALYSIS OF NUMERICAL SIMULATION RESULTS

4.1 Numerical simulation

In this paper, the gas-liquid flow simulation is involved, which is needed to set the fluid volume fraction under inlet and outlet conditions. The free surface was set to be no slip, and the turbulence simulation was the SST model. The wall approach was automatic, and the simulation solving the format was of higher order. The physical timescale was 0.02 s and the maximum iteration step number was 1000.

4.2 Computational results

In this paper, the S-175 standard ship model fluid field distribution conditions are simulated under seven speeds: 0.21 m/s, 0.39 m/s, 0.61 m/s, 0.81 m/s, 1.02 m/s, 1.21 m/s, and 1.42 m/s. And the simulation resistance was compared with experimental results to make the analysis. The comparison results are shown in Table 3.

From Figure 6, the increasing trend of the total resistance calculated with CFD method is the same as the increasing trend of the total resistance measured in the experiment. From Table 3, we can observe that when $0.088 \leq Fr \leq 0.27$, their deviation decreased while the fluid number was increasing. And the deviation achieved a minimum value of 0.954%, when the Froude number was 0.27. However, when the Froude number was greater than 0.27, the deviation was enlarged further.

In the reality model test, when $Fr = 0.32$, waves can be observed on the deck, which had serious effects on the ship posture and made the

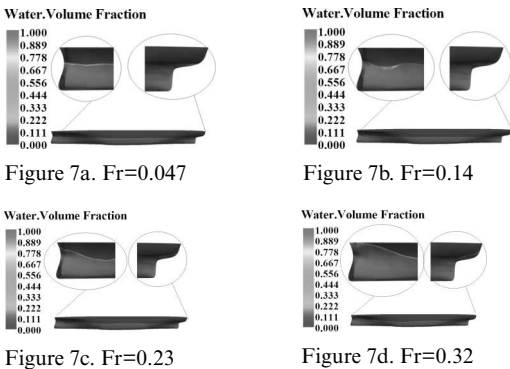

Figure 7. Graphs showing the gas and liquid distributions for different Fr values.

ship extremely unstable in the water. Similarly, in numerical simulation, from this certain speed (Fig. 7d), the phenomenon of the water wave on the deck can be also observed clearly. And so, it was proved that the numerical calculating method

can accurately simulate the flow field distribution and ship posture of the ship model.

4.3 Ship model analysis of the viscous flow field

1. Analysis of the hull surface's gas-liquid distribution:

Figure 7 indicates the hull surface's gas and liquid distribution for different Froude numbers. From the figures, it can be observed that the water wave at the bow and stern were more obvious in which the wave of the bow was the highest. The wave decreased at the middle of the hull and further increased at the stern. With an increase in the ship speed, the wave height of the bow changed obviously, the wave height of the stern also increased but not as obvious as the bow. And the wave resistance was also increased. When $Fr = 0.32$, it can be observed that the wave was on the deck.

2. Simulation analysis of the free surface: In this paper, the VOF method is used to simulate the flow of the free surface. The VOF method is based on the fluid in the grid cell, in every moment, thereby occupying volume fraction F to create and track the free surface. Figure 8 shows the free surface conditions for different Froude numbers. From these figures, the wave of the water and the ship wave for the ship movement can be observed, which are the superposition results of the transverse wave and longitudinal wave. In low speed cases, the wave was not obvious. However, when the speed increased to a certain range, the stern created the stern wake, and its baseline will be stretched when the speed is added. From the figure, it can be observed that the flow field condition of the ship stern was complex.

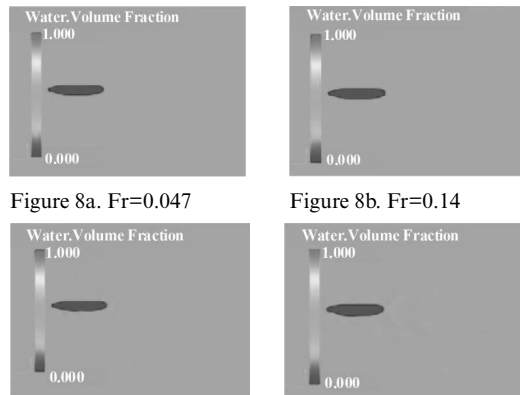

Figure 8. Graphs showing free surface conditions for different Fr values.

In the design of the propeller, the corresponding wave on the stern will affect the efficiency of the propeller. Therefore, the analysis for flow fields on the ship stern is a necessary work.

5 CONCLUSION

According to the comparison of the ship resistance numerical simulation and experimental results of the S-175 ship model, the following conclusions can be drawn:

1. Although the CFD calculation data and the experimental data had a little deviation, the data fit better enough in a certain range. It means that the method used in this paper to forecast the ship resistance is reasonable under certain condition. To forecast the resistance efficiently, the numerical simulation method can be combined with the ship model test.
2. When the ship model operates at a low speed, a tiny disturbance has a considerable effect on the resistance. Therefore, the accuracy of the experimental measurement and numerical simulation of the resistance is affected by test conditions, operational details, parameter settings, etc.
3. Different types of ships have different designed speeds. When the testing speed was set to 1.42 m/s in this paper, the phenomenon of the water wave on the deck can be observed. And so, the ship model test should be less than this speed.
4. When compared with the model test, CFD has obvious advantages to simulate the model flow field and capture the local details and the characteristics of the flow field. With an increase in the Froude number, the wave resistance increases, and the bow and stern wave heights also increase. However, the height increase of the stern wave is not obvious when compared with the bow. Also, with an increase in the speed, the pressure of the bow and the stern has increased obviously. Due to the effect of the water viscosity, under the effect of the hull longitudinal pressure gradient distribution, the stern starts a boundary layer separation, which makes the pressure of the stern lesser than that of the bow. At low speeds, the wave-making was not obvious. When the speed

increased to a certain range, the stern creates the stern wake, and its baseline will be stretched when the speed is increased.

Magnetic memory testing signal analysis of Q345 steel welding parts under the static tension condition

Miao Lou, Xiang-Hui Lv, Fei Lu & Bo Li
North West Institute of Nuclear Technology, Xi'an, China

ABSTRACT: The paper is based on the research object of the Q345R steel butt welding specimen under static tension and analyzes the characteristics and change rule of magnetic memory testing signals in the load process. Results show that the welded specimen can determine the weld parts before magnetic memory testing. In the elastic stage, magnetic field gradient values in weld parts decrease obviously, which are consistent with those of the basic metal. After analysis, it is noted to be caused by the welding residual stress. In the yield phase, local magnetic field gradient values in the weld parts increase slightly and then decrease obviously, which is thought to be due to the fact that after welding, metallographic structures and mechanical properties change, and welding and heating affected the zone display performances, which are inconsistent with those of the basic metal in the tensile process. In the strengthening phase, welded specimens gradually show the same features as the basic metal specimens.

1 INTRODUCTION

Metal magnetic memory testing was put forward by Russian professor Dubois in the late 20th century (Dubov A A, 1999), which can accurately and reliably detect dangerous parts of iron work pieces that are characterized by the area of stress concentration, becoming the only effective nondestructive testing method in the early diagnosing of work pieces on the verge of injury and damage statuses. After nearly 20 years of research and development, the method now has been widely used in boiler pressure vessels, pipelines, turbine blades, engine crankshafts, bridges, railways, and other tastings (Ren Jilin, 2000 & Leng Jiancheng, 2010). Part of structural components in the Q345R steel container implement welding and assembly at the scene; the container is put into use without removing the welding residual stress, and the regular safety inspection is indispensable. In this paper, we carry out an experimental study on whether the ability of early warning in the metal magnetic memory method can conduct tastings and evaluations for the site welding parts of the container, obtain the magnetic memory signal characteristics of the basic metal, and weld assemblies and under the tensile loading process so as to provide channels for security evaluation of the container through a comparative analysis.

2 TEST SPECIMEN PREPARATIONS

The Q345R steel, basic metal and weld tensile specimens are designed by loading in a statically tensile

Figure 1. Butting welded tensile specimens sketch map.

way and are closed down to uninstall in the elastically tensile stage, yield tensile stage, strengthening phase, and shrunken phase. The magnetic memory tastings are carried out on the specimens so as to obtain the magnetic field intensity and its gradient changes of the testing lines. The material tensile strength (σ_b) is 510–640 MPa, yield point (σ_s) is 345 MPa, and elongation rate (S) is 21%. In accordance with the (GB/T 228.1-2010 standard (Roskosz M, 2011), the specimen has the shape of a plate, with a thickness of 6 mm, containing three pieces. Among them, the second and third are the butt welding specimens after longitudinal cuttings, with V-type weld groove of the welding specimens for manually electric arc welding, and the welding materials are J507 welding rods, with welded width of 10 mm. After passing the radiographic testing, it belongs to welding grade I without excessive defects (Long Feifei, 2012), and its welded location is shown in Figure 1.

3 TESTING TIME AND INSTRUMENTS

The aim of closing down the specimens to detect is to test before the tensile loading of the specimens and obtain the initial state signal. The mean

stresses of the elastic stage are 110, 220, and 330 MPa. We selected five points according to the different sizes in the yield stage, randomly selected testing points in the strengthened and necking stages of the specimens, and measured after the specimen are fractured. The specific testing points are shown in Table 1. The positive and negative sides of the specimens are tested respectively, and the magnetic memory test lines are perpendicular to the welded joints, which are located in the middle of the specimens, as shown in Figure 2.

Magnetic memory testing equipment include the TSC-1M-4 metal magnetic memory detectors produced from Russia Dynamic Diagnostic Company. The loading equipment adopt the RAS-250 type of tensile testing machine manufactured by German Scheck.

4 EXPERIMENTAL RESULTS

4.1 Initial state

The test results before loading the specimens are shown in Figure 3.

Table 1. Downtime testing point.

Testing times	Experimental stage	Testing times	Experimental stage
1	Not loaded	8	Yield
2	Stresses 110 MPa	9	Strains 1.6%
3	Stresses 220 MPa	10	Strains 2.2%
4	Stresses 330 MPa	11	Strains 6%
5	Strains 0.2%	12	Strains 10%
6	Strains 0.3%	13	Necking
7	Strains 0.8%	14	Sheared

Figure 2. Sketch maps of the magnetic memory test lines.

Figure 3. Test results before loading.

When not loaded, the magnetic field strength of the first specimen is almost a diagonal line, with its magnetic field gradient values between 4 and 7; the magnetic field intensity values of the first and second specimens in the welded area have mutations, and the magnetic ladder number has obvious peak value compared with the basic metal.

4.2 Elastic stage

In the elastic stage, test results that load the stresses as 110, 220, and 330 MPa are shown in Figures 4–6, respectively.

From Figures 4 to 6, the magnetic field strength is still the oblique line with the loading of the first specimen, the change levels off, and the slope decreases; the change scope of the gradient values continues to narrow, the gradient value is almost a constant until 330 MPa, with a numerical value about 4. The slope rate of the magnetic field intensity for the second and third specimens decreases, the left-hand side is turned into a positive value from a negative value, and the right-hand side is turned into a negative value from a positive value, which leads to the emergence of the deflection phenomenon. The magnetic field gradient value of welded parts decreases to 330 MPa, which is consistent with the basic metal parts, almost being a constant.

Figure 4. Specimen test results under 110 MPa.

Figure 5. Specimen test results under 220 MPa.

Figure 6. Specimen test results under 330 MPa.

4.3 Yield stage

Four measurements are conducted in the yield phase, with the test results of the loading stresses of 0.2%, 0.38%, 0.8%, and 1.65%, which are shown in Figures 7–10, respectively.

From Figures 7 to 10, it can be seen that the magnetic field intensity of the first specimen is almost an oblique line, with its gradient value keeping decreasing; in the yield stage, the magnetic field gradient values of the second and third specimens have significantly local change characteristics compared with the elastic stage, namely the gradient values in the welded parts increase; in the weld seam position, the slope rate of the magnetic field strength increases obviously.

Figure 7. Specimen test result when the stress is 0.2%.

Figure 8. Specimen test result when the stress is 0.38%.

Figure 9. Specimen test result when the stress is 0.8%.

Figure 10. Specimen test result when the stress is 1.65%.

4.4 Reinforcement, constriction, and fracture of specimens

The test results of the specimen stresses are loaded to 2.2%, 6%, 10%, and 15%, which are shown in Figures 11–14, respectively.

With the increase of load, the magnetic field gradient numerical values become smaller, with the numerical values reduced to 0–2 as well as the gradual reduction of the slope rates of the magnetic field intensity. The magnetic field strength of the second and third specimens is almost a diagonal line again, and the numerical value of the magnetic field gradient is almost a constant.

The specimen continues to be loaded, and the apparent constriction appears in the basic metal

Figure 11. Specimen test result when the stress is 2.2%.

Figure 12. Specimen test result when the stress is 6%.

Figure 13. Specimen test result when the stress is 10%.

Figure 14. Specimen test result when the stress is 15%.

parts when the stress is 23.75%, as shown in Figure 15. Then, the specimen continues to be loaded to fracture; magnetic memory scanning and testing are conducted for the fractured specimen, as shown in Figure 16.

It can be seen from Figures 15 and 16 that the specimen enters the strengthening phase to necking until fracture in the end, and the magnetic field intensity value of the specimen exceeds zero, which shows the phenomenon of moving to the right-hand side and left-hand side, respectively, with its numerical values instantaneously jumping for change and the magnetic field gradient of the fracture specimens making a big difference. Magnetic memory testing signals show no obvious reaction to the constriction but demonstrate the most obvious reaction to the fracture.

4.5 Over-zero value point

Over-zero value points of many times of the magnetic field strength values for all specimens are shown in Figure 17, which displays the repeatedly

Figure 15. Specimen test result when the stress is 23.75%.

Figure 16. Testing result of the fractured specimen.

Figure 17. Over-zero value point of the magnetic field strength value.

moving process of over-zero value points, with all specimens' movements having no significant rules to follow. Compared with the actual tensile states of the specimens, the magnetic field intensity value in the fractured part is zero, and its directions change as well as the gradient value obtains the maximum value.

5 CONCLUSIONS

1. The test results can directly reflect the weld positions before loading the specimens.
2. In the elastic stage, along with the increase of load, the magnetic field gradient values in the weld parts of the welding specimens decrease. When loaded to 330 MPa, the detection result gradually converges with that of the basic metal specimen, with its magnetic field gradient value almost a constant. The feature is thought to be caused by being gradually eliminated through the tensile process of welding residual stresses.
3. In the yield stage, the welded parts of welding specimens change obviously locally, and the magnetic field gradient values increase again and then decrease until the value is consistent with that of the basic metal. In the strengthening and necking stages later, the magnetic field gradient values decrease, which are consistent with those of the basic metal of specimens.
4. After the specimen fractures, the magnetic field strength value of the fracture position shows an over-zero value, with the location showing no unified law with the previous zero value points that have been tested.

Research on reliability assessment of success or failure product based on small sample

Han-peng Li, Zhao-long Xuan & Yao-dong Wang
Ordnance Engineering College, Shijiazhuang, China

ABSTRACT: Based on the problem of intelligent ammunition reliability assessment on small sample, in this paper, the three type reliability evaluation methods for success or failure product are introduced, and their applications in small sample cases are compared. The effects of prior test information on reliability with three methods are studied by simulation analysis. The results show that the hybrid Bayesian method has more advantages than the maximum likelihood method and the traditional Bayesian method in the reliability of the small samples of the success or failure components.

1 INTRODUCTION

With the rapid development of information technology, intelligent ammunition came into being. It is able to automatically search, detect, capture and attack targets, due to a variety of optoelectronic components, precision machinery parts of the large number of applications. It is showed a technology intensive, complex structure, high cost and short design life characteristics. For a number of expensive, high-risk ammunition or parts, it is impossible to do a lot of field tests for reliability assessment, which faced a small case. There are many success or failure of products in smart ammunition. Success or failure of the product usually means that its use each time are independent of each other, and only “success” or “failure” of the two possible outcomes. A variety of one-time throwing or firing of ammunition, missiles and launch vehicles (Zhang & Cai 2003), etc. are typical success or failure product. In the development process of their reliability assessment, due to cost, time and other factors, they are often unable to conduct a large number of field tests. Bayes method (Mao et al. 2009) can fully integrate pre-test information such as field test information and historical information, so it can greatly reduce the number of trials, save test products, shorten the test cycle. It has been widely used in recent years.

2 THE CLASSICAL EVALUATION METHOD OF RELIABILITY

Using the classical statistical method to calculate the reliability expressed as “ R ” of the success or failure product, there is the maximum likelihood

estimation (Bar & Lavi & Reiser 1992) method. With the test data $(n - f, n)$, regardless of the pre-test information of the product (“ n ” is the number of trials, “ f ” is the number of failures), likelihood function of the sample for the test data is as follows:

$$L(R) = P\{S = s\} = C_n^{n-f} R^{n-f} (1 - R)^f \quad (1)$$

Where s is number of successful trials.

To facilitate the calculations formula (1), it often is taken the logarithm on both side yields:

$$\ln L(R) = \ln C_n^{n-f} + (n - f) \ln R + f \ln(1 - R) \quad (2)$$

To derive R , let the equation result be zero, the likelihood equation is obtained:

$$\frac{d \ln L(R)}{dR} = \frac{n - f}{R} - \frac{f}{1 - R} = 0 \quad (3)$$

The maximum likelihood estimate of the reliability R is obtained by solving the likelihood equation:

$$\hat{R} = \frac{n - f}{n} \quad (4)$$

When the total number of tests “ n ” is constant, the reliability R of the component is monotonous with the test success number expressed as “ s ”. For the test data $(n - f, n)$, the lower credible limit of product reliability which is expressed as “ R_L ” can be obtained by the formula (5) when the confidence is γ .

$$\sum_{k=0}^f C_n^k R_L^{n-k} (1-R_L)^k = 1-\gamma \quad (5)$$

At present, this method is the most used in many military product reliability assessment. The method is simple and intuitive. And for some relatively low value and production of ammunition products it is very applicable. But for some high-value, high reliability success or failure products there is not a lot of field tests. The method is difficult to meet the acceptance requirements. Bayes method to evaluate the reliability of products of success or failure has been developed.

3 BAYES EVALUATION METHOD FOR RELIABILITY

3.1 Traditional bayesian method

Bayes method in the binomial distribution of the success or failure of the product reliability evaluation, is commonly used conjugate prior method to determine the pre-test distribution, the parameter that the reliability of R conjugate prior for the Beta distribution:

$$\pi(R) = \text{Beat}(a, b) = \frac{R^{a-1} \cdot (1-R)^{b-1}}{\beta(a, b)}, 0 < R < 1 \quad (6)$$

Where $\beta(a, b) = \Gamma(a)\Gamma(b) / \Gamma(a+b)$.

The “ a ” and “ b ” are the hyperparameter of pre-test distribution ($a > 0, b > 0$). Given a total of N number of development phase, the hyperparameter a_i and b_i are the key to determine the pre-test distribution ($i = 1, 2, \dots, N$). In the development number i stage, there are number m_i test information, l_{ij} is the number of trials in each batch ($j = 1, 2, \dots, m_i$). R_{ij} is the expected estimate of product reliability in each batch test ($R_{ij} = (l_{ij} - f_{ij}) / l_{ij}$). Then according to the empirical Bayes method, the a_i and b_i are determined by following principles (Martz & Waller 1976).

1. When tests are enough that m_i are larger:

$$(a_i + b_i) = \frac{m_i^2 \left(\sum_{j=1}^{m_i} R_{ij} - \sum_{j=1}^{m_i} R_{ij}^2 \right)}{m_i \left(m_i \sum_{j=1}^{m_i} R_{ij}^2 - H_i \sum_{j=1}^{m_i} R_{ij} \right) - (m_i - H_i) \left(\sum_{j=1}^{m_i} R_{ij} \right)^2} \quad (7)$$

$$a_i = (a_i + b_i) \bar{R}_i \quad (8)$$

Where $H_i = \sum_{j=1}^{m_i} l_{ij}^{-1}$, $\bar{R}_i = \sum_{j=1}^{m_i} R_{ij} / m_i$.

2. When the number m_i is small, the value of $(a_i + b_i)$ may be negative because of sampling error in Eq. (7). In this case, the following corrections can be made:

$$(a_i + b_i) = \left(\frac{m_i - 1}{m_i} \right) \frac{m_i \sum_{j=1}^{m_i} R_{ij} - \left(\sum_{j=1}^{m_i} R_{ij} \right)^2}{m_i \sum_{j=1}^{m_i} R_{ij}^2 - \left(\sum_{j=1}^{m_i} R_{ij} \right)^2} - 1 \quad (9)$$

3. When $m_i = 1$, and no other pre-experience information such as expert experience, then $a_i = l_i - f_i$, $b_i = f_i$, which is equivalent to take no information before the distribution $\beta(0, 0)$. If according to Bayes assumption that when there is no prior information $\pi(R)$ is uniformly distributed on $[0, 1]$, that is $\beta(1, 1)$. It is desirable $a_i = l_i - f_i + 1$, $b_i = f_i + 1$. If according to the Jeffreys criterion, $\pi(R)$ is $\beta(0.5, 0.5)$ when no pre-test is performed, then $a_i = l_i - f_i + 0.5$, $b_i = f_i + 0.5$. $\beta(0, 0)$ is superior to the latter two distribution in terms of theoretical support and engineering practice, especially in the reliability evaluation of high reliability products. To reduce subjectivity, it is generally recommended $a_i = l_i - f_i$, $b_i = f_i$ (Zhou 1980).

When a_i and b_i are determined, the pre-test distribution $\text{Beta}(a_i, b_i)$ of the development phase i is obtained. At the same time, the traditional Bayesian method is based on the Bayes succession rate, that is, the pre-posterior distribution of the previous stage is the pre-test distribution of the next stage. Finally, combining with the field test information (field test n times, failure f times), the post-mortem distribution can be obtained using Bayes theorem:

$$\pi(R|D) = \text{Beat} \left(\sum_{i=1}^N a_i + n - f, \sum_{i=1}^N b_i + f \right) \quad (10)$$

The traditional Bayes evaluation method does not take account of the difference between the historical test sample with the sample of the field test. In the case of equation (6), the posterior expectation of the reliability R can be obtained.

$$\hat{R}_E = E(R|x) = \frac{a+f}{a+b+n} \quad (11)$$

Where $a = \sum_{i=1}^N a_i$, $b = \sum_{i=1}^N b_i$.

The lower credible limit R_L of the product is got under given confidence γ from formula (12).

$$\int_{R_L}^1 \pi(R|D) dR = \gamma \quad (12)$$

It can be seen from the posteriori expression (11) of the parameter R . This traditional method of pre-distribution construction based on likelihood function actually treats pre-test information and field test information without discrimination. But the historical information and field test information may not be compatible (that means the same population). Even if compatible, it can only be in a certain degree of confidence. Therefore, the correctness of the above method is questionable. In general, the number of $(a + b)$ is much larger than n . It shows that if the two information directly is mixed without distinction of integration, often leads to historical information annihilation of field information and field test results on the final assessment of almost no impact with analysis of formula (11). The number of historical information is often relatively large and the number of field trials is relatively small, so the traditional Bayesian method is obviously very unreasonable.

3.2 Hybrid prior bayesian method

In order to make good use of pre-test information and distinguish the differences between pre-test and on-site information, a mixed beta pre-test distribution (Ming et al. 2008) has been put forward. After obtaining the pre-test distributions for each stage, the pre-mix distribution of the tectonics is as follows:

$$\pi(R) = \sum_{i=1}^N \left[\rho_i \frac{R^{a_i-1} \cdot (1-R)^{b_i-1}}{\beta(a_i, b_i)} \right] + (1-\rho) \quad (13)$$

$$\text{Where } \rho = \sum_{i=1}^N \rho_i, 0 \leq R \leq 1, 0 \leq \rho_i \leq 1, 0 \leq \rho \leq 1.$$

The ρ and ρ_i are called inheritance factors, and $(1-\rho)$ is called update factors. The ρ_i reflects the experimental stage i information and field test information from the overall similarity. The ρ reflects the current product in the reliability of the overall historical information on the degree of succession and the $(1-\rho)$ is described the uncertainty of the current product in terms of reliability. In $\rho = 1$, it's considered that the two populations are the same, and the hybrid priori $\pi_\rho(R)$ is conjugate priori $Beta(a, b)$. In $\rho = 0$, the two populations are completely different, that is, the historical test data have no reference value, and the a priori distribution is conservatively chosen as $Beat(1, 1)$. In $0 < \rho < 1$, the use of mixed a priori is more reasonable. After pretest to determine the distribution, according to Bayes theorem, substitute site information, rearranging the posterior distribution as follows:

$$\begin{aligned} \pi(R|D) &= \frac{(1-\rho)R^{n-f}(1-R)^f + \sum_{i=1}^N \rho_i \frac{R^{n-f+a_i-1}(1-R)^{f+b_i-1}}{\beta(a_i, b_i)}}{(1-\rho)\beta(n-f+1, f+1) + \sum_{i=1}^N \rho_i \frac{\beta(n-f+a_i, f+b_i)}{\beta(a_i, b_i)}} \quad (14) \end{aligned}$$

With (14), the product confidence lower limit R_L and product moments μ_k of the product reliability can be obtained under given confidence γ by follow:

$$\int_{R_L}^1 \pi_\rho(R|D) dR = \gamma \quad (15)$$

$$\mu_k = E(R^k) = \int_{R_L}^1 \pi_\rho(R|D) dR = \gamma \quad (16)$$

3.3 Determination of inheritance factors ρ and ρ_i

To sum up, the ρ and ρ_i have a great influence on product reliability evaluation, so their values must be careful. Therefore, the expert should give the value of ρ according to the improvement degree of the product. When the value of ρ cannot be given accurately, then ρ can be treated as a random variable, and the probability distribution and range of ρ are given by the hierarchical Bayes method. However, the probability distribution and range of ρ are also determined by expert experience. The method is subjective, and it is difficult to deal with mathematical problems when the probability distribution of $N \rho_i$ is given. If the value of ρ is directly determined by the goodness-of-fit test of the two samples from the population, the calculation is simple and its rationality is also well explained. Since ρ is a measure of the overall population of the pre-test information and the overall sample similarity from the field sample, it is necessary to determine ρ before determining ρ_i . Determine ρ using the overall goodness of fit with the field test method. That is required to test information on all stages of synthesis. The so-called synthesis is not a simple addition, but the weight and then sum, so the weight must be first determined of each stage of information. The “ i ” stage historical test sample $\left(\sum_{j=1}^{m_i} (l_{ij} - f_{ij}), \sum_{j=1}^{m_i} l_{ij} \right)$ belongs to population Y , and the field test sample $(n-f, n)$ belongs to population X . The following tables are obtained.

$$K_i = \frac{\left[\left(\sum_{j=1}^{m_i} (l_{ij} - f_{ij}) f \right) - \left(\sum_{j=1}^{m_i} f_{ij} (n-f) \right) \right]^2 \left(n + \sum_{j=1}^{m_i} l_{ij} \right)}{n \sum_{j=1}^{m_i} l_{ij} \left[(n-f) + \sum_{j=1}^{m_i} (l_{ij} - f_{ij}) \right] \left[f + \sum_{j=1}^{m_i} f_{ij} \right]} \quad (17)$$

In the above equation, the K_i is the person statistic and its distribution converges to the χ^2

Table 1. Joint list of two binomial populations.

	Number of success	Number of failures	Sum
X	$n-f$	f	n
Y	$\sum_{i=1}^{m_i} (l_{ij} - f_{ij})$	$\sum_{j=1}^{m_j} f_{ij}$	$\sum_{j=1}^{m_j} l_{ij}$
Sum	$n-f + \sum_{j=1}^{m_j} (l_{ij} - f_{ij})$	$f + \sum_{j=1}^{m_j} f_{ij}$	$n + \sum_{j=1}^{m_j} l_{ij}$

distribution with 1 degree of freedom. It is required that the number of successes and failures of the two samples be greater than 5 in (17). When this condition is not satisfied, it is corrected as follows (Fisher & Yates 1957).

$$K_i = \frac{\left[\left(\sum_{j=1}^{m_j} (l_{ij} - f_{ij}) f \right) - \left(\sum_{j=1}^{m_j} f_{ij} (n-f) \right) \right]^2 - \frac{1}{2} \left(n + \sum_{j=1}^{m_j} l_{ij} \right)^2 \left(n + \sum_{j=1}^{m_j} l_{ij} \right)}{n \sum_{j=1}^{m_j} l_{ij} \left[(n-f) + \sum_{j=1}^{m_j} (l_{ij} - f_{ij}) \right] \left(f + \sum_{j=1}^{m_j} f_{ij} \right)} \quad (18)$$

K_i also approximates the χ^2 distribution of 1 degrees of freedom in the above equation. At a given test level γ , K_i can be used as the test statistic to test whether X and Y are the same population. Even if the compatibility test, two parts of the test information cannot be simply mixed together, it still need to determine each stage of the test information and the similarity of the field information measure T . The goodness of fit $Q_i = P(\chi^2_1 > K_i)$. Q_i represents the degree of similarity between X and Y in probability, and it is related to T_i . But it is difficult to give the function relation of Q_i and T_i exactly. It is desirable that $T_i = Q_i^{1/2}$. Then the number of test L and the success number S can be obtained (Wang & Guo 2006).

$$S = \sum_{i=1}^N \sum_{j=1}^{m_j} (l_{ij} - f_{ij}) \frac{T_i}{T_1 + T_2 + \dots + T_N} \quad (19)$$

$$L = \sum_{i=1}^N \sum_{j=1}^{m_j} l_{ij} \frac{T_i}{T_1 + T_2 + \dots + T_N} \quad (20)$$

The value of K is obtained by Substitute (S, L) and field test sample ($n-f, n$) into formula (17) or (18), and then the value of Q can be obtained by using the following formula.

$$Q = P(\chi^2_1 > K) \quad (21)$$

Taking $\rho = Q_i^{1/2}$, ρ_i can be obtained as follows from the value of ρ .

$$\rho_i = \rho \frac{T_i}{T_1 + T_2 + \dots + T_N} \quad (22)$$

3.4 Simulation calculation and discussion

In this paper, three methods of reliability evaluation are introduced, and their merits and demerits in the reliability evaluation of the success or failure product are studied. The following is a simulation study of the number of pre-test information on the reliability of the three methods of reliability evaluation of the impact of the one-sided lower credible limit. Because the multi-development stage Bayes evaluation method is an extension of the two overall Bayesian evaluation methods, in order to reduce the computational complexity, the historical test information is set as the same population and the same batch. Let history test as (n_0-f_0, n_0) . The simulation parameter is set to $\gamma = 0.8, n = 10, p = 0.9, p_0 = 0.7$ and let n_0 changes (Where p and p_0 are the probabilistic truth values of field test information and historical test information, $p_0 = n_0 - f_0/n, p = n - f/n$). Under the maximum likelihood estimation method, the traditional Bayesian method and the hybrid method, the estimated value R_L of the lower credible limit of the unilateral reliability varies with n_0/n , as shown in Fig. 1.

The simulation parameter is set to $\gamma = 0.9, n = 20, p = 0.95, p_0 = 0.95$ and let n_0 changes. Under the maximum likelihood estimation method, the traditional Bayesian method and the hybrid method, the estimated value R_L of the lower credible limit of the unilateral reliability varies with n_0/n , as shown in Fig. 2.

In Fig. 1, since the classical reliability assessment method does not take into account the historical

Figure 1. The value of RL with $p = 0.9, p_0 = 0.7$.

Figure 2. The value of R_L with $p = 0.95$, $p_0 = 0.95$.

test information, it leads to the lower credible limit R_L is too aggressive. Traditional Bayes method does not consider the difference between historical information and on-site information, which leads to the results evaluation too conservative. And as n_0/n increases, the influence of field test information on R_L evaluation results is getting smaller and smaller. The hybrid method takes into account both the historical information and the historical and field information differences, its evaluation results are more reliable.

In Fig. 2, the results of the classical reliability assessment are too conservative due to less field test information. Traditional Bayes method does not take into account the difference between historical information and on-site information, leading to the results of the evaluation too aggressive. The results of the hybrid method evaluation are between the above two methods. It can be seen from the figure 2 that as n_0/n increases, the difference between the traditional Bayes method and the hybrid method to evaluate the results is reduced.

From the comprehensive analysis of Fig. 1 and Fig. 2, it is found that the evaluation result of the traditional evaluation method is not applicable due to the less information of field test. Traditional Bayesian method does not consider the difference between historical information and field information, that leads to the prior data inundate the posteriori data. The results indicate that the hybrid

prior approach can avoid the problem of that the prior data inundate the posteriori data effectively. And the evaluation results are more reliable.

4 CONCLUSION

This paper presents three reliability evaluation methods for the success or failure product, analyzes and compares the advantages and disadvantages with their assessment methods. Bayes evaluation method for the reliability of success or failure product based on the test information of all development stages not only make full use of historical information, but also consider the different stages of the test sample heterogeneity. The inheritance factor can be determined directly based on goodness of fit without additional information. Its practicality is strong.

Numerical simulation of hydroforming of a stainless steel sink

Qihan Li, Pei Zhu, Xueqiang Guo, Jianwen Hou & Xiaomei Li

School of Mechanical Engineering Changchun University of Technology, Changchun, Jilin, China

ABSTRACT: Box-shaped stainless steel sinks are more difficult to shape. In the stamping process, the factors affecting the flow of material are more complex. On the basis of the technological difficulties and the shape characteristics, this paper uses the Dynaform software to simulate the first drawing of the stainless steel flume by using the technology of hydroforming, which can effectively solve problems such as low pass rate, low surface quality, and rupture of parts. The influence of the loading path and liquid chamber pressure on the result of hydroforming during the forming process was studied. The optimum process parameters were established by simulation. This effectively controls the sidewall wrinkles and the excessive thinning of the corner of punch. The results provide a theoretical guidance and reference for the actual production. Compared with the general deep drawing of the kitchen sink, the quality of the hydroforming sink is much better.

1 INTRODUCTION

1.1 Type area

Low-end manufacturing industries such as resource-intensive, labor-intensive, high-energy-consuming, and high-polluting industries have experienced sluggish growth. However, recently, computer hardware and software technology and related control technology have been widely promoted and used. A number of new technologies and new crafts are widely used in traditional manufacturing. They promote the transformation and upgrading of production methods (Zhang, S. H & Jensen, M. R., 2000). Because of the lightweight and high quality of the parts, the technology of hydroforming has attracted more attention in sheet metal forming.

Hydroforming technology is the use of liquid as a force transmission medium of a processing technology. In the sheet metal stamping, it uses liquid instead of a rigid punch or a die (Dursun T & Soutis C., 2014; Lang Lihui & Xu Nuo, 2013). In the liquid filling process, the sheet will be pressed into the liquid chamber by the punch so that the liquid is pressurized and forms a blank around the punch. The friction generated between the blank and the punch may allow the use of higher pressures. The sheet metal forming performance will be improved, which is called the “friction retention” effect. The liquid pressure will make a blank between the punch and die shoulder to form a raised structure similar to the drawbead, which can help prevent wrinkling of parts (Shihong Zhang & Lixin Zhou, 2003; Hartl C., 2005). In this flexible manufacturing process, the hydraulic

chamber can also be used repeatedly to adapt to the different shapes of parts, greatly saving mold costs. In this paper, the numerical simulation of the hydroforming of the stainless steel sink is carried out. The optimal process parameters are determined, and the failure problem in the forming process is solved. The theoretical guidance is provided for the production.

2 MATERIAL AND DIMENSIONS OF STAINLESS STEEL SINKS

2.1 Shape of the stainless steel sink

Figure 1 shows the three-dimensional digital model parts diagram of a stainless steel sink. Its size is 380 * 330 * 165 mm. With the development

Figure 1. 3D model of sink.

Table 1. Material performance parameters.

Young's modulus/GPa	207
Yield stress, MPa	205
Strain-hardening index, N	0.498
Anisotropic index, r	1.2
Poisson's ratio	0.28
Strain hardening coefficient k	1426

of science and technology and improvement of the quality of life, the performance and quality requirements of the sink has also increased. The most important part of the production process is the drawing process. Because the parts forming has relatively large stretch, and drawing effect is usually a low pass rate, the use of traditional drawing needs repeated mold debugging (Lang L H & Danckert J., 2004). The forms of failure are difficult to control. Through the study of numerical simulation of key process parameters, reasonable control of sheet metal flow in the forming process helps to produce qualified parts.

2.2 Sheet performance parameters

Because of its high temperature, corrosion resistance, and good performance, SS304 steel is used in a wide range of applications in the sink. Table 1 shows the performance parameters.

3 FINITE-ELEMENT MODEL OF LIQUID-FILLED FORMING

3.1 Establishment of finite-element model

The numerical simulation of sheet metal forming is carried out by the ETA Company and LSTC Company. In order to improve the simulation precision, the four-node Belytschko-Tsay shell element is used to mesh, and the maximum grid is set to 2. The die, the punch, and the blank holder are regarded as the rigid body. The rigid four-node element is used to divide the mesh. In the automatic setting module of the software, the tools are defined respectively. Figure 2 shows the finite-element model of the punch, blank, blank holder, and die.

3.2 Setting of simulation conditions

In the simulation of the stainless steel sink, the single-action drawing was adopted. Blank material selects the SS304 anisotropic material model. The punch speed is set at 2000 mm. Then, the contact parameters are defined. The contact type of the tool is surface contact. For the parts forming effect and improving the drawing ratio, the billet and punch friction factor is set to 0.3, and the friction

Figure 2. Sink stamping model.

coefficient between the sheet metal blank holder and the die is set to 0.005. According to Dynaform software calculations and experience, the blank size is 700 mm*700 mm and the thickness is 1 mm.

4 NUMERICAL SIMULATION ANALYSIS OF THE PROCESS OF LIQUID-FILLED FORMING

In the process of hydroforming of stainless steel sink, the process parameters influence the forming quality and control failure form of the sheet metal. They include the size and performance of the sheet metal, the arrangement of the drawbead, the blank holder force, the gap, the pressure of the liquid chamber, the liquid chamber pressure loading curve, and so on (Peng Chengyun and Zou Qiang, 2011; Yuan Shijian & Wang Zhongren, 2000). The key process parameters are liquid chamber pressure and its loading path, which have important influence on the failure forms such as excessive thinning of parts and wrinkling of forming surface. In this paper, the numerical simulation and analysis focus on the influences of liquid chamber pressure loading path in the process of hydroforming of stainless steel sink.

4.1 Liquid pressure loading path and forming effect

In the process of hydroforming, the way of loading liquid chamber pressure is mainly of two types (the passive natural pressurization and active forced pressurization). The former is the punch running into the liquid chamber, thus the liquid in the cavity is compressed to form a reaction. Because of the small initial forming pressure, the forming limit of the plate is low. The latter is the use of valve to control the liquid chamber pressure, which greatly increases the molding limit.

The load path of the liquid chamber pressure has a great influence on the forming quality of

the part. The pressure value will cause the sink to have a different degree of instability (Wang Jianmin & Hu Mi, 2009). “Friction retention” and “fluid lubrication” resulting from the proper liquid chamber pressure can improve the stress and strain in the drawing process. These effects improve the drawing limit of the material and effectively suppress the rupture and wrinkling in the traditional drawing. In order to study the influence of the pressure loading path in the drawing process, eight different loading paths were chosen to simulate the study. The gap was 1.1 mm. In this paper, the simulation test of AUTOSSETUP in Dynaform 5.9.1 was used. In line with the actual production and to determine the appropriate pressure, the maximum pressures of liquid chamber were 10, 20, 25, 28, 30, 32, 35, and 50 MPa, as shown in Fig. 3.

The overflow pressure was the maximum liquid pool pressure. Between 0 and 0.005 s, the pressure of the liquid chamber was zero. Until the punch was down to 0.005 s, the liquid chamber pressure started to load. When the punch was down to 0.008 s, the pressure of the liquid chamber reached 1 MPa and kept 0.002 s. At 0.01 s, the pressures of the liquid chamber linearly increased to 10, 20, 25, 28, 30, 32, 35, and 50 MPa respectively, keeping the hydraulic pressure until the forming end.

4.2 Analysis of pressure loading path of liquid overflow

The overall thickness of the stainless steel sink should be uniform thickness after forming. The thickness was generally 0.7–1.0 mm. In order to improve the service life and enhance the strength, the sink should not be much thin. From the drawing process requirements, the maximum thinning rate should not exceed 35% so that the sheet metal

Figure 3. Liquid overflow pressure.

thickness of the minimum is not less than 0.65 mm in the process.

When using the load curve No. 1, the overflow pressure was 10 MPa, which is not sufficient to reduce the initial tensile stress of the flange part. Therefore, the sheet was cracked at the beginning of drawing, and the rupture position was close to the punch fillet.

When using the load curve No. 8, the relief pressure was 55 MPa. As the overflow pressure setting was too high, the formed part was no longer deformed under the action of favorable frictional force. Under the action of the hydraulic pressure, the unfavorable friction of the flange portion was increased. The radial tensile stress of the sheet near the die cavity in the late stage of forming was too high, and then rupture occurs.

When using the load curve No. 2–No. 7, the overflow pressures were 20, 25, 28, 30, 32, and 35 MPa. The sink could be formed. The change of the thickness distribution of the final shape is shown in Figures 4–8. Observing the changes of color in these figures, as the relief pressure increases, we can find the change of the quality of the formed stainless steel sink.

When the overflow pressure was 20 MPa, as shown in Figure 4, the parts were able to shape.

Figure 4. Thickness of the cloud with 20 MPa.

Figure 5. Thickness of the cloud with 25 MPa.

The thickness changes more uniformly. The largest thinning area occurs in the straight wall near the bottom and edge corner.

The maximum thinning rate is 19.239%, not exceeding the limit, to meet the requirements. As the overflow pressure increases to 25 MPa, as shown in Figure 5, the thickness of the edge corner increases significantly. The maximum thinning area occurs in the straight wall near the bottom. The maximum thinning rate is 18.879% in the extent specified. When the overflow pressure increases to 28 MPa, the maximum thinning rate and the maximum thickening rate are about the same as that at the relief pressure of 25 MPa.

When the relief pressure was 30 MPa, it is clear from Fig. 6 that the distribution of the thickness of the part is not uniform. The straight wall of the bottom part is still the largest thinning area. And the rest is well formed. However, compared with the above thickness distribution, the maximum thinning rate increases significantly. The maximum thinning rate was 31.746%, not exceeding the allowable range, to meet the technical requirements. However, a minimum thickness of less than 0.7 mm did not meet the quality requirements of parts.

When the overflow pressure was 32 MPa, it can be seen from Fig. 7 that the forming quality of the parts was good. The thickness distribution was uniform, and the maximum thinning rate was reduced to 18.826%, which satisfies with the technological requirements and the quality requirements. When the overflow pressure was 35 MPa, it can be seen from Fig. 8 that the maximum thinning rate increases to 31.922%. The overall forming quality was generally as the same as that at 30 MPa, which is not good.

It can be seen that when the relief pressure was 32 MPa, the largest thickness was 1.329 mm. The smallest thickness was 0.812 mm, which is called uniform thickness. The maximum thinning rate

Figure 6. Thickness of the cloud with 30 MPa.

Figure 7. Thickness of the cloud with 32 MPa.

Figure 8. Thickness of the cloud with 35 MPa.

was 18.826%. When the maximum pressures of the sink were 20, 25, 28, 30, 32, and 35 MPa, the sink forming quality was best under the relief pressure of 32 MPa.

5 COMPARISON OF COMMON FORMING AND HYDROFORMING

We can analyze the forming results of the sink in the ordinary deep drawing process and the hydroforming process. The FLD diagram of the sink was used as the evaluation standard to compare the effects of the two forms on the quality. In this simulation, 304 stainless steel was selected as the sheet metal. The thickness was 1.0 mm, and the friction coefficient between the blank and the blank holder was 0.005. The friction coefficient between the punch and the sheet was 0.3. The friction coefficient between sheet metal and die was 0.005. The blank gap was 1.1mm. The punch speed was 2000 mm/s. The loading curve 1 was selected as the loading form. In the ordinary drawing simulation,

Figure 9. FLD of ordinary deep drawing.

Figure 10. FLD of hydroforming.

the friction coefficient between the sheet metal and the punch and blank holder was 0.125, and all the other process parameters were the same.

From the forming effects of the sink in the general drawing, we can see that the drawing of the straight wall part was not fully adequate, which was due to uneven flow of sheet metal. Form the forming effects of the hydroforming process, although wrinkled at the flange, the quality of the sink was not affected. The wrinkling area would be trimmed in the subsequent process, and the other parts were formed in good quality.

It could be seen from Figures 9 and 10 that the formability of the sink using the hydroforming was much higher than that in the ordinary deep drawing. Compared with the ordinary deep drawing, the problem of defects, such as insufficient drawing, was avoided in hydroforming. The forming quality of the parts is remarkably improved.

6 CONCLUSIONS

The advantages of the hydroforming process were mainly in the hydraulic retention effect. The layout of a reasonable hydraulic loading path was the key to the success of qualified parts (Wang Jianmin &

Qian Chunmiao, 2012). It was very important to select the appropriate relief pressure for the hydroforming process (Chen Xuguo & Li Jiguang, 2015). Only when the appropriate relief pressure was determined, the sheet metal forming can proceed smoothly. In the numerical simulation of the sink, when the safe pressure value was 32 MPa, the wall thickness was the most uniform. If the overflow pressure was not appropriate, there will be rupture phenomenon.

By comparing the ordinary deep drawing of the sink with the liquid chamber pressure loading curve No. 1, it was obvious that the quality of the sink under the hydroforming process was better than that of the ordinary deep drawing process.

The fabrication and measurement of a bi-axial thermal convection acceleration sensor

Huan Wang, Yigui Li, Ping Yan & Yuan Huang

School of Science, Shanghai Institute of Technology, Shanghai, China

Susumu Sugiyama

Department of Micro System, Ritsumeikan University, Japan

ABSTRACT: In this paper, a bi-axial (x and y axial) thermal convection acceleration sensor based on MEMS is described. The sensing principal, sensor design, fabrication process and the performance is illustrated. The sensor is fabricated by MEMS process using the SOI wafer. A thermistor with p-type slightly doped silicon beam is fabricated by micro fabrication technology and one end of the beam is fixed and the other end of the beam was free to increase the sensitivity of the sensor because the free end of the beam has a large Temperature Coefficient of Resistance (TCR) value.

1 INTRODUCTION

1.1 MEMS accelerometer

There are different kinds of acceleration sensors, such as thermal accelerometer, piezoelectric accelerometer, semiconductor piezo-resistive accelerometer, electrostatic capacitance accelerometer etc. (MA Ming-jun & RAN Yingling, 2015). In general, an accelerometer sensor uses an inertial mass to detect the acceleration (GUO Wei, 2012 & LI Li-Jie, 2001). Considering the fragility and complexity, a thermal convection chamber can be used instead of the inertial mass to overcome the disadvantages of the usual mechanical accelerometer (LI Li-Jie, 2001; WAN, Cai-xin, 2012; Stephen B. Pope, 2000; Alan J. Chapman, 1987 & S.M. Sze, 1985).

1.2 Gas thermal accelerometer

The accelerometer is based on free thermal convection principle. The heat source can be created by a heater inside a packaged cap. The accelerometer includes two parts, a sensing part and the packaged cap.

The sensing part is consist of an arc thermistor and its center part is fixed on the beam. The sensor may simultaneously detect acceleration at the direction of X and Y axial. The silicon thermistor is slightly p-type doped by doping boron. Further, the thermistor structures have been optimized in thermal stress.

2 PRINCIPLE

2.1 Temperature coefficient of resistance

The detection principle of the device is based on the thermal resistance effect of p-type silicon. The thermal resistance effect is an effect that the lattice scattering of a substance changes due to a temperature change. In general, the metal has a property that its resistance rises almost linearly with scattering of electrons as the temperature rises. If the resistance value at the reference R_0 temperature is T_0 , the resistance value R_1 at temperature T_1 can be expressed by the following equation:

$$R_1 = R_0 \{1 + \alpha(T_1 - T_0)\} \quad (1)$$

In equation (1) α is the temperature coefficient of resistance. The same as metals, semiconductors also have the property that remarkable change of resistance value when temperature changes. And the semiconductors are more sensitive than the metals.

2.2 Detection principle

The sensing chip of the sensor is packaged in an enclosed chamber. The sensing chip is consist of a heater in the center and four micro thermistors surrounding it. The thermistors are designed as free arc-shape, and its center part is fixed on the beam.

Figure 1. Schematic view of the accelerometer.

The heater creates a symmetric temperature distribution in the chamber. When no acceleration, the temperature is no difference on the thermistor. When the sensor is given an acceleration in one direction, the symmetrical distribution is broken, a set of the opposite of the thermistor has a temperature rise while the other is falling. Due to thermal effects, therefore resistance changes with temperature. The calculation formula is as following:

$$R_{a,b} = R(1 + 0.5\alpha\Delta t) \quad (2)$$

Here, R_a , R_b represent the resistance of the opposite thermistor, respectively. R is the resistance of the thermistor at room temperature. The resistance change is converted into an output voltage change by Wheatstone bridge and written equation:

$$V_{out} = \left\{ \frac{(R_a - R_b)}{2(R_a + R_b)} \right\} V_{in} \quad (3)$$

$$V_{out} = 0.25\alpha \cdot \Delta t \cdot V_{in} \quad (4)$$

And the schematic diagram of sensor was shown in Figure 1.

3 DESIGN AND ANALYSIS

3.1 Basic analysis

The mean temperature of the thermistor is an important factor and it directly affects to the performance of the sensor. The high value of the mean temperature means the high sensitivity of the sensor. The temperature of the thermistor is determined by the heat balance equation. In solving this equation, the effect of heat conduction between the tiny thermistor and the huge support arms is ignored.

Temperature distribution along the two thermistor is analyzed by ANSYS, and the result shows that temperature at the ends of the thermistor is higher than the ambient temperature. The dimensions of

each thermistor is designed as $160 \times 6 \times 2.5 \mu\text{m}^3$. Four kinds of materials are used: aluminum wire, light doped-silicon thermistor, high doped-silicon contact hole, and silicon dioxide insulator layer. The size of packaged cap and cavity are studied in the simulation.

3.2 Simulation

Using analysis software ANSYS, the three-dimensional model is built and the temperature distribution of the heat flow in the sensor is simulated.

Cross-sectional view of the sensor is shown in Figure 2 and the influence of cavity size on temperature difference is shown in Figure 3.

The L is the length of the cap, d is diameter of the cavity, the x is the position of the thermistor along the x axial and the x/L means the relative position of the thermistor.

The simulation results show that the length of the cavity L is $2400 \mu\text{m}$ and it is most sensitive. It was determined the size of the sensing chip to some extent. Through simulation it shows the change relationship between the sizes of the

Figure 2. Cross-sectional view of the sensor.

Figure 3. Influence of cavity size on temperature difference.

packaged cap and the heater. The size of the cap cause different sensor sensitivity. The sensitivity of the sensor is increased with the volume of the cap. In other words, the width and the height of the cap increases, the sensitivity increases. However, bigger size makes the frequency characteristic of the sensor worse and that limit the application. Therefore, a suitable packaged cap size was selected to improve the sensitivity of the sensor. Finally the size was $6000 \times 6000 \times 500 \mu\text{m}^3$.

4 FABRICATION PROCESS

SOI wafer is selected for the fabrication of the accelerometer. The fabrication process is shown in Figure 4.

Firstly, a 0.3 μm -thick SiO_2 insulation layer is formed by thermal oxidation on an SOI wafer. Next, photoresist is coated on the wafer and

Figure 4. Fabrication process of the sensor.

photo-lithography is carried out. Thereafter, to etch the oxidation layer, wet etching is performed with BHF, and $3 \mu\text{m} \times 3 \mu\text{m}$ contact holes are made after the removal the resist. When the contact hole is opened, boron is added through the contact hole. Then, in order to improve the metal semiconductor of the contact, p+ diffusion is carried out by putting it into a diffusion furnace. In this process, first, it is placed in a diffusion furnace at 1000°C for 1 hour, then wet etching is carried out by BHF, and then diffusing is carried out again by placing it in a diffusion furnace at 1200°C for 30 minutes. Aluminum wires ($0.15 \mu\text{m}$ -in-thickness) are formed by the process of vacuum vapor deposition, photolithography, and aluminum etching. By placing the material in an annealing furnace at 450°C for 30 minutes, Ohmic contact between aluminum and silicon is formed by sintering. The thermistor is formed by photo-lithography and deep reactive ion etching (Deep-RIE). Deep-RIE is performed only in the front wafer for 3 minutes, and etching is performed. The front surface of the thermistor is coated with photoresist. A layer of polyimide is deposited on the surface to provide the chip from mechanical damage. The rear surface is also etched by deep-RIE for about 5 hours and etching is performed to create the thermistor structure. Then, the HF (hydrofluoric acid) vapor removes the oxide buried to form the supports of the beams. The protective layer of polyimide and photoresist is finally peeled off by removing the underlying photoresist. The fabricated sensor is shown in Figure 5.

5 PERFORMANCE OF THE SENSOR

The output voltage of the sensor is measured at a given acceleration from -6 g to $+6 \text{ g}$. The measurement result is shown in Figure 6.

Figure 5. The fabricated sensor.

Figure 6. The sensor sensitivity.

Figure 7. The TCR value of P-type silicon.

The power of the heater is 14.7 mW and the input voltage is 1 V. The sensor sensitivity is 12 mV/g and the nonlinearity of the full-span output is 0.32% obtained from the measured sensitivity curve.

And the TCR value of the thermistor is tested by placing the sensing chip in an oven and increasing temperature from -30°C to 30°C . The P-type silicon TCR value is shown in Figure 7. The TCR value is 6000 ppm/ $^{\circ}\text{C}$.

6 CONCLUSION

In this paper, bi-axial thermal convection acceleration sensor based on micro-machining is described. The sensing principal, structure design, fabrication process and performance test is illustrated in detail. Based on heat convection simulation results, the sensor was designed and manufactured. The new type structure of the sensor reduces the 93% thermal stress of the thermistor compared with the commonly thermistor.

The convective sensor performance is strongly influenced by the size of cavity and cap of the package. The simulation result shows the sensitivity

change with the sizes of the packaged cap and the cavity. By compromising the accelerometer with the sensitivity and the bandwidth of the frequency, an appropriate size was estimated. The performance of the sensor was tested by experiments, and result shows that a linear relationship between the acceleration and the output signal is obtained.

One end of thermistors is free due to considering thermal stress is the merit of the sensor while that the load concentrates on the fixed end is its disadvantage. Since the large portion of aluminum layer causes very large thermal stress, the future work is to reduce aluminum wire size in order to lower the thermal stress.

Innovative green design of the frog ramming machine based on TRIZ/FRT

Z.G. Xu, J.L. Li & Z.Y. Zhu

School of Mechanical Engineering, Shandong University, Jinan, Shandong, China

ABSTRACT: The green innovation design of the frog ramming machine is done based on FRT (Future Reality Tree) and TRIZ. First, the traditional 39 parameters are classified into four major classes and 16 small classes, which are put into the green conflict parameters. The functions are analyzed for green innovation design, targets are solved, green conflicts are collected, and the subtractive model of the frog ramming machine is obtained by the FRT method. The product design process verified and exemplified the effectiveness of the cooperative TRIZ and FRT model.

1 INTRODUCTION

Yamamoto (1999) pointed out that green product design can improve environmental efficiency five times. Meanwhile, Hsiang-Tang Chang (2004) developed a new ecological design tool, which is proved to be effective in the application of TRIZ theory into green design, and five functional tools are developed: ecological retrieval tool, product evaluation tool by AHP, TRIZ engineering parameters describing the ecological factors, TRIZ invention tools, and invention retrieval tools. S. Vinodh (2014) proposed a quality function deployment on the basis of the awareness of environmental protection (ECQFD), the theory of inventive problem solving (TRIZ), and the Analytic Hierarchy Process (AHP) integration model for computer-aided innovation of auto parts and sustainable design.

The Future Reality Tree (FRT) is mainly used to verify whether the injection scheme can improve the system and achieve the desired results or adverse results after the injection (Qian, 2011). FRT describes the future prospects, the bottom-up approach is used, and the solution injection effect is predicted. FRT systems have two important roles: one is to make a preliminary evaluation scheme to remove the fault scheme, which does not meet the environmental requirements; the other is to find the negative effects through the solution injection and taking measures to prevent or eliminate the negative effects (Liu, 2008). Innovation programs are injected to insert the corresponding problem, and the corresponding FRT chart is illustrated.

2 GREEN CONFLICT RESOLUTION

The optimization goal of green design is to improve the green conflicts of a product. There are three

kinds of parameters: green parameters, general parameters, and half-general half-green parameters. To find out the potential conflicts, we first determine the innovation goal of a green product and then combined the functional model with the substance-field analysis. A detailed analysis of the relationship between subsystems and components determines the potential problem of the product, and then, the problem standardization and TRIZ conflict are found and solved.

Similar forms of substance field analysis model and optimization should be selected to cope with the following five models: complete function model, perfect incomplete function model, noneffective complete function model, excessive functions, and harmful function. The following two need to be removed.

When the improvement of noneffective complete function model increases the harmful functions to the existing system, conflicts will result. Table 1 shows the correspondence between green design factors with the engineering parameters.

The green design conflict resolution model is shown in the following steps.

1. Determine design goals: Subsystems are determined.
2. Establish the substance-field analysis model: According to the relationship between the subsystems, the existing product substance-field analysis model is established.
3. Find the existing problems: According to the product substance-field function analysis model, determine the deficiency function, excess function, harmful function, and the problem of standardization and choose the appropriate TRIZ tool to solve the problem and obtain the final solutions.

Table 1. Green product engineering parameters.

Green design para types	Green design factors	Corresponding engineering parameters
Green environmental factors	Low toxicity of materials	No.31
	Compatibility of materials	No.35
	Reusability of materials	No.23
	Easy degradation of materials	No.31
	Types of materials	No.26
Green energy factor	Reduction of resource consumption	No.1, No.2, No.7, No.8, No.23, No.26, No.32
	Energy use efficiency	No.22, No.23
	Reduction of energy consumption	No.15, No.21, No.22, No.25
Green environmental factors	Energy cleanliness	No.30, No.31
	Vibration noise	No.31
	Emission of pollutants	No.31
Green technology factor	Cleanliness of production	No.30, No.31
	Security	No.13, No.27, No.30
	Degree of intelligence	No.34, No.37, No.38
Green environmental factors	Life	No.15, No.16
	Removable property	No.13, No.25, No.33, No.34, No.36

- Determine the green conflict: Use FRT to determine whether there is a conflict between the target solution and the environment. If yes, product finding needs to optimize the green design parameters and deterioration of parameters and then determine the product of the green conflict.
- Green conflict resolution: According to Table 1, the green conflict into the corresponding engineering parameters, find the conflict matrix, according to the corresponding principle of the invention to get the target solution.
- Innovative program generation: According to the above-mentioned five steps, get the target solution, and the design of personnel knowledge and experience, get the product's green innovation program.

3 GREEN INNOVATION DESIGN OF FROG RAMMING MACHINE

Ramming machine in the work process generates severe vibration and makes a large noise, which can easily cause deviation from the original direction in the process of advancing. Therefore, it needs to be pulled back when advancing, and hard labor works are needed as well as the security of the whole apparatus is enormously reduced.

It is necessary to analyze ramming functions by TRIZ tools to find the existing problem of the ramming machine. TRIZ tools are used to get the target solution. FRT tools are also introduced to find the target solution, and the conflicts between the machine and the environment are classified. The conflicting problems are solved by the conflict matrix.

3.1 Functional model

According to the relationship between the parts of the actual situation and the ramming machine in the process, model function in the process is shown in Fig. 1. Ramming machine is analyzed to find the functional model, where four problems are described as the follows:

Question 1: when reinforcing the soft soil foundation, each time the frog rammer tamps the foundation, there will exist excess soil at the bottom part of the front plate of the compaction;

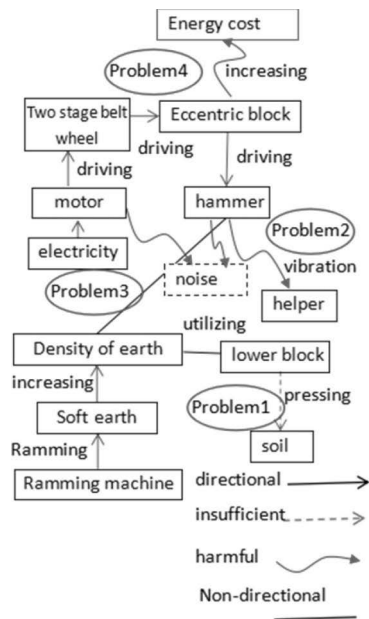

Figure 1. Functional model of the ramming machine.

inhomogeneity of soil distribution caused ramming machine offset line direction; and the pulling back to its original direction needs intensity of manual labor.

Question 2: horizontal centrifugal force generated by the rotation of the eccentric block drives the ramming machine move forward, causing the transverse vibration; rammer lifting caused vertical vibration; in addition, the rotation of the motor caused a certain vibration.

Question 3: tremendous noise is produced in the process of work, by the rotation of the motor, moving forward of the rammer, and the lifting of the hammer.

Question 4: because of the heavy eccentric block, the ramming machine starts very slowly, consuming huge amount of energy.

3.2 Target solution

Problem 1 came from the ill functional structure; substance-field model is used to solve this problem. It is a kind of noneffective complete system. Problem 1 and its substance-field analysis model are shown in Fig. 2. The possible solutions are shown in the following three schemes.

Scheme 1: a small hammer is added in the dynamic consolidation, which is located in the front of the floor, in the large ram compaction foundation, while the small ram compaction of the soil is in front of the floor.

Scheme 2: a “sweeping structure” is installed in the front floor, which is consisted of a cam and rack gear. A cam is arranged on both ends of the intermediate shaft; the cam and spring acted together to drive the reciprocating rack. The drive gear rotated repeatedly, and the gear and a swing rod are made into an integrated structure to remove the front soil.

Scheme 3: A small motor is installed in front of the floor; the small motor drives the fan to blow away surplus soil.

Problems 2 and 3 are very similar, which can be seen as a technical conflict. At the same time, the rammer increases the blow strength as well as the vibration

and noise. If parameter 10 is improved, parameter 31 gets deteriorated, the principles of 13, 3, 36, and 24 are obtained, and the following schemes are suggested:

Solution 4: introduce agent in the motor to absorb vibration caused by the motor.

Plan 5: Principle of acting conversely: adding a bias offset from the existing eccentric block to offset horizontal centrifugal force, thereby offsetting lateral vibration.

Plan 6: Principle of intermediary: installation of vibration damping material in the arm absorbs the transmitted vibration.

Plan 7: Principle of intermediary: add a motor cover, and reduce the noise caused by the motor rotation.

Problem 4 is regarded as a group of physical conflicts; the centrifugal force of eccentric block mass provides large force intensity, but will lead to slow starting of the ramming machine and high energy consumption. Spatial separation principle is used to solve the problems. The following schemes are suggested.

Scheme 8: Separation: the eccentric block is designed to be removed. When the eccentric block up-rotated, it moved upward; when rotated downward, it moved downward.

Plan 9: Local quality: eccentric block is made of hollow magnetic steel balls, with a magnet block installed on the eccentric block near the shaft hole.

4 GREEN DESIGN OF FROG RAMMING MACHINE

Scheme 1 is shown in Fig. 2. The difference between scheme 1 and scheme 2 is that the former has no the “pre-scanning structure”, where a small hammer (10) is utilized to remove the front soil; the view is shown in Fig. 2. Compared with scheme 2, scheme 1 has the following properties: simple structure, material saving, and better effects. Therefore, we adopt scheme 1 in this paper.

The front view of scheme 2 is shown in Figure 3; the down view of scheme 2 is shown in Figure 4.

Figure 2. Structure view of scheme 1.

Figure 3. Front view of scheme 2.

Figure 4. Down view of scheme 2.

Figure 5. Static state view of pulley 3.

Figure 6. Performance view of pulley 3.

A “front sweeping structure” is installed at the bottom front, which is consisted of a cam (10), gear (12), and rack cam (11). The cam is installed in both ends of the intermediate shaft; cam and spring (not marked in the figure) acted together to drive the reciprocating movement of the rack and the gear. The reciprocating rotation gear and a swing rod are made into an integrated structure to remove the front soil.

Compared with scheme 8, scheme 9 has properties of simple structure, material saving, easy to wear, long service life, and so on. Scheme 9 changed the structure of the output belt pulley 3, which is made of a hollow structure containing magnetic steel balls designed near the eccentric block.

In addition, the four ribs have a semi-solid structure. Near the center axis, where the belt wheel is made into a hollow structure and permanent magnet balls are put inside, it consisted of an arc magnet (31) and

a cylindrical magnet (32). The section view of pulley 3 is shown in Figure 4. Figure 4 is the state view of pulley 3; when the ramming machine does not work, the magnetic balls are put inside the arc magnet (31) and (32). Because of the lower weight of the eccentric block, the machine can start work quickly.

When the ramming machine works, the magnetic steel balls move toward the eccentric block; when the hammer was landed, the magnetic ball moved downward, as shown in Figure 6, and crackdown power increased. This scheme reduces the material consumption, improves the starting efficiency, and increases the blowing efforts.

5 CONCLUSIONS

The green conflict resolution model based on TRIZ/FRT is put forward in this paper for the ramming machine green design. Four types of parameters are put forward: green resources, green energy, green environment, and green technology. To sum up, these four aspects of engineering parameters corresponding to green design factors. The design process is verified by the green innovative design of a frog ramming machine, which becomes more complied with environmental requirements.

Rotor fault diagnosis based on SVM and improved D–S theory

Zhan-hong Yan & Ping Liao

College of Mechanical and Electrical Engineering, Central South University, Changsha, China

ABSTRACT: In order to overcome the shortcomings of the D–S (Dempster–Shafer) evidence theory, that is, the basic probability distribution is difficult to determine and the conflicting evidence is poorly treated, a diagnosis method based on improved evidence theory was proposed and applied to rotor fault diagnosis. First, using the pairwise coupling method and the one-to-one support vector machine to obtain the basic probability distribution function, the problem of how to obtain the original evidence was solved. Second, the theory of evidence was improved. The conflicting evidence was judged by the distance function of evidence. Then, the evidence was modified and combined to get fusion results. A variety of rotor fault signals were collected and analyzed in the experiments. The results showed that the diagnosis method was effective.

1 INTRODUCTION

Rotor system always plays an important role in electric power, aviation, and other industries. Its condition is related to equipment safety; therefore, it is necessary to perform research on rotor fault diagnosis. The D–S (Dempster–Shafer) evidence theory can fuse evidence without prior knowledge, so it is widely used in fault diagnosis of rotor system (Chen 2005). However, the D–S theory faces two problems (Sima 2012): (1) how to quantify the sensor information to get the original Basic Probability Assignment (BPA). The main solutions to this problem include the neural network method and the expert experience assignment method. However, neural network training requires a lot of historical data, and there are over fitting, local minimum phenomena in it; the expert experience assignment method relies on subjective judgment, and its scope is limited (Jiang 2012); (2) Uncertainties in measuring systems and error accumulation may bring conflicting evidence, but the D–S theory will cause unreasonable conclusions when dealing with highly conflicting evidence. Although some researchers proposed some improved methods to solve this problem, there are still slow convergence, low accuracy, and some other shortcomings (Yager 1987, Liu 2014).

Therefore, to overcome the aforementioned shortcomings of the D–S theory, we proposed a rotor fault diagnosis method on the basis of Support Vector Machine (SVM) and improved evidence theory. The pairwise coupling (Hastie 1998) and one-to-one SVM were used to obtain the BPA function. Then, the D–S evidence theory was improved to judge the conflicting degree of evidence, and the evidence was modified. Finally,

data fusion was performed to obtain the diagnostic results. The method was applied to the rotor system in unbalance, misalignment, and other conditions. The results showed that the diagnostic accuracy was improved.

2 THEORETICAL BASIS OF THE EVIDENCE THEORY

Supposing that frame of discernment $\Theta = \{A_1, A_2, \dots, A_n\}$ consists of evidence E_1 and E_2 , the BPA functions are $m_1(A_i)$ and $m_2(A'_j)$, the focal elements are A_i and A'_j , and the D–S rule of combination is:

$$\begin{cases} m(\Phi) = 0 \\ \sum_{\substack{A_i, A'_j \in 2^\Theta \\ A_i \cap A'_j = A}} m_1(A_i)m_2(A'_j) \\ m(A) = \frac{\quad}{1 - k}, \forall (A \neq \Phi) \end{cases} \quad (1)$$

where k is the normalization constant:

$$k = \sum_{\substack{A_i, B_j \in 2^\Theta \\ A_i \cap B_j = \Phi}} m_1(A_i)m_2(A'_j) \quad (2)$$

K represents the conflicting degree of evidence. The larger the k , more serious is the conflict of evidence. If we combine the evidence by using equations (1) and (2), it will lead to incorrect results.

3 OBTAINING BPA BASED ON SVM

As the general form of BPA is not given by the D–S theory, in application, obtaining BPA requires a

detailed analysis. SVM is a new machine learning method proposed by Vapnik. Compared with neural network, SVM can achieve a good accuracy with only a small number of training samples. It also has better generalization ability and no local minimum phenomenon (Ai 2005). Meanwhile, SVM has strict theoretical and mathematical basis, so the BPA function obtained from SVM overcomes the shortcomings, which the expert experience method lacks in (Zhou 2014).

However, the output of standard SVM can only judge whether the input samples belong to or not to a certain class. Platt (2000) proposed a method to convert the standard SVM output value f to probability p_i by sigmoid function:

$$p_i = \frac{1}{1 + e^{Af+B}} \quad (3)$$

$$F(A, B) = \min - \sum_t^K [t_i \log(p_i) + (1-t_i) \log(1-p_i)] \quad (4)$$

$$t_i = \begin{cases} t_+ = \frac{N_+ + 1}{N_+ + 2} \\ t_- = \frac{1}{N_- + 2} \end{cases} \quad (5)$$

where p_i is the probability of sample x_i , K is the number of training samples, $t_i = t_+$ or t_- when the classification result is 1 or -1, respectively, and N_+ and N_- are the number of samples classified into 1 or -1, respectively. By solving (4) and (5), we can gain A, B in (3) and then get a function of f and p_i .

The method proposed by Platt is only suitable for dealing with two classification problems and cannot be applied to multiclassification problems directly. Therefore, we use the pairwise coupling classification proposed by Hastie (1998) to convert two classes probabilities into multiclassification probability. By solving the optimization problem of (6), the probability p_i of the class i is obtained as the original BPA function in the D-S rule:

$$\begin{cases} \min_p \sum_{i=1}^k \sum_{j:j \neq i} (r_{ji} p_i - r_{ij} p_j)^2 \\ \sum_{i=1}^k p_i = 1, p_i \geq 0, i = 1, \dots, k \end{cases} \quad (6)$$

where $j=1, \dots, k$, k is the number of classes, $i \neq j$; r_{ij} represents the probability that the sample x_i belongs to class i when pairing the i th class and the j th class. Equation (6) can be rewritten as:

$$\min_p 2 p^T Q p = \frac{1}{2} \min_p p^T Q p \quad (7)$$

$$Q_{ij} = \begin{cases} \sum_{s:s \neq i} r_{si}^2, i = j \\ -r_{ij} r_{ji}, i \neq j \end{cases} \quad (8)$$

Where p should satisfy the following equation:

$$\begin{bmatrix} Q & e \\ e^T & 0 \end{bmatrix} \begin{bmatrix} p \\ b \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \end{bmatrix} \quad (9)$$

Where $p = [p_1, p_2, \dots, p_k]^T$ is the solution of (6), e is a $k \times 1$ vector, whose elements are all one, θ is a $k \times 1$ vector, whose elements are all zero, and b is the Lagrangian multiplier of equality constraint $\sum p_i = 1$.

Wu (2004) gave the following algorithm to compute p :

1. Give initial value to p , which satisfies:

$$\sum_{i=1}^k p_i = 1, p_i > 0 \quad (10)$$

2. Repeat ($t = 1, \dots, k$) (11) and (12):

$$p_i \leftarrow \frac{1}{Q_{ii}} \left[- \sum_{j:j \neq i} Q_{ij} p_j + p^T Q p \right] \quad (11)$$

$$\text{Normalize } p \quad (12)$$

until (9) is satisfied.

4 IMPROVEMENT OF THE D-S THEORY

In practice, the error factors lead to conflicting evidence, but the D-S theory is not suitable for dealing with it. Hence, we use the distance function of evidence as a criterion to determine whether evidence is conflicting to other or not. Then, the evidence will be amended and combined by the D-S rules (Pan 2013, Zhang 2009).

The distance function (d_{ij}) of evidence E_i and E_j in the frame of discernment is defined as:

$$d_{ij} = \sqrt{\frac{1}{2} (\|m_i\|^2 + \|m_j\|^2 - 2 \langle m_i, m_j \rangle)} \quad (13)$$

where $\|m_i\|^2 = \langle m_i, m_i \rangle$, $\langle m_i, m_j \rangle$ is the inner product of m_i, m_j , $d_{ij} \in [0, 1]$ and $d_{ij} = d_{ji}$. d_{ij} describes the distance of evidence. The greater the value, the higher the conflicting degree of evidence E_i and E_j .

If there are X pieces of evidence, the distance function matrix formed by them is:

$$S = \begin{pmatrix} 0 & d_{12} & \cdots & d_{1X} \\ \vdots & & \ddots & \vdots \\ d_{X1} & d_{X2} & \cdots & 0 \end{pmatrix}_{X \times X} \quad (14)$$

Introducing the parameter c_i represents the conflicting degree of E_i and other evidence:

$$c_i = \frac{1}{X} \sum_{\substack{j=1 \\ i \neq j}}^X d_{ij}, i, j = 1, 2, \dots, X \quad (15)$$

As $d_{ij} \in [0, 1]$ and the diagonal elements of the matrix S are all zero, there should be $0 \leq c_i \leq [(X-1)/X]$.

Thus, we introduce the discounted factor, ω_i , as the weight of the evidence. The smaller the c_i , indicating that E_i is more similar to other evidence, the greater the value of ω_i . Otherwise, ω_i should be smaller.

Let $\omega_i = f(c_i)$, ω_i and c_i should meet the following conditions:

- $c_i \rightarrow [(X-1)/X], f(c_i) \rightarrow 0; c_i \rightarrow 0, f(c_i) \rightarrow 1$
- $0 \leq f(c_i) \leq 1, f(c_i)$ should be monotonically decreasing in its interval.
- When c_i small, ω_i should decrease slowly. As c_i increases, ω_i should decrease rapidly to zero.

Thus, $f(c_i)$ should be an exponential function. A similar creditable factor was defined by Pan (2013) and Zhang (2009). We define:

$$\omega_i = \left(1 - c_i \cdot \frac{X}{X-1}\right) \beta^{c_i \cdot \frac{X}{X-1}} \quad (16)$$

Where β is an unknown parameter to be determined. Supposing $t = c_i[X/(X-1)]$, then $0 \leq t < 1$. Taking derivation of t , we have:

$$f'(t) = \beta^t (\ln \beta - t \ln \beta - 1) < 0 \quad (17)$$

Rewriting (17), we get $\beta < e$. When β decreases, $f'(t)$ will decrease slowly, which do not meet the condition c. Therefore, replacing t with c_i , we have:

$$\omega_i = \left(1 - c_i \cdot \frac{X}{X-1}\right) e^{c_i \cdot \frac{X}{X-1}} \quad (18)$$

After the discounted factor ω_i is determined, if the BPA function before modification is $m_i(A_j)$ and that after modification is $m'_i(A_j)$, we use (19) to modify the evidence:

$$\begin{aligned} m'_i(A_j) &= m_i(A_j) \cdot \omega_i, A_j \neq \Theta \\ m'_i(\Theta) &= 1 - \sum_{j=1}^X m'_i(A_j) \end{aligned} \quad (19)$$

Figure 1. Relationship between discounted factor and conflicting degree when $X = 3, 4, 5$.

Finally, the D-S rule is used to combine the modified evidence and then we can obtain the results of evidence fusion.

5 APPLICATION IN ROTOR FAULT DIAGNOSIS

5.1 Diagnostic model

Large rotor common faults include loose bearings, unbalance, misalignment, and rubbing. In order to fully and accurately capture these faults, it is necessary to set multiple measurement points to collect vibration signals in different locations on the rotor system. The vibration signals were used to extract features and form diagnostic eigenvector. Those eigenvectors formed by each measuring point data were input to SVM for training and testing, and the BPA function was generated. The BPA function produced by each measuring point was regarded as a piece of evidence. Then, we can calculate the conflicting degree and modify evidence to eliminate the impact of uncertain information. Finally, the D-S evidence theory can be used to fuse the evidence and get the diagnosis result.

On the basis of the common faults of the large rotor, a rotor fault simulation platform was built. The platform consists of multistage pull rod rotor, motor, eddy current sensors, and brake (Fig. 2). The fault diagnosis system was established by applying the SVM and the improved evidence theory as shown in Figure 3.

5.2 Rotor fault signal feature extraction

The vibration signals generated during the operation can reflect the fault characteristics. Because of error accumulation, analysis of single sensor data is difficult to accurately identify the fault.

Figure 2. Fault simulation platform.

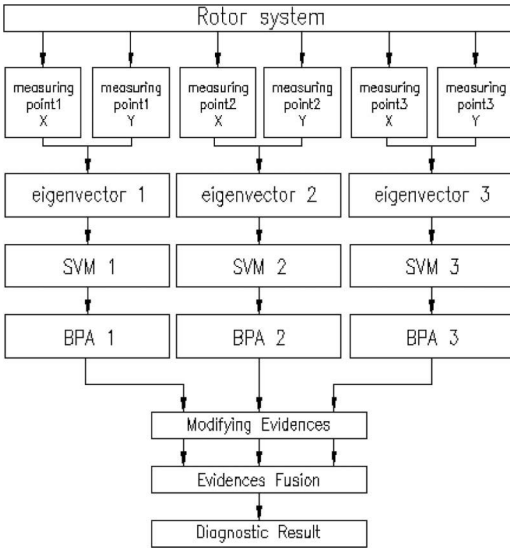

Figure 3. Rotor fault diagnosis system.

To solve this problem, we collected the vibration signals in different positions of the rotor and used the wavelet packet to process the signals to get the diagnostic eigenvector.

The rotor radial vibration signal was measured by setting eddy current sensors in three positions of the rotor. As only the signals measured by two sensors perpendicular to each other can fully describe vibration information (Han 2009), one eddy current sensor was set in horizontal direction and another one in vertical direction. The signals were recorded as $x_1, y_1, x_2, y_2, x_3,$ and y_3 , which represented horizontal and vertical signals in three points. During the experiments, rotor speed was 1460 rpm and sampling frequency was 1 kHz. Some of the fault vibration signals are shown below (unbalanced fault as example).

The frequency band energy distribution of the vibration signal reflects the fault characteristics,

Figure 4. Unbalanced fault, sensor x_2 signal.

Figure 5. Unbalanced fault, sensor y_2 signal.

so we can form the eigenvector of diagnosis by decomposing band energy spectrum. We used the wavelet packet to decompose the signal and obtain the energy spectrum and wavelet energy entropy. The eigenvector, which is the full description of the fault information characteristics (Han 2009), was obtained by combing energy spectrum and the energy entropy. Meanwhile, noticing that $1/2f, 2f, 3f,$ and so on ($f =$ rotor speed) are fault characteristic frequencies (Zhou 2014), in order to capture the fault information more accurately, we decomposed the signal as shown in Table 1.

db12 was selected as the wavelet basis. The x, y signals from one measuring point were filtered and decomposed by wavelet packet. Wavelet reconstruction coefficients obtained from eight nodes were numbered as $S_{x1}(n), S_{y1}(n), S_{x2}(n), \dots, S_{y8}(n)$ in descending order of frequency. Then, the energy spectrum and energy entropy of the j th frequency band were:

$$E_{zj} = \sum_{n=0}^N (|S_{xj}(n)|^2 + |S_{yj}(n)|^2) \quad (20)$$

$$E_{zTotal} = \sum_{j=1}^8 E_{zj} \quad (21)$$

where $N =$ the number of sampling points. Normalizing E_{zj} , we can obtain the vibration signal wavelet relative energy spectrum $q_z = [q_{z1}, \dots, q_{z8}]$

The wavelet energy entropy, H_{zW} , is:

$$H_{zW} = - \sum_{i=1}^8 q_{zi} \log q_{zi} \quad (22)$$

In conclusion, the eigenvector of rotor vibration signal is: $W = [q_{z1}, \dots, q_{z8}, H_{zW}]$

5.3 BPA function design

With the eigenvector, now we can establish the frame of discernment $\Theta = \{A_1, A_2, \dots, A_5\}$ representing misalignment, imbalance, rubbing, loose bearings, and normal five conditions. Several sets of vibration signals were collected under five conditions and some eigenvectors are shown in Table 2:

It can be seen that the decomposition according to Table 1 showed the signal energy distribution under different faults. But considering the noise and error, single sensor information may still cause misjudgment.

According to the algorithm shown in Section 2, 75 sets of data from the measuring point 1 (15 groups for each case) were input as training samples. SVM was set with RBF kernel, and the cross-validation method was used to obtain SVM-related parameters (Wang 2014) to form SVM1. Similarly, SVM2 and SVM3 were formed. For each of the three SVMs, 175 sets of test samples (35 groups for each case) were input. The results of BPA are shown in Table 3.

Table 1. Wavelet packet decomposition nodes.

Node	Frequency range	Node	Frequency range
(1,1)	0–0.3125 <i>f</i>	(4,3)	2.5–3.75 <i>f</i>

...

The accuracy of the diagnosis result was judged according to the following rule (Geng 2006):

$$\begin{aligned} m(A_i) &= \max(m(A_i)) \\ m(A_i) &> \eta \end{aligned} \quad (23)$$

5.4 Evidence fusion

As can be seen in Table 4, relying on information from a single sensor will reduce the accuracy. Therefore, we combined the multisensor information and improved the diagnostic accuracy. According to the improved method shown in Section 2, 175 groups of samples were combined. Taking unbalanced fault as an example, Contrast Yager (1987), Liu (2014, $\tau = 0.5$), D–S and improved D–S theory in Section 4, the following results are obtained.

In Table 5, the probabilities of unbalance fault from SVM1, SVM2, and SVM3 were 0.869, 0.553, and 0.025, respectively. Because of the high conflict, the probability of normal condition (0.584) was higher after treatment by the D–S rule; The uncertainty degree of Yager’s rule was 0.971, which means it is difficult to determine the fault; Only Liu’s (0.582) and the improved method (0.603) produced a result that the rotor was more likely in unbalanced fault, which was consistent with the actual situation.

In Table 6, the BPA functions provided by SVM1, SVM2, and SVM3 were slightly different from each other (the probabilities were 0.799, 0.717, and 0.553, respectively). After the fusion, the uncertainty of Yager’s rule was 0.673, and still

Table 6. Comparison of convergence.

	$m(A_1)$	$m(A_2)$	$m(A_3)$	$m(A_4)$	$m(A_5)$	Θ
SVM1	0.025	0.799	0.025	0.026	0.125	0
SVM2	0.025	0.717	0.025	0.025	0.208	0
SVM3	0.024	0.553	0.024	0.024	0.375	0
D-S	0	0.970	0	0	0.030	0
Liu	0.016	0.791	0.016	0.016	0.161	0
Yager	0	0.317	0	0	0.010	0.673
Improved method	0	0.965	0	0	0.035	0

Table 7. Accuracy of different algorithms.

Methods	Number of correct predictions	Number of test samples	Accuracy
D-S	140	175	80.0%
Liu	146	175	83.4%
Yager	27	175	15.4%
Improved method	162	175	92.3%

it is difficult to determine the type of fault. Liu's method correctly diagnosed the rotor condition but with slow convergence (0.791). Only the results of the D-S method and improved method showed that the probability of the unbalanced fault was more than 0.96, which showed better convergence efficiency as well.

Let the threshold $\eta = 0.9$. 175 groups of test samples be fused. The accuracy of diagnosis is shown in Table 7, according to (23):

It can be seen that all the methods improved the diagnostic accuracy. Among them, the improved method was the best; while Yager's method had the worst result. Liu's method and the D-S method had a certain improvement in the correct rate; however, the effect was not good as that of the improved method.

6 CONCLUSION

The pairwise coupling was combined with SVM to solve the problem of evidence generation and overcame the shortcomings of the expert assignment method and neural networks.

The D-S evidence theory was improved. The conflicting degree of evidence was judged by the distance function of evidence. Then, the evidence was modified and combined. Experiments showed that the improved method could deal with conflicting evidence well and had a high convergence speed.

The fault characteristics of rotor system were analyzed. Combined with the signal characteristics,

a rotor fault diagnosis method was established by using wavelet, SVM, and improved evidence theory. Experiments showed that the accuracy of diagnosis was improved, indicating that the method was valuable in actual rotor fault diagnosis.

A study of the relationship between pre-tightening force and torque in precision instrument assembly

Shuang Huang, Xin Jin, Zifu Wang, Zhijing Zhang, Muzheng Xiao & Can Cui
Beijing Institute of Technology, Beijing, China

ABSTRACT: The screw thread connection is widely used in precision instruments and the quality of threaded connections directly affects the assembly quality and reliability of the product. (Yang X, 2011) With the development of micro precision mechanical and electrical products, the requirement of controlling on micro-thread connection is becoming much higher. The present work aims to embark from theoretical analysis and experimental research to explore the rules and characteristics of high precision threaded connections. During the research, the accurate torque-preloading force mapping relationship of the miniature titanium screw in the aerospace field is measured. (Nassar SA, 2005) The experimental method as well as all the results in the present work can be utilized to improve the accuracy and the dynamic stability of the precision instruments and provide guidance for the assembly process of precision instrument.

1 INTRODUCTION

One of the most important reasons why threaded connection is widely used is that it can provide considerable connection force, besides, it can be repeatedly disassembled and interchanged. In the field of aerospace precision instruments, there are higher requirements for the threaded connections. The precise controlling of the pretightening force has a great influence on the precision and the stability of the instrument, so that the accurate measurement of torque-preload relationship for realizing the quantitative control of assembly has the vital significance. As early as 1953, the screw torque controlling has strict and precise assembly requirements in the assembly process standard of Sidewinder missile. In the field of assembly, researches have done a lot of work in the design of threaded connection form, but rarely involves the study of the torque-preload force accuracy control, especially small size high precision thread connection. (Zaki AM, 2008) Consequently, the aim of the present work is to explore the torque—preload force mapping relationship of the miniature titanium screws in the aerospace field through theoretical analysis and experimental research.

2 MECHANICAL MODEL OF THE TORQUE METHOD IN THE TIGHTENING PROCESS

In the process of uniform tightening bolts as shown in figure 1, there are four kinds of torque. The

tightening torque T is initiatively applied, and the friction torque T_b between the bolt head and the supporting surface which is a passive torque. The friction torque T_t between the screw thread surface and the internal thread surface is another passive torque, and the torque which is provided by lead angle generate the preload force. This is constantly increasing in the process of tightening and has the following relationship:

$$T = T_b + T_t + T_\alpha \quad (1)$$

The yellow ring in figure 2 is the joint surface of threaded connection. The torque of the yellow joint surface is called the face friction torque T_b . If

Figure 1. The mechanical model in the process of tightening.

Figure 2. The schematic diagram of the friction area under the surface of the nut.

the equivalent friction diameter is d_b , the friction torque can be expressed as follows:

$$T_b = \frac{1}{2} d_b F \mu_b \quad (2)$$

F is screw preload force, μ_b is the friction coefficient of the relative sliding surface.

The equivalent friction diameter can be calculated by

$$d_b = \frac{D_1 + D_2}{2} \quad (3)$$

Where D_1 is the washer outer diameter or the outer diameter of bolt head circular contact area, which is the large diameter of contact area, D_2 is thread through hole internal diameter or washer internal diameter, which is the small diameter of contact area.

Take the rectangular bolt nut connecting as an example as shown in Figure 3 (a). The nut is regarded as a slider, and it is applied on the positive pressure F which is equal to the bolt interior preload (parallel to the bolt axis), the thrust F_t (perpendicular to the bolt axis) can be equivalent as the friction torque on the thread surface. In figure 3 (a), spread along pitch diameter of thread to draw the figure 3 (b). If the friction on the supporting surface is ignored, the tightening process can be converted into the oblique plane-block mechanism. In that case, there remain a horizontal force F_t and a vertical pressure F . And if we proceed the orthogonal decomposition, then we can get figure 3 (b), the mechanical relationship of the forces can be expressed as follows:

Figure 3. Rectangular thread force analysis.

$$\begin{aligned} F_t &= F_t \cos \phi - F \sin \phi \\ N &= F \cos \phi + F_t \sin \phi \\ F_t &= \mu_t N = \mu_t (F \cos \phi + F_t \sin \phi) \\ &= F_t \cos \phi - F \sin \phi \\ F_t &= \frac{\mu_t + \tan \phi}{1 - \mu_t \tan \phi} F \end{aligned} \quad (4)$$

Where ϕ is the lead angle, μ_t is the thread surface friction coefficient, N is the support force of the leveling to the sliding block, F is the equivalent preload force, F_t is the equivalent thrust, F_f is the equivalent thread surface friction.

Setting thread surface friction angle as ρ , and put it into the formula (4), the equivalent thrust can be expressed as follows:

$$F_t = \frac{\tan \rho + \tan \phi}{1 - \tan \rho \tan \phi} F = F \tan(\rho + \phi) \quad (5)$$

Setting equivalent friction diameter value is the thread pitch diameter d_2 , so in the tightening process, the friction torque T_t can be expressed as follows:

$$T_t = \frac{d_2}{2} F \tan(\rho + \phi) \quad (6)$$

The equivalent friction angle ρ' of the triangular thread can be expressed as follows:

$$\tan \rho' = \frac{\mu_t}{\cos \alpha'} \quad (7)$$

Where α' is the included angle between the thread flank and the vertical thread axis.

Put ρ' into the formula (6), T_t can be expressed as follows:

$$T_t = \frac{d_2}{2} F \tan(\rho' + \phi) \quad (8)$$

Where d_2 is pitch diameter of thread, at the same time it is also the equivalent friction diameter.

For the average metric triangular thread:

$$25^\circ < \alpha < 30^\circ$$

$$\varphi < 3^\circ$$

Then:

$$1.103 < \frac{1}{\cos \alpha'} < 1.155 \quad (9)$$

$$\tan \varphi < 0.0524 \quad (10)$$

However the scope of the friction coefficient of the general metal materials:

$$0.1 < \mu_t < 0.3 \quad (11)$$

Synthesize the formula (7) to (11), we can get

$$\tan \rho' \tan \varphi \approx 0 \quad (12)$$

Put the formula (12) into the formula (8)

$$T_t = \frac{d_2}{2} F (\tan \rho' + \tan \varphi) \quad (13)$$

For

$$\tan \varphi = \frac{p}{\pi d_2} \quad (14)$$

Putting the formula (2), the formula (7), the formula (13) and the formula (14) into the formula (1), the ordinary triangular thread tightening torque T can be calculated as follows:

$$T = Fd \left(\frac{d_b \mu_b}{2d} + \frac{d_2 \mu_t}{2d \cos \alpha'} + \frac{p}{2\pi d} \right) = KFd \quad (15)$$

From the formula (15), we know the use of empirical the formula (1) can describe the tightening process of the torque method, but there are many factors which will more or less affect the number of K , they will enlarge the dispersion degree of the preload force.

When the thread is loosened, there are still two friction torques. The friction torque on the support surface has an exactly opposite direction, yet the algorithm does not change. In that case, the thrust in the force model of the screw thread reverses at the moment, and the direction of the preload force do not change. Therefore, breakaway torque T' can be calculated as follows:

$$T' = Fd \left(\frac{d_b \mu_b}{2d} + \frac{d_2 \mu_t}{2d \cos \alpha'} - \frac{p}{2\pi d} \right) = K'Fd \quad (16)$$

3 EXPERIMENTAL STUDY

In order to study the rule of F/M mapping in the tightening process of small size screws, an experimental device for screw tightening is designed. Screw tightening conditions can be changed to detect the torque coefficient of the screw in different conditions, then the torque curve and the tension curve in the process of screw tightening can be obtained.

The schematic diagram of the screw tightening experimental apparatus is shown in figure 4. We use the torque tester and high precision sensor to display in real time and collect the tightening torque and the preload. The experimental bolt is fixed on both sides of the support surface by the experiment nut, a replaceable gasket is fixed on the supporting surface, which can simulate the contact between the connected part support surface and the screw lower surface. The experiment nut is fixed on the connecting column by two pressing plates, and the bottom end of the connecting column is connected with the tension-compression sensor which is fixed to the bottom plate. The four corners of the bottom plate have four studs, which are used to support the supporting surface and adjust the distance between the upper and the lower boards. In the tightening process, when the screw rotates under the action of torque, due to friction of the contact area, the nut will rotate to some extent along with the screw. The tighter the bolt screws, the greater the friction and the nut torque is. In order to prevent the tension-compression sensor from the excessive torque damaging, a limit device is designed to limit the rotation of the connecting column.

A torque tester is used to make a real-time detection of the screw tightening torque and a tension-compression sensor is utilized to measure the size of the screw preload force. The experiment is carried out by using the connecting column, which can replace the nut. Besides, each screw corresponding to a nut. The upper gasket will be

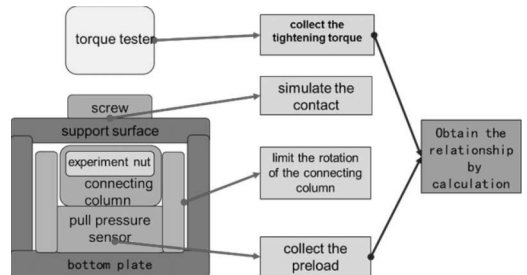

Figure 4. The schematic diagram of the screw tightening experimental apparatus.

Figure 5. The experiment device.

changed to satisfy different materials and different hole sizes.

4 THE MEASUREMENT OF THREAD PITCH DIAMETER

The machine vision detection is the main method that used in precision measurement of micro-miniature device. It is a measurement method which combines optical microscopy techniques and computer vision technology. In this paper, we use a CCD sensor to measure the pitch diameter of the screw. The basic principle is: Place the screw in the field of the CCD view, and then light the screw using a backlight, screw images are optical lens imaging on the light-sensitive chips, light sensitive chip converts the collected image into image signal. With the basis of pixel brightness and pixel color information, we put them into digital signals after image processing system receiving the light-sensitive chips transmit to image signal. Image system takes a variety of operations in order to change these signals into the characteristics of the target, so that realize precision measurement of the tested pieces.

The rapid detection system based on machine vision is shown in figure 6.

The image processing methods is as follow:

First, we take five points in the thread path in order to fit a straight line. Then a contour line on the other side of the thread should be taken. We find the closest point of contour line to the straight line and get the distance between which names L1. Second, we take five points on the large diameter using the same method of screw thread in order to fit a straight line. Then we find the closest point of contour line to straight line, and name the distance between them as L2. Then we can calculate the thread of the large diameter using L1 and L2. Since the M2 screw pitch P is 0.4 mm, and the M3 screw pitch P is 0.5 mm, we can obtain the screw pitch diameter by:

Figure 6. Device rapid detection system based on machine vision.

Figure 7. Experimental sample image.

Figure 8. Measuring the thread.

$$D_2 = 2L_2 - L_1 - 0.6495P \quad (17)$$

The measured results are shown in table 1.

5 RESULTS AND DISCUSSION

Experienced workers of the aviation instrument assembly process are invited to help the experiment, each worker loads and releases respectively

with the load wrench of experimental torque tester and his customary production assembly tools. After the statistical analysis of a number of experimental results, the conclusions and results are shown in table 2.

As shown in table 2, each worker in this experiment loads and unloads for four times. The first three times are loaded with the load wrench of the experimental torque tester, and the last one is loaded with the tools customary used in the assembly. While the front is intended to accurately measure the mapping relationship of torque-preload force of precision aerospace screws, and the latter is intended to measure the magnitude and consistency of torque and preload for threaded fasteners in existing production processes.

Results of the worker shows that the process in the production of bolt pre-tightening force distri-

Figure 9. The average K of all experimental results.

Figure 10. Tightening for the 1st time.

Figure 11. Tightening for the 2nd time.

Figure 12. Tightening for the 3rd time.

bution is around 400 N, but the consistency is not ideal because the variation coefficient is extremely high, therefore, to optimize the assembly process and improve assembly standard is very important.

Figure 9 illustrates the torque coefficient K that a worker tighten a lot of screws three times, and figure 10 to 12 are the results of the individual time. It is found that the average of K is above 0.5, and this does not conform with engineering experience value 0.3, it shows that precision of threaded fasteners in the field of aerospace torque coefficient K have their own different rules.

As is shown in the pictures above, among three times of tightening screw, average torque coefficient K reduce with the increase of the crew tight times. This is because the tight make the thread much smoother, and these can lead to reduction of the torque coefficient, which means less preload can achieve the same torque. Other tighten the supervision of the process have similar laws.

6 CONCLUSION

In this article, we analyzed the research status of precision instrument at home and abroad, and then delve into the influence of threaded fasteners which is precise assembled in mechanical and electronic products in the field of aerospace. A theory research and experimental study on miniature threaded fastener tighten process is implemented, further, the distribution law of coefficient K is summarized and the mapping relationship of preload force is explored. The whole work of the present study makes a foundation for instrument assembly process optimization in the field of aerospace.

Thermal characteristic analysis of a hollow screw based on the fluid structure thermal coupling

X.S. Li, W. Xiong & J.N. Xu

School of Mechanical Engineering, Shenyang Ligong University, Shenyang, P.R. China

ABSTRACT: Thermal deformation problems of the hollow screw of a machine tool were analyzed during the working process. The mathematical models of the screw deformation were established. On the basis of the heat transfer theory, the fluid structure thermal coupling problem of screw was solved under different coolant flow rates and temperatures. According to the temperature field and thermal deformation under different working conditions, the rules of thermal deformation about hollow screw were obtained under different flow rates and coolant temperatures. The analyzing results show the best flow and optimum temperature of cooling fluid.

1 INTRODUCTION

As the ball screw is an important transmission part of a machine tool, its performance directly affects the running state and precision of the tool (Ramesh et al. 2000). If a machine tool works at high speed and heavy loading, the screw-nut and bearing will generate a lot of heat. If the heat could not be spread out in time, then it would lead to a higher temperature and thermal deformation. Therefore, low temperature and narrow thermal deformation are very important to reduce machining errors (Wang et al. 2009).

Much research has been done on the problem of thermal deformation of screw. Kim et al. (1997) obtained the temperature distribution of screw at different speeds and running times using the method of finite-element analysis (FEM). Cao et al. (2011) analyzed the optimum coolant flow value for the hollow screw by the ANSYS thermal analysis module. However, few people have studied the fluid structure thermal coupling effect on the deformation of screw.

The Y-axis hollow screw of a boring-milling machining center named TX1600G is taken as the research object. In this paper, temperature field and thermal deformation were analyzed combining with the actual working conditions, that is, mean different cooling fluid flow and temperature. This paper will provide a theoretical basis for decreasing the thermal deformation of hollow screw.

2 MATHEMATICAL MODEL OF TEMPERATURE FIELD

In the process of heat generation, the heat quantity is directly proportional to the temperature gradient

and the section area in unit time. The direction of heat transfer is opposite to the temperature rise, which is the Fourier law (Guo 2002):

$$q = -\lambda \frac{\partial T}{\partial n} \quad (1)$$

$$-\lambda \frac{\partial T}{\partial n} = \lambda_x \frac{\partial T}{\partial x} n_x + \lambda_y \frac{\partial T}{\partial y} n_y + \lambda_z \frac{\partial T}{\partial z} n_z \quad (2)$$

where q is the heat flux; λ is the coefficient of thermal conductivity; T is the object temperature; λ_x , λ_y , and λ_z are the isothermal surface coefficient thermal conductivities along the x , y , and z directions, respectively; n_x , n_y , and n_z are the isothermal surface components along the x , y , and z directions, respectively; and $\partial T/\partial n$ is the temperature gradient.

Because inner heat source is absent in the working process of the screw, the load form is axisymmetric. The heat conduction differential equation can be expressed as (Sun et al. 2015):

$$\frac{\partial^2 T}{\partial r^2} + \frac{\partial T}{r \partial r} + \frac{\partial^2 T}{\partial z^2} = \frac{\partial T}{\alpha \partial \tau} \quad (3)$$

where α is the thermal diffusivity, T is the temperature, and τ is the time. Its initial temperature was $T_0 = 22^\circ\text{C}$.

3 BOUNDARY CONDITIONS

The heat source of hollow screw mainly includes the bearing rotating friction heat and nut moving frictional heat. The methods of heat exchange with the outside include the cooling liquid convection

heat transfer, the hollow screw and air convection heat transfer, the hollow screw, and the lubricant convection heat transfer.

3.1 Calorific value analysis

3.1.1 Screw–nut pair frictional heat

The equation of calorific value screw per unit time is shown as (Sun et al. 2015)

$$Q = 1.047 \times 10^{-4} M \cdot n \quad (4)$$

where Q is the calorific value in per unit time, N is the rotating speed, and M is the friction torque of screw. Friction torque of screw is mainly caused by the friction torque, which is caused by the pre-tightening force (Liu et al. 2006). The friction torque is calculated as:

$$M = 2Z(M_e + M_g)\cos\beta \quad (5)$$

where Z is the rolling element number, M_e is the group of friction torque, M_g is the geometry sliding friction torque, and β is the rolling spiral angle of the screw.

3.1.2 Friction heat of bearing

Bearing calorific value calculation formula is the same as that of the screw–nut pair, and it also can be calculated using equation (4). The friction torque of bearing is shown as (Chen et al. 1999):

$$\begin{cases} M = M_0 + M_1 \\ M_0 = 10^{-7} f_0 (vn)^{2/3} D_m^3 & (n \geq 2000 \text{ rpm}) \\ M_0 = 160 \times 10^{-7} f_0 D_m^3 & (n < 2000 \text{ rpm}) \\ M_1 = f_1 P_1 D_m \end{cases} \quad (6)$$

where f_0 is a factor related to bearing type and lubrication method, v is the kinematic viscosity of the lubricant, n is the rotating speed of screw, f_1 is a factor related to the bearing type and load, P_1 is the bearing load, and D_m is the mean diameter of the bearing.

3.2 Heat transfer calculation of screw

3.2.1 Screw exchanges heat with air

In the working process, the type of heat exchange between the air and screw is forced convective heat transfer. Therefore, the heat transfer coefficients can be given as follows:

$$h_a = \frac{\lambda Nu}{L} \quad (7)$$

Table 1. Screw thermal boundary conditions.

Parameter	Value
Heat production rate of bearing Q_b	197623 W/m ³
Heat flow density (screw) q_s	2100 W/m ²
Heat flow density (nut) q_n	2784 W/m ²
Heat transfer coefficient (air) h_a	54 W/m ² °C
Heat transfer coefficient (lubricating oil) h_o	288.5 W/m ² °C
Heat transfer coefficient (grease) h_g	235 W/m ² °C

$$Nu = 0.133 Re^{\frac{2}{3}} P_r^{\frac{1}{3}} \quad (8)$$

$$Re = \frac{\omega \times d^2}{\nu} \quad (9)$$

where λ is the coefficient of thermal conductivity, L is the feature size, Nu is the Nusselt number, Re is the Reynolds number, P_r is the Prandtl number, ω is the angular velocity of screw, d is the diameter of screw, and ν is the kinematic viscosity of air.

3.2.2 SCRW exchanges heat with lubricating oil

The hollow screw nut–pair is lubricated by oil, and the heat transfer coefficient is calculated as:

$$h_o = 0.11 \frac{\lambda}{d} (0.5 Re^2 P_r)^{0.35} \quad (10)$$

3.2.3 Bearing exchange heat with grease

Bearing is lubricated by grease, and its heat transfer coefficient is expressed as:

$$h_g = 0.332 \frac{\lambda}{L} P_r^{\frac{1}{3}} R_e^{\frac{1}{2}} \quad (11)$$

The thermal boundary conditions could be calculated while the rotation speed of the screw is 1500 rpm, and the results are shown in Table 1.

4 SCREW HEAT FLOW SIMULATION ANALYSIS

The method of one-way steady-state analysis is used in this paper. This means that the result of fluid analysis is loaded in the static heating analysis and static forces analysis.

4.1 Analysis and calculation of the fluid

The flow field was analyzed with CFX module of Workbench. The analysis results of the flow field can be obtained after setting the fluid inlet

temperature, initial temperature, and cooling fluid velocity. In addition, the fluid outlet pressure is equal to the atmospheric pressure. The coolant flow rate is 3L/min, and the inlet temperature is 20°C. The results are shown in Figure 1.

4.2 Thermal analysis in steady state

At the steady state of thermal analysis, the screw is simplified as a hollow cylinder, and the bearing is simplified as a ring. The boundary conditions of the steady-state thermal analysis are shown in Table 1. The temperature distribution of the screw system is shown in Figure 2.

Figure 1. Temperature distribution of hollow screw.

Figure 2. Temperature distribution of screw system.

Figure 3. Deformation distribution of screw system.

4.3 Coupling analysis

The results of the temperature field were loaded into the model as the thermal load and pre-tightening force. It was also loaded on screw bearing. By setting constraints and the deformation condition, the coupling results are shown in Figure 3.

5 RESULTS OF FINITE-ELEMENT ANALYSIS

5.1 Results under different temperatures of cooling fluid inlet

In thermal characteristic analysis, the rotating speed of the milling shaft screw is 1500 rpm, coolant flow rate is 3 L/min, and the coolant inlet temperature is 22°C. The highest temperature of screw and the temperature difference of cooling fluid are shown in Figure 4.

The relationship between the maximum temperature of the screw and the inlet temperature difference of the cooling liquid is shown in Figure 4. The results show that the lower the inlet temperature of the coolant, the greater the temperature difference between the inlet and outlet.

The screw axial deformation law and total deformation law are always similar in Figure 5. The axial deformation is the main deformation. With the increasing of cooling fluid inlet temperature, the deformation decreases first and then increases. Because the coolant inlet temperature is too low, there is a large temperature difference between the two ends of the lead screw, which produces a large thermal deformation.

Combining with the cooling effect and the deformation of screw, best results are obtained when the inlet temperature of cooling fluid is slightly lower than the temperature of the environment.

5.2 Results of simulation analysis under different cooling fluid flow

Heat flow and solid coupling were analyzed when the rotating speed of the milling shaft screw is 1500 rpm, cooling fluid inlet temperature is 21°C, and cooling fluid flows are 1, 3, 5, 8, and 10 L/min. The highest temperature of the screw and the temperature of cooling fluid between inward and outward are shown in Figure 6.

Figure 6 shows that the temperature of the coolant becomes smaller while the coolant flow rate is higher. Lead screw temperature is significantly reduced first, and then decreased slowly. The results show that the cooling fluid flow is too small and the lead screw undergoes insufficient cooling.

Figure 7 shows that coolant flow rate increases, and the total deformation of the screw decreases

Figure 4. Coolant inlet temperature with its exit temperature, screw temperature curves.

Figure 5. Deformation of screw in all directions under different cooling fluid flow.

Figure 6. Highest temperature of screw and the temperature difference between inward and outward.

Figure 7. Relation curves of deformation and coolant flow.

first and then increases. The deformation of Y-axis direction decreases gradually. It also shows that the coolant flow should be appropriate, or it will cause a larger deformation. Considering the cooling effect, the suitable coolant flow should be 2–3 L/min.

6 CONCLUSION

In this paper, the thermal deformation of the hollow screw rod of the boring and milling center is studied. When the lead screw is at a different temperature and flow rate, the heat, flow, and solid coupling analysis has been carried out in this paper. The influence of cooling fluid on the temperature and deformation of screw is studied. The coolant inlet temperature is lower, the coolant temperature will be higher, and the cooling effect will be better. If the coolant flow is too small, the cooling effect of the screw will be insufficient. If coolant inlet temperature is lower, the temperature difference of both ends of the screw will be higher. Then, a larger thermal deformation will appear.

State Grid Fujian Electric Power Co. Ltd., Zhangzhou Power Supply Company, Fujian, China

Wu Wang

School of Electrical Engineering, Fuzhou University, China

ABSTRACT: To understand the frequent bulge fault of hydraulic operating mechanism of the breaker in a substation, oil pump failure is analyzed, and liquid level and gas sensors are used to design an intelligent exhaust device, which weakens the influence of the environment and improves the safety and reliability of the equipment. This device, with neural network self-learning height measurement algorithm as its core, processes the data obtained by barometric sensor and liquid-level sensor by detecting the breaker, to get an accurate oil-level height and reach real-time control over solenoid valve exhaust device as well as automatic record of system working condition, thus realizing the intelligent detection and automatic identification.

1 INTRODUCTION

Recently, the breaker hydraulic operating mechanism is finding wide application for its small size, large output power, reliability and maintainability (Li Haibo, 2014). High-voltage circuit breaker adopts a hydraulic operating mechanism, but in practical operation, the probability of hydraulic operating mechanism fault is relatively high, in which the frequent oil pump bulge fault accounts for a relatively large part. If breaker is used for an extended time, there will be some gas aggregated in the oil pump's low-pressure section of hydraulic system as well as inside of some high-pressure oil system (energy storage canister and high-pressure oil cylinder) (Zhou Xuan & Zhao Chenguang, 2011). The gases prevent the oil pump from effectively sending the hydraulic oil from the low-pressure section to the high-pressure section, thus resulting in shorter oil pump bulge interval time, and the oil pressure does rise with continuous running of the oil pump.

When the pressure of the oil pump drops below the monitoring working pressure P_1 (32 MPa) or less, the pump is started and it pumps the hydraulic oil from the tank storage cylinder. When the pressure reaches P_1 (32 MPa), the pump is stopped automatically after about 3 minutes. Under normal circumstances, each is weighed one time during 24–48 h (Li Jianming, 2011).

Pressure pump breaker failure occurs once every minute or tens of minutes depending on the severity. Each time it lasts for only about 10s. The hydraulic system over time gradually after stabilization suppresses longer intervals, and each time the interval is extended to 1 h to 10 hours gradually. Through the rapid build pressure relief method, the situation has changed (Li Zhiyong, 2010).

To overcome the breaker operating mechanism fault, intelligent exhaust device is designed in the present paper, in which liquid level and gas sensors are applied to detect the breaker, automatically identify the oil pump's gas content and liquid level, control breaker solenoid valve, to realize intelligent detection and automatic identification.

2 INTELLIGENT EXHAUST DEVICE OPERATING PRINCIPLE

When there is gas in the oil pump of the breaker operating mechanism, oil pump cannot effectively send hydraulic oil from the low-pressure section to the high-pressure section, thus resulting in shorter oil pump bulge interval time, and also the oil pressure does rise with the continuous running of the oil pump (Fan Shouxiang, 2000). To make breaker resume its normal operation, gas in the oil pump and high-pressure oil system need be exhausted in time.

A joint detection of liquid-level sensor and barometric sensor is employed in an intelligent exhaust device. When the liquid level sensor is only used, due to its multiple problems, such as mechanical fraction, short service life, narrow measurement range, it cannot measure oil-level height accurately. In practical measurements, oil temperature within the oil pump and its interior pressure are obtained by barometric sensor first. Then a neural algorithm is used to calculate the network space to be measured, so that the relative oil-level height at current measuring point is obtained indirectly. Finally comparing this measured value to the oil-level height obtained by liquid-level sensor, an accurate oil-level height is obtained. When accurate oil-level height is acquired, oil-level height is alternated to control the solenoid valve to the exhaust. The exhaust when oil level is under the lowest oil-level height set by system, and close to solenoid valve when it is above set oil level, shown as Figure 1.

The exhaust device is equipped with a working condition indicator, shown as Figure 2, a fault

indicator and a buzzer alarm. If abnormal working condition or malfunction is detected by system device through a self-checking program, fault indicator will glow and buzzer will raise an alarm, and it will enter the system protection state. When system resumes the normal working condition, the alarm will disappear and the working indicator will return to normal. The exhaust device is also equipped with system data record and data transmission module to record real-time exhaust valve working condition, which helps to understand working characteristics of master device and benefits maintenance.

3 INTELLIGENT EXHAUST DEVICE HARDWARE DESIGN

The measurement system process of intelligent exhaust device is as shown in Figure 3. The whole measurement system mainly includes a sensor module, analog signal modulation circuit, A/D switching circuit, single chip microcomputer processing unit with STM32F103 as the core and solenoid valve exhaust device.

3.1 Sensor module

The sensor module is composed of BMP085 digital barometric sensor and liquid-level sensor, shown in Figure 4. BMP085 is a digital barometric sensor with high precision and low power consumption, which adopts powerful ceramic leadless chip bearing ultrathin packaging, made up of resistance-type pressure sensor, AD convertor and control unit.

Figure 1. Vent valve of oil pump.

Figure 2. Intelligent exhaust device detection module.

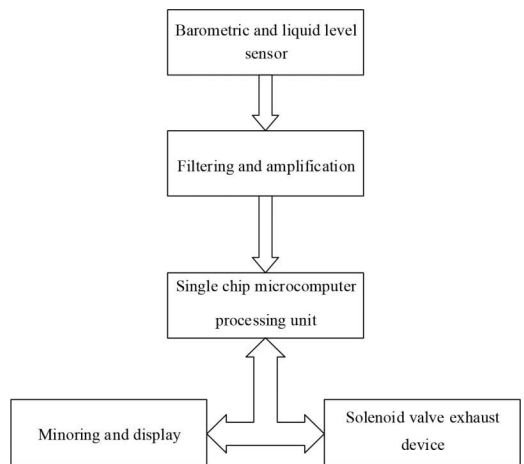

Figure 3. System flow chart.

Figure 4. BMP085 digital barometric sensor and liquid level sensor.

The internal temperature compensation in the BMP085 barometric sensor is always limited. When its measurement is combined with the liquid level sensor, it can reduce pressure height measuring error due to environmental factors such as temperature, reducing fault operation and improving measurement accuracy.

3.2 Analog signal modulation circuit

To guarantee that sensor output signal does not exceed voltage range of analog-digital conversion under a relatively high voltage grade, and is higher than the lowest resolution ratio of the analog-digital conversion, a proportional amplifying circuit is adopted in the design to adjust the input signal amplitude, to make its signal within the optimal range of AD conversion, shown in Figure 5. In consideration of that input signal lower than zero potential, a DC component is superpositioned in input signal in the design.

3.3 Single-chip microcomputer processing unit

A single-chip microcomputer processing unit, shown in Figure 6, takes neural network self-learning height measurement algorithm as its core, processes data obtained by barometric sensor and liquid level sensor, to get an accurate oil-level height and realize real-time control over the solenoid valve module. Single-chip microcomputer processing unit is equipped with circuit to automatically record the working condition while the exhaust valve can automatically conduct relevant operation according to received data.

Figure 5. Analog signal conditioning circuit diagram.

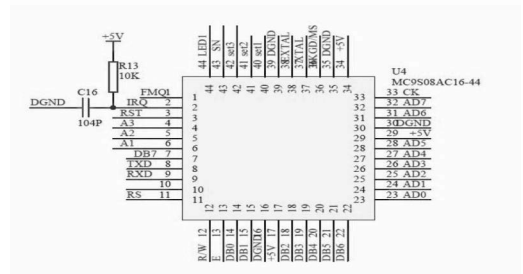

Figure 6. Microcontroller processing block diagram.

4 IMPLEMENTATION PLAN

After powered on, the exhaust device begins to self-check, with working condition indicator and fault indicator lit as along with the one-second buzzer. When self-check is completed, it immediately enters monitoring. When the first entry is made into the working condition, as oil level is under the lowest oil level set by system, system-state indicator is lit on with solenoid valve opened and oil level raised. When oil level reaches the highest oil level set by the system, the system closes the solenoid valve with working green light flashing. When abnormal working condition or fault is detected by the system through the self-checking program, fault light will flash and buzzer will raise an alarm, and device will enter system the protection state. After the system resumes its normal working condition, the alarm will disappear with working green light flashing. Intelligent exhaust device working flow chart is shown in Figure 7.

The exhaust breaker intelligent detection device is shown in Figure 8. When the exhaust solenoid valve system data record and data transmission module are working, all kinds of system working states will be recorded, and system will also receive

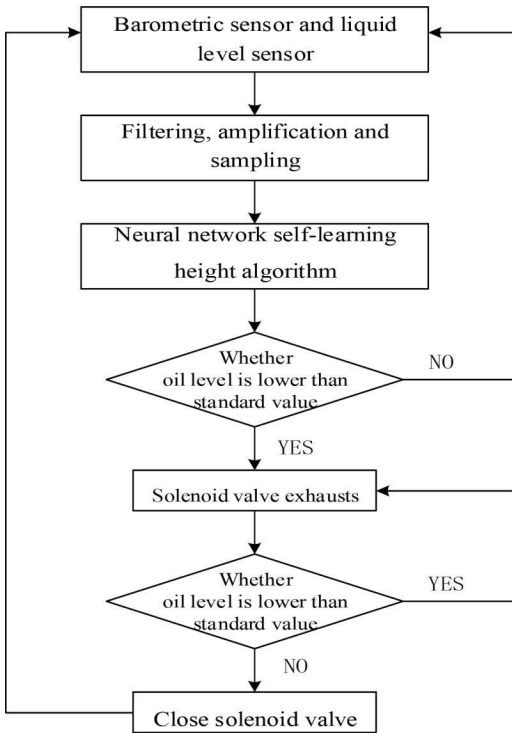

Figure 7. Intelligent exhaust device working flow chart.

Figure 8. Exhaust breaker intelligent detection device.

the command by handheld data recorder, and send the recorded files to it. The exhaust valve data transmission module and portable data recorder can send command and data through photoelectric

coded signal, avoiding mutual interference between high-voltage electromagnetic field and other devices, which is secure and reliable. Data can be stored on the computer room with portable data recorder connected by a wired connection. Exhaust valve serial number responds to equipment serial number one-to-one. A comparison of exhaust valve and master equipment's working state helps to understand some working characteristics of the master equipment, which also benefits master equipment maintenance.

5 CONCLUSION

Intelligent exhaust device processes the data obtained by barometric sensor and liquid level sensor to get an accurate oil-level height, realizing real-time control over solenoid valve exhaust device as well as automatic record of system working condition and intelligent identification.

Combined measurement of gas and liquid level sensors is adopted in an intelligent exhaust device, which weakens environmental influence, avoids regular blind manual exhaustion, reduces the danger of the maintainer touching high-risk equipment during live working, improves equipment working security and reliability, and significantly improves working efficiency.

An improved calibration method for a nondestructive testing system based on infrared thermopile sensors

Wei He, Tong Zhou, Bo Jiang, Yin Wan & Yan Su

School of Mechanical Engineering, Nanjing University of Science and Technology, Nanjing, China

ABSTRACT: This paper presents an improved calibration method for a nondestructive testing system based on infrared thermopile sensors. The method uses reference source radiation to get the calibration parameters. A new two-point with multi-step calibration algorithm serving as the calibration of infrared thermopile sensors was proposed after researching the two-point calibration algorithm used for the calibration of infrared detector array pixels. The experiment verified that this method has advantages of simple operation, is easy to implement and has good calibration effect when compared with the commonly used two-point calibration algorithms.

1 INTRODUCTION

The infrared nondestructive testing technology is currently one of the hot research topics in the field of nondestructive testing, which has broad development prospects in the industry and national defense field. The principle of infrared nondestructive testing is based on thermal radiation characteristics of the object. Any object above the absolute zero kelvin would launch the infrared radiation outward. When heating the surface of the tested sample, the heat will flow inside the material and if there is a defect inside the sample, then the heat will accumulate in the defect, which will lead to the difference of heat distribution between the surface corresponding to defects and the surface corresponding to other no-defects area. Finally, we can detect the defects and their location by using infrared sensors to perceive the difference.

The detection module of nondestructive testing system based on infrared thermopile sensors is composed of a number of thermopile sensors and different sensors tend to have difference at the offset and gain coefficients, which will influence the outcome of the nondestructive testing. So a nondestructive testing system needs to be calibrated before it is used. There are a variety of calibration methods of sensors such as hardware circuit compensation and linear interpolation compensation. However, the hardware circuit compensation will enlarge the size of the system and increase the factors affecting the effects of the calibration. The linear interpolation compensation not only increases the complexity of the calibration but also has the shortcoming of bad calibration when there is a large difference

between the two adjacent sensors. Generally speaking, for the calibration of the sensors, software processing is relatively simple and can accurately correct the nonuniformity error of the system. In this paper, a new two-point with multi-step calibration algorithm used for the calibration of infrared thermopile sensors was proposed based on the two-point calibration algorithm that was used for the calibration of infrared detector array pixels. This method uses reference source radiation to get the calibration parameters. Then the parameter was used to calibrate the thermopile sensors with two-point calibration algorithm and improved two-point with multi-step calibration algorithm. It was demonstrated through experiments that this method is easy to operate and has prior calibration effect than the commonly used two-point calibration algorithms.

2 DESIGN OF AN INFRARED NONDESTRUCTIVE TESTING SYSTEM BASED ON INFRARED THERMOPILE SENSORS

The infrared nondestructive testing system based on infrared thermopile sensors is mainly composed of pulse excitation source, linearity array infrared sensors group, signal conditioning and acquisition module, data output and display module and calibration module for sensors, etc. The system block diagram is shown in Figure 1.

The linear array infrared sensing module is composed of six TPS334L55 infrared thermopile sensors and its working principle connects several thermocouples together.

Figure 1. Block diagram of the infrared nondestructive testing system.

Figure 2. Circuit diagram of signal conditioning and acquisition module.

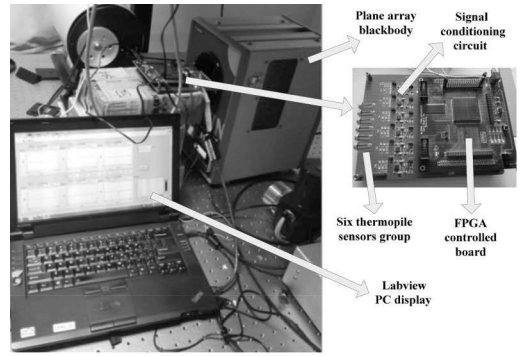

The signal conditioning and acquisition module is mainly responsible for enlarging and filtering the signal voltage transformed by thermopile sensors and then the signal is input into the AD converter modulus. The circuit diagram of this module is shown in figure 2.

The signal was imported by a high common mode rejection ratio differential amplifier circuit and it was then changed to digital signals by a high-speed sampling ADC AD7656 after being enlarged by a single-ended operation amplifier and being filtered by a passive low-pass filter. The system uses FPGA that contains rich IO interface as the main controller. The sampling data was transferred through serial port to the Labview for display and preservation.

3 SELF-CALIBRATION REFERENCE SOURCE EXPERIMENT

The reference source experiment is designed to obtain infrared response data of each sensor, which provides data support for selecting the calibration algorithm. The experiments used temperature-controlled plane array blackbody to radiate the linear array infrared thermopile sensor group uniformly. The physical and schematic diagrams of the system are shown in Figure 3.

The self-calibration experiment system is composed of temperature-controlled plane array

Figure 4. Curves of offset heterogeneity and gain heterogeneity.

blackbody, six-sensor probe group, signal conditioning module, data acquisition and control module and PC labview data display and save module. First, the six-sensor probe group was placed to the center position of plane array blackbody, then the array blackbody is opened and the temperature set in the working state. The system is powered and labview opened to save the data when the temperature of the blackbody tended to be stable and sampling data is saved every 30 s. The working temperature of blackbody is kept from 20°C to 50°C and we tested the output of six sensors under 20°C, 25°C and from 30°C to 50°C at a 2°C interval.

According to the tested data, the curves of offset heterogeneity and the curves of gain coefficient heterogeneity is shown in Figure 4.

As shown from the above figure, the linear array infrared thermopile sensor group has the large offset heterogeneity and gain coefficient heterogeneity. Therefore, the thermopile sensor group needs to be calibrated in order to ensure the accuracy of detection.

4 TWO-POINT CALIBRATION ALGORITHM

4.1 Theory of two-point calibration algorithm

The two-point calibration algorithm is a kind of calibration method that selects two irradiance as punctuation and it takes the output of the sensors' response and incident irradiance as a linear relationship. First, irradiance ψ_1 and ψ_2 are selected as the punctuation within the dynamic response scope of the sensor. Then the average response output $V(\psi_1)$ and $V(\psi_2)$ under ψ_1 and ψ_2 of all N sensors can be obtained according to equation 1:

$$V(\psi) = \sum_{i=1}^N V_i(\psi) / N \quad (1)$$

Provided that any sensor's gain heterogeneity calibration coefficient is m_i and its offset heterogeneity calibration coefficient is n_i , then equation 2 can be obtained:

$$\begin{cases} V(\psi_1) = m_i V_i(\psi_1) + n_i \\ V(\psi_2) = m_i V_i(\psi_2) + n_i \end{cases} \quad (i = 1, 2, 3, \dots, N) \quad (2)$$

$V_i(\psi_1)$ and $V_i(\psi_2)$ are the actual output under the calibration irradiance ψ_1 and ψ_2 . $V(\psi_1)$ and $V(\psi_2)$ means the calibration output under the calibration irradiance ψ_1 and ψ_2 . According to equation 2, there is:

$$\begin{cases} m_i = \frac{V(\psi_2) - V(\psi_1)}{V_i(\psi_2) - V_i(\psi_1)} \\ n_i = V(\psi_1) - m_i V_i(\psi_1) \end{cases} \quad (i = 1, 2, 3, \dots, N) \quad (3)$$

The offset heterogeneity calibration factor and gain coefficient heterogeneity calibration factor of each sensor can be calculated according to equation 3. Then the calibration response output of any sensor under any irradiance can be represented as the following equation:

$$V_i''(\psi) = m_i V_i(\psi) + n_i \quad (i = 1, 2, 3, \dots, N) \quad (4)$$

4.2 Calibration of infrared thermopile sensors based on the two-point calibration algorithm

According to the two-point calibration algorithm, we selected 30°C and 44°C as the fixed point for irradiance. According to equation 1, The average response voltage under 30°C and 44°C is 0.48469V and 2.29675V respectively. The calibration factor of six sensors can be calculated according equation 3. Table 1 shows the gain coefficient nonlinear calibration factor and offset coefficient nonlinear calibration factor of six sensors.

The offset nonlinear calibration parameters and gain nonlinear calibration parameters are loaded from above table in each sensor channel and the same temperature points' response voltage again under the uniform radiation of plane array blackbody is sampled. Then the offset nonlinear curve and gain nonlinear curve can be obtained as shown in Figure 5.

It can be seen from the picture above that the two-point calibration method improved the offset nonlinearity and gain nonlinearity of infrared thermopile sensor group greatly in a certain temperature range. However, in the range of 20°C to 30°C, the offset nonlinearity and gain nonlinearity has not improved, which fit the theory that two-point calibration algorithm is only suitable for a small temperature range.

As we all know that the larger the temperature difference is, the easier the defect can be detected.

Table 1. Calibration parameters of six sensors within 20°C to 50°C.

A4	0.96735	0.10177
A5	0.97105	0.20052
A6	1.00195	-0.03405

(a) Curves of offset heterogeneity

(b) Curves of gain heterogeneity

Figure 5. Curves of offset heterogeneity and gain heterogeneity after two-point calibration.

So the infrared nondestructive testing system needs to adapt to the detection in wide dynamic temperature range and in this case, the two-point calibration method of infrared thermopile sensor group can't adapt to the work environment of the system. In order to meet the calibration in a wide temperature range, the infrared thermopile sensor group needs a new self-calibration algorithm for calibration.

5 AN IMPROVED TWO-POINT WITH MULTI-STEP CALIBRATION ALGORITHM

5.1 Theory of two-point with multi-step calibration algorithm

The two-point calibration algorithm cannot calibrate the infrared thermopile sensors in a wide dynamic temperature range and multipoint interpolation calibration algorithm has the shortcoming of large amount of computation. By referring to the thermal response curve of the thermopile infrared sensors and the idea of multi-point

approximation, an improved two-point with multi-step calibration algorithm was proposed based on two-point calibration algorithm.

The improved two-point with multi-step calibration algorithm divides the dynamic temperature range of the system into a number of intervals, which can be determined according to the practical test response output curves of the sensors. Then the two-point calibration method is used for the calibration again in each interval. As the infrared non-destructive testing system only needs to detect the relative infrared response between surface with defects and surface with no defects, it can minimize the system error as long as it can ensure that each sensor's gain coefficient and offset coefficient changes are synchronized.

The theory of two-point with multi-step calibration is as follows. First, select $M+1$ irradiation punctuation $\psi_i (i = 0, 1, 2, 3, \dots, m)$, under which the radiation for all N sensors is calibrated respectively, and then the average response $V(\psi_i)$ under corresponding irradiance according to equation 1 is calculated. All irradiance is divided into M section (ψ_{j-1}, ψ_j) ($j = 1, 2, 3, \dots, M$) based on the level of irradiance. Then, the sensors are calibrated according to the two-point calibration method in each interval and the gain heterogeneity calibration coefficient $m_{j,i}$ and the offset heterogeneity calibration coefficient $n_{j,i}$ are calculated. As equation 5 shows.

$$\begin{cases} m_{j,i} = \frac{V(\psi_{i-1}) - V(\psi_i)}{V_i(\psi_{i-1}) - V_i(\psi_i)} \\ n_{j,i} = V(\psi_i) - m_{j,i} V_j(\psi_i) \end{cases} \quad (i = 0, 1, 2, 3, \dots, m), (j = 1, 2, 3, \dots, M) \quad (5)$$

Therefore, in any irradiance, the sensors calibration method can be summarized as follows. First, determine which subinterval the sensors' infrared response belongs to, namely:

$$V_j(\psi_i - 1) < V_j(\psi) \leq V_j(\psi_i) \quad (6)$$

Then, the calibration output $V_j^*(\psi)$ can be corrected as follows after judging the irradiance ψ_i according to the interval:

$$V_j^*(\psi) = m_{j,i} V_j(\psi_i) + b_{j,i} \quad (7)$$

$V_j(\psi_i)$ is the actual response output, $m_{j,i}$ is the gain calibration parameter and $b_{j,i}$ is the offset calibration parameter.

It can be seen from the derivation process above that the two-point with multi-step calibration algorithm generally includes two steps including judge interval and two-point calibration algorithm

is employed at every interval. Compared with multipoint interpolation correction algorithm, the two-point with multi-step calibration algorithm reduced the amount of calculation greatly and the defect of narrow calibration temperature that two-point calibration algorithm has been overcome. So it is a simple and effective calibration method.

5.2 Calibration of infrared thermopile sensors based on two-point with multi-step calibration algorithm

It can be seen from figure 4 that the infrared thermopile sensors has good offset linearity and gain coefficient linearity after being calibrated by two-point calibration method at the temperature range from 30°C to 50°C. However, the calibration effect is not ideal at the temperature range from 20°C to 30°C, so the irradiance range is supposed to be divided into two intervals of 20°C to 30°C and 30°C to 50°C. The nonlinear calibration coefficient within 30°C to 50°C still uses the result in Section 3.2 and the nonlinear calibration within 20°C to 30°C is described as follows:

First of all, select 20°C and 30°C as irradiance point. According to equation 1, the average response at corresponding irradiance is $-0.36079V$ and $0.48469V$. Then according equation 3, the offset nonlinearity calibration factor and gain nonlinearity calibration factor can be calculated as follows.

Loading the calibration parameters from 20°C to 30°C and 30°C to 50°C respectively into the infrared sensors response curves of six sensors under radiation of plane array blackbody are obtained. The offset nonlinear curves and gain nonlinear curves can be obtained as shown in Figure 6.

It can be seen from the above figure that the two-point with multi-step calibration algorithm has good correction effect, which meets the design requirements of the system. The two-point with multi-step calibration algorithm can not only solve the problem that the sensor group cannot be calibrated in the whole working temperature

Table 2. Calibration parameters of six sensors within 20°C to 30°C.

Figure 6. Curves of offset heterogeneity and gain heterogeneity after two-point with multi-step calibration.

range by two-point calibration algorithm but also improved the offset linearity and gain linearity of six sensors. In addition, this algorithm has advantages of simple operation, easy implementation and involves a small amount of calculation. Its application in the calibration of linear array infrared thermopile sensors laid a solid foundation to the normal working of the infrared nondestructive test system.

6 CONCLUSION

This article introduced a calibration algorithm of an infrared nondestructive test system based on thermopile sensors. This method obtains calibration parameters by reference source radiation method and it is improved based on the two-point calibration method, which is commonly used in the calibration of infrared sensor array pixels. Finally, compared with experiment, the method demonstrated that the improved two-point with multi-step calibration algorithm has advantages of simple operation, easy implementation and has a good calibration effect.

Evaluation of wind turbine power generation performance based on a multiple distribution model

Shuangquan Guo, Jiarong Yang & Hui Li

Central Academe, Shanghai Electric Group Co. Ltd., China

ABSTRACT: The evaluation of the performance of wind turbine power generation generally focuses on the wind power curve. The power value of wind turbine fluctuates within a reasonable range and follows a different distribution at different speeds caused by wind speed variation, anemometer accuracy, operation control and so on. One evaluation method of wind turbine power generation performance based on a multiple distribution model, which is validated on the history data of wind turbine, is proposed to calculate the performance of the power generation and power loss by data preprocessing steps, training the multi-distribution model and performance evaluation. The result reveals the trend of turbine's power generation performance well and several typical faults are detected before they happen.

1 INTRODUCTION

With the increasing of wind power's installed capacity in recent years, China has become the world's largest country in this field. According to the wind power development plan in the "13th Five-Year" period formulated by the National Energy Administration, the installed capacity of wind power in 2020 will reach to 200 million kilowatts, which is almost twice as much as the current installed capacity, and the market prospects and scale are very large (Xiao Q, 2014). The increase in single turbine capacity and wind farm turning gradually from land to sea are the two major trends in wind power field in the future (Guo S.Q. 2016). At the same time, the maintenance costs are increasing, according to the literature statistics. The maintenance cost of onshore wind turbine accounts for 10% of the total cost, while the maintenance cost of offshore wind turbine is up to 30% (M.I. Blanco, 2009). Therefore, research on the assessment of wind turbine generation performance is of great significance to reduce costs by optimizing operation and maintenance.

At present, the evaluation of the performance of wind turbine power generation mainly focuses on the wind power curve, obtained by general methods include spline curve fitting, self-organizing map, artificial neural network and Gaussian mixture model and so on. However, these methods have some limitations on describing the distribution characteristics of wind power points. In the actual operation process, the fluctuation of wind speed and anemometer accuracy often lead changing the power curve (Chu Zheng, 2014). Meanwhile, each

turbine has different control strategy in different conditions, so the wind-power points are always scattered around the wind-power curve. When the turbine is in normal state, its power fluctuates in a reasonable range and satisfies a certain distribution in a certain wind speed interval. In this paper, a model for the performance of wind turbine power generation based on a multiple distribution model is proposed to evaluate its generation performance and calculate the power loss.

2 WIND-POWER MULTIPLE DISTRIBUTION MODEL

As shown in Figure 1, the wind-power points scattered around the power curve, usually wind turbine has its own design parameters, such as cut-in wind speed v_{In} , cut-out wind speed v_{Out} and rated wind speed v_N . Since the turbine has different control strategy at different speeds, and the power satisfies different distributions, here we partition the whole wind speed range by minimal interval Δv (like 0.2m/s), which is much less than the value of $v_{Out} - v_{In}$, to obtain different operation conditions. We take the average speed of each minimal interval, v_i , as the speed of all points in the interval. Then several common distributions (beta, exponential, gamma, generalized extreme value, logistic, normal, Rayleigh, Weibull, Poisson and so on) are applied to fit the power distribution in each minimal interval of wind speed by maximum likelihood estimation, and the best distribution is selected by the principles such as negative of the log likelihood (NLogL), Bayesian Information Criterion (BIC),

Figure 1. The wind-power scatter diagram, and the minimal interval Δv (like 0.2 m/s), is much less than the value of $V_{Out} - V_{In}$.

or Akaike Information Criterion (AIC) (Liao L, 2010), shown in Equation 1.

$$f(P|v=v_i) = f_{\text{best}}(P) \text{ with } \min(N\text{Log}L, BIC \text{ or } AIC) \quad (1)$$

$best \in (1, 2, 3, \dots, N_d)$

The sign N_d is the number of common distributions.

For a certain period, if the turbine has worked in wide wind speed ranging from the cut-in speed to the cut-out speed, we can build its wind-power multiple distribution model during this period in Equation 2.

$$f(P|v) = \sum_{i=1}^{N_i} \omega_i f(P|v=v_i) \quad (2)$$

The sign N_i is the number of partitions of the whole range, ω_i is the weight of the power point number in the speed interval of $v=v_i$ accounted for the total number of power points.

3 POWER GENERATION PERFORMANCE MODEL

To evaluate the performance of the power generation of wind turbine in a certain period (like two-day period), we should build the wind-power multiple distribution models in the normal-power period and current period respectively, and quantify the difference between the two models as the index of power generation performance of wind turbine. If $f_B(P|v)$ represents the multiple

distribution model of wind turbine in normal or ideal period, namely baseline model, and $f_C(P|v)$ represents the distribution model in current period, namely current model. The power generation performance model of wind turbine in this period, which is given by Equation 3, can be built through evaluating the weighted average of overlapping areas of corresponding distributions between the baseline model and the current model.

$$PGP = \text{Difference}(f_B(P|v), f_C(P|v)) \quad (3)$$

$$= \sum_{i=1}^{N_i} \omega_{i,B} S(f_B(P|v=v_i), f_C(P|v=v_i))$$

In Equation 3, $\omega_{i,B}$ is the weight of each wind speed interval in the baseline model, $S(f_B, f_C)$ is the overlapping area between baseline distribution and current distribution where $v=v_i$. As shown in Figure 2, in the minimal interval corresponding $v=v_i$, the average and variance of baseline distribution $f_B(P|v=v_i)$ and current distribution $f_C(P|v=v_i)$ are (μ_B, σ_B) and (μ_C, σ_C) respectively. The overlapping area of two distributions is expressed by Equation 4.

$$S(f_B(P|v=v_i), f_C(P|v=v_i)) = \frac{\int_{\max(\mu_B + \sigma_B, \mu_C + \sigma_C)}^{\min(\mu_B - \sigma_B, \mu_C - \sigma_C)} \min(f_B(P|v=v_i), f_C(P|v=v_i)) dP}{\int_{\min(\mu_B, \sigma_B, \mu_C - \sigma_C)}^{\max(\mu_B + \sigma_B, \mu_C + \sigma_C)} f_C(P|v=v_i) dP} \quad (4)$$

For a more intuitive understanding of power generation performance, we could also evaluate

Figure 2. Schematic of overlapping area between two distributions, and the averages and variances are (μ_B, σ_B) and (μ_C, σ_C) .

the expectation of power generation based on the baseline model in the current wind condition, and calculate the difference with the actual power generation, namely power loss, shown in Equation 5.

$$P_{loss} = \sum_{i=1}^{N_v} \omega_{i,C} E_B(P|v=v_i) * N_C * \Delta t - \sum_{i=1}^{N_C} P_i * \Delta t \quad (5)$$

The sign $\omega_{i,C}$ is the weight of each wind speed interval in current period, $E_B(P|v=v_i)$ is the expected power at each speed, N_C is the total sample number of this period, and Δt is the sampling interval of power points.

In addition, when partitioning the sample points during the selected period by wind speed intervals, if there are too few points to fit the distributions in some intervals, it can be considered that the distribution characteristic remains unchanged, and take the same distribution parameters of last period, then combine these samples with the samples of next period to evaluate the distribution.

4 APPLICATION EXAMPLE

4.1 Data preprocessing

To verify the practicability of the proposed method, we choose the history sample data of one wind turbine, including the parameters such as wind speed, wind direction, power, pitch angle and wind turbine state. Before training the model, we should filter the data by the principles as follows:

1. Remove the points where power is less than 0.
2. Remove the points where wind speed is out of the range between cut-in speed and cut-out speed.

3. Remove the pitching points where the power is less than the rated power.
4. Remove the points in non-generating state.
5. Filter out the outliers by the principle of Grubb's test.

4.2 Training the baseline model

The data for training the baseline model should be selected from the appropriate period when the turbine works in a normal state without major maintenance or failure records. Here the cut-in speed and cut-out speed of turbine are 3.5 m/s and 17 m/s, and the rated speed is 14 m/s. If we take 0.2 m/s as the minimal interval to partition the whole range, put all the data below the speed 3.5 m/s in the first interval and put all the data beyond the speed 14 m/s in the last interval. Finally, the whole sample would be partitioned to 54 intervals corresponding to the representative speeds (3.5, 3.6, 3.8, ..., 13.6, 13.8, 14.0). Through training, the distribution of each interval can be fitted by Equation 1. Several typical distributions were shown in Figure 3. The fitted distributions at speeds of, 7, 9.6, and 12 m/s are generalized extreme value distribution, log-logistic distribution, normal distribution and extreme value distribution, respectively.

4.3 Power generation performance and power loss

After training the baseline model, we can evaluate the turbine's power generation performance and power loss in different periods. Through partitioning the half-year testing data into different periods every two days and filtering data of each period by the principles in Section 4.1, finally we could obtain the wind turbine's Power Generation Performance (PGP) curve and power loss curve shown in Figures 4 and 5 from Equation 3–5.

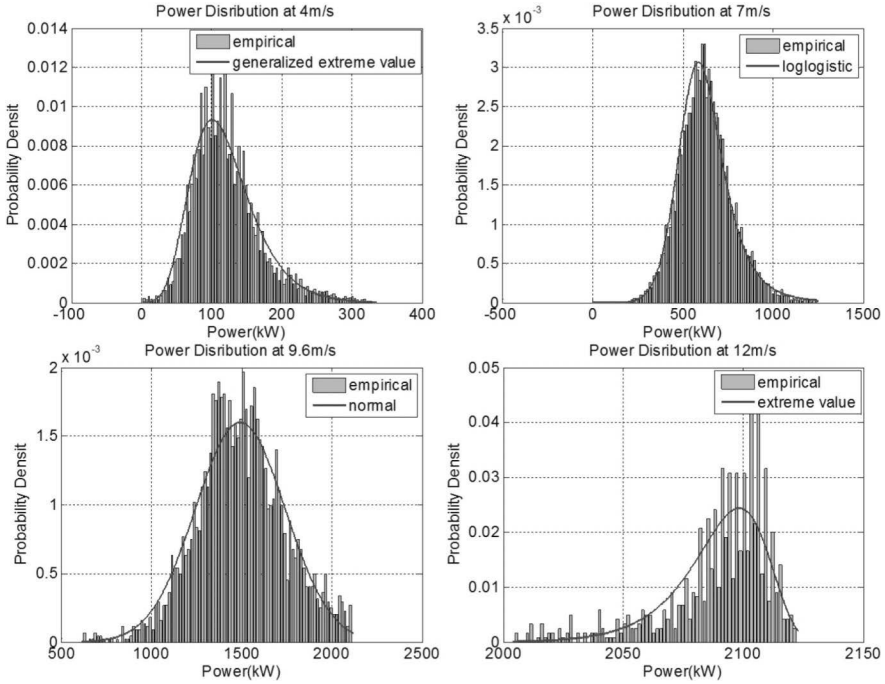

Figure 3. Several typical distributions at different wind speed intervals such as 4 m/s, 7 m/s, 9.6 m/s, and 12 m/s.

Figure 4. Wind turbine's power generation performance curve.

Figure 5. Wind turbine's power loss curve.

From the PGP curve in Figure 4, we find that the turbine works mostly in the condition of $PGP > 0.7$, but the value drops rapidly in early February and late May. The real operation records show that there were respectively an anemometer looseness fault on February 7 and ash cleaning maintenance operation in late May, and PGP value's significant degradations happen earlier than

the actual records. Moreover, in Figure 5, we can find that the wind turbine's power loss are mostly negative during 12 months, namely the late winter and early spring, which is related to good wind condition in this time or the training data selection for the baseline model. At last, a maximum of the power loss value appeared at early March before the pitch lubrication fault alert happened.

5 CONCLUSIONS

In this paper, one evaluation method of performance of wind turbine power generation based on a multiple distribution model has been proposed and the whole process including data preprocessing, baseline training and performance evaluation has been implemented well on the wind turbine's history data. Results show that the PGP value and power loss value are good characterizations of the generation status of wind turbine and can identify several typical faults before the records happen.

The method can also be tentatively applied to the component-level performance evaluation of wind turbine, such as drive train, anemometer, and pitch system. However, there are still some aspects need to improve in the future: (1) take consideration of season factor in the model training and evaluation; (2) partition the wind range by dynamic interval instead of the fixed minimal interval.

Research on the acoustic emission testing of the tank truck and on the defect acoustic emission source location method

Z.W. Ling, M.L. Zheng, D. Bin & X.L. Guo

Zhejiang Provincial Special Equipment Inspection and Research Institute, Hangzhou, China

ABSTRACT: The tank truck is an important type of transportable pressure vessel, which transports poisonous and harmful media. Due to erosion by the natural environment and poisonous and harmful media, corrosion perforation, crack propagation, and fracture of the tank are caused, which can lead to failure of the tank structure resulting in huge economic losses and serious environmental and ecological pollution. In this paper, acoustic emission testing technology carried out to test the overall structure of the tank truck and the location of defect acoustic emission signals were researched. Based on the comparison of several common defect acoustic emission source location methods, a defect acoustic emission source location method combining arbitrary planar triangle location and local scope linear location was proposed. Then, the non-open online detection of the tank truck was realized.

1 INTRODUCTION

Tank truck is an important type of transportable pressure vessel, which transports poisonous and harmful media. Due to erosion by poisonous and harmful media, corrosion perforation, crack propagation and fracture of the tank are caused, which can lead to failure of the tank structure resulting in huge economic losses and serious environmental and ecological pollution.

Currently, the main testing methods for tank truck and other transportable pressure vessels are conventional testing methods such as visual inspection, wall thickness measurement, and surface nondestructive testing and ultrasonic testing if necessary (TSG R0005-2011 2011). However, the conventional testing needs replacement, cleaning, and other pretreatments. If the tank truck contained inflammable, explosive, toxic and harmful media, the replacement, cleaning, and waste liquid discharge is put forward as higher safety and environmental protection requirements. When compared with conventional non-destructive testing, Acoustic Emission (AE) testing can avoid the pre-processing stage of the tank truck. At the same time, without replacement, cleaning and other pretreatments can reduce inspection of the environmental impact and personal risk (Wang 2009).

In this paper, acoustic emission testing technology is carried out to test the overall structure of the tank truck and location of defect acoustic emission signals were researched. Based on the comparison of several common defect acoustic

emission source location methods, a defect acoustic emission source location method combining arbitrary planar triangle location and local scope linear location is proposed. Then, the non-open online detection of the tank container is realized.

2 ACOUSTIC EMISSION TESTING OF THE TANK TRUCK

Acoustic emission testing technology is a kind of dynamic non-destructive testing technology which can realize rapid detection of the overall structure of large size components. The acoustic emission testing of tank trucks is based on structural characteristics of the tank truck and acoustic emission sensors are placed in a specific location on the outer surface of the tank truck. Then, a load is applied to the tank truck. The elastic wave generated by the acoustic emission source is propagated to the surface of the tank material and received by the acoustic emission sensor through the coupling interface, thus causing the displacement vibration of the acoustic emission sensor surface. These sensors convert the mechanical vibration of the materials into electrical signals, which are then amplified and acoustic emission signals filtered. The acoustic emission signals generated by the defects are analyzed and studied by acoustic emission testing instruments. This is followed by deducing the location, state level, and development trend of the internal defect of the material or structure, and then safety status of the tested material or component evaluated.

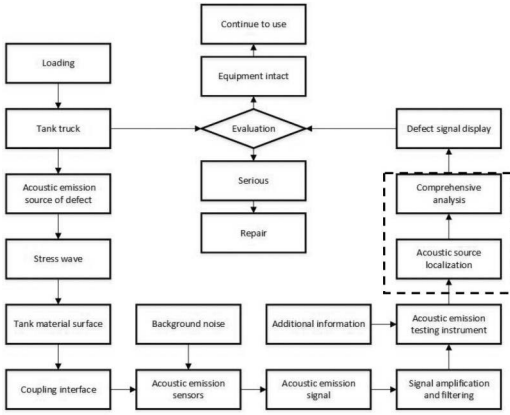

Figure 1. The acoustic emission testing process.

The acoustic emission testing process is shown in Figure 1. In this paper, signal processing and comprehensive analysis, especially the defect acoustic source location, are the most important research contents.

3 LOCATION OF DEFECT ACOUSTIC EMISSION SOURCES

Currently, as shown in Figure 2, during tank truck regular inspection, it has been found that typical defects that have a great impact on safety of the overall structure of the tank truck are as follows: the tank joint crack, the wave preventer fillet weld crack, and tank and nozzle surface corrosion or leakage.

Therefore, the study of acoustic emission characteristics of these defects and accurately locating defects in acoustic emission source is considered important. In engineering practice, the correlation between acoustic emission signal characteristics and extent of damage caused by defects is particularly critical to the acoustic emission testing and structural safety evaluation of the tank truck. Furthermore, accuracy of defect acoustic emission source location is an important indicator in the acoustic emission testing and safety assessment of the tank truck.

In practical engineering, acoustic emission testing is used in a passive manner for defect dynamic testing and acoustic emission signals are usually accompanied with interference noise. Thus, in order to obtain much more accurate location of defects of the acoustic emission source, it is necessary to amplify, filter, and noise-reduce the acoustic emission testing signals first. Currently, there are many location methods for defects of acoustic emission source with the linear location and

A. Leakage of safe valve nozzle

B. The crack of tank reinforcing ring

Figure 2. Defect of the tank truck.

Figure 3. The method of arbitrary planar triangle location.

arbitrary planar triangle location being the most commonly used.

The tank truck is a cylindrical container, but the tank truck outside is usually covered with a thermal insulation layer, which can make an enormous impact on the acoustic emission source location. So based on comprehensive analysis and comparison of several common defect acoustic emission source location methods (Wang 2005, Wang 2008 & Zhang 2012), a defect acoustic emission source location method combining arbitrary planar triangle location and local scope linear location is proposed (Long 2002).

As shown in Figure 3, three acoustic emission sensors are assumed to form an arbitrary triangle, $S_0(0, 0)$, $S_1(x_1, y_1)$, and $S_2(x_2, y_2)$; at the point $P(x, y)$ it has a defect acoustic emission source, r is the distance from S_0 to P , there are:

$$\delta_1 = \Delta t_{10} \cdot v = (t_1 - t_0) \cdot v \quad (1)$$

$$\delta_2 = \Delta t_{20} \cdot v = (t_2 - t_0) \cdot v \quad (2)$$

Where: Δt_{10} is the time difference of the defect acoustic emission source signal when it reaches S_j and S_0 ;

Δt_{20} is the time difference of the defect acoustic emission source signal when it reaches S_2 and S_0 ; v is the sound velocity.

4 ENGINEERING APPLICATION OF ACOUSTIC EMISSION TESTING OF THE TANK TRUCK

Generally, six acoustic emission sensors are arranged on the overall structure for the standard acoustic emission testing of the tank truck, with four sensors arranged on the cylinder body, and a sensor placed on each of the vessel heads as shown in Figure 4. Through these six acoustic emission sensors, the overall structure of acoustic emission testing of the tank truck can be realized.

In this paper, the acoustic emission testing instrument used in testing is the type of EXPRESS 32 produced by PAC Company, USA and the sensor type of DP 151.

The acoustic emission sensors of the tank truck and the defect acoustic emission signal location are shown in Figure 5. The blue marking points in the figure are acoustic emission sensors and the red ones are acoustic emission signal source locations. The acoustic emission signal location point appears from the beginning stage up to the holding stage. At this stage, there are several acoustic emission events near the sensor number 1 and number 3, which disappeared in subsequent pressure stable

Figure 4. Acoustic emission sensor arrangement of the tank truck.

Figure 5. Acoustic emission signal location of the tank truck.

stage. Therefore, the judgment of acoustic emission signal may not be caused by defects in acoustic signal. It is possible that the interference signal during the pressure loading stage, the impact or friction between the loading medium and the tank internal components, and then at the pressure stable stage, were responsible for the acoustic emission signals to disappear.

5 CONCLUSION

1. In the process of acoustic emission testing of the tank truck, at the pressure loading stage, due to the impact or friction of the loading medium and wave preventer inside the tank, it may produce some interference acoustic emission signals, easy to produce some miscalculation or make the true defect signals submerged in the interference signal such that the defect location is not accurate.
2. Acoustic emission testing is only effective for active defects and as such the result of acoustic emission testing relative to conventional non-destructive testing methods poses a slightly higher risk. Therefore, it is proposed to use both the acoustic emission testing and conventional non-destructive testing to reduce the risk of tank container inspection and ensure the safety of the equipment.

Nonlinear dynamic analysis of a cantilever plate for generating electricity based on electromagnetic induction

J.H. Yang, K. Ye, G. Zhu & H. Guo

Beijing Vocational College of Agriculture, Beijing, China

ABSTRACT: The nonlinear dynamic responses of a rectangular cantilever plate to power performance based on electromagnetic induction are studied in this paper. At the end of the rectangular cantilever plate, an electromagnet is placed and a set of coil is wound around the electromagnet. The rectangular cantilever plate is forced by the base excitation which is assumed to be a harmonic load. Based on the von Karman type equations and Reddy's classic plate theory, the nonlinear partial differential governing equations of motion for the cantilever plate are derived using the Hamilton's principle. Numerical simulations are used to investigate the effects of parameters on the steady-state responses of the cantilevered plate. Substituting the physical parameters of cantilever plate into the ordinary differential equation about transverse displacement and the equation of the output voltage, the bifurcation diagram of the cantilevered plate for the output voltage via the base excitation frequency is obtained.

1 INTRODUCTION

With the rapid development of MEMS, wireless communication technology, and computer technology, wireless sensor network technology has become a research hotspot. At present, a vast majority of wireless sensor nodes are battery-powered (Li & Gao 2008). However, the traditional chemical batteries have many shortcomings such as limited life span, the requirement of periodical replacement, environmental pollution, etc. In order to solve this problem, research about energy harvesting devices and spontaneous electrical systems are increasing rapidly (Culler et al. 2004).

In daily production and life, vibration is a common energy form. However, it is not used reasonably and wasted in most cases. If vibrational energy can be converted into electricity, not only can the efficiency of energy utilization be improved, but also a new green method of energy access is provided (Beeby et al. 2007). Thus vibrational energy harvesting technology has become a research hotspot.

The most common energy harvesting mechanisms are electrostatic, electromagnetic, and piezoelectric. Among them, electromagnetic energy harvester has been paid more attention because of small volume, powerful power generation-higher frequency sensing without power supply, and working in harsh environments (Vinod et al. 2009).

2 EQUATIONS OF MOTION

As shown in Figure 1, a rectangular cantilever plate clamped at edge Ob whose edge length and width in the x and y directions are, respectively, a and b and the thickness is h , the harmonic translation $F \cos(\Omega t)$ is subjected at the base of the plate. An electromagnet is placed at the end and a set of coil is wound around the electromagnet. A Cartesian coordinate $Oxyz$ is located on the middle surface of cantilevered rectangular plate.

According to Reddy's classic deformation plate theory and von Karman type equations for geometric nonlinearity, the displacement field of the cantilevered plate is assumed to be (Lim et al. 1998):

Figure 1. The simplified mathematical model of a cantilevered plate structure.

$$\begin{aligned} u_1 &= u(x, y, z, t) = u_0(x, y, t) - z \frac{\partial w_0}{\partial x} \\ u_2 &= v(x, y, z, t) = v_0(x, y, t) - z \frac{\partial w_0}{\partial y} \\ u_3 &= w(x, y, z, t) = w_0(x, y, t) \end{aligned} \quad (1)$$

where (u_1, u_2, u_3) are the displacement of an arbitrary point of the cantilever plate in the x , y , and z directions; (u_0, v_0, w_0) is the deflection of a point on the middle plane ($z = 0$).

The nonlinear strain-displacement relations are given as follows:

$$\begin{aligned} \varepsilon_{xx} &= \frac{\partial u}{\partial x} + \frac{1}{2} \left(\frac{\partial w}{\partial x} \right)^2, \varepsilon_{yy} = \frac{\partial v}{\partial y} + \frac{1}{2} \left(\frac{\partial w}{\partial y} \right)^2, \\ \varepsilon_{xy} &= \frac{1}{2} \left(\frac{\partial u}{\partial y} + \frac{\partial v}{\partial x} + \frac{\partial w}{\partial x} \frac{\partial w}{\partial y} \right) \end{aligned} \quad (2)$$

The stress-strain relationship of the cantilever plate is given as follows:

$$\begin{Bmatrix} \sigma_{xx} \\ \sigma_{yy} \\ \sigma_{xy} \end{Bmatrix} = \begin{Bmatrix} Q_{11} & Q_{12} & 0 \\ Q_{21} & Q_{22} & 0 \\ 0 & 0 & Q_{66} \end{Bmatrix} \begin{Bmatrix} \varepsilon_{xx} \\ \varepsilon_{yy} \\ \gamma_{xy} \end{Bmatrix} \quad (3)$$

$$\begin{aligned} Q_{11} &= \frac{E_1}{1 - \nu_{12}\nu_{21}}, Q_{12} = \frac{\nu_{12}E_2}{1 - \nu_{12}\nu_{21}}, Q_{21} = Q_{12}, \\ Q_{22} &= \frac{E_2}{1 - \nu_{12}\nu_{21}}, Q_{66} = G_{12} \end{aligned} \quad (4)$$

where Q_{ij} ($i, j = 1, 2$) is the elastic stiffness coefficient; E_i ($i = 1, 2$) is the elastic modulus; G_{12} is the shear modulus; ν_{12} and ν_{21} are Poisson's ratio.

The Hamilton's principle is given as follows:

$$\delta \int_{t_1}^{t_2} (T - U) dt + \int_{t_1}^{t_2} \delta W dt = 0 \quad (5)$$

The variation of kinetic energy is shown as follows:

$$\delta \int_{t_1}^{t_2} T dt = \delta \int_{t_1}^{t_2} \left(\int_V \frac{1}{2} \rho \dot{u}_i \dot{u}_i dV + \frac{1}{2} m \dot{u}_i^2 \Big|_{x=a} \right) dt, (i = 1, 2, 3) \quad (6)$$

The variation of potential energy is shown as follows:

$$\delta \int_{t_1}^{t_2} U dt = \int_{t_1}^{t_2} \int_V (\sigma_{xx} \delta \varepsilon_{xx} + \sigma_{yy} \delta \varepsilon_{yy} + \sigma_{xy} \delta \varepsilon_{xy}) dV dt \quad (7)$$

The virtual work is shown as follows:

$$\begin{aligned} \delta \int_{t_1}^{t_2} W dt &= \delta \int_{t_1}^{t_2} \int_{x_1}^{x_2} \int_{y_1}^{y_2} F w_0 dx dy dt \\ &- \delta \int_{t_1}^{t_2} \int_{x_1}^{x_2} \int_{y_1}^{y_2} c_3 \dot{w}_0 w_0 dx dy dt \end{aligned} \quad (8)$$

Substituting Equation (6) (7) (8) into Equation (5) yields the nonlinear governing equations of motion for the cantilever plate:

$$\begin{aligned} \frac{\partial N_{xx}}{\partial x} + \frac{\partial N_{xy}}{\partial y} &= I_0 \ddot{u}_0 - I_1 \frac{\partial \ddot{w}_0}{\partial x}, \\ \frac{\partial N_{yy}}{\partial y} + \frac{\partial N_{xy}}{\partial x} &= I_0 \ddot{v}_0 - I_1 \frac{\partial \ddot{w}_0}{\partial y}, \\ \frac{\partial N_{xx}}{\partial x} \frac{\partial w_0}{\partial x} + \frac{\partial N_{xy}}{\partial x} \frac{\partial w_0}{\partial y} + \frac{\partial N_{xy}}{\partial y} \frac{\partial w_0}{\partial x} \\ &+ \frac{\partial N_{yy}}{\partial y} \frac{\partial w_0}{\partial y} + F \cos(\Omega t) - c_3 \dot{w}_0 \\ &= I_0 \ddot{w}_0 + I_1 \left(\frac{\partial \ddot{u}_0}{\partial x} + \frac{\partial \ddot{v}_0}{\partial y} \right) - I_2 \left(\frac{\partial^2 \ddot{w}_0}{\partial x^2} + \frac{\partial^2 \ddot{w}_0}{\partial y^2} \right) \end{aligned} \quad (9)$$

where the dot represents the partial differentiation with respect to time t ; c_3 is the damping coefficient.

$$\begin{aligned} N_{\alpha\beta} &= \int_{-h/2}^{h/2} \sigma_{\alpha\beta} dz, I_i \\ &= \int_{-h/2}^{h/2} \rho(z) z^i dz, (i = 0, 1, 2) \end{aligned} \quad (10)$$

where $\alpha = x, y; \beta = x, y$.

The stress-strain relations are given as follows:

$$\begin{Bmatrix} N_{xx} \\ N_{yy} \\ N_{xy} \end{Bmatrix} = \begin{Bmatrix} A_{11} & A_{12} & 0 \\ A_{21} & A_{22} & 0 \\ 0 & 0 & A_{66} \end{Bmatrix} \begin{Bmatrix} \varepsilon_{xx} \\ \varepsilon_{yy} \\ \gamma_{xy} \end{Bmatrix} \quad (11)$$

where $A_{ij} = \int_{-h/2}^{h/2} Q_{ij} dz, (i, j = 1, 2, 6)$.

Substituting Equation (10) and Equation (11) into Equation (9), the governing equations of motion in terms of generalized displacement for the cantilever plate are as follows:

$$\begin{aligned} A_{11} \frac{\partial^2 u_0}{\partial x^2} + A_{66} \frac{\partial^2 u_0}{\partial y^2} + (A_{12} + A_{66}) \frac{\partial^2 v_0}{\partial x \partial y} \\ + (A_{12} + A_{66}) \frac{\partial w_0}{\partial y} \frac{\partial^2 w_0}{\partial x \partial y} + A_{11} \frac{\partial w_0}{\partial x} \frac{\partial^2 w_0}{\partial x^2} \\ + A_{66} \frac{\partial w_0}{\partial x} \frac{\partial^2 w_0}{\partial y^2} = I_0 \frac{\partial^2 u_0}{\partial t^2} - I_1 \frac{\partial^3 w_0}{\partial x \partial t^2}, \end{aligned} \quad (12a)$$

$$\begin{aligned} A_{22} \frac{\partial^2 v_0}{\partial y^2} + A_{66} \frac{\partial^2 v_0}{\partial x^2} + (A_{21} + A_{66}) \frac{\partial^2 u_0}{\partial x \partial y} \\ + (A_{21} + A_{66}) \frac{\partial w_0}{\partial x} \frac{\partial^2 w_0}{\partial x \partial y} + A_{22} \frac{\partial w_0}{\partial y} \frac{\partial^2 w_0}{\partial y^2} \\ + A_{66} \frac{\partial w_0}{\partial y} \frac{\partial^2 w_0}{\partial x^2} = I_0 \frac{\partial^2 v_0}{\partial t^2} - I_1 \frac{\partial^3 w_0}{\partial y \partial t^2}, \end{aligned} \quad (12b)$$

$$\begin{aligned}
& -D_{11} \frac{\partial^4 w}{\partial x^4} + (-D_{21} - 4D_{66} - D_{12}) \frac{\partial^4 w}{\partial x^2 \partial y^2} \\
& -D_{22} \frac{\partial^4 w}{\partial y^4} + \frac{3A_{11}}{2} \left(\frac{\partial w}{\partial x} \right)^2 \frac{\partial^2 w}{\partial x^2} \\
& + \left(\frac{1}{2} A_{21} + A_{66} \right) \left(\frac{\partial w}{\partial x} \right)^2 \frac{\partial^2 w}{\partial y^2} \\
& + \left(\frac{1}{2} A_{12} + A_{66} \right) \left(\frac{\partial w}{\partial y} \right)^2 \frac{\partial^2 w}{\partial x^2} \\
& + \frac{3}{2} A_{22} \left(\frac{\partial w}{\partial y} \right)^2 \frac{\partial^2 w}{\partial y^2} + 2 \left(\frac{1}{2} A_{21} + 2A_{66} + \frac{1}{2} A_{12} \right) \\
& \frac{\partial w}{\partial x} \frac{\partial w}{\partial y} \frac{\partial^2 w}{\partial x \partial y} + A_{11} \frac{\partial u}{\partial x} \frac{\partial^2 w}{\partial x^2} + A_{22} \frac{\partial v}{\partial y} \frac{\partial^2 w}{\partial y^2} \\
& + A_{21} \frac{\partial u}{\partial x} \frac{\partial^2 w}{\partial y^2} + A_{12} \frac{\partial v}{\partial y} \frac{\partial^2 w}{\partial x^2} + 2A_{66} \frac{\partial u}{\partial y} \frac{\partial^2 w}{\partial x \partial y} \\
& + 2A_{66} \frac{\partial v}{\partial x} \frac{\partial^2 w}{\partial x \partial y} + (A_{21} + A_{66}) \frac{\partial w}{\partial y} \frac{\partial^2 u}{\partial y \partial x} \\
& + A_{11} \frac{\partial w}{\partial x} \frac{\partial^2 u}{\partial x^2} + A_{66} \frac{\partial w}{\partial x} \frac{\partial^2 u}{\partial y^2} + A_{66} \frac{\partial w}{\partial y} \frac{\partial^2 v}{\partial x^2} \\
& + (A_{12} + A_{66}) \frac{\partial w}{\partial x} \frac{\partial^2 v}{\partial y \partial x} + A_{22} \frac{\partial w}{\partial y} \frac{\partial^2 v}{\partial y^2} \\
& + F \cos(\Omega t) = c_3 \dot{w}_0 + I_0 \ddot{w}_0 - I_2 \frac{\partial^2 \ddot{w}}{\partial x^2} \\
& - I_2 \frac{\partial^2 \ddot{w}}{\partial y^2} + \left(I_1 \frac{\partial \ddot{u}}{\partial x} + I_1 \frac{\partial \ddot{v}}{\partial y} \right)
\end{aligned} \tag{12c}$$

where $D_{ij} = \int_{-h/2}^{h/2} Q_{ij} z^2 dz$, ($i, j = 1, 2, 6$)

The Galerkin method is a numerical analysis method, which can transform partial differential equations to ordinary differential equations (Nayfeh & Mook 1979). Through the experimental study, the first order modal vibration plays a key role in the vibration of the nonlinear system (Yu 2009). So we choose a suitable mode function to satisfy the boundary condition of the cantilever plate and consider nonlinear dynamics of the cantilever plate in the first mode of u_0, v_0, w_0 and F . Thus, we write them in the following forms (Oh & Nayfeh 1996):

$$\begin{aligned}
u_0(x, y, t) &= u_1(t) \sin\left(\frac{\pi x}{2a}\right) \cos\left(\frac{\pi y}{b}\right), \\
v_0(x, y, t) &= v_1(t) \sin\left(\frac{\pi x}{2a}\right) \cos\left(\frac{\pi y}{b}\right), \\
w_0(x, y, t) &= w_1(t) \alpha_1 \beta_1, \\
F(x, y, t) &= F_1(t) \alpha_1 \beta_1, \\
\alpha_1 &= \cosh \frac{k_1 x}{a} - \cos \frac{k_1 x}{a} \\
& - \frac{\sinh k_1 - \sin k_1}{\cosh k_1 + \cos k_1} \left(\sinh \frac{k_1 x}{a} - \sin \frac{k_1 x}{a} \right), \\
\beta_1 &= \sqrt{3} \left(1 - \frac{2y}{b} \right), \\
\cos k_1 \cosh k_1 + 1 = 0, k_1^4 &= \omega^2 \frac{\rho A}{EJ}
\end{aligned} \tag{13}$$

For the cantilever thin plate, transverse displacement is more obvious than the other directions, so all inertia terms in Equation (12) about u_0, v_0 are neglected (Narita 1985). By using the Galerkin method and substituting Equation (13) into Equation (12), we yield the governing ordinary differential equations of transverse motion:

$$\begin{aligned}
\ddot{w}_1 + \mu_1 \dot{w}_1 + q_1 w_1 + q_2 w_1^3 &= f_1 \cos \Omega t \\
\mu_1 &= -\frac{c_3 a^4 b^2}{a^4 b^2 I_0 - a^2 b^2 I_2}, q_1 = \frac{10 D_{11} b^2}{a^4 b^2 I_0 - a^2 b^2 I_2}, \\
q_2 &= \frac{1}{a^4 b^2 I_0 - a^2 b^2 I_2} \\
& \left(-\frac{A_{11} A_{66} a^3 b^2}{8 A_{11} a b^2 + 30 A_{66} a^3} \right. \\
& \left. - \frac{A_{11}^2 a b^4}{1600 A_{11} a b^2 + 6000 A_{66} a^3} \right. \\
& \left. + \frac{A_{11}^2 a b^4}{160 A_{11} a b^2 + 600 A_{66} a^3} - 1.5 A_{11} b^2 \right) \\
f_1 &= \frac{a^4 b^2 F}{a^4 b^2 I_0 - a^2 b^2 I_2}
\end{aligned} \tag{14}$$

According to Faraday's law of electromagnetic induction, the output voltage is equal to the change rate of flux through the closing coil.

$$V = -\frac{d\Phi}{dt} = -\frac{dNBs}{dt} = -\frac{dNBh\dot{w}_1(t)}{dt} = -NBh\dot{w}_1(t) \tag{15}$$

where ϕ denotes magnetic flux; N denotes coil number of turns; B denotes the magnetic induction intensity; l denotes the effective length of the coil; $\dot{w}_1(t)$ represents the ordinary differentiation with respect to time t .

3 NUMERICAL SIMULATION

The fourth-order Runge–Kutta algorithm is used to numerically analyze the nonlinear dynamic

Table 1. Physical parameters of the cantilevered plate.

Physical quantity	Value
a	2 m
b	1 m
h	0.008 m
E_1	125 Gpa
E_2	7.2 Gpa
G_{12}	4.0 Gpa
V_{12}	0.33
ρ	1570 kg/m ³
c_3	2.83×10^{-5}
B	3300 Gs
N	800

responses of the cantilever plate to the output voltage based on the base excitation.

In Table 1, the physical parameters chosen are as follows: a denotes the length, b denotes the width, h denotes thickness of the plate, E_1, E_2 denotes Young's moduli, G_{12} denotes the shear moduli, ν_{12} denotes the Poisson's ratios, ρ denotes the density, c_3 denotes the damping coefficient, N denotes the turns of the coil, B denotes the magnetic induction intensity.

The Equation (14) and Equation (15) are chosen for numerical simulation. The base excitation frequency Ω is used as the controlling parameter to investigate the periodic and chaotic responses of the cantilever plate to generating electricity based on electromagnetic induction.

As shown in Figure 2, the abscissa denotes the frequency of the base excitation while the ordinate denotes the output voltage of the plate. When the base excitation frequency Ω is located in the interval 30 Hz–300 Hz, the bifurcation diagram is obtained.

Analyzing the bifurcation diagram in Figure 2, it is found that the motions of the rectangular cantilever plate are as follows: the periodic motion \rightarrow the multiple periodic motions \rightarrow the chaotic motion \rightarrow the multiple periodic motions \rightarrow the chaotic motion with an increase in the base excitation frequency Ω .

Based on the bifurcation diagram and using the same physical parameters, the base excitation frequency Ω is changed to obtain different waveforms of the cantilever plate, including periodic motion, multiple periodic motion, and chaotic motion.

When the base excitation frequency $\Omega = 60$ Hz, Figure 3(a) shows the existence of periodic motion for the cantilever plate. When the base excitation frequency $\Omega = 170$ Hz, Figure 3(b) shows the existence of multiple periodic motions for the cantilever plate. When the base excitation frequency changes to $\Omega = 230$ Hz, the chaotic motion of the cantilever plate is observed, as shown in Figure 3(c).

Figure 2. The bifurcation diagram of the output voltage V via the base excitation frequency Ω .

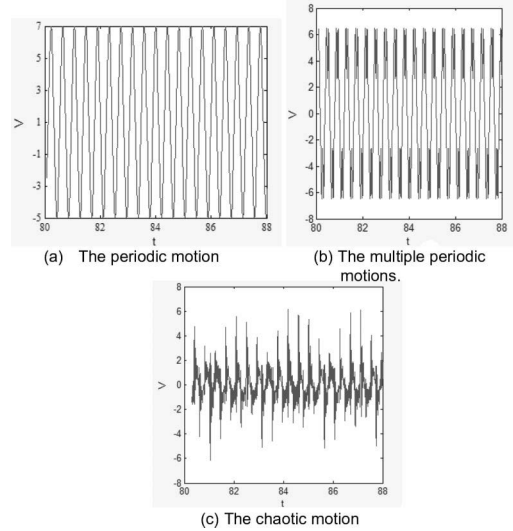

Figure 3. The motion of the cantilever plate.

4 CONCLUSIONS

The nonlinear dynamic responses of a rectangular cantilever plate based on electromagnetic induction to generating electricity subjected to the base excitation were investigated. Based on Reddy's classic deformation plate theory and von Karman type equations, the governing equations of motion for the cantilever rectangular plate was derived by using Hamilton's principle. Numerical simulation is provided by using the fourth-order Runge–Kutta algorithm. The numerical results show that there exist periodic, multiple periodic, and chaotic motions of the cantilever plate under certain conditions.

The bifurcation diagram of the cantilever plate for the output voltage V via the base excitation frequency Ω is obtained. Analyzing the bifurcation diagram, the periodic motion appears firstly, and the multiple periodic motion and chaotic motion appear alternately when the base excitation frequency Ω exceeds a certain value.

The results show that the output voltage of the rectangular cantilever plate is different with a change in the base excitation frequency Ω . In order to get the optimal efficiency of power generation, the appropriate interval of the base excitation frequency Ω must be chosen.

Influence of inductance on an interleaved parallel boost PFC circuit

Zhonghua Kong, Ligang Wu & Zaifei Luo
Ningbo University of Technology, Ningbo, China

ABSTRACT: With power rating enhancing unceasingly, the increasing demand for high-power PFC (Power Factor Correction) converters is becoming stronger, but the traditional boost PFC converter is only suitable for small- and medium-sized power applications. By using the interleaved technology, the current stress of switches can be decreased, the ripple of the input current and switching losses can also be reduced, and the power rating of the PFC converter can be improved. Interleaved boost PFC is very suitable for high power applications. Inductance influence on the characteristics of interleaved parallel boost PFC circuit was studied. So the different material inductance and inductance values are designed, and the characteristics of the interleaved parallel boost PFC circuit are studied in this paper. Experimental results are presented for a prototype boost converter converting universal AC input voltage (85–265 V) to 400 V DC output at up to 1 kW load.

1 INTRODUCTION

With the rapid development of power electronics technology, power electronic devices have been widely used. This may cause severe harmonic pollution posing a serious threat to the health of the grid. Power Factor Correction (PFC) technology is a good way to solve the problem of harmonic pollution caused by power electronic devices. The most commonly used PFC converter in an onboard charger is a single-phase diode bridge rectifier followed by a boost converter. With power rating enhancing unceasingly, the increasing demand for high-power PFC converters is becoming stronger, but the traditional boost PFC converter is only suitable for small- and medium-sized power applications. By using the interleaved technology, the current stress of switches can be decreased, the ripple of the input current and switching losses can also be reduced, and the power rating of the PFC converter can be improved. Interleaved boost PFC is very suitable for high-power applications. Two-phase interleaved power factor correction boost converters in single phase AC-DC converter can reduce input current ripple for the EMI filter, the RMS ripple current for output capacitor and current stress for switches and inductors (L. Huber, 2000; C. Wang, 2008; Choudhury, 2005; T. Grote, 2009; B. A. Miwa, 1992; C. H. Chan, 1997). So this article will use interleaved boost PFC converter as the research object to study the characteristics of interleaved technology. Different material inductance and inductance values are designed, and the characteristics of interleaved parallel boost PFC circuit are studied in this paper. Experimental

results are presented for a prototype boost converter converting universal AC input voltage (85–265 V) to 400 V DC output at up to 1 kW load.

2 DESIGN OF AN INTERLEAVED BOOST CONVERTER

The boost interleaved PFC converter topology is presented in Figure 1. It uses a dedicated diode bridge to rectify the AC input voltage to DC, which is then followed by two boost PFC converters in parallel, operating 180° out of phase. The boost interleaved PFC converter has the advantage of paralleled semiconductors. The input current is the sum of two inductor currents; therefore, it reduces output capacitor high-frequency ripple, but still has the prob-

Figure 1. Interleaved PFC boost converter.

lem of heat management for the input diode bridge rectifiers. The PFC controller adopted is UCC28070. The UCC28070 is an advanced power factor correction device that integrates two pulse-width modulators operating 180° out of phase. This interleaved PWM operation generates a substantial reduction in input and output ripple currents, and the conducted-EMI filtering becomes easier and less expensive. A significantly improved multiplier design provides a shared current reference to two independent current amplifiers that ensure matched average current mode control in both PWM outputs while maintaining a stable, low-distortion sinusoidal input line current.

The interleaved inductors are designed to meet the requirement of high power factor over a wide range of AC line voltages. Two non-coupled inductors are used. The inductance value of inductors should be high enough to avoid Discontinuous Current Mode (DCM) operation of each boost leg and acquire high power factor, low Total Harmonic Distortion (THD), and low Electromagnetic Interference (EMI). As the inductance value of an inductor decreases at higher operating currents, the nominal value of inductance is designed at maximum operating current, corresponding to full load conditions (1 kW) at a lower line voltage (85 Vac). The inductance value is determined by the switching frequency, which is set at 80 kHz and the current ripple of each boost leg, which is selected to be equal to 20% (Δi) of the maximum AC current. The boost inductors (L1 and L2) are selected based on the maximum allowable input ripple current. In universal applications (e.g., 85 V to 265 V RMS input), the maximum input ripple current occurs at the peak of low line, and for this design, the maximum input ripple current was set to 30% of the peak nominal input current at low line.

The following calculations are used to select the appropriate inductance for L1 and L2, where variable D is the converter's duty cycle at the peak of low line operation, the max duty cycle D_{\max} is as follows:

$$D_{\max} = \frac{(V_o - \sqrt{2} \times V_{in\min})}{V_o} = \frac{400 - \sqrt{2} \times 85}{400} = 0.7 \quad (1)$$

where V_o is the output voltage, $V_{in\min}$ is the minimum AC input voltage

Variable $K(D)$ is the ratio of input current to inductor ripple current at the peak of low line operation as follows:

$$k = \frac{2D_{\max} - 1}{D_{\max}} = 0.57 \quad (2)$$

ΔI_L is the boost inductor ripple current at the peak of low line based on the converter input ripple current requirements as follows:

$$\Delta I_L = \frac{P_{out} \times \sqrt{2} \times 0.4}{V_{in\min} \times \eta \times k} = 6.49 A \quad (3)$$

The inductance is calculated as follows:

$$L_1 = L_2 = \frac{V_{in\min} \times \sqrt{2} \times D}{\Delta I_L \times f} = 131 \mu H \quad (4)$$

where f is the switching frequency at 80 kHz.

3 EXPERIMENTAL RESULTS

In order to study the influence of different inductance material and inductance values on the characteristics of the interleaved parallel boost PFC circuit, TDK ferrite N97 and Magnetics Kool M μ 77090 materials are selected as the magnetic core of the inductor. The ferrite core adopted is EE42/21, the boost inductance (L1 and L2) values are 265, 600, and 835 μH , the Kool M μ core adopted is ring cores, and the boost inductance (L1 and L2) values are 290 and 1100 μH . Input voltage and current waveform are shown in Figure 2. The yellow waveform is the voltage, the blue waveform is the current, and the current waveform is close to the sinusoidal waveform. Current waveform of the inductor and voltage waveform of switching are shown in Figure 3. The green waveform is voltage and blue waveform is current, the underpart waveform is a partially enlarged view form of the upper part waveform.

Figure 4 to Figure 6 show the relation between the input voltage and power factor and efficiency, where B is the power factor curve, C is the efficiency curve, and TDK ferrite N97 material is adopted. The values of boost inductors (L1 and L2) are 265,

Figure 6. Relation between the input voltage and power factor and efficiency.

Figure 4. Relation between the input voltage and power factor and efficiency.

Figure 7. Relation between the input voltage and power factor and efficiency.

Figure 5. Relation between the input voltage and power factor and efficiency.

Figure 8. Relation between the input voltage and power factor and efficiency.

600, and 835 μH . Power factor decreases with the increase in input voltage, but efficiency increases with the increase in input voltage. The input current decreases with increase in input voltage, so

power loss of the power device increases with increase in input current. Overall, considering the power factor and efficiency, the boost inductor with 600 μH is better than the other inductors.

Figure 7 and Figure 8 show the relation between the input voltage and power factor and efficiency, B is the power factor curve, C is the efficiency curve, and the Magnetics Kool M μ 77090 is the adopted material, the boost inductor (L1 and L2) values are 295 and 1100 μ H. Efficiency increases with increase in input voltage, power factor is nearly stable under low voltage and decreases with increase in input voltage. So, the characteristics of Magnetics Kool M μ must be considered in the design of switching power supply.

4 CONCLUSION

The relation between the input voltage and power factor and efficiency is studied in this paper. When ferrite material is adopted for power supply, the power factor decreases with increases in input voltage, the efficiency increases with the increase in input voltage, and the boost inductor with 600 μ H is better than the other inductors. When the Magnetics Kool M μ material is adopted for power supply, the efficiency increases with the increase in input voltage, and the power factor is nearly stable under a lower voltage and then decreases with the increase in input voltage. So, the characteristics of Magnetics Kool M μ must be considered in the design of switching power supply.

VOLUME 1

Structural science and architecture engineering

Visual support vector machine-based method for reliability-based design optimization <i>Y. Xie & Y.Z. Wu</i>	3
Study on the tunnel group traffic accident risk using a fuzzy comprehensive evaluation model <i>B. Ma, R. Gao, Y. Gao, X.J. Wang & Z. Guo</i>	9
Applications of new reinforcement methods in city tunnels for shield launching and arriving <i>H. Jun, J.B. Shi, W. Hong & W. Xiaobin</i>	13
Research on the stress characteristics of concrete carrier pile based on finite element analysis <i>J.Y. Li, A.Q. Zhang & X.G. Han</i>	19
Theoretical analysis of the deformation of shield tunnel segment under fire <i>X.B. Han, Y.X. Xia & L.L. Chai</i>	25
Optimization of composition of the claddings of wooden structures <i>M. Halirova, H. Sevcikova, R. Fabian, E. Machovcakova & R. Janousek</i>	31
Evaluation of the ultimate strength of RC I-shaped members subjected to a combined action <i>P. Wang, Z. Huang & Q.S. Wang</i>	37
Three-dimensional centrifuge and numerical modeling of pile group due to twin tunnelling in different depth <i>S.K. Ma, Y. Shao, Y. Liu, J.Y. Chen & J. Jiang</i>	43
Index selection and weight analysis of the underground development of urban municipal public facilities <i>L. Ye & L.M. Zhu</i>	49
Risk assessment of pipelines in operation based on AHP and application of MATLAB <i>L. Chen, G.X. Wang & J. Zhao</i>	55
Effect of ground conditions on design parameters for bridge foundations <i>M.T.A. Chaudhary</i>	61
Research on multisource information fusion of tunnel geological prediction based on evidence theory <i>Z.H. Liu, Y.T. Wang, H. Ke, H. Wu & D. Zhou</i>	67
Pushover analysis of modularized prefabricated column-tree steel frame <i>Z.P. Guo, A.L. Zhang & X.C. Liu</i>	75

Study on reuse of heritages of an old industrial area in Harbin Gongyijie area against the backdrop of urban renewal <i>X.Z. Shan & W. Cheng</i>	83
Research on lateral resistant behavior and design of multicover plates connection for prefabricated steel plate shear wall with beam-only-connected infill plate <i>X. Zhang, A.L. Zhang & X.C. Liu</i>	89
Research on sensitivity and control criteria of cable length error in a double-strut cable dome <i>C. Sun & A.L. Zhang</i>	97
Structural design of a prefabricated steel frame structure with inclined braces <i>X.C. Liu, H.X. Wang & Z.P. Guo</i>	105
A study on the design of an ungated community <i>F. Jia, R.X. Wang & F.L. Ma</i>	115
Protection and utilization of Gaichun Garden ruins of the Summer Palace <i>D. Zhao & L. Zhang</i>	119
Development of a web-based hybrid BIM cost-estimating system for fire safety engineering <i>M.-H. Wen, W.-C. Huang & Y.-W. Wu</i>	125
Test and parametric analysis of postfire seismic performance of SRC column–RC beam joints <i>G.H. Li, L. Xie & D.F. Zhao</i>	135
Using agent-based simulation approach for estimating the efficiency of the building project design team <i>M.H. Tsai</i>	139
Field assessment of window daylighting with prismatic glazing <i>Z. Tian, D. Xue & Y.P. Lei</i>	145
Mechanical analysis of rockburst considering the “locked in” stress in the driving face of the roadway <i>X.-B. Yang, X.-X. Han, H. Wang & T.-B. Zhou</i>	149
Study on the identification of major safety defects in port engineering <i>J.H. Peng</i>	155
Investigating the impact of greenery on the driver’s psychology at a freeway tunnel portal <i>D.Q. Xiao, Z.W. Shen & X.C. Xu</i>	159
Modeling two-dimensional rubble mound breakwater using dolos at armor layer and geotube at the core layer <i>O.C. Pattipawaej & H.J. Dani</i>	167
Shear stress calculation of rubber asphalt overlay and stress-absorbing layer <i>J.Z. Tan, J.G. Wei, C. Pan & K.X. Huang</i>	171
Experimental study on beam-column joints of new prefabricate assembly frame structures <i>W.Z. Zhu & J.C. Zhang</i>	177
Seismic analysis of large span spatial steel frame with isolation system <i>W.Z. Zhu</i>	185
Effect of material ingredients on the cement-based self-leveling material <i>J. Liu, J.J. Hu, R.Q. Liu & Y.Q. Yang</i>	195
Rebuilding the city parks: How great is the effectiveness of environment-friendly constructions? <i>R. Y. Tallar, A.F. Setiawan & J.P. Suen</i>	201
Renaissance with recycled materials: Reconstruction of Guifeng Temple <i>Y.S. Gao & J. Xu</i>	205
Research on safety management of construction projects based on game theory <i>J.X. Zhao, M.M. Wang, J.H. Sun & K. Li</i>	209

Prestress distribution calculation method of a ridge tube cable dome with annular struts <i>A.L. Zhang, Y. Bai, X.C. Liu & C. Sun</i>	215
A new multiple-model analysis method considering structural uncertainty <i>F.Q. Zhu</i>	223
Promotion of transportation on urban spatial distribution and industrial development in Beijing <i>X. Peng</i>	227
Selection of interruptive protection methods in rapid transit underground construction <i>H.-C. Yang & C.-C. Liu</i>	233
Damage mechanism and dynamic analysis of tunnel lining structures under internal blast loading <i>C.Y. Chen, Y.B. Jiang, J. Yang, L.F. Zheng & Z.P. Li</i>	239
The seismic responses of near-fault frame structure cluster on basin induced by the rupture of reverse fault <i>W. Zhong</i>	247
Wave propagation FEA and experimental validation of aluminum plate using piezoelectric elements <i>S. Yan, S. Zhang, Z.Q. Wang, P.T. Zhao & Y. Dai</i>	253
Numerical simulation on seismic behavior of subway station structure under near-fault ground motions <i>B.Z. Tang, S. Chen, X.J. Li & H.Y. Zhuang</i>	259
Finite—infinite element analysis of soil dynamic response under moving load <i>C.Q. Tian & L.Q. Yuan</i>	265
Evaluation of the processing suitability of rural domestic sewage treatment, taking Fangshan in Beijing as a case study <i>Y. Wang</i>	269
Influence analysis of the incremental launching of steel box girder and local stability control <i>F.-J. Xie</i>	275
Study on active strategies for thermal environment regulation in the zero-energy houses of Solar Decathlon, China <i>F. Shi, W. Jin, W.W. Zheng & T. Zhuang</i>	285
Research and enlightening of ecological infrastructure-oriented “multiple planning integration” based on Germany’s spatial order and structure planning—illustrated by the example of Dujiangyan <i>Y.J. Li, F. Fu & Y. Yi</i>	289
Homogeneous generalized yield function and limit analysis of structures with rectangular sections <i>W. Ou, L.F. Yang & W. Zhang</i>	295
Numerical simulation analysis of the influence of shield tunneling on an adjacent tunnel <i>M.D. He & J. Liu</i>	301
Development and validation of the effective stress algorithm of the Davidenkov constitutive model using the Byrne pore pressure increment model <i>B. Ruan, G.X. Chen & D.F. Zhao</i>	309
Urban ITS framework and essential parts of the ITS frame structure <i>M.-Q. Li, Z.-H. Wang, W. Wan & Z.-T. Jing</i>	317
Development and implementation of a product module division system based on the function—principle—structure <i>J. Chen, L.M. Wang & L.L. Yang</i>	321

Parameter optimization of space truss and aerospace load viscoelastic damping composite structure <i>Z. W. Zhang, P. Wang & H. T. Luo</i>	325
A unified theory of thermodynamically consistent microplane elastoplastic damage, and elastoplastic damage models <i>W.S. Li & J.Y. Wu</i>	331
 <i>Building materials and materials science</i>	
Preparation of sebacic acid by a phenol-free method <i>L. Xu, L.L. Mao, Y.M. Feng, J.C. Zhang, M. Wang, T.T. Zhao, X.J. Gao & R. Ren</i>	341
Effects of electrospinning parameters on the pore structure of porous nanofibers <i>Z. Y. Sun & L. Xu</i>	345
Preparation of orderly nanofibers using bubble-electrospinning <i>Z.B. Shao & L. Xu</i>	349
Environmental radioactivity measure and dose estimation of ⁹⁰ Sr in some area <i>L. Ma, X. Ren & K. Zhang</i>	353
Effect of humic acid on the adsorption of levofloxacin to goethite <i>X.P. Qin, H. Hou, L. Zhao, J. Ma, Z.J. Sun, W.J. Xue, F. Liu & G.C. Wang</i>	357
Calcium and manganese affect ethanol fermentation by <i>Pichia stipitis</i> in cadmium-containing medium by inhibiting cadmium uptake <i>M.-T. Gao, X.X. Chen, W. Zheng, Q.Y. Xu & J.J. Hu</i>	363
Performance comparison of Biological Aerated Filters packed with polyurethane sponge and ceramic particles <i>G.L. Yu, X.J. Yan, H. Chen, C.Y. Du, Y.J. Fu & J.X. Zhang</i>	367
Preparation and evaluation of the Ni-Al catalyst derived from LDHs synthesized on γ -Al ₂ O ₃ support <i>X.K. Zhao, Y.Q. Li, Y. Xu, X.H. Du & J.J. Xu</i>	373
Synthesis and hydrodesulfurization performance of NiMo sulfide catalysts supported on an Al-Si mixed oxide <i>Q. Yu, J.C. Zhang, J. Nan, H.B. Yu, X.F. Peng, H. Xiao, G.L. Song, S.Q. Zhang, S. Wang, Y.T. Zhang & G.H. Zhang</i>	377
Study on solidification of Ningbo mucky soil <i>J.Y. Lu, R.Q. Xu, Q. Yan & X. Wang</i>	381
A study on the utilization of iron and steel industrial solid waste <i>Y.B. Zhang, R. Zhu, Y. Wang, C.S. Yue & X.J. Piao</i>	387
Experimental study of the drainage and consolidation characteristics of tailings discharge and accumulation by gradual height rising under the action of drainage material <i>J. Su, X.D. Ou & K.W. Hou</i>	393
LQR control of across-wind responses of tall buildings using composite tuned mass dampers <i>Y.M. Kim, K.P. You, J.Y. You, S.Y. Paek & B.H. Nam</i>	403
Time-dependent reliability analysis of steel fiber-reinforced concrete beams under sustained loads <i>Y. Li, K.H. Tan & S.-M. Yu</i>	411
Research on the heat transfer characteristics of rock and soil under the effects of vertical double U-type buried-pipe heat exchanger <i>X.-D. Ou, X. Pan, H. Dai, Y.-C. Tang & Z.-Y. Liu</i>	417
Nitrogen removal performance of ANAMMOX-PVA granules immobilized by different preparation methods <i>Y.M. Han</i>	425

Seismic response of a long-span cable-stayed bridge with slip-shear metal damper <i>C.K. Jiao & X. Dong</i>	429
Research on the interfacial bond behavior between CFRP sheet and steel plate under the static load <i>L. Zhang & S.-Y. Cao</i>	435
Influence of thick and loose sediments on the vacuum load transfer <i>J.X. Weng</i>	439
Enhancement on fireproof performance of construction coatings using calcium sulfate whiskers prepared from wastewater <i>T.-P. Tsai & H.-C. Yang</i>	447
Simulation of nonlinear ultrasonic waves in anisotropic materials using convolution quadrature time-domain boundary element method <i>T. Saitoh, T. Maruyama & A. Furukawa</i>	451
Study on the layout method of newly-added feeder bus lines coordinating with bus rapid transit <i>Z. Guo, P.H. Wei, X. Peng, C.Z. Chang, L. Tong & J.M. Velásquez</i>	457
Design of a campus view of a virtual roaming system based on VR <i>L. Yu</i>	465
Analysis on sustainable financial framework and fare adjustment strategy of China's urban public transit <i>S. Xu, C. Li, X.L. Liu & Y.K. Du</i>	471
Sanitation improvement and the bottleneck analysis of equity in China: From the perspective of specialists <i>X.L. Li & Y.Q. Miao</i>	479
Ultimate capacity of uniaxially compressed perforated steel plates strengthened by using CFRPs <i>X. Tao & S. Y. Cao</i>	483
Research on the measurement of the permeability coefficient of porous asphalt pavement <i>G.Q. Tang, L. Gao, T.J. Ji & J.G. Xie</i>	489
Mechanical performances of icing atop cement concrete surfaces coated with emulsion wax curing agents <i>J.-L. Yao & M.-J. Qu</i>	495
A study on residential area's adaptability design for the aged in China based on open building theory <i>X. Meng & B.C. Fu</i>	501
Safety management strategies for public infrastructure projects <i>C. W. Liao & T.L. Chiang</i>	507
The influence of the horizontal load on the stress–strain relationship of an asphalt layer <i>Y.H. Wang, X.M. Tan, X.J. He, Y. Wang, C. Wang & T. Liu</i>	511
A study on the protection type of flow-guided porthole dies with twin cavities for semi-hollow Al-profiles <i>R.R. Deng & P. Yun</i>	517
A study on covering and protection type porthole dies for semi-hollow Al-profiles <i>R.R. Deng & P. Yun</i>	521
A study on protection type porthole dies of semi-hollow Al-profiles with four cavities <i>R.R. Deng & P. Yun</i>	525
Numerical and experimental study on stability of aluminium alloy riveted and stiffened panels under in-plane shear <i>D.W. Wang, Z.K. Lei, R.X. Bai & Y. Ma</i>	531

Process optimization for the new nano-complex internal coating and its anti-corrosion and drag reduction properties in natural gas pipes <i>B.H. Hao, B. Sun, Z.H. Liu, Y.L. Han & L.F. Zhao</i>	535
An improved gray wolf optimization algorithm and its application in iron removal from zinc sulfate solution using goethite <i>T.B. Wu, J.H. Liu, Y.L. Liu, Q.M. Zhao & X.J. Li</i>	539
Determination of multi-element in abstergent by ICP-MS with microwave digestion <i>B.L. Wu, Z.X. Wang, J.M. Ye, Z.X. Lin, H. Wang & C. Luo</i>	545
Fabrication and application of superhydrophobic-superoleophilic porous Cu sponge <i>Y.J. Xing, Z.J. Han, J.L. Song, J. Sun, J. Luo, Z.A. Liu, J.Y. Liu, L. Huang & X. Liu</i>	549
Preparation of porous ceramics using CaCO ₃ as the foaming agent <i>J. Li & Y.L. Chen</i>	555
Spacing optimization modeling and simulation of thermo-optic VOA gold thin film interconnect <i>S.T. Ding, L. Xu, F. Huang & M.L. Gong</i>	559
Growth and characterization of thick Ge epilayers on Si and Silicon-on-Insulator (SOI) substrates with low temperature Ge buffers <i>Z. W. Zhou</i>	565
Effect of ZnSO ₄ and SnSO ₄ additions on the morphological of α -Al ₂ O ₃ flakes for pearlescent pigment <i>H. Qin, L. Wang & Y. Xiong</i>	569
A facile cost-effective method for preparing superhydrophobic carbon black coating on Al substrate <i>P. Wang, B. Sun, T. Yao, X. Fan, C. Wang, C. Niu, H. Han & Y. Shi</i>	573
Preparation of multifunctional flake alumina ceramics <i>Q.R. Wang, C. Liu, K.X. Du & Y. Xiong</i>	577
Study on the deformation of plastic films by virtual particle method <i>X.H. Yang, Z. Yang, Y.X. Wang, C.Y. Lv & X. Cheng</i>	581
An experimental study of installing-holes distances parameter optimization for metallic inserts bonded into CFRP laminates <i>J. Liu, H. Zhang & K. Hou</i>	585
Formation and test methods of the thermo-residual stresses for thermoplastic polymer matrix composites <i>C.C. Wang, G.Q. Yue, J.Z. Zhang, J.G. Liu & J. Li</i>	589
Effects of lithium slag from lepidolite on Portland cement concrete <i>Q. Luo, Y.F. Wen, S.W. Huang, W.L. Peng, J.Y. Li & Y.X. Zhou</i>	593
Sorption properties of TEMPO-oxidized natural cellulose to iron ions <i>C.Z. Geng, Y.H. Lou, D. Y. Yan, Z.H. Zhao, Z.X. Xue & Y.Z. Xia</i>	597
Research on the precision of grinding experiments in an iron ore <i>G.M. Shi, L.P. Jiang, J.M. Zhao, R.Q. Zhao, Y.C. Zhou & S.C. He</i>	603

Construction equipment and mechanical science

An experimental study on the dynamic characteristics of compact transmission lines bundles following ice shedding <i>K.P. Ji, B. Liu, X.P. Zhan, X.Z. Fei, C. Deng & L. Liu</i>	609
A single-lens optimal imaging system based on a liquid crystal spatial light modulator and micro-scanning optical wedge <i>N. Xu, Z.-Y. Liu & D. Pu</i>	613

A geometry-based path optimization approach for motion control of the NC grinding machine <i>F. Zhang, J. Gong, Y.J. Liu, W. Xia, M.F. Huang & Y.F. Fu</i>	621
A study on carbon electrode-based photoelectrochemical-type self-powered high-performance UV detectors <i>Q. Meng, X. Fan, E.Q. Wu & L. Chu</i>	625
A scheme study of CFB power generation by using pet coke <i>H.T. Liu, L. Xue & D.F. Xu</i>	629
Design of the pilot-scale double effect evaporator for high-concentration sodium hydroxide production <i>L. Gao</i>	633
Early fault diagnosis of wind turbine gearboxes based on the DSmt <i>Z.Q. Liu & G.C. Chen</i>	641
A study of an improved method for horizontal alignment based on the line element <i>Y.H. Li, Y.J. Liu & Y.L. Li</i>	647
Theoretical analysis of mechanical properties and mechanical design for fabricated zero initial cable force friction dissipation <i>Q.X. Ye & A.L. Zhang</i>	651
An optimal allocation model of residual control rights in the hydraulic PPP project <i>Y.H. Zhang, J.C. Feng, S. Xue & K. Zhang</i>	659
A study on the optimized hydraulic circulation system of the artificial lake <i>Q.N. Jin, A.J. You & H.B. Xu</i>	665
Development of new elastic constant estimation method using laser ultrasonic visualization testing <i>T. Saitoh & A. Mori</i>	669
Selection for the frequency control point of the VAV air supply system in large underground spaces <i>K.D. Xue, Z.H. Zhou, Y.F. Zhang & Y.M. Sun</i>	675
The innovations of the ship lock design for the Tugutang Hydropower Station in the Xiangjiang river <i>H.Y. Liu & C.Y. Wang</i>	679
Knowledge management in construction—the framework of high value density knowledge discovery with graph database <i>Y. Jing, Y.-C. Wang & Z. Wang</i>	685
Research of cold region green hospital design specification and practice <i>Y.Z. Gao, H.Y. Mei & J.F. Dong</i>	689
Development of intelligent residual current devices based on the PIC micro-controller <i>H. Chen, J. Xiang, R. Huang, L.M. Shen, F.S. Chen, K. Li, W.N. Wang, L.M. Bu, X. He & X.Y. Xu</i>	693
Design of Control Moment Gyro equivalent sound source based on transfer function matrix inversion <i>W. Cheng, W.-Q. Sun, G.-Y. Wang, J.-P. Chen, X.-F. Li & J. Jia</i>	699
A study of the magnetic field distribution with saddle-shaped coil of the electromagnetic flow meter <i>H. Jia, Y.M. Wang, W.T. Li & Y.Y. Zhang</i>	707
A study on a localizable CMOS temperature sensor based on wireless transmission <i>L.Y. Chen, J.Q. Li & Y.X. Li</i>	713
Finite element analysis of the roller coaster wheel bridge based on virtual prototype technology <i>Y.M. Wang, J. Ye, X.T. Xu & S. Song</i>	719

Multi-axis coordination control based on siemens S7-CPU315T <i>C.H. Pan, Y.L. Li & M.W. Qin</i>	725
Short-term photovoltaic power forecasting based on the human body amenity and least squares support vector machine with fruit fly optimization algorithm <i>H.B. Chen, W. Han & L. Chen</i>	729
An RFID-enabled CEP model for cloud manufacturing shopfloor <i>K.Q. Chen, Y.Y. Qiu, M.L. Wang, Q.Y. Dai, R.Y. Zhong & C.M. Huang</i>	735
Optimization of extraction of polysaccharides from mulberries by using high-intensity Pulsed Electric Fields <i>S.L. Jin</i>	741
Stress analysis of the interference fit in helical gear transmission <i>T. Zhao</i>	747
A review of transformerless DC–DC boost converters for renewable energy sources <i>J. Luo</i>	753
The linear fatigue cumulative damage analysis of the welding seam <i>Y.Y. Wang</i>	759
Application of wavelet analysis and resonance demodulation in mechanical fault diagnosis <i>C.H. Shen & W. Wang</i>	765
A study on the modeling of the slider-crank mechanism based on parameter identification <i>X.J. Wang, X.H. Tang & J. Shen</i>	769
Angle measurement by comparing the amplitude technique of the sum-difference pattern radiometer <i>H. Wang, J. Xiao & B. Bi</i>	775
Tension control methodology of active continuous discharge and intermittent reciprocating work based on master-slave synchronous motion <i>L. Han, H. Hu, W.H. Ding & J.Y. Li</i>	781
Design and kinematics analysis of a novel liquid-brewing steamer feeding robot <i>J.S. Zhang, B. Li, T.C. Zhang & X.H. Zhao</i>	787
Design and simulation analysis of a new type of multi-gear pump <i>X.H. Zhang, P.Y. Liu, W.J. Wei, H.T. Li & G.P. Tian</i>	793
A study on the torsional fatigue fracture location of steel wires <i>W.J. Wei, D.C. Wang, P. Cheng & C.X. Shao</i>	799
The lightweight design of the support arm <i>Y.Q. Tian, D. Meng & X.Y. Lin</i>	805
An analysis of the thermal elastohydrodynamic lubrication performance of the slope of the thrust bearing <i>Y.L. Liu, Y.H. Li, T.Y. Niu, J.F. Huang & Y.X. Wang</i>	809
Simulation of submarine underwater motion with an external weapon module <i>Y.Q. Lian, C.L. Li & Y. Liu</i>	815
A multi-objective NC drilling parameter optimization model to achieve low energy consumption and costs <i>W. Yan, H. Zhang & Z.G. Jiang</i>	823
An experimental study of the dynamic equivalence leakage of rolling-piston compressors <i>K.H. Geng, W. Wei, X.B. Ma, X. Wang, X.G. Han, T.B. Zhao, C.L. Chen & H. Sun</i>	827

The structure and transmission efficiency analysis research of a new pattern F2C-T pin-cycloid planetary transmission <i>L. Xuan, H. Jiang & T.M. Guan</i>	833
A study on surface zinc plating and heat treatment of welding gears <i>R. Zeng, J.H. Luo, Z.R. Lin & L.L. Wang</i>	839
Development and application of a test platform for a battery management system <i>J. Xiong, Z.H. Jin & Z.C. Li</i>	843
Experimental study on yarn friction slip in the yarn pull-out test <i>W.K. Li, Z.K. Lei, F.Y. Qin, R.X. Ba & Q.C. Fang</i>	847
Analysis and research into the effect of dithering technology on ADC's SNR <i>K.K. Jin & X.L. Chen</i>	851
Design and implementation of a CANopen master stack for servomotor controllers in a 6-DoF manipulator <i>J.H. Ji, Z.H. Tao, T. Zhang & M.Z. Qi</i>	855
Design of a crane intelligent control system <i>C.C. Zhang, S.G. Liu & H.W. Xie</i>	861
Valve clearance fault diagnosis of an internal combustion engine based on wavelet packets and k-nearest neighbors <i>R. Tan, Y. Zhang, T.X. Zheng, B. Yang & Y.J. Wang</i>	865
RV reducer dynamic and static performance test system design <i>W.-B. Fu, C.-S. Ai, C.-L. Tang, Y.-S. Yang, G.-P. Li & H.-H. Zhao</i>	871
Analysis of automotive suspension compliance based on the main effects of rubber bushing <i>B. Chen, J.-H. Fu & Z.-M. Chen</i>	877
Experimental and simulation research on the friction and wear properties of surface textured friction pairs in CST <i>S.N. Sun, L.Y. Xie & R.S. Long</i>	883
Simulation and analysis of MPPT used in photovoltaic grid-connected systems based on the improved disturb-and-observe method <i>J.F. Wang & H.R. Zhao</i>	889
Automatic control loop optimization method of thermal power plant based on internal model control <i>S. Gao, X.K. Pang, J. Li, C.W. Li & H.D. Li</i>	895
Multidisciplinary optimization and parameter analysis of the in-wheel permanent magnet synchronous motor of a tram <i>X.C. Wang & Z.G. Lu</i>	899
Dynamic simulation and muzzle vibration analysis of vehicle-mounted automatic mortar <i>Y. Fang, J.-Q. Qin & C.-C. Di</i>	907
Numerical simulation of aspheric glass lens during the non-isothermal molding process <i>H.J. Duan, Z.L. Xiao & J.Y. Tao</i>	911
Temperature field analysis of a porous modified concrete composite pavement <i>Y.H. Wang, X.M. Tan, X.J. He, T. Liu, Y. Wang & C. Wang</i>	915
A retrieval method based on a CBR finite element template <i>Q.Y. Ma, D.P. Xie, L.H. Song & M.J. Zhou</i>	921
Improved reduction of graphene oxide through femtosecond laser pulse trains <i>R.Y. Yan, P. Zuo & X.J. Li</i>	927
A nanoparticle-decorated silicon substrate for SERS via circularly polarized laser one-step irradiation <i>G. Meng, P. Ran & Y.D. Xu</i>	931

An experimental study on rotation ultrasound-assisted drilling for high-strength engineering of mechanical connection components <i>S. Hong</i>	935
Synthesis of PbO nanosheet-based thin films for all-solid-state supercapacitors <i>J. Zhang, H. Y. Xie & Z.J. Chen</i>	939
A large-scale SERS substrate fabricated by using femtosecond laser with superhydrophobicity <i>Y.D. Xu, G. Meng & P. Ran</i>	945
A study on the ship model resistance test and numerical simulation <i>H.C. Pan, S.N. Yu & Y.J. Yang</i>	949
Magnetic memory testing signal analysis of Q345 steel welding parts under the static tension condition <i>M. Lou, X.-H. Lv, F. Lu & B. Li</i>	955
Research on reliability assessment of success or failure product based on small sample <i>H.-P. Li, Z.-L. Xuan & Y.-D. Wang</i>	959
Numerical simulation of hydroforming of a stainless steel sink <i>Q.H. Li, P. Zhu, X.Q. Guo, J.W. Hou & X.M. Li</i>	965
The fabrication and measurement of a bi-axial thermal convection acceleration sensor <i>H. Wang, Y.G. Li, P. Yan, Y. Huang & S. Sugiyama</i>	971
Innovative green design of the frog ramming machine based on TRIZ/FRT <i>Z.G. Xu, J.L. Li & Z. Y. Zhu</i>	975
Rotor fault diagnosis based on SVM and improved D–S theory <i>Z.-H. Yan & P. Liao</i>	979
A study of the relationship between pre-tightening force and torque in precision instrument assembly <i>S. Huang, X. Jin, Z.F. Wang, Z.J. Zhang, M.Z. Xiao & C. Cui</i>	985
Thermal characteristic analysis of a hollow screw based on the fluid structure thermal coupling <i>X.S. Li, W. Xiong & J.N. Xu</i>	991
Research on intelligent exhaust device design of the breaker in the substation <i>X. Yu & W. Wang</i>	995
An improved calibration method for a nondestructive testing system based on infrared thermopile sensors <i>W. He, T. Zhou, B. Jiang, Y. Wan & Y. Su</i>	999
Evaluation of wind turbine power generation performance based on a multiple distribution model <i>S.Q. Guo, J.R. Yang & H. Li</i>	1005
Research on the acoustic emission testing of the tank truck and on the defect acoustic emission source location method <i>Z. W. Ling, M.L. Zheng, D. Bin & X.L. Guo</i>	1011
Nonlinear dynamic analysis of a cantilever plate for generating electricity based on electromagnetic induction <i>J.H. Yang, K. Ye, G. Zhu & H. Guo</i>	1015
Influence of inductance on an interleaved parallel boost PFC circuit <i>Z.H. Kong, L.G. Wu & Z.F. Luo</i>	1021
Author index	1025

VOLUME 2

Environmental science and environmental engineering

Research on carbon option pricing based on the real option theory <i>H. Qiu</i>	1033
Sustainable development capacity of resource-based cities in the Beijing–Tianjin–Hebei region of China: A comparative study <i>B. Li</i>	1039
PM _{2.5} open-source component spectrum analysis in the harbor area <i>Y. Lin</i>	1047
Distribution of oil spill risk on offshore facilities in the Bohai area based on ETA <i>Y.B. Li, J.X. Liu & W.H. Wu</i>	1051
Developing a low-carbon economy and constructing a low-carbon city—a Xuzhou perspective <i>W.Y. Zhang, C.L. Zhou, F. Chen & J. Ma</i>	1055
Geophysical and geochemical characteristics and mineralization potential in the Taonatu area, Inner Mongolia <i>Q. Liu & R.M. Peng</i>	1061
Effects of genistein supplementation on exhaustive exercise-induced oxidative damage in mice <i>Q.L. Hu, H. Huang & X.L. Huang</i>	1065
Modeling technologies for evaluation system of Jilin Province environmental protection <i>J.Y. Dong & W. Cheng</i>	1069
Analysis and evaluation of the influence factors of waste packaging recycling in a circular economy <i>N. Jiang, K. Liu & J.J. Zhang</i>	1073
Construction and application of a water recycling system in crab–crayfish polyculture purification <i>X.S. Hang, F. He & F.Q. Gan</i>	1077
Sustainable energy industry coupled with social license to operate <i>W. Shen & R.F. Li</i>	1083
Lab-scale treatment of biologically pretreated landfill leachate by the electro-Fenton process in a continuous flow reactor <i>S.P. Yuan, X. Qin, L. Zhang & M.N. Zhou</i>	1089
The water and sediment characteristics numerical simulation of dig-in basin in strong tidal estuary <i>G.-J. Zhang, C.-T. Lu, X.-F. Luo & Y.-F. Han</i>	1095
A method for detecting soil conditions of trenchless projects <i>D.B. Fu, C. Xia & Y.F. Guo</i>	1101
Comparison of thermal hydrolysis and wet air oxidation in sludge treatment in China <i>L. Peng & L.L. Hu</i>	1107
Enhancement of aerobic granulation with real domestic wastewater by powdered activated carbon addition <i>C.W. Wang, B. Li, S.Y. Gong & Y. Zhang</i>	1113
Optimal water strategy for the United States <i>H.-Y. Zheng, J.-C. Lu & M. Hu</i>	1117
A test study on the improved filler from blast furnace slag <i>X.Y. Liu, G.Y. Xu & D.W. Huang</i>	1121
Environmental impact assessment of shipping construction based on the FCE method <i>C. Xu & D.M. Yu</i>	1129
Analysis and prediction of energy sustainability in the developed regions of China <i>P. Wang, X.J. Wang, Z.L. Wang & Y.B. Ren</i>	1135

The interaction between outflow dynamics and removal of $\text{NH}_4^+\text{-N}$ in a vertical flow constructed wetlands treating septage <i>Y. Y. Tan, F. E. Tang, A. Saptoro & E. H. Khor</i>	1141
Water use efficiency of the Lancang-Mekong River basin region in “the Belt and Road Initiative” <i>C. Y. Xie, J. C. Feng & K. Zhang</i>	1147
An accessibility study of elevator Braille signage system in Da Nang City, Vietnam <i>C. Y. Hsia, C. M. Huang & L. Tseng</i>	1153
Investigation and analysis of thermal comfort and IAQ in naturally ventilated primary school classrooms <i>F. S. Ma, C. H. Zhan, X. Y. Xu & Y. Tang</i>	1159
Improvement of the ensemble forecast of typhoon track in the Northwestern Pacific <i>J. Y. Yuan, Y. Pan & Y. P. Chen</i>	1167
An investigation into the system of feasibility study for the revitalizing of idle public facilities through outsourcing of venue management <i>J.-H. Shyng</i>	1171
Distribution characteristics of ammonia emission from the livestock farming industry in Hunan Province <i>X. Rong, C. H. Dai, Y. Deng & P. F. Qin</i>	1175
Application of aerobic bioremediation to cleanup octachlorinated dibenzofuran polluted soils <i>J. L. Lin, Y. T. Sheu, C. M. Kao, W. P. Sung & T. Y. Chen</i>	1181
Experimental study on water-soil interaction influence for environmental change of marine soft soil <i>H.-M. Liu, D. Zhou, H. Wu, W.-C. Jiao & Y.-T. Wang</i>	1185
Energy use and CO_2 emissions in China’s pulp and paper industry: Supply chain approach <i>C. Chen, R. Z. Qiu & J. B. Gan</i>	1193
Research on the limit equilibrium circle theory of entry support <i>Q.-X. Huang, Y.-P. He, Z.-Q. Shi & J. Chen</i>	1201
Evolution characteristics of rainfall erosivity area based on the frequency analysis method in Zhejiang Province <i>J. J. Zhang, G. Li & F. C. Lu</i>	1207
Research on the Norbulingka garden art characteristics under the background of Han-Tibetan cultural blending <i>C. Liu & M. Wang</i>	1211
Releasing flux and characteristic of nitrous oxide from wastewater land treatment systems <i>X. X. Zhang, Y. H. Li, Y. Wang & H. Y. Weng</i>	1215
A study of development planning for conservation areas in Taiwan <i>T.-M. Lee</i>	1219
The study on the control optimization and strategy of indoor visual comfortable environment system <i>D. Wang, H. W. Yin, P. Dong & Y. F. Chen</i>	1223
A study of a low-carbon and intelligent city index system <i>Y.-S. Shen & H.-L. Liu</i>	1229
Exploring the lean strategies to obtain the banking loan for energy service companies <i>A. K. C. Mei, Y. W. Wu, A. Y. P. Wu & C. C. Liu</i>	1233
In-plane lateral load resistance of cast in-situ mortar panels <i>R. Iskandar, S. Suhendi & C. Lesmana</i>	1237
A discussion on how people perceive co-housing that facilitates intergenerational communication <i>S.-Y. Tsai & C.-H. Ou</i>	1241

A note on the ABAQUS Concrete Damaged Plasticity (CDP) model <i>W.S. Li & J.Y. Wu</i>	1247
The cutting parameter model of energy consumption and its characteristics analysis <i>S.H. Hu, S.L. Li & J. Xie</i>	1253
Tibetan question parsing integrated with phrase structure and event feature <i>N. Ma, H.Z. Yu, F.C. Wan & X.Z. He</i>	1259
Study on energy planning and partner selection problems in strategic alliances management of new energy industry <i>J.Z. Zhai & X.N. Zhao</i>	1265
A fractal study on the surface topography of shearing marks <i>B.C. Wang, C. Jing & L.T. Li</i>	1271
 <i>Computer simulation & computer and electrical engineering</i>	
Investigation of denoising methods of infrared imagery <i>M.-K. Yue & J.-H. Deng</i>	1277
Feature optimization approach to improve performance for big data <i>H. Zhu</i>	1283
Influence research on file of software defective testing configuration <i>Y.X. Yu & L. Y. Wang</i>	1287
Webpage automatic summary extraction based on term frequency <i>Y.X. Yu & L. Y. Wang</i>	1293
Research and optimization of the layout of F company truck interior workshop based on GA <i>W. Jiang, Y.H. Ma & Y.C. Pan</i>	1299
The study and implementation of VoIP voice terminal system based on android platform <i>G.J. Zhou</i>	1303
Research on a malicious code behavior acquisition method based on the Bochs virtual machine <i>H. Y. Liu & Y.J. Cui</i>	1309
Research on the network security equipment allocation problem based on Monte Carlo tree search and machine learning <i>C. Chen, H.J. Wang, N.W. Si & Y.Y. Liu</i>	1313
Robust automatic speech recognition based on neural network in reverberant environments <i>L. Bai, H.L. Li & Y.Y. He</i>	1319
Application of association rule mining in electricity commerce <i>H. Yang & Y.C. Pu</i>	1325
Research on a non-guided link discovery technology to obtain an early warning of financial risk <i>C. Y. Xue</i>	1331
Effect of different operating media on the PVT system <i>W. Pang, Y.Z. Zhang, H. Yan, Y. Liu & Y.N. Cui</i>	1335
A practical method for improving the coherence degree between SAR images <i>W. Yu, Z.Q. Chang, X.M. Liu, W. Wang & J. Zhu</i>	1339
Smart management and control of household appliances <i>Q. Y. Lu, S.Z. Chen & T.R. Li</i>	1343
Research and application of online monitoring and positioning systems for partial discharge of high-voltage cables <i>T. Li, X.L. Zhang, Z.H. Wang, P.Y. Zhang & Y. Zhang</i>	1347

The numerical analysis of rainfall erosivity irregularity in Zhejiang province <i>F.C. Lu, G. Li & J.J. Zhang</i>	1351
Module design of container architecture <i>R.T. Zhu</i>	1355
Design of a reflective pulse oximetry sensing system based on the semi-active RFID tag <i>L. Y. Chen, Y. Wang & H.W. Liu</i>	1361
Research of the long-range greenhouse environment monitoring system based on the cloud technology <i>H.-W. Zhang, P.-J. Niu, H.-T. Tian & W.-F. Xue</i>	1367
Negative emotion speech classification for a six-leg rescue robot <i>X.L. Han</i>	1373
Nonlinear vibration of a commensurate fractional-order happiness system <i>Z.J. Guo & W. Zhang</i>	1379
Simulation analysis of airdrop cargo extraction posture <i>H. Wang, X.-H. Chen, Y.-H. Zhou & X. Li</i>	1385
Research on the comparison between the compressed UF-tree algorithm and the UF-Eclat algorithm based on uncertain data <i>C.Q. Chen, X.J. Guo, J.H. Huang & W.Q. Liao</i>	1389
Research on the sync technology of the ARINC659 bus redundancy fault-tolerant system <i>Y. Li, X. Li & G. An</i>	1395
Identity recognition approach based on the improved phase congruency of the gait energy image <i>L.-Y. Jia, C. Liang & D.-C. Shi</i>	1401
Fractional-order generalized augmented Lü system and its application in image encryption <i>H.-Y. Jia & Y.-J. Wu</i>	1407
Ground operation efficiency analysis of a large airport airfield based on computer simulation <i>X. Li, X.Q. Chen & D.X. Wei</i>	1411
Matrix search algorithm of robust common quadratic Lyapunov function for uncertain switched systems <i>X. Y. Zhang, P. Li & B. Shen</i>	1417
HFSS simulation of RCS based on MIMO system <i>Y.Y. Han, L. Sun & C. Hu</i>	1425
Object rough localization of tongue images via clustering and gray projection <i>W.X. Liu, Z. C. Zhang, Y.Y. Lin, D. Y. Shen & Z. Y. Li</i>	1429
Multi-sensor attitude algorithm design for a low-cost strap-down system based on the direction cosine matrix <i>J. Du, J. Li, C.J. Hu & K.Q. Feng</i>	1437
A study on personalized information push service based on context awareness and spatio-temporal correlation <i>X.C. Wang, L. Y. Yuan & G.L. Ge</i>	1445
Design of a new in-flight entertainment terminal <i>H.R. Xu, H. Zhou & H. Yang</i>	1453
The countdown traffic light error detection method based on union color spaces and fuzzy PCA <i>S.Q. Mo, R. Zhang & Y.X. Wen</i>	1459
Study of the optimization evaluation algorithm of improved genetic-BP neural network in the monitoring and diagnosis of shortwave transmitting system <i>Y. Luo & J. Gao</i>	1465

Loyalty model in the networked environment based on catastrophe <i>Q.G. Liu & C.G. Yang</i>	1473
Research on obstacle avoidance of a mobile robot based on visual information <i>J. Jiang</i>	1479
Multifocus image fusion based on defocus map estimation and NSCT <i>R.X. Shi, F.J. Meng, D.L. Shan, P.P. Zeng & Y.L. Wang</i>	1483
A new and effective image retrieval method based on representative regions <i>D.L. Shan, F.J. Meng, R.X. Shi, Y.L. Wang & P.P. Zeng</i>	1489

Preface

The 2016 International Conference on Civil, Architecture and Environmental Engineering (ICCAE 2016) was held on November 4-6, 2016 in Taipei, Taiwan, organized by China University of Technology and Taiwan Society of Construction Engineers, aimed to gather professors, researchers, scholars and industrial pioneers from all over the world. ICCAE 2016 is the premier forum for the presentation and exchange of experiences, new advances and research results in the field of theoretical and industrial experience. The conference contained contributions promoting the exchange of ideas and rational discourse between educators and researchers from all over the world.

ICCAE 2016 is expected to be one of the most comprehensive Conferences focused on civil, architecture and environmental engineering. The conference promotes international academic cooperation and communication, and exchanging research ideas.

We would like to thank the conference chairs, organization staff, and authors for their hard work. By gathering together so many leading experts from the civil, architecture and environmental engineering fields, we believe this conference has been a very enriching experience for all participants. We hope all have had a productive conference and enjoyable time in Taipei!

Conference Chair

Research on carbon option pricing based on the real option theory

Hong Qiu

School of Economy and Management, Tianjin University of Science and Technology, Tianjin, China

ABSTRACT: China's economy has been developing rapidly, which has led to the growth of carbon emissions under the background of global climate change. This paper introduces the carbon option to perfect the carbon market mechanism and points out the necessity and significance of carbon option research. Because the carbon option has strict conditions for the Black–Scholes option pricing formula, this paper will use the Black–Scholes model to establish a carbon option pricing model, build a EUADEC-10–based option by the EU market data, and determine the option price. At last, it puts forward the countermeasures and suggestions for China to integrate into the global carbon market mechanism and participate in international climate negotiations, which provides research ideas for the construction of China's carbon trading market in the future.

1 INTRODUCTION

In the 30 years of China's reform and opening-up, along with the rapid growth of China's economy, the rapid growth of carbon emissions has become a serious challenge to be faced; similarly, the United States and Japan's statistics also show that economic development cannot be separated from energy use and will inevitably result in an increase in carbon emissions. The Kyoto Protocol was an important outcome of the third session of the Conference of the Parties to the United Nations Framework Convention on Climate Change (UNFCCC) in Kyoto, Japan, which came into force on February 16, 2005. The abatement system stipulates that free trade between developed countries or between developed and developing countries are the right to emit greenhouse gas emissions, which is bound to promote the formation of the world's carbon dioxide emissions trading market. The Kyoto Protocol signed the implementation of the start of international carbon reduction initiatives.

In the international carbon trading market, as a developing country, China does not need to implement the total control system, only to participate in the Kyoto Protocol in the Clean Development Mechanism (CDM). Although China's carbon emissions are not limited by the total control, the low carbon economic development needs and international pressure under the dual role of promoting China's carbon emissions limit is the inevitable result. The Chinese government is also considering trying to control the total amount of carbon emissions in selected areas, and gradually form a regional carbon emission

trading market on the basis of the pilot project, so as to create conditions for the final establishment of a national carbon trading market. The primary problem in China's carbon trading market is the initial allocation of carbon credits, the rational allocation of carbon credits, and scientific pricing mechanisms that are important factors influencing the performance of the carbon trading market and the key to the smooth functioning of the carbon trading market. Therefore, the study on the initial allocation method and pricing of carbon emission rights in China is not only of theoretical significance but also of great practical significance.

The importance and urgency of environmental protection are becoming more and more apparent with the development of society. Every country is taking action to control the development of environmental pollution through constant environmental protection measures. As environmental pollution caused by economic problems are increasingly apparent, many scholars of carbon emissions have taken up this cause as the object of their study. Based on the analysis of traditional assessment methods, this paper argues that the conditions for assessing the value of China's carbon emission rights are not very mature and cannot accurately reflect the complete value of the carbon assets, and the evaluation results will not be accurate enough.

This paper is based on the research results of the financial option pricing theory and the real option theory in the field of finance. The real option theory is applied to carbon pricing ideas, which will focus on the real option theory to carbon option pricing of the actual problem.

2 REAL OPTION

Real option is a kind of nonfinancial option, which refers to the right of non-financial business investment to obtain and exploit specific assets in the future. The basic idea of financial options is applied to the real market opportunity, which is the real option. The concept of real option was proposed by Professor Myers Stewart of MIT in 1977. He proposed that an investment projects cash generated by the profits, but from currently owned assets plus a certain price for the future to acquire or sell a real asset or investment plans can be made to the right price for option pricing formula. Real asset investment can be used similarly to the assessment approach to evaluate the general financial option. Because the subject matter is about real option, he called the nature of this kind as real option. Professor Myers has applied the concept of option to real assets, which has brought a new thinking direction for the stagnant asset budget theory.

The valuation of real option is of great significance. The value of any asset not only includes the future cash flow of the value concept, but it should also include the flexibility of selective decision to bring the value of assets included in the future value of real option in the future. It requires investors to pay close attention to developments and changes in the market conditions, and timely project management plans. When the uncertain market environment is conducive to the development trend of discovery, the shareholders are feasible to make options in adverse market conditions directed towards the purchase of equity holders who can choose to exercise the option to exit. It can be seen that the real value of options is actually derived from the uncertainty of future climate change.

Real option is the extension of financial option in the real field, and its subject matter (basic asset) is generally the value of an investment project. While the rights granted by real options are often an investment or management of the right to choose; with real options, the holder can be within a certain period of time according to the basic asset value changes, flexible choice of investment programs or management activities. With the development of real option, its content and form of expression are more and more diverse, and the structure gets extremely complex.

Carbon emission rights can be viewed as real options without dividends and their value is determined by the underlying asset price, strike price, volatility, maturity, and risk-free rate. Assuming that the firm's cost of unit carbon emissions is constant, all carbon emissions are obtained through the purchase of carbon emission rights, without regard to the cost of carbon credits; and

the underlying assets of the carbon emission rights are based on the circumstances of production damage (estimated by the average cost of carbon emissions from the treatment unit) and can be converted into the unit carbon emissions of the enterprise, determined by the firm's production behavior and the market supply-demand relationship. The implementation of carbon emission rights in theory and the price should be the cost of carbon emissions per unit, but because the right to carbon emissions is the right to sell to the enterprises of the sewage compensation, the implementation of the actual price is zero. The deadline for carbon emission rights is set by the government and the environmental protection department based on the average life expectancy of productive enterprises. Risk-free interest rate is generally the corresponding duration of the national debt interest rate or the central bank benchmark interest rate.

3 CARBON OPTION PRICING

3.1 *The Black-Scholes pricing model*

The Black-Scholes model is a mathematical model of a financial market containing derivative investment instruments. From the model, one can deduce the Black-Scholes formula, which gives a theoretical estimate of the price of European-style options.

The Black-Scholes model was first published by Fischer Black and Myron Scholes in their 1973 seminal paper, "The Pricing of Options and Corporate Liabilities", published in the *Journal of Political Economy*. They derived a partial differential equation, now called the Black-Scholes equation, which estimates the price of the option over time. The key idea behind the model is to hedge the option by buying and selling the underlying asset in just the right way and as a consequence to eliminate risk. This type of hedging is called delta hedging and is the basis of more complicated hedging strategies such as those engaged in by investment banks and hedge funds.

The initial allocation of carbon emission rights is based on the combination of free allocation of carbon emission credits and carbon allocation. Therefore, the pricing of carbon emission rights is the pricing of carbon options. Option pricing generally uses the Black-Scholes option pricing formula, but this formula has strict assumptions. Since the carbon option has the following properties, its pricing applies to the Black-Scholes option pricing formula:

1. Carbon option does not pay a dividend to meet the relevant securities;

- The holder of carbon options is allowed to carry out this option at any time, i.e. do not pay dividends of an American call option; in theory, it will hold the expiration and can be seen as an European call option;
- After the introduction of the option mechanism, the carbon trading market is more mature and the transaction cost is reduced, and the quantity of carbon emission trading of different scale and different nature enterprises is quite different, and the quantity is also highly separable, satisfying the assumption that the market is frictionless.
- In the absence of large-scale technological innovation conditions, the carbon market price changes are relatively stable, which satisfies the hypothesis that the price volatility is fixed;
- Carbon emissions are clear of property rights of public resources to prevent arbitrage opportunities in carbon trading, which satisfies the hypothesis that there are no risk-free arbitrage opportunities.

As a kind of financial derivative product, carbon option can be priced by Black–Scholes option pricing model. The Black–Scholes option pricing model is often applied to European option pricing and hedging. We consider European options that do not pay dividend stock. According to Black–Scholes option pricing model, option value is related to stock price, stock price volatility, option exercise price, option expiration date, and risk-free interest rate.

The price of a call option is:

$$C = SN(d_1) - Xe^{-rt}N(d_2) \quad (1)$$

The price of the put option is:

$$C' = Xe^{-rt}N(-d_2) - SN(-d_1) \quad (2)$$

where

$$d_1 = \frac{\ln(S/N) + (r + 1/2\sigma^2)t}{\sigma\sqrt{t}},$$

$$d_2 = \frac{\ln(S/X) + (r - 1/2\sigma^2)t}{\sigma\sqrt{t}} = d_1 - \sigma\sqrt{t}$$

C refers to the price of the call option, S refers to the stock price, X is the exercise price of the option, t is the number of years from the expiration of the option, r is the risk-free rate, N(d1) and N(d2) are the cumulative normal density functions, and σ is the annual standard deviation (volatility) of the stock price. For the carbon market, S, X, r are known. Once the strike price and the

maturity date are determined, the carbon call and put option prices can be calculated from (1)–(2), and it can be seen that both the prices of options is equal, which avoids the divergence between developing and developed countries in fixing option prices.

3.2 Select the parameters for the Black–Scholes model

When using the Black–Scholes model, the following points should be noted when selecting parameters:

- The risk-free interest rate must be in the form of continuous compound interest, a simple or non-continuous risk-free interest rate (set to risk-neutral relative to the concept of risk appetite and risk aversion. In a risk-neutral market, each investor does not require compensation for risk r_0) Once a year compound interest and r_0 requires continuous compound interest. r_0 must be converted into r and can only be substituted into equation (1) calculation. The conversion relationship is:

$$r = \ln(1 + r_0)$$

- The remaining time (T-t) before the due date is expressed as a ratio of one year (365 days).
- The underlying volatility of return on assets should be the annual rate of return volatility, which is usually estimated by the volatility of the underlying historical price of the asset. The first option is valid contract assets consistent with the time interval (January, one day a week, etc.) and is divided into n segments, and then takes a historical price (n+1), calculated as n consecutive composite yield by using this set of data. The calculation formula is as follows:

$$y_i = \ln(x_i / x_{i-1}), (i = 1, 2, 3, \dots, n)$$

Calculate the standard deviation of the sample of the above-mentioned n rate of return, that is, the fluctuation rate (monthly/weekly/daily yield volatility) of the contract term and then by the following formula obtained in the Black–Scholes formula required for annual returns of volatility

$\sigma^2 =$ a term yield volatility of the square \times (1 year included in the number of periods).

4 EMPIRICAL ANALYSIS

Because China is still unable to get the carbon emissions trading market data based on the project

transaction price of carbon indicators, there are too many uncertain factors, so the author of the market data is more abundant with regard to the EU quota to study.

EUADEC-16, which is a long-term futures contract due in late 2015 is designed for a period of one year. For the purposes of this study, it is assumed that EUADEC-16 is a 3-month short-term option with a contract price of $K = 6$ for 92 days and 66 days from April 8, 2015 to July 8, 2015, the spot price $S_0 = 5.26$ EUR, option expiration period $T = \text{number of options valid days}/365 = 0.252$ years.

Based on the closing prices of the EUADEC-16 transactions offered daily on the Nord Pool Web site, trading hours are from March 6, 2015, to April 6, 2015, for a total of 30 days with 24 trading days from which the actual volatility of EUADEC-16 is estimated. Specifically, that is, the natural logarithm of the price of consecutive days to obtain the continuous n of the composite rate of return r .

That is, $r = \ln P_t / \ln P_{t-1}$ where P_t is the historical price of day t of futures and P_{t-1} is the historical price of day $t-1$. Then the standard deviation of the N rate of return is obtained by the monthly return volatility, the use of STDEV, obtained monthly return volatility $\sigma = 0.0488$, the annual volatility is

$$\sigma = 0.0488 * \sqrt{365/24}$$

Assume $R = 4.511\%$, $r = \ln(1 + R) = 0.0441$, then,

$$\begin{aligned} d_1 &= (\ln(S_0/K) + (r + \sigma^2/2)T) / \sigma\sqrt{T} \\ d_2 &= (\ln(S_0/K) + (r - \sigma^2/2)T) / \sigma\sqrt{T} \\ &= d_1 - \sigma\sqrt{T} = -1.3093 \end{aligned}$$

$$N(d_1) = N(-1.2138) = 0.1131$$

$$N(d_2) = N(-1.3093) = 0.0951$$

$$\begin{aligned} C &= N(d_1)S_0 - Ke^{-rT}N(d_2) \\ &= 5.26 * 0.0031 - 6 * e^{-0.0441 * 0.252} * 0.0951 \\ &= 0.0306 \end{aligned}$$

At this point, the EUADEC-16 futures contract 3 months of the option price of 0.0306 Euros.

While pricing analysis of carbon emissions by the Black-Scholes pricing model, we must correctly select r , σ and $(T-t)$ of the 3 parameters. Because the carbon trading is still in the exploratory stage in our country, we get the price of carbon emissions only for EUADEC-16 of the EU quota pricing theory. Although there is no direct reference to China's carbon trading, it provides a new way of thinking and direction for the theoretical study of China's carbon emissions pricing.

5 CONCLUSION

China's carbon trading market has entered a new era. The price of carbon emission rights will become the core focus of operation in the market. However, due to China's late start, carbon emission pricing in the field of research needs further theoretical study and will be of great help and guidance of reality, and will only help continue exploring a variety of methods that can be used to study a more reasonable and realistic conclusion.

Faced with the enormous pressure of emission reduction, China has to bear the mandatory emission reductions that cannot be avoided. The application of Black-Scholes pricing model in the EU's carbon emission right quota pricing provides a good reference for China's carbon emission pricing. We should vigorously build the carbon trading pricing mechanism, carbon financial system, the establishment of carbon emissions trading for buyers and sellers to provide a fair, just, and open dialog mechanism. This will help enhance China's international carbon trading pricing power, and the lowest cost way to save resources, and comprehensively promote China's environmental protection and economically sustainable development.

Because of the complexity and systematic nature of the carbon option research, there are some sustainable research directions for carbon emission trading in China. First, in the analysis of carbon emission trading, we can continue to use the property right theory. Secondly, it is necessary to study the fairness and rationality of the initial option allocation of carbon emission, and further study the stakeholders' behavior in the low-carbon industrial chain. The second part is the further research on the fairness and rationality of the carbon option allocation. Third, we should continue to deepen the theoretical and technical methods to explore the measurement of corporate carbon emissions. We should also study the evaluation index of carbon emission in the quantitative industry. In order to constantly revise the EU-quota based option pricing method, which is determined by the relative weight of quantifiable factors, the paper can make it more perfect.

The final results of this paper are expected to be applied to carbon option practice, especially in large and medium-sized production enterprises in China. The research of this paper can strengthen the application of option theory in the carbon emission trading system. It is hoped that this study will provide reference and decision-making for the healthy development of the low-carbon economy of modern enterprises. In view of the fact that China's production enterprises still play an important role in the national economy, special attention should be paid to specific situations encountered

in the carbon trading system. In this study, the carbon option pricing theory, the optimal executive decision, and optimal option prices can provide reference and decision-making for the production-oriented enterprises to promote the development of China's carbon emissions trading theory.

Sustainable development capacity of resource-based cities in the Beijing–Tianjin–Hebei region of China: A comparative study

Bo Li

*International College of Business and Technology, Tianjin University of Technology, Tianjin, China
Institute of Geographic Sciences and Natural Resources Research, CAS, Beijing, China*

ABSTRACT: Based on the data of prefecture-level and above cities in the Beijing–Tianjin–Hebei region of China in 2013, this paper constructs the index system and evaluates the sustainable development capacity of these cities using Entropy-Weight and TOPSIS evaluation model. Then this paper makes comparative studies between resource-based and non-resource-based cities in the area, and further compares the differences of sustainable capacity among resource-based cities. The results are as follows: (1) from high to low, the ranking based on weights of criteria is Usage of Energy and Natural Resource, Economic Development, Scientific and Educational Level & Support, Environmental Protection, and Employment & Social Security; (2) compared with other cities in this region, the resource-based cities in the Beijing–Tianjin–Hebei region have not lagged behind from the perspective of sustainable development capacity; (3) among these five resource-based cities, it is clear that Zhangjiakou and Tangshan have better sustainable development capacities than other resource-based cities. Based on the results, this paper further discusses the related political implications.

1 INTRODUCTION

1.1 Background

A resource-based city is a type of city that grows because of the exploitation and development of certain kinds of local natural resources and mainly depends on the resource-based industry to support the operation and development of the city. According to *National planning on sustainable development of resource-based cities (2013–2020)* (later referred to as “*National planning*”) issued by the State Council of the People’s Republic of China in 2013, there exists 262 resource-based cities in China, which are generally faced with developmental problems such as low efficiency of resource utilization, weak industrial structure, fragile economic and social structure, and high environmental pressure and lack of driving forces. With the economic development of China, the traditional extensive development model of resource-based cities whose economies depend heavily on the high-level input of resources are faced with increasingly serious problems, which are causing great challenges to the economic transformation, modern industrialization, and new urbanization of China. Due to the problem of gradual scarcity in the supply of natural resources, it is necessary to transform the development model of resource-based cities in order to achieve sustainable development.

In 2014, the Beijing–Tianjin–Hebei Integration Strategy was proposed as a significant national development strategy by the central government of China. The objective of the strategy was to relocate nonessential functions from Beijing in order to adjust the regional economic structure and address problems such as overpopulation, pollution, and resource scarcity. Within the 262 cities, there are five prefecture-level resource-based cities located in Hebei Province. The sustainable development of these cities will definitely affect the successful integration of the Beijing–Tianjin–Hebei region. Therefore, it is of both theoretical and practical significance to evaluate the sustainable development capacity of resource-based cities in the Beijing–Tianjin–Hebei region, so as to find better ways to achieve sustainable and coordinated development for the region.

1.2 Literature review

Through literature review, it is clear that sustainable development of resource-based cities has been a focus of existing studies. Long, et al. 2013 put forward a method for the selection of alternative industries for resource-based cities in China and conducted an empirical analysis on Jiaozuo, a resource-based city in the Henan province of China. Kinnear and Ogden 2014 focused on the

importance of innovation in the economic, social, and environmental development of resource-based cities, and put forward suggestions for innovation-driven sustainable development. Zhang and Yu, et al. 2014 studied the important issues related to sustainable development of resource-based cities in China, including reasonable development and utilization of natural resources, nurturing of sustainable and substitute industries, improvement of local people's welfare, comprehensive treatment of the ecological environment and construction of supportive capacity from the perspectives of resource, economic, social, and environmental sustainability.

Furthermore, some studies have focused on the evaluation of transformation effectiveness of resource-based cities in China. Yu and Yao, et al. 2005 proposed the concept and evaluation model of sustainable development level of mineral resources and further conducted an empirical analysis on Huangshi, a resource-based city in Hubei province of China. Yu and Zhang, et al. 2008 studied issues in the sustainable development of major mining cities in China by identifying principal factors controlling the degree of development of mineral resources. Su, et al. 2010 measured the degree of sustainable development of mineral resources of mining cities in China using the AGA-EAHP-FIJ method in order to support the decision-making of sustainable development for mining cities.

Previous studies have laid the foundation for further studies. Therefore, based on the data of prefecture-level and above cities in the Beijing-Tianjin-Hebei region of China in 2013, this paper makes the evaluation of sustainable development capacity of these cities using the Entropy-Weight and TOPSIS evaluation model. Based on the evaluation results, this paper makes a comparative study between resource-based and non-resource-based cities, so as to provide objective and scientific measures for improving the sustainable development capacity for resource-based cities in the region.

2 METHODS AND DATA

2.1 Entropy weight and TOPSIS

This paper provides effectiveness evaluation of the transformation of resource-based cities in China using the methods of Entropy-Weight and TOPSIS. TOPSIS (Technique for Order Preference by Similarity to Ideal Solution) proposed by Wang and Yoon 1981 is a method falling into the category of Multi-Criteria Decision Making. It has widespread applications in the fields of evaluation and decision making. The main concepts and steps of this method are as follows:

Suppose that there exist m feasible solutions to be evaluated and n indices in the index system. The values of the indices in each feasible solution make up the decision-making matrix Y in which y_{ij} represents the element in the matrix, representing the value of the j th index in the i th feasible solution ($i = 1, 2, \dots, m; j = 1, 2, \dots, n$). The steps of evaluation of Entropy-Weights TOPSIS are as follows:

Step 1: To normalize the decision-making matrix using (1).

$$z_{ij} = y_{ij} / \sqrt{\sum_{i=1}^m y_{ij}^2} \quad (1)$$

Step 2: To calculate the entropy value of the j th index using (2).

$$H_j = -k \sum_{i=1}^m f_{ij} \ln f_{ij} \quad (2)$$

Where $f_{ij} = y_{ij} / \sum_{i=1}^m y_{ij}$, $k = 1/\ln m$.

Step3: To calculate the entropy weight of the j th index using (3).

$$w_j = (1 - H_j) / (n - \sum_{j=1}^n H_j) \quad (3)$$

Then the entropy weight W matrix of the indices is obtained, where $W = (w_1, w_2, \dots, w_n)$.

Step 4: To calculate the weighted and normalized matrix X using (4).

$$x_{ij} = w_j \times z_{ij} \quad (4)$$

Step 5: To determine the ideal positive solution X^+ and the ideal negative solution X^0 .

Let us suppose that x_j^+ is the value of the ideal positive solution of the j th index in X^+ , and x_j^0 is the value of the ideal negative solution of the j th index in X^0 .

For each x^+ , if j th index is a benefit index, then

$$x_j^+ = \max_i x_{ij} \quad (5)$$

If j th index is a cost index, then

$$x_j^+ = \min_i x_{ij} \quad (6)$$

For each x^0 , the calculation method is the opposite.

Step 6: To calculate the Euclidean distances of each feasible solution from the ideal positive solution and ideal negative solution.

The Euclidean distance for each feasible solution from the ideal positive solution and ideal negative solution could be calculated using (7)~(8).

$$d_i^* = \sqrt{\sum_{j=1}^n (x_{ij} - x_j^*)^2}, \quad (7)$$

$$d_i^0 = \sqrt{\sum_{j=1}^n (x_{ij} - x_j^0)^2}, \quad (8)$$

Where d^* denotes the distance of the i th unit from the ideal positive solution, d^0 denotes the distance of the i th unit from the ideal negative solution.

Step 7: To calculate the relative degree of approximation by calculating the Euclidean distance using (9).

$$C_i^* = d_i^0 / (d_i^0 + d_i^*), 0 \leq C_i^* \leq 1, \quad (9)$$

After the calculation, feasible solutions could be ranked according to the value of the relative degree of approximation. The feasible solution with a higher C^* is a better solution.

2.2 Selection of objective cities for study

The *National planning* used a comprehensive grouping method by which all resource-based cities are categorized into 4 different groups including growing cities, mature cities, declining cities, and rebirth cities. According to the study of Zhang, *et al.* 2014, all resource-based cities, by resource type, can be categorized into seven groups including non-metal, ferrous metal, coal, oil and gas, non-ferrous metal, forest industry, and comprehensive groups. According to the definition and classification of *National planning*, there exist 5 prefecture-level resource-based cities located in the Beijing–Tianjin–Hebei region, including Zhangjiakou, Tangshan, Handan, Chengde, and Xingtai. In order to conduct an objective and comprehensive evaluation of sustainable development capacity for these cities, it is necessary to evaluate them together with other non-resource-based cities (Beijing, Tianjin, Qinhuangdao, Langfang, Shijiazhuang, Baoding, Cangzhou, and Hengshui).

2.3 Index system and data

Based on the consideration of comprehensiveness, representation, comparability, and availability, this paper uses 55 indices, which are grouped into 6 criteria under three subsystems to construct the evaluation index system of Sustainable Development Capacity of Cities in the Beijing–Tianjin–Hebei region of China. The details of criteria and indices are shown in Table 1. All the data are extracted from *China City Statistical Yearbook (2013)*.

The indices in criteria A (Economic Development) include: (A1) per capita GDP; (A2) GDP

Table 1. Criteria for evaluation index system for sustainable development capacity.

Criteria	Code
Economic Development	A
Employment & Social Security	B
Scientific & Educational Level & Support	C
Infrastructure Construction	D
Usage of Energy & Natural Resource	E
Environmental Protection	F

growth rate; (A3) secondary industry as percentage of GDP; (A4) tertiary industry as percentage of GDP; (A5) per capita public finance income; (A6) per capita public finance expenditure; (A7) ratio of public finance income to expenditure; (A8) average industrial output value above the designated size (current price); (A9) average industrial profits above the designated size; (A10) per capita retail sales of consumer goods; (A11) per capita amount of foreign capital; (A12) actually utilized; (A13) per capita investment in fixed assets (excluding rural households).

The indices in criteria B (Employment and Social Security) include: (B1) average wage of employed staff and workers; (B2) percentage of employed persons in the secondary industry; (B3) percentage of employed persons in the tertiary industry; (B4) ratio of employees joining urban basic pension insurance to total population; (B5) ratio of persons joining urban basic medical care system to total population; (B6) ratio of persons covered by unemployment insurance to total population.

The indices in criteria C (Scientific and Educational Level and Support) include: (C1) percentage of expenditure for science and technology in public finance expenditure; (C2) percentage of expenditure for education in public finance expenditure; (C3) number of regular institutions of higher education per 1 million persons; (C4) number of regular institutions' vocational secondary schools per 1 million persons; (C5) number of regular institutions' regular secondary schools per 1 million persons; (C6) number of regular institutions' primary schools per 1 million persons; (C7) number of students enrollment of regular institutions for higher education per 10,000 persons; (C8) number of students enrollment in vocational secondary schools per 10,000 persons; (C9) number of collections of public libraries per 100 persons.

The indices in criteria D (Infrastructure Construction) include: (D1) land used for urban construction as percentage to urban area; (D2) number of post offices at year-end per 10,000 persons; (D3) number of subscribers of local telephones at year-end per 10,000 persons; (D4) number of subscribers of mobile telephones at year-end per 10,000

persons; (D5) number of subscribers of Internet services per 10,000 persons; (D6) number of theaters, music halls, and cinemas per 10,000 persons; (D7) number of hospitals and health centers per 10,000 persons; (D8) number of beds at hospitals and health centers per 10,000 persons; (D9) number of doctors (licensed doctors and assistant doctors) per 10,000 persons; (D10) per capita length of city sewage pipes per 10,000 persons; (D11) number of public transportation vehicles per 10,000 population; (D12) per capita area of paved roads in the city.

The indices in criteria E (Usage of Energy and Natural Resource) include: (E1) water supply per 10,000 persons; (E2) annual electricity consumption per 10,000 persons; (E3) electricity consumption for industrial use per 10,000 yuan GDP; (E4) household electricity consumption for urban and rural residences per 10,000 persons; (E5) total gas supply (coal gas, natural gas) per 10,000 persons; (E6) liquefied petroleum gas supply per 10,000 persons.

The indices in criteria F (Environmental Protection) include: (F1) area of green land per 10,000 persons; (F2) area of parks and green land per 10,000 persons; (F3) green covered area as percentage of completed area; (F4) volume of industrial wastewater discharged per 10,000 yuan GDP; (F5) volume of industry sulfur dioxide produced per 10,000 yuan GDP; (F6) volume of sulfur dioxide emission per 10,000 yuan GDP; (F7) volume of industrial soot (dust) emission per 10,000 yuan GDP; (F8) ratio of industrial solid wastes comprehensively utilized; (F9) ratio of waste water centralized and treated for sewage work; (F10) ratio of consumption of wastes treated.

3 ANALYSIS OF THE SUSTAINABLE DEVELOPMENT CAPACITY

3.1 Entropy weights of indices

Using the methods of Entropy-Weight and TOPSIS, this paper first normalizes the original dataset matrix constructed with data of 55 indices in 13 prefecture-level and above cities in the Beijing–Tianjin–Hebei region of China in 2013. Furthermore, this paper calculates the information entropy value and entropy-weight of each index according to (2) and (3). The results are shown in the tables (Table 2 to Table 7). Note that in each table, “+” denotes benefit index/cost index; “–” denotes cost index.

From the tables, it is clear that the ranking based on the weights of criteria (from high to low) is the Usage of Energy and Natural Resources (0.2839), Economic Development (0.20523), Scientific

and Educational Level and Support (0.12816), Environmental Protection (0.1225), Employment and Social Security (0.10379). The results reflect the fact that in order to realize the successful transformation of resource-based cities, more attention should be paid to the usage of energy and natural resources and economic development. At the same time, scientific and educational level and support, environmental protection, and employment and social security should not be ignored.

Further observations show that the top five indices having the largest entropy weights are liquefied petroleum gas supply per 10,000 persons (0.09210), total gas supply (coal gas, natural gas) per 10,000 persons (0.07460), per capita amount of foreign capital actually utilized (0.06240), number of collections of public libraries per 100 persons (0.05790), and per capita public finance income (0.04400). These results indicate that for cities in the Beijing–Tianjin–Hebei region, natural energy utilization, foreign capital utilization, expenditure and public knowledge infrastructure, and financial income are important factors that need to be more focused on in order to achieve sustainable development.

Besides that, the indices that have the highest weights in each criterion include: (1) per capita amount of foreign capital actually utilized (0.06240) in Criteria A “Economic Development”; (2) ratio of persons covered by unemployment insurance to total population (0.04190) in Criteria B “Employment and Social Security”; (3) number of collections of public libraries per 100 persons (0.05790) in Criteria C “Scientific and Educational Level and Support”; (4) per capita length of city sewage pipes per 10,000 persons (0.04320) in Criteria D “Infrastructure Construction”; (5) liquefied petroleum gas supply per 10,000 persons (0.09210) in Criteria E “Usage of Energy and Natural Resources”; (6) area of parks and green land per 10,000 persons (0.02670) in Criteria F “Environmental Protection”.

3.2 Comparative analysis of sustainable development capacity

Based on the entropy weights of indices in Table 2 to Table 7, the evaluation scores of Sustainable Development Capacity of Cities in the Beijing–Tianjin–Hebei region of China could be obtained, as shown in Table 8 (RBC represents the resource-based city, Non-RBC represents non-resource-based city).

As can be seen from the table, the top three cities that have the highest sustainable development capacity score are Tianjin (0.63562), Qinhuangdao (0.53577) and Langfang (0.53050). Furthermore, Qinhuangdao is the first city in Hebei province,

Table 2. Evaluation index system for criteria A.

Criteria	Index	Unit	+/-	Weight
(A)	A1	yuan	+	0.01730
Economic Development (0.20523)	A2	%	+	0.00689
	A3	%	+	0.00146
	A4	%	+	0.00270
	A5	yuan	+	0.04400
	A6	yuan	+	0.02430
	A7	%	+	0.00336
	A8	10,000 yuan	+	0.00598
	A9	10,000 yuan	+	0.00954
	A10	yuan	+	0.01710
	A11	dollar	+	0.06240
	A12	yuan	+	0.01020

Table 3. Evaluation index system for criteria B.

Criteria	Index	Unit	+/-	Weight
(B)	B1	yuan	+	0.00316
Employment and Social Security (0.10379)	B2	%	+	0.00190
	B3	%	+	0.00093
	B4	%	+	0.02500
	B5	%	+	0.03090
	B6	%	+	0.04190

Table 4. Evaluation index system for criteria C.

Criteria	Index	Unit	+/-	Weight
(C)	C1	%	+	0.02730
Scientific and Educational Level and Support (0.12816)	C2	%	+	0.00045
	C3	unit	+	0.02650
	C4	unit	+	0.00345
	C5	unit	+	0.00107
	C6	unit	+	0.00251
	C7	person	+	0.00660
	C8	person	+	0.00238
	C9	copy, piece	+	0.05790

while Beijing has the lowest score (0.43869) in all the prefecture-level and above cities in the region.

From the comparative perspective, as shown in Table 9, the non-parametric statistical test results show that there exists no statistically significant difference in the sustainable development capacity scores between resource-based cities and non-resource-based cities. The results indicate that, compared with other cities in this region, even with Beijing, the resource-based cities in the Beijing–Tianjin–Hebei region have not lagged behind from the perspective of sustainable development capacity.

According to the study of Zhang et al. 2014, from the perspective of resource-based cities (Table 10), most of the these cities in the Beijing–Tianjin–Hebei region of China (Zhangjiakou, Handan, Chengde, and Xingtai) are classified as mature RBC cities, which indicates that these cities have higher capacity of resource support. Only Tangshan is classified as rebirth, which indicates that it has a relatively lower capacity of resource support. Furthermore, most of the resource-based cities (Zhangjiakou, Tangshan, Handan, and Xingtai) are classified as comprehensive resource types, which indicates that in these cities, more than

Table 8. Evaluation results of sustainable development capacity.

City	Score	Rank	City type
Beijing	0.43869	13	Non-RBC
Tianjin	0.63562	1	Non-RBC
Qinhuangdao	0.53577	2	Non-RBC
Langfang	0.53050	3	Non-RBC
Shijiazhuang	0.52345	4	Non-RBC
Baoding	0.52042	6	Non-RBC
Cangzhou	0.51971	8	Non-RBC
Hengshui	0.51664	11	Non-RBC
Zhangjiakou	0.52059	5	RBC
Tangshan	0.52034	7	RBC
Handan	0.51826	9	RBC
Chengde	0.51779	10	RBC
Xingtai	0.51212	12	RBC

Table 9. Comparison of RBC and non-RBC cities.

Statistics and types	Sustainable development capacity score
Mann-Whitney U	12.000
Wilcoxon W	27.000
Z	-1.171
Asymp. Sig. (2-tailed)	0.242
Exact Sig. [2*(1-tailed Sig.)]	0.284*

Note: *Not corrected for ties.

Table 10. Evaluation results of sustainable development capacity of resource-based cities.

City	Score	Classification*	Resource type*
Zhangjiakou	0.52059	Mature	Comprehensive
Tangshan	0.52034	Rebirth	Comprehensive
Handan	0.51826	Mature	Comprehensive
Chengde	0.51779	Mature	Ferrous metal
Xingtai	0.51212	Mature	Comprehensive

Note: *Based on the Study of Zhang et al. (2014).

one type of mining resource is being exploited; therefore, the development of resource-related industries in these cities is more diversified. However, there still exists more complicated ecological and environmental problems caused by multiple-resource exploitation in these cities. Only Chengde is classified as a ferrous metal city in resource type.

Among these five resource-based cities, it is clear that Zhangjiakou and Tangshan have better performance in sustainable development capacity than other resource-based cities in the region. This result indicates that the resource supporting condition and resource type play less important roles in the sustainable development of resource-based cities in the region. Therefore, with the consideration

of entropy weight results for resource-based cities in the Beijing–Tianjin–Hebei region, especially for Handan, Chengde, and Xingtai, more attention should be paid to the utilization of energy and natural resources and economic development in order to achieve sustainable development.

4 CONCLUSIONS AND POLITICAL IMPLICATIONS

Based on the data of prefecture-level and above cities in the Beijing–Tianjin–Hebei region of China in 2013, this paper makes the evaluation of sustainable development capacity of these cities using Entropy-Weight and TOPSIS evaluation model. Based on the evaluation results, this paper provides a comparative study between resource-based and non-resource-based cities, and further compares the difference in sustainable capacity within resource-based cities, so as to provide possible ways for the improvement of sustainable capacity for resource-based cities in the region. The results and conclusions are as follows:

1. Using the methods of Entropy-Weight and TOPSIS, this paper finds that the ranking based on the weights of criteria (from highest to lowest) is Usage of Energy and Natural Resources, Economic Development, Scientific and Educational Level & Support, Environmental Protection, Employment & Social Security. Further observations on the weights of indices show that natural energy utilization, foreign capital utilization, expenditure and public knowledge infrastructure, and financial income are the factors that need more focus in order to achieve sustainable development.
2. The top three cities that have the highest sustainable development capacity score are Tianjin, Qinhuangdao, and Langfang. Qinhuangdao is the top most city in Hebei province, while Beijing has the lowest score in all the prefecture-level and above cities in this region. From the comparative perspective, the results indicate that the resource-based cities in the Beijing–Tianjin–Hebei region have not lagged behind from the perspective of sustainable development capacity compared with other cities in this region, even with Beijing.
3. Among the five resource-based cities in the region, it is clear that Zhangjiakou and Tangshan have better performance in sustainable development capacity than other RBC cities in the region, which indicates that resource-supporting condition and resource type play less important roles in the sustainable development of resource-based cities in the region.

Therefore, more attention should be paid to the utilization of energy and natural resources and economic development in order to achieve sustainable development. Furthermore, the focus should be on aspects including natural energy utilization, foreign capital utilization, expenditure and public knowledge infrastructure, and financial income.

PM_{2.5} open-source component spectrum analysis in the harbor area

Yu Lin

Tianjin Research Institute for Water Transport Engineering, M.O.T, Tianjin, China

ABSTRACT: PM_{2.5} is a major pollutant in the harbor area. The adoption of chemical mass balance model for PM_{2.5} source profiles is an important way to reduce particulate matter pollution and research on the composition of particulates is the basis of the chemical mass balance model. This study collected fugitive dust (yard dust, resuspended dust, road dust, soil dust, construction dust) samples in the Tianjin port area. First, PM_{2.5} samples were collected with the resuspension sampler. Then, the PM_{2.5} source profiles of fugitive dust were established, based on which analysis and research on the characteristics of the composition spectrum were done.

1 INTRODUCTION

Atmospheric particulate matter is the general term for all solid and liquid granular materials except gases in the atmosphere. Among them, particles with aerodynamic diameter less than 2.5 μm are known as fine Particulate Matter (PM_{2.5}). The surface of PM_{2.5} will easily adsorb toxic heavy metals (Pb, Zn, Cu, Cd, As, etc.), harmful organic compounds, bacteria, and viruses. So it has an impact on ambient air quality, human health status, and climate change (Almeida et al., 2006, Almeida et al., 2005, Hwang and Hopke, 2007, Harrison and Yin, 2000). The research on PM_{2.5} pollution sources can be divided into four types: open source, fixed coal source, motor vehicle exhaust, and biomass dust. The biggest difference between open-source dust and fixed source dust is that the former does not pass through the exhaust funnels, causing an irregular, unorganized discharge.

The pollution situation of PM_{2.5} in the harbor area has its own characteristic, which is the diffusion of dust in the atmospheric environment as one of the pollution components in the port area. During the loading and unloading operation, materials falling on the road are repeatedly raised by traffic, and piled coals, metal ores, building materials and other materials in the bulk cargo storage yard are likely to produce more dust due to the flat ground and strong wind. Since Tianjin port is a typical harbor area, we first collected fugitive dust samples in the Tianjin port area. We then used the resuspension sampler to collect PM_{2.5} samples, establishing PM_{2.5} source profiles of fugitive dust and eventually discussing the environmental risk and health risk assessment of heavy metals in the fugitive dust.

2 COLLECTION AND ANALYSIS OF SAMPLES

Tianjin port, the largest comprehensive port in the Bohai Sea, as well as the largest comprehensive foreign trade port and an important logistics center in northern China functions as the main hub of the whole country. It is located in the Binhai New Area. Binhai New Area is a sub-provincial district of Tianjin City under the jurisdiction of the national district and national comprehensive reform pilot area with a resident population of 2.97 million. Therefore, Tianjin port area was chosen as a typical harbor area for the research in this paper.

The PM_{2.5} open sources in the Tianjin port area mainly include yard dust, resuspended dust, road dust, soil dust, and construction dust. Due to the large open-source emission surface, low intensity, and strong interference from the surrounding environment, field sampling is often difficult to obtain. In order to match the particle size in the atmospheric environment and to simulate the real process of particles going into the ambient air, resuspension sampler was put into use while sampling. During the simulation, a sampler for resuspended particulates in the environment and pollution sources cut the powder samples into the size of PM_{2.5}. The selection of the volume sampler was in strict accordance with national standards and the environmental standard. Teflon filter membrane and quartz filter membrane were the two types that were adopted according to the need for chemical analysis after sampling and the membranes' own characteristics in the sampling filters for collection. The Teflon filter membrane prepares for analysis of elements while the quartz filter membrane for ion and carbon analysis.

3 ANALYSIS OF OPEN-SOURCE COMPONENT SPECTRUM

3.1 Composition of component spectrum

In this study, we collected the samples of coal yard dust; ore yard dust, resuspended dust, road dust, soil dust, and construction dust in Tianjin port area and established those component spectrums (Figs 1–6).

In order to facilitate comparison, the chemical composition of the component spectrums was divided into crustal elements, trace elements, ions, Organic Carbon (OC) and Elemental Carbon (EC). Crustal elements include Ti, Al, Si, Mn, Mg, Ca, Fe, K, and Na. Trace elements include V, Cr, Co, Ni, Cu, Zn, As, Cd, and Pb. Ions include NO_3^- , SO_4^{2-} , Cl^- , K^+ , Na^+ , Ca^{2+} , Mg^{2+} , and NH_4^+ (Fig. 7).

It can be seen from the figures that the composition of storage yard dust is highly relevant with coal yard dust materials. EC and OC content are high with the total carbon content reaching 36%. The Fe element content of dust in the ore yard is the highest reaching 37%. Construction dust with components such as cement and other building materials have Ca, Si, Fe, and other content higher. The crustal elements and carbon content in urban dust are higher, reaching 29% and 35% because the resuspended dust in the port area is influenced by the adjacent coal yard. Crustal elements are the most

Figure 1. Chemical composition of coal yard dust.

Figure 2. Chemical composition of ore yard dust.

Figure 3. Chemical composition of construction dust.

Figure 4. Chemical composition of resuspended dust.

Figure 5. Chemical composition of road dust.

Figure 6. Chemical composition of soil dust.

Figure 7. Chemical composition of fugitive dust.

abundant species in road dust and soil dust, which accounts for 45% and 49% of the chemical composition. The content of trace elements is the highest in road dust accounting for 2.11% of the total content followed by re-suspended dust accounting for 1.73% of the total content, which shows that road dust and resuspended dust are more susceptible to anthropogenic sources of pollution.

3.2 Reconstruction of crustal material composition

Open-source particle emission of inorganic chemistry groups divided into the spectrum of unknown components are mainly crustal elements existing in

the form of oxides, so Ho (Ho et al., 2003) rebuilt soil dust and road dust in the crust by Al, Si, Ca, Ti, and Fe mass percentage content and compared it with the total component content. The formula for calculating the percentage content of crustal materials is as follows:

$$\text{Crustal material} = 1.16 (1.90 \text{ Al} + 2.15 \text{ Si} + 1.41 \text{ Ca} + 1.67 \text{ Ti} + 2.09 \text{ Fe}) \quad (1)$$

The 1.16 is to compensate for the mass of MgO, Na₂O, K₂O, and H₂O in the composition of the earth's crust that cannot be calculated. Derived from Formula 1, and expressed as the percentage content in PM_{2.5} of urban dust, road dust, and soil dust was 76.47%, 59.67%, and 88.67%, respectively. The results show that the soil crustal elements occupy the highest proportion in the total component content of PM_{2.5} in the dust area of Tianjin port indicating that soil dust is mainly composed of the crust. The source of urban dust and road dust is relatively complex, prone to be affected by vehicle exhaust dust, cement dust, and coal dust.

4 ENVIRONMENTAL RISK ASSESSMENT OF HEAVY METAL ELEMENTS

Heavy metal pollution of open-source dust is due to persistence, biodegradation, bioaccumulation and toxicity characteristics. Long-term heavy metals pose a great threat to the environment, so the evaluation of the extent of heavy metal pollution in open-source dust and the potential ecological risk is necessary. At present, there is no uniform standard for judging the pollution degree of heavy metals in China and abroad, such as the enrichment factor analysis method, the accumulation index method, the potential ecological risk assessment, and so on.

The Enrichment Factor (EF) is an important method to identify and evaluate elements of natural sources and human sources and is an important indicator to evaluate the degree of element enrichment. The method was first proposed to study the atmospheric particulate matter in the Antarctic and is now widely used to study the sources of heavy metals in atmospheric particulate matter (Banerjee, 2003). The calculation formula is as follows:

$$EF = \frac{C_n / C_{ref}}{B_n / B_{ref}}$$

where C_n measures the value of element n in open-source samples, C_{ref} is the reference element value in open-source samples, B_n is the value of element n in the reference system, and B_{ref} is the reference element value in the reference system.

The selection of a reference element is considered necessary in the analysis of enrichment factors. Different reference elements lead to different calculation results of the enrichment factors, thus the information of pollutants coming from the analysis will vary. Due to the above-mentioned statement, when using enrichment factors to evaluate the elementary pollution status in soil dust, it is crucial to choose variable reference elements according to the actual situation. Those with more stability in the soil, less mobility, and manufactured pollution will make comparatively better options. In China, Cr and Mn are typical pollution elements in the soil. Ca, whose chemical character is active, is the characteristic element in the construction dust, receiving more impact from urban construction and the concrete industry. Construction dust contributes considerably to the rising rate of particles. Highly influenced by manufactured sources, the geo-accumulation index (I_{geo}) of Na tends to be greater in particular areas. This research has picked Al which is that of a steady chemical property, the highest analysis with respect to accuracy and the most widespread use as the reference element.

The background values of heavy metal elements in Tianjin are shown in Table 2.

To calculate the concentration factors of heavy metals in the urban source, soil source, and road source in Tianjin port area refer to Figs 8–10.

It can be seen from Figures 8–10 that the enrichment factors of Mn, V, Co, Ni, Zn, As, and Pb are all less than 1, showing no sign of enrichment. The factor of Cu is between 1 and 2 indicating slight enrichment. The factor of Cd is between 2 and 5 indicating moderate enrichment. The factor of Cr is between 5 and 20, a noteworthy enrichment.

Table 1. Classification criteria of EF values.

Pollution level	EF value	Degree of enrichment
I	$EF \leq 1$	No enrichment
	$1 \leq EF \leq 2$	Slight enrichment
II	$2 \leq EF \leq 5$	Moderate concentration
III	$5 \leq EF \leq 20$	Significant enrichment
IV	$20 \leq EF \leq 40$	Strong enrichment
V	$EF \geq 40$	Very strong enrichment

Table 2. Soil background values of heavy metals in Tianjin (mg.kg⁻¹).

Heavy metals	Cr	Mn	V	Co	Ni
Background value	84.2	686	85.2	13.6	33.3
Heavy metals	Cu	Zn	As	Cd	Pb
Background value	28.8	79.3	9.6	0.09	21

Figure 8. Enrichment factors of heavy metals in re-suspended dust of the Tianjin port area.

Figure 9. Enrichment factors of heavy metals in the soil dust of Tianjin.

Figure 10. Enrichment factors of heavy metals in the road dust of Tianjin.

In soil dust, the enrichment factors of Mn, V, Co, Ni, and As are all less than 1 suggesting that there is no enrichment. Zn has an enrichment factor of a value between 1 and 2 indicating slight enrichment. A moderate enrichment taking place, Cu and Pb have factors valuing between 2 and 5, while Cr and Cd factors are between 5 and 20, appearing to be a significant enrichment phenomenon.

In road dust, the enrichment factors of Mn, V, Co, Ni, Zn, and As are all less than 1 suggesting that there is no enrichment. Pb has an enrichment factor of a value between 1 and 2 indicating slight enrichment. Moderate enrichment takes place with Cu having factors valuing between 2 and 5, while Cr and Cd factors are between 5 and 20 appearing to be a conspicuous enrichment phenomenon.

The element that has the highest amount of enrichment factor in these three types of dust is Cr, indicating a more than significant enrichment. Cu, Pb, and Cr manifest moderate enrichment

while receiving the impact from manufactured sources and natural sources as well. The rest of the elements due to their enrichment factors are all less than 2, mainly coming from crust materials.

5 CONCLUSIONS

The conclusion derived from the research on chemical characteristics of the open-source area in Tianjin port is that the yard dust components are related to storage materials, building materials, and components of cement and other relative construction dust, which is acquired. The earth's crust elements and carbon content in the urban dust are higher because the urban dust in the port area is affected by the adjacent coal yard. Crustal elements account for the highest proportion of road dust and soil dust and the highest percentage of trace elements in road dust followed by urban dust show that road and urban dust were more susceptible to anthropogenic sources of pollution. Through the reconstruction of the crustal materials, crustal elements in the total composition of soil dust $PM_{2.5}$ have the highest proportion indicating that soil dust is mainly composed of the crust. Urban dust and road dust source are complex, prone to be influenced by vehicle exhaust dust, cement dust, and coal dust.

ABSTRACT: This paper proposes to quantitatively analyze the oil spill risk of the offshore facilities in the Bohai area. In particular, the oil spill risk probability of different offshore facilities was calculated by using the Event Tree Analysis (ETA) method. This method was presented based on the comprehensive analysis of the distribution of offshore oil facilities in the Bohai area and the oil spill accidents. To calculate the spatially variant oil spill risk probability, the Bohai area was divided into different grids and the oil spill risk probability was calculated based on the geometrical information related to the grids. Finally, the distribution of oil spill risk in the Bohai area was obtained to provide theoretical support for the oil spill warning in the Bohai area's offshore facilities.

1 INTRODUCTION

Bohai is China's inland sea surrounded on three sides by land, and only connects to the Yellow sea through the Strait of Bohai in the East and has a poor self-purification capacity. Bohai is a pioneer in operating oil and gas developments in the sea. Fixed production platforms account for similar platforms of more than 90% of the total, which include the earliest exploited work and the largest number of drills. The risk of marine oil spill

pollution is increasing because of offshore oil and gas operations, storage, and transportation. At the same time, along with the Bohai rim region and its hinterland's rapid economic growth, maritime traffic density is increasing with the occurrence of traffic accidents among ships, offshore facilities are increasing in the Bohai area and frequency of collision accidents are high. Therefore, the research of distribution of oil spill risk has the significance of oil spill warning and control for the Bohai area's offshore oil facilities.

Figure 1. The distribution of offshore facilities in the Bohai area.

2 STATISTICAL ANALYSIS OF OIL SPILL ACCIDENTS IN THE BOHAI AREA

From 2002 to 2016, there are 27 oil spill accidents from offshore facilities that have occurred in the Bohai area, which include 10 oil spills of submarine pipeline accidents and 16 crude oil leak accidents. The highest frequency is between 2011 and 2012, which is 5 times each year. In the 27 oil spill accidents, the cumulative booms (gas and solid) and suction drag bar used were 11,380 meters and 28,700 meters, respectively. Oil spill source for submarine pipeline accidents accounted for 37% and crude oil spill accounted for 59%.

3 THE OIL SPILL RISK OF OFFSHORE FACILITIES IN BOHAI

3.1 Risk source analysis of offshore facilities

The oil spill sources of offshore facilities in the Bohai area mainly include:

1. The oil spill of offshore facilities

Offshore oil facilities refer to the facilities engaged in offshore oil and gas exploration, development and production operations (including drilling ship) of the mobile offshore drilling rig, fixed offshore platform, single point mooring floating production, storage devices, submarine pipeline, etc. At present, there are 128 offshore oil platforms, 6 Floating Production Storage and Offloading (FPSO) vessels, 177 oil and gas pipelines (1653 km) and 32 oil tanks in the Bohai area. According to development planning, 205 oil platforms will be built in the Bohai area from 2013 to 2030. The average annual number of drilling wells is about 70 and the total export drilling adjustment wells will be 423. At that time, oil production will exceed 40 million squares every year and the new laying oil and gas pipeline will be 1890 km.

The damage to offshore facilities, poor seal, fire and explosion, operational errors, blowout, and so on will lead to oil spill accidents. Offshore facilities are the main risk sources of oil spill accidents.

2. The operations of offshore facilities

Offshore facilities operations include oil exploration, mining, oil transportation, oil refining, and other related products. The oil operation spill refers to the spill that occurs in the process of oil operation and the main reasons include the company's poor environmental awareness, careless thinking, nonstandard operations, human factors, etc.

3.2 The analysis method of oil spill risk

Event tree analysis (referred to as ETA) originated in the decision tree analysis, which is a kind of possible consequence derived from the initial event by time sequence, meaning it is a logical deduction method. When an early event was provided, analysis of events may lead to the result of the sequence of events, and the characteristics of qualitative and quantitative evaluation system, and help the analyst to arrive at the right decision. It is often used as a security system for accident analysis and system reliability analysis.

As the sequence of events is a graphical representation and looks like a fan, so it is named as event tree. Event tree analysis method has the advantage of being strong and flexible. The accident probability model based on ETA can significantly improve the scientific and effective probability calculation of oil spill accidents.

The steps of ETA are as follows:

1. Determining or looking for reasons which may lead to serious consequences of events and classifying them. For those which may lead to the same event tree for different events can be divided into the same class.
2. When we build the event tree, the function event tree is built first followed by the system event tree.
3. Simplify the event tree.
4. Make a quantitative calculation of events.

A branch of the event tree is shown in Figure 2.

From the process shown in the event tree, the probability of event F2 can be expressed as:

$$\begin{aligned}
 P(F_2) &= P(IS_1F_2) + P(IF_1F_2)P(IS_1F_2) \\
 &= P(I) \cdot P(S_1) \cdot P(F_2) \\
 P(IF_1F_2) &= P(I) \cdot P(F_1) \cdot P(F_2)
 \end{aligned}
 \tag{1}$$

As the reason of oil spill accidents occurring in offshore oil platforms is relatively simple, it is suitable to use the ETA to analyze the oil spill risk as shown in Figure 3. The paper will calculate the probability of oil spill accident on the offshore oil platform by constructing the event tree.

According to the planned number of drilling developments in each area of our country, the average annual number of drilling wells is about 70 and the total export drilling adjustment wells will be 423 in the Bohai area from 2016 to 2030. However, the average annual number of drilling wells and adjustment wells is 70 and 90, respectively in the eastern and western part of the South China Sea from 2016 to 2018.

Thus, the average annual total of oil drilling platforms built is far higher in the Bohai area than other areas of our country, and the oil spill risk is more prominent. The annual number of drilling planned in other areas only accounts for 8% to 18% of the Bohai area, and as such the oil spill risk probability is reduced accordingly.

The oil spill probability of wells was calculated based on the ETA method in the Bohai area, which

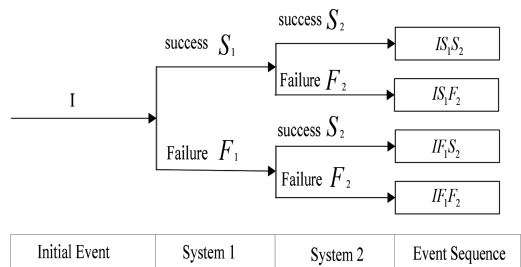

Figure 2. Bifurcation diagram of ETA.

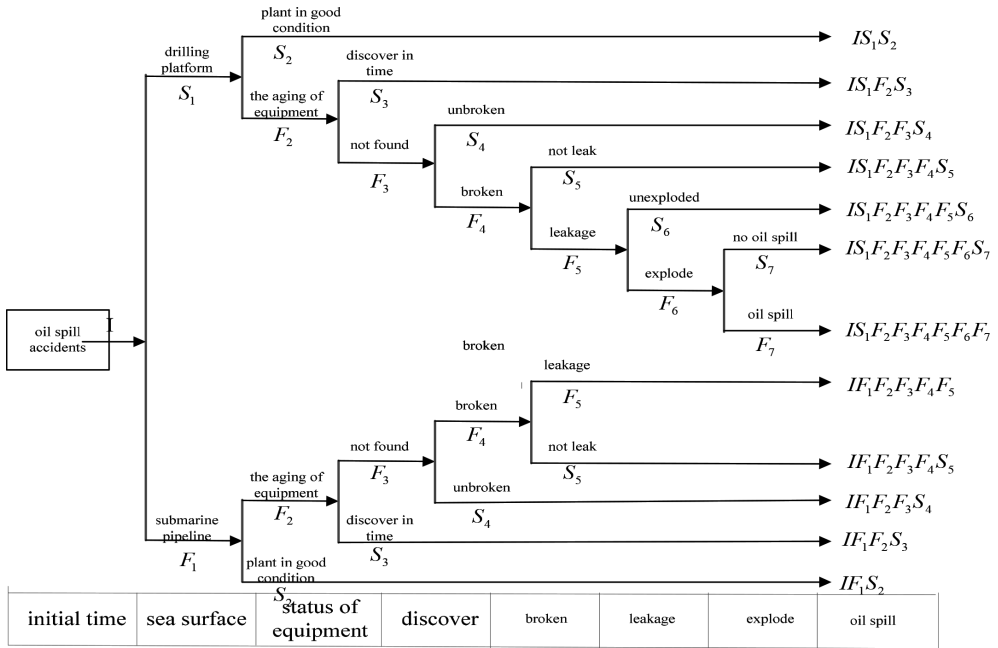

Figure 3. ETA of oil spill from a maritime structure.

Table 1. The oil spill probability of wells in the Bohai area.

Risk	1 ton	10 tons	100 tons	1000 tons
Oil spill probability of exploited well	0.014	0.007	0.004	0.002
Oil spill probability of development well	0.176	0.088	0.044	0.022
Oil spill probability of oil-well blowing	0.152	0.076	0.038	0.019

Table 2. The oil spill probability of submarine pipelines in the Bohai area.

Risk	1 ton	10 tons	100 tons
Oil spill probability of submarine pipelines	0.031	0.011	0.003

is shown in Table 1. The oil spill probability of submarine pipelines in the Bohai area is shown in Table 2.

According to the construction plan of submarine pipelines in the Bohai area, by 2030, the newly laid submarine pipelines will amount to 1890 km and accumulated massive oil spill probability will reach more than 0.001. The oil spill probability of FPSOs in the Bohai area is shown in Table 3.

Table 3. The oil spill probability of FPSOs in the Bohai area.

Risk	Oil spill probability			
	1 ton	10 tons	100 tons	1000 tons
Oil spill probability of FPSOs	0.050	0.015	0.005	0.001

* The large-scale oil spill risk probability of FPSOs in the Bohai area is 0.001.

4 THE DISTRIBUTION OF OIL SPILL RISK ON OFFSHORE FACILITIES IN THE BOHAI AREA

4.1 Risk superposition of oil spill on offshore facilities

According to the analysis of offshore facilities' characteristics and operation mode, the risk superposition of oil spill should be considered when calculating the probability of oil spill. The following are situations where the risk superposition should be considered:

1. Offshore oil facilities are combined together;
2. More than one submarine pipeline has the same route;
3. Production platform is combined with exploitation platform by trestle bridge;

Table 4. Oil spill probability of eight offshore facilities in the Bohai area.

Position of oil spill	BZ25-1	BZ34-2/4	CFD11	JZ9-3	LD	PL19-3	QHD32-6	YingBei
Rate of oil spill accidents	0.461	0.406	0.296	0.339	0.435	0.496	0.376	0.298

Figure 4. The distribution of oil spill risk grades.

Table 5. Corresponding relations between oil spill risk level and colors.

Colors	Red	Pink	Blue	Green	White
Oil spill risk level	High	Less high	Medium	Less low	Low

- Production operation and exploitation operation are operated, respectively;
- The design output of newly built offshore oil production facilities are more than 500 tons (3750 barrels) of crude oil within 10 nautical miles radius of target area in Bohai;
- The newly built submarine pipeline's length is more than 40 km with a diameter of 800 mm length of target area in Bohai;

According to the above method, eight offshore facilities, Tianjin port, Dalian port, and onshore terminal in the Bohai area were dispersed and all the risks of oil spill sources (blowout, production oil spill, FPSO, etc.) was superimposed. After the calculation, the oil spill probability of dispersed areas in Bohai was obtained, which is as shown in Table 4.

4.2 The distribution of oil spill risk

Bohai area was divided into 905 6' × 6' squares according to the latitude and longitude. Considering the characteristics of oil spill accidents in

the Bohai area, combined with the statistical data of oil spill accidents of platforms (drilling spill, development wells spill, oil blowout and production spill), submarine pipelines' spill, FPSOs' spill and terminals' spill, the risk level of different areas was provided based on assessment data of risk probability. Finally, different risk levels were plotted on the electronic chart with different colors. It was included in the oil spill risk grade map in the Bohai area, which is as shown in Figure 4. Corresponding relations between oil spill risk level and colors is shown in Table 5.

5 CONCLUSION

In this paper, the oil spill risk of offshore facilities in the Bohai area was identified by using the ETA method, which concluded the oil spill risk probability based on the statistical analysis of oil spill accidents over the years. According to the distribution characteristics of the Bohai offshore oil facilities, The Bohai area was dispersed into different grids for oil spill risk source and the distribution of oil spill risk grade was provided at last, which can lay the foundation for oil spill risk early warning, prevention, and control in the Bohai area.

Developing a low-carbon economy and constructing a low-carbon city—a Xuzhou perspective

W.Y. Zhang & C.L. Zhou

School of Environment Science and Spatial Informatics, CUMT, Xuzhou, Jiangsu, China

F. Chen & J. Ma

Low Carbon and Energy Institute, CUMT, Xuzhou, Jiangsu, China

ABSTRACT: Developing a low-carbon economy and constructing a low-carbon city has become the trend in the world. China started a national low-carbon city pilot project in 2010. Xuzhou city is a mineral resource city that has a long history of coal mining. Its heavy machinery industry is also well-developed. However, Xuzhou faces several problems such as coal resource exhaustion and mining subsidence. Due to extensive energy consumption, high emissions, as well as other problems of traditional pillar industries, the low-carbon city construction of Xuzhou was hindered. Considering the development situation of the current economy and society and the restrictive factors of low-carbon economic development, this paper provides some suggestions for low-carbon city construction planning: (1) perfecting the law and policy system for low carbon economy; (2) transforming coal mining abandoned land and subsidence land, as well as developing characteristic tourism; (3) accelerating technological innovation and promoting industrial structure adjustment.

1 INTRODUCTION

Economic recovery and population explosion have gradually sharpened the contradiction between environment and development since the Second World War. Scholars began to think about the relationship between humans and nature at the same time. Ecological issues also became more and more important. As the global climate problem draws more international attention, the problem of carbon dioxide emission has become an important issue (Yang 2011). Since the United Nations put forward the concept of “Sustainable Development” in 1992, various countries have started paying more attention to the ecological environment and climate change.

Climate change originated from the interaction between nature and humans. Human beings have seriously affected the natural process through endless developmental activities, and thus the climate and natural environment have changed. In a word, climate change issue is a continuously developing problem. Therefore, if we want to improve the climate, we should change the way how humans survive and develop.

Several scholars have proposed theories that combined environmental protection with economic development. Based on the above-mentioned knowledge, we can understand these theories. In the 1960s,

American economist Kenneth Bolding proposed “circular economy” on the basis of his “spaceship economy” theory. He also put forward the concept of ecological economy for the first time in 1966. The UK has proposed “energy white paper” in 2003 and put forward the concept of “low-carbon economy” (Xue 2011). These three concepts came into being in the same era, but had different emphasis as follows: the core of ecological economy was the sustainable development of economy and nature; circular economy emphasis on resource recycling and low carbon economy underlined low carbon emissions and improved the climate.

In July 2010, NDRC (National Development and Reform Commission) released “The notice on carrying out the pilot work of low carbon provinces and low carbon cities”. China started the low carbon city pilot project. According to the local declaration situation, working foundation, and pilot representative information, the government has decided to carry out the pilot work in Guangdong, Liaoning, Hubei, Shanxi, Yunnan provinces and Tianjin, Chongqing, Shenzhen, Xiamen, Hangzhou, Nanchang, Guiyang, and Baoding cities first. Xuzhou won the national first batch of “the most competitive low carbon city” awards in 2010 which was unique in Jiangsu. All these conditions showed that constructing a low carbon city in Xuzhou was feasible and beneficial.

2 LOW CARBON ECONOMY AND LOW CARBON CITY

2.1 *The definition of low carbon economy and low carbon city*

Under the effect of the concept of sustainable development, low-carbon economy is becoming a new economic forum with characteristics of “low emissions, low energy consumption, low pollution” on energy consumption. Technical innovation, institutional innovation, industrial transformation, new energy development, and low carbon economy are designed to realize the human economic development and ecological environment protection (Xu 2009).

The low-carbon city is a city which was used as a unit to implement low-carbon economy into practice. Its purpose was to realize the unification of ecological benefit, economic benefit, and social benefit within the nature-human-social economy composite system. Also, gradually reducing carbon source and increasing carbon sinks in the city’s economic development process is one of the goals. Meanwhile, city industries have transformed from the traditional high carbon emission industry to low carbon emission industry, as well as the urban consumption transforming from high carbon consumption to low carbon (Fang 2009).

2.2 *Low carbon economy development—present situation at home and abroad*

In 2003, the British government issued a report: “Our Energy Future: Creating a Low Carbon economy”, which proposed the concept of a low carbon economy for the first time. Once put forward, the concept has received wide attention.

China released the “National Assessment Report on Climate Change” in 2006 and “China’s National Program to Address Climate Change” in 2007. The USA released “The Low Carbon Economy Act”. Then the UN climate change conference formulated the “Bali roadmap”. These events marked the efforts of low carbon economy development from all over the world. In December 2009, the World Climate Conference convened in Copenhagen, which became the symbol of world comprehensive transformation into the low carbon era. Countries such as France, Japan, and Canada have taken corresponding policies and measures. Since January 2005, using renewable energy equipment has gotten tax breaks from 40% to 50% in France. With support from the Japanese government, a lot of low carbon technologies in Japan have led the world, such as green residential technology which could slash energy consumption by comprehensive utilization of solar energy and

heat insulation material, wastewater treatment technology and plastic recycling technology (Xu 2009). The transition to low carbon economy has become the major trend of world economic development.

2.3 *Low-carbon city development in China*

China has been making positive efforts in the construction of a low carbon city.

1. Our country has been gradually formulating and maintaining laws and policies for energy conservation and emission reduction. China has formulated a series of laws such as “Law of Cleaning Product Development”, “Water Pollution Prevention and Control Law of China”, etc. These laws and regulations have played an important role in guidance and protection for various industries in the process of low carbon economic development. Some scholars have established an energy conservation and emissions reduction database which includes 1195 policies issued from 1978 to 2013. (Zhang 2014).
2. China is actively developing new energy and renewable energy actively. In recent years, China has positively developed hydroelectric, solar energy, nuclear energy, wind energy, and other sources of clean energy. In 2012, this clean energy accounted for 8.3% of the total energy consumption. In terms of the scope of application and technical level, there is still a large gap between China and the developed countries, but the momentum of application of new energy is good.
3. The country has been actively conducting forest plantation actively to increase carbon sinks.

In addition, the Chinese Society for Urban Studies discussed the implementation of China’s low-carbon eco-city development steps in 2009, distributed in 44 years from 2007 to 2050 into three stages. China would realize the “low-carbon city” dream step-by-step with this implementation.

3 OPPORTUNITIES AND CHALLENGES OF LOW-CARBON CITY DEVELOPMENT IN XUZHOU

3.1 *Xuzhou overview*

Xuzhou, named as “Pengcheng” in ancient times is located in the northwest of Jiangsu province where the Longhai and Jinghu railways meet. The Beijing-Hangzhou Grand Canal runs through Xuzhou. Xuzhou is also the center of Huaihai economic zone, which has the reputation of being called “the

city of engineering and machinery". The terrain is dominated by plains. It has warm temperate zone with a half moist monsoon climatic region with four distinct seasons.

Xuzhou has rich resources and the combination condition is superior. It has large coal reserves, multiple layers, thick coal seam and high quality. It is also an important coal-producing area and the power base of east China (Qu 2010). According to GDP size sorting, the Chinese Academy of Sciences Sustainable Development Strategy Research Group has selected 50 representative cities and classified them based on the differences of urban functions. Xuzhou was categorized as an industrial city (Liu 2013). After years of efforts on industry structure adjustment, the third industry growth rate was more than the rate of the second industry in the year 2014, whereas the proportion of output value was almost unchanged (Hao 2014). In 2015, the GDP of Xuzhou region had achieved 532 billion RMB. The third industrial production structure adjusted to 9.5:44.3, 46.2, and exceeded the secondary industry for the first time.

3.2 *Restraint of low-carbon economy development*

The low carbon city development in Xuzhou was restricted by some factors which were as shown below:

1. The industrial structure biased towards heavy industry and evolved slowly (Liu 2013). Since 1980, the industrial structure of Xuzhou has been adjusted twice. The primary industry has changed from first to second and then dropped to the third position. Up to 2014, the second industry was still in the leading position. The number of heavy industry enterprises was dominant and its comprehensive energy consumption level was high (Li 2011a). In 2015, Xuzhou's tertiary industry exceeded the second industry for the first time and low carbon city construction achieved initial success.
2. The coal industry has strong negative externality and high exit cost. Mining activities have caused significant damage to the ecological and geological environments. Also, strong public negative externality and inter-generational negative externality have been provoked. Xuzhou had more than 100 years of mining history and gradually appeared to show the case of shallow coal resources as reserves fell sharply, and deep mining was too difficult. As a resource-based city, Xuzhou has also established a large number of supporting facilities and mature industry chains in the process of coal development. Once the coal industry development was forced to stop, the corresponding industry chain

would be interrupted and atrophied, resulting in a large number of workers being unemployed and equipment getting shut down, which would affect local economic development seriously.

3. Xuzhou was backward in science and technology and economic development emerged in apparent conflict. Carbon productivity was determined by the technical level, so technology was one of the decisive factors for success in being a low-carbon economy city. Compared with the south of Jiangsu, Xuzhou's science and technology and economic development level was backward, which hindered the low carbon city construction and development. Under the guidance of the economic development goal, stimulating economic growth and promoting consumption were necessary. However, low carbon economy required the reduction of continuous resource consumption and reducing expenditures. There was a significant contradiction between stimulating material consumption and development of "low-carbon economy". If Xuzhou wanted to achieve these two goals at the same time, the government should reach a higher level of economic development at a relatively low energy consumption level. This also meant that Xuzhou needed to assume the economic development requirements of the third-tier city and environmental protection requirements of the first-tier city at the same time. Challenge is huge.

3.3 *Present measures of existing low carbon city development in Xuzhou*

Xuzhou has implemented a series of low carbon measures. The first one was promoting the low-carbon concept actively, such as publishing the low carbon policy, slogans in newspapers, Web sites, billboards, etc. The second was constructing a low-carbon living environment. The traditional architectural crafts were encouraged to be low carbonization, such as reclaimed water cycling, charging low-emission car owners for lower parking fees, increasing community green rate, etc. The third was to promote industrial low carbon transformation. Ecological agriculture, modern service industry, and the energetic photovoltaic industry were developed, while the development of emerging industries was promoted and the industrial structure was adjusted simultaneously. On the other hand, traditional enterprises were rebuilt and transferred. The main measures included: (1) high energy consumption and high pollution enterprises were rectified or banned; (2) government would give some preferential policies and funding support to low carbon transformation of traditional enterprises; (3) high technology was

developed to support the transition of traditional pillar industries. At present, there have been three new industrial parks of solar photovoltaic, new energy equipment manufacturing and clean production in the Xuzhou economic development zone, which is remarkable.

4 XUZHOU LOW-CARBON CITY CONSTRUCTION PLANNING

Even with hard restrictions of the above factors, development of a low-carbon city in Xuzhou still had feasibilities because the low carbon transition of Xuzhou was not only a challenge but also an opportunity. The 100-year-old coal-mining city has been experiencing the bottleneck in development because of the gradual exhaustion of coal resources. But the government's support for low carbon city constructions has also brought rising high-tech industries and the construction of livable environment, which led to correct consumption patterns in the people and economic recovery. Xuzhou's tertiary industry output value exceeded the achievement of the second industry in 2015 for the first time, which inspired people and let them see the possibility of a low carbon city being built.

The low carbon city construction planning of Xuzhou was not perfect, and at present, there were still some problems worthy of thinking deeply in Xuzhou's future low carbon road. Many scholars have studied the low carbon economy development of Xuzhou and provided many suggestions (Yang 2010, Tao 2011, Chang 2012, Li 2012, Zhang 2011). Combined with scholars mentioned above, this paper proposed our own advice as follows:

1. Developing and completing the law and policy for low carbon economy. For the construction of a low-carbon city, China has established laws and policy systems preliminarily. The government of Xuzhou city should adjust the measures according to local conditions and set policies according to local practice for perfection. In the implementation process, the government should pay more attention to quality and avoid getting hot-headed. In this way, good results might be obtained.
2. Transforming mining abandoned land and developing characteristic tourism. Reforming abandoned mines and mining subsidence land was necessary. Safe and well-preserved abandoned mines might be transformed into museums and mining subsidence land can be converted into ecological wetland parks after field investigation and feasibility analysis. There is already a built case named "Pan'an Lake wetland park".

3. Speeding up scientific and technological innovation and promoting industrial structure adjustment. As mentioned above, Xuzhou is an industrial city. Heavy industries had a high proportion consuming intensive energy and producing heavy pollution with high exit cost. On one hand, the government should strengthen scientific and technological innovation, support the transformation and upgrading of traditional pillar industries with science and technology, and perfect pollution treatment. On the other hand, the government should develop new energy sources and train talent for new energy development comprehensively. The coal industry chain and services established during the development of the old coal industry should be applied for the second time so that the coal industry exit cost might be reduced.

5 CONCLUSION

Economic recovery and population explosion have stimulated problems between social situation and environment since the Second World War. Various governments, institutions, and scholars have gradually dabbled in the theory and practice research of the "low-carbon economy" and "low-carbon city". Xuzhou has been making efforts.

According to the social and economic development situation of Xuzhou, the restriction factors of low carbon city construction have been summarized. There were three main factors: (1) the emphasis is biased towards heavy industry and the industrial structure evolution advanced slowly. (2) Coal industry had strong negative externality and high cost to quit. (3) The science and technology level of Xuzhou was backward and economic development showed apparent conflict.

Combined with other research, the development countermeasures have been proposed in this paper: (1) Developing and completing the law and policy for low carbon economy. (2) Transforming mining abandoned land and developing the characteristic of the tourism business. (3) Speeding up scientific and technological innovation and promoting adjustment of industrial structure.

Geophysical and geochemical characteristics and mineralization potential in the Taonatu area, Inner Mongolia

Q. Liu & R.M. Peng

School of Earth Sciences and Resources, China University of Geosciences, Beijing, China

ABSTRACT: The Taonatu area located in the western part of the north margin of the North China Craton in Inner Mongolia has good ore-forming potential. In this paper, a comprehensive prospecting model was applied based on geological, geophysical and geochemical characteristics. By using the 1:50,000 high-precision magnetic survey, we found that the magnetic anomaly is associated with the Agulugou formation and Zenglongchang formation in the Taonatu area, especially with the Agulugou formation. By using the 1:50,000 stream sediment geochemical survey in this area, anomalies of Fe, Zn, Au, Ag, and other polymetallic elements are extracted. Based on the geological study, this paper successfully applied a high-precision magnetic prospecting and stream sediment geochemical survey to explore the mineralization potential in the Taonatu area. It is believed that this area is a potential area for finding polymetallic deposits.

1 INTRODUCTION

With the increasing difficulty of prospecting, it is becoming more and more important to study different kinds of comprehensive prospecting models and interpretation methods for geophysical and geochemical exploration (Nabighian, et al. 2005 & Guan, et al. 2002). The high-precision magnetic survey has been used widely to find hidden magnetic metal deposits and also used in the regional geological survey, and oil and gas exploration. It has got a lot of valuable results. In this paper, combining geological exploration information extracted from the stratum, magmatic rocks, and various mineralized signatures and the relationship between geochemical anomaly and mineralization we reduced the prospecting target area so as to achieve the purpose of mineralization potential analysis in this area.

The Taonatu area is located at the boundary between Alashanzuoqi and Wulatehouqi in Inner Mongolia. It belongs to the western part of the north margin of the North China Platform, which has good metallogenic potential. In the eastern part of the study area, some large and medium-sized copper polymetallic deposits (for example Dongshengmiao, Huogeqi, Tanyaokou) have been found. There are favorable ore-forming background and ore-forming conditions in this area. Therefore, it has good prospecting potential. In this paper, the high-precision magnetic survey and stream sediment geochemical survey are combined to evaluate the mineralization potential in the Taonatu area, Inner Mongolia.

2 GEOLOGICAL BACKGROUND

The Taonatu area is located in the western section of the north of the North China Craton (Peng et al. 2007). Owing to the multi-stage tectonic compression, reworking, and magma intrusion, the strata outcrop incompletely. The exposed stratum are mainly Paleoproterozoic Baoyintu group, Mesoproterozoic Zhaertaishan group, Cretaceous and Quaternary (Figure 1).

Since the late Proterozoic, multi-stage tectonic movements occurred in the Taonatu area, therefore, the intrusive rocks were distributed widely, and the variety of types were complicated from ultrabasic to acidic rocks. The lithologies are mainly granite, diorite, gabbro, etc. The most common rock type is acidic intrusion rock.

3 GEOPHYSICAL CHARACTERISTICS

The instrument used for collecting data is the GSM-19T proton magnetometer which was made in Canada. It has high sensitivity and measurement accuracy. The data collection process includes instrument detection, diurnal variation correction, data observation, data pre-processing and so on, which was done according to "High-precision ground magnetic survey technology regulations". The magnetic survey of 1:50,000 was carried out with space in both 500 m survey lines and 100 m survey points. If data anomaly is obvious, high survey density measurement is needed.

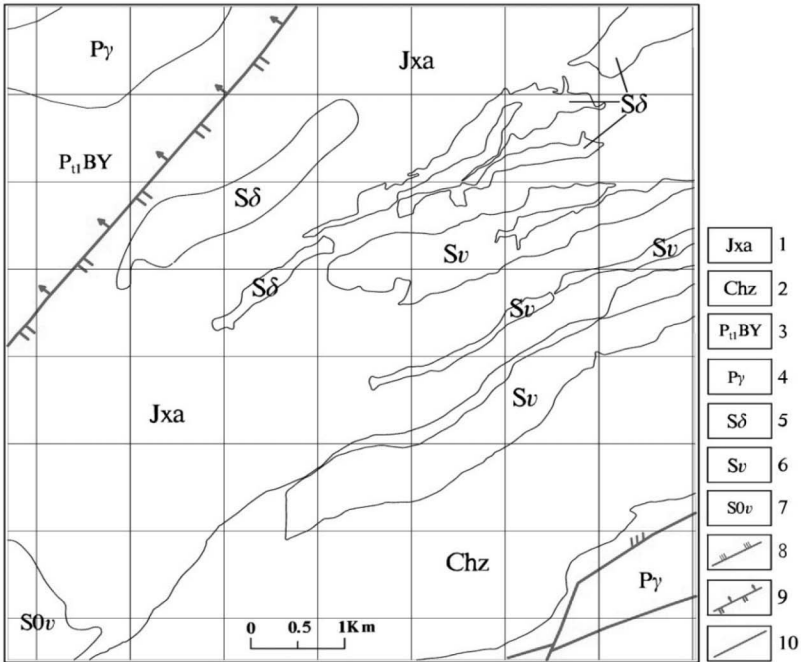

Figure 1. Geological diagram of the Taonatu area, Inner Mongolia.
 1-Agulugou group, 2-Zenglongchang group, 3-Baoyintu group, 4-granite, 5-Quartz diorite, 6-Gabbro, 7-Variable hornblende gabbro, 8-Compressional torsion fracture, 9-Measured reverse fault, 10-Unknown fault.

Figure 2. Contour map of magnetic anomaly in the Taonatu area, Inner Mongolia.

The contour map is as shown in Figure 2.

From Figure 2, the overall area has high magnetic anomaly but the peak was lower. The magnetic anomalies are distributed in the northeastern direction, which is consistent with the distribution of stratum. The distribution of positive and negative magnetic anomalies is consistent with the main geological formation. The positive magnetic anomaly is located mainly in the Agulugou formation and Zenglongchang formation, especially in the Agulugou formation. In addition, there are some anomalies in the basic rock. Negative anomaly distributes mainly in the area of granite. The upward continuation was done and the results show that the rock mass causing anomaly is a whole with a common magma chamber in depth. The locally superimposed anomalies are caused on the one hand by mineralization and alteration near the surface and on the other hand by the hidden magnetic body in depth.

Agulugou formation with magnetic anomaly is a favorable metallogenic area in the Taonatu area. It has good mineralization potential and is beneficial to find iron deposits. It will provide important information for the next geological prospecting work.

4 GEOCHEMICAL CHARACTERISTICS

The sampling medium is stream sediments. The sampling density is 4 samples per square kilometer in the 1:50,000 stream sediment geochemical survey.

Geochemical data processing is the basis for the extraction of anomaly information (Allegre & Lewin 1995). It is a basic problem for the determination of geochemical anomaly threshold in exploration geochemistry (Ren & Wu 1998). The traditional method to determine geochemical

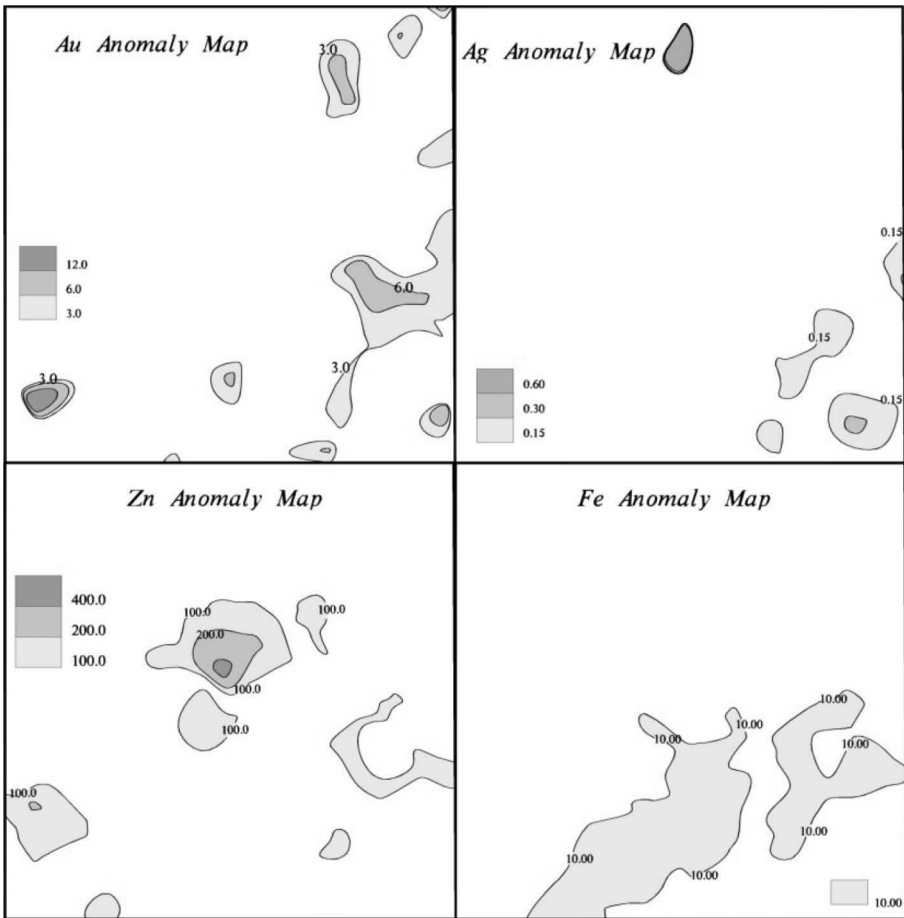

Figure 3. Ag, Au, Fe, Zn element anomaly maps in the Taonatu area.

anomaly threshold is based on an assumption that the data obey the normal or lognormal distribution. The mean value (C) and the standard deviation (σ) are calculated for the data obeying the normal or lognormal distribution, then the anomalous threshold can be calculated by $C+k\sigma$ (k is a multiple of 2).

After determining the geochemical anomaly threshold, we could draw single element geochemical maps. In this paper, GeoExpl software was used to complete geochemistry maps (Figure 3). Based on the comparison of various gridding methods and the spatial structure of geochemical elements in the study area, exponential weighting method was chosen to do interpolation for the geochemical data and establish geochemical anomaly maps. Some obvious anomalies were evaluated and verified preliminarily, which would provide help for the evaluation and analysis of geochemical anomaly.

It has been found that this area has the multi-element combination characteristics of a geochemical anomaly, which is favorable for large-scale metallogenic conditions but there were no deposits in the anomaly area. The metallogenic elements have high anomaly intensity, obvious concentration zones, and centers (Figure 3).

The main geochemical anomaly contour maps of Fe, Zn, Au, and Ag are demonstrated in Figure 3. From Figure 3 we can see:

1. The anomalies of Fe, Zn, Au, and Ag in this area are located mainly in the Agulugou formation and Zaolongchang formation. The anomaly direction is in accordance with the approximate formation and distribution.
2. The Au, Fe, and Zn anomalies which are distributed mainly in the Agulugou formation and Zenglongchang formation have large areas of banding distribution. Concentration centers of Zn and Au are concentrated and the content gradients are obvious.
3. Ag anomalous area is smaller but the anomaly concentration is concentrated and the content gradient is obvious. Ag anomaly needs to be verified in the next work.

5 CONCLUSION

Based on the study of geological, geophysical, and geochemical characteristics, it is considered that

the magnetic anomaly distributed in the Agulugou formation have favorable metallogenic potential in the Taonatu area. Those areas have good metallogenic potential and are favorable locations to find iron deposits. It has provided important information for the next mineral prospecting.

The geochemical anomaly characteristics have multiple elements in superimposition. Metallogenic elements show high anomalous intensity, obvious zone structure, and concentration centers in this area. There are good metallogenic conditions in this area but not any deposits, so we think that this area has good potential to find polymetallic deposits.

This paper applied high-precision magnetic survey and stream sediment geochemical survey to geological prospecting successfully in the Taonatu area, which achieved the aim of metallogenic prediction with comprehensive methods.

Effects of genistein supplementation on exhaustive exercise-induced oxidative damage in mice

Qiongli Hu, Hui Huang & Xiaoling Huang

Department of Physical Education, Central South University, Changsha, Hunan, P.R. China

ABSTRACT: The aim of this study was to evaluate the protective effects of genistein on exercise-induced oxidative damage in mice. Male mice were randomly divided into four groups: a control or one of three genistein treated groups (7, 15, and 30 mg/kg). Genistein was orally administered to mice once a day for 4 weeks, while the control group received physiological saline. After 4 weeks, mice were required to run until exhaustion on the treadmill. Their Creatine Kinase (CK), lactate dehydrogenase (LDH), aspartate aminotransferase (AST) and alanine aminotransferase (ALT) in the serum, as well as superoxide dismutase (SOD), Glutathione Peroxidase (GPx) and malondialdehyde (MDA) in the muscle were determined. As a result, when compared to the control group, genistein supplementation decreased CK, LDH, AST, and ALT levels in the serum, as well as MDA levels in the muscle, and increased SOD and GPx levels in the muscle. The findings suggest that genistein has protective effects against exhaustive exercise-induced oxidative damage.

1 INTRODUCTION

It is well established that regular physical exercise has many beneficial effects to health. It improves cardiovascular function, vascular tone, muscular strength, and endurance (Hamurcu et al. 2010). However, intense or excessive exercise could cause oxidative damage in various kinds of cells and tissues due to excessive free radicals and Reactive Oxygen Species (ROS) produced from the increase in muscle oxygen consumption during exercise (Huang et al. 2013). The main sources of ROS during exercise are the mitochondrial respiratory chain, xanthine oxidase-catalyzed reaction, and neutrophil activation (Suredda et al. 2009). It was also suggested that exercise-induced oxidative damage may be prevented by optimizing nutrition, particularly by increasing the dietary content of nutritional antioxidants (Belviranli et al. 2012).

Flavonoids are found ubiquitously in the plant kingdom. Genistein, a flavonoid in legumes and some herbal medicines (Su et al. 2016) has various pharmacological activities such as antitumor, anti-inflammatory, neuroprotective, antiapoptotic, antidiabetic, and estrogenic activities, as well as protective effects against bone loss and cardiovascular diseases (Wang et al. 2013; Turner et al. 2013). This compound also had a significant antioxidant activity (Wei et al. 1995) and our previous study has shown that genistein had anti-fatigue effects (Hu 2016) suggesting that it may be useful in preventing exercise-induced oxidative damage. To test

this hypothesis, the present study was designed to evaluate the protective effects of genistein on excessive exercise-induced oxidative damage in mice.

2 MATERIALS AND METHODS

2.1 *Materials and chemicals*

Genistein (98.5% purity) was purchased from Zhenzhun Biological Technology Co., Ltd (Shanghai, China). The commercial diagnostic kit for Creatine Kinase (CK) was purchased from Hunan Yonghe-Yanguang Science and Technology Co., Ltd (Changsha, China). The commercial diagnostic kits for lactate dehydrogenase (LDH), Superoxide Dismutase (SOD), Glutathione Peroxidase (GPx) and malondialdehyde (MDA) were purchased from Jiancheng Bioengineering Institute (Nanjing, China). The commercial diagnostic kits for aspartate aminotransferase (AST) and alanine aminotransferase (ALT) were purchased from Kangmei Biotech Co., Ltd (Shenzhen, China). All the other chemicals used were of the highest grade available.

2.2 *Experimental animals*

Male Kunming mice, weighing 20 ± 2 g, were supplied by the Hunan Biological Supplier (Changsha, China). The animals were bred in a temperature-controlled ($(23 \pm 2)^\circ\text{C}$), $(55 \pm 5)\%$ humidity room

with a 12-hour light and 12-hour dark cycle. Standard mouse diet and water were available ad libitum. All animal handling procedures were performed in strict accordance with the principles of Laboratory Animal Care published by the National Institutes of Health and were approved by the Animal Ethics Committee of Central South University (Changsha, China).

2.3 Experimental design

After adaptation for 1 week, mice were divided into four groups, and each group consisted of eight mice.

- i. Control (C) group: mice were allowed free access to a standard mouse diet and were treated with 1.0 mL of physiological saline.
- ii. low-dose genistein treated (GT-L) group: mice were allowed free access to a standard mouse diet and were treated with 7 mg/kg bw of genistein.
- iii. intermediate-dose genistein treated (GT-I) group: mice were allowed free access to a standard mouse diet and were treated with 15 mg/kg bw of genistein.
- iv. high-dose genistein treated (GT-H) group: mice were allowed free access to a standard mouse diet and were treated with 30 mg/kg bw of genistein.

Genistein was dissolved in 1.0 mL of physiological saline and treatments were administered orally by gavage daily for 4 weeks. During the fourth week, mice were introduced to treadmill running with 15 min exercise bouts at 20 m/min and a slope of 5% for a week to accustom them to running.

After final treatment with genistein or physiological saline, mice were required to run to exhaustion on the treadmill at a final speed of 30 m/min, 10% gradient, and approximately 70–75% maximal oxygen consumption (VO_2 max) (Li et al. 2014; Xiao 2015). Exhaustion was defined as the mouse being unable to turn upright by itself when placed on its back (Huang et al. 2009), and the mean time to exhaustion was 84.72 min (range: 62.34–95.48 min).

2.4 Analysis of biochemical parameters

Immediately after exhaustive exercise, mice were anesthetized using sodium pentobarbital and sacrificed by decapitation. Blood samples were collected in the test tube and serum was isolated by centrifugation for the CK, LDH, AST, and ALT analyses. Next, the gastrocnemius muscles were carefully removed, washed with physiological saline, and frozen in liquid nitrogen for storage at -80°C until required for the SOD, GPx, and MDA analyses. Measurements were performed according to the recommended procedures provided by the commercial diagnostic kits.

2.5 Statistical analysis

Data were expressed as mean \pm SD. Statistical analysis was performed using one-way Analysis Of Variance (ANOVA) followed by Tukey's *post hoc* multiple comparison test using SPSS version 16.0 statistical software. Compare value less than 0.05 was considered significant.

3 RESULTS AND DISCUSSION

3.1 Effects of genistein on CK and LDH levels in the serum of mice

CK and LDH are highly inducible enzymes that are released into the blood as a result of the destruction of the cell membrane by oxidative stress or tissue damage, as well as the direct destruction of the cell wall and tissue necrosis (Kim & Chae 2006). Several recent studies have reported that exhaustive exercise elevates CK and LDH levels in serum (Sugino et al. 2007; Huang et al. 2009). Therefore, serum CK and LDH can be used as indexes of muscle damage. Effects of genistein on CK and LDH levels in the serum of mice are shown in Figure 1.

As shown in Figure 1, the CK levels in the GT-L, GT-I and GT-H groups, as well as the LDH levels in the GT-I and GT-H groups were significantly lower compared with that in the C group ($p < 0.05$). The results indicated that genistein could attenuate muscle damage following exhaustive exercise.

3.2 Effects of genistein on AST and ALT levels in the serum of mice

Liver enzymes are normally found within the liver cells, but these enzymes are released into the blood when the liver is damaged. The most critical and most widely used liver enzymes are aminotransferases such as AST and ALT (Salahshoor et al. 2014), which catalyze the transfer of amino

Figure 1. Effects of genistein on CK and LDH levels in the serum of mice. Data are expressed as mean \pm SD. *, $p < 0.05$ compared with the C group.

groups from aspartate and alanine to ketoglutaric acid to generate oxaloacetic and pyruvic acids that are involved in energy production in the presence of oxygen in mitochondria (Bürger-Mendonça et al. 2008). Accumulating evidence indicates that exhaustive exercise temporally increases the activities of AST and ALT, and elevated AST and ALT levels in the absence of other evidence of liver disease should lead to the consideration of muscle damage, which is confirmed by the observed elevation of CK and LDH levels (Hammouda et al. 2012). Effects of genistein on AST and ALT levels in the serum of mice are shown in Figure 2.

As shown in Figure 2, the AST and ALT levels in the GT-I and GT-H groups were significantly lower compared with that in the C group ($p < 0.05$). The results provide further evidence that genistein could protect muscle damage after exhaustive exercise.

3.3 Effects of genistein on SOD and GPx levels in the muscles of mice

It has been well demonstrated that exhaustive exercise is associated with a dramatic increase in oxygen uptake by the whole body and particularly by the skeletal muscle and therefore enhances the production of ROS, such as superoxide anion radical, hydroxyl radical, or hydrogen peroxide (H_2O_2) (Cooper et al. 2002). As a result, accumulated excessive ROS can attack the vital biomolecules, such as plasma membrane lipids and proteins, and therefore deteriorate normal cellular functions (Yu et al. 2012). Antioxidant enzymes including SOD and GPx were regarded as the first line of defense against ROS generated during exhaustive exercise (Huang et al. 2008). SOD is a superoxide radical scavenging factor converting superoxide radicals to H_2O_2 . GPx reduces H_2O_2 or hydroperoxides to H_2O and alcohol (Wu et al. 2013). The effects of

Figure 2. Effects of genistein on AST and ALT levels in the serum of mice. Data are expressed as mean \pm SD. *, $p < 0.05$ compared with the C group.

genistein on SOD and GPx levels in the muscles of mice are shown in Figure 3.

As shown in Figure 3, the SOD levels in the GT-I and GT-H groups, as well as the GPx levels in the GT-L, GT-I, and GT-H groups were significantly higher compared with that in the C group ($p < 0.05$). The results indicated that genistein could effectively enhance antioxidant enzyme activities to protect exercise-induced oxidative damage.

3.4 Effects of genistein on MDA levels in the muscles of mice

Increasing evidence indicates that ROS generated by exhaustive exercise could attack polyunsaturated fatty acids, which will lead to lipid peroxidation (Qi et al. 2014). Lipid peroxidation is a complex phenomenon involving the generation of many products. MDA, one of the most important end-products of lipid peroxidation is a popular index of the first condition on oxidative damage (Lu et al. 2006). Effects of genistein on MDA levels in the muscles of mice are shown in Figure 4.

Figure 3. Effects of genistein on SOD and GPx levels in the muscles of mice. Data are expressed as mean \pm SD. *, $p < 0.05$ compared with the C group.

Figure 4. Effects of genistein on MDA levels in the muscles of mice. Data are expressed as mean \pm SD. *, $p < 0.05$ compared with the C group.

As shown in Figure 4, the MDA levels in the GT-L, GT-I, and GT-H groups were significantly lower compared with that in the C group ($p < 0.05$). The results indicated that genistein could effectively reduce lipid peroxidation, and indirectly reflected genistein could protect oxidative damage after exhaustive exercise.

4 CONCLUSION

In conclusion, the results of the present study indicated that genistein supplementation afforded significant protection against exhaustive exercise-induced oxidative damage in mice. The protective effect is mediated by the lowering of CK, LDH, AST, and ALT levels in the serum, as well as MDA levels in the muscle, and elevating of the SOD and GPx levels in the muscle. However, further studies are needed to investigate the underlying mechanisms for the protective effects of genistein.

Bangkok Thonburi University, Bangkok, Thailand

Wen Cheng

Harbin Institute of Technology, Harbin, China

ABSTRACT: Based on confirmation of the target of environmental protection planning text semantics, this study listed formal analysis and content analysis methods. Two kinds of modeling technology for planning evaluation are put forward: the modeling technology based on the driving force of the model and the modeling technology based on interest—driven model. The future research directions related to semantic modeling technology are suggested: 1) promoting computer information search and statistical techniques in the field of text form analysis. 2) paying attention to the stakeholders' claim, anxiety, dispute and the corresponding solutions during the evaluation process.

1 THE GOAL OF THE SEMANTIC ANALYSIS OF PLANNING TEXTS

In general, both planning of public sectors and the overall planning of private sectors are essentially a collection of 5 aspects: analysis of the present situation, prediction of future trends, goals in different stages, tasks to implement, and manpower, financial power and other institutional safeguard measures. The five-year environmental protection plan in Jilin Province, as an important part of the planning system of Jilin Province, covers contents of the above-mentioned 5 aspects.

The implementation of the five-year environmental protection plan of Jilin Province is evaluated, and the focus of the evaluation is placed on 3 aspects, that is, the attainment of staged goals, the progress of implementing specific tasks, and the implementation of manpower, financial and other institutional safeguard measures. Therefore, in the semantic analysis of planning texts, work should be done from 3 aspects to figure out which goals to attain in different stages, which tasks to complete, and who assumes responsibility of implementing the tasks and which sources provide funds for supporting the task implementation. To make clear the 3 questions, planning texts are usually analyzed through 2 analytical methods: form analysis and content analysis. The form analytical method is adopted to form key points and detailed rules for evaluation outlined by planning goals and tasks (Junyan Dong, 2014). On the basis of a form

analysis, a content analysis is made of planning texts, to determine requirements for the progress of implementing the goals and tasks, and identify manpower, financial and other institutional safeguard measures, thus eventually forming detailed items for the evaluation of plans.

2 FORM ANALYTICAL METHODS OF PLANNING TEXTS

The planning text refers to an information structure which is made by specific people or organizations and has special symbols. Semantics of planning texts would inevitably reveal the specific standpoint, views, values, and interests of compilers (or principals). These specific standpoints, views, values and interests can be reflected by the form of texts, such as feature words, word frequency, word number, number and so on (Junyan Dong, 2011). Therefore, through a form analysis of planning texts, intention and motivation of planning compilers (or principals) can be roughly inferred, to provide direction and guidance for the content analysis of planning texts, and simplify and standardize contents of evaluating planning texts.

2.1 Selection of feature words

The selection of feature items is the basic work in the text analysis. A scientific and reasonable selection of feature items can have a multiplier effect on

the text analysis and deconstruction. In accordance with the requirements of planning evaluation, feature words in the environmental protection plan of Jilin Province can be generally classified into 3 categories: a set of feature words about goals (such as goal, objective, main indicator, etc.), a set of feature words about tasks and projects (such as task, project, facility, supervision, etc.), a set of feature words about policies and measures (such as policy, measure, system, mechanism, law, standard, etc) (Junyan Dong, 2015). A complex collection of feature words can be further divided into sub-sets.

2.2 *Statistics of the frequency of feature words*

The word frequency of a given word refers to the number of occurrences of the given word in a text. The importance of a word increases along with the increase in the number of its occurrence in the text. Statistics is made of the word frequency of feature words selected from the environmental protection plan of Jilin Province (Junyan Dong, 2015). Through statistics of the word frequency, we can not only validate, select and identify feature words for the evaluation of this planning text, but also make a preliminary evaluation of the importance of evaluation indicators for the feature words.

2.3 *Clustering analysis of feature words*

In a given text, feature words often frequently appear in paragraphs with greater relevance in meaning, but rarely appear in paragraphs with smaller relevance in meaning. Through a clustering analysis of the position of feature words in a planning text, we can match the feature words with corresponding text modules, to facilitate the subsequent analysis of the word number, the number, other forms and contents of the text.

2.4 *Statistics of the word count*

Through a clustering analysis of feature words, paragraphs with greater relevance in the meaning of feature words are classified into the same part. Moreover, the clustering analysis can help to gain a more intuitive understanding of the importance of relevant evaluating contents. An analysis of text contents is combined to give further suggestions for specific perspectives and evaluation technology used to evaluate feature words.

3 CONTENT ANALYTICAL METHODS OF PLANNING TEXTS

Compared with the form analysis of texts, in the content analysis of texts, evaluators are required to have a more comprehensive structure of evaluation

knowledge, make more detailed and complicated analyses and take a more subjective viewpoint. After a form analysis of planning texts, a sentence or several sentences containing a specific meaning group will be clearly separated. According to semantic contents of the text, text contents are further analyzed to develop basic items for the evaluation and analysis.

In general, basic elements (concepts) in the text content analysis include: event, action, role, subject/actor, object/receptor, thing, matter, etc. The purpose of the text content analysis is to identify the meaning of a sentence, paragraph or article. To put it simply, the text content analysis is to find answers to 4 W1H (Who, What, When, Where and How). In the “Environmental Protection Plan in Jilin Province”, sentences have 4 kinds of semantics, including the statement of the past and present situation, prediction of related factors, guiding requirements and constraints of specific targeted issues. Specific methods for the text content analysis are as follows.

3.1 *Requirements for developing evaluation items of declarative sentences*

Generally speaking, in the “Five-year Environmental Protection Plan in Jilin Province”, declarative sentences are mainly used to declare past achievements and existing problems. In the content analysis, existing problems should be listed in detail, in order to facilitate preliminary judgments of the problem-oriented logic for the subsequent implementation.

3.2 *Methods for developing evaluation items of predictive sentences*

In the five-year environmental protection plan of Jilin Province, predictive sentences are mainly used to predict the future social and economic development. In the content analysis, trend prediction should be quantified, and the impact on specific issues and goals in the planning text should be built, to facilitate planning evaluation.

3.3 *Methods for developing evaluation items of restrictive sentences*

In the five-year environmental protection plan of Jilin Province, restrictive sentences are mainly used to put forward requirements for goals and specific requirements for tasks and some policy measures. The plan-implementing situation is evaluated mainly based on the semantics of these sentences. In the process of developing items for restrictive sentences, focus should be placed on finding out the personal liable for the plan implementation (who), time of implementation (when), place of implementation (where), the goal of implementation (what) and the way of implementation (how), to facilitate subsequent work in planning evaluation.

Table 1. Constraint statement entry production demonstration table.

Who	When	Where	What	Ways to achieve
The Government of the city seat	To 2016	City and county	All to build sewage treatment facilities	Government investment and other
The Government of the city seat	To 2016	City and county	Sewage treatment rate is not less than 70%	Government investment and other
The Government of the city where the city is located	To 2016	Whole province	Sewage treatment capacity reached 10 thousand tons/day	Government investment and other

For example, in the “11th five-year environmental protection plan of Jilin Province”, “in 2010, all cities should build sewage treatment facilities. The urban sewage treatment rate should not be lower than 70%, and the national urban sewage treatment capacity should reach 100 million tons/day.” These sentences are restrictive ones. 3 items of evaluation are developed by analyzing contents of restrictive sentences. Specific analytical results are shown in Table 1.

From the perspective of form, many restrictive sentences contain numerals. However, some restrictive sentences do not contain numerals, but use the logic word “whether (this work is done)” and introduce specific achievements. For example, “make total analysis and monitoring of the centralized drinking water quality at least once a year.” “Launch comprehensive collection of fees on urban sewage, garbage, hazardous waste, medical waste disposal and radioactive waste collection and storage.” These tasks have well-defined requirements, obvious achievements and great significance (see the plan-compiling specification and expert consultation, etc.). Items should be strictly developed for restrictive sentences in the text, to facilitate the follow-up planning evaluation.

The definition of the responsibility of restrictive sentences can be omitted, because the responsibility is usually allocated in advance, or the labor division is made in the jurisdiction competition, for completing goals, tasks or projects planned. The part with no well-defined liable person can be temporarily in the charge of the department of overall coordination.

4 SEMANTIC MODELING TECHNOLOGY FOR PLANNING EVALUATION

When the environmental protection plan of Jilin province is evaluated, the semantic model building is the end point for the constructive understanding of evaluation standards, as well as the starting point for the evaluation system building, so the semantic model building is a key link between the preceding and the following. The internal logical self-consistency and completeness of the semantic

model design directly determine the veracity and applicability of the evaluation results.

Through a form analysis and content analysis of the environmental protection planning text of Jilin province, evaluation items which have clear semantics and basically fixed categories are developed. When analyzing simply-structured planning texts (such as texts which just contain goals and specific issues to implement), we can achieve semantic logical integration of evaluation items simply by observing the relationship of feature word sets, to establish a general evaluation model framework. However, when planning contexts whose evaluation items have causality, inclusion, inclusion, overlapping and other complex relationships, correspondence, transformation, exhaustion, exclusion, deduction, induction and other logical analytical methods should be used to deeply analyze semantic logical relationships between the items. Meanwhile, the hierarchy process, logical framework analysis and PSR model analysis should be combined to build a semantic logical model for the planning texts. In general, semantic modeling technology for planning evaluation falls into two categories. One is the driving force-based model-building technology which has been quite mature, while the other is the interests-driven model-building technology which is emerging.

4.1 *Driving force-based model-building technology*

The “implementation of environmental protection plan in Jilin Province” as a comprehensive planning evaluation, in essence, is to evaluate multiple processes and issues in the environmental protection plan implementation. The driving force (mechanism) of these issues is a natural basis for building an evaluation semantic model. The driving force-based model-building method usually adopts the input-output, pressure-state-response or DPSIR (Driving force-Pressure-State-Impact-Response) model. This model-building technology is relatively mature and widely-applied, so unnecessary details would not be discussed in this paper.

4.2 *Benefit-driven model-building technology*

The stakeholder-based model building technology stresses that various stakeholders are involved in evaluation and the stakeholders have different opinions, run into disputes or even show anxiety in evaluation, so evaluators should focus on detecting the difference in stakeholders' demands for interests, coordinate or ease the difference according to the principle of equal rights and obligation, and eventually reach evaluation results that all stakeholders accept.

This evaluation model-building method should satisfy the following 2 conditions. On the one hand, evaluation is made up of opinions, anxiety and disputes of stakeholders. On the other hand, the constructivist paradigmatic methodology (that is, the methodology of hermeneutics: a common construction is established based on the same situation through continuous exposition, analysis, re-exposition and re-analysis of stakeholders. Evaluation is seen as a form of intents and actions which occur simultaneously and interact with each other.

1. Identify all stakeholders at risk in the planning evaluation;
2. Analyze each stakeholder group to figure out their construction of the evaluation object and desired opinions, anxiety and disputes related to the evaluation object;
3. Follow the information consistency, logical consistency, value consistency, rights-and-liability consistency and other principles of social consensus, so that different constructs, opinions, anxiety and disputes can be understood, criticized and considered;
4. Gain as much consensus as possible from the understanding, criticism and consideration;
5. Design one or more reports, so that stakeholders have convenience to communicate with each other about their constructs, opinions, anxiety and disputes;
6. Repeat the evaluation for those unresolved constructs and opinions, anxiety and disputes attached to the constructs. Results obtained in the last round of evaluation can be used for the next round of evaluation. Therefore, evaluation will never end, but can only be suspended.

5 CONCLUSION

It is recommended that the following evaluation technologies should be studied, in the process of semantic model building.

1. Popularize the application of computer information search and statistical technology in the analysis of text form, to improve the operation efficiency of the text form analytical technology.

2. The semantic modeling technology for evaluation should not just limited to get evaluation results based on the traditional cognition and modeling paradigm, but focus more on opinions, anxiety and disputes of stakeholders and their solutions and put forward more feasible recommendations for planning evaluation.

This paper introduced form analytical methods and content analytical methods of planning texts, presented 2 modeling technologies for planning evaluation, that is, driving force-based model-building technology and interests-driven model-building technology, and gave the following 2 recommendations for the future development of related semantic modeling technology. First of all, popularize the application of computer information search and statistical technology in the analysis of text form. Moreover, focus should be placed on opinions, anxiety and disputes of stakeholders and explore corresponding negotiated solutions.

Analysis and evaluation of the influence factors of waste packaging recycling in a circular economy

Ning Jiang, Kai Liu & Junjie Zhang

Department of Business Administration, Qingdao Vocational and Technical College of Hotel Management, Qingdao, China

ABSTRACT: Waste packaging is a kind of resource recycling. Recovery and recycling of waste packaging is an important part of developing a recycling economy and promoting energy savings and environmental protection. Now, the overall recovery rate of waste packaging is low in China. How to recycle and reuse the packaging material efficiently has become a subject, which everyone must face and participate in. This paper summarizes the related factors that affect the packaging recovery efficiency, adopts SPSS statistical software for factor analysis, finds out the main influence and corresponding evaluation index, and uses a practical example to verify its practicality and effectiveness.

1 INTRODUCTION

The circular economy is the mode of economic growth, which under the guidance of sustainable development achieves waste reduction, efficient use of resources, and recycling. The packaging industry is a resource consumption industry. Every year, the waste packaging material accounts for about one-third of urban domestic waste. Although some of the packaging has been recycled, such as cartons, bottles, and so on, the rate of most waste packaging is low. Therefore, putting the packaging industry into the orbit of the circular economy has become an urgent problem, and it is very much necessary to analyze and evaluate the factors that affect the recycling of waste packaging.

2 FACTORS AFFECTING THE RECOVERY OF PACKAGING

At present, the recycling of waste packaging, such as packaging collection, classification, transportation and other sectors are responsible for the third-part recycling enterprises. The packaging manufacturer is not directly involved in the recovery. It is only responsible for reprocessing of the “product” (Wu 2011). The main pattern of operation is shown in Figure 1.

Considering each node in the recycling network is referring to the previous research results of many scholars, we know that the recycling of waste packaging is affected by many factors such as manufacturing enterprises, recycling enterprises, consumers, and the government (Li 2013,

Liu 2008, Wang 2012). The influencing factors are shown in Figure 2.

Because there is a certain correlation between each factor, the information reflected will overlap to a certain extent, which causes information redundancy and reduces the actual operability. For this reason, the factor analysis method was used to screen and simplify the factor index, and to find and design one or more comprehensive factors.

Figure 1. Operation pattern diagram of waste packaging recovery.

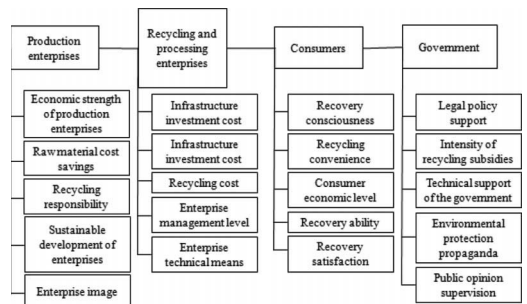

Figure 2. Influencing factors of waste packaging recycling.

3 BASIC PRINCIPLE OF FACTOR ANALYSIS

Factor analysis is an important branch of multivariate statistical analysis and its purpose is to condense data. The main information of the original variables is expressed by the correlation study.

Assuming there are n samples for the multi-criteria problem $X = (X_1, X_2, \dots, X_k)$, and the reasons for the problem are various, in which the common reason is called the common factor, using F_j to express it, among them are mutually orthogonal. Each component of X_i has its special reason, called special factor, using e_i to express it and that they are not related to each other, and only have an effect on the corresponding X_i . F and E are independent of each other. So the mathematical model of factor analysis can be expressed as:

$$\begin{cases} X_1 = a_{11}F_1 + a_{12}F_2 + \dots + a_{1m}F_m + e_1 \\ \dots \\ X_k = a_{k1}F_1 + a_{k2}F_2 + \dots + a_{km}F_m + e_k \end{cases} \quad m < k; a_{ij} \text{ is}$$

the load of a common factor, which is the j factor

of i variable. Matrix $A = \begin{bmatrix} a_{11} & a_{12} & \dots & a_{1m} \\ a_{21} & a_{22} & \dots & a_{2m} \\ \dots & \dots & \dots & \dots \\ a_{k1} & a_{k2} & \dots & a_{km} \end{bmatrix}$ is a com-

ponent matrix of the common factor. Finding out the common factor is done using some method to find out the factor component matrix A . For each factor, it is observed that there is a load on the variable that is larger and a load on the variable that is smaller, then according to the variable content

of heavy load, the meaning of factor is explained. Factor analysis model can also be expressed as $X = AF + e$ (Wang 2002).

4 EXAMPLE ILLUSTRATION

In order to study the main reasons for the low recovery rate of waste packaging, SD province conducted a special investigation, including the above 20 influential factors. Through visiting inquiring, on-the-spot investigation, the results of the investigation were finally obtained in 10 regions. Because the content of the investigation contained many qualitative indicators, so the first thing to do was to quantify the qualitative indicators, and then conduct a comprehensive evaluation and scoring by experts, and finally obtain the impact factor table, as shown in Table 1.

By observing the data in Table 1, statistical analysis software SPSS would be used to carry out the factor analysis, where the factors involved will be analyzed respectively. Here take the recycling processing enterprise as an example to explain the process of factor analysis.

Using the factor analysis method to deal with the factors of enterprise recovery processing, we can get the eigenvalue and contribution of correlation matrix R (as shown in Table 2 total variance explained), and can draw the scree plot of the common factor and the eigenvalue as shown in Figure 3 (horizontal coordinate is the component number and the vertical coordinate is the eigenvalue).

Table 1. The influence factors on the reverse recovery of waste packaging in different regions.

District	Factors	1	2	3	4	5	6	7	8	9	10

Environmental protection propaganda	0.184	0.835
Public opinion supervision	-0.080	0.812

largest, indicating that these 2 public factors can provide the original 5 indicators of sufficient information. At the same time, it is difficult to find the actual significance factor if the initial factor component matrix does not satisfy “simple structure principle”, so we adopt a method of rotating component matrix to achieve the purpose of simplifying the structure (Wang 2002) as shown in Table 3.

According to the above steps, we can get the results of factor analysis of manufacturing enterprises, consumers, and the government as shown in Tables 4–6.

5 MODEL RESULT ANALYSIS

From the data in Tables 3–6, it can be analyzed:

For recycling and processing enterprises, factor 1 mainly explains infrastructure investment cost, recycling channel construction, enterprise management level, and indicates that the basic

construction investment of recycling enterprises has a great influence on the recovery of waste packaging.

Factor 2 mainly reflects the impact of recycling cost, enterprise technical means, and indicates that the enterprise's recycling ability is also an important influence factor.

For production enterprises, factor 1 mainly explains the impact of the economic strength of production enterprises, the economic strength of production enterprises, sustainable development of enterprises.

Factor 2 mainly represents raw material cost savings, Enterprise image.

For consumers, factor 1 has a greater contribution on recycling convenience, Consumer economic level, recovery ability.

Factor 2 mainly reflects the impact of recovery consciousness, recovery satisfaction.

From the perspective of government, factor 1 has a greater contribution to legal policy support, the intensity of recycling subsidies, technical support of the government.

Factor 2 mainly reflects the impact of environmental protection propaganda, public opinion supervision.

Therefore, we can interpret above factors as recycling enterprises infrastructure investment, recycling enterprises processing capacity, production enterprise investment, the economic efficiency of production enterprises, residents' recycling literacy, residents' recycling environment, policy support of the government, social propaganda and supervision (Zhou 2012).

6 CONCLUSION

Factor analysis is a common method of multivariate statistical analysis to deal with high dimensional data. It can guarantee the minimum loss of

data information and can quickly extract important information from the original database, which makes it possible for people to make a full and comprehensive understanding of the problem.

In this paper, we selected the relevant data of 10 regions in SD province and studied the influencing factors of the reverse recycling of packaging waste. Taking into account the desirability of data, the paper selected 20 indicators to build an index system, and avoid the one-sidedness of the single index. Through factor analysis, 8 common factors were extracted and the evaluation results were obtained.

However, due to limitations of the index selection, some indicators are excluded due to data sources, and the factor analysis may affect the comprehensive evaluation of the final.

Construction and application of a water recycling system in crab–crayfish polyculture purification

Xiaoshuai Hang & Fei He

Nanjing Institute of Environmental Science, Ministry of Environmental Protection of China, Nanjing, China

Fangqun Gan

College of Environment and Ecology, Jiangsu Open University, Nanjing, China

ABSTRACT: Aquatic contamination caused by aquaculture has become a major concern in recent years, and the main pollutants are COD_{Mn} , Suspended Substance (SS), ammonia nitrogen ($\text{NH}_3\text{-N}$), Total Nitrogen (TN), and Total Phosphorus (TP). A water recycling system of attapulgite and artificial wetland was constructed to purify polyculture wastewater from crab (*Eriocheir sinensis* H. Milne-Edwards) and crayfish (*Procambarus clarkii*) pond breeding, and then the operation effect was also evaluated. Additional constructions were also designed in this system, including Aquaculture Pond (AP), Precipitation System (PS), Ecological Ditch (ED), Adsorption System (AS), Artificial Wetland (AW), water quality testing system (WS), and External Reservoir (ER). Attapulgite clay in AS had an excellent adsorption capacity of TP and $\text{NH}_3\text{-N}$ in synthetic wastewater due to its structure and physicochemical properties. $\text{NH}_3\text{-N}$ and TN concentrations in water decreased significantly in AW. Dissolved Oxygen (DO) in water increased in ED and AW, and the ED has good effects on SS and COD_{Mn} removal. The results of the recycling system indicate that it has an excellent performance of relieving aquatic pollution in crab–crayfish polyculture, without any wastewater discharge.

1 INTRODUCTION

The environment problem caused by the aquaculture industry has been increasingly serious in recent years and the major issue is water contamination and sediment pollution. The excreta of aquatic products, residual breeding baits, and medicines used in inland aquaculture farms could result in increasing accumulation of Nitrogen (N), Phosphorus (P) and COD_{Mn} into both water and sediments in downstream rivers and estuaries, which becomes an important source of eutrophication and other environmental problems (Boxall et al. 2004).

China is one of the countries with a long history of aquaculture in the world. According to the China fishery statistics yearbook 2016, there is 66,996,500 tons of total output aquatic product in China in 2015, and the amount of aquaculture is 49,379,000 tons. The national per capita share of aquatic products is 48.74 kg in China. The aquaculture area is 84,650 km^2 in China in the year 2015, mariculture and freshwater aquaculture area are 2317.6 km^2 and 61,472.4 km^2 , respectively. The proportion of freshwater aquaculture is 72.6%, including ponds, reservoirs, lakes, ditches, and so on. Ponds form the largest area in freshwater aquaculture, which is 27,012.2 km^2 . A great majority

of aquaculture is produced by inland-based freshwater or brackish water ponds, which rely on periodic effluent discharges into surrounding water bodies (Bostock et al. 2010).

Interactions between aquaculture and its surrounding environment are diverse and complex (Edwards 2015). The rapid expansion and intensification of pond aquaculture in China over the last two decades have attracted a lot of attention in the country, although there have been few studies on water quality used in aquaculture, the relationship between water quality and farm activity, and the impact of pond effluents on receiving waters. (Cao et al. 2007, Li et al. 2011). The Ministry of Agriculture in China has launched a nationwide initiative since 2006. The Action Plan for Promoting Healthy Aquaculture Development is to improve the efficiency and decrease the adverse environmental impact of pond aquaculture through improved land use and pond water recirculation with fewer effluents that cause pollution (Li et al. 2011).

There are many control measures of aquaculture tail water, such as physical methods, chemical methods, biological methods, and ecological methods. While most methods are expensive and also difficult to operate to meet the need of water recycling use, the artificial wetland is designed with the

concept of ecological regeneration and it becomes more and more popular in aquaculture wastewater treatment. In addition, the aquaculture tail water treated by artificial wetland can be used to recycle water. It has been reported that attapulgite clay can remove P and N from polluted water (Gan et al. 2010, Shi et al. 2013, Yin et al. 2016). Based on the excellent performance of both attapulgite and artificial wetland, there is a hypothesis that combining attapulgite and artificial wetland could better purify pond feeding tail water and implement tail water recycling. So this paper's aims are: (1) to evaluate pollution status of crab–crayfish polyculture water of an aquaculture farm in Xuyi County of Jiangsu Province; (2) to assess the removal capacity and performance of attapulgite from Xuyi County; (3) to construct and evaluate the recycling system with attapulgite and artificial wetland for crab–crayfish polyculture water in the aquaculture farm in Xuyi county.

2 MATERIALS AND METHODS

2.1 The study area

Xuyi is an important county in central Jiangsu Province in east China with a total area of 2497 km² and a population of 0.80 million at the end of 2015. The region is located at 32°43'~33°13'N and 118°11'~118°54'E. It has a warm and humid subtropical climate with an annual temperature of 14.7°C, rainfall of 1005.4 mm. Xuyi County is located downstream of the Huaihe River, and south bank of Hongze Lake. The study aquaculture farm is located at western Xuyi County, and the area of the aquaculture pond is 135 ha. Its main breeds are crab and crayfish.

2.2 Sorption capacity of attapulgite from water

The natural attapulgite clay samples were collected from the study aquaculture farm at Xuyi County (China). The adsorbent sample used was manually ground and selected for particles <100 mesh.

Artificial phosphate and ammonia nitrogen solutions were used throughout the sorption tests. Initially, a stock solution of 1000 mg/L in phosphorus and ammonia nitrogen was prepared by dissolving a certain amount of chemically pure K₂HPO₄•H₂O and NH₄Cl in distilled water, respectively. An aliquot of the stock solution was mixed with a certain volume of water so that phosphate and ammonia nitrogen solution were prepared at the desired experimental concentration.

To evaluate the phosphate and ammonia nitrogen sorption capacity of natural attapulgite, natural samples were used. The 25 mL of phosphate

stock solution with phosphate concentrations of 0.4 mg/L and 1.0 mg/L was added to 0.25 g adsorbent. The mixture was stirred at 200 rpm in a thermostatic shaker for 24 h at 25°C to ensure approximate equilibrium. After phosphate sorption, the solution was filtered through a 0.22 mm membrane filter and then analyzed for P. The quantity of adsorbed phosphate (sorption capacity) was calculated from the decrease in phosphate concentration in solution.

The 25 mL of ammonia nitrogen stock solution with concentrations of 0.5 mg/L and 5.0 mg/L was added to 0.1 g adsorbent. The mixture was stirred at 200 rpm in a thermostatic shaker for 24 h at 25°C to ensure approximate equilibrium. After ammonia nitrogen sorption, the solution was filtered through a 0.22 mm membrane filter and then analyzed for ammonia nitrogen. The quantity of ammonia nitrogen removal (sorption capacity) was calculated from the decrease in ammonia nitrogen concentration in solution.

2.3 Construction of recycling system for crab–crayfish polyculture water

The recycling system for crab–crayfish polyculture wastewater treatment consisted of aquaculture pond, precipitation system, ecological ditch, adsorption system, artificial wetland, water quality testing system, and external reservoir (Figure 1).

1. Aquaculture pond: Crab and crayfish were bred in a pond with mixed aquaculture. The crab stocking density is 12,000 heads per hectare on March every year and crayfishes have natural reproduction. There are many aquatic plants in the ponds such as *Elodea nuttallii*, *Vallisneria spiralis* (Lour.) Hara, and *Hydrilla verticillata*. Some snails and silver carps are also being bred in the ponds. Through the food chain cycle of producers, consumers, and producers, a three-dimensional aquatic ecological environment is constructed.
2. Precipitation system: Tail water from the aquaculture pond enters into the PS through a siphon device. There are many shrimps and shellfishes in the PS, which can help suspended substances settle down in the aquatic pattern. The suspended matter will be removed through a sand tank at the end of the PS.
3. Ecological ditch: The ED part mainly cultivates a lot of small indigenous grass, as well as a small amount of grass-eating fish.
4. Adsorption system: The AS is a ditch with its sediment mainly composed of attapulgite clay.
5. Artificial wetland: There are many aquatic economic plants and native landscape plants in the AW and an appropriate amount of grass-eating

Figure 1. Water recycling system of aquaculture tail water.

fishes and aquatic animals are also being bred in the ponds in the AW.

6. Water quality testing system: The indices of water quality were analyzed after treatment, including physical and chemical index, and biological indicators. The water quality was also tested by certain aquaculture products. In order to improve the aquaculture water quality, water will be pumped from WS to AP after meeting the requirements of aquaculture.
7. External reservoir: In order to maintain a cyclic water balance, the ER is used to add fresh water to the WS.

2.4 Sampling and sample analysis

Since the crayfish is on sale from June 10th to September 30th and the crab comes into the market from September 20th to December 30th, the water quality is the poorest in September from crab and crayfish polyculture. To test the purification effect of pond tail water by the water recycling system, the water samples were collected in September 2013 and 2014, respectively. The pH, DO, SS, TP, TN, $\text{NH}_3\text{-N}$, and COD_{Mn} in water samples are determined by the portable water quality analyzer (Hach, DR2800).

3 RESULTS AND DISCUSSION

3.1 Pollution status of crab–crayfish polyculture water

The quality of crab–crayfish polyculture water in 3 ponds is presented in Table 1. According to the relative standard values of Water Quality Standard for Fisheries (GB11607-89), Environmental Quality Standards for Surface Water (GB 3838-2002), and Quality Standards for Surface Water Resources (SL63-94), the values of SS, COD_{Mn} , $\text{NH}_3\text{-N}$, and TN in pond water samples were seriously beyond their threshold. The TP values in water samples from pond 2 and pond 3 were above its threshold value. Meanwhile, DO values in water samples are also not achieving its standard. These data indicate that the crab–crayfish polyculture pond could lead to water pollution. The pollution sources are excreta of aquatic products and residual concentrations of aquaculture baits and medicines used in polyculture ponds.

3.2 Sorption ability of attapulgite in wastewater

The P and $\text{NH}_3\text{-N}$ removal capacities of natural samples were analyzed from synthetic wastewater.

The results show that attapulgite adsorbent had a good phosphate removal capacity, which was 45.1% and 37.2% from initial synthetic wastewater with phosphate concentrations of 0.4 mg/L and 1.0 mg/L, respectively. Attapulgite adsorbent also had a good NH₃-N removal performance, which was 66.7% and 38.5% from initial synthetic wastewater with NH₃-N concentrations of 0.5 mg/L and 5.0 mg/L, respectively. Attapulgite is a vital non-metallic mineral resource at Xuyi and the total resource of attapulgite is 2.18 billion tons. Because

of its structure and physicochemical properties, the attapulgite clay has excellent adsorption properties (Gan et al. 2009) and could be used as a potential adsorbent.

3.3 Application effect of recycling system in crab–crayfish polyculture water

The application effect of the water recycling system in September 2013 and 2014 were presented in Table 2 and Table 3, respectively. The results

Table 1. The water quality of crab and crayfish polyculture ponds.

Pond	Time	pH	SS	COD _{Mn}	NH ₃ -N	TN	DO	TP

ER	6.85	15	6	0.86	0.97	8.98	0.03	
III standard value*		6~9	30	6	1.0	1.0	5	0.2

* III standard value of environmental quality standards for surface water (GB3838-2002).

Table 3. Operating results of the polyculture water recycling system in September 2014.

	pH	SS	COD _{Mn}	NH ₃ -N	TN	DO	TP	
WS	8.26	34	18.2	0.32	2.93	10.9	0.08	
Pond-1	8.11	46	26.5	0.62	3.49	4.6	0.17	
Pond-2	7.77	52	69.6	2.49	5.09	4.5	0.44	
Pond-3	8.33	42	76.3	1.39	5.09	6.5	0.40	
ED	7.82	12	39.4	1.03	3.09	8.2	0.22	
AS-1	8.65	28	18.3	0.69	1.93	12.1	0.07	
AS-2	8.55	30	22.9	0.46	4.82	12.2	0.07	
AW	8.68	8	12.7	0.13	1.53	11.7	0.02	
ER	7.34	14	26	1.08	2.02	2.5	0.46	
III standard value*		6~9	30	6	1.0	1.0	5	0.2

* III standard value of environmental quality standards for surface water (GB3838-2002).

suggest that the water recycling system had an excellent application effect. The ED has good effects on the SS and COD removal. The attapulgite in AS has a good adsorption capacity of TP in water. The $\text{NH}_3\text{-N}$ and TN in water significantly decreased in AW. The DO in water was improved in ED and AW. The crab–crayfish polyculture water could wholly meet the III standard value of Environmental Quality Standards for Surface Water (GB3838-2002) after the water recycling system. Owing to external causes, the water quality in ER was poor in September 2014. To maintain the cycle of water balance, the recycling water flowed into WS on one hand, and fresh water from the ER also added to the WS on the other hand. Water recycling was implemented in the whole system, and there was no wastewater discharge.

4 CONCLUSIONS

The crab–crayfish polyculture could result in water pollution. Artificial wetlands designed with the ecological regeneration concept become increasingly popular in aquaculture wastewater purification. Attapulgite clays have a good adsorption capacity of P and $\text{NH}_3\text{-N}$ in synthetic wastewater because of its structure and physicochemical properties. A combination of attapulgite and artificial wetland could be an enhanced method to purify polyculture tail water and the real application effect of the water recycling system indicates that it truly had an excellent performance on purifying the crab–crayfish polyculture water.

Sustainable energy industry coupled with social license to operate

Wan Shen & Ruifeng Li

Shenhua Science and Technology Research Institute, Beijing, China

ABSTRACT: From the present to the predictable future, coal remains the basic energy source around the world. Exploitation and utilization of coal resources plays a key role in sustainable development of world economy. Therefore, to ensure that coal resources can be exploited successfully, it's necessary to realize the sustainable development of the coal industry. The utilization of Social License to Operate in a scientific and reasonable way is closely associated with not only the successful implementation of an engineering project, but the healthy development of mining companies and social stability. This research conducts a data mining analysis on internet data in connection with coal exploitation in the past decade. A statistical review of factors affecting Social License to Operate of coal exploitation has been conducted on worldwide network media, search amount of internet users and report coverage of six representative print media. Through the above three channels, the order of importance regarding factors affecting Social License to Operate in connection with coal exploitation is obtained and verified. The results would provide strategic support and advice to world coal industry on sustainable mining on a global scale.

1 INTRODUCTION

With economic and social development, the requirement for energy is not limited to meet people's basic living standards. Comprehensive utilization of energy resources, reduction on damage to the ecological environment and concentration on the relationships with surrounding communities have become a new trend. With advancement of industrial technology, long term and significant development has been achieved for coal industry. The consumption of coal has occupied an important position in the energy mix. As one of main energies in the world, coal plays a key role in supplying energies required for economic growth and social development, as it has large reserve, relatively obtainable and highly reliable to satisfy energy needs in the world (Kraft John & Lee Chien-Chiang, 2008).

Coal is the most economic fossil fuel with large reserves and extensive distribution. The advantages also provide a guarantee for coal's leading role in the energy industry. However, the more the coal exploitation and consumption, the more ecological damage and environment pollution are and the more negative social image aroused. The coal industry will inevitably bring extensive, grave and even irreversible environmental problems while it guarantees economic development (Zhu Shuwen, 2010). The coal industry has caused large-scale damage to the land and vegetation, especially damage to the local landscape resulting from surface mining, which causes substantial imbalance between

regional environment and ecological systems. Coal gangue discharged during the production process causes severe pollution to lands, rivers and air. Industrial sewage discharged outside also cause severe pollution to underground water and rivers, lakes and seas. Meanwhile, a large amount of dust, CO₂, and SO₂ are produced in the process of coal production and consumption (Bian, H.I., 2010 & M.J. Chadwick, 1996). These problems have a direct effect on mining companies' development while negatively affect people's health physically and psychologically.

As the economy, politics and social culture are continuously developing, the relationships between coal companies, communities and society are also changing from time to time. Those conditions that coal companies depend on in their daily operations changes, thus coal companies must seek better approaches to deal with the relationships with local communities. Especially in recent years, as more and more people have kept their eyes on the social responsibilities of mining companies about environmental protection and sustainable development, the conflicts arising between coal companies and communities have become more furious. Coal mining offers job opportunities, builds industrial bases, and boosts taxation and incomes. On the other hand, coal mining has many negative effects on the society and environment, i.e. widening gap between the rich and poor, poor working conditions, corruptions, damage to environment and to physical and psychological health of employees. Thus coal industry has received more and more

criticisms from government, non-government organizations and local communities. Due to coal companies' involvements in the energy sector, their social responsibilities will be given more attention from society.

Pursuit of harmonious development among resources, environment, economy and society has become the focal point. The major and important topic that needs to be resolved imperatively in the theoretical research and practical exploration of the current phase is how to find an emerging industrialized path with respect to harmonious advancement of coal mining and social development. The concept of Social License to Operate (SLO) indicates a direction for the development of the coal industry (R.G. Boutilier, 2014). At the United Nations Conference on Environment and Development held in 1992, companies' social and environmental responsibilities were raised on the agenda followed by establishment of the International Coal and Metal Commission, which is an authority organization for the resource industry. At the same time, the review commission required the mining industry to issue the Transparent Mining Initiative. Since then, this concept has been rapidly accepted by mining companies around the world. Enormous large international mining companies began to employ sociologists, anthropologists and even genealogists to offer advice on social and environmental problems encountered in coal industry. From then on, the Social License to Operate has progressively become a requirement for normal operation of coal companies (S. Bice, K, 2014 & D.M. Franks, 2010).

The acquisition of a Social License to Operate is necessary for the reduction of social conflict risks and to boost a company's reputation. If no Social License to Operate has been obtained, additional economic loss will occur. There will be difficulties in employing a labor force and all kinds of cost increases will incurred and consequently cause operating costs to rise, the company to stop its production and even cause the closure of the mine due to objections from communities. The social actions of the mining company will have a direct effect on the social evaluation and authentication from communities. Therefore, acquisition of the Social License to Operate from local communities would enable companies to avoid potential risks, conflicts and extra costs. Grant of the Social License to Operate means communities will benefit from the company's project and both parties will aim at the same objectives. In the whole life cycle of exploitation, the company will realize development toward a win-win situation.

As the mining companies also are part of the social system, not only their actions affect the surrounding environment, but also the surrounding

environment and interested parties will affect mining companies in turn. And obtaining the Social License to Operate implies that this company acknowledges social responsibilities in the respect of environment and local communities, thus the local government would speed up to issue administrative approval and local residents will trust the company. Consequently, the company and the locals will form a positive relationship which is in favor of the development of the whole company. Once conflicts arise between the company and communities or any problem harmful to Social License to Operate caused by failure to maintain the relationships with people in the mining area, the company should find out factors affecting relationships and the influential extent, i.e. research factors affecting the Social License to Operate, then according to the extent of importance order to take measures. Only in this way most prominent social problems encountered by the company can be effectively identified and resolved in the priority order for specific purpose. In this case the risks incurred to the company arising from prominent problems will be avoided. Thus, the research on the Social License to Operate in connection with coal exploitation is of great significance for coal industries' sustainable development.

2 RESEARCH METHODS

This research applied data mining and analysis on mass information collected from the internet. First, this research carries out a statistical analysis on report coverage made by worldwide network media on factors affecting the Social License to Operate of coal exploitation. Based on the report coverage, the degree of attention to respective influencing factors by network media in the past decade is obtained. This degree of attention implies the significance of the order of respective factors affecting the Social License to Operate in connection with coal exploitation, thus we acquire the significance order of different influencing factors through the first channel. Next, we conduct a statistical analysis on the search amount on related influencing factors by worldwide internet users. According to the result, combined with the difference on search amount among respective factors, we obtain the degree of attention to respective influencing factors by worldwide internet users, where we acknowledge that the degree of attention to related factors by internet users is a decisive factor regarding significance of the Social License to Operate in connection with coal exploitation. Therefore, we acquire the significance order of different influencing factors through the second channel.

3 FACTORS AFFECTING THE SOCIAL LICENSE TO OPERATE

Social License to Operate (SLO) refers to the acceptance or support degree within local government, communities and media of the mining project developed by a mining company. SLO does not refer to a formal agreement or document, and does not have a formal or formalized assessment process or appropriate and institutionalized evaluation criteria. It depends on current creditability, reliability, and acceptance of mining companies and the projects. SLO mainly involves the relationships with stakeholders, especially with the local communities. The SLO is dynamic because stakeholders' perceptions can change over time and by region.

Firstly, the acquisition of the SLO has become a necessary process of mining companies to carry out mining operations. Similar to a business license, the SLO has become an indispensable part for mining companies to obtain mining rights. If they cannot obtain the SLO, it's hard to operate the mining operations in the local community due to difficulties in hiring employees, relocation or land occupancy.

Secondly, the acquisition and long-term maintenance of SLO is a necessary condition to reduce social conflicts. Company development is inseparable from the understanding and support of the community. This support is critical not only for dealing with "bilateral relations", but for their own long term development. Mining operations will inevitably bring to the local community problems, such as land occupancy, water pollution, etc. If the companies cannot get community support, then social conflicts may occur and result in delays or even coal mine shutdown.

Finally, the acquisition and maintenance of SLO can effectively reduce unnecessary expenditure and reduce financial costs. If a mining company cannot obtain the SLO, it means that the company has low social recognition, its credibility may be poor and investors will be more careful in investment. Thus, in order to attract business investors or social financing, the company will encounter big challenges to promote corporate image and earn business reputation. We must clearly understand that the cost to regain a SLO is far more than needed to maintain it.

In the above description, we have illustrated that coal companies cannot operate in isolation, and SLO has become a prerequisite for business success. Over the past decades, the coal industry has continued to make breakthroughs in technology, but the company profits increasingly depends on its ability to solve the "non-technical" issues, such as how to deal with the community,

non-governmental organizations, government departments and other stakeholders. Technology is not the only tool leading to business success. For business operations, "social license" is also a prerequisite. For coal enterprises, consider how to get SLO the first problem to be solved is to identify factors which influence obtainment of SLO. By survey of key stakeholders and through a literature research, we identified that the main factors affecting coal mining operation can be divided into eight areas: environmental pollution, safety, land resources, water resources, human rights, community engagement, low-carbon technologies and greenhouse gases.

4 ANALYSIS

For the importance of factors, this paper carries out a statistical analysis on related data of eight factors relating to coal exploitation (environmental pollution, safety, land resources, water resources, human rights, community engagement, low-carbon technologies and greenhouse gases) through three methods, so as to obtain the significance order of the eight factors affecting SLO of coal exploitation, and provide guidance and advice for factors needed to be given priority. The three methods are report coverage of global Internet media, search amount of global internet users and report coverage of global print media.

Analysis on the significance of influencing factors through report coverage of global internet media is conducted from the perspective of internet media in order to analyze the degree of attention on related factors by network media. As the fastest news communication media, the degree of attention on related factors by internet media reflects to a certain extent the significance degree of such factors. Analysis on the significance of influencing factors through search amount of internet users is conducted from the perspective of social publics in order to analyze the degree of attention to related factors by publics. As the direct stakeholder for development of coal companies, the degree of attention to related factors by social publics directly determines the significance degree of such factors.

Analysis on the significance of influencing factors through report coverage of print media is conducted from the perspective of print media in order to analyze the degree of attention to influencing factors by the society. Articles published in print media are usually relative specific, objective and even authoritative, as in terms of social event, print media will publish more detailed reports. Commentary articles reflect the degree of attention on such events by specialists and scholars.

Thus to study the factors affecting the SLO of coal exploitation, the degree of attention also embodies to a certain extent the significance degree of related factors.

After the significance orders are obtained through above three methods, we conduct comparative analysis on each of the three orders so as to summarize and verify their consistencies and conduct analysis on their differences, thus determining the significance order of factors affecting the SLO of the coal industry. This order result will provide a basis for the World Coal Industry to identify priority areas for future strategies, and also advices on the priority of influencing factors for companies to obtain the SLO.

In the results of the statistical analysis regarding the report coverage from global internet media on factors affecting the SLO of coal mining, our data mainly come from search results by applying the Google search engine for “coal + ‘influencing factor’” from September 2003 to October 2013. Statistics result is shown below:

From Figure 2, we can clearly observe, as time goes by, the report numbers of the Internet media on factors affecting the SLO of coal mining is constantly increasing, and with the simultaneous growth in this background, the report numbers of network media on each factor has apparent

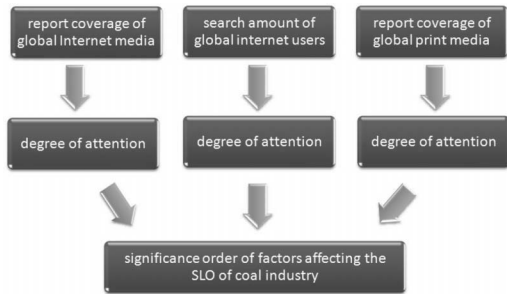

Figure 1. Three methods used to research on factors affecting the SLO of coal mining.

Figure 2. The reports numbers of global internet media on factors affecting the SLO of coal mining in the past decade.

difference and the report numbers from less to more are community engagement, low-carbon technologies, human rights, greenhouse gases, pollution, safety, land resources and water resources.

The Google trend platform is used for conducting statistical analysis on quantity of internet users’ search on factors which affect coal mining and social license to operate. The statistics on search quantity of internet users still adopts the eight keywords in the above-mentioned research. By conducting statistics on search quantity of relevant factors between October 2003 and October 2013, we can obtain the search quantity collecting figure. By analysis on statistic results and information represented by the figure, the search quantity of influence factors and attention paid on influence factors are obtained in line with the sequence. The following figure shows the statistical result.

Figure 3 takes the maximum search numbers of the eight factors between October 2003 and October 2013 as 100, and other search values are respectively displayed in 0–100 compared to the maximum value. It can be clearly observed from the figure that the search quantity of every factor shows certain volatility in the past ten years, but there are obvious differences in search quantities on different factors. The search quantity can be ordered as community engagement, human rights, low-carbon technology, greenhouse gases, land resources, safety, and environmental pollution and water resources.

Whether there is pressure of social opinion or enterprise social responsibility, both make print media comply with strict malfunction system and regulations in the course of publishing information and auditing contributions, ensuring preciseness, authenticity and even authority, especially for some print media with long history and large social influence. The report quantity of print media in allusion to influence factors objectively embodies attention degree of relevant experts, scholars and even government departments on influence factors. The difference in the attention also determines importance degree of influence factors in

Figure 3. Search quantity of internet users on factors influencing coal mining and social license to operate in last ten years.

the view of experts, scholars and even government departments.

In allusion to the impact of internet media, print media also improves its operation mode to avoid being eliminated. Netizens can read and inquire periodicals published respectively via the website of print media. This research adopts the retrieval mode of using “coal + influence factors” in official websites of relevant print media, to obtain report quantity of news reports or commentary articles of a certain media on influence factors related to social license to operate of coal mining from January 2010 to October 2013, then gathering retrieved results of all media and drawing out the figure, to analyze importance degree of influence factors and conduct the significance sequence.

This research selects 6 print media including the New York Times, The Economist, The Times, Financial Times, Wall Street Journal and TIME magazine. The following information briefly introduces the six print media and the reason for selecting them as statistical objects. The six media have a long history with wide circulation, authority in news reporting and commentary articles and high influence on the global scale. The six media all meet the requirements of this research in quantity and quality, so they are selected as statistical objects.

In the following statistical results, a curve chart is used for analyzing statistical results of different media. The horizontal axis is time and the vertical axis is report quantity. The statistical results of New York Times as an example are listed in the Figure 4.

Following the importance ordering of the factors for the statistical results obtained through the above three channels, we could divided these factors into 3 tiers. The summary of the three tiers is as follows.

Through the above summary table we can see that the three channels have totally the same idea

Figure 4. Quantity of report of New York Times on relevant factors in the past 13 years.

Table 1. Summary of the importance ordering of the factors obtained from three research channels.

	Extremely important	Important	Less important
Report amount by the global Internet media	Water	Land Safety Pollution	Human rights Greenhouse gas Low-carbon Community engagement
Search amount by the global Internet users	Water	Pollution Safety Land	Greenhouse gas Human rights Low-carbon Community engagement
Report amount by the print media	Water	Pollution Safety Land	Human rights Greenhouse gas Low-carbon Community engagement

on the importance of “water”, which is in the “extremely important” position in the three orderings. Therefore, we consider “water” as the most important factor affecting the social license to operate for coal mining. Meanwhile, the three channels also have a high degree of agreement on the importance of the three factors “land resources”, “safety problem” and “environment problem”. Though a slight difference in the degree of importance exists in the interior of the level, it does not affect our view about the general importance degree. Therefore, due to the consistency on the results, we treat the “land resources”, “safety problem” and “environment problem” as the “important” level. The three channels have certain differences on the importance degree for the four factors of “human rights”, “greenhouse gas”, and low-carbon” and “community engagement” with the main reason that the report quantity and retrieval quantity for these four factors are relatively less; thus, we combine these four factors into one hierarchy, the “less important” level.

5 CONCLUSIONS

SLO has become necessary and mandatory for coal enterprises to remain in operation; for coal enterprises to obtain an SLO is not only required for them to launch a coal mining operation, but also an effective guarantee to save their costs and improve their social image and reputation. Therefore, the coal industry should evaluate the importance of SLO and promote it among its member enterprises and organizations. Meanwhile, by collecting and using the data on the Internet in the abovementioned research, we also obtained the important

sequence of the factors which have influence on the SLO for coal mining, distribution charts of the global attention rate on each influencing factor and several well-known media's attention rates on relevant influencing factors. By making the research, we observed that the factor which has the most influence on the SLO for coal mining in current phase is water resources problems caused by coal mining, followed by land resources, environment and safety problems, and finally human rights, greenhouse gas, low-carbon technology and participation problems.

Based on the results, coal industry can take Public Relation (PR) strategies accordingly, providing specific countries or cities with help in respect to resources to improve the image of coal industry, promoting coal enterprises to obtain a wider SLO, winning understanding and support from the whole society. Simultaneously, we also research on influencing factors by different media, and we observed that different media pay different attention to different influencing factors, which is important for coal industry to select PR media and information releasing platforms.

Lab-scale treatment of biologically pretreated landfill leachate by the electro-Fenton process in a continuous flow reactor

Shaopeng Yuan, Xia Qin, Li Zhang & Mengnan Zhou

College of Environmental and Energy Engineering, Beijing University of Technology, Beijing, P.R. China

ABSTRACT: The lab-scale treatment of biologically pretreated landfill leachate by electro-Fenton (E-Fenton) was carried out in a continuous flow reactor using Ti/RuO₂-IrO₂ mesh anodes and cathodes. The effects of important parameters including voltage, hydraulic retention time, H₂O₂/Fe²⁺ molar ratio, and H₂O₂/COD₀ molar ratio on COD removal were investigated, and the optimum conditions for this advanced oxidation process were found. There was an optimal H₂O₂/Fe²⁺ and H₂O₂/COD₀ molar ratio so that the highest COD removal rate was achieved. The Dissolved Organic Matters (DOM) in the leachate were analyzed using ultraviolet spectrum and Excitation Emission Matrix (EEM) spectrofluorimetry. About 84.58% COD was removed and colority was completely removed after the E-Fenton process. The results indicate that the E-Fenton process is an effective technology for the treatment of biologically pretreated landfill leachate.

1 INTRODUCTION

Landfill leachate is strongly polluted wastewater that contains complex pollutants including organic compounds, ammonia, heavy metals, inorganic salts, etc. (Wu, 2011). Conventional biological treatment is an economical way to remove biodegradable organic compounds in the leachate. However, mature landfill leachate contains significant amounts of recalcitrant organic compounds such as Humic Acid (HA), Fulvic Acid (FA), and hydrophilic fractions, which cannot be effectively removed by conventional biological treatment (Atmaca, 2009). Therefore, the effluent of biologically treated mature leachate usually contains considerable amounts of refractory organic pollutants, which may pose hazards to the environment. The biologically treated effluents then have to be properly treated before they can be discharged into the environment.

In the past two decades, Advanced Oxidation Processes (AOPs) have received great attention as alternative methods for the treatment of various wastewaters and they have advantages over other conventional treatment techniques such as high removal efficiency, minimum treatment time, and less sludge production (Antonopoulou, 2014; Oturan, 2014). Moreover, AOPs are capable of transforming nonbiodegradable pollutants into nontoxic biodegradable substances (Wang, 2011). Since the year 2000, the electro-Fenton process has been used for the treatment of mature landfill leachate (Lin, 2000; Zhang, 2007; Orkun,

2012). Compared with the classic Fenton process, E-Fenton oxidation could offer significant advantages such as the continuous regeneration of ferrous ion at the cathode and consequently minimization of sludge production (Brillas, 2009), and the synergistic effect between the electrochemical process and the Fenton process (Lin, 2000 & Zhang, 2007). The reaction mechanism of E-Fenton technology is complicated, but its main involved reactions can be described by the following equations (Brillas, 2009, Rosales, 2012; Wang, 2013).

Generally, few studies have reported a lab-scale use of electro-Fenton technology in continuous mode for the treatment of landfill leachate. For this reason, a continuous E-Fenton reactor was developed in order to validate this technique in landfill leachate treatment at lab scale. The effects of various operating factors on E-Fenton performance were evaluated to determine the optimal reaction conditions, such as voltage, Hydraulic Retention Time (HRT), H₂O₂/Fe²⁺ molar ratio, and H₂O₂/initial COD (COD₀) molar ratio. The results indicated that E-Fenton treatment was an effective way to degrade the refractory organics in biologically pretreated landfill leachate. The average removal efficiencies of COD and colority up to 85.58% and 100% were achieved with 40 min of the

E-Fenton treatment. In order to gain insight into the dissolved organic matter in the landfill leachate before and after treatment, leachate composition in the influent and effluent of the E-Fenton reactor was analyzed by ultraviolet spectrum and Excitation Emission Matrix (EEM) spectrofluorimetry.

2 MATERIALS AND METHODS

2.1 Leachate collection and characterization

The leachate samples used in this study were sampled from a municipal landfill site (Beijing, China). In the landfill plant, the leachate had been treated via a combined process of UASB-aerobic-oxic (A-O) and submerged membrane bioreactor treatment (MBR). Its characteristics on average are shown in Table 1.

2.2 Chemical reagents

Hydrogen peroxide (30%, w/w), ferrous sulfate (FeSO_4) and all other chemicals used were in analytical grade unless noted otherwise. All solutions were prepared with deionized water.

2.3 Experimental apparatus and treatment procedure

The experiments were carried out in a rectangular electrolytic reactor with 12 L of working volume. E-Fenton experiments were conducted with Direct Current (DC) power supply. Seven 25 cm \times 17 cm mesh anodes ($\text{Ti/RuO}_2\text{-IrO}_2$) and seven same dimension anodes were positioned alternately, parallel to each other with the selected inter-electrode gap.

Sampling 5 L leachate, the initial pH value of the leachate was adjusted to 3 with diluted sulfuric acid and sodium hydroxide. When the DC power supply was initiated, the leachate was pumped into the reactor by a peristaltic pump. Then the hydrogen peroxide solution and ferrous iron solution were fed into the reactor separately. The treated waste water was discharged out of the reactor and

Table 1. The characteristics of landfill leachate.

Parameter	Value
COD (mg/L)	661.2–1016.74
Ammonia nitrogen (mg/L)	81.04–132.56
pH	7.98–8.06
Colority	850–1500
Color	Yellow

Table 2. Factor levels.

Level	Factors			
	Voltage/V	HRT/min	$\text{H}_2\text{O}_2/\text{COD}_0$	$\text{H}_2\text{O}_2/\text{Fe}^{2+}$
1	4.0	20	1	1
2	4.5	30	2	2
3	5.0	40	3	3

quenched the reaction by increasing pH to 8.5 by sodium hydroxide and diluted sulfuric acid.

2.4 Analytical methods

In order to determine the importance of various factors in treating biologically pretreated landfill leachate, an orthogonal experiment was designed to optimize the experiment condition. Factor levels are shown in Table 2.

After processing, the COD was measured by the potassium dichromate method. Dissolved Organic Matters (DOM) were measured with fluorescence and ultraviolet absorption spectrum.

3 RESULTS AND DISCUSSION

3.1 Analysis of the results

Orthogonal experiment design and results are shown in Table 3, and variance analysis shown in Table 4.

The range R_i is employed to evaluate the important order of the factors on the indicator. The factors with large range become the main factors while the ones with smaller values become secondary factors. From Table 3, the important order of these geometric factors on the indicator 'the COD removal rate' is as follows: $\text{HRT} > \text{Voltage} > \text{H}_2\text{O}_2/\text{Fe}^{2+}$ molar ratio $> \text{H}_2\text{O}_2/\text{COD}_0$ molar ratio.

The ANOVA results for calculated models are shown in Table 4. The ANOVA indicates that HRT plays an important role in the COD removal rate, whereas, in the selected range, $\text{H}_2\text{O}_2/\text{Fe}^{2+}$ and $\text{H}_2\text{O}_2/\text{COD}_0$ do not have significant effects on the removal of COD. Therefore, the process of practical application should focus on regulating HRT to enhance the COD removal rate.

Above all, the optimized conditions for the lab-scale continuous flow treatment of biologically pretreated landfill leachate by the E-Fenton process is a voltage of 5.0 V, HRT of 40 min, $\text{H}_2\text{O}_2/\text{Fe}^{2+} = 1$, and $\text{H}_2\text{O}_2/\text{COD}_0 = 1$. A further experiment was performed under proposed conditions and the removal rate of COD is 84.58%, the COD value of effluent water is 101.96 mg/L, the colority is almost zero.

Test (COD ₀ = 661.20 mg/L)					
No.	Voltage HRT		H ₂ O ₂ /Fe ²⁺ COD		
	(v)	(min)	H ₂ O ₂ /COD ₀	removal rate	
1	4.0	20	1	1	45.26%
2	4.0	30	2	2	44.35%
3	4.0	40	3	3	57.68%
4	4.5	20	2	3	36.49%
5	4.5	30	3	1	65.05%
6	4.5	40	1	2	71.57%
7	5.0	20	3	2	45.08%
8	5.0	30	1	3	72.09%
9	5.0	40	2	1	84.49%
\bar{K}_1	49.10	42.28	62.97	64.93	
\bar{K}_2	57.70	60.50	55.11	53.67	
\bar{K}_3	67.22	71.25	55.94	55.42	
R ₁	18.12	28.97	7.86	11.27	

Table 4. ANOVA of the COD removal rate.

Source of variance	Variance	F	F _α	Significant level
Voltage	246.5485	2.966	F _{0.05} = 4.46	
HRT	643.3960	7.739		*
H ₂ O ₂ /COD ₀	56.0150	0.674		
H ₂ O ₂ /Fe ²⁺	110.2575	1.326		
Pooled error	83.1375			

Note: F = variance (factor)/variance (error).
F_α is obtained from F value table for analysis of variance.
* stands for playing an important role.

3.2 Ultraviolet spectrum analysis to the DOM before and after processing

SUVA₂₅₄ represents the aromatic constituents in DOM and has been widely accepted as an index of the aromatic structure during composting (Wang K, 2013). The SUVA₂₅₄ values decreased indicating that the degree of aromaticity becomes lower in the liquid phase of the leachate (Caricasole, 2010). E-Fenton can also oxidize macromolecular organic matter to small molecules compounds containing the conjugated system and the double bond so that the molecular weight become lower.

Using the E-Fenton process to deal with biologically pretreated landfill leachate, the water quality parameters before and after processing are as shown in Table 5.

It can be seen from Table 5, SUVA₂₅₄ has greatly reduced after processing, indicating that the E-Fenton technology has a good removal effect

on the degree of aromaticity in the leachate and has a high conversion degree of macromolecular organic matter to small molecule compounds in the leachate.

3.3 Fluorescence analysis to the DOM before and after processing

Excitation-Emission Matrix (EEM) fluorescence spectroscopy has been widely used to characterize and monitor fluorescent Dissolved Organic Matter (DOM) in marine, freshwater, soil, and wastewater samples. EEM fluorescence spectroscopy is a highly sensitive, potent, and useful tool for characterizing DOM in wastewater (Maqbool, 2016). This technique has the advantages of being non-destructive, highly sensitive, rapid, and relatively inexpensive (Fellman, 2010). Fluorescence regional integration has been widely used for many environmental settings to characterize DOM, including landfill leachates (He, 2011, Wu, 2012). Filtered water samples are typically irradiated with excitation wavelengths from 200 to 450 nm and emission wavelengths recorded from 250 to 550 nm.

Generally, five regions in an EEM were operationally defined using consistent excitation (EX) and emission (EM) wavelength boundaries based on the fluorescence of model compounds and DOM fractions (Leenheer, 2003). The five defined regions are shown in Table 6 and Figure 1.

In Table 6, humic acid-like was a kind of degradation-resistant hydrophilic polymer based on diverse quinone and polyphenol as the aromatic core, which was formed by C, H, O, N, S, P, etc. elements. On the aromatic core, there has groups of carboxyl, phenolic groups, carbonyl, peptide, etc. In addition, there are a large number of benzene

Table 5. Water quality parameters before and after processing.

Water quality parameters	COD (mg/L)	SUVA ₂₅₄
Before processing	661.2	4.736
After processing	101.96	1.805

Table 6. The five defined regions of EEM fluorescence spectrum.

Regions	Ex (nm)	Em (nm)	Description
I	200–250	280–330	aromatic protein I
II	200–250	330–380	aromatic protein II
III	200–250	380–550	fulvic acid-like
IV	250–400	280–380	soluble microbial byproduct-like
V	250–400	380–550	humic acid-like

rings and functional groups such as -OH, -COOH, >C=O, -PO₃H₂, -NH₂, -CH₃, -SO₃H, -OCH₃, etc. Under the action of the oxidant, the class humic acid can be oxidatively decomposed.

The EEM fluorescence spectrums before and after processing are shown in Figure 2a and 2b.

As can be seen from Figure 2a, only humic acid-like is in the fluorescence of DOM, Figure 2b shows that after processing, the intensity of region V has greatly reduced which is about 20. Most of the humic acid absolutely mineralizes into CO₂ and H₂O with little changes into small molecule intermediates like aromatic protein and fulvic acid-like.

Fluorescence index $f_{450/500}$ refers to the intensity of fluorescence emission spectrum in the ratio of 450 nm to 500 nm, when the excitation wavelength was 370 nm. The $f_{450/500}$ and the aromaticity of humic acid showed a negative correlation relationship, the greater the $f_{450/500}$ value, the weaker the aromaticity of humic acid and lesser the benzene ring structures.

Figure 1. The five defined regions of EEM fluorescence spectrum.

Figure 2a. The EEM fluorescence spectrum before processing.

Figure 2b. The EEM fluorescence spectrum after processing.

Table 7. Index $f_{450/500}$ before and after processing.

Fluorescence intensity ratio	$f_{450/500}$
Before processing (a)	1.6
After processing (b)	3.1

Fluorescence spectral characteristics of DOM in the leachate samples before and after processing are shown in Table 7.

After processing, the $f_{450/500}$ value increased, indicating that after oxidation treatment, the aromaticity of humic acid attenuated in the leachate, so the benzene ring structure decreased, and this is consistent with the change of $SUVA_{254}$.

4 CONCLUSIONS

The results of the orthogonal experiment show the importance of the factors in treating biologically pretreated landfill leachate: HRT > voltage > H₂O₂/Fe²⁺ > H₂O₂/COD₀. Optimum conditions of dynamic continuous flow running mode for E-Fenton were found to be voltage 5V, HRT 40 min, H₂O₂/Fe²⁺ = 1, and H₂O₂/COD₀ = 1. Three parallel experiments were done under the conditions above, the average removal of COD and colority achieved were 84.58% and 100%, respectively. Hence, E-Fenton was recommended as a powerful technique for the degradation and decolorization of landfill leachate.

UV spectrum analysis results show that the E-Fenton process has a good removal effect on aromatic compounds. EEM spectrofluorimetry results show that E-Fenton oxidation technology has a good removal of macromolecular humic acid in the biologically pretreated landfill leachate.

Most of the organic matter can be decomposed into CO₂ and H₂O.

The water and sediment characteristics numerical simulation of dig-in basin in strong tidal estuary

Gong-jin Zhang, Chuan-teng Lu, Xiao-feng Luo & Yu-fang Han

Nanjing Hydraulic Research Institute, Nanjing, China

ABSTRACT: Taking Dandong Port as the representative of dig-in basin in strong tidal estuary, the author intends to make a research on the water and sediment characteristics of dig-in basin. By means of numerical simulation method, the study suggests that the hydrodynamic and sediment concentration decrease gradually from the harbor entrance to terminus in Donggou 1# basin. The differences of hydrodynamic and sediment concentration in harbor entrance are larger than that of harbor terminus. The harbor sedimentation intensity of spring tide is higher than that of neap tide, and the harbor sedimentation intensity in harbor entrance is higher than that of harbor terminus.

1 INTRODUCTION

Dug-in basin has been widely used in domestic port because of the less occupied or not occupied deep water coastline and the convenience of operation with a good mooring condition in the basin. The study about the excavated-in basin may be classified into four kinds on the basis of the research content:

The layout:

The main goal of the layout of dug-in basin was to determine the water area, the shape of entrance, and the trend of the channel entering the port. The size of water area of the basin would take an impact on the project investment and dock operation. After analysing the data of domestic excavated-in basin, Han Shi Lin (2005) suggests that it is necessary to increase the basin width of the criterion for more than one berth in the port side. Chen Jie (2013) argues that the shape of the entrance in the port will affect the mooring condition and the amount of back silting in the basin. Moreover, Pan Bao Xiong (1994) has highlighted the waterway axis direction into port and the effect on sediment volume and stability conditions.

The hydro-dynamics and berthing stability:

The study of dynamics in port always focuses on the backflow. In most recent years, it has been analysed by physical model or numerical simulation. Shen Xiao Xiong (2003) has compared the difference of the plane flow of port in variable angle between water flow and the dock; Wang Jia Hui (2009) has researched the three-dimensional flow characteristics in dug-in port; Ge Jian Zhong (2013) has studied the effect on the surrounding waters by excavating the pool of Hengsha East

Shoal. The calculation of surge element by wave mathematical model has been the subject of many classic studies in the mooring stability condition of excavated-in harbor.

Back silt:

The sediment in dig-in port is always caused by the reflux and the density flow (Xu, 2008). It appears the condition that the slit near entrance is more than that inside (Yu, 2011). Several methods about deposition reduction have been proposed. For instance: Xu Ying (2008) has studied the effect of entrance direction and stream in dock bottom to back silt, while She Xiao Jian (2014) has discussed the influence of bulwark at outlet.

Exchange of water:

The capability of water exchange is associated with the water area, the size of entrance and the local hydro-dynamics condition. Liu Pei (2014) has investigated the influence of the width of the gate on the water exchange capacity of the water body of dig-in basin in Lvsi harbor of JiangSu province. He Jie (2007) has studied on the water exchange ability for the excavated-in harbor basin impacted by the linked river's position and dredged way.

This paper researches on the hydrodynamic and back-silting characteristics of excavated-in harbor in strong tidal stream estuary by numerical model, detailing the understanding of dig-in port.

Dandong harbor is located at southeast of the Liaodong peninsula, the west bank of Yalu River estuary, north to the Yellow Sea, adjacent to Dalian, facing Korean Peninsula to the east across the Yalu River. It is the convenient and appropriate sea passage of domestic trade and international trade in east of the Northeast China and the easternmost global commerce port in mainland

Figure 1. Sketch map of DanDong Port Dadong harbor district.

coastline. There are three main ports in Dandong: the East Port, the LangTou Port and the HaiYang-Hong port. The East port (Figure 1) is located in the south of Donggang City, the west shore of the Yalu River mouth.

2 MATHEMATICAL EQUATIONS AND COMPUTATIONAL METHODS

The water flow and sediment transport equations can be written as:

$$\begin{aligned} \frac{\partial z}{\partial t} + \frac{\partial(Hu)}{\partial x} + \frac{\partial(Hv)}{\partial y} &= 0 \\ \frac{\partial u}{\partial t} + u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} + g \frac{\partial z}{\partial x} - fv + g \frac{u\sqrt{u^2 + v^2}}{C^2 h} \\ &= N_x \frac{\partial^2 u}{\partial^2 x} + N_y \frac{\partial^2 u}{\partial^2 y} \\ \frac{\partial v}{\partial t} + u \frac{\partial v}{\partial x} + v \frac{\partial v}{\partial y} + g \frac{\partial z}{\partial y} + fu + g \frac{v\sqrt{u^2 + v^2}}{C^2 h} \\ &= N_x \frac{\partial^2 v}{\partial^2 x} + N_y \frac{\partial^2 v}{\partial^2 y} \\ \frac{\partial HS}{\partial t} + u \frac{\partial HS}{\partial x} + v \frac{\partial HS}{\partial y} - \frac{\partial}{\partial x} \left(D_x \frac{\partial HS}{\partial x} \right) \\ - \frac{\partial}{\partial y} \left(D_y \frac{\partial HS}{\partial y} \right) &= F_s \end{aligned}$$

Among them:

H -total depth (m); z -water level (m); u, v the velocity component (m/s) along the direction of x and y ; t -time (s); f -Coriolis coefficient ($f=2w \sin \varphi$, w is the angular velocity of the earth rotation, φ is the area dimension); g - acceleration of gravity (m/s²); C -Chezy coefficient (m^{1/2}/s); N_x, N_y , The

turbulence viscosity coefficient in the direction of x, y (m²/s); S -sediment concentration (kg/m³); D_x, D_y suspended sediment diffusion coefficient in the direction of x, y (m²/s). F_s - sediment source function or sediment flushing silt function (kg/(m² s)); M_{ax}, M_{oy} the direction at the bottom of the river bed elevation changes in the direction of x, y ; M_{fx}, M_{fy} the direction of the bottom friction term in the direction of x, y .

Using triangular element mesh, the finite volume method is used to analyse the flow equation (1), with reference to the literature (Lu, 2013).

3 ESTABLISHMENT OF MATHEMATICAL MODEL

3.1 Model scope and calculation parameters

The upper boundary of the model is Dandong port, the offshore boundary is 30 m depth isobath, the west side of the boundary is the ocean red, and the east boundary is to south Xuanchuan of North Korea. The total length of model is 90 km, and the width is 76 km. The grid of local sea area of 1#

Figure 2. Sketch map of the range of mathematical model.

Table 1. Mathematical model calculation parameters.

Name	Parameter
Total number of units	109487
Minimum grid length	15 m
Time step	6 s
Roughness	0.013+0.013/h
The turbulence viscosity coefficient	1.5
Moving boundary	0.02 m
Sediment diffusion coefficient	10
Incipient velocity of sediment	Dou guoren formula
Sediment-carrying capacity	$S_s = \alpha U^2 / (hw)$

harbor pool of DaDong port was compacted, as shown in Figure 2. The terrain of mathematical model is the latest data of Donggang District in 2013, and the calculation of parameters can be seen in Table 1.

3.2 Mathematical model validation

3.2.1 Water level verification

The validation data from the synchronous observation of large, middle and neap tide level included velocity and sediment concentration on May 8th to May 16th, 2014. The location of the station can be seen in Figure 1.

Tidal results are shown in Figure 3, the trend of validation in Figure 4, and the sediment concentration in Figure 5. We can see from the results that in addition to individual points, the calculated data is similar to the measured data, and the relative error was less than 10%. Due to the situation that it can't simulate the difference of different waters and sediment particle size, bulk density, particle shape in the process of calculation, the verification bias of sediment is relatively large, but overall, the verify of sediment concentration can reflect the variation characteristics of sediment station.

3.2.2 Verification of the deposition of the harbor basin

In May 2013, Donggou 1# harbor has been excavated to the design of the bottom elevation, according to the measured data analysis of harbor twice on November 18, 2013 and April 14, 2014. Figure 6 (left). The sedimentation in harbor entrance is large, about 0.3 m. The sedimentation is more than 0.5 m in some area of harbor entrance

Figure 3. Validation of the tide.

Figure 4. Validation of power flow.

Figure 5. Verification of sediment concentration.

Figure 6. Verification of change of erosion and deposition of Donggou 1# (The left is the site map, The right is the mathematical model verification diagram).

inside. The more into the bottom of the basin, the smaller the sedimentation rate will be.

Figure 6 (right) is the mathematical model verification diagram. It can be seen from the chart that in Donggou 1#, the maximum sedimentation thickness is near the harbor entrance, and the sedimentation thickness is small in the internal harbour and smaller at the bottom end of the basin. The erosion and deposition population distribution of mathematical model is consistent with the actual measurement in general.

4 THE STUDY IN THE HYDRODYNAMIC FORCE AND SEDIMENT CHARACTERS FOR ESTUARY OF DIG-IN BASIN IN A STRONG TIDE AND WEAK FLOW.

The Yalu River estuary is a typical estuary of strong tide and weak flow in China, whose annual average tidal range is 4.51 m. The biggest rate of fluctuation is no more than 1.5 m/s during the spring tide. Then, we will study the hydrodynamic force and sediment characters of dredged harbor basins in the strong tide and weak flow estuary by using the Dandong Port, Dadong harbour district, 1# harbor basins as a representation.

4.1 Hydrodynamic characters of harbor basins

Figure 7 is the distribution of the biggest rate of fluctuation around the Dandong Port, Dadong harbour district, 1# harbor basins during a spring tide. We can see from the figure that at the entrance, the water power is relatively stronger. From the entrance to the basin interior, the water power weakens gradually. The water power of the central basin is stronger than that of both sides of the basin, which is related to the arrangement of entrance.

Figure 8 and Figure 9 are the comparison of hydrodynamic force entre spring tide and neap tide, and the sampling points are shown in Figure 7. From these figures, the hydrodynamic force of spring tide is obviously stronger than that of neap tide, and from the entrance to the internal part, hydrodynamic force will decrease. At the entrance, the biggest rate of fluctuation of spring tide is smaller than that of neap tide. Concerning the biggest rate of flood, spring tide is approximately 1 m/s, and neap tide is 0.5 m/s. Concerning the biggest rate of ebb tides, spring tide is approximately 0.8 m/s, and neap tide is 0.4 m/s. At the bottom of basin, the biggest rate of fluctuation of spring tide is larger than that of neap tide. The biggest rate of flood of spring tide is 0.04 m/s more than that of neap tide. However, the two biggest rates of ebb tides are approximate.

Figure 7. The biggest rate of fluctuation near the harbour.

Figure 8. The flood maximum velocity distribution.

Figure 9. The ebb maximum velocity distribution.

4.2 Basin sediment concentration distribution characters

Figure 10 shows the basin average sediment concentration of spring tide and maximum sediment concentration distribution. The main basin sediment concentration comes from offshore into interior of basin at the entrance. From the entrance to the bottom of the basin, with the gradual decrease of hydrodynamic force, a decrease trend of sediment concentration is also found.

Figure 11 and 12 show the basin sediment concentration distribution. These figures tell us that the sediment concentration gradually decreases from entrance to the interior of basin. While it is a spring tide, the hydrodynamic force is fort, and the sediment concentration is obviously higher than that of a neap tide. From the entrance to the bottom of the basin, the difference of sediment concentration entre spring tide and neap tide weakens gradually. At the entrance, the average and the maximum sediment concentration for spring tide are 0.20 kg/m^3 and 0.32 kg/m^3 , and for neap tide are 0.14 kg/m^3 and 0.11 kg/m^3 . At the bottom, the difference entre spring tide and neap tide is much smaller.

4.3 Basin back-silting characters

Figure 13 shows us the back-silting intensity distribution of spring tide and neap tide. Due to the water sediment concentration of spring tide being significantly greater than that of the neap tide, the back-silting intensity of spring tide is also greater than that of the neap tide. While it is a spring tide, from the entrance to the bottom of the basin, back-silting intensity decreases at a fast

Figure 10. The average sediment concentration (left) and maximum sediment concentration (right) when spring tide in harbour.

Figure 11. The average sediment concentration when spring tide in harbour.

Figure 12. Maximum sediment concentration when spring tide in harbour.

Figure 13. Characteristic distribution of the back and back in harbour.

rate. At the entrance, the back-silting intensity of Z-14#~Z-17# is similar, which is about 2.3 mm/d for spring tide and 1.2 mm/d for neap tide. From the entrance to the bottom, the back-silting intensity decreases. At the bottom, the back-silting intensity of spring tide and neap tide is close to each other, about 0.8 mm/d.

5 CONCLUSION

1. Based on the Dandong Port, the Dadong harbour district, and the 1# harbor basins, we can construct a tidal sediment mathematical model for estuary dredged harbor basins with a strong tide. The model hydrodynamic sediment and back-silting verify well.
2. For the Donggou 1# harbor basin, from the entrance to the bottom, the sediment concentration and hydrodynamic force decrease gradually. At the entrance, the difference of sediment concentration and hydrodynamic force entre spring tide and neap tide is bigger, and on the contrary, the difference is smaller at the bottom.
3. The back-silting intensity of spring tide is obviously greater than that of the neap tide, and at the same time, it is greater than that of the interior part at the entrance.

A method for detecting soil conditions of trenchless projects

D.B. Fu & C. Xia

Fuzhou Planning Design and Research Institute, Fuzhou, China

Y.F. Guo

Fujian Key Laboratory of Geohazard Prevention, Fuzhou, China

ABSTRACT: Trenchless technologies have been steadily growing in underground projects in urban areas. It is essential to obtain soil data at trenchless zones in order to successfully complete construction of underground projects. Consequently, a method for detecting soil conditions has been developed in this paper by the integrating Horizontal Directional Drilling (HDD) technique and cross-hole seismic tomography. Firstly, several small-diameter holes along trenchless projects are drilled by using the HDD technique, and Polyethylene (PE) pipes are installed along the designed path followed by placing detecting instrumentations in PE pipes. Travel times of each source–receiver pair are collected to reconstruct the velocity distributions between the boreholes. Finally, the soil conditions and anomalous zones are determined. To verify the feasibility of the proposed method, a main waterpipe constructed by the pipe jacking technique is taken as an example to detect obstacles distributed beneath bridges. The field results show that the proposed method is capable of detecting soil conditions for trenchless projects.

1 INTRODUCTION

Trenchless technologies such as pipe jacking and microtunneling have been used progressively in the installation and renovation of underground pipelines in urban areas owing to little disruption to traffic and nearby businesses (Struzziery et al. 1998). Compared to open-cut methods, the soil data is seen indirectly for trenchless methods, which may bring high risks during construction. Therefore, it is fundamental to develop a favorable method for detecting the subsurface conditions at a site.

Several geophysical exploration methods have been used extensively to detect underground information, which was primitively developed for natural resources exploration (Gupta & Roy 2007). Sakai & Takatsuka (1999) listed major geophysical exploration methods and their survey areas. Unlike borehole method, geophysical exploration methods assess ground conditions by measuring indirect data (such as velocity, attenuation, and wavelength of sound), which is controlled by ground properties. Among these existing geophysical exploration methods, the cross-hole seismic tomography is the most efficient exploration tool for detecting ground conditions. So far, a large number of applications and research about this method have been reported in the literature. Sakai & Takatsuk (1999) developed a new electric wave exploration system for detecting shallow strata boundaries in

urban areas and gave three experiments to verify its effectiveness. Bichkar et al. (1998) presented a genetic algorithm approach for detecting subsurface voids in cross-hole seismic tomography. Trivino & Mohanty (2015) assessed the crack initiation and propagation in rock from explosion-induced stress waves and gas expansion by cross-hole seismometry and FEM-DEM method. However, with the investigation and application increasing, problems gradually emerged in the cross-hole seismic method applied to detection of ground conditions, which involves:

1. Cross-hole configuration. Boreholes are perpendicular to the ground. Because underground pipelines in urban areas are usually linear underground structures, the borehole is simply able to show the results at the sections and the limit number along the planned route give insufficient information.
2. Image resolution and accuracy. The distances of boreholes directly determine the image resolution and accuracy. In the field surveys, the cross-hole configuration scheme needs to consider the distance of boreholes and the cost.
3. Complex surface conditions. Municipal pipelines are commonly seen beneath the road and constructed using the trenchless method when roads appear. Drilling the ground inevitably affects the traffic. In addition, difficulties exist in the detection of soil conditions beneath

existing structures when a subway crosses the existing buildings.

On account of the above issues, a geographical exploration technique for detecting obstacles of trenchless engineering (PN: ZL201310305447.5) is proposed (Xia et al. 2013). By integrating the HDD technology and cross-hole seismic tomography, the soil conditions in trenchless zones are perceived. The main water pipe constructed by pipe jacking technique is taken as an example to verify the feasibility of the proposed method.

2 A BRIEF DESCRIPTION OF EXISTING TECHNIQUES

2.1 Horizontal directional drilling technique

The HDD technology dates back to 1891 when the first patent was granted for equipment to place a horizontal hole from a vertical well (Carpenter 2002). The use of this technology has increased dramatically since the mid-1980s because of its environmentally friendly character.

The HDD process consists of three stages: pilot bore, back reaming, and pipe installation (Gokhale et al. 1999). The pilot bore stage consists of drilling a borehole along the designed path by using a small-diameter drill. Once the pilot hole is completed, the drill head is switched to a reamer. During the back-reaming stage, the reamer is pulled back to enlarge the bore path. On the final pipe installation stage, the pipe installation can either be performed in conjunction with the reaming stage or after the reaming is completed.

2.2 Cross-hole seismic tomography

The cross-hole seismic tomography involves the measurement of travel times of the ray path between two or more boreholes aiming to derive an image of seismic velocity in the intervening ground (Jackson et al. 2001).

The cross-hole seismic tomographic processing consists of measuring the travel times of all rays and restructuring the velocity distribution of target exploration zones. Firstly, the seismic sources and seismic receivers are placed in two boreholes. The travel times of each source–receiver pair are collected. Then the velocity distributions between the boreholes are reconstructed with the aid of mathematical inversion approaches such as the back-projection technique (Gilbert 1972), the algebraic reconstruction technique (Gordon 1974), and the genetic algorithm-based technique (Bichkar 1998) and so on. Because each soil property is corresponding to a velocity value, the anomaly

of the resulting velocity image can be regarded as obstacles.

3 A METHOD FOR DETECTING SOIL CONDITIONS OF TRENCHLESS PROJECTS

In this paper, a method based on HDD technique and cross-hole seismic tomography is developed to detect the soil condition in tunneling zones of trenchless projects, especially linear underground engineering (see Figure 1).

The proposed method includes five steps and is shown in Figure 2.

Step 1: Exploration scheme design

According to the field condition and exploration accuracy, the test scheme is designed, including determining the start point, end point, pipe number, and so forth. Three bore path schemes are delivered in Figure 3.

Figure 1. A method for detecting soil conditions of trenchless engineering.

Figure 2. Steps of the proposed method.

(a) Scheme 1

(b) Scheme 2

(c) Scheme 3

Figure 3. Design path schemes.

Step 2: Drilling and pipe installation

Several horizontal holes along the tunneling direction are drilled by utilizing HDD technique. These holes are close to the tunneling zones. Small-diameter PE pipes (usually 90 mm) are placed in holes due to its flexibility, abrasion resistance, and toughness.

Step 3: Coordinate measurement

The coordinate of boreholes is measured by the use of a gyroscope to minimize the error of velocity image.

Step 4: Instrument installation

Sources and receivers are placed in boreholes. The borehole layouts are dependent on the tunneling area and exploration. Figure 4 illustrates three borehole layouts.

Step 5: Cross-hole seismic tomography

The velocity image is termed a tomogram by using measurements, which has taken a large number of rays with wide angular ray coverage (as illustrated in Figure 5). Consequently, the soil conditions and anomalous velocity zones are able to be determined.

(a) Scheme 1

(b) Scheme 2

(c) Scheme 3

Figure 4. Schematic diagrams of drill layouts.

Figure 5. Cross-hole configuration.

Figure 6. Exploration zone.

4 EXAMPLE

The proposed technique is applied to explore the tunneling zone of the main water pipe beneath the existing bridge. The pipe is constructed by the pipe jacking technique. The diameter and depth of

Figure 7. Source-receiver geometry and test sections.

Table 1. Anomalous zones.

Section	Number	Stake	Depth
W1	1	40.5 ~ 44	-10.5 ~ -11.5
	2	59.5 ~ 61	-10 ~ -11.5
	3	78.5 ~ 81.5	-9 ~ -9.5
	4	86.5 ~ 89	-10 ~ -11
W2	1	42.5 ~ 46	-8.5 ~ -9
	2	61 ~ 64	-10 ~ -11
	3	71 ~ 78	-9 ~ -10.5
	4	86 ~ 91	-8.5 ~ -10

water pipe are 1000 mm and 10.5 m. The bridge width is approximately 30 meters. The field condition is shown in Figure 6.

The obstacles such as the piers of the bridge, ripraps, and root may appear in the tunneling zones. Therefore, it is necessary to explore the distribution of obstacles for successfully constructing the water pipe.

4.1 Exploration scheme

The test zone is taken as the width of bridge plus 14 meters on both sides. The borehole path of HDD technique is designed as shown in Figure 3 (c). The entry angle and exit angle of PE pipes are 20°. The maximum pullback force and torque of the device for horizontal drilling are 380 kN and 12 kN·m. A total of three PE pipes defined as Q1, Q2, and Q3 are placed. The diameter of these pipes is 90 mm. The sparker source is placed in Q1, while the hydrophone receivers are placed in Q2 and Q3. The distance between the source and receiver are 3 meters. A total of two sections defined as W1 and W2 are tested. The source-receiver geometry and test sections are shown in Figure 7.

4.2 Results and discussion

Figures 8 and 9 show the result images of W1 and W2. It seems that the average velocity of test zones is 1800 m/s, and some anomalous zones (as listed in Table 1) appear in the exploration zone. These anomalous zones are beneath bridges, which may be stones. The following boreholes verify these results. It shows that the proposed method is able to detect the soil conditions and identify obstacles.

Figure 8. Inversion imaging results of W1.

Figure 9. Inversion imaging results of W2.

5 CONCLUSIONS

A new method based on HDD technique and cross-hole seismic tomography is developed to detect the soil conditions in the tunneling zones of trenchless projects. A water pipe project constructed by pipe jacking technique is taken as an example to verify the feasibility of the proposed method. The test results demonstrate that the proposed method is capable of identifying the anomalous zones and has little impact on field conditions. Yet, this method has been applied to several projects and produced a good effect. Authors believe that this method would be able to expand on another similar engineering, such as subway, electric power tunnel, and utility tunneling, and so on.

Comparison of thermal hydrolysis and wet air oxidation in sludge treatment in China

L. Peng & L.L. Hu

Sichuan College of Architecture Technology, Deyang, Sichuan, China

ABSTRACT: Wet Air Oxidation (WAO) and Thermal Hydrolysis (TH) are both associated with high temperature and high pressure. Both processes have been receiving increasing attention in sludge treatment over the last five years, especially TH as a pretreatment for Anaerobic Digestion (AD) has become a research hotspot in the world, including China. Sludge source and characteristics, energy consumption, and running cost technology are important factors. Both WAO and TH can reuse energy and heat by steam recycling, heat exchange, and system design. Typical commercial applications of WAO and TH in China are illustrated. WAO has been applied to sludge treatment to reduce moisture to 45%–48% from 80% with a running cost of 150–200 RMB per ton, while TH is used as an independent technology to achieve 50% of water content from 80% with 120–150 RMB per ton.

1 INTRODUCTION

As China is in the course of urbanization, the number and capacity of wastewater treatment plants are growing rapidly, and more and more attention is paid to sludge treatment and disposal. Sewage sludge commonly contains large amounts of water (including free water, interstitial water, and bound water), microorganisms, and mineral components (Qi and Thapa 2011, Vaxelaire and Cézac 2004). Chemical sludge from various factories usually includes toxic pollutants such as heavy metals, refractory organic matter, hormones, and colored substances.

Some current disposal and reuse practices are prohibited or questioned. Since land can no more be filled constantly, the landfill is not the recommended technology in China. Destruction of organic matter of biosolids is achieved by incineration, but secondary air pollutants and the high cost of building and running the facility makes it hard to be widely applied. Recycled sludge as an adsorbent, microbial consortium, plant, bulking agent (wheat husk) and nutrients are researched in the study of toxic materials in sludge (Nanekar and et al 2015). Compared to incineration, Wet Air Oxidation (WAO), which is a well-established process for toxic and hazardous organic wastewater treatment (Kanhaiya and Anurag 2015), generates minimal air pollution problems, maximum sludge solid reduction, and low environmental impact with a closed-loop water system. But industrial facilities used in the 1990s in the world were closed or capacity reduced because of high energy

consumption with a temperature of 240–300°C. Anaerobic Digestion (AD), which is mostly applied in China (25 sludge treatment plants of 400 wastewater plants by the year of 2008) (Wu and et al 2008) is suggested by Chinese technology policy, but high cost in building and low efficiency of gas production raise barriers to its development. Thermal Hydrolysis (TH) is a kind of pretreatment usually used before AD to improve dewaterability of sludge by destroying microbial cells and increasing biogas production (Neyens and Baeyens 2003). To reduce the costs of sludge management and handling, sludge dewatering is crucial, no matter which technology is adopted.

WAO and TH are considered as optimal solutions to the sludge problem and have been widely researched. However, no work has been attempted to compare TH and WAO in research studies and industrial applications in sludge treatment, especially in China. This paper summarized and compared the research studies of TH and WAO in research trends of sludge treatment and industrial factors combined with the actual situation in China. Finally, typical industrial facilities of WAO and TH in China and their conditions are illustrated.

2 RESEARCH STUDIES

To compare the research trends of two technologies in the world and China, data collection and analysis were accomplished in a database of Web of Science and China National Knowledge

Infrastructure, which reflect the research studies in the world and China, respectively.

In a brief search in Web of Science, hits were obtained for the term “wet air oxidation *sludge”, compared with the term “thermal hydrolysis* sludge” (Figure 1).

WAO and TH both have a long history of sludge treatment. Thermal hydrolysis was mainly used to improve the sludge dewatering performance in the 1930s, with an increase in the anaerobic digestion performance sludge in the late 1970s and carbon source of denitrification in the 1990s (Zhi jun et al 2003). While research on Thermal Hydrolysis (TH) in sludge treatment have been booming over the past 10 years, it has contributed to the rapid development of Anaerobic Digestion (AD) technology, taking TH as a favorable pretreatment, as 80% of the TH studies have been related to AD. WAO was developed in 1967, and various techniques of WAO in sludge treatment were developed between 1990 and 1995 and applied for industrial use in Europe (Debellefontaine and Foussard 2000). For high temperature and pressure, WAO was regarded to be an energy-extensive solution to sludge, as well as resource wasting technology as it oxidizes the organic substance instead of reusing them.

Same keywords in Chinese were searched in China National Knowledge Infrastructure (CNKI), and results were as shown in Figure 2.

Research on WAO in China mostly concentrates in the introduction, parameter adjusting, and optimal conditions before the year 2000. In the recent 15 years, catalysis, dewatering character of sludge, and organic recomposing process were investigated (Baroutian et al 2013). TH technology focused on the transformation of pollutants in the process and influence followed in AD with different parameters (Feng et al 2014,) or effects of mixing with different waste (Lombardi and et al 2015).

Study trends of WAO and TH in China both show a good correlation, no matter the technology,

Figure 1. Published work number (data search in Web of Science).

Figure 2. Published work number (data search in CNKI).

parameter, or material. The research on WAO in China has at least a 10 years lag than abroad (1980 compared with 1970), which simply reported the technology compared with the effect study with experiments, while the delay time of TH is shortened to 5 years (1998 compared with 2003) with the wide spread of Internet and awareness of the importance of dissolving problems of sludge disposal in China.

3 INDUSTRIAL APPLICATIONS IN CHINA

3.1 Sludge types

According to the source of sludge, it can be briefly divided into sewage sludge or similar sludge and industrial sludge, but in commercial applications, composition and characteristics of sludge are the key factors in selecting the treating technology.

In the past decades, a lot of research focused on the technology of treatment of the sludge from the sewage plant such as agriculture and soil reclamation, ocean disposal, sanitary landfill, burning method, and other recycling technology. (Yu and Tian 2014, Wang 2013). There are plenty of studies on the dehydration properties of sludge and the conclusion indicated that the pretreatment of TH has a positive impact on sludge dehydration (enhances gas production and accelerates reaction) (Xun and Wang 2009). Characteristics of sludge and property change in the process, especially water content and organic composition were researched widely. Based on sludge research, the application of WAO (Bengao and You 2014) or catalytic WAO in sludge treatment has been studied.

3.2 Energy consumption

In many cases, energy requirement impacts the commercial application of TH and WAO processes

in sludge treatment systems, especially in a developing country like China. TH and anaerobic digestion are usually discussed and evaluated together. It was found that the feed concentration of sludge must be increased (from 3%-7% in total solids) in order to become energetically self-sufficient in the TH system (Pérez-Elvira et al 2008). An energy integration scheme which considered heat recovery from the flash vapor outlet of the reactor can lower the required feed concentration.

To maintain the reaction temperatures, TH processes generally require more input of energy than WAO, which becomes auto-thermal at higher temperatures due to exothermic oxidation. As an independent process in sludge treatment, TH and WAO both need sludge heating while the energy in those processes is mostly spent. Implementing an energy integration scheme of the system to recover excess heat will be necessary for decreasing the heat energy consumed in TH and WAO process. There is another option that changes the energy source. The most widely used heat source now in China is steam, but electric heating is occasionally employed, as well as solar energy, microwave radiation, and heat pump.

Steam production needs a generator and it has been mostly used when a power plant or central steam supply is available around. Microwave heating has been widely used in system design as the system can achieve rapid heating both internal and external (Jones and Lelyveld 2002). As a microwave generator, developing and applying it in the industry can be a sound heat source for it can reduce reacting time of TH from 5 to 15 min and from 30 to 60 min (Qiao et al 2008). In sewage sludge treatment, microwaves are researched and used in sludge drying (Idris and Khalid 2004), stabilizing, and quality adjusting. Solar energy and heat pumps are usually applied to the drying process of sludge for energy reservation in a small temperature scale.

Despite consumption, energy recovery from waste treatment process is a trend in the world. Also, recycling and utilization of energy and resources of sludge are encouraged in the technology policy of China (Ministry of Environmental Protection of the People's Republic of China 2009).

3.3 Final disposal paths

For sludge, the final disposal of TH and WAO products from the industry can be divided into three phases, solid, liquid, and gas. The largest volume of sludge is in liquid form, but it is usually flowed back to wastewater treatment plants and decomposed by microorganisms, so that biodegradability and toxicity of liquids are vital parameters in evaluating. Gas contains organic and inorganic

gases, which can be adsorbed by adsorbent or microorganisms, washed out or burned. Solid is most refractory for its high moisture and perishable organics, which makes it hard to transport, landfill, incinerate, and reuse. The content of cake dry solids is required to be greater than 40% (w/w) according to some China Standards (GB16889-2008, GB/T 24602-2009) if the solids take the landfills or incineration as the final disposal.

The final disposal path of solid products as an important part of sludge treatment is determined by the process adopted. According to requirements of the urban sewage treatment plant, sludge treatment and pollution control technology policy of China (2011), the principle of "safety and environmental protection, recycling, saving energy and reducing consumption, adjustment measures to local conditions, steady and reliable" are all raised in the sludge treatment and disposal process. The landfill, incineration, and compost are commonly chosen now in China, but TH combined with AD, even TH alone, and WAO receive more attention in industry applications for its green final disposal in liquid, solid, and gaseous state at the same time.

4 TYPICAL INDUSTRIAL FACILITIES IN CHINA

4.1 Yancang sludge disposal center

The Athos process by Veolia Water is one of the main WAO sludge treatment technologies currently provided commercially, which operates at temperatures between 250–300°C, using air or pure oxygen as the oxidant and claims to produce mineral products, clean gas emissions, and biodegradable liquids. As far as observed, no typical Athos process is employed in China.

A Chinese patent about Partial Wet Air Oxidation (PWAO) in sludge treatment was granted in the year 2013. The biggest feature of PWAO are lower reacting temperature and pressure (160–220°C, 1.5–3.0 MPa), with its export of solid moisture below 50%, and the solid disposal can be used as a plant food or matrix for improving soil quantity. Partial oxidation means oxidizing 30%–50% of organic matter that is unstable and perishable by macromolecules.

The first commercial PWAO in a sludge treatment plant began operating in 2014 in Yancang (Zhejiang province of China), to treat 100 tons per day (moisture 80%) of mixed sludge with 70% leather processing sludge and 30% municipal sludge from a wastewater treatment plant in the industrial zone. This system consists of three parts as shown in Figure 3.

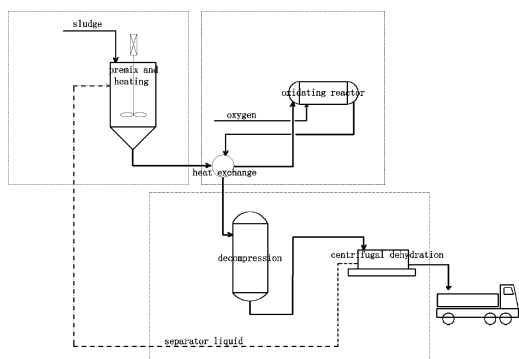

Figure 3. Process flow diagrams of PWAO in Yancang.

The sludge treatment plant was located in the wastewater plant right beside the workshop of sludge dewatering. Mixed sludge and liquid flowed back forming slurry with 86%–92% moisture and was heated in the premix heating part. At the oxidation reactor, the oxidation of organic ingredients starts when temperatures rise between 160 and 180°C. The oxidized liquor in high temperature is piped back to the premixed part after centrifugal dehydration. Energy and heat recovery and exchange sections are designed to lower the energy consumption. The solid products of the line are used as a matrix of soil improvers or to be land-filled with the moisture between 45%–48%.

The heat source of the plant is electricity, which is flexible and plenty in many places. The global treatment cost is reported to be only 150–200 RMB for one ton of sludge with the moisture of 80%. If steam can be used as a heat source or the product has been sold out, the cost can be further decreased.

4.2 Mianzhu municipal sludge treatment equipment

To meet the standard which retained the moisture below 60%, dewater property can be enhanced by TH alone. Despite that it is not followed by AD, the product can be landfilled within a short reacting time (30–90 min) with a small-scale equipment instead of a large anaerobic digestion tank.

A commercial sludge treatment plant in Mianzhu (Sichuan province of China) was operating for over one year since 2013 with its capacity of 50 tons a day (80% moisture). The diagram of the system is as shown in Figure 4.

Sludge from the wastewater treatment plant is piped into three stage heating with reused steam and steam from the generator. Then the sludge is passed through the laminar flow reactor in order to maintain enough time at a given temperature (150–180°C). Two-stage decompressions make the

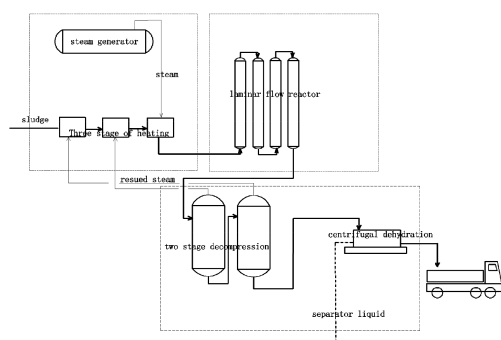

Figure 4. Process flow diagrams of TH in Mianzhu.

sludge easy to be dewatered by centrifugal dehydration and recycling the steam heat. The separated liquid is delivered back to the wastewater treatment plant or treated by a supporting device.

Sound and stable effect has been achieved. The line exported solid maintains 50% moisture, but additional section needs to be set if the solid has to be reused because of smell that comes from the unoxidized organic matter in solid form. The cost for the line is 120–150 RMB for one ton of sludge with the moisture of 80% since steam is applied as a heat source.

5 CONCLUSION

Wet Air Oxidation (WAO) and Thermal Hydrolysis (TH) were both paid increasing attention in sludge treatment in the last 5 years, especially TH as a pretreatment of Anaerobic Digestion (AD) is hot worldwide, as well as in China. Sludge source and characteristics, energy consumption and running cost of sludge treatment technology are important in selecting the method. Both WAO and TH can reuse energy and heat by steam recycling, heat exchange, and system designing. Typical commercial applications of WAO and TH in China are illustrated. Partial Wet Air Oxidation (PWAO) is developed from WAO and has been applied to sludge treatment, which can reduce moisture to 45%–48% with running cost of 150–200 RMB per ton (80% moisture). TH used as an independent technology to treat sewage sludge and 50% of water content can be achieved with 120–150 RMB per ton (80% moisture).

Enhancement of aerobic granulation with real domestic wastewater by powdered activated carbon addition

Changwen Wang, Bao Li, Shaoyan Gong & Ying Zhang
College of Resource and Environment, Linyi University, Linyi, China

ABSTRACT: Aerobic granulation with real domestic wastewater is difficult to be achieved and usually takes a long granulation time. This study investigated the feasibility of adding powdered activated carbon to enhance the granulation process. It was found that only 37 days were needed to form granular-dominant sludge in the reactor, which could be comparable with the granulation process with artificial wastewater. After 55 days operation, COD and ammonia removal efficiency were 84.63% and 93.86% respectively. Effluent nitrite accumulation was observed in the reactor indicating partial nitrification could be achieved. This study presents a novel operational strategy to cultivate aerobic granular sludge with low COD level real domestic wastewater.

1 INTRODUCTION

After more than a score years' exploration, aerobic granular sludges have been successfully cultivated in well-controlled lab-scale reactors with high- or middle-strength synthetic wastewaters (Beun et al. 1999, Peng et al. 1999, Moy et al. 2002, Arrojo et al. 2004, Su & Yu 2005). However, there are only a few studies that reported the aerobic granulation with real domestic wastewater which is usually characterized as a low-strength wastewater (Liu et al. 2011, Liu et al. 2010). How to cultivate active and compact aerobic granulars with the low-strength municipal wastewater is crucial for its full application. Moreover, the rapid aerobic granulation in pilot-scale or full-scale reactor is still the bottleneck that restricts its full application.

Fortunately, some forerunner explored the unknown area. de Kreuk (de Kreuk 2006) tried to cultivate aerobic granules by using pre-settled sewage as influent. After 20 days' operation at a high Chemical Oxygen Demand (COD) loading, heterogeneous aerobic granular structures were observed, with a Sludge Volume Index (SVI) after 10 min settling of 38 ml/g and an average diameter of 1.1 mm. This led to a pilot-scale plant setup at a WasteWater Treatment Plant (WWTP) in Ede, The Netherlands. Two bubble columns with a diameter of 0.6 m and height of 6 m were used. After about one year cultivation, dry weight concentration was 10 g/L, of which 80% consisted of granular sludge with a diameter larger than 0.212 mm. The influent concentration to the SBR in their work was in a range of 270–400 mg COD/L. These results provided valuable information for potential

application of aerobic granules for the treatment of domestic sewage and municipal wastewater.

Although the long-term stability of aerobic granular sludge in pilot-scale reactor with real wastewater has obtained validation (Liu et al. 2010), the granulation process is still time consuming. 6–13 months were still needed to form granular dominant sludge in pilot-scale reactors with real wastewater (Liu et al. 2010, Ni et al. 2009), which is much longer than that required in the lab-scale reactors such as 2–4 weeks. Liu et al. reported that only 17 days were needed to form granule-dominant sludge and COD and $\text{NH}_4^+\text{-N}$ removal efficiencies could reach above 80% and 90% respectively after 50-day operation, however, COD of the wastewater used in their experiment was about 800 mg/L on average (Liu et al. 2011). In general, the COD concentration of municipal wastewater in China is typically lower than 200 mg/L. Such a low COD level would severely impact the granulation process and could be a great barrier for the wide application of this novel technology. Moreover, adding external organic carbon source to raise the COD concentration is not an applicable engineering strategy. Successful granulation of activated sludge with such a low-strength municipal wastewater has not been reported yet. Therefore, exploring the possible operational strategies for rapid aerobic granulation with low-strength wastewater has very important scientific and engineering value. This work aims to enhance the aerobic granulation process with real domestic wastewater by adding Powdered Activated Carbon (PAC), which would be very useful for the development and application of aerobic granular sludge process.

2 MATERIALS AND METHODS

2.1 Reactor setup and operation

A bubble column with a diameter of 20 cm, a height of 60 cm and working volume of 18.8 L was used for the cultivation of aerobic granulars. The sand disk diffuser with the same cross section area was installed at the reactor bottom for air supply and mixing. The Dissolved Oxygen (DO) concentration in the aeration stage was in the range of 2.5–6.5 mg/L. Effluent was discharged from the middle port of the reactor and the exchange ratio was 60% with a 10 h hydraulic retention time. A 12 h operation cycle was implemented in each reactor operation, comprising 5-min feeding, 700-min aeration, 3-min settling (shortened from 30-min to 3-min gradually), 5-min decanting and 7-min idling.

2.2 Seed sludge, wastewater and powered activated carbon

The seed sludge, obtained from Gaobeidian wastewater treatment plant, Beijing, China, was seeded directly into the reactor without any acclimation. The initial Mixed Liquor Suspended Solid (MLSS) was 4200 mg/L. The wastewater used in this study was collected from the sewers of campus residential area. The characteristics of the wastewater are summarized in Table 1. Apparently, the feeding wastewater used here was typically low COD level.

Fine PAC particles were used to enhance aerobic granulation process with the real domestic wastewater. The PAC had a mean size of 50 μm having a specific surface area of 1130 m^2/g and an bulk density of 1.125 g/m^3 . A PAC concentration of 4000 mg/L was added in the reactor. The whole experiment was carried out under room temperature, and the influent wastewater temperature was 20–23°C.

2.3 Analytical procedures

COD, $\text{NH}_4^+\text{-N}$, $\text{NO}_2^-\text{-N}$, $\text{NO}_3^-\text{-N}$, Sludge Volume Index (SVI) and MLVSS were measured according to standard methods (APHA, 1995). DO and pH were continuously monitored by pH/oxi340i meter with DO and pH probes (WTW Multi-340i, Germany). Microscopic examination was performed using an Olympus-BX51 (Olympus, Japan).

Table 1. The characteristics of feeding wastewater.

COD (mg/L)	221.80 \pm 23.83	TP (mg/L)	5.52 \pm 0.73
$\text{NH}_4^+\text{-N}$ (mg/L)	77.17 \pm 5.72	pH	7.0~7.8
TN (mg/L)	93.35 \pm 6.82	Temperature (°C)	20~25

3 RESULTS AND DISCUSSIONS

Formation of aerobic granular sludge with powdered activated carbon addition.

The evolution of sludge morphologies were shown in Figure 1. After sludge was seeded into the reactor 4000 mg/L PAC was added following. Mixed by mixing function of aeration, PAC was dispersed in the reactor and contacted with activated sludge flocs. From Figure 1A, we could see that PAC is adhered onto the activated sludge flocs, so the settleability of the flocs could be improved thus more flocs could be maintained in the reactor. After 20 days' operation, from Figure 1B, granular sludges with compact structure and clear boundary could be observed, but flocculent sludge was still dominant. On day 37, granular sludges were obviously much more than before and the particle size grew bigger (Figure 1C). The domination of granular sludge in the reactor and the distinct spherical shape could state clearly that the aerobic granular sludge was cultivated successfully. The granulation process using only 37 days was as short as the granulation processes with artificial wastewater (Qin et al. 2004, Liu et al. 2005, McSwain et al. 2004). The results indicated the addition of powered activated carbon could enhance the granulation process with real domestic wastewater. The cultivated PAC-aerobic granular sludge appeared compact and small particle size (Figure 1D).

Shortening settling time to form selection pressure was employed to form aerobic granular sludge (Qin et al. 2004). The pattern of shortening settling time and variations of sludge characteristics (MLSS, MLVSS/MLSS and SV_{30}) were shown in Figure 2. After the inoculation of activated sludge, the settling time was set at 30 min. During the following operation, the settling time was

Figure 1. Images analysis of aerobic granulation process on different operation day 0 (a), 20 (b), 37 (c) (both by microscope) and 55 (d) (by digital camera).

shortened according to the sludge settling ability till to 3 min. Under the short settling time, the sludge flocs with poor settling ability were washed out, which directly led to the decrease of MLSS from 8000 mg/L (including 4000 mg/L PAC) to 720 mg/L. The corresponding SV_{30} were 32 and 7 respectively, which were improved by the addition of PAC. In the aerobic granulation process with no auxiliary substances addition, the MLVSS/MLSS ratio usually has a significant decrease due to the accumulation of inorganic substances in aerobic granulars, which is of great importance to aerobic granulation (Qin et al. 2004). In this study, because of the addition of PAC, the MLVSS/MLSS ratio was very low at the beginning, moreover, only had a slight decline from 0.69 to 0.5.

3.1 COD and Nitrogen removal

The wastewater influent substrate concentration of real domestic wastewater are varying compared with the artificial wastewater. As shown in Figure 3, the influent COD concentration varied from 45.15 mg/L to 173.10 mg/L. Although the

Figure 2. Profiles of reactor sludge MLSS, MLVSS/MLSS SV_{30} , during the whole operation period.

Figure 3. Performance of reactor with respect to COD removal over operation time.

MLSS decreased during the operation period, the COD removal efficiency kept an increase trend. From day 35 to day 55, the MLSS was below 1000 mg/L and almost only 50% was the MLVSS, but the COD removal efficiency was kept at 85%. The results indicating that the addition of PAC could maintain the function bacteria. From day 0 to day 55, the average influent COD concentration was 113.15 mg/L, which was a low organic substances level. The wild fluctuation and low level of influent COD concentration of real domestic wastewater may lead to the slow granulation process. But it took only 37 days to form granular sludge in this study, which mainly due to the addition of PAC.

The variations of NH_4^+-N removal and effluent $NO_2^- -N$, $NO_3^- -N$ were shown in Figure 4. The effluent NH_4^+-N was below 10 mg/L during the 55 days' operation except for several days at the process of granular sludge formation. The NH_4^+-N removal efficiency did not have an obvious fluctuation and average NH_4^+-N removal efficiency was 87.19%. Along with the shortening of settling time, the NH_4^+-N removal efficiency decreased slightly due to the wash out of biomass. But after granular sludge was formed from day 37, the NH_4^+-N removal efficiency kept a steady increase trend to about 95%.

3.2 Partial nitrification

The effluent $NO_2^- -N$ and $NO_3^- -N$ had a great change in the granulation process. From day 1 to day 23, NH_4^+-N was nitrified completely, so $NO_3^- -N$ was the mainly nitrogen in the effluent and there was no $NO_2^- -N$. After that, the effluent $NO_2^- -N$ increased while the effluent $NO_3^- -N$ declined indicating a partial nitrification in the reactor.

The wash out of the activated sludge during granulation process will result in the incomplete nitrification, which is equivalent to stop aeration

Figure 4. Performance of reactor with respect to nitrogen removal over operation time.

before “ammonia valley” (Guo et al. 2007, Yang et al. 2007). Moreover, the granular structure was suitable to maintain the slow growing Ammonia Oxidizing Bacteria (AOB) (Vázquez-Padín et al. 2010). Thus, the cultivation process of aerobic granular sludge is naturally to favor the formation of partial nitrification. From day 42, the effluent NO_2^- -N was higher than NO_3^- -N and kept an increasing trend. The nitrifying granular sludge was proposed as an alternative to obtain partial nitrification, but the previous reports mainly used the artificial wastewater. The results of this study indicated that stable partial nitrification with real domestic wastewater could be achieved by aerobic granular sludge.

4 CONCLUSIONS

Aerobic granulation process with real domestic wastewater was enhanced by the addition of PAC. It took only 37 days to form distinct and compact granular sludge, which could be comparable with those with artificial wastewater. MLSS was very low due to the short settling time, but wastewater treatment efficiency could be ensured. The COD and NH_4^+ -N removal efficiency were 84.63% and 93.86% respectively after 55 days operation. Effluent NO_2^- -N was accumulated after granular sludge formed indicating partial nitrification with real domestic wastewater could be achieved.

ABSTRACT: The main objective of this paper is to address the various uses of water to an ideal weight ratio, solve the storage and movement, form saline alkali, and protect the water during the process, covering the economic, physical, and environmental benefits. The Analytic Hierarchy Process (AHP) model is adopted to filter all the influencing factors and extract the final 10 criteria to determine the use of water in these three parts. After computing their weights, the abstract problem is successfully transferred to a mathematical model. The second step that we refer to is the grey correlation model to further determine the priority order of different states in the water using the calculated weight ratio. Due to the geographical location and climate change in the United States, in particular, we confirm the temperature coefficient, in this study, in every aspect of the water demand that can be in some densely populated areas and the lack of water in the area. By using these two models, through which we will model the multi-objective decision analysis model and genetic algorithm, and combined with all the water supply in each country's three regional branches of the classification, the final optimal solution can be obtained.

1 MATHEMATICAL MODEL

1.1 AHP model

The evaluation criteria for the distribution of rivers or lakes are involved in many aspects such as economy, water resources, and environment. In order to divide the United States according to the conditions of the natural environment, we need to figure out the social economic condition, development, and utilization degree of water resources and state of the ecological environment as the three swordsmen.

Social economic condition

- GDP.
- Modulus of agriculture output.
- Hydropower production.
- Urbanization level.

Development and utilization degree of water resources

- Proportion of the number of people by water resources (self-sustaining).
- Average temperature.
- Precipitation.
- Percentage of brine.

State of ecological environment

- Modulus of soil and water loss.
- Industrial sewage emission.
- Ratio of underground water in water use.

1.2 Comparison matrix

Starting from the rule hierarchy (the second criteria of the hierarchy figure above), comparison matrix is structured by the Comparison Method of the number 1–9 (each represents a different degree of importance). Table 1 shows the weights of the social economic condition, development, and utilization degree of water resources and state of the ecological environment.

From the four tables presented above, we have confirmed that the entire consistency ratio is correct. The combination weight vector of criterion with respect to the evaluation method of distribution of American river basins is shown in Table 5.

1.3 Grey correlation model

The steps in grey correlation analysis are as follows:

STEP 1: Note reference data series as the ideal comparison criteria. In general, reference data series consists of the optimal value of every criterion. We can also choose other reference data by different evaluation destination. The relationship is shown as follows:

$$A_0 = (a_0(1), a_0(2), \dots, a_0(m))$$

In which, we choose every optimal value as reference data series, which is $A_0 = (1, 1, \dots, 1)$.

Table 1. Pairwise comparison matrix of hierarchy.

Comprehensive impact	Social economic condition	Development and utilization degree of water resources	State of ecological environment	Weight
Social economic condition	1	1/3	5	0.2746
Development and utilization degree of water resources	3	1	8	0.6571
State of ecological environment	1/5	1/8	1	0.0683

By computing the weights of the three main factors, we get the final maximum eigenvalue $\lambda = 3.0444$, consistency ratio = 0.0383.

Table 2. Pairwise comparison matrix of hierarchy II–III.

Comprehensive impact	GDP	Modulus of agriculture output	Hydropower production	Urbanization level	Weight
GDP	1	6	4	2	0.5125
Modulus of agriculture output	1/6	1	1/2	1/4	0.0743
Hydropower production	1/4	2	1	1/2	0.1377
Urbanization level	1/2	4	2	1	0.2755

Based on the calculation of the weight of the four factors of the social economic condition, the maximum eigenvalue $\lambda = 4.0104$, consistency ratio = 0.0039.

Table 3. Pairwise comparison matrix of hierarchy II–III.

Comprehensive impact	Proportion of the number of people by water resources	Average temperature	Precipitation	Percentage of brine	Weight
Proportion of the number of people by water resources	1	1/2	3	5	0.2963
Average temperature	2	1	5	8	0.5351
Precipitation	1/3	1/5	1	2	0.1085
Percentage of brine	1/5	1/8	1/2	1	0.0601

After ciphering the weight of the three elements for the development and utilization degree of water resources, the maximum eigenvalue $\lambda = 4.0104$, consistency ratio = 0.0039.

Table 4. Pairwise comparison matrix of hierarchy II–III.

Comprehensive impact	Modulus of soil and water loss	Industrial sewage emission	Ratio of underground water in water use	Weight
Modulus of soil and water loss	1	1/2	5	0.3258
Industrial sewage emission	2	1	8	0.6039
Ratio of underground water in water use	1/5	1/8	1	0.0703

When it comes to the final three branches of the state of the ecological environment, the maximum eigenvalue $\lambda = 3.0055$, consistency ratio = 0.0048.

STEP 2: Calculate the absolute difference between comparison series and reference data series of every evaluated object. That is, $\Delta_i = (j) = |a_i(j) - a_0(j)|$. In which, I represents the sequence of states, j

represents the sequence of criterion, $a_0(j)$ represents the reference data of the j th evaluation criterion.
STEP 3: Determine the value of p and q .

$$p = \min_{1 \leq i \leq n} \min_{1 \leq j \leq m} \{\Delta_i(j)\}$$

$$q = \max_{1 \leq i \leq n} \max_{1 \leq j \leq m} \{\Delta_i(j)\}$$

STEP 4: According to the equation, we can calculate the correlation coefficient with respect to every comparison series and reference data series.

$$y_i(j) = \frac{(p + q\beta)}{(\Delta_i(j) + q\beta)} \quad j = 1, 2, \dots, m$$

STEP 5: To find the relationship between every evaluated object and reference data series, we calculate the average value of correlation coefficient of every evaluation criterion and reference data series. We define it as correlation, which is shown as follows:

$$r_j = \frac{1}{n} \sum_{i=1}^n y_i(j)$$

STEP 6: Calculate the weight of each evaluation criterion.

Table 5. Criterion's weights to overall objects.

Criterion	Weight
GDP	0.1407
Modulus of agriculture output	0.0204
Hydropower production	0.0378
Urbanization level	0.0757
Proportion of the number of people by water resources	0.1858
Average temperature	0.3516
Precipitation	0.0713
Percentage of brine	0.0395
Modulus of soil and water loss	0.0223
Industrial sewage emission	0.0412
Ratio of underground water in water use	0.0048

Figure 1. Final water allocation scheme concerning three ways of using water.

$$r'_j = \frac{r_j}{r_1 + r_2 + \dots + r_m} \quad j = 1, 2, \dots, m$$

STEP 7: Construct a general evaluation model.

$$Z_i = r'_1 a_i(1) + r'_2 a_i(2) + \dots + r'_m a_i(m) \quad i = 1, 2, \dots, n$$

2 ERROR ANALYSIS

2.1 Error from statistical data

Data from Web sites and encyclopedia are not absolutely correct and precise. It has systematic errors and random errors. Since the water allocation plan is totally dependent on those data, the errors from the data we collected will bring about errors at the conclusion.

2.2 Error from the model

The weights of the evaluation criterion that we use in the AHP model have strong subjectivity and randomness; therefore, the weight of each criterion is not that credible. In the grey correlation model, we divided America into three parts solely according to the regional distribution, this division method will cause some errors in the conclusion because the river we calculate might not flow through the state while our MATLAB program deems it would. In other words, we did not consider the topography and geography. In the multi-objective decision analysis model, the use of trend prediction is not that precise because rivers have a periodical nature and also a constellation of whatever ecological and environmental-related affair does not fit our trend model; therefore, it also leads to error in the conclusion.

2.3 Error from the algorithm

The Genetic Algorithm has high computational requirements and cannot identify the global optimum. Because we have a two-object function, the ratio of priority of function is determined by intuition and common sense, neither of which is a scientific resort to obtain this key factor in computing the optimum solution.

3 CONCLUSIONS

We have come up with a water allocation scheme for 2013–2025 in America, in the industrial age, in which massive production is the main theme. In this sense, we should allocate most of the water to production. The massive production brings about massive pollution, in that we should give second

priority to ecological water use. As the society develops, production will become more effective and environment-friendly and the water use in production will have a descending trend, and as the water saving concept is accepted by the people, the ratio of domestic water use will have a descending trend too. As we all know, during the last two centuries after the industrial revolution, the environment issue was intentionally or unintentionally overlooked for a long time, so the environmental and ecological condition was altered severely. In order to surrogate this, we should give more attention to environment conditioning. In this sense, environmental water supply should have an ascending trend.

Dawei Huang

Engineering Research Center of Railway Environmental Vibration and Noise, Ministry of Education, East China Jiaotong University, Nanchang, China

ABSTRACT: Large direct shear test and compression test for the improved filler from blast furnace slag by the large direct shear apparatus were conducted, and relevant mechanical parameters of the improved filler were obtained. Test results show that water content has little influence on the mechanical index as fine particle cannot fill the interspace of coarse particles, so the filler has good water stability. There is little occlusion cohesion of the mixture filler when the vertical stress is less than 150 kPa and large occlusion cohesion if it is more than 150 kPa. The less the vertical stress, the more the shear shrinkage at the initial stage and the less the shear dilation at a later stage. When the vertical stress is more than 150 kPa, the shear dilation reduces to a greater degree than the shear zone formed by the fragmentation and breakage of coarse particles. Compression at the stage of loading is mainly concerned with the smashed edges and corners and long flat shape particles breaking off. The settlement calculation of the foundation should refer to the deformation modulus at the stage of reloading when the foundation is constructed by dynamic consolidation.

1 INTRODUCTION

Substantial amounts of solid wastes have been produced during the rapid development of the iron and steel industry and blast furnace slag is a major waste. The fact that there has been plenty of research on the application of blast furnace slag has not changed the situation of little consumption with a high cost. To reduce the land covered by slag, how to utilize and consume it remains the most urgent problem in the process of steel and iron production. Research and analysis indicate that the application of blast furnace slag in filling foundations or roadbeds is one of the major methods to substantially consume it (Jin Xia, 2005 & Wang Haifeng, 2007). Normally dynamic consolidation with heavy hammers are adopted when blast furnace slag are utilized as fillers for high-filled foundations or roadbeds to lower the possibility of settlement and improve the grain size of fillers (Yang Youhai, 2011; Gao Zhengguo, 2013; Yang Youhai, 2012; Huang Dawei, 2012). Improved fillers with relatively large grain size are considered coarse particles. The shear strength and compression modulus of fillers are usually tested indoor to calculate the stability and high-filled foundation or roadbed as well as the possible settlement after construction (Zhu Jungao, 2011; Chen Xiaobin, 2007; Ding Zhouxiang, 2007; Huang Dawei, 2012).

In this article, a large-size direct shear apparatus was involved here to conduct improved filler direct shear test and compression test and we tried to analyze the fillers' direct shear property and compression property. We have analyzed the shear dilation of the blast furnace slag under different normal stressors by means of vertical displacement of the vertical loading plate and provided suggestions on compression modulus while calculating the settlement according to test results.

2 FILLERS' GRADATION PROPERTY

As solid wastes are produced during the process of steel and iron production, blast furnace slags feature irregular shapes, large grain size, and a certain amount of pores inside the grains with the average internal porosity being 10.5% and the solid density of blast furnace slag (break off the large-size slags before testing to ensure no closed pores are included and adopt the measuring flask method) being 2.535 g/cm³. The Curve 1 in Figure 1 shows the gradation curve of blast furnace slags according to the particle analysis while Table 1 shows composition parameters of slag particles. It can be seen from the two graphs that blast furnace slags are majorly composed of large size particles. Suppose the particles with a diameter larger than 5 mm

are referred to as coarse particles represented by P_5 (proportion of slags with d larger than 5 mm) (Huang Dawei, 2012), it can be seen from Table 1 that P_5 is 98.99. Based on the calculation, the non-homogeneous coefficient and curvature coefficient of blast furnace slag are $C_u = 2.38$ and $C_c = 0.95$, respectively. According to the Rules of Geotechnical Testing (SL237-1999), some blast furnace slags are defined with bad gradation and filler category falls into the group of mixture fillers with giant particles.

Having doped with fly ashes, ground layer-by-layer and conducted using dynamic consolidation with heavy hammers, we again layer the blast furnace slag and get samples. Results show that the particle composition of each layer resembles a lot. The Curve 2 in Figure 1 is the gradation curve when all fillers are equally mixed. Also see particle composition in Table 1 where P_5 is 87.56, non-homogeneous coefficient $C_u = 6.58$, and curvature coefficient $C_c = 1.29$. Mixture fillers feature great gradation and filler category falls into gravel soil. From this, we can know that the mixture, compaction, and dynamic consolidation clearly increase the number of fine particles and gradation of

blast furnace slag as fillers are greatly improved. Through the back calculation of fine particle content, we get to know that the proportion of actual fly ashes mixed in total fillers on-site is 2%.

According to the *Rules*, the largest particle diameter of sample fillers for large-scale direct shear and compression testing should not be larger than 60 mm. In order to achieve this, we run mixture fillers through a soil analysis sieve of 60 mm pore diameter and obtain filler samples for compression testing, its gradation curve being Curve 3 in Figure 1 and particle composition being seen in Table 1. It can be read from the parameters of Figure 1 and Table 1 that the composition of fillers for compression test is similar to that of the mixture filler. The test results can be considered as compression performance parameters for on-site filling.

3 TESTING APPARATUS AND TESTING PROGRAM

3.1 Introduction to the apparatus and ways to prepare filler samples

The direct shear test that is to say large-scale shear test using large structural surface shear apparatus (shear apparatus for short) is suitable to be applied to the shear test when coarse fillers are involved. The large-scale shear apparatus involved here is a stress and strain double-controlled one, as shown in Figure 2. In this test, we adopt a strain-controlled apparatus whose direct shear rate is 2 mm/min. The direct shear box is in a rectangle shape, size being height*width*length = 200*400*600 (the bottom shear box height is 100 mm, the upper shear box height 110 mm and 10 mm is left for the normal loading plate when packing). This kind of direct shear apparatus is only applicable when the largest diameter is no larger than 60 mm. There is a vertical displacement sensor on the

Figure 1. Grading curves of the blast furnace slag and the filler sample.

Table 1. Index of particle composition for the blast furnace slag and filler sample.

Sample	Fine granule content (%)	Coarse granule content (%)	Coefficient of uniformity C_u	Coefficient of curvature C_c	Grading	Soil classification
Blast furnace slag	0.15	98.99	2.38	0.95	Poor	Soil mixtures with giant grains
Mixed soil sample	1.27	87.56	6.58	1.29	Well	Gravelly soil
Tested soil sample	2.48	85.34	9.66	1.86	Well	Gravelly soil

Note: There is good particle gradation ($C_u \geq 5$, and $C_c = 1-3$) and bad gradation ($C_u < 5$, and $C_c \neq 1-3$), among which non-homogeneous coefficient $C_u = d_{60}/d_{10}$, and curvature coefficient $C_c = d_{30}/(d_{10} \times d_{60})$, d_{10} , d_{30} , and d_{60} are in accordance with 10%, 30%, and 60% particle diameter in the particle gradation curve. Coarse granule means the soil of which particle size is more than 5 mm and fine granule less than 0.075 mm.

Figure 2. Large direct shear apparatus.

large direct shear apparatus, which imposes constant normal loading by means of liquid pressure. Also by collecting vertical displacement data from the vertical loading plate, we have obtained shear shrinkage and shear dilation property exposed in the direct shear test.

The large compression apparatus should be adopted in the case of coarse fillers for they are mostly composed of large-size particles. According to *Rules of Geotechnical Testing (SL237-1999)* (Chen Zhongyi, 1992), the ratio between the solidification container diameter (D) and its height (H) is 2~2.5 and generally, people use large gathering ring type compression apparatus. However, being different from large direct shear apparatuses, the large compression apparatuses are not widely utilized by science and research institutions. Considering this, the large shear apparatus is innovatively adopted in this test.

When a large direct shear apparatus is adopted in the direct shear test and compression test, there is difficulty in obtaining originally-shaped fillers and samples are normally obtained through disturbance. We learn from Figure 1 and Table 1 that in this test fillers majorly comprise of large size particles, which will probably lead to segregation between coarse and fine particles when preparing samples and the segregation is more serious than an on-site one. To avoid such things from happening, actions should be taken to separate coarse fillers and fine fillers before making samples (setting 10 mm as a benchmark). While preparing samples, dump one-third of the coarse filler into the direct shear box, smoothen it and then pour one-third of the fine filler. Again smoothen the surface and utilize an iron shovel and an iron bar to harden it until the coarse and fine fillers are evenly spread. Repeat the same procedure three times and make sure the thickness of each layer resembles one another. By doing all this, we make sure that the shear plane is even and the mechanical index obtained indoor is close to that of an on-site test.

Table 2. Experimental scheme.

Test number	Moisture content (%)	Weight of the dry sample (kg)	Dry density (g/cm^3)	Initial void ratio
1	0	75	1.56	0.4602
2	0	79.4	1.65	0.3801
3	8	86.3	1.80	0.2687

Figure 3. The curve of vertical compressive stress and time.

3.2 Test programs

The main purpose of this test is to find out the impact of shear strength and filler water content on basic mechanical parameters after the mixture, compaction, and dynamic consolidation of the blast furnace slag is completed. During the test, we have separately conducted a direct shear test on dry fillers (air drying) and wet fillers adopting the same filling method and compacting method. As for the dry filler, conduct the test while it remains dry; as for the wet filler, the water content is 8%. The dry density for both the dry filler and the wet filler is $1.78 \text{ g}/\text{cm}^3$ during the test.

The main purpose of this large compression test is to find out the impact of compression parameters as well as filler water content on compression parameters after the mixture, compaction, and dynamic consolidation of the improved blast furnace slag is completed. We adopt the same filling and compacting procedure during the test. Table 2 reveals the filler parameters in three compression tests, in which dry fillers are air-dried indoor and water content of the wet filler is 8% in terms of fillers with a diameter less than 5 mm. Graded loading, graded unloading, and graded reloading are adopted in the compression test. The stability time for every loading (unloading) is determined by the vertical displacement of the normal loading plate. Usually, if no vertical displacement occurs in 2 min, another graded loading (unloading) will be triggered. Figure 3 is the relationship curve of “vertical compressive stress–time” in one compression test.

4 TEST RESULT ANALYSIS

4.1 Shear strength parameter property analysis

The direct shear test results of dry filler and wet filler under different vertical pressures are shown in Table 3 and Figure 4 and Figure 5. While analyzing, draw all dots on the coordinates together with a smooth curve and try to fit it into the linear tendency line. We have obtained shear strength parameters of the two fillers from the fitted linear tendency line and rendered them in Table 4. It can be learned from shear strength parameters of dry fillers and wet fillers that water content produces little impact on the fillers' shear strength parameters and fillers have great water stability. It can also be learned from particle analysis that fillers comprise majorly of large-sized particles (P5 is about 85.34); water mainly influences fine fillers' strength and since blast furnace slag boasts of great water stability, water exerts little influence on large-size particles. That is because when fine particles are not enough to fill up pores between coarse particles, fine particles will be free between pores while coarse particles make up as filler skeleton. Therefore, water content has limited influence on shear strength parameters.

Table 3. Direct shear scheme and results.

Moisture content: 0		Moisture content: 8%	
Vertical pressure (kPa)	Maximum shearing force (kN)	Vertical pressure (kPa)	Maximum shearing force (kN)
50	103.33	50	101.67
100	236.25	75	184.58
150	343.33	150	345.00
275	501.25	275	502.92
400	647.92	500	764.17
500	769.17		

Figure 4. The relationship between shearing strength and vertical pressure of a dry sample.

Figure 5. The relationship between shearing strength and vertical pressure of a wet sample.

It can be seen from shear strength parameters that despite the lack of cohesion between filler particles, filler cohesion can be seen from a direct shear test that is occlusion cohesion.

It can be seen from Figure 4 and Figure 5 that a smoothed curve is in good accordance with the linear tendency line, that is to say both corresponding dots of 150 kPa and 275 kPa normal stress are over the tendency line; the slope of circular curve tends to reduce; all coordinates with normal stress larger than 150 kPa are seen to lie in one line.

The destructive plane (shear plane) in the direct shear test is decided by workers. During the test, both strain and stress are non-homogeneous and quite complicated. Different coordinates have different stress and stress paths. The main stress varies surrounding the shear plane in a spiral direction. Here is the Coulomb equation:

$$\tau_f = c + \sigma \tan \varphi \quad (1)$$

where

τ_f is the fillers' shear strength (kPa);

c is the fillers' occlusion cohesion (kPa);

σ is the normal stress imposed on the shear plane (kPa);

φ is the fillers' internal friction angle ($^\circ$);

For non-cohesive fillers, the occlusion cohesion is $c = 0$ when shear strength is in direct proportion to the normal stress imposed on the shear plane, which indicates that the τ_f of non-cohesive fillers is determined by the frictional resistance between particles. However, the frictional resistance between particles is made up by sliding friction and additional resistance provided by mutual occlusion, and the value of frictional resistance is determined by the size, gradation, density, and coarseness of the particles. Hence, it can be understood that conditional on small vertical stress, blast furnace slag shows no occlusion cohesion and when vertical stress is relatively large (150 kPa for example), shear strength shows occlusion cohesion.

4.2 Shear dilation analysis

During the direct shear test, as soon as shear displacement reaches 20 mm, both upper and bottom shear boxes begin to gradually open up as shown in Figure 6. The analysis shows that shear dilation is responsible for the opening up of shear boxes and upper box fillers' side friction leads the upper box to translate. We have measured the vertical displacement of the vertical stress loading plate as a way to analyze the shear dilation in a large direct shear test, as shown in Figure 7. It can be seen from Figure 7 that downward displacement of the vertical stress loading plate can be observed at an early stage of the shear test and the largest downward displacement is about 1 mm. The larger the vertical stress is, the larger the vertical displacement will be at an early stage. That is to say, as the shear compression continues to increase with continuing increase of shear displacement, and the vertical stress loading plate starts to move upward. It can be seen from Figure 7 that larger the vertical stress is, larger is the shear compression at an early stage and smaller the shear dilation at a later stage.

Shear compression occurs when fillers' volume reduces because of mutual embedding and

breaking off of long and flat particles during the shear deformation process. Hence, conditional on the same consolidation, the larger the normal stress is, the larger the shear compression will be. Shear dilation occurs when fillers' volume increases owing to particle re-arranging because of the shear moving and tumbling. However, conditional on larger normal stress, when the force that breaks a particle is smaller than the force that causes shear moving and tumbling, particles will break off. Conditional on the same consolidation, the smaller the normal stress is, the larger the shear dilation will be.

The destructive plane (shear plane) in the shear test is not a whole plane but a complex zone where coarse fillers impose force on each other. Under these complex mutual interactions, embedding, crushing, shear moving, tumbling, and breaking off are supposed to take place at the same time; where embedding and crushing can be regarded as a decrease of the volume; particle shear moving and tumbling are regarded as an increase in the volume; and particles breaking off are regarded as remaining same of the volume. During the direct shear test, particles work differently when under different normal stress or at different stages of shear displacement and particles breaking off mostly take place conditional on large vertical stress and large shear displacement. It can be seen from Figure 10 that when normal stress is larger than 150 kPa, the vertical displacement of the vertical loading plate is much smaller than the displacement when normal stress is 150 kPa and it is close to the normal stress at 50 kPa. Therefore, it can be deduced that when the fillers' normal stress is larger than 150 kPa, the breaking off of particles is mainly responsible for the shear plane. This is the reason for the obvious decrease in shear dilation. The fillers also show large occlusion cohesion at the same time. We learn from these test results that there are more breaking off particles when normal stress is over 150 kPa. See Figure 8.

Figure 6. Opened shear box.

Figure 7. The relationship between the vertical displacement of the upload plate and shear displacement for a dry sample.

Figure 8. Broken particles by shear.

4.3 The compression property of improved blast furnace slag

Figure 9 shows the curve of settlement of the loading plate and time, where it can be seen that the longest time is needed for a stable vertical displacement of the uploading plate at each level stage, longer time for the reloading stage, and least time for the downloading stage.

Figure 10 shows the curve of “settlement-vertical stress” when the loading plate displacement is stable at different loading/downloading levels during the three compression tests. It can be seen that among the three compression tests, there is a slight difference in loading plate settlement between the prior three levels of the first loading and for other loading/downloading at different levels the settlement is pretty close. According to the definition of fillers’ confining deformation modulus E_s from *Soil Mechanics*, if we randomly choose the slope of a small secant line as the confining deformation modulus in relevant range, then the equation will be:

$$E_s = \frac{\Delta\sigma'}{\Delta\varepsilon} \quad (2)$$

Figure 9. The curve of settlement of the loading plate and time.

Figure 10. Curves of settlement of the loading plate and vertical compressive stress.

where

$\Delta\sigma'$ is effective stress increase

$\Delta\varepsilon$ is compression strain increase

Confining deformation modulus E_s obtained from different stages of uploading/downloading stages according to Equation (2) are listed in Table 4, where it can be seen that the compression parameters of dry and wet improved blast furnace slag are pretty close indicating blast furnace slag particles have good water stability. Few fine particles are seen and they are barely involved in the formation of filler skeleton and that is why water content exerts little influence on the fillers’ compression property.

It can be seen from Table 3 that when stress is growing from 100 kPa to 200 kPa, the E_s remains to be 15 MPa, and according to the reference value of filler compression from *Soil Mechanics* (when stress is growing from 100 kPa to 200 kPa, the confining compression modulus lower than 4 MPa will be regarded as high compression fillers, 4~20 MPa medium compression fillers, and larger than 20 MPa low compression fillers), the blast furnace slag adopted in this test falls in the group of medium compression fillers.

Draw curves of E_s from different uploading/downloading stages in Figure 11 (the abscissa of coordinates come from the average of vertical stress of both starts and ends of all levels of uploading and downloading). It can be seen from Figure 11 that E_s are small the first time when loading and the values are all smaller than 25 MPa; E_s (supposed to rebound modulus) will be generally larger when downloading, and with the increase of downloading it gradually decreases; when reloading, it will first increase and then decrease; it will be larger when reloading than the E_s at the first

Table 4. Confining deformation modulus E_s for different stages of loading and unloading (MPa).

Stages (kPa)	No. 1	No. 2	No. 3	
Loading	0→50	2.59	4.22	2.47
	50→100	8.95	6.05	8.95
	100→200	13.11	9.93	12.85
	200→300	14.27	14.18	16.33

loading mainly owing to great deformation that has taken place during the first loading.

Improved blast furnace slag fillers mainly comprise of broken slags whose edges and corners are quite obvious. Samples are obtained through indoor disturbance. During the compression test, all edges and corners are compressed and therefore the stress is highly focused on breaking off particles; besides, the lack of fine particle content makes it impossible for fine particles to fill up space between coarse particles, which leads to the occurrence of tensile stress between large-size and flat particles as shown in Figure 12. Hence, the improved blast furnace slag adopted in indoor compression test belongs to the medium compressive filler. In order to make sure that fine particles will fill up the space between coarse fillers, a number of particles with a diameter smaller than 5 mm should not be less than 30% of total fillers.

Dynamic consolidation with heavy hammers is adopted while alternating foundation with improved blast furnace slag high fillers. During

dynamic consolidation, a majority part of edges and corners of particles under concentrated stress will be broken off and large tensile stress takes place. Large size particles and flat particles are also broken off. When the heavy hammer falls on the ground, it produces stress much larger than the one that is produced by the later upper filler. The dynamic consolidation foundation is similar to preloading, however, filler samples prepared by indoor filler disturbance is difficult to match the actual contact between fillers and particles after dynamic consolidation. Hence, the compression modulus of reloading is highly recommended in light of the analysis of high fill foundation compression property of blast furnace slag after an on-site dynamic consolidation with a heavy hammer.

5 CONCLUSIONS

1. The results of the large direct shear test and compression test of the improved filler from blast furnace slag indicate that owing to the lack of fine particles (P_5 is about 85.34), they hardly involve in the formation of the fillers' skeleton and also blast furnace slag particles feature great water stability. Water content has little influence on the fillers' mechanical properties. Fillers adopted in this test have good water stability.
2. The direct shear test of improved blast furnace slag fillers also shows that conditional on the same compaction, lower normal stress leads to small shear compression at an early stage but a large shear dilation at a later stage and larger normal stress leads to a large shear compression at an early stage, but a small shear dilation at a later stage.
3. Conditional on normal stress less than 150 kPa, the shear plane formation of blast furnace slag mainly results from the particle shear moving and tumbling in the shear zone; conditional on normal stress larger than 150 kPa, the shear plane formation mainly results from the shear cutting and breaking off of particles in the shear zone.
4. The improved blast furnace slag mainly comes from the breaking of large size slag through compaction and dynamic consolidation with a heavy hammer. Sample fillers are mainly comprised of the skeleton formed by particles with obvious edges and corners in this compression test. The compression of the first loading in the indoor compression test is caused by the crushing of edges and corners of particles as well as the breaking off of long and flat large size particles. Hence, despite the fact that blast furnace slag improved fillers are coarse particles, they

Figure 11. Curves of confining deformation modulus and vertical compressive stress.

Figure 12. Edges and corners smashed and long flat shape particles breaking off.

still are medium compressive fillers at the first loading in the indoor large compression test.

- Disturbed soil is adopted as filler samples in the improved blast furnace slag indoor compression test, which is difficult to match the practical contact between filler compaction and particles after dynamic consolidation. Considering the characteristics of dynamic consolidation, the compression modulus of reloading is recommended in light of the compressive analysis of improved blast furnace slag high fill foundation with dynamic consolidation.

Environmental impact assessment of shipping construction based on the FCE method

C. Xu & D.M. Yu

Central South University, Changsha, Hunan, China

ABSTRACT: In comparison with highway and railway construction, shipping construction's concepts such as ecological and green construction and environmental protection are still in their infancy. In this paper, shipping construction's environmental impact assessment index system is presented. By introducing the Analytic Hierarchy Process (AHP) to determine the weight, this paper utilizes the Fuzzy Comprehensive Evaluation (FCE) method to conduct the comprehensive evaluation, with the 1st-phase of Xiangxi Autonomous prefecture shipping construction project in Hunan Province as the case study. The case results demonstrate that the impact of shipping construction is slightly negative on the overall environment. The research results can support theoretical guidance for the reasonable design, green construction, and environmental protection of shipping construction. In addition, they can provide auxiliary information and scientific basis for the development of the project of environmental management and economic development planning along the route.

1 INTRODUCTION

The purpose of shipping construction is to eliminate shoal, jet flow, rapids and other shipping obstruction phenomena, which are created by the rivers under natural conditions, and then to improve the channel dimension, the shipping conditions, and to expand the passing capacity. The measures taken for shipping engineering mainly include damming, dredge, bank revetment, reef explosion, and channelization. Shipping construction is a developmental activity that has a far-reaching impact on the society and the economy, and this construction and operations have an impact on the natural and social environment. Therefore, we need to efficiently handle the relationship between the project implementation and the environmental protection.

Vast research has been conducted on the environmental impact of shipping construction in China and foreign countries. Technological and industrial developmental project activities disturb the natural ecosystem and have multiple direct and indirect environmental consequences (Gupta, R. et al. 2003). Environmental Impact Assessment (EIA) is an anticipatory environmental management tool, which is of great significance to the sustainable development of the society (Jay, S. et al. 2007, Liu, K. F. R. et al. 2013). Information related to different environmental impacts produced by the execution of shipping construction activities and projects has been limited, described by semantic variables, and is affected by a high degree of inaccuracy and uncertainty (Peche, R. & Rodriguez, E. 2009). Environmental impact caused

by construction processes are reflected in three aspects: the impact on public, the impact on natural resources, and the impact on the ecological system (Zolfagharian, S. et al. 2012). The ecological environmental impact phase of highway construction project is divided into two periods: construction and operation period (Long, X. 2010). Desert railways, a kind of railways in special regions, have many particularities with respect to the climate, geography, and ecological environment. Due to these particularities, seven factors are taken into consideration to set up a factor set, which includes the water environment, soil environment, sand disaster, vegetation cover, wild flora and fauna, climate environment, and noise environment (Shao, L. et al. 2009). The environmental impact of inland waterway engineering is manifested in mainly six aspects: ecological environment, air environment, surface water environment, sound environment, solid waste, water loss, and soil erosion (Chen, G. J. 2011). From the perspective of "people-oriented", the discussion about human health cannot be ignored in terms of EIA (Bhatia, R. & Wernham, A. 2008, Harpet, C. & Le Gall, A.R. 2013). However, studies such as the current domestic one, aiming at assessing the degree of effect of shipping construction on the overall regional environment are few.

There are various kinds of evaluation methods, which include a complex method system. Foreign researchers use the Fuzzy Analytical Hierarchy Process (FAHP) to assess the impact of a mineral project on groundwater environment (Aryafar, A. et al. 2013) and evaluate the teaching performance

(Chen, J.F. et al. 2015). Online static security assessment and hazard assessment of organic chemicals are based on artificial neural networks (Sunitha, R. et al. 2013, Germashev, I. V. et al. 2009). A fuzzy multi-criteria approach is used to assess the ex-ante impact of food safety policies (Mario, M. et al. 2013). Chinese researchers use Fuzzy Comprehensive Evaluation (FCE) method to evaluate the landscape ecology system in highway and ground-water quality (Zhang, X. B. et al. 2012, Kou, W. J. 2013). Zhou Hong (2016) introduced the ecological footprint method and the energy analysis method of ecological economics, which can be applied to large engineering construction projects and transform comprehensive evaluation into ecological evaluation. Based on the principle of the Analytic Hierarchy Process (AHP) and the characteristics of evaluation index system about tourism, an improved AHP-TOPSIS model has been established. It aims at solving the problem of quantitative assessment of World Expo influencing the Shanghai tourism industry (Yang, J. K. et al. 2012). Through the comparative analysis of various methods and combining the characteristics of shipping construction, this paper uses the FCE method to conduct the assessment of shipping construction's EIA.

2 EVALUATION INDEX SYSTEM

Choosing evaluation index should follow certain principles, which mainly include hierarchical principle, system integrity principle, relative independence principle, intuition principle, and feasibility principle. To make the index system operational and comprehensive, after referring to the "Environmental impact assessment specification for inland waterway project" (JTJ 227-2001) and "Technical guidelines for environmental impact assessment" (HJ/T 2.1~2.3-93), literature searching, experts consulting, engineering analyzing, and other means, the evaluation index set is divided into three layers through analysis and selection. The first, target layer u ; the second, criteria layer $\{u_1, u_2, u_3\}$ the third, index layer $\{u_{11}, u_{12}, u_{13}, u_{14}, u_{15}\}, \{u_{21}, u_{22}, u_{23}, u_{24}\}$, and $\{u_{31}, u_{32}, u_{33}, u_{34}\}$. In this paper, the structure and the specific meaning of each index are shown in Table 1.

3 ENVIRONMENTAL IMPACT COMPREHENSIVE EVALUATION MODEL OF SHIPPING CONSTRUCTION

3.1 Evaluation set

An evaluation index set is a kind of language description of every evaluation index level, which

Table 1. The index system of environmental impact assessment of shipping construction.

Target layer	Criteria layer	Index layer	
Environmental impact assessment of shipping construction u	Natural environment u_1	Sound environment u_{11}	
		Water environment u_{12}	
		Atmospheric environment u_{13}	
		Soil u_{14}	
		Natural landscape u_{15}	
		Ecological environment u_2	Terrestrial animal u_{21}
			Land resources u_{22}
	Land vegetation u_{23}		
	Aquatic ecosystem u_{24}		
	Social environment u_3		Land requisition and demolishing u_{31}
			Immigrant resettlement u_{32}
			Cultural facilities u_{33}
		Human health u_{34}	

is a collection of comments given by an evaluator on evaluation indicators. The impacts of shipping construction on EIA are not the same; they can be either positive or negative and have different degrees. Degree set $v = \{v_1, v_2, v_3, v_4, v_5\}$ where $v_1 \sim v_5$ respectively denotes that shipping construction has a negative and serious impact; a negative and slight impact; a negligible impact; a positive and slight impact; and a positive and major impact on the environment. In order to facilitate the evaluation, this paper uses the score to show the evaluation criteria for each level. Scores of 50, 40, 30, 20, 10 denote the level of evaluation criteria v_1, v_2, v_3, v_4, v_5 respectively.

3.2 The determination of the weight

When conducting the FCE, the weight has an effect on the final evaluation results. Different weights can sometimes derive a completely different conclusion.

Therefore, the choice of weight being appropriate or inappropriate is directly related to the success or failure of the model (Du, D. & Pang, Q. H. 2006.). A number of different kinds of methods can be used to determine the weight, such as the expert estimation method, the AHP (Li, Z.Y. 2004), etc. The complexity of the system and the

practical need are the basis of making choices. This paper uses the AHP to determine the weight.

1. Construct the judgment matrices

First, the experts construct the judgment matrix $S = (U_{ij})_{n \times n}$ using Saaty scale (Saaty, T. L. 2008), and calculate the largest eigenvalue λ_{\max} and its eigenvector A of judgment matrix using MATLAB. This feature vector is the importance ranking of each evaluation factor.

2. Check consistency

Certain errors arise between the judgment matrix constructed by the expert's scoring method and the theoretical judgment matrix. In order to minimize the error, we need to do a consistency check (Zhu, Y. et al. 2015). The standard for inspection is CI , and the calculation method is shown below:

$$CI = \frac{\lambda_{\max} - n}{n - 1} \quad (1)$$

where λ_{\max} is the largest eigenvalue of the judgment matrix, and n is dimension of the judgment matrix.

When $CI = 0$, judgment matrix has complete consistency. The greater the value of CI , the poorer the consistency of the judgment matrix.

3. Find the corresponding mean random consistency index RI

Table 2 shows the mean random consistency index of $n \times n$ positive reciprocal matrix ($n = 1, 2, \dots, 8$). The results of the mean random consistency indexes are calculated after 1000 times.

4. Calculation of the consistency ratio

Using the random consistency ratio to judge the result of AHP ranking, the formula is as follows:

$$CR = \frac{CI}{RI} \quad (2)$$

When $CR < 0.10$, the AHP has a satisfactory consistency. If the AHP does not have a satisfactory consistency, we would need to adjust the judgment matrix element value and re-assign the value of the weights.

3.3 Single factor fuzzy judgment

Single factor fuzzy judgment matrix, which makes assessments based on a single factor, determines the degree of membership that evaluation object has on evaluation set V . Suppose the degree

of membership that u_i ($i = 1, 2, \dots, m$) has on v_j ($j = 1, 2, \dots, n$) is r_{ij} , where v_j ($j = 1, 2, \dots, n$) is the j th element of the evaluation set V . So we get the single factor fuzzy judgment matrix as follows:

$$R = \begin{bmatrix} R_1 \\ R_2 \\ \vdots \\ R_m \end{bmatrix} = \begin{bmatrix} r_{11} & r_{12} & \cdots & r_{1n} \\ r_{21} & r_{22} & \cdots & r_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ r_{m1} & r_{m2} & \cdots & r_{mn} \end{bmatrix} \quad (3)$$

Drop half trapezoid model (Song, H. J. 2014.) is used to determine the membership function. Suppose V_j and V_{j+1} are adjacent of two grading standards. Clearly, $V_j > V_{j+1}$; thus, the factors for membership function on V_j are defined as follows:

$$r(X) = \begin{cases} \frac{X - V_{j+1}}{V_j - V_{j+1}} & V_{j+1} \leq X \leq V_j \\ 0 & X < V_{j+1} \text{ or } X > V_j \end{cases} \quad (4)$$

The membership function of v_{j+1} is defined as follows:

$$r(X) = \begin{cases} \frac{V_j - X}{V_j - V_{j+1}} & V_{j+1} \leq X \leq V_j \\ 0 & X < V_{j+1} \text{ or } X > V_j \end{cases} \quad (5)$$

3.4 Fuzzy comprehensive evaluation

Using the appropriate mathematical operations to combine weight vector A with fuzzy judgment matrix R of evaluated objects, we get the result vector B of FCE of evaluated objects; b_j is the degree of membership that evaluation object has on evaluation set from an overall perspective. Thus, the equation is

$$B = A \cdot R = (a_1 \ a_2 \ \cdots \ a_m) \cdot \begin{bmatrix} r_{11} & r_{12} & \cdots & r_{1n} \\ r_{21} & r_{22} & \cdots & r_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ r_{m1} & r_{m2} & \cdots & r_{mn} \end{bmatrix} = (b_1 \ b_2 \ \cdots \ b_n) \quad (6)$$

4 CASE ANALYSIS

4.1 Use of the AHP to determine the index weight

Through the project team interview experts and analysis of similar engineering, the environment impact report of the 1st-phase of XAP shipping construction project in Hunan Province (2009) is combined, which is compiled by the Hunan Province Research Institute of Environmental Protection. Those questionnaires are combined behind the report, after which, according to the

Table 2. Mean random consistency index.

n	1	2	3	4	5	6	7	8
RI	0	0	0.52	0.89	1.12	1.26	1.36	1.41

AHP, the judgment matrix of the second layer is established as follows:

$$S = \begin{bmatrix} 1 & 4 & 3 \\ 1/4 & 1 & 1/3 \\ 1/3 & 3 & 1 \end{bmatrix} \quad CR = \frac{CI}{RI} = \frac{0.037}{0.52} = 0.07 < 0.10$$

$$CI = \frac{\lambda_{\max} - n}{n - 1} = \frac{3.074 - 3}{3 - 1} = 0.037$$

Use MATLAB to calculate the judgment matrix's largest eigenvalue $\lambda_{\max} = 3.074$. Then, check Table 2, when n is 3, $RI = 0.52$ and the random consistency ratio:

Matrix S meets the consistency requirement, and the distribution of weights is reasonable. As a normalized processing, the criteria layer's weight vector is $A = (0.615, 0.117, 0.268)$. Similarly, judgment matrix of the third layer is established as follows:

$$S_1 = \begin{bmatrix} 1 & 1 & 2 & 3 & 5 \\ 1 & 1 & 2 & 3 & 4 \\ 1/2 & 1/2 & 1 & 2 & 3 \\ 1/3 & 1/3 & 1/2 & 1 & 3 \\ 1/5 & 1/4 & 1/3 & 1/3 & 1 \end{bmatrix}$$

$$S_2 = \begin{bmatrix} 1 & 5 & 3 & 1 \\ 1/5 & 1 & 2 & 1/5 \\ 1/3 & 1/2 & 1 & 1/3 \\ 1 & 5 & 3 & 1 \end{bmatrix}$$

$$S_3 = \begin{bmatrix} 1 & 1 & 5 & 1/2 \\ 1 & 1 & 5 & 1/2 \\ 1/5 & 1/5 & 1 & 1/5 \\ 2 & 2 & 5 & 1 \end{bmatrix}$$

Using MATLAB to calculate judgment matrix's largest eigenvalue and checking the consistency, the weights of natural environment, ecological environment, and social environment are as shown below:

$$A_1 = (0.326, 0.314, 0.181, 0.119, 0.060)$$

$$A_2 = (0.394, 0.112, 0.100, 0.394)$$

$$A_3 = (0.254, 0.254, 0.061, 0.431)$$

4.2 Single factor fuzzy judgment

Based on the actual situation, the scores of sound environment, water environment, atmospheric environment, soil, and natural landscape are (38, 42, 32, 34, 25); the scores of terrestrial animal, land resources, land vegetation, and aquatic ecosystem are (31, 17, 32, 36); the scores of land requisition and demolishing, immigrant resettlement, cultural facilities, and human health are (35, 36, 17, 31). According to the formulae (4) and (5), the

corresponding single factor evaluation matrix is thus the following:

$$R_1 = \begin{bmatrix} r_1 \\ r_2 \\ r_3 \\ r_4 \\ r_5 \end{bmatrix} = \begin{bmatrix} 0 & 0.8 & 0.2 & 0 & 0 \\ 0.2 & 0.8 & 0 & 0 & 0 \\ 0 & 0.3 & 0.7 & 0 & 0 \\ 0 & 0.4 & 0.6 & 0 & 0 \\ 0 & 0 & 0.5 & 0.5 & 0 \end{bmatrix}$$

$$R_2 = \begin{bmatrix} r_1 \\ r_2 \\ r_3 \\ r_4 \end{bmatrix} = \begin{bmatrix} 0 & 0.1 & 0.9 & 0 & 0 \\ 0 & 0 & 0 & 0.7 & 0.3 \\ 0 & 0.2 & 0.8 & 0 & 0 \\ 0 & 0.6 & 0.4 & 0 & 0 \end{bmatrix}$$

$$R_3 = \begin{bmatrix} r_1 \\ r_2 \\ r_3 \\ r_4 \end{bmatrix} = \begin{bmatrix} 0 & 0.5 & 0.5 & 0 & 0 \\ 0 & 0.6 & 0.4 & 0 & 0 \\ 0 & 0 & 0 & 0.7 & 0.3 \\ 0 & 0.1 & 0.9 & 0 & 0 \end{bmatrix}$$

4.3 Fuzzy comprehensive evaluation

Putting weight vector and single factor evaluation matrix into formula (6), the first level results of FCE are shown below:

$$B_1 = (0.063, 0.614, 0.293, 0.030, 0)$$

$$B_2 = (0, 0.296, 0.592, 0.078, 0.034)$$

$$B_3 = (0, 0.322, 0.617, 0.043, 0.018)$$

The second level results of FCE are shown below:

$$B = A \cdot R = (0.615, 0.117, 0.268) \cdot \begin{bmatrix} 0.063 & 0.614 & 0.293 & 0.030 & 0 \\ 0 & 0.296 & 0.592 & 0.078 & 0.034 \\ 0 & 0.322 & 0.617 & 0.043 & 0.018 \end{bmatrix}$$

$$= (0.039, 0.498, 0.415, 0.039, 0.009)$$

To sum up, based on the principle of maximum degree of membership, the impact degree of the 1st-phase of XAP shipping construction project in Hunan Province is negative and slight in the aspect of natural environment. The impact is negligible on ecological environment and social environment. The impact is negative and slight on the overall environment.

5 CONCLUSIONS

1. Compared with highway construction and railway construction's EIA, the contents of shipping construction's EIA have not formed a complete index system yet. Shipping

construction's environmental impact index system established in this paper can better reflect the impact of shipping construction on the environment.

2. Currently, the preparation of environmental assessment report is based on the technical guidance and evaluation specification, including the evaluation of the scope, contents, key points, and so on; however, it does not propose a specific comprehensive evaluation method. The model established in this paper combines the quantitative analysis with the qualitative analysis, which is feasible, and provides a scientific, reasonable, and simple method for the comprehensive evaluation of impact of shipping construction on the environment.
3. Evaluation results obtained from the comprehensive evaluation can provide decision-making basis for scheme comparison and selection during the shipping construction planning stage; provide auxiliary information and scientific basis for the development of the project of environmental management and economic development planning along the route; and promote the sustainable development of the economy and the environment in the areas along the route.

ABSTRACT: Energy, which accounts for two-thirds of today's greenhouse gas emissions, is the key toward reducing greenhouse gas emissions and decelerating global warming. In this paper, the IPCC-recommended reference approach and scenario analysis are applied to evaluate the dynamic change in the energy supply and energy-related carbon dioxide emissions during the period of 1995–2010 in the Yangtze River Delta Region (YRDR). The results show that energy importing reliance reached 85% in 2010, and that the energy structure has become more diversified in the YRDR. In addition, the per capita CO₂ emission is significantly higher whereas the carbon intensity is lower than that of the national average. Under the Low Carbon (LC) scenario, CO₂ emissions will begin to fall for the first time in 2017. Hence, if energy-saving and emission-reduction strategy and regional planning for the YRDR are implemented thoroughly, the YRDR will achieve the national emission reduction targets by 2020 and will have a great CO₂ mitigation potential in the future.

1 INTRODUCTION

For a century, both carbon intensity and global temperature have been on the rise. Furthermore, at the same time, human society has gradually become aware of the consequences of climate change due to the “greenhouse effect”, especially of carbon dioxide emissions, making it one of the crucial international political issues at present. Energy, which accounts for two-thirds of today's greenhouse gas emissions, is at the heart of the problem and therefore must form the core of the solution (IEA 2015). In recent years, the famous international institutions such as Intergovernmental Panel on Climate Change (IPCC), International Energy Agency (IEA), World Bank (WB) and the Energy Department of Germany, England and America have issued energy reports periodically in order to mitigate greenhouse gas emissions and climate change. The detailed inventory of energy and future projections in light of the recent economic and policy developments come from these institutions, and other institutions and countries are

increasingly influencing other countries. However, the regional-scale studies of energy and CO₂ emissions are comparatively scarce (Moriarty 2009, WB 2014).

The Yangtze River Delta Region (YRDR), China's most developed region (GDP was 22.1% of the nation's total, NBSC 2015), is now in the middle and later periods of industrialization, possessing energy-intensive and capital-intensive features. The rapid urbanization and industrialization are still escalating YRDR's rigid demand of energies. At the moment, enhancing energy security, maintaining economic growth and reducing greenhouse gas emission are becoming the major issues that challenge the future of the region. Therefore, we estimated the past and the present energy supply and CO₂ emissions in the YRDR by applying the IEA and IPCC-recommended approaches and projected the future trends of energy demand and CO₂ emissions based on China's Medium and Long Term Energy Strategy and 2011–2020 regional planning for the YRDR. According to the results, we have put forward a sustainable development

project for the YRDR's future energy planning and policy making, which may provide some general insights into the effectiveness of regional-level energy conservation and GHG reduction for other regions as well.

2 METHODOLOGY AND DATA

2.1 Estimation of energy supply

Total Primary Energy Supply (TPES) is made up of production, imports, exports, international marine bunkers, international aviation bunkers and stock changes. Beginning with the 2009 IEA edition, international aviation bunkers are subtracted from the supply in the same way as international marine bunkers (IEA 2010). According to energy balance table data of the YRDR, energy supply can be calculated using the following expression:

$$E = \sum_i (P_i + R_i + I_i \pm S_i) \quad (1)$$

where E is the total primary energy supply (Mtce, million tons of coal equivalent); the subscript i represents various fuels; and P_i , R_i , I_i , E_i and S_i denote primary production, recoveries, imports, exports and stock changes of fuel i , respectively.

For the analysis of the final energy consumption in the YRDR, the total and sectoral energy data for the period of 1995–2010 were obtained from the energy balance tables of the Shanghai Statistical Yearbook by Shanghai Statistical Bureau; Jiangsu Statistical Yearbook by Jiangsu Statistical Bureau; Zhejiang Statistical Yearbook by Zhejiang Statistical Bureau; and Yearbook database. The with final energy consumption sector is divided into four parts: primary industry (such as agriculture, forestry, animal husbandry and fishery), secondary industry (such as industry and construction), tertiary industry (such as transport, storage, post and communications, wholesale, retail sales, catering trade and others) and household consumption. This study considers mainly three types of energy: primary energy (such as coal, oil, natural gas), secondary energy (washed coal, other coal washing, mold coal, coke, coke oven gas, other gases, gasoline, kerosene, diesel oil, fuel oil, liquefied petroleum gas, refinery gas, other petroleum products, other coking products, heat and electricity) and other energy in the energy balance tables of the YRDR.

2.2 Estimation of CO₂ emissions

Based on the energy data, the following expression provides the detailed calculation to estimate

carbon dioxide (CO₂) emissions from fossil fuel combustion from the YRDR using the IPCC-recommended reference approach (1996).

$$E_{CO_2} = \sum_i (A_i e_i c_i \times 10^{-3} - S_i) o_i M \quad (2)$$

where E_{CO_2} is the total carbon dioxide emitted from fossil fuel combustion in kilograms (kt CO₂); A_i is the apparent consumption of fuel i (kt or 100 million m³ for natural gas); e_i is the net calorific value of fuel i (TJ/kt); c_i is the carbon emission factor of fuel i (t C/TJ), $S_i = A_i e_i c_i s_i$, is the carbon in products from non-energy uses of fossil fuels (kt C), o_i is the carbon oxidation rate of fuel i , and M is the molecular-to-atomic weight ratio of CO₂ to carbon (44/12). Calorific values and emission factors of fuels were gathered from “the Revised 1996 IPCC Guidelines for National Greenhouse Gas Inventories (The IEA is still using the 1996 IPCC Guidelines)”.

2.3 Scenario analysis

Scenarios are self-consistent storylines of how a future energy system might evolve over time under a particular set of conditions (Kadian 2007). In order to analyze possible effects of series policies for energy saving and emission mitigation, two scenarios were set up: the Business As Usual (BAU) scenario and the Low Carbon (LC) scenario. The BAU scenario assumes that the indicators of energy-saving and emission reduction will be the same as before. Considering the development of new and renewable energy, the rates of energy-saving and emission reduction during 2011–2020 under the LC scenario will be increased by 0.5–1% compared with BAU. The calculation of energy consumption per unit of output value (CSUS 2009) and the major assumptions for the BAU and LC scenarios are as follows (Table 1):

Table 1. The basic assumptions for key variables in the YRDR.

Key variables	2010 ^a	2015	2020
Population ^b (millions)	149.91	157.71	165.92
Population growth rate ^c (%)	1.02	1.02	1.02

Table 1. (Continued)

Key variables		2010 ^a	2015	2020
Saving rate of energy intensity ^g (%)	BAU	4.0	4.0	4.0
	LC	4.5	5.0	5.0
Reduction rate of carbon intensity ^h (%)	BAU	6.5	6.5	6.5
	LC	7.0	7.5	7.5

^aThe key variables are from the YRDR Statistical Yearbook, 2011.

^bThe population used in this paper is the resident population in the YRDR.

^c1.02% was the average annual population growth rate during 1995–2010.

^dGDP per capita for different time periods are assigned based on the 2011–2020 regional planning for the YRDR.

^eGDP = Population × GDP per capita.

^f14% was the average annual GDP growth rate during 1995–2010.

^gSaving rates of energy consumption per unit of GDP for different time period are assigned based on the 11th Five-Year Plan for National Economic and Social Development in Shanghai, Jiangsu, Zhejiang.

^hReduction rates of CO₂ emissions per unit of GDP for different time period are assigned based on the average annual reduction rates of energy consumption per unit of GDP during 1995–2010 in the YRDR and Medium and Long-Term Development Plan for Renewable Energy in China.

$$\frac{E_0}{G_0}(1-m)^t = \frac{E_t}{G_t} = \frac{E_t}{G_0(1+n)^t} \quad (3)$$

$$E_t = E_0 \left[(1-m)^t \times (1+n)^t \right] \quad (4)$$

$$\frac{C_0}{G_0}(1-nt)^t = \frac{C_x}{G_x} = \frac{C_x}{G_0(1+n)^t} \quad (5)$$

3 RESULTS AND DISCUSSION

3.1 The energy status in the YRDR

3.1.1 Energy supply in the YRDR

Based on energy balance table, the YRDR's energy demand rose rapidly with the continuing growth in population and economic. During 1995–2010, the energy supply increased from 170.51 to 436.55 Mtce, representing an annual rate of increase of 8.11%. However, primary energy production was only 40.45 Mtce in 2010, an increase of 60.32% over 1995 levels; however, it was only 9.26% of the YRDR's total supply, compared to 14.79% in 1995. An average of nearly 85% of energy supply for the period of 1995–2010 must have been met by imports from overseas and other domestic regions. Oil imports were 79.73 Mtce in

Figure 1. Energy supply by source in the YRDR.

2010, which was 10 times as large as in 1995, as shown in Figure 1.

3.1.2 The final energy consumption in the YRDR

The analysis showed that the final energy consumption in the YRDR rose from 169.32 Mtce in 1995 to 399.73 Mtce in 2010, accounting for 16.7% of total final energy consumption of China (2338.61 Mtce in 2010). In recent years, the energy structure has become more diversified in the YRDR: the coal share has decreased from 74% in 1995 to 63% in 2010, and the share of crude oil, natural gas and outdoor electricity has increased by 1%, 2% and 6% in 2010, respectively (Figure 2). From 1995 to 2010, the energy consumption from industry contributed the largest shares, followed by household consumption and transport, as shown in Figure 3. In 2010, the total final energy consumption of the industry sector in the YRDR reached 274.87 Mtce and accounted for 69% of the total. This was a substantial decline of 8 percentage points from 77% in 1995. Yet, construction sector was the smallest energy consumer in the energy consumption. The construction sector consumed 6.82 Mtce in 2010, accounting for just 2% of total final energy consumption. In contrast to its small share, however, the construction sector's energy consumption grew at a leading rate of 16% a year on an average during the period of 1995–2010.

3.1.3 CO₂ emissions in the YRDR

CO₂ emissions from fuel combustion in the YRDR increased from 361.29 million tons in 1995 to 901.86 million tons in 2010, with an average annual growth rate of 7.88%. The emission of CO₂ per capita in the year 2010 was 6.3 tons (based on resident population), which is higher than the world average and the national average in China. In contrast to per capita emissions, carbon intensity, measured as emissions per unit of GDP, was 37% lower than that of China's average and 25% higher than that of the world average level in the

Figure 2. Shares of various fuel types in final energy consumption.

Figure 3. Final energy consumption by sector in the YRDR.

Table 2. Comparisons of CO₂ emission indicators, 2010.

	World	China	India	USA	YRDR
Population (million)	6614	1327	1123	306	144
Share of world population (%)	100	20	17	5	11
GDP (\$2011 trillion, PPP)	67.2	7.6	3.1	14.1	1.8
Share of world GDP (%)	100	11	5	21	22
Share of world CO ₂ emissions (%)	100	21	5	20	15
CO ₂ emissions per capita (t)	4.4	4.6	1.2	18.7	6.3
CO ₂ intensity (kg/\$2011, ppp)	0.4	0.8	0.4	0.4	0.5

*a,b,c Share of population, GDP and CO₂ emissions in China, respectively. Sources: IEA analysis (2012).

same period (Table 2). On the other hand, due to the rapid urbanization and economic development of urban areas in the YRDR, CO₂ emissions from urban areas were 623.36 million tons in 2010, which was 69% of the total (Figure 4).

Figure 4. Urban carbon dioxide emissions as percentage of the total.

3.2 The energy future in the YRDR

3.2.1 Energy demand

Based on the assumptions of socio-economic development in the YRDR and the various parameters for scenarios in the calculation, the total energy demand under the BAU scenario will increase to 814.88 Mtce in 2020, which is twice as large as in 2010 (Figure 5). Under the LC scenario, it will reach to 722.46 Mtce in 2020, suppressing the growth of total energy demand by 0.98% annually compared to BAU. The energy intensity was 0.76 tce/10,000 yuan in 2010, and it would be 0.44 and 0.39 tce/10,000 yuan in 2020 for the BAU and LC scenarios, respectively. While the energy intensity has improved in the YRDR, the improvements have only been able to decrease the demand growth to some extent, but have not halted it, owing to rapid economic and population growth.

3.2.2 CO₂ emissions

Two important turning points occurred in 2017 (Figure 6): under the BAU scenario, CO₂ emissions will maintain a 0.03% lower average annual growth rate during the period of 2017–2020 compared to 3.54% during 2010–2017. Due to the series of energy-saving and emission-reduction policies and measures, for the first time in 2017, CO₂ emissions under the LC scenario will begin to fall. CO₂ emissions will reach 1055.70 million tons in 2020, suppressing the growth of total CO₂ emissions by 0.95% annually compared to BAU. In per capita terms, this means 7.20 and 6.36 tons in 2020 under the BAU and LC scenarios, respectively, compared to 6.30 tons in 2010. The CO₂ intensities of the economy for the BAU and LC scenarios will be reduced by 58% and 63% in 2020 compared with that in 2010, respectively. The results show that the YRDR will achieve the national emission reduction targets (a 40–45% reduction target, Uwasu 2010) only when it continues to implement

Figure 5. Trends of energy demand for two scenarios.

Figure 6. Trends of CO₂ emissions for two scenarios.

its past emission reduction targets and regional plans related to energy saving and environmental protection.

4 CONCLUSIONS

In this study, the IPCC-recommended reference approach and scenario analysis were applied to the YRDR to analyze the dynamic change in the energy supply and energy-related CO₂ emissions for the period of 1995–2010 and project the energy demand and CO₂ emissions up to 2020 under the BAU and BP scenarios. The main conclusions drawn from the present study may be summarized as follows: 1) The GDP and energy consumption of the YRDR occupied nearly 22.1% and 16.7% of our country in 2010, respectively. However, it was one of the serious short-energy regions, and energy importing reliance reached 85% during the period 1995–2010; this affected the development of the local socio-economy and made the regional energy security situation grimed. 2) At present, despite the energy structure becoming more diversified in the YRDR, the energy system is heavily dominated by coal. In addition, industry

has long been the largest final user of energy, reaching 69% of total final consumption in 2010. The construction sector was the smallest, at 2%; however, its energy consumption grew at a leading rate of 16% a year on an average over the period 1995–2010. 3) CO₂ emissions from fuel combustion in the YRDR reached 901.86 million tons in 2010, and annual CO₂ emission growth rate was 1/2 of that of GDP. In the YRDR, the per capita emission was significantly higher, whereas carbon intensity was lower than that of the national average in China. In addition, CO₂ emissions from urban areas reached 69% of the total in 2010. 4) Combining low carbon development with the 2011–2020 regional planning for the YRDR, scenario analysis results show that total energy demand will remain relatively high and continue to grow. However, under the LC scenario, CO₂ emissions will begin to fall for the first time in 2017, and the growth rates of total energy demand and CO₂ emissions will be smaller, 0.98% and 0.95% separately, than the BAU scenario in the YRDR from 2011 to 2020. Thus, if these energy-saving and emission reduction plans are implemented thoroughly, the YRDR will achieve the national emission reduction targets in 2020.

Based on the above research results, the following strategies should be undertaken in order to increase geographic and fuel-supply diversity, to curb the growth in energy demand and to mitigate greenhouse gas emissions: 1) In the YRDR, energy security has emerged as a central policy issue and is increasingly affecting regional economic and development policy. The government should ensure regional supply by diversifying the geographic sources of oil and physical supply route, strengthening energy infrastructure construction and increasing domestic production of conventional fuels. 2) We must continue implementing recent energy-saving and ejection-decreasing policies to promote the adjustment and upgrading of industrial structure, as prescribed in China's Medium and Long Term Energy Conservation Plan. Development and deployment of clean energies should be carried out in a more cost-effective manner to phase in the fuel switch from coal dominance to more shares of clean energy types such as natural gas and electricity (Hannah 2016). 3) Despite a rapid decline in carbon intensity in the YRDR, there is still much potential for carbon intensity to decline further, especially in some urban areas. Therefore, pursuing closer cooperation between cities and building integrated regional management platform are becoming the major tasks, which will further accelerate the spread of the information technique and ensure that energy policy challenges facing the region are addressed in a consistent manner.

The interaction between outflow dynamics and removal of $\text{NH}_4^+\text{-N}$ in a vertical flow constructed wetlands treating septage

Y.Y. Tan, F.E. Tang, A. Saptoro & E.H. Khor

Faculty of Engineering and Science, Curtin University Sarawak Malaysia, Miri, Sarawak, Malaysia

ABSTRACT: This study investigated the influence of outflow dynamics on the treatment efficiency of $\text{NH}_4^+\text{-N}$ in a pilot-scale Vertical Flow Constructed Wetland (VFCW) designed for septage treatment. Continuous samplings had been carried out to measure the temporal effluent flux and the associated concentration of nitrogen compounds. The effluent shows a dependency on the sludge thickness at the wetland surface. The proposed system demonstrated a promising treatment for Total Nitrogen (TN), where the average removal reaches $69.21 \pm 16.75\%$. Nevertheless, it was observed that the overall removal of $\text{NH}_4^+\text{-N}$ is still below 50% and the concentration of $\text{NO}_3^-\text{-N}$ is high in the effluent. Comparisons between the peak of effluent flux and removal rate and linear regression analysis of the outflow and $\text{NH}_4^+\text{-N}$ dynamics revealed that the removal of $\text{NH}_4^+\text{-N}$ was greatly affected by the hydraulic behavior. As the nitrification is the main process in removing $\text{NH}_4^+\text{-N}$, the percolating rate through the wetland bed determines the contact time with the attached-growth biofilm which eventually govern the treatment performance.

1 INTRODUCTION

Septage is a sludge-based wastewater removed from the septic tanks (Crites and Tchobanoglous, 1998). Vertical Flow Constructed Wetland (VFCW) has become an attractive system in septage treatment due to its reasonable cost, low energy consumption and simple operation (Tan et al., 2015). The raw septage is loaded on the wetland surface with respect to the specified hydraulic or solid load. Then, it percolates through the wetland bed and then is freely drained from the bottom of the bed. In general, the VFCW system is fed after the previous batch of raw septage has been completely drained to allow the restoration of oxygen during the draining period. Studies have indicated that this type of septage treatment system showed a promising treatment for solids content and organic matter, where the removal of these parameters generally reach 80% in the existing system (Lienard and Payraastre, 1996; Koottatep et al., 2001; Paing and Voisin, 2005; Kengne et al., 2009; Troesch et al., 2009; Jong and Tang, 2014). Nevertheless, the removal of nitrogen is less consistent, where the removal efficiency of ammonium-nitrogen ($\text{NH}_4^+\text{-N}$) is below 60% in some systems (Lienard and Payraastre, 1996; Troesch et al., 2009) and the concentration of nitrate-nitrogen ($\text{NO}_3^-\text{-N}$) is generally increased after the treatment (Lienard and Payraastre, 1996; Koottatep et al., 2001; Paing and Voisin, 2005; Kengne et al., 2009; Troesch et al., 2009; Jong and Tang, 2014).

Nitrogen content in the raw septage, which mostly exist in the form of organic nitrogen (Org-N) and $\text{NH}_4^+\text{-N}$, are removed by means of physical and biochemical processes (Vymazal, 2007). The particulate Org-N is physically filtered at the wetland surface with other solids content to form a layer of sludge deposit. Meanwhile, the removal of dissolved Org-N and $\text{NH}_4^+\text{-N}$ mainly rely on sequential ammonification-nitrification. Nevertheless, the absence of denitrification due to the dominant aerobic environment results in excessive $\text{NO}_3^-\text{-N}$ (Vymazal, 2010). In VFCW system, the microorganisms involved in the biochemical process develop as a biofilm attached on the surface of porous medium (Kadlec and Wallace, 2008), and thus the treatment performance is governed by the flow rate through the wetland bed.

The influence of the system configuration (e.g. design of wetland bed, vegetation) and operational regimes (e.g. hydraulic and solids loading rate) to the overall nitrogen removal in VFCW-based septage treatment system have been well studied (Koottatep et al., 2001; Jong and Tang, 2014). Nevertheless, the study relevant to the relation between the outflow dynamics and effluent nitrogen content within a feed-drain cycle is very limited in the literature. Therefore, this research work aims to carry out a preliminary study to enhance the nitrogen treatment in the first stage treatment of a pilot-scale, two-staged VFCW-based septage treatment plant by controlling the hydraulic behaviour in the system. The hydraulic efficiency of the

system including the recovery of water and peak flux in the effluent was evaluated in respect to the hydraulic load, solids load and sludge thickness. Then, the outflow dynamics were compared to the concentrations of $\text{NH}_4^+\text{-N}$ and $\text{NO}_3^-\text{-N}$ concentration to identify their effect on the efficiency of $\text{NH}_4^+\text{-N}$ removal.

2 METHODOLOGY

Experimental data were collected from the first stage treatment of a pilot-scale, two-staged VFCW-based septage treatment system located at Curtin University Sarawak Malaysia. Two wetland beds were constructed in 1 m^3 polyethylene tanks, which have a surface area of 1.1 m^2 as shown in Figure 1. A 20 cm drainage layer was built using large gravel ($\text{Ø} > 5 \text{ cm}$) at the bottom of the bed. The main layer consists of two different sizes of crushed gravel, where a 27 cm thick medium-sized gravel layer ($\text{Ø} 2.5\text{--}3.75 \text{ cm}$) was topped by a 27 cm thick small-sized gravel layer ($\text{Ø} 0.95\text{--}1.25 \text{ cm}$). Two vertical ventilation pipes were installed along the wetland bed to enhance the reaeration. Nine clumps of common reeds (*Phragmites Karka*) were transplanted to each wetland bed. Prior to the data collection, the wetland bed was acclimatized with diluted raw septage for 2 months to stimulate the growth of vegetation and biofilm.

Raw septage was fed into the pilot-scale wetland bed through batch loading process in between November 2015 to February 2016. The raw septage was collected from the household area and was stored in two 400-gallon polyethylene tanks. During the operation, the raw septage was discharged to a 250-gallon feeding tank and was manually homogenised with a PVC stirrer. The hydraulic loads were varied at five different values of 50 l, 75 l, 100 l, 125 l and 150 l. Volume of the effluent was sampled and measured with respect

to the time after loading. The percentage of water recovery was calculated as a fraction of the volume of effluent and influent:

$$\text{Water Recovery (\%)} = \frac{\sum_{i=0}^N V_{e_i}}{V_0} \times 100\% \quad (1)$$

where N is the number of sample collections (-), V_e is the volume of effluent (l), and V_0 is the hydraulic load (l). The effluent flow rate (l min^{-1}) was converted to per unit area (cm min^{-1}) in the analysis.

Concentrations of Dissolved Oxygen (DO), $\text{NH}_4^+\text{-N}$ and $\text{NO}_3^-\text{-N}$ were measured using a HACH HQ40d portable multi-parameter meter with specific probes. The concentration Total Nitrogen (TN) in the raw septage and effluent were determined using Test'N Tube method with HACH DR2800 spectrophotometer. As the water loss was mainly attributed to the incomplete infiltration of influent, the Mass Removal Rate (MRR%) is estimated using a conservative equation to minimize overestimation of treatment performance:

$$\text{MRR(\%)} = \frac{C_0 \sum_{i=0}^N V_{e_i} - \sum_{i=0}^N C_{e_i} V_{e_i}}{C_0 \sum_{i=0}^N V_{e_i}} \times 100\% \quad (2)$$

where C_0 is the influent concentration (mg l^{-1}) and C_e is the effluent concentration (mg l^{-1}).

3 RESULTS

Eighteen sets of data were collected from the experimental work. Each case of hydraulic load was carried out for four runs except for 150 l, which was only carried out for two runs. Table 1 summarizes the operating conditions, comprising the hydraulic loads, thickness of surface deposit and solids content, and the experimental results of hydraulic performance, including the water recovery and peak effluent flux.

Due to the continuous operation and regular maintenance, the thickness of sludge deposit varied from 3 cm to 12 cm. Moreover, different batches of raw septage collection and varying hydraulic load led to the fluctuating solids load throughout the experiment, ranging from 105 g to 2325 g. The water recovery shifts between 9.72% and 90%. In a similar way, the peak effluent flux ranged from 0.004 to $0.073 \text{ cm min}^{-1}$. The mean water recovery and peak flux are $58.28 \pm 23.54\%$ and $0.027 \pm 0.018 \text{ cm min}^{-1}$, respectively.

The water recovery and peak effluent flux are highly dynamic with respect to hydraulic load and solids load. On the other hand, both parameters appears to be lower when the thickness of sludge

deposit layer reaches 8 cm as described in Figure 2. This observation highlights the importance of sludge thickness to the hydraulic performance. Nevertheless, neither high water recovery nor rapid effluent flux was solely influenced by a thin sludge deposit layer, where these hydraulic performances are still affected by varying hydraulic and solid load.

The DO concentration is extremely low in the raw septage (0.38 ± 0.32 mg l⁻¹). The average concentration of influent TN is 170.78 ± 104.96 mg l⁻¹, while the average influent concentration of NH₄⁺-N and NO₃⁻-N are 53.11 ± 12.49 mg l⁻¹ and 8.90 ± 4.63 mg l⁻¹, respectively. The high SD indicates the highly variable quality of septage throughout the experiment. As the concentration of nitrite in raw septage was very low and can be assumed negligible, the concentration of Org-N was estimated from the nitrogen balance. It was found that an average value of Org-N is 126.90 ± 96.44 mg l⁻¹. Table 2 displays the removal performance of nitrogen compounds in each case. In general, the treatment efficiency of TN was between 60% and 80%, which gave an average efficiency of $69.21 \pm 16.75\%$. The treatment of NH₄⁺-N is less effective since the average removal rate is less than 50%. The influent was well aerated and the concentration of NO₃⁻-N increased

throughout the treatment due to the favourable nitrification. Figure 3 illustrates that the removal rate of NH₄⁺-N tends to be proportional to the peak effluent flux, where a lower peak effluent flux most likely resulted in a better removal rate.

Figure 4 shows an example of the comparisons between outflow dynamics and the concentration of NH₄⁺-N and NO₃⁻-N in effluent of case 75A. The effluent flux typically reached maximum rate at the early stage of the feed-drain cycle. Then, the effluent flux gradually decelerated and stabilized at the late stage. The dynamics of NH₄⁺-N suggests a similar trend with the outflow dynamics, where the concentration is proportional to the effluent flux. Meanwhile, the NO₃⁻-N appears to show a progressive rise. Linear regression analysis was employed to establish the relation between

the outflow dynamics and $\text{NH}_4^+\text{-N}$ as shown in Figure 5. The results of coefficient of determination (R^2) are presented in Table 2. There are only three out of eighteen cases having a R^2 value below 0.7, and the average value of R^2 is 0.76 ± 0.15 .

4 DISCUSSION

The batch loading in the pilot-scale VFCW-based septage treatment system is described using a feed-drain cycle. Such a cycle is crucial in generating a variably-saturated condition to aerate the wetland bed during the dry period. Under this condition, the hydraulic behavior in the substrate

can be highly fluctuating, especially related to the alteration of hydraulic load and solids load. Theoretically, a higher hydraulic load creates a larger head difference at the wetland surface that accelerates the infiltration, and thus eventually results in a rapid effluent flux (Richards, 1931). Nevertheless, the solids content in the raw septage is retained and forms a sludge deposit layer instantaneously at the wetland surface during infiltration and subsequently influences the hydraulic behavior in the wetland bed.

The water recovery and peak effluent flux are found to be governed by the thickness of this low permeable layer, which is similar to the finding by Molle (2014). However, the sludge thickness is greatly affected by the operating strategies and influent quality.

These parameters are unable to be altered easily and directly. As a result, although the hydraulic and solids load did not show any direct impact on the water recovery and the peak effluent flux, these parameters are still crucial in governing the accumulation rate of sludge deposit. Xu et al. (2013) highlighted that higher hydraulic and solids load tend to generate a rapid sludge accumulation and ultimately lead to the clogging of wetland bed.

Org-N and $\text{NH}_4^+\text{-N}$ are found to be the major forms of nitrogen compounds in the raw septage. Meanwhile, the concentration of $\text{NO}_3^-\text{-N}$ is typically low. The Org-N exists in particulate and dissolved form. The former is mainly filtered at the wetland surface and the latter is hydrolyzed to $\text{NH}_4^+\text{-N}$ by ammonification. The favorable aerobic condition in a VFCW system promotes nitrification to oxidized $\text{NH}_4^+\text{-N}$ to $\text{NO}_3^-\text{-N}$. It should be noted that the nitrification is a transformative process. It is not an ultimate removal mechanism of nitrogen, where the changes of TN may be insignificant from this process. Therefore, the major removal of TN in the system is attributed to the straining of particulate Org-N in the wetland bed. This also explains the relatively consistent removal rate of TN compared to $\text{NH}_4^+\text{-N}$.

Adsorption is another important $\text{NH}_4^+\text{-N}$ removal pathway in the VFCW system. The adsorbed $\text{NH}_4^+\text{-N}$ is nitrified during resting and is washed out in the following feeding, so-called a two-step process (Woźniak et al., 2007). The flush out of $\text{NO}_3^-\text{-N}$ is observed at the early phase of effluent, which is illustrated in Figure 5. The limitation of anaerobic condition in the VFCW system inhibits the occurrence of denitrification (Vymazal, 2007), and thus the concentration of $\text{NO}_3^-\text{-N}$ generally remained high in the effluent throughout the experiment. The plant uptake is a potential mechanism for $\text{NH}_4^+\text{-N}$ and $\text{NO}_3^-\text{-N}$ treatment, however, its contribution to the overall nitrogen treatment is insignificant (Vymazal, 2007). In summary, the current system still requires

further improvements in delivering a complete nitrogen removal, especially for NO_3^- -N. A secondary treatment is required to enhance the removal of NH_4^+ -N and to eliminate excessive NO_3^- -N in the effluent.

As the nitrification involves biochemical mechanisms, the contact time between influent, attached-growth biofilm and oxygen content ultimately drive the treatment efficiency (Torrens et al., 2009). Under the operating regime of feed-and-drain, the Hydraulic Retention Time (HRT) in the VFCW system can be described as the percolating rate throughout the wetland bed. Figure 4 indicates that the overall removal of NH_4^+ -N shows a dependency on the peak effluent flux. The outflow and concentration of NH_4^+ -N are linearly correlated as their linear regression has high values of average R^2 . Accordingly, the treatment of NH_4^+ -N can be improved by controlling the percolating rate in the wetland bed.

The poor treatment efficiency of NH_4^+ -N in this study can be attributed to the rapid percolating rate throughout the wetland bed, where the HRT is relatively short to enhance nitrification. The experimental results indicate that the peak effluent flux is required to be control below 0.02 cm min^{-1} to achieve 50% of NH_4^+ -N removal.

According to Table 1, neither the loading regime with hydraulic load nor solid load effectively controls the HRT, as both factors show less effect on the effluent flux. Low HRT can be addressed by accumulating a thicker sludge deposit layer to decelerate the effluent flux. Nevertheless, the extended infiltration period is impractical from the view of productivity. Therefore, a further study is required to optimize the removal of NH_4^+ -N with a reasonable HRT. In addition to the optimization of operation, the identification of the correlation between outflow and nitrogen dynamics in a VFCW system treating septage will gains useful insight towards its numerical modelling. Langergraber and Šimůnek (2005) highlighted the importance of hydraulic simulation in modelling the VFCW system. Linear relationship proposed in this study will be able to simplify the calibration procedure in the modelling of nitrogen dynamics.

5 CONCLUSION

The first stage treatment of a pilot-scale VFCW system was tested and it was found that it demonstrates a promising treatment for TN. Nevertheless, the overall removal of NH_4^+ -N and NO_3^- -N were less efficient. Linear regression analysis was employed to obtain a correlation between the effluent flux and the associated NH_4^+ -N concentration. The high average R^2 (0.76 ± 0.15) indicates

that the NH_4^+ -N dynamics is greatly affected by outflow dynamics. In a VFCW system, the percolating flow rate determines the contact time between the contaminants and attached-growth biofilm. This parameter subsequently governs the nitrification rate and ultimately affects the overall treatment efficiency. A thicker sludge thickness is capable of extending the retention time of influent in the bed, however, it may reduce the productivity of the system at the same time. Therefore, a further study is required to optimize the treatment of nitrogen compounds with a reasonable HRT. These outcomes gain useful insights towards the optimization of operation and numerical modelling.

ABSTRACT: Water is an important resource in “the Belt and Road Initiative”. As the most important transboundary river in Asia, the Lancang-Mekong River plays a significant role in the development of aquatic ecosystems in “the Belt and Road Initiative”. For this reason, in this paper, non-radial direction distance function is used to analyze the water use efficiency of the Lancang-Mekong River Basin region from two perspectives (total-factor and water-factor indicators). Then, the influencing factors of water use efficiency in the Lancang-Mekong River are discussed using gray correlation analysis. The result shows that water use efficiency of Thailand, Cambodia, Yunnan and Qinghai is at a relatively optimal level, whereas for Vietnam, Tibet, Laos and Myanmar, it is relatively low. Economic development level, technological progress, industrial structure and trade and foreign investment have an impact on water use efficiency. Among the influencing factors, economic development level has the greatest impact.

1 INTRODUCTION

In September 2013, Chinese President Jinping Xi put forward “the Silk Road Economic Belt and the 21st-Century Maritime Silk Road” (referred to as “the Belt and Road”) during his visit to the Central Asian and Southeast Asian countries. The Silk Road Economic Belt region is ecologically fragile, comprising arid inland areas, where clean water is limited and per capita water resources are deficient. Serious water issue has become one of the most important resource factors that constraints “the Belt and Road Initiative”.

In March 2016, the Lancang-Mekong cooperation mechanism was established around the implementation of sustainable development and cooperation in the Lancang-Mekong River in order to promote regional integration process that includes water resource management, disaster response, etc. In fact, in 1992, the Asian Development Bank (ADB) had initiated the Greater Mekong Sub-regional Economic Cooperation Program (GMS) to strengthen the economic ties among the basin countries.

With the progress of “the Belt and Road”, many scholars studied the problem of water resources of Lancang-Mekong River. In China, the scholars

are concerned with issues such as sustainable water utilization (Guo et al., 2013) and co-management among Mekong river basin countries (Piao et al., 2013). Scholars from other countries pay more attention to China’s water exploitation on upper Mekong River from the perspective of international relations and its political effect (Menniken, 2007; Hensengerth, 2009).

The importance of Lancang-Mekong River has concerned scholars, but existing research mostly analyzes water utilization from a macro level. However, due to the challenge of increasing scarce water resources, improving water use efficiency seems to be the effective solution to improve water imbalance between supply and demand and for sustainable use of water (Allan, 1999; Deason et al., 2001). Former EPA Administrator William Reilly points out that water use efficiency is not high in the world, and typically 50% of the water is wasted. The UK government ensures improvement of water use efficiency and reduction of water pollution to achieve both environmental protection and sustainable utilization of water resources. China’s *Water Law* clearly indicates the improvement in water use efficiency through reasonable water resource allocation of agricultural water, industrial water and domestic water.

In this view, we studied water utilization of Lancang-Mekong River Basin regions from the perspective of water use efficiency using quantitative analysis. Because of the difference of geographical conditions, economic development level and the dependence on water resources, water use efficiency is different. Then, we explored the factors that influence water use efficiency on the basis of the estimated water use efficiency. Finally, some suggestions have been put forward to increase the water use efficiency in order to achieve sustainable development of the water resources of the Lancang-Mekong River Basin region.

2 METHODOLOGY

2.1 Non-radial directional distance functions

In the current research (Zhang et al., 2014), non-radial directional distance function is established to estimate water use efficiency from two perspectives: total-factor indicator and water-factor indicator.

Suppose there are N regions, and each region uses capital (K), labor (L), and water (W) as inputs, and gross domestic product (Y) as output. Then, the production technology can be described as follows:

$$T = \left\{ (K, L, W, Y) : \sum_{n=1}^N \lambda_n K_n \leq K, \sum_{n=1}^N \lambda_n L_n \leq L, \sum_{n=1}^N \lambda_n W_n \leq W, \sum_{n=1}^N \lambda_n Y_n \geq Y, \lambda_n \geq 0, n = 1, 2, \dots, N \right\} \quad (1)$$

The non-radial directional distance functions of water use efficiency can be defined as follows:

$$\bar{D}(K, L, W, Y; g) = \sup \{ w^T \beta : ((K, L, W, Y) + g \times \text{diag}(\beta)) \in T \} \quad (2)$$

where, $w = (w_K, w_L, w_W, w_Y)^T$ denotes the normalized weight vector relevant to the numbers of inputs and outputs; $\beta = (\beta_K, \beta_L, \beta_W, \beta_Y)^T \geq 0$ denotes a vector of scaling factors representing individual inefficiency measures for each input/output; and $g = (-g_K, -g_L, -g_W, g_Y)$ is the explicit directional vector representing the expectation of each input/output to reduce/increase.

Considering water resource investment and other inputs, the total-factor non-radial direction distance function can be calculated using the following DEA-type model:

$$\begin{aligned} \bar{D}(K, L, W, Y; g) &= \max w_K \beta_K + w_L \beta_L + w_W \beta_W + w_Y \beta_Y \\ \text{s.t. } \sum_{n=1}^N \lambda_n K_n &\leq K - \beta_K g_K, \sum_{n=1}^N \lambda_n L_n \leq L - \beta_L g_L, \\ \sum_{n=1}^N \lambda_n W_n &\leq W - \beta_W g_W, \sum_{n=1}^N \lambda_n Y_n \geq Y + \beta_Y g_Y, \\ \lambda_n &\geq 0, n = 1, 2, 3, \dots, N, \beta_K, \beta_L, \beta_W, \beta_Y \geq 0 \end{aligned} \quad (3)$$

If $\bar{D}(K, L, W, Y; g) = 0$, then the region to be evaluated is located along the best-practice frontier in the g direction. Assume that the input and output are equally important, both to be given weight 1/2. Then, the average is given the weight 1/2 to three inputs. Therefore, we set the weight vector as $w^T = (1/6, 1/6, 1/6, 1/2)$ and the directional vectors as $g = (-K, -L, -W, Y)$.

Suppose that $\beta_K^*, \beta_L^*, \beta_W^*, \beta_Y^*$ represent the optimal solution to Eqs. (3). We define the average efficiency of each factor as Total-Factor Efficiency Index (TEI). Then, the TEI can be formulated as follows:

$$\begin{aligned} TEI &= \frac{1}{3} \left[\frac{(1 - \beta_K^*) + (1 - \beta_L^*) + (1 - \beta_W^*)}{1 + \beta_Y^*} \right] \\ &= \frac{1 - \frac{1}{3}(\beta_K^* + \beta_L^* + \beta_W^*)}{1 + \beta_Y^*} \end{aligned} \quad (4)$$

To measure the pure water use efficiency, it is better to fix non-water inputs. Assuming that capital and labor are fixed, the maximum reduction ratio of water and the maximum increase ratio of output are evaluated. We set the weight vector as $w^T = (0, 0, 1/2, 1/2)$ and the directional vectors as $g = (0, 0, -g_W, g_Y)$. Then, the Water-Factor Efficiency Index (WEI) is expressed as follows:

$$WEI = (1 - \beta_W^*) / (1 + \beta_Y^*) \quad (5)$$

The TEI and the WEI both lie between zero and unity. If the TEI/WEI is equal to unity, it means that the region is located along the frontier of best practice.

2.2 Gray correlation analysis

Gray correlation analysis model can be formulated as follows:

Let reference sequence $X_0 = (x_0(1), x_0(2), \dots, x_0(n))$ and compare sequence $X_1 = (x_1(1), x_1(2), \dots, x_1(n))$, $X_2 = (x_2(1), x_2(2), \dots, x_2(n))$, ..., $X_m = (x_m(1), x_m(2), \dots, x_m(n))$.

For $\rho \in (0, 1)$, let

$$\gamma(x_0(k), x_i(k)) = \frac{\min_k \min_i |x_0(k) - x_i(k)| + \rho \max_k \max_i |x_0(k) - x_i(k)|}{|x_0(k) - x_i(k)| + \rho \max_k \max_i |x_0(k) - x_i(k)|} \quad (6)$$

$$\gamma(X_0, X_i) = \frac{1}{n} \sum_{k=1}^n \gamma(x_0(k), x_i(k)) \quad (7)$$

where, ρ denotes the distinguishing coefficient, usually with a value of 0.5. The value does not affect the results of the sort, only changes the size of the relative value; $\gamma(X_0, X_i)$ denotes gray correlation degree between X_0 and X_i .

2.3 Data

In comparison with other five countries, China has a vast territory and complicated geographical features, and the economic scale and population also vary greatly. In order to increase the comparability, we selected Qinghai, Tibet and Yunnan, which are the regions the Mekong flows through in China, as the research object was to analyze water use efficiency of the Mekong River Basin regions.

Due to the availability of data, we selected the statistical data of eight regions of the Mekong River Basin in 2013. The data was respectively collected from the *World Bank WDI database*, *IMF database*, *WTO database*, *UNCTAD FDI database* and *China Statistical Yearbook*.

We measured the output (Y) of each region by GDP and the capital input (K) by gross fixed capital formation. The labor input (L) was measured by the number of employees in each region. Due to different statistical standards, the water input of Laos, Myanmar, Thailand, Cambodia and Vietnam was measured by annual freshwater withdrawals, whereas the water input of Qinghai, Tibet and Yunnan was measured by the annual total water use.

The following factors influencing water use efficiency were considered. (1) Water use efficiency is affected by regional economic and social development. Economically developed regions are more likely to show greater water efficiency (Zhang et al., 2014). Economic development level was measured by the per capita GDP of each region. (2) Upgrading water-saving technology is the direct path to improve water use efficiency. We measured technological progress by the ratio of capital to labor. (3) The difference of water use efficiency stems from different economic structures (Deng et al., 2016). Agriculture is the largest sector of water consumption. The ratio of added value of agricultural sector to GDP was measured to influence water use efficiency. (4) Imports of virtual water can increase the supply of water in the importing country and reduce their water pressure. Therefore, trade inevitably influences water consumption and use efficiency. Therefore, import trade (import/GDP) and export trade (export/GDP) are assumed to affect water use efficiency. (5) Foreign investment helps improve water use efficiency through technology spillover. We measured foreign investment in terms of foreign direct investment.

3 RESULTS AND DISCUSSION

3.1 Estimation results of water use efficiency

Water use efficiency is calculated and showed in Figure 1. From Figure 1, it can be observed that the average TEI of the Mekong River Basin region is 0.8239. Thailand, Cambodia, Yunnan and Qinghai show the highest TEI values (unity), indicating that water use efficiency of these regions is at a relatively optimum level. The TEIs of Vietnam, Tibet and Laos are 0.6995, 0.6702 and 0.5962, respectively. The TEI in Myanmar is the lowest, with the value of 0.4492. The average WEI of the Mekong River Basin region is 0.7082. Thailand, Cambodia, Yunnan and Qinghai still show the highest WEI values (unity). In these regions, the level of water usage and output are in optimal frontier. They have less improved space. The WEI in Vietnam, Tibet, Laos and Myanmar are all less than 0.5, with the value of 0.4698, 0.3469, 0.3042 and 0.2528, respectively. The average TEI is higher than the average WEI, indicating that the Mekong River Basin regions show better performance in TEI than WEI.

TEI and WEI both indicate that in the process of economic development, the capital, labor and water accomplish optimum allocation in Thailand, Cambodia, Yunnan and Qinghai of water resources. In Vietnam, Tibet, Laos and Myanmar, the capital, labor and water are largely the inputs, but the output efficiency is low. This means that water allocation deviates from the optimal configuration because of capital, labor and water input redundancy or output deficiency. Extensive mode of development and low water recycling rate may be the causes of low water use efficiency in these regions. There is huge potential in these areas in terms of saving water resources; improving water use efficiency; and increasing the output.

3.2 Factor analysis of water use efficiency

Gray correlation degree between TEI/WEI and its factors are shown in Table 1. It can be observed

Figure 1. Comparison of TEI and WEI for Mekong River basin regions.

Table 1. Gray correlation degree between water use efficiency and its factors.

Efficiency index	TEI	WEI
Economic development level	0.8166	0.8579
Technical progress	0.7469	0.8037
Industrial structure	0.6031	0.6244
Trade		
Import	0.7693	0.7976
Export	0.7266	0.7607
Foreign investment	0.7003	0.7265

that the correlation degree between economic development level and TEI is the highest, with values of 0.8166; the next factor is import trade, and correlation degree is 0.7693; the correlation degree of technological advances and TEI, export trade and TEI, foreign investment and TEI are 0.7469, 0.7266 and 0.7003, respectively; the correlation degree between industrial structure and TEI is the lowest, with the value of 0.6031. Compared with correlation degree between TEI and its factors, the order of correlation degree between WEI and its factors is slightly different. Specifically, the correlation degree between economic development level and WEI is still the highest, with the value of 0.8575, whereas the correlation degree between industrial structure and WEI is still the lowest, with the value of 0.6244; the correlation degree between technological progress and WEI comes in the second place, with the value of 0.8037; and the correlation degree of import trade, export trade and foreign investment are 0.7976, 0.7607 and 0.7265, respectively.

Overall, the result shows the following. (1) Economic development level has a great impact on the water use efficiency. Higher level of economic development provides support for the water use efficiency and stabilizes the water infrastructure construction. (2) Technological progress improves the water-saving technology and equipment, thereby improving water use efficiency directly. (3) The effect of import trade is greater than export trade. Using import and export commodity, considering local water use efficiency and water use by using comparative advantage theory, the region can reduce water consumption and improve water use efficiency. (4) Local enterprises can get access to advanced international knowledge and production management experience through technology spillover from foreign-invested enterprises. It is conducive to improve water use efficiency. (5) The higher the proportion of agriculture in the economic structure, the more the agricultural water consumption. Low efficiency of agricultural water consumption reduces overall water use efficiency.

4 CONCLUSIONS AND SUGGESTIONS

Using non-radial direction distance function, this paper analyzes water use efficiency of the Lancang-Mekong River Basin regions from the perspective of total-factor and water-factor indicators. Then, the influencing factors of water use efficiency are discussed using gray correlation analysis. The result shows that water use efficiency of Thailand, Cambodia, Yunnan and Qinghai are at a relatively optimal level, whereas Vietnam, Tibet, Laos and Myanmar are relatively low. Economic development level, technological progress, industrial structure and trade and foreign investment have an impact on water use efficiency. Among the influencing factors, economic development level has the greatest impact, followed by technological progress and trade, and the effect of industrial structure is relatively low.

On this basis, we propose the following suggestions. (1) The modernization level of water conservancy and paddy field irrigation can be improved, water-saving agricultural technology can be spread, and methods for low water consumption in agriculture can be developed. China already has certain mature water-saving irrigation techniques such as sprinkling irrigation and drip irrigation. Through technical output and cooperation with the Mekong River Basin regions, regions with low water use efficiency can reduce water waste and improve water use efficiency. (2) Regions with low water use efficiency can import water-intensive commodity, while using inadequate water for economic activities can produce higher economic returns. (3) The agricultural structure can be adjusted. The Lower Mekong countries are agricultural countries, and rice is the agricultural pillar industry. However, the water consumption of rice is large. To alleviate water shortage, the regions can reduce rice cultivation while enriching cash crops species. (4) Institutionally, as one of the economic instruments that optimizes water resource allocation and water shortage relieving, establishing water price rationally can encourage farmers to increase crop production and save irrigation water. For crops with high yield per unit area and low water consumption, low water prices can be levied; for crops with low yield per unit area and high water consumption, high water prices can be levied. (5) At the national level, the basin countries play a complete role in “the Belt and Road Initiative” and Lancang-Mekong cooperation mechanisms. On the one hand, they enhance environmental protection and increase the total amount of water resources, and on the other hand, they strengthen communication and coordination to achieve reasonable allocation of water resources and benefit sharing.

An accessibility study of elevator Braille signage system in Da Nang City, Vietnam

C.Y. Hsia & C.M. Huang

Program in Civil and Hydraulic Engineering, Feng Chia University, Taichung, Taiwan

Liang Tseng

Department of Architecture, Feng Chia University, Taichung, Taiwan

ABSTRACT: This paper is about elevator equipment in Da Nang City, Vietnam. The research project is based on the accessibility norms of the Braille system of barrier-free elevator equipment set up, and the differences are analyzed. The research purposes are as follows: first, Da Nang City elevator Braille system’s analysis and explanation of the meaning of its contents; second, according to the Vietnamese TCXDVN 264-202, houses and buildings, basic rules of accessible design and construction are applied for people with disabilities, where 64.3% of Braille panel used English Braille and 21.4% used Korean Braille. Elevator equipment should comply with the provisions of the concept of universal design.

1 INTRODUCTION

The subject of this study is accessible elevator Braille systems in Da Nang City, Vietnam. The research background and motivation and objectives of this study are as follows.

1.1 Background and motivation

This study investigates the limitations of inaccessible elevators with Braille System and the literal meanings of Braille symbols, locations, and floor setups in elevators in public transport systems, departmental stores, office buildings, and hospitals in Da Nang City with reference to Vietnamese Construction Standards TCXDVN 264:2002. The study compares the elevator specifications from three aspects: design, use, and construction.

1.1.1 Design aspect

According to section 5.8.3 of the Vietnamese Construction Standards TCXDVN 264:2002 specifications, Braille systems must be provided in accessible elevators in public buildings, venues, and public transport systems for the aid of the disabled, as shown in Fig. 1.

1.1.2 Use aspect

During the research that examined the accuracy of Braille symbol placement in elevators, field studies were conducted and photographs were captured. Braille chips are typically placed in two locations: (a) at the lower part of the

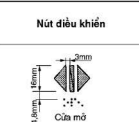

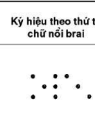

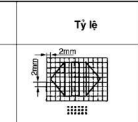

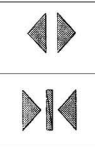

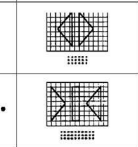

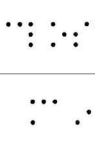

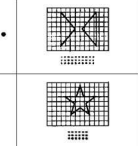

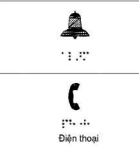

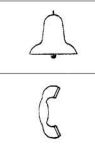

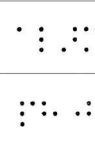

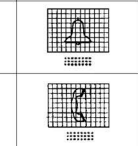

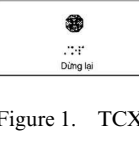

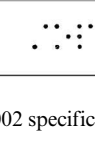

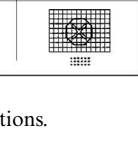

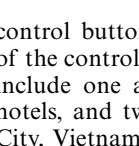

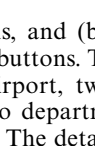

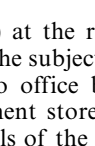

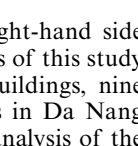

Nút điều khiển	Ký hiệu quy ước	Ký hiệu theo thứ tự chữ nổi brail	Tỷ lệ
			
			
			
			
			
			

Figure 1. TCXDVN 264:2002 specifications.

control buttons, and (b) at the right-hand side of the control buttons. The subjects of this study include one airport, two office buildings, nine hotels, and two department stores in Da Nang City, Vietnam. The details of the analysis of the

Table 1. Da Nang City, to investigate the object tables.

current situation of accessible elevator facilities are listed below.

Representations of these buildings are presented in Table 1. According to the Vietnamese construction law regulations, Braille symbols must be placed “at the lower part of control buttons.” Therefore, the cases collected from the field studies are compared against the current regulations in Vietnam for an accurate analysis.

1.1.3 Construction aspect

Since construction workers may not have sufficient knowledge of Braille, they may not accurately place the symbols, which could lead to incorrect arrangement of Braille symbols. This study will review the contents of Braille, construction, location, and whether or not they are in the correct proportions.

1.2 Research objectives

The refinement of elevator Braille signage systems that better suit elevator deployment scenarios is subsequently based on the survey results in areas as follows:

1. Braille systems in elevator facilities;
 2. Functional meanings and the positioning of control buttons;
 3. Braille systems in use.
- It is expected that the findings of this study can be used as a reference for accessible elevator Braille chip system design and construction in Taiwan, in addition to as a reference for a universal design complying with international standards.

2 RESEARCH SUBJECT AND PROCEDURE

The subjects of this study include one airport, two office buildings, nine hotels, and two department

stores of Da Nang City, Vietnam. The details of the analysis of the current situation of accessible elevator facilities are listed below.

Representations of these buildings have been shown in Table 1.

2.1 Procedures of research and analysis

2.1.1 Determining the subject

Four types of organizations were selected as the research subjects: airports, office buildings, hotels, and departmental stores.

2.1.2 Aspect analysis

This analysis included the design aspect, user aspect, and construction aspect.

2.1.3 Problem definition

- A. Based on the design aspect, problems were divided into two categories: Braille systems and literal meanings.
- B. Based on the user aspect, problems were divided into two categories: chip positioning and chip recognition.
- C. Based on the construction aspect: the problem definition was from the point of view of whether the construction workers misplace the Braille signs.

2.1.4 Functional divisions

Functions were divided into internal and external functions.

2.1.5 Individual buttons

Up, down; open, close; floor; and alarm.

2.1.6 Solutions

Solutions for problem resolution are provided using the following analysis.

2.1.7 Conclusion

A Braille symbol table is developed for design referencing.

3 CASE ANALYSES OF VARIOUS ASPECTS

In this study, accessible elevator facilities in airports, office buildings, hotels, and departmental stores in Da Nang City were examined. Various aspects of the data were gathered from a survey and processed with statistical procedures for the analysis.

Analysis from the design aspect: (Tables preceding with letter A): two codes (A1 and A2) are used for elevator Braille panel design and their meanings.

A. Braille System (i.e., English Braille, numeric, and Korean letters). B. Meanings of words.

3.1 A1-1: Analytical comparisons on the landing call buttons of the Braille signage system

- A. The number of cases adopting A1 Braille system in elevators with English Braille systems and Braille signage systems with another language were statistically analyzed.
- B. Functional division: A1-1, [up · down]; the up and down buttons of the elevator outside the control panel buttons.
- C. Statistical comparison: A1-1 [up · down]; function buttons using Braille signage system proportion. 50.00% were with English Braille; 21.43% were with Korean Braille; 7.14% were with Braille Chinese Roman pronunciation, and 21.43% systems did not have Braille signs.

The Vietnam construction standard TCXDVN 264:2002 does not regulate up · down Braille.

3.2 A2-2: Analytical comparisons of the literal meanings of the open and close buttons

- A. Problem definition: Statistical analysis of the variance of A2 word meanings against the collected cases.
- B. Functional division: A2-1, open and close section: opening or closing the door by controlling the open and close buttons on the internal control panel.
- C. Statistical comparisons: Analysis of the Braille system open buttons, function buttons content word meaning [opn] with 42.86%, [open] with 14.29%, [op“en”] with 7.14%, Korean Braille [ㄹ] ke] with 21.42%, Chinese Braille [k “ai” m “en”] with 14.29%. Analysis Braille close buttons, Function buttons literal content [cls] with 14.29%, [“sh”ut] with 35.71%, [close] with 7.14%, [shut] with 7.14%, Korean Braille [ㅍ] pye] with 21.43%, Chinese Braille [g “wan” m “en”] with 14.29%.

3.3 B1-2: Analytical comparisons between chip positions in open and close buttons

- A. Problem definition: Statistical analysis of the case for the position of the elevator Braille signage with the buttons' positioning.
- B. Functional division: B1-2, open and close section: the elevator control panel of the button inside the elevator door button.
- C. Statistical comparisons: open and close buttons. The positional relationship between the proportion of function buttons with Braille signage. Analysis Braille position [open] buttons, Braille

elevator buttons located at the lower part of the button comprise 71.43%, 21.43% are located on the left-hand side, and 7.14% are located on the left-hand side of the button. Analysis of position of Braille [close] buttons: 71.43% are located in the lower part of the button; 7.14% are located on the left-hand side of the button; 14.29% are located on the right-hand side of the button; and 7.14% are located on the left-hand side of the button.

4 PROBLEMS AND COUNTERMEASURES

Fourteen public buildings of Da Nang City, Vietnam were selected for the analysis from various aspects, and the problems and countermeasures are as follows.

4.1 Design aspect

A. Problems: Inconsistent abbreviations of English usage in the Braille system.

- a. Braille systems with English characters comprised 64.29%, other 21.43% used Korean Braille, and 14.29% used Chinese Braille (Roman alphabet).
- b. For example, among the close buttons, up to 35.7% used the English word “sh u t”, which is different from the word “close” as recommended by Vietnamese standard.
- c. The up and down buttons used the English words “up” and “down”, with three elevators adopting the Korean Braille system. Two elevators adopted the Chinese Braille system.
- c. Several English words for the alarm buttons were used, including “alm” and “alarm”. The “alm” did not conform to the Vietnamese standard, but was used in 14.28% of the cases.

4.2 The use aspect

- A. Problems: Braille symbols should accommodate the tactile-based reading behaviors of people with visual impairments. Therefore, Braille symbols should be prominently positioned at the bottom of the control buttons for easy recognition. Currently, ground floors are represented by multiple variations of the English Braille symbols, including 1 and G, causing confusion.
- B. Countermeasures: In accordance with Vietnamese standards, the English words representing the floor landing call buttons have not been standardized. Users with visual impairments spend a lot of time confirming the control buttons.

Figure 2. Braille clip site-position of U.D.

4.3 The construction aspect

- A. Problems: For Braille signs located on the button below, whether a tactile behavior will affect the visually impaired, the Vietnamese construction standards TCXDVN 264:2002 specification left.
- B. Countermeasures: For the Braille tactile position, the behavior of the visually impaired must also be considered. The use of left button keyboard as keys to increase the area. Therefore, Braille located beneath the bump button is easy to discern with clarity, and using the function keys helps in reducing the time for confirmation by the visually impaired people.

This is in accordance with the Vietnamese construction standards TCXDVN 264:2002 specification left.

5 CONCLUSION

In Da Nang, Vietnam, 14 public buildings’ (barrier-free elevator) elevator Braille systems were compared and analyzed, and the following resulting conclusions and solution proposals were made:

- A. According to the Vietnamese construction standards TCXDVN 264:2002 standard, the proportion abbreviation system is as follows: [close] 7.14%, [open] 14.29%, [alarm] 21.44%, and Braille [phone] 14.28%. The efficiency of the implementation details need to be discussed.
- B. In Vietnam, usually, floor 1 (ground floor) begins with number [1] and G Floor (Ground Floor), proposal on the ground floor label with the number [1] F (most used) representative, while still underground floors with B1, B2, B3 (the current situation most used).
- C. The universal design is divided into the two parts: first, with the universal design, Braille is located in the lower part of the button using English Braille; second, the local language Braille System is located at the left-hand side of the button. The English Braille and the sign should be printed into a single button. The local

language Braille should be placed on the left-hand side separately (as shown in Fig. 2).

- D. The universal design should be installed in all the accessible elevators in public transportation facilities where frequent international travelling occurs, such as in airports or mass rapid transition, e.g. the subway stations.

Investigation and analysis of thermal comfort and IAQ in naturally ventilated primary school classrooms

Fusheng Ma & Changhong Zhan

School of Architecture, Heilongjiang Cold Climate Architecture Science Key Laboratory, Harbin Institute of Technology, Harbin, China
Institute of Architecture Design and Research, Shenyang Jianzhu University, Shenyang, China

Xiaoyang Xu & Yu Tang

School of Architecture and Urban Planning, Shenyang Jianzhu University, Shenyang, China

ABSTRACT: This research studied the variables of the thermal environment and Indoor Air Quality (IAQ) of classrooms in a naturally ventilated primary school in Shenyang during winter. Some features of thermal sensation and IAQ satisfaction of pupils and teachers in the classrooms were revealed. Field measurements were carried out in 6 classrooms occupied with 32 teachers and 197 pupils in total from November to December 2015, while the heating system was used. The results indicated that classrooms' IAQ was bad. Thermal comfort and IAQ satisfaction of pupils and teachers in the classroom were significantly different. Most of the pupils could not make accurate judgments of the indoor air quality. It was demonstrated that the existing ventilation mode could not meet the needs of thermal comfort and IAQ of classroom in winter.

1 INTRODUCTION

Thermal environment and IAQ are two essential components to evaluation on quality of indoor environment in severe cold region. Researchers started to evaluate the indoor environment of schools from the students' perspective on thermal comfort in the 1970s (Table 1).

By studying children' thermal comfort and preference, Humphreys found that most children under the age of seven, usually less sensitive to thermal environment than adults, can understand and use simple expressions to describe their thermal sensations (Humphreys 1977). Sander ter Mors, a Dutch scholar, found that the comfortable temperatures of pupils were lower than previous theoretical predictions from thermal comfort models and they prefer a cooler environment (Mors et al. 2011). Teli, a British scholar, found that students had different thermal sensations compared to adults in the classrooms (Teli et al. 2012).

Different regional groups usually have different thermal demand due to the theory of thermal comfort of the human body. Although the researches on the thermal comfort of the children were gradually enriched recently, there were few researches on thermal comfort of minors under natural ventilation in winter. In winter of Shenyang China, the main type of ventilation in classrooms is natural ventilation. However, teachers and pupils control

Table 1. Thermal comfort field studies in school classrooms.

*NV = natural ventilation; *AC = air-conditioning; *MM = mixed-mode ventilation.

the ventilation into the classrooms by thermal comfort rather than air quality. The indoor air quality was poor due to the lack of ventilation to keep the indoor air temperature. The above suggests that there was a need for research on the thermal perception of children in Shenyang's school classrooms to obtain a deeper understanding of pupil thermal preferences. The aim of this study was to extend the knowledge base of pupils' response towards their classrooms' thermal environment. The main objectives were as follows; to record the current situation of the environment, to analyze the influence of gender on indoor thermal sensation, to compare the difference of thermal sensation between pupils and teachers, to test whether pupils have the ability to evaluate the quality of the classroom.

2 THERMAL COMFORT FIELD STUDY

2.1 *The school for case study*

The object of this study was located in Shenyang, that northeast of China (Fig. 1). In the Chinese building climate district, Shenyang is belong to the severe cold region. The average annual temperature of Shenyang was 6.2 to 9.7 degrees, and the average temperature in January was less than or equal to -10°C . Shenyang had 5 months in winter, so from the beginning of November to March of next years, the central heating be used.

This school had two buildings. The case study part was denoted as B on Figure 1. The case study building had 6 floors. It was a typical frame structure without thermal insulation structure. The case study building used hot water radiation. The main ventilation type was natural ventilation.

Figure 1. Main plan of school building and school ground.

Occasionally the teachers opened doors and windows for ventilation.

The case study building had 34 classrooms. These classrooms were arranged in two sides along the corridor. In this study, we selected 6 classrooms in the fourth floor. There were 4 classrooms in south orientation and 2 classrooms in north orientation. The classroom size was 6600 mm \times 8400 mm. There were two doors, three windows and one internal window in each classroom. The door size was 2100 mm \times 900 mm, the window size was 2100 mm \times 1500 mm, and the internal window size was 600 mm \times 1500 mm. Inside windows and outside windows were sliding windows. Ventilation was achieved through manually opening the classroom windows, which was usually undertaken by the teachers or students near the windows.

There were 197 pupils in 6 classrooms aged 9~12, in grades 5~6. There were 97 boys and 100 girls. The information of classroom was shown in Table 2.

2.2 *Measurement instruments*

Indoor temperature and relative humidity were selected to denote the comfort level of indoor thermal environment. The CO_2 concentration was measured as an important indicator of IAQ. The test were lasted from November 24th to December 24th in 2015, using RR002 temperature/RH logger and handheld Telaire 7001 CO_2 tester (Fig. 3). Figure 4 showed outdoor temperature of Shenyang during test period.

The above parameters were measured at a height of 1.1 m except for the middle measured point. The middle measured point in the classrooms was measured at a height of 0.75 m. The measuring performance specification was shown in Table 3.

2.3 *Survey questionnaire*

The questionnaire was divided into teachers' questionnaire and students' questionnaire. The questionnaire includes; 1) gender, age 2) the thermal sensation, humidity sensation 3) the satisfaction evaluation of thermal sensation 4) the satisfaction degree of the air quality evaluation.

The questionnaires were issued from November to December in 2015. 197 questionnaires were distributed to the students in this study, and 197 valid questionnaires were recovered. 32 questionnaires were distributed to the teachers, and 32 valid questionnaires were recovered. The thermal sensation.

(TSV) scales and satisfaction scales used in the questionnaire were shown in Table 4.

3 RESULTS AND DISCUSSION

3.1 Indoor thermal environment and air quality in winter

Table 5, which is organized by classroom, gives the mean, Standard Deviation (SD), maximum and minimum values of each environmental parameter measured during the surveys. It was found the 6 classrooms almost did not open windows in class during test period. The air speed was tested several times as 0m/s while windows kept closed. Hence, the study does not treat air speed as the environment parameter.

Table 5 showed that the temperatures of classroom No.1 to No.4 varied greatly. Indoor temperatures of classroom No.2 and No.3 were lower than the standard value (18°C). That because windows of classroom No.1 to No.4 were opened randomly by teachers or students during the class interval. Times of opening windows in classroom No.2 and No.3 were more than other classrooms. Classroom No.5 and No.6 almost don't open the window. So the temperatures of them were higher than the other classroom. Thus, winter ventilation by opening windows is the main cause of indoor heat loss in severe cold region.

In the aspect of indoor relative humidity, the relative humidity of the six classrooms was significantly different. The relative humidity of classroom No.1 and No.3 was slightly higher than the standard value (40%-60%).

The concentration of carbon dioxide in the six classrooms was significantly higher than that of the national standard (1500ppm). Because of insufficient ventilation rate. Ventilation for a short time could not solve the problem of indoor air quality.

3.2 User evaluation of thermal environment and air quality

Pupils' evaluation of indoor air quality was illustrated in figure 5. Generally speaking, students' evaluation of indoor air quality is satisfactory. Table 5 shows that the six classrooms IAQ were poor in the actual measurement, but pupils had a good evaluation of indoor air quality. There was a significant difference between the subjective evaluation of pupils and the objective measurement of IAQ.

The main reason was divided into the following points; 1) Pupils' knowledge of IAQ is not enough. Most pupils know little about IAQ. 2) It might

Figure 5. Pupils' evaluation of indoor air quality.

Figure 7. Pupils' evaluation of relative humidity.

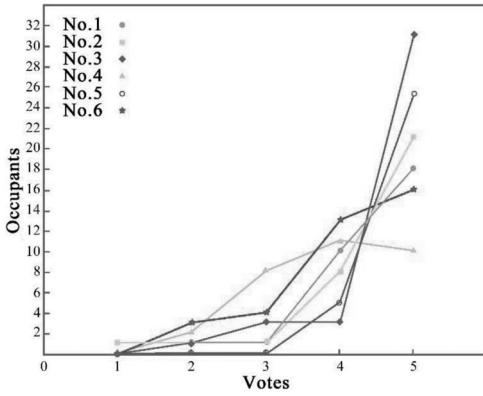

Figure 6. Pupils' evaluation of indoor temperature.

has a certain adaptability to the indoor air quality, because pupils had to remain staying in the classrooms for a relatively long time.

Study shows that pupils have a certain ability to evaluate the indoor air quality, but the gap between the evaluation and the actual measurement results was huge.

Figure 6 was shown that the pupils' evaluation of indoor temperature was very good. Among them, pupils in the classroom 4 had the highest degree of satisfaction with the temperature. Although there were two classroom temperatures slightly lower than 18°C and the excessive temperature differentials.

Figure 7 describes the degree of satisfaction with the relative humidity of the pupils. In general, pupils were satisfied with the relative humidity of the classrooms. Most students know little about relative humidity. But under the guidance of teachers, pupils were able to make the evaluation of indoor relative humidity.

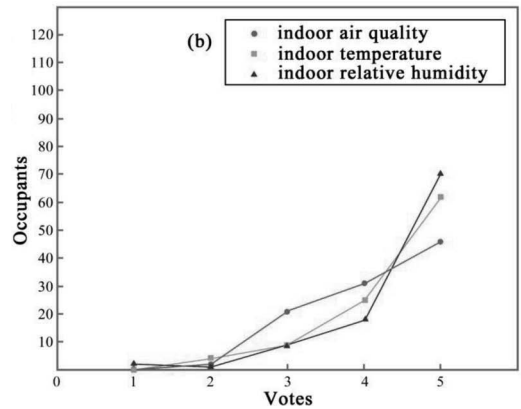

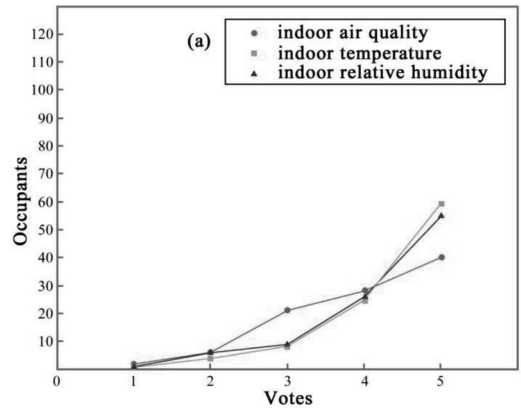

Figure 8. Influence of gender on evaluation (a) The satisfaction votes of boys, (b) The satisfaction votes of girls.

According to the comparison figure 8 (a) and (b), there was no significant difference between boys and girls of the evaluations of IAQ, indoor temperature and indoor relative humidity. It means

there was no influence of gender on evaluation of IAQ, indoor temperature and indoor relative humidity.

Figure 9 was shown that pupils' and teachers' evaluation in the classroom of IAQ, temperature, and relative humidity was very different. Pupils' evaluations to the classroom air quality, temperature, relative humidity were very high, but teachers' evaluations to the classroom air quality, temperature, relative humidity were not so good. The reasons that lead to the difference between teachers and students were; differences in educational

background, attention of environment and evaluation criteria.

4 CONCLUSION

The study shows the existing ventilation mode couldn't meet the needs of IAQ in the classroom during heating seasons. The indoor temperature varies greatly due to the ventilation by randomly opening window. Ventilation by open window would make a great waste of heat. Therefore, the appropriate ventilation mode should be used in the classroom during winter. The objective test showed that the air quality in the six classrooms was quite poor, because the concentration of carbon dioxide in all of the six classrooms exceeded the level for body health. There were obvious differences between pupils and teachers in the subjective evaluation results. Pupils could not make accurate evaluation of indoor air quality. Appropriate monitoring equipment should be used in school classroom.

Improvement of the ensemble forecast of typhoon track in the Northwestern Pacific

J.Y. Yuan

State Key Laboratory of Hydrology-Water Resources and Hydraulic Engineering, Hohai University, Nanjing, China

Y. Pan & Y.P. Chen

College of Harbor, Coastal and Offshore Engineering, Hohai University, Nanjing, China

ABSTRACT: An accurate forecast of typhoon track is essential for the effective mitigation of typhoon-induced loss in the coastal areas. Based on the dynamical analysis of forecast errors of typhoon track at four weather forecast centers, i.e. China Meteorological Administration (CMA), Japan Meteorological Agency (JMA), Joint Typhoon Warning Center (JTWC) of USA, and Taiwan Meteorological Center (TMC), in this paper, the ensemble forecast method is proposed and further improved by using the running training scheme during the entire typhoon process. The performance of the method is examined by the forecasting of two typical typhoons, i.e. “Damrey” (No. 1210) and “Fitow” (No. 1323), in the region of Northwestern Pacific. The results show that better accuracy is achieved using the ensemble forecast method compared to the results from the four individual forecast centers and the existing method for both the typhoons.

1 INTRODUCTION

The region of northwestern Pacific is often attacked by typhoons. During a typhoon, the sea water level rises rapidly, and storm surge disasters appear under the effect of strong wind and low pressure, which may cause serious economic losses and casualties. In order to reduce the typhoon-induced damages, it is essential to provide a high-precision forecast service of storm surges in coastal areas, which needs a reliable forecasting of typhoon tracks. In recent years, many weather forecast centers have been using numerical models for the typhoon forecast, which, however, cause some errors to arise from the inaccurate initial boundary conditions, physical parameters, numerical schemes, etc. In order to reduce such kinds of errors, an ensemble of forecast methods based on the initial disturbance or the mode perturbation are usually employed (Zhang and Krishnamurti, 1997; Zhu and Dai, 2000; Zhou et al, 2003; Wang and Liang, 2007). These methods can generate multiple groups of forecast results through the combination of different initial conditions, physical parameters, or even different meteorological models (e.g. Duan and Wang, 2004; Rao and Srinivas, 2014). On the basis of statistical analysis, the methods have been proved to be able

to present more reliable typhoon track forecast. However, the computational time cost by using these methods turns out to be very high. In order to tackle this problem, Krishnamurti et al. (1999, 2000) proposed a multi-mode super-ensemble forecasting method. It contains more than one independent modal forecasting result, which can rapidly achieve multi-sample ensemble forecast, and effectively improve the results of wind field forecast. Due to its low cost of computational time, simplicity, and practicability, this method has been widely used in meteorological and hydrological forecasting in recent years (Zhi et al., 2009; Cane et al., 2013; Chen et al., 2014). The relevant research shows that ensemble forecast is a method that makes full use of the results of central modal forecast to reduce systemic deviation. It gives a significant direction to the current numerical forecast technological development. This paper focuses on the application of super ensemble method in the forecast of typhoon tracks. An improved ensemble method is proposed and applied in the forecast of two typical typhoons that occurred in the region of Northwestern Pacific. The accuracy of the method is examined in comparison to the individual forecast results from four different forecast centers. The details are presented in the following sections.

2 METHODOLOGY

2.1 General introduction

This super ensemble method is proposed based on the weighted average of forecast results from different weather centers. Without any loss of representativeness, the 24-hour forecast data from four operational weather forecast centers—China Meteorological Administration (CMA), Japan Meteorological Agency (JMA), Joint Typhoon Warning Center (JTWC) of USA, and Taiwan Meteorological Center (TMC)—is used for the study. The forecast procedure is divided into two periods: training period and forecasting period. The weighted coefficients for each center are determined by the center’s performance of typhoon forecast in the training period. A higher weighted coefficient will be assigned to the center that performed more accurately in the training period.

2.2 Existing method

The existing method proposed by Ding et al. (2015) uses the dynamical training scheme to calculate the weight coefficients along with the changes of forecasting typhoons in more than one typhoon forecast. The forecasting period is for a single typhoon, whereas the training period is for the previous k typhoons adjacent to the forecasting one, as illustrated in Figure 1. As the weight coefficients are adjusted according to the changes of the training samples, the forecasting result is related to the value of k .

With a series of numerical experimental tests, the scheme of $k = 40$ without “double typhoon” samples is recommended. Compared with static training method, this method has following merits: (1) the most recent typhoons can be taken into account in the training period; (2) the overall forecast errors become quite stable when $k \geq 40$. However, this method also has some limitations: (1) it requires a large amount of data; (2) the weight coefficients for the different weather forecast centers remain unchanged during the entire forecasting period; (3) the size of the training sample is 40, but the specificity, type, and landing area of the 40

Figure 1. Illustration of a moving training method.

typhoons are not completely equivalent. Therefore, there is a need for this method to be improved.

2.3 Improved method

In order to tackle the limitations of the existing method, an improved method is proposed, which is based on the dynamic analysis of forecast errors at the four weather forecast centers during the entire typhoon process. By studying the typhoon track graph, we found that the forecast tracks are consistent with the actual typhoon track in the general trend. Based on this finding, we used forecast and the corresponding measured values in the first two moments as raw data. Then, the raw data was extended linearly to obtain the 24-hour forecast value and the corresponding measured value of the certain typhoon in every start time. The revised deviation between the linearized forecast value and the real forecast value was regarded as the revised error in ensemble forecast, and the distance of forecast deviation of each model was gained. The smaller the deviation is, the bigger the weighted coefficient (α_i) will be. It can be described as

$$\alpha_i = \frac{E_i}{\sum_{i=1}^N E_i} \quad (1)$$

in which α_i is the weighted coefficient for the i -th forecast center; and E_i is the multiplicative inverse of the mean forecast errors of i -th forecast center in the training period.

Once the weighted coefficient is determined, the forecast values can be calculated by using the bias-removed ensemble mean (WEM) method. As the typhoon track cannot be absolutely smooth, a distance correction parameter is introduced. The parameter value is 0.3 according to experience, which is described as

$$\begin{cases} F_{WEM} = \sum_{i=1}^N \alpha_i F_i \\ F_i = f_i + D_i * 0.3 \end{cases} \quad (2)$$

in which F_{WEM} is the forecast value; F_i is the forecast value of the i -th forecast center; N is the number of the forecast centers, with $N = 4$ in this study; f_i is the real forecast value of the i -th center; and D_i is the forecast deviation of the i -th center in the training period.

3 ENSEMBLE FORECAST ANALYSIS

To examine the performance of the modified method on the typhoon track forecast, two

typical typhoons that occurred in the region of Northwestern Pacific, i.e. “Damrey” (No. 1210) and “Fitow” (No. 1323), were taken as examples for the case studies. The results are presented as follows.

Typhoon Damrey is the strongest typhoon that landed in the north of the Yangtze River since 1949. It strengthened slowly in the early stage, and its track direction was changeable. Besides, it moved slowly and strengthened stably offshore. The forecast tracks and the actual track are shown in Figure 2, and the average track forecast error is shown in Figure 3.

It can be observed from Figure 2 that with the advancement of typhoon to the coasts, the forecast results tend to be closer to the actual track. The corresponding forecast errors decrease significantly. This is because at the beginning, the movement of the typhoon center has large uncertainties, and there is no obvious regularity of the typhoon track; therefore, there is fluctuation of the forecasting results. With the ensemble method, the forecast tracks are generally closer to the actual ones compared to the results from single forecast centers because of the real-time revision of the forecast errors; this shows that revised errors have a great influence on the accuracy of typhoon track forecast. As it can be seen from Figure 3, the track error of ensemble forecasting method decreased evidently compared with JTWC, JMA, CMA, and TMC by 20.14%, 21.26%, 19.45%, and 11.69%, respectively. Compared to the existing method, the proposed ensemble method decreased by 6.82%. The existing method also revised the weight coefficients and track errors in the forecasting of new typhoon; however, their coefficients remained unchanged during one single typhoon, and a large

amount of typhoon data were required. Furthermore, there might be major deviance when using typhoons from the history. This is why the dynamical training method uses the same typhoon for training and forecasting period, which can improve the forecast precision.

Based on the track error analysis of “Damrey”, this paper chose 1323 “Fitow” for ensemble forecast to further demonstrate the improvement in the method created on the forecast precision of a single typhoon.

A severe tropical typhoon, Fitow (1323) was the strongest typhoon landing that was encountered in China’s mainland after October. It caused economic losses that amounted to 62.33 billion RMB to China and ranked only second to Typhoon Herb (9609). It formed on September 30th in 2013 in the eastern ocean of the Philippines and slowly developed in the early stage. It intensified into a strong typhoon on October 4th and landed at Fuding in Fujian Province of China at 01:15 on October 7th. The typhoon was weakened into a tropical storm at 5 a.m. on the same day and disappeared near the coast of Jianou in Fujian Province of China at 9 a.m. on the same day. The similar results for the typhoon “Fitow” are shown in Figures 4 and 5.

Figure 2. Damrey’s forecast tracks and the actual track.

Figure 3. Damrey’s average track forecast errors.

Figure 4. Fitow’s forecast tracks and the actual track.

Figure 5. Fitow's average track forecast errors.

As it can be observed from the figures, in the process of typhoon track forecast of "Fitow", the forecasting track error obtained by revised ensemble forecast diminished by 9.31% compared with the best station (TMC). Compared to the existing method, the track forecast error diminished by 11.83%. Through these case studies, we found that the modified training method evidently diminished the track error and greatly improved the forecast accuracy.

4 CONCLUSION

Based on the forecast data obtained from CMA, JMA, JTWC of USA, and TMC, the ensemble forecasting of 24-hour typhoon tracks was conducted for two typical typhoons that occurred over the Northwestern Pacific. We used the forecast and the corresponding measured values at the first two moments as the raw data, and they were extended linearly to calculate the weighted coefficients and bias for each weather forecast center. The revised deviation between the linearized forecast value and the real forecast value is regarded as the revised error in ensemble forecast. The results are listed as follows:

- a. The idea of estimation proposed in this paper is feasible. According to the statistical results, the revised deviation has a great impact on the ensemble forecast value. The distance correction parameter is introduced when calculating the ensemble forecast, and 0.3 is reasonable as the correction parameter. The modified method could improve the accuracy of track forecast.
- b. According to the analysis of some typical typhoons like "Damrey" and "Fitow", we found that the track error of ensemble forecasting method is less than that of the single stations. In addition, the precision of track forecast is better compared with the existing method. Although the existing method also revised the weight coefficients and track errors in the forecasting of new

typhoon, their coefficients remained unchanged during a single typhoon. Moreover, there might be major deviance when using typhoons from the history. This is why the dynamical training method uses the same typhoon for training and forecasting period, which can improve the forecast precision.

- c. The modified method does not need to use historical data, and it builds a strong operability system in forecasting typhoon track. Besides, the modified method provides forecast with high accuracy and realizes the real-time correction of the weight coefficient and forecast deviation.

An investigation into the system of feasibility study for the revitalizing of idle public facilities through outsourcing of venue management

Jyh-Harnng Shyng

Department of Environment and Property Management, Jin-wen University of Technology, Taipei, Taiwan

ABSTRACT: This study found that any proposed revitalization strategy through outsourcing of venue management must be subject to proper feasibility studies and negotiations. Public departments shall refer to the “profitability” and “economic benefits” of the public facilities to formulate various tendering criteria. Private entities, on the other hand, must determine whether these tendering criteria would be compliant to their investment expectations and “financial benefits”. Under reasonable “financial benefits”, feasibility studies and negotiations shall then be carried out in order to determine whether the revitalization strategy of the public facility is capable of complying with the features of the public facilities and the objectives of providing socio-economic and public benefits.

1 INTRODUCTION

1.1 *Research background*

The Executive Yuan of Taiwan has initiated a “Program for Promoting the Revitalization of Idle Public Facilities” and established a cross-departmental taskforce responsible for promoting revitalization work. A number of taskforce evaluation meetings have been held. In 2016, the Public Construction Commission of the Executive Yuan continued to compile a list of idle public facility construction projects that were completed but failed to be used according to its planned objectives or were underutilized, as well as public facility construction projects that had been suspended for extended periods of time but may offer social economic potential. This list will help an “evaluation to be made of the feasibility of revitalizing idle public facilities” and initiate a diverse selection of revitalization strategies that include “improvement of facility functions”, “transformation and reutilization”, and “outsourcing”.

1.2 *Experimental objectives and scope*

The objectives of this study would be to introduce novel forms of management for public assets by private entities. Such public assets and facilities have the advantages of added support from public departments and the dynamism and innovative management approaches of private entities, resulting in a mutually beneficial opportunity for both public and private organizations involved.

The scope of this research focused on the negotiation process between public departments and

private entities to establish revitalization strategies and decision making mechanisms needed for feasibility studies that take place for the “outsourcing of venue management”.

2 LITERATURE REVIEW

2.1 *Studies of outsourcing processes of idle public facilities in other countries*

According to past experiences in other countries and current trends of privatization and diversification, the “outsourcing of venue management” model was adopted to introduce the dynamism and management experiences of private enterprises. This would be a key strategy for the revitalization of public construction and facilities. The following lists the experiences of outsourced management by the governments of the UK, the US, Canada, and Japan (Chang and Chang, 2006):

1. Outsourcing experiences in the UK: Bevir, Mark & David O’Brien (2001), Woods and Rober (2000), Clarke and John (2000), and Falconer, Peter K. & Kathleen McLaughlin (2000) provided the following reference: Step-by-step process of “activation, search for potential partners, collaboration, and project investigation” for public-private partnerships.
2. Outsourcing experiences of the US: Raffe, Jeffrey A., Debar A. Auger, & Kathryn G. Denhardt (1997), Savas, E. S. (2000) and DeHoog & Ruth Hoogland (1990) provided the following reference: Using “clear” and

“flexible” principles to construct a contract-based management system.

3. Outsourcing experiences of the federal and provincial government of Canada: “Partnership contracts” were used to establish a positive partnership between government and private organizations in order to review the necessity of government tasks.
4. In the 21st century, Japan utilized the concept of “transformation” in order to promote effective utilization of urban areas.

2.2 Outsourcing theories and their suitability for public facilities

According to Li Tsung-Hsun (2002), the theoretical basis for the outsourcing of government processes adopted the general concept of “best value”, which would be used to introduce various other theoretical perspectives.

Savas, E.S. (2000) proposed that certain degrees of categorization should be employed for the nature of various public facilities. There is a number of steps that the public department must exercise control over during the overall outsourcing process. These steps include: leading feasibility evaluations, creating a competitive environment, establishing benefits or qualifications criteria, and preparing a tendering manual.

2.3 Key aspects that influence the outsourcing process

Experiences of outsourced public construction projects and literature review found that “financial issues” were the key determinant of the success of the outsourcing process (Huang, 2003). Outsourcing was also defined as a “revolutionary revitalization strategy for management models”.

The mutual influences included within this model could be divided into 4 categories, including: (1) “Differences between the roles of the

public departments and private entities”. Public departments must comply with specifications and guidelines defined by law or policy. (2) “Uncertainties that influence financial factors”. (3) “Feasibility of the financial planning provided for the development project”. (4) “Comprehensiveness of the negotiations, evaluations, and decision-making mechanisms” as shown in Figure 1.

3 RESULTS OF INVESTIGATIONS CARRIED OUT INTO IDLE CASES

This study referred to other studies and compiled a total of 6 feasibility study indicators for the outsourced management of public facilities. Relevant studies as well as the context and results of evaluations conducted by the Public Construction Commission were also referenced to generate 6 major feasibility categories with 37 primary variables. The categories were “Policy and legal systems”; “economic environment”; “market environment”; “project planning”; “project finances”; and “project negotiation system”. The targets reviewed in this study included 153 public facilities that had been listed by the Executive Yuan Public Construction Commission. A total of 119 effective results were recovered for a recovery rate of 77.8%.

4 ANALYSIS OF THE INDICATORS AND DIMENSIONS FOR THE FEASIBILITY STUDY OF THE OUTSOURCING PROCESS

This study analyzed the reliability values of 3 dimensions. Factor 1 was the dimension of “concession criteria and factors”; factor 2 was the “external criteria and packages”; and factor 3 was “influences of the economic environment”. The reliability scores for each of the 3 dimensions exceeded 0.9. Cumulative variance of the 3 dimensions was 70.765%, showing that these dimensions provided adequate representativeness. The reliability of the dimensions was very close and consistent with the overall dimension. Reliability for each of the factor dimensions exceeded 0.9, which was acceptable.

Several dimensions were extracted after the aforementioned factor analysis. These were: “discussion of concessions, external criteria and packages”, and “influences of the economic environment”. This also helped to clarify the interpretation and meaning of the “feasibility study of the outsourcing of public facilities” in order to construct indicators and dimensions of the feasibility study (Figure 2).

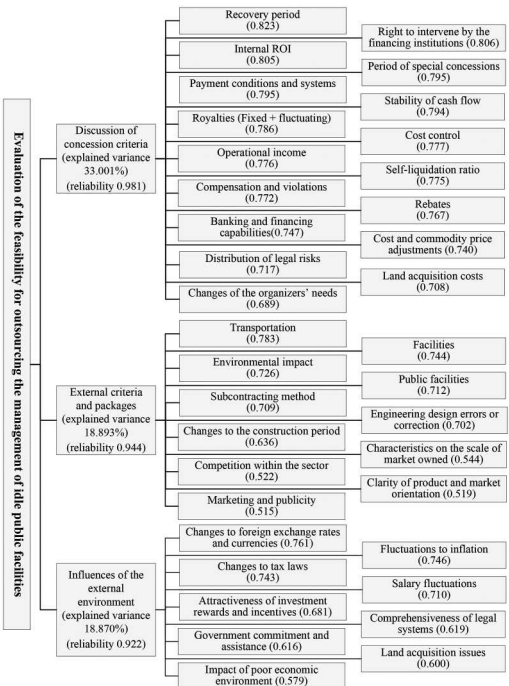

Figure 1. Aspects that may influence the negotiations and evaluation system for the feasibility of outsourced projects.

* Total cumulative explained variance was 70.765% with an eigenvalue of 21.682.

Figure 2. Indicators and dimensions for the feasibility study of the outsourcing of idle public facilities.

5 FEASIBILITY STUDY OF THE OUTSOURCING

Revitalization of public facilities through outsourcing would be mainly carried out through public-private partnerships. Under this arrangement, both parties must arrive at a consensus and establish a partnership model.

5.1 Using “management profitability” to categorize factors that may influence the feasibility study

The term “Differences between the roles of the public departments and private entities” mainly refers to the legal or policy standards guidelines with which public guidelines must comply. These would be the prerequisites for establishing public facilities.

The nature and type of the public facilities shall be divided into 2 categories of “profitable public facilities” and “non-profit public facilities”. The 3 dimensions listed above would therefore each include 2 hidden factors listed in the following:

1. “Financial influence” could be regarded as “uncertainties that influence the financial factors” and “feasibility of the financial planning of the development project”.
2. “Planning environment” could be regarded as “comprehensiveness of the negotiations, evaluations, and decision-making system” which would be similar to the factor of influences of the economic environment.

These two categories of factors could therefore be compiled as contents of the “financial dimension of the overall development project” used to formulate the “tendering criteria”. These criteria would be key during negotiations between public departments and private entities needed to establish partnerships between the two.

5.2 Evaluations and decision-making processes when employing outsourcing as a revitalization strategy

The Executive Yuan raised a total of 3 revitalization strategies: “improving facility functions”; “transformation and reutilization”; and “outsourcing”. The profitability of public facilities would be used to conduct feasibility studies and negotiations for the revitalization process. This study specifically analyzed the feasibility study procedure for the third revitalization strategy of “outsourcing” (Figure 3).

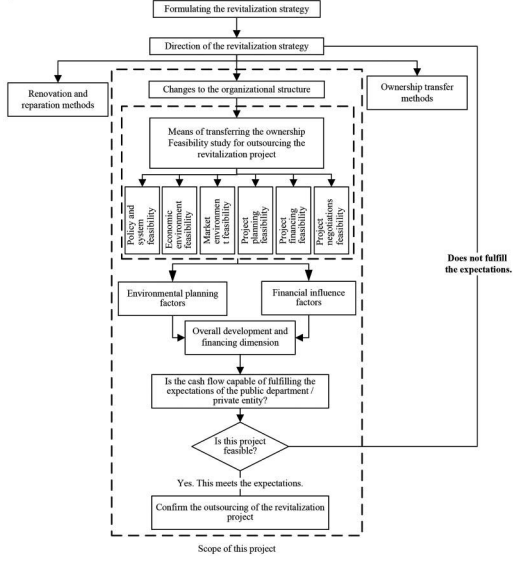

Figure 3. Evaluation and decision-making processes when using outsourcing as a revitalization strategy for idle public facilities.

Public and private departments and entities must comply with the principles of partnerships. Where planning was led by public departments, these requirements would be known as the “tendering criteria”. If private entities submit development applications to the public departments pursuant to the articles of the “Act for Promotion of Private Participation in Infrastructure Projects”, these requirements would be regarded as “application criteria”.

Regardless of the type of criteria used, public-private partnerships must include factors that influence the planning process, details that may influence the finances, and maintain a certain degree of flexibility for the adjustment process. Negotiation systems and flexibility must be provided for. The decision-making procedure and factors influencing the development project will differ according to the tendering mode along with factors that influence project finances. Hence, the negotiation system for the revitalization of public facilities through outsourcing would also generate different revitalization strategies.

6 CONCLUSION AND RECOMMENDATIONS

Decision making processes for the revitalization strategies of idle public facilities must undergo feasibility study or a relevant system. The first step must involve the characterization of the “management profitability” of the specified public facility. A suitable feasibility study must then be selected to carry out feasibility studies and evaluations by both the public department and private entities. Various performance indicators and factors under the categories of “environmental planning” and “financial criteria” must then undergo negotiations and sensitivity analysis. It is only by performing these previous steps that planners will be able to conduct accurate feasibility studies and generate proper details of the revitalization strategy.

Public departments must consider the economic benefits (employment opportunities and encouragement of peripheral industries) of the public facilities. Private entities must refer to the tendering criteria of the public departments to determine whether these projects are able to meet their investment expectations and “financial benefits”. During the phase of the feasibility study, “tendering criteria” proposed by the public departments and financial reviews by the interested private entities

will generate a reasonable “financial benefits plan” to review the project and determine whether the revitalization strategy selected is capable of meeting the expected socio-economic benefits as well as public policy objectives for developing public facilities.

Distribution characteristics of ammonia emission from the livestock farming industry in Hunan Province

Xing Rong, Chunhao Dai, Ying Deng & Pufeng Qin

Resources and Environmental Sciences, Hunan Agricultural University, Changsha, Hunan Province, China

ABSTRACT: The distribution characteristics of livestock ammonia emissions in Hunan Province were investigated by applying the foreign average emission factor as the calculating factor. The total ammonia emissions of poultry feeding industry in Hunan province are 39.84×10^4 t in 2014, among which the maximum city emission was in Hengyang City as much as 5.50×10^4 t·a⁻¹. Moreover, the intensity of ammonia emissions in 2014 from livestock in Hunan Province averaged 1.88 t/km², and the Xiangtan City emission intensity went up to 3.87 t/km² as the maximum. The results showed the reduction of ammonia emissions was mainly attributed to the gradual expansion of exit and prohibited area. Furthermore, pig breeding was found to be the largest source of ammonia emission, as the proportion to 54.82%.

1 INTRODUCTION

Atmospheric fine particulate matters have posed a serious threat to human health and ecological environment, attracting much public attention in recent years. The formation mechanism of fine particles in the atmosphere is complex, including primary particles that are directly formed and secondary particles that form indirectly. Primary particles are mainly composed of dust particles and generated by combustion of carbon black (organic carbon) fuel particles. Besides, secondary particles are mainly water-soluble aerosol particles (sulfates, nitrates and ammonium salts), which account for about 57% of mass concentration of the atmospheric fine particles.

Ammonia (NH₃) is one of the most important trace gases in the atmosphere involved in the nitrogen cycle. As the most important alkaline substances in the atmosphere, ammonia plays an important role in cushioning the underlying atmosphere acidification, acid deposition and the forming of secondary particles. Meanwhile, the NH₃ emissions into the atmosphere would produce the greenhouse effect. Back in 1997, ammonia was discovered as an important precursor of fine particulate matter (PM_{2.5}). SO₄²⁻, NO₃⁻, and NH₄⁺ were the major components of PM_{2.5} while NO₃⁻, NH₄⁺ and ammonia were closely related. Recently, due to the association between ammonia emission and formation of the secondary particles, which posed a considerable threat to human health, a number of researches on ammonia emissions were carried out. Ammonia and nitrate-forming nitrate aerosols will significantly increase the total particulate matter; for example, much of the ammonium nitrate aerosol could be found in PM_{2.5} particles.

Ammonia emissions include anthropogenic and natural sources. Ammonia emissions from anthropogenic sources were increasingly serious, among which the ammonia emissions from livestock were the largest source and caused the most negative impact increasingly. Hunan province is a big producer of livestock and poultry breeding in China because of its breeding scale. It is in the forefront of China with regard to livestock breeding, which leads to more serious ammonia emission pollution. Obviously the characteristics of ammonia distribution influences the prevention and control of atmospheric pollution, provided the basic data on the fine particulate matter source spectra is available. Therefore, the main goal of the present study was to investigate the distribution of ammonia emission from livestock and poultry breeding in Hunan province in 2004–2014.

2 RESEARCH METHOD

Research areas include 13 prefecture-level cities as follows: Changsha, Zhuzhou, Xiangtan, Shaoyang, Huaihua, Changde, Yiyang, Yueyang, Hengyang, Yongzhou, Chenzhou, Loudi, Zhangjiajie City and Xiangxi Tujia and Miao autonomous prefecture, which were studied from 2004 to 2014.

2.1 Calculation method

Up to now, the emission factor method was adopted in the domestic and international research on the source of ammonia emission inventory. Emission factor multiplied by the corresponding number

Table 1. Ammonia emission factors in the livestock farming industry/kg·a⁻¹.

(from the Hunan Provincial Environmental Protection Office 2004–2014 annual environmental statistics) was applied to calculate ammonia emissions from farming. Ammonia emissions divided by each region area were equal to the emission intensity.

2.2 Determination of the emission factor

Due to the complexity of many factors affecting the ammonia emission factors, it is difficult to determine the emission factor. Meaningful reports and review articles on these studies have appeared and have been published abroad. Therefore, much literature on ammonia emissions of livestock and poultry breeding industry almost refer to the foreign emission factors. However, foreign emission factors largely depend on the specific situation, which caused some differences between China and worldwide and pose a remarkable negative impact on the estimation accuracy of ammonia emission. Thus, referring to some data on foreign emission factors, the average value was used as the calculation values in this study. These values are shown in the Table 1.

3 RESULTS AND DISCUSSION

According to the calculation, all kinds of livestock and poultry ammonia emissions in Hunan province during 2004–2014 are shown in Table 2.

3.1 Spatial distribution of ammonia emission from the livestock and poultry breeding industry in Hunan Province

Fig.1(a) showed the spatial distribution of livestock and poultry breeding in Hunan province in 2014. The total amount of ammonia emission from livestock and poultry breeding industry in Hunan province was 39.84×10^4 tons, within which the district-level emission per unit was 2.85×10^4 tons on average. One of the biggest emissions was Hengyang, whose emission was as much as 5.50×10^4

tons, followed by Changde city, Shaoyang city and Changsha city. Comparatively, Zhangjiajie was the minimal emission source, at the level of 0.48×10^4 tons and the key reason was that Zhangjiajie was the tourist area and therefore covered less amount of livestock and poultry breeding than Hunan Hengyang.

3.2 Spatial distribution of livestock and poultry breeding in Hunan province ammonia emission intensity

The spatial distribution of ammonia emission from livestock and poultry breeding in Hunan province in 2014 is shown in Figure 1(b). The Xiangtan city was the emitter with the strongest intensity, with a value of $3.87 \text{ t}\cdot\text{km}^{-2}$ in 2014. It was followed by Hengyang and Changsha city, which emitted significantly more than $3 \text{ t}\cdot\text{km}^{-2}$. Meanwhile, there was a large proportion of the population and industrial emitter in Changsha and Xiangtan, which could make it easier to transform the pollutants into secondary aerosols. Therefore, Changsha and Xiangtan city were chosen for the management and treatment of livestock and poultry breeding ammonia emissions. Apart from these results, the lowest emission was 0.37 tons per square kilometers in western Hunan noticeably.

According to some literature and reports on emission intensity of ammonia due to the livestock and poultry breeding, Beijing, Tianjin, Hubei province, Jiangxi province, Jiangsu and Guizhou were 2.95, 2.54, 1.27, 0.59, 2.74, 1.09 tons per square kilometers, respectively. Compared to these areas, the average emission intensity in Hunan province was $1.88 \text{ t}\cdot\text{km}^{-2}$, which belongs to the medium level among the above-mentioned areas.

3.3 Temporal distribution of ammonia emissions from livestock and poultry breeding in Hunan province

Temporal distribution of livestock and poultry breeding in Hunan province in terms of ammonia

Table 2. Ammonia emission in the livestock farming industry/ $10^4\text{t}\cdot\text{a}^{-1}$.

Year	Pig	Dairy cattle	Beef	Laying hen	Broiler chicken	Goat	Total
2004	22.2	5.7	6.2	2.5	4.5	0.8	41.8
2005	23.5	6.0	6.4	0.3	1.3	0.9	38.4
2006	23.9	6.1	6.5	0.3	1.5	0.9	39.3
2007	23.7	6.0	6.4	0.4	2.1	0.9	39.6
2008	20.4	4.2	4.5	1.9	5.6	0.7	37.3
2009	21.1	0.9	10.5	3.0	6.1	0.7	42.4
2010	21.8	2.2	7.8	3.6	5.7	0.7	41.7
2011	21.8	4.4	4.7	3.6	4.7	0.7	39.8
2012	21.1	5.3	5.8	3.0	3.8	0.6	39.6
2013	19.5	5.2	5.7	0.3	1.8	0.5	33.0
2014	19.4	5.3	5.5	0.5	1.1	0.5	32.2

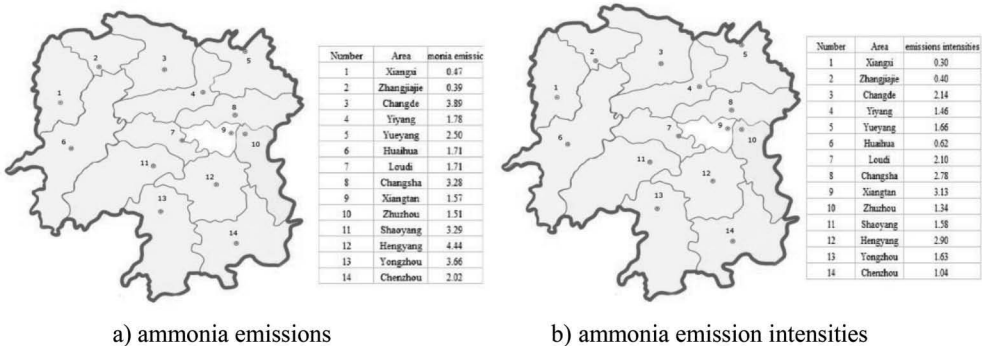

Figure 1. Spatial distribution of ammonia emissions from the livestock farming industry in 2014 in Hunan/ 10^4t .

Figure 2. Temporal distribution of ammonia emissions from the livestock farming industry in 2014 in Hunan.

emissions in 2014 is illustrated in Figure 2. It could be seen that the total annual ammonia emission fluctuated and showed a downward trend since 2001. However, there was a sharp

maximum in 2009 and the total emission reached $42.4 \times 10^4\text{t}\cdot\text{a}^{-1}$ in the Hunan province. The primary cause was the significantly increased pig-breeding quantity.

Figure 3. Ammonia emissions of different livestock in 2014 in Hunan.

3.4 Distribution of livestock and poultry ammonia emissions in Hunan province

The ammonia emissions of different livestock in 2014 in Hunan are showed in Figure 3. In proportion to 54.82%, the pig-breeding was the largest ammonia emitter. Although its emission factor is not high, nearly 0.22 million slaughters and huge pig-producing quantities led to the strong emissions. Differing from the situation in Pearl River Delta of China and Beijing, the pig-breeding was further manifested as the main ammonia emitter in Hunan province.

4 CONCLUSIONS

Ammonia emissions from livestock and poultry farming in Hunan province ranged from 32.2 to $42.4 \times 10^4 \text{t} \cdot \text{a}^{-1}$ when foreign emission factor is applied in the calculation. In 2014, the strongest emitter was Hengyang city, with an emission of $5.50 \times 10^4 \text{t} \cdot \text{a}^{-1}$. In contrast, Zhangjiajie is the least polluter, with an emission of $0.48 \times 10^4 \text{t} \cdot \text{a}^{-1}$. Moreover, the total annual emission fluctuated and showed a downward trend since 2001 due to the expanded area of banning and retirement. Furthermore, the average emission intensity in Hunan province was $1.88 \text{t} \cdot \text{km}^{-2}$, among which the biggest emissions was Hengyang, with a value of 5.50×10^4 tons and the lowest emission was 0.37 tons per square kilometers in western Hunan. The results also show that pig-breeding contributed most (54.82%) to ammonia emission.

Application of aerobic bioremediation to cleanup octachlorinated dibenzofuran polluted soils

J.L. Lin, Y.T. Sheu & C.M. Kao

Institute of Environmental Engineering, National Sun Yat-Sen University, Kaohsiung, Taiwan

W.P. Sung & T.Y. Chen

Department of Landscape Architecture, National Chin-Yi University of Technology, Taichung, Taiwan

ABSTRACT: In this study, effectiveness of using *Pseudomonas mendocina* NSYSU (*P. mendocina* NSYSU) on the bioremediation of octachlorinated dibenzofuran (OCDF)-polluted soils was evaluated through batch and bioreactor experiments under aerobic conditions. The goal of the research were to assess the feasibility of biodegradation of OCDF by indigenous soil bacteria and isolated bacterial strain (*P. mendocina* NSYSU) from OCDF-polluted soils, and Results show that *P. mendocina* NSYSU was able to degrade OCDF through the aerobic cometabolic mechanisms with the addition of carbon substrates. Up to 62% of OCDF was removed after a 50-day operation with carbon substrate supplement. Results indicate that primary substrate supplement is required for the enhancement of aerobic biodegradation of OCDF, and OCDF could not be used as the sole carbon source for the growth of *P. mendocina* NSYSU. Results reveal that an aerobic bioremediation system using *P. mendocina* NSYSU as the inocula would be a cost-effective system to remediate furan-polluted soils.

1 INTRODUCTION

Polychlorinated dibenzofuran (PCDF) isomers, which are usually produced thermal processes, have been classified as the mutagens and carcinogens (Coutinho et al. 2015; Squadrone et al. 2015). Incinerators and boilers have been considered as the major causes of PCDFs production after waste burnings (Wittsiepe et al. 2015; Pongpiachan et al. 2016). Production of PCDFs cause the ecosystem and environmental media contamination (Klees et al. 2015; Kruse et al. 2014; Shin et al. 2016). PCDFs have strong environmental persistent characteristics and they are also subjected to biomagnification as well as bioaccumulation effects in many living organisms (Hanano et al. 2014; Wu et al. 2014; Yang et al. 2015). Different furan isomers including octachlorinated dibenzofuran (OCDF, a highly chlorinated furan), have been observed in different environmental media (e.g., sediments, soils) in many industrialized areas (Govindan and Moon 2015; Urban et al. 2014).

As a result of their hydrophobic and xenobiotic nature, OCDFs usually are very persistent in ecosystems (Liu et al. 2014; Zhao et al. 2015). Due to their highly adsorptive, less biodegradable, and highly toxic natures, remediation of PCDF-polluted media (e.g., soils, sediments) can be a necessity but costly (Anasonye et al. 2014; Zhao

et al. 2015). Compared to physical and chemical remedial methods, biological method can reduce the cleanup cost for the PCDF-polluted sites if significant amounts of media need to be remediated (Tue et al. 2016; Vallejo et al. 2015). The microbial species involved in bioremediation technologies include aerobic and anaerobic processes depending on the nature of contaminant and microorganisms (Megharaj et al. 2014). Compared to anaerobic process, aerobic bioremediation of PCDF-polluted media can be more efficient, and thus, remediation time can be reduced (Chen et al. 2016; Hanano et al. 2014).

One promising remedial method for the remediation of chlorinated compounds polluted soils is aerobic bioremediation by aerobic or facultative bacterial species (Futagami et al. 2008; Lai and Becker 2013). Some aerobic microorganisms have specific metabolic processes, which enable them to biodegrade less-biodegradable and persistent chlorinated compounds.

Supplement of carbon sources for the use of primary substrates is necessary to enhance the aerobic cometabolic mechanisms (Kruse et al. 2014; Liu et al. 2014; Zhen et al. 2014). Currently, the information related to the biodegradation of higher chlorinated PCDFs under aerobic conditions is limited (Kuokka et al. 2014; Liu et al. 2014; Tu et al. 2014). A pentachlorophenol (PCP)-biodegrading

bacterial strain, *Pseudomonas mendocina* NSYSU (*P. mendocina* NSYSU), was isolated from PCP, dioxin and furan-contaminated soils (Kao et al. 2005). The site was also polluted by OCDF with concentrations up to 10.8 mg/kg (NSC 2012). In this study, a biodegradation study was performed to assess if *P. mendocina* NSYSU could bioremediate OCDF-polluted soils in an aerobic system. The major tasks of this study were as follows: (1) evaluation of the feasibility of improving OCDF biodegradation by *P. mendocina* NSYSU under aerobic conditions, and (2) assessment of the existence of functional genes for the anaerobic OCDF biodegradation.

2 MATERIALS AND METHODS

2.1 Medium and growth of *P. mendocina* NSYSU

P. mendocina NSYSU culture was incubated in nutrient medium. The components of the media included the following: The mineral medium contained the following components (mg/L): Mg₂SO₄·7H₂O, 98.6; H₂PO₄, 326.4; NH₄Cl, 10.7; CaCl₂·2H₂O, 44.1; Na₂HPO₄, 1263.8; and 3.35 mg of trace elements (CuCl₂·2H₂O, 0.25; Na₂B₄O₇·10H₂O, 0.25; MnSO₄·4H₂O, 1; FeSO₄·7H₂O, 1; CoCl₂·6H₂O, 0.25; ZnCl₂, 0.25; NH₄VO₃, 0.1; (NH₄)₆Mo₇O₂₄·4H₂O, 0.25). The pH of this buffer solution was 7.5. The medium solution was autoclaved before use. The *P. mendocina* NSYSU solution was cultured at 200 rpm for 48 h in a 50 mL flask (sealed with butyl rubber stopper) at 20°C under aerobic conditions. Density of the bacteria was analyzed by the spectrophotometer (Hach Co., USA).

2.2 OCDF biodegradation experiment

The biodegradation of OCDF under aerobic conditions was investigated in the batch experiment. In
